$$H(t) = H_0 + \left(\sum_{k=1}^{N} \lambda_k |\psi_k\rangle\langle\psi_k| \right) \sum_{n=0}^{\infty} \delta(t - nT), \tag{1}$$

where $\lambda_k \in \mathbb{R}$ and each vector $|\psi_k\rangle$ is a linear combination of the H_0 basis states, $|\phi_n\rangle$,

$$|\psi_k\rangle = \sum_{n=0}^{\infty} (a_k)_n |\phi_n\rangle.$$

The states $|\psi_k\rangle$ are orthogonal

$$\langle\psi_k|\psi_l\rangle = \delta_{kl}.$$

The Floquet operator is

$$V \equiv U(T) = e^{-iH_0 T/\hbar} e^{-i(\Sigma_k \lambda_k |\psi_k\rangle\langle\psi_k|)/\hbar}.$$

(Our Floquet operator differs from that in Combescure[6] and Bourget.[7,8] An erronous T was introduced in Ref. 6 and it has been carried through in the literature. Note that the theorems proved therein are not invalidated in any way by this error.) The basic result, as established in Ref. 1 is that if every $|\psi_k\rangle$ is in $l_1(H_0)$, the spectrum will remain pure point for almost every perturbation strength.

If this condition is dropped for any one of the $|\psi_k\rangle$, then we no longer have $V_{\lambda_1,\ldots,\lambda_N}$ pure point. In fact, on the subspace $\mathcal{H}_k$ defined by that space for which $|\psi_k\rangle$ is a cyclic vector for operator U, the spectrum is purely continuous. At this point, we note that Milek and Seba[5] have incorrectly concluded from Combescure's work that the existence of a ψ such that ψ is in the continuous subspace of $\mathcal{H}$ implies that the whole of $\mathcal{H}$ is continuous for the operator V. This statement would require the assumption that ψ is a cyclic vector for U, which is simply impossible for $|\psi\rangle\langle\psi|$ as an arbitrary projection.

For Milek and Seba's work to be properly justified, we show that a sufficient condition is that Vinogradov's number-theoretic conjecture, stated over 50 years ago, is true. (The reference is to the 1954 English translation of Vinogradov's original work, published in 1947. The work in Vinogradov's 1947 monograph incorporates results from a series of papers and a first monograph from 1937. It is unknown to us when the conjecture referred to was first presented, but it was at least 50 years ago.) This observation is linked to the conjecture put forward by Combescure[6] and partially addressed by Bourget.[7] After the completion of this work, we became aware of a recent paper by Bourget[8] which successfully resolves the issues with Milek and Seba's work by building on the earlier work in Ref. 7. Bourget's new work in no way invalidates the arguments presented here—the two approaches are complimentary.

In Sec. II we extend Combescure's rank-1 theorem on the pure point spectral nature of V to the rank-N case. In Sec. III we then show the existence of a continuous spectrum for the case where H_0 is the harmonic oscillator and the perturbation is rank-N. In Sec. IV we investigate Combescure's conjecture, the answer provided by Bourget and the link to number theory and Vinogradov's conjecture. Finally, in Sec. V, we extend Milek and Seba's work to the rank-N case, correcting a number of subtle errors. We emphasize that their work has only recently been fully justified (by Bourget in Ref. 8). We provide a complimentary justification, linked to the number-theoretic investigations and Vinogradov's conjecture just mentioned.

II. RANK-*N* GENERALIZATION OF COMBESCURE'S FIRST THEOREM

We consider the measures

$$m_{k,\lambda_k} = \langle\psi_k| E_{\lambda_k}(S) |\psi_k\rangle.$$

Each $|\psi_k\rangle$ admits a cyclic subspace of $\mathcal{H}$, $\mathcal{H}_k$. As argued in the later part of the proof of Theorem 4.3 in Ref. 1, on the space $\mathcal{H} \ominus (\oplus_{k=1}^{N} \mathcal{H}_k)$, the perturbation

$$\sum_{k=1}^{N} \lambda_k |\psi_k\rangle\langle\psi_k|$$

is null and thus $V=U$ is trivially pure point. Henceforth, we may safely restrict our proof to the subspace $\oplus_{k=1}^{N}\mathcal{H}_k$ for which the vectors $|\psi_k\rangle$ form a cyclic set.

Directly following Combescure, the measure for a point $x \in [0, 2\pi)$ for the operator V acting on the state $|\psi_k\rangle$ is given by

$$m_{k,\lambda_k}(\{x\}) = \frac{-4(1+\mu_k)}{\mu_k^2} B_k(x), \tag{2}$$

where

$$\mu_k = e^{i\lambda_k/\hbar} - 1$$

and

$$B_k(x) = \left[\int_0^{2\pi} dm_{k,\lambda_k=0}(\theta)(\sin^2[(x-\theta)/2])^{-1} \right]^{-1}.$$

This result is the essence of Lemma 1 in Ref. 6. When H_0 is pure point, it is a trivial calculation to show that

$$B_k^{-1}(x) = \sum_{n=0}^{\infty} \frac{|(a_k)_n|^2}{\sin^2[(x-\theta_n)/2]}. \tag{3}$$

Corollary 2 in Ref. 6 is replaced with the following.

Theorem II.1: *Assume H_0 is pure point, with $\{\phi_n\}_{n\in\mathbb{N}}$ and $\{\alpha_n\}_{n\in\mathbb{N}}$ as eigenstates and eigenvalues. Let each*

$$\psi_k = \sum_{n=0}^{\infty} (a_k)_n \phi_n$$

be cyclic for H_0 (hence, cyclic for U and V) on $\mathcal{H}_k$ and $\langle\psi_k|\psi_l\rangle = \delta_{kl}$. Then e^{ix} belongs to the point spectrum of $V_{\lambda_1,\ldots,\lambda_N}$ if and only if

$$\prod_{k=1}^{N} B_k^{-1}(x) < \infty,$$

where

$$\theta_n = 2\pi\{\alpha_n/2\pi\hbar\},$$

$\{z\}$ *being the fractional part of z.*

Proof II.1: The proof follows that in Ref. 6. By the cyclicity of each $|\psi_k\rangle$ on $\mathcal{H}_k$ and the argument in Theorem 4.3 of Ref. 1, e^{ix} is an eigenvalue of $V_{\lambda_1,\ldots,\lambda_N}$ if and only if every $m_{k,\lambda_k}(\{\theta\}) \neq 0$ at $\theta=x$. As already mentioned, using

$$\mathrm{d}m_{k,\lambda_k=0} = \sum_{n=0}^{\infty} |(a_k)_n|^2 \delta(\theta-\theta_n)\mathrm{d}\theta$$

we obtain, for each k,

$$B_k^{-1}(x) = \sum_{n=0}^{\infty} \frac{|(a_k)_n|^2}{\sin^2[(x-\theta_n)/2]}.$$

We now consider the eigenvalue e^{ix}. If it were to be that for some k, $m_{k,\lambda_k}(\{x\})=0$, then we would have found a vector, namely $|\psi_k\rangle$, such that $V|\psi_k\rangle$ was continuous. We have in fact found that the whole subspace $\mathcal{H}_k$ is continuous. Thus, for V to be pure point, we require every $m_{k,\lambda_k}(\{\theta\}) \neq 0$. Thus, we are lead to consider the requirement

$$\prod_{k=1}^{N} B_k^{-1}(x) < \infty.$$

□

As in Ref. 6, the relationship

$$\sum_{n=0}^{\infty} |(a_k)_n|^2 \operatorname{cotg}\left(\frac{x-\theta_n}{2}\right) = \operatorname{cotg}\frac{\lambda_k}{2\hbar} \tag{4}$$

also holds for each k. To show (4), we consider each k separately. The proof is the same as for the rank-1 case. See Ref. 6. Points to consider are that each projection operator in the rank-N projection is normalized and hence for every k we have

$$\sum_{n=0}^{N} |(a_k)_n|^2 = 1.$$

□

In order to complete the generalization of Combescure's first theorem, we require, just as in Ref. 6, two additional Lemmas.

Lemma II.2: If $\Sigma_{n=0}^{\infty}|(a_k)_n| < \infty$, *then* $B_k^{-1}(x) < \infty$ *for almost every* $x \in \mathbb{R}$.

For each $k \in 1, \ldots, N$, the proof is identical to that in Ref. 6.

Lemma II.3: The following two statements are equivalent.

(a) *For almost every* $(\lambda_1, \ldots, \lambda_N)$, $V_{\lambda_1,\ldots,\lambda_N}$ *has only a point spectrum.*
(b) *For every* $k \in \{1, \ldots, N\}$ *and for almost every* x, $B_k(x) \neq 0$.

The proof is again virtually identical to Combescure's proof. For each k, the continuous part of the spectrum is supported outside the set $E_k=\{x \in [0,2\pi) : B_k(x) \neq 0\}$ and, for $\lambda_k \neq 0$, the point part of $\mathrm{d}m_{k,\lambda_k}$ is supported by the set E_k. Thus, for $V_{\lambda_1,\ldots,\lambda_N}$ to be pure point for almost every $\lambda_1, \ldots, \lambda_N$ and for every k, we require

$$m_{k,\lambda_k}([0,2\pi) \setminus E_k) = 0.$$

This in turn implies that for every k

$$\int_0^{2\pi} \mathrm{d}\lambda_k' h(\lambda_k') m_{k,\lambda_k}([0,2\pi) \setminus E_k) = 0,$$

where $\lambda_k' = \lambda_k/\hbar$ and

$$h(\lambda) = 2\Re \frac{1}{1 - ce^{i\lambda}}$$

for some $|c| < 1$.

Lemma 5 in Ref. 6 trivially applies for each k. Thus, we have generalized Combescure's work to obtain the result that the Floquet operator for the rank-N perturbed Hamiltonian has a pure point spectrum. The result matches that in Ref. 1.

III. RANK-*N* GENERALIZATION OF COMBESCURE'S SECOND THEOREM

Having shown that the Floquet operator remains pure point for perturbations constructed from the vectors $|\psi_k\rangle \in l_1(H_0)$, Combescure relaxes this condition to allow for the emergence of a continuous spectral component of the Floquet operator. This result is easily generalized to the rank-N case. The key point is that the technique in Ref. 6 applies independently for each k. We do not discuss the details of the rank-1 proof here at all, delaying an analysis to Sec. IV where we will have the opportunity to generalize the result still further. Here, we simply provide the argument for why each k may be treated independently. Before proceeding, some subtleties of what Combescure actually shows are highlighted. They are seemingly overlooked by some in the literature (e.g., Ref. 5).

The cyclicity requirement was essential in the proof that the Floquet operator spectrum was pure point. Here, we can happily ignore the cyclicity conditions, as our only goal is to establish the existence of a state in the continuous subspace $\mathcal{H}_{\text{cont}}$. We need not try and ensure the result obtained by considering $\langle\psi|E(S)|\psi\rangle$ is applicable to all other vectors in $\mathcal{H}$—the very idea is ill-formed as the perturbation is null on a subset of $\mathcal{H}$ and thus there is always part of $\mathcal{H}$ where V has a discrete spectrum. Milek and Seba seem to have missed this point, restating Theorem 1 in Ref. 6 in a way that implies that all ψ are in $\mathcal{H}_{\text{cont}}$.

If

$$\langle\psi_k|E(\{x\})|\psi_k\rangle = 0$$

then $\mathcal{H}_{\text{ac}}$ contains at least the state $|\psi_k\rangle$. The point to be mindful of is that this does not allow one to conclude that the Hilbert space for the operator V has $\mathcal{H}_{pp}=\emptyset$, as implied by Milek and Seba.[5] To draw that conclusion would require an argument to show that a cyclic vector does in fact exist for V. This does not seem possible in the general context we have here.

Combescure's proof (Lemma 6 in Ref. 6) that $\sigma_{\text{cont}}(V)\neq\emptyset$ is based on showing that $B^{-1}(x)\rightarrow\infty$ [Eq. (3)]. As the spectral measure of a single point x is proportional to $B(x)$ [Eq. (2)], if $B^{-1}(x)\rightarrow\infty$, then the contribution of the single point is zero. That is, e^{ix} is in the continuous spectrum of the Floquet operator. Combescure argues (see Sec. IV for details) that

$$B^{-1}(x) \geqslant \#S(x),$$

where $\#S(x)$ is the number of element of a particular set S. She then shows (the bulk of the proof) that $\#S(x)\rightarrow\infty$ and thus $B^{-1}(x)\rightarrow\infty$. We generalize the result in a straightforward manner.

Theorem III.1: *Assume* $\alpha_n=n\hbar\omega$ *with* ω *irrational. If* $|\psi_k\rangle \notin l_1(H_0)$ *for at least one* $k \in 1,\ldots,N$, *then* $\sigma_{\text{cont}}(V)\neq\emptyset$.

Proof III.1: Following the same argument as for the rank-1 case, we take

$$|(a_k)_n| = n^{-\gamma}2\pi$$

for the state $|\psi_k\rangle$, in such a way that the condition $\langle\psi_k|\psi_l\rangle=\delta_{kl}$ is preserved.

With this construction, the proof that the number of elements in $S(x)$ is infinite[6] applies to each subsequence $S_k(x)$. The number of elements, $\#S_k(x)$, in each subsequence for which $|psi_k\rangle \notin l_1(H_0)$, is infinite. The Floquet operator for the rank-N perturbed harmonic oscillator obtains a continuous spectral component. □

Discussion. It must be noted that the proof of Lemma 6 in Ref. 6 is only valid for the eigenvalue spectrum,

$$\alpha_n = n\hbar\omega,$$

of the harmonic oscillator. Combescure does however conjecture that the argument will be valid for more general eigenvalue spectra, including the rotor

$$\alpha_n \propto n^2.$$

For Milek and Seba's numerical work (using the rotor) to be based on valid mathematical arguments, a proof of this conjecture is required. It was only very recently that a proof was developed,[8] some 15 years after the numerical results of Milek and Seba were published. As already mentioned, the work presented here, aiming to justify Milek and Seba's numerical work, was developed independently and is complimentary to Bourget's approach.

In Sec. IV we show that if a conjecture from number theory on the estimation of exponential sums is true, then Milek and Seba's work can be justified. The rank-N generalization is straightforward. Considering the number theory conjecture has stood for some 50 years, it seems we may have to wait quite some time for a proof. (Of course, now that Bourget has provided a direct proof for the rotor, the numerical simulations are on safe ground.)

For more general eigenvalue spectra (loosely $\alpha_n \propto n^j$) the situation is similar. For $j \geqslant 3$ Bourget[7] made significant progress. He has now covered the $j=2$ case.[8] A continuous component of the Floquet operator exists for certain constructions of $|\psi\rangle$. The conditions, for all $j \geqslant 2$, are complicated and more restrictive than the $|\psi\rangle \notin l_1(H_0)$ condition for the harmonic oscillator. The result is easily extended to the rank-N case due to the independence of each k as already discussed. Here, by utilizing a number-theoretic conjecture, we will provide improvements to the work of Bourget (both the $j \geqslant 3$ and $j=2$ cases). See Sec. IV.

Returning to the harmonic oscillator case, by applying Theorem III.1 we may conclude that for each $|\psi_k\rangle \notin l_1(H_0)$, $\mathcal{H}_k$ is purely continuous. Thus, by dropping the l_1 condition for all $|\psi_k\rangle$, we have shown that V is purely continuous on the subspace of $\mathcal{H}$ where the perturbation is nonzero. On the subspace of $\mathcal{H}$ where the perturbation is zero, $V=U$ trivially and thus that portion of the Hilbert space remains pure point.

IV. DISCUSSION OF COMBESCURE'S CONJECTURE

Combescure[6] makes a remark (Remark c.) that she believes Theorem III.1 (Lemma 6, Ref. 6) is generalizable to include systems other than the harmonic oscillator. Explicitly, she conjectures that Hamiltonians, H_0, with eigenvalues, α_n, of the form

$$\alpha_n = \hbar \sum_{j=0}^{p} \beta_j n^j \tag{5}$$

with $\beta_j T/2\pi$ Diophantine for some $j: 1 \leqslant j \leqslant p$ will have the vector ψ in the continuous spectral subspace of V_λ.

At an intuitive level, one would expect this to be true. The precise nature of the eigenvalue spectra (proportional to n or a polynomial in n) should not make a significant difference. Milek[9] argues that Combescure's work can be used in the n^2 case based on evidence from some numerical work that shows that the sequences obtained are "almost random"—however, the argument is not entirely convincing to us. The cited numerical work of Casati *et al.*[10] discusses the existence of correlations in the energy levels, rather than the lack of correlations. While the deviations from a Poisson distribution look small to the naked eye, Casati *et al.*[10] find deviations from the expected Poisson distribution of up to 17 standard deviations. The energy levels are correlated—it is arguable that they are not characterizable as "almost random" as Milek asserts.

In late 2002, Bourget[7] produced a proof of a slightly modified conjecture for all but the $p=2$ case in (5). The techniques used by Bourget are similar to those followed in this work. We will analyze Bourget's work, and highlight the key breakthrough made. We also provide a modified argument to obtain the proof which is, we believe, significantly easier to follow. Importantly, it also covers the $p=2$ case, unresolved by Bourget (until very recently) due to technical difficulties. However, it comes at the expense of relying upon a conjecture. Our result plays a complementary role in understanding, or perhaps appreciating, Bourget's proof. The reliance on the conjecture removes the need for much of the technical wizardry in Bourget's proof, and also strengthens the work. Our analysis also indicates, or highlights, that Combescure's conjecture is solved by a

number-theoretic conjecture that has stood for over 50 years. What seems a perfectly reasonable conjecture on physical grounds is shown to be directly related to an abstract mathematical conjecture.

In what follows, we rely heavily upon the lemmas and theorems in Chapter 2 of Ref. 11. We also use some results on Weyl sums from Ref. 12. Of key importance is an understanding of the proof of Lemma 6 in Ref. 6 on the emergence of a continuous spectrum for the kicked harmonic oscillator. This will be discussed at the appropriate time in this section.

A. Number theory

To discuss the conjecture, we require two concepts from number theory—the classification of irrational numbers and the *discrepancy* of a sequence. We first introduce the concepts and define the relevant ideas. We then proceed to analyze the conjecture and the proof provided by Bourget. As the discussion progresses, the new work that we have done will be presented.

For any number β, we define

(1) $[\beta]$, the integer part of β,
(2) $\{\beta\}$, the fractional part of β, and
(3) $\langle\beta\rangle = \min(\{\beta\}, 1-\{\beta\})$.

$\langle\beta\rangle$ is simply the "distance to the nearest integer." Definition IV.1 is taken directly from Kuipers and Niederreiter (Definition 3.4, p. 121, Ref. 11).

Definition IV.1: η Let be a positive real number or infinity. The irrational β of type η if η is the supremum of all τ for which

$$\lim_{n\to\infty} q^{\tau}\langle q\beta\rangle = 0, \tag{6}$$

where q runs through the positive integers.

The idea behind this definition can be seen by considering *rational* $\beta = p/q'$ for some p and q'. Run through the positive integers q. At $q=q'$, $\langle q\beta\rangle = 0$, so there is no supremum η for τ in (6). In effect, $\eta\to\infty$. For irrational β, $\langle q\beta\rangle$ is never equal to zero but will approach zero. If the approach is very slow, then a small τ is enough to prevent (6) from approaching zero. $\langle q\beta\rangle$ approaching zero slowly is, in a sense, indicative of β being badly approximated by rational numbers. Even for very large q', p/q' remains a poor approximation to β. Thus, the smaller η, the stronger the irrationality of β. This is reasonable in the sense that rational β's act like numbers with $\eta\to\infty$. As stated in Ref. 11, all numbers β have type $\eta \geqslant 1$.

We now define the discrepancy of a sequence—a measure of the nonuniformity of the sequence. We consider a sequence of numbers x_n in $[0, 1)$

$$\omega = (x_n)_{n\in\mathbb{N}} \text{ with } x_n \in [0,1).$$

(Equivalently, consider any sequence x_n and consider the discrepancy of the sequence modulo 1.) For $0 \leqslant a < b \leqslant 1$ and positive integer N, $A([a,b),N)$ counts the number of terms of the sequence (up to x_N) contained in the interval $[a,b)$,

$$A([a,b),N) = \#\{n \leqslant N : x_n \in [a,b)\}.$$

Definition IV.2: The discrepancy D_N of the sequence ω is

$$D_N(\omega) = \sup_{0\leqslant a<b\leqslant 1} \left| \frac{A([a,b),N)}{N} - (b-a) \right|. \tag{7}$$

If the sequence ω is uniformly distributed in $[0, 1)$ then $D_N \to 0$ as $N\to\infty$. In this case, every interval $[a,b]$ in $[0, 1)$ gets its "fair share" of terms from the sequence ω.

Estimating the discrepancy of a sequence will turn out to be vital in the analysis of Combescure's work. The sequence of interest is basically the eigenvalue sequence for H_0, but we will discuss this in greater detail later.

The starting point for the estimations that we require is Eq. (2.42), Chap. 2, Ref. 11. This is a famous result obtained by Erdös and Turán. It states that

$$D_N \leqslant C\left(\frac{1}{m}+\sum_{h=1}^{m}\frac{1}{h}\left|\frac{1}{N}\sum_{n=1}^{N}e^{2\pi i h x_n}\right|\right) \tag{8}$$

for any real numbers $x_1 \ldots x_N$ and any positive integer m. The sum

$$S=\sum_{n=1}^{N}e^{2\pi i h x_n}$$

is an example of a class of exponential sums known as *Weyl sums*, reflecting the pioneering work of Weyl on providing estimations for them. Vinogradov[12] improved on some of the estimations of Weyl. Weyl and Vinogradov's results concern the modulus of the sum, $|S|$, and characterize it as

$$|S| \leqslant \gamma N,$$

where N is the number of terms in the sum and γ tends to zero as $N \to \infty$. The subtle behavior of γ is linked to the rational/irrational nature of the terms in the sequence.

We will use some basic results from the introductory chapter of Ref. 12. In general, we write

$$S=\sum_{n=1}^{N}\exp(2\pi i F(n))$$

for some function $F(n)$. The application here is when

$$F(n)=\beta n^j.$$

For β rational (*not* the case we will be interested in) Hau proved that $|S|$ was of order

$$N^{1-(1/j)+\epsilon}$$

(p. 3, Ref. 12) and that this estimate could not be much improved. Here, we are interested in the case where β is irrational. Estimations are much more difficult, and form the major aspect of the work by Vinogradov. The estimations depend upon making a rational approximation to β and are complicated functions of N and j. Very loosely, he obtains results like

$$|S|=O(N^{1-\rho'}),$$

where

$$\rho'=\frac{1}{3(j-1)^2\log 12j(j-1)}. \tag{9}$$

Vinogradov states

> It is a plausible conjecture that the estimate in (9) holds with ρ' replaced be $1/j-\epsilon\ldots$. A proof or disproof of this conjecture would be very desirable.

As the conjecture plays a central role in what follows, we state it formally.

Conjecture IV.3: Consider the sum

$$S=\sum_{n=1}^{N}\exp 2\pi i n^j\beta_j.$$

For all N greater than some critical value, we have

$$|S| \leqslant cN^{1-(1/j)+\epsilon}$$

for all $\epsilon > 0$ *and some constant* $c \in \mathbb{R}$.

We do not attempt to prove Conjecture IV.3. Given the lengths gone to by Vinogradov to obtain the results presented above, it seems rather unlikely that a proof or disproof will be found any time soon. (Incremental improvements on the estimations presented by Vinogradov in Ref. 12 have been made over time. While Bourget[7,8] makes use of these improved results, the conjecture itself remains unproven which is the only result of any consequence in this discussion.)

B. Upper and lower bounds on discrepancy

Armed with the estimations on Weyl sums, we now proceed to derive both upper and lower bounds on the discrepancy for sequences of the type

$$\omega_j = (n^j \beta)$$

for β of any type $\eta \geqslant 1$. It must be remembered that the upper bound obtained is contingent upon Conjecture IV.3. The lower bound obtained is not dependent upon any unproved conjectures. The result obtained highlights the "best possible" nature of the conjectured upper bound.

First, (Lemma 3.2, p. 122, Ref. 11) is generalized to arbitrary j.

Lemma IV.4: The discrepancy $D_N(\omega_j)$ *of* $\omega_j = (n^j \beta)$ *satisfies*

$$D_N(\omega_j) \leqslant C\left(\frac{1}{m} + N^{1-(1/j)+\epsilon} c' \sum_{h=1}^{m} \frac{1}{h\langle h\beta \rangle}\right)$$

for any positive integer m and $\epsilon > 0$, *where C and c′ are absolute constants.*

Proof (IV.4): Consider (8). It is applicable to the first N terms of the sequence ω_j. We have

$$D_N(\omega_j) \leqslant C\left(\frac{1}{m} + \frac{1}{N}\sum_{h=1}^{m} \frac{1}{h}\left|\sum_{n=1}^{N} e^{2\pi i h n^j \beta}\right|\right) \tag{10}$$

for any positive integer m. Consider the sum over n,

$$\left|\sum_{n=1}^{N} e^{2\pi i h n^j \beta}\right|.$$

Conjecture IV.3 allows this sum to be bounded by

$$cN^{1-(1/j)+\epsilon}.$$

We are free to write

$$c = \frac{c'}{|\sin \pi h\beta|}$$

as $\sin \pi h\beta$ is just some positive real number. Substituting this result into (10), we obtain

$$D_N(\omega_j) \leqslant C\left(\frac{1}{m} + N^{-(1/j)+\epsilon} c' \sum_{h=1}^{m} \frac{1}{h} \frac{1}{|\sin \pi h\beta|}\right).$$

Now following the argument at the end of (Lemma 3.2, Ref. 11) the desired result is obtained.

□

We now give the generalization of (Theorem 3.2, Ref. 11). It provides the "best" upper bound one could hope for when estimating the discrepancy of the sequence $\omega_j=(n^j\beta)$. Again, remember that the proof relies on Conjecture IV.3.

Theorem IV.5: *Assume Conjecture IV.3 is true. Let β be of finite type η. Let j be a positive integer $j\geqslant 1$. Then, for every $\epsilon>0$, the discrepancy $D_N(\omega_j)$ of $\omega_j=(n^j\beta)$ satisfies*

$$D_N(\omega_j) = O(N^{-1/(\eta j)+\epsilon}).$$

Proof (IV.5): Let $\epsilon>0$ be fixed. By (Lemma 3.1 and Lemma 3.3, p. 121-3, Ref. 11),

$$\sum_{h=1}^{m} \frac{1}{h\langle h\beta\rangle} = O(m^{\eta-1+\epsilon'})$$

for a fixed $\epsilon'>0$. Combining this with Lemma IV.4, gives

$$D_N(\omega_j) \leqslant C\left(\frac{1}{m} + N^{-(1/j)+\epsilon''} m^{\eta-1+\epsilon'}\right)$$

for all $m\geqslant 1$. Now choose $m=[N^{1/(\eta j)}]$. We obtain

$$D_N(\omega_j) \leqslant C(N^{-1/(\eta j)} + N^{-(1/j)+\epsilon''+(1/j)-1/(\eta j)+\epsilon'/(\eta j)}) = O(N^{-1/(\eta j)+\epsilon}),$$

where $\epsilon=\epsilon''+\epsilon'/(\eta j)$. □

Theorem IV.5 is, in a sense, optimal. For functions f,g, define $f=\Omega(g)$ if $f/g \nrightarrow 0$.

Theorem IV.6: *Let β be of finite type η. Let j be a positive integer $j\geqslant 1$. Then, for every $\epsilon>0$, the discrepancy $D_N(\omega_j)$ of $\omega_j=(n^j\beta)$ satisfies*

$$D_N(\omega_j) = \Omega(N^{-1/(\eta j)-\epsilon}).$$

Proof (IV.6): Let $\epsilon>0$ be fixed. For any given $\epsilon'>0$, there exists $0<\delta<\eta$ with $1/(\eta-\delta) = (1/\eta)+\epsilon'$. By (Definition 3.4, p. 121, Ref. 11), we have $\lim_{q\to\infty} q^{\eta-(\delta/2)}\langle q\beta-j\rangle=0$ and thus

$$\langle q\beta_j\rangle < q^{-\eta+(\delta/2)}$$

for an infinite number of positive integers q. There are infinitely many positive integers q and p such that

$$|\beta - p/q| < q^{-1-\eta+(\delta/2)}.$$

That is, by choosing q large enough, we can always find a p such that $|q\beta-p|=\langle q\beta\rangle$. As q increases p/q is a better approximation to the irrational β. For θ some irrational with $|\theta|<1$, we have

$$\beta = p/q + \theta q^{-1-\eta+(\delta/2)}.$$

Pick a q such that the above relations are valid. Set

$$N = [q^{j(\eta-\delta)}].$$

Then for $1\leqslant n^j \leqslant N^{1/j}$,

$$n^j\beta = n^j(p/q) + \theta_n,$$

with

$$|\theta_n| = |n^j\theta q^{-1-\eta+(\delta/2)}| < n^j q^{-1-\eta+(\delta/2)} \leqslant q^{[j(\eta-\delta)]^{1/j}-1-\eta+(\delta/2)} = q^{-1-(\delta/2)}.$$

Thus, none of the fractional parts $\{\beta\},\{2^j\beta\},\ldots,\{[N^{1/j}]\beta\}$ lie in the interval $J=[q^{-1-(\delta/2)}, q^{-1}-q^{-1-(\delta/2)})$, so

$$D_N(\omega_j) \geqslant \left| \frac{A(J,N)}{N} - \lambda(J) \right| = \lambda(J)$$

where $\lambda(J)$, is simply the "size" of the set J. For large enough q we have $\lambda(J) \geqslant 1/2q$. But from the definition of N it is clear that

$$N \leqslant q^{j(\eta-\delta)} \leqslant N+1 \leqslant 2N,$$

so

$$q^{-1} \geqslant cN^{-[j(\eta-\delta)]^{-1}}.$$

Combining these inequalities, we obtain

$$D_N(\omega_j) \geqslant c' N^{-[j(\eta-\delta)]^{-1}} = c' N^{-(1/j)(1/(\eta-\delta))} = c' N^{-(1/j)((1/\eta)+\epsilon')} = c' N^{-1/(\eta j)-\epsilon},$$

where $\epsilon = \epsilon'/j$. That is, we have shown, for all $\epsilon > 0$, that

$$D_N(\omega_j) = \Omega(N^{-1/(\eta j)-\epsilon}).$$

□

C. Combescure's conjecture, Bourget's work, and new results

Before discussing the conjecture, we must clearly understand Combescure's proof for the harmonic oscillator case. As stated in Sec. III, the aim is to show that

$$B^{-1}(x) = \sum_{n=0}^{\infty} |a_n|^2 \left(\frac{2}{\sin(x-\theta_n)} \right)^2 \to \infty.$$

We define the set $S(x)$,

$$S(x) = \{n : |x-\theta_n| \leqslant |a_n| = n^{-\gamma} 2\pi\}. \tag{11}$$

Each n is an element of $S(x)$ if x is "close to θ_n." Note that $\theta_n = 2\pi\{\alpha_n/2\pi\hbar\}$, where $\{.\}$ is the fractional part, not "set" and α_n are the eigenvalues of the base Hamiltonian H_0.

Given that $\sin x \leqslant x$ for all $x \geqslant 0$, a lower bound for $B^{-1}(x)$ is obtained,

$$B^{-1}(x) \geqslant \sum_{n=0}^{\infty} |a_n|^2 \left(\frac{2}{x-\theta_n} \right)^2 \geqslant \sum_{n \in S(x)} \frac{4|a_n|^2}{(x-\theta_n)^2} \geqslant 4 \,\#\, S(x). \tag{12}$$

Each $n \in S(x)$ gives a contribution to the sum of greater than one as $|a_n|/|x-\theta_n| \geqslant 1$. By only considering $\#S(x)$, we simply count a "1" each time.

The results on discrepancy of sequences are now used, with the sequence $\omega_{\mathrm{HO}} = (\theta_n/2\pi)$. Note that each element of the sequence ω_{HO} is in $[0, 1)$.

Consider the interval, defined for every $x \in (0, 2\pi)$ and centered around $x/2\pi$,

$$J_N(x) = \left[\frac{x}{2\pi} - N^{-\gamma}, \frac{x}{2\pi} + N^{-\gamma} \right]. \tag{13}$$

For large enough $N, J_N(x) \subset [0,1)$. The size of the interval is $2N^{-\gamma}$. Using this particular subset and noting that the definition of discrepancy (7) involves taking the supremum over all subsets of $[0, 1)$, Combescure obtains

$$|N^{-1} A(J_N(x), N) - 2N^{-\gamma}| \leqslant D_N(\omega_{\mathrm{HO}}).$$

Multiplying through by N gives

$$|A(J_N(x),N) - 2N^{1-\gamma}| \leqslant ND_N(\omega_{\mathrm{HO}}). \tag{14}$$

As $|\psi\rangle \notin l_1(H_0)$

$$\sum |a_n| \to \infty$$

and thus

$$1/2 < \gamma \leqslant 1$$

from simple convergence arguments. Therefore, $N^{1-\gamma}$ grows at a rate less than $N^{1/2}$. [Interestingly, it can in fact not grow at all ($\gamma=1$) which is a subtle point seemingly missed by Combescure and others. The rank-1 projection operator from the vector $|\psi\rangle$ constructed with $\gamma=1$ is not shown to lead to the emergence of a continuous spectrum. Therefore, the statement that $|\psi\rangle \notin l_1(H_0)$ implies $|\psi\rangle \in \mathcal{H}_{\mathrm{cont}}$ is not in fact proved to be true. There are vectors not in $l_1(H_0)$ that may not be in the continuous spectrum. In practice (numerical, experimental work) this should not cause any trouble. It is clearly easy to avoid $\gamma=1$.] At this stage, Combescure utilizes the theorems discussed above on the discrepancy of sequences. For the eigenvalue sequence, $\alpha_n=n\hbar\omega$, of the harmonic oscillator the $j=1$ case of Theorem IV.5 applies which is exactly (Theorem 3.2, Ref. 11). (Do not confuse ω, the harmonic oscillator frequency, with ω_{HO}, the label for the sequence in $[0, 1)$, the discrepancy of which is being bounded.) Combescure obtains the result

$$D_N(\omega_{\mathrm{HO}}) = O(N^{-1(/\eta)+\epsilon}).$$

(This is not based on a conjecture as for $j=1$ a direct proof is possible, bypassing Conjecture IV.3. See. Ref. 11.) For the sequence $\omega_{\mathrm{HO}}, \beta=\omega/2\pi$. If β is an irrational of constant type ($\eta=1$), the strongest type of irrational, then

$$ND_N(\omega_{\mathrm{HO}}) = O(N^{\epsilon}).$$

As the right-hand side of (14) can be made to grow arbitrarily slowly, we conclude that the left-hand side must grow slowly too. Thus, to cancel out the growth of $2N^{1-\gamma}$, $A(J_N(x),N)$ must grow at a rate arbitrarily close to that of $2N^{1-\gamma}$. We see that

$$A(J_N(x),N) \to \infty$$

as $N\to\infty$. It is now a simple observation[6] that this implies that $\#S(x)\to\infty$ and thus $B^{-1}(x)\to\infty$. Thus, e^{ix} is in the continuous spectral subspace of the Floquet operator V.

The importance of the eigenvalue sequence is seen in that if we cannot limit the right-hand side of (14), then we cannot place a lower limit on $A(J_N(x),N)$ and thus we cannot conclude that $B^{-1}(x)\to\infty$. Two barriers to limiting the right-hand side of this equation exist—j and η. If, still in the harmonic oscillator case, we wished for $\beta=\omega/2\pi$ to only be of a weaker type, say $\eta=2$, we would no longer be able to conclude that $B^{-1}\to\infty$. The right-hand side would grow like $N^{(1/2)+\epsilon}$, which is always faster than $2N^{1-\gamma}$ for $1/2<\gamma\leqslant 1$ which grows at a rate of $N^{(1/2)-\epsilon}$. Thus, no suitable lower limit for $A(J_N(x),N)$ can be found. Similarly, if the eigenvalue sequence is generalized (Combescure's conjecture) then we run into trouble. For $j=2$, the lowest possible growth rate for the right-hand side we can obtain, taking Conjecture IV.3 as true, applying Theorem 5 and noting Theorem IV.6 which says we cannot do any better, is, once again, $N^{(1/2)+\epsilon}$. For larger j, the situation only gets worse.

Given these seemingly significant problems, the natural question to ask is: "How does one get around this problem?" The answer is provided in the work of Bourget.[7] Bourget proves a weaker theorem than Combescure's conjecture. Where the same requirement on $|\psi\rangle$ is kept in Ref. 6, that it be in $l_1(H_0)$, Bourget has a j dependent requirement. Essentially, for increasing j the a_n terms used to construct $|\psi\rangle$ must decrease more slowly with n. See Bourget's work for the exact requirement, which depends on the best estimates available for Weyl sums discussed earlier and thus is a nontrivial function of j.

The key insight in obtaining the proof is to modify the set $S(x)$ [Eq. (11)] and the corresponding interval $J_N(x)$ [Eq. (13)] that we consider. Importantly, they become j dependent. Bourget reduces the shrinking rate of the set $J_N(x)$ as a function of N just enough so as to allow the weaker limits on the discrepancy to be good enough to force the right-hand side of the equivalent to (14) to be less than the left-hand side, while keeping strong enough control on terms in the new set $S(x)$ to still argue that $B^{-1}\to\infty$.

Using the best available estimations on Weyl sums and plugging these into the upper bound formulas for discrepancy (as discussed earlier when introducing the work by Vinogradov), Bourget manages to provide a rigorous proof of the existence of a continuous spectral component of the Floquet operator (the essence of Combescure's conjecture) for $j\geqslant 3$[7] and $j=2$.[8] The proof is, unfortunately, unavoidably clouded by the "messy" estimates available for Weyl sums and thus, the essence of the proof is difficult to see. Here, we will revisit the proof, but (utilizing Conjecture IV.3) apply Theorem IV.5 which says (using 2ϵ, rather than ϵ for technical reasons), for all $\epsilon>0$,

$$D_N(\omega)=O(N^{-1/(\eta j)+2\epsilon}).$$

With this very clean estimate, it is far easier to see how Bourget's work provides a proof that a continuous spectral component of the Floquet operator exists. It covers all $j\geqslant 2$. We highlight the fact that a solution to Vinogradov's conjecture provides an elegant solution to Combescure's physics conjecture. The j-dependence of the a_n's used to construct $|\psi\rangle$ is straightforward.

Theorem IV.7: *Assume Conjecture IV.3 is true and thus Theorem IV.5 follows. Assume β is irrational and of type η. Then for all positive integers, j, the Floquet operator, V, has $\sigma_{\mathrm{cont}}(V)\neq\emptyset$ if $1/2<\gamma<1/2+1/(2\eta j)$.*

Proof (IV.7): The proof relies upon the techniques utilized by Bourget. In essence, we simply increase the size of the interval [Eq. (13)] from $2N^{-\gamma}$ to $2N^{2((1/2)-\gamma)}(\log N)^{-1/2}$. The important change is the first factor. The $\log N$ term is essential for technical reasons, but has a negligibly small effect on the shrinkage rate of the interval for large N. As $\log N/N^{4\delta}\to 0$ as $N\to\infty$ for all $\delta>0$, for N large enough we have

$$2N^{2((1/2)-\gamma)}(\log N)^{-1/2}>2N^{2((1/2)-\gamma-\delta)}.$$

Using this underestimate for the size of the interval, we easily obtain the equivalent of (14),

$$|A(J_N(x),N)-2N^{2(1-\gamma-\delta)}|\leqslant ND_N(\omega_j),$$

for the sequence $\omega_j=(n^j\beta)$. Now, using Theorem IV.5, it is evident that to ensure $A(J_N(x),N)\to\infty$, we must have

$$2(1-\gamma-\delta)>1-1/(\eta j)+2\epsilon,$$

or

$$\gamma<1/2+1/(2\eta j)-\epsilon-\delta.$$

The condition

$$1/2<\gamma<1/2+1/(2\eta j), \tag{15}$$

where the "$<$" sign has absorbed the arbitrarily small numbers ϵ and δ, must be satisfied to force $A(J_N(x),N)\to\infty$.

Finally, we must show that $B^{-1}(x)\to\infty$ when this larger interval is used. Corresponding to the new interval $J_N(x)$, we introduce the new set $S(x)$,

$$S(x)=\{n:|x-\theta_n|\leqslant 2\pi N^{2((1/2)-\gamma)}\log N^{-1/2}\}.$$

The estimate (12) is the same, except with the new set $S(x)$, which no longer has all terms greater than unity. Thus, it is not enough to simply count the number of terms in $S(x)$. A more subtle

estimate is required. Replacing the numerator, $|a_n|$, with something smaller, $N^{-\gamma}$, and the denominator, $(x-\theta_n)$, with something larger, $2\pi N^{2((1/2)-\gamma)} \log N^{-1/2}$, we obtain

$$B^{-1}(x) \geqslant \frac{1}{\pi^2} \sum_{n \in S(x)} \frac{\log N}{N^{2(1-\gamma)}},$$

which is essentially the estimate Bourget obtains. The estimate contained therein (Lemma 3.5 in Ref. 7) then shows that $B^{-1}(x) \to \infty$ and the argument is complete. □

Examining (15) we note that for $j=1$ (for $\eta=1$) we recover the simple result of Combescure. For all $j \geqslant 2$, we have a stronger (j-dependent) condition on $|\psi\rangle$ than simply $|\psi\rangle \notin l_1(H_0)$. This complication is the main weakening of Combescure's conjecture that Bourget and we have been forced to make. Note that the restriction on γ takes into account the end point subtleties referred to in the preceding discussions.

We have replaced the requirement that $|\psi\rangle \notin l_1(H_0)$ (i.e., $1/2 < \gamma \leqslant 1$) with the j dependent requirement $1/2 < \gamma < 1/2 + 1/(2j)$. In Bourget's work, the requirement is stronger—directly related to the replacement of the known limits on Weyl sums (in terms of ρ in the earlier sections) with the "best possible" estimate from our Conjecture IV.3 of $(1/j) - \epsilon$.

D. Summary

Reliance on Conjecture IV.3 and the result of Theorem IV.5 derived from it has allowed us to discuss Bourget's proof without the complications of the messy estimations on Weyl sums. Bourget's proof is also n-dependent (m in his work) while ours is n-independent. This simplified discussion highlights the key aspects of Bourget's proof, both for $j \geqslant 3$[7] and $j=2$.[8] It has also shown that the emergence of a continuous spectral component of the Floquet operator is solved by Vinogradov's conjecture. A proof of Vinogradov's conjecture is no longer just of mathematical interest. It has a direct mathematical physics consequence.

Finally, note that the rank-N equivalent of this work follows in the same way as presented for the harmonic oscillator case in Sec. III, providing a complete rank-N generalization of the work of Combescure.[6]

V. GENERALIZING THE RESULTS OF MILEK AND SEBA

Having established that the continuous subspace of $\mathcal{H}$, $\mathcal{H}_{\text{cont}}$ is not empty, we wish to characterize it—by identifying the singular and absolutely continuous components. Here, we extend the result of Milek and Seba to rank-N perturbations.

Theorem V.1: *Assume $H(t)$ is given by* (1) *and that* (2) *applies. Assume that $B_k^{-1}(x) \to \infty$ and thus $\mathcal{H}_{\text{cont}} \neq \emptyset$. Then $\mathcal{H}_{ac} = \emptyset$ and thus $\mathcal{H}_{sc}$ is not-empty. The Floquet operator, V, has a nonempty singular continuous spectrum.*

Proof (V.1): As shown in the proof of Theorem II.4a, (Ref. 1) and easily calculated, the Floquet operator can be written in the form

$$V = U + \sum_{k=1}^{N} R_k,$$

where

$$R_k = (e^{i\lambda_k/\hbar} - 1)|\psi_k\rangle\langle\psi_k|U. \tag{16}$$

We can now use either (Theorem 5, Ref. 13) or (Theorem 1, Ref. 14). The theorem from the paper of Birman and Krein is more direct, so we use it here. It states that if we have two unitary operators, U and V, that differ by a trace class operator, then the wave operators

$$\Omega_{\pm} = \mathrm{s} - \lim_{\nu \to \pm\infty} V^{\nu} U^{-\nu} P_{\mathrm{ac}}(U)$$

exist and their range is the absolutely continuous subspace of V,

$$R(\Omega_{\pm}) = \mathcal{H}_{\mathrm{ac}}(V). \tag{17}$$

We must show that the difference $V-U$ is finite. With the notation in Ref. 1, where the perturbation W is given by $A^{*}A$ and

$$A = |\psi\rangle\langle\psi|,$$

with

$$|\psi\rangle = \sum_{n} a_n \phi_n,$$

we obtain

$$\mathrm{Tr}\, A^{*}A = \mathrm{Tr}\, A = \sum_{l} \langle \phi_l | A | \phi_l \rangle = \sum_{l,m,n} \langle \phi_l | a_n | \phi_n \rangle \langle \phi_m | a_m^{*} | \phi_l \rangle = \sum_{l,m,n} a_n a_m^{*} \delta_{ln} \delta_{ml} = \sum_{l} |a_l|^2 = 1$$

as $|\psi\rangle \in l_2(H_0)$ and is normalized. The perturbation to the Hamiltonian is trace class. The difference in unitary operators, U and V, is also trace class. By the triangle inequality for norms,

$$\|R_k\|_{\mathrm{Tr}} \leqslant \|(e^{i\lambda_k/\hbar} - 1)\| \, \| \, |\psi_k\rangle\langle\psi_k| \|_{\mathrm{Tr}} \|U\|_{\mathrm{Tr}}.$$

As $\|U\|_{\mathrm{Tr}} = 1$,

$$\mathrm{Tr}\left(\sum_{k=1}^{N} R_k \right) \leqslant \sum_{k} \|(e^{i\lambda_k/\hbar} - 1 \, \| \sum_{l,m,n} \langle \phi_l | (a_k)_n | \phi_n \rangle \langle \phi_m | (a_k)_m^{*} | \phi_l \rangle = \sum_{k} |e^{i\lambda_k \hbar} - 1| = \sum_{k} \sqrt{2(1 - \cos \lambda_k/\hbar)}.$$

Armed with a trace-class perturbation, we conclude that the wave operators exist. The existence of the operators $\Omega_{\pm}$ means that they are defined for all vectors in the Hilbert Space $\mathcal{H}$. Note [Eq. (17)] that the subspace $\mathcal{H}_{\mathrm{ac}}(V)$ is equal to the range of these operators. However, $P_{\mathrm{ac}}(U)$ gives zero when acting on any state in $\mathcal{H}$ because U is pure point. Thus, $\mathcal{H}_{\mathrm{ac}}(V)$ is empty. As $\mathcal{H}_{\mathrm{cont}}$ is not empty, $\mathcal{H}_{\mathrm{sc}}$ must be nonempty, and we have proved that a singular continuous subspace of the Floquet operator V exists. □

The key assumption in Theorem V.1 is that $B_k^{-1}(x) \to \infty$. This is certainly true for $j=1$ if $|\psi_k\rangle \neq l_1(H_0)$. For $j \geqslant 2$, Bourget[7,8] showed that one can construct vectors $|\psi_k\rangle$ for which $B_k^{-1}(x) \to \infty$. The results were discussed in detail in Sec. IV. We have shown, in Conjecture IV.7, that if Conjecture IV.3 is true then this result may be improved—the requirements on the states $|\psi_k\rangle$ are less restrictive. The result was also extended to rank-N perturbations.

Discussion. Milek and Seba make a number of incorrect statements in obtaining this result for the rank-1 case. First, they state that the operator $R=[\exp(i\lambda/\hbar)-1]|\psi\rangle\langle\psi|U$ is rank-1 which it is not—the presence of the unitary operator U stops R from being rank-1. [As we are dealing with the rank-1 case, the subscript k may be dropped from (16).] This is not, however, important. The applicability of the theorems in Refs. 13 and 14 does not rely upon the rank of the operator R, but upon it being of trace-class. Second, they claim that the existence of the wave operators implies that

$$\sigma_{\mathrm{ac}}(V) \subset \sigma_{\mathrm{ac}}(U). \tag{18}$$

This is, again, not true. Given that $\sigma_{\mathrm{ac}}(U)$ is empty, it is indeed possible to conclude that $\sigma_{\mathrm{ac}}(V)$ is empty, as discussed earlier, but the relation (18) does not follow. Consider the situation where $\sigma_{\mathrm{cont}}(U)$ is not empty. Then there is a set of vectors in $\mathcal{H}$ which are continuous for U. These vectors form the domain for the operator V^{ν} in the wave operators. The action with V^{ν} does not however keep us in the subspace $\mathcal{H}_{\mathrm{cont}}(U)$ as the space we get to (the range for V^{ν}) is only

invariant for $\mathcal{H}_{\mathrm{cont}}(V)$, not $\mathcal{H}_{\mathrm{cont}}(U)$. Thus, we may obtain a vector, necessarily in $\mathcal{H}_{\mathrm{cont}}(V)$ due to invariance, but possibly in $\mathcal{H}_{\mathrm{s}}(U)$, and thus, we cannot conclude that $\sigma_{\mathrm{ac}}(V) \subset \sigma_{\mathrm{ac}}(U)$. These two points discussed do not make the final results of Milek and Seba wrong, but "only" the proofs.

Of greatest concern is the use of Lemma 6 in Ref. 6 without justification. Milek and Seba have assumed that Combescure's conjecture is true. It has taken 15 years, and a significant amount of work by Bourget, for that to be shown to be the case. We have shown that the conjecture is directly linked to a long-standing number-theoretic conjecture. The work has also been extended to cover rank-N perturbations.

VI. SUMMARY

We have generalized the work of both Combescure[6] and Milek and Seba[5] from rank-1 to rank-N. We have also discussed in detail Combescure's conjecture, our work on estimations of discrepancy and the demonstration by Bourget[7] that a continuous spectral component of the Floquet operator does exist for certain constructions of $|\psi\rangle$. This covers the essential aim of Combescure's conjecture on the existence of a continuous spectral component. A clear view of the essence of Bourget's proof has been provided by taking a reasonable number-theoretic conjecture to be true. With this clear view, the work of Bourget becomes more accessible. A resolution to Vinogradov's conjecture would have direct implications in mathematical physics.

An in-depth critical analysis of the work of Milek and Seba was also undertaken; we highlighted a number of misconceptions in the work. A proof of Vinogradov's conjecture, allowing our work to provide an elegant solution to Combescure's conjecture, remains desirable.

On the exceptional $N=6$ superconformal algebra

Elena Poletaeva[a)]
Department of Mathematics, University of California, Riverside, California 92521

(Received 21 April 2005; accepted 13 July 2005; published online 10 October 2005; publisher error corrected 12 January 2006)

We realize the exceptional $N=6$ superconformal algebra, spanned by 32 fields, inside the Lie superalgebra of pseudodifferential symbols on the supercircle $S^{1|3}$. Correspondingly, we obtain two nonisomorphic one-parameter families of irreducible representations of this superconformal algebra in a superspace spanned by 8 fields. © *2005 American Institute of Physics*. [DOI: 10.1063/1.2035029]

I. INTRODUCTION

A *superconformal algebra* is a simple complex Lie superalgebra $\mathfrak{g}$ spanned by the coefficients of a finite family of pairwise local fields $a(z)=\sum_{n\in\mathbb{Z}}a_{(n)}z^{-n-1}$; one of the members of this family is the Virasoro field $L(z)$.[1–4] Superconformal algebras play an important rôle in the string theory and conformal field theory.

The Lie superalgebra $K(N)$ of contact vector fields with Laurent polynomials as coefficients (with N odd variables) is a superconformal algebra which is characterized by its action on a contact 1-form.[1,2,5,6] These Lie superalgebras are also known to physicists as the $SO(N)$ superconformal algebras.[7] Note that $K(N)$ is spanned by 2^N fields. It is simple if $N\neq 4$, if $N=4$, then the derived Lie superalgebra $K'(4)$ is simple. The nontrivial central extensions of $K(1)$, $K(2)$, and $K'(4)$ are well known: they are isomorphic to the Neveu-Schwarz superalgebra, and the so-called "$N=2$," and "big $N=4$" superconformal algebra, respectively.[7]

The superalgebra $K(6)$ contains a simple subsuperalgebra spanned by 32 fields. This new exceptional superconformal algebra was constructed in Ref. 1 (and denoted by CK_6) and in Ref. 8 (and denoted by $\mathfrak{kas}$); see also Refs. 5 and 9–13. It was proven in Refs. 1 and 5 that CK_6 has no nontrivial central extensions. It was also pointed out that CK_6 appears to be the only new superconformal algebra, which completes their list; see Refs. 2–6.

Martinez and Zelmanov[14,15] obtained CK_6 using their construction of superalgebras $CK(R,d)$, where R is an associative commutative superalgebra with an even derivation d.

In this work we realize CK_6 inside the Poisson superalgebra $P(6)$ of pseudodifferential symbols on the supercircle $S^{1|3}$ and inside its deformation $P_h(6)$.

It is known that a Lie algebra of contact vector fields can be realized as a subalgebra of Poisson algebra.[16] In particular, the Lie algebra $Vect(S^1)$ of complex polynomial vector fields on the circle has a natural embedding into the Poisson algebra $P(0)$ of formal Laurent series on the cylinder $T^*S^1\backslash S^1$. One can consider a family of Lie algebras P_h, $h\in\,]0,1]$, having the same vector space, which contracts to $P(0)$.[17–20] Analogously, $K(2N)$ is embedded into the Poisson superalgebra $P(2N)$ of pseudodifferential symbols on the supercircle $S^{1|N}$, and there is a family of Lie superalgebras $P_h(2N)$, which contracts to $P(2N)$; see Ref. 21.

A natural question is whether there exists an embedding

$$K(2N)\subset P_h(2N). \tag{1.1}$$

Recall that the answer is "yes" if $N=2$, more precisely, there exists an embedding

a)*Electronic mail*: elena@math.ucr.edu

$$\hat{K}'(4) \subset P_h(4), \tag{1.2}$$

where $K'(4)=[K(4),K(4)]$ is a simple ideal of $K(4)$ of codimension one, and $\hat{K}'(4)$ is one of three independent central extensions of $K'(4)$. Associated with the embedding (1.2), there is a one-parameter family of irreducible representations of this central extension $\hat{K}'(4)$ realized on 4 fields.[21]

Note that embedding (1.1) does not hold if $N>2$.[22] However, it is remarkable that it is possible to embed CK_6, which is "one half" of $K(6)$, into $P_h(6)$. We construct two such embeddings, and obtain the corresponding one-parameter families of irreducible representations of CK_6 realized on 8 fields. In particular, we obtain representations of CK_6 in 8 fields, which preserve an odd nondegenerate supersymmetric or superskew-symmetric bilinear form. We also show how the superalgebra CK_6 is generated inside $P_h(6)$.

II. CONTACT SUPERCONFORMAL ALGEBRA *K*(2*N*)

Let $\Lambda(2N)$ be the Grassmann algebra in $2N$ variables $\xi_1,\dots,\xi_N$, $\eta_1,\dots,\eta_N$, and let $\Lambda(1,2N)=\mathbb{C}[t,t^{-1}]\otimes\Lambda(2N)$ be the associative superalgebra with natural multiplication and with the following parity of generators: $p(t)=\overline{0}$, $p(\xi_i)=p(\eta_i)=\overline{1}$ for $i=1,\dots,N$. Let $W(2N)$ be the Lie superalgebra of all derivations of $\Lambda(1,2N)$. Let ∂_t, ∂_{ξ_i}, and ∂_{η_i} stand for $\partial/\partial t,\partial/\partial\xi_i$, and $\partial/\partial\eta_i$, respectively. By definition,

$$K(2N)=\{D\in W(2N)\mid D\Omega=f\Omega \quad \text{for some } f\in\Lambda(1,2N)\}, \tag{2.1}$$

where $\Omega=\mathrm{d}t+\Sigma_{i=1}^{N}(\xi_i\,\mathrm{d}\eta_i+\eta_i\,\mathrm{d}\xi_i)$ is a differential 1-form, which is called a *contact form*; see Refs. 1, 2, 5, 6, 8, and 11–13, and 23. Let the Euler operator be defined by

$$E=\sum_{i=1}^{N}(\xi_i\partial_{\xi_i}+\eta_i\partial_{\eta_i}). \tag{2.2}$$

Set also:

$$\Delta=2-E, \quad H_f=(-1)^{p(f)+1}\sum_{i=1}^{N}(\partial_{\xi_i}f\partial_{\eta_i}+\partial_{\eta_i}f\partial_{\xi_i}), \tag{2.3}$$

for any $f\in\Lambda(1,2N)$.

There is a one-to-one correspondence between the differential operators $D\in K(2N)$ and the functions $f\in\Lambda(1,2N)$. The correspondence $f\leftrightarrow D_f$ is given by

$$D_f=\Delta(f)\frac{\partial}{\partial t}+\frac{\partial f}{\partial t}E-H_f. \tag{2.4}$$

The contact bracket on $\Lambda(1,2N)$ is

$$\{f,g\}_K=\Delta(f)\partial_t g-\partial_t f\Delta(g)-\{f,g\}_{P.b}, \tag{2.5}$$

where

$$\{f,g\}_{P.b}=(-1)^{p(f)+1}\sum_{i=1}^{N}(\partial_{\xi_i}f\partial_{\eta_i}g+\partial_{\eta_i}f\partial_{\xi_i}g) \tag{2.6}$$

is the Poisson bracket. Thus $[D_f,D_g]=D_{\{f,g\}_K}$.

Let $\Theta=\xi_1\xi_2\xi_3\eta_1\eta_2\eta_3$.

Proposition 2.1: (See Refs. 1,5, and 8.) The superalgebra $K(6)$ contains an exceptional $N=6$ superconformal algebra CK_6. It is spanned by the following 32 fields:

$$L_n = t^{n+1} - (\partial_t)^3 t^{n+1}\Theta,$$

$$G_n^i = t^{n+1}\xi_i + (\partial_t)^2 t^{n+1}\partial_{\eta_i}\Theta, \quad \widetilde{G}_n^i = t^n\eta_i + (\partial_t)^2 t^n \partial_{\xi_i}\Theta, \quad i=1,2,3,$$

$$T_n^{ij} = t^n\xi_i\eta_j - (\partial_t)t^n\partial_{\eta_i}\partial_{\xi_j}\Theta, \quad i\neq j, \quad T_n^i = t^n\xi_i\eta_i - (\partial_t)t^n\partial_{\eta_i}\partial_{\xi_i}\Theta, \quad i=1,2,3,$$

$$S_n^i = t^n\xi_i(\xi_j\eta_j + \xi_k\eta_k), \quad \widetilde{S}_n^i = t^{n-1}\eta_i(\xi_j\eta_j - \xi_k\eta_k), \quad i=1,2,3, \tag{2.7}$$

$$I_n^i = t^{n-1}\xi_i\eta_j\eta_k, \quad i=1,2,3, \quad I_n = t^{n+1}\xi_1\xi_2\xi_3,$$

$$J_n^{ij} = t^{n+1}\xi_i\xi_j - (\partial_t)t^{n+1}\partial_{\eta_i}\partial_{\eta_j}\Theta, \quad \widetilde{J}_n^{ij} = t^{n-1}\eta_i\eta_j - (\partial_t)t^{n-1}\partial_{\xi_i}\partial_{\xi_j}\Theta, \quad i<j,$$

where $n\in\mathbb{Z}$; (i,j,k) is the cycle $(1,2,3)$ in the formulas for $S_n^i, \widetilde{S}_n^i$ and I_n^i.

III. POISSON SUPERALGEBRA $P(2N)$ OF PSEUDODIFFERENTIAL SYMBOLS ON $S^{1|N}$

The *Poisson algebra* $P(0)$ *of pseudodifferential symbols on the circle* is formed by the formal series $A(t,\tau)=\sum_{-\infty}^{n} a_i(t)\tau^i$, where $a_i(t)\in\mathbb{C}[t,t^{-1}]$, and the even variable τ corresponds to ∂_t. The Poisson bracket is defined as follows:

$$\{A(t,\tau),B(t,\tau)\} = \partial_\tau A(t,\tau)\partial_t B(t,\tau) - \partial_t A(t,\tau)\partial_\tau B(t,\tau). \tag{3.1}$$

The Poisson algebra $P(0)$ has a deformation P_h, where $h\in\,]0,1]$. The associative multiplication in the vector space P is determined as follows:

$$A(t,\tau)\circ_h B(t,\tau) = \sum_{n\geqslant 0}\frac{h^n}{n!}\partial_\tau^n A(t,\tau)\partial_t^n B(t,\tau). \tag{3.2}$$

The Lie algebra structure on P_h is given by $[A,B]_h = A\circ_h B - B\circ_h A$, so that the family P_h contracts to $P(0)$. The Lie algebra P_h is called the *Lie algebra of pseudodifferential symbols on the circle*.[17–20]

The *Poisson superalgebra* $P(2N)$ *of pseudodifferential symbols on the supercircle* $S^{1|N}$ has the underlying vector space $P\otimes\Lambda(2N)$. The Poisson bracket is defined as follows:

$$\{A,B\} = \partial_\tau A\partial_t B - \partial_t A\partial_\tau B + \{A,B\}_{P.b}. \tag{3.3}$$

Let $\Lambda_h(2N)$ be an associative superalgebra with generators $\xi_1,\ldots,\xi_N,\ \eta_1,\ldots,\eta_N$ and relations:

$$\xi_i\xi_j = -\xi_j\xi_i, \eta_i\eta_j = -\eta_j\eta_i, \eta_i\xi_j = h\delta_{i,j} - \xi_j\eta_i. \tag{3.4}$$

Let $P_h(2N)=P_h\otimes\Lambda_h(2N)$ be a superalgebra with the product of $A=A_1\otimes X$ and $B=B_1\otimes Y$, where $A_1,B_1\in P_h$, and $X,Y\in\Lambda_h(2N)$, given by

$$AB = \frac{1}{h}(A_1\circ_h B_1)\otimes(XY). \tag{3.5}$$

The Lie bracket in $P_h(2N)$ is $[A,B]_h = AB - (-1)^{p(A)p(B)}BA$, and $\lim_{h\to 0}[A,B]_h = \{A,B\}$. There exist natural embeddings: $W(N)\subset P(2N)$ and $W(N)\subset P_h(2N)$, where $W(N)$ is the Lie superalgebra of all derivations of $\mathbb{C}[t,t^{-1}]\otimes\Lambda(\xi_1,\ldots,\xi_N)$ (∂_{ξ_i} is identified with η_i), so that the commutation relations in $P(2N)$ and in $P_h(2N)$, when restricted to $W(N)$, coincide with the commutation relations in $W(N)$. The Lie superalgebra $P_h(2N)$ is called the *Lie superalgebra of pseudodifferential symbols on* $S^{1|N}$ (see Ref. 21).

IV. REALIZATION OF CK_6 INSIDE THE POISSON SUPERALGEBRA

Theorem 4.1: The superalgebra CK_6 is spanned by the following 32 fields inside $P(6)$:

$$L_{n,0}=t^{n+1}\tau,$$

$$G^i_{n,0}=t^{n+1}\tau\xi_i,\quad \widetilde{G}^i_{n,0}=t^n\eta_i-nt^{n-1}\tau^{-1}\xi_j\eta_i\eta_j,\quad i=1,2,3,$$

$$T^{ij}_{n,0}=t^n\xi_i\eta_j-nt^{n-1}\tau^{-1}\xi_k\xi_i\eta_k\eta_j,\quad i\neq j\neq k,$$

$$\begin{aligned}T^i_{n,0}&=-t^n(\xi_j\eta_j+\xi_k\eta_k)+nt^{n-1}\tau^{-1}\xi_j\xi_k\eta_j\eta_k,\quad i=1,2,3,\\ S^i_{n,0}&=-t^n\xi_i(\xi_j\eta_j+\xi_k\eta_k)+nt^{n-1}\tau^{-1}\xi_i\xi_j\xi_k\eta_j\eta_k,\quad i=1,2,3,\end{aligned}\tag{4.1}$$

$$\widetilde{S}^i_{n,0}=t^{n-1}\tau^{-1}(\xi_j\eta_j-\xi_k\eta_k)\eta_i,\quad i=1,2,3,$$

$$I^i_{n,0}=t^{n-1}\tau^{-1}\xi_i\eta_j\eta_k,\quad i=1,2,3,\quad I_{n,0}=t^{n+1}\tau\xi_1\xi_2\xi_3,$$

$$J^{ij}_{n,0}=t^{n+1}\tau\xi_i\xi_j,\quad \widetilde{J}^{ij}_{n,0}=t^{n-1}\tau^{-1}\eta_i\eta_j,\quad i<j,$$

where $n\in\mathbb{Z}$; (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\widetilde{G}^i_{n,0}$, $T^i_{n,0}$, $S^i_{n,0}$, $\widetilde{S}^i_{n,0}$, and $I^i_{n,0}$.

Proof: Note that there exists an embedding

$$K(2N)\subset P(2N),\quad N\geqslant 0,\tag{4.2}$$

(see Ref. 21). Consider a $\mathbb{Z}$ grading of the associative superalgebra

$$P(2N)=\oplus_{i\in\mathbb{Z}}P_{(i)}(2N)\tag{4.3}$$

defined by $\deg_{Lie}f=\deg f-1$, where deg is defined as follows:

$$\begin{aligned}&\deg t=\deg\xi_i=0\quad \text{for } i=1,\ldots,N,\\ &\deg\tau=\deg\eta_i=1\quad \text{for } i=1,\ldots,N.\end{aligned}\tag{4.4}$$

With respect to the Poisson bracket,

$$\{P_{(i)}(2N),P_{(j)}(2N)\}\subset P_{(i+j)}(2N).\tag{4.5}$$

Thus $P_{(0)}(2N)$ is a subsuperalgebra of $P(2N)$, and we will show that $P_{(0)}(2N)\cong K(2N)$. Equivalently, $P_{(0)}(2N)$ is singled out as the set of all (Hamiltonian) functions $A(t,\tau,\xi_i,\eta_i)\in P(2N)$ such that the corresponding vector fields supercommute with the semi-Euler operator:

$$\left[H_A,\tau\partial_\tau+\sum_{i=1}^N\eta_i\partial_{\eta_i}\right]=0,\tag{4.6}$$

where

$$A(t,\tau,\xi_i,\eta_i)\to H_A=\partial_\tau A\partial_t-\partial_t A\partial_\tau-(-1)^{p(A)}\sum_{i=1}^N(\partial_{\xi_i}A\partial_{\eta_i}+\partial_{\eta_i}A\partial_{\xi_i}).\tag{4.7}$$

To describe an isomorphism of $K(2N)$ with $P_{(0)}(2N)$, we change the variable t in $\Lambda(1|2N)$: $t\overset{\chi}{\to}2t-\Sigma_{i=1}^N\xi_i\eta_i$. Then we have the following contact bracket on $\Lambda(1|2N)$:

$$\{f,g\}_{\widetilde{K}} = \widetilde{\Delta}(f)\partial_t g - \partial_t f\widetilde{\Delta}(g) - \{f,g\}_{P.b}, \tag{4.8}$$

where $\widetilde{\Delta}=1-\widetilde{E}$ and $\widetilde{E}=\Sigma_{i=1}^{N}\eta_i\partial_{\eta_i}$. Note that the corresponding contact form is $\widetilde{\Omega}=\mathrm{d}t+\Sigma_{i=1}^{N}\xi_i\mathrm{d}\eta_i$. Define a map $\varphi:\Lambda(1|2N)\to P_{(0)}(2N)$ as follows:

$$f\overset{\varphi}{\to}A_f=(-1)^s\tau^{1-s}f, \tag{4.9}$$

where s is a scalar given by $\widetilde{E}(f)=sf$. Then

$$\{A_f,A_g\}=A_{\{f,g\}_{\widetilde{K}}}. \tag{4.10}$$

Applying the isomorphism $\psi=\varphi\circ\chi$ to the fields (2.7), we obtain the following fields:

$$\begin{gathered}
\psi(L_n)=2^{n+1}L_{n,0}-2^{n-1}(n+1)(T^1_{n,0}+T^2_{n,0}+T^3_{n,0}),\\
\psi(G^i_n)=2^{n+1}G^i_{n,0}-2^n(n+1)S^i_{n,0},\quad \psi(\widetilde{G}^i_n)=-2^n\widetilde{G}^i_{n,0}+2^{n-1}n\widetilde{S}^i_{n,0},\\
\psi(T^{ij}_n)=-2^nT^{ij}_{n,0},\quad \psi(T^i_n)=2^{n-1}(-T^i_{n,0}+T^j_{n,0}+T^k_{n,0}),\\
\psi(S^i_n)=2^nS^i_{n,0},\quad \psi(\widetilde{S}^i_n)=2^{n-1}\widetilde{S}^i_{n,0},\\
\psi(I^i_n)=2^{n-1}I^i_{n,0},\quad \psi(I_n)=2^{n+1}I_{n,0},\\
\psi(J^{ij}_n)=2^{n+1}J^{ij}_{n,0},\quad \psi(\widetilde{J}^{ij}_n)=2^{n-1}\widetilde{J}^{ij}_{n,0},
\end{gathered} \tag{4.11}$$

where (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\psi(T^i_n)$. □

V. REALIZATION OF CK_6 INSIDE THE LIE SUPERALGEBRA OF PSEUDODIFFERENTIAL SYMBOLS

Given the embedding (4.2) it is natural to ask whether there exists an embedding

$$K(2N)\subset P_h(2N). \tag{5.1}$$

Recall that $K'(4)=[K(4),K(4)]$ is a simple ideal in $K(4)$ of codimension one defined from the exact sequence

$$0\to K'(4)\to K(4)\to \mathbb{C}D_{t^{-1}\xi_1\xi_2\eta_1\eta_2}\to 0. \tag{5.2}$$

Recall also (see Ref. 21) that the superalgebra $K'(4)\subset P(4)$ is spanned by the 16 fields: By the 12 fields:

$$f(\xi_1,\xi_2,t)\tau,\quad f(\xi_1,\xi_2,t)\eta_i\quad (i=1,2), \tag{5.3}$$

which form a subsuperalgebra isomorphic to $W(2)$, and 4 more fields F^i_n, where $0\leqslant i\leqslant 3$ and $n\in\mathbb{Z}$:

$$\begin{gathered}
F^0_n=t^{n-1}\tau^{-1}\eta_1\eta_2,\\
F^i_n=t^{n-1}\tau^{-1}\xi_i\eta_1\eta_2,\quad i=1,2,\\
F^3_n=t^{n-1}\tau^{-1}\xi_1\xi_2\eta_1\eta_2,\quad n\neq 0.
\end{gathered} \tag{5.4}$$

Proposition 5.1: (See Ref. 21.) The superalgebra $\hat{K}'(4)\subset P_h(4)$ is spanned by the 12 fields given in (5.3) and 4 more fields $F^i_{n,h}$:

$$F^0_{n,h}=\tau^{-1}\circ_h t^{n-1}\eta_1\eta_2,$$

$$F^i_{n,h}=\tau^{-1}\circ_h t^{n-1}\eta_1\eta_2\xi_i,\quad i=1,2, \tag{5.5}$$

$$F^3_{n,h}=\tau^{-1}\circ_h t^{n-1}\eta_1\eta_2\xi_1\xi_2+\frac{h}{n}t^n,\quad n\neq 0,$$

and the central element $h\in P_h(4)$, so that $\lim_{h\to 0}\hat{K}'(4)=K'(4)\subset P(4)$.

Note that we cannot obtain the embedding (5.1) if $N>2$.[22] However, the following theorem holds.

Theorem 5.2: There exists an embedding $i_h: CK_6\to P_h(6)$ for each $h\in\,]0,1]$ such that $\lim_{h\to 0} i_h(CK_6)=CK_6\subset P(6)$.

Proof: $i_h(CK_6)$ is spanned by the following fields inside $P_h(6)$:

$$L_{n,h}=t^{n+1}\tau,$$

$$G^i_{n,h}=t^{n+1}\tau\xi_i,\quad \widetilde{G}^i_{n,h}=t^n\eta_i-n\tau^{-1}\circ_h t^{n-1}\eta_i\eta_j\xi_j,\quad i=1,2,3,$$

$$T^{ij}_{n,h}=t^n\xi_i\eta_j-n\tau^{-1}\circ_h t^{n-1}\eta_k\eta_j\xi_k\xi_i,\quad i\neq j\neq k,$$

$$\begin{aligned} T^i_{n,h}&=-t^n(\xi_j\eta_j+\xi_k\eta_k)+n\tau^{-1}\circ_h t^{n-1}\eta_j\eta_k\xi_j\xi_k+ht^n,\quad i=1,2,3,\\ S^i_{n,h}&=-t^n\xi_i(\xi_j\eta_j+\xi_k\eta_k)+n\tau^{-1}\circ_h t^{n-1}\eta_j\eta_k\xi_i\xi_j\xi_k+ht^n\xi_i,\quad i=1,2,3, \end{aligned} \tag{5.6}$$

$$\widetilde{S}^i_{n,h}=\tau^{-1}\circ_h t^{n-1}(\eta_j\eta_i\xi_j-\eta_k\eta_i\xi_k),\quad i=1,2,3,$$

$$I^i_{n,h}=\tau^{-1}\circ_h t^{n-1}\eta_j\eta_k\xi_i,\quad i=1,2,3,\quad I_{n,h}=t^{n+1}\tau\xi_1\xi_2\xi_3,$$

$$J^{ij}_{n,h}=t^{n+1}\tau\xi_i\xi_j,\quad \widetilde{J}^{ij}_{n,h}=\tau^{-1}\circ_h t^{n-1}\eta_i\eta_j,\quad i<j,$$

where $n\in\mathbb{Z}$; (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\widetilde{G}^i_{n,h}$, $T^i_{n,h}$, $S^i_{n,h}$, $\widetilde{S}^i_{n,h}$, and $I^i_{n,h}$. Let $h\in[0,1]$. Set $J^{ij}_{n,h}=-J^{ji}_{n,h}$ and $\widetilde{J}^{ij}_{n,h}=-\widetilde{J}^{ji}_{n,h}$ for $i>j$. Given $h\in[0,1]$, set

$$L_n:=L_{n,h},\quad \ldots,\quad \widetilde{J}^{ij}_n:=\widetilde{J}^{ij}_{n,h}. \tag{5.7}$$

Recall that if $h=0$, then (5.7) gives elements (4.1). The nonvanishing commutation relations between the elements (5.7) are as follows: let $i\neq j\neq k$, then

$$[L_n,L_m]=(m-n)L_{n+m},$$

$$[L_n,G^i_m]=(m-n)G^i_{n+m},\quad [L_n,\widetilde{G}^i_m]=m\widetilde{G}^i_{n+m},$$

$$[L_n,T^{ij}_m]=mT^{ij}_{n+m},\quad [L_n,T^i_m]=mT^i_{n+m},$$

$$[L_n,S^i_m]=mS^i_{n+m},\quad [L_n,\widetilde{S}^i_m]=(m+n)\widetilde{S}^i_{n+m},$$

$$[L_n,I^i_m]=(m+n)I^i_{n+m},\quad [L_n,I_m]=(m-n)I_{n+m},$$

$$[L_n,J^{ij}_m]=(m-n)J^{ij}_{n+m},\quad [L_n,\tilde{J}^{ij}_m]=(m+n)\tilde{J}^{ij}_{n+m},$$

$$[G^i_n,G^j_m]=(m-n)J^{ij}_{n+m},\quad [G^i_n,\tilde{G}^j_m]=mT^{ij}_{n+m},$$

$$[G^i_n,T^{ji}_m]=-G^j_{n+m}+mS^j_{n+m},\quad [G^i_n,T^i_m]=mS^i_{n+m},$$

$$[G^i_n,T^j_m]=G^i_{n+m},\quad [G^i_n,S^j_m]=J^{ij}_{n+m},$$

$$[G^i_n,\tilde{S}^j_m]=T^{ij}_{n+m},\quad [\tilde{G}^i_n,\tilde{G}^j_m]=(m-n)\tilde{J}^{ij}_{n+m},$$

$$[\tilde{G}^i_n,S^i_m]=T^i_{n+m},\quad [\tilde{G}^i_n,S^j_m]=T^{ji}_{n+m},$$

$$[\tilde{G}^i_n,\tilde{S}^j_m]=-\tilde{J}^{ij}_{n+m},\quad [\tilde{G}^i_n,J^{ij}_m]=G^j_{n+m},$$

$$[T^{ij}_n,T^{ji}_m]=T^i_{n+m}-T^j_{n+m},\quad [T^{ij}_n,T^{jk}_m]=T^{ik}_{n+m},$$

$$[T^{ij}_n,T^{ki}_m]=-T^{kj}_{n+m},\quad [T^{ij}_n,T^i_m]=-T^{ij}_{n+m},$$

$$[T^{ij}_n,T^j_m]=T^{ij}_{n+m},\quad [T^{ij}_n,S^j_m]=S^i_{n+m},$$

$$[T^{ij}_n,\tilde{S}^i_m]=\tilde{S}^j_{n+m},\quad [T^{ij}_n,\tilde{S}^k_m]=-2I^i_{n+m},$$

$$[T^{ij}_n,I^j_m]=-\tilde{S}^k_{n+m},\quad [T^{ij}_n,J^{jk}_m]=J^{ik}_{n+m},$$

$$[T^{ij}_n,\tilde{J}^{ik}_m]=-\tilde{J}^{jk}_{n+m},\quad [T^j_n,S^i_m]=-S^i_{n+m},$$

$$[T^j_n,\tilde{S}^i_m]=\tilde{S}^i_{n+m},\quad [T^i_n,I^i_m]=2I^i_{n+m},$$

$$[T^i_n,I_m]=-2I_{n+m},\quad [T^i_n,J^{ij}_m]=[T^j_n,J^{ij}_m]=-J^{ij}_{n+m},$$

$$[T^k_n,J^{ij}_m]=-2J^{ij}_{n+m},\quad [T^i_n,\tilde{J}^{ij}_m]=[T^j_n,\tilde{J}^{ij}_m]=\tilde{J}^{ij}_{n+m},$$

$$[T^k_n,\tilde{J}^{ij}_m]=2\tilde{J}^{ij}_{n+m},\quad [J^{ij}_n,\tilde{J}^{ij}_m]=T^k_{n+m},$$

$$[J^{ij}_n,\tilde{J}^{ik}_m]=-T^{jk}_{n+m},\quad [J^{ij}_n,\tilde{J}^{jk}_m]=T^{ik}_{n+m}. \tag{5.8}$$

Let (i,j,k) be the cycle $(1,2,3)$, then

$$[G^i_n,\tilde{G}^i_m]=L_{n+m}-mT^k_{n+m},\quad [G^i_n,\tilde{S}^i_m]=T^j_{n+m}-T^k_{n+m},$$

$$[G^i_n,I^j_m]=T^{jk}_{n+m},\quad [G^i_n,I^k_m]=-T^{kj}_{n+m},$$

$$[G_n^i, J_m^{jk}] = (m-n)I_{n+m}, \quad [G_n^i, \widetilde{J}_m^{jk}] = (m+n)I_{n+m}^i,$$

$$[G_n^i, \widetilde{J}_m^{ij}] = \widetilde{G}_{n+m}^j - (n+m)\widetilde{S}_{n+m}^j, \quad [G_n^i, \widetilde{J}_m^{ik}] = \widetilde{G}_{n+m}^k,$$

$$[\widetilde{G}_n^i, T_m^{ij}] = \widetilde{G}_{n+m}^j - n\widetilde{S}_{n+m}^j, \quad [\widetilde{G}_n^i, T_m^{ik}] = \widetilde{G}_{n+m}^k - (n+m)\widetilde{S}_{n+m}^k,$$

$$[\widetilde{G}_n^i, T_m^{jk}] = (m+n)I_{n+m}^j, \quad [\widetilde{G}_n^i, T_m^{kj}] = (n-m)I_{n+m}^k,$$

$$[\widetilde{G}_n^i, T_m^j] = -\widetilde{G}_{n+m}^i + m\widetilde{S}_{n+m}^i, \quad [\widetilde{G}_n^i, T_m^k] = -\widetilde{G}_{n+m}^i,$$

$$[\widetilde{G}_n^i, I_m^i] = \widetilde{J}_{n+m}^{jk}, \quad [\widetilde{G}_n^i, I_m] = J_{n+m}^{jk},$$

$$[S_n^i, J_m^{jk}] = -2I_{n+m}, \quad [S_n^i, \widetilde{J}_m^{ij}] = -\widetilde{S}_{n+m}^j,$$

$$[S_n^i, \widetilde{J}_m^{ik}] = \widetilde{S}_{n+m}^k, \quad [S_n^i, \widetilde{J}_m^{jk}] = 2I_{n+m}^i,$$

$$[\widetilde{S}_n^i, J_m^{ij}] = S_{n+m}^j, \quad [\widetilde{S}_n^i, J_m^{ik}] = -S_{n+m}^k,$$

$$[I_n^i, J_m^{jk}] = -S_{n+m}^i, \quad [I_n, \widetilde{J}_m^{ij}] = S_{n+m}^k. \tag{5.9}$$

□

VI. REPRESENTATION OF CK_6 ASSOCIATED WITH ITS EMBEDDING INTO $P_{h=1}(6)$

Recall that the embedding (1.2) for $h=1$ allows us to define a one-parameter family of spinor-like representations of $K'(4)$ in the superspace spanned by 2 even and 2 odd fields, where the central element $1 \in P_1(4)$ acts by the identity operator.[21]

Theorem 6.1: There exists a one-parameter family of irreducible representations of CK_6, depending on parameter $\mu \in \mathbb{C}$, in a superspace spanned by 4 even fields and 4 odd fields.

Proof: Let $V^\mu = t^\mu \mathbb{C}[t,t^{-1}] \otimes \Lambda(3)$, where $\Lambda(3) = \Lambda(\xi_1, \xi_2, \xi_3)$ is the Grassmann algebra, and $\mu \in \mathbb{C}\backslash\mathbb{Z}$. Let $\{v_m^i, \hat{v}_m^i\}$, where $m \in \mathbb{Z}$ and $1 \leqslant i \leqslant 4$, be the following basis in V^μ:

$$v_m^i = \frac{t^{m+\mu}}{m+\mu}\xi_i, \quad \hat{v}_m^i = t^{m+\mu}\xi_j\xi_k, \quad 1 \leqslant i \leqslant 3, \quad v_m^4 = \frac{t^{m+\mu}}{m+\mu}, \quad \hat{v}_m^4 = -t^{m+\mu}\xi_1\xi_2\xi_3, \tag{6.1}$$

where (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\hat{v}_m^i$. We define a representation of CK_6 in V^μ according to the formulas (5.6), where $h=1$. Namely, ξ_i is the operator of multiplication in $\Lambda(3)$, η_i is identified with ∂_{ξ_i}, and τ^{-1} is identified with the antiderivative:

$$\tau^{-1}g(t) = \int g(t)\mathrm{d}t, \quad g \in t^\mu \mathbb{C}[t,t^{-1}]. \tag{6.2}$$

Notice that

$$(\tau^{-1} \circ_{h=1} f)(g) = \tau^{-1}(fg) \tag{6.3}$$

for any $f \in \mathbb{C}[t,t^{-1}]$ and $g \in t^\mu \mathbb{C}[t,t^{-1}]$. Observe that

$$\tau^{-1}\circ_{h=1} f = \sum_{n=0}^{\infty} (-1)^n (\tau^n f)\tau^{-n-1}. \tag{6.4}$$

Thus the formula (6.3) is simply the formula of integration by parts:

$$f\int g\,\mathrm{d}t - f'\int\int g\,\mathrm{d}t^2 + f''\int\int\int g\,\mathrm{d}t^3 - \cdots = \int fg\,\mathrm{d}t. \tag{6.5}$$

The superalgebra CK_6 acts on $V^\mu = Span(v_m^i, \hat{v}_m^i \mid 1 \leqslant i \leqslant 4, m \in \mathbb{Z})$ as follows (see (5.7) for notations):

$$\begin{gathered}
L_n(v_m^i) = (m+n+\mu)v_{m+n}^i, \quad L_n(\hat{v}_m^i) = (m+\mu)\hat{v}_{m+n}^i,\\
G_n^i(v_m^4) = (m+n+\mu)v_{m+n}^i, \quad G_n^i(\hat{v}_m^i) = -(m+\mu)\hat{v}_{m+n}^4,\\
G_n^i(v_m^j) = \hat{v}_{m+n}^k, \quad G_n^i(v_m^k) = -\hat{v}_{m+n}^j,\\
\widetilde{G}_n^i(v_m^i) = v_{m+n}^4, \quad \widetilde{G}_n^i(\hat{v}_m^4) = -\hat{v}_{m+n}^i,\\
\widetilde{G}_n^i(\hat{v}_m^j) = -(m+\mu)v_{m+n}^k, \quad \widetilde{G}_n^i(\hat{v}_m^k) = (m+n+\mu)v_{m+n}^j,\\
T_n^{ij}(v_m^j) = v_{m+n}^i, \quad T_n^{ij}(\hat{v}_m^i) = -\hat{v}_{m+n}^j,\\
T_n^i(v_m^i) = v_{m+n}^i, \quad T_n^i(v_m^4) = v_{m+n}^4,\\
T_n^i(\hat{v}_m^i) = -\hat{v}_{m+n}^i, \quad T_n^i(\hat{v}_m^4) = -\hat{v}_{m+n}^4,\\
S_n^i(v_m^4) = v_{m+n}^i, \quad S_n^i(\hat{v}_m^i) = \hat{v}_{m+n}^4,\\
\widetilde{S}_n^i(\hat{v}_m^j) = v_{m+n}^k, \quad \widetilde{S}_n^i(\hat{v}_m^k) = v_{m+n}^j,\\
I_n^i(\hat{v}_m^i) = -v_{m+n}^i, \quad I_n(v_m^4) = -\hat{v}_{m+n}^4,\\
J_n^{ij}(v_m^4) = \hat{v}_{m+n}^k, \quad J_n^{ij}(v_m^k) = -\hat{v}_{m+n}^4,\\
\widetilde{J}_n^{ij}(\hat{v}_m^k) = -v_{m+n}^4, \quad \widetilde{J}_n^{ij}(\hat{v}_m^4) = v_{m+n}^k,
\end{gathered} \tag{6.6}$$

where (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\widetilde{G}_n^i$, $\widetilde{S}_n^i$, J_n^{ij}, and $\widetilde{J}_n^{ij}$. □

Remark 6.2: We have posed the condition $\mu \in \mathbb{C}\backslash\mathbb{Z}$ in the definition of V^μ. However, formulas (6.6) actually define a representation of CK_6 in a superspace spanned by v_m^i, $\hat{v}_m^i$ for an arbitrary $\mu \in \mathbb{C}$. (See also Sec. VIII.)

VII. SECOND FAMILY OF REPRESENTATIONS OF CK_6

Note that the embedding of infinite-dimensional Lie superalgebras

$$CK_6 \subset K(6), \tag{7.1}$$

considered in this work, is naturally related to the embedding of finite-dimensional Lie superalgebras

$$\hat{\mathcal{P}}(4) \subset P(0|6). \tag{7.2}$$

Recall that $P(0|6)$ is the Poisson superalgebra with 6 odd generators: $\xi_1, \xi_2, \xi_3, \eta_1, \eta_2, \eta_3$, and the Poisson bracket is given by (2.6). The simple Lie superalgebra $\mathcal{P}(n)$ is defined as follows. Let $\widetilde{\mathcal{P}}(n)$ be the Lie superalgebra, which preserves the odd nondegenerate supersymmetric bilinear form antidiag $(1_n, 1_n)$ on the $(n|n)$-dimensional superspace. Thus

$$\widetilde{\mathcal{P}}(n) = \left\{ \begin{pmatrix} A & B \\ C & -A^t \end{pmatrix} \middle| A \in \mathfrak{gl}(n), \quad B^t = B, \quad C^t = -C \right\}. \tag{7.3}$$

$\mathcal{P}(n)$ is a subsuperalgebra of $\widetilde{\mathcal{P}}(n)$ such that $A \in \mathfrak{sl}(n)$.[24] A. Sergeev has proved that $\mathcal{P}(n)$ has a nontrivial central extension if and only if $N=4$; see Refs. 5, 8, 12, and 13. Note that $\dim \hat{\mathcal{P}}(4) = (16|16)$. It was pointed out in Refs. 5, 8, 9, 12, and 13 that $\hat{\mathcal{P}}(4)$ has a family spin_λ of $(4|4)$-dimensional irreducible representations. In fact, there exist two non-isomorphic families: they correspond to two families of embeddings of $\hat{\mathcal{P}}(4)$ into $P(0|6)$.

For every $\lambda \neq 0$ we can realize $\hat{\mathcal{P}}(4)$ inside $P(0|6)$ as follows:

$$\hat{\mathcal{P}}(4) = Span(L, G^i, \widetilde{G}^i, T^{ij}, T^i, S^i, \widetilde{S}^i, I^i, I, J^{ij}, \widetilde{J}^{ij}), \tag{7.4}$$

where

$$L = \lambda, \quad G^i = \lambda \eta_i, \quad \widetilde{G}^i = \xi_i,$$

$$T^{ij} = \eta_i \xi_j, \quad i \neq j, \quad T^i = -\eta_j \xi_j - \eta_k \xi_k,$$

$$S^i = -\eta_i(\eta_j \xi_j + \eta_k \xi_k), \quad \widetilde{S}^i = \frac{1}{\lambda}(\eta_j \xi_j - \eta_k \xi_k)\xi_i, \tag{7.5}$$

$$I^i = \frac{1}{\lambda}\eta_i \xi_j \xi_k, \quad I = \lambda \eta_1 \eta_2 \eta_3,$$

$$J^{ij} = \lambda \eta_i \eta_j, \quad \widetilde{J}^{ij} = \frac{1}{\lambda}\xi_i \xi_j, \quad i < j,$$

so that L is its central element; (i,j,k) is the cycle $(1,2,3)$ in the formulas for T^i, S^i, J^i, and I^i. Correspondingly, there is an embedding $j_h : \hat{\mathcal{P}}(4) \to P_h(0|6)$ given by

$$L_h = \lambda, \quad G_h^i = \lambda \eta_i, \quad \widetilde{G}_h^i = \xi_i,$$

$$T_h^{ij} = \eta_i \xi_j, \quad T_h^i = -\eta_j \xi_j - \eta_k \xi_k + h,$$

$$S_h^i = -\eta_i(\eta_j \xi_j + \eta_k \xi_k) + h\eta_i, \quad \widetilde{S}_h^i = \frac{1}{\lambda}(\xi_j \xi_i \eta_j - \xi_k \xi_i \eta_k),$$

$$I_h^i = \frac{1}{\lambda}\xi_j \xi_k \eta_i, \quad I_h = \lambda \eta_1 \eta_2 \eta_3,$$

$$J_h^{ij} = \lambda \eta_i \eta_j, \quad \tilde{J}_h^{ij} = \frac{1}{\lambda} \xi_i \xi_j, \tag{7.6}$$

and $\lim_{h\to 0} j_h(\hat{\mathcal{P}}(4)) = \hat{\mathcal{P}}(4) \subset P(0|6)$. The nonvanishing commutation relations between the elements (7.5) and between the elements (7.6) are as in (5.8) and (5.9), where the indices $m=n=0$.

Associated to this embedding (for $h=1$) there is a family spin_λ^1 of representations of $\hat{\mathcal{P}}(4)$ in the superspace $\Lambda(\xi_1, \xi_2, \xi_3)$. We choose the basis

$$v^i = \xi_i, \quad \hat{v}^i = \frac{1}{\lambda} \xi_j \xi_k, \quad 1 \leqslant i \leqslant 3, \quad v^4 = 1, \quad \hat{v}^4 = -\frac{1}{\lambda} \xi_1 \xi_2 \xi_3, \tag{7.7}$$

where (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\hat{v}^i$. Explicitly,

$$\text{spin}_\lambda^1 : \begin{pmatrix} A & B \\ C & -A^t \end{pmatrix} + \mathbb{C}L \to \begin{pmatrix} A & B - \lambda \tilde{C} \\ C & -A^t \end{pmatrix} + \mathbb{C}\lambda \cdot 1_{4|4}, \tag{7.8}$$

where $1_{4|4}$ is the identity matrix, and if $C_{ij} = E_{ij} - E_{ji}$, then $\tilde{C}_{ij} = C_{kl}$, so that the permutation $(1,2,3,4) \mapsto (i,j,k,l)$ is even; cf. Refs. 5,8,9,12, and 13. Formula (7.8) also gives the standard representation spin_0^1.

The second family of embeddings of $\hat{\mathcal{P}}(4)$ into $P(0|6)$ and into $P_h(0|6)$ is given by (7.4)–(7.6), where ξ_i is interchanged with η_i for all i in all the formulas. There is a family spin_λ^2 of representations of $\hat{\mathcal{P}}(4)$ associated to this embedding (for $h=1$) in the superspace $\Lambda(\xi_1, \xi_2, \xi_3)$, so that $\Pi(\text{spin}_\lambda^2) \cong \text{spin}_\lambda^1$, as $\hat{\mathcal{P}}(4)$ modules, for all λ.

(Π denotes the change of parity). Theorem 6.1 has the following corollary.

Corollary 7.1: Under the restriction of the representation of CK_6 in V^μ to $\hat{\mathcal{P}}(4)$, V^μ decomposes into a direct sum of irreducible $(4|4)$-dimensional submodules of the family spin_λ^2.

Proof: Naturally, there are embeddings:

$$\hat{\mathcal{P}}(4) \subset CK_6, \quad P(0|6) \subset K(6). \tag{7.9}$$

The first embedding is given as follows:

$$\hat{\mathcal{P}}(4) = \{x \in CK_6 \mid [L_0, x] = 0\}. \tag{7.10}$$

Hence $\hat{\mathcal{P}}(4)$ is spanned by the elements (5.7), where $n=0$, and L_0 is its central element. The nontrivial 2-cocycle on $\mathcal{P}(4)$ is $(G_0^i, \tilde{G}_0^j) = \delta_{i,j} L_0$. It follows from (6.6) that V^μ is a direct sum of $(4|4)$-dimensional $\hat{\mathcal{P}}(4)$ submodules:

$$V^\mu = \oplus_{m \in \mathbb{Z}} V_m^\mu, \quad V_m^\mu = Span(v_m^i, \hat{v}_m^i \mid 1 \leqslant i \leqslant 4), \tag{7.11}$$

where $V_m^\mu \cong \text{spin}_{m+\mu}^2$. □

It is possible to define another embedding of CK_6 into $P(6)$ (respectively, into $P_h(6)$) by interchanging ξ_i with η_i in all the formulas (4.1) (respectively, in (5.6)), and then obtain a one-parameter family of representations of CK_6 in V^μ by repeating the previous construction. Thus the following theorem holds.

Theorem 7.2: Consider the following basis in V^μ:

$$v_m^i = t^{m+\mu} \xi_i, \quad \hat{v}_m^i = \frac{t^{m+\mu}}{m+\mu} \xi_j \xi_k, \quad 1 \leqslant i \leqslant 3, \quad v_m^4 = t^{m+\mu}, \quad \hat{v}_m^4 = -\frac{t^{m+\mu}}{m+\mu} \xi_1 \xi_2 \xi_3, \tag{7.12}$$

where (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\hat{v}_m^i$. Then the action of CK_6 on V^μ is defined as follows

$$L_n(v_m^i) = (m+\mu) v_{m+n}^i, \quad L_n(\hat{v}_m^i) = (m+n+\mu) \hat{v}_{m+n}^i,$$

$$G_n^i(v_m^i) = (m+\mu)v_{m+n}^4, \quad G_n^i(\hat{v}_m^4) = -(m+n+\mu)\hat{v}_{m+n}^i,$$

$$G_n^i(\hat{v}_m^k) = v_{m+n}^j, \quad G_n^i(\hat{v}_m^j) = -v_{m+n}^k,$$

$$\widetilde{G}_n^i(v_m^4) = v_{m+n}^i, \quad \widetilde{G}_n^i(\hat{v}_m^i) = -\hat{v}_{m+n}^4,$$

$$\widetilde{G}_n^i(v_m^k) = -(m+n+\mu)\hat{v}_{m+n}^j, \quad \widetilde{G}_n^i(v_m^j) = (m+\mu)\hat{v}_{m+n}^k,$$

$$T_n^{ij}(v_m^i) = -v_{m+n}^j, \quad T_n^{ij}(\hat{v}_m^j) = \hat{v}_{m+n}^i,$$

$$T_n^i(v_m^i) = -v_{m+n}^i, \quad T_n^i(v_m^4) = -v_{m+n}^4, \tag{7.13}$$

$$T_n^i(\hat{v}_m^i) = \hat{v}_{m+n}^i, \quad T_n^i(\hat{v}_m^4) = \hat{v}_{m+n}^4,$$

$$S_n^i(v_m^i) = -v_{m+n}^4, \quad S_n^i(\hat{v}_m^4) = -\hat{v}_{m+n}^i,$$

$$\widetilde{S}_n^i(v_m^k) = -\hat{v}_{m+n}^j, \quad \widetilde{S}_n^i(v_m^j) = -\hat{v}_{m+n}^k,$$

$$I_n^i(v_m^i) = \hat{v}_{m+n}^i, \quad I_n(\hat{v}_m^4) = v_{m+n}^4,$$

$$J_n^{ij}(\hat{v}_m^k) = -v_{m+n}^4, \quad J_n^{ij}(\hat{v}_m^4) = v_{m+n}^k,$$

$$\widetilde{J}_n^{ij}(v_m^4) = \hat{v}_{m+n}^k, \quad \widetilde{J}_n^{ij}(v_m^k) = -\hat{v}_{m+n}^4,$$

where (i,j,k) is the cycle $(1,2,3)$ in the formulas for $\widetilde{G}_n^i$, $\widetilde{S}_n^i$, J_n^{ij}, and $\widetilde{J}_n^{ij}$. Thus V^μ is a direct sum of $(4|4)$-dimensional $\hat{\mathcal{P}}(4)$ submodules, see (7.11), where $V_m^\mu \cong \mathrm{spin}_{m+\mu}^1$.

VIII. FINAL REMARKS

Theorem 8.1: $CK_6 \subset P_h(6)$ is generated by $t^n\tau\Lambda(\xi_1,\xi_2,\xi_3)$ and $\tau^{-1}\circ_h t^n\eta_i\eta_j$, where $n\in\mathbb{Z}$.

Proof: It follows from (5.7)–(5.9) that $L_{n,h}$, $G_{n,h}^i$, $J_{n,h}^{ij}$, $I_{n,h}$, and $\widetilde{J}_{n,h}^{ij}$ generate CK_6. □

We fix $h=1$. Let $\mu\in(0,1)$. In each V^μ we defined a basis by (6.1). We will denote it now by $\{v_{\underline{m}}^i(\mu),\hat{v}_m^i(\mu)\}$. Let $\underline{V}=Span(v_m^i,\hat{v}_m^i \mid 1\leqslant i\leqslant 4, m\in\mathbb{Z})$, be a superspace such that $p(\hat{v}_m^i)=p(v_m^4)=\overline{0}$, $p(v_m^i)=p(\hat{v}_m^4)=\overline{1}$. Let $v\in V$ and let $v(\mu)\in V^\mu$ be the vector with the same coordinates as v with respect to the basis (6.1). Consider the odd nondegenerate superskew-symmetric bilinear form on each V^μ given by

$$(v_m^i(\mu),\hat{v}_l^i(\mu)) = -(\hat{v}_l^i(\mu),v_m^i(\mu)) = -(v_m^4(\mu),\hat{v}_l^4(\mu)) = (\hat{v}_l^4(\mu),v_m^4(\mu)) = \delta_{m+l,0}, \tag{8.1}$$

where $1\leqslant i\leqslant 3$. The odd nondegenerate superskew-symmetric bilinear form on V is given by

$$(v_m^i,\hat{v}_l^i) = -(\hat{v}_l^i,v_m^i) = -(v_m^4,\hat{v}_l^4) = (\hat{v}_l^4,v_m^4) = \delta_{m+l,0}. \tag{8.2}$$

Theorem 8.2: Let $X\in CK_6$. Then

$$\lim_{\mu\to 0}[(Xv(\mu),w(\mu)) + (-1)^{p(X)p(v(\mu))}(v(\mu),Xw(\mu))] = 0 \quad \text{for all } v,w\in V. \tag{8.3}$$

There is a representation of CK_6 in V given by (6.6), where $\mu=0$, and this action preserves the form (8.2).

Remark 8.3: There is a representation of CK_6 in V given by (7.13), where $\mu=0$, and this action preserves the odd nondegenerate supersymmetric bilinear form on V:

$$(v_m^i,\hat{v}_l^i)=(\hat{v}_l^i,v_m^i)=\delta_{m+l,0},\quad 1\leqslant i\leqslant 4. \tag{8.4}$$

Remark 8.4: Each of the representations of CK_6 in V given by (6.6) and (7.13), where $\mu=0$, decomposes into a direct sum of irreducible $\hat{\mathcal{P}}(4)$ modules:

$$V=\oplus_{m\in\mathbb{Z}}V_m,\quad V_m=Span(v_m^i,\hat{v}_m^i \mid 1\leqslant i\leqslant 4), \tag{8.5}$$

where $V_m\cong \mathrm{spin}_m^2$ for the representation (6.6), and $V_m\cong \mathrm{spin}_m^1$ for the representation (7.13).

(Received 6 July 2005; accepted 15 July 2005; published online 10 October 2005)

We reexpress the quantum Calogero-Sutherland model for the Lie algebra E_7 and the particular value of the coupling constant $\kappa=1$ by using the fundamental irreducible characters of the algebra as dynamical variables. For that, we need to develop a systematic procedure to obtain all the Clebsch-Gordan series required to perform the change of variables. We describe how the resulting quantum Hamiltonian operator can be used to compute more characters and Clebsch-Gordan series for this exceptional algebra. © *2005 American Institute of Physics.*

I. INTRODUCTION

Integrable systems are important because they can be considered as 0th order perturbative approximations to nonintegrable systems. By integrability we mean here integrability in the sense of Liouville, that is, the existence of a complete set of mutually commuting integrals of motion. During the three last decades of the past century, a plethora of highly nontrivial (classical and quantum) mechanical integrable systems were discovered, see Refs. 1 and 2 for comprehensive reviews. Among these, the Calogero-Sutherland models form a distinguished class. The first analysis of a system of this kind was performed by Calogero[3] who studied, from the quantum standpoint, the dynamics on the infinite line of a set of particles interacting pairwise by rational plus quadratic potentials, and found that the problem was exactly solvable. Soon afterwards, Sutherland[4] arrived to similar results for the quantum problem on the circle, this time with trigonometric interaction; and later Moser[5] proved, in terms of Lax pairs, that the classical counterparts of these models also enjoyed integrability.

The identification of the general scope of these discoveries came with the work of Olshanetsky and Perelomov,[6–8] who realized that it is possible to associate models of this kind to all the root systems of the simple Lie algebras, and that all these models are integrable, both in the classical and the quantum framework,[9,10] for interactions of the type rational (or inverse-square), q^{-2}; rational+quadratic, $q^{-2}+\omega^2 q^2$; trigonometric, $\sin^{-2} q$; hyperbolic, $\sinh^{-2} q$. For the most general case, given by the Weierstrass elliptic function $\mathcal{P}(q)$, see Refs. 2 and 10. Nowadays, there is a widespread interest in this kind of integrable systems, and many mathematical and physical applications for them have been found, see for instance Ref. 11. In Physics, we mention, among others, the remarkable connection established[12,13] between the different Calogero-Sutherland models and the properties of the equations describing the physics of disordered wires (the DMPK equation); the results are in good agreement with the experimental observations.

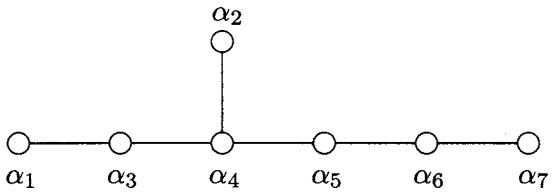

FIG. 1. The Dynkin diagram for the Lie algebra E_7.

The study of the form and properties of the Schrödinger eigenfunctions for the quantum version of these models constitutes by itself an interesting line of research. In fact, these eigenfunctions have very rich mathematical properties. In particular, for the trigonometric case, if we tune the coupling constants to some special values, the wave functions correspond to the characters of the simple Lie algebras, while if we select a different tuning, we can make them to coincide with zonal spherical functions. Thus, the Calogero-Sutherland theories provide us with a new tool for computing these quantities. In this spirit, we will describe in the present paper how to use the trigonometric Calogero-Sutherland model to obtain both particular characters and Clebsch-Gordan series for the exceptional Lie algebra E_7. The main point of our approach is to express the Hamiltonian in a suitable set of independent variables, indeed the fundamental characters of E_7. The use of such types of variables has been quite useful to solve the Schrödinger equation for the models associated to some algebras.[6,14–21]

The organization of the paper is as follows. Section II is a reminder of the properties of E_7 relevant for the contents of the paper. Section III describes the main properties of the Calogero-Sutherland models associated to root systems and explains how to find the Hamiltonian in the variables mentioned above. Section IV gives some account of the computation of the Clebsch-Gordan series of E_7 needed to pass to the new variables. In Sec. V we present the Hamiltonian in these variables and describe its use for computing new characters and to reduce tensor products of representations. Some conclusions are given in Sec. VI, and finally, the appendixes show some explicit results for characters and Clebsch-Gordan series of E_7.

II. SUMMARY OF RESULTS ON THE LIE ALGEBRA E_7

In this section, we review some standard facts about the root and weight systems of the Lie algebra E_7, with the aim of fixing the notation and help the reader to follow the rest of the paper. More extensive and sound treatments of these topics can be found in many excellent textbooks, see for instance Refs. 22 and 23.

The complex Lie algebra E_7 has dimension 133 and rank 7, as the name suggests. From the geometrical point of view, it admits (with some subtleties, see Ref. 24) an interpretation which extends the standard-one for the classical algebras: in the same way that these correspond to the isometries of projective spaces over the first three normed division algebras—$\mathrm{SO}(n+1) \simeq \mathrm{Isom}(\mathbf{R}P^n)$, $\mathrm{SU}(n+1) \simeq \mathrm{Isom}(\mathbf{C}P^n)$, $\mathrm{Sp}(n+1) \simeq \mathrm{Isom}(\mathbf{H}P^n)$—$F_4$, E_6, E_7, and E_8 are the Lie algebras of the projective planes over extensions of the octonions, giving rise to the so-called "magic square," $F_4 \simeq \mathrm{Isom}(\mathbf{O}P^2)$, $E_6 \simeq \mathrm{Isom}[(\mathbf{C}\otimes\mathbf{O})P^2]$, $E_7 \simeq \mathrm{Isom}[(\mathbf{H}\otimes\mathbf{O})P^2]$, $E_8 \simeq \mathrm{Isom}[(\mathbf{O}\otimes\mathbf{O})P^2]$.

The Dynkin diagram of E_7, see Fig. 1, encodes the Euclidean relations $A_{ij}=(\alpha_i,\alpha_j)$ among the simple roots, which are

$$(\alpha_i,\alpha_i)=2, \quad i=1,\ldots,7,$$

$$(\alpha_i,\alpha_{i+2})=-1, \quad i=1,2,$$

$$(\alpha_i,\alpha_{i+1})=-1, \quad i=3,\ldots,6,$$

$$(\alpha_i, \alpha_j) = 0, \quad \text{in all other cases.} \tag{1}$$

Therefore, the Cartan matrix $A=(A_{ij})$ and its inverse $A^{-1}=(A_{ij}^{-1})$ read

$$A = \begin{pmatrix} 2 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 2 & 0 & -1 & 0 & 0 & 0 \\ -1 & 0 & 2 & -1 & 0 & 0 & 0 \\ 0 & -1 & -1 & 2 & -1 & 0 & 0 \\ 0 & 0 & 0 & -1 & 2 & -1 & 0 \\ 0 & 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & 0 & 0 & -1 & 2 \end{pmatrix}, \quad A^{-1} = \frac{1}{2}\begin{pmatrix} 4 & 4 & 6 & 8 & 6 & 4 & 2 \\ 4 & 7 & 8 & 12 & 9 & 6 & 3 \\ 6 & 8 & 12 & 16 & 12 & 8 & 4 \\ 8 & 12 & 16 & 24 & 18 & 12 & 6 \\ 6 & 9 & 12 & 18 & 15 & 10 & 5 \\ 4 & 6 & 8 & 12 & 10 & 8 & 4 \\ 2 & 3 & 4 & 6 & 5 & 4 & 3 \end{pmatrix}. \tag{2}$$

Throughout this paper we will use a realization of this root system in terms of a system of vectors $\{v_i\}_{i=1,\ldots,8}$ of $\mathbf{R}^8$ [endowed with the standard Euclidean product $(,)$] satisfying the relations $(v_i, v_j) = -\frac{1}{8} + \delta_{ij}$.[22] With reference to this system, E_7 is the root system in the hyperplane $V \subset \mathbf{R}^8$ of equation $\sum_i v_i = 0$ given by $\mathcal{R} = \{v_i - v_j, v_i + v_j + v_k + v_l \,|\, i \neq j \neq k \neq l\}$, the positive ones being those in the subset $\mathcal{R}^+ = \{v_i - v_j, v_8 - v_i, v_i + v_j + v_k + v_8 \,|\, i < j < k < 8\}$. There are 63 positive roots, which can be classified by heights as indicated in Table I. The seven simple roots are

$$\alpha_1 = v_1 - v_2, \quad \alpha_2 = v_4 + v_5 + v_6 + v_7,$$

$$\alpha_3 = v_2 - v_3, \quad \alpha_4 = v_3 - v_4,$$

$$\alpha_5 = v_4 - v_5, \quad \alpha_6 = v_5 - v_6,$$

$$\alpha_7 = v_6 - v_7, \tag{3}$$

which clearly satisfy the relations (1).

The hyperplane V can be viewed as $\mathbf{R}^7$, and the basis made with the vectors $v_1, \ldots, v_7$ is related to the canonical basis $\{e_k\}_{k=1,\ldots,7}$ by $v_k = e_k - \frac{1}{7}[1 + (1/\sqrt{8})]\sum_{j=1}^{7} e_j$; thus, the simple roots α_i are given by

$$\alpha_1 = e_1 - e_2,$$

$$\alpha_2 = \frac{1}{7}\left(3 - \frac{2}{\sqrt{2}}\right)\sum_{j=4}^{7} e_j - \frac{4}{7}\left(1 + \frac{1}{\sqrt{8}}\right)\sum_{j=1}^{3} e_j,$$

$$\alpha_k = e_{k-1} - e_k, \quad k = 3, \ldots, 7. \tag{4}$$

The fundamental weights $\lambda_i = \sum_{j=1}^{7} A_{ji}^{-1} \alpha_j$ are

$$\lambda_1 = v_1 - v_8,$$

$$\lambda_2 = -2v_8,$$

$$\lambda_3 = v_1 + v_2 - 2v_8,$$

$$\lambda_4 = v_1 + v_2 + v_3 + 3v - 3v_8,$$

$$\lambda_5 = v_1 + v_2 + v_3 + v_4 - 2v_8,$$

TABLE I. Heights of positive roots of E_7.

ht	Positive roots
1	$\alpha_1,\ \alpha_2,\ \alpha_3,\ \alpha_4,\ \alpha_5,\ \alpha_6,\ \alpha_7$
2	$\alpha_1+\alpha_3,\ \alpha_3+\alpha_4,\ \alpha_4+\alpha_5,\ \alpha_5+\alpha_6,\ \alpha_2+\alpha_4,\ \alpha_6+\alpha_7$
3	$\alpha_1+\alpha_3+\alpha_4,\ \alpha_3+\alpha_4+\alpha_5,\ \alpha_4+\alpha_5+\alpha_6,\ \alpha_2+\alpha_3+\alpha_4,\ \alpha_2+\alpha_4+\alpha_5,\ \alpha_5+\alpha_6+\alpha_7$
4	$\alpha_1+\alpha_3+\alpha_4+\alpha_5,\ \alpha_3+\alpha_4+\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+\alpha_4,\ \alpha_2+\alpha_3+\alpha_4+\alpha_5,$ $\alpha_2+\alpha_4+\alpha_5+\alpha_6,\ \alpha_4+\alpha_5+\alpha_6+\alpha_7$
5	$\alpha_1+\alpha_3+\alpha_4+\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+\alpha_4+\alpha_5,\ \alpha_2+\alpha_3+2\alpha_4+\alpha_5,$ $\alpha_2+\alpha_3+\alpha_4+\alpha_5+\alpha_6,\ \alpha_2+\alpha_4+\alpha_5+\alpha_6+\alpha_7,\ \alpha_3+\alpha_4+\alpha_5+\alpha_6+\alpha_7$
6	$\alpha_1+\alpha_2+\alpha_3+2\alpha_4+\alpha_5,\ \alpha_1+\alpha_2+\alpha_3+\alpha_4+\alpha_5+\alpha_6,\ \alpha_2+\alpha_3+2\alpha_4+\alpha_5+\alpha_6,$ $\alpha_1+\alpha_3+\alpha_4+\alpha_5+\alpha_6+\alpha_7,\ \alpha_2+\alpha_3+\alpha_4+\alpha_5+\alpha_6+\alpha_7$
7	$\alpha_1+\alpha_2+2\alpha_3+2\alpha_4+\alpha_5,\ \alpha_2+\alpha_3+2\alpha_4+2\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+2\alpha_4+\alpha_5+\alpha_6,$ $\alpha_1+\alpha_2+\alpha_3+\alpha_4+\alpha_5+\alpha_6+\alpha_7,\ \alpha_2+\alpha_3+2\alpha_4+\alpha_5+\alpha_6+\alpha_7$
8	$\alpha_1+\alpha_2+2\alpha_3+2\alpha_4+\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+2\alpha_4+2\alpha_5+\alpha_6,$ $\alpha_1+\alpha_2+\alpha_3+2\alpha_4+\alpha_5+\alpha_6+\alpha_7,\ \alpha_2+\alpha_3+2\alpha_4+2\alpha_5+\alpha_6+\alpha_7$
9	$\alpha_1+\alpha_2+2\alpha_3+2\alpha_4+2\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+\alpha_3+2\alpha_4+2\alpha_5+\alpha_6+\alpha_7,$ $\alpha_1+\alpha_2+2\alpha_3+2\alpha_4+\alpha_5+\alpha_6+\alpha_7,\ \alpha_2+\alpha_3+2\alpha_4+2\alpha_5+2\alpha_6+\alpha_7$
10	$\alpha_1+\alpha_2+\alpha_3+2\alpha_4+2\alpha_5+2\alpha_6+\alpha_7,\ \alpha_1+\alpha_2+2\alpha_3+2\alpha_4+2\alpha_5+\alpha_6+\alpha_7,$ $\alpha_1+\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+\alpha_6$
11	$\alpha_1+2\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+\alpha_6,\ \alpha_1+\alpha_2+2\alpha_3+2\alpha_4+2\alpha_5+2\alpha_6+\alpha_7,$ $\alpha_1+\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+\alpha_6+\alpha_7$
12	$\alpha_1+\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+2\alpha_6+\alpha_7,\ \alpha_1+2\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+\alpha_6+\alpha_7$
13	$\alpha_1+\alpha_2+2\alpha_3+3\alpha_4+3\alpha_5+2\alpha_6+\alpha_7,\ \alpha_1+2\alpha_2+2\alpha_3+3\alpha_4+2\alpha_5+2\alpha_6+\alpha_7$
14	$\alpha_1+2\alpha_2+2\alpha_3+3\alpha_4+3\alpha_5+2\alpha_6+\alpha_7$
15	$\alpha_1+2\alpha_2+2\alpha_3+4\alpha_4+3\alpha_5+2\alpha_6+\alpha_7$
16	$\alpha_1+2\alpha_2+3\alpha_3+4\alpha_4+3\alpha_5+2\alpha_6+\alpha_7$
17	$2\alpha_1+2\alpha_2+3\alpha_3+4\alpha_4+3\alpha_5+2\alpha_6+\alpha_7$

$$\lambda_6 = v_1 + v_2 + v_3 + v_4 + v_5 - v_8,$$

$$\lambda_7 = v_1 + v_2 + v_3 + v_4 + v_5 + v_6,$$

as it follows from (2) and (3). As E_7 is simply laced, the geometry of the weight system is summarized by the relations $(\lambda_i,\lambda_j)=A_{ij}^{-1}$. The Weyl vector is

$$\rho = \frac{1}{2}\sum_{\alpha\in\mathcal{R}^+}\alpha = \sum_{i=1}^{7}\lambda_i = \frac{1}{2}(34\alpha_1 + 49\alpha_2 + 66\alpha_3 + 96\alpha_4 + 75\alpha_5 + 52\alpha_6 + 27\alpha_7),$$

and has length $|\rho|=\sqrt{798}/2$. The Weyl formula for dimensions applied to the irreducible representation associated to the integral dominant weight $\mu=\Sigma_{i=1}^{7}m_i\lambda_i$ gives

$$\dim R_\mu = \prod_{\alpha\in\mathcal{R}^+} \frac{(\alpha,\mu+\rho)}{(\alpha,\rho)} = \frac{P}{2^6\cdot 3^6\cdot 4^6\cdot 5^6\cdot 6^5\cdot 7^5\cdot 8^4\cdot 9^4\cdot 10^3\cdot 11^3\cdot 12^2\cdot 13^2\cdot 14\cdot 15\cdot 16\cdot 17},$$

where P is a product extended to the set of positive roots in which the root $\alpha=\Sigma_{i=1}^7 a_i\alpha_i$ contributes with a factor $\mathrm{ht}(\alpha)+\Sigma_{i=1}^7 a_i m_i$, where $\mathrm{ht}(\alpha)$ is the height of α. In particular, for the basic representations R_{λ_k}, one finds

$$\dim R_{\lambda_1} = 133, \quad \dim R_{\lambda_2} = 912,$$

$$\dim R_{\lambda_3} = 8645, \quad \dim R_{\lambda_4} = 365\,750,$$

$$\dim R_{\lambda_5} = 27\,664, \quad \dim R_{\lambda_6} = 1539,$$

$$\dim R_{\lambda_7} = 56.$$

All the irreducible representations are self-adjoint; R_{λ_1} is the adjoint representation and R_{λ_7}, the fundamental one.

III. THE TRIGONOMETRIC CALOGERO-SUTHERLAND MODEL ASSOCIATED TO A ROOT SYSTEM

First of all, we review briefly the general theory of the quantum trigonometric Calogero-Sutherland model related to a root system $\mathcal{R}$ associated to a simple Lie algebra L of rank r, and later study explicity the E_7 case. For Calogero-Sutherland systems other than trigonometric see Ref. 10; see also Ref. 25.

The trigonometric Calogero-Sutherland model related to the root system $\mathcal{R}$ of rank r is the quantum system in a Euclidean space $\mathbf{R}^r$ defined by the standard Hamiltonian operator

$$H = \frac{1}{2}\sum_{j=1}^{r} p_j^2 + \sum_{\alpha\in\mathcal{R}^+} \kappa_\alpha(\kappa_\alpha-1)\sin^{-2}(\alpha,q), \tag{5}$$

where $q=(q_j)$ is a Cartesian coordinate system and $p_j=-i\partial_{q_j}$; $\mathcal{R}^+$ is the set of the positive roots of L, and the coupling constants κ_α are such that $\kappa_\alpha=\kappa_\beta$ if $|\alpha|=|\beta|$. We will restrict ourselves to the case of simply laced root systems (as the E series is), for which the Calogero-Sutherland model depends only on one coupling constant κ.

Although the Hamiltonian (5) is defined in all $\mathbf{R}^r$, the configuration space is confined by the singularities (infinite walls) $(\alpha,q)=0$. If the q coordinates are assumed to take values in the $[0,\pi]$ interval, H can be interpreted as describing the dynamics of a system of r unit mass particles moving on the circle with interaction $V(q)=\kappa(\kappa-1)\Sigma_\alpha \sin^{-2}(\alpha,q)$, but notice that there is not translational invariance. The wave functions must be π periodic.

The main problem is to find the stationary states, i.e., to solve the Schrödinger eigenvalue problem $H\Psi=E\Psi$. The following important facts about this family of quantum mechanical systems were well established in Refs. 6 and 10.

(a) They are integrable, and moreover they are exactly solvable. The configuration space is confined to the Weyl alcove $\Lambda_W=\{q\in\mathbf{R}^r \,|\, 0<(\alpha,q)<\pi\}$.

(b) The ground state energy and (non-normalized) wave function are

$$E_0(\kappa) = 2\rho^2\kappa^2,$$

$$\Psi_0^\kappa(q) = \prod_{\alpha\in\mathcal{R}^+} \sin^\kappa(\alpha,q),$$

while the excited states are indexed by the highest weights $\mu=\Sigma m_i\lambda_i \in P^+$ (P^+ is the cone of dominant weights) of the irreducible representations of L, that is, by the r-tuple of non-negative integers $\mathbf{m}=(m_1,\ldots,m_r)$ (the quantum numbers), and the wave functions satisfy

$$\begin{aligned} H\Psi_{\mathbf{m}}^\kappa &= E_{\mathbf{m}}(\kappa)\Psi_{\mathbf{m}}^\kappa, \\ E_{\mathbf{m}}(\kappa) &= 2(\mu+\kappa\rho,\mu+\kappa\rho). \end{aligned} \tag{6}$$

(c) It is natural to look for the solutions $\Psi_{\mathbf{m}}^\kappa$ in the form

$$\Psi_{\mathbf{m}}^\kappa(q) = \Psi_0^\kappa(q)\Phi_{\mathbf{m}}^\kappa(q), \tag{7}$$

and consequently we are led to the eigenvalue problem

$$\Delta^\kappa\Phi_{\mathbf{m}}^\kappa = \varepsilon_{\mathbf{m}}(\kappa)\Phi_{\mathbf{m}}^\kappa, \tag{8}$$

where Δ^κ is the linear differential operator

$$\Delta^\kappa = -\frac{1}{2}\sum_{j=1}^r \partial_{q_j}^2 - \kappa\sum_{\alpha\in\mathcal{R}^+}\cot(\alpha,q)(\alpha,\nabla_q), \tag{9}$$

and the eigenvalues $\varepsilon_{\mathbf{m}}(\kappa)$ are the energies over the ground level, i.e.,

$$\varepsilon_{\mathbf{m}}(\kappa) = E_{\mathbf{m}}(\kappa) - E_0(\kappa) = 2(\mu,\mu+2\kappa\rho). \tag{10}$$

Taking into account that $(\lambda_j,\lambda_k)=A_{jk}^{-1}$, it is possible to give a more explicit expression for the eigenvalues $\varepsilon_{\mathbf{m}}(\kappa)$,

$$\varepsilon_{\mathbf{m}}(\kappa) = 2\sum_{j,k=1}^r A_{jk}^{-1}m_jm_k + 4\kappa\sum_{j,k=1}^r A_{jk}^{-1}m_j. \tag{11}$$

We will write $\varepsilon_j(\kappa)$ for the fundamental weight λ_j, i.e., for the quantum numbers $(0,\ldots,1^{(j)},\ldots,0)$.

(d) In the case $\kappa=0$ the wave functions (8) are (proportional to) the monomial symmetric functions

$$M_\lambda(q) = \sum_{w\in W} e^{2i(w\cdot\lambda,q)}, \quad \lambda\in P^+, \tag{12}$$

W being the Weyl group of L. And the wave functions in the case $\kappa=1$ are (proportional to) the characters of the irreducible representations

$$\boldsymbol{\chi}_\lambda(q) = \frac{\sum_{w\in W}(\det w)e^{2i(w\cdot(\lambda+\rho),q)}}{\sum_{w\in W}(\det w)e^{2i(w\cdot\rho,q)}}, \quad \lambda\in P^+. \tag{13}$$

Both M_λ and $\boldsymbol{\chi}_\lambda$ are sums over the orbit of λ under W, and consequently, W invariant; as wave functions, they represent superpositions of plane waves whose momenta are consistent with the required π periodicity.

(d) Due to the Weyl symmetry of the Hamiltonian, the wave functions $\Phi^{\kappa}_{\mathbf{m}}(q)$ are W invariant, and the best way to solve the eigenvalue problem (8) is to use the set of independent W-invariant variables $z_k=\boldsymbol{\chi}_{\lambda_k}(q)$, in terms of which the wave functions $\Phi^{\kappa}_{\mathbf{m}}$ are polynomials.

Unfortunately, the expression of these characters z_k in terms of the q variables is complicated and makes the direct change of variables $z=z(q)$ very cumbersome. We are thus forced to follow a much more convenient, indirect route, which has proven to be useful for other root systems.[20,21]

To this goal, the starting point is to write the operator Δ^{κ} in the z variables,

$$\Delta^{\kappa}=\sum_{j,k} a_{jk}(z)\partial_{z_j}\partial_{z_k}+\sum_j [b^0_j(z)+\kappa b^1_j(z)]\partial_{z_j}, \tag{14}$$

with $a_{jk}=a_{kj}$. Now, if we take into account the fact that, as pointed above, $b^0_j(z)+b^1_j(z)=\Delta^1 z_j=\varepsilon_j(1)z_j$, the full expression for the coefficients $b_j(q)=b^0_j(z)+b^1_j(z)$ appearing in Δ^1 is completely determined by the Cartan matrix of the algebra; explicitly,

$$b_j(z)=2\left(A^{-1}_{jj}+2\sum_k A^{-1}_{kj}\right)z_j, \quad j=1,\ldots,r. \tag{15}$$

On the other hand, in order to find the coefficients a_{jk} we will rely on the quadratic Clebsh-Gordan series

$$R_{\lambda_j}\otimes R_{\lambda_k}=\sum_{\mu\in Q_{jk}} N_{\mu;jk}R_{\mu}, \tag{16}$$

where $Q_{jk}\subset P^+$ is the set of dominant weights in the irreducible representation of highest weight $\lambda_j+\lambda_k$, and $N_{\lambda;jk}$ is the multiplicity of the irreducible representation R_{λ} in that series; in particular, $N_{\lambda_j+\lambda_k;jk}=1$. In these expressions we will write $\mathbf{m}$ or $(m_1,\ldots,m_r)$ instead of $\mu=\Sigma_i m_i\lambda_i$. The Clebsh-Gordan series (16) yield the formulas

$$z_j z_k=\sum_{\mathbf{m}\in Q_{jk}} N_{\mathbf{m};jk}\boldsymbol{\chi}_{\mathbf{m}}(z) \tag{17}$$

for the products of fundamental characters $z_j z_k$, and consequently we obtain the coefficients a_{jk} by applying the operator Δ^1 to the two members of (17),

$$2a_{jk}(z)=\sum_{\mathbf{m}\in Q_{jk}} N_{\mathbf{m};jk}\varepsilon_{\mathbf{m}}(1)\boldsymbol{\chi}_{\mathbf{m}}(z)-b_j(z)z_k-b_k(z)z_j, \quad j,k=1,\ldots,r. \tag{18}$$

Therefore, to accomplish the task of fixing the form of the coefficents a_{jk} we need the list of all the quadratic Clebsh-Gordan series, the explicit expressions of the characters entering in them, and the coefficients b_j. Although there are some results for E_7 already available in the literature,[22,26] most of the required Clebsch-Gordan series and characters remain, to our knowledge, to be calculated.

The remaining step to achieve the complete expression of Δ^{κ} is to look for the coefficients $b^0_j(z)$. These can be found if we know enough monomial symmetric functions M_{λ} in terms of the z variables. Suppose that the relations $M_k=M_k(z)$ are known, where $M_k=M_{\lambda_k}$, $k=1,\ldots,r$; then, from the eigenvalue equation $\Delta^0 M_k=\varepsilon_k(0)M_k$ we obtain the following linear system for the b^0's:

$$\sum_{i,j} a_{ij}(z)\frac{\partial^2 M_k}{\partial z_i\partial z_j}+\sum_j b^0_j(z)\frac{\partial M_k}{\partial z_j}=2\lambda_k^2 M_k(z). \tag{19}$$

This system has a unique solution (b^0_j) because each of the sets of characters and monomial symmetric functions constitutes a basis of W-invariant functions.

Recently[27] we have found how to find the functions $M_k(z)$ in the E_6 case. In the present paper we will study only the case $\kappa=1$ and consequently we do not need to calculate the b^0 coefficients now.

IV. THE QUADRATIC CLEBSH-GORDAN SERIES FOR E_7

We have developed a systematic strategy, entirely based on a few elementary facts, to obtain all quantities needed for application of the formula (18). This strategy, which is essentially the same as that used in the previous paper[21] for the case of E_6, was described there in full detail, so we will confine ourselves here to mention some very general but important points. First of all, the series should be computed starting from those involving the most external dots of the Dynkin diagram, and going gradually towards the center of it. This is the order that allows the most efficient use of the orthogonality relations. Second, the orthogonality relations should be used not only to fix the multiplicity of some of the weights of lower height, but also to determine linear equations among the multiplicities of several weights of intermediate height. While for E_6 this is not of great importance, for the more complicated case of E_7 an extensive use of such linear constraints is required. These constraints, along with the bounds on multiplicities established in Ref. 28, make it posible to write a system of diophantine equations with unique solution for these multiplicities. Finally, once all the series are found, the inversion of them to obtain the second-order characters appearing in (18) requires the computation of many other characters of third, fourth, and fifth order. The best way to perform these computations is as follows. Starting from the outer region of the Dynkin diagram, we build in each step the part of the Δ^1 operator which only requires the characters that we already know. Then, we can use one of the procedures described in Sec. V below to compute the characters needed to obtain the next coefficient through (18), and so on. This is possible because (18) gives each coefficient $a_{ij}(z)$ in terms of characters associated to weights whose height is lower or equal than $\lambda_i+\lambda_j$.

By means of these techniques, one finally arrives at the following list of Clebsch-Gordan series:

$$R_{\lambda_1}\otimes R_{\lambda_1}=R_{2\lambda_1}\oplus R_{\lambda_6}\oplus R_{\lambda_3}\oplus R_{\lambda_1}\oplus 1,$$

$$R_{\lambda_1}\otimes R_{\lambda_2}=R_{\lambda_1+\lambda_2}\oplus R_{\lambda_7}\oplus R_{\lambda_2}\oplus R_{\lambda_1+\lambda_7}\oplus R_{\lambda_5},$$

$$R_{\lambda_1}\otimes R_{\lambda_3}=R_{\lambda_1+\lambda_3}\oplus R_{\lambda_4}\oplus R_{\lambda_1}\oplus R_{\lambda_6}\oplus R_{\lambda_3}\oplus R_{2\lambda_1}\oplus R_{\lambda_1+\lambda_6}\oplus R_{\lambda_2+\lambda_7},$$

$$R_{\lambda_1}\otimes R_{\lambda_4}=R_{\lambda_1+\lambda_4}\oplus R_{\lambda_2+\lambda_5}\oplus R_{\lambda_3+\lambda_6}\oplus R_{\lambda_1+\lambda_2+\lambda_7}\oplus R_{\lambda_5+\lambda_7}\oplus R_{2\lambda_2}\oplus R_{\lambda_1+\lambda_3}\oplus R_{\lambda_4}\oplus R_{\lambda_1+\lambda_6}\oplus R_{\lambda_2+\lambda_7}\oplus R_{\lambda_3},$$

$$R_{\lambda_1}\otimes R_{\lambda_5}=R_{\lambda_1+\lambda_5}\oplus R_{\lambda_2+\lambda_6}\oplus R_{\lambda_2}\oplus R_{\lambda_5}\oplus R_{\lambda_1+\lambda_2}\oplus R_{\lambda_1+\lambda_7}\oplus R_{\lambda_3+\lambda_7}\oplus R_{\lambda_6+\lambda_7},$$

$$R_{\lambda_1}\otimes R_{\lambda_6}=R_{\lambda_1+\lambda_6}\oplus R_{\lambda_2+\lambda_7}\oplus R_{\lambda_3}\oplus R_{\lambda_6}\oplus R_{2\lambda_7}\oplus R_{\lambda_1},$$

$$R_{\lambda_1}\otimes R_{\lambda_7}=R_{\lambda_1+\lambda_7}\oplus R_{\lambda_2}\oplus R_{\lambda_7},$$

$$R_{\lambda_2}\otimes R_{\lambda_2}=R_{2\lambda_2}\oplus R_{\lambda_1}\oplus R_{2\lambda_7}\oplus R_{\lambda_6}\oplus R_{2\lambda_1}\oplus R_{\lambda_3}\oplus R_{\lambda_2+\lambda_7}\oplus R_{\lambda_1+\lambda_6}\oplus R_{\lambda_4}\oplus 1,$$

$$R_{\lambda_2}\otimes R_{\lambda_3}=R_{\lambda_2+\lambda_3}\oplus R_{\lambda_1+\lambda_5}\oplus R_{\lambda_2}\oplus R_{\lambda_5}\oplus R_{\lambda_7}\oplus R_{\lambda_2+\lambda_6}\oplus R_{\lambda_3+\lambda_7}\oplus R_{\lambda_6+\lambda_7}\oplus 2R_{\lambda_1+\lambda_7}\oplus 2R_{\lambda_1+\lambda_2}\oplus R_{2\lambda_1+\lambda_7},$$

$$R_{\lambda_2}\otimes R_{\lambda_4}=R_{\lambda_2+\lambda_4}\oplus R_{\lambda_3+\lambda_5}\oplus R_{\lambda_1+\lambda_2+\lambda_6}\oplus R_{2\lambda_2+\lambda_7}\oplus R_{\lambda_1+\lambda_3+\lambda_7}\oplus R_{\lambda_5+\lambda_6}\oplus R_{\lambda_4+\lambda_7}\oplus R_{\lambda_1+\lambda_6+\lambda_7}$$
$$\oplus R_{2\lambda_1+\lambda_2}\oplus 2R_{\lambda_2+\lambda_3}\oplus R_{\lambda_2+2\lambda_7}\oplus 2R_{\lambda_1+\lambda_5}\oplus R_{2\lambda_1+\lambda_7}\oplus 2R_{\lambda_2+\lambda_6}\oplus 2R_{\lambda_3+\lambda_7}\oplus 2R_{\lambda_1+\lambda_2}$$
$$\oplus R_{\lambda_6+\lambda_7}\oplus R_{\lambda_5}\oplus R_{\lambda_1+\lambda_7}\oplus R_{\lambda_2},$$

$$R_{\lambda_2}\otimes R_{\lambda_5}=R_{\lambda_2+\lambda_5}\oplus R_{\lambda_3+\lambda_6}\oplus R_{2\lambda_6}\oplus R_{\lambda_1+\lambda_2+\lambda_7}\oplus R_{2\lambda_2}\oplus R_{\lambda_1+\lambda_3}\oplus R_{\lambda_5+\lambda_7}\oplus R_{\lambda_4}\oplus R_{\lambda_1+2\lambda_7}$$
$$\oplus 2R_{\lambda_1+\lambda_6}\oplus 2R_{\lambda_2+\lambda_7}\oplus R_{2\lambda_7}\oplus R_{2\lambda_1}\oplus R_{\lambda_3}\oplus R_{\lambda_6}\oplus R_{\lambda_1},$$

V. THE CALOGERO-SUTHERLAND HAMILTONIAN Δ^1 IN E_7: SOME APPLICATIONS

The coefficients $b_j(z)$ in the expression of Δ^1 are easily obtained from (15) and (2),

$$b_1(z) = 72z_1, \quad b_2(z) = 105z_2, \quad b_3(z) = 144z_1, \quad b_4(z) = 216z_4,$$

$$b_5(z) = 165z_5, \quad b_6(z) = 112z_5, \quad b_7(z) = 57z_7.$$

After having computed in Sec. IV the necessary series and characters, we can now follow the lines indicated in Sec. III to obtain the Hamiltonian operator in the limit $\kappa=1$. The result for the coefficients $a_{jk}(z)$ in (14) for $\kappa=1$ is

$$a_{11}(z) = 4(-19 - 10z_1 + z_1^2 - z_3 - 5z_6),$$

$$a_{12}(z) = 2(-7z_2 + 2z_1z_2 - 5z_5 - 19z_7 - 13z_1z_7),$$

$$a_{13}(z) = 2(10 - 14z_1 - 19z_1^2 + 13z_3 + 3z_1z_3 - 3z_4 - 4z_6 - 9z_1z_6 - 6z_2z_7 + 9z_7^2),$$

$$\begin{aligned} a_{14}(z) = 2(&-10 - 2z_1 + 18z_1^2 - 7z_2^2 - 24z_3 - 6z_1z_3 + 14z_4 + 4z_1z_4 - 4z_2z_5 + 8z_6 + 12z_1z_6 - 4z_3z_6 + 4z_6^2 \\ &- 14z_2z_7 - 5z_1z_2z_7 - 9z_5z_7 - 9z_7^2 + 9z_1z_7^2), \end{aligned}$$

$$a_{15}(z) = 2(-12z_2 - 6z_1z_2 + 8z_5 + 3z_1z_5 - 5z_2z_6 + 19z_7 + 5z_1z_7 - 5z_3z_7 - 13z_6z_7),$$

$$a_{16}(z) = 4(9 - 3z_1 - 3z_3 + 2z_6 + z_1z_6 - 3z_2z_7 - 9z_7^2),$$

$$a_{17}(z) = 2(-7z_2 - 19z_7 + z_1z_7),$$

$$a_{22}(z) = -40 + 24z_1 - 36z_1^2 + 7z_2^2 + 24z_3 - 4z_4 + 44z_6 - 16z_1z_6 - 12z_2z_7 - 36z_7^2,$$

$$a_{23}(z) = 2(9z_2 - 14z_1z_2 + 4z_2z_3 + 16z_5 - 4z_1z_5 - 5z_2z_6 + 4z_1z_7 - 12z_1^2z_7 + 7z_3z_7 - z_6z_7),$$

$$\begin{aligned} a_{24}(z) = 2(&-7z_2 - 4z_1z_2 - 6z_1^2z_2 - z_2z_3 + 6z_2z_4 + 20z_5 - 6z_1z_5 - 3z_3z_5 + 14z_2z_6 - 4z_1z_2z_6 - 5z_5z_6 \\ &- 10z_1z_7 + 22z_1^2z_7 - 6z_2^2z_7 - 12z_3z_7 - 5z_1z_3z_7 + 12z_4z_7 - \ 10z_6z_7 + 13z_1z_6z_7 - 9z_2z_7^2), \end{aligned}$$

$$\begin{aligned} a_{25}(z) = 40 &- 24z_1 + 12z_1^2 - 14z_2^2 + 12z_3 - 12z_1z_3 + 28z_4 + 9z_2z_5 + 16z_6 - 12z_1z_6 - 8z_3z_6 - 24z_6^2 \\ &+ 12z_2z_7 - 10z_1z_2z_7 + 14z_5z_7 - 2z_7^2 - 2z_1z_7^2, \end{aligned}$$

$$a_{26}(z) = 2(17z_2 - 6z_1z_2 + 8z_5 + 3z_2z_6 - 24z_1z_7 - 5z_3z_7 - 13z_6z_7),$$

$$a_{27}(z) = -48z_1 - 12z_3 - 28z_6 + 3z_2z_7,$$

$$\begin{aligned} a_{33}(z) = 4(&-20 + 16z_1 - 5z_1^2 - 9z_1^3 + 8z_3 + 12z_1z_3 + 3z_3^2 - 7z_4 - z_1z_4 - 2z_2z_5 - 9z_6 + - 3z_1z_6 - 4z_1^2z_6 \\ &+ 2z_3z_6 - 3z_6^2 + 6z_2z_7 - 6z_1z_2z_7 + 8z_5z_7 + z_7^2 + 7z_1z_7^2), \end{aligned}$$

$$a_{67}(z) = 2(-7z_2 - 3z_5 - 19z_7 - 11z_1z_7 + 2z_6z_7),$$

$$a_{77}(z) = -60 - 24z_1 - 4z_6 + 3z_7^2.$$

With the explicit expression of Δ^1 at our disposal, we can now try to use the Schrödinger equation as an efficient mean to compute particular characters of E_7. Given that all these characters are polynomials in the z variables, the Schrödinger equation can be solved by applying a systematic procedure, which is suitable to be implemented in a computer program able to carry out symbolic calculations. We propose two alternative methods to find the Schrödinger eigenfunctions.

(1) Given a weight $\nu=\sum_{i=1}^7 n_i\lambda_i \in P^+$, let us denote $z^{\mathbf{n}}$ (or z^ν) the monomial $z^{\mathbf{n}}=\prod_{i=1}^7 z_i^{n_i}$; thus $z_i=z^{\lambda_i}$. The operator Δ^1 acting on $z^{\mathbf{n}}$ gives

$$\Delta^1 z^{\mathbf{n}} = \sum_{\beta\in\Lambda} S_{\beta,\mathbf{n}} z^{\mathbf{n}-\beta} = \varepsilon_{\mathbf{m}}(1) z^{\mathbf{m}} + \sum_{0\neq\beta\in\Lambda} S_{\beta,\mathbf{n}} z^{\mathbf{n}-\beta}, \tag{20}$$

where Λ only includes integral linear combinations of the simple roots with non-negative coefficients and, of course, in the exponent of (20) we express β in the basis of fundamental weights. The eigenfunctions $\boldsymbol{\chi}_{\mathbf{m}}$ can be written as

$$\boldsymbol{\chi}_{\mathbf{m}} = \sum_{\lambda\in Q^+_{\mathbf{m}}} C_\lambda z^{\mathbf{m}-\lambda} = z^{\mathbf{m}} + \sum_{0\neq\lambda\in Q^+_{\mathbf{m}}} C_\lambda z^{\mathbf{m}-\lambda},$$

where again the λ in $Q^+_{\mathbf{m}}$ are integral linear combinations of the simple roots with non-negative coefficients such that they do not give rise to negative powers of the z's. By substituting in the Schrödinger equation $\Delta^1\boldsymbol{\chi}_{\mathbf{m}}=\varepsilon_{\mathbf{m}}(1)\boldsymbol{\chi}_{\mathbf{m}}$ we find the iterative formula

$$C_\lambda = \frac{1}{\varepsilon_{\mathbf{m}}(1) - \varepsilon_{\mathbf{m}-\lambda}(1)} \sum_{0\neq\beta\in\Lambda} S_{\beta,\mathbf{m}-(\lambda-\beta)} C_{\lambda-\beta}.$$

To use this formula in practice, one should take into account the heights of the λ's involved, because each coefficient C_λ can depend only on some of the C_ν such that $\mathrm{ht}(\nu)<\mathrm{ht}(\lambda)$.

(2) The Clebsch-Gordan series for the product $\prod_{i=1}^7 z_i^{m_i}$ reads

$$z_1^{m_1}z_2^{m_2}z_3^{m_3}z_4^{m_4}z_5^{m_5}z_6^{m_6}z_7^{m_7} = \boldsymbol{\chi}_{\mathbf{m}} + \sum_{\beta\in Q_{\mathbf{m}}} D_\beta \boldsymbol{\chi}_{\mathbf{m}-\beta}.$$

Here it is not difficult, in each particular case, to elaborate a list with all the elements in $Q_{\mathbf{m}}$ (i.e., the integral dominant weights appearing in the series). Furthermore, the operator $\Delta^1-\varepsilon_{\mathbf{n}}(1)$ annihilates the character $\boldsymbol{\chi}_{\mathbf{n}}$. Taking this into account, we can make use of the simple-looking formula

$$\boldsymbol{\chi}_{\mathbf{m}}=\left\{\prod_{\beta\in Q_{\mathbf{m}}}[\Delta^1-\varepsilon_{\mathbf{m}-\beta}(1)]\right\}z^{\mathbf{m}}$$

to obtain the eigenfunctions.

Through any of these methods, it is possible to compute the characters rather quickly. As an illustration, we offer a list of the third order characters in Appendix A.

Once we have a method for the computation of the characters, we can extend it to produce an algorithm for calculating the Clebsch-Gordan series. Suppose that we want to obtain the series for $\boldsymbol{\chi}_{\mathbf{m}}\cdot\boldsymbol{\chi}_{\mathbf{n}}$. We list the possible dominant weights entering in the series arranged by heights

$$\boldsymbol{\chi}_{\mathbf{m}}\cdot\boldsymbol{\chi}_{\mathbf{n}}=\boldsymbol{\chi}_{\mathbf{m+n}}+N_{\mu_1}\boldsymbol{\chi}_{\mu_1}+N_{\mu_2}\boldsymbol{\chi}_{\mu_2}+\cdots .$$

The multiplicity N_{μ_1} is simply the difference between the coefficients of z^{μ_1} in $\boldsymbol{\chi}_{\mathbf{m}}\cdot\boldsymbol{\chi}_{\mathbf{n}}$ and in $\boldsymbol{\chi}_{\mathbf{m+n}}$. Then, N_{μ_2} is the difference between the coefficient of z^{μ_2} in $\boldsymbol{\chi}_{\mathbf{m}}\cdot\boldsymbol{\chi}_{\mathbf{n}}$ and the sum of the corresponding coefficients in $\boldsymbol{\chi}_{\mathbf{m+n}}$ and $\boldsymbol{\chi}_{\mu_1}$, and so on. As an example, we present in Appendix B a list with a few cubic Clebsch-Gordan series. The complete list can be found in Ref. 29.

The approach we are describing is also useful to find the general structure of the series for products of some specific types. Let us consider, for instance, series of the type $z_7\boldsymbol{\chi}_{n\lambda_7}$ with arbitrary integer $n>0$. The weights of the representation R_{λ_7} are given by the linear combinations $\pm(v_i+v_j)$, $i\neq j$.[22] If we expand these weights in the basis of fundamental weights, we see that there are only four whose coefficients for all λ_i with $i\neq 7$ are non-negative, λ_7, $\lambda_6-\lambda_7$, $\lambda_1-\lambda_7$, and $-\lambda_7$. Hence, the form of the series should be

$$z_7\boldsymbol{\chi}_{0,0,0,0,0,0,n}=\boldsymbol{\chi}_{0,0,0,0,0,0,n+1}+a\boldsymbol{\chi}_{0,0,0,0,0,1,n-1}+b\boldsymbol{\chi}_{1,0,0,0,0,0,n-1}+c\boldsymbol{\chi}_{0,0,0,0,0,0,n-1}, \tag{21}$$

where we must fix a, b, and c. Now, by solving the Schrödinger equation by means of the first of the two methods described above, one finds

$$\boldsymbol{\chi}_{0,0,0,0,0,0,n}=z_7^n+(1-n)z_6z_7^{n-2}-z_1z_7^{n-2}+\cdots ,$$

$$\boldsymbol{\chi}_{0,0,0,0,0,1,n-1}=z_6z_7^{n-1}-z_1z_7^{n-1}+\cdots .$$

If we substitute this in (21), we can solve for a and b, obtaining $a=b=1$. We can now fix c by adjusting dimensions in (21). This gives $c=1$.

We list below the series of the form $z_7\boldsymbol{\chi}_{n\lambda_k}$ obtained through the same procedure,

$$z_7\boldsymbol{\chi}_{n,0,0,0,0,0,0}=\boldsymbol{\chi}_{n,0,0,0,0,0,1}+\boldsymbol{\chi}_{n-1,1,0,0,0,0,0}+\boldsymbol{\chi}_{n-1,0,0,0,0,0,1},$$

$$z_7\boldsymbol{\chi}_{0,n,0,0,0,0,0}=\boldsymbol{\chi}_{0,n,0,0,0,0,1}+\boldsymbol{\chi}_{0,n-1,1,0,0,0,0}+\boldsymbol{\chi}_{0,n-1,0,0,0,1,0}+\boldsymbol{\chi}_{1,n-1,0,0,0,0,0},$$

$$z_7\boldsymbol{\chi}_{0,0,n,0,0,0,0}=\boldsymbol{\chi}_{0,0,n,0,0,0,1}+\boldsymbol{\chi}_{1,1,n-1,0,0,0,0}+\boldsymbol{\chi}_{0,0,n-1,0,1,0,0}+\boldsymbol{\chi}_{1,0,n-1,0,0,0,1}+\boldsymbol{\chi}_{0,1,n-1,0,0,0,0},$$

$$\begin{aligned}z_7\boldsymbol{\chi}_{0,0,0,n,0,0,0}=&\boldsymbol{\chi}_{0,0,0,n,0,0,1}+\boldsymbol{\chi}_{0,1,1,n-1,0,0,0}+\boldsymbol{\chi}_{1,0,0,n-1,1,0,0}+\boldsymbol{\chi}_{0,1,0,n-1,0,1,0}+\boldsymbol{\chi}_{0,0,1,n-1,0,0,1}\\&+\boldsymbol{\chi}_{1,1,0,n-1,0,0,0}+\boldsymbol{\chi}_{0,0,0,n-1,1,0,0},\end{aligned}$$

$$\begin{aligned}z_7\boldsymbol{\chi}_{0,0,0,0,n,0,0}=&\boldsymbol{\chi}_{0,0,0,0,n,0,1}+\boldsymbol{\chi}_{0,0,0,1,n-1,0,0}+\boldsymbol{\chi}_{1,0,0,0,n-1,1,0}+\boldsymbol{\chi}_{0,1,0,0,n-1,0,1}+\boldsymbol{\chi}_{0,0,1,0,n-1,0,0}\\&+\boldsymbol{\chi}_{0,0,0,0,n-1,1,0},\end{aligned}$$

$$z_7\chi_{0,0,0,0,0,n,0} = \chi_{0,0,0,0,0,n,1} + \chi_{0,0,0,0,1,n-1,0} + \chi_{1,0,0,0,0,n-1,1} + \chi_{0,1,0,0,0,n-1,0} + \chi_{0,0,0,0,0,n-1,1}.$$

VI. CONCLUSIONS

In this paper we have shown how the Calogero-Sutherland Hamiltonian for the Lie algebra E_7 can be used to compute both Clebsch-Gordan series and characters of that algebra. The treatment we have presented can be applied to the cases of other simple algebras. It can be also extended to deal with the system of orthogonal polynomials based on E_7 for general values of the parameter κ. The way in which this should be done is the subject of a research now in progress and will be presented elsewhere.

(Received 21 May 2005; accepted 21 July 2005; published online 11 October 2005)

We study the spectral properties of polyatomic molecules near a scattering level. We prove that in the Born-Oppenheimer approximation this study can be reduced to the one of a family of finite matrices of semiclassical pseudodifferential operators. More precisely, we show that any resonance of the molecule which is close enough to the real axis can be obtained from the discrete spectrum of one of these matrixes. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2037547]

I. INTRODUCTION

Consider a quantum system of $(n+p+1)$ particles, among which $(n+1)$ (the nuclei) are assumed to be heavy (with a mass of order $M \gg 1$), and p other ones (the electrons) are light (with a mass of order 1). Removing the center of mass motion of this system, and choosing properly the coordinates, one can describe it with a Hamiltonian of the type

$$P = -h^2\Delta_x - \Delta_y + V(x,y) \quad \text{on } L^2(\mathbb{R}^{3(n+p)}),$$

where h is a small parameter proportional to $M^{-1/2}$, and V is the sum of all the interactions between the particles. Moreover, we write $x=(x_1,\ldots,x_n) \in \mathbb{R}^{3n}$ for the Jacobi coordinates of $(n+1)$-nuclei in the center of mass frame; $y=(y_1,\ldots,y_p) \in \mathbb{R}^{3p}$ for the postion of p electrons.

Then, one defines the so-called electronic levels to be the discrete eigenvalues $\lambda_1(x) \leqslant \lambda_2(x) \leqslant \cdots$ of the operator

$$Q(x) = -\Delta_y + V(x,y) \quad \text{on } L^2(\mathbb{R}^{3p}_y).$$

Born and Oppenheimer in Ref. 2 realize that the study of P can be approximately reduced, when h is small, to the one of the family of operators,

$$-h^2\Delta_x + \lambda_j(x) \quad \text{on } L^2(\mathbb{R}^{3n}_x), \quad j = 1,2,\ldots .$$

In particular, when, for example, $\lambda_1(x)$ admits a nondegenerate point well at some energy level λ_0, the eigenvalues of P near λ_0 admits a complete asymptotic expansion in half-powers of h.

Such a result was proved both for smooth interactions in Refs. 6, 14, 13, 18, 19, and 3 and for Coulomb potentials (Refs. 12, 7, and 17). As we shall see, the main problem comes from the fact that, when one has singular (e.g., Coulomb) interactions, the eigenvalues and the eigenfunctions of $Q(x)$ are only C^2 with respect to the x variables (Combes-Seiler[4]).

Nevertheless, one can overcome this difficulty by introducing some x-dependent changes in the y variables that will regularize the potential V, the eigenvalues and the eigenfunctions of $Q(x)$.

[b]Present address: Université Libre de Bruxelles, Boulevard du Triomphe, Campus Plaine CP 214, B1050 Brussels, Belgium. Electronic mail: asenouss@ulb.ac.be

Since these changes can only be done locally in x, one then must glue them together, at least in a compact region, and to construct a kind of semiclassical pseudodifferential calculus adapted to these changes.

This will be enough to construct the complete expansion of the discrete spectrum of P, as in Klein-Martinez-Seiler-Wong.[12]

However, this technique is not sufficient when one wants to study the continuous spectrum of P (see Messirdi-Senoussaoui[20]), or *a fortiori* its resonances, the reason for this being that the classically allowed region (with respect to x) becomes unbounded.

We assume that any electron can be ionized near the energy level λ_0, and that the eigenvalues of $\lambda_j(x)$ of the operator $Q(x)$ are not degenerate at infinity [see (2.9) and (2.13) below]. This last assumption is essential to obtain a good behavior of the spectral projectors of $Q(x)$ near infinity. This is because our techniques stand strongly on pseudodifferential calculus, which requires a lot of regularity.

One must first make a change of variables whose purpose is to localize in a compact region the x-dependent singularities with respect to y in the interactions. After that the previous ideas can be adapted to any complex distortion of P (the resonances of P are accessible from the analytic distortions introduced by Hunziker[10] and developed by Messirdi[17,19]), and the study of P can be reduced to the one of a matrix of smooth h-pseudodifferential operators on $L^2(\mathbb{R}^{3n}_x)$.

In this paper, we show that one can reduce the problem to a finite matrix of regular h-pseudodifferential operators for polyatomic molecules and a class of potentials which includes the physically interesting case of Coulombic interactions.

More precisely, we construct a change of type

$$y=(y_1,\ldots,y_p)\mapsto y'=(G^0_x(y_1),\ldots,G^0_x(y_p)),$$

where x is outside the collision set of the molecule, $G^0_x(y_j)=y_j/|x|$ when $|y_j|\leqslant|x|$ and $G^0_x(y_j)=N_{y_j}$ (N is fixed large enough) when $|y_j|\geqslant 2N|x|$. In this way the domain in y will not be changed, the singularities become localized in the ball $|y'|\leqslant 1$ and the distorted operator P_μ of P is now regular. Finally, by the Feshbach method we get the reduction result: z is a resonance of P if and only if there exists μ complex small enough, $\mathrm{Im}\,\mu>0$, such that $0\in\sigma_{\mathrm{disc}}a^{\varsigma}_{\mu,-+}(z)$.

$a^{\varsigma}_{\mu,-+}(z)$ is a finite matrix of h-pseudodifferential operators analytic on μ, and depending on a function ς which regularizes P_μ in the elliptic region.

II. ANALYTIC DISTORTION, RESONANCES, *h*-PSEUDODIFFERENTIAL OPERATORS, HYPOTHESIS AND RESULT

A. Analytic distortion

We study the operator

$$P=-h^2\Delta_x-\Delta_y+V(x,y) \tag{2.1}$$

on $L^2(\mathbb{R}^{3n}_x\times\mathbb{R}^{3p}_y)$, when h tends to 0^+, with $V(x,y)=V(x_1,\ldots,x_n,y_1,\ldots,y_p)$ of the form

$$V(x,y)=\sum_{\substack{j,k=1\\ j\neq k}}^{n}\frac{\alpha_{jk}}{|x_j-x_k|}+\sum_{\substack{1\leqslant l\leqslant p\\ 1\leqslant k\leqslant n}}\left(\frac{\alpha^+_{lk}}{|y_l+x_k|}+\frac{\alpha^-_{lk}}{|y_l-x_k|}\right)+\sum_{\substack{l,q=1\\ l\neq q}}^{p}\frac{\beta_{lq}}{|y_l-y_q|}=W(x)+V_1(x,y), \tag{2.2}$$

where α_{jk}, $\alpha^{\pm}_{lk}$, and β_{lq} are real constants, and $\alpha_{jk}>0$, $\forall\, j,k\in\{1,\ldots,n\}$. $W(x)$ and $V_1(x,y)$ denote, respectively, the interaction potentials between the nuclei of the molecule and between the nuclei electrons and electrons electrons. The constants $\alpha^{\pm}_{lk}$ indicate the charges of the nuclei (in particular, if $\alpha^+_{lk}=\alpha^-_{lk}$, the molecule is symmetric).

It is well known that P with domain in $H^2(\mathbb{R}^{3n}_x\times\mathbb{R}^{3p}_y)$ is self-adjoint in $L^2(\mathbb{R}^{3n}_x\times\mathbb{R}^{3p}_y)$, and one can define the resonances of P by analytic distortion introduced by Hunziker in Ref. 10 and

developed afterwards in Refs. 17 and 18. More precisely, let $\omega \in C^\infty(\mathbb{R}^3,\mathbb{R}^3)$ be a C^∞-vector field satisfying $\omega=0$ near the collision set $\mathcal{C}$ of all the nuclei of the molecule:

$$\mathcal{C}=\{x=(x_1,\ldots,x_n)\in\mathbb{R}^{3n};\exists\, i\neq j, x_i=x_j\} \tag{2.3}$$

and ω is the identity far from $\mathcal{C}$, in the following sense:

$$\omega(x_i)=0 \quad \text{if } x=(x_1,\ldots x_i,\ldots,x_n)\in v(\mathcal{C}), \quad i\in\{1,\ldots,n\},$$

$$\omega(x_i)=x_i \quad \text{if } x=(x_1,\ldots x_i,\ldots,x_n)\notin v(\mathcal{C}), \quad |x_i|\to+\infty, \quad i\in\{1,\ldots,n\},$$

where $v(\mathcal{C})$ denote an adequate small neighborhood of $\mathcal{C}$ in the (t,x), the variable t take different positions from 1 to n. For μ real small enough, the analytic distortion U_μ associated to ω is defined on $C_0^\infty(\mathbb{R}^{3n}\times\mathbb{R}^{3p})$ by

$$U_\mu\varphi(x,y)=\varphi(x_1+\mu\omega(x_1),\ldots,x_n+\mu\omega(x_n),y_1+\mu\omega(y_1),\ldots,y_p+\mu\omega(y_p))|J_\mu(x,y)|^{1/2}, \tag{2.4}$$

where $J_\mu(x,y)=\Pi_{j=1}^n\det(1+\mu D\omega(x_j))\Pi_{l=1}^p\det(1+\mu D\omega(y_l))$ is the Jacobian of the transformation

$$F_\mu:(x,y)\to(x_1+\mu\omega(x_1),\ldots,x_n+\mu\omega(x_n),y_1+\mu\omega(y_1),\ldots,y_p+\mu\omega(y_p)). \tag{2.5}$$

The distorted operator $P_\mu=U_\mu P U_\mu^{-1}$ can be extended to small enough complex values of μ as an analytic family of type A in the sense of Kato.[11]

B. Resonances

We say that a complex number ρ is a resonance of the operator P if $\mathrm{Re}\,\rho>\mathrm{Inf}\,\sigma_{\mathrm{ess}}(P)$ and there exists μ small enough, $\mathrm{Im}\,\mu>0$, such that $\rho\in\sigma_{\mathrm{disc}}(P_\mu)$ (see Ref. 15). We denote

$$\Gamma(P)=\bigcup_{\mathrm{Im}\,\mu>0,\ \mu\ \text{small enough}}\sigma_{\mathrm{disc}}(P_\mu)$$

the set of the resonances of P.

In particular, $\Gamma(P)$ (except limit point at a threshold) is a discrete set, and $\Gamma(P)\subset\{z\in\mathbb{C};\ \mathrm{Im}\,z<0\}$, we consider here just the resonances of P which are near the real axis.

C. *h*-pseudodifferential operators (see, e.g., Refs. 21, 22, and 16)

A family of unbounded operators $A_\mu(h)$ on $L^2(\mathbb{R}^{3n}),\mu\in\mathbb{C}$, with fixed domain $H^{k_0}(\mathbb{R}^{3n}),k_0\geqslant 0$, is said to be h-pseudodifferential if there exists a sequence $(a_j(x,\xi))_{j\geqslant 0}$ of C^∞ functions on $T^*\mathbb{R}^{3n}$ satisfying

$$\forall\,\alpha,\beta\in\mathbb{N}^{3n},\exists\, C_{\alpha\beta}>0,\ |\partial_x^\alpha\partial_\xi^\beta a_j(x,\xi)|\leqslant C_{\alpha\beta}(1+|\xi|^2)^{k_0-|\beta|} \tag{2.6}$$

uniformly on $T^*\mathbb{R}^{3n}$, and such that for any N large enough, $A(h)$ can be written

$$A(h)=\sum_{j=0}^{N}h^j\,\mathrm{Op}(a_j)+h^N R_N(h),$$

where $R_N(h)\in\mathcal{L}(L^2(\mathbb{R}^{3n}))$, for h small enough and Op denotes the usual h-quantization of symbols,

$$\mathrm{Op}(a_j)\varphi(x)=(2\pi h)^{-3n}\int_{\mathbb{R}^{6n}}e^{i(x-y)\xi/h}a_j(x,\xi)\varphi(y)\mathrm{d}y\,\mathrm{d}\xi \tag{2.7}$$

for $\varphi\in C_0^\infty(\mathbb{R}^{3n})$. The right-hand side being defined as an oscillatory integral (see, e.g., Ref. 9). $\Sigma_{j=0}^\infty h^j a_j(x,\xi)$ is called the symbol of $A(h),a_0(x,\xi)$ is its principal symbol.

Finally the family $A_\mu(h), \mu$ complex small enough, depends analytically on μ, if for any h small enough it forms an analytic family of type A, when μ varies in a complex neighborhood of zero independent of h.

D. Hypothesis and result

For $x \in \mathbb{R}^{3n} \backslash \mathcal{C}$, we denote

$$Q(x) = -\Delta_y + V(x,y) \tag{2.8}$$

which acts on $L^2(\mathbb{R}^{3p}_y)$ with domain $H^2(\mathbb{R}^{3p})$ and we fix a scattering energy level $\lambda_0 \in \sigma_{\text{ess}}(P) \backslash \{\text{thresholds of } P\}$ such that

$$\forall x \in \mathbb{R}^{3n} \backslash \mathcal{C}, \sigma(Q(x)) \cap]-\infty, \lambda_0] = \sigma_{\text{disc}}(Q(x)) \cap]-\infty, \lambda_0] \tag{2.9}$$

and such that there exists $M \geqslant 0$ satisfying

$$\forall x \in \mathbb{R}^{3n} \backslash \mathcal{C}, \quad \#\sigma_{\text{disc}}(Q(x)) \geqslant M \quad \text{and } \#\sigma(Q(x)) \cap]-\infty, \lambda_0] \leqslant M. \tag{2.10}$$

Denoting $\lambda_1(x) \leqslant \lambda_2(x) \leqslant \cdots \leqslant \lambda_M(x)$ the first M eigenvalues of $Q(x)$, we assume that there exists a gap between them and the rest of the spectrum $\sigma(Q(x))$ of $Q(x)$; then there exists a constant $\delta > 0$, such that for any $\lambda \in \sigma(Q(x)) \backslash \{\lambda_1(x), \ldots, \lambda_M(x)\}$, one has

$$\operatorname*{Inf}_{x \in \mathbb{R}^{3n} \backslash \mathcal{C}} \operatorname*{Inf}_{1 \leqslant j \leqslant M} |\lambda - \lambda_j(x)| \geqslant \delta, \tag{2.11}$$

(2.11) assures that the spectral projector $\pi(x)$ of $Q(x)$ associated to $\{\lambda_1(x), \ldots, \lambda_M(x)\}$ is C^2 regular with respect to x (see Ref. 4).

We also assume the existence of $C > 0$ such that

$$\operatorname*{Sup}_{x \in \mathbb{R}^{3n} \backslash \mathcal{C}} \tilde{\lambda}_M(x) \leqslant C, \tag{2.12}$$

where

$$\tilde{\lambda}_s(x) = \lambda_s(x) - \sum_{\substack{j,k=1 \\ j \neq k}}^{n} \frac{\alpha_{jk}}{|x_j - x_k|}, \quad 1 \leqslant s \leqslant M,$$

and each of the λ_s's are nondegenerate at infinity,

$$\operatorname*{Inf}_{\substack{x \in \mathbb{R}^{3n} \backslash \mathcal{C} \\ |x| \geqslant c}} \operatorname*{Inf}_{j \neq k} |\lambda_j(x) - \lambda_k(x)| \geqslant \frac{1}{C}. \tag{2.13}$$

The condition (2.12) is automatically satisfied if, e.g., $\alpha^{\pm}_{lk} \leqslant 0$, but (2.13) excludes the case of symmetric molecules, for which $\alpha^{+}_{lk} = \alpha^{-}_{lk}$, $l \in \{1, \ldots, p\}$, $k \in \{1, \ldots, n\}$, but where the projectors of $Q(x)$ depend smoothly on x near infinity (see, e.g., Ref. 5 for $p=1$).

Now we fix $N > 0$ large enough so that $\omega(x_i) = 0$, on

$$\left\{ x = (x_1, \ldots, x_i, \ldots, x_n) \in \mathbb{R}^{3n}; d(x, \mathcal{C}) \leqslant \frac{2}{N} \right\}, \quad i \in \{1, \ldots, n\},$$

where d denotes the Euclidian distance in $\mathbb{R}^{3n}$, and we first regularize P_μ near $\mathcal{C}$ by cancelling the potential $V(x,y)$ in this region with a regular function ζ.

We note $V_N = \{x \in \mathbb{R}^{3n}; d(x, C) \leqslant 1/2N\}$, and we remark that $V_N \cap S^{3n-1} \neq \emptyset$ and $(\mathbb{R}^{3n} \backslash V_N) \cap S^{3n-1} \neq \emptyset$, where S^{3n-1} is the unit sphere of $\mathbb{R}^{3n}$. Let the function $\zeta \in C^\infty(\mathbb{R}^{3n}, \mathbb{R})$ such that

$$\zeta = 1 \quad \text{on } [2/N, +\infty[\cdot [1, +\infty[\cdot (V_N \cap S^{3n-1}),$$
$$\zeta = 0 \quad \text{on } \mathbb{R}^{3n} \setminus [3/2N, +\infty[\cdot [1, +\infty[\cdot (V_N \cap S^{3n-1}), \tag{2.14}$$

the conic form appearing in (2.14) results from the expression $x = d(x,\mathcal{C})[|x|/d(x,\mathcal{C})](x/|x|)$ and the definition of the set V_N. Here we denote by

$$AB = \{z = xy; (x,y) \in A \times B\}.$$

Fixing $\alpha_0 > \lambda_0$, we set

$$Q_\mu^\zeta(x) = -U_\mu \Delta_y U_\mu^{-1} + \zeta(x) V_\mu(x,y) + (1-\zeta(x))\alpha_0,$$

$$V_\mu(x,y) = U_\mu V(x,y) U_\mu^{-1} = V(x_1 + \mu\omega(x_1), \ldots, x_n + \mu\omega(x_n), y_1 + \mu\omega(y_1), \ldots, y_p + \mu\omega(y_p)).$$

We also denote

$$P_\mu^\zeta(x) = -h^2 U_\mu \Delta_x U_\mu^{-1} + Q_\mu^\zeta(x)$$

with domain $H^2(\mathbb{R}^{3n} \times \mathbb{R}^{3p})$.

Let us remark that under rather general assumptions, one can show in a similar way as in Ref. 8 that near λ_0, $\sigma(P_\mu)$ and $\sigma(P_\mu^\zeta)$ coincide up to exponentially small error terms (see Ref. 17). This explains why we will study P_μ^ζ instead of P_μ.

Our main result is the following.

Theorem 2.1: *Under assumptions* (2.10) *to* (2.13), *and for any z complex close enough to* λ_0, *there exists a family of* $M \times M$*-matrices* $E_{\mu,-+}^\zeta(z)$, *of h-pseudodifferential operators on* $\mathbb{R}^{3n}$, *depending analytically on* μ *complex small enough, such that*

$$z \in \Gamma(P^\zeta) \Leftrightarrow \exists\, \mu \in \mathbb{C}, \mu \text{ small enough}, \operatorname{Im}\mu > 0, 0 \in \sigma_{\text{disc}}(E_{\mu,-+}^\zeta(z)).$$

The principal symbol of $E_{\mu,-+}^\zeta(z)$ *is of the form*

$$z - [|(1+\mu D\omega)^{-1}\xi|^2 I_M + \mathcal{M}_\mu^\zeta(x)],$$

where I_M *is the identity of* $\mathbb{C}^M$ *and* $\mathcal{M}_\mu^\zeta(x)$ *is a matrix of* C^∞*-functions on* $\mathbb{R}^{3n}$, *with eigenvalues* $\lambda_1(x_1+\mu\omega(x_1), \ldots, x_n+\mu\omega(x_n)), \ldots, \lambda_M(x_1+\mu\omega(x_1), \ldots, x_n+\mu\omega(x_n))$ *on* $\zeta(x)=1$, *and satisfying* $\operatorname{Re}\mathcal{M}_\mu^\zeta(x) \geqslant \lambda_0 + \delta$ *on* $\zeta(x) \neq 1$ *for some positive constant* δ. *Finally* $E_{\mu,-+}^\zeta(z)$ *depends analytically on z near* λ_0 *and is* $O(3)$*-invariant if the function* ζ *is also chosen* $O(3)$*-invariant, where* $O(3)$ *is the orthogonal group of* $\mathbb{R}^3$.

III. THE DISTORTED FESHBACH METHOD

The Feshbach method is a way to construct an effective Hamiltonian of P which is a nice h-pseudodifferential operator on $\mathbb{R}^{3n}$. To do this we will use a so-called Grushin problem associated to the distorted operator P_μ of P and a convenient choice of sections of Ran $\pi(x)$.

For $x \in \mathbb{R}^{3n} \setminus \mathcal{C}$, we denote

$$Q_\mu(x) = U_\mu Q(x + \mu\omega(x)) U_\mu^{-1}, \tag{3.1}$$

here U_μ is considered as acting on $L^2(\mathbb{R}_y^{3p})$, and we can easily see that $Q_\mu(x)$ extends for small enough μ to an analytic family of type A (see Ref. 19), and that the singularities of $V(x,y)$ are not changed if ω is taken as an odd function.

Denoting also

$$\widetilde{Q}_\mu(x) = Q_\mu(x) - \sum_{\substack{j,k=1 \\ j\neq k}}^{n} \frac{\alpha_{jk}}{|x_j + \mu\omega(x_j) - x_k - \mu\omega(x_k)|},$$

$$\widetilde{Q}(x) = \widetilde{Q}_0(x) = Q(x) - \sum_{\substack{j,k=1 \\ j\neq k}}^{n} \frac{\alpha_{jk}}{|x_j - x_k|}. \tag{3.2}$$

We first have the following.

Lemma 3.1: $\exists C_1 > 0$ *such that for all* $x \in \mathbb{R}^{3n}\backslash C$, *one has*

$$\sum_{\substack{j,k=1 \\ j\neq k}}^{n} \frac{\alpha_{jk}}{|x_j - x_k|} \leqslant \lambda_1(x) + C_1.$$

Proof: We must prove that $(\widetilde{Q}(x)+\lambda)^{-1} \in \mathcal{L}(L^2(\mathbb{R}^{3p}))$ for $\lambda \in \mathbb{R}_+$ large enough independently of x.

For $\forall x \in \mathbb{R}^{3n}\backslash\mathcal{C}$, we have

$$(\widetilde{Q}(x) + \lambda)(-\Delta_y + \lambda)^{-1} = 1 + \widetilde{V}(x,y)(-\Delta_y + \lambda)^{-1}, \tag{3.3}$$

where

$$\widetilde{V}(x,y) = V(x,y) - \sum_{\substack{j,k=1 \\ j\neq k}}^{n} \frac{\alpha_{jk}}{|x_j - x_k|}$$

and

$$\widetilde{V}(x,y)(-\Delta_y + \lambda)^{-1} = \sum_{\substack{1\leqslant l\leqslant p \\ 1\leqslant k\leqslant n}} \left(\frac{\alpha^+_{lk}}{|y_l + x_k|} + \frac{\alpha^-_{lk}}{|y_l - x_k|} \right)(-\Delta_y + \lambda)^{-1} + \sum_{\substack{l,q=1 \\ l\neq q}}^{p} \frac{\beta_{lq}}{|y_l - y_q|}(-\Delta_y + \lambda)^{-1}. \tag{3.4}$$

Each term of (3.4) is unitarily equivalent to the operator $(1/|y_1|)(-\Delta_y+\lambda)^{-1}$. But $1/|y_1|$ is Δ_{y_1}-compact on $L^2(\mathbb{R}^3)$ and by taking the Fourier transform of $(1/|y_1|)(-\Delta_y+\lambda)^{-1}$ this operator can be written $(1/|y_1|)(-\Delta_{y_1}+1)^{-1}(-\Delta_{y_1}+1)(-\Delta_y+\lambda)^{-1}$ or $K_{\xi_1}[(\xi_1^2+1)/(\xi^2+\lambda)]$ where the kernel K_{ξ_1} of the operator $(1/|y_1|)(-\Delta_{y_1}+\lambda)^{-1}$ acts in the ξ_1-variable only and is compact on $L^2(\mathbb{R}^3)$, and $[(\xi_1^2+1)/(\xi^2+\lambda)]$ tends to 0 as λ tends to $+\infty$. Consequently $(1/|y_1|)(-\Delta_y+\lambda)^{-1}$ tends to 0 in norm as λ tends to $+\infty$, and this proves in view of (3.4) that $\widetilde{V}(x,y)(-\Delta_y+\lambda)^{-1}$ tend to 0 in norm as λ tends to $+\infty$ uniformly with respect to x.

Therefore by (3.3), $(\widetilde{Q}(x)+\lambda)$ becomes invertible for any $x \in \mathbb{R}^{3n}\backslash\mathcal{C}$ if λ is chosen sufficiently large enough. □

Now, let $\gamma(x)$ be a continuous family of simple loops of $\mathbb{C}$, enclosing $\widetilde{\lambda}_1(x), \ldots, \widetilde{\lambda}_M(x)$ and having the rest of $\sigma(\widetilde{Q}(x))$ in its exterior. By the gap condition (2.11), we may also assume that

$$\operatorname*{Min}_{x\in\mathbb{R}^{3n}\backslash\mathcal{C}} \operatorname{dist}(\gamma(x), \sigma(\widetilde{Q}(x))) \geqslant \frac{\delta}{2} > 0, \tag{3.5}$$

dist is the distance on $\mathbb{C}$. Moreover, using Lemma 3.1 and condition (2.12), $\gamma(x)$ can be taken in a fixed compact set of $\mathbb{C}$.

We deduce also from the proof of Lemma 3.1 and the assumption (3.5) the following result.

Lemma 3.2: For any $k \in \{1,\dots,n\}, l,q \in \{1,\dots,p\}, l \neq q, \alpha \in \mathbb{N}^{3p}, |\alpha| \leqslant 2$, *the operators*

$$\frac{1}{|y_l \pm x_k|}(\widetilde{Q}(x)-z)^{-1}, \quad \frac{1}{|y_l - y_q|}(\widetilde{Q}(x)-z)^{-1}, \quad \partial^{\alpha}(\widetilde{Q}(x)-z)^{-1}$$

are uniformly bounded on $L^2(\mathbb{R}^{3p})$ *as* $x \in \mathbb{R}^{3n}\backslash\mathcal{C}$ *and* $z \in \gamma(x)$.

We now study the continuity of $\widetilde{Q}_{\mu}(x)$ with respect to μ.

Lemma 3.3: If μ *is a small enough complex number, then for any* $x \in \mathbb{R}^{3n}\backslash\mathcal{C}$ *and* $z \in \gamma(x)$, *the operator* $(\widetilde{Q}_{\mu}(x)-z)^{-1}$ *exists and satisfies uniformly*

$$(\widetilde{Q}_{\mu}(x)-z)^{-1} - (\widetilde{Q}(x)-z)^{-1} = \mathcal{O}(|\mu|).$$

Proof: We have

$$\begin{aligned}(\widetilde{Q}_{\mu}(x)-z) &= 1 + \widetilde{Q}_{\mu}(x) - \widetilde{Q}(x)\widetilde{Q}(x) - z^{-1}\widetilde{Q}(x) - z,\\ \widetilde{Q}_{\mu}(x) - \widetilde{Q}(x) &= \sum_{|\beta|\leqslant 2} |\mu| a_{\beta,\mu}(y)\partial_y^{\beta} + \widetilde{V}_{\mu}(x) - \widetilde{V}(x,y),\end{aligned} \tag{3.6}$$

where

$$\widetilde{V}_{\mu}(x,y) = V_{\mu}(x,y) - \sum_{\substack{j,k=1\\ j\neq k}}^{n} \frac{\alpha_{jk}}{|x_j + \mu\omega(x_j) - x_k - \mu\omega(x_k)|}, \quad \widetilde{V}(x,y) = \widetilde{V}_0(x,y),$$

and the $a_{\beta,\mu}$'s are in $C^{\infty}(\mathbb{R}^{3p})$ and uniformly bounded along with all their derivatives as μ tends to 0 in $\mathbb{C}$ (see Ref. 19). Moreover,

$$\begin{aligned}\widetilde{V}_{\mu}(x,y) - \widetilde{V}(x,y) = &\sum_{\substack{1\leqslant l\leqslant p\\ 1\leqslant k\leqslant n}} \alpha_{lk}^{\pm}\left(\frac{1}{|y_l + \mu\omega(y_l) \pm x_k \pm \mu\omega(x_k)|} - \frac{1}{|y_l \pm x_k|}\right)\\ &+ \sum_{\substack{l,q=1\\ l\neq q}}^{p} \beta_{lq}\left(\frac{1}{|y_l + \mu\omega(y_l) - y_q - \mu\omega(y_q)|} - \frac{1}{|y_l - y_q|}\right)\end{aligned}$$

and thus we have from the construction of the vector field ω,

$$|\widetilde{V}_{\mu}(x,y) - \widetilde{V}(x,y)| \leqslant C_2|\mu|\left(\sum_{\substack{1\leqslant l\leqslant p\\ 1\leqslant k\leqslant n}} \frac{1}{|y_l \pm x_k|} + \sum_{\substack{l,q=1\\ l\neq q}}^{p} \frac{1}{|y_l - y_q|}\right),$$

for some constant $C_2 > 0$. Then, the result follows from (3.6) and Lemma 3.2. □

We can now define for μ, a complex small enough for the spectral projector associated to $\widetilde{Q}_{\mu}(x)$ and the loops $\gamma(x)$,

$$\pi_{\mu}(x) = \frac{1}{2\pi i}\oint_{\gamma(x)} (z - \widetilde{Q}_{\mu}(x))^{-1}\,\mathrm{d}z. \tag{3.7}$$

This projector is of rank M and it helps us to construct the Grushin problem associated to P_{μ}^{ξ}.

On the one hand, using the fact that $\pi(x) = \pi_0(x)$ depends continuously on $x \in \mathbb{R}^{3n}\backslash\mathcal{C}$ (see Ref. 4), we can then find an orthonormal family of M continuous sections $\{v_1(x),\dots,v_M(x)\}$ generating Ran $\pi(x)$. On the other hand, we well know that $\lambda_1(x),\dots,\lambda_M(x)$ depend only on $|x|$ and can be

indexed in such a way each of them becomes analytic with respect to $x \in \mathbb{R}^{3n}\backslash\mathcal{C}$. Let $\{v_{1,\mu}(x),\ldots,v_{M,\mu}(x)\}$ denote a family of Ran $\pi_\mu(x)$, depending analytically on μ for μ small enough and normalized in $L^2(\mathbb{R}^{3p})$ by

$$\langle v_{k,\mu}(x), v_{l,\bar{\mu}}(x)\rangle_{L^2(\mathbb{R}^{3p})} = \delta_{k,l}. \tag{3.8}$$

We associate the two following operators:

$$R_\mu^- : \bigoplus_1^M L^2(\mathbb{R}^{3n}) \to L^2(\mathbb{R}^{3(n+p)}),$$

$$u^- = (u_1^-,\ldots,u_M^-) \mapsto R_\mu^- u^- = \sum_{k=1}^M u_k^- v_{k,\mu}(x), \tag{3.9}$$

$$R_\mu^+ = (R_\mu^-)^* : L^2(\mathbb{R}^{3(n+p)}) \to \bigoplus_1^M L^2(\mathbb{R}^{3n}),$$

$$u \mapsto R_\mu^+ u = \bigoplus_1^M \langle u, v_{k,\bar{\mu}}(x)\rangle_{L^2(\mathbb{R}^{3p})}. \tag{3.10}$$

We then consider a Grushin problem that will lead to the Feshbach reduction. For $z \in \mathbb{C}$, define

$$A_\mu^\zeta(z) = \begin{pmatrix} (P_\mu^\zeta - z) & R_\mu^- \\ R_\mu^+ & 0 \end{pmatrix} \tag{3.11}$$

on

$$H^2(\mathbb{R}^{3(n+p)}) \oplus \left(\bigoplus_1^M L^2(\mathbb{R}^{3n})\right)$$

to

$$L^2(\mathbb{R}^{3(n+p)}) \oplus \left(\bigoplus_1^M H^2(\mathbb{R}^{3n})\right).$$

Using Lemma 3.3, and (2.11), one can easily prove that the operator $\hat{\pi}_\mu(x)(P_\mu^\zeta - z)$ is invertible on $\{u \in H^2(\mathbb{R}^{3(n+p)}); \hat{\pi}_\mu(x)u = u\}$, where $\hat{\pi}_\mu(x) = 1 - \pi_\mu(x)$, and its inverse is bounded and denoted by $P_\mu'^{\xi} - z^{-1}$ for $z \in \mathbb{C}$ close enough to λ_0.

It follows that $A_\mu^\zeta(z)$ is invertible for $z \in \mathbb{C}$ close enough to λ_0,

$$(A_\mu^\zeta(z))^{-1} = \begin{pmatrix} a_\mu^\zeta(z) & a_{\mu,+}^\zeta(z) \\ a_{\mu,-}^\zeta(z) & a_{\mu,-+}^\zeta(z) \end{pmatrix} \tag{3.12}$$

with

$$\begin{gathered} a_\mu^\zeta(z) = (P_\mu'^{\zeta} - z)^{-1}\hat{\pi}_\mu(x), \quad a_{\mu,+}^\zeta(z) = R_\mu^- - a_\mu^\zeta(z)P_\mu^\zeta R_\mu^-, \\ a_{\mu,-}^\zeta(z) = R_\mu^+ - R_\mu^+ P_\mu^\zeta a_\mu^\zeta(z), \quad a_{\mu,-+}^\zeta(z) = zI_M - R_\mu^+(P_\mu^\zeta - P_\mu^\zeta a_\mu^\zeta(z)P_\mu^\zeta)R_\mu^-, \end{gathered} \tag{3.13}$$

where I_M is the identity of $\mathbb{C}^M$, and $a_{\mu,-+}^\zeta(z)$ depends only on x defined from $\oplus_{k=1}^M H^2(\mathbb{R}^{3n})$ to $\oplus_{k=1}^M L^2(\mathbb{R}^{3n})$. Consequently we have the following.

Lemma 3.4: *For $z \in \mathbb{C}$ close enough to λ_0, $z \in \Gamma(P^\zeta)$ if and only if there exists $\mu \in \mathbb{C}$, small enough*, Im $\mu > 0$, *such that* $0 \in \sigma_{\text{disc}}(a_{\mu,-+}^\zeta(z))$.

Now, we can prove with a suitable choice of the family $\{v_{1,\mu}(x),\ldots,v_{M,\mu}(x)\}$ that $a^{\xi}_{\mu,-+}(z)$ becomes a family of $M\times M$ matrices of h-pseudodifferential operators on $\mathbb{R}^{3n}$, analytic with respect to μ complex small enough. The main idea consists, before localizing the singularities of the potential, to construct as in Ref. 12 a x-dependent change of the y variables, in such a way the operators $Q_\mu(x)$ become smooth with respect to x.

IV. LOCALIZATION OF THE SINGULARITIES

In this section we use the idea of Martinez-Messirdi (see Ref. 17). By adequate change of variables we localize in a compact set of $\mathbb{R}^{3n}$ the x-dependent singularities with respect to y appearing in the interaction potentials.

Let $\chi\in C_0^\infty(\mathbb{R}_+)$ satisfying $0\leqslant\chi\leqslant 1$, $\chi'\leqslant 0$ and

$$\chi(s)=\begin{cases}1 & \text{if } 0\leqslant s\leqslant 1,\\ 0 & \text{if } s\geqslant 2.\end{cases}$$

We choose $N\geqslant 1$ large enough such that $\omega(x_i)=0$, $\forall i\in\{1,\ldots,n\}$ on $\{d(x,\mathcal{C})\leqslant 2/N\}$. Let us define for $r\geqslant 1/N$ and $t\geqslant 0$, the function

$$\rho(r,t)=\frac{t}{r}\chi\left(\frac{t}{r}\right)+Nt\left(1-\chi\left(\frac{t}{r}\right)\right). \tag{4.1}$$

We clearly see that

(i) $\partial\rho/\partial t>0$ on $[1/N,+\infty[\times\mathbb{R}_+$,
(ii) $\rho(r,t)$ is surjective on $\mathbb{R}_+$,
(iii) $\forall k\geqslant 1$, $\partial^k\rho/\partial t^k$ is uniformly bounded on $[1/N,+\infty[\times\mathbb{R}_+$.

The function $t\to\rho(r,t)$ is a diffeomorphism on $\mathbb{R}_+$, we denote by α_r its inverse.

By construction, we have $\alpha_r(t)=t/N$ if $t\geqslant 2Nr$ and $\alpha_r(r)=rt$ if $t\leqslant 1$.

For $x\in\mathbb{R}^3$, such that $d(x,\mathcal{C})\geqslant 1/N$, we define the function

$$\theta_x:\mathbb{R}^3\ni s\to\alpha_{|x|}(|s|)\frac{s}{|s|}.$$

θ_x has the following properties.

Lemma 4.1: *(see Ref. 17)*

(i) $\forall x\in\mathbb{R}^{3n}$, $d(x,\mathcal{C})\geqslant 1/N$, *the function* θ_x *is a diffeomorphism of* $\mathbb{R}^3$ *depending smoothly on* x, *and satisfying*
(ii) $\forall\alpha\in\mathbb{N}^{3n}\backslash\{0\}$, $\partial_x^\alpha\theta_x$ *is uniformly bounded on* $\{d(x,\mathcal{C})\geqslant 1/N, s\in\mathbb{R}^3\}$.

$$\theta_x(x_i/|x|)=x_i,\quad x=(x_1,\ldots,x_i,\ldots,x_n),\quad \forall\, i\in\{1,\ldots,n\},$$

$$\theta_x(s)=\frac{s}{N}\quad \textit{if } |s|\geqslant 2N|x|,$$

$$\theta_x(s)=|x|s\quad \textit{if } |s|\leqslant 1.$$

Denote $\tilde{\sigma}_x=\theta_x^{-1}$ the inverse diffeomorphism of θ_x on $\mathbb{R}^3$. It satisfies $\tilde{\sigma}_x(s)=Ns$ if $|s|\geqslant 2|x|$ and $\tilde{\sigma}_x(s)=s/|x|$ if $|s|\leqslant|x|$.

Let the function $\mathbb{R}^{3p}\ni y=(y_1,\ldots,y_p)\to\tilde{\sigma}_x(y)=(\tilde{\sigma}_x(y_1),\ldots,\tilde{\sigma}_x(y_p))$, then σ_x is a diffeomorphism on $\mathbb{R}^{3p}$, moreover the transformed potential $\hat{V}_\mu(x,y)$ of $V_\mu(x,y)$ under the change of variables $y'=\sigma_x(y)$ is given by [denoting $I_\mu(s)=s+\mu\omega(s)$]

$$\hat{V}_\mu(x,y)=\sum_{\substack{j,k=1\\ j\neq k}}^{n}\frac{\alpha_{jk}}{|I_\mu(x_j)-I_\mu(x_k)|}+\sum_{\substack{1\leqslant l\leqslant p\\ 1\leqslant k\leqslant n}}\frac{\alpha_{lk}^{\pm}}{\left|I_\mu(\theta_x(y_l'))\pm I_\mu\left(\theta_x\left(\frac{x_k}{|x|}\right)\right)\right|}+\sum_{\substack{l,q=1\\ l\neq q}}^{p}\frac{\beta_{lk}}{|I_\mu(\theta_x(y_l'))\pm I_\mu(\theta_x(y_q'))|}. \tag{4.2}$$

It is then advantageous to study $\hat{V}_\mu(x,y)$ instead of $V_\mu(x,y)$ because their x-dependent singularities are now localized in the compact set $\cup_{l,k}\{y_l'=\pm x_k/|x|\}$.

V. REGULARIZATION OF THE OPERATOR

Since $\{x\in\mathbb{R}^{3n}, d(x,\mathcal{C})\leqslant 1/N\}\subset\mathbb{R}^{3n}\backslash[3/2N,+\infty[\cdot[1,+\infty[\cdot(V_N\cap S^{3n-1})$, then P^ζ is a nice h-pseudodifferential operator in the region $\mathbb{R}^{3n}\backslash[1/2N,+\infty[\cdot[1,+\infty[\cdot(V_N\cap S^{3n-1})$, with operator valued symbol to regularize P^ζ on the region $[1/2N,+\infty[\cdot[1,+\infty[\cdot(V_N\cap S^{3n-1})$, we use a change of variables similar to the one used in Refs. 12 and 20 coupled with the one of Sec. IV.

For any x_0 fixed in $]1/2N,+\infty]\cdot]1,+\infty]\cdot(V_N\cap S^{3n-1})$ [then $d(x_0,\mathcal{C})\geqslant 1/2N, x_0\notin\mathcal{C}$] and for $x\in\mathbb{R}^{3n}\backslash\mathcal{C}$, with $x/|x|$ close enough to $x_0/|x_0|$ [equivalently $x_j/|x|$ close enough to $x_j^0/|x_0|, \forall j\in\{1,\ldots,n\}, x_0=(x_1^0,\ldots,x_n^0)$], we consider the C^∞-function defined on $\mathbb{R}^3$ by

$$F_{x_0}(x,s)=s+\sum_{j=1}^{n}\left(\frac{x_j}{|x|}-\frac{x_j^0}{|x_0|}\right)(f_j(s)-f_j(-s)), \tag{5.1}$$

where $f_j\in C_0^\infty(\mathbb{R}^3,\mathbb{R})$, $f_j(x_k^0/|x_0|)=\delta_{jk}$, and $f_j(-x_k^0/|x_0|)=0, \forall j,k\in\{1,\ldots,n\}$.

It is clear that for $x/|x|$ in some small neighborhood ω_{x_0} of $x_0/|x_0|$, the function $F_{x_0}(x,.)$ is C^∞-diffeomorphism of $\mathbb{R}^3$, satisfying

$$F_{x_0}\left(x,\frac{x_k^0}{|x_0|}\right)=\frac{x_k}{|x|},\quad F_{x_0}\left(x,-\frac{x_k^0}{|x_0|}\right)=-\frac{x_k}{|x|},\quad \forall k\in\{1,\ldots,n\}. \tag{5.2}$$

$\forall\alpha\in\mathbb{N}^{3n}, \exists c_\alpha>0, \forall x\in\mathbb{R}_+^*\omega_{x_0}, \forall s,s'\in\mathbb{R}^3$,

$$\frac{1}{C_0}|s-s'|\leqslant|F_{x_0}(x,s)-F_{x_0}(x,s')|\leqslant C_0|s-s'|,$$

$$|\partial_x^\alpha F_{x_0}(x,s)-\partial_x^\alpha F_{x_0}(x,s')|\leqslant C_\alpha|s-s'|,$$

$$|\partial_x^\alpha F_{x_0}(x,s)|\leqslant C_\alpha(|\alpha|\geqslant 1). \tag{5.3}$$

With the notations of the preceding section, let us denote for $x\in[1/N,+\infty[\cdot[1,+\infty[\cdot\omega_{x_0}$,

$$G_x^0:\mathbb{R}^{3p}\to\mathbb{R}^{3p},$$

$$y=(y_1,\ldots,y_p)\mapsto G_x^0(y)=(\theta_x(F_{x_0}(x,y_1)),\ldots,\theta_x(F_{x_0}(x,y_p))).$$

Using Lemma 4.1 and the properties (5.3), we obtain the following.

Lemma 5.1: $\forall\alpha\in\mathbb{N}^3$, *there exists a constant* $C_\alpha'>0$ *such that* $\forall x\in[1/N,+\infty[\cdot[1,+\infty[\cdot\omega_{x_0}, \forall y,y'\in\mathbb{R}^{3p}$, *one has*

$$\frac{1}{C_0'}|s-s'|\leqslant|G_x^0(y)-G_x^0(y')|\leqslant C_0'(1+|x|)|y-y'|,$$

$$|\partial_x^\alpha G_x^0(y) - \partial_x^\alpha G_x^0(y')| \leqslant C'_\alpha |y - y'| \quad (|\alpha| \geqslant 1), \tag{5.4}$$

$$|\partial_x^\alpha G_x^0(y)| \leqslant C'_\alpha \quad (|\alpha| \geqslant 1).$$

Now using the fact that G_x^0 is a diffeomorphism of $\mathbb{R}^{3p}$, with the abuse of notation $G_x^0(y) = (G_x^0(y_1), \ldots, G_x^0(y_p))$, we consider the change of variables $y' = (G_x^0)^{-1}(y)$ which transforms the operator Q_μ^ζ into

$$Q_{\mu,x_0}^\zeta(x) = t_{\mu,x_0}(x,y',h\Delta_{y'},h) + \sum_{\substack{j,k=1 \\ j\neq k}}^{n} \frac{\alpha_{jk}\zeta(x)}{|I_\mu(x_j) - I_\mu(x_k)|} + \sum_{\substack{1\leqslant l\leqslant p \\ 1\leqslant k\leqslant n}} \frac{\alpha_{lk}^{\pm}\zeta(x)}{\left| I_\mu(G_x^0(y_l')) \pm I_\mu\left(G_x^0\left(\frac{x_0^k}{|x_0|} \right) \right) \right|}$$

$$+ \sum_{\substack{l,q=1 \\ l\neq q}}^{p} \frac{\beta_{lk}\zeta(x)}{|I_\mu(G_x^0(y_l')) \pm I_\mu(G_x^0(y_q'))|} + (1-\zeta(x))\alpha_0 = t_{\mu,x_0}(x,y',hD_{y'},h) + V_{x_0}^\zeta(x,y'), \tag{5.5}$$

where $t_{\mu,x_0}(x,y',hD_{y'},h)$ is an elliptic second order differential operator in y', the coefficients depending smoothly on x and y' and being uniformly bounded in $\{x \in \mathbb{R}^{3n}, d(x,\mathcal{C}) \leqslant 1/N\} \times \mathbb{R}^{3p}$.

By Lemma 5.1, we obtain that $V_{x_0}^\zeta(x,y')$ is smooth with respect to x as a self-adjoint operator from $H^2(\mathbb{R}^{3p})$ to $L^2(\mathbb{R}^{3p})$.

We have consequently proved the following result.

Proposition 5.2: For $\forall x_0 \in V_N \cap S^{3n-1}$, *there exists a neighborhood* ω_{x_0} *of* x_0 *in* $V_N \cap S^{3n-1}$ *and a* C^∞ *application*,

$$G_0 : [1/N, +\infty[\cdot [1, +\infty[\cdot \omega_{x_0} \times \mathbb{R}^{3p} \to \mathbb{R}^{3p},$$

$$(x,y) \mapsto G_0(x,y) = G_x^0(y),$$

such that for any x, G_x^0 *is a diffeomorphism of* $\mathbb{R}^{3p}$. *If we denote*

$$U_0(x)\varphi(y) = \varphi(G_0(x,y))|\det(\partial_y G_0(x,y))|^{1/2}, \tag{5.6}$$

then the family of operators $Q_{\mu,x_0}^\zeta(x) = U_0(x)Q_\mu^\zeta(x)U_0^{-1}(x)$ *is in* $C_b^\infty([1/N, +\infty[\cdot [1, +\infty[\cdot \omega_{x_0}, \mathcal{L}(H^2(\mathbb{R}^{3p}), L^2(\mathbb{R}^{3p}))$. *($C_b^\infty$ denotes the space of C^∞ functions that have their derivatives uniformly bounded for any order.)*

Remark 5.3: *Under* (5.6) *the operator* P_μ^ζ *is transformed into the differential operator*

$$\tilde{P}_\mu^\zeta = \tilde{t}_{\mu,x_0}(x,y',hD_{y'},h) + Q_{\mu,x_0}^\zeta(x),$$

where $\tilde{t}_{\mu,x_0}$ *has the same properties as* t_{μ,x_0} *in* (5.5).

By compactness, we can cover $V_N \cap S^{3n-1}$ with a finite family of open subsets $(w_j)_{j=1}^{j_0}$, such that for any $j \in \{1, \ldots, j_0\}$ there exists a C^∞ application G_j from $[1/N, +\infty[\cdot [1, +\infty[\cdot w_j \times \mathbb{R}^{3p}$ to $\mathbb{R}^{3p}$, and for any $x \in [1/N, +\infty[\cdot [1, +\infty[\cdot w_j, G_j(x,.)$ is a diffeomorphism of $\mathbb{R}^{3p}$.

If we denote $U_j(x)\varphi(y) = \varphi(G_j(x,y))|\det(\partial_y G_j(x,y))|^{1/2}$, then

$$Q_{\mu,j}^\zeta(x) = U_j(x)Q_\mu^\zeta(x)U_j^{-1}(x) \in C_b^\infty\left(\left]\frac{1}{N}, +\infty\right[\cdot \right]1, +\infty[\cdot \omega_j, \mathcal{L}(H^2(\mathbb{R}^{3p}), L^2(\mathbb{R}^{3p})) \right). \tag{5.7}$$

VI. CHARACTERIZATION OF RESONANCES

Using the idea of Ref. 18 and assumptions (2.10)–(2.13), we can construct as in Refs. 12 and 17 a $L^2(\mathbb{R}^{3p}_y)$-orthonormalized family [see (3.8)] $(\omega_{k,\mu}(x,y))_{1\leqslant k\leqslant M}$ of M continuous functions from $\mathbb{R}^{3n}$ to $H^2(\mathbb{R}^{3p})$ depending analytically on μ, such that

(i) $(\omega_{k,\mu})_{1\leqslant k\leqslant M}$ form a basis of Ran $\pi_\mu(x)$ in $[3/2N,+\infty[\cdot[1,+\infty[\cdot(V_N\cap S^{3n-1})\times\mathbb{R}^{3p}$,
(ii) $\omega_{k,\mu}\in C^\infty(\mathbb{R}^{3n}\backslash[1/2N,+\infty[\cdot[1,+\infty[\cdot(V_N\cap S^{3n-1}),H^2(\mathbb{R}^{3p}))$.
(iii) For $|x|$ large enough, $\omega_{k,\mu}(x,.)$ is an eigenfunction of $Q_\mu(x)$ associated to $\lambda_k(x_1+\mu\omega(x_1),\ldots,x_n+\mu\omega(x_n))$, $x=(x_1,\ldots,x_n)$,
(iv) $\forall j\in\{1,\ldots,j_0\}, U_j(x)\omega_{k,\mu}(x,.)\in C_b^\infty(]1/N,+\infty[\cdot[1,+\infty[\cdot w_j,H^2(\mathbb{R}^{3p}))$.

Now, let for any $j\in\{1,\ldots,j_0\}, \psi_j\in C_0^\infty(w_j)$ be such that $\Sigma_{j=1}^{j_0}\psi_j^4=1$ on $V_N\cap S^{3n-1}$, and $\chi_0\in C^\infty(\mathbb{R}^{3n})$ such that $(1-\chi_0^4)^{1/4}\in C^\infty(\mathbb{R}^{3n})$ and

$$\chi_0=\begin{cases}1 & \text{in } \mathbb{R}^{3n}\backslash[1/N,+\infty[\cdot[1,+\infty[\cdot(V_N\cap S^{3n-1}),\\ 0 & \text{in } [3/2N,+\infty[\cdot[1,+\infty[\cdot(V_N\cap S^{3n-1}).\end{cases}$$

For $j\in\{1,\ldots,j_0\}$, we denote $\chi_j(x)=(1-\chi_0^4(x))^{1/4}\psi_j(x/|x|)$. Thanks to the choice of χ_0, we have

$$\sum_{j=0}^{j_0}\chi_j^4=1 \quad \text{in } \mathbb{R}^{3n}$$
$$\text{supp } \chi_j\subset[1/N,+\infty[\cdot[1,+\infty[\cdot w_j,\ \forall\, j\in\{1,\ldots,j_0\}. \tag{6.1}$$

To study the spectrum of P_μ^ζ near λ_0, we consider the Grushin operator

$$A_\mu^\zeta(z)=\begin{pmatrix}(P_\mu^\zeta-z) & R_\mu^-\\ R_\mu^+ & 0\end{pmatrix}, \tag{6.2}$$

where the operators $R_\mu^\pm$ are defined in (3.9) and (3.10), but here with $\omega_{k,\mu}$, $\omega_{k,\bar\mu}$ instead of $v_{k,\mu}$, $v_{k,\bar\mu}$.

$A_\mu^\zeta(z)$ is invertible as in (3.12) and (3.13), we propose now to construct its inverse in the class of h-pseudodifferential operators.

Denoting $U_0=1$ and extending the action of U_j to functions depending on x and y, we set for $j\in\{0,\ldots,j_0\}$,

$$\mathcal{U}_j=\begin{pmatrix}U_j & 0\\ 0 & 1\end{pmatrix} \text{ on } L^2([1/N,+\infty[\cdot[1,+\infty[\cdot w_j\times\mathbb{R}^{3p})\oplus(L^2(\mathbb{R}^{3n})^M,$$
$$A_{\mu,j}^\zeta(z)=\mathcal{U}_j\chi_jA_\mu^\zeta(z)\mathcal{U}_j^{-1}\chi_j, \tag{6.3}$$

which has a meaning thanks to (6.1).

By (5.7) (which extends to the case $j=0$) and the properties of the family $(\omega_{k,\mu})_{1\leqslant k\leqslant M}$, $A_{\mu,j}^\zeta(z)$ is a h-pseudodifferential operator with a $\mathcal{L}(H^2(\mathbb{R}^{3p})\oplus\mathbb{C}^M,L^2(\mathbb{R}^{3p})\oplus\mathbb{C}^M)$ valued symbol (see Refs. 12 and 20). Its principal symbol is given by

$$P_{\mu,j}^\xi(x,\xi;z)=\chi_j^2(x)\begin{pmatrix}t_\mu(\xi)+Q_{\mu,j}^\zeta(x)-z & R_{\mu,j}^-(x)\\ R_{\mu,j}^+(x) & 0\end{pmatrix}=\chi_j^2(x)\tilde P_{\mu,j}(x,\xi;z), \tag{6.4}$$

where $t_\mu(\xi)$ is the principal symbol of $-h^2U_\mu\Delta_xU_\mu^{-1}$, and $R_{\mu,j}^\pm(x)$ are defined as $R_\mu^\pm$ but with $\omega_{k,\mu}(x,.),\omega_{k,\bar\mu}(x,.)$ replaced by $U_j\omega_{k,\mu}(x,.),U_j\omega_{k,\bar\mu}(x,.)$, $1\leqslant k\leqslant M$.

Since $t_\mu(\xi)$ is elliptic and using the gap assumption (2.11), one can see that, for z close enough to λ_0 and for any $(x,\xi)\in T^*(\text{supp }\chi_j), j=0,\ldots,j_0, \tilde P_{\mu,j}(x,\xi;z)$ is invertible with inverse

$$q_{\mu,j}(x,\xi,z)=\begin{pmatrix} a^{\zeta}_{\mu,j}(x,\xi;z) & R^{-}_{\mu,j}(x) \\ R^{+}_{\mu,j}(x) & b_{\mu}(x,\xi;z)\end{pmatrix}. \tag{6.5}$$

Here $a^{\zeta}_{\mu,j}(x,\xi;z)=\hat{\pi}_{\mu,j}(x)[\hat{\pi}_{\mu,j}(x)(t_{\mu}(\xi)+Q^{\zeta}_{\mu,j}(x)-z)\hat{\pi}_{\mu,j}(x)]^{-1}\hat{\pi}_{\mu,j}(x)$, $\hat{\pi}_{\mu,j}(x)=1-\pi_{\mu,j}(x)$, $\pi_{\mu,j}(x)=U_j(x)\pi(x)U_j^{-1}(x)$, and $b_{\mu}(x,\xi;z)$ is the $M\times M$ matrix defined by

$$b_{\mu}(x,\xi;z)=z-(\langle\omega_{k,\mu}(x,y),(t_{\mu}(\xi)+Q^{\zeta}_{\mu}(x))\omega_{l,\bar{\mu}}(x,y)\rangle_{L^2(\mathbb{R}^{3p})}) \tag{6.6}$$

[in particular, $b_{\mu}(x,\xi;z)$ does not depend on j, if $M=1$ and $\mu=0$, then $t_{\mu}(\xi)=\xi^2$ and $b_{\mu}(x,\xi;z)=z-\xi^2-\langle\omega_1(x,y),Q^{\zeta}(x)\omega_1(x,y)\rangle_{L^2(\mathbb{R}^{3p})}$].

We set

$$B_{\mu}(z)=\sum_{j=0}^{j_0}\mathcal{U}_j^{-1}\chi_j^3(x)\mathrm{Op}(q_{\mu,j}(x,\xi,z))\mathcal{U}_j\chi_j(x) \tag{6.7}$$

[where Op is the usual quantification of symbols defined in (2.7)]. Using the composition theorem of h-pseudodifferential operators (see, e.g., Refs. 1, 16, and 22) we have

$$\begin{aligned} A^{\zeta}_{\mu}(z)B_{\mu}(z)&=1+hR_{\mu}(z),\\ R_{\mu}(z)&=\sum_{j=0}^{j_0}\mathcal{U}_j^{-1}\chi_{j,1}R_{\mu,j}(z)\mathcal{U}_j\chi_{j,1},\end{aligned} \tag{6.8}$$

where $\chi_{j,1}\in C_b^{\infty}(]1/N,+\infty[\cdot]1,+\infty[\cdot w_j)$ is supported in $[1/N,+\infty[\cdot[1,+\infty[\cdot w_{j,1}, w_{j,1}\subset\subset w_j$ for $j\geqslant 1$, $\chi_{0,1}$ is chosen as χ_0, and $R_{\mu,j}(z)$ is a h-pseudodifferential operator uniformly bounded (with respect to h) on $L^2(\mathbb{R}^{3(n+p)})\oplus(H^2(\mathbb{R}^{3n}))^M$.

From (6.8), we deduce

$$A^{\zeta}_{\mu}(z)^{-1}=B_{\mu}(z)\sum_{m=0}^{\infty}(-hR_{\mu}(z))^m. \tag{6.9}$$

Applying the calculus of Ref. 12, (6.9) can be written modulo $\mathcal{O}(h^{\infty})$:

$$A^{\zeta}_{\mu}(z)^{-1}=\sum_{j=0}^{j_0}\mathcal{U}_j^{-1}\tilde{\chi}_j\mathcal{E}_{\mu,j}(z)\mathcal{U}_j\tilde{\chi}_j, \tag{6.10}$$

where the $\mathcal{E}_{\mu,j}(z)$'s are h-pseudodifferential operators depending analytically on μ, $\tilde{\chi}_0$ is defined as χ_0 and $\tilde{\chi}_j\in C_b^{\infty}([1/N,+\infty[\cdot[1,+\infty[\cdot w_j)$ is supported in $]1/N,+\infty[\cdot]1,+\infty[\cdot\tilde{w}_j,\tilde{w}_j\subset\subset w_j, j\in\{1,\ldots,j_0\}$.

Denoting $A^{\zeta}_{\mu}(z)^{-1}$ as in (3.12), we obtain in particular from (6.10) that $a^{\zeta}_{\mu,-+}(z)$ is a $M\times M$ matrix of h-pseudodifferential operator on $\mathbb{R}^{3n}_x$. Moreover, in view of (6.6) and (6.10) and also Corollary 1.4 of Ref. 12, its principal symbol is just $b_{\mu}(x,\xi;z)$.

This paper is part of a series that lays the groundwork for a structure and classification theory of second-order superintegrable systems, both classical and quantum, in real or complex conformally flat spaces. Here we consider classical superintegrable systems with nondegenerate potentials in three dimensions. We show that there exists a standard structure for such systems, based on the algebra of 3×3 symmetric matrices, and that the quadratic algebra always closes at order 6. We show that the spaces of truly second-, third-, fourth-, and sixth-order constants of the motion are of dimension 6, 4, 21, and 56, respectively, and we construct explicit bases for the fourth- and sixth order constants in terms of products of the second order constants. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2037567]

I. INTRODUCTION AND EXAMPLES

The goal of this series of papers,[1,2] is a structure and classification theory of second-order superintegrable systems, both classical and quantum, in conformally flat spaces. An n-dimensional Riemannian space is conformally flat if and only if it admits a set of local coordinates $x_1,\ldots,x_n$ such that the contravariant metric tensor takes the form $g^{ij}=\delta^{ij}/\lambda(\mathbf{x})$. In other words, the metric is $ds^2=\lambda(\mathbf{x})(\Sigma_{i=1}^n dx_i^2)$. A classical superintegrable system $\mathcal{H}=\Sigma_{ij}g^{ij}p_ip_j+V(\mathbf{x})$ on the phase space of this manifold is one that admits $2n-1$ functionally independent generalized symmetries (or constants of the motion) $\mathcal{S}_k, k=1,\ldots,2n-1$ with $\mathcal{S}_1=\mathcal{H}$. That is, $\{\mathcal{H},\mathcal{S}_k\}=0$ where

$$\{f,g\}=\sum_{j=1}^{n}(\partial_{x_j}f\partial_{p_j}g-\partial_{p_j}f\partial_{x_j}g)$$

is the Poisson bracket for functions $f(\mathbf{x},\mathbf{p}),g(\mathbf{x},\mathbf{p})$ on phase space.[3–10] Note that $2n-1$ is the maximum possible number of functionally independent symmetries and, locally, such symmetries always exist. (In this paper $n=3$ so we have five functionally independent symmetries.) The main interest is in symmetries that are polynomials in the p_k and are globally defined, except for lower dimensional singularities such as poles and branch points. Many tools in the theory of Hamiltonian systems have been brought to bear on superintegrable perintegrable systems, such as R-matrix theory, Lax pairs, exact solvability, quasiexact solvability, and the Jacobi metric.[11–15] However, the most detailed and complete results are obtained from separation of variables methods in those cases where they are applicable. Standard orthogonal separation of variables techniques are associated with second-order symmetries, e.g., Refs. 16–21 and multiseparable Hamiltonian systems provide numerous examples of superintegrability. In these papers we concentrate on second-order

superintegrable systems, that is those in which the symmetries take the form $\mathcal{S}=\Sigma a^{ij}(\mathbf{x})p_ip_j+W(\mathbf{x})$, quadratic in the momenta.

There is an analogous definition for second-order quantum superintegrable systems with Schrödinger operator

$$H=\Delta+V(\mathbf{x}),\quad \Delta=\frac{1}{\sqrt{g}}\sum_{ij}\partial_{x_i}(\sqrt{g}g^{ij})\partial_{x_j},$$

the Laplace-Beltrami operator plus a potential function.[16] Here there are $2n-1$ second-order symmetry operators

$$S_k=\frac{1}{\sqrt{g}}\sum_{ij}\partial_{x_i}(\sqrt{g}a^{ij}_{(k)})\partial_{x_j}+W^{(k)}(\mathbf{x}),\quad k=1,\ldots,2n-1$$

with $S_1=H$ and $[H,S_k]\equiv HS_k-S_kH=0$. Again multiseparable systems yield many examples of superintegrability, though not all multiseparable systems are superintegrable and not all second-order superintegrable systems are multiseparable. There is also a quantization problem in extending the results for classical systems to operator systems. This problem turns out to be not difficult to solve for the nondegenerate systems that we study in this paper.

Superintegrable systems can (1) be solved explicitly, and (2) they can be solved in multiple ways. It is the information gleaned from comparing the distinct solutions and expressing one solution set in terms of another that is a primary reason for their interest.

We give a few simple three-dimensional (3D) examples to illustrate some of the main features of superintegrable systems. (To make clearer the connection with quantum theory and Hilbert space methods we shall, for these examples alone, adopt standard physical normalizations, such as using the factor $-\frac{1}{2}$ in front of the free Hamiltonian.) Consider the Schrödinger eigenvalue equation $H\Psi=E\Psi$ or ($\hbar=m=1, x_1=x, x_2=y, x_3=z$)

$$H\Psi=-\frac{1}{2}\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}\right)\Psi+V(x,y,z)\Psi=E\Psi. \tag{1}$$

The generalized anisotropic oscillator corresponds to the four-parameter potential

$$V(x,y,z)=\frac{\omega^2}{2}(x^2+y^2+4(z+\rho)^2)+\frac{1}{2}\left[\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right]. \tag{2}$$

(This potential is "nondegenerate" in the precise sense that we will explain in Sec. III.) The corresponding Schrödinger equation has separable solutions in five coordinate systems, Cartesian coordinates, cylindrical polar coordinates, cylindrical elliptic coordinates, cylindrical parabolic coordinates, and parabolic coordinates. The energy eigenstates for this equation are degenerate and important special function identities arise by expanding one basis of separable eigenfunctions in terms of another. A second order symmetry operator for this equation is a second-order linear differential operator S such that $[H,S]=0$ where $[A,B]=AB-BA$. A basis for these operators is

$$M_1=\partial_x^2-\omega^2x^2+\frac{k_1^2-\frac{1}{4}}{x^2},\quad M_2=\partial_y^2-\omega^2y^2-\frac{k_2^2-\frac{1}{4}}{y^2}, \tag{3}$$

$$P=\partial_z^2-4\omega^2(z+\rho)^2,\quad L=L_{12}^2-\left(k_1^2-\frac{1}{4}\right)\frac{y^2}{x^2}-\left(k_2^2-\frac{1}{4}\right)\frac{x^2}{y^2}-\frac{1}{2}, \tag{4}$$

$$S_1=-\frac{1}{2}(\partial_xL_{13}+L_{13}\partial_x)+\rho\partial_x^2+(z+\rho)\left(\omega^2x^2-\frac{k_1^1-\frac{1}{4}}{x^2}\right),$$

$$S_2 = -\frac{1}{2}(\partial_y L_{23} + L_{23}\partial_y) + \rho\partial_y^2 + (z+\rho)\left(\omega^2 y^2 - \frac{k_2^2 - \frac{1}{4}}{y^2}\right), \tag{5}$$

where $L_{ij} = x_i\partial_{x_j} - x_j\partial_{x_i}$. Remarkably, these symmetries generate a "quadratic algebra" that closes at level six. Indeed, the nonzero commutators of the above basis are

$$[M_1, L] = [L, M_2] = Q, \quad [L, S_1] = [S_2, L] = B, \quad [M_i, S_i] = A_i, \quad [P, S_i] = -A_i.$$

Nonzero commutators of the basis symmetries with Q (fourth-order symmetries) are expressible in terms of the second-order symmetries,

$$[M_i, Q] = [Q, M_2] = 4\{M_1, M_2\} + 16\omega^2 L, \quad [S_1, Q] = [Q, S_2] = 4\{M_1, M_2\},$$

$$[L, Q] = 4\{M_1, L\} - 4\{M_2, L\} + 16(1 - k_1^2)M_1 - 16(1 - k_2^2)M_2.$$

There are similar expressions for commutators with B and the A_i. Also the squares of Q, B, A_i and products such as $\{Q, B\}$ (all sixth-order symmetries) are expressible in terms of second-order symmetries. For example,

$$Q^2 = \tfrac{8}{3}\{L, M_1, M_2\} + 8\omega^2\{L, L\} - 16(1 - k_1^2)M_1^2 - 16(1 - k_2^2)M_2^2 + \tfrac{64}{3}\{M_1, M_2\} - \tfrac{128}{3}\omega^2 L - 128\omega^2(1 - k_1^2)(1 - k_2^2),$$

$$\{Q, B\} = -\tfrac{8}{3}\{M_2, L, S_1\} - \tfrac{8}{3}\{M_1, L, S_2\} + 16(1 - k_1^2)\{M_2, S_2\} + 16(1 - k_2^2)\{M_1, S_1\} - \tfrac{64}{3}\{M_1, S_2\} - \tfrac{64}{3}\{M_2, S_1\}.$$

Here $\{C_1, \ldots, C_j\}$ is the completely symmetrized product of operators $C_1, \ldots, C_j$. (For complete details of all the possible products and commutators, see Ref. 22.) The point is that the algebra generated by products and commutators of the second order symmetries closes at order 6.

Another example in Euclidean space is given by the Schrödinger equation with three-parameter extended Kepler-Coulomb potential,

$$\left(\frac{\partial^2\Psi}{\partial x^2} + \frac{\partial^2\Psi}{\partial y^2} + \frac{\partial^2\Psi}{\partial z^2}\right) + \left[2E + \frac{2\alpha}{\sqrt{x^2 + y^2 + z^2}} - \left(\frac{k_1^2 - \frac{1}{4}}{x^2} + \frac{k_2^2 - \frac{1}{4}}{y^2}\right)\right]\Psi = 0.$$

This equation admits separable solutions in the four coordinates systems: spherical, sphero conical, prolate spheroidal, and parabolic coordinates. Again the bound states are degenerate and important special function identities arise by expanding one basis of separable eigenfunctions in terms of another. However, the space of second-order symmetries is only five dimensional and, although there are useful identities among the generators and commutators that enable one to derive spectral properties algebraically, there is no finite quadratic algebra structure. The key difference with our first example is, as we shall show later, that the three-parameter Kepler-Coulomb potential is degenerate and it cannot be extended to a four-parameter potential.

An example on the three-sphere is given by

$$g^{ij} = \delta_{ij} z_i - z_i z_j, \quad 1 \leqslant i, j \leqslant 3.$$

Then $\det(g^{ij}) = g^{-1} = z_1 z_2 z_3 (1 - z)$ where $z = z_1 + z_2 + z_3$ and

$$g_{ij} = \frac{1}{1 - z} + \frac{\delta_{ij}}{z_i}.$$

Thus $ds^2 = \Sigma_{i,j=1}^3 g_{ij}\, dz_i\, dz_j$. To identify this space we introduce Cartesian coordinates x_0, x_1, x_2, x_3 in four-dimensional Euclidean space and restrict these coordinates by the conditions

$$x_0^2 = 1 - z, \quad x_1^2 = z_1, \quad x_2^2 = z_2, \quad x_3^2 = z_3.$$

Note that $x_0^2+x_1^2+x_2^2+x_3^2=1$. Defining a metric ds^2 by $ds^2=\Sigma_{m=0}^3(dx_m)^2$ we find

$$ds^2 = \frac{1}{4}\sum_{i,j=1}^{3}\left(\frac{1}{1-z}+\frac{\delta_{ij}}{z_i}\right)dz_i\,dz_j.$$

Thus the space corresponds to a portion of the three-sphere S^n. The Schrödinger equation is

$$\left(\Delta + \sum_{i=1}^{3}\frac{\gamma_i}{z_i} + \frac{\gamma_4}{1-z}\right)\Psi = E\Psi,$$

where Δ is the Laplace-Beltrami operator. This is a nondegenerate potential. The six second-order operators

$$S_{ij} = 4z_iz_j(\partial_{z_i}-\partial_{z_j})^2 + 4(g_iz_j - g_jz_i)(\partial_{z_i}-\partial_{z_j}) = S_{ji}, \quad 1 \leqslant i < j \leqslant 3,$$

$$S_{0i} = 4z_i(1-z)\partial_{z_i}^2 + 4[g_i(1-z) - g_0z_i]\partial_{z_i} = S_{i0}, \quad 1 \leqslant i \leqslant 3,$$

for $g_i=1+\frac{1}{2}\sqrt{1-16\gamma_i}$ form a basis for the space of second-order symmetries. In particular

$$8H = \sum_{i,j=1}^{n} S_{ij} + 2\sum_{i=1}^{n} S_{0i}.$$

This equation separates in six coordinate systems on the three sphere. Further it can be shown that the quadratic algebra generated by the second-order symmetries closes at order 6.

For our last example we take the space with metric

$$ds^2 = \lambda(A,B,C,D,E,\mathbf{x})(dx^2+dy^2+dz^2),$$

where

$$\lambda = A(x+iy) + B\left(\frac{3}{4}(x+iy)^2 + \frac{z}{4}\right) + C\left((x+iy)^3 + \frac{1}{16}(x-iy) + \frac{3z}{4}(x+iy)\right)$$
$$+ D\left(\frac{5}{16}(x+iy)^4 + \tfrac{z^2}{16} + \tfrac{1}{16}(x^2+y^2) + \tfrac{3z}{8}(x+iy)^2\right) + E,$$

the nondegenerate potential is $V=\lambda(\alpha,\beta,\gamma,\delta,\epsilon,\mathbf{x})/\lambda(A,B,C,D,E,\mathbf{x})$. If $A=B=C=D=0$ this is a superintegrable system on complex Euclidean space. The quadratic algebra always closes, and for general values of A,B,C,D,E the space is not of constant curvature. This is an example of a superintegrable system that is Stäckel equivalent to a system on complex Euclidean space. We will take up the study of such systems in the next paper in this series.

Observed common features of superintegrable systems (and features that we make precise and verify in these papers) are that they are usually multiseparable and that the eigenfunctions of one separable system can be expanded in terms of the eigenfunctions of another. This is the source of nontrivial special function expansion theorems.[23] The symmetry operators are in formal self-adjoint form and suitable for spectral analysis. Also, the quadratic algebra identities allow us to relate eigenbases and eigenvalues of one symmetry operator to those of another. Indeed the representation theory of the abstract quadratic algebra can be used to derive spectral properties of the second-order generators in a manner analogous to the use of Lie algebra representation theory to derive spectral properties of quantum systems that admit Lie symmetry algebras.[23–26] (Note however that for superintegrable systems with nondegenerate potential, there is no first-order Lie symmetry.)

Another common feature of quantum superintegrable systems is that they can be modified by a gauge transformation so that the Schrödinger and symmetry operators are acting on a space of polynomials.[27] This is closely related to the theory of exactly and quasi exactly solvable systems.[13,28] The characterization of ODE quasiexactly solvable systems as embedded in PDE superintegrable systems provides considerable insight into the nature of these phenomena.

The classical analogs of the above examples are obtained by the replacements $\partial_{x_i} \to p_{x_i}$. Commutators go over to Poisson brackets. The operator symmetries become second-order constants of the motion. Symmetrized operators become products of functions. The quadratic algebra relations simplify, the highest order terms agree with the operator case but there are fewer nonzero lower order terms.

Many examples of 3D superintegrable systems are known, although they have not been classified.[29–34] Here, rather than focus on particular spaces and systems, we employ a theoretical method based on integrability conditions to derive structure common to all such systems, with a view to complete classification, at least for nondegenerate potentials. In this paper we consider classical superintegrable systems on a general 3D conformally flat spaces, real or complex, and uncover their common structure. We show that for systems with nondegenerate potentials there exists a standard structure based on the algebra of 3×3 symmetric matrices, and that the quadratic algebra closes at level 6. For two dimensional (2D) nondegenerate superintegrable systems we can show that the three functionally independent constants of the motion are (with one exception) also linearly independent, so at each regular point we can find a unique constant of the motion that matches a quadratic expression in the momenta at that point. However, for 3D systems we have only five functionally independent constants of the motion and the quadratic forms span a six-dimensional space. This is a major problem. However, for nondegenerate potentials we can prove the "5⇒6 Theorem" to show that the space of second-order constants of the motion is in fact six dimensional, there is a symmetry that is functionally dependent on the symmetries that arise from superintegrability, but linearly independent of them. With that result established, the treatment of the 3D case proceeds in analogy with the nondegenerate 2D case treated in Ref. 1. Though the details are quite complicated, we show that the spaces of truly second-, third-, fourth-, and sixth-order constants of the motion are of dimension 6, 4, 21, and 56, respectively. Finally we construct explicit bases for the fourth- and sixth-order constants in terms of products of the second-order constants. These bases are our principal result. They guarantee closure of the quadratic algebra and provide a means for analyzing its structure. This paper is a major advance toward one of our goals, to obtain a demonstrably complete list of 3D superintegrable potentials.

In the next paper in this series we will show that all 3D superintegrable systems with nondegenerate potential are multiseparable. We will study the Stäckel transform, or coupling constant metamorphosis,[35,36] for 3D classical superintegrable systems. This is a conformal transformation of a superintegrable system on one space to a superintegrable system on another space. We will prove that all nondegenerate 3D superintegrable systems are Stäckel transforms of constant curvature systems. We will also extend our results to the quantum analogs of 2D and 3D classical systems.

II. CONFORMALLY FLAT SPACES IN THREE DIMENSIONS

We assume that there is a coordinate system x,y,z and a nonzero function $\lambda(x,y,z) = \exp[G(x,y,z)]$ such that the Hamiltonian is

$$\mathcal{H} = \frac{p_1^2 + p_2^2 + p_3^2}{\lambda} + V(x,y,z). \tag{6}$$

A quadratic constant of the motion (or generalized symmetry)

$$\mathcal{S}=\sum_{k,j=1}^{3} a^{kj}(x,y,z)p_k p_j + W(x,y,z) \equiv \mathcal{L} + W, \quad a^{jk}=a^{kj} \tag{7}$$

must satisfy $\{\mathcal{H},\mathcal{S}\}=0$. The conditions are thus

$$a_i^{ii} = -G_1 a^{1i} - G_2 a^{2i} - G_3 a^{3i},$$

$$2a_i^{ij} + a_j^{ii} = -G_1 a^{1j} - G_2 a^{2j} - G_3 a^{3j}, \quad i \neq j,$$

$$a_k^{ij} + a_j^{ki} + a_i^{jk} = 0, \quad i,j,k \text{ distinct} \tag{8}$$

and

$$W_k = \lambda \sum_{s=1}^{3} a^{sk} V_s, \quad k=1,2,3. \tag{9}$$

(Here a subscript j denotes differentiation with respect to x_j.) The requirement that $\partial_{x_\ell} W_j = \partial_{x_j} W_\ell, \ell \neq j$ leads from (9) to the second-order Bertrand-Darboux partial differential equations for the potential,

$$\sum_{s=1}^{3} [V_{sj}\lambda a^{s\ell} - V_{s\ell}\lambda a^{sj} + V_s((\lambda a^{s\ell})_j - (\lambda a^{sj})_\ell)] = 0. \tag{10}$$

For second-order superintegrabilty in 3D there must be five functionally independent constants of the motion (including the Hamiltonian itself). Thus the Hamilton-Jacobi equation admits four additional constants of the motion

$$\mathcal{S}_h = \sum_{j,k=1}^{3} a_{(h)}^{jk} p_k p_j + W_{(h)} = \mathcal{L}_h + W_{(h)}, \quad h=1,\ldots,4. \tag{11}$$

We assume that the four functions $\mathcal{S}_h$ together with $\mathcal{H}$ are functionally independent in the six-dimensional phase space, i.e., that the differentials $d\mathcal{S}_h, d\mathcal{H}$ are linearly independent. (Here the possible V will always be assumed to form a vector space and we require functional independence for each such V and the associated $W^{(h)}$. This means that we also require that the five quadratic forms $\mathcal{L}_h, \mathcal{H}_0$ are functionally independent.) We say that the functions are weakly functionally independent if $d\mathcal{S}_h, d\mathcal{H}$ are linearly independent for nonzero potentials, but not necessarily for the zero potential.

III. FUNCTIONAL LINEAR INDEPENDENCE

We first shed some light on the relationship between functional independence and functional linear independence for the set $\{\mathcal{H},\mathcal{S}_1,\ldots,\mathcal{S}_4\}$

Theorem 1: *The functionally independent set* $\{\mathcal{H},\mathcal{S}_1,\ldots,\mathcal{S}_4\}$ *is also functionally linearly independent in the sense that if the relation* $\Sigma_{h=0}^{4} c^{(h)}(x)\mathcal{L}_h \equiv 0$ *holds in an open set, then* $c^{(h)}(x) \equiv 0$ *for all* h.

Proof: Suppose that the set is functionally linearly dependent. Then we can express one of the quadratic parts of the constants of the motion $\hat{\mathcal{L}}_0$ as a linear combination of a linearly independent subset $\{\hat{\mathcal{L}}_1,\ldots,\hat{\mathcal{L}}_r, 1 \leqslant r \leqslant 4\}$,

$$\hat{\mathcal{L}}_0 = \sum_{\ell=1}^{r} c^{(\ell)}(x)\hat{\mathcal{L}}_\ell.$$

Taking the Poisson bracket of both sides of this equation with $(p_1^2+p_2^2+p_3^3)/\lambda$ and using the fact that each of the $\hat{\mathcal{S}}_h$ is a constant of the motion, we obtain the identity

$$\sum_{\ell=1}^{r}\sum_{i,j=1}^{3} (\partial_{x_k} c^{(\ell)}) a^{ij}_{(\ell)} p_i p_j p_k = 0. \tag{12}$$

It is straightforward to check that this identity can be satisfied if and only if

$$\sum_{\ell=1}^{r} (\partial_{x_k} c^{(\ell)}) a^{ij}_{(\ell)} = 0, \quad 1 \leqslant i,j,k \leqslant 3.$$

Since the set $\{\hat{\mathcal{L}}_1,\ldots,\hat{\mathcal{L}}_r\}$, is linearly independent, we have $\partial_{x_k} c^{(\ell)} \equiv 0$ for $1 \leqslant k \leqslant 3, 1 \leqslant \ell \leqslant r$. Hence the $c^{(\ell)}$ are constants, which means that

$$\hat{\mathcal{L}}_0 - \sum_{\ell=1}^{r} c^{(\ell)}\hat{\mathcal{L}}_\ell = c,$$

where c is a constant. Thus the set $\{\mathcal{H}_0,\mathcal{L}_1,\ldots,\mathcal{L}_4\}$ is functionally dependent. This is a contradiction. Q.E.D.

Corollary 1: The weakly functionally independent set $\{\mathcal{H}=\mathcal{S}_0,\mathcal{S}_1,\ldots,\mathcal{S}_4\}$ *is also functionally linearly independent in the sense that if the relation* $\Sigma_{h=0}^4 c^{(h)}(x)\mathcal{S}_h \equiv 0$ *holds in an open set, then* $c^{(h)}(x) \equiv 0$ *for all* h.

Proof: Suppose that the set is functionally linearly dependent. Then we can express one of the constants of the motion $\hat{\mathcal{S}}_{0'}$ as a linear combination of a linearly independent subset $\{\hat{\mathcal{S}}_1,\ldots,\hat{\mathcal{L}}_r, 1 \leqslant r \leqslant 4\}$,

$$\hat{\mathcal{S}}_0 = \sum_{\ell=1}^{r} c^{(\ell)}(x)\hat{\mathcal{S}}_\ell.$$

Taking the Poisson bracket of both sides of this equation with $(p_1^2+p_2^2+p_3^3)/\lambda + V$ and using the fact that each of the $\hat{\mathcal{S}}_h$ is a constant of the motion, we obtain the identities

$$\sum_{\ell=1}^{r} (\partial_{x_k} c^{(\ell)}) a^{ij}_{(\ell)} = 0, \sum_{\ell=1}^{r} \partial_{x_k} c^{(\ell)} W_{(\ell)}, \quad 1 \leqslant i,j,k \leqslant 3.$$

Since the set $\{\hat{\mathcal{S}}_1,\ldots,\hat{\mathcal{S}}_r\}$, is functionally linearly independent, we have $\partial_{x_k} c^{(\ell)} \equiv 0$ for $1 \leqslant k \leqslant 3, 1 \leqslant \ell \leqslant r$. Hence the $c^{(\ell)}$ are constants, which means that

$$\hat{\mathcal{S}}_0 - \sum_{\ell=1}^{r} c^{(\ell)}\hat{\mathcal{S}}_\ell = 0.$$

Thus the set $\{\mathcal{S}_0,\ldots,\mathcal{S}_4\}$ is functionally dependent. This is a contradiction. Q.E.D.

We can write the system of Bertrand-Darboux equations in the matrix form $Cv = \tilde{v}^{(1)}V_1 + \tilde{v}^{(2)}V_2 + \tilde{v}^{(3)}V_3$, or

$$\begin{pmatrix} 0 & a^{12} & a^{11}-a^{22} & a^{31} & -a^{32} \\ a^{13} & 0 & -a^{23} & a^{21} & a^{11}-a^{33} \\ a^{32} & -a^{32} & -a^{13} & a^{22}-a^{33} & a^{12} \end{pmatrix} \begin{pmatrix} V_{33}-V_{11} \\ V_{22}-V_{11} \\ V_{12} \\ V_{32} \\ V_{31} \end{pmatrix}$$
$$= \frac{1}{\lambda}\begin{pmatrix} (\lambda a^{12})_1-(\lambda a^{11})_2 \\ (\lambda a^{31})_1-(\lambda a^{11})_3 \\ (\lambda a^{31})_2-(\lambda a^{21})_3 \end{pmatrix} V_1 + \frac{1}{\lambda}\begin{pmatrix} (\lambda a^{22})_1-(\lambda a^{21})_2 \\ (\lambda a^{32})_1-(\lambda a^{12})_3 \\ (\lambda a^{32})_2-(\lambda a^{22})_3 \end{pmatrix} V_2 + \frac{1}{\lambda}\begin{pmatrix} (\lambda a^{32})_1-(\lambda a^{31})_2 \\ (\lambda a^{33})_1-(\lambda a^{13})_3 \\ (\lambda a^{33})_2-(\lambda a^{23})_3 \end{pmatrix} V_3. \quad (13)$$

Corollary 2: Suppose the set $\{\mathcal{H},\mathcal{S}_1,\ldots,\mathcal{S}_4\}$ *is functionally independent. Then for general* x *the* 4×5 *matrix*

$$A = \begin{pmatrix} a^{33}_{(1)}-a^{11}_{(1)}, & a^{22}_{(1)}-a^{11}_{(1)}, & a^{12}_{(1)}, & a^{31}_{(1)}, & a^{32}_{(1)} \\ a^{33}_{(2)}-a^{11}_{(2)}, & a^{22}_{(2)}-a^{11}_{(2)}, & a^{12}_{(2)}, & a^{31}_{(2)}, & a^{32}_{(2)} \\ a^{33}_{(3)}-a^{11}_{(3)}, & a^{22}_{(3)}-a^{11}_{(3)}, & a^{12}_{(3)}, & a^{31}_{(3)}, & a^{32}_{(3)} \\ a^{33}_{(4)}-a^{11}_{(4)}, & a^{22}_{(4)}-a^{11}_{(4)}, & a^{12}_{(4)}, & a^{31}_{(4)}, & a^{32}_{(4)} \end{pmatrix}$$

has rank 4, *where the functions* $a^{ij}_{(h)}(\mathbf{x})$ *are given by* (11).

There are four sets of equations (13), one for each of the functionally independent symmetries (in addition to the Hamiltonian). We can write them as a single matrix equation $Bv=b$ where B is 12×5, b is 12×1 and

$$v = \begin{pmatrix} V_{33}-V_{11} \\ V_{22}-V_{11} \\ V_{12} \\ V_{32} \\ V_{31} \end{pmatrix}.$$

Lemma 1: If the set $\{\mathcal{H},\mathcal{S}_1,\ldots,\mathcal{S}_4\}$ *is functionally independent, the matrix* B *has rank* 5.

Proof: In the neighborhood of a general point (x_0,y_0,z_0) the matrix A of Corollary 2 has rank 4. Thus the possible reduced row equivalence forms (RREF) for A at (x_0,y_0,z_0) are

$$\text{I}\ \begin{pmatrix} 1, & 0, & 0, & 0, & \alpha \\ 0, & 1, & 0, & 0, & \beta \\ 0, & 0, & 1, & 0, & \gamma \\ 0, & 0, & 0, & 1, & \delta \end{pmatrix};\quad \text{II}\ \begin{pmatrix} 1, & 0, & 0, & \alpha, & 0 \\ 0, & 1, & 0, & \beta, & 0 \\ 0, & 0, & 1, & \gamma, & 0 \\ 0, & 0, & 0, & 0, & 1 \end{pmatrix};\quad \text{III}\ \begin{pmatrix} 1, & 0, & \alpha, & 0, & 0 \\ 0, & 1, & \beta, & 0, & 0 \\ 0, & 0, & 0, & 1, & 0 \\ 0, & 0, & 0, & 0, & 1 \end{pmatrix};$$

$$\text{IV}\ \begin{pmatrix} 1, & \alpha, & 0, & 0, & 0 \\ 0, & 0, & 1, & 0, & 0 \\ 0, & 0, & 0, & 1, & 0 \\ 0, & 0, & 0, & 0, & 1 \end{pmatrix};\quad \text{V}\ \begin{pmatrix} 0, & 1, & 0, & 0, & 0 \\ 0, & 0, & 1, & 0, & 0 \\ 0, & 0, & 0, & 1, & 0 \\ 0, & 0, & 0, & 0, & 1 \end{pmatrix}.$$

For each canonical form it is straightforward to check that the associated 12×5 matrix B has rank 5. Q.E.D.

By choosing a rank 5 minor of B we can solve for v and obtain a solution of the form

$$V_{22} = V_{11} + A^{22}V_1 + B^{22}V_2 + C^{22}V_3,$$

$$V_{33} = V_{11} + A^{33}V_1 + B^{33}V_2 + C^{33}V_3,$$

$$V_{12} = A^{12}V_1 + B^{12}V_2 + C^{12}V_3,$$

$$V_{13} = A^{13}V_1 + B^{13}V_2 + C^{13}V_3,$$

$$V_{23} = A^{23}V_1 + B^{23}V_2 + C^{23}V_3. \tag{14}$$

If the augmented matrix (B,b) has rank $r' > r$ then there will be $r'-r$ additional conditions of the form $D^1_{(s)}V_1 + D^2_{(s)}V_2 + D^3_{(s)}V_3 = 0, s = 1, \ldots, r'-r$. Here the $A^{ij}, B^{ij}, C^{ij}, D^i_{(s)}$ are functions of x that can be calculated explicitly. For convenience we take $A^{ij} \equiv A^{ji}, B^{ij} \equiv B^{ji}, C^{ij} \equiv C^{ji}$.

Suppose now that the superintegrable system is such that $r' = r$ so that relations (14) are equivalent to $Bv = b$. Further, suppose the integrability conditions for system (14) are satisfied identically. In this case we say that the potential is nondegenerate. Otherwise the potential is degenerate. If V is nondegenerate then at any point $\mathbf{x}_0$, where the A^{ij}, B^{ij}, C^{ij} are defined and analytic, there is a unique solution $V(\mathbf{x})$ arbitrarily prescribed values of $V_1(\mathbf{x}_0), V_2(\mathbf{x}_0), V_3(\mathbf{x}_0), V_{11}(\mathbf{x}_0)$ [as well as the value of $V(\mathbf{x}_0)$ itself]. The points $\mathbf{x}_0$ are called *regular*. The points of singularity for the A^{ij}, B^{ij}, C^{ij} form a manifold of dimension <3. Degenerate potentials depend on fewer parameters. For example, we could have $r' = r$ but the integrability conditions are not satisfied identically. This occurs for the generalized Kepler-Coulomb potential where the integrability conditions lead to an additional equation of the form $V_{11} = A^{11}V_1 + B^{11}V_2 + C^{11}V_3$ so that V_{11} cannot be prescribed arbitrarily.

From this point on we assume that V is nondegenerate. Substituting the requirement for a nondegenerate potential (14) into the Bertrand-Darboux equations (10) we obtain three equations for the derivatives a^{jk}_i, the first of which is

$$\begin{aligned}(a^{11}_3 - a^{31}_1)V_1 + (a^{12}_3 - a^{32}_1)V_2 + (a^{13}_3 - a^{33}_1)V_3 + a^{12}(A^{23}V_1 + B^{23}V_2 + C^{23}V_3) - (a^{33} - a^{11}) \\ \times (A^{13}V_1 + B^{13}V_2 + C^{13}V_3) - a^{23}(A^{12}V_1 + B^{12}V_2 + C^{12}V_3) + a^{13}(A^{33}V_1 + B^{33}V_2 + C^{33}V_3) \\ = (-G_3a^{11} + G_1a^{13})V_1 + (-G_3a^{12} + G_1a^{23})V_2 + (-G_3a^{13} + G_1a^{33})V_3,\end{aligned} \tag{15}$$

and the other two are obtained in a similar fashion.

Since V is nondegenerate we can compute all of the third partial derivatives of V. In fact, differentiating each of the equations (14) with respect to $x_j, j = 1, 2, 3$ we obtain 15 equations for the 10 distinct partial derivatives V_{ijk}. For example,

$$\begin{aligned}V_{123} = \partial_2 V_{13} &= A^{13}_2 V_1 + B^{13}_2 V_2 + C^{13}_2 V_3 + A^{13}V_{12} + B^{13}V_{22} + C^{13}V_{23} \\ &= \partial_1 V_{23} = A^{23}_1 V_1 + B^{23}_1 V_2 + C^{23}_1 V_3 + A^{23}V_{11} + B^{23}V_{12} + C^{23}V_{13} \\ &= \partial_3 V_{12} = A^{12}_3 V_1 + B^{12}_3 V_2 + C^{12}_3 V_3 + A^{12}V_{13} + B^{12}V_{23} + C^{12}V_{33},\end{aligned}$$

$$\begin{aligned}V_{111} &= (A^{12}_2 - A^{22}_1)V_1 + (B^{12}_2 - B^{22}_1)V_2 + (C^{12}_2 - C^{22}_1)V_3 - A^{22}V_{11} \\ &\quad + B^{12}V_{22} + (A^{12} - B^{22})V_{12} - C^{22}V_{13} + C^{12}V_{23} \\ &= (A^{13}_3 - A^{33}_1)V_1 + (B^{13}_3 - B^{33}_1)V_2 + (C^{13}_3 - C^{33}_1)V_3 - A^{33}V_{11} \\ &\quad + C^{13}V_{33} + (A^{13} - C^{33})V_{13} - B^{33}V_{12} + B^{13}V_{23},\end{aligned}$$

$$\begin{aligned}V_{223} = (A^{31}_1 + A^{22}_3)V_1 + (B^{31}_1 + B^{22}_3)V_2 + (C^{31}_1 + C^{22}_3)V_3 + A^{31}V_{11} + C^{22}V_{33} + B^{13}V_{21} + (C^{31} + A^{22})V_{13} \\ + B^{22}V_{23} = A^{23}_2 V_1 + B^{23}_2 V_2 + C^{23}_2 V_3 + A^{23}V_{12} + C^{23}V_{32} + B^{23}V_{22},\end{aligned}$$

$$V_{332} = (A_1^{12} + A_2^{33})V_1 + (B_1^{12} + B_3^{33})V_2 + (C_1^{12} + C_2^{33})V_3 + A^{12}V_{11} + B^{33}V_{22} + C^{12}V_{31} + (B^{12} + A^{33})V_{12}$$
$$+ C^{33}V_{23} = A_3^{23}V_1 + B_3^{23}V_2 + C_3^{23}V_3 + A^{23}V_{13} + B^{23}V_{23} + C^{23}V_{33}, \tag{16}$$

with analogous expressions for the other third derivatives. Similarly all higher order derivatives of V can be computed from these. The right-hand side of each of these equations can be expressed as an explicit linear combination of V_1, V_2, V_3, V_{11} with analytic functions of x_1, x_2, x_3 as coefficients. Thus if the potential V belongs to the solution space then V can depend on at most four parameters, in addition to a trivial additive constant. We can choose these parameters to be $V_1(x_0, y_0, z_0), V_2(x_0, y_0, z_0), V_3(x_0, y_0, z_0), V_{11}(x_0, y_0, z_0)$ for any fixed regular point (x_0, y_0, z_0). Then all higher derivatives can be computed by successive differentiation of relations (14). Thus our potential is nondegenerate, i.e., it depends non trivially on these four arbitrary parameters, so that *all* higher-order integrability conditions are satisfied.

Then, equating coefficients of V_1, V_2, V_3, V_{11} on each side of the conditions $\partial_1 V_{23} = \partial_2 V_{13} = \partial_3 V_{12}, \partial_3 V_{23} = \partial_2 V_{33}$, etc., we obtain integrability conditions, the simplest of which include

$$A^{23} = B^{13} = C^{12}, \quad B^{12} - A^{22} = C^{13} - A^{33},$$

$$B^{23} = A^{31} + C^{22}, \quad C^{23} = A^{12} + B^{33},$$

$$A_1^{12} + B^{12}A^{12} + A_2^{33} + A^{33}A^{12} + B^{33}A^{22} + C^{33}A^{23} = A_3^{23} + B^{23}A^{23} + C^{23}A^{33},$$

$$A_2^{13} + A^{13}A^{12} + B^{13}A^{22} + C^{13}A^{23} = A_1^{23} + B^{23}A^{12} + C^{23}A^{13} = A_3^{12} + A^{13}A^{12} + B^{12}A^{23} + C^{12}A^{33}. \tag{17}$$

All of these conditions, analytic expressions in x, y, z, must hold identically in a common domain to have a nondegenerate system. Note that if $r' > r$ then there will be conditions relating the parameters $V_1(x_0, y_0, z_0), V_2(x_0, y_0, z_0), V_3(x_0, y_0, z_0), V_{11}(x_0, y_0, z_0)$, so we cannot have a nondegenerate system in that case.

We can further clarify the situation by introducing the dependent variables $W^{(1)} = V_1, W^{(2)} = V_2, W^{(3)} = V_3, W^{(4)} = V_{11}$, the vector

$$\mathbf{w} = \begin{pmatrix} W^{(1)} \\ W^{(2)} \\ W^{(3)} \\ W^{(4)} \end{pmatrix}, \tag{18}$$

and the matrices

$$\mathbf{A}^{(1)} = \begin{pmatrix} 0 & 0 & 0 & 1 \\ A^{12} & B^{12} & C^{12} & 0 \\ A^{13} & B^{13} & C^{13} & 0 \\ A^{14} & B^{14} & C^{14} & B^{12} - A^{22} \end{pmatrix}, \tag{19}$$

$$\mathbf{A}^{(2)} = \begin{pmatrix} A^{12} & B^{12} & C^{12} & 0 \\ A^{22} & B^{22} & C^{22} & 1 \\ A^{23} & B^{23} & C^{23} & 0 \\ A^{24} & B^{24} & C^{24} & A^{12} \end{pmatrix}, \tag{20}$$

$$\mathbf{A}^{(3)} = \begin{pmatrix} A^{13} & B^{13} & C^{13} & 0 \\ A^{23} & B^{23} & C^{23} & 0 \\ A^{33} & B^{33} & C^{33} & 1 \\ A^{34} & B^{34} & C^{34} & A^{13} \end{pmatrix}, \tag{21}$$

where

$$\begin{aligned} A^{14} &= A_2^{12} - A_1^{22} + B^{12}A^{22} + A^{12}A^{12} - B^{22}A^{12} - C^{22}A^{13} + C^{12}A^{23} \\ &= A_3^{13} - A_1^{33} + B^{13}A^{23} + A^{13}A^{13} - B^{33}A^{12} - C^{33}A^{13} + C^{13}A^{33}, \end{aligned}$$

$$\begin{aligned} B^{14} &= B_2^{12} - B_1^{22} + B^{12}B^{22} + A^{12}B^{12} - B^{22}B^{12} - C^{22}B^{13} + C^{12}B^{23} \\ &= B_3^{13} - B_1^{33} + B^{13}B^{23} + A^{13}B^{13} - B^{33}B^{12} - C^{33}B^{13} + C^{13}B^{33}, \end{aligned}$$

$$\begin{aligned} C^{14} &= C_2^{12} - C_1^{22} + B^{12}C^{22} + A^{12}C^{12} - B^{22}C^{12} - C^{22}C^{13} + C^{12}C^{23} \\ &= C_3^{13} - C_1^{33} + B^{13}C^{23} + A^{13}C^{13} - B^{23}C^{12} - C^{33}C^{13} + C^{13}C^{33}, \end{aligned}$$

$$A^{24} = A_1^{12} + B^{12}A^{12} + C^{12}A^{13}, \quad B^{24} = B_1^{12} + B^{12}B^{12} + C^{12}B^{13},$$

$$C^{24} = C_1^{12} + B^{12}C^{12} + C^{12}C^{13},$$

$$A^{34} = A_1^{13} + B^{13}A^{12} + C^{13}A^{13}, \quad B^{34} = B_1^{13} + B^{13}B^{12} + C^{13}B^{13},$$

$$C^{34} = C_1^{13} + B^{13}C^{12} + C^{13}C^{13}. \tag{22}$$

Then the conditions (17) must hold as well as the integrability conditions for the system

$$\partial_{x_j}\mathbf{w} = \mathbf{A}^{(j)}\mathbf{w}, \quad j = 1,2,3. \tag{23}$$

The integrability conditions are

$$A_i^{(j)} - A_j^{(i)} = A^{(i)}A^{(j)} - A^{(j)}A^{(i)} \equiv [A^{(i)}, A^{(j)}]. \tag{24}$$

The integrability conditions (17) and (24) are analytic expressions in x_1, x_2, x_3 and must hold identically. Then the system has a solution V depending on four parameters (plus an arbitrary additive parameter). For convenience in the arguments to follow we set

$$\mathcal{U}^1 = A_2^{(3)} - A_3^{(2)} - [A^{(2)}, A^{(3)}], \quad \mathcal{U}^2 = A_3^{(1)} - A_1^{(3)} - [A^{(3)}, A^{(1)}],$$

$$\mathcal{U}^3 = A_1^{(2)} - A_2^{(1)} - [A^{(1)}, A^{(2)}], \tag{25}$$

so that the identities are

$$\mathcal{U}^1 = \mathcal{U}^2 = \mathcal{U}^3 = 0. \tag{26}$$

We have shown that a weakly functionally independent set of five symmetries (or constants of the motion) is functionally linearly independent. For systems with nondegenerate potentials, the converse holds.

Theorem 2: *Let*

$$\mathcal{S}_h = \sum_{j,k=1}^{3} a_{(h)}^{jk} p_k p_j + W_{(h)}, \quad h = 1, \ldots, 5, \quad \mathcal{H} = \mathcal{S}_1$$

be functionally linearly independent symmetries for a system with nondegenerate potential $V = W_{(1)}$. *Then these symmetries are weakly functionally independent.*

Proof: By assumption, the set $\{\mathcal{S}_h\}$ is functionally linearly independent. Suppose it is also functionally dependent. This means that the set of differentials $\{\mathrm{d}\mathcal{S}_h\}$ is dependent, i.e., that the 5×6 matrix

$$\begin{pmatrix} \sum_i a^{i1}_{(1)}p_i & \sum_i a^{i2}_{(1)}p_i & \sum_i a^{i3}_{(1)}p_i & K_{14}+\sum_i a^{j1}_{(1)}V_j & K_{15}+\sum_i a^{j2}_{(1)}V_j & K_{16}+\sum_i a^{j3}_{(1)}V_j \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \sum_i a^{i1}_{(5)}p_i & \sum_i a^{i2}_{(5)}p_i & \sum_i a^{i3}_{(5)}p_i & K_{54}+\sum_i a^{j1}_{(5)}V_j & K_{55}+\sum_i a^{j2}_{(5)}V_j & K_{56}+\sum_i a^{j3}_{(5)}V_j \end{pmatrix},$$

where

$$K_{\ell,3+s} = \sum_{ij} a^{ij}_{(\ell),s}p_i p_j,$$

is of rank <5 for all values of p_j, V_j. Thus all 5×5 minors must vanish identically in p_j, V_j. It is an easy consequence of this that all 5×5 minors of the 5×6 matrix

$$\begin{pmatrix} a^{11}_{(1)} & a^{12}_{(1)} & a^{13}_{(1)} & a^{22}_{(1)} & a^{23}_{(1)} & a^{33}_{(1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ a^{11}_{(5)} & a^{12}_{(5)} & a^{13}_{(5)} & a^{22}_{(5)} & a^{23}_{(5)} & a^{33}_{(5)} \end{pmatrix}$$

vanish, hence that this matrix have rank <5. Thus $\{\mathcal{L}_h : h=1,\ldots,5\}$ is functionally linearly dependent. Contradiction. Q.E.D.

Since (as we assume) the potential is nondegenerate, at any regular point $\mathbf{x}_0$ the first derivatives V_1, V_2, V_3 can be chosen arbitrarily. Thus the coefficients of V_j on both sides of equation (13) must be equal. From this, we obtain the relations

$$a^{11}_3 - a^{31}_1 = -a^{12}A^{23} + (a^{33}-a^{11})A^{13} + a^{23}A^{12} - a^{13}A^{33} - G_3a^{11} + G_1a^{13},$$

$$a^{12}_3 - a^{32}_1 = -a^{12}B^{23} + (a^{33}-a^{11})B^{13} + a^{23}B^{12} - a^{13}B^{33} - G_3a^{12} + G_1a^{23},$$

$$a^{13}_3 - a^{33}_1 = -a^{12}C^{23} + (a^{33}-a^{11})C^{13} + a^{23}C^{12} - a^{13}C^{33} - G_3a^{13} + G_1a^{33},$$

with six analogous relations from the other two Bertrand-Darboux equations. Using these nine relations and Eqs. (8) we can solve for all of the first partial derivatives a^{jk}_i to obtain

$$a^{11}_1 = -G_1a^{11} - G_2a^{12} - G_3a^{13},$$

$$a^{22}_2 = -G_1a^{12} - G_2a^{22} - G_3a^{23},$$

$$a^{33}_3 = -G_1a^{13} - G_2a^{23} - G_3a^{33},$$

$$3a^{12}_2 = a^{12}A^{22} - (a^{22}-a^{11})A^{12} - a^{23}A^{13} + a^{13}A^{23} + G_2a^{11} - 2G_1a^{12} - G_2a^{22} - G_3a^{23},$$

$$3a^{11}_2 = -2a^{12}A^{22} + 2(a^{22}-a^{11})A^{12} + 2a^{23}A^{13} - 2a^{13}A^{23} - 2G_2a^{11} + G_1a^{12} - G_2a^{22} - G_3a^{23},$$

$$3a^{13}_3 = -a^{12}C^{23} + (a^{33}-a^{11})C^{13} + a^{23}C^{12} - a^{13}C^{33} - G_1a^{11} - G_2a^{12} - 2G_3a^{13} + G_1a^{33},$$

$$3a^{33}_1 = 2a^{12}C^{23} - 2(a^{33}-a^{11})C^{13} - 2a^{23}C^{12} + 2a^{13}C^{33} - G_1a^{11} - G_2a^{12} + G_3a^{13} - 2G_1a^{33},$$

$$3a_2^{23} = a^{23}(B^{33} - B^{22}) - (a^{33} - a^{22})B^{23} - a^{13}B^{12} + a^{12}B^{13} - G_1a^{13} - 2G_2a^{23} - G_3a^{33} + G_3a^{22},$$

$$3a_3^{22} = -2a^{23}(B^{33} - B^{22}) + 2(a^{33} - a^{22})B^{23} + 2a^{13}B^{12} - 2a^{12}B^{13} - G_1a^{13} + G_2a^{23} - G_3a^{33} - 2G_3a^{22},$$

$$3a_1^{13} = -a^{23}A^{12} + (a^{11} - a^{33})A^{13} + a^{13}A^{33} + a^{12}A^{23} - 2G_1a^{13} - G_2a^{23} - G_3a^{33} + G_3a^{11},$$

$$3a_3^{11} = 2a^{23}A^{12} + 2(a^{33} - a^{11})A^{13} - 2a^{13}A^{33} - 2a^{12}A^{23} + G_1a^{13} - G_2a^{23} - G_3a^{33} - 2G_3a^{11},$$

$$3a_2^{33} = -2a^{13}C^{12} + 2(a^{22} - a^{33})C^{23} + 2a^{12}C^{13} - 2a^{23}(C^{22} - C^{33}) - G_1a^{12} - G_2a^{22} + G_3a^{23} - 2G_2a^{33},$$

$$3a_3^{23} = a^{13}C^{12} - (a^{22} - a^{33})C^{23} - a^{12}C^{13} - a^{23}(C^{33} - C^{22}) - G_1a^{12} - G_2a^{22} - 2G_3a^{23} + G_2a^{33},$$

$$3a_2^{12} = -a^{13}B^{23} + (a^{22} - a^{11})B^{12} - a^{12}B^{22} + a^{23}B^{13} - G_1a^{11} - 2G_2a^{12} - G_3a^{13} + G_1a^{22},$$

$$3a_1^{22} = 2a^{13}B^{23} - 2(a^{22} - a^{11})B^{12} + 2a^{12}B^{22} - 2a^{23}B^{13} - G_1a^{11} + G_2a^{12} - G_3a^{13} - 2G_1a^{22},$$

$$\begin{aligned}3a_1^{23} = {} & a^{12}(B^{23} + C^{22}) + a^{11}(B^{13} + C^{12}) - a^{22}C^{12} - a^{33}B^{13} + a^{13}(B^{33} + C^{23}) - a^{23}(C^{13} + B^{12}) \\ & - 2G_1a^{23} + G_2a^{13} + G_3a^{12},\end{aligned}$$

$$\begin{aligned}3a_3^{12} = {} & a^{12}(-2B^{23} + C^{22}) + a^{11}(C^{12} - 2B^{13}) - a^{22}C^{12} + 2a^{33}B^{13} + a^{13}(-2B^{33} + C^{23}) \\ & + a^{23}(-C^{13} + 2B^{12}) - 2G_3a^{12} + G_2a^{13} + G_1a^{23},\end{aligned}$$

$$\begin{aligned}3a_2^{13} = {} & a^{12}(B^{23} - 2C^{22}) + a^{11}(B^{13} - 2C^{12}) + 2a^{22}C^{12} - a^{33}B^{13} + a^{13}(B^{33} - 2C^{23}) + a^{23}(2C^{13} - B^{12}) \\ & - 2G_2a^{13} + G_1a^{23} + G_3a^{12},\end{aligned} \tag{27}$$

plus the linear relations

$$A^{23} = B^{13} = C^{12}, \quad B^{23} - A^{13} - C^{22} = 0,$$

$$B^{12} - A^{22} + A^{33} - C^{13} = 0, \quad B^{33} + A^{12} - C^{23} = 0.$$

Using the linear relations we can express $C^{12}, C^{13}, C^{22}, C^{23}$, and B^{13} in terms of the remaining 10 functions.

Since the above system of first-order partial differential equations is involutive the general solution for the six functions a^{jk} can depend on at most six parameters, the values $a^{jk}(\mathbf{x}_0)$ at a fixed regular point $\mathbf{x}_0$. For the integrability conditions we define the vector-valued function

$$\mathbf{h}(x,y,z) = \begin{pmatrix} a^{11} \\ a^{12} \\ a^{13} \\ a^{22} \\ a^{23} \\ a^{33} \end{pmatrix}$$

and directly compute the 6×6 matrix functions $\mathcal{A}^{(j)}$ to get the first-order system

$$\partial_{x_j}\mathbf{h} = \mathcal{A}^{(j)}\mathbf{h}, \quad j = 1,2,3. \tag{28}$$

The integrability conditions for this system are are

$$\mathcal{A}_i^{(j)}\mathbf{h} - \mathcal{A}_j^{(i)}\mathbf{h} = \mathcal{A}^{(i)}\mathcal{A}^{(j)}\mathbf{h} - \mathcal{A}^{(j)}\mathcal{A}^{(i)}\mathbf{h} \equiv [\mathcal{A}^{(i)}, \mathcal{A}^{(j)}]\mathbf{h}. \tag{29}$$

In terms of the 6×6 matrices

$$\mathcal{S}^{(1)} = \mathcal{A}_2^{(3)} - \mathcal{A}_3^{(2)} - [\mathcal{A}^{(2)}, \mathcal{A}^{(3)}], \quad \mathcal{S}^{(2)} = \mathcal{A}_3^{(1)} - \mathcal{A}_1^{(3)} - [\mathcal{A}^{(3)}, \mathcal{A}^{(1)}],$$

$$\mathcal{S}^{(3)} = \mathcal{A}_1^{(2)} - \mathcal{A}_2^{(1)} - [\mathcal{A}^{(1)}, \mathcal{A}^{(2)}],$$

the integrabilty conditions are

$$\mathcal{S}^{(1)}\mathbf{h} = \mathcal{S}^{(2)}\mathbf{h} = \mathcal{S}^{(3)}\mathbf{h} = 0. \tag{30}$$

IV. THE 5⇒6 THEOREM

Now assume that the system of equations (27) admits a six-parameter family of solutions a^{jk}. (The requirement of superintegrability appears to guarantee only a five-parameter family of solutions.) Thus at any regular point we can prescribe the values of the a^{jk} arbitrarily. This means that (29) and (30) holds identically in $\mathbf{h}$. Thus $\mathcal{S}^{(1)}=\mathcal{S}^{(2)}=\mathcal{S}^{(3)}=0$. Using these expressions, we can perform a tedious but straightforward Maple-assisted computation that yields

(1) An expression for each of the first partial derivatives $\partial_\ell A^{ij}, \partial_\ell B^{ij}, \partial_\ell C^{ij}$, for the 10 independent functions as homogeneous polynomials of order at most two in the $A^{i'j'}, B^{i'j'}, C^{i'j'}$. There are $30=3\times 10$ such expressions in all. An example is

$$B_2^{12} = \tfrac{2}{3}A^{12}B^{12} - \tfrac{1}{6}B^{12}G_2 - \tfrac{5}{6}G_1A^{12} - \tfrac{1}{6}G_1G_2 + \tfrac{1}{3}B^{22}B^{12} + \tfrac{1}{3}B^{22}G_1 + \tfrac{1}{3}A^{23}B^{23} - \tfrac{7}{6}G_3A^{23} + \tfrac{1}{2}G_{12}.$$

(2) Exactly five quadratic identities for the 10 independent functions,

(a)

$$-A^{23}B^{33} - A^{12}A^{23} + A^{13}B^{12} + B^{22}A^{23} + B^{23}A^{33} + \tfrac{1}{2}A^{22}G_3 - \tfrac{1}{2}A^{33}G_3 - \tfrac{1}{2}B^{12}G_3 - \tfrac{1}{2}G_1G_3 - \tfrac{1}{2}A^{13}G_1 + \tfrac{3}{2}G_{13} - \tfrac{1}{2}A^{23}G_2 - A^{22}B^{23} = 0,$$

(b)

$$(A^{33})^2 + B^{12}A^{33} - A^{33}A^{22} - B^{33}A^{12} - C^{33}A^{13} + B^{22}A^{12} - B^{12}A^{22} + A^{13}B^{23} - (A^{12})^2 + \tfrac{3}{2}G_{22} - \tfrac{1}{2}G_y^2 - \tfrac{3}{2}G_{33} + \tfrac{1}{2}A^{13}G_3 + \tfrac{1}{2}B^{33}G_2 - \tfrac{1}{2}A^{22}G_1 + \tfrac{1}{2}A^{33}G_1 - \tfrac{1}{2}B^{23}G_3 - \tfrac{1}{2}B^{22}G_2 + \tfrac{1}{2}C^{33}G_3 + \tfrac{1}{2}(G_3)^2 = 0,$$

(c)

$$-(B^{33})^2 - B^{33}A^{12} + B^{33}B^{22} + B^{12}A^{33} + B^{23}C^{33} - (B^{23})^2 + (B^{12})^2 + \tfrac{1}{2}(G_1)^2 - \tfrac{3}{2}G_{11} + \tfrac{3}{2}G_{33} - \tfrac{1}{2}B^{33}G_2 - \tfrac{1}{2}A^{33}G_1 - \tfrac{1}{2}(G_3)^2 - \tfrac{1}{2}C^{33}G_3 = 0, \tag{31}$$

(d)

$$-B^{12}A^{23} - A^{33}A^{23} + A^{13}B^{33} + A^{12}B^{23} + \tfrac{3}{2}G_{23} - \tfrac{1}{2}A^{23}G_1 - \tfrac{1}{2}A^{12}G_3 - \tfrac{1}{2}B^{23}G_2 - \tfrac{1}{2}G_2G_3 - \tfrac{1}{2}B^{33}Ga_3 = 0,$$

(e)

$$A^{12}B^{12} + C^{33}A^{23} - A^{23}B^{23} + B^{33}A^{22} - B^{33}A^{33} + \tfrac{3}{2}G_{12} - \tfrac{1}{2}G_1G_2 - \tfrac{1}{2}A^{12}G_1 - \tfrac{1}{2}B^{12}G_2 - \tfrac{1}{2}A^{23}G_3 = 0,$$

There are no nontrivial conditions in which some derivative of G is involved as a factor in each term.

Theorem 3 (5 → 6): *Let V be a nondegenerate potential corresponding to a conformally flat space in three dimensions that is superintegrable, i.e., suppose V satisfies the equations (14), where conditions (17) and (24) hold, and there are five functionally independent constants of the motion. Then the space of second-order symmetries for the Hamiltonian $\mathcal{H}=(p_x^2+p_y^2+p_z^2)/\lambda(x,y,z)+V(x,y,z)$ (excluding multiplication by a constant) is of dimension $D=6$.*

Corollary 3: If $\mathcal{H}+V$ is a superintegrable conformally flat system with nondegenerate potential, then the dimension of the space of second-order symmetries

$$\mathcal{S}=\sum_{k,j=1}^{3} a^{kj}(x,y,z)p_kp_j+W(x,y,z)$$

is 6. At any regular point (x_0,y_0,z_0) and given constants $\alpha^{kj}=\alpha^{jk}$ there is exactly one symmetry $\mathcal{S}$ (up to an additive constant) such that $a^{kj}(x_0,y_0,z_0)=\alpha^{kj}$. Given a set of five functionally independent second-order symmetries $\mathcal{L}=\{\mathcal{S}_\ell:\ell=1,\ldots,5\}$ associated with the potential, there is always a sixth second-order symmetry $\mathcal{S}_6$ that is functionally dependent on $\mathcal{L}$, but functionally linearly independent.

Corollary 4: The previous theorem and corollary remain true for five weakly functionally independent second-order symmetries, if the corresponding quadratic forms $\Sigma_{k,j}a_{(\ell)}^{kj}p_kp_j, 1\leqslant\ell\leqslant 5$ are functionally linearly independent.

Proof of theorem: The proof takes many steps, most of which must be carried out with computer algebra software. We give the logic behind the proof and describe the steps in order.

If there is only a five-parameter family of solutions then (30) holds only for the $\boldsymbol{h}$ that lie in a five-dimensional space. By appropriate Euclidean transformation of coordinates, if necessary, we use Gauss-Jordan elimination and show that there is a basis for the space of the form $\tilde{\mathbf{h}}^j, j=1,\ldots,5$ where

$$(\tilde{\mathbf{h}}^1,\tilde{\mathbf{h}}^2,\tilde{\mathbf{h}}^3,\tilde{\mathbf{h}}^4,\tilde{\mathbf{h}}^5)=\begin{pmatrix}1&0&0&0&0\\0&1&0&0&0\\0&0&1&0&0\\0&0&0&1&0\\0&0&0&0&1\\\alpha_1(x,y,z)&\alpha_2(x,y,z)&\alpha_3(x,y,z)&\alpha_4(x,y,z)&\alpha_5(x,y,z)\end{pmatrix}.$$

Here we mean that if $\mathbf{h}$ belongs to the solution space then there are unique differentiable functions $g_j(x,y,z)$ such that $\mathbf{h}=\Sigma_{j=1}^5 g_j\tilde{\mathbf{h}}^j$. It follows that the integrabilty conditions become

$$\mathcal{S}_{kj}^{(\ell)}+\alpha_j\mathcal{S}_{k6}^{(\ell)}=0,\quad \ell=1,\ldots,3,\quad k=1,\ldots,6,\quad j=1,\ldots,5. \tag{32}$$

Further, the conditions (30) must hold. The question that we need to decide is whether the conditions (30) and (32) imply

$$\mathcal{S}^{(1)}=\mathcal{S}^{(2)}=\mathcal{S}^{(3)}=0.$$

Some of the elements of the matrices $\mathcal{S}^{(i)}$ vanish identically. Indeed

$$\mathcal{S}_{16}^{(1)}=\mathcal{S}_{26}^{(1)}=\mathcal{S}_{46}^{(1)}=\mathcal{S}_{14}^{(2)}=\mathcal{S}_{34}^{(2)}=\mathcal{S}_{64}^{(2)}=\mathcal{S}_{41}^{(3)}=\mathcal{S}_{51}^{(3)}=\mathcal{S}_{61}^{(3)}\equiv 0.$$

Also

$$\mathcal{S}_{16}^{(2)}\equiv\mathcal{S}_{15}^{(1)}\equiv-\mathcal{S}_{11}^{(2)},\quad \mathcal{S}_{54}^{(1)}\equiv-\mathcal{S}_{23}^{(1)},$$

$$\mathcal{S}_{25}^{(1)}\equiv-\mathcal{S}_{31}^{(1)},\quad \mathcal{S}_{34}^{(1)}\equiv\mathcal{S}_{26}^{(2)},\quad 3\mathcal{S}_{11}^{(3)}\equiv 2\mathcal{S}_{11}^{(1)},$$

$$\mathcal{S}_{44}^{(2)} \equiv -\tfrac{2}{3}\mathcal{S}_{22}^{(2)}, \quad \mathcal{S}_{46}^{(3)} \equiv -\mathcal{S}_{43}^{(1)}.$$

This implies that the following conditions must hold no matter what are the values of the α_j:

$$\mathcal{S}_{ij}^{(1)} = 0, \quad i = 1,2,4,6, \quad 1 \leqslant j \leqslant 6, \quad \mathcal{S}_{31}^{(1)} = 0, \tag{33}$$

$$\mathcal{S}_{1j}^{(2)} = \mathcal{S}_{4j}^{(3)} = 0, \quad 1 \leqslant j \leqslant 6, \quad \mathcal{S}_{54}^{(1)} = 0, \quad \mathcal{S}_{44}^{(2)} = 0.$$

We will show that the identities (33), plus the identities (26) (that must always hold) suffice to prove that

$$\mathcal{S}^{(1)} = \mathcal{S}^{(2)} = \mathcal{S}^{(3)} = 0,$$

hence that the integrabilty conditions are satisfied identically and there is a six-parameter family of symmetries. In the first step we compute all of the identities (26) and (33) and use a subset of 17 of the identities (33) and 12 of the identities (26) to solve for each of the 30 independent partial derivatives

$$\partial_k A^{12}, \quad \partial_k A^{13}, \quad \partial_k A^{22}, \quad \partial_k A^{23}, \quad \partial_k A^{33}, \quad \partial_k B^{12}, \quad \partial_k B^{22}, \quad \partial_k B^{23}, \quad \partial_k B^{33}, \quad \partial_k C^{33}, \quad k = 1,2,3,$$

save $\partial_z C^{33}$ which does not occur in these expressions. In each case we obtain an expression for the derivative as a polynomial in the 10 variables $A^{12},\ldots,C^{33}$ with coefficients in the linear and zero-order terms that involve derivatives of G. Then we substitute these expressions back into the remaining conditions (26) and (33). This yields a set of four independent second-order polynomial identities, a subset of the identities (31). These identities are sufficient to verify that

$$\mathcal{S}_{36}^{(1)} = \mathcal{S}_{56}^{(1)} = \mathcal{S}_{26}^{(2)} = \mathcal{S}_{36}^{(2)} = \mathcal{S}_{46}^{(2)} = 0.$$

By conditions (32) this immediately implies $\mathcal{S}^{(1)}=0$, and $\mathcal{S}_{jk}^{(2)}=0$ for $j=2$, 3, 4 and $1\leqslant k\leqslant 6$. Substituting our expressions for the derivatives into these identities we obtain the full set of five identities (31), and can solve for $\partial_x C^{33}$. This set is now sufficient to verify that

$$\mathcal{S}_{56}^{(2)} = \mathcal{S}_{66}^{(2)} = \mathcal{S}_{16}^{(3)} = \mathcal{S}_{26}^{(3)} = \mathcal{S}_{36}^{(3)} = \mathcal{S}_{56}^{(3)} = \mathcal{S}_{66}^{(3)} = 0,$$

which implies $\mathcal{S}^{(2)}=\mathcal{S}^{(3)}=0$. Q.E.D.

V. THIRD-ORDER CONSTANTS OF THE MOTION

Now we investigate the space of third-order constants of the motion, assuming a nondegenerate potential. We have

$$\mathcal{K} = \sum_{k,j,i=1}^{3} a^{kji}(x,y,z)p_k p_j p_i + b^{\ell}(x,y,z)p_{\ell}, \tag{34}$$

which must satisfy $\{\mathcal{H},\mathcal{K}\}=0$. Here a^{kji} is symmetric in the indices k,j,i.

The conditions are

$$a_i^{iii} = -\frac{3}{2}\sum_s a^{sii}(\ln\lambda)_s,$$

$$3a_i^{jii} + a_j^{iii} = -3\sum_s a^{sij}(\ln\lambda)_s, \quad i \neq j,$$

$$a_i^{ijj} + a_j^{iij} = -\frac{1}{2}\sum_s a^{sjj}(\ln\lambda)_s - \frac{1}{2}\sum_s a^{sii}(\ln\lambda)_s, \quad i \neq j,$$

$$2a_i^{ijk} + a_j^{kii} + a_k^{jii} = -\sum_s a^{sjk}(\ln \lambda)_s, \quad i,j,k \text{ distinct}, \tag{35}$$

$$b_k^j + b_j^k = 3\lambda \sum_s a^{skj} V_s, \quad j \neq k, \quad j,k = 1,2,3,$$

$$b_j^j = \frac{3}{2}\lambda \sum_s a^{sjj} V_s - \frac{1}{2}\sum_s b^s (\ln \lambda)_s, \quad j = 1,2,3, \tag{36}$$

and

$$\sum_s b^s V_s = 0. \tag{37}$$

The a^{kji} is just a third-order Killing tensor. We will, as usual, require the potential V to be superintegrable and non degenerate. Again, as usual, we require that the highest order terms, the a^{kji} in the constant of the motion, be independent of the four independent parameters in V. However, the b^ℓ must depend on these parameters. We set

$$b^\ell(x,y,z) = \sum_{j=1}^{3} f^{\ell,j}(x,y,z) V_j(x,y,z).$$

[Here we are excluding the purely first-order symmetries. Also, we could add a term $f^{\ell,11}(x,y,z)V_{11}(x,y,z)$ to the preceding expression. However condition (37) implies $f^{\ell,11} \equiv 0$.] Substituting this expression into (37) we see that

$$f^{\ell,j} + f^{j,\ell} = 0, \quad 1 \leqslant \ell, j \leqslant 3.$$

Further

$$b_j^i = \sum_{\ell \neq 1} (f_j^{i,\ell} V_\ell + f^{i,\ell} V_{j\ell}),$$

where the subscript j denotes the partial derivative with respect to x_j. Substituting these results and expressions (14) into the defining equations (36) and equating coefficients of V_1, V_2, V_3, V_{11}, respectively, we obtain the following independent conditions [$G_s \equiv (\ln \lambda)_s$]:

$$\lambda a^{111} = \frac{2}{3}(f^{1,2}A^{12} + f^{1,3}A^{13}) + \frac{1}{3}\sum_{s=1}^{3} f^{s,1} G_s,$$

$$\lambda a^{222} = \frac{2}{3}(-f^{1,2}B^{12} + f^{2,3}B^{23}) + \frac{1}{3}\sum_{s=1}^{3} f^{s,2} G_s,$$

$$\lambda a^{333} = \frac{2}{3}(-f^{1,3}C^{13} - f^{2,3}C^{23}) + \frac{1}{3}\sum_{s=1}^{3} f^{s,3} G_s,$$

$$\lambda a^{112} = \frac{2}{9}(f^{1,2}(A^{22} + B^{12}) + 2f^{1,3}A^{23} + f^{2,3}A^{13}) + \frac{1}{9}\sum_{s=1}^{3} f^{s,2} G_s,$$

$$\lambda a^{113} = \frac{2}{9}(2f^{1,2}A^{23} + f^{1,3}(A^{33} + C^{13}) - f^{2,3}A^{12}) + \frac{1}{9}\sum_{s=1}^{3} f^{s,3}G_s,$$

$$\lambda a^{122} = \frac{2}{9}(f^{1,2}(-A^{12} + B^{22}) + f^{1,3}B^{23} + 2f^{2,3}A^{23}) + \frac{1}{9}\sum_{s=1}^{3} f^{s,1}G_s,$$

$$\lambda a^{223} = \frac{2}{9}(-2f^{1,2}A^{23} - f^{1,3}B^{12} + f^{2,3}(-B^{22} + B^{33} + C^{23})) + \frac{1}{9}\sum_{s=1}^{3} f^{s,3}G_s,$$

$$\lambda a^{133} = \frac{2}{9}(f^{1,2}C^{23} + f^{1,3}(-A^{13} + C^{33}) - 2f^{2,3}A^{23}) + \frac{1}{9}\sum_{s=1}^{3} f^{s,1}G_s,$$

$$\lambda a^{233} = \frac{2}{9}(-f^{1,2}C^{13} - 2f^{1,3}A^{23} + f^{2,3}(-B^{23} - C^{22} + C^{33})) + \frac{1}{9}\sum_{s=1}^{3} f^{s,2}G_s,$$

$$\lambda a^{123} = \frac{2}{9}(f^{1,2}C^{22} + f^{1,3}B^{33} + f^{2,3}(-B^{12} + C^{13})), \tag{38}$$

$$f_1^{1,2} = \frac{1}{3}(f^{1,2}(A^{22} - 2B^{12}) - f^{1,3}A^{23} + f^{2,3}A^{13}) - \frac{1}{3}\sum_{s=1}^{3} f^{s,2}G_s,$$

$$f_2^{1,2} = \frac{1}{3}(f^{1,2}(-2A^{12} - B^{22}) - f^{1,3}B^{23} + f^{2,3}A^{23}) + \frac{1}{3}\sum_{s=1}^{3} f^{s,1}G_s,$$

$$f_1^{1,3} = \frac{1}{3}(-f^{1,2}A^{23} + f^{1,3}(A^{33} - 2C^{13}) - f^{2,3}A^{12}) - \frac{1}{3}\sum_{s=1}^{3} f^{s,3}G_s,$$

$$f_3^{1,3} = \frac{1}{3}(-f^{1,2}C^{23} + f^{1,3}(-2A^{13} - C^{33}) - f^{2,3}A^{23}) + \frac{1}{3}\sum_{s=1}^{3} f^{s,1}G_s,$$

$$f_2^{2,3} = \frac{1}{3}(f^{1,2}A^{23} - f^{1,3}B^{12} + f^{2,3}(-B^{22} + B^{33} - 2C^{23})) - \frac{1}{3}\sum_{s=1}^{3} f^{s,3}G_s,$$

$$f_3^{2,3} = \frac{1}{3}(f^{1,2}C^{13} - f^{1,3}A^{23} + f^{2,3}(-2B^{23} + C^{22} - C^{33})) + \frac{1}{3}\sum_{s=1}^{3} f^{s,2}G_s, \tag{39}$$

and

$$f_1^{2,3} + f_2^{1,3} = \tfrac{1}{3}(-f^{1,2}C^{22} + f^{1,3}(2B^{33} - 3C^{23}) - f^{2,3}(2B^{12} + C^{13})),$$

$$-f_1^{2,3} + f_3^{1,2} = \tfrac{1}{3}(-f^{1,2}(2A^{13} + B^{23}) - f^{1,3}B^{33} + f^{2,3}(B^{12} + 2C^{13})). \tag{40}$$

We have eight equations for the nine derivatives $f_k^{i,j}$, and by differentiating these we have 18 independent conditions for the 18 second derivatives $f_{k\ell}^{i,j}$. Thus the system closes. A solution is determined by 12 parameters $f_k^{i,j}(\mathbf{x}_0), f_{k\ell}^{i,j}(\mathbf{x}_0)$ at a regular point, and these parameters are constrained by at least eight linearly independent conditions. Thus the solution space, which is obviously of dimension $\geqslant 3$ must be of dimension $\leqslant 4$. We must still apply the conditions that the a^{ijk} are third-order Killing tensors.

Theorem 4: *Let $\mathcal{K}$ be a third-order constant of the motion for a conformally flat superintegrable system with nondegenerate potential V,*

$$\mathcal{K} = \sum_{k,j,i=1}^{3} a^{kji}(x,y,z)p_k p_j p_i + \sum_{\ell=1}^{3} b^{\ell}(x,y,z)p_\ell.$$

Then

$$b^{\ell}(x,y,z) = \sum_{j=1}^{3} f^{\ell,j}(x,y,z)V_j(x,y,z)$$

with $f^{\ell,j}+f^{j,\ell}=0, 1\leqslant \ell, j\leqslant 3$. The a^{ijk}, b^{ℓ} are uniquely determined by the four numbers

$$f^{1,2}(x_0,y_0,z_0), \quad f^{1,3}(x_0,y_0,z_0), \quad f^{2,3}(x_0,y_0,z_0), \quad f_3^{1,2}(x_0,y_0,z_0)$$

at any regular point (x_0,y_0,z_0) of V.

Let

$$\mathcal{S}_1 = \sum a_{(1)}^{kj} p_k p_j + W_{(1)}, \quad \mathcal{S}_2 = \sum a_{(2)}^{kj} p_k p_j + W_{(2)}$$

be second-order constants of the motion for a superintegrable system with nondegenerate potential and let $\mathcal{A}_{(i)}(x,y,z)=\{a_{(i)}^{kj}(x,y,z)\}, i=1, 2$ be 3×3 matrix functions. Then the Poisson bracket of these symmetries is given by

$$\{\mathcal{S}_1,\mathcal{S}_2\} = \sum_{k,j,i=1}^{3} a^{kji}(x,y,z)p_k p_j p_i + b^{\ell}(x,y,z)p_\ell,$$

where

$$f^{k,\ell} = 2\lambda \sum_j (a_{(2)}^{kj} a_{(1)}^{j\ell} - a_{(1)}^{kj} a_{(2)}^{j\ell}). \tag{41}$$

Differentiating, we find

$$f_i^{k,\ell} = 2\lambda \sum_j (\partial_i a_{(2)}^{kj} a_{(1)}^{j\ell} + a_{(2)}^{kj}\partial_i a_{(1)}^{j\ell} - \partial_i a_{(1)}^{kj} a_{(2)}^{j\ell} - a_{(1)}^{kj}\partial_i a_{(2)}^{j\ell}) + G_i f^{k,\ell}. \tag{42}$$

Clearly, $\{\mathcal{S}_1,\mathcal{S}_2\}$ is uniquely determined by the skew-symmetric matrix $[\mathcal{A}_{(2)},\mathcal{A}_{(1)}] \equiv \mathcal{A}_{(2)}\mathcal{A}_{(1)}-\mathcal{A}_{(1)}\mathcal{A}_{(2)}$, hence by the constant matrix $[\mathcal{A}_{(2)}(x_0,y_0,z_0),\mathcal{A}_{(1)}(x_0,y_0,z_0)]$ evaluated at a regular point, and by the number $\mathcal{F}(x_0,y_0,z_0)=f_3^{1,2}(x_0,y_0,z_0)$.

For superintegrable nondegenerate potentials there is a standard structure allowing the identification of the space of second-order constants of the motion with the space S_3 of 3×3 symmetric matrices, as well as identification of the space of third-order constants of the motion with a subspace of the space $K_3\times F$ of 3×3 skew-symmetric matrices K_3, crossed with the line $F=\{\mathcal{F}(\mathbf{x}_0)\}$. Indeed, if $\mathbf{x}_0$ is a regular point then there is a linear correspondence between second-order symmetries $\mathcal{S}$ and their associated symmetric matrices $\mathcal{A}_{(\mathbf{x}_0)}$. Let $\{\mathcal{S}_1,\mathcal{S}_2\}'=\{\mathcal{S}_2,\mathcal{S}_1\}$ be the reversed Poisson bracket. Then the map

$$\{\mathcal{S}_1,\mathcal{S}_2\}' \Leftrightarrow [\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)]$$

is an algebraic homomorphism. Here, $\mathcal{S}_1,\mathcal{S}_2$ are in involution if and only if matrices $\mathcal{A}_{(1)}\times(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)$ commute and $\mathcal{F}(\mathbf{x}_0)=0$. If $\{\mathcal{S}_1,\mathcal{S}_2\}\neq 0$ then it is a third-order symmetry and can be uniquely associated with the skew-symmetric matrix $[\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)]$ and the parameter $\mathcal{F}(\mathbf{x}_0)$. Let $\mathcal{E}^{ij}$ be the 3×3 matrix with a 1 in row i, column j and 0 for every other matrix element. Then the symmetric matrices

$$\mathcal{A}^{(ij)}=\tfrac{1}{2}(\mathcal{E}^{ij}+\mathcal{E}^{ji})=\mathcal{A}^{(ji)},\quad i,j=1,2,3 \tag{43}$$

form a basis for the 6-dimensional space of symmetric matrices. Moreover,

$$[\mathcal{A}^{(ij)},\mathcal{A}^{(k\ell)}]=\tfrac{1}{2}\big(\delta_{jk}\mathcal{B}^{(i\ell)}+\delta_{j\ell}\mathcal{B}^{(ik)}+\delta_{ik}\mathcal{B}^{(j\ell)}+\delta_{i\ell}\mathcal{B}^{(jk)}\big), \tag{44}$$

where

$$\mathcal{B}^{(ij)}=\tfrac{1}{2}(\mathcal{E}^{ij}-\mathcal{E}^{ji})=-\mathcal{B}^{(ji)},\quad i,j=1,2,3.$$

Here $\mathcal{B}^{(ii)}=0$ and $\mathcal{B}^{(12)},\mathcal{B}^{(23)},\mathcal{B}^{(31)}$ form a basis for the space of skew-symmetric matrices. To obtain the commutation relations for the second-order symmetries we need to use relations (42) to compute the parameter $\mathcal{F}(\mathbf{x}_0)$ associated with each commutator $[\mathcal{A}^{(ij)},\mathcal{A}^{(k\ell)}]$. The results are straightforward to compute, using relations (27).

Commutator	$3\mathcal{F}/\lambda$
$[\mathcal{A}^{(12)},\mathcal{A}^{(11)}]=\mathcal{B}^{(21)}$	$-3A^{13}-B^{23}-G_3$
$[\mathcal{A}^{(13)},\mathcal{A}^{(11)}]=\mathcal{B}^{(31)}$	$A^{12}-B^{33}+G_2$
$[\mathcal{A}^{(22)},\mathcal{A}^{(11)}]=0$	$-4A^{23}$
$[\mathcal{A}^{(23)},\mathcal{A}^{(11)}]=0$	$2(A^{22}-A^{33})$
$[\mathcal{A}^{(33)},\mathcal{A}^{(11)}]=0$	$4A^{23}$
$[\mathcal{A}^{(13)},\mathcal{A}^{(12)}]=\frac{1}{2}\mathcal{B}^{(32)}$	$\frac{1}{2}(3B^{12}-A^{22}+3A^{33}-G_1)$
$[\mathcal{A}^{(22)},\mathcal{A}^{(12)}]=\mathcal{B}^{(21)}$	$-3B^{23}-A^{13}-G_3$
$[\mathcal{A}^{(23)},\mathcal{A}^{(12)}]=\frac{1}{2}\mathcal{B}^{(31)}$	$\frac{1}{2}(-3B^{33}-3A^{12}+2B^{22}+G_2)$
$[\mathcal{A}^{(33)},\mathcal{A}^{(12)}]=0$	$2(B^{23}-A^{13})$
$[\mathcal{A}^{(22)},\mathcal{A}^{(13)}]=0$	$-2B^{33}$
$[\mathcal{A}^{(23)},\mathcal{A}^{(13)}]=\frac{1}{2}\mathcal{B}^{(21)}$	$-C^{33}+\frac{1}{2}B^{23}-\frac{1}{2}A^{13}-\frac{1}{2}G_3$
$[\mathcal{A}^{(33)},\mathcal{A}^{(13)}]=\mathcal{B}^{(31)}$	$A^{12}+B^{33}+G_2$
$[\mathcal{A}^{(23)},\mathcal{A}^{(22)}]=\mathcal{B}^{(32)}$	$A^{33}-A^{22}-B^{12}-G_1$
$[\mathcal{A}^{(33)},\mathcal{A}^{(22)}]=0$	$-4A^{23}$
$[\mathcal{A}^{(33)},\mathcal{A}^{(23)}]=\mathcal{B}^{(32)}$	$A^{22}-A^{33}-B^{12}-G_1$

Suppose the dimension of the space of *truly* third-order symmetries generated by commutators of second-order symmetries is 3. This means that whenever the matrices of two second-order symmetries commute at a regular point $\mathbf{x}_0$, so that $f^{1,2}(x_0,y_0,z_0)=f^{1,3}(x_0,y_0,z_0)=f^{2,3}(x_0,y_0,z_0)=0$, then $f_3^{1,2}(x_0,y_0,z_0)=0$. From the table above we see that

$$A^{23}=0,\quad A^{22}=A^{33},\quad B^{23}=A^{13},\quad B^{33}=0.$$

Further, since $[\mathcal{A}^{(12)},\mathcal{A}^{(11)}]-[\mathcal{A}^{(22)},\mathcal{A}^{(12)}]=0$, etc., we have

$$B^{12}=-\tfrac{1}{2}A^{33},\quad B^{22}=2A^{12},\quad C^{33}=2A^{13}.$$

Substituting these results into the integrability conditions for the potential and the symmetries, we find that there exists a function $U(x,y,z)$ such that

$$A^{33}=2(\ln U)_x,\quad A^{12}=-(\ln U)_y,\quad A^{13}=-(\ln U)_z,$$

where

$$U_{xx} = U_{yy} = U_{zz}, \quad U_{xy} = U_{yz} = U_{zx} = 0.$$

Note that U is an instance of the isotropic oscillator potential

$$U = \alpha(x^2 + y^2 + z^2) + \beta x + \gamma y + \delta z.$$

(Further, the defining second-order symmetries for the isotropic oscillator are only weakly functionally independent.) By analogy with the 2D Stäckel transform studied in Ref. 2 (whose 3D form will be studied in our next presentation) it is straightforward to see that the potential of our system is a Stäckel transform by U of the isotropic oscillator potential. By taking the inverse Stäckel transform we can obtain $A^{ij}=B^{ij}=C^{ij}\equiv 0$ for all i,j. Plugging these values into the integrability conditions for the symmetries, we find that $G_1=G_2=G_3=0$ so λ is a constant. Thus the Stäckel transformed system is just the isotropic harmonic oscillator in flat space.

Corollary 5: Let V be a superintegrable nondegenerate potential on a conformally flat space, not a Stäckel transform of the isotropic oscillator. Then the space of truly third-order constants of the motion is four-dimensional and is spanned by Poisson brackets of the second-order constants of the motion.

VI. THE STANDARD BASIS

To gain a deeper understanding of our standard basis structure, it is useful to reformulate the problem of determining the second-order symmetries for a nondegenerate superintegrable potential. We set

$$W(x) = f^1 V_1 + f^2 V_2 + f^3 V_3 + f^{11} V_{11}$$

and substitute this result into $W_i=\lambda\Sigma_{j=1}^3 a^{ij}V_j$. Additionally we must impose the Killing tensor conditions,

$$a_i^{ii} = -G_1 a^{1i} - G_2 a^{2i} - G_3 a^{3i},$$

$$2a_i^{ij} + a_j^{ii} = -G_1 a^{1j} - G_2 a^{2j} - G_3 a^{3j}, \quad i \neq j,$$

$$a_k^{ij} + a_j^{ki} + a_i^{jk} = 0, \quad i,j,k \text{ distinct}.$$

From the expressions for W_i we obtain the equations for the a^{ij},

$$\begin{aligned}
\lambda a^{11} &= f_1^1 + f^2 A^{12} + f^3 A^{13} + f^{11} A^{14},\\
\lambda a^{12} &= f_2^1 + f^1 A^{12} + f^2 A^{22} + f^3 A^{32} + f^{11} A^{24},\\
\lambda a^{13} &= f_3^1 + f^1 A^{13} + f^2 A^{23} + f^3 A^{33} + f^{11} A^{34},\\
\lambda a^{22} &= f_2^2 + f^1 B^{12} + f^2 B^{22} + f^3 B^{32} + f^{11} B^{24},\\
\lambda a^{23} &= f_3^2 + f^1 B^{13} + f^2 B^{23} + f^3 B^{33} + f^{11} B^{34},\\
\lambda a^{33} &= f_3^3 + f^1 C^{13} + f^2 C^{23} + f^3 C^{33} + f^{11} C^{34},
\end{aligned} \tag{45}$$

and the condition on the first derivatives of the f^i,

$$\begin{aligned}
f_2^1 - f_1^2 &= -f^1 A^{12} + f^2 (B^{12} - A^{22}) + f^3 (B^{13} - A^{23}) + f^{11} (B^{14} - A^{24}),\\
f_3^1 - f_1^3 &= -f^1 A^{13} + f^2 (C^{12} - A^{23}) + f^3 (C^{13} - A^{33}) + f^{11} (C^{14} - A^{34}),
\end{aligned} \tag{46}$$

$$f_3^2 - f_2^3 = f^1(C^{12} - B^{13}) + f^2(C^{22} - B^{23}) + f^3(C^{23} - B^{33}) + f^{11}(C^{24} - B^{34}).$$

Note the expressions for f_1^{11} and f_2^{11} in terms of f^1, f^2, f^{11},

$$f_1^{11} = -f^1 - f^{11}(B^{12} - A^{22}), \quad f_2^{11} = -f^2 - f^{11}A^{12}, \quad f_3^{11} = -f^3 - f^{11}A^{13}.$$

Differentiating (46) with respect to each of x_1, x_2, x_3 and substituting (45) into the Killing equations we see that we can express each of the second derivatives of f^1, f^2, f^3 in terms of lower order derivatives of $f^1, f^2 f^3, f^{11}$. Thus the system is in involution at the second derivative level, but not at the first derivative level because we have only three conditions for the nine derivatives f_j^i. We can uniquely determine a symmetry at a regular point by choosing the 10 parameters

$$(f^1, f^2, f^3, f^{11}, f_1^1, f_2^1, f_3^1, f_2^2, f_3^2, f_3^3).$$

The values of f^1, f^2, f^3, f^{11} at the regular point are analogous to the four parameters that we can add to the potentials in the four parameter family. For our standard basis, we fix $(f^1, f^2, f^3, f^{11})_{\mathbf{x}_0} = (0,0,0,0)$. Then from (45) and (46) we have

$$\begin{pmatrix} f_1^1 & f_2^1 & f_3^1 \\ f_1^2 & f_2^2 & f_3^2 \\ f_1^3 & f_2^3 & f_3^3 \end{pmatrix} = \lambda \begin{pmatrix} a^{11} & a^{12} & a^{13} \\ a^{21} & a^{22} & a^{23} \\ a^{31} & a^{32} & a^{33} \end{pmatrix}.$$

Thus we can define a standard set of basis symmetries $\mathcal{S}^{(jk)} = \Sigma a^{ij}(\mathbf{x}) p_i p_j + W^{(ij)}(\mathbf{x})$ corresponding to a regular point $\mathbf{x}_0$ by

$$\frac{1}{\lambda} \begin{pmatrix} f_1^1 & f_2^1 & f_3^1 \\ f_1^2 & f_2^2 & f_3^2 \\ f_1^3 & f_2^3 & f_3^3 \end{pmatrix}_{\mathbf{x}_0} = \begin{pmatrix} a^{11} & a^{12} & a^{13} \\ a^{21} & a^{22} & a^{23} \\ a^{31} & a^{32} & a^{33} \end{pmatrix}_{\mathbf{x}_0} = \mathcal{A}^{(jk)}, \quad W^{(jk)}(\mathbf{x}_0) = 0.$$

The condition on $W^{(jk)}$ is actually four conditions since $W^{(jk)}$ depends on four parameters.

VII. MAXIMUM DIMENSIONS OF THE SPACES OF POLYNOMIAL CONSTANTS

In order to demonstrate the existence and structure of quadratic algebras for 3D superintegrable systems on conformally flat spaces, it is important to compute the dimensions of the spaces of symmetries of these systems that are of orders 4 and 6. These symmetries are necessarily of a special type. The highest order terms in the momenta are independent of the parameters in the potential, while the terms of order 2 less in the momenta are linear in these parameters, those of order 4 less are quadratic, and those of order 6 less are cubic. We will obtain these dimensions exactly, but first we need to establish sharp upper bounds.

A. Quartic constants

We investigate the space of fourth-order constants of the motion

$$\mathcal{F} = \sum_{\ell,k,j,i=1}^{3} a^{\ell kji}(x,y,z) p_\ell p_k p_j p_i + \sum_{m,q=1}^{3} b^{mq}(x,y,z) p_m p_q + W(x,y,z), \tag{47}$$

which must satisfy $\{\mathcal{H}, \mathcal{F}\} = 0$. Here $a^{\ell kji}, b^{mq}$ are symmetric in all indices.

The conditions are

$$a_i^{iiii} = -2 \sum_s \frac{\lambda_s}{\lambda} a^{siii},$$

$$4a_i^{jiii}+a_j^{iiii}=-6\sum_s\frac{\lambda_s}{\lambda}a^{sjii},\quad i\neq j,$$

$$3a_i^{jjii}+2a_j^{iiij}=-\sum_s\frac{\lambda_s}{\lambda}a^{siii}-3\sum_s\frac{\lambda_s}{\lambda}a^{sijj},\quad i\neq j, \tag{48}$$

$$3a_i^{iijk}+a_j^{kiii}+a_k^{jiii}=-6\sum_s\frac{\lambda_s}{\lambda}a^{sijk},\quad i,j,k \text{ distinct},$$

$$2a_i^{ijjk}+2a_j^{jiik}+a_k^{iijj}=-\sum_s\frac{\lambda_s}{\lambda}(a^{skii}+a^{skjj}),\quad i,j,k \text{ distinct},$$

$$b_i^{jk}+b_k^{ij}+b_j^{ki}=6\lambda\sum_s a^{skji}V_s,\quad i,j,k \text{ distinct},$$

$$2b_i^{ij}+b_j^{ii}=6\lambda\sum_s a^{sjii}V_s-\sum_s\frac{\lambda_s}{\lambda}b^{si},\quad i\neq j, \tag{49}$$

$$b_i^{ii}=2\lambda\sum_{s=1}^{3}a^{siii}V_s-\sum_s\frac{\lambda_s}{\lambda}b^{si},$$

and

$$\lambda\sum_s b^{si}V_s=W_i. \tag{50}$$

Clearly, the $a^{\ell kji}$ is a fourth-order Killing tensor. We require the potential V to be superintegrable and nondegenerate. Also we require that the highest order terms, the $a^{\ell kji}$ in the constant of the motion be independent of the four independent parameters in V. However, the b^{mq} must depend linearly and W quadratically on these parameters.

We set

$$b^{jk}=\sum_{\alpha=1}^{4}f^{jk,\alpha}W^{(\alpha)},\quad f^{jk,\alpha}=f^{kj,\alpha},$$

where $W^{(\alpha)}$ is defined by (18). Then conditions (49) take the form

$$\partial_{x_h}f^{jk,\alpha}+\partial_{x_k}f^{hj,\alpha}+\partial_{x_j}f^{kh,\alpha}-\lambda a^{\alpha hjk}=\cdots, \tag{51}$$

where the right-hand side depends only on the $f^{jk,\alpha}, 1\leqslant j,k,h\leqslant 3$ and we set $a^{4hjk}\equiv 0$. From the integrability conditions $\partial_{x_j}(\partial W/\partial x_i)=\partial_{x_i}(\partial W/\partial x_j), i\neq j$ for Eq. (50) we obtain the conditions

$$\partial_{x_j}f^{\beta k,\alpha}+\partial_{x_j}f^{\alpha k,\beta}-\partial_{x_k}f^{\beta j,\alpha}-\partial_{x_k}f^{\alpha j,\beta}=\cdots, \tag{52}$$

where the right-hand side depends only on the $f^{jk,\alpha}, j\neq k, 1\leqslant\alpha,\beta\leqslant 4$ and we set $f^{4j,\alpha}\equiv 0$.

There are 30 independent equations (51) with $\alpha\neq 4$ and we use 15 of these to define the 15 components a^{ihjk} as linear combinations of $\partial_{x_h}f^{jk,\alpha}$ and $f^{jk,\alpha}$. We can then eliminate the a^{ihjk} from the remaining 15 equations to obtain 15 conditions relating $\partial_{x_h}f^{jk,\alpha}$ and $f^{jk,\alpha}$. There are 18 terms of the form $\partial_{x_h}f^{jk,4}$. Equations (52) with $\alpha=\beta=4$ are satisfied identically. There are nine equations (52) with $\beta=4, 1\leqslant\alpha\leqslant 3$ and 10 equations (51) with $\alpha=4$. Thus all terms of the form $\partial_{x_h}f^{jk,4}$ can be expressed as linear combinations of $f^{jk,\alpha}$. There are a total of 54 distinct terms of the form

$\partial_{x_h} f^{jk,m}, 1 \leqslant h,j,k,m \leqslant 3$. We have seen that there are 15 conditions on these terms remaining from (51); there are an additional 18 such conditions from (52) with $\alpha,\beta \neq 4$. Thus there is a shortfall of 21 conditions on the first derivatives $\partial_{x_h} f^{jk,m}$.

There are a total of 108 distinct terms of the form $\partial_{x_h}\partial_{x_\ell} f^{jk,m}$ with $1 \leqslant hj,k,\ell,m \leqslant 3$. Differentiating with respect to x_1, x_2, and x_3 the 15 first-order conditions of (51), from which the a^{ihjk} have been eliminated, we obtain 45 independent conditions on these second derivatives. Differentiating each of our expressions for the a^{ihjk} and substituting into equations (48) we find 63 additional conditions on the second derivatives. This allows us to express each second-order derivative as a linear combination of lower order derivatives, Thus the system is in involution. Also, we can differentiate the 18 equations from (52) with $\alpha,\beta \neq 4$ to obtain 54 additional conditions on the second derivatives (which may or may not be independent of those already found).

We conclude that any fourth-order symmetry is uniquely determined by the values $f^{jk,\alpha}(\mathbf{x}_0)$ and a subset of 21 of the values $\partial_{x_h} f^{jk,m}(\mathbf{x}_0)$ at a regular point $\mathbf{x}_0$. Note that by adding an appropriate linear combination of purely second-order symmetries to the fourth-order symmetry we can achieve $f^{jk,\alpha}(\mathbf{x}_0)=0$ for all j,k,α, so the maximum possible dimension of the space of purely fourth-order symmetries for a nondegenerate potential is 21.

B. Sixth-order constants

We take the general sixth-order symmetry for a nondegenerate potential to be of the form

$$\mathcal{L} = \sum a^{hijklt} p_h p_i p_j p_k p_l p_t + \sum b^{hijk} p_h p_i p_j p_k + \sum c^{ij} p_i p_j + W,$$

where the functions $a^{hijklt}, b^{hijk}, c^{ij}$ are symmetric in all indices. Here a^{hijklt} is independent of the parameters $V_\alpha, \alpha = 1,\ldots,4$, b^{hijk} is a homogeneous quadratic polynomial in the $W^{(\alpha)}$, c^{ij} is homogeneous fourth order, and W is homogeneous sixth order in the $W^{(\alpha)}$. The Poisson bracket of $\mathcal{H}$ and $\mathcal{L}$ is polynomial in the momenta and the parameters $W^{(\alpha)}$ and for it to vanish at a regular point, each coefficient of this polynomial must vanish separately. The conditions are (for $1 \leqslant i,j,k \leqslant k$ and i,j,k pairwise distinct and for $s=1, 2, 3$)

$$a_i^{iiiiii} = -3\sum_s \frac{\lambda_s}{\lambda} a^{siiiii},$$

$$6a_i^{jiiiii} + a_j^{iiiiii} = -15\sum_s \frac{\lambda_s}{\lambda} a^{sjiiii},$$

$$5a_i^{jjiiii} + 2a_j^{jiiiii} = -\sum_s \frac{\lambda_s}{\lambda} a^{siiiii} - 10\sum_s \frac{\lambda_s}{\lambda} a^{sjjiii},$$

$$4a_i^{jjjiii} + 3a_j^{jjiiii} = -3\sum_s \frac{\lambda_s}{\lambda} a^{sjiiii} - 12\sum_s \frac{\lambda_s}{\lambda} a^{sjjjii},$$

$$5a_i^{jkiiii} + a_k^{jiiiii} + a_j^{kiiiii} = -10\sum_s \frac{\lambda_s}{\lambda} a^{sjkiii},$$

$$4a_i^{jjkiii} + 2a_j^{jkiiii} + a_k^{jjiiii} = -6\sum_s \frac{\lambda_s}{\lambda} a^{sjjkii} - \sum_s \frac{\lambda_s}{\lambda} a^{skiiii},$$

$$3a_i^{jjkkii}+2a_j^{jkkiii}+2a_k^{kjjiii}=-90\sum_s\frac{\lambda_s}{\lambda}a^{sijjkk}-30\sum_s\frac{\lambda_s}{\lambda}a^{skkiii}-30\sum_s\frac{\lambda_s}{\lambda}a^{sjjiii}, \tag{53}$$

$$b_i^{iiii}=3\lambda\sum_s a^{siiiii}W^{(s)}-2\sum_s\frac{\lambda_s}{\lambda}b^{siii},$$

$$b_j^{iiii}+4b_i^{jiii}=15\lambda\sum_s a^{sjiiii}W^{(s)}-6\sum_s\frac{\lambda_s}{\lambda}b^{sjii},$$

$$2b_j^{iiij}+3b_i^{jjii}=15\lambda\sum_s a^{sjjiii}W^{(s)}-\sum_s\frac{\lambda_s}{\lambda}(2b^{siii}+6b^{sjji}), \tag{54}$$

$$b_j^{iiik}+b_k^{iiij}+3b_i^{ijjk}=15\lambda\sum_s a^{siiijk}W^{(s)}-6\sum_s\frac{\lambda_s}{\lambda}b^{sijk},$$

$$b_k^{ijjj}+2b_j^{ijjk}+2b_i^{ijjk}=15\lambda\sum_s a^{siijjk}W^{(s)}-2\sum_s\frac{\lambda_s}{\lambda}(b^{siik}+b^{sjjk}),$$

$$c_i^{ii}=2\lambda\sum_s b^{siii}W^{(s)}-\sum_s\frac{\lambda_s}{\lambda}c^{si},$$

$$2c_i^{ij}+c_j^{ii}=6\lambda\sum_s b^{siij}W^{(s)}-\sum_s\frac{\lambda_s}{\lambda}c^{si}, \tag{55}$$

$$c_k^{ij}+c_j^{ik}+c_i^{kj}=6\lambda\sum_s b^{sijk}W^{(s)},$$

$$\sum_s(c_j^{si}-c_i^{sj})W^{(s)}=\frac{1}{\lambda}\sum_s(c^{sj}(\lambda W^{(s)})_i-c^{si}(\lambda W^{(s)})_j). \tag{56}$$

We set

$$c^{ij}=\sum_{\alpha,\beta=1}^{4}c^{ij,\alpha\beta}W^{(\alpha)}W^{(\beta)},\quad c^{ij,\alpha\beta}=c^{ij,\beta\alpha}.$$

There are $6\times10=60$ independent terms $c^{ij,\alpha\beta}$. There are $60\times3=180$ terms $c_k^{ij,\alpha\beta}$ of which 108 are of the form $c_k^{ij,st}$, 54 are of the form $c_k^{ij,4s}$, and 18 are of the form $c_k^{ij,44}$. Equations (56) give 30 conditions relating the derivatives $c_k^{ij,\alpha\beta}$, 18 conditions relating the derivatives $c_k^{ij,4s}$, and 8 conditions relating the derivatives $c_k^{ij,44}$. The 100 independent equations (55) allow us to solve for the 15 terms $b^{ijk\ell,4}$ and the 45 terms $b^{ijk\ell,s}$ where

$$b^{ijk\ell}=\sum_{\alpha=1}^{4}b^{ijk\ell,\alpha}W^{(\alpha)}.$$

Further, they yield 10 conditions relating the derivatives $c_k^{ij,44}$, 15 equations relating the derivatives $c_k^{ij,4s}$, and 15 equations relating the derivatives $c_k^{ij,st}$. It follows that all 18 terms of the form $c_k^{ij,44}$

can be expressed as linear combinations of the $c^{ij,\alpha\beta}$. There are a total of 78 conditions on the remaining 162 terms.

There are 360 terms $c_{k\ell}^{ij,\alpha\beta}$ of which we can ignore the 36 terms $c_{k\ell}^{ij,44}$. The 84 equations (54) allow us to solve for the 28 terms $a^{hijk\ell m}$ and give 21 conditions for $c_{k\ell}^{ij,4s}$ and 35 conditions for $c_{k\ell}^{ij,st}$. Further differentiating our previously obtained 78 conditions on the first derivatives we obtain $78\times 3=234$ conditions, 99 on $c_{k\ell}^{ij,st}$ and 135 independent conditions on $c_{k\ell}^{ij,st}$. It follows that all 108 terms of the form $c_{k\ell}^{ij,4s}$ can be expressed as linear combinations of lower order terms and there is a total of $35+135=160$ independent conditions on the 216 terms $c_{k\ell}^{ij,st}$. Finally, differentiating the previous conditions obtained for the $c_{k\ell}^{ij,st}$ and using the 31 equations (53) we obtain at least 360 independent conditions for the 360 terms $c_{k\ell m}^{ij,st}$. Thus the maximal number of parameters in a solution of the sixth order symmetry equations is $60+84+56=200$, excluding the 35 independent additive terms $W^{(\alpha)}W^{(\beta)}W^{(\gamma)}$.

We know that the dimension of the space of second-order symmetries for a superintegrable system with nondegenerate potential is 6. Now let us suppose (as we will prove) the dimension of the space of quartic symmetries is 21. Then there are exactly $84=21\times 4$ independent sixth-order symmetries that are also quartic symmetries, and $6\times 10=60$ independent sixth-order symmetries that are also quadratic. Thus the maximal possible dimension of the space of truly sixth-order symmetries is $200-84-60=56$. We will show that this bound of 56 is actually achieved.

VIII. BASES FOR THE FOURTH- AND SIXTH-ORDER CONSTANTS OF THE MOTION

It follows from Sec. VII A that, for a superintegrable system with nondegenerate potential, the dimension of the space of truly fourth-order constants of the motion is at most 21. Note from Sec. VI that at any regular point $\mathbf{x}_0$, we can define a standard basis of six second-order constants of the motion $\mathcal{S}^{(ij)}=A^{(ij)}+W^{(ij)}$ where the quadratic form $A^{(ij)}$ has matrix $\mathcal{A}^{(ij)}$ defined by (43) and $W^{(ij)}$ is the potential term with $W^{(ij)}(\mathbf{x}_0)\equiv 0$ identically in the parameters $W^{(\alpha)}$. By taking homogeneous polynomials of order two in the standard basis symmetries we can construct fourth order symmetries.

Question: Is every fourth-order symmetry a polynomial in the second-order symmetries?

Answer: Yes Also the dimension of the space of fourth-order symmetries is exactly 21.

Theorem 5: *The 21 distinct standard monomials* $\mathcal{S}^{(ij)}\mathcal{S}^{(jk)}$, *defined with respect to a regular point* $\mathbf{x}_0$, *form a basis for the space of fourth-order symmetries*.

Proof: We choose the basis symmetries in the form

$$(1)\quad (\mathcal{S}^{(ii)})^2,\ \mathcal{S}^{(ii)}\mathcal{S}^{(ij)},\ \mathcal{S}^{(ii)}\mathcal{S}^{(jj)},\ \mathcal{S}^{(ii)}\mathcal{S}^{(jk)}$$

$$(2)\quad \mathcal{S}^{(ii)}\mathcal{S}^{(jj)}-(\mathcal{S}^{(ij)})^2$$

$$(3)\quad \mathcal{S}^{(ij)}\mathcal{S}^{(ik)}-\mathcal{S}^{(ii)}\mathcal{S}^{(jk)}$$

for $i,j,k=1,\ldots,3$ i,j,k pairwise distinct (three possibilities).

If we evaluate this set at the regular point the first class of symmetries will be $p_i^4, p_i^3p_jp_i^2p_j^2, p_i^2p_jp_k$, respectively, whereas the last two classes of symmetries will vanish. Thus the only possible linear dependencies are those relating the six symmetries

$$F^{(12)}=\mathcal{S}^{(11)}\mathcal{S}^{(22)}-(\mathcal{S}^{(12)})^2,\quad F^{(13)}=\mathcal{S}^{(11)}\mathcal{S}^{(33)}-(\mathcal{S}^{(13)})^2,\quad F^{(23)}=\mathcal{S}^{(22)}\mathcal{S}^{(33)}-(\mathcal{S}^{(23)})^2,$$

$$G^{(23)}=\mathcal{S}^{(12)}\mathcal{S}^{(13)}-\mathcal{S}^{(11)}\mathcal{S}^{(23)},\quad G^{(13)}=\mathcal{S}^{(12)}\mathcal{S}^{(23)}-\mathcal{S}^{(22)}\mathcal{S}^{(13)},\quad G^{(12)}=\mathcal{S}^{(13)}\mathcal{S}^{(23)}-\mathcal{S}^{(33)}\mathcal{S}^{(12)}.$$

The second-order terms in the symmetry $F^{(ij)}$ are

$$\mathcal{F}^{(ij)}=\mathcal{A}^{(ii)}W^{(jj)}+\mathcal{A}^{(jj)}W^{(ii)}-2\mathcal{A}^{(ij)}W^{(ij)}.$$

Now $\mathcal{F}^{(ij)}$ vanishes at the regular point but its derivatives at the point are

$$\mathcal{F}_i^{(ij)} = p_j^2 V_i - p_i p_j V_j, \quad \mathcal{F}_j^{(ij)} = p_i^2 V_j - p_j p_i V_i, \quad \mathcal{F}_k^{(ij)} = 0.$$

Similarly the second-order terms in the symmetry $G^{(jk)}$ are

$$\mathcal{G}^{(jk)} = \mathcal{A}^{(ij)} W^{(ik)} + \mathcal{A}^{(ik)} W^{(ij)} - \mathcal{A}^{(ii)} W^{(jk)} - \mathcal{A}^{(jk)} W^{(ii)}.$$

Again $\mathcal{G}^{(ij)}$ vanishes at the regular point but its derivatives at the point are

$$\mathcal{G}_i^{(jk)} = \tfrac{1}{2} p_i p_j V_k + \tfrac{1}{2} p_i p_k V_j - p_j p_k V_i, \quad \mathcal{G}_j^{(jk)} = \tfrac{1}{2} p_i p_k V_i - \tfrac{1}{2} p_i^2 V_k, \quad \mathcal{G}_k^{(jk)} = \tfrac{1}{2} p_i p_j V_i - \tfrac{1}{2} p_i^2 V_j.$$

Since V_1, V_2, V_3 are arbitrary, it is clear that these six terms are linearly independent. Thus the 21 symmetries form a basis. Q.E.D.

Now we know that for a superintegrable system with nondegenerate potential the space of purely fourth-order constants of the motion is exactly 21. Thus from Sec. VII B the dimension of the space of purely sixth-order constants of the motion is at most 56. Again we shall show that the 56 independent homogeneous third-order polynomials in the symmetries $\mathcal{S}^{(ij)}$ form a basis for this space.

At the sixth-order level we have the symmetries

$$(1) \quad (\mathcal{S}^{(ii)})^3,\ (\mathcal{S}^{(ii)})^2 \mathcal{S}^{(ij)},\ (\mathcal{S}^{(ii)})^2 \mathcal{S}^{(jj)},\ (\mathcal{S}^{(ii)})^2 \mathcal{S}^{(jk)}$$

for $i,j,k=1,\ldots,3$ i,j,k pairwise distinct (18 possibilities),

$$(2) \quad \mathcal{S}^{(ii)} \mathcal{S}^{(ij)} \mathcal{S}^{(jj)},\ \mathcal{S}^{(ii)} \mathcal{S}^{(ij)} \mathcal{S}^{(jk)},\ \mathcal{S}^{(ii)} \mathcal{S}^{(jj)} \mathcal{S}^{(kk)}$$

$$(3) \quad \mathcal{S}^{(\ell m)} (\mathcal{S}^{(ii)} \mathcal{S}^{(jj)} - (\mathcal{S}^{(ij)})^2)$$

$$(4) \quad \mathcal{S}^{(\ell m)} \left(\mathcal{S}^{(ij)} \mathcal{S}^{(ik)} - \mathcal{S}^{(ii)} \mathcal{S}^{(jk)} \right)$$

for $i,j,k=1,\ldots,3$ i,j,k pairwise distinct (18 possibilities).

Theorem 6: *The 56 distinct standard monomials* $\mathcal{S}^{(hi)} \mathcal{S}^{(jk)} \mathcal{S}^{(\ell m)}$, *defined with respect to a regular* $\mathbf{x}_0$, *form a basis for the space of sixth-order symmetries*.

Proof: Rather than using the monomials directly we choose the polynomials in the forms (1)–(4) above. Suppose some linear combination $\mathcal{C}$ of these 56 polynomials has identically vanishing sixth-order terms. This implies immediately that the coefficients of the first 28 polynomials are zero. Thus $\mathcal{C}$ must be a linear combination of the six fourth-order symmetries $F^{(ij)}, G^{(ij)}$ of Theorem 5. Now the first derivatives of the second-order terms in $\mathcal{C}$ all vanish at $\mathbf{x}_0$ so by the proof of Theorem 5 the linear combination of fourth-order basis symmetries must vanish. Thus we must have $\mathcal{C} \equiv 0$. Then evaluating the expressions

$$\partial_{x_h} \mathcal{C}(\mathbf{x}_0) = 0, \quad \partial^2_{x_h x_\ell} \mathcal{C}(\mathbf{x}_0) = 0.$$

and making use of the expressions for $\mathcal{F}^{ij}, \mathcal{G}^{ij}$ in the proof of Theorem 5 it is straightforward to show that the coefficients of all 28 terms in $\mathcal{C}$ must vanish. The 56 terms are linearly independent and all nonzero linear combinations are truly sixth order. Q.E.D.

We conclude that the quadratic algebra closes.

A recursive parametrization of unitary matrices

C. Jarlskog[a)]
Division of Mathematical Physics LTH, Lund University, Box 118, S-22100 Lund, Sweden

(Received 18 May 2005; accepted 25 July 2005; published online 11 October 2005)

A simple recursive scheme for parametrization of n-by-n unitary matrices is presented. The n-by-n matrix is expressed as a product containing the $(n-1)$-by-$(n-1)$ matrix and a unitary matrix that contains the additional parameters needed to go from $n-1$ to n. The procedure is repeated to obtain recursion formulas for n-by-n unitary matrices. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2038607]

I. THE PARAMETRIZATION

It has been known for a long time that unitary transformations play a central role in physics. An excellent example is Wigner's paper of 1939,[1] which has had a great impact on the development of physics and is still important.

It is also a known fact that a general n-by-n unitary matrix $X^{(n)}$ may be expressed as a product of three unitary matrices,

$$X^{(n)} = \Phi^{(n)}(\vec{\alpha}) V^{(n)} \Phi^{(n)}(\vec{\beta}), \tag{1}$$

where the matrices Φ are diagonal unitary matrices,

$$\Phi^{(n)}(\vec{\alpha}) = \begin{pmatrix} e^{i\alpha_1} & & & & \\ & e^{i\alpha_2} & & & \\ & & \cdot & & \\ & & & \cdot & \\ & & & & e^{i\alpha_n} \end{pmatrix}. \tag{2}$$

$\Phi(\vec{\beta})$ is defined analogously; the α's and β's being real. The matrix $X^{(n)}$ has n^2 real parameters. In the following, for simplicity, the word parameter stands for real parameter. The quantities $\vec{\alpha}$ and $\vec{\beta}$ take care of $2n-1$ parameters of $X^{(n)}$ because only the sums $\alpha_i+\beta_j$ enter, where i and j run from 1 to n. The remaining $(n-1)^2$ parameters reside in the nontrivial matrix $V^{(n)}$, which is the subject of this study.

We start by putting $V^{(1)}=1$, whereby $X^{(1)}=e^{i(\alpha_1+\beta_1)}$ is the most general one-by-one unitary "matrix." For $n \geqslant 2$, we write the matrix $V^{(n)}$ in the form

$$V^{(n)} = \begin{pmatrix} V^{(n-1)} + (1-c_n)|A^{(n-1)}\rangle\langle B^{(n-1)}| & s_n|A^{(n-1)}\rangle \\ s_n\langle B^{(n-1)}| & c_n \end{pmatrix}. \tag{3}$$

Here we have introduced an angle denoted by θ_n and have used the common notation $s_n=\sin\theta_n$, $c_n=\cos\theta_n$. The complex vectors "$A^{(n-1)}$" and "$B^{(n-1)}$" each have $n-1$ components, i.e.,

a)Electronic mail: cecilia.jarlskog@matfys.lth.se

$$|A^{(n-1)}\rangle = \begin{pmatrix} a_1^{(n-1)} \\ a_2^{(n-1)} \\ \cdot \\ \cdot \\ a_{n-1}^{(n-1)} \end{pmatrix}, \quad |B^{(n-1)}\rangle = \begin{pmatrix} b_1^{(n-1)} \\ b_2^{(n-1)} \\ \cdot \\ \cdot \\ b_{n-1}^{(n-1)} \end{pmatrix}. \tag{4}$$

Furthermore,

$$\langle B^{(n-1)}| = (b_1^{(n-1)\star}, b_2^{(n-1)\star}, \ldots, b_{n-1}^{(n-1)\star}) \tag{5}$$

and

$$(|A^{(n-1)}\rangle\langle B^{(n-1)}|)_{ij} \equiv a_i^{(n-1)} b_j^{(n-1)\star}. \tag{6}$$

$A^{(n-1)}$ and $B^{(n-1)}$ are not arbitrary but are required to satisfy the conditions

$$\langle A^{(n-1)}|A^{(n-1)} = 1, \quad |B^{(n-1)}\rangle = -V^{(n-1)\dagger}|A^{(n-1)}\rangle, \tag{7}$$

whereby

$$\langle B^{(n-1)}|B^{(n-1)} = 1, \quad |A^{(n-1)}\rangle = -V^{(n-1)}|B^{(n-1)}\rangle. \tag{8}$$

We can easily check that if the matrix $V^{(n-1)}$, in Eq. (3), is unitary so is $V^{(n)}$. In order for $V^{(n)}$ to be the most general n-by-n unitary matrix, modulus the phase matrices Φ, it must have the required number of parameters. The vector $A^{(n-1)}$, having $n-1$ complex components, would seem to represent $2(n-1)$ parameters. But it has only $2(n-2)$ because it is normalized and its overall phase can be absorbed into the matrices Φ, i.e., the transformation

$$|A^{(n-1)}\rangle \to e^{i\eta}|A^{(n-1)}\rangle \tag{9}$$

yields

$$|B^{(n-1)}\rangle \to e^{i\eta}|B^{(n-1)}\rangle \tag{10}$$

and

$$V^{(n)} \to \Phi(0,0,\ldots,e^{-i\eta})V^{(n)}\Phi(0,0,\ldots,e^{i\eta}). \tag{11}$$

The parameter counting, therefore, goes as follows. On the left-hand side of Eq. (3) we need to have $(n-1)^2$ parameters. On the right-hand side, we have $(n-2)^2$ from $V^{(n-1)}$ and $2(n-2)$ from the vector $A^{(n-1)}$. Thus, together with the angle θ_n, the number of parameters is $(n-2)^2+2(n-2)+1$ which equals $(n-1)^2$ as required.

We may use the relation (7) between $A^{(n-1)}$ and $B^{(n-1)}$ to rewrite the matrix $V^{(n)}$ in terms of either $A^{(n-1)}$ or $B^{(n-1)}$. In terms of $A^{(n-1)}$, we have

$$V^{(n)} = \begin{pmatrix} 1-(1-c_n))|A^{(n-1)}\rangle\langle A^{(n-1)}| & s_n|A^{(n-1)}\rangle \\ -s_n\langle A^{(n-1)}| & c_n \end{pmatrix} \begin{pmatrix} V^{(n-1)} & 0 \\ 0 & 1 \end{pmatrix} \equiv A_{n,n-1} \begin{pmatrix} V^{(n-1)} & 0 \\ 0 & 1 \end{pmatrix}. \tag{12}$$

While writing the matrix in terms of $B^{(n-1)}$ yields

$$V^{(n)} = \begin{pmatrix} V^{(n-1)} & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1-(1-c_n))|B^{(n-1)}\rangle\langle B^{(n-1)}| & -s_n|B^{(n-1)}\rangle \\ s_n\langle B^{(n-1)}| & c_n \end{pmatrix} \equiv \begin{pmatrix} V^{(n-1)} & 0 \\ 0 & 1 \end{pmatrix} B_{n,n-1}. \tag{13}$$

These relations allow for a systematic construction of unitary matrices order by order. By repeating the above noted procedure for the matrix $V^{(n-1)}$ in terms of $A^{(n-2)}$ and $B^{(n-2)}$, and following down the chain we find the recursion formulas that we are looking for,

$$V^{(n)} = A_{n,n-1}A_{n,n-2}\ldots A_{n,2}A_{n,1}, \tag{14}$$

$$V^{(n)} = B_{n,1}B_{n,2}\ldots B_{n,n-2}B_{n,n-1}. \tag{15}$$

The matrices $A_{n,n-1}$ and $B_{n,n-1}$ were previously defined in Eqs. (12) and (13). For $j<n-1$ we have

$$A_{n,j} = \begin{pmatrix} \begin{pmatrix} 1-(1-c_{j+1}))|A^{(j)}\rangle\langle A^{(j)}| & s_{j+1}|A^{(j)}\rangle \\ -s_{j+1}\langle A^{(j)}| & c_{j+1} \end{pmatrix} & 0 \\ 0 & I_{n-j-1} \end{pmatrix}, \tag{16}$$

$$B_{n,j} = \begin{pmatrix} \begin{pmatrix} 1-(1-c_{j+1}))|B^{(j)}\rangle\langle B^{(j)}| & -s_{j+1}|B^{(j)}\rangle \\ s_{j+1}\langle B^{(j)}| & c_{j+1} \end{pmatrix} & 0 \\ 0 & I_{n-j-1} \end{pmatrix}. \tag{17}$$

Here I_{n-j-1} is the unit matrix of order $n-j-1$. The two unitary matrices $A_{n,j}$ and $B_{n,j}$ are related by

$$A_{n,j} = \begin{pmatrix} V^{(j)} & 0 \\ 0 & I_{n-j} \end{pmatrix}, \quad B_{n,j}\begin{pmatrix} V^{(j)\dagger} & 0 \\ 0 & I_{n-j} \end{pmatrix}. \tag{18}$$

II. SIMPLE EXAMPLES

The simplest case is $n=2$ for which we take $|A^{(1)}\rangle=1$ whereby $|B^{(1)}\rangle=-1$. Using $V^{(1)}=1$ we obtain, from Eqs. (12) and (13),

$$V^{(2)} = A_{2,1} = B_{2,1} = \begin{pmatrix} c_2 & s_2 \\ -s_2 & c_2 \end{pmatrix}. \tag{19}$$

This is the familiar rotation matrix $R_2(\theta_2), \theta_2$ being the rotation angle in two dimensions.

The next simplest case is $n=3$ for which we may either use the "mixed form" or the pure forms. For the mixed form we have

$$V^{(3)} = \begin{pmatrix} R_2(\theta) + (1-c_3)|A^{(2)}\rangle\langle B^{(2)}| & s_3|A^{(2)}\rangle \\ s_3\langle B^{(2)}| & c_3 \end{pmatrix}. \tag{20}$$

Here $R_2(\theta)$ is again the rotation matrix in Eq. (19) and we may put

$$|A^{(2)}\rangle = \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}, \quad |B^{(2)}\rangle = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix}. \tag{21}$$

From Eq. (7) it follows that

$$|A^{(2)}\rangle = -R_2(\theta)|B^{(2)}\rangle, \quad |B^{(2)}\rangle = -R_2(-\theta)|A^{(2)}\rangle. \tag{22}$$

Hence these vectors represent two parameters, for example

$$|A^{(2)}\rangle = \begin{pmatrix} \cos\gamma \\ \sin\gamma e^{i\delta} \end{pmatrix}, \tag{23}$$

where γ and δ are real. The pure forms are also obtained very simply, for example

$$V^{(3)} = \begin{pmatrix} 1-(1-c_3)|A^{(2)}\rangle\langle A^{(2)}| & s_3|A^{(2)}\rangle \\ -s_3\langle A^{(2)}| & c_3 \end{pmatrix}\begin{pmatrix} R_2(\theta_2) & 0 \\ 0 & 1 \end{pmatrix}, \tag{24}$$

where $A^{(2)}$ is as defined in Eq. (23). Evidently, depending on the application one has in mind some choices may be more convenient than others. This is demonstrated in Refs. 2 and 3 which deal

with the so-called quark and lepton mixing matrices. The essential point is that $V^{(3)}$ is described in a rather simple fashion by four parameters as it should be. For the case of $n=4$ we could, for example, take $A^{(3)}$ to be

$$|A^{(3)}\rangle = \begin{pmatrix} \cos\rho \\ \sin\rho\cos\sigma e^{i\delta_1} \\ \sin\rho\sin\sigma e^{i\delta_2} \end{pmatrix}, \tag{25}$$

where ρ, σ, δ_1, and δ_2 are the four parameters needed to define the most general $A^{(3)}$.

In principle, the above recursive procedure may "easily" be extended to much larger n with the help of computers.

Z. N. Zhu[a)]
Departamento de Matemáticas, Universidad de Salamanca, Plaza de la Merced 1, 37008 Salamanca, Spain

(Received 1 April 2005; accepted 29 July 2005; published online 13 October 2005)

We give a new nonisospectral generalization of the Volterra lattice equation to 2+1 dimensions. We use this to construct a new nonisospectral lattice hierarchy in 2+1 dimensions, along with its underlying linear problem. Reductions yield a variety of new integrable hierarchies, including generalizations of known discrete Painlevé hierarchies, all along with their corresponding linear problems. This represents an extension of previously developed techniques to the discrete case. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2041347]

I. INTRODUCTION

The representation of a nonlinear system as the compatibility condition of linear equations is an idea that is central to our understanding of the word "integrability." This concept dates to the introduction of the inverse scattering transform (IST) as a tool for solving the initial value problem, under certain conditions on initial data, for completely integrable partial differential equations (PDEs).[1–3] Of course, this idea is not only useful within the context of PDEs in 1+1 dimensions: it has also been succesfully applied to partial differential equations in multidimensions,[4,5] to differential-difference (or lattice) equations,[6] and to ordinary differential equations,[7] as well as to many other integrable nonlinear systems.

Among our aims in the present paper, we extend ideas related to a particular kind of integrable nonlinear system, namely those having a corresponding *nonisospectral* scattering problem. The first example of a nonlinear equation having such a scattering problem is due to Calogero[8] (see also Ref. 9); since then, a great many papers have been published on such systems, both continuous, e.g. Refs. 10–14, and discrete, e.g., Refs. 15 and 16. In a series of recent papers[17–19] (see also Ref. 20), two of the current authors have shown how certain nonisospectral extensions of well-known integrable equations, to 2+1 dimensions, can be understood as embodying information about the entire hierarchy associated to that integrable equation. This involves interpreting the nonisospectral version of the PDE as defining a recursion relation between successive members of the hierarchy. Thus far, this idea has been used within the context of continuous systems. However, its application to lattice systems would require seeking an equation of the form

$$u_t^{(n)} = R^{(n)} u_\tau^{(n)}, \quad u^{(n)} = u(n,t,\tau), \tag{1}$$

where n is a discrete variable and t and τ are continuous variables, and where $R^{(n)}$ is a discrete recursion operator—together with an underlying non-isospectral linear problem. To the best of our knowledge, such equations are unknown. Here we give an example of such an equation, and show how it can be used to extend the approach used in Refs. 17–20 to the discrete case. In this way we

[a)]Permanent address: Department of Mathematics, Shanghai Jiao Tong University, Shanghai 200030, People's Republic of China.

obtain a new hierarchy of 2+1-dimensional nonisospectral lattice equations.

However, in addition to the role played by equations having nonisospectral scattering problems in the construction of integrable hierarchies and their associated linear problems, there are many other reasons why they are of interest, as discussed in Ref. 18. One such is the link between nonisospectral scattering problems for PDEs or lattice equations, and linear problems for ODEs or discrete equations, respectively.[21] This link, in the case of continuous equations, was exploited, and generalized, in Refs. 17–20. Another of our aims in this paper is to extend these results to the discrete case, by considering reductions to hierarchies of discrete equations.

In fact, the consideration of reductions for the 2+1-dimensional lattice hierarchy constructed here appears to yield richer results than for 2+1-dimensional PDE hierarchies, in the sense that not only do we obtain hierarchies of lattice equations and discrete equations (where previously reductions were to hierarchies of PDEs and ODEs), but also hierarchies of differential-delay equations. The consideration of such reductions is a third aim in our paper.

The layout of our paper is as follows. In Sec. II we construct an equation of the form (1), or, in fact, a generalization thereof, along with an underlying nonisospectral linear problem. This 2+1-dimensional lattice equation is based on the Volterra equation, but is distinct from the 2+1-dimensional Volterra equation considered in Ref. 22. We recall that the Volterra equation itself arises in plasma physics and population dynamics. In Sec. III we use our 2+1-dimensional generalization of the Volterra equation to construct a new 2+1-dimensional lattice hierarchy. In Sec. IV we consider reductions to lattice and differential-delay hierarchies, and in Sec. V to hierarchies of discrete equations. A variety of new results are obtained, including novel differential-delay hierarchies and a new generalized discrete first Painlevé (dP_I) hierarchy. We summarize our results in the Conclusions (Sec. VI).

II. A 2+1 NONISOSPECTRAL VOLTERRA LATTICE EQUATION

We begin by considering a generic nonisospectral discrete linear problem of order p, in 2+1 dimensions (with n a discrete variable, and t and τ continuous variables), of the form

$$E\phi^{(n)} = F^{(n)}\phi^{(n)}, \tag{2}$$

$$\phi_t^{(n)} = \omega(\lambda)\phi_\tau^{(n)} + G^{(n)}\phi^{(n)}, \tag{3}$$

where $\phi^{(n)}=\phi(n,t,\tau)$ is a p vector, $F^{(n)}$ and $G^{(n)}$ are $p\times p$ matrices, E is the shift operator, i.e., $Ez^{(n)}=z^{(n+1)}$, and $\lambda(t,\tau)$ satisfies a nonisospectral condition,

$$\lambda_t = \omega(\lambda)\lambda_\tau + \sum_{j=r}^{s} \gamma_j \lambda^j, \quad \gamma_j = \gamma_j(t,\tau), \tag{4}$$

for some integers r, s. In later sections the notation ∂_x will be used to denote a partial derivative with respect to x, and similarly for other independent variables. The compatibility condition of the system (2) and (3) is

$$F_t^{(n)} - \omega(\lambda)F_\tau^{(n)} + F^{(n)}G^{(n)} - G^{(n+1)}F^{(n)} = 0, \tag{5}$$

or equivalently,

$$F_t^{(n)} - \omega(\lambda)F_\tau^{(n)} - (\Delta G^{(n)})F^{(n)} + [F^{(n)}, G^{(n)}] = 0, \tag{6}$$

where $\Delta G^{(n)}=(E-1)G^{(n)}=G^{(n+1)}-G^{(n)}$ is the discrete derivative of $G^{(n)}$.

We now consider the case $p=2$, and make a choice of $F^{(n)}$ corresponding to the Volterra lattice[23–25] (see also Refs. 21, 26, and 27),

$$F^{(n)} = \begin{pmatrix} 1 & u^{(n)} \\ 1/\lambda & 0 \end{pmatrix}. \tag{7}$$

We also assume $\omega(\lambda)=\lambda$, and $G^{(n)}$ to be of the form

$$G^{(n)} = \lambda \begin{pmatrix} a^{(n)} & b^{(n)} \\ c^{(n)} & d^{(n)} \end{pmatrix} + \begin{pmatrix} e^{(n)} & f^{(n)} \\ g^{(n)} & h^{(n)} \end{pmatrix}, \tag{8}$$

where all entries are functions of (n,t,τ). We note that if we assume $a^{(n)}=b^{(n)}=c^{(n)}=d^{(n)}=0$, then we must have $u_\tau^{(n)}=0$, and so are restricted to equations in (n,t) only.

The substitution of (7) and (8) into (5) with $\omega(\lambda)=\lambda$ leads us to a nonisospectral condition (4) with $r=1$ and $s=2$,

$$\lambda_t = \lambda\lambda_\tau + \gamma_1\lambda + \gamma_2\lambda^2, \tag{9}$$

and corresponding form of the matrix $G^{(n)}$,

$$G^{(n)} = \lambda \begin{pmatrix} \tilde{a} & g^{(n+1)}u^{(n)} \\ 0 & \tilde{a} - \gamma_2 - g^{(n)} \end{pmatrix} + \begin{pmatrix} e^{(n)} & 0 \\ g^{(n)} & e^{(n-1)} - \gamma_1 \end{pmatrix}, \tag{10}$$

where γ_1, γ_2, and $\tilde{a}$ are all arbitrary functions of (t,τ). Clearly, without loss of generality, we may set $\tilde{a}=0$. The compatibility condition (5) consists of the three coupled equations,

$$u_t^{(n)} + u^{(n)}(e^{(n-1)} - e^{(n+1)}) - \gamma_1 u^{(n)} = 0, \tag{11}$$

$$e^{(n)} - e^{(n+1)} + u^{(n)}g^{(n)} - u^{(n+1)}g^{(n+2)} = 0, \tag{12}$$

$$-u_\tau^{(n)} + u^{(n)}(g^{(n+1)} - g^{(n)}) - \gamma_2 u^{(n)} = 0. \tag{13}$$

The second of these equations can be used to eliminate $e^{(n)}$ in the first, to give

$$u_t^{(n)} + u^{(n)}[g^{(n+2)}u^{(n+1)} + u^{(n)}(g^{(n+1)} - g^{(n)}) - g^{(n-1)}u^{(n-1)}] - \gamma_1 u^{(n)} = 0. \tag{14}$$

Alternatively, we may simply solve the second equation to obtain

$$e^{(n)} = (E-1)^{-1}(u^{(n)} - u^{(n+1)}E^2)g^{(n)}, \tag{15}$$

or

$$e^{(n)} = \sum_{j=1}^{n-1} (u^{(j)} - u^{(j+1)}E^2)g^{(j)}, \tag{16}$$

where, without loss of generality, we have set the arbitrary summation function of (t,τ) to zero. Here $g^{(n)}$ is given by the third equation of the system (11)–(13),

$$g^{(n+1)} - g^{(n)} = \gamma_2 + \frac{u_\tau^{(n)}}{u^{(n)}}, \tag{17}$$

as

$$g^{(n)} = (E-1)^{-1}\left(\gamma_2 + \frac{u_\tau^{(n)}}{u^{(n)}}\right) = \tilde{g} + (n-1)\gamma_2 + (E-1)^{-1}\left(\frac{u_\tau^{(n)}}{u^{(n)}}\right), \tag{18}$$

or

$$g^{(n)} = \tilde{g} + (n-1)\gamma_2 + \sum_{j=1}^{n-1} \frac{u_\tau^{(j)}}{u^{(j)}}, \tag{19}$$

where $\tilde{g}=g^{(1)}$ is an arbitrary summation function of (t,τ). We thus obtain that $u^{(n)}$ satisfies a differential-difference equation in 2+1 dimensions,

$$u_t^{(n)} = \mathcal{R}^{(\mathrm{n})} u_\tau^{(n)} + \tilde{g} u^{(n)}(u^{(n-1)} - u^{(n+1)}) + \gamma_1 u^{(n)} + \gamma_2 u^{(n)}((n-2)u^{(n-1)} - u^{(n)} - (n+1)u^{(n+1)}), \tag{20}$$

where $\mathcal{R}^{(\mathrm{n})}$ is the recursion operator of the Volterra lattice,

$$\mathcal{R}^{(\mathrm{n})} = u^{(n)}(1+E^{-1})(u^{(n)} - u^{(n+1)}E^2)(E-1)^{-1}(u^{(n)})^{-1}. \tag{21}$$

(The fact that nonisospectral scattering problems can be used in order to obtain recursion operators is an observation due to one of the current authors.[28]) This last equation represents a nonisospectral generalization of the Volterra lattice to 2+1 dimensions, and is new. We now use this result to construct a hierarchy of nonisospectral differential-difference equations in 2+1 dimensions, along with their underlying linear problems. We do this by following the approach used in Refs. 17–20.

III. A 2+1 NONISOSPECTRAL VOLTERRA LATTICE HIERARCHY

First of all, we note that

$$\mathcal{R}^{(\mathrm{n})} u^{(n)} = u^{(n)}((n-2)u^{(n-1)} - u^{(n)} - (n+1)u^{(n+1)}), \tag{22}$$

and summarize the results of Sec. II as follows: the differential-difference equation,

$$u_t^{(n)} = \mathcal{R}^{(\mathrm{n})} u_\tau^{(n)} + \tilde{g} K_1^{(n)} + \gamma_1 u^{(n)} + \gamma_2 \mathcal{R}^{(\mathrm{n})} u^{(n)}, \tag{23}$$

where

$$K_1^{(n)} = u^{(n)}(u^{(n-1)} - u^{(n+1)}), \tag{24}$$

$\mathcal{R}^{(\mathrm{n})}$ is as given by (21), and $\tilde{g}$, γ_1, and γ_2 are all arbitrary functions of (t,τ), has the linear problem

$$E\phi^{(n)} = \begin{pmatrix} 1 & u^{(n)} \\ 1/\lambda & 0 \end{pmatrix} \phi^{(n)}, \tag{25}$$

$$\phi_t^{(n)} = \lambda \phi_\tau^{(n)} + G^{(n)}\phi^{(n)} = \lambda \phi_\tau^{(n)} + \begin{pmatrix} e^{(n)} & \lambda u^{(n)} g^{(n+1)} \\ g^{(n)} & e^{(n-1)} - \lambda g^{(n)} - \gamma_1 - \lambda\gamma_2 \end{pmatrix} \phi^{(n)}, \tag{26}$$

where

$$e^{(n)} = (E-1)^{-1}(u^{(n)} - u^{(n+1)}E^2) g^{(n)}, \tag{27}$$

$$g^{(n)} = \tilde{g} + (n-1)\gamma_2 + (E-1)^{-1}\left(\frac{u_\tau^{(n)}}{u^{(n)}}\right), \tag{28}$$

and λ satisfies the nonisospectral condition

$$\lambda_t = \lambda\lambda_\tau + \gamma_1\lambda + \gamma_2\lambda^2. \tag{29}$$

We now consider iterating on the above results, following the approach used in Refs. 17–20. We first set $t=t_m$, $\tau=t_{m-1}$, $\tilde{g}=\alpha_m$, $\gamma_1=\beta_m$, and $\gamma_2=0$, in order to obtain the equation we use to iterate between successive members of the hierarchy,

$$u_{t_m}^{(n)} = \mathcal{R}^{(n)} u_{t_{m-1}}^{(n)} + \alpha_m K_1^{(n)} + \beta_m u^{(n)}, \quad m > 1, \tag{30}$$

together with the equations we use to iterate between successive evolution equations for the eigenfunction $\phi^{(n)}$, and between associated nonisospectral conditions,

$$\phi_{t_m}^{(n)} = \lambda \phi_{t_{m-1}}^{(n)} + G_m^{(n)} \phi^{(n)}, \quad \lambda_{t_m} = \lambda \lambda_{t_{m-1}} + \beta_m \lambda, \quad m > 1, \tag{31}$$

where we use the subscript m in $G_m^{(n)}$ to denote the matrix $G^{(n)}$ in (26) with $e^{(n)}$ and $g^{(n)}$ defined as in (27) and (28) but with $\tau = t_{m-1}$, and, of course, with $\tilde{g} = \alpha_m$, $\gamma_1 = \beta_m$, and $\gamma_2 = 0$. We then set $t = t_1$, $\tau = y$, $\tilde{g} = \alpha_1$, $\gamma_1 = \beta_1$, and $\gamma_2 = \beta_0$ in order to obtain the base equation of our hierarchy,

$$u_{t_1}^{(n)} = Q_1^{(n)} = \mathcal{R}^{(n)} u_y^{(n)} + \alpha_1 K_1^{(n)} + \beta_0 \mathcal{R}^{(n)} u^{(n)} + \beta_1 u^{(n)}, \tag{32}$$

together with the corresponding evolution equation for the eigenfunction $\phi^{(n)}$, and the associated nonisospectral condition,

$$\phi_{t_1}^{(n)} = \lambda \phi_y^{(n)} + G_1^{(n)} \phi^{(n)}, \quad \lambda_{t_1} = \lambda \lambda_y + \beta_1 \lambda + \beta_0 \lambda^2, \tag{33}$$

where the subscript 1 in $G_1^{(n)}$ is used to denote $G^{(n)}$ in (26) with $e^{(n)}$ and $g^{(n)}$ as in (27) and (28) but with $\tau = y$, and, of course, with $\tilde{g} = \alpha_1$, $\gamma_1 = \beta_1$, and $\gamma_2 = \beta_0$.

We now consider a generic member of our 2+1-dimensional hierarchy,

$$u_{t_m}^{(n)} = Q_m^{(n)}, \tag{34}$$

together with the corresponding evolution equation for the eigenfunction $\phi^{(n)}$, and associated nonisospectral condition,

$$\phi_{t_m}^{(n)} = \Gamma_m \phi_y^{(n)} + H_m^{(n)} \phi^{(n)}, \quad \lambda_{t_m} = \Lambda_m, \tag{35}$$

which for $m = 1$ correspond to (32) and (33). We thus obtain the recursion relations

$$Q_m^{(n)} = \mathcal{R}^{(n)} Q_{m-1}^{(n)} + \alpha_m K_1^{(n)} + \beta_m u^{(n)}, \tag{36}$$

$$\Gamma_m = \lambda \Gamma_{m-1}, \tag{37}$$

$$H_m^{(n)} = \lambda H_{m-1}^{(n)} + G_m^{(n)}, \tag{38}$$

$$\Lambda_m = \lambda \Lambda_{m-1} + \beta_m \lambda. \tag{39}$$

Iteration then yields the 2+1-dimensional hierarchy

$$u_{t_m}^{(n)} = Q_m^{(n)} = (\mathcal{R}^{(n)})^m u_y^{(n)} + \sum_{j=0}^{m-1} \alpha_{m-j} (\mathcal{R}^{(n)})^j K_1^{(n)} + \sum_{j=0}^{m} \beta_{m-j} (\mathcal{R}^{(n)})^j u^{(n)}, \tag{40}$$

together with the corresponding hierarchy of underlying linear problems,

$$E\phi^{(n)} = \begin{pmatrix} 1 & u^{(n)} \\ 1/\lambda & 0 \end{pmatrix} \phi^{(n)}, \tag{41}$$

$$\phi_{t_m}^{(n)} = \Gamma_m \phi_y^{(n)} + H_m^{(n)} \phi^{(n)} = \lambda^m \phi_y^{(n)} + \left(\sum_{j=1}^{m} \lambda^{m-j} G_j^{(n)} \right) \phi^{(n)}, \tag{42}$$

and associated nonisospectral condition

$$\lambda_{t_m} = \lambda^m \lambda_y + \sum_{j=0}^{m} \lambda^{m+1-j} \beta_j. \tag{43}$$

Here all α_k and β_k are functions of (t_m, y), any m, and each $G_j^{(n)}$ is given by

$$G_j^{(n)} = \begin{pmatrix} A_j^{(n)} & B_j^{(n)} \\ C_j^{(n)} & D_j^{(n)} \end{pmatrix}, \tag{44}$$

where for $j > 1$,

$$A_j^{(n)} = (E-1)^{-1}(u^{(n)} - u^{(n+1)}E^2)\left[\alpha_j + (E-1)^{-1}\left(\frac{Q_{j-1}^{(n)}}{u^{(n)}}\right)\right], \tag{45}$$

$$B_j^{(n)} = \lambda u^{(n)}\left[\alpha_j + (E-1)^{-1}\left(\frac{Q_{j-1}^{(n+1)}}{u^{(n+1)}}\right)\right], \tag{46}$$

$$C_j^{(n)} = \left[\alpha_j + (E-1)^{-1}\left(\frac{Q_{j-1}^{(n)}}{u^{(n)}}\right)\right], \tag{47}$$

$$D_j^{(n)} = (E-1)^{-1}(u^{(n-1)} - u^{(n)}E^2)\left[\alpha_j + (E-1)^{-1}\left(\frac{Q_{j-1}^{(n-1)}}{u^{(n-1)}}\right)\right] - \lambda\left[\alpha_j + (E-1)^{-1}\left(\frac{Q_{j-1}^{(n)}}{u^{(n)}}\right)\right] - \beta_j, \tag{48}$$

and

$$A_1^{(n)} = (E-1)^{-1}(u^{(n)} - u^{(n+1)}E^2)\left[\alpha_1 + (n-1)\beta_0 + (E-1)^{-1}\left(\frac{u_y^{(n)}}{u^{(n)}}\right)\right], \tag{49}$$

$$B_1^{(n)} = \lambda u^{(n)}\left[\alpha_1 + n\beta_0 + (E-1)^{-1}\left(\frac{u_y^{(n+1)}}{u^{(n+1)}}\right)\right], \tag{50}$$

$$C_1^{(n)} = \left[\alpha_1 + (n-1)\beta_0 + (E-1)^{-1}\left(\frac{u_y^{(n)}}{u^{(n)}}\right)\right], \tag{51}$$

$$D_1^{(n)} = (E-1)^{-1}(u^{(n-1)} - u^{(n)}E^2)\left[\alpha_1 + (n-2)\beta_0 + (E-1)^{-1}\left(\frac{u_y^{(n-1)}}{u^{(n-1)}}\right)\right] - \lambda\left[\alpha_1 + (n-1)\beta_0 + (E-1)^{-1}\left(\frac{u_y^{(n)}}{u^{(n)}}\right)\right] - \beta_1 - \lambda\beta_0. \tag{52}$$

The first term on the right-hand-side of Eq. (40) corresponds to a nonisospectral extension of the Volterra lattice hierarchy to 2+1 dimensions; the second term consists of a sum of standard (isospectral) Volterra lattice flows. The third term consists of additional 1+1-dimensional nonisospectral terms, which in the general case are both nonautonomous (depend explicitly on n) and nonlocal.

To the best of our knowledge, the 2+1-dimensional hierarchy (40) is new, although 1+1-dimensional nonisospectral modifications of Volterra lattice flows, or indeed such terms

alone, have been considered before, e.g., in Refs. 21, 26, and 27. We now consider reductions of our hierarchy (40), which yield a variety of new hierarchies, including differential-delay hierarchies and generalized discrete Painlevé hierarchies.

IV. LATTICE AND DIFFERENTIAL-DELAY HIERARCHIES

We begin by remarking that, of course, instead of the hierarchy (40), we can always extend our results in order to obtain linear problems and associated nonisospectral conditions for 2+1 lattice equations of the form

$$\sum_{j=0}^{p} a_j(\mathcal{R}^{(n)})^j u_t^{(n)} + \sum_{j=0}^{q} b_j(\mathcal{R}^{(n)})^j u_y^{(n)} + \sum_{j=0}^{r} c_j(\mathcal{R}^{(n)})^j K_1^{(n)} + \sum_{j=0}^{s} d_j(\mathcal{R}^{(n)})^j u^{(n)} = 0, \tag{53}$$

where all a_k, b_k, c_k, and d_k are functions of (y,t). Thus it is also possible to derive more general results than those presented in Secs. IV and V here. However, for our present purposes, it is sufficient to consider reductions of the hierarchy (40). In this section we give the reduced hierarchies and nonisospectral conditions. We also consider explicitly the case $m=1$, for which we give, in addition, the corresponding linear problems.

First of all we rewrite our earlier results for the case $m=1$, in order to simplify the subsequent presentation of reductions in this particular case. For $m=1$, Eq. (40) gives our 2+1-dimensional nonisospectral Volterra lattice in $u^{(n)}=u(n,t_1,y)$, i.e., Eq. (32),

$$u_{t_1}^{(n)} = \mathcal{R}^{(n)} u_y^{(n)} + \alpha_1 K_1^{(n)} + \beta_0 \mathcal{R}^{(n)} u^{(n)} + \beta_1 u^{(n)}, \tag{54}$$

where α_1, β_0, and β_1 are functions of t_1 and y. In order to avoid nonlocal terms, we write this equation using a potential as

$$\begin{aligned} u_{t_1}^{(n)} = {} & u^{(n)}(u^{(n)}w^{(n)} + u^{(n-1)}w^{(n-1)} - u^{(n)}w^{(n+1)} - u^{(n+1)}w^{(n+2)}) + \alpha_1 u^{(n)}(u^{(n-1)} - u^{(n+1)}) \\ & + \beta_0 u^{(n)}((n-2)u^{(n-1)} - u^{(n)} - (n+1)u^{(n+1)}) + \beta_1 u^{(n)}, \end{aligned} \tag{55}$$

where

$$w^{(n+1)} - w^{(n)} = \frac{u_y^{(n)}}{u^{(n)}}. \tag{56}$$

This equation has the linear problem

$$E\phi^{(n)} = \begin{pmatrix} 1 & u^{(n)} \\ 1/\lambda & 0 \end{pmatrix} \phi^{(n)}, \tag{57}$$

$$\phi_{t_1}^{(n)} = \lambda \phi_y^{(n)} + \begin{pmatrix} v^{(n)} & \lambda u^{(n)}(\alpha_1 + n\beta_0 + w^{(n+1)}) \\ \alpha_1 + (n-1)\beta_0 + w^{(n)} & v^{(n-1)} - \beta_1 - \lambda\beta_0 - \lambda(\alpha_1 + (n-1)\beta_0 + w^{(n)}) \end{pmatrix} \phi^{(n)} \tag{58}$$

where

$$v^{(n+1)} - v^{(n)} = (u^{(n)} - u^{(n+1)}E^2)(\alpha_1 + (n-1)\beta_0 + w^{(n)}) \tag{59}$$

and $\lambda=\lambda(t_1,y)$ satisfies the nonisospectral condition

$$\lambda_{t_1} = \lambda\lambda_y + \beta_1\lambda + \beta_0\lambda^2. \tag{60}$$

We now turn to our reductions.

A. Reductions to 1+1 lattice hierarchies

We begin by considering the reduction $\partial_y=0$ of the hierarchy (40), which yields a hierarchy of nonisospectral extensions of Volterra lattice flows,

$$u^{(n)}_{t_m}=\sum_{j=0}^{m-1}\alpha_{m-j}(\mathcal{R}^{(n)})^jK_1^{(n)}+\sum_{j=0}^{m}\beta_{m-j}(\mathcal{R}^{(n)})^ju^{(n)}, \tag{61}$$

where now all α_k and β_k are functions of each t_m only. The nonisospectral condition satisfied by $\lambda=\lambda(t_m)$ is

$$\lambda_{t_m}=\sum_{j=0}^{m}\lambda^{m+1-j}\beta_j. \tag{62}$$

In the case where all $\beta_k=0$, we obtain the (isospectral) Volterra lattice hierarchy,

$$u^{(n)}_{t_m}=\sum_{j=0}^{m-1}\alpha_{m-j}(\mathcal{R}^{(n)})^jK_1^{(n)}. \tag{63}$$

As remarked earlier, all of these equations are known.

Second, we consider the reduction $\partial_{t_m}=\epsilon\partial_y$, ϵ constant, which then gives the nonisospectral 1+1-dimensional lattice hierarchy,

$$(\mathcal{R}^{(n)})^mu_y^{(n)}-\epsilon u_y^{(n)}+\sum_{j=0}^{m-1}\alpha_{m-j}(\mathcal{R}^{(n)})^jK_1^{(n)}+\sum_{j=0}^{m}\beta_{m-j}(\mathcal{R}^{(n)})^ju^{(n)}=0, \tag{64}$$

where now all α_k and β_k are functions of y only, and where $\lambda=\lambda(y)$ satisfies the corresponding nonisospectral condition

$$(\lambda^m-\epsilon)\lambda_y+\sum_{j=0}^{m}\lambda^{m+1-j}\beta_j=0. \tag{65}$$

In the case where all $\beta_k=0$, we obtain from (64) the isospectral flows

$$(\mathcal{R}^{(n)})^mu_y^{(n)}-\epsilon u_y^{(n)}+\sum_{j=0}^{m-1}\alpha_{m-j}(\mathcal{R}^{(n)})^jK_1^{(n)}=0. \tag{66}$$

Clearly in the hierarchies (64) and (66) we can also consider the special case $\epsilon=0$.

1. Examples: m=1

Our first reduction of (55), $\partial_y=0$, gives the equation in $u^{(n)}=u(n,t_1)$,

$$u^{(n)}_{t_1}=\alpha_1u^{(n)}(u^{(n-1)}-u^{(n+1)})+\beta_0u^{(n)}((n-2)u^{(n-1)}-u^{(n)}-(n+1)u^{(n+1)})+\beta_1u^{(n)}, \tag{67}$$

where now α_1, β_0, and β_1 are functions of t_1 only. This equation has the linear problem

$$E\phi^{(n)}=\begin{pmatrix}1 & u^{(n)}\\ 1/\lambda & 0\end{pmatrix}\phi^{(n)}, \tag{68}$$

$$\phi^{(n)}_{t_1}=\begin{pmatrix}v^{(n)} & \lambda u^{(n)}(\alpha_1+n\beta_0)\\ \alpha_1+(n-1)\beta_0 & v^{(n-1)}-\beta_1-\lambda\beta_0-\lambda(\alpha_1+(n-1)\beta_0)\end{pmatrix}\phi^{(n)}, \tag{69}$$

where $v^{(n)}=v(n,t_1)$ satisfies the equation

$$v^{(n+1)} - v^{(n)} = (u^{(n)} - u^{(n+1)}E^2)(\alpha_1 + (n-1)\beta_0), \tag{70}$$

and where $\lambda = \lambda(t_1)$ satisfies the nonisospectral condition

$$\lambda_{t_1} = \beta_1\lambda + \beta_0\lambda^2. \tag{71}$$

In the case $\beta_0 = \beta_1 = 0$, we have an isospectral linear problem.

Our second reduction of (55), $\partial_{t_1} = \epsilon\partial_y$, gives the equation in $u^{(n)} = u(n,y)$,

$$\begin{aligned} &u^{(n)}(u^{(n)}w^{(n)} + u^{(n-1)}w^{(n-1)} - u^{(n)}w^{(n+1)} - u^{(n+1)}w^{(n+2)}) - \epsilon u_y^{(n)} + \alpha_1 u^{(n)}(u^{(n-1)} - u^{(n+1)}) \\ &\quad + \beta_0 u^{(n)}((n-2)u^{(n-1)} - u^{(n)} - (n+1)u^{(n+1)}) + \beta_1 u^{(n)} = 0, \end{aligned} \tag{72}$$

where $w^{(n)} = w(n,y)$ is related to $u^{(n)}$ as in Eq. (56), and α_1, β_0, and β_1 are now functions of y only. This equation has the linear problem

$$E\phi^{(n)} = \begin{pmatrix} 1 & u^{(n)} \\ 1/\lambda & 0 \end{pmatrix}\phi^{(n)}, \tag{73}$$

$$\phi_y^{(n)} = \frac{1}{\epsilon - \lambda}\begin{pmatrix} v^{(n)} & \lambda u^{(n)}(\alpha_1 + n\beta_0 + w^{(n+1)}) \\ \alpha_1 + (n-1)\beta_0 + w^{(n)} & v^{(n-1)} - \beta_1 - \lambda\beta_0 - \lambda(\alpha_1 + (n-1)\beta_0 + w^{(n)}) \end{pmatrix}\phi^{(n)}, \tag{74}$$

where $v^{(n)} = v(n,y)$ satisfies the equation

$$v^{(n+1)} - v^{(n)} = (u^{(n)} - u^{(n+1)}E^2)(\alpha_1 + (n-1)\beta_0 + w^{(n)}) \tag{75}$$

and $\lambda = \lambda(y)$ satisfies the nonisospectral condition

$$\lambda_y = \frac{1}{\epsilon - \lambda}(\beta_1\lambda + \beta_0\lambda^2). \tag{76}$$

In the case $\beta_0 = \beta_1 = 0$, we have an isospectral linear problem.

B. Reductions to 1+1 differential-delay hierarchies

We now give reductions to 1+1 differential-delay hierarchies (in fact, to hierarchies that are purely differential with respect to one of the independent variables, and differential delay with respect to the other). We believe these results to be new.

We begin by considering what may be described—through an abuse of notation—as the reduction $\partial_{t_m} = \kappa\partial_n (\equiv \kappa\partial_x)$, κ constant, so that E now shifts the continuous variable x. We thus obtain from the hierarchy (40) the 1+1 hierarchy,

$$\kappa u_x(x,y) = \tilde{\mathcal{R}}^m u_y(x,y) + \sum_{j=0}^{m-1} \alpha_{m-j}\tilde{\mathcal{R}}^j\tilde{K}_1 + \sum_{j=0}^{m} \beta_{m-j}\tilde{\mathcal{R}}^j u(x,y), \tag{77}$$

where all α_k and β_k are now functions of y only, where $\tilde{\mathcal{R}}$ is defined as

$$\tilde{\mathcal{R}} = u(x,y)(1 + E^{-1})(u(x,y) - u(x+1,y)E^2)(E-1)^{-1}(u(x,y))^{-1}, \tag{78}$$

and $\tilde{K}_1$ as

$$\tilde{K}_1 = u(x,y)(u(x-1,y) - u(x+1,y)), \tag{79}$$

and where $\lambda = \lambda(y)$ satisfies the corresponding nonisospectral condition,

$$\lambda_y + \sum_{j=0}^{m} \lambda^{1-j}\beta_j = 0. \tag{80}$$

Clearly, in the case where all $\beta_k=0$, i.e., for the hierarchy

$$\kappa u_x(x,y) = \tilde{\mathcal{R}}^m u_y(x,y) + \sum_{j=0}^{m-1} \alpha_{m-j}\tilde{\mathcal{R}}^j\tilde{K}_1, \tag{81}$$

we have an isospectral linear problem.

We now consider an alternative reduction of the hierarchy (40), a reduction perhaps best described—again through an abuse of notation—as $\partial_y=\kappa\partial_n(\equiv\kappa\partial_x)$, κ constant, so that E once again now shifts the continuous variable x. We thus obtain the $1+1$ hierarchy

$$u_{t_m}(x,t_m) = \kappa\overline{\mathcal{R}}^m u_x(x,t_m) + \sum_{j=0}^{m-1} \alpha_{m-j}\overline{\mathcal{R}}^j\overline{K}_1 + \sum_{j=0}^{m} \beta_{m-j}\overline{\mathcal{R}}^j u(x,t_m), \tag{82}$$

where all α_k and β_k are now functions of t_m only, where $\overline{\mathcal{R}}$ is defined as

$$\overline{\mathcal{R}} = u(x,t_m)(1+E^{-1})(u(x,t_m) - u(x+1,t_m)E^2)(E-1)^{-1}(u(x,t_m))^{-1} \tag{83}$$

and $\overline{K}_1$ as

$$\overline{K}_1 = u(x,t_m)(u(x-1,t_m) - u(x+1,t_m)), \tag{84}$$

and where $\lambda=\lambda(t_m)$ satisfies the corresponding nonisospectral condition

$$\lambda_{t_m} = \sum_{j=0}^{m} \lambda^{m+1-j}\beta_j. \tag{85}$$

Once again, in the case where all $\beta_k=0$,

$$u_{t_m}(x,t_m) = \kappa\overline{\mathcal{R}}^m u_x(x,t_m) + \sum_{j=0}^{m-1} \alpha_{m-j}\overline{\mathcal{R}}^j\overline{K}_1, \tag{86}$$

we have an isospectral linear problem.

1. Examples: m=1

Our first reduction of (55), $\partial_{t_1}=\kappa\partial_n(\equiv\kappa\partial_x)$, gives the equation in $u(x,y)$,

$$\begin{aligned}\kappa u_x(x,y) = {} & u(x,y)[u(x,y)w(x,y) + u(x-1,y)w(x-1,y) - u(x,y)w(x+1,y) - u(x+1,y)w(x+2,y)] \\ & + \alpha_1 u(x,y)[u(x-1,y) - u(x+1,y)] + \beta_0 u(x,y)[(x-2)u(x-1,y) - u(x,y) \\ & - (x+1)u(x+1,y)] + \beta_1 u(x,y),\end{aligned} \tag{87}$$

where now α_1, β_0, and β_1 are functions of y only and where

$$w(x+1,y) - w(x,y) = \frac{u_y(x,y)}{u(x,y)}. \tag{88}$$

This equation has the linear problem

$$E\phi(x,y) = \begin{pmatrix} 1 & u(x,y) \\ 1/\lambda & 0 \end{pmatrix}\phi(x,y), \tag{89}$$

$$\kappa\phi_x(x,y) = \lambda\phi_y(x,y) + \begin{pmatrix} v(x,y) & \lambda u(x,y)(\alpha_1 + x\beta_0 + w(x+1,y)) \\ \alpha_1 + (x-1)\beta_0 + w(x,y) & v(x-1,y) - \beta_1 - \lambda\beta_0 - \lambda(\alpha_1 + (x-1)\beta_0 + w(x,y)) \end{pmatrix} \times \phi(x,y), \tag{90}$$

where $v(x,y)$ satisfies the equation

$$v(x+1,y) - v(x,y) = (u(x,y) - u(x+1,y)E^2)(\alpha_1 + (x-1)\beta_0 + w(x,y)) \tag{91}$$

and $\lambda = \lambda(y)$ satisfies the nonisospectral condition

$$\lambda_y + \beta_1 + \beta_0\lambda = 0. \tag{92}$$

In the case $\beta_0 = \beta_1 = 0$ we have an isospectral linear problem.

Our second reduction of (55), $\partial_y = \kappa\partial_n (\equiv \kappa\partial_x)$, gives the equation in $u(x,t_1)$,

$$\begin{aligned} u_{t_1}(x,t_1) = {} & u(x,t_1)[u(x,t_1)w(x,t_1) + u(x-1,t_1)w(x-1,t_1) \\ & - u(x,t_1)w(x+1,t_1) - u(x+1,t_1)w(x+2,t_1)] + \alpha_1 u(x,t_1)[u(x-1,t_1) - u(x+1,t_1)] \\ & + \beta_0 u(x,t_1)[(x-2)u(x-1,t_1) - u(x,t_1) - (x+1)u(x+1,t_1)] + \beta_1 u(x,t_1), \end{aligned} \tag{93}$$

where now α_1, β_0, and β_1 are functions of t_1 only and where

$$w(x+1,t_1) - w(x,t_1) = \kappa\frac{u_x(x,t_1)}{u(x,t_1)}. \tag{94}$$

This equation has the linear problem

$$E\phi(x,t_1) = \begin{pmatrix} 1 & u(x,t_1) \\ 1/\lambda & 0 \end{pmatrix}\phi(x,t_1), \tag{95}$$

$$\phi_{t_1}(x,t_1) = \lambda\kappa\phi_x(x,t_1) + \begin{pmatrix} v(x,t_1) & \lambda u(x,t_1)(\alpha_1 + x\beta_0 + w(x+1,t_1)) \\ \alpha_1 + (x-1)\beta_0 + w(x,t_1) & v(x-1,t_1) - \beta_1 - \lambda\beta_0 - \lambda(\alpha_1 + (x-1)\beta_0 + w(x,t_1)) \end{pmatrix} \times \phi(x,t_1), \tag{96}$$

where $v(x,t_1)$ satisfies the equation

$$v(x+1,t_1) - v(x,t_1) = (u(x,t_1) - u(x+1,t_1)E^2)(\alpha_1 + (x-1)\beta_0 + w(x,t_1)) \tag{97}$$

and $\lambda = \lambda(t_1)$ satisfies the nonisospectral condition

$$\lambda_{t_1} = \beta_1\lambda + \beta_0\lambda^2. \tag{98}$$

In the case $\beta_0 = \beta_1 = 0$, we have an isospectral linear problem.

C. Reductions to ordinary differential-delay hierarchies

Setting $\partial_y = 0$ in (77)—or (abusing notation) $\partial_{t_m} = \kappa\partial_n (\equiv \kappa\partial_x)$ in (61)—yields the hierarchy of ordinary differential-delay equations (recall that E shifts x),

$$\kappa u_x(x) = \sum_{j=0}^{m-1} \alpha_{m-j} \widetilde{\mathcal{R}}^j \widetilde{K}_1 + \sum_{j=0}^{m} \beta_{m-j} \widetilde{\mathcal{R}}^j u(x), \tag{99}$$

where $\widetilde{\mathcal{R}}$ and $\widetilde{K}_1$, which are now y independent, are defined as above. We may also consider the special case where all $\beta_k=0$; we note that in this special case, the ordinary differential-delay equation that results for $m=2$ has been given in Ref. 21.

Setting $\partial_{t_m}=\epsilon\kappa\partial_x$ in (82)—or (abusing notation) $\partial_y=\kappa\partial_n(\equiv\kappa\partial_x)$ in (64)—yields the hierarchy of ordinary differential-delay equations (again, E shifts x),

$$\kappa\overline{\mathcal{R}}^m u_x(x) - \epsilon\kappa u_x(x) + \sum_{j=0}^{m-1} \alpha_{m-j} \overline{\mathcal{R}}^j \overline{K}_1 + \sum_{j=0}^{m} \beta_{m-j} \overline{\mathcal{R}}^j u(x) = 0, \tag{100}$$

where $\overline{\mathcal{R}}$ and $\overline{K}_1$, which now depend only on x, are defined as above. In the above hierarchy we may also consider the special cases $\epsilon=0$ or all $\beta_k=0$.

Clearly, both of the above can be included in the single hierarchy

$$\sigma\overline{\mathcal{R}}^m u_x(x) - \rho u_x(x) + \sum_{j=0}^{m-1} \alpha_{m-j} \overline{\mathcal{R}}^j \overline{K}_1 + \sum_{j=0}^{m} \beta_{m-j} \overline{\mathcal{R}}^j u(x) = 0, \tag{101}$$

where σ and ρ are two arbitrary constants. This hierarchy, which again we believe to be new, arises as the compatibility condition

$$\left(\sum_{j=0}^{m} \lambda^{m+1-j}\beta_j\right) F_\lambda(x) - (\lambda^m\sigma-\rho)F_x(x) + F(x)H_m(x) - H_m(x+1)F(x) = 0 \tag{102}$$

of the associated hierarchy of linear systems,

$$E\phi(x) = F(x)\phi(x), \tag{103}$$

$$\left(\sum_{j=0}^{m} \lambda^{m+1-j}\beta_j\right) \phi_\lambda(x) = (\lambda^m\sigma-\rho)\phi_x(x) + H_m(x)\phi(x), \tag{104}$$

where

$$F(x) = \begin{pmatrix} 1 & u(x) \\ 1/\lambda & 0 \end{pmatrix}, \quad H_m(x) = \sum_{j=1}^{m} \lambda^{m-j} G_j(x), \tag{105}$$

and the matrices $G_j(x)$ are obtained from the $G_j^{(n)}$ of Sec. III in the appropriate way. We remark in passing the great interest of "delay Painlevé equations."[21]

1. Example: m=1

In the case $m=1$, Eq. (101) reads as

$$u(x)[u(x)w(x) + u(x-1)w(x-1) - u(x)w(x+1) - u(x+1)w(x+2)] - \rho u_x(x) + \alpha_1 u(x)[u(x-1) - u(x+1)] + \beta_0 u(x)[(x-2)u(x-1) - u(x) - (x+1)u(x+1)] + \beta_1 u(x) = 0, \tag{106}$$

where now α_1, β_0, and β_1 are constants and where

$$w(x+1) - w(x) = \sigma\frac{u_x(x)}{u(x)}. \tag{107}$$

This equation arises as the compatibility condition of the linear system,

$$E\phi(x) = \begin{pmatrix} 1 & u(x) \\ 1/\lambda & 0 \end{pmatrix} \phi(x), \tag{108}$$

$$\begin{aligned}(\beta_0\lambda^2 + \beta_1\lambda)\phi_\lambda(x) &= (\lambda\sigma - \rho)\phi_x(x) \\ &+ \begin{pmatrix} v(x) & \lambda u(x)(\alpha_1 + x\beta_0 + w(x+1)) \\ \alpha_1 + (x-1)\beta_0 + w(x) & v(x-1) - \beta_1 - \lambda\beta_0 - \lambda(\alpha_1 + (x-1)\beta_0 + w(x)) \end{pmatrix} \\ &\times \phi(x),\end{aligned} \tag{109}$$

where $v(x)$ satisfies the equation

$$v(x+1) - v(x) = (u(x) - u(x+1)E^2)(\alpha_1 + (x-1)\beta_0 + w(x)). \tag{110}$$

V. GENERALIZED DISCRETE PAINLEVÉ HIERARCHIES

If in the 1+1 lattice hierarchy (61) we now take the further reduction $\partial_{t_m}=0$, we obtain a hierarchy of discrete equations:

$$\sum_{j=0}^{m-1} \alpha_{m-j}(\mathcal{R}^{(n)})^j K_1^{(n)} + \sum_{j=0}^{m} \beta_{m-j}(\mathcal{R}^{(n)})^j u^{(n)} = 0. \tag{111}$$

Alternatively, we may derive this discrete hierarchy by taking $\partial_y=0$ in (64), or by making appropriate reductions in the hierarchies (77) and (82), or by setting $\rho=\sigma=0$ in (101). This hierarchy arises as the compatibility condition

$$\left(\sum_{j=0}^{m} \lambda^{m+1-j}\beta_j\right) F_\lambda^{(n)} + F^{(n)}H_m^{(n)} - H_m^{(n+1)}F^{(n)} = 0 \tag{112}$$

of the associated hierarchy of linear problems,

$$E\phi^{(n)} = F^{(n)}\phi^{(n)}, \tag{113}$$

$$\left(\sum_{j=0}^{m} \lambda^{m+1-j}\beta_j\right) \phi_\lambda^{(n)} = H_m^{(n)}\phi^{(n)}, \tag{114}$$

where

$$F^{(n)} = \begin{pmatrix} 1 & u^{(n)} \\ 1/\lambda & 0 \end{pmatrix}, \quad H_m^{(n)} = \sum_{j=1}^{m} \lambda^{m-j} G_j^{(n)}, \tag{115}$$

and the matrices $G_j^{(n)}$ are obtained from those of Sec. III in the appropriate way. Here all α_k and β_k are constants.

This hierarchy contains, in the general case, nonlocal terms: although we could consider this hierarchy in its full generality, by introducing auxiliary potential functions, we prefer here to consider the case where $\beta_k=0$, $k=0,1,\ldots,m-2$, i.e.,

$$P_m^{(n)} \equiv \frac{1}{u^{(n)}}\left(\sum_{j=0}^{m-1} \alpha_{m-j}(\mathcal{R}^{(n)})^j K_1^{(n)} + \beta_{m-1}\mathcal{R}^{(n)}u^{(n)} + \beta_m u^{(n)}\right) = 0. \tag{116}$$

For $m=1$, (116) gives the linear equation

$$P_1^{(n)} \equiv \alpha_1(u^{(n-1)} - u^{(n+1)}) + \beta_0((n-2)u^{(n-1)} - u^{(n)} - (n+1)u^{(n+1)}) + \beta_1 = 0, \tag{117}$$

and for $m=2$, the first of our nonlinear equations,

$$P_2^{(n)} \equiv \alpha_1[u^{(n+1)}(u^{(n)}+u^{(n+1)}+u^{(n+2)})-u^{(n-1)}(u^{(n)}+u^{(n-1)}+u^{(n-2)})]+\alpha_2(u^{(n-1)}-u^{(n+1)})$$
$$+\beta_1((n-2)u^{(n-1)}-u^{(n)}-(n+1)u^{(n+1)})+\beta_2=0. \tag{118}$$

This last equation has the linear problem formed by (113), together with

$$(\beta_1\lambda^2+\beta_2\lambda)\phi_\lambda^{(n)}=\begin{pmatrix} -\alpha_1\lambda u^{(n)}+v^{(n)} & \lambda^2\alpha_1u^{(n)}+\lambda u^{(n)}(\alpha_2+n\beta_1 \\ & -\alpha_1(u^{(n+1)}+u^{(n)})) \\ \lambda\alpha_1+\alpha_2+(n-1)\beta_1 & v^{(n-1)}-\beta_2-\lambda\beta_1 \\ -\alpha_1(u^{(n)}+u^{(n-1)}) & -\lambda(\alpha_2+(n-1)\beta_1 \\ & -\alpha_1(u^{(n)}+u^{(n-1)})) \\ & -\alpha_1\lambda u^{(n-1)}-\alpha_1\lambda^2 \end{pmatrix}\phi^{(n)}, \tag{119}$$

where $v^{(n)}$ satisfies the equation

$$v^{(n+1)}-v^{(n)}=(u^{(n)}-u^{(n+1)}E^2)(\alpha_2+(n-1)\beta_1-\alpha_1(u^{(n)}+u^{(n-1)})). \tag{120}$$

As we now show, Eq. (118) is a generalization of a well-known discrete first Painlevé (dP_I) equation. Thus, our hierarchy of discrete equations (116) corresponds to a new generalized dP_I hierarchy. First we note that (118) can be written in the form

$$(E^2-1)\left[\alpha_1u^{(n-1)}(u^{(n)}+u^{(n-1)}+u^{(n-2)})-\alpha_2u^{(n-1)}+\left(\frac{1}{2}\beta_2\right)n\right]$$
$$-\beta_1(E+1)[u^{(n-1)}+(E-1)((n-1)u^{(n-1)})]=0, \tag{121}$$

and so we can sum to obtain

$$\tilde{P}_2^{(n)} \equiv (E-1)\left[\alpha_1u^{(n-1)}(u^{(n)}+u^{(n-1)}+u^{(n-2)})-\alpha_2u^{(n-1)}+\left(\frac{1}{2}\beta_2\right)n\right]$$
$$-\beta_1[u^{(n-1)}+(E-1)((n-1)u^{(n-1)})]-\omega_2(-1)^n=0, \tag{122}$$

where ω_2 (labeled using m) is an arbitrary constant. This third-order discrete equation can be summed once again in order to give, for each of the cases $\beta_1=0$ and $\beta_1\neq0$, a second-order equation.

In the case $\beta_1=0$, we obtain (after a shift on n) the second-order discrete equation

$$\alpha_1u^{(n)}(u^{(n+1)}+u^{(n)}+u^{(n-1)})-\alpha_2u^{(n)}+\left(\frac{1}{2}\beta_2\right)n-\nu_2-\mu_2(-1)^n=0, \tag{123}$$

where $\mu_2=\frac{1}{2}\omega_2$ and ν_2 is a second arbitrary constant (again labeled using m). Equation (123) is the version of dP_I containing a parity-dependent term, which includes both the first and second Painlevé equations among its continuum limits; see Ref. 29, as well as Refs. 21 and 30. In our framework this equation corresponds to the special case $\beta_1=0$ of our more general integrable discrete equation (118) [or (122)]. We note that it is straightforward, using our above results, to give a linear problem for (123) not involving the potential $v^{(n)}$, whose compatibility condition is precisely Eq. (123) rather than the higher-order equivalents (118) or (122) with $\beta_1=0$.

In the case $\beta_1\neq0$, we obtain the second-order discrete equation

$$D_{34} \equiv u^{(n-1)}(\alpha_1u^{(n)}+\alpha_1u^{(n-1)}-\beta_1n+2\delta)(\alpha_1u^{(n-1)}+\alpha_1u^{(n-2)}-\beta_1(n-1)+2\delta)$$
$$-\frac{\beta_2}{\beta_1}\left(\alpha_1u^{(n-1)}-C-\frac{1}{2}\beta_1(n-1)+\delta\right)\left(\alpha_1u^{(n-1)}+C-\frac{1}{2}\beta_1n+\delta\right)$$
$$-\omega_2(\alpha_1u^{(n-1)}(-1)^{n-1}+\delta(-1)^{n-1}+B_n)=0, \tag{124}$$

where C is an arbitrary constant,

$$\delta = \frac{1}{2}\left(-\alpha_2 + \beta_1 + \alpha_1 \frac{\beta_2}{\beta_1}\right), \tag{125}$$

and

$$B_n = \begin{cases} \dfrac{1}{2}\beta_1 n, & n \text{ even}, \\ -\dfrac{1}{2}\beta_1 (n-1), & n \text{ odd}. \end{cases} \tag{126}$$

Here we have made use of the summing factor $(\alpha_1 u^{(n)} + \alpha_1 u^{(n-1)} - \beta_1 n + 2\delta)$:

$$(\alpha_1 u^{(n)} + \alpha_1 u^{(n-1)} - \beta_1 n + 2\delta)\widetilde{P}_2^{(n)} = (E-1)(D_{34}). \tag{127}$$

Equation (124), which we will call the dP_{34} equation, is a generalized version of the known discrete 34th Painlevé equation. We note that when summing we have retained the parity-dependent terms that appear in (122). In the special case $\omega_2 = 0$ this equation yields the discrete 34th Painlevé equation of Ref. 30.

We see from the previous discussion that we have obtained a new generalized dP_I hierarchy (116): the first member of this hierarchy is a generalized dP_I equation since, for the choice $\beta_1 = 0$, it sums to a known dP_I equation. In addition, we have seen that this first member, for the choice $\beta_1 \neq 0$, sums to a new dP_{34} equation.

We also give here the case $m=3$ of (116), which may be written as

$$\begin{aligned}(E^2-1)\Big[&-\alpha_1 u^{(n-1)}(u^{(n)}u^{(n+1)} + u^{(n)2} + 2u^{(n-1)}u^{(n)} + u^{(n-2)}u^{(n-3)} + u^{(n-2)2} + 2u^{(n-1)}u^{(n-2)} + u^{(n-1)2} \\ &+ u^{(n-2)}u^{(n)}) + \alpha_2 u^{(n-1)}(u^{(n)} + u^{(n-1)} + u^{(n-2)}) - \alpha_3 u^{(n-1)} + \left(\frac{1}{2}\beta_3\right)n\Big] - \beta_2(E+1)\big[u^{(n-1)} \\ &+ (E-1)((n-1)u^{(n-1)})\big] = 0. \end{aligned} \tag{128}$$

The linear problem for this equation may also be given explicitly using the results given earlier, but we choose not to do so here. We note that in the special case $\beta_2 = 0$, we can sum this last equation twice to obtain (again after a shift on n) the fourth-order discrete equation

$$\begin{aligned} &-\alpha_1 u^{(n)}(u^{(n+1)}u^{(n+2)} + u^{(n+1)2} + 2u^{(n)}u^{(n+1)} + u^{(n-1)}u^{(n-2)} + u^{(n-1)2} + 2u^{(n)}u^{(n-1)} + u^{(n)2} + u^{(n-1)}u^{(n+1)}) \\ &+ \alpha_2 u^{(n)}(u^{(n+1)} + u^{(n)} + u^{(n-1)}) - \alpha_3 u^{(n)} + \left(\frac{1}{2}\beta_3\right)n - \nu_3 - \mu_3(-1)^n = 0, \end{aligned} \tag{129}$$

where ν_3 and μ_3 are two arbitrary constants. This last is the fourth-order dP_I equation, as given in Ref. 30. We expect, of course, that our hierarchy (116), in the special case $\beta_{m-1} = 0$, is equivalent to the dP_I hierarchy given in Ref. 30. We also expect that our hierarchy (116), in the case $\beta_{m-1} \neq 0$, sums to give a dP_{34} hierarchy that generalizes the results of Ref. 30 in the same way as does our dP_{34} equation (124).

VI. CONCLUSIONS

Here we briefly summarize our results.

- We have extended the method used in Refs. 17–20 which allows the construction of hierarchies of integrable equations along with their underlying linear problems, from the continuous to the discrete case.
- We have given a new 2+1-dimensional generalization of the Volterra hierarchy.

- We have obtained reductions to a variety of new hierarchies of integrable equations, along with their underlying linear problems. These last derive from those given for the 2+1-dimensional case.
- We have obtained a new generalized dP_I hierarchy, and also a generalized dP_{34} hierarchy, each once again along with their underlying linear problems.

(Received 24 January 2005; accepted 5 August 2005; published online 13 October 2005)

Using the corepresentation of the quantum supergroup $OSp_q(1/2)$ a general method for constructing noncommutative spaces covariant under its coaction is developed. In particular, a one-parameter family of covariant algebras, which may be interpreted as noncommutative superspheres, is constructed. It is observed that embedding of the supersphere in the $OSp_q(1/2)$ algebra is possible. This realization admits to the infinitesimal characterization by Koornwinder. A covariant oscillator realization of the supersphere is also presented. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2042969]

I. INTRODUCTION

Lie supergroups and superalgebras have been used as basic tools in various fields of theoretical physics. Supersymmetry in quantum field theories and string field theory is the most well-known example of application of Lie superalgebras. Other examples are found in exactly solvable lattice models, interacting boson-fermion models in nuclear physics, extended *t-J* models in condensed matter physics, and so on. On the other hand, importance of noncommutative geometry in theoretical physics, especially in string theory and quantum gravity, has come into focus recently.[1] Therefore if these two notions are combined to form a noncommutative geometry of supersymmetric nature, we can expect that the combination will play important roles in various fields in physics. An attempt to introduce a noncommutative superspace was made by Manin[2] in the context of quantum supergroup. Then differential calculus on the noncommutative superspace was developed by two different approaches.[3,4] The present authors extended the notions of noncommutative differential geometry such as connection and curvature to the supersymmetric case and investigated[5] the superspace for super-Jordanian deformed $OSp(1/2)$ group.

A supersphere having bosonic and fermionic coordinates is defined as an algebra whose defining relations are covariant under the coaction of the quantum supergroup $OSp_q(1/2)$. In this paper, we construct a one-parameter family of superspheres by developing a general procedure based on the representation theory of $OSp_q(1/2)$ and its dual $U_q[osp(1/2)]$. By this method, quantum superspaces and superspheres are described in a unified way. Furthermore, the method can be used to find higher dimensional noncommutative superspaces covariant under $OSp_q(1/2)$. Our work is motivated for two reasons, (1) in order to investigate noncommutative geometry, it is important to have explicit examples of noncommutative superspaces. Manin's work is an analogue of flat space, while here we consider an analogue of curved space. (2) There exist some models of integrable quantum field theories with $OSp(m/2n)$ symmetries where superspheres appear.[6] Consideration of quantum group extensions of such models will require quantum superspheres. We start with the simplest and the most important group $OSp_q(1/2)$ to construct quantum superspheres.

Let us briefly recall the studies of noncommutative sphere based on quantum groups, since supersymmetric counterparts of some of them are considered in this paper. Podleś introduced[7] an algebra which is covariant under the adjoint corepresentation of quantum group $SU_q(2)$. The

algebra is interpreted as a noncommutative version of two sphere, and called q-sphere. The q-sphere has one more parameter in addition to its radius and the deformation parameter q. Thus what Podleś constructed is a one-parameter family of noncommutative two spheres. The parameter is specific to q-sphere and does not have a commutative counterpart. Differential calculus on the q-sphere was initiated by Podleś,[8] then classification of differential structures on q-sphere was made in Refs. 9–11. An interesting relation of q-sphere to q-hypergeometric functions is discussed in Ref. 12, where orthogonal bases on q-sphere are explicitly determined in terms of big q-Jacobi polynomials. The q-sphere can be realized by embedding it in $\mathrm{SU}_q(2)$. This embedding admits an elegant description[13] of q-sphere as an algebra which is invariant under left and right actions of a twisted primitive element of the quantum algebra $\mathrm{U}_q[\mathrm{su}(2)]$. Podleś q-sphere has been generalized in two different directions, higher dimensional and Jordanian SU(2). Higher dimensional q-spheres, more precisely, noncommutative analogue of $(2n+1)$-spheres were constructed in a similar way by replacing $\mathrm{SU}_q(2)$ with $\mathrm{SU}_q(n+1)$. Furthermore, an invariant integral on quantum $(2n+1)$-sphere is obtained in Ref. 14. Another family of quantum two-spheres is obtained[15] by using Jordanian deformation of SL(2). One of its distinctions from Podleś q-sphere is that the Jordanian quantum sphere requires different twisted primitive elements for left and right invariances.

Throughout this paper, the quantum superalgebra $\mathrm{U}_q[\mathrm{osp}(1/2)]$ and the quantum supergroup $\mathrm{OSp}_q(1/2)$ are denoted by $\mathcal{U}$ and $\mathcal{A}$, respectively. We assume that q is generic in this paper. The plan of this paper is as follows. In the first two preliminary sections we fix our notations and conventions, and list formulas used in subsequent sections. Section II is a summary of definitions and representation theory of $\mathcal{U}$. For computational purpose, we give all the defining relations of $\mathcal{A}$ explicitly in Sec. III. A relation between representations of $\mathcal{U}$ and corepresentations of $\mathcal{A}$ is given in Sec. IV. A product law of two corepresentations, which is a quantum supergroup analogue of Wigner's product law in the quantum theory of angular momentum, is also derived in Sec. IV. A general prescription to find an algebra covariant under the coaction of $\mathcal{A}$ is given in Sec. V. As a simple application of the method, the most general form of quantum superspaces is derived. The method is applied to construct a one-parameter family of quantum superspheres in Sec. VI. Properties of the quantum supersphere are examined and the similarities to those for q-sphere are pointed out.

II. $\mathrm{U}_q[\mathrm{osp}(1/2)]$ AND ITS REPRESENTATIONS

A. Definition and representations

The universal enveloping algebra $\mathcal{U}=\mathrm{U}_q[\mathrm{osp}(1/2)]$ is generated by the two even $K^{\pm 1}$, and the two odd elements $v_\pm$ satisfying the commutation properties[16]

$$KK^{-1}=K^{-1}K=1, \quad Kv_\pm = q^{\pm 1/2}v_\pm K,$$

$$\{v_+,v_-\} = -\frac{K^2-K^{-2}}{q^4-q^{-4}}. \tag{2.1}$$

The Casimir element is given by

$$C=\left(\frac{q^{1/2}K^2-q^{-1/2}K^{-2}}{q^4-q^{-4}}\right)^2 - \frac{qK^2+q^{-1}K^{-2}}{(q+q^{-1})(q^2+q^{-2})}v_-v_+ - (q^{1/2}+q^{-1/2})^2 v_-^2 v_+^2. \tag{2.2}$$

The coproduct (Δ), the counit (ϵ), and the antipode (S) maps read

$$\Delta(K^{\pm 1}) = K^{\pm 1}\otimes K^{\pm 1}, \quad \Delta(v_\pm) = v_\pm \otimes K^{-1} + K \otimes v_\pm, \tag{2.3}$$

$$\epsilon(K^{\pm 1}) = 1, \quad \epsilon(v_\pm) = 0, \tag{2.4}$$

$$S(K^{\pm 1}) = K^{\mp 1}, \quad S(v_\pm) = -q^{\mp 1/2}v_\pm. \tag{2.5}$$

The finite dimensional irreducible representations of the $\mathcal{U}$ algebra are said to be of the grade-star[17] type. Each irreducible representation is specified by a non-negative integer ℓ and the corresponding $(2\ell+1)$-dimensional graded vector space $V^{(\ell)}$ that admits a nondegenerate Hermitian bilinear form denoted by (,). The subspaces of $V^{(\ell)}$ having different parities are orthogonal with respect to the bilinear form. The graded adjoint operation $(*)$ is defined by

$$(A^* f,g) = (-1)^{\hat{A}\hat{f}}(f,Ag), \quad A \in \mathcal{U}, \quad f,g \in V^{(\ell)}, \tag{2.6}$$

where $\hat{A}$ denotes the parity of A. The $*$-operation is assumed to be an algebra anti-isomorphism and coalgebra isomorphism,

$$(A_1A_2)^* = (-1)^{\hat{A}_1\hat{A}_2}A_2^*A_1^*, \quad (A_1 \otimes A_2)^* = A_1^* \otimes A_2^*. \tag{2.7}$$

The grade-star representation of $\mathcal{U}$ is characterized by

$$K^* = K, \quad v_\pm^* = \pm(-1)^\varepsilon v_\mp, \quad \varepsilon = 0,1, \tag{2.8}$$

where ε refers to the class of the representation.

Let $\{e_m^\ell(\lambda)\,|\,m=\ell,\ell-1,\ldots,-\ell\}$ be a basis of $V^{(\ell)}$, where each basis vector has a definite parity. The index $\lambda=0,1$ specifies the parity of the highest weight vector $e_\ell^\ell(\lambda)$. The parity of $e_m^\ell(\lambda)$ equals $\ell-m+\lambda$, as it is obtained by the application of $v_-^{\ell-m}$ on $e_\ell^\ell(\lambda)$. For the superalgebras the norm of the representation basis need not be chosen positive definite. In this work, however, we assume the positive definiteness of the basis elements,

$$(e_m^\ell(\lambda), e_{m'}^{\ell'}(\lambda)) = \delta_{\ell\ell'}\delta_{mm'}. \tag{2.9}$$

It turns out that this convention relates the parity λ and the class ε as follows:

$$\lambda = \varepsilon + 1 (\mathrm{mod}\ 2). \tag{2.10}$$

With these settings, the irreducible representations of $\mathcal{U}$ are given by

$$Ke_m^\ell(\lambda) = q^{m/2}e_m^\ell(\lambda),$$

$$v_+e_m^\ell(\lambda) = \sqrt{[\ell-m][\ell+m+1]\varrho}\,e_{m+1}^\ell(\lambda),$$

$$v_-e_m^\ell(\lambda) = (-1)^{\ell-m-1}\sqrt{[\ell+m][\ell-m+1]\varrho}\,e_{m-1}^\ell(\lambda), \tag{2.11}$$

where $[n]$ and ϱ are defined by

$$[n] = \frac{q^{-n/2}-(-1)^n q^{n/2}}{q^{-1/2}+q^{1/2}}, \quad \varrho = \frac{q^{-1/2}+q^{1/2}}{q^{-4}-q^4}. \tag{2.12}$$

Our phase convention for $v_\pm$ agrees with that of Ref. 16, but it differs from that of Ref. 17. For later convenience, the representation matrices for $\ell=1,2$ cases are given explicitly. The generators in the $\ell=1$ representation read

$$K = \mathrm{diag}(q^{1/2},1,q^{-1/2}),$$

$$v_+ = \sqrt{[2]\varrho}\begin{pmatrix}0&1&0\\0&0&1\\0&0&0\end{pmatrix}, \quad v_- = \sqrt{[2]\varrho}\begin{pmatrix}0&0&0\\-1&0&0\\0&1&0\end{pmatrix}, \tag{2.13}$$

and for the $\ell=2$ case they are given by

$$K = \mathrm{diag}(q, q^{1/2}, 1, q^{-1/2}, q^{-1}),$$

$$v_+ = \begin{pmatrix} 0 & \sqrt{[4]\varrho} & 0 & 0 & 0 \\ 0 & 0 & \sqrt{[3]!\varrho} & 0 & 0 \\ 0 & 0 & 0 & \sqrt{[3]!\varrho} & 0 \\ 0 & 0 & 0 & 0 & \sqrt{[4]\varrho} \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$v_- = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ -\sqrt{[4]\varrho} & 0 & 0 & 0 & 0 \\ 0 & \sqrt{[3]!\varrho} & 0 & 0 & 0 \\ 0 & 0 & -\sqrt{[3]!\varrho} & 0 & 0 \\ 0 & 0 & 0 & \sqrt{[4]\varrho} & 0 \end{pmatrix}. \tag{2.14}$$

The eigenvalue of the Casimir element depends only on the highest weight,

$$Ce_m^\ell(\lambda) = \left(\frac{q^{\ell+1/2} - q^{-\ell-1/2}}{q^4 - q^{-4}} \right)^2 e_m^\ell(\lambda). \tag{2.15}$$

The quantity $[n]$, known[16,17] as Kulish symbol, plays a role similar to the q-number. For a positive integer n its factorial is defined as $[n]! \equiv [n][n-1]\cdots[1]$.

B. Tensor product representations

Tensor product of the irreducible representations of $\mathcal{U}$ has been discussed in Refs. 16 and 17. The decomposition of tensor product in the irreducible representations is identical to the classical case

$$V^{(\ell_1)} \otimes V^{(\ell_2)} = V^{(\ell_1+\ell_2)} \oplus V^{(\ell_1+\ell_2-1)} \oplus \cdots \oplus V^{(|\ell_1-\ell_2|)}.$$

The explicit formulas of the Clebsch-Gordan coefficients (CGC) are obtained in Ref. 17. We list below the relations which will be used in the later sections.

In spite of our assumption (2.9) of the positivity of the basis states, the norm of the tensor product of the bases is not always positive definite. For instance, the following norm can be negative for some combinations of ℓ_a, $m_a (a=1,2)$, and λ:

$$(e_{m_1}^{\ell_1}(\lambda) \otimes e_{m_2}^{\ell_2}(\lambda), e_{m_1}^{\ell_1}(\lambda) \otimes e_{m_2}^{\ell_2}(\lambda)) = (-1)^{(\ell_1-m_1+\lambda)(\ell_2-m_2+\lambda)} (e_{m_1}^{\ell_1}(\lambda), e_{m_1}^{\ell_1}(\lambda))(e_{m_2}^{\ell_2}(\lambda), e_{m_2}^{\ell_2}(\lambda)). \tag{2.16}$$

The irreducible basis of the tensor product representations is obtained by using the CGC,

$$e_m^\ell(\ell_1, \ell_2, \Lambda) = \sum_{m_1, m_2} C_{m_1 m_2 m}^{\ell_1 \ell_2 \ell} e_{m_1}^{\ell_1}(\lambda) \otimes e_{m_2}^{\ell_2}(\lambda), \tag{2.17}$$

where $m = m_1 + m_2$, and $\Lambda = \ell_1 + \ell_2 + \ell \pmod 2$ is the parity of the highest weight vector $e_\ell^\ell(\ell_1, \ell_2, \Lambda)$. Since our phase convention for representations of $v_\pm$ differs from that of Ref. 17, we cannot use the expression of CGC given therein. The CGC in our convention is explicitly given by

$$C^{\ell_1\ell_2\ell}_{m_1m_2m} = (-1)^{(\ell_1-\ell+m_2)(\ell-m+\lambda)+(\ell_1-\ell+m_2)(\ell_1-\ell+m_2+1)/2} q^{m_2(m+1)/2+(\ell_1-\ell_2)(\ell_1+\ell_2+1)/4-\ell(\ell+1)/4}$$
$$\times \left([2\ell+1] \frac{[\ell_1+\ell_2-\ell]![\ell+m]![\ell-m]![\ell_1-m_1]![\ell_2-m_2]!}{[\ell_1+\ell_2+\ell+1]![\ell_1-\ell_2+\ell]![-\ell_1+\ell_2+\ell]![\ell_1+m_1]![\ell_2+m_2]!} \right)^{1/2}$$
$$\times \sum_k (-1)^{k(k-1)/2+k(\ell_1+\ell_2-m)} q^{k(\ell+m+1)/2} \frac{[\ell_1+\ell-m_2-k]![\ell_2+m_2+k]!}{[k]![\ell-m-k]![\ell_1-\ell+m_2+k]![\ell_2-m_2-k]!}, \tag{2.18}$$

where the index k runs over all non-negative integers maintaining the arguments of $[x]$ non-negative. The derivation of (2.18) is described in Appendix A. All the CGC are, we note, of parity zero. The basis (2.17) is pseudo-orthogonal,

$$(e^{\ell'}_{m'}(\ell_1,\ell_2,\Lambda), e^{\ell}_{m}(\ell_1,\ell_2,\Lambda)) = (-1)^{(\ell-m+\lambda)(\ell_1+\ell_2+\ell+\lambda)} \delta_{\ell'\ell}\delta_{m'm}. \tag{2.19}$$

The CGC satisfies two pseudo-orthogonality relations,

$$\sum_{m_1,m_2} (-1)^{(\ell_1-m_1+\lambda)(\ell_2-m_2+\lambda)} C^{\ell_1\ell_2\ell'}_{m_1m_2m'} C^{\ell_1\ell_2\ell}_{m_1m_2m} = (-1)^{(\ell-m+\lambda)(\ell_1+\ell_2+\ell+\lambda)} \delta_{\ell\ell'}\delta_{mm'}, \tag{2.20}$$

$$\sum_{\ell,m} (-1)^{(\ell-m+\lambda)(\ell_1+\ell_2+\ell+\lambda)} C^{\ell_1\ell_2\ell}_{m_1'm_2'm} C^{\ell_1\ell_2\ell}_{m_1m_2m} = (-1)^{(\ell_1-m_1+\lambda)(\ell_2-m_2+\lambda)} \delta_{m_1'm_1}\delta_{m_2'm_2}. \tag{2.21}$$

Using (2.21), the construction (2.17) is readily inverted,

$$e^{\ell_1}_{m_1}(\lambda) \otimes e^{\ell_2}_{m_2}(\lambda) = (-1)^{(\ell_1-m_1)(\ell_2-m_2)} \sum_{\ell,m} (-1)^{(\ell-m)(\ell_1+\ell_2+\ell)} C^{\ell_1\ell_2\ell}_{m_1m_2m} e^{\ell}_{m}(\ell_1,\ell_2,\Lambda). \tag{2.22}$$

III. QUANTUM SUPERGROUP $OSp_q(1/2)$

The quantum supergroup $\mathcal{A}=OSp_q(1/2)$ is defined as a Hopf dual to the universal enveloping algebra $\mathcal{U}$.[16] In this section, all defining relations of $\mathcal{A}$ will be given explicitly. The universal $\mathcal{R}$-matrix of $\mathcal{U}$ is given in Ref. 16. For the defining $\ell=1$ representation, it reads

$$\mathcal{R}^{(\ell=1)} = \left(\begin{array}{ccc|ccc|ccc}
q & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & 1 & \cdot & \omega & \cdot & \cdot & \cdot & \cdot & \\
\cdot & \cdot & q^{-1} & \cdot & \lambda & \cdot & \rho & \cdot & \cdot \\
\hline
\cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & 1 & \cdot & \lambda & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot & \omega & \cdot \\
\hline
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & q^{-1} & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & q
\end{array}\right), \tag{3.1}$$

where

$$\omega = q - q^{-1}, \quad \lambda = -q^{-1/2}\omega, \quad \rho = (1+q^{-1})\omega, \tag{3.2}$$

and the dot is used instead of zero for better readability. Let P be a permutation operator, $P(v \otimes w) = (-1)^{\hat{v}\hat{w}} w \otimes v$. Standard *FRT* (Ref. 18) construction is obtained via the matrix R,

$$R = P\mathcal{R}^{(\ell=1)}P = \left(\begin{array}{ccc|ccc|ccc} q & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & 1 & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & q^{-1} & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \hline \cdot & \omega & \cdot & 1 & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & -\lambda & \cdot & 1 & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot \\ \hline \cdot & \cdot & \rho & \cdot & -\lambda & \cdot & q^{-1} & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \omega & \cdot & 1 & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & q \end{array}\right) \tag{3.3}$$

The quantum T-matrix, whose elements generate the algebra $\mathcal{A}$ is given by

$$T = (t_{ij}) = \begin{pmatrix} a & \alpha & b \\ \gamma & e & \beta \\ c & \delta & d \end{pmatrix}, \tag{3.4}$$

where the entries in latin (greek) characters are of even (odd) parity. The parity of the supermatrix T is zero, i.e., $\hat{t}_{ij}=\hat{i}+\hat{j}$. The RTT-relation describes the exchange properties on the entries of T. The q-orthosymplectic condition reads

$$T^{st}CT = DC, \quad TC^{-1}T^{st} = DC^{-1}, \tag{3.5}$$

where

$$C = \begin{pmatrix} 0 & 0 & -q^{-1/2} \\ 0 & 1 & 0 \\ q^{1/2} & 0 & 0 \end{pmatrix}, \quad C^{-1} = \begin{pmatrix} 0 & 0 & q^{-1/2} \\ 0 & 1 & 0 \\ -q^{1/2} & 0 & 0 \end{pmatrix}, \tag{3.6}$$

and the superdeterminant D is given by

$$D = ad - qbc - q^{1/2}\alpha\delta. \tag{3.7}$$

The T^{st} denotes the supertranspose of T. The supertranspose of an arbitrary matrix is given as $A^{st}_{ij}=(-1)^{\hat{i}(\hat{j}+1)}A_{ji}$. The RTT relations require D to be central.

The coproduct and counit of T are given as usual

$$\Delta(T) = T\dot{\otimes}T, \quad \epsilon(T) = \mathrm{diag}(1,1,1). \tag{3.8}$$

The grouplike property of the superdeterminant $\Delta(D)=D\otimes D$ is obtained by taking the coproduct of both sides of the relation (3.5). This allows us to set the constraint

$$D = ad - qbc - q^{1/2}\alpha\delta = 1. \tag{3.9}$$

The antipode of T satisfies $S(T)T=TS(T)=1$, and it explicitly reads

$$S(T) = C^{-1}T^{st}C = \begin{pmatrix} d & q^{-1/2}\beta & -q^{-1}b \\ -q^{1/2}\delta & e & q^{-1/2}\alpha \\ -qc & -q^{1/2}\gamma & a \end{pmatrix}. \tag{3.10}$$

The RTT relations reveal that not all the entries of T are independent. We express the elements e, β, and γ in terms of the rest. Using (2,2) component of the first relation in (3.5),

$$e^2 = 1 - 2q^{-1/2}\alpha\delta + \omega bc, \tag{3.11}$$

we solve for e and its inverse e^{-1},

$$e = 1 - q^{-1/2}\alpha\delta + (q-1)bc,$$

$$e^{-1} = (1 + q^{-1/2}\alpha\delta - (q-1)bc)(1 + q^{-1}(q-1)^2 bc)^{-1}. \tag{3.12}$$

Inclusion of the element e^{-1} allows us to solve for β and γ,

$$\beta = q^{-3/2}b\delta - q^{1/2}d\alpha, \quad \gamma = q^{-1/2}a\delta - q^{3/2}c\alpha, \quad \alpha\delta = \gamma\beta. \tag{3.13}$$

In summary, the algebra $\mathcal{A}$ is generated by a, b, c, d, α, and δ. The generators satisfy the relations

$$ab = q^2 ba, \quad ac = q^2 ca, \quad [a,d] = -\lambda\alpha\delta + \rho bc,$$

$$a\alpha = q\alpha a, \quad a\delta = q\delta a + q\omega c\alpha, \quad [b,c] = 0,$$

$$bd = q^2 db, \quad b\alpha = q^{-1}\alpha b, \quad b\delta = q\delta b,$$

$$cd = q^2 dc, \quad c\alpha = q^{-1}\alpha c, \quad c\delta = q\delta c,$$

$$d\alpha = q^{-1}\alpha d - \omega\delta b, \quad d\delta = q^{-1}\delta d, \quad \alpha\delta = -q\delta\alpha - q\lambda bc,$$

$$\alpha^2 = -q^{-1}[2]ab, \quad \delta^2 = -q^{-1}[2]cd. \tag{3.14}$$

For later convenience, the commutation relations involving e, β, and γ are listed below,

$$[a,e] = \omega\gamma\alpha, \quad a\beta = q\beta a + q\omega b\gamma, \quad a\gamma = q\gamma a,$$

$$[b,e] = 0, \quad b\beta = q\beta b, \quad b\gamma = q^{-1}\gamma b,$$

$$[c,e] = 0, \quad c\beta = q\beta c, \quad c\gamma = q^{-1}\gamma c,$$

$$[d,e] = \omega\delta\beta, \quad d\beta = q^{-1}\beta d, \quad d\gamma = q^{-1}\gamma d - \omega\beta c,$$

$$[e,\alpha] = -\lambda\gamma b, \quad [e,\beta] = \lambda b\delta, \quad [e,\gamma] = \lambda\alpha c,$$

$$[e,\delta] = -\lambda c\beta, \quad \{\alpha,\beta\} = -\omega eb, \quad \{\alpha,\gamma\} = 0,$$

$$\beta\gamma = -q^{-1}\gamma\beta - \lambda bc, \quad \{\beta,\delta\} = 0, \quad \{\gamma,\delta\} = \omega ce,$$

$$\beta^2 = -q^{-1}[2]bd, \quad \gamma^2 = -q^{-1}[2]ac. \tag{3.15}$$

Additional relations may also be proved,

$$e\alpha = q^{1/2}(b\gamma - \beta a), \quad e\beta = q^{1/2}\delta b - q^{-1/2}\alpha d,$$

$$e\gamma = q^{1/2}(\delta a - c\alpha), \quad e\delta = q^{-1/2}\gamma d - q^{1/2}\beta c. \tag{3.16}$$

The duality between $\mathcal{U}$ and $\mathcal{A}$ is given by a nondegenerate pairing $\langle,\rangle$,

$$\langle K,T\rangle = \mathrm{diag}(q^{1/2},1,q^{-1/2}),$$

$$\langle v_+,T\rangle = \sqrt{[2]\varrho}\begin{pmatrix}0&1&0\\0&0&-1\\0&0&0\end{pmatrix},\quad \langle v_-,T\rangle = \sqrt{[2]\varrho}\begin{pmatrix}0&0&0\\1&0&0\\0&1&0\end{pmatrix}. \tag{3.17}$$

The pairing can be extended to tensor product algebras by setting

$$\langle X_1\otimes X_2,a_1\otimes a_2\rangle = (-1)^{\hat{X}_2\hat{a}_1}\langle X_1,a_1\rangle\langle X_2,a_2\rangle. \tag{3.18}$$

IV. COREPRESENTATIONS OF $\mathcal{A}$

A vector space V is called a right $\mathcal{A}$-comodule if there exists a linear mapping $\varphi_R: V\to V\otimes\mathcal{A}$ satisfying

$$(\varphi_R\otimes \mathrm{id})\circ\varphi_R = (\mathrm{id}\otimes\Delta)\circ\varphi_R,\quad (\mathrm{id}\otimes\epsilon)\circ\varphi_R = \mathrm{id}. \tag{4.1}$$

Similarly, the left $\mathcal{A}$-comodule is defined as a vector space V equipped with a linear mapping $\varphi_L: V\to\mathcal{A}\otimes V$ such that

$$(\mathrm{id}\otimes\varphi_L)\circ\varphi_L = (\Delta\otimes\mathrm{id})\circ\varphi_L,\quad (\epsilon\otimes\mathrm{id})\circ\varphi_L = \mathrm{id}. \tag{4.2}$$

The mapping $\varphi_R(\varphi_L)$ is called a corepresentation, or, equivalently, a right (left) coaction of $\mathcal{A}$ on V.

Employing the duality of the algebras $\mathcal{U}$ and $\mathcal{A}$, we may follow the standard[19] construction of the action of $\mathcal{U}$ on a $\mathcal{A}$-comodule V. Namely, starting from the corepresentations of $\mathcal{A}$, we may obtain representations of $\mathcal{U}$. Reversing the argument, we now obtain the hitherto unknown corepresentations of $\mathcal{A}$ from the already known irreducible representations of $\mathcal{U}$.

Let an arbitrary element $X\in\mathcal{U}$ act on the vector space $V^{(\ell)}$ described in Sec. II A. The matrix representation of X on $V^{(\ell)}$ is denoted by $D^\ell(X;\lambda)$,

$$Xe^\ell_m(\lambda) = \sum_{m'} e^\ell_{m'}(\lambda)D^\ell_{m'm}(X;\lambda). \tag{4.3}$$

The parity of the element $T^\ell_{m'm}(\lambda)$ of $\mathcal{A}$, defined via the duality relation

$$D^\ell_{m'm}(X;\lambda) = (-1)^{\hat{X}(\ell-m'+\lambda)}\langle X,T^\ell_{m'm}(\lambda)\rangle, \tag{4.4}$$

may be assigned as

$$\widehat{T^\ell_{m'm}}(\lambda) = m'+m(\mathrm{mod}\,2). \tag{4.5}$$

To prove this, we compare the parity of both sides of (4.3). The resultant equation $\widehat{D^\ell_{m'm}}(X;\lambda) = \hat{X}+m'+m\ (\mathrm{mod}\,2)$ establishes the relation (4.5). Though we know, via (2.11), that all nonvanishing entries of the representation matrices are even, we should keep the parity of $D^\ell(X;\lambda)$ in the present formulation. Next we obtain the coproduct and counit maps for $T^\ell_{m'm}(\lambda)$,

$$\Delta(T^\ell_{m'm}(\lambda)) = \sum_{m''} T^\ell_{m'm''}(\lambda)\otimes T^\ell_{m''m}(\lambda),\quad \epsilon(T^\ell_{m'm}(\lambda)) = \delta_{m'm}. \tag{4.6}$$

The matrix $D^\ell(X;\lambda)$, being a representation of $X\in\mathcal{U}$, obeys the rule

$$D^{\ell}_{m'm}(XY;\lambda) = \sum_{m''} D^{\ell}_{m'm''}(X;\lambda) D^{\ell}_{m''m}(Y;\lambda) \quad \forall\, X,Y \in \mathcal{U}. \tag{4.7}$$

Both sides [left-hand side (lhs) and right-hand side (rhs)] of (4.7) may be rewritten by using (4.4),

$$\text{lhs} = (-1)^{\widehat{XY}(\ell-m'+\lambda)} \langle XY, T^{\ell}_{m'm}(\lambda)\rangle = (-1)^{\widehat{XY}(\ell-m'+\lambda)} \langle X \otimes Y, \Delta(T^{\ell}_{m'm}(\lambda))\rangle,$$

$$\text{rhs} = \sum_{m''} (-1)^{\hat{X}(\ell-m'+\lambda)+\hat{Y}(\ell-m''+\lambda)} \langle X, T^{\ell}_{m'm''}(\lambda)\rangle \langle Y, T^{\ell}_{m''m}(\lambda)\rangle = \sum_{m''} (-1)^{(\hat{X}+\hat{Y})(\ell-m'+\lambda)} \langle X \otimes Y, T^{\ell}_{m'm''}(\lambda) \otimes T^{\ell}_{m''m}(\lambda)\rangle.$$

The property (4.7) now assumes the form

$$\left\langle X \otimes Y, \Delta(T^{\ell}_{m'm}(\lambda)) - \sum_{m''} T^{\ell}_{m'm''}(\lambda) \otimes T^{\ell}_{m''m}(\lambda) \right\rangle = 0. \tag{4.8}$$

Since the relation (4.8) is true for arbitrary X, Y, and the pairing is nondegenerate, we obtain the coproduct map in (4.6). To obtain the counit map, we consider

$$D^{\ell}_{m'm}(1;\lambda) = \langle 1, T^{\ell}_{m'm}(\lambda)\rangle \equiv \epsilon(T^{\ell}_{m'm}(\lambda)), \tag{4.9}$$

and use the fact that the unit element of $\mathcal{U}$ is always represented by the identity matrix $(\delta_{m'm})$. This completes the proof of (4.6).

Defining the map $\varphi_R : V^{(\ell)} \to V^{(\ell)} \otimes \mathcal{A}$ by

$$\varphi_R(e^{\ell}_m(\lambda)) = \sum_{m'} e^{\ell}_{m'}(\lambda) \otimes T^{\ell}_{m'm}(\lambda), \tag{4.10}$$

it is easy to show, via (4.6), that $V^{(\ell)}$ equipped with φ_R is a right $\mathcal{A}$-comodule. Thus the quantum supermatrix $T^{\ell}(\lambda)$ provides the $(2\ell+1)$-dimensional corepresentation of $\mathcal{A}$ on $V^{(\ell)}$. The relation between representations and corepresentations is summarized in the same form as the nonsuper case,[19]

$$X e^{\ell}_m(\lambda) = (\mathrm{id} \otimes X) \circ \varphi_R(e^{\ell}_m(\lambda)), \tag{4.11}$$

where the action of $\mathcal{U}$ on $\mathcal{A}$ is defined by the nondegenerate pairing. It is easy to find $T^{\ell}(\lambda)$ for $\ell = 0, 1$ from (4.4),

$$T^0_{00}(\lambda) = 1 \quad \text{for } \lambda = 0, 1, \tag{4.12}$$

$$T^1(0) = T = \begin{pmatrix} a & \alpha & b \\ \gamma & e & \beta \\ c & \delta & d \end{pmatrix}, \quad T^1(1) = \begin{pmatrix} a & -\alpha & b \\ -\gamma & e & -\beta \\ c & -\delta & d \end{pmatrix}, \tag{4.13}$$

where the indices of rows and columns of $T^1(\lambda)$ run over 1, 0, and −1.

One of the important properties of the corepresentations $T^{\ell}(\lambda)$ is that they satisfy the product law which gives a rule to combine two corepresentations to get the third one,

$$\delta_{\ell'\ell} T^{\ell}_{m'm}(\Lambda) = \sum_{\substack{m_1,m_2 \\ m_1',m_2'}} (-1)^p C^{\ell_1\ell_2\ell'}_{m_1'm_2'm'} C^{\ell_1\ell_2\ell}_{m_1m_2m} T^{\ell_1}_{m_1'm_1}(\lambda) T^{\ell_2}_{m_2'm_2}(\lambda),$$

$$p=(m_1'+m_1)(\ell_2-m_2'+\lambda)+(\ell_1-m_1')(\ell_2-m_2')+(\ell'-m')(\ell_1+\ell_2+\ell'). \tag{4.14}$$

To prove the above product law, we first derive the fusion rule of representation matrices $D^{\ell}(X;\lambda)$ of $\mathcal{U}$, and then apply the duality argument by the proof of (4.6).

Denoting the coproduct of $X\in\mathcal{U}$ as $\Delta(X)=\Sigma_a X_a\otimes X^a$, we use the projection relation (2.17) to obtain

$$Xe_m^{\ell}(\ell_1,\ell_2,\Lambda)=\sum_{m_1,m_2,a}(-1)^{\hat{X}^a(\ell_1-m_1+\lambda)}C^{\ell_1\ell_2\ell}_{m_1m_2m}X_a e^{\ell_1}_{m_1}(\lambda)\otimes X^a e^{\ell_2}_{m_2}(\lambda). \tag{4.15}$$

We employ (4.3) to compute both sides of (4.15),

$$\begin{aligned}\text{rhs}=&\sum_{\substack{m_1,m_2\\ m_1',m_2'}}\sum_a(-1)^{\hat{X}^a(\ell_1-m_1+\lambda)}(-1)^{(\hat{X}_a+m_1'+m_1)(\ell_2-m_2'+\lambda)}\\ &\times C^{\ell_1\ell_2\ell}_{m_1m_2m}(e^{\ell_1}_{m_1'}\otimes e^{\ell_2}_{m_2'})D^{\ell_1}_{m_1'm_1}(X_a;\lambda)D^{\ell_2}_{m_2'm_2}(X^a;\lambda)\\ =&\sum_{\substack{m_1,m_2\\ m_1',m_2'}}\sum_{a,\ell',m'}(-1)^{\hat{X}^a(\ell_1-m_1+\lambda)+\hat{X}_a(\ell_2-m_2'+\lambda)+p}\\ &\times C^{\ell_1\ell_2\ell'}_{m_1'm_2'm'}C^{\ell_1\ell_2\ell}_{m_1m_2m}e^{\ell'}_{m'}(\ell_1,\ell_2,\Lambda')D^{\ell_1}_{m_1'm_1}(X_a;\lambda)D^{\ell_2}_{m_2'm_2}(X^a;\lambda),\end{aligned}$$

where (2.22) is used in the last equality. The lhs of (4.15) follows directly from (4.3):

$$\text{lhs}=\sum_{m'}e^{\ell}_{m'}(\ell_1,\ell_2,\Lambda)D^{\ell}_{m'm}(X;\Lambda),$$

yielding the product law of $D^{\ell}(X,\lambda)$,

$$\begin{aligned}\delta_{\ell'\ell}D^{\ell}_{m'm}(X,\Lambda)=&\sum_{\substack{m_1,m_2\\ m_1',m_2'}}\sum_a(-1)^{\hat{X}^a(\ell_1-m_1+\lambda)+\hat{X}_a(\ell_2-m_2'+\lambda)+p}\\ &\times C^{\ell_1\ell_2\ell'}_{m_1'm_2'm'}C^{\ell_1\ell_2\ell}_{m_1m_2m}D^{\ell_1}_{m_1'm_1}(X_a;\lambda)D^{\ell_2}_{m_2'm_2}(X^a;\lambda).\end{aligned} \tag{4.16}$$

To derive the fusion rule for $T^{\ell}(\lambda)$, we consider the dual pairing,

$$\begin{aligned}\langle X,T^{\ell_1}_{m_1'm_1}(\lambda)T^{\ell_2}_{m_2'm_2}(\lambda)\rangle=\langle\Delta(X),T^{\ell_1}_{m_1'm_1}(\lambda)\otimes T^{\ell_2}_{m_2'm_2}(\lambda)\rangle=&\sum_a(-1)^{\hat{X}^a(m_1'+m_1)}\\ &\times(-1)^{\hat{X}_a(\ell_1-m_1'+\lambda)+\hat{X}^a(\ell_2-m_2'+\lambda)}D^{\ell_1}_{m_1'm_1}(X_a;\lambda)D^{\ell_2}_{m_2'm_2}(X^a;\lambda),\end{aligned}$$

which, in turn, allows us to evaluate the following sum:

$$\begin{aligned}&\sum_{\substack{m_1,m_2\\ m_1',m_2'}}(-1)^pC^{\ell_1\ell_2\ell'}_{m_1'm_2'm'}C^{\ell_1\ell_2\ell}_{m_1m_2m}\langle X,T^{\ell_1}_{m_1'm_1}(\lambda)T^{\ell_2}_{m_2'm_2}(\lambda)\rangle\\ &\quad=(-1)^{\hat{X}(\ell-m'+\Lambda)}\sum_{\substack{m_1,m_2\\ m_1',m_2'}}\sum_a(-1)^{\hat{X}^a(\ell_1-m_1+\lambda)+\hat{X}_a(\ell_2-m_2'+\lambda)+p}\\ &\qquad\times C^{\ell_1\ell_2\ell'}_{m_1'm_2'm'}C^{\ell_1\ell_2\ell}_{m_1m_2m}D^{\ell_1}_{m_1'm_1}(X_a;\lambda)D^{\ell_2}_{m_2'm_2}(X^a;\lambda)=\delta_{\ell'\ell}(-1)^{\hat{X}(\ell-m'+\Lambda)}D^{\ell}_{m'm}(X;\Lambda)\end{aligned}$$

$$= \langle X, \delta_{\ell'\ell} T^{\ell}_{m'm}(\Lambda) \rangle .$$

The second equality is due to (4.16). Invoking the arbitrariness of $X \in \mathcal{U}$, and the nondegeneracy of dual pairing $\langle , \rangle$, we obtain the fusion rule (4.14).

V. $\mathcal{A}$-COVARIANT ALGEBRAS

A. General prescription

In this section, we will give a general prescription to find $\mathcal{A}$-covariant algebras. By $\mathcal{A}$-covariant algebras, we mean algebras whose defining relations are covariant under the right coaction φ_R of $\mathcal{A}$ defined by (4.10). Probably, the simplest way to find such an algebra is to introduce an algebraic structure on the representation space $V^{(\ell)}$. Assuming μ to be a multiplication map in $V^{(\ell)}$, i.e., $\mu(f \otimes g) = fg; f, g \in V^{(\ell)}$, we specifically construct the following composite object:

$$E^L_M(\Lambda) \equiv \mu(e^L_M(\ell, \ell, \Lambda)) = \sum_{m_1, m_2} C^{\ell\ \ell\ L}_{m_1 m_2 M} e^{\ell}_{m_1}(\lambda) e^{\ell}_{m_2}(\lambda), \tag{5.1}$$

where $\Lambda = L (\mathrm{mod}\, 2)$. The right coaction on $E^L_M(\Lambda)$ is shown to be

$$\varphi_R(E^L_M(\Lambda)) = \sum_{M'} E^L_{M'}(\Lambda) \otimes T^L_{M'M}(\Lambda). \tag{5.2}$$

The proof may be done in a straightforward way by inverting the relation (5.1),

$$e^{\ell}_{m_1}(\lambda) e^{\ell}_{m_2}(\lambda) = (-1)^{(\ell - m_1)(\ell - m_2)} \sum_{L,M} (-1)^{(L-M)L} C^{\ell\ \ell\ L}_{m_1 m_2 M} E^L_M(\Lambda), \tag{5.3}$$

and subsequently using the product law (4.14),

$$\begin{aligned}
\varphi_R(E^L_M(\Lambda)) &= \sum_{m_1, m_2} C^{\ell\ \ell\ L}_{m_1 m_2 M} \varphi_R(e^{\ell}_{m_1}(\lambda)) \varphi_R(e^{\ell}_{m_2}(\lambda)) \\
&= \sum_{\substack{m_1, m_2 \\ m_1', m_2'}} (-1)^{(m_1' + m_1)(\ell - m_2' + \lambda)} C^{\ell\ \ell\ L}_{m_1 m_2 M} e^{\ell}_{m_1'}(\lambda) e^{\ell}_{m_2'}(\lambda) \otimes T^{\ell}_{m_1' m_1}(\lambda) T^{\ell}_{m_2' m_2}(\lambda) \\
&\overset{(5.3)}{=} \sum_{\substack{m_1, m_2 \\ m_1', m_2'}} \sum_{L', M'} (-1)^{p'} C^{\ell\ \ell\ L}_{m_1 m_2 M} C^{\ell\ \ell\ L'}_{m_1' m_2' M'} E^{L'}_{M'}(\Lambda) \otimes T^{\ell}_{m_1' m_1}(\lambda) T^{\ell}_{m_2' m_2}(\lambda) \\
&\overset{(4.14)}{=} \sum_{M'} E^L_{M'}(\Lambda) \otimes T^L_{M'M}(\Lambda),
\end{aligned}$$

where $p' = (m_1' + m_1)(\ell - m_2' + \lambda) + (\ell - m_1')(\ell - m_2') + (L' - M')L'$.

Employing (5.2) we now extract a set of relations which are covariant under φ_R. The $L = 0$ relation $\varphi_R(E^0_0(0)) = E^0_0(0)$ signifies that $E^0_0(0)$ is a scalar under the right coaction. It may be equated to a constant parameter r,

$$E^0_0(0) = \sum_{m_1, m_2} C^{\ell\ \ell\ 0}_{m_1 m_2 0} e^{\ell}_{m_1}(\lambda) e^{\ell}_{m_2}(\lambda) = r. \tag{5.4}$$

If $L = \ell$ and $\lambda = \ell \ (\mathrm{mod}\, 2)$, then $E^{\ell}_m(\lambda)$ and $e^{\ell}_m(\lambda)$ have the same parity, and they transform identically under φ_R. Therefore $E^{\ell}_m(\lambda)$ is, in general, proportional to $e^{\ell}_m(\lambda)$. It may be noted that the following relations are covariant:

$$E_m^\ell(\lambda) = \sum_{m_1,m_2} C_{m_1 m_2 m}^{\ell\ \ell\ \ell} e_{m_1}^\ell(\lambda) e_{m_2}^\ell(\lambda) = \xi e_m^\ell(\lambda), \tag{5.5}$$

where the proportionality constant $\xi \to 0$ as $q \to 1$. For the case $\lambda \neq \ell \pmod 2$, $E_m^\ell(\ell)$ has different parity from $e_m^\ell(\lambda)$, even though they transform identically. In this case, the constant ξ in (5.5) is regarded as a Grassmann number that also vanish at $q=1$. For $L \neq 0, \ell$, the element $E_m^\ell(\ell)$ cannot be proportional to $e_m^\ell(\lambda)$ as they transform differently. The relevant covariant relations are, therefore, of the form

$$E_M^L(\Lambda) = \sum_{m_1,m_2} C_{m_1 m_2 M}^{\ell\ \ell\ L} e_{m_1}^\ell(\lambda) e_{m_2}^\ell(\lambda) = 0. \tag{5.6}$$

As will be seen in the subsequent sections, the simultaneous use of all relations from (5.4)–(5.6) gives an inconsistent result, since some of them do not have correct classical limits. In order to obtain a consistent covariant algebra, we must make a choice regarding the relations to be used for defining the algebra. Then the consistency must be verified. As it is clear from the above discussion, the covariant algebras can have at most two more parameters (r, ξ) in addition to the deformation parameter q. It is emphasized that the origin of the parameters is clearly explained in the framework of the representation theory.

We have formulated a method to construct $\mathcal{A}$-covariant algebras with respect to the right coaction. It is possible to repeat the same discussion for the left coaction.

B. Quantum superspace ($\ell=1, \lambda=0$)

Let us investigate the covariant algebra for the $\ell=1$ case, where the relevant tensor product decomposition is given by $1 \otimes 1 = 2 \oplus 1 \oplus 0$. We assume that $\lambda=0$, and denote the basis of $V^{(1)}$ by $z_m = e_m^1(0)$. Thus $z_{\pm 1}$ are parity even and z_0 is parity odd. The CGC for the decomposition is given in Appendix C. For $L=0$, we obtain from (5.4),

$$q^{1/2} z_{-1} z_1 + z_0^2 - q^{-1/2} z_1 z_{-1} = r. \tag{5.7}$$

For $L=1$, we have $\Lambda \neq \lambda$, and, therefore, the parameter ξ is a Grassmann number,

$$-q^{1/2} z_0 z_1 + q^{-1/2} z_1 z_0 = \xi z_1,$$

$$z_{-1} z_1 + (q^{-1/2} + q^{1/2}) z_0^2 - z_1 z_{-1} = \xi z_0,$$

$$q^{1/2} z_{-1} z_0 - q^{-1/2} z_0 z_{-1} = \xi z_{-1}. \tag{5.8}$$

For $L=2$, we obtain, using (5.6), unacceptable relations such as

$$z_1^2 = 0, \quad q^{-1/2} z_0 z_1 + q^{1/2} z_1 z_0 = 0.$$

Thus we take (5.7) and (5.8) as defining relations of our covariant algebra. We need to check the following conditions in order to verify whether or not the algebra is well defined:

(a) The constant r commutes with all generators.
(b) Product of three generators, say $z_1 z_0 z_{-1}$, has two ways of reversing its ordering,

$$\begin{array}{ccccc} & & z_1 z_0 z_{-1} & \to & z_1 z_{-1} z_0 & & \\ & \nearrow & & & & \searrow & \\ z_0 z_1 z_{-1} & & & & & & z_{-1} z_1 z_0. \\ & \searrow & & & & \nearrow & \\ & & z_0 z_{-1} z_1 & \to & z_{-1} z_0 z_1 & & \end{array}$$

These two ways give the same result.

It is straightforward to verify that the condition (a) is satisfied. The condition (b), however, requires setting $\xi=0$.

Therefore, we define our covariant algebra by combining relations (5.7) and (5.8), while maintaining $\xi=0$,

$$z_1 z_0 = q z_0 z_1, \quad z_0 z_{-1} = q z_{-1} z_0,$$

$$z_1 z_{-1} = q^2 z_{-1} z_1 - q(q^{-1/2} + q^{1/2}) r,$$

$$z_0^2 = -q^{-1}[2] z_1 z_{-1} - q^{-1} r. \tag{5.9}$$

This may be interpreted as the most general form of a quantum superspace. The simplest quantum superspace corresponds to the choice of $r=0$.

C. Quantum superspace ($\ell=1, \lambda=1$)

In this section, we study another quantum superspace where the parity is opposite to the previous example. Setting $\theta_m = e^1_m(1)$, we note that $\theta_{\pm 1}$ have odd parity, while θ_0 has even parity. Following (5.4), we obtain

$$q^{1/2}\theta_{-1}\theta_1 - \theta_0^2 - q^{-1/2}\theta_1\theta_{-1} = r. \tag{5.10}$$

The $L=1$ relations may be obtained from (5.5) except that in this case, as $\Lambda=\lambda$ holds, the parameter ξ is not a Grassmann number. However, these relations such as

$$q^{1/2}\theta_0\theta_1 + q^{-1/2}\theta_1\theta_0 = \xi\theta_1$$

are unacceptable as they include, in the $q \to 1$ limit, anticommutators for the product of even and odd elements. On the other hand, $L=2$ relations have proper classical limits,

$$\theta_{\pm 1}^2 = 0,$$

$$q^{-1/2}\theta_0\theta_1 - q^{1/2}\theta_1\theta_0 = 0,$$

$$q^{-1}\theta_{-1}\theta_1 - [2]\theta_0^2 + q\theta_1\theta_{-1} = 0,$$

$$-q^{-1/2}\theta_{-1}\theta_0 + q^{1/2}\theta_0\theta_{-1} = 0. \tag{5.11}$$

An interesting observation for this case is that we have two kinds of quantum superspaces. First we note that the relations (5.11) are enough to define a covariant algebra, since it may be shown that the condition (b) of Sec. V B is satisfied. Thus the relations (5.11) define a quantum superspace. Alternately, combining (5.11) with (5.10) we obtain another set of covariant relations

$$\theta_{\pm 1}^2 = 0, \quad q\theta_1\theta_0 = \theta_0\theta_1, \quad q\theta_0\theta_{-1} = \theta_{-1}\theta_0,$$

$$\theta_1\theta_{-1} + \theta_{-1}\theta_1 = -\frac{[2]}{[3]} r, \quad \theta_0^2 = -(q^{-1/2} + q^{1/2})\theta_1\theta_{-1} - q^{1/2}\frac{[2]}{[3]} r, \tag{5.12}$$

which have correct classical limit for an arbitrary value of r. With these relations, it may be checked that the conditions (a) and (b) of Sec. V B are satisfied. Thus we define the second quantum superspace by (5.12).

The above quantum superspaces are covariant under the coaction,

$$\varphi_R(\theta_m) = \sum_{m'} \theta_{m'} \otimes T^1_{m'm}(1), \tag{5.13}$$

where $T^1(1)$ is given by (4.13). Defining a new basis of the quantum superspace by

$$\theta'_0 = \theta_0, \quad \theta'_{\pm 1} = -\theta_{\pm 1}, \tag{5.14}$$

we observe that the θ'_m are covariant under the same corepresentation matrix as the case of $\lambda = 0$,

$$\theta'_m = \sum_{m'} \theta'_{m'} \otimes T^1_{m'm}(0). \tag{5.15}$$

VI. $\mathcal{A}$-COVARIANT SPHERE

A. Construction

In this section, we investigate an algebra covariant under the coaction of $T^2(\lambda)$, i.e., the adjoint corepresentation of $\mathcal{A}$. This may be interpreted as a supersymmetric extension of a noncommutative sphere. The corepresentation matrices $T^2(\lambda)$ are found from (2.14) and (4.4), or, alternately, by coupling the elements of two $T^1(\lambda)$ matrices via the product law (4.14). We restrict ourselves to the case of $\lambda = 0$,

$$T^2(0) = \begin{pmatrix} a^2 & \kappa_1 a\alpha & \kappa_3 ab & \kappa_1 \alpha b & b^2 \\ \kappa_1 a\gamma & ae + q^{-1}\gamma\alpha & \kappa_2(a\beta + q^{-1}\gamma b) & -\alpha\beta + q^{-1}eb & \kappa_1 b\beta \\ \kappa_3 ac & \kappa_2(a\delta + c\alpha) & ad + q^{-1}[2]\alpha\delta + q^{-2}bc & \kappa_2(\alpha d + \delta b) & \kappa_3 bd \\ \kappa_1 \gamma c & \gamma\delta + q^{-1}ce & \kappa_2(\gamma d + q^{-1}c\beta) & ed + q^{-1}\beta\delta & \kappa_1 \beta d \\ c^2 & \kappa_1 c\delta & \kappa_3 cd & \kappa_1 \delta d & d^2 \end{pmatrix}, \tag{6.1}$$

where

$$\kappa_1 = \sqrt{\frac{[4]}{q[2]}}, \quad \kappa_2 = \sqrt{q^{-1}[3]}, \quad \kappa_3 = \kappa_1\kappa_2. \tag{6.2}$$

The basis of $V^{(2)}$ is denoted by $Y_m = e^2_m(0)$, where $m = 0, \pm 1, \pm 2$. Here $Y_0, Y_{\pm 2}$ are even, and $Y_{\pm 1}$ are odd. Following the prescription in Sec. V A, we seek a covariant algebra under the right coaction of $T^2(0)$. The CGC for $\ell = 2$ are found in Appendix D. The relation for $L = 0$ is obtained via (5.4),

$$q^{-1}Y_2Y_{-2} - q^{-1/2}Y_1Y_{-1} - Y_0^2 + q^{1/2}Y_{-1}Y_1 + qY_{-2}Y_2 = r, \tag{6.3}$$

where r is a constant. Equation (6.3) may be regarded as the radius relation of the quantum supersphere. Explicit constructions for the $L = 2$ case are obtained from (5.5),

$$q^{-3/2}Y_2Y_0 - \left(\frac{[3]!}{[4]}\right)^{1/2} Y_1^2 - q^{3/2}Y_0Y_2 = \xi Y_2,$$

$$q^{-1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_2Y_{-1} + q^{-1/2}\mu_{21}Y_1Y_0 - q^{1/2}\mu_{22}Y_0Y_1 - q^{1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_{-1}Y_2 = \xi Y_1,$$

$$q^{1/2}Y_2Y_{-2} - \mu_{22}Y_1Y_{-1} + \mu_{23}Y_0^2 - \mu_{21}Y_{-1}Y_1 - q^{-1/2}Y_{-2}Y_2 = \xi Y_0,$$

$$q^{-1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_1Y_{-2} + q^{-1/2}\mu_{21}Y_0Y_{-1} - q^{1/2}\mu_{22}Y_{-1}Y_0 - q^{1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_{-2}Y_1 = \xi Y_{-1},$$

$$q^{-3/2}Y_0Y_{-2} - \left(\frac{[3]!}{[4]}\right)^{1/2} Y_{-1}^2 - q^{3/2}Y_{-2}Y_0 = \xi Y_{-2}, \tag{6.4}$$

where ξ is a constant vanishing in the classical limit, and

$$\mu_{21} = \frac{[2]}{[4]}(q^{-2} + q^{3/2}[2]), \quad \mu_{22} = \frac{[2]}{[4]}(q^2 - q^{-3/2}[2]), \quad \mu_{23} = \frac{[2]^2}{[4]}\left(\frac{[8]}{[4]} + 2\frac{[4]}{[2]} + 1\right). \tag{6.5}$$

The construction (5.6) may be applied to the remaining values of L. The relations for the $L=3$ case read

$$q^{-1}Y_2Y_1 - qY_1Y_2 = 0,$$

$$Y_2Y_0 - \mu_{31}Y_1^2 - Y_0Y_2 = 0,$$

$$qY_2Y_{-1} - \mu_{32}Y_1Y_0 + \mu_{33}Y_0Y_1 - q^{-1}Y_{-1}Y_2 = 0,$$

$$-q^2Y_2Y_{-2} + q^{1/2}([3] + q^2)Y_1Y_{-1} + [3]\omega Y_0^2 + q^{-1/2}([3] + q^{-2})Y_{-1}Y_1 + q^{-2}Y_{-2}Y_2 = 0,$$

$$qY_1Y_{-2} - \mu_{32}Y_0Y_{-1} + \mu_{33}Y_{-1}Y_0 - q^{-1}Y_{-2}Y_1 = 0,$$

$$Y_0Y_{-2} - \mu_{31}Y_{-1}^2 - Y_{-2}Y_0 = 0,$$

$$q^{-1}Y_{-1}Y_{-2} - qY_{-2}Y_{-1} = 0, \tag{6.6}$$

where

$$\mu_{31} = -\frac{\sqrt{[4]!}}{[2]^2}\omega, \quad \mu_{32} = \left(\frac{[4]}{[3]!}\right)^{1/2}(q^2 + q^{-1/2}[2]), \quad \mu_{33} = \left(\frac{[4]}{[3]!}\right)^{1/2}(q^{-2} - q^{1/2}[2]). \tag{6.7}$$

We observe that the relations (6.4) together with (6.6) have the correct classical limits. We have obtained a set of 12 relations for five generators. To test whether they consistently define an algebra, we need to check for the conditions (a) and (b) mentioned in Sec. V B. It may be proved by direct computation that the said conditions are, however, not satisfied.

In order to make the algebra well defined, we incorporate the $L=1$ relations listed below,

$$q^{-3/2}Y_2Y_{-1} - q^{-1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_1Y_0 - q^{1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_0Y_1 + q^{3/2}Y_{-1}Y_2 = 0,$$

$$-q^{-1/2}Y_2Y_{-2} + q^{-1}\mu_{11}Y_1Y_{-1} + \varpi\frac{[3]!}{[4]}Y_0^2 - q\mu_{12}Y_{-1}Y_1 - q^{1/2}Y_{-2}Y_2 = 0,$$

$$-q^{-3/2}Y_1Y_{-2} + q^{-1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_0Y_{-1} + q^{1/2}\left(\frac{[3]!}{[4]}\right)^{1/2} Y_{-1}Y_0 - q^{3/2}Y_{-2}Y_1 = 0, \tag{6.8}$$

where

$$\varpi = q^{1/2} + q^{-1/2}, \quad \mu_{11} = q + q^{-1}\frac{[2]}{[4]}, \quad \mu_{12} = q^{-1} + q\frac{[2]}{[4]}. \tag{6.9}$$

The remaining $L=4$ relations cannot be incorporated, because they contain unacceptable equations such as $Y_{\pm 2}^2 = 0$.

As all the relations in (6.4), (6.6), and (6.8) are covariant by construction, their linear combinations are also covariant. Taking linear combination of the 15 relations, 12 "commutation relations" of generators and three constraints are obtained. The commutation relations read

$$Y_2Y_1 = q^2Y_1Y_2, \quad Y_{-1}Y_{-2} = q^2Y_{-2}Y_{-1},$$

$$q^{-2}Y_2Y_0 = q^2Y_0Y_2 + \varpi\frac{[4][3]}{[6]}\xi Y_2,$$

$$q^{-2}Y_0Y_{-2} = q^2Y_{-2}Y_0 + \varpi\frac{[4][3]}{[6]}\xi Y_{-2},$$

$$q^{-3}Y_2Y_{-1} = q^3Y_{-1}Y_2 + \varpi\frac{[3]\sqrt{[4]!}}{[6]}\xi Y_1,$$

$$q^{-3}Y_1Y_{-2} = q^3Y_{-2}Y_1 + \varpi\frac{[3]\sqrt{[4]!}}{[6]}\xi Y_{-1},$$

$$q^{-1}Y_1Y_0 = qY_0Y_1 + \varpi\frac{[3]!}{[6]}\xi Y_1,$$

$$q^{-1}Y_0Y_{-1} = qY_{-1}Y_0 + \varpi\frac{[3]!}{[6]}\xi Y_{-1},$$

$$q^{-1}\mu_{11}Y_2Y_{-2} = q\mu_{12}Y_{-2}Y_2 - F_1Y_0^2 + F_2Y_0,$$

$$q^{-1/2}Y_1Y_{-1} = -q^{1/2}Y_{-1}Y_1 + \omega Y_0^2 + \frac{\varpi}{q+1+q^{-1}}\xi Y_0,$$

$$Y_1^2 = \frac{1}{\mu_{31}}(Y_2Y_0 - Y_0Y_2), \quad Y_{-1}^2 = \frac{1}{\mu_{31}}(Y_0Y_{-2} - Y_{-2}Y_0), \tag{6.10}$$

where

$$F_1 = \varpi(q^2+q+1+q^{-1}+q^{-2})\frac{[2]^2}{[4]},$$

$$F_2 = \varpi(q^2+2q+2q^{-1}+q^{-2})\frac{[3]![2]}{[6][4]}\xi. \tag{6.11}$$

Classical commutation properties immediately follow from (6.10) in the limit $q \to 1$. Three said constraints are given by

$$Y_2Y_{-1} = \frac{q^2}{[3]}\left(\frac{[3]!}{[4]}\right)^{1/2}Y_1Y_0 + q^{1/2}\frac{[2]}{[6]}\left(\frac{[3]!}{[4]}\right)^{1/2}\xi Y_1,$$

$$Y_1Y_{-2} = \frac{q^2}{[3]}\left(\frac{[3]!}{[4]}\right)^{1/2}Y_0Y_{-1} + q^{1/2}\frac{[2]}{[6]}\left(\frac{[3]!}{[4]}\right)^{1/2}\xi Y_{-1},$$

$$Y_0^2 = q^{-1}\frac{[4]}{[2]}Y_2Y_{-2} - q^{-1/2}(q+q^{-1})\mu_{12}Y_1Y_{-1} - q^{-3/2}\frac{[3]!}{[6]}\xi Y_0. \tag{6.12}$$

The classical limit of these constraints are not required in the commutative case. However, *we need the constraints to satisfy the two important requirements* given in Sec. V B. Verification of these conditions is straightforward but requires dull lengthy computation. Since the two conditions are satisfied, we define a one-parameter family of $\mathcal{A}$-covariant quantum superspheres by the radius relation (6.3), the commutation relations (6.10), and the constraints (6.12). We denote this quantum supersphere by $S^0_{q,\xi}$. The superscript 0 indicates the parity $\lambda=0$ and ξ is a free parameter which does not have a classical counterpart. The origin of the parameter and the fact that the quantum superspheres cannot have more parameters clearly follows from the formulation in Sec. V A.

B. Properties of $S^0_{q,\xi}$

In this section, three properties of the quantum supersphere $S^0_{q,\xi}$ are investigated. First, we consider a realization of $S^0_{q,\xi}$ in terms of elements of $\mathcal{A}$. Then it turns out that this realization admits an infinitesimal characterization of $S^0_{q,\xi}$. A representation of $S^0_{q,\xi}$ in terms of a $\mathcal{U}$-covariant oscillator is also given.

Analogous to the example of Podleś q-sphere, embedding of $S^0_{q,\xi}$ in $\mathcal{A}$ may be done by realizing its generators in terms of entries of $T^2(0)$ matrix. Denoting $T^2(0)$ by T, it is straightforward to verify that the embedding is given by

$$\begin{aligned}
Y_2 &= g_1T_{2,2} + g_2T_{0,2} + g_3T_{-2,2},\\
Y_1 &= g_1T_{2,1} + g_2T_{0,1} + g_3T_{-2,1},\\
Y_0 &= g_1T_{2,0} + g_2T_{0,0} + g_3T_{-2,0},\\
Y_{-1} &= g_1T_{2,-1} + g_2T_{0,-1} + g_3T_{-2,-1},\\
Y_{-2} &= g_1T_{2,-2} + g_2T_{0,-2} + g_3T_{-2,-2},
\end{aligned} \tag{6.13}$$

where the coefficients g_1, g_2, and g_3 need to satisfy the constraint

$$g_1g_3 = \frac{[3]!}{[4]}g_2^2. \tag{6.14}$$

In this embedding, the radius r and the parameter ξ are given as functions of g_2,

$$r = ([2]g_2)^2, \quad \xi = \frac{[6]}{[3]}g_2. \tag{6.15}$$

This embedding allows us to treat $S^0_{q,\xi}$ as a subalgebra of $\mathcal{A}$. This fact suggests that $S^0_{q,\xi}$ has an infinitesimal characterization as shown by Koornwinder.[13] To demonstrate this, we extend the left and right actions of $U_q[su(2)]$ on $SU_q(2)$ defined in Ref. 13 to the supersymmetric case. In the following we assume $u,v\in\mathcal{U}; a,b\in\mathcal{A}$, and use Sweedler's notation to denote coproducts, e.g., $\Delta(a)=\Sigma a_{(1)}\otimes a_{(2)}$. With a slight change of notation from Ref. 13, we now define elements $u\odot a$ and $a\odot u$ of $\mathcal{A}$ by

$$u\odot a = (\mathrm{id}\otimes u)(\Delta(a)) = \sum (-1)^{\hat{u}\hat{a}_{(1)}}a_{(1)}\langle u, a_{(2)}\rangle, \tag{6.16}$$

$$a\odot u=(-1)^{\hat{a}\hat{u}}(u\otimes \mathrm{id})(\Delta(a))=\sum (-1)^{\hat{a}\hat{u}}\langle u,a_{(1)}\rangle a_{(2)}. \tag{6.17}$$

The coassociativity of $\mathcal{A}$ then leads to

$$(uv)\odot a=u\odot(v\odot a),\quad a\odot(uv)=(a\odot u)\odot v. \tag{6.18}$$

Moreover, we also have

$$u\odot(ab)=\sum (-1)^{\hat{u}_{(2)}\hat{a}}(u_{(1)}\odot a)(u_{(2)}\odot b),$$

$$(ab)\odot u=\sum (-1)^{\hat{u}_{(1)}\hat{b}}(a\odot u_{(1)})(b\odot u_{(2)}). \tag{6.19}$$

Thus, $u\odot a$ and $a\odot u$ define left and right actions of u on a, respectively. The actions of generators of $\mathcal{U}$ on the T^{ℓ}-matrix of $\mathcal{A}$ are calculated by using (2.11). Explicitly, the left actions are given by

$$K^{\pm 1}\odot T^{\ell}_{m_1m_2}(\lambda)=q^{\pm m_2/2}T^{\ell}_{m_1m_2}(\lambda),$$

$$v_+\odot T^{\ell}_{m_1m_2}(\lambda)=(-1)^{\ell+m_1+\lambda}\sqrt{[\ell-m_2][\ell+m_2+1]\varrho}\,T^{\ell}_{m_1m_2+1}(\lambda),$$

$$v_-\odot T^{\ell}_{m_1m_2}(\lambda)=(-1)^{m_1+m_2+\lambda+1}\sqrt{[\ell+m_2][\ell-m_2+1]\varrho}\,T^{\ell}_{m_1m_2-1}(\lambda), \tag{6.20}$$

while the right actions read

$$T^{\ell}_{m_1m_2}(\lambda)\odot K^{\pm 1}=q^{\pm m_1/2}T^{\ell}_{m_1m_2}(\lambda),$$

$$T^{\ell}_{m_1m_2}(\lambda)\odot v_+=(-1)^{\ell+m_2+\lambda}\sqrt{[\ell-m_1+1][\ell+m_1]\varrho}\,T^{\ell}_{m_1-1m_2}(\lambda),$$

$$T^{\ell}_{m_1m_2}(\lambda)\odot v_-=(-1)^{m_1+m_2+\lambda}\sqrt{[\ell+m_1+1][\ell-m_1]\varrho}\,T^{\ell}_{m_1+1m_2}(\lambda). \tag{6.21}$$

An element $u\in\mathcal{U}$ possessing a coproduct structure $\Delta(u)=g\otimes u+u\otimes g^{-1}$ with $g\in\mathcal{U}$ being a grouplike element, is known as twisted primitive with respect to g. For a twisted primitive element u, it is straightforward to verify that

$$u\odot a=0\quad\text{and}\quad u\odot b=0\Rightarrow u\odot(ab)=0, \tag{6.22}$$

$$a\odot u=0\quad\text{and}\quad b\odot u=0\Rightarrow (ab)\odot u=0. \tag{6.23}$$

Thus a set of elements of $\mathcal{A}$ annihilated by a twisted primitive element u form a subalgebra of $\mathcal{A}$. Indeed, the quantum supersphere $S^0_{q,\xi}$ embedded into $\mathcal{A}$ is a subalgebra of $\mathcal{A}$ that is annihilated by the twisted primitive element $\mathcal{P}_R$,

$$\mathcal{P}_R=-\sqrt{g_3}v_+ +\sqrt{g_1}v_-, \tag{6.24}$$

$$Y_k\odot\mathcal{P}_R=0,\quad k=\pm 2,\pm 1,0. \tag{6.25}$$

The algebra $\mathcal{U}$ has three twisted primitive elements, $K-K^{-1}$, v_+, and v_-. However, $\mathcal{P}_R$ consists of only odd twisted primitive elements. This is a difference from the q-sphere for $\mathrm{SU}_q(2)$. In that example, all the twisted primitive elements contribute to the annihilation operator of the q-sphere.

We now turn to an oscillator realization of $S^0_{q,\xi}$. In Ref. 20, a $\mathcal{U}$-covariant oscillator algebra is introduced. This oscillator algebra is generated by a pair of even creation/annihilation operators ($^-$,), and an odd operator obeying the relations

$$^{-} = q^{-}, \qquad = q^{-1} \quad , \qquad ^{-} - q^{-2-} = 1,$$

$$^{2} = q^{-1}[2]^{-} + \varpi^{-1}. \tag{6.26}$$

These relations are determined by two steps. First, the action of $\mathcal{U}$ on the oscillator is defined via the coproduct of $\mathcal{U}$. Then the commutation properties of the oscillator is fixed by demanding that the triplet $(^{-}, \ , - \ )$ transforms under the $\ell=1$ representation of $\mathcal{U}$. This suggests that the $\mathcal{U}$-covariant oscillator has a close kinship to the quantum space discussed in Sec. V B. Indeed, the $\mathcal{U}$-covariant oscillator is isomorphic to the quantum plane for a special value of r,

$$z_1 = ^{-}, \quad z_0 = \ , \quad z_{-1} = - \ , \quad r = - q\varpi^{-1}. \tag{6.27}$$

Employing the $\mathcal{U}$-covariant oscillator, it is possible to realize $S^0_{q,\xi}$,

$$Y_2 = ^{-2}, \quad Y_1 = q^{-1/2}\left(\frac{[4]}{[2]}\right)^{1/2} - \ ,$$

$$Y_0 = - \frac{\sqrt{[4]!}}{q[2]} - \ - \frac{q^{-1/2}}{\varpi}\left(\frac{[4]}{[3]!}\right)^{1/2},$$

$$Y_{-1} = - q^{-1/2}\left(\frac{[4]}{[2]}\right)^{1/2} \ , \quad Y_{-2} = \ ^{2}. \tag{6.28}$$

In this realization, the radius r and the parameter ξ of $S^0_{q,\xi}$ assume the following values:

$$r = \frac{q^2}{\varpi^2}\frac{[4]}{[3]!}, \quad \xi = \frac{[6]}{[3]!}r^{1/2}. \tag{6.29}$$

An advantage of this realization is that we may represent $S^0_{q,\xi}$ with matrices, since matrix representation of $\mathcal{U}$-covariant oscillator via that of Biedenharn-Macfarlane q-boson algebra exists.[20]

VII. CONCLUDING REMARKS

We have developed the general prescription for constructing $\mathcal{A}$-covariant algebras. By the method, four $\mathcal{A}$-covariant algebras have been obtained, namely, three quantum superspaces and a one-parameter family of quantum superspheres. The special cases of the quantum superspaces correspond to the Manin's quantum superplane and $\mathcal{U}$-covariant oscillator algebra. The quantum superspheres are realized by $\mathcal{A}$ so that it can be regarded as a subalgebra of $\mathcal{A}$. This subalgebra is characterized by the fact that it is annihilated by the right action of a particular combination of the twisted primitive elements of $\mathcal{U}$. These are the similarities to the q-spheres for $SU_q(2)$. It has also been shown that the quantum superspheres have $\mathcal{U}$-covariant oscillator realization that allows us to have matrix representations of the quantum supersphere.

We believe that the results of this paper are useful for making progress in constructing supersymmetric versions of noncommutative geometry. For instance, we may consider differential calculi on the quantum supersphere, then compute its curvature, metric, and so on based on the framework of Ref. 5. In connection with the classification of differential calculi, it is interesting to determine the dual coalgebra of $S^0_{q,\xi}$. The corresponding computation for $SU_q(2)$ q-sphere was made recently and applied to the classification of differential calculi.[11] Furthermore, the general method in Sec. V A is applied to construct higher dimensional quantum superspaces by taking higher values of ℓ.

It is worth pointing out that, because of the similarity of the representation theory of $\mathcal{U}$ to that of $U_q[su(2)]$, the method developed in Sec. V A is valid for $SU_q(2)$. This procedure allows us to treat quantum plane, deformed oscillator and Podleś q-sphere in a unified way. The reason for q-spheres being a one-parameter family becomes clear in this framework. It is also possible to construct hitherto unknown higher dimensional $SU_q(2)$-covariant quantum spaces. We will present these results elsewhere.

APPENDIX A: CGC OF $\mathcal{U}$

In this appendix, the general expression of CGC in our conventions is derived. Let us write the highest weight vector as

$$e^{\ell}_{\ell}(\ell_1,\ell_2,\Lambda)=\sum_{m_1,m_2} A_{m_1m_2}e^{\ell_1}_{m_1}(\lambda)\otimes e^{\ell_2}_{m_2}(\lambda), \tag{A1}$$

where, for simplicity of notation, the CGC is denoted by $A_{m_1m_2}$. The highest weight condition $\Delta(v_+)e^{\ell}_{\ell}(\ell_1,\ell_2,\Lambda)=0$ gives the recurrence relation for $A_{m_1m_2}$,

$$\sqrt{[\ell_1-m_1][\ell_1+m_1+1]}q^{-m_2/2}A_{m_1m_2}-(-1)^{\ell_1-m_1+\lambda}q^{(m_1+1)/2}\sqrt{[\ell_2+m_2][\ell_2-m_2+1]}A_{m_1+1m_2-1}=0. \tag{A2}$$

It is easy to find the solution of this relation

$$A_{m_1m_2}=(-1)^{\lambda(\ell_1-m_1)+(\ell_1-m_1)(\ell_1-m_1+1)/2}q^{(\ell+1)(\ell_1-m_1)/2}\times\left(\frac{[\ell_1+\ell_2-\ell]![\ell_1+m_1]![\ell_2+m_2]!}{[\ell_2-\ell_1+\ell]![2\ell_1]![\ell_1-m_1]![\ell_2-m_2]!}\right)^{1/2}A_{\ell_1\ell-\ell_1}. \tag{A3}$$

The normalization of the highest weight vector (A1) determines $A_{\ell_1\ell-\ell_1}$ as follows:

$$\begin{aligned}(e^{\ell}_{\ell}(\ell_1,\ell_2,\Lambda),e^{\ell}_{\ell}(\ell_1,\ell_2,\Lambda))&=\sum_{m_1,m_2}(-1)^{(\ell_1-m_1+\lambda)(\ell_2-m_2+\lambda)}A^2_{m_1m_2}\\&=(-1)^{(\ell_1+\lambda)(\ell_2+\ell+\lambda)}\frac{[\ell_1+\ell_2-\ell]!}{[\ell_2-\ell_1+\ell]![2\ell_1]!}A^2_{\ell_1\ell-\ell_1}\\&\quad\times\sum_{m_1}(-1)^{m_1(\ell_1+\ell_2+\ell+1)}q^{(\ell+1)(\ell_1-m_1)}\frac{[\ell_1+m_1]![\ell_2+\ell-m_1]!}{[\ell_1-m_1]![\ell_2-\ell+m]!}.\end{aligned}$$

The summation over m_1 is computed by using the formula (B5). Setting

$$a=\ell_1-m_1,\quad k=\ell_1+\ell_2-\ell,\quad -n=\ell_1-\ell_2+\ell+1,\quad -r=-\ell_1+\ell_2+\ell+1$$

in (B5), while noticing that all these quantities are positive integers, we obtain

$$\sum_{m_1}(-1)^{(\ell_1-m_1)(\ell_1+\ell_2+\ell+1)}q^{(\ell+1)(\ell_1-m_1)}\frac{[\ell_1+m_1]![\ell_2+\ell-m_1]!}{[\ell_1-m_1]![\ell_2-\ell+m]!}$$
$$=q^{(-\ell_1+\ell_2+\ell+1)(\ell_1+\ell_2-1)/2}\frac{[\ell_1+\ell_2+\ell+1]![\ell_1-\ell_2+\ell]![-\ell_1+\ell_2+\ell]!}{[\ell_1+\ell_2-\ell]![2\ell+1]!}.$$

Thus the norm of the highest weight vector reads

$$\|e_\ell^\ell(\ell_1,\ell_2,\Lambda)\|^2=(-1)^{\lambda(\ell_1+\ell_2+\ell+1)}q^{(-\ell_1+\ell_2+\ell+1)(\ell_1+\ell_2-1)/2}A^2_{\ell_1\ell-\ell_1}\frac{[\ell_1+\ell_2+\ell+1]![\ell_1-\ell_2+\ell]!}{[2\ell+1]![2\ell_1]!}.$$

This leads to

$$A_{\ell_1\ell-\ell_1}=q^{-(-\ell_1+\ell_2+\ell+1)(\ell_1+\ell_2-1)/4}\left(\frac{[2\ell+1]![2\ell_1]!}{[\ell_1+\ell_2+\ell+1]![\ell_1-\ell_2+\ell]!}\right)^{1/2}, \tag{A4}$$

where the phase is chosen such that the expression coincides with the result in Ref. 17.

To obtain the other vectors in this irreducible representation we need the following results, which may be verified by induction:

$$v_-^k e_m^\ell(\lambda)=(-1)^{(\ell-m)k+k(k+1)/2}\left(\frac{[\ell+m]![\ell-m+k]!}{[\ell-m]![\ell+m-k]!}\varrho^k\right)^{1/2}e^\ell_{m-k}(\lambda), \tag{A5}$$

$$\Delta(v_-^n)=\sum_{k=0}^n\begin{bmatrix}n\\k\end{bmatrix}(-1)^{k(n-k)}v_-^{n-k}K^k\otimes v_-^kK^{-n+k}. \tag{A6}$$

Using (A5) we obtain

$$e_m^\ell(\ell_1,\ell_2,\Lambda)=(-1)^{(\ell-m)(\ell-m+1)/2}\left(\frac{[\ell+m]!}{[2\ell]![\ell-m]!\varrho^{\ell-m}}\right)^{1/2}\Delta(v_-^{\ell-m})e_\ell^\ell(\ell_1,\ell_2,\Lambda). \tag{A7}$$

The right-hand side is computed by using (A6) and (A1). After some algebra, we derive

$$\Delta(v_-^{\ell-m})e^{\ell_1}_{m_1}(\lambda)\otimes e^{\ell_2}_{m_2}(\lambda)=\sum_k\begin{bmatrix}\ell-m\\k\end{bmatrix}(-1)^{k(\ell_2-m_2+\lambda)+(\ell_1-m_1)(\ell-m)+(\ell-m)(\ell-m+1)/2}q^{km_1/2+(-\ell+m+k)m_2/2}$$
$$\times\left(\frac{[\ell_1+m_1]![\ell_2+m_2]![\ell_1+\ell-m_1-m-k]![\ell_2-m_2+k]!}{[\ell_1-m_1]![\ell_2-m_2]![\ell_1-\ell+m_1+m+k]![\ell_2+m_2-k]!}\varrho^{\ell-m}\right)^{1/2}$$
$$\times e^{\ell_1}_{m_1-\ell+m+k}(\lambda)\otimes e^{\ell_2}_{m_2-k}(\lambda). \tag{A8}$$

Equations (A3) and (A4) allow us to derive

$$e_m^\ell(\ell_1,\ell_2,\Lambda)=\sum_{m_1,m_2}(-1)^{(\ell_1-\ell+m_2)(\ell-m+\lambda)+(\ell_1-\ell+m2)(\ell_1-\ell+m_2+1)/2}q^{m_2(m+1)/2+(\ell_1-\ell_2)(\ell_1+\ell_2+1)/4-\ell(\ell+1)/4}$$
$$\times\left([2\ell+1]\frac{[\ell_1+\ell_2-\ell]![\ell+m]![\ell-m]![\ell_1-m_1]![\ell_2-m_2]!}{[\ell_1+\ell_2+\ell+1]![\ell_1-\ell_2+\ell]![-\ell_1+\ell_2+\ell]![\ell_1+m_1]![\ell_2+m_2]!}\right)^{1/2}$$
$$\times\sum_k(-1)^{k(k-1)/2+k(\ell_1+\ell_2-m)}q^{k(\ell+m+1)/2}$$
$$\times\frac{[\ell_1+\ell-m_2-k]![\ell_2+m_2+k]!}{[k]![\ell-m-k]![\ell_1-\ell+m_2+k]![\ell_2-m_2-k]!}e^{\ell_1}_{m_1}(\lambda)\otimes e^{\ell_2}_{m_2}(\lambda). \tag{A9}$$

APPENDIX B: SUMMATION FORMULA FOR KULISH SYMBOL

A summation formula for Kulish symbol which is used in the preceding section is derived in this appendix. Corresponding binomial coefficient is usually defined for $y \geqslant x \geqslant 0$ as

$$\begin{bmatrix} y \\ x \end{bmatrix} = \frac{[y]!}{[y-x]![x]!} = \frac{[y][y-1]\cdots[y-x+1]}{[x]!}. \tag{B1}$$

We may extend this to $y<0$ by using the property

$$[-n] = (-1)^{n+1}[n], \quad n \geqslant 0, \tag{B2}$$

and define the binomial coefficient for negative y by the rightmost formula of (B1),

$$\begin{bmatrix} y \\ x \end{bmatrix} = \frac{[-(-y)][-(-y+1)]\cdots[-(-y+x-1)]}{[x]!} = (-1)^{xy+x(x+1)/2}\frac{[-y][-y+1]\cdots[-y+x-1]}{[x]!}.$$

Thus for $y<0$ and $x \geqslant 0$, the binomial coefficient is given by

$$\begin{bmatrix} y \\ x \end{bmatrix} = (-1)^{xy+x(x+1)/2}\begin{bmatrix} x-y-1 \\ x \end{bmatrix}. \tag{B3}$$

The following formula, proved by induction, is found in Ref. 17:

$$\begin{bmatrix} n+r \\ k \end{bmatrix} = \sum_a \begin{bmatrix} n \\ k-a \end{bmatrix}\begin{bmatrix} r \\ a \end{bmatrix}(-1)^{(k-a)(r-a)}q^{(r-a)(n+r)/2-r(n-k+r)/2}, \tag{B4}$$

where a runs over any positive integers such that the arguments of $[x]$ in the binomial coefficients are non-negative. We assume $n,r<0$, and apply (B3) to this formula,

$$\text{lhs} = (-1)^{k(n+r)+k(k+1)/2}\begin{bmatrix} k-n-r-1 \\ k \end{bmatrix},$$

$$\text{rhs} = (-1)^{k(n+r)+k(k+1)/2}q^{rk/2}\sum_a (-1)^{an}q^{-a(n+r)/2}\begin{bmatrix} k-a-n-1 \\ k-a \end{bmatrix}\begin{bmatrix} a-r-1 \\ a \end{bmatrix}.$$

From this, the following summation formula of Kulish symbols is obtained:

$$\sum_a (-1)^{an}q^{-a(n+r)/2}\frac{[k-a-n-1]![a-r-1]!}{[k-a]![a]!} = q^{-rk/2}\frac{[k-n-r-1]![-n-1]![-r-1]!}{[k]![-n-r-1]!}. \tag{B5}$$

APPENDIX C: CGC FOR $1\otimes 1 = 2\oplus 1\oplus 0$

Tables I–III contain the values of $C^{1\ 1\ \ell}_{m_1\ m-m_1\ m}$ for a given ℓ. The columns provide the values of m_1, while the rows indicate m. The rightmost column of Table I, titled as "OF," indicates the overall factors that are common to all entries in the row. In Table II and III, the overall factors are common for all entries of the tables.

(Received 21 December 2004; accepted 8 August 2005; published online 17 October 2005)

We study a Monte Carlo algorithm for approximating multivariate Feynman–Kac path integrals parameterized by initial value and potential d-variate functions. This problem suffers from the curse of dimensionality in the worst case deterministic setting. That is why we study the randomized setting in which the functions are sampled at randomized points and the algorithm uses a finite number of such samples. We achieve optimality of the randomized algorithm due to variance reduction obtained by Smolyak's algorithm for approximating tensor product functions. The optimal convergence depends on the smoothness of initial value and potential functions. When the initial value and potential functions are r times continuously differentiable we obtain the optimal convergence of order $m^{-1/2-r/d}$ for m function samples. Thus, if r/d is negligible we do not gain much over the commonly used classical Monte Carlo algorithm whose convergence is of order $m^{-1/2}$. Hence, the classical Monte Carlo algorithm turns out to be almost optimal if r/d is small. On the other hand, we can significantly improve the classical Monte Carlo convergence if r/d is not negligible. © *2005 American Institute of Physics.*

I. INTRODUCTION

Due to numerous applications, approximation of path integrals with respect to the Wiener measure attracts attention in many fields, including physics, chemistry, and financial mathematics. In this article we consider a special case of such integrals, namely, the multivariate Feynman–Kac path integral that yields the solution of the initial value problem for the diffusion equation. This problem depends on d-variate initial value and potential functions.

We know that deterministic algorithms for the problem of approximating multivariate Feynman–Kac path integrals with the worst case error assurance are highly inefficient for large d, see Ref. 1. This is caused by the *provable* curse of dimensionality of this problem. More precisely, the convergence of any deterministic algorithm cannot be better than of order $m^{-r/d}$. Here, r measures the smoothness of the initial value and potential functions and m is the number of function samples. Hence, the convergence decreases exponentially with d. A popular remedy to vanquish the curse of dimensionality is through randomization. For this approach the path integral is approximated by a multivariate integral, and then this integral is approximately evaluated by a randomized algorithm, e.g., by the celebrated Monte Carlo algorithm, see e.g., Refs. 2 and 3. This yields the convergence of order $m^{-1/2}$ and the dependence on d disappears. It is important to study whether the convergence $m^{-1/2}$ can be further improved. We prove that this is indeed possible as long as the smoothness r is positive.

This article uses the technique presented in Ref. 4 which was then generalized and modified in Ref. 1. This technique utilizes the smoothness of the initial value and potential functions and yields an algorithm with the optimal convergence roughly of order $m^{-1/2-r/d}$, see also Ref. 5. This is proved by using techniques developed by information-based complexity whose extensive overview is presented in Ref. 6, see also Ref. 7. Thus, the classical Monte Carlo algorithm turns out to be almost optimal when the ratio r/d is negligible. In this case, the algorithm presented here shows very little advantage. However, when r/d is not negligible the convergence of the classical Monte Carlo algorithm is significantly improved.

We plan to implement and test the algorithm presented here and we will report the results in a follow-up article.

II. MULTIVARIATE FEYNMAN-KAC PATH INTEGRATION

The multivariate Feynman–Kac formula yields the solution of the initial value problem for the diffusion equation

$$\frac{\partial z}{\partial t}(\mathbf{u},t) = \tfrac{1}{2}\Delta z(\mathbf{u},t) + V(\mathbf{u})z(\mathbf{u},t) \text{ for } (\mathbf{u},t) \in \mathbb{R}^d \times (0,\infty), \tag{1}$$

$$z(\mathbf{u},0) = v(\mathbf{u}). \tag{2}$$

Here $v, V: \mathbb{R}^d \to \mathbb{R}$ are the initial value and the potential functions, respectively. As usual Δ denotes the Laplacian.

The solution z of (1) and (2) is given by the Feynman–Kac formula

$$z(\mathbf{u},t) = \int_{\mathcal{C}} v(\mathbf{x}(t)+\mathbf{u}) \exp\left(\int_0^t V(\mathbf{x}(s)+\mathbf{u}) \mathrm{d}s \right) w(\mathrm{d}\mathbf{x}). \tag{3}$$

Here, $\mathcal{C}$ is the set of continuous functions $\mathbf{x}: [0,\infty) \to \mathbb{R}^d$ such that $\mathbf{x}(0)=\mathbf{0}$. The path integral (3) is with respect to the d-dimensional Wiener measure w, see Refs. 8 and 9. In Sec. III we formulate precisely the assumptions about the initial value v and the potential V which make the path integral (3) well defined and permit feasible numerical approximation.

III. ASSUMPTIONS ON INITIAL VALUE AND POTENTIAL FUNCTIONS

We assume that the initial value v and the potential V belong to the normed space F satisfying the following assumptions.

(A1) To make the path integral (3) well defined we assume that for every $\mathbf{u} \in \mathbb{R}^d$, the functional $L_{\mathbf{u}}: F \to \mathbb{R}$ defined by $L_{\mathbf{u}} f = f(\mathbf{u})$ is continuous, and for arbitrary $a, t \in \mathbb{R}_+$ we have

$$\int_{\mathcal{C}} \|L_{\mathbf{x}(t)}\|_F \exp\left(a \int_0^t \|L_{\mathbf{x}(s)}\|_F \mathrm{d}s \right) w(\mathrm{d}\mathbf{x}) < \infty. \tag{4}$$

By Fernique's theorem, see e.g., Ref. 10, condition (4) holds if there exists $\alpha \in (0,2)$ such that $\|L_{\mathbf{x}}\|_F = O(\|\mathbf{x}\|^\alpha)$ for $\|\mathbf{x}\|$ approaching infinity, see Ref. 4 for details. Here and elsewhere, $\|\mathbf{x}\| = \sqrt{\sum_{i=1}^d x_i^2}$ is the Euclidean norm in $\mathbb{R}^d$.

(A2) We assume that F is continuously embedded into $L_\infty(\mathbb{R}^d)$. That is, $F \subset L_\infty(\mathbb{R}^d)$ and there exists a positive K such that

$$\|f\|_{L_\infty(\mathbb{R}^d)} \leqslant K \|f\|_F, \quad \forall\, f \in F. \tag{5}$$

This assumption permits us to relate the multivariate Feynman–Kac path integration problem to uniform approximation. By uniform approximation we mean the approximation of functions from F in the norm of $L_\infty(\mathbb{R}^d)$, i.e., given, $\varepsilon > 0$ we want to find a function $\overline{f} \in L_\infty(\mathbb{R}^d)$ such that

$$\|f-\overline{f}\|_{L_\infty(\mathbb{R}^d)} \leqslant \varepsilon \|f\|_F.$$

(A3) We assume that we can compute a uniform approximation $\overline{f}$ of the function f from the class F by a linear algorithm,

$$\overline{f} = \sum_{i=1}^{n_{\mathrm{APP}}} f(\mathbf{u}_i)\zeta_i, \quad \mathbf{u}_i \in \mathbb{R}^d, \quad \zeta_i \in L_\infty(\mathbb{R}^d), \tag{6}$$

that uses n_{APP} function evaluations and

$$n_{\mathrm{APP}} = n_{\mathrm{APP}}(\varepsilon, F) = O(\varepsilon^{-\alpha(F)}) \quad \text{as } \varepsilon \to 0, \tag{7}$$

for some positive $\alpha(F)$. The asymptotic constant in (7) may depend on the dimension d. Usually the exponent $\alpha(F)$ depends on the smoothness and on the number of variables of functions from F, see Sec. VIII. We stress that these assumptions are not essentially restrictive. It is known that optimal algorithms for the uniform approximation problem are of the form (6), see Ref. 11. Moreover the number of function evaluations often depends on ε as in (7), see also Sec. VIII.

(A4) We restrict the norms of the initial value and potential functions. Namely, we assume that $\|v\|_F \leqslant \beta$ and $\|V\|_f \leqslant B$ for given positive β, B. In other words, the pair (v, V) belong to the class

$$B_F = \{(f_1, f_2) \in F \times F : \|f_1\|_F \leqslant B, \|f_2\|_F \leqslant \beta\}. \tag{8}$$

IV. RANDOMIZED ALGORITHMS

We are interested in approximating $z(\mathbf{u}, t)$, i.e., the exact value of the path integral (3) at a certain point $(\mathbf{u}, t) \in (0, \infty) \times \mathbb{R}^d$. We approximate $z(\mathbf{u}, t)$ by a randomized algorithm Φ. This algorithm uses the initial value and the potential sampled at randomized points. The error of the algorithm Φ is measured by the maximum with respect to the class B_F of the root mean square error with respect to the distribution of randomized points,

$$\sup_{(v,V) \in B_F} (\mathbb{E}(z(\mathbf{u}, t) - \Phi(v, V))^2)^{1/2}. \tag{9}$$

V. FEYNMAN–KAC FORMULA AS A SERIES OF MULTIVARIATE INTEGRALS

We briefly recall some results from Ref. 1, where the worst case approximation of the multivariate Feynman–Kac path integrals is analyzed.

Without loss of generality we can assume $\mathbf{u} = \mathbf{0}$ in (3); otherwise we shift the initial value and the potential appropriately. Then we can express the path integral (3) as a series of multivariate weighted integrals

$$z(\mathbf{0}, t) = \sum_{k=0}^{\infty} I_k(h_k), \tag{10}$$

where $h_k(\mathbf{z}_1, \ldots, \mathbf{z}_{k+1}) = v(\mathbf{z}_{k+1}) \prod_{i=1}^{k} V(\mathbf{z}_i)$, and

$$I_k(h_k) = \int_{\mathbb{R}^{(k+1)d}} h_k(\mathbf{z}_1, \ldots, \mathbf{z}_{k+1}) g_{k+1}(\mathbf{z}_1, \ldots, \mathbf{z}_{k+1}) \mathrm{d}\mathbf{z}_1 \ldots \mathrm{d}\mathbf{z}_{k+1}, \tag{11}$$

with

$$g_k(\mathbf{z}_1, \ldots, \mathbf{z}_{k+1}) = \int_{0 \leqslant t_1 \leqslant \cdots \leqslant t_k \leqslant t} f_{k+1}(t_1, \ldots, t_k, t, \mathbf{z}_1, \ldots, \mathbf{z}_{k+1}) \mathrm{d}t_1 \ldots \mathrm{d}t_k \tag{12}$$

and

$$f_k(t_1,\ldots,t_k,t,\mathbf{z}_1,\ldots,\mathbf{z}_{k+1}) = ((2\pi)^{k+1}t_1(t_2-t_1)\cdots(t-t_k))^{-d/2} \times \exp\left(-\frac{1}{2}\left(\frac{\|\mathbf{z}_1\|^2}{t_1}+\frac{\|\mathbf{z}_2-\mathbf{z}_1\|^2}{t_2-t_1}+\cdots+\frac{\|\mathbf{z}_{k+1}-\mathbf{z}_k\|^2}{t-t_k}\right)\right).$$

Note that the integral (11) depends on the input functions v and V only through the product h_k, whereas the weight functions g_{k+1} are independent of v and V, and

$$\|g_k\|_{L_1(\mathbb{R}^{(k+1)d})} = \frac{t^k}{k!} \quad \text{for } k \geqslant 0. \tag{13}$$

VI. APPROXIMATION OF ONE TERM OF THE SERIES

We present algorithms approximating one term (11) of the series (10). To utilize the power of randomization we apply the technique known as variance reduction which is achieved by Smolyak's algorithm. This algorithm uses deterministic uniform approximation of the function h_k and takes advantage of the smoothness of the functions v and V. For the reader's convenience, we include a short overview of Smolyak's algorithm in the next subsection.

A. Smolyak's algorithm

Smolyak's algorithm can be used to approximate wide spectrum of the tensor product problems. We only sketch this algorithm for uniform approximation, for more details see e.g., Ref. 12.

We define F_k as k-fold tensor product of the space F

$$F_k = \overbrace{F \otimes \cdots \otimes F}^{k}.$$

In this section we assume $k>1$. Clearly the domain of functions from F_k is $\mathbb{R}^{kd}$. We want to approximate a function $f_k \in F_k$ uniformly, i.e., we want to find a function $\overline{f_k} \in L_\infty(\mathbb{R}^{kd})$ such that

$$\|f_k - \overline{f_k}\|_{L_\infty(\mathbb{R}^{kd})} \leqslant \varepsilon \|f\|_{F_k}. \tag{14}$$

Smolyak's algorithm is based on the sequence of uniform approximation algorithms A_i, $i=0,1,\ldots,$

$$A_i f = \sum_{j=1}^{n_i} f(\mathbf{u}_j)\zeta_j, \quad \mathbf{u}_j \in \mathbb{R}^d, \quad \zeta_j \in L_\infty(\mathbb{R}^d). \tag{15}$$

These algorithms approximate functions from the space F as assumed in Secs. III A 2 and III A 3.

We impose three conditions on these algorithms.

(C1) $A_0 \equiv 0$ is the zero algorithm.

(C2) The error of the algorithm A_i satisfies

$$\|f - A_i f\|_{L_\infty(\mathbb{R}^d)} \leqslant C2^{-i}, \quad i=0,1,2,\ldots. \tag{16}$$

for some constant $C>0$.

(C3) The number n_i of function evaluations used by the algorithm A_i is bounded by

$$n(A_i) \leqslant D(2^{i\alpha(F)}-1), \quad i=0,1,2,\ldots$$

for some constant $D>0$, with $\alpha(F)$ defined Sec. III A 3. Note that C2 and C3 are consistent with the assumption Sec. III A 3.

We also define

$$\Delta_i = A_i - A_{i-1}, \quad i = 1,2,3, \ldots,$$

and, finally, for multiindices $\mathbf{i}=[i_1,\ldots,i_k] \in \mathbb{N}^k$ and $q \in \mathbb{N}$, we define

$$U_q = \sum_{1 \leqslant \mathbf{i}, |\mathbf{i}| \leqslant q} \overset{k}{\underset{j=1}{\otimes}} \Delta_{i_j}. \tag{17}$$

The sum above is over all multiindices $\mathbf{i}$ whose all coordinates are at least 1 and $|\mathbf{i}| := \Sigma_{i=1}^k i_k \leqslant q$. We can rewrite (17) as

$$U_q = \sum_{1 \leqslant \mathbf{i}, q-k+1 \leqslant |\mathbf{i}| \leqslant q} (-1)^{q-|\mathbf{i}|} \binom{k-1}{q-|\mathbf{i}|} \overset{k}{\underset{j=1}{\otimes}} A_{i_j},$$

see Ref. 12 for a more detailed analysis. Thus by (15) we obtain

$$U_q(f_k) = \sum_{1 \leqslant \mathbf{i}, q-k+1 \leqslant |\mathbf{i}| \leqslant q} (-1)^{q-|\mathbf{i}|} \binom{k-1}{q-|\mathbf{i}|} \sum_{\mathbf{j} \leqslant \mathbf{n_i}} f_k(\mathbf{u}_{j_1}, \ldots, \mathbf{u}_{j_k}) \zeta_{\mathbf{j}}, \tag{18}$$

where the second sum is over all vectors $\mathbf{j}=[j_1,\ldots,j_k]$ whose coordinates are at most the respective coordinates of the vector $\mathbf{n_i}=[n_{i_1},\ldots,n_{i_k}]$ and $\zeta_{\mathbf{j}} = \otimes_{j=1}^k \zeta_{i_j}$.

Assume, as before, $k>1$. The bound on the error of the algorithm U_q with $q>$k follows from Ref. 12 (Lemma 2),

$$\|f_k - U_q(f_k)\|_{L_\infty(\mathbb{R}^d)} \leqslant CH^{k-1} \binom{q}{k-1} 2^{-q} \|f\|_{F_k}, \tag{19}$$

where $H=\max\{2K,3C\}$. Using Stirling's formula we obtain

$$\|f_k - U_q(f_k)\| \leqslant CH^{k-1} \frac{1}{\sqrt{2\pi}} \sqrt{\frac{q}{k(q-k)}} \left(\frac{qe}{k-1}\right)^{k-1} 2^{-q} e^{1/6q}. \tag{20}$$

Let N_q be the number of function evaluations used by U_q with $q>$k. Then, Ref. 12 (Lemma 7) yields

$$N_q \leqslant D^k \left(1 - \frac{1}{2^{\alpha(F)}}\right)^{k-1} 2^{q\alpha(F)} \binom{q-1}{k-1}. \tag{21}$$

Now, given $\varepsilon>0$ and (20), it is easy to choose $q=q(\varepsilon,k)$ as the smallest integer such that

$$CH^{k-1} \frac{1}{\sqrt{2\pi}} \sqrt{\frac{q}{k(q-k)}} \left(\frac{qe}{k-1}\right)^{k-1} 2^{-q} e^{1/6q} \leqslant \varepsilon. \tag{22}$$

After straightforward but tedious calculations we obtain the following bound on $N_{q(\varepsilon,k)}$, i.e., on the number of function evaluations used by $U_{q(\varepsilon,k)}$,

$$N_{q(\varepsilon,k)} \leqslant D_k \left(\log_2 \frac{1}{\varepsilon}\right)_+^{(k-1)(\alpha(F)+1)} \left(\frac{1}{\varepsilon}\right)^{\alpha(F)} \tag{23}$$

with D_k independent on ε and at most exponential in k.

B. Variance reduction

We now use Smolyak's algorithm to reduce the variance of the function $h_k \in F_{k+1}$ defined in (11). The algorithm U_q applied to the function h_k can be written as

$$U_q(h_k) = \sum_{1\leqslant \mathbf{i}, q-k\leqslant |\mathbf{i}|\leqslant q} (-1)^{q-|\mathbf{i}|}\binom{k}{q-|\mathbf{i}|} \sum_{\mathbf{j}\leqslant \mathbf{n}_\mathbf{i}} v(\mathbf{u}_{j_{k+1}}) \prod_{s=1}^{k} V(\mathbf{u}_{j_s})\zeta_\mathbf{j}.$$

In order to get the error bound of the form

$$\|h_k - U_q(h_k)\|_{L_\infty(\mathbb{R}^{(k+1)d})} \leqslant \varepsilon \|v\|_F \|V\|_F^k, \tag{24}$$

we need to take $q=q(\varepsilon,k+1)$ which was defined in the Sec. VI A. The algorithm $U_{q(\varepsilon,k)}$ requires at most

$$N_{q(\varepsilon,k+1)} \leqslant D_{k+1}\left(\log_2 \frac{1}{\varepsilon}\right)_+^{k(\alpha(F)+1)} \left(\frac{1}{\varepsilon}\right)^{\alpha(F)}$$

function evaluations.

The idea underlying variance reduction is as follows. First we compute

$$\overline{h}_{k,\varepsilon} = U_{q(\varepsilon,k+1)}(h_k)$$

using $N_{q(\varepsilon,k+1)}$ function values. Then we compute

$$I_k(\overline{h}_{k,\varepsilon}) = \sum_{1\leqslant \mathbf{i}, q-k\leqslant |\mathbf{i}|\leqslant q} (-1)^{q-|\mathbf{i}|}\binom{k}{q-|\mathbf{i}|} \sum_{\mathbf{j}\leqslant \mathbf{n}_\mathbf{i}} v(\mathbf{u}_{j_{k+1}}) \prod_{s=1}^{k} V(\mathbf{u}_{j_s}) I_k(\zeta_\mathbf{j})$$

with $q=q(\varepsilon,k+1)$. Observe that the functions $\zeta_\mathbf{j}$ do not depend on the input functions v and V so the integrals $I_k(\zeta_\mathbf{j})$ can be precomputed.

We stress that $\overline{h}_{k,\varepsilon}$ and $I_k(\overline{h}_{k,\varepsilon})$ are deterministic. We then use the classical Monte Carlo algorithm to approximate the multivariate integrals $I_k(h_k-\overline{h}_{k,\varepsilon})$. The error depends on the variance of $h_k-\overline{h}_{k,\varepsilon}$ which is bounded by $\|h_k-\overline{h}_{k,\varepsilon}\|_{L_\infty(\mathbb{R}^{(k+1)d})}$. Since this is now small, we obtain variance reduction.

C. Monte Carlo algorithm

We use a randomized algorithm of the form

$$\phi_{\varepsilon,m}(v,V) = I_k(\overline{h}_{k,\varepsilon}) + \mathrm{MC}_m(h_k - \overline{h}_{k,\varepsilon}). \tag{25}$$

Here

$$\mathrm{MC}_m(f) = \frac{1}{m}\sum_{j=1}^{m} f(x_j) \tag{26}$$

denotes the classical Monte Carlo algorithm with m randomized sample points. Randomized sample points $x_j \in \mathbb{R}^{(k+1)d}$ are chosen with respect to the density $g_{k+1}/\|g_{k+1}\|_{L_1(\mathbb{R}^{(k+1)d})}$.

Using the well known error formula for the classical Monte Carlo algorithm and denoting $\overline{f}_{k,\varepsilon}=h_k-\overline{h}_{k,\varepsilon}$, we conclude that the error of the algorithm $\phi_{\varepsilon,m}$ satisfies

$$(\mathbb{E}(I_k(h_k) - \phi_{\varepsilon,m}(v,V))^2)^{1/2} = (\mathbb{E}(I_k(\overline{f}_{k,\varepsilon}) - \mathrm{MC}_m(\overline{f}_{k,\varepsilon}))^2)^{1/2} = \frac{1}{\sqrt{m}}(\mathrm{Var}(\overline{f}_{k,\varepsilon}))^{1/2},$$

with

$$\mathrm{Var}(\overline{f}_{k,\varepsilon}) = I_k(\overline{f}_{k,\varepsilon}^2) - (I_{k+1}(\overline{f}_{k,\varepsilon}))^2.$$

Clearly, from (24) and then from (8) and (12) we get

$$(\mathrm{Var}(\overline{f}_{k,\varepsilon}))^{1/2} \leqslant \frac{t^k}{k!}\|\overline{f}_{k,\varepsilon}\|_{L_\infty(\mathbb{R}^{(k+1)d})} \leqslant \varepsilon\frac{\|v\|_F\|V\|_F^k t^k}{k!} \leqslant \varepsilon\frac{B\beta^k t^k}{k!}.$$

This yields the error estimate

$$(\mathbb{E}(I_k(h_k) - \phi_{\varepsilon,m}(v,V))^2)^{1/2} \leqslant \frac{\varepsilon}{\sqrt{m}}\frac{B\beta^k t^k}{k!} \tag{27}$$

and the total number $n(\phi_{\varepsilon,m})$ of function evaluations is bounded by

$$n(\phi_{\varepsilon,m}) \leqslant N_{q(\varepsilon,k+1)} + m. \tag{28}$$

VII. THE ALGORITHM

Based on the previous section we are ready to present an algorithm Φ_ε which computes an ε approximation of a multivariate Feynman–Kac path integral, i.e., whose error defined by (9) does not exceed ε. We assume that the initial value and the potential belong to the class B_F. We approximate the consecutive terms $I_k(h_k)$ of the series $z(\mathbf{0},t)=\sum_{k=0}^\infty I_k(h_k)$ by the algorithms $\phi_{\varepsilon_k,m}$ with the accuracy ε_k being

$$\varepsilon_k = \varepsilon^{2/(\alpha(F)+2)}\frac{k!}{B\beta^k t^k 2^{k+1}}, \tag{29}$$

and the number of randomized sample points m being

$$m = \lceil \varepsilon^{-2\alpha(F)/(\alpha(F)+2)} \rceil. \tag{30}$$

Since the required error ε_k goes to infinity super exponentially fast we need to approximate only a finite number of the series terms. Thus the final form of the algorithms approximating $z(\mathbf{0},t)$ is

$$\Phi_\varepsilon(v,V) = \sum_{k=0}^{N_\varepsilon} \phi_{\varepsilon_k,m}$$

with the sum limit N_ε determined in the next section.

A. Error analysis

From (27), (29), and (30), it is easy to check that

$$(\mathbb{E}(I_k(h_k) - \phi_{\varepsilon_k,m}(v,V))^2)^{1/2} \leqslant \frac{\varepsilon}{2^{k+1}}. \tag{31}$$

It is also easy to see that we need to approximate only a few terms of the series. Indeed, for k approaching infinity, we have ε_k also tending to infinity. Assume that

$$k!\varepsilon^{1+\alpha(F)/\alpha(F)+2} \geqslant B\beta^k t^k (2K)^{k+1},$$

with K being the embedding constant in (5). This implies

$$\frac{\varepsilon_k}{m} \geqslant K^{k+1},$$

and by (5) and (27) we see that for such k the deterministic zero algorithm provides sufficient accuracy. Thus, we need to use the algorithms $\phi_{\varepsilon_k,m}$ only for $k=O(\ln \varepsilon^{-1})$. Hence, we get $N_\varepsilon = O(\ln \varepsilon^{-1})$.

Summing up the bounds (31) over $k=1,2,\ldots$ we obtain an error estimate of the algorithm Φ_ε

$$(\mathbb{E}(z(\mathbf{0},t)-\Phi_\varepsilon(v,V))^2)^{1/2}\leqslant\varepsilon. \tag{32}$$

This means that the algorithm Φ_ε computes an ε-approximation of the multivariate Feynman–Kac path integral.

B. Number of function evaluations

In this section we derive estimates on the number of function values $n(\Phi_\varepsilon)$ of the algorithm Φ_ε. By the bounds (23) and (28) we get an obvious estimate

$$n(\Phi_\varepsilon)=O\left(1+\sum_{k=0}^{\infty}D_{k+1}(\log_2\varepsilon_k^{-1})_+^{k(\alpha(F)+1)}\left(\frac{B\beta^k t^k 2^{k+1}}{k!}\right)^{\alpha(F)}\right)\varepsilon^{-2\alpha(F)/(\alpha(F)+2)}.$$

We can now use an argument similar to that in the proof of Ref. 4 (Theorem 1) to show that

$$\sum_{k=0}^{\infty}D_{k+1}(\log_2\varepsilon_k^{-1})_+^{k(\alpha(F)+1)}\left(\frac{B\beta^k t^k 2^{k+1}}{k!}\right)^{\alpha(F)}=O(\varepsilon^{-\delta})$$

for all $\delta>0$. Thus we finally get

$$n(\Phi_\varepsilon)=O(\varepsilon^{-2\alpha(F)/(\alpha(F)+2)-\delta})\quad\text{for all }\delta>0. \tag{33}$$

It is easy to see that both parts of each of the algorithms $\phi_{\varepsilon_k,m}$—the variance reduction and the integral approximation—are linear with respect to the functions h_k. This means that their total computational cost (the number of arithmetic operations and comparisons) is proportional to the number of function evaluations. This also holds for the final algorithm Φ_ε, thus the estimate (33) holds also for the total cost of Φ_ε.

C. Optimality of the algorithm Φ_ε

It turns out that the algorithm Φ_ε is optimal modulo δ in (33), as long as the exponent $\alpha(F)$ in (7) is given as the minimal one. The proof of this fact exceeds the scope of this article and requires a more extensive use of information-based complexity. We refer the reader to the follow-up article[5] for more details.

VIII. EXAMPLE

We now consider an example of the class F of initial value and potential functions satisfying the assumptions from Secs. II and III.

Let F be a class of d variate r times continuously differentiable functions whose supports are contained in a cube $[a,b]^d\subset\mathbb{R}^d, a,b\in\mathbb{R}$. Thus F is a subclass of the Sobolev space $W_\infty^{r,d}([a,b]^d)$ with the norm

$$\|f\|_{W_\infty^{r,d}([a,b]^d)}=\sum_{|\boldsymbol{\alpha}|\leqslant r}\|f^{(\boldsymbol{\alpha})}\|_{L_\infty([a,b]^d)},$$

here $\boldsymbol{\alpha}=[\alpha_1,\ldots,\alpha_d]\in\mathbb{N}^d$ and $f^{(\boldsymbol{\alpha})}=\partial^{|\alpha|}/\partial^{\alpha_1}\ldots\partial^{\alpha_d}$.

Clearly, the assumptions Secs. II A 1 and II A 2 are satisfied. We also know an optimal uniform approximation algorithm that satisfies Sec. II A 3 with the exponent $\alpha(F)=d/r$, see Refs. 11, 13, and 14. Based on this algorithm and the results from Secs. VI and VII we can construct the algorithm Φ_ε computing an ε-approximation of the multivariate Feynman–Kac path integral (3) in the sense of (9) with the number of function evaluations being roughly of order $O(\varepsilon^{-2/(1+2r/d)})$. We see that the exponent of ε^{-1} is at most 2 and decreases with the increase of the ratio r/d. Unfortunately, the factor hidden in the big O notation that comes from the use of uniform approximation and Smolyak's algorithm depends exponentially on the dimension d. The limiting value 2 of the exponent $2/(1+2r/d)$ corresponds to the algorithm without variance reduction.

We present a systematic method to express all su(N) invariant tensors in terms of forests, i.e., products of tree tensors. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2049168]

I. INTRODUCTION

It is a well known fact that in a simple Lie algebra of rank r there are exactly r independent Casimir invariants. This causes a direct restriction on algebra of su(N) tensors since naively one could produce an infinite amount of invariants by contracting d, f tensors. The Cayley-Hamilton theorem, which is the reason why higher Casimir invariants are dependent on the first r ones, clearly gives additional d_{ijk} tensor identities. The systematic, computer friendly, approach to obtain these formulas was presented by Sudbery.[1] One may also define matrices $[F_i]_{jk}=f_{ijk}$, $F=a_iF_i$, $a_i \in \mathbf{C}$ and use Cayley-Hamilton equation to obtain analogous identities for f_{ijk}, which was elaborated in detail in Ref. 2. In this paper we will use a geometrical approach to find formulas on su(N) loop tensors in term of su(N) tree tensors. In this way we give a recursive method which allows one to express any su(N) invariant tensor in terms of basic ones, i.e., forests (products of trees). In Sec. III we prove several lemmas and eventually the main result. In Sec. IV we present a few examples to give insights into the method.

We will use the following conventions:

$$\lambda_i\lambda_j = \frac{2}{N}\delta_{ij}\mathbf{1} + d_{ijk}\lambda_k + if_{ijk}\lambda_k, \tag{1}$$

where λ_i's are su(N) generators in fundamental representation and d_{ijk}, f_{ijk} are completely symmetric/antisymmetric structure tensors. Multiplication law (1) together with Jacobi identities for λ_i's give identities that have been known for a long time.[3] We will make special use of

$$f_{i_1i_2k}d_{ki_3i_4} + f_{i_1i_3k}d_{ki_2i_4} + f_{i_1i_4k}d_{ki_2i_3} = 0, \tag{2}$$

and

$$f_{i_1i_2k}f_{ki_3i_4} = \frac{2}{N}(\delta_{i_1i_3}\delta_{i_2i_4} - \delta_{i_1i_4}\delta_{i_2i_3}) + d_{i_1i_3k}d_{ki_2i_4} - d_{i_1i_4k}d_{ki_2i_3}. \tag{3}$$

II. BIRD TRACKS

In order to grasp the variety of all possible invariant tensors it is helpful to introduce the diagrammatic notation for d and f tensors (Fig. 1). Each leg corresponds to one index and summing over any two indices is simply gluing appropriate legs. This notation is very convenient because now any tensor may be represented by a graph.

[a)]Electronic mail: trzetrzelewski@th.if.uj.edu.pl

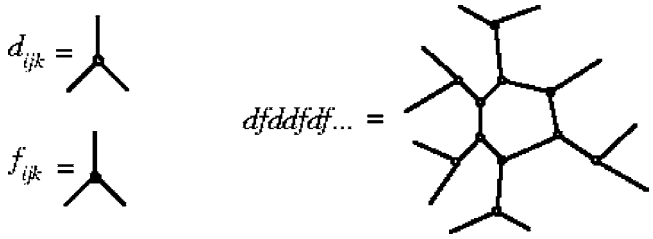

FIG. 1. d_{ijk}, f_{ijk} diagrams and a typical tensor diagram.

Such a diagrammatic approach was already introduced a long time ago by Cvitanovič. The d, f tensors are called bird tracks since they look like tracks of a bird. The reader is referred to Ref. 4 where a vast amount of group properties is rediscovered in such diagrammatic language. Since d_{ijk} is totally symmetric the order of the corresponding legs is irrelevant. For f_{ijk} we have to set, e.g., counterclockwise convention. A special group of diagrams are loop and tree diagrams (Fig. 2).

One may rotate any diagram on the plane without changing the value of the corresponding tensor. Reflections (or rotations in three dimensions) are allowed as well, however in this case one has to take care of the sign since f tensor is antisymmetric. If a diagram consists only of d tensors then reflections will not affect its value. Several definitions are now in order.

The index that corresponds to the d/f tensor is called the d/f index. A loop L_1 is smaller than loop L_2 if the number of f, d tensors in L_2 is smaller than the number of f, d tensors on L_1. Note that, in general, trees can be attached to loops. In that case we will call it a tree loop diagram. Similarly a tree loop L_1 is smaller than tree loop L_2 if the number of f, d tensors within loop in L_2 is smaller than the number of f, d tensors within loop in L_1.

A loop diagram is called n loop if it consists of n tensors. A loop diagram is called d loop if it consists of d tensors only. A loop diagram is called $1f/2f$ loop if it consists of one/two f tensor and d tensors.

III. LOOP REDUCTION

This section consists of several lemmas and eventually a theorem which gives a computational method for expressing loops by trees.

Lemma 1: Any loop is a linear combination of d loops and $1f$ loops.

Proof: Let us rewrite (3) in diagrammatic notation (*). (Instead of writing i_1, i_2, i_3, i_4, etc., we prefer 1, 2, 3, 4 since it causes no misunderstanding and gives a better idea of the structure of indices. Take attention of the order of indices 3 and 4. There is no mistake. The whole diagram is supposed to be read with the counterclockwise convention.) Therefore it is sufficient to consider loops where f tensor is between d tensors (d1)

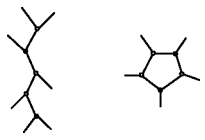

FIG. 2. A tree and a loop diagram.

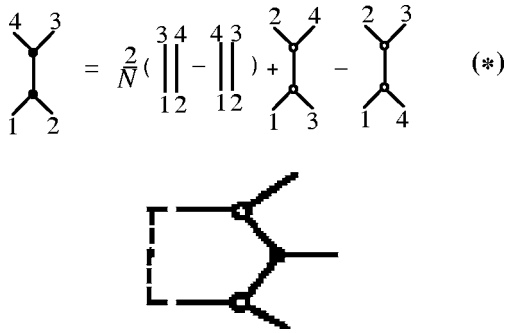
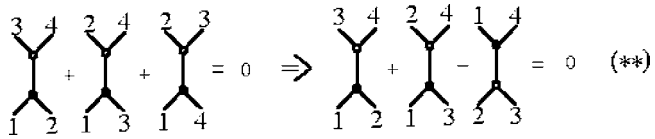


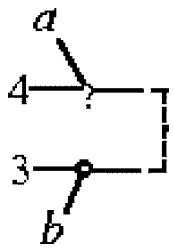
(d1)

However in such case one can use Jacobi identities (2)



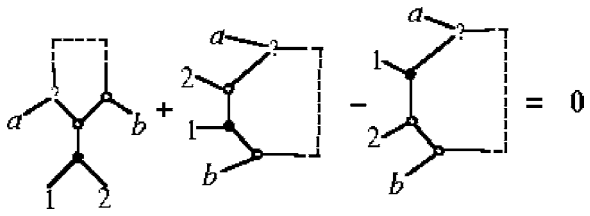
(d2)

therefore attaching (the question mark means that there may be f tensor or d tensor)



(d3)

we get

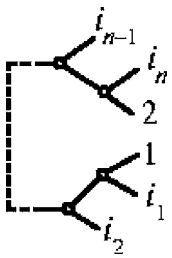


(d4)

The last identity means that we can "move" f tensor along the loop producing a smaller tree loop. Eventually such f tensor will "meet" another f tensor (if there is another one in the loop) and one can use (*) again to get rid of f tensors. This procedure stops on d loops or $1f$ loops. □

Lemma 2: Let A be a d loop or $1f$ loop. Then any permutation of d indices of A does not change the value of A up to trees and smaller tree loops.

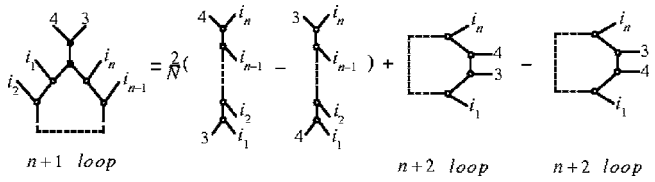
Proof: Consider identity (*) and attach the tensor



(d5)

where the dashed lines correspond to d tensors only.

The result is

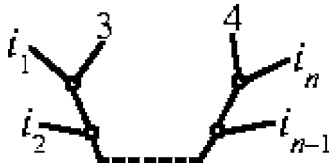


(d6)

Therefore the permutation of indices 3, 4 does not change the d loop up to trees and smaller tree loops. Since indices 3, 4 are not distinguished we can do any permutation of any two indices and the d loop will not change the value up to trees and smaller tree loops. Since any permutation is a proper composition of transpositions the Lemma 2 follows for d loops. The proof for $1f$ loops is analogous. □

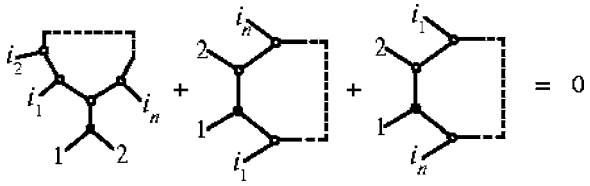
Lemma 3: Any $1f$ loop is a linear combination of trees and smaller tree loops.

Proof: Consider the Jacobi identities (**) and attach the tree diagram (consisting of d tensors only)



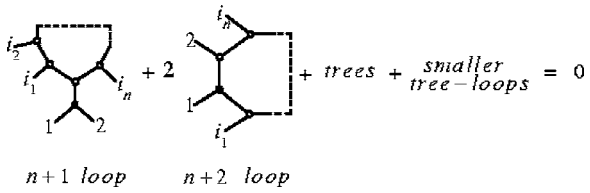
(d7)

The result is



(d8)

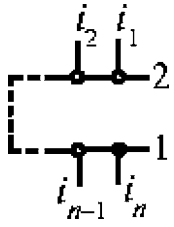
From Lemma 2 it follows that



(d9)

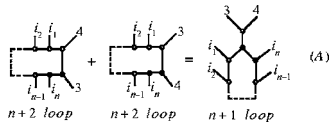
Lemma 4: Any d loop is a linear combination of trees and smaller tree loops.

Proof: Consider Jacobi identity (**) and attach the following tree (consisting of one f tensor and $n-1$ d tensors)



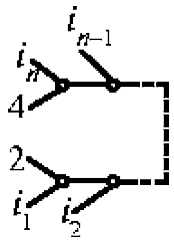
(d10)

The result is



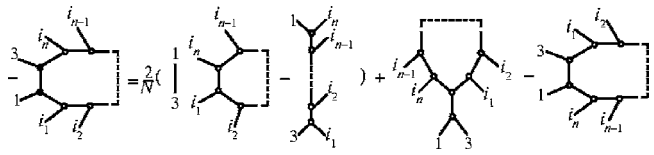
(d11)

Therefore the symmetrization of indices 3, 4 in such $2f$ loop is equal to smaller tree loop. Now for the proof of Lemma 4 consider identity (*) and attach the tree tensor (consisting of d tensors only)



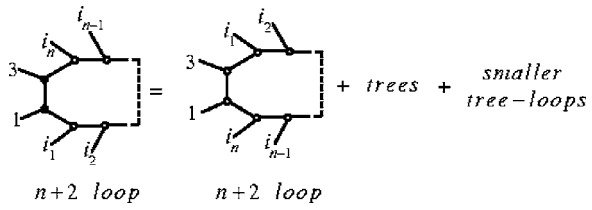
(d12)

The result is



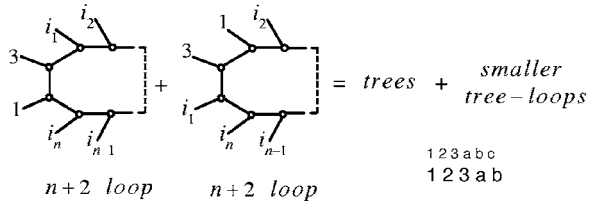
(d13)

Or simply



(d14)

According to (A) the symmetrization over indices 1 and i_1 gives



(d15)

Due to Lemma 2, Lemma 4 follows. □

Theorem: Any loop diagram is a linear combination of forests.

Proof: From Lemma 1 it is sufficient to consider d loops and $1f$ loops. From Lemma 3 and Lemma 4 we may recursively reduce $1f$ loop and d loop to arbitrary small loops and ultimately to trees. □

Corollary 1: Any diagram is a linear combination of forests.

Proof: Any loop in the diagram may be replaced by a linear combination of trees. This will in general produce more loops however the number of d, f tensors will be smaller after such replacement. Following the induction with respect to the number of d, f tensors we finely reduce all loops. □

Corollary 2: Any diagram is a linear combination of products of trace tensors $\mathrm{Tr}(\lambda_{i_1}\ldots\lambda_{i_n})$ where λ_i's are su(N) Gell-Mann matrices.

Proof: According to Corollary 1 it is sufficient to consider tree diagrams. With help of (1) we have

$$\mathrm{Tr}(\lambda_{i_1}\ldots\lambda_{i_n}) = \frac{1}{N}\mathrm{Tr}(\lambda_{i_1}\lambda_{i_2})Tr(\lambda_{i_3}\ldots\lambda_{i_n}) + (d_{i_1i_2k} + if_{i_1i_2k})Tr(\lambda_k\lambda_{i_3}\ldots\lambda_{i_n})$$

therefore

$$d_{i_1i_2k}\mathrm{Tr}(\lambda_k\lambda_{i_3}\ldots\lambda_{i_n}) = \frac{1}{2}\mathrm{Tr}(\lambda_{(i_1}\lambda_{i_2)}\lambda_{i_3}\ldots\lambda_{i_n}) - \frac{1}{N}\mathrm{Tr}(\lambda_{i_1}\lambda_{i_2})Tr(\lambda_{i_3}\ldots\lambda_{i_n})$$

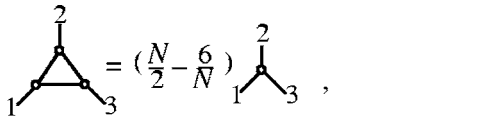
and

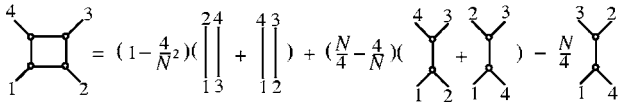
$$f_{i_1i_2k}Tr(\lambda_k\lambda_{i_3}\ldots\lambda_{i_n}) = \tfrac{1}{2}\mathrm{Tr}(\lambda_{[i_1}\lambda_{i_2]}\lambda_{i_3}\ldots\lambda_{i_n}),$$

hence Corollary 2 follows by induction. □

IV. EXAMPLES

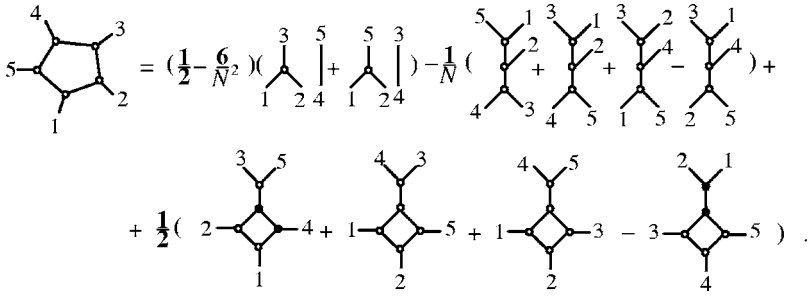
In the following we give su(N) formulas for the lowest d loops, i.e., triangles, squares, and pentagons. The identities for triangles and squares are already in the literature in Refs. 3 and 5, respectively. However to the knowledge of the author these identities are missing for pentagons and higher loops. The results are





(d16)

and



(d17)

The last identity in standard notation is

$$\begin{aligned}\mathrm{Tr}(D_{i_1}D_{i_2}D_{i_3}D_{i_4}D_{i_5}) = \left(\frac{1}{2} - \frac{6}{N}\right)(d_{i_1i_2i_3}\delta_{i_4i_5} + d_{i_1i_2i_5}\delta_{i_4i_3}) + -\frac{1}{N}(d_{i_3i_4k}d_{ki_2l}d_{li_1i_5} + d_{i_4i_5k}d_{ki_2l}d_{li_1i_3}\\ + d_{i_1i_5k}d_{ki_4l}d_{li_2i_3} - d_{i_2i_5k}d_{ki_4l}d_{li_1i_3}) + \frac{1}{2}(\mathrm{Tr}(D_{i_2}D_{i_1}F_{i_4}F_k)d_{ki_5i_3}\\ + \mathrm{Tr}(D_{i_1}D_{i_2}D_{i_5}D_k)d_{ki_3i_4} + \mathrm{Tr}(D_{i_1}D_{i_2}D_{i_3}D_k)d_{ki_5i_4} - \mathrm{Tr}(D_{i_3}D_{i_4}D_{i_5}F_k)f_{ki_1i_2}).\end{aligned}$$

It should be noted that all these identities have been verified in MATHEMATICA with perfect agreement.

V. SUMMARY

The aim of this paper was to give a systematic approach to compute loop tensors. The reason for doing so lies in the analysis of systems based on su(N) group. In fact the author came across this problem while studying supersymmetric Yang-Mills quantum mechanics for arbitrary N and large N limit.[6,7] These issues will be published elsewhere. The method agrees with recent results[2] where the problem was solved via characteristic equation for F matrices. Let us note that it is a laborious task to obtain this equation for arbitrary su(N), therefore a big loop diagram for large N is in general difficult to reduce. In a diagrammatic approach this problem does not exist since we make no use of characteristic equation. Indeed the lemmas presented here are so simple that one could write a computer program for arbitrary loop reduction. What is even more remarkable is that the derivation of our result is based only on Jacobi identities and multiplication law (1). We did not use the relations derived by Sudbery[1] although it is evident that one may contract his formulas with, e.g., d_{ijk} providing a constraint on a d loop.

The diagrammatic method may be applied to arbitrary Lie algebra. However since the multiplication rule (1) is different in other cases than su(N) we expect the conclusions to be different. Indeed in the g_2 case the situation is so different that the simplest triangle d loop is not proportional to d_{ijk} tensor.[8]

Finally let us note that the method[2] gives no information about lower degree traces (e.g., $\mathrm{Tr}(F^4), \mathrm{Tr}(F^6), \mathrm{Tr}(F^8), \mathrm{Tr}(F^{10})$ in su(5) cannot be written as polynomials in lower degree traces). One may however apply different arguments[5] to derive formulas for fourfold traces. Our results also agree with them. Unfortunately these arguments get more complicated while analyzing bigger loops.

A generic degenerate Lagrangian system of even and odd fields is examined in algebraic terms of the Grassmann-graded variational bicomplex. Its Euler–Lagrange operator obeys Noether identities which need not be independent, but satisfy first-stage Noether identities, and so on. We show that, if a certain necessary and sufficient condition holds, one can associate to a degenerate Lagrangian system the exact Koszul–Tate complex with the boundary operator whose nilpotency condition restarts all its Noether and higher-stage Noether identities. This complex provides a sufficient analysis of the degeneracy of a Lagrangian system for the purpose of its BV quantization. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2054647]

I. INTRODUCTION

As well-known, quantization of a Lagrangian field system essentially depends on the analysis of its degeneracy. One says that a Lagrangian system is degenerate if its Euler–Lagrange operator obeys nontrivial Noether identities. They need not be independent, but satisfy the first-stage Noether identities, which in turn are subject to the second-stage ones, and so on. The hierarchy of reducible Noether identities characterizes the degeneracy of a Lagrangian system in full. Noether's second theorem states the relation between the Noether identities and the gauge symmetries of a Lagrangian system.[1,2] If Noether identities and gauge symmetries are finitely generated, they are parametrized by the modules of antifields and ghosts, respectively. An original Lagrangian is extended to these antifields and ghosts in order to satisfy the so-called master equation. This extended Lagrangian is the starting point of the Batalin–Vilkovisky (BV) quantization of a degenerate Lagrangian field system.[3,4]

Let us note that the notion of a reducible Noether identity has come from that of a reducible constraint. Their Koszul–Tate complex has been invented by analogy with that of constraints[5] under a rather restrictive regularity condition that field equations as well as Noether identities of arbitrary stage can be locally separated into the independent and dependent ones.[6,7] This condition also comes from the case of a constraint locally given by a finite number of functions to which the

[a)]Electronic mail: bashkir@phys.msu.ru
[b)]Electronic mail: giovanni.giachetta@unicam.it
[c)]Electronic mail: luigi.mangiarotti@unicam.it
[d)]Electronic mail: sard@grav.phys.msu.su

inverse mapping theorem can be applied. In contrast with constraints, Noether and higher-stage Noether identities are differential operators. They are locally given by a set of functions and their jet prolongations on an infinite order jet manifold. Since the latter is a Fréchet, but not Banach manifold, the inverse mapping theorem fails to be valid. Here, we follow the general definition of Noether identities of differential operators.[8] This definition reproduces that in Refs. 1 and 2 if Noether identities are finitely generated. Their Koszul–Tate complex is constructed iff a certain homology regularity condition holds.

Our goal is the following. Bearing in mind BV quantization, we address a generic Lagrangian systems of even and odd fields on an arbitrary smooth manifold X ($\dim X=n$). It is algebraically described in terms of a certain bigraded differential algebra (henceforth BGDA) $\mathcal{S}^*_\infty[F;Y]$ which is split into the Grassmann-graded variational bicomplex, generalizing the variational bicomplex on fiber bundles (Sec. II). If a fiber bundle $Y\to X$ of even fields is affine, this algebra has been defined as the product of graded algebras of odd and even fields.[2,9] Here, its definition is generalized to an arbitrary fiber bundle $Y\to X$. In this case, elements of $\mathcal{S}^*_\infty[F;Y]$ are Grassmann-graded differential forms on the infinite order jet manifold $J^\infty Y$ of sections of $Y\to X$, but not on X. Let $L\in\mathcal{S}^{0,n}_\infty[F;Y]$ be a Lagrangian and $\delta L\in\mathcal{S}^{1,n}_\infty[F;Y]$ its Euler–Lagrange operator. We associate to δL the chain complex (13) whose boundaries vanish on-shell, i.e., on $\operatorname{Ker}\delta L$ (Proposition 4). It is a complex of a certain $C^\infty(X)$-module $\mathcal{P}^{0,n}_\infty[\bar{Y}^*;F;Y;\bar{F}^*]$ of Grassmann-graded densities on the infinite order jet manifold $J^\infty Y$. For our purpose, this complex can be replaced with the short zero-exact complex $\mathcal{P}^{0,n}_\infty[\bar{Y}^*;F;Y;\bar{F}^*]_{\leqslant 2}$ (14).

Remark 1: If there is no danger of confusion, elements of homology are identified to its representatives. A chain complex is called r-exact if its homology of $k\leqslant r$ is trivial.

The Noether identities of the Euler–Lagrange operator δL are defined as nontrivial elements of the first homology $H_1(\bar{\delta})$ of the complex (14) (Definition 5). Let this homology be finitely generated by a projective graded $C^\infty(X)$-module of finite rank. In accordance with the Serre–Swan theorem generalized to graded manifolds (Theorem 1), one can introduce the corresponding module of antifields and extend the complex (14) to the one-exact complex $\mathcal{P}^{0,n}_\infty[\bar{E}^*\bar{Y}^*;F;Y;\bar{F}^*\bar{V}^*]_{\leqslant 3}$ (22) with the boundary operator δ_0 (21) whose nilpotency conditions are equivalent to the above-mentioned Noether identities (Proposition 6). First-stage Noether identities are defined as two-cycles of this complex. They are trivial if two-cycles are boundaries, but the converse need not be true. Trivial first-stage Noether identities are boundaries iff a certain homology condition (called the two-homology regularity condition) holds (Proposition 8). In this case, the first-stage Noether identities are identified to nontrivial elements of the second homology of the complex (22). If this homology is finitely generated, the complex (22) is extended to the two-exact complex $\mathcal{P}^{0,n}_\infty[\bar{E}^*_1\bar{E}^*\bar{Y}^*;F;Y;\bar{F}^*\bar{V}^*\bar{V}^*_1]_{\leqslant 4}$ (33) with the boundary operator δ_1 (32) whose nilpotency conditions are equivalent to the Noether and first-stage Noether identities (Proposition 10). If the third homology of this complex is not trivial, the second-stage Noether identities exist, and so on. Iterating the arguments, we come to the following.

We have the $(N+1)$-exact complex $\mathcal{P}^{0,n}_\infty\{N\}_{\leqslant N+3}$ (37) such that (i) the nilpotency conditions of its boundary operator δ_N (35) reproduce Noether and k-stage Noether identities for $k\leqslant N$, (ii) the $(N+1)$-homology regularity condition holds. This condition states that any $\delta_{k<N-1}$-cycle $\phi\in\mathcal{P}^{0,n}_\infty\{k\}_{k+3}$ is a δ_{k+1}-boundary (Definition 11). Then the $(N+1)$-stage Noether identities are defined as $(N+2)$-cycles of this complex. They are trivial if cycles are boundaries, while the converse is true iff the $(N+2)$-homology regularity condition is satisfied. In this case, $(N+1)$-stage Noether identities are identified to nontrivial elements of the $(N+2)$-homology of the complex (37) [item (i) of Theorem 13]. Let this homology be finitely generated. By means of antifields, this complex is extended to the $(N+2)$-exact complex $\mathcal{P}_\infty\{N+1\}_{\leqslant N+4}$ (45) with the boundary operator δ_{N+1} (44) whose nilpotency restarts all the Noether identities up to stage $(N+1)$ [item (ii) of Theorem 13].

This iteration procedure results in the exact Koszul–Tate complex of antifields with the boundary operator whose nilpotency conditions reproduce all Noether and higher Noether identities characterizing the degeneracy of a differential operator δL.

In Sec. V, we address the particular variant of topological BF theory with the Lagrangian (47) for a scalar A and $(n-1)$-form B as an example of a reducible degenerate Lagrangian system[1] where the homology regularity condition is verified (Lemma 14), Noether and k-stage Noether identities are proved to be finitely generated, and its Koszul–Tate complex (62) is constructed.

Remark 2: Throughout the paper, smooth manifolds are assumed to be real, finite-dimensional, Hausdorff, second-countable (consequently, paracompact) and connected. By a Grassmann algebra over a ring $\mathcal{K}$ is meant a $\mathbb{Z}_2$-graded exterior algebra of some $\mathcal{K}$-module. We restrict our consideration to graded manifolds $(Z,\mathfrak{A})$ with structure sheaves $\mathfrak{A}$ of Grassmann algebras of finite rank.[10,11] The symbols $|.|$ and $[.]$ stand for the form degree and Grassmann parity, respectively. We denote by Λ, Σ, Ξ, Ω the symmetric multi-indices, e.g., $\Lambda=(\lambda_1\cdots\lambda_k)$, $\lambda+\Lambda=(\lambda\lambda_1\cdots\lambda_k)$. Summation over a multi-index $\Lambda=(\lambda_1\cdots\lambda_k)$ throughout means separate summation over each index λ_i.

II. GRASSMANN-GRADED LAGRANGIAN SYSTEMS

Let $Y\to X$ be a fiber bundle and J^rY be the jet manifolds of its sections. They form the inverse system

$$X\overset{\pi}{\leftarrow}Y\overset{\pi^1_0}{\leftarrow}J^1Y\leftarrow\cdots J^{r-1}Y\overset{\pi^r_{r-1}}{\leftarrow}J^rY\leftarrow\cdots, \tag{1}$$

where π^r_{r-1} are affine bundles, and $r=0$ conventionally stands for Y. Its projective limit $(J^\infty Y;\pi^\infty_r:J^\infty Y\to J^rY)$ is a paracompact Fréchet manifold. A bundle atlas $\{(U_Y;x^\lambda,y^i)\}$ of $Y\to X$ induces the coordinate atlas

$$\begin{gathered}\{((\pi^\infty_0)^{-1}(U_Y);x^\lambda,y^i_\Lambda)\},\quad y'^i_{\lambda+\Lambda}=\frac{\partial x^\mu}{\partial x'^\lambda}d_\mu y'^i_\Lambda,\quad 0\leqslant|\Lambda|,\\ d_\lambda=\partial_\lambda+\sum_{0\leqslant|\Lambda|}y^i_{\lambda+\Lambda}\partial^\Lambda_i,\quad d_\Lambda=d_{\lambda_1}\circ\cdots\circ d_{\lambda_k},\end{gathered} \tag{2}$$

of $J^\infty Y$, where d_λ are total derivatives. We further assume that the cover $\{\pi(U_Y)\}$ of X is also the cover of atlases of all fiber bundles over X in question. The inverse system (1) yields the direct system

$$\mathcal{O}^*X\overset{\pi^*}{\to}\mathcal{O}^*Y\overset{\pi^{1*}_0}{\to}\mathcal{O}^*_1Y\to\cdots\mathcal{O}^*_{r-1}Y\overset{\pi^{r}_{r-1}{}^*}{\to}\mathcal{O}^*_rY\to\cdots \tag{3}$$

of algebras $\mathcal{O}^*_rY$ of exterior forms on jet manifolds J^rY with respect to the pull-back monomorphisms $\pi^r_{r-1}{}^*$. Its direct limit is the graded differential algebra (henceforth GDA) $\mathcal{O}^*_\infty Y$ of all exterior forms on finite order jet manifolds modulo the pull-back identification.

Let us extend the GDA $\mathcal{O}^*_\infty Y$ to graded forms on graded manifolds whose bodies are jet manifolds J^rY of Y.[2,9] Note that there are different approaches to treat odd fields on a smooth manifold X, but the following variant of the Serre–Swan theorem motivates us to describe them in terms of graded manifolds whose body is X.

Theorem 1: Let Z be a smooth manifold. A Grassmann algebra $\mathcal{A}$ over the ring $C^\infty(Z)$ of smooth real functions on Z is isomorphic to the Grassmann algebra of graded functions on a graded manifold with a body Z iff it is the exterior algebra of some projective $C^\infty(Z)$-module of finite rank.

Proof: The proof follows at once from the Batchelor theorem[10] and the Serre–Swan theorem generalized to an arbitrary smooth manifold.[11,12] The Batchelor theorem states that any graded manifold $(Z,\mathfrak{A})$ with a body Z is isomorphic to the one $(Z,\mathfrak{A}_Q)$ with the structure sheaf $\mathfrak{A}_Q$ of germs of sections of the exterior bundle,

$$\wedge Q^* = \mathbb{R} \underset{Z}{\oplus} Q^* \underset{Z}{\oplus} \overset{2}{\wedge} Q^* \underset{Z}{\oplus} \cdots ,$$

where Q^* is the dual of some vector bundle $Q \to Z$. Let us call $(Z, \mathfrak{A}_Q)$ the simple graded manifold with the structure vector bundle Q. Its ring $\mathcal{A}_Q$ of graded functions (sections of $\mathfrak{A}_Q$) is the $\mathbb{Z}_2$-graded exterior algebra of the $C^\infty(Z)$-module of sections of $Q^* \to Z$. By virtue of the Serre–Swan theorem, a $C^\infty(Z)$-module is isomorphic to the module of sections of a smooth vector bundle over Z iff it is a projective module of finite rank.

In field models, Batchelor's isomorphism is usually fixed from the beginning. Therefore, we further consider simple graded manifolds $(Z, \mathfrak{A}_Q)$. One associates to $(Z, \mathfrak{A}_Q)$ the following BGDA $\mathcal{S}^*[Q;Z]$.[10] Let $\mathfrak{d}\mathfrak{A}_Q$ be the sheaf of graded derivations of $\mathfrak{A}_Q$. Its global sections make up the real Lie superalgebra $\mathfrak{d}\mathcal{A}_Q$ of graded derivations of the $\mathbb{R}$-ring $\mathcal{A}_Q$. Then the Chevalley–Eilenberg complex of $\mathfrak{d}\mathcal{A}_Q$ with coefficients in $\mathcal{A}_Q$ can be constructed.[13] Its subcomplex $\mathcal{S}^*[Q;Z]$ of $\mathcal{A}_Q$-linear morphisms is the Grassmann-graded Chevalley–Eilenberg differential calculus

$$0 \to \mathbb{R} \to \mathcal{A}_Q \overset{d}{\to} \mathcal{S}^1[Q;Z] \overset{d}{\to} \cdots \mathcal{S}^k[Q;Z] \overset{d}{\to} \cdots$$

over a $\mathbb{Z}_2$-graded commutative $\mathbb{R}$-ring $\mathcal{A}_Q$. The graded exterior product $\wedge$ and Chevalley–Eilenberg coboundary operator d (the graded exterior differential) make $\mathcal{S}^*[Q;Z]$ into a BGDA whose elements obey the relations

$$\phi \wedge \phi' = (-1)^{|\phi||\phi'|+[\phi][\phi']} \phi' \wedge \phi, \quad \mathrm{d}(\phi \wedge \phi') = \mathrm{d}\phi \wedge \phi' + (-1)^{|\phi|} \phi \wedge \mathrm{d}\phi' .$$

Given the GDA $\mathcal{O}^*Z$ of exterior forms on Z, there are the monomorphism $\mathcal{O}^*Z \to \mathcal{S}^*[Q;Z]$ and the body epimorphism $\mathcal{S}^*[Q;Z] \to \mathcal{O}^*Z$. The following facts are essential.[9,11] □

Lemma 2: The BGDA $\mathcal{S}^*[Q;Z]$ is a minimal differential calculus over $\mathcal{A}_Q$, i.e., it is generated by elements $\mathrm{d}f$, $f \in \mathcal{A}_Q$.

Lemma 3: Given a ring R, let $\mathcal{K}$, $\mathcal{K}'$ be R-rings and $\mathcal{A}$, $\mathcal{A}'$ the Grassmann algebras over $\mathcal{K}$ and $\mathcal{K}'$, respectively. Then a homomorphism (respectively, a monomorphism) $\rho: \mathcal{A} \to \mathcal{A}'$ yields a homomorphism (respectively, a monomorphism) of the minimal Chevalley–Eilenberg differential calculus over a $\mathbb{Z}_2$-graded R-ring $\mathcal{A}$ to that over $\mathcal{A}'$ given by the map $\mathrm{d}a \mapsto \mathrm{d}(\rho(a))$, $a \in \mathcal{A}$.

One can think of elements of the BGDA $\mathcal{S}^*[Q;Z]$ as being graded exterior forms on Z as follows. Given an open subset $U \subset Z$, let $\mathcal{A}_U$ be the Grassmann algebra of sections of the sheaf $\mathfrak{A}_Q$ over U, and let $\mathcal{S}^*[Q;U]$ be the Chevalley–Eilenberg differential calculus over $\mathcal{A}_U$. Given an open set $U' \subset U$, the restriction morphisms $\mathcal{A}_U \to \mathcal{A}_{U'}$ yield a homomorphism of BGDAs $\mathcal{S}^*[Q;U] \to \mathcal{S}^*[Q;U']$. Thus, we obtain the presheaf $\{U, \mathcal{S}^*[Q;U]\}$ of BGDAs on a manifold Z and the sheaf $\mathfrak{S}^*[Q;Z]$ of BGDAs of germs of this presheaf. Since $\{U, \mathcal{A}_U\}$ is the canonical presheaf of $\mathfrak{A}_Q$, the canonical presheaf of $\mathfrak{S}^*[Q;Z]$ is $\{U, \mathcal{S}^*[Q;U]\}$. In particular, $\mathcal{S}^*[Q;Z]$ is the BGDA of global sections of the sheaf $\mathfrak{S}^*[Q;Z]$, and there is the restriction morphism $\mathcal{S}^*[Q;Z] \to \mathcal{S}^*[Q;U]$ for any open $U \subset Z$. Due to this morphism, elements of $\mathcal{S}^*[Q;Z]$ can be written in the following local form.

Given bundle coordinates (z^A, q^a) on Q and the corresponding fiber basis $\{c^a\}$ for $Q^* \to X$, the tuple (z^A, c^a) is called a local basis for the graded manifold $(Z, \mathfrak{A}_Q)$.[9] With respect to this basis, graded functions read

$$f = \sum_{k=0} \frac{1}{k!} f_{a_1 \cdots a_k} c^{a_1} \cdots c^{a_k}, \quad f \in C^\infty(Z), \tag{4}$$

where we omit the symbol of the exterior product of elements c^a. Due to the canonical vertical splitting $VQ = Q \times Q$, the fiber basis $\{\partial_a\}$ for vertical tangent bundle $VQ \to Q$ of $Q \to Z$ is the dual of $\{c^a\}$. Then graded derivations take the local form $u = u^A \partial_A + u^a \partial_a$, where u^A, u^a are local graded functions. They act on graded functions (4) by the rule

$$u(f_{a\cdots b}c^a\cdots c^b) = u^A\partial_A(f_{a\cdots b})c^a\cdots c^b + u^d f_{a\cdots b}\partial_d \rfloor (c^a\cdots c^b). \tag{5}$$

Relative to the dual local bases $\{\mathrm{d}z^A\}$ for T^*Z and $\{\mathrm{d}c^b\}$ for Q^*, graded one-forms read $\phi = \phi_A\,\mathrm{d}z^A + \phi_a\,\mathrm{d}c^a$. The duality morphism is given by the interior product

$$u \rfloor \phi = u^A\phi_A + (-1)^{[\phi_a]}u^a\phi_a, \quad u \in \mathfrak{d}\mathcal{A}_Q, \quad \phi \in \mathcal{S}^1[Q;Z].$$

The graded exterior differential reads

$$\mathrm{d}\phi = \mathrm{d}z^A \wedge \partial_A\phi + \mathrm{d}c^a \wedge \partial_a\phi,$$

where the derivations ∂_A and ∂_a act on coefficients of graded exterior forms by the formula (5), and they are graded commutative with the graded exterior forms $\mathrm{d}z^A$ and $\mathrm{d}c^a$.

We define jets of odd fields as simple graded manifolds modelled over jet bundles over X.[2,9] This definition differs from the definition of jets of a graded commutative ring[11] and that of jets of a graded fiber bundle,[14] but reproduces the heuristic notion of jets of odd ghosts in Lagrangian BRST theory.[7,15]

Given a vector bundle $F \to X$, let us consider the simple graded manifold $(J^rY, \mathfrak{A}_{F_r})$ whose body is J^rY and the structure bundle is the pull-back

$$F_r = J^rY \underset{X}{\times} J^rF$$

onto J^rY of the jet bundle $J^rF \to X$, which is also a vector bundle. Given the simple graded manifold $(J^{r+1}Y, \mathfrak{A}_{F_{r+1}})$, there is an epimorphism of graded manifolds

$$(J^{r+1}Y, \mathfrak{A}_{F_{r+1}}) \to (J^rY, \mathfrak{A}_{F_r}).$$

It consists of the open surjection π_r^{r+1} and the sheaf monomorphism $\pi_r^{r+1*}\mathfrak{A}_{F_r} \to \mathfrak{A}_{F_{r+1}}$, where $\pi_r^{r+1*}\mathfrak{A}_{F_r}$ is the pull-back onto $J^{r+1}Y$ of the topological fiber bundle $\mathfrak{A}_{F_r} \to J^rY$. This sheaf monomorphism induces the monomorphism of the canonical presheaves $\bar{\mathfrak{A}}_{F_r} \to \bar{\mathfrak{A}}_{F_{r+1}}$, which associates to each open subset $U \subset J^{r+1}Y$ the ring of sections of $\mathfrak{A}_{F_r}$ over $\pi_r^{r+1}(U)$. Accordingly, there is the monomorphism of $\mathbb{Z}_2$-graded rings $\mathcal{A}_{F_r} \to \mathcal{A}_{F_{r+1}}$. By virtue of Lemmas 2and 3, this monomorphism yields the monomorphism of BGDAs,

$$\mathcal{S}^*[F_r;J^rY] \to \mathcal{S}^*[F_{r+1};J^{r+1}Y]. \tag{6}$$

As a consequence, we have the direct system of BGDAs

$$\mathcal{S}^*[Y \underset{X}{\times} F;Y] \to \mathcal{S}^*[F_1;J^1Y] \to \cdots \mathcal{S}^*[F_r;J^rY] \to \cdots, \tag{7}$$

whose direct limit $\mathcal{S}^*_\infty[F;Y]$ is a BGDA of all graded differential forms $\phi \in \mathcal{S}^*[F_r;J^rY]$ on jet manifolds J^rY modulo monomorphisms (6). The monomorphisms $\mathcal{O}^*_rY \to \mathcal{S}^*[F_r;J^rY]$ provide the monomorphism $\mathcal{O}^*_\infty Y \to \mathcal{S}^*_\infty[F;Y]$ of their direct limits. In particular, $\mathcal{S}^*_\infty[F;Y]$ is an $\mathcal{O}^0_\infty Y$-algebra. Accordingly, the body epimorphisms $\mathcal{S}^*[F_r;J^rY] \to \mathcal{O}^*_rY$ yield the epimorphism of $\mathcal{O}^0_\infty Y$-modules $\mathcal{S}^*_\infty[F;Y] \to \mathcal{O}^*_\infty Y$.

If $Y \to X$ is an affine bundle, we recover the BGDA introduced in Refs. 2 and 9 by restricting the ring $\mathcal{O}^0_\infty Y$ to its subring $\mathcal{P}^0_\infty Y$ of polynomial functions, but now elements of $\mathcal{S}^*_\infty[F;Y]$ are graded exterior forms on $J^\infty Y$. Indeed, let $\mathfrak{S}^*[F_r;J^rY]$ be the sheaf of BGDAs on J^rY and $\bar{\mathfrak{S}}^*[F_r;J^rY]$ its canonical presheaf whose elements are the Chevalley–Eilenberg differential calculus over elements of the presheaf $\bar{\mathfrak{A}}_{F_r}$. Then the presheaf monomorphisms $\bar{\mathfrak{A}}_{F_r} \to \bar{\mathfrak{A}}_{F_{r+1}}$ yield the direct system of presheaves

$$\bar{\mathfrak{S}}^*[Y\times F;Y]\to\bar{\mathfrak{S}}^*[F_1;J^1Y]\to\cdots\bar{\mathfrak{S}}^*[F_r;J^rY]\to\cdots, \tag{8}$$

whose direct limit $\bar{\mathfrak{S}}^*_\infty[F;Y]$ is a presheaf of BGDAs on the infinite order jet manifold $J^\infty Y$. Let $\mathfrak{T}^*_\infty[F;Y]$ be the sheaf of BGDAs of germs of the presheaf $\bar{\mathfrak{S}}^*_\infty[F;Y]$. The structure module $\Gamma(\mathfrak{T}^*_\infty[F;Y])$ of sections of $\mathfrak{T}^*_\infty[F;Y]$ is a BGDA such that, given an element $\phi\in\Gamma(\mathfrak{T}^*_\infty[F;Y])$ and a point $z\in J^\infty Y$, there exist an open neighborhood U of z and a graded exterior form $\phi^{(k)}$ on some finite order jet manifold J^kY so that $\phi|_U=\pi^{\infty *}_k\phi^{(k)}|_U$. In particular, there is the monomorphism $\mathcal{S}^*_\infty[F;Y]\to\Gamma(\mathfrak{T}^*_\infty[F;Y])$.

Due to this monomorphism, one can restrict $\mathcal{S}^*_\infty[F;Y]$ to the coordinate chart (2) and say that $\mathcal{S}^*_\infty[F;Y]$ as an $\mathcal{O}^0_\infty Y$-algebra is locally generated by the elements

$$(1,c^a_\Lambda,\mathrm{d}x^\lambda,\theta^a_\Lambda=\mathrm{d}c^a_\Lambda-c^a_{\lambda+\Lambda}\,\mathrm{d}x^\lambda,\theta^i_\Lambda=\mathrm{d}y^i_\Lambda-y^i_{\lambda+\Lambda}\,\mathrm{d}x^\lambda),\quad 0\leqslant|\Lambda|.$$

We agree to call (y^i,c^a) the local basis for $\mathcal{S}^*_\infty[F;Y]$. Let the collective symbol s^A stand for its elements. Accordingly, the notation s^A_Λ and $\theta^A_\Lambda=\mathrm{d}s^A_\Lambda-s^A_{\lambda+\Lambda}\,\mathrm{d}x^\lambda$ is introduced. For the sake of simplicity, we further denote $[A]=[s^A]$.

The BGDA $\mathcal{S}^*_\infty[F;Y]$ is decomposed into $\mathcal{S}^0_\infty[F;Y]$-modules $\mathcal{S}^{k,r}_\infty[F;Y]$ of k-contact and r-horizontal graded forms. Accordingly, the graded exterior differential d on $\mathcal{S}^*_\infty[F;Y]$ falls into the sum $d=d_H+d_V$ of the total and vertical differentials, where

$$d_H(\phi)=\mathrm{d}x^\lambda\wedge d_\lambda(\phi),\quad d_\lambda=\partial_\lambda+\sum_{0\leqslant|\Lambda|}s^A_{\lambda+\Lambda}\partial^\Lambda_A.$$

Given the projector

$$\varrho=\sum_{k>0}\frac{1}{k}\bar{\varrho}\circ h_k\circ h^n,\quad \bar{\varrho}(\phi)=\sum_{0\leqslant|\Lambda|}(-1)^{|\Lambda|}\theta^A\wedge[d_\Lambda(\partial^\Lambda_A\rfloor\phi)],\quad \phi\in\mathcal{S}^{>0,n}_\infty[F;Y],$$

and the graded variational operator $\delta=\varrho\circ d$, the BGDA $\mathcal{S}^*_\infty[F;Y]$ is split into the above-mentioned Grassmann-graded variational bicomplex.[7,8] We restrict our consideration to its short variational subcomplex

$$0\to\mathbb{R}\to\mathcal{S}^0_\infty[F;Y]\overset{d_H}{\to}\mathcal{S}^{0,1}_\infty[F;Y]\cdots\overset{d_H}{\to}\mathcal{S}^{0,n}_\infty[F;Y]\overset{\delta}{\to}\mathbf{E}_1,\quad \mathbf{E}_1=\varrho(\mathcal{S}^{1,n}_\infty[F;Y]).$$

One can think of its even elements

$$\begin{gathered}L=\mathcal{L}\omega\in\mathcal{S}^{0,n}_\infty[F;Y],\quad \omega=\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n,\\ \delta L=\theta^A\wedge\mathcal{E}_A\omega=\sum_{0\leqslant|\Lambda|}(-1)^{|\Lambda|}\theta^A\wedge d_\Lambda(\partial^\Lambda_A L)\omega\in\mathbf{E}_1\end{gathered} \tag{9}$$

as being a graded Lagrangian and its Euler–Lagrange operator. A pair $(\mathcal{S}^*_\infty[F;Y],L)$ is further called a graded Lagrangian system.

Let $\vartheta\in\mathfrak{d}\mathcal{S}^0_\infty[F;Y]$ be a graded derivation of the $\mathbb{R}$-ring $\mathcal{S}^0_\infty[F;Y]$.[2,9] The interior product $\vartheta\rfloor\phi$ and the Lie derivative $\mathbf{L}_\vartheta\phi$, $\phi\in\mathcal{S}^*_\infty[F;Y]$, are defined by the formulas

$$\vartheta\rfloor\phi=\vartheta^\lambda\phi_\lambda+(-1)^{[\phi_A]}\vartheta^A\phi_A,\quad \phi\in\mathcal{S}^1_\infty[F;Y],$$

$$\vartheta\rfloor(\phi\wedge\sigma)=(\vartheta\rfloor\phi)\wedge\sigma+(-1)^{|\phi|+[\phi][\vartheta]}\phi\wedge(\vartheta\rfloor\sigma),\quad \phi,\sigma\in\mathcal{S}^*_\infty[F;Y],$$

$$\mathbf{L}_\vartheta\phi=\vartheta\rfloor\mathrm{d}\phi+d(\vartheta\rfloor\phi),\quad \mathbf{L}_\vartheta(\phi\wedge\sigma)=\mathbf{L}_\vartheta(\phi)\wedge\sigma+(-1)^{[\vartheta][\phi]}\phi\wedge\mathbf{L}_\vartheta(\sigma).$$

A graded derivation ϑ is said to be contact if the Lie derivative $\mathbf{L}_\vartheta$ preserves the ideal of contact graded forms of the BGDA $\mathcal{S}^*_\infty[F;Y]$. With respect to the local basis $\{s^A\}$ for the BGDA $\mathcal{S}^*_\infty[F;Y]$, any contact graded derivation takes the form

$$\vartheta = \vartheta_H + \vartheta_V = \vartheta^\lambda d_\lambda + \left(\vartheta^A \partial_A + \sum_{0<|\Lambda|} d_\Lambda \vartheta^A \partial_A^\Lambda\right),$$

where the tuple of graded derivations $\{\partial_\lambda, \partial_A^\Lambda\}$ is the dual of the tuple $\{dx^\lambda, ds_\Lambda^A\}$ of generating elements of the $\mathcal{S}^0_\infty[F;Y]$-algebra $\mathcal{S}^*_\infty[F;Y]$, and ϑ^λ, ϑ^A are local graded functions.

We restrict our consideration to vertical contact graded derivations

$$\vartheta = \sum_{0\leqslant|\Lambda|} d_\Lambda \upsilon^A \partial_A^\Lambda. \tag{10}$$

Such a derivation is completely determined by its first summand

$$\upsilon = \upsilon^A(x^\lambda, s_\Lambda^A)\partial_A, \quad 0 \leqslant |\Lambda| \leqslant k, \tag{11}$$

called a generalized graded vector field. It is said to be nilpotent if

$$\mathbf{L}_\vartheta(\mathbf{L}_\vartheta\phi) = \sum_{0\leqslant|\Sigma|,0\leqslant|\Lambda|} (\upsilon_\Sigma^B \partial_B^\Sigma(\upsilon_\Lambda^A)\partial_A^\Lambda + (-1)^{[B][\upsilon^A]}\upsilon_\Sigma^B \upsilon_\Lambda^A \partial_B^\Sigma \partial_A^\Lambda)\phi = 0$$

for any horizontal graded form $\phi \in \mathcal{S}^{0,*}_\infty[F;Y]$. One can show that ϑ (10) is nilpotent only if it is odd and iff all υ^A obey the equality

$$\vartheta(\upsilon^A) = \sum_{0\leqslant|\Sigma|} \upsilon_\Sigma^B \partial_B^\Sigma(\upsilon^A) = 0. \tag{12}$$

For the sake of simplicity, the common symbol further stands for a generalized vector field (11), the contact graded derivation (10) determined by this field and the Lie derivative $\mathbf{L}_\vartheta$. We agree to call all these operators the graded derivation of the BGDA $\mathcal{S}^*_\infty[F;Y]$.

III. NOETHER IDENTITIES IN A GENERAL SETTING

Given a graded Lagrangian system $(\mathcal{S}^*_\infty[F;Y], L)$, let us construct the manifested Koszul–Tate complex of its Noether identities.

The main ingredient in this construction is BGDAs of the following type. Given a vector bundle $E \to X$, let us consider the BGDA $\mathcal{S}^*_\infty[F;E_Y]$, where E_Y denotes the pull-back of E onto Y. There are monomorphisms of $\mathcal{O}^0_\infty Y$-algebras,

$$\mathcal{S}^*_\infty[F;Y] \to \mathcal{S}^*_\infty[F;E_Y], \quad \mathcal{O}^*_\infty E \to \mathcal{S}^*_\infty[F;E_Y],$$

whose images contain the common subalgebra $\mathcal{O}^*_\infty Y$. Let us consider (i) the subring $\mathcal{P}^0_\infty E_Y \subset \mathcal{O}^0_\infty E_Y$ of polynomial functions in fiber coordinates of the vector bundles $J^r E_Y \to J^r Y$, $r \in \mathbb{N}$, (ii) the corresponding subring $\mathcal{P}^0_\infty[F;E_Y] \subset \mathcal{S}^0_\infty[F;E_Y]$ of graded functions with polynomial coefficients belonging to $\mathcal{P}^0_\infty E_Y$, (iii) the subalgebra $\mathcal{P}^*_\infty[F;Y;E]$ of the BGDA $\mathcal{S}^*_\infty[F;E_Y]$ over the subring $\mathcal{P}^0_\infty[F;E_Y]$. Given vector bundles V, V', E, E' over X, we further use the notation

$$\mathcal{P}^*_\infty[V'V;F;Y;EE'] = \mathcal{P}^*_\infty[V' \underset{X}{\times} V \underset{X}{\times} F;Y;E \underset{X}{\times} E'].$$

By a density-dual of a vector bundle $E \to X$ is meant

$$\overline{E}^* = E^* \underset{X}{\otimes} \overset{n}{\wedge} T^*X.$$

For the sake of simplicity, we restrict our consideration to Lagrangian systems where a fiber bundle $Y \to X$ of even fields admits the vertical splitting $VY = Y \times W$, where W is a vector bundle over X. This is the case of almost all field models. In a general setting, one must require that transition functions of fiber bundles over Y under consideration do not vanish on-shell. Let $\overline{Y}^*$ denote the density-dual of W in the above-mentioned vertical splitting.

Proposition 4: One can associate to a graded Lagrangian system $(\mathcal{S}^*_\infty[F;Y],L)$, a chain complex whose boundaries vanish on shell [see the complex (13) below].

Proof: Let us extend the BGDA $\mathcal{S}^*_\infty[F;Y]$ to the BGDA $\mathcal{P}^*_\infty[\overline{Y}^*;F;Y;\overline{F}^*]$ whose local basis is $\{s^A,\overline{s}_A\}$, where $[\overline{s}_A]=([A]+1)\mathrm{mod}\,2$. Following the terminology of Lagrangian BRST theory,[2,5] we call $\overline{s}_A$ the antifields of antifield number 1. The BGDA $\mathcal{P}^0_\infty[\overline{Y}^*;F;Y;\overline{F}^*]$ is provided with the nilpotent graded derivation $\overline{\delta}=\overleftarrow{\partial}{}^A d\mathcal{E}_A$, where $\mathcal{E}_A$ are the graded variational derivatives (9) and the tuple of graded right derivations $\{\overleftarrow{\partial}{}^{\Lambda A}\}$ is the dual of the tuple of contact graded forms $\{\theta_{\Lambda A}\}$. Because of the expression (9) for δL, it is convenient to deal with a graded derivation $\overline{\delta}$ acting on graded functions and forms ϕ on the right by the rule

$$\overline{\delta}(\phi)=\mathrm{d}\phi\rfloor\overline{\delta}+d(\phi\rfloor\overline{\delta}),\quad \overline{\delta}(\phi\wedge\phi')=(-1)^{[\phi']}\overline{\delta}(\phi)\wedge\phi'+\phi\wedge\overline{\delta}(\phi').$$

We call $\overline{\delta}$ the Koszul–Tate differential. Let us consider the module $\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]$ of graded densities. It is split into the chain complex

$$0\leftarrow\mathcal{S}^{0,n}_\infty[F;Y]\overset{\overline{\delta}}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_1\cdots\overset{\overline{\delta}}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_k\cdots \tag{13}$$

graded by the antifield number of its elements. It is readily observed that the boundaries of the complex (13) vanish on-shell.

Note that the homology groups $H_*(\overline{\delta})$ of the complex (13) are $\mathcal{S}^0_\infty[F;Y]$-modules, but these modules fail to be torsion-free. Indeed, given a cycle $\phi\in\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_k$ and an element $f=\overline{\delta}\sigma$ of the ring $\mathcal{S}^0_\infty[F;Y]\subset\mathcal{P}^0_\infty[\overline{Y}^*;F;Y;\overline{F}^*]$, we obtain that $f\phi=\overline{\delta}(\sigma\phi)$ is a boundary. Therefore, one cannot apply the Künneth formula to the homology of this complex, though any term $\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_k$ is isomorphic to the graded commutative k-tensor product of the $\mathcal{S}^0_\infty[F;Y]$-module $\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_1$.

The homology $H_0(\overline{\delta})$ of the complex (13) is not trivial, but this homology and the higher ones $H_{k\geqslant 2}(\overline{\delta})$ are not essential for our consideration. Therefore, we replace the complex (13) with the finite one

$$0\leftarrow\mathrm{Im}\,\overline{\delta}\overset{\overline{\delta}}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_1\overset{\overline{\delta}}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_2 \tag{14}$$

of graded densities of antifield number $k\leqslant 2$. It is exact at $\mathrm{Im}\,\overline{\delta}$, and its first homology coincides with that of the complex (13). Let us consider this homology.

A generic one-chain of the complex (14) takes the form

$$\Phi=\sum_{0\leqslant|\Lambda|}\Phi^{A,\Lambda}\overline{s}_{\Lambda A}\omega,\quad \Phi^{A,\Lambda}\in\mathcal{S}^0_\infty[F;Y], \tag{15}$$

and the cycle condition $\overline{\delta}\Phi=0$ reads

$$\sum_{0\leqslant|\Lambda|}\Phi^{A,\Lambda}d_\Lambda\mathcal{E}_A\omega=0. \tag{16}$$

One can think of this equality as being a reduction condition on the graded variational derivatives $\mathcal{E}_A$. Conversely, any reduction condition of form (16) comes from some cycle (15). The reduction condition (16) is trivial if a cycle is a boundary, i.e., it takes the form

$$\Phi=\sum_{0\leqslant|\Lambda|,|\Sigma|}T^{(A\Lambda)(B\Sigma)}d_\Sigma\mathcal{E}_B\overline{s}_{\Lambda A}\omega,\quad T^{(A\Lambda)(B\Sigma)}=-(-1)^{[A][B]}T^{(B\Sigma)(A\Lambda)}. \tag{17}$$

□

Definition 5: A graded Lagrangian system is called degenerate if there exist nontrivial reduction conditions (16), called Noether identities.

One can say something more if the $\mathcal{S}^0_\infty[F;Y]$-module $H_1(\overline{\delta})$ is finitely generated, i.e., it possesses the following particular structure. There are elements $\Delta \in H_1(\overline{\delta})$ making up a $\mathbb{Z}_2$-graded projective $C^\infty(X)$-module $\mathcal{C}_{(0)}$ of finite rank which, by virtue of the Serre–Swan theorem, is isomorphic to the module of sections of the product $\overline{V}^* \underset{X}{\times} \overline{E}^*$ of the density-duals of some vector bundles $V \to X$ and $E \to X$. Let $\{\Delta_r\}$ be local bases for this $C^\infty(X)$-module. Every element $\Phi \in H_1(\overline{\delta})$ factorizes

$$\Phi = \sum_{0 \leqslant |\Xi|} G^{r,\Xi} d_\Xi \Delta_r \omega, \quad G^{r,\Xi} \in \mathcal{S}^0_\infty[F;Y], \tag{18}$$

$$\Delta_r = \sum_{0 \leqslant |\Lambda|} \Delta_r^{A,\Lambda} \overline{s}_{\Lambda A}, \quad \Delta_r^{A,\Lambda} \in \mathcal{S}^0_\infty[F;Y], \tag{19}$$

via elements of $\mathcal{C}_{(0)}$, i.e., any Noether identity (16) is a corollary of Noether identities

$$\sum_{0 \leqslant |\Lambda|} \Delta_r^{A,\Lambda} d_\Lambda \mathcal{E}_A = 0. \tag{20}$$

Clearly, the factorization (18) is independent of specification of local bases $\{\Delta_r\}$. We say that the Noether identities (20) are complete, and call $\Delta \in \mathcal{C}_{(0)}$ the Noether operators. Note that, being representatives of $H_1(\overline{\delta})$, the graded densities Δ_r (19) are not $\overline{\delta}$-exact.

Proposition 6: If the homology $H_1(\overline{\delta})$ of the complex (14) is finitely generated, this complex can be extended to a one-exact complex with a boundary operator whose nilpotency conditions are just complete Noether identities [see the complex (22) below].

Proof: Let us extend the BGDA $\mathcal{P}^*_\infty[\overline{Y}^*;F;Y;\overline{F}^*]$ to the BGDA $\mathcal{P}^*_\infty[\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*]$ possessing the local basis $\{s^A, \overline{s}_A, \overline{c}_r\}$, where $[\overline{c}_r] = ([\Delta_r]+1) \bmod 2$ and $\mathrm{Ant}[\overline{c}] = 2$. It is provided with the nilpotent graded derivation

$$\delta_0 = \overline{\delta} + \overleftarrow{\partial}^r \Delta_r, \tag{21}$$

called the extended Koszul–Tate differential. Its nilpotency conditions (12) are equivalent to the complete Noether identities (20). Then the module $\mathcal{P}^{0,n}_\infty[\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*]_{\leqslant 3}$ of graded densities of antifield number $\mathrm{Ant}[\phi] \leqslant 3$ is split into the chain complex

$$0 \leftarrow \mathrm{Im}\,\overline{\delta} \xleftarrow{\overline{\delta}} \mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_1 \xleftarrow{\delta_0} \mathcal{P}^{0,n}_\infty[\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*]_2$$

$$\xleftarrow{\delta_0} \mathcal{P}^{0,n}_\infty[\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*]_3. \tag{22}$$

Let $H_*(\delta_0)$ denote its homology. We have $H_0(\delta_0) = H_0(\overline{\delta}) = 0$. Furthermore, any one-cycle Φ up to a boundary takes the form (18) and, therefore, it is a δ_0-boundary,

$$\Phi = \sum_{0 \leqslant |\Sigma|} G^{r,\Xi} d_\Xi \Delta_r \omega = \delta_0 \left(\sum_{0 \leqslant |\Sigma|} G^{r,\Xi} \overline{c}_{\Xi r} \omega \right).$$

Hence, $H_1(\delta_0) = 0$, i.e., the complex (22) is one-exact. □

IV. THE KOSZUL–TATE COMPLEX OF NOETHER IDENTITIES

Turn now to the homology $H_2(\delta_0)$ of the complex (22). A generic two-chain reads

$$\Phi = G + H = \sum_{0\leqslant|\Lambda|} G^{r,\Lambda}\overline{c}_{\Lambda r}\omega + \sum_{0\leqslant|\Lambda|,|\Sigma|} H^{(A,\Lambda)(B,\Sigma)}\overline{s}_{\Lambda A}\overline{s}_{\Sigma B}\omega,$$
$$G^{r,\Lambda}\in\mathcal{S}^0_\infty[F;Y], \quad H^{(A,\Lambda)(B,\Sigma)}\mathcal{V}\in\mathcal{S}^0_\infty[F;Y], \quad \mathcal{V}\in\mathcal{O}^nX. \tag{23}$$

The cycle condition $\delta_0\Phi=0$ takes the form

$$\sum_{0\leqslant|\Lambda|} G^{r,\Lambda}d_\Lambda\Delta_r\omega + \overline{\delta}H = 0. \tag{24}$$

One can think of this equality as being the reduction condition on the Noether operators (19). Conversely, let

$$\Phi = \sum_{0\leqslant|\Lambda|} G^{r,\Lambda}\overline{c}_{\Lambda r}\omega \in \mathcal{P}^{0,n}_\infty[\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*]_2$$

be a graded density such that the reduction condition (24) holds. Obviously, it is a cycle condition of the two-chain (23). The reduction condition (24) is trivial either if a two-cycle Φ (23) is a boundary or its summand G vanishes on-shell.

Definition 7: A degenerate graded Lagrangian system in Proposition 6 is said to be one-stage reducible if there exist nontrivial reduction conditions (24), called the first-stage Noether identities.

Proposition 8: First-stage Noether identities can be identified to nontrivial elements of the homology $H_2(\delta_0)$ iff any $\overline{\delta}$-cycle $\Phi\in\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_2$ is a δ_0-boundary.

Proof: It suffices to show that, if the summand G of a two-cycle Φ (23) is $\overline{\delta}$-exact, then G is a boundary. If $G=\overline{\delta}\Psi$, then

$$\Phi = \delta_0\Psi + (\overline{\delta}-\delta_0)\Psi + H. \tag{25}$$

The cycle condition reads

$$\delta_0\Phi = \overline{\delta}((\overline{\delta}-\delta_0)\Psi + H) = 0.$$

Then $(\overline{\delta}-\delta_0)\Psi+H$ is δ_0-exact since any $\overline{\delta}$-cycle $\phi\in\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_2$, by assumption, is a δ_0-boundary. Consequently, Φ (25) is δ_0-exact. Conversely, let $\Phi\in\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_2$ be an arbitrary $\overline{\delta}$-cycle. The cycle condition reads

$$\overline{\delta}\Phi = 2\Phi^{(A,\Lambda)(B,\Sigma)}\overline{s}_{\Lambda A}\overline{\delta}\overline{s}_{\Sigma B}\omega = 2\Phi^{(A,\Lambda)(B,\Sigma)}\overline{s}_{\Lambda A}d_\Sigma\mathcal{E}_B\omega = 0. \tag{26}$$

It follows that $\Phi^{(A,\Lambda)(B,\Sigma)}\overline{\delta}\overline{s}_{\Sigma B}=0$ for all indices (A,Λ). Omitting a $\overline{\delta}$-boundary term, we obtain

$$\Phi^{(A,\Lambda)(B,\Sigma)}\overline{s}_{\Sigma B} = G^{(A,\Lambda)(r,\Xi)}d_\Xi\Delta_r.$$

Hence, Φ takes the form

$$\Phi = G'^{(A,\Lambda)(r,\Xi)}d_\Xi\Delta_r\overline{s}_{\Lambda A}\omega. \tag{27}$$

We can associate to it the three-chain,

$$\Psi = G'^{(A,\Lambda)(r,\Xi)}\overline{c}_{\Xi r}\overline{s}_{\Lambda A}\omega$$

such that

$$\delta_0\Psi = \Phi + \sigma = \Phi + G''^{(A,\Lambda)(r,\Xi)} d_\Lambda \mathcal{E}_A \overline{c}_{\Xi r}\omega.$$

Owing to the equality $\overline{\delta}\Phi=0$, we have $\delta_0\sigma=0$. Since σ is $\overline{\delta}$-exact, it by assumption is δ_0-exact, i.e., $\sigma=\delta_0\psi$. Then we obtain that $\Phi=\delta_0\Psi-\delta_0\psi$. □

Lemma 9: It is easily justified that a two-cycle $\Phi\in\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_2$ is δ_0-exact iff Φ up to a $\overline{\delta}$-boundary takes the form

$$\Phi = \sum_{0\leqslant|\Lambda|,|\Sigma|} G'^{(r,\Sigma)(r',\Lambda)} d_\Sigma\Delta_r d_\Lambda \Delta_{r'}\omega. \tag{28}$$

If the condition of Proposition 8 (called the two-homology regularity condition) is satisfied, let us assume that the first-stage Noether identities are finitely generated as follows. There are elements $\Delta_{(1)}\in H_2(\delta_0)$ making up a $\mathbb{Z}_2$-graded projective $C^\infty(X)$-module $\mathcal{C}_{(1)}$ of finite rank which is isomorphic to the module of sections of the product $\overline{V}^*_1\underset{X}{\times}\overline{E}^*_1$ of the density-duals of some vector bundles $V_1\to X$ and $E_1\to X$. Let $\{\Delta_{r_1}\}$ be local bases for this $C^\infty(X)$-module. Every element $\Phi\in H_2(\delta_0)$ factorizes

$$\Phi = \sum_{0\leqslant|\Xi|} \Phi^{r_1,\Xi} d_\Xi \Delta_{r_1}\omega, \quad \Phi^{r_1,\Xi}\in\mathcal{S}^0_\infty[F;Y], \tag{29}$$

$$\Delta_{r_1} = G_{r_1} + h_{r_1} = \sum_{0\leqslant|\Lambda|} \Delta^{r,\Lambda}_{r_1}\overline{c}_{\Lambda r} + h_{r_1}, \quad h_{r_1}\omega\in\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*], \tag{30}$$

via elements of $\mathcal{C}_{(1)}$, i.e., any first-stage Noether identity (24) results from the equalities

$$\sum_{0\leqslant|\Lambda|} \Delta^{r,\Lambda}_{r_1} d_\Lambda\Delta_r + \overline{\delta}h_{r_1} = 0, \tag{31}$$

called the complete first-stage Noether identities. Elements of $\mathcal{C}_{(1)}$ are called the first-stage Noether operators. Note that first summands G_{r_1} of operators Δ_{r_1} (30) are not $\overline{\delta}$-exact.

Proposition 10: Given a reducible degenerate Lagrangian system, let the associated one-exact complex (22) obey the two-homology regularity condition and let its homology $H_2(\delta_0)$ (first-stage Noether identities) be finitely generated. Then this complex is extended to the two-exact one with a boundary operator whose nilpotency conditions are equivalent to complete Noether and first-stage Noether identities [see the complex (33) below].

Proof: Let us consider the BGDA $\mathcal{P}^*_\infty[\overline{E}^*_1\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*\overline{V}^*_1]$ with the local basis $\{s^A,\overline{s}_A,\overline{c}_r,\overline{c}_{r_1}\}$, where $[\overline{c}_{r_1}]=([\Delta_{r_1}]+1)\mathrm{mod}\,2$ and $\mathrm{Ant}[\overline{c}_{r_1}]=3$. It can be provided with the first-stage Koszul–Tate differential defined as the nilpotent graded derivation,

$$\delta_1 = \delta_0 + \overleftarrow{\partial}^{r_1}\Delta_{r_1}. \tag{32}$$

Its nilpotency conditions (12) are equivalent to complete Noether identities (20) and complete first-stage Noether identities (31). Then the module $\mathcal{P}^{0,n}_\infty[\overline{E}^*_1\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*\overline{V}^*_1]_{\leqslant 4}$ of graded densities of antifield number $\mathrm{Ant}[\phi]\leqslant 4$ is split into the chain complex

$$0\leftarrow \mathrm{Im}\,\overline{\delta}\overset{\overline{\delta}}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_1\overset{\delta_0}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*]_2$$

$$\overset{\delta_1}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{E}^*_1\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*\overline{V}^*_1]_3\overset{\delta_1}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{E}^*_1\overline{E}^*\overline{Y}^*;F;Y;\overline{F}^*\overline{V}^*\overline{V}^*_1]_4. \tag{33}$$

Let $H_*(\delta_1)$ denote its homology. It is readily observed that

$$H_0(\delta_1) = H_0(\overline{\delta}), \quad H_1(\delta_1) = H_1(\delta_0) = 0.$$

By virtue of the expression (29), any two-cycle of the complex (33) is a boundary

$$\Phi = \sum_{0\leqslant|\Xi|} \Phi^{r_1,\Xi} d_\Xi \Delta_{r_1} \omega = \delta_1 \left(\sum_{0\leqslant|\Xi|} \Phi^{r_1,\Xi} \overline{c}_{\Xi r_1} \right) \omega.$$

It follows that $H_2(\delta_1)=0$, i.e., the complex (33) is two-exact.

If the third homology $H_3(\delta_1)$ of the complex (33) is not trivial, there are reduction conditions on the first-stage Noether operators, and so on. Iterating the arguments, we come to the following.

Let $(\mathcal{S}^*_\infty[F;Y],L)$ be a degenerate graded Lagrangian system whose Noether identities are finitely generated. In accordance with Proposition 6, we associate to it the one-exact chain complex (22). Given an integer $N\geqslant 1$, let $V_1,\ldots,V_N,E_1,\ldots,E_N$ be some vector bundles over X and

$$\mathcal{P}^*_\infty\{N\} = \mathcal{P}^*_\infty[\overline{E}^*_N \cdots \overline{E}^*_1 \overline{E}^* \overline{Y}^*; F; Y; \overline{F}^* \overline{V}^* \overline{V}^*_1 \cdots \overline{V}^*_N] \tag{34}$$

a BGDA with local bases $\{s^A, \overline{s}_A, \overline{c}_r, \overline{c}_{r_1}, \ldots, \overline{c}_{r_N}\}$ graded by antifield numbers $\mathrm{Ant}[\overline{c}_{r_k}]=k+2$. Let $k=-1,0$ further stand for $\overline{s}_A$ and $\overline{c}_r$, respectively. We assume the following:

(i) the BGDA $\mathcal{P}^*_\infty\{N\}$ (34) is provided with a nilpotent graded derivation

$$\delta_N = \delta_0 + \sum_{1\leqslant k\leqslant N} \overleftarrow{\partial}^{r_k} \Delta_{r_k}, \tag{35}$$

$$\Delta_{r_k} = G_{r_k} + h_{r_k} = \sum_{0\leqslant|\Lambda|} \Delta^{r_{k-1},\Lambda}_{r_k} \overline{c}_{\Lambda r_{k-1}} + \sum_{0\leqslant\Sigma,0\leqslant\Xi} (h^{(A,\Xi)(r_{k-2},\Sigma)}_{r_k} \overline{s}_{\Xi A} \overline{c}_{\Sigma r_{k-2}} + \cdots), \tag{36}$$

of antifield number -1;

(ii) the module $\mathcal{P}^{0,n}_\infty\{N\}_{\leqslant N+3}$ of graded densities of antifield number $\mathrm{Ant}[\phi]\leqslant N+3$ is split into the $(N+1)$-exact chain complex

$$0 \leftarrow \mathrm{Im}\,\overline{\delta} \overset{\overline{\delta}}{\leftarrow} \mathcal{P}^{0,n}_\infty[\overline{Y}^*; F; Y; \overline{F}^*]_1 \overset{\delta_0}{\leftarrow} \mathcal{P}^{0,n}_\infty\{0\}_2 \overset{\delta_1}{\leftarrow} \mathcal{P}^{0,n}_\infty\{1\}_3 \cdots$$
$$\overset{\delta_{N-1}}{\leftarrow} \mathcal{P}^{0,n}_\infty\{N-1\}_{N+1} \overset{\delta_N}{\leftarrow} \mathcal{P}^{0,n}_\infty\{N\}_{N+2} \overset{\delta_N}{\leftarrow} \mathcal{P}^{0,n}_\infty\{N\}_{N+3}, \tag{37}$$

which satisfies the $(N+1)$-homology regularity condition in accordance with the forthcoming Definition 11. □

Definition 11: One says that the complex (37) obeys the $(N+1)$-homology regularity condition if any $\delta_{k<N-1}$-cycle $\phi\in\mathcal{P}^{0,n}_\infty\{k\}_{k+3}\subset\mathcal{P}^{0,n}_\infty\{k+1\}_{k+3}$ is a δ_{k+1}-boundary.

Remark 3: The $(N+1)$-exactness of the complex (37) implies that any $\delta_{k<N-1}$-cycle $\phi\in\mathcal{P}^{0,n}_\infty\{k\}_{k+3}$, $k<N$, is a δ_{k+2}-boundary, but not necessarily a δ_{k+1} one.

If $N=1$, the complex $\mathcal{P}^{0,n}_\infty\{1\}_{\leqslant 4}$ (37) restarts the complex (33) associated to a first-stage reducible graded Lagrangian system by virtue of Proposition 10. Therefore, we agree to call δ_N (35) the N-stage Koszul–Tate differential. Its nilpotency implies complete Noether identities (20), first-stage Noether identities (31) and the equalities

$$\sum_{0\leqslant|\Lambda|} \Delta^{r_{k-1},\Lambda}_{r_k} d_\Lambda \left(\sum_{0\leqslant|\Sigma|} \Delta^{r_{k-2},\Sigma}_{r_{k-1}} \overline{c}_{\Sigma r_{k-2}} \right) + \overline{\delta} \left(\sum_{0\leqslant\Sigma,0\leqslant\Xi} h^{(A,\Xi)(r_{k-2},\Sigma)}_{r_k} \overline{s}_{\Xi A} \overline{c}_{\Sigma r_{k-2}} \right) = 0, \tag{38}$$

for $k=2,\ldots,N$. One can think of the equalities (38) as being complete k-stage Noether identities because of their properties which we will justify in the case of $k=N+1$. Accordingly, Δ_{r_k} (36) are said to be the k-stage Noether operators.

Let us consider the $(N+2)$-homology of the complex (37). A generic $(N+2)$-chain $\Phi\in\mathcal{P}^{0,n}_\infty\{N\}_{N+2}$ takes the form

$$\Phi = G + H = \sum_{0\leqslant|\Lambda|} G^{r_N,\Lambda}\overline{c}_{\Lambda r_N}\omega + \sum_{0\leqslant\Sigma,0\leqslant\Xi} (H^{(A,\Xi)(r_{N-1},\Sigma)}\overline{s}_{\Xi A}\overline{c}_{\Sigma r_{N-1}} + \cdots)\omega. \tag{39}$$

Let it be a cycle. The cycle condition $\delta_N\Phi=0$ implies the equality

$$\sum_{0\leqslant|\Lambda|} G^{r_N,\Lambda} d_\Lambda\left(\sum_{0\leqslant|\Sigma|} \Delta^{r_{N-1},\Sigma}_{r_N}\overline{c}_{\Sigma r_{N-1}}\right) + \overline{\delta}\left(\sum_{0\leqslant\Sigma,0\leqslant\Xi} H^{(A,\Xi)(r_{N-1},\Sigma)}\overline{s}_{\Xi A}\overline{c}_{\Sigma r_{N-1}}\right) = 0. \tag{40}$$

One can think of this equality as being the reduction condition on the N-stage Noether operators (36). Conversely, let

$$\Phi = \sum_{0\leqslant|\Lambda|} G^{r_N,\Lambda}\overline{c}_{\Lambda r_N}\omega \in \mathcal{P}^{0,n}_\infty\{N\}_{N+2}$$

be a graded density such that the reduction condition (40) holds. Then this reduction condition can be extended to a cycle one as follows. It is brought into the form

$$\delta_N\left(\sum_{0\leqslant|\Lambda|} G^{r_N,\Lambda}\overline{c}_{\Lambda r_N} + \sum_{0\leqslant\Sigma,0\leqslant\Xi} H^{(A,\Xi)(r_{N-1},\Sigma)}\overline{s}_{\Xi A}\overline{c}_{\Sigma r_{N-1}}\right)$$

$$= -\sum_{0\leqslant|\Lambda|} G^{r_N,\Lambda} d_\Lambda h_{r_N} + \sum_{0\leqslant\Sigma,0\leqslant\Xi} H^{(A,\Xi)(r_{N-1},\Sigma)}\overline{s}_{\Xi A} d_\Sigma \Delta_{r_{N-1}}.$$

A glance at the expression (36) shows that the term on the right-hand side of this equality belongs to $\mathcal{P}^{0,n}_\infty\{N-2\}_{N+1}$. It is a δ_{N-2}-cycle and, consequently, a δ_{N-1}-boundary $\delta_{N-1}\Psi$ in accordance with the $(N+1)$-homology regularity condition. Then the reduction condition (40) is a $\overline{c}_{\Sigma r_{N-1}}$-dependent part of the cycle condition

$$\delta_N\left(\sum_{0\leqslant|\Lambda|} G^{r_N,\Lambda}\overline{c}_{\Lambda r_N} + \sum_{0\leqslant\Sigma,0\leqslant\Xi} H^{(A,\Xi)(r_{N-1},\Sigma)}\overline{s}_{\Xi A}\overline{c}_{\Sigma r_{N-1}} - \Psi\right) = 0,$$

but $\delta_N\Psi$ does not make a contribution to this reduction condition.

Being a cycle condition, the reduction condition (40) is trivial either if a cycle Φ (39) is a δ_N-boundary or its summand G is $\overline{\delta}$-exact, i.e., it is a boundary, too, as we have stated above. Then Definition 7 can be generalized as follows.

Definition 12: A degenerate graded Lagrangian system is said to be $(N+1)$-stage reducible if there exist nontrivial reduction conditions (40), called the $(N+1)$-stage Noether identities.

Theorem 13: (i) The $(N+1)$-stage Noether identities can be identified to nontrivial elements of the homology $H_{N+2}(\delta_N)$ of the complex (37) iff this homology obeys the $(N+2)$-homology regularity condition. (ii) If the homology $H_{N+2}(\delta_N)$ is finitely generated as defined below, the complex (37) admits an $(N+2)$-exact extension.

Proof: (i) The $(N+2)$-homology regularity condition implies that any δ_{N-1}-cycle $\Phi\in\mathcal{P}^{0,n}_\infty\{N-1\}_{N+2}\subset\mathcal{P}^{0,n}_\infty\{N\}_{N+2}$ is a δ_N-boundary. Therefore, if Φ (39) is a representative of a nontrivial element of $H_{N+2}(\delta_N)$, its summand G linear in $\overline{c}_{\Lambda r_N}$ does not vanish. Moreover, it is not a $\overline{\delta}$-boundary. Indeed, if $\Phi=\overline{\delta}\Psi$, then

$$\Phi = \delta_N\Psi + (\overline{\delta} - \delta_N)\Psi + H. \tag{41}$$

The cycle condition takes the form

$$\delta_N\Phi = \delta_{N-1}((\overline{\delta} - \delta_N)\Psi + H) = 0.$$

Hence, $(\overline{\delta}-\delta_N)\Psi+H$ is δ_N-exact since any δ_{N-1}-cycle $\phi\in\mathcal{P}^{0,n}_\infty\{N-1\}_{N+2}$ is a δ_N-boundary. Consequently, Φ (41) is a boundary. If the $(N+2)$-homology regularity condition does not hold, trivial reduction conditions (40) also come from nontrivial elements of the homology $H_{N+2}(\delta_N)$. (ii) Let the $(N+1)$-stage Noether identities be finitely generated. Namely, there exist elements $\Delta_{(N+1)}$

$\in H_{N+2}(\delta_N)$ making up a $\mathbb{Z}_2$-graded projective $C^\infty(X)$-module $\mathcal{C}_{(N+1)}$ of finite rank which is isomorphic to the module of sections of the product $\overline{V}^*_{N+1}\underset{X}{\times}\overline{E}^*_{N+1}$ of the density-duals of some vector bundles $V_{N+1}\to X$ and $E_{N+1}\to X$. Let $\{\Delta_{r_{N+1}}\}$ be local bases for this $C^\infty(X)$-module. Then any element $\Phi\in H_{N+2}(\delta_N)$ factorizes

$$\Phi=\sum_{0\leqslant|\Xi|}\Phi^{r_{N+1},\Xi}d_\Xi\Delta_{r_{N+1}}\omega,\quad \Phi^{r_{N+1},\Xi}\in\mathcal{S}^0_\infty[F;Y], \tag{42}$$

$$\Delta_{r_{N+1}}=G_{r_{N+1}}+h_{r_{N+1}}=\sum_{0\leqslant|\Lambda|}\Delta^{r_N,\Lambda}_{r_{N+1}}\overline{c}_{\Lambda r_N}+h_{r_{N+1}}, \tag{43}$$

via elements of $\mathcal{C}_{(N+1)}$. Clearly, this factorization is independent of specification of local bases $\{\Delta_{r_{N+1}}\}$. Let us extend the BGDA $\mathcal{P}^*_\infty\{N\}$ (34) to the BGDA $\mathcal{P}^*_\infty\{N+1\}$ possessing local bases

$$\{s^A,\overline{s}_A,\overline{c}_r,\overline{c}_{r_1},\ldots,\overline{c}_{r_N},\overline{c}_{r_{N+1}}\},\quad \mathrm{Ant}[\overline{c}_{r_{N+1}}]=N+3,\quad [\overline{c}_{r_{N+1}}]=([\Delta_{r_{N+1}}]+1)\mathrm{mod}\,2.$$

It is provided with the nilpotent graded derivation

$$\delta_{N+1}=\delta_N+\overleftarrow{\partial}{}^{r_{N+1}}\Delta_{r_{N+1}} \tag{44}$$

of antifield number -1. With this graded derivation, the module $\mathcal{P}^{0,n}_\infty\{N+1\}_{\leqslant N+4}$ of graded densities of antifield number $\mathrm{Ant}[\phi]\leqslant N+4$ is split into the chain complex,

$$0\leftarrow \mathrm{Im}\,\overline{\delta}\overset{\overline{\delta}}{\leftarrow}\mathcal{P}^{0,n}_\infty[\overline{Y}^*;F;Y;\overline{F}^*]_1\overset{\delta_0}{\leftarrow}\mathcal{P}^{0,n}_\infty\{0\}_2\overset{\delta_1}{\leftarrow}\mathcal{P}^{0,n}_\infty\{1\}_3\cdots$$

$$\overset{\delta_{N-1}}{\leftarrow}\mathcal{P}^{0,n}_\infty\{N-1\}_{N+1}\overset{\delta_N}{\leftarrow}\mathcal{P}^{0,n}_\infty\{N\}_{N+2}\overset{\delta_{N+1}}{\leftarrow}\mathcal{P}^{0,n}_\infty\{N+1\}_{N+3}\overset{\delta_{N+1}}{\leftarrow}\mathcal{P}^{0,n}_\infty\{N+1\}_{N+4}. \tag{45}$$

It is readily observed that this complex is $(N+2)$-exact. In this case, the $(N+1)$-stage Noether identities (40) come from the complete $(N+1)$-stage Noether identities

$$\sum_{0\leqslant|\Lambda|}\Delta^{r_N,\Lambda}_{r_{N+1}}d_\Lambda\Delta_r\omega+\overline{\delta}h_{r_{N+1}}\omega=0,$$

which are reproduced as the nilpotency conditions of the graded derivation (44).

The iteration procedure based on Theorem 13 can be prolonged up to an integer $N_{\max}$ when the $N_{\max}$-stage Noether identities are irreducible, i.e., the homology $H_{N_{\max}+2}(\delta_{N_{\max}})$ is trivial. This iteration procedure may also be infinite. It results in the manifested exact Koszul–Tate complex with the Koszul–Tate boundary operator whose nilpotency conditions reproduce all Noether and higher Noether identities of an original Lagrangian system. □

V. EXAMPLE

Let us consider a fiber bundle

$$Y=\mathbb{R}\underset{X}{\times}\overset{n-1}{\wedge}T^*X, \tag{46}$$

coordinated by $(x^\lambda,A,B_{\mu_1\cdots\mu_{n-1}})$. The corresponding BGDA is $\mathcal{S}^*_\infty[Y]=\mathcal{O}^*_\infty Y$. There is the canonical $(n-1)$-form

$$B = \frac{1}{(n+1)!} B_{\mu_1 \cdots \mu_{n-1}} \, \mathrm{d}x^{\mu_1} \wedge \cdots \wedge \mathrm{d}x^{\mu_{n-1}} \in \mathcal{O}^*_\infty Y$$

on Y (46). A Lagrangian of topological BF theory in question reads

$$L_{\mathrm{BF}} = \frac{1}{n} \mathrm{Ad}_H B. \tag{47}$$

The corresponding Euler–Lagrange operator (9) takes the form

$$\begin{gathered} \delta L = \mathrm{d}A \wedge \mathcal{E}\omega + \mathrm{d}B_{\mu_1 \cdots \mu_{n-1}} \wedge \mathcal{E}^{\mu_1 \cdots \mu_{n-1}} \omega, \\ \mathcal{E} = \epsilon^{\mu\mu_1 \cdots \mu_{n-1}} d_\mu B_{\mu_1 \cdots \mu_{n-1}}, \quad \mathcal{E}^{\mu_1 \cdots \mu_{n-1}} = -\epsilon^{\mu\mu_1 \cdots \mu_{n-1}} d_\mu A, \end{gathered} \tag{48}$$

where ϵ is the Levi–Civita symbol.

Let us extend the BGDA $\mathcal{O}^*_\infty Y$ to the BGDA $\mathcal{P}^*_\infty[\overline{Y}^*; Y]$ where

$$VY = Y \underset{X}{\times} Y, \quad \overline{Y}^* = (\mathbb{R} \underset{X}{\times} \overset{n-1}{\wedge} TX) \underset{X}{\otimes} \overset{n}{\wedge} T^*X.$$

This BGDA possesses the local bases $\{A, B_{\mu_1 \cdots \mu_{n-1}}, \overline{s}, \overline{s}^{\mu_1 \cdots \mu_{n-1}}\}$, where $\overline{s}, \overline{s}^{\mu_1 \cdots \mu_{n-1}}$ are odd of antifield number 1. With the nilpotent Koszul–Tate differential

$$\overline{\delta} = \frac{\overleftarrow{\partial}}{\partial \overline{s}} \mathcal{E} + \frac{\overleftarrow{\partial}}{\partial \overline{s}^{\mu_1 \cdots \mu_{n-1}}} \mathcal{E}^{\mu_1 \cdots \mu_{n-1}},$$

we have the complex (14),

$$0 \leftarrow \mathrm{Im}\, \overline{\delta} \overset{\overline{\delta}}{\leftarrow} \mathcal{P}^{0,n}_\infty[\overline{Y}^*; Y]_1 \overset{\overline{\delta}}{\leftarrow} \mathcal{P}^{0,n}_\infty[\overline{Y}^*; Y]_2.$$

A generic one-chain reads

$$\Phi = \sum_{0 \leqslant |\Lambda|} (\Phi^\Lambda \overline{s}_\Lambda + \Phi^\Lambda_{\mu_1 \cdots \mu_{n-1}} \overline{s}^{\mu_1 \cdots \mu_{n-1}}_\Lambda) \omega,$$

and the cycle condition $\overline{\delta}\Phi = 0$ takes the form

$$\Phi^\Lambda \mathcal{E}_\Lambda + \Phi^\Lambda_{\mu_1 \cdots \mu_{n-1}} \mathcal{E}^{\mu_1 \cdots \mu_{n-1}}_\Lambda = 0. \tag{49}$$

If Φ^Λ and $\Phi^\Lambda_{\mu_1 \cdots \mu_{n-1}}$ are independent of the variational derivatives (48) (i.e., Φ is a nontrivial cycle), the equality (49) is split into the following:

$$\Phi^\Lambda \mathcal{E}_\Lambda = 0, \tag{50}$$

$$\Phi^\Lambda_{\mu_1 \cdots \mu_{n-1}} \mathcal{E}^{\mu_1 \cdots \mu_{n-1}}_\Lambda = 0. \tag{51}$$

The equality (50) holds iff $\Phi^\Lambda = 0$, i.e., there is no Noether identities for $\mathcal{E}$. The equality (51) is satisfied iff

$$\Phi^{\lambda_1 \cdots \lambda_k}_{\mu_1 \cdots \mu_{n-1}} \epsilon^{\mu\mu_1 \cdots \mu_{n-1}} = -\Phi^{\mu\lambda_2 \cdots \lambda_k}_{\mu_1 \cdots \mu_{n-1}} \epsilon^{\lambda_1 \mu_1 \cdots \mu_{n-1}}.$$

It follows that Φ factorizes as

$$\Phi = \sum_{0\leqslant|\Xi|} G^{\Xi}_{\nu_2\cdots\nu_{n-1}} d_{\Xi}\Delta^{\nu_2\cdots\nu_{n-1}}\omega$$

via local graded densities

$$\Delta^{\nu_2\cdots\nu_{n-1}} = \Delta^{\nu_2\cdots\nu_{n-1},\lambda}_{\alpha_1\cdots\alpha_{n-1}}\overline{s}^{\alpha_1\cdots\alpha_{n-1}}_{\lambda} = \delta^{\lambda}_{\alpha_1}\delta^{\nu_2}_{\alpha_2}\cdots\delta^{\nu_{n-1}}_{\alpha_{n-1}}\overline{s}^{\alpha_1\cdots\alpha_{n-1}}_{\lambda} = d_{\nu_1}\overline{s}^{\nu_1\nu_2\cdots\nu_{n-1}}, \tag{52}$$

which provide the complete Noether identities[1]

$$d_{\nu_1}\mathcal{E}^{\nu_1\nu_2\cdots\nu_{n-1}} = 0. \tag{53}$$

The local graded densities (52) form the bases of a projective $C^{\infty}(X)$-module of finite rank which is isomorphic to the module of sections of the vector bundle

$$\overline{V}^* = \wedge^{n-2} TX \underset{X}{\otimes} \wedge^{n} T^*X, \quad V = \wedge^{n-2} T^*X.$$

Therefore, let us extend the BGDA $\mathcal{P}^*_{\infty}[\overline{Y}^*;Y]$ to the BGDA $\mathcal{P}^*_{\infty}\{0\}=\mathcal{P}^*_{\infty}[\overline{Y}^*;Y;V]$ possessing the local bases

$$\{A, B_{\mu_1\cdots\mu_{n-1}}, \overline{s}, \overline{s}^{\mu_1\cdots\mu_{n-1}}, \overline{c}^{\mu_2\cdots\mu_{n-1}}\},$$

where $\overline{c}^{\mu_2\cdots\mu_{n-1}}$ are even of antifield number 2. Let

$$\delta_0 = \overline{\delta} + \frac{\overleftarrow{\partial}}{\partial\overline{c}^{\mu_2\cdots\mu_{n-1}}}\Delta^{\mu_2\cdots\mu_{n-1}}$$

be its nilpotent graded derivation. Its nilpotency is equivalent to the Noether identities (53). Then we have the one-exact complex

$$0 \leftarrow \mathrm{Im}\,\overline{\delta} \overset{\overline{\delta}}{\leftarrow} \mathcal{P}^{0,n}_{\infty}[\overline{Y}^*;Y]_1 \overset{\delta_0}{\leftarrow} \mathcal{P}^{0,n}_{\infty}\{0\}_2 \overset{\delta_0}{\leftarrow} \mathcal{P}^{0,n}_{\infty}\{0\}_3,$$

and so on. Iterating the arguments we come to the following $(N+1)$-exact complex (37) for $N \leqslant n-3$.

Let us consider the vector bundles

$$V_k = \wedge^{n-k-2} T^*X, \quad k = 1, \ldots, N,$$

and the corresponding BGDA

$$\mathcal{P}^*_{\infty}\{N\} = \mathcal{P}^*_{\infty}[\cdots V_3 V_1 \overline{Y}^*; Y; VV_2V_4\cdots],$$

possessing the local bases

$$\{A, B_{\mu_1\cdots\mu_{n-1}}, \overline{s}, \overline{s}^{\mu_1\cdots\mu_{n-1}}, \overline{c}^{\mu_2\cdots\mu_{n-1}}, \ldots, \overline{c}^{\mu_{N+2}\cdots\mu_{n-1}}\},$$

$$[\overline{c}^{\mu_{k+2}\cdots\mu_{n-1}}] = (k+1) \bmod 2, \quad \mathrm{Ant}[\overline{c}^{\mu_{k+2}\cdots\mu_{n-1}}] = k+3.$$

It is provided with the nilpotent graded derivation

$$\delta_N = \delta_0 + \sum_{1\leqslant k\leqslant N} \frac{\overleftarrow{\partial}}{\partial \overline{c}^{\mu_{k+2}\cdots\mu_{n-1}}} \Delta^{\mu_{k+2}\cdots\mu_{n-1}},$$
$$\Delta^{\mu_{k+2}\cdots\mu_{n-1}} = d_{\mu_{k+1}} c^{\mu_{k+1}\mu_{k+2}\cdots\mu_{n-1}}, \tag{54}$$

of antifield number -1. The nilpotency results from the Noether identities (53) and the equalities

$$d_{\mu_{k+2}} \Delta^{\mu_{k+2}\cdots\mu_{n-1}} = 0, \quad k = 0, \ldots, N, \tag{55}$$

which are k-stage Noether identities.[1] Then the above-mentioned $(N+1)$-exact complex is

$$0 \leftarrow \operatorname{Im} \overline{\delta} \overset{\overline{\delta}}{\leftarrow} \mathcal{P}^{0,n}_\infty[\overline{Y}^*; Y]_1 \overset{\delta_0}{\leftarrow} \mathcal{P}^{0,n}_\infty\{0\}_2 \overset{\delta_1}{\leftarrow} \mathcal{P}^{0,n}_\infty\{1\}_3 \cdots$$
$$\overset{\delta_{N-1}}{\leftarrow} \mathcal{P}^{0,n}_\infty\{N-1\}_{N+1} \overset{\delta_N}{\leftarrow} \mathcal{P}^{0,n}_\infty\{N\}_{N+2} \overset{\delta_N}{\leftarrow} \mathcal{P}^{0,n}_\infty\{N\}_{N+3}. \tag{56}$$

It obeys the $(N+2)$-homology regularity condition as follows.

Lemma 14: Any $(N+2)$-cycle $\Phi \in \mathcal{P}^{0,n}_\infty\{N-1\}_{N+2}$ up to a δ_{N-1}-boundary takes the form

$$\Phi = \sum_{k_1+\cdots+k_i+3i=N+2} \sum_{0\leqslant|\Lambda_1|,\ldots,|\Lambda_i|} G^{\Lambda_1\cdots\Lambda_i}_{\mu^1_{k_1+2}\cdots\mu^1_{n-1};\cdots;\mu^i_{k_i+2}\cdots\mu^i_{n-1}}$$
$$d_{\Lambda_1}\Delta^{\mu^1_{k_1+2}\cdots\mu^1_{n-1}} \cdots d_{\Lambda_i}\Delta^{\mu^i_{k_i+2}\cdots\mu^i_{n-1}}\omega, \quad k = -1,0,1,\ldots,N, \tag{57}$$

where $k=-1$ stands for

$$\overline{c}^{\mu_1\cdots\mu_{n-1}} = \overline{s}^{\mu_1\cdots\mu_{n-1}}, \quad \Delta^{\mu_1\cdots\mu_{n-1}} = \mathcal{E}^{\mu_1\cdots\mu_{n-1}}.$$

It follows that Φ is a δ_N-boundary.

Proof: Let us choose some basis element $\overline{c}^{\mu_{k+2}\cdots\mu_{n-1}}$ and denote it simply by $\overline{c}$. Let Φ contain a summand $\phi_1\overline{c}$, linear in $\overline{c}$. Then the cycle condition reads

$$\delta_{N-1}\Phi = \delta_{N-1}(\Phi - \phi_1\overline{c}) + (-1)^{[\overline{c}]}\delta_{N-1}(\phi_1)\overline{c} + \phi\Delta = 0, \quad \Delta = \delta_{N-1}\overline{c}.$$

It follows that Φ contains a summand $\psi\Delta$ such that

$$(-1)^{[\overline{c}]+1}\delta_{N-1}(\psi)\Delta + \phi\Delta = 0.$$

This equality implies the relation

$$\phi_1 = (-1)^{[\overline{c}]+1}\delta_{N-1}(\psi) \tag{58}$$

because the reduction conditions (55) involve total derivatives of Δ, but not Δ. Hence,

$$\Phi = \Phi' + \delta_{N-1}(\psi\overline{c}),$$

where Φ' contains no term linear in $\overline{c}$. Furthermore, let $\overline{c}$ be even and Φ has a summand $\Sigma\phi_r\overline{c}^r$ polynomial in $\overline{c}$. Then the cycle condition leads to the equalities

$$\phi_r\Delta = -\delta_{N-1}\phi_{r-1}, \quad r \geqslant 2.$$

Since ϕ_1 (58) is δ_{N-1}-exact, then $\phi_2=0$ and, consequently, $\phi_{r>2}=0$. Thus, a cycle Φ up to a δ_{N-1}-boundary contains no term polynomial in $\overline{c}$. It reads

$$\Phi = \sum_{k_1+\cdots+k_i+3i=N+2} \sum_{0<|\Lambda_1|,\ldots,|\Lambda_i|} G^{\Lambda_1\cdots\Lambda_i}_{\mu^1_{k_1+2}\cdots\mu^1_{n-1};\cdots;\mu^i_{k_i+2}\cdots\mu^i_{n-1}} \overline{c}^{\mu^1_{k_1+2}\cdots\mu^1_{n-1}}_{\Lambda_1} \cdots \overline{c}^{\mu^i_{k_i+2}\cdots\mu^i_{n-1}}_{\Lambda_i} \omega. \tag{59}$$

However, the terms polynomial in $\overline{c}$ may appear under general covariant transformations

$$\overline{c}'^{\,\nu_{k+2}\cdots\nu_{n-1}} = \det\left(\frac{\partial x^\alpha}{\partial x'^\beta}\right) \frac{\partial x'^{\,\nu_{k+2}}}{\partial x^{\mu_{k+2}}} \cdots \frac{\partial x'^{\,\nu_{n-1}}}{\partial x^{\mu_{n-1}}} \overline{c}^{\mu_{k+2}\cdots\mu_{n-1}}$$

of a chain Φ (59). In particular, Φ contains the summand

$$\sum_{k_1+\cdots+k_i+3i=N+2} F_{\nu^1_{k_1+2}\cdots\nu^1_{n-1};\cdots;\nu^i_{k_i+2}\cdots\nu^i_{n-1}} \overline{c}'^{\,\nu^1_{k_1+2}\cdots\nu^1_{n-1}} \cdots \overline{c}'^{\,\nu^i_{k_i+2}\cdots\nu^i_{n-1}},$$

which must vanish if Φ is a cycle. This takes place only if Φ factorizes through the graded densities $\Delta^{\mu_{k+2}\cdots\mu_{n-1}}$ (54) in accordance with the expression (57).

Following the proof of Lemma 14, one can show that any $(N+2)$-cycle $\Phi \in \mathcal{P}^{0,n}_\infty\{N\}_{N+2}$ up to a boundary takes the form

$$\Phi = \sum_{0\leqslant|\Lambda|} G^\Lambda_{\mu_{N+2}\cdots\mu_{n-1}} \Delta^{\mu_{N+2}\cdots\mu_{n-1}} \omega, \tag{60}$$

i.e., the homology $H_2(\delta_N)$ of the complex (56) is finitely generated by the cycles $\Delta^{\mu_{N+2}\cdots\mu_{n-1}}$. Thus, the complex (56) admits the $(N+2)$-exact extension (45).

The iteration procedure is prolonged until $N=n-3$. Given the BGDA $\mathcal{P}^*\{n-3\}$, the corresponding $(n-2)$-exact complex (56) has the following $(n-1)$-exact extension. Let us consider the BGDA $\mathcal{P}^*\{n-2\}$, where $V_{n-2}=X\times\mathbb{R}$. It possesses the local bases

$$\{A, B_{\mu_1\cdots\mu_{n-1}}, \overline{s}, \overline{s}^{\mu_1\cdots\mu_{n-1}}, \overline{c}^{\mu_2\cdots\mu_{n-1}}, \ldots, \overline{c}^{\mu_{n-1}}, \overline{c}\},$$

where $[\overline{c}]=(n-1) \bmod 2$ and $\mathrm{Ant}[\overline{c}]=n+1$. It is provided with the nilpotent graded derivation

$$\delta_{n-2} = \delta_0 + \sum_{1\leqslant k\leqslant n-3} \frac{\overleftarrow{\partial}}{\partial \overline{c}^{\mu_{k+2}\cdots\mu_{n-1}}} \Delta^{\mu_{k+2}\cdots\mu_{n-1}} + \frac{\overleftarrow{\partial}}{\partial \overline{c}} \Delta, \quad \Delta = d_{\mu_{n-1}} \overline{c}^{\mu_{n-1}}. \tag{61}$$

Then the above-mentioned $(n-1)$-exact complex is

$$\begin{aligned} 0 \leftarrow \mathrm{Im}\,\overline{\delta} \overset{\overline{\delta}}{\leftarrow} \mathcal{P}^{0,n}_\infty[\overline{Y}^*; Y]_1 \overset{\delta_0}{\leftarrow} \mathcal{P}^{0,n}_\infty\{0\}_2 \overset{\delta_1}{\leftarrow} \mathcal{P}^{0,n}_\infty\{1\}_3 \cdots \\ \overset{\delta_{n-3}}{\leftarrow} \mathcal{P}^{0,n}_\infty\{n-3\}_{n-1} \overset{\delta_{n-2}}{\leftarrow} \mathcal{P}^{0,n}_\infty\{n-2\}_n \overset{\delta_{n-2}}{\leftarrow} \mathcal{P}^{0,n}_\infty\{n-2\}_{n+1}. \end{aligned} \tag{62}$$

Following the proof of Lemma 14, one can show that the n-homology regularity condition is satisfied. Therefore, any n-cycle up to a δ_{n-3}-boundary takes the form

$$\Phi = \sum_{0\leqslant|\Lambda|} G^\Lambda \overline{c}_\Lambda.$$

The cycle condition reads

$$\delta_{n-2}\Phi = \sum_{0\leqslant|\Lambda|} G^\Lambda d_\Lambda \Delta = 0.$$

It follows that $G^\Lambda=0$ and, consequently, $\Phi=0$. Thus, the n-homology of the complex (62) is trivial, and this complex is exact. It is a desired Koszul–Tate complex of a Lagrangian system in question. The nilpotency conditions of its boundary operator (61) restarts all the Noether identities of this Lagrangian system. □

We study the semirelativistic Hamiltonian operator composed of the relativistic kinetic energy and a static harmonic-oscillator potential in three spatial dimensions and construct, for bound states with vanishing orbital angular momentum, its eigenfunctions in "compact form," i.e., as power series, with expansion coefficients determined by an explicitly given recurrence relation. The corresponding eigenvalues are fixed by the requirement of normalizability of the solutions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2054648]

I. INTRODUCTION: RELATIVISTIC HARMONIC-OSCILLATOR PROBLEM

The simplest and perhaps most straightforward generalization of the Schrödinger operators of standard nonrelativistic quantum theory towards the inclusion of relativistic kinematics leads to Hamiltonians H that involve the relativistic kinetic energy, or relativistically covariant form of the free energy, of a particle of mass m and momentum $\mathbf{p}$ given by the square-root operator

$$T(p) \equiv \sqrt{p^2 + m^2}, \quad p \equiv |\mathbf{p}|,$$

and a coordinate-dependent static interaction potential $V(\mathbf{x})$. In the one-body case, they read

$$H = \sqrt{p^2 + m^2} + V(\mathbf{x}). \tag{1}$$

The eigenvalue equation of this Hamiltonian is usually called the "spinless Salpeter equation." It may be regarded as a well-defined approximation to the Bethe-Salpeter formalism[1] for the description of bound states within relativistic quantum field theories, obtained when assuming that all bound-state constituents interact *instantaneously* and propagate like *free* particles.[2] Among others, it yields semirelativistic descriptions of hadrons as bound states of quarks.[3,4]

In general, the above semirelativistic Hamiltonian H is, unfortunately, a *nonlocal* operator, either the relativistic kinetic energy, $T(p)$, *in configuration space* or, in general, the interaction

potential *in momentum space* is a nonlocal operator. Because of the nonlocality it is somewhat difficult to obtain rigorous *analytical* statements about the solutions of its eigenvalue equation. Thus sophisticated methods have been developed to extract information about these solutions; for details and comparisons of the various approaches, consult, for example, Refs. 5–10.

Analytical or, at least, semianalytical (we regard a bound on some eigenvalue of a given self-adjoint operator as *semianalytical* if it can be derived by the—in general, numerical—optimization of an analytically known expression over a single real variable) expressions for both upper and lower bounds on the eigenvalues of some self-adjoint operator may be found by combining the minimum-maximum principle[11–13] and appropriate operator inequalities.[14–18] The outcome of this procedure is sometimes called the "spectral comparison theorem." In Sec. III below, we will use this kind of bounds in order to estimate the accuracy of our findings for the eigenvalues of the operator (1). Accordingly, we recall in the Appendix the proof of the "translation" of some inequality satisfied by two operators into the corresponding relations between their discrete eigenvalues, by briefly sketching all basic assumptions and the line of argument. A very systematic path for obtaining such operator inequalities is provided by rather simple geometrical considerations summarized under the notion "envelope theory."[19–24] These envelope techniques may be generalized to systems composed of arbitrary numbers of relativistically moving interacting particles.[25–27] For particular potentials V, semianalytical lower bounds on the ground-state energy eigenvalue of the semirelativistic Hamiltonian (1), and hence on the entire spectrum of H, can be found by the appropriate generalization of the local-energy theorem[13,28–30] to our case of relativistic kinematics,[23,31] or by applying the optimized (Beckner-Brascamp-Lieb) version of Young's inequality for convolutions to some integral formulation of the spinless Salpeter equation.[32]

Purely numerical solutions of the spinless Salpeter equation may be computed in numerous ways. The semirelativistic Hamiltonian H can be approximated by some effective Hamiltonian which is of nonrelativistic shape but uses parameters that depend on expectation values of the momenta.[33,34] Upper bounds of, in principle, arbitrarily high precision on the eigenvalues of a self-adjoint operator can be found[18,35–39] with the help of the Rayleigh-Ritz (variational) technique as immediate consequence of the minimum-maximum theorem.[11–13] The spinless Salpeter equation may also be converted into an equivalent matrix eigenvalue problem.[40–45]

A particular role for H is played by the spherically symmetric harmonic-oscillator potential

$$V(\mathbf{x}) = ar^2, \quad r \equiv |\mathbf{x}|, \quad a > 0,$$

this potential defines the "relativistic harmonic-oscillator problem," posed by the Hamiltonian

$$H = \sqrt{p^2 + m^2} + ar^2. \tag{2}$$

The eigenvalue equation of H, for eigenstates $|\psi\rangle$, $H|\psi\rangle = E|\psi\rangle$, involves only one parameter, upon factorizing off some overall energy scale $a^{1/3}$ by performing the canonical transformation

$$r \to \frac{r}{a^{1/3}}, \quad p \to a^{1/3} p$$

and rescaling both mass m and eigenvalue E according to $m = a^{1/3}\mu$ and $E = a^{1/3}\varepsilon$, it reads

$$(\sqrt{p^2 + \mu^2} + r^2)|\psi\rangle = \varepsilon|\psi\rangle.$$

In momentum-space representation this eigenvalue equation reduces to a Schrödinger problem,

$$[-\Delta_p + V(p)]\psi(p) = \varepsilon\psi(p), \tag{3}$$

with an interaction potential reminiscent of the square root of the relativistic kinetic energy,

$$V(p) \equiv \sqrt{p^2 + \mu^2}.$$

We would like to take advantage of this facet of the relativistic harmonic-oscillator problem in order to derive for its bound-state eigenfunctions, in this analysis, a compact expression and to move thereby beyond only numerically calculated exact solutions without having to rely on perturbation theory, maybe paving the way for the eventual construction of analytic solutions.

II. ANALYTICAL SOLUTIONS FOR BOUND-STATE EIGENFUNCTIONS

We exploit the fact that, in contrast to the general case, for a harmonic-oscillator potential (as, with due care, for any potential of the form $V \propto r^{2n}$, $n=1, 2, 3, \ldots$) the eigenvalue equation of the Hamiltonian H is an ordinary differential equation, parametrized by μ and its eigenvalue ε.

Focusing on the ground state or purely radial excitations, let us introduce, for eigenstates with vanishing relative orbital angular momentum ℓ, the reduced radial wave function $y(p)$ by

$$y(p) \equiv \sqrt{4\pi} p \psi(p) \quad (\ell = 0),$$

which is, of course, subject to the normalization condition

$$\int_0^\infty dp |y(p)|^2 = 1.$$

In accordance with Eq. (3) the reduced radial wave function satisfies a reduced radial equation,

$$\frac{\mathrm{d}^2 y}{\mathrm{d}p^2}(p) = [V(p) - \varepsilon] y(p). \tag{4}$$

From its definition, this *reduced* radial wave function $y(p)$ must vanish at the origin, $y(0)=0$. Moreover, the analysis of the *normalizable* solutions of the eigenvalue equation (4) reveals that $y(p)$ behaves like p for small p, that is, for $p \ll 1$; hence, its derivative with respect to p at the point $p=0$ is a *nonvanishing* constant, which may be absorbed into the overall normalization,

$$\frac{\mathrm{d}y}{\mathrm{d}p}(0) = 1.$$

We construct all solutions of Eq. (4) in the form of the Taylor-series expansions by using the ansatz

$$y(p) = \sum_{n=0}^{\infty} c_n \frac{p^n}{n!}$$

with the expansion coefficients

$$c_n \equiv \frac{\mathrm{d}^n y}{\mathrm{d}p^n}(0), \quad n = 0,1,2,\ldots .$$

The solution of the eigenvalue equation (4) is then clearly tantamount to the determination of the expansion coefficients c_n. The first three of these expansion coefficients are known trivially,

$$c_0 = y(0) = 0,$$

$$c_1 = \frac{\mathrm{d}y}{\mathrm{d}p}(0) = 1,$$

$$c_2 = \frac{\mathrm{d}^2 y}{\mathrm{d}p^2}(0) = [(V-\varepsilon)y](0) = 0.$$

[For the sake of notational simplicity, we suppress, in accordance with our above remark, in the following that normalization factor of $y(p)$ which guarantees its unity norm and assume $y(p)$ to be normalized such that the value of the first nonvanishing expansion coefficient is one, $c_1=1$.] Upon insertion of the eigenvalue equation (4) followed by the application of Leibniz's theorem, the nontrivial expansion coefficients c_n, $n \geqslant 3$, may be shown to satisfy the recurrence relation

$$\begin{aligned} c_{n+2} &= \frac{\mathrm{d}^{n+2} y}{\mathrm{d}p^{n+2}}(0) = \frac{\mathrm{d}^n}{\mathrm{d}p^n}\left[\frac{\mathrm{d}^2 y}{\mathrm{d}p^2}\right](0) = \frac{\mathrm{d}^n[(V-\varepsilon)y]}{\mathrm{d}p^n}(0) = \sum_{k=0}^{n}\binom{n}{k}\left[\frac{\mathrm{d}^k(V-\varepsilon)}{\mathrm{d}p^k}\frac{\mathrm{d}^{n-k}y}{\mathrm{d}p^{n-k}}\right](0) \\ &= (\mu-\varepsilon)c_n + \sum_{k=1}^{n}\binom{n}{k}\frac{\mathrm{d}^k V}{\mathrm{d}p^k}(0)c_{n-k} = (\mu-\varepsilon)c_n + \sum_{k=1}^{n}\binom{n}{k}\mu^{1-k}d_k c_{n-k}, \quad n = 1,2,3,\ldots . \end{aligned} \tag{5}$$

Here, for the last step, we abbreviated the kth derivative of the potential V by a coefficient d_k,

$$d_k \equiv \mu^{k-1}\frac{\mathrm{d}^k V}{\mathrm{d}p^k}(0) = \frac{\mathrm{d}^k\sqrt{x^2+1}}{\mathrm{d}x^k}(0), \quad x \equiv \frac{p}{\mu}, \quad \mu > 0, \quad k = 0,1,2,\ldots .$$

In the case $\mu=m=0$, the solutions involve Airy's function $\mathrm{Ai}(z)$; cf., e.g., Refs. 18,23,33 and 34. According to the above definition, we have $d_0=1$. Furthermore, by inspection of the function $f(x)=\sqrt{x^2+1}$, it is easy to convince oneself that all odd derivatives of $f(x)$ vanish at $x=0$,

$$d_{2k+1} = 0 \quad \text{for all } k = 0,1,2,\ldots , \tag{6}$$

whereas all even derivatives of $f(x)$ at $x=0$ necessarily satisfy the (simple) recurrence relation

$$d_{2k+2} = (1-4k^2)d_{2k}, \quad k = 0,1,2,\ldots .$$

By induction, the solution of this recurrence relation for the nonvanishing coefficients d_{2k} reads

$$d_{2k} = (-1)^{k-1}(2k-1)\left[\frac{(2k-2)!}{2^{k-1}(k-1)!}\right]^2, \quad k = 1,2,3,\ldots . \tag{7}$$

Taking into account the observation (6), we obtain $c_3=\mu-\varepsilon$ and, for the coefficients c_n, $n \geqslant 4$,

$$c_{n+2} = (\mu-\varepsilon)c_n + \sum_{k=1}^{[n/2]}\binom{n}{2k}\mu^{1-2k}d_{2k}c_{n-2k}, \quad n = 2,3,4,\ldots ,$$

where

$$\left[\frac{n}{2}\right] \equiv \begin{cases} \frac{n}{2} & \text{for } n \text{ even, } n = 2,4,6,\ldots , \\ \frac{n-1}{2} & \text{for } n \text{ odd, } n = 3,5,7,\ldots . \end{cases}$$

Thus the recurrence relation (5) for all expansion coefficients c_n decomposes into one involving only the even coefficients c_{2n}, $n=2, 3, 4, \ldots$, and one involving only the odd coefficients c_{2n+1}, $n=2, 3, 4, \ldots$; recalling $c_0=0$ and $c_2=0$, we conclude that all the *even* coefficients c_n vanish,

$$c_{2n} = 0 \quad \text{for all } n = 0,1,2,\ldots .$$

With the result (7), the recurrence relation for the (nonvanishing) *odd* coefficients finally reads

$$c_{2n+3} = (\mu - \varepsilon)c_{2n+1} + \sum_{k=1}^{n} \binom{2n+1}{2k} \mu^{1-2k} d_{2k} c_{2n-2k+1} = (\mu - \varepsilon)c_{2n+1}$$

$$+ \sum_{k=1}^{n} \binom{2n+1}{2k} c_{2n-2k+1} \mu^{1-2k} (-1)^{k-1} (2k-1) \left[\frac{(2k-2)!}{2^{k-1}(k-1)!} \right]^2, \quad n = 1,2,3,\ldots . \tag{8}$$

In summary, upon constructing the relevant expansion coefficients according to this recurrence relation the analytical expressions for all reduced radial wave functions (of $\ell = 0$ bound states) $y(p)$ of the relativistic harmonic-oscillator problem (2) are given by the power-series expansion

$$y(p) = \sum_{n=0}^{\infty} c_{2n+1} \frac{p^{2n+1}}{(2n+1)!}. \tag{9}$$

The various solutions $y(p)$ of the eigenvalue equation (3) are characterized or discriminated by different sets of expansion coefficients c_n. By construction, apart from the first coefficient c_1, all expansion coefficients for a given solution depend on the corresponding energy eigenvalue ε. Evaluating the recurrence relation (8) for just the first term, the series (9) explicitly starts with

$$y(p) = p \left\{ 1 + (\mu - \varepsilon) \frac{p^2}{3!} + \left[(\mu - \varepsilon)^2 + \frac{3}{\mu} \right] \frac{p^4}{5!} + \cdots \right\}.$$

III. EXPLICIT BOUND-STATE EIGENFUNCTIONS AND ENERGY LEVELS

The central result of our present investigation of the "relativistic harmonic-oscillator problem" defined by the Hamiltonian H of Eq. (2) is an analytical expression for the reduced radial parts $y(p)$ of all eigenfunctions $\psi(p)$ of H for vanishing angular momentum in form of a Taylor series

$$y(p) \equiv \sqrt{4\pi} p \psi(p) = \sum_{n=0}^{\infty} c_{2n+1} \frac{p^{2n+1}}{(2n+1)!},$$

where the corresponding expansion coefficients c_{2n+1}, $n = 0, 1, 2, \ldots$, are either fixed to $c_1 = 1$, $c_3 = \mu - \varepsilon$ or, for c_{2n+1}, $n \geqslant 2$, determined by the recurrence relation (8). For a given solution of this eigenvalue problem these expansion coefficients and thus the resulting reduced radial wave function $y(p)$ depend on the parameter $\mu \equiv m/a^{1/3}$ and the corresponding energy eigenvalue ε. Taking into account the necessary requirement of normalizability of Hilbert-space eigenstates, the inversion of the latter relation may be exploited to determine the energy eigenvalues ε from the knowledge of the dependence of ε on the coefficients c_n, as derived in the preceding section. In order to fulfill its normalization condition, any solution $y(p)$ must vanish in the limit $p \to \infty$,

$$\lim_{p \to \infty} y(p) = 0. \tag{10}$$

Fixing the energy eigenvalue ε of a chosen bound state in this manner and using this particular value of the parameter ε in the expansion (9) then yields the corresponding wave function $y(p)$.

Our principal concern is beyond doubt the semianalytical approach developed in Sec. II and summarized above. Nevertheless, it might be instructive to construct explicitly a few examples of solutions in numerical or graphical form. These results can be compared with the outcome of some straightforward (but merely numerical) integration of the Schrödinger equation (4). This will provide a useful check of the correctness of our solutions and justify the present formalism.

In actual computations, the infinite series (9) must be truncated, for practical purposes, to a reasonably large but definitely finite number N of terms considered in this expansion of $y(p)$,

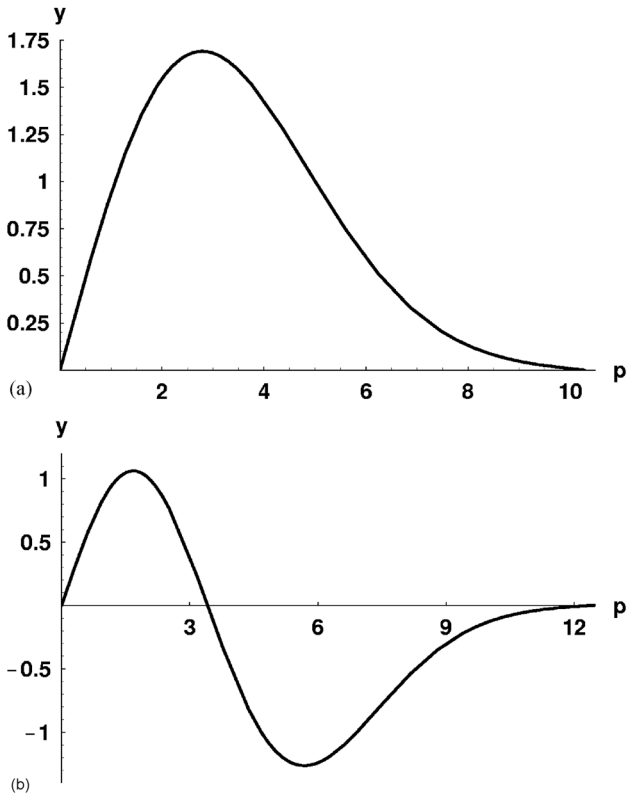

FIG. 1. Radial eigenfunctions in momentum space $y(p) \equiv \sqrt{4\pi} p \psi(p)$ of the ground state (a) and the first radial excitation (b) of the relativistic harmonic-oscillator problem, defined by the Hamiltonian $H=\sqrt{p^2+\mu^2}+r^2$, with $\mu=30$, and for 45 terms in the Taylor expansion of $y(p)$.

$$y(p) \simeq \sum_{n=0}^{N} c_{2n+1} \frac{p^{2n+1}}{(2n+1)!}. \tag{11}$$

In this case, the wave function $y(p)$ will approach zero, as required by the constraint (10), not at infinity but already for a finite value, say $\hat{p}$, of the momentum p— before it starts to diverge. This technique gives the energy eigenvalues ε with a precision determined by one's choice of N, $\varepsilon = \varepsilon(N)$. Likewise, the momentum boundary $\hat{p}$ will also change with N, $\hat{p}=\hat{p}(N)$. For a given value of μ, which quantifies the relative importance of particle mass m and harmonic-oscillator coupling strength a, every wave function resulting from this truncation procedure involves two dimensionless parameters, the relevant energy eigenvalue $\varepsilon(N)$ of the Hamiltonian (2), and the characteristic momentum $\hat{p}(N)$. Their values will be determined simultaneously, in accordance with the above requirement on $y(p)$ [to approach zero at $\hat{p}(N)$] by an appropriate fit procedure. In other words, the value of $\hat{p}(N)$, in particular, cannot be varied freely; it is fixed for chosen N.

Let us illustrate this procedure for both ground state and first radial excitation, i.e., for the two bound states defined by vanishing orbital angular momentum and radial quantum number $n_r=0$, 1, respectively. Figure 1 shows the corresponding reduced radial wave functions $y(p)$ for $\mu=30$ as obtained by inspecting the functional form of $y(p)$ resulting from different choices of ε and $\hat{p}$, if taking into account 45 terms in their Taylor series (9), that is, if choosing $N=44$ in Eq. (11). Table I summarizes the relevant numerical parameter values emerging from such construction.

The exact results can be easily computed with the aid of a (standard) integration technique designed for solving the Schrödinger equation numerically.[46] For our two examples the exact wave functions $y(p)$ prove to be practically indistinguishable, at least by the eye, from the ones extracted from the series (11) with $N=44$. This explains why we refrain from plotting also the former in Fig.

TABLE I. Dimensionless (by scaling) energy eigenvalues $\varepsilon(N)$ and characteristic momenta $\hat{p}(N)$ of the relativistic harmonic-oscillator problem posed by the Hamiltonian $H=\sqrt{p^2+\mu^2}+r^2$ as well as the classical turning points $\bar{p}$ of the corresponding nonrelativistic motion for the ground state and the first radial excitation (identified by their radial quantum number $n_r=0$, 1), with mass vs coupling strength parameter $\mu=30$, and $N=44$ or $N=14$ in our Taylor series (11).

N	n_r	$\varepsilon(N)-\mu$	$\hat{p}(N)$	$\bar{p}$
44	0	0.386 27	10	4.82
	1	0.898 64	12	7.36
14	0	0.388 54	8.5	4.82

1. For the momentum range depicted in Fig. 1, that is, for $0 \leqslant p \leqslant \hat{p}$, the relative differences of the areas under corresponding curves are (of the order) 10^{-8}; more precisely, they are given by 2×10^{-8} for $n_r=0$, the ground state, and 3×10^{-8} for $n_r=1$, the first excited level.

From a straightforward consideration of the "classical turning points" of the corresponding (and well understood) nonrelativistic harmonic-oscillator problem defined by the Hamiltonian

$$H_{\mathrm{NR}} = \mu + \frac{p^2}{2\mu} + r^2,$$

the maximum "classical" momenta, $\bar{p}$, are found, in terms of the radial quantum number n_r, as

$$\bar{p}^2 = (4n_r + 3)\sqrt{2\mu}, \quad n_r = 0,1,2,\ldots .$$

By inspecting Table I we note with satisfaction that for both energy levels under consideration the numerical values of the suitable $\hat{p}$ turn out to be far beyond their classical counterparts $\bar{p}$.

In order to get, at least, some vague idea of the dependence of our findings on the amount of truncation represented by $N<\infty$, we inspect the ground-state wave function $y(p)$ constructed again for $\mu=30$ but by truncating the expansion (9) to the rather modest number of 15 terms, which means to set $N=14$ in Eq. (11). Figure 2 confronts this approximate wave function $y(p)$ with its exact behavior for the ground state. While for small and intermediate momenta there is still perfect agreement with the exact result,[46] we observe a clearly discernible discrepancy between approximate and exact curve for large momenta. Table I tells us that even for $N=14$ our crucial momentum $\hat{p}$ is still comfortably above the corresponding classical turning point, $\bar{p}$. Moreover, comparing

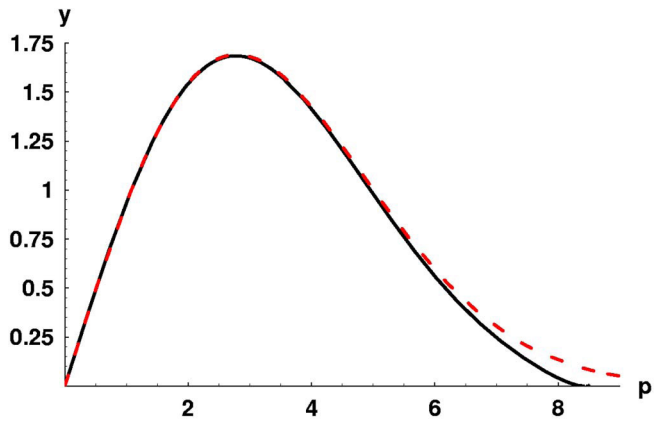

FIG. 2. (Color online) Momentum-space wave function $y(p)$ of Fig. 1(a) resulting from consideration of only 15 terms in its polynomial approximation (11) (full line), in comparison with the corresponding exact ground-state wave function of the relativistic harmonic-oscillator operator (dashed line).

TABLE II. Numerical values of the parameter P_L used by envelope theory for the lower bounds on the energy levels of the relativistic harmonic-oscillator problem in three spatial dimensions, for the lowest-lying $\ell=0$ bound states identified by their radial quantum number $n_r=0, 1, 2, \ldots$.

n_r	P_L
0	1.376 083 5
1	3.181 312 9
2	4.992 554 3
3	6.805 136 9
4	8.618 226 9

the cases $N=14$ and $N=44$, we learn that the value of $\hat{p}$ increases with increasing number N. Of course, the naive expectation would be that $\hat{p}$ behaves like $\hat{p}\to\infty$ for $N\to\infty$, that is, when removing the truncation and restoring the full series expansion for $y(p)$.

The minimum number of terms to be taken into account in the Taylor-series expansions (9) required in order to achieve some given precision of one's results will depend, of course, on both the bound state under study and the desired accuracy. From our above remarks we feel entitled to conclude that a reasonable (and manageable) number $N\simeq 40$ produces satisfactory results.

To our knowledge, at present the best *semianalytical* upper and lower bounds to the energy eigenvalues of the relativistic harmonic-oscillator problem are provided simultaneously by the combination of minimum-maximum principle with operator inequalities[18] and the envelope theory,[19,21] at least for the relativistic harmonic oscillator the envelope bounds[19,21] may be shown[23] to be quantitatively equivalent to the bounds derived in Appendix A of Ref. 18. However, a discussion, in full generality, of all implications of such operator inequalities for the eigenvalues of the operators considered appears clearly off the mainstream of our presentation. Therefore, as already promised in the Introduction, the general relationship is demonstrated in the Appendix. The bounds we need here are derived from this general theorem by specializing to the case of the relativistic harmonic-oscillator problem posed by the Hamiltonian operator (2); all operator inequalities required by this procedure may be generated by, e.g., envelope theory. For a bound state of vanishing relative orbital angular momentum ℓ, that is, for a purely radial excitation, identified by the radial quantum number $n_r=0, 1, 2, \ldots$ (identical to the number of nodes of the corresponding wave function), the bounds on the dimensionless eigenvalue ε read

$$\min_{r>0}\left(\sqrt{\mu^2+\frac{P_L^2}{r^2}}+r^2\right)\leqslant\varepsilon\leqslant\min_{r>0}\left(\sqrt{\mu^2+\frac{P_U^2}{r^2}}+r^2\right),$$

where, in three spatial dimensions, our envelope-theory upper-bound parameter P_U is given by

$$P_U=2n_r+\tfrac{3}{2},\quad n_r=0,1,2,\ldots,$$

while the lower-bound parameter P_L required for our envelope bounds is related to the zeros z_0 of Airy's function Ai(z) (Ref. 47) ($-z_0=2.338\,107, 4.087\,949, 5.520\,560, 6.786\,708, 7.944\,134, \ldots$) by

$$P_{\mathrm{L}}=2\left(\frac{-z_0}{3}\right)^{3/2},\quad \mathrm{Ai}(z_0)=0.$$

Resulting values of P_L for the lowest-lying $\ell=0$ bound states are listed in Table II.[9,19,21–23]

Table III compares, for the lowest four $\ell=0$ energy levels (identified by their radial quantum number $n_r=0, 1, 2, 3$) of our Hamiltonian (2), the approximate eigenvalues, $\varepsilon(N)$, obtained by the present approach by a truncation of the power series (11) to $N=14$ or $N=44$ terms, with the corresponding semianalytical upper (ε_U) and lower (ε_L) bounds mentioned above as well as with the (numerically exact) eigenvalues $\varepsilon_{\mathrm{num}}$, computed by a method developed for the purely numeri-

TABLE III. "Compact-origin" eigenvalues $\varepsilon(N)$, their upper (ε_U) and lower (ε_L) bounds, and their exact values ε_{num} for the lowest $\ell=0$ states of the Hamiltonian $H/a^{1/3}$ in Eq. (2), with $\mu=30$.

Radial excitation n_r	0	1	2	3
$\varepsilon_U-\mu$	0.386 68	0.900 32	1.411 79	1.921 11
$\varepsilon_L-\mu$	0.354 78	0.818 62	1.282 22	1.744 40
$\varepsilon_{\text{num}}-\mu$	0.386 27	0.898 57	1.407 68	1.913 66
$\varepsilon(N=14)-\mu$	0.388 54	0.936 16		
$\varepsilon(N=44)-\mu$	0.386 27	0.898 64	1.410 32	1.943 19

cal solution of (nonrelativistic) Schrödinger equations.[46] For $N=14$, the polynomial in ε resulting from the suitably adapted boundary condition (10) has only two real roots at all. Moreover, both of these approximate values are still above our (semianalytical) upper bounds. In contrast to this rather crude approximation, for $N=44$ the eigenvalues $\varepsilon(N)$ of already the three lowest energy levels fit perfectly to the ranges spanned by the semianalytical bounds. For the ground state, in particular, $\varepsilon(44)$ reproduces the exact result at least to five decimal places.

IV. SUMMARY AND CONCLUSIONS

Our compact result for the reduced $\ell=0$ eigenfunctions of the Hamiltonian (2) is given by the power series (9), with expansion coefficients $c_1=1$, $c_3=\mu-\varepsilon$, and c_{2n+1}, $n\geqslant 2$, determined by the recurrence relation (8). Both the numerical determination of all energy eigenvalues and the explicit construction of the corresponding eigenfunctions of the relativistic harmonic-oscillator problem is then achieved by forcing our solutions to satisfy, in addition, the constraint imposed by the requirement of normalizability of bound-state wave functions. Comparing these explicit solutions with the outcomes of purely numerical integration procedures reveals that at least for the lowest-lying energy levels our semianalytical approach reproduces, already for a truncation of the Taylor series (9) to a moderate number of expansion terms, the exact solutions with high accuracy. Of course, if one is interested only in numerical solutions of the problem under study, their straightforward computation with the help of some integration algorithm should produce the desired result more easily than their extraction from our Taylor series by means of Eq. (10).

APPENDIX: COMBINATION OF MINIMUM-MAXIMUM PRINCIPLE WITH OPERATOR INEQUALITY: "SPECTRAL COMPARISON THEOREM"

It is a simple exercise to relate discrete eigenvalues of two operators satisfying some inequality.

Consider for some operator A, with domain $\mathcal{D}(A)$, its eigenvalue equation $A|\alpha_k\rangle=a_k|\alpha_k\rangle$, $k=0, 1, 2, \ldots$, for its set of eigenstates $\{|\alpha_k\rangle, k=0,1,2,\ldots\}$, corresponding to its eigenvalues

$$a_k \equiv \frac{\langle\alpha_k|A|\alpha_k\rangle}{\langle\alpha_k|\alpha_k\rangle}, \quad k=0,1,2,\ldots,$$

and likewise for some operator B, with domain $\mathcal{D}(B)$, its eigenvalue equation $B|\beta_k\rangle=b_k|\beta_k\rangle$, $k=0, 1, 2, \ldots$, for its set of eigenstates $\{|\beta_k\rangle, k=0,1,2,\ldots\}$, corresponding to its eigenvalues

$$b_k \equiv \frac{\langle \beta_k | B | \beta_k \rangle}{\langle \beta_k | \beta_k \rangle}, \quad k = 0,1,2,\ldots .$$

Assume that both these operators A and B are self-adjoint, $A^\dagger = A$, $B^\dagger = B$. This implies that all their eigenvalues are real, $a_k^* = a_k$, $b_k^* = b_k$, $k = 0, 1, 2, \ldots$. Let these eigenvalues be ordered according to $a_0 \leqslant a_1 \leqslant a_2 \leqslant \cdots$, $b_0 \leqslant b_1 \leqslant b_2 \leqslant \cdots$. Consider only the discrete eigenvalues a_k of A below the onset of the essential spectrum of the operator A. Assume that the operator A is bounded from below. Assume that the operators A and B are related by an operator inequality of the form $A \leqslant B$, which implies that B too is bounded from below. In order to derive, for any $k = 0, 1, 2, \ldots$, the relationship between a_k and b_k, focus on some arbitrary $(k+1)$-dimensional subspace D_{k+1} of the domain $\mathcal{D}(A)$ of A, $D_{k+1} \subseteq \mathcal{D}(A)$. Employing the appropriate form of the minimum-maximum principle, the operator inequality $A \leqslant B$ translates into an upper bound on the eigenvalue a_k of A which involves all expectation values of B within this subspace D_{k+1},

$$a_k \leqslant \sup_{|\psi\rangle \in D_{k+1}} \frac{\langle \psi | A | \psi \rangle}{\langle \psi | \psi \rangle} \leqslant \sup_{|\psi\rangle \in D_{k+1}} \frac{\langle \psi | B | \psi \rangle}{\langle \psi | \psi \rangle} \quad \text{for all } k = 0,1,2,\ldots . \tag{A1}$$

Now, in order to relate the supremum over the expectation values of B to the eigenvalues b_k of B, consider a particular subspace D_{k+1}, namely, that space that is spanned by the first $k+1$ eigenvectors of the operator B, that is, by precisely those eigenvectors of B that correspond to the first $k+1$ eigenvalues $b_0, b_1, \ldots, b_k$ of B, $D_{k+1} \subseteq \mathcal{D}(B) \subseteq \mathcal{D}(A)$. Then, clearly, every $|\psi\rangle$ in D_{k+1} is a linear combination of the eigenstates $\{|\beta_i\rangle, i = 0, 1, \ldots, k\}$ of B, with coefficients c_i,

$$|\psi\rangle = \sum_{i=0}^{k} c_i |\beta_i\rangle \quad \text{for all } |\psi\rangle \in D_{k+1}.$$

For any subspace D_{k+1}, $k = 0, 1, 2, \ldots$, use of this expansion of $|\psi\rangle$ yields for its norm squared,

$$\langle \psi | \psi \rangle = \sum_{i=0}^{k} |c_i|^2 \langle \beta_i | \beta_i \rangle \quad \text{for all } |\psi\rangle \in D_{k+1}$$

and, with this and $b_i \leqslant b_k$ for all $i = 0, 1, \ldots, k$, an upper bound on all expectation values of B,

$$\langle \psi | B | \psi \rangle = \sum_{i=0}^{k} |c_i|^2 b_i \langle \beta_i | \beta_i \rangle \leqslant b_k \sum_{i=0}^{k} |c_i|^2 \langle \beta_i | \beta_i \rangle = b_k \langle \psi | \psi \rangle \quad \text{for all } |\psi\rangle \in D_{k+1},$$

which means

$$\frac{\langle \psi | B | \psi \rangle}{\langle \psi | \psi \rangle} \leqslant b_k \quad \text{for all } |\psi\rangle \in D_{k+1},$$

$$\frac{\langle \psi | B | \psi \rangle}{\langle \psi | \psi \rangle} = b_k \quad \text{for } |\psi\rangle = |\beta_k\rangle \in D_{k+1}.$$

Therefore the supremum of all expectation values of B over D_{k+1} is just the eigenvalue b_k of B,

$$\sup_{|\psi\rangle \in D_{k+1}} \frac{\langle \psi | B | \psi \rangle}{\langle \psi | \psi \rangle} = b_k \quad \text{for all } k = 0,1,2,\ldots .$$

Thus, inserting this identity in the chain of inequalities (A1) proves that corresponding discrete eigenvalues a_k, b_k of semibounded self-adjoint operators A, B that satisfy $A \leqslant B$ are related by

$$a_k \leqslant b_k \quad \text{for all } k = 0,1,2,\ldots .$$

(Received 7 July 2005; accepted 22 August 2005; published online 21 October 2005)

A novel *solvable* extension of the goldfish N-body problem is presented. Its Newtonian equations of motion read $\ddot{\zeta}_n=2a\dot{\zeta}_n\zeta_n+2\Sigma_{m=1,m\neq n}^{N}(\dot{\zeta}_n-a\zeta_n^2)(\dot{\zeta}_m-a\zeta_m^2)/(\zeta_n-\zeta_m)$, $n=1,\ldots,N$, where a is an arbitrary (nonvanishing) constant and the rest of the notation is self-evident. The *isochronous* version of this model is characterized by the Newtonian equations of motion $\ddot{z}_n-3i\omega\dot{z}_n-2\omega^2z_n=2a(\dot{z}_n-i\omega z_n)z_n+2\Sigma_{m=1,m\neq n}^{N}(\dot{z}_n-i\omega z_n-az_n^2)(\dot{z}_m-i\omega z_m-az_m^2)/(z_n-z_m)$, $n=1,\ldots,N$, where ω is an arbitrary *positive* constant and the points $z_n(t)$ move now necessarily in the *complex* z-plane. The *generic* solution of this second model is *completely periodic* with a period $T_k=kT$ which is an *integer* multiple k (not larger than $N!$, indeed generally much smaller) of the basic period $T=2\pi/\omega$ and which is independent of the initial data (for sufficiently small, but otherwise arbitrary, changes of such data). These many-body models have an intriguing variety of equilibrium configurations (genuine: with no two particles sitting at the same place), but only for small values of N ($N=2,3,4$ for the first model, $N=2,3,4,5$ for the second). Other versions of these models are also discussed. The study of the behavior of the second, *isochronous* model around its equilibrium configurations yields some amusing *diophantine* results. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2061547]

I. INTRODUCTION

Recently a convenient technique to identify solvable dynamical systems has been introduced and used to identify two solvable extensions of the goldfish many-body model, characterized by the Newtonian equations of motion[3]

$$\ddot{\zeta}_n=2\sum_{m=1,m\neq n}^{N}\frac{\dot{\zeta}_n\dot{\zeta}_m}{\zeta_n-\zeta_m}+a\sum_{m=1}^{N}\frac{\dot{\zeta}_n\dot{\zeta}_m}{\zeta_m}, \tag{1}$$

respectively[4]

$$\ddot{\zeta}_n=2a\dot{\zeta}_n\zeta_n+2\sum_{m=1,m\neq n}^{N}\frac{\dot{\zeta}_n\dot{\zeta}_m}{\zeta_n-\zeta_m}. \tag{2}$$

Here and hereafter, unless otherwise specified, N is an arbitrary positive integer, indices such as n,m run from 1 to N, the dependent variables $\zeta_n\equiv\zeta_n(t)$ are the coordinates of the particles (which are generally supposed to move in the *complex* plane; but *real* solutions also exist if the constant a is *real*), and superimposed dots indicate differentiations with respect to the *real* independent

[b)]Electronic mail: saiona@tin.it

variable t ("time"). Of course when the constant a vanishes both these N-body problems reduce to the standard goldfish model[1] (and we refer to Ref. 2 for additional information on this model). And *isochronous* variants of these models have also been investigated.[3,4]

In this paper we identify and discuss a third *solvable* extension of the goldfish many-body problem, characterized by the Newtonian equations of motion

$$\ddot{\zeta}_n = 2a\dot{\zeta}_n\zeta_n + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{\zeta}_n - a\zeta_n^2)(\dot{\zeta}_m - a\zeta_m^2)}{\zeta_n - \zeta_m}, \tag{3}$$

as well as its *isochronous* variant

$$\ddot{z}_n - 3i\omega\dot{z}_n - 2\omega^2 z_n = 2a(\dot{z}_n - i\omega z_n)z_n + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n - i\omega z_n - az_n^2)(\dot{z}_m - i\omega z_m - az_m^2)}{z_n - z_m}. \tag{4}$$

In all these models the *arbitrary* constants a and ω could of course be rescaled away, but we prefer to keep them in evidence. Whenever discussing the *isochronous* model (4) we assume the constant ω to be *positive*, $\omega > 0$, and we associate to it the basic *period*

$$T = \frac{2\pi}{\omega}. \tag{5}$$

Of course for $\omega = 0$ the *isochronous* model (4) reduces back to the model (3), but the behavior of the solutions of these two models is *qualitatively* different and it is therefore convenient to treat them separately. Indeed the *generic* motions of the *isochronous* model (4) are *completely periodic* with a period $T_k = kT$ which is an *integer* multiple k of the basic period T and does not depend on the initial data, at least for sufficiently small (but otherwise arbitrary) changes of them (hence having the full dimensionality in phase space). This is in contrast to the phenomenology characteristic of model (3), which features a periodic motion only exceptionally, i.e., only for a special set of initial data (having lower dimensionality in phase space). The more interesting phenomenology obtains when one considers the (nonvanishing!) constant a, and the dependent variables $\zeta_n(t)$, respectively $z_n(t)$, to be *complex*, because motions in the (*complex*) plane allow a much richer gamut of behaviors than motions on the (*real*) line; moreover, as we indicate in the following, it is possible to reinterpret the motions of the points $\zeta_n(t)$ and $z_n(t)$ in the *complex* plane as motions of *real* two-vectors in the (*real*) horizontal plane, allowing thereby a more physical interpretation of these models as genuine many-body problems (with *covariant*, even *rotation-invariant*, Newtonian equations of motion). Of course in the *isochronous* case the dependent variables $z_n(t)$ are *necessarily complex*, because the equations of motion (4) are themselves *complex* (the symbol i appearing in them is of course the imaginary unit, $i \equiv \sqrt{-1}$).

We submit that the phenomenology displayed by these models is sufficiently remarkable to justify calling them "novel," as we did in the title of this paper.

In the following section we report an overview of our main findings, namely the solutions of the two models, first in the *one-body* case and then in the *many-body* case, and their equilibrium configurations (in the *many-body* case). These results are proven in Sec. III, which also contains some other interesting findings. In Sec. IV other versions of these models are introduced and discussed. In Sec. V the behavior is discussed of the *isochronous* model (4), and of its version of Sec. IV, in the neighborhood of their equilibrium configurations, and some amusing *diophantine* relations are thereby obtained.

Finally, we like to add a few words to clarify the character of the model we study in this paper and our justification (admittedly debatable) for referring to it as a "Newtonian many-body problem." We feel entitled to do so because of the possibility to reformulate the *complex* equations of motion (3) and (4), respectively, describing the motions of N points ζ_n and z_n in the *complex* ζ-plane and z-plane, as *real* equations of motions describing the movement of N unit-mass point-particles the positions of which are identified by N *real* two-vectors in the (horizontal) plane. And these *real* equations of motion seem rather naturally interpretable as *Newtonian* equations of

motion, inasmuch as they correspond to the statement that the *acceleration* of each particle is directly given by the *force* that acts on it. Moreover these equations of motion can be formulated in *covariant*, and even in *rotation-invariant*, form (although for simplicity this is explicitly done in the following only in the one-body case, see Sec. II A; the treatment in the many-body case is analogous, as described in detail elsewhere, see for instance Chap. 4 of Ref. 2). And moreover the *forces* featured by this model are just *one-body* and *two-body* forces. On the other hand these forces are *velocity-dependent*, and they do not correspond to any specific physical model; in particular they have no resemblance to the forces characterizing the gravitational N-body problem, which undoubtedly has a much more justified claim than our model to be qualified as "Newtonian"!

II. MAIN RESULTS

In the following we report our main findings. Those for the *one-body* case, treated in Sec. II A, might be considered trivial, but they provide an illuminating introduction to the results for the *many-body* case reported in Sec. II B.

A. The one-body case

For $N=1$ the model (3) reads simply (with $\zeta_1(t) \equiv \zeta(t)$)

$$\ddot{\zeta} = 2a\dot{\zeta}\zeta. \tag{6}$$

This ODE can be reformulated as a problem in the physical (*real*) horizontal plane via the positions

$$\vec{\rho} \equiv (\mathrm{Re}[\zeta], \mathrm{Im}[\zeta], 0), \quad \vec{a} = (\mathrm{Re}[a], -\mathrm{Im}[a], 0); \tag{7}$$

note the minus sign in the second equation. The equation of motion (6) takes then the following *covariant* form:

$$\ddot{\vec{\rho}} = 2[\vec{\rho}(\vec{a} \cdot \dot{\vec{\rho}}) + \dot{\vec{\rho}}(\vec{a} \cdot \vec{\rho}) - \vec{a}(\vec{\rho} \cdot \dot{\vec{\rho}})]. \tag{8a}$$

This Newtonian equation of motion is *covariant*, but not *rotation-invariant*, because the constant vector $\vec{a}$ identifies a preferred direction in the horizontal plane; but this model can be made *rotation-invariant* via the following gimmick: consider the vector $\vec{a}$ in (8a) as an additional *dependent* variable, and then supplement this equation of motion with the additional trivial equation

$$\dot{\vec{a}} = 0. \tag{8b}$$

Note that these two vector equations of motion, (8a) and (8b), are yielded, in the standard manner, by the Hamiltonian

$$H(\vec{\rho}, \vec{a}, \vec{q}; \vec{\pi}, \vec{\alpha}, \vec{\gamma}) = 2(\vec{\pi} \cdot \vec{\rho})(\vec{a} \cdot \vec{\rho}) - (\vec{\pi} \cdot \vec{a})(\vec{\rho} \cdot \vec{\rho}) + (\vec{q} \cdot \vec{\pi}), \tag{9}$$

where $\vec{\rho}$, $\vec{a}$ respectively $\vec{\gamma}$ are the (vector) canonical variables, and $\vec{\pi}$, $\vec{\alpha}$ respectively $\vec{\gamma}$ are the corresponding (vector) canonical momenta: of course the fact that this Hamiltonian does not depend at all on the canonical momenta $\vec{\alpha}$ respectively $\vec{\gamma}$ is consistent with (8b) respectively with the fact that $\vec{q}$ is as well constant. Indeed the first Hamiltonian equation, $\dot{\vec{\rho}} = \partial H / \partial \vec{\pi}$, yielded by the Hamiltonian (9) identifies this vector $\vec{q}$ as the following constant of motion:

$$\vec{q} = \dot{\vec{\rho}} - 2\vec{\rho}(\vec{a} \cdot \vec{\rho}) + \vec{a}(\vec{\rho} \cdot \vec{\rho}), \tag{10}$$

and the time-derivative of this equation yields just the Newtonian equation of motion (8a).

Hereafter we work for convenience with the (*complex*) formulation (6) of the equation of

motion, although we also provide the more physical *real* version of some formulas, as entailed by (7). The solution of the initial-value problem for (6) is

$$\zeta(t) = \frac{\zeta(0) + a^{-1}\Omega \tan(\Omega t)}{1 - a\zeta(0)\Omega^{-1} \tan(\Omega t)}, \tag{11a}$$

$$\Omega^2 = a[\dot{\zeta} - a\zeta^2]. \tag{11b}$$

The right-hand side of (11a) depends clearly on Ω^2 rather than Ω, and this justifies the way we wrote the second of these formulas; and note that, in the definition of Ω^2, it is unnecessary to specify the time at which ζ and $\dot{\zeta}$ are evaluated, since clearly Ω^2 is a constant of motion for the evolution equation (6). The diligent reader will verify that via (7) the solution formula (11a) with (11b) can be written as follows:

$$\vec{\rho}(t) = \frac{\Xi(t)\vec{\rho}(0) + \hat{\Xi}\hat{k} \wedge \vec{\rho}(0) + \Psi(t)\vec{a} + \hat{\Psi}(t)\hat{k} \wedge \vec{a}}{-1 + (\vec{a} \cdot \vec{a})(\vec{\rho}(0) \cdot \vec{\rho}(0))|\Omega^{-1} \tan(\Omega t)|^2 + 2\Xi(t)}, \tag{12a}$$

$$\Omega^2 = (\vec{a} \cdot \vec{q}) + i(\hat{k} \cdot \vec{a} \wedge \vec{q}), \tag{12b}$$

where the constant of motion vector $\vec{q}$ is defined by (10), $\hat{k} \equiv (0,0,1)$ is the unit vector orthogonal to the horizontal plane, the symbol $\wedge$ denotes the standard three-dimensional vector product, and the four *real* functions $\Xi(t)$, $\hat{\Xi}(t)$, $\Psi(t)$, $\hat{\Psi}(t)$ are defined as follows:

$$\Xi(t) = 1 - (\vec{a} \cdot \vec{\rho}(0))\mathrm{Re}\left[\frac{\tan(\Omega t)}{\Omega}\right] + (\hat{k} \cdot \vec{a} \wedge \vec{\rho}(0))\mathrm{Im}\left[\frac{\tan(\Omega t)}{\Omega}\right], \tag{12c}$$

$$\hat{\Xi}(t) = (\vec{a} \cdot \vec{\rho}(0))\mathrm{Im}\left[\frac{\tan(\Omega t)}{\Omega}\right] + (\hat{k} \cdot \vec{a} \wedge \vec{\rho}(0))\mathrm{Re}\left[\frac{\tan(\Omega t)}{\Omega}\right], \tag{12d}$$

$$\Psi(t) = \frac{\Xi(t)\mathrm{Re}[\Omega \tan(\Omega t)] - \hat{\Xi}(t)\mathrm{Im}[\Omega \tan(\Omega t)]}{(\vec{a} \cdot \vec{a})}, \tag{12e}$$

$$\hat{\Psi}(t) = \frac{\Xi(t)\mathrm{Im}[\Omega \tan(\Omega t)] + \hat{\Xi}(t)\mathrm{Re}[\Omega \tan(\Omega t)]}{(\vec{a} \cdot \vec{a})}. \tag{12f}$$

Note that, in writing these formulas, we took good care to distinguish the squared modulus $(\vec{a} \cdot \vec{a}) = |a|^2$ of the (*real*) vector $\vec{a}$, see (7), from the (generally *complex*) number a^2.

Clearly in the *real* case (with a and ζ both *real*) a necessary and sufficient condition to guarantee that this solution, see (11), remains *nonsingular* for all positive time $t > 0$ is validity of the inequality

$$a\dot{\zeta}(0) < 0, \tag{13a}$$

which entails that Ω is *imaginary*. Then

$$\zeta(\pm\infty) = \mp \frac{|\Omega|}{a}. \tag{13b}$$

In the *complex* case the solution (11) is clearly *periodic* with period π/Ω if Ω^2 is *real* and *positive* (in which case we assume Ω to be positive, $\Omega > 0$), provided the imaginary part of $a\zeta(0)$ does *not* vanish, $\mathrm{Im}[a\zeta(0)] \neq 0$ or equivalently $\vec{a} \wedge \vec{\rho}(0) \neq 0$ (to exclude that the solution becomes

singular at some finite time $t=t_s$, $0<t_s<\pi/\Omega$). The condition on the initial data such that indeed Ω^2 be *positive* can be read directly from (11b) or (12b). In the *generic* case when Ω^2 is *not real* the *complex* coordinate $\zeta(t)$ tends—both in the remote past and future—to finite limiting values, see (13b), and the motion is generically *nonsingular*, although there is a lower-dimensional set of initial data yielding singular motions (they are of course those values such that the denominator $1-a\zeta(0)\Omega^{-1}\tan(\Omega t)$ vanishes for some *positive* value of the time t, see (11a)). The diligent reader will formulate the analogous results appropriate to the "physical" formulation in the *real* horizontal plane (see (8a) and (12)).

The *isochronous* version of this model (6) is characterized by the Newtonian equation of motion

$$\ddot{z}-3i\omega\dot{z}-2\omega^2 z=2a(\dot{z}-i\omega z)z. \tag{14}$$

Clearly this equation of motion reduces to the previous one, (6), for $\omega=0$ (entailing $z(t)=\zeta(t)$). As already mentioned, whenever we discuss *isochronous* versions of our models we assume ω to be *positive*, $\omega>0$.

The solution of the initial-value problem for this equation of motion, (14), reads

$$z(t)=\exp(i\omega t)\frac{z(0)+a^{-1}\widetilde{\Omega}\tan(\widetilde{\Omega}\tau)}{1-az(0)\widetilde{\Omega}^{-1}\tan(\widetilde{\Omega}\tau)}, \tag{15a}$$

$$\widetilde{\Omega}^2=a[\dot{z}(0)-i\omega z(0)-az^2(0)]. \tag{15b}$$

Here and always in the following the *complex* time-like variable τ is related to the (*real*, "physical") time variable t by the relation

$$\tau\equiv\tau(t)=\frac{\exp(i\omega t)-1}{i\omega}, \tag{16}$$

which entails that τ is a *periodic* function of t with period T, see (5). And this in turn entails the *isochronous* character of the solution (15a) of (14), which is clearly as well *periodic* with period T, $z(t+T)=z(t)$, for *generic* initial conditions $z(0)$ and $\dot{z}(0)$: the initial data that yield a *singular* solution are indeed *nongeneric*, being characterized by the requirement that the (generally *complex*) denominator $1-az(0)\Omega^{-1}\tan(\widetilde{\Omega}\tau)$, see (15a) with (16), vanishes for some *positive* value of the time $t=\widetilde{t}_s$, with $0<\widetilde{t}_s<T$.

The diligent reader will formulate the analogous results appropriate to the "physical" formulation in the *real* horizontal plane (see (7)).

B. The many-body case

The solution of the initial-value problem for the N-body problem (3) is given by

Proposition 1: the coordinates $\zeta_n(t)$ of the N moving particles are the N eigenvalues of the $N\otimes N$ matrix

$$U(t)=[1-aU(0)t]^{-1}\Bigg\{U(0)+[\chi(t)]^{-1}\Bigg\{[q(t)U(0)+r(t)]P+\Bigg[1-\cos(\Omega t)+\frac{\sin(\Omega t)-\Omega t}{\Omega}aU(0)\Bigg]P[1-aU(0)t]^{-1}U(0)\Bigg\}\Bigg\}, \tag{17a}$$

where

$$\chi(t)=\sum_{n=1}^{N}\left[\left(\frac{\Omega_n^2}{\Omega^2}\right)\frac{\Omega\cos(\Omega t)-\sin(\Omega t)a\zeta_n(0)}{\Omega[1-a\zeta_n(0)t]}\right], \tag{17b}$$

$$q(t) = \sum_{n=1}^{N} \left[\left(\frac{\Omega_n^2}{\Omega^2} \right) \frac{[1 - \cos(\Omega t)][1 + a\zeta_n(0)t] - \Omega t \sin(\Omega t)}{1 - a\zeta_n(0)t} \right], \tag{17c}$$

$$r(t) = \left(\frac{\Omega}{a} \right) \sum_{n=1}^{N} \left[\left(\frac{\Omega_n^2}{\Omega^2} \right) \frac{\Omega \sin(\Omega t) - 2[1 - \cos(\Omega t)]a\zeta_n(0)}{\Omega[1 - a\zeta_n(0)t]} \right], \tag{17d}$$

the diagonal $N \otimes N$ *matrix* $U(0)$ *is given in terms of the initial values of the coordinates* ζ_n *by the simple formula*

$$U(0) = \mathrm{diag}[\zeta_n(0)], \tag{17e}$$

and the dyadic $N \otimes N$ *matrix* P is *defined as follows:*

$$P_{nm} = \frac{\Omega_n \Omega_m}{\Omega^2}. \tag{17f}$$

In these formulas the scalars Ω_n *and* Ω *are defined in terms of the initial data as follows:*

$$\Omega_n = \{a[\dot{\zeta}_n(0) - a\zeta_n^2(0)]\}^{1/2}, \tag{17g}$$

$$\Omega^2 = a \sum_{n=1}^{N} (\dot{\zeta}_n - a\zeta_n^2) = \sum_{n=1}^{N} \Omega_n^2, \tag{17h}$$

so that the dyadic $N \otimes N$ *matrix* P *is actually a* projector, $P^2 = P$.

Several comments on these findings (proven in the following section) are now appropriate. (i) The formula (17h) defines Ω^2 rather than Ω, consistent with the fact that the right-hand side of (17a) is indeed a function of Ω^2 rather than Ω. (ii) In the spirit of the initial value problem the values of $\dot{\zeta}_n$ and ζ_n^2 to be inserted in the right-hand side of expression (17h) of Ω^2 would be evaluated at the initial time $t=0$, as implied by its second version, see (17g); but let us emphasize that this quantity, Ω^2 (see the first version of (17h)), is a constant of motion for our system, as is apparent by summing its equations of motion, (3), over the index n from 1 to N and then noticing that the double sum on the right-hand side vanishes due to the antisymmetry of the summand under exchange of the two dummy indices n and m, while the resulting equation clearly entails that the time-derivative of Ω^2 vanishes. (iii) In writing formula (17a) we assumed that the constant Ω does not vanish; but the formula remains valid, via an obvious limiting procedure, even if Ω does vanish.

Let us emphasize the remarkable time dependence exhibited by the solution formula (17a), that features (see also, (17b)–(17d)) a rational dependence *both* on t and on circular functions of Ωt (with Ω generally *complex*, see (17h)). A terse discussion of this formula is therefore in order.

First let us note that $\chi(0)=1$ (see (17b) with (17g) and (17h)), while $q(0)=r(0)=0$ (see (17c) and (17d)). The consistency of the solution formula (17a) at $t=0$ is thereby apparent.

Second, as $t \to \pm\infty$, there clearly hold (up to corrections of order $1/t$), the asymptotic relations

$$U(t) \approx \left(\frac{\Omega}{a} \right) \frac{b \tan(\Omega t) - 1}{\tan(\Omega t) + b} P \quad \text{if } \mathrm{Im}[\Omega] = 0, \tag{18a}$$

$$U(t) \approx \pm \,\mathrm{sign}[\mathrm{Im}(\Omega)] \frac{i\Omega}{a} P \quad \text{if } \mathrm{Im}[\Omega] \neq 0, \tag{18b}$$

with

$$b = \frac{a}{\Omega}\sum_{n=1}^{N}\left[\zeta_n(0) - \frac{\dot{\zeta}_n(0)}{a\zeta_n(0)}\right]. \tag{18c}$$

We therefore conclude (because the $N\otimes N$ matrix P, being a projector, has a single unit eigenvalue with all the other $N-1$ vanishing) that *generically* (i.e., excluding *nongeneric* solutions that become *singular* due to the occurrence of a particle collision), as $t\to\pm\infty$, *all but one* of the coordinates $\zeta_n(t)$ tend to the origin, while one of them, if $\mathrm{Im}[\Omega]=0$, approaches asymptotically (up to corrections of order $1/t$) the *periodic* trajectory

$$\zeta_{\mathrm{asy}}(t) = \left(\frac{\Omega}{a}\right)\frac{b\tan(\Omega t)-1}{\tan(\Omega t)+b} \tag{19a}$$

(provided $\mathrm{Im}[b]\neq 0$, so that this asymptotic trajectory is *not singular*), and if instead $\mathrm{Im}[\Omega]\neq 0$ it approaches asymptotically (again, up to corrections of order $1/t$) the asymptotic value

$$\bar{\zeta}_{\mathrm{asy}} = \pm\,\mathrm{sign}[\mathrm{Im}(\Omega)]\frac{i\Omega}{a}. \tag{19b}$$

The *isochronous* variant of the model (3) is characterized by the Newtonian equations of motion (4). These equations of motion reduce of course to the previous ones, see (3), for $\omega=0$ (entailing $z_n(t)=\zeta_n(t)$), but, as already indicated earlier, whenever we refer to this *isochronous* model we assume instead that the constant ω is *positive* and we associate with it the basic period T, see (5). Note that in this *isochronous* case the dependent variables $z_n\equiv z_n(t)$ denote N points that move *necessarily* in the *complex* z-plane.

The solution of the initial-value problem for this N-body problem, (4), is given by

Proposition 2: the coordinates $z_n(t)$ of the N moving particles are the N eigenvalues of the $N\otimes N$ matrix

$$\widetilde{U}(t) = \exp(i\omega t)[1-a\widetilde{U}(0)\tau]^{-1}\left\{\widetilde{U}(0) + [\widetilde{\chi}(\tau)]^{-1}\left\{[\widetilde{q}(\tau)\widetilde{U}(0)+\widetilde{r}(\tau)]\widetilde{P} + \left[1-\cos(\widetilde{\Omega}\tau) + \frac{\sin(\widetilde{\Omega}\tau)-\widetilde{\Omega}\tau}{\widetilde{\Omega}}a\widetilde{U}(0)\right]\widetilde{P}[1-a\widetilde{U}(0)\tau]^{-1}\widetilde{U}(0)\right\}\right\} \tag{20a}$$

where $\tau\equiv\tau(t)$ is given by (16),

$$\widetilde{\chi}(\tau) = \sum_{n=1}^{N}\left[\left(\frac{\widetilde{\Omega}_n^2}{\widetilde{\Omega}^2}\right)\frac{\widetilde{\Omega}\cos(\widetilde{\Omega}\tau)-\sin(\widetilde{\Omega}\tau)az_n(0)}{\widetilde{\Omega}[1-az_n(0)\tau]}\right], \tag{20b}$$

$$\widetilde{q}(\tau) = \sum_{n=1}^{N}\left[\left(\frac{\widetilde{\Omega}_n^2}{\widetilde{\Omega}^2}\right)\frac{[1-\cos(\widetilde{\Omega}\tau)][1+az_n(0)\tau]-\widetilde{\Omega}\tau\sin(\widetilde{\Omega}\tau)}{1-az_n(0)\tau}\right], \tag{20c}$$

$$\widetilde{r}(\tau) = \left(\frac{\widetilde{\Omega}}{a}\right)\sum_{n=1}^{N}\left[\left(\frac{\widetilde{\Omega}_n^2}{\widetilde{\Omega}^2}\right)\frac{\widetilde{\Omega}\sin(\widetilde{\Omega}\tau)-2[1-\cos(\widetilde{\Omega}\tau)]az_n(0)}{\widetilde{\Omega}[1-az_n(0)\tau]}\right], \tag{20d}$$

the diagonal *$N\otimes N$ matrix $\widetilde{U}(0)$ is given in terms of the initial values of the coordinates z_n by the simple formula*

$$\widetilde{U}(0) = \mathrm{diag}[z_n(0)], \tag{20e}$$

and the dyadic *$N\otimes N$ matrix $\widetilde{P}$* is *defined as follows:*

$$\widetilde{P}_{nm} = \frac{\widetilde{\Omega}_n \widetilde{\Omega}_m}{\widetilde{\Omega}^2}. \tag{20f}$$

In these formulas the scalars $\widetilde{\Omega}_n$ *and* $\widetilde{\Omega}$ *are defined in terms of the initial data as follows:*

$$\widetilde{\Omega}_n = \{a[\dot{z}_n(0) - i\omega z_n(0) - a z_n^2(0)]\}^{1/2}, \tag{20g}$$

$$\widetilde{\Omega}^2 = a\sum_{n=1}^{N} (\dot{z}_n(0) - i\omega z_n(0) - a z_n^2(0)) = \sum_{n=1}^{N} \widetilde{\Omega}_n^2, \tag{20h}$$

so that the dyadic $N \otimes N$ *matrix* $\widetilde{P}$ *is actually a* projector, $\widetilde{P}^2 = \widetilde{P}$.

The validity of *Proposition 2* is a simple consequence of *Proposition 1*, because the equations of motion (4) of the *isochronous* model are related to those of the previous model (3) by the simple relation (the so-called "trick")

$$z_n(t) = \exp(i\omega t)\zeta_n(\tau) \tag{21}$$

with τ related to t via (16), entailing the following relations among the respective initial data:

$$\zeta_n(0) = z_n(0), \quad \dot{\zeta}_n(0) = \dot{z}_n(0) - i\omega z_n(0). \tag{22}$$

Since clearly the matrix $\widetilde{U}(t)$ is periodic in t with period T,

$$\widetilde{U}(t+T) = \widetilde{U}(t) \tag{23a}$$

(see (20a) with (16) and (5)), the set $\{z_n(t)\}$ of its N eigenvalues is as well *periodic* with the same period; this does not necessarily entail that each of its individual eigenvalues is *periodic* with this period, since during the time evolution (which now necessarily takes place in the *complex* z-plane) an exchange of eigenvalues might occur. But this mechanism can only increase the periodicity of each individual eigenvalue by an integer factor not exceeding $N!$ (indeed, generally much smaller[5]). Hence we conclude that the *generic* solution of the *isochronous* model (4) is (*nonsingular* and) *completely periodic*,

$$z_n(t + \widetilde{T}) = z_n(t), \tag{23b}$$

with a period $\widetilde{T} = kT$, where k is a positive integer not larger (indeed, generally much smaller[5]) than $N!$ (k depends of course on the particular solution under consideration, but its value does not change for sufficiently small changes of the initial data, hence the set of initial data yielding the same period is *open*, with full dimensionality in phase space). The only *nonperiodic* solutions are the *nongeneric* ones that obtain for the *special* set of initial data that cause a "particle collision," namely the coincidence at some time $t_c < T$ of two or more particle positions $z_n(t)$, or equivalently of two or more eigenvalues of the matrix $\widetilde{U}(t_c)$, see (20); the surfaces in phase space on which such special sets of initial data live separate the sets of initial data yielding different periods.

C. Equilibrium configurations in the many-body case

Let us now report our main findings concerning the *equilibrium configurations* of these models, which are of course always defined up to arbitrary permutations of the N equal particles (this obvious *caveat* will not be repeated in the following). But before reporting these findings let us emphasize that here we only consider "genuine" equilibrium configurations, characterized by the requirement that no two particles sit at the same location. Let us also note that, for the first model, (3), clearly any particle sitting initially at the origin with vanishing velocity (i.e., with $\zeta_n(0) = \dot{\zeta}_n(0) = 0$) always remains there without influencing at all the motion of the other particles; and, for the *isochronous* model (4), this is as well true both for a particle sitting at the origin (i.e., with

$z_n(0)=\dot{z}_n(0)=0$) and for a particle sitting at the point $-i\omega/a$ (i.e., with $z_n(0)=-i\omega/a$ and $\dot{z}_n(0)=0$). In the following we also take account of such particles when discussing the equilibrium configurations, but, consistent with the above-mentioned definition of "genuine" equilibrium configurations, we allow at most one particle to sit in such a position.

The first model, (3), has no (genuine) equilibrium configurations for $N\geqslant 5$. For $N=2$ there is only the trivial configuration $\zeta_1=0$, $\zeta_2=\bar{\zeta}$ with $\bar{\zeta}$ an *arbitrary* constant. For $N=3$ at equilibrium its three coordinates ζ_n take three values out of the following four:

$$\tilde{\zeta}_k=\eta\exp\left(\frac{2\pi ki}{3}\right),\quad k=1,2,3 \text{ and } \bar{\zeta}_4=0. \tag{24}$$

For $N=4$ at equilibrium the four coordinates ζ_n take these four values. Here and in the following η is an *arbitrary* (but *nonvanishing*) constant.

To describe the phenomenology of the (genuine) equilibrium configurations of the second, *isochronous* model (4) it is convenient to identify them as follows:

$$z_n(t)=\left(\frac{\omega}{ia}\right)u_n,\quad \dot{z}_n(t)=0,\quad u_n\neq u_m. \tag{25}$$

For $N=2$ there are only two equilibrium configurations: $u_1=0$, $u_2=1$, respectively,

$$u_{1,2}=\frac{3\pm i\sqrt{3}}{2}. \tag{26}$$

For $N=3$, a one-parameter set of equilibrium configurations is

$$u_k(\eta)=1+\eta\exp\left(\frac{2\pi ik}{3}\right),\quad k=1,2,3, \tag{27}$$

with η an *arbitrary* (but *nonvanishing*, $\eta\neq 0$) constant; and there is an additional equilibrium configuration, $u_{1,2}=(3\pm i\sqrt{3})/2$, $u_3=1$. (Note that the configuration with one particle at the origin, say $u_3(\eta)=0$, is included in (27) with $\eta=-1$). For $N=4$ there are *two* one-parameter sets of equilibrium configurations, $u_k=u_k(\eta)$, $k=1,2,3$ (see (27)) and $u_4=0$ and $u_4=1$, respectively (and η again *arbitrary* but *nonvanishing*, $\eta\neq 0$, with, in the first case, the additional restriction $\eta\neq-\exp(-2\pi ik/3)$, $k=1,2,3$, to exclude that any one of the three numbers $u_k(\eta)$ vanish). For $N=5$ there is only a single one-parameter set of equilibrium configurations, $u_k=u_k(\eta)$, $k=1,2,3$, $u_4=0$, $u_5=1$, with $u_k(\eta)$ defined as above, see (27) (and η again *arbitrary* except for the *two* restrictions $\eta\neq 0$ and $\eta\neq-\exp(-2\pi ik/3)$, $k=1,2,3$, to exclude that any one of the three numbers $u_k(\eta)$ vanish or be unity). And for $N>5$ there are no (genuine) equilibrium configurations.

Let us finally note that the equations of motion (4) for the N *complex* dependent variables $z_n(t)$ can be reformulated as *real* and *covariant* Newtonian equations describing the motion of N equal unit-mass point particles moving in the horizontal plane, by introducing as dependent variables the N vectors $\vec{r}_n\equiv\vec{r}_n(t)$ related to the *complex* numbers $z_n(t)$ by the relations $\vec{r}_n(t)\equiv(\mathrm{Re}[z_n(t)],\mathrm{Im}[z_n(t)],0)$, and the constant vector $\vec{a}$ related to the *complex* constant a (see (4)) by the relation $\vec{a}\equiv(\mathrm{Re}[a],-\mathrm{Im}[a],0)$ (note the minus sign in the second component!). All these vectors are formally written as three vectors, but they of course describe motions taking place in the horizontal plane; the three-dimensional notation is convenient to exhibit the covariance of these equations of motion (via the additional introduction of the unit vector $\hat{k}\equiv(0,0,1)$ orthogonal to the horizontal plane). The resulting equations—whose explicit display is left as a trivial if tedious exercise for the diligent reader—are of course *not* invariant under rotations in the plane, since the vector $\vec{a}$ identifies a preferred direction there. They can be made *rotation-invariant* via the following gimmick (see above): consider the vector $\vec{a}$ in these equations as an additional (hence formally time-dependent) variable, and then complement the Newtonian equations of mo-

tion for the N dependent variables $\vec{r}_n(t)$ with the following (also *rotation-invariant*, if quite trivial) equation of motion: $\dot{\vec{a}}=0$.

III. PROOFS, AND SOME OTHER RESULTS

In the following we prove the findings reported in Sec. II, we discuss some of them in more detail than was done there, and we also provide some additional results.

A. Solution of the equations of motion

Let the $N\otimes N$ matrix $U\equiv U(t)$ satisfy the first-order matrix ODE

$$\dot{U}=f(U)+C, \tag{28}$$

where C is a constant $N\otimes N$ matrix and the function $f(u)$ is scalar, namely the matrix $f(U)$ depends on no other matrix besides U, entailing that, for any invertible $N\otimes N$ matrix R,

$$Rf(U)R^{-1}=f(RUR^{-1}). \tag{29}$$

Let us assume now that $U(t)$ is diagonalized by the matrix $R(t)$,

$$U=RZR^{-1}, \quad Z=\mathrm{diag}(\zeta_n), \tag{30}$$

so that the N quantities $\zeta_n\equiv\zeta_n(t)$ are the N eigenvalues of the matrix $U(t)$. Note that, without spoiling the validity of (30), the matrix R could be replaced by the matrix

$$\widetilde{R}=RD, \tag{31}$$

with $D\equiv D(t)$ an *arbitrary diagonal* matrix. Let us also introduce the $N\otimes N$ matrix $\Gamma(t)$ by setting

$$C=R\Gamma R^{-1}, \quad \Gamma=R^{-1}CR. \tag{32}$$

Clearly the relations (30) and (32) entail

$$\dot{U}=R\{\dot{Z}+[M,Z]\}R^{-1}, \quad \dot{C}=R\{\dot{\Gamma}+[M,\Gamma]\}R^{-1}, \tag{33}$$

where we introduced the $N\otimes N$ matrix $M(t)$ by setting

$$M=R^{-1}\dot{R}. \tag{34}$$

Note that the replacement, in this definition of M, of R with $\widetilde{R}$ (see (31)) entails a corresponding replacement of M with

$$\widetilde{M}=\widetilde{R}^{-1}\dot{\widetilde{R}}=D^{-1}MD+D^{-1}\dot{D}. \tag{35}$$

Hence the matrix M is defined up to the addition of the *arbitrary diagonal* matrix $D^{-1}\dot{D}$, which implies that its *diagonal* elements can be assigned *arbitrarily*, provided of course the *off-diagonal* elements are then properly adjusted, see (35).

The original matrix ODE (28) entails, via (33) and (30),

$$\dot{Z}+[M,Z]=\Gamma+f(Z), \tag{36a}$$

and the time-independence of the matrix C entails, via (33) and (32),

$$\dot{\Gamma}+[M,\Gamma]=0. \tag{36b}$$

Let us now write out separately, componentwise, the *diagonal* and *off-diagonal* parts of these two matrix equations (36) (also indicating, for notational convenience, with γ_n and μ_n, respec-

tively, the diagonal elements of the matrices Γ and M, $\gamma_n \equiv \Gamma_{nn}$, $\mu_n \equiv M_{nn}$):

$$\dot{\zeta}_n = \gamma_n + f(\zeta_n), \tag{37a}$$

$$-M_{nm}(\zeta_n - \zeta_m) = \Gamma_{nm}, \quad n \neq m, \tag{37b}$$

$$\dot{\gamma}_n = \sum_{m=1, m\neq n}^{N} (\Gamma_{nm} M_{mn} - \Gamma_{mn} M_{nm}), \tag{37c}$$

$$\dot{\Gamma}_{nm} = -(\mu_n - \mu_m)\Gamma_{nm} + (\gamma_n - \gamma_m) M_{nm} + \sum_{\ell=1, \ell\neq m,n}^{N} (\Gamma_{n\ell} M_{\ell m} - \Gamma_{\ell m} M_{n\ell}), \quad n \neq m. \tag{37d}$$

The first *two* of these four equations can be immediately solved for γ_n and M_{nm}, respectively, whereby the last *two* of these four equations become

$$\ddot{\zeta} = \dot{\zeta}_n f'(\zeta_n) + 2 \sum_{m=1, m\neq n}^{N} \frac{\Gamma_{nm}\Gamma_{mn}}{\zeta_n - \zeta_m}, \tag{38a}$$

$$\dot{\Gamma}_{nm} = -(\mu_n - \mu_m)\Gamma_{nm} - \frac{\{[\dot{\zeta}_n - f(\zeta_n)] - [\dot{\zeta}_m - f(\zeta_m)]\}\Gamma_{nm}}{\zeta_n - \zeta_m} + \sum_{\ell=1, \ell\neq m,n}^{N} \{\Gamma_{n\ell}\Gamma_{\ell m}[(\zeta_n - \zeta_\ell)^{-1} + (\zeta_m - \zeta_\ell)^{-1}]\}, \quad n \neq m. \tag{38b}$$

In (38a) and hereafter the prime appended to a function denotes differentiation with respect to its argument, e.g., $f'(\zeta) \equiv df(\zeta)/d\zeta$.

Let us now set

$$\Gamma_{nm} = \{[\dot{\zeta}_n - g(\zeta_n)][\dot{\zeta}_m - g(\zeta_m)]\}^{1/2} \eta_{nm}, \tag{39}$$

where the quantities $\eta_{nm} \equiv \eta_{nm}(t)$ are new dependent variables (hence this assignment entails no loss of generality), and we reserve the privilege to assign later the function $g(\zeta)$. Insertion of this *ansatz* in (38a) yields

$$\ddot{\zeta}_n = \dot{\zeta}_n f'(\zeta_n) + 2 \sum_{m=1, m\neq n}^{N} \frac{[\dot{\zeta}_n - g(\zeta_n)][\dot{\zeta}_m - g(\zeta_m)]\eta_{nm}\eta_{mn}}{\zeta_n - \zeta_m}, \tag{40a}$$

and its insertion in (38b) yields (via (40a))

$$\frac{\dot{\eta}_{nm}}{\eta_{nm}} + \mu_n - \mu_m - \frac{f(\zeta_n) - g(\zeta_n) - [f(\zeta_m) - g(\zeta_m)]}{\zeta_n - \zeta_m} + \frac{\dot{\zeta}_n[f'(\zeta_n) - g'(\zeta_n)]}{2[\dot{\zeta}_n - g(\zeta_n)]} + \frac{\dot{\zeta}_m[f'(\zeta_m) - g'(\zeta_m)]}{2[\dot{\zeta}_m - g(\zeta_m)]} = \sum_{\ell=1, \ell\neq m,n}^{N} \left\{ [\dot{\zeta}_\ell - g(\zeta_\ell)] \left(\frac{\eta_{n\ell}\eta_{\ell m}}{\eta_{nm}} - 1 \right) [(\zeta_n - \zeta_\ell)^{-1} + (\zeta_m - \zeta_\ell)^{-1}] \right\}, \quad n \neq m. \tag{40b}$$

The system of second-order ODEs (40a) is clearly interpretable as a Newtonian many-body problem, but it contains, in addition to the "particle coordinates" ζ_n, the auxiliary variables η_{nm}, which themselves evolve according to the system of first-order ODEs (40b). Since in this paper we are interested in identifying solvable systems of ODEs interpretable as Newtonian many-body problems *without* additional variables, we now try and see how to get rid of the auxiliary variables

η_{nm}. Clearly a possibility to do so, suggested by the structure of these two systems (40a) and (40b) of ODEs, is to set

$$\eta_{nm}(t) = \frac{\eta_n(t)}{\eta_m(t)}. \tag{41}$$

Via this assignment the auxiliary variables indeed disappear altogether from the first set (40a) of ODEs, which then read

$$\ddot{\zeta}_n = \dot{\zeta}_n f'(\zeta_n) + 2 \sum_{m=1, m\neq n}^{N} \frac{[\dot{\zeta}_n - g(\zeta_n)][\dot{\zeta}_m - g(\zeta_m)]}{\zeta_n - \zeta_m}, \tag{42a}$$

while the second set, (40b), of ODEs becomes

$$\frac{\dot{\eta}_n}{\eta_n} + \mu_n - \left(\frac{\dot{\eta}_m}{\eta_m} + \mu_m\right) = \frac{f(\zeta_n) - g(\zeta_n) - [f(\zeta_m) - g(\zeta_m)]}{\zeta_n - \zeta_m} - \frac{\dot{\zeta}_n[f'(\zeta_n) - g'(\zeta_n)]}{2[\dot{\zeta}_n - g(\zeta_n)]}$$

$$- \frac{\dot{\zeta}_m[f'(\zeta_m) - g'(\zeta_m)]}{2[\dot{\zeta}_m - g(\zeta_m)]}, \quad n \neq m. \tag{42b}$$

There now remains to see whether this second set, (42b), of ODEs can be satisfied.

We note first of all that the left-hand sides of these equations, (25), are antisymmetric under the exchange of the two indices n and m, while the right-hand sides are symmetrical. Hence they must both vanish.

The vanishing of the left-hand side is easily achieved, by setting

$$\mu_n(t) = -\frac{\dot{\eta}_n(t)}{\eta_n(t)}, \tag{43}$$

an assignment which is permitted since we are free to choose at our convenience the diagonal elements $\mu_n(t)$ of the matrix $M(t)$, see the remark made earlier (after (35)).

To achieve the vanishing of the right-hand side of (42b) (which is quite overdetermined, especially because the functions f and g are required to be independent of the "velocities" $\dot{\zeta}$) we can take advantage of our freedom to assign the function $g(\zeta)$. This can be conveniently done in two quite different manners.

A first assignment is

$$g(\zeta) = 0, \tag{44}$$

which has the merit to eliminate altogether from (42b) the presence of the "velocities" $\dot{\zeta}_n$ and $\dot{\zeta}_m$. The requirement that the right-hand sides of (42b) vanish yields then the following (apparently still overdetermined, but see the following) set of ODEs for the function $f(z)$:

$$\frac{f(\zeta_n) - f(\zeta_m)}{\zeta_n - \zeta_m} = \frac{f'(\zeta_n) + f'(\zeta_m)}{2}, \quad n \neq m. \tag{45a}$$

It is easily seen that the general solution of this system of ODEs is

$$f(\zeta) = a\zeta^2 + b\zeta + c, \tag{45b}$$

with a, b, and c three *arbitrary* constants. The corresponding version of the original matrix evolution equation (28) reads

$$\dot{U} = aU^2 + bU + c + C. \tag{46a}$$

Without significant loss of generality this matrix ODE can be replaced by its simpler version

$$\dot{U} = aU^2 + C. \tag{46b}$$

which obtains by setting $b=c=0$ in (46a), but clearly could as well be obtained from (46a) by shifting the two $N\otimes N$ matrices U and C by two appropriate *constant* multiples of the $N\otimes N$ *unit* matrix, resulting merely in a shift of all the eigenvalues $\zeta_n(t)$ of the $N\otimes N$ matrix U by a *common constant*, and in a redefinition of the matrix C which in any case does not feature in the system of ODEs (42a). We conclude that the many-body problem yielded by this choice is characterized by the equations of motion

$$\ddot{\zeta}_n = 2a\dot{\zeta}_n\zeta_n + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{\zeta}_n\dot{\zeta}_m}{\zeta_n - \zeta_m}, \tag{47}$$

yielded by (42a) with (44) and with (45b) which takes now the simpler form

$$f(\zeta) = a\zeta^2. \tag{48}$$

But this many-body model, (47), is *not* new (see (2)): its solvability and properties were demonstrated and investigated in Ref. 4, by a technique analogous to that described earlier except that the starting point in that treatment was the second-order matrix ODE

$$\ddot{U} = a(\dot{U}U + U\dot{U}), \tag{49}$$

rather than the matrix ODE (46b). It is indeed plain that these two matrix ODE, (46b) and (49), are equivalent (at least as long as we restrict our consideration to autonomous equations, namely we consider the scalar a and the matrix C to be time-independent, as we always did hitherto).

A second, and in fact more obvious, assignment of the function $g(\zeta)$ which also achieves the vanishing of the right-hand side of (42b) is

$$g(\zeta) = f(\zeta). \tag{50}$$

Hence, by inserting this assignment in (42a), we conclude that the many-body system

$$\ddot{\zeta}_n = \dot{\zeta}_n f'(\zeta_n) + 2\sum_{m=1,m\neq n}^{N} \frac{[\dot{\zeta}_n - f(\zeta_n)][\dot{\zeta}_m - f(\zeta_m)]}{\zeta_n - \zeta_m} \tag{51}$$

is *solvable*, provided the corresponding $N\otimes N$ matrix evolution ODE (28), with an *arbitrary* constant $N\otimes N$ matrix C, is itself *solvable*: indeed our treatment entails that the time evolution of the N "particle coordinates" $\zeta_n(t)$ coincides then with the time evolution of the N eigenvalues of the $N\otimes N$ matrix $U(t)$ (with an appropriate assignment, in terms of the initial data $\zeta_n(0)$, $\dot{\zeta}_n(0)$, of the initial value $U(0)$ of the matrix $U(t)$ and of the constant matrix C: see the following). Let us also point out that a more general choice of the function $g(\zeta)$, also consistent with the vanishing of the right-hand side of (42b), would add an *arbitrary* constant c to the right-hand side of the formula (50); the alert reader will work out the marginal extension of our results entailed by this possibility.

It is remarkable that, to obtain these Newtonian equations of motion, (51), no restriction has been required so far on the function $f(\zeta)$. However, to the best of our knowledge, the *only* case in which the matrix ODE (28) is *solvable* is for the assignment (45b) of the function $f(\zeta)$, and for the reasons explained earlier no significant loss of generality is then caused by restricting this assignment to the form (48). The corresponding many-body problem is then (3). The corresponding version of the matrix ODE is (46b), and it is easy to verify that the solution to the initial-value problem for this matrix ODE is provided by the following formulas:

$$U(t) = a^{-1}[\cos(Ft) - EF^{-1}\sin(Ft)]^{-1}[F\sin(Ft) + E\cos(Ft)], \tag{52a}$$

$$E = aU(0), \tag{52b}$$

$$F^2 = aC. \tag{52c}$$

Note that the expression on the right-hand side of (52a) depends on the matrix F^2 rather than the matrix F, and this provides a justification for the way we wrote the last of these matrix equations, (52c). We now note that, via (30) and (32), the last two equations can be rewritten as follows:

$$E = aR(0)\mathrm{diag}[\zeta_n(0)][R(0)]^{-1}, \tag{53a}$$

$$F^2 = aR(0)\Gamma(0)[R(0)]^{-1}. \tag{53b}$$

Note that to write the last equation we took advantage of the time-independence of the matrix C in order to evaluate it, conveniently, at $t=0$.

We now note that we are free to assign the initial value $R(0)$ of the diagonalizing matrix $R(t)$, hence we make hereafter the convenient choice $R(0)=1$ (not that these make any substantial difference; we are interested in the eigenvalues of the matrix $U(t)$, see (52a), and the presence of the matrix $R(0)$ in (53) amounts merely to a similarity transformation of the matrix $U(t)$, which does not affect its eigenvalues). Using this choice, as well as (37a) and (39) with (50), (48), and (41), we get

$$E = a\ \mathrm{diag}[\zeta_n(0)], \tag{54}$$

$$(F^2)_{nm} = \delta_{nm}a[\dot{\zeta}_n(0) - a\zeta_n^2(0)] + (1-\delta_{nm})a\{[\dot{\zeta}_n - a\zeta_n^2(0)][\dot{\zeta}_m - a\zeta_n^2(0)]\}^{1/2}\frac{\eta_n(0)}{\eta_m(0)}. \tag{55}$$

We now note that we are as well free to assign the initial values $\eta_n(0)$ of the quantities $\eta_n(t)$, hence we make hereafter the convenient choice $\eta_n(0)=1$ (again, this makes no substantial difference, since clearly the presence of these numbers on the right-hand side of (55) only entails a similarity transformation for the matrix $U(t)$).

We thus see that the matrix F^2 is proportional to the *dyadic* matrix P, see (17f)–(17h):

$$F^2 = \Omega^2 P. \tag{56}$$

We now use the following (rather obvious) property of any *dyadic* matrix W:

$$W_{nm} = v_n v_m \tag{57a}$$

entails

$$\varphi(XW) = \varphi(0) + \frac{\varphi(x)-\varphi(0)}{x}XW \tag{57b}$$

with

$$x = \sum_{n,m=1}^{N} v_n x_{nm} v_m. \tag{57c}$$

Here X is an *arbitrary* $N\otimes N$ matrix whose matrix elements are denoted as x_{nm} and $\varphi(x)$ is any scalar function for which these formulas make good sense. We actually use in the following only the special version of these formulas with $W=P$, see (17f)–(17h), and with a *diagonal* matrix X, namely such that $x_{nm}=x_n\ \delta_{nm}$, in which case the definition (57c) takes the simpler form

$$x = \sum_{n=1}^{N}\left(\frac{\Omega_n^2}{\Omega^2}\right)x_n. \tag{57d}$$

In particular for $X=t^2\mathbf{1}$ and $\varphi(x)=\cos(x^{1/2})$, $\varphi(x)=x^{-1/2}\sin(x^{1/2})$, respectively, $\varphi(x)=x^{1/2}\sin(x^{1/2})$ we get from (56) and (60d), respectively,

$$\cos(Ft) = 1 + [\cos(\Omega t) - 1]P, \tag{58a}$$

$$F^{-1}\sin(Ft) = t + \frac{\sin(\Omega t) - \Omega t}{\Omega}P, \tag{58b}$$

$$F\sin(Ft) = \Omega\sin(\Omega t)P. \tag{59}$$

The insertion in (52a) of these expressions, (58), and of (52b), yields the formula

$$U(t) = \left\{1 + [\cos(\Omega t) - 1]P - aU(0)\left[t + \frac{\sin(\Omega t) - \Omega t}{\Omega}P\right]\right\}^{-1} \cdot \left\{U(0)(1 + [\cos(\Omega t) - 1]P) + \frac{\Omega\sin(\Omega t)}{a}P\right\}, \tag{60a}$$

which can be conveniently rewritten as follows:

$$U(t) = [1 - X^{(1)}(t)P]^{-1}[1 - aU(0)t]^{-1}U(0)[1 - X^{(2)}(t)P], \tag{60b}$$

with the two *diagonal* matrices $X^{(1)}(t)$ and $X^{(2)}(t)$ defined as follows:

$$X^{(1)}(t) = [1 - aU(0)t]^{-1}\left[1 - \cos(\Omega t) + \frac{\sin(\Omega t) - \Omega t}{\Omega}aU(0)\right], \tag{60c}$$

$$X^{(2)}(t) = 1 - \cos(\Omega t) - \Omega\sin(\Omega t)[aU(0)]^{-1}. \tag{60d}$$

Next we use again the formula (57b) with (57d) entailing

$$[1 - X^{(1)}(t)P]^{-1} = 1 + \frac{X^{(1)}(t)P}{1 - x^{(1)}(t)} \tag{61a}$$

with

$$x^{(1)}(t) = \sum_{n=1}^{N}\left(\frac{\Omega_n^2}{\Omega^2}\right)\frac{\Omega[1 - \cos(\Omega t)] + [\sin(\Omega t) - \Omega t]a\zeta_n(0)}{\Omega[1 - a\zeta_n(0)t]}, \tag{61b}$$

and we thereby rewrite (60b) as follows:

$$U(t) = X^{(0)}(t) + \widetilde{X}^{(1)}(t)PX^{(0)}(t) - X^{(0)}(t)X^{(2)}(t)P - \widetilde{X}^{(1)}(t)PX^{(0)}(t)X^{(2)}(t)P, \tag{61c}$$

with the *diagonal* matrices $X^{(0)}(t)$ and $\widetilde{X}^{(1)}(t)$ defined as follows:

$$X^{(0)}(t) = [1 - aU(0)t]^{-1}U(0), \tag{61d}$$

$$\widetilde{X}^{(1)}(t) = \frac{X^{(1)}(t)}{1 - x^{(1)}(t)}. \tag{61e}$$

Finally we note that clearly

$$PX^{(0)}(t)X^{(2)}(t)P = \sum_{n=1}^{N}\left(\frac{\Omega_n^2}{\Omega^2}\right)\frac{[1 - \cos(\Omega t)]a\zeta_n(0) - \Omega\sin(\Omega t)}{a[1 - a\zeta_n(0)t]}P \tag{62}$$

and we thereby get from this formula the solution formula (17). *Proposition 1* is thereby proven.

As for *Proposition 2*, the fact that it is a consequence via (21) with (16) of *Proposition 1* was already explained in the preceding section.

B. Equilibrium configurations

Let us discuss first the (genuine) equilibrium configurations of the system of Newtonian equations of motion (3), namely the solutions (with $\overline{\zeta}_n \neq \overline{\zeta}_m$ if $n \neq m$) of the set of N algebraic equations

$$\sum_{m=1,m\neq n}^{N} \frac{(\overline{\zeta}_m)^2}{\overline{\zeta}_n - \overline{\zeta}_m} = 0. \tag{63}$$

It is obvious that there are no genuine equilibrium configurations for $N=2$, so we can hereafter assume that $N \geqslant 3$. Let us then prove first of all that these equations entail

$$\sum_{n=1}^{N} \overline{\zeta}_n = 0. \tag{64}$$

Indeed by summing (63) over n from 1 to N we get

$$0 = \sum_{m,n=1,m\neq n}^{N} \frac{(\overline{\zeta}_m)^2}{\overline{\zeta}_n - \overline{\zeta}_m} = \sum_{m,n=1,m\neq n}^{N} \frac{(\overline{\zeta}_m)^2 - (\overline{\zeta}_n)^2 + (\overline{\zeta}_n)^2}{\overline{\zeta}_n - \overline{\zeta}_m} = \sum_{m,n=1,m\neq n}^{N} (\overline{\zeta}_m + \overline{\zeta}_n) = 2(N-1)\sum_{n=1}^{N} \overline{\zeta}_n, \tag{65}$$

which proves (64).

Introduce then the polynomial of degree N (assuming that it exists)

$$\psi(\zeta) = \prod_{n=1}^{N} (\zeta - \overline{\zeta}_n). \tag{66a}$$

It is then easy to show (or see Eqs. 2.3.3(12) and 2.3.3(15) of Ref. 2) that

$$\zeta\psi'(\zeta) - N\psi(\zeta) = \psi(\zeta)\sum_{n=1}^{N} (\zeta - \overline{\zeta}_n)^{-1}\overline{\zeta}_n, \tag{66b}$$

$$\zeta^2\psi''(\zeta) - N(N-1)\psi(\zeta) = 2\psi(\zeta)\sum_{n=1}^{N} (\zeta - \overline{\zeta}_n)^{-1} \sum_{m=1,m\neq n}^{N} \frac{(\overline{\zeta}_n)^2}{\overline{\zeta}_n - \overline{\zeta}_m}. \tag{66c}$$

We now replace on the right-hand side of the last formula the quantity $(\overline{\zeta}_n)^2$ with $(\overline{\zeta}_n)^2 - (\overline{\zeta}_m)^2 + (\overline{\zeta}_m)^2$, ignore the last of these three terms thanks to (63), and by taking advantage of (64) and (66b) we find that the polynomial $\psi(\zeta)$ must satisfy the linear ODE

$$\zeta^2\psi''(\zeta) - 2(N-2)\zeta\psi'(\zeta) + N(N-3)\psi(\zeta) = 0. \tag{66d}$$

The *general* solution of this equation is (up to a multiplicative constant)

$$\psi(\zeta) = \zeta^{N-3}(\zeta^3 - \eta^3), \tag{66e}$$

with η an *arbitrary* constant. Clearly this polynomial $\psi(\zeta)$ has the root $\overline{\zeta}=0$ with multiplicity $N-3$, and the three roots $\overline{\zeta}_k = \eta \exp(2\pi ik/3)$. And it is plain that these results entail the findings reported in the preceding section.

Let us then turn our attention to the second, *isochronous* system (4). It is easily seen that

insertion of the definition (25) in the equations of motion (4) yields the following set of N algebraic equations for the N numbers u_n:

$$(u_n - u_n^2)\left\{1 - \sum_{m=1,m\neq n}^{N} \frac{u_m - u_m^2}{u_n - u_m}\right\} = 0. \tag{67a}$$

It is clear from these equations that, if the set $\{u_1, u_2, \ldots, u_N\}$ of N numbers u_n provide a solution to the set of N algebraic equations

$$\sum_{m=1,m\neq n}^{N} \frac{u_m - u_m^2}{u_n - u_m} = 1, \tag{67b}$$

with none of the numbers u_n vanishing ($u_n \neq 0$, $n=1,\ldots,N$), then the set $\{u_1, u_2, \ldots, u_N, 0\}$ of $N+1$ numbers u_n provide a solution to the set of $N+1$ algebraic equations which obtain from (67a) by replacing N with $N+1$ as upper limit of the sum and by letting the index n run from 1 to $N+1$ rather than from 1 to N. Likewise, if the N numbers u_n provide a solution to the set of algebraic equations (67b) with none of these numbers u_n being unity ($u_n \neq 1$, $n=1,\ldots,N$), then the set $\{u_1, u_2, \ldots, u_N, 1\}$ of $N+1$ numbers u_n provide a solution to the set of $N+1$ algebraic equations which obtain from (67a) by replacing N with $N+1$ as upper limit of the sum and by letting the index n run from 1 to $N+1$ rather than from 1 to N. And moreover, if the N numbers u_n provide a solution to the set of algebraic equations (67b) with none of these numbers u_n neither vanishing nor being unity ($u_n \neq 0$ and $u_n \neq 1$, $n=1,\ldots,N$), then the set $\{u_1, u_2, \ldots, u_N, 0, 1\}$ of $N+2$ numbers u_n provide a solution to the set of $N+2$ algebraic equations which obtain from (67a) by replacing N with $N+2$ as upper limit of the sum and by letting the index n run from 1 to $N+1$ rather than from 1 to N. Hence, we can now only focus on the system of algebraic equations (67b), and then extend our conclusions about the equilibrium configurations by taking advantage of these observations.

To find all the solution of (67b) (with $u_n \neq u_m$) we note first of all that this system of N algebraic equations entails

$$S \equiv \sum_{n=1}^{N} u_n = \sum_{n=1}^{N} u_n^2, \tag{68}$$

as can be easily seen by multiplying (67b) by $u_n - u_n^2$, then summing over the index n from 1 to N and noting that thereby the double sum on the left-hand side vanishes due to the antisymmetry of the summand under the exchange of the two dummy indices m and n.

Next we prove that

$$S = \frac{N(N+1)}{2(N-1)}. \tag{69}$$

To obtain this result we sum (67b) from 1 to N over the index n, and use the identities

$$\sum_{m,n=1,m\neq n}^{N} \frac{u_m}{u_n - u_m} = -\frac{1}{2} \sum_{m,n=1,m\neq n}^{N} \frac{u_n - u_m}{u_n - u_m} = -\frac{N(N-1)}{2}, \tag{70a}$$

$$\sum_{m,n=1,m\neq n}^{N} \frac{u_m^2}{u_n - u_m} = -\frac{1}{2} \sum_{m,n=1,m\neq n}^{N} \frac{u_n^2 - u_m^2}{u_n - u_m} = -\sum_{m,n=1,m\neq n}^{N} u_n = -S(N-1). \tag{70b}$$

Next, we multiply by u_n the relation (67b), and again sum from 1 to N over the index n. Now we use the identities

$$\sum_{m,n=1,m\neq n}^{N} \frac{u_n u_m}{u_n - u_m} = 0, \tag{71a}$$

$$\sum_{m,n=1,m\neq n}^{N} \frac{u_n u_m^2}{u_n - u_m} = -\frac{1}{2} \sum_{m,n=1,m\neq n}^{N} \frac{u_n u_m (u_n - u_m)}{u_n - u_m} = -\frac{1}{2} \sum_{m,n=1,m\neq n}^{N} u_n u_m = \frac{S - S^2}{S}. \tag{71b}$$

Note that to obtain the second of these identities we used in the end both formulas (68). In this manner we obtain the relation

$$S(S-3) = 0, \tag{72}$$

which implies that $S=0$ or $S=3$. The first possibility is clearly incompatible with (69). So we conclude that $S=3$, and, via (69), we then conclude that the only values of N for which the set of algebraic equations (67b) can have solutions are $N=2$ and $N=3$. And we can now rewrite the relations (68) in the more explicit form

$$\sum_{n=1}^{N} u_n = \sum_{n=1}^{N} u_n^2 = 3. \tag{73}$$

Using these two formulas as well as (67b) we easily conclude that for $N=2$ the only solution of these equations is (26).

Likewise, for $N=3$, from these equations and one of the equations (67b) one easily gets the solution (27).

Let us also mention that another, perhaps more elegant, route to get all these results is via the same technique used earlier (or see Sec. 2.3.3 of Ref. 2), implying that the solutions u_n of (67b) are the zeros of the polynomial $y(u)$ of degree N (if it exists) that satisfies the ODE

$$uy'' - 2(N-S)y' = u^2 y'' + 2(2-N)uy' + N(N-3)y. \tag{74}$$

In particular, for $S=3$ and for $N=2$ this ODE becomes simply

$$uy'' + 2y' = u^2 y'' - 2y, \tag{75a}$$

and its polynomial solution is (up to a multiplicative constant)

$$y(u) = u^2 - 3u + 3, \tag{75b}$$

and the two zeros of this polynomial are clearly given by (26). Likewise, for $S=3$ and for $N=3$ this ODE, (74), becomes simply

$$uy'' = u^2 y'' - 2uy', \tag{76a}$$

which clearly has (up to a multiplicative constant) the general solution

$$y(u) = (u-1)^3 - \eta^3, \tag{76b}$$

with η an arbitrary constant, implying that its three zeros are indeed given by (27).

IV. OTHER VERSIONS OF THESE SOLVABLE MODELS

In this section we provide other versions of the solvable model (3) and of its *isochronous* variant (4).

The idea is to introduce the time-dependent monic polynomial $\varphi(\zeta,t)$, of degree N in the variable ζ, that has the N zeros $\zeta_n(t)$, and to then consider the time evolution of its N coefficients $b_m(t)$:

$$\varphi(\zeta,t)=\prod_{n=1}^{N}[\zeta-\zeta_n(t)]=\zeta^N+\sum_{m=1}^{N}b_m(t)a^{-m}\zeta^{N-m}. \tag{77}$$

Indeed it is rather easily seen—by using techniques analogous to those used in the preceding section (or see again Sec. 2.3.3 of Ref. 2)—that, if the zeros $\zeta_n(t)$ evolve according to the Newtonian system of ODEs (3), the polynomial $\varphi(\zeta,t)$ evolves according to the second-order PDE

$$\begin{aligned}&\varphi_{tt}+2a\zeta^2\varphi_{\zeta t}+a^2\zeta^4\varphi_{\zeta\zeta}+2[b_1-(N-1)a\zeta]\varphi_t+2a\zeta^2[b_1-(N-2)a\zeta]\varphi_\zeta\\&\quad+[2b_2-2(N-1)ab_1\zeta+N(N-3)a^2\zeta^2]\varphi=0.\end{aligned} \tag{78}$$

Here and throughout subscripted variables denote partial differentiations, e.g., $\varphi_{\zeta t}\equiv\partial^2\varphi(\zeta,t)/\partial\zeta\partial t$.

Clearly this PDE entails that the N coefficients $b_m(t)$ evolve according to the following system of N ODEs:

$$\ddot{b}_m-2m\dot{b}_{m+1}+(m+2)(m-1)b_{m+2}=-2b_1(\dot{b}_m-mb_{m+1})-2b_2b_m, \tag{79a}$$

supplemented by the boundary conditions

$$b_{N+1}=b_{N+2}=0. \tag{79b}$$

Let us recall that, according to the above-announced convention, the index m in (79a) runs from 1 to N (actually (79a) is identically satisfied also for $m=0$, if one sets $b_0=1$, consistently with (77)).

The solvability of this nonlinear system of ODEs is of course implied by the solvability (see *Proposition 1*) of the system (3), since the relation (77) entails that the coefficients b_m can be expressed in terms of the zeros ζ_n,

$$b_1=-a\sum_{n=1}^{N}\zeta_n,\quad b_2=\frac{1}{2}\left(b_1^2-a^2\sum_{n=1}^{N}\zeta_n^2\right),\ \dots\ . \tag{80}$$

Hence, for instance,

$$b_1(t)=-a\ \mathrm{trace}[U(t)],\quad b_N(t)=(-a)^N\det[U(t)], \tag{81}$$

where the $N\otimes N$ matrix $U(t)$ is given by (17)—with the two constant $N\otimes N$ matrices $U(0)$ and C, as well as the scalar Ω, expressed of course via the initial values $b_m(0)$, $\dot{b}_m(0)$ through the explicit formulas that relate the initial values of the N zeros and of their time-derivatives, $\zeta_n(0)$ and $\dot{\zeta}_n(0)$, to these initial values $b_m(0)$, $\dot{b}_m(0)$, see (77) (at $t=0$) and the following formula (at $t=0$) that obtains by differentiating (77) and equates two polynomials in ζ of degree $N-1$:

$$\varphi_t(\zeta,t)=-\varphi(\zeta,t)\sum_{n=1}^{N}[\zeta-\zeta_n(t)]^{-1}\dot{\zeta}_n(t)=\sum_{m=1}^{N}\dot{b}_m(t)a^{-m}\zeta^{N-m}. \tag{82}$$

The fact that the nonlinear system (79) is *solvable* (namely, that its solution can be in principle obtained by merely algebraic operations) is a nontrivial result (up to the observation that all correct mathematical findings are in some sense trivial—after their validity has been proven!). Note that the first ODE of this system, namely that corresponding to $m=1$,

$$\ddot{b}_1-2\dot{b}_2=-2b_1\dot{b}_1, \tag{83a}$$

can be integrated once, yielding

$$b_2 = \tfrac{1}{2}(\dot{b}_1 + b_1^2 + \alpha^2), \tag{83b}$$

with α^2 an arbitrary constant. But, even for $N=2$, the next equation (for $m=2$) of this system,

$$\ddot{b}_2 = -2b_1\dot{b}_2 - 2b_2^2, \tag{84a}$$

which via (83b) becomes the following third-order ODE for the single dependent variable $b_1(t) \equiv \theta(t)$,

$$\dddot{\theta} + 4\ddot{\theta}\theta + 3\dot{\theta}^2 + 6\theta^2\dot{\theta} + \theta^4 + 2\alpha^2(\dot{\theta} + \theta^2) + \alpha^4 = 0, \tag{84b}$$

does not look trivially integrable (even just once, let alone three times!). Indeed the fact that this ODE admits the explicit solution

$$\begin{aligned}\theta(t) = &\left(\left\{\theta(0) + \frac{1}{2}[\theta^2(0) + \dot{\theta}(0) + \alpha^2]t\right\}\cos(\alpha t) + \frac{1}{2}\{\theta^2(0) + \dot{\theta}(0) - \alpha^2 + [\ddot{\theta}(0) + 3\dot{\theta}(0)\theta(0) + \theta^3(0)\right.\\ &\left. + \alpha^2\theta(0)]t\}\frac{\sin(\alpha t)}{\alpha}\right)\cdot\left(\left\{1 - \frac{1}{2\alpha^2}[\ddot{\theta}(0) + 3\dot{\theta}(0)\theta(0) + \theta^3(0) + \alpha^2\theta(0)]t\right\}\cos(\alpha t)\right.\\ &\left. + \frac{1}{2\alpha^2}\{\ddot{\theta}(0) + 3\dot{\theta}(0)\theta(0) + \theta^3(0) + 3\alpha^2\theta(0) + [\theta^2(0) + \dot{\theta}(0) + \alpha^2]\alpha^2 t\}\frac{\sin(\alpha t)}{\alpha}\right)^{-1}\end{aligned} \tag{84c}$$

is remarkable, as the diligent reader who tries and verifies this fact will note (at least if he or she tries to do so without any computer assistance).

An analogous variant of the *isochronous* system (4) leads to the autonomous system of ODEs

$$\begin{aligned}&\ddot{c}_m - i(2m+1)\omega\dot{c}_m - 2m\dot{c}_{m+1} - \omega^2 m(m+1)c_m + 2im(m+1)\omega c_{m+1} + (m+2)(m-1)c_{m+2}\\ &\quad = -2c_1(\dot{c}_m - im\omega c_m - mc_{m+1}) - 2c_2c_m,\end{aligned} \tag{85a}$$

with the boundary conditions

$$c_{N+1} = c_{N+2} = 0, \tag{85b}$$

which might just as well be obtained by inserting the *ansatz*

$$c_m(t) = \exp(im\omega t)b_m(\tau), \quad \tau = \frac{\exp(i\omega t) - 1}{i\omega}, \tag{86}$$

in (79). This of course implies that this system of ODEs, (85a), is just as *solvable* as the system of ODEs for the coefficients $b_m(t)$, see (79) and, e.g., (81); moreover *all* the solutions $c_m(t)$ of this system of N coupled ODEs, (85a), are clearly *periodic* with period T, see (5), $c_m(t+T) = c_m(t)$.

V. BEHAVIOR NEAR THE EQUILIBRIUM CONFIGURATIONS, AND SOME DIOPHANTINE RELATIONS

In the following we discuss the behavior of the *isochronous* system (4), and of its variant (85), in the neighborhood of the respective equilibrium configurations, and we thereby derive some amusing *diophantine* relations.

To get the linearized equations of motion describing the motion of the *isochronous* system (4) in the neighborhood of its equilibrium configuration we set

$$z_n(t) = \left(\frac{\omega}{ia}\right)u_n + \varepsilon w_n(t), \tag{87}$$

where the numbers u_n characterize the equilibrium configurations, see (25), and ε is a small parameter. We thereby obtain the following linearized equations of motion:

$$\ddot{\underline{w}} + i\omega\underline{\Gamma}\,\dot{\underline{\omega}} + \omega^2\underline{\Lambda}\underline{w} = 0, \tag{88}$$

where $\underline{w} \equiv (w_1 \ldots, w_N)$ indicates of course an N-vector and the two $N \otimes N$ matrices $\underline{\Gamma}$ and $\underline{\Lambda}$ are defined as follows:

$$\Gamma_{nm} = \delta_{nm}\left[-3 + 2u_n + 2\sum_{\ell=1,\ell\neq n}^{N}\frac{(u_\ell - u_\ell^2)}{u_n - u_\ell}\right] + (1-\delta_{nm})\frac{2(u_n - u_n^2)}{u_n - u_m}, \tag{89}$$

$$\Lambda_{nm} = 2\delta_{nm}\left[2u_n - 1 + \sum_{\ell=1,\ell\neq n}^{N}\frac{(u_\ell - 2u_\ell u_n + u_n^2)(u_\ell - 1)u_\ell}{(u_n - u_\ell)^2}\right] + (1-\delta_{nm})\frac{2u_n(u_n - 2u_m u_n + u_m^2)(1-u_n)}{(u_n - u_m)^2}. \tag{90}$$

Here and always in the following $\delta_{nm} \equiv \delta_{n,m}$ is the usual Kronecker symbol.

The general solution of the linear system of ODEs (88) reads

$$\underline{w}(t) = \sum_{m=1}^{2N}\alpha_m \exp(i\lambda_m \omega t)\underline{v}^{(m)}, \tag{91}$$

where the $2N$ constants α_n are *arbitrary* and the $2N$ numbers λ_m respectively the $2N$ constant N-vectors $\underline{v}^{(m)}$ are the eigenvalues respectively the eigenvectors of the following eigenvalue problem:

$$[-\lambda_m^2\underline{1} - \lambda_m\underline{\Gamma} + \underline{\Lambda}]\underline{v}^{(m)} = 0, \quad m = 1, \ldots, 2N. \tag{92}$$

Hence the eigenvalues λ_m are the $2N$ roots of the following polynomial equation (of degree $2N$ in λ):

$$D^{(N)}(\lambda) \equiv \det[\lambda^2\underline{1} + \lambda\underline{\Gamma} - \underline{\Lambda}] = 0. \tag{93}$$

But the *exact* solution of the *isochronous* system (4) is *completely periodic* with period T, see (5), hence the same property of isochronicity must be shared by its behavior in the neighborhood of the equilibrium configurations. We therefore conclude that *all* the roots of this algebraic equation must be *integers*. Later we display the corresponding *diophantine equations*.

Analogous results obtain by applying the same approach to the version (85) of our *isochronous* system. To get them we set in (85)

$$c_m(t) = (-i\omega)^m[a_m + \varepsilon\gamma_m(t)], \tag{94}$$

where the N constants a_m satisfy the N algebraic equations

$$-m(m+1)a_m + 2m(m+1)a_{m+1} - (m+2)(m-1)a_{m+2} = 2ma_1(a_m - a_{m+1}) + 2a_2a_m, \tag{95}$$

which obtain (to the zeroth order in ε) by inserting (94) in (85).

Likewise, to the first order in ε, we get the following *linear* system of N equations of motion:

$$\ddot{\gamma}_m - i(2m+1)\omega\dot{\gamma}_m + 2im\omega\dot{\gamma}_{m+1} - 2i\omega a_1\dot{\gamma}_m - m(m+1)\omega^2\gamma_m + 2m(m+1)\omega^2\gamma_{m+1} - 2m\omega^2 a_1\gamma_m - (m^2+m-2)\omega^2\gamma_{m+2} + 2m\omega^2 a_1\gamma_{m+1} - 2\omega^2 a_2\gamma_m - 2m\omega^2 a_m\gamma_1 + 2m\omega^2 a_{m+1}\gamma_1 - 2\omega^2 a_m\gamma_2 = 0, \tag{96a}$$

with the boundary condition

$$\gamma_{N+1}(t) = \gamma_{N+2}(t) = 0. \tag{96b}$$

Equivalently this system of ODEs reads

$$\ddot{\underline{\gamma}} + i\omega \underline{M}\,\dot{\underline{\gamma}} + \omega^2 \underline{L}\,\underline{\gamma} = 0 \tag{97}$$

with the two $N \otimes N$ matrices $\underline{M}$ and $\underline{L}$ defined as follows:

$$M_{nm} = -(2n+1)\delta_{n,m} + 2n\delta_{n+1,m} - 2a_1\delta_{n,m} \tag{98}$$

$$\begin{aligned} N_{nm} = {} & -n(n+1)\delta_{n,m} + 2n(n+1)\delta_{n+1,m} - 2na_1\delta_{n,m} - (n^2+n-2)\delta_{n+2,m} + 2na_1\delta_{n+1,m} - 2a_2\delta_{n,m} \\ & - 2na_n\delta_{1,m} + 2na_{n+1}\delta_{1,m} - 2a_n\delta_{2,m}. \end{aligned} \tag{99}$$

The general solution of this system reads

$$\underline{\gamma}(t) = \sum_{m=1}^{2N} \beta_m \exp(i\lambda_m \omega t)\underline{\mu}^{(m)}, \tag{100}$$

where the $2N$ constants β_n are *arbitrary* and the $2N$ numbers λ_m respectively the $2N$ constant N-vectors $\underline{v}^{(m)}$ are the eigenvalues respectively the eigenvectors of an eigenvalue problem that clearly entails,

$$\widetilde{D}^{(N)}(\lambda) \equiv \det[\lambda^2 \underline{1} + \lambda \underline{M} - \underline{L}] = 0. \tag{101}$$

As indicated by our notation, the eigenvalues λ_m coincide of course with those defined just above; therefore, by the same token this polynomial equation of degree $2N$ in λ must have a *diophantine* character (i.e., integer roots). The corresponding results are exhibited in the following.

Equilibrium configurations and diophantine relations. In the following formulas the symbols $D_j^{(N)}$ and $\widetilde{D}_j^{(N)}$ denote the determinants (93) and (101), respectively with the index j distinguishing (if need be) different equilibrium configuration.

For $N=2$ to the *first* equilibrium configuration

$$u_1 = 0, \quad u_2 = 1; \quad a_1 = -1, \quad a_2 = 0, \tag{102a}$$

there correspond the *diophantine* equations

$$\begin{aligned} D_1^{(2)}(\lambda) \equiv \det\begin{pmatrix} (\lambda-1)(\lambda-2) & 0 \\ 0 & (\lambda+1)(\lambda-2) \end{pmatrix} = \widetilde{D}_1^{(2)}(\lambda) \equiv \det\begin{pmatrix} (\lambda+1)(\lambda-2) & 2(\lambda-2) \\ 0 & (\lambda-1)(\lambda-2) \end{pmatrix} \\ = \lambda^4 - 4\lambda^3 + 3\lambda^2 + 4\lambda - 4 = (\lambda-1)(\lambda+1)(\lambda-2)^2. \end{aligned} \tag{102b}$$

And to the *second* equilibrium configuration,

$$u_{1,2} = \frac{3 \pm i\sqrt{3}}{2}; \quad a_1 = -3, \quad a_2 = 3, \tag{103a}$$

there corresponds the *diophantine* equations

$$\begin{aligned} D_2^{(2)}(\lambda) \equiv \det\begin{pmatrix} \lambda^2 + \lambda(i\sqrt{3}+2) - 2 & -2(\lambda - i\sqrt{3}+1) \\ -2((\lambda + i\sqrt{3}+1)) & \lambda^2 + \lambda(-i\sqrt{3}+2) - 2 \end{pmatrix} = \widetilde{D}_2^{(2)}(\lambda) \\ \equiv \det\begin{pmatrix} (\lambda+5)(\lambda-2) & 2(\lambda-2) \\ 12 & \lambda^2+\lambda+6 \end{pmatrix} = P_4(\lambda). \end{aligned} \tag{103b}$$

Here and in the following

$$P_4(\lambda) \equiv \lambda^4 + 4\lambda^3 - \lambda^2 - 16\lambda - 12 = (\lambda-2)(\lambda+3)(\lambda+2)(\lambda+1). \tag{104}$$

For $N=3$ to the one-parameter set of equilibrium configurations

$$u_k(\eta) = 1 + \eta \exp\left(\frac{2\pi i}{3}k\right), \quad k = 1,2,3,$$
$$a_1 = -3, \quad a_2 = 3, \quad a_3 = -\eta^3 - 1, \tag{105a}$$

there correspond the following *diophantine* equations:

$$D_1^{(3)}(\lambda) \equiv \det[\underline{H}] = \tilde{D}_1^{(3)}(\lambda) \equiv \det\begin{pmatrix} (\lambda+5)(\lambda-2) & 2(\lambda-2) & 0 \\ 4(\eta^3+4) & \lambda^2+\lambda+6 & 4\lambda \\ -6(\eta^3+1) & -2(\eta^3+1) & \lambda(\lambda-1) \end{pmatrix}$$
$$= \lambda^6 + 3\lambda^5 - 5\lambda^4 - 15\lambda^3 + 4\lambda^2 + 12\lambda = \lambda(\lambda-1)P_4(\lambda). \tag{105b}$$

Here and in the following

$$\underline{H}(\lambda,\eta) \equiv \begin{pmatrix} h_1(\lambda,\eta) & h_{12}(\lambda,\eta) & h_{13}(\lambda,\eta) \\ h_{21}(\lambda,\eta) & h_2(\lambda,\eta) & h_{23}(\lambda,\eta) \\ h_{31}(\lambda,\eta) & h_{32}(\lambda,\eta) & h_3(\lambda,\eta) \end{pmatrix}, \tag{106a}$$

$$h_k(\lambda,\eta) \equiv \lambda^2 + \lambda\left[1 + 2\eta\exp\left(\frac{2i\pi k}{3}\right)\right] + \frac{2}{3}\left[\eta\exp\left(\frac{2i\pi k}{3}\right) + 1\right]\left[\eta\exp\left(\frac{2i\pi k}{3}\right) - 2\right], \tag{106b}$$

$$h_{jk}(\lambda,\eta) \equiv -\frac{2}{3}\exp\left(\frac{is_{jk}\pi}{6}\right)\left[\eta\exp\left(\frac{2i\pi j}{3}\right) + 1\right] \cdot \left\{\sqrt{3}\lambda + \exp\left(\frac{is_{jk}\pi}{6}\right)\left[\sqrt{7}\eta\exp\left[i\left(\frac{2\pi k}{3} - s_{jk}\varphi\right)\right] + 1\right]\right\} \tag{106c}$$

where

$$\exp(i\varphi) = \frac{5}{2\sqrt{7}} + \frac{1}{2\sqrt{7}}i\sqrt{3} \tag{106d}$$

and $s_{jk}=+$ if $k=j+1 \bmod(3)$, $s_{jk}=-$ if $k=j+2 \bmod(3)$. Note the independence of the determinants from the value of the *arbitrary* constant η (this remark will not be repeated in the following, when this phenomenon will recur). And to the additional equilibrium configuration,

$$u_{1,2} = \frac{3 \pm i\sqrt{3}}{2}, \quad u_3 = 1; \quad a_1 = -4, \quad a_2 = 6, \quad a_3 = -3, \tag{107a}$$

there correspond the following *diophantine* equations:

$$D_2^{(3)}(\lambda) \equiv \det\begin{pmatrix} \lambda^2+\lambda(i\sqrt{3}+2)-2 & -2(\lambda-i\sqrt{3}+1) & -(i\sqrt{3}+3)(\lambda+1) \\ -2(\lambda+i\sqrt{3}+1) & \lambda^2+\lambda(-i\sqrt{3}+2)-2 & (i\sqrt{3}-3)(\lambda+1) \\ 0 & 0 & (\lambda+4)(\lambda+1) \end{pmatrix}$$
$$= (\lambda+4)(\lambda+1)D_2^{(2)}(\lambda) = \tilde{D}_2^{(3)}(\lambda) \equiv \det\begin{pmatrix} (\lambda+7)(\lambda-2) & 2(\lambda-2) & 0 \\ 36 & \lambda^2+3\lambda+14 & 4(\lambda+1) \\ -18 & -6 & \lambda(\lambda+1) \end{pmatrix}$$
$$= \lambda^6 + 9\lambda^5 + 23\lambda^4 - 5\lambda^3 - 96\lambda^2 - 124\lambda - 48 = (\lambda+1)(\lambda+4)P_4(\lambda). \tag{107b}$$

For $N=4$ to the *first* one-parameter set of equilibrium configurations,

$$u_k(\eta) = 1 + \eta \exp\left(\frac{2\pi i}{3}k\right), \quad k = 1,2,3, \quad u_4 = 0,$$
$$a_1 = -3, \quad a_2 = 3, \quad a_3 = 1 - \eta^3, \quad a_4 = 0, \tag{108a}$$

there correspond the following *diophantine* equations:

$$D_1^{(4)}(\lambda) \equiv \det\begin{pmatrix} \underline{H}(\lambda,\eta) & \vec{\sigma}^T(\lambda,\eta) \\ 0 & (\lambda-1)(\lambda-2) \end{pmatrix} = \tilde{D}_1^{(4)}(\lambda)$$
$$\equiv \det\begin{pmatrix} (\lambda+5)(\lambda-2) & 2\lambda-4 & 0 & 0 \\ 4(\eta^3+4) & \lambda^2+\lambda+6 & 4\lambda & 4 \\ -6(\eta^3+1) & -2(\eta^3+1) & \lambda(\lambda-1) & 6(\lambda-1) \\ 0 & 0 & 0 & (\lambda-1)(\lambda-2) \end{pmatrix}$$
$$= \lambda^8 - 12\lambda^6 + 6\lambda^5 + 39\lambda^4 - 30\lambda^3 - 28\lambda^2 + 24\lambda = \lambda(\lambda-1)^2(\lambda-2)P_4(\lambda); \tag{108b}$$

where the three components of the column three-vector $\vec{\sigma}^T(\lambda,\eta)$ are defined as follows:

$$\sigma_k^T = -2\eta \exp\left(\frac{2\pi i}{3}k\right)(\lambda-1), \quad k = 1,2,3; \tag{108c}$$

and to the second,

$$u_k(\eta) = 1 + \eta \exp\left(\frac{2\pi i}{3}k\right), \quad k = 1,2,3, \quad u_4 = 1,$$
$$a_1 = -4, \quad a_2 = 6, \quad a_3 = -4 - \eta^3, \quad a_4 = 1 + \eta^3, \tag{109a}$$

there correspond the following *diophantine* equations:

$$D_2^{(4)}(\lambda) \equiv \det\begin{pmatrix} \underline{H}(\lambda,\eta) & \vec{\pi}^T(\lambda,\eta) \\ 0 & (\lambda+1)(\lambda+4) \end{pmatrix} = D_2^{(4)}(\lambda)$$
$$\equiv \det\begin{pmatrix} (\lambda+7)(\lambda-2) & 2(\lambda-2) & 0 & 0 \\ 4(\eta^3+10) & 3\lambda+\lambda^2+14 & 4(\lambda+1) & 4 \\ -6(2\eta^3+5) & -2(\eta^3+4) & \lambda(\lambda+1) & 6\lambda \\ 8(\eta^3+1) & 2(\eta^3+1) & 0 & \lambda(\lambda-1) \end{pmatrix}$$
$$= \lambda^8 + 8\lambda^7 + 14\lambda^6 - 28\lambda^5 - 91\lambda^4 - 28\lambda^3 + 76\lambda^2 + 48\lambda$$
$$= \lambda(\lambda+1)(\lambda+4)(\lambda-1)P_4(\lambda), \tag{109b}$$

where the three components of the column three-vector $\vec{\pi}^T(\lambda,\eta)$ are defined as follows:

$$\pi_k^T(\lambda,\eta) = -2\left[\eta \exp\left(\frac{2\pi i}{3}k\right) + 1\right](\lambda+1), \quad k = 1,2,3. \tag{109c}$$

Finally for $N=5$ to the single equilibrium configuration

$$u_k(\eta) = 1 + \eta \exp\left(\frac{2\pi i}{3}k\right), \quad k = 1,2,3, \quad u_4 = 0, \quad u_5 = 1,$$
$$a_1 = -4, \quad a_2 = 6, \quad a_3 = -4 - \eta^3, \quad a_4 = 1 + \eta^3, \quad a_5 = 0, \tag{110a}$$

there correspond the following *diophantine* equations:

$$D^{(5)}(\lambda) \equiv \det\begin{pmatrix} \underline{H}(\lambda,\eta) & \vec{\sigma}^T(\lambda,\eta) & \vec{\pi}^T(\lambda,\eta) \\ 0 & (\lambda-1)(\lambda-2) & 0 \\ 0 & 0 & (\lambda+1)(\lambda+4) \end{pmatrix} = \widetilde{D}^{(5)}(\lambda)$$

$$\equiv \det\begin{pmatrix} (\lambda+7)(\lambda-2) & 2(\lambda-2) & 0 & 0 & 0 \\ 4(\eta^3+10) & \lambda^2+3\lambda+14 & 4(\lambda+1) & 4 & 0 \\ -6(2\eta^3+5) & -2(\eta^3+4) & \lambda(\lambda+1) & 6\lambda & 10 \\ 8(\eta^3+1) & 2(\eta^3+1) & 0 & \lambda(\lambda-1) & 8(\lambda-1) \\ 0 & 0 & 0 & 0 & (\lambda-1)(\lambda-2) \end{pmatrix}$$

$$= \lambda^{10} + 5\lambda^9 - 8\lambda^8 - 54\lambda^7 + 21\lambda^6 + 189\lambda^5 - 22\lambda^4 - 236\lambda^3 + 8\lambda^2 + 96\lambda$$

$$= \lambda(\lambda+1)(\lambda+4)(\lambda-1)^2(\lambda-2)P_4(\lambda). \tag{110b}$$

(Received 12 August 2005; accepted 25 August 2005; published online 24 October 2005)

A large class of noncommutative spherical manifolds was obtained recently from cohomology considerations. A one-parameter family of twisted three-spheres was discovered by Connes and Landi, and later generalized to a three-parameter family by Connes and Dubois-Violette. The spheres of Connes and Landi were shown to be homogeneous spaces for certain compact quantum groups. Here we investigate whether this property can be extended to the noncommutative three-spheres of Connes and Dubois-Violette. Upon restricting to quantum groups which are continuous deformations of Spin(4) and SO(4) with standard coactions, our results suggest that this is not the case. © *2005 American Institute of Physics.*

I. INTRODUCTION

The recent interest in noncommutative geometry[1] has led to an on-going search for nontrivial examples of noncommutative spaces. Noncommutative generalizations of spheres in various dimensions are known (for a review see Ref. 2), but many of these suffer from a drop in dimensions. Actually, the dimension of a noncommutative space is not uniquely defined. One choice which uses concepts which are natural in noncommutative geometry is the Hochschild dimension. It plays an important role for the three-parameter family of deformations of the sphere S^3 introduced by Connes and Dubois-Violette,[3] which generalizes the one-parameter family discovered previously by Connes and Landi.[4] The Hochschild dimension of the corresponding algebra remains constant (and equal to three) for the deformation. A generalization to higher dimensions is possible for the one-parameter subset, the so-called twisted spheres. This particular subset has another important characteristic. It has been shown[5,6] that the spheres in the one parameter subset carry a coaction of the multiparametric quantum orthogonal groups $\mathrm{SO}_\theta(n+1)$;[7] i.e., they are homogeneous spaces of quantum groups. The aim of this paper is to investigate the possibility of defining a group coaction for the three-parameter 3-spheres as well.

The algebra of the three-parameter spheres S^3_u (Ref. 3) is generated by Hermitian operators $\hat{x}_\mu$, $\mu=0,1,2,3$, subject to

$$\hat{x}_\mu \hat{x}_\mu = \mathbb{1}, \tag{1.1}$$

where $\mathbb{1}$ is the unit operator, and quadratic commutation relations

$$[\hat{x}_\mu, \hat{x}_\nu] = i\hat{E}_{\mu\nu,\rho\sigma}\hat{x}_\rho \hat{x}_\sigma. \tag{1.2}$$

The constant coefficients $\hat{E}_{\mu\nu,\rho\sigma}$ are expressed in terms of four angles ϕ_μ,

[a]Electronic mail: fedele.lizzi@na.infn.it
[b]Also at: Department of Physics, University of Alabama, Tuscaloosa, Alabama 35487, Electronic mail: astern@bama.ua.edu
[c]Electronic mail: patrizia.vitale@na.infn.it

$$\hat{E}_{\mu\nu,\rho\sigma} = \epsilon_{\mu\nu\rho\sigma} \frac{\sin(\phi_\rho - \phi_\sigma)}{\cos(\phi_\mu - \phi_\nu)}, \quad \text{no sum on repeated indices.} \tag{1.3}$$

$\hat{E}_{\mu\nu,\rho\sigma}$ is antisymmetric in the first two indices and symmetric in the last two indices. These commutation relations hold provided no two angles differ by $\pi/2$. Because they depend only on the difference of angles there are three independent deformation parameters, and so one angle, say ϕ_0, can be set to zero. The Connes-Landi case has two of the remaining angles equal with the third zero; e.g., $\phi_1 = \phi_2 = \phi/2$ and $\phi_3 = 0$.[4]

In the search for continuous symmetries, we shall consider linear, as well as spinor, transformations. When all angles are set to zero we require that the symmetries reduce to SO(4) and Spin(4) transformations, respectively. On the other hand, we cannot get Lie group transformations when any of the independent parameters are nonvanishing, since (1.2) would in general not be preserved. If they exist, such symmetries should correspond to quantum group transformations. As the Connes–Dubois–Violette three-spheres are three-parameter deformations of the sphere, their symmetries should correspond to multiparametric deformations of SO(4) and Spin(4). Multiparametric deformations of orthogonal groups[7,8] can be obtained from the standard one-parameter quantum group by applying a twist F, which depends on additional parameters q_{ab}, to the quantum R-matrix. The twist is required to be a specific function in the universal enveloping algebra of the Lie group under consideration. Under these assumptions the quantum deformation becomes at most two-parametric in the case of SO(4). Therefore these kind of q-groups cannot be associated with symmetries for the full three-parameter family of noncommutative spheres. Alternatively, it is possible that there exist symmetries associated with quantum groups which are not deformable to Lie groups. Here, however, our primary focus will be on continuous deformations of Spin(4) and SO(4). We are then justified in looking at the limit of small angles where the search for continuous symmetries is considerably simplified. This is the commutative limit, where the noncommutative sphere goes to S^3, with $\hat{x}_\mu$ going to real commuting coordinates x_μ, $x_\mu x_\mu = 1$, and the noncommutativity gets replaced by a nontrivial Poisson structure on S^3. The commutative limit of the quantum group associated with a continuous symmetry, if it exists, is a Lie-Poisson group,[9] a Lie group with a Poisson bracket on the group manifold which is compatible with the group multiplication.

The search for Lie-Poisson symmetry in the case of the commutative limit of the Connes and Dubois-Violette spheres is carried in Secs. II and III. The Poisson brackets are recovered from (1.2) in the limit of small angles $\phi_\mu \to \epsilon_\mu$

$$\{x_\mu, x_\nu\} = E_{\mu\nu,\rho\sigma} x_\rho x_\sigma, \tag{1.4}$$

where

$$E_{\mu\nu,\rho\sigma} = \epsilon_{\mu\nu\rho\sigma}(\epsilon_\rho - \epsilon_\sigma), \quad \text{no sum on repeated indices.} \tag{1.5}$$

Our approach is to express the Poisson brackets on S^3 in terms of a constant matrix, with the intention of utilizing it as a classical R-matrix for a Lie-Poisson group. In Sec. III we consider Spin(4) transformations. For this one expresses the coordinates in terms of an SU(2) matrix u, with the $\mathrm{Spin}(4) = \mathrm{SU}(2) \times \mathrm{SU}(2)$ transformation given by

$$u \to u' = guh^{-1}, \tag{1.6}$$

where g and h are independent elements of SU(2). The problem is then to find a Poisson structure on Spin(4) which is compatible with the Poisson algebra on S^3. This means that both group multiplication and the action on S^3 are Poisson maps. The former property defines the Lie-Poisson group. Expressing the Poisson brackets on the group in terms of a classical R-matrix, which by definition satisfies the classical Yang-Baxter equations, insures that the Jacobi identity is satisfied. If such a classical R-matrix is found, the group is a Lie-Poisson group, and the space under consideration would be a homogeneous space of the Lie-Poisson group. In Sec. II we find a consistent classical R-matrix only in the Connes-Landi limit, and thus we only get a Poisson map

of Spin(4) in this case. In Sec. III we get the same result for SO(4). We assume the usual linear SO(4) transformations

$$x_\mu \to x'_\mu = M_{\mu\nu} x_\nu, \tag{1.7}$$

$M_{\mu\nu}$ being SO(4) matrix elements. A candidate for the Poisson brackets of $M_{\mu\nu}$ can be written in terms of a constant 16×16 matrix, but the latter only defines a classical R-matrix, i.e., satisfies the classical Yang-Baxter equations, in the Connes-Landi limit.

After ruling out symmetries associated with continuous deformations of Spin(4) and SO(4), there still is the possibility of symmetries at certain finite angles ϕ_μ. This case is more difficult to analyze since it involves going to the full noncommutative theory. In Sec. IV we investigate the full noncommutative theory and search symmetries associated with spinor-type transformations. We express the algebra for the twisted three-sphere in terms of a possible quantum R-matrix. The quantum Yang-Baxter equations should be satisfied for the corresponding quantum group algebra to be coassociative. This cannot be true for arbitrary continuous deformations of the commutative sphere, since in the limit of small angles we recover the system of Sec. II. In Sec. IV we further find no finite values of ϕ_μ, other than those in the Connes-Landi limit, for which the candidate R-matrix satisfies the quantum Yang-Baxter equations.

In Sec. V we Wick rotate the system of Connes and Dubois-Violette, leading to "noncommutative hyperboloids" in Minkowski space, and repeat some of the previous analysis in search of quantum deformations of the Lorentz group which have twisted hyperboloids as homogeneous spaces. As before the search is only successful for a one parameter subset of hyperboloids, namely being the Wick rotation of Connes-Landi spheres.

In Sec. VI we give concluding remarks and discuss the prospects for a more exhaustive study of the full noncommutative theory.

II. POISSON ACTION OF Spin(4)

As u appearing in (1.6) is in the defining representation of SU(2) it can be expressed in terms of the coordinates according to

$$u = x_\mu \tau^\mu, \tag{2.1}$$

where τ^0 is the 2×2 identity matrix $\tau^0 = \mathbb{1}_{2\times 2}$ and τ^i are i times the Pauli matrices, $\tau^i = i\sigma^i$, $i = 1,2,3$. τ^μ satisfy

$$\tfrac{1}{2}\,\mathrm{Tr}(\tau^\mu \tau^\nu) = \eta^{\mu\nu} = \mathrm{diag}(1,-1,-1,-1) \tag{2.2}$$

u has real trace and the traceless part is anti-Hermitian. Hermitian conjugation corresponds to a parity transformation.

We next show that the Poisson brackets (1.4) can be written in the form

$$\{ \underset{1}{u}, \underset{2}{u} \} = \underset{2}{u}\underset{1}{r}\underset{2}{u} - \underset{1}{u}\underset{2}{r}\underset{1}{u}, \tag{2.3}$$

where by u_1 and u_2 is meant $u\otimes \mathbb{1}$ and $\mathbb{1}\otimes u$, respectively, and r is a 4×4 matrix which we need to determine. (For a more general starting ansatz see the end of this section.) From

$$uu^\dagger = u^\dagger u = \mathbb{1}_{2\times 2}, \tag{2.4}$$

r must be Hermitian. From the antisymmetry of the Poisson bracket r should be invariant under exchange of the two tensor product spaces; i.e., $r = r_{12} = r_{21}$. Finally in order to recover the Poisson brackets (1.4) from (2.3) r should satisfy

$$\underset{2}{\tau^\rho}\underset{1}{r}\underset{2}{\tau^\sigma} - \underset{1}{\tau^\rho}\underset{2}{r}\underset{1}{\tau^\sigma} + \underset{2}{\tau^\sigma}\underset{1}{r}\underset{2}{\tau^\rho} - \underset{1}{\tau^\sigma}\underset{2}{r}\underset{1}{\tau^\rho} = 2E_{\mu\nu,\rho\sigma}\underset{1}{\tau^\mu}\underset{2}{\tau^\nu}. \tag{2.5}$$

The solution (up to a term proportional to the identity matrix $\mathbb{1}_{4\times 4} = \tau^0 \times \tau^0$) is

$$r = \kappa_1 \tau^1 \otimes \tau^1 + \kappa_2 \tau^2 \otimes \tau^2 + \kappa_3 \tau^3 \otimes \tau^3, \tag{2.6}$$

where κ_i are given by

$$\begin{aligned} \kappa_1 &= \tfrac{1}{2}(-\epsilon_0 - \epsilon_1 + \epsilon_2 + \epsilon_3), \\ \kappa_2 &= \tfrac{1}{2}(-\epsilon_0 + \epsilon_1 - \epsilon_2 + \epsilon_3), \\ \kappa_3 &= \tfrac{1}{2}(-\epsilon_0 + \epsilon_1 + \epsilon_2 - \epsilon_3). \end{aligned} \tag{2.7}$$

The standard action of Spin(4) on S^3 is (1.6), where g and h are independent elements of SU(2) in the defining representation. The Poisson algebra (2.3) is not preserved under this action. Instead, (2.3) goes to

$$\{ \underset{1}{u'}, \underset{2}{u'} \} = \underset{2\,12}{u'} \underset{12\,1}{r'} \underset{1}{u'} - \underset{1\,21}{u'} \underset{21\,2}{r'} \underset{2}{u'}, \tag{2.8}$$

where

$$\underset{12}{r'} = \underset{1\,2}{g} \underset{2}{h} \underset{2}{r} \underset{2}{h^{-1}} \underset{1}{g^{-1}}. \tag{2.9}$$

On the other hand, if we can consistently assign the following Poisson structure to Spin(4),

$$\{ \underset{1}{g}, \underset{2}{h} \} = -[\, \underset{12}{r}, \underset{1\,2}{gh}\,], \quad \{ \underset{1}{g}, \underset{2}{g} \} = \{ \underset{1}{h}, \underset{2}{h} \} = 0, \tag{2.10}$$

the brackets (2.3) are invariant in the sense that (1.6) is a Poisson map. For these Poisson brackets to be consistent we need that they are antisymmetric and satisfy the Jacobi identity. This means that r should satisfy the classical Yang-Baxter equations,

$$[\, \underset{12}{r}, \underset{13}{r} + \underset{23}{r}\,] + [\, \underset{13}{r}, \underset{23}{r}\,] = I', \tag{2.11}$$

where I' is an adjoint invariant for Spin(4). Note that the classical Yang-Baxter equations did not have to be satisfied for (2.3) to be consistent with the Jacobi identity. It is easily seen that the classical Yang-Baxter and hence the Jacobi identity for (2.10) are satisfied when all κ_i but one vanishes. This corresponds to two angles being equal while the third is zero, i.e., the Connes-Landi case. *Moreover, the Yang-Baxter equations and Jacobi identity are only satisfied in this case,* and thus only then do g and h generate a Lie-Poisson group. In that case we can introduce spinors $\psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}$ and $\bar{\psi} = (\bar{\psi}_1 \bar{\psi}_2)$ with Poisson brackets

$$\{\psi_a, \bar{\psi}_b\} = r_{ad,cb} \psi_c \bar{\psi}_d, \tag{2.12}$$

for which

$$\psi \to \psi' = g\psi, \quad \bar{\psi} \to \bar{\psi}' = \bar{\psi} h^{-1} \tag{2.13}$$

will be a Poisson map. Then the Poisson algebra for $\psi\bar{\psi}$ is identical to that for u in (2.3).

Concerning (2.3), we could start with the most general ansatz which is linear in both u_1 and u_2,

$$\{ \underset{1}{u}, \underset{2}{u} \} = \underset{1\,2}{r^{(1)}} \underset{1\,2}{uu} + \underset{1\,2}{uu} \underset{1\,2}{r^{(2)}} - \underset{2}{u} \underset{1}{r^{(3)}} \underset{1}{u} - \underset{1}{u} \underset{2}{r^{(4)}} \underset{2}{u}, \tag{2.14}$$

where we have introduced four 4×4 matrices $r^{(A)}$, $A = 1,2,3,4$. Now (1.6) is a Poisson map when (2.10) is generalized to

$$\begin{aligned}
\{ \underset{1}{g}, \underset{2}{g} \} &= [r^{(1)}, \underset{1\,2}{gg}], \\
\{ \underset{1}{h}, \underset{2}{h} \} &= [r^{(2)}, \underset{1\,2}{hh}], \\
\{ \underset{1}{g}, \underset{2}{h} \} &= [r^{(3)}, \underset{1\,2}{gh}], \\
\{ \underset{1}{h}, \underset{2}{g} \} &= [r^{(4)}, \underset{1\,2}{hg}].
\end{aligned} \tag{2.15}$$

The matrices $r^{(A)}$, $A=1,2,3,4$, are not fully determined from the Poisson brackets (1.4) of the coordinates. The ambiguity can be fixed once one imposes the requirements that the Poisson brackets for the matrix elements of g and h be antisymmetric and consistent with $\det g = \det h = 1$. However, it can be shown, that then the brackets (2.14) and (2.15) collapse to (2.3) and (2.10), and so the previous conclusions apply.

III. POISSON ACTION OF SO(4)

From the Spin(4) transformations (1.6) we can construct the corresponding SO(4) transformations (1.7), and since the former defines a Poisson map in the Connes-Landi case so does the latter. In that case SO(4) matrix elements $M_{\mu\nu}$ are expressed as quadratic functions of group elements g and h,

$$M_{\mu\nu}(g,h) = \tfrac{1}{2}\mathrm{Tr}(\tau_\mu g \tau^\nu h^{-1}), \tag{3.1}$$

where the indices on τ are raised and lowered with the Minkowski metric (2.2). More generally, if we do not make assumptions like (3.1), it may be possible to find a Poisson map of a group even when no Poisson map is induced by its covering group. However, we find that not to be the case for SO(4) acting on the noncommutative three-sphere, i.e., like Spin(4), SO(4) has a Poisson action only in the Connes-Landi case.

The Poisson brackets (1.4) are not preserved under the action (1.7) of SO(4). Rather they are transformed to

$$\{x'_\mu, x'_\nu\} = E'_{\mu\nu,\rho\sigma} x'_\rho x'_\sigma, \tag{3.2}$$

where

$$E'_{\mu\nu,\rho\sigma} = M_{\mu\alpha} M_{\nu\beta} M_{\rho\gamma} M_{\sigma\delta} E_{\alpha\beta,\gamma\delta}. \tag{3.3}$$

On the other hand, it may be possible to have Poisson brackets on SO(4) which define a Lie-Poisson group and make (1.7) a Poisson map. The Poisson brackets are required to satisfy

$$(\{M_{\mu\gamma}, M_{\nu\delta}\} - E_{\mu\nu,\rho\sigma} M_{\rho\gamma} M_{\sigma\delta} + M_{\nu\sigma} M_{\mu\rho} E_{\rho\sigma,\gamma\delta}) x_\gamma x_\delta = 0, \tag{3.4}$$

in addition to antisymmetry and the Jacobi identity. Equation (3.4) is solved by

$$\{ \underset{1}{M}, \underset{2}{M} \} = [R, \underset{1\,2}{MM}], \tag{3.5}$$

where

$$R_{\mu\nu,\rho\sigma} = E_{\mu\nu,\rho\sigma} + A_{\mu\nu,\rho\sigma}, \tag{3.6}$$

and A is antisymmetric in the last two indices, $A_{\mu\nu,\rho\sigma} = -A_{\mu\nu,\sigma\rho}$. From the requirement that M is orthogonal it follows that R should be a symmetric matrix $R_{\mu\nu,\rho\sigma} = R_{\rho\sigma,\mu\nu}$. This then fixes $A_{\mu\nu,\rho\sigma} = E_{\rho\sigma,\mu\nu}$, and hence R becomes

$$R_{\mu\nu,\rho\sigma} = \epsilon_{\mu\nu\rho\sigma}(\epsilon_\mu - \epsilon_\nu + \epsilon_\rho - \epsilon_\sigma). \tag{3.7}$$

Antisymmetry of the Poisson bracket follows since R is antisymmetric under exchange of the tensor product spaces. The R can be expressed in terms of tensor products of SO(4) generators J_i and $K_i, i=1,2,3$, written in the defining representation,

$$J_1 = \frac{1}{2\sqrt{2}}\begin{pmatrix} 0 & 1 & 0 & 1 \\ -1 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \\ -1 & 0 & -1 & 0 \end{pmatrix}, \quad K_1 = \frac{1}{2\sqrt{2}}\begin{pmatrix} 0 & -1 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ -1 & 0 & 0 & 1 \\ 0 & -1 & -1 & 0 \end{pmatrix},$$

$$J_2 = \frac{1}{2\sqrt{2}}\begin{pmatrix} 0 & 1 & 0 & -1 \\ -1 & 0 & -1 & 0 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & -1 & 0 \end{pmatrix}, \quad K_2 = \frac{1}{2\sqrt{2}}\begin{pmatrix} 0 & 1 & 1 & 0 \\ -1 & 0 & 0 & 1 \\ -1 & 0 & 0 & -1 \\ 0 & -1 & 1 & 0 \end{pmatrix}, \tag{3.8}$$

$$J_3 = \frac{1}{2}\begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}, \quad K_3 = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}.$$

They satisfy

$$[J_i, J_j] = \epsilon_{ijk} J_k,$$

$$[K_i, K_j] = \epsilon_{ijk} K_k, \tag{3.9}$$

$$[J_i, K_j] = 0.$$

Defining $J_\pm = \sqrt{2}(J_1 \pm J_2)$ and $K_\pm = \sqrt{2}(K_1 \pm K_2)$, R can be written

$$R = 2\kappa_1(J_- \otimes K_3 - K_3 \otimes J_-) + 2\kappa_2(K_+ \otimes J_3 - J_3 \otimes K_+) + \kappa_3(K_- \otimes J_+ - J_+ \otimes K_-), \tag{3.10}$$

where κ_i are again given by (2.7). Finally we need to check that (3.5) satisfies the Jacobi identity, or equivalently that R satisfies the classical Yang-Baxter equations,

$$[\underset{12}{R}, \underset{13}{R} + \underset{23}{R}] + [\underset{13}{R}, \underset{23}{R}] = I, \tag{3.11}$$

where I is an adjoint invariant for SO(4). From $[J_i, K_j]=0$, it is easily seen that (3.11) is satisfied when all κ_i but one vanishes. Thus the Jacobi identity is satisfied when two angles are equal and the third is zero. *Just as with Spin(4), the Yang-Baxter equations and Jacobi identity are only satisfied in this case, and* $[M_{\mu\nu}]$ *generate a Lie-Poisson group only in this case*. It can be checked that the results in this case agree with the lowest order commutation relations in Ref. 6.

Above we have argued that we can consistently define a Poisson algebra for SO(4) matrices only in the Connes-Landi case. This algebra is obtainable from the Poisson algebra (2.10) on Spin(4) using (3.1),

$$\{M_{\mu\nu},M_{\rho\sigma}\}(g,h) = \tfrac{1}{4}\underset{12}{\mathrm{Tr}}\ \tau_{\mu}\ \tau_{\rho}\{\ g\ \tau^{\nu}\ h^{-1},g\ \tau^{\sigma}\ h^{-1}\ \}$$
$$= \tfrac{1}{4}\underset{12}{\mathrm{Tr}}\ \tau_{\mu}\ \tau_{\rho}(\ g\ \tau^{\nu}(\ g\ r\ h^{-1} - h^{-1}\ r\ g\ )\tau^{\sigma}\ h^{-1} + g\ \tau^{\sigma}(\ h^{-1}\ r\ g - g\ r\ h^{-1}\ )\tau^{\nu}h^{-1}\ ), \tag{3.12}$$

where Tr_{12} means a trace over both tensor product spaces. We then recover the expression (3.5) with R given by

$$R_{\mu\nu,\rho\sigma} = \tfrac{1}{4}\underset{12}{\mathrm{Tr}}[\tau_{\rho}\otimes\tau^{\nu},\tau^{\mu}\otimes\tau_{\sigma}]r. \tag{3.13}$$

After substituting in the general expression for r given in (2.6) one then gets (3.7).

IV. QUANTUM Spin(4) TRANSFORMATION

Here we generalize to the full noncommutative theory with the goal of searching for symmetries of the noncommutative three-sphere occurring at finite angles ϕ_{μ}. For simplicity we restrict to spinor-type transformations thereby generalizing the discussion of Sec. II.

We begin by replacing the 2×2 matrix u by another 2×2matrix $\hat{u}$, the latter having noncommuting matrix elements. The property of unitarity,

$$\hat{u}\hat{u}^{\dagger} = \hat{u}^{\dagger}\hat{u} = \mathbb{1}_{2\times 2}, \tag{4.1}$$

can be maintained although $\hat{u}$ does not have to have unit determinant. For this (2.1) should be generalized to

$$\hat{u} = \hat{x}_{\mu}e^{i\phi_{\mu}\tau^{\mu}}. \tag{4.2}$$

The sum over $\mu=0,1,2,3$ is assumed. The unitarity condition was shown[3] to be consistent with the commutation relations (1.2). We next show that the commutation relations can be expressed as

$$\underset{1}{\hat{u}}\ \hat{r}\ \underset{2}{\hat{u}} = \underset{2}{\hat{u}}\ \hat{r}\ \underset{1}{\hat{u}} \tag{4.3}$$

for some 4×4 matrix $\hat{r}$. These relations are invariant under interchange of the two tensor product spaces provided $\hat{r}$ is invariant under interchange of the two tensor product spaces; i.e., $\hat{r}=\hat{r}_{12}=\hat{r}_{21}$. In the limit of small angles $\phi_{\mu}\to\epsilon_{\mu}$, $\hat{r}$ should reduce to $\mathbb{1}_{4\times 4}+ir$, with r given in (2.6), for then the commutator of $\hat{u}_1$ with $\hat{u}_2$ goes to i times the Poisson bracket in (2.3),

$$\underset{1}{\hat{u}}\ \underset{2}{\hat{u}} - \underset{2}{\hat{u}}\ \underset{1}{\hat{u}} \to i\ \underset{2}{\hat{u}}\ r\ \underset{1}{\hat{u}} - i\ \underset{1}{\hat{u}}\ r\ \underset{2}{\hat{u}}. \tag{4.4}$$

So the task is to find $\hat{r}$ so that the commutation relations (4.3) agree with (1.2). Substituting (4.2) into (4.3), we get

$$e^{i(\phi_{\rho}+\phi_{\sigma})}(\ \underset{2}{\tau^{\rho}}\ \hat{r}\ \underset{1}{\tau^{\sigma}} - \underset{1}{\tau^{\rho}}\ \hat{r}\ \underset{2}{\tau^{\sigma}}\ )\hat{x}_{\rho}\hat{x}_{\sigma} = 0, \tag{4.5}$$

where the sum over indices is again assumed. We cannot equate coefficients of $\hat{x}_{\rho}\hat{x}_{\sigma}$ to zero because they are not all independent. Rather from (1.2) they are related by

$$\hat{x}_{\rho}\hat{x}_{\sigma} = \tfrac{1}{2}(S_{\rho\sigma,\alpha\beta} + i\hat{E}_{\rho\sigma,\alpha\beta})\hat{x}_{\alpha}\hat{x}_{\beta}, \tag{4.6}$$

where

$$S_{\rho\sigma,\alpha\beta} = \delta_{\alpha\rho}\delta_{\beta\sigma} + \delta_{\alpha\sigma}\delta_{\beta\rho} \tag{4.7}$$

and $\hat{E}_{\rho\sigma,\alpha\beta}$ is given in (1.3). Both $S_{\rho\sigma,\alpha\beta}$ and $\hat{E}_{\rho\sigma,\alpha\beta}$ are symmetric in the last two indices. Equation (4.6) then shows that all quadratic combinations of $\hat{x}_{\mu}$ can be expressed in terms of just the

symmetric ones. If we substitute into (4.5) we can then equate coefficients of all the symmetric combinations of $\hat{x}_\alpha \hat{x}_\beta$ to zero. The result is a generalization of (2.5),

$$\underset{2}{\tau^\rho}\ \underset{}{\hat{r}}\ \underset{1}{\tau^\sigma} - \underset{1}{\tau^\rho}\ \underset{}{\hat{r}}\ \underset{2}{\tau^\sigma} + \underset{2}{\tau^\sigma}\ \underset{}{\hat{r}}\ \underset{1}{\tau^\rho} - \underset{1}{\tau^\sigma}\ \underset{}{\hat{r}}\ \underset{2}{\tau^\rho} = -ie^{i(\phi_\mu+\phi_\nu-\phi_\rho-\phi_\sigma)}\hat{E}_{\mu\nu,\rho\sigma}\left(\underset{2}{\tau^\mu}\ \underset{}{\hat{r}}\ \underset{1}{\tau^\nu} - \underset{1}{\tau^\mu}\ \underset{}{\hat{r}}\ \underset{2}{\tau^\nu}\right). \tag{4.8}$$

Up to an overall constant factor, it is solved by

$$\hat{r} = \frac{1}{2}\begin{pmatrix} e^{2i(\phi_0-\phi_2)}+e^{2i(\phi_0-\phi_1)} & 0 & 0 & e^{2i(\phi_0-\phi_2)}-e^{2i(\phi_0-\phi_1)} \\ 0 & e^{2i(\phi_0-\phi_3)}+1 & e^{2i(\phi_0-\phi_3)}-1 & 0 \\ 0 & e^{2i(\phi_0-\phi_3)}-1 & e^{2i(\phi_0-\phi_3)}+1 & 0 \\ e^{2i(\phi_0-\phi_2)}-e^{2i(\phi_0-\phi_1)} & 0 & 0 & e^{2i(\phi_0-\phi_2)}+e^{2i(\phi_0-\phi_1)} \end{pmatrix}, \tag{4.9}$$

or equivalently,

$$\hat{r} = \mathbb{1}_{4\times 4} + i\hat{\kappa}_\mu \tau^\mu \otimes \tau^\mu, \tag{4.10}$$

with a sum over μ and

$$\begin{aligned} \hat{\kappa}_0 &= \frac{i}{4}(3 - e^{2i(\phi_0-\phi_1)} - e^{2i(\phi_0-\phi_2)} - e^{2i(\phi_0-\phi_3)}), \\ \hat{\kappa}_1 &= -\frac{i}{4}(1 + e^{2i(\phi_0-\phi_1)} - e^{2i(\phi_0-\phi_2)} - e^{2i(\phi_0-\phi_3)}), \\ \hat{\kappa}_2 &= -\frac{i}{4}(1 - e^{2i(\phi_0-\phi_1)} + e^{2i(\phi_0-\phi_2)} - e^{2i(\phi_0-\phi_3)}), \\ \hat{\kappa}_3 &= -\frac{i}{4}(1 - e^{2i(\phi_0-\phi_1)} - e^{2i(\phi_0-\phi_2)} + e^{2i(\phi_0-\phi_3)}). \end{aligned} \tag{4.11}$$

The expressions for $\hat{\kappa}_i, i=1,2,3$, reduce κ_i to (2.7) in the limit of small angles $\phi_\mu \to \epsilon_\mu$, while $\hat{\kappa}_0$ is arbitrary in the limit.

The relations (4.3) are not invariant under Spin(4). Alternatively, we can try to define a deformation of Spin(4), parametrized by two nonsingular 2×2 matrices $\hat{g}$ and $\hat{h}$ with noncommuting matrix elements with an involution. The coaction on $\hat{u}$ is

$$\hat{u} \to \hat{u}' = \hat{g}\hat{u}\hat{h}^{-1}. \tag{4.12}$$

In order to preserve (4.1) we demand that $\hat{g}$ and $\hat{h}$ are unitary. Transformation (4.12) preserves the commutation relations (4.3) provided

$$\underset{1}{\hat{r}}\ \underset{2}{\hat{g}}\ \underset{1}{\hat{h}} = \underset{2}{\hat{h}}\ \underset{1}{\hat{g}}\ \underset{}{\hat{r}}, \quad [\underset{1}{\hat{g}}, \underset{2}{\hat{g}}] = [\underset{1}{\hat{h}}, \underset{2}{\hat{h}}] = 0. \tag{4.13}$$

This is easily shown. Under the coaction, the left-hand side of (4.3) transforms to

$$\begin{aligned} \underset{1}{\hat{u}'}\ \underset{}{\hat{r}}\ \underset{2}{\hat{u}'} &= \underset{1}{\hat{g}}\ \underset{1}{\hat{u}}\ \underset{1}{\hat{h}^{-1}}\ \underset{}{\hat{r}}\ \underset{2}{\hat{g}}\ \underset{2}{\hat{u}}\ \underset{2}{\hat{h}^{-1}} = \underset{1}{\hat{g}}\ \underset{1}{\hat{u}}\ \underset{2}{\hat{g}}\ \underset{}{\hat{r}}\ \underset{1}{\hat{h}^{-1}}\ \underset{2}{\hat{u}}\ \underset{2}{\hat{h}^{-1}} = \underset{2}{\hat{g}}\ \underset{1}{\hat{g}}\ \underset{1}{\hat{u}}\ \underset{}{\hat{r}}\ \underset{2}{\hat{u}}\ \underset{2}{\hat{h}^{-1}}\ \underset{1}{\hat{h}^{-1}} = \underset{2}{\hat{g}}\ \underset{1}{\hat{g}}\ \underset{2}{\hat{u}}\ \underset{}{\hat{r}}\ \underset{1}{\hat{u}}\ \underset{2}{\hat{h}^{-1}}\ \underset{1}{\hat{h}^{-1}} \\ &= \underset{2}{\hat{g}}\ \underset{2}{\hat{u}}\ \underset{1}{\hat{g}}\ \underset{}{\hat{r}}\ \underset{2}{\hat{h}^{-1}}\ \underset{1}{\hat{u}}\ \underset{1}{\hat{h}^{-1}} = \underset{2}{\hat{g}}\ \underset{2}{\hat{u}}\ \underset{2}{\hat{h}^{-1}}\ \underset{}{\hat{r}}\ \underset{1}{\hat{g}}\ \underset{1}{\hat{u}}\ \underset{1}{\hat{h}^{-1}} = \underset{2}{\hat{u}'}\ \underset{}{\hat{r}}\ \underset{1}{\hat{u}'}. \end{aligned} \tag{4.14}$$

In order for the algebra generated by $\hat{g}$ and $\hat{h}$ to be associative it is necessary for $\hat{r}$ to satisfy the quantum Yang-Baxter equations,

$$\underset{12}{\hat{r}}\ \underset{13}{\hat{r}}\ \underset{23}{\hat{r}} = \underset{23}{\hat{r}}\ \underset{13}{\hat{r}}\ \underset{12}{\hat{r}}. \tag{4.15}$$

On the other hand, the quantum Yang-Baxter equations did not have to be satisfied for the algebra generated by $\hat{u}$ to be associative. Finally substitute (4.10) into (4.15). As in the infinitesimal cases, we get an identity only when two angles are equal and the third is zero. Hence the spinor-type transformations (4.12) correspond to symmetries only in the Connes-Landi case. For example, choose $\phi_0=\phi_4=0$ and $\phi_1=\phi_2=\phi/2$. Then $\hat{r}$ simplifies to $\mathrm{diag}(q,1,1,q)$, where $q=e^{-i\phi}$, and the condition (1.1) is equivalent to

$$\det_q \hat{u} \equiv \hat{u}_{11}\hat{u}_{22} - q\hat{u}_{12}\hat{u}_{21} = 1. \tag{4.16}$$

This condition is preserved under (4.12) provided $\det \hat{g}\ \det \hat{h}^{-1}=1$, after using (4.3) along with the commutation relations for matrix elements of $\hat{g}$ with $\hat{h}^{-1}$. It can be checked that both $\det \hat{g}$ and $\det \hat{h}^{-1}$ are Casimirs of the algebra and hence can be set to one. From (4.12) one can obtain the left coaction of the coordinates

$$\hat{x}_\mu \rightarrow \hat{x}'_\mu = \hat{M}_{\mu\nu}\hat{x}_\nu, \tag{4.17}$$

with

$$\hat{M}_{\mu\nu}(\hat{g},\hat{h}) = \tfrac{1}{2}e^{i(\phi_\nu-\phi_\mu)}\,\mathrm{Tr}(\tau_\mu \hat{g}\tau^\nu \hat{h}^{-1}). \tag{4.18}$$

The commutation relations for $\hat{M}_{\mu\nu}$ are then determined from the commutation relations for matrix elements of $\hat{g}$ with $\hat{h}^{-1}$.

V. NONCOMMUTATIVE HYPERBOLOIDS

The sphere of Connes and Dubois-Violette can be Wick rotated to Minkowski space. The result is a three-parameter family of "noncommutative hyperboloids." We can then repeat the previous analysis and search for quantum deformations of the Lorentz group which have noncommutative hyperboloids as homogeneous spaces. For simplicity, we only examine the first order system and write it in spinor notation. The result is that there is a Lie-Poisson action of a Lie-Poisson group acting on a one parameter subgroup of noncommutative hyperboloids, namely the Wick rotated version Connes-Landi spheres.

The Wick rotation of the Poisson structure (1.4) is

$$\{x_\mu, x_\nu\} = E_{\mu\nu,\rho\sigma}x^\rho x^\sigma, \tag{5.1}$$

where $E_{\mu\nu,\rho\sigma}$ are again given in terms of three independent parameters by (1.5) and the indices of x are raised and lowered by the Minkowski metric $\eta_{\mu\nu}=\mathrm{diag}(-1,1,1,1)$. $\eta_{\mu\nu}x^\mu x^\nu$ is a Casimir for the Poisson algebra and so we can restrict to a hyperboloid. In the quantized theory, the time component x_0 will be noncommuting for any nontrivial values of the parameters.

The algebra can be reexpressed in terms of a Hermitian matrix $x=x_\mu\sigma^\mu$, where σ^0 is the 2×2 identity matrix and $\sigma^i, i=1,2,3$, are the Pauli matrices. The Poisson brackets (5.1) can be written as

$$\{\underset{1}{x},\underset{2}{x}\} = i\,\underset{2}{x}\,\underset{1}{r}\,\underset{1}{x} - i\,\underset{1}{x}\,\underset{2}{r}\,\underset{2}{x}, \tag{5.2}$$

using the definition of r in (2.6). The Casimir is now expressed as $\det x$, the latter being invariant under $\mathrm{SL}(2,C)$ transformations

$$x \rightarrow x' = sxs^\dagger, \quad s \in \mathrm{SL}(2,C). \tag{5.3}$$

The Poisson algebra is not preserved under this action, but if we can assign the following Poisson structure to $\mathrm{SL}(2,C)$,

$$\{ \underset{1}{s}, \underset{2}{\bar{s}} \} = -i[\underset{1}{r}, \underset{1}{s} \underset{2}{\bar{s}}], \quad \{ \underset{1}{s}, \underset{2}{s} \} = \{ \underset{1}{s}, \underset{2}{\bar{s}} \} = 0, \tag{5.4}$$

where $\bar{s}=s^{\dagger^{-1}}$, then the brackets (5.2) are invariant in the sense that (5.3) is a Poisson map. Once again for consistency we need to check the Jacobi identity, or equivalently the classical Yang-Baxter equations for r. But as before these conditions are only satisfied when all but one κ_i vanish, and so we only get a consistent deformation of $\mathrm{SL}(2,C)$ in the Connes-Landi limit. For a classification of consistent quantum deformations of $\mathrm{SL}(2,C)$ see Ref. 10.

VI. CONCLUDING REMARKS

Our search for quantum deformations of Spin(4) and SO(4) for which the noncommutative three-spheres of Connes and Dubois-Violette are homogeneous spaces, and which have a smooth commutative limit in the Lie-Poisson sense, has yielded only the known symmetries of twisted Connes-Landi spheres. The question arises as to whether a more involved analysis can yield any other quantum deformations, possibly without a smooth commutative limit. Other possibilities which are currently under investigation would allow for more general Poisson structures on the group at the Poisson level, or commutation relations at the quantum level. In this regard, although the brackets (2.10), if they could have been consistently defined, would have assured that (1.6) is a Poisson map, other possibilities for the Poisson structure on g and h can be explored. For example, one might try dropping the relations $\{g_1,g_2\}=\{h_1,h_2\}=0$. The difficulty is to make this consistent with the requirement that (1.6) be a Poisson map. Moreover, at the quantum level, one can consider generalizing the commutation relations (4.13), possibly dropping $[\hat{g}_1,\hat{g}_2]=[\hat{h}_1,\hat{h}_2]=0$. The task then would be to find the analog of (4.14). Finally, throughout this paper we have insisted upon writing Poisson brackets and commutations relations in terms of an R-matrix. While this is an important case, other possibilities should be investigated for an exhaustive study.

(Received 3 May 2005; accepted 25 August 2005; published online 28 October 2005)

The nonlocal conserved quantities of the $N=1$ Super KdV are obtained using a Gardner map. A fermionic substitution semigroup and the resulting Gardner category are defined and several propositions concerning their algebraic structure are obtained. This algebraic framework makes it possible to define general transformations between different nonlinear SUSY differential equations. A SUSY ring extension is then introduced to deal with the nonlocal conserved quantities of SKdV. The algebraic version of the nonlocal conserved quantities is solved in terms of the exponential function applied to the D^{-1} of the local conserved quantities of SKdV. Finally the same formulas are shown to work for rapidly decreasing superfields.
 [DOI: 10.1063/1.2073289]

I. INTRODUCTION

The supersymmetric algebra is the unique extension of the super-Poincaré algebra which is consistent with the S-matrix of quantum field theory. The most remarkable SUSY theory explains how superstrings and other extended SUSY objects can be consistently tied together in what also has been called M-theory.

Free (string) superstring theory is a two-dimensional supersymmetric theory whose local symmetry group is generated by the (Virasoro) Super-Virasoro algebra.

These algebras may be realized as algebras of the (potential) superpotential of (KdV) SKdV[1,2] equations when the second Hamiltonian structure (with the corresponding Poisson structure) is considered.[3]

It is then reasonable to think that the hierarchy of (KdV) SKdV is related to the loop expansion of (string) superstring theory in terms of the genus of Riemann surfaces.[4]

The SKdV hierarchy also arises from supersymmetric quantum mechanics. In fact, it was proven in Refs. 5 and 6 that the entire SKdV hierarchy appears in the asymptotic expansion of the Green's function $g(t,x,\theta,y,\theta')$ of the super heat operator, as $t\to 0^+$ and $g(t,x,\theta,y,\theta')$ is restricted to the diagonal $x=y$, $\theta=\theta'$. The same result holds for the pure "bosonic" (non-SUSY) KdV hierarchy arising from the Green's function of the heat operator with potential, that is, the "Euclidean" Schrödinger operator.[7]

The KdV equation has an infinite number of discrete conserved quantities (CQs). The SUSY extension of these conserved quantities are also CQs for the SKdV equation; but a remarkable

[a)]Electronic mail: sandrea@usb.ve
[b)]Electronic mail: arestu@usb.ve
[c)]Electronic mail: sotomayo@fis.usb.ve

difference between the two equations is that SKdV has a second sequence of CQs, these being nonlocal and intrinsically supersymmetric in nature. They have been interpreted[8] as the Poisson square root of the local CQs, in the sense that

$$\{J,J'\}=H,$$

where J and J' are nonlocal CQs and H is a local CQ of SKdV.

The conservation laws of KdV and SKdV may be obtained from the Lax representations of these equations; for a review see Ref. 8. The nonlocal CQs of SKdV were first obtained by analyzing the infinite set of symmetries of SKdV, e.g., Ref. 9. Later on they were obtained from the Lax operator in Ref. 10.

Another way to obtain these conservation laws is through the supersymmetric extension[1,11] of the Gardner transformation.[12] It may be interpreted as a one-parameter integrable deformation of SKdV. The deformation is

$$\phi=\chi+\varepsilon D^2\chi-\varepsilon^2\chi D\chi,$$

where ε is the deformation parameter.

If the superfield χ satisfies the S-Gardner equation[1] then ϕ satisfies SKdV. Then, using the fact that $H=\int \mathrm{d}x\,\mathrm{d}\theta\chi$ is a conserved quantity of the S-Gardner equation, it was shown[1] that all the local conserved quantities of SKdV arise in the formal expansion of H in powers of ε.

It was left as an open problem, OP1 in the review of Mathieu,[8] to find the nonlocal conserved quantities of SKdV from some integrable ε-deformation.

In the present paper OP1 is solved, by first rephrasing it in a completely algebraic framework. Working first in the free SUSY derivation ring constructed in Ref. 5, a fermionic substitution semigroup is introduced. The resulting Gardner category is an algebraic construction modeled on the possibility of more general Gardner transforms between different nonlinear SUSY differential equations. In the particular case of SKdV the local conserved quantities are constructed from this formalism.

We then introduce SUSY ring extensions in order to deal with the possibility of nonlocal conserved quantities. The algebraic version of the nonlocal CQ problem is solved, using the exponential function applied to the D^{-1} of the local conserved quantities which the ring extensions provide.

Finally the same formulas are shown to work for rapidly decreasing superfields, and the nonlocal CQs so obtained are shown to agree with those found in the literature.

II. THE FERMIONIC SUBSTITUTION SEMIGROUP

Let $\mathcal{A}$ be the free SUSY derivation ring on a single fermionic generator a_1. This ring is generated by its fermionic elements $a_1,a_3,a_5,\ldots$ and bosonic elements $a_2,a_4,a_6,\ldots$ and its superderivation $D:\mathcal{A}\to\mathcal{A}$ is determinated by $Da_n=a_{n+1}$ for $n\geqslant 1$.

The ring extension $\mathcal{A}[\varepsilon]\supset\mathcal{A}$ consists of all formal power series $h=\Sigma_{n=0}^{\infty}\varepsilon^n h_n$ with coefficients $h_n(a_1,a_2,\ldots)\in\mathcal{A}$. Its involution $h\to\bar{h}$ and superderivation $h\to Dh$ are defined componentwise from the same operations in $\mathcal{A}$. The supercommutativity equation $gh=\pm hg$ holds when $\bar{g}=\pm g$ and $\bar{h}=\pm h$, a minus sign when $\bar{g}=-g$ and $\bar{h}=-h$, and a plus sign in the other three cases.

When $f,g\in\mathcal{A}[\varepsilon]$ with $\bar{f}=-f$, the substitution of f in g produces another element $g\circ f\in\mathcal{A}[\varepsilon]$. It is defined by the formulas

$$g=\sum_0^{\infty}\varepsilon^n g_n(a_1,a_2,\ldots),$$

$$g \circ f = \sum_0^\infty \varepsilon^n g_n(f, Df, \dots).$$

The following propositions may be proven.

Proposition 1: When $f, g, h \in \mathcal{A}[\varepsilon]$ *with* $\bar{f} = -f$ *one has*

$$(g+h) \circ f = (g \circ f) + (h \circ f),$$

$$(gh) \circ f = (g \circ f)(h \circ f),$$

which is to say that the operation $g \to g \circ f$ *is a ring homomorphism* $\mathcal{A}[\varepsilon] \to \mathcal{A}[\varepsilon]$, *for any fixed* $\bar{f} = -f$.

Proposition 2: When $f, g \in \mathcal{A}[\varepsilon]$ *with* $\bar{f} = -f$, *one has*

$$D(g \circ f) = (Dg) \circ f.$$

Now let $\mathcal{A}_1[\varepsilon] \subset \mathcal{A}[\varepsilon]$ be the subset of all fermionic elements. The substitution product gives $g \circ f \in \mathcal{A}_1[\varepsilon]$ if $g, f \in \mathcal{A}_1[\varepsilon]$.

Proposition 3: The substitution product is associative:

$$(h \circ g) \circ f = h \circ (g \circ f),$$

when g, h, f *are in* $\mathcal{A}_1[\varepsilon]$.

Thus $\mathcal{A}_1[\varepsilon]$ is made into a semigroup by the substitution construction. Evidently the element $a_1 \in \mathcal{A}_1 \subset \mathcal{A}_1[\varepsilon]$ acts as the identity element of this semigroup.

When an element of $\mathcal{A}_1[\varepsilon]$ has the value a_1 when $\varepsilon = 0$ it is invertible:

Proposition 4: Given $f = a_1 + \varepsilon f_1 + \varepsilon^2 f_2 + \cdots \in \mathcal{A}_1[\varepsilon]$ *there exists* $g = a_1 + \varepsilon g_1 + \varepsilon^2 g_2 + \cdots \in \mathcal{A}_1[\varepsilon]$ *with* $g \circ f = a_1$.

An easy corollary shows that left and right inverses are the same.

Proposition 5: Given $f = a_1 + \Sigma_{k=1}^\infty \varepsilon^k f_k$ *and* $g = a_1 + \Sigma_{k=1}^\infty \varepsilon^k g_k$ *in* $\mathcal{A}_1[\varepsilon]$. *If* $f \circ g = a_1$ *then* $g \circ f = a_1$.

Frechet derivative operator. Associated with the ring $\mathcal{A}$ and its superderivation $D: \mathcal{A} \to \mathcal{A}$ there is a ring $\mathcal{O}_p\mathcal{A}$ whose elements are the finite order differential operators $L = \Sigma_{k=0}^N l_k D^k$ with $l_k \in \mathcal{A}$. Each L acts linearly in $\mathcal{A}$, and the product of two operators is computed from repeated applications of the SUSY product rule $D(gh) = (Dg)h + \bar{g}(Dh)$.

When $\bar{f} = -f \in \mathcal{A}_1[\varepsilon]$, the substitution of f in L is defined by

$$L \circ f = \sum_{k=0}^N (l_k \circ f) D^k.$$

Thus $L \circ f$, a formal power series with operator coefficients, is in the ring $(\mathcal{O}_p\mathcal{A})[\varepsilon]$ whose elements are the sums $\Sigma_{m,n} \varepsilon^m l_{m,n} D^n$ with $l_{m,n} \in \mathcal{A}$ and $l_{m,n} = 0$ for $n \gg 0$, at any given m.

Given $L \in (\mathcal{O}_p\mathcal{A})[\varepsilon]$ and $h \in \mathcal{A}[\varepsilon]$, the element $Lh \in \mathcal{A}[\varepsilon]$ is well-defined because $(\Sigma \varepsilon^m L_m)(\Sigma \varepsilon^n h_n)$ is again a power series with coefficients in $\mathcal{A}$. The effect of f-substitution is as to be expected.

The following proposition may be shown:

Proposition 6: If $L \in (\mathcal{O}_p\mathcal{A})[\varepsilon]$, $h \in \mathcal{A}[\varepsilon]$, and $f \in \mathcal{A}_1[\varepsilon]$, *then*

$$(Lh) \circ f = (L \circ f)(h \circ f).$$

The foregoing constructions come into play when we ask for the first variation of the substitution operation. Given any $f = \Sigma_{m=0}^\infty \varepsilon^m f_m(a_1, a_2, \dots)$ in $\mathcal{A}_1[\varepsilon]$, its Frechet derivative operator is

$$f' = \sum_{m=0}^{\infty} \sum_{n=1}^{\infty} \varepsilon^m \frac{\partial}{\partial a_n} f_m(a_1, a_2, \dots) D^{n-1} \in (\mathcal{O}_p \mathcal{A})[\varepsilon].$$

Then for any $\psi \in \mathcal{A}_1[\varepsilon]$ the substitution by $a_1 + t\psi \in \mathcal{A}_1[\varepsilon]$ gives

$$f \circ (a_1 + t\psi) = f + tf' \psi + \cdots,$$

the full right side of the equation being a power series in t with $\mathcal{A}[\varepsilon]$ coefficients.

A more general formula appears when a_1 is replaced by $\varphi \in \mathcal{A}_1[\varepsilon]$ and

$$f \circ (\varphi + t\psi) = f \circ \varphi + t(f' \circ \varphi)\psi + \cdots,$$

valid when $f, \varphi, \psi \in \mathcal{A}_1[\varepsilon]$.

The chain rule is now immediate.

Proposition 7: When $f, g \in \mathcal{A}_1[\varepsilon]$ one has

$$(f \circ g)' = (f' \circ g) g'.$$

III. THE GARDNER CATEGORY

An element $f = \Sigma_{m=0}^{\infty} \varepsilon^m f_m(a_1, a_2, \dots)$ of $\mathcal{A}_1[\varepsilon]$ may be taken to represent a nonlinear differential equation

$$\frac{\partial}{\partial t} \alpha(x,t) = \sum_{m=0}^{\infty} \varepsilon^m f_m(\alpha(x,t), D_1 \alpha(x,t), \dots),$$

where $\alpha(x,t)$ is a fermionic superfield (see Sec. V) and the superderivation $D_1 = \partial/\partial\theta + \theta(\partial/\partial x)$ is also known as the covariant derivative.

A second element $g \in \mathcal{A}_1[\varepsilon]$ represents a second differential equation, for an unknown superfield $\beta(x,t)$.

Then given a third element $r \in \mathcal{A}_1[\varepsilon]$, one might want the transformation

$$\beta(x,t) = \sum_{m=0}^{\infty} \varepsilon^m r_m(\alpha(x,t), D_1 \alpha(x,t), \dots)$$

to transform solutions of the first equation into solutions of the second. After some computation one sees that this happens if

$$g \circ r = r' f.$$

Accordingly, f and g can be called "objects" in the Gardner category, and r a "morphism" from f to g, written $g \overset{r}{\leftarrow} f$, if the above equality holds in $\mathcal{A}_1[\varepsilon]$.

Obviously the choice $r = a_1 \in \mathcal{A}$, $r' = I \in \mathcal{O}_p \mathcal{A}$ gives the identity automorphism of each object. But the composition of morphisms must be checked.

Proposition 8: Given $f, g, h, r, s \in \mathcal{A}_1[\varepsilon]$.

If $h \overset{s}{\leftarrow} g$ and $g \overset{r}{\leftarrow} f$ then $h \overset{s \circ r}{\leftarrow} f$.

Proof of Proposition 8: From $h \circ s = s' g$ it follows that

$$h \circ s \circ r = s' g \circ r = (s' \circ r)(g \circ r)$$

after applying Proposition 6 to $s' \in \mathcal{O}_p \mathcal{A}[\varepsilon]$ and $g \in \mathcal{A}_1[\varepsilon]$. But $g \circ r = r' f$, giving

$$h \circ (s \circ r) = (s' \circ r) r' f = (s \circ r)' f$$

by the chain rule, Proposition 7. This completes the proof.

The possibility of isomorphism classes in the Gardner category leads one to examine the invertible elements. One has the following result:

Proposition 9: Given $f,g,r,s \in \mathcal{A}_1[\varepsilon]$ *with* $r\circ s=s\circ r=a_1$.

If $g \overset{r}{\leftarrow} f$

then $f \overset{s}{\leftarrow} g$.

The Gardner transform. The SUSY KdV equation is represented by $g=a_7+3a_1a_4+3a_2a_3$, and the Gardner transform by $r=a_1+\varepsilon a_3-\varepsilon^2 a_1a_2$.

A "modified" KdV equation will be represented by some $f \in \mathcal{A}_1[\varepsilon]$. If f can be chosen so that

$$g \circ r = r' f$$

then we will have found an algebraic analog of the Gardner transformation's action on superfield solutions of the two differential equations.

The choice $f=g-3\varepsilon^2\chi$ satisfies $g\circ r=r'f$, which is to say that $g \overset{r}{\leftarrow} f$ in category language.

By Propositions 4 and 5 there exists an inverse Gardner transform

$$s = a_1 - \varepsilon a_3 + \cdots \in \mathcal{A}[\varepsilon]$$

satisfying $r\circ s=s\circ r=a_1$ and hence also, by Proposition 9, $f\circ s=s'g$.

However $f=Dh$ for

$$h = (a_6 + 3a_2^2 - 3a_1a_3) + \varepsilon^2(3a_1a_2a_3 - 2a_2^3).$$

Consequently all the coefficients in the power series $s'g$ are in $D\mathcal{A}\subset\mathcal{A}$.

If $s_n(a_1,a_2,\ldots)$ is the coefficient of ε^n, then this condition implies that $\int \mathrm{d}x\, d\,\theta s_n(\phi,D_1\phi,\ldots)$ remains constant while the superfield ϕ evolves in time with the SUSY KdV equation, and $D_1=\partial/\partial\theta+\theta(\partial/\partial x)$.

IV. RING EXTENSIONS AND NONLOCAL CONSERVATION LAWS

In the general situation $D:\mathcal{B}\to\mathcal{B}$ of an oriented supercommutative ring and a superderivation, an element $u\in\mathcal{B}$ may or may not have the form $u=Dv$ for some $v\in\mathcal{B}$. But for a fermionic $u=-\bar{u}$ one can always pass to the extension $\tilde{D}:\tilde{\mathcal{B}}\to\tilde{\mathcal{B}}$ where $\tilde{\mathcal{B}}$ is the ring of polynomials with $\mathcal{B}$ coefficients in a commuting indeterminate λ, and the new superderivation is $\tilde{D}=D+u(\partial/\partial\lambda)$. (If the extension was unnecessary then $\tilde{D}v=u$ will have more than one solution in $\tilde{B}$.)

The natural first example is given by $u=a_1$, the generator of $\mathcal{A}(a_1,a_2,\ldots)$, the free SUSY derivation ring on a single fermionic generator. The extension just described is $\mathcal{A}(a_0,a_1,a_2,\ldots)$, the free SUSY derivation ring on a bosonic generator a_0, with $Da_n=a_{n+1}$ for $n\geqslant 0$.

The ring of formal power series $\mathcal{A}(a_0,a_1,a_2,\ldots)[\varepsilon]$ has the same universal property seen earlier in the fermionic case. That is, given any $\tilde{D}:\tilde{\mathcal{B}}\to\tilde{\mathcal{B}}$ and some formal power series $b=\Sigma_0^\infty\varepsilon^n b_n$ with all $b_n=\bar{b}_n\in\mathcal{B}$, the substitution operation $g\mapsto g\circ b$ takes $g=\Sigma_0^\infty\varepsilon^n g_n(a_0,a_1,a_2,\ldots)$ to $g\circ b=\Sigma_0^\infty\varepsilon^m g_m(b,\tilde{D}b,\ldots)$.

Then $\Omega(g)=g\circ b$ is a well-defined map of the power series ring extensions

$$\Omega:\mathcal{A}(a_0,a_1,a_2,\ldots)[\varepsilon]\to\tilde{\mathcal{B}}[\varepsilon].$$

In fact Ω is a ring homomorphism which commutes with the respective involutions and satisfies $\Omega D=\tilde{D}\Omega$: The proof is the same as for the Propositions 1 and 2 given earlier.

Ring extensions of the fermionic ring $\mathcal{A}(a_1,a_2,\ldots)$ are now constructed so as to incorporate D^{-1} of all the local conserved quantities of the SUSY KdV equation. From the formulas

$$r = a_1 + \varepsilon a_3 - \varepsilon^2 a_1 a_2$$

for the Gardner transform and

$$s = s_0 + \varepsilon s_1 + \varepsilon^2 s_2 + \cdots$$

for its inverse, which satisfy $r \circ s = s \circ r = a_1$, one can compute for example

$$s_0 = a_1,$$

$$s_1 = -a_3,$$

$$s_2 = a_5 + a_1 a_2,$$

$$s_3 = -a_7 - 2a_1 a_4 - 2a_2 a_3,$$

$$s_4 = a_9 + (3a_1 a_6 + 3a_2 a_5 + 5a_3 a_4) + 2a_1 a_2 a_2.$$

It was shown before that

$$f \circ s = s' g$$

for

$$g = a_7 + 3a_1 a_4 + 3a_2 a_3,$$

$$f = g - 3\varepsilon^2 (a_1 a_2 a_4 + a_2^2 a_3).$$

However $f = Dh$ for $h = (a_6 + 3a_2^2 - 3a_1 a_3) + \varepsilon^2 (3a_1 a_2 a_3 - 2a_2^3)$.

Therefore $D(h \circ s) = s' g$.

As pointed out before, this is a proof that $s_0, s_1, \ldots$ are conserved quantities for the SUSY KdV equation.

For each s_n the ring extension is made which incorporates $\lambda_n = D^{-1} s_n$. Done successively for $s_0, s_1, \ldots$ this gives $\tilde{\mathcal{B}} = \mathcal{A}(\lambda_0, \lambda_1, \ldots)$, the ring of polynomials in the commuting indeterminates $\lambda_0, \lambda_1, \ldots$, with coefficients in $\mathcal{A}(a_1, a_2, \ldots)$. The new superderivation $\tilde{D}: \tilde{\mathcal{B}} \to \tilde{\mathcal{B}}$ is $\tilde{D} = D + \sum_{n=0}^{\infty} s_n (\partial / \partial \lambda_n)$.

Supposing $\mu(\lambda_0, \lambda_1, \ldots)$ to be a polynomial with constant coefficients we ask for the first variation with respect to g. When $\mu = \lambda_n$ this is

$$\dot{\lambda}_n = \left. \frac{\mathrm{d}}{\mathrm{d}t} \right|^{t=0} D^{-1}(s_n \circ (a_1 + tg)) = D^{-1}(s_n' g) = (h \circ s)_n \in \mathcal{A}(a_1, a_2, \ldots),$$

where $(h \circ s)_n$ is the coefficient of ε^n in the power series $h \circ s$.

This shows that $\mu(\lambda_0, \lambda_1, \ldots)$ is a conserved quantity if

$$\sum_{n=0}^{\infty} (h \circ s)_n \frac{\partial \mu}{\partial \lambda_n} \in \tilde{D}(\tilde{\mathcal{B}}).$$

We now work with $\lambda = \sum_0^{\infty} \varepsilon^n \lambda_n \in \tilde{\mathcal{B}}[\varepsilon]$.

Theorem 1: *The coefficients of $e^{\varepsilon \lambda}$ are all nonlocal conserved quantities for the algebraic version of the SUSY KdV equation.*

Proof of Theorem 1: With

$$e^{\varepsilon \lambda} = 1 + \varepsilon \mu_1 + \varepsilon^2 \mu_2 + \cdots,$$

$$\frac{\partial}{\partial \lambda_n} e^{\varepsilon\lambda} = \varepsilon^{n+1} e^{\varepsilon\lambda}$$

one has $(\partial/\partial\lambda_n)\mu_p = \mu_{p-n-1}$ and $\dot{\mu}_p = \Sigma_{n=0}^{p-1} \mu_{p-n-1}\dot{\lambda}_n$.

This is the coefficient of ε^{p-1} in the power series $e^{\varepsilon\lambda}(h \circ s)$.

Evidently $e^{\varepsilon\lambda}(h \circ s) \in \tilde{B}[\varepsilon]$.

The proof of the theorem is complete when we have shown that

$$e^{\varepsilon\lambda}(h \circ s) \in \tilde{D}(\tilde{B}[\varepsilon]).$$

However the substitution operation $\Omega(g) = g \circ \lambda$ gives a ring homomorphism

$$\Omega : \mathcal{A}(a_0, a_1, \ldots)[\varepsilon] \to \tilde{B}[\varepsilon].$$

Obviously $\Omega(e^{\varepsilon a_0}) = e^{\varepsilon\lambda}$, while

$$\Omega(a_1) = a_1 \circ \lambda = D\lambda = s,$$

$$\Omega(a_n) = D^n s \text{ for } n \geqslant 1.$$

This shows that

$$\Omega(h) = h \circ s,$$

giving

$$\Omega(e^{\varepsilon a_0} h(a_1, a_2, \ldots, \varepsilon)) = e^{\varepsilon\lambda}(h \circ s).$$

The search for antiderivatives can therefore be done in the more accessible ring $\mathcal{A}(a_0, a_1, \ldots)[\varepsilon]$. Indeed

$$e^{\varepsilon a_0} h = Dl$$

with $l = e^{\varepsilon a_0}(F_0 + \varepsilon F_1 + \varepsilon^2 F_2)$ and F_0, F_1, F_2 certain fermionic elements of $\mathcal{A}(a_1, a_2, \ldots)$. The desired equation reduces to

$$DF_0 = a_6 + 3a_2 a_2 - 3a_1 a_3,$$

$$DF_1 + a_1 F_0 = 0,$$

$$DF_2 + a_1 F_1 = 3a_1 a_2 a_3 - 2a_2^3,$$

$$a_1 F_2 = 0.$$

These equations are satisfied by

$$F_0 = a_5 + 3a_1 a_2, \quad F_1 = a_1 a_4 - a_2 a_3, \quad F_2 = -2a_1 a_2^2.$$

Because the ring homomorphism satisfies $\Omega D = \tilde{D}\Omega$ we conclude that from

$$\Omega(e^{\varepsilon a_0} h) = e^{\varepsilon\lambda}(h \circ s)$$

we may infer

$$e^{\varepsilon\lambda}(h \circ s) = \tilde{D}(\Omega l).$$

This completes the proof of the theorem.

V. CONSERVATION LAWS FOR SUPERFIELDS

The algebraic constructions done so far will now be applied to the SUSY KdV equation. This equation deals with superfields, which may be described as follows.

Suppose Λ is a finite dimensional Grassmann algebra generated by anticommuting elements $\theta, \eta_1, \eta_2, \ldots$ which satisfy $\theta^2=\eta_1^2=\eta_2^2=\cdots=0$.

Any element of Λ, after reorderings and sign changes, may be written uniquely as

$$\phi = v(\eta_1, \eta_2, \ldots) + \theta u(\eta_1, \eta_2, \ldots).$$

Then the superderivation $\partial/\partial\theta: \Lambda \to \Lambda$ is defined by $\partial\phi/\partial\theta = u$.

A superfield is any infinitely differentiable function $\phi: \mathbb{R} \to \Lambda$, and the ring of all superfields is denoted by $\mathcal{C}^\infty(\mathbb{R}, \Lambda)$. A superfield is called "bosonic" when $\bar{\phi}=\phi$ and fermionic when $\bar{\phi}=-\phi$. To avoid confusion with the algebraic case, the superderivation in this ring is written $D_1 = \partial/\partial\theta + \theta(\partial/\partial x)$.

Thus $\phi(x) = v(x) + \theta u(x)$ and $D_1\phi = u(x) + \theta v'(x)$.

Ring homomorphisms from algebra to analysis are given by substitution of elements of $\mathcal{C}^\infty(\mathbb{R}, \Lambda)$. For example if $\phi=-\bar{\phi}$ in $\mathcal{C}^\infty(\mathbb{R}, \Lambda)$ one has the ring homomorphism

$$\mathcal{A}(a_1, a_2, \ldots) \to \mathcal{C}^\infty(\mathbb{R}, \Lambda)$$

which sends $f(a_1, a_2, \ldots)$ to $f \circ \phi = f(\phi, D_1\phi, \ldots)$. This homomorphism interrelates the two superderivations, in the sense that

$$D_1(f \circ \phi) = (Df) \circ \phi.$$

The associativity equation $(g \circ f) \circ \phi = g \circ (f \circ \phi)$ continues to hold when $f=-\bar{f}$ in $\mathcal{A}(a_1, a_2, \ldots)$ and $\phi=-\bar{\phi}$ in $\mathcal{C}^\infty(\mathbb{R}, \Lambda)$, while $g \in \mathcal{A}(a_1, a_2, \ldots)$ is arbitrary.

For the convergence of integrals one must work in subrings of $\mathcal{C}^\infty(\mathbb{R}, \Lambda)$.

Let $\mathcal{C}^\infty_\downarrow(\mathbb{R}, \Lambda)$ be the superfields that diminish rapidly at $x=\pm\infty$ together with all derivatives. When Φ satisfies $D_1\Phi \in \mathcal{C}^\infty_\downarrow$, Φ and all its derivatives are bounded functions, and in particular $(\partial/\partial\theta)\Phi \in \mathcal{C}^\infty_\downarrow$. Thus $\psi\Phi \in \mathcal{C}^\infty_\downarrow$ when $\psi \in \mathcal{C}^\infty_\downarrow$ and $D_1\Phi \in \mathcal{C}^\infty_\downarrow$.

The nonlocal extension of $\mathcal{C}^\infty_\downarrow$ may be defined to be

$$\mathcal{C}^\infty_{\mathrm{NL}}(\mathbb{R}, \Lambda) = \{\Phi \in \mathcal{C}^\infty(\mathbb{R}, \Lambda) : D_1\Phi \in \mathcal{C}^\infty_\downarrow(\mathbb{R}, \Lambda)\}.$$

Then $\mathcal{C}^\infty_{\mathrm{NL}}$ is again a derivation ring, and it contains $\mathcal{C}^\infty_\downarrow$ as an ideal. The formulas

$$\phi(x) = v(x) + \theta u(x),$$

$$D_1^{-1}\phi(x) = \int_{-\infty}^{x} u(s)\mathrm{d}s + \theta v(x)$$

give an explicit mapping $D_1^{-1}: \mathcal{C}^\infty_\downarrow \to \mathcal{C}^\infty_{\mathrm{NL}}$, with $D_1^{-1}D_1\phi = \phi$ as well as $D_1D_1^{-1}\phi = \phi$ for all $\phi \in \mathcal{C}^\infty_\downarrow$.

When $\Phi(x) = V(x) + \theta U(x) \in \mathcal{C}^\infty_{\mathrm{NL}}$ one can define the integral of $\Phi(x)$ to be

$$\int \Phi = \int_{-\infty}^{\infty} U(x)\mathrm{d}x.$$

Thus, integration is an additive mapping from $\mathcal{C}^\infty_{\mathrm{NL}}(\mathbb{R}, \Lambda)$ to the Grassmann algebra Λ.

And, when $\phi \in \mathcal{C}^\infty_\downarrow \subset \mathcal{C}^\infty_{\mathrm{NL}}$ one has

$$\int D_1\phi = 0.$$

These preparations done we turn to the SUSY KdV equation, which is represented by $g=a_7+3a_1a_4+3a_2a_3$: if ϕ is a time-dependent superfield then

$$\frac{\partial}{\partial t}\phi = \dot{\phi} = g \circ \phi.$$

With $s=\Sigma_0^\infty \varepsilon^n s_n(a_1,a_2,\ldots)$ the inverse Gardner transform, and any $\phi=-\bar{\phi}\in\mathcal{C}_\downarrow^\infty$, we define

$$\Phi = D_1^{-1}(s\circ\phi),$$

a formal power series with $\mathcal{C}_{\mathrm{NL}}^\infty$ coefficients.

Then

$$J(\phi) = \int e^{\varepsilon\Phi}$$

will be shown to be a power series whose coefficients are nonlocal conservation laws for the SUSY KdV equation.

To compute $\dot{\Phi}=\mathrm{d}/\mathrm{d}t|^{t=0}\Phi(\phi+t\dot{\phi})$ we recall first that

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|^{t=0} s\circ(a_1+tg) = D(h\circ s)$$

in the ring of formal power series $\mathcal{A}(a_1,a_2,\ldots)[\varepsilon]$, with $h=\Sigma_0^\infty\varepsilon^n h_n(a_1,a_2,\ldots)$ as computed before.

The substitution homomorphism given by ϕ then gives $(\mathrm{d}/\mathrm{d}t)|^{t=0}s\circ(\phi+t\dot{\phi})=D_1(h\circ s\circ\phi)$. Consequently

$$\dot{\Phi} = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|^{t=0} D_1^{-1}(s\circ(\phi+t\dot{\phi})) = h\circ s\circ\phi.$$

Since $\dot{J}=\varepsilon\int e^{\varepsilon\Phi}\dot{\Phi}$, the proof will be complete when it has been shown that

$$\int e^{\varepsilon\Phi}(h\circ s\circ\phi) = 0.$$

However, it was shown earlier that there exists $F=\Sigma_0^\infty\varepsilon^n F_n(a_1,a_2,\ldots)$ satisfying

$$e^{\varepsilon a_0}h = D(e^{\varepsilon a_0}F)$$

in the ring $\mathcal{A}(a_0,a_1,\ldots)[\varepsilon]$ of formal power series with $\mathcal{A}(a_0,a_1,\ldots)$ coefficients. Under the operation of substitution by Φ this equation becomes

$$e^{\varepsilon\Phi}(h\circ s\circ\phi) = D_1(e^{\varepsilon\Phi}(F\circ s\circ\phi))$$

in the ring $\mathcal{C}_{\mathrm{NL}}^\infty(\mathbb{R},\Lambda)[\varepsilon]$, because $D_1\Phi=s\circ\phi$ and h and F do not involve a_0.

The coefficients of $e^{\varepsilon\Phi}$ are in $\mathcal{C}_{\mathrm{NL}}^\infty$ while the coefficients of $F\circ s\circ\phi$ are in $\mathcal{C}_\downarrow^\infty$.

Therefore their product is in $\mathcal{C}_\downarrow^\infty$, where $\psi\in\mathcal{C}_\downarrow^\infty$ implies $\int D_1\psi=0$.

This completes the proof that $J(\phi)=\int e^{\varepsilon\Phi}$ is a conserved quantity for the SUSY KdV equation.

In closing we may compare $\int e^{\varepsilon\Phi}$ with conserved quantities found in the literature. Starting with $\phi=-\bar{\phi}\in\mathcal{C}_\downarrow^\infty$, the first few coefficients of $\Phi=\Sigma_0^\infty\varepsilon^n\Phi_n=D^{-1}(s\circ\phi)$ can be found from the corresponding coefficients of the inverse Gardner transform $\Sigma_0^\infty\varepsilon^n s_n(a_1,a_2,\ldots)$. After replacing D_1 by the shorter notation $D=\partial/\partial\theta+\theta(\partial/\partial x)$ one finds that

$$\Phi_0 = D^{-1}\phi,$$

$$\Phi_1 = -D\phi,$$

$$\Phi_2 = D^3\phi + D^{-1}(\phi D\phi),$$

$$\Phi_3 = -D^5\phi - 2(D\phi)^2 + 2\phi(D^2\phi).$$

These elements of $\mathcal{C}^{\infty}_{\mathrm{NL}}$ are all bosonic, and the first few coefficients of $e^{\varepsilon\Phi} = 1 + \Sigma_{n=1}^{\infty}\varepsilon^n\Delta_n$ are

$$\Delta_1 = \Phi_0,$$

$$\Delta_2 = \tfrac{1}{2}\Phi_0^2 + \Phi_1,$$

$$\Delta_3 = \tfrac{1}{6}\Phi_0^3 + \Phi_0\Phi_1 + \Phi_2,$$

$$\Delta_4 = \tfrac{1}{24}\Phi_0^4 + \tfrac{1}{2}\Phi_0^2\Phi_1 + \Phi_0\Phi_2 + \tfrac{1}{2}\Phi_1^2 + \Phi_3.$$

Because we are only interested in the integrals of $\Delta_n(\phi)$, terms which fall into $D\mathcal{C}^{\infty}_{\downarrow}$ can be left out because they have identically zero integrals. For example

$$\Phi_0\Phi_1 = -(D^{-1}\phi)(D\phi) = -D((D^{-1}\phi)\phi).$$

After rewriting the Δ_n in terms of $D^{-1}\phi, \phi, \ldots$ and simplifying in the manner just described we arrive at

$$\Delta_1 = D^{-1}\phi,$$

$$\Delta_2 = \tfrac{1}{2}(D^{-1}\phi)^2,$$

$$\Delta_3 = \tfrac{1}{6}(D^{-1}\phi)^3 + D^{-1}(\phi D\phi),$$

$$\Delta_4 = \tfrac{1}{24}(D^{-1}\phi)^4 - \tfrac{1}{2}(D\phi)^2 + (D^{-1}\phi)D^{-1}(\phi D\phi).$$

Replacing ϕ by $-\phi$ in these formulas we obtain constant multiples of the integrands which appear in the nonlocal conserved quantities $J_{\frac{1}{2}}, J_{\frac{3}{2}}, J_{\frac{5}{2}}, J_{\frac{7}{2}}$ presented in Ref. 10.

The sign change comes from the ambiguity $g = \pm a_7 + 3a_1a_4 + 3a_2a_3$ in the definition of the SUSY KdV equation.

The two versions are interchanged by the transformation $T: \mathcal{A}(a_1, a_2, \ldots) \to \mathcal{A}(a_1, a_2, \ldots)$ given by $(Tf)(a_1, a_2, \ldots) = -f(-a_1, -a_2, \ldots)$.

This transformation is not a ring homomorphism but it satisfies $DT = TD$. In terms of the substitution operation, $Tg = -(g \circ (-a_1))$ in general, with $Tf = (-a_1) \circ f \circ (-a_1)$ when $\bar{f} = -f$.

The associativity and the cancellation $(-a_1) \circ (-a_1) = a_1$ then give

$$T(g \circ f) = (Tg) \circ (Tf).$$

Therefore T also exchanges the respective Gardner transforms and conservation laws.

VI. CONCLUSIONS

We introduced the fermionic substitution semigroup and the resulting Gardner category. We obtained several propositions concerning their algebraic structure. This algebraic framework made it possible to define general Gardner transformations between different nonlinear SUSY differen-

tial equations. We then introduced a SUSY ring extension which, in the same algebraic setting, permitted the construction of all the known nonlocal conserved quantities of $N=1$ SKdV. All these nonlocal conserved quantities are then obtained from the Super-Gardner equation using a Gardner map. They may be expressed in terms of the exponential function applied to the D^{-1} of the local conserved quantities of $N=1$ SKdV. As in the case of the local conserved quantities of $N=1$ SKdV, one conserved quantity of the Super-Gardner equation generates all the known nonlocal conserved quantities of $N=1$ SKdV.

An interesting problem to be considered would be to apply the construction we introduced here to obtain the conserved quantities of $N=2$ SKdV.[13]

On the structure of the supplementary series of unitary, irreducible representations of the proper, orthochronous Lorentz group

J. Kubieniec[a)]
Marian Smoluchowski Institute of Physics, Jagellonian University, Reymonta 4, 30-059 Kraków, Poland

(Received 13 July 2005; accepted 30 August 2005; published online 28 October 2005)

Representations from the supplementary series of unitary, irreducible representations of the proper, orthochronous Lorentz group are classified according to the parameter z, $0<z<1$. The representations with $0<z<1/2$ are qualitatively different from those with $1/2<z<1$. This is shown in the form of the following theorem: the Casimir operator of the little group of a spacelike vector has for $0<z<1/2$ a single bound state, i.e., a single normalizable eigenstate which disappears for $1/2<z<1$. To this end the scalar product for the supplementary series is explicitly calculated in both regions, $0<z<1/2$ and $1/2<z<1$ in a coordinate system provided by common eigenfunctions of the Casimir operator of the little group of a spacelike vector and the commuting generator of a parabolic rotation. The choice of this coordinate system allows to use the well established properties of the Kontorovich-Lebedev pair of integral transforms. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2080455]

I. INTRODUCTION

The supplementary series of unitary, irreducible representations of the proper, orthochronous Lorentz group was discovered simultaneously and independently by Gelfand and Neumark,[1] Bargmann,[2] and Harish-Chandra.[3] It is described in several textbooks, e.g., in the textbook by Gelfand, Graev, and Vilenkin.[4] The structure of the supplementary series was investigated by Mukunda,[5] and Boyer.[6] They calculated the scalar product for the supplementary series in a canonical coordinate system provided by common eigenfunctions of two commuting observables, viz. the Casimir operator of the little group of a spacelike vector and the generator of a rotation. In this way they discovered a bound state of the Casimir operator.

In this paper we shall investigate the structure of the supplementary series in the following way. We shall calculate the scalar product for the supplementary series in a special coordinate system provided by common eigenfunctions of two commuting observables, viz. the Casimir operator of the little group of a spacelike vector and the generator of a parabolic rotation. The reason for the choice of the generator of the parabolic rotation is that common eigenfunctions are then proportional to MacDonald functions of imaginary order. Thus the decomposition of an arbitrary function can be carried out with the aid of the pair of Kontorovich-Lebedev transforms. Moreover, we shall use the theory of the supplementary series described in Ref. 7. This approach makes the Lorentz invariance of all calculations manifest at each step. It also reveals the physical shape of the bound state of the Casimir operator which is completely absent in the papers mentioned above. The mathematics which is necessary to see this was first elaborated by Staruszkiewicz.[8] He discovered a bound state of the first Casimir operator of the proper, orthochronous Lorentz group in his theory of the quantum Coulomb field.

We use units such that $\hbar=1=c$. We use the metric tensor $g_{\mu\nu}$ such that $xx=g_{\mu\nu}x^\mu x^\nu\equiv(x^0)^2-(x^1)^2-(x^2)^2-(x^3)^2$ is the square of the length of the vector x.

II. THE SUPPLEMENTARY SERIES

We present the supplementary series of unitary, irreducible representations of the proper, orthochronous Lorentz group, following Ref. 7.

The upper light cone (here in the momentum space) is a figure formed by positive frequency null vectors $kk=0$, $k^0>0$. It consists of null directions. A null direction is a set of null vectors parallel to a given null vector. The set of null directions has the Lorentz invariant volume, which Gelfand, Graev, and Vilenkin give on p. 426 of their textbook[4] and Staruszkiewicz[9] applies to calculate several useful integrals,

$$\mathrm{d}^2k=\frac{k^1\,\mathrm{d}k^2\wedge\mathrm{d}k^3+k^2\,\mathrm{d}k^3\wedge\mathrm{d}k^1+k^3\,\mathrm{d}k^1\wedge\mathrm{d}k^2}{k^0}. \tag{1}$$

Here $\wedge$ denotes the outer product. The function $f(k)$ defined on the upper light cone is said to be homogeneous of degree $z-2$, $0<z<1$, if

$$f(\rho k)=\rho^{z-2}f(k)\quad\text{for each }\rho>0. \tag{2}$$

Functions homogeneous of degree $z-2$ form a linear space over the field of complex numbers. Introducing in this space the manifestly Lorentz invariant nonlocal scalar product

$$\langle f|f\rangle_z=\int\frac{\mathrm{d}^2k\,\mathrm{d}^2l}{(kl)^z}\overline{f(k)}f(l) \tag{3}$$

we obtain the Hilbert space appropriate for the supplementary series.

III. THE CASIMIR OPERATOR OF THE LITTLE GROUP OF A SPACELIKE VECTOR AND THE GENERATOR OF A PARABOLIC ROTATION: THEIR COMMON EIGENFUNCTIONS

Let a and b be two fixed orthogonal spacelike vectors, $ab=0$, $aa=-1$, $bb=-1$. Let q be a fixed null vector orthogonal to the vectors a and b, $qq=0$, $aq=0$, $bq=0$.

The set of proper, orthochronous Lorentz transformations which preserve a fixed vector is called the little group of this vector. In what follows we consider the spacelike vector a. The Casimir operator of the little group of this vector written in a manifestly Lorentz invariant form is

$$C=-a_\mu\overset{*}{M}{}^{\mu\nu}a^\rho\overset{*}{M}{}_{\rho\nu}. \tag{4}$$

Here $\overset{*}{M}{}^{\mu\nu}=(1/2)\epsilon^{\mu\nu\rho\sigma}M_{\rho\sigma}$ is the dual pseudotensor associated with generators $M_{\mu\nu}=-M_{\nu\mu}$ of the proper, orthochronous Lorentz group. $\epsilon^{\mu\nu\rho\sigma}$ denotes the Levi-Civita symbol, $\epsilon^{0123}=1$.

There are three kinds of one-parameter subgroups of the proper, orthochronous Lorentz group, elliptic rotations (rotations), which preserve a timelike plane, hyperbolic rotations (Lorentz "boosts"), which preserve a spacelike plane, and parabolic rotations, which preserve a null plane. In what follows we consider the parabolic rotation which preserves the null plane spanned by the spacelike vector a and the null vector q. The generator of this parabolic rotation written in a manifestly Lorentz invariant form is

$$M=a^\mu q^\nu\overset{*}{M}{}_{\mu\nu}=-b^\mu q^\nu M_{\mu\nu}. \tag{5}$$

Let us choose a basis such that $a=(0,0,0,1)$, $b=(0,0,1,0)$, $q=(1,1,0,0)$. Then

$$C=M_{01}^2+M_{02}^2-M_{12}^2, \tag{6}$$

$$M = M_{02} + M_{12}, \tag{7}$$

which shows that C and M commute.

Reflection of the null direction k in the timelike hyperplane orthogonal to the spacelike vector a is the null direction k' such that

$$k' = k + 2(ak)a. \tag{8}$$

It is seen that this reflection changes the sign of the variable ak. Thus its representation in the representation space appropriate for the supplementary series is simply the parity operator P. P is invariant under the little group of a generated by operators $a^\mu M^*_{\mu\nu}$. As a consequence we obtain the following corollary: P commutes with C and M. Hence we can find even and odd common eigenfunctions of C and M, respectively, $f^+_{\tau\lambda}(k)$ and $f^-_{\tau\lambda}(k)$, such that

$$Cf^\pm_{\tau\lambda}(k) = \left(\frac{1}{4} + \tau^2\right) f^\pm_{\tau\lambda}(k),$$

$$Mf^\pm_{\tau\lambda}(k) = \lambda f^\pm_{\tau\lambda}(k),$$

$$Pf^\pm_{\tau\lambda}(k) = \pm f^\pm_{\tau\lambda}(k). \tag{9}$$

The generators of the proper, orthochronous Lorentz group for the spinless case in the momentum space written in a manifestly Lorentz covariant form are

$$M_{\mu\nu} = i\left(k_\mu \frac{\partial}{\partial k^\nu} - k_\nu \frac{\partial}{\partial k^\mu}\right). \tag{10}$$

Since $M_{\mu\nu}(kk) \equiv 0$, the formally four-dimensional differential operator $M_{\mu\nu}$ is in fact an internal differential operator on the light cone $kk=0$. Then the system of partial differential equations (9) can be separated in the stereographic variables ak/qk and bk/qk. One finds thus even and odd common eigenfunctions of C and M to be the following:

$$f^+_{\tau\lambda}(k) = |ak|^{z-2} \left|\lambda \frac{ak}{qk}\right|^{1/2} K_{i\tau}\left(\left|\lambda \frac{ak}{qk}\right|\right) \exp\left(i\lambda \frac{bk}{qk}\right),$$

$$f^-_{\tau\lambda}(k) = \operatorname{sign}(ak)|ak|^{z-2} \left|\lambda \frac{ak}{qk}\right|^{1/2} K_{i\tau}\left(\left|\lambda \frac{ak}{qk}\right|\right) \exp\left(i\lambda \frac{bk}{qk}\right),$$

$$\tau \geqslant 0, \quad -\infty < \lambda < \infty. \tag{11}$$

$K_{i\tau}$ is the MacDonald function of imaginary order $i\tau$ such that

$$K_{i\tau}(|x|) = \int_0^\infty \mathrm{d}t\, e^{-|x|\cosh t} \cos(\tau t) \tag{12}$$

and sign is the signum function.

An arbitrary homogeneous of degree $z-2$ function $f(k)$ defined on the upper light cone can be resolved into even and odd parts, respectively, $f^+(k)$ and $f^-(k)$,

$$f(k) = f^+(k) + f^-(k). \tag{13}$$

Using the pair of Kontorovich-Lebedev transforms[10] we get the decomposition of functions $f^+(k)$, $f^-(k)$,

$$f^{\pm}(k)=\int_0^{\infty}\mathrm{d}\tau\int_{-\infty}^{\infty}\mathrm{d}\lambda\, g^{\pm}(\tau,\lambda)f^{\pm}_{\tau\lambda}(k),$$

$$g^{\pm}(\tau,\lambda)=\frac{1}{2\pi^3}\frac{\tau\sinh(\pi\tau)}{|\lambda|}\int \mathrm{d}^2k|ak|^{2-2z}f^{\pm}(k)\overline{f^{\pm}_{\tau\lambda}(k)}. \tag{14}$$

IV. THE SCALAR PRODUCT FOR THE SUPPLEMENTARY SERIES

It is easy to show that

$$\langle f^{+}_{\tau\lambda}|f^{-}_{\tau'\lambda'}\rangle_z=0. \tag{15}$$

To calculate the scalar product for the supplementary series we need besides the following lemma, which is proved in Appendix A: there exist functions $K^{+}(z;\tau)$, $K^{-}(z;\tau)$ such that

$$\int\frac{\mathrm{d}^2k}{(kl)^z}f^{\pm}_{\tau\lambda}(k)=f^{\pm}_{\tau\lambda}(l)\cdot|al|^{2-2z}\cdot K^{\pm}(z;\tau). \tag{16}$$

The function $K^{+}(z;\tau)$ is calculated in Appendix B. It exists for $1/2<z<1$ and can be expressed by the gamma function Γ,

$$K^{+}(z;\tau)=\pi^2\frac{2^z}{\Gamma^2(z)\sin(\pi z)}\frac{\Gamma\left(\frac{z-1/2+i\tau}{2}\right)\Gamma\left(\frac{z-1/2-i\tau}{2}\right)}{\Gamma\left(\frac{3/2-z+i\tau}{2}\right)\Gamma\left(\frac{3/2-z-i\tau}{2}\right)}. \tag{17}$$

The function $K^{-}(z;\tau)$ is calculated in Appendix C. It exists for $1/2<z<1$ and can be expressed by the gamma function Γ and the generalized hypergeometric function ${}_3F_2$,

$$\begin{aligned}K^{-}(z;\tau)=&\frac{\pi^{3/2}}{2}\frac{2^z}{\Gamma(z)\cos\frac{\pi}{2}\left(z-\frac{1}{2}\right)}\frac{1}{\Gamma\left(\frac{3/2-z+i\tau}{2}\right)\Gamma\left(\frac{3/2-z-i\tau}{2}\right)\cosh\left(\frac{\pi}{2}\tau\right)}\\&\times\left[\frac{1}{1-z}\left(\frac{3/2-z+i\tau}{2}\right)^{-1}{}_3F_2\left(\frac{1}{2},1,\frac{3/2-z+i\tau}{2};2-z,\frac{7/2-z+i\tau}{2};1\right)+\text{c.c.}\right.\\&\left.+2\left(\frac{1/2+z+i\tau}{2}\right)^{-1}{}_3F_2\left(z,1,\frac{1/2+z+i\tau}{2};\frac{3}{2},\frac{5/2+z+i\tau}{2};1\right)+\text{c.c.}\right].\end{aligned} \tag{18}$$

Utilizing Eqs. (14) and (16) we have for $1/2<z<1$,

$$\langle f^{\pm}_{\tau\lambda}|f^{\pm}_{\tau'\lambda'}\rangle_z=2\pi^3\frac{|\lambda|}{\tau\sinh(\pi\tau)}K^{\pm}(z;\tau)\delta(\tau-\tau')\delta(\lambda-\lambda'). \tag{19}$$

Hence the scalar product for the supplementary series valid for $1/2<z<1$ has the form

$$\begin{aligned}\langle f|f\rangle_z=&2\pi^3\int_0^{\infty}\mathrm{d}\tau\int_{-\infty}^{\infty}\mathrm{d}\lambda\frac{|\lambda|}{\tau\sinh(\pi\tau)}K^{+}(z;\tau)|g^{+}(\tau,\lambda)|^2\\&+2\pi^3\int_0^{\infty}\mathrm{d}\tau\int_{-\infty}^{\infty}\mathrm{d}\lambda\frac{|\lambda|}{\tau\sinh(\pi\tau)}K^{-}(z;\tau)|g^{-}(\tau,\lambda)|^2.\end{aligned} \tag{20}$$

To find the equivalent of Eq. (20) valid for $0<z<1/2$ one must notice what follows. For $1/2<z<1$, Eq. (20) can be rewritten as[11]

$$\langle f|f\rangle_z = \int \mathrm{d}^2k\mathrm{d}^2l|ak|^{-z}\overline{f^+(k)}|al|^{-z}f^+(l)\frac{1}{4\pi}\int_0^\infty \mathrm{d}\tau\,\tau\tanh(\pi\tau)P_{-1/2+i\tau}(u)K^+(z;\tau)$$
$$+\int \mathrm{d}^2k\,\mathrm{d}^2l\,\mathrm{sign}(ak)|ak|^{-z}\overline{f^-(k)}\,\mathrm{sign}(al)|al|^{-z}f^-(l)\frac{1}{4\pi}\int_0^\infty \mathrm{d}\tau\,\tau\tanh(\pi\tau)P_{-1/2+i\tau}(u)K^-(z;\tau), \tag{21}$$

where $u=\mathrm{sign}(ak)\mathrm{sign}(al)+kl/(|ak||al|)$. $P_{-1/2+i\tau}$ is the conical function. The original scalar product $\langle f|f\rangle_z$, given by Eq. (3), is an analytic function of z. Thus the correct expression for the scalar product $\langle f|f\rangle_z$ valid for $0<z<1/2$ is the analytic continuation of the functions of z given by the integrals

$$\frac{1}{4\pi}\int_0^\infty \mathrm{d}\tau\,\tau\tanh(\pi\tau)P_{-1/2+i\tau}(u)K^\pm(z;\tau). \tag{22}$$

They can be treated as contour integrals in the complex τ-plane. It is seen then that when z changes from $1/2<z<1$ to $0<z<1/2$, two simple poles of $K^+(z;\tau)$ cross the contour. Residues at these poles must be subtracted, since $\langle f|f\rangle_z$ is a given analytic function of z, the same for all z.

The scalar product for the supplementary series valid for $0<z<1/2$, calculated in accordance with the above mathematical principle, has the form

$$\langle f|f\rangle_z = 2\pi^3\int_0^\infty \mathrm{d}\tau\int_{-\infty}^\infty \mathrm{d}\lambda\frac{|\lambda|}{\tau\sinh(\pi\tau)}K^+(z;\tau)|g^+(\tau,\lambda)|^2$$
$$+2\pi^3\int_0^\infty \mathrm{d}\tau\int_{-\infty}^\infty \mathrm{d}\lambda\frac{|\lambda|}{\tau\sinh(\pi\tau)}K^-(z;\tau)|g^-(\tau,\lambda)|^2$$
$$+16\pi^5\frac{1}{2^z\left(\frac{1}{2}-z\right)^2}\frac{\Gamma(2z)}{\Gamma^2(z)\cos(\pi z)}\int_{-\infty}^\infty \mathrm{d}\lambda|\lambda|\left|g^+\left(i\left(\frac{1}{2}-z\right),\lambda\right)\right|^2. \tag{23}$$

V. SPECTRUM OF THE CASIMIR OPERATOR OF THE LITTLE GROUP OF A SPACELIKE VECTOR

From Eqs. (20) and (23) it follows that the Casimir operator C of the little group of the spacelike vector a, $aa=-1$, given by Eq. (4), has for $0<z<1/2$ a single normalizable eigenstate, i.e., a single bound state which disappears for $1/2<z<1$. One can show that for $0<z<1/2$ the function

$$f_\lambda^+(k) = (qk)^{z-2}\delta\left(\frac{ak}{qk}\right)\exp\left(i\lambda\frac{bk}{qk}\right) \tag{24}$$

is an eigenfunction of C with the eigenvalue $0<z(1-z)<1/4$,

$$Cf_\lambda^+(k) = z(1-z)f_\lambda^+(k). \tag{25}$$

The scalar product of two such functions is[11]

$$\langle f_\lambda^+|f_{\lambda'}^+\rangle_z = 2\pi^2\frac{2^z|\lambda|^{2z-1}}{\Gamma(2z)\cos(\pi z)}\delta(\lambda-\lambda'), \tag{26}$$

which means as usual that wave packets obtained by superposing various values of λ will be normalizable. Thus the momentum wave function of the bound state of C is localized in the circle $ak=0$.

We summarize our results in the form of the following theorem: the spectrum of the Casimir operator C of the little group of the unit spacelike vector a consists of only positive numbers greater than or equal to $1/4$ if $1/2<z<1$ and positive numbers greater than or equal to $1/4$ and additionally the single number $0<z(1-z)<1/4$ if $0<z<1/2$. It reveals that the parameter $z=1/2$ is critical and separates two different classes of representations from the supplementary series.

ACKNOWLEDGMENT

I thank Professor A. Staruszkiewicz for many helpful explanations.

APPENDIX A: THE USEFUL LEMMA

Let us notice first that in expressions like $M_{\mu\nu}(k)(kl)$ it is necessary to write the argument k of the differential operator $M_{\mu\nu}$. It indicates the variable with respect to which the differentiation is carried out. Now, applying this convention, we have

$$\int \frac{\mathrm{d}^2k}{(kl)^z} M_{\mu\nu} f(k) = -\int \mathrm{d}^2k\, M_{\mu\nu}(k)(kl)^{-z}\cdot f(k)$$
$$= \int \mathrm{d}^2k\, M_{\mu\nu}(l)(kl)^{-z}\cdot f(k) = M_{\mu\nu}\int \frac{\mathrm{d}^2k}{(kl)^z} f(k) \tag{A1}$$

and

$$\int \frac{\mathrm{d}^2k}{(kl)^z} M_{\mu\nu}M_{\rho\sigma} f(k) = M_{\mu\nu}\int \frac{\mathrm{d}^2k}{(kl)^z} M_{\rho\sigma} f(k) = M_{\mu\nu}M_{\rho\sigma}\int \frac{\mathrm{d}^2k}{(kl)^z} f(k). \tag{A2}$$

As an obvious consequence we obtain

$$\int \frac{\mathrm{d}^2k}{(kl)^z} M f(k) = M\int \frac{\mathrm{d}^2k}{(kl)^z} f(k) \tag{A3}$$

and

$$\int \frac{\mathrm{d}^2k}{(kl)^z} C f(k) = C\int \frac{\mathrm{d}^2k}{(kl)^z} f(k). \tag{A4}$$

The integrals

$$\int \frac{\mathrm{d}^2k}{(kl)^z} f^{\pm}_{\tau\lambda}(k) \tag{A5}$$

are manifestly Lorentz invariant, homogeneous of degree $-z$ in l, and even and odd in a, respectively. On the basis of these facts and Eqs. (A3) and (A4), we infer that there exist functions $K^+(z;\tau,\lambda)$, $K^-(z;\tau,\lambda)$ such that

$$\int \frac{\mathrm{d}^2k}{(kl)^z} f^{\pm}_{\tau\lambda}(k) = f^{\pm}_{\tau\lambda}(l)\cdot |al|^{2-2z}\cdot K^{\pm}(z;\tau,\lambda). \tag{A6}$$

On both sides of Eq. (A6) the eigenvalue λ can be absorbed into the null vector q, which does not change the definition of q. Hence the functions $K^+(z;\tau,\lambda)$, $K^-(z;\tau,\lambda)$ cannot depend on λ and this leads directly to Eq. (16).

APPENDIX B: CALCULATION OF THE FUNCTION $K^+(z;\tau)$

All integrals necessary to calculate the function $K^+(z;\tau)$ are given in Ref. 11.

For the even case in Eq. (16) we substitute $\lambda=1$, multiply both sides by $|bl|^{-\alpha}(ql)^{-\beta}$, $z+\alpha+\beta=2$ and integrate over l. In this way we obtain

$$\int d^2k|ak|^{z-2}\left|\frac{ak}{qk}\right|^{1/2}K_{i\tau}\left(\left|\frac{ak}{qk}\right|\right)\exp\left(i\frac{bk}{qk}\right)\int d^2l(kl)^{-z}|bl|^{-\alpha}(ql)^{-\beta}$$
$$=K^+(z;\tau)\int d^2l|bl|^{-\alpha}(ql)^{-\beta}|al|^{-z}\left|\frac{al}{ql}\right|^{1/2}K_{i\tau}\left(\left|\frac{al}{ql}\right|\right)\exp\left(i\frac{bl}{ql}\right). \tag{B1}$$

The integral

$$\int d^2l(kl)^{-z}|bl|^{-\alpha}(ql)^{-\beta} \tag{B2}$$

is manifestly Lorentz invariant, homogeneous of degree $-z$ in k and $-\beta$ in q, and even in b. On the basis of these facts, we infer that there exists a function $A(z;\alpha)$ such that

$$\int d^2l(kl)^{-z}|bl|^{-\alpha}(ql)^{-\beta}=|bk|^{\beta-z}\cdot(qk)^{-\beta}\cdot A(z;\alpha). \tag{B3}$$

It is easy to show that

$$A(z;\alpha)=2^z\int\frac{d\xi\,d\eta}{|\eta|^\alpha[\xi^2+(\eta-1)^2]^z}, \tag{B4}$$

$\xi=al/ql$ and $\eta=bl/ql$ being the stereographic variables. The integral over ξ can be calculated in a simple way. Then the integral over η boils down to the convolution and can be calculated with the aid of the convolution theorem. It is thus seen that the function $A(z;\alpha)$ exists for $1/2<z<1$, $2-2z<\alpha<1$ and has the form

$$A(z;\alpha)=\frac{2^{z+2}}{\sqrt{\pi}}\frac{\Gamma\left(z-\frac{1}{2}\right)}{\Gamma(z)}\Gamma(2-2z)\cos\frac{\pi}{2}(2-2z)\Gamma(2z+\alpha-2)$$
$$\times\cos\frac{\pi}{2}(2z+\alpha-2)\Gamma(1-\alpha)\cos\frac{\pi}{2}(1-\alpha). \tag{B5}$$

Therefore for $1/2<z<1$, $2-2z<\alpha<1$, Eq. (B1) can be rewritten as

$$A(z;\alpha)\int d^2k|bk|^{2-2z-\alpha}(qk)^{z+\alpha-2}|ak|^{z-2}\left|\frac{ak}{qk}\right|^{1/2}K_{i\tau}\left(\left|\frac{ak}{qk}\right|\right)\exp\left(i\frac{bk}{qk}\right)$$
$$=K^+(z;\tau)\int d^2l|bl|^{-\alpha}(ql)^{z+\alpha-2}|al|^{-z}\left|\frac{al}{ql}\right|^{1/2}K_{i\tau}\left(\left|\frac{al}{ql}\right|\right)\exp\left(i\frac{bl}{ql}\right). \tag{B6}$$

Both integrals in Eq. (B6) exist for $1/2<z<1$, $2-2z<\alpha<1$; the integral on the left-hand side equals

$$2^{z-1/2}\Gamma\left(\frac{z-1/2+i\tau}{2}\right)\Gamma\left(\frac{z-1/2-i\tau}{2}\right)\Gamma(3-2z-\alpha)\cos\frac{\pi}{2}(3-2z-\alpha), \tag{B7}$$

and the integral on the right-hand side equals

$$2^{3/2-z}\Gamma\left(\frac{3/2-z+i\tau}{2}\right)\Gamma\left(\frac{3/2-z-i\tau}{2}\right)\Gamma(1-\alpha)\cos\frac{\pi}{2}(1-\alpha). \tag{B8}$$

This leads directly to Eq. (17).

APPENDIX C: CALCULATION OF THE FUNCTION $K^{-}(z;\tau)$

All integrals necessary to calculate the function $K^{-}(z;\tau)$ are also given in Ref. 11.

For the odd case in Eq. (16) we substitute $\lambda=1$, multiply both sides by $|bl|^{-\alpha}(ql)^{-\beta}\,\mathrm{sign}(al)$, $z+\alpha+\beta=2$ and integrate over l. In this way we obtain

$$\int \mathrm{d}^2k\,\mathrm{sign}(ak)|ak|^{z-2}\left|\frac{ak}{qk}\right|^{1/2}K_{i\tau}\left(\left|\frac{ak}{qk}\right|\right)\exp\left(i\frac{bk}{qk}\right)\int \mathrm{d}^2l(kl)^{-z}|bl|^{-\alpha}(ql)^{-\beta}\,\mathrm{sign}(al)$$

$$=K^{-}(z;\tau)\int \mathrm{d}^2l|bl|^{-\alpha}(ql)^{-\beta}|al|^{-z}\left|\frac{al}{ql}\right|^{1/2}K_{i\tau}\left(\left|\frac{al}{ql}\right|\right)\exp\left(i\frac{bl}{ql}\right). \tag{C1}$$

The integral

$$\int \mathrm{d}^2l(kl)^{-z}|bl|^{-\alpha}(ql)^{-\beta}\,\mathrm{sign}(al) \tag{C2}$$

is manifestly Lorentz invariant, homogeneous of degree $-z$ in k and $-\beta$ in q, even in b, and odd in a. Utilizing these facts we calculate that

$$\int \mathrm{d}^2l(kl)^{-z}|bl|^{-\alpha}(ql)^{-\beta}\,\mathrm{sign}(al)=|bk|^{\beta-z}\cdot(qk)^{-\beta}\cdot\mathrm{sign}(ak)\cdot A(z;\alpha;k), \tag{C3}$$

where

$$A(z;\alpha;k)=2^z\int\frac{\mathrm{d}\xi'\,\mathrm{d}\eta'\,\mathrm{sign}(\xi')}{|\eta'|^{\alpha}\left[\left(\xi'-\left|\frac{ak}{bk}\right|\right)^2+(\eta'-1)^2\right]^z}, \tag{C4}$$

$\xi'=\xi/|bk/qk|$ and $\eta'=\eta/|bk/qk|$ being the scaled stereographic variables. The integral over η' can be calculated in a simple way. It is proportional to the associated Legendre function $P^{1/2-z}_{z+\alpha-3/2}$, which for $\alpha=3/2-z$ has the simplest form, i.e., does not contain the hypergeometric function ${}_2F_1$. Then the integral over ξ' can be calculated. Hence we choose $\alpha=3/2-z$. It is thus seen that the function $A(z;3/2-z;k)\equiv A(z;k)$ exists for $1/2<z<1$ and has the form

$$A(z;k)=2^{2-z}\sqrt{\pi}\frac{\Gamma\left(z-\frac{1}{2}\right)}{\Gamma(z)}\left[\frac{1}{1-z}\zeta^{1-z}(1+\zeta)^{-1/2}\,{}_2F_1\left(\frac{1}{2},1;2-z;\frac{\zeta}{1+\zeta}\right)\right.$$

$$\left.+2\zeta^{1/2}(1+\zeta)^{-z}\,{}_2F_1\left(z,1;\frac{3}{2};\frac{\zeta}{1+\zeta}\right)\right], \tag{C5}$$

where $\zeta=(1/2)(\sqrt{1+|ak/bk|^2}-1)$. Therefore for $1/2<z<1$, $\alpha=3/2-z$, Eq. (C1) can be rewritten as

$$\int \mathrm{d}^2k\,A(z;k)|bk|^{1/2-z}(qk)^{-1/2}|ak|^{z-2}\left|\frac{ak}{qk}\right|^{1/2}K_{i\tau}\left(\left|\frac{ak}{qk}\right|\right)\exp\left(i\frac{bk}{qk}\right)$$

$$=K^{-}(z;\tau)\int \mathrm{d}^2l|bl|^{z-3/2}(ql)^{-1/2}|al|^{-z}\left|\frac{al}{ql}\right|^{1/2}K_{i\tau}\left(\left|\frac{al}{ql}\right|\right)\exp\left(i\frac{bl}{ql}\right). \tag{C6}$$

Both integrals in Eq. (C6) exist for $1/2<z<1$; the integral on the left-hand side equals

$$\frac{\sqrt{2}\pi^{3/2}}{\cosh\left(\frac{\pi}{2}\tau\right)}\frac{\Gamma\left(z-\frac{1}{2}\right)}{\Gamma(z)}\left[\frac{1}{1-z}\left(\frac{3/2-z+i\tau}{2}\right)^{-1}{}_3F_2\left(\frac{1}{2},1,\frac{3/2-z+i\tau}{2};2-z,\frac{7/2-z+i\tau}{2};1\right)+\text{c.c.}\right.$$

$$\left.+2\left(\frac{1/2+z+i\tau}{2}\right)^{-1}{}_3F_2\left(z,1,\frac{1/2+z+i\tau}{2};\frac{3}{2},\frac{5/2+z+i\tau}{2};1\right)+\text{c.c.}\right], \tag{C7}$$

and the integral on the right-hand side equals

$$2^{3/2-z}\Gamma\left(\frac{3/2-z+i\tau}{2}\right)\Gamma\left(\frac{3/2-z-i\tau}{2}\right)\Gamma\left(z-\frac{1}{2}\right)\cos\frac{\pi}{2}\left(z-\frac{1}{2}\right). \tag{C8}$$

This leads directly to Eq. (18).

JOURNAL OF MATHEMATICAL PHYSICS **46**, 103519 (2005)

Gauge theory on nonassociative spaces

S. Majid[a)]
School of Mathematical Sciences, Queen Mary, University of London, 327 Mile End Rd., London E1 4NS, United Kingdom

(Received 24 August 2005; accepted 30 August 2005; published online 31 October 2005)

We show how to do gauge theory on the octonions and other nonassociative algebras such as "quasi-$\mathbb{R}^4$" models proposed in string theory. We use the theory of quasialgebras obtained by cochain twist introduced previously. The gauge theory in this case is twisting–equivalent to the usual gauge theory on the underlying classical space. We give a general $U(1)$-Yang–Mills example for any quasialgebra and a full description of the moduli space of flat connections in this theory for the cube $\mathbb{Z}_2^3$ and hence for the octonions. We also obtain further results about the octonions themselves; an explicit Moyal-product description of them as a nonassociative quantization of functions on the cube, and a characterization of their cochain twist as invariant under Fourier transform. © *2005 American Institute of Physics.*

I. INTRODUCTION

There has been a lot of interest recently in "nonassociative geometry" as a further extension of the ideas of noncommutative geometry, with now the "coordinate algebra" allowed to be nonassociative. The framework which we use of "quasialgebras" was already established and used to describe the octonions as "quasispaces" some years ago.[2] These were, moreover, constructed as a "cochain twist" of a classical associative space. Differential geometry on such quasispaces was introduced in Ref. 1 and in this paper we add "gauge theory."

The need for nonassociative geometry for noncommutative differential forms (even when the coordinate algebra itself remains associative) was shown in Ref. 5, where it was proven that all differential form algebras on the standard q-deformation quantum groups, if they are to be bicovariant and to have classical dimensions, must indeed be nonassociative. Thus the usual assumption in noncommutative geometry, including in Ref. 8, that differential forms should be associative, appears to be too strong. From a physics point of view also, there are suggestions that the world volume algebras on certain string theories are naturally nonassociative[9], and this has been realized quite concretely in some form in the context of reduced matrix models, see Refs. 19, 12, and 20. In the latter is posed the problem of gauge theory on such spaces, with apparently higher order differentials being required. We start by making precise what is fairly clear that the simplified "fuzzy" algebras in Ref. 20 are indeed quasialgebras in our required sense. We then show that in this case there is a natural formulation of gauge theory on them looking much more like the classical case. We describe this theory for any quasialgebra (or algebra in a nonassociative monoidal category) at an algebraic level and give a general construction for examples equivalent to $U(1)$-Yang–Mills in the associative case. The framework allows for non-Abelian gauge theory as well. Also, we do not discuss Lagrangians here but all of the necessary data and methods for these are known in the associative case, see notably Refs. 17 and 18, and apply equivalently to quasialgebras obtained by cochain twists.

As well as covering the strings-motivated example, we explore fully the octonions as finite "quasigeometries" par excellence. We show that the cochain $F(\vec{a},\vec{b})$ in Ref. 2 that modifies the

a)Electronic mail: s.majid@qmul.ac.uk

group algebra of the cube $\mathbb{Z}_2^3$ to the octonion product has the very remarkable feature of being invariant under $\mathbb{Z}_2^3$-Fourier transform. Using this, we also find an explicit more geometrical $\bullet$-product description of the octonion as a nonassociative quantization of the coordinate algebra on the Fourier-dual cube $\mathbb{Z}_2^3$ by means of a (finite difference) bidifferential operator. This is in the spirit of the Moyal-product of functions on $\mathbb{R}^n$, but now nonassociative. The associative quantization (Clifford algebra) case is also covered.

The paper begins in Sec. II with a brief introduction to the theory of quasialgebras obtained by cochain twist,[2,1] as algebras in a (symmetric) monoidal category. Sections II A and II B, respectively, outline the continuous case deforming $\mathbb{R}^n$ and the finite case deforming group algebras. In Sec. III A we recall from Ref. 14 the formulation of gauge theory in such a general monoidal category and the diagrammatic notation for it. Section III B applies this at an algebraic level to describe gauge theory on cochain twist quasialgebras in general. Section III C gives a canonical general example where the "gauge group" can be chosen canonically. Although appearing non-Abelian (and nonassociative) we show that this particular choice gives a theory equivalent to the undeformed $U(1)$-Yang–Mills theory. Note that in noncommutative geometry even the $U(1)$ theory has $F(\alpha)=\mathrm{d}\alpha+\alpha\wedge\alpha$ and we use the phrase Yang–Mills to distinguish this nonlinear theory from the Maxwell case where $F(\alpha)=\mathrm{d}\alpha$.

In Sec. IV we apply the theory of the quasialgebra versions of $\mathbb{R}^n$ of interest in Ref. 19 under heading of a simplified "quasi-$\mathbb{R}^n$." Section IV A introduces the required nonassociative differential calculus and Sec. IV B the promised gauge theory. Finally, in Sec. V we apply the theory of the octonions. Section V A warms up with the new results about the octonions as $\bullet$-product. Section V B has the gauge theory worked out for the octonions. In fact the example of deformed nonassociative gauge theory that we finally arrive at here takes the remarkably workable form

$$F_\bullet(\alpha)=\mathrm{d}\alpha+\sum F(|\alpha|,|\alpha'|)\alpha\bullet\alpha',$$

$$\alpha^\gamma_\bullet=\sum F(|\gamma^{-1}|,|\gamma|)F(|\alpha|,|\gamma|)(\gamma^{-1}\bullet\alpha)\bullet\gamma+\sum F(|\gamma^{-1}|,|\gamma|)\gamma^{-1}\bullet\mathrm{d}\gamma,$$

where the sum is over the different graded Fourier components of each object and to this end α' denotes a second independent copy of α. Such a description also works for the quasi-$\mathbb{R}^4$ if one works in terms of plane waves and their differentials; this is already the case for the octonions where the generators have in our picture the interpretation of deformed plane waves on the cube. In the octonions case $F(\vec{a},\vec{b})$ has values ±1 but is not simply an exponential bilinear of the vector degrees (the three-momentum) as its exponent has cubic terms. It is not known if such quasigeometry of the octonions has a direct physical role, but see for example Ref. 7. We also note the link between the octonions and particle physics;[10] their geometry might play a role in the context of the direct product of spacetime by the finite geometry.

Section V C fills a gap in the literature, namely a complete description of the moduli space of flat $U(1)$-Yang–Mills fields up to gauge transformation on $\mathbb{Z}_2^2$ and $\mathbb{Z}_2^3$, using the same methods as for the symmetric group S_3 in Ref. 18. The above-mentioned equivalence means that the $\mathbb{Z}_2^3$ case also classifies flat connections in the nonassociative theory on the octonions. We note that flat connections on finite groups are also of interest in pure mathematics in connection with Schubert calculus on flag varieties, Ref. 16. Going back to physics, the quantum $U(1)$-Yang–Mills theory on $\mathbb{Z}_2^2$ is fully worked out in Ref. 17 and is renormalizable and computable. The $\mathbb{Z}_2^3$ and octonion cases could in principle be similarly computed. This would be one of several directions for further work.

We also note the related paper[6] where cochain twists are used to describe associative quantizations in which the differential calculus, however, is nonassociative. It turns out that several popular associative quantizations in physics fall into this category; the algebra of coordinates is associative but the nonassociative gauge theory described here still plays a role in view of the differential calculus. Examples in this category include $U(\mathfrak{g})$ as quantization of the Kirillov–Kostant bracket, now expressed as a cochain twist at least to lower order, see Ref. 6.

II. QUASIALGEBRAS BY COCHAIN TWIST

The constructions in the paper come out of quantum group theory (i.e., we use the language of Hopf algebras) but we apply them to classical (not quantum) enveloping algebras and finite group algebras. Thus, let H be a Hopf algebra with coproduct $\Delta: H \to H \otimes H$, counit $\epsilon: H \to \mathbb{C}$ and antipode $S: H \to H$, see Ref. 15. Let $F \in H \otimes H$ be a cochain, i.e., F is invertible and $(\epsilon \otimes \mathrm{id})F = 1 = (\mathrm{id} \otimes \epsilon)F$. Associated to F is its non-Abelian cohomology coboundary

$$\Phi = \partial F = F_{23}((\mathrm{id} \otimes \Delta)F)((\Delta \otimes \mathrm{id})F^{-1})F_{12}^{-1},$$

where $F_{23} = 1 \otimes F \in H^{\otimes 3}$, etc. By construction Φ, called the "associator," is a three-cocycle in the required sense. These data go back to V.G. Drinfeld and it is known that H^F defined by the same algebra as H and with coproduct $\Delta_F = F(\Delta\,)F^{-1}$ and suitable S_F gives a quasi-Hopf algebra.[11]

Now let A be an H-covariant associative algebra. The cochain-twisted quasialgebra A_F is defined as the same vector space as A but with a new product

$$a \bullet b = \cdot(F^{-1} \triangleright (a \otimes b)),$$

where $\triangleright$ denotes the action of each copy of H. The new A_F is nonassociative but obeys

$$(a \bullet b) \bullet c = \bullet(\mathrm{id} \otimes (\bullet))(\Phi \triangleright (a \otimes b \otimes c))$$

for all a, b, c, and is covariant under H^F.

Moreover, when $\Omega(A)$ is an algebra of differential forms on A that is H-covariant, then $\Omega(A_F) = \Omega(A)_F$ defines for us the wedge product algebra of differential forms on A_F, covariant under H^F and again potentially nonassociative.[1] Note that d is not deformed and assumed to commute with the action of H, hence

$$a \bullet \mathrm{d}b = F^{-(1)} \triangleright a \mathrm{d}(F^{-(2)} b), \quad \mathrm{d}a \bullet b = \mathrm{d}(F^{-(1)} \triangleright a) F^{-(2)} \triangleright b, \quad \mathrm{d}a \bullet \mathrm{d}b = (\mathrm{d}F^{-(1)} \triangleright a) \wedge \mathrm{d}(F^{-(2)} \triangleright b)$$

for the deformed wedge product in terms of the undeformed one, where $F^{-1} = F^{-(1)} \otimes F^{-(2)}$ (summation understood) is a notation.

The two examples that will be fully computed in this article are of the general types which we now describe. Note that we work over $\mathbb{C}$ for convenience and because in physical examples there are further unitarity restrictions (otherwise, the general constructions work over any field, though one should avoid certain characteristics in the examples). Also, we use the H-module version of the cochain twist theory as mentioned previously because actions are more familiar to physicists; there is a parallel and in many ways better version of the theory with H coacting on the algebra.

A. Quasi-$\mathbb{R}^n$

Let $H = U(\mathbb{R}^n)$, with Hopf algebra structure

$$\Delta \partial^i = \partial^i \otimes 1 + 1 \otimes \partial^i, \quad \epsilon \partial^i = 0, \quad S\partial^i = -\partial^i.$$

Here $\mathbb{R}^n$ acts on $\mathbb{R}^n$ by translation and hence on its coordinate algebra $A = \mathbb{C}[\mathbb{R}^n]$ by differentiation operators $\partial = \{\partial^i\}$ and we think of the latter quite concretely as generating $U(\mathbb{R}^n)$. Let F be a nowhere vanishing function of two vector coordinates (i.e., a function on $\mathbb{R}^{2n}$) with value 1 when either argument is zero. We consider $F \in H \otimes H$ (or in some completion of this space if F is not a polynomial) as a cochain. Because H is commutative, $H^F = H$ as an algebra and as a coalgebra, but is still regarded with

$$\Phi(\partial_1, \partial_2, \partial_3) = \frac{F(\partial_2, \partial_3) F(\partial_1, \partial_2 + \partial_3)}{F(\partial_1 + \partial_2, \partial_3) F(\partial_1, \partial_2)}$$

as a quasi-Hopf algebra. Here $\partial_1 = \partial \otimes 1 \otimes 1$, $\partial_2 = 1 \otimes \partial \otimes 1$, $\partial_3 = 1 \otimes 1 \otimes \partial$ in $H^{\otimes 3}$ so Φ is a function of these $3n$ variables.

Then A_F has a new product

$$a \bullet b = \cdot F^{-1}(\partial_1, \partial_2) a \otimes b,$$

where $a(x), b(x)$ are acted upon by ∂_1, ∂_2, respectively, and then the result multiplied. Quasiassociativity will take the above-mentioned form, as

$$(a \bullet b) \bullet c = \bullet(\mathrm{id} \otimes (\bullet))\Phi(\partial_1, \partial_2, \partial_3)(a \otimes b \otimes c),$$

where ∂_1 means ∂ acting on a, ∂_2 means ∂ acting on b, ∂_3 means ∂ acting on c, and products are in A_F. Recall that ∂ itself is a vector, namely the momentum vector operator generating translations in $\mathbb{R}^n$.

Of interest in physics seems to be the following special case. Let $\Box = \Sigma \partial^i \otimes \partial^j \eta_{ij} = \partial_1 \cdot \partial_2$ taken with the Euclidean metric say (or any other fixed tensor η on $\mathbb{R}^n$ in place of the dot product). Let f be any nowhere vanishing function in *one* variable and take

$$F(\partial_1, \partial_2) = f(\Box), \quad \Phi(\partial_1, \partial_2, \partial_3) = \frac{f(\Box_{23}) f(\Box_{12} + \Box_{13})}{f(\Box_{13} + \Box_{23}) f(\Box_{12})},$$

where $\Box_{13} = \partial_1 \cdot \partial_3$ is $\Box$ embedded in the first and third tensor positions, etc.

If f is an exponential then $\Phi = 1$ and A_F is associative. For example, if η_{ij} is antisymmetric one has the usual Moyal product for the Heisenberg–Weyl algebra or so-called noncommutative $\mathbb{R}^n$ used for example by Seiberg and Witten for the effective description of the ends of open strings on 2-branes. At the other extreme would be η_{ij} the Euclidean metric in which case the algebra remains commutative and associative. In general if F remains symmetric but f is no longer an exponential then the algebra A_F will be commutative but not associative. This covers the example in Ref. 20 where

$$F(\partial_1, \partial_2) = \left(1 + \frac{\lambda}{m} \Box\right)^{-m}$$

which becomes approximately an exponential $\exp(\lambda \Box)$ as $m \to \infty$. Here λ is the deformation parameter which is taken with value m^{-1} in Ref. 20, but one can also keep these parameters λ, m independent. We have

$$\Phi(\partial_1, \partial_2, \partial_3) = \left(1 + \frac{\frac{\lambda^2}{m^2} \Box_{13}(\Box_{12} - \Box_{23})}{1 + \frac{\lambda}{m}(\Box_{12} + \Box_{13} + \Box_{23}) + \frac{\lambda^2}{m^2} \Box_{23}(\Box_{12} + \Box_{13})}\right)^m.$$

Another interesting family of commutative but nonassociative quasi-$\mathbb{R}^n$ is with

$$F(\partial_1, \partial_2) = e^{-(\lambda/2)\Box^2}, \quad \Phi = e^{-\lambda \Box_{13}(\Box_{12} - \Box_{23})} = e^{-\lambda \eta_{ij} \eta_{kl} (\partial^i \partial^k \otimes \partial^j \otimes \partial^l - \partial^i \otimes \partial^k \otimes \partial^j \partial^l)}$$

when we unpack our compact notation (summation convention understood).

A third variant is with $H = U(\mathbb{R}^n \rtimes \mathbb{R})$ where an extra "dilation" generator D is added. Its relations, coproduct and action on coordinates are

$$[D, \partial^i] = -\partial^i, \quad \Delta D = D \otimes 1 + 1 \otimes D, \quad D \triangleright x_i = x_i$$

(so that D has action p on a monomial of total degree p). In this way $A = \mathbb{C}[\mathbb{R}^n]$ is again covariant under this extended H. One can now have more interesting cochains, for example

$$F = e^{-\lambda \Box - v(D \otimes D)}$$

for a "potential function" v. If $v = 0$ we have $\Phi = 1$ as explained previously. In general, it is tempting to think of the introduction of nonbilinears in the exponent of F as a way to encode interactions as nonassociativity. The passage from the free theory to the interacting theory would then be a matter of a cochain twist by the interaction.[1] This last example is in that spirit.

Clearly a great many models along the above lines are equally possible, as any cochain F is allowed in our framework.

B. Quasi-$\mathbb{Z}_2^n$

Here we take $H=\mathbb{C}(G)$, the functions on a finite group. This has basis of delta functions $\{\delta_a\}$ labeled by $a\in G$ and coproduct $\Delta\delta_a=\Sigma_{bc=a}\delta_b\otimes\delta_c$, counit $\epsilon\delta_a=\delta_{a,e}$ and antipode $S\delta_a=\delta_{a^{-1}}$. Here e is the group identity. We take $A=\mathbb{C}G$ the group algebra of G. This has basis $\{e_a\}$ labeled again by group elements. The product is just the product of G, so $e_ae_b=e_{ab}$. This is covariant under $\mathbb{C}(G)$ with action

$$\delta_a\triangleright e_b=\delta_{a,b}e_b.$$

A cochain on H is a suitable $F\in H\otimes H$, i.e., a nowhere vanishing 2-argument function $F(a,b)$ on the group with value 1 when either argument is the group identity e. Then

$$\Phi(a,b,c)=\frac{F(b,c)F(a,bc)}{F(ab,c)F(a,b)}$$

is the usual group-cohomology coboundary of F and is a group 3-cocycle. Then H^F is the same algebra and coalgebra as H but is viewed as a quasi-Hopf algebra with this Φ. Finally, the canonical example of a quasialgebra here is the twisted group algebra A_F with the new product

$$e_a\bullet e_b=F^{-1}(a,b)e_{ab}.$$

An example is $G=\mathbb{Z}_2^3$ which we write additively as 3-vectors $\vec{a}$ with entires in $\mathbb{Z}_2$. We take

$$\vec{a}^T\begin{pmatrix}1&1&1\\0&1&1\\0&0&1\end{pmatrix}\vec{b}+a_1b_2b_3+b_1a_2b_3+b_1b_2a_3$$

$$F(\vec{a},\vec{b})=(-1)\qquad,\quad \Phi(\vec{a},\vec{b},\vec{c})=(-1)^{\vec{a}\cdot(\vec{b}\times\vec{c})}$$

The new product

$$e_{\vec{a}}\bullet e_{\vec{b}}=F(\vec{a},\vec{b})e_{\vec{a}+\vec{b}}$$

is that of the octonions $\mathbb{O}$ as explained in Ref. 2. If we think of this in the same spirit as the models above, we note that Φ comes from the cubic "interaction term" in the exponent of F. Thus the octonions are a cochain quantization of the finite group $\mathbb{Z}_2^3$ as a quasialgebra. Without the cubic interaction term one has the Clifford algebra in three dimensions. Similarly $n=2$ gives the quaternions or (over $\mathbb{C}$) the algebra of 2×2 matrices.

One can do the same for larger $\mathbb{Z}_2^n$. For the same bilinear form as the previous one, one obtains the Clifford algebra as an associative cochain quantization of $\mathbb{Z}_2^n$, whereas further "interaction" terms give higher Cayley–Dickson and other quasialgebras of interest, see Refs. 2 and 4. Many other examples could be of interest, e.g., for $G=\mathbb{Z}_n$ see Ref. 3.

III. GAUGE THEORY IN MONOIDAL CATEGORIES

With the above-mentioned background the main question we address in this article is that of gauge theory on nonassociative spaces. For the ones in Sec. II A of interest in string theory, a somewhat complex approach has been proposed in Ref. 20 whereas here we propose a simpler one. Briefly, geometry including gauge theory can be done in any monoidal Abelian category $\mathcal{C}$.[13,14] We explain this in Sec. III A and give a concrete algebraic setting in Secs. III B and III C, which are the new results of the section.

Before doing this, let us explain the problem at the simplest level. If we have an associative algebra with a differential calculus obeying the Leibniz rule, one can write down the simplest "$U(1)$-Yang–Mills" theory where a connection is a differential 1-form $\alpha\in\Omega^1$, decreed to transform as

$$\alpha\mapsto \gamma^{-1}\alpha\gamma+\gamma^{-1}\mathrm{d}\gamma \tag{1}$$

for γ any invertible element of the algebra. The fundamental lemma of gauge theory is that then the curvature $F(\alpha)=\mathrm{d}\alpha+\alpha\wedge\alpha$ transforms by conjugation to $\gamma^{-1}F(\alpha)\gamma$. Note that the nonlinear term need not vanish in noncommutative geometry even in this simplest case. The moduli space of flat connections up to gauge transformations is highly nontrivial even for the simplest commutative or noncommutative algebras[18] and carries a lot of "homotopy" information. We will describe it for the functions on the cube $\mathbb{Z}_2^3$ in Sec. V C under a further unitarity restriction (in the *-algebra case one requires $\gamma^*=\gamma^{-1}$, i.e., unitary).

Let us try this now when the algebra is nonassociative. The simplest part of the abovementioned lemma is that $\alpha=\gamma^{-1}\mathrm{d}\gamma$ should have zero curvature. Being careful about brackets, we have

$$\mathrm{d}(\gamma^{-1}\mathrm{d}\gamma)+(\gamma^{-1}\mathrm{d}\gamma)(\gamma^{-1}\mathrm{d}\gamma)=(\mathrm{d}\gamma^{-1})\mathrm{d}\gamma+(\gamma^{-1}\mathrm{d}\gamma)(\gamma^{-1}\mathrm{d}\gamma)=-((\gamma^{-1}\mathrm{d}\gamma)\gamma^{-1})\mathrm{d}\gamma+(\gamma^{-1}\mathrm{d}\gamma)(\gamma^{-1}\mathrm{d}\gamma)$$

which is nonzero precisely when $\gamma^{-1}\mathrm{d}\gamma,\gamma^{-1},\mathrm{d}\gamma$ fail to associate. The computation of $\mathrm{d}\gamma^{-1}$ here is from $\mathrm{d}(\gamma^{-1}\gamma)=0$ and the Leibniz rule, being careful about brackets. This could work for some γ in the algebra but not for all invertible or unitary elements as in the associative case.

A. Diagrammatic gauge theory

A monoidal category $\mathcal{C}$ means a collection of objects with a tensor product between any two objects and an associator natural isomorphism $\Phi_{V,W,Z}:(V\otimes W)\otimes Z\to V\otimes(W\otimes Z)$ for any three objects, obeying the usual properties, notably Mac Lane's pentagon identity. The latter says that the two routes to rebracket

$$((U\otimes V)\otimes W)\otimes Z\to U\otimes(V\otimes(W\otimes Z))$$

are the same. In that case the coherence theorem of Mac Lane says that all other bracketting ambiguities are resolved, i.e., we can and should freely insert associators Φ in order for expressions to make sense and different ways to do that will give the same result. In that case we can adopt a diagrammatic notation in which we omit brackets entirely. We also denote $\otimes$ by omission. We write maps between objects (morphisms) as beads on a string flowing down from one object to the other. We also require direct sums $\oplus$ to be defined and to be compatible in the usual way with $\otimes$. Now, because brackets are omitted, gauge theory *must* work at this level because usual associative gauge theory works when expressed by the same diagrams. In the nonassociative case, however, the translation of the diagrams back into algebra requires the insertion of the nontrivial associator Φ for rebrackettings. We recall here only the "basic level" of gauge theory[13] in this diagrammatic form; there is a more geometrical theory with diagrammatic principal bundles etc.[13]

As an example an associative algebra $\mathcal{A}$ in a monoidal category means an object $\mathcal{A}$ with a product Y such that the two ways to feed the result of Y into another Y give the same. As a result we can depict the iterated product as a node with three lines coming in and one coming out (i.e., collapse the two equivalent tree graphs). We will use such a notation. A coalgebra $\mathcal{B}$ is an object $\mathcal{B}$ with a coproduct $\Delta:\mathcal{B}\to\mathcal{B}\otimes\mathcal{B}$ which we denote by an inverted Y and which "coassociates" similarly. The unit axiom for an algebra says that a 1 branching into a product can be "pruned" off. Similarly a counit $\epsilon:\mathcal{B}\to\underline{1}$ (the latter denoted by omission) is a branch emerging from a coproduct node and can be pruned. More details of "algebra" in such diagrams are in Ref. 15. A coalgebra $\mathcal{B}$ can "coact" on an object $\mathcal{V}$ and we use the inverted Y also to denote the coaction $\mathcal{V}\to\mathcal{V}\otimes\mathcal{B}$.

Similarly, a differential calculus Ω on $\mathcal{A}$ means a graded algebra in the category with $\mathcal{A}$ in degree zero, and d a morphism (hence a node) increasing degree by 1, obeying a graded-Leibniz rule and $\mathrm{d}^2=0$. All of this translates directly into (sums of) diagrams. One usually assumes that Ω

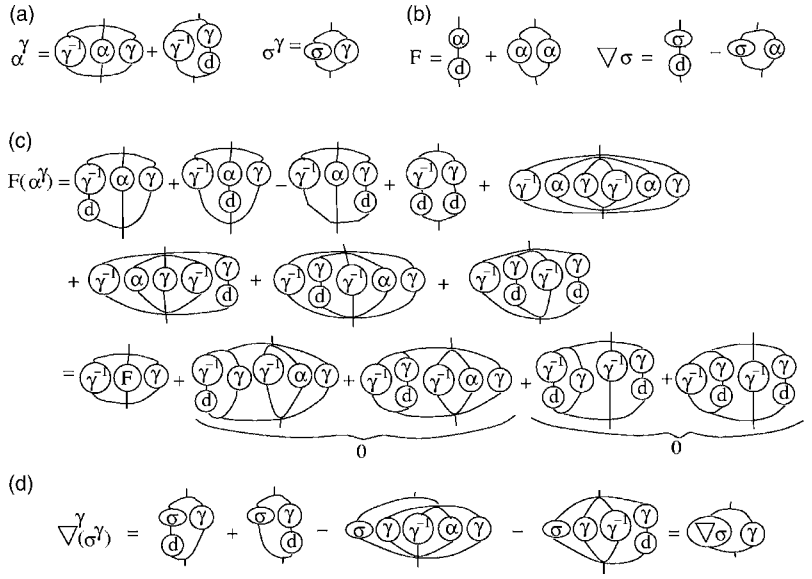

FIG. 1. Local gauge theory in a monoidal category: (a) gauge transform by γ of gauge and matter fields, (b) definition of curvature and covariant derivative, and (c) and (d) proof of covariance of F, ∇.

is generated by $\mathcal{A}$ and the 1-forms Ω^1 but this is not necessary for the basic level of gauge theory that we describe here. We use Y also to denote products in this exterior algebra.

We are now ready to define matter fields as morphisms $\sigma: \mathcal{V} \to \mathcal{A}$. One can consider that σ has "values in $\mathcal{V}^*$" (but it is more convenient to view it is a morphism). Similarly, a gauge field is a morphism $\alpha: \mathcal{B} \to \Omega^1$ where $\mathcal{B}$ is at least a coalgebra. Typically it might be a Hopf algebra in the category if this is braided, but such an assumption is again not needed for the basic level of gauge theory. One may think of α as a 1-form with values in the algebra $\mathcal{B}^*$, i.e., we do general possibly non-Abelian gauge theory here, but again it is more convenient to view α as a morphism. Finally, a gauge transformation is a morphism $\gamma: \mathcal{B} \to \mathcal{A}$ with inverse γ^{-1} in the sense

$$\cdot(\gamma \otimes \gamma^{-1})\Delta = \cdot(\gamma^{-1} \otimes \gamma)\Delta = 1 \circ \varepsilon$$

or in diagrams: if we split using the coproduct, apply γ, γ^{-1} and close up with a product Y, this composition is the same either way as the counit map ϵ into nothing, followed by the unit map 1 coming from nothing. The action of such gauge transformations is shown in Fig. 1(a). The basic covariant objects of interest namely the curvature and covariant derivative (the former is in a suitable sense the square of the latter) are shown in Fig. 1(b).

The fundamental lemmas of gauge theory are then shown in Figs. 1(c) and 1(d); we check that $F(\alpha^\gamma) = F(\alpha)^\gamma$ and that $\nabla(\sigma^\gamma) = (\nabla\sigma)^\gamma$. In Fig. 1(c), we expand d on the "conjugated" α using the Leibniz rule to obtain the first three terms. The next term is d applied to "$\gamma^{-1}\mathrm{d}\gamma$" again using the Leibniz rule, followed by $\mathrm{d}^2 = 0$. The remaining four terms are an expansion of "$(\alpha^\gamma)^2$." Of the various terms, the second and fifth (after canceling $\gamma\gamma^{-1}$ to obtain a unit and counit and "pruning" these as explained previously) give the transform of $F(\alpha)$ as required. The first (after inserting $\gamma\gamma^{-1}$) and seventh combine via Leibniz to give zero in view of $\mathrm{d}(1) = 0$. The fourth (inserting $\gamma\gamma^{-1}$) and eighth likewise give zero for the same reason. In (d) we compute ∇ using the transformed quantities. The second and fourth terms cancel (after canceling $\gamma\gamma^{-1}$) and we identify the required result.

This establishes "local gauge theory" at this diagrammatic level, cf. Ref. 14 (where the focus was on the universal calculus, not assumed here). For principal bundles etc at this level see Ref. 13. The latter contains explicit (associative) examples.

B. Algebraic construction of nonassociative gauge theory by twisting

The questions arise: how to obtain nonassociative examples of such a diagrammatic gauge theory and how does it look in explicit calculations? We will address the first in the remainder of the section, and the second in the remainder of the article.

We do this by extending the cochain twisting theory in Sec. II. Thus let A be an algebra with calculus covariant under a background symmetry H as in Sec. II. Here A could be functions on a classical manifold and H the enveloping algebra of an ordinary Lie algebra, for example. Let now B be an H-covariant coalgebra. It means that there is a coproduct $\Delta_B: B \to B \otimes B$ which is an intertwiner for the action of H. Also a counit ϵ_B. Suppose now that

$$\alpha: B \to \Omega^1(A), \quad \gamma: B \to A, \quad F(\alpha): B \to \Omega^2(A), \quad \sigma: V \to \Omega^1(A),$$

and ∇ are as in Sec. III A, i.e., a connection, gauge transformation etc. These form a gauge theory with the usual tensor product on the associative algebra A as in Sec. III A. This theory can also be written without diagrams by means of the "convolution product" $*$ of maps from a coalgebra to an algebra or module. Thus

$$\alpha * \alpha = \wedge(\alpha \otimes \alpha)\Delta_B, \quad F = \mathrm{d}\alpha + \alpha * \alpha, \quad \alpha^\gamma = \gamma^{-1} * \alpha * \gamma + \gamma^{-1} * \mathrm{d}\gamma$$

and so forth. If $B = \mathbb{C}.1$ with $\Delta_B 1 = 1 \otimes 1$, we have the simplest case of gauge theory mentioned in the preamble above. When $B = \mathbb{C}(G)$ the functions on a Lie group one has a general form of usual non-Abelian gauge theory. One can take here H to be trivial, otherwise one has an equivariant gauge theory.

Now let $F \in H \otimes H$ be a cochain and define $B_F = B$ as a vector space but with deformed coproduct

$$\Delta_\bullet = F \triangleright \Delta_B$$

and unchanged ϵ_B. First, it can be seen that B_F is covariant under the twisted H^F. Indeed,

$$h \triangleright (F \triangleright \Delta_B b) = F(\Delta h)F^{-1} \triangleright (F \triangleright \Delta_B b) = F \triangleright ((\Delta h) \triangleright \Delta_B b) = F \triangleright \Delta_B (h \triangleright b)$$

as the quasi-Hopf algebra H^F acts on tensor products by its twisted coproduct Δ_F as explained in Sec. II. Moreover, B_F is a coalgebra but only in the monoidal category of H^F-modules, i.e., a "quasicoalgebra" in the sense:

$$\Phi_{B,B,B}(\Delta_\bullet \otimes \mathrm{id})\Delta_\bullet = (\mathrm{id} \otimes \Delta_\bullet)\Delta_\bullet$$

as may be verified by direct computation. The theory is dual to that of twisting algebras so we omit the details. Similarly if $\Delta_V: V \to V \otimes B$ is a coaction covariant under H, we define V_F to be the same vector space but with deformed coaction $\Delta_{V\bullet} = F \triangleright \Delta_V$, and can check that it is covariant under H^F and a coaction of B_F in the monoidal category.

We now claim that the same maps viewed as morphisms

$$\alpha: B_F \to \Omega^1(A_F), \quad \gamma: B_F \to A_F, \quad F(\alpha): B_F \to \Omega^2(A_F), \quad \sigma: V_F \to A_F$$

form a gauge theory in the monoidal category of H^F-covariant objects, i.e., are an example of the constructions in Sec. III A and enjoy the same relationships as before twisting. For example, if we compute $\alpha *_\bullet \alpha$ where the subscript means in the deformed nonassociative theory,

$$\alpha *_\bullet \alpha = \bullet(\alpha \otimes \alpha)\Delta_\bullet = \bullet(F^{-1} \triangleright (\alpha \otimes \alpha) F \triangleright \Delta_B) = \wedge(\alpha \otimes \alpha)\Delta_B = \alpha * \alpha$$

because each α is an intertwiner, i.e., covariant under the action of H. We use $\bullet$ for the deformed product in the exterior algebra including wedge products. Similarly for all other expressions. In other words *the twisted nonassociative theory is fully equivalent to the original associative one*. This is an important requirement from a deformation-theoretic point of view; if one thinks of the

twisting as quantization, this is an extension of the correspondence principle from classical gauge theory to gauge theory on the quantum (possibly nonassociative) space.

On the other hand, computed entirely in the nonassociative deformed category, the gauge theory appears quite different. Remembering that the products are quasiassociative, we must fix brackettings when translating the diagrams into algebra and we do so by a convention to bracket by default to the left, inserting associators Φ according to Mac Lane's coherence theorem whenever a different bracketting is needed. Thus for example,

$$\alpha^\gamma_\bullet = ((\bullet)\otimes\bullet)((\gamma^{-1}\otimes\alpha)\otimes\gamma)(\Delta_\bullet\otimes\mathrm{id})\Delta_\bullet + \bullet(\gamma^{-1}\otimes\gamma)\Delta_\bullet$$

as a morphism $B_F\to\Omega^1(A_F)$. Provided one inserts Φ as specified (and where there is more than one way to do it one has the same result for any choice), the diagrammatic proof in Sec. III A becomes an algebraic proof that

$$F_\bullet(\alpha) = \mathrm{d}\alpha + \bullet(\alpha\otimes\alpha)\Delta_\bullet$$

obeys

$$F_\bullet(\alpha^\gamma_\bullet) = ((\bullet)\otimes\bullet)((\gamma^{-1}\otimes F_\bullet)\otimes\gamma)(\Delta_\bullet\otimes\mathrm{id})\Delta_\bullet$$

i.e., the fundamental lemma of (nonassociative) gauge theory. When there are matter fields we have similarly

$$\sigma^\gamma_\bullet(v) = \bullet(\sigma\otimes\gamma)\Delta_\bullet,\quad \nabla_\bullet\sigma(v) = \mathrm{d}\sigma(v) - \bullet(\sigma\otimes\alpha)\Delta_\bullet,\quad \nabla^\gamma_\bullet(\sigma^\gamma_\bullet) = (\nabla_\bullet\sigma)^\gamma.$$

C. Canonical example equivalent to *U*(1)-Yang–Mills

Finally, let us give a canonical example of an equivariant gauge theory and its twisting, that requires only the data for a cochain quantization as in Sec. II, i.e., there is a canonical choice of B.

Thus, let H be a Hopf algebra and A an algebra with calculus which is H-covariant. We then set $B=H$ as a coalgebra, $\Delta_B=\Delta$ (the coproduct of H, ignoring the algebra structure of H). This is automatically covariant under the action of H on B by left-multiplication:

$$h\triangleright\Delta_B(b) = \Delta_H(h)\triangleright\Delta_B(b) = \Delta_H(h)\Delta_H(b) = \Delta_H(hb) = \Delta_B(h\triangleright b).$$

On the other hand, since every element of B is obtained by acting by H on 1, and since α,γ,F etc. are morphisms, they are fully determined by their values on 1, i.e., by

$$\alpha(1)\in\Omega^1(A),\quad \gamma(1)\in A,\quad F(\alpha)(1)\in\Omega^2(A).$$

Here $\alpha(1),\gamma(1)$ etc. are chosen freely and form a usual gauge theory of the simplest $U(1)$-Yang–Mills type described in the preamble on any algebra. This is because $\Delta(1)=1\otimes 1$ so all the coproducts in Fig. 1 disappear when specialized to acting on 1, so

$$\alpha^\gamma(1) = \gamma^{-1}(1)\alpha(1)\gamma(1) + \gamma^{-1}(1)\mathrm{d}\gamma(1),\quad F(1) = \mathrm{d}\alpha(1) + \alpha(1)\wedge\alpha(1),$$

etc. Our construction "amplifies" this standard $U(1)$-Yang–Mills gauge theory on an algebra to an H-equivariant one for any H by $\alpha(b)=\alpha(b\triangleright 1)=b\triangleright\alpha(1)$ and $\gamma(b)=\gamma(b\triangleright 1)=b\triangleright\gamma(1)$.

For matter fields, the requirement that the coaction: $V\to V\otimes B$ is a morphism makes V into some form of "Hopf module," i.e. a vector space on which H both acts and coacts in a suitably compatible manner, namely here

$$\Delta_V(h\triangleright v) = (\Delta h)\triangleright\Delta_V(v).$$

Hopf modules are fully determined by their space

$$V^H = \{v \in V | \Delta_V(v) = v \otimes 1\}$$

of elements invariant under the coaction. The Hopf module-lemma ensures that these invariant elements $v \in V^H$ generate all of V through the action. Note that this is usually done for action and coaction in the same side but with care works also in our case where the action is a left one and the coaction a right one. Indeed, we have

$$H \otimes V^H \to V, \quad h \otimes v \to h \triangleright v, \quad V \to H \otimes V^H, \quad v \mapsto v^{(2)}{}_{(2)} \otimes S^{-1} v^{(2)}{}_{(1)} \triangleright v^{(1)},$$

where the antipode S of the Hopf algebra is assumed to be invertible and where $\Delta_V(v) \equiv v^{(1)} \otimes v^{(2)}$ and $\Delta h \equiv h_{(1)} \otimes h_{(2)}$ are standard Hopf algebra notations. It is straightforward to see then that these two maps are mutually inverse, so $V \cong H \otimes V^H$ and that the second map indeed lands in $H \otimes V^H$ (this is not obvious but can be checked using routine Hopf algebra methods). Conversely, given any vector space W we can define $V = H \otimes W$ with action and coaction of H

$$h \triangleright (g \otimes w) = hg \otimes v, \quad \Delta_V(h \otimes w) = (h_{(1)} \otimes w) \otimes h_{(2)}, \quad h, g \in H,\ w \in W,$$

and check that $W = V^H$; the previous discussion tells us that any crossed module V is equivalent to one of this standard type. In short, the input data for matter fields in the theory boils down to choosing a vector space.

Moreover, since $\sigma: V \to A$ is assumed to be H-covariant, it is fully determined by its values on this vector space V^H, since $\sigma(\Sigma_p h_p \triangleright v_p) = \Sigma_p h_p \triangleright \sigma(v_p)$ for any basis $\{v_p\}$ of V^H. So the gauge theory above is equivalent to specifying a map $\sigma: V^H \to A$ or a multiplet of matter fields $\sigma(v_p)$ if we fix a basis of V^H. Thus our theory becomes equivalent to usual $U(1)$-theory with a multitplet of matter fields. Indeed, $\sigma(v_p) \in A$ obeys

$$\sigma^\gamma(v_p) = \sigma(v_p)\gamma(1), \quad (\nabla\sigma)(v_p) = \mathrm{d}\sigma(v_p) - \sigma(v_p)\alpha(1)$$

as would be expected for $U(1)$ fields.

We now are ready simply to twist this theory using the method in Sec. III B. B_F now has "deformed coproduct" $\Delta_\bullet = F\Delta$. A gauge field is again determined by $\alpha(1)$ but $\Delta_\bullet(1) = F \in H \otimes H$ so

$$F_\bullet(\alpha)(1) = \mathrm{d}\alpha(1) + (\alpha *_\bullet \alpha)(1) = \mathrm{d}\alpha(1) + \bullet(\alpha \otimes \alpha)(F),$$

$$\alpha^\gamma_\bullet(1) = ((\bullet)\bullet)((\gamma^{-1} \otimes \alpha) \otimes \gamma)((\Delta \otimes \mathrm{id})F) + \bullet(\gamma^{-1} \otimes \mathrm{d}\gamma)(F)$$

in terms of the deformed bullet product on $\Omega(A_F)$. As previously, our convention is to read the diagrams with brackets accumulating to the left, with Φ to be inserted as needed for any other bracketting that may be required. The expressions above will be equal as linear maps to $F(\alpha(1)), \alpha^\gamma(1)$, etc. as explained in Sec. III B, so the deformed theory is in correspondence with the original theory before twisting, but is well-formed in its own right.

Finally, if we have matter fields and elements v_p that are invariant under the coaction, then the deformed coaction and hence gauge transform of matter fields is

$$\Delta_{V\bullet}(v_p) = F^{(1)} \triangleright v_p \otimes F^{(2)}, \quad \sigma^\gamma_\bullet(v) = \sigma(F^{(1)} \triangleright v_p)\gamma(F^{(2)}), \quad F \equiv F^{(1)} \otimes F^{(2)}.$$

Here we see that as with the gauge fields mentioned previously, it is the entire "amplified" theory that twists into a nonassociative one. It remains, however, equivalent to the $U(1)$-gauge theory with matter.

IV. DIFFERENTIALS AND GAUGE THEORY ON QUASI-$\mathbb{R}^n$

In this section we illustrate the above formalism on the example of quasi-$\mathbb{R}^n$. To be concrete, we focus calculations on the main example where $f = (1 + \lambda\Box/m)^{-m}$ in Sec. II A, but the same methods apply for the other versions of quasi-$\mathbb{R}^n$. We start with the algebra and differentials in more detail, and then turn to the gauge theory.

A. Algebra and differentials on quasi-$\mathbb{R}^n$

From Sec. II A, we have

$$a \bullet b = \sum_{r=0}^{m} \binom{m}{r} \left(\frac{\lambda}{m}\right)^r (\partial^{i_1} \cdots \partial^{i_r} a)(\partial_{i_1} \cdots \partial_{i_r} b),$$

where we use η_{ij} to lower indices. We call this algebra $\mathbb{R}^n_{m,\lambda}$; the case in string theory is with $\lambda = 1/m$. For example, with the usual coordinates x_μ of $\mathbb{R}^n$ we have the bullet product

$$x_\mu \bullet x_\nu = x_\mu x_\nu + \lambda \delta_{\mu,\nu}$$

which is a simplified version[20] of higher-dimensional so-called "fuzzy spheres" that arise from the truncated matrix product in certain string matrix models. Here m is a truncation order and the algebra becomes associative as $m \to \infty$.

For our purposes we also need a differential calculus and we use the same F built from f but now with the ∂^i acting by Lie derivative on differential forms. Then the usual $\Omega(\mathbb{R}^n)$ deforms to a (nonassociative) $\Omega(\mathbb{R}^n_{m,\lambda})$. Notice that Lie derivative commutes with exterior d, so the classical differential calculus is indeed covariant as required. Then

$$a \bullet \mathrm{d}b = \sum_{r=0}^{m} \binom{m}{r} \left(\frac{\lambda}{m}\right)^r (\partial^{i_1} \cdots \partial^{i_r} a) \mathrm{d}\partial_{i_1} \cdots \partial_{i_r} b$$

$$\mathrm{d}a \bullet \mathrm{d}b = \sum_{r=0}^{m} \binom{m}{r} \left(\frac{\lambda}{m}\right)^r \mathrm{d}(\partial^{i_1} \cdots \partial^{i_r} a) \mathrm{d}\partial_{i_1} \cdots \partial_{i_r} b$$

for functions a, b. For example,

$$x_\mu \bullet \mathrm{d}x_\nu = x_\mu \mathrm{d}x_\nu, \quad x_\mu \bullet \mathrm{d}(x_\nu \bullet x_\rho) = x_\mu \bullet \mathrm{d}(x_\mu x_\nu) = x_\mu \mathrm{d}(x_\nu x_\rho) + \lambda(\delta_{\mu,\nu}\mathrm{d}x_\rho + \delta_{\mu,\rho}\mathrm{d}x_\nu),$$

$$\mathrm{d}x_\mu \bullet \mathrm{d}x_\nu = \mathrm{d}x_\mu \wedge \mathrm{d}x_\nu = -\mathrm{d}x_\nu \wedge \mathrm{d}x_\mu = -\mathrm{d}x_\nu \bullet \mathrm{d}x_\mu,$$

and so forth. This deformed 'quasidifferential calculus' is the classical one at lowest order but differentials of functions of degree p will be modified by descendants of lower degree. Because $\mathrm{d}1 = 0$ the relations involving $\mathrm{d}x_\mu$ are necessarily unchanged,

$$\mathrm{d}a = (\partial^\mu a)\mathrm{d}x_\mu = (\partial^\mu a) \bullet \mathrm{d}x_\mu, \quad a \bullet \mathrm{d}x_\mu = a\mathrm{d}x_\mu = (\mathrm{d}x_\mu)a = \mathrm{d}x_\mu \bullet a.$$

B. Gauge fields on quasi-$\mathbb{R}^n$

We are now ready to construct gauge theory on the above-mentioned quasi-$\mathbb{R}^n$ using the general construction in Sec. III C.

First of all, we recall that here $H = U(\mathbb{R}^n) = \mathbb{C}[\partial^1, \ldots, \partial^n]$ has coproduct $\Delta\partial^i = \partial^i \otimes 1 + 1 \otimes \partial^i$ on the generators. We take for B the same coalgebra, but to avoid confusion we denote this second copy $B = U(\mathbb{R}^n) = \mathbb{C}[f^1, \ldots, f^n]$ with polynomial generators f^i. As before, we use a fixed (say Euclidean) η_{ij} to lower indices. A gauge field is a covariant map $\alpha: B \to \Omega^1(\mathbb{R}^n)$ so it is first of all a collection of 1-forms $\alpha(1)$, $\alpha(f^i)$, $\alpha(f^i f^j)$ etc. in $\Omega^1(\mathbb{R}^n)$. However, that α is a morphism requires

$$\alpha(f^i) = \mathcal{L}_i(\alpha(1)) = \partial^i \alpha(1)^\mu \mathrm{d}x_\mu, \ldots, \quad \alpha(f^{i_1} \cdots f^{i_p}) = \mathcal{L}_{i_i} \cdots \mathcal{L}_{i_p}(\alpha(1)) = \partial^{i_1} \cdots \partial^{i_p} \alpha(1)^\mu \mathrm{d}x_\mu,$$

where $\mathcal{L}_i$ denotes the Lie derivative by the vector field ∂^i acting here on 1-forms. This is just action by ∂^i on the components $\alpha(1)^\mu$ in the coordinate basis. This is how $\alpha(b)$ is determined from $\alpha(1) \in \Omega^1(\mathbb{R}^n)$. Similarly

$$\gamma(f^i)=\partial^i\gamma(1),\ldots,\quad \gamma(f^{i_1}\cdots f^{i_p})=\partial^{i_1}\cdots\partial^{i_p}\gamma(1)$$

and similarly for γ^{-1}. This inverse is defined by the "convolution product," which involves the coproduct above, so for example

$$\gamma^{-1}(1)\gamma(1)=1,\quad \gamma^{-1}(f^i)\gamma(1)+\gamma(1)\gamma(f^i)=0,$$

$$\gamma^{-1}(f^if^j)\gamma(1)+\gamma^{-1}(f^i)\gamma(f^j)+\gamma^{-1}(f^j)\gamma(f^i)+\gamma^{-1}(1)\gamma(f^if^j)=0,$$

etc., which agrees with $\gamma^{-1}(f^i)=\partial^i\gamma^{-1}(1)$ etc., as required by covariance. Similarly, we know that $\alpha^\gamma(1)=\alpha(1)^{\gamma(1)}=\alpha(1)+\gamma^{-1}(1)\mathrm{d}\gamma(1)$. For higher order we compute the convolution product as

$$\begin{aligned}\alpha^\gamma(f^i)&=\gamma^{-1}(f^i)\alpha(1)\gamma(1)+\gamma^{-1}(1)\alpha(f^i)\gamma(1)+\gamma^{-1}(1)\alpha(1)\gamma(f^k)+\gamma^{-1}(f^i)\mathrm{d}\gamma(1)+\gamma^{-1}(1)\mathrm{d}\gamma(f^i)\\&=\alpha(f^i)+\gamma^{-1}(1)\mathrm{d}\gamma(f^i)-\gamma^{-2}(1)\gamma(f^i)\mathrm{d}\gamma(1)=\alpha(f^i)+\mathrm{d}(\gamma^{-1}(1)\gamma(f^i))=\mathcal{L}_i(\alpha^\gamma(1))\end{aligned}$$

as it should as all our constructions are covariant under H. Likewise, we know that $F(\alpha)(1)=F(\alpha(1))=\mathrm{d}\alpha(1)$. At next order we have

$$F(\alpha)(f^i)=\mathrm{d}\alpha(f^i)+\alpha(f^i)\wedge\alpha(1)+\alpha(1)\wedge\alpha(f^i)=\mathrm{d}\alpha(f^i)=\mathcal{L}_i(F(\alpha)(1))$$

as it should. Thus the higher $\alpha(f^i)$ etc., behave like further auxiliary classical $U(1)$-gauge fields but are in fact determined from the $\alpha(1)$ gauge theory. This gives the flavor of the amplified theory and its equivalence with usual $U(1)$ theory on $\mathbb{R}^n$.

Next we deform to the coproduct of B_F,

$$\Delta_\bullet f^i=\left(1+\frac{\lambda}{m}f^j\otimes f_j\right)^{-m}(f^i\otimes 1+1\otimes f^i)=f^i\otimes 1+1\otimes f^i-\lambda f^if^j\otimes f_j-\lambda f^j\otimes f_jf^i+\cdots .$$

The action of H on B is multiplication by $\partial^i=f^i$.

As explained in Sec. III C a gauge field still means an H-covariant map determined by $\alpha(1)\in\Omega^1(\mathbb{R}^n_{m,\lambda})$, i.e., some differential form $\alpha(1)=\alpha^\mu\bullet\mathrm{d}x_\mu$. Its curvature from Sec. III C is

$$\begin{aligned}F_\bullet(\alpha)(1)&=\mathrm{d}\alpha(1)+\bullet(\alpha\otimes\alpha)(F)\\&=\mathrm{d}\alpha(1)+F^{(1)}\triangleright\alpha(1)\bullet F^{(2)}\triangleright\alpha(1)\\&=\mathrm{d}\alpha(1)+\sum_{r=0}^{\infty}\binom{m+r-1}{r}\left(-\frac{\lambda}{m}\right)^r(\partial^{i_1}\cdots\partial^{i_r}\alpha^\mu\bullet\mathrm{d}x_\mu)\bullet(\partial_{i_1}\cdots\partial_{i_r}\alpha^\nu\bullet\mathrm{d}x_\nu).\end{aligned}$$

We know from the equivalence with the classical gauge theory that this will in fact equal $\mathrm{d}\alpha(1)$ but this is a nontrivial computation from the point of view of the nonassociative theory. Similarly, we have

$$(\Delta\otimes\mathrm{id})(F)=\left(1+\frac{\lambda}{m}(\square_{13}+\square_{23})\right)^{-m}$$

and hence

$$\begin{aligned}\alpha^\gamma_\bullet(1)=((\bullet)\bullet)&\left(1+\frac{\lambda}{m}(\square_{13}+\square_{23})\right)^{-m}(\gamma^{-1}(1)\otimes\alpha(1)\otimes\gamma(1))+\sum_{r=0}^{\infty}\binom{m+r-1}{r}\\&\times\left(-\frac{\lambda}{m}\right)^r\partial^{i_1}\cdots\partial^{i_r}\gamma^{-1}(1)\bullet\mathrm{d}\partial_{i_1}\cdots\partial_{i_r}\gamma(1),\end{aligned}$$

where the first term can again be expanded as a powerseries as we have done for the second term. The action of a ∂^i on α is understood here to be via the Lie derivative. The second term is "pure gauge" and we know by the equivalence with the untwisted theory that it is equal to $\gamma^{-1}(1)\mathrm{d}\gamma(1)$

and hence its curvature is zero, as promised. From the point of view of the nonassociative theory, however, these are nontrivial powerseries in the $\bullet$ product. Matter fields if present can similarly be included according to the theory at the end of Sec. III C.

V. OCTONIONS AS A FINITE QUASIGEOMETRY AND GAUGE THEORY

Here we illustrate the formalism of Sec. III on the octonions viewed as a nonassociative coordinate ring obtained by quantizing the classical space $\mathbb{Z}_2^3$. The first section makes this point of view precise and is a main result of the article. We then consider gauge theory on this space.

A. Octonions as quantization and their differentials

The "classical" algebra of functions in the form of the group algebra $A=\mathbb{C}\mathbb{Z}_2^3$ before deformation is generated by commuting u, v, w say with $u^2=v^2=w^2=1$. A general basis element is

$$e_{\vec{a}}=u^{a_1}v^{a_2}w^{a_3}.$$

The deformed product has relations

$$u\bullet u=v\bullet v=w\bullet w=-1,\quad u\bullet v=-v\bullet u,\quad u\bullet w=-uw=-w\bullet u,\quad v\bullet w=-wv=-w\bullet v$$

which is indeed the usual octonions if one puts $i=u$, $j=v$ and $k=u\bullet v$. Here

$$F(\vec{a},\vec{a})=(-1)^{a_1+a_2+a_3+a_1a_2+a_1a_3+a_2a_3+a_1a_2a_3}=\begin{cases}1 & \text{if } \vec{a}=0\\ -1 & \text{else,}\end{cases}$$

which ensures that $k^2=-1$ as it should. Similarly one may check that

$$k\bullet i=(u\bullet v)\bullet u=-(v\bullet u)\bullet u=-v\bullet(u\bullet u)=v=j$$

and so forth. Note from Sec. II B that

$$e_{\vec{a}}\bullet(e_{\vec{b}}\bullet e_{\vec{c}})=(e_{\vec{a}}\bullet e_{\vec{b}})\bullet e_{\vec{c}}$$

whenever $\vec{a}$, $\vec{b}$, and $\vec{c}$ are linearly dependent over $\mathbb{Z}_2$. This expresses the "alternativity" property of the octions in our formulation.

Next, the classical differential calculus on A is fixed as follows. By Fourier transform $A=\mathbb{C}(\hat{\mathbb{Z}}_2^3)$ where $\hat{\mathbb{Z}}_2^3$ is position space if the previous $\mathbb{Z}_2^3$ above was momentum space. Each $\hat{\mathbb{Z}}_2$ of position space is a finite set of two points and it has only one possible differential calculus, the universal one. It is then natural to take the three copies commuting (direct product calculus), giving

$$\mathrm{d}u u=-u\mathrm{d}u,\quad \mathrm{d}u v=v\mathrm{d}u,\quad \mathrm{d}u w=w\mathrm{d}u$$

and cyclic rotations. The wedge product is then fixed by the graded Leibniz rule as

$$\mathrm{d}u\mathrm{d}u=0,\quad \mathrm{d}u\mathrm{d}v=-\mathrm{d}v\mathrm{d}u,\quad \mathrm{d}u\mathrm{d}w=-\mathrm{d}w\mathrm{d}v$$

and cyclic rotations of this. Notice that the more important objects here are the left-invariant closed 1-forms

$$\tau_1=-\frac{1}{2}u^{-1}\mathrm{d}u,\quad \tau_2=-\frac{1}{2}v^{-1}\mathrm{d}v,\quad \tau_3=-\frac{1}{2}w^{-1}\mathrm{d}w$$

and the geometrical picture is that of a 3-torus with the circle S^1 approximated by $\hat{\mathbb{Z}}_2$. Moreover, the calculus has noncommutative de Rahm cohomology generated by these τ_i, exactly as for a classical 3-torus. These τ_i anticommute among themselves in the wedge product and

$$\tau_i e_{\vec{a}} = (-1)^{a_i} e_{\vec{a}} \tau_i, \quad \mathrm{d}e_{\vec{a}} = -2e_{\vec{a}} a_i \tau_i.$$

We see that there is only a small amount of noncommutativity in our classical calculus attributable to the discrete nature of the underlying space.

The geometric picture here is clearer after making the above Fourier transform explicit. Thus, let

$$e_{\vec{a}}(x) = (-1)^{a_i x_i}, \quad u = (-1)^{x_1}, \quad v = (-1)^{x_2}, \quad w = (-1)^{x_3}$$

be the plane waves, where x is a point in position space (a $\mathbb{Z}_2$-valued vector). The exterior derivative here is

$$\mathrm{d}f = (\partial^i f)\tau_i, \quad \partial^i e_{\vec{a}} = -2a_i e_{\vec{a}},$$

where ∂^i is the finite-difference operator in the i-direction. We see that the differentials act by multiplication in momentum space.

In general, the Fourier transform of $f(x)$ is a function $f_{\vec{a}}$ on momentum space characterized by $f(x) = \Sigma_{\vec{a}} f_{\vec{a}} e_{\vec{a}}(x)$. The inverse is

$$f_{\vec{a}} = \frac{1}{8} \sum_x f(x) e_{\vec{a}}(x).$$

Now, we have given the $\bullet$ deformation of $\mathbb{Z}_2^3$ into the octonions in momentum space as multiplication by $F(\vec{a},\vec{b})$. Let $F(x,y)$ be the same function before Fourier transform. Then

$$(f \bullet g)(x) = \sum_{\vec{a},\vec{b}} f_{\vec{a}} g_{\vec{b}} F(\vec{a},\vec{b}) e_{\vec{a}+\vec{b}}(x) = \frac{1}{64} \sum_{y,z,\vec{a},\vec{b}} f(y) g(z) e_{\vec{a}}(y) e_{\vec{b}}(z) e_{\vec{a}+\vec{b}}(x) F(\vec{a},\vec{b})$$

$$= \frac{1}{64} \sum_{y,z} \sum_{y,z,\vec{a},\vec{b}} f(y) g(z) e_{\vec{a}}(x+y) e_{\vec{b}}(x+z) F(\vec{a},\vec{b}) = \frac{1}{64} \sum_{y,z} F(y,z) f(x+y) g(x+z).$$

Here

$$F(y,z) = \sum_{\vec{a},\vec{b}} (-1)^{a_1(b_1+b_2+b_3)+a_2(b_2+b_3)+a_3b_3+b_1a_2a_3+a_1b_2a_3+a_1a_2b_3+a_iy_i+b_iz_i}$$

$$= 2 \sum_{a_2,a_3,b_2,b_3} (-1)^{(z_1+a_2a_3+a_2)(b_2+b_3)+a_3b_3+(z_1+a_2a_3)(b_2a_3+a_2b_3)+(z_1+a_2a_3+z_1)y_1+a_2y_2+a_3y_3+b_2z_2+b_2z_3}$$

$$= 2^2 \sum_{a_3,b_3} (-1)^{(z_2+(z_1+z_2)a_3)b_3+a_3b_3+(z_1+z_2+a_3z_1)(z_1+a_3)b_3+y_1(z_1+a_3z_2)+y_2(z_1+z_2+a_2z_1)+y_3a_3+b_3z_3},$$

where we do the b_1 summation which gives a constraint $a_1+a_2a_3+z_1=0$ which eliminates a_1; then we do the b_2 summation to obtain a constraint $a_2+z_1+z_2+a_3z_1=0$ to eliminate a_2. We next do the b_3 summation to obtain a constraint $a_3+z_1+z_2+z_1z_2+z_3=0$, giving

$$y^T \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 1 & 1 & 1 \end{pmatrix} z + y_1z_2z_3 + z_1y_2z_3 + z_1z_2y_3.$$

$$F(y,z) = 8(-1)$$

We see that *the cochain F that defines the octonions has the remarkable property that up to a relabelling, it is its own Fourier transform*, i.e., $F(y,z)$ has just the same form in position space as $F(\vec{a},\vec{b})$ in momentum space after a rotation of the indices $1 \to 2 \to 3 \to 1$. Note that the factor 8 in

$F(y,z)$ is an artifact due to our use of $1/8$ on one side of each Fourier transform rather than a symmetrical $1/\sqrt{8}$.

Note also that $f(x+y)=(R_1^{y_1}R_2^{y_2}R_3^{y_3})f(x)$, where R_i is translation in the i direction. Since $\partial^i = R_i - 1$, we have $f(x+y)=((1+\partial^1)^{y_1}(1+\partial^2)^{y_2}(1+\partial^3)^{y_3}f)(x)$ which expresses the above-mentioned result as a finite "bidifferential" operator

$$
\begin{aligned}
f \bullet g = \cdot \Bigg(& \frac{1}{8}\sum_{y,z} (-1)^{y_1(z_1+z_2)+y_2z_2+y_3(z_1+z_2+z_3)+y_1z_2z_3+z_1y_2z_3+z_1z_2y_3} \\
& \times (1+\partial^1)^{y_1}(1+\partial^2)^{y_2}(1+\partial^3)^{y_3} \otimes (1+\partial^1)^{z_1}(1+\partial^2)^{z_2}(1+\partial^3)^{z_3} \Bigg)(f \otimes g) \\
= \cdot \Bigg(& 1 \otimes 1 - \frac{1}{2}(\partial^1 \otimes \partial^1 + \partial^2 \otimes \partial^1 + \partial^3 \otimes \partial^1 + \partial^2 \otimes \partial^2 + \partial^3 \otimes \partial^2 + \partial^3 \otimes \partial^3 + \partial^1\partial^2 \otimes \partial^1 + \partial^1\partial^3 \\
& \otimes \partial^1 + \partial^2\partial^3 \otimes \partial^1 + \partial^2\partial^3 \otimes \partial^2 + \partial^2 \otimes \partial^1\partial^2 + \partial^3 \otimes \partial^1\partial^3 + \partial^3 \otimes \partial^2\partial^3 + \partial^1\partial^2\partial^3 \otimes \partial^1 + \partial^2\partial^3 \otimes \partial^1\partial^2) \\
& - \frac{1}{4}(-\partial^1 \otimes \partial^2\partial^3 + \partial^2 \otimes \partial^1\partial^3 + \partial^3 \otimes \partial^1\partial^2 - \partial^1 \otimes \partial^1\partial^2\partial^3 + \partial^2 \otimes \partial^1\partial^2\partial^3 + \partial^3 \otimes \partial^1\partial^2\partial^3 + \partial^1\partial^2 \\
& \otimes \partial^1\partial^2 + \partial^1\partial^2 \otimes \partial^1\partial^3 - \partial^1\partial^2 \otimes \partial^2\partial^3 + \partial^1\partial^3 \otimes \partial^1\partial^3 + \partial^2\partial^3 \otimes \partial^1\partial^3 + \partial^2\partial^3 \otimes \partial^2\partial^3 + \partial^1\partial^2\partial^3 \otimes \partial^1\partial^2 \\
& + \partial^1\partial^2\partial^3 \otimes \partial^1\partial^3 + \partial^2\partial^3 \otimes \partial^1\partial^2\partial^3) - \frac{1}{8}\partial^1\partial^2\partial^3 \otimes \partial^1\partial^2\partial^3 \Bigg)(f \otimes g).
\end{aligned}
$$

These results have been obtained with MATHEMATICA. This makes precise the sense in which, in finite geometry, the octonions are a "quantization" of functions on $\hat{\mathbb{Z}}_2^3$.

For comparison, if we do the same for the cocycle that defines Clifford algebras as a simpler associative quantization of $\mathbb{Z}_2^n$, we have

$$F(a,b) = (-1)^{a_1(b_1+\cdots+b_n)+a_2(b_2+\cdots+b_n)+\cdots+a_nb_n},$$

$$F(y,z) = 2^n(-1)^{(y_1+y_2)z_1+(y_2+y_3)z_2+\cdots+(y_{n-1}+y_n)z_{n-1}+y_nz_n}.$$

The derivation of the latter is rather simpler than the above; we compute

$$
\begin{aligned}
F(y,z) &= (-1)^{a_1(b_1+\cdots+b_n)+a_2(b_2+\cdots+b_n)+\cdots+a_nb_n+\Sigma_{i=1}^n a_iy_i+\Sigma_{i=1}^n b_iz_i} \\
&= 2(-1)^{z_1(y_1+y_2)}(-1)^{a_2(b_2+\cdots+b_n)+a_3(b_3+\cdots+b_n)+\cdots+a_nb_n+\Sigma_{i=2}^n a_iy_i+\Sigma_{i=2}^n b_iz_i},
\end{aligned}
$$

where we do the b_1 integral to obtain the constraint $a_1+z_1=0$, and change variables $a_2+z_1 \to a_2$ in the result. What we obtain is $F(y,z)$ for $\mathbb{Z}_2^{n-1}$ in the remaining variables. The result then follows by induction. The $\bullet$-product description of the Clifford algebra in n-dimensions is then given as a quantization of $\mathbb{Z}_2^n$ by this $F(y,z)$ by a similar formula as previously. For example, for $n=3$ we have

$$
\begin{aligned}
f \bullet g = \cdot \Bigg(& \frac{1}{8}\sum_{y,z} (-1)^{(y_1+y_2)z_1+(y_2+y_3)z_2+y_3z_3}(1+\partial^1)^{y_1}(1+\partial^2)^{y_2}(1+\partial^3)^{y_3} \otimes (1+\partial^1)^{z_1}(1+\partial^2)^{z_2}(1+\partial^3)^{z_3} \Bigg) \\
& \times (f \otimes g) = \cdot \Bigg(1 \otimes 1 - \frac{1}{2}(\partial^1 \otimes \partial^1 + \partial^2 \otimes \partial^2 + \partial^3 \otimes \partial^3 + \partial^3 \otimes \partial^2 + \partial^2\partial^3 \otimes \partial^2 + 1 \otimes \partial^1\partial^2 \\
& + \partial^1 \otimes \partial^1\partial^2 + \partial^2 \otimes \partial^1\partial^2 + \partial^3 \otimes \partial^1\partial^2 + \partial^3 \otimes \partial^2\partial^3 + \partial^2\partial^3 \otimes \partial^1\partial^2) - \frac{1}{4}(\partial^3 \otimes \partial^1\partial^2\partial^3 \\
& + \partial^1\partial^2 \otimes \partial^1\partial^2 + \partial^1\partial^3 \otimes \partial^1\partial^2 - \partial^1\partial^3 \otimes \partial^1\partial^3 + \partial^2\partial^3 \otimes \partial^2\partial^3 + \partial^2\partial^3 \otimes \partial^1\partial^2\partial^3 + \partial^1\partial^2\partial^3 \otimes \partial^1\partial^2)
\end{aligned}
$$

$$-\frac{1}{8}\partial^1\partial^2\partial^3\otimes\partial^1\partial^2\partial^3\Big)(f\otimes g).$$

Finally, we turn to the differential geometry of the octonions. As a cochain twist we have that the relations involving the left-invariant forms τ_i are unchanged (because F acts trivially on them).

Hence

$$\mathrm{d}e_{\vec{a}}=(\partial^i e_{\vec{a}})\tau_i=(\partial^i e_{\vec{a}})\bullet\tau_i,\quad e_{\vec{a}}\bullet\tau_i=e_{\vec{a}}\tau_i=(-1)^{a_i}\tau_i e_{\vec{a}}=(-1)^{a_i}\tau_i\bullet e_{\vec{a}}$$

in this basis. For a more algebraic picture within the octonions, let us also consider

$$E_{\vec{a}}=(u^{a_1}\bullet v^{a_2})\bullet w^{a_3}=(-1)^{a_1a_2a_3}u^{a_1}\bullet(v^{a_2}\bullet w^{a_3})=(-1)^{a_1a_2+a_1a_3+a_2a_3}e_{\vec{a}}$$

after a short computation using F and Φ. Since the $e_{\vec{a}}$ have square 1 with their initial product, and from the form of $F(\vec{a},\vec{a})$ above, we know that $E_{\vec{a}}\bullet E_{\vec{a}}=e_{\vec{a}}\bullet e_{\vec{a}}=-1$ with the exception of $E_0=1$. So these are all 'unit octonions'. Moreover, from the previous,

$$\mathrm{d}E_{\vec{a}}=-2E_{\vec{a}}\bullet a_i\tau_i,\quad E_{\vec{a}}\bullet\tau_i=(-1)^{a_i}\tau_i\bullet E_{\vec{a}}$$

in this basis. We can then deduce

$$\tau_1=\tfrac{1}{2}u^{-1}\bullet\mathrm{d}u,\quad \tau_2=\tfrac{1}{2}v^{-1}\bullet\mathrm{d}v,\quad \tau_3=\tfrac{1}{2}w^{-1}\bullet\mathrm{d}w,$$

where inverse is in the octonions or bullet product algebra and eventually that

$$\mathrm{d}u\bullet u=-u\bullet\mathrm{d}u,\quad \mathrm{d}u\bullet v=-v\bullet\mathrm{d}u,\quad \mathrm{d}u\bullet w=-w\bullet\mathrm{d}u,$$

$$\mathrm{d}u\bullet\mathrm{d}u=0,\quad \mathrm{d}u\bullet\mathrm{d}v=\mathrm{d}v\bullet\mathrm{d}u,\quad \mathrm{d}u\bullet\mathrm{d}w=\mathrm{d}w\bullet\mathrm{d}u$$

and cyclic rotations of this. The latter are obtained by applying d and the graded-Leibniz rule which still holds. One can also obtain these results by direct computation from the action of F and the initial calculus on $\hat{\mathbb{Z}}_2^3$ as in Ref. 1.

B. Gauge fields on the octonions

We have a basis of H given by the δ-functions $\{\delta_{\vec{a}}\}$ on momentum space, with coalgebra

$$\Delta\delta_{\vec{a}}=\sum_{\vec{b}+\vec{c}=\vec{a}}\delta_{\vec{b}}\otimes\delta_{\vec{c}}.$$

Their action on $A=\mathbb{C}\mathbb{Z}_2^3=\mathbb{C}(\hat{\mathbb{Z}}_2^3)$ is

$$\delta_{\vec{a}}\triangleright f(x)=f_{\vec{a}}e_{\vec{a}}(x),\quad \delta_{\vec{a}}\triangleright(fg)=\sum_{\vec{b}+\vec{c}=\vec{a}}(\delta_{\vec{b}}\triangleright f)(\delta_{\vec{c}}\triangleright g),$$

i.e., it projects out the corresponding term in the Fourier expansion and behaves as shown on products. We use the same coalgebra B with the same basis element $\delta_{\vec{a}}$ denoted $f^{\vec{a}}$ to avoid confusion and the same form of coproduct as the above. The action of H is by $\delta_{\vec{a}}\triangleright f_{\vec{b}}=\delta_{\vec{a},\vec{b}}f_{\vec{b}}$. A gauge field is then a covariant map $\alpha:B\to\Omega^1(\hat{\mathbb{Z}}_2^3)$, i.e., a collection of 1-forms

$$\alpha(f_{\vec{a}})=\alpha(\delta_{\vec{a}}\triangleright 1)=\delta_{\vec{a}}\triangleright\alpha(1)=(\delta_a\triangleright\alpha(1)^i)\tau_i,$$

where the H acts trivially on the τ_i as explained in Sec. V A. Thus the collection is fully determined from $\alpha(1)=\Sigma_{\vec{a}}\alpha(f_{\vec{a}})$. Similarly the collection

$$\gamma(f_{\vec a}) = \delta_{\vec a} \triangleright \gamma(1), \quad \gamma(1) = \sum_{\vec a} \gamma(f_{\vec a})$$

is determined from the point-wise invertible function $\gamma(1)(x)$ in $\mathbb{C}(\hat{\mathbb{Z}}_2^3)$. The inverse $\gamma^{-1}(1) = \gamma(1)^{-1}$. More generally

$$\sum_{\vec b+\vec c=\vec a} \gamma^{-1}(f_{\vec b})\gamma(f_{\vec c}) = \delta_{\vec a,0}$$

which is consistent with $\gamma^{-1}(f_{\vec a}) = \delta_{\vec a} \triangleright \gamma^{-1}(1)$. A gauge transform of $\alpha(1)$ is as usual

$$\begin{aligned}\alpha^\gamma(1) &= \alpha(1)^{\gamma(1)} = \gamma^{-1}(1)\alpha(1)\gamma(1) + \gamma^{-1}(1)\mathrm{d}\gamma(1)\\ &= \gamma(1)^{-1}(R_i\gamma(1))\alpha(1)^i\tau_i + \gamma(1)^{-1}\partial^i\gamma(1)\tau_i = \alpha(1) + (\gamma(1)^{-1}\partial^i\gamma(1))\phi(1)^i\tau_i,\end{aligned}$$

where there is a sum over i and $\phi(1)^i = \alpha(1)^i + 1$. Note that unlike the quasi-$\mathbb{R}^n$ case the initial $U(1)$ theory already has a nontrivial conjugation because functions do not commute with the τ_i basic 1-forms. The change of variables to ϕ is quite useful (see Sec. V C) and ϕ transforms by conjugation. For other components we have

$$\begin{aligned}\alpha^\gamma(f_{\vec a}) &= \sum_{\vec b+\vec c+\vec d=\vec a} \gamma^{-1}(f_{\vec b})\alpha(f_{\vec c})\gamma(f_{\vec d}) + \sum_{\vec b+\vec c=\vec a} \gamma^{-1}(f_{\vec b})\mathrm{d}\gamma(f_{\vec c})\\ &= \sum_i \sum_{\vec b+\vec c+\vec d=\vec a} \gamma^{-1}(f_{\vec b})R_i(\gamma(f_{\vec d}))\alpha(f_{\vec c})^i\tau_i + \delta_{\vec c,0}\gamma^{-1}(f_{\vec b})\partial^i\gamma(f_{\vec d})\tau_i\\ &= \alpha(f_{\vec a}) + \sum_i \sum_{\vec b+\vec c+\vec d=\vec a} (\gamma^{-1}(f_{\vec b})\partial^i\gamma(f_{\vec d}))(\alpha(f_{\vec c})^i + \delta_{\vec c,0})\tau_i = \delta_{\vec a} \triangleright (\alpha^\gamma(1))\end{aligned}$$

as it should. For the last step we identify $\delta_{\vec c,0} = \delta_{\vec c} \triangleright 1$ as $1 = e_0(x)$ and use the action of $\delta_{\vec a}$ on triple products along the lines of its action on a product explained previously. Thus the theory looks like a collection of 1-forms with gauge-like transformation properties but determined consistently from the single theory for $\alpha(1)$. Similarly, for the curvature we have

$$\begin{aligned}F(\alpha)(1) = F(\alpha(1)) &= \mathrm{d}\alpha(1) + \alpha(1)\wedge\alpha(1) = \sum_{i,j} (\partial^i\alpha(1)^j + \alpha(1)^i R_i\alpha(1)^j)\tau_i\wedge\tau_j\\ &= \sum_{ij} (\partial^i\alpha(1)^j + \alpha(1)^i\partial^i\alpha(1)^i + \alpha(1)^i\alpha(1)^j)\tau_i\wedge\tau_j = \sum_{ij} \phi(1)^i\partial^i\phi(1)^j\tau_i\wedge\tau_j,\end{aligned}$$

where $\alpha(1)^i\alpha(1)^j\tau_i\wedge\tau_j = 0$ as the τ_i anticommute. This is a standard form for the $U(1)$-Yang–Mills curvature on a discrete space in noncommutative geometry. The other components may similarly be computed as

$$F(\alpha)(f_{\vec a}) = \mathrm{d}\alpha(f_{\vec a}) + \sum_{\vec b+\vec c=\vec a} \alpha(f_{\vec b})\wedge\alpha(f_{\vec c}) = \sum_{ij} \sum_{\vec b+\vec c=\vec a} \phi(f_{\vec b})^i\partial^i\phi(f_{\vec c})^j\tau_i\wedge\tau_j = \delta_{\vec a} \triangleright F(\alpha(1))$$

as it should, where $\delta_{\vec a}$ acts on the coefficients of $\tau_i\wedge\tau_j$, i.e., the other components have a similar form but are determined by $F(\alpha(1))$.

The above "amplification" of $\alpha(1)$ to a collection of gauge fields can be made even more explicit by a different basis $e_y \equiv \Sigma_{\vec a} e_y(\vec a)\delta_{\vec a}$ of H where $e_y(\vec a) = e_{\vec a}(y) = (-1)^{y_i a_i}$. These elements have $\Delta e_y = e_y \otimes e_y$ (this is the isomorphism $\mathbb{C}(\mathbb{Z}_2^3) \cong \mathbb{C}\hat{\mathbb{Z}}_2^3$). They act on functions by $(e_y \triangleright f)(x) = f(x+y)$ and $\alpha(e_{\vec x})$ behave more explicitly like $\alpha(1)$, which is one of the collection via $e_0 = 1$.

We now turn to the twisted nonassociative theory. The coproduct of B_F is

$$\Delta_\bullet f_{\vec a}=\sum_{\vec b+\vec c=\vec a} F(\vec b,\vec c) f_{\vec b}\otimes f_{\vec c},\quad \Delta_\bullet E_x=\frac{1}{64}\sum_{y,z} F(y,z)E_{x+y}\otimes E_{x+z};\quad E_y\equiv\sum_{\vec a} e_y(\vec a) f_{\vec a},$$

where the cochain and its Fourier transform are (if we want the octonions) as in Sec. V A. As explained in Sec. III C a gauge field still means an H-covariant map determined by $\alpha(1)\in\Omega^1(\mathbb{O})$, i.e., some differential form $\alpha(1)=\alpha^i\bullet\tau_i=(\phi^i-1)\bullet\tau_i$ (sum over i). The curvature according to Sec. III C is

$$F_\bullet(\alpha)(1)=\mathrm{d}\alpha(1)+\bullet(\alpha\otimes\alpha)(F)=\mathrm{d}\alpha(1)+\sum_{\vec b,\vec c} F(\vec b,\vec c)(\delta_{\vec b}\triangleright\alpha(1))\bullet(\delta_{\vec c}\triangleright\alpha(1)).$$

Similarly, we have

$$(\Delta\otimes\mathrm{id})(F)=\sum_{\vec a,\vec b,\vec c} F(\vec a+\vec b,\vec c)\delta_{\vec a}\otimes\delta_{\vec b}\otimes\delta_{\vec c}=\sum_{\vec a,\vec b,\vec c} F(\vec a,\vec c)F(\vec b,\vec c)\delta_{\vec a}\otimes\delta_{\vec b}\otimes\delta_{\vec c}=F_{13}F_{23}$$

for the particular form of F for the octonions (which is linear in the exponent with respect to the first argument). Then

$$\alpha^\gamma_\bullet(1)=\sum_{\vec a,\vec b,\vec c} F(\vec a,\vec c)F(\vec b,\vec c)((\delta_{\vec a}\triangleright\gamma^{-1}(1)\bullet\delta_{\vec b}\triangleright\alpha(1))\bullet\delta_{\vec c}\triangleright\gamma(1))+\sum_{\vec b,\vec c} F(\vec b,\vec c)\delta_{\vec b}\triangleright\gamma^{-1}(1)\bullet\mathrm{d}\delta_{\vec c}\triangleright\gamma(1).$$

Matter fields can similarly be included from the general theory in Sec. III C

Next, although our view of the octonions as a nonassociative quantization of functions on the cube is the "geometrical one," it remains very convenient to work with our original plane-wave basis $\{e_{\vec a}\}$ for calculations. Here $f\in H$ acts diagonally as multiplication by $f(\vec a)$ on an element of degree $\vec a$. Here the degree is multiplicative and d does not change degree, so for example $e_{\vec a}\mathrm{d}e_{\vec b}$ has degree $|e_{\vec a}\mathrm{d}e_{\vec b}|=\vec a+\vec b$. Similarly after deformation with the $E_{\vec a}$. Here for example $E_{\vec a}\bullet\mathrm{d}E_{\vec b}=F(\vec a,\vec b)e_{\vec a}de_{\vec b}$ etc. The hard part from this point of view is to find the inverse in the underformed algebra of a general gauge transformation $\gamma=\Sigma_{\vec a}\gamma_{\vec a}e_{\vec a}$. The answer is to construct $\gamma^{-1}=\Sigma_{\vec a}\gamma_{\vec a}^{-1}e_a$ by Fourier transform of the inversion operation:

$$\gamma_{\vec a}^{-1}=\frac{1}{8}\sum_x\frac{e_{\vec a}}{\gamma(x)}=\frac{1}{8}\sum_x\frac{e_{\vec a}}{\sum_{\vec b}\gamma_{\vec b}e_{\vec b}(x)},$$

where we require the $\gamma(x)$ (the sum in the denominator) to be nonzero for each x, i.e., all signed sums of the $\gamma_{\vec b}$ coefficients should be non-zero. Otherwise, since the action of $\delta_{\vec a}$ on any expression in the exterior algebra is to pick out the degree $\vec a$ part, we have more simply in this basis:

$$F_\bullet(\alpha)=\mathrm{d}\alpha+\sum F(|\alpha|,|\alpha'|)\alpha\bullet\alpha',$$

$$\alpha^\gamma_\bullet=\sum F(|\gamma^{-1}|,|\gamma|)F(|\alpha|,|\gamma|)(\gamma^{-1}\bullet\alpha)\bullet\gamma+\sum F(|\gamma^{-1}|,|\gamma|)\gamma^{-1}\bullet\mathrm{d}\gamma,$$

where the sum is over the different graded components of each object and to this end α' denotes a second independent copy of α. Also, we omit writing that these are the gauge and other fields at 1, i.e., $\alpha\equiv\alpha(1)$ etc. Even though the amplification to the collection of fields is needed for the diagrammatic picture of Sec. III A, all formulas are by now referred back to their values on 1. If one wants to be more explicit and write the homogeneous degree components explicitly, we have

$$F_\bullet(\alpha)=\mathrm{d}\alpha+\sum_{\vec a,\vec b} F(\vec a,\vec b)\alpha_{\vec a}\bullet\alpha_{\vec b},$$

$$\alpha^{\gamma}_{\bullet} = \sum F(\vec{a},\vec{c})F(\vec{b},\vec{c})(\gamma^{-1}_{\vec{a}}E_{\vec{a}} \bullet \alpha_{\vec{a}}) \bullet \gamma_{\vec{c}}E_{\vec{c}} + \sum_{\vec{a},\vec{b}} F(\vec{a},\vec{b})\gamma^{-1}_{\vec{a}}E_{\vec{a}}\mathrm{d}\gamma_{\vec{b}}E_{\vec{b}},$$

where $\alpha=\Sigma_{\vec{a}}\alpha_{\vec{a}}$ is the decomposition into homogeneous components (this is a slightly different notation from the Fourier decomposition of γ into components $\gamma_{\vec{a}}E_{\vec{a}}$). The quasi-$\mathbb{R}^n$ example in Sec. IV B can likewise be computed more simply in this "momentum space" point of view.

Finally, we demonstrate this gauge theory with an example of a completely explicit computation. Thus, let

$$\gamma = \lambda u + \mu v, \quad \gamma^{-1} = \frac{1}{\lambda^2 - \mu^2}(\lambda\mu - \mu v),$$

where $u=e_{(1,0,0)}$, $v=e_{(0,1,0)}$ are two of the octonion generators as explained in Sec. V A, and $\lambda \neq \pm\mu$. These are necessarily also inverse in the convolution-algebra $\gamma^{-1}*_{\bullet}\gamma=1$ as one may verify directly. Similarly, since $F(|u|,|u|)=F(|v|,|v|)=F(|u|,|v|)=-1, F(|v|,|u|)=1$, we have

$$\gamma^{-1}*_{\bullet}\mathrm{d}\gamma = \frac{1}{\lambda^2 - \mu^2}(-\lambda^2 u \bullet \mathrm{d}u - \lambda\mu(u \bullet \mathrm{d}v + v \bullet \mathrm{d}u) + \mu^2 v \bullet \mathrm{d}v).$$

Let us check that the curvature of this pure gauge part is zero:

$$\mathrm{d}(\gamma^{-1}*_{\bullet}\mathrm{d}\gamma) = -\frac{\lambda\mu}{\lambda^2 - \mu^2}(\mathrm{d}u \bullet \mathrm{d}v + \mathrm{d}v \bullet \mathrm{d}u) = -2\frac{\lambda\mu}{\lambda^2 - \mu^2}\mathrm{d}u \bullet \mathrm{d}v$$

using the relations in the octonion calculus from Section V A. Meanwhile, when we square $\gamma^{-1}*_{\bullet}\gamma$ in the convolution product we must insert the factors $F(\vec{a},\vec{b})$ when multiplying components of degrees $\vec{a},\vec{b}$ as explained above. Here $|u\bullet\mathrm{d}v| = |v\bullet\mathrm{d}u| = (1,1,0)$ while $u\bullet\mathrm{d}u$ and $v\bullet\mathrm{d}v$ have degree 0. Hence of the 16 terms only four come in with a negative sign. Moreover, when we multiply out the 16 terms we can, in these particular expressions, associate, because the degree vectors for $u, v, u\bullet\mathrm{d}v, v\bullet\mathrm{d}u$ are linearly dependent, so Φ for them is trivial. This results in all but four of the terms zero or cancelling pairwise. For example

$$(u \bullet \mathrm{d}v) \bullet (u \bullet \mathrm{d}v) = u \bullet ((\mathrm{d}v \bullet u) \bullet \mathrm{d}v) = -u \bullet (u \bullet (\mathrm{d}v \bullet \mathrm{d}v)) = 0,$$

$$\begin{aligned}(u \bullet \mathrm{d}v) \bullet (v \bullet \mathrm{d}u) &= u \bullet ((\mathrm{d}v \bullet v) \bullet \mathrm{d}u) = -u \bullet (v \bullet (\mathrm{d}v \bullet \mathrm{d}u)) = -(u \bullet v) \bullet (\mathrm{d}u \bullet \mathrm{d}v) \\ &= (v \bullet u) \bullet (\mathrm{d}u \bullet \mathrm{d}v) = -(v \bullet \mathrm{d}u) \bullet (u \bullet \mathrm{d}v)\end{aligned}$$

using the relations from Sec. V A (the last step is analogous to the first sequence). What remains is

$$\begin{aligned}(\gamma^{-1}*_{\bullet}\mathrm{d}\gamma)*_{\bullet}(\gamma^{-1}*_{\bullet}\mathrm{d}\gamma) = \frac{\lambda\mu}{(\lambda^2 - \mu^2)^2}(\lambda^2((u \bullet \mathrm{d}u) \bullet (u \bullet \mathrm{d}v) + (u \bullet \mathrm{d}v) \bullet (u \bullet \mathrm{d}u)) \\ - \mu^2((v \bullet \mathrm{d}v) \bullet (v \bullet \mathrm{d}u) + (v \bullet \mathrm{d}u) \bullet (v \bullet \mathrm{d}v))) = 2\frac{\lambda\mu}{\lambda^2 - \mu^2}\mathrm{d}u \bullet \mathrm{d}v\end{aligned}$$

by similar computations

$$(u \bullet \mathrm{d}u) \bullet (u \bullet \mathrm{d}v) = u \bullet ((\mathrm{d}u \bullet u) \bullet \mathrm{d}v) = -u \bullet ((u \bullet \mathrm{d}u) \bullet \mathrm{d}v) = -(u \bullet u) \bullet (\mathrm{d}u \bullet \mathrm{d}v) = \mathrm{d}u \bullet \mathrm{d}v,$$

etc., using the relations of the octonion calculus. Hence the curvature of this pure gauge part is zero as promised.

C. Moduli of zero-curvature $U(1)$-Yang–Mills connections on $\mathbb{Z}_2^n$ and octonions

By construction the above mentioned example of gauge theory on the octonions (not the only possible one, depending on the choice of gauge group coalgebra), is equivalent to that in the classical object $\mathbb{Z}_2^3$. Maxwell theory on $\mathbb{Z}_2^n$ (but not Yang–Mills) has been covered in Ref. 17 and also quantum Yang–Mills theory on $\mathbb{Z}_2^2$ but the analysis for classical $U(1)$-Yang–Mills and in particular the moduli space of zero curvature solutions has not to our knowledge been given even for $\mathbb{Z}_2^2$. We fill this gap now. As to be expected on a torus, this moduli space is nontrivial. We work with $\mathbb{Z}_2^n$ as position space.

We use the classical calculus on $\mathbb{Z}_2^n$ as described in Sec. V A before deformation to the octonions when $n=3$. The exterior algebra is generated by the plane-wave functions $e_{\vec{a}}(x)$ (now $\vec{a}$ an n-vector) and $\tau_i, i=1,\ldots,n$ as in Sec. V A but now for general n. They anticommute among themselves, etc.

A $U(1)$-Yang–Mills gauge field means $\alpha=\alpha^i\tau_i\in\Omega^1(\mathbb{Z}_2^n)$ where the $\alpha^i(x)$ are the component functions. The curvature $F=\mathrm{d}\alpha+\alpha\wedge\alpha$ is

$$F=\sum_{i<j}F^{ij}\tau_i\wedge\tau_j,\quad F^{ij}=\partial^i\alpha^i-\partial^j\alpha^i+\alpha^iR_i\alpha^j-\alpha^jR_j\alpha^i.$$

We change variables to $\phi^i=1+\alpha^i$ or $\alpha=\phi-\vartheta$, where $\phi=\phi^i\tau_i$ and $\vartheta=\Sigma_i\tau_i$ is a zero curvature "reference" connection that is closed, not exact and squares to zero. The moduli of flat connections contains at least this nonzero gauge-invariant element. Indeed, let γ be a pointwise invertible function on position space. The gauge transformation of α and the expression for the curvature in terms of ϕ^i are

$$(\phi^\gamma)^i=\frac{\gamma}{R_i\gamma}\phi^i,\quad F^{ij}=\rho_i\phi^j-\rho_j\phi^i,$$

where $\rho_i\equiv\phi^iR_i$. Finally, to be physical, we fix unitarity conditions. As in Ref. 18 we require the τ_i to be invariant under a $*$-operation extending the point-wise complex conjugation operation on position space. We then require the α to be Hermitian, which translates in view of the commutation relations between the τ_i and functions to

$$\overline{\phi^i}=R_i\phi^i,\quad \gamma=e^{\iota\xi},\quad (\phi^\gamma)^i=e^{-\iota\partial^i\xi}\phi^i.$$

The middle equation is because if the reality of all the ϕ^i is preserved one may deduce that $\partial^i(\bar{\gamma}\gamma)=0$ so γ is without loss of generality pointwise unitary. We then put this into the transformation of ϕ^i.

By a similar argument to the proof for S_3 in Ref. 18 we have for all i,j in the case of a zero-curvature solution:

$$\rho_i\rho_i\phi^j=\phi^iR_i(\phi^iR_i\phi^j)=\lambda_i^2\phi^j=\rho_i\rho_j\phi^i=\phi^iR_i(\phi^jR_j\phi^i)=\rho_i(\phi^j)R_jR_i\phi^i=\rho_j(\phi^i)R_iR_j\phi^i=\phi^jR_j(\lambda_i^2),$$

where

$$\phi^i=\lambda_ie^{\iota\theta_i},\quad \lambda_i^2=|\phi^i|^2=\phi^iR_i\phi^i$$

is a polar decomposition. We conclude that at each point $R_i\lambda_i=\lambda_i$ by the reality and at each point either $\lambda_i=0$ or $R_i\lambda_j=\lambda_j$ by the above-mentioned computation, i.e.,

$$\lambda_i\partial^i\lambda_j=0,\quad \forall\, i,j,\quad \partial^i\lambda_i=0,\quad \forall\, i.$$

These λ_i are gauge-invariant and we now use them to analyze the possible solutions.

Case 1: $\exists$ *a point with all* $\lambda_i\neq 0$ *(constant maximal case).* In this case each λ_j will be unchanged moving in every direction to an adjacent point. Hence at each adjacent point they will all be nonzero. We conclude that all the λ_i are constant functions.

Moreover, in this case the zero-curvature equations become

$$e^{\iota\theta_i}e^{\iota R_i\theta_j}e^{-\iota R_j\theta_i}e^{-\iota\theta_j}=1$$

after canceling $\lambda_i\lambda_j$ from both sides. If we think of $e^{\iota\theta_i(x)}$ to be a factor for parallel transport along the edge in direction i from x, then this says that the holonomy around the plaquet with bottom left corner x and edges in the i and j directions is trivial. In this case, from such a solution we construct the following gauge transform:

$$\gamma(0)=1,\quad \gamma(x)=e^{\iota\Sigma_a i\theta.\mathrm{d}a},$$

where we take any path a from 0 to x and multiply the parallel transports on the edges of the path. As in usual gauge theory, this transforms all the $\phi^i\to\lambda_i$, i.e., eliminates all the phases as gauge degrees. Hence the solutions up to gauge equivalence in this case are of the form

$$\alpha=\lambda_i\tau_i-\vartheta,\quad \lambda_i\in\mathbb{R}_{>0},\quad i=1,\ldots,n.$$

Case 2: $\exists$ *a point with exactly one* $\lambda_i=0$ *(split case).* In this case all $\lambda_j\neq 0$ for $j\neq i$, at the point in question. Therefore moving in all directions other than i, we have the same value for all λ_j, i.e., a constant maximal solution on the subspace $\mathbb{Z}_2^{n-1}$. We also have the same value of $\lambda_i=0$ throughout this subspace. Moreover, moving in the i direction from any point in the subspace keeps $\lambda_i=0$ (hence $\lambda_i\equiv 0$ everywhere) but says nothing about the values of any of the $\lambda_j, j\neq i$. Hence the solution is two independent copies of $n-1$-dimensional solutions, in which the first copy is maximal by assumption and the second copy is unconstrained.

For example, if the second copy is also maximal on the subspace, we have

$$\alpha=x_i\lambda_j\tau_j+(1-x_i)\mu_j\tau_j-\vartheta,\quad \lambda_j,\mu_j\in\mathbb{R}_{>0},\quad j\neq i$$

and again any solution in this case is equivalent to something of this form (one may gauge away the phases in each $\mathbb{Z}_2^{n-1}$ space separately). The value of $\partial^j\xi$ between the two copies could produce a gauge phase factor but this is irrelevant as $\lambda_i\equiv 0$ everywhere.

Case $2'$*:* What arises naturally here is the weaker assumption just that there is some i with $\lambda_i\equiv 0$ throughout the space. In this case the solution necessarily splits into independent solutions of one dimension lower, of whatever type. This is therefore covered by induction. Hence it remains only to classify the remaining cases under the assumption that the solution is not split in any direction.

Case 3: $\exists$ *a point with exactly two* $\lambda_i=\lambda_j=0$ *and no splitting.* Here as before there is a $\mathbb{Z}_2^{n-2}$ subset containing the point with $\lambda_k\neq 0$ for all $k\neq i,j$, and $\lambda_i=\lambda_j=0$ throughout. Moreover, stepping in the i direction carries over $\lambda_i=0$ to the entire adjacent quadrant, but none of the other information. Similarly stepping in the j direction carries over $\lambda_j=0$ to that quadrant. We then relate the quadrants by further analysis; see the following example.

One may proceed in this way to classify the cases with more and more assumed degeneracy. Among the solutions are those of the same form as the constant maximal case above but allowing any of the $\lambda_i=0$. These are multiply-split solutions and include each τ_i alone as a zero-curvature flat connection, as well as $\alpha=-\vartheta$.

To be concrete we now offer a complete classification for $n=2$ and $n=3$ which demonstrates the method. The $n=3$ case is in correspondence with solutions on the octonions by twisting as we have mentioned.

For $n=2$ we have two cases: (i) the constant maximal solution is

$$\alpha=\lambda_1\tau_1+\lambda_2\tau_2-\vartheta,\quad \lambda_i\in\mathbb{R}_{>0}.$$

(ii) We have a splitting $\lambda_1\equiv 0$, with λ_2 unconstrained other than being constant in the 2-direction, i.e.

$$\alpha=\lambda\tau_2-\vartheta,\quad \partial^2\lambda=0,$$

where λ is a function just in the x_1 variable and up to gauge equivalence can be taken real and non-negative in its values. Similarly for a splitting $\lambda_2\equiv 0$:

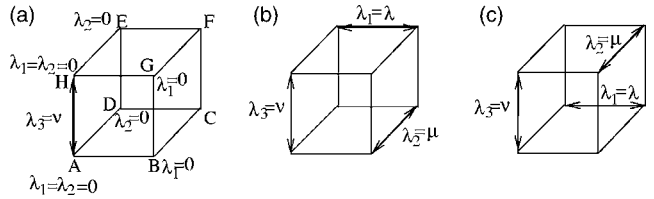

FIG. 2. Flat connections of type (iii) in the cube: (a) Initial assumption, (b) solution, and (c) its mirror image as the only possible. In (b) and (c) only the nonzero λ_i are shown.

$$\alpha = \lambda\tau_1 - \vartheta, \quad \partial^1\lambda = 0$$

for a real and nonnegative function λ of x_2 alone.

For $n=3$ we have three cases: (i) the constant maximal solution

$$\alpha = \lambda_1\tau_1 + \lambda_2\tau_2 + \lambda_3\tau_3 - \vartheta, \quad \lambda_i \in \mathbb{R}_{>0}.$$

(ii) We have a splitting $\lambda_1 \equiv 0$:

$$\alpha = x_1\phi + (1-x_1)\psi - \vartheta,$$

where ϕ, ψ correspond to two independent solutions on the $\mathbb{Z}_2^2$ subsets (faces) with $x_1=0$ and $x_1=1$ respectively. Up to gauge transformation they can be taken real and positive, i.e., without phases. Similarly in the other two directions.

(iii) we suppose that there does not exist a splitting, but there does exist a point with, say, $\lambda_1=\lambda_2=0$ and $\lambda_3=\nu\neq 0$. To be concrete let this point be A the origin in the standard cube shown in Fig. 2. These are also the values at H by the above argument; the equal value of λ_3 is shown in Fig. 2(a) by labeling the arrowed edge, and such a nonzero edge "transports" the other values from A to H by the previous arguments. We also see that $\lambda_1=0$ at B and G, whereas $\lambda_2=0$ at D and E, by the reality condition.

Now suppose that $\lambda_2=\mu\neq 0$ at corners B and C (the two must be the same value) as shown by the arrowed edge in Fig. 2(b). Then at B we must have $\lambda_3=0$ to avoid a split (to avoid the existence of a point with two nonzero λ_i). In this case $\lambda_1=\lambda_3=0$ also at C. Hence $\lambda_1=0$ at D. We conclude also that $\lambda_3=0$ at D (and hence all $\lambda_i=0$ at D) for if not, we could deduce the same values at E and hence that $\lambda_1=0$ at F, which would be a split with $\lambda_1\equiv 0$. Then $\lambda_1=\lambda\neq 0$ at E and F (to avoid a split with $\lambda_1\equiv 0$). Hence $\lambda_2=\lambda_3=0$ at E and F. Hence $\lambda_2=0$ also at G, and since $\lambda_3=0$ at A it must also vanish at G, i.e., all three λ_i vanish at G. The solution is then fully determined by the three nonzero values λ, μ, ν and all three λ_i vanishing at D, G as shown in Fig. 2(b). We mark only the nonzero edges, which imply those value on their endpoints; all other values are zero.

Alternatively, if $\lambda_2=0$ at B and C, then $\lambda_2=\mu\neq 0$ at F and G (the arrowed edge shown in Figure 2 part (c)) to avoid a split with $\lambda_2\equiv 0$. Hence $\lambda_3=0$ at G to avoid a maximal solution, and hence also at B (so all three $\lambda_i=0$ at B). Moreover, the values $\lambda_1=\lambda_3=0$ are transported to F. Hence $\lambda_3=0$ at C also, and $\lambda_1=0$ at E also. Finally, $\lambda_1=\lambda\neq 0$ at C, D (the final arrowed edge shown in part (c)) to avoid a split $\lambda_1\equiv 0$. This transports $\lambda_3=0$ also to D and hence to E, therefore we deduce the mirror image solution to the one above, where the $\lambda_i=0$ now at B, E as shown in part (c) of the figure.

The explicit formula in the first case, if A is the origin of a standard cube, is

$$\alpha = x_2x_3\lambda\tau_1 + x_1(1-x_3)\mu\tau_2 + (1-x_1)(1-x_2)\nu\tau_3 - \vartheta, \quad \lambda, \mu, \nu \in \mathbb{R}_{>0}.$$

Of course, we can rotate this solution by picking any other origin and initial non-zero edge, and we also have the mirror image solution. Finally, phases can be removed by gauge transformation in a similar manner to the above. This exhausts the moduli space for flat connections for the cube $n=3$ up to gauge equivalence.

Noncommutative model with spontaneous time generation and Planckian bound

We illustrate the thesis that if time did not exist, we would have to create it if space is noncommutative, and extend functions by something like Schrödinger's equation. We propose that the phenomenon is a somewhat general mechanism within noncommutative geometry for "spontaneous time generation." We show in detail how this works for the su_2 algebra $[x_i,x_j]=2\imath\lambda\epsilon_{ij}{}^k x_k$ as noncommutative space, by explicitly adjoining the forced time variable. We find the natural induced noncommutative Schrödinger's equation and show that it has the correct classical limit for a particle of some mass $m\neq 0$, which is generated as a second free parameter by the theory. We show that plane waves exist provided $|\vec{p}|<\pi/2\lambda$, i.e., we find a Planckian bound on spatial momentum. We also propose dispersion relations $|\partial p^0/\partial\vec{p}|=|\tan(\lambda|\vec{p}|)|/m\lambda$ for the model and explore some elements of the noncommutative geometry. The model is complementary to our previous bicrossproduct one. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2084748]

I. INTRODUCTION

The origin of a time direction is a fundamental issue in any theory of quantum gravity, as likewise is the origin of mass for elementary particles. In this article we point out that previously known results on noncommutative differential calculi on quantum algebras can be viewed as evidence for a general phenomenon which we call "spontaneous time generation" in which both time and nonzero mass can be created by even a small amount of noncommutativity in space (or more precisely in its geometry). Put another way, a noncommutative deformation of space by a parameter λ can induce its own canonical evolution, forced by nothing other than the most minimal assumptions on existence of a differential structure on the space.

It is important that we use here the absolutely minimal and generally accepted notion of differential calculus or "exterior algebra" applicable to a noncommutative algebra A and common to all main approaches, i.e., we will not put in anything beyond this "by hand." This is to specify a bimodule of "1-forms" Ω^1 with left and right multiplication by a "function" in A, and a $\mathrm{d}:A\to\Omega^1$ operation obeying the Leibniz rule

$$\mathrm{d}(ab)=a\mathrm{d}b+(\mathrm{d}a)b.$$

One also requires that elements of the form $a\mathrm{d}b$ span Ω^1 and (a connectedness condition) that $\mathrm{d}a=0$ if and only if a is a constant. These are minimal properties that nevertheless suffice to do basic gauge theory on any algebra.

Next we note that for noncommutative algebras there is typically an element $\theta\in\Omega^1$ that generates the calculus in the sense

a)Electronic mail: s.majid@qmul.ac.uk

$$[\theta, a] = \lambda \mathrm{d}a$$

where λ is a parameter controlling the noncommutativity of the algebra A. Both sides go to zero when $\lambda \to 0$ (because classical 1-forms commute with functions), so this is a purely "quantum" phenomenon. The reason for the quotation marks here is that in our application λ is not related to $\hbar$ but is a new parameter in physics controlling a possible noncommutativity in space or space-time, or equivalently "cogravity" as curvature in momentum space.[18] The element θ must exist for example in the case of a semisimple Hopf algebra and a translation-covariant calculus, but also more generally whenever the geometry of A is fully noncommutative. On the other hand there is no reason at all to have such an element in the classical case as the equation above is empty. Therefore as we deform the classical algebra and its geometry, the constraints of noncommutative geometry will force the existence of a generating 1-form θ which *will have no reason to have any classical counterpart*. We are going to interpret this element θ as a time direction and the phenomenon then is that there may or may not be such a direction $\mathrm{d}t$ in our classical geometry with θ its deformation, but if there is not such a time direction it will have to be adjoined. This is what we propose here as "spontaneous generation" of time in our quantum groups approach to noncommutative geometry. Moreover, the partial derivative ∂^0 associated to this $\theta = \mathrm{d}t$ will generally have a classical limit for ∂^0/λ and this will be our induced *classical* Hamiltonian generated by the noncommutative geometry. Finally, we are free to change the normalization of θ in the previous discussion, which appears then as a new parameter induced at the same time.

In this article we will demonstrate this phenomenon in detail for one of the most basic noncommutative three-dimensional (3D) spaces, namely the angular momentum space

$$[x_i, x_j] = 2\imath\lambda \epsilon_{ij}{}^k x_k \tag{1}$$

of which the noncommutative geometry was studied in Ref. 5. This is the usual quantization of $\mathbb{R}^3$ as the coadjoint space su_2^* with its Kirillov–Kostant Poisson bracket, denoted $\mathbb{R}^3_\lambda$. The need for an extra direction θ in the calculus, as well as the link with Schrödinger's equation was proposed here, and in this sequel we develop it in detail. Section II is a reprise of the noncommutative differential geometry on (1) that we need from Ref. 5 except that we leave the normalization θ as a free nonzero parameter μ. Section III gives a quick account of quantum group Fourier transform and a direct derivation of formulae for the partial derivatives on 3D plane waves, which will also be needed.

In Section IV we proceed to explicitly adjoin a new variable t, commuting with x_i, such that $\theta = \mathrm{d}t$. In this extended space-time algebra the natural equation

$$\partial^t \psi(x,t) = 0 \tag{2}$$

(or that $\mathrm{d}\psi$ is purely spatial) is now our proposed noncommutative Schrödinger's equation (NCSE). We show that in the limit $\lambda \to 0$ this reproduces the usual Schrödinger equation for ψ for a particle of mass m with Compton wavelength $\mu = 1/m$. *We work throughout in units* $\hbar = c = 1$. In fact it turns out that as m approaches $1/\lambda$ we have to the next order a noncommutative version of the four-dimensional (4D) Euclidean wave equation for $e^{-\imath m t}\psi(x,t)$, suggesting a Euclidean aspect to the theory. Our construction is, however, very much tied to the nonrelativistic coordinate system consisting of x_i space and the induced t although it does not preclude the possibility of a Lorentz or 4D Euclidean (quantum) group action in the deformed theory. There is at least a full spatial Euclidean group of motions preserved in the construction, as the quantum group double $D(U(\mathrm{su}_2))$.[5] In Sec. V we finally solve the NCSE on plane waves, with solutions $e^{\imath \vec{p}\cdot x} e^{\imath p^0 t}$ of energy

$$p^0 = -\frac{1}{m\lambda^2} \ln(\cos(\lambda |\vec{p}|)) \tag{3}$$

provided $|\vec{p}| < \pi/2\lambda$. We also find the group velocity computed naively by differentiation of (3). It is a deformation of $|\vec{p}|/m$.

Our model comes out of noncommutative geometry and is not tied to specific values of λ, m. Our own view is that the theory could also be applicable in certain circumstances as an effective description of position "fuzziness" within quantum mechanics at the Compton wavelength scale of an ordinary particle, in the spirit of Ref. 21. However, if the theory appeared as a next-to-classical effective theory in a theory of quantum gravity, λ would be expected to be of the order of the Planck scale and hence we would have a Planckian spatial momentum cutoff for our particle. In fact it is known that the quantum double $D(U(\mathrm{su}_2))$ controls the tensor products of certain states in 2+1 quantum gravity,[3,22] therefore the result[5] that this quantum group acts covariantly on $\mathbb{R}^3_\lambda$ suggested that the latter should indeed be the effective noncommutative space in the next-to-classical approximation of 2+1 Chern–Simons quantum gravity. The algebra $\mathbb{R}^3_\lambda$ has also been proposed in string theory and in the reduction of certain matrix models but more usually in this context projected to a matrix algebra by setting the casmir equal to $j(j+1)$, which is to say a "fuzzy sphere."[1,4] However, we do not make such a projection here and we do not use the ad-hoc derivations-based matrix methods previously used for such objects. The noncommutative geometry in our case and with time adjoined is actually very rich and explored in Sec. VI where we show the existence of a closed radial polar coordinate system and some elements of gauge theory.

We note also that a Planckian cutoff is already a feature of the bicrossproduct spacetime[20] and we provide a comparison with this older model in the Appendix. In fact it has been known for some time that the zero-mass shell equation in the bicrossproduct model is deformed to

$$|\vec{p}| = \frac{1}{\lambda}(1 - e^{-\lambda p^0}) \quad \text{or} \quad p^0 = -\frac{1}{\lambda}\ln(1 - \lambda|\vec{p}|),$$

see (A2) in the Appendix, which (obviously) has the bound $|\vec{p}| < 1/\lambda$. Recently, some authors have dubbed models with such a Planckian cutoff as "doubly special" under the claim that the asymptotic feature of special relativity is now "doubled" by this additional asymptotic bound.[10] Although debatable, our own view is that such rebranding of the bicrossproduct model (which remains the main model in the theory) is unjustified as we also explain in the Appendix: What actually happens in our view is that the usual mass-shell hyperboloid is deformed nonlinearly and what used to be a 45° cone is now bent into a cylinder with vertical walls, rather than being a new bound. We also outline a different point of view on the cutoff in line with Ref. 13 (where p was viewed as position space rather than momentum) as an event-horizon-like coordinate singularity. In the present model part of the reason for a cutoff is rather more transparent: momentum space is compactified to a sphere $S^3 = \mathrm{SU}_2$ according to the quantum group Fourier transform.

Returning to the general phenomenon of spontaneous time creation, we note that for $\mathbb{C}_q[\mathrm{SU}_2]$ it is again known that the smallest bicovariant calculus is 4D not 3D and that the extra direction θ is linked to the Laplace operator, now on the quantum group as a noncommutative S^3. It is also already known that the local 4D cotangent bundle indeed has a natural q-Minkowski space metric, see Ref. 16 for a review and, for example, Ref. 8 for full calculations at q a root of unity (which is likely to be the physical case if such a deformation arises from quantum gravity in view of the well-known role of this quantum group in conformal field theory). The consistent addition of a time variable, however, and an analysis along the lines of the present paper is somewhat technical and will be presented elsewhere.

Finally, let us note that our proposal on time has no relation that we are aware of to the modular group in the theory of von-Neuman algebras; our results are purely algebraic and not connected with functional analysis. Briefly, Tomita and Takesaki in the 1970s showed that every von-Neumann algebra carries with it a 1-parameter automorphism group σ_t generated by the positive part Δ in the polar decomposition of the $*$-operation relative to a state. Translation by a finite imaginary interval in t is used to characterize KMS states in equilibrium quantum statistical mechanics on the algebra. Hence some authors, notably in Ref. 7, have proposed that t here should be viewed as time canonically associated to the von-Neumann algebra in a suitable setting. Although such a point of view is interesting, the phenomenon we propose in the "quantum groups approach" to noncommutative geometry is a rather more concrete one in which we shall show that a parameter t has to be adjoined and wave functions with respect to it naturally obey Schrödinger's

equation for some mass m. Our theory at the present level does not determine m, only that it must be nonzero, although $m=1/\lambda$ does present some simplifications in the mathematical structure as noted previously.

According to our analysis this mass and time generation is forced by the axioms of a differential calculus. We mention one alternative, which is to change these axioms by giving up associativity. At the semiclassical level it corresponds to curvature of an underlying Poisson-compatible preconnection.[6] (If one simply drops the θ terms in the calculus one would have such a situation with Poisson curvature and nonassociativity appearing at order λ^2). This gives an alternative idea of the nature of the obstruction involved. In physical terms one could say that the spatial translation group (as expressed in the differentials) is "anomalous" under the process of deformation quantization, with anomaly controlled by the above-mentioned Poisson curvature and nullified by adding an extra dimension.

II. REPRISE OF DIFFERENTIAL CALCULUS AND PLANE WAVES ON $\mathbb{R}^3_\lambda$

Since the calculus is crucial to our entire analysis, let us briefly reprise the construction in Ref. 5. For Lie groups it is well known that the translation-invariant differential structure is unique; for quantum groups there is a parallel theory for the weaker minimal axioms above that translation-invariant Ω^1 are freely generated over their space of invariant 1-forms and this latter space can be classified in terms of ideals in the augmentation ideal (the kernel of the counit) of the Hopf algebra. See Ref. 19 for a modern review of the theory. In general we refer to Ref. 16 for the notations and more basic theory of Hopf algebras.

Of course, $\mathbb{R}^3_\lambda$ is an additive Hopf algebra (in fact a classical enveloping algebra) with

$$\Delta x_i = x_i \otimes 1 + 1 \otimes x_i, \quad \epsilon x_i = 0, \quad S x_i = -x_i,$$

so we may use Hopf algebra or quantum group methods, and we do. The augmentation ideal in our case is the subalgebra $U(\mathrm{su}_2)^+$ generated by the x_i but not including 1. So left-invariant calculi (which will automatically be bicovariant in the present context) will be classified by ideals in here. These in turn are given by the kernels of matrix representations, more precisely by pairs (ρ, v) consisting of a representation and a ray in the representation space. The kernel of the map consisting of applying ρ to v is the ideal we need, and the left-invariant forms become identified with the orbit of v (which is the whole representation space for a cyclic vector). In our case, one can compute the differential calculi for the spin 0, 1/2, and 1 representations, of dimension 1,2,3, respectively. Especially, the last of these might be expected to be the correct calculus but in all these cases one may compute that d has a large kernel so these calculi are not successful. The next smallest is $\frac{1}{2}\otimes\frac{1}{2}$ which is to say the Pauli matrix representation on $M_2(\mathbb{C})$ where the algebra acts from the left and from the right (a 4D representation) by Pauli matrices. The canonical vector v is the identity matrix. This 4D calculus as shown to fulfill the connectedness property and is as we see the smallest such. We refer to Ref. 5 for details. We are assuming that $\lambda \neq 0$ (otherwise we could have the classical calculus).

The resulting calculus has commutation relations

$$\mathrm{d}x_i = \lambda \sigma_i, \quad x_i\theta - \theta x_i = \iota \frac{\lambda^2}{\mu} \mathrm{d}x_i,$$

$$(\mathrm{d}x_i)x_j - x_j \mathrm{d}x_i = \iota\lambda \varepsilon_{ij}{}^k \mathrm{d}x_k + \iota\mu\delta_{ij}\theta,$$

where θ is a multiple of the 2×2 identity matrix and, together with the Pauli matrices σ_i, completes the basis of left-invariant 1-forms. In the present paper relative to Ref. 5 we have put in a critical factor of ι and scale factor $\mu \neq 0$ in the normalization of θ to express explicitly that we are free to choose this normalization. One might expect $\mu \sim \lambda$ if both are generated by some deeper theory, or one might consider μ as second and independent length scale in the theory. The factor ι is justified as follows: to speak about unitarity all our algebras will be $*$-algebras and

thinking of the x_i as observables in the quantum algebra and real functions in the classical limit, we require

$$x_i^* = x_i,$$

which is consistent with λ real for the conventions used for $\mathbb{R}^3_\lambda$. Next, it is reasonable that $(\mathrm{d}x_i)^* = \mathrm{d}x_i$ if we want these also to be observables and to be identified with real 1-forms in the classical limit. The entire exterior algebra is generated by 1-forms, our case with the usual anticommutative wedge product, and we require this to be a $*$-algebra with

$$(\mathrm{d}\alpha)^* = (-1)^{|\alpha|}\mathrm{d}(\alpha^*)$$

for a form of degree $|\alpha|$. These conventions are not always adhered to in the literature (there are other equivalent ones in other contexts) but at least here, where there is a clear match with the classical limit, they are reasonable. For example, one of the main things one does with differential 1-forms is gauge theory. If u is unitary then

$$(u^{-1}\mathrm{d}u)^* = (\mathrm{d}u)^* u = (\mathrm{d}u^{-1})u = \mathrm{d}(1) - u^{-1}\mathrm{d}u = -u^{-1}\mathrm{d}u$$

is antihermitian. So connection 1-forms α are antihermitian. Then the curvature obeys

$$F(\alpha)^* = (\mathrm{d}\alpha + \alpha\wedge\alpha)^* = -\mathrm{d}\alpha^* + \alpha^*\wedge\alpha^* = F(\alpha)$$

which is to say behaves homogeneously under $*$. This justifies our reality conventions for the calculus. Indeed, a $U(1)$ connection in such a (trivial bundle) gauge theory would be $\imath$ times a real 1-form in classical geometry.

For our purposes we likewise require that $\theta^* = \theta$, i.e., a real 1-form in the classical limit, which determines the normalization used. An alternative is to require that $\theta^* = -\theta$ which would be more suitable for applications in which θ has the interpretation of a reference connection. The latter was the convention and application for θ in Ref. 5 for example.

Once one has fixed the differential calculus, the partial derivatives ∂^i as operators on $\mathbb{R}^3_\lambda$ are completely determined by

$$\mathrm{d}\psi(x) = (\partial^i\psi)\mathrm{d}x_i + (\partial^0\psi)\theta.$$

They are not derivations (that would be an older and widely discredited approach to noncommutative geometry); rather they are braided derivations with respect to a certain solution of the Yang–Baxter equations (induced from the quantum double).

Finally plane waves take the form of group elements in the enveloping algebra $\mathbb{R}^3_\lambda$,

$$\psi_{\vec{p}}(x) = e^{\imath\vec{p}\cdot x}, \quad \vec{p}\in\mathbb{R}^3.$$

The momenta p_i are nothing but local coordinates for the corresponding point $e^{\imath\lambda\vec{p}\cdot\sigma}\in \mathrm{SU}_2$ where $\lambda\sigma$ is the representation by Pauli matrices. It is really elements of this curved space SU_2 where momenta live, as evident in the addition law for momenta determined by the plane waves:

$$\psi_{\vec{p}}\cdot\psi_{\vec{p}'} = \psi_{C(\vec{p},\vec{p}')},$$

where $C(\vec{p},\vec{p}')$ is the Campbell–Baker–Hausdorf series. This is the general procedure for any enveloping algebra of a Lie algebra and the one we use here. Other coordinate systems are also possible, for example by Euler angles. We will show next that our plane waves are eigenfunctions of the ∂^i. The result is in Ref. 5 but the proof now is entirely different and self-contained.

III. QUANTUM GROUP FOURIER TRANSFORM AND ACTION ON PLANE WAVES

The algebra $\mathbb{R}^3_\lambda = U(\mathrm{su}_2)$ has dual $\mathbb{C}[\mathrm{SU}_2]$ and Hopf algebra Fourier transform (after suitable completion) takes one between these spaces. Thus, in one direction

$$\mathcal{F}(f)=\int_{\mathrm{SU}_2}\mathrm{d}u f(u)u\approx\int_{\mathbb{R}^3}\mathrm{d}^3pJ(\vec{p})f(\vec{p})e^{\imath\vec{p}\cdot x}$$

for f a function on SU_2. We use the Haar measure on SU_2. The local result on the right has J the Jacobian for the change to the local $\vec{p}$ coordinates and f is written in terms of these. Differential operators on $\mathbb{R}^3_\lambda$ are given by the action of elements of $\mathbb{C}[\mathrm{SU}_2]$ and are diagonal on these plane waves,

$$f\cdot\psi_{\vec{p}}=f(\vec{p})\psi_{\vec{p}},$$

which corresponds under Fourier transform simply to pointwise multiplication in $\mathbb{C}[\mathrm{SU}_2]$. This quantum group Fourier transform approach to noncommutative geometry whereby it becomes equivalent to a theory of classical but *curved* momentum space was introduced by the author in Ref. 17 more than a decade ago. We refer to Ref. 18 for a more recent review. Of course Fourier transform by other more conventional methods such as spherical harmonics is also possible but the quantum groups Fourier transform exactly takes us to noncommutative spaces such as $\mathbb{R}^3_\lambda$ which is what we need now.

Next, we show that the partial derivatives indeed act diagonally on plane waves as

$$\partial^i=\imath\frac{p^i}{\lambda|\vec{p}|}\sin(\lambda|\vec{p}|)=\frac{\imath}{2\lambda}\mathrm{Tr}(\sigma_i(\ \ )),\tag{4}$$

$$\partial^0=\frac{\imath\mu}{\lambda^2}(\cos(\lambda|p|)-1)=\frac{\imath\mu}{2\lambda^2}(\mathrm{Tr}-2).\tag{5}$$

The second expressions in each case are just the functions in $\mathbb{C}[\mathrm{SU}_2]$ whose evaluation on plane waves gives the first expression in each case. Thus

$$\mathrm{Tr}\,\psi_{\vec{p}}=\mathrm{Tr}(e^{\imath\lambda\vec{p}\cdot\sigma})\psi_{\vec{p}}=2\cos(\lambda|p|)\psi_{\vec{p}}$$

and so forth. It remains to prove the first expressions for the ∂^μ.

The full action of the ∂^μ are rather complicated but we need them only for functions of

$$X=\imath\vec{p}\cdot x.$$

Then from the relations for the calculus, we find the subcalculus

$$(\mathrm{d}X)\cdot X=X\mathrm{d}X-\imath\nu\theta,\quad \theta X=X\theta-\imath\nu'\mathrm{d}X,$$

where

$$\nu=\mu p^2,\quad \nu'=\frac{\lambda^2}{\mu}.$$

We let

$$\mathrm{d}X^n=f_n(X)\mathrm{d}X+g_n(X)\theta$$

and using the above-mentioned relations and the Leibniz rule we have

$$\begin{aligned}\mathrm{d}X^n&=(\mathrm{d}X^{n-1})X+X^{n-1}\mathrm{d}X=f_{n-1}\mathrm{d}X\cdot X+X^{n-1}\mathrm{d}X+g_{n-1}\theta X\\&=f_{n-1}X\mathrm{d}X-\imath\nu f_{n-1}\theta+X^{n-1}\mathrm{d}X+g_{n-1}X\theta-\imath\nu' g_{n-1}\mathrm{d}X\end{aligned}$$

hence, the recurrence relations

$$f_n = f_{n-1}X - \imath\nu' g_{n-1} + X^{n-1}, \quad g_n = g_{n-1}X - \imath\nu f_{n-1}, \quad f_1 = 1, \quad g_1 = 0.$$

These can be easily solved and yield

$$f_n = -\frac{\imath}{2\sqrt{\nu\nu'}}((X + \imath\sqrt{\nu\nu'})^n - (X - \imath\sqrt{\nu\nu'})^n),$$

$$g_n = -\frac{\imath}{\nu'}X^n + \frac{\imath}{2\nu'}((X + \imath\sqrt{\nu\nu'})^n + (X - \imath\sqrt{\nu\nu'})^n),$$

or

$$\mathrm{d}X^n = \frac{\imath}{2\lambda|\vec{p}|}\left((X - \imath\lambda|\vec{p}|)^n\left(\frac{\mu}{\lambda}|\vec{p}|\theta + \mathrm{d}X\right) + (X + \imath\lambda|\vec{p}|)^n\left(\frac{\mu}{\lambda}|\vec{p}|\theta - \mathrm{d}X\right)\right) - \frac{\imath\mu}{\lambda^2}X^n\theta.$$

In particular, we see that

$$e^{-X}\mathrm{d}e^X = \frac{\imath}{2\lambda|\vec{p}|}\left(e^{-\imath\lambda|\vec{p}|}\left(\frac{\mu}{\lambda}|\vec{p}|\theta + \mathrm{d}X\right) + e^{\imath\lambda|\vec{p}|}\left(\frac{\mu}{\lambda}|\vec{p}|\theta - \mathrm{d}X\right)\right) - \frac{\imath\mu}{\lambda^2}\theta$$

$$= \frac{\imath\mu}{\lambda^2}(\cos(\lambda|\vec{p}|) - 1)\theta + \frac{1}{\lambda|\vec{p}|}\sin(\lambda|\vec{p}|)\mathrm{d}X$$

which translates into ∂^μ acting as stated on plane waves. Through quantum group Fourier transform this allows one to compute them in principle on any $\psi(x)$. We will not need to do this explicitly, however.

IV. LAPLACIAN AND NONCOMMUTATIVE SCHRÖDINGER'S EQUATION

From the partial derivatives (4) and (5) on plane waves, we compute the 3D Laplacians on plane waves:

$$\nabla^2 = \partial_i\partial^i = -\frac{1}{\lambda^2}\sin^2(\lambda|\vec{p}|)$$

which has the correct classical limit $-|\vec{p}|^2$ as $\lambda \to 0$. Comparing with the expression in momentum space for ∂^0 we deduce that

$$\partial^0 = \frac{\imath\mu}{\lambda^2}(\sqrt{1 + \lambda^2\nabla^2} - 1) \tag{6}$$

on plane waves and hence in general for modes with $\nabla^2 \geqslant -1/\lambda^2$. Expanding this we find

$$\partial^0\psi = \imath\frac{\mu}{2}\nabla^2\psi + O(\lambda^2) \tag{7}$$

which is of the form of Schrödinger's equation with respect to an auxiliary "time" variable and a particle with Compton wavelength μ corresponding to mass m,

$$\mu = \frac{1}{m}. \tag{8}$$

Our point of view is that λ might be of the order of the Planck scale, so if μ is also of this scale then the effective mass of the particle being described is of the order of the Planck mass. We are not tied to such a value for either parameter, however.

We now proceed to develop this point of view. Thus let t be a time variable adjoined to the theory, commuting with the position generators and such that

$$\theta = \mathrm{d}t$$

which is consistent with our reality assumptions if $t^* = t$. For consistency with the relations in the differential calculus we need

$$0 = \mathrm{d}([t, x_i]) = \theta x_i + t\mathrm{d}x_i - (\mathrm{d}x_i)t - x_i\theta$$

so we require

$$[t, \mathrm{d}x_i] = \imath\frac{\lambda^2}{\mu}\mathrm{d}x_i$$

which implies that

$$(\mathrm{d}x_i)f(t) = f\left(t - \imath\frac{\lambda^2}{\mu}\right)\mathrm{d}x_i.$$

In this case for the Jacobi identity

$$0 = [\mathrm{d}x_i, [x_j, t]] + [x_j, [t, \mathrm{d}x_i]] + [t, [\mathrm{d}x_i, x_j]]$$

we need

$$[t, \theta] = \imath\frac{\lambda^2}{\mu}\theta.$$

Since $\theta = \mathrm{d}t$ we see that

$$f\left(t - \imath\frac{\lambda^2}{\mu}\right)\mathrm{d}t = (\mathrm{d}t)f(t)$$

holds as well, which in turn can be used to show that

$$\mathrm{d}f(t) = (\partial^t f(t))\mathrm{d}t, \quad \partial^t f(t) \equiv \frac{f(t) - f\left(t - \imath\frac{\lambda^2}{\mu}\right)}{\imath\frac{\lambda^2}{\mu}}$$

is necessarily a finite difference operator. Applying d again gives the usual anticommutation relations between $\mathrm{d}t$ and the $\mathrm{d}x_i$ (as among themselves). In summary, we can adjoin a t variable but for consistency with the spatial noncommuative calculus we will need its calculus to be a noncommutative finite difference one.

The differential on functions $a(x)$ just of x is unchanged:

$$\mathrm{d}a(x) = \partial^i a(x)\mathrm{d}x_i + \partial^0 a(x)\mathrm{d}t.$$

When we look in the extended algebra we will have functions generated by products of functions $a(x)$ and $f(t)$ and here we find, using the Leibniz rule,

$$\begin{aligned}\mathrm{d}(a(x)f(t)) &= (\partial^i a\mathrm{d}x_i)f + (\partial^0 a\mathrm{d}t)f + a\partial^t f\mathrm{d}t \\ &= (\partial^i a)f\left(t - \imath\frac{\lambda^2}{\mu}\right)\mathrm{d}x_i + \left((\partial^0 a)f\left(t - \imath\frac{\lambda^2}{\mu}\right) + a\partial^t f\right)\mathrm{d}t \equiv \tilde{\partial}^i(af)\mathrm{d}x_i + \tilde{\partial}^0(af)\mathrm{d}t.\end{aligned}$$

This defines the partial derivatives $\tilde{\partial}^\mu$ acting on general functions in the calculus. Here $\tilde{\partial}^0$ reduces to ∂^0 as before acting on $a(x)$ and to ∂^t acting on $f(t)$ alone. The braided Liebniz rule is evident here on products as the extra shift by $-i\lambda^2/\mu$ and is typical of noncommutative vector fields.

The calculus is clearly an unusual one in which the ∇^2 is built into $\tilde{\partial}^0$. Because we have adjoined the t the natural formulation of Schrödingers equation is now

$$\tilde{\partial}^0\psi(x,t)=0, \tag{9}$$

i.e., functions which are "constant" with respect to the extended differential calculus in the sense that $\mathrm{d}\psi$ is purely spatial. We can write this more explicitly using the above as

$$\frac{\imath\mu}{\lambda^2}\left(\psi(x,t)-\psi\left(x,t-\imath\frac{\lambda^2}{\mu}\right)\right)=\partial^0\psi\left(x,t-\imath\frac{\lambda^2}{\mu}\right) \tag{10}$$

exhibiting ∂^t as a finite difference operation in the continuous time variable t. Putting in our previous expression for ∂^0 this is

$$\psi(x,t)-\psi\left(x,t-\imath\frac{\lambda^2}{\mu}\right)=(\sqrt{1+\lambda^2\nabla^2}-1)\psi\left(x,t-\imath\frac{\lambda^2}{\mu}\right)$$

or

$$\psi\left(x,t+\imath\frac{\lambda^2}{\mu}\right)=(\sqrt{1+\lambda^2\nabla^2})\psi(x,t) \tag{11}$$

after a change of variable $t\to t+\imath\lambda^2/\mu$. Writing the left-hand side as the action of $e^{\imath(\lambda^2/\mu)(\partial/\partial t)}$ in terms of usual derivatives, and taking ln of the operators on both sides, we have formally (or not formally on plane waves),

$$\frac{\partial}{\partial t}\psi=-\imath\frac{\mu}{2\lambda^2}\ln(1+\lambda^2\nabla^2)=-\frac{\imath}{2m}\left(\nabla^2-\frac{\lambda^2}{2}\nabla^4+\frac{\lambda^4}{3}\nabla^6\cdots\right) \tag{12}$$

for small λ. Thus our equation explicitly deforms the usual Schrödingers equation with higher derivative terms.

Note that we can also expand the left-hand side of (11) in a Taylor series and the right-hand side in a binomial series so

$$\imath\frac{\partial}{\partial t}\psi-\frac{\lambda^2}{2\mu}\frac{\partial^2}{\partial t^2}\psi+\cdots=\frac{\mu}{2}\nabla^2\psi-\frac{\lambda^2\mu}{8}\nabla^4\psi+\cdots.$$

Now *if* we choose $\mu=\lambda$ and keep terms to $O(\lambda^2)$ then this reads in terms of m as

$$\frac{\partial}{\partial t}\psi=-\frac{\imath}{2m}\nabla^2\psi-\frac{\imath}{2m}\frac{\partial^2}{\partial t^2}\psi+O\left(\left(\frac{1}{m}\right)^3\right)$$

which is the 4D Euclidean wave equation for $\phi(x,t)=e^{-\imath mt}\psi(x,t)$ in terms of ψ. Here

$$\left(\frac{\partial^2}{\partial t^2}+\nabla^2+m^2\right)\phi=-2\imath me^{\imath mt}\dot{\psi}+e^{\imath mt}\ddot{\psi}+e^{\imath mt}\nabla^2\psi.$$

On the other hand, ∇ itself is a deformation and at least on plane waves brings its own corrections to the same order so that the above is a formal observation.

When $\mu=\lambda$ we also have a formal Euclidean aspect in the noncommutative wave operator. In fact we are not proposing an $SO_{1,3}$ or SO_4 symmetry in the noncommutative model (in our construction we have preserved spatial rotations only, and induced time from it). However, it is interesting to note that we have the following modified wave operator in the original (spatial) theory, from (4) and (5):

$$\Box^{(3)} = (\partial^0)^2 + \nabla^2 = \frac{2}{\lambda^2}(\cos(\lambda|p|) - 1) = \frac{1}{\lambda^2}(\mathrm{Tr} - 2) \tag{13}$$

which again has the usual limit $-|\vec{p}|^2$ as $\lambda \to 0$. The fact that this has such a nice description via the action of $\mathrm{Tr} \in \mathbb{C}[\mathrm{SU}_2]$ suggests that it is somewhat natural; if one takes instead $-(\partial^0)^2$ the result is similar but does not have such a simple expression. Here Tr−2 is the Casimir in $D(U(\mathrm{su}_2)) = \mathbb{C}[\mathrm{SU}_2] \rtimes U(\mathrm{su}_2)$ as explained in Ref. 5.

V. DISPERSION RELATIONS AND CUT-OFF

We can also immediately solve the NCSE on plane waves, using the results of Sec. III. We let $\psi(x,t) = e^{\imath\vec{p}\cdot x} f(t)$. Then from (11) and the value of ∂^0 on plane waves, we require

$$f\left(t + \imath\frac{\lambda^2}{\mu}\right) = \cos(\lambda|\vec{p}|) f(t)$$

which is solved by

$$\psi_{\vec{p}}(x,t) = e^{\imath\vec{p}\cdot x + \imath p^0 t}, \quad e^{-(\lambda^2/\mu)p^0} = \cos(\lambda|\vec{p}|), \quad |\vec{p}| < \frac{\pi}{2\lambda}. \tag{14}$$

Notice that the spatial momentum is bounded above for there to be a primary solution, which is a typical feature of quantum gravity as discussed in Sec. I. We also have unphysical solutions $5\pi/2 > |\vec{p}| > 3\pi/2\lambda$ etc. according to the periodicity of cos, which we consider an artefact of the local coordinate system. Recall that the p^i are local coordinates in momentum space which is actually here a sphere S^3 not flat, and this is also the reason for the cutoff in the first place.

Differentiating the p^0 equation immediately gives

$$e^{-(\lambda^2/\mu)p^0}\frac{\partial p^0}{\partial p^i} = \frac{\mu}{\lambda}\sin(\lambda|\vec{p}|)\frac{p^i}{|\vec{p}|}$$

and hence our proposed dispersion relation

$$\left|\frac{\partial p^0}{\partial \vec{p}}\right| = \frac{\mu}{\lambda}|\tan(\lambda|\vec{p}|)| = \frac{1}{m\lambda}|\tan(\lambda|\vec{p}|)|,$$

i.e., the group velocity is linear for small momentum as expected for a particle of mass m in our nonrelativistic coordinates, but blows up at the cutoff value. Note, however, that a detailed analysis of how plane waves in the noncommutative model might be measured experimentally and their group velocity is still needed in order to see if such a naive derivation is justified. In the bicrossproduct model calculation[2] this was somewhat justified by a natural normal-ordering postulate for the identification of noncommutative expressions with their classical counterparts. In the present model we can in principle do better; we can look at the plane waves in actual representations of the noncommutative algebra on the basis that it is such expectation values that are presumably observed. We propose to use here the coherent states $|j,\phi,\psi\rangle$ in which the coordinates behave with minimal uncertainty[5] and with expectation values

$$\langle x\rangle \equiv \langle j,\phi,\psi|\vec{x}|j,\phi,\psi\rangle = 2j\lambda(\sin\phi\cos\psi, \sin\phi\sin\psi, \cos\phi)$$

for a particle at angle ϕ,ψ and radius $2j\lambda$ (which we see is quantized). Explicitly,

$$|j,\phi,\psi\rangle = \sum_{k=0}^{2j} 2^{-j}\sqrt{\binom{2j}{k}}(1+\cos\phi)^{(2j-k)/2}(1-\cos\phi)^{k/2}e^{\imath k\psi}|j,j-k\rangle$$

in terms of usual spin j states and in the present conventions. In such a state our plane waves have a classical "shadow" as waves in polar coordinates. For example,

$$\left\langle \frac{1}{2},\phi,\psi \middle| e^{\imath\vec{p}\cdot x} \middle| \frac{1}{2},\phi,\psi \right\rangle = \cos\lambda|\vec{p}| + \imath\frac{\vec{p}\cdot\langle x\rangle}{\lambda|\vec{p}|}\sin\lambda|\vec{p}|$$

which should be compared with the classical value at this radius of

$$e^{\imath\lambda(p_1\sin\phi\cos\psi+p_2\sin\phi\sin\psi+p_3\cos\phi)} = e^{\imath\vec{p}\cdot\langle x\rangle}.$$

The approximation gets better for large spin. This suggests that the noncommutative plane waves would appear as something with comparable periodicity in the expectation values, and hence comparable group velocity to the extent that the expectation values appear wavelike. Note also that

$$|\langle j,\phi,\psi|j,\phi',\psi'\rangle|^2 = \left(\frac{1}{2}(1+\cos(\text{angle}(\phi,\psi|\phi',\psi')))\right)^{2j},$$

where the angle is the classical angle between vectors in directions (ϕ,ψ) and (ϕ',ψ') in polar coordinates. The point of view here is in the spirit of Ref. 21 but rather than a spin network we use noncommutative geometry. See also Ref. 9 concerning coherent states.

VI. POLAR COORDINATES AND GAUGE THEORY

The model with time adjoined has in fact a rich noncommutative geometry. Here we note that there is a closed algebra among the t and the Casimir $c=\vec{x}\cdot\vec{x}$. These from a commutative subalgebra of rotationally invariant functions varying in time, but as we show now with noncommutative differentials. First of all, we note that

$$\mathrm{d}c = x_i\mathrm{d}x_i + (\mathrm{d}x_i)x_i = 2x_i\mathrm{d}x_i + 3\imath\mu\theta \tag{15}$$

and $[c,x_i]=0$ implies that

$$\begin{aligned}
[\mathrm{d}c_i,x_i] &= -[c,\mathrm{d}x_i] = -x_j[x_j,\mathrm{d}x_i] - [x_j,\mathrm{d}x_i]x_j \\
&= \imath\lambda\epsilon_{ijk}x_j\mathrm{d}x_k + \imath\mu x_i\theta + \imath\lambda\epsilon_{ijk}(\mathrm{d}x_k)x_j + \imath\mu\theta x_i \\
&= 2\imath\lambda\epsilon_{ijk}x_j\mathrm{d}x_k - (\imath\lambda)^2\epsilon_{ijk}\epsilon_{kmj}\mathrm{d}x_m + \imath\mu(x_i\theta+\theta x_i) \\
&= 2\imath\lambda\epsilon_{ijk}x_j\mathrm{d}x_k + 2\lambda^2\mathrm{d}x_i + \imath\mu\left(2x_i\theta - \imath\frac{\lambda^2}{\mu}\mathrm{d}x_i\right) \\
&= 2\imath\lambda\epsilon_{ijk}x_j\mathrm{d}x_k + 3\lambda^2\mathrm{d}x_i + 2\imath\mu x_i\theta
\end{aligned}$$

using the relations in the calculus. From this and (15) we find that

$$\begin{aligned}
[\mathrm{d}c,c] &= [\mathrm{d}c,x_i]x_i + x_i[\mathrm{d}c,x_i] \\
&= -4\lambda^2x_i\mathrm{d}x_i + 3\lambda^2(\mathrm{d}x_i)x_i + 2\imath\mu x_i\theta x_i + x_i3\lambda^2\mathrm{d}x_i + 2\imath\mu c\theta \\
&= 4\lambda^2x_i\mathrm{d}x_i + 9\lambda^2\imath\mu\theta + 4\imath\mu c\theta = 2\lambda^2\mathrm{d}c + 4\imath\mu\left(c+\frac{3}{4}\lambda^2\right)\mathrm{d}t.
\end{aligned} \tag{16}$$

Meanwhile, from $[t,c]=0$ and $\theta=\mathrm{d}t$ as generator of d, we have

$$[\mathrm{d}c,t] = [\mathrm{d}t,c] = \frac{\lambda^2}{\imath\mu}\mathrm{d}c, \quad [\mathrm{d}t,t] = \frac{\lambda^2}{\imath\mu}\mathrm{d}t \tag{17}$$

to give a closed algebra (16) and (17) among the t, c, dt, and dc. As in Sec. IV we immediately conclude that

$$\mathrm{d}t.f(t)=f\left(t-\imath\frac{\lambda^2}{\mu}\right)\mathrm{d}t,\quad \mathrm{d}c.f(t)=f\left(t-\imath\frac{\lambda^2}{\mu}\right)\mathrm{d}c$$

for any function $f(t)$, whereas the commutation relations with some function $a(c)$ has to be determined by induction. Likewise $\mathrm{d}f(t)=\partial^t f\mathrm{d}t$ given by a finite difference as in Sec. IV, whereas $\mathrm{d}a(c)$ has to be determined by induction.

To this end, let

$$\begin{aligned}\mathrm{d}c^n &\equiv f_n\mathrm{d}c+g_n\mathrm{d}t=\mathrm{d}c^{n-1}.c+c^{n-1}\mathrm{d}c\\ &=f_{n-1}\mathrm{d}c.c+g_{n-1}\mathrm{d}t.c+c^{n-1}\mathrm{d}c\\ &=\left((c+2\lambda^2)f_{n-1}+c^{n-1}-\imath\frac{\lambda^2}{\mu}g_{n-1}\right)\mathrm{d}c+\left(cg_{n-1}+4\imath\mu\left(c+\frac{3}{4}\lambda^2\right)f_{n-1}\right)\mathrm{d}t\end{aligned}$$

which gives a recursion relation for f_n, g_n with $f_1=1$ and $g_1=0$. This can be solved to obtain $\mathrm{d}c^n$, or on any $a(c)$ to compute partial differentials ∂^c and $\partial^t{}_{|_c}$ defined by

$$\mathrm{d}a(c)\equiv(\partial^c a)\mathrm{d}c+(\partial^t_{|c}a)\mathrm{d}t.$$

Here the $|_c$ is to remind us that this is with respect to c and implicit angular coordinates being held constant, which is not quite the same as ∂^0 in Sec. IV where the x_i were being held constant. We find

$$\partial^c a(c)=\frac{a(c+\lambda^2+2\lambda\sqrt{c+\lambda^2})-a(c+\lambda^2-2\lambda\sqrt{2c+\lambda^2})}{4\lambda\sqrt{c+\lambda^2}}$$

$$\partial^t_{|c}a(c)=\frac{\mu}{\imath\lambda^2}\left(a(c)+\lambda^2\partial^c a(c)-\frac{a(c+\lambda^2+2\lambda\sqrt{c+\lambda^2})+a(c+\lambda^2-2\lambda\sqrt{c+\lambda^2})}{2}\right).$$

These extend to products by a braided derivation rule and by the same computation as in Sec. IV we find

$$\partial^c(af)=(\partial^c a)f\left(t-\imath\frac{\lambda^2}{\mu}\right),\quad \partial^t_{|c}(af)=(\partial^t_{|c}a)f\left(t-\imath\frac{\lambda^2}{\mu}\right)+a\partial^t f$$

for $a(c)f(t)$. This gives the partial derivatives and d on a general function $\psi(c,t)$ in polar coordinates.

As an application, we can write our NCSE in polar form as follows. The equation says that d is purely in the $\mathrm{d}x_i$ direction. Writing $\mathrm{d}a(c)=(\partial^i a)\mathrm{d}x_i+(\partial^0 a)\mathrm{d}t$ as in Sec. IV, we have in view of (15) that

$$\partial^i a(c)=(\partial^c a)2x_i,\quad \partial^0 a(c)=\partial^t_{|c}a+3\imath\mu\partial^c a.$$

The latter comes out as

$$\begin{aligned}\partial^0 a(c)=\frac{\imath\mu}{\lambda^2}\Bigg(&\frac{1}{2}\left(1+\frac{\lambda}{\sqrt{c+\lambda^2}}\right)a(c+\lambda^2+2\lambda\sqrt{c+\lambda^2})\\ &+\frac{1}{2}\left(1-\frac{\lambda}{\sqrt{c+\lambda^2}}\right)a(c+\lambda^2-2\lambda\sqrt{c+\lambda^2})-a(c)\Bigg)\end{aligned}\tag{18}$$

using the above results. This compares with (6) or (5) computed in our previous plane wave basis. We will not attempt to solve the NCSE here, for one thing one needs to have suitable proposals for a potential term for, say, a hydrogen atom. Suffice it to say that any such calculation is best done

in polar coordinates and (18) provides the radial part of the effective Laplacian to be used in (10), now on wave functions $\psi(c,t)$. One may compute for example that

$$\partial^0\left(\frac{1}{\sqrt{c+\lambda^2}}\right)=0$$

where $\rho=\sqrt{c+\lambda^2}$, makes for a reasonably nice answer and suggests that this is the appropriate analog of r in usual polar coordinates. This is the right answer when $\lambda\to 0$ (the radial Laplacian vanishes on $1/r$). Similarly one may check that

$$\partial^0 c=3\iota\mu,\quad \partial^0 c^2=\iota\mu(10c+9\lambda^2),\quad \partial^0\sqrt{c+\lambda^2}=\iota\mu\frac{1}{\sqrt{c+\lambda^2}}$$

as expected for $\iota\mu$ times $1/2$ the radial Laplacian as in (7) if c is understood as r^2 in the classical limit or more precisely ρ as r.

Another application of polar coordinates is for computations in the associated $U(1)$ gauge theory. As mentioned in Sec. II at the basic level a gauge field is a connection $\alpha=\alpha^\mu \mathrm{d}x_\mu$ with suitable reality properties. The curvature in the Maxwell theory is just

$$F_M(\alpha)=\mathrm{d}\alpha=\partial^\mu\alpha^\nu \mathrm{d}x_\mu\wedge\mathrm{d}x_\nu$$

which may be computed as usual using the partial derivatives. The theory is sensitive to cohomology and a gauge transformation is the addition of an exact differential. In the noncommutative case we also have the option of a nonlinear $U(1)$ Yang–Mills-type theory with curvature

$$F_{YM}(\alpha)=\mathrm{d}\alpha+\alpha\wedge\alpha=\partial^\mu\alpha^\nu \mathrm{d}x_\mu\wedge\mathrm{d}x_\nu+\alpha^\mu\mathrm{d}x_\mu\wedge\alpha^\nu\mathrm{d}x_\nu$$

and which detects homotopy. This needs also the commutation relations between functions and differentials. We look briefly at the electrostatic Maxwell case.

First, we look at gauge fields of the form

$$\alpha=a(c)\mathrm{d}t,$$

where $a(c)$ does not depend on t. This has

$$F_M=\partial^c a\mathrm{d}c\wedge\mathrm{d}t+\partial^t_{|c}a(\mathrm{d}t)^2=\partial^c a 2x_i\mathrm{d}x_i\wedge\mathrm{d}t$$

in view of (15) and $(\mathrm{d}t)^2=0$ in the calculus. We recall that the $\mathrm{d}x_\mu$ anticommute as usual. Thus we have an electric field

$$E_i=\partial^c a(c)2x_i$$

more or less as usual. For example, $a(c)=1/\sqrt{c+\lambda^2}$ gives

$$E_i=-\frac{x_i}{c\sqrt{c+\lambda^2}}$$

which is an inverse square law in the classical limit. Its divergence gives the corresponding charge density.

More surprisingly, we have also a different way of producing an electric field, namely

$$\alpha=a(c)2x_i\mathrm{d}x_i=a(c)\mathrm{d}c-3\iota\mu a(c)\mathrm{d}t$$

in view of (15). We have chosen α here to have purely spatial components in the $\mathrm{d}x_\mu$ basis but we have the same conclusion below (with a different coefficient) even if we do not include the second term. The curvature is

$$F_M = \partial^{\mathcal{F}} a(\mathrm{d}c)^2 + \partial^t_{|c} a \mathrm{d}t \wedge \mathrm{d}c - 3\imath\mu\partial^{\mathcal{F}} a \mathrm{d}c \wedge \mathrm{d}t$$

which we compute using

$$\begin{aligned}\mathrm{d}c \wedge \mathrm{d}c &= 4x_i \mathrm{d}x_i \wedge x_j \mathrm{d}x_j + 6\imath\mu x_i \mathrm{d}x_i \wedge \mathrm{d}t + 6\imath\mu \mathrm{d}t \wedge x_i \mathrm{d}x_i \\ &= 4x_i \mathrm{d}x_i \wedge x_j \mathrm{d}x_j = 2[x_i, x_j]\mathrm{d}x_i \wedge \mathrm{d}x_j + 4x_i[\mathrm{d}x_i, x_j] \wedge \mathrm{d}x_j \\ &= 4\imath\lambda\epsilon_{ijk} x_k \mathrm{d}x_i \wedge \mathrm{d}x_j + 4\imath\lambda x_i \epsilon_{ijk} \mathrm{d}x_k \wedge \mathrm{d}x_j + 4\imath\mu x_i \mathrm{d}t \wedge \mathrm{d}x_i \\ &= 2\imath\mu \mathrm{d}t \wedge \mathrm{d}c = -2\imath\mu \mathrm{d}c \wedge \mathrm{d}t\end{aligned}$$

using (15) and $(\mathrm{d}t)^2=0$ in the first line and that $[\mathrm{d}t, x_i] \propto \mathrm{d}x_i$ in the second line which produces nothing as $(\mathrm{d}x_i)^2=0$ for each i (and that $\mathrm{d}t, \mathrm{d}x_i$ anticommute as usual). We then use the commutation relations in the calculus and in the algebra. The same observations imply that $\mathrm{d}c, \mathrm{d}t$ anticommute. Hence

$$F_M = -(2\imath\mu\partial^{\mathcal{F}} a + \partial^0 a)\mathrm{d}c \wedge \mathrm{d}t = -(5\imath\mu\partial^{\mathcal{F}} a + \partial^t_{|c} a) 2x_i \mathrm{d}x_i \wedge \mathrm{d}t$$

which is again a radial electric field. Such a potential in the classical case would be absent as α would be pure gauge with zero curvature. There are clearly many other possibilities to be explored here including time dependent (such as standing wave) solutions. Also in this preliminary analysis we do not discuss source terms for the potentials since this would require a study of the suitable currents produced by matter fields. Finally, all of these remarks are more complicated for the Yang–Mills version.

APPENDIX: COMPARISON WITH BICROSSPRODUCT MODELS

The model above with noncommuting position and commuting t is complementary to the bicrossproduct model where the spacetime $\mathbb{R}^{1,3}_\lambda$ in Ref. 20 is

$$[t, x_i] = \imath\lambda x_i, \quad [x_i, x_j] = 0. \tag{A1}$$

Here the position coordinates commute and t is noncommutative, but we shall note similar features nevertheless. Some authors write $\kappa = 1/\lambda$ as a mass scale instead.

This time the relevant Lie algebra in (19) is the solvable one b_+ (say) and computations are rather easier using normal ordering as explained in Ref. 20. Hence we parametrize the plane waves as

$$\psi_{\vec{p}\cdot p^0} = e^{\imath\vec{p}\cdot x} e^{\imath p^0 t}, \quad \psi_{\vec{p},p^0}\psi_{\vec{p}',p^{0\prime}} = \psi_{\vec{p}+e^{-\lambda p^0}\vec{p}', p^0+p^{0\prime}}$$

which identifies the p^μ as the coordinates of a non-Abelian group B_+ with Lie algebra b_+. The group law in these coordinates is read off as usual from the above product of plane waves. The right-invariant Haar measure on B_+ in these coordinates is the usual $\mathrm{d}^4 p$ so the quantum group Fourier transform[17] reduces to the usual one but normal ordered,

$$\mathcal{F}(f) = \int_{\mathbb{R}^4} \mathrm{d}^4 p f(p) e^{\imath\vec{p}\cdot x} e^{\imath p^0 t}.$$

As before, the action of elements of $\mathbb{C}[B_+]$ define differential operators on $\mathbb{R}^{1,3}_\lambda$ and these act diagonally on plane waves.

There is also known to be a natural differential calculus with

$$(\mathrm{d}x_j)x_\mu = x_\mu \mathrm{d}x_j, \quad (\mathrm{d}t)x_\mu - x_\mu \mathrm{d}t = \imath\lambda \mathrm{d}x_\mu$$

which we see already has a generator with $\theta = \mathrm{d}t$; so we do not need to adjoin a further t in this model. The unitarity or $*$-structure is $x_i^* = x_i$, $t^* = t$ and the same for their differentials. The calculus recovers the partial derivatives[20]

$$\partial^i\psi =: \frac{\partial}{\partial x_i}\psi(x,t) := \imath p^i \,.\, \psi,$$

$$\partial^0\psi =: \frac{\psi(x,t+\imath\lambda)-\psi(x,t)}{\imath\lambda} := \frac{\imath}{\lambda}(1-e^{-\lambda p^0})\psi$$

for normal ordered polynomial functions ψ or as shown in terms of the action of the momenta p^μ. It was shown in Ref. 2 that by using adjusted derivatives $L^{-1/2}\partial^\mu$ where

$$L\psi =: \psi(x,t+\imath\lambda) := e^{-\lambda p^0}\psi$$

the 4D Laplacian $\Box = L^{-1}((\partial^0)^2 - \Sigma_i(\partial^i)^2)$ acts on plane waves as

$$\Box = -\frac{2}{\lambda^2}(\cosh(\lambda p^0)-1) + \vec{p}^2 e^{\lambda p^0} = e^{\lambda p^0}\left(\vec{p}^2 - \frac{1}{\lambda^2}(1-e^{-\lambda p^0})^2\right) \tag{A2}$$

which is the action of the Casimir of the bicrossproduct quantum group. The first expression should be compared with (13) in our previous model, as a hyperbolic version of it.

We recall that this bicrossproduct Poincaré quantum group $U(\mathrm{so}_{1,3})\triangleright\!\blacktriangleleft \mathbb{C}[B_+]$ in terms of translation generators p^μ, rotations M_i and boosts N_i, is[20]

$$[p^\mu,p^\nu]=0, \quad [M_i,M_j]=\imath\epsilon_{ij}{}^k M_k,$$

$$[N_i,N_j]=-\imath\epsilon_{ij}{}^k M_k, \quad [M_i,N_j]=\imath\epsilon_{ij}{}^k N_k,$$

$$[p^0,M_i]=0, \quad [p^i,M_j]=\imath\epsilon^i{}_{jk}p^k, \quad [p^0,N_i]=-\imath p_i,$$

as usual, and the modified relations and coproduct

$$[p^i,N_j]=-\frac{\imath}{2}\delta^i_j\left(\frac{1-e^{-2\lambda p^0}}{\lambda}+\lambda\vec{p}^2\right)+\imath\lambda p^i p_j,$$

$$\Delta N_i = N_i\otimes 1 + e^{-\lambda p^0}\otimes N_i + \lambda\epsilon_{ijk}p^j\otimes M_k,$$

$$\Delta p^i = p^i\otimes 1 + e^{-\lambda p^0}\otimes p^i$$

and the usual linear ones on p^0, M_i. We raise and lower i,j,k indices using the Euclidean metric. It follows from the general theory of bicrossproducts that this Hopf algebra acts on $U(b_+)=\mathbb{R}^{1,3}_\lambda$.

Part of the motivation for this model[20] consisting of noncommutative spacetime and associated bicrossproduct quantum group acting covariantly on it was a previous "κ-Poincaré" version of the Hopf algebra alone obtained[11] in another context (by contraction of $U_q(\mathrm{so}_{2,3})$). The bicrossproduct model should not be confused with this, however, because its generators and relations are fundamentally different and have very different physical content; for example the Lorentz generators in Ref. 11 do not close among themselves but mix with momentum. Moreover, prior to Ref. 20 there was either no action of κ-Poincaré on any spacetime or it was taken to act on classical Minkowski space with inconsistent results (there is no such covariant action).

Also key and fundamentally different in the bicrossproduct model from κ-Poincaré is that in the bicrossproduct case the Lorentz group is actually undeformed; rather the deformation is in a nonlinear but entirely geometrical action of it on the "curved" momentum group B_+. This is as part of the solution of a nonlinear set of "matched pair" equations[13] (the other part of the matched pair is a "backreaction" of B_+ on the manifold of the Lorentz group). Because of this fundamental difference it would be a mistake to view the bicrossproduct quantum group as merely a "change of basis" from κ-Poincaré. In particular, because of the classical geometry behind it one can see what

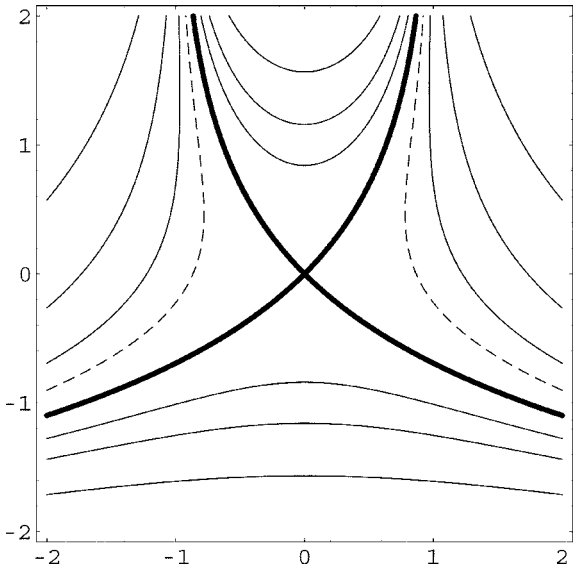

FIG. 1. Deformed mass-shell orbits in the bicrossproduct curved momentum space for $\lambda=1$.

is going on in terms of the curved momentum space, as shown in Fig. 1, which is a contour plot of p^0 against $|\vec{p}|$. The nonlinear action of the Lorentz group means that Lorentz group orbits in B_+ are now deformed hyperboloids. Because neither group here is compact one expects again from the general theory of bicrossproducts to have limiting accumulation regions and we see that indeed the $p^0>0$ mass shells are now cups with almost vertical walls, compressed into the vertical tube $|\vec{p}|<\lambda^{-1}$. In other words, the 3-momentum is bounded above by the Planck momentum scale (if λ is the Planck time), but this does not appear as a new "second bound" in addition to Einstein's postulate on the speed of light as sometimes claimed in the literature, but rather a deformation of it.

Such accumulation regions were already visible in the simplest "Planck-scale Hopf algebra"[13] from the 1980s under a different point of view. Under this point of view p^i above are position and not momentum coordinates and the quantum group is the algebra of obervables for a quantum particle moving on oribits under (in the present case Lorentz) group action. The flows for this action are geodesics on the orbits, which fit together to a natural 4D space that could be called a "pseudo-black hole." Here the physical region of Fig. 1 is the orbits that come in from spatial infinity and remain outside the tapered cylinder of radius $1/\lambda$. One such orbit comes in at large positions, bends upwards and asymptotically approaches the cylinder from the outside for large t (which points upwards), much as for an event horizon. Another orbit (dashed) crosses the asymptote and approaches it from the inside. The detailed geometry of this setup will be presented elsewhere. Such coordinate singularities are a generic feature of the nonlinear "matched pair" equations behind the model and is the reason that they were proposed in Ref. 13 as a toy version of Einstein's equations.

Finally, we point out what does not appear to be well known that the above-mentioned bicrossproduct is part of a family of which the 3D Euclidean bicrossproduct $\mathbb{C}[B_+]\blacktriangleright\!\!\triangleleft U(\mathrm{su}_2)$ was already obtained in the 1980s in Refs. 12, 14, and 15 actually as a Hopf–von-Neuman algebra and which has the following algebraic structure. First, B_+ is now a 3D version of the same solvable group, with Lie algebra

$$[x_3,x_i]=\imath\lambda x_i,\quad [x_i,x_j]=0 \tag{A3}$$

for $i=1,2$. This Lie algebra (with generators denoted $\{l_i\}$) and the required nonlinear solution of the matched pair equations are in Ref. 14. The original interpretation of $\mathbb{C}[B_+]\blacktriangleright\!\!\triangleleft U(\mathrm{su}_2)$ was different (namely particles moving in orbits in B_+ as position space) but there is of course nothing

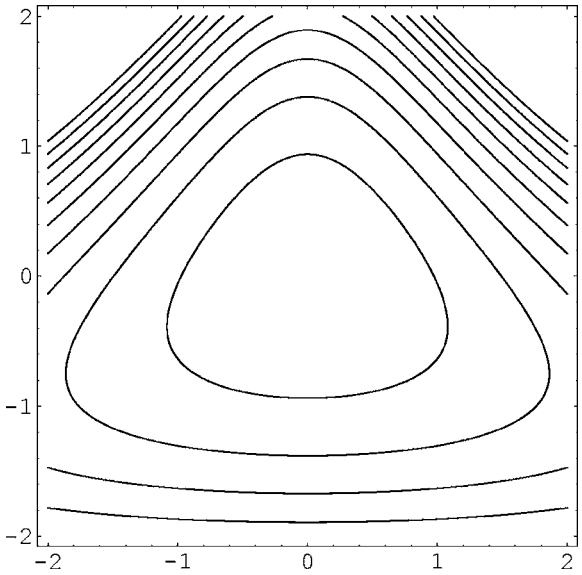

FIG. 2. Deformed spherical orbits in the 3D bicrossproduct model for $\lambda=1$.

stopping one considering it as a deformation of the group of motions on $\mathbb{R}^3$. The only difference is to denote the generators of $\mathbb{C}[B_+]$ by the symbols p^i, which we also combine with a cosmetic change to a logarithmic coordinate and explication of the deformation parameter, i.e.,

$$e^{-\lambda p_3}=\frac{1}{X_3+1},\quad \lambda p_i=\frac{X_i}{X_3+1}$$

in terms of the B_+ coordinates $\{X_i\}$ written in lower case in Refs. 16 and 17. We reserve x_i instead for the auxiliary noncommutative space (A3) on which the quantum group necessarily acts. Then the bicrossproduct has the form

$$[p_i,p_j]=0,\quad [M_i,M_j]=\imath\epsilon_{ij}{}^kM_k,$$

$$[M_3,p_j]=\imath\epsilon_{3j}{}^kp_k,\quad [M_i,p_3]=\imath\epsilon_{i3}{}^kp_k$$

as usual, for $i,j=1,2,3$, and the modified relations

$$[M_i,p_j]=\frac{\imath}{2}\epsilon_{ij}{}^3\left(\frac{1-e^{-2\lambda p_3}}{\lambda}-\lambda\vec{p}^2\right)+\imath\lambda\epsilon_{ij}{}^3p_jp_k$$

for $i,j=1,2$ and $\vec{p}^2=p_1^2+p_2^2$. The coproducts are

$$\Delta M_i=M_i\otimes e^{-\lambda p_3}+\lambda M_3\otimes p_i+1\otimes M_i,$$

$$\Delta p_i=p_i\otimes e^{-\lambda p_3}+1\otimes p_i$$

for $i=1,2$ and the usual linear ones for p_3, M_3.

The deformed spherical orbits under the nonlinear rotation in B_+ are constant values of the Casimir for the above algebra. This is found in Ref. 14 as

$$\frac{2}{\lambda^2}(\cosh(\lambda p_3) - 1) + \vec{p}^2 e^{\lambda p_3}$$

in our present coordinates, which is the Euclidean precursor to (A2). These deformed orbits are shown in Fig. 2. The model here is a Euclidean inhomogeneous one. The noncommutative differential geometry on (A3) is broadly similar to the 4D case.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 112101 (2005)

Analytic and contour representations in the unit disk based on SU(1,1) coherent states

C. Lei and A. Vourdas
Department of Computing, University of Bradford, Bradford BD7 1DP, United Kingdom

A. Wünsche
Institut für Physik, Humboldt-Universität, Newtonstrasse 15, 12489 Berlin, Germany

(Received 3 August 2005; accepted 2 September 2005; published online 7 November 2005)

A contour representation in the unit disk based on SU(1,1) coherent states is introduced. The scalar product is given by a contour integral. The regions of convergence of the functions representing ket and bra states are studied. An analytic representation in the unit disk is also considered, where the scalar product is represented by an integral over the unit disk, with the Lobachevsky measure. Various relations which connect these analytic functions with other phase-space quantities are derived. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2098527]

I. INTRODUCTION

Analytic representations are a powerful mathematical tool in quantum mechanics. The most familiar example is the Bargmann analytic representation in the Euclidean plane.[1] This is intimately connected to the Glauber coherent states.

Another analytic representation is the "elliptic analytic representation" in the extended complex plane (which is topologically equivalent to a sphere).[2] This is intimately connected to SU(2) coherent states.

Another analytic representation is the "hyperbolic analytic representation" in the unit disk (or half-plane).[3–11] This is intimately connected to SU(1,1) coherent states.

To each of these analytic representations corresponds a "contour representation." They represent the ket states with the same function as the corresponding analytic representation; but they represent the bra states with a different function so that the scalar product is given by a contour integral. Dirac[12] and later other authors[13,14] studied extensively the "Euclidean contour representation." The "elliptic contour representation" in the extended complex plane has been presented in Ref. 15. A preliminary work for the "hyperbolic contour representation" in the unit disk has been presented in Ref. 16 An important problem in this representation is the regions of convergence of the series that represent the ket and bra states.

The purpose of the present paper is to study analytic and contour representations in the unit disk, with emphasis on the relationship among them and also on their relationship with other phase-space quantities like the P, Q, and Wigner functions. In Sec. II we present briefly SU(1,1) coherent states and we define the notation. In Sec. III we study the analytic representation in the unit disk. The requirement for convergent scalar products leads to constraints on the growth of these functions near the unit circle. In Sec. IV we discuss the contour representation in the unit disk. We study carefully the regions of convergence of the functions representing ket and bra states. In order to express the scalar products as contour integrals, the region of convergence of the ket states should overlap with the region of convergence of the bra states. Although this is not always true, we find large subspaces within the full Hilbert space where this is the case. In Sec. V we derive relations which connect the analytic functions with other phase-space quantities. In Sec. VI we discuss briefly some physical applications. We give a Hamiltonian which is a combination of SU(1,1) generators and which is used to describe optical amplifiers. The time evolution of systems with this Hamiltonian can be studied using the contour representation in the unit disk. We conclude in Sec. VII with a discussion of our results. In the Appendix we present briefly the

elliptic contour representation in the extended complex plane in connection with the SU(2) group, so that the reader can compare and contrast the hyperbolic with the elliptic contour representation.

II. SU(1,1) COHERENT STATES

The representations of SU(1,1) have been studied in detail in Ref. 17 (see also Ref. 10). They are classified into the continuous series, the discrete series, and the supplementary. In this paper we are interested in the discrete series.

We consider the SU(1,1) generators K_0, K_+, K_- which obey the commutation relations

$$[K_0, K_\pm] = \pm K_\pm, \quad [K_-, K_+] = 2K_0,$$

$$K^2 = K_0^2 - \frac{1}{2}(K_+K_- + K_-K_+). \tag{1}$$

The operator K^2 is a Casimir operator. We also consider the standard basis $|k,n\rangle$

$$K^2|k,n\rangle = k(k-1)|k,n\rangle,$$

$$K_0|k,n\rangle = (k+n)|k,n\rangle,$$

$$K_-|k,n\rangle = [n(n+2k-1)]^{1/2}|k,n-1\rangle,$$

$$K_+|k,n\rangle = [(n+1)(n+2k)]^{1/2}|k,n+1\rangle, \quad k = 1/2, 1, 3/2, \ldots, \quad n = 0, 1, 2, \ldots, \tag{2}$$

where k characterizes the representation.

Coherent states in the unit disk $D(|z|<1)$ [which is related to $\mathrm{SU}(1,1)/U(1)$] are defined as follows:

$$|k,z\rangle = (1-|z|^2)^k \sum_{n=0}^{\infty} d(k,n) z^n |k,n\rangle, \tag{3}$$

$$d(k,n) = \left[\frac{\Gamma(n+2k)}{\Gamma(n+1)\Gamma(2k)}\right]^{1/2}. \tag{4}$$

An alternative equivalent definition is

$$S(k;\gamma,\theta,\lambda)|k,0\rangle = \exp(i\lambda k)|k,z\rangle, \tag{5}$$

where

$$S(k;\gamma,\theta,\lambda) \equiv S(k;z,\lambda) \equiv \exp\left[-\frac{1}{2}\gamma e^{-i\theta}K_+ + \frac{1}{2}\gamma e^{i\theta}K_-\right]\exp(i\lambda K_0), \tag{6}$$

$$z = -\tanh\frac{\gamma}{2}e^{-i(\lambda-\theta)}. \tag{7}$$

The overlap between two coherent states is given by

$$\langle k,z|k,w\rangle = \frac{(1-|z|^2)^k(1-|w|^2)^k}{(1-z^*w)^{2k}}. \tag{8}$$

The resolution of the identity of these states is given by

$$\frac{2k-1}{\pi}\int_D |k,z\rangle\langle k,z| d\mu(z) = \mathbf{1}; \quad d\mu(z) = (1-|z|^2)^{-2} d^2 z. \tag{9}$$

An interesting relation that involves the integration of $S(k;z,0)$ over the unit disk is

$$\frac{2k}{\pi}\int_D d\mu(z)(1-|z|^2)^{k+1} S(k;z,0) = |k,0\rangle\langle k,0|. \tag{10}$$

III. ANALYTIC REPRESENTATION IN THE UNIT DISK

A. Quantum states

We consider an arbitrary normalized state

$$|f\rangle = \sum_{n=0}^{\infty} f_n |k,n\rangle; \quad \langle f| = \sum_{n=0}^{\infty} f_n^* \langle k,n|; \quad \sum_{n=0}^{\infty} |f_n|^2 = 1. \tag{11}$$

This state is represented by the analytic function $f(z;k)$ defined as

$$f(z;k) = \sum_{n=0}^{\infty} f_n d(k,n) z^n = (1-|z|^2)^{-k} \langle k, z^*|f\rangle. \tag{12}$$

The scalar product of two such states is given by

$$\langle f|g\rangle = \sum_{N=0}^{\infty} f_N^* g_N = \frac{2k-1}{\pi}\int_D f^*(z;k) g(z;k)(1-|z|^2)^{2k} d\mu(z). \tag{13}$$

Convergence of this integral puts restrictions on the growth of the analytic functions near the unit circle. For an analytic function f in $\mathcal{D}$, we define its hyperbolic exponential type,[18]

$$t(f) = \lim_{|z|\to 1^-} \sup \frac{\log|f(z)|}{\log \dfrac{1}{1-|z|}}. \tag{14}$$

In our case $t(f) \leqslant k-1$.

Using Eq. (10), we prove that

$$\frac{2k}{\pi}\int_D d\mu(z)(1-|z|^2)^{2k+1} f(z;k) = f_0. \tag{15}$$

As examples, we easily show that

$$|k,n\rangle \to d(k,n) z^n, \tag{16}$$

$$|k,w\rangle \to \frac{(1-|w|^2)^k}{(1-zw)^{2k}}. \tag{17}$$

B. SU(1,1) transformations as Möbius mappings

SU(1,1) transformations in the unit disk are implemented through Mobius conformal mappings

$$w = \frac{az+b}{b^* z + a^*}; \quad |a|^2 - |b|^2 = 1. \tag{18}$$

The operators K_+, K_-, K_0 can be represented with the differential operators

$$K_+ = z^2\partial_z + 2kz, \quad K_0 = z\partial_z + k, \quad K_- = \partial_z. \tag{19}$$

Then, the transformations

$$|f\rangle \to S(k;\gamma,\theta,\lambda)|f\rangle, \tag{20}$$

are implemented as

$$f(z;k) \to f\left(\frac{az+b}{b^* z + a^*};k\right)(b^* z + a^*)^{-2k}, \tag{21}$$

where

$$a = e^{i\lambda}\cosh\frac{\gamma}{2}, \quad b = e^{i\theta}\sinh\frac{\gamma}{2}. \tag{22}$$

C. Parity transformations

We first consider reflections around some point w in the unit disk. A point ζ is transformed to the point

$$\xi = \frac{-(1+|w|^2)\zeta + 2w}{-2w^*\zeta + (1+|w|^2)}, \tag{23}$$

which is also in the unit disk.

The parity operator around the origin U_0 is defined as

$$U_0 = \sum_n (-1)^n |k,n\rangle\langle k,n|. \tag{24}$$

The displaced parity operator around a point w, is defined as

$$U(w) = S(k;\gamma,\theta,\lambda)U_0 S^\dagger(k;\gamma,\theta,\lambda); \quad w = -\tanh\frac{\gamma}{2}e^{-i(\lambda-\theta)}. \tag{25}$$

Acting on coherent states with it, we get[19]

$$U(w)|k,\zeta\rangle = |k,\xi\rangle. \tag{26}$$

For later use, we prove that

$$U(w;z_1,z_2) \equiv \langle k,z_1|U(w)|k,z_2\rangle = \frac{(1-|z_1|^2)^k(1-|z_2|^2)^k(1-|w|^2)^{2k}}{[(w-z_2)(w^*-z_1^*)+(1-w^* z_2)(1-wz_1^*)]^{2k}}. \tag{27}$$

Using the displaced parity operator, we can define the Wigner function of an arbitrary operator Θ as

$$W(\Theta;z) = \mathrm{Tr}(\Theta U(z)). \tag{28}$$

D. Operators

An arbitrary operator Θ

$$\Theta = \sum_{m,n=0}^{\infty} \Theta_{mn} |k,m\rangle\langle k,n|, \tag{29}$$

can be represented as follows:

$$A(z_1,z_2^*;\Theta) \equiv [(1-|z_1|^2)(1-|z_2|^2)]^{-k}\langle k,z_1^*|\Theta|k,z_2^*\rangle = \sum_{m,n=0}^{\infty} d(k,m)d(k,n)\Theta_{mn} z_1^m z_2^{*n}, \tag{30}$$

where A indicates "analytic" representation. The state $\Theta|f\rangle$ is then represented by the function

$$\frac{2k-1}{\pi}\int_D A(z,w^*;\Theta) f(w)(1-|w|^2)^{2k} d\mu(w). \tag{31}$$

Convergence of this integral implies that $t(A) \leqslant k-1$ [where $t(A)$ has been defined in Eq. (14)].

The product $\Theta = \Theta_1\Theta_2$ of two operators is given by

$$A(z_1,z_2^*;\Theta) = \frac{2k-1}{\pi}\int_D d\mu(z_3)(1-|z_3|^2)^{2k} A(z_1,z_3^*;\Theta_1)A(z_3,z_2^*;\Theta_2). \tag{32}$$

As an axample we consider the unit operator $\mathbf{1}$, $\Theta_{mn} = \delta_{mn}$ and

$$A(z_1,z_2;\mathbf{1}) = (1-z_1 z_2^*)^{-2k}. \tag{33}$$

We also consider the operators K_0, K_+, K_- which are represented by the kernels

$$A(z_1,z_2^*;K_0) = \frac{2k[-(z_1z_2^*)^2 + z_1z_2^* + 1]}{(1-z_1z_2^*)^{2k}},$$

$$A(z_1,z_2^*;K_+) = 2kz_1(1-z_1z_2^*)^{-(2k-1)},$$

$$A(z_1,z_2^*;K_-) = 2kz_2^*(1-z_1z_2^*)^{-(2k-1)}. \tag{34}$$

These integral representations are consistent with the differential representations of Eq. (19). Indeed, we can prove

$$\frac{2k-1}{\pi}\int_D d\mu(w)(1-|w|^2)^{2k} A(z,w^*;K_0) f(w) = (z\partial_z + k) f(z),$$

$$\frac{2k-1}{\pi}\int_D d\mu(w)(1-|w|^2)^{2k} A(z,w^*;K_+) f(w) = (z^2\partial_z + 2kz) f(z),$$

$$\frac{2k-1}{\pi}\int_D d\mu(w)(1-|w|^2)^{2k} A(z,w^*;K_-) f(w) = \partial_z f(z). \tag{35}$$

We first prove these relations for $f(w) = d(k,N)w^N$; then, summation proves the general result.

The trace of operator Θ can be expressed as

$$\mathrm{Tr}\Theta = \frac{2k-1}{\pi}\int_D d\mu(z)(1-|z|^2)^{2k} A(z,z^*;\Theta), \tag{36}$$

and the trace of product of two operators can be similarly expressed as

$$\mathrm{Tr}(\Theta_1\Theta_2)=\frac{(2k-1)^2}{\pi^2}\int_D d\mu(z)\int_D d\mu(z')(1-|z|^2)^{2k}(1-|z'|^2)^{2k}A(z,z'^*;\Theta_1)A(z',z^*;\Theta_2). \tag{37}$$

IV. HYPERBOLIC CONTOUR REPRESENTATION IN THE UNIT DISK

Dirac[12] introduced a contour representation in the Euclidean plane in which ket states are represented with analytic functions and bra states are represented with functions which are analytic in some region $|z|>R$ (where R depends on the state). In this representation the scalar product is a contour integral. Several authors[13,14] have discussed this method further in the Euclidean plane. The contour representation in the extended complex plane $C\cup\infty$ [which is topologically equivalent to a sphere, and is related to the SU(2)/U(1)], has been discussed in Ref. 15.

In this paper we study this method in the unit disk. We stress that in the unit disk there are convergence difficulties, and we need to define very carefully the regions of convergence of the various functions. This is the central problem in this paper. In contrast, in the SU(2) case we have polynomials and there are no convergence difficulties. In the Appendix we present briefly the contour representation for the SU(2) case so that the reader can compare and contrast it with the SU(1,1) case.

A. Quantum states

We consider the (arbitrary) normalized state of Eq. (11). In the contour representation it is represented as

$$|f\rangle\rightarrow f_k(z;k)=\sum_n f_n d(k,n)z^n, \tag{38}$$

$$\langle f|\rightarrow f_b(z;k)=\sum_n f_n^* d(k,n)^{-1}z^{-n-1}, \tag{39}$$

where the indices k and b refer to ket and bra, respectively. The function $f_k(z;k)$ is identical to that in Eq. (12). In order to study the convergence of the series associated with $f_k(z;k)$, we use the convergence criterion of the limit of the ratio of two successive terms. This ratio is

$$r_N=\frac{|f_{N+1}|}{|f_N|}\left[\frac{N+2k}{N+1}\right]^{1/2}|z|. \tag{40}$$

Since $\Sigma|f_N|^2=1$, the limit of the ratio $|f_{N+1}|/|f_N|$ does not exceed 1. Therefore, the $f_k(z;k)$ always converges in the unit disk. We next consider the case

$$\lim_{N\rightarrow\infty}\frac{|f_{N+1}|}{|f_N|}=1-\epsilon;\quad 0<\epsilon\leqslant 1. \tag{41}$$

Then, the $f_k(z;k)$ of the corresponding states also converges in the annulus $1<|z|<(1-\epsilon)^{-1}$ outside the unit disk. We call $\mathcal{H}_\epsilon$ the space

$$\mathcal{H}_\epsilon=\left\{|f\rangle:\lim_{N\rightarrow\infty}\frac{|f_{N+1}|}{|f_N|}\leqslant 1-\epsilon\right\}. \tag{42}$$

It is easily seen that when $\epsilon'>\epsilon$, then $\mathcal{H}_{\epsilon'}$ is a subspace of $\mathcal{H}_\epsilon$.

We next study the covergence of the series associated with $f_b(z;k)$. In this case the ratio of two successive terms is

$$r_N = \frac{|f_{N+1}|}{|f_N|}\left[\frac{N+1}{N+2k}\right]^{1/2}\frac{1}{|z|}. \tag{43}$$

Therefore, the $f_b(z;k)$ always converges in the exterior of the unit disk. For the states which satisfy Eq. (42) we easily see that the $f_b(z;k)$ also converges in the annulus $1>|z|>1-\epsilon$ within the unit disk. Therefore, for the states in the space $\mathcal{H}_\epsilon$ both the $f_k(z;k)$ and the $f_b(z;k)$ converge, at least within the annulus

$$\mathcal{R}_\epsilon = \left\{1-\epsilon<|z|<\frac{1}{1-\epsilon}\right\}. \tag{44}$$

Of course, there are many states for which the limit of the ratio $|f_{N+1}|/|f_N|$ is 1 and for which the $f_k(z;k)$ diverges outside the unit disk; also, the $f_b(z;k)$ diverges within the unit disk. Therefore, for any positive ϵ the space $\mathcal{H}_\epsilon$ is *not* dense in the full Hilbert space.

We consider the following example:

$$|k,n\rangle \to f_k(z;k) = d(k,n)z^n, \tag{45}$$

$$\langle k,n| \to f_b(z;k) = d(k,n)^{-1}z^{-n-1}. \tag{46}$$

In this example the $f_k(z;k)$ converges in the whole plane (it has singularity at infinity), and the $f_b(z;k)$ converges in the whole plane with a singularity at zero. The same result is true for any state which is a superposition of a *finite* number of $|k;k+N\rangle$ states.

We also consider the coherent states example

$$|k,\zeta\rangle \to f_k(z;k) = \frac{(1-|\zeta|^2)^k}{(1-z\zeta)^{2k}},$$

$$\langle k,\zeta| \to f_b(z;k) = (1-|\zeta|^2)^k\sum_{n=0}^{\infty}\frac{\zeta^n}{z^{n+1}} = \frac{(1-|\zeta|^2)^k}{z-\zeta}. \tag{47}$$

In this example the $f_k(z;k)$ converges in the disk $|z|<|\zeta|^{-1}$, which is larger than the unit disk (since $|\zeta|<1$). The $f_b(z;k)$ converges for $|z|>|\zeta|$.

We next show that for the states in the space $\mathcal{H}_\epsilon$

$$\oint_{c\in\mathcal{R}_\epsilon}\frac{dw}{2\pi i}f_b(w;k)(1-z^*w)^{-2k} = [f_k(z;k)]^*, \tag{48}$$

where c is an anticlockwise contour within the annulus $\mathcal{R}_\epsilon$ which does not enclose the singularity $w=1/z^*$.

The inverse formula is given by

$$\frac{2k-1}{z}\int_0^\infty\frac{dt}{(1+t)^{n+2k}}\left[f_k\left(\frac{t}{z^*};k\right)\right]^* = f_b(z;k), \quad k>\frac{1}{2}. \tag{49}$$

These two relations show how we calculate $f_k(z;k)$ if we know $f_b(z;k)$, and vice versa. In order to prove these relations we first perform the integrations for the case $f(w)=d(k,N)w^N$; summation then proves the general result.

We next consider two states $|f\rangle, |g\rangle$ in the space $\mathcal{H}_\epsilon$. The inner product is given by

$$\langle f|g\rangle = \oint_{c\in\mathcal{R}_\epsilon}\frac{dz}{2\pi i}f_b(z;k)g_k(z;k) = \sum_N f_N^* g_N, \tag{50}$$

where c is an anticlockwise contour within the annulus $\mathcal{R}_\epsilon$.

B. Operators

An arbitary operator

$$\Theta = \sum_{mn} \Theta_{mn} |k,m\rangle\langle k,n|, \tag{51}$$

is represented as follows:

$$C(z_1,z_2;\Theta) = \sum_{mn} \frac{\Theta_{mn} d(k,m) z_1^m}{d(k,n) z_2^{n+1}}, \tag{52}$$

where C indicates the "contour" representation. This function is useful if the double series converges in some region $\mathcal{A}_1(\Theta)\times\mathcal{A}_2(\Theta)$, where z_1 takes values in $\mathcal{A}_1(\Theta)$ and z_2 takes values in $\mathcal{A}_2(\Theta)$.

For a state in $\mathcal{H}_\epsilon$, the ket state $\Theta|f\rangle$ is given by

$$\oint_c \frac{d\zeta}{2\pi i} C(z,\zeta;\Theta) f_k(\zeta), \tag{53}$$

where c is an anticlockwise contour enclosing the singularities in $\mathcal{A}_2(\Theta)\cap\mathcal{R}_\epsilon$. The bra state $\langle f|\Theta$ is given by

$$\oint_c \frac{d(w)}{2\pi i} f_b(w;k) C(w,z;\Theta), \tag{54}$$

where c is an anticlockwise contour enclosing the singularities in $\mathcal{R}_\epsilon\cap\mathcal{A}_1(\Theta)$.

We next show that the product $\Theta=\Theta_1\Theta_2$ of two operators is given by

$$C(z_1,z_2;\Theta) = \oint_c \frac{dw}{2\pi i} C(z_1,w;\Theta_1) C(w,z_2;\Theta_2), \tag{55}$$

where c is an anticlockwise contour enclosing the singularities in $\mathcal{A}_2(\Theta_1)\cap\mathcal{A}_1(\Theta_2)$.

For the unit operator $\mathbf{1}$, $\Theta_{mn}=\delta_{mn}$ and

$$C(z_1,z_2;\mathbf{1}) = \frac{1}{z_2 - z_1} \quad |z_1| < |z_2|. \tag{56}$$

In the case $|z_1|\geqslant|z_2|$ the sum of Eq. (52) diverges. In this example $\mathcal{A}_1(\mathbf{1})=\{|z_1|<R\}$ and $\mathcal{A}_2(\mathbf{1})=\{|z_2|>R\}$ for arbitrary R.

Similarly, we calculate the representations of the operators K_0, K_+, K_-

$$C(z_1,z_2;K_0) = \frac{kz_2 + (1-k)z_1}{(z_2 - z_1)^2} \quad |z_1| < |z_2|, \tag{57}$$

$$C(z_1,z_2;K_+) = \frac{(1-2k)z_1^2 + 2kz_2z_1}{(z_2 - z_1)^2} \quad |z_1| < |z_2|, \tag{58}$$

$$C(z_1,z_2;K_-) = \frac{1}{(z_2 - z_1)^2} \quad |z_1| < |z_2|. \tag{59}$$

In these examples also $\mathcal{A}_1=\{|z_1|<R\}$ and $\mathcal{A}_2=\{|z_2|>R\}$ for arbitrary R. We note that the operators K_0, K_+, K_- can also be represented with the differential operators of Eq. (19); consistency between the two representations is proved with the following relations:

$$\oint_c \frac{d\zeta}{2\pi i} C(z,\zeta;K_0) f(\zeta) = (z\partial_z + k) f(z),$$

$$\oint_c \frac{d\zeta}{2\pi i} C(z,\zeta;K_+) f(\zeta) = (z^2\partial_z + 2kz) f(z),$$

$$\oint_c \frac{d\zeta}{2\pi i} C(z,\zeta;K_-) f(\zeta) = \partial_z f(z). \tag{60}$$

V. RELATIONSHIP BETWEEN THE VARIOUS REPRESENTATIONS

The Q and P representations of an arbitrary operator Θ are defined as follows:

$$Q(\Theta;z) = \langle k,z|\Theta|k,z\rangle, \tag{61}$$

$$\Theta = \frac{2k-1}{\pi} \int d\mu(z) P(\Theta;z) |k,z\rangle\langle k,z|. \tag{62}$$

It is easily seen that the trace of an operator is given by

$$\mathrm{Tr}\Theta = \frac{2k-1}{\pi} \int_D d\mu(z) Q(\Theta;z), \tag{63}$$

and also that the trace of the product of two operators is given by

$$\mathrm{Tr}(\Theta_1\Theta_2) = \frac{2k-1}{\pi} \int_D d\mu(z) P(\Theta_1;z) Q(\Theta_2;z). \tag{64}$$

In this section we derive relationships between $A(z_1,z_2;\Theta)$, $C(z_1,z_2;\Theta)$ and the $Q(\Theta;z)$ and $P(\Theta;z)$.

We first combine Eqs. (61) and (62) and prove easily that for $k>1/2$

$$Q(\Theta;z) = \frac{2k-1}{\pi} \int_D d\mu(w) P(\Theta;w) \frac{[(1-|z|^2)(1-|w|^2)]^{2k}}{|1-z^*w|^{4k}}. \tag{65}$$

We also combine Eqs. (30), (62), and (8), and prove that for $k>1/2$

$$A(z_1,z_2^*;\Theta) = \frac{2k-1}{\pi} \int_D d\mu(z) P(\Theta;z) \frac{(1-|z|^2)^{2k}}{(1-z_1z)^{2k}(1-z^*z_2^*)^{2k}}. \tag{66}$$

Equations (30) and (61) show easily that

$$Q(\Theta;z) = (1-|z|^2)^{2k} A(z^*,z;\Theta). \tag{67}$$

We next study the relatioship between the two analytic representations. Equations (48) and (52) show that

$$\oint_c \frac{dw}{2\pi i} C(\zeta,w;\Theta)(1-z^*w)^{-2k} = A(\zeta,z^*;\Theta), \tag{68}$$

where c is an anticlockwise contour within the annulus $\mathcal{A}_2(\Theta)$ which does not enclose the singularity $w=1/z^*$. From this, we easily see that

$$Q(\Theta;z)=(1-|z|^2)^{2k}\oint_c \frac{dw}{2\pi i}C(z^*,w;\Theta)(1-z^*w)^{-2k}, \tag{69}$$

The inverse of Eq. (68) is found by using Eqs. (49) and (52) to prove

$$\frac{2k-1}{z}\int_0^\infty \frac{dt}{(1+t)^{n+2k}}A\left(\zeta,\frac{t}{z};\Theta\right)=C(\zeta,z;\Theta),\quad k>\frac{1}{2}. \tag{70}$$

The relationship between $W(\Theta;z)$ and $P(\Theta;w)$ is found by using Eqs. (28) and (64) to prove

$$W(\Theta;z)=\frac{2k-1}{\pi}\int_D d\mu(w)P(\Theta;w)U(z;w,w). \tag{71}$$

Using Eqs. (37) and (30), we get the Wigner function $W(\Theta;z)$ in terms of the $A(z_1,z_2^*;\Theta)$

$$W(\Theta;z)=\frac{(2k-1)^2}{\pi^2}\int_D d\mu(z_1)\int_D d\mu(z_2)A(z_1,z_2^*;\Theta)U(z;z_2^*,z_1^*). \tag{72}$$

From this we easily prove that

$$W(\Theta;z)=\frac{(2k-1)^2}{\pi^2}\oint_c \frac{dz_3}{2\pi i}\int_D d\mu(z_1)\int_D d\mu(z_2)(1-z_2^*z_3)^{-2k}\times C(z_1,z_3;\Theta)U(z;z_2^*,z_1^*), \tag{73}$$

where c is an anticlockwise contour within the annulus $\mathcal{A}_2(\Theta)$ which does not enclose the singularity $z_3=1/z_2^*$.

VI. APPLICATIONS

In many quantum optics problems related to amplifiers, we have two-mode Hamiltonians of the type

$$h=\omega_1 a_1^\dagger a_1+\omega_2 a_2^\dagger a_2+\lambda a_1 a_2+\lambda^* a_1^\dagger a_2^\dagger, \tag{74}$$

where $a_1^\dagger, a_1$, and $a_2^\dagger, a_2$ are creation and annihilation operators. These Hamiltonians can be studied with the formalism developed in this paper.

We first point out the connection of the various terms in the Hamiltonian of Eq. (74) to the SU(1,1) generators

$$K_+=a_1^\dagger a_2^\dagger;\quad K_-=a_1 a_2,$$

$$K_0=\frac{1}{2}(a_1^\dagger a_1+a_2^\dagger a_2+1),$$

$$K^2=\frac{1}{4}K_C^2-\frac{1}{4};\quad K_C=a_1^\dagger a_1-a_2^\dagger a_2,$$

$$[K_C,K_0]=[K_C,K_+]=[K_C,K_-]=0. \tag{75}$$

The Hamiltonian can now be written as

$$h = (\omega_1 + \omega_2)\left(K_0 - \frac{1}{2}\right) + \frac{1}{2}(\omega_1 - \omega_2)K_C + \lambda K_- + \lambda^* K_+. \tag{76}$$

SU(1,1) techniques have been used extensively in the study of the time evolution of systems with this Hamiltonian (e.g., Ref. 20). The contour representation studied in this paper can be used for the study of these systems.

VII. DISCUSSION

We have studied an analytic representation in the unit disk, and the corresponding contour representation. They are both related to the SU(1,1) group and the corresponding coherent states.

The contour representation uses the functions $f_k(z;k)$ of Eq. (38) for ket states, and the functions $f_b(z;k)$ of Eq. (39) for bra states. The relationship between $f_k(z;k)$ and $f_b(z;k)$ is given in Eqs. (48) and (49). The analytic representation uses the functions $f(z;k)$ of Eq. (12), which are identical to $f_k(z;k)$. Therefore, Eqs. (48) and (49) also provide the relationship between the analytic representation and the contour representation.

An important task of the paper is to discuss carefully the regions of convergence for these functions, and to find annuli where both $f_k(z;k)$ and $f_b(z;k)$ converge, so that we can write the scalar product in the form of Eq. (50). The operators are represented with analytic functions of two complex variables; again, the regions of convergence are very important and have been discussed explicitly in Sec. IV B.

The relationship between these two representations and other phase-space quantities like the displaced parity operator and the P,Q,W functions has been discussed in Sec. V. The application of hyperbolic contour representation in the study of the time evolution of optical amplifiers with the Hamiltonian of Eq. (74) has been discussed in Sec. VI.

The work bridges the gap between the many phases space and analytic approaches to SU(1,1) systems.

APPENDIX: ELLIPTIC CONTOUR REPRESENTATIONS

In this appendix we discuss briefly the elliptic contour representation in the extended complex plane $C \cup \infty$, which is topologically equivalent to a sphere and is related to the $SU(2)/U(1)$.[15] The purpose is to compare and contrast the hyperbolic contour representation in the unit disk, which is the subject of this paper, with the elliptic contour representation in the extended complex plane.

In this case the Hilbert space is $2j+1$-dimensional, and we consider an orthonormal basis of angular momentum states $|j,n\rangle$. SU(2) coherent states are defined as

$$|z\rangle = (1+|z|^2)^{-j} \sum_{n=-j}^{j} d(j,n) z^{j+n} |j,n\rangle; \quad d(j,n) = \left[\frac{(2j)!}{(j+n)!(j-n)!}\right]^{1/2}. \tag{A1}$$

In the elliptic contour representation in the extended complex plane, an arbitrary ket state $|f\rangle$ is represented by the function

$$|f\rangle = \sum_{n=-j}^{j} f_n |j,n\rangle \to f_k(z) = \sum_{n=-j}^{j} d(j,n) f_n z^{j+n}, \tag{A2}$$

and the corresponding bra state $\langle f|$ is represented by the function $f_b(z)$

$$\langle f| = \sum_{n=-j}^{j} f_n^* \langle j,n| \to f_b(z) = \sum_{n=-j}^{j} \frac{f_n^*}{d(j,n) z^{j+n+1}}. \tag{A3}$$

The function $f_k(z)$ is a polynomial of z of order $2j$ and has singularity at ∞ (which is the north pole). The function $f_b(z)$ is a polynomial of z^{-1} of order $2j+1$ and has singularity at 0 (which is the south pole). We stress that all sums here are finite and there are no difficulties with convergence.

In this analytic representation the scalar product is given by

$$\langle f|g\rangle = \oint_C \frac{dz}{2\pi i} f_b(z) g_k(z) = \sum f_n^* g_n, \tag{A4}$$

where C is an anticlockwise contour around the origin, which is the singularity for $f_b(z)$. We stress that in the elliptic contour representation both functions $f_k(z)$ and $f_b(z)$ are well defined for $0 < |z| < \infty$, and we have no difficulty in choosing a contour C. In contrast, in the hyperbolic contour representation there is only the narrow annulus of Eq. (44), where both functions $f_k(z)$ and $f_b(z)$ converge, and the contour has to be restricted within it.

The following transformations take the bra representation to the ket representation and vice versa:[15]

$$\oint_C \frac{dw}{2\pi i} f_b(w)(1 + z^* w)^{2j} = [f_k(z)]^*, \tag{A5}$$

$$\frac{2j+1}{z} \int_0^\infty \frac{dt}{(1+t)^{2j+2}} \left[f_k\left(\frac{t}{z^*}\right) \right]^* = f_b(z). \tag{A6}$$

They should be compared and contrasted to Eqs. (48) and (49).

Relations between P, Q, and the other representations in the SU(2) case have been studied by various authors (e.g., Refs. 15, 21, and 22).

In this paper, a general method of treating Hamiltonians of deformed nanoscale systems is proposed. This method is used to derive a second-order approximation both for the strong and weak formulations of the eigenvalue problem. The weak formulation is needed in order to allow deformations that have discontinuous first derivatives at interfaces between different materials. It is shown that, as long as the deformation is twice differentiable away from interfaces, the weak formulation is equivalent to the strong formulation with appropriate interface boundary conditions. It is also shown that, because the Jacobian of the deformation appears in the weak formulation, the approximations of the weak formulation is not equivalent to the approximations of the strong formulation with interface boundary conditions. The method is applied to two one-dimensional examples (a sinusoidal and a quantum-well potential) and one two-dimensional example (a freestanding quantum wire), where it is shown that the energy eigenvalues of the second-order approximations lie within 1% of the exact energy eigenvalues for a linear strain of up to 9.8%, whereas the first-order approximation has an error of less than 1% for a linear strain of up to 5.5%. © *2005 American Institute of Physics.*

I. INTRODUCTION

Nanoscale semiconductor devices, such as quantum wells, wires, and dots, usually consist of materials with different lattice constants; hence, these structures will be strained. It is known that strain strongly affects the electronic and optical properties. This has for example been used in band structure engineering of quantum-well systems; see Ref. 1 for a review including theoretical and experimental results. Also, Johnson and Bose[2] have shown the necessity of including strain in the modeling of a system of coupled quantum dots, and it is known that the formation of pyramidal InAs quantum dots on GaAs substrates (self-assembled structures) is driven by the large lattice mismatch between the two semiconductors.[3] Thus, in order to be able to model these devices it is important to account for strain effects. It is well known how to incorporate homogeneous strain in electronic band structure calculations,[4] but in nanoscale heterostructures strain is no longer homogeneous. Zhang[5] and Suzuki[6] have proposed two different methods to include linear inhomogeneous strain terms in the Hamiltonian under certain assumptions for the strain and the potential. In this paper, a general method of treating Hamiltonians of deformed nanoscale systems (e.g., an inhomogeneous strained Hamiltonian) is proposed based on a Taylor series expansion. The advantage of this method is that fewer assumptions for the strain and the Hamiltonian are needed

compared to previous models[4–6] and, in addition, it is easily extended to a higher-order approximation. Finally, because the weak formulation of the problem is used, discontinuities in the gradient of the deformation are handled in an appropriate manner. Higher-order theories for Hamiltonian systems have previously been handled in the literature, e.g., in connection with Lagrangian systems for classical mechanics and field theory; see Ref. 7 and references therein.

In Sec. II, the problem is presented and the Hamiltonian appropriate for calculating the quantum-mechanical energy eigenvalues and corresponding eigenstates is specified. In Sec. II A, the mathematical tools needed to make a Taylor series expansion of the Hamiltonian with respect to a deformation of the system is presented. Section II B is concerned with the derivation of the second-order Taylor series expansion of the Hamiltonian and in Sec. II C the weak formulation of the problem is given, after which the second-order Taylor series expansion is derived for the weak formulation. Finally, in Sec. III, three examples of the application of the method are presented.

II. THEORY

The problem under investigation in this paper is how to model the behavior of an electron in a deformed system in general, and, more specifically, how to model the behavior of an electron in a deformed inhomogeneous crystal structure, based on the Schrödinger equation. Assuming that an undeformed domain $\mathcal{B}\subseteq\mathbb{R}^3$, e.g., a crystal volume, is given, a deformation ϕ: $\mathcal{B}\rightarrow\mathbb{R}^3$ of the undeformed domain $\mathcal{B}$ is defined to be a C^2 map satisfying certain requirements to be specified in the next section. Primed ($'$) coordinates, functions, and operators always refer to the domain $\mathcal{B}$ in the following, while unprimed coordinates, functions, and operators refer to the domain $\phi(\mathcal{B})$.

The deformation of a nanoscale system, as well as any material system in general, is found by minimizing the elastic energy of the system. There are basically two main approaches, an atomic approach[8] and a continuum approach.[9–11] If the deformation has been found using an atomic approach, it is necessary to use the information about how the individual atoms are shifted to construct a C^2 map, but this is outside the scope of this article, i.e., it will just be assumed that the deformation has been found using a continuum approach and that this results in a C^2 map (the C^2 demand will be weakened slightly in Sec. II C).

Assuming that an electron in a potential deformed by ϕ is subject to the potential $\tilde{V}_\phi$, the Hamiltonian of the deformed system, referred to as the deformed Hamiltonian, is given by the Schrödinger equation

$$\tilde{H}_\phi = -\frac{\hbar^2}{2m}\Delta + \tilde{V}_\phi.$$

It should be noted that the potential is a function of the deformed domain $\phi(\mathcal{B})$, i.e., $\tilde{V}_\phi(x)$, where x are coordinates on $\phi(\mathcal{B})$. The energies E and corresponding wave functions ψ are found by solving the eigenvalue equation

$$\tilde{H}_\phi\psi = E\psi, \tag{1}$$

subject to certain boundary conditions. For an electron in a crystal, the most important potential contributions are

$$\tilde{V}_\phi = V_\phi + \hat{H}^{\mathrm{SO}} = V_\phi - i\frac{\hbar^2}{2m^2c^2}(\nabla V_\phi \times \nabla)\cdot\sigma,$$

where V_ϕ is the potential of the deformed crystal without spin, $\hat{H}^{\mathrm{SO}}$ is the spin-orbit part, and σ are the Pauli spin matrices. This is the situation considered in this work, but it should be noted that the procedure can be used on any potential which is a differential function of ϕ in a sense to be defined later. In order to incorporate spin, operators on the function space $\mathcal{F}$ are extended to $\mathcal{F}\times\mathcal{F}$ by operating on each element of the pair separately, e.g., let $f\in\mathcal{F}\times\mathcal{F}$, i.e., $f=\binom{f_+}{f_-}$, where $f_+, f_-\in\mathcal{F}$; then

$$V_\phi f = V_\phi \begin{pmatrix} f_+ \\ f_- \end{pmatrix} = \begin{pmatrix} V_\phi f_+ \\ V_\phi f_- \end{pmatrix}.$$

The function f_+ corresponds to the spin-up state and f_- corresponds to the spin-down state.

The potential of the undeformed domain is usually better known than the potential of the deformed domain. Assuming that the deformation is known, it is therefore advantageous to express the deformed Hamiltonian with respect to the deformation and the undeformed potential. This can be achieved by making a Taylor series expansion of the deformed Hamiltonian with respect to the deformation. In order to do so, the deformed Hamiltonian is written with respect to coordinates on $\mathcal{B}$. This can be done as long as the deformation is invertible with twice differentiable inverse. The deformed Hamiltonian is, in that case, given by

$$\tilde{H}_\phi = -\frac{\hbar^2}{2m}\Delta + V_\phi - i\frac{\hbar^2}{2m^2c^2}(\nabla V_\phi \times \nabla)\cdot\sigma. \tag{2}$$

Changing to coordinates on $\mathcal{B}$, the deformed Hamiltonian takes the form

$$H_\phi = K_F + V_\phi \circ \phi + H_\phi^{\mathrm{SO}}, \tag{3}$$

where $F=\nabla'\phi$ and the kinetic and spin-orbit parts (K_F and H_ϕ^{SO}, respectively) are given by

$$K_F = -\frac{\hbar^2}{2m}[F^{-1}(\phi(\mathbf{r}'))]_{ji}\frac{\partial}{\partial x_j'}\left([F^{-1}(\phi(\mathbf{r}'))]_{ki}\frac{\partial}{\partial x_k'}\right), \tag{4}$$

and

$$H_\phi^{\mathrm{SO}} = -i\frac{\hbar^2}{4m^2c^2}([F^{-1}(\phi(\mathbf{r}'))]^T\nabla' V_\phi(\phi(\mathbf{r}')) \times [F^{-1}(\phi(\mathbf{r}'))]^T\nabla')\cdot\sigma. \tag{5}$$

Here and throughout the paper, Einstein's summation convention is applied, i.e., summation over repeated indices, e.g., $a_i b_i = \Sigma_{i=1}^3 a_1 b_i$. It should be noted that $\tilde{H}_\phi$ in Eq. (2) and H_ϕ in Eq. (3) are related by a unitary transformation (change of coordinates). It is possible to use other unitary transformations to write the Hamiltonian with respect to coordinates on $\mathcal{B}$, e.g., a transformation similar to the one used in Hislop *et al.*[12] in connection with spectral deformation theory, which take into account the determinant of the deformation gradient appearing in the probability distribution by solving for $\sqrt{\det F}\psi(\mathbf{r})$ instead of $\psi(\mathbf{r})$. The Taylor series expansion will of course reflect the choice of transformation, but the order of the approximation will stay the same.

The idea now is to make a Taylor series expansion of H_ϕ [Eq. (3)] with respect to the deformation ϕ. Hence, it is necessary to set up the mathematical theory required to handle the above situation. This will be done in the next section.

A. Mathematical tools

The first thing needed in order to use a Taylor series expansion is to define a derivative applicable in the given situation. The weakest notion of a derivative is the Gâteaux derivative, and this will be used in the present work. Let U and V be normed linear spaces, $S\subseteq U$ an open set, and P an operator from S to V. In addition, let $u_0\in S$, $\eta\in U$ nonzero, and $\mathcal{I}=(-\alpha,\alpha)$, where $\alpha\in\mathbb{R}$ is chosen such that $u_0+t\eta\in U$ for all $t\in\mathcal{I}$. The Gâteaux differential of P at u_0 in the direction η is then defined to be

$$DP(u_0)\cdot\eta \equiv \frac{d}{dt}(P(u_0+t\eta)) = \lim_{t\to 0}\frac{1}{t}(P(u_0+t\eta)-P(u_0)), \tag{6}$$

when the limit exists. An operator P which has a Gâteaux differential at each point in S in any direction is said to have a Gâteaux differential on S.[13] The higher-order differentials are introduced inductively in the usual manner. It should be noted that when the Gâteaux derivative fulfills certain

additional requirements it is equal to the stronger, and more widely used, concept of a derivative called Frechet differentiability.[14] This concept has, among other things, the advantage of being linear in η, which is not always the case for the Gâteaux derivative.

The version of Taylor's theorem that is relevant for this work is given as follows.

Theorem II.1. *Let U and V be normed linear spaces. Suppose that the space V is complete and that the region S of the space U is convex, and suppose that the function P from S to V has an nth Gâteaux differential on S. Suppose also that for every* u_1, u_2 *in S the function of r,* $D^n P(u_1+(u_2-u_1)r)\cdot(u_2-u_1)^n$, *is bounded on the interval (0, 1) and its set of discontinuities is of measure zero. Then, for every* u_1, u_2 *in S we have*

$$P(u_2) = P(u_1) + \sum_{i=1}^{n-1} \frac{D^i P(u_1)\cdot(u_2-u_1)^i}{i!} + R_n(u_1,u_2),$$

where

$$R_n(u_1,u_2) = \int_0^1 D^n P(u_1+(u_2-u_1)r)\cdot(u_2-u_1)^n \frac{(1-r)^{n-1}}{(n-1)!} dr.$$

The statement that a subset of an interval is of measure zero is equivalent to the statement that the total length of the subset is zero. For a proof of this theorem and a definition of the Riemann integral appearing in the theorem, refer to Ref. 13. In order to see how this theorem can be used in the situation given above, a more precise definition of a deformation, and of the corresponding deformed Hamiltonian, is necessary. This will be given in the following.

First, the overall normed linear space that a deformation belongs to is defined. Let f be a once differentiable function from $\mathcal{B}$ to $\mathbb{R}^3$, and define

$$\|f\|_{C^1} = \left\{ \sup_{\mathcal{B}} \left[f_1^2 + \sum_{i=1}^{3} \left(\frac{\partial f_1}{\partial x_i} \right)^2 + f_2^2 + \sum_{i=1}^{3} \left(\frac{\partial f_2}{\partial x_i} \right)^2 + f_3^2 + \sum_{i=1}^{3} \left(\frac{\partial f_3}{\partial x_i} \right)^2 \right] \right\}^{1/2}, \tag{7}$$

where $f=(f_1,f_2,f_3)$. Denote with $\hat{C}^2$ the normed linear space consisting of all the twice differentiable functions from $\mathcal{B}$ to $\mathbb{R}^3$ that have a finite norm given by (7). A deformation ϕ: $\mathcal{B}\to\mathbb{R}^3$ of the undeformed domain $\mathcal{B}$ is defined to be an injective $\hat{C}^2$ map satisfying $\inf(\det(\nabla'\phi))>0$. The last requirement is needed to ensure that the map has a twice differentiable inverse; this is guaranteed by the inverse function theorem. The existence of the inverse ensures that the deformation does not destroy parts of the domain, e.g., by collapsing or tearing parts of the domain. It is assumed that $\mathcal{B}$ is bounded; this ensures boundedness of considered operators. The space of all deformations of $\mathcal{B}$ is denoted $\mathcal{D}$. It can be shown that the function g: $\hat{C}^2\to\mathbb{R}$ given by $g(\phi)=\inf(\det(\nabla'\phi))$ is continuous, and $\mathcal{D}$ is, as a consequence, open in $\hat{C}^2$ (it is the inverse image of the open set $]\infty,0[$).

Next, the deformed Hamiltonian is shown to be a function from $\mathcal{D}$ to a normed linear space. The domain of the deformed Hamiltonian is, in this article, chosen to be the product of Sobolev spaces: $H^2(\phi(\mathcal{B}))\times H^2(\phi(\mathcal{B}))$. This is the largest space for which the deformed Hamiltonian is defined.[15] The deformation has, according to the inverse function theorem, a twice differentiable inverse. This ensures that H_ϕ can be written with respect to coordinates on $\mathcal{B}$, as it was done in Eq. (3). As a consequence, the deformed Hamiltonian can be viewed as an operator

$$\hat{H}:\mathcal{D}\to L(H^2(\mathcal{B})\times H^2(\mathcal{B}),\quad L^2(\mathcal{B})\times L^2(\mathcal{B})),$$

given by $\phi\mapsto H_\phi$, where $L(\mathcal{F},\mathcal{G})$ is the space of bounded linear mappings from $\mathcal{F}$ to $\mathcal{G}$ and $L^2(\mathcal{B})$ is the Lebesgue space. The Lebesgue space is needed here because of the definition of the Sobolev space.[15] It is also the appropriate space with respect to wave functions, because these give the probability that an electron is in a certain area, and, as a consequence, they only need to be defined

almost everywhere, i.e., up to sets of zero measure. The spaces $H^2(\mathcal{B})\times H^2(\mathcal{B})$ and $L^2(\mathcal{B})\times L^2(\mathcal{B})$ are equipped with the L^2 norm

$$\|\psi\|_{L^2}=\left(\int_{\mathcal{B}}\psi_+^*\psi_+ \mathrm{d}V\right)^{1/2}+\left(\int_{\mathcal{B}}(\psi_-^*\psi_-)\mathrm{d}V\right)^{1/2},$$

where $\psi=\binom{\psi_+}{\psi_-}$ and ψ_+,ψ_- are functions from $\mathcal{B}$ to $\mathbb{C}$. The space $L^2(\mathcal{B})\times L^2(\mathcal{B})$ equipped with this norm is a complete normed linear space. The space $L(H^2(\mathcal{B})\times H^2(\mathcal{B}),L^2(\mathcal{B})\times L^2(\mathcal{B}))$ is equipped with the operator norm

$$\|A\|_O=\sup\{\|A\psi\|_{L^2}|\psi\in H^2(\mathcal{B})\times H^2(\mathcal{B}),\quad \|\psi\|_{L^2}\leqslant 1\},$$

where $A\in L(H^2(\mathcal{B})\times H^2(\mathcal{B}),L^2(\mathcal{B})\times L^2(\mathcal{B}))$. This makes the space $L(H^2(\mathcal{B})\times H^2(\mathcal{B}),L^2(\mathcal{B})\times L^2(\mathcal{B}))$ into a complete normed linear space (see Theorem III.2.3 in Ref. 16).

The function to be approximated by a Taylor series expansion is the function $\hat{H}$, i.e., with respect to Theorem II.1: $P=\hat{H}$, $U=\hat{C}^2$, and $V=L(H^2(\mathcal{B})\times H^2(\mathcal{B}),L^2(\mathcal{B})\times L^2(\mathcal{B}))$. Depending on which element of $\mathcal{D}$ the deformed Hamiltonian is expanded about, the convexity requirement can be fulfilled by restricting the domain of $\hat{H}$ to the largest open ball with respect to the norm[7] that contains the element of expansion and is contained in $\mathcal{D}$. This restriction normally poses no problems because Taylor series expansions are in general only accurate within small deviations from the element of expansion. The restricted domain is the set S in Theorem II.1. That the Gâteaux derivatives exists and that $D^nP(u_1+(u_2-u_1)r)\cdot(u_2-u_1)^n$ fulfills the given requirements has to be verified for each specific potential V_ϕ.

B. Second-order deformed Hamiltonian

In this section, the second-order Taylor series expansion of the deformed Hamiltonian around the identity map *id* on $\mathcal{B}$ is presented. In order to find the second-order Taylor series expansion, it is necessary to find the first- and second-order Gâteaux derivatives. This is done in Appendix A. It is assumed that V_ϕ is well enough behaved such that Theorem II.1 can be used. The Taylor series expansion of the deformed Hamiltonian to the second order in ϕ around *id* is then given by

$$H_\phi\approx H_{id}+D^{(1)}(\phi-id)+D^{(1)}_{\mathrm{SO}}(\phi-id)+D^{(2)}(\phi-id,\phi-id)+D^{(2)}_{\mathrm{SO}}(\phi-id,\phi-id),\tag{8}$$

where

$$H_{id}=-\frac{\hbar^2}{2m}\nabla'^2+V_{id}-i\frac{\hbar^2}{4m^2c^2}(\nabla' V_{id}\times\nabla')\cdot\sigma,$$

$$D^{(1)}(\phi-id)=\frac{\hbar^2}{2m}\left\{[F+F^T-2I]_{jk}\frac{\partial}{\partial x_j'}\frac{\partial}{\partial x_k'}+\frac{\partial}{\partial x_i'}([F-I]_{ki})\frac{\partial}{\partial x_k'}\right\}+DV_{id}\cdot(\phi-id),$$

$$\begin{aligned}D^{(1)}_{\mathrm{SO}}(\phi-id)=&-i\frac{\hbar^2}{4m^2c^2}\{(\nabla'(DV_{id}\cdot(\phi-id))\times\nabla')\cdot\sigma-((F-I)^T\nabla' V_{id}\times\nabla')\cdot\sigma\\&-(\nabla' V_{id}\times(F-I)^T\nabla')\cdot\sigma\},\end{aligned}$$

$$D^{(2)}(\phi - id, \phi - id) = -\frac{\hbar^2}{2m}\Bigg\{[(F-I)(F-I)^T + (F-I)^2 + (F^T-I)^2]_{jk}\frac{\partial}{\partial x_j'}\frac{\partial}{\partial x_k'} + [(F-I)]_{ji}\frac{\partial}{\partial x_j'}([F-I]_{ki})\frac{\partial}{\partial x_k'} + \frac{\partial}{\partial x_i'}[(F-I)^2]_{ki}\frac{\partial}{\partial x_k'}\Bigg\} + \frac{1}{2}D^2V_{id}\cdot((\phi - id),(\phi - id)),$$

$$D_{\mathrm{SO}}^{(2)}(\phi - id, \phi - id) = -i\frac{\hbar^2}{4m^2c^2}\Bigg\{-((F-I)^T\nabla'(DV_{id}\cdot(\phi - id))\times\nabla')\cdot\sigma - (\nabla'(DV_{id}\cdot(\phi - id))\times(F-I)^T\nabla')\cdot\sigma + ((F-I)^T\nabla'V_{id}\times(F-I)^T\nabla')\cdot\sigma + \frac{1}{2}(\nabla'(D^2V_{id}\cdot((\phi - id),(\phi - id)))\times\nabla')\cdot\sigma + ((F^T-I)^2\nabla'V_{id}\times\nabla')\cdot\sigma + (\nabla'V_{id}\times(F^T-I)^2\nabla')\cdot\sigma\Bigg\},$$

and $F=\nabla'\phi$.

To connect these expressions with the strain tensor, note that the Green–Lagrange–St. Venant strain tensor is given by

$$\epsilon = \frac{1}{2}(F^TF - I),$$

and the linear strain tensor is given by

$$\epsilon^{\mathrm{lin}} = \frac{1}{2}(F + F^T - 2I). \tag{9}$$

In the case where F is symmetric, Eq. (9) becomes

$$\epsilon^{\mathrm{lin}} = F - I.$$

If only the first-order terms of the Taylor series expansion are used, and if the linear strain is used with a symmetric deformation gradient, then the herein derived first-order approximation to the deformed Hamiltonian is identical to the one proposed by Zhang.[5] In the case where the deformation is homogeneous, the first-order approximation is the same as the one derived by Bir *et al.*[4]

C. Weak formulation

The preceding sections are all concerned with deformations that are twice differentiable, but there are many situations where the deformations do not satisfy this. For example, in the quantum-well case the deformation is piecewise linear with different slopes inside and outside the well.[17] Therefore, to be able to handle this kind of deformations, an extension of the theory to a larger class of deformations is needed.

Let $\mathcal{A}$ be the set of injective functions from $\mathcal{B}$ to $\mathbb{R}^3$ that are once differentiable on $\mathcal{B}\backslash\Gamma$ with both a finite C^1 norm [Eq. (7)] and a positive Jacobian determinant, where Γ is a finite set of piecewise smooth surfaces (two-dimensional manifolds). This set of functions includes the deformations considered in quantum-well, as well as quantum-wire and quantum-dot structures (according to continuum mechanical models[9–11]). The problem with the functions belonging to $\mathcal{A}$ is that they are not necessarily once differentiable on $\mathcal{B}$ because the first derivative can have discon-

tinuities at interfaces. Therefore, caution is needed when "pulling back" the deformed Hamiltonian to coordinates on $\mathcal{B}$ [Eq. (3)]. The correct formalism to use in this case is the weak formalism, i.e., instead of solving the eigenvalue equation

$$H_\phi \tilde{\psi} = E\tilde{\psi},$$

subject to some boundary conditions (in this work either Dirichlet or periodic boundary conditions), a solution to the weak equation

$$\int_{\phi(\mathcal{B})} \xi_+^* (H_\phi \tilde{\psi})_+ \mathrm{d}V + \int_{\phi(\mathcal{B})} \xi_-^* (H_\phi \tilde{\psi})_- \mathrm{d}V = \int_{\phi(\mathcal{B})} \xi_+^* E\tilde{\psi}_+ \mathrm{d}V + \int_{\phi(\mathcal{B})} \xi_-^* E\tilde{\psi}_- \mathrm{d}V, \tag{10}$$

for all $\xi_+, \xi_- \in C_c^\infty(\phi(\mathcal{B}), \mathbb{C})$ (smooth functions with compact support; see, e.g., Ref. 16) is found, where $(H_\phi \tilde{\psi})_+$ is the first factor of $H_\phi \tilde{\psi}$ and $(H_\phi \tilde{\psi})_-$ is the last factor. The solution still has to satisfy the boundary conditions. Introducing

$$K_\phi^\pm(\eta_\pm, \zeta) = \frac{\hbar^2}{2m} \int_{\mathcal{B}\backslash\Gamma} [(F^{-1} \circ \phi)(F^{-1} \circ \phi)^T]_{ij} \frac{\partial(\eta_\pm)^*}{\partial x_i'} \frac{\partial \zeta_\pm}{\partial x_j'} \det F \mathrm{d}V', \tag{11}$$

$$V_\phi^\pm(\eta_\pm, \zeta) = \int_{\mathcal{B}} \eta_\pm^* V_\phi \circ \phi \zeta_\pm \det F \mathrm{d}V', \tag{12}$$

$$H_\phi^{\mathrm{SO},\pm}(\eta_\pm, \zeta) = -i \frac{\hbar^2}{4m^2c^2} \int_{\mathcal{B}\backslash\Gamma} \eta_\pm^* (F^T \sigma \times \nabla' V_\phi \circ \phi \cdot \nabla' \zeta)_\pm \mathrm{d}V', \tag{13}$$

$$W_\phi(\eta, \zeta; E) = K_\phi^+(\eta_\pm, \zeta) + V_\phi^+(\eta_\pm, \zeta) + H^{\mathrm{SO},+}{}_\phi(\eta_\pm, \zeta) - \int_{\mathcal{B}} \eta_+^* E\zeta_+ \det F \mathrm{d}V' + K_\phi^-(\eta_\pm, \zeta) + V_\phi^-(\eta_\pm, \zeta)$$

$$+ H^{\mathrm{SO},-}{}_\phi(\eta_\pm, \zeta) - \int_{\mathcal{B}} \eta_-^* E\zeta_- \det F \mathrm{d}V', \tag{14}$$

where $\eta = \binom{\eta_+}{\eta_-}$, $\zeta = \binom{\zeta_+}{\zeta_-}$, $\eta_+, \eta_- \in H^2(\mathcal{B})$, and $\zeta_+ \circ \phi^{-1}, \zeta_- \circ \phi^{-1} \in C_c^\infty(\phi(\mathcal{B}), \mathbb{C})$, the weak formulation [Eq. (10)] can be put in the form: Find $\tilde{\psi}$ and E such that

$$W_\phi(\xi \circ \phi, \tilde{\psi} \circ \phi; E) = 0,$$

for all $\xi_+, \xi_- \in C_c^\infty(\phi(\mathcal{B}), \mathbb{C})$. The expression for the kinetic part [Eq. (11)] is found by integrating by parts, using that ξ_+ and ξ_- have compact support, changing coordinates, and using the chain rule. The integral is restricted to $\mathcal{B}\backslash\Gamma$ for the chain rule to apply. This is possible because Γ has measure zero (zero volume). Finding the expression for the potential part [Eq. (12)] is straightforward, and the expression for the spin-orbit part [Eq. (13)] is found again by changing coordinates and using the chain rule; in addition, the rule that $Av_1 \times Av_2 \cdot Av_3 = \det(A) v_1 \times v_2 \cdot v_3$, for a 3×3 matrix A and $v_1, v_2, v_3 \in \mathbb{R}^3$ is used.

According to Theorem B.1 in the Appendix, the above weak formulation is equivalent to finding ψ and E such that

$$W_\phi(\eta, \psi; E) = 0, \tag{15}$$

for all $\eta_+, \eta_- \in C_c^\infty(\mathcal{B}, \mathbb{C})$, in which case $\tilde{\psi} = \psi \circ \phi^{-1}$. Equation (15) is a weak formulation of the problem with respect to the domain $\mathcal{B}$.

The operator W defined in Eq. (14) can be viewed as an operator $W: \mathcal{A} \to L(H^2(\mathcal{B}) \times H^2(\mathcal{B}), C_c^\infty(\mathcal{B}, \mathbb{C}) \times C_c^\infty(\mathcal{B}, \mathbb{C}); A(\mathbb{R}, \mathbb{R}))$, where $L(\mathcal{F}_1, \mathcal{F}_2; \mathcal{G})$ is the space of bilinear mappings

from $\mathcal{F}_1 \times \mathcal{F}_2$ to $\mathcal{G}$ and $A(\mathbb{R},\mathbb{R})$ is the space of affine mappings from $\mathbb{R}$ to $\mathbb{R}$. The space $A(\mathbb{R},\mathbb{R})$ is a finite-dimensional normed vector space, and because of this it is complete. It follows that the range of W is complete so, according to Theorem II.1, the Taylor series expansion of W exists, assuming that the Gâteaux derivative exists and fulfills given requirements. The domain of W can be restricted to an open convex set using similar arguments as in Sec. II A.

In Appendix B the derivatives needed to write out the second-order Taylor series expansion of W are found, giving

$$W_\phi \approx W_{id} + W^{(1)}(\phi - id) + W^{(1)}_{\mathrm{SO}}(\phi - id) + W^{(2)}(\phi - id, \phi - id) + W^{(2)}_{\mathrm{SO}}(\phi - id, \phi - id),$$

where

$$W^{(1)}(\phi - id)(\eta,\psi;E) = \sum_{s=+,-} \left\{ -\frac{\hbar^2}{2m}\int_{\mathcal{B}\setminus\Gamma} [F + F^T - 2I]_{ij} \frac{\partial(\eta_s)^*}{\partial x_i'}\frac{\partial \psi_s}{\partial x_j'} - \frac{\partial(\eta_s)^*}{\partial x_i'}\frac{\partial \psi_s}{\partial x_i'}\,\mathrm{Tr}(F-I)\mathrm{d}V' \right.$$
$$\left. + \int_{\mathcal{B}} \eta_s^*(DV_{id}\cdot(\phi - id) + (V_{id} - E)\mathrm{Tr}(F-I))\psi_s \mathrm{d}V' \right\},$$

$$W^{(2)}(\phi - id, \phi - id)(\eta,\psi;E) = \sum_{s=+,-} \left\{ \frac{\hbar^2}{2m}\int_{\mathcal{B}\setminus\Gamma} [(F-I)^2 + (F^T - I)^2 + (F-I)(F-I)^T]_{ij} \frac{\partial(\eta_s)^*}{\partial x_i'}\frac{\partial \psi_s}{\partial x_j'}\mathrm{d}V' \right.$$
$$- \frac{\hbar^2}{2m}\int_{\mathcal{B}\setminus\Gamma} [F + F^T - 2I]_{ij}\,\mathrm{Tr}(F-I)\frac{\partial(\eta_s)^*}{\partial x_i'}\frac{\partial \psi_s}{\partial x_j'}\mathrm{d}V'$$
$$+ \frac{\hbar^2}{2m}\int_{\mathcal{B}\setminus\Gamma} \frac{\partial(\eta_s)^*}{\partial x_i'}\frac{\partial \psi_s}{\partial x_i'}\,\mathrm{Tr}([F-I]_{co})\mathrm{d}V'$$
$$+ \frac{1}{2}\int_{\mathcal{B}} \eta_s^* D^2 V_{id}\cdot(\phi - id, \phi - id)\psi_s \mathrm{d}V,$$
$$\left. + \int_{\mathcal{B}} \eta_s^*(DV_{id}\cdot(\phi - id)\mathrm{Tr}(F-I) + (V_{id} - E)\mathrm{Tr}([F-I]_{co}))\psi_s \mathrm{d}V' \right\},$$

$$W^{(1)}_{\mathrm{SO}}(\phi - id)(\eta,\psi) = \sum_{s=+,-} -i\frac{\hbar^2}{4m^2c^2}\int_{\mathcal{B}\setminus\Gamma} \{\eta_s^*((F-I)^T\sigma \times \nabla' V_{id}\cdot\nabla'\psi)_s$$
$$+ \eta_s^*(\sigma\times\nabla'(DV_{id}\cdot(\phi - id))\cdot\nabla'\psi)_s\}\mathrm{d}V',$$

and

$$W^{(2)}_{\mathrm{SO}}(\phi - id, \phi - id)(\eta,\psi) = \sum_{s=+,-} \left\{ -i\frac{\hbar^2}{4m^2c^2}\int_{\mathcal{B}\setminus\Gamma} \eta_s^*((F-I)^T\sigma\times\nabla'(DV_{id}\cdot(\phi - id))\cdot\nabla'\psi)_s \mathrm{d}V' \right.$$
$$\left. - i\frac{\hbar^2}{4m^2c^2}\int_{\mathcal{B}\setminus\Gamma} \eta_s^*\left(\sigma\times\nabla'\left(\frac{1}{2}D^2V_{id}\cdot(\phi - id, \phi - id)\right)\cdot\nabla'\psi\right)_s \mathrm{d}V' \right\}.$$

In contrast to the previous deformed Hamiltonian models by Bir and Pikus,[4] Zhang,[5] and Suzuki,[6] the present model describes a general rigoristic mathematical model for incorporating nonsmooth (and of course, smooth) deformation fields in Hamiltonians.

1. Strong formulation with interface boundary conditions

The weak form can, as long as the deformations lie in $\mathcal{A}$ and are twice differentiable on $\mathcal{B}\backslash\Gamma$, be reformulated in a strong form with interface boundary conditions. This is done using integration by parts in the kinetic term [Eq. (11)]. Let $\mathbf{n}=(n_1,n_2,n_3)$ be a unit normal vector field on the interface Γ; then

$$K_{\phi}^{\pm}(\eta_{\pm},\zeta) = \frac{\hbar^2}{2m}\int_{\Gamma} n_i \Bigg\{ \left([(F^{-1}\circ\phi)(F^{-1}\circ\phi)^T]_{ij} (\eta_{\pm})^* \frac{\partial \zeta_{\pm}}{\partial x_j'} \det F \right)_{m1} - \left([(F^{-1}\circ\phi)(F^{-1}\circ\phi)^T]_{ij} (\eta_{\pm})^* \frac{\partial \zeta_{\pm}}{\partial x_j'} \det F \right)_{m2} \Bigg\} \mathrm{d}A' - \frac{\hbar^2}{2m}\int_{\mathcal{B}\backslash\Gamma} (\eta_{\pm})^* [F^{-1}\circ\phi]_{ji} \frac{\partial}{\partial x_j'} \left([F^{-1}\circ\phi]_{ki} \frac{\partial \zeta_{\pm}}{\partial x_k'} \right) \det F \mathrm{d}V', \tag{16}$$

where the subscripts $m1$ and $m2$ symbolize that the expression in brackets is found as the limit taken from the region that the normal vector points out of and into, respectively. To get this result, it has also been used that

$$\frac{\partial}{\partial x_i}(F^{-1}_{ik} \det F) = \frac{\partial}{\partial x_i}([F_{co}]_{ki}) = 0,$$

for $k=1,2,3$, where F_{co} is the matrix of cofactors of F. This result can easily be verified. From Eq. (16) it can be inferred that the weak formulation is equivalent to solving the eigenvalue equation

$$H_{\phi}\zeta = E\zeta,$$

on $\mathcal{B}\backslash\Gamma$, where H_{ϕ} is given in Eq. (3), subject to the interface boundary condition

$$n_i \left([(F^{-1}\circ\phi)(F^{-1}\circ\phi)^T]_{ij} \frac{\partial \zeta_{\pm}}{\partial x_j} \det F \right)_{m1} = n_i \left([(F^{-1}\circ\phi)(F^{-1}\circ\phi)^T]_{ij} \frac{\partial \zeta_{\pm}}{\partial x_j'} \det F \right)_{m2}. \tag{17}$$

Notice that the interface boundary condition should be satisfied simultaneously for both ζ_+ and ζ_- in order for the surface integral appearing in (16) to vanish.

The advantage of formulating the problem in strong form with interface boundary conditions [Eq. (17)] is that solution methods no longer are restricted to weak methods. Hence, it is possible to find solutions by any convenient numerical or exact method. This kind of procedure can be used in most situations involving derivatives of discontinuous quantities, e.g., $k\cdot p$ theory.

III. ONE- AND TWO-DIMENSIONAL EXAMPLES

A. Sinusoidal potential

The one-dimensional sinusoidal potential is chosen as a first example. This potential is given by

$$V_{id}(x') = V_0 + A\cos\left(\frac{2\pi}{a}x'\right),$$

for $x' \in \,]-Na, Na[$ (see Fig. 1). The real number a is the distance between the maximal value of the potential, and $N \in \mathbb{N}$ is a fixed number. In this example the values $V_0=0$ eV and $A=5$ eV are chosen. In addition, periodic boundary conditions are used. Assuming that the whole potential is deformed when subjected to some deformation ϕ, the deformed potential is given by

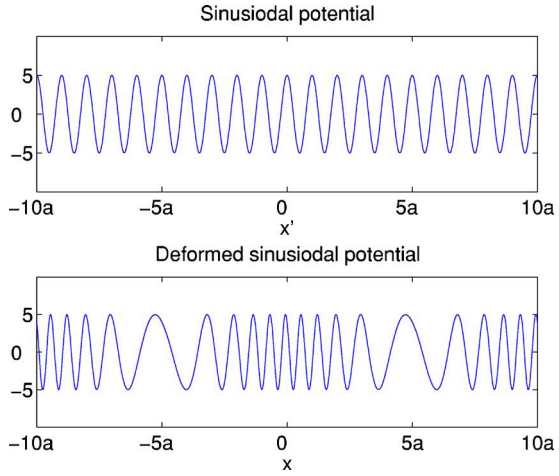

FIG. 1. (Color online) A figure showing the undeformed and deformed sinusoidal potential for $N=10$ and $\epsilon=0.1$.

$$V_\phi(x) = V_{id}(\phi^{-1}(x)) = V_0 + A\cos\left(\frac{2\pi}{a}\phi^{-1}(x)\right).$$

To get an idea of the influence of the deformation on the energies, the deformation is chosen such that

$$\phi^{-1}(x) = x + \epsilon a \sin\left(\frac{2\pi}{10a}x\right), \tag{18}$$

where it is assumed that $N/10 \in \mathbb{N}$ and $\epsilon \in \mathbb{R}$ is chosen such that $\partial\phi^{-1}/\partial x > 0$ for all $x \in [-Na, Na]$. In Fig. 1 the deformed potential is shown for $N=10$ and $\epsilon=0.1$. The inverse is specified because this insures that it is possible to solve the exact eigenvalue equation and, as a consequence, the first- and second-order approximations can be compared against the exact solution.

This example can be extended to a three-dimensional example by assuming that there is translational symmetry in the y' and z' directions, and that the system is only deformed in the x' direction. The undeformed region can, in this case, be chosen as $\mathcal{B}=]-Na, Na[\times]-Na, Na[\times]-Na, Na[$ with periodic boundary conditions. The potential can then be viewed as originating from a periodic array of plates perpendicular to the x' direction. The number a is, in this case, the period of the structure. Ignoring spin, the deformed Hamiltonian is given by

$$H_\phi = -\frac{\hbar^2}{2m}\Delta + V_\phi.$$

According to Eq. (8), the second-order Taylor series expansion is

$$H_\phi \approx H_{id} + D^{(1)}(\phi - id) + D^{(2)}(\phi - id, \phi - id).$$

Because of the translational symmetry, the solutions to the eigenvalue problem [Eq. (1)] can always be chosen such that

$$\tilde{\psi}(x', y', z') = \psi(x')e^{ik_{y'}y'}e^{ik_{z'}z'}.$$

Solving at the zone center, i.e., for $k_{y'}=0$ and $k_{z'}=0$, it is found that Eq. (8) takes the form

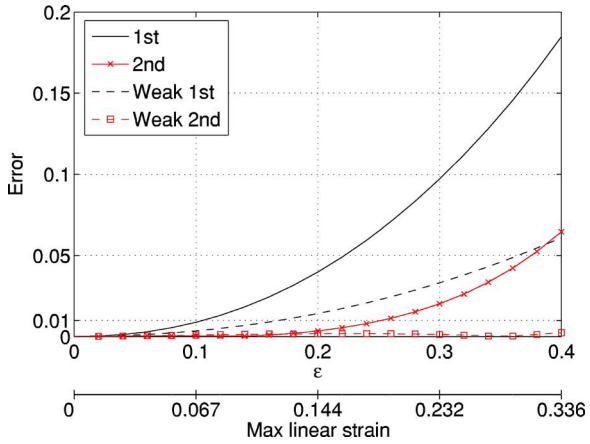

FIG. 2. (Color online) Graph showing the error in the energies for the sinusoidal potential when using the first- and second-order approximations.

$$H_\phi \approx -\frac{\hbar^2}{2m}\left\{\left(1-2\left(\frac{\partial\phi}{\partial x'}-1\right)+3\left(\frac{\partial\phi}{\partial x'}-1\right)^2\right)\frac{\partial^2}{\partial x'^2}+\left(-\frac{\partial^2\phi}{\partial x'^2}+3\left(\frac{\partial\phi}{\partial x'}-1\right)\frac{\partial^2\phi}{\partial x'^2}\right)\frac{\partial}{\partial x'}\right\}+V_{id}(x').$$

The reason why the Taylor series expansion of the potential is exact is that $V_\phi(x)=V_{id}(\phi^{-1}(x))=V_{id}(x')$. Another way of arriving at Eq. (19) is to derive a theory similar to the one in this article just for the one-dimensional case.

The eigenvalue equation has been solved numerically using FEMLAB, i.e., using a finite-element method, both for the first- and second-order approximation of the deformed Hamiltonian with respect to $((\partial\phi/\partial x')-1)$. The exact problem, i.e., without making the Taylor series expansion, was also solved using FEMLAB. In Fig. 2 a plot of the error in using the first- and second-order approximation as a function of ϵ and the maximum of the linear strain is presented (the solid lines), where the linear strain is given by $((\partial\phi/\partial x')-1)$. The errors of the first- and the second-order Hamiltonians are given by

$$\mathrm{Error}^x=\left|\frac{E_1^x-E_1^{\mathrm{Exact}}}{E_1^x}\right|,$$

$x=1\mathrm{st},2\mathrm{nd}$, respectively, where E_1^{Exact}, $E_1^{1\mathrm{st}}$, and $E_1^{2\mathrm{nd}}$ are the energy of the ground state calculated with the exact, first-order, and second-order Hamiltonians, respectively. From this graph it can be seen that the second-order approximation (crossed red line) is considerably more accurate then the first-order approximation (black line). The first-order approximation has an error of less than 1% for a max linear strain of up to 6.7%, whereas the second-order approximation is accurate to with in 1% up to a max linear strain of 18.6%.

Even though it is not necessary to use the weak formulation for the problem in this example (because the deformation is smooth over the whole domain), it is still interesting to see how accurate the results are using the weak approach. First of all, it should be noted that the exact results obtained with the weak formulation are identical to the exact results obtained with the strong formulation. This should also be the case because the formulations are equivalent when everything is smooth. Which formulation is used does however matter when the Taylor series expansion is made. In the weak formulation the Jacobian is present as a consequence of the coordinate transformation of the integral, and it is not present in the strong formulation. So, it is actually the influence of the Jacobian that is under investigation in the following.

According to Sec. II C, the second-order Taylor series expansion of the weak eigenvalues problem has the following form disregarding spin: Find $\tilde{\psi}$ and E such that

$$W(\phi)(\eta,\tilde{\psi},E)=0, \tag{19}$$

for all $\eta\in C_c^\infty(\mathcal{B},\mathbb{C})$, where

$$W(\phi)(\eta,\tilde{\psi},E)\approx\frac{\hbar^2}{2m}\int_{-Na}^{Na}\left[\left(1-\left(\frac{\partial\phi}{\partial x'}-1\right)+\left(\frac{\partial\phi}{\partial x'}-1\right)^2\right)\frac{\partial\hat{\eta}^*}{\partial x'}\frac{\partial\psi}{\partial x'}\right]\mathrm{d}x'$$
$$+\int_{-Na}^{Na}\left[(V_{id}-E)\frac{\partial\phi}{\partial x'}\hat{\eta}^*\psi\right]\mathrm{d}x',$$

and

$$\hat{\eta}=\int_{-Na}^{Na}\int_{-Na}^{Na}\eta\,\mathrm{d}y'\,\mathrm{d}z'.$$

The first- and second-order approximation of the eigenvalue equation (19) with respect to $((\partial\phi/\partial x')-1)$ is again solved using FEMLAB. The dashed lines in Fig. 2 show the error introduced by using the first- and second-order approximation (black and boxed red lines, respectively). From this figure, it is seen that the second-order approximation is again substantially better than the first-order approximation. In this case, the first-order approximation has an error of less then 1% for a max linear strain of up to 12%, and the second-order approximation is within an error of 1% in the whole interval shown, i.e., at least up to a max linear strain of 33.6%. It is also seen that the first- and second-order approximations of the weak problem are considerably more precise than the first- and second-order approximations of the strong problem. The reason for this goes back to the presence of the Jacobian in the weak formulation in the following way.

First, observe that $\partial\phi^{-1}/\partial x\circ\phi=1/(\partial\phi/\partial x')$ and $\det(\nabla'\phi)=\partial\phi/\partial x'$. From this it is seen that $\partial\phi^{-1}/\partial x\circ\phi\det(\nabla'\phi)=1$. Because of this, Eq. (14) reduces to

$$W(\phi)(\eta,\tilde{\psi},E)=\frac{\hbar^2}{2m}\int_{-Na}^{Na}\left[\frac{\partial\phi^{-1}}{\partial x}\circ\phi\frac{\partial\hat{\eta}^*}{\partial x}\frac{\partial\psi}{\partial x'}+(V_{id}-E)\frac{\partial\phi}{\partial x'}\hat{\eta}^*\psi\right]\mathrm{d}x'.$$

The reason why the Taylor approximations of this equation is more precise than the Taylor approximations of the strong problem is simply that the first- and second-order Taylor series expansion of $\partial\phi^{-1}/\partial x\circ\phi=1/(\partial\phi/\partial x')$ is more accurate than the first- and second-order Taylor series expansion of $((\partial\phi^{-1}/\partial x)\circ\phi)^2=(1/(\partial\phi/\partial x'))^2$. Hence, the reason why the approximations of the weak formulation are more accurate than the approximations of the strong formulation is that this example is, in essence, a one-dimensional problem. This will be confirmed in the quantum-wire example analyzed later.

B. Quantum well

In this section the influence of deformations on the quantum-well problem is investigated. This is done in order to give an example of a situation where the weak formulation is needed. The quantum-well problem is the one-dimensional problem where the undeformed potential is given by the step function

$$V_{id}(x')=\begin{cases}V_0, & x'\in\,]-d,-a[\\ V_1, & x'\in[-a,a]\\ V_0, & x'\in\,]a,d[\end{cases}.$$

To simplify matters, spin is again neglected. In this example the following values are used: $V_0=5$ eV, $V_1=0$ eV, $a=5$ nm, and $d=25$ nm, and Dirichlet boundary conditions are imposed. Again, it is assumed that the whole potential is deformed when it is subjected to a deformation ϕ, i.e., $V_\phi(x)=V_{id}(\phi^{-1}(x))$. In nanoscale semiconductor quantum wells, the well material will be de-

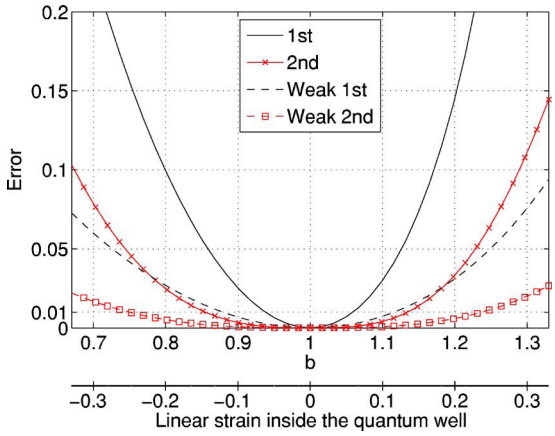

FIG. 3. (Color online) Graph showing the error in the energies for the quantum well when using the first- and second-order approximations.

formed homogeneously, whereas the barrier material will stay undeformed [see, e.g. (18)], i.e., the deformation will have the form

$$\phi(x') = \begin{cases} x' - a(b-1), & x' \in]-d,-a[\\ bx', & x' \in [-a,a] \\ x' + a(b-1), & x' \in]a,d[\end{cases},$$

for some $b>0$. The deformation is not differentiable at the interfaces and, as a consequence, the weak formulation is needed. Proceeding as in the sinusoidal example above, it is found that the second-order Taylor series expansion of the weak eigenvalue problem takes the form given in Eq. (19) and the equations that follow.

The first- and second-order approximations have again been solved using FEMLAB. The inverse of the deformation is easily found and, as a consequence, it is also possible to solve the exact weak eigenvalue problem, i.e., without making a Taylor series expansion. The error in the energy of the ground state in using the first- and second-order approximation is shown in Fig. 3 (dashed black and boxed red lines). Here, it is seen that the error introduced by using the first-order approximation is within 1% for a linear strain of up to 11.6%, whereas the error introduced by using the second-order approximation lies within 1% for a linear strain of up to 23.8%. Again, it is seen that the second-order approximation is substantially better than the first-order approximation.

In the sinusoidal example above, it was seen that the approximations of the weak formulation gave considerably more accurate results than the approximations of the strong formulation. In order to investigate whether this is the case for the quantum-well problem also, the strong form of the problem with interface boundary conditions (Sec. II C 1) has been solved, again using FEMLAB. It should be noted that the exact solution to the strong form with interface boundary conditions, i.e., without making a Taylor series expansion, is equal to the exact solution to the weak form. This has to be the case because the two formalisms are equivalent as long as no approximations have been made. The second-order approximation of the strong form is given by Eq. (19) above, and the interface boundary conditions are as follows:

$$\left(\frac{\partial \phi^{-1}}{\partial x} \circ \phi(x_0) \frac{\partial \psi}{\partial x'}(x_0)\right)_L = \left(\frac{\partial \phi^{-1}}{\partial x} \circ \phi(x_0) \frac{\partial \psi}{\partial x'}(x_0)\right)_R,$$

for $x_0 = -a, a$, where $L(R)$ indicates that the expression in brackets is taken in the limit from the left (right). The second-order Taylor series expansion of the interface boundary conditions takes the form

$$\left(\left(1-\left(\frac{\partial\phi}{\partial x'}(x_0)-1\right)+\left(\frac{\partial\phi}{\partial x'}(x_0)-1\right)^2\right)\frac{\partial\psi}{\partial x'}(x_0)\right)_L$$
$$=\left(\left(1-\left(\frac{\partial\phi}{\partial x'}(x_0)-1\right)+\left(\frac{\partial\phi}{\partial x'}(x_0)-1\right)^2\right)\frac{\partial\psi}{\partial x'}(x_0)\right)_R,$$

for $x_0=-a,a$.

The solid black and crossed red lines in Fig. 3 show the error introduced by using the first- and second-order approximation of the strong form with interface boundary conditions, denoted SForm-first and SForm-second, respectively. Here, we see that the error in using SForm-first is less than 1% for a linear strain of up to 5.9%, whereas the error introduced using SForm-second is within 1% for a linear strain of up to 13.5%. So again, it is seen that the second-order approximation is more accurate than the first-order approximation. In addition, it can be seen that the approximations of the weak form are substantially more accurate than the approximations of the strong form with interface boundary conditions. This is expected because this is also a one-dimensional problem, so the same reasoning as in the sinusoidal example can be applied.

C. Quantum wire

In this section a square-shaped, two-dimensional quantum-wire problem with infinite barrier is investigated. This is done in order to see whether or not the approximations of the weak problem are more accurate than the approximations of the strong form for a two-dimensional problem.

The undeformed two-dimensional domain under investigation is given by $]-5,5[\times]-5,5[$ (in nanometers) and the potential is zero. Dirichlet boundary conditions must be applied because of the infinite barrier. To simplify matters, the following homogeneous deformation is chosen:

$$\phi(\dot{x}',y')=\begin{pmatrix} b & b-1 \\ 0 & b \end{pmatrix}\begin{pmatrix} x' \\ y' \end{pmatrix},$$

where $b\neq 0$ (this ensures that the Jacobian determinant is positive). The second-order Taylor series expansion of the Strong formulation of the eigenvalue equation takes the form: Find ψ and E such that

$$H_\phi\psi=E\psi,$$

where

$$H_\phi\approx-\frac{\hbar^2}{2m}\left(\frac{\partial^2\psi}{\partial x'\partial x'}+\frac{\partial^2\psi}{\partial y'\partial y'}-2(b-1)\left(\frac{\partial^2\psi}{\partial x'\partial x'}+\frac{\partial^2\psi}{\partial y'\partial y'}+\frac{\partial^2\psi}{\partial x'\partial y'}\right)\right.$$
$$\left.+(b-1)^2\left(4\frac{\partial^2\psi}{\partial x'\partial x'}+3\frac{\partial^2\psi}{\partial y'\partial y'}+6\frac{\partial^2\psi}{\partial x'\partial y'}\right)\right).$$

This can either be derived in a similar manner to the three-dimensional case, or the quantum-wire problem can be extended to a three-dimensional problem by assuming translational symmetry in the third direction. If it is then solved at the zone center in the third direction, the second-order approximation of the deformed Hamiltonian will have the above form. In the latter case the problem is actually closer to a real problem, although a idealized version, because such quantum-wire structures can be grown in reality [see Ref. 18].

The solid lines in Fig. 4 show the error resulting from using the first- and second-order approximations (the black and crossed red lines, respectively). Here, it is seen that the first-order approximation is within an error of 1% for $b-1$ between -0.058 and 0.055, whereas the energies of the second-order approximation are within an error of 1% for $b-1$ between -0.197 and 0.098. Again, it can be seen that the second-order approximation gives substantially better results.

The second-order Taylor series expansion of the weak formulation of the problem takes the form: Find ψ and E such that

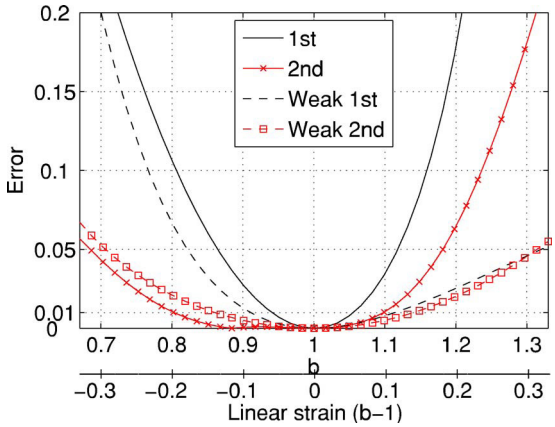

FIG. 4. (Color online) Graph showing the error in the energies for the quantum wire when using the first- and second-order approximations.

$$W(\phi)(\eta,\psi,E)=0,$$

for all $\eta\in C_c^\infty(]-5,5[\times]-5,5[,\mathbb{C})$, where

$$W(\phi)(\eta,\tilde{\psi},E)\approx\int_{-5}^{5}\int_{-5}^{5}\left\{\frac{\hbar^2}{2m}\left[\frac{\partial\eta^*}{\partial x'}\frac{\partial\psi}{\partial x'}+\frac{\partial\eta^*}{\partial x'}\frac{\partial\psi}{\partial x'}+(-(b-1)+(b-1)^2)\left(\frac{\partial\eta^*}{\partial x'}\frac{\partial\psi}{\partial y'}+\frac{\partial\eta^*}{\partial y'}\frac{\partial\psi}{\partial x'}\right)\right.\right.$$
$$\left.\left.+(b-1)^2\frac{\partial\eta^*}{\partial x'}\frac{\partial\psi}{\partial x'}\right]+(V_{id}-E)(1+2(b-1)+(b-1)^2)\hat{\eta}^*\psi\right\}\mathrm{d}x'\mathrm{d}y'.$$

From this, the energies can be calculated with respect to a first- and a second-order approximation of the weak form. The dashed lines in Fig. 4 show the error in the energy introduced by using the first- and the second-order approximation of the weak form as a function of both b and $b-1$ (black and boxed red lines, respectively). Here, it is seen that the first-order approximation of the weak form has an error of less than 1% for $b-1$ between −0.089 and 0.114, whereas the error of the second-order approximation of the weak form is within an error of 1% for $b-1$ between −0.139 and 0.14. It is seen, as expected, that the second-order approximation of the weak form is much better than the first-order approximation of the weak form. But, when the approximations of the weak form are compared to the approximations of the strong form, it is seen that the second-order approximation of the strong form is actually more accurate than the second-order approximation of the weak form in the negative direction, whereas it is the second-order approximation of the weak form which is more accurate in the positive direction. Hence, for this two-dimensional problem it is not easy to say which of the two formulations gives the best results. This differs from the observations made in the one-dimensional examples above, where it was seen that the approximations of the weak formulation always were more accurate than the approximations of the strong formulation.

IV. CONCLUSION

In this article a method to incorporate deformation effects in Hamiltonians has been presented based on a Taylor series expansion with respect to the deformation. This method was exemplified with a Hamiltonian of an inhomogeneous crystal structure including spin. For this Hamiltonian, the second-order Taylor series expansion of the eigenvalue problem was found both in a strong and a weak formulation. The weak formulation was needed in order to be able to handle deformations that might not be differentiable at interfaces. It was also shown that the weak formulation could be transformed into a strong formulation with interface boundary conditions.

One- and two-dimensional examples were presented, where it was shown that the Taylor series approximations give quite accurate results. In actual fact, an error in the energy within 1% for a linear strain of up to 5.5% for the first-order approximations and 9.8% for the second-order approximations was obtained. For the one-dimensional examples, it was also seen that the approximations of the weak formulation gave considerably more accurate results than the approximations of the strong formulation. But, for the two-dimensional example, this was not the case.

APPENDIX A: TAYLOR EXPANSION (STRONG FORMULATION)

First, it should be noted that all the functions under investigation in this appendix, except the potential V_ϕ, are Frechet differentiable. As a consequence, all the usual rules normally associated with derivatives can be applied.

In the course of finding the Gâteaux derivative of $\hat{H}$, the following lemma will be used:

Lemma A.1. Let F: $\mathcal{D}\to C(\mathcal{B},M(3,\mathbb{R}))$ *be given by* $F(\phi)=\nabla'\phi$, $G\in C(\mathcal{B},M(3,\mathbb{R}))$, *and* $\chi\in\hat{C}^2$, *where* $M(3,\mathbb{R})$ *is the set of* 3×3 *matrices with real coefficients; then*

$$DF(\phi)\cdot\chi=\nabla'\chi,$$

$$DF^{-1}(I)\cdot G=-G,$$

$$D\det F(I)\cdot G=\mathrm{Tr}(G)$$

where $I\in C(\mathcal{B},GL(3,\mathbb{R}))$ *is given by* $I(\mathbf{r}')_{ij}=\delta_{ij}$, F^{-1} *is the mapping* $F\mapsto F^{-1}$ *for* $F\in C(\mathcal{B},GL(3,\mathbb{R}))$, *and* $\det F$ *is the mapping* $F\mapsto\det F$. *In addition*

$$D^2F^{-1}(I)\cdot(G,G)=2(G)^2,$$

and

$$D^2\det F(I)\cdot(G,G)=2\,\mathrm{Tr}([G]_{co})=2(G_{11}G_{22}-G_{12}G_{21}+G_{11}G_{33}-G_{13}G_{31}+G_{22}G_{33}-G_{23}G_{32}),$$

where $[G]_{co}$ *is the matrix of cofactors of* G.

Proof of Lemma A.1. Using Eq. (6), it is seen that

$$DF(\phi)\cdot\chi=\frac{d}{dt}\{\nabla'(\phi+t\chi)\}\big|_{t=0}=\nabla'\chi.$$

Let F_0, $G\in C(\mathcal{B},M(3,\mathbb{R}))$, F_0 invertible, and let $\alpha\in\mathbb{R}$ be given such that F_0+tG is invertible for all $t\in(-\alpha,\alpha)$. Observe that

$$\frac{(F_0-tG)^{-1}-F_0^{-1}}{t}=\frac{F_0^{-1}}{t}((I+tGF_0^{-1})^{-1}-I)=-F_0^{-1}(I+tGF_0^{-1})^{-1}GF_0^{-1}.$$

From this it follows that the limit for $t\to 0$ exists and

$$DF^{-1}(F_0)\cdot G=-F_0^{-1}GF_0^{-1}. \tag{A1}$$

With $F_0=I$ the second result in Lemma A.1 is found. From Eq. (A1) it is also found that

$$D^2F^{-1}(F_0)\cdot(G,G) = D(-F^{-1}GF^{-1})(F_0)\cdot(G) = 2F_0^{-1}GF_0^{-1}GF_0^{-1}.$$

With $F_0=I$, the third result is obtained.

It is known that

$$\det F = F_1 \times F_2 \cdot F_3, \tag{A2}$$

where F_i is the ith column of F. From Eq. (A2), it is seen that

$$D\det F(F_0)\cdot G = G_1 \times [F_0]_2 \cdot [F_0]_3 + [F_0]_1 \times G_2 \cdot [F_0]_3 + [F_0]_1 \times [F_0]_2 \cdot G_3, \tag{A3}$$

i.e.,

$$D\det F(I)\cdot G = \mathrm{Tr}\, G.$$

Using Eq. (A3), it is found that

$$D^2\det F(F_0)\cdot G = 2(G_1 \times G_2 \cdot [F_0]_3 + [F_0]_1 \times G_2 \cdot G_3 + G_1 \times [F_0]_2 \cdot G_3),$$

giving

$$D^2\det F(I)\cdot G = 2\,\mathrm{Tr}\, G_{co}.$$

□

1. The kinetic part $K(F)$

The second-order Taylor series expansion is given by

$$K_F \approx K_I + DK_I\cdot(F-I) + \frac{1}{2}D^2K_I\cdot(F-I,F-I),$$

where K_F is given in Eq. (4). Using the chain rule, Lemma A.1, and the definition of the Gâteaux derivative, it can be shown that

$$DK_{F_0}\cdot G = \frac{\hbar^2}{2m}\left\{[DF^{-1}(F_0)\cdot G]_{ji}\frac{\partial}{\partial x_j'}\left([F_0^{-1}\circ\phi_0]_{ki}\frac{\partial}{\partial x_k'}\right) + [F_0^{-1}\circ\phi_0]_{ji}\frac{\partial}{\partial x_j'}\left([DF^{-1}(F_0)\cdot G]_{ki}\frac{\partial}{\partial x_k'}\right)\right\}, \tag{A4}$$

That is

$$DK_I\cdot G = \frac{\hbar^2}{2m}\left\{[G+G^T]_{jk}\frac{\partial}{\partial x_j'}\frac{\partial}{\partial x_k'} + \frac{\partial}{\partial x_i'}([G]_{ki})\frac{\partial}{\partial x_k'}\right\}.$$

The second derivative of the kinetic part $K(F)$ can be found from Eq. (A4) using that $D^2F(\phi_0)\cdot\chi=0$ for all χ and ϕ_0, giving

$$D^2K_I\cdot(G,G) = -\frac{\hbar^2}{m}\left\{[GG^T]_{jk}\frac{\partial}{\partial x_j'}\frac{\partial}{\partial x_k'} + [G]_{ji}\frac{\partial}{\partial x_j'}([G]_{ki})\frac{\partial}{\partial x_k'} + [G^2+[G^T]^2]_{jk}\frac{\partial}{\partial x_j'}\frac{\partial}{\partial x_k'} + \frac{\partial}{\partial x_i'}([G^2]_{ki})\frac{\partial}{\partial x_k'}\right\}.$$

2. The spin-orbit part, H_{SO}

The second-order Taylor series expansion of the spin-orbit part is given by

$$H_{\phi}^{SO} \approx H_{id}^{SO} + DH_{id}^{SO} \cdot (\phi - id) + \frac{1}{2} D^2 H_{id}^{SO} \cdot (\phi - id, \phi - id),$$

where H_{ϕ}^{SO} is given in Eq. (5). Again using (6), Lemma A.1, and the chain rule, it is straightforward to show that

$$\begin{aligned} DH_{\phi_0}^{SO} \cdot \chi = -i\frac{\hbar^2}{4m^2c^2}\{&([F_0^{-1} \circ \phi_0]^T \nabla'(DV_{\phi_0} \cdot \chi)) \times ([F_0^{-1} \circ \phi_0]^T \nabla') \cdot \sigma \\ &+ (D[F^{-1}]^T(F_0) \cdot (\nabla'\chi)\nabla' V_{\phi_0}) \times ([F_0^{-1} \circ \phi_0]^T \nabla') \cdot \sigma \\ &+ ([F_0^{-1} \circ \phi_0]^T \nabla' V_{\phi_0}) \times (D[F^{-1}]^T(F_0) \cdot (\nabla'\chi)\nabla') \cdot \sigma\}, \end{aligned} \tag{A5}$$

where $F_0 = \nabla' \phi_0$. That is

$$DH_{id}^{SO} \cdot \chi = -i\frac{\hbar^2}{4m^2c^2}\{(\nabla'(DV_{id} \cdot \chi)) \times \nabla' \cdot \sigma - (\nabla'\chi^T \nabla' V_{id}) \times \nabla' \cdot \sigma - (\nabla' V_{id}) \times \nabla' \chi^T \nabla' \cdot \sigma\}.$$

From Eq. (A5), the second derivative of H_{SO} is found, arriving at

$$\begin{aligned} D^2 H_{id}^{SO} \cdot (\chi, \chi) = -i\frac{\hbar^2}{2m^2c^2}\Bigg\{&-(\nabla'\chi^T \nabla'(DV_{id} \cdot \chi)) \times \nabla' \cdot \sigma - (\nabla'(DV_{id} \cdot \chi)) \times (\nabla'\chi^T \nabla') \cdot \sigma \\ &+ \frac{1}{2}(\nabla'(D^2 V_{id} \cdot (\chi, \chi))) \times (\nabla') \cdot \sigma + (\nabla'\chi^T \nabla' V_{id}) \times (\nabla'\chi^T \nabla') \cdot \sigma \\ &+ ([\nabla'\chi^T]^2 \nabla' V_{id}) \times \nabla p' \cdot \sigma + (\nabla' V_{id}) \times ([\nabla'\chi^T]^2 \nabla') \cdot \sigma \Bigg\}. \end{aligned}$$

APPENDIX B: TAYLOR EXPANSION (WEAK FORMULATION)

In the course of determining the weak formulation, Theorem B.1 was used. First, two problems are introduced.

(I) Find ζ and E such that

$$W(\phi)(\xi \circ \phi, \zeta, E) = 0,$$

for all $\xi_+, \xi_- \in C_c^{\infty}(\phi(\mathcal{B}), \mathbb{C})$.

(II) Find ζ and E such that

$$W(\phi)(\eta, \zeta, E) = 0,$$

for all $\eta_+, \eta_- \in C_c^{\infty}(\mathcal{B}, \mathbb{C})$.

Theorem B.1. *Problem I and II are equivalent.*

Proof. Let ζ and E be a solution to problem (II), and assume that there exists a $\xi = (\xi_+, \xi_-)^T$, with $\xi_+, \xi_- \in C_c^{\infty}(\phi(\mathcal{B}), \mathbb{C})$, such that $W(\phi)(\xi \circ \phi, \zeta, E) \neq 0$. It is easily seen, using a regularizer (see Ref. 19), that there exists two sequences of functions in $C_c^{\infty}(\mathcal{B}, \mathbb{C})$, denoted $\xi_{+\epsilon}$ and $\xi_{-\epsilon}$, such that $(\xi_{+\epsilon}, \xi_{-\epsilon})^T \to \xi \circ \phi$ for $\epsilon \to 0$. Using the dominated convergence theorem (see Ref. 16), it can be shown that

$$\lim_{\epsilon \to 0}(W(\phi)((\xi_{+\epsilon}, \xi_{-\epsilon})^T, \zeta, E)) = W(\phi)(\xi \circ \phi, \zeta, E);$$

at the same time using that ζ and E is a solution to problem (II), it is found that

$$\lim_{\epsilon\to 0}(W(\phi)((\xi_{+\epsilon},\xi_{-\epsilon})^T,\zeta,E))=0.$$

But, this contradicts the assumption that $W(\phi)(\xi\circ\phi,\zeta,E)\neq 0$. From this it is seen that $W(\phi)(\xi\circ\phi,\zeta,E)=0$ for all $\xi_+,\xi_-\in C_c^\infty(\phi(\mathcal{B}),\mathbb{C})$, showing that ζ and E is also a solution to problem (I).

That a solution to problem (I) is also a solution to problem (II) is shown in a similar manner by changing to coordinates on $\phi(\mathcal{B})$ in the integrals. □

1. The kinetic part, $K^{\pm}_{\phi}$

Using the expressions in Lemma A.1, it is found that

$$\begin{aligned}[DK^{\pm}_{\phi_0}\cdot\chi](\eta_\pm,\zeta)=\frac{\hbar^2}{2m}\int_{\mathcal{B}\setminus\Gamma}\Big\{&[(DF^{-1}(F_0)\cdot\nabla'\chi)(F_0^{-1}\circ\phi)^T]_{ij}\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_j'}\det F_0\\&+[(F_0^{-1}\circ\phi)(DF^{-1}(F_0)\cdot\nabla'\chi)^T]_{ij}\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_j'}\det F_0\,\mathrm{d}V'\\&+[(F_0^{-1}\circ\phi)(F_0^{-1}\circ\phi)^T]_{ij}\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_j'}D\det F(F_0)\cdot\nabla'\chi\Big\}\mathrm{d}V',\end{aligned}\tag{B1}$$

where $F_0=\nabla'\phi_0$, giving

$$[DK^{\pm}_{id}\cdot\chi](\eta_\pm,\zeta)=-\frac{\hbar^2}{2m}\int_{\mathcal{B}\setminus\Gamma}[\nabla'\chi+\nabla'\chi^T]_{ij}\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_j'}-\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_i'}\mathrm{Tr}(\nabla'\chi)\mathrm{d}V'.$$

Continuing from Eq. (B1), it is seen that

$$\begin{aligned}[D^2K^{\pm}_{id}\cdot(\chi,\chi)](\eta_\pm,\zeta)=\frac{\hbar^2}{m}\int_{\mathcal{B}\setminus\Gamma}\Big\{&[(\nabla'\chi)^2+(\nabla'\chi^T)^2+(\nabla'\chi)(\nabla'\chi)^T]_{ij}\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_j'}\mathrm{d}V'\\&-[\nabla'\chi+\nabla'\chi^T]_{ij}\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_j'}\mathrm{Tr}(\nabla'\chi)\mathrm{d}V'+\frac{\partial(\eta_\pm)^*}{\partial x_i'}\frac{\partial\zeta_\pm}{\partial x_i'}\mathrm{Tr}([\nabla'\chi]_{co})\Big\}\mathrm{d}V'.\end{aligned}$$

2. The potential part, $V^{\pm}_{\phi}$

Again using Lemma A.1, it is found that

$$[DV^{\pm}_{\phi_0}\cdot\chi](\eta_\pm,\zeta)=\int_{\mathcal{B}}\eta_\pm^*(DV_{\phi_0}\cdot\chi\det F_0+V_{\phi_0}\circ\phi_0 D\det F(F_0)\cdot\nabla'\chi)\zeta_\pm\mathrm{d}V',\tag{B2}$$

that is

$$[DV^{\pm}_{id}\cdot\chi](\eta_\pm,\zeta)=\int_{\mathcal{B}}\eta_\pm^*(DV_{id}\cdot\chi+V_{id}\,\mathrm{Tr}(\nabla'\chi))\zeta_\pm\mathrm{d}V'.$$

The second-order derivative is found using Eq. (B2) and Lemma A.1, giving

$$[D^2V^{\pm}_{\phi_0}\cdot\chi](\eta_\pm,\zeta)=\int_{\mathcal{B}}\eta_\pm^*(D^2V_{id}\cdot(\chi,\chi)+2DV_{id}\cdot\chi\,\mathrm{Tr}(\nabla'\chi)+2V_{id}\,\mathrm{Tr}([\nabla'\chi]_{co}))\zeta_\pm\mathrm{d}V'.$$

3. The spin-orbit part, $H_{\phi}^{\mathrm{SO},\pm}$

Finding the derivatives of the spin-orbit part is straightforward, giving

$$[DH_{id}^{\mathrm{SO},\pm}\cdot\chi](\eta_{\pm},\zeta)=-i\frac{\hbar^2}{2m^2c^2}\int_{\mathcal{B}\setminus\Gamma}\eta_{\pm}^{*}(\nabla'\chi^{T}\sigma\times\nabla'V_{id}\cdot\nabla'\zeta+\sigma\times\nabla'(DV_{id}\cdot\chi)\cdot\nabla'\zeta)_{\pm}\mathrm{d}V'$$

and

$$\begin{aligned}[D^2H_{id}^{\mathrm{SO},\pm}\cdot(\chi,\chi)](\eta_{\pm},\zeta)=&-i\frac{\hbar^2}{2m^2c^2}\int_{\mathcal{B}\setminus\Gamma}\eta_{\pm}^{*}(2\nabla'\chi^{T}\sigma\times\nabla'(DV_{id}\cdot\chi)\cdot\nabla'\zeta)_{\pm}\mathrm{d}V'\\&-i\frac{\hbar^2}{2m^2c^2}\int_{\mathcal{B}\setminus\Gamma}\eta_{\pm}^{*}(\sigma\times\nabla'(D^2V_{id}\cdot(\chi,\chi))\cdot\nabla'\zeta)_{\pm}\mathrm{d}V'.\end{aligned}$$

We present an estimate for the space-time integral of classical solutions to the repulsive Wigner-Poisson system. We use Markowich's formalism between Wigner-Possion and Schrödinger-Poisson systems. Through this formalism and Morawetz interaction potentials, we derive the same *a priori* estimate given by Chae and Ha for the repulsive Vlasov-Poisson system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2101068]

I. INTRODUCTION

In this paper, we are interested in the Wigner-Poisson (WP) system in the absence of collisions,

$$\partial_t w + v \cdot \nabla_x w - \frac{i}{\hbar}\Theta[V]w = 0, \quad x \in \mathbb{R}^3, \quad v \in \mathbb{R}^3, \quad t > 0,$$

$$\Delta V = -4\pi n, \quad n := \int_{\mathbb{R}^3} w(x,v,t)\mathrm{d}v,$$

$$w(x,v,t=0) = w_0(x,v), \tag{1.1}$$

where w and $\hbar$ denote the Wigner density distribution function of a system of quantum mechanical particles and a constant proportional to the Planck constant, respectively, and the pseudodifferential operator $\Theta[V]$ is given as

$$(\Theta[V]w)(x,v,t) := \frac{1}{(2\pi)^3}\int\int_{\mathbb{R}^3\times\mathbb{R}^3}\left(V\left(x+\frac{\hbar}{2}\eta,t\right)-V\left(x-\frac{\hbar}{2}\eta,t\right)\right)w(x,v',t)e^{i(v-v')\eta}\,\mathrm{d}v'\,\mathrm{d}\eta. \tag{1.2}$$

Here we have taken the mass of an electron to be unit for simplicity.

The quantum Liouville system (1.1) models the quantum mechanical motion of a large electron ensemble in a vacuum under the action of the Coulomb force generated by the charge of the electrons, and was first derived by Wigner[32] in 1932 from the Schrödinger equation as the quantum analog of the classical Liouville equation (see Refs. 3 and 24 for details). Recent miniaturization process of semiconductor devices has led to the need for a quantum transport model that can be used for numerical simulations.[12,13,26,31]

The global existence of one- and two-dimensional WP system was first established by Steinrück[30] and Anold-Nier,[2] respectively. For the case of three dimension, the global existence

[a)]Electronic mail: mchae@kias.re.kr
[b)]Electronic mail: syha@math.snu.ac.kr
[c)]Electronic mail: hjhuh3@math.snu.ac.kr

was obtained using the Markowich's reformulation[23] of the WP system as a system of infinitely many Schrödinger equations coupled with the Poisson system by Brezzi-Markowich[5] for the repulsive case. Ilner-Zweifel-Lange later extended the result of Ref. 5 to both repulsive and attractive potentials in Ref. 19 and also gave some dispersion estimates of the solutions.

On the other hand, the classical limit $\hbar \to 0$ from (1.1) to the Vlasov-Poisson system (1.3) was settled by Lions-Paul[21] and Markowich-Mauser,[24]

$$\begin{gathered} \partial_t f + v \cdot \nabla_x f - \nabla_x V \cdot \nabla_v f = 0, \quad x \in \mathbb{R}^3, \quad v \in \mathbb{R}^3, \quad t > 0, \\ \Delta V = -4\pi \int_{\mathbb{R}^3} f \, \mathrm{d}v, \quad f(x,v,t=0) = f_0(x,v), \end{gathered} \tag{1.3}$$

where $f(x,v,t)$ is the distribution function for charged particles at time t, at a phase space position (x,v). Recently Chae and Ha[8] derived an estimate for the space-time integral for the classical solutions to (1.3). More precisely, they explicitly constructed a Lyapunov functional which is nonincreasing along smooth solutions and satisfies the identity

$$\mathcal{D}(f(t)) + \int_0^t \int\int\int_{\mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3} f(x,v,s) f(x,v_*,s) \mathrm{d}v_* \, \mathrm{d}v \, \mathrm{d}x \, \mathrm{d}s = \mathcal{D}(f_0), \quad t \geqslant 0.$$

This yields

$$\int_0^\infty \int\int\int_{\mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3} f(x,v,t) f(x,v_*,t) \mathrm{d}v_* \, \mathrm{d}v \, \mathrm{d}x < \infty, \tag{1.4}$$

which might be useful to analyze the time-asymptotic behavior of solutions as in Ref. 16. The key ingredients of their constructions are the time decay of local density and detailed analysis of the characteristics, which is not useful to (1.1) due to the pseudodifferential operator $(\Theta[V]w)$.

The purpose of this paper is to derive the estimate (1.4), incorporating two key ingredients. First, we use *Markowich's formalism* which establishes the equivalence between the Wigner-Poisson system and Schrödinger-Poisson system under some reasonable initial data assumption. Second, we employ *Morawetz interaction potential* which has been widely used for the study on dispersive equations especially on the nonlinear defocusing Schrödinger equation as listed in Ref. 9. Below we briefly explain Markowich's formalism between WP system and countably many Schrödinger-Poisson systems following the presentation of Ref. 17. In the sequel we set the renormalized Planck constant to be unity ($\hbar = 1$).

Let $\mathcal{F}_v(f)$ be the Fourier transform of f in v variable and $\mathcal{F}_\eta^{-1}(f)$ be its inverse Fourier transform,

$$\mathcal{F}_v(f)(x,\eta) = \int_{\mathbb{R}^3} f(x,v) e^{-iv\cdot\eta} \, \mathrm{d}v \quad \text{and } \mathcal{F}_\eta^{-1}(g)(x,v) = \frac{1}{(2\pi)^3} \int_{\mathbb{R}^3} g(x,\eta) e^{iv\cdot\eta} \, \mathrm{d}\eta.$$

We take the Fourier transform of (1.1) to get

$$\partial_t \mathcal{F}_v(w) + i \nabla_\eta \cdot \nabla_x \mathcal{F}_v(w) - i \delta V \mathcal{F}_v(w) = 0, \tag{1.5}$$

where δV is the symbol of the pseudodifferential operator $(\Theta[V]w)(x,v,t)$,

$$\delta V := V\left(x + \frac{\eta}{2}, t\right) - V\left(x - \frac{\eta}{2}, t\right).$$

We now introduce a set of coordinates,

$$r = x + \frac{\eta}{2}, \quad s = x - \frac{\eta}{2},$$

and one-particle density matrix z defined as

$$z(r,s,t) := \frac{1}{(2\pi)^3}\mathcal{F}_v(w)(x,\eta,t).$$

Then (1.1) is transformed to the *Heisenberg equation*,

$$iz_t - \left(\tfrac{1}{2}\Delta_s + V(s,t)\right)z + \left(\tfrac{1}{2}\Delta_r + V(r,t)\right)z = 0. \tag{1.6}$$

Note that

$$n(x,t) = \int_{\mathbb{R}^3} w(x,v,t)\mathrm{d}v = \mathcal{F}_v(x,0,t) = (2\pi)^3 z(x,x,t).$$

Suppose that datum w_0 in (1.1) satisfies the following assumption.

$(\mathcal{A})$: $z(r,s,0) \in L^2(\mathbb{R}^3 \times \mathbb{R}^3)$ is the kernel of a non-negative self-adjoint trace class operator in $L^2(\mathbb{R}^3)$,

$$\int_{\mathbb{R}^3} z(r,r,0) = 1 \text{ (trace class)}, \quad z(r,s,0) = \overline{z}(s,r,0) \text{ (self-adjoint)}.$$

Then it follows from the spectral theorem that

$$z(r,s,0) = \sum_{k=1}^{\infty} \lambda_k \overline{\varphi_k(r)}\varphi_k(s), \tag{1.7}$$

where λ_k and ϕ_k satisfy

$$\lambda_k \geqslant 0, \quad \sum_{k=1}^{\infty} \lambda_k = 1, \quad \varphi_k \in L^2(\mathbb{R}^3), \quad \|\varphi_k\|_{L^2} = 1, \quad \text{for } k \geqslant 1,$$

and the series converges in $L^2(\mathbb{R}^3_r \times \mathbb{R}^3_s)$. Hence it is easy to see that

$$z(r,s,t) := \sum_{k=1}^{\infty} \lambda_k \overline{\psi_k(r,t)}\psi_k(s,t) \tag{1.8}$$

is the solution of (1.6), when the functions $\{\psi_k(x,t)\}_{k\in\mathbb{N}}$ are solutions of the Schrödinger-Poisson system,

$$\begin{aligned} i\partial_t\psi_k + \tfrac{1}{2}\Delta\psi_k &= V\psi_k, \quad x \in \mathbb{R}^3, \quad t > 0, \\ \psi_k(x,t=0) &= \varphi_k(x), \end{aligned} \tag{1.9}$$

where V is an electric potential,

$$V(x,t) = \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{n(y,t)}{|x-y|}\mathrm{d}y$$

with the density n given by

$$n(x,t) = \sum_{k=1}^{\infty} \lambda_k |\psi_k(x,t)|^2. \tag{1.10}$$

The solution w of (1.1) is given by

$$w(x,v,t) = \mathcal{F}_{\eta}^{-1}\left(z\left(x + \frac{\eta}{2}, x - \frac{\eta}{2} \right) \right), \tag{1.11}$$

and local mass density $n(\cdot,t)$ defined by (1.10) is in $L^1(\mathbb{R}^3_x)$ and non-negative under the assumption $(\mathcal{A})$. The main result of this paper is as follows.

Theorem 1.1: *Suppose that initial datum $\omega_0 \in L^2(\mathbb{R}^3_x \times \mathbb{R}^3_v)$ is real-valued and its corresponding initial density matrix $z_0 = z(\cdot,\cdot,0)$ satisfies $(\mathcal{A})$ and*

$$\sum_{m=1}^{\infty} \lambda_m \|\varphi_m\|_{H^2(\mathbb{R}^3)} < \infty.$$

Then the classical solution of (1.1) *satisfies*

$$\int_0^{\infty} \int\int\int_{\mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3} w(x,v,t) w(x,v_*,t) \mathrm{d}v_* \, \mathrm{d}v \, \mathrm{d}x \, \mathrm{d}t < \infty. \tag{1.12}$$

Remark 1.1: (1) *The above covariance-type estimate has been obtained for other classical kinetic models such as the Boltzmann equation, Vlasov-Poisson system in Refs. 8 and 16 for small algebraically decaying initial data by using appropriate Lyapunov functionals. However, it seems that such a functional approach does not give an explicit time-decay rate for solutions of aforementioned models including the Wigner-Poisson system (1.1). For the Vlasov-Poisson system describing collisionless plasma, there are estimates yielding explicit time-decay rates of the electric field E and the local density ρ with smooth, compactly supported initial data in three dimensions.*[18,29]

(2) *The asymptotic behavior of the repulsive Wigner-Poisson system was studied in many literatures, for example, the explicit time-decay rates of solution, local density, and the potential were studied in Ref. 6 for initial data satisfying*

$$\sum_{m=1}^{\infty} \lambda_m (\|\varphi_m\|_{L^2(\mathbb{R}^3)} + \|x\varphi_m\|_{L^2(\mathbb{R}^3)}) < \infty. \tag{1.13}$$

The dispersion estimate was first considered in Ref. 19 for H^2-initial data with the second condition of (1.13) using the methods from Ref. 11. In particular, the following dispersion estimate for the local density $n(x,t)$ was obtained in Refs. 6 and 9.

$$\|n(\cdot,t)\|_{L^2(\mathbb{R}^3)} \leqslant C(1+t)^{-3/4}, \quad \text{for } t \geqslant 0,$$

hence this implies the space-time estimate (1.12), apart that the initial data in Theorem 1.1 does not need the one moment condition in x variable as above. On the other hand, there is a qualitative study on asymptotic behavior of the three-dimensional Schrödinger-Poisson equation (pure quantum state) using a scaling group,[22] *where the limit behavior of the solution is described by the solutions of the corresponding linear equation.*

The rest of this paper is organized in the following manner. In Sec. II, we address time-evolution estimate of Morawetz interaction potential for the defocusing Schrödinger-Poisson system. Finally in Sec. III, we present the proof of Theorem 1.1. In the Appendix we see that the inequality (2.7) also holds for Hartree-type equations and can provide a simpler proof of scattering result for Hatree-type equations.

Notations: Throughout the paper, we use the following notations:

$$f \lesssim g \Leftrightarrow f \leqslant Cg \quad \text{for some generic positive constant } C,$$

$$\|u(t)\|_{L^p} := \|u(\cdot,t)\|_{L^p(\mathbb{R}^3)}, \quad \|u(t)\|_{H^k} := \|u(\cdot,t)\|_{H^k(\mathbb{R}^3)}.$$

II. PRELIMINARIES

In this section we present the time-evolution estimate of the Morawetz interaction potential to Schrödinger-Poisson system (see Refs. 21, 23, and 26 for details).

Consider first *pure quantum state* or the Hartree equation which corresponds to the case $\lambda_1 = 1$, $\lambda_{m>1} = 0$ in the Schrödinger-Poisson system,

$$\begin{aligned} i\partial_t\psi + \tfrac{1}{2}\Delta\psi = V(|\psi|^2)\psi, \quad x \in \mathbb{R}^3, \quad t > 0, \\ \psi(x, t=0) = \psi_0(x), \end{aligned} \tag{2.1}$$

where $V(|\psi|^2)$ is the Newtonian potential of $|\psi|^2$, i.e.,

$$V(|\psi|^2) := \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{|\psi(y,t)|^2}{|x-y|}\mathrm{d}y.$$

More generally we set

$$V(|\psi|^2)(x,t) = \int v(x-y)|\psi(y,t)|^2\,\mathrm{d}y$$

for a non-negative function v with some integrability condition. We refer to Eq. (2.1) with such a general potential to be of Hartree type, which will be considered in the Appendix. In the sequel, we often drop the $|\psi|^2$ dependence in $V(|\psi|^2)$ for notational simplicity, i.e., $V := V(|\psi|^2)$. The conservation of L^2-norm and the energy defined as

$$E[t] := \int_{\mathbb{R}^3} (|\nabla\psi(t)|^2 + V|\psi(t)|^2)\mathrm{d}x$$

follow from the lemma below.

Lemma 2.1: Let ψ be a classical solution of (2.1) and decay fast enough at infinity. Then the following conservation laws hold:

$$\partial_t|\psi|^2 + \mathrm{div}(\mathrm{Im}\,\bar{\psi}\nabla\psi) = 0,$$

$$\partial_t(|\nabla\psi|^2 + V(\psi)|\psi|^2) + \mathrm{div}\left(2\,\mathrm{Re}(\nabla\bar{\psi}\partial_t\psi) - \frac{1}{2\pi}V\nabla\partial_t V - \frac{1}{4\pi}\partial_t(\nabla\cdot(V\nabla V))\right) = 0.$$

Proof: For the detailed proof, we refer to Ref. 7. □

We next turn to the Morawetz interaction potential introduced in Ref. 9. For given classical solution ψ of (2.1), define Morawetz interaction potential $M[\psi(t)]$ by

$$M[\psi(t)] := \int_{\mathbb{R}^3} |\psi(x,t)|^2 \underbrace{\left(\int_{\mathbb{R}^3} \mathrm{Im}[\bar{\psi}(y,t)\nabla\psi(y,t)]\cdot\frac{y-x}{|y-x|}\mathrm{d}y\right)}_{:=M_x[\psi(t)]}\mathrm{d}x. \tag{2.2}$$

We note that

$$|M_x[\psi(t)]| \leqslant \|\psi(t)\|_{L^2}\|\nabla\psi(t)\|_{L^2} \leqslant \|\psi_0\|_{L^2}E[0].$$

This yields *a priori* bound for $M[\psi(t)]$,

$$|M[\psi(t)]| \leqslant \|\psi_0\|_{L^2}^3 E[0].$$

We first study the time evolution of the weight $M_x[\psi(t)]$.

Lemma 2.2: Let ψ be the classical solution of (2.1). Then we have

$$(1) \quad \frac{d}{dt} M_x[\psi(t)] = 2\pi|\psi(x,t)|^2 + \int_{\mathbb{R}^3} \frac{|\nabla_x \psi(y,t)|^2}{|y-x|} dy + \int_{\mathbb{R}^3} \frac{1}{|y-x|} \left(\frac{y-x}{|y-x|} \cdot \nabla V(y,t) \right)^2 dy,$$

$$(2) \quad \nabla_x M_x[\psi(t)] = -2 \int_{\mathbb{R}^3} \frac{\mathrm{Im}[\bar{\psi}(y,t) \nabla \psi(y,t)]}{|y-x|} dy,$$

where $V(x,t) = V(|\psi|^2)$ and $\nabla_x \psi$ denotes the angular part of $\nabla \psi$, i.e.,

$$\nabla_x \psi = \nabla \psi - \frac{y-x}{|y-x|} \left(\frac{y-x}{|y-x|} \cdot \nabla \psi \right).$$

Proof: (1) We first rewrite

$$M_x[\psi(t)] = \mathrm{Im} \int_{\mathbb{R}^3} \bar{\psi}(y,t) \partial_r \psi(y,t) dy = \mathrm{Im} \int_{\mathbb{R}^3} \bar{\psi}(y,t) \left(\partial_r + \frac{1}{r} \right) \psi(y,t) dy = \mathrm{Im} \int_0^\infty \int_{\mathbb{S}^2} r \bar{\psi} \partial_r (r\psi) d\omega \, dr, \tag{2.3}$$

where we used

$$r = |y-x|, \quad \mathbb{S}^2 = \{y \in \mathbb{R}^3 : |y-x| = 1\} \quad \text{and} \quad \mathrm{Im} \int_{\mathbb{R}^3} \frac{1}{r} |\psi(y,t)|^2 \, dy = 0.$$

We use integration by parts and the equation (2.1) to see

$$\begin{aligned}
\frac{d}{dt} M_x(t) &= \mathrm{Im} \int_0^\infty \int_{\mathbb{S}^2} (\overline{r\psi}) \partial_r (r\psi_t) + (\overline{r\psi_t}) \partial_r (r\psi) d\omega \, dr \\
&= -2 \, \mathrm{Im} \int_0^\infty \int_{\mathbb{S}^2} \partial_r (\overline{r\psi}) (r\psi_t) d\omega \, dr \\
&= -2 \, \mathrm{Im} \int_0^\infty \int_{\mathbb{S}^2} \partial_r (\overline{r\psi}) \left(\frac{i}{2} \partial_r^2 (r\psi) + \frac{i}{2r} \Delta_\omega \psi - irV\psi \right) d\omega \, dr \\
&= -\mathrm{Re} \int_0^\infty \int_{\mathbb{S}^2} \partial_r (\overline{r\psi}) \partial_r^2 (r\psi) d\omega \, dr - \mathrm{Re} \int_0^\infty \int_{\mathbb{S}^2} \partial_r (\overline{r\psi}) \frac{1}{r} \Delta_\omega \psi \, d\omega \, dr \\
&\quad + 2 \, \mathrm{Re} \int_0^\infty \int_{\mathbb{S}^2} \partial_r (\overline{r\psi}) rV\psi \, d\omega \, dr := \mathcal{I}_1 + \mathcal{I}_2 + \mathcal{I}_3,
\end{aligned}$$

where we used

$$\Delta \psi = \partial_r^2 \psi + \frac{2}{r} \partial_r \psi + \frac{1}{r^2} \Delta_w \psi.$$

By the same arguments given in Ref. 9, $\mathcal{I}_1$ and $\mathcal{I}_2$ satisfy

$$\mathcal{I}_1+\mathcal{I}_2=2\pi|\psi(x,t)|^2+\int_{\mathbb{R}^3}\frac{1}{|y-x|}|\nabla_x\psi(y,t)|^2\,\mathrm{d}y.$$

For the quantity $\mathcal{I}_3$, we have

$$\begin{aligned}2\,\mathrm{Re}\int_0^\infty\int_{\mathbb{S}^2}\partial_r(\overline{r\psi})rV\psi\,\mathrm{d}\omega\,\mathrm{d}r&=\int_0^\infty\int_{\mathbb{S}^2}\partial_r(r^2|\psi|^2)V\,\mathrm{d}\omega\,\mathrm{d}r\\&=\int_{\mathbb{R}^3}\frac{y-x}{|y-x|^3}\cdot\nabla(r^2|\psi|^2)V\,\mathrm{d}y\\&=-\int_{\mathbb{R}^3}|\psi|^2\frac{y-x}{|y-x|}\cdot\nabla V\,\mathrm{d}y=\int_{\mathbb{R}^3}\Delta V\frac{y-x}{|y-x|}\cdot\nabla V\,\mathrm{d}y,\end{aligned}$$

where we used

$$2\,\mathrm{Re}\{\partial_r(\overline{r\psi})rV\psi\}=\partial_r(r^2|\psi|^2)V\quad\text{and}\quad-|\psi(y,t)|^2=\Delta V.$$

Note that

$$\int_{\mathbb{R}^3}\Delta V\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\mathrm{d}y=\int_{\mathbb{R}^3}\nabla_j\nabla_jV\frac{y_i-x_i}{|y-x|}\nabla_iV(y,t)\mathrm{d}y.$$

On the other hand, if $i\neq j$ we have

$$\int_{\mathbb{R}^3}\nabla_j\nabla_jV\frac{y_i-x_i}{|y-x|}\nabla_iV(y,t)\mathrm{d}y=\int_{\mathbb{R}^3}\frac{(y_i-x_i)(y_j-x_j)}{|y-x|^3}\nabla_iV\nabla_jV+\frac{1}{2}\left(\frac{1}{|y-x|}-\frac{(y_i-x_i)^2}{|y-x|^3}\right)\nabla_jV\nabla_jV\,\mathrm{d}y.\tag{2.4}$$

If $i=j$, then

$$\int_{\mathbb{R}^3}\nabla_i\nabla_iV\frac{y_i-x_i}{|y-x|}\nabla_iV(y,t)\mathrm{d}y=\int_{\mathbb{R}^3}-\frac{1}{2}\left(\frac{1}{|y-x|}-\frac{(y_i-x_i)^2}{|y-x|^3}\right)\nabla_iV\nabla_iV\,\mathrm{d}y.\tag{2.5}$$

Adding (2.4) and (2.5) and considering $i,j=1,2,3$ we obtain

$$-\int_{\mathbb{R}^3}|\psi(y,t)|^2\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\mathrm{d}y=\int_{\mathbb{R}^3}\frac{1}{|y-x|}\left(\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\right)^2\mathrm{d}y.$$

(2) We use

$$\nabla_x\cdot\left(\frac{y-x}{|y-x|}\right)=-\frac{2}{|y-x|}$$

to find

$$\nabla_xM_x[\psi(t)]=\nabla_x\left(\int_{\mathbb{R}^3}\mathrm{Im}(\bar{\psi}(y,t)\,\nabla\,\psi(y,t))\cdot\frac{y-x}{|y-x|}\mathrm{d}y\right)=-2\int_{\mathbb{R}^3}\frac{1}{|y-x|}\,\mathrm{Im}(\bar{\psi}(y,t)\,\nabla\,\psi(y,t))\mathrm{d}y.$$

□

Remark 2.1: (1) *The above Morawetz interaction potential was introduced to simplify the well-known Morawetz-type estimate by Lin-Strauss*[22] *for the nonlinear Schrödinger equation in Ref. 9.*

(2) *The Morawetz interaction potential is in spirit similar to the interaction potentials*[4,8,16] *in*

classical kinetic theory. As described in Ref. 10 when u satisfies a defocusing nonlinear Schrödinger equation

$$iu_t + \Delta u = |u|^{p-1}u, \quad p > 1,$$

we can define Morawetz interaction potential more generally by $M^a(t) := \partial_t V^a$, *where*

$$V^a(t) := \int\int_{\mathbb{R}^3\times\mathbb{R}^3} T_{00}(t,x)T_{00}(t,y)a(x-y)\mathrm{d}x\,\mathrm{d}y$$

with mass density $T_{00}=|u|^2$ *for an arbitrary real valued function* $a(x)$. *We let* $a(x)=|x|$ *for the above Morawetz interaction potential* $M(t)$.

Since the linear Schrödinger equation is transformed to the linear transport equation through Wigner transformation,

$$f(x,v,t) = \frac{1}{(2\pi)^n}\int_{\mathbb{R}^3} e^{-iv\cdot y}u\left(x+\frac{y}{2},t\right)\bar{u}\left(x-\frac{y}{2},t\right)\mathrm{d}y,$$

and mass density $|u|^2$ *corresponds to* $\int f(x,v,t)\mathrm{d}v$ *in the phase space, we would define*

$$M^a(t) := \partial_t \underbrace{\int\int\int\int}_{\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}^3} f(x,v,t)f(y,v_*,t)a(x-y)\mathrm{d}v\,\mathrm{d}v_*\,\mathrm{d}x\,\mathrm{d}y$$

for a phase space density function f. *If* f *satisfies the Boltzmann equation*,

$$\partial_t f(x,v,t) + v\cdot\nabla_x f(x,v,t) = Q(f,f)(x,v,t),$$

we have

$$M^a(t) = \underbrace{\int\int\int\int}_{\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}^3} (v-v_*)\cdot b(x-y)f(x,v,t)f(y,v_*,t)\mathrm{d}v\,\mathrm{d}v_*\,\mathrm{d}x\,\mathrm{d}y$$

with $b(x)=\nabla_x a(x)$, *employing conservation of mass and momentum. If we let* $b(\cdot)=\chi_{x\geqslant 0}(\cdot)$ *for the one-dimensional case, we obtain the celebrating Bony's interaction potential for the one-dimensional Boltzmann model*,

$$I[f](t) = \underbrace{\int\int}_{y<x}\int\int_{\mathbb{R}\times\mathbb{R}} (v-v_*)f(x,v,t)f(y,v_*,t)\mathrm{d}y\,\mathrm{d}x\,\mathrm{d}v\,\mathrm{d}v_*,$$

which enjoys

$$\partial_t I[f](t) = \frac{1}{2}\int\int\int_{\mathbb{R}\times\mathbb{R}\times\mathbb{R}} (v-v_*)^2 f(x,v,t)f(y,v_*,t)\mathrm{d}x\,\mathrm{d}v\,\mathrm{d}v_*.$$

The interaction potentials $\mathcal{D}(f(t))$ *in Refs. 8 and 16 can be considered as a generalization of Bony's potential*.

Proposition 2.1: Let ψ *be a classical solution of (2.1) with finite mass and energy. Then we have*

$$(1)\quad \frac{\mathrm{d}M[\psi(t)]}{\mathrm{d}t} \geqslant 2\pi\int_{\mathbb{R}^3}|\psi(x,t)|^4\,\mathrm{d}x + \int\int_{\mathbb{R}^3\times\mathbb{R}^3}\frac{|\psi(x,t)|^2}{y-x}\left(\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\right)^2\mathrm{d}y\,\mathrm{d}x,$$

$$(2)\quad \int_0^\infty \int_{\mathbb{R}^3} |\psi(x,t)|^4 \,\mathrm{d}x\,\mathrm{d}t \leqslant \|\psi_0\|^3_{L^2(\mathbb{R}^3)} E(0).$$

Proof: (1) We use Lemma 2.2 to see

$$\begin{aligned}\frac{d}{\mathrm{d}t}M[t] &= \int_{\mathbb{R}^3} [(\partial_t|\psi(x,t)|^2)M_x[t] + |\psi(x,t)|^2\partial_t M_x[t]]\mathrm{d}x = \int_{\mathbb{R}^3} [(\partial_t|\psi(x,t)|^2)M_x[t] \\ &+ 2\pi\int_{\mathbb{R}^3} |\psi(x,t)|^4 \,\mathrm{d}x + \int\int_{\mathbb{R}^3\times\mathbb{R}^3} \frac{|\psi(x,t)|^2|\nabla_x\psi(y,t)|^2}{|y-x|}\mathrm{d}y\,\mathrm{d}x \\ &+ \int\int_{\mathbb{R}^3\times\mathbb{R}^3} \frac{|\psi(x,t)|^2}{|y-x|}\left(\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\right)^2 \mathrm{d}y\,\mathrm{d}x := \mathcal{J}_1[t] + \mathcal{J}_2[t] + \mathcal{J}_3[t] + \mathcal{J}_4[t].\end{aligned}$$

We next show

$$\mathcal{J}_1[t] + \mathcal{J}_3[t] \geqslant 0. \tag{2.6}$$

It follows from Lemma 2.1 that

$$\partial_t|\psi(x,t)|^2 = -\nabla_x\cdot(\mathrm{Im}[\bar{\psi}(x,t)\,\nabla\,\psi(x,t)]).$$

Then $\mathcal{J}_1[t]$ becomes

$$\mathcal{J}_1[t] = -\int\int_{\mathbb{R}^3\times\mathbb{R}^3} \nabla_x\cdot(\mathrm{Im}[\bar{\psi}(x,t)\nabla_x\psi(x,t)])\mathrm{Im}[\bar{\psi}(y)\nabla_x\psi(y,t)]\cdot\frac{y-x}{|y-x|}\mathrm{d}y\,\mathrm{d}x.$$

Define the momentum vector $\mathbf{P}(x,t)=\mathrm{Im}[\bar{\psi}(x,t)\nabla\psi(x,t)]$. We use integration by parts in y and the identity

$$\partial_{x_j}\left(\frac{y_i-x_i}{|y-x|}\right) = -\frac{\delta_{ji}}{|y-x|} + \frac{(y_j-x_j)(y_i-x_i)}{|y-x|^3}$$

to obtain

$$\begin{aligned}\mathcal{J}_1[t] &= -\int\int_{\mathbb{R}^3\times\mathbb{R}^3}\left[\mathbf{P}(x,t)\cdot\mathbf{P}(y,t) - \left(\mathbf{P}(x,t)\cdot\frac{y-x}{|y-x|}\right)\left(\mathbf{P}(y,t)\cdot\frac{y-x}{|y-x|}\right)\right]\frac{\mathrm{d}y\,\mathrm{d}x}{|y-x|} \\ &\geqslant -\int\int_{\mathbb{R}^3\times\mathbb{R}^3} |\psi(x,t)||\nabla_x\psi(x,t)||\psi(y,t)||\nabla_x\psi(y,t)|\frac{\mathrm{d}y\,\mathrm{d}x}{|y-x|}.\end{aligned}$$

We apply the inequality $|ab|\leqslant\frac{1}{2}(a^2+b^2)$ with $a=|\nabla_x\psi(x,t)||\psi(y,t)|$ and $b=|\psi(x,t)||\nabla_x\psi(y,t)|$ to see (2.6). Finally we have

$$\frac{d}{\mathrm{d}t}M[\psi(t)] \geqslant 2\pi\int_{\mathbb{R}^3}|\psi(x,t)|^4\,\mathrm{d}x + \int\int_{\mathbb{R}^3\times\mathbb{R}^3}\frac{|\psi(x,t)|^2}{|y-x|}\left(\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\right)^2\mathrm{d}y\,\mathrm{d}x.$$

(2) We integrate the above inequality from $t=0$ to $t=T$ to see

$$2\pi\int_0^T\int_{\mathbb{R}^3}|\psi(y,t)|^4\,\mathrm{d}y\,\mathrm{d}t \leqslant 2\sup_{t\in[0,T]}|M[\psi(t)]| \leqslant 2\|\psi_0\|^3_{L^2}E(0). \tag{2.7}$$

□

III. *A PRIORI* DISPERSION ESTIMATE

In this section, we present the proof of the Theorem 1.1 via Markowich's formalism between WP system and SP system and Morawetz's interaction potential in Sec. II.

Let w be the classical solutions to (1.1) with initial data satisfying the assumption of Theorem 1.1. Then we have

$$w(x,v,t)=\sum_{k=1}^{\infty}\lambda_k w[\psi_k],\quad \lambda_k\geqslant 0,$$

where $\psi_k(k=1,2,3,\ldots)$ is the solution of the Schrödinger-Poisson system

$$\begin{aligned} &i\partial_t\psi_k+\tfrac{1}{2}\Delta\psi_k=V\psi_k,\quad k\in\mathbb{N},\\ &\psi_k(x,t=0)=\varphi_k, \end{aligned} \tag{3.1}$$

where the electric potential V is defined by the Newtonian potential of n,

$$V=\frac{1}{4\pi}\int_{\mathbb{R}^3}\frac{n(y,t)}{|y-x|}\mathrm{d}y\quad\text{and } n(x,t)=\sum_{k=1}^{\infty}\lambda_k|\psi_k(x,t)|^2. \tag{3.2}$$

In the similar manner to the preceding section, we define a Morawetz interaction potential $\mathcal{M}[t]$ for (3.1),

$$\mathcal{M}[t]:=\sum_{k,m=1}^{\infty}\mathcal{M}_{km}[t],$$

$$\mathcal{M}_{km}[t]:=\int_{\mathbb{R}^3}(\lambda_k|\psi_k(x,t)|^2)(\lambda_m M_x[\psi_m(t)])\mathrm{d}x=\lambda_k\lambda_m\int_{\mathbb{R}^3}|\psi_k(x,t)|^2M_x[\psi_m(t)]\mathrm{d}x,$$

where $M_x[\psi_m(t)]$ is the functional defined in Sec. II. Then we have *a priori* estimates

$$|\mathcal{M}[t]|\leqslant\left(\sum_{k=1}^{\infty}\lambda_k\|\varphi_k\|^2_{L^2(\mathbb{R}^3)}\right)\left(\sum_{m=1}^{\infty}(\lambda_m\|\varphi_m\|^2_{L^2(\mathbb{R}^3)}+\lambda_m\|\nabla\varphi_m\|^2_{L^2(\mathbb{R}^3)})\right)\leqslant\left(\sum_{k=1}^{\infty}\lambda_k\|\varphi_k\|^2_{L^2(\mathbb{R}^3)}\right)E(0)<\infty. \tag{3.3}$$

Below we study the time evolution of $\mathcal{M}[t]$.

Lemma 3.1: Let $\psi_k,k=1,2,3,\ldots$ be a classical solutions of (3.1) decaying at infinity in x. Then we have

$$\begin{aligned} \frac{d}{\mathrm{d}t}\mathcal{M}[t]\geqslant{}&2\pi\sum_{k,m=1}^{\infty}\lambda_k\lambda_m\int_{\mathbb{R}^3}|\psi_k(x,t)|^2|\psi_m(x,t)|^2\,\mathrm{d}x\\ &+\sum_{k,m=1}^{\infty}\lambda_k\lambda_m\int\int_{\mathbb{R}^3\times\mathbb{R}^3}\frac{|\psi_k(x,t)|^2}{|y-x|}\left(\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\right)^2\mathrm{d}y\,\mathrm{d}x. \end{aligned}$$

Proof: Let $k,m\in\mathbf{N}$, then it follows from Proposition 2.1 that

$$\frac{d}{dt}\int_{\mathbb{R}^3}|\psi_k(x,t)|^2 M_x[\psi_m(t)]dx = \int_{\mathbb{R}^3}(\partial_t|\psi_k(x,t)|^2)M_x[\psi_m(t)]dx + \int_{\mathbb{R}^3}|\psi_k(x,t)|^2(\partial_t M_x[\psi_m(t)])dx$$

$$= \int_{\mathbb{R}^3}(\partial_t|\psi_k(x,t)|^2)M_x[\psi_m(t)]dx$$

$$+ \int\int_{\mathbb{R}^3\times\mathbb{R}^3}\frac{|\psi_k(x,t)|^2|\nabla_x\psi_m(y,t)|^2}{|y-x|}dy\,dx$$

$$+ 2\pi\int_{\mathbb{R}^3}|\psi_k(x,t)|^2|\psi_m(x,t)|^2\,dx$$

$$+ \int\int_{\mathbb{R}^3\times\mathbb{R}^3}\frac{|\psi_k(x,t)|^2}{|y-x|}\left(\frac{y-x}{|y-x|}\cdot\nabla V(y,t)\right)^2 dy\,dx.$$

We multiply the above inequality by $\lambda_k\lambda_m$ and sum up over k, m to find the desired result. □

The proof of Theorem 1.1: Define an interaction production functional $\Lambda[w]$ introduced in Ref. 8,

$$\Lambda[w(t)] := \int\int\int_{\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}^3} w(x,v,t)w(x,v_*,t)dv\,dv_*\,dx. \tag{3.4}$$

This can be regarded as functionals measuring *imaginary* collisions between quantum particles, although the physical situation is not clear unlike to the classical analogous case.[8] Then for given $T>0$, we have

$$\int_0^T\Lambda[w(t)]dt = \int_0^T\int\int\int_{\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}^3}\sum_{k,m=1}^{\infty}\lambda_k\lambda_m w[\psi_k](x,v,t)w[\psi_m](x,v_*,t)dv\,dv_*\,dx\,dt$$

$$= \sum_{k,m=1}^{\infty}\int_0^T\int_{\mathbb{R}^3}\lambda_k\lambda_m\int_{\mathbb{R}^3}w[\psi_k](x,v,t)dv\,dt\int_{\mathbb{R}^3}w[\psi_m](x,v_*,t)dv_*\,dx$$

$$= \sum_{k,m=1}^{\infty}\int_0^T\int_{\mathbb{R}^3}\lambda_k\lambda_m|\psi_k(x,t)|^2|\psi_m(x,t)|^2\,dx\,dt \leqslant \frac{1}{2\pi}(|\mathcal{M}[t]|+|\mathcal{M}[0]|)$$

$$\leqslant \left(\sum_{k=1}^{\infty}\lambda_k\|\psi_{k0}\|^2_{L^2(\mathbb{R}^3)}\right)E(0).$$

This completes the proof.

Remark 3.1: The computation in Secs. II and III is also valid assuming $\psi\in H^1(\mathbb{R}^3)$ for Hartree equation and $\psi_k\in H^1(\mathbb{R}^3)$, $k=1,2,3,\ldots$ such that $\{\psi_k:\Sigma_{k=1}^{\infty}\lambda_k\|\psi_k\|_{H^1(\mathbb{R}^3)}\}<\infty$ for the Schrödinger-Poisson system. In fact, the global well-posedness in $H^1(\mathbb{R}^3)$ space can be easily proved combining the energy conservation and the Stricharz estimate for the Schrödinger equation, as in the same manner in Ref. 6.

APPENDIX: ENERGY SCATTERING FOR HARTREE-TYPE EQUATIONS

In this section we provide a simpler proof of the scattering result of Refs. 14 and 27 for Hartree-type equations in dimension 3,

$$\begin{aligned} i\partial_t u + \tfrac{1}{2}\Delta u = (v * |u|^2)u, \quad x \in \mathbb{R}^3, \quad t > 0, \\ u(x,t=0) = u_0(x). \end{aligned} \tag{A1}$$

More precisely we obtain the same space-time estimate in Proposition 2.1 for (A1) to prove the asymptotic completeness part of the scattering result. The initial value problem of (A1) is globally well-posed for data $u_0 \in H^1(\mathbb{R}^3)$ if $v \in L^{p_1}+L^{p_2}$ with $1 \leqslant p_1 \leqslant p_2 \leqslant \infty$ (Ref. 14).

Lemma A.1: Let u be the classical solution of (A1) *with* $v \in L^{p_1}+L^{p_2}$, $1 \leqslant p_1 \leqslant p_2 \leqslant \infty$, *and* $v(x)=v(|x|)$. *If we define the Morawetz interaction potential for u by* (2.2), *then we have*

$$\begin{aligned} (1) \quad \frac{d}{dt}M_x[u(t)] &= 2\pi|u(x,t)|^2 + \int_{\mathbb{R}^3} \frac{|\nabla_x u(y,t)|^2}{|y-x|}\,dy \\ &\quad - \frac{1}{2}\int\int_{\mathbb{R}^3\times\mathbb{R}^3} v'(|y-z|)\frac{y-z}{|y-z|}\cdot\left(\frac{y-x}{|y-x|}-\frac{z-x}{|z-x|}\right)|u(y)|^2|u(z)|^2\,dz\,dy, \end{aligned}$$

$$\begin{aligned} (2) \quad \frac{dM[u(t)]}{dt} &\geqslant 2\pi\int_{\mathbb{R}^3}|u(x,t)|^4\,dx - \frac{1}{2}\underbrace{\int\int\int}_{\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}^3} v'(|y-z|)\frac{y-z}{|y-z|}\cdot\left(\frac{y-x}{|y-x|}-\frac{z-x}{|z-x|}\right) \\ &\quad \times|u(x)|^2|u(y)|^2|u(z)|^2\,dz\,dy\,dx. \end{aligned}$$

We note that if $v(|x|)$ *is nonincreasing in* $|x|$, *then the third terms in the item* (1), (2) *are nonnegative since* $v' \leqslant 0$ *and*

$$\frac{y-z}{|y-z|}\cdot\left(\frac{y-x}{|y-x|}-\frac{z-x}{|z-x|}\right) \geqslant 0.$$

Proof: We only need to modify the estimate of the quantity $\mathcal{I}_3$ in Lemma 2.2 as

$$\begin{aligned} 2\,\mathrm{Re}\int_0^\infty\int_{S^2}\partial_r(\overline{ru})rVu\,d\omega\,dr &= \int_0^\infty\int_{S^2}\partial_r(r^2|u|^2)V\,d\omega\,dr \\ &= \int_{\mathbb{R}^3}\frac{y-x}{|y-x|^3}\cdot\nabla(r^2|u|^2)V\,dy = -\int_{\mathbb{R}^3}|u|^2\frac{y-x}{|y-x|}\cdot\nabla V\,dy \\ &= -\int_{\mathbb{R}^3}|u(y)|^2\frac{y_i-x_i}{|y-x|}\int_{\mathbb{R}^3}v'(|y-z|)\frac{y_i-z_i}{|y-z|}|u(z)|^2\,dz\,dy \\ &= -\frac{1}{2}\int\int v'(|y-z|)\frac{y-z}{|y-z|}\cdot\left(\frac{y-x}{|y-x|}-\frac{z-x}{|z-x|}\right)|u(y)|^2|u(z)|^2\,dz\,dy. \end{aligned}$$

□

The energy defined by

$$E[t] := \int_{\mathbb{R}^3}|\nabla u|^2 + (v * |u|^2)|u|^2\,dx$$

and $\|u(t)\|_{L^2}$ are conserved for Eq. (A1). Therefore under the same condition in the above lemma, we have

$$\int_0^\infty \int_{\mathbb{R}^3} |u|^4(x,t)\mathrm{d}x\,\mathrm{d}t \leqslant M[u(t)] \leqslant \|u(0)\|_{L^2}^3 E[0] \tag{A2}$$

if $v(|x|)$ is non-negative and nonincreasing in $|x|$.

Theorem A.1: *Assume that a non-negative* $v \in L^{p_1}+L^{p_2}$ *satisfying* $1 \leqslant p_1 \leqslant p_2 < 3/2$ *and* $v(x)=v(|x|)$ *with* $v(|x|)$ *nonincreasing in* $|x|$. *Then there is scattering for* H^1 *solutions. Precisely, for any solution* u *of* (A1) *with* $u(0) \in H^1(\mathbb{R}^3)$, *there exists a solution* w *of the free Schrödinger equation with* $w(0) \in H^1(\mathbb{R}^3)$ *such that* $\|u(t)-w(t)\|_{H^1} \to 0$ *as* $t \to \infty$. *In other words, the equation is asymptotically complete in* $H^1(\mathbb{R}^3)$. *Moreover, the correspondence* $u(0) \mapsto w(0)$ *defines a homeomorphism in* $H^1(\mathbb{R}^3)$.

According to Sec. 4 in Ref. 14, asymptotic completeness will follow once we establish that the global solution belongs to $X^1(\mathbb{R})$, where

$$X^1(\mathbb{R}) = \{u : u \text{ and } \nabla u \in X(\mathbb{R})\},$$

$$X(\mathbb{R}) = \{u : u \in C(\mathbb{R},L^2) \text{ and } u \in L^q(\mathbb{R},L^r) \text{ for admissible pair } (q,r)\}.$$

We refer to (q,r) as the admissible pair when $q,r \geqslant 2$, and

$$\frac{1}{q}+\frac{3}{2r}=\frac{3}{4}.$$

We recall the Strichartz estimates of the Schrödinger equation in three space dimension.

Proposition A.1: Suppose that (q,r), $(\tilde{q},\tilde{r})$ *are any two Schrödinger admissible pairs as the above. Suppose that* $u(x,t)$ *is a solution of the problem*

$$i\partial_t u(x,t) + \Delta u(x,t) = F(x,t), \quad (x,t) \in \mathbb{R}^3 \times [0,T],$$

for some data $u(0)$ *and* $T>0$. *Then we have the estimate*

$$\|u\|_{L_t^q L_x^r([0,T]\times\mathbb{R}^3)} \lesssim \|u(0)\|_{L^2(\mathbb{R}^3)} + \|F\|_{L_t^{\tilde{q}'} L_x^{\tilde{r}'}([0,T]\times\mathbb{R}^3)}, \tag{A3}$$

where

$$\frac{1}{\tilde{q}}+\frac{1}{\tilde{q}'}=1, \quad \frac{1}{\tilde{r}}+\frac{1}{\tilde{r}'}=1.$$

Let us define $Z(t)$ as

$$Z(t) = \sup_{(q,r)\ \text{admissible}} \|\langle\nabla\rangle u\|_{L_t^q L_x^r([0,t]\times\mathbb{R}^3)}. \tag{A4}$$

$\langle A\rangle = (1+A^2)^{1/2}$, and $\langle\nabla\rangle^s$ for the operator with Fourier multiplier $(1+|\xi|^2)^{s/2}$. We omit the index in case that $s=1$.

We claim that

$$Z(t) \leqslant C(\|u(0)\|_{H^1})$$

and this will settle the asymptotic completeness. Following the same manner in Ref. 9, we can decompose thanks to (A2) the time interval $(0,\infty)$ into a finite number of disjoint intervals $J_1, J_2, \ldots, J_K$ where for $i=1,\ldots,K$ we have

$$\|u\|_{L_{x,t}^4(J_i\times\mathbb{R}^3)} \leqslant \delta \tag{A5}$$

for a constant δ depending only on $\|u(0)\|_{H1}$ to be chosen later.

Choosing $\tilde{q}', \tilde{r}' = \frac{10}{7}$, the estimate (A3) gives for all $t \in J_1$,

$$Z(t) \lesssim \|u(0)\|_{H^1(\mathbb{R}^3)} + \|(v * |u|^2)u\|_{L_{t,x}^{10/7}([0,t]\times\mathbb{R}^3)} + \|\nabla((v * |u|^2)u)\|_{L_{t,x}^{10/7}([0,t]\times\mathbb{R}^3)}.$$

In the following we assume $p_1=p_2=3/(2+\varepsilon)$ for some $\varepsilon \in (0,1]$ and denote both by p without loss of generality.

(i) Estimate of $\|(v*\nabla|u|^2)u\|_{L_{t,x}^{\frac{10}{7}}}$.

By using the Hölder and Young inequality, we have

$$\|(v * \nabla|u|^2)u\|_{L_{t,x}^{\frac{10}{7}}([0,t]\times\mathbb{R}^3)} \leqslant \|v * \nabla|u|^2\|_{L_{t,x}^{\frac{20}{9}}([0,t]\times\mathbb{R}^3)}\|u\|_{L_{t,x}^4([0,t]\times\mathbb{R}^3)}.$$

When $0<\varepsilon<\frac{1}{4}$,

$$\|v * \bigtriangledown |u|^2\|_{L_{t,x([0,t]\times\mathbb{R}^3)}^{\frac{20}{9}}} \leqslant \|v\|_{L_x^{\frac{3}{2+\epsilon}}}\left(\int \|u \bigtriangledown u\|_{L_x^{\frac{60}{47-20\epsilon}}}^{\frac{20}{9}} dt\right)^{\frac{9}{20}}$$

$$\leqslant C(\|v\|_{L_x^{\frac{3}{2+\epsilon}}}, \|\bigtriangledown u\|_{L_t^\infty L_x^2([0,t]\times R^3)})\left(\int \|u\|_{L_x^{\frac{60}{17-20\epsilon}}}^{\frac{20}{9}} dt\right)^{\frac{9}{20}}$$

$$\leqslant C(\|v\|_{L_x^{\frac{3}{2+\epsilon}}}, \|\bigtriangledown u\|_{L_t^\infty L_x^2}([0,t]\times R^3), \|u\|_{L_t^\infty L_x^{\frac{12}{1-4\epsilon}}([0,t]\times R^3)})\|u\|_{L_t^{\frac{20}{9}}L_x^5([0,t]\times R^3)}$$

When $\frac{1}{4}\leqslant\epsilon\leqslant 1$,

$$\|v * \bigtriangledown |u|^2\|_{L_{t,x}^{\frac{20}{9}}([0,t]\times\mathbb{R}^3)} \leqslant \|v\|_{L_x^{\frac{3}{2+\epsilon}}}\|\nabla u\|_{L_t^{\frac{20}{9}}L_t^5([0,t]\times\mathbb{R}^3)}\|u\|_{L_t^\infty L_x^{\frac{12}{7-4\epsilon}}([0,t]\times\mathbb{R}^3)}.$$

Note that $\|u\|_{L_t^\infty L_x^m([0,\infty])\times R^3)}$ is bounded by $\|u(0)\|_{L_x^2}$ and the energy for any $2\leqslant m<\infty$, and that $(\frac{20}{9},5)$ is admissible. Thus we have

$$\|(v * \nabla|u|^2)u\|_{L_{t,x}^{\frac{10}{7}}([0,t]\times\mathbb{R}^3)} \lesssim \delta\|v\|_{L_x^p}Z(t).$$

(ii) Estimate of $\|(v*|u|^2)\nabla u\|_{L_{t,x}^{10/7}([0,t]\times\mathbb{R}^3)}$.

By using the Hölder and Young inequality, we have

$$\|(v * |u|^2)\nabla u\|_{L_{t,x}^{10/7}([0,t]\times\mathbb{R}^3)} \leqslant \|v * |u|^2\|_{L_{t,x}^{5/2}([0,t]\times\mathbb{R}^3)}\|\nabla u\|_{L_{t,x}^{10/3}([0,t]\times\mathbb{R}^3)}$$

$$\leqslant \|v * |u|^2\|_{L_{t,x}^{5/2}([0,t]\times\mathbb{R}^3)}Z(t) \leqslant \|v\|_{L_x^p}\|u\|_{L_t^5 L_x^{2\tilde{p}}([0,t]\times\mathbb{R}^3)}^2 Z(t),$$

where

$$\frac{1}{p}+\frac{1}{\tilde{p}}-1=\frac{2}{5}.$$

Note that $\tilde{p}=15/(11-5\varepsilon)$. By L^p interpolation and Hölder inequality, we have

$$\|u\|_{L_t^5 L_x^{2\tilde{p}}} \leqslant \left(\int_0^t \|u\|_{L_4^{5a}}^{5a}\|u\|_{L_x^q}^{5(1-a)}\,\mathrm{d}t\right)^{1/5} \leqslant \|u\|_{L_t^{5ac}L_x^4([0,t]\times\mathbb{R}^3)}^a \|u\|_{L_t^{5(1-a)c'}L_x^q([0,t]\times\mathbb{R}^3)}^{(1-a)},$$

where

$$\frac{1}{2\tilde{p}}=\frac{a}{4}+\frac{1-a}{q}, \quad 0\leqslant a\leqslant 1, \quad \frac{1}{c}+\frac{1}{c'}=1.$$

If we let $5ac=4$,

$$\|u\|_{L_t^5 L_x^{2\bar{p}}} \leqslant \|u\|^a_{L^4_{t,x}([0,t]\times\mathbb{R}^3)} \|u\|^{(1-a)}_{L_t^{[20(1-a)]/(4-5a)} L_x^q([0,t]\times\mathbb{R}^3)} \quad \text{for } 0 < a \leqslant \tfrac{4}{5}.$$

The pair $([20(1-a)]/(4-5a), r)$ is admissible for $3/r = 1+1/[10(1-a)]$. On the other hand, the norm $\|u\|_{L_x^q}$ is bounded by Sobolev embedding,

$$\|u\|_{L_x^q} \leqslant \|\langle\nabla\rangle^s u\|_{L_x^r} \quad \text{for } s = \frac{3}{r} - \frac{3}{q}.$$

Since

$$\frac{1}{q} = \frac{11-5\varepsilon}{30(1-a)} - \frac{a}{4(1-a)},$$

we have

$$s = 1 - \frac{4-3a-2\varepsilon}{4(1-a)}.$$

We locate $s \in (0,1)$ if a is smaller than min $[(4-2\varepsilon)/3, 2\varepsilon]$ so that

$$\|(v * |u|^2)\nabla u\|_{L^{10/7}_{t,x}([0,t]\times\mathbb{R}^3)} \lesssim \|v\|_{L_x^p} \delta^{2a} Z(t)^{3-2a}.$$

Thus we have

$$\|(v * |u|^2)u\|_{L^{10/7}_{t,x}([0,t]\times\mathbb{R}^3)} + \|(v * |u|^2)\nabla u\|_{L^{10/7}_{t,x}([0,t]\times\mathbb{R}^3)} \lesssim \delta^{\epsilon_1} Z(t)^{1+\epsilon_2}$$

for $\epsilon_1, \epsilon_2 > 0$ and finally

$$Z(t) \lesssim \|u(0)\|_{H^1} + \delta\|v\|_{L_x^p} Z(t) + \delta^{\epsilon_1} Z(t)^{1+\epsilon_2}. \tag{A6}$$

For sufficiently small choice of δ, the bound (A6) yields

$$Z(t) \leqslant C(\|u(0)\|_{H^1})$$

for all $t \in J_1$. Since $\|u(t)\|_{H^1}$ is bounded by the initial energy, we may repeat this argument to cover the whole intervals. (Also see Refs. 1, 15, 20, 25, 28, and 33.)

We consider the thermal equilibrium distribution at inverse temperature β, or canonical ensemble, of the wave function Ψ of a quantum system. Since L^2 spaces contain more nondifferentiable than differentiable functions, and since the thermal equilibrium distribution is very spread out, one might expect that Ψ has probability zero to be differentiable. However, we show that for relevant Hamiltonians the contrary is the case: with probability 1, Ψ is infinitely often differentiable and even analytic. We also show that with probability 1, Ψ lies in the domain of the Hamiltonian. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2109767]

I. INTRODUCTION

We address the question whether the wave function Ψ of a typical system from the canonical ensemble of thermodynamics with inverse temperature β is differentiable. As pointed out in Ref. 7, the thermal equilibrium distribution of the wave function, corresponding to the canonical ensemble, is the "Gaussian adjusted projected measure" GAP(ρ), a probability measure on the unit sphere in Hilbert space whose definition we recall in Sec. II, for $\rho=\rho_\beta$, the density matrix of the canonical ensemble, given by (see, e.g., Refs. 8 and 10)

$$\rho_\beta = \frac{1}{Z(\beta,H)} \mathrm{e}^{-\beta H}, \text{ with } Z(\beta,H) = \mathrm{Tr}\, \mathrm{e}^{-\beta H}. \tag{1}$$

Thus, we take Ψ to be a random unit vector with distribution GAP(ρ_β). The surprising result is that in many relevant cases Ψ has probability 1 to be infinitely often differentiable and even analytic, i.e., $\mathrm{GAP}(\rho_\beta)(C^\infty)=\mathrm{GAP}(\rho_\beta)(C^\omega)=1$.

We explore four kinds of arguments concerning the smoothness of Ψ, each requiring somewhat different assumptions on the Hamiltonian H and leading to somewhat different conclusions. Some of the arguments do not depend on the special measure GAP(ρ_β) but show that, for suitable Hamiltonians H, every distribution whose density matrix is ρ_β will be concentrated on the smooth (respectively, analytic) functions; other arguments use the way the measure GAP(ρ) is constructed from a Gaussian measure. The measure GAP(ρ) is discussed in detail in Ref. 7. It has density matrix ρ and is stationary if ρ is.

The first argument aims at showing that the Fourier coefficients of Ψ go to zero so fast that they are still square summable after multiplication by any power of the wave number k. This can be easily applied to cases in which the eigenfunctions of H are plane waves, such as for the free Schrödinger equation in a box. The second argument is based on the assumption that the eigenfunctions of H are smooth, and the theorem asserting that, for a series of functions, summation and differentiation commute if the series of the derivatives converges uniformly. We formulate a condition on H that entails this kind of convergence almost surely (a.s.) for the expansion of Ψ in

[a)]Electronic mail: tumulka@everest.mathematik.uni-tuebingen.de
[b)]Electronic mail: zanghi@ge.infn.it

eigenfunctions of H. The third argument, which supposes that Ψ is a function on an interval $I \subseteq \mathbb{R}$, aims at showing that the increments are not too large, $|\Psi(q+\Delta q)-\Psi(q)| \lesssim \Delta q$, which suggests differentiability; however, the rigorous version of this argument provides only a very weak result. The fourth argument, the simplest and most elegant one, is of a more abstract nature: it concerns not the question $\Psi \in C^\infty$ but instead the related question $\Psi \in \mathrm{domain}(H^\ell)$ for $\ell \in \mathbb{N}$; indeed, we obtain without further assumptions on H that a.s. $\Psi \in C^\infty(H) := \cap_{\ell=1}^\infty \mathrm{domain}(H^\ell)$ for almost all β for which thermal equilibrium exists at all. We also provide a variant of this argument concerning the space of analytic vectors of H.

The paper is organized as follows. In Sec. II, we recall from Ref. 7 the definition of the measure $\mathrm{GAP}(\rho_\beta)$ representing the canonical ensemble. In Sec. III, we study as an example of H the Laplacian on the circle. We conclude smoothness and analyticity of Ψ from an analysis of the decay behavior of the Fourier coefficients of Ψ. In Sec. IV, we apply the same argument to the (relativistic or nonrelativistic) ideal gas in a box. In Sec. V, we take into account the symmetrization of the wave function for describing bosons or fermions. In Sec. VI, we give the second kind of argument, providing a general criterion on the Hamiltonian that is sufficient for concluding that Ψ is a.s. smooth. The criterion concerns bounds on the derivatives of the eigenfunctions of H. In Sec. VII, we discuss the third argument, which concerns the direct estimation of the difference quotients of Ψ. In Sec. VIII, we describe the fourth argument, which allows to conclude that Ψ lies in the domain of H and all its powers. In Sec. IX, we conclude, as an application of our results, that Ψ a.s. possesses a Bohmian velocity field.

II. CANONICAL ENSEMBLE

In this section we give the definition of the measure $\mathrm{GAP}(\rho)$ on the unit sphere $\mathcal{S}(\mathcal{H})$ of Hilbert space $\mathcal{H}$, as introduced in Ref. 7.

The measure $\mathrm{GAP}(\rho)$ is defined for every density matrix ρ (positive operator with $\mathrm{Tr}\rho=1$) on $\mathcal{H}$. We obtain the thermal equilibrium measure $\mathrm{GAP}(\rho_\beta)$ by using the canonical density matrix (1) for a self-adjoint operator H (the Hamiltonian) and a number $\beta>0$ (the inverse temperature) such that

$$Z(\beta,H) = \mathrm{Tr}\ \mathrm{e}^{-\beta H} < \infty. \tag{2}$$

The measure $\mathrm{GAP}(\rho)$ is defined as the distribution of the random vector

$$\Psi^{\mathrm{GAP}} = \Psi^{\mathrm{GA}}/\|\Psi^{\mathrm{GA}}\|, \tag{3}$$

where Ψ^{GA} is a random vector with distribution $\mathrm{GA}(\rho)$ (the "Gaussian adjusted measure") defined by

$$\mathrm{GA}(\rho)(\mathrm{d}\psi) = \|\psi\|^2 G(\rho)(\mathrm{d}\psi), \tag{4}$$

where $G(\rho)$ is the Gaussian measure on $\mathcal{H}$ with covariance matrix ρ.

More explicitly, for a random vector Ψ^G to be $G(\rho)$-distributed means that for any $\phi_1, \phi_2 \in \mathcal{H}$ the components $Z_1=\langle\phi_1|\Psi^G\rangle$ and $Z_2=\langle\phi_2|\Psi^G\rangle$ of Ψ^G are complex Gaussian random variables with mean zero and covariance

$$\mathbb{E}Z_1Z_2^* = \mathbb{E}\langle\phi_1|\Psi^G\rangle\langle\Psi^G|\phi_2\rangle = \langle\phi_1|\rho|\phi_2\rangle, \tag{5}$$

where $\mathbb{E}$ denotes expectation. In particular, if $\{|\varphi_n\rangle\}$ is an orthonormal basis of $\mathcal{H}$ consisting of eigenvectors of ρ with eigenvalues p_n, then the coefficients $\langle\varphi_n|\Psi^G\rangle$ of Ψ^G are independent complex Gaussian random variables with mean zero and variances

$$\mathbb{E}|\langle\varphi_n|\Psi^G\rangle|^2 = p_n. \tag{6}$$

If ρ is of the form (1) then the φ_n are also eigenvectors of H.

Although we are interested only in those ρ of the form (1) for physically relevant Hamiltonians, we will sometimes, when this makes the mathematics clearer and more elegant, formulate facts or conditions in terms of an arbitrary density matrix ρ.

For any probability measure μ on $\mathcal{S}(\mathcal{H})$, its density matrix is given by

$$\rho_\mu = \int_{\mathcal{S}(\mathcal{H})} \mu(\mathrm{d}\psi)|\psi\rangle\langle\psi|, \tag{7}$$

or $\rho_\mu = \mathbb{E}_\mu|\psi\rangle\langle\psi|$, where $\mathbb{E}_\mu$ denotes the expectation with respect to μ. In particular, $\mathbb{E}_\mu|\langle\varphi|\psi\rangle|^2 = \langle\varphi|\rho_\mu|\varphi\rangle$ for every fixed $\varphi \in \mathcal{H}$. [If a probability measure μ on $\mathcal{H}$ is not concentrated on $\mathcal{S}(\mathcal{H})$, the notion of density matrix of μ does not make sense any more; however (7), or $\mathbb{E}_\mu|\psi\rangle\langle\psi|$, is still the *covariance matrix* of μ.] As mathematically expressed by $\mathbb{E}_\mu\langle\psi|P|\psi\rangle = \mathrm{Tr}(\rho_\mu P)$ for every projection P, ρ_μ provides the distribution of outcomes of any quantum experiment on a system with μ-distributed random wave function. The density matrix of GAP(ρ) is indeed ρ. This and other fundamental properties of the measure GAP(ρ) are discussed in Ref. 7.

The following simple fact will sometimes be useful, as it reduces the task of showing smoothness of $\Psi = \Psi^{\mathrm{GAP}}$ to showing smoothness of the Gaussian random vector Ψ^G with distribution $G(\rho)$. For any subspace W of $\mathcal{H}$, we have that

$$\text{if } G(\rho)(W) = 1 \text{ then } \mathrm{GAP}(\rho)(W) = 1. \tag{8}$$

To see this, note that GA(ρ) has the same null sets as $G(\rho)$ [as it is absolutely continuous with respect to $G(\rho)$ with a density that vanishes only at one point], so that, if $G(\rho)(W)=1$, $0=G(\rho)(\mathcal{H}\backslash W)=\mathrm{GA}(\rho)(\mathcal{H}\backslash W)$and thus $\mathrm{GA}(\rho)(W)=1$; but, by definition (3), if $\Psi^{\mathrm{GA}} \in W$ then also $\Psi^{\mathrm{GAP}} \in W$.

III. CASE STUDY: LAPLACIAN ON THE CIRCLE

In this section we consider a single particle moving on a circle S^1 with the free Schrödinger Hamiltonian

$$H = -\frac{\hbar^2}{2m}\frac{\partial^2}{\partial q^2}, \tag{9}$$

where m denotes the mass of the particle, q the angular coordinate on the circle, and wave functions are written as periodic functions of q. The result we derive is that relative to any measure μ on $\mathcal{S}(\mathcal{H})$ with density matrix ρ_β with $\beta > 0$ (or, in fact, any measure μ on $\mathcal{H}$ with covariance matrix ρ_β), almost every wave function ψ is smooth, $\psi \in C^\infty(\mathbb{R})$; we then go on to show that μ-almost every wave function is analytic, $\psi \in C^\omega(\mathbb{R})$.

We begin with considering, instead of differentiability, a closely related property: existence (in L^2) of the distributional derivative. In other words, we consider the property of a wave function ψ that $|k|\hat{\psi}(k)$ is still square integrable, where $\hat{\psi}$ is the Fourier transform of ψ. Since the functions we are considering are 2π-periodic in q, the appropriate property is that the Fourier coefficients c_k, defined by

$$\psi(q) = \sum_{k\in\mathbb{Z}} c_k \mathrm{e}^{\mathrm{i}kq}, \tag{10}$$

are still square summable after multiplication with $|k|$. Let W^ℓ denote the ℓth Sobolev space, i.e., the subspace of $L^2([0,2\pi])$ containing those functions whose Fourier coefficients c_k satisfy

$$|k|^\ell c_k \text{ is square summable, i.e., } \sum_{k\in\mathbb{Z}} |k|^{2\ell}|c_k|^2 < \infty. \tag{11}$$

We ask whether $\psi \in W^\ell$ for a random wave function ψ with distribution μ. Since the eigenfunctions of H are the plane waves

$$\varphi_n(q) = \frac{1}{\sqrt{2\pi}} e^{inq}, \quad n \in \mathbb{Z}, \tag{12}$$

the energy coefficients of a wave function are just the Fourier coefficients. The eigenvalues are

$$E_n = \frac{\hbar^2}{2m} n^2, \quad n \in \mathbb{Z}. \tag{13}$$

Thus, our question about ψ amounts to asking for which $\ell \in \mathbb{N}$ we have

$$\sum_{n\in\mathbb{Z}} n^{2\ell} |\langle \varphi_n | \psi \rangle|^2 < \infty. \tag{14}$$

This indeed holds μ-a.s. for all $\ell \in \mathbb{N}$ for every probability measure μ on $\mathcal{S}(\mathcal{H})$ with density matrix ρ_β; to see this, note that (with numbers on top of equality signs indicating which equation is being applied)

$$\mathbb{E}_\mu \sum_{n\in\mathbb{Z}} n^{2\ell} |\langle \varphi_n | \psi \rangle|^2 = \sum_{n\in\mathbb{Z}} n^{2\ell} \mathbb{E}_\mu |\langle \varphi_n | \psi \rangle|^2 \tag{15a}$$

$$\overset{(7)}{=} \sum_{n\in\mathbb{Z}} n^{2\ell} \frac{e^{-\beta E_n}}{Z(\beta,H)} \overset{(13)}{=} \frac{1}{Z(\beta,H)} \sum_{n\in\mathbb{Z}} n^{2\ell} e^{-(\beta\hbar^2/2m)n^2} < \infty, \tag{15b}$$

because for any constant $\gamma > 0$ and for sufficiently large $|n|$

$$(2\ell+2)\log|n| < \gamma |n|^2 \text{ and thus } |n|^{2\ell} e^{-\gamma|n|^2} < \frac{1}{|n|^2}. \tag{16}$$

If the expectation (15) of a $[0,\infty]$-valued random variable is finite, the variable is a.s. finite. Thus

$$\mu\left(\sum_{n\in\mathbb{Z}} n^{2\ell} |\langle \varphi_n | \psi \rangle|^2 = \infty \right) = 0 \text{ or } \mu(W^\ell) = 1, \tag{17}$$

for all $\ell \in \mathbb{N}$.

We now make the connection between W^ℓ and C^ℓ, i.e., with classical differentiability: by the Sobolev lemma (Ref. 9, p. 52), every function in W^ℓ is equal Lebesgue-almost-everywhere to a function in $C^{\ell-1}$. Hence, every function in $\cap_{\ell=1}^\infty W^\ell$ is equal Lebesgue-almost-everywhere to a function in C^∞. In particular, μ-a.s. there is a $\phi \in C^\infty$ such that $\psi(q) = \phi(q)$ Lebesgue-almost-everywhere.

We now turn to analyticity. By a similar argument as given in (15) and (16), one can see that

$$\mu\left(\sum_{n\in\mathbb{Z}} e^{2\alpha|n|} |\langle \varphi_n | \psi \rangle|^2 = \infty \right) = 0, \tag{18}$$

for every $\alpha > 0$, so that

$$e^{\alpha|k|} c_k \text{ is a.s. square summable.} \tag{19}$$

Regarding the variable q in (10) as complex, we observe that the right-hand side of (10) converges, as a consequence of (19), uniformly in every strip $-\alpha+\varepsilon < \operatorname{Im} q < \alpha-\varepsilon$ with $0 < \varepsilon < \alpha$. (To see this, we use that square-summable sequences are bounded, $e^{\alpha|k|}|c_k| \leqslant C$, so that for q in the strip, $|c_k e^{ikq}| = |c_k| e^{-k \operatorname{Im} q} < |c_k| e^{|k|(\alpha-\varepsilon)} \leqslant C e^{-|k|\varepsilon}$, which is summable over $k \in \mathbb{Z}$.) Since the uniform limit of analytic functions on an open set in the complex plane is analytic (by virtue of the Cauchy integral formula), ψ is analytic in the strip $-\alpha < \operatorname{Im} q < \alpha$; since α was arbitrary, ψ is entire (i.e., analytic on the whole complex plane). More precisely, μ-a.s. there is an entire function ϕ such that $\psi(q) = \phi(q)$ Lebesgue-almost-everywhere in $\mathbb{R}$.

IV. IDEAL GAS IN A BOX

In a similar way, we can treat any Hamiltonian whose eigenfunctions are plane waves. A particularly relevant case is that of the ideal gas: N noninteracting particles in a d-dimensional box $[0,\pi]^d$ with Hamiltonian

$$H = -\sum_{i=1}^{N} \frac{\hbar^2}{2m}\Delta_i, \tag{20}$$

with Dirichlet boundary conditions, where Δ_i is the Laplacian acting on the coordinates of the ith particle. Our conclusion will again be that $\mu(C^\infty)=\mu(C^\omega)=1$ for every measure μ on $\mathcal{H}$ whose covariance matrix is ρ_β, and in particular for $\mu=\mathrm{GAP}(\rho_\beta)$. For the moment, we ignore the symmetrization postulate; we will treat bosons and fermions in Sec. V.

The Hamiltonian H on $\mathcal{H}=L^2([0,\pi]^{Nd})$ has eigenfunctions (Ref. 3 p. 78)

$$\varphi_n(q) = \left(\frac{2}{\pi}\right)^{Nd/2} \prod_{i=1}^{N}\prod_{a=1}^{d} \sin(n_{i,a}q_{i,a}), \tag{21}$$

where $n=(n_{1,1},\ldots,n_{N,d})\in\mathbb{N}^{Nd}$ and $q=(q_{1,1},\ldots,q_{N,d})\in[0,\pi]^{Nd}$, and eigenvalues

$$E_n = \sum_{i=1}^{N}\sum_{a=1}^{d} \frac{\hbar^2}{2m} n_{i,a}^2 = \frac{\hbar^2}{2m}\|n\|^2. \tag{22}$$

The right-hand side of (21) extends in an obvious way to a function on $\mathbb{R}^{Nd}$ that is 2π-periodic in every variable, which we also call φ_n; using the coefficients $\langle\varphi_n|\psi\rangle$ of the energy expansion we have a natural extension of any $\psi\in\mathcal{H}$ to a function ϕ on $\mathbb{R}^{Nd}$ that is 2π-periodic in every variable, $\phi=\Sigma_n\langle\varphi_n|\psi\rangle\varphi_n$. Its Fourier coefficients are

$$c_k = (-i)^{Nd}\left(\prod_{i=1}^{N}\prod_{a=1}^{d}\mathrm{sign}(k_{i,a})\right)\langle\varphi_{|k_{1,1}|,\ldots,|k_{N,d}|}|\psi\rangle, \tag{23}$$

where $k=(k_{1,1},\ldots,k_{N,d})\in\mathbb{Z}^{Nd}$ and we set $\mathrm{sign}(0)=0$.

We begin with the existence in L^2 of the ℓ-fold distributional derivative. We assert that μ-a.s. for all $\ell\in\mathbb{N}$

$$\sum_{k\in\mathbb{Z}^{Nd}} \|k\|^{2\ell}|c_k|^2 < \infty. \tag{24}$$

This follows from

$$\mathbb{E}_\mu \sum_{k\in\mathbb{Z}^{Nd}} \|k\|^{2\ell}|c_k|^2 = 2^{Nd}\sum_{n\in\mathbb{N}^{Nd}} \|n\|^{2\ell}\mathbb{E}_\mu|\langle\varphi_n|\psi\rangle|^2 \tag{25a}$$

$$\overset{(7)}{=} \frac{2^{Nd}}{Z(\beta,H)}\sum_{n\in\mathbb{N}^{Nd}} \|n\|^{2\ell}\mathrm{e}^{-\beta E_n} \overset{(22)}{=} \frac{2^{Nd}}{Z(\beta,H)}\sum_{n\in\mathbb{N}^{Nd}} \|n\|^{2\ell}\mathrm{e}^{-(\beta\hbar^2/2m)\|n\|^2} \tag{25b}$$

$$\overset{(26)}{\leqslant} \frac{2^{Nd}}{Z(\beta,H)}\sum_{n\in\mathbb{N}^{Nd}} (1+n_{1,1})^{2\ell}\cdots(1+n_{N,d})^{2\ell}\mathrm{e}^{-(\beta\hbar^2/2m)\|n\|^2} \tag{25c}$$

$$= \frac{1}{Z(\beta,H)} \left(2 \sum_{\nu \in \mathbb{N}} (1+\nu)^{2\ell} \mathrm{e}^{-(\beta\hbar^2/2m)\nu^2} \right)^{Nd} \overset{(16)}{<} \infty, \tag{25d}$$

where we used

$$\|n\|^2 = \sum_{i,a} n_{i,a}^2 \leqslant \prod_{i,a} (1 + 2n_{i,a} + n_{i,a}^2) = \prod_{i,a} (1+n_{i,a})^2. \tag{26}$$

Inequality (24) means that ϕ lies in the Sobolev space W^ℓ, and by the Sobolev lemma (Ref. 9, p. 52) also in C^m for all $m < \ell - Nd/2$. Since ℓ was arbitrary, ϕ is μ-a.s. smooth, and thus so is ψ, its restriction to $[0,\pi]^{Nd}$.

The same argument can be applied to the relativistic case, in which the Hamiltonian is the free Dirac operator

$$H = -\sum_{i=1}^{N} (\mathrm{i}c\hbar\, \alpha_i \cdot \nabla_i + mc^2 \beta_i), \tag{27}$$

with c the speed of light, m the mass, and α_i and β_i the Dirac alpha and beta matrices acting on the ith spin index of the wave function. Again, one obtains that $\mu(C^\infty)=1$ for all μ with covariance matrix ρ_β.

We turn to analyticity, and to this end assert that μ-a.s. for all $\alpha > 0$

$$\sum_{k \in \mathbb{Z}^{Nd}} \mathrm{e}^{2\alpha\|k\|} |c_k|^2 < \infty. \tag{28}$$

This follows from the fact that, by the same reasoning as in (25),

$$\mathbb{E}_\mu \sum_{k \in \mathbb{Z}^{Nd}} \mathrm{e}^{2\alpha\|k\|} |c_k|^2 = \frac{2^{Nd}}{Z(\beta,H)} \sum_{n \in \mathbb{N}^{Nd}} \mathrm{e}^{2\alpha\|n\|} \mathrm{e}^{-(\beta\hbar^2/2m)\|n\|^2} < \infty,$$

because for any constant $\gamma > 0$ and for all but finitely many $n \in \mathbb{N}^{Nd}$, $2\alpha\|n\| - \gamma\|n\|^2 < -(\gamma/2)\|n\|^2$, while $\mathrm{e}^{-(\gamma/2)\|n\|^2}$ is summable over $\mathbb{N}^{Nd}$ by (16). By the same argument as in the last paragraph of Sec. III, one can conclude from (28) that ϕ is analytic in the cylinder $\{q \in \mathbb{C}^{Nd} : \|\mathrm{Im}\, q\| < \alpha\}$. Since α was arbitrary, ϕ is entire. Thus, μ-a.s. there is an entire function ϕ such that $\psi(q) = \phi(q)$ Lebesgue-almost-everywhere in $[0,\pi]^{Nd}$. (For the Dirac equation, since the energy eigenvalues grow like $c\hbar\|k\|$, ψ a.s. possesses an analytic continuation to the cylinder $\|\mathrm{Im}\, q\| < \beta c\hbar/2$.)

V. BOSONS AND FERMIONS

In the previous section, we ignored the symmetrization of the wave function for systems of bosons or fermions. If one takes the symmetrization into account, one reaches the same conclusion: smoothness is almost sure. But, instead of going through the calculation of the previous section again, we provide a simple argument why GAP(ρ_β) must be concentrated on C^∞ for indistinguishable particles (with symmetrized wave functions) if it is concentrated on C^∞ for distinguishable particles (with unsymmetrized wave functions).

The symmetric (respectively, antisymmetric) state vectors form a subspace of $\mathcal{H} = L^2([0,\pi]^{Nd})$; let P denote the projection to that subspace; the subspace can be written $P\mathcal{H}$. Since the Hamiltonian (20) is invariant under permutations, we have that $HP = PH = PHP$. Thus, the canonical density matrix for indistinguishable particles is

$$\rho_\beta(PH, P\mathcal{H}) = cP\rho_\beta(H,\mathcal{H})P, \tag{29}$$

where we have made explicit the dependence of ρ_β on the given Hamiltonian and Hilbert space, and $c = Z(\beta,H)/Z(\beta,PHP)$.

Now, observe that for a Gaussian measure with covariance ρ, we have that $G(P\rho P)=G(\rho)\circ P^{-1}$, where P^{-1} is understood as mapping subsets of $P\mathcal{H}$ to their preimages in $\mathcal{H}$, in other words $\Psi^{G(P\rho P)}=P\Psi^{G(\rho)}$ in distribution.

In our case, P is the symmetrization (respectively, antisymmetrization) operator, which maps smooth functions to smooth functions. Since Ψ^G is a.s. smooth (by the result of the previous section), so is $P\Psi^G$; with (8) we conclude that $\mathrm{GAP}(\rho_\beta(PH,P\mathcal{H}))(C^\infty)=1$. The same argument works with analyticity.

VI. GENERAL SUFFICIENT CONDITION FOR SMOOTHNESS

We now present a second kind of argument, different from the one used in the previous sections; it applies to the measure $\mathrm{GAP}(\rho)$ but not to all measures with density matrix ρ. The argument provides us with a condition [see (30) below] on any given density matrix ρ (and thus, for $\rho=\rho_\beta$, on the Hamiltonian) ensuring that $\mathrm{GAP}(\rho)(C^\infty)=1$.

Theorem 1: *Let $\mathcal{Q}$ be an open subset of $\mathbb{R}^d$. Suppose that the density matrix ρ on $\mathcal{H}=L^2(\mathcal{Q},\mathbb{C}^m)$ has C^∞ eigenfunctions $\varphi_n(q)$ with $\|\varphi_n\|=1$ and eigenvalues p_n, such that for all n and all $\ell=0,1,2,3,\ldots$, the ℓth derivative of φ_n is bounded*

$$\|\nabla^\ell\varphi_n\|_\infty=\sup_{q\in\mathcal{Q}}|\nabla^\ell\varphi_n(q)|<\infty,$$

where by absolute values we mean

$$|\nabla^\ell\psi(q)|^2=\sum_{i_1,\ldots,i_\ell=1}^{d}\sum_{s=1}^{m}\left|\frac{\partial^\ell\psi_s}{\partial q_{i_1}\cdots\partial q_{i_\ell}}(q)\right|^2.$$

If for all $\ell=0,1,2,3,\ldots$

$$\sum_n\|\nabla^\ell\varphi_n\|_\infty\sqrt{p_n}<\infty, \tag{30}$$

then $\mathrm{GAP}(\rho)(C^\infty(\mathcal{Q},\mathbb{C}^m))=1$.

Proof: To begin with, for a complex Gaussian random variable Z with $\mathbb{E}Z=0$ and $\mathbb{E}|Z|^2=\sigma^2$, one can determine that

$$\mathbb{E}|Z|=\int_{\mathbb{R}^2}\mathrm{d}x\,\mathrm{d}y\frac{\sqrt{x^2+y^2}}{\pi\sigma^2}\exp\left(-\frac{x^2+y^2}{\sigma^2}\right)=\frac{\sqrt{\pi}}{2}\sigma. \tag{31}$$

Setting $Z=\langle\varphi_n|\Psi^G\rangle$, we obtain that

$$\mathbb{E}\sum_n\|\nabla^\ell\varphi_n\langle\varphi_n|\Psi^G\rangle\|_\infty=\mathbb{E}\sum_n|\langle\varphi_n|\Psi^G\rangle|\|\nabla^\ell\varphi_n\|_\infty=\sum_n\mathbb{E}|\langle\varphi_n|\Psi^G\rangle|\|\nabla^\ell\varphi_n\|_\infty\overset{(31)}{=}\sum_n\frac{\sqrt{\pi}}{2}\sqrt{p_n}\|\nabla^\ell\varphi_n\|_\infty\overset{(30)}{<}\infty,$$

and therefore

$$\mathrm{Prob}\left(\sum_n\|\nabla^\ell\varphi_n\langle\varphi_n|\Psi^G\rangle\|_\infty<\infty\right)=1.$$

Since this is true of every ℓ, we have that in the expansion

$$\Psi^G(q)=\sum_n\varphi_n(q)\langle\varphi_n|\Psi^G\rangle \tag{32}$$

(having C^∞ partial sums), a.s. the ℓ*th* derivatives of the partial sums converge uniformly; and in particular (32) itself converges uniformly. It is a standard theorem (see, e.g., Ref. 4, p. 118) that, if a sequence f_n of functions converges pointwise and the derivatives ∇f_n uniformly, then the limit

function f is differentiable and has derivative $\nabla f = \lim \nabla f_n$. Therefore, a.s. $\Psi^G \in C^\infty(\mathcal{Q})$, and the derivatives are

$$\nabla^\ell \Psi^G(q) = \sum_n \nabla^\ell \varphi_n(q) \langle \varphi_n | \Psi^G \rangle. \tag{33}$$

By (8), a.s. $\Psi^{\mathrm{GAP}} \in C^\infty(\mathcal{Q})$, which completes the proof. □

By applying this proof to local coordinates, we can generalize the result to Riemannian manifolds and vector bundles as follows. *Let $\mathcal{Q}$ be a Riemannian C^∞ manifold, E a C^∞ complex vector bundle over $\mathcal{Q}$ with positive-definite C^∞ Hermitian inner products on the fiber spaces, and let ∇ be the covariant derivative operator corresponding to a C^∞ connection on E. Let $\mathcal{H} = L^2(E)$ be the Hilbert space of square-integrable (with respect to the Riemannian volume) measurable cross sections of E, and $C^\infty(E)$ the space of smooth cross sections. Suppose that the density matrix ρ on $\mathcal{H}$ has C^∞ eigen-cross sections $\varphi_n(q)$ with $\|\varphi_n\| = 1$ and eigenvalues p_n, such that for all n and all $\ell = 0, 1, 2, 3, \ldots$, the ℓth covariant derivative of φ_n is bounded*

$$\|\nabla^\ell \varphi_n\|_\infty = \sup_{q \in \mathcal{Q}} |\nabla^\ell \varphi_n(q)| < \infty, \tag{34}$$

where the absolute values are taken with respect to the Riemannian inner product on tangent spaces and the Hermitian inner product on fiber spaces. If for all $\ell = 0, 1, 2, 3, \ldots$

$$\sum_n \|\nabla^\ell \varphi_n\|_\infty \sqrt{p_n} < \infty, \tag{35}$$

then $\mathrm{GAP}(\rho)(C^\infty(E)) = 1$.

Another easy generalization of Theorem 1 concerns analyticity: *Let $\mathcal{Q}_{\mathbb{C}}$ be an open subset of $\mathbb{C}^d$ and $\mathcal{Q} := \{(q_1, \ldots, q_d) \in \mathcal{Q}_{\mathbb{C}} : q_1, \ldots, q_d \in \mathbb{R}\} \subseteq \mathbb{R}^d$. Suppose that the density matrix ρ on $\mathcal{H} = L^2(\mathcal{Q}, \mathbb{C}^m)$ has eigenvalues p_n with normalized eigenvectors $\varphi_n \in C^\omega(\mathcal{Q}_{\mathbb{C}})$, with $C^\omega(\mathcal{Q}_{\mathbb{C}})$ the space of L^2 functions on $\mathcal{Q}$ that possess analytic continuations to $\mathcal{Q}_{\mathbb{C}}$. If for every compact set $K \subseteq \mathcal{Q}_{\mathbb{C}}$*

$$\sum_n \|\varphi_n|_K\|_\infty \sqrt{p_n} < \infty \tag{36}$$

(writing also φ_n for the analytic continuation and $\varphi_n|_K$ for its restriction to K), then $\mathrm{GAP}(\rho)(C^\omega(\mathcal{Q}_{\mathbb{C}})) = 1$.

Proof: By (36) and (31)

$$\mathbb{E} \sum_n \|\varphi_n|_K\|_\infty |\langle \varphi_n | \Psi^G \rangle| = \sum_n \|\varphi_n|_K\|_\infty \frac{\sqrt{\pi}}{2} \sqrt{p_n} < \infty,$$

and thus a.s. $\Sigma_n \|\varphi_n|_K\|_\infty |\langle \varphi_n | \Psi^G \rangle| < \infty$. As a consequence, the expansion

$$\Psi^G(q) = \sum_n \varphi_n(q) \langle \varphi_n | \Psi^G \rangle, \tag{37}$$

converges not only for $q \in \mathcal{Q}$ but also for $q \in \mathcal{Q}_{\mathbb{C}}$, in fact uniformly on every compact set $K \subseteq \mathcal{Q}_{\mathbb{C}}$. Since uniform limits of analytic functions are analytic, Ψ^G and thus also Ψ^{GAP} are a.s. analytic. □

In order to demonstrate that the conditions (30), (35), and (36) are not unreasonably strong, we show that they are satisfied for the Laplacian on the circle. Here, the eigenfunctions are given by (12), and their derivatives, respectively, analytic continuations to disks $K = \{q \in \mathcal{Q}_{\mathbb{C}} = \mathbb{C} : |q| \leq \alpha\}$, have bounds

$$\|\nabla^\ell \varphi_n\|_\infty = \frac{|n|^\ell}{\sqrt{2\pi}}, \quad \|\varphi_n|_K\|_\infty = \frac{1}{\sqrt{2\pi}} e^{\alpha |n|}.$$

In this case, (30), respectively (35), is satisfied since

$$\sum_{n\in\mathbb{Z}} \|\nabla^\ell \varphi_n\|_\infty e^{-(1/2)\beta E_n} = \frac{1}{\sqrt{2\pi}} \sum_{n\in\mathbb{Z}} |n|^\ell e^{-(\beta\hbar^2/4m)n^2} < \infty,$$

by (16), and similarly (36), since

$$\sum_{n\in\mathbb{Z}} \|\varphi_n|_K\|_\infty e^{-(1/2)\beta E_n} = \frac{1}{\sqrt{2\pi}} \sum_{n\in\mathbb{Z}} e^{\alpha|n|} e^{-(\beta\hbar^2/4m)n^2} < \infty.$$

VII. ESTIMATING DIFFERENCE QUOTIENTS

In this section, we follow another line of reasoning for studying regularity properties of Ψ, based on a standard theorem on the regularity of sample paths of a Gaussian process. However, the result is much weaker than what we obtained in the previous section.

Assume for simplicity that the configuration space is an open interval $I\subseteq\mathbb{R}$, and that $\mathcal{H}=L^2(I,\mathbb{C})$. The idea in this section is to consider the increments $\Psi^G(q+\Delta q)-\Psi^G(q)$ of the Gaussian process Ψ^G, and to argue that for reasonable Hamiltonians they are of the order of magnitude of $\Delta q>0$

$$|\Psi^G(q+\Delta q)-\Psi^G(q)| \lesssim \Delta q, \tag{38}$$

which suggests that difference quotients converge to differential quotients as $\Delta q\to 0$, i.e., that Ψ^G be differentiable. However, what can rigorously be concluded from a statement about the variance of the increment analogous to (38) is less than differentiability, namely Hölder continuity with exponent $1-\varepsilon$.

We now describe the argument in detail. We pretend that Ψ^G is everywhere defined in I (although, strictly speaking, vectors in Hilbert space are equivalence classes of functions coinciding Lebesgue-almost-everywhere) in such a way that it is a Gaussian process in the sense that, for any choice of $q_1,\ldots,q_n\in I$, the joint distribution of $\Psi^G(q_1),\ldots,\Psi^G(q_n)$ in $\mathbb{C}^n$ is Gaussian. It follows that for any $\Delta q>0$, the increment $\Psi^G(q+\Delta q)-\Psi^G(q)$ is a Gaussian variable, and we can compute its variance

$$\mathbb{E}|\Psi^G(q+\Delta q)-\Psi^G(q)|^2 = \rho(q+\Delta q,q+\Delta q) - 2\,\mathrm{Re}\,\rho(q,q+\Delta q) + \rho(q,q), \tag{39}$$

where $\rho(q,q')=\langle q|\rho|q'\rangle$ are the "matrix elements" in the position representation of the density matrix $\rho=\rho_\beta$. Assuming that

$$\rho(q,q') \text{ is a smooth function}, \tag{40}$$

which would appear to be a reasonable assumption on the Hamiltonian, we can employ a Taylor expansion of ρ to the second order around (q,q) and obtain from (39) that

$$\mathbb{E}|\Psi^G(q+\Delta q)-\Psi^G(q)|^2 = \left.\frac{\partial^2\rho}{\partial q\partial q'}\right|_{q'=q} \Delta q^2 + O(\Delta q^3). \tag{41}$$

It is a standard result (Ref. 6, Theorem 8 of Chap. III) that for a Gaussian process Ψ^G with the following bound on the variances of the increments:

$$\mathbb{E}|\Psi^G(q+\Delta q)-\Psi^G(q)|^2 \leqslant K\Delta q^p, \tag{42}$$

where $K>0$ and $p>0$ are constants, the realization a.s. satisfies

$$|\Psi^G(q+\Delta q)-\Psi^G(q)| \leqslant K'\Delta q^{p/2}|\log\Delta q|^{1+\delta}, \tag{43}$$

for arbitrary $\delta>0$ and a suitable constant $K'=K'(\delta)>0$. Inserting (41) into (42), we obtain from (43), in the case $\partial^2\rho/\partial q\partial q'\neq 0$, that a.s.

$$|\Psi^G(q+\Delta q)-\Psi^G(q)| \leqslant K''\Delta q^{1-\varepsilon}, \tag{44}$$

for arbitrary $\varepsilon>0$, i.e., Hölder continuity of degree $1-\varepsilon$.

In order to obtain a stronger estimate than (44), one might hope that

$$\left.\frac{\partial^2\rho}{\partial q\partial q'}\right|_{q'=q} = 0 \text{ for all } q \in I. \tag{45}$$

This would allow us to replace the exponent in (44) by $3/2-\varepsilon$, which would give us in particular local Lipschitz continuity, so that Ψ^G would be differentiable Lebesgue-almost-everywhere. But, any exponent greater than 1 is too good to be true. Indeed, as we shall show presently (45) holds only for one particular density matrix ρ_0, the projection to the one-dimensional subspace of constant functions. For $\rho=\rho_0$, $\Psi(q)$ is constant with modulus determined by normalization and random phase.

To see $\rho=\rho_0$, write ρ in terms of its eigenfunctions $\varphi_n(q)$ and eigenvalues p_n, $\rho(q,q')=\Sigma_n p_n\varphi_n(q)\varphi_n^*(q')$, and observe that

$$\left.\frac{\partial^2\rho}{\partial q\partial q'}\right|_{q'=q} = \left.\sum_n p_n\varphi_n'(q)\varphi_n'^*(q')\right|_{q'=q} = \sum_n p_n|\varphi_n'(q)|^2,$$

where φ_n' denotes the derivative of φ_n. The only way this quantity can vanish for all q is that all φ_n have identically vanishing derivative and thus are constant, which implies $\rho=\rho_0$.

VIII. CONCENTRATION ON THE DOMAIN OF *H*

In this section we utilize a fourth kind of argument, different from those of the previous sections. It is our most elegant argument, particularly simple and direct, as it deals only with the eigenvalues and eigenvectors, but also more abstract. This argument applies not only to GAP(ρ_β) but to every probability measure μ on $\mathcal{S}(\mathcal{H})$ with density matrix ρ_β.

The question we address is whether $\mu(\text{domain}(H))=1$. The answer is yes. Even more, we show that, for any self-adjoint H and almost all β for which $Z(\beta,H)<\infty$, any μ with density matrix ρ_β is supported by the domain of H^ℓ for every $\ell\in\mathbb{N}$. [Whether $\psi\in\text{domain}(H)$ implies differentiability depends of course on H.] After that, we show further that GAP(ρ_β) for sufficiently large β is concentrated on the *subspace of analytic vectors*[1] of H.

Theorem 2: *Let ρ be a density matrix on the Hilbert space $\mathcal{H}$, μ a probability measure on $\mathcal{S}(\mathcal{H})$ with density matrix ρ, and $f:[0,1]\to\mathbb{R}$ a measurable function. If*

$$\text{Tr}(\rho f(\rho)^2) < \infty, \tag{46}$$

then $\mu(\text{domain}(f(\rho)))=1$, where the domain of $f(\rho)$ can be defined, in terms of an orthonormal basis $\{|\varphi_n\rangle\}$ of eigenvectors of ρ with eigenvalues p_n, by

$$\text{domain}(f(\rho)) = \left\{\psi\in\mathcal{H}: \sum_n |f(p_n)\langle\varphi_n|\psi\rangle|^2 < \infty\right\}. \tag{47}$$

Proof: From (46), it follows that

$$\mathbb{E}_\mu \sum_n |f(p_n)\langle\varphi_n|\psi\rangle|^2 = \sum_n f(p_n)^2\mathbb{E}_\mu|\langle\varphi_n|\psi\rangle|^2 = \sum_n f(p_n)^2 p_n < \infty.$$

Therefore, μ-a.s. $\Sigma_n|f(p_n)\langle\varphi_n|\psi\rangle|^2<\infty$, or $\mu(\text{domain}(f(\rho)))=1$. □

Corollary 1: Let H be a self-adjoint operator on the Hilbert space $\mathcal{H}$. Suppose $Z(\beta_0,H)<\infty$ for some $\beta_0>0$, which implies $Z(\beta,H)<\infty$ for every $\beta>\beta_0$. Then, for every $\beta>\beta_0$ and every probability measure μ on $\mathcal{S}(\mathcal{H})$ with density matrix ρ_β, $\mu(C^\infty(H))=1$, where $C^\infty(H)=\cap_{\ell=1}^\infty \text{domain}(H^\ell)$.

Proof: For ρ given by (1), we have that $H=-(1/\beta)\log\rho+E_0 id$ for some constant E_0. Define

$f(x)=(-(1/\beta)\log x+E_0)^\ell$ for $x>0$ and $f(x)=0$ for $x=0$. Since $f(\rho)=H^\ell$, Theorem 2 yields the claim if we can confirm the condition (46), which we do now.

Since $\mathrm{Tr}\exp(-\beta_0 H)<\infty$, there is a basis $\{|\varphi_n\rangle : n\in\mathbb{N}\}$ of eigenvectors of H with eigenvalues E_n. Furthermore, only finitely many of the eigenvalues lie below zero, so that the set $\mathcal{N}:=\{n\in\mathbb{N}: E_n>0\}$ contains all except finitely many numbers. Observe that for every $\beta>\beta_0$

$$\infty > \mathrm{Tr}\, \mathrm{e}^{-\beta_0 H} = \sum_{n\in\mathbb{N}} \mathrm{e}^{-\beta_0 E_n} \geqslant \sum_{n\in\mathcal{N}} \mathrm{e}^{-\beta_0 E_n} > \sum_{n\in\mathcal{N}} \mathrm{e}^{-\beta E_n},$$

and thus $Z(\beta,H)<\infty$. For $\varepsilon>0$ with $\varepsilon<\beta-\beta_0$, we find, for any $\ell\in\mathbb{N}$

$$\infty > \sum_{n\in\mathcal{N}} \mathrm{e}^{-(\beta-\varepsilon)E_n} = \sum_{n\in\mathcal{N}} \mathrm{e}^{-\beta E_n}\mathrm{e}^{\varepsilon E_n} > \sum_{n\in\mathcal{N}} \mathrm{e}^{-\beta E_n}\sum_{k=0}^{2\ell}\frac{\varepsilon^k E_n^k}{k!} = \sum_{k=0}^{2\ell}\frac{\varepsilon^k}{k!}\sum_{n\in\mathcal{N}} E_n^k \mathrm{e}^{-\beta E_n}.$$

In particular

$$\sum_{n\in\mathcal{N}} E_n^{2\ell}\mathrm{e}^{-\beta E_n} < \infty,$$

which implies $\mathrm{Tr}(\rho_\beta H^{2\ell})<\infty$. □

If $\beta>2\beta_0$ (with $Z(\beta_0,H)<\infty$), we obtain the stronger result for the measure $\mathrm{GAP}(\rho_\beta)$ that it is concentrated on the subspace $C^\omega(H)$ of analytic vectors of H, i.e., those vectors $\psi\in C^\infty(H)$ with

$$\sum_{\ell=0}^{\infty}\frac{\|H^\ell\psi\|\varepsilon^\ell}{\ell!}<\infty, \tag{48}$$

for some $\varepsilon>0$.[1] It is sufficient for $\psi\in C^\omega(H)$ that

$$\sum_n \mathrm{e}^{\varepsilon|E_n|}|\langle\varphi_n|\psi\rangle|<\infty, \tag{49}$$

because then

$$\sum_{\ell=0}^{\infty}\frac{\varepsilon^\ell}{\ell!}\|H^\ell\psi\| = \sum_{\ell=0}^{\infty}\frac{\varepsilon^\ell}{\ell!}\left\|\sum_n E_n^\ell|\varphi_n\rangle\langle\varphi_n|\psi\rangle\right\| \leqslant \sum_n\sum_{\ell=0}^{\infty}\frac{\varepsilon^\ell}{\ell!}|E_n|^\ell|\langle\varphi_n|\psi\rangle| = \sum_n \mathrm{e}^{\varepsilon|E_n|}|\langle\varphi_n|\psi\rangle|<\infty.$$

For $0<\varepsilon<\beta/2-\beta_0$ (49) is a.s. true of $\psi=\Psi^G$, and thus also of $\psi=\Psi^{\mathrm{GAP}}$, because, assuming without loss of generality that all $E_n>0$, we have by (31) that

$$\mathbb{E}\sum_n \mathrm{e}^{\varepsilon E_n}|\langle\varphi_n|\Psi^G\rangle| = \sum_n \mathrm{e}^{\varepsilon E_n}\frac{\sqrt{\pi}}{2\sqrt{Z(\beta)}}\mathrm{e}^{-\beta E_n/2} \leqslant \frac{\sqrt{\pi}}{2\sqrt{Z(\beta)}}\sum_n \mathrm{e}^{-\beta_0 E_n}<\infty.$$

IX. EXISTENCE OF BOHMIAN VELOCITIES

As a final remark, we mention an application of smoothness of the wave function: differentiability is needed in Bohmian mechanics,[2] a theory ascribing trajectories to the particles of nonrelativistic quantum mechanics. This is because the Bohmian law of motion, which for N particles with masses $m_1,\ldots,m_N$ at the configuration $Q(t)=(\boldsymbol{Q}_1(t),\ldots,\boldsymbol{Q}_N(t))$ reads

$$\frac{\mathrm{d}\boldsymbol{Q}_i}{\mathrm{d}t} = \boldsymbol{v}_i^\psi(Q) = \frac{\hbar}{m_i}\,\mathrm{Im}\,\frac{\psi^*\nabla_i\psi}{\psi^*\psi}(Q),$$

involves the derivative of the wave function. Suppose the wave function ψ is chosen at random according to the canonical distribution $\mathrm{GAP}(\rho_\beta)$ with inverse temperature β. Then, any condition on the Hamiltonian entailing that ψ is a.s. smooth also implies that the Bohmian velocity vector

field v^ψ on configuration space $\mathcal{Q}=\mathbb{R}^{3N}$, whose ith component is $\boldsymbol{v}_i^\psi$, is a.s. well defined everywhere outside the nodes of ψ.

The analogous conclusion holds, as we shall explain presently, for the numerous further variants of Bohmian mechanics that have been considered (such as Bohmian mechanics on curved spaces, on the configuration space of a variable number of particles,[5] for wave functions that are cross sections of a complex vector bundle, and variants suitable for the Dirac equation or for photons). The laws of motion of these variants

$$\frac{\mathrm{d}Q}{\mathrm{d}t} = v^\psi(Q),$$

are defined by giving the appropriate expression for the velocity vector field v^ψ on the manifold $\mathcal{Q}$, and these definitions of v^ψ can be summarized by the formula[5]

$$v^\psi(q)\cdot\nabla f(q) = \mathrm{Re}\,\frac{\psi^*(q)\left(\frac{i}{\hbar}[H,f]\psi\right)(q)}{\psi^*(q)\psi(q)} \qquad \forall\, f\in C_0^\infty(\mathcal{Q}). \tag{50}$$

Here, $f:\mathcal{Q}\to\mathbb{R}$ is an arbitrary smooth function with compact support playing the role of a coordinate function, and numerator and denominator involve inner products in the value space of ψ (which may be a fiber space of a vector bundle of which ψ is a cross section). For $\psi\in\mathrm{domain}(H)$ and $f\in C_0^\infty(\mathcal{Q})$, the right-hand side of (50) will be well defined since multiplication by f maps the domain of H to itself, since H is the sum of a differential operator (of up to second order) and a multiplication operator. Since the f's from $C_0^\infty(\mathcal{Q})$ suffice for determining v^ψ (up to changes on a null set), one obtains indeed a vector field v^ψ, defined on $\mathcal{Q}\setminus\{q:\psi(q)=0\}$, for every ψ from the domain of H.

Hence, every wave function ψ from the domain of H is sufficiently regular to define a Bohm-type velocity field. By Corollary 1, the random wave function Ψ with the thermal equilibrium distribution $\mathrm{GAP}(\rho_\beta)$ possesses a velocity field v^Ψ with probability 1, provided that there is $\beta_0<\beta$ with $Z(\beta_0,H)<\infty$.

ACKNOWLEDGMENTS

We gratefully acknowledge that the consideration of the magnitude of difference quotients (carried out in Sec. VII) was suggested to us by Detlef Dürr of LMU München, Germany; that the result (43) was pointed out to us by Matthias Birkner of WIAS Berlin, Germany; and that analyticity as a consequence of our estimates was pointed out to us by Jean Bricmont of UC Louvain-la-neuve, Belgium. We thank Sheldon Goldstein of Rutgers University, New Jersey, for helpful discussions.

(Received 18 July 2005; accepted 15 September 2005; published online 14 November 2005)

We derive recursively the perturbation series for the ground-state energy of the *D*-dimensional anharmonic oscillator and resum it using variational perturbation theory (VPT). From the exponentially fast converging approximants, we extract the coefficients of the large-*D* expansion to higher orders. The calculation effort is much smaller than in the standard field-theoretic approach based on the Hubbard-Stratonovich transformation. © *2005 American Institute of Physics.*

I. INTRODUCTION

The properties of nontrivial physical systems can only be calculated via efficient approximation schemes. Most easily accessible are perturbation expansions, but they are usually divergent and need resummation. To this end, a variational approach was developed by Feynman and Kleinert,[1] which has been systematically extended to an efficient nonperturbative approximation scheme called *variational perturbation theory* (VPT).[2–5] It allows the conversion of divergent weak-coupling into convergent strong-coupling expansions and has been applied successfully in various fields, such as quantum mechanics, quantum statistics, condensed matter physics, and critical phenomena. In fact, the most accurate critical exponents come from this theory,[6] as has been verified by recent satellite experiments.[7]

The convergence of VPT has been analyzed up to very high orders for the ground-state energy of the one-dimensional anharmonic oscillator,

$$V(x) = \tfrac{1}{2}\omega^2 x^2 + g x^4, \tag{1}$$

and was found to be exponentially fast.[8,9] This surprising result has been confirmed later by studying other physical systems and was proven to hold on general grounds.[3,4] Furthermore, the exponential convergence seems to be uniform with respect to other system parameters. In this manner, the variational resummation of perturbation series yields approximations which are generically reasonable for all temperatures,[10–12] space and time coordinates,[13–16] magnetic field strengths,[17] coupling constants,[18–20] etc.

In this paper, we show that the exponential convergence of VPT is uniform with respect to the space dimension *D*. To this end, we consider the *D*-dimensional generalization of the anharmonic oscillator (1), i.e.,

$$V(\mathbf{x}) = \tfrac{1}{2}\omega^2 \mathbf{x}^2 + g(\mathbf{x}^2)^2 \tag{2}$$

with $\mathbf{x}=(x_1,\cdots,x_D)$, and determine its ground-state energy as a function of the coupling constant *g*. In Sec. II, we derive the corresponding weak-coupling series by evaluating connected vacuum

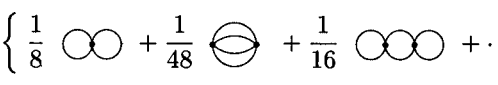
[a)]Electronic mail: sbrandt@physics.wustl.edu
[b)]Electronic mail: pelster@uni-essen.de

diagrams. In Sec. III, we show how this perturbation series can be obtained more efficiently by means of Bender-Wu-type recursion relations.[21] In Sec. IV, we resum the weak-coupling series by applying VPT and examine the resulting convergence, which is again exponentially fast and improves uniformly with increasing dimension D. In Sec. V, we show that the latter observation is not surprising, since the ground-state energy of the anharmonic oscillator (2) can be determined with the help of a systematic large-D expansion. In Sec. VI, we apply VPT to extract the large-D expansion to higher orders, which have so far been inaccessible to other methods.

II. PERTURBATION THEORY

The perturbation series for the ground-state energy of the anharmonic oscillator (2) can be calculated from connected vacuum diagrams. Up to the second order in the coupling constant g, the ground-state energy is given by the Feynman diagrams

$$E = \frac{\omega}{2} - \lim_{\beta\to\infty}\frac{1}{\beta}\left\{ \frac{1}{8} \quad + \frac{1}{48} \quad + \frac{1}{16} \quad + \cdots \right\}, \tag{3}$$



with the propagator

$$a \bullet \overset{i}{\longrightarrow} \bullet b \quad \equiv \quad \frac{\delta_{ij}}{2\omega} e^{-\omega|\tau_a-\tau_b|} \tag{4}$$

and the vertices

$$i \overset{j}{\underset{l}{\overset{|}{-}\!\bullet\!-}} k \quad \equiv \quad -\frac{g}{3}\,(\delta_{ij}\delta_{kl}+\delta_{ik}\delta_{jl}+\delta_{il}\delta_{jk})\int_0^\beta d\tau_a\,. \tag{5}$$

The connected vacuum diagrams (3) are derived most easily by an efficient graphical recursion method.[22] Evaluating these Feynman diagrams produces the following analytic expression for the ground-state energy:

$$E = \frac{D\omega}{2} + \frac{D(D+2)g}{4\omega^2} - \frac{D(2D^2+9D+10)g^2}{8\omega^5} + \cdots\,. \tag{6}$$

Only low perturbation orders are accessible by this procedure. If we want to study higher orders, we better use Bender-Wu-type recursion relations.[21]

III. BENDER-WU-TYPE RECURSION RELATIONS

The potential (2) of the D-dimensional anharmonic oscillator is rotationally symmetric. Hence, the ground-state wave function depends only on the distance $x=|\mathbf{x}|$. We solve the corresponding Schrödinger eigenvalue equation

$$\left[-\frac{1}{2}\left(\frac{\partial^2}{\partial x^2}+\frac{D-1}{x}\frac{\partial}{\partial x}\right)+\frac{1}{2}\omega^2x^2+gx^4\right]\psi(x)=E\psi(x) \tag{7}$$

as follows. We write the wave function $\psi(x)$ as

$$\psi(x)=\left(\frac{\omega}{\pi}\right)^{1/4}\exp\left[-\frac{1}{2}\hat{x}^2+\phi(\hat{x})\right], \tag{8}$$

with the abbreviation $\hat{x}=x\sqrt{\omega}$, and expand the exponent in powers of the dimensionless coupling constant $\hat{g}=g/\omega^3$ by using

TABLE I. Expansion coefficients for the ground-state energy of the anharmonic oscillator (2) up to the fifth order.

k	ϵ_k
1	$D(D+2)/4$
2	$-D(2D^2+9D+10)/8$
3	$D(8D^3+59D^2+146D+120)/16$
4	$-D(168D^4+1773D^3+7144D^2+12960D+8840)/128$
5	$D(1024D^5+14325D^4+82222D^3+241464D^2+360736D+216960)/256$

$$\phi(\hat{x}) = \sum_{k=1}^{\infty} \phi_k(\hat{x}) \hat{g}^k. \tag{9}$$

The $\phi_k(\hat{x})$ are expanded in powers of the rescaled coordinate $\hat{x}$,

$$\phi_k(\hat{x}) = \sum_{m=1}^{k+1} c_m^{(k)} \hat{x}^{2m}. \tag{10}$$

For the ground-state energy we make the ansatz

$$E = \omega \left(\frac{D}{2} + \sum_{k=1}^{\infty} \epsilon_k \hat{g}^k \right). \tag{11}$$

Inserting (8)–(11) into (7), we obtain to first order

$$c_1^{(1)} = -\frac{D+2}{4}, \quad c_2^{(1)} = -\frac{1}{4}, \quad \epsilon_1 = \frac{D(D+2)}{4}. \tag{12}$$

For $k \geqslant 2$, we find the following recursion relation for the expansion coefficients in (10):

$$c_m^{(k)} = \frac{(m+1)(D+2m)}{2m} c_{m+1}^{(k)} + \sum_{l=1}^{k-1} \sum_{n=1}^{m} \frac{n(m+1-n)}{m} c_n^{(l)} c_{m+1-n}^{(k-l)}, \tag{13}$$

with $c_m^{(k)} \equiv 0$ for $m > k+1$. The expansion coefficients of the ground-state energy follow from

$$\epsilon_k = -D c_1^{(k)}. \tag{14}$$

Table I shows the resulting coefficients ϵ_k up to the fifth order. For $D=1$, they reduce to the well-known one-dimensional results.[21]

IV. VARIATIONAL RESUMMATION

Now we consider the strong-coupling limit of the perturbation series (11). Rescaling the coordinate according to $x \to x g^{-1/6}$, the Schrödinger equation (7) becomes

$$\left[-\frac{1}{2} \left(\frac{\partial^2}{\partial x^2} + \frac{D-1}{x} \frac{\partial}{\partial x} \right) + \frac{1}{2} g^{-2/3} \omega^2 x^2 + x^4 \right] \psi(x) = g^{-1/3} E \psi(x). \tag{15}$$

Expanding the wave function and the ground-state energy in powers of the coupling constant yields

$$\psi(x) = \psi_0(\hat{x}) + \psi_1(\hat{x}) \hat{g}^{-2/3} + \psi_2(\hat{x}) \hat{g}^{-4/3} + \cdots, \tag{16}$$

TABLE II. Numerical results for the leading strong-coupling coefficient b_0 of the ground-state energy (17).

$b_0(D=2)$	1.4771497535779972(31)
$b_0(D=3)$	2.3936440164822970(37)
$b_0(D=10)$	10.758265165443755(69)

$$E = \omega \hat{g}^{1/3}(b_0 + b_1 \hat{g}^{-2/3} + b_2 \hat{g}^{-4/5} + \cdots). \tag{17}$$

By considering (15) in the limit $g \to \infty$, we find that the leading strong-coupling coefficient b_0 equals the ground-state energy associated with the Hamilton operator

$$H = -\tfrac{1}{2}\boldsymbol{\Delta} + (\mathbf{x}^2)^2. \tag{18}$$

Precise numerical values for this ground-state energy for different dimensions D are listed in Table II.

The weak-coupling series (11) is of the form

$$E^{(N)}(g,\omega) = \omega\left[\frac{D}{2} + \sum_{k=1}^{N} \epsilon_k \left(\frac{g}{\omega^3}\right)^k\right]. \tag{19}$$

The alternating signs and fast growing coefficients in Table I suggest that (19) is a divergent Borel series which is resummable by VPT.[2–5] In order to perform the variational resummation, an artificial frequency parameter Ω is introduced in the perturbation series most easily by Kleinert's square-root trick,

$$\omega \to \Omega\sqrt{1 + gr}, \tag{20}$$

with

$$r = \frac{\omega^2 - \Omega^2}{g\Omega^2}. \tag{21}$$

One replaces the frequency ω in the weak-coupling series (19) according to (20) and reexpands the resulting expression in powers of g up to the order g^N. Afterwards, the parameter r is replaced according to (21). This procedure has the effect that the power series of order N for the ground-state energy becomes dependent on the variational parameter Ω,

$$E^{(N)}(g,\omega,\Omega) = \sum_{k=0}^{N} \epsilon_k g^k \Omega^{1-3k} \sum_{l=0}^{N-k} \binom{(1-3k)/2}{l} \left(\frac{\omega^2}{\Omega^2} - 1\right)^l. \tag{22}$$

The influence of Ω is then optimized according to the principle of minimal sensitivity,[23] the ground-state energy to Nth order is approximated by

$$E^{(N)} = E^{(N)}(g,\omega,\Omega^{(N)}), \tag{23}$$

where $\Omega^{(N)}$ denotes that value of the variational parameter for which $E^{(N)}(g,\omega,\Omega)$ has an extremum or a turning point.

As an example, consider the weak-coupling series (19) to first order,

$$E^{(1)} = \frac{D\omega}{2} + \frac{D(D+2)}{4\omega^2} g. \tag{24}$$

Inserting (20), reexpanding in g to first order, and taking into account (21), we find

$$E^{(1)}(g,\omega,\Omega)=\frac{D\Omega}{4}+\frac{D\omega^2}{4\Omega}+\frac{D(D+2)}{4\Omega^2}g. \tag{25}$$

Extremizing this and going to large coupling constants, we obtain the strong-coupling behavior of the variational parameter

$$\Omega^{(1)}=\omega\hat{g}^{1/3}(\Omega_0^{(1)}+\Omega_1^{(1)}\hat{g}^{-2/3}+\Omega_2^{(1)}\hat{g}^{-4/3}+\cdots), \tag{26}$$

with

$$\Omega_0^{(1)}=(2D+4)^{1/3},\quad \Omega_1^{(1)}=\frac{\omega^2}{3(2D+4)^{1/3}},\quad \Omega_2^{(1)}=\frac{\omega^4}{108(D+2)},\quad \cdots. \tag{27}$$

Inserting the result (26) and (27) into (25), we obtain the strong-coupling series (17) with the first-order coefficients

$$b_0^{(1)}=\frac{3D}{8}(2D+4)^{1/3},\quad b_1^{(1)}=\frac{D\omega^2}{4(2D+4)^{1/3}},\quad b_2^{(1)}=-\frac{D\omega^4}{48(D+2)},\quad \cdots. \tag{28}$$

For $D=1$, this reduces to earlier VPT results in Refs. 8 and 9.

In order to determine the strong-coupling coefficient b_0 in (17) to higher orders, we proceed as follows. We observe that the strong-coupling behavior of the variational parameter is for any order N of the form

$$\Omega^{(N)}=\omega\hat{g}^{1/3}(\Omega_0^{(N)}+\Omega_1^{(N)}\hat{g}^{-2/3}+\Omega_2^{(N)}\hat{g}^{-4/3}+\cdots), \tag{29}$$

which corresponds to (26). Inserting (29) into (22), the leading strong-coupling coefficient turns out to be given by

$$b_0^{(N)}(\Omega_0^{(N)})=\sum_{k=0}^{N}\sum_{l=0}^{N-k}\binom{(1-3k)/2}{l}(-1)^l\epsilon_k(\Omega_0^N)^{1-3k}, \tag{30}$$

where the inner sum can be further simplified by using[24]

$$\sum_{l=0}^{m}(-1)^l\binom{\alpha}{l}=(-1)^m\binom{\alpha-1}{m}. \tag{31}$$

Thus, the leading strong-coupling coefficient reduces to

$$b_0^{(N)}(\Omega_0^{(N)})=\sum_{k=0}^{N}\binom{(1-3k)/2-1}{N-k}(-1)^{N-k}\epsilon_k(\Omega_0^{(N)})^{1-3k}. \tag{32}$$

Determining the optimized $\Omega_0^{(N)}$ for which $b_0^{(N)}(\Omega_0^{(N)})$ has an extremum or a turning point then leads to the approximation $b_0^{(N)}(\Omega_0^{(N)})$ of the leading strong-coupling coefficient b_0.

By carrying the expansion to high orders, VPT yields approximations whose relative deviation from the exact value vanishes exponentially.[3,4] In our case, we have for large N

$$\frac{|b_0^{(N)}(D)-b_0(D)|}{b_0(D)}\sim\exp[A(D)-B(D)N^{1/3}], \tag{33}$$

where the exponent 1/3 is determined by the structure of the strong-coupling series (17). Due to the exponential convergence of VPT, it turns out that the accuracy of our numerical results for the leading strong-coupling coefficients b_0 in Table II is not sufficient for a useful examination of the convergence behavior of VPT in high orders. Therefore, we use our results from the 80th VPT order as a more precise approximation for b_0. Table III summarizes our high-precision VPT results, where in each case the uncertainty of b_0 has been estimated by examining the deviation

TABLE III. High-precision VPT results from the 80th order for the leading strong-coupling coefficient b_0 of the ground-state energy (17).

$b_0(D=2)$	1.4771497535779944356(33)
$b_0(D=3)$	2.39364401648230308 95(77)
$b_0(D=10)$	10.75826516544379740 8091(18)

from the result of the previous order. For $D=2$ and $D=10$, the VPT results lie within the error margins of the numerical results. However, this is not the case for $D=3$, where the VPT result lies just outside of the corresponding numerical error margins. We attribute this discrepancy to an overly optimistic error estimate for the numerical result. The precision of the results shown in Table III improves with increasing dimension, which already indicates that the calculation converges faster in higher dimensions. Figure 1 shows the convergence of the VPT results for the three different cases. Fitting the data to straight lines yields for the parameters $A(D)$ and $B(D)$ in (33),

$$A(D=2)=5.98(72), \quad B(D=2)=9.89(23), \tag{34}$$

$$A(D=3)=7.43(48), \quad B(D=3)=10.67(15), \tag{35}$$

$$A(D=10)=11.89(63), \quad B(D=10)=13.33(20). \tag{36}$$

Thus, we find that the convergence of the VPT result indeed improves uniformly with increasing dimension D. This tendency does not come as a surprise, since for $D\to\infty$ the ground-state energy of an oscillator with quartic anharmonicity can be determined exactly as we will see in the following section.

V. LARGE-*D* EXPANSION

Now, we elaborate the systematic large-D expansion for the ground-state energy of the anharmonic oscillator (2) based on standard field-theoretic methods (see, for instance, Refs. 3, 25, and 26).

A. Effective potential

We start with the path integral representation of the quantum-statistical partition function at finite temperature T,

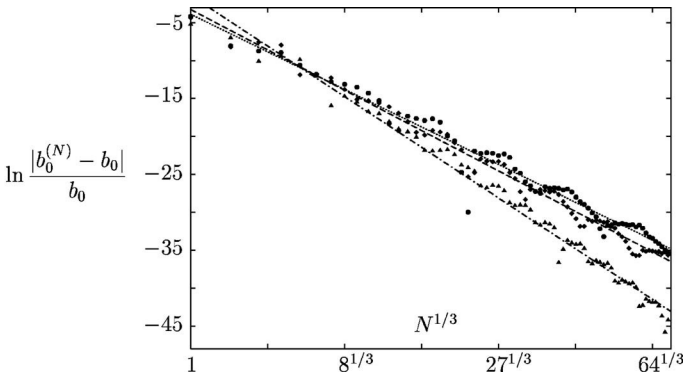


FIG. 1. Logarithm of the relative deviation of the VPT result for the leading strong-coupling coefficient $b_0(D)$ for $D=2$ (circles), $D=3$ (diamonds), and $D=10$ (triangles) plotted as a function of the cubic root of the perturbation order up to the 70th order. The dashed lines represent least squares fits of the data to straight lines.

$$Z = \oint \mathcal{D}\mathbf{x}\, e^{-\mathcal{A}[\mathbf{x}]}, \tag{37}$$

where the Euclidean action reads

$$\mathcal{A}[\mathbf{x}] = \int_0^\beta \mathrm{d}\tau \left\{ \frac{1}{2}\dot{\mathbf{x}}^2(\tau) + \frac{1}{2}\omega^2\mathbf{x}^2(\tau) + g[\mathbf{x}^2(\tau)]^2 \right\}. \tag{38}$$

The paths are periodic in the imaginary time τ with period $\beta \equiv 1/T$. Applying a Hubbard-Stratonovich transformation,

$$\oint \mathcal{D}\sigma \exp\left\{ -\int_0^\beta \mathrm{d}\tau \left[\frac{1}{g}\sigma^2(\tau) + 2i\mathbf{x}^2(\tau)\sigma(\tau) \right] \right\} = \exp\left\{ -g\int_0^\beta \mathrm{d}\tau [\mathbf{x}^2(\tau)]^2 \right\}, \tag{39}$$

the $\mathbf{x}(\tau)$-path integral (37) and (38) becomes harmonic and leads to

$$Z = \oint \mathcal{D}\sigma\, e^{-D\mathcal{A}[\sigma]}, \tag{40}$$

where we have introduced the Euclidean action

$$\mathcal{A}[\sigma] = \frac{1}{Dg}\int_0^\beta \mathrm{d}\tau\, \sigma^2(\tau) + \frac{1}{2}\mathrm{Tr}\ln\left[-\frac{\mathrm{d}^2}{\mathrm{d}\tau^2} + \omega^2 + 4i\sigma(\tau) \right]. \tag{41}$$

The remaining path integral (40) and (41) over $\sigma(\tau)$ is then performed in the limit of large D by regarding the modified coupling constant $\tilde{g} = Dg$ as being independent of D, and by applying the background method.[3,27,28] Thus, we take into account order by order the effect of the fluctuations $\delta\sigma(\tau) \equiv \sigma(\tau) - \sigma_0$ of the paths $\sigma(\tau)$ from the background σ_0. This determines the effective potential

$$V_{\mathrm{eff}}(\sigma_0) = -\frac{1}{\beta}\ln Z \tag{42}$$

in the form of the loop expansion

$$V_{\mathrm{eff}}(\sigma_0) = \sum_{l=0}^{\infty} V_{\mathrm{eff}}^{(l)}(\sigma_0), \tag{43}$$

where the term of loop order l turns out to be of order D^{1-l}.

B. Loop orders $l=0$ and $l=1$

The leading term is the tree-level and follows from evaluating (41) for the background σ_0,

$$V_{\mathrm{eff}}^{(0)}(\sigma_0) = D\left[\frac{\sigma_0^2}{\tilde{g}} + \frac{1}{\beta}\ln\left(\sinh\frac{\beta\Omega}{2} \right) \right], \tag{44}$$

with the auxiliary frequency

$$\Omega = \sqrt{\omega^2 + 4i\sigma_0}. \tag{45}$$

The one-loop correction is given by

$$V_{\mathrm{eff}}^{(1)}(\sigma_0) = \frac{1}{2\beta}\mathrm{Tr}\ln G^{-1}(\tau_1, \tau_2), \tag{46}$$

where the operator

$$G^{-1}(\tau_1,\tau_2) = \left.\frac{\delta^2\mathcal{A}[\sigma]}{\delta\sigma(\tau_1)\delta\sigma(\tau_2)}\right|_{\sigma(\tau)=\sigma_0} \tag{47}$$

turns out to be

$$G^{-1}(\tau_1,\tau_2) = \frac{2}{\tilde{g}}\delta(\tau_1-\tau_2) + 8G_\Omega^2(\tau_1,\tau_2). \tag{48}$$

Here, the correlation function $G_\Omega(\tau_1,\tau_2)$ has the spectral representation

$$G_\Omega(\tau_1,\tau_2) = \sum_{m=-\infty}^{\infty} \frac{e^{-i\omega_m(\tau_1-\tau_2)}}{\beta(\omega_m^2+\Omega^2)}, \tag{49}$$

with the Matsubara frequencies $\omega_m = 2\pi m/\beta$. Inserting (49) in (48) yields

$$G^{-1}(\tau_1,\tau_2) = \frac{1}{\beta}\sum_{m=-\infty}^{\infty} G_m^{-1} e^{-i\omega_m(\tau_1-\tau_2)}, \tag{50}$$

with the coefficients

$$G_m^{-1} = \frac{2}{\tilde{g}} + \frac{8}{\beta}\sum_{m'=-\infty}^{\infty} \frac{1}{(\omega_{m'}^2+\Omega^2)(\omega_{m-m'}^2+\Omega^2)}. \tag{51}$$

For the quantum-mechanical ground-state energy to be calculated we only need the zero-temperature limit $\beta\to\infty$ of the above quantum statistical expressions. Thus, we obtain from (44),

$$V_{\text{eff}}^{(0)}(\sigma_0) \to D\left(\frac{\sigma_0^2}{\tilde{g}} + \frac{\Omega}{2}\right), \tag{52}$$

and the Matsubara sum (51) reduces to an integral,

$$\sum_{m=-\infty}^{\infty} f(\omega_m) \to \frac{\beta}{2\pi}\int_{-\infty}^{\infty} \mathrm{d}\omega_m\, f(\omega_m), \tag{53}$$

yielding

$$G_m^{-1} = \frac{2}{\tilde{g}} + \frac{8}{\Omega(\omega_m^2+4\Omega^2)}. \tag{54}$$

Correspondingly, Eq. (46) becomes

$$V_{\text{eff}}^{(1)}(\sigma_0) = \frac{1}{2\beta}\sum_{m=-\infty}^{\infty} \ln G_m^{-1} \to \frac{1}{4\pi}\int_{-\infty}^{\infty} \mathrm{d}\omega_m \ln G_m^{-1} = \frac{\tilde{\Omega}}{2} - \Omega, \tag{55}$$

where

$$\tilde{\Omega} = 2\sqrt{\Omega^2 + \frac{\tilde{g}}{\Omega}} \tag{56}$$

denotes another auxiliary frequency.

C. Loop order $l=2$

The higher loop orders of the effective potential with $l \geqslant 2$ consist of all one-particle irreducible vacuum diagrams with the propagator

$$1 \text{ —— } 2 \quad \equiv \quad G(\tau_1, \tau_2) \tag{57}$$

defined by the identity

$$\int_0^\beta \mathrm{d}\tau_2\, G^{-1}(\tau_1, \tau_2) G(\tau_2, \tau_3) = \frac{1}{D}\delta(\tau_1 - \tau_3) \tag{58}$$

and the vertices

$$\begin{array}{ccc} & 2 & \\ 1 & \text{—}\bullet\text{—} & 3 \\ & n & \end{array} \quad \equiv -D \int_0^\beta d\tau_1 \int_0^\beta d\tau_2 \int_0^\beta d\tau_3 \cdots \int_0^\beta d\tau_n \left. \frac{\delta^n \mathcal{A}[\sigma]}{\delta\sigma(\tau_1)\delta\sigma(\tau_2)\delta\sigma(\tau_3)\cdots\delta\sigma(\tau_n)} \right|_{\sigma(\tau)=\sigma_0} . \tag{59}$$

For instance, the two-loop contribution is given by the Feynman diagrams

$$V_{\text{eff}}^{(2)}(\sigma_0) = \frac{1}{8} \quad + \frac{1}{12} \quad . \tag{60}$$

In order to evaluate (60), we need the third and fourth functional derivatives of the Euclidean action (41). They are given by

$$\left. \frac{\delta^3 \mathcal{A}[\sigma]}{\delta\sigma(\tau_1)\delta\sigma(\tau_2)\delta\sigma(\tau_3)} \right|_{\sigma(\tau)=\sigma_0} = -64 i G_\Omega(\tau_1, \tau_2) G_\Omega(\tau_2, \tau_3) G_\Omega(\tau_3, \tau_1) \tag{61}$$

and

$$\begin{aligned} \left. \frac{\delta^4 \mathcal{A}[\sigma]}{\delta\sigma(\tau_1)\delta\sigma(\tau_2)\delta\sigma(\tau_3)\delta\sigma(\tau_4)} \right|_{\sigma(\tau)=\sigma_0} = -256 [& G_\Omega(\tau_1, \tau_2) G_\Omega(\tau_2, \tau_3) G_\Omega(\tau_3, \tau_4) G_\Omega(\tau_4, \tau_1) \\ & + G_\Omega(\tau_1, \tau_2) G_\Omega(\tau_2, \tau_4) G_\Omega(\tau_4, \tau_3) G_\Omega(\tau_3, \tau_1) \\ & + G_\Omega(\tau_1, \tau_3) G_\Omega(\tau_3, \tau_2) G_\Omega(\tau_2, \tau_4) G_\Omega(\tau_4, \tau_1)], \end{aligned} \tag{62}$$

where the explicit form of the correlation function $G_\Omega(\tau_1, \tau_2)$ at zero temperature follows from (49) and (53):

$$G_\Omega(\tau_1, \tau_2) = \frac{1}{2\Omega} e^{-\Omega|\tau_1 - \tau_2|}. \tag{63}$$

Furthermore, we must solve (58) for the propagator (57). Performing at arbitrary temperature the decomposition

$$G(\tau_1, \tau_2) = \frac{1}{\beta} \sum_{m=-\infty}^{\infty} G_m e^{-i\omega_m(\tau_1 - \tau_2)}, \tag{64}$$

the coefficient G_m turns out to be

$$G_m = \frac{1}{D G_m^{-1}}. \tag{65}$$

Using (54) and (65), we evaluate the Matsubara sum (64) at zero temperature according to (53) and obtain

$$G(\tau_1,\tau_2)=\frac{\tilde{g}}{2D}\left[\delta(\tau_1-\tau_2)-\frac{2\tilde{g}}{\Omega\tilde{\Omega}}e^{-\tilde{\Omega}|\tau_1-\tau_2|}\right]. \tag{66}$$

From (59) we read off that each vertex is of order D, whereas each propagator is of order $1/D$ due to (66). Thus both Feynman diagrams in (60) are, indeed, of order $1/D$. The first and second Feynman diagram in (60) lead to the expressions

$$V_{\mathrm{eff}}^{(2,1)}(\sigma_0)=\frac{1}{\beta D}\left\{-\frac{\tilde{g}^2}{2\Omega^4}[2I_2(2\Omega)+I_2(4\Omega)]+\frac{2\tilde{g}^3}{\Omega^5\tilde{\Omega}}[2I_3(\Omega,\Omega,\Omega+\tilde{\Omega})+I_3(2\Omega,2\Omega,\tilde{\Omega})]\right.$$
$$\left.-\frac{2\tilde{g}^4}{\Omega^6\tilde{\Omega}^2}[2I_4(\Omega+\tilde{\Omega},0,\Omega,\Omega,0,\Omega+\tilde{\Omega})+I_4(\tilde{\Omega},\Omega,\Omega,\Omega,\Omega,\tilde{\Omega})]\right\}, \tag{67}$$

$$V_{\mathrm{eff}}^{(2,2)}(\sigma_0)$$
$$=\frac{1}{\beta D}\left[\frac{2\tilde{g}^3}{3\Omega^6}I_3(2\Omega,2\Omega,2\Omega)-\frac{4\tilde{g}^4}{\Omega^7\tilde{\Omega}}I_4(\Omega,\Omega,\tilde{\Omega},2\Omega,\Omega,\Omega)\right.$$
$$\left.+\frac{8\tilde{g}^5}{\Omega^8\tilde{\Omega}^2}I_5(\Omega,\Omega,\tilde{\Omega},0,\Omega,0,\tilde{\Omega},\Omega,\Omega,\Omega)-\frac{16\tilde{g}^6}{3\Omega^9\tilde{\Omega}^3}I_6(\Omega,\Omega,\tilde{\Omega},0,0,\Omega,0,\tilde{\Omega},0,0,0,\tilde{\Omega},\Omega,\Omega,\Omega)\right], \tag{68}$$

respectively. Here we have introduced an abbreviation for multiple integrals with respect to imaginary times,

$$I_n(\Omega_{12},\ldots,\Omega_{1n},\Omega_{23},\ldots,\Omega_{2n},\ldots)=\int_0^\beta \mathrm{d}\tau_1\int_0^\beta \mathrm{d}\tau_2\cdots\int_0^\beta \mathrm{d}\tau_n\exp\left(-\sum_{i=1}^{n}\sum_{j=i+1}^{n}\Omega_{ij}|\tau_i-\tau_j|\right). \tag{69}$$

Considering the low-temperature limit $\beta\to\infty$, the first three of these integrals read in closed form[29]

$$I_2(\Omega_{12})=\frac{2\beta}{\Omega_{12}}, \tag{70}$$

$$I_3(\Omega_{12},\Omega_{13},\Omega_{23})=\frac{4\beta(\Omega_{12}+\Omega_{13}+\Omega_{23})}{(\Omega_{12}+\Omega_{13})(\Omega_{12}+\Omega_{23})(\Omega_{13}+\Omega_{23})}, \tag{71}$$

$$I_4(\Omega_{12},\Omega_{13},\Omega_{14},\Omega_{23},\Omega_{24},\Omega_{34})$$
$$=2\beta\times\left\{\frac{1}{\Omega_{12}+\Omega_{13}+\Omega_{24}+\Omega_{34}}\left[\frac{1}{\Omega_{12}+\Omega_{13}+\Omega_{14}}+\frac{1}{\Omega_{14}+\Omega_{24}+\Omega_{34}}\right]\right.$$
$$\times\left[\frac{1}{\Omega_{12}+\Omega_{23}+\Omega_{24}}+\frac{1}{\Omega_{13}+\Omega_{23}+\Omega_{34}}\right]+\frac{1}{\Omega_{12}+\Omega_{14}+\Omega_{23}+\Omega_{34}}$$
$$\times\left[\frac{1}{\Omega_{12}+\Omega_{23}+\Omega_{24}}+\frac{1}{\Omega_{14}+\Omega_{24}+\Omega_{34}}\right]\left[\frac{1}{\Omega_{12}+\Omega_{13}+\Omega_{14}}+\frac{1}{\Omega_{13}+\Omega_{23}+\Omega_{34}}\right]$$
$$\left.+\frac{1}{\Omega_{13}+\Omega_{14}+\Omega_{23}+\Omega_{24}}\left[\frac{1}{\Omega_{13}+\Omega_{23}+\Omega_{34}}+\frac{1}{\Omega_{14}+\Omega_{24}+\Omega_{34}}\right]\right.$$

$$\times\left[\frac{1}{\Omega_{12}+\Omega_{13}+\Omega_{14}}+\frac{1}{\Omega_{12}+\Omega_{23}+\Omega_{24}}\right]\Bigg\}. \tag{72}$$

Furthermore, in order to evaluate (68), we need one particular integral with respect to five and six imaginary times, respectively,

$$I_5(\Omega,\Omega,\tilde{\Omega},0,\Omega,0,\tilde{\Omega},\Omega,\Omega,\Omega)=\frac{\beta(3\tilde{\Omega}^5+42\tilde{\Omega}^4\Omega+227\tilde{\Omega}^3\Omega^2+568\tilde{\Omega}^2\Omega^3+656\tilde{\Omega}\Omega^4+288\Omega^5)}{2\Omega^2(\tilde{\Omega}+\Omega)^2(\tilde{\Omega}+2\Omega)^4(\tilde{\Omega}+4\Omega)}, \tag{73}$$

$$\begin{aligned}&I_6(\Omega,\Omega,\tilde{\Omega},0,0,\Omega,0,\tilde{\Omega},0,0,0,\tilde{\Omega},\Omega,\Omega,\Omega)\\&\quad=\frac{3\beta(\tilde{\Omega}^5+14\tilde{\Omega}^4\Omega+73\tilde{\Omega}^3\Omega^2+160\tilde{\Omega}^2\Omega^3+136\tilde{\Omega}\Omega^4+32\Omega^5)}{\tilde{\Omega}\Omega^2(\tilde{\Omega}+\Omega)^2(\tilde{\Omega}+2\Omega)^4(\tilde{\Omega}+4\Omega)}.\end{aligned} \tag{74}$$

From (44) and (67)–(74) we read off the effective potential for zero temperature up to the order $1/D$,

$$\begin{aligned}V_{\mathrm{eff}}(\sigma_0)=D\left(\frac{\sigma_0^2}{\tilde{g}}+\frac{\Omega}{2}\right)+\frac{\tilde{\Omega}}{2}-\Omega+\frac{1}{D}\Bigg[&-\frac{5\tilde{g}^2}{4\Omega^5}+\frac{\tilde{g}^3(\tilde{\Omega}^3+4\tilde{\Omega}^2\Omega+44\tilde{\Omega}\Omega^2+128\Omega^3)}{4\Omega^8\tilde{\Omega}(\tilde{\Omega}+2\Omega)^2}\\&-\frac{\tilde{g}^4(3\tilde{\Omega}^5+31\tilde{\Omega}^4\Omega+150\tilde{\Omega}^3\Omega^2+392\tilde{\Omega}^2\Omega^3+656\tilde{\Omega}\Omega^4+480\Omega^5)}{\Omega^9\tilde{\Omega}^2(\tilde{\Omega}+\Omega)(\tilde{\Omega}+2\Omega)^3(\tilde{\Omega}+4\Omega)}\\&+\frac{4\tilde{g}^5(3\tilde{\Omega}^5+42\tilde{\Omega}^4\Omega+227\tilde{\Omega}^3\Omega^2+568\tilde{\Omega}^2\Omega^3+656\tilde{\Omega}\Omega^4+288\Omega^5)}{\Omega^{10}\tilde{\Omega}^2(\tilde{\Omega}+\Omega)^2(\tilde{\Omega}+2\Omega)^4(\tilde{\Omega}+4\Omega)}\\&-\frac{16\tilde{g}^6(\tilde{\Omega}^5+14\tilde{\Omega}^4\Omega+73\tilde{\Omega}^3\Omega^2+160\tilde{\Omega}^2\Omega^3+136\tilde{\Omega}\Omega^4+32\Omega^5)}{\Omega^{11}\tilde{\Omega}^4(\tilde{\Omega}+\Omega)^2(\tilde{\Omega}+2\Omega)^4(\tilde{\Omega}+4\Omega)}\Bigg]+\mathcal{O}\left(\frac{1}{D^2}\right).\end{aligned} \tag{75}$$

The ground-state energy of the anharmonic oscillator (2) is found by extremizing the effective potential (75) with respect to the background σ_0 while taking into account the auxiliary frequencies (45) and (56).

D. Weak coupling

In order to cross-check our large-D result, we specialize now to the weak-coupling regime where the extremal background is expanded according to

$$\sigma_0=-i(s_1\tilde{g}+s_2\tilde{g}^2+s_3\tilde{g}^3+s_4\tilde{g}^4+s_5\tilde{g}^5+\cdots). \tag{76}$$

Inserting (76) into the vanishing first derivative of (75) and reexpanding in $\tilde{g}$, we obtain a system of equations which are solved by

$$s_1=\frac{1}{2\omega}, \tag{77}$$

$$s_2=-\frac{1}{2\omega^4}-\frac{1}{\omega^4 D}, \tag{78}$$

$$s_3=\frac{5}{4\omega^7}+\frac{45}{8\omega^7 D}+\frac{25}{4\omega^7 D^2}, \tag{79}$$

$$s_4 = -\frac{4}{\omega^{10}} - \frac{59}{2\omega^{10}D} - \frac{73}{\omega^{10}D^2}, \tag{80}$$

$$s_5 = \frac{231}{16\omega^{13}} + \frac{19503}{128\omega^{13}D} + \frac{9823}{16\omega^{13}D^2} + \frac{275}{2\omega^{13}D^3}, \quad \cdots . \tag{81}$$

Inserting (76)–(81) into (75) and reexpanding in $\tilde{g}=Dg$ yields again the weak-coupling series (11), where the weak-coupling coefficients ϵ_k of Table I are reproduced in the first three terms of order D^{k+1}, D^k, and D^{k-1}.

E. Strong coupling

We now derive the large-D expansion for the ground-state energy in the strong-coupling regime. There, we use for the extremal background the ansatz

$$\sigma_0 = -i\tilde{g}^{2/3}(S_1 + S_2\tilde{g}^{-2/3} + \cdots) \tag{82}$$

and find for the leading coefficient the expansion

$$S_1 = \frac{1}{2^{4/3}} + (2^{1/6}\times 3^{1/2} - 2^{5/3})\frac{1}{6D} + \left(27\times 6^{1/2} - \frac{73}{2}\right)^{1/3}\frac{1}{18D^2} + \mathcal{O}\left(\frac{1}{D^3}\right). \tag{83}$$

From (75), (82), and (83) we then obtain the strong-coupling series (17) where the leading strong-coupling coefficient has the large-D expansion

$$b_0 = \sum_{k=0}^{\infty} B_k D^{4/3-k}, \tag{84}$$

with

$$B_0 = \frac{3\times 2^{1/3}}{8}, \tag{85}$$

$$B_1 = \frac{3^{1/2} - 2^{1/2}}{2^{1/6}} \approx 0.283\,160\,794\,322\,179\,118\,844\,664\,604\,794\,882\,036\,512\,3, \tag{86}$$

$$B_2 = -\frac{239}{18\times 2^{2/3}(25 + 12\times 6^{1/2})} \approx -0.153\,776\,055\,939\,928\,491\,319\,576\,108\,549\,970\,570\,159\,0. \tag{87}$$

Figure 2 shows the leading strong-coupling coefficient (84)–(86) up to the first two orders plotted as a function of the dimension D.

VI. LARGE-D EXPANSION FROM VPT

In this section, we study how the large-D expansion (84) follows from VPT. Thereby, we numerically determine the large-D expansion coefficients up to B_6 with high precision.

A. Coefficients B_1 and B_2

To first order, VPT gives (28), and we obtain the expansion (84) simply by expanding the cubic root in (28) in powers of $1/D$. The first three coefficients in the expansion (84) read

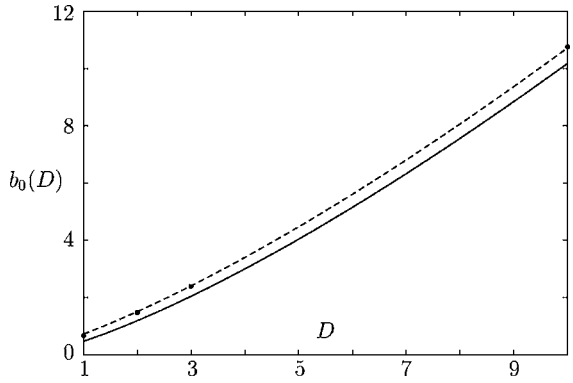

FIG. 2. Strong-coupling coefficient $b_0(D)$ versus dimension D. Solid and dashed lines represent leading and subleading results of the large-D expansion (84)–(86), respectively. For $D=1$, the dot represents the earlier result from Refs. 8 and 9; for $D=2,3,10$, the dots indicate the highly accurate VPT values obtained from the 80th order, as given in Table III.

$$B_0^{(1)} = \frac{3\times 2^{1/3}}{8}, \quad B_1^{(1)} = \frac{2^{1/3}}{4}, \quad B_2^{(1)} = -\frac{2^{1/3}}{6}. \tag{88}$$

The leading coefficient (85) is reproduced exactly, while the next two subleading coefficients B_1 and B_2 are missed by 11.2% and 36.6%, respectively. In the second order of VPT, Eq. (32) yields

$$b_0^{(2)}(\Omega_0^{(2)}) = \frac{3D\Omega_0^{(2)}}{16} + \frac{D(2+D)}{2(\Omega_0^{(2)})^2} - \frac{D(10+9D+2D^2)}{8(\Omega_0^{(2)})^5}, \tag{89}$$

which must be extremized with respect to the variational parameter $\Omega_0^{(2)}$. Setting the derivative of (89) to zero, the large-D expansion

$$\Omega_0^{(2)} = D^{1/3}\left(C_0^{(0,2)} + \frac{C_1^{(0,2)}}{D} + \frac{C_2^{(0,2)}}{D^2} + \cdots\right) \tag{90}$$

leads to a system of equations for the expansion coefficients whose solutions read

$$C_0^{(2)} = 2^{1/3}, \quad C_1^{(2)} = \frac{13\times 2^{1/3}}{12}, \quad C_2^{(2)} = -\frac{113\times 2^{1/3}}{288}, \quad \cdots. \tag{91}$$

Thus, by inserting the optimized variational parameter (90) and (91) into (89) and expanding in $1/D$ we obtain the first three coefficients in (84) to second order of VPT,

$$B_0^{(2)} = \frac{3\times 2^{1/3}}{8}, \quad B_1^{(2)} = \frac{7\times 2^{1/3}}{32}, \quad B_2^{(2)} = -\frac{71\times 2^{1/3}}{768}. \tag{92}$$

The leading large-D coefficient B_0 remains the same, whereas the error of the subleading coefficient $B_1^{(2)}$ is reduced to 2.67% and the next subleading coefficient $B_2^{(2)}$ now comes out with an error of 24.2%. Figure 3 shows that the VPT approximants $B_1^{(N)}$ and $B_2^{(N)}$ converge exponentially fast to their exact values B_1 and B_2 in (86) and (87). If we had not known the exact analytic result for the subleading coefficients B_1 and B_2, we could have extracted its value from the VPT approximants as follows. Figure 3 shows that the VPT approximants for odd and even orders converge towards the exact value independently. Extrapolating the values of $B_1^{(\mathrm{odd})}$ and $B_1^{(\mathrm{even})}$ for $N\to\infty$ leads to the limiting values

$$B_1^{(\mathrm{odd})} \approx 0.283\,160\,794\,322\,179\,118\,844\,664\,604\,794\,882\,038\,08, \tag{93}$$

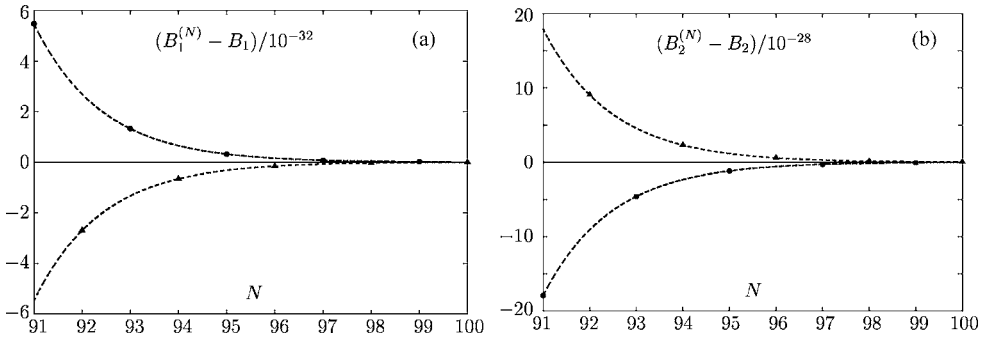

FIG. 3. Deviation of the VPT approximants for (a) $B_1^{(N)}$ and (b) $B_2^{(N)}$ from their exact values B_1 and B_2 in Eqs. (86) and (87), respectively. Odd orders are represented by circles; even orders by triangles. The dashed lines represent fits of the data to exponential functions.

$$B_1^{(\text{even})} \approx 0.283\,160\,794\,322\,179\,118\,844\,664\,604\,794\,882\,035\,75. \tag{94}$$

Assuming that the exact value lies within this interval, we obtain from this extrapolation method the result

$$B_1^{(\text{extrap})} = 0.283\,160\,794\,322\,179\,118\,844\,664\,604\,794\,882\,036\,9(24). \tag{95}$$

An analogous procedure can be applied to extract a numerical value for the subsequent coefficient B_2. Applying the extrapolation method for odd and even orders, we obtain the result

$$B_2^{(\text{extrap})} = -0.153\,776\,055\,939\,928\,491\,319\,576\,108\,549\,961(60). \tag{96}$$

B. Coefficients up to B_6

Figure 4 shows that the VPT approximants for B_1 and B_2 rapidly converge towards their exact values. For the large-D expansion coefficients of higher orders in $1/D$, however, the VPT approximants first fluctuate and then enter the regime of exponentially fast convergence. If we want to obtain the coefficients of the expansion (84) to higher orders and with good accuracy, we must therefore drive our VPT calculation to high orders. To this end, we specialize the expression for

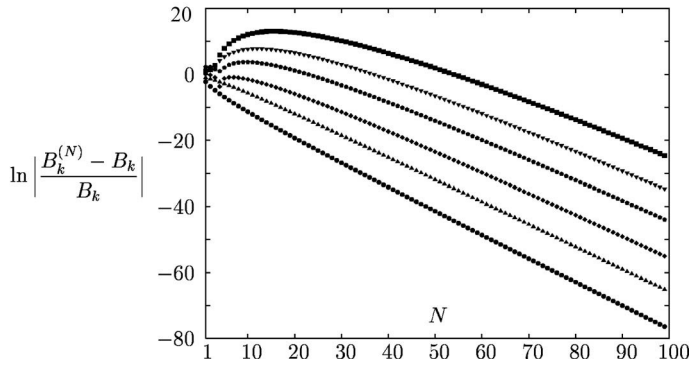

FIG. 4. Logarithm of the relative deviation of the VPT results $B_k^{(N)}$ for the coefficients B_1 through B_6 in the large-D expansion (84) versus the order N of VPT. The lowest curve (circles) is for $B_1^{(N)}$; the uppermost curve (squares) is for $B_6^{(N)}$; intermediate curves are for $B_2^{(N)}$ through $B_5^{(N)}$ ($B_2^{(N)}$, triangles; $B_3^{(N)}$, diamonds; $B_4^{(N)}$, pentagons; $B_5^{(N)}$, upside-down triangles). For $B_1^{(N)}$ and $B_2^{(N)}$ the exact values from (86) and (87) were used in order to determine the relative deviation. For $B_3^{(N)}$ through $B_6^{(N)}$ we used our extrapolation results from Table IV.

the leading strong-coupling coefficient as given in (32) in such a way that we can read off the corresponding large-D expansion. The weak-coupling coefficients for the ground-state energy ϵ_k can be expanded in powers of the spatial dimension D,

$$\epsilon_k = \sum_{j=1}^{k+1} \epsilon_j^{(k)} D^j, \tag{97}$$

whereas the variational parameter $\Omega_0^{(N)}$ can be expanded in $1/D$,

$$\Omega_0^{(N)} = D^{1/3} \sum_{j=0}^{M} C_j^{(0,N)} D^{-j}. \tag{98}$$

Here, M denotes the highest order to which we seek to drive the large-D expansion (84). Furthermore, recall the multinomial expansion

$$(x_1 + x_2 + \cdots + x_m)^n = \sum_{a_1=0}^{n} \sum_{a_2=0}^{n} \cdots \sum_{a_m=0}^{n} \delta\left(n, \sum_{k=1}^{m} a_k\right) \frac{n!}{a_1! a_2! \cdots a_m!} \prod_{l=1}^{m} x_l^{a_l}, \tag{99}$$

where n is an integer and where the Kronecker delta δ_{ij} is written as $\delta(i,j)$. This multinomial expansion can be generalized to hold for real exponents and infinite series as follows:

$$(1 + x_1 + x_2 + \cdots)^\alpha = \sum_{m=0}^{\infty} \left[\sum_{a_1=0}^{\infty} \sum_{a_2=0}^{\infty} \cdots \sum_{a_m=0}^{\infty} \delta\left(m, \sum_{l=1}^{m} l a_l\right) \times \frac{\Gamma(\alpha+1)}{\Gamma(\alpha - a_1 - a_2 - \cdots - a_m + 1) a_1! a_2! \cdots a_m!} \prod_{l=1}^{m} x_l^{a_l} \right]. \tag{100}$$

Using (97) and (98) in (32) and applying the multinomial expansion (100), we obtain

$$b_0^{(N)}(\Omega_0^{(N)}) = D^{1/3} \left\{ \frac{D}{2} \sum_{j=0}^{M} C_j^{(0,N)} D^{-j} + \sum_{k=1}^{N} \binom{(1-3k)/2 - 1}{N-k} (-1)^{N-k} D^{-k} (C_0^{(0,N)})^{1-3k} \times \left[\sum_{j=1}^{k+1} \epsilon_j^{(k)} D^j + \sum_{j=2}^{M+k} \sum_{m=1}^{\mathrm{Min}\{j-1, \lfloor (M+j-k)/2 \rfloor - 1\}} \epsilon_{j-m}^{(k)} K_{m,k}^{(N)} D^{j-2m} \right] \right\}, \tag{101}$$

where the coefficients $K_{m,k}^{(N)}$ are given by

$$K_{m,k}^{(N)} = \sum_{a_1=0}^{M} \sum_{a_2=0}^{M} \cdots \sum_{a_m=0}^{M} \delta\left(m, \sum_{l=1}^{m} l a_l\right) \frac{(3k - 2 + a_1 + a_2 + \cdots a_m)!}{(3k-2)! a_1! a_2! \cdots a_m!} (-1)^{a_1 + a_2 + \cdots + a_m} \prod_{l=1}^{m} \left(\frac{C_l^{(0,N)}}{C_0^{(0,N)}} \right)^{a_l}. \tag{102}$$

The summation boundaries in (101) are determined by the two conditions that (i) $\epsilon_j^{(k)} = 0$ for $j < 1 \vee j > k+1$ and (ii) we can neglect contributions containing coefficients $C_k^{(0,N)}$ with $k > M$. Note that a similar expansion holds for the derivative of the leading strong-coupling coefficient with respect to the variational parameter $\mathrm{d}b_0^{(N)}/\mathrm{d}\Omega_0^{(N)}$. Using (101) and (102) we can efficiently calculate the VPT approximants to high orders. In each order of VPT, the leading large-D coefficient B_0 comes out exactly. Furthermore, the expansion coefficients $C_k^{(0,N)}$ for the variational parameter are found by solving linear equations. Figure 4 shows the convergence behavior of our VPT approximants for B_1 through B_6 up to $N=100$. By extrapolating the VPT results $B_k^{(N)}$ for $k \geqslant 3$ in the limit $N \to \infty$, we are able to determine the coefficients in the large-D expansion to high accuracy. The numerical results are shown in Table IV.

TABLE IV. VPT results for the coefficients in the large-D expansion (84) of the leading strong-coupling coefficient b_0.

VII. SUMMARY

We have determined the weak-coupling series of the ground-state energy for the D-dimensional anharmonic oscillator (2) and used variational perturbation theory to extract the coefficients of the large-D expansion to higher orders than accessible by standard field-theoretic methods based on the Hubbard-Stratonovich transformation.

We prove the existence of two-cluster threshold resonances in *N*-body problems and study their perturbation by intercluster interactions. As application, we construct concrete examples based on Yukawa potentials for which the *N*-body Efimov effect happens with $N \geqslant 4$. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2118467]

I. INTRODUCTION

In Ref. 15, the first author of the present work proved the existence of the *N*-body Efimov effect for $N \geqslant 4$ which says that if the bottom of essential spectrum is attained by a unique three-cluster decomposition and if the three resulting two-cluster sub-Hamiltonians possess a threshold resonance at this threshold, then the number of discrete eigenvalues is always infinite even if the interaction potentials decay rapidly at the infinity. This phenomenon is similar to the famous three-body Efimov effect, discovered by the physicist. Efimov[4] and studied in mathematics literature by many authors. See, for example, Refs. 2, 8–12 and 17. For *N*-body quantum systems with $N \geqslant 4$, it has been unknown for a long time whether the Efimov effect exists. In Ref. 1, Amado and Greenwood argued that the zero eigenvalue and zero resonance of $(N-1)$-particle subsystems do not produce an infinite number of eigenvalues in *N*-body problems when $N \geqslant 4$. Note that in spite of the title, the result of Ref. 15 is not in discrepancy with Ref. 1, because it corresponds to a different spectral configuration, and that a mathematical proof of the affirmation of Ref. 1 is always lacking. After the work,[15] a question has then naturally been raised as how to give concrete examples such that all conditions acquired in Ref. 15 are satisfied, especially the existence of two-cluster threshold energy resonances with any number of particles. Trivial examples can be constructed from two-body zero resonance by adding some particles with independent variables. The goal of this work is to show the existence of two-cluster threshold resonances and the Efimov effect for a class of nontrivial interactions. We will show that mathematically, one can produce the *N*-body Efimov effect by adjusting parameters in Yukawa-type interactions of the form $-\alpha e^{-\epsilon\alpha|x|}/|x|$, α, $\epsilon > 0$. Yet, even for such concrete potentials, our proof for the existence of two-cluster *N*-body threshold resonance is abstract. We leave the interested reader to make numerical simulation or physical experiment.

Our example will be given in terms of atomic type four-body Schrödinger operators. This leads us to consider generalized *N*-body Schrödinger operators which include both atomic-type and regular *N*-body operators. Let *P* denote a generalized *N*-body Schrödinger operator of the form $P=-\Delta+\Sigma_{a\in\mathcal{A}}V_a(x^a)$ in $L^2(\mathbf{X})$, where $\mathcal{A}$ denotes the set of all cluster decompositions of the *N*-particle system labeled by $\{1,\ldots,N\}$, $x^a \in \mathbf{X}^a$ and $\{\mathbf{X}^a\}$ is a family of linear subspaces of $\mathbf{X}$

[b)]Electronic mail: yfwang@math.amss.ac.cn

satisfying some axioms. See Ref. 3. A typical example of such operators is regular N-body Schrödinger operator obtained by removing the mass-center from the operator

$$-\sum_{j=1}^{N}\frac{1}{2m_j}\Delta_{x_j}+\sum_{1\leqslant i\leqslant j\leqslant N}V_{ij}(x_i-x_j),\quad x_j\in\mathbb{R}^3, \tag{1.1}$$

where x_j and m_j denote the position and mass of the jth particle. P is regarded as a self-adjoint operator in $L^2(\mathbf{X})$, where $\mathbf{X}$ is the $3(N-1)$-dimensional real vectorial space, $\mathbf{X}=\{(x_1,\ldots,x_N)\in\mathbb{R}^{3N};\Sigma_{j=1}^{N}m_jx_j=0\}$. For $a\in\mathcal{A}$, let $\#a$ denote the number of clusters in a and P^a the sub-Hamiltonian associated with a. For $i,j\in\{1,\ldots,N\}$, $i\neq j$, we write $(ij)\in a$ if i and j belong to a same cluster in a. If a,b are two cluster decompositions, we write $b\subset a$ if b is a refinement of a. If a be a k-cluster decomposition $a=(a_1,\ldots,a_k)$, then $\mathbf{X}^a=\{x\in\mathbf{X};\Sigma_{l\in a_j}m_lx_l=0,j=1,\ldots,k\}$ the intracluster space and $\mathbf{X}_a=\{x\in\mathbf{X};x_i=x_j$ if $(ij)\in a_m$ for some $m\in\{1,\ldots,k\}\}$ the intercluster space. $\mathbf{X}^a$ and $\mathbf{X}_a$ give an orthogonal decomposition for $\mathbf{X}$ relative to the quadratic form $q(x)=\Sigma_j2m_j|x_j|^2$, $x\in\mathbf{X}$. For $x\in\mathbf{X}$, we have the orthogonal decomposition, $x=x^a+x_a$ with $x^a\in\mathbf{X}^a$ and $x_a\in\mathbf{X}_a$. The N-body Schrödinger operator, P, obtained above can be written in the form $P=P_0+V(x)$ where $P_0=-\Delta$ is the Laplace-Beltrami operator on the Euclidean space $(\mathbf{X},q)$ and $V(x)=\Sigma_{a\in\mathcal{A}}V_a(x^a)$ with $V_a(x^a)=V_{ij}(x_i-x_j)$ if a is an $(N-1)$-cluster decomposition and $(ij)\in a$; $V_a(x^a)=0$, otherwise. The atomic-type N-body operators can also be written in the form of generalized N-body operators. Let $-\Delta^a$ ($-\Delta_a$, respectively) denote the restriction of P_0 on $\mathbf{X}^a$ (on $\mathbf{X}_a$, respectively). For $a\in\mathcal{A}$, denote $P^a=-\Delta^a+\Sigma_{b\subseteq a}V_b(x^b),P_a=P^a-\Delta_a,I_a(x)=\Sigma_{b\nsubseteq a}V_b(x^b)$. P^a is the sub-Hamiltonian associated with the cluster decomposition a and I_a is the sum of all intercluster interactions. Assume that $V_a(x^a)$ is real and relatively form-compact with respect to $-\Delta^a$ in $L^2(\mathbf{X}^a)$, satisfying the decay

$$|V_a(x^a)|\leqslant C\langle x^a\rangle^{-\rho_0},\quad \rho_0>2, \tag{1.2}$$

for x^a outside some compact of $\mathbf{X}^a$. P is regarded as self-adjoint operator in $L^2(\mathbf{X})$ with form domain $H^1(\mathbf{X})$. Let $\mathcal{T}=\cup_{a\in\mathcal{A},\#a\geqslant2}\sigma_p(P^a)$ be the set of thresholds of P. The HVZ theorem says that the bottom of the essential spectrum, $E_0\triangleq\inf\sigma_{\mathrm{ess}}(P)$, of P is given by

$$E_0=\min_{a\in\mathcal{A},\#a\geqslant2}\inf\sigma(P^a)=\min_{a\in\mathcal{A},\#a=2}\inf\sigma(P^a).$$

Assume that E_0 is attained by a unique three-cluster decomposition, b, with $b=(b_1,b_2,b_3)$

$$\inf\sigma(P^b)=E_0=\inf\sigma_{\mathrm{ess}}(P). \tag{1.3}$$

Let $a_k=(b_i\cup b_j,b_k)$, where i, j, and k take different values in {1, 2, 3}. Throughout this paper, we suppose that $\dim\mathbf{X}^{a_j}\cap\mathbf{X}_b=3$, which is always satisfied for the operator obtained from (1.1). By HVZ theorem, one has $\sigma(P^{a_k})=[E_0,\infty[$. We assume that these are the only cluster decompositions attaining E_0,

$$\inf\sigma(P^a)=E_0,a\in\{b,a_1,a_2,a_3\},\quad \inf\sigma(P^a)>E_0,\quad a\notin\{b,a_1,a_2,a_3\},\#a\geqslant2. \tag{1.4}$$

Assume that the intercluster interactions related to b are attractive,

$$V_a(x^a)\leqslant0\quad\text{for } a\nsubseteq b. \tag{1.5}$$

Definition: Let Q be a generalized N-body Schrödinger operator with $N\geqslant3$. Let $E_0=\inf\sigma_{\mathrm{ess}}(Q)$. (a) Q is called *unique two-cluster* if there exits only one two-cluster decomposition a_0 such that $\inf\sigma(Q^{a_0})=E_0$. (b) E_0 is called a *threshold resonance* of Q if the equation $Qu=E_0u$ has a solution $u\in H^{1,-s}(\mathbf{X})\backslash L^2(\mathbf{X})$ for any $s>\frac{1}{2}$.

In our work, Q plays the role of one of the two-cluster sub-Hamiltonians P^{a_j} and $a_0=b$. Under the assumptions (1.2) and (1.4), the analysis of threshold resonances made in Ref. 14 is valid for P^{a_j}. One knows that if E_0 is a resonance of P^{a_j}, then it is simple and the corresponding resonant state u behaves like

$$u(x^{a_j}) = O(e^{-\delta|x^b|}|x_b^{a_j}|^{-1}), \quad |x^{a_j}| \to \infty, \quad \delta > 0. \tag{1.6}$$

Note the threshold resonances studied in Ref. 14 are two-cluster in nature and it is an interesting open question to study the many-cluster threshold resonances. See Ref. 16 for threshold resonances in geometric setting.

Theorem 1.1 (Ref. 15): *Let $N \geqslant 4$. Let the conditions (1.2) with $\rho > 2$, (1.4) and (1.5) be satisfied. Assume that each of the two-cluster sub-Hamiltonians P^{a_j}, $j=1,2,3$, have a threshold resonance at E_0. Let $N(\lambda)$ denote the number of the eigenvalues of P below $\lambda < E_0$. Then, there exists $C_0 > 0$ depending only on the reduced masses of b_1, b_2, b_3 such that*

$$N(\lambda) \geqslant C_0|\log|\lambda - E_0||, \quad \lambda \to E_0. \tag{1.7}$$

Assumption (1.4) may be realized when some particles are remarkably distinct from the others. In this work, we study the existence of two-cluster threshold resonances by varying some coupling constant. We will prove the following.

Theorem 1.2: *Let Q be an N-body operator with potentials V_c satisfying (1.2) and let a be a two-cluster decomposition. Assume that $V_c \leqslant 0$ for all $c \not\subseteq a$, $I_a = \Sigma_{c \not\subseteq a} V_c \neq 0$, $E_0 = \inf \sigma(Q^a) \in \sigma_d(Q^a)$. Denote $Q(g) = Q_a + gI_a$. Let g_0 be the critical coupling constant defined by*

$$g_0 = \sup\{g \geqslant 0; \inf \sigma(Q(g)) = \inf \sigma_{\mathrm{ess}}(Q(g)) = E_0\}. \tag{1.8}$$

Then, if $Q(g_0)$ is unique two-cluster, E_0 is a threshold resonance of $Q(g_0)$.

We will also give a sufficient condition to guarantee the unique two-cluster property of $Q(g_0)$ and study the perturbation of threshold resonance (Theorem 3.1), which is in some sense a converse of Theorem 1.2.

The idea of varying coupling constant limit is used in Ref. 7 for the study of absorption of discrete eigenvalues into a unique two-cluster threshold. In Ref. 7, the authors deduced their results by splitting some reduced operator into sum of a compact continuous part and a bounded holomorphic part. Our proof of Theorem 1.2 relies on the idea of Ref. 14, where the notion of N-body threshold resonance is introduced. In the proof of existence of resonant state (Proposition 2.3), the compactness of the whole reduced operator is essential.

Using Theorem 1.2, we will show that for appropriate constant $\alpha_1 > 0$, $\epsilon > 0$ small enough, there exists $g_j \in]0,1[$, $j=1,2,3$, such that Theorem 1.1 holds for the atomic-type four-body Schrödinger operator with Yukawa potentials

$$P = -\Delta_{x_1} - \Delta_{x_2} - \Delta_{x_3} - \frac{\alpha_1 e^{-\epsilon\alpha_1|x_1|}}{|x_1|} - g_1\frac{e^{-\epsilon|x_2-x_3|}}{|x_2-x_3|} - g_2\left(\frac{e^{-\epsilon|x_2|}}{|x_2|} + \frac{e^{-\epsilon|x_1-x_2|}}{|x_1-x_2|}\right) - g_3\left(\frac{e^{-\epsilon|x_3|}}{|x_3|} + \frac{e^{-\epsilon|x_1-x_3|}}{|x_1-x_3|}\right), \quad x_j \in \mathbb{R}^3. \tag{1.9}$$

The plan of this work is as follows. In Sec. II, we prove the existence of two-cluster threshold resonance. In Sec. III, we show that if E_0 is a two threshold resonance of $Q(g)$ for $g=g_0$, it is shifted to the left to become a nondegenerate discrete eigenvalue when g increases. These results are applied to the study of the N-body Efimov effect in Sec. IV; we give more explicit sufficient conditions under which Theorem 1.1 holds and establish a lower bound on the number of discrete eigenvalues of $P(g)$ as $g \to g_0$ and $g > g_0$, where $P = P(g_0)$ satisfies the assumptions of Theorem 1.1.

Notation: For $s \in \mathbb{R}$ and $k \in \mathbb{Z}$, we denote by $L^{2,s}$ and $H^{k,s}$ the weighted-L^2 and weighted-Sobolev spaces $L^2(\langle x\rangle^{2s}\,\mathrm{d}x)$ and $H^k(\langle x\rangle^{2s}\,\mathrm{d}x)$, respectively, and by $\mathcal{L}(s;s')$ and $\mathcal{L}(k,s;k',s')$ the space of bounded operators from $L^{2,s}$ to $L^{2,s'}$ and from $H^{k,s}$ to $H^{k',s'}$, respectively.

II. EXISTENCE OF TWO-CLUSTER THRESHOLD RESONANCES

The N-body Hamiltonian $Q = -\Delta + \Sigma_{c \in \mathcal{A}} V_c$ studied in Secs. II and III corresponds to a two-cluster sub-Hamiltonian in the Efimov effect with four or more particles. Thus let $N \geqslant 3$. Let a be

a two-cluster decomposition such that $\dim \mathbf{X}_a = 3$. Set $E_0 = \inf \sigma(Q^a)$. Assume that E_0 is in $\sigma_d(Q^a)$. Let φ_a be an associated eigenfunction, $Q^a\varphi_a = E_0\varphi_a$, $\|\varphi_a\| = 1$. We want to show that by varying the coupling constant g in $Q(g) = Q_a + gI_a(x)$, we can find a critical value g_0 such that E_0 is a threshold resonance of $Q(g_0)$. Let Π denote the orthogonal projection in $L^2(\mathbf{X})$ induced by φ_a,

$$\Pi u = (\varphi_a, u)_a \otimes \varphi_a, \quad u \in L^2(\mathbf{X}),$$

where $(,\cdot,\cdot)_a$ denotes the scalar product in x^a-variables. Let $\Pi' = 1 - \Pi$. Assume that for any $b \in \mathcal{A}$, $b \not\subseteq a$, $V_b \leqslant 0$, and V_b is $-\Delta$-form compact and outside some bounded set in $\mathbf{X}^b$,

$$|V_b(x^b)| \leqslant C|x^b|^{-\rho_0}, \quad \rho_0 > 2. \tag{2.1}$$

Assume that the intercluster interaction I_a is not identically zero. Set

$$Q(g) = Q^a - \Delta_a + gI_a, \quad Q'(g) = \Pi' Q(g) \Pi', \tag{2.2}$$

where $g > 0$ is a coupling constant. It is natural to expect that for g small, the bottom of the essential spectrum of $Q(g)$ remains to be E_0, while for g large, it may be shifted to the left.

Lemma 2.1: Let V_b be $-\Delta_{x^b}$-form compact. There exists $\mu_0 > 0$ such that if

$$g\|(-\Delta_{x^b} + 1)^{-1/2} V_b (-\Delta_{x^b} + 1)^{-1/2}\| \leqslant \mu_0, \tag{2.3}$$

then $\inf \sigma_{\mathrm{ess}}(Q(g)) = E_0$ *and a is the unique two-cluster decomposition which attains E_0: $\forall a' \in \mathcal{A}$, $\#a' = 2$ and $a' \neq a$, $\inf \sigma(Q^{a'}) > E_0$.*

Proof: Since E_0 is the discrete spectrum of Q^a, by HVZ theorem, for any $b \in \mathcal{A}$, $b \subset a$ (which means that b is a decomposition finer than a), one has

$$Q^b \geqslant E_0 + \epsilon_b$$

for some $\epsilon_b > 0$. Let a' be another two-cluster decomposition of the N-body system with $a' \neq a$. Take $b = a \cap a'$. Then, $b \subset a$ and the sub-Hamiltonian associated to a' can be decomposed as

$$Q_{a'}(g) = Q_b + g \sum_{c \subseteq a', c \not\subseteq a} V_c. \tag{2.4}$$

An argument of perturbation shows that if μ_0 is small enough, one has $Q_{a'} \geqslant E_0 + \epsilon_b/2$. By HVZ theorem, $\inf \sigma_{\mathrm{ess}}(Q(g)) = \min_{\#c=2} \inf \sigma(Q^c(g)) = \inf \sigma(Q^a) = E_0$. ∎

For potentials satisfying (2.1), with Lemma 2.1, one can apply the result on finiteness of discrete spectrum in N-body problems (Refs. 5 and 13) to conclude that $Q(g)$ has only a finite number of discrete eigenvalues for $g > 0$ small. In particular, if $g > 0$ is small enough, there is no discrete spectrum and $E(g) \triangleq \inf \sigma(Q(g))$ verifies $E(g) = \inf \sigma_{\mathrm{ess}}(Q(g)) = E_0$. Set

$$g_0 = \sup\{g > 0; E(g) = E_0, \inf \sigma_{\mathrm{ess}}(Q(g)) = E_0\}. \tag{2.5}$$

By Lemma 2.1, one has $g_0 > 0$. Since $I_a \leqslant 0$ and $I_a \neq 0$, one can show that for g large enough, there exists some sub-Hamiltonian $Q^{a'}(g)$, $a' \neq a$, such that $\inf \sigma(Q^{a'}(g)) < E_0$. Therefore $g_0 \epsilon]0, +\infty[$ is well defined. It may happen that when g increases from 0 to g_0, the bottom of the essential spectrum, E_0, of $Q(g_0)$ is attained by several two-cluster sub-Hamiltonians. In the following, we give the proof of Theorem 1.2, under the condition that $Q(g_0)$ is still unique two-cluster. By Theorem 3.3 (a) of Ref. 15, E_0 is not an eigenvalue of $Q(g_0)$. Therefore, to prove Theorem 1.2, we need only to construct a nontrivial solution for the equation $(Q(g_0) - E_0)u = 0$ with $u \in H^{1,-s}$ for any $s > \frac{1}{2}$. Then E_0 is a threshold resonance of $Q(g_0)$. The construction of a resonant state is based on the reduction made in Ref. 14.

According to whether or not E_0 is in $\sigma_p(Q'(g))$, the spectral property of $Q(g)$ at E_0 is determined either by an operator of the form $-\Delta_{x_a} + V_0$ or by an operator of the form

$$\begin{pmatrix} -\Delta_{x_a} + V_0 & C \\ C^* & 0 \end{pmatrix},$$

where V_0 is some effective potential and C some finite rank operator. Part (b) of the following lemma shows that we are actually in the first simpler situation.

Lemma 2.2: Assume that Q_a is the unique two-cluster Sub-Hamiltonian of $Q(g_0)$ which attains the bottom of its spectrum. There exists $\delta_0>0$ such that for $|g-g_0|<\delta_0$, one has

(a) $\inf \sigma_{\mathrm{ess}}(Q(g))=E_0$;
(b) $Q'(g)\geqslant(E_0+\epsilon_0)\Pi'$, *for some* $\epsilon_0>0$.

Proof: (a) By the unique two-cluster assumption for $Q(g_0)$, one has for any two-cluster decomposition $b\neq a Q_b(g_0)\geqslant(E_0+\epsilon_b)$ for some $\epsilon_b>0$. The same argument as in Lemma 2.1 shows that

$$\inf \sigma_{\mathrm{ess}}(Q(g) = \inf_{\#b=2} \sigma(Q^b(g)) = \inf \sigma(Q^a) = E_0$$

for g near g_0.

(b) We note that $E_0\notin\sigma_p(Q'(g_0))$. In fact, if $E_0\in\sigma_p(Q'(g_0))$, the associated eigenfunction ψ with $\|\psi\|=1$, would verify $\Pi'\psi=\psi$ and

$$E_0=\langle Q'(g_0)\psi,\psi\rangle=\langle Q(g_0)\psi,\psi\rangle.$$

Since $Q(g_0)\geqslant E_0$, this would imply $Q(g_0)\psi=E_0\psi$, which is impossible because by (a) of Theorem 3.3,[15] E_0 is not an eigenvalue of $Q(g_0)$. By Lemma 2.1 of Ref. 14, one has $\inf\sigma_{\mathrm{ess}}(Q'(g_0))\geqslant(E_0+\delta)$ for some $\delta>0$. Since $Q'(g_0)\geqslant E_0\Pi'$ and $E_0\notin\sigma_p(Q'(g_0))$, one sees that $Q'(g_0)\geqslant(E_0+\epsilon)\Pi'$ for some $\epsilon>0$. An easy argument of perturbation shows that for g sufficiently near g_0, $Q'(g)=Q'(g_0)+(g-g_0)\Pi' I_a\Pi'\geqslant(E_0+\epsilon/2)\Pi'$. ■

Lemma 2.2 (a) shows that for $g\in\,]g_0,g_0+\delta_0[$, $\delta_0>0$ small, $E(g)$ is in the discrete spectrum of $Q(g)$. It is clear that $E(g)\to E_0$ as $g\to g_0$.

With Lemma 2.2 (b), we can apply the reduction of Sec. III in Ref. 14 which says that for E near E_0, E is an eigenvalue (respectively, threshold resonance) of $Q(g)$ if and only if 0 is an eigenvalue (respectively, threshold resonance) of operator $\epsilon_{+-}(\lambda)$,

$$\epsilon_{+-}(\lambda,g)=\lambda-(-\Delta_{x_a}+V(\lambda,g)), \tag{2.6}$$

where $\lambda=E-E_0$, $R'(z,g)=(Q'(g)-z)^{-1}\Pi'$ and

$$V(\lambda,g)=([gI_a-g^2I_aR'(\lambda+E_0,g)I_a](\varphi_a\otimes\,\cdot\,),\varphi_a)_a.$$

Note that $I_a\leqslant 0$ and $R'(\lambda+E_0,g)\geqslant 0$ for λ near 0. $V(\lambda,g)$ is a negative self-adjoint operator, analytic in λ near 0 and g near g_0. Set

$$K(\lambda,g)=(-\Delta_{x_a}-\lambda)^{-1}V(\lambda,g). \tag{2.7}$$

Then, $K(\lambda,g):H^{1,-s}\to H^{1,-s}$ is compact operator-valued for $1/2<s<(\rho_0-1)/2$ and is continuous in λ near 0 and g near g_0. Clearly, u belongs to the kernel of $\epsilon_{+-}(\lambda,g)$ in $H^{1,-s}$ if and only if

$$(1+K(\lambda,g))u=0. \tag{2.8}$$

Proposition 2.3: One has $\dim\ker(1+K(0,g_0))_{H^{1,-s}}=1$.

Proof: By the assumption on $Q(g_0)$, for any $g>g_0$ sufficiently close to g_0, $E(g)$ is an eigenvalue of $Q(g)$ with $E(g)<E_0$ and $E(g)\to E_0$ as $g\to g_0$. Therefore, there exists a family of functions $u(g)\in H^1$ such that

$$u(g) = -K(\lambda(g), g)u(g), \quad \|u(g)\|_{H^{1,-s}} = 1, \quad \lambda(g) = E(g) - E_0.$$

The compactness of $K(\lambda(g), g)$ allows to extract a subsequence $\{u(g_k)\}$ of $\{u(g)\}$ such that $u(g_k) = -K(\lambda(g_k), g_k)u(g_k)$ converges (strongly) in $H^{1,-s}$. Let u_0 denote its limit. It is clear that $u_0 = -K(0, g_0)u_0$, $\|u_0\|_{H^{1,-s}} = 1$. This proves that 0 is an eigenvalue of $1 + K(0, g_0)$. Theorem 3.3 (a) of Ref. 15 implies that 0 is not an eigenvalue of $-\Delta_{x_a} + V_0$, where $V_0 = V(0, g_0)$. Therefore $u_0 \notin H^1$. Since the threshold resonance of $-\Delta_{x_a} + V_0$ at zero is at most simple,[6,14] one sees that $\ker(1 + K(0, g_0))$ in $H^{1,-s}$ is of dimension one and is spanned by u_0. ■

Proof of Theorem 1.2: Since $(-\Delta_{x_a} + V_0)u_0 = 0$, a direct calculation shows that

$$\psi_0 = \varphi_a \otimes u_0 - g_0 R'(E_0, g_0) I_a(\varphi_a \otimes u_0) \neq 0$$

verifies $(Q(g_0) - E_0)\psi_0 = 0$. See Ref. 14. Since $u_0 \in H^{1,-s}(\mathbf{X}_a) \backslash H^1(\mathbf{X}_a)$, $\psi_0 \in H^{1,-s}(\mathbf{X}) \backslash H^1(\mathbf{X})$ for any $s > 1/2$. E_0 is thus a threshold resonance of $Q(g_0)$. ■

Corollary 2.4: Let $Q = Q_a + I_a$, where a is a two-cluster decomposition, $I_a = \Sigma_{b \not\subset a} V_b$, $V_b \leqslant 0$, such that $E_0 \triangleq \inf \sigma(Q^a) \in \sigma_d(Q^a)$ and that $Q^{a'} > E_0$ for any other two-cluster decompositions $a' \neq a$. Assume in addition that Q has at least one discrete eigenvalue strictly below E_0. Then, E_0 is a threshold resonance of $Q(g_0)$.

Proof: It suffices to remark that g_0 defined by (2.5) is given by

$$g_0 = \inf\{g \in]0, 1\,]\,; \inf \sigma(Q(g)) < E_0, \tag{2.9}$$

and $g_0 \in]0, 1[$. $Q(g_0)$ is still unique two-cluster, because for any $a' \in \mathcal{A}$ with $\#a' = 2$ and $a' \neq a$, (2.4) shows that the sub-Hamiltonian of $Q(g_0)$ associated with a' satisfies $Q^{a'}(g_0) \geqslant Q^{a'}(1) > E_0$ for $g_0 \in]0, 1[$. Theorem 1.2 gives the desired result. ■

As an application of Corollary 2.4, we give a concrete example for the existence of two-cluster threshold resonance for three-body atomic-type Schrödinger operator with Yukawa-type potentials. Similar examples can be constructed for any number of particles.

Example: Consider an atomic-type three-body Schrödinger operator with Yukawa potentials,

$$Q(g) = -\Delta_{x_1} - \Delta_{x_2} - \frac{\alpha_1 e^{-\epsilon\alpha_1|x_1|}}{|x_1|} - g\left(\frac{\alpha_2 e^{-\epsilon\alpha_2|x_2|}}{|x_2|} + \frac{\alpha_3 e^{-\epsilon\alpha_3|x_1 - x_2|}}{|x_1 - x_2|}\right), \tag{2.10}$$

where the nucleus is fixed at the origin, $x_j \in \mathbb{R}^3$, α_i, ϵ, and g are suitable positive constants with $\alpha_1 > \max\{\alpha_2, \alpha_3\}$. We want to show Corollary 2.4 can be applied with $a = \{(01), (2)\}$. Consider first the two-body operator

$$Q(\alpha, \epsilon) = -\Delta - \frac{\alpha e^{-\alpha\epsilon|x|}}{|x|}, \quad x \in \mathbb{R}^3,$$

with $\alpha, \epsilon > 0$. By the change of variables $y = \alpha x$, one sees that $Q(\alpha, \epsilon)$ is unitarily equivalent with $\alpha^2 Q_1(\epsilon)$ where

$$Q_1(\epsilon) = -\Delta_y - \frac{e^{-\epsilon|y|}}{|y|}.$$

Using the perturbation theory around $Q_1(0) = -\Delta_y - (1/|y|)$, one sees that for $\epsilon > 0$ small,

$$\inf \sigma(Q_1(\epsilon)) = -\tfrac{1}{4} + c_0\epsilon + O(\epsilon^2).$$

This shows that there exists $\epsilon_0 > 0$ such that

$$\inf \sigma(Q(\alpha, \epsilon)) = \alpha^2\left(-\tfrac{1}{4} + c_0\epsilon + O(\epsilon^2)\right) < 0 \tag{2.11}$$

for all $0 < \epsilon < \epsilon_0, \alpha > 0$. For $g = 1$, let P_j denote the three two-body sub-Hamiltonians of $Q(1)$ associated with the cluster decompositions {(01), 2}, {(02), (1)}, {(12), (0)}, respectively. Using (2.11), one sees that their respective bottoms of spectrum are given by

$$E_j = a_j^2\left(-\tfrac{1}{4} + O(\epsilon)\right), \quad j = 1,2, \quad E_3 = \alpha_3^2\left(-\tfrac{1}{8} + O(\epsilon)\right),$$

which are all negative if $\epsilon > 0$ is small enough. So $Q(1)$ is unique two-cluster, since $\inf \sigma_{\mathrm{ess}}(Q(1)) = E_1 < \min\{E_2, E_3\}$. By minimax principle, one can easily check that $Q(1)$ has at least one discrete eigenvalue e_0 with $e_0 \leqslant E_1 + E_2 < E_1$. By Corollary 2.4, there exists some $g_0 \in]0,1[$ such that $E_0 = E_1$ is a two-cluster threshold resonance of $Q(g_0)$.

III. PERTURBATION OF TWO-CLUSTER THRESHOLD RESONANCES

In this section, we want to show that under intercluster perturbation, a two-cluster threshold resonance may be shifted to the left to produce discrete eigenvalue of the N-body system. Let $a \in \mathcal{A}$ be a two-cluster decomposition of an N-body system such that $\dim \mathbf{X}_a = 3$. With the notation of Sec. II, assume that

(i) $E_0 \triangleq \inf \sigma(Q^a) \in \sigma_d(Q^a)$;
(ii) for any $b \not\subseteq a$, $V_b(x^b) = O(\langle x^b \rangle^{-\rho_0})$, $\rho_0 > 2$, and $V_b \leqslant 0$ with $I_a \triangleq \Sigma_{b \not\subseteq a} V_a \neq 0$;
(iii) let $Q(g) = Q_a + gI_a$. Assume that there exists $g_0 > 0$ such that $Q(g_0)$ unique two-cluster at E_0, $Q(g_0) \geqslant E_0$ and that E_0 is a threshold resonance of $Q(g_0)$.

Note that different from Sec. II, here we do not assume that g_0 is the critical coupling constant such that $\inf \sigma(Q(g)) < E_0$ for any $g > g_0$.

Theorem 3.1: *Under the above assumptions, there exists* $\delta_0 > 0$ *such that for* $g \in]g_0, g_0 + \delta_0[$, $Q(g)$ *possesses only one eigenvalue* $E(g) \in]E_0 - \delta_0, E_0[$ *which is nondegenerated and satisfies*

$$E(g) = E_0 + E_1(g - g_0)^2 + o((g - g_0)^2), \tag{3.1}$$

as $g \to g_0$, *where* $E_1 < 0$.

Proof: We use the idea of Ref. 14 and only sketch the proof. Under the assumptions of Theorem 3.1, as in Sec. II, one has $Q'(g) \geqslant (E_0 + \epsilon_0/2)\Pi'$ for g near g_0. We can then apply the reduction made in Sec. III of Ref. 14 which implies that for $\delta_0 > 0$ small enough such that $E \in]E_0 - \delta_0, E_0 + \delta_0[$, $|g - g_0| < \delta_0$, E is an eigenvalue or threshold resonance of $Q(g)$ if and only if 0 is an eigenvalue or threshold resonance of $\epsilon_{+-}(\lambda, g)$ with the same multiplicity, where $\lambda = E - E_0$ and $\epsilon_{+-}(\lambda, g)$ is given by (2.6). Let

$$G_0 = \lim_{z \to 0, \Im z > 0} (-\Delta_{x_a} - z)^{-1} : H^{-1,s} \to H^{1,-s'}, s, s' > 1/2, s + s' > 2.$$

Denote $V_0 = V(0, g_0)$. The zero resonance of $\epsilon_{+-}(0, g_0)$ is simple[6,14] and Theorem 3.3 (a) of Ref. 15 shows that 0 is not an eigenvalue of $\epsilon_{+-}(0, g_0)$. Therefore the kernel of $\epsilon_{+-}(0, g_0)$ in $H^{1,-s}$ is of dimension one. Let u_0 be the resonant state of $\epsilon_{+-}(0, g_0)$ normalized by $\langle u_0^*, u_0 \rangle_a = 1$, where $u_0^* = -V_0 u_0$. Let $W(\lambda, g) = 1 + K(\lambda, g)$ with $K(\lambda, g)$ defined as in Sec. II. Study the Grushin problem associated with the operator

$$\mathcal{P}(\lambda, g) = \begin{pmatrix} W(\lambda, g) & T \\ S & 0 \end{pmatrix} : H^{1,-s} \times \mathbb{C} \to H^{1,-s} \times \mathbb{C},$$

where $s > 1/2$, $T : \mathbb{C} \ni c \to c u_0 \in H^{1,-s}$ and $S : H^{1,-s} \ni f \to \langle u_0^*, f \rangle \in \mathbb{C}$. Define $Q : H^{1,-s} \to H^{1,-s}$ by $Qf = \langle u_0^*, f \rangle_a u_0$. Denote $F = \mathrm{Range}(1 + G_0 V_0)$. Then, $Q' = 1 - Q$ is a projection from $H^{1,-s}$ onto F and $Q'(1 + G_0 V_0)Q'$ is invertible on F. For λ near 0 and g near g_0, one has

$$\begin{aligned} Q' W(\lambda, g) Q' (Q'(1 + G_0 V_0) Q')^{-1} Q' &= Q' + Q'(K(\lambda, g) - K(0, g_0)) Q' (Q'(1 + G_0 V_0) Q')^{-1} Q' \\ &= Q' + O(|\lambda|^{\epsilon} + |g - g_0|), \quad \epsilon > 0, \end{aligned} \tag{3.2}$$

in $\mathcal{L}(1, -s; 1, -s)$. We deduce that $Q' W(\lambda, g) Q'$ is invertible on F for $|\lambda|$ small and g near g_0. Let

$$D(\lambda,g) = (Q'W(\lambda,g)Q')^{-1}Q'.$$

Then for any $s>1/2$, one has

$$D(\lambda,g) = (Q'W(0,g_0)Q')^{-1}Q' + O(|\lambda|^{\epsilon} + |g-g_0|), \tag{3.3}$$

as operator on $H^{1,-s}$. Using $D(\lambda,g)$ to construct an approximate inverse, one can show that for λ near 0 and g near g_0, the operator $\mathcal{P}(\lambda,g)$ is invertible from $H^{1,-s}\times\mathbb{C}$ to $H^{1,-s}\times\mathbb{C}$ with the inverse given by

$$\mathcal{P}(\lambda,g)^{-1} = \begin{pmatrix} E(\lambda,g) & E_+(\lambda,g) \\ E_-(\lambda,g) & E_{+-}(\lambda,g) \end{pmatrix},$$

where

$$E(\lambda,g) = D(\lambda,g), \quad E_+(\lambda,g) = T - D(\lambda,g)Y, \tag{3.4}$$

$$E_-(\lambda,g) = S - SX, \quad E_{+-}(\lambda,g) = -SW(\lambda,g)T + SXY, \tag{3.5}$$

with

$$X = QW(\lambda,g)Q'D(\lambda,g), \quad Y = Q'W(\lambda,g)T.$$

Note that $E_{+-}(\lambda,g)$ is a scalar and that 0 is an eigenvalue of $1+K(\lambda,g)$ if and only if

$$E_{+-}(\lambda,g) = \langle V_0 u_0, (1 - W(\lambda,g)Q'D(\lambda,g)Q')W(\lambda,g)u_0\rangle = 0.$$

One has the asymptotic expansion

$$(-\Delta_a - \lambda)^{-1} = G_0 + i\lambda^{1/2}G_1 + O(|\lambda|^{1/2+\delta})$$

as operator from $H^{-1,s}$ to $H^{1,-s}$ with $s>3/2$, for some $\delta>0$. Set $\gamma=g-g_0$, $V_0=V(0,g_0)$. One has

$$V(\lambda,g) = V_0 + \gamma B_1 + \lambda C_1 + O((|\gamma| + |\lambda|)^2)$$

as operator from $H^{1,s}$ to $H^{1,s+\rho_0}$, where

$$B_1 = ([I_a - 2g_0 I_a R'(E_0,g_0)I_a](\varphi_a \otimes \cdot), \varphi_a)_a \tag{3.6}$$

$$+ (g_0^2 I_a R'(E_0,g_0))I_a R'\ (E_0,g_0)I_a(\varphi_a \otimes \cdot), \varphi_a)_a \leqslant 0 \tag{3.7}$$

as a sum of three negative self-adjoint operators in x_a variables. Since $u_0 \in H^{1,-s}$ for any $s>1/2$, $V_0u_0 \in H^{-1,s_0}$ for some $3/2<s_0<\rho_0-1/2$. By a direct calculation, one obtains

$$E_{+-}(\lambda,g) = b_1\gamma + c_1 i\lambda^{1/2} + O(\gamma^2 + \gamma|\lambda|^{1/2} + |\lambda|^{1/2+\delta_0}), \tag{3.8}$$

where

$$b_1 = -\langle u_0, B_1 u_0\rangle_a, \quad c_1 = \frac{1}{4\pi}|\langle V_0(u_0), 1\rangle_a|^2.$$

$c_1>0$ because u_0 is a resonant state so that $\langle V_0(u_0), 1\rangle_a \neq 0$ (Ref. 14), and

$$b_1 \geqslant -\langle I_a(\varphi_a \otimes u_0), (\varphi_a \otimes u_0)\rangle > 0,$$

because $I_a \leqslant 0$ and is not identically zero. It follows from (3.8) that for each $\gamma>0$ small enough, $\lambda \to E_{+-}(\lambda, g_0+\gamma)$ has a zero $\Lambda(g_0+\gamma)<0$ satisfying

$$\Lambda(g_0+\gamma)=E_1\gamma^2+O(\gamma^{2+\epsilon}), \tag{3.9}$$

where $E_1<0$. This shows that the generalized eigenvalue problem $(Q(g)-E)u=0$, $E\in]E-\delta_0,E+\delta_0[$, $u\in H^{1,-s}$, has only one solution $(E(g),u(g))$ with $E(g)=E_0+\Lambda(g)$. Since $E(g)<\inf\sigma_{\mathrm{ess}}(Q(g))$, by the method of *a priori* energy estimate, one can show that $u(g)\in H^1$. Thus, $E(g)$ is the unique eigenvalue of $Q(g)$ in $]E-\delta_0,E+\delta_0[$ and $E(g)$ is simple. This proves Theorem 3.1. ■

If g_0 be defined as in Sec. II, under the conditions of Theorem 1.2, one can apply Theorem 3.1 to conclude that $E(g)=\inf\sigma(Q(g))$ satisfies

$$E(g)=E_0+E_1(g-g_0)^2+o((g-g_0)^2), \tag{3.10}$$

as $g\to g_0$ and $g>g_0$. Equation (3.10) is known for C_0^∞ potentials.[7] If all potentials are dilation analytic, one can show that $E_{+-}(\lambda,g)$ has homomorphic extension for $\lambda\in\mathbb{C}$ in a small rotated half-disk around 0 and for g near g_0. From (3.8), we can derive that for $g<g_0$ and g near g_0, $\lambda\to E_{+-}(\lambda,g)$ has a zero $\Lambda(g)\in\mathbb{C}$ with $\Re\Lambda(g)>0$ and $\Im\Lambda(g)<0$. $E_0+\Lambda(g)$ is then a resonance of $Q(g)$ as pole of its resolvent.

IV. APPLICATIONS TO THE *N*-BODY EFIMOV EFFECT

Let $\mathcal{P}=-\Delta+\Sigma_a V_a(x^a)$ be an N-body Schrödinger operator, $N\geqslant 4$. Let $b\in\mathcal{A}$ with $\#b=3$, $E_0=\inf\sigma(\mathcal{P}^b)$. Assume that

(i) (1.5) is satisfied and $\inf\sigma(\mathcal{P}^a)>E_0$, $a\notin\{b,a_1,a_2,a_3\}$;
(ii) each $\mathcal{P}^{a_j}$ admits a discrete eigenvalue strictly below E_0.

Note that I_b can be decomposed as $I_b=I_1+I_2+I_3$ with $I_j=\Sigma_{c\not\subseteq b,c\subseteq a_j}V_c(x^c)$.

Theorem 4.1: *Under the above conditions, let* $\mathcal{P}^{a_j}(g)=\mathcal{P}^b-\Delta_{x_b^{a_j}}+gI_j$, *where* $-\Delta_{x_b^{a_j}}=-\Delta|_{\mathbf{x}^{a_j}\cap\mathbf{x}_b}$. *Then there exists* $g_j\in]0,1[$ *such that* E_0 *is a threshold resonance of* $P^{a_j}=\mathcal{P}^{a_j}(g_j)$, $j=1,2,3$. *In particular, Theorem 1.1 holds for the N-body operator* $P=\mathcal{P}_b+\Sigma_{j=1}^3 g_jI_j$.

Proof: Theorem 4.1 follows easily from Corollary 2.4. In fact, $\mathcal{P}^b$ can be regarded as a two-cluster sub-Hamiltonian of $\mathcal{P}^{a_j}=\mathcal{P}^b-\Delta_{x_b^{a_j}}+I_j$, $j=1,2,3$. The assumptions made on $\mathcal{P}^b$ imply that $\mathcal{P}^b$ is the only two-cluster sub-Hamiltonian of $\mathcal{P}^{a_j}$ such that $\inf\sigma(\mathcal{P}^c)=\inf\sigma_{\mathrm{ess}}(\mathcal{P}^{a_j})$, $c\subset a_j$, $c\neq a_j$, that is, $\mathcal{P}^{a_j}$ is unique two-cluster. Since $\mathcal{P}^{a_j}$ admits at least one discrete eigenvalue strictly below $E_0=\inf\sigma(P^b)$, Corollary 2.4 with $Q=\mathcal{P}^{a_j}$, $j=1,2,3$, says that there exists $g_j\in]0,1[$ such that $P^{a_j}=\mathcal{P}^{a_j}(g_j)=\mathcal{P}^b-\Delta_{x_b^{a_j}}+g_jI_j$ satisfies that $\inf\sigma(P^{a_j})=E_0$ and that E_0 is a threshold resonance of P^{a_j}. Now, for the N-body Hamiltonian $P=\mathcal{P}_b+\Sigma_{j=1}^3 g_jI_j$, one has $\inf\sigma(P^c)\geqslant\inf\sigma(\mathcal{P}^c)>E_0$ for $c\notin\{b,a_1,a_2,a_3\}$. Therefore, (1.4) is satisfied for P. It is clear that all conditions of Theorem 1.1 are verified for P. ■

Let us give an example of atomic-type four-body Schrödinger operator with Yukawa potentials such that all conditions of Theorem 1.1 are satisfied. Consider an atomic-type four-body quantum system labeled by {0, 1, 2, 3}, where the particle 0 denotes the nucleus with position at the origin in $\mathbb{R}^3$. Let $x_j\in\mathbb{R}^3$ denote the relative position between the jth electron and the nucleus. Consider the four-body Schrödinger operator with Yukawa potentials,

$$P(\alpha,\gamma,\epsilon)=\sum_{j=1}^{3}(-\Delta_{x_j}+V_j(x_j))+\sum_{1\leqslant j<k\leqslant 3}V_{jk}(x_j-x_k), \tag{4.1}$$

where

$$V_\beta(y)=-\frac{\gamma_\beta\alpha_\beta e^{-\epsilon_\beta\alpha_\beta|y|}}{|y|}$$

with $\alpha=(\alpha_\beta)$, $\gamma=(\gamma_\beta)$, $\epsilon=(\epsilon_\beta)$, the subscript β taking values in i or (jk) for $i,j,k\in\{1,2,3\}$, $j<k$. Here $\alpha_\beta,\epsilon_\beta>0$ and $\gamma_\beta\in]0,1]$. Let $b=\{(01),(2),(3)\}$ be the three-cluster decomposition of

the four-body system. The three resulting two-cluster decompositions are

$$a_1 = \{(01),(23)\}, \quad a_2 = \{(012),(3)\}, \quad a_3 = \{(013),(2)\}.$$

Let $Q(\alpha)$ be the four-body Schrödinger operator with Coulomb potentials

$$Q(\alpha) = \sum_{j=1}^{3} (-\Delta_{x_j} + W_j(x_j)) + \sum_{1 \leqslant j < k \leqslant 3} W_{jk}(x_j - x_k), \tag{4.2}$$

where

$$W_\beta(y) = -\frac{\alpha_\beta}{|y|}.$$

Let $E' = \min\{\inf(\sigma(Q^c(\alpha)) \ ; \ c \in \mathcal{A}, \#c = 2, c \not\supseteq b\}$. E' is independent of α_1. Take

$$\alpha_1 > 2\sqrt{-E'} \quad \text{and} \quad \gamma_1 = 1. \tag{4.3}$$

Denote

$$P^b = -\Delta_{x_1} - \frac{\alpha_1 e^{-\epsilon_1 \alpha_1 |x_1|}}{|x_1|}, \quad E_0 = \inf \sigma(P^b). \tag{4.4}$$

Let $\epsilon_\beta > 0$ be small enough such that the infimum of the spectrum of each two-particle sub-Hamiltonian,

$$-\Delta_y - \frac{\alpha_\beta e^{-\epsilon_\beta \alpha_\beta |y|}}{|y|}$$

is a negative eigenvalue. Then

$$E_0 = \inf \sigma(P^b) = \frac{\alpha_1^2}{4}(-1 + O(\epsilon_1)) \tag{4.5}$$

for ϵ_1 small enough. Since $P^a(\alpha, \gamma, \epsilon) \geqslant Q^a(\alpha)$ for any $a \in \mathcal{A}$ and for any $\gamma_\beta \in]0,1]$, one has

$$\inf \sigma(P^b) < E' \leqslant \min\{\inf(\sigma(P^c(\alpha, \gamma, \epsilon)); c \in \mathcal{A}, \# c = 2, c \not\supseteq b \}. \tag{4.6}$$

This shows that for any $\gamma_\beta \in]0,1]$, $\beta \neq 1$, $\inf \sigma_{\text{ess}}(P(\alpha, \gamma, \epsilon)) = E_0$ and that it can only be attained by the sub-Hamiltonians associated with $a \in \{b, a_1, a_2, a_3\}$. Note that $P^b(\alpha, \gamma, \epsilon)$ can be regarded as a two-cluster sub-Hamiltonian of $P^{a_j}(\alpha, \gamma, \epsilon)$. By the example given in Sec. II, for $k = 2, 3$, there exists $\gamma_k = \gamma_{1k} = g_k \in]0,1[$ such that

$$P^{a_k} = -\Delta_{x_1} - \Delta_{x_k} - \frac{\alpha_1 e^{-\epsilon_1 \alpha_1 |x_1|}}{|x_1|} - g_k \left(\frac{\alpha_k e^{-\epsilon_k \alpha_k |x_k|}}{|x_k|} + \frac{\alpha_{1k} e^{-\epsilon_{1k} \alpha_{1k} |x_1 - x_k|}}{|x_1 - x_k|} \right)$$

satisfies

$$\inf \sigma(P^{a_k}) = \inf \sigma(P^b) = E_0 \text{ and } E_0 \text{ is a threshold resonance of } P^{a_k}, \quad k = 2,3. \tag{4.7}$$

Using $y = x_2 - x_3$ as part of intracluster coordinates, one can write P^{a_1} as

$$P^{a_1} = -\Delta_{x_1} - 2\Delta_y - \frac{\alpha_1 e^{-\epsilon_1 \alpha_1 |x_1|}}{|x_1|} - \frac{\gamma_{23} \alpha_{23} e^{-\epsilon_{23} \alpha_{23} |y|}}{|y|}.$$

This is a particular case of the example of Sec. II. Let g_1 be defined

$$g_1 = \sup\left\{ \gamma_{23} > 0; -2\Delta_y - \frac{\gamma_{23}\alpha_{23}e^{-\epsilon_{23}\alpha_{23}|y|}}{|y|} \geqslant 0 \right\}.$$

Then, (4.7) is also satisfied for $k=1$ with $\gamma_{23}=g_1$. All assumptions of Theorem 1.1 are thus satisfied and Theorem 1.1 affirms that the Efimov effect takes place for $P(\alpha,\gamma,\epsilon)$ with the parameters adjusted as above. In particular, if $\alpha_\beta=1$ for $\beta\neq 1$, and $\epsilon_\beta=\epsilon$, our result claims that for any $\alpha_1>2\sqrt{-E'}$ and for any $\epsilon>0$ small enough, there exists $g_j\in\,]0,1[$, $j=1,2,3$, such that the Efimov effect happens at the energy $E_0=-(\alpha_1^2/4)+O(\epsilon)$ for the atomic-type four-body Schrödinger operator,

$$P = -\Delta_{x_1} - \Delta_{x_2} - \Delta_{x_3} - \frac{\alpha_1 e^{-\epsilon\alpha_1|x_1|}}{|x_1|} - g_1\frac{e^{-\epsilon|x_2-x_3|}}{|x_2-x_3|} - g_2\left(\frac{e^{-\epsilon|x_2|}}{|x_2|} + \frac{e^{-\epsilon|x_1-x_2|}}{|x_1-x_2|}\right) - g_3\left(\frac{e^{-\epsilon|x_3|}}{|x_3|} + \frac{e^{-\epsilon|x_1-x_3|}}{|x_1-x_3|}\right). \tag{4.8}$$

As application of Theorem 3.1, we give the following result which is an improvement of Theorem 5.1 of Ref. 15, where the additional condition $V_c\in C_0^\infty$ for $c\not\subset b$ was needed.

Theorem 4.2: *Let $b\in\mathcal{A}$ with $\#b=3$ and $P(g)=P_b+gI_b$. Assume the conditions of Theorem 1.1 satisfied for $P=P(g_0)$. Then for $g>g_0$ and g near g_0, the total number of discrete eigenvalues, $\mathcal{N}(g)$, of $P(g)$ is finite and satisfies*

$$\mathcal{N}(g) \geqslant 2C_0|\log(g-g_0)| - C_1, \tag{4.9}$$

as $g\to g_0$. Here $C_0>0$ is the same as in Theorem 1.1 and C_1 is a constant independent of g.

With the results of Secs. II and III, one has for $g>g_0$ and g near g_0,

$$\Sigma_3(g) \triangleq \min_{\#c=3} \inf \sigma(P^c(g)) = E_0$$

and

$$\Sigma_2(g) \triangleq \min_{\#c=2} \inf \sigma(P^c(g)) = \min_{1\leqslant j\leqslant 3} \inf \sigma(P^{a_j}(g)).$$

Applying Theorem 3.1 to $P^{a_j}(g)$ with P^a replaced by P^b, one has

$$\inf \sigma(P^{a_j}(g)) = E_0 + E_{1,j}(g-g_0)^2 + o((g-g_0)^2), \quad E_{1,j}<0.$$

This shows that

$$\Sigma_2(g) = E_0 + E_1(g-g_0)^2 + o((g-g_0)^2) < \Sigma_3(g),$$

where $E_1=\min_j\{E_{1,j}\}<0$. Since $\rho_0>2$, the number of discrete eigenvalues of $P(g)$ is finite. Noticing that $P(g)\leqslant P(g_0)$ for $g>g_0$, one has $\mathcal{N}(g)\geqslant N(\Sigma_2(g))$. Theorem 1.1 gives the desired result.

(Received 17 March 2005; accepted 12 September 2005; published online 11 November 2005)

We consider a model of quantum electrodynamics (QED) on a graph as the generalization of dimensional deconstruction with the Abelian symmetry. Arbitrary structures of the theory space correspond to the graphs consisting of vertices and edges. The mass spectrum of the model is expressed in terms of eigenvalues of the Laplacian for the graph. We also find that physical massless scalar modes are associated with the fundamental tie set matrix on the graph. We further investigate the one-loop divergences in the model by use of the background field method. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2109687]

I. INTRODUCTION

One of the most important problems in modern particle physics is to understand the existence of largely different mass scales within a unified theory. On many occasions, we use the idea of supersymmetry (SUSY) to control the quantum correction in order to understand the mass hierarchy.

Recently, the scenario for the electroweak symmetry breaking without SUSY has been suggested and studied by many authors. The seminal paper in recent development is Ref. 1. The divergent diagrams are mutually canceled among contributions from a number of bosonic fields.

The basic idea of such a mechanism is now attributed to dimensional deconstruction,[2] where copies of a four-dimensional "theory" as well as a new set of fields linking pairs of these "theories" are considered. Then, the resulting whole theory given by the "theory space" may be equivalent to a higher-dimensional theory with discretized extra dimensions.

The present authors considered previously a generalization of the deconstruction.[3] A generalization of deconstruction is also argued in Ref. 4. We identify the theory space as a graph consisting of vertices and edges. In the present paper, we further investigate the divergences in the field theory on a graph, particularly focusing on an Abelian theory. Although the non-Abelian structure and alignment of fields in a certain representation may be essential for realistic models, the substantial behavior of divergences can be viewed from a simpler model. Recently, a model with extra massive vector boson was studied by Körs and Nath,[5] where the Stueckelberg formalism was utilized. Our model can be applied to a generalization of their work.

We organize the present paper in the following way. In Sec. II, we review graph theory and matrices associated with a graph, including the Laplacian of a graph. The Lagrangian for gauge fields on a graph is described in Sec. III. The Lagrangian for fermion fields is described in Sec. IV. In Sec. V, the one-loop logarithmical divergences in effective Lagrangian density are discussed. In

[a)]Electronic mail: b1834@sty.cc.yamaguchi-u.ac.jp
[b)]Electronic mail: shiraish@yamaguchi-u.ac.jp

Sec. VI, we study the one-loop finiteness of the effective potential for a constant background link scalar fields. Comment on the non-Abelian generalization is given in Sec. VII. We close with Sec. VIII, where summary and prospects are given.

II. GRAPH THEORY AND MATRICES ASSOCIATED WITH A GRAPH

In this section, after a brief description of "graph,"[6] some matrices associated with a graph are introduced.

Let $G(V,E)$ be a graph with vertex set V and edge set E. The set of edges connects the vertices. A graph which does not have multiple edges (edges connecting the same two vertices) and self-loops (edges from a vertex to itself) is called a simple graph. We only consider simple graphs in the present paper. The order of G, denoted by p in this paper, is the number of vertices in the graph, while the size of G, denoted by q in this paper, is the number of edges in the graph. A pair of vertices u and v is said to be adjacent, denoted $u \sim v$, if there exists an edge $e \in E$ which connects u and v. Such edge is denoted as $e=\{u,v\}$.

The adjacency matrix A is defined as

$$(A)_{vv'} = \begin{cases} 1 & \text{if } v \sim v' \ (v \text{ is adjacent to } v') \\ 0 & \text{otherwise} \end{cases} . \tag{1}$$

The degree of a vertex v, denoted $\deg(v)$, is the number of edges directly connected to (in other words, is incident with) v. The (diagonal) degree matrix D is defined as

$$(D)_{vv'} = \begin{cases} \deg(v) & \text{if } v = v' \\ 0 & \text{otherwise} \end{cases} . \tag{2}$$

The graph Laplacian (or combinatorial Laplacian) $\Delta(G)$ is defined[7] by

$$\Delta_{vv'} = (D-A)_{vv'} = \begin{cases} \deg(v) & \text{if } v = v' \\ -1 & \text{if } v \text{ and } v' \text{ are adjacent } (v \sim v') \\ 0 & \text{otherwise} \end{cases} , \tag{3}$$

where $v,v' \in V$, and $\deg(v)$ denotes the degree of v.

The $(\text{mass})^2$ matrix for vector fields in the Hill-Leibovich model[8] is proportional to Δ for a cycle graph[6] with N vertices (denoted as C_N).

Next, we consider a directed graph. An oriented edge $e=[u,v]$ $(u,v \in V(G))$ connects the origin $u=o(e)$ and the terminus $v=t(e)$ (and an unoriented edge does not distinguish its origin and terminus).

The incidence matrix (for a directed graph) E is defined by

$$(E)_{ve} = \begin{cases} 1 & \text{if } v = o(e) \\ -1 & \text{if } v = t(e) \\ 0 & \text{otherwise} \end{cases} . \tag{4}$$

Our important observation is

$$\Delta = EE^T, \tag{5}$$

for any given graph.

III. VECTOR FIELDS (+SCALAR FIELDS)

The simplest model with the Abelian symmetry is studied by Hill and Leibovich.[8] We consider here the extension of the model constructed on a general graph.

We associate vector fields with vertices of a graph G. Further, we introduce a link field U_e on each edge. We can write the Lagrangian density for vector fields whose $(\text{mass})^2$ matrix is $\Delta(G)$ as[5]

$$\mathcal{L}_V = -\frac{1}{4g^2}\sum_{v\in V} F_v^{\mu\nu}F_{v\mu\nu} + \frac{1}{2}v^2\sum_{e\in E}|D^\mu U_e|^2, \tag{6}$$

where g is a gauge coupling and $F_v^{\mu\nu}=\partial^\mu A_v^\nu-\partial^\nu A_v^\mu$ $(\mu,\nu=0,1,2,3)$ stands for the field strength. In this section the metric signature is $(+---)$. The covariant derivative is defined as $D^\mu U_e = \partial^\mu U_e - i(A^\mu_{o(e)}U_e - U_e A^\mu_{t(e)})$.

The Lagrangian is invariant under the following gauge transformations:

$$\begin{aligned} A_v^\mu &\to A_v^\mu + \partial^\mu \omega_v, \\ U_e &\to \exp(i\omega_{o(e)})U_e \exp(-i\omega_{t(e)}). \end{aligned} \tag{7}$$

Now, we assume that the absolute value of each link field $|U_k|$ has a common value 1. If we express U_e as $\exp(-i\chi_e)$, the Lagrangian (6) becomes

$$\begin{aligned} \mathcal{L}_V &= -\frac{1}{4g^2}\sum_{v\in V} F_v^{\mu\nu}F_{v\mu\nu} + \frac{1}{2}v^2\sum_{e\in E}(\partial^\mu\chi_e + A^\mu_{o(e)} - A^\mu_{t(e)})^2 \\ &= -\frac{1}{4g^2}\sum_{v\in V} F_v^{\mu\nu}F_{v\mu\nu} + \frac{1}{2}v^2\sum_{e\in E}(\partial^\mu\chi_e + (E^TA^\mu)_e)^2, \end{aligned} \tag{8}$$

where $(E^TA^\mu)_e$ is an abbreviated form of $\Sigma_{v\in V}(E^T)_{ev}A_v^\mu$.

We find that the term including χ_e resembles the gauge kinetic term of the extra "fifth" index, $\propto(F_{\mu 5})^2$, when we regard $gv(A^\mu_{t(e)}-A^\mu_{o(e)})$ as a discretization of differentiation and $A_5\propto\chi$. Then, the gauge transformation on χ_e is $\chi_e\to\chi_e+\delta\chi_e$, with

$$\delta\chi_e = \omega_{t(e)} - \omega_{o(e)} = -(E^T\omega)_e. \tag{9}$$

The degrees of freedom in this gauge transformation are $p-1$, and $(p-1)$ scalar fields can be gauged away from the Lagrangian. Therefore, there are $(q-p+1)$ physical, massless scalar fields. As explained in Ref. 8, the vector fields absorb massive modes of the link scalar fields, and the zero modes of the link fields survive as physical fields. Thus, except for the zero modes, the massive modes of link fields χ_e are nothing but the Stueckelberg fields.[9]

The physical massless scalar modes $\chi_0^{(i)}(i=1,\ldots,q-p+1)$ are orthogonal to the gauge transformation, i.e., $\Sigma_{e\in E}\chi_{0e}^{(i)}(E^T\omega)_e=0$. Thus, the zero modes satisfy $(E\chi_0^{(i)})_v=0$. Actually, the graph includes $(q-p+1)$ fundamental circuits, that is, independent (undirected) cycles as subgraphs. The number of fundamental circuit $n(G)$ is called the *cyclomatic number* of the graph G, or its *nullity*. For the ith fundamental circuit $C^{(i)}$

$$\chi_{0e}^{(i)} \propto \begin{cases} \pm 1 & \text{if } e\in E(C^{(i)}) \\ 0 & \text{otherwise} \end{cases}, \tag{10}$$

where the minus sign is chosen when the edge has the opposite direction to an orientation of the fundamental circuit, satisfies $(E\chi_0^{(i)})_v=0$. Then, $\chi_0^{(i)}$ is represented by rows of the *fundamental tie set matrix* F_f, since *rank* $F_f=n(G)$. For the definition of fundamental circuits and fundamental tie set matrix, in other words, fundamental circuit matrix, and for a related theorem, see Ref. 6. For example, for the graph including a (directed) fundamental circuit of length three, the incidence matrix includes

$$\begin{pmatrix} 1 & 0 & -1 \\ -1 & 1 & 0 \\ 0 & -1 & 1 \end{pmatrix}, \tag{11}$$

as a submatrix. Then, $\chi_0\propto(1,1,1,0,\ldots,0)$ is a zero mode.

Now and then the part of the Lagrangian for the link fields gives a mass term for the vector fields. For example, we consider a cycle graph C_5. The (mass)^2 matrix for vector fields takes the form

$$(gv)^2\Delta(C_5) = (gv)^2\begin{pmatrix} 2 & -1 & 0 & 0 & -1 \\ -1 & 2 & -1 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 \\ 0 & 0 & -1 & 2 & -1 \\ -1 & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{12}$$

Up to the dimensionful coefficient g^2v^2, this matrix is identified with the Laplacian matrix for the graph C_p, the cycle graph with p vertices. We find, indeed, any theory space can be associated with the graph.

Next, we will manage to perform gauge fixing. We choose the gauge fixing term as

$$\mathcal{L}_{gf} = -\sum_{v\in V}\frac{1}{2g^2\xi}(\partial_\mu A_v^\mu - \xi(gv)^2(E\chi)_v)^2, \tag{13}$$

where $(E\chi)_v$ means $\Sigma_{e\in E}E_{ve}\chi_e$.

For this gauge choice, we introduce the ghost field and its Lagrangian

$$\mathcal{L}_{ghost} = \sum_{v\in V}\overline{c_v}[-(\partial^2 + \xi(gv)^2EE^T)c]_v, \tag{14}$$

because $\delta(\partial_\mu A_v^\mu - \xi(gv)^2(E\chi)_v) = \partial^2\omega_v + \xi(gv)^2(EE^T\omega)_v$.

The gauge-fixed Lagrangian $\mathcal{L}_{V\xi} = \mathcal{L}_V + \mathcal{L}_{gf} + \mathcal{L}_{ghost}$ becomes

$$\begin{aligned}\mathcal{L}_{V\xi} = &-\frac{1}{2g^2}\sum_{v\in V}\left[(\partial_\mu A_v^\nu)^2 - \left(1-\frac{1}{\xi}\right)(\partial_\mu A_v^\mu)^2\right] + \frac{1}{2}v^2\sum_{v\in V}A_v^\mu(EE^TA_\mu)_v + \frac{1}{2}\sum_{e\in E}(\partial^\mu X_e)^2 \\ &-\frac{1}{2}\xi(gv)^2\sum_{e\in E}X_e(E^TEX)_e + \sum_{v\in V}\overline{c_v}[-(\partial^2 + \xi(gv)^2EE^T)c]_v,\end{aligned} \tag{15}$$

where we rewrite the scalar fields as $X_e \equiv v\chi_e$. The massive scalar modes are the would-be Nambu-Goldstone bosons that become a longitudinal component of vector fields, while the massless modes are physical massless scalars. The massive scalar modes are associated with the *fundamental cutset matrix* C_f, since $F_fC_f^T = 0$.[10]

If we choose $\xi = 1$ gauge, we can apparently find that vector fields (physical and unphysical), scalar fields, and ghost fields have the same mass spectrum up to zero modes, since EE^T and E^TE have the same nonzero eigenvalues. Indeed, $\mathrm{Tr}\, e^{-EE^Tt} - \mathrm{Tr}\, e^{-E^TEt} = p - q$ is an "index theorem" in graph theory as well as the theory of non-negative matrices.

The treatment of the "unexpected" scalars in the phenomenological point of view will be discussed after considering the coupling to fermions in the successive section.

IV. FERMIONS ON A GRAPH

We associate right-handed fermion fields with vertices of a graph G, and left-handed fermion fields with edges of G. The Lagrangian density for Dirac fields associated with the directed graph can be written by

$$\mathcal{L}_f = \sum_{v\in V}\overline{\psi}_{Rv}i\gamma^\mu\partial_\mu\psi_{Rv} + \sum_{e\in E}\overline{\psi}_{Le}i\gamma^\mu\partial_\mu\psi_{Le} - m\left(\sum_{e\in E}\sum_{v\in V}\overline{\psi}_{Le}E_{ev}^T\psi_{Rv} + \mathrm{H.c.}\right). \tag{16}$$

The equations of motion are derived from this Lagrangian as

$$\partial^2 \psi_{Rv} + m^2 (EE^T \psi_R)_v = 0,$$
$$\partial^2 \psi_{Le} + m^2 (E^T E \psi_L)_e = 0. \tag{17}$$

Here, we already know that the graph Laplacian matrix $\Delta \equiv EE^T$ has a single zero eigenvalue for a simple connected graph.[7] Moreover, it is well known that the matrix $E^T E$ has the same eigenvalues as EE^T and $(q-p)$ zero modes. Therefore, the particle spectrum contains one right-handed Weyl fermion, $(q-p+1)$ left-handed Weyl fermions (or, one massless Dirac fermion and $(q-p)$ left-handed fermion), and $(p-1)$ massive Dirac fermions.

Now, we introduce the coupling between gauge and link fields. In addition to (7), we will impose the gauge symmetry and assume the following gauge transformation on fermions:

$$\psi_{Rv} \to \exp(i\omega_v)\psi_{Rv},$$
$$\psi_{Le} \to \exp(i\omega_{o(e)})\psi_{Le}. \tag{18}$$

The invariant Lagrangian is

$$\begin{aligned}\mathcal{L}_f &= \sum_{v\in V} \overline{\psi}_{Rv} i\gamma_\mu (\partial^\mu - iA_v^\mu)\psi_{Rv} + \sum_{e\in E} \overline{\psi}_{Le} i\gamma_\mu (\partial^\mu - iA_{o(e)}^\mu)\psi_{Le} - m\left(\sum_{e\in E} \overline{\psi}_{Le}(\psi_{Ro(e)} - U_e \psi_{Rt(e)}) + \text{H.c.}\right) \\ &= \sum_{v\in V} \overline{\psi}_{Rv} i\gamma_\mu D_v^\mu \psi_{Rv} + \sum_{e\in E} \overline{\psi}_{Le} i\gamma_\mu D_e^\mu \psi_{Le} - m\left(\sum_{e\in E}\sum_{v\in V} \overline{\psi}_{Le} \hat{E}_{ev}^\dagger \psi_{Rv} + \text{H.c.}\right),\end{aligned} \tag{19}$$

where the weighted incidence matrix $\hat{E}$ is defined as

$$(\hat{E})_{ve} = \begin{cases} 1 & \text{if } v = o(e) \\ -U_e^\dagger & \text{if } v = t(e) \\ 0 & \text{otherwise} \end{cases}. \tag{20}$$

The $(\text{mass})^2$ matrix, or modified graph Laplacian, can be read as

$$(\hat{\Delta})_{vv'} = (\hat{E}\hat{E}^\dagger)_{vv'} = \begin{cases} \deg(v) & \text{if } v = v' \\ -U_e^\dagger & e = [v', v] \in E(G) \\ -U_e & e = [v, v'] \in E(G) \\ 0 & \text{otherwise} \end{cases}. \tag{21}$$

Getting the gauge field Lagrangian in the previous section and the fermion Lagrangian together, we have a QED-like theory on a graph. When we investigate the model in view of quantum theory, we find that there appears chiral anomaly in general except for the $p=q$ case. The cancellation of anomaly requires more charged fermion species. We do not treat the problem of anomaly in the present paper. Another problem for phenomenologically viable models is the existence of exactly massless fermions. Even in the $p=q$ case a massless Dirac field appears. Of course, additional mass terms can be introduced into the model, but the origin of such a small "electron mass" is not discussed here.

Now, we study the coupling between zero-mode fields, which describes the low-energy physics $E \ll v, m$. The lowest-order interactions can be read as

$$\mathcal{L}_{\text{int}} = \sum_{v\in V} \overline{\psi}_{Rv} \gamma_\mu A_v^\mu \psi_{Rv} + \sum_{e\in E} \overline{\psi}_{Le} \gamma_\mu A_{o(e)}^\mu \psi_{Le} - \frac{m}{v}\left(\sum_{e\in E} \overline{\psi}_{Le} i X_e \psi_{Rt(e)} + \text{H.c.}\right). \tag{22}$$

We consider here the simplest case, $p=q$. Then, the graph contains one circuit $\tilde{C}_{\tilde{p}}$ with length $\tilde{p}(\leqslant p)$. The zero-mode fields of A^μ and ψ_R are expressed as

$$A_v^\mu = \frac{1}{\sqrt{p}} A_0^\mu, \quad \psi_{Rv} = \frac{1}{\sqrt{p}} \psi_{R0}, \quad \forall\, v \in V(G). \tag{23}$$

On the other hand, the zero-mode fields of X and ψ_L are expressed as

$$X_e = \frac{1}{\sqrt{\tilde{p}}} X_0, \quad \psi_{Le} = \frac{1}{\sqrt{\tilde{p}}} \psi_{L0}, \quad \forall\, e \in E(\tilde{C}_{\tilde{p}}). \tag{24}$$

Then, the zero-mode interactions can be written as

$$\mathcal{L}_{\text{int}0} = \frac{1}{\sqrt{p}} \bar{\psi}_{R0} \gamma_\mu A_0^\mu \psi_{R0} + \frac{1}{\sqrt{p}} \bar{\psi}_{L0} \gamma_\mu A_0^\mu \psi_{L0} - \frac{1}{\sqrt{p}} \frac{m}{v} (\bar{\psi}_{L0} i X_0 \psi_{R0} + \text{H.c.}). \tag{25}$$

The gauge coupling is $g/\sqrt{p}$, while the link scalar coupling is $(m/v)/\sqrt{p}$, which is the same order as the gauge coupling if the fermion mass equals the vector boson mass, $m=gv$.

We do not know the massless scalar interaction in the real world. One way to avoid the difficulty in the existence of scalars is to assume that the massless scalar interacts very weakly with matter fields. Unfortunately, here we found that the suppression of the scalar interaction due to the choice of a graph cannot be expected in general. We can only arrange the two scales m and v for this purpose.

A special case is the choice of a graph with $p=q+1$, called the tree (graph).[6] All link scalar fields are absorbed by massive vector bosons, leaving a massless vector field. The simplest tree graph, path graph P_p,[6] corresponds to the dimensional deconstruction of an orbifold S^1/Z_2.

Another method to discard the massless scalar is incorporation of the plaquette-type term, $\text{Re}(U_{e_1} \cdots U_{e_{q'}})$ where $e_1, \ldots, e_{q'} \in E(C)$ and C is a cycle in a graph, in the Lagrangian. The plaquette-type term will be studied elsewhere.

In the rest of the present paper, we will concentrate on the study of one-loop UV divergence of the model.

V. ONE-LOOP DIVERGENCES IN EFFECTIVE ACTION

We investigate the one-loop divergence in the model by calculating the effective action by the heat-kernel method with background fields.[11] In this section, we use the Euclidean signature for the metric. The gamma matrices satisfy $\{\gamma^\mu, \gamma^\nu\} = -2\delta^{\mu\nu}$. We assemble the fermion fields as

$$\Psi \equiv \begin{pmatrix} \psi_R \\ \psi_L \end{pmatrix}, \tag{26}$$

and define a derivative operator

$$i\mathcal{D} \equiv \begin{pmatrix} iD_V & -m\hat{E} \\ -m\hat{E}^\dagger & iD_E \end{pmatrix}, \tag{27}$$

and

$$i\mathcal{D}^\dagger \equiv \begin{pmatrix} iD_V & m\hat{E} \\ m\hat{E}^\dagger & iD_E \end{pmatrix}, \tag{28}$$

where $D_V = \text{diag}(\gamma^\mu D_{v_1}^\mu, \gamma^\mu D_{v_2}^\mu, \ldots, \gamma^\mu D_{v_p}^\mu)$ and $D_E = \text{diag}(\gamma^\mu D_{e_1}^\mu, \gamma^\mu D_{e_2}^\mu, \ldots, \gamma^\mu D_{e_q}^\mu)$. Then, the Euclidean Lagrangian is expressed as $\mathcal{L}_f = \bar{\Psi}^\dagger i\mathcal{D}\Psi$.

As a preparation, we write the quadratic operator $\mathcal{D}^\dagger\mathcal{D}$ explicitly as

$$\mathcal{D}^\dagger\mathcal{D} = \begin{pmatrix} D_V^2 + m^2\hat{E}\hat{E}^\dagger & \mathrm{i}\,\mathrm{m}(D_V\hat{E} - \hat{E}D_E) \\ \mathrm{i}\,\mathrm{m}(D_E\hat{E}^\dagger - \hat{E}^\dagger D_V) & D_E^2 + m^2\hat{E}^\dagger\hat{E} \end{pmatrix}, \tag{29}$$

where

$$(D_V^2)_{vv'} = \begin{cases} -(D_v^\mu)^2 - \dfrac{i}{2}\gamma^\mu\gamma^\nu F_v^{\mu\nu} & \text{if } v = v' \\ 0 & \text{otherwise} \end{cases}, \tag{30}$$

$$(D_E^2)_{ee'} = \begin{cases} -(D_e^\mu)^2 - \dfrac{i}{2}\gamma^\mu\gamma^\nu F_{o(e)}^{\mu\nu} & \text{if } e = e' \\ 0 & \text{otherwise} \end{cases}, \tag{31}$$

$$(D_V\hat{E} - \hat{E}D_E)_{ve} = \begin{cases} -\gamma^\mu(D^\mu U_e)^\dagger & \text{if } v = t(e) \\ 0 & \text{otherwise} \end{cases}, \tag{32}$$

and

$$(D_E\hat{E}^\dagger - \hat{E}^\dagger D_V)_{ev} = \begin{cases} -\gamma^\mu(D^\mu U_e) & \text{if } v = t(e) \\ 0 & \text{otherwise} \end{cases}. \tag{33}$$

The effective action at the one-loop level can be written as (see Ref. 11 and references therein).

$$\Gamma = -\frac{1}{2}\mathrm{Tr}\,\ln(\mathcal{D}^\dagger\mathcal{D}) = \frac{1}{2}\int_0^\infty \frac{dt}{t}\mathrm{Tr}\,e^{-\mathcal{D}^\dagger\mathcal{D}t} = \frac{1}{2}\int_0^\infty \frac{dt}{t}\int d^4x\,\mathrm{Tr}\langle x|e^{-\mathcal{D}^\dagger\mathcal{D}t}|x\rangle. \tag{34}$$

Here, we use

$$\langle x|f(D_\mu)|x\rangle = \int \frac{d^4k}{(2\pi)^4}\langle x|f(D_\mu + ik_\mu)|0\rangle, \tag{35}$$

where $|0\rangle$ is a zero momentum state ($\langle x|0\rangle = 1$), to calculate the effective Lagrangian.[11]

To evaluate the t^2 term in the expansion of the integrand, we need the following explicit form:

$$\mathrm{Tr}(D_V^2)^2 = 2\sum_{v\in V}\left[(D_v^\mu)^2(D_v^\nu)^2 + \frac{1}{2}F_v^{\mu\nu}F_v^{\mu\nu}\right], \tag{36}$$

and

$$\mathrm{Tr}(D_E^2)^2 = 2\sum_{e\in E}\left[(D_e^\mu)^2(D_e^\nu)^2 + \frac{1}{2}F_{o(e)}^{\mu\nu}F_{o(e)}^{\mu\nu}\right], \tag{37}$$

where the coefficient 2 comes from the projection to the left/right-handed fermions.

Therefore, the logarithmically divergent part (with the Euclidean signature) turns out to be

$$\frac{1}{24\pi^2}\int\frac{dt}{t}\left[\sum_{v\in V}\frac{1}{4}(F_v^{\mu\nu})^2 + \sum_{e\in E}\frac{1}{4}(F_{o(e)}^{\mu\nu})^2 + \frac{3}{2}m^2\sum_{e\in E}|D^\mu U_e|^2 + \cdots\right]. \tag{38}$$

The coefficients of kinetic terms of gauge and link fields are logarithmically divergent.

In particular, the gauge coupling runs logarithmically. If every vertex is an origin of an edge for $p=q$ graph, the beta function is the same as the usual QED

$$\mu\frac{dg}{d\mu}=\frac{g^3}{12\pi^2}. \tag{39}$$

In the general case, if we define the individual gauge coupling for each gauge field on a vertex, such that the kinetic term becomes $\Sigma_{v\in V}(1/4g_v^2)F_{\mu\nu\,v}F_v^{\mu\nu}$, their beta functions are

$$\mu\frac{dg_v}{d\mu}=\frac{(1+d^+(v))g_v^3}{24\pi^2}, \tag{40}$$

where $d^+(v)$ is the *outgoing degree* of a vertex v, which is the number of edges whose origin is v. Note that the average of $d^+(v)$ is q/p.

The running of the individual gauge coupling is interesting for the possibility of variating the mass spectrum. However, the existence of zero modes is still unchanged, expressed as in (23). Thus, this running-coupling effect is not useful for symmetry breaking even when the model is generalized to the non-Abelian one.

For the non-Abelian case, the quantum fluctuation of the gauge fields and link fields also induces the logarithmic divergent contribution to the gauge and link field kinetic terms.

VI. ONE-LOOP FINITENESS IN EFFECTIVE POTENTIAL

The effective potential for constant background link field can be written as

$$\begin{aligned}V&=-\frac{1}{2}\int_0^\infty\frac{dt}{t}\int\frac{d^4k}{(2\pi)^4}e^{-k^2t}2[\mathrm{Tr}_p\exp(-m^2\hat{E}\hat{E}^\dagger t)+\mathrm{Tr}_q\exp(-m^2\hat{E}^\dagger\hat{E}t)]\\&=-\frac{1}{(4\pi)^2}\int_0^\infty\frac{dt}{t^3}[\mathrm{Tr}_p\exp(-m^2\hat{E}\hat{E}^\dagger t)+\mathrm{Tr}_q\exp(-m^2\hat{E}^\dagger\hat{E}t)],\end{aligned} \tag{41}$$

where Tr_M means the trace only on $(M\times M)$ matrices.

Since $\mathrm{Tr}_p(\hat{E}\hat{E}^\dagger)^n=\mathrm{Tr}_q(\hat{E}^\dagger\hat{E})^n$ for $n\geqslant 1$, the integrand can be expanded as

$$\frac{1}{2}[\mathrm{Tr}_p\exp(-m^2\hat{E}\hat{E}^\dagger t)+\mathrm{Tr}_q\exp(-m^2\hat{E}^\dagger\hat{E}t)]=\frac{p+q}{2}-m^2\,\mathrm{Tr}_p\,\hat{\Delta}t+\frac{1}{2}m^4\,\mathrm{Tr}_p\,\hat{\Delta}^2t^2+O(t^3). \tag{42}$$

Owing to $U_eU_e^\dagger=1$, $\mathrm{Tr}_p\,\hat{\Delta}=\mathrm{Tr}_p\,D$ obviously and $\mathrm{Tr}_p\,\hat{\Delta}^2=\mathrm{Tr}_p\,D^2+\mathrm{Tr}_p\,D$. In other words, the same relation as that on Δ holds. The expression (41) includes divergences, but they not depend on the background link fields.

This is the origin of the one-loop finiteness of the scalar potential in the deconstructed theory. This nature is preserved for non-Abelian generalization.

In the present Abelian case, the zero-mode field of the link variable acquires mass by the one-loop quantum effect. The explicit calculation for models with a cycle graph C_N can be carried out as in Refs. 8 and 12.

VII. GRAPH HOSOTANI MECHANISM?

If some non-Abelian gauge symmetry is introduced, a symmetry-breaking mechanism becomes possible in the theory on a graph, just as in the case of the Hosotani mechanism.[13]

Let the length of the shortest cycle $c=(e_1,\ldots,e_N)$ in G be $N(\geqslant 3)$. The trace of the kernel of $\hat{\Delta}$, $\mathrm{Tr}\exp(-\hat{\Delta}t)$, for matter fields coupled to the link fields, includes a term $\mathrm{Re}\,\mathrm{Tr}\,U_{e_1}\cdots U_{e_N}$ and its coefficient is $O(t^N)$. Therefore, the one-loop effective potential for the zero mode of link fields is finite (up to a field-independent divergence).

If we take a graph C_n into a model and consider the limit $n\to\infty$, the model reduces to the original Hosotani model[13] (it should be read $A_5\sim\chi$, where $U=e^{-i\chi}$).

The realization of non-Abelian symmetry breaking in the field theory on a graph may not be

so easy as in the Hosotani models. The simplest idea is that we abandon the *local symmetry on a whole graph*. Suppose that we dare to replace such a term $\overline{\psi_{Le}}(\psi_{Ro(e)}-U_e\psi_{Rt(e)})$ by $\overline{\psi_{Le}}(\psi_{Ro(e)}-\psi_{Rt(e)})$ on some edges. Then, the *local* symmetry on a graph disappears but *global* symmetry on a graph such as $\psi_{Rv}\to\exp(i\omega)\psi_{Rv}$, $\psi_{Le}\to\exp(i\omega)\psi_{Le}$ [where $\omega_v(x)=\omega(x)$ for all $v\in V$ and $\omega_e(x)=\omega(x)$ for all $e\in E$] remains. Thus, the model still has usual local gauge symmetry in space–time, at the classical level. In this case, the induced term like $\mathrm{Re}\,\mathrm{Tr}\,U_{e_1}\cdots U_{e_N}$, where some Us are replaced by unity, may lead to a novel phase structure of vacuum.

We will study the dynamical symmetry breaking in field theory on a graph which has edges with and without some weight functions elsewhere.

VIII. SUMMARY AND PROSPECTS

In conclusion, we clarified the divergences of the one-loop effective Lagrangian in the Abelian gauge field theory on graphs.

We must consider the following possibilities. To consider the generalization of the Hosotani model, we should investigate non-Abelian gauge theory on a graph. We also need adjoint matter fields or fields in other representations on vertices or edges. At the same time, we should study the possible inclusion of plaquette-like self-interaction of link fields in bare Lagrangian. By the way, to consider superfields on a graph is also an interesting subject.

We are interested also in the two-loop effective action. We still hope that the knowledge of algebraic graph theory may be useful to investigate higher-loop divergence as well as tree-level calculation of reaction amplitude mediated by the excited modes.

ACKNOWLEDGMENT

We would like to thank Y. Cho for his valuable comments and for reading the manuscript.

Solutions of types N and III with twisting rays are derived in the linear approximation by means of complex coordinate transformations. Some solutions are shown to have Riemann tensors which vanish asymptotically and are everywhere regular. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2113412]

I. INTRODUCTION

Over the past 40 years, a great deal of progress has been made in studying the spacetimes with degenerate Weyl tensors.[2] For type III fields built around expanding and hypersurface orthogonal rays, the field equations reduce to a single one which specifies that, on each wavefront, the Laplacian of the Gaussian curvature should vanish. An example of this solution was given by Robinson and Trautman in 1962.[7] Stephani[8] has analyzed the symmetries of this equation and found that this method did not lead to any new solutions simply because the only known one, Robinson-Trautman, is a fixed point for the set of symmetry transformations.

For metrics with twisting rays, a class has been identified by Robinson and Robinson,[6] in which the system of field equations separate into a nonlinear background and a linear equation. The only known solution for this background equation is the old Robinson-Trautman solution; and since this is a stationary solution, so are all the spaces determined from it. Therefore these are examples of a rather restricted type of radiation. In any case, all solutions obtained this way appear to have directional singularities.

The lack of exact solutions and methods of discovering them increased the interest for approximate ones. For example, in the twisting type N case, only Kundt's solution was known until recently; Ivanov[1] found another one. However, both solutions are more difficult to understand, analyze or to work with than the regular approximate ones found by MacAlevey in Ref. 3.

In this paper we obtain approximate type III solutions in the case of pure radiation with twisting rays. The method we use was described and used by Trautman[9] to obtain solutions to linear special relativistic partial differential equations. One starts with a solution analytic in all four coordinates, continues it for complex values of the coordinates, makes a complex inhomogeneous Lorentz transformation and restricts the resulting solution to real values of the coordinates. Applying this method to Maxwell's equations and the linearized Einstein's equations one works throughout with the complex self-dual form of the field. The transformation then leaves invariant the algebraic structure of the field, i.e., the distinctness or coincidence of the principal

[b)]Electronic mail: paulmac@utdallas.edu
[c)]Electronic mail: p2downes@hotmail.com

null directions. By these means Trautman obtained the null electromagnetic field built around the Robinson congruence given explicitly a year later. The method has also been applied extensively by Newman (see, e.g., Ref. 4).

We carry out this procedure explicitly starting with a linear approximation of a type III space-time built around the Robinson congruence. After complexifying and setting conditions for self-duality, we apply a complex transformation to obtain the most general expression for type III solutions built around what might be described as a generalized Kerr congruence. A large subclass of these solutions are shown to be regular using a scalar obtained from their Bel-Robinson tensor.

II. SELF-DUAL ROBINSON-TRAUTMAN SPACES

We can complexify the Robinson-Trautman metric given in Ref. 7, in a purely formal way, by taking the coordinates ρ, σ, ζ, $\tilde{\zeta}$ to be independent complex variables and the defining functions $m(\sigma)$ and $p(\sigma,\zeta,\tilde{\zeta})$ to be complex. It is easy to see that the Weyl tensor is self-dual if, and only if, $m=0$ and $p^{-1}p_{,\tilde{\zeta}\tilde{\zeta}}$ is a function of $\tilde{\zeta}$ only. By means of a coordinate transformation we can strengthen the last condition to $p_{,\tilde{\zeta}\tilde{\zeta}}=0$. The line element is then given by

$$\mathrm{d}s^2 = 2\,\mathrm{d}\rho\,\mathrm{d}\sigma + \left(K - 2\rho\frac{p_{,\sigma}}{p}\right)\mathrm{d}\sigma^2 - \frac{2\rho^2}{p^2}\mathrm{d}\zeta\,\mathrm{d}\tilde{\zeta}, \tag{1}$$

$$K = 2(AB_{,\zeta} - A_{,\zeta}B), \quad p = A + \tilde{\zeta}B, \tag{2}$$

where A and B are arbitrary functions of ζ and σ. The Weyl tensor is

$$C_{klmn} = \frac{p}{2\rho^2}K_{,\zeta}(M_{kl}N_{mn} + N_{kl}M_{mn}) - \frac{1}{2\rho^2}(p^2K_{,\zeta})_{,\zeta}N_{kl}N_{mn} + \frac{p^2}{\rho}(p^{-1}p_{,\zeta\zeta})_{,\sigma}N_{kl}N_{mn}, \tag{3}$$

where

$$N_{kl} = 2\frac{\rho}{p}\sigma_{,[k\zeta,l]}, \tag{4}$$

$$M_{kl} = 2\left(\sigma_{,[k\rho,l]} - \frac{\rho^2}{p^2}\zeta_{,[k\tilde{\zeta},l]}\right). \tag{5}$$

III. COMPLEX COORDINATE TRANSFORMATION

It is worth remarking that, at least in a special case, one can put this line element into the standard form for one with twisting rays. The special case is defined by $p=A(\zeta)+\tilde{\zeta}B(\zeta)$. The transformation

$$\rho = r - i\Sigma,$$

$$\zeta = z, \tag{6}$$

$$\tilde{\zeta} = \frac{r+ia}{r-ia}\tilde{z},$$

where

$$\Sigma = a\frac{A(z) - \tilde{z}B(z)}{P} \tag{7}$$

and

$$P = A(z) + \tilde{z}B(z), \tag{8}$$

a being a real parameter, transforms (1) into

$$ds'^2 = 2\lambda\nu - 2\mu\tilde{\mu}, \tag{9}$$

where

$$\lambda = d\sigma \mp 2L\, dz, \tag{10}$$

$$\mu = P^{-1}(r - i\Sigma)dz, \tag{11}$$

$$\tilde{\mu} = P^{-1}(r + i\Sigma)d\tilde{z}, \tag{12}$$

$$\nu = dr + i(\Sigma_z\, dz - \Sigma_{\tilde{z}}\, d\tilde{z}) + \tfrac{1}{2}K\lambda, \tag{13}$$

and

$$L = \frac{ai\tilde{z}}{P^2}. \tag{14}$$

In the coordinates, the bivectors N and M are given by

$$N_{kl} = \frac{r - ia}{r - i\Sigma}N'_{kl}, \tag{15}$$

$$M_{kl} = M'_{kl} + \frac{2PKL}{r - i\Sigma}N'_{kl}, \tag{16}$$

where

$$N'_{kl} = 2\frac{\rho}{p}\lambda_{[k\mu l]}, \tag{17}$$

(18)

$$M'_{kl} = 2\left(\lambda_{[k\nu l]} - \mu_{[k\tilde{\mu}l]}\right).$$

Making this transformation on the flat space line element

$$ds_0^2 = 2\, d\rho\, d\sigma \mp 2k\, d\sigma^2 - \frac{2\rho^2}{p_0^2}d\zeta\, d\tilde{\zeta}, \tag{19}$$

$$p_0 = 1 + k\zeta\tilde{\zeta}, \tag{20}$$

writing $\overline{z}$ for $\tilde{z}$ and setting

$$\sigma = u - ia\frac{z\overline{z}}{P_0} \tag{21}$$

with

$$P_0 = 1 + kz\overline{z} \tag{22}$$

we get

$$ds^2 = 2\lambda(dr + i\Sigma_z\, dz - i\Sigma_{\overline{z}}\, d\overline{z} + k\lambda) - \frac{2(r^2+\Sigma^2)}{P_0^2} dz\, d\overline{z}, \tag{23}$$

where

$$\lambda = du + iaP_0^{-2}(\overline{z}\, dz - z\, d\overline{z}) \tag{24}$$

and

$$\Sigma = a\frac{1 - kz\tilde{z}}{1 + kz\tilde{z}}. \tag{25}$$

For $k=0$, this is the transformation given in Trautman;[9] for $k>0$, it is equivalent to that of Newman.[4]

IV. LINEAR APPROXIMATION

Suppose that in the line element given by Eqs. (1) and (2), the function p is expanded as a power series

$$p = p_0 + \epsilon p_1 + \epsilon^2 p_2 + \cdots, \tag{26}$$

where p_0 is given by (20) and

$$p_1 = \alpha_{,\zeta} + \beta\overline{\zeta} + k\overline{\zeta}(\zeta\alpha_{,\zeta} - 2\alpha), \tag{27}$$

α and β being arbitrary functions of ζ and σ. In the expansion of the Weyl tensor we have

$$C_{0\ klmn} = 0, \tag{28}$$

$$C_{1\ klmn} = \frac{1}{\rho^2} p_0 \Phi(M_{kl}N_{mn} + N_{kl}M_{mn}) - \left[\frac{1}{\rho^2}\left(p_0^2\Phi\right)_{,\zeta} - \frac{1}{\rho} p_0\left(\Psi p_0 + \Phi_{,\sigma}\tilde{\zeta}\right)\right] N_{kl}N_{mn}, \tag{29}$$

where $\Phi = \beta_{,\zeta\zeta}$ and $\Psi = \alpha_{,\zeta\zeta\zeta\sigma}$.

Next we transform to the coordinates u, r, z, $\overline{z}$, restrict ourselves to the space-time in which u and r are real and in which z and $\overline{z}$ are complex conjugates. Consider the line element

$$ds^2 = ds_0^2 + \epsilon\left(ds_1^2 + d\vec{s}_1^2\right). \tag{30}$$

In the lowest approximation the line element is given by (23), (24), and (25). The next approximation to the line element is more complicated; fortunately, the Weyl tensor in the linear approximation is quite simple, using (29) and our expression for the transformed bivectors, we get

$$C_{klmn} = \epsilon[X(M'_{kl}N'_{mn} + N'_{kl}M'_{mn}) + YN'_{kl}N'_{mn}] + \text{complex conjugate}, \tag{31}$$

where

$$X = \frac{P}{(r - ia)(r - i\Sigma)}\Phi, \tag{32}$$

$$Y = -\frac{P}{(r - ia)^2}\left[\frac{2k\overline{z}(r + ia)}{r - i\Sigma}\Phi + P\Phi_{,z} - \Psi P(r - i\Sigma) - \Phi_{,\sigma}(r + ia)\overline{z}\right]. \tag{33}$$

The Bel-Robinson tensor can then be written as

$$\tfrac{1}{2}P_{abcd} = {}^{+}_{1}C_{amnc}\,{}^{-}_{1}C_{b}{}^{mn}{}_{d} = 4|\Gamma|^2[\lambda_{(a}\lambda_b\lambda_c\nu_{d)} + 3\lambda_{(a}\lambda_b\mu_c\overline{\mu}_{d)}] + 4\Gamma\overline{\Delta\lambda}_{(a}\lambda_b\lambda_c\overline{\mu}_{d)} + 4\overline{\Gamma}\Delta\lambda_{(a}\lambda_b\lambda_c\mu_{d)} + |\Delta|^2\lambda_a\lambda_b\lambda_c\lambda_d, \tag{34}$$

where

$$\Gamma = X\frac{r-ia}{r-i\Sigma}, \tag{35}$$

$$\Delta = \frac{2XPKL(r-ia)}{(r-i\Sigma)^2} + Y\left(\frac{r-ia}{r-i\Sigma}\right)^2. \tag{36}$$

V. THE GRAVITATIONAL DENSITY

A well-known measure of the strength of the gravitational field is the density

$$D = P_{abcd}t^a t^b t^c t^d, \tag{37}$$

where t^a is a unit timelike vector field. Here, we can reduce the arbitrariness of D by requiring that t^a should be covariantly constant with respect to the Minkowskian metric of the linear approximation. D then has the following interpretation: it is the sum of squares of the components of the Weyl tensor in Minkowskian coordinates with t_a as the time direction. For these components to be all regular and/or asymptotically vanishing, it is necessary and sufficient that D should have the same properties. We shall show that both these conditions can be satisfied by certain solutions with $k=0$. In this case the tetrad given by

$$\hat{\nu} = \nu, \tag{38}$$

$$\hat{\mu} = \mu + z\nu, \tag{39}$$

$$\hat{\lambda} = \lambda + \overline{z}\mu + z\overline{\mu} + z\overline{z}\nu \tag{40}$$

is constant. We may take, for example, $t_a = (1/\sqrt{2})(\hat{\lambda}_a + \hat{\mu}_a)$. Then

$$D = \tfrac{1}{2}(1+z\overline{z})^2[4|\Gamma|^2 + |4\overline{z}\Gamma - (1+z\overline{z})\Delta|^2] \tag{41}$$

and

$$\Gamma = \frac{\Phi}{(r-ia)^2}, \tag{42}$$

$$\Delta = Y|_{k=0} = -\frac{1}{(r-ia)^2}[\Phi_{,z} - \Psi(r-ia) - \Phi_{,\sigma}(r+ia)\overline{z}]. \tag{43}$$

Φ and Ψ are disposable functions of z and σ $(=u-iaz\overline{z})$. We may take, for example,

$$\Phi = c_1(\sigma - i)^{-n}, \quad \Psi = c_2(\sigma - i)^{-m}, \tag{44}$$

where $n \geqslant 2$, $m \geqslant 3$ and c_1, c_2 are constants. It is easy to verify that D is then regular and asymptotically vanishing.

VI. CONCLUSIONS

In this paper we have described the construction of pure radiative solutions of Einstein's field equations in the linear approximation. A large subclass of these (i.e., for $k=0$) were shown to be

regular and asymptotically vanishing using a scalar obtained from their Bel-Robinson tensor. The second approximation was also studied in Ref. 5 and, although only a partial result, it was shown to exhibit nice regularity properties. For solutions with $k>0$ the directional singularities were unavoidable (see Ref. 5).

(Received 20 July 2005; accepted 21 September 2005; published online 16 November 2005)

We reexamine here the issue of consistency of minimal action formulation with the minimal coupling procedure (MCP) in spaces with torsion. In Riemann-Cartan spaces, it is known that a proper use of the MCP requires that the trace of the torsion tensor be a gradient, $T_\mu = \partial_\mu \theta$, and that the modified volume element $\tau_\theta = e^\theta \sqrt{g} \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n$ be used in the action formulation of a physical model. We rederive this result here under considerably weaker assumptions, reinforcing some recent results about the inadequacy of propagating torsion theories of gravity to explain the available observational data. The results presented here also open the door to possible applications of the modified volume element in the geometric theory of crystalline defects. © *2005 American Institute of Physics.*

I. INTRODUCTION

The use of modified volume elements in physical models has been receiving considerable interest in recent years. In the context of the Einstein-Cartan theory of gravity,[1] for instance, the introduction of a new volume element gave rise to some models possessing several interesting characteristics, such as propagation of torsion,[2,3] interaction between torsion and gauge fields without violation of the gauge symmetry,[4] and a geometrical interpretation of string-theory inspired models of gravity.[5] Noncanonical volume elements have also proved to be useful in other contexts. For recent applications in field and string theory, see, for instance, Ref. 6.

Geometries with torsion, on the other hand, have a long tradition in Physics. For instance, in Einstein-Cartan theory of gravity,[1] space-time is assumed to be a Riemann-Cartan manifold, i.e., a manifold endowed with a Lorentzian metric and a nonsymmetrical metric-compatible linear connection. The anti-symmetrical part of the connection (the torsion tensor) is also relevant to field theory, mainly with respect to renormalization issues.[7] The very active area of defects in crystal microstructures also takes advantage of these non-Riemannian geometries: disclinations and dislocations in a crystal can be described by means of curvature and torsion (for a revision, see Refs. 8 and 9). Dislocations, in particular, are described by the Burgers vector, which has the torsion tensor as its surface density (see Fig. 1).

The motivation for the introduction of the modified volume element proposed in Ref. 10 was the observation that, in the presence of torsion, the minimal coupling procedure (MCP) performed at the action level is not equivalent to that performed directly at the corresponding field equations, a conflict known since long before, see, for instance, Ref. 11. The same volume element is shown in Ref. 12 to be mandatory in order to assure unitary evolution of a Klein-Gordon field in spaces with torsion. In Ref. 12, it is also shown that the introduction of a nonholonomic version of the minimal action principle can cure these problems. As shown in Ref. 10, in Riemann-Cartan spaces the equivalence between the MCP performed at the action and at the field equations can be

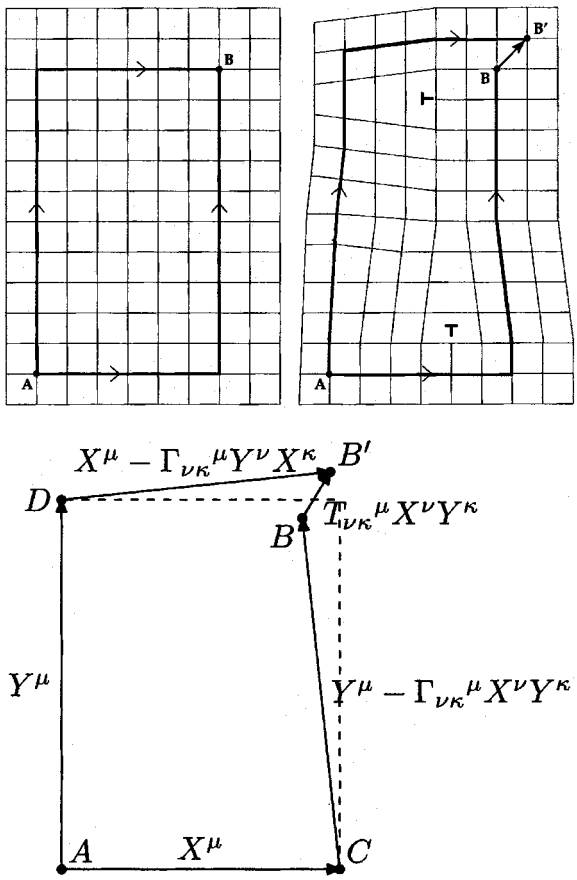

FIG. 1. We show, for illustrative purposes only, a lattice with two edge dislocation defects (upper right) and a reference one (upper left). A closed rectangular path in the reference lattice becomes unclosed in the presence of the defects. The vector $\overline{BB'}$, the so-called Burgers vector, measures how the path fails to close. In the associated geometrical description of the path generated by the (infinitesimal) vectors X^μ and Y^μ at the point A, the vector $\overline{CB}$ is obtained by parallel transport of Y^μ along X^μ, and $\overline{DB'}$ is obtained by transporting X^μ along Y^μ. The Burgers vector in this case is given by $\overline{BB'}=T_{\nu\kappa}{}^\mu X^\nu Y^\kappa$.

recovered, with the usual minimal action principle, provided that the trace of the torsion tensor be a gradient, $T_\mu=\partial_\mu\theta$, and that the usual volume element $\tau_0=\sqrt{g}\,\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n$ be deformed to

$$\tau_\theta = e^\theta \tau_0. \tag{1}$$

In Ref. 3, Fiziev reinterpreted the model based in volume element (1) as a Transposed-Equi-Affine Theory of Gravity, since, as we will see, the covariant derivative of densities used in Ref. 10 can be related to a certain "transposed" connection. Such a transposed connection, however, is a highly artificial object, being generically not metric-compatible even when the initial connection is. Besides, at first glance, the very motivation of demanding equivalence between the MCP as applied to the action level and to the field equations may be contested on physical grounds. In fact, even in the case of General Relativity (where the connection is torsion-free), the naive minimal coupling between the electromagnetic field and gravity does not satisfy such equivalence requirement if one does not choose carefully in which set of equations the MCP should be applied. In such a case, the field equations contain partial derivatives of higher order, which renders the MCP, if applied directly to some field equations, ill-defined.[13] The usual solution for this kind of difficulty is to assume that the MCP should always be applied at the Lagrangian level.

The aim of this paper is to show that the modified volume element (1) follows from a more fundamental hypothesis, reinforcing its mathematical and physical relevance. We will show that the existence of the modified volume element (1) is a necessary and sufficient condition to render

the MCP well-defined even when considered solely at the action level. In particular, we will show that the results presented in Ref. 10 can be obtained without recourse to transposed connections. Our conclusions apply to any physical model where torsion is regarded as a dynamical entity that couples to the remaining fields via the MCP. In this way, one can expect that the results presented here can also be useful in the geometric theory of crystalline defects,[9,14] since the expressions for the free and interaction energies of defects and the equations for phonons and other test fields can be obtained by arguments very similar to the MCP.

We observe that the model proposed in Ref. 2 was carefully studied in Refs. 15 and 16. By considering solutions describing compact (neutron) stars and some solar system experiments, it was shown[15] that the predictions of the model[2] are in contradiction with General Relativity and, more important, with the available observational data. The propagating torsion model proposed in Ref. 2, therefore, is not a viable alternative to General Relativity. As we will see, the results presented here make the conclusions of Ref. 15 much stronger, since we will show that the existence of (1) is required to ensure the very consistency of the action formulation via the MCP. In other words, the results of Ref. 15 would allow us to conclude that the very reasonable requirement of consistency of the action formulation with the MCP *imply*, on account of the observational data, that the trace of the torsion tensor of space-time should vanish.

This work is organized as follows. The next section is a brief review of the mathematical framework necessary to set up the problem. Section III contains our main results, and the last section is devoted to some final remarks. Mathematical proofs are left to the Appendix, where we also discuss how the results presented here relate to the earlier approach of Refs. 2–5 and 10.

II. NOTATION

In order to introduce the problem, we briefly recall some definitions. For the sake of clarity, we employ here a more mathematically oriented notation, which slightly differs from that used in the original works.[2–5,10] Let $\mathcal{M}$ be an n-dimensional manifold. In the following, the components of the covariant derivative of a vector field $A=A^\nu e_\nu$, with respect to a local basis in $T\mathcal{M}$, are denoted by $D_\mu A^\nu$, so that $\nabla_\mu A=(D_\mu A^\nu)e_\nu$, with $D_\mu A^\nu=\partial_\mu A^\nu+\Gamma_{\mu\sigma}{}^\nu A^\sigma$. The components of the torsion tensor associated with the connection ∇,

$$T(X,Y)=\nabla_X Y-\nabla_Y X-[X,Y], \tag{2}$$

are given, in a coordinate basis, by

$$T_{\mu\nu}{}^\kappa=\Gamma_{\mu\nu}{}^\kappa-\Gamma_{\nu\mu}{}^\kappa. \tag{3}$$

Whenever the manifold $\mathcal{M}$ is endowed with a metric $g_{\mu\nu}$, the connection coefficients $\Gamma_{\mu\nu}{}^\kappa$ can be decomposed as

$$\Gamma_{\mu\nu}{}^\kappa=\left\{{\kappa\atop\mu\nu}\right\}+K_{\mu\nu}{}^\kappa+V_{\mu\nu}{}^\kappa, \tag{4}$$

where $\left\{{\kappa\atop\mu\nu}\right\}$ are the Christoffel symbols associated with the underlying Levi-Civita connection (uniquely defined metric-compatible connection without torsion on $(\mathcal{M},g)$),

$$K_{\mu\nu\kappa}=-\tfrac{1}{2}(T_{\nu\kappa\mu}+T_{\mu\kappa\nu}-T_{\mu\nu\kappa}) \tag{5}$$

is the contorsion tensor associated with ∇, and

$$V_{\mu\nu\kappa}=-\tfrac{1}{2}(D_\mu g_{\nu\kappa}+D_\nu g_{\kappa\mu}-D_\kappa g_{\mu\nu}) \tag{6}$$

provides a measure of the nonmetricity associated with ∇. Relevant quantities here are the trace of the above-defined tensors and their associated one-forms

$$\begin{aligned} T_\nu&=T_{\mu\nu}{}^\mu, \quad t=T_\nu\,\mathrm{d}x^\nu,\\ V_\nu&=V_{\mu\nu}{}^\mu, \quad v=V_\nu\,\mathrm{d}x^\nu. \end{aligned} \tag{7}$$

A volume element on an n-dimensional manifold $\mathcal{M}$ is a nowhere vanishing n-form on $\mathcal{M}$.[17] If $\mathcal{M}$ is endowed with a metric, an arbitrary volume element τ can be written as

$$\tau = f\tau_0, \tag{8}$$

where f is a nowhere vanishing smooth function on $\mathcal{M}$ and τ_0 is the canonical volume element

$$\tau_0 = \theta^1 \wedge \cdots \wedge \theta^n = \sqrt{g}\, \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n, \tag{9}$$

where $\{\theta^i\}$ is a local orthonormal basis.

III. MINIMAL COUPLING AND EQUIVALENT LAGRANGIANS

Let $\mathcal{L}$ be a Lagrangian density describing a given physical model defined on flat space or space-time $\mathcal{M}$. There is a natural equivalence relation $\sim$ on the set of such Lagrangians, defined by $\mathcal{L}_1 \sim \mathcal{L}_2$ if and only if $\mathcal{L}_1$ and $\mathcal{L}_2$ give rise to *identical* field equations on M. Except for scale transformations, we then have

$$\mathcal{L}_1 \sim \mathcal{L}_2 \Leftrightarrow \mathcal{L}_1 - \mathcal{L}_2 = \mathrm{div}(X) \tag{10}$$

for some vector field X, where, for flat $\mathcal{M}$,

$$\mathrm{div}(X) = \partial_\mu X^\mu. \tag{11}$$

This follows trivially from Gauss theorem, since integration of the Lagrangian density immediately yields

$$\int \mathrm{div}(X)\tau_0 = [\text{surface term}], \tag{12}$$

with no contribution to the Euler-Lagrange equations. We emphasize that, in the context of flat space (and of Special Relativity), *any choice* $\mathcal{L}$ in a given class $[\mathcal{L}]$ of Lagrangians leads to completely equivalent physical models.

Suppose now that the metric and connection on $\mathcal{M}$ become dynamical, describing in this way physical fields interacting with test particles or fields on $\mathcal{M}$. This would be the case, for instance, of General Relativity, in which gravity is described by a dynamical metric $g_{\mu\nu}$ with its associated Levi-Civita connection. Other examples are the Einstein-Cartan theory of gravity,[1] where torsion becomes an additional dynamical quantity, and the geometric theory of defects,[8,9] where curvature and torsion are related to the density of dislocations and disclinations of the crystalline lattice structure.

The MCP is the standard prescription to obtain the curved space equations from the flat space ones. It states that one needs merely to substitute ordinary derivatives by covariant ones and the Minkowskian metric tensor by its nonflat counterpart. It is worth noting that the MCP is used with success in nearly all physically relevant gauge theories, including General Relativity.[18]

Let us denote the Lagrangian density obtained from $\mathcal{L}$, via MCP, by $\mathcal{L}^*$. Similar to the flat-space case discussed above, the condition for $\mathcal{L}_1^*$ and $\mathcal{L}_2^*$ to be equivalent (i.e., to yield the same Euler-Lagrange equations) is given by

$$\mathcal{L}_1^* - \mathcal{L}_2^* = \mathrm{div}_\tau(X) \tag{13}$$

for some vector field X, with the definition of divergence now being given by[17]

$$(\mathrm{div}_\tau X)\tau = \pounds_X \tau, \tag{14}$$

where τ is a volume form on $\mathcal{M}$ and $\pounds_X$ denotes the Lie derivative along the vector field X. This is the most natural definition of divergence in this context, since $\pounds_X\tau = \mathrm{d}i_X\tau$ (where d denotes the exterior derivative and i_X the contraction by X)[17] leads directly to Gauss theorem

$$\int_{\mathcal{M}} \mathrm{div}_\tau(X)\tau = \int_{\partial\mathcal{M}} i_X\tau = [\text{surface term}]. \tag{15}$$

If $\mathcal{L}_1$ and $\mathcal{L}_2$ are equivalent Lagrangians in flat-space, we get, after applying the MCP,

$$\mathcal{L}_1 - \mathcal{L}_2 = \partial_\mu X^\mu \xrightarrow{\text{MCP}} \mathcal{L}_1^* - \mathcal{L}_2^* = D_\mu X^\mu. \tag{16}$$

Therefore, if the equivalence class of Lagrangians $[\mathcal{L}]$ is required to be preserved under the MCP, we need to have

$$D_\mu X^\mu = \mathrm{div}_\tau(X), \tag{17}$$

or, equivalently,

$$\pounds_X\tau = (D_\mu X^\mu)\tau. \tag{18}$$

The necessary and sufficient conditions to the existence of solutions for (17) can be obtained from the following proposition, whose (simple) proof is left to the Appendix.

Proposition 1: *Let $\mathcal{M}$ be a differentiable manifold endowed with a metric g and a connection ∇. Let $\tau=f\tau_0$ be a volume form on $\mathcal{M}$. Then, for every vector field X on $\mathcal{M}$,*

$$D_\mu X^\mu = \mathrm{div}_\tau X + t(X) + v(X) - X(\ln f),$$

where t and v are defined in Eq. (7).

MCP in affine manifolds

In order to illustrate the previous results, let us recall their application to the case of the metric-affine theory of gravity,[19] where space-time is represented by a manifold endowed with a connection with possibly nonzero curvature, torsion, and nonmetricity. We note that this contains, as a particular case, the Einstein-Cartan theory of gravity, where the associated connection presents curvature and torsion but is still metric-compatible (i.e., $D_\kappa g_{\mu\nu}=0$).

For this case, Proposition 1 implies that the canonical volume form τ_0 yields

$$D_\mu X^\mu - \mathrm{div}_{\tau_0} X = (T_\mu + V_\mu)X^\mu. \tag{19}$$

It follows from our previous discussion that equivalent Lagrangian densities of Special Relativity will be mapped, via MCP, to *nonequivalent* Lagrangian densities in the corresponding nonflat space-time. Therefore, since there is no canonical representative of $[\mathcal{L}]$ in Special Relativity, the MCP turns out to be essentially ill-defined in this context.

This difficulty can be circumvented with the help of Proposition 1 itself. The above-mentioned incompatibility arises only when $D_\mu X^\mu \neq \mathrm{div}_\tau X$. However, admitting a more general volume form $\tau=f\tau_0$ on $\mathcal{M}$, one can get $D_\mu X^\mu=\mathrm{div}_\tau X$ by choosing f such that

$$t(\partial_\mu) + v(\partial_\mu) - \partial_\mu \ln f = 0, \tag{20}$$

which is equivalent to

$$T_\mu + V_\mu = \partial_\mu\theta, \quad \tau = e^\theta\tau_0. \tag{21}$$

Therefore, the MCP is well defined (preserves equivalence classes of Lagrangians) precisely when:

1. $t+v$ is an exact form, say $t+v=d\theta$, and

2. the volume element on $\mathcal{M}$ is given by $\tau = e^{\theta}\tau_0$.

Again, since in the context of flat space (Special Relativity) there is no canonical choice of representative of a given class of Lagrangians, our results imply that the MCP is well defined only in the presence of the modified volume element (1).

This is our main result: in order to preserve a given class $[\mathcal{L}]$ of Lagrangians under the MCP, one must have $T_\mu + V_\mu = \partial_\mu \theta$ and, obligatorily, to use the modified volume element (1). If the sum of traces $T_\mu + V_\mu$ is not a gradient, the MCP turns out to be ill-defined, since it produces non-equivalent theories out of equivalent flat-space Lagrangians, even at the classical level.

The λ-symmetry

In an affine manifold, the Riemann tensor is invariant under the transformation

$$\Gamma_{\mu\nu}{}^{\kappa} \to \Gamma_{\mu\nu}{}^{\kappa} + \delta^{\kappa}_{\nu}\partial_\mu \lambda, \tag{22}$$

where λ is an arbitrary function. This is the so-called λ-symmetry,[20] introduced by Einstein in his pioneering work on unified field theory, which has been proved to be very useful in the analysis of affine theories of gravity.[21] In a λ-invariant theory, the function λ can be properly chosen in order to cancel some parts of the torsion tensor and/or of the nonmetricity, simplifying the overall analysis. Under (22), the torsion tensor and $V_{\mu\nu\kappa}$ are changed as

$$\begin{aligned} T_{\mu\nu\kappa} &\to T_{\mu\nu\kappa} + (g_{\kappa\nu}\partial_\mu \lambda - g_{\kappa\mu}\partial_\nu \lambda), \\ V_{\mu\nu\kappa} &\to V_{\mu\nu\kappa} + (g_{\kappa\nu}\partial_\mu \lambda + g_{\kappa\mu}\partial_\nu \lambda - g_{\mu\nu}\partial_\kappa \lambda), \end{aligned} \tag{23}$$

implying to their traces

$$T_\nu \to T_\nu - (n-1)\partial_\nu \lambda, \quad V_\nu \to V_\nu + n\partial_\nu \lambda. \tag{24}$$

One sees from (23) that a λ-transformation does not preserve the spaces of symmetric or metric-compatible connections. However, the condition ensuring the consistency of MCP, namely that $T_\mu + V_\mu$ be a gradient, is indeed preserved under (22). The Einstein-Hilbert action is, obviously, also preserved under (22). Hence, provided that the matter content action is also λ-invariant, the λ-transformation will map distinct solutions in a metric-affine theory of gravity governed by the Einstein-Hilbert action, preserving all the isometries if λ is properly chosen.

An interesting consequence arises from the transformation of the modified volume element under a λ-transformation,

$$e^{\theta}\tau_0 \to e^{\theta+\lambda}\tau_0. \tag{25}$$

Starting with, for instance, a Riemann-Cartan manifold with a gradient torsion trace and an Einstein-Hilbert action with the modified volume element, it is possible to choose $\lambda = -\theta$ and to get an equivalent theory, where the MCP is also well-defined, formulated in an affine manifold (the connection is not metric-compatible anymore) but with the usual volume element. In other words, in this new manifold, $D_\mu X^\mu = \mathrm{div}_{\tau_0} X$ for any vector field X.

IV. FINAL REMARKS

Before discussing possible applications of the results presented here to the study of crystalline defects, let us recall how they reinforce the results of Ref. 15 about the inadequacy of the propagating torsion model proposed in Ref. 2 to explain the available observational data. The modified volume element (1) was introduced in the model of Ref. 2 by means of exclusively geometrical arguments, and, hence, there is no free parameter associated with the field θ, which is responsible for the propagating components of the torsion. Moreover, by employing the MCP, no extra parameters, besides the Newtonian constant G, should arise in any gravitational model. Thus, the only way of fitting the available observational data described in Ref. 15 is to have θ constant,

leading to the already mentioned conclusion that the results of Ref. 15 would allow us to deduce that the observational data and the very reasonable requirement of consistency of the action formulation with the MCP *imply* that the trace of the torsion tensor of space-time should vanish.

Condensed matter is a vast subject but, to the best of our knowledge, the ideas presented here were not yet applied to the study of crystalline defects, which possess a geometrical description since the seminal works of Kondo in the fifties (see, for references, Ref. 8). The physics of crystalline defects is a promising arena to test experimentally the ideas of the last sections, with special emphasis on new effects that might be associated with the modified volume element (1). The first conclusion about the modified volume element in this context is that, in principle, it has no relation to the *real* volume (area, in this case) of the polygon depicted in Fig. 1. As discussed in Ref. 8, contributions to the elementary area coming from the Burgers vector are of higher order and should vanish in the linear continuum limit. Incidentally, for X^μ and Y^μ orthogonal in a Riemann-Cartan manifold ($D_\kappa g_{\mu\nu}=0$), the area of the polygon of Fig. 1 is given, up to higher order terms, by

$$A = |X||Y|\left(1 - \tfrac{1}{2}(X^\mu + Y^\mu)T_\mu\right), \tag{26}$$

from where one sees that, despite being unclosed, its area coincides with the area of the parallelogram with sides X^μ and Y^μ if $T_\mu=0$. However, the modified volume element (1) cannot represent a physical area since any geometrical property of the crystalline lattice should be invariant under a transformation of the type $\theta\rightarrow\theta+\Lambda$, with constant Λ, and the modified volume element, under this transformation, behaves as $\tau\rightarrow e^{\Lambda}\tau$. This behavior, on the other hand, is allowed in the minimal action formulation, since, as was already noted, a scale transformation of a Lagrangian preserves the dynamics. The dynamics of defects, on the other hand, are governed by their free energy, which can be expressed by means of a Lagrangian density related to the Einstein-Hilbert Lagrangian.[14,22] The use of the modified volume element in the action of the free energy would define a new dynamics to the torsion and metric tensors, analogous to that proposed in Ref. 2 in the context of Einstein-Cartan theory of gravity. An immediate consequence would be the propagation of the trace of the torsion tensor and, consequently, of the associated Burgers vector.

The free energy plays the role of the kinetic term in the geometrical action formulation of defects. However, kinetic terms are not, *a priori*, specified by the MCP. Our analysis seems more suitable to the study of fields/particles propagating on the crystalline lattice, such as phonons, impurities, and vacancies.[14] If the perturbation energy associated with these objects is small enough, their backreaction on the lattice may be ignored, and they can be considered *test* fields. Phonons are nothing more than small elastic (sound) excitations in the crystal; in the geometrical description, they correspond to gauge independent linearized perturbations of the metric.[9] On the other hand, one can also consider impurities or vacancies moving on the background medium defined by the solid with crystalline defects. The effect of the background on such test fields/particles can be gotten from the MCP by demanding that the corresponding equations for phonons, impurities, and vacancies be obtained, from the equations for the regular lattice, by changing the ordinary derivative to the covariant one and the Euclidean metric to the metric associated with the background medium. With use of MCP and the modified volume element, testable predictions for the propagation of phonons, impurities, and vacancies could arise. For instance, the modified volume element should affect the wave functions and energy spectrum of impurities and vacancies[14] in the presence of a crystalline defect. The occurrence of bound states due to dislocations[23] can also be studied in light of the present results. One probably, however, needs to go beyond the eikonal approximation for the test fields, since in this case the trajectory of the associated particle is assumed to be a geodesic curve,[14] a good approximation for high-frequency fields, but with no contributions from the torsion tensor. These points are now under investigation.

APPENDIX

Let us first discuss how the results of this paper relate to the earlier approach of Refs. 2–5 and 10. Unlike the approach presented here, the analysis of these works explicitly uses the concept of covariant derivative of densities, which are defined as follows. Let h be a scalar density on $\mathcal{M}$. One can define the covariant derivative of h in two different ways:

$$D_\mu h = \partial_\mu h - \Gamma_{\mu\kappa}{}^{\kappa} h, \tag{A1}$$

or

$$\tilde{D}_\mu h = \partial_\mu h - \Gamma_{\kappa\mu}{}^{\kappa} h. \tag{A2}$$

The definition (A1) can be called the *usual* covariant derivative, since, as we show in the following,

$$\nabla_X(h\, \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n) = [X^\mu D_\mu h]\mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n. \tag{A3}$$

The covariant derivative (A2), used also, for instance, in Ref. 24, is the so-called transposed derivative,[3] since it can be interpreted as the covariant derivative with respect to the transposed connection $\tilde{\Gamma}_{\mu\nu}{}^{\kappa} = \Gamma_{\nu\mu}{}^{\kappa}$ (see, in this context, the volume-preserving connection introduced in Ref. 19). Note that, according to Eq. (3), $\tilde{D}_\mu h = D_\mu h$ provided that the trace of the torsion tensor vanishes so that, in this case, no ambiguity concerning the definition of the covariant derivative of densities arises. The covariant derivative (A2) is closer to the *Lie derivative* on $\mathcal{M}$, since it satisfies, as we will see,

$$\pounds_X(h\, \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n) = [(D_\mu X^\mu)h + X^\mu(\tilde{D}_\mu h)]\mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n. \tag{A4}$$

The mathematical property that distinguishes the volume element (1) in Ref. 10 is that, whereas the canonical volume element (9) is covariantly constant with respect to the usual derivative,

$$D_\mu \sqrt{g} = 0, \tag{A5}$$

the volume element (1) is covariantly constant with respect to the transposed derivative,

$$\tilde{D}_\mu(e^\theta \sqrt{g}) = 0, \tag{A6}$$

provided that

$$T_\mu + V_\mu = \partial_\mu \theta. \tag{A7}$$

By comparing with Eq. (A4), we see that (18) holds if and only if one chooses a volume form $\tau = f\tau_0$ such that

$$\tilde{D}_\mu(f\sqrt{g}) = 0, \tag{A8}$$

which has a solution only if $T_\mu + V_\mu = \partial_\mu \theta$ and $f = e^\theta$.[10] This shows how the earlier approach of Refs. 2–5 and 10 relates to the present work, which, as discussed in the previous sections, is based on weaker physical assumptions.

We end by providing proofs of identities (A3) and (A4), and of Proposition 1. Identity (A3) can be proved as follows:

$$\nabla_X(h\,\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n)=(\nabla_X h)\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n+h\sum\nolimits_\kappa \mathrm{d}x^1\wedge\cdots\wedge\nabla_X\mathrm{d}x^\kappa\wedge\cdots\wedge\mathrm{d}x^n$$
$$=X(h)\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n+h\sum\nolimits_\kappa \mathrm{d}x^1\wedge\cdots\wedge(-X^\mu\Gamma_{\mu\nu}{}^\kappa\,\mathrm{d}x^\nu)\wedge\cdots\wedge\mathrm{d}x^n$$
$$=X^\mu(\partial_\mu h-\Gamma_{\mu\kappa}{}^\kappa)\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n. \tag{A9}$$

As for (A4), since $\pounds_X$ and d commute, we have

$$\pounds_X\,\mathrm{d}x^\kappa=\mathrm{d}\pounds_X x^\kappa=\mathrm{d}X^\kappa=\partial_\nu X^\kappa\,\mathrm{d}x^\nu, \tag{A10}$$

which leads to

$$\pounds_X(h\,\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n)=\pounds_X(h)\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n+h\sum\nolimits_\kappa \mathrm{d}x^1\wedge\cdots\wedge\pounds_X\,\mathrm{d}x^\kappa\wedge\cdots\wedge\mathrm{d}x^n \tag{A11}$$

$$=[X(h)+h\partial_\kappa X^\kappa]\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n \tag{A12}$$

$$=[hD_\mu X^\mu+X^\mu(\partial_\mu h-h\Gamma_{\kappa\mu}{}^\kappa)]\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n. \tag{A13}$$

Finally, Proposition 1 can be proved as follows. We first notice that

$$D_\kappa X^\kappa=\partial_\kappa X^\kappa+\Gamma_{\kappa\mu}{}^\kappa X^\mu \tag{A14}$$

$$=\partial_\kappa X^\kappa+\left(\left\{{\kappa\atop\kappa\mu}\right\}+K_{\kappa\mu}{}^\kappa+V_{\kappa\mu}{}^\kappa\right)X^\mu \tag{A15}$$

$$=\partial_\kappa X^\kappa+\left(\partial_\kappa\ln\sqrt{g}+T_\kappa+V_\kappa\right)X^\kappa. \tag{A16}$$

On the other hand, it follows from Eq. (A12) that

$$\pounds_X\left(f\sqrt{g}\,\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^n\right)=\left(X^\kappa\partial_\kappa\ln(f\sqrt{g})+\partial_\kappa X^\kappa\right)\tau. \tag{A17}$$

Thus, from definition (14),

$$\mathrm{div}_\tau X=X^\kappa\partial_\kappa\ln(f\sqrt{g})+\partial_\kappa X^\kappa, \tag{A18}$$

which finally yields

$$D_\kappa X^\kappa=\mathrm{div}_\tau X+\left(T_\kappa+V_\kappa-\partial_\kappa\ln f\right)X^\kappa. \tag{A19}$$

(Received 14 June 2005; accepted 21 September 2005; published online 21 November 2005)

We prove that the mathematical framework for the de Sitter top system is the de Sitter fiber bundle. In this context, the concept of soldering associated with a fiber bundle plays a central role. We comment on the possibility that our formalism may be of particular interest in different contexts including MacDowell-Mansouri theory, two time physics, and oriented matroid theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2121227]

In 1974, Hanson and Regge proposed a Lagrangian theory for a relativistic top.[1,2] One year later the importance and advantage of this formulation was shown when the equations of motion of a top in a gravitational field were derived by using the equivalence gravitational principle.[3] Furthermore, one of the original motivations for the Lagrangian formulation of the top was to quantize the system by means of Dirac's method for constraint Hamiltonian systems. Moreover, with the idea of making supersymmetric the Lagrangian of the system the square root of a bosonic top was proposed.[4] In this direction it was shown that the quantum top also allows a BFV[5] and BRST quantization.[6] It turned out that these pioneer developments motivated a generalization of the original theory to the so-called superstringtop theory[7,8] which combines, in a Lagrangian context, the concepts of string and top.

Recently, the de Sitter top theory[9] has been proposed (see also Ref. 10) which is a higher dimensional Lagrangian formulation of a special kind of a spherical relativistic top characterized by a Regge trajectory constraint of the de Sitter form $m^2+(1/2r^2)\Sigma^2+m_0^2=0$, where m is the mass of the top, Σ is the internal angular momentum, and r and m_0 are constants. One of the interesting aspects of the de Sitter top system is that by using the Kaluza-Klein mechanism[11,12] the equation of motion of the top in a gravitational field can be derived. Since Kaluza-Klein theory is closely linked to the fiber bundle concept[13,14] one should expect a geometric formulation of the de Sitter top in terms of such a concept. Although this idea has been outlined in Refs. 9 and 10 the precise connection between fiber bundle structure and the de Sitter top needs to be addressed. In this work, we claim that the soldered fiber bundle structure is the natural mathematical framework for a formal description of the de Sitter top. It turns out that the soldered bundle concept has been extensively used by Drechsler (see Ref. 15, and references therein) in particle physics. In particular, Drechsler has proposed a gauge theory for extended elementary objects based in the soldered bundle concept. These applications of the soldered bundle concept are, however, more focused on a gauge field scenario of the systems[16,17] rather than in a gravitational context. Moreover, part of the motivation of these applications are at the level of hadrons[18–21] and not a deeper level as is the case of the de Sitter top. Nevertheless, in this work we show that some of the mathematical tools in the soldered bundle theory can be used for describing the de Sitter top. We complement our

a)Electronic mail: nieto@uas.uasnet.mx

analysis of the de Sitter top by observing that the soldered bundle concept may provide the mathematical tool to clarify some aspects of the MacDowell-Mansouri formalism[22] (see also Ref. 23) and two time physics.[24]

Let us start writing the de Sitter top Lagrangian[9]

$$L = -m_0\left(-\tfrac{1}{2}\omega_M^{AB}\omega_{NAB}\dot{x}^M\dot{x}^N\right)^{1/2}, \tag{1}$$

where m_0 is a constant measuring the inertia of the system and $\dot{x}^M=(\mathrm{d}/\mathrm{d}\tau)x^M$, with M,N running from 0 to 9 and τ is an arbitrary parameter. Here, $\omega_M^{AB}=-\omega_M^{BA}$ denotes a connection associated with the de Sitter group SO(1,4) [or anti de Sitter group SO(2,3)]. Indeed, ω_M^{AB} is determined by the ansatz

$$\omega_M^{AB} = \begin{pmatrix} \omega_\mu^{5a}(x) & \omega_\mu^{ab}(x) \\ 0 & \omega_i^{ab}(y) \end{pmatrix}. \tag{2}$$

When writing (2) the coordinates x^M were separated in the form (x,y), with x corresponding to the four-dimensional base manifold M^4 and y parametrizing the group manifold SO(1,4). The Lagrangian (1) is interesting because it leads to a Regge trajectory constraint of the de Sitter form $m^2+(1/2r^2)\Sigma^2+m_0^2=0$ (see Refs. 1 and 2 and also Refs. 25 and 26) connecting the mass m and the spin Σ of the system.

Consider the antisymmetric pair $[ab]$ of the four valued indices a,b in the form $a'=([12],[13],[14],[23],[24],[34])$. Using this notation one discovers that if one makes the identifications ($\sim$),

$$\omega_\mu^{5a}(x) \sim e_\mu^a(x), \tag{3}$$

$$\omega_\mu^{ab}(x) \sim E_\mu^{a'}(x), \tag{4}$$

$$\omega_i^{ab}(y) \sim E_i^{a'}(y), \tag{5}$$

and

$$\omega_M^{AB} \to E_M^{\hat{A}}, \tag{6}$$

then the ansatz (2) becomes

$$E_M^{\hat{A}} = \begin{pmatrix} e_\mu^a(x) & E_\mu^{a'}(x) \\ 0 & E_i^{a'}(y) \end{pmatrix}, \tag{7}$$

which may be recognized as the typical form of the Kaluza-Klein ansatz.[11,12] This suggests introducing the metric

$$\gamma_{MN} = E_M^{\hat{A}}E_N^{\hat{B}}\eta_{\hat{A}\hat{B}}, \tag{8}$$

which according to (7) can be separated in the form

$$\gamma_{\mu\nu} = g_{\mu\nu} + E_\mu^{a'}E_\nu^{b'}\eta_{a'b'},$$

$$\gamma_{\mu i} = E_\mu^{a'}E_i^{b'}\eta_{a'b'}, \tag{9}$$

$$\gamma_{ij} = E_i^{a'}E_j^{b'}\eta_{a'b'} = g_{ij}(y),$$

where

$$g_{\mu\nu}(x) = e^a_\mu(x) e^b_\nu(x)\, \eta_{ab}. \tag{10}$$

Here, η_{ab} and $\eta_{a'b'}$ are flat metrics corresponding to M^4 and B, respectively.

From of the point of view of Kaluza-Klein theory the splitting (9) is the result of compactifying a $4+D$-dimensional space-time manifold M^{4+D} in the form $M^{4+D} \to M^4 \times B$, where M^4 is a four-dimensional base space manifold and B is a group manifold whose dimension is D. In the case of the de Sitter top it is not clear what the meaning of M^{4+D} and B is. Moreover, the meaning of the identification (3) is unclear. One may choose M^{4+D} as SO(1,4) and B as SO(1,3) but in this case M^4 will be completely determined without using the gravitational field equations. Thus, although the identifications (3)–(6) are suggestive they are not complete requiring a deeper analysis. We shall show that these aspects of the de Sitter top can be clarified through the so-called *soldered fiber bundle* notion. In order to achieve our goal we first observe that the object ω^{AB}_M may be identified with the fundamental one-form

$$\omega = g^{-1} dg + g^{-1} \Omega g, \tag{11}$$

where

$$\omega = \tfrac{1}{2} \omega^{AB}_M S_{AB} \mathrm{d}x^M \tag{12}$$

and

$$\Omega = \tfrac{1}{2} \omega^{AB}_\mu S_{AB} \mathrm{d}x^\mu. \tag{13}$$

Here, $g \in \mathrm{SO}(1,4)$ and S_{AB} are the generators of the de Sitter group SO(1,4) [or anti de Sitter group SO(2,3)]. In turn, (13) can be understood as a one-form connection in the cotangent space $T^*(P)$, where P is a principal bundle $P(M^4, \mathrm{SO}(1,4))$. Locally, $P(M^4, \mathrm{SO}(1,4))$ looks like $M^4 \times \mathrm{SO}(1,4)$ but once again this picture is incomplete in the sense that it leaves without answer the meaning of the relation (3). Nevertheless, this analysis motivates one to find a framework beyond the simple principal bundle $P(M^4, \mathrm{SO}(1,4))$.

In general, it is well known that given a principal bundle $P(M,G)$ one may construct an associated fiber bundle $E(M,F,G)$ where F is a fiber manifold and conversely, a fiber bundle $E(M,F,G)$ naturally induces a principal bundle $P(M,G)$ associated with it (see Ref. 27, Sec. 9.4.2, for details). Thus, the principal bundle $P(M^4, \mathrm{SO}(1,4))$ may have an associated fiber bundle $E(M^4, F, \mathrm{SO}(1,4))$. In principle F can be any vector space but in the case of the de Sitter top one may think of SO(1,4) as a group acting transitively over F. Moreover, by Inönü-Wigner contraction one should expect that de Sitter top is reduced to the usual relativistic top which is invariant under the Lorentz transformations determined by the Lorentz group SO(1,3) (see Ref. 2). Now, since SO(1,3) is an isotropy subgroup of SO(1,4) this suggests considering the coset space $\mathrm{SO}(1,4)/\mathrm{SO}(1,3)$. Applying a well-known theorem (see Ref. 28, Sec. 1.6, and see also Ref. 29) one can establish the homeomorphism $F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3)$. Therefore, the fiber bundle which we are interested to relate to the de Sitter top is

$$E(M^4, F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3), \mathrm{SO}(1,4)). \tag{14}$$

This is a fiber bundle of the Cartan type possessing as a fiber de Sitter space $dS_4 \equiv F$ which is homeomorphic to the noncompact coset space

$$\mathrm{SO}(1,4)/\mathrm{SO}(1,3).$$

Since $\dim G/H = \dim G - \dim H$ we find that

$$\dim \mathrm{SO}(1,4)/\mathrm{SO}(1,3) = \dim \mathrm{SO}(1,4) - \dim \mathrm{SO}(1,3) = 4$$

and therefore the dimension of dS_4 is four, the same as M^4. This result is an indication that the bundle (14) may admit a soldered fiber bundle structure. But before we present the definition of a

soldered fiber bundle let us motivate further the idea of soldering in connection with the de Sitter top.

Let us introduce a gauge parameter $\lambda=\frac{1}{2}\lambda^{AB}(x)S_{AB}$. The transformation associates with ω, given in (12), can be written as

$$\omega' = g\omega g^{-1} + g^{-1}dg, \tag{15}$$

which as an infinitesimal gauge transformation reads as

$$\delta\omega = \mathrm{d}\lambda + [\lambda, \omega]. \tag{16}$$

In components (16) leads to the expression

$$\delta\omega^{AB} = d\lambda^{AB} + \omega^{AC}\lambda^{B}_{C} + \omega^{AC}\lambda^{B}_{C}, \tag{17}$$

which can be separated in the form

$$\delta\omega^{5a} = D\lambda^{5a} + \omega^{5c}\lambda^{a}_{c} \tag{18}$$

and

$$\delta\omega^{ab} = D\lambda^{ab} + \omega^{a5}\lambda^{b}_{5} + \omega^{b5}\lambda^{a}_{5}. \tag{19}$$

Here, D means covariant derivative with ω^{ab} as a connection. Thus, if we set

$$\omega^{5a}_{\mu} = e^{a}_{\mu} \tag{20}$$

one sees that the expressions (18) and (19) lead to

$$\delta e^{a}_{\mu} = D_{\mu}\xi^{a} + e^{c}_{\mu}\lambda^{a}_{c} \tag{21}$$

and

$$\delta\omega^{ab}_{\mu} = D_{\mu}\lambda^{ab} + e^{a}_{\mu}\xi^{b} - e^{b}_{\mu}\xi^{a}, \tag{22}$$

respectively. But formulas (21) and (22) indicate that neither e^{a}_{μ} nor ω^{ab}_{μ} transform properly under Lorentz transformations SO(1,3) and therefore in general they cannot be identified with the Lorentz tetrad and connection, respectively. For this to be possible it is required that the parameter ξ^{a} vanishes in (21) and (22). In turn this implies that the de Sitter group SO(1,4) is broken leading to the Lorentz group SO(1,3). To set the parameter ξ^{a} equal to zero in a consistent way is not so simple and in fact requires one to introduce the soldering concept which we shall now formally define.

A bundle $E(M, F=G/H, G)$ over a base manifold M with homogeneous fiber $F=G/H$ and associated principle bundle $P(M, G)$ is soldered if[15]

(i) G acts transitively on F,
(ii) $\dim F = \dim M$,
(iii) E admits a global cross section σ and the structural group G of E can be reduced to H.
(iv) The tangent bundle $T(M)$ over M and the bundle $T(E)=T(F)$ of all tangent vectors to F at the section σ are isomorphic.

It is clear that the bundle $E(M^4, F\cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3), \mathrm{SO}(1,4))$ which we try to associate to the de Sitter top satisfies (i), (ii), and (iii). The only remaining point is to impose condition (iv). It turns out that (iv) is equivalent to the two properties[15]

(a) $\theta(X')=0$ for $X' \in T(P'(M,H))$ if and only if X' is vertical.

(b) $\theta(dR_h X') = h^{-1} X' h$ for $X' \in T(P'(M,H))$ and $h \in H$,

which are satisfied for the so-called one-form of soldering θ. The reason to be interested in the one-form θ is because a connection ω in $P(M,G)$ can be written in terms of a connection in $P'(M,H)$ and the soldering one-form θ as follows:

$$\omega = \omega' + \theta. \tag{23}$$

Actually, the equivalence between (iv) and (a)–(b) is achieved when one assumes the reductive algebra

$$[\mathcal{L}(H), \Lambda] \subseteq \Lambda, \tag{24}$$

associated with the decomposition $\mathcal{L}(G) = \mathcal{L}(H) \oplus \Lambda$ of the Lie algebra of G, where $\mathcal{L}(H)$ corresponds to the subalgebra of H and Λ is required to be a vector subspace of G with dimension $\dim M = \dim G - \dim H$. In fact such equivalence is obtained when one assumes the existence of Λ-valued one-form θ satisfying (a) and (b) (see Refs. 15 and 30 for details). In connection with (23) two observations are necessary. First, the decomposition (23) does not require the additional condition

$$[\Lambda, \Lambda] \subseteq \mathcal{L}(H), \tag{25}$$

implying that $F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3)$ is a symmetric space, and second, since ω is a $\mathcal{L}(G)$-valued one-form in the cotangent bundle $T^*(P)$ we can write $\omega = \omega(x,y)$, where the coordinates x and y parametrize locally M and F, respectively, and consequently, in general, we should have $\omega' = \omega'(x,y)$ and $\theta = \theta(x,y)$. However, (a) and (b) imply that we can write $\theta = \theta(x)$.

Let us now specialize (23) to the case of the de Sitter fiber bundle $E(M^4, F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3), \mathrm{SO}(1,4))$. First let us observe that since S_{AB} are the generators of the de Sitter group SO(1,4) (or anti de Sitter group SO(2,3)) we can write the algebra

$$-i[S_{AB}, S_{CD}] = \eta_{AC} S_{BD} - \eta_{AD} S_{BC} + \eta_{BD} S_{AC} - \eta_{BC} S_{AD}, \tag{26}$$

where $\eta_{AC} = \mathrm{diag}(-1,1,1,1,1)$. From (26) we get

$$-i[S_{ab}, S_{cd}] = \eta_{ac} S_{bd} - \eta_{ad} S_{bc} + \eta_{bd} S_{ac} - \eta_{bc} S_{ad}, \tag{27}$$

$$-i[S_{5b}, S_{cd}] = \eta_{bd} S_{5c} - \eta_{bc} S_{5d}, \tag{28}$$

and

$$-i[S_{5b}, S_{5d}] = S_{bd}. \tag{29}$$

Thus, we conclude that S_{ab} are the generators of the subgroup SO(1,3) and that (28) is in agreement with (24). This in turn implies that the SO(1,4) valued one-form connection ω given in (12) can be written in terms of a SO(1,3) valued one-form connection ω^{ab} and the one-form ω^{5b} as

$$\omega = \tfrac{1}{2} \omega^{ab} S_{ab} + \omega^{5b} S_{5b}. \tag{30}$$

Comparing (30) with (23) one discovers that one can make the identifications $\omega'^{ab} = \omega^{ab}$ and $\theta^b = \omega^{5b}$. Since in general $\omega^{AB} = \omega^{AB}(x,y)$ [see expressions (11) and (12)], one finds that ω^{AB} can be split into the form

$$\theta^a = \omega_\mu^{5a} \mathrm{d}x^\mu + \omega_i^{5a} \mathrm{d}y^i \tag{31}$$

and

$$\omega^{ab} = \omega_{\mu}^{ab} \mathrm{d}x^{\mu} + \omega_{i}^{ab} \mathrm{d}y^{i}. \tag{32}$$

Now, the condition (a)–(b) for θ means that the soldering concept allows one to set $\omega_i^{5a}=0$ and therefore we have

$$\theta^{a} = \omega_{\mu}^{5a} \mathrm{d}x^{\mu}. \tag{33}$$

This is consistent with (iv) and in fact one should be able to write θ^a in terms of the base $e_\mu^a \in T(M^4)$. In particular one can set $\theta_\mu^a = e_\mu^a$, that is, $\omega_\mu^{5a} = e_\mu^a$. Consequently, one discovers that the complete connection ω_M^{AB} can be written as

$$\omega_M^{AB} = \begin{pmatrix} e_\mu^a(x) & \omega_\mu^{ab}(x,y) \\ 0 & \omega_i^{ab}(x,y) \end{pmatrix}, \tag{34}$$

which by using the Kaluza-Klein mechanism can be reduced to (2). Summarizing, we have explicitly shown that the geometrical framework for the de Sitter top is the de Sitter soldering fiber bundle $E(M^4, F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3), \mathrm{SO}(1,4))$ as Fukuyama had anticipated.[9]

Until now we have focused more on the de Sitter top description determined by the line element (1) rather than in the dynamics of the background itself where the system moves. In other words, besides the mathematical framework for the de Sitter top one may be interested in the field equations which govern the evolution of the connection ω_M^{AB} given in (2). Since e_μ^a and $\omega_M^{ab}(x)$ are considered as independent variables one may think in Einstein-Cartan theory (linear in the curvature), as the more appropriate candidate. However, there exists another gravitational theory which seems to be closer to the spirit of the ansatz (2) than the Einstein-Cartan theory. We refer to the so-called MacDowell-Mansouri theory[22] (see also Ref. 23) which is one of the closest proposals for achieving a gauge theory for gravity. The idea in this theory is precisely to consider the field variables e_μ^a and $\omega_\mu^{ab}(x)$ as part of a bigger connection $\omega_\mu^{AB}(x)$ associated with the de Sitter group SO(1,4). In fact, by taking $e_\mu^a = \omega_\mu^{5a}(x)$ one verifies that the action

$$S = \int \mathrm{d}^4 x \varepsilon^{\mu\nu\alpha\beta} \mathcal{R}_{\mu\nu}^{ab} \mathcal{R}_{\alpha\beta}^{cd} \varepsilon_{abcd}, \tag{35}$$

where

$$\mathcal{R}_{\mu\nu}^{ab} = R_{\mu\nu}^{ab} + e_\mu^a e_\nu^b - e_\mu^b e_\nu^a, \tag{36}$$

with $R_{\mu\nu}^{ab}$ the curvature in terms of ω_μ^{ab}, leads to the two terms: the Euler-Pontrjagin topological invariant and the Einstein Hilbert action with a cosmological constant. One observes that the action (35) is intrinsically four dimensional and therefore there seems to be enough room for the additional part $\omega_i^{ab}(y)$. However, recently[31] in an effort to generalize the Ashtekar formalism to higher dimensions a generalization of (35) to eight dimensions has been proposed which may allow full background description of the connection (2). In fact, in Ref. 31 it was proposed the action

$$S = \int d^8 x \eta^{MNRS} \mathcal{R}_{MN}^{\hat{A}\hat{B}} \mathcal{R}_{MN}^{\hat{C}\hat{D}} \eta_{\hat{A}\hat{B}\hat{C}\hat{D}}, \tag{37}$$

where the object η^{MNRS} is connected with the algebra of octonions (see Ref. 31 for details). Our conjecture is that the background field equations, where the de Sitter top evolves, can be derived from the action (37). Assuming that the action (37) describes the evolution of the de Sitter connection $\omega_M^{\hat{A}\hat{B}}$ we observe that an interesting possibility arises. This has to do with the fact that a theory based on the action (30) would lead to a de Sitter vacuum solution for the base manifold M^4 rather than the Minkowski space. Consequently, the de Sitter soldering fiber bundle $E(M^4, F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3), \mathrm{SO}(1,4))$ will be such that both M^4 and the fiber F are de Sitter (or anti-de Sitter) type spaces. Besides these observations our formalism may help one to understand

why the choice $e_\mu^a = \omega_\mu^{5a}(x)$ works in this context. In general this has been a mystery, but according to our discussion such a choice is the result of a soldering process associated with the fiber bundle

$$E(M^4, F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3), \mathrm{SO}(1,4)).$$

Our observation that the de Sitter top may be described by the de Sitter soldering bundle may also be useful for a possible connection between the de Sitter top and two time physics. In fact, it turns out that two time physics is determined by the action[24]

$$S = \int_{\tau_i}^{\tau_f} \mathrm{d}\tau \left(\frac{1}{2} \varepsilon^{ab} \dot{x}_a^\mu x_b^\nu \eta_{\mu\nu} - \frac{1}{2} \lambda^{ab} (x_a^\mu x_b^\nu \eta_{\mu\nu} + m_{ab}^2) \right), \tag{38}$$

where $x_1^\mu = x_a^\mu$, $x_2^\mu = p^\mu$, $\lambda^{ab} = \lambda^{ba}$ is a Lagrange multiplier and m_{ab}^2 are constants which can be zero or different from zero. If $m_{ab}^2 = 0$ then the action (38) has the manifest $\mathrm{Sp}(2,R)$ (or $\mathrm{SL}(2,R)$) invariance and the action is consistent if the flat metric $\eta_{\mu\nu}$ admits signature with two time. However if $m_{ab}^2 \neq 0$ this symmetry is broken and the action leads to the constraint

$$\Omega_{ab} = x_a^\mu x_b^\nu \eta_{\mu\nu} + m_{ab}^2 = 0 \tag{39}$$

(see Ref. 32 for details). Choosing $m_{11}^2 = -R^2$, $m_{22}^2 = m_0^2$, and $m_{12}^2 = 0$ one discovers that (39) gives

$$x^\mu x_\mu - R^2 = 0, \tag{40}$$

$$x^\mu p_\mu = 0, \tag{41}$$

and

$$p^\mu p_\mu + m_0^2 = 0. \tag{42}$$

The formula (40) describes an anti-de Sitter space-time and therefore in a sense the system can be understood as a relativistic point particle moving in an anti-de Sitter background which is precisely the idea underlying the de Sitter top.

Finally, there are at least two possible interesting generalizations of our formalism for the de Sitter top. In the first case one may think in the de Sitter top as a result of Clifford geometry as presented by Castro (see Ref. 33, and references therein). The second possibility may arise from the so-called oriented matroid theory.[34] It has been shown that oriented matroid theory can be connected not only to string theory but also to any p-brane, supergravtiy and Chern-Simons theory.[35–39] These connections were possible thanks to the notion of *matroid bundle* introduced first by MacPherson[40] and generalized by Anderson and Davis[41] and Biss.[42] It turns out that matroid bundle is a generalization of the concept of a fiber bundle. Thus, it seems natural to associate with the bundle $E(M^4, F \cong \mathrm{SO}(1,4)/\mathrm{SO}(1,3), \mathrm{SO}(1,4))$ some kind of the de Sitter matroid bundle and therefore a de Sitter matroid top or a de Sitter "topoid." At present all these possibilities concerning the background (2) are under investigation and we expect to report our results somewhere in the not too distant future.

Finite-dimensional reductions of the two-dimensional dispersionless Toda hierarchy constrained by the "string equation" are studied. These include solutions determined by polynomial, rational, or logarithmic functions, which are of interest in relation to the "Laplacian growth" or Hele-Shaw problem governing interface dynamics. The consistency of such reductions is proved, and the Hamiltonian structure of the reduced dynamics is derived. The Poisson structure of the rationally reduced dispersionless Toda hierarchies is also derived. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2104307]

I. INTRODUCTION

This paper concerns rational and logarithmic reductions of the two-dimensional dispersionless Toda hierarchy of integrable equations (henceforth 2dToda). The subject is motivated by important applications to problems in interface dynamics and statistical physics.

Laplacian growth is a process that governs the dynamics of the boundary in the plane separating two disjoint, open regions $\mathcal{D}_+$ and $\mathcal{D}_-$ in which harmonic (scalar) fields are defined. These may be interpreted as the pressure fields for two incompressible viscous fluids (Hele-Shaw problem). The movement of the boundary is determined (according to Darcy's law, in the case of viscous fluids) by equating the normal velocity of the boundary to the boundary values of the gradients of the fields. In particular, one region (say, the "interior" region $\mathcal{D}_+$) may be chosen to be bounded and have constant harmonic field (corresponding to zero viscosity) with the boundary condition for the "exterior" $\mathcal{D}_+$ region at infinity such that there is a unit sink, implying that the area of the interior region grows linearly in time.[15] Denoting the harmonic field (e.g., the pressure) in the exterior region by $P(X,Y)$, this satisfies the conditions:

$$\Delta P(X,Y) = 0, \tag{1}$$

$$P \to (4\pi)^{-1} \ln(X^2 + Y^2) \text{ as } X^2 + Y^2 \to \infty \tag{2}$$

in the Cartesian coordinates (X,Y). The normalized exterior normal velocity at the boundary is given by

[a)]Electronic mail: harnad@crm.umonreal.ca
[b)]Electronic mail: loutsenk@maths.ox.ac.uk
[c)]Electronic mail: yermola@fm.sissa.it

$$v_n = -\nabla P. \tag{3}$$

In the case where the boundary is an analytic curve it is usual to use the Riemann mapping theorem to introduce a time-dependent conformal map from the exterior of the unit circle in the complex w plane to the exterior region $\mathcal{D}_-$ in the "physical" plane $z=X+iY$ taking the unit circle to the boundary $\partial\mathcal{D}_+$.

$$z = z(w,x), \quad w = \exp(i\phi), \quad 0 < \phi < 2\pi, \tag{4}$$

where x stands for the physical time of the Hele-Shaw problem. We choose this unusual notation for time for consistency with that used in the literature on the dispersionless integrable systems.

Simple considerations[14,4,11] show (see Appendix A) that Eqs. (1) and (3) are equivalent to

$$\mathrm{Im}\left(\frac{\partial z}{\partial \phi}\frac{\partial \bar{z}}{\partial x}\right) = w\left(\frac{\partial z(w,x)}{\partial w}\frac{\partial \bar{z}(1/w,x)}{\partial x} - \frac{\partial z(w,x)}{\partial x}\frac{\partial \bar{z}(1/w,x)}{\partial w}\right) = 1, \tag{5}$$

where bar stands for complex conjugation (and $\bar{w}=w^{-1}$ on the boundary curve). In our notations $\bar{z}(w)=\Sigma_i \bar{z}_i w^i$ if $z(w)=\Sigma_i z_i w^i$, while $\overline{z(w)}=\Sigma_i \bar{z}_i \bar{w}^i$.

Known as the Galin-Polubarinova equation[6,14] in the Hele-Shaw problem, Eq. (5) plays an essential role in the theory of infinite-dimensional integrable hierarchies in the dispersionless limit. The relation between the boundary dynamics above and the dispersionless limit of the integrable Toda hierarchy constrained by (5) was shown in Refs. 11 and 19.

Equation (5) may be interpreted as a constraint on an infinite commuting set of dynamical systems defined in the space $z(x,w)$ of one-parameter families of conformal maps. This constraint represents fixed points of an "additional symmetry"[12] and is called the "string equation" in the theory of integrable systems. The most interesting aspect of such constrained dToda flows is that they admit finite-dimensional reductions, which include so-called "multi-finger" solutions.[7] These solutions are of great importance in practical applications and describe numerous phenomena, such as viscous fingering in a Hele-Shaw cell[7,9,16] and pattern formation in the quantum Hall effect.[1]

In what follows, we consider finite-dimensional reductions of (5) in the context of the 2dToda hierarchy. We first study algebraic solutions of the problem, ignoring the real structure and treating $z,\bar{z}$ as independent functions, and w as a formal variable. Returning to the applications to interface dynamics we identify bar with complex conjugation.

II. 2DTODA HIERARCHY AND STRING EQUATION

The 2dToda hierarchy is a dispersionless limit[17] of the two-dimensional Toda hierarchy and is defined in terms of two functions $z(w,x)$ and $\bar{z}(w^{-1},x)$ of the form:

$$z(w,x) = r(x)w + \sum_{k=0}^{\infty} u_k(x)w^{-k}, \tag{6}$$

$$\bar{z}(w^{-1},x) = r(x)w^{-1} + \sum_{k=0}^{\infty} \bar{u}_k(x)w^{k}. \tag{7}$$

The 2dToda flow equations are

$$\partial_{t_k} z = \{H_k, z\}, \quad \partial_{\bar{t}_k}\bar{z} = \{\bar{H}_k, \bar{z}\},$$

$$\partial_{t_k} \bar{z} = \{H_k, \bar{z}\}, \quad \partial_{\bar{t}_k} z = \{\bar{H}_k, z\}, \tag{8}$$

where the "Poisson-Lax" bracket notation here denotes

$$\{f,g\} := w\frac{\partial f}{\partial w}\frac{\partial g}{\partial x} - w\frac{\partial f}{\partial x}\frac{\partial g}{\partial w} \tag{9}$$

and the coefficients $r(x), u_k(x), \bar{u}_k(x)$ are viewed as coordinate functions on the phase space. The evolution functions are defined as follows:

$$H_k = (z^k)_+ + 1/2(z^k)_0, \quad \bar{H}_k = (\bar{z}^k)_- + 1/2(\bar{z}^k)_0, \tag{10}$$

where subscripts $\pm, 0$ denote the negative/positive and zero parts of the formal Laurent expansion in w (i.e. $f_+ = \Sigma_{i>0} f_i w^i, f_- = \Sigma_{i<0} f_i w^i$ if $f = \Sigma_i f_i w^i$).

It is important to note that, despite the notation, (9) is not really a Poisson bracket defined on the infinite-dimensional phase space of the 2dToda system (8) (with coordinates $r, u_k, \bar{u}_k$), but rather a "quasiclassical" $\hbar \to 0$ limit of commutators in the Lax representation of the dispersive version of (8) (where $\hbar$ stands for the lattice spacing, see Ref. 17). Values (10) are dispersionless analogs of the upper or lower diagonal parts of the powers of Lax matrices.

The 2dToda system is nevertheless an integrable Hamiltonian system of PDEs for the functions $r(x, t_1, \ldots, \bar{t}_1 \ldots), u_k(x, t_1, \ldots, \bar{t}_1 \ldots), \bar{u}_k(x, t_1, \ldots, \bar{t}_1 \ldots)$, obtained by equating coefficients of (8) as Laurent polynomials in the dummy variable w. One can easily verify that vector fields (8) commute, i.e.,

$$\frac{\partial^2}{\partial t_i \partial t_j}\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = \frac{\partial^2}{\partial t_j \partial t_i}\begin{pmatrix} z \\ \bar{z} \end{pmatrix}, \quad \frac{\partial^2}{\partial \bar{t}_i \partial t_j}\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = \frac{\partial^2}{\partial t_j \partial \bar{t}_i}\begin{pmatrix} z \\ \bar{z} \end{pmatrix}, \quad \frac{\partial^2}{\partial \bar{t}_j \partial \bar{t}_i}\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = \frac{\partial^2}{\partial \bar{t}_i \partial \bar{t}_j}\begin{pmatrix} z \\ \bar{z} \end{pmatrix}$$

due to the "zero curvature" condition

$$\frac{\partial H_i}{\partial t_j} - \frac{\partial H_j}{\partial t_i} - \{H_i, H_j\} = 0, \quad \frac{\partial H_i}{\partial \bar{t}_j} - \frac{\partial \bar{H}_j}{\partial t_i} - \{H_i, \bar{H}_j\} = 0, \quad \frac{\partial \bar{H}_i}{\partial \bar{t}_j} - \frac{\partial \bar{H}_j}{\partial \bar{t}_i} - \{\bar{H}_i, \bar{H}_j\} = 0,$$

which follows from equations of motion (8) and definitions (9) and (10).

The Galin-Polubarinova equation (5) for the Hele-Shaw problem written in terms of the Poisson-Lax bracket (9)

$$\{z(w,x), \bar{z}(w^{-1},x)\} = 1, \tag{11}$$

is the string equation.

It is fundamental that Eq. (11) is invariant under the flows generated by (8). Indeed

$$\partial_{t_k}\{z,\bar{z}\} = \{\partial_{t_k} z, \bar{z}\} + \{z, \partial_{t_k}\bar{z}\} = \{\{H_k, z\}, \bar{z}\} + \{z, \{H_k, \bar{z}\}\} = \{\{\bar{z}, z\}, H_k\} = 0, \tag{12}$$

where we have used (8) and (11), and the Jacobi identity for the Lax-Poisson bracket (9).

Thus the string equation (11) defines an invariant manifold under the Toda flows (8) and a reduction of the Toda hierarchy. On the other hand, the Toda flows may be viewed as symmetries generating new solutions of Eq. (11).

III. REDUCTIONS OF THE 2DTODA HIERARCHY CONSTRAINED BY THE STRING EQUATION

The reduction of the 2dToda hierarchy by the string equation is still a compatible set of infinite-dimensional dynamical systems.

Indeed, as seen from (6) and (7) the string equation (11) is a system of ODEs of the form

$$\mathrm{d}r/\mathrm{d}x = R(r, u_1, \ldots, \bar{u}_1, \ldots), \quad \mathrm{d}u_i/\mathrm{d}x = U_i(r, u_1, \ldots, \bar{u}_1, \ldots), \quad \mathrm{d}\bar{u}_i/\mathrm{d}x = \bar{U}_i(r, u_1, \ldots, \bar{u}_1, \ldots). \tag{13}$$

In what follows we will be interested in further "functional" reductions where $z, \bar{z}$ are polynomial, rational, or logarithmic functions of w. As shown in the following, such reductions are

consistent with (8) (i.e., the corresponding ansatz for z is preserved by the two-dimensional Toda flows) if the string equation (11) holds. Thus, for consistency we need a double ("functional" plus "string") reduction. These pairs of reductions define finite-dimensional invariant sub-manifolds in the phase space of the general 2dToda hierarchy. Indeed, functional reduction leaves a finite number of discrete indices in the ansatz for z as a function of w, while the string equation fixes the dependence of z on x, leaving finite number of degrees of freedom. These degrees of freedom are connected with the integration constants of system (13), which becomes finite-dimensional after functional reductions.

A. Polynomial reductions

We begin with polynomial reductions of the 2dToda hierarchy

$$z(w) = rw + \sum_{i=-N}^{0} u_i w^i, \tag{14}$$

$$\bar{z}(w^{-1}) = rw^{-1} + \sum_{i=0}^{N} \bar{u}_i w^i \tag{15}$$

constrained by the string equation (11).

The following proposition states the consistency of the polynomial reductions under the Toda flows:

Proposition 1: If the string equation (11) holds, then (14) and (15) is a finite dimensional reduction invariant under the t_i and $\bar{t}_i$ 2dToda flows, $0<i<N+2$ (8). This manifold has dimension $2N+3$ with local coordinates chosen as the initial values of the solutions $r=r(x), u_i=u_i(x), \bar{u}_i=\bar{u}_i(x)$ to the reduced string equation (13).

Proof: We must prove that z remains of the form (14), under the flows generated by $H_k, \bar{H}_k$ provided the string equation (11) holds. In other words, we have to show that the evolution does not change the highest and lowest degrees of the Laurent polynomial (14). The proof for $\bar{z}$ is analogous.

1. First we proceed with the projections to z of the flows which are identical to those appearing in 1dToda system, i.e., those generated by H_k. These flows will be referred to as the "proper" flows.

The lowest degree of w in z is $-N$. Since

$$H_k = (z^k)_+ + 1/2(z^k)_0 = h_k w^k + h_{k-1} w^{k-1} + \ldots + h_0 \tag{16}$$

is a Laurent polynomial of positive degree in w, the lowest degree of the bracket $\{z, H_k\}$ is not less than $-N$, as follows from (9). On the other hand, the complement $z^k - H_k$ of (16) is a polynomial in $1/w$ and so,

$$\{H_k, z\} = -\{z^k - H_k, z\}$$

is a Laurent polynomial whose highest degree in w does not exceed 1.

2. Unlike the H_k-flows, the form-invariance of z (14) under the flows generated by $\bar{H}_k$ requires extra restrictions on derivatives $\partial_x u_i$ (the string equation). These flows will be referred as the "cross-flows."

Since

$$\bar{H}_k = (\bar{z}^k)_- + 1/2(\bar{z}^k)_0$$

is a Laurent polynomial of nonpositive degree, it conserves the highest degree of $z(w)$ under the evolution (8), but not the lowest degree, in general. Indeed,

$$\bar{H}_k = \bar{z}^k - ((\bar{z}^k)_+ + 1/2(\bar{z}^k)_0)$$

is a difference between $\bar{z}^k$ and a polynomial of nonnegative degree, so that

$$\{\bar{H}_k, z\} = \{\bar{z}^k, z\} - \{((\bar{z}^k)_+ + 1/2(\bar{z}^k)_0), z\}.$$

The second bracket in the last expression preserves the lowest degree of z. Thus the lowest degree of $\{\bar{H}_k, z\}$ equals the lowest degree of $\{\bar{z}^k, z\} = k\bar{z}^{k-1}\{\bar{z}, z\}$. Imposing the extra restriction (11) (string equation), we see that the lowest degree does not exceed that of $\bar{z}^{k-1}$. Since the lowest degree of $\bar{z}$ is -1 and that of z is $-N$, it follows that $k < N+2$.

Therefore, the form of (14) is preserved by $t_i, \bar{t}_i$ Toda flows with $i = 1, \ldots, N+1$, provided the string equation (11) holds. This completes the proof.

It is easy to prove the converse to Proposition 1, i.e.,

Proposition 2: The string equation (11) is a necessary condition for the existence of integrable polynomial flows of the form (10), (14), and (15)

Proof: This essentially uses the same arguments as those leading to the result of Proposition 1. For the first $N+1$ z flows to be consistent with the polynomial reduction it is necessary that the Laurent expansion of $\{\bar{z}, z\}$ be of the form $\{\bar{z}, z\} = f(x) + \Sigma_{i>0} U_i(x)/w^i$. The corresponding condition for the $\bar{z}$ flows is $\{\bar{z}, z\} = \bar{f}(x) + \Sigma_{i>0} \bar{U}_i(x) w^i$. Both can be simultaneously satisfied only if

$$\{\bar{z}, z\} = f(x) = \bar{f}(x)$$

is independent of w. Differentiating with respect to t_i (or $\bar{t}_i$), i.e., along the flow lines, using the equations of motion (8), and the Jacobi identity we get

$$\frac{\partial f}{\partial t_i} = \{H_i, f\} = w \frac{\partial f}{\partial x} \frac{\partial H_i}{\partial w}.$$

Since $w(\partial H_i/\partial w)$ is w-dependent, while f is not, it follows that $\partial f/\partial x = \partial f/\partial t_i = 0$ and similarly $\partial f/\partial \bar{t}_i = 0$. Therefore f is a constant in x and also constant along the flows, implying (up to a constant scaling) that the string equation (11) holds.

In the following we consider rational and logarithmic reductions as well as their Hamiltonian structures. Polynomial solutions can then be viewed as a special case. Nevertheless the corresponding limiting procedures are rather cumbersome and it is easier to consider the polynomial case separately. A derivation of the canonical linearizing variables in the polynomial case is given in Appendix B. This closely follows the analogous procedure given in Sec. IV for the logarithmic case. Local canonical linearizing variables, which are constant and linear in the hierarchy times, turn out to be "Richardson's harmonic moments" of the Hele-Shaw (Laplacian growth) problem when $z(w)$ and $\bar{z}(\bar{w})$ are identified with the conformal mapping from the w to the z plane. This is a simple proof of the relation (originally established in Ref. 11) between the "times" of the 2dToda hierarchy and harmonic moments of the exterior Hele-Shaw problem.

An important consequence of the present section is the fact that the string equation (11) necessarily holds for reduced conformal mappings evolving under a sufficient number of 2dToda flows (i.e., sufficient for complete integrability). In the context of interface dynamics, *Darcy's law thus turns out to be a corollary of integrability* for reduced systems.

B. Rational reductions

We now consider a rational reduction for $z(w)$ and $\bar{z}(w), N > 1$ given by

$$z(w) = \frac{q_{N+1}(w)}{p_N(w)} = \frac{r w^{N+1} + \Sigma_{i=0}^{N} a_i w^i}{w^N + \Sigma_{i=0}^{N-1} b_i w^i}, \tag{17}$$

$$\bar{z}(w^{-1}) = \frac{\bar{q}_{N+1}(w^{-1})}{\bar{p}_N(w^{-1})} = \frac{rw^{-(N+1)} + \sum_{i=0}^{N} \bar{a}_i w^{-i}}{w^{-N} + \sum_{i=0}^{N-1} \bar{b}_i w^{-i}}. \tag{18}$$

The following Lemma states the consistency of such rational reductions under the t_i Toda flows for (17) and the $\bar{t}_i$ flows for (18).

Lemma 1: The form of the function $z(w)$ in (17) is invariant under the t_i flows and the form (18) of $\bar{z}(w^{-1})$ is invariant under the $\bar{t}_i$ flows for any $i>0$.

Proof: Consider the flows generated by H_k. Since

$$H_k = (z^k)_+ + 1/2(z^k)_0 \tag{19}$$

is a polynomial of non-negative degree in w, its complement $z^k - H_k$ is a polynomial in $1/w$. The Laurent expansion of brackets (9) $\{H_k, z\} = -\{z^k - H_k, z\}$ around infinity therefore has the following form:

$$\{H_k, z\} = k_1(T)w + k_0(T) + k_{-1}(T)w^{-1} + \cdots . \tag{20}$$

However the Lax bracket (9) also implies that it is rational of the form

$$\{H_k, z\} = Q(w)/p_N(w)^2.$$

It follows from (20) that the degree of polynomial $Q(w)$ does not exceed $2N+1$.

On the other hand,

$$\partial_{t_k} z = P(w)/{p_N}^2(w), \quad P(w) = p_N \partial_{t_k} q_{N+1} - q_{N+1} \partial_{t_k} p_N,$$

where the degree of the polynomial $P(w)$ also does not exceed $2N+1$. Equating the coefficients of polynomial $P(w) - Q(w)$ to zero, we get a system of differential equations for r, a, b. The number of equations is $2N+2$. Thus we get a compatible system of differential equations for $2N+2$ unknowns r, a, b. A similar argument shows the form invariance of (18) under the $\bar{t}_k$ flows.

The consistency of the rational reduction defined in (18) under the t_i flows and (17) under $\bar{t}_i$ flows, respectively, requires additional restrictions such as the string equation. But this only suffices to ensure form invariance under t_1 and $\bar{t}_1$ flows, respectively.

Lemma 2: The string equation (11) is a sufficient condition for $z(w)$ and $\bar{z}(w)$ [(17) and (18)] to be form invariant under the first two-Toda flows. Flows generated by $H_k, \bar{H}_k$ with $k>1$ are inconsistent with the rational reduction (17) and (18).

Remark: In the next section, we will show how to choose $4N+2$ independent commuting flows preserving the rational form of z (17) and $\bar{z}$ (18), generated by vector fields that are infinite linear combinations of those generating the 2dToda hierarchy.

Proof: In order to prove that z remains of the same form (17) under the $\bar{t}_i$ Toda flows we would have to find a compatibility condition for a system of differential equations for $r(T), a(T), b(T)$, induced by (8).

These "cross" flows are generated by $\bar{H}_k$. Again we write

$$\partial z/\partial \bar{t}_k = S(w)/{p_N}^2(w), \quad S(w) = p_N \partial_{\bar{t}_k} q_{N+1} - q_{N+1} \partial_{\bar{t}_k} p_N$$

with $S(w)$ a polynomial in w of order at most $2N+1$.

Since

$$\bar{H}_k = (\bar{z}^k)_- + 1/2(\bar{z}^k)_0 = \bar{h}_k w^{-k} + \bar{h}_{k-1} w^{-k+1} + \ldots + \bar{h}_0 \tag{21}$$

is a Laurent polynomial of non-positive degree in w, the Laurent expansion of the corresponding bracket has the following form:

$$\{\bar{H}_k, z\} = k_1(T)w + k_0(T) + k_{-1}(T)w^{-1} + \cdots .$$

The definition of the Lax bracket (9) and the expansion (21) implies that

$$\{\bar{H}_k, z\} = (U(w) + R(1/w))/p_N(w)^2,$$

where $U(w)$ is a polynomial of degree at most $2N+1$ and $R = w^{-1}(\eta_{k-1}(T)w^{-k+1} + \ldots + \eta_0)$ is a polynomial in w^{-1}. If $R(1/w) = 0$, the number of equations will not exceed the number of unknowns. However, as we show in the following, the string equation does not imply the vanishing of R.

Introduce the new variable $y = w^{-1}$. The vanishing of R is equivalent to the following form of expansion in y

$$\{\bar{H}_k, z\} = f_0(T) + f_{-1}(T)y^{-1} + \cdots . \tag{22}$$

Consider this as a function of y and, as before, express $\bar{H}_k$ as a difference of $\bar{z}_k$ and a polynomial of no-negative degree. Then

$$\{\bar{H}_k, z\} = \{\bar{z}^k, z\} - \{((\bar{z}^k)_+ + 1/2(\bar{z}^k)_0), z\} = k\bar{z}^{k-1}\{z, \bar{z}\} - \{((\bar{z}^k)_+ + 1/2(\bar{z}^k)_0), z\}. \tag{23}$$

Imposing the string equation (11) we see that the only flow that allows the above expansion (22) corresponds to $k=1$. A similar argument shows that only the t_1 flow preserves the form (18) of $\bar{z}$ even if the string equation is imposed.

As seen from the above-presented proof, there are only two flows generated by evolution operators of the form (10) compatible with the rational reduction. In fact, we should not expect more invariant flows associated with the simple poles at $w=0$ and $w=\infty$. In the polynomial case, the number of invariant flows was equal to the number of variables (polynomial coefficients), since one can associate n invariant flows to a pole of nth order, and the poles at zero and infinity are immovable.

However, in the following we introduce additional flows related to movable singularities of $z(w)$ and $\bar{z}(w^{-1})$ which do preserve the rational reduction (17) and (18), extending results of Krichever for the KP case.

C. Additional flows for rational reductions of dKP hierarchy

In this section we recall the theory of flows related to poles at a finite number of finite points applying an approach previously used by Krichever for dKP hierarchy. In the dispersionless limit, the dKP and 1dToda hierarchies are quite similar, while in 2dToda the existence of finite-dimensional reductions requires extra constraints.

Let us start by recalling[5] that on the phase space of extended Benney systems, i.e., rational dKP, there arise some new flows related to the pole structure of the corresponding maps. These additional flows were introduced by Krichever (see Ref. 8).

Consider the partial fraction expansion under the above-noted assumptions and the flows of the t_i type only. For the dKP hierarchy[5,18] these reductions have the form

$$z(w) = w + u_0 + \sum_{\alpha=1}^{N} \frac{u_\alpha}{w - w_\alpha}. \tag{24}$$

The new flows associated with the poles are defined similarly to the polynomial case

$$\partial_{t_{k,\alpha}} z = \{B_{k,\alpha}, z\}, \quad \alpha = \infty, 1, 2, \ldots, \quad k = 0, 1, 2, \ldots . \tag{25}$$

The evolution functions associated with the pole structure of z are as follows :

$$B_{k,\infty} = (z(w)^k)_{\geqslant 0}, \quad ()_{\geqslant 0} := ()_+ + ()_0$$

for an immovable pole at infinity, while for each finite-distance pole there appear additional flows with evolution functions:

$$B_{k,\alpha} = (z(w)^k)_\alpha, \quad B_{0,\alpha} = \log(w_\alpha - w).$$

Here $z(w)_\alpha$ denotes the negative part of a formal Laurent expansion of $z(w)$ near the pole w_α:

$$f(w)_\alpha = \sum_{i>0} \frac{f_i}{(w-w_\alpha)^i} \quad \text{if } f = \sum_{i\in Z} \frac{f_i}{(w-w_\alpha)^i}. \tag{26}$$

These additional flows commute amongst themselves and with the ordinary 1dToda or dKP flows (associated with poles at infinity).

D. Additional invariant flows of 2dToda system

In the following, we will look at reductions of the 2dToda systems analogous to the above-mentioned Benney-Krichever reductions of KP. We will thus choose the rational functions $z(w), \bar{z}(1/w)$ appearing in (17) and (18) to have only simple poles and express these in the partial fraction form

$$\begin{aligned} z(w) &= rw + u_0 + \textstyle\sum_{j=1}^n \frac{u_j}{w-w_j}, \\ \bar{z}(1/w) &= r/w + \bar{u}_0 + \textstyle\sum_{j=1}^n \frac{\bar{u}_j}{1/w-\bar{w}_j}. \end{aligned} \tag{27}$$

Now, introduce a new set of $4n+2$ evolution functions $H_{0,j}, H_{1,j}, H_{1,\infty}, \bar{H}_{0,j}, \bar{H}_{1,j}, \bar{H}_{1,\infty}$ defined by

$$H_{k,j}(w) = B_{k,j}(w) - \tfrac{1}{2}B_{k,j}(w=0), \quad \bar{H}_{k,j}(y) = \bar{B}_{k,j}(y) - \tfrac{1}{2}\bar{B}_{k,j}(y=0), \tag{28}$$

where $k=0,1, j=1,\ldots,n$ and

$$\begin{aligned} &B_{1,\infty}(w) = (z(w))_{\geqslant 0}, \quad B_{0,j} = \log(r(w_j - w)), \quad B_{1,j}(w) = (z(w))_j \\ &\bar{B}_{1,\infty}(y) = (\bar{z}(y))_{\geqslant 0}, \quad \bar{B}_{0,j} = \log(r(\bar{w}_j - y)), \quad \bar{B}_{1,j}(y) = (\bar{z}(y))_j, \quad y = 1/w. \end{aligned} \tag{29}$$

We denote the flow variables associated with $H_{0,j}$ as τ_{2j}, those associated with $H_{1,j}$ as τ_{2j-1}, and that associated with $H_{1,\infty}$ as τ_0. The flow variables associated with $\bar{H}_{0,j}\bar{H}_{1,j}$, and $\bar{H}_{0,\infty}$ are denoted $\bar{\tau}_{2j}, \bar{\tau}_{2j-1}, \bar{\tau}_0$, respectively. Correspondingly, we denote the evolution functions

$$h_0 = H_{1,\infty} = rw + u_0/2, \quad \bar{h}_0 = \bar{H}_{1,\infty} = r/w + \bar{u}_0/2,$$

$$h_{2j-1} = H_{1,j} = \tfrac{u_j}{w-w_j} + \tfrac{u_j}{2w_j}, \quad \bar{h}_{2j-1} = \bar{H}_{1,j} = \tfrac{\bar{u}_j}{\bar{w}_j - 1/w} + \tfrac{1}{2}\bar{u}_j/\bar{w}_j$$

$$h_{2j} = H_{0,j} = \log(w_j - w) + 1/2\,\log(r/w_j), \quad \bar{h}_{2j} = \bar{H}_{0,j} = \log(\bar{w}_j - 1/w) + 1/2\,\log(r/\bar{w}_j). \tag{30}$$

Then the following proposition holds

Proposition 3: The $4n+2$ commuting Toda-Krichever flows

$$\partial_{\tau_j} z = \{h_j, z\}, \quad \partial_{\bar{\tau}_j} z = \{\bar{h}_j, z\}$$
$$j = 0, \ldots, 2n \tag{31}$$
$$\partial_{\tau_j} \bar{z} = \{h_j, \bar{z}\}, \quad \partial_{\bar{\tau}_j} \bar{z} = \{\bar{h}_j, \bar{z}\}$$

preserve the rational form of $z(w)$ *and* $\bar{z}(1/w)$ *(27) [or equally (17) and (18)] provided the string equation (11) holds. The dimension of the reduced phase space equals* $4n+3$.

We defer the proof, since this follows as a limiting case of the more general logarithmic reduction introduced in Sec. III E.

As in the polynomial case, the total number of form invariant flows preserving the string equation equals the dimension of the reduced phase space minus one. In what follows we show that these flows are Hamiltonian. Since the dimension of the phase space is odd and equals $4n+3$, it is in fact a Poisson manifold whose symplectic leafs have dimension $4n+2$, which is exactly the number of commuting Toda-Krichever flows.

The above-presented result holds for a more general setting. In the following we introduce a logarithmic reduction of the 2dToda hierarchy and prove an analog of proposition 3 for logarithmic functions. Proposition 3 follows as a limiting case.

E. Logarithmic flows

It is easier to prove the consistency of the rational reductions with the dynamics of the 2dToda system by first considering the more general logarithmic functions and then taking limits in which the branch points degenerate in pairs. Let us set

$$z = r(x)w + u(x) + \sum_{i=1}^{n+1} a_i \log(w_i(x) - w),$$
$$\bar{z} = r(x)w^{-1} + \bar{u}(x) + \sum_{i=1}^{n+1} \bar{a}_i \log(\bar{w}_i(x) - w^{-1}), \tag{32}$$

where $a_i, \bar{a}_i$ are arbitrary constants, subject to the conditions

$$\sum_{i=1}^{n+1} a_i = 0, \quad \sum_{i=1}^{n+1} \bar{a}_i = 0, \tag{33}$$

which ensure absence of logarithmic singularities at infinity.

Introduce evolution functions as follows:

$$\mathcal{H}_0 = r(x)w + \tfrac{1}{2}u(x), \quad \bar{\mathcal{H}}_0 = \bar{r}(x)w^{-1} + \tfrac{1}{2}\bar{u}(x),$$
$$\mathcal{H}_j = \log(w_j(x) - w) + \tfrac{1}{2}\log(r(x)/w_j(x)), \quad j = 1, \ldots, n+1 \tag{34}$$
$$\bar{\mathcal{H}}_j = \log(\bar{w}_j(x) - w^{-1}) + \tfrac{1}{2}\log(r(x)/\bar{w}_j(x)).$$

We then have

Proposition 4: The string equation (11) is a necessary and sufficient condition for the existence of $2n+4$ *commuting flows on the* $2n+5$ *dimensional space of functions of the form (32)*

$$\partial_{\tau_i} z = \{\mathcal{H}_i, z\}, \quad \partial_{\bar{\tau}_i} z = \{\bar{\mathcal{H}}_i, z\},$$
$$i = 0, \ldots, n+1, \tag{35}$$

$$\partial_{\tau_i}\bar{z} = \{\mathcal{H}_i, \bar{z}\}, \quad \partial_{\bar{\tau}_i}\bar{z} = \{\bar{\mathcal{H}}_i \bar{z}\}.$$

In other words, the flows generated by (34) and (35) are tangential to the manifold of such logarithmic functions if the string condition is imposed (and conversely). We therefore have $2n+4$ flows leaving invariant a $2n+5$ dimensional sub-manifold of the 2dToda system. These will be shown to be infinite linear combinations of vector fields generating the 2dToda flows (8). See Eq. (46) and (47) in which we show how to express corresponding 2dToda times $t_i, \bar{t}_i$ in terms of the logarithmic flow parameters $\tau_i, \bar{\tau}_i$.

Proof:

1. *Commutativity* : This will be shown to follow as Corollary 1 to Proposition 5 below.

2. *Consistency of (32) with equations of motion (35):* As in the polynomial and rational cases the consistency of the $\partial_{\tau_i} z$ and $\partial_{\bar{\tau}_i}\bar{z}$ equations with the logarithmic reduction (32) follows from the fact that the structure of the Lax-Poisson brackets $\{\mathcal{H}_i, z\}, \{\bar{\mathcal{H}}_i, \bar{z}\}$ is identical to the infinitesimal deformations in z and $\bar{z}$ induced by ones in the functions $r, \bar{u}, u, \bar{w}_i, w_i$. However the consistency of the $\partial_{\tau_i}\bar{z}$ and $\partial_{\bar{\tau}_i} z$ equations with the logarithmic reduction requires an extra constraint, the string equation. First, we prove this for $\partial_{\bar{\tau}_i} z$.

Differentiating z in (32) with respect to $\bar{\tau}_i$ using the equation of motion (35), we get

$$\partial_{\bar{\tau}_i} z = w\partial_{\bar{\tau}_i} r + \partial_{\bar{\tau}_i} u + \sum_{j=1}^{n+1} \frac{a_i \partial_{\bar{\tau}_i} w_j}{w - w_j} = \{\bar{\mathcal{H}}_i, z\}. \tag{36}$$

The left-hand side of (36) may contain any terms that are linear in w at $w=\infty$ and simple poles at $w=w_j, j=1,\ldots,n+1$. Since the Lax-Poisson bracket (9) is a bi-derivation, the singularities in w that may occur in $\{\mathcal{H}_i, z\}$ consist either of simple poles at $w=w_j, j=1,\ldots,n+1$, linear terms at $w=\infty$ or a simple pole at $w=1/\bar{w}_i$. We show that the latter is absent.

Note that $\bar{z}$ can be represented as a sum over $\bar{\mathcal{H}}_i, i=0,\ldots,n+1$ plus a w-independent function $f(x)$;

$$\bar{z} = \sum_{i=0}^{n+1} \bar{a}_i \bar{\mathcal{H}}_i + f(x), \tag{37}$$

where $\bar{a}_0 := 1, f(x) = \frac{1}{2}(\bar{u}(x) - \Sigma_{i=1}^{n+1} a_i \log \bar{w}_i(x))$. Now, using (37) we get

$$\bar{a}_i\{\bar{\mathcal{H}}_i, z\} = \{\bar{z} - \sum_{j\neq i} \bar{a}_j \bar{\mathcal{H}}_j - f(x), z\} = \{\bar{z}, z\} - \sum_{j\neq i} \bar{a}_j \{\bar{\mathcal{H}}_j, z\} - \{f(x), z\}. \tag{38}$$

Since $f(x)$ is independent of w, the last term in (38) contains only linear terms in w plus simple poles at $w_j, j=1,\ldots,n+1$. The term $\Sigma_{j\neq i}\bar{a}_j\{\bar{\mathcal{H}}_j, z\}$ could, in principle, contain poles at $w=1/\bar{w}_j$ for $j\neq i$, but these must cancel since $\{\bar{\mathcal{H}}_i, z\}$ contains no such poles. Furthermore, this term contains no pole at $w=1/\bar{w}_i$, because $\bar{\mathcal{H}}_i$ is omitted in the sum. Since the string equation (11) holds by assumption, we see that the right-hand side of (36) only contains terms of the type induced by infinitesimal deformations in the functions r, u, w_j, showing that the $\partial_{\bar{\tau}_i} z$ equation, together with the string equation, is compatible with the reduction (32). The proof for the $\partial_{\tau_i}\bar{z}$ equation is similar.

The above proves the sufficiency of the string equation for the validity of Proposition 4. The necessity is proved similarly to Proposition 2. By Eq. (38), if the rational reduction (32) is preserved under the $\bar{\tau}_i$ flows, $\{\bar{z}, z\}$ can have no pole at $w=1/\bar{w}_i$ for any i or at zero. Similarly to preserve (32) under the τ_i flows it can have no poles at $w_i, i=1,\ldots,n+1$ or ∞. But since the only possible poles in $\{\bar{z}, z\}$ are at these points, we conclude that $\{\bar{z}, z\}$ is constant in w and hence can only be a function (say q) of $x, \tau, \bar{\tau}$,

$$\{\bar{z},z\}=q.$$

Differentiating the last equation with respect to τ_i (or $\bar{\tau}_i$) using the equation of motion (35), the Jacobi identity and the definition of the Lax-Poisson bracket we get

$$\frac{\partial q}{\partial \tau_i}=w\frac{\partial q}{\partial x}\frac{\partial \mathcal{H}_i}{\partial w}.$$

Since $w(\partial\mathcal{H}_i/\partial w)$ is w-dependent, while q is not, it follows that $\partial q/\partial x=\partial q/\partial\tau_i=0$ (similarly $\partial q/\partial\bar{\tau}_i=0$). Therefore $q=$const and the string equation (11) holds.

The demonstration that the reduced phase space is of dimension $2n+5$ is similar to the polynomial case. We view the string equation (11) together with the logarithmic reduction (32) as a set of $(2n+5)$ first-order ODEs for the $(2n+5)$ functions $r(x),u(x),\bar{u}(x),w_i(x),\bar{w}_i(x),i=1,\ldots,n+1$,

$$\frac{\mathrm{d}r}{\mathrm{d}x}=R(r,u,\bar{u},w_1,\ldots,\bar{w}_1,\ldots),\quad \frac{\mathrm{d}u}{\mathrm{d}x}=U(r,u,\bar{u},w_1,\ldots,\bar{w}_1,\ldots),\quad \frac{\mathrm{d}\bar{u}}{\mathrm{d}x}=\bar{U}(r,u,\bar{u},w_1,\ldots,\bar{w}_1,\ldots),$$

$$\frac{\mathrm{d}w_i}{\mathrm{d}x}=W_i(r,u,\bar{u},w_1,\ldots,\bar{w}_1,\ldots),\quad \frac{\mathrm{d}\bar{w}_i}{\mathrm{d}x}=\bar{W}_i(r,u,\bar{u},w_1,\ldots,\bar{w}_1,\ldots),\quad i=1,\ldots,n+1$$

which, at least locally, determine the dependence of these functions uniquely in terms of their values $r_0,u_0,\bar{u}_0,w_{i0},\bar{w}_{i0},i=1,\ldots,n+1$ at some initial value $x=x_0$,

$$r=r(r_0,u_0,\bar{u}_0,w_{1,0},\ldots,\bar{w}_{1,0},\ldots,x),\quad u=u(r_0,u_0,\bar{u}_0,w_{1,0},\ldots,\bar{w}_{1,0},\ldots,x),$$
$$\bar{u}=\bar{u}(r_0,u_0,\bar{u}_0,w_{1,0}\ldots\bar{w}_{1,0}\ldots,x),$$

$$w_i=w_i(r_0,u_0,\bar{u}_0,w_{10}\ldots,\bar{w}_{1,0}\ldots,x),\quad \bar{w}_i=\bar{w}_i(r_0,u_0,\bar{u}_0,w_{1,0},\ldots,\bar{w}_{1,0}\ldots,x),\quad i=1,\ldots,n+1.$$

The $2n+5$ initial values $r_0,u_0,\bar{u}_0,w_{i0},\bar{w}_{i0},i=1,\ldots,n+1$ may be viewed as coordinates of the reduced phase space.

Proof of Proposition 3: This follows from taking limits in which the logarithmic branch points w_{2i},w_{2i-1} coalesce in pairs.

Setting

$$\begin{aligned} &a_{2i-1}=1/\epsilon,\quad a_{2i}=-1/\epsilon,\quad w_{2i}=w_{2i-1}+\epsilon u_i,\\ &\bar{a}_{2i-1}=1/\epsilon,\quad \bar{a}_{2i}=-1/\epsilon,\quad \bar{w}_{2i}=\bar{w}_{2i-1}+\epsilon\bar{u}_i \end{aligned} \tag{39}$$

in (32) we get (27) in the $\epsilon\to 0$ limit.

The evolution functions (30), generating flows on the space of rational reduction (27), are then obtained as follows:

$$h_0=\lim_{\epsilon=0}\mathcal{H}_0,\quad \bar{h}_0=\lim_{\epsilon=0}\bar{\mathcal{H}}_0,$$

$$h_{2i-1}=\lim_{\epsilon=0}\tfrac{1}{\epsilon}(\mathcal{H}_{2i}-\mathcal{H}_{2i-1}),\quad \bar{h}_{2i}=\lim_{\epsilon=0}\tfrac{1}{\epsilon}(\bar{\mathcal{H}}_{2i}-\bar{\mathcal{H}}_{2i-1}),$$

$$h_{2i}=\lim_{\epsilon=0}\mathcal{H}_{2i-1},\quad \bar{h}_{2i-1}=\lim_{\epsilon=0}\bar{\mathcal{H}}_{2i-1}.$$

We thus obtain evolution functions for the rational reductions, where $z,\bar{z}$ have simple poles only, as a limiting degenerating logarithmic case. One may deduce structures related to general rational reductions by degenerating arbitrary numbers of logarithmic singularities at different finite points as well as at infinity.

IV. POISSON STRUCTURE OF LOGARITHMIC REDUCTIONS OF THE 2TODA HIERARCHY

In the following we study the Poisson structure of logarithmic reductions of the 2dToda hierarchy, which will be shown to define finite-dimensional completely integrable systems. We find explicit expressions leading to a canonical Hamiltonian structure on the phase space of rational reductions of the 2dToda system.

The Poisson structure of rational reductions of the 1dToda hierarchy (which are infinite-dimensional, having no string equation constraint) is described in Appendix C. It is related to the Poisson structure of the Benney system considered in Ref. 13.

Hamiltonians, action-angle variables. Let us now introduce the following $2n+5$ functions on the reduced phase space defined by (32) with $z,\bar{z}$ solutions to (11), extended by the auxiliary variable x,

$$r,u,\bar{u},w_1,\ldots,w_{n+1},\bar{w}_1,\ldots,\bar{w}_{n+1} \to Q,I_0,I_1,\ldots,I_{n+1},\bar{I}_0,\bar{I}_1,\ldots,\bar{I}_{n+1}, \tag{40}$$

where the new variables are defined as follows:

$$I_0 = \tfrac{1}{2i\pi}\oint_\infty \bar{z}\mathrm{d}\ln z, \quad \bar{I}_0 = \tfrac{1}{2i\pi}\oint_0 z\mathrm{d}\ln\bar{z},$$

$$I_j = \tfrac{1}{2i\pi}\oint_{w_j} \bar{z}\mathrm{d}z, \quad \bar{I}_j = \tfrac{1}{2i\pi}\oint_{1/\bar{w}_j} z\mathrm{d}\bar{z}, \quad j=1,\ldots,n+1$$

$$Q = \tfrac{1}{4i\pi}\sum_{i=0}^{n+1}\oint_{1/\bar{w}_i} z\mathrm{d}\bar{z} + \oint_{w_i}\bar{z}\mathrm{d}z.$$

Using (32), we may evaluate the contour integrals in the last equation, expressing these explicitly in terms of the old parametrization $r,u,\bar{u},w_j,\bar{w}_j,j=1,\ldots,n+1$,

$$I_0 = \bar{z}(1/w=0) = \bar{u} + \textstyle\sum_{j=1}^{n+1}\bar{a}_j\ln(\bar{w}_j), \quad \bar{I}_0 = z(0) = u + \sum_{j=1}^{n+1} a_j\ln(w_j),$$

$$\begin{aligned} I_j &= a_j\bar{z}(w_j^{-1}) = a_j\Big(rw_j^{-1} + \bar{u} + \textstyle\sum_{k=1}^{n+1}\bar{a}_k\ln(\bar{w}_k - w_j^{-1})\Big), \\ \bar{I}_j &= \bar{a}_j z(\bar{w}_j^{-1}) = \bar{a}_j\Big(r\bar{w}_j^{-1} + u + \textstyle\sum_{k=1}^{n+1} a_k\ln(w_k - \bar{w}_j^{-1})\Big), \quad j=1,\ldots,n+1, \end{aligned} \tag{41}$$

$$Q = \tfrac{1}{2}r\Big(\Big(\tfrac{\partial z(w)}{\partial w}\Big)_{w=0} + \Big(\tfrac{\partial\bar{z}(1/w)}{\partial(1/w)}\Big)_{1/w=0}\Big) - \tfrac{1}{2}\textstyle\sum_{j=1}^{n+1}(I_j+\bar{I}_j) = r^2 - \tfrac{1}{2}\sum_{j=1}^{n+1}\Big(r\Big(\tfrac{a_j}{w_j} + \tfrac{\bar{a}_j}{\bar{w}_j}\Big) + I_j + \bar{I}_j\Big). \tag{42}$$

Proposition 5:The functions $I_k,\bar{I}_k,Q$ (41) and (42) are linearizing variables of the system (35) satisfying

$$\partial_{\tau_j}Q = 0, \quad \partial_{\bar{\tau}_j}Q = 0,$$

$$\partial_{\tau_j} I_k = \delta_{jk}, \quad \partial_{\bar{\tau}_j} I_k = 0, \tag{43}$$

$$\partial_{\tau_j} \bar{I}_k = 0, \quad \partial_{\bar{\tau}_j} \bar{I}_k = -\delta_{jk}.$$

Proof: We first calculate derivatives of each I_k with respect to the times $\tau_j, j=0,\ldots,n+1$. Applying integration by parts, we get

$$2\pi i \frac{\partial I_k}{\partial \tau_j} = \frac{\partial}{\partial \tau_j} \oint_{w_k} \bar{z} \frac{\partial z}{\partial w} \mathrm{d}w = \oint_{w_k} \frac{\partial}{\partial w}\left(\bar{z}\frac{\partial z}{\partial \tau_j}\right)\mathrm{d}w + \oint_{w_k} \left(\frac{\partial \bar{z}}{\partial \tau_j}\frac{\partial z}{\partial w} - \frac{\partial z}{\partial \tau_j}\frac{\partial \bar{z}}{\partial w}\right)\mathrm{d}w.$$

By the equations of motion (35) and the definition of the Lax-Poisson brackets (9) this equals

$$\oint_{w_k} \frac{\partial}{\partial w}\left(\bar{z}\frac{\partial z}{\partial \tau_j}\right)\mathrm{d}w + \oint_{w_k} \left(\{\mathcal{H}_j, \bar{z}\}\frac{\partial z}{\partial w} - \{\mathcal{H}_j, z\}\frac{\partial \bar{z}}{\partial w}\right)\mathrm{d}w$$
$$= \oint_{w_k} \frac{\partial}{\partial w}\left(\bar{z}\frac{\partial z}{\partial \tau_j}\right)\mathrm{d}w + \oint_{w_k} \frac{\partial \mathcal{H}_j}{\partial w} w \left(\frac{\partial z}{\partial w}\frac{\partial \bar{z}}{\partial x} - \frac{\partial z}{\partial x}\frac{\partial \bar{z}}{\partial w}\right)\mathrm{d}w,$$

which by the string equation (11) reduces to

$$\oint_{w_k} \frac{\partial}{\partial w}\left(\bar{z}\frac{\partial z}{\partial \tau_j}\right)\mathrm{d}w + \oint_{w_k} \frac{\partial \mathcal{H}_j}{\partial w}\mathrm{d}w = 2\pi i \delta_{kj}, \quad \delta_{jk} = \begin{cases} 1, & j = k \\ 0, & j \neq k \end{cases}.$$

The first term on the left-hand side vanishes, because $\bar{z}(\partial z/\partial \tau_j)$ is univalent in a neighborhood of $w_k, k=1,\ldots,n+1$ [and at ∞ due to (33)] and the remaining integral is evaluated by substituting expression (34) for $\mathcal{H}_j$. We have thus proved that

$$\frac{\partial I_i}{\partial \tau_j} = \delta_{ij}.$$

The rest of the proposition is proved by similar computations.

Corollary 1:The vector fields defining (35) commute.

Proof: Since $z, \bar{z}$ are completely determined by the new coordinates $Q, I, \bar{I}$, infinitesimal deformations of the former under the τ_i flows can be expressed via the chain rule through the infinitesimal deformations of the latter. It follows from Proposition 5 that

$$\frac{\delta}{\delta \tau_i}\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = \frac{\partial}{\partial I_i}\begin{pmatrix} z \\ \bar{z} \end{pmatrix}, \quad \frac{\delta}{\delta \bar{\tau}_i}\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = \frac{\partial}{\partial \bar{I}_i}\begin{pmatrix} z \\ \bar{z} \end{pmatrix}$$

so we have

$$\left(\frac{\delta}{\delta \tau_i}\frac{\delta}{\delta \tau_j} - \frac{\delta}{\delta \tau_j}\frac{\delta}{\delta \tau_i}\right)\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = \left(\frac{\partial}{\partial I_i}\frac{\partial}{\partial I_j} - \frac{\partial}{\partial I_j}\frac{\partial}{\partial I_i}\right)\begin{pmatrix} z \\ \bar{z} \end{pmatrix} = 0.$$

The commutativity of the other flows is seen to similarly follow from Proposition 5.

Choosing Poisson structure for Eq. (43) in a canonical way

$$\{I_i, \bar{I}_j\}_p = \delta_{ij}, \quad \{I_i, I_j\}_p = \{\bar{I}_i, \bar{I}_j\}_p = 0, \quad \{Q, \bar{I}_j\}_p = \{Q, I_j\}_p = 0 \tag{44}$$

we may interpret $I, \bar{I}$ as canonical linearizing variables and Q as a Casimir invariant. The equations of motion induced by the evolution operators $\mathcal{H}_i$ or $\bar{\mathcal{H}}_i$ are seen to be Hamiltonian and generated by the Hamiltonians

$$\mathrm{H}_i = \bar{I}_i, \quad \bar{\mathrm{H}}_i = I_i. \tag{45}$$

The Poisson brackets $\{,\}_p$ in (44) are different from $\{,\}$ in (9); they define a Poisson structure on the finite dimensional space of logarithmic reductions of the phase space satisfying the string equation, while the latter (the Lax-Poisson bracket) is a dispersionless limit of the commutator.

Remark: Linearizing coordinates similar to (41) appeared in Ref. 10 in connection with the Laplacian Growth problem as integrals of the Laplacian Growth (string) equation, without the introduction of the compatible τ_i and $\bar{\tau}_i$ flows considered here.

The following proposition makes explicit the fact that the string equation implies the finite dimensionality of the reduced phase space.

Proposition 6:The functions (41) form a set of integrals of the string equation (11). The string equation (11) implies

$$\frac{\partial I_i}{\partial x} = \frac{\partial \bar{I}_i}{\partial x} = 0, \quad \frac{\partial Q}{\partial x} = 1.$$

Equivalently, this may be integrated to

$$Q - x = c_0, \quad I_i = c_i, \quad \bar{I}_i = \bar{c}_i, \quad i = 0, \ldots, n = 1,$$

where c_i, c_i are constants in x, which may be interpreted as coordinates on the $2n+5$ dimensional reduced phase space.

Proof: This is similar to the proof of proposition (5); one simply differentiates with respect to x and evaluates corresponding residues.

As mentioned in Sec I, the Laplacian growth problem is recovered by identifying $\bar{z}$ as the complex conjugate of z. As seen from Proposition 6, the Casimir Q, which is proportional to the area of $\mathcal{D}_+$, grows with unit speed in physical time x, while $I_k, \bar{I}_k$ are functions of the harmonic moments of the boundary curve.

To obtain similar results for the rational case we take a limit as in (39).

Corollary 2: Let $z, \bar{z}$ be of the rational reduction form (27). Then the following $2n+3$ quantities

$$I_0 = \bar{u}_0 - \sum_{i=1}^n \bar{u}_i/\bar{w}_i, \quad \bar{I}_0 = u_0 - \sum_{i=1}^n u_i/w_i,$$

$$I_{2i-1} = r w_i^{-1} + \bar{u}_0 + \sum_{j=1}^n \frac{\bar{u}_j}{1/w_i - \bar{w}_j}, \quad \bar{I}_{2i-1} = r \bar{w}_i^{-1} + u_0 + \sum_{j=1}^n \frac{u_j}{1/\bar{w}_i - w_j}, \quad i = 1, \ldots, n$$

$$I_{2i} = \left(r - \sum_{j=1}^n \frac{\bar{u}_j}{(1/w_i - \bar{w}_j)^2} \right) \frac{u_i}{w_i^2}, \quad \bar{I}_{2i} = \left(r - \sum_{j=1}^N \frac{u_j}{(1/\bar{w}_i - w_j)^2} \right) \frac{\bar{u}_i}{\bar{w}_i^2},$$

$$Q = r^2 - \frac{1}{2} \sum_{i=1}^n \left(r \left(\frac{\bar{u}_i}{\bar{w}_i^2} + \frac{u_i}{w_i^2} \right) + \bar{I}_{2i} + I_{2i} \right)$$

the linearizing canonical variables for the rational reduction, i.e., variables in terms of which the equations of motion (31) for the rational reduction (27) have the canonical form (43).

The logarithmic or rational flows are infinite linear combinations of the 2dToda flows (8). As shown in Appendix B, harmonic moments of the conformal mapping $z(w)$ are linear in the 2dToda times. Therefore to express $t_i, \bar{t}_i, i=1, 2\ldots$ through $\tau_i, \bar{\tau}_i, i=0, \ldots, n+1$ one has to evaluate the integrals

$$M_k(z,\bar{z}) = \frac{1}{2k\pi i}\oint_{\infty} \bar{z}z^{-k}\frac{\partial z}{\partial w}\mathrm{d}w, \quad \bar{M}_k(z,\bar{z}) = \frac{1}{2k\pi i}\oint_{0} z\bar{z}^{-k}\frac{\partial \bar{z}}{\partial w}\mathrm{d}w, \tag{46}$$

which are functions of coordinates $z,\bar{z}$ of the reduced phase space (32), and then express $z,\bar{z}$ through $Q,I_i,\bar{I}_i, i=0,\ldots,n+1$. Then

$$M_k(Q,I,\bar{I}) = M_k(z(Q,I,\bar{I}),\bar{z}(Q,I,\bar{I})), \quad \bar{M}_k(Q,I,\bar{I}) = M_k(z(Q,I,\bar{I}),\bar{z}(Q,I,\bar{I})). \tag{47}$$

Since, modulo integration constants

$$M_i = t_i, \quad \bar{M}_i = \bar{t}_i, \quad i > 0,$$

$$I_i = \tau_i, \quad \bar{I}_i = \bar{\tau}_i, \quad i = 0,\ldots,n+1$$

and $Q=x$, it follows that Eq. (47) expresses $t_i,\bar{t}_i$ in terms of $\tau_i,\bar{\tau}_i$.

V. CONCLUSIONS

We have derived consistent finite dimensional logarithmic and rational reductions of certain flows related to the 2dToda hierarchy. The requirement for the consistency of these reductions was the string equation. Since the latter may also be viewed as the Galin-Polubarinova equation for the Hele-Shaw (Laplacian growth) process, this also established the latter as a compatible constraint for such reduced 2dToda flows.

More generally, it would be of interest to determine all finite dimensional reductions of the 2dToda hierarchy that imply fulfillment of the Darcy law in various forms.

Also, it would be useful to study integrable systems connected to various kinds of Hele-Shaw flows. This could include boundary conditions which are more general than a point sink at infinity. For instance, one can consider an exterior problem with a steady and uniform viscous flow at infinity. This can describe the evolution of a bubble surrounded by a viscous liquid moving through a wide channel, or a bubble within a viscous flow generated by a source and a sink of equal magnitude separated by a large distance. In such models, the constraint on $z,\bar{z}$ (6) and (7) has the form

$$\{z(w,x),\bar{z}(w^{-1},x)\} = (1/w + w)r(x).$$

This is an exterior analog of the interior problem with a dipole source inside the domain. In contrast to a monopole sink, this implies that the first harmonic moment changes with the time x, while the others (including area) remain unchanged. In general any combination of n-pole sources could be considered:

$$\{z(w,x),\bar{z}(w^{-1},x)\} = f(x,w),$$

where f is defined by the asymptotics of the hydrodynamic potential.

APPENDIX A: STRING EQUATION AND DARCY LAW

We recall here the derivation of the Galin-Polubarinova equation. Consider evolution of the exterior $\mathcal{D}_-$ of a simply connected planar domain bounded by an analytic curve on z plane. The

curve is an image of the unit circle in the w plane under a conformal mapping (4). As stated in the introduction the pressure field $P(X,Y)$ is constant in the interior domain $\mathcal{D}_+$ and at the boundary $\partial\mathcal{D}_+$, so that at $\partial\mathcal{D}_+$,

$$0 = \mathrm{d}P/\mathrm{d}x = \partial P/\partial x + v_n \nabla P = \partial P/\partial x - (\nabla P)^2,$$

where we used Darcy law (3) and the pressure gradient is taken in the exterior vicinity of the curve. Since P is harmonic in $\mathcal{D}_-$ [cf. (1)], it is the real part of a homomorphic function (hydrodynamic potential) $P=\mathrm{Re}\,\phi(z)$. It follows that

$$0 = \mathrm{Re}\left(\frac{\partial\phi}{\partial x} - \frac{\partial\phi}{\partial z}\overline{\left(\frac{\partial\phi}{\partial z}\right)}\right).$$

The hydrodynamic potential can be chosen as $\phi(z,x)=1/2\pi \log w(z,x)$ due to the logarithmic asymptotic in (1). Then

$$0 = \mathrm{Re}\left(\overline{w(z,x)}\frac{\partial w(z,x)}{\partial x} - \frac{\partial w(z,x)}{\partial z}\overline{\left(\frac{\partial w(z,x)}{\partial z}\right)}\right),$$

where $w(z,x)$ stands for the map inverse to $z(w,x)$. Using the facts that $z=z(w(z,x),x)$, i.e.,

$$\frac{\partial z(w,x)}{\partial w}\frac{\partial w(z,x)}{\partial x} + \frac{\partial z(w,x)}{\partial x} = 0, \quad \frac{\partial w(z,x)}{\partial z} = 1 \Big/ \frac{\partial z(w,x)}{\partial w}$$

and $\bar{w}=1/w$ on $\partial\mathcal{D}_+$, we arrive at (5).

APPENDIX B: POISSON STRUCTURE OF POLYNOMIAL REDUCTIONS

Following steps similar to the proof of Proposition 5, one arrives at the following result for polynomial reductions (10), (14), and (15) of the 2dToda system.

Proposition 7: The following quantities

$$M_k = \frac{1}{2i\pi k}\oint_\infty \bar{z}z^{-k}\mathrm{d}z, \quad \bar{M}_i = \frac{1}{2i\pi k}\oint_0 z\bar{z}^{-k}\mathrm{d}\bar{z},$$

$$Q = \frac{1}{4i\pi}\left(\oint_\infty \bar{z}dz - \oint_0 zd\bar{z}\right)$$

are canonical linearizing variables of the (polynomially) reduced 2dToda system (8), (10), (14), and (15):

$$M_k(z,\bar{z}) = t_k + \mathrm{const}, \quad \bar{M}_k(z,\bar{z}) = \bar{t}_k + \mathrm{const}, \quad Q(z,\bar{z}) = x + \mathrm{const}.$$

Solutions to the string equation (11) are then defined by the set of algebraic equations

$$Q(z,\bar{z}) = x + c_0, \quad M_k(z,\bar{z}) = c_k, \quad \bar{M}_k(z,\bar{z}) = \bar{c}_k,$$

where $c_k,\bar{c}_k$ are arbitrary constants.

Proof: Evaluating $\partial M_j/\partial t_k, \partial M_j/\partial \bar{t}_k$ by arguments similar to those of Proposition 5, we get

$$\frac{\partial M_j}{\partial t_k} = -\frac{1}{2i\pi j}\oint_\infty \frac{\partial H_k}{\partial w}z^{-i}\mathrm{d}w, \quad \frac{\partial M_i}{\partial \bar{t}_j} = \frac{1}{2i\pi j}\oint_\infty \frac{\partial \bar{H}_k}{\partial w}z^{-i}\mathrm{d}w.$$

Using the fact that

$$H_k = (z(w)^k)_+ + \tfrac{1}{2}(z(w)^k)_0 = z(w)^k - (z(w)^k)_- - \tfrac{1}{2}(z(w)^k)_0$$

and the negative part of the Laurent expansion does not contribute to the integral, we obtain

$$\frac{\partial M_j}{\partial t_k} = \frac{1}{2i\pi j}\oint_\infty z(w)^{-i}\frac{\partial z(w)^j}{\partial w}\mathrm{d}w = \delta_{kj}.$$

Using the fact that the evolution functions $\bar{H}_j = (\bar{z}^j)_- + 1/2(\bar{z}^j)_0$ generating the $\bar{\tau}_i$ flows are polynomials of non-negative degrees in $1/w$, we obtain

$$\frac{\partial M_i}{\partial \bar{t}_j} = 0.$$

In the context of the Hele-Shaw problem, the first $N+1$ Richardson moments[15] equal the first $N+1$ dToda times. Indeed, in the Hele-Shaw problem $z(w)$ has the meaning of a conformal mapping from w to the z plane. In the exterior problem, the exterior of the unit circle (i.e., domain $|w|>1$) is mapped to the exterior $\mathcal{D}_-$ of the boundary curve $z(w)$. The exterior harmonic moments are, by Green's theorem,

$$\frac{1}{2j\pi i}\int_{|w|>1} z^{-j}\mathrm{d}z\,\mathrm{d}\bar{z} = \frac{1}{2j\pi i}\oint_{|w|=1}\bar{z}(1/w)z(w)^{-j}\mathrm{d}z.$$

Since the mapping $z(w)$ is univalent in $\mathcal{D}_-$, all zeros of $z(w)$ are located in $\mathcal{D}_+$ and we can move the integration contour to infinity if $i \geqslant 1$. Thus, we get

$$\frac{1}{2j\pi i}\oint_\infty \bar{z}(1/w)z(w)^{-j}\mathrm{d}z = M_i$$

which, by Proposition 7 equals t_i modulo an integration constant.

APPENDIX C: POISSON STRUCTURE OF 1DTODA HIERARCHY.

In this section we consider the Poisson structure of rational reductions of 1dToda system. Recall that for the 1dToda system one takes into account only the t_i flows,

$$\partial_{t_i} z = \{H_i, z\}, \quad H_i = (z(w)^i)_+ + 1/2(z(w)^i)_0, \quad i = 0, \ldots \infty. \tag{C1}$$

This system is bi-Hamiltonian (for general information, e.g., see Ref. 3) with two (linear and quadratic) compatible Poisson structures. For generic Toda system (6), the dispersionless linear Poisson brackets for the "field variables" $u_i, i=1,\ldots,\infty$ (6) have the following form:[2]

$$\{u_n(x), u_m(y)\}_1 = 2(c_n + c_m - 1)[(n+m)u_{n+m}(x)\delta'(x-y) + mu'_{n+m}(x)\delta(x-y)], \tag{C2}$$

where

$$c_k = \begin{cases} 1 & \text{if } k > 0 \\ 1/2 & \text{if } k = 0 \\ 0 & \text{if } k < 0 \end{cases}$$

while the quadratic brackets are

$$\{u_n(x), u_m(y)\}_2 = \left[\frac{1}{2}(n-m)u_n(x)u'_m(x) + \left(\sum_{k=1}^{1-n}(n-m+k)u_{n+k}(x)u'_{m-k}(x) + ku'_{n+k}(x)u_{m-k}(x)\right)\right] \times \delta(x-y) + \left[1/2(n-m)u_n u_m + \left(\sum_{k-1}^{1-n}(n-m+2k)u_{n+k}u_{m-k}\right)\right]\delta(x-y). \tag{C3}$$

As seen from Lemma 1, the rational functions

$$z(w) = \frac{q_{N+1}(w)}{p_N(w)} = \frac{w^{N+1} + \Sigma_{i=0}^{N} a_i w^i}{\Sigma_{i=0}^{N} b_i w^i} \tag{C4}$$

are form-invariant under all the 1dToda flows (C1), without any extra restriction (e.g., no string equation is needed).

We obtain corresponding Poisson structures for the variables a_i, b_i, by using result (C3), expressing u_i in terms of $a_i, b_i, i=0,\ldots N$. Both the linear (C2) and the quadratic (C3) Poisson structures lead to quadratic brackets for a_i, b_i . Namely, the second Poisson structure for (C4)) becomes

$$\{a_k(x), a_l(y)\}_2 = \left[\sum_{n=1} (l+n-k) a_{k-n}(x) a_{l+n}(y) + n a_{k-n}(y) a_{l+n}(x) + (l-N-1) a_k(x) a_l(y)\right] \delta'(x-y), \tag{C5}$$

$$\{b_k(x), b_l(y)\}_2 = \left[\sum_{n=1} (k-l-n) b_{k-n}(x) b_{l+n}(y) - n b_{k-n}(y) b_{l+n}(x) + \frac{k-\ell}{2} b_k(x) b_l(y)\right] \delta'(x-y), \tag{C6}$$

$$\{a_k(x), b_l(y)\}_2 = \frac{k-N-1}{2} a_k(x) b_l(y)\, \delta'(x-y). \tag{C7}$$

The first Poisson structure can be obtained from (C5)–(C7) with the help of a linear transformation (shift by constant)

$$a_i \to a_i + \lambda b_i, \quad z(w,x) \to z(w,x) + \lambda$$

and using a bi-Hamiltonian nature of (C2) and (C3),

$$\{a_k(x), a_l(y)\}_1 = \left[\sum_{n=1} (k-l-n)(a_{k-n}(x) b_{l+n}(y) + b_{k-n}(x) a_{l+n}(y)) - n(a_{k-n}(y) b_{l+n}(x) + b_{k-n}(y) a_{l+n}(x)) + \frac{N+1-l}{2} b_k(x) a_l(y) + \frac{k+N+1-2l}{2} a_k(x) b_l(y)\right] \delta'(x-y), \tag{C8}$$

$$\{a_k(x), b_l(y)\}_1 = \left[\sum_{n=1} ((k-l-n) b_{k-n}(x) b_{l+n}(y) - n b_{k-n}(y) b_{l+n}(x)) + \frac{N+1-l}{2} b_k(x) b_l(y)\right] \delta'(x-y), \tag{C9}$$

$$\{b_k(x), b_l(y)\}_1 = 0. \tag{C10}$$

In all the above expressions $a_{N+1}=1$ and $a_i=0$ if i goes beyond the range $i=0,\ldots N+1$ (and $b_j=0$ if $j \neq 0,\ldots,N$).

These brackets form a bi-Hamiltonian structure for rational reductions of 1dToda hierarchy:

$$\partial_{t_i} z = \{H_i, z\}_1 = \{H_{i-1}, z\}_2 \tag{C11}$$

with the following Hamiltonians:

$$\mathrm{H}_i = \frac{1}{i+1} \int (z^{i+1}(x))_0 dx \tag{C12}$$

(Received 8 July 2005; accepted 7 September 2005; published online 9 November 2005)

The role of gradient dependent constitutive spaces is investigated on the example of Extended Thermodynamics of rigid heat conductors. Different levels of nonlocality are developed and the different versions of extended thermodynamics are classified. The local form of the entropy density plays a crucial role in the investigations. The entropy inequality is solved under suitable constitutive assumptions. Balance form of evolution equations is obtained in special cases. Closure relations are derived on a phenomenological level. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2101087]

I. INTRODUCTION

Weakly nonlocal thermodynamic theories are those that introduce the space derivatives of the basic variables into constitutive functions.[1] Second law restricts considerably the form of the constitutive quantities and gives a genuine insight into the structure of the theories. Weakly nonlocal constitutive functions are mostly investigated in relation of material microstructure in mechanics[2,3] or to find nonlocal extensions of classical theories.[1]

In this paper we investigate nonlocal constitutive spaces with different levels of nonlocality, namely of different order of derivatives. However, we derive also the restrictions that are due to locality assumptions on different levels. In our analysis we assume a nonequilibrium entropy function that can be approximated by its values measured at the equilibrium. Such an assumption is referred to as *local state* hypothesis.[4]

We restrict ourselves to extended thermodynamic theories of rigid heat conductors[5–7] and introduce the heat flux together with a second order tensor as internal variables. The balance structure of the evolution equations is not postulated. Furthermore, the entropy current is regarded as a constitutive quantity and we are to give a complete solution of the thermodynamic constraints, i.e., both the equalities and the residual dissipation inequality.

In a previous work[8] the local theory has been developed in the details and the evolution equations for fluxes of higher tensorial order have been obtained. Also it was proved that under particular assumptions on the entropy density and the entropy current the balance form can be recovered. Moreover, the system of equations was closed, in that the evolution equations for the highest order variable in the hierarchy—ordinary differential equations—can be interpreted as a closure relation.

In the present paper we extend our investigation to the case of weakly nonlocal constitutive state spaces. The solutions are derived with the help of minimal assumptions on the form of the

[a)]Electronic mail: cimmelli@unibas.it
[b)]Author to whom correspondence should be addressed. Electronic mail: vpet@eik.bme.hu

entropy, on its flux or on the evolution equations of the internal variables. In this way the different solutions of the entropy inequality are clearly classified. The most general assumption, that covers all existing phenomenological theories lies on the concept of *current multipliers*, which represent some constitutive functions entering the entropy current. We will see that the final evolution equations are more general than the traditional balance ones. The conditions to recover the classical cases are clarified.

In Sec. II we investigate first order nonlocality by applying Liu procedure[9,10] for the exploitation of second law.

In Sec. III we solve the Liu equation in the case of local state and local evolution equations for the dynamic variables. These assumptions result in a set of rather unusual restrictions from which we argue that some kind of nonlocality, either of the constitutive space or of the evolution equations, seems to be unavoidable. On the other hand, if we face with nonlocal state but local evolution equations then the entropy current is local, provided that the entropy density does not depend on the gradient of the internal energy.

In Sec. IV we investigate the traditional assumptions of Extended Irreversible Thermodynamics based on the following form of the local entropy:[11]

$$s(e,q_i,\Phi_{ij}) = s_0 - \tfrac{1}{2}m_{ij}q_iq_j - \tfrac{1}{2}n_{ijkl}\Phi_{ij}\Phi_{kl}, \tag{1.1}$$

where the matrices m_{ij} and n_{ijkl} are constitutive functions and s_0 is the *equilibrium entropy*, that depends only on the internal energy. We first suppose the entropy current is given as[12]

$$j_i = A_{ij}q_j + B_{ijk}\Phi_{jk}, \tag{1.2}$$

where A_{ij} and B_{ijk} are constitutive functions, the so-called current multipliers. Then we explore the less general case,[13] too

$$j_i = \frac{\partial s}{\partial e}q_i + \frac{\partial s}{\partial q_k}\Phi_{ki}. \tag{1.3}$$

It is worth noticing that the general form of the entropy current (1.2) reduces to (1.3) when $A_{ij} = (\partial s/\partial e)\delta_{ij}$ and $B_{ijk} = (\partial s/\partial q_j)\delta_{ik}$. We investigate different assumptions that can be compatible with the balance form of the evolution equations.

In Sec. V we consider second order nonlocality but conserve the form (1.1) of the entropy density and the expression (1.2) of the entropy current. In such a case, due to the enlargement of the state space, the balance form can be obtained even if the general constitutive equation (1.2) holds true. We show that all previous examples can be recovered under simple special assumptions.

In Sec. VI we point out some nonlocal effects arising in thermal wave propagation at low temperature, which are described by the celebrated Guyer-Krumhansl equation.[14–16] Such an equation has been derived by the authors by solving a linearized Boltzmann equation for phonon gas hydrodynamic. Here we prove that it can be obtained in the classical macroscopic framework of nonlocal irreversible thermodynamics.

The previous results are discussed in Sec. VII, where a table shows the connections between the constitutive assumptions and the thermodynamic restrictions, as far as the locality and nonlocality are concerned.

II. FIRST ORDER NONLOCALITY—EXPLOITATION OF THE SECOND LAW

In a rigid heat conductor at rest we start from the following local balance equation of the internal energy:

$$\dot{e} + q_{i',i} = 0, \tag{2.1}$$

where e is the density of internal energy, q_i $i=1,2,3$ are the components of the heat flux, $\dot{f} \equiv \partial f/\partial t$, $f_{,i} \equiv \partial f/\partial x_i$, x_i $i=1,2,3$ are the Cartesian coordinates of the points of the body and the

Einstein convention of summation over the repeated indices has been applied. The only equilibrium variable will be the internal energy e, while the first dynamic variable is supposed to be the heat flux q_i. As a further dynamic variable let us choose a second order tensor, whose components will be denoted by Φ_{ij}, $i,j=1,2,3$. Hence the *basic state space* (the wanted fields) in our investigations will be spanned by the variables (e,q_i,Φ_{ij}). This is a 13 field theory, because the number of the independent fields is 13. However, some reductions are possible. For instance in Extended Thermodynamics tensor Φ_{ij} is identified with the symmetric momentum flux $N_{[ij]}$ coming from kinetic theory.[7] Then the unknown fields reduce to 10 and we are left with a 10-field theory. Furthermore it is possible to decompose $N_{[ij]}$ into an isotropic part, which is related to the internal energy, and a deviatoric part according to the equation $N_{[ij]}=\frac{1}{3}e\delta_{[ij]}+N_{\langle ij\rangle}$, where $N_{\langle ij\rangle}$ is symmetric and traceless.[17] In such a particular case the internal energy coincides with one of the six independent components of $N_{[ij]}$ and we deal with a 9-field theory. We are investigating a first order weak nonlocality in all variables of the basic state, therefore the *constitutive space* is spanned by the basic state and its spacial derivatives, that is the fields $(e,q_i,\Phi_{ij},e_{,i},q_{i'j},\Phi_{ij'k})$. We assume that the evolution equations for the heat current q_i and for Φ_{ij} can be written in the following rather general form:

$$\dot{q}_i = g_i, \tag{2.2}$$

$$\dot{\Phi}_{ij} = f_{ij}, \tag{2.3}$$

where g_i and f_{ij} are constitutive functions. With the assumption of first order nonlocality the spacial derivatives of the above equations give further restrictions,[18,19]

$$\dot{e}_{,i} + q_{j'ji} = 0, \tag{2.4}$$

$$\dot{q}_{i'j} - g_{i,j} = 0, \tag{2.5}$$

$$\dot{\Phi}_{ij'k} - f_{ij'k} = 0. \tag{2.6}$$

These equations are sometimes referred to as *prolonged forms* of the evolution equations (2.1)–(2.3).

The local balance of entropy is given by

$$\dot{s} + j_{i'i} = \sigma_s, \tag{2.7}$$

with s standing for the entropy density, j_i, $i=1,2,3$ for the components of the entropy current and σ_s for the density of entropy production. Second law of thermodynamics forces σ_s to be nonnegative.

In the following we will investigate the restrictions from the inequality of the second law with the general assumption that both the entropy and the entropy flux are constitutive quantities. The method of the exploitation is given by the Liu procedure.[9] However, according to our calculations, in the present case a generalized Coleman-Noll[20] procedure gives identical results.

Let us introduce the Lagrange-Farkas multipliers[9,10] Γ^1, Γ^2_i, and Γ^3_{ij} for the evolution equations (2.1)–(2.3), respectively. The multipliers Γ^4_i, Γ^5_{ij}, and Γ^6_{ijk} are for the prolonged evolution equations (2.4)–(2.6), respectively.

Now, Liu procedure gives

$$\begin{aligned}
&\partial_1 s\dot{e} + (\partial_2 s)_i\dot{q}_i + (\partial_3 s)_{ij}\dot{\Phi}_{ij} + (\partial_4 s)_i\dot{e}_{,i} + (\partial_5 s)_{ij}\dot{q}_{i'j} + (\partial_6 s)_{ijk}\dot{\Phi}_{ij'k} + (\partial_1 j_i)e_{,i} + (\partial_2 j_i)_j q_{j'i} + (\partial_3 j_i)_{jk}\Phi_{jk'i}\\
&\quad + (\partial_4 j_i)_j e_{,ij} + (\partial_5 j_i)_{jk} q_{j'ki} + (\partial_6 j_i)_{jkl}\Phi_{jk'li} - \Gamma^1(\dot{e} + q_{i'i}) - \Gamma^2_i(\dot{q}_i - g_i) - \Gamma^3_{ij}(\dot{\Phi}_{ij} - f_{ij}) - \Gamma^4_i(\dot{e}_{,i}\\
&\quad + q_{j'ji}) - \Gamma^5_{ij}(\dot{q}_{i'j} - (\partial_1 g_i)e_{,j} - (\partial_2 g_i)_k q_{k'j} - (\partial_3 g_i)_{kl}\Phi_{kl'j} - (\partial_4 g_i)_k e_{,kj} - (\partial_5 g_i)_{kl} q_{k'lj}
\end{aligned}$$

$$-(\partial_6 g_i)_{klm}\Phi_{kl'lmj}) - \Gamma^6_{ijk}(\dot{\Phi}_{ij'k} - (\partial_1 f_{ij})e_{,l} - (\partial_2 f_{ij})_l q_{l'k} - (\partial_3 f_{ij})_{lm}\Phi_{lm'k} - (\partial_4 f_{ij})_l e_{,lk}$$
$$-(\partial_5 f_{ij})_{lm} q_{l'mk} - (\partial_6 f_{ij})_{lmn}\Phi_{lm'nk}) \geqslant 0.$$

Here ∂_n, $n=1,2,3,4,5,6$ denotes the partial derivatives of the constitutive functions according to the variables $(e, q_i, \Phi_{ij}, e_{,i}, q_{i'j}, \Phi_{ij'k})$, respectively. After some rearrangements of the inequality one obtains the Lagrange-Farkas multipliers from the first set of the Liu equations. These are obtained by imposing that the coefficients of the time derivatives vanish,

$$\partial_1 s = \Gamma^1, \tag{2.8}$$

$$(\partial_2 s)_i = \Gamma^2_i, \tag{2.9}$$

$$(\partial_3 s)_{ij} = \Gamma^3_{ij}, \tag{2.10}$$

$$(\partial_4 s)_i = \Gamma^4_i, \tag{2.11}$$

$$(\partial_5 s)_{ij} = \Gamma^5_{ij}, \tag{2.12}$$

$$(\partial_6 s)_{ijk} = \Gamma^6_{ijk}. \tag{2.13}$$

The second set of Liu equations is obtained by taking equal to zero the multipliers of the second order space derivatives. By applying (2.8)–(2.13) one can write them as

$$(\partial_4 j_i)_j + (\partial_5 s)_{il}(\partial_4 g_l)_j + (\partial_6 s)_{kli}(\partial_4 f_{kl})_j = 0, \tag{2.14}$$

$$(\partial_5 j_i)_{jk} - (\partial_4 s)_i \delta_{jk} + (\partial_5 s)_{mi}(\partial_5 g_m)_{jk} + (\partial_6 s)_{mni}(\partial_5 f_{mn})_{jk} = 0, \tag{2.15}$$

$$(\partial_6 j_i)_{jkl} + (\partial_5 s)_{mi}(\partial_6 g_m)_{jkl} + (\partial_6 s)_{mni}(\partial_6 f_{mn})_{jkl} = 0. \tag{2.16}$$

Finally the residual dissipation inequality can be written in the following form:

$$[\partial_1 j_i + (\partial_5 s)_{ji}\partial_1 g_j + (\partial_6 s)_{jki}\partial_1 f_{jk}]e_{,i} + [(\partial_2 j_j)_i - \partial_1 s\,\delta_{ij} + (\partial_5 s)_{kj}(\partial_2 g_k)_i + (\partial_6 s)_{klj}(\partial_2 f_{kl})_i]q_{i'j} + [(\partial_3 j_k)_{ij}$$
$$+ (\partial_5 s)_{lk}(\partial_3 g_l)_{ij} + (\partial_6 s)_{lmk}(\partial_3 f_{lm})_{ij}]\Phi_{ij'k} + (\partial_2 s)_i g_i + (\partial_3 s)_{ij} f_{ij} \geqslant 0. \tag{2.17}$$

It is easily seen that the Liu system (2.14)–(2.16) is composed by 117 differential equations constraining the set of the 832 partial derivatives of the constitutive functions s, j_i, g_i, f_{ij} with respect to the elements of the constitutive space $(e, q_i, \Phi_{ij}, e_{,i}, q_{i'j}, \Phi_{ij'k})$. Without some simplifications there is no hope to solve such a system.

In the following sections we are looking for special simplifying assumptions to solve the Liu equations (2.14)–(2.16) and the dissipation inequality (2.17). First we will investigate cases where some of the constitutive functions are assumed to be local.

III. SOLUTIONS OF THE LIU EQUATIONS—LOCALITY ASSUMPTIONS

A. Local state

Let us start the assumption of the local state in the form that the entropy is independent of the gradients,

$$s := s(e, q_i, \Phi_{ij}). \tag{3.1}$$

In this case the Liu equations (2.14)–(2.16) are simplified considerably and as a solution we obtain a local entropy current,

$$j_i = j_i(e, q_i, \Phi_{ij}). \tag{3.2}$$

The dissipation inequality (2.17) also simplifies,

$$\begin{aligned}&\partial_1 j_i e_{,i} + [(\partial_2 j_j)_i - \partial_1 s\,\delta_{ij}] q_{i'j} + (\partial_3 j_k)_{ij} \Phi_{ij'k} + (\partial_2 s)_i g_i + (\partial_3 s)_{ij} f_{ij} \\ &\quad = (j_i)_{,i} - \partial_1 s q_{i'i} + (\partial_2 s)_i g_i + (\partial_3 s)_{ij} f_{ij} \geqslant 0. \end{aligned} \tag{3.3}$$

B. Local state and local evolution

Let us investigate now the case when the evolution equations of the internal variables are ordinary differential equations, that is we assume that the constitutive quantities g_i and f_{ij} take the local form,

$$g_i := g_i(e, q_j, \Phi_{jk}), \tag{3.4}$$

$$f_{ij} := f_{ij}(e, q_j, \Phi_{jk}). \tag{3.5}$$

Now the dissipation inequality simplifies further the possible constitutive functions, because the coefficients of the derivatives should disappear. These restrictions result in a rather unusual material, since we get

$$j_i = j_i(q_j), \quad \frac{\partial j_i}{\partial q_j} = \frac{\partial s}{\partial e}\delta_{ij}. \tag{3.6}$$

On the other hand, the dissipation inequality can be written in a force-current form and can be solved for the constitutive functions g_i and f_{ij},

$$(\partial_2 s)_i g_i + (\partial_3 s)_{ij} f_{ij} \geqslant 0.$$

By (3.6) it follows that the temperature of the material $\partial s/\partial e$ is independent of the internal energy. Such a property is in contrast with the physical reality. We conclude that some nonlocality is necessary in modelling rigid heat conductors.

C. Local evolution

Let us assume now that the evolution of the internal variables is local, but there is no local state, therefore we require (3.4) and (3.5), but (3.1) is not assumed. In this case the entropy current is nonlocal, but the nonlocality is rather reduced. The Liu equations (2.14) and (2.16) give that the entropy current does not depend on the gradients of e and Φ, and (2.15) simplifies to

$$\frac{\partial j_i}{\partial q_{j'k}} = \frac{\partial s}{\partial e_{,i}}\delta_{jk}.$$

The nonlocality in the q_i is due to balance form of the evolution equation of the internal energy (2.1). From the above constraint one can easily see, that the entropy current is local if we further assume that the entropy is local in the internal energy,

$$s := s(e, q_i, \Phi_{ij}, q_{i'j}, \Phi_{ij'k}).$$

IV. SOLUTIONS OF THE ENTROPY INEQUALITY IN CASE OF LOCAL STATE

As we have seen above, the Liu equations are trivially solvable in the local state. However, the solution of the dissipation inequality can be achieved only with further assumptions. Moreover, there are different assumptions to have physical models, to introduce suitable gradient dependencies. In Classical Irreversible Thermodynamics[5] and in Rational Thermodynamics[20] the mentioned requirement of nonlocality is achieved by introducing the gradient of temperature (or, equiva-

lently, of the internal energy) into the constitutive space. In Extended Thermodynamics[6,7] the constitutive space is local but the evolution equations are balances, they have a special nonlocal form. All kinds of theories of Extended Thermodynamics resulted in more or less satisfactory models of different phenomena, but they provide different solutions of the entropy inequality.

A. Local state and special nonlocal evolution: linear nonlocality

In this case the evolution equations depend linearly on the gradients,

$$g_i := A_{ij}e_{,j} + B_{ijk}q_{k'j} + C_{ijkl}\Phi_{kl'j}, \tag{4.1}$$

$$f_{ij} := D_{ijk}e_{,k} + E_{ijkl}q_{l'k} + F_{ijklm}\Phi_{lm'k}, \tag{4.2}$$

where $A_{ij}, B_{ijk}, C_{ijkl}, D_{ijk}, E_{ijkl}, F_{ijklm}$ are local constitutive functions.

Now the dissipation inequality (2.17) reduces to a solvable form as

$$(\partial_1 j_i + (\partial_2 s)_j A_{jk} + (\partial_3 s)_{jk} D_{jki}) e_{,i} \tag{4.3}$$

$$+ ((\partial_2 j_j)_i - \partial_1 s\,\delta_{ij} + (\partial_2 s)_k B_{kji} + (\partial_3 s)_{kl} E_{klji}) q_{i'j} \tag{4.4}$$

$$+ ((\partial_3 j_k)_{ij} + (\partial_2 s)_l C_{lkij} + (\partial_3 s)_{lm} F_{lmkij}) \Phi_{ij'k} \geqslant 0. \tag{4.5}$$

As the quantities in the parentheses are local functions they should be zero, respectively. Therefore we get

$$\partial_1 j_i = -(\partial_2 s)_j A_{jk} - (\partial_3 s)_{jk} D_{jki}, \tag{4.6}$$

$$(\partial_2 j_j)_i = \partial_1 s\,\delta_{ij} - (\partial_2 s)_k B_{kji} - (\partial_3 s)_{kl} E_{klji}, \tag{4.7}$$

$$(\partial_3 j_k)_{ij} = -(\partial_2 s)_l C_{lkij} - (\partial_3 s)_{lm} F_{lmkij}. \tag{4.8}$$

These equations cannot be solved without any further ado. However, we can see that even if we do not know anything on the entropy current j_i they result in strong correlations on the entropy derivatives and the evolution equation, as the mixed partial derivatives of j_i should be equal. On the other hand, let us observe that in this case the entropy production is zero, there is no dissipation.

B. Local state and special local evolution: balance form

In this case one assumes, that the evolution equations have a special balance form. Therefore there are potentials Q_{ij} and H_{ijk} of the fields $(A_{ij}, B_{ijk}, C_{ijkl})(e, q_i, \Phi_{ij})$ and $(D_{ijk}, E_{ijkl}, F_{ijklm}) \times (e, q_i, \Phi_{ij})$, respectively. The evolution equations can be written as

$$g_i := \partial_1 Q_{ij} e_{,j} + (\partial_2 Q_{ij})_k q_{k'j} + (\partial_3 Q_{ij})_{kl} \Phi_{kl'j}, \tag{4.9}$$

$$f_{ij} := \partial_1 H_{ijk} e_{,k} + (\partial_2 H_{ijk})_l q_{l'k} + (\partial_3 H_{ijk})_{lm} \Phi_{lk'k}. \tag{4.10}$$

The conditions (4.6)–(4.8) can be written as

$$\partial_1 j_i = -(\partial_2 s)_j \partial_1 Q_{ij} - (\partial_3 s)_{jk} \partial_1 H_{ijk}, \tag{4.11}$$

$$(\partial_2 j_j)_i = \partial_1 s\,\delta_{ij} - (\partial_2 s)_k (\partial_2 Q_{ij})_k - (\partial_3 s)_{kl} (\partial_2 H_{ijk})_l, \tag{4.12}$$

$$(\partial_3 j_k)_{ij} = -(\partial_2 s)_l (\partial_3 Q_{ij})_{kl} - (\partial_3 s)_{lm} (\partial_3 H_{ijk})_{lm}. \tag{4.13}$$

As a consequence the above system of equations can be solved, as the entropy current is a potential of the field (q_i, Q_{ij}, H_{ijk}), therefore it can be conveniently written as

$$j_i(e, q_i, \Phi_{ij}) = \tilde{j}_i(q_i, Q_{ij}, H_{ijk}). \tag{4.14}$$

This fact can be expressed also with differential forms, according to the traditions of thermodynamics

$$\mathrm{d}\tilde{j}_i = \partial_1 s \, \mathrm{d}q_i + (\partial_2 s)_j \, \mathrm{d}Q_{ji} + (\partial_3 s)_{jk} \, \mathrm{d}H_{jki} = \Gamma^1 \, \mathrm{d}q_i + \Gamma^2_j \, \mathrm{d}Q_{ji} + \Gamma^3_{jk} \, \mathrm{d}H_{jki}. \tag{4.15}$$

The derivatives of the entropy current are identical to the intensives, the derivatives of the entropy functions. However, the variables are different. This form results in serious restrictions of the entropic intensives, and the currents Q_{ij} and H_{ijk} because the mixed second partial derivatives should be equal in these variables, too. Expressed in the basic variables the above requirements are rather ugly

$$(\partial_{22} s)_{kj} \partial_1 Q_{ki} + (\partial_{23} s)_{lkj} \partial_1 H_{lki} = \partial_{11} s \, \delta_{ij} + (\partial_{12} s)_k (\partial_2 Q_{ik})_j + (\partial_{13} s)_{lk} (\partial_2 H_{lki})_j, \tag{4.16}$$

$$(\partial_{32} s)_{ljk} \partial_1 Q_{li} + (\partial_{33} s)_{lmjk} \partial_1 H_{lmi} = (\partial_{12} s)_l (\partial_3 Q_{li})_{jk} + (\partial_{13} s)_{lm} (\partial_3 H_{lmi})_{jk}, \tag{4.17}$$

$$(\partial_{31} s)_{kl} \delta_{ij} + (\partial_{32} s)_{mkl} (\partial_2 Q_{im})_j + (\partial_{33} s)_{mnkl} (\partial_2 H_{mni})_j = (\partial_{22} s)_{ml} (\partial_3 Q_{mi})_{jk} + (\partial_{32} s)_{mnl} (\partial_3 H_{mni})_{jk}. \tag{4.18}$$

The property (4.15) is an important consequence of the balance form of the evolution equations. It is independent of the choice of the basic variables. If one assumes, e.g., that the chosen internal variable is the current of the heat flux, $\Phi_{ij} = Q_{ij}$, as it is usual in extended thermodynamics, then the above system of requirements simplifies but does not disappear.

In Rational Extended Thermodynamics it was shown that the above result of the phenomenological theory can be in accordance with the kinetic theory of gases, at least with a classical formulation of kinetic physics. A crucial step in the different systems was the choice of the phenomenological variables (we will see that all of the currents cannot be chosen as internal variables without any further ado) and the use of source terms in the balances.

C. Local state and balance form evolution: isotropy

The system (4.16)–(4.18) does not have a general solution for the currents. Q_{ij} and H_{ijk} cannot be determined by the entropy function in general. Therefore we have lost one of the basic flavors of irreversible thermodynamics, that the requirements of the second law can be exploited constructively to find the appropriate evolution equations. Now the dissipation inequality was solved, but the evolution equations cannot be determined constitutively.

Jou *et al.* gave some simplifying conditions to have a solution of the conditions (4.16)–(4.18) on the phenomenological level.[21] They have assumed a local state, balance form evolution equations and a simpler set of variables, they introduced only q_i as an additional variable. Then only condition (4.16) applies in a simplified form as

$$(\partial_{22} s)_{kj} \partial_1 Q_{ki} = \partial_{11} s \, \delta_{ij} + (\partial_{12} s)_k (\partial_2 Q_{ik})_j.$$

Moreover they have assumed *isotropic materials*, when all scalar valued functions, including the entropy, depend only on $q^2 = q_i q_i$ and the flux of the heat current and the entropy current can be written as

$$Q_{ij} = \beta(e, q^2) + \psi(e, q^2) q_i q_j, \tag{4.19}$$

$$j_i = \Psi(e, q^2) q_i. \tag{4.20}$$

Now the requirement (4.15) results in the following system of equations, as (4.2)–(4.4) in Ref. 21:

$$\partial_e \Psi = 2\partial_{q^2} s(\partial_e \beta + \partial_e \psi q^2), \tag{4.21}$$

$$\Psi = \partial_{e^s} + 2\partial_{q^2} s \psi q^2, \tag{4.22}$$

$$\partial_{q^2} \Psi = 2\partial_{q^2} s(\partial_{q^2} \beta + \partial_{q^2} \psi q^2). \tag{4.23}$$

Therefore the entropy current can be written as

$$j_i = (\partial_e s + 2\partial_{q^2} s \psi q^2) q_i. \tag{4.24}$$

After further calculations, considering also the requirement (4.16), one can get explicit solutions for the functions β and ψ together with some additional restriction on the form of the entropy function.

V. LOCAL STATE AND SPECIAL ENTROPY CURRENT

A different solution of the dissipation inequality can be given with the help of the entropy current. As in our previous work[8] we consider the local entropy of the form (1.1). This general form is motivated by the requirement of the thermodynamic stability, or, equivalently the requirement of the concavity of the entropy function on the nonequilibrium part of the state space (spanned by q_i and Φ_{ij}). Therefore, m_{ij} and n_{ijkl} are positive definite constitutive functions. Moreover, let us assume the entropy current takes the form (1.2) and let us introduce the convenient notations $\hat{m}, \hat{n}, \tilde{n}, \tilde{m}$ as follows:

$$(\partial_2 s)_i = -m_{ij} q_j - \tfrac{1}{2}(\partial_2 m_{lj})_i q_l q_j - \tfrac{1}{2}(\partial_2 n_{rjkl})_i \Phi_{rj} \Phi_{kl} = -\hat{m}_{ij} q_j - (\partial_2 \tilde{n}_{jk})_i \Phi_{jk}, \tag{5.1}$$

$$(\partial_3 s)_{ij} = -\tfrac{1}{2}(\partial_3 m_{lk})_{ij} q_l q_k - n_{ijkl} \Phi_{kl} - \tfrac{1}{2}(\partial_3 n_{lkrs})_{ij} \Phi_{lk} \Phi_{rs} = -(\partial_3 \tilde{m}_k)_{ij} q_k - \hat{n}_{ijkl} \Phi_{kl}. \tag{5.2}$$

If m_{ij} and n_{ijkl} are constant, then $\hat{m}_{ij}=m_{ij}$, $\hat{n}_{ijkl}=n_{ijkl}$, $(\partial_3 \tilde{m}_k)_{ij}=0$, and $(\partial_2 \tilde{n}_{jk})_i=0$.

Let us emphasize again that the entropy, written in the Gyarmati form (1.1) and the entropy current, written in (1.2) are only convenient notations as long as the corresponding inductivities and current multipliers are general constitutive functions.

With the (1.2) form of the entropy current and using the notations of (5.1) and (5.2) the dissipation inequality (3.3) in local state can be written in the following form:

$$[A_{ji'j} - \hat{m}_{ij} g_j - (\partial_3 m)_{kji} f_{ik}] q_i + [A_{ij} - \partial_1 s \delta_{ij}] q_{j'i} + [B_{kij'k} - (\partial_2 n)_{kji} g_k - \hat{n}_{ijkl} f_{kl}] \Phi_{ij} + B_{ijk} \Phi_{jk'i} \geqslant 0. \tag{5.3}$$

Seemingly the system is a normal force-current system, because the coefficients of the thermodynamic forces $q_i, q_{i,j}, \Phi_{ij}, \Phi_{ijk}$ all contain undetermined constitutive quantities $A_{ij}, g_i, f_{ij}, B_{ijk}$, respectively. However, let us observe that in local state g_i and f_{ij} are nonlocal but all other terms are local in the above inequality. This fact introduces degeneracy since, although the coefficients of the derivatives $q_{i'j}$ and $\Phi_{ij'k}$ cannot disappear, their possible couplings are rather reduced, e.g., B_{ijk} is local, therefore cannot depend on its own force $\Phi_{ij'k}$.

In this degenerate case the solution of the dissipation inequality is not straightforward.

Fortunately we can avoid the treatment of degeneracy, e.g., by assuming that m_{ij} and n_{ijkl} depend only on the internal energy and introducing the form (1.3) of the entropy current with the assumptions $A_{ij}=\partial_1 s \delta_{ij}$ and $B_{ijk}=(\partial_2 s)_k \delta_{ij}$. In this particular case the dissipation inequality reduces to

$$((\partial_1 s)_{,i} - m_{ij}g_j - m_{ki}\Phi_{jk'j})q_i + (-m_{jl}q_{l'i} - n_{ijkl}f_{kl})\Phi_{ij} \geqslant 0. \tag{5.4}$$

This is a force-current system, with the following Onsagerian solution:

$$-m_{ij}(\dot{q}_j + \Phi_{kj'k}) + (\partial_1 s)_{,i} = L^{11}_{ij}q_j + L^{12}_{ijk}\Phi_{jk}, \tag{5.5}$$

$$-n_{ijkl}\dot{\Phi}_{kl} - m_{jl}q_{l'i} = L^{21}_{ijk}q_k + L^{22}_{ijkk}\Phi_{kl}. \tag{5.6}$$

The system above conserves the structure already obtained in Ref. 8 in the case of local state. One should emphasize the central role of the invertibility of the matrices m_{ij} and n_{ijkl} in order to obtain the balance form. Such a property is not trivial since there exist real materials for which it is not guaranteed. A classical example is given in Ref. 22, where an electric circuit described by dynamic variables is considered.

As it was observed in Ref. 8 the second equation is a phenomenological closure of the system (2.1) and (5.5). It is remarkable that we have recovered the usual phenomenological structure of extended irreversible thermodynamics keeping the entropy current of the form (1.3). The same is not true for the constitutive equation (1.2) which, in the case of first order nonlocality, seems to be much too general. However, the compatibility of the entropy current of Verhás (1.3) and the requirements of the balance form (4.15) is valid only with the restriction that the conductivities depend only on the internal energy. The mentioned solution of Jou *et al.* (4.24) clearly does not have the Verhás form and indicates the necessity of a more general treatment.

In the next section we study the same problem in the presence of second order nonlocality.

VI. SECOND ORDER NONLOCALITY—SOLUTION IN LOCAL STATE

Now we will extend our investigations to consider second order nonlocalities. However, for the sake of simplicity we will investigate only the case of local entropy, i.e., systems in local state. The basic state is spanned by the variables (e, q_i, Φ_{ij}) as previously. However, the constitutive space contains the second order space derivatives and is spanned by $(e, q_i, \Phi_{ij}, e_{,i}, q_{i'j}, \Phi_{ij'k}, e_{,ij}, q_{i'jk}, \Phi_{ij'kl})$. Therefore, in the exploitation of the entropy inequality (2.7) we should consider as constraints the evolution equations (2.1)–(2.3), their first prolongations (2.4)–(2.6) and also their second prolongations as follows:

$$\dot{e}_{,ij} + q_{j'jik} = 0, \tag{6.1}$$

$$\dot{q}_{i'jk} - g_{i,jk} = 0, \tag{6.2}$$

$$\dot{\Phi}_{ij'kl} - f_{ij'kl} = 0. \tag{6.3}$$

Our simplifying condition of local entropy can be written as

$$s = s(e, q_i, \Phi_{ij}).$$

Let us introduce again the Lagrange-Farkas multipliers Γ^1, Γ^2_i, Γ^3_{ij}, Γ^4_i, Γ^5_{ij}, and Γ^6_{ijk} for the evolution equations (2.1)–(2.3) and their prolonged forms (2.4)–(2.6), respectively. The multipliers Γ^7_{ij}, Γ^8_{ijk}, and Γ^9_{ijkl} stand for the second prolongations (6.1)–(6.3), respectively. The Liu procedure gives

$$\begin{aligned}
&\partial_1 s\dot{e} + (\partial_2 s)_i\dot{q}_i + (\partial_3 s)_{ij}\dot{\Phi}_{ij} + (\partial_1 j_i)e_{,i} + (\partial_2 j_i)_j q_{j'i} + (\partial_3 j_i)_{jk}\Phi_{jk'i} + (\partial_4 j_i)_j e_{,ij} + (\partial_5 j_i)_{jk}q_{j'ki} \\
&\quad + (\partial_6 j_i)_{jkl}\Phi_{jk'li} + (\partial_7 j_i)_{jk}e_{,ijk} + (\partial_8 j_i)_{jkl}q_{j'kli} + (\partial_9 j_i)_{jklm}\Phi_{jk'lmi} - \Gamma^1(\dot{e} + q_{i'i}) - \Gamma^2_i(\dot{q}_i - g_i) \\
&\quad - \Gamma^3_{ij}(\dot{\Phi}_{ij} - f_{ij}) - \Gamma^4_i(\dot{e}_{,i} + q_{j'ji}) - \Gamma^5_{ij}[\dot{q}_{i'j} - (\partial_1 g_i)e_{,j} - (\partial_2 g_i)_k q_{k'j} - (\partial_3 g_i)_{kl}\Phi_{kl'j} - (\partial_4 g_i)_k e_{,kj}
\end{aligned}$$

$$
\begin{aligned}
&-(\partial_5 g_i)_{kl} q_{k'lj} - (\partial_6 g_i)_{klm} \Phi_{kl'mj} - (\partial_7 g_i)_{kl} e_{,klj} - (\partial_8 g_i)_{klm} q_{k'lmj} - (\partial_9 g_i)_{klmn} \Phi_{kl'mnj}] - \Gamma^6_{ijk} [\dot{\Phi}_{ij'k} \\
&- (\partial_1 f_{ij}) e_{,k} - (\partial_2 f_{ij})_l q_{l'k} - (\partial_3 f_{ij})_{lm} \Phi_{lm'k} - (\partial_4 f_{ij})_l e_{,lk} - (\partial_5 f_{ij})_{lm} q_{l'mk} - (\partial_6 f_{ij})_{lmn} \Phi_{lm'nk} \\
&- (\partial_7 f_{ij})_{lm} e_{,lmk} - (\partial_8 f_{ij})_{lmn} q_{l'mnk} - (\partial_9 f_{ij})_{lmno} \Phi_{lm'nok}] - \Gamma^7_{ij} (\dot{e}_{ij} + q_{k'kij}) - \Gamma^8_{ijk} (\dot{q}_{i'jk} - g_{i'jk}) \\
&- \Gamma^9_{ijkl} (\dot{\Phi}_{ij'kl} - f_{ij'kl}) \geqslant 0.
\end{aligned}
$$

Here ∂_n, $n=1,2,3,4,5,6,7,8,9$ denotes the partial derivatives of the constitutive functions according to the variables of the constitutive space $(e, q_i, \Phi_{ij}, e_{,i}, q_{i'j}, \Phi_{ij'k}, e_{,ij}, q_{i'jk}, \Phi_{ij'kl})$, respectively. The first set of Liu equations defines the Lagrange-Farkas multipliers as the derivatives of the entropy and gives that the last six multipliers are zero, due to the local state,

$$\partial_1 s = \Gamma^1, \tag{6.4}$$

$$(\partial_2 s)_i = \Gamma^2_i, \tag{6.5}$$

$$(\partial_3 s)_{ij} = \Gamma^3_{ij}, \tag{6.6}$$

$$\Gamma^4_i = 0, \tag{6.7}$$

$$\Gamma^5_{ij} = 0, \tag{6.8}$$

$$\Gamma^6_{ijk} = 0, \tag{6.9}$$

$$\Gamma^7_{ij} = 0, \tag{6.10}$$

$$\Gamma^8_{ijk} = 0, \tag{6.11}$$

$$\Gamma^9_{ijkl} = 0. \tag{6.12}$$

Considering (6.7)–(6.12) the second set of Liu equations are also simple,

$$(\partial_7 j_i)_{jk} = 0, \tag{6.13}$$

$$(\partial_8 j_i)_{jkl} = 0, \tag{6.14}$$

$$(\partial_9 j_i)_{jklm} = 0. \tag{6.15}$$

Therefore the entropy current presents only first order nonlocalities

$$j_i = j_i(e, q_i, \Phi_{ij}, e_{,i}, q_{i'j}, \Phi_{ij'k}).$$

Considering the above conditions the dissipation inequality can be written exactly in the same form as it was in case of first order nonlocal constitutive space (3.3),

$$(j_i)_{,i} - \partial_1 s q_{i'i} + (\partial_2 s)_i g_i + (\partial_3 s)_{ij} f_{ij} \geqslant 0. \tag{6.16}$$

On the other hand, now the constitutive quantities are higher orderly nonlocal, the entropy current is a first order nonlocal quantity and g_i and f_{ij} are second order nonlocal quantities. Let us introduce the same assumptions on the form of the entropy and of the entropy current as previ-

ously with assuming (1.1) and (1.2) with the notations (5.1) and (5.2) but letting the current multipliers A_{ij} and B_{ijk} to contain first order nonlocalities. The dissipation inequality can be written in the same form as above

$$[A_{ji'j} - \hat{m}_{ij}g_j - (\partial_3 m)_{kji}f_{ik}]q_i + [A_{ij} - \partial_1 s\delta_{ij}]q_{j'i} + [B_{kij'k} - (\partial_2 n)_{kji}g_k - \hat{n}_{ijkl}f_{kl}]\Phi_{ij} + B_{ijk}\Phi_{jk'i} \geqslant 0. \tag{6.17}$$

However, in this case it is a nondegenerate force-current system, due to the extension of the constitutive state space. All additive terms contain unknown functions. Therefore one can give an Onsagerian solution as follows:

$$-\hat{m}_{ij}g_j - (\partial_3 m)_{ijk}f_{jk} + A_{ji'j} = L^{11}_{ij}q_j + L^{12}_{ijk}q_{j'k} + L^{13}_{ijk}\Phi_{jk} + L^{14}_{ijkl}\Phi_{jk'l}, \tag{6.18}$$

$$A_{ij} - \partial_1 s\delta_{ij} = L^{21}_{ijk}q_k + L^{22}_{ijkl}q_{k'l} + L^{23}_{ijkl}\Phi_{kl} + L^{24}_{ijklm}\Phi_{kl'm}, \tag{6.19}$$

$$-(\partial_2 n)_{kji}g_k - \hat{n}_{ijkl}f_{kl} + B_{kij'k} = L^{31}_{ijk}q_k + L^{32}_{ijkl}q_{k'l} + L^{33}_{ijkl}\Phi_{kl} + L^{34}_{ijklm}\Phi_{kl'm}, \tag{6.20}$$

$$B_{ijk} = L^{41}_{ijkl}q_l + L^{42}_{ijklm}q_{l'm} + L^{43}_{ijklm}\Phi_{lm} + L^{44}_{ijklmn}\Phi_{lm'n}. \tag{6.21}$$

Here $L^{11}, L^{12}, L^{13}, L^{14}, L^{21}, L^{22}, L^{23}, L^{24}, L^{31}, L^{32}, L^{33}, L^{34}, L^{41}, L^{42}, L^{43}, L^{44}$ are constitutive functions with the suitable definiteness restrictions. Moreover (6.18) and (6.20) are the candidates of balances under suitable restrictions. It is worth noticing, that the current multipliers A_{ij} and B_{ijk} are given explicitly. Therefore, they can be easily eliminated from the above system substituting (6.19) into (6.18) and (6.21) into (6.20). The resulting set of equations is closed and contains first and second order derivatives of the basic state,

$$\begin{aligned} &-\hat{m}_{ij}\dot{q}_j - (\partial_3 m)_{ijk}\dot{\Phi}_{jk} + [\partial_1 s\delta_{ij} + L^{21}_{ijk}q_k + L^{22}_{ijkl}q_{k'l} + L^{23}_{ijkl}\Phi_{kl} + L^{24}_{ijklm}\Phi_{kl'm}]_{,j} \\ &\quad = L^{11}_{ij}q_j + L^{12}_{ijk}q_{j'k} + L^{13}_{ijk}\Phi_{jk} + L^{14}_{ijkl}\Phi_{jk'l}, \end{aligned} \tag{6.22}$$

$$\begin{aligned} &-(\partial_2 n)_{kji}\dot{q}_k - \hat{n}_{ijkl}\dot{\Phi}_{kl} + [L^{41}_{ijkl}q_l + L^{42}_{ijklm}q_{l'm} + L^{43}_{ijklm}\Phi_{lm} + L^{44}_{ijklmn}\Phi_{lm'n}]_{,k} \\ &\quad = L^{31}_{ijk}q_k + L^{32}_{ijkl}q_{k'l} + L^{33}_{ijkl}\Phi_{kl} + L^{34}_{ijklm}\Phi_{kl'm}. \end{aligned} \tag{6.23}$$

As one can see, the evolution equations are rather general. They are more general than those given with the help of the entropy currents (1.3). On the other hand, the entropy current (4.24) is also a special case of the general (1.2). However, the compatibility to the current potential structure, expressed by (4.15), cannot be expressed explicitly in general. Equation (1.2) is definitely more general regarding the nonlocality, moreover, (4.24) proves, that it can be compatible with the potential structure in special cases. However, it definitely restricts the functional form of the current multipliers A_{ij} and B_{ijk}.

Moreover, the potential structure is unavoidable requiring locality and balance form evolution equations. If m_{ij} and n_{ijkl} are constant a balance structure similar to that obtained in Ref. 8 is recovered. This fact represents the main effect of the enlargement of the state space since the balance structure is compatible with more general entropy fluxes.

VII. NONLOCAL SECOND SOUND: THE GUYER-KRUMHANSL EQUATION

Thermal wave propagation, sometime referred to as second sound, is a low temperature phenomenon which can be observed, for instance, in dielectric crystals such as sodium fluoride (NaF) and bismuth (Bi).[23,24,17] It requires an extension of the classical Fourier's theory in order to remove the paradox of infinite speed of propagation of thermal disturbances.[25] Phonon gas hydrodynamics[26,27] supplies a satisfactory explanation of heat transport at low temperature.

Phonons are quasiparticles which obey the Bose-Einstein statistics. In a solid crystal they form a rarefied gas whose kinetic equation can be derived similarly to that of an ordinary gas. Phonons may interact among themselves and with lattice imperfections through two different types of processes:

(i) normal (N) processes, that conserve the phonon momentum;
(ii) resistive (R) processes, in which the phonon momentum is not conserved.

The frequencies ν_N and ν_R of normal and resistive processes determine the characteristic relaxation times $\tau_N=1/\nu_N$ and $\tau_R=1/\nu_R$. Diffusive processes take over when there are many more R processes than N processes. If instead there are only a few R processes and many more N processes, then a wavelike energy transport may occur.

Such a phenomenology is satisfactorily described by the Guyer-Krumhansl equation,[14] Eq. (57) (see also Refs. 28 and 15).

$$\dot{q}_i+\frac{1}{\tau_R}q_i+\frac{1}{3}c^2c_V T_{,i}=\frac{1}{5}\tau_N c^2(q_{i'jj}+2q_{j'ji}), \tag{7.1}$$

where $T=\hat{T}-T_0$ is the temperature variation (T is the temperature and T_0 is the average temperature). c_V is the specific heat and c means the Debye phonons velocity. Such an equation, which generalizes the Maxwell-Cattaneo-Vernotte equation[25]

$$\tau_R\dot{q}_i+q_i=-\tau_R\tfrac{1}{3}c^2c_V T_{,i}, \tag{7.2}$$

was the first in the literature to include both relaxation times. It can be obtained by the linearized Boltzman equation for phonons in the Debye approximation, if one maintains terms $O(\tau_N)$.[14] The material coefficients τ_N, τ_R, and c_V are all dependent on the temperature. According to experimental observations[16] one can get

$$c_V=aT^3,\quad \tau_R=de^{-\alpha/T},\quad \tau_N=bT^{-m}.$$

Here a,b,d,α are constant coefficients and $m\in\{3,4,5\}$ depending on the material. Let us remark that the last function, a temperature dependent τ_N is clearly contradictory to the assumptions made by Guyer and Krumhansl,[14] and did not consider, that (7.1) is a linearized equation.

In extended thermodynamics the Guyer-Krumhansl equation can be recovered in a 4-field theory provided one assumes weakly nonlocal constitutive equations for the internal energy e and for the momentum flux.[17]

However, such an approach seems to be questionable because

(i) a nonlocal constitutive space is in contrast with the basic assumptions of extended thermodynamics,
(ii) a nonlocal internal energy does not assure that the specific heat $c_V=\partial e/\partial T$ is positive,
(iii) a nonlocal internal energy would modify also the energy balance.

The last observation was pointed out also by Dreyer and Struchtrup and they suggested to consider higher order moments.[6,7] The other important question is the temperature dependency of the coefficients. A phenomenological theory cannot predict the exact form to the constitutive functions, but gives restrictions and interrelations. These restrictions on the temperature dependencies are frequently treated rather loosely to get the compatibility with the *linearized* kinetic theory.[14,6]

These problems do not arise in the present theory. In fact, we can obtain the equation (7.1) by considering a 4-field model with second order nonlocality, namely the balance equation (6.22) with $\Phi_{ij}=0$ and m_{ij} depending only on the internal energy. It yields

$$-m_{ij}\dot{q}_j+\left[\partial_1 s\,\delta_{ij}+L^{21}_{ijk}q_k+L^{22}_{ijkl}q_{k'l}\right]_{,j}=L^{11}_{ij}q_j+L^{12}_{ijk}q_{j'k}. \tag{7.3}$$

It is convenient to choose as equilibrium thermodynamic variable the absolute temperature T_a instead of the internal energy e. Let us assume the constitutive equations $L^{21}_{ijk}=L^{12}_{ijk}=0$. We may exploit the thermodynamic relation $1/T_a=\partial s/\partial e$ and introduce the temperature perturbation T by $T_a=T_0+T$, where T_0 is a background (average) temperature. Now, Eq. (7.3) reduces to

$$m_{ij}\dot{q}_j+L^{11}_{ij}q_j+\frac{1}{T^2}T_{,i}=L^{22}_{ijkl}q_{k'lj}. \tag{7.4}$$

Here m_{ij}, L^{11}_{ij}, and L^{22}_{ijkl} can depend on the background temperature T_0. Finally, equation (7.1) is easily obtained by (7.4) under the further constitutive assumptions,

$$m_{ij}=\frac{3}{c^2aT^5}\delta_{ij}, \tag{7.5}$$

$$L^{11}_{ij}=\frac{3}{c^2aT^5}e^{\alpha/T}\delta_{ij}, \tag{7.6}$$

$$L^{22}_{ijkl}=\frac{3b}{5aT^{5+m}}\delta_{ij}\delta_{kl}. \tag{7.7}$$

That way, the Guyer-Krumhansl theory may be obtained in a classical macroscopic framework. Let us remark, that the previous phenomenological linearization is only a last step in the calculation based on the linearization of the Boltzmann equation [Eq. (57)–Eq. (59) in Ref. 14]. A similar result has been obtained in Ref. 29.

VIII. CONCLUSIONS

We have shown that Classical Irreversible Thermodynamics supplemented with dynamic degrees of freedom is consistent with the idea of higher order fluxes as independent thermodynamic variables. In such a framework the balance form of the evolution equations can be obtained under suitable constitutive assumptions. The locality of the entropy density, i.e., the local state assumption, plays a central role. Moreover, the nonlocality of the constitutive functions results in a wide class of materials including the classical Cattaneo and Guyer-Krumhansl heat conductors, which normally are derived from kinetic theory. Let us observe that the model above encompasses all extended thermodynamic models, since the balance structure represents a very particular form of nonlocal evolution equations (2.2) and (2.3).

Considering that the balance is not the only possible form of the evolution equations, the nomination of the internal variable as a "higher order flux" can be misleading. However, if the tensorial order of the internal variables increases and we are in a local state, the evolution equations are close to a balance form (except the closure) and the flux interpretation is straightforward. However, the exploitation method of the second law reveals applications far beyond the heat conduction problem. An internal variable can be responsible for different microstructural effects with a well-defined microphysical interpretation where one must consider the most general expression of the entropy current (and sometimes it is not enough). Here we only want to call the attention to the role of the entropy current in the thermodynamic derivations of the Ginzburg-Landau equation where the microstructure have a definite meaning.[3,30,31,19]

Although in the present investigations the highest order flux is only the flux of the heat flux (Φ_{ij}), there is no principal reason of restricting ourselves to the second order case. One can easily extend the ideas of the recent investigation to the higher order cases and to derive, e.g., closure relations at a higher level of the hierarchy.

Figure 1 shows the connections between the constitutive assumptions and the thermodynamic restrictions, as far as the locality and nonlocality are concerned. The last column refers to the

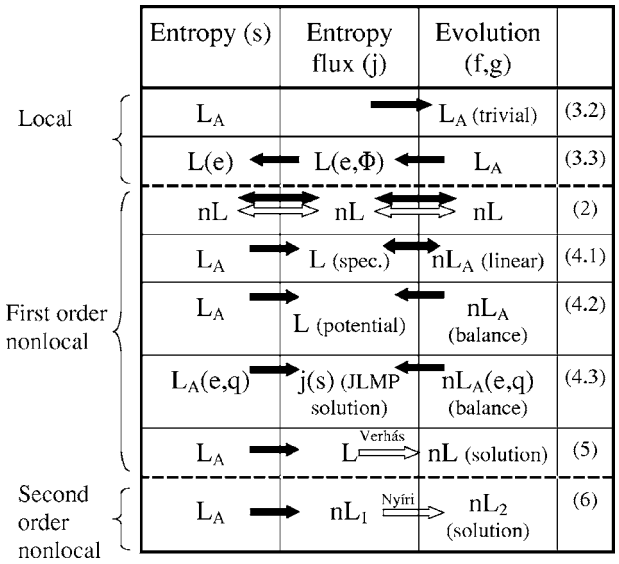

FIG. 1. Logical relations of nonlocality assumptions in nonequilibrium thermodynamics. Interplay of nonlocality in entropy (s), in entropy flux (j) and in the evolution of higher order fluxes (f,g) (2.2)–(2.2). Notations, L, local; nL, nonlocal; $L(e)$, local in the variable e; L_A, assumed locality; L_i, ith order nonlocal, black arrow, consequence of the Liu equations, white arrow, consequence of the dissipation inequality.

corresponding section of the paper. L_A denotes a locality assumption. The double-headed arrows denote specific interrelations, e.g., the black double-headed arrows in the first row denote equations (2.14)–(2.16), that give conditions between the entropy and entropy current functions and evolution equations. The fifth row refers to Rational Extended Thermodynamics and the sixth row to the specific solution of the potential restriction given by Jou *et al.* As in Extended Thermodynamics the dissipations inequality is fulfilled as an equality, we cannot conclude anything on the dissipative constitutive functions (that is why there are no white arrows in these rows). Let us observe, that assumptions on the form of the entropy current makes possible to build all requirements of the second law into the evolution equations in general (last two rows). In this case the second law becomes a material property, satisfied independently of the initial conditions and the resulted constitutive functions depend only on the material.

It is worth noticing that the potential form of the entropy current and the balance structure is compatible with the general form of the entropy current, such as that proposed by Nyíri, which yields (1.3) when $A_{ij}=\partial_1 s\,\delta_{ij}$ and $B_{ijk}=(\partial_2 s)_k\delta_{ij}$. In this case the balance structure results in restrictions for the current multipliers from the potential requirement (4.15).

We obtained closure relations both with local and nonlocal entropy current and in the first case the closure for the highest order flux was an ordinary differential equation. The obtained thermodynamic closure of the hierarchical structure stresses some deeper relations between the thermodynamic and the more detailed kinetic structure, similar to that recognized, e.g., in Ref. 32.

We reinspected the thermal wave propagation at low temperature and proved that the Guyer-Krumhansl theory of second sound can be derived in the framework of macroscopic nonlocal irreversible thermodynamics.

An invariant variational principle for canonical flows on Lie groups

Zoltán Muzsnay[a)]
Department of Mathematics, University of Debrecen, Debrecen, H-4032, Hungary

(Received 18 May 2005; accepted 19 September 2005; published online 18 November 2005)

In this paper we examine the existence of Lie groups, whose canonical geodesic flows are variational with respect to a left-invariant regular—but not necessarily quadratic (i.e., metric)—Lagrange function. We give effective necessary and sufficient conditions for the existence of an invariant variational principle generating the canonical flow. With these results, taken in conjunction with the classification of Lie algebras, we solve the inverse problem of invariant Lagrangian dynamics in dimensions up to four. © *2005 American Institute of Physics.*

I. INTRODUCTION

One of the basic objects of classical physics is the equation of motion of a system. In the most relevant cases it can be derived as the Euler-Lagrange equation of a regular Lagrange function. An old, and in the general case still unsolved problem, posed first in 1887 by Helmholtz, is the determination and classification of second order differential equations derivable from a variational principle. This is the inverse problem of the calculus of variations. Moreover, since the Euler-Lagrange equation inherits the symmetries of the Lagrangian, one can also consider the invariant version of the inverse problem of the calculus of variations, determine if an equation of motion possessing some symmetry property can be derived as the Euler-Lagrange equation of a regular Lagrangian having the same symmetry.

There are interesting examples of this phenomena in the cases of motions on Lie groups governed by the canonical symmetric, linear connections of the Lie group.[1] We remark that the corresponding canonical flow occurs in the one-dimensional reductions of well-known models of theoretical physics, like the σ or chiral models. One can say that all possible situations occur in these deceptively simple systems. This claim is illustrated by the following examples: (1) on a semisimple Lie group the canonical flow can be derived from the Lagrangian corresponding to the bi-invariant Killing metric of the Lie algebra. In this case the Lagrangian is obviously invariant; (2) on the Heisenberg group or on the affine group of the line the canonical flows are variational, but the Lagrangians are not invariant with respect to the natural action of the groups (see paragraph 5); (3) on the four-dimensional Lie groups $A_{4,7}$, $A_{4,9b}$, and $A_{4,11a}$ the canonical flows are not variational.[9]

Moreover, one can investigate the unicity of the Lagrangian (up to an inessential total derivative term). The unicity problem and the existence of invariant variational principle might be related to each other in some cases, as if the equation of motion has some symmetry, but the Lagrangian does not possess that one, then the Lagrangian is necessarily nonunique, as a new Lagrangian obtained from the old one by a symmetry transformation must give the same Euler-Lagrange equation.

In this paper we examine the existence of Lie groups, other than the semisimple groups, where the geodesic flow associated to the canonical connection is variational with respect to a left-invariant regular (but not necessarily quadratic, i.e., metric) Lagrange function. In this case we

[a)]Electronic mail: muzsnay@math.klte.hu

will say that there exists a G-invariant variational principle for the canonical flow of the group G. We give an effective necessary and sufficient condition for the existence of a G-invariant variational principle for the canonical flow. Using this result, we determine the Lie groups up to four dimensions for which the canonical flow is variational with respect to a nondegenerate left-invariant Lagrangian.

II. INVERSE PROBLEM OF THE CALCULUS OF VARIATIONS ON LIE GROUPS

On a Lie group G there are three kinds of natural linear connections, the plus, minus, and zero connections introduced first by Cartan and Schouten.[1] A simple way to define these connections is to give their values on left-invariant vector-fields X, Y by

$$\nabla^+_X Y = [X,Y], \quad \nabla^-_X Y = 0, \quad \nabla^0_X Y = \tfrac{1}{2}[X,Y],$$

and extend them to arbitrary vector fields by making them tensorial in the X argument and satisfy the Leibniz rule in the Y argument. The curvature tensors of the minus and plus connections are zero, but in general, the corresponding torsion tensors are nonvanishing. All three of the natural connections have the same geodesics. We shall denote ∇^0 simply by ∇ and refer to it as the canonical symmetric, linear connection.

Let $E: TG \to \mathbb{R}$ be a smooth function on the tangent bundle of a Lie group G, called the Lagrange function. For an arbitrary curve $g(t): [t_0, t_1] \to G$ one can consider the functional $I[g] := \int_{t_0}^{t_1} E(g(t), \dot{g}(t))\mathrm{d}t$. A standard argument shows that the functions $g(t)$ giving extrema of this functional (in the class of variations preserving the endpoints) satisfy the Euler-Lagrange equations. In standard local coordinates $\{g^i\}$ on G they are

$$\frac{d}{\mathrm{d}t}\left(\frac{\partial E}{\partial \dot{g}^i}\right) - \frac{\partial E}{\partial g^i} = 0. \tag{1}$$

If the Lagrangian E is regular, then (1) is a second order ordinary differential equation.

In a series of papers, Thompson and his co-workers investigated the inverse problem of Lagrangian dynamics for the geodesic flow associated to ∇ (see Refs. 2, 7, and 9). Here one wishes to decide if there exists a Lagrangian function defined on an open subset of the tangent bundle of the Lie group whose Euler-Lagrange equations coincide with the geodesic equations of ∇. In this paper we consider the invariant version of this problem. We examine the existence of Lie groups, whose canonical geodesic flows are variational with respect to a left-invariant regular—but not necessarily quadratic—Lagrange function.

III. DIFFERENTIAL GEOMETRIC BACKGROUND OF THE INVERSE PROBLEM OF THE CALCULUS OF VARIATIONS

We present here the basic objects that play a role in the theory. More details can be found in Refs. 5 and 7

If M is a manifold TM denotes its tangent space and π the natural submersion. Let $J: TTM \to TTM$ be the canonical vertical endomorphism, and let $C \in \mathfrak{X}(TM)$ be the Liouville vector field, if (x^α) is a local coordinate system on M and (x^α, y^α) is the induced coordinate system on TM, then

$$J = \mathrm{d}x^\alpha \otimes \frac{\partial}{\partial y^\alpha}, \quad C = y^\alpha \frac{\partial}{\partial y^\alpha}. \tag{2}$$

A *(non-linear) connection* on M is a tensor field of type (1-1) Γ on TM such that $J\Gamma = J$ and $\Gamma J = -J$ (see Ref. 4). If Γ is a connection, then $\Gamma^2 = id_{TTM}$ and the eigenspace corresponding to the eigenvalue -1 is the vertical space V_z. Then, at any $z \in TM$, we have the splitting $T_z TM = H_z \oplus V_z$, where H_z is the eigenspace corresponding to $+1$. The subspace H_z is called the horizontal space. In the sequel we will write

$$h := \tfrac{1}{2}(I+\Gamma), \quad v := \tfrac{1}{2}(I-\Gamma),$$

for the *horizontal* and *vertical* projectors.

Definition 1: A Lagrangian is a map $E: TM \to \mathbb{R}$ *that is smooth on at least an open subset of* TM. *The Lagrangian* E *is said to be regular if*

$$\det\left(\frac{\partial^2 E}{\partial y^\alpha \partial y^\beta}\right) \neq 0. \tag{3}$$

The Lagrangian E is regular if and only if the 2-form $\Omega_E := \mathrm{d}d_J E$ has maximal rank. In this case, the vector field S on TM defined by the equation

$$i_S \Omega_E = d(E - \mathcal{L}_C E) \tag{4}$$

is a spray (that is $JS=C$), and the paths of S are the solutions of the Euler-Lagrange equations,[3]

$$\frac{d}{\mathrm{d}t}\frac{\partial E}{\partial \dot{x}^\alpha} - \frac{\partial E}{\partial x^\alpha} = 0, \quad \alpha = 1, \ldots, n. \tag{5}$$

Let us fix a second order differential equation, or in other words a spray S on the manifold M. Then, to every Lagrangian E a scalar 1-form ω_E can be associated by

$$\omega_E := i_S \Omega_E + \mathrm{d}\mathcal{L}_C E - \mathrm{d}E, \tag{6}$$

which is called *Euler-Lagrange* form. According to Eq. (4) we have $\omega_E \equiv 0$ if and only if the path of the spray is the solution of the Euler-Lagrange equation (5) associated to E. (See Refs. 5 and 7.)

IV. LEFT-INVARIANT VARIATIONAL PRINCIPLE FOR THE CANONICAL CONNECTION

In the sequel we will consider the case, where $M := G$ is a Lie group. We will denote by $L_x g$ or simply by xg the left translation of $g \in G$ by $x \in G$. Let (x) be coordinates on G, and let (x,y) be the standard associated coordinate system on TG. We will also use the "left invariant" coordinates (x,α) on $TG \simeq G \times \mathfrak{g}$, where $\alpha = (L_{x^{-1}})_* y$ is the Maurer-Cartan form. The corresponding coordinates on TTG are (x,α,X,A), that is,

$$(x,\alpha,X,A) = X \left.\frac{\partial}{\partial x}\right|_{(x,\alpha)} + A \left.\frac{\partial}{\partial \alpha}\right|_{(x,\alpha)}.$$

Since the coordinates $\alpha=(\alpha_i)$ and $A=(A_i)$ are left-invariant coordinates, we find that the left translation by a group element g induces on TTG the following action:

$$L_g(x,\alpha,X,A) = (gx,\alpha,gX,A) = gX \left.\frac{\partial}{\partial x}\right|_{(gx,\alpha)} + A \left.\frac{\partial}{\partial \alpha}\right|_{(gx,\alpha)}.$$

The canonical projection $\pi: TG \to G$ is $(x,\alpha) \to x$, therefore $\pi_*: TTG \to TG$ is given by $(x,\alpha,X,A) \to (x,x^{-1}X)$ and the vertical subspace on $(x,\alpha) \in TG$ is

$$V_{(x,\alpha)}TG := \mathrm{Ker}\ \pi_* = \{(x,\alpha,0,b) | b \in \mathfrak{g}\}.$$

Second order differential equations are described by vector-fields S (called spray) on the tangent space, that have the characteristic property $JS=C$. On a Lie group the geodesic flow of the canonical connection is described by the system

$$\ddot{x} = \dot{x}x^{-1}\dot{x}, \tag{7}$$

and the vector field on the tangent space, corresponding to the geodesic flow of the canonical connection is the spray S where

$$S_{(x,\alpha)} = (x,\alpha,x\alpha,0) = x\alpha \left.\frac{\partial}{\partial x}\right|_{(x,\alpha)}. \tag{8}$$

Then γ_t is a geodesic of ∇ if and only if the equation $S_{\dot\gamma} = \ddot\gamma$ holds. The horizontal and vertical projections of the connection $\Gamma := [J,S]$ associated the spray S are h and v where

$$v(x,b,xa,c) = \left(x,b,0,\frac{1}{2}[a,b]+c\right) = \left(\frac{1}{2}[a,b]+c\right) \left.\frac{\partial}{\partial\alpha}\right|_{(x,b)},$$

$$h(x,b,xa,c) = \left(x,b,xa,-\frac{1}{2}[a,b]\right) = xa \left.\frac{\partial}{\partial x}\right|_{(x,b)} - \frac{1}{2}[a,b] \left.\frac{\partial}{\partial\alpha}\right|_{(x,b)},$$

therefore the horizontal and vertical lifts of a left-invariant vector field $X=(x,a)$ are

$$X^h_{(x,\alpha)} = \left(x,\alpha,xa,-\frac{1}{2}[a,\alpha]\right) = xa \left.\frac{\partial}{\partial x}\right|_{(x,\alpha)} - \frac{1}{2}[a,\alpha] \left.\frac{\partial}{\partial\alpha}\right|_{(x,\alpha)}, \tag{9}$$

$$X^v_{(x,\alpha)} = (x,\alpha,0,a) = a \left.\frac{\partial}{\partial\alpha}\right|_{(x,\alpha)}. \tag{10}$$

Moreover, with (x,α) as a local coordinate system, the vertical endomorphism and the Liouville vector fields are

$$J = (x^{-1}\,\mathrm{d}x)\otimes\frac{\partial}{\partial\alpha}, \quad C = \alpha\frac{\partial}{\partial\alpha}.$$

Indeed,

$$C_{(x,\alpha)} = \left.\frac{d}{\mathrm{d}t}\right|_{t=0} (x,e^t\alpha) = (x,\alpha,0,\alpha),$$

$$J(x,\alpha,A,B) = \left.\frac{d}{\mathrm{d}t}\right|_{t=0} (x,\alpha+tx^{-1}A) = (x,\alpha,0,x^{-1}A).$$

For more details see Ref. 7.

Let us examine the existence of a left-invariant variational principle for the canonical flow of Lie groups. We have the following.

Proposition 2: The canonical flow of the Lie group G is variational with respect a left-invariant Lagrangian if and only if there exists an ad-invariant function $\mathcal{E}:\mathfrak{g}\to\mathbb{R}$ with nondegenerate Hessian.

To prove the proposition, we compute the Euler-Lagrange equation for the canonical flow of G. Using the notation introduced in (6), the Euler-Lagrange partial differential equation associated to a spray S can be written as

$$\omega_E \equiv 0, \tag{11}$$

where the unknown is the Lagrangian E. Let us compute explicitly the equation (11). If $X=(x,a)$ denotes a left-invariant vector field on G corresponding to $a\in\mathfrak{g}$, and X^v, X^h are its vertical and horizontal lifts, then we have $\omega_E(X^v)\equiv 0$, since ω_E is semibasic. Moreover, we have

$$\begin{aligned}\omega_E(X^h) &= (i_S\,\mathrm{d}d_J E + \mathrm{d}\mathcal{L}_C\,E - \mathrm{d}E)(X^h) = \mathrm{d}d_J\,E(S,X^h) + \mathrm{d}\mathcal{L}_C\,E(X^h) - \mathrm{d}E(X^h)\\ &= S(JX^h(E)) - X^h(JS(E)) - J[S,X^h]E + X^h(C(E)) - X^hE\\ &= S(X^v(E)) - J[S,X^h]E - X^hE.\end{aligned}$$

Taking into account (8) and the local expression (9) of X^h we have

$$[X^h,S] = \left[xa\frac{\partial}{\partial x} - \frac{1}{2}[a,\alpha]\frac{\partial}{\partial\alpha}, x\alpha\frac{\partial}{\partial x}\right] = \frac{1}{2}x[a,\alpha]\frac{\partial}{\partial x},$$

$$J[X^h,S] = \frac{1}{2}J\left(x[a,\alpha]\frac{\partial}{\partial x}\right) = \frac{1}{2}[a,\alpha]\frac{\partial}{\partial\alpha},$$

and

$$\begin{aligned}\omega_E(X^h) &= x\alpha\frac{\partial}{\partial x}\left(a\frac{\partial}{\partial\alpha}(E)\right) - \frac{1}{2}[a,\alpha]\frac{\partial}{\partial\alpha}(E) - \left(xa\frac{\partial}{\partial x} - \frac{1}{2}[a,\alpha]\frac{\partial}{\partial\alpha}\right)E\\ &= x\alpha a\frac{\partial^2E}{\partial x\partial\alpha} + \frac{1}{2}[a,\alpha]\frac{\partial E}{\partial\alpha} - xa\frac{\partial E}{\partial x} + \frac{1}{2}[a,\alpha]\frac{\partial E}{\partial\alpha}\\ &= [a,\alpha]\frac{\partial E}{\partial\alpha} + x\alpha a\frac{\partial^2E}{\partial x\partial\alpha} - xa\frac{\partial E}{\partial x}.\end{aligned}$$

If the Lagrangian is left-invariant, then $\partial E/\partial x=0$ and we obtain that

$$\omega(X^h) = [a,\alpha]\frac{\partial E}{\partial\alpha},$$

consequently the canonical connection of the group G is variational with respect to a left-invariant regular Lagrangian E if and only if

$$\frac{\partial E}{\partial x} = 0, \tag{12}$$

$$[a,\alpha]\frac{\partial E}{\partial\alpha} = 0, \quad \forall\, a \in \mathfrak{g}, \tag{13}$$

where (12) expresses the fact that E is left-invariant and (13) expresses that E is a solution of the Euler-Lagrange equation (11). Therefore the canonical flow is variational with respect to an invariant Lagrangian if and only if the Frobenius differential system (12) and (13) has a solution $E: TG \simeq G\times\mathfrak{g}\to\mathbb{R}$ satisfying the regularity condition, or equivalently, there exists a function $\mathcal{E}:\mathfrak{g}\to\mathbb{R}$ satisfying the equation

$$[a,\alpha]\frac{\partial\mathcal{E}}{\partial\alpha} = 0, \tag{14}$$

for all $a\in\mathfrak{g}$, such that the Hessian matrix $(\partial^2\mathcal{E}/\partial\alpha_i\partial\alpha_j)$ is nondegenerate. The equation (14) is identically satisfied if and only if $\mathcal{E}$ is constant on the orbit of the *ad* representation of $\mathfrak{g}$.

□

Let $\{e_1,\ldots,e_n\}$ be a basis of $\mathfrak{g}$. Then the structure constants $C^\gamma_{\alpha\beta}$ of the Lie algebra $\mathfrak{g}$ are defined by

$$[e_\alpha,e_\beta] = C^\gamma_{\alpha\beta}e_\gamma. \tag{15}$$

We denote by (α_i) the coordinate of $\alpha\in\mathfrak{g}$. We have the following.

Theorem 3: *There exists a left-invariant variational principle for the canonical flow of the Lie group G in a neighborhood of a generic element $\alpha \in \mathfrak{g}$ if and only if the linear system*

$$C_{ij}^k \alpha_j x_k = 0, \quad i = 1, \ldots, n, \tag{16}$$

$$C_{ij}^k x_k + C_{jm}^k \alpha_m x_{ik} = 0, \quad i,j = 1, \ldots, n, \tag{17}$$

has a solution $\{x_i = \epsilon_i,\ x_{ij} = \epsilon_{ij}\}$ satisfying the condition $\det(\epsilon_{ij}) \neq 0$.

Proof: Let us consider the distribution Δ in the tangent space of $\mathfrak{g}$ defined as

$$\Delta_\alpha := \left\{ X_a := [a,\alpha] \left.\frac{\partial}{\partial \alpha}\right|_\alpha \middle| a \in \mathfrak{g} \right\},$$

for $\alpha \in \mathfrak{g}$. If a and b are two elements of the Lie algebra $\mathfrak{g}$, then

$$\left[[a,\alpha]\frac{\partial}{\partial \alpha}, [b,\alpha]\frac{\partial}{\partial \alpha} \right] = [[\alpha,a],b]\frac{\partial}{\partial \alpha} - [[\alpha,b],a]\frac{\partial}{\partial \alpha} = [\alpha,[a,b]]\frac{\partial}{\partial \alpha},$$

that is for every $X_a \in \Delta$ and $X_b \in \Delta$ we have $[X_a, X_b] = X_{[a,b]} \in \Delta$. This shows that Δ is involutive and the system (14) is integrable.

Let us denote by $J_1(\mathfrak{g},\mathbb{R})$ and by $J_2(\mathfrak{g},\mathbb{R})$ the first and second order jet spaces of real valued functions on $\mathfrak{g}$. As usual, a local coordinates system on $J_1(\mathfrak{g},\mathbb{R})$ and $J_2(\mathfrak{g},\mathbb{R})$ can be given as follows: if $\mathcal{E}: \mathfrak{g} \to \mathbb{R}$, then

$$j_{1,\alpha}(\mathcal{E}) = (\alpha, \epsilon, \epsilon_i), \quad j_{2,\alpha}(\mathcal{E}) = (\alpha, \epsilon, \epsilon_i, \epsilon_{ij}),$$

where

$$\epsilon = \mathcal{E}(\alpha), \quad \epsilon_i = \left.\frac{\partial \mathcal{E}}{\partial \alpha_i}\right|_\alpha, \quad \epsilon_{ij} = \left.\frac{\partial^2 \mathcal{E}}{\partial \alpha_i \partial \alpha_j}\right|_\alpha.$$

Since (14) is integrable, the first prolongation of (14) is also integrable. Therefore for every initial condition $j_{2,\alpha} \in J_2(\mathfrak{g},\mathbb{R})$ at α, there exists a solution $\mathcal{E}: \mathfrak{g} \to \mathbb{R}$ in the neighborhood of α such that $j_2(\mathcal{E}) = j_{2,\alpha}$. On the other hand, the jet $j_{2,\alpha} = \{\alpha, \epsilon, \epsilon_i, \epsilon_{ij}\}$ is a second order initial condition of the prolongated system if and only if $\{\epsilon_i, \epsilon_{ij}\}$ is a solution of the system composed by (16) and (17). Moreover the solution $\mathcal{E}$ corresponding to $j_{2,\alpha}$ is nondegenerate if and only if $\det(\epsilon_{ij}) \neq 0$.

□

Corollary 1: The canonical connection of a commutative Lie group is variational with respect to a left-invariant Lagrangian.

In that case $C_{ij}^k = 0$ for all $i,j,k = 1, \ldots, n$, and there is no obstruction to choose a nondegenerate initial condition for the system (14). □

Corollary 2: If the derived Lie algebra is one dimensional, then there is no left-invariant variational principle for the canonical flow.

In that case all the solutions $\{x_i = \epsilon_i,\ x_{ij} = \epsilon_{ij}\}$ of the system composed by (16) and (17) are degenerate, and therefore there is no nondegenerate initial condition for the differential system (14). □

Remark: The Lagrangian $E(\alpha) = K(\alpha,\alpha)$, where K is the Killing form of G, is always a solution to the equations (12) and (13). *That way we rediscover the well-known property of semisimple Lie groups: the canonical connection is variational with respect to a left-invariant Lagrangian.*

Indeed, E is left-invariant, it is not dependent on the x coordinates in the (x,α) system, and (12) is satisfied. Moreover, at every $\alpha \in \mathfrak{g}$ and $a \in \mathfrak{g}$ we have

$$[a,\alpha]\frac{\partial E}{\partial \alpha} = \left.\frac{d}{dt}\right|_{t=0} K(\alpha + t[a,\alpha]; \alpha + t[a,\alpha]) = K([a,\alpha],\alpha) + K(\alpha,[a,\alpha]) = 0$$

and Eq. (13) is satisfied. □

V. SOLUTION OF THE GROUP-INVARIANT INVERSE PROBLEM IN DIMENSIONS UP TO FOUR

The variationality of the geodesic flow of the canonical connection of Lie groups was studied in Refs. 9 and 2, where the inverse problem for Lie groups up to dimension 4 were solved. Here we determine if there exits group-invariant variational principle for canonical geodesic flows. Theorem 3 formulates a necessary and sufficient condition for the Lie algebra so that the canonical flow is variational with respect to a group-invariant Lagrangian.

Jacobson in Ref. 6 gives the classification of Lie algebras of dimension 3 or less. The classification of Lie algebras of dimensions 4 and 5 can be found in Ref. 8.

A. Two-dimensional Lie groups

There are, up to isomorphism, two algebras distinguished according to whether or not $[,]$ is trivial or not. In the former case we have the Abelian Lie algebra, and according to Corollary 1 it is variational with respect to a G-invariant Lagrangian.

The latter one is the Lie algebra of the affine group of the line. Up to isomorphism the Lie algebra of the affine group of the line is the only non-Abelian two-dimensional Lie algebra. A representation of the group G is given by $g=\left(\begin{smallmatrix} x & y \\ 0 & 1 \end{smallmatrix}\right)$ where $x \neq 0$. The corresponding Lie algebra is given by the 2×2 matrices $\left(\begin{smallmatrix} x & y \\ 0 & 0 \end{smallmatrix}\right)$. Let us consider the basis $\{e_1, e_2\}$, where $e_1 := \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ and $e_2 := \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$. Then $[e_1, e_2] = e_2$, i.e., the nonzero structure constants are $C^2_{12} = -C^2_{21} = 1$. If (a_1, a_2) and (α_1, α_2) denote the coordinates of a and α with respect to this basis, then Eq. (13) is $[a,\alpha] = (a_1\alpha_2 - a_2\alpha_1)e_2$ which gives $\partial E/\partial \alpha_2 = 0$. Since any solution of the prolongations is nonregular we conclude that there is no invariant variational principle for the canonical connection of the affine group of the line.

B. Three-dimensional Lie groups

In Ref. 9, Thompson proved that all the canonical connections on Lie groups of dimension 3 have variational locally geodesic equations. On the other hand, Jacobson's classification of the three-dimensional Lie algebras depends primarily on the dimension of the first derived algebra $g^{(1)}$ where g is the original algebra. We have the following possibilities.

If $\dim(g^{(1)}) = 0$, then g is Abelian and, according to Corollary 1, the canonical connection of a commutative Lie group is variational with respect to a left-invariant Lagrangian. If $\dim(g^{(1)}) = 3$, then g is simple and we have $g = s\ell(2,\mathbb{R})$ or $g = so(3)$. In both cases the Killing form provides a metric and so the connections are variational.

If $\dim(g^{(1)}) = 1$ there are, up to isomorphism, two algebras distinguished according to whether $g^{(1)}$ lies inside the center of g. In the former case g may be realized as the Lie algebra of the group of matrices of the form $\begin{bmatrix} 1 & x & y \\ 0 & 1 & z \\ 0 & 0 & 1 \end{bmatrix}$, $(x,y,z \in \mathbb{R})$ and $\mathfrak{g}$ is the Heisenberg algebra. Its canonical connection is a flat connection and so it is variational. The latter case g is isomorphic to the Lie algebra of the group of nonsingular 2×2 upper triangular matrices and so it is again variational.

Let us consider the Heisenberg group. A basis of the Lie algebra is given by $\{e_1, e_2, e_3\}$, where

$$e_1 := \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad e_2 := \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad e_3 := \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}.$$

If (a_1, a_2, a_3) and $(\alpha_1, \alpha_2, \alpha_3)$ denotes the coordinates of a and α with respect to this basis, then

$$(a_1\alpha_3 - a_3\alpha_1)\frac{\partial E}{\partial \alpha_2} = 0$$

and Eq. (13) gives $\partial E/\partial \alpha_2 = 0$. Since any solution of the prolongations is nonregular we conclude that there is no invariant variational principle for the canonical connection of the Heisenberg group.

Next we consider the Lie group of 2×2 upper triangular matrices $\left(\begin{smallmatrix} x & y \\ 0 & z \end{smallmatrix}\right)$ where $xz \neq 0$. Here $\{e_1, e_2, e_3\}$ is a basis of the Lie algebra, where

$$e_1 := \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad e_2 := \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad e_3 := \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

If (a_1, a_2, a_3) and $(\alpha_1, \alpha_2, \alpha_3)$ are the coordinates of a and α, then

$$(a_1\alpha_2 + a_2\alpha_3 - a_1\alpha_2 - a_3\alpha_3)\frac{\partial E}{\partial \alpha_2} = 0,$$

and Eq. (14) gives again $\partial E/\partial \alpha_2 = 0$. Therefore any solution will be nonregular. Consequently there is no invariant variational principle in this case.

C. Four-dimensional Lie groups

There are 12 classes of Lie algebras in dimension 4 denoted in Ref. 8 as $A_{4,i}$, $i = 1, \ldots, 12$. The generators of the algebras are listed as $\{e_1, e_2, e_3, e_4\}$ and in each case we list the nonzero Lie brackets. Several of the Lie algebras have parameters denoted by a or b or both. The generic solution of the linear system (16) at a point $\alpha = \alpha_i e_i$ will be denoted by $\epsilon := \{\epsilon_i, \epsilon_{ij}\}$.

In Ref. 2, Thompson and his co-workers computed all the canonical connections on Lie groups of dimension 4 and determined whether the connection is variational or not. He has shown that the Lie groups with Lie algebras $A_{4,7}$, $A_{4,9b}$, and $A_{4,11a}$, where the brackets are defined as

$$A_{4,7}, \quad [e_2, e_3] = e_1, \quad [e_1, e_4] = 2e_1, \quad [e_2, e_4] = e_2, \quad [e_3, e_4] = e_2 + e_3,$$

$$A_{4,9b}, \quad [e_2, e_3] = e_1, \quad [e_1, e_4] = (1+b)e_1, \quad [e_2, e_4] = e_2, \quad [e_3, e_4] = be_3,$$

$$A_{4,11a}, \quad [e_2, e_3] = e_1, \quad [e_1, e_4] = 2ae_1, \quad [e_2, e_4] = ae_2 - e_3, \quad [e_3, e_4] = e_2 + ae_3,$$

$-1 < b < 1$ and $0 < a$, are not variational.

$A_{4,2a}$, the brackets are

$$[e_1, e_4] = ae_1, \quad [e_2, e_4] = e_2, \quad [e_3, e_4] = e_2 + e_3, \quad a \neq 0.$$

Equation (16) leads to a solution $\{\epsilon_i, \epsilon_{ij}\}$, where $\epsilon_{ij} = 0$ for every $(i, j) \neq (4, 4)$. Therefore the condition (13) entails that the matrix ϵ_{ij} is singular, whatever is the value of a. Therefore the canonical flow is variational, but there is no left-invariant regular Lagrangian for its geodesics.

In the case of the Lie groups with Lie algebras $A_{4,1}$, $A_{4,3}$, $A_{4,4}$, $A_{4,9}$, and $A_{4,12}$, the nontrivial brackets of the algebras are determined as

$$A_{4,1}, \quad [e_2, e_4] = e_1, \quad [e_3, e_4] = e_2,$$

$$A_{4,3}, \quad [e_1, e_4] = e_1, \quad [e_3, e_4] = e_2,$$

$$A_{4,4}, \quad [e_1, e_4] = e_1, \quad [e_2, e_4] = e_1 + e_2, \quad [e_3, e_4] = e_2 + e_3,$$

$$A_{4,9}, \quad [e_2, e_3] = e_1, \quad [e_1, e_4] = 2e_1, \quad [e_2, e_4] = e_2, \quad [e_3, e_4] = e_3,$$

$$A_{4,12}, \quad [e_1,e_3]=e_1, \quad [e_2,e_3]=e_2, \quad [e_1,e_4]=-e_2, \quad [e_2,e_4]=e_1.$$

We can find that the general solution of Eq. (16) can be described as follows: $\epsilon_{33},\epsilon_{34},\epsilon_{44}$ are arbitrary numbers and the other components are all zero. Therefore

$$\epsilon_{ij}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & \epsilon_{33} & \epsilon_{34} \\ 0 & 0 & \epsilon_{34} & \epsilon_{44} \end{pmatrix}.$$

Since ϵ_{ij} is singular, there is no left-invariant regular Lagrangian for the geodesics of the canonical connection. The situation is analogous in the following.

$\mathbf{A_{4,5ab}}$, the Lie algebra relations are

$$[e_1,e_4]=e_1, \quad [e_2,e_4]=ae_2, \quad [e_3,e_4]=be_3.$$

Depending on the value of a and b we have four cases,

$$\text{if } a=0, \quad b=0, \text{ then } \epsilon_{ij}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & \epsilon_{22} & \epsilon_{23} & \epsilon_{24} \\ 0 & \epsilon_{23} & \epsilon_{33} & \epsilon_{34} \\ 0 & \epsilon_{24} & \epsilon_{34} & \epsilon_{44} \end{pmatrix},$$

$$\text{if } a=0, \quad b\neq 0, \text{ then } \epsilon_{ij}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & \epsilon_{22} & 0 & \epsilon_{24} \\ 0 & 0 & 0 & 0 \\ 0 & \epsilon_{24} & 0 & \epsilon_{44} \end{pmatrix},$$

$$\text{if } a\neq 0, \quad b=0, \text{ then } \epsilon_{ij}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & \epsilon_{33} & \epsilon_{34} \\ 0 & 0 & \epsilon_{34} & \epsilon_{44} \end{pmatrix},$$

$$\text{if } a\neq 0, \quad b\neq 0, \text{ then } \epsilon_{ij}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \epsilon_{44} \end{pmatrix}.$$

In all three cases the Lagrangian must be nonregular, and therefore there is no left-invariant regular Lagrangian for the geodesics of the canonical connection.

$\mathbf{A_{4,6ab}}$, the Lie algebra relations are

$$[e_1,e_4]=ae_1, \quad [e_2,e_4]=be_2-e_3, \quad [e_3,e_4]=be_3,$$

with $a\neq 0$, $b\geqslant 0$. Depending on the value of a and b we have two cases,

$$\text{if } b \neq 0, \text{ then } \epsilon_{ij} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \epsilon_{44} \end{pmatrix},$$

$$\text{if } b = 0, \text{ then } \epsilon_{ij} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & \epsilon_{22} & 0 & \epsilon_{24} \\ 0 & 0 & 0 & 0 \\ 0 & \epsilon_{24} & 0 & \epsilon_{44} \end{pmatrix}.$$

In both cases the Lagrangian must be degenerate and therefore there is no left-invariant regular Lagrangian for the geodesics of the canonical connection.

$\mathbf{A_{4,8}}$, the Lie algebra relations are

$$[e_2, e_3] = e_1, \quad [e_2, e_4] = e_2, \quad [e_3, e_4] = -e_3.$$

$\epsilon_3, \epsilon_4, \epsilon_{3,2}, \epsilon_{4,1}, \epsilon_{4,4}$ are free and the matrix (ϵ_{ij}) is

$$\begin{pmatrix} \frac{\alpha_4^2(\alpha_2\epsilon_{32} - \epsilon_3)}{\alpha_2^2\alpha_3} & -\frac{\alpha_4(\alpha_2\epsilon_{23} - \epsilon_3)}{\alpha_2^2} & -\frac{\alpha_4(\alpha_2\epsilon_{32} - \epsilon_3)}{\alpha_2\alpha_3} & \epsilon_{14} \\ -\frac{\alpha_4(\alpha_2\epsilon_{23} - \epsilon_3)}{\alpha_2^2} & \frac{\alpha_3(\alpha_2\epsilon_{32} - \epsilon_3)}{\alpha_2^2} & \epsilon_{23} & -\frac{\alpha_3(\alpha_2\epsilon_{14} + \epsilon_3)}{\alpha_2\alpha_4} \\ -\frac{\alpha_4(\alpha_2\epsilon_{32} - \epsilon_3)}{\alpha_2\alpha_3} & \epsilon_{23} & \frac{\alpha_2\epsilon_{23} - \epsilon_3}{\alpha_3} & -\frac{\alpha_2\epsilon_{41} + \epsilon_3}{\alpha_4} \\ \epsilon_{14} & -\frac{\alpha_3(\alpha_2\epsilon_{14} + \epsilon_3)}{\alpha_2\alpha_4} & -\frac{\alpha_2\epsilon_{41} + \epsilon_3}{\alpha_4} & \epsilon_{44} \end{pmatrix}.$$

In Ref. 9 Thompson showed that $A_{4,8}$ admits a bi-invariant metric. In order to give a regular initial condition we can choose the free components as

$$\epsilon_3 := \alpha_2\epsilon_{32}, \quad \epsilon_{4,1} := -\epsilon_{23},$$

ϵ_4, $\epsilon_{4,4}$ arbitrary, $\epsilon_{3,2}$ arbitrary nonzero and compute the other components. Then we obtain a solution $\epsilon = \{\epsilon_i, \epsilon_{ij}\}$ of the system (16),

$$\begin{pmatrix} 0 & 0 & 0 & -\epsilon_{23} \\ 0 & 0 & \epsilon_{23} & 0 \\ 0 & \epsilon_{23} & 0 & 0 \\ -\epsilon_{23} & 0 & 0 & \epsilon_{44} \end{pmatrix},$$

where $\det(\epsilon_{ij}) = (\epsilon_{23})^4 \neq 0$. According to Theorem 3 there exists an invariant regular Lagrangian generating the canonical geodesic flow.

$\mathbf{A_{4,10}}$, the Lie algebra relations are

$$[e_2,e_3]=e_1, \quad [e_2,e_4]=-e_3, \quad [e_3,e_4]=e_2.$$

The ϵ_3, ϵ_4, $\epsilon_{3,3}$, $\epsilon_{4,2}$, and $\epsilon_{4,4}$ are free components and the matrix (ϵ_{ij}) is

$$\begin{pmatrix} \frac{\alpha_4^2(\alpha_3\epsilon_{33}-\epsilon_3)}{\alpha_3^3} & \frac{\alpha_2\alpha_4(\alpha_3\epsilon_{33}-\epsilon_3)}{\alpha_3^3} & \frac{\alpha_4(\alpha_3\epsilon_{33}-\epsilon_3)}{\alpha_3^2} & \frac{\alpha_4\alpha_3\epsilon_{24}+\alpha_2\epsilon_3}{\alpha_2\alpha_3} \\ \frac{\alpha_2\alpha_4(\alpha_3\epsilon_{33}-\epsilon_3)}{\alpha_3^3} & \frac{\alpha_2^2\alpha_3\epsilon_{33}+(\alpha_3^2-\alpha_2^2)\epsilon_3}{\alpha_3^3} & \frac{\alpha_2(\alpha_3\epsilon_{33}-\epsilon_3)}{\alpha_3^2} & \epsilon_{4,2} \\ \frac{\alpha_4(\alpha_3\epsilon_{33}-\epsilon_3)}{\alpha_3^2} & \frac{\alpha_2(\alpha_3\epsilon_{33}-\epsilon_3)}{\alpha_3^2} & \epsilon_{33} & \frac{\alpha_3\epsilon_{24}}{\alpha_2} \\ \frac{\alpha_4\alpha_3\epsilon_{24}+\alpha_2\epsilon_3}{\alpha_2\alpha_3} & \epsilon_{24} & \frac{\alpha_3\epsilon_{24}}{\alpha_2} & \epsilon_{44} \end{pmatrix}.$$

A nondegenerate initial condition can be chosen as follows:

$$\epsilon_3 := x_3\epsilon_{33}, \quad \epsilon_{4,2} := 0,$$

ϵ_4, $\epsilon_{4,1}$, $\epsilon_{4,4}$ arbitrary, $\epsilon_{3,2}$ arbitrary nonzero and the other components zero. We have

$$\begin{pmatrix} 0 & 0 & 0 & \epsilon_{33} \\ 0 & \epsilon_{33} & 0 & 0 \\ 0 & 0 & \epsilon_{33} & 0 \\ \epsilon_{33} & 0 & 0 & \epsilon_{44} \end{pmatrix}$$

and $\det(\epsilon_{ij})=-(\epsilon_{33})^4\neq 0$. As in the previous case, Theorem 3 guarantees the existence of an invariant regular Lagrangian generating the canonical geodesic flow.

We remark that in Ref. 9 Thompson has already shown that a Lie group with $A_{4,8}$ or $A_{4,10}$ as Lie algebra has a bi-invariant metric which generates its canonical geodesic flow.

We present a general classification of Hamiltonian multivector fields and of Poisson forms on the extended multiphase space appearing in the geometric formulation of first order classical field theories. This is a prerequisite for computing explicit expressions for the Poisson bracket between two Poisson forms. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2116320]

I. INTRODUCTION AND GENERAL SETUP

The present paper is a continuation of previous work on Poisson brackets of differential forms in the multiphase space approach to classical field theory.[1,2] Our aim is to specialize the general constructions of Ref. 2 from abstract (exact) multisymplectic manifolds to the extended multiphase spaces of field theory, which at present seem to be the only known examples of multisymplectic manifolds, to clarify the structure of Hamiltonian multivector fields, of Hamiltonian forms and of Poisson forms on these spaces and to give explicit formulas for the Poisson bracket between the latter introduced in Refs. 1 and 2.

The structure of this paper is as follows. In the remainder of this introduction, we briefly review the geometric constructions needed in the paper. We put particular emphasis on the consequences that arise from the existence of a certain vector field, the scaling or Euler vector field. Also, we fix the notation to be used in what follows. In Sec. II, we present an explicit classification of locally Hamiltonian multivector fields on extended multiphase space in terms of adapted local coordinates and, following the logical inclusion from locally Hamiltonian to (globally) Hamiltonian to exact Hamiltonian multivector fields, show how the last two are situated within the first. Sec. III is devoted to the study of Hamiltonian forms and Poisson forms that are associated with (globally) Hamiltonian multivector fields. In Sec. IV, we use the outcome of our previous analysis to derive expressions for the Poisson bracket between two Poisson forms. In Sec. V, we summarize our main conclusions and comment on the relation of our results to other approaches, as well as on perspectives for future research. Finally, in order to make the paper self-contained, we include in an appendix a proposition that is not new but is needed in some of the proofs.

We begin with a few comments on the construction of the extended multiphase space of field theory,[3–7] which starts out from a given general fiber bundle over space-time, with base space

M ($\dim M=n$), total space E, bundle projection $\pi: E \to M$ and typical fiber Q ($\dim Q=N$). It is usually referred to as the configuration bundle since its sections constitute the possible field configurations of the system. (Of course, the manifold M represents space-time, whereas the manifold Q plays the role of a configuration space.) The extended multiphase space, which we shall simply denote by P, is then the total space of a larger fiber bundle over M and in fact the total space of a vector bundle over E which can be defined in several equivalent ways, e.g., by taking the twisted affine dual $J^{\circledast}E$ of the first order jet bundle JE of E or by taking the bundle $\Lambda^n_{n-1}T^*E$ of $(n-1)$-horizontal n-forms on E; see Refs. 2, 5, and 7 for details. Therefore, there is a natural class of local coordinate systems on P, namely those that arise from combining fiber bundle charts of E over M with vector bundle charts of P over E: these so-called adapted local coordinates (x^μ, q^i, p^μ_i, p) are completely fixed by specifying local coordinates x^μ for M (the space-time coordinates), local coordinates q^i for Q (the position variables) and a local trivialization of E over M, and are such that the induced local coordinates p^μ_i (the multimomentum variables) and p (the energy variable) are linear along the fibers of P over E. For details, we refer to Ref. 2, where one can also find the explicit transformation law for the multimomentum variables and the energy variable induced by a change of the space-time coordinates, of the position variables and of the local trivialization.

A first important feature of the extended multiphase space P is that it carries a naturally defined multicanonical form θ whose exterior derivative is, up to a sign, the multisymplectic form ω,

$$\omega = -\,\mathrm{d}\theta. \tag{1}$$

The global construction can be found in Refs. 2, 5, and 7, so we shall just state their explicit form in adapted local coordinates,

$$\theta = p^\mu_i\, \mathrm{d}q^i \wedge \mathrm{d}^n x_\mu + p\mathrm{d}^n x. \tag{2}$$

$$\omega = \mathrm{d}q^i \wedge \mathrm{d}p^\mu_i \wedge \mathrm{d}^n x_\mu - \mathrm{d}p \wedge \mathrm{d}^n x. \tag{3}$$

Here, we have already employed part of the following conventions concerning local differential forms defined by a system of adapted local coordinates, which will be used systematically throughout this paper,

$$\mathrm{d}^n x = \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^n, \quad \mathrm{d}^n x_{\mu_1 \ldots \mu_r} = i_{\partial_{\mu_r}} \cdots i_{\partial_{\mu_1}} \mathrm{d}^n x.$$

For later use, we also recall the definition of the Lie derivative of a differential form α along an r-multivector field X,

$$L_X \alpha = \mathrm{d} i_X \alpha - (-1)^r i_X\, \mathrm{d}\alpha, \tag{4}$$

which leads to the following relations, valid for any differential form α and any two multivector fields X and Y of tensor degrees r and s, respectively,

$$\mathrm{d}L_X \alpha = (-1)^{r-1} L_X\, \mathrm{d}\alpha, \tag{5}$$

$$i_{[X,Y]}\alpha = (-1)^{(r-1)s} L_X i_Y \alpha - i_Y L_X \alpha, \tag{6}$$

$$L_{[X,Y]}\alpha = (-1)^{(r-1)(s-1)} L_X L_Y \alpha - L_Y L_X \alpha, \tag{7}$$

$$L_{X\wedge Y}\alpha = (-1)^s i_Y L_X \alpha + L_Y i_X \alpha, \tag{8}$$

where $[X,Y]$ denotes the Schouten bracket of X and Y. For decomposable multivector fields $X = X_1 \wedge \cdots \wedge X_r$ and $Y = Y_1 \wedge \cdots \wedge Y_s$, it can be defined in terms of the Lie bracket of vector fields according to the formula

$$[X,Y]=\sum_{i=1}^{r}\sum_{j=1}^{s}(-1)^{i+j}[X_i,X_j]\wedge X_1\wedge\cdots\hat{X}_i\cdots\wedge X_r\wedge Y_1\wedge\cdots\hat{Y}_j\cdots\wedge Y_s,$$

where as usual the hat over a symbol denotes its omission. We shall also write

$$L_X Y=[X,Y],$$

for any two multivector fields X and Y. For properties of the Schouten bracket, we refer to Ref. 8. A proof of the above identities relating the Schouten bracket and the Lie derivative of forms along multivector fields can be found in the appendix of Ref. 2.

A second property of the extended multiphase space P which provides additional structures for tensor calculus on this manifold is that it is the total space of a fiber bundle, which implies that we may speak of vertical vectors and horizontal covectors. In fact, it is so in no less than three different ways. Namely, P is the total space of a fiber bundle over M (with respect to the so-called source projection), the total space of a vector bundle over E (with respect to the so-called target projection) and the total space of an affine line bundle over the ordinary multiphase space P_0.[2] Therefore, the notions of verticality for multivector fields and of horizontality for differential forms on P admit different interpretations, depending on which projection is used. In any case, one starts by defining tangent vectors to the total space of a fiber bundle to be vertical if they are annihilated by the tangent map to the bundle projection, or what amounts to the same thing, if they are tangent to the fibers. Dually, a k-form on the total space of a fiber bundle is said to be l-horizontal if it vanishes whenever one inserts at least $k-l+1$ vertical tangent vectors; the standard horizontal forms are obtained by taking $l=k$. Finally, an r-multivector on the total space of a fiber bundle is said to be s-vertical if its contraction with any $(r-s+1)$-horizontal form vanishes. It is not difficult to show that these definitions are equivalent to requiring that, locally, an l-horizontal k-form should be a sum of exterior products of k one-forms, among which there are at least l horizontal ones, and that an s-vertical r-multivector field should be a sum of exterior products of r tangent vectors, among which there are at least s vertical ones. Using this rule, properties of verticality for multivectors or horizontality for forms are easily derived from the corresponding properties for vectors or one-forms, respectively. In what follows, the terms "vertical" and "horizontal" will usually refer to the source projection, except when explicitly stated otherwise.

A third important feature of the extended multiphase space P is that it carries a naturally defined vector field Σ, the scaling vector field or Euler vector field, which exists on any manifold that is the total space of a vector bundle. In adapted local coordinates,

$$\Sigma=p_i^\mu\frac{\partial}{\partial p_i^\mu}+p\frac{\partial}{\partial p}.$$

It is then easy to verify the following relations (see Proposition 2.1 of Ref. 2):

$$i_\Sigma\theta=0,\quad i_\Sigma\omega=-\theta,\quad L_\Sigma\theta=\theta,\quad L_\Sigma\omega=\omega. \tag{9}$$

The main utility of Σ is that taking the Lie derivative L_Σ along Σ provides a device for controlling the dependence of functions and, more generally, of tensor fields on P on the multimomentum variables and the energy variable, that is, along the fibers of P over E: L_Σ has only integer eigenvalues, and eigenfunctions of L_Σ with eigenvalue k are homogeneous polynomials of degree k in these variables.

As we shall see soon, homogeneity under L_Σ plays a central role in the analysis of various classes of multivector fields and differential forms on P.

Let us recall a few definitions. An r-multivector field X on P is called *locally Hamiltonian* if $i_X\omega$ is closed, or equivalently, if

$$L_X\omega=0. \tag{10}$$

It is called *globally Hamiltonian* if $i_X\omega$ is exact, that is, if there exists an $(n\text{-}r)$-form f on P such that

$$i_X\omega = \mathrm{d}f. \tag{11}$$

In this case, f is said to be a *Hamiltonian form associated with* X. Finally, it is called *exact Hamiltonian* if

$$L_X\theta = 0. \tag{12}$$

Of course, exact Hamiltonian multivector fields are globally Hamiltonian [to show this, set $f=(-1)^{r-1}i_X\theta$ and apply Eqs. (4) and (1)], and globally Hamiltonian multivector fields are obviously locally Hamiltonian. Conversely, an $(n\text{-}r)$-form f on P is called a *Hamiltonian form* if there exists an r-multivector field X on P such that Eq. (11) holds; in this case, X is said to be a *Hamiltonian multivector field associated with* f. Moreover, f is called a *Poisson form* if in addition, it vanishes on the kernel of ω, that is, if for any multivector field Z, we have

$$i_Z\omega = 0 \Rightarrow i_Zf = 0. \tag{13}$$

A trivial example of a Poisson form is the multisymplectic form ω itself. Another example is provided by the multicanonical form θ, since it can be written as $\theta=-i_\Sigma\omega$.

Concerning stability under the Lie derivative along the scaling vector field Σ, we have the following.

Proposition 1.1: The space $\mathfrak{X}^\wedge_{LH}(P)$ *of locally Hamiltonian multivector fields, the space* $\mathfrak{X}^\wedge_{H}(P)$ *of globally Hamiltonian multivector fields, the space* $\mathfrak{X}^\wedge_{EH}(P)$ *of exact Hamiltonian multivector fields and the space* $\mathfrak{X}^\wedge_{0}(P)$ *of multivector fields taking values in the kernel of* ω *are all invariant under the Lie derivative along the scaling vector field* Σ,

$$L_X\omega = 0 \;\Rightarrow\; L_{[\Sigma,X]}\omega = 0, \tag{14}$$

$$i_X\omega = \mathrm{d}f \;\Rightarrow\; i_{[\Sigma,X]}\omega = \mathrm{d}(L_\Sigma f - f), \tag{15}$$

$$L_X\theta = 0 \;\Rightarrow\; L_{[\Sigma,X]}\theta = 0, \tag{16}$$

$$i_\xi\omega = 0 \;\Rightarrow\; i_{[\Sigma,\xi]}\omega = 0. \tag{17}$$

Proof: All these relations can be shown by direct calculation. □

Dually, we have the following.

Proposition 1.2: The space $\Omega_H(P)$ *of Hamiltonian forms, the space* $\Omega_0(P)$ *of forms that vanish on the kernel of* ω *and the space* $\Omega_P(P)$ *of Poisson forms are all invariant under the Lie derivative along the scaling vector field* Σ,

$$\mathrm{d}f = i_X\omega \;\Rightarrow\; \mathrm{d}(L_\Sigma f) = i_{X+[\Sigma,X]}\omega. \tag{18}$$

Proof: The first statement is a consequence of Eq. (18), which follows directly from combining Eqs. (5) and (6) with Eq. (9). For the second statement, assume that f vanishes on the kernel of ω. Then if ξ is any multivector field ϑ taking values in the kernel of ω, the multivector field $[\Sigma,\xi]$ takes values in the kernel of ω as well [cf. Eq. (17)], so that according to Eq. (6),

$$i_\xi(L_\Sigma f) = L_\Sigma i_\xi f - i_{[\Sigma,\xi]}f = 0.$$

But this means that $L_\Sigma f$ vanishes on the kernel of ω. Finally, the third statement follows by combining the first two. □

A special class of multivector fields and of differential forms on P which will be of particular importance in what follows is that of *fiberwise polynomial multivector fields* and of *fiberwise polynomial differential forms* on P: their coefficients are polynomials along the fibers of P over E,

or in other words, polynomials in the multimomentum variables and the energy variable. The main advantage of working with tensor fields on the total space of a vector bundle which are fiberwise polynomial is that they allow a unique and globally defined (or in other words, coordinate independent) decomposition into homogeneous components, according to the different eigenspaces of the Lie derivative L_Σ along Σ; the corresponding eigenvalue will in what follows be called the *scaling degree* (to distinguish it from the ordinary tensor degree). In doing so, it must be borne in mind that, in an expansion with respect to an adapted local coordinate system, the scaling degree receives contributions not only from the coefficient functions but also from some of the coordinate vector fields and differentials since the vector fields $\partial/\partial x^\mu$, $\partial/\partial q^i$, $\partial/\partial p_i^\mu$, and $\partial/\partial p$ carry scaling degree 0, 0, −1, and −1, respectively, while the differentials dx^μ, dq^i, dp_i^μ, and dp carry scaling degree 0, 0, +1, and +1, respectively; moreover, the scaling degree is additive under the exterior product, since L_Σ is a derivation. Therefore, a fiberwise polynomial r-multivector field on P admits a globally defined decomposition into a finite sum

$$X = \sum_{s \geqslant -r} X_s,$$

where X_s is its homogeneous component of scaling degree s,

$$L_\Sigma X_s = s X_s.$$

Each X_s can be obtained from X by applying a projector which is itself a polynomial in L_Σ,

$$X_s = \prod_{\substack{s' \geqslant -r \\ s' \neq s}} \frac{1}{s - s'} (L_\Sigma - s') X.$$

Similarly, a fiberwise polynomial $(n\text{-}r)$-form f on P admits a globally defined decomposition into a finite sum

$$f = \sum_{s \geqslant 0} f_s,$$

where f_s is its homogeneous component of scaling degree s,

$$L_\Sigma f_s = s f_s.$$

Again, the f_s can be obtained from f,

$$f_s = \prod_{\substack{s' \geqslant 0 \\ s' \neq s}} \frac{1}{s - s'} (L_\Sigma - s') f.$$

The relevance of these decompositions for locally Hamiltonian multivector fields and for Hamiltonian forms on the extended multiphase space P stems from the following theorem, whose proof will follow from statements to be derived in the course of the next two sections, by means of explicit calculations in adapted local coordinates.

Theorem 1.3: *For $0 < \tau < n$ and up to trivial contributions (τ-multivector fields taking values in the kernel of ω and closed $(n-r)$-forms, respectively), locally Hamiltonian τ-multivector fields and Hamiltonian $(n-\tau)$-forms on P are fiberwise polynomial and have non-trivial homogeneous components of scaling degree s only for $s = -1, 0, \ldots, r-1$ and for $s = 0, 1, \ldots, r$, respectively. More precisely, we have*

(i) *Every fiberwise polynomial locally Hamiltonian (Hamiltonian, exact Hamiltonian) r-multivector field X on P, admits a unique, globally defined decomposition into homogeneous components with respect to scaling degree, which can be written in the form (we abbreviate X_{-1} as X_-)*

$$X = X_- + X_+ + \xi \quad \text{with } X_+ = \sum_{s=0}^{r-1} X_s, \tag{19}$$

where each X_s is locally Hamiltonian (Hamiltonian, exact Hamiltonian) and

$$\xi = \sum_{-r \leqslant s \leqslant -2} \xi_s + \sum_{s \geqslant r} \xi_s \tag{20}$$

is a fiberwise polynomial r-multivector field on P taking values in the kernel of ω.

(ii) *Every fiberwise polynomial Hamiltonian form (Poisson form) f of degree $n-r$ on P, admits a unique, globally defined decomposition into homogeneous components with respect to scaling degree, which can be written in the form*

$$f = f_0 + f_+ + f_c \quad \text{with } f_+ = \sum_{s=1}^{r} f_s, \tag{21}$$

where each f_s is Hamiltonian (Poisson) and

$$f_c = \sum_{s \geqslant r+1} (f_c)_s \tag{22}$$

is a fiberwise polynomial closed $(n-r)$-form on P.

The cases $r=0$ and $r=n$ are exceptional and must be dealt with separately; see Propositions 2.2 and 3.2 for $r=0$ and Propositions 2.3 and 3.1 for $r=n$.

In view of this theorem, it is sufficient to study locally Hamiltonian multivector fields and Hamiltonian forms which are homogeneous under the Lie derivative along the scaling vector field Σ. This condition of homogeneity is also compatible with the correspondence between globally Hamiltonian multivector fields X and Hamiltonian forms f established by the fundamental relation (11), because ω itself is homogeneous: according to Eq. (9), ω has scaling degree 1. Indeed, except for the ambiguity inherent in this correspondence (f determines X only up to a multivector field taking values in the kernel of ω and X determines f only up to a closed form), Eq. (11) preserves the scaling degree, up to a shift by 1: X is homogeneous with scaling degree $s-1$ if and only if f is homogeneous with scaling degree s,

$$\begin{array}{c} L_\Sigma X = (s-1)X \\ \text{modulo multivector fields} \\ \text{taking values in the kernel of } \omega \end{array} \quad \Leftrightarrow \quad \begin{array}{c} L_\Sigma f = sf \\ \text{modulo closed forms} \end{array}. \tag{23}$$

For a proof, note that the condition on the left-hand side (lhs) amounts to requiring that $i_{[\Sigma,X]}\omega = (s-1) i_X \omega$, while the condition on the right-hand side (rhs) amounts to requiring that $\mathrm{d} L_\Sigma f = s\, \mathrm{d}f$, so the equivalence stated in Eq. (23) is an immediate consequence of Eq. (18). A particular case occurs when $s=1$, since the locally Hamiltonian multivector fields which are homogeneous of scaling degree 0 are precisely the exact Hamiltonian multivector fields: for $L_X\omega = 0$,

$$\begin{array}{c} L_\Sigma X = 0 \\ \text{modulo multivector fields} \\ \text{taking values in the kernel of } \omega \end{array} \quad \Leftrightarrow \quad L_X \theta = 0. \tag{24}$$

Indeed, the properties of θ and ω give

$$L_X \theta = -L_X i_\Sigma \omega = (-1)^r (i_{[X,\Sigma]}\omega - i_\Sigma L_X \omega) = (-1)^{r-1} i_{[\Sigma,X]}\omega. \tag{25}$$

More generally, the fundamental relation (11) preserves the property of being fiberwise polynomial, in the following sense: If X is a fiberwise polynomial Hamiltonian r-multivector field and f is a Hamiltonian $(n-r)$-form associated with X, then modifying f by addition of an appropriate

closed $(n-r)$-form if necessary, we may always assume, without loss of generality, that f is fiberwise polynomial as well. Conversely, if f is a fiberwise polynomial Hamiltonian $(n-r)$-form and X is a Hamiltonian r-multivector field associated with f, then modifying X by addition of an appropriate r-multivector field taking values in the kernel of ω if necessary, we may always assume, without loss of generality, that X is fiberwise polynomial as well.

II. HAMILTONIAN MULTIVECTOR FIELDS

Our aim in this section is to determine the explicit form, in adapted local coordinates, of locally Hamiltonian r-multivector fields on the extended multiphase space P, where $0 \leqslant r \leqslant n+1$. (Multivector fields of tensor degree $>n+1$ are uninteresting since they always take their values in the kernel of ω.)

As a first step towards this goal, we shall determine the explicit form, in adapted local coordinates, of the multivector fields on P taking values in the kernel of ω; this will also serve to identify, in the next section, the content of the kernel condition (13) that characterizes Poisson forms. To this end, note first that ω being a homogeneous differential form (of degree $n+1$), its kernel is graded, that is, if an inhomogeneous multivector field takes values in the kernel of ω, so do all its homogeneous components.

Proposition 2.1: Every r-multivector field X on P admits, in adapted local coordinates, a unique decomposition of the form

$$X = \frac{1}{r!} X^{\mu_1 \cdots \mu_r} \frac{\partial}{\partial x^{\mu_1}} \wedge \cdots \wedge \frac{\partial}{\partial x^{\mu_r}} + \frac{1}{(r-1)!} X^{i,\mu_2 \cdots \mu_r} \frac{\partial}{\partial q^i} \wedge \frac{\partial}{\partial x^{\mu_2}} \wedge \cdots \wedge \frac{\partial}{\partial x^{\mu_r}}$$
$$+ \frac{1}{r!} X_i^{\mu_1 \cdots \mu_r} \frac{\partial}{\partial p_i^{\mu_1}} \wedge \frac{\partial}{\partial x^{\mu_2}} \wedge \cdots \wedge \frac{\partial}{\partial x^{\mu_r}} + \frac{1}{(r-1)!} \tilde{X}^{\mu_2 \cdots \mu_r} \frac{\partial}{\partial p} \wedge \frac{\partial}{\partial x^{\mu_2}} \wedge \cdots \wedge \frac{\partial}{\partial x^{\mu_r}} + \xi, \tag{26}$$

where all coefficients are totally antisymmetric in their space-time indices and ξ takes values in the kernel of ω.

Proof: This is an immediate consequence of the particular form of ω in adapted local coordinates, Eq. (3). For more details, see Ref. 9. □

With this local coordinate representation at hand, we are in a position to analyze the restrictions imposed on the coefficients $X^{\mu_1 \cdots \mu_r}$, $X^{i,\mu_2 \cdots \mu_r}$, $X_i^{\mu_1 \cdots \mu_r}$, and $\tilde{X}^{\mu_2 \cdots \mu_r}$ by requiring X to be locally Hamiltonian. (Of course, it makes no sense to discuss the question which locally Hamiltonian multivector fields are also globally Hamiltonian when working in local coordinates.) As a warm-up exercise, we shall settle the extreme cases of tensor degree 0 and $n+1$.

Proposition 2.2: A function on P, regarded as a 0-multivector field, is locally Hamiltonian if and only if it is constant; it is then also exact Hamiltonian. Similarly, an $(n+1)$-multivector field on P, with standard local coordinate representation

$$X = \tilde{X} \frac{\partial}{\partial p} \wedge \frac{\partial}{\partial x^1} \wedge \cdots \wedge \frac{\partial}{\partial x^n} + \xi, \tag{27}$$

where ξ takes values in the kernel of ω, is locally Hamiltonian if and only if the coefficient function $\tilde{X}$ is constant and is exact Hamiltonian if and only if it vanishes.

Proof: For functions, we use the fact that the operator i_1 corresponding to the constant function 1 on a manifold is defined to be the identity, so that the operator i_f corresponding to an arbitrary function f on a manifold is simply multiplication by f. Therefore, we have for any differential form α

$$L_f \alpha = \mathrm{d}(i_f \alpha) - i_f \, \mathrm{d}\alpha = \mathrm{d}(f\alpha) - f \, \mathrm{d}\alpha = \mathrm{d}f \wedge \alpha,$$

implying that if f is constant, $L_f \alpha = 0$ no matter what α one chooses. On the other hand, an explicit calculation in adapted local coordinates shows that the condition $L_f \omega = 0$ forces all partial deriva-

tives of f to vanish; see Ref. 9. Similarly, for multivector fields of degree $n+1$, it is clear that, as r equals $n+1$, the first three terms in Eq. (26) also take values in the kernel of ω and can thus be incorporated into ξ. Therefore, by setting $\widetilde{X}^{\mu_1\cdots\mu_n}=\epsilon^{\mu_1\cdots\mu_n}\widetilde{X}$, we see that $i_X\omega=-\widetilde{X}$. But $L_X\omega=\mathrm{d}(i_X\omega)-(-1)^n i_X\,\mathrm{d}\omega=\mathrm{d}(i_X\omega)$ and $L_X\theta=\mathrm{d}(i_X\theta)-(-1)^{n+1}i_X\,\mathrm{d}\theta=(-1)^{n+1}i_X\omega$, so the proposition follows. □

The intermediate cases $(0<r\leqslant n)$ are much more interesting. However, the situation for tensor degree n is substantially different from that for tensor degree $<n$ and hence will be dealt with first. To simplify the notation, we write

$$X^{\mu_1\cdots\mu_n}=\epsilon^{\mu_1\cdots\mu_n}\widetilde{X},\quad X^{i,\mu_2\cdots\mu_n}=\epsilon^{\mu_2\cdots\mu_n\mu}X^i_\mu,$$

$$X^{\mu_1\cdots\mu_n}_i=\epsilon^{\mu_1\cdots\mu_n}X_i,\quad \widetilde{X}^{\mu_2\cdots\mu_n}=\epsilon^{\mu_2\cdots\mu_n\mu}X_\mu,$$

so that we obtain

$$i_X\omega=(-1)^{n-1}\widetilde{X}\,\mathrm{d}p+X^i_\mu\,\mathrm{d}p^\mu_i-(-1)^{n-1}X_i\,\mathrm{d}q^i-X_\mu\,\mathrm{d}x^\mu, \tag{28}$$

and

$$i_X\theta=p\widetilde{X}+(-1)^{n-1}p^\mu_iX^i_\mu,$$

respectively.

Proposition 2.3: An n-multivector field X on P is locally Hamiltonian if and only if, locally and modulo terms taking values in the kernel of ω, it can be written in terms of a single function f, as follows:

$$\begin{aligned}X=&-\frac{1}{(n-1)!}\epsilon^{\mu_2\cdots\mu_n\mu}\left(\frac{\partial f}{\partial x^\mu}\frac{\partial}{\partial p}-\frac{1}{n}\frac{\partial f}{\partial p}\frac{\partial}{\partial x^\mu}\right)\wedge\frac{\partial}{\partial x^{\mu_2}}\wedge\cdots\wedge\frac{\partial}{\partial x^{\mu_n}}\\&+\frac{1}{(n-1)!}\epsilon^{\mu_2\cdots\mu_n\mu}\left(\frac{\partial f}{\partial p^\mu_i}\frac{\partial}{\partial q^i}-\frac{1}{n}\frac{\partial f}{\partial q^i}\frac{\partial}{\partial p^\mu_i}\right)\wedge\frac{\partial}{\partial x^{\mu_2}}\wedge\cdots\wedge\frac{\partial}{\partial x^{\mu_n}}.\end{aligned} \tag{29}$$

Moreover, X is exact Hamiltonian if and only if f is a linear function of the multimomentum variables p^ρ_r and the energy variable p.

Proof: Obviously, X is locally Hamiltonian if and only if, locally, $i_X\omega=\mathrm{d}f$ for some function f, which in view of Eq. (28) leads to the following system of equations for the coefficients $\widetilde{X}$, X^i_μ, X_i, and X_μ of X:

$$\widetilde{X}=(-1)^{n-1}\frac{\partial f}{\partial p},\quad X^i_\mu=\frac{\partial f}{\partial p^\mu_i},\quad X_i=(-1)^n\frac{\partial f}{\partial q^i},\quad X_\mu=-\frac{\partial f}{\partial x^\mu}.$$

Inserting this back into X, we arrive at Eq. (29). Note also that then,

$$i_X\theta=(-1)^{n-1}p\frac{\partial f}{\partial p}+(-1)^{n-1}p^\mu_i\frac{\partial f}{\partial p^\mu_i}=(-1)^{n-1}L_\Sigma f.$$

Next, X will be exact Hamiltonian if and only if, in addition,

$$f=(-1)^{n-1}i_X\theta,$$

which in view of the preceding equation means that f must be an eigenfunction of the scaling operator L_Σ with eigenvalue 1, this is well known to be the case if and only if f is linear in the multimomentum variables p^ρ_r and the energy variable p. □

Now we turn to multivector fields of tensor degree $<n$. Here, the main result is the following.

Theorem 2.4: *An r-multivector field X on P, with $0<r<n$, is locally Hamiltonian if and only*

if the coefficients $X^{\mu_1\cdots\mu_r}$, $X^{i,\mu_2\cdots\mu_r}$, $X_i^{\mu_1\cdots\mu_r}$, *and* $\widetilde{X}^{\mu_2\cdots\mu_r}$ *in its standard local coordinate representation (26) satisfy the following conditions:*

(1) *The coefficients* $X^{\mu_1\cdots\mu_r}$ *depend only on the local coordinates* x^ρ *for* M *and, in the special case* $N=1$, *also on the local fiber coordinates* q^r *for* E,

(2) *The coefficients* $X^{i,\mu_2\cdots\mu_r}$ *are "antisymmetric polynomials in the multimomentum variables" of degree* $r-1$, *i.e., they can be written in the form*

$$X^{i,\mu_2\cdots\mu_r}=\sum_{s=1}^{r}X_{s-1}^{i,\mu_2\cdots\mu_r}, \tag{30}$$

with

$$X_{s-1}^{i,\mu_2\cdots\mu_r}=\frac{1}{(s-1)!}\frac{1}{(r-s)!}\sum_{\pi\in S_{r-1}}(-1)^\pi p_{i_2}^{\mu_{\pi(2)}}\cdots p_{i_s}^{\mu_{\pi(s)}}Y_{s-1}^{ii_2\cdots i_s,\mu_{\pi(s+1)}\cdots\mu_{\pi(r)}}, \tag{31}$$

where S_{r-1} *denotes the permutation group of* $\{2,\ldots,r\}$ *and the coefficients* $Y_{s-1}^{ii_2\cdots i_s,\mu_{s+1}\cdots\mu_r}$ *depend only on the local coordinates* x^ρ *for* M *as well as the local fiber coordinates* q^r *for* E *and are totally antisymmetric in* $i,i_2,\ldots,i_s$ *as well as in* $\mu_{s+1},\ldots,\mu_r$.

(3) *The remaining coefficients* $X_i^{\mu_1\cdots\mu_r}$ *and* $\widetilde{X}^{\mu_2\cdots\mu_r}$ *can be expressed in terms of the previous ones and of new coefficients* $X_-^{\mu_1\cdots\mu_r}$ *depending only on the local coordinates* x^ρ *for* M *as well as the local fiber coordinates* q^r *for* E *and are totally antisymmetric in* $\mu_1,\ldots,\mu_r$, *according to*

$$\begin{aligned}X_i^{\mu_1\cdots\mu_r}=&-p\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial q^i}+p_i^\mu\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial x^\mu}-\sum_{s=1}^{r}p_i^{\mu_s}\frac{\partial X^{\mu_1\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}\\&-\Sigma^{-1}\left(\sum_{s=1}^{r}(-1)^{s-1}p_j^{\mu_s}\frac{\partial X^{j,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial q^i}\right)+\frac{\partial X_-^{\mu_1\cdots\mu_r}}{\partial q^i},\end{aligned} \tag{32}$$

(the first term being absent as soon as $N>1$*) and*

$$\begin{aligned}\widetilde{X}^{\mu_2\cdots\mu_r}=&(-1)^r p\frac{\partial X^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}-\Sigma^{-1}\left(p_i^\mu\frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial x^\mu}-\sum_{s=2}^{r}p_i^{\mu_s}\frac{\partial X^{i,\mu_2\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}\right)\\&-(-1)^r\frac{\partial X_-^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}.\end{aligned} \tag{33}$$

It is exact Hamiltonian if and only if, in addition, the coefficents $X^{i,\mu_2\cdots\mu_r}$ *depend only on the local coordinates* x^ρ *for* M *as well as the local fiber coordinates* q^r *for* E *and the coefficients* $X_-^{\mu_1\cdots\mu_r}$ *vanish.*

Proof: The proof will be carried out by "brute force" computation.[9] We obtain for the Lie derivative of ω along X the expression

$$\begin{aligned}L_X\omega=&-\frac{1}{(r-2)!}\frac{\partial\widetilde{X}^{\mu_3\cdots\mu_r\nu}}{\partial x^\nu}\mathrm{d}^n x_{\mu_3\cdots\mu_r}-\frac{1}{(r-1)!}\left(\frac{\partial\widetilde{X}^{\mu_2\cdots\mu_r}}{\partial q^i}-(-1)^{r-1}\frac{\partial X_i^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}\right)\mathrm{d}q^i\wedge\mathrm{d}^n x_{\mu_2\cdots\mu_r}\\&-\frac{1}{(r-1)!}\left(\frac{\partial\widetilde{X}^{\mu_2\cdots\mu_r}}{\partial p_i^\mu}+\frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial x^\mu}-\sum_{s=2}^{r}\delta_\mu^{\mu_s}\frac{\partial X^{i,\mu_2\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}\right)\mathrm{d}p_i^\mu\wedge\mathrm{d}^n x_{\mu_2\cdots\mu_r}\\&-\frac{1}{(r-1)!}\left(\frac{\partial\widetilde{X}^{\mu_2\cdots\mu_r}}{\partial p}+(-1)^{r-1}\frac{\partial X^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}\right)\mathrm{d}p\wedge\mathrm{d}^n x_{\mu_2\cdots\mu_r}\\&-\frac{(-1)^r}{r!}\left(\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial q^i}+\frac{\partial X_i^{\mu_1\cdots\mu_r}}{\partial p}\right)\mathrm{d}q^i\wedge\mathrm{d}p\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r}\end{aligned}$$

$$
\begin{aligned}
&-\frac{(-1)^r}{r!}\left(\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial p_i^\mu}-\sum_{s=1}^r(-1)^{s-1}\delta_\mu^{\mu_s}\frac{\partial X^{i,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial p}\right)\mathrm{d}p_i^\mu\wedge\mathrm{d}p\wedge\mathrm{d}^nx_{\mu_1\cdots\mu_r}\\
&+\frac{(-1)^r}{r!}\left(\delta_i^k\delta_\kappa^\mu\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial x^\mu}-\sum_{s=1}^r\delta_i^k\delta_\kappa^{\mu_s}\frac{\partial X^{\mu_1\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}\right.\\
&\left.-\sum_{s=1}^r(-1)^{s-1}\delta_\kappa^{\mu_s}\frac{\partial X^{k,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial q^i}-\frac{\partial X_i^{\mu_1\cdots\mu_r}}{\partial p_k^\kappa}\right)\mathrm{d}q^i\wedge\mathrm{d}p_k^\kappa\wedge\mathrm{d}^nx_{\mu_1\cdots\mu_r}\\
&-\frac{(-1)^r}{r!}\frac{\partial X_i^{\mu_1\cdots\mu_r}}{\partial q^j}\mathrm{d}q^i\wedge\mathrm{d}q^j\wedge\mathrm{d}^nx_{\mu_1\cdots\mu_r}+\frac{(-1)^{r-1}}{(r-1)!}\frac{\partial X^{l,\mu_2\cdots\mu_r}}{\partial p_k^\kappa}\mathrm{d}p_k^\kappa\wedge\mathrm{d}p_l^\lambda\wedge\mathrm{d}^nx_{\lambda\mu_2\cdots\mu_r}\\
&-\frac{1}{r!}\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial q^j}\mathrm{d}q^i\wedge\mathrm{d}q^j\wedge\mathrm{d}p_i^\mu\wedge\mathrm{d}^nx_{\mu\mu_1\cdots\mu_r}-\frac{1}{r!}\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial p_k^\kappa}\mathrm{d}q^l\wedge\mathrm{d}p_k^\kappa\wedge\mathrm{d}p_l^\lambda\wedge\mathrm{d}^nx_{\lambda\mu_1\cdots\mu_r}\\
&+\frac{1}{r!}\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial p}\mathrm{d}q^i\wedge\mathrm{d}p_i^\mu\wedge\mathrm{d}p\wedge\mathrm{d}^nx_{\mu\mu_1\cdots\mu_r}.
\end{aligned}
$$

(Note that the last three terms would have to be omitted if $r=n$.)

Let us number the terms in this equation from 1 to 12. As we shall see, each of these terms must vanish separately.

Term No. 12: After contraction with a suitably chosen $(n-r+2)$-multivector field, we see that $X^{\kappa_1\cdots\kappa_r}$ cannot depend on p.

Term No. 11: Given indices i, μ and mutually different indices $\kappa_1,\ldots,\kappa_r$, we choose indices j and $\nu\notin\{\kappa_1,\ldots,\kappa_r\}$ (here we use the hypothesis that $r<n$) such that either $j\neq i$ or $\nu\neq\mu$ and, when $r<n-1$, a complementary set of indices $\nu_1,\ldots,\nu_{n-r-1}$ to contract this term with the multivector field $\partial_j\wedge\partial_\mu^i\wedge\partial_\nu^j\wedge\partial_{\nu_1}\wedge\cdots\wedge\partial_{\nu_{n-r-1}}$ (no sum over j), concluding that $X^{\kappa_1\cdots\kappa_r}$ cannot depend on p_i^μ. Obviously, there is one case where this argument does not work, namely when $N=1$, $r=n-1$, and $\mu\notin\{\kappa_1,\ldots,\kappa_r\}$. This situation will however be covered in the next item.

Term No. 6: Given indices k, κ and mutually different indices $\kappa_1,\ldots,\kappa_r$ such that $\kappa\notin\{\kappa_1,\ldots,\kappa_r\}$, we choose a complementary set of indices $\nu_1,\ldots,\nu_{n-r-1}$ to contract this term with the multivector field $\partial_\kappa^k\wedge\partial_0\wedge\partial_\kappa\wedge\partial_{\nu_1}\wedge\cdots\wedge\partial_{\nu_{n-r-1}}$, concluding that $X^{\kappa_1\cdots\kappa_r}$ cannot depend on p_k^κ, since in this case the second term in the bracket gives no contribution. In particular, this settles the remaining case of the previous item.

Term No. 10: After contraction with a suitably chosen $(n-r+2)$ - multivector field, we see that $X^{\kappa_1\cdots\kappa_r}$ cannot depend on q^l if $N>1$. For $N=1$, the whole term vanishes identically, and no conclusion can be drawn.

This proves the statements in item (1) of the theorem. Moreover, it allows to simplify *term No. 6*, as follows:

$$
-\frac{(-1)^{r-1}}{(r-1)!}\frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial p}\mathrm{d}p_i^\mu\wedge\mathrm{d}p\wedge\mathrm{d}^nx_{\mu\mu_2\cdots\mu_r}.
$$

As before, contraction with a suitably chosen $(n-r+2)$-multivector field shows that $X^{k,\kappa_2\cdots\kappa_r}$ cannot depend on p.

Next we analyze *term No. 9*, which will give an important restriction on the coefficients $X^{i,\mu_2\cdots\mu_r}$. Given indices i,j,μ,ν and mutually different indices $\kappa_2,\ldots,\kappa_r$, we choose a set of indices $\nu_1,\ldots,\nu_{n-r}$ such that $\{\kappa_2,\ldots,\kappa_r\}\cap\{\nu_1,\ldots,\nu_{n-r}\}=\emptyset$ to contract this term with the multivector field $\partial_\mu^i\wedge\partial_\nu^j\wedge\partial_{\nu_1}\wedge\cdots\wedge\partial_{\nu_{n-r}}$, obtaining

$$\frac{\partial X^{j,\mu_2\cdots\mu_r}}{\partial p_i^\mu}\epsilon_{\nu\mu_2\cdots\mu_r\nu_1\cdots\nu_{n-r}}=\frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial p_j^\nu}\epsilon_{\mu\mu_2\cdots\mu_r\nu_1\cdots\nu_{n-r}}. \tag{34}$$

Now assume the index ν to be chosen such that $\nu\notin\{\kappa_2,\ldots,\kappa_r,\nu_1,\ldots,\nu_{n-r}\}$. Then if $\mu\notin\{\kappa_2,\ldots,\kappa_r\}$, we can take $\mu=\nu_1$, say, to conclude that $X^{j,\kappa_2\cdots\kappa_r}$ cannot depend on p_i^μ,

$$\frac{\partial X^{j,\mu_2\cdots\mu_r}}{\partial p_i^\mu}=0 \quad \text{if } \mu\notin\{\mu_2,\ldots,\mu_r\}. \tag{35}$$

Moreover, if $\mu\in\{\kappa_2,\ldots,\kappa_r\}$, this result implies that applying an operator $\partial_\mu^{i'}$ (with arbitrary i') to Eq. (34) gives zero since on the right-hand side (rhs), the ϵ-tensor kills all terms in the sum over the indices $\mu_2,\ldots,\mu_r$ in which the index μ appears among them,

$$\frac{\partial^2 X^{j,\mu_2\cdots\mu_r}}{\partial p_{i_1}^\mu\partial p_{i_2}^\mu}=0 \quad \text{if } \mu\in\{\mu_2,\ldots,\mu_r\} \quad (\text{no sum over } \mu). \tag{36}$$

The general solution to Eqs. (35) and (36) can be written in the form

$$X^{j,\mu_2\cdots\mu_r}=\sum_{s=1}^{r}\frac{1}{(s-1)!}\frac{1}{(r-s)!}\sum_{\pi\in S_{r-1}}(-1)^\pi p_{j_2}^{\mu_{\pi(2)}}\cdots p_{j_s}^{\mu_{\pi(s)}}Y_{s-1}^{j,j_2\cdots j_s,\mu_{\pi(s+1)}\cdots\mu_{\pi(r)}},$$

where S_{r-1} denotes the permutation group of $\{2,\ldots,r\}$ and the newly introduced coefficients $Y_{s-1}^{i,j_2\cdots j_s,\mu_{s+1}\cdots\mu_r}$ are local functions on E, they do not depend on the multimomentum variables p_k^κ or the energy variable p and are totally antisymmetric both in $j_2,\ldots,j_s$ and in $\mu_{s+1},\ldots,\mu_r$. Differentiating this expression with respect to p_i^μ with $\mu=\mu_2$ gives

$$\begin{aligned}&\frac{\partial X^{j,\mu\mu_3\cdots\mu_r}}{\partial p_i^\mu}\epsilon_{\nu\mu\mu_3\cdots\mu_r\nu_1\cdots\nu_{n-r}} \quad (\text{no sum over } \mu)\\ &=\sum_{s=2}^{r}\frac{1}{(s-2)!}\frac{1}{(r-s)!}\sum_{\pi\in S_{r-2}}(-1)^\pi p_{j_3}^{\mu_{\pi(3)}}\cdots p_{j_s}^{\mu_{\pi(s)}}Y_{s-1}^{j,ij_3\cdots j_s,\mu_{\pi(s+1)}\cdots\mu_{\pi(r)}}\epsilon_{\nu\mu\mu_3\cdots\mu_r\nu_1\cdots\nu_{n-r}},\end{aligned}$$

where S_{r-2} denotes the permutation group of $\{3,\ldots,r\}$, which shows that Eq. (34) will hold provided that

$$Y_{s-1}^{j,ij_3\cdots j_s,\mu_{\pi(s+1)}\cdots\mu_{\pi(r)}}=-Y_{s-1}^{i,jj_3\cdots j_s,\mu_{\pi(s+1)}\cdots\mu_{\pi(r)}}.$$

This proves the statements in item (2) of the theorem.

We proceed with *terms Nos. 4 and 5* which imply

$$\frac{\partial\widetilde{X}^{\mu_2\cdots\mu_r}}{\partial p}=(-1)^r\frac{\partial X^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}, \quad \frac{\partial X_i^{\mu_1\cdots\mu_r}}{\partial p}=-\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial q^i}. \tag{37}$$

We observe first of all that the rhs of both equations does not depend on the energy variable, so they can be immediately integrated with respect to p.

From *term No. 3* we infer

$$\frac{\partial\widetilde{X}^{\mu_2\cdots\mu_r}}{\partial p_i^\mu}=-\frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial x^\mu}+\sum_{s=2}^{r}\delta_\mu^{\mu_s}\frac{\partial X^{i,\mu_2\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}. \tag{38}$$

An explicit calculation shows that the rhs of this equation does not depend on the p_j^μ, not only when $\mu\notin\{\mu_2,\ldots,\mu_r\}$ but even when $\mu\in\{\mu_2,\ldots,\mu_r\}$. (Of course, it also does not depend on p.) Thus, according to Lemma A.2 formulated in the appendix, we can integrate Eq. (38) explicitly to obtain (recall that Σ^{-1} is the operator that acts on polynomials in the multimomentum variables

and the energy variable without constant term by multiplying the homogeneous component of degree s by $1/s$)

$$\widetilde{X}^{\mu_2\cdots\mu_r} = (-1)^r p \frac{\partial X^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu} - \Sigma^{-1}\left(p_i^\mu \frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial x^\mu} - \sum_{s=2}^{r} p_i^{\mu_s} \frac{\partial X^{i,\mu_2\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu} \right) + \widetilde{Y}^{\mu_2\cdots\mu_r}, \tag{39}$$

where the $\widetilde{Y}^{\mu_2\cdots\mu_r}$ are local functions on E: they do not depend on the multimomentum variables or on the energy variable.

The same procedure works for *term No. 7*. There, we are left with

$$\frac{\partial X_i^{\mu_1\cdots\mu_r}}{\partial p_k^\kappa} = \delta_i^k \delta_\kappa^\mu \frac{\partial X^{\mu_1\cdots\mu_r}}{\partial x^\mu} - \sum_{s=1}^{r} \delta_i^k \delta_\kappa^{\mu_s} \frac{\partial X^{\mu_1\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu} - \sum_{s=1}^{r} (-1)^{s-1} \delta_\kappa^{\mu_s} \frac{\partial X^{k,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial q^i}. \tag{40}$$

Using the same argument as before, we show that the rhs does not depend on the p_l^κ, not only when $\kappa \notin \{\mu_1, \ldots, \mu_r\}$ but even when $\kappa \in \{\mu_1, \ldots, \mu_r\}$, and neither does it depend on p. Therefore, we can integrate Eq. (40) explicitly to obtain

$$\begin{aligned} X_i^{\mu_1\cdots\mu_r} = &- p \frac{\partial X^{\mu_1\cdots\mu_r}}{\partial q^i} + p_i^\mu \frac{\partial X^{\mu_1\cdots\mu_r}}{\partial x^\mu} - \sum_{s=1}^{r} p_i^{\mu_s} \frac{\partial X^{\mu_1\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu} \\ &- \Sigma^{-1}\left(\sum_{s=1}^{r} (-1)^{s-1} p_k^{\mu_s} \frac{\partial X^{k,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial q^i} \right) + Y_i^{\mu_1\cdots\mu_r}, \end{aligned} \tag{41}$$

where the $Y_i^{\mu_1\cdots\mu_r}$ are local functions on E: they do not depend on the multimomentum variables or on the energy variable.

Finally, we turn to *terms Nos. 1, 2, and 8*. They imply

$$\frac{\partial \widetilde{X}^{\mu_3\cdots\mu_r\nu}}{\partial x^\nu} = 0, \quad \frac{\partial \widetilde{X}^{\mu_2\cdots\mu_r}}{\partial q^i} = (-1)^{r-1} \frac{\partial X_i^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}, \quad \frac{\partial X_i^{\mu_1\cdots\mu_r}}{\partial q^j} = \frac{\partial X_j^{\mu_1\cdots\mu_r}}{\partial q^i},$$

respectively. With the help of (39), these reduce to

$$\frac{\partial \widetilde{Y}^{\mu_3\cdots\mu_r\nu}}{\partial x^\nu} = 0, \quad \frac{\partial \widetilde{Y}^{\mu_2\cdots\mu_r}}{\partial q^i} = (-1)^{r-1} \frac{\partial Y_i^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}, \quad \frac{\partial Y_i^{\mu_1\cdots\mu_r}}{\partial q^j} = \frac{\partial Y_j^{\mu_1\cdots\mu_r}}{\partial q^i},$$

which is easily solved by setting

$$\widetilde{Y}^{\mu_2\cdots\mu_r} = (-1)^{r-1} \frac{\partial X_-^{\mu_2\cdots\mu_r\mu}}{\partial x^\mu}, \quad Y_i^{\mu_1\cdots\mu_r} = \frac{\partial X_-^{\mu_1\cdots\mu_r}}{\partial q^i}. \tag{42}$$

Here, the $X_-^{\mu_1\cdots\mu_r}$ are local functions on E: they do not depend on the multimomentum variables or on the energy variable. This completes the proof of the statements in item (3) of the theorem.

All that remains to be shown are the final statements concerning exact Hamiltonian multivector fields. To this end, we calculate

$$
\begin{aligned}
L_X\theta = \frac{1}{(r-1)!}\Bigg(&\frac{\partial X^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}p - (-1)^r\frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial x^\mu}p_i^\mu \\
&+ (-1)^r\sum_{s=2}^{r}\frac{\partial X^{i,\mu_2\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}p_i^{\mu_s} - (-1)^r\widetilde{X}^{\mu_2\cdots\mu_r}\Bigg)\mathrm{d}^n x_{\mu_2\cdots\mu_r} \\
&- \frac{1}{r!}\Bigg(\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial x^\mu}p_i^\mu - \sum_{s=1}^{r}\frac{\partial X^{\mu_1\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}p_i^{\mu_s} - \frac{\partial X^{\mu_1\cdots\mu_r}}{\partial q^i}p \\
&- \sum_{s=1}^{r}(-1)^{s-1}\frac{\partial X^{j,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial q^i}p_j^{\mu_s} - X_i^{\mu_1\cdots\mu_r}\Bigg)\mathrm{d}q^i\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r} \\
&+ \frac{1}{r!}\Bigg(\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial p_j^\nu}p + \sum_{s=1}^{r}(-1)^{s-1}\frac{\partial X^{i,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial p_j^\nu}p_i^{\mu_s}\Bigg)\mathrm{d}p_j^\nu\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r} \\
&+ \frac{1}{r!}\Bigg(\frac{\partial X^{\mu_1\cdots\mu_r}}{\partial p}p + \sum_{s=1}^{r}(-1)^{s-1}\frac{\partial X^{i,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial p}p_i^{\mu_s}\Bigg)\mathrm{d}p\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r},
\end{aligned}
$$

where we have omitted four terms that vanish because X is locally Hamiltonian. Moreover, using the expressions derived above for locally Hamiltonian multivector fields, we see that the other terms vanish as well if and only if we have

$$
(\Sigma^{-1}-1)\Bigg(\sum_{s=1}^{r}(-1)^{s-1}p_j^{\mu_s}\frac{\partial X^{j,\mu_1\cdots\mu_{s-1}\mu_{s+1}\cdots\mu_r}}{\partial q^i}\Bigg) = 0,
$$

$$
(\Sigma^{-1}-1)\Bigg(p_i^\mu\frac{\partial X^{i,\mu_2\cdots\mu_r}}{\partial x^\mu} - \sum_{s=2}^{r}p_i^{\mu_s}\frac{\partial X^{i,\mu_2\cdots\mu_{s-1}\nu\mu_{s+1}\cdots\mu_r}}{\partial x^\nu}\Bigg) = 0,
$$

and

$$
\frac{\partial X_-^{\mu_1\cdots\mu_r}}{\partial q^i} = 0, \quad \frac{\partial X_-^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu} = 0.
$$

But this means that the coefficients of the multimomentum variables in the above expressions must be independent of the multimomentum variables and that the coefficients $X_-^{\mu_1\cdots\mu_r}$ can without loss of generality be assumed to vanish, which completes the proof of the theorem. □

Proof of Theorem 1.3, part 1: The statements of Theorem 1.3 about multivector fields are, in their local form, based on the local decomposition given in Proposition 2.1, taking into account the scaling behavior of the coefficient functions that follows from Theorem 2.4, together with that of the coordinate vector fields. The global version of these statements can be obtained by glueing together such local decompositions using appropriate partitions of unity. To see that the homogeneous components X_s, $s=-1,\ldots,r-1$, of a fiberwise polynomial locally Hamiltonian r-multivector field X are locally Hamiltonian, we compute

$$
0 = (L_\Sigma)^k\,\mathrm{d}i_X\,\omega = \sum_{s=0}^{r-1}(s+1)^k\,\mathrm{d}i_{X_s}\,\omega, \quad k=1,\ldots,r-1.
$$

Together with $\mathrm{d}i_X\omega=0$, this leads to a Vandermonde matrix equation with entries $0,2,3,\ldots,r-1$ annihilating the vector $(\mathrm{d}i_{X_{-1}}\omega,\ldots,\mathrm{d}i_{X_{r-1}}\omega)^T$. As the determinant of a Vandermonde matrix does not vanish, the above vector must vanish. □

The following proposition clarifies the interpretation of homogeneous locally Hamiltonian multivector fields.

Proposition 2.5: Let X be a locally Hamiltonian r-multivector field on P. Then

(1) X is exact Hamiltonian iff $[\Sigma, X]$ *takes values in the kernel of* ω.

(2) If $[\Sigma, X] - sX$ *takes values in the kernel of* ω, *for some integer s between 0 and* $r-1$, *then X is globally Hamiltonian with associated Poisson form*

$$\frac{(-1)^{r-1}}{s+1} i_X \theta.$$

(3) If $[\Sigma, X] + X$ *takes values in the kernel of* ω, *then* $i_X \theta = 0$.

Proof: The first statement follows immediately from Eq. (25). Similarly, the second claim can be proved by multiplying Eq. (25) by $(-1)^{r-1}/(s+1)$ and combining it with Eq. (1) and Eq. (4) to give

$$\mathrm{d}\left(\frac{(-1)^{r-1}}{s+1} i_X \theta\right) = \frac{(-1)^{r-1}}{s+1} L_X \theta + \frac{1}{s+1} i_X \omega = \frac{1}{s+1} i_{[\Sigma,X]+X} \omega,$$

which equals $i_X \omega$ since, by hypothesis, $i_{[\Sigma,X]-sX}\omega = 0$. Finally, the third statement follows by observing that the kernel of ω is contained in the kernel of θ and hence according to the hypothesis made,

$$0 = i_{[\Sigma,X]+X}\theta = L_\Sigma i_X \theta - i_X L_\Sigma \theta + i_X \theta = L_\Sigma i_X \theta,$$

where we have used the invariance of θ under Σ. Therefore, according to Proposition A.1, $i_X \theta$ is the pull-back to P of an n-form on E via the projection that defines P as a vector bundle over E, which in turn can be obtained as the pull-back to E of $i_X \theta$ via the zero section of P over E. But this pull-back is zero, since θ vanishes along the zero section of P over E. □

It may be instructive to spell all this out more explicitly for locally Hamiltonian vector fields $(r=1)$.

We begin by writing down the general form of a locally Hamiltonian vector field X: in adapted local coordinates, it has the representation

$$X = X^\mu \frac{\partial}{\partial x^\mu} + X^i \frac{\partial}{\partial q^i} + X^\mu_i \frac{\partial}{\partial p^\mu_i} + \widetilde{X} \frac{\partial}{\partial p},$$

where according to Theorem 2.4, the coefficient functions X^μ and X^i depend only on the local coordinates x^ρ for M and on the local fiber coordinates q^r for E (the X^μ being independent of the latter as soon as $N > 1$), whereas the coefficient functions X^μ_i and $\widetilde{X}$ are explicitly given by

$$X^\mu_i = -p \frac{\partial X^\mu}{\partial q^i} + p^\nu_i \frac{\partial X^\mu}{\partial x^\nu} - p^\mu_i \frac{\partial X^\nu}{\partial x^\nu} - p^\mu_j \frac{\partial X^j}{\partial q^i} + \frac{\partial X^\mu_-}{\partial q^i} \tag{43}$$

(the first term being absent as soon as $N > 1$) and

$$\widetilde{X} = -p \frac{\partial X^\nu}{\partial x^\nu} - p^\mu_i \frac{\partial X^i}{\partial x^\mu} + \frac{\partial X^\nu_-}{\partial x^\nu} \tag{44}$$

with coefficient functions X^μ_- that once again depend only on the local coordinates x^ρ for M and on the local fiber coordinates q^r for E. Regarding the decomposition (19), the situation here is particularly interesting and somewhat special since ω is nondegenerate on vector fields, so there are no nontrivial vector fields taking values in the kernel of ω and hence the decomposition (19) can be improved.

Corollary 2.6: Any locally Hamiltonian vector field X on P can be uniquely decomposed into the sum of two terms,

$$X = X_- + X_+, \tag{45}$$

where

(i) *X_- has scaling degree -1, i.e., $[\Sigma, X_-] = -X_-$, and is vertical with respect to the projection onto E.*

(ii) *X_+ has scaling degree 0, i.e., $[\Sigma, X_+] = 0$, is exact Hamiltonian, is projectable onto E and coincides with the canonical lift of its projection onto E.*

Proof: In adapted local coordinates, the two contributions to X are, according to Eqs. (43) and (44), given by

$$X_- = \frac{\partial X_-^\mu}{\partial q^i}\frac{\partial}{\partial p_i^\mu} + \frac{\partial X_-^\nu}{\partial x^\nu}\frac{\partial}{\partial p}$$

and

$$X_+ = X^\mu \frac{\partial}{\partial x^\mu} + X^i \frac{\partial}{\partial q^i} - \left(\frac{\partial X^j}{\partial q^i} p_j^\mu - \frac{\partial X^\mu}{\partial x^\nu} p_i^\nu + \frac{\partial X^\nu}{\partial x^\nu} p_i^\mu + \frac{\partial X^\mu}{\partial q^i} p\right)\frac{\partial}{\partial p_i^\mu} - \left(\frac{\partial X^i}{\partial x^\mu} p_i^\mu + \frac{\partial X^\nu}{\partial x^\nu} p\right)\frac{\partial}{\partial p}.$$

Thus all statements of the corollary follow from what has already been shown, except for the very last one, which is based on the following remark. □

Remark: Every bundle automorphism of E (as a fiber bundle over M) admits a canonical lift to a bundle automorphism of its first order jet bundle JE (as an affine bundle over E) and, by appropriate (twisted affine) dualization, to the extended multiphase space P (as a vector bundle over E). Similarly, passing to generators of one-parameter groups, one sees that every vector field X_E on E that is projectable to a vector field X_M on M admits a canonical lift to a vector field X_{JE} on JE and, by appropriate (twisted affine) dualization, to a vector field X_P on P. (See, for example, Ref. 7, Sec. 4B.) When $N=1$, lifting to P is even possible for arbitrary diffeomorphisms of E and arbitrary vector fields on E, since in this case P can be identified with the nth exterior power of the cotangent bundle of E. Explicitly, in terms of adapted local coordinates (x^μ, q^i, p_i^μ, p), we may write

$$X_M = X^\mu \frac{\partial}{\partial x^\mu} \quad \text{and } X_E = X^\mu \frac{\partial}{\partial x^\mu} + X^i \frac{\partial}{\partial q^i},$$

where, except for $N=1$, the X^μ do not depend on the q^r; then the coordinate expression for the lifted vector field, X_P, is precisely given by the expression for X_+ above. Obviously, X_P has scaling degree 0 and hence is not only locally but even exact Hamiltonian. Conversely, starting with an exact Hamiltonian vector field X_+, we can obtain X_M and X_E by projection onto M and E, respectively. Thus, the coordinate expression for X_+ shows that *precisely all exact Hamiltonian vector fields are obtained by this lifting procedure*. Similarly, one can show that all diffeomorphisms of P that preserve the multicanonical form θ are obtained by lifting of automorphisms or, for $N=1$, diffeomorphisms of E, this is the field theoretical analog of a well-known theorem in geometric mechanics, according to which all diffeomorphisms of a cotangent bundle that preserve the canonical form θ are induced by diffeomorphisms of its base manifold.

To conclude this section, let us note that the definition of projectability of vector fields can be immediately generalized to multivector fields: an r-multivector field X_E on the total space E of a fiber bundle over a manifold M with bundle projection $\pi: E \to M$ is called *projectable* if for any two points e_1 and e_2 in E,

$$\Lambda^r T_{e_1}\pi \cdot X_E(e_1) = \Lambda^r T_{e_2}\pi \cdot X_E(e_2) \quad \text{if } \pi(e_1) = \pi(e_2),$$

or in other words, if there exists an r-multivector field X_M on M such that

$$\Lambda^r T\pi \circ X_E = X_M \circ \pi.$$

In adapted local coordinates, this amounts to requiring that if we write

$$X_E = \frac{1}{r!} X^{\mu_1 \cdots \mu_r} \frac{\partial}{\partial x^{\mu_1}} \wedge \cdots \wedge \frac{\partial}{\partial x^{\mu_r}} + \cdots ,$$

where the dots denote 1-vertical terms, the coefficients $X^{\mu_1 \cdots \mu_r}$ should depend only on the local coordinates x^ρ for M but not on the local fiber coordinates q^r for E. Now we introduce the following terminology.

Definition 2.7: An r-multivector field on P is called projectable if it is projectable with respect to any one of the three projections from P: to P_0, to E, and to M.

With this terminology, Theorem 2.4 states that for $0 < r < n$, locally Hamiltonian r-multivector fields on P are projectable as soon as $N > 1$ and are projectable to E but not necessarily to P_0 or to M when $N = 1$. [Inspection of Eq. (32) shows, however, that they are projectable to P_0 if and only if they are projectable to M.]

Considering the special case of vector fields ($r = 1$), we believe that vector fields on the total space of a fiber bundle over space-time which are not projectable should be regarded as pathological, since they generate transformations which do not induce transformations of space-time. It is hard to see how such transformations might be interpreted as candidates for symmetries of a physical system. By analogy, we shall adopt the same point of view regarding multivector fields of higher degree, since although these do not generate diffeomorphisms of E as a manifold, they may perhaps allow for an interpretation as generators of superdiffeomorphisms of an appropriate supermanifold built over E as its even part.

III. POISSON FORMS AND HAMILTONIAN FORMS

Our aim in this section is to give an explicit construction of Poisson $(n-r)$-forms and, more generally, of Hamiltonian $(n-r)$-forms on the extended multiphase space P, where $0 \leqslant r \leqslant n$. [Note that Eq. (11) only makes sense for r in this range.] A special role is played by closed forms, since closed forms are always Hamiltonian and closed forms that vanish on the kernel of ω are always Poisson, these are in a sense the trivial examples. In other words, the main task is to understand the extent to which general Hamiltonian forms deviate from closed forms and general Poisson forms deviate from closed forms that vanish on the kernel of ω.

As a warm-up exercise, we shall settle the extreme cases of tensor degree 0 and n. The case $r = n$ has already been analyzed in Ref. 2, so we just quote the result.

Proposition 3.1: A function f on P, regarded as a 0-form, is always Hamiltonian and even Poisson. Moreover, its associated Hamiltonian n-multivector field X is, in adapted local coordinates and modulo terms taking values in the kernel of ω, given by Eq. (29).

The case $r = 0$ is equally easy.

Proposition 3.2: An n-form f on P is Hamiltonian or Poisson if and only if it can be written as the sum of a constant multiple of θ with a closed form which is arbitrary if f is Hamiltonian and vanishes on the kernel of ω if f is Poisson.

Indeed, if f is a Hamiltonian n-form, the multivector field X that appears in Eq. (11) will in fact be a function which must be locally Hamiltonian and hence, by Proposition 2.2, constant. Thus $\mathrm{d}f$ must be proportional to ω and so f must be the sum of some constant multiple of θ and a closed form.

The intermediate cases $(0 < r < n)$ are much more interesting. To handle them, the first step is to identify the content of the kernel condition (13) in adapted local coordinates (for completeness, we also include the two extreme cases).

Proposition 3.3: An $(n-r)$-form f on P, with $0 \leqslant r \leqslant n$, vanishes on the kernel of ω if and only if, in adapted local coordinates, it can be written in the form

$$f = \frac{1}{r!} f^{\mu_1 \cdots \mu_r} \mathrm{d}^n x_{\mu_1 \cdots \mu_r} + \frac{1}{(r+1)!} f_i^{\mu_0 \cdots \mu_r} \, \mathrm{d}q^i \wedge \mathrm{d}^n x_{\mu_0 \cdots \mu_r} + \frac{1}{r!} f^{i, \mu_1 \cdots \mu_r} \, \mathrm{d}p_i^\mu \wedge \mathrm{d}^n x_{\mu \mu_1 \cdots \mu_r}$$
$$+ \frac{1}{(r+1)!} f'^{\mu_0 \cdots \mu_r} (\mathrm{d}p \wedge \mathrm{d}^n x_{\mu_0 \cdots \mu_r} - \mathrm{d}q^i \wedge \mathrm{d}p_i^\mu \wedge \mathrm{d}^n x_{\mu_0 \cdots \mu_r \mu}), \tag{46}$$

where the second term in the last parentheses is to be omitted if $r=n-1$ *whereas only the first term remains if* $r=n$.

Note that for one-forms (just as for functions), the kernel condition (13) is void, since ω is nondegenerate. Also, it is in this case usually more convenient to replace Eq. (46) by the standard local coordinate representation

$$f = f_\mu \, \mathrm{d}x^\mu + f_i \, \mathrm{d}q^i + f^i_\mu \, \mathrm{d}p^\mu_i + f_0 \, \mathrm{d}p. \tag{47}$$

Proof: From the particular expression for ω in adapted local coordinates, we see first of all that forms of degree $n-r$ vanishing on the kernel of ω must be $(n-r-2)$-horizontal (since they vanish on 3-vertical multivector fields) and that the only term which is not $(n-r-1)$-horizontal is

$$\mathrm{d}q^i \wedge \mathrm{d}p^\kappa_k \wedge \mathrm{d}^n x_{\mu_0 \cdots \mu_r \mu}.$$

Furthermore, f must vanish on the bivectors

$$\frac{\partial}{\partial q^i} \wedge \frac{\partial}{\partial p^\kappa_k} + \delta^k_i \frac{\partial}{\partial p} \wedge \frac{\partial}{\partial x^\kappa} \quad \text{and} \quad \frac{\partial}{\partial p^\mu_i} \wedge \frac{\partial}{\partial x^\nu} + \frac{\partial}{\partial p^\nu_i} \wedge \frac{\partial}{\partial x^\mu}$$

which yields the statement of the proposition. For more details, see Ref. 9 □

The proposition above can be used to prove the following interesting and useful fact.

Proposition 3.4: An $(n-r)$*-form* f *on* P, *with* $0 \leqslant r \leqslant n$, *vanishes on the kernel of* ω *if and only if there exists an* $(r+1)$*-multivector field* X *on* P *such that*

$$f = i_X \omega. \tag{48}$$

Then obviously,

$$\mathrm{d}f = L_X \omega. \tag{49}$$

In particular, f *is closed if and only if* X *is locally Hamiltonian*.

At every point of P, the statement that the inclusion of the kernel of ω in the kernel of f implies that there is a multivector Y such that $i_Y \omega = f$ at this point, can be shown without reference to the particular form of ω.[10] However, the expression for ω in adapted local coordinates shows that we can even obtain a multivector field Y with this property.

Proof: The "if" part being obvious, observe that it suffices to prove the "only if" part locally, in the domain of definition of an arbitrary system of adapted local coordinates, by constructing the coefficients of X from those of f. [Indeed, since the relation between f and X postulated in Eq. (48) is purely algebraic, i.e., it does not involve derivatives, we can construct a global solution patching together local solutions with a partition of unity.] A comparison of $i_X \omega$, where X is an $(r+1)$-multivector field [!] given by Eq. (26), with (46) shows that when $r < n$, this can be achieved by setting

$$X^{\mu_0 \cdots \mu_r} = (-1)^r f'^{\mu_0 \cdots \mu_r}, \quad X^{i,\mu_1 \cdots \mu_r} = (-1)^r f^{i,\mu_1 \cdots \mu_r}, \tag{50}$$

$$X^{\mu_0 \cdots \mu_r}_i = (-1)^{r+1} f^{\mu_0 \cdots \mu_r}_i, \quad \widetilde{X}^{\mu_1 \cdots \mu_r} = -f^{\mu_1 \cdots \mu_r}, \tag{51}$$

while for $r=n$, only the last equation is pertinent [for $r=n-1$, the same conclusion can also be reached by comparing (28) and (47)]. □

Corollary 3.5: An $(n-r)$*-form* f *on* P, *with* $0 \leqslant r \leqslant n$, *is a Hamiltonian form if and only if* $\mathrm{d}f$ *vanishes on the kernel of* ω *and is a Poisson form if and only if both* $\mathrm{d}f$ *and* f *vanish on the kernel of* ω.

With these preliminaries out of the way, we can proceed to the construction of Poisson forms which are not closed. As we shall see, there are two such constructions which, taken together, will be sufficient to handle the general case.

The first construction is a generalization of the universal multimomentum map of Ref. 2, which to each exact Hamiltonian r-multivector field F on P associates a Poisson $(n-r)$-form $J(F)$ on P defined by Eq. (52) below. What remained unnoticed in Ref. 2 is that this construction works even when X is only locally Hamiltonian. In fact, we have the following generalization of Proposition 4.3 of Ref. 2.

Proposition 3.6: For every locally Hamiltonian r-multivector field F on P, with $0 \leqslant r \leqslant n$, *the formula*

$$J(F) = (-1)^{r-1} i_F \theta \tag{52}$$

defines a Poisson $(n-r)$*-form* $J(F)$ *on* P *whose associated Hamiltonian multivector field is* $F+[\Sigma,F]$, *that is, we have*

$$\mathrm{d}(J(F)) = i_{F+[\Sigma,F]}\omega. \tag{53}$$

Proof: Obviously, $J(F)$ vanishes on the kernel of ω since this is contained in the kernel of θ. Moreover, since $L_F\omega$ is supposed to vanish, we can use the algebraic relations for the Lie derivative along multivector fields and $\theta = -i_\Sigma \omega$ to compute

$$\mathrm{d}(J(F)) = (-1)^{r-1}\mathrm{d}(i_F\theta) = (-1)^{r-1}L_F\theta - i_F\,\mathrm{d}\,\theta = (-1)^r L_F i_\Sigma\omega + i_\Sigma L_F\omega + i_F\omega = -i_{[F,\Sigma]}\omega + i_F\omega.$$

□

The second construction uses differential forms on E, pulled back to differential forms on P via the target projection $\tau: P \to E$. Characterizing which of these are Hamiltonian forms and which are Poisson forms is a simple exercise.

Proposition 3.7: Let f_0 *be an* $(n-r)$*-form on* E, *with* $0 < r < n$. *Then*

(i) $\tau^* f_0$ *is a Hamiltonian form on P if and only if* $\mathrm{d}f_0$ *is* $(n-r)$*-horizontal.*

(ii) $\tau^* f_0$ *is a Poisson form on P if and only if* f_0 *is* $(n-r-1)$*-horizontal and* $\mathrm{d}f_0$ *is* $(n-r)$*-horizontal.*

Proof: In adapted local coordinates (x^μ, q^i) for E and (x^μ, q^i, p_i^μ, p) for P, we can write

$$f_0 = \frac{1}{r!} f_0^{\mu_1\cdots\mu_r}\mathrm{d}^n x_{\mu_1\cdots\mu_r} + \frac{1}{(r+1)!}(f_0)_i^{\mu_0\cdots\mu_r}\,\mathrm{d}q^i \wedge \mathrm{d}^n x_{\mu_0\cdots\mu_r} + \cdots, \tag{54}$$

where the dots denote higher order terms containing at least two $\mathrm{d}q$'s. Now applying Proposition 3.3 to $\tau^* f_0$, we see that $\tau^* f_0$ will vanish on the kernel of ω if and only if the terms denoted by the dots all vanish, i.e., if f_0 can be written in the form

$$f_0 = \frac{1}{r!} f_0^{\mu_1\cdots\mu_r}\mathrm{d}^n x_{\mu_1\cdots\mu_r} + \frac{1}{(r+1)!}(f_0)_i^{\mu_0\cdots\mu_r}\,\mathrm{d}q^i \wedge \mathrm{d}^n x_{\mu_0\cdots\mu_r}. \tag{55}$$

But this is precisely the condition for the $(n-r)$-form f_0 to be $(n-r-1)$-horizontal. (Note that this equivalence holds even when $r=n-1$, provided we understand the condition of being 0-horizontal to be empty.) Similarly, since Proposition 3.4 implies that a form on P is Hamiltonian if and only if its exterior derivative vanishes on the kernel of ω, the same argument applied to $\mathrm{d}(\tau^* f_0) = \tau^*\,\mathrm{d}f_0$ shows that, irrespectively of whether $\tau^* f_0$ itself vanishes on the kernel of ω or not and hence whether we use Eq. (54) or Eq. (55) as our starting point, $\tau^* f_0$ will be Hamiltonian if and only if

$$\mathrm{d}f_0 = \frac{1}{(r-1)!}\frac{\partial f_0^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}\mathrm{d}^n x_{\mu_2\cdots\mu_r} + \frac{1}{r!}\left(\frac{\partial f_0^{\mu_1\cdots\mu_r}}{\partial q^i} - \frac{\partial (f_0)_i^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu}\right)\mathrm{d}q^i \wedge \mathrm{d}^n x_{\mu_1\cdots\mu_r}.$$

But this is precisely the condition for the $(n-r+1)$-form $\mathrm{d}f_0$ to be $(n-r)$-horizontal. Moreover, it is easy to write down an associated Hamiltonian r-multivector field X_0,

$$X_0 = \frac{(-1)^r}{r!}\left(\frac{\partial f_0^{\mu_1\cdots\mu_r}}{\partial q^i} - \frac{\partial (f_0)_i^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu}\right)\frac{\partial}{\partial p_i^{\mu_1}} \wedge \frac{\partial}{\partial x^{\mu_2}} \wedge \cdots \wedge \frac{\partial}{\partial x^{\mu_r}}$$
$$- \frac{1}{(r-1)!}\frac{\partial f_0^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}\frac{\partial}{\partial p} \wedge \frac{\partial}{\partial x^{\mu_2}} \wedge \cdots \wedge \frac{\partial}{\partial x^{\mu_r}}.$$

□

Note also that if f_0 is $(n-r-1)$-horizontal and thus has the form stated in Eq. (55), $\mathrm{d}f_0$ would contain just one additional higher order term, namely

$$\frac{1}{(r+1)!}\frac{\partial (f_0)_j^{\mu_0\cdots\mu_r}}{\partial q^i}\mathrm{d}q^i \wedge \mathrm{d}q^j \wedge \mathrm{d}^n x_{\mu_0\cdots\mu_r}.$$

Its absence means that

$$\frac{\partial (f_0)_j^{\mu_0\cdots\mu_r}}{\partial q^i} = \frac{\partial (f_0)_i^{\mu_0\cdots\mu_r}}{\partial q^j},$$

so there exist local functions $f_0^{\mu_0\cdots\mu_r}$ on E such that

$$(f_0)_i^{\mu_0\cdots\mu_r} = \frac{\partial f_0^{\mu_0\cdots\mu_r}}{\partial q^i}.$$

This implies that f_0 can be written as the sum

$$f_0 = f_h + f_c \tag{56}$$

of a horizontal form f_h and a closed form f_c, defined by setting

$$f_h = \frac{1}{r!}\left(f_0^{\mu_1\cdots\mu_r} - \frac{\partial f_0^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu}\right)\mathrm{d}^n x_{\mu_1\cdots\mu_r}$$

and

$$f_c = \frac{1}{r!}\frac{\partial f_0^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu}\mathrm{d}^n x_{\mu_1\cdots\mu_r} + \frac{1}{(r+1)!}\frac{\partial f_0^{\mu_0\cdots\mu_r}}{\partial q^i}\mathrm{d}q^i \wedge \mathrm{d}^n x_{\mu_0\cdots\mu_r}.$$

The same kind of local decomposition into the sum of a horizontal form and a closed form can also be derived if f_0 is arbitrary and thus has the form stated in Eq. (54); this case can be handled by decreasing induction on the number of $\mathrm{d}q$'s that appear in the higher order terms denoted by the dots in Eq. (54). We shall refrain from working this out in detail, since unfortunately the decomposition (56) depends on the system of adapted local coordinates used in its construction: under coordinate transformations, the terms f_h and f_c mix. Therefore, this decomposition has no coordinate independent meaning and is in general valid only locally.

Finally, we note that in the above discussion, we have deliberately excluded the extreme cases $r=0$ (n-forms) and $r=n$ (functions). For n-forms, the equivalences stated above would be incorrect since if f_0 has tensor degree n and hence X_0 has tensor degree 0, $i_{X_0}\omega$ would by Proposition 2.2 be a constant multiple of ω whereas $\mathrm{d}(\tau^* f_0)$ would be reduced to a linear combination of terms of the form $\mathrm{d}q^i \wedge \mathrm{d}^n x$, implying that $\tau^* f_0$ can only be Hamiltonian if it is closed. For functions, the construction is uninteresting since according to Proposition 3.1, all functions on P are Poisson, and not just the ones lifted from E.

Now we are ready to state our main decomposition theorem. (In what follows, we shall simply write f_0 instead of $\tau^* f_0$ when there is no danger of confusion, the main exception being the proof of Theorem 3.8 below.)

Theorem 3.8: *Any Hamiltonian $(n-r)$-form and, in particular, any Poisson $(n-r)$-form f on P, with $0<r<n$, admits a unique decomposition*

$$f = f_0 + f_+ + f_c \quad \text{with } f_+ = \sum_{s=1}^{r} f_s, \tag{57}$$

where

(1) *f_0 is (the pull-back to P of) an $(n-r)$-form on E whose exterior derivative is $(n-r)$-horizontal and which is otherwise arbitrary if f is Hamiltonian whereas it is restricted to be $(n-r-1)$-horizontal iff f is Poisson.*

(2) *f_+ is of the form*

$$f_+ = J(F) = (-1)^{r-1} i_F \theta \quad \text{with } F = (1 + L_\Sigma)^{-1} X_+, \tag{58}$$

and correspondingly, for $s = 1, \ldots, r$, f_s is of the form

$$f_s = \frac{(-1)^{r-1}}{s} i_{X_{s-1}} \theta, \tag{59}$$

where X is any fiberwise polynomial Hamiltonian r-multivector field associated with f, decomposed according to Eq. (19).

(3) *f_c is a closed $(n-r)$-form on P which vanishes on the zero section of P (as a vector bundle over E) and which is otherwise arbitrary if f is Hamiltonian whereas it is restricted to vanish on the kernel of ω iff f is Poisson.*

We shall refer to Eq. (57) and to Eq. (60) below as the canonical decomposition of Hamiltonian forms or Poisson forms on P.

Proof: Let f be a Poisson $(n-r)$-form and X be a Hamiltonian r-multivector field associated with f. As already mentioned in the introduction, we may without loss of generality assume X to be fiberwise polynomial and decompose it into homogeneous components with respect to scaling degree, according to Eq. (19),

$$X = X_- + X_+ + \xi \quad \text{with } X_+ = \sum_{s=1}^{r} X_{s-1}.$$

Then defining F as in the theorem, or equivalently, by

$$F = \sum_{s=1}^{r} F_{s-1} \quad \text{with } F_{s-1} = \frac{1}{s} X_{s-1},$$

we obtain

$$F + [\Sigma, F] = X_+,$$

and hence according to Eq. (53), the exterior derivative of the difference $f - J(F)$ is given by

$$\mathrm{d}(f - J(F)) = \mathrm{d}f - \mathrm{d}(J(F)) = i_X \omega - i_{X_+} \omega = i_{X_-} \omega.$$

Applying the equivalence stated in Eq. (23), we see that since X_- has scaling degree -1, $i_{X_-}\omega$ must have scaling degree 0 and hence, according to Proposition A.1, is the pull-back to P of some $(n-r)$-form f_0' on E,

$$\mathrm{d}(f - J(F)) = i_{X_-} \omega = \tau^* f_0'.$$

Next, we define f_0 to be the restriction of $f - J(F)$ to the zero section of P, or more precisely, its pull-back to E with the zero section $s_0 : E \to P$,

$$f_0 = s_0^*(f - J(F)),$$

and set

$$f_c = f - \tau^* f_0 - J(F).$$

Then

$$\mathrm{d}f_c = \mathrm{d}(f - J(F)) - \mathrm{d}(\tau^* s_0^*(f - J(F))) = \mathrm{d}(f - J(F)) - \tau^* s_0^* \mathrm{d}(f - J(F)) = \tau^* f_0' - \tau^* s_0^* \tau^* f_0' = 0,$$

and

$$s_0^* f_c = s_0^*(f - J(F)) - s_0^* \tau^* f_0 = f_0 - s_0^* \tau^* f_0 = 0,$$

showing that indeed, f_c is closed and vanishes on the zero section of P. □

Proof of Theorem 1.3, part 2: The statements of Theorem 1.3 about differential forms are immediate consequences of Theorem 3.8. □

Remark: It should be noted that despite appearances, the decompositions (57) of Theorem 3.8 and (21) of Theorem 1.3 are not necessarily identical: for $s = 1, \ldots, r$, the f_s of Eq. (57) and the f_s of Eq. (21) may differ by homogeneous closed $(n-r)$-forms of scaling degree s. But the decomposition (57) of Theorem 3.8 seems to be the more natural one.

Theorem 3.8 implies that Poisson forms have a rather intricate local coordinate representation, involving two locally Hamiltonian multivector fields. Indeed, if we take f to be a general Poisson $(n-r)$-form on P, with $0 < r < n$, we can apply Propositions 3.4 and 3.6 to rewrite Eq. (57) in the form

$$f = f_0 + (-1)^{r-1} i_F \theta + (-1)^r i_{F_c} \omega, \tag{60}$$

where f_0 is as before while F and F_c are two locally Hamiltonian multivector fields on P of tensor degree r and $r+1$, respectively, satisfying $F_- = 0$ and $(F_c)_- = 0$. [The condition $(F_c)_- = 0$ will guarantee that $i_{F_c}\omega$ vanishes on the zero section of P.] In terms of the standard local coordinate representations (46) for f, (55) for f_0, (26) for F and for F_c, and for θ and ω, Eqs. (2) and (3), we obtain

$$f^{\mu_1 \cdots \mu_r} = (-1)^{r-1} p F^{\mu_1 \cdots \mu_r} + \sum_{s=1}^{r} (-1)^{r-s} p_i^{\mu_s} F^{i, \mu_1 \cdots \mu_{s-1} \mu_{s+1} \cdots \mu_r} + f_0^{\mu_1 \cdots \mu_r} + (-1)^{r-1} (\widetilde{F}_c)^{\mu_1 \cdots \mu_r}, \tag{61}$$

$$f_i^{\mu_0 \cdots \mu_r} = -\sum_{s=0}^{r} (-1)^s p_i^{\mu_s} F^{\mu_0 \cdots \mu_{s-1} \mu_{s+1} \cdots \mu_r} + (f_0)_i^{\mu_0 \cdots \mu_r} - (F_c)_i^{\mu_0 \cdots \mu_r}, \tag{62}$$

$$f^{i, \mu_1 \cdots \mu_r} = (F_c)^{i, \mu_1 \cdots \mu_r}, \tag{63}$$

$$f'^{\mu_0 \cdots \mu_r} = (F_c)^{\mu_0 \cdots \mu_r}, \tag{64}$$

where the coefficients of F and of F_c are subject to the constraints listed in Theorem 2.4; in particular, the coefficients $(F_c)_i^{\mu_0 \cdots \mu_r}$ and $(\widetilde{F}_c)^{\mu_1 \cdots \mu_r}$ can be completely expressed in terms of the coefficients $(F_c)^{\mu_0 \cdots \mu_r}$ and $(F_c)^{i, \mu_1 \cdots \mu_r}$, according to Eqs. (32) and (33) (with r replaced by $r+1$, X replaced by F_c, and X_- replaced by 0). In particular, we see that the coefficients $f^{\mu_1 \cdots \mu_r}$ are "antisymmetric polynomials in the multimomentum variables" of degree r. More explicitly, we can rewrite Eq. (61) in the form

$$f^{\mu_1\cdots\mu_r} = (-1)^{r-1} pF^{\mu_1\cdots\mu_r} + \sum_{s=1}^{r} f_s^{\mu_1\cdots\mu_r} + f_0^{\mu_1\cdots\mu_r} + (-1)^{r-1}(\widetilde{F}_c)^{\mu_1\cdots\mu_r},$$

where inserting the expansion (31) [with X replaced by F, X_{s-1} replaced by F_{s-1} and Y_{s-1} replaced by $G_{s-1}=(1/s)g_s$] gives, after a short calculation,

$$f_s^{\mu_1\cdots\mu_r} = (-1)^{r-1}\frac{1}{s!}\frac{1}{(r-s)!}\sum_{\pi\in S_r}(-1)^{\pi} p_{i_1}^{\mu_{\pi(1)}}\cdots p_{i_s}^{\mu_{\pi(s)}} g_s^{i_1\cdots i_s,\mu_{\pi(s+1)}\cdots\mu_{\pi(r)}}.$$

Finally, we want to clarify the relation between Poisson forms and Hamiltonian multivector fields in terms of their standard local coordinate representations.

Theorem 3.9: *Let f be a Poisson $(n-r)$-form and X be a Hamiltonian r-multivector field on P associated with f. Assume that, in adapted local coordinates, f and X are given by Eqs* (46) and (26), *respectively. Then*

$$X^{\mu_1\cdots\mu_r} = (-1)^{r-1}\left(\frac{\partial f^{\mu_1\cdots\mu_r}}{\partial p} - \frac{\partial f'^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu}\right), \tag{65}$$

$$X^{i,\mu_2\cdots\mu_r} = \frac{1}{n-r+1}\frac{\partial f^{\mu_2\cdots\mu_r\mu}}{\partial p_i^\mu}, \tag{66}$$

$$X_i^{\mu_1\cdots\mu_r} = (-1)^{r}\left(\frac{\partial f^{\mu_1\cdots\mu_r}}{\partial q^i} - \frac{\partial f_i^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu}\right), \tag{67}$$

$$\widetilde{X}^{\mu_2\cdots\mu_r} = -\frac{\partial f^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}, \tag{68}$$

that is, locally and modulo terms taking values in the kernel of ω, X is given by

$$\begin{aligned} X = &-\frac{1}{(r-1)!}\left(\frac{\partial f^{\mu_2\cdots\mu_r\mu}}{\partial x^\mu}\frac{\partial}{\partial p} - \frac{1}{r}\frac{\partial f^{\mu_2\cdots\mu_r\mu}}{\partial p}\frac{\partial}{\partial x^\mu} + \frac{1}{r}\frac{\partial f'^{\mu_2\cdots\mu_r\mu\nu}}{\partial x^\nu}\frac{\partial}{\partial x^\mu}\right)\wedge\frac{\partial}{\partial x^{\mu_2}}\wedge\cdots\wedge\frac{\partial}{\partial x^{\mu_r}} \\ &+\frac{1}{(r-1)!}\left(\frac{1}{n-r+1}\frac{\partial f^{\mu_2\cdots\mu_r\mu}}{\partial p_i^\mu}\frac{\partial}{\partial q^i} - \frac{1}{r}\frac{\partial f^{\mu_2\cdots\mu_r\mu}}{\partial q^i}\frac{\partial}{\partial p_i^\mu} + \frac{1}{r}\frac{\partial f_i^{\mu_2\cdots\mu_r\mu\nu}}{\partial x^\nu}\frac{\partial}{\partial p_i^\mu}\right)\wedge\frac{\partial}{\partial x^{\mu_2}}\wedge\cdots\wedge\frac{\partial}{\partial x^{\mu_r}}. \end{aligned} \tag{69}$$

If, in the canonical decomposition (57) and (60) *of f, the closed term $f_c=(-1)^r i_{F_c}\omega$ is absent, then $f'^{\mu_0\cdots\mu_r}=0$. If f is horizontal with respect to the projection onto M, then $f_i^{\mu_0\cdots\mu_r}=0$. In these cases, the above formulas simplify accordingly.*

Proof: There are several methods for proving this, with certain overlaps. Let us begin with the "trivial" case of closed forms f, for which we must have $X=0$. Assuming f to be of the form $f_c=(-1)^r i_{F_c}\omega$ and using Eqs. (61)–(64) to rewrite the expressions on the rhs of the above equations in terms of the components of F_c, we must show that

$$\frac{\partial(\widetilde{F}_c)^{\mu_1\cdots\mu_r}}{\partial p} + (-1)^r\frac{\partial(F_c)^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu} = 0, \quad \frac{\partial(\widetilde{F}_c)^{\mu_2\cdots\mu_r\mu}}{\partial p_i^\mu} = 0,$$

$$\frac{\partial(\tilde{F}_c)^{\mu_1\cdots\mu_r}}{\partial q^i}-(-1)^r\frac{\partial(F_c)_i^{\mu_1\cdots\mu_r\nu}}{\partial x^\nu}=0,\quad \frac{\partial(\tilde{F}_c)^{\mu_2\cdots\mu_r\nu}}{\partial x^\nu}=0.$$

But this follows directly from the pertinent relations for locally Hamiltonian multivector fields derived in the proof of Theorem 1.3 which hold since F_c is locally Hamiltonian. To handle the remaining cases where f is of the form $f=f_0+(-1)^{r-1}i_F\theta$, it is easier to proceed by direct inspection of Eq. (11). Indeed, we may for a general Poisson form f apply the exterior derivative to Eq. (46) and compare the result with the expression for $i_X\omega$. In this way, Eqs. (68), (67), and (65) can be obtained directly by equating the coefficients of $\mathrm{d}^n x_{\mu_2\cdots\mu_r}$, of $\mathrm{d}q^i\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r}$ and of $\mathrm{d}p\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r}$, respectively. The only case which requires an additional argument is Eq. (66), since collecting terms proportional to $\mathrm{d}p_i^\mu\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r}$ leads to

$$\begin{aligned}&\frac{(-1)^{r-1}}{(r-1)!}X^{i,\mu_2\cdots\mu_r}\,\mathrm{d}p_i^\mu\wedge\mathrm{d}^n x_{\mu\mu_2\cdots\mu_r}\\&\quad=\frac{1}{r!}\frac{\partial f^{\mu_1\cdots\mu_r}}{\partial p_i^\mu}\mathrm{d}p_i^\mu\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r}-\frac{1}{(r-1)!}\frac{\partial f^{i,\mu_2\cdots\mu_r\nu}}{\partial x^\nu}\mathrm{d}p_i^\mu\wedge\mathrm{d}^n x_{\mu\mu_2\cdots\mu_r}\\&\quad-\frac{(-1)^r}{r!}\frac{\partial f^{i,\mu_1\cdots\mu_r}}{\partial x^\mu}\mathrm{d}p_i^\mu\wedge\mathrm{d}^n x_{\mu_1\cdots\mu_r}.\end{aligned}$$

But when f is of the form $f=f_0+(-1)^{r-1}i_F\theta$, Eq. (63) implies that the last two terms on the rhs of the equation above vanish. Moreover, since F is Hamiltonian, we know from Theorem 2.4 that the $F^{\mu_1\cdots\mu_r}$ depend on the p_i^μ only if $\mu\in\{\mu_1,\ldots,\mu_r\}$, and hence according to Eq. (61), the same is true for the $f^{\mu_1\cdots\mu_r}$. This reduces the first term on the rhs of the above equation to an expression which, when compared with the lhs, leads to the conclusion that for any choice of mutually different indices μ and $\mu_2,\ldots,\mu_r$, we have

$$X^{i,\mu_2\cdots\mu_r}=\frac{\partial f^{\mu_2\cdots\mu_r\mu}}{\partial p_i^\mu}\quad\text{if }\mu\notin\{\mu_2,\ldots,\mu_r\}\quad(\text{no sum over }\mu).$$

Summing over μ gives Eq. (66). □

IV. POISSON BRACKETS

In the characterization of locally Hamiltonian multivector fields and of Poisson forms derived in the preceding two sections, the decomposition into homogeneous terms with respect to scaling degree plays a central role. It is therefore natural to ask how this decomposition complies with the Schouten bracket of Hamiltonian multivector fields and with the Poisson bracket of Poisson forms. To this end, let us first recall the definition of the Poisson bracket between Poisson forms given in Ref. 1 for $(n-1)$-forms and in Ref. 2 for forms of arbitrary degree.

Definition 4.1: Let f and g be Poisson forms of tensor degree $n-r$ and $n-s$ on P, respectively. Their Poisson bracket is the Poisson form of tensor degree $n-r-s+1$ on P defined by

$$\{f,g\}=(-1)^{r(s-1)}i_Yi_X\omega+\mathrm{d}((-1)^{(r-1)(s-1)}i_Yf-i_Xg-(-1)^{(r-1)s}i_Yi_X\theta),\tag{70}$$

where X and Y are Hamiltonian multivector fields associated with f and g, respectively.

We find the following properties of the two mentioned bracket operations with respect to scaling degree.

Proposition 4.2: Let X and Y be homogeneous multivector fields on P of scaling degree k and l, respectively. Then their Schouten bracket $[X,Y]$ is of scaling degree $k+l$,

$$L_\Sigma X=kX,\quad L_\Sigma Y=lY\quad\Rightarrow\quad L_\Sigma[X,Y]=(k+l)[X,Y].\tag{71}$$

Proof: The proposition is a consequence of the graded Jacobi identity for multivector fields,[8]

which can be rewritten as the statement that the Schouten bracket with a given multivector field Z of odd/even tensor degree acts as an even/odd superderivation,

$$[Z,[X,Y]] = [[Z,X],Y] + (-1)^{(t-1)(r-1)}[X,[Z,Y]].$$

In particular, since Σ has tensor degree 1,

$$[\Sigma,[X,Y]] = [[\Sigma,X],Y] + [X,[\Sigma,Y]],$$

from which the proposition follows immediately. □

Corollary 4.3: Let X and Y be locally Hamiltonian multivector fields on P of scaling degree -1. *Then their Schouten bracket* $[X,Y]$ *takes values in the kernel of* ω.

Proof: From the preceding proposition, $[X,Y]$ is a locally Hamiltonian multivector field of scaling degree -2. and hence, by Theorem 1.3, must take values in the kernel of ω. □

For the Poisson bracket of Poisson forms, we have the following property.

Proposition 4.4: Let f and g be homogeneous Poisson forms on P of scaling degree k and l, respectively. Then their Poisson bracket $\{f,g\}$ *is of scaling degree* $k+l-1$*:*

$$L_\Sigma f = kf, \quad L_\Sigma g = lg \quad \Rightarrow \quad L_\Sigma\{f,g\} = (k+l-1)\{f,g\}. \tag{72}$$

Proof: As explained in the last paragraph of Sec. I [see, in particular, Eq. (23)], we can find homogeneous Hamiltonian multivector fields X of scaling degree $k-1$ and Y of scaling degree $l-1$ such that $i_X\omega = \mathrm{d}f$ and $i_Y\omega = \mathrm{d}g$. We shall consider each of the terms in the definition of the Poisson bracket separately. We find

$$L_\Sigma(i_Y i_X \omega) = i_Y L_\Sigma i_X \omega + i_{[\Sigma,Y]} i_X \omega = i_Y i_X L_\Sigma \omega + i_Y i_{[\Sigma,X]}\omega + i_{[\Sigma,Y]} i_X \omega = (k+l-1) i_Y i_X \omega.$$

The same calculation works with ω replaced by θ, so that, since L_Σ commutes with d,

$$L_\Sigma(\mathrm{d}(i_Y i_X \theta)) = (k+l-1)\mathrm{d}(i_Y i_X \theta).$$

Moreover,

$$L_\Sigma(\mathrm{d}(i_Y f)) = \mathrm{d}(L_\Sigma i_Y f) = \mathrm{d}(i_Y L_\Sigma f + i_{[\Sigma,Y]} f) = (k+l-1)\mathrm{d}(i_Y f),$$

and similarly $L_\Sigma(\mathrm{d}(i_X g)) = (k+l-1)\mathrm{d}(i_X g)$. Putting the pieces together, the proposition follows. □

Having shown in what sense both the Schouten bracket and the Poisson bracket respect scaling degree, let us use the canonical decomposition of Poisson forms to express their Poisson bracket in terms of known operations on the simpler objects from which they can be constructed. To start with, we settle the case of homogeneous Poisson forms of positive scaling degree.

Proposition 4.5: Let X_{k-1} *be a homogeneous locally Hamiltonian r-multivector field on P of scaling degree* $k-1$, *with* $1 \leqslant k \leqslant r$, *and* Y_{l-1} *be a homogeneous locally Hamiltonian s-multivector field on P of scaling degree* $l-1$, *with* $1 \leqslant l \leqslant s$. *Set*

$$f_k = \frac{(-1)^{r-1}}{k} i_{X_{k-1}}\theta, \quad g_l = \frac{(-1)^{s-1}}{l} i_{Y_{l-1}}\theta.$$

Then

$$\{f_k, g_l\} = \frac{(-1)^{r+s}}{k+l-1} i_{[Y_{l-1},X_{k-1}]}\theta - (-1)^{(r-1)s}\frac{(k-1)(l-1)(k+l)}{kl(k+l-1)}\mathrm{d}(i_{X_{k-1}} i_{Y_{l-1}}\theta).$$

Proof: From the defining equation (70) for the Poisson bracket, we find

$$\{f_k,g_l\} = (-1)^{r(s-1)} i_{Y_{l-1}} i_{X_{k-1}} \omega + \mathrm{d}\left(\frac{(-1)^{(r-1)s}}{k} i_{Y_{l-1}} i_{X_{k-1}} \theta - \frac{(-1)^{(s-1)}}{l} i_{X_{k-1}} i_{Y_{l-1}} \theta - (-1)^{(r-1)s} i_{Y_{l-1}} i_{X_{k-1}} \theta \right)$$

$$= (-1)^{r(s-1)} i_{Y_{l-1}} i_{X_{k-1}} \omega + (-1)^{(r-1)s} \left(\frac{1}{k} + \frac{1}{l} - 1 \right) \mathrm{d}(i_{Y_{l-1}} i_{X_{k-1}} \theta).$$

On the other hand, one verifies that $\mathrm{d} i_{X_{k-1}} \theta = k(-1)^{r-1} i_{X_{k-1}} \omega$ and hence

$$i_{[Y_{l-1},X_{k-1}]}\theta = (-1)^{(s-1)r} L_{Y_{l-1}} i_{X_{k-1}} \theta - i_{X_{k-1}} L_{Y_{l-1}} \theta$$

$$= (-1)^{(s-1)r} \mathrm{d} i_{Y_{l-1}} i_{X_{k-1}} \theta + (-1)^{s(r-1)} (k+l-1) i_{Y_{l-1}} i_{X_{k-1}} \omega.$$

Thus,

$$\{f_k,g_l\} = \frac{(-1)^{r+s}}{k+l-1} i_{[Y_{l-1},X_{k-1}]}\theta - \frac{(-1)^{(r-1)s}}{k+l-1} \mathrm{d}(i_{Y_{l-1}} i_{X_{k-1}} \theta) + (-1)^{(r-1)s} \left(\frac{1}{k} + \frac{1}{l} - 1 \right) \mathrm{d}(i_{Y_{l-1}} i_{X_{k-1}} \theta), \tag{73}$$

which implies the asserted relation. □

As a special case, consider homogeneous Poisson forms of scaling degree 1, which arise by contracting θ with a Hamiltonian multivector field of scaling degree 0, that is, with an exact Hamiltonian multivector field (see the first statement in Proposition 2.5). These Poisson forms have been studied in Ref. 2 under the name "universal multimomentum map."

Corollary 4.6: The space of homogeneous Poisson forms on P of scaling degree 1 closes under the Poisson bracket.

Obviously, it also follows from the proposition that no such statement holds for homogeneous Poisson forms of scaling degree >1, since the second term in the expression in Proposition 4.5 vanishes only for $k=1$ or $l=1$.

Turning to homogeneous Poisson forms on P of scaling degree 0, which come from forms on E by pull-back, we have the following.

Proposition 4.7: The space of homogeneous Poisson forms on P of scaling degree 0 is Abelian under the Poisson bracket,

$$\{f_0,g_0\} = 0. \tag{74}$$

Proof: Without loss of generality, we may assume the Hamiltonian multivector fields X_- and Y_- associated with f_0 and with g_0, respectively, to be homogeneous of scaling degree -1. Therefore, using the fact that if a multivector field X is homogeneous of scaling degree k and a differential form α is homogeneous of scaling degree l, then the differential form $i_X\alpha$ is homogeneous of scaling degree $k+l$,

$$L_\Sigma X = kX, \quad L_\Sigma \alpha = l\alpha \quad \Rightarrow \quad L_\Sigma i_X \alpha = (k+l) i_X \alpha,$$

which follows immediately from the formula $L_\Sigma i_X \alpha = i_X L_\Sigma \alpha + i_{[\Sigma,X]}\alpha$, we see that all four terms in the definition (70) of the Poisson bracket between f_0 and g_0 are differential forms of scaling degree -1 and hence must vanish. □

For the mixed case of the Poisson bracket between a homogeneous Poisson form of strictly positive scaling degree with one of scaling degree zero, we find the following result.

Proposition 4.8: Let X_{k-1} be a homogeneous locally Hamiltonian r-multivector field on P of scaling degree $k-1$, with $1 \leqslant k \leqslant r$, and let g_0 be a homogeneous Poisson $(n-s)$-form on P of scaling degree zero, with associated Hamiltonian s-multivector field Y_-. Set

$$f_k = \frac{(-1)^{r-1}}{k} i_{X_{k-1}} \theta. \tag{75}$$

Then

$$\{f_k, g_0\} = -L_{X_{k-1}} g_0. \tag{76}$$

Proof: By Proposition 2.5, $i_{Y\_}\theta$ vanishes. Hence only two of the four terms in the defining equation (70) for the Poisson bracket survive,

$$\{f_k, g_0\} = (-1)^{r(s-1)} i_{Y\_} i_{X_{k-1}} \omega - \mathrm{d} i_{X_{k-1}} g_0 = -(\mathrm{d} i_{X_{k-1}} g_0 - (-1)^r i_{X_{k-1}} \mathrm{d} g_0) = -L_{X_{k-1}} g_0.$$

□

Finally, let us consider closed Poisson forms, whose associated Hamiltonian multivector fields vanish. Still, the Poisson bracket of a closed Poisson form with an arbitrary Poisson form does not vanish, but it is once again a closed Poisson form.

Proposition 4.9: Let f be a Poisson $(n-r)$-form on P, with associated Hamiltonian r-multivector field X, and let g be a closed Poisson $(n-s)$-form on P. Set

$$g = (-1)^s i_{G_c} \omega. \tag{77}$$

Then

$$\{f, g\} = (-1)^{r+s-1} i_{[G_c, X]} \omega. \tag{78}$$

Proof: As the Hamiltonian multivector field associated with g vanishes, only one of the four terms in the defining equation (70) for the Poisson bracket survives,

$$\{f, g\} = -\mathrm{d}(i_X g) = (-1)^{s-1} \mathrm{d}(i_X i_{G_c} \omega) = (-1)^{rs-1} i_{[X, G_c]} \omega = (-1)^{r+s-1} i_{[G_c, X]} \omega.$$

(For the penultimate equation, see, e.g., Proposition 3.3 of Ref. 2.) □

In view of the canonical decomposition for Poisson forms stated in Theorem 3.8, the above propositions exhaust the possible combinations for the computation of Poisson brackets.

V. CONCLUSIONS AND OUTLOOK

In this paper, we have achieved three goals. First, we have determined the general structure of locally Hamiltonian multivector fields on the extended multiphase space of classical first order field theories. According to Theorem 2.4, the basic structure that arises from explicit calculations in adapted local coordinates is the decomposition of any such multivector field X, of tensor degree r $(0<r<n)$, into a sum of terms of homogeneous scaling degree plus a remainder ξ which is a multivector field taking values in the kernel of ω,

$$X = X_{-1} + X_0 + \cdots + X_{r-1} + \xi \quad \text{with } L_\Sigma X_k = k X_k. \tag{79}$$

Moreover, according to Proposition 2.5, all homogeneous locally Hamiltonian multivector fields of non-negative scaling degree are in fact globally Hamiltonian, and they are exact Hamiltonian if and only if they have zero scaling degree. At the level of local coefficient functions, this decomposition arises because the coefficient functions must be antisymmetric polynomials in the multimomentum variables; see Eqs. (30) and (31).

Second, we have extended the scaling degree analysis to the study of Hamiltonian forms by means of the formula

$$L_\Sigma i_X \omega = i_{X + [\Sigma, X]} \omega.$$

As shown in Theorem 3.8, this leads to a canonical decomposition of any Hamiltonian $(n-r)$-form f $(0<r<n)$ into a sum of terms of homogeneous scaling degree plus a remainder f_c which is a closed form,

$$f = f_0 + f_1 + \cdots + f_r + f_c \quad \text{with } L_\Sigma f_s = s f_s. \tag{80}$$

Moreover, if X is a Hamiltonian multivector field associated with f, then

$$f_s = \frac{(-1)^{r-1}}{s} i_{X_{s-1}} \theta \quad \text{for } s > 0, \tag{81}$$

where the X_{s-1} are the homogeneous components of X of non-negative scaling degree as described before, whereas f_0 arises by pull-back from a form on the total space of the configuration bundle of the theory. Locally, this form can be decomposed into the sum of a horizontal form and a closed form (we prove this explicitly only for Poisson forms), but this decomposition has no global, coordinate invariant meaning. The canonical decomposition of Poisson forms is also useful for deriving local formulas for X in terms of f; these are given in Theorem 3.9. They clearly show that the situation in multisymplectic geometry resembles that encountered in symplectic geometry but exhibits a significantly richer structure. In particular, the notion of conjugate variables requires a conceptual extension.

Third, we have used the canonical decomposition of Poisson forms to derive explicit formulas for the Poisson bracket between Poisson forms. The resulting Lie algebra shows an interesting and nontrivial structure. It has a trivial part, namely the space of closed Poisson forms, which constitutes an ideal that one might wish to divide out; this ideal is Abelian but not central. It commutes with the most interesting and useful part, namely the subalgebra of homogeneous Poisson forms of scaling degree 1, which by means of Eq. (81), specialized to the case $s=1$, correspond to the exact Hamiltonian multivector fields, and in such a way that the Poisson bracket on this subalgebra corresponds to the Schouten bracket for exact Hamiltonian multivector fields (up to signs). The nontrivial mixing occurs through the spaces of homogeneous Poisson forms of scaling degree 0 and of scaling degree >1, they close under the operation of taking the Poisson bracket with a homogeneous Poisson forms of scaling degree 1 but not under the operation of taking mutual Poisson brackets, since these contain contributions lying in the ideal of closed Poisson forms.

An important aspect of our results is that they confirm, once again, the apparently unavoidable appearance of strong constraints on the dependence of Hamiltonian multivector fields and Hamiltonian forms on the multimomentum variables and the energy variable in extended multiphase space, expressed through the "antisymmetric polynomial" structure of their coefficient functions. This strongly suggests that there should be some product structure complementing the Poisson bracket operation. So far, such a structure seems to exist only for a very restricted class of Poisson forms, namely the horizontal forms studied by Kanatchikov.[11] Also, one might wonder whether the structural properties derived here still hold in the multisymplectic formulation of higher order field theories.[6]

Finally, a central question that remains is how the various proposals of Poisson brackets in the multisymplectic formalism that can be found in the literature, including the one proposed in Refs. 1 and 2, relates to the Peierls-DeWitt bracket that comes from the functional approach based on the concept of covariant phase space. Briefly, covariant phase space is defined as the space $\mathcal{S}$ of solutions of the equations of motion and, formally viewed as an infinite-dimensional manifold, carries a naturally defined symplectic form Ω.[12–14] A systematic general investigation of the Peierls-DeWitt bracket in the multisymplectic framework, including a proof of the fact that it is precisely the canonical Poisson bracket for functionals on $\mathcal{S}$ derived from the symplectic form Ω on $\mathcal{S}$, has been carried out recently.[15,16] In order to establish the desired relation, we must restrict this bracket to a certain class of functionals, namely functionals F obtained by using fields to pull Hamiltonian forms or Poisson forms f on extended multiphase space back to space-time and then integrate over submanifolds Σ of the corresponding dimension. Explicitly, using the notation of Ref. 16, we have

$$\mathsf{F}[\phi] = \int_{\Sigma} (\mathbb{F}\mathcal{L} \circ (\varphi, \partial\varphi))^* f \tag{82}$$

in the Lagrangian framework and

$$\mathsf{F}[\phi] = \int_{\Sigma} (\mathcal{H} \circ (\varphi, \pi))^* f \tag{83}$$

in the Hamiltonian framework. Now using the classification of Hamiltonian vector fields and Hamiltonian $(n-1)$-forms obtained in this paper, it has been shown recently that the Peierls-DeWitt bracket $\{\mathsf{F},\mathsf{G}\}$ between two functionals F and G derived from Hamiltonian $(n-1)$-forms f and g, respectively, is the functional derived from the Hamiltonian $(n-1)$-form $\{f,g\}$;[17] details will be published elsewhere. The question of how to extend this result to Poisson forms of other degree is currently under investigation.

APPENDIX

Proposition A.1: Let V be a vector bundle over a manifold M with projection π and let Σ be the scaling or Euler vector field on V. A differential form α on the total space V will be the pull-back of a differential form α_0 on the base space M to V via π if and only if it is scale invariant,

$$\alpha = \pi^* \alpha_0 \quad \Leftrightarrow \quad L_\Sigma \alpha = 0.$$

Proof: Assume first that the form α on V is the pull-back of a form α_0 on M; then $\alpha = \pi^* \alpha_0$ and hence $\mathrm{d}\alpha = \pi^* \mathrm{d}\alpha_0$. Therefore, α and $\mathrm{d}\alpha$ are both horizontal. This means that for any vertical vector field X on V, including Σ, we have $i_X \alpha = 0$ as well as $i_X \mathrm{d}\alpha = 0$, so $L_X \alpha = 0$.

Conversely, assume that the form α on V, of degree r, say, satisfies $L_\Sigma \alpha = 0$, so α is invariant under the flow F of Σ,[9]

$$\frac{\mathrm{d}}{\mathrm{d}\lambda} F_\lambda^* \alpha = 0.$$

This means that given $v \in V$ and $w_1, \ldots, w_r \in T_v V$, the expression

$$(F_\lambda^* \alpha)_v (w_1, \ldots, w_r) = \alpha_{F_\lambda(v)} (T_v F_\lambda \cdot w_1, \ldots, T_v F_\lambda \cdot w_r)$$

does not depend on λ, so its value $\alpha_v(w_1, \ldots, w_r)$ at $\lambda = 0$ is equal to its value $\alpha_{v_0}((w_1)_0, \ldots, (w_r)_0)$ obtained in the limit $\lambda \to -\infty$, where v_0 denotes the zero vector in the fiber of v. But this means that α is equal to $\pi^* \alpha_0$ where α_0 is defined with the help of the zero section $i_0 : M \to V$ of V as $\alpha_0 = i_0^* \alpha$. □

The following lemma is used in the proof of Theorem 2.4.

Lemma A.2: Let f be a polynomial of degree s in a set of variables x^μ. Let f_r, $0 \leq r \leq s$, be the homogeneous component of degree r of f. Then

$$f = \sum_{r=1}^{s} \frac{1}{r} x^\mu \frac{\partial f_r}{\partial x^\mu} + f_0.$$

Proof: For the operator $x^\mu (\partial / \partial x^\mu)$, the homogeneous polynomials f_r are eigenvectors with eigenvalue r. Writing this as $f_r = (1/r) x^\mu (\partial f_r / \partial x^\mu)$ for $0 < r \leq s$, we obtain

$$f = \sum_{r=0}^{s} f_r = f_0 + \sum_{r=1}^{s} \frac{1}{r} x^\mu \frac{\partial f_r}{\partial x^\mu}.$$

Ideality criterion for unilateral constraints in time-dependent impulsive mechanics

Stefano Pasquero[a)]
Dipartimento di Matematica dell'Università di Parma, Parco Area delle scienze 53/A, 43100 Parma (Italia)

(Received 29 June 2005; accepted 22 September 2005; published online 23 November 2005)

We construct a new geometric framework based on the concepts of left and right jet-bundles of a classical space-time $\mathcal{V}$ in order to analyze the impulsive behavior of a unilateral constraint $\mathcal{S}$. The setup allows deep insights into how one can choose an ideality criterion for the constraint $\mathcal{S}$ when the hypothesis of conservation of kinetic energy is assumed. We show that the conservation of kinetic energy alone univocally determines the impulsive reaction when the codimension of $\mathcal{S}$ is 1, and that it leaves the impulsive reaction partially undetermined when the codimension of $\mathcal{S}$ is greater than 1. If the codimension of $\mathcal{S}$ is greater than 1, we prove that an additional minimality requirement determines a physically meaningful constitutive characterization of $\mathcal{S}$. We show that both the Newton-like and the Poisson-like approaches to the description of the reactive impulse are equivalent, in the sense that both give the same results about the ideality criterion. Moreover, we prove that the same results hold using the classical approach based on reflection operators, possible only in case of codimension 1. We present also several physically meaningful examples. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2121247]

I. INTRODUCTION

The geometric approach to Impulsive Mechanics played a role of minor interest in the study of Classical Mechanics until the last decade of the last century. There were essentially two main reasons for this: first, the difficulty, due to the intrinsic nonsmoothness of its problems, of framing Impulsive Mechanics in a differential geometric context without involving the technicalities of Functional Analysis or Differential Geometry of manifolds with boundary. This difficulty effectively stopped, with very few exceptions, the evolution of the geometric studies of Impulsive Mechanics at the level of the first half of the last century, while Analytical Mechanics fruitfully and continuously applied the techniques of smooth Differential Geometry along the years (see, for example, among the many resources, Refs. 1–5, and references therein). The second reason for the minor role of the geometric approach is the deep and fruitful insights in Impulsive Mechanics obtained by the standard local approach (see, for example, once again among the many resources, Refs. 6–11, and the references therein).

However, in recent years, a clever use of classical differential geometric techniques (see Refs. 12–16) and, later, the introduction of new differential geometric setups particularly suited for Impulsive Mechanics (see Refs. 17–19), have shed new light on the potential effectiveness of a formal geometric approach. Such an approach could allow a deeper understanding and produce significant results about the concept of free impulse,[17] the classification of constraints,[14,18] and the energy balance[15,19] in both time-independent and time-dependent cases.

This paper goes precisely in this direction: we embody in the geometric setup of the (left and right) jet-bundles associated to the classical space-time bundle $\mathcal{V}$ of a time-dependent mechanical system the presence of a unilateral constraint $\mathcal{S}$, viewed as a subbundle of $\mathcal{V}$. The fibered immer-

a)Electronic mail: stefano.pasquero@unipr.it

sion $i:\mathcal{S}\to\mathcal{V}$ allows the construction, using the concept of pull-back bundle, of a new environment suitable for a strictly geometric study of the concepts of impulsive reaction and of constitutive characterization of the constraint. The new environment inherits several structures and properties of the jet-extensions of $\mathcal{V}$. Among them are the affine or vector structures of the bundles, the vertical metric, the nonrigid frames of reference viewed as special vector fields, and the corresponding concepts of relative velocity and relative kinetic energy associated to a frame. Moreover, the immersion $i:\mathcal{S}\to\mathcal{V}$ produces natural splits of the velocity spaces of the system. This enriches the structure with projection operators that turn out to be related to the classical Gauss minimality requirement (see, for example, Refs. 20 and 21).

Due to the explicit time dependence of the context, the condition of conservation of kinetic energy, naturally required in order to determine ideality criterion for $\mathcal{S}$, selects a special class $\mathcal{H}$ of frames of reference. This class coincides with the class of frames of reference tangent to $\mathcal{S}$, that, together with an obvious geometric meaning, also has a clear physical meaning: it is the set of all possible frames "of rest" of the constraint or, what is the same, the set of all possible "internal motions" of $\mathcal{S}$. Heuristically speaking, the requirement of conservation of kinetic energy in the impact process for all the frames in $\mathcal{H}$ parallels the well-known situation that the reactive behavior of a bilateral smooth surface constraining a point mass is not affected by the internal motions of the surface itself.

The main result of the paper is essentially based on this idea: we prove that the requirement of conservation of kinetic energy for all the frames in $\mathcal{H}$ drastically reduces the possible ideal constitutive characterizations of $\mathcal{S}$. In particular, when $\mathrm{codim}(\mathcal{S})=1$ (as submanifold of $\mathcal{V}$) the condition selects a unique possible constitutive characterization. This case covers almost all the physically meaningful situations, such as point masses or balls bouncing on walls, rods impacting with the floor and so on.

Some specific, but somewhat artificial, problems, such as the simultaneous impact of a ball with two different walls, or a point mass moving in three-dimensional space and impacting with a thread, give rise to constraints for which $\mathrm{codim}(\mathcal{S})>1$. In this case the condition on kinetic energy alone does not determine a unique constitutive characterization but splits the reaction into two well-defined parts. An additional, but natural, requirement of minimality of one of these parts of the reaction once again univocally determines a physically meaningful constitutive characterization.

In the paper, the main analysis of the impulsive problem is based on a Newton-type approach, i.e., considering the impulsive reaction as a single object. Nevertheless, it is also shown that the same results can be obtained following a Poisson-type approach, based on the separation of the impulsive reaction into two parts with different physical meaning. Moreover, when $\mathrm{codim}(\mathcal{S})=1$, the geometric formulation of the problem allows yet another approach based on reflection operators. We show that even this third possibility gives the same results.

Before concluding the introduction, a brief remark should be made about the geometric approach to Impulsive Mechanics. In Analytical Mechanics the correspondence between the physical problem in study (such as point particles moving on a surface, or balls moving respecting rolling conditions) and the geometric objects involved in its description (such as manifolds, bundles, and smooth maps) is clearly stated and formalized. In Impulsive Mechanics we are great at the beginning of our understanding of this correspondence, even for very simple mechanical problems, such as nonconvex rigid bodies impacting with walls, balls impacting with threads, or in case of articulated mechanical systems.

This problem of correspondence will not be analyzed in detail in this paper. However in Sec. V some examples (one is the ball impacting with the thread) will be briefly presented in order to illustrate this problem.

The paper is divided into four main sections: Section II contains the basic ideas and results about the geometric approach to time-dependent Mechanics, both in the Lagrangian and in the Impulsive cases. This is a well-known material that we recall in order to fix notation and to keep the paper self-contained.

Section III presents the construction of the geometric setup for unilateral constraints in Im-

pulsive Mechanics, in both the coordinate-free and the coordinate-dependent cases. It contains the kinematical aspects of the problem, such as the splits of the velocity spaces, the corresponding projectors and their relations with assigned frames of reference.

Section IV introduces the concept of constitutive characterization in the Newton-type approach and presents the results about the choice of an ideality criterion, in both the $\mathrm{codim}(\mathcal{S})=1$ and the $\mathrm{codim}(\mathcal{S})>1$ cases. Moreover, it presents the discussion about the Poisson-type and the "reflection operators" approaches.

Section V is devoted to examples. Four physically meaningful examples are presented, all of them with some peculiarities: the first is a disk moving in the plane and impacting with a straight line; the second is a rod moving in the plane and impacting with a straight line; the third is a ball moving in the space and impacting with a thread; the last is an articulated system with three different possible kinds of impact.

II. PRELIMINARIES

In the following we recall, also in order to fix notation, the structures and the principal properties of the geometric environments of Lagrangian and Impulsive Mechanics. The following contains standard material that is presented, very briefly, to keep the paper self-contained. More ample discussions can easily be found in literature (see, for example, Refs. 22–24, 5, and 25, and references therein for additional commentary on Lagrangian Mechanics and Refs. 17 and 18 for additional background on Impulsive Mechanics).

A. The classical Lagrangian environment

The geometric setup generally used to study the time-dependent Lagrangian Mechanics of a system with a finite number n of degrees of freedom is constructed starting from the *configuration space-time* bundle, i.e., an $(n+1)$-dimensional fiber bundle $\pi:\mathcal{V}\to\mathbb{E}_1$ where $\mathbb{E}_1$ denotes the one-dimensional Euclidean space, and the first and second jet-extensions of this bundle.[4,21,24,5] All the fibers of $\pi:\mathcal{V}\to\mathbb{E}_1$ are diffeomorphic to an n-dimensional manifold $\mathcal{M}$, usually thought of as the *configuration space* of the system. The configuration space-time takes into account, intrinsically, the positional bilateral constraints acting on the mechanical system. Its first jet-extension $\pi:J_1(\mathcal{V})\to\mathcal{V}$ represents the *absolute velocity bundle* of the system, which takes into account the restrictions on the velocities of the mechanical system due to the positional bilateral constraints. Since Impulsive Mechanics mainly deals with velocities, it is not necessary, in this paper, to introduce higher jet-extensions.

The following properties and notation (see Refs. 21, 24, 22, and 25) will be extensively used throughout.

i) The composition $t\circ\pi:\mathcal{V}\to\mathbb{R}$ of the projection $\pi:\mathcal{V}\to\mathbb{E}_1$ and the Cartesian coordinate t defined on $\mathbb{E}_1$ is the absolute time function, expressing the Absolute Time Axiom of Classical Mechanics in this context. With a mild abuse of language, it will be briefly denoted by $t:\mathcal{V}\to\mathbb{R}$. It selects *admissible* coordinate systems $(t,x^1,\ldots,x^n)$ having t as first coordinate. The rules of variation of such a system

$$\begin{cases}\bar{t}=t,\\ \bar{x}^i=\bar{x}^i(t,x^k), \quad i=1,\ldots,n,\end{cases}$$

distinguish $\mathcal{V}$ from $\mathbb{R}\times\mathcal{M}$ (see Ref. 25). Henceforth, the restriction to admissible coordinates will be always assumed.

ii) The velocity bundle $\pi:J_1(\mathcal{V})\to\mathcal{V}$ is an affine bundle modeled on the *vertical* vector bundle $\pi:V(\mathcal{V})\to\mathcal{V}$ of the tangent vectors $X\in T(\mathcal{V})$ satisfying the condition $t_*(X)=0$. Admissible coordinates (t,x^i) in $\mathcal{V}$ determine admissible jet-coordinates $(t,x^i,\dot{x}^i)$, in $J_1(\mathcal{V})$, whose use will be always assumed. Both $J_1(\mathcal{V})$ and $V(\mathcal{V})$ can be viewed as subbundles of the tangent bundle $T(\mathcal{V})$ as follows:

$$J_1(\mathcal{V}) = \{\mathbf{X} \in T(\mathcal{V}) | \langle \mathrm{d}t, \mathbf{X} \rangle = 1\},$$
$$V(\mathcal{V}) = \{\mathbf{X} \in T(\mathcal{V}) | \langle \mathrm{d}t, \mathbf{X} \rangle = 0\}, \tag{1}$$

where $\langle , \rangle$ denotes the usual pairing between one-forms and tangent vectors. The elements $\mathbf{x} \in J_1(\mathcal{V})$ then admit a representation of the form $\mathbf{x} = \partial/\partial t + \dot{x}^i(\partial/\partial x^i)$, while the elements $\mathbf{U} \in V(\mathcal{V})$ have the form $\mathbf{U} = U^i \partial/\partial x^i$.

iii) The Absolute Space Axiom is introduced in this context by assigning a Riemannian metric on each fiber of $t: \mathcal{V} \to \mathbb{R}$, i.e., we introduce a differentiable positive definite scalar product $\Phi: V(\mathcal{V}) \times_{\mathcal{V}} V(\mathcal{V}) \to \mathbb{R}$, where $\times_{\mathcal{V}}$ denotes the usual fiber product of bundles on $\mathcal{V}$. The scalar product Φ will be called the *vertical* scalar product of $\mathcal{V}$. As usual, we denote by g_{ij} the functions

$$g_{ij}(p) = \Phi\left(\left(\frac{\partial}{\partial x^i}\right)_p, \left(\frac{\partial}{\partial x^j}\right)_p\right), \quad p \in \mathcal{V}, \tag{2}$$

and we recall that the g_{ij} take intrinsically into account the mass properties of the system (see Ref. 24).

iv) Each global section $\mathbf{H}: \mathcal{V} \to J_1(\mathcal{V})$ can be represented as a vector field $\mathbf{H} = \partial/\partial t + H^i(t, x^j)\partial/\partial x^i$ and, due to the affine structure (1) of the velocity bundle $J_1(\mathcal{V})$, it determines a diffeomorphism $\Delta_{\mathbf{H}}$ defined by

$$\Delta_{\mathbf{H}}: J_1(\mathcal{V}) \to V(\mathcal{V}) \text{ such that } \Delta_{\mathbf{H}}(\mathbf{x}) = \mathbf{x} - \mathbf{H}(\pi(\mathbf{x})). \tag{3}$$

A global section $\mathbf{H}: \mathcal{V} \to J_1(\mathcal{V})$ represents a frame of reference for the system (without any assumption of rigidity. See Refs. 25 and 5). Given a frame $\mathbf{H}$, the vertical vector ${}^{\mathbf{H}}\mathbf{v}(\mathbf{x}) = \Delta_{\mathbf{H}}(\mathbf{x})$ is the *relative velocity* of $\mathbf{x} \in J_1(\mathcal{V})$ with respect to $\mathbf{H}$. Moreover, the function

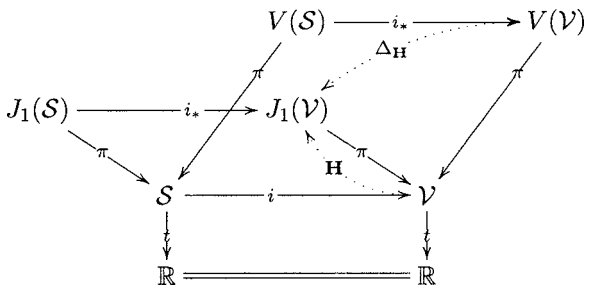
$${}^{\mathbf{H}}\mathcal{K}: J_1(\mathcal{V}) \to \mathbb{R} \text{ such that } {}^{\mathbf{H}}\mathcal{K}(\mathbf{x}) = \tfrac{1}{2}\Phi({}^{\mathbf{H}}\mathbf{v}(\mathbf{x}), {}^{\mathbf{H}}\mathbf{v}(\mathbf{x})) \tag{4}$$

is the *kinetic energy* of the system with respect to $\mathbf{H}$.

Additional positional constraints acting on the system can be introduced in this context by assigning a globally time-fibered subbundle $i: \mathcal{S} \to \mathcal{V}$, where the manifold $\mathcal{S}$ has dimension $(r+1)$, $r < n$. Of course, the bundle $t: \mathcal{S} \to \mathbb{R}$ is the space-time bundle of the system that takes into account the constraint $\mathcal{S}$ acting bilaterally on the system. As with the bundle $t: \mathcal{V} \to \mathbb{R}$, the bundle $t: \mathcal{S} \to \mathbb{R}$ admits its own admissible coordinates $(t, q^1, \ldots, q^r)$. Moreover, it determines its own first jet-extension $\pi: J_1(\mathcal{S}) \to \mathcal{S}$, that is described by admissible jet-coordinates $(t, q^\alpha, \dot{q}^\alpha)$, $\alpha = 1, \ldots, r$ and that is an affine bundle modeled on the vertical bundle $\pi: V(\mathcal{S}) \to \mathcal{S}$. The elements $\mathbf{q}$ of $J_1(\mathcal{S})$ admit the vector representation $\mathbf{q} = \partial/\partial t + \dot{q}^\alpha \partial/\partial q^\alpha$, while the elements $\mathbf{V} \in V(\mathcal{V})$ have the form $\mathbf{V} = V^\alpha \partial/\partial q^\alpha$.

The restrictions of the tangent map $i_*: T(\mathcal{S}) \to T(\mathcal{V})$ determine the fibered immersions $i_*: J_1(\mathcal{S}) \to J_1(\mathcal{V})$ and $i_*: V(\mathcal{S}) \to V(\mathcal{V})$. As a consequence, the vertical scalar product Φ of $\mathcal{V}$ can be pulled back to $V(\mathcal{S})$, defining the vertical scalar product φ of $\mathcal{S}$.

The entire geometric context can be summarized with the following diagram:



(5)

B. The bilateral impulsive environment

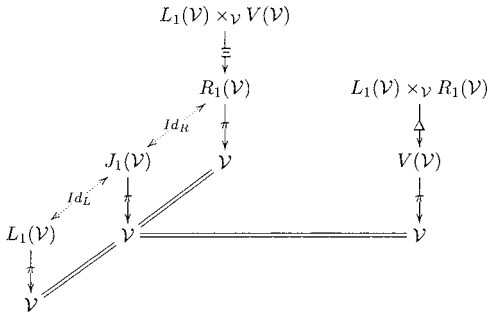
The explicit construction of the velocity bundle $J_1(\mathcal{V})$ made by considering the equivalence classes of sections $\gamma:\mathbb{R}\to\mathcal{V}$ having a first-order contact in a point $p\in\mathcal{V}$ (see, for example, Ref. 22) can be repeated using the left and the right derivatives of γ in p separately.[17] This procedure gives rise to the bundles $\pi:L_1(\mathcal{V})\to\mathcal{V}$ of the left velocities of the system and $\pi:R_1(\mathcal{V})\to\mathcal{V}$ of the right velocities which are each canonically isomorphic to $J_1(\mathcal{V})$ in the geometric sense, but whose physical interpretation is slightly different from that of $J_1(\mathcal{V})$. The following properties are straightforward consequences of the definitions of $L_1(\mathcal{V})$ and $R_1(\mathcal{V})$.

i) $\pi:L_1(\mathcal{V})\to\mathcal{V}$ and $\pi:R_1(\mathcal{V})\to\mathcal{V}$ are affine bundles modeled on the vertical bundle $V(\mathcal{V})$. The canonical isomorphisms with $J_1(\mathcal{V})$ will be denoted by Id_L and Id_R, respectively, and their action will be from now on implicitly understood when necessary. We use the jet-coordinates $(t,x^i,\dot{x}^i_L)$ to describe $L_1(\mathcal{V})$ and the jet-coordinates $(t,x^i,\dot{x}^i_R)$ to describe $R_1(\mathcal{V})$. The elements $\mathbf{x}_L$ of $L_1(\mathcal{V})$ can then be represented in the vector form $\mathbf{x}_L=\partial/\partial t+\dot{x}^i_L\partial/\partial x^i$ and, analogously, $\mathbf{x}_R\in R_1(\mathcal{V})$ can be written as $\mathbf{x}_R=\partial/\partial t+\dot{x}^i_R\partial/\partial x^i$.

ii) The natural action of the modeling vector bundle $V(\mathcal{V})$ on the affine bundle $J_1(\mathcal{V})$ and the natural isomorphisms Id_L, Id_R allow the definition of fibered maps

$$\begin{aligned}&\Xi:\ L_1(\mathcal{V})\times_{\mathcal{V}}V(\mathcal{V})\to R_1(\mathcal{V})\ \text{such that}\ \Xi(\mathbf{x}_L,\mathbf{U})=\mathbf{x}_L+\mathbf{U},\\&\Delta:\ L_1(\mathcal{V})\times_{\mathcal{V}}R_1(\mathcal{V})\to V(\mathcal{V})\ \text{such that}\ \Delta(\mathbf{x}_L,\mathbf{x}_R)=\mathbf{x}_R-\mathbf{x}_L.\end{aligned}\tag{6}$$

The entire geometric context can be summarized by the following diagram:



(7)

III. THE UNILATERAL IMPULSIVE ENVIRONMENT

In the following we construct a geometric setup adapted to the study of the impulsive behavior of the system due to the presence of a unilateral constraint acting on the system itself. From the geometric point of view, the following do not present new ideas, since the setup is constructed through the standard concept of pull-back. However, from the point of view of Impulsive Mechanics of unilateral constraints, the setup allows a different approach from those usually found in literature (see, for example, Refs. 14 and 15, and references therein).

Section III A presents the coordinate free construction of the setup and the coordinate free description of its properties. Section III B shows, using admissible coordinates, the explicit coordinate representations of the spaces and the properties of the setup itself.

A. The coordinate free description

The geometric framework of unilateral problems can be constructed, starting from the bundle $\mathcal{V}$ and the assignment of an additional positional constraint $\mathcal{S}$, through the concept of pull-back bundle.[26,27]

The standard pull-back bundle construction applied to $J_1(\mathcal{V})$, $L_1(\mathcal{V})$, $R_1(\mathcal{V})$, gives three affine bundles $i^*(J_1(\mathcal{V}))$, $i^*(L_1(\mathcal{V}))$, $i^*(R_1(\mathcal{V}))$ locally described by admissible coordinates $(t,q^\alpha,\dot{x}^i)$,

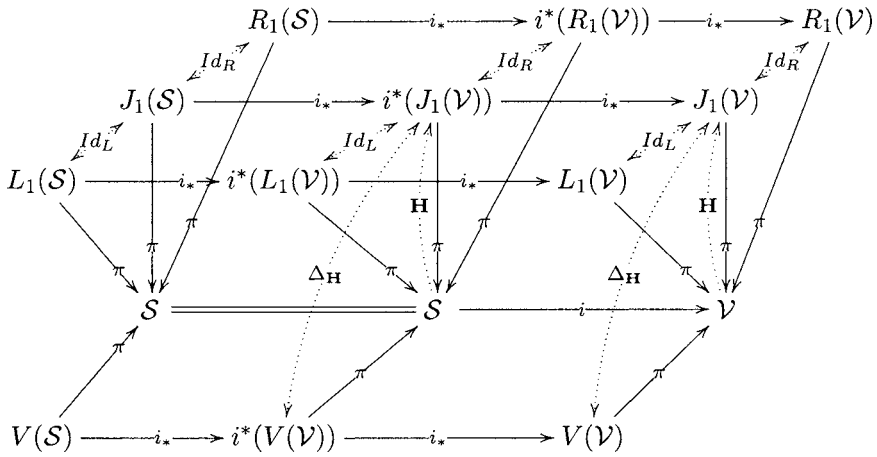
$((t,q^\alpha,\dot{x}^i_L)$, $(t,q^\alpha,\dot{x}^i_R)$. By construction $\pi:i^*(J_1(\mathcal{V}))\to\mathcal{S}$ is the bundle of all possible velocities of the system in a configuration of $\mathcal{S}$, and analogously the bundles $\pi:i^*(L_1(\mathcal{V}))\to\mathcal{S}$ and $\pi:i^*(R_1(\mathcal{V}))\to\mathcal{S}$ are the bundles of all possible left and right velocities of the system in a configuration of $\mathcal{S}$.

The pull-back bundle construction can also be applied to the vertical bundle $V(\mathcal{V})$ giving rise to the bundle $\pi:i^*(V(\mathcal{V}))\to\mathcal{S}$ of the vectors that are vertical with respect to $\mathcal{V}$ and with base point in $\mathcal{S}$. The vertical scalar product (2) of $\mathcal{V}$ can be pulled back to a vertical scalar product $\Phi:i^*(V(\mathcal{V}))\times_{\mathcal{S}}i^*(V(\mathcal{V}))\to\mathbb{R}$.

The immersion $i_*:J_1(\mathcal{S})\to J_1(\mathcal{V})$ can be split into two maps $J_1(\mathcal{S})\to i^*(J_1(\mathcal{V}))\to J_1(\mathcal{V})$, that (with a mild abuse of language) will both be called i_*. The image $i_*(J_1(\mathcal{S}))$ is an affine subbundle of $i^*(J_1(\mathcal{V}))$. The same splitting can also be applied to the maps $i_*:L_1(\mathcal{S})\to L_1(\mathcal{V})$, $i_*:R_1(\mathcal{S})\to R_1(\mathcal{V})$ and $i_*:V(\mathcal{S})\to V(\mathcal{V})$. The images $i_*(L_1(\mathcal{S}))$ and $i_*(R_1(\mathcal{S}))$ are then affine subbundles of $i^*(L_1(\mathcal{V}))$ and $i^*(R_1(\mathcal{V}))$, respectively, while $i_*(V(\mathcal{S}))$ is a vector subbundle of $i^*(V(\mathcal{V}))$.

Any assigned frame of reference $\mathbf{H}$ of $\mathcal{V}$, viewed as a section of the velocity bundle $J_1(\mathcal{V})$, can be restricted to a section $\mathbf{H}:\mathcal{S}\to i^*(J_1(\mathcal{V}))$ and gives a diffeomorphism $\Delta_{\mathbf{H}}:i^*(J_1(\mathcal{V}))\to i^*(V(\mathcal{V}))$. The kinetic energy (4) relative to a frame $\mathbf{H}$ can be restricted to a kinetic energy function ${}^{\mathbf{H}}\mathcal{K}:i^*(J_1(\mathcal{V}))\to\mathbb{R}$.

The whole construction, taking into account diagrams (5) and (7) can be synthesized by the following diagram



(8)

The slice in the middle of diagram (8), together with its own subbundles given by the slice in the left part of the diagram, is, in a very natural way, the correct geometric environment for the study of the impulsive behavior of $\mathcal{S}$ viewed as unilateral constraint acting on the system. Therefore, in the next part of this section, we focus our attention on these parts of the diagram. We recall once again that, using the (restrictions of the) isomorphisms between $i^*(J_1(\mathcal{V}))$, $i^*(L_1(\mathcal{V}))$, and $i^*(R_1(\mathcal{V}))$, all the geometric properties of the bundle $i^*(J_1(\mathcal{V}))$ have corresponding properties in $i^*(L_1(\mathcal{V}))$ and $i^*(R_1(\mathcal{V}))$.

The simultaneous presence of the vertical metric Φ and of the vector subbundle $i_*(V(\mathcal{S}))$ allows the splitting of the vector bundle $i^*(V(\mathcal{V}))$ into

$$i^*(V(\mathcal{V}))=i_*(V(\mathcal{S}))\oplus(i_*(V(\mathcal{S})))^\perp. \tag{9}$$

The vertical scalar product Φ can then be decomposed into the sum of a scalar product φ acting on $i_*(V(\mathcal{S}))$ and a scalar product ψ acting on $(i_*(V(\mathcal{S})))^\perp$, so that

$$\Phi=\varphi\otimes\psi. \tag{10}$$

Recalling that both $i_*(J_1(\mathcal{S}))$ and $i^*(J_1(\mathcal{V}))$ have an affine nature, an analogous splitting can be performed on the affine bundle $i^*(J_1(\mathcal{V}))$, so that

$$i^*(J_1(\mathcal{V})) = i_*(J_1(\mathcal{S})) \oplus (i_*(V(\mathcal{S})))^\perp, \tag{11}$$

where in this case the meaning of the symbol $\oplus$ is related to the action of the modeling bundle $i^*(V(\mathcal{V}))$ on the affine bundle $i^*(J_1(\mathcal{V}))$ and will be clarified by the coordinate expression in Sec. III B. The decompositions (9) and (11) allow the definitions of projection operators

$$\begin{gathered}\mathcal{P}_{\mathcal{V}}\colon i^*(V(\mathcal{V})) \to i_*(V(\mathcal{S})), \quad \mathcal{P}^\perp_{\mathcal{V}}\colon i^*(V(\mathcal{V})) \to (i_*(V(\mathcal{S})))^\perp, \\ \mathcal{P}\ \colon i^*(J_1(\mathcal{V})) \to i_*(J_1(\mathcal{S})), \quad \mathcal{P}^\perp\colon i^*(J_1(\mathcal{V})) \to (i_*(V(\mathcal{S})))^\perp.\end{gathered} \tag{12}$$

Note that (see, for example, Refs. 21 and 14), from the computational point of view, the operators $\mathcal{P}$ and $\mathcal{P}^\perp$ can be determined through a minimum principle, since, for every point $\mathbf{x} \in i^*(J_1(\mathcal{V}))$, the projection $\mathcal{P}\ (\mathbf{x})$ realizes the minimum of the scalar function

$$f_{\mathbf{x}}\colon i_*(J_1(\mathcal{S})) \to \mathbb{R} \text{ such that } f_{\mathbf{x}}(\mathbf{y}) = \Phi(\mathbf{x}-\mathbf{y}, \mathbf{x}-\mathbf{y}).$$

Proposition 3.1: For each $\mathbf{x}_1, \mathbf{x}_2 \in i^*(J_1(\mathcal{V}))$, *for each* $\mathbf{v} \in i^*(V(\mathcal{V}))$, *the following properties hold*:

(i) $\mathcal{P}_{\mathcal{V}}(\mathbf{x}_1 - \mathbf{x}_2) = \mathcal{P}\ (\mathbf{x}_1) - \mathcal{P}\ (\mathbf{x}_2)$,
(ii) $\mathcal{P}^\perp_{\mathcal{V}}(\mathbf{x}_1 - \mathbf{x}_2) = \mathcal{P}^\perp(\mathbf{x}_1) - \mathcal{P}^\perp(\mathbf{x}_2)$,
(iii) $\mathcal{P}\ (\mathbf{x}_1 + \mathbf{v}) = \mathcal{P}\ (\mathbf{x}_1) + \mathcal{P}_{\mathcal{V}}(\mathbf{v})$,
(iv) $\mathcal{P}^\perp(\mathbf{x}_1 + \mathbf{v}) = \mathcal{P}^\perp(\mathbf{x}_1) + \mathcal{P}^\perp_{\mathcal{V}}(\mathbf{v})$.

Proof: Obviously *(iii)* implies *(i)* and *(iv)* implies *(ii)* choosing $\mathbf{v} = \mathbf{x}_2 - \mathbf{x}_1$. The proof of *(iii)* and *(iv)* is straightforward using admissible coordinates (see also Sec. III B) and is left to the reader. □

The vertical vector $\mathcal{P}^\perp(\mathbf{x}) \in (i_*(V(\mathcal{S})))^\perp$ associated to a velocity $\mathbf{x} \in i^*(J_1(\mathcal{V}))$ is the natural candidate for the orthogonal component of the velocity $\mathbf{x}$ with respect to the constraint $\mathcal{S}$. Unfortunately, the concept of velocity as vertical vector is intrinsically related to the knowledge of a frame of reference $\mathbf{H}$: the following discussion shows that $\mathcal{P}^\perp(\mathbf{x})$ actually is the orthogonal component of the relative velocity $\Delta_{\mathbf{H}}(\mathbf{x})$, not only for a single frame, but even for all the frames in a wide (and geometrically important) class.

Proposition 3.2: Given a frame of reference $\mathbf{H}$, *the following conditions are equivalent*

a) $\exists \mathbf{K}\colon \mathcal{S} \to J_1(\mathcal{S})$ *such that* $\mathbf{H} = i_*(\mathbf{K})$,
b) $\mathcal{P}\ (\mathbf{H}) = \mathbf{H}$,
c) $\mathcal{P}^\perp(\mathbf{H}) = 0$.

Proof: The equivalence *b)* $\Leftrightarrow$ *c)* and the arrow *a)* $\Rightarrow$ *b)* are obvious. The arrow *b)* $\Rightarrow$ *a)* is a consequence of the fact that i_* is an isomorphism between $T(\mathcal{S})$ and its image, so that $\mathbf{K} = (i_*)^*(\mathbf{H})$. □

Definition 1: A frame of reference $\mathbf{H}\colon \mathcal{S} \to i^*(J_1(\mathcal{V}))$ *will be called tangent to* $\mathcal{S}$ *if it obeys one of the equivalent conditions of Proposition (3.2). The set of frames tangent to* $\mathcal{S}$ *will be denoted by* $\mathcal{H}$.

Taking into account the splitting (9), for each velocity $\mathbf{x} \in i^*(J_1(\mathcal{V}))$ and frame $\mathbf{H}$ we have (with the obvious meaning of the symbol $\mathbf{v}^{\|}$) the decomposition

$$\Delta_{\mathbf{H}}(\mathbf{x}) = {}^{\mathbf{H}}\mathbf{v}(\mathbf{x}) = \mathcal{P}_{\mathcal{V}}({}^{\mathbf{H}}\mathbf{v}(\mathbf{x})) + \mathcal{P}^\perp_{\mathcal{V}}({}^{\mathbf{H}}\mathbf{v}(\mathbf{x})) = {}^{\mathbf{H}}\mathbf{v}^{\|}(\mathbf{x}) + {}^{\mathbf{H}}\mathbf{v}^{\perp}(\mathbf{x}). \tag{13}$$

At first glance, there appears to be no relation between the relative "orthogonal" velocity ${}^{\mathbf{H}}\mathbf{v}^{\perp}(\mathbf{x})$, that is, in general, dependent on $\mathbf{H}$, and the vertical vector $\mathcal{P}^\perp(\mathbf{x})$. The following result shows however that the class of frames for which the identity ${}^{\mathbf{H}}\mathbf{v}^{\perp}(\mathbf{x}) = \mathcal{P}^\perp(\mathbf{x})$ holds coincides with the class of the frames tangent to $\mathcal{S}$.

Theorem 3.1: *Given a frame* $\mathbf{H}$, *the condition* ${}^{\mathbf{H}}\mathbf{v}^{\perp}(\mathbf{x}) = \mathcal{P}^\perp(\mathbf{x})\ \forall\, \mathbf{x} \in i^*(J_1(\mathcal{V}))$ *holds if and only if* $\mathbf{H}$ *obeys one of the equivalent conditions of Proposition (3.2).*

Proof: The proof follows easily from property *(ii)* of Proposition (3.1) applied to the vector ${}^{\mathbf{H}}\mathbf{v}(\mathbf{x})=\Delta_{\mathbf{H}}(\mathbf{x})=\mathbf{x}-\mathbf{H}$. □

Definition 3.2: For each $\mathbf{x}\in i^*(J_1(\mathcal{V}))$, *the vertical vector* $\mathcal{P}^{\perp}(\mathbf{x})\in(i_*(V(\mathcal{S})))^{\perp}$ *will be called the orthogonal velocity of* $\mathbf{x}$ *with respect to* $\mathcal{S}$, *and will be denoted by* $\mathbf{v}^{\perp}(\mathbf{x})$ *(or briefly* $\mathbf{v}^{\perp}$ *when no confusion can arise*).

The set $\mathcal{H}$ will play a crucial role in the choice of an ideal constitutive characterization of the reactive impulse of $\mathcal{S}$. We will see that in Sec. IV. Moreover, note that a meaningful definition of the concept of frame of rest of the constraint $\mathcal{S}$ must involve the set $\mathcal{H}$ (see Ref. 25).

B. The coordinate description

All the immersions, projection operators, and properties described in Sec. III A can be rewritten using local admissible coordinates.

The immersion $i:\mathcal{S}\to\mathcal{V}$ can be described in local admissible coordinates as

$$\begin{cases} t=t, \\ x^i=x^i(t,q^\alpha) \end{cases} \tag{14}$$

or by its Cartesian representation

$$g_A(t,x^1,\ldots,x^n)=0, \quad A=1,\ldots,n-r. \tag{15}$$

Using the vector representation (in admissible coordinates), the bundles of the slice in the middle of diagram (8) are described by

$$\begin{aligned} i^*(J_1(\mathcal{V}))&=\left\{\mathbf{x}=\left(\frac{\partial}{\partial t}\right)_{(t,q^\alpha)}+\dot{x}^i\left(\frac{\partial}{\partial x^i}\right)_{(t,q^\alpha)}\right\}, \\ i^*(V(\mathcal{V}))&=\left\{\mathbf{U}=u^i\left(\frac{\partial}{\partial x^i}\right)_{(t,q^\alpha)}\right\}, \end{aligned} \tag{16}$$

and similar expressions hold for the bundles $i^*(L_1(\mathcal{V}))$ and $i^*(R_1(\mathcal{V}))$, substituting $\dot{x}^i$ with $\dot{x}^i_L$ and $\dot{x}^i_R$, respectively.

The corresponding subbundles obtained through the map i_*, omitting the coordinates of the application point of the vectors, are described by

$$\begin{aligned} i_*(J_1(\mathcal{S}))&=\left\{\mathbf{q}=\frac{\partial}{\partial t}+\left(\frac{\partial x^i}{\partial t}+\dot{q}^\alpha\frac{\partial x^i}{\partial q^\alpha}\right)\frac{\partial}{\partial x^i}\right\}, \\ i_*(V(\mathcal{S}))&=\left\{\mathbf{V}=\dot{q}^\alpha\frac{\partial x^i}{\partial q^\alpha}\frac{\partial}{\partial x^i}\right\}, \end{aligned} \tag{17}$$

and similar expressions hold for the bundles $i_*(L_1(\mathcal{S}))$ and $i_*(R_1(\mathcal{S}))$, substituting $\dot{q}^i$ with $\dot{q}^i_L$ and $\dot{q}^i_R$, respectively.

Note that expression (17) points out the affine nature of the injection $i_*:i_*(J_1(\mathcal{S}))\to i^*(J_1(\mathcal{V}))$ and the linear nature of $i_*:i_*(V(\mathcal{S}))\to i^*(V(\mathcal{V}))$.

The vertical metric Φ in $i^*(V(\mathcal{V}))$ is described by the functions $g_{ij}(t,q^\alpha)=g_{ij}(t,x^k(t,q^\alpha))$, while its restriction φ to $i_*(V(\mathcal{S}))$ is described by

$$\gamma_{\alpha\beta}=g_{ij}\frac{\partial x^i}{\partial q^\alpha}\frac{\partial x^j}{\partial q^\beta}. \tag{18}$$

As usual, we denote by g^{ij} and $\gamma^{\alpha\beta}$ the inverse matrices of g_{ij} and $\gamma_{\alpha\beta}$, respectively.

The projection operator $\mathcal{P}_{\mathcal{V}}:i^*(V(\mathcal{V}))\to i_*(V(\mathcal{S}))$ has the (linear) coordinate description

$$\mathcal{P}_{\mathcal{V}}\colon i^*(V(\mathcal{V})) \to i_*(V(\mathcal{S})),$$
$$U^i\frac{\partial}{\partial x^i} \rightsquigarrow \gamma^{\xi\eta} g_{rs}\frac{\partial x^r}{\partial q^\xi}\frac{\partial x^i}{\partial q^\eta}U^s\frac{\partial}{\partial x^i} := A^i_s U^s\frac{\partial}{\partial x^i}. \tag{19}$$

Using (for conciseness) the matrix $A^i_s = \gamma^{\xi\eta} g_{rs}(\partial x^r/\partial q^\xi)(\partial x^i/\partial q^\eta)$, the other projection operators (12) are described by

$$\mathcal{P}^\perp_{\mathcal{V}}\colon i^*(V(\mathcal{V})) \to (i_*(V(\mathcal{S})))^\perp,$$
$$U^i\frac{\partial}{\partial x^i} \rightsquigarrow (\delta^i_s - A^i_s)U^s\frac{\partial}{\partial x^i};$$

$$\mathcal{P}\ :\ i^*(J_1(\mathcal{V})) \to i_*(J_1(\mathcal{S})),$$
$$\frac{\partial}{\partial t} + \dot{x}^i\frac{\partial}{\partial x^i} \rightsquigarrow \frac{\partial}{\partial t} + \left(\frac{\partial x^i}{\partial t} + A^i_s\left(\dot{x}^s - \frac{\partial x^s}{\partial t}\right)\right)\frac{\partial}{\partial x^i}; \tag{20}$$

$$\mathcal{P}^\perp\colon i^*(J_1(\mathcal{V})) \to (i_*(V(\mathcal{S})))^\perp,$$
$$\frac{\partial}{\partial t} + \dot{x}^i\frac{\partial}{\partial x^i} \rightsquigarrow (\delta^i_s - A^i_s)\left(\dot{x}^s - \frac{\partial x^s}{\partial t}\right)\frac{\partial}{\partial x^i}.$$

These expressions allow a tedious but straightforward check of properties *(iii)* and *(iv)* of Proposition 3.1. Moreover, the computation $\mathcal{P} + \mathcal{P}^\perp = \text{Ident}$ clarifies the decomposition (11).

Once a frame **H** is assigned, relations (20) allow an easy check of the condition

$${}^{\mathbf{H}}\mathbf{v}^\perp(\mathbf{x}) = \mathcal{P}^\perp(\mathbf{x})\ \forall\ \mathbf{x} \in i^*(J_1(\mathcal{V})) \Leftrightarrow \mathcal{P}^\perp(\mathbf{H}) = 0.$$

This gives an alternative proof of Theorem (3.1).

IV. IMPULSIVE MECHANICS

In the following the environment previously introduced is applied to give a constitutive characterization of $\mathcal{S}$, based on the simplest criterion of conservation of kinetic energy, particularly suitable to be assumed as an ideality criterion for $\mathcal{S}$. Although very simple, the criterion is strong enough to be directly applied to the wide class of constraints of codimension 1. The case of codimension greater than 1 is, in general, very artificial and physically irrelevant, but can also be treated by adding a very natural requirement of minimality of the impulsive reaction. The discussion is presented following a Newton-type approach, but it is proved that the Poisson-type approach gives the same results. Also the classical approach using reflection operators is applicable to the particular case of constraints of codimension 1. Once again it is proved that it is equivalent to the Newton-type and Poisson-type approaches.

From now on, unless otherwise specified, each frame of reference **H** will be considered as tangent to $\mathcal{S}$.

A. Ideality criterion

A constitutive characterization of the impulsive action of the constraint $\mathcal{S}$ is a map $\tilde{I}: i^*(L_1(\mathcal{V})) \to i^*(R_1(\mathcal{V}))$ assigning to each "entrance" or left velocity $\mathbf{x}_L \in i^*(L_1(\mathcal{V}))$ of the system in the constraint $\mathcal{S}$ a corresponding "exit" or right velocity $\mathbf{x}_R = \tilde{I}(\mathbf{x}_L) \in i^*(R_1(\mathcal{V}))$. Alternatively, and preferably in order to preserve some structural analogies with the force acting on the system (see Refs. 24 and 17), a constitutive characterization of $\mathcal{S}$ is a map $\mathbf{I}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ assigning to each velocity $\mathbf{x}$ a corresponding jump $\mathbf{I}(\mathbf{x})$.

The equivalence of the definitions is obtained through the isomorphisms Id_L, Id_R, noting that $\mathbf{x}_L=\mathrm{Id}_L(\mathbf{x})$ and $\mathbf{x}_R=\mathrm{Id}_R(\mathbf{x}+\mathbf{I}(\mathbf{x}))$. Alternatively, recalling (6), we have that $\mathbf{I}(\mathbf{x})=\Delta(\mathbf{x}_L,\tilde{I}(\mathbf{x}_L))$. We will often use the brief (mild abuse of) notation $\mathbf{x}_R=\mathbf{x}_L+\mathbf{I}$.

Usually, an "impenetrability" condition of the form $\Phi(\mathbf{v}^{\perp}(\mathbf{x}_L),\mathbf{v}^{\perp}(\tilde{I}(\mathbf{x}_L)))\leqslant 0\,\forall\,\mathbf{x}_L \in i^*(L_1(\mathcal{V}))$, or equivalently $\Phi(\mathbf{v}^{\perp}(\mathbf{x}),\mathbf{I}(\mathbf{x}))\leqslant 0\,\forall\,\mathbf{x}\in i^*(J_1(\mathcal{V}))$, is further assumed to ensure the unilaterality of $\mathcal{S}$. Even with this condition, a trivial constitutive characterization $\mathbf{I}_0: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ assigning to each velocity $\mathbf{x}$ the null jump $\mathbf{I}_0(\mathbf{x})\equiv 0$ is theoretically admissible, but its physical meaning is that $\mathcal{S}$ is not a constraint for the system.

In order to define an ideal constitutive characterization of the impulsive reaction, two requirements are very natural. The first, parallelizing the analogous problem in Analytical Mechanics, is that the ideality criterion should have a geometric nature: something like orthogonality with respect to some natural spaces, maybe in addition with a "minimality" criterion (see, for example, Refs. 21, 24, 14, and 15). This requirement then suggests that one avoids the introduction of additional structures, such as, for example, the frame of reference of the rest of the constraint. To clarify this idea, consider for example a point particle bilaterally constrained to the surface of a sphere. The ideal constitutive characterization does not take into account the internal motion of the points of the sphere, on condition that the shape of the sphere does not vary. Moreover, the reaction is orthogonal to the constraint and it has minimum norm. Differently, a constitutive characterization taking into account the presence of friction implies the necessity of knowing the velocity of the point particle with respect to the points of the sphere, and then the knowledge of the frame of the rest of the sphere.

The second natural requirement for an ideal characterization is the conservation of kinetic energy before and after impact. Unfortunately, in contrast to the time-independent approach where an intrinsic choice of a frame of reference is done *a priori* (see Refs. 25 and 19), in a time-dependent environment, kinetic energy is indissolubly related to the knowledge of a frame of reference.

It can be easily proved that is not possible to impose the conservation of kinetic energy in the impact process for every frame of reference, due to the law of variation of kinetic energy with the frame (see Refs. 25 and 18). The conservation of kinetic energy could be imposed in a specific frame of reference tangent to $\mathcal{S}$ chosen as the frame of rest of the constraint, but in this case we should select (arbitrarily) one of the tangent frames. This is in contradiction with the first requirement.

We analyze, then, the consequences of imposing the conservation of kinetic energy before and after the impact in every frame of reference in the class $\mathcal{H}$. With this aim, we state the following.

Lemma 4.1: Let V be a finite dimensional vector space, Φ *a positive definite scalar product on V, and let* $\theta: V\to V$ *be a map such that*

$$\Phi(v+\theta(v),v+\theta(v))=\Phi(v,v),\quad \forall\, v\in V. \tag{21}$$

Let $\|\,\|$ *denote the norm induced on V by* Φ *and let* $\mathcal{B}(u,\epsilon)$ *the ball with center u and radius* ϵ *in V. Then the following conditions hold:*

1) $\theta(v)\in\partial\mathcal{B}(-v,\sqrt{\Phi(v,v)})\,\forall\, v\in V$;
2) there exists a map $\xi_\theta: V\to V$ *obeying the conditions*

$$\begin{cases}\theta(v)=-2v+\xi_\theta(v),\\ \Phi(\theta(v),\xi_\theta(v))=0,\end{cases}\quad \forall\, v\in V, \tag{22}$$

3) the map $\theta_{\min}$ *obeying (21) and having minimum norm is* $\theta_{\min}(v)\equiv 0$;
4) the map $\theta_{\max}$ *obeying (21) and having maximum norm is* $\theta_{\max}(v)=-2v$.

Proof:

1) Using the norm function $\|\,\|$, condition (21) can be rewritten as

$$\|v + \theta(v)\|^2 = \|v\|^2,$$

that is the thesis.

2) Condition (21) can be rewritten as

$$\Phi(2v + \theta(v), \theta(v)) = 0,$$

so that $\xi_\theta(v) := 2v + \theta(v)$ obeys condition $\Phi(\theta(v), \xi_\theta(v)) = 0$.

3,4) Independent of the fact that 3) is obvious, and of the geometric meaning of the first statement of the lemma, conditions 3,4) can be simultaneously proved using coordinates in V. We have

$$\Phi(\theta(v), \theta(v)) = \|\theta(v)\|^2 = g_{ij}\theta^i\theta^j,$$

$$\Phi(2v + \theta(v), \theta(v)) = 0 \Leftrightarrow g_{ij}(2v^i + \theta^i)\theta^j = 0.$$

The standard Lagrange multipliers minimization procedure applied to the function $F(\theta^i, \lambda) = g_{ij}\theta^i\theta^j + \lambda g_{ij}(2v^i + \theta^i)\theta^j$ gives the conditions

$$\begin{cases} \theta^j = -\dfrac{\lambda}{1+\lambda}v^i, \\ \lambda = 0 \text{ or } \lambda = -2 \end{cases}$$

and then both the conclusions. □

We can now prove the following:

Theorem 4.1: *Let* $\mathbf{I}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ *be a nontrivial constitutive characterization of* $\mathcal{S}$ *satisfying the condition*

$$^{\mathbf{H}}\mathcal{K}(\mathbf{x} + \mathbf{I}(\mathbf{x})) = {}^{\mathbf{H}}\mathcal{K}(\mathbf{x}), \quad \forall\, \mathbf{x} \in i^*(J_1(\mathcal{V})), \quad \forall\, \mathbf{H} \in \mathcal{H}. \tag{23}$$

Then:

1) $\mathcal{P}_{\mathcal{V}}(\mathbf{I}(\mathbf{x})) = 0\ \forall\, \mathbf{x} \in i^*(J_1(\mathcal{V}))$ *or, equivalently,* $\mathbf{I}(\mathbf{x}) = \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I}(\mathbf{x}))\ \forall\, \mathbf{x} \in i^*(J_1(\mathcal{V}))$.

2) there exists a map $\mathbf{Z}: i^*(J_1(\mathcal{V})) \to (i_*(V(\mathcal{S})))^{\perp}$ *satisfying the conditions*

$$\begin{cases} \mathbf{I}(\mathbf{x}) = -2\mathbf{v}^{\perp}(\mathbf{x}) + \mathbf{Z}(\mathbf{x}), \\ \Phi(\mathbf{I}(\mathbf{x}), \mathbf{Z}(\mathbf{x})) = 0. \end{cases} \quad \forall\, \mathbf{x} \in i^*(J_1(\mathcal{V})), \tag{24}$$

Proof: 1) By definition, recalling the decomposition (10) and omitting the dependence on $\mathbf{x}$, we have

$$\begin{aligned} {}^{\mathbf{H}}\mathcal{K}(\mathbf{x} + \mathbf{I}) &= \tfrac{1}{2}\Phi(\mathbf{x} - \mathbf{H} + \mathbf{I}, \mathbf{x} - \mathbf{H} + \mathbf{I}) = \tfrac{1}{2}\Phi({}^{\mathbf{H}}\mathbf{v} + \mathbf{I}, {}^{\mathbf{H}}\mathbf{v} + \mathbf{I}) \\ &= \tfrac{1}{2}\Phi({}^{\mathbf{H}}\mathbf{v}^{\|} + \mathbf{v}^{\perp} + \mathcal{P}_{\mathcal{V}}(\mathbf{I}) + \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I}), {}^{\mathbf{H}}\mathbf{v}^{\|} + \mathbf{v}^{\perp} + \mathcal{P}_{\mathcal{V}}(\mathbf{I}) + \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) \\ &= \tfrac{1}{2}\varphi({}^{\mathbf{H}}\mathbf{v}^{\|} + \mathcal{P}_{\mathcal{V}}(\mathbf{I}), {}^{\mathbf{H}}\mathbf{v}^{\|} + \mathcal{P}_{\mathcal{V}}(\mathbf{I})) + \tfrac{1}{2}\psi(\mathbf{v}^{\perp} + \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I}), \mathbf{v}^{\perp} + \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) \end{aligned}$$

and analogously

$$^{\mathbf{H}}\mathcal{K}(\mathbf{x}) = \tfrac{1}{2}\Phi(\mathbf{x} - \mathbf{H}, \mathbf{x} - \mathbf{H}) = \tfrac{1}{2}\varphi({}^{\mathbf{H}}\mathbf{v}^{\|}, {}^{\mathbf{H}}\mathbf{v}^{\|}) + \tfrac{1}{2}\psi(\mathbf{v}^{\perp}, \mathbf{v}^{\perp}).$$

By comparison, Eq. (23) implies

$$\varphi({}^{\mathbf{H}}\mathbf{v}^{\|}, \mathcal{P}_{\mathcal{V}}(\mathbf{I})) + \tfrac{1}{2}\varphi(\mathcal{P}_{\mathcal{V}}(\mathbf{I}), \mathcal{P}_{\mathcal{V}}(\mathbf{I})) + \psi(\mathbf{v}^{\perp}, \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) + \tfrac{1}{2}\psi(\mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I}), \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) = 0.$$

Since both $\mathbf{x} \in i^*(J_1(\mathcal{V}))$ and $\mathbf{H} \in \mathcal{H}$ are arbitrary, the vector ${}^{\mathbf{H}}\mathbf{v}^{\|} \in i_*(V(\mathcal{S}))$ is also arbitrary. Therefore we have that

$$\begin{cases} \varphi({}^{\mathbf{H}}\mathbf{v}^{\parallel}, \mathcal{P}_{\mathcal{V}}(\mathbf{I})) = 0, \\ \frac{1}{2}\varphi(\mathcal{P}_{\mathcal{V}}(\mathbf{I}), \mathcal{P}_{\mathcal{V}}(\mathbf{I})) + \psi(\mathbf{v}^{\perp}, \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) + \frac{1}{2}\psi(\mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I}), \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) = 0 \end{cases}$$

and then

$$\begin{cases} \mathcal{P}_{\mathcal{V}}(\mathbf{I}) = 0 \Leftrightarrow \mathbf{I} = \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I}), \\ \psi(\mathbf{v}^{\perp}, \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) + \frac{1}{2}\psi(\mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I}), \mathcal{P}^{\perp}_{\mathcal{V}}(\mathbf{I})) = 0. \end{cases}$$

The conclusion follows immediately from Lemma (4.1). □

The theorem has an immediate application to the class of constraints $\mathcal{S}$ of codimension 1.

Corollary 4.1: Let $\mathcal{S}$ be such that codim$(\mathcal{S})=1$ and let $\mathbf{I}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ be a nontrivial constitutive characterization for $\mathcal{S}$ satisfying the hypotheses of Theorem (4.1). Then

$$\mathbf{I}(\mathbf{x}) = -2\mathbf{v}^{\perp}(\mathbf{x}), \quad \forall\, \mathbf{x} \in i^*(J_1(\mathcal{V})). \tag{25}$$

Proof: Since $\dim((i_*(V(\mathcal{S})))^{\perp})=1$, conditions (24) imply that $\mathbf{Z}(\mathbf{x})=0\,\forall\,\mathbf{x} \in i^*(J_1(\mathcal{V}))$. Moreover, the impenetrability condition $\Phi(\mathbf{v}^{\perp}(\mathbf{x}), \mathbf{I}(\mathbf{x})) \leqslant 0\,\forall\,\mathbf{x} \in i^*(J_1(\mathcal{V}))$ has a straightforward verification. □

The case codim$(\mathcal{S})>1$ is not particularly significant from the physical point of view: a simple example is given by a point particle moving in a three-dimensional space and colliding with a one-dimensional straight line. Anyway, Theorem (4.1) allows a simple treatment of such cases by requiring an additional "minimality" criterion. Of course, due to results 3,4) of Lemma (4.1), the minimality must be required for the part $\mathbf{Z}(\mathbf{x})$ of the reactive impulse $\mathbf{I}(\mathbf{x})$ or, alternatively, a "maximality" condition must be required for $\mathbf{I}(\mathbf{x})$. A minimality requirement on $\mathbf{I}(\mathbf{x})$ would give in fact the trivial (null) reaction.

The described procedure applied to a point particle moving in a three-dimensional space and colliding with a one-dimensional straight line gives a very natural result: the impulsive reaction belongs to the plane determined by $\mathbf{v}^{\perp}$ and the constraint. The detailed calculation will not be presented in the following, since we prefer to discuss more significant examples.

B. The Poisson-type approach

The Poisson-type approach to impulsive problems divides the reactive impulse $\mathbf{I}$ due to $\mathcal{S}$ into two parts $\mathbf{I}_{\text{in}}$ and $\mathbf{I}_{\text{out}}$ with different physical meanings (see, for example, Ref. 28, and references therein).

The part $\mathbf{I}_{\text{in}}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ is related to the "entrance" of the system in the constraint $\mathcal{S}$ viewed, roughly speaking, as a "suddenly appearing positional constraint." Then, with the previous discussion about the natural requirements to ask of an ideal constitutive characterization kept in mind, we see that $\mathbf{I}_{\text{in}}$ must satisfy the property

$$\mathbf{x} + \mathbf{I}_{\text{in}}(\mathbf{x}) \in i_*(J_1(\mathcal{S})), \quad \forall\, \mathbf{x} \in i^*(J_1(\mathcal{V})) \tag{26}$$

and $\mathbf{I}_{\text{in}}$ should be dependent only on the geometric objects of the setup. The most natural choice of a constitutive characterization for $\mathbf{I}_{\text{in}}$ follows from the requirement $\mathbf{x}+\mathbf{I}_{\text{in}}(\mathbf{x})=\mathcal{P}\ (\mathbf{x})$. Moreover, this is the same result given by the application of the usual minimality principle. The requirement $\mathbf{x}+\mathbf{I}_{\text{in}}(\mathbf{x})=\mathcal{P}\ (\mathbf{x})$ implies $\mathbf{I}_{\text{in}}(\mathbf{x})=-\mathbf{v}^{\perp}(\mathbf{x})$.

The part $\mathbf{I}_{\text{out}}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ is related to the "exit" of the system from the constraint $\mathcal{S}$, and it is subject to additional requirements, which, in general, express mechanical properties of the impulsive problem. For example, one such property could be the conservation of kinetic energy. Once again the conservation of energy cannot be required for every frame of reference and should not be required for a single rest frame. The discussion of a constitutive characterization for $\mathbf{I}_{\text{out}}$ can be phrased in terms of the properties of the total reactive impulse $\mathbf{I}_{\text{tot}}=\mathbf{I}_{\text{in}}+\mathbf{I}_{\text{out}}$ as presented in Theorem 4.1. Alternatively, it can be presented *ex novo* starting from the condition

$$^{\mathbf{H}}\mathcal{K}(\mathbf{x}-\mathbf{v}^{\perp}(\mathbf{x})+\mathbf{I}_{\text{out}}(\mathbf{x}))=\,^{\mathbf{H}}\mathcal{K}(\mathbf{x}),\quad \forall\,\mathbf{x}\in i^{*}(J_1(\mathcal{V})),\quad \forall\,\mathbf{H}\in\mathcal{H}$$

and repeating the procedure of Theorem 4.1. In both cases it easily follows that

$$\mathbf{I}_{\text{out}}(\mathbf{x})+\mathbf{v}^{\perp}(\mathbf{x})=\mathbf{Z}(\mathbf{x}),\quad \forall\,\mathbf{x}\in i^{*}(J_1(\mathcal{V})). \tag{27}$$

The latter gives results completely analogous to the ones of the Newton-type approach both when $\text{codim}(\mathcal{S})=1$ and when $\text{codim}(\mathcal{S})>1$.

C. The reflection operator approach

The case $\text{codim}(\mathcal{S})=1$ can be approached in a classical, but different, way through the use of reflection operators.

We recall that once a scalar product Φ is known in a vector space V, it is possible to associate to each assigned vector $N\in V$, with $\|N\|=1$, a reflection operator

$$\mathbf{R}_N\colon V\to V \text{ such that } v\rightsquigarrow \mathbf{R}_N(v)=v-2\Phi(v,N)N. \tag{28}$$

When $\text{codim}(\mathcal{S})=1$ we can introduce a unitary generator $\mathbf{N}$ of $(i_*(V(\mathcal{S})))^{\perp}$ and then we can define its associated reflection operator $\mathbf{R}_{\mathbf{N}}\colon i^{*}(V(\mathcal{V}))\to i^{*}(V(\mathcal{V}))$, that will be denoted simply by $\mathbf{R}$.

Recalling that each frame of reference $\mathbf{H}$ determines the diffeomorphism $\Delta_{\mathbf{H}}\colon i^{*}(J_1(\mathcal{V}))\to i^{*}(V(\mathcal{V}))$, a possible choice of a constitutive characterization of $\mathcal{S}$ can be given by the rule

$$\tilde{I}_{\mathbf{R}}\colon i^{*}(L_1(\mathcal{V}))\to i^{*}(R_1(\mathcal{V})) \text{ such that } \mathbf{x}_L\rightsquigarrow \mathbf{x}_R=\Delta_{\mathbf{H}}^{-1}(\mathbf{R}(^{\mathbf{H}}\mathbf{v}(\mathbf{x}_L))). \tag{29}$$

A straightforward calculation shows that this characterization is the same as

$$\mathbf{I}_{\mathbf{R}}\colon i^{*}(J_1(\mathcal{V}))\to i^{*}(V(\mathcal{V})) \text{ such that } \mathbf{x}\rightsquigarrow \mathbf{I}_{\mathbf{R}}(\mathbf{x})=-2\Phi(\mathbf{x}-\mathbf{H},\mathbf{N})\mathbf{N}. \tag{30}$$

Unfortunately, following this line of argument brings us to the same difficulty we mentioned earlier, since any constitutive characterization of type (30) depends on the frame $\mathbf{H}$. The relation with the constitutive characterization of Sec. IV A is clarified by the following.

Corollary 4.2: The constitutive characterization $\mathbf{I}_{\mathbf{R}}$ *does not depend on the frame* $\mathbf{H}$ *if and only if* $\mathbf{H}$ *is chosen in the class* $\mathcal{H}$ *of the frames tangent to* $\mathcal{S}$. *In this case, the characterization* $\mathbf{I}_{\mathbf{R}}$ *coincides with the characterization* $\mathbf{I}$ *of Sec. IV A.*

Proof: Since the single vector $\mathbf{N}$ forms a unitary basis of $(i_*(V(\mathcal{S})))^{\perp}$, the vector $\Phi(\mathbf{x}-\mathbf{H},\mathbf{N})\mathbf{N}$ is the component $^{\mathbf{H}}\mathbf{v}^{\perp}\in(i_*(V(\mathcal{S})))^{\perp}$ of the velocity $\mathbf{x}$. Then Theorem (3.1) gives the first statement of the corollary. Once $\mathbf{H}\in\mathcal{H}$, then

$$\begin{aligned}\mathbf{I}_{\mathbf{R}}(\mathbf{x})&=-2\Phi(\mathbf{x}-\mathbf{H},\mathbf{N})\mathbf{N}\\&=-2\Phi(\mathbf{v}^{\perp}(\mathbf{x}),\mathbf{N})\mathbf{N}=-2\psi(\mathbf{v}^{\perp}(\mathbf{x}),\mathbf{N})\mathbf{N}=-2\mathbf{v}^{\perp}\end{aligned}$$

from which the result follows. □

V. EXAMPLES

The main reason for the choice of the examples in the following is to show in detail the application of the ideal constitutive characterization for impulsive constraints acting on some significant mechanical systems. Secondarily, in order to prove the naturalness of the ideal characterization, our choice of examples is based on the intention of illustrating the clear physical interpretation of some peculiar results regarding specific mechanical systems. A third reason is the possibility of returning to some arguments, such as the geometric representation of constraints in Impulsive Mechanics, that were only skimmed in the previous discussions.

For these reasons, the simplest example of a point particle moving in a plane and impacting with a straight line is left to the reader.

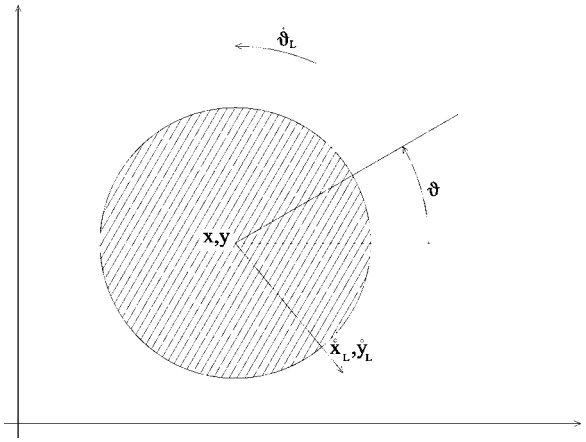


FIG. 1. Example 1.

A. Example 1

A homogeneous disk of mass m and radius R is moving in a plane and impacts with a smooth straight line.

The space-time bundle $\mathcal{V}$ is a four-dimensional manifold. Local admissible coordinates can be chosen as (t,x,y,ϑ) where x,y are the Cartesian coordinates of the center of the disk in the plane of the motion and ϑ is the orientation of the disk (see Fig. 1). The configuration space is $\mathbb{R}^2 \times \mathbb{S}^1$. The vertical scalar product Φ on $\mathcal{V}$ is described by the matrix $g_{ij}=\mathrm{diag}(m,m,A)$ with $A=\frac{1}{2}mR^2$. The constraint $\mathcal{S}$ can be described by the condition $y=R$ or, choosing admissible coordinates (t,x,ϑ) in $\mathcal{S}$, by the injection

$$i:\mathcal{S}\to\mathcal{V} \text{ such that } (t,x,\vartheta)\rightsquigarrow(t,x,R,\vartheta). \tag{31}$$

Therefore in this example $\mathrm{codim}(\mathcal{S})=1$. The scalar product φ on $\mathcal{S}$ is described by the matrix $\gamma_{\alpha\beta}=\mathrm{diag}(m,A)$. The velocity and vertical spaces are:

$$i^*(J_1(\mathcal{V}))=\left\{\mathbf{x}=\frac{\partial}{\partial t}+\dot{x}\frac{\partial}{\partial x}+\dot{y}\frac{\partial}{\partial y}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$i^*(V(\mathcal{V}))=\left\{\mathbf{U}=\dot{x}\frac{\partial}{\partial x}+\dot{y}\frac{\partial}{\partial y}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$i_*(J_1(\mathcal{S}))=\left\{\mathbf{q}=\frac{\partial}{\partial t}+\dot{x}\frac{\partial}{\partial x}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$i_*(V(\mathcal{S}))=\left\{\mathbf{V}=\dot{x}\frac{\partial}{\partial x}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$(i_*(V(\mathcal{S})))^\perp=\left\{\mathbf{W}=w\frac{\partial}{\partial y}\right\}.$$

A unit vector generating $(i_*(V(\mathcal{S})))^\perp$ is $\mathbf{N}=(1/\sqrt{m})\partial/\partial y$.

Given a left velocity $\mathbf{x}_L=\partial/\partial t+\dot{x}_L\partial/\partial x+\dot{y}_L\partial/\partial y+\dot{\vartheta}_L\partial/\partial\vartheta$, we have $\mathbf{v}^\perp(\mathbf{x}_L)=\mathcal{P}^\perp(\mathbf{x}_L)=\dot{y}_L\partial/\partial y$ and the corresponding ideal reactive impulse is $\mathbf{I}(\mathbf{x}_L)=-2\mathbf{v}^\perp(\mathbf{x}_L)=-2\dot{y}_L\partial/\partial y$. It follows that

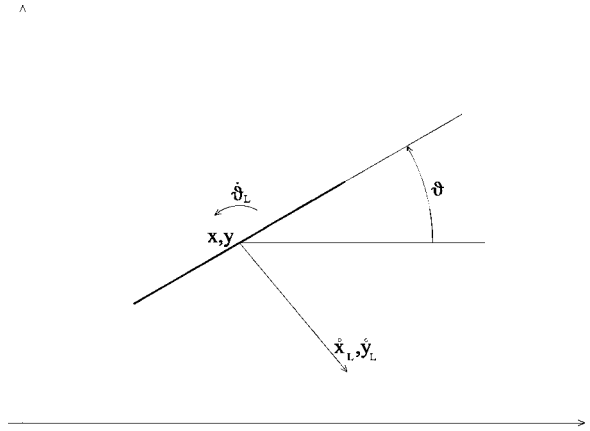

FIG. 2. Example 2.

$$\mathbf{x}_R = \mathbf{x}_L + \mathbf{I}(\mathbf{x}_L) = \frac{\partial}{\partial t} + \dot{x}_L \frac{\partial}{\partial x} - \dot{y}_L \frac{\partial}{\partial y} + \dot{\vartheta}_L \frac{\partial}{\partial \vartheta}. \tag{32}$$

The result has a clear physical interpretation: both the velocity along the x axis and the angular velocity of the disk do not vary with the impact, while the velocity of the disk along the y axis simply reverses. This is of course in perfect agreement with the reflection operator approach.

B. Example 2

A homogeneous rod of mass m and length $2L$ is moving in a plane and one of its ends impacts with a smooth straight line.

The space-time bundle $\mathcal{V}$ is again a four-dimensional manifold with local admissible coordinates (t,x,y,ϑ), where x,y are the Cartesian coordinates of the center of mass of the rod in the plane of the motion and ϑ is the angle formed by the rod with the x axis (see Fig. 2). Once again, the configuration space is $\mathbb{R}^2 \times \mathbb{S}^1$. The vertical scalar product Φ on $\mathcal{V}$ is described by the matrix $g_{ij}=\mathrm{diag}(m,m,A)$ with $A=\frac{1}{3}mL^2$. The constraint $\mathcal{S}$ can be described by the condition $y-L\sin\vartheta=0$ or, choosing admissible coordinates (t,x,ϑ) in $\mathcal{S}$, by the injection

$$i:\mathcal{S} \to \mathcal{V} \text{ such that } (t,x,\vartheta) \rightsquigarrow (t,x,L\sin\vartheta,\vartheta). \tag{33}$$

Therefore $\mathrm{codim}(\mathcal{S})=1$. We avoid the possibility that all the points of the rod simultaneously impact with $\mathcal{S}$ by requiring $\vartheta \in (0,\pi)$. The scalar product φ on $\mathcal{S}$ is described by the matrix $\gamma_{\alpha\beta}=\mathrm{diag}(m,A(1+3\cos^2\vartheta))$. The velocity and vertical spaces are:

$$i^*(J_1(\mathcal{V})) = \left\{ \mathbf{x} = \frac{\partial}{\partial t} + \dot{x}\frac{\partial}{\partial x} + \dot{y}\frac{\partial}{\partial y} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} \right\},$$

$$i^*(V(\mathcal{V})) = \left\{ \mathbf{U} = \dot{x}\frac{\partial}{\partial x} + \dot{y}\frac{\partial}{\partial y} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} \right\},$$

$$i_*(J_1(\mathcal{S})) = \left\{ \mathbf{q} = \frac{\partial}{\partial t} + \dot{x}\frac{\partial}{\partial x} + L\dot{\vartheta}\cos\vartheta\frac{\partial}{\partial y} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} \right\},$$

$$i_*(V(\mathcal{S})) = \left\{ \mathbf{V} = \dot{x}\frac{\partial}{\partial x} + L\dot{\vartheta}\cos\vartheta\frac{\partial}{\partial y} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} \right\},$$

$$(i_*(V(\mathcal{S})))^{\perp} = \left\{ \mathbf{W} = w\left(\frac{\partial}{\partial y} - \frac{3}{L}\cos\vartheta \frac{\partial}{\partial \vartheta} \right) \right\}.$$

Given a left velocity $\mathbf{x}_L = \partial/\partial t + \dot{x}_L \partial/\partial x + \dot{y}_L \partial/\partial y + \dot{\vartheta}_L \partial/\partial \vartheta$, we have

$$\mathbf{v}^{\perp}(\mathbf{x}_L) = \left(\dot{y}_L - \frac{mL\dot{y}_L \cos\vartheta + A\dot{\vartheta}_L}{A(1+3\cos^2\vartheta))} L\cos\vartheta \right) \frac{\partial}{\partial y} + \left(\dot{\vartheta}_L - \frac{mL\dot{y}_L \cos\vartheta + A\dot{\vartheta}_L}{A(1+3\cos^2\vartheta))} \right) \frac{\partial}{\partial \vartheta}.$$

It follows that

$$\mathbf{x}_R = \mathbf{x}_L + \mathbf{I}(\mathbf{x}_L) = \frac{\partial}{\partial t} + \dot{x}_L \frac{\partial}{\partial x} + \left(2\frac{mL\dot{y}_L \cos\vartheta + A\dot{\vartheta}_L}{A(1+3\cos^2\vartheta))} L\cos\vartheta - \dot{y}_L \right) \frac{\partial}{\partial y}$$
$$+ \left(2\frac{mL\dot{y}_L \cos\vartheta + A\dot{\vartheta}_L}{A(1+3\cos^2\vartheta))} - \dot{\vartheta}_L \right) \frac{\partial}{\partial \vartheta}.$$

A simple test of reasonableness of the result follows from the analysis of the particular case of impact configuration with the rod orthogonal to the constraint, that is when $\vartheta = \pi/2$. A straightforward substitution gives $\mathbf{v}^{\perp}(\mathbf{x}_L) = \dot{y}_L \partial/\partial y$, from which follows the expected result $\mathbf{x}_R = \partial/\partial t + \dot{x}_L \partial/\partial x - \dot{y}_L \partial/\partial y + \dot{\vartheta}_L \partial/\partial \vartheta$.

Another possible test follows from an analysis of the dependence on the "impact angle" ϑ of the behavior of the rod when the rod collides with left velocity $\mathbf{x}_L = \partial/\partial t + \dot{x}_L \partial/\partial x + \dot{y}_L \partial/\partial y$, that is with null angular velocity. A first result, once again easily predicted, is that the component $\dot{x}_R$ of the right velocity along the x axis coincides with $\dot{x}_L$, that is the component of the velocity of the center of mass along the x axis is not affected by the impact. A second result is the existence of two symmetric angles, determined by the condition $\dot{y}_R = 0$ and given by $\cos^2\vartheta = \frac{1}{3}$. It can be easily seen that, for impact angles ϑ with $\cos^2\vartheta < \frac{1}{3}$, the component $\dot{y}_R$ of the right velocity along the y axis has the opposite sign of $\dot{y}_L$ (the rod "rebounds" off the constraint) while for impact angles ϑ with $\cos^2\vartheta > \frac{1}{3}$, the component $\dot{y}_R$ of the right velocity along the y axis has the same sign of $\dot{y}_L$ (the center of mass of the rod "continues its approach" to the constraint). However in both cases an angular velocity $\dot{\vartheta}_R \neq 0$ appears (with a sign correctly determined by the impact angle).

C. Example 3

A homogeneous sphere of mass m and radius R is moving in a three-dimensional space and impacts with a smooth straight line (see Fig. 3).

In this example the space-time bundle $\mathcal{V}$ is a seven-dimensional manifold with local admissible coordinates $(t,x,y,z,\psi,\vartheta,\phi)$, where x,y,z are the Cartesian coordinates of the center of mass of the sphere and ψ,ϑ,ϕ are the usual Euler angles. The configuration space is $\mathbb{R}^3 \times \mathbf{SO(3)}$. The vertical scalar product Φ on $\mathcal{V}$ is described by the matrix

$$g_{ij} = \begin{pmatrix} m & 0 & 0 & 0 & 0 & 0 \\ 0 & m & 0 & 0 & 0 & 0 \\ 0 & 0 & m & 0 & 0 & 0 \\ 0 & 0 & 0 & A & 0 & A\cos\vartheta \\ 0 & 0 & 0 & 0 & A & 0 \\ 0 & 0 & 0 & A\cos\vartheta & 0 & A \end{pmatrix}$$

with $A = \frac{2}{5}mR^2$. The constraint $\mathcal{S}$ can be described by the condition $y^2 + z^2 = R$ or, choosing admissible coordinates $(t,x,\alpha,\psi,\vartheta,\phi)$ in $\mathcal{S}$, by the injection

$$i:\mathcal{S} \to \mathcal{V} \text{ such that } (t,x,\alpha,\psi,\vartheta,\phi) \rightsquigarrow (t,x,R\cos\alpha,R\sin\alpha,\psi,\vartheta,\phi). \tag{34}$$

Again $\operatorname{codim}(\mathcal{S}) = 1$. With the additional condition $\sin\vartheta \neq 0$, the velocity and vertical spaces are:

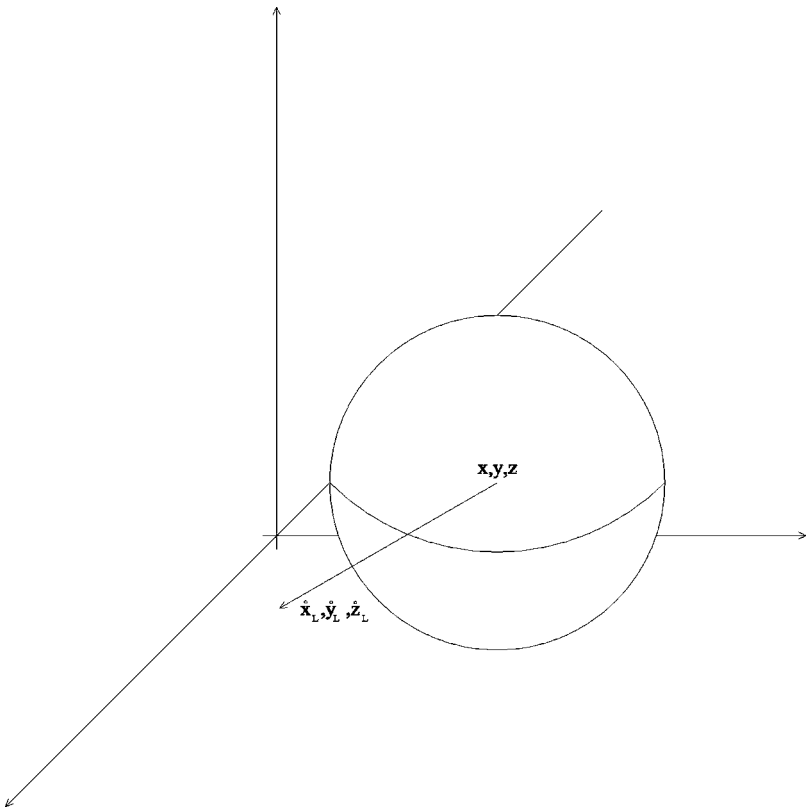

FIG. 3. Example 3.

$$i^*(J_1(\mathcal{V})) = \left\{ \mathbf{x} = \frac{\partial}{\partial t} + \dot{x}\frac{\partial}{\partial x} + \dot{y}\frac{\partial}{\partial y} + \dot{z}\frac{\partial}{\partial z} + \dot{\psi}\frac{\partial}{\partial \psi} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} + \dot{\phi}\frac{\partial}{\partial \phi} \right\},$$

$$i^*(V(\mathcal{V})) = \left\{ \mathbf{U} = \dot{x}\frac{\partial}{\partial x} + \dot{y}\frac{\partial}{\partial y} + \dot{z}\frac{\partial}{\partial z} + \dot{\psi}\frac{\partial}{\partial \psi} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} + \dot{\phi}\frac{\partial}{\partial \phi} \right\},$$

$$i_*(J_1(\mathcal{S})) = \left\{ \mathbf{q} = \frac{\partial}{\partial t} + \dot{x}\frac{\partial}{\partial x} - \dot{\alpha}R\sin\alpha\frac{\partial}{\partial y} + \dot{\alpha}R\cos\alpha\frac{\partial}{\partial z} + \dot{\psi}\frac{\partial}{\partial \psi} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} + \dot{\phi}\frac{\partial}{\partial \phi} \right\},$$

$$i_*(V(\mathcal{S})) = \left\{ \mathbf{V} = \dot{x}\frac{\partial}{\partial x} - \dot{\alpha}R\sin\alpha\frac{\partial}{\partial y} + \dot{\alpha}R\cos\alpha\frac{\partial}{\partial z} + \dot{\psi}\frac{\partial}{\partial \psi} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} + \dot{\phi}\frac{\partial}{\partial \phi} \right\},$$

$$(i_*(V(\mathcal{S})))^\perp = \left\{ \mathbf{W} = w\left(\cos\alpha\frac{\partial}{\partial y} + \sin\alpha\frac{\partial}{\partial z} \right) \right\}.$$

Given a left velocity $\mathbf{x}_L = \partial/\partial t + \dot{x}_L\partial/\partial x + \dot{y}_L\partial/\partial y + \dot{z}_L\partial/\partial z + \dot{\psi}_L\partial/\partial \psi + \dot{\vartheta}_L\partial/\partial \vartheta + \dot{\phi}_L\partial/\partial \phi$, we have

$$\mathbf{v}^\perp(\mathbf{x}_L) = [(\dot{y}_L\cos\alpha + \dot{z}_L\sin\alpha)\cos\alpha]\frac{\partial}{\partial y} + [(\dot{y}_L\cos\alpha + \dot{z}_L\sin\alpha)\sin\alpha]\frac{\partial}{\partial z}.$$

It follows that

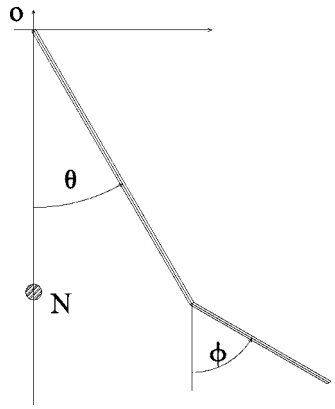

FIG. 4. Example 4.

$$\mathbf{x}_R = \mathbf{x}_L + \mathbf{I}(\mathbf{x}_L) = \frac{\partial}{\partial t} + \dot{x}_L \frac{\partial}{\partial x} + (\dot{y}_L - 2\cos\alpha(\dot{y}_L \cos\alpha + \dot{z}_L \sin\alpha))\frac{\partial}{\partial y}$$
$$+ (\dot{z}_L - 2\sin\alpha(\dot{y}_L \cos\alpha + \dot{z}_L \sin\alpha))\frac{\partial}{\partial z} + \dot{\psi}_L \frac{\partial}{\partial \psi} + \dot{\vartheta}_L \frac{\partial}{\partial \vartheta} + \dot{\phi}_L \frac{\partial}{\partial \phi}.$$

Once again, simple tests of reasonableness of the result follow from the analysis of particular cases of impact configurations. For example, an impact with $\dot{y}_L < 0$, $\dot{z}_L = 0$, $\alpha = \pi/4$ gives $\dot{y}_R = 0$, $\dot{z}_R = -\dot{y}_L$ and leaves invariant the other component of the left velocity.

However, one important peculiarity of this example is that it points out the fact, only alluded to in the introduction of the paper, that the translation of the physical problem with its constraints (the ball impacting with the line) into the geometric context can transform the thread $y = z = 0$, that is a constraint with codimension greater than 1, into a constraint with codimension 1 (the "cylinder" $\mathcal{S}$).

D. Example 4

A mechanical system is formed by two rods of mass $2m$ and m and length $2L$ and L, respectively, moving in a plane. The first rod has one of its ends fixed at a point O of the plane (so that it can only rotate around O), the second rod has one of its ends fixed at the second end of the first rod. A nail N is fixed in the plane at a distance $\sqrt{3}L$ from O (see Fig. 4). Then there are three different kinds of impact: the first rod impacts with the nail while the second rod is far from the nail; the second rod impacts with the nail while the first rod is far from the nail; both the rods impact simultaneously with the nail.

In this example the space-time bundle $\mathcal{V}$ is a three-dimensional manifold with local admissible coordinates (t, ϑ, ϕ), where ϑ is the angle formed by the first rod and the straight line determined by O and N while ϕ is the angle formed by the second rod and the direction of the straight line ON. The configuration space of the system is the two-dimensional torus $\mathbb{T}^2$ and the vertical scalar product Φ on $\mathcal{V}$ is described by the matrix

$$g_{ij} = \begin{pmatrix} \frac{10}{3}mL^2 & mL^2\cos(\vartheta - \phi) \\ mL^2\cos(\vartheta - \phi) & \frac{1}{6}mL^2 \end{pmatrix}.$$

The constraint $\mathcal{S}$ is the union of the zero sets described by the two conditions $\mathcal{S}_1, \mathcal{S}_2$, where

$$\mathcal{S}_1 : \vartheta = 0,$$

$$\mathcal{S}_2:\begin{cases}\phi=\dfrac{3\pi}{2}+\arctan\left(\dfrac{\frac{\sqrt{3}}{2}-\cos\vartheta}{\sin\vartheta}\right) & \text{if } \vartheta\in\left[0,\dfrac{\pi}{6}\right)\\ \phi=\dfrac{\pi}{2}+\arctan\left(\dfrac{\frac{\sqrt{3}}{2}-\cos\vartheta}{\sin\vartheta}\right) & \text{if } \vartheta\in\left(\dfrac{11\pi}{6},2\pi\right].\end{cases}$$

The codimension of the constraint requires a discussion, due to the three different kinds of impact: the impact with $\mathcal{S}_1$, the impact with $\mathcal{S}_2$, and the impact with $\mathcal{S}_1\cap\mathcal{S}_2$.

We leave it to the reader to verify that in the first two situations the codimension of the constraint is 1 and the behavior of the system is very natural. In the third case the codimension of the constraint is 2 and Corollary 4.1 cannot be applied.

One might hope that to analyze the third case it would be enough to first consider Case 1 and then follow it by Case 2 (or vice versa). Unfortunately, the conclusion one obtains depends on the order in which we consider the cases. Consequently, the hope remains unrealized. On the contrary, the additional "minimality" requirement discussed at the end of Sec. IV A applied to the third case gives rise to a well-defined and naturally interpretable right velocity.

VI. OUTLOOKS AND WISHES

The results and techniques described in the paper to approach the study of time-dependent unilateral constraints could be (we hope…) useful tools to investigate several other aspects of Impulsive Mechanics. The most natural step in the direction traced out by the paper seems to be the study of the so-called kinetically constrained impulsive motion, i.e., the impulsive motion of a mechanical system subject to kinetic constraints, possibly of permanent or instantaneous nature. The most classical example is the billiard ball, rolling on a rough plane (and then subject to a permanent kinetic constraint) and impacting with a rough wall (and then subject to the unilateral impulsive constraint given by the wall and the instantaneous kinetic impulsive constraint due to the roughness of the wall).

Another possible application of the results of the paper is the study of impacts between different parts of the same mechanical system (or between two different systems, such as two billiard balls), and the analysis of the conservation of linear and angular momenta.

It goes without saying that the most interesting development of this geometric approach to Impulsive Mechanics consists in the study of the behavior of time-dependent systems subject to nonideal unilateral impulsive constraints. Surely, at the present time, this problem is almost totally open, but, in our opinion, a possible first step is a consistent definition of the coefficient of restitution, that, in the time-dependent case, seems to be strictly related to the concept of frame of rest of the constraint.

(Received 23 April 2004; accepted 11 October 2005; published online 30 November 2005)

We introduce the notion of Gauss-Landau-Hall magnetic field on a Riemannian surface. The corresponding Landau-Hall problem is shown to be equivalent to the dynamics of a massive boson. This allows one to view that problem as a globally stated, variational one. In this framework, flowlines appear as critical points of an action with density depending on the proper acceleration. Moreover, we can study global stability of flowlines. In this equivalence, the massless particle model corresponds with a limit case obtained when the force of the Gauss-Landau-Hall magnetic field increases arbitrarily. We also obtain properties related with the completeness of flowlines for general magnetic fields. The paper also contains results relative to the Landau-Hall problem associated with a uniform magnetic field. For example, we characterize those revolution surfaces whose parallels are all normal flowlines of a uniform magnetic field. © *2005 American Institute of Physics.*

I. INTRODUCTION

Classically, the Landau-Hall problem consists of the motion study of a charged particle in the presence of a static magnetic field, H. In this setting, free of any electric field, a particle, of charge e and mass m, evolves with velocity v satisfying the Lorentz force law,[1]

$$\frac{\mathrm{d}P}{\mathrm{d}t} = \frac{e}{c} v \times H,$$

where c denotes the light speed, $P=(\epsilon/c^2)v$ stands for the momentum of the particle, and $\epsilon = mc^2[1-(\|v\|^2/c^2)]^{-1/2}$ is its energy. Since $\mathrm{d}P/\mathrm{d}t$ is orthogonal to P, then $(d/\mathrm{d}t)(\|P\|^2)=0$. This implies the constancy of both $\|v\|$ and ϵ. Assume H is stationary, i.e., H is a time-independent vector of the Euclidean space $\mathbb{R}^3$. With the choice of a suitable orthonormal reference system, we may assume that $H=h(0,0,1)$, for some $h \in \mathbb{R}$. In this framework, we have

$$\frac{d}{\mathrm{d}t} v_1(t) = \omega v_2(t), \quad \frac{d}{\mathrm{d}t} v_2(t) = -\omega v_1(t), \quad \frac{d}{\mathrm{d}t} v_3(t) = 0,$$

where $\omega=(ehc)/\epsilon$ is constant. Then

$$x_1(t) = x_1^0 + r\sin(\omega t + \alpha), \quad x_2(t) = x_2^0 + r\cos(\omega t + \alpha), \quad x_3(t) = x_3^0 + v_3^0 t,$$

where $r = \|v\|/\omega$. In particular, if $v_3^0 = 0$, then the particle describes a circle in the plane $x_3 = x_3^0$, with center (x_1^0, x_2^0, x_3^0) and radius r. Now, in this plane we consider the 2-form F defined by $F(X,Y) = \varepsilon\langle X \times Y, H\rangle$, where $\varepsilon = \pm 1$ is the sign of h/ω. It is clear that F is covariantly constant, and therefore it is a constant multiple of the area element, indeed $F = \varepsilon h\, \mathrm{d}x_1 \wedge \mathrm{d}x_2$. Now, consider the metric g on the plane defined by $g := \varepsilon(h/\omega)g^0$, where $g^0 = \langle , \rangle$ denotes the Riemannian metric on the plane induced by the usual one of $\mathbb{R}^3$. Define the operator Φ, g-equivalent to F, by $g(\Phi(X), Y) = F(X,Y)$. Then, the Lorentz force law can be expressed in terms of this form by

$$\frac{d}{\mathrm{d}t} v(t) = \Phi(v(t)). \tag{1}$$

This approach to the classical picture can be obviously extended to a more general setting. In fact, it seems natural to define a *magnetic field* on a $n(\geqslant 2)$-dimensional Riemannian manifold (M,g), as a closed 2-form F on M. The *Lorentz force* of a magnetic background (M,g,F) is defined to be the skew-symmetric operator, Φ, given by

$$g(\Phi(X), Y) = F(X,Y), \tag{2}$$

for any couple of vector fields X, Y on M. Let us remark that Φ is metrically equivalent to F, so no information is lost when Φ is considered instead of F. In classical terminology, it is said that Φ is obtained from F by raising its second index, and Φ and F are then said to be physically equivalent. On the other hand, there exists another operator Φ' defined from F via g in a similar way, namely $g(X, \Phi'(Y)) = F(X,Y)$, but it is easily seen that $\Phi' = -\Phi$. So, the choice from among Φ or Φ' to represent F, using g, is not relevant. Along this paper, we will use Φ to denote the Lorentz force induced from (M,g,F).

A (smooth) curve γ in (M,g) is called a *flowline* of the dynamical system associated with the magnetic field F [or simply a flowline of F, or a *magnetic curve* of (M,g,F)], if its velocity vector field, γ', satisfies the following (Landau-Hall) differential equation:

$$\text{(LH)} \quad \nabla_{\gamma'} \gamma' = \Phi(\gamma'),$$

where ∇ is the Levi-Civita connection of g [compare with Eq. (1)].

For the trivial magnetic field, $F = 0$, the case without the force of a magnetic field, magnetic curves correspond with the geodesics of (M,g). As it is well known, they are nicely characterized as critical points of an energy action and so they represent the trajectories for free fall particles (moving under the influence of only gravity). In the general case, however, magnetic flows are important examples of dynamical systems on Riemannian manifolds whose flowlines, being the trajectories of charged particles in (nontrivial) magnetic fields, are not geodesics (Proposition 2.1) but, as we will see later, they are closely related with the Riemannian structure.

Nevertheless, the magnetic curves of (M,g,F) can be also viewed, at least locally, as the solutions of a variational principle. In fact, let U be an open subset of M where $F = \mathrm{d}\omega$ for some potential 1-form ω [this open subset could be the whole M when $H^2(M) = 0$]. For any two fixed points p, $q \in U$, we consider the space Γ_{pq} of smooth curves in U that connect these two points. Now, we choose the action $\mathcal{LH}: \Gamma_{pq} \to \mathbb{R}$ defined by

$$\mathcal{LH}(\gamma) = \frac{1}{2}\int_\gamma g(\gamma', \gamma')\mathrm{d}t - \int_\gamma \omega(\gamma')\mathrm{d}t. \tag{3}$$

The tangent space of Γ_{pq} in γ is made up of the smooth vector fields, V, along γ that vanish at the endpoints p, $q \in U$. A standard computation involving integration by parts allows one to compute the first variation of this action to be

$$\delta(\mathcal{LH})(\gamma)[V] = -\int_{\gamma} g(\nabla_{\gamma'}\gamma' - \Phi(\gamma'), V)\mathrm{d}t.$$

As a consequence, we get

$$\delta(\mathcal{LH})(\gamma)[V] = 0, \quad \text{for any } V \in T_{\gamma}\Gamma_{pq} \quad \text{if and only if } \gamma \text{ is a solution of (LH)}.$$

This argument shows that the differential equation (LH) is indeed the Euler-Lagrange equation associated with the functional $\mathcal{LH}$.

However, it seems natural to realize the old idea of characterizing magnetic curves from a global variational principle. In other words, to obtain the magnetic trajectories of (M,g,F) as solutions of a variational problem that neither it does not involve any local potential nor it does not constraint the topology of M. This is, in general, an interesting open problem. One of the main aims of this paper is just to solve it for certain magnetic fields on surfaces.

To be precise, we introduce the notion of a Gauss-Landau-Hall magnetic field (in brief, GMF) on an oriented Riemannian surface (M,g). First, we do it in the natural context that surfaces are immersed in Euclidean space $\mathbb{R}^3$ using the Gauss map. However, we notice that the notion of GMF is absolutely intrinsic so it can be considered on surfaces even if they are not regarded in $\mathbb{R}^3$. Then, we are able to obtain an amazing result which characterizes the normal flowlines of a GMF as the solutions of a variational principle globally stated. Therefore, those flowlines appear as critical points of an action whose Lagrangian density involves the proper acceleration of particles (relativistic particles with rigidity of order one, in the sense of Plyushchay[2,3]). *A priori*, these actions describe a massive relativistic boson. However, massless particles with arbitrary helicity are obtained as a limit case, just when the Lorentz force of the GMG increases arbitrarily.

Other details on the paper are the following. We first provide in Sec. II an analysis of the existence, uniqueness, extendibility, and completeness of the magnetic curves associated with a given (M,g,F). Section III deals with uniform magnetic fields on Riemannian surfaces, while the particular case when (M,g) is a revolution surface is studied in Sec. IV. In Sec. V, a one-parameter family $\mathcal{F}_m$ of functionals is considered on an appropriate space of curves Λ in the surface. The Euler-Lagrange equation associated to the variational problem is then obtained. In Sec. VI we define a Gauss-Landau-Hall magnetic field on a surface, first in $\mathbb{R}^3$, and then in general. In this section, we obtain the main result, Theorem 6.1, which asserts that the normal flowlines of a GMF coincide with the critical points of the appropriate functional $\mathcal{F}_m$. Stability of the field equation solutions is also studied. In Sec. VII, we show a characterization theorem for those revolution surfaces whose parallels are all normal magnetic curves associated to a GMF. We close the section studying some particular examples.

II. COMPLETENESS OF MAGNETIC CURVES AND MORE

An early property of the magnetic curves is the following conservation's law. Particles evolve with constant speed, and so constant energy, along the magnetic trajectories

$$\frac{d}{\mathrm{d}t}g(\gamma',\gamma') = 2g(\Phi(\gamma'),\gamma') = 0. \tag{4}$$

In particular, a magnetic curve γ is said to be *normal* if it has unit energy, i.e., $\|\gamma'\|^2 \equiv 1$.

The existence and uniqueness of geodesics, remains true when one considers magnetic curves. Thus, for each $p \in M$ and $v \in T_pM$ there is exactly one inextendible (i.e., maximal) magnetic curve, $\gamma:(-a,a)\to M$, of (M,g,F) with $\gamma(0)=p$ and $\gamma'(0)=v$ (see for instance Ref. 4, p. 91). Since the proof of this result does not make use of neither the definiteness of g nor the skew-symmetry of Φ, one has a *present determines the future* type result for an indefinite metric, Lorentzian in particular, and for any smooth operator. Even more, the result also works for solutions of a differential equation that extends that of Landau-Hall in the following terms:[5]

$$\nabla_{\gamma'}\gamma' = \Phi(\gamma') + X \circ \gamma,$$

where X is a vector field on a semi-Riemannian manifold. This setting includes the important case in Mechanics where $X=-\nabla V$, and V standing for smooth function on M (Ref. 6, Proposition 3.7.4).

Nevertheless, the well-known homogeneity result for geodesics, works quite different in nontrivial magnetic fields. Therefore, if γ is the inextendible magnetic curve of (M,g,F) determined from the initial data (p,v), the curve β, defined by $\beta(t)=\gamma(\lambda t)$, $\lambda \in \mathbb{R}\backslash\{0\}$, is a magnetic trajectory of $(M,g,\lambda F)$ and also, when $\lambda>0$, of $(M,(1/\lambda)g,F)$, in both cases determined from initial data $(p,\lambda v)$. Furthermore, the whole families of magnetic curves of (M,g,F) and $(M,\lambda g,\lambda F)$ coincides, for any constant $\lambda>0$. Consequently, we have the following.

Proposition 2.1: Let F be a nontrivial magnetic field on a Riemannian manifold (M,g). *Then, there exists no affine connection on M whose geodesics are the magnetic curves of* (M,g,F).

A magnetic field (M,g,F) with Lorentz force Φ, provides, in a similar way as in Ref. 7, Proposition 3.28, with a unique vector field Q_Φ on the tangent bundle TM. This is defined to have integral curves being the lifting to TM of the magnetic curves, that is, $t\mapsto(\gamma(t),\gamma'(t))$, where γ is a magnetic curve of (M,g,F) (compare with Ref. 8). Certainly this vector field is nothing but the geodesic flow when $F=0$. Once more, neither the definiteness of g nor the skew symmetry of Φ is needed to define Q_Φ.[5] On the other hand, the fact that any integral curve of Q_Φ is the velocity of its projection on M, allows us to think of Q_Φ as a nice example of the classically so-called *second order differential equation* on M. Because the comment previous to Proposition 2.1, Q_Φ is not a *spray*, in general.

A dynamical system with complete trajectories is often thought in Physics to be persisting eternally. But in many circumstances one must deal with incompleteness. So, because of its importance, we next give criteria to assert when it holds true. An important tool to study the completeness of the inextendible magnetic curves, i.e., under what assumptions all the inextendible magnetic curves are defined on all $\mathbb{R}$, is the vector field Q_Φ. By using Lemma 1.56 in Ref. 7, it is easily seen as the following result.

Proposition 2.2: Let (M,g) *be a Riemannian manifold*, F *a magnetic field on* M, *and* $\gamma:[a,b)\to M$, $a<b$, *a magnetic curve of F. The following are equivalent:*

(a) γ *is extendible to b as a magnetic curve*.
(b) *There exists a sequence* $\{t_n\}\to b$, $t_n\in[a,b)$ *such that the sequence of velocities* $\{\gamma'(t_n)\}$ *converges in TM*.

Accordingly, a magnetic curve $\gamma:(a,b)\to M$, a, $b\in\mathbb{R}$, $a<b$, of (M,g,F) can be extended to some open interval I, $(a,b)\subset I$, if and only if $\gamma(a,b)$ is contained in a compact subset of M. Therefore, we get (compare with Theorem 2.1.18 in Ref. 6) the following.

Proposition 2.3: Let γ *be an inextendible magnetic curve of* (M,g,F) *such that* $\gamma(a,b)$ *lies in a compact subset of* M, *for every finite interval* (a,b) *in its domain. Then,* γ *must be complete*.

In particular, if M is assumed to be compact, then we get that any inextendible magnetic curve of (M,g,F) must be complete. This fact can be also obtained as a consequence of Corollary 2.4, and it will be stated in Remark 2.5 (a), from a different approach.

Now, let $\gamma:[a,b)\to M$ be a magnetic curve. Its length $L(\gamma)$ satisfies $L(\gamma)\leqslant(b-a)\sqrt{e}$, where e is the (constant) energy of γ. For each $t\in[a,b)$, the distance between $\gamma(a)$ and $\gamma(t)$ satisfies $d(\gamma(a),\gamma(t))\leqslant L(\gamma|_{[a,t]})\leqslant(b-a)\sqrt{e}$, which shows that $\gamma([a,b))$ is contained in the closed metric ball B centered at $\gamma(a)$ and with radius $(b-a)\sqrt{e}$. Therefore,

$$\gamma'([a,b)) \subset \{(p,v)\in TM : p\in B,\ g(v,v)=e\} \subset TM.$$

Then, we have the following:

Corollary 2.4: Let F be any magnetic field on a geodesically complete Riemannian manifold (M,g). *Then, all the inextendible magnetic curves of* (M,g,F) *are complete*.

Proof: If (M,g) is assumed to be geodesically complete, then the Hopf-Rinow theorem implies that B must be compact. Hence $\{(p,v)\in TM : p\in B,\ g(v,v)=e\}$ is a compact subset of TM.

Take now a sequence $\{t_n\}\to b$, $t_n\in[a,b)$, then $\{\gamma'(t_n)\}$ lies in a compact subset of TM. So, by passing to a subsequence of $\{t_n\}$, we are under the assumption (b) of Proposition 2.2, concluding that γ is extendible to b as a magnetic curve.

Remark 2.5:

(a) If M is assumed to be compact [therefore (M,g) is geodesically complete for any Riemannian metric g on M], then we can give an alternative proof of Corollary 2.4. In fact, the previous conservation's law [Eq. (4)] for the length of velocity vectors of magnetic curves, implies that the vector field Q_Φ on TM can be restricted to each spherical tangent bundle $U_eM\{(p,v)\in TM: g(v,v)=e\}\subset TM$, $e>0$. But U_eM is compact whenever M is compact, and hence the restriction of Q_Φ to U_eM is a complete vector field. This proves that all the inextendible magnetic curves of F are complete.

(b) Proposition 2.1 has shown a remarkable difference between magnetic curves and geodesics. The following nonconnectness fact complements that result. Let us consider the unit 2-sphere $\mathbb{S}^2(1)$ endowed with its standard round metric g, and let F be the magnetic field $F=\mu\Omega_2$, where Ω_2 is the area 2-form and $\mu\in\mathbb{R}$, $\mu\neq 0$. As we will show later (see the comment after Proposition 3.2), the associated magnetic curves with energy e are circles on $\mathbb{S}^2(1)$ with radius $r=[1+(\mu^2/e)]^{-1/2}$. Then, as $r<1$, any two antipodal points cannot be connected by a magnetic curve of $(\mathbb{S}^2,g,F)$. Moreover, for any $p\in\mathbb{S}^2$, all the inextendible magnetic curves γ of $(\mathbb{S}^2\backslash\{-p\},g,F)$ such that $\gamma(0)=p$ are complete.

(c) Let (M,g) be a Riemannian manifold where g is an incomplete metric. If F is a magnetic field on (M,g), then there exists a pointwise conformal metric f^2g such that the inextendible magnetic curves of (M,f^2g,F) are complete. In fact, there exists $f\in C^\infty(M)$, $f>0$, such that f^2g is geodesically complete.[9] Therefore, Corollary 2.4 gives that the magnetic curves of (M,f^2g,F) are complete.

(d) It should be observed that the closedness assumption on the 2-form F in Corollary 2.4 was not used. On the other hand, the skew symmetry of the tensor field F has played a crucial role [recall the conservation's law (4)]. In fact, consider the tensor field $F=-2x\,\mathrm{d}x^2$ on the Euclidean plane $(\mathbb{R}^2,g^0=\mathrm{d}x^2+\mathrm{d}y^2)$. If Φ denotes the operator defined from F using Eq. (2), then $\Phi(\partial/\partial x)=-2x(\partial/\partial x)$ and $\Phi(\partial/\partial y)=0$. Therefore, $\gamma(t)=(x(t),y(t))$ satisfies the equation (LH) if and only if $x''(t)+2x(t)x'(t)=0$ and $y''(t)=0$. So, $\gamma(t)=(1/t,t)$ is an inextendible incomplete trajectory of $(\mathbb{R}^2,g^0,F)$.

(e) Finally, let us point out that Corollary 2.4 cannot be also extended to the indefinite case. In fact, consider $\mathbb{R}^2$ endowed with the Lorentzian metric $g_L=\mathrm{d}x^2-\mathrm{d}y^2$, and define the magnetic field $F=-x\,\mathrm{d}x\wedge\mathrm{d}y$. A curve $(x(t),y(t))$ is a magnetic curve of $(\mathbb{R}^2,g_L,F)$ if and only if it satisfies $x''(t)=x(t)y'(t)$, $y''(t)=x(t)x'(t)$. Then, $\gamma(t)=(2/t,-2/t)$ is an inextendible magnetic curve which is defined on $(0,\infty)$.

III. UNIFORM MAGNETIC FIELDS

From now on, M will be an oriented Riemannian surface with standard complex structure J, and area element Ω_2 so that $\Omega_2(X,JX)=1$ for any unit vector field X in M.

Given a curve γ in M such that $g(\gamma',\gamma')=e>0$ is constant, its Frenet apparatus is $\{T=(1/\sqrt{e})\gamma', N=JT\}$. If κ denotes the curvature function, we have the following well-known Frenet equations

$$\nabla_{\gamma'}T=\kappa\sqrt{e}N,\quad \nabla_{\gamma'}N=-\kappa\sqrt{e}T.$$

Obviously, any magnetic field on a surface, M, is determined from a smooth function, f (the *strength*), by $F=f\Omega_2$. Therefore, the matrix of Φ in any orthonormal frame, $\{X,JX\}$ is given by

$$\begin{pmatrix} 0 & -f \\ f & 0 \end{pmatrix}.$$

In particular, along a magnetic curve γ of (M,g,F), with energy e, and relative to its Frenet frame, the Lorentz force is obtained to be

$$\begin{pmatrix} 0 & -\kappa\sqrt{e} \\ \kappa\sqrt{e} & 0 \end{pmatrix}.$$

Therefore, we get the following.

Proposition 3.1: The curvature of the magnetic curves with energy e is given by $\kappa = f/\sqrt{e}$. *So, the curvature of the normal magnetics curves completely determines the Lorentz force, i.e.,* $f = \kappa$ *along these flowlines*.

A parallel magnetic field F, i.e., a magnetic field with constant strength $f = \mu$, is called a *uniform magnetic field*. This class of magnetic fields has been extensively considered in the literature from different points of view (Refs. 8 and 10–16, etc.). The geometric partner of the Landau-Hall problem, for uniform magnetic fields, is nothing but the computation of curves with constant curvature. To be precise, we have the following.

Proposition 3.2: Let $F = \mu\Omega_2$ *be a uniform magnetic field, with constant strength* μ, *on a Riemannian surface* (M,g). *A curve* γ *in* M, *with constant energy* e, *is a magnetic curve of* (M,g,F) *if and only if it has constant curvature* $\kappa = \mu/\sqrt{e}$.

On surfaces of constant Gauss curvature, the feature of the normal flowlines of a nontrivial uniform magnetic field $F = \mu\Omega_2$ is well known for any uniform magnetic field. On the Euclidean plane, $\mathbb{R}^2$, they are circles with radius $1/|\mu|$. On the 2-sphere of radius r, $\mathbb{S}^2(r)$, flowlines with energy e are circles with radius $(r\sqrt{e})/\sqrt{e + r^2\mu^2} (< r)$. In these two backgrounds, the flowlines are always closed.

On the other hand, the situation in a hyperbolic plane is quite different. Let $\mathbb{H}^2(-G)$ be the upper half-plane (in $\mathbb{R}^2$) endowed with the Lobatchevski metric of curvature $-G$, $G > 0$, that is, the Poincaré plane. We use Proposition 3.2 with the basic knowledge of the curves of constant curvature in $\mathbb{H}^2(-G)$ (see any basic text of Riemannian geometry) to make trivial the following description of the flowlines which is due to Comtet,[11] and has been mentioned along a large list of references. The behavior of normal magnetic curves changes according to the ratio between the strength, μ, and the curvature of $\mathbb{H}^2(-G)$. Namely,

(i) If $|\mu|/\sqrt{G} > 1$, then the trajectories are geodesic circles, and therefore they are closed curves.
(ii) If $|\mu|/\sqrt{G} \leqslant 1$, then the trajectories are nonclosed curves which intersect the boundary line, $\partial\mathbb{H}^2(-G)$, of the upper half-plane. In particular, they are tangent to this boundary, and so they are horocycles when $|\mu| = \sqrt{G}$.

Remark 3.3:

(a) Let γ be a curve with constant geodesic curvature $\kappa \neq 0$ in any of the three previous constant curvature surfaces. Then, for a given uniform magnetic field $F = \mu\Omega_2$, a suitable fitting of the constant speed (and hence, the energy) of γ makes this curve to be a magnetic curve of F.
(b) Let (M,g) be again one of the three above space forms and $F = \mu\Omega_2$ a uniform magnetic field on (M,g). Then, any magnetic curve γ with energy e of (M,g,F) can be then considered as a *normal* magnetic curve of $(M,(1/e)g,(1/e)F)$ (see the comment previous to Proposition 2.1).

IV. THE LANDAU-HALL PROBLEM IN A SURFACE OF REVOLUTION

Let $\alpha(s)=(f(s),h(s))$, $a<s<b$, $f(s)>0$, be a parameterization by the arclength of a curve, C, contained in the $\{xz\}$-plane of $\mathbb{R}^3$. We rotate C around the z-axis to obtain a surface of revolution, say M_α, with canonical parametrization in $\mathbb{R}^3$,

$$X(s,v)=(f(s)\cos v, f(s)\sin v, h(s)), \quad 0 \leqslant v \leqslant 2\pi. \tag{5}$$

Of course we consider that M_α is endowed with the induced metric g of the Euclidean one of $\mathbb{R}^3$.

Each point of C describes a parallel, γ_s, which can be parametrized by arclength in the following way:

$$\gamma_s(t)=\left(f(s)\cos\frac{t}{f(s)},\ f(s)\sin\frac{t}{f(s)},\ h(s)\right),$$

where $0\leqslant t\leqslant 2\pi f(s)$.

The curvature, κ_s, of γ_s in M_α, is computed to be

$$\kappa_s(t)=\|\nabla_{T_s}T_s\|=\frac{f'(s)}{f(s)},$$

where $T_s=\gamma_s'$ and ∇ is the Levi-Civita connection of M_α. In particular, κ_s is constant along γ_s, and so this curve is a good candidate to be a flowline of a suitable uniform magnetic field on M_α.

Let $F=\mu\Omega_2$ be a uniform magnetic field on M_α with constant strength μ. Then γ_s is a normal magnetic flowline of $(M_\alpha,g,F=\mu\Omega_2)$ if and only if $\kappa_s=\mu$ (Proposition 3.2). Therefore, the set of magnetic parallels of $(M_\alpha,g,F=\mu\Omega_2)$ can be identified with the following subset of the interval (a,b):

$$\Gamma_\mu=\{s\in(a,b): f'(s)=\mu f(s)\}.$$

To determine those surfaces of revolution whose parallels are all normal magnetic curves of a given uniform magnetic field [that is, those with $\Gamma_\mu=(a,b)$] we need to solve the ordinary differential equation

$$f'(s)=\mu f(s).$$

Obviously, we have two possibilities. The trivial one, corresponding with the case of a trivial magnetic field (the strength vanishes), the flowlines are then geodesics, and the surface of revolution is a right circular cylinder. Otherwise, since the Gauss curvature of a surface of revolution (in the canonical parametrization) is given by

$$G(s,t)=-\frac{f''(s)}{f(s)}, \tag{6}$$

we get that $G(s,t)=-\mu^2$, and hence the surface has constant negative curvature. In particular, we have the following.

Proposition 4.1: The parallels of a surface of revolution, M_α, are all normal magnetic flowlines of a uniform magnetic field, $F=\mu\Omega_2$, if and only if either

(1) *M_α is a right circular cylinder (when $\mu=0$), or*
(2) *M_α is a bugle surface with Gaussian curvature $-\mu^2$.*

Let us consider the torus of revolution, $\mathbf{T}(r,R)$, obtained by rotating the circle, $\mathbf{C}$, centered at $(R,0,0)$ and with radius $r(R>r)$, around the z axis. The circle can be arclength parametrized by $\alpha(s)=(R+r\cos(s/r),0,r\sin(s/r))$. Therefore, $f(s)=R+r\cos(s/r)$, with $0\leqslant s\leqslant 2\pi r$.

Given a uniform magnetic field $F=\mu\Omega_2$ on $\mathbf{T}(r,R)$, the set of normal magnetic parallels is identified to

$$\Gamma_\mu = \{s \in [0,2\pi r]: H_\mu(s) = 0\},$$

where

$$H_\mu(s) = R\mu + r\mu \cos\left(\frac{s}{r}\right) + \sin\left(\frac{s}{r}\right).$$

To study $\Gamma_\mu = H_\mu^{-1}(0)$, we use elemental calculus. First, we assume that $\mu \neq 0$, otherwise $\Gamma_0 = H_0^{-1}(0)$ is made up of the two parallels that are geodesics in $\mathbf{T}(r,R)$. In this setting, we see that H_μ has exactly two critical points on $\mathbf{C}$ (the maximum and the minimum) which are antipodal. In fact, $H'_\mu(s)=0$ if and only if $\cot(s/r)=r\mu$ and it happens just in the following two antipodal points:

$$p_\mu = \left(\cos\frac{s}{r},\ \sin\frac{s}{r}\right) = \left(\frac{r\mu}{\sqrt{1+r^2\mu^2}},\ \frac{1}{\sqrt{1+r^2\mu^2}}\right),$$

$$q_\mu = \left(\cos\frac{s}{r},\ \sin\frac{s}{r}\right) = -\left(\frac{r\mu}{\sqrt{1+r^2\mu^2}},\ \frac{1}{\sqrt{1+r^2\mu^2}}\right).$$

The values of H_μ in p_μ and q_μ are

$$H_\mu(p_\mu) = R\mu + \sqrt{1+r^2\mu^2}, \quad \text{the maximum of } H_\mu,$$

$$H_\mu(q_\mu) = R\mu - \sqrt{1+r^2\mu^2}, \quad \text{the minimum of } H_\mu.$$

We call D_μ the diameter in $\mathbf{C}$ determined by p_μ and q_μ, and let $\rho=(R^2-r^2)^{-1/2}$. We distinguish two cases.

(A) If $\mu>0$, then the point p_μ, where H_μ gets its maximum, lies in the first quadrant of the circle $\mathbf{C}$. Since $H_\mu(p_\mu)>0$, then $\Gamma_\mu \neq \emptyset$ if and only if $H_\mu(q_\mu)\leqslant 0$ (the minimum is nonpositive) that is $\mu \leqslant \rho$. Certainly if the equality holds, then H_ρ vanishes only at $q_\rho=(-r/R,-1/(\rho R))$. Otherwise, H_μ vanishes exactly in two points, say z_μ and w_μ, which are separated by D_μ so they lie in different half circles.

(B) If $\mu<0$, then the point p_μ, where H_μ gets its maximum, lies in the second quadrant of the circle $\mathbf{C}$. Since the minimum is negative, $H_\mu(q_\mu)<0$, then $\Gamma_\mu \neq \emptyset$ if and only if $H_\mu(p_\mu)\geqslant 0$ and it happens if and only if $\mu \geqslant -\rho$. It is clear that when the equality holds, then H_ρ vanishes just at $p_\rho=(-r/R,1/(\rho R))$. However, if $\mu>-\rho$, then H_μ has exactly two zeroes, say z'_μ and w'_μ, which are obviously separated by D_μ so they lie in different half circles.

All this information can be summarized in the following statement.

Proposition 4.2: Let $F=\mu\Omega_2$ be a uniform magnetic field on a torus of revolution, $\mathbf{T}(r,R)$. Then $(\mathbf{T}(r,R),g,\mu\Omega_2)$ has normal magnetic parallels if and only if $\mu \in [-\rho,\rho]$. Furthermore,

(1) *If $\mu=-\rho$, then there is one normal magnetic parallel obtained by rotating the point $(R+(r^2/R),r/(\rho R)) \in \mathbf{C}$.*
(2) *If $\mu=\rho$, then there is one normal magnetic parallel obtained by rotating the point $(R-(r^2/R),-r/(\rho R)) \in \mathbf{C}$.*
(3) *If $\mu \in (-\rho,\rho)$, then H_μ has exactly two normal magnetic parallels obtained by rotating two points of $\mathbf{C}$ that are separated by D_μ.*

Example 4.3: Let C be the cathenoid generated by revolving the cathenary curve $\alpha(t)=(\cosh t,0,t)$, $t \in \mathbb{R}$ around the z axis. Let F be a uniform magnetic field with constant strength $\mu \neq 0$, defined on C. Then, it can be shown that there exist magnetic parallels if and only if $\mu \in [-1/2,1/2]$. Moreover, we have the following.

(1) If $\mu=1/2$ (respectively, $\mu=-1/2$), there exists only a normal magnetic parallel corresponding to $t=\ln(1+\sqrt{2})$ [respectively, $t=-\ln(1+\sqrt{2})$].

(2) If $\mu \in (-1/2,0)$ [respectively, $\mu \in (0,1/2)$], then C has two normal magnetic parallels which are located in the region $t>0$ (respectively, $t<0$).

Example 4.4: Let S be the revolution surface obtained by rotating the cycloid curve $\alpha(t) = (a(1-\cos t),0,a(t-\sin t))$, $t \in (0,2\pi)$ around the z axis. It is easy to see the following.

(1) If $\mu>0$, then S has only a normal magnetic parallel corresponding to the parameter value $t_0 = 2\arccos[(-1+\sqrt{1+16a^2\mu^2})/(4a\mu)]$.
(2) If $\mu<0$, then S has also only a normal magnetic parallel corresponding to $t_1 = 2\pi - t_0$.

Example 4.5: Finally, let us consider the cone M generated by the line $\alpha(t)=(at,0,bt)$, $a^2+b^2=1$, $t>0$ around the z axis. Then, it can be seen that for any $\mu>0$, there exists a unique normal magnetic parallel given by $t=1/\mu$.

V. RELATIVISTIC PARTICLES WITH RIGIDITY OF ORDER ONE

The search for Lagrangians describing spinning particles (both massive and massless) has a long history. An interesting and unconventional approach is to provide the necessary extra degrees of freedom by actions whose densities depend on higher order geometrical invariants. In particular, this means that those extra bosonic variables must be encoded in the geometry of the world trajectories. The simplest models are those involving density Lagrangians that depend on the curvature, κ, of the worldlines (Refs. 17–19, etc.). In particular, actions that depend linearly from κ (Refs. 2 and 18–22, etc.) will be considered in this section. These models describing a massive relativistic boson.[3]

Suppose that Λ is a suitable space of curves (closed curves or clamped curves, for instance) in a Riemannian surface (M,g). Define a one-parameter family of functionals $\mathcal{F}_m: \Lambda \to \mathbb{R}$, $m \in \mathbb{R}$, by

$$\mathcal{F}_m(\gamma) = \int_\gamma (\kappa + m)\mathrm{d}s, \tag{7}$$

where s stands for the arclength parameter of curves $\gamma \in \Lambda$. In order to obtain the first variation of these actions, we use the following standard machinery (see for instance Ref. 20). For a curve $\gamma:[0,L]\to M$, we take variations $\Theta = \Theta(t,r):[0,L]\times(-\varepsilon,\varepsilon)\to M$ with $\Theta(t,0)=\gamma(t)$. Then, we have the variation vector field $W=W(t)=(\partial\Theta/\partial r)(t,0)$ along the curve γ. We also set $V=V(t,r) = (\partial\Theta/\partial t)(t,r)$, $W=W(t,r)$, $v=v(t,r)=\|V(t,r)\|$, $T=T(t,r)$, $N=N(t,r)$, with the obvious meanings. The corresponding reparametrizations will be denoted by $V(s,r)$, $W(s,r)$, etc. The variations of v and κ in γ, in the direction of W, can be obtained to be

$$W(v) = g(\nabla_T W, T)v, \tag{8}$$

$$W(\kappa) = g(\nabla_T^2, W, N) - 2g(\nabla_T, W, T)\kappa + Gg(W,N), \tag{9}$$

here G denotes the Gauss curvature of (M,g) and ∇ its Levi-Civita connection.

To obtain the first derivative of $\mathcal{F}_m$, we use (8) and (9) and proceed as follows:

$$\delta\mathcal{F}_m(\gamma)[W] = \int_\gamma W(\kappa)\mathrm{d}s + \int_0^L (\kappa+m)W(v)\mathrm{d}t = \int_\gamma W(\kappa)\mathrm{d}s + \int_\gamma (\kappa+m)g(\nabla_T W,T)\mathrm{d}s$$

$$= \int_\gamma [g(\nabla_T^2 W,N) - (\kappa-m), g(\nabla_T W,T) + Gg(W,N)]\mathrm{d}s.$$

Then, we use, as usual, suitable integrations by parts to get

$$\delta\mathcal{F}_m(\gamma)[W] = \int_\gamma g(\Omega(\gamma), W)\mathrm{d}s + [\mathcal{B}(\gamma, W)]_0^L, \tag{10}$$

where $\Omega(\gamma)$ and $\mathcal{B}(\gamma, W)$ denote the Euler-Lagrange and the boundary operators and they are, respectively, given by

$$\Omega(\gamma) = (G - m\kappa)N,$$

$$\mathcal{B}(\gamma, W) = g(\nabla_T W, N) + mg(W, T).$$

Proposition 5.1 (Clamped curves): Given points q_1, $q_2 \in M$ *and unit vectors* $x_1 \in T_{q_1}M$ *and* $x_2 \in T_{q_2}M$, *define the space of curves*

$$\Lambda = \{\gamma:[t_1, t_2] \to M: \gamma(t_i) = q_i,\ T(t_i) = x_i,\ N(t_i) = Jx_i,\ 1 \leqslant i \leqslant 2\}.$$

Then, the critical points of the functional $\mathcal{F}_m: \Lambda \to \mathbb{R}$ *are characterized by the following Euler-Lagrange equation:*

$$G|_\gamma = m\kappa,$$

where $G|_\gamma$ *denotes the Gauss curvature of* (M, g) *along* γ.

Proof: Let $\gamma \in \Lambda$ and $W \in T_\gamma\Lambda$, then W defines a curve in Λ associated with a variation Θ of γ. Since $V = \mathrm{d}\Theta(\partial_t)$ and $W = \mathrm{d}\Theta(\partial_r)$, then $[V, W] = 0$ along Θ. Furthermore, we use $V = vT$ to have

$$\nabla_T W = W(\ln v)T + \nabla_W T,$$

along Θ. We evaluate this formula along γ by making $r = 0$ and use that Θ is a curve in the space Λ to obtain

$$[\mathcal{B}(\gamma, W)]_{t_1}^{t_2} = 0.$$

Therefore, using Eq. (10), we have that γ is a critical point of $\mathcal{F}_m: \Lambda \to \mathbb{R}$, that is $\delta\mathcal{F}_m(\gamma)[W] = 0$ for any $W \in T_\gamma\Lambda$ if and only if $\Omega(\gamma) = 0$ which proves the statement.

Similarly, we can obtain the following.

Proposition 5.2 (Closed curves): Let $\mathcal{C}$ *be the space of immersed closed curves in* (M, g). *The critical points of the functional* $\mathcal{F}_m: \mathcal{C} \to \mathbb{R}$ *are those closed curves that are solutions of the following Euler-Lagrange equation:*

$$G|_\gamma = m\kappa.$$

VI. GAUSSIAN MAGNETIC FIELDS

Let M be a surface immersed in the Euclidean three-space, $\mathbb{R}^3$, so the metric, g is the induced one. We denote by $N: M \to \mathbb{S}^2$ its Gauss map and $\mathrm{d}\sigma^2$ will stand for the area element on the unit round sphere $\mathbb{S}^2$. The two form $N^*(d\sigma^2)$ on M can be used, for example, to measure areas of the spherical images or topological total charges of solitons in the $O(3)$ nonlinear sigma model (see for instance Refs. 23 and 24, and references therein). In this section we will consider magnetic fields of the type

$$F = \frac{1}{m}N^*(\mathrm{d}\sigma^2),$$

where m is a nonzero constant. We call them *Gaussian magnetic fields* (GMF). It is well known that $N^*(\mathrm{d}\sigma^2) = G\Omega_2$, G denoting the Gaussian curvature of (M, g) and this, in particular, implies that we can consider these kinds of magnetic fields with no mention to the surrounding space. Namely, a GMF is always of the type

$$F = \frac{G}{m}\Omega_2. \tag{11}$$

The Lorentz force of a GMF is computed to be $\Phi=(G/m)J$, where J is the standard complex structure in M. In particular, for any unit vector field, X, on M, the matrix of Φ, in the terminology of Sec. III, with respect to an orthonormal frame $\{X, JX\}$ is given by

$$\begin{pmatrix} 0 & -\frac{G}{m} \\ \frac{G}{m} & 0 \end{pmatrix}.$$

In this framework, we can combine Proposition 3.1 and the field equations of the particle models defined from $\mathcal{F}_m$, see Eq. (7), to obtain the following amazing relationship between the flow of a GMF and the worldline trajectories of relativistic particles with order one. To be precise, we have the following.

Theorem 6.1: *Let* $\gamma \in \Lambda$ *be a curve* (clamped or closed) *in* (M, g). *Then it is a normal flowline of* $(M, g, F=(G/m)\Omega_2)$ *if and only if it is a critical point* (worldline) *of the action* $\mathcal{F}_m : \Lambda \to \mathbb{R}$ *given by*

$$\mathcal{F}_m(\gamma) = \int_\gamma (\kappa + m)\mathrm{d}s.$$

At this point, we can take advantage of the variational approach to study stability of the GMF flowlines. Therefore, we need the second derivative of $\mathcal{F}_m$ in a critical point, say γ in a suitable space of curves, Λ (recall closed or clamped curves). After some long computations (see Ref. 17 for details) one can obtain the following expression:

$$\delta^2\mathcal{F}_m(\gamma)[W] = \int_\gamma g\,(W, \nabla_W \Psi)\big|_\gamma \,\mathrm{d}s, \tag{12}$$

where Ψ denotes the vector field, along a variation of γ, given by $\Psi=(G-m\kappa)N$. Now, we choose $W=\Phi N$ to obtain

$$g\,(W, \nabla_W \Psi)\big|_\gamma = \Phi^2 N(G - m\kappa),$$

where the right-hand term is restricted to γ. However the variation of κ was given in Eq. (9); so, in particular, we have $N(\kappa)=\kappa^2+G$. Then, one gets from Eq. (12),

$$\delta^2\mathcal{F}_m(\gamma)[W] = \int_\gamma \Phi^2\left(N(G) - \frac{1}{m}(G^2 + m^2 G)\right)\mathrm{d}s.$$

Hence, we have the following useful test of stability.

Proposition 6.2: A critical point, $\gamma \in \Lambda$, *of* $\mathcal{F}_m$ *is stable if and only if the function* $N(G) - (1/m)(G^2+m^2G)$ *is signed along* γ.

It should be observed that the previous test has the following geometrical meaning. Set $\varphi = G - m\kappa$, then $\gamma \subset \varphi^{-1}(0)$, because it is a critical point of $\mathcal{F}_m$, and then stability means that γ is made up of regular points of φ. Moreover, observe that this happens if 0 is a regular value of φ.

Now, let us use all this information in the following elemental setting. We consider $M = \mathbb{S}^2(1)$ the unit round sphere. Then any GMF, $F=(G/m)\Omega_2=(1/m)\Omega_2$, is uniform. However, when studying uniform magnetic fields on a round sphere, we cannot talk about stability of magnetic trajectories. This is not the case of our approach.

In this setting, the magnetic curves are, according to Theorem 6.1, the critical points of the functional

$$\mathcal{F}_m(\gamma) = \int_\gamma (\kappa + m)\mathrm{d}s = \int_\gamma \kappa\, \mathrm{d}s + mL(\gamma),$$

and they are nothing but those curves that satisfy $1 = m\kappa$, that is geodesic circles with geodesic curvature $\kappa = 1/m$.

On the other hand, we can use the Gauss-Bonnet formula to see that this variational problem is equivalent to that associated with the action $\mathcal{D}_m : \mathbf{D} \to \mathbb{R}$ defined by

$$\mathcal{D}_m(\Delta) = \int_\Delta G\Omega_2 + m\int_{\partial\Delta} \mathrm{d}s = \mathrm{Area}(\Delta) + mL(\partial\Delta),$$

acting on the space (D) of simply connected domains, Δ in $\mathbb{S}^2$, with the same boundary $\gamma = \partial\Delta$. This is nothing but the isoperimetric problem in the round sphere. The solution is a couple of domains Δ_1 and Δ_2 (the maximum and the minimum) with common boundary a geodesic circle, γ, of curvature $\kappa = 1/m$. Since $N(G) = 0$ then, $-(1+m^2)/m$ has obvious sign for any choice of the coupling constant m. Consequently, calling to Proposition 6.2, the solutions are stable.

The case where $m = 0$ deserves a few words. First of all GMF with $m = 0$ could be considered as a limiting case, however, after our variational approach, it can be identified with the massless Plyushchay model,[21] which is governed by the Lagrangian

$$\mathcal{F}_0(\gamma) \equiv \int_\gamma \kappa\, \mathrm{d}s.$$

This model has been considered with detail in Ref. 18. For example, the sphere does not admit, non-only minima (maxima) for this model but also critical points. However, an anchor ring has two critical points corresponding to the two parallels of parabolic points.

VII. GMF FLOWLINES ON SOME NONCONSTANT GAUSS CURVATURE SURFACES

In this section we would like to analyze when certain relevant curves on some nonconstant Gauss curvature surfaces are in fact magnetic.

We recalled the explicit expression of the Gauss curvature, $G(s,v)$, of a surface of revolution, M_α, see Eq. (6). Consequently, we can assert now that a parallel, γ_s, is a normal flowline of the GMF given by $(G/m)\Omega_2$ on M_α if and only if

$$f''(s) + mf'(s) = 0. \tag{13}$$

Next, we will obtain the surfaces of revolution whose parallels are all normal flowline of a GMF. In contrast to the case of a uniform magnetic field, where only the bugle surface appeared as a solution (see Proposition 4.1), now the general solution is made up of a three parameter family of surfaces which includes the bugle surface too.

Theorem 7.1: *The normal flow of a GMF,* $(G/m)\Omega_2$, *in a surface of revolution,* M_α, *is invariant under rotations if and only if the profile curve of* M_α *lies in the following three parameter family of arclength parametrized plane curves:*

$$\alpha(s) = \left(f(s), \int_0^s \sqrt{1 - f'(s)^2}\, \mathrm{d}s \right),$$

where

$$f(s) = \frac{1}{m}[a + c\exp(-ms + b)], \quad a,b,c \in \mathbb{R} \text{ with } a > 0.$$

Observe that the general solution of the ordinary differential equation (13) has the form $f(s)=[a+c\exp(-ms+b)]/m$, so the proof of the last result becomes obvious. Observe also that the above characterized class of surfaces of revolution includes the bugle surface ($a=0$) and the right circular cylinder ($c=0$) too.

It should be noticed the following coupling phenomenon in a surface of revolution, M_α, between the GMF, $F_1=(G/m)\Omega_2$ and the uniform magnetic field $F_2=-m\Omega_2$, for some values of the coupling constant m. Suppose, for example, that $M_\alpha=\mathbf{T}(r,R)$ is a torus of revolution and $\rho=(R^2-r^2)^{-1/2}$ (notation as in Sec. IV). Then, F_1 always has two parallels being normal magnetic curves, no matter the value of m. Now, we use Proposition 4.2 to obtain the following statement.

Proposition 7.2: If $-m\in(-\rho,\rho)$, then both F_1 and F_2 have two normal magnetic parallels coming from points alternatively placed in the profile circle. Moreover they collapse when $-m$ goes to $-\rho$ or ρ.

Proof: For any value of m in $\mathbb{R}$, $(\mathbf{T}(r,R),g,F_1)$ has two normal magnetic parallels obtained by rotation of the two antipodal points in $\mathbf{C}$, defined by $\cot(s/r)=-rm$. These two points are just those determining the diameter D_{-m} that separates the two magnetic parallel of $(\mathbf{T}(r,R),g,F_2)$ when $-m\in(-\rho,\rho)$. The second part of this statement follows similarly when we use points 1 and 2 of Proposition 4.2.

We finish the paper showing several examples.

Example 7.3: Let $\beta(s)$ be an arclength parametrized curve contained in a plane, Π (with unit normal vector B_0), in $\mathbb{R}^3$. We denote by $\{T(s),N(s)\}$ a Frenet frame along $\beta(s)$, so that $T(s)\wedge N(s)=B_0$, and $\kappa(s)$ will stand for its curvature function. For a suitable $r>0$, we define a tube of radius r, say $T_\beta(r)$, as the surface given by

$$X(s,v)=\beta(s)+r(\cos(v)N(s)+\sin(v)B_0).$$

We denote by $\Lambda_\beta=\{\gamma_v,:v\in[0,2\pi]\}$ the family of curves in the tube obtained when we make v constant. The curvature of these curves in $T_\beta(r)$ can be obtained, from a direct computation, to be

$$\kappa_v(s)=\frac{\kappa(s)\sin(v)}{1-r\kappa(s)\cos(v)}.$$

Notice that it is not constant unless $\beta(s)$ is chosen to be constant curvature.

On the other hand, the Gauss curvature of the tube $T_\beta(r)$ is computed to be

$$G(s,v)=-\frac{\kappa(s)\cos(v)}{r(1-r\kappa(s)\cos(s))}.$$

Now, we can apply these formulas together with the Euler-Lagrange equations associated with the GMF, $F=(G/m)\Omega_2$ (Propositions 5.1 and 5.2), to see that there exist exactly two curves (clamped or closed) in Λ_β that are normal magnetic trajectories. They are obtained for $\cot(v)=-rm$ and this is, formally, the same result that we have obtained for a torus of revolution (Proposition 4.2) which can be regarded as a tube around a circle.

Example 7.4: Similarly, for a curve, $\beta(s)$, in $\mathbb{R}^3$ with Frenet frame $\{T(s),N(s),B(s)\}$, curvature $\kappa(s)$ and torsion $\tau(s)$, one can define the tube $T_\beta(r)$ by

$$X(s,v)=\beta(s)+r(\cos(v)N(s)+\sin(v)B(s)).$$

In particular, if $\beta(s)$ is a helix (κ and τ are both constant) then the curvature function, $\kappa_v(s)$ of the curves in $\Lambda_\beta=\{\gamma_v,:v\in[0,2\pi]\}$ satisfy

$$\kappa_v^2=\frac{\kappa^2\sin^2(v)}{(1-r\kappa\cos(v))^2+r^2\tau^2}.$$

Now, the curves in Λ_β that are normal flowlines of $(G/m)\Omega_2$ on the helicoidal tube $T_\beta(r)$ correspond with the zeroes of the function $\vartheta:\mathbb{S}^1\to\mathbb{R}$ defined by

$$\vartheta(v) = (1 - r\kappa\cos(v))^2(\cos^2(v) - r^2m^2\sin^2(v)) + r^2\tau^2\cos^2(v).$$

However, we have

$$\vartheta(0) = \vartheta(\pi) = (1 - r\kappa)^2 + r^2\tau^2 > 0 \quad \text{and} \quad \vartheta\left(\frac{\pi}{2}\right) = \vartheta\left(\frac{3\pi}{2}\right) = -r^2m^2 < 0.$$

Therefore, there exist four curves of Λ_β in the flow of $(G/m)\Omega_2$.

Example 7.5: On the cathenoid (Example 4.3), the GMF given by $(G/m)\Omega_2$ has a unique normal magnetic parallel for all m. If $m>0$, it is obtained for a $t_0<0$. If $m<0$, then it is obtained for a $t_0'=-t_0>0$.

Example 7.6: On the hyperboloid of revolution obtained from Eq. (5) by setting $f(t)=\cosh t$ and $h(t)=\sinh t$, the GMF given by $(G/m)\Omega_2$ has also a unique normal magnetic parallel for all m, analogously to the previous case.

Example 7.7: On the cicloidal surface (Example 4.4), the GMF given by $(G/m)\Omega_2$ has a unique normal magnetic parallel for $m\in(-\infty,-1/(4a))\cup(1/(4a),\infty)$. If $m>0$, $t_0=\arccos((1/(4am))$, whereas if $m<0$, then $t_0'=2\pi-t_0$.

VIII. CONCLUSIONS

Oriented surfaces, M, in $\mathbb{R}^3$ admit two natural 2-forms. First, the area element, Ω_2, associated with the induced metric, g. Second, the area element, $N^*(\mathrm{d}\sigma^2)$, of its spherical image under the Gauss map, $N:M\to\mathbb{S}^2$. It is well known that these 2-forms are nicely related by

$$N^*(\mathrm{d}\sigma^2) = G\Omega_2,$$

where G denotes the Gaussian curvature of g. In particular, both 2-forms are intrinsic and then they are defined once we know a Riemannian metric, g, on M. Associated with these 2-forms appear two classes of magnetic fields on (M,g).

(1) The class made up of the constant multiples of the former one, $\mathcal{C}_1=\{\mu\Omega_2:\mu\in\mathbb{R}\}$, provides that of uniform magnetic fields, with strength μ, on (M,g). The corresponding Landau-Hall problem has been widely studied along the literature. Even in this paper, we have obtained some new information relative to uniform magnetic field essentially in a surface of revolution. For example, we have characterized right circular cylinders and bugle surfaces as the only surfaces of revolution whose parallels are all normal magnetic flowlines of uniform magnetic fields.

(2) The class of the constant multiples of the latter one, $\mathcal{C}_2=\{\mu N^*(\mathrm{d}\sigma_2):\mu\in\mathbb{R}\}$, constitutes a class of magnetic fields that in this paper are introduced under the terminology of Gauss-Landau-Hall magnetic fields. In this case the strength is given by μG and obviously both classes coincide when (M,g) has constant curvature.

In this paper, we wish to state the importance and nice interest of GMF on surfaces. In fact, the chief result of the paper appears when we study the Landau-Hall problem associated with a GMF (which we call the Gauss-Landau-Hall problem). Then, we are able to show that this problem is equivalent to the dynamics of a massive relativistic boson. This provides an amazing relationship between two, *a priori*, quite different physical phenomena.

Therefore, we can use two points of view to study each of the two involved problems. On the one hand, one can study completeness, homogeneity and so on, in the dynamical study of bosonic worldlines. By the way, we have introduced a section with results on these topics. But on the other hand, the Gauss-Landau-Hall problem can be regarded as a variational problem globally stated. In this setting, flowlines are critical points of an action which has been used to model relativistic particles with order one rigidity. In particular, we can talk about, and so we study, global stability of normal flowlines of a GMF. Say finally that under this equivalence, the model to describe a massless particle with arbitrary helicity corresponds with a limit case obtained when the force of the GMF increases arbitrarily.

We believe that this point of view in the study of GMF is physically remarkable and it could be extended to other classes of magnetic fields.

(Received 26 May 2005; accepted 19 September 2005; published online 15 November 2005)

A kinetic model for a granular gas interacting with a given background by binary dissipative collisions is analyzed, with particular reference to the derivation of macroscopic equations for the fundamental observables. Particles are modelled as inelastic hard spheres under the assumption of collision dominated regime (small mean free path). Closure of the relevant moment equations is achieved by resorting to a maximum entropy principle, and two specific entropy functionals have been worked out in detail, in the class of the admissible ones for the relevant linear extended Boltzmann equation. Considered macroscopic fields include density, mass velocity, and granular temperature. In the hydrodynamic limit when the mean free path tends to zero, a single drift-diffusion equation of Navier-Stokes type is recovered for the only hydrodynamic variable of the physical problem. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2118468]

I. INTRODUCTION

In the last few years, kinetic models for granular materials have attracted significant interest in the mathematical and physical communities.[13,8] The largest attention has been devoted to nonlinear models for dilute flows based on generalizations of the Boltzmann-Enskog equation describing energy dissipation in binary encounters. Most of the analytic investigation has been performed in the frame of the so-called pseudo-Maxwellian inelastic particles,[6] both in the free case in which granular temperature decays to zero, and in the driven case in which there is an external energy supply. Some results are available also for the more realistic, but much more difficult to deal with, inelastic hard sphere model.[7]

Very important for practical applications are also linear kinetic equations for dissipative interactions of dilute granular matter with a given background, though this kind of inelastic process has been much less addressed. The relevant physical problem may be considered as limiting case of a binary mixture made up by species with different masses and densities, and describes typically the diffusion of fine polluting powders in a much denser medium (like air).

Though grains are in principle macroscopic objects, and their interaction with background molecules is a complex process that would require an adequate treatment,[23] we shall stick here to the standard approximation of extremely tiny grains undergoing localized and instantaneous mechanical encounters with a single partner. Collision integrals in the kinetic equation describe then binary interactions of a test particle of the granular gas with a field particle of the fixed background. The most significant recent results, together with the general existence and stability analysis by Pettersson,[24] concern the unique determination of collision equilibria as Maxwellian distributions, with number density as the only free parameter, whereas mass velocity coincides with the background drift, and granular temperature is smaller than the temperature of the host medium, with a reduction factor depending on the crucial control parameters, namely mass ratio and coefficient of inelasticity.[21,25,1,19] It has also been possible to prove[19] an essential ingredient of

[a)]Electronic mail: giampiero.spiga@unipr.it

any kinetic-type approach, namely a space homogeneous H-theorem, in terms of an entire class of different possible entropy functionals, each of them being determined by a suitable convex function, as indeed typical in linear kinetic theory.[20]

On the other hand, what people are interested in for practical applications is mainly availability of consistently derived and justified macroscopic equations for the observable fields, moments of the distribution function. Peculiar feature of the linear Boltzmann equation, both elastic and inelastic, is that there exists only one collision invariant, and consequently only one hydrodynamic variable (number density). With respect to the nonlinear case of rarefied gas dynamics, "conservation" equations for momentum and energy become balance equations, with nonvanishing collision contributions describing exchange rates with the background. Hydrodynamic closure at the Navier-Stokes level may be still achieved by a Chapman-Enskog asymptotic expansion in the collision dominated regime, and results in a single drift-diffusion equation for density, available already also in the inelastic frame,[25] but only, to our knowledge, for the simplified pseudo-Maxwellian model.[6] However, it would be obviously desirable to include also drift velocity and temperature as unknown fields into the macroscopic equations, though they are not conserved quantities, as they would be in the nonlinear case. Such equations should then be regarded as moment equations for higher order moments, and would play a role similar to that of Grad's equations[16] of gas dynamics,[10,17] where the additional nonhydrodynamic moments are instead viscous stress tensor and heat flux vector. To our knowledge, first numerical results in this respect have been worked out, and not yet published, in very recent times.[12] This is the problem that will be dealt with in the present paper, by resorting to a suitable expansion technique in a neighborhood of the collision equilibrium. We consider in fact a hard sphere granular gas, inelastically scattering with a given background, and with a mean free path much smaller than the macroscopic scale. The investigation will be developed in the spirit of the maximum entropy principle (MEP)[18,22,15] as moment closure strategy. In addition, using the Knudsen number (ratio of the mean free path to the macroscopic length) as small parameter, a standard Chapman-Enskog algorithm allows to achieve in the simplest way the pertinent hard-sphere diffusive hydrodynamic equation with first order corrections (thus, at the Navier-Stokes level).

The paper is organized as follows. The governing kinetic Boltzmann-type equation and its main features are presented and discussed in Sec. II, where also previous results needed in the subsequent investigation are recalled. Then, the existence of an infinite number of admissible entropy functionals implies of course an ample choice of disparate normal form expansions satisfying a MEP to be used for closing the exact nonclosed set of moment equations. For the sake of simplicity, in this work we shall confine ourselves to the consideration of the most important moments, the first five (density, the three components of mass velocity, and temperature), though additional fields, like the viscous stress tensor (completing the second order moments), could be treated with only technical extra difficulties. Also, only two (the most common) entropy functionals will be worked out, the quadratic entropy, probably the simplest one, in Sec. III, and the very popular logarithmic entropy in Sec. IV. The resulting closed moment equations differ of course from each other, though exhibiting a common structure. Other macroscopic equations would follow of course from other functionals. Such indeterminacy is obvious consequence of the existence, in the linear framework, of an infinite set of entropies, as mentioned above. Clearly, an immediate question arises: which of the closed sets of partial differential equations gives the best approximations with respect to the kinetic results? A detailed comparative analysis, including numerical calculations, is scheduled as future work. However, the relevant hydrodynamic equations in the asymptotic limit coincide exactly up to the first order corrections. Of course, this is not surprising, since Navier-Stokes equations could be determined, independently from any chosen entropy, by the Chapman-Enskog algorithm applied directly to the kinetic equation. Unfortunately we have not been able to prove yet a universality result in this respect, namely that the hydrodynamic limit of the closed set of moment equations is the same for any admissible entropy functional, and this also will be the matter of further studies. When needed, manipulations whose length and heaviness could compromise presentation and clarity are shifted to the Appendix.

II. KINETIC EQUATION

We start from the linear dissipative Boltzmann equation for granular test particles (tp) subjected to hard-sphere collisions against the field particles (fp) of a fixed (in general, nonuniform) background, labelled by a superscript B in the following notation. The host medium is supposed in local thermodynamical equilibrium with given density n^B, drift velocity $\mathbf{u}^B$, and temperature T^B, thus with a Maxwellian distribution function $f^B=n^BM^B$, where $M^B=M(\mathbf{v};m^B,\mathbf{u}^B,T^B)$ and M is a normalized Gaussian. Symbols m and d are used to denote particle mass and diameter, and (tp,tp) interactions are negligible. All (binary) (tp,fp) encounters, with ingoing velocities $(\mathbf{v},\mathbf{w})$, preserve momentum but dissipate kinetic energy of the relative motion according to the rule (a prime denotes post-collision values)

$$\mathbf{g}'\cdot\hat{\mathbf{n}}=-e(\mathbf{g}\cdot\hat{\mathbf{n}}),\quad \mathbf{g}'-(\mathbf{g}'\cdot\hat{\mathbf{n}})\hat{\mathbf{n}}=\mathbf{g}-(\mathbf{g}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}}, \tag{1}$$

where $\mathbf{g}=\mathbf{v}-\mathbf{w}$ is the relative velocity, $\hat{\mathbf{n}}$ the unit vector of the apse line, and e, with $0<e\leqslant 1$, is the so-called restitution coefficient (supposed to be constant in this paper), which measures the amount of inelasticity. As is well known, test particles exchange momentum and energy with the background even in the elastic case $e=1$. The collision mechanism and the apse line determine uniquely the post-collision velocities associated to $\mathbf{v}$ and $\mathbf{w}$ as

$$\mathbf{v}'=\mathbf{v}-2\alpha(1-\beta)(\mathbf{g}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}},\quad \mathbf{w}'=\mathbf{w}+2(1-\alpha)(1-\beta)(\mathbf{g}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}}, \tag{2}$$

where the dimensionless parameters α and β, with $0<\alpha<1$, $0\leqslant\beta<\frac{1}{2}$, are defined as

$$\alpha=\frac{m^B}{m+m^B},\quad \beta=\frac{1-e}{2} \tag{3}$$

and represent, respectively, mass ratio and degree of inelasticity. Dissipation implies that the dual collision associated to $(\mathbf{v},\mathbf{w})$ (i.e., the one which produces $\mathbf{v}$ and $\mathbf{w}$ as final output) may not be obtained starting from $(\mathbf{v}',\mathbf{w}')$, and in fact the precollision velocities associated to $\mathbf{v}$ and $\mathbf{w}$ turn out to be

$$\mathbf{v}''=\mathbf{v}-2\alpha\frac{1-\beta}{1-2\beta}(\mathbf{g}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}},\quad \mathbf{w}''=\mathbf{w}+2(1-\alpha)\frac{1-\beta}{1-2\beta}(\mathbf{g}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}}. \tag{4}$$

A standard phase-space balance, under the usual assumptions underlying the Boltzmann equation, leads to the linear integro-differential equation

$$\frac{\partial f}{\partial t}+\mathbf{v}\cdot\nabla_{\mathbf{x}}f=n^B\left(\frac{d+d^B}{2}\right)^2\int_{\mathbb{R}^3}\int_{S_+^2}(\mathbf{g}\cdot\hat{\mathbf{n}})\left[\frac{1}{e^2}f(\mathbf{v}'')M^B(\mathbf{w}'')-f(\mathbf{v})M^B(\mathbf{w})\right]d_3\mathbf{w}d_2\hat{\mathbf{n}}, \tag{5}$$

where explicit dependence on $\mathbf{x}$ and t is not shown just for simplicity, and S_+^2 is the positive unit sphere, defined by $\mathbf{g}\cdot\hat{\mathbf{n}}>0$. As usual, it is convenient to introduce suitable scalings and make (5) dimensionless. Assuming the Strouhal number of order unity, and measuring distances in units of a characteristic length L, if $\bar{n}^B$ denotes a typical value of background density, manipulations single out in a spontaneous way the mean free path

$$\lambda=\left[\bar{n}^B\pi\left(\frac{d+d^B}{2}\right)^2\right]^{-1} \tag{6}$$

and the Knudsen number

$$Kn=\frac{\lambda}{L}\equiv\varepsilon, \tag{7}$$

where the symbol ε is used as a reminder of the fact that we are mainly interested here in the continuum limit $Kn\ll 1$, in which the process is dominated by collisions. If the same dimensional

symbol is retained for all scaled quantities, the kinetic equation may be rewritten as

$$\frac{\partial f}{\partial t}+\mathbf{v}\cdot\nabla_{\mathbf{x}}f=\frac{n^B}{2\pi\varepsilon}\int_{\mathbb{R}^3}\int_{S^2}|\mathbf{g}\cdot\hat{\mathbf{n}}|\left[\frac{1}{e^2}f(\mathbf{v}'')M^B(\mathbf{w}'')-f(\mathbf{v})M^B(\mathbf{w})\right]d_3\mathbf{w}d_2\hat{\mathbf{n}}=\frac{n^B}{\varepsilon}Q(f), \tag{8}$$

where ε labels the importance of the collision integral, n^B may be set equal to unity for a homogeneous steady background, and

$$M^B(\mathbf{v})=\left(\frac{m^B}{2\pi T^B}\right)^{3/2}\exp\left[-\frac{m^B}{2T^B}(\mathbf{v}-\mathbf{u}^B)^2\right]. \tag{9}$$

The macroscopic parameters n^B, $\mathbf{u}^B$, T^B fulfill the classical Euler equations valid in local thermodynamical equilibrium,[9]

$$\frac{\partial n^B}{\partial t}+\frac{\partial(n^Bu_k^B)}{\partial x_k}=0,$$

$$\frac{\partial u_i^B}{\partial t}+u_k^B\frac{\partial u_i^B}{\partial x_k}=-\frac{1}{n^Bm^B}\frac{\partial(n^BT^B)}{\partial x_i}, \tag{10}$$

$$\frac{\partial T^B}{\partial t}+u_k^B\frac{\partial T^B}{\partial x_k}=-\frac{2}{3}T^B\frac{\partial u_k^B}{\partial x_k}.$$

The most convenient tool of investigation is the weak form associated to (8). Taken any smooth test function $\varphi=\varphi(\mathbf{v})$, if $\langle\cdot,\cdot\rangle$ denotes the usual dual product with respect to the kinetic variable $\mathbf{v}$, under standard smoothness assumptions we may write

$$\frac{\partial}{\partial t}\langle\varphi,f\rangle+\nabla_{\mathbf{x}}\cdot\langle\mathbf{v}\varphi,f\rangle=\frac{n^B}{\varepsilon}\langle\varphi,Q(f)\rangle \tag{11}$$

with

$$\langle\varphi,Q(f)\rangle=\frac{1}{2\pi}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\int_{S^2}|\mathbf{g}\cdot\hat{\mathbf{n}}|f(\mathbf{v})M^B(\mathbf{w})[\varphi(\mathbf{v}')-\varphi(\mathbf{v})]d_3\mathbf{v}d_3\mathbf{w}d_2\hat{\mathbf{n}}. \tag{12}$$

This expression of the weak form of the collision operator, where the effects of collisions are accounted for only by the test function evaluated at the post-collision velocity $\mathbf{v}'$, is crucial for future developments. It is easy to see that $\varphi(\mathbf{v})=1$ is the only collision invariant, and thus density n is the only conserved quantity. Moreover, macroscopic fields in which we are interested are simply amenable to the first power moments of f, namely

$$n=\langle 1,f\rangle=\int_{\mathbb{R}^3}f(\mathbf{v})d_3\mathbf{v},$$

$$n\mathbf{u}=\langle\mathbf{v},f\rangle=\int_{\mathbb{R}^3}\mathbf{v}f(\mathbf{v})d_3\mathbf{v},$$

$$n\left(u^2+\frac{3T}{m}\right)=\langle v^2,f\rangle=\int_{\mathbb{R}^3}v^2f(\mathbf{v})d_3\mathbf{v}, \tag{13}$$

hence transport equations for the first five moments of the distribution function are nothing but the specialization of (11) to $\varphi=1,\mathbf{v},v^2$. Unfortunately, power moments of $Q(f)$ are not amenable to

the corresponding power moments of f, as it would occur for pseudo-Maxwellian molecules,[6,25] and not even to higher order moments. More precisely, collision contributions (12) relevant to the weights $\varphi=\mathbf{v},v^2$ involve the differences:

$$\begin{aligned}\mathbf{v}'-\mathbf{v}&=-2\alpha(1-\beta)(\mathbf{g}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}},\\ (v')^2-v^2&=-4\alpha(1-\beta)(\mathbf{g}\cdot\hat{\mathbf{n}})(\mathbf{v}\cdot\hat{\mathbf{n}})+4\alpha^2(1-\beta)^2(\mathbf{g}\cdot\hat{\mathbf{n}})^2.\end{aligned} \tag{14}$$

They exhibit simple dependencies on the unit vector $\hat{\mathbf{n}}$, so that the required angular integrations may be performed explicitly as

$$\begin{aligned}\int_{S^2}|\mathbf{g}\cdot\hat{\mathbf{n}}|(\mathbf{g}\cdot\hat{\mathbf{n}})^2d_2\hat{\mathbf{n}}&=\pi g^3,\\ \int_{S^2}|\mathbf{g}\cdot\hat{\mathbf{n}}|(\mathbf{g}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}}d_2\hat{\mathbf{n}}&=\pi g\mathbf{g},\end{aligned} \tag{15}$$

where $g=|\mathbf{g}|$. By collecting such results, the macroscopic equations for the first five moments may be finally cast, in indicial notation, as

$$\frac{\partial n}{\partial t}+\frac{\partial}{\partial x_k}(nu_k)=0,$$

$$\begin{aligned}&\frac{\partial}{\partial t}(nu_i)+\frac{\partial}{\partial x_k}\left(nu_ku_i+\frac{P_{ki}}{m}\right)\\ &\quad=-\frac{n^B}{\varepsilon}\alpha(1-\beta)\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}gg_if(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w},\ i=1,2,3,\end{aligned}$$

$$\begin{aligned}&\frac{\partial}{\partial t}\left(nu^2+\frac{3nT}{m}\right)+\frac{\partial}{\partial x_k}\left[u_k\left(nu^2+\frac{3nT}{m}\right)+\frac{2}{m}P_{kj}u_j+\frac{2}{m}q_k\right]=-\frac{n^B}{\varepsilon}2\alpha(1-\beta)\\ &\quad\times\left[\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}gg_iv_if(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w}-\alpha(1-\beta)\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}g^3f(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w}\right],\end{aligned} \tag{16}$$

where $\mathbf{P}$ is the pressure tensor, and $\mathbf{q}$ the heat flux. As anticipated, only the first, the continuity equation, represents a conservation law, and the complete set is not closed because of the presence of viscous stress $p_{ij}=P_{ij}-nT\delta_{ij}$ and heat flux q_i in the streaming terms, and because of the three collision integrals on the right-hand sides, describing exchange of momentum and energy with the background. They are affected by the inelasticity parameter β, but would be nonzero even in the elastic case $\beta=0$. For future convenience, macroscopic equations (16) can be rewritten in convective form, by taking into account in each equation the ones relevant to lower moments, in order to single out exactly the time derivatives of $n,\mathbf{u},T$,

$$\frac{\partial n}{\partial t}+\frac{\partial}{\partial x_k}(nu_k)=0,$$

$$n\frac{\partial u_i}{\partial t}+nu_k\frac{\partial u_i}{\partial x_k}+\frac{1}{m}\frac{\partial nT}{\partial x_i}+\frac{1}{m}\frac{\partial p_{ij}}{\partial x_j}=-\frac{n^B}{\varepsilon}\alpha(1-\beta)\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}gg_if(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w},$$

$$n\frac{\partial T}{\partial t}+nu_k\frac{\partial T}{\partial x_k}+\frac{2}{3}nT\frac{\partial u_k}{\partial x_k}+\frac{2}{3}p_{hk}\frac{\partial u_h}{\partial x_k}+\frac{2}{3}\frac{\partial q_k}{\partial x_k}$$
$$=-\frac{n^B}{\varepsilon}\alpha(1-\beta)\frac{2}{3}m\left\{\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}gg_i(v_i-u_i)f(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w}\right.$$
$$\left.-\alpha(1-\beta)\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}g^3f(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w}\right\}. \tag{17}$$

Concerning well posedness of the mathematical problem, existence and uniqueness have been established in general in Ref. 24. In order to proceed further towards closed macroscopic equations, two important theorems, that we quote from the literature, mainly from Ref. 19, are essential. More precisely we will resort to the following result, which extends to hard-sphere collisions a theorem already established for the pseudo-Maxwellian model.[25]

Theorem 1: *The Maxwellian distribution*

$$M^*(\mathbf{v})=M(\mathbf{v};m,\mathbf{u}^B,T^*)=\left(\frac{m}{2\pi T^*}\right)^{3/2}\exp\left[-\frac{m}{2T^*}(\mathbf{v}-\mathbf{u}^B)^2\right] \tag{18}$$

with temperature

$$T^*=\frac{(1-\alpha)(1-\beta)}{1-\alpha(1-\beta)}T^B \tag{19}$$

is collision equilibrium for (8), i.e., $f=nM^*$ solves the integral equation $Q(f)(\mathbf{v})=0$, $\forall\mathbf{v}\in\mathbb{R}^3$.

The proof goes through a clever exploitation of the Fourier transformed collision operator Q and of Bobylev's lemma,[5] and quantifies the fact that the granular gas is in equilibrium under collisions if, irrespective of density, it has a Gaussian distribution at the background velocity and at a suitable temperature ranging in the interval $(0,T^B)$. Such temperature T^* is determined by the control parameters α and β, as a balance of the competing processes of energy dissipation (driving granular temperature to 0) and of energy exchange with the medium by scattering (driving granular temperature to T^B). The other result is the H-theorem appropriate in this context.

Theorem 2: *Take the space-homogeneous version of (8). Let $\phi:\mathbb{R}^+\to\mathbb{R}$ be any convex C^1 function and define the functional*

$$H_\phi(f)=\int_{\mathbb{R}^3}M^*(\mathbf{v})\phi\left[\frac{f(\mathbf{v})}{M^*(\mathbf{v})}\right]d_3\mathbf{v}. \tag{20}$$

Consider the initial value problem in a stationary background, with initial datum f_0 such that $H_\phi(f_0)<\infty$, and let $f(\mathbf{v},t)$ be its (unique) solution, necessarily with constant number density $n(t)=n_0$. Then $H_\phi(f)$ is a Lyapunov functional, in the sense that

(a) $H_\phi(f)>H_\phi(n_0M^*)$ *for* $f\neq n_0M^*$,

(b) $\frac{d}{dt}H_\phi(f(t))\leqslant 0$, $\forall t\geqslant 0$.

The proof resorts to suitable applications and generalizations of typical convexity arguments. A simple corollary is that n_0M^* is the unique stationary solution of the considered initial value problem, and the whole theorem implies, as discussed in Ref. 19, that the overall effect of collisions is pushing the shape of test particle distribution function towards the normal distribution M^* defined by (18) and (19). This will strongly affect of course the hydrodynamic description of the space-dependent problem (8) in the continuum limit, since collisions are the dominant process governing evolution in such a regime.

In the next sections we shall deal with the closure problem and the asymptotic limit for the moment equations (17) on the basis of the previously established collision equilibria and entropy functionals.

III. QUADRATIC ENTROPY

The simplest choice in (20) to get a Lyapunov functional is of course $\phi(z)=z^2/2$, and its opposite provides then a suitable entropy for the MEP. Since our approximate distribution function $\bar{f}$ must reproduce the actual density, velocity, and temperature fields, we introduce Lagrange multipliers and apply the variational principle to

$$U_q(f) = -\frac{1}{2}\int_{\mathbb{R}^3} \frac{f(\mathbf{v})^2}{M^*(\mathbf{v})} d_3\mathbf{v} + \lambda_1\left(\int_{\mathbb{R}^3} f(\mathbf{v}) d_3\mathbf{v} - n\right) + \boldsymbol{\lambda_2}\cdot\left(\int_{\mathbb{R}^3} \mathbf{v} f(\mathbf{v}) d_3\mathbf{v} - n\mathbf{u}\right) + \lambda_3\left(\int_{\mathbb{R}^3} v^2 f(\mathbf{v}) d_3\mathbf{v} - nu^2 - \frac{3nT}{m}\right). \tag{21}$$

Standard manipulations yield then

$$\bar{f}(\mathbf{v}) = M^*(\mathbf{v})(\lambda_1 + \boldsymbol{\lambda_2}\cdot\mathbf{v} + \lambda_3 v^2), \tag{22}$$

where the Lagrange multipliers are uniquely determined in terms of $n, \mathbf{u}, T$ by the constraints

$$\langle 1, \bar{f}\rangle = n, \quad \langle \mathbf{v}, \bar{f}\rangle = n\mathbf{u}, \quad \langle v^2, \bar{f}\rangle = nu^2 + \frac{3nT}{m}. \tag{23}$$

It is now only a matter of some algebra to obtain

$$\lambda_1 = n - \frac{m}{T^*} n(\mathbf{u}-\mathbf{u}^B)\cdot\mathbf{u}^B + \frac{m^2}{6(T^*)^2} n\left[(\mathbf{u}-\mathbf{u}^B)^2 + \frac{3(T-T^*)}{m}\right]\left((u^B)^2 - \frac{3T^*}{m}\right),$$

$$\boldsymbol{\lambda_2} = \frac{m}{T^*} n(\mathbf{u}-\mathbf{u}^B) - \frac{m^2}{3(T^*)^2} n\mathbf{u}^B\left[(\mathbf{u}-\mathbf{u}^B)^2 + \frac{3(T-T^*)}{m}\right],$$

$$\lambda_3 = \frac{m^2}{6(T^*)^2} n\left[(\mathbf{u}-\mathbf{u}^B)^2 + \frac{3(T-T^*)}{m}\right], \tag{24}$$

so that we end up with

$$\bar{f}(\mathbf{v}) = nM^*(\mathbf{v})\left\{1 + \frac{m}{T^*}(\mathbf{u}-\mathbf{u}^B)\cdot(\mathbf{v}-\mathbf{u}^B) + \frac{m}{3T^*}\left[(\mathbf{u}-\mathbf{u}^B)^2 + \frac{3(T-T^*)}{m}\right]\left[\frac{m}{2T^*}(\mathbf{v}-\mathbf{u}^B)^2 - \frac{3}{2}\right]\right\}. \tag{25}$$

As for Grad's 13-moments expansion, this polynomial correction to the collision equilibrium does not fulfill positivity, but may be considered as a complete polynomial expansion truncated after few addends, where correction terms are small in the considered hydrodynamic regime, since, out of initial and boundary layers, $\mathbf{u}$ and T are close to their equilibrium values $\mathbf{u}^B$ and T^*. Now, as regards the streaming contributions to (17), higher order moments can be computed easily by using (25) in their definitions

$$\mathbf{P} = m\int_{\mathbb{R}^3} (\mathbf{v}-\mathbf{u})\otimes(\mathbf{v}-\mathbf{u}) f(\mathbf{v}) d_3\mathbf{v}, \quad \mathbf{q} = \frac{1}{2} m\int_{\mathbb{R}^3} |\mathbf{v}-\mathbf{u}|^2 (\mathbf{v}-\mathbf{u}) f(\mathbf{v}) d_3\mathbf{v}. \tag{26}$$

It turns out convenient to translate the integration variable $\mathbf{v}-\mathbf{u}^B \to \mathbf{v}$, so that, neglecting the terms whose integration vanishes simply by parity arguments, the pressure tensor corresponding to $\bar{f}$ is provided by

$$\begin{aligned} P_{ij} = mn\left(\frac{m}{2\pi T^*}\right)^{3/2} \Bigg\{ & \left[1 - \frac{1}{2T^*}[m(\mathbf{u}-\mathbf{u}^B)^2 + 3(T-T^*)]\right] \int_{\mathbb{R}^3} [v_i v_j + (u_i - u_i^B)(u_j - u_j^B)] \\ & \times \exp\left[-\frac{m}{2T^*} v^2\right] d_3\mathbf{v} - \frac{m}{T^*}(u_h - u_h^B) \int_{\mathbb{R}^3} [(u_i - u_i^B) v_j v_h + (u_j - u_j^B) v_i v_h] \exp\left[-\frac{m}{2T^*} v^2\right] d_3\mathbf{v} \\ & + \frac{m}{6(T^*)^2}[m(\mathbf{u}-\mathbf{u}^B)^2 + 3(T-T^*)] \int_{\mathbb{R}^3} [v^2 v_i v_j + v^2 (u_i - u_i^B)(u_j - u_j^B)] \exp\left[-\frac{m}{2T^*} v^2\right] d_3\mathbf{v} \Bigg\}. \end{aligned}$$

By resorting now to the Gaussian integrals (A1) reported in the Appendix, we get

$$P_{ij} = nT\delta_{ij} - \rho\left[(u_i - u_i^B)(u_j - u_j^B) - \tfrac{1}{3}\delta_{ij}|\mathbf{u}-\mathbf{u}^B|^2\right], \tag{27}$$

where $\rho = mn$ denotes mass density and δ is the Kronecker symbol. Analogous computations allow the evaluation of the heat flux vector, which results in

$$q_i = n(u_i - u_i^B)\left[\tfrac{1}{6} m|\mathbf{u}-\mathbf{u}^B|^2 - \tfrac{5}{2}(T-T^*)\right]. \tag{28}$$

As remarked in the preceding section, the scattering contributions appearing on the right-hand sides of (17) are in general not directly amenable to macroscopic fields. However, with the particular assumption (25) for the distribution function, all collision integrals may be solved explicitly, and we shall end up with a closed set of five (approximated) macroscopic evolution equations. More precisely, in (17) we must evaluate three integrals of the form

$$n^B \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \Phi(\mathbf{g},\mathbf{G}) \bar{f}(\mathbf{v}) M^B(\mathbf{w}) d_3\mathbf{v} d_3\mathbf{w}, \tag{29}$$

where $\mathbf{g} = \mathbf{v}-\mathbf{w}$ is the relative velocity, while $\mathbf{G} = (1-\alpha)\mathbf{v} + \alpha\mathbf{w}$ represents the center of mass velocity. Let us perform again the usual translation $\mathbf{v}-\mathbf{u}^B \to \mathbf{v}$, $\mathbf{w}-\mathbf{u}^B \to \mathbf{w}$; consequently, the integral (29) becomes

$$\begin{aligned} & \frac{nn^B}{(2\pi)^3}\left(\frac{mm^B}{T^* T^B}\right)^{3/2} \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \hat{\Phi}(\mathbf{g},\mathbf{G}) \exp\left[-\frac{m}{2T^*} v^2\right] \exp\left[-\frac{m^B}{2T^B} w^2\right] \\ & \times \left\{1 + \frac{m}{T^*}(\mathbf{u}-\mathbf{u}^B)\cdot\mathbf{v} + [m(\mathbf{u}-\mathbf{u}^B)^2 + 3(T-T^*)]\left[\frac{m}{6(T^*)^2} v^2 - \frac{1}{2T^*}\right]\right\} d_3\mathbf{v} d_3\mathbf{w}, \end{aligned} \tag{30}$$

and the three functions $\hat{\Phi}$ involved in our macroscopic equations are $\hat{\Phi}(\mathbf{g},\mathbf{G}) = g g_i, g^3, g g_i (G_i + \alpha g_i - (u_i - u_i^B))$. At this point, it seems convenient to use $(\mathbf{g},\mathbf{G})$ as integration variables; bearing in mind also the relation (19) between T^* and T^B we have

$$\begin{aligned} & \exp\left[-\frac{m}{2T^*} v^2\right] \exp\left[-\frac{m^B}{2T^B} w^2\right] \\ & \quad = \exp\left\{-\frac{m}{2T^*}\frac{1}{1-\alpha(1-\beta)}[G^2 + \alpha(\alpha\beta + (1-\alpha)(1-\beta)) g^2 + 2\alpha\beta \mathbf{G}\cdot\mathbf{g}]\right\}. \end{aligned} \tag{31}$$

Since a little algebra yields

$$G^2+\alpha[\alpha\beta+(1-\alpha)(1-\beta)]g^2+2\alpha\beta\mathbf{G}\cdot\mathbf{g}=(\mathbf{G}+\alpha\beta\mathbf{g})^2+\alpha(1-\beta)[1-\alpha(1-\beta)]g^2,$$

setting $\tilde{\mathbf{g}}=\mathbf{g}$ and $\tilde{\mathbf{G}}=\mathbf{G}+\alpha\beta\mathbf{g}$ the integral (30) can be finally cast as

$$\begin{aligned}&\frac{nn^B}{(2\pi)^3}\left(\frac{mm^B}{T^*T^B}\right)^{3/2}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\tilde{\Phi}(\tilde{\mathbf{g}},\tilde{\mathbf{G}})\exp\left[-\frac{m}{2T^*}\frac{1}{1-\alpha(1-\beta)}\tilde{G}^2\right]\exp\left[-\frac{m}{2T^*}\alpha(1-\beta)\tilde{g}^2\right]\\&\quad\times\left\{1+\frac{m}{T^*}(\mathbf{u}-\mathbf{u}^B)\cdot[\tilde{\mathbf{G}}+\alpha(1-\beta)\tilde{\mathbf{g}}]+[m(\mathbf{u}-\mathbf{u}^B)^2+3(T-T^*)]\right.\\&\quad\left.\times\left[\frac{m}{6(T^*)^2}[\tilde{\mathbf{G}}+\alpha(1-\beta)\tilde{\mathbf{g}}]^2-\frac{1}{2T^*}\right]\right\}d_3\tilde{\mathbf{G}}d_3\tilde{\mathbf{g}}.\end{aligned}\tag{32}$$

Now we can make it explicit for the three weight functions $\tilde{\Phi}$ appearing in our collision contributions. For $\tilde{\Phi}(\tilde{\mathbf{g}},\tilde{\mathbf{G}})=\tilde{g}\tilde{g}_i$, the unique term in (32) that provides a nonvanishing result is

$$\begin{aligned}&\frac{nn^B}{(2\pi)^3}\left(\frac{mm^B}{T^*T^B}\right)^{3/2}\frac{m}{T^*}\alpha(1-\beta)(u_h-u_h^B)\\&\quad\times\int_{\mathbb{R}^3}\tilde{g}\tilde{g}_i\tilde{g}_h\exp\left[-\frac{m}{2T^*}\alpha(1-\beta)\tilde{g}^2\right]d_3\tilde{\mathbf{g}}\int_{\mathbb{R}^3}\exp\left[-\frac{m}{2T^*}\frac{1}{1-\alpha(1-\beta)}\tilde{G}^2\right]d_3\tilde{\mathbf{G}}.\end{aligned}$$

By resorting to the integrals (A2) reported in the Appendix we get

$$n^B\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}gg_i\bar{f}(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w}=\frac{1}{\sqrt{\alpha(1-\beta)}}\frac{8}{3}nn^B\sqrt{\frac{2T^*}{m\pi}}(u_i-u_i^B),\tag{33}$$

that shows a linear dependence on the macroscopic unknown fields n and $\mathbf{u}$. Analogous computations lead to the evaluation of the contributions relevant to $\tilde{\Phi}(\tilde{\mathbf{g}},\tilde{\mathbf{G}})=\tilde{g}^3$ and $\tilde{\Phi}(\tilde{\mathbf{g}},\tilde{\mathbf{G}})=\tilde{g}\tilde{g}_i[\tilde{G}_i+\alpha(1-\beta)\tilde{g}_i-(u_i-u_i^B)]$. Skipping further technical details, they finally result in

$$\begin{aligned}n^B\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}g^3\bar{f}(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w}&=\left[\frac{1}{\alpha(1-\beta)}\right]^{3/2}\frac{4}{m}nn^B\sqrt{\frac{2T^*}{m\pi}}\\&\quad\times\{2T^*+\alpha(1-\beta)[m(\mathbf{u}-\mathbf{u}^B)^2+3(T-T^*)]\},\end{aligned}\tag{34}$$

$$\begin{aligned}n^B\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}g\mathbf{g}\cdot(\mathbf{v}-\mathbf{u})\bar{f}(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w}&=\sqrt{\frac{1}{\alpha(1-\beta)}}\frac{8}{m}nn^B\sqrt{\frac{2T^*}{m\pi}}\\&\quad\times\left\{T+\frac{1}{6}\alpha(1-\beta)[m(\mathbf{u}-\mathbf{u}^B)^2+3(T-T^*)]\right\},\end{aligned}\tag{35}$$

presenting both a linear dependence on the variables n, T and a quadratic dependence on the velocity $\mathbf{u}$.

In conclusion, by inserting the results (27), (28), and (33)–(35) into the macroscopic equations (17) we obtain the following closed set of evolution equations:

$$\frac{\partial n}{\partial t}+\frac{\partial}{\partial x_k}(nu_k)=0,$$

$$n\frac{\partial u_i}{\partial t}+nu_k\frac{\partial u_i}{\partial x_k}+\frac{1}{m}\frac{\partial}{\partial x_i}(nT)+\frac{1}{3}\frac{\partial}{\partial x_i}[n(\mathbf{u}-\mathbf{u}^B)^2]-\frac{\partial}{\partial x_k}[n(u_i-u_i^B)(u_k-u_k^B)]$$
$$=-\frac{1}{\varepsilon}\sqrt{\alpha(1-\beta)}\frac{8}{3}nn^B\sqrt{\frac{2T^*}{m\pi}}(u_i-u_i^B),\quad i=1,2,3,$$

$$n\frac{\partial T}{\partial t}+nu_k\frac{\partial T}{\partial x_k}+\frac{2}{3}nT\frac{\partial u_k}{\partial x_k}+\frac{2}{9}nm(\mathbf{u}-\mathbf{u}^B)^2\frac{\partial u_k}{\partial x_k}-\frac{2}{3}nm(u_h-u_h^B)(u_k-u_k^B)\frac{\partial u_h}{\partial x_k}$$
$$+\frac{1}{9}m\frac{\partial}{\partial x_k}[n(u_k-u_k^B)(\mathbf{u}-\mathbf{u}^B)^2]-\frac{5}{3}\frac{\partial}{\partial x_k}[n(u_k-u_k^B)(T-T^*)]$$
$$=-\frac{1}{\varepsilon}\sqrt{\alpha(1-\beta)}\frac{16}{3}nn^B\sqrt{\frac{2T^*}{m\pi}}\left\{[1-\alpha(1-\beta)](T-T^*)-\frac{1}{3}\alpha(1-\beta)m(\mathbf{u}-\mathbf{u}^B)^2\right\}. \quad (36)$$

They are five equations for the fundamental moments $n,\mathbf{u},T$ appearing in the expression of $\bar{f}$. The option $\beta=0$ corresponds to elastically scattering hard spheres: as anticipated above, even in this particular frame collision contributions do not vanish. As for classical Grad's equations,[14,2] the macroscopic system (36) is of course approximated, since in the whole procedure the distribution function f has been replaced by the truncated polynomial expansion $\bar{f}$, but it provides a "robust" approximation of the evolution, in the sense that the right-hand sides of (36) are vanishing if and only if $\mathbf{u}=\mathbf{u}^B$ and $T=T^*$, which reproduce the macroscopic moments of the Maxwellian equilibrium M^*. In space homogeneous conditions the equilibrium $(\mathbf{u}^B,T^*)$ is asymptotically stable, and the relaxation to the equilibrium values is as fast as the convergence of the distribution function towards M^*. It is easily checked in fact that eigenvalues of the relevant Jacobian matrix are all negative, and that the asymptotic trend is exponential with relaxation times of order ε for both $\mathbf{u}$ and T.[26] This behavior differs from other nonconservative kinetic frames, for instance chemical reacting mixtures,[2] in which the distribution evolves very rapidly towards a local Maxwellian, whose macroscopic parameters reach more slowly the corresponding equilibrium values. Indeed, we can even show that the dynamical system originated by (36) in space homogeneous conditions admits a Lyapunov function (finite dimensional entropy), proving convergence to equilibrium $(n_0,\mathbf{u}^B,T^*)$ from any initial datum $(n_0,\mathbf{u}_0,T_0)$. With $n=\text{constant}=n_0$ it is sufficient in fact to consider, for the evolution of $\mathbf{u}$ and T by effects of collisions, the function

$$V_q(\mathbf{u},T)=\frac{m}{T^*}(\mathbf{u}-\mathbf{u}^B)^2+\frac{1}{6}\left[\frac{m}{T^*}(\mathbf{u}-\mathbf{u}^B)^2+3\frac{T-T^*}{T^*}\right]^2. \quad (37)$$

It is immediately seen that V_q is positive definite with respect to $\mathbf{u}=\mathbf{u}^B$ and $T=T^*$, and some simple algebra provides its time derivative along solutions

$$\dot{V}_q(\mathbf{u},T)=\nabla_{\mathbf{u}}V_q\cdot\dot{\mathbf{u}}+\frac{\partial V_q}{\partial T}\dot{T}=-\frac{16}{3}\frac{\sqrt{\alpha(1-\beta)}}{\varepsilon}n^B\sqrt{\frac{2T^*}{\pi m}}$$
$$\times\left\{\frac{m}{T^*}(\mathbf{u}-\mathbf{u}^B)^2+\frac{1-\alpha(1-\beta)}{3}\left[\frac{m}{T^*}(\mathbf{u}-\mathbf{u}^B)^2+3\frac{T-T^*}{T^*}\right]^2\right\}. \quad (38)$$

This function is everywhere nonpositive, and vanishes only when both its nonpositive addends vanish, which leads again to the unique point $(\mathbf{u}^B,T^*)$. Therefore $\dot{V}_q$ is negative definite and Lyapunov's theorem is proved.

In order to achieve a hydrodynamic equation at the Navier-Stokes level for the unique hydrodynamic variable n, we shall perform an asymptotic analysis of Chapman-Enskog type to the system (36), following the main steps outlined in Refs. 9 and 11 and already applied in Refs. 3 and 4 in different (dissipative) physical contexts. The small parameter is the Knudsen number *Kn*

$\equiv \varepsilon$, that appears in the kinetic equation (5) as a consequence of the adimensionalization. As already pointed out in the literature,[17] it is not necessary to apply the classical Chapman-Enskog procedure directly to the kinetic level, expanding f in powers of ε and determining the relevant coefficients, since we already have a polynomial expansion $\bar{f}$ for f, hence the corresponding macroscopic system (36) may be considered as a useful intermediate step between the kinetic and the hydrodynamic level. Keeping unexpanded n, the field corresponding to the unique collision invariant, we expand the other macroscopic variables in powers of ε,

$$\mathbf{u} = \boldsymbol{\nu}^0 + \varepsilon \boldsymbol{\nu}^1, \quad T = \Upsilon^0 + \varepsilon \Upsilon^1, \tag{39}$$

and we insert these expansions into the equations (36). Neglecting $O(\varepsilon^2)$ terms, the continuity equation becomes

$$\frac{\partial n}{\partial t} + \frac{\partial}{\partial x_k}(n\nu_k^0) + \varepsilon \frac{\partial}{\partial x_k}(n\nu_k^1) = 0. \tag{40}$$

To close this equation, we must determine the first two coefficients of the expansion of $\mathbf{u}$. Going on in the asymptotic analysis of (36), from the evolution law for $\mathbf{u}$ the leading order ($O(\varepsilon^{-1})$) terms provide the equality

$$-\sqrt{\alpha(1-\beta)}\frac{8}{3} n n^B \sqrt{\frac{2T^*}{m\pi}}(\nu_i^0 - u_i^B) = 0 \quad \forall\, i, \tag{41}$$

hence

$$\boldsymbol{\nu}^0 = \mathbf{u}^B. \tag{42}$$

Then, taking into account this result, equating the coefficients of the power ε^0 we get

$$\nu_i^1 = -\frac{1}{\sqrt{\alpha(1-\beta)}} \frac{3}{8nn^B} \sqrt{\frac{m\pi}{2T^*}} \left[n \frac{\partial u_i^B}{\partial t} + n u_k^B \frac{\partial u_i^B}{\partial x_k} + \frac{1}{m} \frac{\partial}{\partial x_i}(n\Upsilon^0) \right] \quad \forall\, i. \tag{43}$$

Therefore the determination of the coefficient $\boldsymbol{\nu}^1$ requires also the evaluation of Υ^0. Leading terms of the equation for temperature in (36) give

$$-\sqrt{\alpha(1-\beta)}[1-\alpha(1-\beta)]\frac{16}{3} n n^B \sqrt{\frac{2T^*}{m\pi}}(\Upsilon^0 - T^*) = 0, \tag{44}$$

that yields immediately

$$\Upsilon^0 = T^*. \tag{45}$$

Finally, bearing in mind that the host medium fulfills the Euler equations (10), the mass velocity of granular test particles turns out to be, up to $O(\varepsilon)$ accuracy,

$$\mathbf{u} = \mathbf{u}^B - \varepsilon \frac{1}{\sqrt{\alpha(1-\beta)}} \frac{3}{8n^B} \sqrt{\frac{m\pi}{2T^*}} \left[\frac{1}{nm} \nabla_{\mathbf{x}}(nT^*) - \frac{1}{n^B m^B} \nabla_{\mathbf{x}}(n^B T^B) \right]. \tag{46}$$

By inserting this expression into the continuity equation (40), we find the hydrodynamic "Navier-Stokes" equation for the number density of hard spheres inelastically (elastically only for $\beta = 0$) colliding with a fixed background

$$\frac{\partial n}{\partial t} + \nabla_{\mathbf{x}} \cdot (n\mathbf{u}^B) = \varepsilon \frac{3}{8} \sqrt{\frac{m\pi}{2}} \nabla_{\mathbf{x}} \cdot \left\{ \frac{1}{n^B \sqrt{T^* \alpha(1-\beta)}} \left[\frac{1}{m} \nabla_{\mathbf{x}}(nT^*) - \frac{n}{n^B m^B} \nabla_{\mathbf{x}}(n^B T^B) \right] \right\}. \tag{47}$$

The time evolution of n involves spatial derivatives (up to the second order) of n itself, together with gradients of the known (but in general nonconstant) background macroscopic fields

$n^B, \mathbf{u}^B, T^B$. Equation (47) is of "drift-diffusion" type, the convective term depends on the mean velocity of the host medium, while the diffusive part involves the two (different) kinetic temperatures T^* (equilibrium temperature) and T^B.

In the particular case of spatially homogeneous background, if in the adimensionalization we assume n^B as typical density, then (46) simplifies to

$$\mathbf{u} = \mathbf{u}^B - \varepsilon \frac{1}{\sqrt{\alpha(1-\beta)}} \frac{3}{8n} \sqrt{\frac{\pi T^*}{2m}} \nabla_{\mathbf{x}} n, \tag{48}$$

while the drift-diffusion equation (47) becomes

$$\frac{\partial n}{\partial t} + \mathbf{u}^B \cdot \nabla_{\mathbf{x}} n = \varepsilon \frac{3}{8} \sqrt{\frac{\pi}{2m}} \sqrt{\frac{T^*}{\alpha(1-\beta)}} \nabla_{\mathbf{x}}^2 n. \tag{49}$$

The main difference with respect to the corresponding hydrodynamic equation relevant to pseudo-Maxwellian particles, derived in detail in Ref. 25, is the factor $\sqrt{T^*/\alpha(1-\beta)}$ instead of $T^*/\alpha(1-\beta)$, as typical for the temperature dependence of transport coefficients relevant to the two different collision models.[11]

Finally, it is worth to remark that considering $O(1)$ terms of the temperature equation in (36), and recalling again Euler equations (10), we get

$$\Upsilon^1 = 0, \tag{50}$$

hence the granular temperature T in the hydrodynamic description coincides with its equilibrium value T^* apart from $O(\varepsilon^2)$ corrections.

In low inelasticity regimes, with the inelasticity parameter β of the same order of magnitude as the Knudsen number ($\beta = \gamma\varepsilon$), the hydrodynamic diffusive equation (47) does not contain any more inelastic corrections, that would appear only at the Burnett level, namely to the second order accuracy.

IV. LOGARITHMIC ENTROPY

The most popular choice in kinetic theory to get a Lyapunov functional out of (20) is $\phi(z) = z \log z$, from which the familiar relative entropy of the linear framework follows. Again, taking into account the same constraints of the preceding section, the variational principle in order to enforce the MEP closure concerns the functional

$$U_l(f) = -\int_{\mathbb{R}^3} f(\mathbf{v}) \log \frac{f(\mathbf{v})}{M^*(\mathbf{v})} d_3\mathbf{v} + \lambda_1 \left(\int_{\mathbb{R}^3} f(\mathbf{v}) d_3\mathbf{v} - n \right) + \boldsymbol{\lambda_2} \cdot \left(\int_{\mathbb{R}^3} \mathbf{v} f(\mathbf{v}) d_3\mathbf{v} - n\mathbf{u} \right)$$
$$+ \lambda_3 \left(\int_{\mathbb{R}^3} v^2 f(\mathbf{v}) d_3\mathbf{v} - nu^2 - \frac{3nT}{m} \right). \tag{51}$$

Now manipulations lead to an approximate distribution $\tilde{f}$ of the form ($\lambda_1 - 1 \to \lambda_1$),

$$\tilde{f}(\mathbf{v}) = M^*(\mathbf{v}) \exp(\lambda_1 + \boldsymbol{\lambda_2} \cdot \mathbf{v} + \lambda_3 v^2), \tag{52}$$

so that one immediately realizes that the requirement of recovering from $\tilde{f}$ the exact fundamental fields amounts simply to

$$\tilde{f}(\mathbf{v}) = n \left(\frac{m}{2\pi T} \right)^{3/2} \exp\left[-\frac{m}{2T} (\mathbf{v} - \mathbf{u})^2 \right] = n M_{\mathrm{loc}}(\mathbf{v}), \tag{53}$$

where by $M_{\mathrm{loc}}(\mathbf{v}) = M(\mathbf{v}; m, \mathbf{u}, T)$ we denote the well-known local Maxwellian associated to the distribution function f. This entropy leads then to a 5-moments closure in terms of the local Maxwellian. The exponential form of (52) implies also positivity for the approximate normal form

distribution (53). It remains a perturbation of collision equilibrium when $\mathbf{u}$ and T are close to $\mathbf{u}^B$ and T^*, as in the physical situation we are interested in. Immediate implication of the Maxwellian shape is then that viscous stress and heat flux vanish, so that (27) and (28) may be simply replaced by

$$P_{ij} = nT\delta_{ij}, \quad q_i = 0. \tag{54}$$

As concerns the scattering contributions, we consider at first the general form

$$n^B \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \Phi(\mathbf{g},\mathbf{G}) \tilde{f}(\mathbf{v}) M^B(\mathbf{w}) d_3\mathbf{v} d_3\mathbf{w}, \tag{55}$$

specializing then the function Φ to the ones appearing in (17). Unlike the corresponding integral (29) of the preceding section, now the two integration variables are not affected by the same translation in the exponentials, since the mean value of the Gaussian function $\tilde{f}$ is the granular drift velocity $\mathbf{u}$ instead of the background velocity $\mathbf{u}^B$. It is again convenient to resort to the change of variables $(\mathbf{v},\mathbf{w}) \to (\mathbf{G},\mathbf{g})$, providing

$$\frac{nn^B}{(2\pi)^3}\left(\frac{mm^B}{TT^B}\right)^{3/2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \Phi(\mathbf{g},\mathbf{G}) \exp\left[-\frac{m}{2T}(\mathbf{G}+\alpha\mathbf{g}-\mathbf{u})^2\right]$$
$$\times \exp\left[-\frac{m^B}{2T^B}(\mathbf{G}-(1-\alpha)\mathbf{g}-\mathbf{u}^B)^2\right] d_3\mathbf{G} d_3\mathbf{g}. \tag{56}$$

Setting now

$$\mathbf{s} = a(\mathbf{G}+\alpha\mathbf{g}-\mathbf{u}) + b(\mathbf{u}-\mathbf{u}^B-\mathbf{g}), \tag{57}$$

where

$$a = \sqrt{\frac{mT^B + m^B T}{TT^B}} \text{ and } b = \frac{m^B}{T^B}\sqrt{\frac{TT^B}{mT^B + m^B T}},$$

simple manipulations show that the integral (56) takes the form

$$\frac{nn^B}{(2\pi)^3}\left[\frac{\alpha m}{(1-\alpha)T^B + \alpha T}\right]^{3/2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \tilde{\Phi}(\mathbf{g},\mathbf{s}) \exp\left(-\frac{1}{2}s^2\right)$$
$$\times \exp\left[-\frac{1}{2}\frac{\alpha m}{(1-\alpha)T^B + \alpha T}(\mathbf{g}+\mathbf{u}^B-\mathbf{u})^2\right] d_3\mathbf{g} d_3\mathbf{s}. \tag{58}$$

At this point, the contributions corresponding to the weight functions $\tilde{\Phi}(\mathbf{g},\mathbf{s}) = gg_i, g^3$ can be easily made explicit by using the integrals (A3a) and (A3b), respectively, getting

$$n^B \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} gg_i \tilde{f}(\mathbf{v}) M^B(\mathbf{w}) d_3\mathbf{v} d_3\mathbf{w} = nn^B \frac{4}{3}\sqrt{\frac{2}{\pi}}\sqrt{\frac{\alpha m}{(1-\alpha)T^B + \alpha T}}\left[2\frac{(1-\alpha)T^B + \alpha T}{\alpha m} + \frac{1}{5}(\mathbf{u}-\mathbf{u}^B)^2\right]$$
$$\times (u_i - u_i^B), \tag{59}$$

$$n^B \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} g^3 \tilde{f}(\mathbf{v}) M^B(\mathbf{w}) d_3\mathbf{v} d_3\mathbf{w} = nn^B \frac{1}{5}\sqrt{\frac{2}{\pi}}\sqrt{\frac{\alpha m}{(1-\alpha)T^B + \alpha T}}\left\{(\mathbf{u}-\mathbf{u}^B)^4 + 20\frac{(1-\alpha)T^B + \alpha T}{\alpha m}(\mathbf{u}\right.$$
$$\left. - \mathbf{u}^B)^2 + 40\left[\frac{(1-\alpha)T^B + \alpha T}{\alpha m}\right]^2\right\}. \tag{60}$$

Similar computations allow to evaluate the other collision term in the evolution equation (17) for

granular temperature: its weight function can be rearranged in terms of the variables $(\mathbf{g},\mathbf{s})$ as

$$\tilde{\Phi}(\mathbf{g},\mathbf{s}) = g\mathbf{g}\cdot\left\{\frac{1}{a}\mathbf{s}+\frac{b}{a}[\mathbf{g}-(\mathbf{u}-\mathbf{u}^B)]\right\},$$

so that by resorting again to (A3a) and (A3b) it finally results in

$$\begin{aligned} n^B\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} g\mathbf{g}\cdot(\mathbf{v}-\mathbf{u})\tilde{f}(\mathbf{v})M^B(\mathbf{w})d_3\mathbf{v}d_3\mathbf{w} \\ = nn^B\sqrt{\frac{2\alpha m}{\pi}}\frac{\alpha T}{[(1-\alpha)T^B+\alpha T]^{3/2}} \\ \times\left\{-\frac{1}{15}(\mathbf{u}-\mathbf{u}^B)^4+\frac{4}{3}\frac{(1-\alpha)T^B+\alpha T}{\alpha m}(\mathbf{u}-\mathbf{u}^B)^2+8\left[\frac{(1-\alpha)T^B+\alpha T}{\alpha m}\right]^2\right\}. \end{aligned} \tag{61}$$

All integrals (59)–(61) depend, obviously, on $n,\mathbf{u},T$, in particular, they present a polynomial dependence on the drift velocity $\mathbf{u}$, which may be cast in terms of the scaled variable $\alpha m(\mathbf{u}-\mathbf{u}^B)^2/((1-\alpha)T^B+\alpha T)$.

By inserting the results (54) and (59)–(61) into the equations (17), we find the following closed set of balance laws for the macroscopic fields $n,\mathbf{u},T$:

$$\frac{\partial n}{\partial t}+\frac{\partial}{\partial x_k}(nu_k)=0,$$

$$\begin{aligned} n\frac{\partial u_i}{\partial t}+nu_k\frac{\partial u_i}{\partial x_k}+\frac{1}{m}\frac{\partial}{\partial x_i}(nT) = -\frac{\alpha(1-\beta)}{\varepsilon}\frac{4}{3}nn^B\sqrt{\frac{2}{\pi}}\sqrt{\frac{\alpha m}{(1-\alpha)T^B+\alpha T}} \\ \times\left[\frac{1}{5}(\mathbf{u}-\mathbf{u}^B)^2+2\frac{(1-\alpha)T^B+\alpha T}{\alpha m}\right](u_i-u_i^B), \quad i=1,2,3, \end{aligned} \tag{62}$$

$$\begin{aligned} n\frac{\partial T}{\partial t}+nu_k\frac{\partial T}{\partial x_k}+\frac{2}{3}nT\frac{\partial u_k}{\partial x_k} = \frac{\alpha(1-\beta)}{\varepsilon}\frac{2}{3}mnn^B\sqrt{\frac{2}{\pi}}\sqrt{\frac{\alpha m}{(1-\alpha)T^B+\alpha T}} \\ \times\left\{\frac{1}{5}\left[\alpha(1-\beta)+\frac{1}{3}\frac{\alpha T}{(1-\alpha)T^B+\alpha T}\right](\mathbf{u}-\mathbf{u}^B)^4+4\frac{(1-\alpha)T^B+\alpha T}{\alpha m}\right. \\ \times\left[\alpha(1-\beta)-\frac{1}{3}\frac{\alpha T}{(1-\alpha)T^B+\alpha T}\right](\mathbf{u}-\mathbf{u}^B)^2+8\left[\frac{(1-\alpha)T^B+\alpha T}{\alpha m}\right]^2 \\ \left.\times\left[\alpha(1-\beta)-\frac{\alpha T}{(1-\alpha)T^B+\alpha T}\right]\right\}. \end{aligned}$$

Like (36), this system is in general not exact, since it has been achieved assuming that during the evolution the granular medium is accomodated at a local thermodynamical equilibrium (LTE) configuration. Notice that (62) is more difficult than (36) to be studied analytically, since collision contributions depend on $\mathbf{u}$ and T in a more complicated fashion. In space homogeneous conditions, collision equilibria of equations (62) reproduce the results of the kinetic level, namely $\mathbf{u}=\mathbf{u}^B$ and $T=T^*$, as in the preceding section. Again this is a good indication of robustness, and also shows that equilibrium can be reached through LTE states. In fact, convergence to the equilibrium $(\mathbf{u}^B,T^*)$ from any initial point $(\mathbf{u}_0,T_0)$ in the space homogeneous case can be proved again by means of Lyapunov's theorem. As a tentative entropy we may select $H[\tilde{f}]$, which, upon discarding inessential constants, turns out to be

$$V_l(\mathbf{u},T)=\frac{m}{2T^*}(\mathbf{u}-\mathbf{u}^B)^2+\frac{3}{2}\frac{T-T^*}{T^*}-\frac{3}{2}\log\frac{T}{T^*}. \tag{63}$$

It is clearly positive definite with respect to $\mathbf{u}=\mathbf{u}^B$ and $T=T^*$ as sum of two separate positive definite functions of a single variable. The computation of time derivative along trajectories $\dot{V}_l=\nabla_{\mathbf{u}}V_l\cdot\dot{\mathbf{u}}+(\partial V_l/\partial T)\dot{T}$ requires some patient manipulations, due to the heavy structure of the right-hand sides of equations (62). A careful rearrangement yields

$$\dot{V}_l(\mathbf{u},T)=-\frac{2}{3}\sqrt{\frac{2}{\pi}}\frac{\alpha(1-\beta)}{\varepsilon}n^B\sqrt{\frac{\alpha m}{(1-\alpha)T^B+\alpha T}}$$
$$\times[A(T,T^*)|\mathbf{u}-\mathbf{u}^B|^4+B(T,T^*)|\mathbf{u}-\mathbf{u}^B|^2+C(T,T^*)(T-T^*)^2], \tag{64}$$

where $A(T,T^*)$ is proportional, by a positive factor, to

$$3\alpha(1-\beta)[1-\alpha(1-\beta)]\left(\frac{T}{T^*}\right)^2+2[2-3\alpha(1-\beta)+3\alpha^2(1-\beta)^2]\frac{T}{T^*}+3\alpha(1-\beta)[1-\alpha(1-\beta)],$$

which in turn is positive for any pair (T,T^*) since also the prefactor of T/T^* can be easily seen to be positive. Therefore we have $A(T,T^*)>0$. Analogously, $B(T,T^*)$ is given by a positive quantity times the quadratic term

$$3\alpha(1-\beta)[1-\alpha(1-\beta)]\left(\frac{T}{T^*}\right)^2+2[1-3\alpha(1-\beta)+3\alpha^2(1-\beta)^2]\frac{T}{T^*}+3\alpha(1-\beta)[1-\alpha(1-\beta)],$$

and the same reasoning holds for this slightly different expression, so that also $B>0$. Finally we get simply

$$C(T,T^*)=12\frac{[1-\alpha(1-\beta)][T^*+\alpha(1-\beta)(T-T^*)]}{\alpha m(1-\beta)TT^*},$$

which is clearly positive $\forall T$, T^*, and therefore $\dot{V}_l$, as given by (64), is the sum of three nonpositive addends, and vanishes if and only if $\mathbf{u}=\mathbf{u}^B$ and $T=T^*$. This completes the required proof that V_l is a strict entropy function for (62).

Let us apply now a Chapman-Enskog asymptotic procedure to the system (62), in order to build up a fluid-dynamic Navier-Stokes equation for the number density n. Proceeding as in the preceding section, we substitute into (62) the expansions of the nonhydrodynamic variables $\mathbf{u}$ and T in powers of the chosen small parameter $Kn\equiv\varepsilon$, as given in (39). In order to close the continuity equation we must determine the coefficients $\boldsymbol{\nu}^0$ and $\boldsymbol{\nu}^1$. The main difference with respect to the previous closure approach is the presence in (62) of quantities of the kind $[(1-\alpha)T^B+\alpha T]^{-\kappa}$ (with $\kappa=1,\ 1/2$) which, containing T, must be expanded in powers of ε,

$$[(1-\alpha)T^B+\alpha T]^{-\kappa}=[(1-\alpha)T^B+\alpha\Upsilon^0]^{-\kappa}\left[1-\kappa\frac{\alpha\Upsilon^1}{(1-\alpha)T^B+\alpha\Upsilon^0}\varepsilon+O(\varepsilon^2)\right].$$

Hence, by considering $O(\varepsilon^{-1})$ terms appearing in the equation for $\mathbf{u}$ we have

$$-\alpha(1-\beta)\frac{4}{3}nn^B\sqrt{\frac{2}{\pi}}\sqrt{\frac{\alpha m}{(1-\alpha)T^B+\alpha\Upsilon^0}}\left[\frac{1}{5}(\boldsymbol{\nu}^0-\mathbf{u}^B)^2+2\frac{(1-\alpha)T^B+\alpha\Upsilon^0}{\alpha m}\right]$$
$$\times(\nu_i^0-u_i^B)=0\quad\forall\, i, \tag{65}$$

thus we get again

$$\boldsymbol{\nu}^0=\mathbf{u}^B. \tag{66}$$

Then, the next step [$O(1)$ terms] of the asymptotic procedure yields

$$\nu_i^1 = -\frac{1}{\alpha(1-\beta)}\frac{3}{8nn^B}\sqrt{\frac{\pi}{2}}\sqrt{\frac{\alpha m}{(1-\alpha)T^B+\alpha\Upsilon^0}}\left[n\frac{\partial u_i^B}{\partial t}+nu_k^B\frac{\partial u_i^B}{\partial x_k}+\frac{1}{m}\frac{\partial}{\partial x_i}(n\Upsilon^0)\right], \tag{67}$$

so that we need also the coefficient Υ^0. As before, we must consider the leading order of the temperature evolution equation, and this provides

$$\alpha^2(1-\beta)\frac{16}{3}nn^Bm\sqrt{\frac{2}{\pi}}\left[\frac{(1-\alpha)T^B+\alpha\Upsilon^0}{\alpha m}\right]^{3/2}\left[(1-\beta)-\frac{\Upsilon^0}{(1-\alpha)T^B+\alpha\Upsilon^0}\right]=0, \tag{68}$$

hence

$$\Upsilon^0=\frac{(1-\alpha)(1-\beta)}{1-\alpha(1-\beta)}T^B=T^*. \tag{69}$$

By inserting this result into (67) and recalling the Euler equations (10) for the background medium, finally we get for the drift velocity $\mathbf{u}$ the same approximation (46), accurate to $O(\varepsilon)$, achieved in the previous approach. Consequently, the present fluid-dynamic equation for the number density n coincides with (47). Moreover, equating zero order terms in the equation for T, we find again, after some algebra, $\Upsilon^1=0$, hence $T=T^*+O(\varepsilon^2)$.

V. DISCUSSION AND CONCLUSIONS

The two different closure strategies performed in this work have provided then, as anticipated, different moment equations but the same fluid-dynamic limit, at least up to the first order in the small parameter ε. Both closures are approximations justified by a maximum entropy principle applied to a specific choice of entropy functional, and, in the considered collision dominated regime, describe relaxation towards collision equilibrium, which maximizes all possible entropies. The different entropies imply different constraints on the evolutions, which explain the different macroscopic equations. However, in the hydrodynamic limit, it is conceivable that closeness to collision equilibrium, valid outside initial and boundary layers, implies the same fluid-dynamic equation of drift-diffusion type at the Navier-Stokes level. This matter will be the object of future separate investigations. Validation of the trends provided by the different closures by comparison with kinetic calculations will also be one of the first steps in the scheduled future work. This will be essential in order to ascertain which macroscopic equations best approximate the solution of the kinetic problem, and to possibly investigate whether there exists an optimal entropy in this sense, among the infinite possible ones. For now, it is worth concluding this paper with some observations arising from the general structure of the analytical results and from the simple numerical experiments that are easily performed in space homogeneous conditions. A sample of them is reported here just for illustrative purposes, with randomly selected numerical values of the involved parameters, chosen on their physically pertinent ranges. The presented results are relevant to physical situations in which the discrepancies between the two entropies are large enough to be seen in the figures. No discrepancy would occur for the pseudo-Maxwellian model, since moment equations would be exact in the absence of spatial gradients. In any case, evolution reduces now to relaxation to (the correct) equilibrium, which is reached after few collision times, so that differences can be seen only in such small initial layer. Computed velocities and temperatures are shown in Figs. 1 and 2 for $m=1$, $\mathbf{u}^B=(1,2,3)$, $T^B=2$, starting from initial conditions $\mathbf{u}_0=\mathbf{0}$, $T_0=3$. The Knudsen number Kn is only a scaling factor and does not affect the evolution if time is measured in mean collision times. For this reason results are plotted versus the microscopic time scale t/Kn and are universal with respect to Kn. A quantity like n^B is also merely a scaling factor and its value may be considered as included into Kn. Crucial control parameters are here mass ratio α and inelasticity coefficient β, that in fact have been varied in Figs. 1 and 2, respectively. Increasing α for fixed β amounts to enhancing the rate of exchange of momentum and energy with the background, and at the same time makes the equilibrium temperature T^* lower and lower. In fact, a faster relaxation of both $\mathbf{u}$ to $\mathbf{u}^B$ and T to T^*, accompanied by a slight decrease of T^*, may

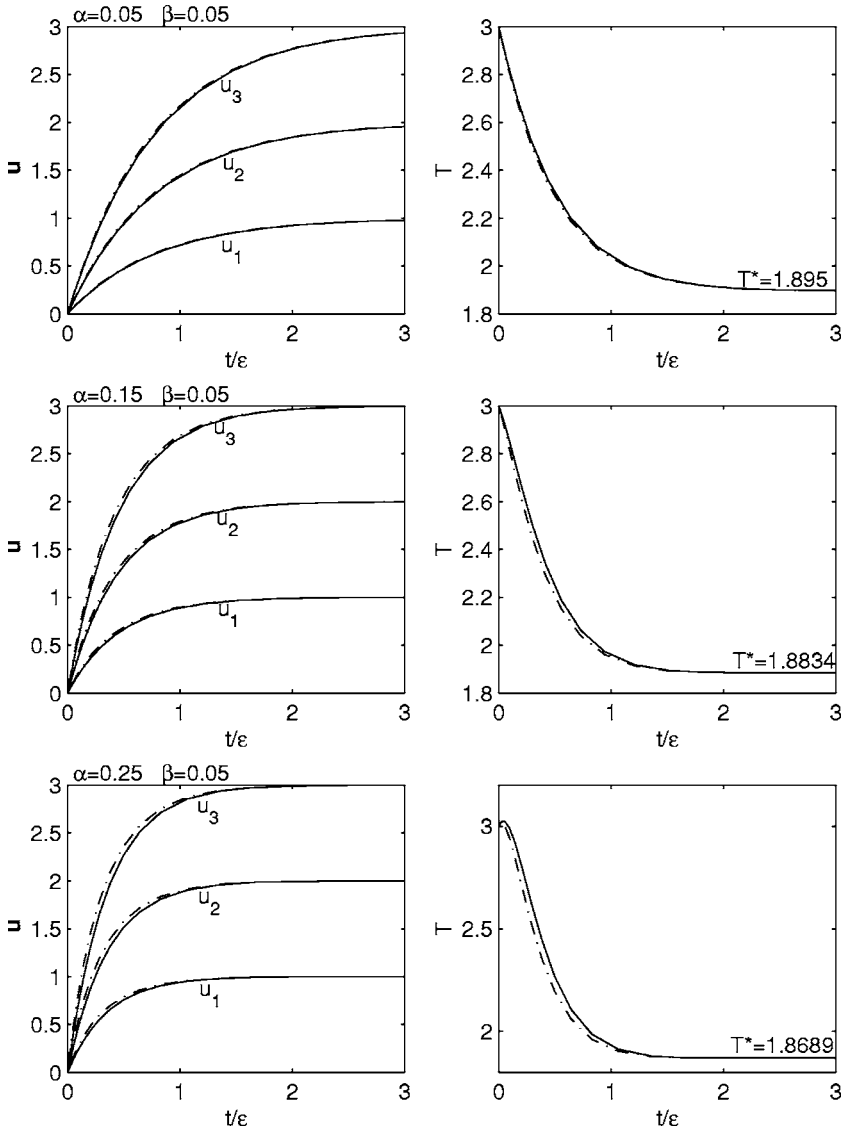

FIG. 1. Evolution of mass velocity **u** and temperature T for varying α in the microscopic time scale t/ε for the values of parameters given in the text: quadratic entropy (solid line) versus logarithmic entropy (dashed dotted line).

be observed in Fig. 1. Notice that, just because a higher α implies a stronger impact of collisions, discrepancies in the plots become larger and larger for increasing α. Similar arguments apply to the effects of the parameter β, based again on physical grounds, and quantitatively described by collision contributions in Eqs. (36) and (62). Results are shown in Fig. 2. Now increasing β makes the relaxation rate slightly smaller, and at the same time causes a sensible decrease of the equilibrium temperature. A general feature that has been observed systematically is that the logarithmic entropy produces a faster relaxation than the quadratic one. Of course it will be interesting to compare these trends with kinetic computations.

Random multi-overlap structures for optimization problems

Luca De Sanctis[a)]

(Received 5 August 2005; accepted 22 September 2005;
published online 28 November 2005)

We extend to the K-SAT and *p*-XOR-SAT optimization problems the results recently achieved, by introducing the concept of random multi-overlap structure, for the Viana-Bray model of diluted mean field spin glass. More precisely we can prove a generalized bound and an extended variational principle for the free energy per site in the thermodynamic limit. Moreover a trial function implementing ultrametric breaking of replica symmetry is exhibited. The ultrametric structure exhibits the same factorization property as the optimal structures for the Viana-Bray model and the Sherrington-Kirkpatrick nondiluted model. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2121267]

I. INTRODUCTION

In the case of nondiluted spin glasses, Aizenman, Sims, and Starr[1] introduced the idea of random overlap structure (ROSt) to express in a very elegant manner the free energy of the model as an infimum over a rich probability space, to exhibit an optimal structure (the so-called Boltzmann one), to write down a general trial function through which one can formulate various ansatzs for the free energy of the model. It was also described how to formulate in particular the Parisi ansatz within this formalism. In Refs. 2 and 3 we extended those results to the case of diluted spin glass (Viana-Bray model). Here we extend the same results to optimization problems, the K-SAT and the *p*-XOR-SAT. The latter is the simple extension to *p*-body interactions of the Viana-Bray model, which is the diluted version of the famous model of Sherrington and Kirkpatrick (SK) of mean field spin glass. We also prove that the optimal structures must enjoy a certain factorization property, known as invariance with respect to the cavity step, that was first found by Guerra in Ref. 5 for the SK model, and that turned out to be valid also for the Viana-Bray dilute spin glass model.[2] The ultrametric ansatz we propose verifies such a property.

Many of the calculations in the present paper are quite simple and standard, and as a general reference with many details the reader can take for instance Refs. 4 and 7.

II. MODEL, NOTATIONS, DEFINITIONS

Consider configurations of Ising spins σ: $i \to \sigma_i = \pm 1$, $i = 1, \ldots, N$. Let P_ζ be a Poisson random variable of mean ζ, and $\{i_\nu^\mu\}$ be independent identically distributed random variables, uniformly distributed over points $\{1, \ldots, N\}$. If $\{J_\nu^\mu\}$ are independent identically distributed copies of a symmetric random variable $J = \pm 1$, then the Hamiltonian of random K-SAT is

a)Electronic mail: lde@math.princeton.edu

$$H = -\sum_{\nu=1}^{P_{\alpha N}} \frac{1}{2}(1 + J_\nu^1 \sigma_{i_\nu^1}) \cdots \frac{1}{2}(1 + J_\nu^K \sigma_{i_\nu^K}).$$

Here $\alpha \geqslant 0$ is the degree of connectivity and K is assumed to be even. We do not consider the presence of an external field, but all the results trivially extend to this case as well. By ω we mean the Bolztmann-Gibbs average

$$\omega(\mathcal{O}) = Z_N^{-1} \sum_{\{\sigma\}} \mathcal{O}(\sigma) \exp(-\beta H), \quad Z_N = \sum_{\{\sigma\}} \exp(-\beta H).$$

We will denote by $\mathbb{E}$ the average over all the other (quenched) random variables, and the free energy f_N per site and its thermodynamic limit are defined by

$$-\beta f_N = \frac{1}{N} \mathbb{E} \ln Z_N, \quad f = \lim_{N \to \infty} f_N.$$

The existence of the above-mentioned limit has been proven in Ref. 4 (see also Ref. 2 for the proof in the framework of overlap structures). We will use the notation Ω for the product of the needed number of independent copies (replicas) of ω and $\langle \cdot \rangle$ for the composition of an $\mathbb{E}$-type average over some quenched variables and some sort of Boltzmann-Gibbs average over the spin variables, which will be clear from the context. The multi-overlaps are defined (using replicas) by

$$q_{1,\cdots,n} = \frac{1}{N} \sum_{i=1}^{N} \sigma_i^{(1)} \cdots \sigma_i^{(n)}.$$

Definition 1: A random multi-overlap structure (*RaMOSt*) $\mathcal{R}$ *is a triple* $(\Sigma, \{\tilde{q}_n\}, \xi)$ *where*

1. Σ *is a discrete space*;
2. ξ: $\Sigma \to \mathbb{R}_+$ *is a system of random weights*;
3. $\tilde{q}_{r_1,\cdots,r_{2l}}$: $\Sigma_{r_1} \times \cdots \times \Sigma_{r_l} \to [0,1]$, $l \in \mathbb{N}$, $|\vec{q}| \leqslant 1$ *is a positive definite* multi-overlap kernel.

III. THE STRUCTURE OF THE MODEL

In order to understand what is the underlying structure of the model, it is well known that it is useful to compute the derivative of the free energy with respect to the somewhat basic parameter. In the case of nondiluted spin glasses such a parameter is the strength of the couplings (and it is equivalent to differentiating with respect to the inverse temperature). In the case of diluted spin glasses such a parameter is the connectivity.

It is very easy to show (see, e.g., Ref. 4) by pretty standard calculation that

$$\frac{\mathrm{d}}{\mathrm{d}\alpha} \frac{1}{N} \mathbb{E} \ln \sum_{\sigma} \exp(-\beta H) = \sum_{n>0} \frac{(-1)^{n+1}}{n} \left(\frac{e^{-\beta} - 1}{2^K} \right)^n \langle (1 + Q_n(q))^K \rangle, \tag{1}$$

where

$$Q_n(q) = \sum_{l=1}^{[n/2]} \sum_{r_1 < \cdots < r_{2l}}^{1,n} q_{r_1,\ldots,r_{2l}}.$$

The fundamental quantities governing the model are therefore the multi-overlaps, like for diluted spin glasses.[2,3] That is why we use RaMOSt in this context as well. The main difference is that here the function $1 + Q_n$ takes the place of the mere multi-overlaps.

As should be clear from Refs. 1–3 we must therefore introduce also two random variables $\tilde{H}(\gamma, \alpha; \tilde{J})$ and $\hat{H}(\gamma, \alpha; \hat{J})$ such that

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\mathbb{E}\ln\sum_{\gamma}\xi_{\gamma}\exp(-\beta\tilde{H}_{\cdot})=K\sum_{n>0}\frac{(-1)^{n+1}}{n}\left(\frac{e^{-\beta}-1}{2^{K-1}}\right)^{n}\langle(1+Q_n(\tilde{q}))^{K-1}\rangle, \tag{2}$$

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\frac{1}{N}\mathbb{E}\ln\sum_{\gamma}\xi_{\gamma}\exp(-\beta\hat{H})=(K-1)\sum_{n>0}\frac{(-1)^{n+1}}{n}\left(\frac{e^{-\beta}-1}{2^{K}}\right)^{n}\langle(1+Q_n(\tilde{q}))^{K}\rangle. \tag{3}$$

Finally, we introduce as expected the following trial function:

$$G_N(\mathcal{R},\tilde{H},\hat{H})=\frac{1}{N}\mathbb{E}\ln\frac{\Sigma_{\sigma,\gamma}\xi_{\gamma}\exp\left(-\beta\Sigma_{i=1}^{N}\tilde{H}_i\frac{1}{2}(1+J_i\sigma_i)\right)}{\Sigma_{\gamma}\xi_{\gamma}\exp(-\beta\hat{H})},$$

where $\tilde{H}_i$ are independent copies of $\tilde{H}_{\cdot}$. We will construct explicitly $\tilde{H}_{\cdot}$ and $\hat{H}$ in the next sections. Lastly, let us define

$$\tilde{H}=\sum_{i=1}^{N}\tilde{H}_i\frac{1}{2}(1+J_i\sigma_i).$$

IV. GENERAL THEOREMS

Let us state the extension to the K-SAT model of the results presented in Refs. 1, 5, and 2. The first result is a general bound for the free energy per spin.

Theorem 1 (Generalized Bound):

$$-\beta f_N\leqslant\inf_{\mathcal{R}}G_N.$$

Proof: Consider the interpolating Hamiltonian

$$H_{\gamma}(t)=H(t)+\tilde{H}(1-t)+\hat{H}(t),\quad t\in[0,1],$$

where t is understood to multiply the connectivity, and consider also

$$R(t)=\frac{1}{N}\mathbb{E}\ln\frac{\Sigma_{\gamma,\sigma}\xi_{\gamma}\exp(-\beta H_{\gamma}(t))}{\Sigma_{\gamma}\xi_{\gamma}\exp(-\beta\hat{H}_{\gamma})}.$$

Now observe that $R(1)=-\beta f_N$, $R(0)=G_N$, and compute the t-derivative of $R(t)$ using the expressions in Sec. III,

$$\frac{\mathrm{d}}{\mathrm{d}t}R(t)=-\alpha\sum_{n>0}\frac{1}{n}\left(\frac{e^{-\beta}-1}{2^{K}}\right)^{n}$$
$$\times\langle(1+Q_n(q))^{K}-K(1+Q_n(q))(1+Q_n(\tilde{q}))^{K-1}+(K-1)(1+Q_n(\tilde{q}))^{K}\rangle.$$

Therefore the derivative above is nonpositive since the function $x^K-Kxy^{K-1}+(K-1)y^K$ of x and y is non-negative. This completes the proof of the theorem. □

The second result is the explicit construction of a RaMOSt which provides the proof of the existence of such structures and a reversed bound to the one in the previous theorem. This RaMOSt is called Boltzmann, and it is equivalent to the existence of the thermodynamic limit for the free energy per site.[6]

Definition 2 (Boltzmann RaMOSt): The Boltzmann RaMOSt $\mathcal{R}_B(M)$ is the triple

1. $\Sigma=\{-1,1\}^M\ni\tau$,
2. $\xi_{\tau}=\exp(-\beta H_M(\tau))$,

3. $\tilde{q}_{r_1\cdots r_l}=1/M\Sigma_j \tau_j^{(r_1)}\cdots\tau_j^{(r_l)}$.

We choose

$$\tilde{H}_\tau = -\sum_{\nu=1}^{P_{K\alpha N}} \frac{1}{2}(1+\tilde{J}_\nu^1 \tau_{j_\nu^1})\cdots\frac{1}{2}(1+\tilde{J}_\nu^{K-1}\tau_{j_\nu^{K-1}})\frac{1}{2}(1+J_\nu^K\sigma_{i_\nu}),$$

$$\hat{H}_\tau = -\sum_{\nu=1}^{P_{(K-1)\alpha N}} \frac{1}{2}(1+\hat{J}_\nu^1 \tau_{j_\nu^1})\cdots\frac{1}{2}(1+\hat{J}_\nu^K\tau_{j_\nu^K}),$$

where the independent random variables $j_\cdot^\cdot$ are uniformly distributed over $1,\ldots,M$ and $\tilde{J}_\cdot^\cdot, \hat{J}_\cdot^\cdot$ are independent copies of J.

Theorem 2 (Reversed Bound):

$$-\beta f \geqslant \lim_{N\to\infty}\liminf_{M\to\infty} G_N(\mathcal{R}_B(M)).$$

Proof: It is clearly enough to show

$$-\beta f = \mathbf{C}\lim_M \frac{1}{N}\mathbb{E}\ln\frac{Z_{M+N}}{Z_M} \geqslant \liminf_N \liminf_M G_N(\mathcal{R}_B(M)), \tag{4}$$

where the limit **C** lim is in the Cesàro sense. We can rewrite G_N as

$$\frac{1}{N}\mathbb{E}\ln\left[\frac{\Sigma_{\tau,\sigma}e^{-\beta(H_M+\tilde{H})}}{Z_{N+M}(\alpha')}\frac{Z_{N+M}(\alpha')}{Z_{N+M}(\alpha)}\frac{Z_{N+M}(\alpha)}{Z_M(\alpha)}\frac{Z_M(\alpha)}{\Sigma_\tau e^{-\beta(H_M+\hat{H})}}\right]$$

and therefore we have four terms. If we now take

$$\alpha' = \alpha\left(1+(K-1)\frac{N}{M}\right)$$

we see that the fourth fraction is the same as $Z_M(\alpha)/Z_M(\alpha')$, and it cancels out with the second in the limit of large M (just like in Ref. 2). We also know that the third fraction tends to $-\beta f$.

Now we keep proceeding like in Ref. 2. In the denominator of the first fraction we can split the mean $\alpha'(N+M)$ into the sum of three means such that H_{N+M} splits into the sum of three Hamiltonians with the first depending only on cavity spins τ, the second containing exactly one spin from the original system in its interactions, the third has the interactions with at least two spins σ. Hence the three coefficients of the connectivities, up to corrections vanishing when M is large, will be M^K, KM^{K-1}, and a negligible third (of order M^{K-2}), respectively. Incidentally, this means that when the cavity is large the added spins do not interact with one another (asymptotically).

The choice of α' we made guarantees that numerator and denominator contain two (up to a negligible third in the denominator) identical Hamiltonians with the same connectivities. As a consequence, the first fraction in G_N vanishes in the limit and the theorem is proven. □

An immediate consequence of the two bounds is clearly the following

Theorem 3 (Extended Variational Principle):

$$-\beta f = \lim_{N\to\infty}\inf_{\mathcal{R}} G_N.$$

All the RaMOSts yielding the correct value of the free energy per site in the thermodynamic limit are called optimal, and they enjoy the same factorization property that is found for both nondilute spin glasses and the Viana-Bray model of dilute spin glass.[2] This statement is made precise by factorizing the cavity part of the trial free energy[2]

$$c_1 \cdots c_N = \sum_{\sigma} \exp(-\beta \tilde{H}), \tag{5}$$

in the next

Theorem 4: *In the whole region where the parameters are uniquely defined, the following Cesàro limit is linear in N and* $\bar{\alpha}$:

$$\mathbf{C} \lim_{M} \mathbb{E} \ln \Omega_M \left\{ \sum_{\sigma} c_1 \cdots c_N \exp[-\beta(\hat{H}(\bar{\alpha}/N))] \right\} = N(-\beta f + \alpha A) + \bar{\alpha} A, \tag{6}$$

where

$$A = \sum_{n>0} \frac{(-1)^{n+1}}{n} \left(\frac{e^{-\beta} - 1}{2^K} \right)^n \langle (1 + Q_n(q))^K \rangle.$$

Proof: As expected, the proof is similar to that of the analogous theorem in Ref. 2 and to that of Theorem 2 above, except here we will choose

$$\alpha' = \alpha + (K-1)\frac{1}{M}(\alpha N + \bar{\alpha})$$

and use only three fractions, re-writing the left-hand side of (6) as

$$\frac{1}{N} \mathbb{E} \ln \left[\frac{\Sigma_{\tau,\sigma} \exp(-\beta(H_M + \tilde{H}))}{Z_{N+M}(\alpha')} \frac{Z_{N+M}(\alpha')}{Z_{N+M}(\alpha)} \frac{Z_{N+M}(\alpha)}{Z_M(\alpha)} \right].$$

Notice that this choice of α' reduces to the previous one of Theorem 2 for $\bar{\alpha}=0$, as it should do. □

V. REPLICA SYMMETRY BREAKING AND ULTRAMETRIC RaMOSt

Now we are equipped with the main theorems about the random multi-overlap structures in the case of the K-SAT problem, and we are about to extend the results of Ref. 3 to the K-SAT. We want to construct a trial function depending on ultrametric trial multi-overlaps, that fulfills the generalized bound and obeys the factorization property of the optimal structures.

Definition 3 (Ultrametric RaMOSt): The R-level replica symmetry breaking ultrametric RaMOSt $\mathcal{R}_U$ *is the triple*

1. $\Sigma = \mathbb{N}^R \ni \gamma = (\gamma_1, \ldots, \gamma_R)$;
2. $\xi_\gamma(m_1, \ldots, m_R)$ *from the random probability cascades*;
3. $\tilde{q}_{r_1 \cdots r_l} = (\tilde{q}^{(1)}_{r_1,\cdots,r_l} - \tilde{q}^{(0)}_{r_1 \cdots r_l}) \delta_{\gamma_1^{r_1},\cdots,\gamma_1^{r_l}} + \cdots + (\tilde{q}^{(R)}_{r_1,\cdots,r_l} - \tilde{q}^{(R-1)}_{r_1,\cdots,r_l}) \delta_{\gamma_1^{r_1} \cdots \gamma_1^{r_l}} \cdots \delta_{\gamma_R^{r_1} \cdots \gamma_R^{r_l}}$ *is the ultrametric multi-overlap, given partitions* $q^{(a)}_{r_1,\cdots,r_l}$, $0 \leqslant a \leqslant R$ *of the interval [0,1].*

Denoting by X the map

$$X: \tilde{\alpha}_a \to m_a$$

satisfying (7), we can consider the trial function $G(\mathcal{R}_U)$ as a function $G(X)$ of X.

Theorem 5: *There exist* $\tilde{H}$, $\hat{H}$ *satisfying* (2) and (3) *with* $\tilde{q}$ *ultrametric and the ultrametric trial function* $G(X)$ *satisfying the bound*

$$-\beta f(\beta, \alpha) \leqslant \inf_X G(X)$$

as a special case of the generalized bound. Moreover, the Ultrametric RaMOSt enjoys the same factorization property as in Theorem 4.

Proof: Take

$$\tilde{H}_\gamma = \sum_{\nu=1}^{P_{KaN}} \tilde{u}_\nu^\gamma \frac{1}{2}(1 + J_\nu \sigma_{i_\nu}) - \frac{1}{\beta} \ln \cosh(\beta \tilde{u}_\nu^\gamma),$$

$$\hat{H}_\gamma = \sum_{\nu=1}^{P_{(K-1)aN}} \hat{u}_\nu^\gamma - \frac{1}{\beta} \ln \cosh(\beta \hat{u}_\nu^\gamma)$$

with $\tilde{u}_\gamma$, $\hat{u}_\gamma$ defined by

$$\tanh(\beta \tilde{u}_\gamma) = (e^{-\beta} - 1)\tfrac{1}{2}(1 + \tilde{J}^1 W_\gamma^1) \cdots \tfrac{1}{2}(1 + \tilde{J}^{K-1} W_\gamma^{K-1}),$$

$$\tanh(\beta \hat{u}_\gamma) = (e^{-\beta} - 1)\tfrac{1}{2}(1 + \hat{J}^1 W_\gamma^1) \cdots \tfrac{1}{2}(1 + \hat{J}^K W_\gamma^K)$$

in which W_γ is the same as in Ref. 3

$$W_\gamma = \tilde{\omega}_{\tilde{\alpha}_1}(\rho_{k_\nu}) \bar{J}_{\gamma_1} + \cdots + \tilde{\omega}_{\tilde{\alpha}_R}(\rho_{k_\nu}) \bar{J}_{\gamma_1, \cdots, \gamma_R},$$

where $\tilde{\omega}_{\tilde{\alpha}}(\rho_{k_\nu})$ is the infinite volume limit of the Boltzmann-Gibbs average of a random spin from an auxiliary system with a Viana-Bray one-body interaction Hamiltonian at connectivity $\tilde{\alpha}^3$ and $\bar{J} = \pm 1$ is symmetric. Notice that

$$\mathbb{E}\tilde{\omega}_{\tilde{\alpha}}^n(\rho_k) = \langle \tilde{q}_n \rangle_{\tilde{\alpha}} = \tilde{q}_n(\tilde{\alpha}).$$

The indices, the bar, the tilde, and the caret mean independent copies of the corresponding variables. Let us now report a comment from Ref. 2. Given any partition $\{x^a\}_{a=0}^R$ of the interval [0, 1], there exists a sequence $\{\tilde{\alpha}_a\}_{a=0}^R \in [0, \infty]$ such that $\tilde{q}_{1,\cdots,n}(\tilde{\alpha}_a) = x_a - x_{a-1}$. In other words, a sequence $\{\tilde{\alpha}_a\}_{a=0}^R \in [0, \infty]$ generates for each $n \in \mathbb{N}$ a partition of [0, 1] considered as the set of trial values of $\tilde{q}_{1,\cdots,n}$, provided the $\tilde{\alpha}_a$ are not too large

$$\sum_{a \leqslant R} \tilde{q}_{1,\cdots,n}(\tilde{\alpha}_a) \leqslant 1. \tag{7}$$

We limit our trial multi-overlaps to belong to partitions generated in this way. This implies that the points of the generated partitions tend to get closer to zero as n increases. This is good, since in any probability space $\langle \tilde{q}_n \rangle$ decreases as n increases and therefore the probability integral distribution functions tend to grow faster near zero. Now put inductively

$$\mathbb{E}\tilde{\Omega}_{\tilde{\alpha}_a}(\tau_{k_\nu}^{(r_1)} \cdots \tau_{k_\nu}^{(r_l)}) = \tilde{q}_{r_1,\cdots,r_l}(\tilde{\alpha}_a) = \tilde{q}_{r_1,\cdots,r_l}^{(a)} - \tilde{q}_{r_1,\cdots,r_l}^{(a-1)}, \quad \tilde{q}_{r_1,\cdots,r_l}^{(0)} = 0,$$

then an elementary calculation shows that

$$\mathbb{E}\tanh^n(\beta \tilde{u}_\gamma) = \left(\frac{e^{-\beta} - 1}{2^{K-1}}\right)^n (1 + Q_n(\tilde{q}))^{K-1},$$

$$\mathbb{E}\tanh^n(\beta \hat{u}_\gamma) = \left(\frac{e^{-\beta} - 1}{2^K}\right)^n (1 + Q_n(\tilde{q}))^K$$

with $\tilde{q}$ ultrametric,[3] i.e.,

$$\tilde{q}_{r_1,\cdots,r_l} = (\tilde{q}_{r_1,\cdots,r_l}^{(1)} - \tilde{q}_{r_1,\cdots,r_l}^{(0)}) \delta_{\gamma_1^{r_1} \cdots \gamma_1^{r_l}} + \cdots + (\tilde{q}_{r_1,\cdots,r_l}^{(R)} - \tilde{q}_{r_1,\cdots,r_l}^{(R-1)}) \delta_{\gamma_1^{r_1} \cdots \gamma_1^{r_l}} \cdots \delta_{\gamma_R^{r_1} \cdots \gamma_R^{r_l}}.$$

Hence we reproduced the setting of the generalized bound in the particular case of ultrametric multi-overlap, and therefore we just proved that

$$-\beta f \leqslant \inf_X G(X).$$

At this point we only need to make sure that the ultrametric RaMOSt passes the invariance test prescribed by Theorem 4. Notice that $G(X)$ does not depend on N (see Lemma 1 in Appendix A of Ref. 3). Moreover $\tilde{W}$ and $\hat{W}$ are chosen to be independent, therefore the factorization property of the optimal RaMOSts holds:

$$\mathbb{E} \ln \Omega_{\xi}[c_1 \cdots c_N \exp(-\beta \hat{H}(\bar{\alpha}/N))] = NB + \bar{\alpha}A$$

for some B, and we are again using the definition (5). □

VI. CONCLUSIONS

The RaMOSt is the minimal generalization of the ROSt, and what we showed here and in Ref. 2 is that the minimal generalization is enough to formulate the variational principle and also exhibit a concrete RaMOSt analogous to the Parisi one for SK. As a consequence, it is enough to restrict the space of trial functions to those expressible in terms of fixed multi-overlaps (i.e., a set of numbers, not random variables to be averaged).

Unfortunately the case of odd K still escapes our approach.

APPENDIX: THE *p*-XOR-SAT

The Hamiltonian of the random p-XOR-SAT coincides with the one of the diluted p-spin glass

$$H = -\sum_{\nu=1}^{P_{\alpha N}} J_\nu \sigma_{i_\nu^1} \cdots \sigma_{i_\nu^p}.$$

It is therefore elementary, assuming p even, to extend all the results of Refs. 2 and 3 to this case, also when in the presence of an external field. Since it is easy to show[2]

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\frac{1}{N}\mathbb{E} \ln \sum_{\sigma} \exp(-\beta H) = \sum_{n>0} \frac{1}{2n}\mathbb{E} \tanh^{2n}(\beta J)(1 - \langle q_{2n}^p \rangle),$$

the structure of the model is the same RaMOSt valid for the case of the Viana-Bray model, but the above-mentioned equality suggests to try and get the non-negative convex function $x^p - pxy^{p-1} + (p-1)y^p$ whenever we got the square $x^2 - 2xy + y^2$ in the Viana-Bray case. That is why here $\tilde{H}$ and $\hat{H}$ are chosen such that

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\mathbb{E} \ln \sum_{\gamma} \xi_\gamma \exp(-\beta \tilde{H}_\cdot) = p \sum_{n>0} \frac{1}{2n}\mathbb{E} \tanh^{2n}(\beta J)(1 - \langle \tilde{q}_{2n}^{p-1} \rangle),$$

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\frac{1}{N}\mathbb{E} \ln \sum_{\gamma} \xi_\gamma \exp(-\beta \hat{H}) = (p-1) \sum_{n>0} \frac{1}{2n}\mathbb{E} \tanh^{2n}(\beta J)(1 - \langle \tilde{q}_{2n}^{p} \rangle)$$

and plugged into

$$G_N(\mathcal{R},\tilde{H},\hat{H}) = \frac{1}{N}\mathbb{E}\ln\frac{\Sigma_{\sigma,\gamma}\xi_\gamma \exp\left(-\beta\Sigma_{i=1}^N \tilde{H}_i\sigma_i\right)}{\Sigma_\gamma \xi_\gamma \exp(-\beta\hat{H})}.$$

The generalized bound clearly holds, the Boltzmann RaMOSt is the one with $\xi_\tau=\exp(-\beta H_M)$ and

$$\tilde{H}_\tau = -\sum_{\nu=1}^{P_{p\alpha N}} \tilde{J}_\nu \tau_{j_\nu^1}\cdots\tau_{j_\nu^{p-1}}\sigma_{i_\nu}, \quad \hat{H}_\tau = -\sum_{\nu=1}^{P_{(p-1)\alpha N}} \hat{J}_\nu \tau_{j_\nu^1}\cdots\tau_{j_\nu^p}$$

(same couplings as the original system) and it is optimal so that we can also state the extended variational principle. The broken replica symmetry ultrametric RaMOSt (which includes as a trivial case the replica symmetric one) relies on the weights ξ_γ of the random probability cascades as in Ref. 7 and on

$$\tilde{H}_\gamma = -\sum_{\nu=1}^{P_{p\alpha N}} \left(\frac{1}{\beta}\ln\frac{\cosh(\beta J)}{\cosh(\beta\tilde{J}_\nu^\gamma)} + \tilde{J}_\nu^\gamma\sigma_{i_\nu}\right),$$

$$\hat{H}_\gamma = -\sum_{\nu=1}^{P_{(p-1)\alpha N}} \left(\frac{1}{\beta}\ln\frac{\cosh(\beta J)}{\cosh(\beta\hat{J}_\nu^\gamma)} + \hat{J}_\nu^\gamma\right)$$

with

$$\tanh(\beta\tilde{J}_\gamma) = \tanh(\beta J)\tilde{W}_\gamma^1\cdots\tilde{W}_\gamma^{p-1},$$

$$\tanh(\beta\hat{J}_\gamma) = \tanh(\beta J)\tilde{W}_\gamma^1\cdots\tilde{W}_\gamma^{p},$$

where $\tilde{W}_\gamma$ are independent copies of

$$\tilde{W}_\gamma(\bar{J},k_\nu) = \tilde{\omega}_{\tilde{\alpha}_1}(\rho_{k_\nu})\bar{J}_{\gamma_1} + \cdots + \tilde{\omega}_{\tilde{\alpha}_R}(\rho_{k_\nu})\bar{J}_{\gamma_1,\cdots,\gamma_R}$$

with $\bar{J}_\cdot = \pm 1$ symmetric.

(Received 23 December 2004; accepted 2 September 2005;
published online 7 November 2005)

The Hodge equations for 1-forms are studied on Beltrami's projective disk model for hyperbolic space. Ideal points lying beyond projective infinity arise naturally in both the geometric and analytic arguments. An existence theorem for weakly harmonic 1-fields, changing type on the unit circle, is derived under Dirichlet conditions imposed on the noncharacteristic portion of the boundary. A similar system arises in the analysis of wave motion near a caustic. A class of elliptic-hyperbolic boundary-value problems is formulated for those equations as well. For both classes of boundary-value problems, an arbitrarily small lower-order perturbation of the equations is shown to yield solutions which are strong in the sense of Friedrichs. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2098529]

I. INTRODUCTION

The projective disk was introduced by Beltrami[3] in 1868. His construction was an early example of a Euclidean model for a non-Euclidean space, in this case, a space having curvature equal to −1. The projective disk has the striking property that even points infinitely distant from the origin are enclosed by the Euclidean unit circle centered at the origin of $\mathbb{R}^2$. This implies the possibility of points in projective space which lie beyond the curve at infinity. It is known that such *ideal points* arise naturally in the process of constructing normal and translated lines for chords of the projective disk. In this sense ideal points may be said to be intrinsic to the model, rather than only a theoretical possibility allowed by the model. We call the union of the conventional projective disk $\mathbb{P}^2$ and its ideal points the *extended projective disk*.

Hua[9] considered a second-order partial differential equation for scalar functions on the extended projective disk. He proved the existence of solutions to certain boundary-value problems of *Tricomi type*, in which data are given on characteristic curves, which represent trajectories of generalized wavefronts. Hua's work was extended to other problems of Tricomi type by Ji and Chen.[10,11] The existence of a class of weak solutions to the Hodge equations for harmonic 1-fields on extended $\mathbb{P}^2$, with data prescribed only on the noncharacteristic part of the boundary, was proven in Ref. 23. Locally, the Hodge equations reduce in the smooth scalar case to the equation studied by Hua.

This communication provides a geometric and analytic context for such results (Sec. I). In addition, we prove an existence theorem for weakly harmonic 1-fields which includes the results of Ref. 23 as a special case (Sec. II A), and consider a similar system that arises in optics (Secs. III A and III B). Boundary-value problems are formulated for both systems, in which the boundary contains points in both the elliptic and hyperbolic regions of the equations. These problems are shown in Secs. II B and III C to be an arbitrarily small, lower-order perturbation away from problems possessing a unique, strong solution.

Because both scalar equations and systems are discussed, we distinguish a vector-valued solution by writing it in boldface. However, for typographic simplicity, coefficient matrices and operators are not written in boldface.

A. A geometric classification of linear second-order operators

The highest-order terms of any linear second-order partial differential equation on a domain $\Omega \subset \mathbb{R}^2$ can be written in the form

$$Lu = \alpha(x,y)u_{xx} + 2\beta(x,y)u_{xy} + \gamma(x,y)u_{yy},$$

where (x,y) are coordinates on Ω and α, β, and γ are given functions. (A subscripted variable denotes partial differentiation in the direction of the variable.)

If the discriminant

$$\Delta(x,y) = \alpha\gamma - \beta^2$$

is positive, then the equation associated with the operator L is said to be of *elliptic type*. The simplest example is Laplace's equation, for which $\alpha=\gamma=1$ and $\beta=0$. If the discriminant is negative, then the equation associated with the operator L is said to be of *hyperbolic type*. The simplest example is the normalized wave equation, for which $\alpha=1$, $\gamma=-1$, $\beta=0$; other forms are $\alpha=-1$, $\gamma=1$, $\beta=0$, or $\alpha=\gamma=0$, $\beta=1$. If $\Delta=0$, then the equation associated with the operator L is said to be of *parabolic type;* examples are equations which model diffusion. If the discriminant is positive on part of Ω and negative elsewhere on Ω, then the equation associated with the operator L is said to be of *mixed elliptic-hyperbolic type*. A simple example of an elliptic-hyperbolic equation is the Lavrent'ev–Bitsadze equation, for which $\alpha=\mathrm{sgn}(y)$, $\beta=0$, and $\gamma=1$.

If we take Ω to be a smooth but curved surface, then we may not be able to cover Ω by a single system of Cartesian coordinates. However, we can always introduce Cartesian coordinates (x^1,x^2) *locally* on any smooth surface, in the neighborhood of a point on the surface. In terms of such coordinates, the distance element $\mathrm{d}s$ on Ω can be written in the form

$$\mathrm{d}s^2 = \sum_{i=1}^{2}\sum_{j=1}^{2} g_{ij}(x^1,x^2)\mathrm{d}x^i\,\mathrm{d}x^j,$$

where g_{ij} is a symmetric 2×2 matrix, the *metric tensor* on Ω. [In the sequel we will understand repeated indices to have been summed from 1 to $\dim(\Omega)$ without writing out the summation notation each time.] A natural differential operator on functions u defined on such a space is the *Laplace-Beltrami operator*

$$Lu = \frac{1}{\sqrt{|g|}}\frac{\partial}{\partial x^i}\left(g^{ij}\sqrt{|g|}\frac{\partial u}{\partial x^j}\right),$$

where g^{ij} is the inverse of the matrix g_{ij} and g is its determinant.

Laplace's equation can be associated with the Laplace-Beltrami operator on the Euclidean metric for which g_{ij} is the identity matrix. The wave equation for $\beta=0$ can be associated with the Laplace-Beltrami operator on the two-dimensional Minkowski metric $g_{11}=1$, $g_{22}=-1$, $g_{12}=g_{21}=0$. The Lavrent'ev–Bitsadze equation can be associated with the Laplace-Beltrami operator on a metric which is Euclidean above the x-axis and Minkowskian below the x-axis.

In this classification, the type of a linear second-order equation is not a function of the associated linear operator at all; that operator is always the Laplace-Beltrami operator. Rather, the type of the equation is a feature of the metric tensor on an underlying surface. A Riemannian metric, in which the distance between distinct points of Ω is always positive, corresponds to an elliptic equation, whereas a pseudo-Riemannian metric, for which the distance between distinct points may be zero, corresponds to a hyperbolic equation. The Laplace-Beltrami operator on a surface for which the metric is Riemannian on part of a surface and pseudo-Riemannian elsewhere

will be of mixed elliptic-hyperbolic type. However, any *sonic*—or *parabolic*—curve on which the change of type occurs will necessarily represent a singularity of the metric tensor, as the determinant g will vanish along that curve. (The term *sonic curve* is borrowed from compressible fluid dynamics, in which the equations for the velocity field of a steady ideal flow change from elliptic to hyperbolic type at the speed of sound. The underlying pseudo-Riemannian metric in that case is called the *flow metric*.[4])

One definition of the *signature* of a metric is the sign of the diagonal entries of the metric tensor. Any change in the signature which results in a change in sign of the determinant g will change the Laplace-Beltrami operator on the metric from elliptic to hyperbolic type. The Laplace-Beltrami operator on surface metrics for which such a change occurs along a smooth curve will correspond to planar elliptic-hyperbolic operators in local coordinates.

If we consider the distance element

$$\mathrm{d}s_L^2 \equiv \alpha(x,y)\mathrm{d}y^2 - 2\beta(x,y)\mathrm{d}x\,\mathrm{d}y + \gamma(x,y)\mathrm{d}x^2,$$

then *null geodesics* on the corresponding surface are solutions of the ordinary differential equation

$$\mathrm{d}s_L^2 = 0.$$

The graphs of these solutions are called *characteristic curves* of the equation $Lu=0$. Hyperbolic operators, which are associated with wave propagation, always have real-valued *characteristics,* or null geodesics.

In determining the qualitative behavior of solutions to partial differential equations we often ignore lower-order terms, but this neglect is only justified when considering purely second-order properties such as the nature of the sonic curve. The importance to this paper of lower-order terms is related to the fact that the Laplace-Beltrami equations on the extended projective disk are not of *real principal type* in the sense of Ref. [6]; see Ref. 27 for an accessible discussion of scalar elliptic-hyperbolic operators of real principal type and their properties.

B. The geometry and analysis of ideal points

Here we review basic properties of Laplace-Beltrami equations on Beltrami's hyperbolic metric on the projective disk:

$$\mathrm{d}s^2 = \frac{(1-y^2)\mathrm{d}x^2 + 2xy\,\mathrm{d}x\,\mathrm{d}y + (1-x^2)\mathrm{d}y^2}{(1-x^2-y^2)^2}$$

(see, e.g., Ref. 32, Vol. I, Sec. 65 and Vol. II, Sec. 138, for a derivation). In this metric the unit circle is the *absolute:* the locus of points at infinity.

The existence of points lying beyond the curve at infinity on the projective disk is natural from a geometric point of view. For example, choose a point p in the interior of the projective disk and draw a vertical line ℓ_v through it. A *hyperbolic line* in the Beltrami metric is any open chord of the unit circle, so ℓ_v is a hyperbolic line plus two points at infinity and an *ideal extension* to points outside the unit circle. Denote by $F(p)$ the family of hyperbolic lines created by rotating ℓ_v about p. Move p along the horizontal line ℓ_h through p, and consider the effect of this motion on the family $F(p)$. As p passes through the boundary of the unit circle κ into the $\mathbb{R}^2$ complement of κ, the family of hyperbolic rotations becomes a family of hyperbolic translations. For this reason, hyperbolic translations inside the unit disk can be interpreted as rotations about a point in $\mathbb{R}^2$ lying beyond the unit disk.

As another example, consider that the *pole* of a hyperbolic line ℓ is the intersection of those two tangents to the unit circle which intersect ℓ at the two points of its contact with the unit circle. (We call these the *polar lines* of ℓ.) Thus, any two hyperbolic lines ℓ_1 and ℓ_2 are orthogonal if and only if the pole of ℓ_2 lies on the ideal extension of ℓ_1 and vice versa.

These and other geometric constructions on extended $\mathbb{P}^2$ are described in more detail in Chap. 4 of Ref. 28.

In order to see that ideal points also arise naturally in analysis, consider the Laplace-Beltrami operator on the projective disk with Beltrami's metric. We have

$$L[u] = (1 - x^2 - y^2)[(1 - x^2)u_{xx} - 2xyu_{xy} + (1 - y^2)u_{yy} + \text{lower order terms}].$$

The characteristics of the equation $L[u]=0$ satisfy the ordinary differential equation

$$(1 - y^2)\mathrm{d}x^2 + 2xy\ \mathrm{d}x\ \mathrm{d}y + (1 - x^2)\mathrm{d}y^2 = 0. \tag{1}$$

This equation has solutions

$$x\cos\theta + y\sin\theta = 1, \tag{2}$$

where, as is conventional, we take θ to be the angle between the radial vector and the positive x-axis. Solutions of Eq. (2) correspond geometrically to the family of tangent lines to the unit circle centered at the origin of $\mathbb{R}^2$.

Thus the characteristic lines always include ideal points, and wave propagation can only occur on regions composed of such points.

The Laplace-Beltrami equations on extended $\mathbb{P}^2$ come with a natural gauge theory in the following sense: The characteristic equation is obviously invariant under the projective group. So although the equations in the form in which we study them change type on the unit circle in $\mathbb{R}^2$, they are projectively equivalent to a system which changes type on any conic section. Note that whereas classical gauge theories are invariant under groups of Euclidean motions, which are inertial transformations, this kind of gauge invariance is with respect to a group of non-Euclidean motions, which are noninertial. Also, the gauge theories which are familiar from particle physics act "upstairs" on a fiber bundle of physical states. The transformation group under which the Laplace-Beltrami equations are invariant acts "downstairs" on the underlying metric, in the manner of the gauge group of general relativity. Indeed, analysis of wave motion on extended $\mathbb{P}^2$ has certain similarities to the analysis of wave motion in the vicinity of a light cone (cf. Ref. 30). The timelike and spacelike regions are inverted, and characteristic lines for the Laplace-Beltrami equation are analogous to the paths of photons.

II. HARMONIC 1-FIELDS ON THE EXTENDED PROJECTIVE DISK

We can solve, instead of the Laplace-Beltrami equation, a system of two first-order equations of the form

$$|g|^{-1/2}\partial_i(g^{ij}\sqrt{|g|}u_j) = 0, \tag{3}$$

$$\frac{1}{2}(\partial_i u_j - \partial_j u_i) = 0, \tag{4}$$

where $u_i = u_i(x^1, x^2)$, $i = 1, 2$. As in the second-order equation, g_{ij} is a metric tensor on the underlying surface. Solutions $\mathbf{u} = (u_1, u_2)$ of this first-order system are (locally) *harmonic 1-fields*. Notice that if the scalar function $\varphi(x^1, x^2)$ satisfies $\varphi_{x^1} = u_1$ and $\varphi_{x^2} = u_2$, then φ satisfies the Laplace-Beltrami equations. But there are solutions φ of the Laplace-Beltrami system for which the pair $(\varphi_{x^1}, \varphi_{x^2})$ is not a harmonic 1-field.

Consider a system of first-order equations on $\mathbb{R}^2$ having the form

$$L\mathbf{u} = \mathbf{f}, \tag{5}$$

where

$$L = (L_1, L_2), \quad \mathbf{f} = (f_1, f_2),$$

$$\mathbf{u} = (u_1(x,y), u_2(x,y)), \quad (x,y) \in \Omega \Subset \mathbb{R}^2.$$

Let $\mathbf{u}$ satisfy (5) with

$$(L\mathbf{u})_1 = [(1-x^2)u_1]_x - 2xyu_{1y} + [(1-y^2)u_2]_y + k_1xu_1 + k_2yu_2, \tag{6}$$

and

$$(L\mathbf{u})_2 = (1-y^2)(u_{1y} - u_{2x}) + k_3xu_1 + k_4yu_2, \tag{7}$$

where Ω is chosen so that $y^2 \neq 1$ there. Here k_1, k_2, k_3, and k_4 are constants representing lower-order coefficients. In this section we consider three particular distributions of lower-order terms, studied in Ref. 23:

Case 1: $k_1=k_2=-2$, $k_3=k_4=0$. The domain of Eqs. (5)–(7) in this case will be called Ω_1.

Case 2: $k_1=-2$, $k_2=k_3=0$, $k_4=2$. The domain of Eqs. (5)–(7) in this case will be called Ω_2.

Case 3: $k_1=k_2=k_3=k_4=0$. The domain of Eqs. (5)–(7) in this case will be called Ω_3. This case corresponds to Eqs. (3) and (4).

The union of the domains Ω_1, Ω_2, and Ω_3 will be called Ω.

A system of first-order equations can also be said to be of elliptic or hyperbolic type, and thus may change type along a singular curve. See, e.g., Ref. 5, Chap. III.2. The higher-order terms of the preceding system can be written in the form $A^1\mathbf{u}_x + A^2\mathbf{u}_y$, where

$$A^1 = \begin{bmatrix} 1-x^2 & 0 \\ 0 & -(1-y^2) \end{bmatrix} \tag{8}$$

and

$$A^2 = \begin{bmatrix} -2xy & 1-y^2 \\ 1-y^2 & 0 \end{bmatrix}. \tag{9}$$

If $y^2 \neq 1$, the characteristic equation

$$|A^1 - \lambda A^2| = -(1-y^2)[(1-y^2)\lambda^2 + 2xy\lambda + (1-x^2)]$$

possesses two real roots λ_1, λ_2 on Ω precisely when $x^2+y^2>1$. Thus the system is elliptic in the intersection of Ω with the open unit disk centered at (0, 0) and hyperbolic in the intersection of Ω with the complement of the closure of this disk. The boundary of the unit disk, along which this change in type occurs, is the line at infinity on the projective disk and a line singularity of the tensor g_{ij}.

Denote by Ω a region of the plane for which part of the boundary $\partial\Omega$ consists of a family of curves Γ composed of points satisfying Eq. (1) and the remainder $C=\partial\Omega\backslash\Gamma$ of the boundary consists of points (x,y) which do not satisfy Eq. (1). We seek solutions of Eqs. (5)–(7) which satisfy the boundary condition

$$u_1\frac{dx}{ds} + u_2\frac{dy}{ds} = 0, \tag{10}$$

where s denotes arc length, on the noncharacteristic part C of the domain boundary. Because the tangent vector $\mathbf{T}$ on C is given by

$$\mathbf{T} = \frac{dx}{ds}\mathbf{i} + \frac{dy}{dx}\mathbf{j},$$

a geometric interpretation of this boundary condition is that the dot product of the vector $\mathbf{u} = (u_1, u_2)$ and the tangent vector to C vanishes, i.e., $\mathbf{u}$ is normal to the boundary $\partial\Omega$ on the boundary section C. We call these *homogeneous Dirichlet conditions*.

A. Weak solutions

In Ref. 23, weak solutions to (5)–(7) and (10) are shown to exist in certain weighted L^2 spaces on a class of domains. Here we extend that result to the case in which the domain is formed by the polar lines of a hyperbolic line ℓ and a smooth curve C extending between the two polar lines of ℓ. The curve C must have the property that $\mathrm{d}y_{|C} \leqslant 0$ when $\partial\Omega$ is traversed in a counterclockwise direction. However, as long as this condition is met, C need not intersect the polar lines of ℓ at their points of tangency with the unit circle. Thus C may extend into both the elliptic and the hyperbolic regions.

This domain is the analog of the "ice-cream cone"-shaped domain associated to the *Tricomi equation*[31]

$$yu_{xx} + u_{yy} = 0,$$

where in our case the curve C is the boundary of the ice-cream part and the polar lines, which are characteristics of Eqs. (5)–(7), are the boundary of the cone part. The unit circle is the analog of the x-axis, which is the sonic curve for the Tricomi equation.

We initially consider the distribution of lower-order terms in case 1 of Eqs. (6) and (7). Let θ lie in the interval $[0, \pi/4]$, and denote by Ω_1 the region of the first and fourth quadrants bounded by the characteristic line

$$\Gamma_1 : x \cos\theta + y \sin\theta = 1,$$

the characteristic line

$$\Gamma_2 : x \cos\theta - y \sin\theta = 1,$$

and a smooth curve C. Let C intersect the lines Γ_1, Γ_2 at two distinct points c_1, c_2, respectively. Assume that $\forall (x,y) \in \Omega_1$, $1/\sqrt{2} \leqslant x < \sqrt{2}$ and $-1/\sqrt{2} \leqslant y \leq 1/\sqrt{2}$ and that $\mathrm{d}y \leqslant 0$ on C. A cusp is permitted for $\theta = \pi/4$ at the points $c_1, c_2 = (1/\sqrt{2}, \pm 1/\sqrt{2})$. Otherwise, the boundary will have piecewise continuous tangent (so that Green's theorem can be applied to it). Note that the domain considered in Sec. 3 of Ref. 23 is equivalent to this domain in the degenerate special case $\theta = 0$.

Define U to be the vector space consisting of all pairs of measurable functions $\mathbf{u} = (u_1, u_2)$ for which the weighted L^2 norm

$$\|\mathbf{u}\|_* = \left[\int \int_{\Omega_1} (|2x^2 - 1| u_1^2 + |2y^2 - 1| u_2^2) \mathrm{d}x \, \mathrm{d}y \right]^{1/2}$$

is finite. Notice that this expression vanishes at the intersection of ℓ with its polar lines at the value $\theta = \pi/4$. Denote by W the linear space defined by pairs of functions $\mathbf{w} = (w_1, w_2)$ having continuous derivatives and satisfying:

$$w_1 \mathrm{d}x + w_2 \, \mathrm{d}y = 0 \tag{11}$$

on $\Gamma = \Gamma_1 \cup \Gamma_2$;

$$w_1 = 0 \tag{12}$$

on C; and

$$\int \int_{\Omega_1} [|2x^2 - 1|^{-1} (L^* \mathbf{w})_1^2 + |2y^2 - 1|^{-1} (L^* \mathbf{w})_2^2] \mathrm{d}x \, \mathrm{d}y < \infty.$$

Here

$$(L^* \mathbf{w})_1 = [(1 - x^2) w_1]_x - 2xy w_{1y} + [(1 - y^2) w_2]_y + 2x w_1,$$

and

$$(L^*\mathbf{w})_2 = (1-y^2)(w_{1y} - w_{2x}) + 2yw_1.$$

Define the Hilbert space H to consist of pairs of measurable functions $\mathbf{h}=(h_1,h_2)$ for which the norm

$$\|\mathbf{h}\|^* = \left[\int\int_{\Omega_1} (|2x^2-1|^{-1}h_1^2 + |2y^2-1|^{-1}h_2^2)\mathrm{d}x\,\mathrm{d}y\right]^{1/2}$$

is finite.

We say that $\mathbf{u}$ is a *weak solution* of the system (5)–(7) and (10) in case 1 on Ω_1 if $\mathbf{u}\in U$ and for every $\mathbf{w}\in W$

$$-(\mathbf{w},\mathbf{f}) = (L^*\mathbf{w},\mathbf{u}),$$

where

$$(\mathbf{w},\mathbf{f}) = \int\int_{\Omega_1} (w_1 f_1 + w_2 f_2)\mathrm{d}x\,\mathrm{d}y.$$

In case 2, we restrict the domain Ω_2 to lie in the fourth quadrant of the Cartesian plane. Define $\Gamma_1,\Gamma_2\subset\Gamma$ to be characteristic lines which are tangent to the unit circle at distinct points in the fourth quadrant and which intersect at a point in the complement of the unit disk in $\mathbb{R}^2$. The curve C is defined analogously to the corresponding curve of Ω_1. In particular, $\mathrm{d}y_{|C}\leqslant 0$ on Ω_2 when C is traversed in a counterclockwise direction. Replace U by the space U' of all pairs $\mathbf{u}$ of measurable functions (u_1,u_2) for which the weighted L^2 norm

$$\|\mathbf{u}\|'_* = \left[\int\int_{\Omega_2} (xu_1^2 + |y|u_2^2)\mathrm{d}x\,\mathrm{d}y\right]^{1/2}$$

is finite. Replace W by the space W' defined by pairs of continuously differentiable functions $\mathbf{w}=(w_1,w_2)$ satisfying Eq. (11) on Γ, Eq. (12) on C, and

$$\int\int_{\Omega_2} [x^{-1}(L^*\mathbf{w})_1^2 + |y|^{-1}(L^*\mathbf{w})_2^2]\mathrm{d}x\,\mathrm{d}y < \infty.$$

In this case

$$(L^*\mathbf{w})_1 = [(1-x^2)w_1]_x - 2xyw_{1y} + [(1-y^2)w_2]_y + 2xw_1,$$

and

$$(L^*\mathbf{w})_2 = (1-y^2)(w_{1y} - w_{2x}) - 2yw_2.$$

Finally, we replace H by the space H' of measurable functions $\mathbf{h}=(h_1,h_2)$ for which the norm

$$\|\mathbf{h}\|'^* = \left[\int\int_{\Omega_2} (x^{-1}h_1^2 + |y|^{-1}h_2^2)\mathrm{d}x\,\mathrm{d}y\right]^{1/2}$$

is finite.

Because k_4 is nonzero in case 2, the consistency condition (4) is violated and $\mathbf{u}$ cannot be the gradient of a scalar potential, even locally. Harmonic fields in which condition (4) is violated arise in various contexts—see Sec. 4 of Ref. 25 for a nonlinear example—and correspond physically to stationary fields having sources.

In case 3, we restrict the domain, Ω_3, to lie in the first quadrant. Define $\Gamma_1,\Gamma_2\subset\Gamma$ to be characteristic lines which are tangent to the unit circle at distinct points in the first quadrant, and which intersect at a point in the complement of the unit disk in $\mathbb{R}^2$. In this case we replace U and

H by L^2. We replace W by the space of pairs of L^2 functions (w_1, w_2) which satisfy (11) on Γ and (12) on C. Note that L is self-adjoint in case 3. In addition, we fix positive numbers $\delta \ll 1/2$ and $\varepsilon \ll 1/2$, and require Ω_3 to lie in the semi-infinite rectangle

$$\frac{1}{\sqrt{2}} < x, \quad \frac{1}{\sqrt{2-\delta}} < y \leqslant \sqrt{1-\varepsilon}.$$

Weak solutions in cases 2 and 3 are defined exactly analogously to case 1, with appropriate replacement of the domain and function spaces.

Theorem 1: *Let the lower-order terms in Eqs. (6) and (7) be distributed as in cases 1, 2, or 3, on the domains* Ω_1, Ω_2, *or* Ω_3, *respectively. Then there exists a weak solution of the boundary-value problem (5)–(7) and (10) for every* $\mathbf{f} \in H$.

Proof: The proof is an extension of the arguments in Ref. 23, so we will be brief. We derive a *basic inequality*, that there is a $K \in \mathbb{R}^+$ such that $\forall \mathbf{w} \in W$

$$K\|\mathbf{w}\|_* \leqslant \|L^*\mathbf{w}\|^*$$

(with the norms appropriately adjusted in cases 2 and 3). We derive this inequality by choosing a scalar multiplier a, computing the L^2 inner product $(L^*\mathbf{w}, a\mathbf{w})$, and integrating by parts. Denoting the coefficients of w_1^2 off the boundary by α, those of w_2^2 by γ, and those of $w_1 w_2$ by 2β, we choose, in case 1, $a = x^2$ and obtain

$$\alpha = x(3x^2 - 1), \quad \gamma = x(1 - y^2),$$

and

$$\beta = yx^2,$$

where

$$2\beta w_1 w_2 \geqslant -2x|xw_1||yw_2| \geqslant -(x^3 w_1^2 + xy^2 w_2^2).$$

In case 2 we choose $a = 1$ and obtain

$$\alpha = 2x, \quad \gamma = -2y,$$

and $\beta = 0$.

In case 3 we choose $a = xy$ and obtain

$$\alpha = \frac{y}{2}(3x^2 - 1), \quad \gamma = \frac{y}{2}(1 - y^2),$$

and

$$2\beta = -(1 - y^2)x.$$

The quadratic form $\alpha\gamma - \beta^2$ can be shown to be non-negative in case 3 by noticing that the argument in Sec. 6.2 of Ref. 23 does not use the restriction $x \leqslant 1$ and thus extends to our more general case.

The remainder of the proof is essentially the same for all three cases. Applying Green's theorem to derivatives of products in $(L^*\mathbf{w}, a\mathbf{w})$, we obtain a boundary integral I having the form

$$\int_{\partial\Omega} \frac{a}{2}[(1 - x^2)w_1^2\, dy + 2xyw_1^2\, dx] - \int_{\partial\Omega} a\left[(1 - y^2)w_1 w_2\, dx + \frac{1}{2}(1 - y^2)w_2^2\, dy\right].$$

Because w_1 vanishes identically on C, the boundary integral is non-negative on C by the hypothesis on $dy_{|C}$. On the characteristic curves, we no longer have the property that $dx = 0$, which we used in deriving the basic inequality of Ref. 23. However,

$$I_{|\Gamma} = \int_{\Gamma} \frac{a}{2}\{(1-x^2)w_1^2\,\mathrm{d}y + [2xyw_1^2 - (1-y^2)w_1w_2]\mathrm{d}x\},$$

where we have used the fact that

$$w_2\,\mathrm{d}y = -w_1\,\mathrm{d}x$$

on characteristic lines. In fact, we have

$$\begin{aligned} I_{|\Gamma} &= \int_{\Gamma} \frac{a}{2}\left[(1-x^2)w_1^2\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right) + 2xyw_1^2 - (1-y^2)w_1w_2\right]\mathrm{d}x \\ &= \int_{\Gamma} \frac{a}{2}\left[-(1-x^2)w_1w_2\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2 + 2xyw_1^2 - (1-y^2)w_1w_2\right]\mathrm{d}x, \end{aligned}$$

by the same identity. Equation (1) implies that

$$-(1-x^2)\left(\frac{\mathrm{d}y}{\mathrm{d}x}\right)^2 = 2xy\frac{\mathrm{d}y}{\mathrm{d}x} + 1 - y^2,$$

so we can write

$$I = \int_{\Gamma} \frac{a}{2}\left[2xy\frac{\mathrm{d}y}{\mathrm{d}x} + 1 - y^2\right]w_1w_2\,\mathrm{d}x + \int_{\Gamma} \frac{a}{2}\left[2xyw_1\left(-w_2\frac{\mathrm{d}y}{\mathrm{d}x}\right) - (1-y^2)w_1w_2\right]\mathrm{d}x = 0.$$

This establishes the basic inequality.

Proceeding as in Ref. 19, we use the basic inequality to apply the Riesz representation theorem and obtain an element $\mathbf{h} \in H$ for which

$$-(\mathbf{w},\mathbf{f}) = -(L^*\mathbf{w},\mathbf{h})^*,$$

where the product on the right is the inner product on H (or on H' or L^2 in cases 2 or 3, respectively). Writing h_1 and h_2 of $\mathbf{h}$ in terms of appropriate rescalings of u_1 and u_2,[23] we obtain

$$-(L^*\mathbf{w},\mathbf{h})^* = (L^*\mathbf{w},\mathbf{u}),$$

which completes the proof.

B. Strong solutions

By a *strong solution* of the boundary-value problem (5) and (10) we mean an element $\mathbf{u} \in L^2(\Omega)$ for which there exists a sequence $\mathbf{u}^\nu$ of continuously differentiable vectors satisfying the boundary condition (10), for which

$$\lim_{\nu\to\infty} \|\mathbf{u}^\nu - \mathbf{u}\|_{L^2} = 0,$$

and

$$\lim_{\nu\to\infty} \|L\mathbf{u}^\nu - \mathbf{f}\|_{L^2} = 0.$$

For $\mathbf{u}=(u_1(x,y),u_2(x,y))$, $(x,y) \in \Omega \Subset \mathbb{R}^2$, define the operator $L=(L_1,L_2)$ by the matrix equation

$$L\mathbf{u} = A^1\mathbf{u}_x + A^2\mathbf{u}_y + B\mathbf{u}, \tag{13}$$

for matrices A^1, A^2, and B. We say that L is *symmetric positive*[7,15,16] if the matrices A^1 and A^2 are symmetric and the matrix

$$Q \equiv 2B^* - A_x^1 - A_y^2$$

is bounded below by a positive multiple of the identity matrix. Here

$$B^* = \frac{1}{2}(B + B^t),$$

where for a matrix $W=[w_{ij}]$, $W^t=[w_{ji}]$.

In cases for which L is not symmetric positive, there may be a nonsingular matrix E such that EL is symmetric positive. In that case we replace the equation

$$L\mathbf{u} = \mathbf{f}$$

by the equation

$$EL\mathbf{u} = E\mathbf{f},$$

and try to show that the operator EL is symmetric positive. (The conversion of L into a symmetric-positive operator by the construction of a suitable multiplier E will not be used in this section, but will be used in Sec. III C.)

Suppose that $N(x,y)$, $(x,y) \in \partial\Omega$, is a linear subspace of the vector space V, where $\mathbf{u}$ is regarded as a mapping $\mathbf{u}:\Omega \cup \partial\Omega \to V$, and that $N(x,y)$ depends smoothly on x and y. Define the matrix

$$\beta = n_1 A^1_{|\partial\Omega} + n_2 A^2_{|\partial\Omega},$$

where $\mathbf{n}=(n_1,n_2)$ is the outward-pointing normal vector to $\partial\Omega$. The boundary condition that u lie in N is said to be *admissible*[15] if N is a maximal subspace of V and if the quadratic form $(\mathbf{u},\beta\mathbf{u})$ is non-negative on $\partial\Omega$.

A sufficient condition[7] for admissibility is that there exist a decomposition

$$\beta = \beta_+ + \beta_-,$$

for which the direct sum of the null spaces for β_+ and β_- spans the restriction of V to the boundary, the intersection of the ranges of β_+ and β_- have only the vector $\mathbf{u}=0$ in common, and the matrix $\mu=\beta_+-\beta_-$ satisfies

$$\mu^* = \frac{\mu + \mu^t}{2} \geqslant 0.$$

In this case the boundary condition

$$\beta_-\mathbf{u} = 0 \text{ on } \partial\Omega$$

is admissible for the boundary-value problem

$$L\mathbf{u} = f \text{ in } \Omega.$$

Moreover, the boundary condition

$$\beta_+^t\mathbf{w} = 0 \text{ on } \partial\Omega$$

is admissible for the adjoint problem

$$L^*\mathbf{w} = \mathbf{h} \text{ in } \Omega.$$

These two problems possess unique, strong solutions whenever the differential operators are symmetric positive and the boundary conditions are admissible.[7,15]

In this section we give sufficient conditions for the existence of certain strong solutions arising from an arbitrarily small lower-order perturbation of the Laplace-Beltrami equations on extended $\mathbb{P}^2$. We do so by showing that the differential operator L given by (5)–(7) with $k_1=k_2=k_3=k_4=0$ is arbitrarily close to a symmetric-positive operator and by stating an admissible boundary condition. The existence of strong solutions to a different perturbation on an explicit domain will be shown in Sec. III C.

If the matrices A^1 and A^2 of Eq. (13) are given by Eqs. (8) and (9), and the matrix B is given by

$$\begin{pmatrix} -2x & -2y \\ 0 & 0 \end{pmatrix},$$

then the quantity Q is zero. Thus we replace the matrix B by a matrix B_ε, which differs from B by an arbitrarily small perturbation and takes the form

$$B_\varepsilon = \begin{pmatrix} -2x+\varepsilon_1 & -2y+\varepsilon_2 \\ (1-y^2)\varepsilon_3 & (1-y^2)\varepsilon_4 \end{pmatrix}, \tag{14}$$

where $\varepsilon_1>0$, $\varepsilon_4>0$, and $\varepsilon_2+(1-y^2)\varepsilon_3>0$. If we choose the domain of L in such a way that $y^2<1$ there, then this replacement converts Q into a positive-definite matrix and L into a symmetric-positive operator.

Denote by Ω_4 a domain having C^2 boundary $\partial\Omega_4=E\cup F$ such that $y^2<1$ on Ω_4. Let the components of the normal vector $\mathbf{n}$ on $\partial\Omega_4$ be given by (n_1,n_2). Assume that n_1 and n_2 never vanish at the same point of $\partial\Omega_4$. We place conditions on n_1,n_2, and $\partial\Omega_4$ sufficient to guarantee admissibility of the boundary condition

$$u_1n_2-u_2n_1=0 \tag{15}$$

on F, with no condition given on E.

Let $n_1\geqslant 0, n_2\leqslant 0$ on F and $n_1\leqslant 0, n_2\geqslant 0$ on E. Defining the adjoint space as in Sec. II A, for $\mathbf{w}\in V^*$ we take $\mathbf{w}=(0,w_2)$ on F and

$$w_1n_2-w_2n_1=0$$

on E. Define

$$\alpha=[-(1-y^2)n_2/n_1+2xy-(1-x^2)n_1/n_2]n_2.$$

Assume that $\alpha=0$ on E, and that $\alpha\leqslant 0$ on F.

Theorem 2: *The boundary-value problem*

$$L\mathbf{u}=A^1\mathbf{u}_x+A^2\mathbf{u}_y+B_\varepsilon\mathbf{u}=\mathbf{f},$$

for $(x,y)\in\Omega_4$, *with* A^1, A^2, *and* B_ε *given by Eqs. (8), (9), and (14), respectively, and with condition (15) imposed on the curve F of* $\partial\Omega_4$, *possesses a unique, strong solution* $\mathbf{u}(x,y)$ *for every* $\mathbf{f}\in L^2(\Omega_4)$.

Proof: Because the matrix B_ε has been constructed in such a way that L is symmetric positive, it remains only to show that the boundary condition (15) is admissible on Ω_4.

We have

$$\beta=\begin{pmatrix} -\alpha-(1-y^2)n_2^2/n_1 & (1-y^2)n_2 \\ (1-y^2)n_2 & -(1-y^2)n_1 \end{pmatrix}.$$

Note that the apparent singularities in β at $n_1=0$ and in α at $n_2=0$ are removable.

On F, choose

$$\beta_+ = \begin{pmatrix} -\alpha & 0 \\ 0 & 0 \end{pmatrix}$$

and

$$\beta_- = (1-y^2)n_2 \begin{pmatrix} -n_2/n_1 & 1 \\ 1 & -n_1/n_2 \end{pmatrix}.$$

On E, choose

$$\beta_+ = (1-y^2)n_2 \begin{pmatrix} -n_2/n_1 & 1 \\ 1 & -n_1/n_2 \end{pmatrix}$$

and

$$\beta_- = \begin{pmatrix} -\alpha & 0 \\ 0 & 0 \end{pmatrix}.$$

If $\mathbf{u} \in V_{|F}$, then (15) implies that $\beta_-\mathbf{u}=0$. The properties of V^* imply that $\mathbf{w}^t\beta_+=0$ for $\mathbf{w} \in V^*_{|F}$. If $\mathbf{u} \in V_{|E}$, then $\beta_-\mathbf{u}=0$ for all values of $\mathbf{u}$ and $\mathbf{w}^t\beta_+=0$ by the properties of V^* and α. So the direct sum of the null spaces of β_- and β_+ spans V on $\partial\Omega_4$. Moreover, the hypotheses guarantee that the ranges of β_- and β_+ have only the zero vector in their intersection. Finally,

$$\beta_+ - \beta_- = \mu^* \geqslant 0$$

on both E and F.

This completes the proof of Theorem 2.

III. AN ANALOGOUS PROBLEM FROM OPTICS

Geometrical optics is a zero-wavelength approximation to classical wave mechanics in which the governing differential equations are replaced by the Euclidean geometry of rays. The limitations of the geometrical optics approximation are apparent in the neighborhood of *caustics*, which are envelopes of a family of rays. It is not simply that geometrical optics predicts infinite intensity in such regions, whereas diffractive effects reduce the predicted intensity to a finite number. Even in applications for which the agreement between the predictions of geometrical optics and experiment is generally good, the former may predict singularities, e.g., cusps, which are entirely smoothed out by diffraction. A dramatic example of this for the case of water waves is illustrated in Figs. 5.6.1 and 5.6.2 of Ref. 29. This is, of course, far from the only drawback of the geometrical optics approximation. See, for example, the discussion of the rainbow caustic in Sec. 6.3 of Ref. 22.

The accuracy of the geometrical optics approximation can be improved by considering waves of arbitrarily high frequency obtained by uniform asymptotic approximation of solutions to the Helmholtz equation (Sec. III A). While the older of these approximations also fail at caustics, an asymptotic formula introduced independently by Kravtsov[12] and Ludwig[17] retains its meaning even in the neighborhood of a caustic; see Ref. 13 for a review.

Recently, Magnanini and Talenti studied a nonlinear elliptic-hyperbolic equation, implied by the Ludwig-Kravtsov approximation, having the form[18]

$$(|\nabla v|^4 - v_y^2)v_{xx} + 2v_x v_y v_{xy} + (|\nabla v|^4 - v_x^2)v_{yy} = 0, \tag{16}$$

where $v=v(x,y)$, $(x,y) \in \mathbb{R}^2$. Those authors were able to show the existence of weak solutions to the full Dirichlet problem for the linear elliptic-hyperbolic equation

$$[(p^2+q^2)^2 - p^2]V_{pp} - 2pqV_{pq} + [(p^2+q^2)^2 - q^2]V_{qq} = 0, \tag{17}$$

which is related to Eq. (16) by the *Legendre transformation*

$$V_L(p,q) = xp + yq - v(x,y). \tag{18}$$

Magnanini and Talenti's result is remarkable in that it is difficult to formulate a full Dirichlet problem which is well-posed for a given elliptic-hyperbolic equation, even in the weak sense. (By *full* we mean that data are prescribed on the entire boundary.) Morawetz's proof of the existence of weak solutions to the full Dirichlet problem for the Tricomi equation, the most intensively studied elliptic-hyperbolic equation, required a delicate argument.[20,27] The full Dirichlet problems for other important elliptic-hyperbolic equations remain unknown. For example, the full Dirichlet problem has not been correctly formulated even for weak solutions to a scalar elliptic-hyperbolic equation associated to electromagnetic wave propagation in cold plasma, although a well-posed Dirichlet problem for weak solutions has been formulated for data prescribed only on part of the boundary.[24]

The existence of a well-posed Dirichlet problem is important because physical reasoning often suggests that the full Dirichlet problem is the correct problem even in the case of equations for which mathematical reasoning suggests otherwise.

Two questions suggested by Magnanini and Talenti's paper are

(i) The transformation (18) itself fails at caustics (which are not generally identical to the caustics of the physical model). One would like to characterize regions at which this linearization method fails and the nature of the singularities that arise in such regions. See, for example, Proposition 2 of Ref. 26.

(ii) The result proven in Ref. 18 requires the domain boundary to lie entirely within the elliptic region of the equation. It is an important quality of Eq. (17) that the elliptic region surrounds the hyperbolic region, a property not shared by other elliptic-hyperbolic equations. Thus there is some mathematical interest in asking whether solutions of (17) exist with boundary points lying in both the elliptic and hyperbolic regions, a situation in which this special condition is no longer applicable. We consider this question in Sec. III C.

Equation (16) is a special case of the system

$$[(p^2+q^2)^2 - q^2]p_x + 2pqp_y + [(p^2+q^2)^2 - p^2]q_y = 0, \tag{19}$$

$$p_y - q_x = 0. \tag{20}$$

This system is equivalent to Eq. (16) if there is a continuously differentiable scalar function $v(x,y)$ for which $v_x = p$ and $v_y = q$. [Such a function always exists locally, by Eq. (20).]

Consider any two-dimensional quasilinear system of two equations having the form

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \frac{\partial}{\partial x}\begin{pmatrix} p \\ q \end{pmatrix} + \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \frac{\partial}{\partial y}\begin{pmatrix} p \\ q \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{21}$$

where the entries of the coefficient matrices depend only on p and q. Then the coordinate transformation $(x,y) \to (p,q)$ takes Eq. (21) into the linear form

$$\begin{bmatrix} b_{12} & -a_{12} \\ b_{22} & -a_{22} \end{bmatrix} \frac{\partial}{\partial p}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{bmatrix} -b_{11} & a_{11} \\ -b_{21} & a_{21} \end{bmatrix} \frac{\partial}{\partial q}\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

provided the Jacobian of the transformation

$$J = \frac{\partial(x,y)}{\partial(p,q)} = \frac{\partial x}{\partial p}\frac{\partial y}{\partial q} - \frac{\partial y}{\partial p}\frac{\partial x}{\partial q}$$

is nonzero. This special case of the Legendre transformation is called a *hodograph map*, and the space having coordinates (p,q) is called the *hodograph plane;* see, e.g., Sec. V.2.2 of Ref. 5.

The coordinate systems (p,q) and (x,y) are related by Eq. (18), where

$$(x,y)=\left(\frac{\partial V}{\partial p},\frac{\partial V}{\partial q}\right)$$

and

$$(p,q)=\left(\frac{\partial v}{\partial x},\frac{\partial v}{\partial y}\right).$$

Applying a hodograph transformation to Eqs. (19) and (20) yields the system

$$[(p^2+q^2)^2-p^2]x_p-2pqx_q+[(p^2+q^2)^2-q^2]y_q=0, \tag{22}$$

$$x_q-y_p=0. \tag{23}$$

This system is equivalent to Eq. (17) if there is a continuously differentiable scalar function $V(x,y)$ for which $V_p=x$ and $V_q=y$. (Again, this can always be arranged locally.)

As in Sec. II, we write the second-order terms of Eqs. (22) and (23) in the form $A^1\mathbf{u}_x+A^2\mathbf{u}_y$, where $\mathbf{u}=\mathbf{u}(x,y)$ and in this case

$$A^1=\begin{bmatrix}(x^2+y^2)^2-x^2 & 0\\ 0 & -1\end{bmatrix}$$

and

$$A^2=\begin{bmatrix}-2xy & (x^2+y^2)^2-y^2\\ 1 & 0\end{bmatrix}.$$

The characteristic equation

$$|A^1-\lambda A^2|=-\{[(x^2+y^2)^2-y^2]\lambda^2+2xy\lambda+[(x^2+y^2)^2-x^2]\}$$

possesses two real roots λ_1,λ_2 precisely when $x^2+y^2>(x^2+y^2)^2$, that is, when $x^2+y^2<1$. Thus the system is hyperbolic at points lying inside the open unit disk centered at $(x,y)=(0,0)$ and elliptic outside the closure of this disk. The circle $x^2+y^2=1$, along which the change in type occurs, is the parabolic region of the system.

A. Uniform asymptotic approximations

Substitution of the simplest formula for an oscillatory wave into the wave equation results in the *Helmholtz equation*

$$\Delta U(\mathbf{x})+k^2\nu^2U(\mathbf{x})=0, \tag{24}$$

where we take $\mathbf{x}$ to be a vector in $\mathbb{R}^2$, and where k and ν are physical constants. In the standard application, ν is the refractive index of the medium and k is inversely proportional to wavelength. In the region of visible light, the wavelength is sufficiently small that k dominates over all other mathematically relevant parameters, an undesirable property known as *stiffness*.

For this reason, short-wave solutions of (24) are usually approximated by *uniform asymptotic expansions*[12,17] which satisfy (24) to arbitrarily high order in k^{-1}. These approximations are valid in regions which contain smooth and convex caustics such as a circular caustic. The size of the region of validity is independent of k. Take $\nu\equiv 1$ and approximate the solution to (24) by an expansion having the form

$$U_{\text{approx}}(x,y)=\left\{Z(k^{2/3}u)\left(\sum_{j=0}^{\infty}W_j(\mathbf{r})\cdot(ik)^{-j}\right)+\frac{i}{k^{1/3}}Z'(k^{2/3}u)\left(\sum_{j=0}^{\infty}X_j(\mathbf{r})\cdot(ik)^{-j}\right)\right\}\times\exp[ikv(x,y)],$$

where $u(x,y)$, $v(x,y)$, $W_j(\mathbf{r})$, and $X_j(\mathbf{r})$ are functions which do not depend on k and which are to

be determined with the solution; the function $Z(t)$ is a solution of the *Airy equation*

$$Z''(t) - tZ(t) = 0,$$

with initial conditions

$$Z(0) = \frac{3^{-2/3}}{\Gamma(2/3)}$$

and

$$Z'(0) = -\frac{3^{-1/3}}{\Gamma(1/3)},$$

where $\Gamma(\,)$ is the gamma function.

This model implies the following system of equations for u and v:

$$u(u_x^2 + u_y^2) - (v_x^2 + v_y^2) + 1 = 0,$$

$$u_x v_x + u_y v_y = 0.$$

In Ref. 18 three possible solutions of this system are enumerated:

$$u = 0, \quad |\nabla v|^2 = 1;$$

$$|\nabla u| = 0, \quad |\nabla v|^2 = 1;$$

the third possibility is that Eq. (16) is satisfied.

Obviously, the third alternative is the most interesting, and this case is studied in Ref. 18. This case is linearized to Eq. (17) by a hodograph transformation.

B. A first-order system

Thus we are led to a system resembling Eqs. (5)–(7):

$$L\mathbf{u} = \mathbf{g}, \tag{25}$$

where

$$L = (L_1, L_2), \quad \mathbf{g} = (g_1, g_2),$$

$$\mathbf{u} = (u_1(x,y), u_2(x,y)), \quad (x,y) \in \Omega \Subset \mathbb{R}^2,$$

$$(L\mathbf{u})_1 = [f(x,y) - x^2]u_{1x} - 2xyu_{1y} + [f(x,y) - y^2]u_{2y}, \tag{26}$$

and

$$(L\mathbf{u})_2 = [f(x,y) - y^2](u_{1y} - u_{2x}), \tag{27}$$

for

$$f(x,y) = (x^2 + y^2)^2. \tag{28}$$

The domain is chosen so that

$$f(x,y) - y^2 \neq 0,$$

under which system (25)–(28) becomes an inhomogeneous generalization of Eqs. (22) and (23). If, in particular, $g_1 = g_2 = 0$, $u_1 = V_x$, and $u_2 = V_y$, where $V(x,y)$ is a scalar function, then Eqs. (25)–(28) reduce to Eq. (17).

As in the preceding sections, the second-order terms of Eqs. (25)–(28) can be written in the form $A^1\mathbf{u}_x + A^2\mathbf{u}_y$, where

$$A^1 = \begin{bmatrix} f(x,y) - x^2 & 0 \\ 0 & -(f(x,y) - y^2) \end{bmatrix}$$

and

$$A^2 = \begin{bmatrix} -2xy & f(x,y) - y^2 \\ f(x,y) - y^2 & 0 \end{bmatrix}.$$

We find that the system is hyperbolic in the intersection of Ω with the open unit disk centered at (0,0) and elliptic in the intersection of Ω with the complement of the closure of this disk.

C. Strong solutions in an annulus

Writing Eq. (17) in polar coordinates $(r,\theta), r \geqslant 0, -\pi < \theta \leqslant \pi$, we obtain[18]

$$(r^2 - 1)V_{rr} + rV_r + V_{\theta\theta} = 0. \tag{29}$$

Letting $u_1 = V_r$ and $u_2 = V_\theta$ transforms Eq. (29) into a first-order system of the form

$$L\mathbf{u} = A^1\mathbf{u}_r + A^2\mathbf{u}_\theta + B\mathbf{u} = \mathbf{f}, \tag{30}$$

with $\mathbf{u} = (u_1(r,\theta), u_2(r,\theta))$, $\mathbf{f} = (0,0)$,

$$A^1 = \begin{pmatrix} r^2 - 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad A^2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{31}$$

and

$$B = \begin{pmatrix} r & 0 \\ 0 & 0 \end{pmatrix}.$$

As in Sec. II B, the matrices are symmetric and we find that $Q = 2B^* - A^1_r - A^2_\theta$ is exactly zero, suggesting that an arbitrarily small perturbation of the matrix B will result in a symmetric-positive operator. However we find that we can retain the consistency condition $u_{1\theta} - u_{2r} = 0$ if we employ a multiplier E as described in Sec. II B. Thus we define

$$E = \begin{pmatrix} a & c(1 - r^2) \\ c & a \end{pmatrix},$$

where $a = a(r,\theta)$ and $c = c(r,\theta)$ are continuously differentiable functions to be chosen. We replace B by the matrix

$$B_\varepsilon = \begin{pmatrix} r + \varepsilon_1 & \varepsilon_2 \\ 0 & 0 \end{pmatrix}, \tag{32}$$

where $\varepsilon_1, \varepsilon_2$ are arbitrarily small, strictly negative constants.

Replacing Eq. (30) by the system

$$EL = EA^1\mathbf{u}_r + EA^2\mathbf{u}_\theta + EB_\varepsilon\mathbf{u} = E\mathbf{f}, \tag{33}$$

with A^1, A^2, and B_ε given by Eqs. (31) and (32), we find that EL is a symmetric-positive operator provided we choose $0<\varepsilon_0\leqslant r\leqslant R<\infty$, $a=-r$, and

$$c = -\left(\frac{M}{r} + \theta\right),$$

where M is a large, positive constant.

We will solve Eq. (33) in the annulus Ω_5 given by $\varepsilon_0\leqslant r\leqslant R$, where $R>1$, imposing Dirichlet conditions on the outer boundary and composite boundary conditions on the inner boundary. Annular domains are natural when numerical methods are used to study an equation, such as Eq. (17), which is known to be singular at the origin, with the singular point excluded. The problem is also of some historical interest. An equation differing from (17) only in its lower-order terms was one of the first elliptic-hyperbolic equations to be studied, more than 75 years ago, by Bateman (Sec. 9 of Ref. 1). That equation arose from the solution of Laplace's equation in toroidal coordinates.[2] At the time, Bateman raised the question of the existence and uniqueness of solutions in an annular region containing the unit circle, in which the outer boundary lies in the elliptic region and the inner boundary lies in the hyperbolic region of the equation. Finally, the boundary-value problem in an annulus highlights the similarity between Eqs. (25)–(28) and (5)–(7), as we will use virtually the same argument to solve annular boundary-value problems in the two cases.

Although the system that we consider is a small perturbation of the one studied in Ref. 18, we note that the original equation is itself an approximation, as described in Sec. III A.

Theorem 3: *Equation (33), with boundary conditions*

$$\tau(\theta)u_1 + \sigma(\theta)u_2 = 0, \tag{34}$$

where $\tau(\theta)\sigma(\theta)>0$ *at* $r=\varepsilon_0$ *and* $\sigma=0$, $\tau=1$ *at* $r=R$, *possesses a unique, strong solution on the annulus* Ω_5.

Proof: Although the equations are different, the argument is similar to the proof by Torre[30] of the corresponding assertion for the helically reduced wave equation.

The matrices E and B_ε have been constructed in such a way that the operator EL is manifestly symmetric positive (for large M), and the proof again reduces to a demonstration that the boundary conditions are admissible. At the inner boundary, choose

$$\mathbf{n}_{\text{inner}} = (\varepsilon_0^2 - 1)^{-1}\mathrm{d}r.$$

Then

$$\beta_{\text{inner}} = \begin{pmatrix} a & c \\ c & -(\varepsilon_0^2-1)^{-1}a \end{pmatrix}\mathrm{d}r.$$

Choose

$$\beta_{\text{inner}^-} = \frac{1}{\sigma^2+\tau^2}\begin{pmatrix} \sigma\tau c + \tau^2 a & \sigma^2 c + \sigma\tau a \\ -\sigma\tau(\varepsilon_0^2-1)^{-1}a + \tau^2 c & -\sigma^2(\varepsilon_0^2-1)^{-1}a + \sigma\tau c \end{pmatrix}\mathrm{d}r.$$

Then

$$\beta_{\text{inner}^+} = \frac{1}{\sigma^2+\tau^2}\begin{pmatrix} -\sigma\tau c + \sigma^2 a & \tau^2 c - \sigma\tau a \\ \sigma\tau(\varepsilon_0^2-1)^{-1}a + \sigma^2 c & -\tau^2(\varepsilon_0^2-1)^{-1}a - \sigma\tau c \end{pmatrix}\mathrm{d}r.$$

Notice that $\beta_{\text{inner}^+}+\beta_{\text{inner}^-}=\beta_{\text{inner}}$ and that $\beta_{\text{inner}^-}\mathbf{u}=0$, as (34) implies that $u_2=-(\tau/\sigma)u_1$ on the circle $r=\varepsilon_0$. Moreover,

$$\mu = \frac{1}{\sigma^2+\tau^2}\begin{pmatrix} (\sigma^2-\tau^2)a - 2\sigma\tau c & (\tau^2-\sigma^2)c - 2\sigma\tau a \\ (\sigma^2-\tau^2)c + 2\sigma\tau(\varepsilon_0^2-1)^{-1}a & (\sigma^2-\tau^2)(\varepsilon_0^2-1)^{-1}a - 2\sigma\tau c \end{pmatrix} \mathrm{d}r,$$

implying that

$$\mu^* = \frac{1}{\sigma^2+\tau^2}\begin{pmatrix} (\sigma^2-\tau^2)a - 2\sigma\tau c & \sigma\tau a[(\varepsilon_0^2-1)^{-1}-1] \\ \sigma\tau a[(\varepsilon_0^2-1)^{-1}-1] & (\sigma^2-\tau^2)(\varepsilon_0^2-1)^{-1}a - 2\sigma\tau c \end{pmatrix} \mathrm{d}r.$$

But this matrix is non-negative for our choices of a and c, given that $0<\varepsilon_0<1, \sigma\tau>0$, provided that we choose M sufficiently large.

On the upper boundary we choose

$$\mathbf{n}_{\text{outer}} = (R^2-1)^{-1}\mathrm{d}r.$$

Then

$$\beta_{\text{outer}} = \begin{pmatrix} a & c \\ c & -(R^2-1)^{-1}a \end{pmatrix} \mathrm{d}r.$$

Choose

$$\beta_{\text{outer}^-} = \begin{pmatrix} a & 0 \\ c & 0 \end{pmatrix} \mathrm{d}r.$$

Then

$$\beta_{\text{outer}^+} = \begin{pmatrix} 0 & c \\ 0 & -(R^2-1)^{-1}a \end{pmatrix} \mathrm{d}r.$$

Applying (34) with the Dirichlet condition $\sigma=0$, $\tau=1$, we find that $\beta_{\text{outer}^-}\mathbf{u}=0$ on the circle $r=R$. Moreover,

$$\mu = \begin{pmatrix} -a & c \\ -c & -(R^2-1)^{-1}a \end{pmatrix} \mathrm{d}r,$$

so

$$\mu^* = \begin{pmatrix} -a & 0 \\ 0 & -(R^2-1)^{-1}a \end{pmatrix} \mathrm{d}r.$$

This matrix is positive, as $a<0$ and $R>1$.

Because conditions have been imposed on all of $\partial\Omega_5$, in this case the null space of β_- alone spans V on the boundary.

This completes the proof of Theorem 3.

As expected, this proof fails if the outer boundary is taken to lie inside the unit circle.

We note that we can prove an analogous result for a generalization to systems of an arbitrarily small perturbation of the Laplace-Beltrami equations on extended $\mathbb{P}^2$. As in the case of Theorem 3, we do not need to perturb the compatibility equations in order to obtain strong solutions on the annulus Ω_5. A similar problem was considered in the scalar case by Hua (Sec. III, heuristic consideration 2, of the supplement to Ref. 9); that scalar problem was solved using Fourier expansions.

Write the second-order form of Eqs. (3) and (4) in the polar form

$$r^2(1-r^2)\varphi_{rr} + r(1-2r^2)\varphi_r + \varphi_{\theta\theta} = 0.$$

Let $u_1 = r^2\varphi_r$ and $u_2 = \varphi_\theta$ on the annulus Ω_5. We obtain a first-order system of the form (30) with $\mathbf{f}=0$,

$$A^1 = \begin{pmatrix} 1-r^2 & 0 \\ 0 & -r^2 \end{pmatrix}, \quad A^2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{35}$$

and

$$B = \begin{pmatrix} -1/r & 0 \\ 0 & 0 \end{pmatrix}.$$

This operator L is symmetric, but fails to be symmetric positive for $r \leqslant 1$. So we replace B by the matrix

$$B_\varepsilon = \begin{pmatrix} \varepsilon_1 - 1/r & \varepsilon_2 \\ 0 & 0 \end{pmatrix}, \tag{36}$$

for $\varepsilon_1 > 0$ and $\varepsilon_2 > 0$.

Theorem 4: *Define the matrices A^1, A^2, B_ε, as in Eqs. (35) and (36). Impose boundary condition (34), taking $\sigma\tau > 0$ on the outer boundary and $\sigma = 0$, $\tau = 1$ on the inner boundary. Then there exists a unique, strong solution to Eq. (33) on Ω_5 for every $\mathbf{f} \in L^2(\Omega_5)$.*

Proof: Choose

$$E = \begin{pmatrix} a & c(1-r^2)/r^2 \\ c & a \end{pmatrix},$$

where $a = 1/r$ and $c = (M/r) + \theta$, for a sufficiently large constant M. Because ε_1 and ε_2 are positive, the operator EL is symmetric positive.

Choose

$$n_{\text{inner}} = (\varepsilon_0^2 - 1)^{-1} \mathrm{d}r$$

and

$$n_{\text{outer}} = (R^2 - 1)^{-1} \mathrm{d}r.$$

Then

$$\beta(r) = \begin{pmatrix} -a(r) & -c(r,\theta) \\ -c(r,\theta) & [r^2/(1-r^2)]a \end{pmatrix} \mathrm{d}r,$$

where $r = \varepsilon_0$ on the inner radius and $r = R$ on the outer radius. Choose β_{inner^+}, β_{inner^-}, β_{outer^+}, and β_{outer^-} analogously to the choices made in the proof of Theorem 3, with coefficients of the form $r^2 - 1$ in those matrices replaced by coefficients of the form $r^2/(1-r^2)$. The proof is then completed as in the proof of Theorem 3.

We note that if the outer boundary is taken to lie within the elliptic region, then the proof of Theorem 4 will work with Dirichlet conditions imposed on both the inner and outer boundaries, as expected.[14]

IV. A REMARK ON TERMINOLOGY AND NOTATION

Hodge[8] originally considered a p-form ω to be harmonic if it satisfies the first-order equations

$$\mathrm{d}\omega = \delta\omega = 0, \tag{37}$$

where $\mathrm{d}: \Lambda^p \to \Lambda^{p+1}$ is the exterior derivative and $\delta: \Lambda^{p+1} \to \Lambda^p$ is the adjoint of d. If the underlying space is $\mathbb{R}^2$ and ω is a 1-form given by

$$\omega = p\,\mathrm{d}x + q\,\mathrm{d}y,$$

where p and q are continuously differentiable functions, then the Hodge equations (37) reduce to the Cauchy-Riemann equations for p and $-q$. However, although d is independent of the underlying metric, its adjoint δ has a different local form for different metrics. Thus for a surface having metric tensor g_{ij}, the Hodge equations for 1-forms are equivalent to the system (3) and (4). A discussion of exterior forms and their properties is given in, e.g., Ref. 21.

The standard definition of a *harmonic form* is given in terms of a second-order operator: it is a solution of the form-valued Laplace-Beltrami equations

$$(\mathrm{d}\delta + \delta\mathrm{d})\omega = 0.$$

If the domain has *zero boundary* (either no boundary or the prescribed value $\omega \equiv 0$ on the boundary), then the definitions in terms of first- and second-order operators are equivalent. Otherwise, one distinguishes them by calling a form that satisfies Eq. (37) a *harmonic field*. In words, the Hodge equations assert that a harmonic field ω is both *closed* ($\mathrm{d}\omega = 0$) and *coclosed* ($\delta\omega = 0$) under the exterior derivative d. Obviously, every harmonic field is a harmonic form, but the converse is false.

Notice that in Eqs. (6) and (7), $L_1 \neq \delta$ and $L_2 \neq \mathrm{d}$. For example, L_2 includes a factor of $1 - y^2$ whereas d does not, and δ includes determinants of the metric tensor, whereas L_1 does not. In addition, cases 1 and 2 of (6) and (7) include additional lower-order terms. Thus for example δ and d are self-adjoint, whereas L_1 and L_2 are not unless $k_1 = k_2 = k_3 = k_4 = 0$.

I. INTRODUCTION

The theory of algebraic curves is a fundamental ingredient in the analysis of integrable nonlinear differential equations as it is shown, for example, by its relevance in the description of the finite-gap solutions or the formulation of the Whitham averaging method.[1–8] A particularly interesting problem is characterizing and classifying integrable deformations of algebraic curves. Indeed, as it is shown in a series of recent papers,[9–12] these deformations lie at the crossroads of intricate connections between the theory of random matrices and several models of Laplacian growth processes. It turns out that the integrable models underlying these applications are members of the Whitham hierarchies of dispersionless integrable models introduced by Krichever in Refs. 6 and 7. Moreover, the corresponding solutions are usually characterized in terms of solutions of hydrodynamic systems.

Natural deformations of algebraic curves arise in the dynamics of the *algebraic orbits*[7] of the Whitham hierarchies. For example, algebraic orbits of the Zabolotskaya-Khokhlov dispersionless KP (dKP) hierarchy

$$\frac{\partial k}{\partial t_n} = \{Q_n, k\}, \quad n \geqslant 1, \tag{1}$$

where

$$k = p + \sum_{n=1}^{\infty} \frac{a_n(x,t)}{p^n}, \quad Q_n := (k^n)_{\geqslant 0}, \quad t := (t_1, t_2, \dots) \tag{2}$$

are deformations of algebraic curves

$$f(k) = E(p,x,t), \tag{3}$$

where $E=E(p,x,t)$ is a meromorphic function of p, such that (3) determines a reduction of the dKP hierarchy. In the Gelfand-Dikii case the function E depends on the variables (x,t) through a finite number of functions which evolve according to a system of hydrodynamic type. Neverthe-

less, other deformations of algebraic curves have been formulated which do not correspond to algebraic orbits of the standard dispersionless hierarchies. For example, the integrable hierarchy associated to the *energy-dependent* Schrödinger problem[13] admits a dispersionless limit which leads to a family of deformations of the curves[14,15]

$$p^2 = k^{2N+1} + \sum_{n=1}^{N} u_n k^{2n-1}. \tag{4}$$

These curves do not constitute any reduction of the dKP hierarchy and, as it is shown in Ref. 14, their deformations must be formulated in terms of the singular sectors of a dKdV Grassmannian structure.

A different approach for determining integrable deformations of general algebraic curves $\mathcal{C}$ defined by monic polynomial equations,

$$\mathcal{C}: F(p,k) := p^N - \sum_{n=1}^{N} u_n(k) p^{N-n} = 0, \quad u_n \in \mathbb{C}[k], \tag{5}$$

was proposed in Refs. 14 and 15. It applies for finding deformations $\mathcal{C}(x,t)$ of $\mathcal{C}$ with the deformation parameters (x,t), such that the multiple-valued function $\mathbf{p}=\mathbf{p}(k)$ determined by (5) obeys an equation of the form of conservation laws

$$\partial_t \mathbf{p} = \partial_x \mathbf{Q}, \tag{6}$$

where the flux $\mathbf{Q}$ is given by an element from $\mathbb{C}[k,p]/\mathcal{C}$,

$$\mathbf{Q} = \sum_{r=1}^{N} a_r(k,x,t)\mathbf{p}^{r-1}, \quad a_r \in \mathbb{C}[k].$$

Starting with (6), changing to the dynamical variables u_n and using Lenard-type relations (see Ref. 15) one gets a scheme for finding consistent deformations of (5). One should also note that (6) provides an infinite number of conservation laws, when one expands $\mathbf{p}$ and $\mathbf{Q}$ in Laurent series in z with $k=z^r$ for some r. In this sense, we say that Eq. (6) is integrable.

Our strategy can be applied to the *generic case* where the coefficients (*potentials*) u_n of (5) are general polynomials in k,

$$u_n(k) = \sum_{i=0}^{d_n} u_{n,i} k^i,$$

with all the coefficients $u_{n,i}$ being considered as independent dynamical variables, i.e., $u_{n,i} = u_{n,i}(x,t)$. However, with appropriate modifications, the scheme can be also applied to cases in which constraints on the potentials are imposed. A complete description of these deformations for the generic case of hyperelliptic curves ($N=2$) was given in Ref. 15.

The present paper is devoted to the deformations of cubic curves ($N=3$),

$$p^3 - wp^2 - vp - u = 0, \quad u,v,w \in \mathbb{C}[k], \tag{7}$$

and it considers not only the generic case but also the important constrained case $w \equiv 0$. Although some of the curves may be conformally equivalent (with, for example, the dispersionless Miura transformation), we will not discuss the classification problem under this equivalence in this paper (we will discuss the details of the problem elsewhere). In Sec. II a general approach to construct integrable deformations of algebraic curves is reported briefly. Section III is devoted to the analysis of the cubic case (7). We emphasize the role of Lagrange resolvents, describe the Hamiltonian structure of integrable deformations and present several illustrative examples including Whitham-type deformations.

II. SCHEMES OF DEFORMATIONS OF ALGEBRAIC CURVES

In order to describe deformations of the curve $\mathcal{C}$ defined by (5), one may use the potentials u_n, as well as the N branches $p_i=p_i(k)$ $(i=1,\dots,N)$ of the multiple-valued function $\mathbf{p}=\mathbf{p}(k)$ satisfying

$$F(p,k)=\prod_{i=1}^{N}(p-p_i(k)). \tag{8}$$

The potentials can be expressed as elementary symmetric polynomials s_n (Refs. 16–18) of the branches p_i,

$$u_n=(-1)^{n-1}s_n(p_1,p_2,\dots)=(-1)^{n-1}\sum_{1\leqslant i_1<\cdots<i_n\leqslant N}p_{i_1}\cdots p_{i_n}. \tag{9}$$

However, notice that, according to the famous Abel theorem,[16] for $N>4$ the branches p_i of the generic equation (5) cannot be written in terms of the potentials u_n by means of rational operations and radicals.

There is an important result concerning the branches p_i which is useful in our analysis. Let $\mathbb{C}((\lambda))$ denote the field of Laurent series in λ with at most a finite number of terms with positive powers,

$$\sum_{n=-\infty}^{N}c_n\lambda^n,\quad N\in\mathbb{Z}.$$

Then we have the following.[19,20]

Theorem 1 (Newton theorem): *There exists a positive integer l such that the N branches*

$$p_i(z):=(p_i(k))|_{k=z^l}, \tag{10}$$

are elements of $\mathbb{C}((z))$. Furthermore, if $F(p,k)$ is irreducible as a polynomial over the field $\mathbb{C}((k))$ then $l_0=N$ is the least permissible l and the branches $p_i(z)$ can be labelled so that

$$p_i(z)=p_N(\epsilon^i z),\quad \epsilon:=\exp\frac{2\pi i}{N}.$$

Notation convention: Henceforth, given an algebraic curve $\mathcal{C}$ we will denote by z the variable associated with the least positive integer l_0 for which the substitution $k=z^{l_0}$ implies $p_i\in\mathbb{C}((z))$, $\forall\, i$.The number l_0 will be referred to as the Newton exponent of the curve.

For the generic case the method proposed in Ref. 15 may be summarized as follows: Given an algebraic curve (5), we define an evolution equation for $\mathbf{u}:=(u_1,\dots,u_N)$ in the form

$$\partial_t\mathbf{u}=J_0(T\nabla_{\mathbf{u}}R)_+,\quad R(z,\mathbf{p})=\sum_i f_i(z)p_i, \tag{11}$$

where $(\cdot)_+$ indicates the part of non-negative powers of a Laurent series in k and

$$f_i\in\mathbb{C}((z)),\quad \nabla_{\mathbf{u}}R:=\left(\frac{\partial R}{\partial u_1}\dots\frac{\partial R}{\partial u_N}\right)^{\mathsf{T}},$$
$$J_0:=T^{\mathsf{T}}V^{\mathsf{T}}\partial_x V, \tag{12}$$

$$T := \begin{pmatrix} 1 & -u_1 & \cdots & -u_{N-1} \\ 0 & 1 & \cdots & -u_{N-2} \\ & & \cdots & \\ 0 & & \cdots & 1 \end{pmatrix}, \quad V := \begin{pmatrix} 1 & p_1 & \cdots & p_1^{N-1} \\ & & \cdots & \\ & & \cdots & \\ 1 & p_N & \cdots & p_N^{N-1} \end{pmatrix}. \tag{13}$$

Let d_{nm} and d_n be the degrees of the matrix elements $(J_0)_{nm}$ and the potentials u_n as polynomials in k, respectively. Then (11) defines a deformation of the curve, if d_{nm} and d_n satisfy the consistency conditions

$$\max\{d_{nm}, m = 1,2,3\} \leqslant d_n + 1, \quad n = 1,2,3, \tag{14}$$

and the components of $\nabla_{\mathbf{u}} R$ are in $\mathbb{C}((k))$ with $k = z^{l_0}$.

Equivalently, in terms of branches

$$\mathbf{p} := (p_1, \ldots, p_N)^{\mathsf{T}},$$

the system (11) can be written as

$$\partial_t \mathbf{p} = \partial_x (V \mathbf{r}_+), \tag{15}$$

where

$$\mathbf{r} := T \nabla_{\mathbf{u}} R(z, \mathbf{p}) = V^{-1} \mathbf{f}(z), \tag{16}$$

with $\mathbf{f}(z) := (f_1(z), \ldots, f_N(z))^{\mathsf{T}}$. Notice that $\mathbf{r}$ is a solution of the Lenard relation

$$J_0 \mathbf{r} = 0. \tag{17}$$

Although there is not a general procedure for analyzing constrained cases, one may try a similar strategy. First, we start from the equation for branches (6) and then, by expressing the potentials in terms of the independent branches only, we look for a formulation of the flows as

$$\partial_t \mathbf{u} = J_0 \mathbf{a}, \quad \mathbf{a} := (a_1, \ldots, a_N)^{\mathsf{T}}, \tag{18}$$

for a certain operator J_0. Finally, we use solutions $\mathbf{r}$ of Lenard relations (17) and set $\mathbf{a} = \mathbf{r}_+$.

Another scheme for defining integrable deformations of algebraic curves of genus *zero* (i.e., rational curve) is implicit in the theory of integrable systems of dispersionless type developed in Refs. 7 and 8 which we refer to them as the Whitham deformations. It is concerned with algebraic curves characterized by equations of the form

$$k = p^N + v_{N-2} p^{N-2} + \cdots + v_0 + \sum_{r=1}^{M} \sum_{i=1}^{n_r} \frac{v_{r,i}}{(p - w_r)^i}, \tag{19}$$

where v_n, $v_{r,i}$, w_r are k-independent coefficients. These curves arise in the theory of algebraic orbits of the genus-zero Whitham hierarchy,[7,8] where the function k represents the Landau-Ginzburg potential of the associated topological field theory. We may rewrite the equation of the curve (19) in the polynomial form (5) with potentials u_n of degrees $d_n \leqslant 1$ and satisfying a certain system of constraints.

To describe the deformations of (19) determined by Whitham flows we introduce local coordinates $\{z_0, z_1, \ldots, z_M\}$ of the extended p-plane at the punctures $\{w_0 := \infty, w_1, \ldots, w_M\}$ such that

$$k = z_0^N = z_1^{n_1} = \cdots = z_{n_M}^{n_M}. \tag{20}$$

It is clear that there are N branches of $\mathbf{p}$ which have expansions in powers of $k^{1/N}$ and that, for each puncture w_r, $(r = 1, \ldots, M)$, there are n_r branches of $\mathbf{p}$ having expansions in powers of k^{1/n_r}. Therefore, the Newton exponent l_0 is given by the least common multiple of the set of integers

$\{N, n_1, \ldots, n_M\}$. Furthermore, it is clear that only in the absence of finite punctures ($M=0$) the curve (19) is irreducible over $\mathbb{C}((k))$.

At each puncture in $\{\infty, w_1, \ldots, w_M\}$, there is an infinite family of Whitham deformations of (19). They can be expressed by equations of the form (see Refs. 7 and 8)

$$\partial_t \mathbf{p} = \partial_x \mathbf{Q}_{\alpha,n}, \tag{21}$$

where

$$\mathbf{Q}_{\alpha,n} = (z_\alpha^n)_\oplus(\mathbf{p}), \quad \alpha = 0,1,\ldots,M,\ n \geqslant 1,$$

$$\mathbf{Q}_{r,0} = \ln(\mathbf{p} - w_r), \quad r = 1,\ldots,M.$$

Here $(z_\alpha^n)_\oplus$ stands for the singular part of $z_\alpha^n(p)$ at the puncture w_α, with $(z_r^n)_\oplus(\infty)=0$ for $1 \leqslant r \leqslant M$. There exist also commuting flows for the negative n in (21) with logarithmic terms which correspond to the descendant flows of $Q_{r,0}$ (see Ref. 8 for the details).

In the absence of finite punctures ($M=0$), Whitham deformations become the dispersionless Gelfand-Dikii flows. They can be described by our scheme[15] as the reductions $u_1 \equiv 0$, $u_N = k - v_0$ of the generic case corresponding to $d_n = \delta_{Nn}$. However, for $M \geqslant 1$ it can be seen that, in general, Whitham deformations of (19) are not reductions of the flows (11) provided by our method. Some examples of this situation for cubic curves are shown below.

III. DEFORMATIONS OF CUBIC CURVES

For our subsequent analysis we introduce a basic tool of the theory of third order polynomial equations,[16] the so-called *Lagrange resolvents*, defined by

$$\mathcal{L}_i := \sum_{j=1}^{3} (\epsilon^i)^j p_j, \quad i = 1,2,3, \quad \epsilon := e^{2\pi i/3}, \tag{22}$$

or, equivalently,

$$\mathcal{L}_1 := \epsilon p_1 + \epsilon^2 p_2 + p_3,$$

$$\mathcal{L}_2 := \epsilon^2 p_1 + \epsilon p_2 + p_3,$$

$$\mathcal{L}_3 := p_1 + p_2 + p_3.$$

They can be expressed in terms of the potentials $\mathbf{u} = (w, v, u)^{\mathsf{T}}$ by using the identities

$$\mathcal{L}_1 \cdot \mathcal{L}_2 = 3v + w^2, \quad \mathcal{L}_3 = w,$$

$$\mathcal{L}_1^3 + \mathcal{L}_2^3 = 27u + 9vw + 2w^3,$$

which lead to

$$2\mathcal{L}_1^3 = 27u + 9vw + 2w^3 + \sqrt{(27u + 9vw + 2w^3)^2 - 4(3v + w^2)^3},$$

$$2\mathcal{L}_2^3 = 27u + 9vw + 2w^3 - \sqrt{(27u + 9vw + 2w^3)^2 - 4(3v + w^2)^3}.$$

The fundamental advantage of Lagrange resolvents is that they provide explicit expressions of the branches p_i in terms of the potentials according to Cardano formulas

$$3p_i = \sum_{j=1}^{3} (\epsilon^{-i})^j \mathcal{L}_j, \quad i = 1,2,3, \tag{23}$$

or, equivalently,

$$3p_1 = \epsilon^2 \mathcal{L}_1 + \epsilon \mathcal{L}_2 + \mathcal{L}_3,$$

$$3p_2 = \epsilon \mathcal{L}_1 + \epsilon^2 \mathcal{L}_2 + \mathcal{L}_3,$$

$$3p_3 = \mathcal{L}_1 + \mathcal{L}_2 + \mathcal{L}_3.$$

As we will prove below, the Lagrange resolvents are essential to determine consistent deformations of cubic equations.

A. Generic case

As it was found in, Ref. 15 for $N=3$ the operator J_0 reads

$$J_0 = \begin{pmatrix} 3\partial_x & w\partial_x + w_x & (2v + w^2)\partial_x + (2v + w^2)_x \\ -2w\partial_x & 2v\partial_x + v_x & (3u + vw)\partial_x + 2u_x + 2vw_x \\ -v\partial_x & 3u\partial_x + u_x & uw\partial_x + 2uw_x \end{pmatrix}. \tag{24}$$

Thus if d_1, d_2, and d_3 are the degrees in k of the potential functions w, v, and u, respectively, the consistency conditions (14) are

$$d_1 \leqslant 1, \quad d_2 \leqslant d_1 + 1,$$

$$d_3 \leqslant d_2 + 1, \quad d_2 \leqslant d_3 + 1,$$

which lead to the following 12 nontrivial choices for (d_1, d_2, d_3):

$$\begin{gathered} (0,0,1), \quad (0,1,0), \quad (0,1,1), \quad (0,1,2), \\ (1,0,0), \quad (1,0,1), \quad (1,1,0), \quad (1,1,1), \\ (1,1,2), \quad (1,2,1), \quad (1,2,2), \quad (1,2,3). \end{gathered} \tag{25}$$

By using (23) and (24) it is straightforward to determine the Newton exponent l_0 for each of the cases (25). Thus one finds three categories

l_0	3	2	1
	(0,0,1), (0,1,2)	(0,1,0), (0,1,1,)	(1,0,1), (1,1,0)
		(1,0,0), (1,1,2)	(1,1,1), (1,2,1)
			(1,2,2), (1,2,3)

Only the cases with $l_0=3$ correspond to irreducible curves over the field $\mathbb{C}((k))$. We also note here that our deformations for the trigonal curves (5) in the generic case allow one to have only the curves with genus less than or equal to 1 (the details will be discussed elsewhere).

Once the Newton exponent l_0 is known, in order to derive the associated hierarchy of integrable deformations according to our scheme, two steps are still required:

(1) To determine the functions $R(z,\mathbf{p})=\Sigma_i f_i(z)p_i$ such that the components of $\nabla_{\mathbf{u}}R$ are in $\mathbb{C}((k))$ with $k=z^{l_0}$.
(2) To find the explicit form of the gradients $\nabla_{\mathbf{u}}R$ in terms of the potentials.

Both problems admit a convenient treatment in terms of Lagrange resolvents. Thus by introducing the following element σ_0 of the Galois group of the curve:

$$\sigma_0(p_i)(z) := p_i(\epsilon_0 z), \quad \epsilon_0 := e^{2\pi i/l_0}, \tag{26}$$

we see that our first problem can be fixed by determining functions R invariants under σ_0, i.e., $R(\epsilon_0 z, \sigma_0 \mathbf{p}) = R(z, \mathbf{p})$. In this way, we have the following forms of R.

For the case $l_0=3$, the element σ_0 is given by the permutation

$$\sigma_0 = \begin{pmatrix} p_1 & p_2 & p_3 \\ p_2 & p_3 & p_1 \end{pmatrix}, \tag{27}$$

or, in terms of Lagrange resolvents,

$$\sigma_0 = \begin{pmatrix} \mathcal{L}_1 & \mathcal{L}_2 & \mathcal{L}_3 \\ \epsilon^2 \mathcal{L}_1 & \epsilon \mathcal{L}_2 & \mathcal{L}_3 \end{pmatrix}. \tag{28}$$

Thus we get the invariant functions

$$R = z f_1(z^3)\mathcal{L}_1 + z^2 f_2(z^3)\mathcal{L}_2 + f_3(z^3)\mathcal{L}_3, \tag{29}$$

with $f_i(z^3)$ being arbitrary functions in $\mathbb{C}((z^3))$.

For the case $l_0=2$, σ_0^2 is the identity permutation, so that under the action of σ_0 two branches are interchanged while the other remains invariant. If we label the branches in such a way that

$$\sigma_0 = \begin{pmatrix} p_1 & p_2 & p_3 \\ p_2 & p_1 & p_3 \end{pmatrix}, \tag{30}$$

then

$$\sigma_0 = \begin{pmatrix} \mathcal{L}_1 & \mathcal{L}_2 & \mathcal{L}_3 \\ \mathcal{L}_2 & \mathcal{L}_1 & \mathcal{L}_3 \end{pmatrix}, \tag{31}$$

and we obtain the invariant functions

$$R = f_1(z^2)(\mathcal{L}_1 + \mathcal{L}_2) + z f_2(z^2)(\mathcal{L}_1 - \mathcal{L}_2) + f_3(z^2)\mathcal{L}_3, \tag{32}$$

where $f_i(z^2)$ are arbitrary functions in $\mathbb{C}((z^2))$.

For the case $l_0=1$, we have $z=k$ and σ_0 is the identity, so that any function $R(k, \mathbf{p})$ is invariant under σ_0.

Now the problem of finding the gradients of R reduces to determine the gradients of the Lagrange resolvents. To this end we differentiate (23) and obtain

$$\mathcal{L}_2 \nabla_{\mathbf{u}} \mathcal{L}_1 + \mathcal{L}_1 \nabla_{\mathbf{u}} \mathcal{L}_2 = (2w, 3, 0)^{\mathsf{T}},$$

$$\mathcal{L}_1^2 \nabla_{\mathbf{u}} \mathcal{L}_1 + \mathcal{L}_2^2 \nabla_{\mathbf{u}} \mathcal{L}_2 = (2w^2 + 3v, 3w, 9)^{\mathsf{T}},$$

so that

$$(\mathcal{L}_1^3 - \mathcal{L}_2^3)\nabla_{\mathbf{u}} \mathcal{L}_1 = ((2w^2 + 3v)\mathcal{L}_1 - 2w\mathcal{L}_2^2, 3(w\mathcal{L}_1 - \mathcal{L}_2^2), 9\mathcal{L}_1)^{\mathsf{T}},$$

$$(\mathcal{L}_2^3 - \mathcal{L}_1^3)\nabla_{\mathbf{u}} \mathcal{L}_2 = ((2w^2 + 3v)\mathcal{L}_2 - 2w\mathcal{L}_1^2, 3(w\mathcal{L}_2 - \mathcal{L}_1^2), 9\mathcal{L}_2)^{\mathsf{T}}.$$

Hence the gradients of the generic density R for (29) and (32) are given as follows.

For $l_0=3$, we have

$$\nabla_{\mathbf{u}}R = \frac{zf_1(z^3)}{\mathcal{L}_1^3 - \mathcal{L}_2^3}\begin{pmatrix} (2w^2+3v)\mathcal{L}_1 - 2w\mathcal{L}_2^2 \\ 3(w\mathcal{L}_1 - \mathcal{L}_2^2) \\ 9\mathcal{L}_1 \end{pmatrix} - \frac{z^2 f_2(z^3)}{\mathcal{L}_1^3 - \mathcal{L}_2^3}\begin{pmatrix} (2w^2+3v)\mathcal{L}_2 - 2w\mathcal{L}_1^2 \\ 3(w\mathcal{L}_2 - \mathcal{L}_1^2) \\ 9\mathcal{L}_2 \end{pmatrix} + f_3(z^3)\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.$$

For $l_0=2$, we get

$$\nabla_{\mathbf{u}}R = \frac{f_1(z^2)}{\mathcal{L}_1^3 - \mathcal{L}_2^3}\begin{pmatrix} (2w^2+3v)(\mathcal{L}_1 - \mathcal{L}_2) + 2w(\mathcal{L}_1^2 - \mathcal{L}_2^2) \\ 3(w\mathcal{L}_1 - \mathcal{L}_2^2) - 3(w\mathcal{L}_2 - \mathcal{L}_1^2) \\ 9(\mathcal{L}_1 - \mathcal{L}_2) \end{pmatrix}$$
$$+ \frac{zf_2(z^2)}{\mathcal{L}_1^3 - \mathcal{L}_2^3}\begin{pmatrix} (2w^2+3v)(\mathcal{L}_1 + \mathcal{L}_2) - 2w(\mathcal{L}_1^2 + \mathcal{L}_2^2) \\ 3(w\mathcal{L}_1 - \mathcal{L}_2^2) + 3(w\mathcal{L}_2 - \mathcal{L}_1^2) \\ 9(\mathcal{L}_1 + \mathcal{L}_2) \end{pmatrix} + f_3(z^2)\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.$$

From these expressions and (28) and (31) it follows that the corresponding components of $\nabla_{\mathbf{u}}R$ are in $\mathbb{C}((k))$.

Example 1: The case $l_0=3$ with $(d_1,d_2,d_3)=(0,0,1)$. Taking into account (24) and (23) it is clear that there are two trivial equations corresponding to w_0 and u_1. Then, we take for the potentials

$$w = 1, \quad v = v_0(x,t), \quad u = k + u_0(x,t).$$

Thus, by using (29) with

$$f_1 \equiv f_3 \equiv 0, \quad f_2(z^3) = \frac{27(1-\sqrt{3}i)}{4}z^3,$$

we obtain

$$v_{0t} = \tfrac{5}{3}(2 + 27u_0 + 9v_0)u_{0x} + \tfrac{5}{18}(7 + 54u_0 + 36v_0 + 27v_0^2)v_{0x},$$

$$u_{0t} = \tfrac{5}{18}(-1 - 54u_0 + 27v_0{}^2)u_{0x} + \tfrac{5}{9}v_0(2 + 27u_0 + 9v_0)v_{0x}.$$

It can be checked that this system corresponds to the one obtained by setting $M=0$, $N=3$ in (19), and $\alpha=0$, $n=5$ in (21).

Example 2: The case $l_0=2$ with $(d_1,d_2,d_3)=(0,1,0)$, $(l_0=2)$. From (24) and (23) we see that $v_{1t}=0$. We then take

$$w = w_0(x,t), \quad v = k + v_0(x,t), \quad u = u_0(x,t),$$

and

$$f_1(z^2) = z^4, \quad f_2 \equiv f_3 \equiv 0.$$

Thus it follows

$$w_{0t} = 4(w_0u_{0x} + v_0v_{0x} + u_0w_{0x}),$$

$$v_{0t} = -2(w_0^2u_{0x} - 2u_0v_{0x} + u_0w_0w_{0x}) + 2v_0(2u_{0x} - w_0v_{0x}),$$

$$u_{0t} = -2(v_0w_0u_{0x} + u_0(-2u_{0x} + w_0v_{0x} + v_0w_{0x})).$$

It turns out that this system can also be found among the Whitham deformations, by setting $M=1$, $N=2$ in (19), and $\alpha=0$, $n=4$ in (21).

Example 3: The case $l_0=2$ with $(d_1,d_2,d_3)=(1,0,0)$. From (23) and (24) it is easy to see that $(u_0/w_1)_t=0$. If we choose

$$w(k,x,t)=w_1(x,t)k+w_0(x,t),\quad v(k,x,t)=v_0(x,t),$$

$$u(k,x,t)=w_1(x,t),$$

and set

$$f_1(z^2)=z^4,\quad f_2\equiv f_3\equiv 0$$

in (32), then the following system arises:

$$w_{1t}=2w_1^{-2}(w_1w_{0x}-w_0w_{1x}),$$

$$w_{0t}=2w_1^{-3}(w_1(v_{0x}+w_0w_{0x})-(2v_0+w_0^2)w_{1x}),$$

$$v_{0t}=w_1^{-3}(-4w_1w_{1x}+2v_0(w_1w_{0x}-w_0w_{1x})).$$

This is one of the flows in the dispersionless Dym hierarchy corresponding to the curve, $w_1k=p-w_0-v_0p^{-1}-w_1p^{-2}$. Also note that the linear flow, i.e., $w_{1t}=cw_{1x}$, etc., with $c=$constant, can be obtained by the choice $f_2\propto z^{-2}$ with $f_1=f_3=0$.

Example 4: The case $l_0=1$ with $(d_1,d_2,d_3)=(1,0,1)$. From (23) and (24) one finds that $(u_1/w_1)_t=0$. By setting

$$w(k,x,t)=w_1(x,t)k+w_0(x,t),\quad v(k,x,t)=v_0(x,t),$$

$$u(k,x,t)=w_1(x,t)k+u_0(x,t),$$

and

$$R=\frac{2(1+\sqrt{3}i)}{\sqrt{3}}k\mathcal{L}_1,$$

we obtain

$$w_{1t}=u_{0x}+w_{0x},$$

$$w_{0t}=w_1^{-2}(w_1(v_{0x}+u_0w_{0x})-(3+v_0)w_{1x}-w_0^2w_{1x}+w_0(w_1(u_{0x}+2w_{0x})-u_0w_{1x})),$$

$$v_{0t}=w_1^{-2}(w_1(2(2+v_0)u_{0x}+u_0v_{0x}+w_0v_{0x}+2v_0w_{0x})-2(u_0(3+v_0)-(1-v_0)w_0)w_{1x}),$$

$$u_{0t}=w_1^{-2}(-w_0w_1u_{0x}-3u_0^2w_{1x}+v_0(w_1v_{0x}+(1-v_0)w_{1x})+u_0(w_1(4u_{0x}+w_{0x})+w_0w_{1x})).$$

We also note that the linear flow is obtained by choosing $R\propto\mathcal{L}_1$, and the higher flows in the hierarchy can be obtained by $R\propto k^n\mathcal{L}_1$.

Example 5: The case $l_0=1$ with $(d_1,d_2,d_3)=(1,1,0)$. From (23) and (24) we deduce that $(v_1/w_1)_t=0$. Now we take

$$w(k,x,t)=w_1(x,t)k+w_0(x,t),\quad v(k,x,t)=w_1(x,t)k+v_0(x,t),$$

$$u(k,x,t)=u_0(x,t)$$

and set

$$R = \frac{\sqrt{3}+i}{2\sqrt{3}} k\mathcal{L}_2.$$

Then the following system is obtained:

$$w_{1t} = 2u_{0x} - v_{0x},$$

$$w_{0t} = w_1^{-2}(w_1((3+2w_0)u_{0x} - (2+w_0)v_{0x} + (2u_0 - v_0)w_{0x}) + (v_0(2+w_0) - u_0(3+2w_0))w_{1x}),$$

$$v_{0t} = w_1^{-2}(w_1((-2+4v_0-2w_0)u_{0x} + (2u_0 - 3v_0 + w_0)v_{0x}) + (v_0(2v_0 - w_0) + u_0(3-4v_0+2w_0))w_{1x}),$$

$$u_{0t} = w_1^{-2}((-2v_0 + w_0)w_1u_{0x} - 6u_0^2w_{1x} + u_0(w_1(8u_{0x} - 3v_{0x} + w_{0x}) + 2(2v_0 - w_0)w_{1x})).$$

B. Hamiltonian structures

The general structure of integrable deformations (11) does not exhibit a direct Hamiltonian form. However, the analysis of particular cases reveals the presence of certain Hamiltonian structures. We look for a Hamiltonian operator J such that for certain appropriate densities R it verifies

$$J_0(T\nabla_{\mathbf{u}}R)_+ = J(\nabla_{\mathbf{u}}R)_+, \tag{33}$$

where

$$T := \begin{pmatrix} 1 & -w & -v \\ 0 & 1 & -w \\ 0 & 0 & 1 \end{pmatrix}.$$

Thus, if (33) holds then the flows (11) can be written in the pre-Hamiltonian form

$$\partial_t \mathbf{u} = J(\nabla_{\mathbf{u}}R)_+. \tag{34}$$

To achieve our aim we require a k-independent operator T_0 verifying

$$T\nabla_{\mathbf{u}}R = T_0\nabla_{\mathbf{u}}R, \tag{35}$$

so that $J := J_0 \cdot T_0$ is a Hamiltonian operator.

Let us consider first the case $l_0=3$. It involves two classes of cubic curves.

For the case with $(d_1,d_2,d_3)=(0,0,1)$, the potentials are of the form

$$w = w_0(x), \quad v(x) = v_0(x), \quad u = u_0(x) + ku_1(x).$$

The matrix T is k independent so that by setting $J=J_0 \cdot T$ we find the Hamiltonian operator

$$J = \begin{pmatrix} 3\partial_x & -2\partial_x \cdot w & -\partial_x \cdot v \\ -2w\partial_x & 2w\partial_x \cdot w + 2v\partial_x + v_x & (3u+vw)\partial_x + 2u_x + wv_x \\ -v\partial_x & (3u+vw)\partial_x + vw_x + u_x & v\partial_x \cdot v - 2uw\partial_x - (uw)_x \end{pmatrix}. \tag{36}$$

It represents the dispersionless limit of the Hamiltonian structure of the Boussinesq hierarchy.

For the case with (0,1,2) the potentials now are

$$w = w_0(x), \quad v(x) = v_0(x) + kv_1(x),$$

$$u = u_0(x) + ku_1(x) + k^2u_2(x).$$

From (33) one deduces

$$T\nabla_{\mathbf{u}}\mathcal{L}_i = T_0\nabla_{\mathbf{u}}\mathcal{L}_i, \quad i=1,2,$$

$$T\nabla_{\mathbf{u}}\mathcal{L}_3 = \mathcal{L}_3, \tag{37}$$

where T_0 is the k-independent matrix

$$T_0 = \begin{pmatrix} -2 & w & 0 \\ 0 & 1 & -w \\ 0 & 0 & 1 \end{pmatrix}. \tag{38}$$

Moreover $J := J_0 \cdot T_0$ takes the Hamiltonian form

$$J = \begin{pmatrix} -6\partial_x & 4\partial_x \cdot w & 2\partial_x \cdot v \\ 4w\partial_x & -2w\partial_x \cdot w + 2v\partial_x + v_x & (3u - vw)\partial_x + 2u_x - wv_x \\ 2v\partial_x & (3u - vw)\partial_x - vw_x + u_x & -2uw\partial_x - (uw)_x \end{pmatrix}. \tag{39}$$

Thus by setting

$$R = zf_1(z^3)\mathcal{L}_1 + z^2 f_2(z^3)\mathcal{L}_2,$$

equation (11) reduces to the form (34).

For the remaining cases of $l_0=2$ and $l_0=1$, the situation is as follows:

(1) For the sets of degrees (0,1,0) and (0,1,1) for $l_0=2$, the identities (37) with the same operator (38) hold, so that by setting

$$R = f_1(z^2)(\mathcal{L}_1 + \mathcal{L}_2) + zf_2(z^2)(\mathcal{L}_1 - \mathcal{L}_2),$$

Eq. (11) reduces to the form (34) with the Hamiltonian operator (39).

(2) For the sets of degrees (two cases of $l_0=2$ and all the cases of $l_0=1$),

$$(1,0,0),\ (1,0,1),\ (1,1,0),\ (1,1,1),$$

$$(1,1,2),\ (1,2,1),\ (1,2,2),\ (1,2,3),$$

there is no k-independent operator T_0 satisfying (36) for $\nabla_{\mathbf{u}}\mathcal{L}_i$, $(i=1,2)$.

C. Deformations of cubic curves with $w=0$

Deformations of cubic curves of the form

$$p^3 - vp - u = 0, \tag{40}$$

cannot be obtained simply by setting $w=0$ in the above analysis. Indeed, as it is clear from the expression (24) for J_0, the constraint $w=0$ does not constitute a reduction of the flows (11). Therefore, we must apply our deformation scheme to (40) directly.

In terms of the branches p_i the condition $w=0$ reads

$$p_1 + p_2 + p_3 = 0,$$

which is preserved by deformations

$$\partial_t p_i = \partial_x(a_1 + a_2 p_i + a_3 p_i^2) \tag{41}$$

satisfying

$$3a_1 = -(p_1^2 + p_2^2 + p_3^2)a_3. \tag{42}$$

By expressing the potentials as functions of the branches p_1 and p_2,

$$v = p_1^2 + p_2^2 + p_1p_2, \quad u = -(p_1^2p_2 + p_1p_2^2), \tag{43}$$

and using (41) and (42), we obtain

$$\partial_t \mathbf{u} = \mathcal{J}_0 \mathbf{a}, \quad \mathbf{u} := (v\ u)^{\mathsf{T}}, \quad \mathbf{a} := (a_1\ a_2)^{\mathsf{T}}, \tag{44}$$

where

$$\mathcal{J}_0 = \begin{pmatrix} 2p_1 + p_2 & 2p_2 + p_1 \\ -2p_1p_2 - p_2^2 & -2p_1p_2 - p_1^2 \end{pmatrix} \partial_x \begin{pmatrix} p_1 & \frac{1}{3}p_1^2 - \frac{2}{3}(p_2^2 + p_1p_2) \\ p_2 & \frac{1}{3}p_2^2 - \frac{2}{3}(p_1^2 + p_1p_2) \end{pmatrix} = \begin{pmatrix} 2v\partial_x + v_x & 3u\partial_x + 2u_x \\ 3u\partial_x + u_x & \frac{1}{3}(2v^2\partial_x + 2vv_x) \end{pmatrix}. \tag{45}$$

According to our strategy for finding consistent deformations, we use Lenard-type relations

$$\mathcal{J}_0 \mathbf{R} = 0, \quad \mathbf{R} := (r_1\ r_2)^{\mathsf{T}}, \quad r_i \in \mathbb{C}((k)),$$

to generate systems of the form

$$\mathbf{u}_t = \mathcal{J}_0 \mathbf{a}, \quad \mathbf{a} := \mathbf{R}_+. \tag{46}$$

Here $(\cdot)_+$ and $(\cdot)_-$ indicate the parts of non-negative and negative powers in k, respectively. Now from the identity

$$\mathcal{J}_0 \mathbf{a} = \mathcal{J}_0 \mathbf{R}_+ = -\mathcal{J}_0 \mathbf{R}_-,$$

it is clear that a sufficient condition for the consistency of (46) is that the degrees d_2 and d_3 of v and u as polynomials of k satisfy

$$d_3 \leqslant d_2 + 1, \quad 2d_2 \leqslant d_3 + 1.$$

Hence only four nontrivial cases arise for (d_2, d_3)

$$(0,1), \quad (1,1), \quad (1,2), \quad (2,3). \tag{47}$$

We notice that they represent the dispersionless versions of the standard Boussinesq hierarchy and all three hidden hierarchies found by Antonowicz, Fordy, and Liu for the third-order spectral problem.[21]

Solutions of the Lenard relation can be generated by noticing that the operator $\mathcal{J}_0$ admits the factorization

$$\mathcal{J}_0 = U^{\mathsf{T}} \cdot \frac{1}{3} \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix} \partial_x \cdot U, \tag{48}$$

where

$$U := \begin{pmatrix} 2p_1 + p_2 & -2p_1p_2 - p_2^2 \\ 2p_2 + p_1 & -2p_1p_2 - p_1^2 \end{pmatrix} = \begin{pmatrix} \dfrac{\partial v}{\partial p_1} & \dfrac{\partial u}{\partial p_1} \\ \dfrac{\partial v}{\partial p_2} & \dfrac{\partial u}{\partial p_2} \end{pmatrix}. \tag{49}$$

This shows two things,

(i) $\mathcal{J}_0$ is a Hamiltonian operator.
(ii) The gradients $\nabla_{\mathbf{u}} p_i$ of the branches p_1 and p_2 solve the Lenard relations.

Thus our candidates to deformations are the equations of the form

$$\partial_t \mathbf{u} = \mathcal{J}_0(\nabla_{\mathbf{u}} R)_+, \quad R(z,\mathbf{p}) = f_1(z)p_1 + f_2(z)p_2. \tag{50}$$

At this point one applies the same strategy as that used for the curves (7) Sec. III A. We first determine the Newton exponents of the four cases (47) which turn out to be given by

l_0	3	2	1
	(0,1) (1,2)	(1,1)	(2,3)

Then, with the help of Lagrange resolvents, we characterize the functions $R(z,\mathbf{p})$ verifying $\nabla_{\mathbf{u}} R \in \mathbb{C}((k))$ with $k=z^{l_0}$. In summary, one finds the following.

For the case $l_0=3$,

$$R = zf_1(z^3)\mathcal{L}_1 + z^2 f_2(z^3)\mathcal{L}_2, \quad k = z^3. \tag{51}$$

For the case $l_0=2$,

$$R = f_1(z^2)(\mathcal{L}_1 + \mathcal{L}_2) + zf_2(z^2)(\mathcal{L}_1 - \mathcal{L}_2), \quad k = z^2. \tag{52}$$

For the case $l_0=1$, we have $z=k$, so that any function $R(k,\mathbf{p})=f_1(k)\mathcal{L}_1+f_2(k)\mathcal{L}_2$ is appropriate.

Example 1: The case $l_0=3$ with $(d_2,d_3)=(1,2)$. From (44) and (45) we have that $u_{2t}=0$. Then if one takes

$$u(k,x,t) = k^2 + u_1(x,t)k + u_0(x,t), \quad v(k,x,t) = v_1(x,t)k + v_0(x,t),$$

and sets

$$f_1(z^3) = \tfrac{1}{2}(1 + i\sqrt{3})z^3, \quad f_2 \equiv 0,$$

in (51), one gets

$$v_{1t} = -2u_{1x} + \tfrac{5}{9}v_1^2 v_{1x},$$

$$v_{0t} = \tfrac{1}{9}(-18u_{0x} + v_1^2 v_{0x} + 4v_0 v_1 v_{1x}),$$

$$u_{1t} = \tfrac{1}{9}(v_1^2 u_{1x} - 6v_0 v_{1x} - 6v_1 v_{0x} + 6v_1 u_1 v_{1x}),$$

$$u_{0t} = \tfrac{1}{9}(v_1^2 u_{0x} - 6v_0 v_{0x} + 6u_0 v_1 v_{1x}),$$

i.e., the dispersionless version of the *coupled Boussinesq system* (3.20b) in Ref. 21.

Example 2: The case $l_0=2$ with $(d_2,d_3)=(1,1)$. Now, one can see that $v_{1t}=0$. By setting

$$u(k,x,t) = u_1(x,t)k + u_0(x,t), \quad v(k,x,t) = -k + v_0(x,t),$$

and

$$f_1(z^2) = -z^2, \quad f_2 \equiv 0,$$

in (52), we find the system,

$$v_{0t} = -2u_{0x} - 2v_0 u_{1x} - u_1 v_{0x},$$

$$u_{1t} = -4u_1 u_{1x} + \tfrac{2}{3}v_{0x},$$

$$u_{0t} = -u_1 u_{0x} - 3u_0 u_{1x} - \tfrac{2}{3} v_0 v_{0x}.$$

This is the dispersionless version of the system (4.13) in Ref. 21.

D. Whitham deformations of cubic curves

There are four types of cubic curves of the form (19) given by the following equations:

M	0	1	2
	$k=p^3+v_1p+v_0$	$k=p^2+v_0+\dfrac{v_1}{p-w_1}$	$k=p+\dfrac{v_{1,1}}{p-w_1}+\dfrac{v_{2,1}}{p-w_2}$
		$k=p+\dfrac{v_1}{p-w_1}+\dfrac{v_2}{(p-w_1)^2}$	

Note here that the Newton exponent l_0 is given by $l_0=3-M$. Also in Ref. 18, two cases in $M=1$ are shown to be conformally equivalent, i.e., $p=\infty \leftrightarrow p=w_1$.

For $M=0$ the Whitham deformations are reductions of our flows with $w\equiv 0$. But, in general, other Whitham deformations are not of that form. To illustrate this point let us take the class with $M=1$ and $N=2$. The corresponding Newton exponent is $l_0=2$ and there the branches of $\mathbf{p}$ have the following asymptotic behavior as $z\to\infty$:

$$p_1(z) = z + \mathcal{O}\left(\frac{1}{z}\right),$$

$$p_2(z) = p_1(-z) = -z + \mathcal{O}\left(\frac{1}{z}\right),$$

$$p_3(z) = w_1 + \mathcal{O}\left(\frac{1}{z}\right).$$

Let us consider now the Whitham flows (21) associated with the puncture at $p=\infty$,

$$\mathbf{Q}_{0,n} = (z^n)_{\oplus}(\mathbf{p}).$$

In terms of the potentials $\mathbf{u}=(w,v,u)^{\mathsf{T}}$ they read

$$\partial_t \mathbf{u} = J_0 \mathbf{a}, \tag{53}$$

where

$$\mathbf{a} = \left(V^{-1} \begin{pmatrix} (z^n)_{\oplus}(p_1) \\ (z^n)_{\oplus}(p_2) \\ (z^n)_{\oplus}(p_3) \end{pmatrix} \right)_{+}.$$

One easily sees that all matrix elements of V^{-1} are of order $\mathcal{O}(1/z)$ with the exception of

$$(V^{-1})_{13} = 1 + \mathcal{O}\left(\frac{1}{z}\right).$$

On the other hand, we have

$$(z^n)_{\oplus}(p_1) = z^n + \mathcal{O}\left(\frac{1}{z}\right),$$

$$(z^n)_\oplus(p_2) = (-z)^n + \mathcal{O}\left(\frac{1}{z}\right),$$

$$(z^n)_\oplus(p_3) = (z^n)_\oplus(w_1) + \mathcal{O}\left(\frac{1}{z}\right).$$

Therefore one gets

$$\mathbf{a} = \left(z^n V^{-1} \begin{pmatrix} 1 \\ (-1)^n \\ 0 \end{pmatrix} \right)_+ + (z^n)_\oplus(w_1)\mathbf{e}_3,$$

where $\mathbf{e}_3 = (0,0,1)^\mathsf{T}$, so that Eq. (53) becomes

$$\partial_t \mathbf{u} = J_0(T\nabla_\mathbf{u}[z^n(p_1 + (-1)^n p_2)])_+ + J_0((z^n)_\oplus(w_1)\mathbf{e}_3). \tag{54}$$

Similar expressions can be obtained for the deformations generated by the Whitham flows (21) for $\alpha = 1$ and $n \geqslant 1$.

Ince's limits for confluent and double-confluent Heun equations

B. D. Bonorino Figueiredo[a)]

(Received 19 May 2005; accepted 9 September 2005; published online 9 November 2005)

We find pairs of solutions to a differential equation which is obtained as a special limit of a generalized spheroidal wave equation (this is also known as confluent Heun equation). One solution in each pair is given by a series of hypergeometric functions and converges for any finite value of the independent variable z, while the other is given by a series of modified Bessel functions and converges for $|z|>|z_0|$, where z_0 denotes a regular singularity. For short, the preceding limit is called Ince's limit after Ince who have used the same procedure to get the Mathieu equations from the Whittaker-Hill ones. We find as well that, when z_0 tends to zero, the Ince limit of the generalized spheroidal wave equation turns out to be the Ince limit of a double-confluent Heun equation, for which solutions are provided. Finally, we show that the Schrödinger equation for inverse fourth- and sixth-power potentials reduces to peculiar cases of the double-confluent Heun equation and its Ince's limit, respectively. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2104267]

I. INTRODUCTION

First, we construct two linear differential equations whose solutions behave at infinity as the so-called subnormal Thomé solutions, in contrast to solutions of a confluent and double-confluent Heun equations,[1] from which the former equations are obtained by a limit process. Second, we provide solutions which afford the expected asymptotic behavior for these equations. Finally, we find that the Schrödinger equation with inverse fourth- and sixth-power potentials reduces to particular instances of the double-confluent Heun equation and its Ince limit, respectively.

In the first place, let us introduce the two equations under consideration. Our starting point is the generalized spheroidal wave equation (GSWE) in the form used by Leaver,[2] namely,

$$z(z-z_0)\frac{\mathrm{d}^2U}{\mathrm{d}z^2}+(B_1+B_2z)\frac{\mathrm{d}U}{\mathrm{d}z}+\left[B_3-2\eta\omega(z-z_0)+\omega^2z(z-z_0)\right]U=0,\quad(\omega\neq0),\tag{1}$$

where B_i, η, and ω are constants (notice that, if $\omega=0$ and η is fixed, the equation may be transformed into a hypergeometric equation). The points $z=0$ and $z=z_0$ are regular singularities with indices $(0,1+B_1/z_0)$ and $(0,1-B_2-B_1/z_0)$, respectively, while the infinity is an irregular singularity in which the behavior of $U(z)$, inferred from the normal Thomé solutions,[3] is given by

$$\lim_{z\to\infty}U(z)\sim e^{\pm i\omega z}z^{\mp i\eta-(B_2/2)}.\tag{2}$$

Since its parameters are not specified, the above noted GSWE is equivalent to the confluent Heun equation,[1] an equation that is more general than the original Wilson GSWE.[4] Furthermore, as noted by Leaver, for $z_0=0$ we obtain a double-confluent Heun equation (DCHE) having five parameters, rather than four as in other contexts,[5,6] namely,

[a)]Electronic mail: barto@cbpf.br

$$z^2\frac{d^2U}{dz^2}+(B_1+B_2z)\frac{dU}{dz}+\left[B_3-2\eta\omega z+\omega^2z^2\right]U=0,\quad(\omega\neq0,B_1\neq0),\tag{3}$$

where the singular points $z=0$ and $z=\infty$ are both irregular. For $\omega=0$ and/or $B_1=0$ (with η fixed) this equation degenerates into confluent hypergeometric equations (see Appendix A). At infinity, the behavior of $U(z)$ is again given by (2), while at $z=0$ we find in the usual way[3] that

$$\lim_{z\to0}U(z)\sim1\ \text{or}\ \lim_{z\to0}U(z)\sim e^{B_1/z}z^{2-B_2}.\tag{4}$$

The Leaver procedure also allows us to obtain solutions to the DCHE from solutions to the GSWE when z_0 goes to zero. The known Leaver-type solutions[2,7] are appropriate to solve, for instance, the Teukolsky equations for the extreme upper limit of the rotation parameter,[2] the time dependence of Dirac test fields in dust-dominated Friedmann-Robertson-Walker spacetimes, and the Schrödinger equation with asymmetric double-Morse potentials.[7] They are suitable for handling the Schrödinger equation with inverse fourth-power potentials, as we will see.

Now, to get the equations we are interested in, the Leaver limit is combined with a limit that Ince[8] had used to derive the Mathieu equation from the Whittaker-Hill equation. The Ince limit is obtained by taking

$$\omega\to0,\quad\eta\to\infty,\quad\text{such that}\ 2\eta\omega=-q,\tag{5}$$

where q is a constant. Thus, the Ince limit of the GSWE is

$$z(z-z_0)\frac{d^2U}{dz^2}+(B_1+B_2z)\frac{dU}{dz}+[B_3+q(z-z_0)]U=0,\quad(q\neq0).\tag{6}$$

This is a generalization of the Mathieu equation, for by setting

$$z_0=1,\quad B_1=-1/2,\quad B_2=1,\quad z=\cos^2(\sigma u),\quad W(u)=U(z),\tag{7a}$$

we obtain

$$\frac{d^2W}{du^2}+\sigma^2[2q-4B_3-2q\cos(2\sigma u)]W=0,\tag{7b}$$

that is, the Mathieu equation if $\sigma=1$, and the modified Mathieu equation if $\sigma=i$.[9] In fact, inserting $z_0=1, B_1=-1/2$, and $B_2=1$ into Eq. (6), one recovers the algebraic Lindemann form for the Mathieu equation.[10] Nevertheless, the trigonometric form (7b) with $4B_3=2q-a$ is useful to verify that our solutions for the Ince limit of the GSWE give solutions already known for the Mathieu equation.

On the other hand, the Ince limit of the DCHE—or Leaver limit of Eq. (6)—is

$$z^2\frac{d^2U}{dz^2}+(B_1+B_2z)\frac{dU}{dz}+(B_3+qz)U=0,\quad(q\neq0,B_1\neq0),\tag{8}$$

which degenerates into simpler equations if $q=0$ and/or $B_1=0$ (see Appendix A). Solutions are obtained for this special DCHE by taking the Leaver limit of solutions for Eq. (6). By the way, we shall see that the Schrödinger equation for an inverse sixth-power potential is a particular case of Eq. (8), as stated in the first paragraph.

We emphasize that the Ince limits of the GSWE and DCHE, unlike the original GSWE and DCHE, require solutions behaving according to the subnormal Thomé solutions,[3] that is,

$$\lim_{z\to\infty}U(z)\sim e^{\pm2i\sqrt{qz}}z^{(1/4)-(B_2/2)}.\tag{9}$$

Despite this, our main mathematical issue consists in deriving pairs of series solutions to Eqs. (6) and (8)—having the behavior stipulated above at the singular points—from pairs of solutions to

the GSWE. For this we shall again employ the Ince and Leaver limits. The solutions in each pair have the same series coefficients and these satisfy three-term recurrence relations.

In Sec. II, a pair of solutions for the Ince limit of the GSWE is obtained by taking the Ince limit (5) of a known pair of solutions for the GSWE. One solution is given by an expansion in series of hypegeometric functions and converges for any finite z; the other solution is given by an expansion in series of modified Bessel functions and converges for $|z|>|z_0|$. Other pairs are generated by using transformation rules. These rules result from variable substitutions that preserve the form of the differential equations but modify their parameters and/or arguments.

In Sec. III, we find pairs of solutions for the Ince limit of the DCHE by taking the Leaver limit $(z_0\to 0)$ of solutions for the Ince limit of the GSWE. Solutions in series of irregular confluent hypergeometric functions result from expansions in series of hypergeometric functions and converge for any finite z. The other solution in each pair is given by a series of modified Bessel functions and converges for $|z|>0$.

In both of these sections we deal with solutions with and without a phase parameter ν. In general, this ν is introduced in order to assure the convergence of the series when there is no free constant in the differential equation, as in some scattering problems or in equations where z is a variable related to the time.[2,7] Solutions with a phase parameter are two-sided in the sense that the summation index n runs from $-\infty$ to ∞. However, if there is an arbitrary parameter in the equation, we can truncate the series by requiring that $n\geqslant 0$. In this manner, we obtain ν in terms of parameters of the differential equation.

In Sec. IV, we show that the Schrödinger equation with inverse fourth- and sixth-power potentials in fact leads to the DCHE and its Ince limit. Some additional considerations are provided in Sec. V, while in Appendix A we discuss the degenerate cases of the DCHEs, in Appendix B we present an alternative derivation of the expansions in Bessel functions, and in Appendix C we rewrite the Leaver-type solutions for the DCHE in a form appropriate to solve the Schrödinger equation with an inverse fourth-power potential.

II. INCE'S LIMITS FOR THE GENERALIZED SPHEROIDAL WAVE EQUATION

In the following we use transformation rules that permit us to generate new solutions from a given solution for the Ince limit of the GSWE. The rules T_1, T_2, and T_3 in the following are derived from the ones valid for the GSWE[7] and can be checked by substitution of variables. If $U(z)=U(B_1,B_2,B_3;z_0,q;z)$ denotes one solution for Eq. (6), the effects of these rules are as follows

$$T_1U(z)=z^{1+B_1/z_0}U(C_1,C_2,C_3;z_0,q;z),\quad z_0\neq 0,$$

$$T_2U(z)=(z-z_0)^{1-B_2-B_1/z_0}U(B_1,D_2,D_3;z_0,q;z),\quad z_0\neq 0, \tag{10a}$$

$$T_3U(z)=U(-B_1-B_2z_0,B_2,B_3-qz_0;z_0,-q;z_0-z),$$

where

$$C_1=-B_1-2z_0,\quad C_2=2+B_2+\frac{2B_1}{z_0},\quad C_3=B_3+\left(1+\frac{B_1}{z_0}\right)\left(B_2+\frac{B_1}{z_0}\right),$$

$$D_2=2-B_2-\frac{2B_1}{z_0},\quad D_3=B_3+\frac{B_1}{z_0}\left(\frac{B_1}{z_0}+B_2-1\right). \tag{10b}$$

We use only T_1 and T_2. The rule T_3 exchange the position of the regular singular points $z=z_0\leftrightarrow z=0$ and may be used to get an alternative representation for the solutions, but these are not proper for getting the limit $z_0\to 0$.

In Sec. II A we derive two pairs of solutions for the Ince limit of the GSWE—denoted by $(U^0_{i\nu},U^\infty_{i\nu}),i=1,2$—with a phase parameter ν. The superscript "zero" indicates that the series con-

verges in any finite part of the complex plane, while the superscript "infinity" indicates convergence for $|z|>|z_0|$. The second pair of solutions results from the first by means of the rule T_2. In Sec. II B, we truncate these series by taking $n \geqslant 0$ and obtain four pairs of solutions without phase parameter.

A. Solutions with a phase parameter

Denoting by b_n the series coefficients of a solution, their recurrence relations will have the general form

$$\alpha_n b_{n+1} + \beta_n b_n + \gamma_n b_{n-1} = 0, \quad (-\infty < n < \infty), \tag{11a}$$

where $\alpha_n, \beta_n, \gamma_n$, and b_n depend on a phase parameter ν which may be determined from a characteristic equation given as a sum of two infinite continued fractions, namely,

$$\beta_0 = \frac{\alpha_{-1}\gamma_0}{\beta_{-1}-}\frac{\alpha_{-2}\gamma_{-1}}{\beta_{-2}-}\frac{\alpha_{-3}\gamma_{-2}}{\beta_{-3}-}\cdots + \frac{\alpha_0\gamma_1}{\beta_1-}\frac{\alpha_1\gamma_2}{\beta_2-}\frac{\alpha_2\gamma_3}{\beta_3-}\cdots . \tag{11b}$$

For a specific pair of solutions we add a superscript in each of these quantities.

The first pair of solutions for the Ince limit of the GSWE comes from the following pair of solutions of the GSWE[7]

$$U^0_{1\nu}(z) = e^{i\omega z}\sum_{n=-\infty}^{\infty} b_n^{(1)} F\left(\frac{B_2}{2} - n - \nu - 1, n + \nu + \frac{B_2}{2}; B_2 + \frac{B_1}{z_0}; 1 - \frac{z}{z_0}\right),$$

$$U^\infty_{1\nu}(z) = e^{i\omega z} z^{1-(B_2/2)} \sum_{n=-\infty}^{\infty} b_n^{(1)} (-2i\omega z)^{n+\nu} \Psi(n + \nu + 1 + i\eta, 2n + 2\nu + 2; -2i\omega z), \tag{12a}$$

where $F(a,b;c;y)$ and $\Psi(a,b;y)$ denote, respectively, the hypergeometric functions and the irregular confluent hypergeometric functions.[11,12] The solution $U^0_{1\nu}$ converges for any finite z, whereas $U^\infty_{1\nu}$ converges for $|z|>|z_0|$. In the recurrence relations (11a) for $b_n^{(1)}$ we have

$$\alpha_n^{(1)} = i\omega z_0 \frac{\left(n + \nu + 2 - \frac{B_2}{2}\right)\left(n + \nu + 1 - \frac{B_2}{2} - \frac{B_1}{z_0}\right)(n + \nu + 1 - i\eta)}{2(n + \nu + 1)\left(n + \nu + \frac{3}{2}\right)},$$

$$\beta_n^{(1)} = -B_3 - \eta\omega z_0 - \left(n + \nu + 1 - \frac{B_2}{2}\right)\left(n + \nu + \frac{B_2}{2}\right) - \frac{\eta\omega z_0\left(\frac{B_2}{2} - 1\right)\left(\frac{B_2}{2} + \frac{B_1}{z_0}\right)}{(n + \nu)(n + \nu + 1)}, \tag{12b}$$

$$\gamma_n^{(1)} = -i\omega z_0 \frac{\left(n + \nu + \frac{B_2}{2} - 1\right)\left(n + \nu + \frac{B_2}{2} + \frac{B_1}{z_0}\right)(n + \nu + i\eta)}{2\left(n + \nu - \frac{1}{2}\right)(n + \nu)}.$$

Note that ν cannot be integer or half-integer in order to avoid vanishing denominators in the coefficients of the recurrence relations. Moreover, for an integer or half-integer ν, we would have two equal hypergeometric or confluent hypergeometric functions (for different values of n), contrary to the hypothesis that all the terms of the series are independent. On the other hand, the hypergeometric functions are not defined if $B_2+(B_1/z_0)$ is zero or a negative integer. Nonetheless, a transformation rule supplies another solution which is valid for these values of $B_2+(B_1/z_0)$.

The three-term recurrence relations (11a) constitute an infinite system of homogeneous linear equations for which nontrivial solutions for the coefficients b_n demand that the determinant of respective tridiagonal matrix vanishes. Equivalently, the characteristic equation must be satisfied and this is a condition necessary also to assure the convergence of the series by means of a Poincaré-Perron theorem.[13] However, there are two possibilities to satisfy this requirement.

On the one hand, if there is some free constant in the differential equation, that constant must be determined so that the characteristic equation is fulfilled for the admissible values of ν (that is, neither integer nor half-integer). In this case, the freedom of choosing ν may be used in two different ways: (i) to obtain two-sided solutions $(-\infty<n<\infty)$ by ascribing appropriate values for ν, or (ii) to obtain one-sided solutions by choosing ν such that $n\geqslant 0$. At the end of the present section, we use the first alternative to rederive some Poole's solutions[14,15] for the Mathieu equation, having period $2\pi m$, where m is any integer equal or greater than 2. In Sec. II B, we use the second alternative for the general case. These latter solutions afford solutions with period π or 2π for the Mathieu equation, in contrast to the solutions obtained in the first alternative.

On the other hand, if there is no arbitrary parameter in the differential equation, the parameter ν takes the role of free parameter in the sense that it must be adjusted to ensure the validity of the characteristic equation and, consequently, the convergence of the series. For this reason, ν is also called characteristic index or parameter.[16] Examples of equations requiring a phase parameter are discussed in Sec. IV.

From the above-noted pair of solutions for the GSWE, by using the Ince limit (5), we readily find the solution $U_{1\nu}^{0}(z)$ written in the first pair in the following. To get the Ince limit of the solution $U_{1\nu}^{\infty}(z)$, we define c_n as

$$b_n^{(1)}=(i\eta)^{n+\nu}\Gamma(i\eta-n-\nu)c_n.$$

This implies that

$$U_{1\nu}^{\infty}(z)=e^{i\omega z}z^{1-(B_2/2)}\sum_{n=-\infty}^{\infty}c_n\Gamma(i\eta-n-\nu)(-qz)^{n+\nu}\Psi\left(n+\nu+1+i\eta,2n+2\nu+2;-\frac{qz}{i\eta}\right),$$

where $q=-2\eta\omega$. The recurrence relations for c_n are

$$\bar{\alpha}_n c_{n+1}+\beta_n^{(1)}c_n+\bar{\gamma}_n c_{n-1}=0,\quad (-\infty<n<\infty)$$

with

$$\bar{\alpha}_n=\frac{i\eta}{i\eta-n-\nu-1}\alpha_n^{(1)},\quad \bar{\gamma}_n=\frac{i\eta-\nu-1}{i\eta}\gamma_n^{(1)}.$$

On the other hand, we have[12]

$$\lim_{a\to\infty}[\Gamma(a+1-c)\Psi(a,c;x/a)]=2x^{(1-c)/2}K_{c-1}(2\sqrt{x}),\tag{13}$$

where $K_\lambda(\xi)$ denotes the modified Bessel function of the second kind[17] whose definition in terms of irregular confluent hypergeometric functions is[12]

$$K_\lambda(\xi)=K_{-\lambda}(\xi)=\sqrt{\pi}e^{-\xi}(2\xi)^{\lambda}\Psi\left(\lambda+\tfrac{1}{2},2\lambda+1;2\xi\right).\tag{14}$$

Then, using (13) we find that for $i\eta\to\infty$ (n fixed and q=constant)

$$\Gamma(i\eta-n-\nu)(-qz)^{n+\nu}\Psi\left(n+\nu+1+i\eta,2n+2\nu+2;-\frac{qz}{i\eta}\right)$$
$$\to 2(-qz)^{1/2}K_{2n+2\nu+1}(\pm 2i\sqrt{qz}),\quad \lim\bar{\alpha}_n\to\lim\alpha_n^{(1)},\lim\bar{\gamma}_n\to\lim\gamma_n^{(1)}\Rightarrow\lim c_n\to\lim b_n^{(1)}.$$

Using these results, we find the Ince limit of $U_{1\nu}^{\infty}$, written in the first pair in the following. Although this is a formal derivation, the solution may be checked by inserting it into Eq. (6) (see Appendix B). In addition, from the relation[17]

$$\lim_{|\xi|\to\infty} K_\lambda(\xi) \sim \sqrt{\frac{\pi}{2\xi}} e^{-\xi}, \quad -\frac{3\pi}{2} < \arg\,\xi < \frac{3\pi}{2} \tag{15}$$

we see that the expansions in series of Bessel functions have the behavior given by

$$\lim_{z\to\infty} U^{\infty}_{j\nu}(z) \sim e^{\pm 2i\sqrt{qz}} z^{(1/4)-(B_2/2)}, \quad -\frac{3\pi}{2} < \arg(\pm 2i\sqrt{qz}) < \frac{3\pi}{2}, \quad (j=1,2)$$

in accordance with Eq. (9). The second pair of solutions follows from the first one through the rule T_2, as mentioned before. Moreover, solutions for the Mathieu equation are obtained by using Eq. (7a) and by noting that in this case the hypergeometric functions can be rewritten in terms of trigonometric functions.

First pair:

$$U^0_{1\nu}(z) = \sum_{n=-\infty}^{\infty} b_n^{(1)} F\left(\frac{B_2}{2} - n - \nu - 1, n + \nu + \frac{B_2}{2}; B_2 + \frac{B_1}{z_0}; 1 - \frac{z}{z_0}\right),$$

$$U^{\infty}_{1\nu}(z) = z^{(1-B_2)/2} \sum_{n=-\infty}^{\infty} b_n^{(1)} K_{2n+2\nu+1}(\pm 2i\sqrt{qz}), \tag{16a}$$

where in the recurrence relations (11a)

$$\alpha_n^{(1)} = qz_0 \frac{\left(n+\nu+2-\frac{B_2}{2}\right)\left(n+\nu+1-\frac{B_2}{2}-\frac{B_1}{z_0}\right)}{(n+\nu+1)\left(n+\nu+\frac{3}{2}\right)},$$

$$\beta_n^{(1)} = 4B_3 - 2qz_0 + 4\left(n+\nu+1-\frac{B_2}{2}\right)\left(n+\nu+\frac{B_2}{2}\right) - 2qz_0 \frac{\left(\frac{B_2}{2}-1\right)\left(\frac{B_2}{2}+\frac{B_1}{z_0}\right)}{(n+\nu)(n+\nu+1)}, \tag{16b}$$

$$\gamma_n^{(1)} = qz_0 \frac{\left(n+\nu+\frac{B_2}{2}-1\right)\left(n+\nu+\frac{B_2}{2}+\frac{B_1}{z_0}\right)}{\left(n+\nu-\frac{1}{2}\right)(n+\nu)}.$$

If $B_2+(B_1/z_0)$ is zero or a negative integer we have the solution $U^0_{2\nu}$ instead of $U^0_{1\nu}$.

For the Mathieu equation we use Eq. (7a) and the formula[11]

$$F\left[-a, a; (1/2); \sin^2(\sigma u)\right] = \cos(2a\sigma u).$$

Then, we obtain even solutions with respect to u, namely,

$$W^0_{1\nu}(u) = \sum_{n=-\infty}^{\infty} b_n^{(1)} \cos[(2n+2\nu+1)\sigma u], \quad |\cos(\sigma u)| < \infty,$$

$$W^{\infty}_{1\nu}(u) = \sum_{n=-\infty}^{\infty} b_n^{(1)} K_{2n+2\nu+1}[\pm 2i\sqrt{q}\cos(\sigma u)], \quad |\cos(\sigma u)| > 1, \tag{17a}$$

with the simplified recurrence relations ($a=2q-4B_3$)

$$qb_{n+1}^{(1)} + \left[(2n+2\nu+1)^2 - a\right] b_n^{(1)} + qb_{n-1}^{(1)} = 0. \tag{17b}$$

Second pair:

$$U_{2\nu}^{0}(z)=(z-z_0)^{1-B_2-B_1/z_0}z^{1+B_1/z_0}\sum_{n=-\infty}^{\infty}b_n^{(2)}$$
$$\times F\left(-n-\nu-\frac{B_2}{2}+1,n+\nu+2-\frac{B_2}{2};2-B_2-\frac{B_1}{z_0};1-\frac{z}{z_0}\right),$$

$$U_{2\nu}^{\infty}(z)=(z-z_0)^{1-B_2-B_1/z_0}z^{B_1/z_0+B_2/2-\frac{1}{2}}\sum_{n=-\infty}^{\infty}b_n^{(2)}K_{2n+2\nu+1}(\pm 2i\sqrt{qz}), \tag{18a}$$

where

$$\alpha_n^{(2)}=qz_0\frac{\left(n+\nu+\frac{B_2}{2}\right)\left(n+\nu+1+\frac{B_2}{2}+\frac{B_1}{z_0}\right)}{(n+\nu+1)\left(n+\nu+\frac{3}{2}\right)},\quad \beta_n^{(2)}=\beta_n^{(1)},$$
$$\gamma_n^{(2)}=qz_0\frac{\left(n+\nu+1-\frac{B_2}{2}\right)\left(n+\nu-\frac{B_2}{2}-\frac{B_1}{z_0}\right)}{\left(n+\nu-\frac{1}{2}\right)(n+\nu)}, \tag{18b}$$

in the recurrence relations (11a) for $b_n^{(2)}$. If $B_2+(B_1/z_0)$ is a positive integer equal or greater than 2 we have the solution $U_{1\nu}^{0}$ instead of $U_{2\nu}^{0}$. Note that, in writing the solution $U_{2\nu}^{0}$, we have used

$$F(a,b;c;y)=(1-y)^{c-a-b}F(c-a,c-b;c;y). \tag{19}$$

For the Mathieu equation we use[11]

$$F\left(a,1-a;\frac{3}{2};\sin^2(\sigma u)\right)=\frac{\sin[(2a-1)\sigma u]}{(2a-1)\sin(\sigma u)}$$

and, in addition, define c_n as $b_n^{(2)}=(2n+2\nu+1)c_n$. So, we find that the recurrence relations for c_n become identical to the ones for $b_n^{(1)}$, giving the odd solutions

$$W_{2\nu}^{0}(u)=\sum_{n=-\infty}^{\infty}b_n^{(1)}\sin[(2n+2\nu+1)\sigma u],$$
$$W_{2\nu}^{\infty}(u)=\tan(\sigma u)\sum_{n=-\infty}^{\infty}(2n+2\nu+1)b_n^{(1)}K_{2n+2\nu+1}[\pm 2i\sqrt{q}\cos(\sigma u)], \tag{20}$$

where $|\cos(\sigma u)|<\infty$ and $|\cos(\sigma u)|>1$, respectively.

As we have explained earlier, if there is a free parameter in the differential equation, it is possible to satisfy the characteristic equation for any noninteger or half-integer ν. We use this fact to rederive some Poole's solutions[14,15] to the Mathieu equation. For this, in the previous $W_{1\nu}^{0}(u)$ and $W_{1\nu}^{0}(u)$ we take

$$2\nu+1=l/m,\quad \sigma=1, \tag{21}$$

where l and m are integers prime to one another, $l<m$. Then, we find the two-sided Poole solutions $W_1^P(u)$ and $W_1^P(u)$ given by

$$W_1^P(u) = \sum_{n=-\infty}^{\infty} b_n^{(1)} \cos\left[\left(2n + \frac{l}{m}\right)u\right] \quad , W_2^P(u) = \sum_{n=-\infty}^{\infty} b_n^{(1)} \sin\left[\left(2n + \frac{l}{m}\right)u\right]. \tag{22}$$

The first is even with respect to u and the second is odd, and both of them have period $2\pi m, m > 1$. Since they have the same series coefficients, we can combine them to find another Poole solution, that is,

$$W^P(u) = \sum_{n=-\infty}^{\infty} b_n^{(1)} \exp\left[i\left(2n + \frac{l}{m}\right)u\right]. \tag{23}$$

Furthermore, for an arbitrary ν we find

$$W(u) = \sum_{n=-\infty}^{\infty} b_n^{(1)} \exp[i(2n + 2\nu + 1)u], \tag{24}$$

which is also a solution already known in the literature.[11,15]

B. Solutions without phase parameter

Now we truncate the solutions obtained in Sec. II A by taking $n \geqslant 0$. This gives ν in terms of some parameters of the differential equation. The resulting solutions are convergent only if there is a free parameter to be determined from the characteristic equation.

This truncation reverses the procedure by which the solution $U_{1\nu}^0(z)$ for the GSWE, given in Eq. (12a), was obtained. Indeed, that solution was constructed[18] as a generalization of a one-sided series of Jacobi polynomials, constructed by Fackerell and Crossman[19] to solve the angular Teukolsky equations of the relativistic astrophysics. Despite this, the truncated solutions found in Ref. 7 are more general than the Fackerell-Crossman ones because no particular values are attached to the parameters of the GSWE and also because the truncation was extended to the Leaver expansion $U_{1\nu}^{\infty}(z)$. In addition, these one-sided series are suitable to get solutions in finite series, the so called quasi-polynomial solutions. In effect, a solution whose coefficients b_n obey recurrence relations as

$$\alpha_n b_{n+1} + \beta_n b_n + \gamma_n b_{n-1} = 0, \quad n \geqslant 0, \quad b_{-1} = 0$$

becomes a quasi-polynomial solution with $0 \leqslant n \leqslant N-1$ whenever $\gamma_N = 0$ for some $n = N$.[20]

For the truncated solutions—denoted by $(U_i^0, U_i^{\infty}), i = 1,2,3,4$—the recurrence relations and the characteristic equations have one of the three forms written in the following. The first case ($\alpha_{-1} = 0$) is the general one and the others ($\alpha_{-1} \neq 0$) may occur only for special cases,

$$\left.\begin{array}{c} \alpha_0 b_1 + \beta_0 b_0 = 0 \\ \alpha_n b_{n+1} + \beta_n b_n + \gamma_n b_{n-1} = 0 (n \geqslant 1) \end{array}\right\} \Rightarrow \beta_0 = \frac{\alpha_0\gamma_1}{\beta_1 -} \frac{\alpha_1\gamma_2}{\beta_2 -} \frac{\alpha_2\gamma_3}{\beta_3 -} \cdots . \tag{25}$$

$$\left.\begin{array}{c} \alpha_0 b_1 + \beta_0 b_0 = 0 \\ \alpha_1 b_2 + \beta_1 b_1 + [\alpha_{-1} + \gamma_1] b_0 = 0 \\ \alpha_n b_{n+1} + \beta_n b_n + \gamma_n b_{n-1} = 0 (n \geqslant 2) \end{array}\right\} \Rightarrow \beta_0 = \frac{\alpha_0[\alpha_{-1} + \gamma_1]}{\beta_1 -} \frac{\alpha_1\gamma_2}{\beta_2 -} \frac{\alpha_2\gamma_3}{\beta_3 -} \cdots . \tag{26}$$

$$\left.\begin{array}{c} \alpha_0 b_1 + [\beta_0 + \alpha_{-1}] b_0 = 0 \\ \alpha_n b_{n+1} + \beta_n b_n + \gamma_n b_{n-1} = 0 (n \geqslant 1) \end{array}\right\} \Rightarrow \beta_0 + \alpha_{-1} = \frac{\alpha_0\gamma_1}{\beta_1 -} \frac{\alpha_1\gamma_2}{\beta_2 -} \frac{\alpha_2\gamma_3}{\beta_3 -} \cdots . \tag{27}$$

Note that we have $n \geqslant -1$ in $\alpha_n, n \geqslant 0$ in β_n and $n \geqslant 1$ in γ_n.

These forms for the recurrence relations are the same that appear in truncation of the expansions (12a) for the GSWE.[7] As a matter of fact, the solutions of the present section are the Ince

limit of solutions for the GSWE given in Sec. 3 of Ref. 7. However, in order to illustrate how these recurrence relations are obtained, we insert the solution $U_{1\nu}^{\infty}$ given in (16a) into the Ince limit of the GSWE. Then, for $n \geqslant 0$, from Eq. (B4) we find that

$$\sum_{n=0}^{\infty} \alpha_{n-1}^{(1)} b_n^{(1)} K_{2n+2\nu-1}(\xi) + \sum_{n=0}^{\infty} \beta_n^{(1)} b_n^{(1)} K_{2n+2\nu+1}(\xi) + \sum_{n=0}^{\infty} \gamma_{n+1}^{(1)} b_n^{(1)} K_{2n+2\nu+3}(\xi) = 0.$$

Setting $m=n-1, m=n$, and $m=n+1$ in the first, second, and third terms, respectively, this equation becomes

$$\alpha_{-1} b_0 K_{2\nu-1}(\xi) + [\alpha_0 b_1 + \beta_0 b_0] K_{2\nu+1}(\xi) + [\alpha_1 b_2 + \beta_1 b_1 + \gamma_1 b_0] K_{2\nu+3}(\xi) + \sum_{n=2}^{\infty} [\alpha_n b_{n+1} + \beta_n b_n + \gamma_n b_{n-1}] K_{2n+2\nu+1}(\xi) = 0, \tag{28}$$

where we have dropped the upper suffixes. Therefore, if we can choose ν so that $\alpha_{-1}=0$, we find the first set of recurrence relations. However, notice that

$$\alpha_{-1} = \frac{q z_0 \left(\nu + 1 - \frac{B_2}{2}\right)\left(\nu - \frac{B_1}{z_0} - \frac{B_2}{2}\right)}{2\nu(\nu + 1/2)} = 0 \quad \text{if} \begin{cases} \nu = \frac{B_2}{2} - 1 \text{ for } B_2 \neq 1,2; \\ \nu = \frac{B_1}{z_0} + \frac{B_2}{2} \text{ for } \frac{B_1}{z_0} + \frac{B_2}{2} \neq 0, \frac{1}{2}. \end{cases}$$

Hence we see that there are two possible choices for ν and, for each of them we have two cases in which α_{-1} may differ from zero. Let us consider only the case $\nu=(B_2/2)-1$. Then, for the exceptional case $B_2=1(\nu=-1/2)$, we find $K_{2\nu-1}=K_{2\nu+3}=K_2$ (since $K_\lambda=K_{-\lambda}$) and therefore the Bessel functions in the first and third terms of Eq. (28) are equal, giving the recurrence relations (26). Similarly, if $B_2=2(\nu=0)$ we find $K_{2\nu-1}=K_{2\nu+1}=K_1$ and this leads to the recurrence relations (27). In this manner we obtain the first pair given in the following. The remaining can be derived from this by using the transformations rules T_1 and T_2 as

$$(U_1^0, U_1^{\infty}) \overset{T_1}{\leftrightarrow} (U_2^0, U_2^{\infty}) \overset{T_2}{\leftrightarrow} (U_3^0, U_3^{\infty}) \overset{T_1}{\leftrightarrow} (U_4^0, U_4^{\infty}) \overset{T_2}{\leftrightarrow} (U_1^0, U_1^{\infty}).$$

The condition on each pair is imposed in order to assure that the special functions are independent in both solutions; it guarantees that there is no vanishing denominator in the recurrence relations. Furthermore, we have additional restrictions on the parameters of the solutions U_i^0. Thus, if $B_2 + (B_1/z_0)$ is zero or a negative integer, the hypergeometric functions are not defined in U_1^0 and U_2^0 but are defined in U_3^0 and U_4^0, and vice versa. The results for the Mathieu equations are already known,[9] but note that the recurrence relations for this case come from the three equations (25)–(27) above.

First pair: $B_2 \neq 0, -1, -2, \ldots$. This first pair corresponds to $\nu=(B_2/2)-1$ in $(U_{1\nu}^0, U_{1\nu}^{\infty})$,

$$U_1^0(z) = \sum_{n=0}^{\infty} b_n^{(1)} F\left(-n, n + B_2 - 1; B_2 + \frac{B_1}{z_0}; 1 - \frac{z}{z_0}\right),$$

$$U_1^{\infty}(z) = z^{(1-B_2)/2} \sum_{n=0}^{\infty} b_n^{(1)} K_{2n+B_2-1}(\pm 2i\sqrt{qz}), \tag{29a}$$

with the following coefficients

$$\alpha_n^{(1)} = \frac{q z_0 (n+1)\left(n - \frac{B_1}{z_0}\right)}{\left(n + \frac{B_2}{2}\right)\left(n + \frac{B_2}{2} + \frac{1}{2}\right)},$$

$$\beta_n^{(1)} = 4B_3 - 2qz_0 + 4n(n+B_2-1) - \frac{2qz_0\left(\frac{B_2}{2}-1\right)\left(\frac{B_2}{2}+\frac{B_1}{z_0}\right)}{\left(n+\frac{B_2}{2}-1\right)\left(n+\frac{B_2}{2}\right)}, \tag{29b}$$

$$\gamma_n^{(1)} = \frac{qz_0(n+B_2-2)\left(n+B_2+\frac{B_1}{z_0}-1\right)}{\left(n+\frac{B_2}{2}-\frac{3}{2}\right)\left(n+\frac{B_2}{2}-1\right)},$$

in the recurrence relations for the $b_n^{(1)}$, namely: Eq. (25) if $B_2 \neq 1, 2$; Eq. (26) if $B_2=1$; Eq. (27) if $B_2=2$.

For the Mathieu equation we find solutions

$$W_1^0(u) = \sum_{n=0}^{\infty} b_n^{(1)} \cos(2n\sigma u), \quad |\cos(\sigma u)| < \infty,$$
$$W_1^{\infty}(u) = \sum_{n=0}^{\infty} b_n^{(1)} K_{2n}[\pm 2i\sqrt{q}\,\cos(\sigma u)], \quad |\cos(\sigma u)| > 1, \tag{30a}$$

with the simplified recurrence relations

$$qb_1^{(1)} - ab_0^{(1)} = 0, \quad qb_2^{(1)} + [4-a]b_1^{(1)} + 2qb_0^{(1)} = 0,$$
$$qb_{n+1}^{(1)} + [4n^2 - a]b_n^{(1)} + qb_{n-1}^{(1)} = 0 (n \geqslant 2). \tag{30b}$$

These solutions are even with respect to u and, for $\sigma=1$, the solution $W_1^0(u)$ has period π.

Second pair: $(B_2/2)+(B_1/z_0) \neq -1, -3/2, -2, -5/2 \cdots$. This pair of solutions can also be obtained by taking $\nu=(B_2/2)+(B_1/z_0)$ in $(U_{1\nu}^0, U_{1\nu}^0)$,

$$U_2^0(z) = z^{1+(B_1/z_0)} \sum_{n=0}^{\infty} b_n^{(2)} F\left(-n, n+1+B_2+\frac{2B_1}{z_0}; B_2+\frac{B_1}{z_0}; 1-\frac{z}{z_0}\right),$$
$$U_2^{\infty}(z) = z^{(1-B_2)/2} \sum_{n=0}^{\infty} b_n^{(2)} K_{2n+1+B_2+(2B_1/z_0)}(\pm 2i\sqrt{qz}), \tag{31a}$$

where

$$\alpha_n^{(2)} = \frac{qz_0(n+1)\left(n+2+\frac{B_1}{x_0}\right)}{\left(n+1+\frac{B_2}{2}+\frac{B_1}{z_0}\right)\left(n+\frac{3}{2}+\frac{B_2}{2}+\frac{B_1}{z_0}\right)},$$

$$\beta_n^{(2)} = 4B_3 - 2qz_0 + 4\left(n+1+\frac{B_1}{x_0}\right)\left(n+B_2+\frac{B_1}{x_0}\right) - \frac{2qz_0\left(\frac{B_2}{2}-1\right)\left(\frac{B_2}{2}+\frac{B_1}{z_0}\right)}{\left(n+\frac{B_2}{2}+\frac{B_1}{x_0}\right)\left(n+1+\frac{B_2}{2}+\frac{B_1}{x_0}\right)},$$

$$\gamma_n^{(2)} = \frac{qz_0\left(n+B_2+\frac{B_1}{x_0}-1\right)\left(n+B_2+\frac{2B_1}{z_0}\right)}{\left(n-\frac{1}{2}+\frac{B_2}{2}+\frac{B_1}{z_0}\right)\left(n+\frac{B_2}{2}+\frac{B_1}{z_0}\right)}, \tag{31b}$$

in the recurrence relations for $b_n^{(2)}$: Eq. (25) if $(B_2/2)+(B_1/z_0) \neq 0, -1/2$; Eq. (26) if $(B_2/2)+(B_1/z_0)=-1/2$; Eq. (27) if $(B_2/2)+(B_1/z_0)=0$.

For the Mathieu equation we again have even solutions

$$W_2^0(u) = \sum_{n=0}^{\infty} b_n^{(2)} \cos[(2n+1)\sigma u], \quad |\cos(\sigma u)| < \infty,$$

$$W_2^{\infty}(u) = \sum_{n=0}^{\infty} b_n^{(2)} K_{2n+1}[\pm 2i\sqrt{q}\,\cos(\sigma u)], \quad |\cos(\sigma u)| > 1, \tag{32a}$$

with the recurrence relations

$$qb_1^{(2)} + [q+1-a]b_0^{(2)} = 0,$$

$$qb_{n+1}^{(2)} + [(2n+1)^2 - a]b_n^{(2)} + qb_{n-1}^{(2)} = 0 (n \geqslant 1). \tag{32b}$$

If $\sigma=1$ the solution $W_2^0(u)$ has period 2π.

Third pair: $B_2 \neq 4, 5, 6, \cdots$. This corresponds to $\nu = 1-(B_2/2)$ in $(U_{2\nu}^0, U_{2\nu}^{\infty})$,

$$U_3^0(z) = (z-z_0)^{1-B_2-B_1/z_0} z^{1+B_1/z_0} \sum_{n=0}^{\infty} b_n^{(3)} F\left(-n, n+3-B_2; 2-B_2-\frac{B_1}{z_0}; 1-\frac{z}{z_0}\right),$$

$$U_3^{\infty}(z) = (z-z_0)^{1-B_2-B_1/z_0} z^{B_1/z_0+B_2/2-1/2} \sum_{n=0}^{\infty} b_n^{(3)} K_{2n+3-B_2}(\pm 2i\sqrt{qz}), \tag{33a}$$

with the coefficients

$$\alpha_n^{(3)} = \frac{qz_0(n+1)\left(n+2+\frac{B_1}{z_0}\right)}{\left(n+2-\frac{B_2}{2}\right)\left(n+\frac{5}{2}-\frac{B_2}{2}\right)},$$

$$\beta_n^{(3)} = 4B_3 - 2qz_0 + 4(n+1)(n+2-B_2) - \frac{2qz_0\left(\frac{B_2}{2}-1\right)\left(\frac{B_2}{2}+\frac{B_1}{z_0}\right)}{\left(n+1-\frac{B_2}{2}\right)\left(n+2-\frac{B_2}{2}\right)}, \tag{33b}$$

$$\gamma_n^{(3)} = \frac{qz_0(n+2-B_2)\left(n+1-B_2-\frac{B_1}{z_0}\right)}{\left(n+\frac{1}{2}-\frac{B_2}{2}\right)\left(n+1-\frac{B_2}{2}\right)}.$$

in the recurrence relations: Eq. (25) if $B_2 \neq 2, 3$; Eq. (26) if $B_2=3$; Eq. (27) if $B_2=2$.

For the Mathieu equation we redefine the coefficients $b_n^{(3)}$ as $b_n^{(3)} \to (2n+2)b_n^{(3)}$. Then we find the odd solutions

$$W_3^0(u) = \sum_{n=0}^{\infty} b_n^{(3)} \sin[(2n+2)\sigma u], \quad |\cos(\sigma u)| < \infty,$$

$$W_3^{\infty}(u) = \tan(\sigma u) \sum_{n=0}^{\infty} (2n+2) b_n^{(3)} K_{2n+2}[\pm 2i\sqrt{q}\cos(\sigma u)], \quad |\cos(\sigma u)| > 1, \tag{34a}$$

with the recurrence relations

$$qb_1^{(3)} + [4-a]b_0^{(3)} = 0,$$

$$qb_{n+1}^{(3)} + [4(n+1)^2 - a]b_n^{(3)} + qb_{n-1}^{(3)} = 0, \quad (n \geqslant 1). \tag{34b}$$

For $\sigma=1$ the solution $W_3^0(u)$ has period π.

Fourth pair: $(B_2/2)+(B_1/z_0)\neq 1,3/2,2,5/2\cdots$. This can also be obtained by setting $\nu=-(B_2/2)-(B_1/z_0)$ in $(U^0_{2\nu},U^\infty_{2\nu})$,

$$U_4^0=(z-z_0)^{1-B_2-B_1/z_0}\sum_{n=0}^{\infty}b_n^{(4)}F\left(-n,n+1-B_2-\frac{2B_1}{z_0};2-B_2-\frac{B_1}{z_0};1-\frac{z}{z_0}\right),$$

$$U_4^\infty=(z-z_0)^{1-B_2-B_1/z_0}z^{B_1/z_0+B_2/2-\frac{1}{2}}\sum_{n=0}^{\infty}b_n^{(4)}K_{2n+1-B_2-(2B_1/z_0)}(\pm 2i\sqrt{qz}), \tag{35a}$$

with coefficients

$$\alpha_n^{(4)}=\frac{qz_0(n+1)\left(n-\frac{B_1}{z_0}\right)}{\left(n+1-\frac{B_2}{2}-\frac{B_1}{z_0}\right)\left(n+\frac{3}{2}-\frac{B_2}{2}-\frac{B_1}{z_0}\right)},$$

$$\beta_n^{(4)}=4B_3-2qz_0+4\left(n-\frac{B_1}{z_0}\right)\left(n-B_2+1-\frac{B_1}{z_0}\right)-\frac{2qz_0\left(\frac{B_2}{2}-1\right)\left(\frac{B_2}{2}+\frac{B_1}{z_0}\right)}{\left(n-\frac{B_2}{2}-\frac{B_1}{z_0}\right)\left(n+1-\frac{B_2}{2}-\frac{B_1}{z_0}\right)}, \tag{35b}$$

$$\gamma_n^{(4)}=\frac{qz_0\left(n+1-B_2-\frac{B_1}{z_0}\right)\left(n-B_2-\frac{2B_1}{z_0}\right)}{\left(n-\frac{1}{2}-\frac{B_2}{2}-\frac{B_1}{z_0}\right)\left(n-\frac{B_2}{2}-\frac{B_1}{z_0}\right)},$$

in the recurrence relations: Eq. (25) if $(B_2/2)+(B_1/z_0)\neq 0,1/2$; Eq. (26) if $(B_2/2)+(B_1/z_0)=1/2$; Eq. (27) if $(B_2/2)+(B_1/z_0)=0$.

For the Mathieu equation we redefine $b_n(4)$ according to $b_n^{(4)}\to(2n+1)b_n^{(4)}$ and find the odd solutions

$$W_4^0(u)=\sum_{n=0}^{\infty}b_n^{(4)}\sin[(2n+1)\sigma u],\quad |\cos(\sigma u)|<\infty,$$

$$W_4^\infty(u)=\tan(\sigma u)\sum_{n=0}^{\infty}(2n+1)b_n^{(4)}K_{2n+1}[\pm 2i\sqrt{q}\cos(\sigma u)],\quad |\cos(\sigma u)|>1, \tag{36a}$$

with the recurrence relations

$$qb_4^{(4)}+[1-q-a]b_0^{(4)}=0,$$

$$qb_{n+1}^{(4)}+[(2n+1)^2-a]b_n^{(4)}+qb_{n-1}^{(4)}=0(n\geqslant 1). \tag{36b}$$

Now, for $\sigma=1$, $W_4^0(u)$ has period 2π.

III. INCE'S LIMITS FOR THE DOUBLE-CONFLUENT HEUN EQUATION

As in the case of the Ince limit of the GSWE, we have found no solution in the literature for the Ince limit of the DCHE. The solutions in the following are obtained by taking the limit $z_0\to 0$ (Leaver limit) of the solutions given in Sec. II for the Ince limit of the GSWE. For this we use the formulas[12]

$$\lim_{c\to\infty}F\left(a,b;c;1-\frac{c}{y}\right)=y^a\Psi(a,a+1-b;y), \tag{37a}$$

$$\lim_{\alpha\to\infty}\left(1+\frac{y}{\alpha}\right)^{\alpha}=e^{y}\Rightarrow\lim_{z_0\to 0}\left(1-\frac{z_0}{z}\right)^{-B_1/z_0}=e^{B_1/z}. \tag{37b}$$

Actually, it is not necessary to use the second equation above, since we can get one pair of solutions as the limit of the first pair of Sec. II A and, then, generate the other pair by means of the transformation rule

$$\tau U(z)=e^{B_1/z}z^{2-B_2}U(-B_1,4-B_2,B_3+2-B_2;q;z), \tag{38}$$

where $U(z)=U(B_1,B_2,B_3;q;z)$ denotes known solutions of Eq. (8). On the other hand, to check that the solutions $U_i^0(z)$ exhibit the behavior given in Eq. (4) when $z\to 0$, we may use the relation[12]

$$\lim_{|y|\to\infty}\Psi(a,b;y)\sim y^{-a}[1+O(|y|^{-1}],\quad -\frac{3\pi}{2}<\arg y<\frac{3\pi}{2}. \tag{39}$$

A. Solutions with a phase parameter

For the solution $U_{1\nu}^0$ of Sec. II A, we find that the limit of the hypergeometric functions when z_0 tends to zero, B_2 and B_1 being fixed ($c=B_2+B_1/z_0\to\infty$), is given by

$$\lim_{z_0\to 0}F\left(n+\nu+\frac{B_2}{2},-n-\nu-1+\frac{B_2}{2};B_2+\frac{B_1}{z_0};1-\frac{z}{z_0}\right)$$
$$\propto z^{-\nu-\frac{B_2}{2}}\left(\frac{B_1}{z}\right)^{n}\Psi\left(n+\nu+\frac{B_2}{2},2n+2\nu+2;\frac{B_1}{z}\right).$$

Then, considering also the solution $U_{1\nu}^{\infty}$ and the limits for the coefficients in the recurrence relations, we get the first pair of solutions with a phase parameter ν (different of integer or half-integer). The rule τ leads to the second pair.

First pair:

$$U_{1\nu}^0(z)=z^{-\nu-B_2/2}\sum_{n=-\infty}^{\infty}b_n^{(1)}\left(\frac{B_1}{z}\right)^{n}\Psi\left(n+\nu+\frac{B_2}{2},2n+2\nu+2;\frac{B_1}{z}\right),$$
$$U_{1\nu}^{\infty}(z)=z^{(1-B_2)/2}\sum_{n=-\infty}^{\infty}b_n^{(1)}K_{2n+2\nu+1}(\pm 2i\sqrt{qz}), \tag{40a}$$

where in the recurrence relations (11a))

$$\alpha_n^{(1)}=-\frac{qB_1\left(n+\nu+2-\frac{B_2}{2}\right)}{(n+\nu+1)\left(n+\nu+\frac{3}{2}\right)},$$

$$\beta_n^{(1)}=4B_3+4\left(n+\nu+1-\tfrac{B_2}{2}\right)\left(n+\nu+\tfrac{B_2}{2}\right)-\frac{qB_1(B_2-2)}{(n+\nu)(n+\nu+1)},$$

$$\gamma_n^{(1)}=\frac{qB_1\left(n+\nu+\frac{B_2}{2}-1\right)}{\left(n+\nu-\frac{1}{2}\right)(n+\nu)}. \tag{40b}$$

Second pair:

$$U_{2\nu}^0(z)=e^{B_1/z}z^{-\nu-B_2/2}\sum_{n=-\infty}^{\infty}b_n^{(2)}\left(-\frac{B_1}{z}\right)^{n}\Psi\left(n+\nu+2-\frac{B_2}{2},2n+2\nu+2;-\frac{B_1}{z}\right), \tag{41a}$$

$$U_{2\nu}^{\infty}(z) = e^{B_1/z} z^{(1-B_2)/2} \sum_{n=-\infty}^{\infty} b_n^{(2)} K_{2n+2\nu+1}(\pm 2i\sqrt{qz}),$$

where

$$\alpha_n^{(2)} = \frac{qB_1\left(n+\nu+\frac{B_2}{2}\right)}{(n+\nu+1)\left(n+\nu+\frac{3}{2}\right)}, \quad \beta_n^{(2)} = \beta_n^{(1)}, \quad \gamma_n^{(2)} = -\frac{qB_1\left(n+\nu+1-\frac{B_2}{2}\right)}{\left(n+\nu-\frac{1}{2}\right)(n+\nu)}, \tag{41b}$$

in the recurrence relations (11a) for $b_n^{(2)}$.

B. Solutions without phase parameter

These solutions may be derived by truncating the solutions of Sec. III A. In this case, we see that there is only one choice for ν in each pair. Alternatively, the solutions can be found by applying the Leaver procedure to the first and third pairs of Sec. II B.

First pair: $B_2 \neq 0, -1, -2, \cdots$. This corresponds to $\nu=(B_2/2)-1$ in $(U_{1\nu}^0, U_{1\nu}^{\infty})$.

$$U_1^0(z) = z^{1-B_2} \sum_{n=0}^{\infty} b_n^{(1)} \left(\frac{B_1}{z}\right)^n \Psi\left(n + B_2 - 1, 2n + B_2; \frac{B_1}{z}\right),$$

$$U_1^{\infty}(z) = z^{(1-B_2)/2} \sum_{n=0}^{\infty} b_n^{(1)} K_{2n+B_2-1}(\pm 2i\sqrt{qz}), \tag{42a}$$

with the following coefficients:

$$\alpha_n^{(1)} = -\frac{qB_1(n+1)}{\left(n+\frac{B_2}{2}\right)\left(n+\frac{B_2}{2}+\frac{1}{2}\right)},$$

$$\beta_n^{(1)} = 4B_3 + 4n(n+B_2-1) - \frac{qB_1(B_2-2)}{\left(n+\frac{B_2}{2}-1\right)\left(n+\frac{B_2}{2}\right)}, \tag{42b}$$

$$\gamma_n^{(1)} = \frac{qB_1(n+B_2-2)}{\left(n+\frac{B_2}{2}-\frac{3}{2}\right)\left(n+\frac{B_2}{2}-1\right)}.$$

in the recurrence relations for the $b_n^{(1)}$: Eq. (25) if $B_2 \neq 1, 2$; Eq. (26) if $B_2=1$; Eq. (27) if $B_2=2$.

Second pair: $B_2 \neq 4, 5, 6, \cdots$. It corresponds to $\nu=1-(B_2/2)$ in $(U_{2\nu}^0, U_{2\nu}^{\infty})$ but can also be obtained from the first pair via the rule τ.

$$U_2^0(z) = e^{B_1/z} z^{-1} \sum_{n=0}^{\infty} b_n^{(2)} \left(-\frac{B_1}{z}\right)^n \Psi\left(n + 3 - B_2, 2n + 4 - B_2; -\frac{B_1}{z}\right),$$

$$U_2^{\infty}(z) = e^{B_1/z} z^{(1-B_2)/2} \sum_{n=0}^{\infty} b_n^{(2)} K_{2n+3-B_2}(\pm 2i\sqrt{qz}), \tag{43a}$$

where

$$\alpha_n^{(3)} = \frac{qB_1(n+1)}{\left(n+2-\frac{B_2}{2}\right)\left(n+\frac{5}{2}-\frac{B_2}{2}\right)},$$

$$\beta_n^{(3)} = 4B_3 + 4(n+1)(n+2-B_2) - \frac{qB_1(B_2-2)}{\left(n+1-\frac{B_2}{2}\right)\left(n+2-\frac{B_2}{2}\right)}, \tag{43b}$$

$$\gamma_n^{(3)} = -\frac{qB_1(n+2-B_2)}{\left(n+\frac{1}{2}-\frac{B_2}{2}\right)\left(n+1-\frac{B_2}{2}\right)}.$$

in the recurrence relations for $b_n^{(2)}$: Eq. (25) if $B_2 \neq 2,3$; Eq. (26) if $B_2=3$; Eqs. (27) if $B_2=2$.

IV. POTENTIAL APPLICATIONS

As we have mentioned, the Schrödinger equation with inverse fourth- and sixth-power potentials can be reduced, respectively, to the double-confluent Heun equation (3) and its Ince limit (8). Singular potentials like these have appeared in the description of intermolecular forces[21] and in the scattering of ions by polarizable atoms. For the sake of illustration, we consider the last problem.

Before discussing these examples, let us present the so-called normal forms of the DCHE, that is, the forms in which there is no first-order derivative terms in the differential equations. The general procedure for this, consists in writing the equation as

$$\frac{\mathrm{d}^2U}{\mathrm{d}z^2} + p(z)\frac{\mathrm{d}U}{\mathrm{d}z} + q(z)U = 0.$$

Then, the substitution

$$U(z) = F(z)\exp\left(-\frac{1}{2}\int p(z)\mathrm{d}z\right)$$

gives a first normal form, namely,

$$\frac{\mathrm{d}^2F}{\mathrm{d}z^2} + I(z)F = 0, \quad I(z) = q(z) - \frac{1}{2}\frac{\mathrm{d}p(z)}{\mathrm{d}z} - \frac{1}{4}[p(z)]^2.$$

From this, other normal forms are obtained by the transformations

$$z = h(\vartheta), \quad F(z) = \sqrt{\frac{\mathrm{d}h}{\mathrm{d}\vartheta}}G(\vartheta)$$

which yield

$$\frac{\mathrm{d}^2G}{\mathrm{d}\vartheta^2} + J(\vartheta)G = 0, \quad J(\vartheta) = I[h(\vartheta)]\left(\frac{\mathrm{d}h}{\mathrm{d}\vartheta}\right)^2 + \frac{1}{2}\frac{\mathrm{d}^3h}{\mathrm{d}\vartheta^3}\Big/\frac{\mathrm{d}h}{\mathrm{d}\vartheta} - \frac{3}{4}\left(\frac{\mathrm{d}^2h}{\mathrm{d}\vartheta^2}\Big/\frac{\mathrm{d}h}{\mathrm{d}\vartheta}\right)^2.$$

By employing this procedure, Lemieux and Bose[22] have derived several normal forms for the general Heun equation and its confluent cases, excepting the triconfluent equation. These forms are useful to recognize whether a given equation belongs to the Heun class. Nevertheless, to find the solutions for the equation, we have to come back to the form for which the solutions were established, as in the following. The three Lemieux-Bose normal forms for the DCHE, together with the transformations of variables, are the following:

$$\begin{gathered} U(z) = z^{-B_2/2}e^{B_1/(2z)}F(z), \\ \frac{\mathrm{d}^2F}{\mathrm{d}z^2} + \left[\omega^2 - \frac{2\eta\omega}{z} + \frac{1}{z^2}\left(B_3 - \frac{B_2^2}{4} + \frac{B_2}{2}\right) + \frac{B_1}{z^3}\left(1 - \frac{B_2}{2}\right) - \frac{B_1^2}{4z^4}\right]F = 0; \end{gathered} \tag{44}$$

$$\begin{gathered} z = \rho^2, \quad U(z) = \rho^{(1-2B_2)/2}e^{B_1/(2\rho^2)}G(\rho) \Leftrightarrow G(\rho) = z^{(2B_2-1)/4}e^{-B_1/(2z)}U(z), \\ \frac{\mathrm{d}^2G}{\mathrm{d}\rho^2} + \left[4\omega^2\rho^2 - 8\eta\omega + \frac{4}{\rho^2}\left(B_3 - \frac{B_2^2}{4} + \frac{B_2}{2} - \frac{3}{16}\right) + \frac{4B_1}{\rho^4}\left(1 - \frac{B_2}{2}\right) - \frac{B_1^2}{\rho^6}\right]G = 0; \end{gathered} \tag{45}$$

$$z=e^{\lambda u},\quad U(z)=H(u)\exp\left[\frac{1}{2}\lambda(1-B_2)u+\frac{B_1}{2}e^{-\lambda u}\right]\Leftrightarrow H(u)=z^{(B_2-1)/2}e^{-B_1/(2z)}U(z),$$
$$\frac{\mathrm{d}^2H}{\mathrm{d}u^2}+\lambda^2\left[B_3-\left(\frac{1-B_2}{2}\right)^2-\frac{B_1^2}{4}e^{-2\lambda u}-B_1\left(\frac{B_2}{2}-1\right)e^{-\lambda u}-2\eta\omega e^{\lambda u}+\omega^2e^{2\lambda u}\right]H=0, \tag{46}$$

where λ is a constant at our disposal, for example, $\lambda=1$ or $\lambda=i$. Note that, since these transformations involve neither η nor ω, their Ince limits are obtained by putting $\omega^2=0$ and $2\eta\omega=-q$.

Now we proceed with the scattering problem. The radial part $R(r)=\chi(r)/r$ of the wave function for the Schrödinger equation in three dimensions, for a particle with mass μ and energy E, is

$$\frac{\mathrm{d}^2\chi(r)}{\mathrm{d}r^2}+\left[k^2-\frac{l(l+1)}{r^2}-\frac{2\mu}{\hbar^2}V(r)\right]\chi(r)=0, \tag{47}$$

where $k^2=2\mu E/\hbar^2$, l is the angular momentum, and $V(r)$ is the potential. Now, according to Kleinman, Hahn, and Spruch,[23] for the interaction of a light particle of charge e' with a fixed atom of charge $Z\bar{e}$ containing z' electrons, we have

$$V(r)=\frac{(Z-z')\bar{e}e'}{r}-\frac{\alpha_1'(e')^2}{2r^4}-(\alpha_2'-6a_0\beta_1')\frac{(e')^2}{2r^6}, \tag{48}$$

where r is the distance from the incident ion to the atom, $a_0=\hbar^2/(\mu\bar{e}^2)$ is the Bohr radius, α_1', and α_2' are, respectively, the electric dipole and quadrupole polarizabilities of the atom and β_1' is a parameter resulting from a nonadiabatic correction (α_1',α_2', and β_1' are constants which describe the properties of the target only). For this potential, the Schrödinger equation becomes

$$\frac{\mathrm{d}^2\chi}{\mathrm{d}r^2}+\left[k^2-\frac{2\mu(Z-z')\bar{e}e'}{\hbar^2r}-\frac{l(l+1)}{r^2}+\frac{\mu\alpha_1'(e')^2}{\hbar^2r^4}+\frac{\mu(\alpha_2'-6a_0\beta_1')(e')^2}{\hbar^2r^6}\right]\chi=0. \tag{49}$$

Therefore, for neutral targets ($Z=z'$) this is a particular case of the Ince limit of the DCHE, as we see from Eq. (45) with $\omega^2=0,2\eta\omega=-q$, and $z=\rho^2=r^2$. On the other hand, if the inverse sixth-power term vanishes ($\alpha_2'=6a_0\beta_1'$), this radial Schrödinger equation is a particular case of the DCHE as seen from Eq. (44) with $B_2=2$, for neutral or ionized targets. In both cases the energy of the incident particle (k^2) is given and, consequently, there is no free parameter in these equations since the other constants are also fixed. Then, convergent solutions require a phase parameter ν, analogous to the scattering by the field of an electric dipole.[2] To obtain the radial dependence $R(r)$ we must convert Eq. (49) into the DCHE (3) and its limit (8). In the following we discuss only the asymptotic behaviors of solutions for each case. For this reason, we do not write the recurrence relations for the coefficients.

Potential with inverse fourth- and sixth-power terms. Equation (45) suggests the substitutions

$$z=r^2,\quad \chi(r)=e^{-B_1/(2r^2)}r^{B_2-(1/2)}U(z=r^2)\ \text{with}$$

$$B_1=\pm\frac{e'}{\hbar}\sqrt{\mu(6a_0\beta_1'-\alpha_2')},\quad B_2=2-\frac{\alpha_1'(e')^2}{2\hbar^2B_1},\quad (6a_0\beta_1'\neq\alpha_2'),$$

which transform the Schrödinger equation (49) into

$$z^2\frac{\mathrm{d}^2U}{\mathrm{d}z^2}+(B_1+B_2z)\frac{\mathrm{d}U}{\mathrm{d}z}+\left[\left(\frac{B_2}{2}-\frac{1}{4}\right)\left(\frac{B_2}{2}-\frac{3}{4}\right)-\frac{l(l+1)}{4}+\frac{k^2}{4}z-\frac{\mu}{2}(Z-z')\sqrt{z}\right]U=0.$$

Then, for $Z\neq z'$, the Schrödinger equation is more general than the Ince limit of DCHE. However, assuming a neutral target, we may form two pairs of solutions according to

$$R_{i\nu}(r) = \frac{1}{r}\chi_{i\nu}(r) = e^{-B_1/(2r^2)} r^{B_2-(3/2)} U_{i\nu}(z=r^2) \quad (i=1,2), \tag{50}$$

where on the right-hand side the $U_{i\nu}$ represent the solutions with a phase parameter for the Ince limit of the DCHE, given in Sec. III A. Then, taking into account that for this case $q=k^2/4 = \mu E/(2\hbar^2)$ and $z=r^2$, we find

$$R^0_{1\nu}(r) = e^{-B_1/(2r^2)} r^{-2\nu-3/2} \sum_{n=-\infty}^{\infty} b_n^{(1)} \left(\frac{B_1}{r^2}\right)^n \Psi\left(n+\nu+\frac{B_2}{2}, 2n+2\nu+2; \frac{B_1}{r^2}\right),$$

$$R^\infty_{1\nu}(r) = e^{-B_1/(2r^2)} r^{-1/2} \sum_{n=-\infty}^{\infty} b_n^{(1)} K_{2n+2\nu+1}(\pm ikr); \tag{51}$$

$$R^0_{2\nu}(r) = e^{B_1/(2r^2)} r^{-2\nu-3/2} \sum_{n=-\infty}^{\infty} b_n^{(2)} \left(-\frac{B_1}{r^2}\right)^n \Psi\left(n+\nu+2-\frac{B_2}{2}, 2n+2\nu+2; -\frac{B_1}{r^2}\right),$$

$$R^\infty_{2\nu}(r) = e^{B_1/(2r^2)} r^{-1/2} \sum_{n=-\infty}^{\infty} b_n^{(2)} K_{2n+2\nu+1}(\pm ikr). \tag{52}$$

From these expressions we obtain

$$\lim_{r\to\infty} R^\infty_{1\nu}(r) \propto \lim_{r\to\infty} R^\infty_{2\nu}(r) \sim \frac{e^{\mp ikr}}{r}, \quad -\frac{3\pi}{2} < \arg(\pm ikr) < \frac{3\pi}{2}, \tag{53}$$

where we have employed the limit (15) for the modified Bessel functions. Thus, when $r\to\infty$, the solutions $R^\infty_{i\nu}$ are bounded even if k is a pure imaginary, since in this case $\exp(ikr)$ or $\exp(-ikr)$ goes to zero. At $r=0$, Eq. (39) implies that

$$\lim_{r\to 0} R^0_{1\nu}(r) \sim e^{-B_1/r^2} r^{B_2-(3/2)}, \quad -\frac{3\pi}{2} < \arg\frac{B_1}{r^2} < \frac{3\pi}{2},$$

$$\lim_{r\to 0} R^0_{2\nu}(r) \sim e^{B_1/r^2} r^{(5/2)-B_2}, \quad -\frac{3\pi}{2} < \arg\left(-\frac{B_1}{r^2}\right) < \frac{3\pi}{2}. \tag{54}$$

Then, if B_1 is a positive real number, the first limit goes to zero; if B_1 is a negative real number, the second limit goes to zero. However, if B_1 is a pure imaginary, we write

$$B_1 = iC, \quad B_2 = 2 + \frac{i\alpha_1'(e')^2}{2\hbar^2 C},$$

where C is real. Thus we find

$$|R^0_{1\nu}(r)| \propto |R^0_{2\nu}(r)| \sim \sqrt{r} \to 0.$$

Therefore, it is possible to find at least one pair of solutions for which both the solutions are bounded at the singularities.

Potential without inverse sixth-power term. From Eq. (44) we find that the substitutions

$$z = r, \quad \chi(r) = e^{-B_1/(2r)} r^{B_2/2} U(z=r) \quad \text{with } \hbar^2 B_1^2 = -4\mu(e')^2, \quad B_2 = 2$$

transform the Schrödinger equation (49) into

$$r^2\frac{\mathrm{d}^2U}{\mathrm{d}r^2}+(B_1+2r)\frac{\mathrm{d}U}{\mathrm{d}r}+\left[-l(l+1)-\frac{2\mu}{\hbar^2}(Z-z')\bar{e}e'r+k^2r^2+\frac{\mu(\alpha_2'-6a_0\beta_1')(e')^2}{\hbar^2r^4}\right]U=0. \tag{55}$$

Thus, in the absence of the inverse sixth-power term, the radial Schrödinger equation, even if we have a Coulomb term in the potential, may be solved by

$$R_{i\nu}(r)=e^{-B_1/(2r)}U_{i\nu}(z=r), \tag{56}$$

where $U_{i\nu}(z=r)$ are solutions with a phase parameter for the DCHE with $z=r$ and $B_2=2$ (see Appendix B). As

$$\omega=\pm k\leftrightarrow\pm\eta=\pm\frac{\mu}{k\hbar^2}(Z-z')\bar{e}e',\quad k=\frac{\sqrt{2\mu E}}{\hbar}, \tag{57}$$

those solutions give

$$\begin{aligned}R_{1\nu}^0(r)&=e^{\pm ikr-B_1/2r}\sum_{n=-\infty}^{\infty}b_n\left(\frac{B_1}{r}\right)^{n+\nu+1}\Psi\left(n+\nu+1,2n+2\nu+2;\frac{B_1}{r}\right),\\ R_{1\nu}^{\infty}(r)&=e^{\pm ikr-B_1/2r}\sum_{n=-\infty}^{\infty}b_n(\mp 2ikr)^{n+\nu}\Psi(n+\nu+1\pm i\eta,2n+2\nu+2;\mp 2ikr);\end{aligned} \tag{58}$$

$$\begin{aligned}R_{2\nu}^0(r)&=e^{\pm ikr+B_1/2r}\sum_{n=-\infty}^{\infty}b_n\left(-\frac{B_1}{r}\right)^{n+\nu+1}\Psi\left(n+\nu+1,2n+2\nu+2;-\frac{B_1}{r}\right),\\ R_{2\nu}^{\infty}(r)&=e^{\pm ikr+B_1/2r}\sum_{n=-\infty}^{\infty}b_n(\mp 2ikr)^{n+\nu}\Psi(n+\nu+1\pm i\eta,2n+2\nu+2;\mp 2ikr).\end{aligned} \tag{59}$$

Using Eq. (39), we find

$$\lim_{r\to\infty}R_{1\nu}^{\infty}(r)\propto\lim_{r\to\infty}R_{2\nu}^{\infty}(r)\sim r^{\mp i\eta}\frac{e^{\pm ikr}}{r},\quad -\frac{3\pi}{2}<\arg(\mp ikr)<\frac{3\pi}{2}. \tag{60}$$

Thus, when $r\to\infty$, the solutions $R_{i\nu}^{\infty}$ are bounded even if k is a pure imaginary number, since in this case the behavior of $\exp(ikr)$ or $\exp(-ikr)$ predominates over the other factor. At $r=0$, by using Eq. (39) we get

$$\begin{aligned}\lim_{r\to 0}R_{1\nu}^0(r)&\sim e^{-B_1/(2r)},\quad -\frac{3\pi}{2}<\arg\frac{B_1}{r}<\frac{3\pi}{2},\\ \lim_{r\to 0}R_{2\nu}^0(r)&\sim e^{B_1/(2r)},\quad -\frac{3\pi}{2}<\arg\left(-\frac{B_1}{r}\right)<\frac{3\pi}{2}.\end{aligned} \tag{61}$$

As B_1 is a pure imaginary number, we find that

$$|R_{1\nu}^0(r)|\propto|R_{2\nu}^0(r)|\sim 1.$$

Therefore, in this case we can form two pairs of solutions which are regular at the singular points, both pairs having the same series coefficients. For neutral targets ($\eta=0$) the previous results have already been found by Bühring who has treated the Schrödinger equation as a DCHE.[16,24] Before this author, the Schrödinger equation (for neutral targets and an inverse fourth-power polarization potential) had been transformed into a Mathieu equation.[25,26] Thus, the Bühring approach is

profitable since it works for ionized targets, too. In addition, as we have seen, for inverse sixth-power polarization potential, the Schrödinger equation may be transformed to the Ince limit of the DCHE, provided that the target is neutral.

V. FINAL REMARKS

We have constructed the differential equation (6) by applying the Ince limit, defined in Eq. (5), to a generalized spheroidal wave equation (GSWE). The Leaver limit ($z_0 \to 0$) of that equation has afforded Eq. (8) that turns out to be the Ince limit of a double-confluent Heun equation (DCHE) as well. The subnormal Thomé behavior at $z=\infty$, for the solutions of the these Ince limits of the GSWE and DCHE, distinguishes such equations from the original GSWE and DCHE hitherto considered in the literature.

In sec. II, a pair of solutions (with a phase parameter) for the Ince limit of the GSWE have been found as the Ince limit of a pair of solutions for the original GSWE. One solution is given by a series of hypergeometric functions and the other by a series of modified Bessel functions of the second kind. Both solutions in that pair have the same series coefficients but different regions of convergence, as in solutions for the Mathieu equations. Another pair has followed from the first one by means of a transformation rule. Hence, four pairs of solutions without phase parameter have resulted from the truncation of the series with a phase parameter, that is, by restricting the summation index of the series to $n \geqslant 0$.

In Sec. III, solutions for the Ince limit of the DCHE have been established by taking the Leaver limit of solutions for the Ince limit of the GSWE. These solutions, given by series of irregular confluent hypergeometric functions and modified Bessel functions, present the appropriate behavior at the irregular singularities $z=0$ and $z=\infty$. Note, nonetheless, that in Secs. III and IV we have dealt with expansions in series of modified Bessel functions only. Other possibilities may be investigated, especially solutions in series of Bessel function products, as these could have important properties as regards the convergence of the series.

In the solutions without phase parameter for the Ince limits of the GSWE and DCHE, there are three possible forms to the recurrence relations for the series coefficients. This fact is relevant in itself and, in particular, is essential to recover solutions for the Mathieu equation from the ones for the Ince limit of the GSWE.

The solutions we have obtained for the Mathieu equation are already known and exhibit the usual parity and periodicity properties. This includes also the solutions found by Poole, given by two-sided series ($-\infty < n < \infty$) and having period $2\pi m$, where m is any integer greater than 1. However, we note that other types of solutions for the Mathieu equations (and also for the Whittaker-Hill equations) are possible, since these equations may be considered as particular cases of both the GSWE and double-confluent Heun equations as well.[27]

At last, notice that we have pointed out no application for Ince limit of the GSWE. Nevertheless, in Sec. IV we have seen that the Schrödinger equation (49) for the scattering of low-energy particles by polarizable targets leads to a DCHE and its Ince limit. The exception is the Schrödinger equation with Coulomb and inverse sixth-power terms which requires solutions for a more general equation, possibly similar to an equation considered by Kurth and Schmidt in Ref. 28.

ACKNOWLEDGMENTS

I thank Herman J. Mosquera Cuesta for his careful reading of this manuscript and valuable suggestions. I also thank the participants of the ICRA-BR "Pequenos Seminários" for discussions and insight on potential physical applications of the results of the present investigation.

APPENDIX A: DEGENERATE DCHEs

Let us show that DCHE

$$z^2\frac{d^2U}{dz^2}+(B_1+B_2z)\frac{dU}{dz}+(B_3-2\eta\omega z+\omega^2z^2)U=0,\quad (B_1\neq 0,\omega\neq 0),$$

for $B_1=0$ and/or $\omega=0$ degenerates into a confluent hypergeometric equation or an equation with constant coefficients. Thus, if $B_1=0$ and $\omega\neq 0$, the substitutions

$$y=-2i\omega z,\quad U(z)=e^{-y/2}y^{\alpha}f(y),\quad \alpha^2-(1-B_2)\alpha+B_3=0$$

give the confluent hypergeometric equation

$$y\frac{d^2f}{dy^2}+[(2\alpha+B_2)-y]\frac{df}{dy}-\left(i\eta+\alpha+\frac{B_2}{2}\right)f=0.$$

If $B_1\neq 0$ and $\omega=0$, the change of variables

$$y=B_1/z,\quad U(z)=y^{\beta}g(y),\quad \beta^2-(B_2-1)\beta+B_3=0$$

leads to

$$y\frac{d^2g}{dy^2}+[(2\beta+2-B_2)-y]\frac{dg}{dy}-\beta g=0.$$

If $B_1=\omega=0$, we find an equation with constant coefficients by taking $z=\exp y$.

Now let us show that the Ince limit of the DCHE

$$z^2\frac{d^2U}{dz^2}+(B_1+B_2z)\frac{dU}{dz}+(B_3+qz)U=0,\quad (q\neq 0,B_1\neq 0)$$

also gives degenerate cases if $q\neq 0$ and/or $B_1\neq 0$. In fact, if $q=0$ and $B_1\neq 0$, this equation is equivalent to the DCHE with $\omega=0$ and $B_1\neq 0$. If $q\neq 0$ and $B_1=0$, the substitutions

$$\xi=\pm 2i\sqrt{qz},\quad U(z)=\xi^{1-B_2}T(\xi)$$

reduce the equation to the modified Bessel equation

$$\xi^2\frac{d^2T}{d\xi^2}+\xi\frac{dT}{d\xi}-[(1-B_2)^2-4B_3+\xi^2]T=0.$$

Finally, for $q=B_1=0$, we find again an equation with constant coefficients by taking $z=\exp y$.

APPENDIX B: THE SOLUTIONS IN SERIES OF BESSEL FUNCTIONS

The solution $U_{1\nu}^{\infty}(z)$ in series of Bessel functions can also be constructed as follows. We perform the substitutions

$$\xi=\pm 2i\sqrt{qz},\quad U(z)=\xi^{1-B_2}Y(\xi) \tag{B1}$$

in the Ince limit of the GSWE (6). This yields

$$\xi^2\frac{d^2Y}{d\xi^2}+\xi\frac{dY}{d\xi}-\xi^2Y=-4qz_0\frac{d^2Y}{d\xi^2}-\frac{4q(z_0-2B_1-2B_2z_0)}{\xi}\frac{dY}{d\xi}+\left[4q(1-B_2)\frac{2B_1+B_2z_0+z_0}{\xi^2}+(1-B_2)^2+4qz_0-4B_3\right]Y. \tag{B2}$$

Now we expand $Y(\xi)$ according to

$$Y(\xi)=\sum_{n=-\infty}^{\infty} b_n^{(1)} K_\lambda(\xi), \quad \lambda=2n+2\nu+1, \tag{B3}$$

where $K_\lambda(\xi)$ denotes the modified Bessel function of the second kind.[17] The last equation and (B1) afford the solution $U_{1\nu}^{\infty}(z)$.

When we insert (B3) into (B2), we use some difference-differential relations derived from the properties of K_λ.[17] Thus, we have

$$\xi^2\frac{\mathrm{d}^2K_\lambda(\xi)}{\mathrm{d}\xi^2}+\xi\frac{\mathrm{d}K_\lambda(\xi)}{\mathrm{d}\xi}-\xi^2K_\lambda(\xi)=\lambda^2K_\lambda(\xi)$$

on the left-hand side and

$$4\frac{\mathrm{d}^2K_\lambda(\xi)}{\mathrm{d}\xi^2}=K_{\lambda+2}(\xi)+2K_\lambda(\xi)+K_{\lambda-2}(\xi), \quad \frac{4}{\xi}\frac{\mathrm{d}K_\lambda(\xi)}{\mathrm{d}\xi}=-\frac{4\lambda}{\xi^2}K_\lambda(\xi)+\frac{2}{\lambda-1}[K_{\lambda-2}(\xi)-K_\lambda(\xi)]$$

on the right-hand side. This gives

$$\begin{aligned} qz_0\sum_{n=-\infty}^{\infty}\left[1+\frac{2[1-2B_2-(2B_1/z_0)]}{\lambda-1}\right]b_n^{(1)}K_{\lambda-2}(\xi)+\sum_{n=-\infty}^{\infty}\Bigg[\lambda^2+4B_3-2qz_0-(1-B_2)^2 \\ -\frac{2qz_0[1-2B_2-(2B_1/z_0)]}{\lambda-1}\Bigg]b_n^{(1)}K_\lambda(\xi)+qz_0\sum_{n=-\infty}^{\infty}b_n^{(1)}K_{\lambda+2}(\xi) \\ =qz_0\sum_{n=-\infty}^{\infty}\left[\left(1-2B_2-\frac{2B_1}{z_0}\right)\lambda+(1-B_2)\left(1+B_2+\frac{2B_1}{z_0}\right)\right]b_n^{(1)}\frac{4K_\lambda(\xi)}{\xi^2}. \end{aligned}$$

To remove the term $4K_\lambda(\xi)/\xi^2$ on the right-hand side we use the relation

$$\frac{4K_\lambda(\xi)}{\xi^2}=\frac{K_{\lambda-2}(\xi)}{\lambda(\lambda-1)}-\frac{2K_\lambda(\xi)}{(\lambda-1)(\lambda+1)}+\frac{K_{\lambda+2}(\xi)}{\lambda(\lambda+1)}.$$

Then, recalling that $\lambda=2n+2\nu+1$, we find

$$\sum_{n=-\infty}^{\infty}\alpha_{n-1}^{(1)}b_n^{(1)}K_{2n+2\nu-1}(\xi)+\sum_{n=-\infty}^{\infty}\beta_n^{(1)}b_n^{(1)}K_{2n+2\nu+1}(\xi)+\sum_{n=-\infty}^{\infty}\gamma_{n+1}^{(1)}b_n^{(1)}K_{2n+2\nu+3}(\xi)=0, \tag{B4}$$

where the coefficients $\alpha_n^{(1)},\beta_n^{(1)}$, and $\gamma_n^{(1)}$ are just the ones given in Eq. (16b)). To get the recurrence relations with the form given in (11a), we change $n\to m+1$ and $n\to m-1$ in the first and third terms, respectively. After this, we equate to zero the coefficients of each independent $K_{2m+2\nu+1}(\xi)$.

On the other hand, to study the convergence of the series, we apply a Perron-Kreuser theorem[13] for the minimal solutions of the recurrence relations for $b_n^{(1)}$ and obtain (if $z_0\neq 0$)

$$\lim_{n\to\infty}\frac{b_{n+1}^{(1)}}{b_n^{(1)}}=\lim_{n\to-\infty}\frac{b_{n-1}^{(1)}}{b_n^{(1)}}=-\frac{qz_0}{4n^2}. \tag{B5}$$

Using also the relation[17]

$$\lim_{\lambda\to\infty}K_\lambda(\xi)=\frac{1}{2}\Gamma(\lambda)\left(\frac{\xi}{2}\right)^{-\lambda}$$

and $K_{-\lambda}(\xi)=K_\lambda(\xi)$, we get

$$\lim_{n\to\infty}\frac{K_{2n+2\nu+3}(\xi)}{K_{2n+2\nu+1}(\xi)}=\lim_{n\to-\infty}\frac{K_{2n+2\nu-1}(\xi)}{K_{2n+2\nu+1}(\xi)}=-\frac{4n^2}{qz}.$$

Hence, we have

$$\lim_{n\to\infty}\frac{b_{n+1}^{(1)}K_{2n+2\nu+3}(\xi)}{b_n^{(1)}K_{2n+2\nu+1}(\xi)}=\lim_{n\to-\infty}\frac{b_{n-1}^{(1)}K_{2n+2\nu-1}(\xi)}{b_n^{(1)}K_{2n+2\nu+1}(\xi)}=\frac{z_0}{z}.$$

Therefore, by the ratio test the series converges for $|z|>|z_0|$. In (B5) we have supposed that $z_0\neq 0$ but, if $z_0=0$, we find

$$\lim_{n\to\infty}\frac{b_{n+1}^{(1)}}{b_n^{(1)}}=\lim_{n\to-\infty}\frac{b_{n-1}^{(1)}}{b_n^{(1)}}=-\frac{B_1}{4n^3}\Rightarrow\lim_{n\to\infty}\frac{b_{n+1}^{(1)}K_{2n+2\nu+3}(\xi)}{b_n^{(1)}K_{2n+2\nu+1}(\xi)}=\lim_{n\to-\infty}\frac{b_{n-1}^{(1)}K_{2n+2\nu-1}(\xi)}{b_n^{(1)}K_{2n+2\nu+1}(\xi)}=\frac{B_1}{nz}.$$

Thus, in this limit the series converges for $|z|>0$ and per se this result is already included in $|z|>|z_0|$.

APPENDIX C: SOLUTIONS FOR THE DCHE OF SEC. IV

The Leaver-type solutions for the DCHE (3) present some simplifications for $B_2=2$. The solutions given in Ref. 7 are expansions in series of regular and irregular confluent hypergeometric functions. However, to obtain the expected behavior at the singular points $z=0$ and $z=\infty$, we have to choose the irregular functions. Then, by using the same notation of Secs. II A and III A, we find that for $B_2=2$ the first pair of solutions with a phase parameter is given by

$$U_{1\nu}^{0}(z)=e^{i\omega z}\sum_{n=-\infty}^{\infty}b_n\left(\frac{B_1}{z}\right)^{n+\nu+1}\Psi\left(n+\nu+1,2n+2\nu+2;\frac{B_1}{z}\right),$$

$$U_{1\nu}^{\infty}(z)=e^{i\omega z}\sum_{n=-\infty}^{\infty}b_n(-2i\omega z)^{n+\nu}\Psi(n+\nu+1+i\eta,2n+2\nu+2;-2i\omega z), \tag{C1}$$

and the second pair takes the form

$$U_{2\nu}^{0}(z)=e^{i\omega z+B_1/z}\sum_{n=-\infty}^{\infty}b_n\left(-\frac{B_1}{z}\right)^{n+\nu+1}\Psi\left(n+\nu+1,2n+2\nu+2;-\frac{B_1}{z}\right),$$

$$U_{2\nu}^{\infty}(z)=e^{i\omega z+B_1/z}\sum_{n=-\infty}^{\infty}b_n(-2i\omega z)^{n+\nu}\Psi(n+\nu+1+i\eta,2n+2\nu+2;-2i\omega z). \tag{C2}$$

Then, we see that the two pairs have the same series coefficients b_n and the coefficients in the recurrence relations (11a) are simply

$$\alpha_n=i\omega B_1\left(\frac{n+\nu+1-i\eta}{2n+2\nu+3}\right),\quad \beta_n=B_3+(n+\nu)(n+\nu+1),\gamma_n=i\omega B_1\left(\frac{n+\nu+i\eta}{2n+2\nu-1}\right). \tag{C3}$$

In these solutions ν cannot be integer or half-integer and the $U_{i\nu}^{0}$ converge for any finite z, whereas the $U_{i\nu}^{\infty}$ converge for $|z|>0$. Note, moreover, that the irregular confluent hypergeometric functions that appear in $U_{i\nu}^{0}$ could be rewritten in terms of modified Bessel of the second kind by using the definition (14). In the solutions $U_{i\nu}^{\infty}$ the confluent hypergeometric functions could be rewritten in terms of the Hankel functions $H_{\nu}^{(1)}$ but only if $\eta=0$ (neutral target, in the problem of Sec. IV. For this we have to use the relation[12]

$$\Psi\left(\rho+\frac{1}{2},2\rho+1;-2ix\right)=\frac{i}{2\sqrt{\pi}}e^{i(\rho\pi-x)}H_{\rho}^{(1)}(x),\rho=n+\nu+\frac{1}{2}.$$

The asymptotic behaviors of the solutions given in (C1) and (C2) may be found by using Eq. (39).

A classification of generalized quantum statistics associated with basic classical Lie superalgebras

N. I. Stoilova[a] and J. Van der Jeugt[b]

(Received 5 April 2005; accepted 12 September 2005; published online 10 November 2005)

Generalized quantum statistics such as para-statistics is usually characterized by certain triple relations. In the case of para-Fermi statistics these relations can be associated with the orthogonal Lie algebra $B_n=so(2n+1)$; in the case of para-Bose statistics they are associated with the Lie superalgebra $B(0|n)=osp(1|2n)$. In a previous paper, a mathematical definition of "a generalized quantum statistics associated with a classical Lie algebra G" was given, and a complete classification was obtained. Here, we consider the definition of "a generalized quantum statistics associated with a basic classical Lie *superalgebra* G." Just as in the Lie algebra case, this definition is closely related to a certain $\mathbb{Z}$-grading of G. We give in this paper a complete classification of all generalized quantum statistics associated with the basic classical Lie superalgebras $A(m|n), B(m|n), C(n)$, and $D(m|n)$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2104287]

I. INTRODUCTION

A historically important extension of Bose and Fermi statistics has been known for 50 years, namely the para-Bose and para-Fermi statistics as developed by Green.[1] In para-statistics, the usual bilinear commutators or anti-commutators for bosons and fermions are replaced by certain trilinear or triple relations. For example, for n pairs of para-Bose creation and annihilation operators B_i^{ξ} ($\xi=\pm$ and $i=1,\ldots,n$), the defining relations are

$$[\{B_j^{\xi},B_k^{\eta}\},B_l^{\epsilon}]=(\epsilon-\xi)\delta_{jl}B_k^{\eta}+(\epsilon-\eta)\delta_{kl}B_j^{\xi}, \quad \xi,\eta,\epsilon=\pm \text{ or } \pm 1; \quad j,k,l=1,\ldots,n. \tag{1.1}$$

Similar triple relations hold for the para-Fermi operators F_i^{ξ},[1] see (1.1) in Ref. 2. Both for para-Bose and para-Fermi statistics, there is a group theoretical setting. It was shown[3] that the Lie algebra generated by the $2n$ elements F_i^{ξ}, with $\xi=\pm$ and $i=1,\ldots,n$, subject to the para-Fermi relations is $B_n=so(2n+1)$ (as a Lie algebra defined by means of generators and relations).

Twenty years after the connection between para-Fermi statistics and the Lie algebra $so(2n+1)$, a new connection, between para-Bose statistics and the orthosymplectic Lie superalgebra $B(0|n)=osp(1|2n)$[4] was discovered.[5] The Lie superalgebra generated by $2n$ odd elements B_i^{ξ}, with $\xi=\pm$ and $i=1,\ldots,n$, subject to the triple relations (1.1), is $osp(1|2n)$ (as a Lie superalgebra defined by means of generators and relations). Moreover, there is a certain representation of $osp(1|2n)$, the so-called Bose representation $\mathcal{B}$, that yields the classical Bose relations, i.e., where the representatives $\mathcal{B}(B_i^{\xi})$ satisfy the relations of classical Bose statistics. For more general para-Bose statistics, a class of infinite dimensional $osp(1|2n)$ representations needs to be investigated.

These examples show that para-statistics, as introduced by Green[1] and further developed by others (see Ref. 6 and references therein), can be associated with representations of the Lie (super)algebras of class B [namely B_n and $B(0,n)$]. Whether alternative types of generalized

quantum statistics can be found in the framework of other classes of simple Lie algebras or superalgebras has been considered in particular by Palev.[7–15] Building upon his examples and inspired by the definition of creation and annihilation operators in Ref. 11, a mathematical definition of "generalized quantum statistics" was given in Ref. 2. Furthermore, a complete classification was given of all the classes of generalized quantum statistics for the classical Lie algebras A_n, B_n, C_n, and D_n,[2] by means of their algebraic relations. In the present paper we make a similar classification for the basic classical Lie superalgebras.

For certain examples of quantum statistics associated with Lie superalgebras, see Refs. 14 and 15. However, a complete classification was never made. A particularly interesting example was described for the Lie superalgebra $sl(1|n)=A(0|n-1)$.[15] For this superalgebra, a set of odd creation and annihilation operators was given,[11] and it was shown that these n pairs of operators a_i^{ξ}, with $\xi=\pm$ and $i=1,\ldots,n$, subject to the defining relations

$$[\{a_i^+,a_j^-\},a_k^+]=\delta_{jk}a_i^+-\delta_{ij}a_k^+,$$

$$[\{a_i^+,a_j^-\},a_k^-]=-\delta_{ik}a_j^-+\delta_{ij}a_k^-,$$

$$\{a_i^+,a_j^+\}=\{a_i^-,a_j^-\}=0, \tag{1.2}$$

$(i,j,k=1,\ldots,n)$, generate the special linear Lie superalgebra $sl(1|n)$ (as a Lie superalgebra defined by means of generators and relations). Just as in the case of para-Bose relations, (1.2) has two interpretations. On the one hand, it describes the algebraic relations of a new kind of generalized statistics, in this case A-superstatistics or a statistics related to the Lie superalgebra $A(0|n-1)$. On the other hand, (1.2) yields a set of defining relations for the Lie superalgebra $A(0|n-1)$ in terms of generators and relations. Observe that certain microscopic and macroscopic properties of this statistics have already been studied.[15]

A description similar to (1.2) for the Lie algebra A_n was given for the first time by Jacobson[16] in the context of "Lie triple systems." Therefore, this type of generator is often referred to as "Jacobson generators." In this context, we shall mainly use the terminology "creation and annihilation operators (CAOs) for $sl(1|n)$."

Following the mathematical definition of "generalized quantum statistics associated with a Lie algebra," given in Ref. 2, this notion will be extended to Lie superalgebras G. This definition, and the corresponding classification method, are described in Sec. II. Just as for the case of Lie algebras, the method leads to a classification of certain gradings of G, and to regular subalgebras of G. In this process, Dynkin diagram techniques play a crucial role. For the basic classical Lie superalgebras however, the description by means of a Dynkin diagram is not unique: besides the so-called distinguished Dynkin diagram, other nonequivalent Dynkin diagrams exist.[4,17] This feature will make it harder to obtain a complete classification of all generalized quantum systems. In the remaining sections, the classification results are presented for all basic classical Lie superalgebras. A final section discusses some possible applications.

For the basic classical Lie superalgebras,[4] we use the notation $A(m|n)=sl(m+1|n+1)$, $B(m|n)=osp(2m+1|2n)$, $C(n)=osp(2|2n-2)$, and $D(m|n)=osp(2m|2n)$. The algebra $B(0|n)=osp(1|2n)$ has a different structure and is usually considered separately (also here). For the classical simple Lie algebras, we use the notation $A_n=sl(n+1)$, $B_n=so(2n+1)$, $C_n=sp(2n)$ and $D_n=so(2n)$; note the difference between C_n and $C(n)$. Note also that for trivial values of m or n, a Lie superalgebra coincides with a Lie algebra: $sl(r|0)=sl(0|r)=sl(r)$, $B(m|0)=B_m$, $D(m|0)=D_m$, $D(0|n)=C_n$.

II. DEFINITION AND CLASSIFICATION METHOD

Let G be a basic classical Lie superalgebra. G has a $\mathbb{Z}_2$-grading $G=G_{\bar{0}}\oplus G_{\bar{1}}$; an element x of $G_{\bar{0}}$ is an even element $[\deg(x)=0]$, an element y of $G_{\bar{1}}$ is an odd element $[\deg(y)=1]$. The elements which are purely even or odd are called homogeneous elements. The Lie superalgebra bracket is denoted by $[\![x,y]\!]$. In the universal enveloping algebra of G, this stands for

$$[\![x,y]\!]=xy-(-1)^{\deg(x)\deg(y)}yx,$$

if x and y are homogeneous. So the bracket can be a commutator or an anti-commutator.

Just as for a Lie algebra,[2] a generalized quantum statistics associated with G is determined by a set of N creation operators x_i^+ and N annihilation operators x_i^-. Following the ideas of para-Bose statistics and those of Ref. 2, these $2N$ operators should generate the Lie superalgebra G, subject to certain triple relations. Let G_{+1} and G_{-1} be the subspaces of G spanned by these elements:

$$G_{+1}=\mathrm{span}\{x_i^+;i=1,\ldots,N\},\quad G_{-1}=\mathrm{span}\{x_i^-;i=1,\ldots,N\}. \tag{2.1}$$

We do not require that these subspaces are homogeneous. The space $[\![G_{+1},G_{+1}]\!]$ can be zero [in which case the creation operators mutually supercommute, as in (1.2)] or nonzero [as in (1.1)]. A similar statement holds for the annihilation operators and $[\![G_{-1},G_{-1}]\!]$. Putting $G_{\pm 2}=[\![G_{\pm 1},G_{\pm 1}]\!]$ and $G_0=[\![G_{+1},G_{-1}]\!]$, the condition that G is generated by the $2N$ elements subject to triple relations only, leads[2] to the requirement that $G=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$, and this must be a $\mathbb{Z}$-grading of G. Since these subspaces are not necessarily homogeneous, this $\mathbb{Z}$-grading is in general not consistent with the $\mathbb{Z}_2$-grading.

Just as in Ref. 2, we shall impose two further requirements: first of all, the generating elements $x_i^\pm$ must be root vectors of G. Second, $\omega(x_i^+)=x_i^-$, where ω is the standard antilinear anti-involutive mapping of G [in terms of root vectors e_α,ω satisfies $\omega(e_\alpha)=e_{-\alpha}$]. This leads to the following definition, completely analogous as in Ref. 2:

Definition 1: Let G be a basic classical Lie superalgebra, with antilinear anti-involutive mapping ω. A set of $2N$ root vectors $x_i^\pm(i=1,\ldots,N)$ is called a set of creation and annihilation operators for G if:

- $\omega(x_i^\pm)=x_i^\mp$,
- $G=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ *is a* $\mathbb{Z}$*-grading of* G, *with* $G_{\pm 1}=\mathrm{span}\{x_i^\pm,i=1,\ldots,N\}$ *and* $G_{j+k}=[\![G_j,G_k]\!]$.

The algebraic relations $\mathcal{R}$ satisfied by the operators $x_i^\pm$ are the relations of a generalized quantum statistics (GQS) associated with G.

This is a *mathematical* generalization of quantum statistics. Whether all such GQS actually lead to physically acceptable quantum statistics remains to be seen; in this sense one should interpret our GQS as "candidates for generalizations of quantum statistics."

A GQS is characterized by a set $\{x_i^\pm\}$ of CAOs and the set of algebraic relations $\mathcal{R}$ they satisfy. A consequence of this definition is that G is generated by G_{-1} and G_{+1}, i.e., by the set of CAOs, and since $G_{j+k}=[\![G_j,G_k]\!]$, it follows that

$$G=\mathrm{span}\{x_i^\xi,[\![x_i^\xi,x_j^\eta]\!];\quad i,j=1,\ldots,N,\xi,\eta=\pm\}. \tag{2.2}$$

This implies that it is necessary and sufficient to give all relations of the following type:
(R1) The set of all linear relations between the elements $[\![x_i^\xi,x_j^\eta]\!](\xi,\eta=\pm,i,j=1,\ldots,N)$.
(R2) The set of all triple relations of the form $[\![[\![x_i^\xi,x_j^\eta]\!],x_k^\zeta]\!]$=linear combination of x_l^θ.
So $\mathcal{R}$ consists of a set of quadratic relations and a set of triple relations. Also, as a Lie superalgebra defined by generators and relations, G is uniquely characterized by the set of generators $x_i^\pm$ subject to the relations $\mathcal{R}$.

A consequence of this definition is that G_0 itself is a subalgebra of G spanned by root vectors of G.[2] It follows that G_0 is a regular subalgebra containing the Cartan subalgebra H of G. By the adjoint action, the remaining G_i's are G_0-modules. Thus the technique of Ref. 2 can be used in order to obtain a complete classification of all GQS associated with G:

1. Determine all regular subalgebras G_0 of G. If not yet contained in G_0, replace G_0 by G_0+H.
2. For each regular subalgebra G_0, determine the decomposition of G into simple G_0-modules g_k $(k=1, 2,\ldots)$.
3. Investigate whether there exists a $\mathbb{Z}$-grading of G of the form

$$G = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}, \tag{2.3}$$

where each G_i is either directly a module g_k or else a sum of such modules $g_1 \oplus g_2 \oplus \cdots$, such that $\omega(G_{+i})=G_{-i}$.

If the $\mathbb{Z}$-grading is of the form (2.3) with $G_{\pm 2} \neq 0$, we shall say that it has *length* 5; if $G_{+2}=0$ (then $G_{-2}=0$, but $G_{\pm 1} \neq 0$), then the $\mathbb{Z}$-grading is of length 3.

To find regular subalgebras one can use the method of (extended) Dynkin diagrams.[18] The second stage is straightforward by means of representation theoretical techniques. The third stage requires most of the work: one must try out all possible combinations of the G_0-modules g_k, and see whether it is possible to obtain a grading of the type (2.3). In this process, if one of the simple G_0-modules g_k is such that $\omega(g_k)=g_k$, then it follows that this module should be part of G_0. In other words, such a case reduces essentially to another case with a larger regular subalgebra.

In the following sections we shall give a summary of the classification process for the basic classical Lie superalgebras $A(m|n), B(m|n), B(0|n), D(m|n)$, and $C(n)$. Note that, in order to identify a GQS associated with G, it is sufficient to give only the set of CAOs, or alternatively, to give the subspace G_{-1} [then the x_i^- are the root vectors of G_{-1}, and $x_i^+=\omega(x_i^-)$]. The set $\mathcal{R}$ then consists of all quadratic relations (i.e., the linear relations between the elements $[[x_i^{\xi}, x_j^{\eta}]]$) and all triple relations, and all of these relations follow from the known supercommutation relations in G. Because, in principle, $\mathcal{R}$ can be determined from the set $\{x_i^{\pm}; i=1,\ldots,N\}$, we will not always give it explicitly.

Finally, observe that two different sets of CAOs $\{x_i^{\pm}; i=1\ldots,N\}$ and $\{y_i^{\pm}; i=1\ldots,N\}$ (same N) are said to be isomorphic if, for a certain permutation τ of $\{1,2,\ldots,N\}$, the relations between the elements $x_{\tau(i)}^{\pm}$ and $y_i^{\pm}$ are the same. In that case, the regular subalgebra G_0 spanned by $\{[[x_i^+, x_j^-]]\}$ is isomorphic (as a Lie superalgebra) to the regular subalgebra spanned by $\{[[y_i^+, y_j^-]]\}$.

III. THE LIE SUPERALGEBRA $A(m|n)$

Let G be the special linear Lie superalgebra $A(m|n) \equiv sl(m+1|n+1)$, consisting of traceless $(m+n+2)\times(m+n+2)$ matrices. The Cartan subalgebra H of G is the subspace of diagonal matrices. The root vectors of G are known to be the elements $e_{jk}(j \neq k=1,\ldots,m+n+2)$, where e_{jk} is a matrix with zeros everywhere except a 1 on the intersection of row j and column k. The $\mathbb{Z}_2$-grading is such that $\deg(e_{jk})=\theta_{jk}=\theta_j+\theta_k$, where

$$\theta_j = \begin{cases} 0 & \text{if } j = 1, \ldots, m+1 \\ 1 & \text{if } j = m+2, \ldots, m+n+2. \end{cases} \tag{3.1}$$

The root corresponding to $e_{jk}(j,k=1,\ldots,m+1)$ is given by $\epsilon_j-\epsilon_k$; for $e_{m+1+j,m+1+k}(j,k=1,\ldots,n+1)$ it is $\delta_j-\delta_k$; and for $e_{j,m+1+k}$, respectively, $e_{m+1+k,j}(j=1,\ldots,m+1, k=1,\ldots,n+1)$, it is $\epsilon_j-\delta_k$, respectively, $\delta_k-\epsilon_j$. The anti-involution is such that $\omega(e_{jk})=e_{kj}$. The distinguished set of simple roots and the distinguished Dynkin diagram of $A(m|n)$ are given in Table I, and so is the extended distinguished Dynkin diagram.

To find regular subalgebras of $G=A(m|n)$, one should delete nodes from the Dynkin diagrams of $A(m|n)$ (first the ordinary, and then the extended). This goes in systematic steps. For each step, we shall investigate whether it leads to a grading of type (2.3).

TABLE I. Classical Lie superalgebras, their (extended) Dynkin diagrams with a labeling of the nodes and the corresponding simple roots.

LSA	Dynkin diagram and extended Dynkin diagram
$A(m\|n)$	$B(m\|n)$	$B(0\|n)$	$D(m\|n)$	$C(n)$	
Step 1. Delete node i from the distinguished Dynkin diagram. Then the corresponding diagram is the Dynkin diagram of $G_0=sl(i)\oplus sl(m+1-i|n+1)$ for $i=1,\ldots,m+1$ and of $G_0=sl(m+1|i-m-1)\oplus sl(n+m+2-i)$ for $i=m+2,\ldots,m+n+1$. There are only two G_0-modules and

$$G_{-1}=\text{span}\{e_{kl};k=1,\ldots,i,\quad l=i+1,\ldots,m+n+2\},\tag{3.2}$$

$$G_{+1}=\text{span}\{e_{lk};k=1,\ldots,i,\quad l=i+1,\ldots,m+n+2\}.\tag{3.3}$$

Therefore $A(m|n)$ has a grading of length 3, $A(m|n)=G_{-1}\oplus G_0\oplus G_{+1}$, and the number of creation and annihilation operators is $N=i(m+n+2-i)$.

The most interesting realizations are those with $i=1, i=m+n+1, i=2$ and $i=m+n$. We shall give the explicit supercommutation relations between the CAOs for some of these cases.

For $i=1, N=m+n+1$. Putting

$$a_j^-=e_{1,j+1},\quad a_j^+=e_{j+1,1},\quad j=1,\ldots,m+n+1,$$

the relations $\mathcal{R}$ are

$$\begin{aligned}&[\![a_j^+,a_k^+]\!]=[\![a_j^-,a_k^-]\!]=0,\\ &[\![[\![a_j^+,a_k^-]\!],a_l^+]\!]=(-1)^{\theta_{j+1}}\delta_{jk}a_l^+ +\delta_{kl}a_j^+,\\ &[\![[\![a_j^+,a_k^-]\!],a_l^-]\!]=-(-1)^{\theta_{j+1}}\delta_{jk}a_l^- -(-1)^{\theta_{j+1,k+1}\theta_{l+1}}\delta_{jl}a_k^-.\end{aligned}\tag{3.4}$$

For $m=0$, these are the relations of A-superstatistics,[11,15] see (1.2). Also for general m and n, these relations have been considered in another context.[14]

For $i=m+n+1, N=m+n+1$. Putting

$$a_j^-=e_{j,m+n+2},\quad a_j^+=e_{m+n+2,j},\quad j=1,\ldots,m+n+1$$

one finds:

$$\begin{aligned}&[\![a_j^+,a_k^+]\!]=[\![a_j^-,a_k^-]\!]=0,\\ &[\![[\![a_j^+,a_k^-]\!],a_l^+]\!]=\delta_{jk}a_l^+ -(-1)^{\theta_k}\delta_{kl}a_j^+,\\ &[\![[\![a_j^+,a_k^-]\!],a_l^-]\!]=-\delta_{jk}a_l^- -(-1)^{(\theta_j+1)(\theta_k+1)}\delta_{jl}a_k^-.\end{aligned}\tag{3.5}$$

The relations (3.4) and (3.5) are similar; however the corresponding GQS are not isomorphic. For instance, in (3.4) there are m even and $n+1$ odd pairs of CAOs, and in (3.5) there are n even and $m+1$ odd pairs of CAOs.

For $i=2, N=2(m+n)$. One puts

$$a_{-,j}^-=e_{1,j+2},\quad a_{+,j}^-=e_{2,j+2},\quad j=1,\ldots,m+n,$$

$$a_{-,j}^+=e_{j+2,1},\quad a_{+,j}^+=e_{j+2,2},\quad j=1,\ldots,m+n.$$

Then the corresponding relations read ($\xi,\eta,\epsilon=\pm;j,k,l=1,\ldots,m+n$):

$$[\![a_{\xi j}^+,a_{\eta k}^+]\!]=[\![a_{\xi j}^-,a_{\eta k}^-]\!]=0,$$

$$[\![a_{\xi j}^+,a_{-\xi k}^-]\!]=0,\quad j\neq k,$$

$$[\![a_{-j}^+,a_{-k}^-]\!]=[\![a_{+j}^+,a_{+k}^-]\!],\quad j\neq k,$$

$$[\![a^+_{+j},a^-_{-j}]\!]=[\![a^+_{+k},a^-_{-k}]\!],\quad \text{for } \theta_j=\theta_k,$$

$$[\![a^+_{-j},a^-_{+j}]\!]=[\![a^+_{-k},a^-_{+k}]\!],\quad \text{for } \theta_j=\theta_k,$$

$$[\![[\![a^+_{\xi j},a^-_{\eta k}]\!],a^+_{\epsilon l}]\!]=(-1)^{\deg(a^+_{\xi j})\deg(a^-_{\eta k})+\delta_{\xi,-\eta}\theta_{12}\deg(a^+_{\epsilon l})}\delta_{\eta\epsilon}\delta_{jk}a^+_{\xi l}+\delta_{\xi\eta}\delta_{kl}a^+_{\epsilon j},$$

$$[\![[\![a^+_{\xi j},a^-_{\eta k}]\!],a^-_{\epsilon l}]\!]=-(-1)^{\deg(a^+_{\xi j})\deg(a^-_{\eta k})}\delta_{\xi\epsilon}\delta_{jk}a^-_{\eta l}-(-1)^{\theta_{j+2,k+2}\deg(a^-_{\epsilon l})}\delta_{\xi\eta}\delta_{jl}a^-_{\epsilon k}. \tag{3.6}$$

Such relations are definitely more complicated than (3.4) or (3.5). However, they are still proper defining relations for $A(m|n)$.

Step 2. Delete node i and j from the distinguished Dynkin diagram. We have $G_0=H+sl(i)\oplus sl(j-i)\oplus sl(m+1-j|n+1)$ for $1\leqslant i<j\leqslant m+1$, $G_0=H+sl(i)\oplus sl(m+1-i|j-m-1)\oplus sl(m+n+2-j)$ for $1\leqslant i\leqslant m+1, m+2\leqslant j\leqslant m+n+1$ and $G_0=H+sl(m+1|i-m-1)\oplus sl(j-i)\oplus sl(m+n+2-j)$ for $m+2\leqslant i<j\leqslant m+n+1$. There are six simple G_0-modules. All the possible combinations of these modules give rise to gradings of length 5. There are essentially three different ways in which these G_0-modules can be combined. To characterize these three cases, it is sufficient to give only G_{-1}:

$$G_{-1}=\text{span}\{e_{kl},e_{lp};\quad k=1,\ldots,i,\quad l=i+1,\ldots,j,\quad p=j+1,\ldots,m+n+2\},$$
$$\text{with } N=(j-i)(m+n+2-j+i); \tag{3.7}$$

$$G_{-1}=\text{span}\{e_{kl},e_{pk};\quad k=1,\ldots,i,\quad l=i+1,\ldots,j,\quad p=j+1,\ldots,m+n+2\},$$
$$\text{with } N=i(m+n+2-i); \tag{3.8}$$

$$G_{-1}=\text{span}\{e_{kl},e_{lp};\quad k=1,\ldots,i,\quad p=i+1,\ldots,j,\quad l=j+1,\ldots,m+n+2\},$$
$$\text{with } N=j(m+n+2-j). \tag{3.9}$$

Note that a part of the solutions in (3.8) and (3.9) is isomorphic to some of those given by (3.7). The isomorphic cases can be recognized as those having the same Dynkin diagram of G_0 and the same N-value.

For reasons explained earlier, we shall no longer give the corresponding set of relations explicitly for all possible cases. As an example, we consider here the case $j-i=1$ and (3.7). Then there are $N=m+n+1$ pairs of CAOs, which we can label as follows:

$$a^-_k=e_{k,i+1},\quad a^+_k=e_{i+1,k},\quad k=1,\ldots,i;$$

$$a^-_k=e_{i+1,k+1},\quad a^+_k=e_{k+1,i+1},\quad k=i+1,\ldots,m+n+1.$$

Using

$$\langle k\rangle=\begin{cases}0 & \text{if } k=1,\ldots,i\\ 1 & \text{if } k=i+1,\ldots,m+n+1,\end{cases} \tag{3.10}$$

the quadratic and triple relations now read:

$$[\![a^+_k,a^+_l]\!]=[\![a^-_k,a^-_l]\!]=0,\quad k,l=1,\ldots,i \text{ or } k,l=i+1,\ldots,m+n+1,$$

$$[\![a^-_k,a^+_l]\!]=[\![a^+_k,a^-_l]\!]=0,\quad k=1,\ldots,i,\quad l=i+1,\ldots,m+n+1,$$

$$[[[a_k^+,a_l^-],a_p^+]] = (-1)^{\langle l\rangle+\langle p\rangle+\langle k\rangle\theta_{k+1,i+1}}\delta_{kl}a_p^+ + (-1)^{\langle l\rangle+\langle p\rangle+(1-\langle l\rangle)\theta_{l,i+1}(\theta_{lk}+\theta_{k,i+1})}\delta_{lp}a_k^+, \quad k,l=1,\cdots,i,$$
$$\text{or } k,l=i+1,\ldots,m+n+1,$$

$$[[[a_k^+,a_l^-],a_p^-]] = -(-1)^{\langle l\rangle+\langle p\rangle+\deg(a_k^+)[\langle k\rangle\theta_{k+1,l+1}+(1-\langle l\rangle)\theta_{l,i+1}]}\delta_{kp}a_l^- - (-1)^{\langle l\rangle+\langle p\rangle+\langle k\rangle\theta_{k+1,i+1}}\delta_{kl}a_p^-,$$
$$k,l=1,\ldots,i, \text{or } k,l=i+1,\ldots,m+n+1,$$

$$[[[a_k^\xi,a_l^\xi]],a_p^{-\xi}]] = -(-1)^{\frac{1}{2}\theta_{p,i+1}[(1+\xi)\theta_{l+1,i+1}+(1-\xi)\theta_{k,l+1}]}\delta_{kp}a_l^\xi + (-1)^{\frac{1}{2}(1+\xi)\theta_{l+1,i+1}(\theta_{k,i+1}+\theta_{k,l+1})}\delta_{lp}a_k^\xi,$$
$$k=1,\ldots,i, \quad l=i+1,\ldots,m+n+1,$$

$$[[[a_k^\xi,a_l^\xi]],a_p^\xi]] = 0, \quad \xi=\pm; \quad k,l,p=1,\ldots,m+n+1. \tag{3.11}$$

Step 3. If we delete three or more nodes from the distinguished Dynkin diagram, the resulting $\mathbb{Z}$-gradings of $A(m|n)$ are no longer of the form (2.3). So these cases are not relevant for our classification.

Step 4. Next, we move on to the extended distinguished Dynkin diagram, also given in Table I. If we delete node i from this extended diagram, the remaining diagram is again (a nondistinguished Dynkin diagram) of type $A(m|n)$, so $G_0=G$, and there are no CAOs.

Step 5. If we delete node i and j $(i<j)$ from the extended distinguished Dynkin diagram, then $A(m|n)=G_{-1}\oplus G_0\oplus G_{+1}$ with $G_0=H+sl(m|n+1)$ or $H+sl(m+1|n)$ when the nodes are adjacent, and $G_0=H+sl(k|l)\oplus sl(p|q)$ with $k+p=m+1$ and $l+q=n+1$ when the nodes are nonadjacent. Note that p or q can be zero: $sl(r|0)=sl(0|r)=sl(r)$. Now

$$G_{-1}=\text{span}\{e_{kl}; \quad k=i+1\ldots,j, \quad l\neq i+1,\ldots,j\}. \tag{3.12}$$

The number of annihilation operators is $N=(j-i)(n+m+2-j+i)$. A part of these solutions is isomorphic to some of those of Step 1. The isomorphic cases are again characterized by the fact that their G_0's are isomorphic Lie superalgebras and their N-values coincide.

Step 6. If we delete nodes i,j, and k from the extended distinguished Dynkin diagram $(i<j<k)$, then the corresponding $\mathbb{Z}$-gradings are of the form (2.3). If the three nodes are adjacent $G_0=H+sl(m-1|n+1),H+sl(m|n)$, or $H+sl(m+1|n-1)$. When two adjacent and one nonadjacent nodes are deleted, $G_0=H+sl(l|p)\oplus sl(q|r)$ with $l+q=m,p+r=n+1$ or $l+q=m+1,p+r=n$. If all three nodes are nonadjacent then $G_0=H+sl(l|p)\oplus sl(q|r)\oplus sl(s|t)$ with $l+q+s=m+1,p+r+t=n+1$. One or two of these three Lie superalgebras is $sl(r|0)=sl(0|r)=sl(r)$. There are three different ways in which the corresponding G_0-modules can be combined. We give here only G_{-1}:

$$G_{-1}=\text{span}\{e_{ps},e_{sq}; \quad p=1,\ldots,i,k+1,\ldots,n+m+2, \quad s=i+1,\ldots,j, \quad q=j+1,\ldots,k\},$$
$$\text{with } N=(j-i)(n+m+2-j+i); \tag{3.13}$$

$$G_{-1}=\text{span}\{e_{ps},e_{qp}; \quad p=1,\ldots,i,k+1,\ldots,n+m+2, \quad s=i+1,\ldots,j, \quad q=j+1,\ldots,k\},$$
$$\text{with } N=(k-i)(n+m+2+i-k); \tag{3.14}$$

$$G_{-1}=\text{span}\{e_{pq},e_{qs}; \quad p=1,\ldots,i,k+1,\ldots,n+m+2, \quad s=i+1,\ldots,j, \quad q=j+1,\ldots,k\}$$
$$\text{with } N=(k-j)(n+m+2+j-k). \tag{3.15}$$

Again a part of these solutions is isomorphic to some of those in Step 2 (characterized by an isomorphic G_0 and the same N).

Step 7. If we delete four or more nodes from the extended distinguished Dynkin diagram, the corresponding $\mathbb{Z}$-grading of $A(m|n)$ no longer has the required properties (i.e., there are non zero subspaces G_i with $|i|>2$).

Step 8. Next, one should repeat the process for all non distinguished Dynkin diagrams of G

and their extensions. This is what makes the work harder than the corresponding classification for Lie algebras (which have only one Dynkin diagram and one extension). A general Dynkin diagram is determined by a general simple root system. All the systems of simple roots $\Pi_{S,T}$ of $A(m|n)$ are determined by two increasing sequences[4,17]

$$S=\{s_1<s_2<\ldots\} \text{ and } T=\{t_1<t_2<\ldots\}$$

and a sign:

$$\Pi_{S,T}=\pm\{\epsilon_1-\epsilon_2,\epsilon_2-\epsilon_3,\ldots,\epsilon_{s_1}-\delta_1,\delta_1-\delta_2,\ldots,\delta_{t_1}-\epsilon_{s_1+1},\ldots\}.$$

The Dynkin diagram itself looks like

where each dot can be a white or gray circle (depending upon whether the corresponding simple root is even or odd). Let $\pm(\eta_i-\eta'_j)$ be the last element of $\Pi_{S,T}$ (η and η' can be ϵ or δ). Then the zero node of the extended Dynkin diagram corresponds to $\pm(\eta'_j-\epsilon_1)$ and it is uniquely determined.

If we repeat the whole procedure with the nondistinguished Dynkin diagrams (ordinary and extended), the only new result corresponds to Step 6 deleting three nonadjacent nodes from the extended Dynkin diagram. We have $G_0=H+sl(l|p)\oplus sl(q|r)\oplus sl(s|t)$ with $l+q+s=m+1, p+r+t=n+1$ and in some cases none of the three algebras is $sl(r|0)=sl(0|r)=sl(r)$. Just as in Step 2 or 6, there are three different ways in which the G_0-modules can be combined; the explicit expression is left to the reader.

IV. THE LIE SUPERALGEBRAS $B(m|n)$

$G=B(m|n)\equiv osp(2m+1|2n)$ is the subalgebra of $sl(2m+1|2n)$ consisting of matrices of the form:

$$\begin{pmatrix} a & b & u & x & x_1 \\ c & -a^t & v & y & y_1 \\ -v^t & -u^t & 0 & z & z_1 \\ y_1^t & x_1^t & z_1^t & d & e \\ -y^t & -x^t & -z^t & f & -d^t \end{pmatrix}, \tag{4.1}$$

where a is any $(m\times m)$-matrix, b and c are antisymmetric $(m\times m)$-matrices, u and v are $(m\times 1)$-matrices, x,y,x_1,y_1 are $(m\times n)$-matrices, z and z_1 are $(1\times n)$-matrices, d is any $(n\times n)$-matrix, and e and f are symmetric $(n\times n)$-matrices. The even elements have $x=y=x_1=y_1=0, z=z_1=0$ and the odd elements are those with $a=b=c=0, u=v=0, d=e=f=0$. We shall consider $m=0$ separately in the next section. The Cartan subalgebra H of G is again the subspace of diagonal matrices D. Putting $\epsilon_i(D)=D_{ii}, i=1,\cdots,m$ and $\delta_i(D)=D_{2m+i+1,2m+i+1}, i=1,\ldots,n$, the even root vectors and corresponding roots of G are given by,

$$e_{jk}-e_{k+m,j+m}\leftrightarrow\epsilon_j-\epsilon_k,\quad j\neq k=1,\ldots,m,$$

$$e_{j,k+m}-e_{k,j+m}\leftrightarrow\epsilon_j+\epsilon_k,\quad j<k=1,\ldots,m,$$

$$e_{j+m,k}-e_{k+m,j}\leftrightarrow-\epsilon_j-\epsilon_k,\quad j<k=1,\ldots,m,$$

$$e_{j,2m+1}-e_{2m+1,j+m}\leftrightarrow\epsilon_j,\quad j=1,\ldots,m,$$

$$e_{j+m,2m+1} - e_{2m+1,j} \leftrightarrow -\epsilon_j, \quad j = 1,\ldots,m,$$

$$e_{2m+1+j,2m+1+k} - e_{n+2m+1+k,n+2m+1+j} \leftrightarrow \delta_j - \delta_k, \quad j \neq k = 1,\ldots,n,$$

$$e_{2m+1+j,2m+1+k+n} + e_{2m+1+k,2m+1+j+n} \leftrightarrow \delta_j + \delta_k, \quad j \leqslant k = 1,\ldots,n,$$

$$e_{2m+1+n+j,2m+1+k} + e_{2m+1+n+k,2m+1+j} \leftrightarrow -\delta_j - \delta_k, \quad j \leqslant k = 1,\ldots,n,$$

and the odd ones by

$$e_{j,2m+1+k} - e_{2m+1+n+k,j+m} \leftrightarrow \epsilon_j - \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n,$$

$$e_{m+j,2m+1+k} - e_{2m+1+n+k,j} \leftrightarrow -\epsilon_j - \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n,$$

$$e_{2m+1,2m+1+k} - e_{2m+1+n+k,2m+1} \leftrightarrow -\delta_k, \quad k = 1,\ldots,n,$$

$$e_{j,2m+1+n+k} + e_{2m+1+k,m+j} \leftrightarrow \epsilon_j + \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n,$$

$$e_{m+j,2m+1+n+k} + e_{2m+1+k,j} \leftrightarrow -\epsilon_j + \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n,$$

$$e_{2m+1,2m+1+n+k} + e_{2m+1+k,2m+1} \leftrightarrow \delta_k, \quad k = 1,\ldots,n.$$

The distinguished set of simple roots and the corresponding Dynkin diagram of $B(m|n)$ are given in Table I.

Step 1. Delete node i from the distinguished Dynkin diagram. The corresponding diagram is the Dynkin diagram of $G_0 = H + sl(i) \oplus B(m|n-i)$ for $i = 1,\ldots,n$ and of $G_0 = H + sl(j|n) \oplus B_{m-j}$ for $i = n+j, j = 1,\ldots,m$. There are four simple G_0-modules and $B(m|n) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$, where for $i = 1,\ldots n$:

$$\begin{aligned} G_{-1} = \text{span}\{&e_{2m+1,2m+1+n+k} + e_{2m+1+k,2m+1}, e_{2m+1+k,2m+1+n+l} + e_{2m+1+l,2m+1+n+k}, e_{2m+1+k,2m+1+l} \\ &- e_{n+2m+1+l,n+2m+1+k}, e_{p,2m+1+n+k} + e_{2m+1+k,m+p}, e_{m+p,2m+1+n+k} + e_{2m+1+k,p}; \\ &k = 1,\ldots,i, \quad l = i+1,\ldots,n, \quad p = 1,\ldots,m\}, \quad \text{with } N = 2i(m+n) - i(2i-1); \end{aligned} \tag{4.2}$$

and for $i = n+j, j = 1,\ldots m$:

$$\begin{aligned} G_{-1} = \text{span}\{&e_{2m+1,2m+1+n+k} + e_{2m+1+k,2m+1}, e_{p,2m+1} - e_{2m+1,m+p}, e_{p,m+q} - e_{q,m+p}, e_{pq} \\ &- e_{m+q,m+p}, e_{q,2m+1+n+k} + e_{2m+1+k,m+q}, e_{m+q,2m+1+n+k} + e_{2m+1+k,q}; \\ &k = 1,\ldots,n, \quad p = 1,\ldots,j, \quad q = j+1,\ldots,m\}, \quad \text{with } N = 2i(m+n) - i(2i-1). \end{aligned} \tag{4.3}$$

It is interesting to give $\mathcal{R}$ for $i = n+m$, because then the number of creation or annihilation operators is $N = n+m$. One can label (and rescale) the CAOs as follows:

$$\begin{aligned} b_j^- \equiv B_j^- &= -\sqrt{2}(e_{2m+1,2m+1+n+j} + e_{2m+1+j,2m+1}), \quad j = 1,\ldots,n, \\ b_j^+ \equiv B_j^+ &= \sqrt{2}(e_{2m+1,2m+1+j} - e_{2m+1+n+j,2m+1}), \quad j = 1,\ldots,n, \\ b_{n+j}^- \equiv F_j^- &= \sqrt{2}(e_{j,2m+1} - e_{2m+1,m+j}), \quad j = 1,\ldots,m, \end{aligned} \tag{4.4}$$

$$b_{n+j}^{+} \equiv F_j^{+} = \sqrt{2}(e_{2m+1,j} - e_{m+j,2m+1}), \quad j = 1,\ldots,m. \tag{4.5}$$

Note that

$$\deg(b_j^{\pm}) = \langle j \rangle = \begin{cases} 1 & \text{if } j = 1,\ldots,n \\ 0 & \text{if } j = n+1,\ldots,n+m. \end{cases} \tag{4.6}$$

There are no quadratic relations, and $\mathcal{R}$ consists of triple relations only:

$$\begin{gathered} [[[b_j^{\xi}, b_k^{\eta}], b_l^{\epsilon}]] = -2\delta_{jl}\delta_{\epsilon,-\xi}\epsilon^{\langle l \rangle}(-1)^{\langle k \rangle \langle l \rangle} b_k^{\eta} + 2\epsilon^{\langle l \rangle}\delta_{kl}\delta_{\epsilon,-\eta} b_j^{\xi}, \\ \xi, \eta, \epsilon = \pm \text{ or } \pm 1; \quad j,k,l = 1,\ldots,n+m. \end{gathered} \tag{4.7}$$

Note that $B_j^{\pm}, j=1,\ldots,n$ (respectively, $F_k^{\pm}, k=1,\ldots,m$) are para-Bose (respectively, para-Fermi) CAOs, namely

$$\begin{gathered} [\{B_j^{\xi}, B_k^{\eta}\}, B_l^{\epsilon}] = (\epsilon - \xi)\delta_{jl} B_k^{\eta} + (\epsilon - \eta)\delta_{kl} B_j^{\xi}, \\ \xi, \eta, \epsilon = \pm \text{ or } \pm 1; \quad j,k,l = 1,\ldots,n; \end{gathered} \tag{4.8}$$

$$\begin{gathered} [[F_j^{\xi}, F_k^{\eta}], F_l^{\epsilon}] = \tfrac{1}{2}(\epsilon - \eta)^2 \delta_{kl} F_j^{\xi} - \tfrac{1}{2}(\epsilon - \xi)^2 \delta_{jl} F_k^{\eta}, \\ \xi, \eta, \epsilon = \pm \text{ or } \pm 1; \quad j,k,l = 1,\ldots,m. \end{gathered} \tag{4.9}$$

The fact that $B(m|n)$ can be generated by n pairs of para-Bose and m pairs of para-Fermi operators has been discoved in Ref. 19.

Step 2. If we delete two or more nodes from the distinguished Dynkin diagram, the resulting $\mathbb{Z}$-gradings of $B(m|n)$ are no longer of the form (2.3).

Step 3. Now we continue with the extended Dynkin diagram, also given in Table I. Delete node $i=0,1,\ldots,n+m$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0 = B(m|n), A_1 \oplus B(m|n-1), C_2 \oplus B(m,n-2), \ldots, C_{n-1} \oplus B(m|1), C_n \oplus B_m, C(n+1) \oplus B_{m-1}, D(2|n) \oplus B_{m-2}, \ldots, D(m-1|n) \oplus A_1, D(m|n)$. In all these cases there is only one G_0-module, so there are no contributions to the classification.

Step 4. Delete the adjacent nodes $(i-1)$ and i, $i=2,3,\ldots,n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\widetilde{G}_0 = A_1 \oplus B(m|n-2)$ for $i=2$, of $\widetilde{G}_0 = C_{i-1} \oplus B(m|n-i)$ for $i=3,\ldots,n-1$ and of $\widetilde{G}_0 = C_{n-1} \oplus B_m$ for $i=n$. In each case there are seven $\widetilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0 = H + \widetilde{G}_0 + g_1$, and in each case one finds $G_0 \equiv H + B(m|n-1)$. Now there are four G_0-modules and $B(m|n) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$ with

$$\begin{aligned} G_{-1} = \operatorname{span}\{ & e_{2m+1,2m+1+n+i} + e_{2m+1+i,2m+1}, e_{2m+1+i,2m+1+n+j} + e_{2m+1+j,2m+1+n+i}, e_{2m+1+i,2m+1+j} \\ & - e_{n+2m+1+j,n+2m+1+i}, \quad i \neq j = 1,\ldots,n; e_{k,2m+1+n+i} + e_{2m+1+i,m+k}, e_{m+k,2m+1+n+i} + e_{2m+1+i,k}, \\ & k = 1,\ldots,m\}, \end{aligned}$$

and $N = 2(m+n)-1$. Observe that in this case $G_{-2} = \operatorname{span}\{e_{2m+1+i,2m+1+n+i}\}$, and all these cases are isomorphic to that of Step 1 with $i=1$.

Step 5. Delete the adjacent nodes $(i-1)$ and i, $i=n+j$, $j=1,2,\ldots,m$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\widetilde{G}_0 = C_n \oplus B_{m-1}$ for $j=1$, of $\widetilde{G}_0 = C(n+1) \oplus B_{m-2}$ for $j=2$, of $\widetilde{G}_0 = D(j-1|n) \oplus B_{m-j}$ for $j=3,\ldots,m-2$, of $\widetilde{G}_0 = D(m-2|n) \oplus A_1$ for $j=m-1$, and of $\widetilde{G}_0 = D(m-1|n)$ for $j=m$. In each case there are five $\widetilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0 = H + \widetilde{G}_0 + g_1$, and in each case one finds $G_0 \equiv H + B(m-1|n)$. Now there are two G_0-modules and $B(m|n) = G_{-1} \oplus G_0 \oplus G_{+1}$ with

$$G_{-1}=\mathrm{span}\{e_{j,2m+1}-e_{2m+1,j+m},e_{j,k+m}-e_{k,j+m},e_{jk}-e_{k+m,j+m},\quad j\neq k=1,\ldots,m;e_{j,2m+1+n+l}+e_{2m+1+l,m+j},e_{j,2m+1+l}-e_{2m+1+n+l,j+m},\quad l=1,\ldots,n\},\tag{4.10}$$

and $N=2(m+n)-1$. All these cases are mutually isomorphic.

Step 6. Delete the nonadjacent nodes i,j, $i<j-1$, $j=3,\ldots,n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=C_i\oplus sl(j-i)\oplus B(m|n-j)$ (for $i=1$ instead of C_i we have A_1). In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0\equiv H+sl(j-i)\oplus B(m|n-j+i)$. Now there are four G_0-modules and $B(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$. All these cases are isomorphic to those in Step 1 with $i=2,\ldots,n-1$.

Step 7. Delete the nonadjacent nodes i,j, $i=1,\ldots,n$, $j=n+1,\ldots,n+m$ [but $(i,j)\neq(n,n+1)$] from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=C_i\oplus sl(j-n|n-i)\oplus B_{n+m-j}$ (for $i=1$ instead of C_i we have A_1). In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and one always finds $G_0\equiv H+sl(j-n|n-i)\oplus B(n+m-j|i)$. Now there are four G_0-modules and $B(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$, where

$$\begin{aligned}G_{-1}=\mathrm{span}\{&e_{k,2m+1}-e_{2m+1,k+m},e_{2m+1,2m+1+n+l}+e_{2m+1+l,2m+1},e_{k,2m+1+n+p}+e_{2m+1+p,m+k},e_{k,2m+1+p}\\&-e_{2m+1+n+p,m+k},e_{2m+1+l,2m+1+n+p}+e_{2m+1+p,2m+1+n+l},e_{2m+1+l,2m+1+p}\\&-e_{2m+1+n+p,2m+1+n+l},e_{s,2m+1+n+l}+e_{2m+1+l,m+s},e_{m+s,2m+1+n+l}+e_{2m+1+l,s},\\&k=1,\ldots,j-n,\quad l=i+1,\ldots,n,\quad p=1,\ldots,i,\quad s=j+1-n,\ldots,m\},\end{aligned}\tag{4.11}$$

with $N=2(j-i)(m+n)-(j-i)(2(j-i)-1)$. All these cases are new (i.e., not isomorphic to an earlier case).

Step 8. Delete the nonadjacent nodes i,j, $i<j-1$, $i=n+1,\ldots,n+m-2$, $j=n+3,n+4,\ldots,n+m$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=D(i-n|n)\oplus sl(j-i)\oplus B_{n+m-j}$ [for $i=n+1$ instead of $D(i-n|n)$ we have $C(n+1)$]. In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and one finds $G_0\equiv H+sl(j-i)\oplus B(m-j+i|n)$. Now there are four G_0-modules, and $B(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$, where

$$\begin{aligned}G_{-1}=\mathrm{span}\{&e_{k,2m+1}-e_{2m+1,k+m},e_{k,m+l}-e_{l,m+k},e_{kl}-e_{m+l,m+k},e_{k,2m+1+n+p}+e_{2m+1+p,m+k},e_{k,2m+1+p}\\&-e_{2m+1+n+p,m+k},\\&k=i-n+1,i-n+2,\ldots,j-n,\quad l=1,2,\ldots,i-n,j-n+1,j-n+2,\ldots,m,\quad p=1,2,\ldots,n\},\end{aligned}\tag{4.12}$$

with $N=2(j-i)(m+n)-(j-i)(2(j-i)-1)$. All these cases are isomorphic to cases of Step 7.

Step 9. If we delete three or more nodes from the extended distinguished Dynkin diagram, the corresponding $\mathbb{Z}$-grading of $B(m|n)$ no longer has the required properties (i.e., there are non zero subspaces G_i with $|i|>2$).

The next step consists of repeating this procedure for the nondistinguished Dynkin diagrams and their extensions. Following Ref. 17 one can obtain all such Dynkin diagrams of $B(m|n)$. We have repeated this procedure for all of them, leading to a lot of case studies but not leading to any new results (i.e., each case is isomorphic to one described already by means of the distinguished diagram).

V. THE LIE SUPERALGEBRAS $B(0|n)$

We consider the Lie superalgebra $B(0|n)$ separately because the distinguished choice of the simple roots for $B(0|n)$ is different than that of $B(m|n)$. In Table I the distinguished simple roots, the distinguished Dynkin diagram, and the extended distinguished Dynkin diagram are given.

Step 1. Delete node i, $i=1,\ldots,n$ from the distinguished Dynkin diagram. The corresponding diagram is the Dynkin diagram of $G_0=H+sl(i)\oplus B(0|n-i)$. There are four simple G_0-modules and $B(0|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$, where

$$G_{-1}=\mathrm{span}\{e_{1,1+n+k}+e_{1+k,2m+1},e_{1+k,1+n+l}+e_{1+l,1+n+k},e_{1+k,1+l}-e_{n+1+l,n+1+k},\\ k=1,\ldots,i,\quad l=i+1,\ldots,n,\}, \tag{5.1}$$

with $N=2i(n-i)+i$. We give $\mathcal{R}$ for $i=n$, because then the number of creation or annihilation operators is $N=n$. One can label the CAOs as follows:

$$B_j^-=-\sqrt{2}(e_{1,1+n+j}+e_{1+j,1}),\quad j=1,\ldots,n,\\ B_j^+=\sqrt{2}(e_{1,1+j}-e_{1+n+j,1}),\quad j=1,\ldots,n. \tag{5.2}$$

These are all odd generators of $B(0|n)$ and the relations $\mathcal{R}$ consist of the triple para-Bose relations given already in (4.8).

Step 2. If we delete two or more nodes from the distinguished Dynkin diagram, the resulting $\mathbb{Z}$-gradings of $B(0|n)$ are no longer of the form (2.3).

Step 3. Delete node i, $i=0,1,\ldots,n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0=B(0|n),A_1\oplus B(0|n-1),C_2\oplus B(0,n-2),\ldots,C_{n-1}\oplus B(0|1),C_n$. In all these cases there is only one G_0-module, so there are no contributions to the classification.

Step 4. Delete the adjacent nodes $(i-1)$ and i, $i=2,3,\ldots,n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=A_1\oplus B(0|n-2)$ for $i=2$, of $\tilde{G}_0=C_{i-1}\oplus B(0|n-i)$ for $i=3,\ldots,n-1$, and of $\tilde{G}_0=C_{n-1}$ for $i=n$. In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0\equiv H+B(0|n-1)$. Now there are four G_0-modules and $B(0|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{1,1+n+i}+e_{1+i,1},e_{1+i,1+n+j}+e_{1+j,1+n+i},e_{1+i,1+j}-e_{n+1+j,n+1+i},\quad i\neq j=1,\ldots,n\},$$

$N=2n-1$, and $G_{-2}=\mathrm{span}\{e_{1+i,1+n+i}\}$. All these cases are isomorphic to those of Step 1 with $i=1$.

Step 5. Delete the nonadjacent nodes i,j from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=C_i\oplus sl(j-i)\oplus B(0|n-j)$ [for $i=1,\tilde{G}_0=A_1\oplus sl(j-1)\oplus B(0|n-j)$; for $j=n,\tilde{G}_0=C_i\oplus sl(n-i)$]. In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0\equiv H+sl(j-i)\oplus B(0|n-j+i)$. Now there are four G_0-modules and $B(0|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$. All these cases are isomorphic to those in Step 1 with $i=2,\ldots,n-1$.

Step 6. If we delete three or more nodes from the extended distinguished Dynkin diagram, the corresponding $\mathbb{Z}$-grading of $B(0|n)$ no longer has the required properties (i.e., there are nonzero subspaces G_i with $|i|>2$).

In the case of $B(0|n)$ any other choice of simple roots is equivalent to the distinguished choice, so there are no more cases to study.

VI. THE LIE SUPERALGEBRAS $D(m|n)$

$G=D(m|n)\equiv osp(2m|2n)$ is the subalgebra of $sl(2m|2n)$ consisting of matrices of the form (4.1) with the middle row and column deleted. The Cartan subalgebra H of G is again the subspace of diagonal matrices D. Putting $\epsilon_i(D)=d_{ii},i=1,\ldots,m,\delta_i(D)=d_{2m+i,2m+i},i=1,\ldots,n$, the even root vectors and corresponding roots of G are given by

$$e_{jk}-e_{k+m,j+m}\leftrightarrow\epsilon_j-\epsilon_k,\quad j\neq k=1,\ldots,m,$$

$$e_{j,k+m} - e_{k,j+m} \leftrightarrow \epsilon_j + \epsilon_k, \quad j < k = 1,\ldots,m,$$

$$e_{j+m,k} - e_{k+m,j} \leftrightarrow -\epsilon_j - \epsilon_k, \quad j < k = 1,\ldots,m,$$

$$e_{2m+j,2m+k} - e_{n+2m+k,n+2m+j} \leftrightarrow \delta_j - \delta_k, \quad j \neq k = 1,\ldots,n,$$

$$e_{2m+j,2m+k+n} + e_{2m+k,2m+j+n} \leftrightarrow \delta_j + \delta_k, \quad j \leqslant k = 1,\ldots,n,$$

$$e_{2m+n+j,2m+k} + e_{2m+n+k,2m+j} \leftrightarrow -\delta_j - \delta_k, \quad j \leqslant k = 1,\ldots,n,$$

and the odd root vectors and roots by

$$e_{j,2m+k} - e_{2m+n+k,j+m} \leftrightarrow \epsilon_j - \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n,$$

$$e_{m+j,2m+k} - e_{2m+n+k,j} \leftrightarrow -\epsilon_j - \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n,$$

$$e_{j,2m+n+k} + e_{2m+k,m+j} \leftrightarrow \epsilon_j + \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n,$$

$$e_{m+j,2m+n+k} + e_{2m+k,j} \leftrightarrow -\epsilon_j + \delta_k, \quad j = 1,\ldots,m, \quad k = 1,\ldots,n.$$

The distinguished set of simple roots, the corresponding Dynkin diagram and its extension are given in Table I.

Step 1. Delete node i, $i=1,\ldots,m+n-2$ from the distinguished Dynkin diagram. The corresponding diagram is that of $G_0=H+D(m|n-1)$ for $i=1$, of $G_0=H+sl(i)\oplus D(m|n-i)$ for $i=2,\ldots,n-1$, of $G_0=H+sl(n)\oplus D_m$ for $i=n$, of $G_0=H+sl(i-n|n)\oplus D_{m+n-i}$ for $i=n+1,\ldots,m+n-3$, and of $G_0=H+sl(m-2|n)\oplus A_1\oplus A_1$ for $i=m+n-2$. There are four simple G_0-modules and $D(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$, where for, $i=1,\ldots,n$:

$$G_{-1} = \mathrm{span}\{e_{2m+j,2m+n+k} + e_{2m+k,2m+j+n}, e_{2m+j,2m+k} - e_{n+2m+k,n+2m+j}, e_{l,2m+n+j} + e_{2m+j,m+l}, e_{m+l,2m+n+j} + e_{2m+j,l}; \quad j = 1,\ldots,i, \quad k = i+1,\ldots,n, \quad l = 1,\ldots,m\} \tag{6.1}$$

with $N=2i(m+n-i)$; whereas for $i=n+1,\ldots,m+n-2$:

$$G_{-1} = \mathrm{span}\{e_{k,2m+n+j} + e_{2m+j,m+k}, e_{m+k,2m+n+j} + e_{2m+j,k}, e_{l,m+k} - e_{k,m+l}, e_{lk} - e_{m+k,m+l}; \quad j = 1,\ldots,n, \quad k = i-n+1,\ldots,m, \quad l = 1,\ldots,i-n,\}, \tag{6.2}$$

with $N=2i(m+n-i)$.

Step 2. Delete node $m+n-1$ or $m+n$ from the distinguished Dynkin diagram. The corresponding diagram is the Dynkin diagram of $G_0=H+sl(m|n)$. There are two simple G_0-modules and $D(m|n)=G_{-1}\oplus G_0\oplus G_{+1}$, where, for $m+n-1$:

$$G_{-1} = \mathrm{span}\{e_{j,m+k} - e_{k,m+j}, \quad j < k = 1,\ldots,m-1, \quad e_{2m+q,2m+n+s} + e_{2m+s,2m+n+q}, \quad q \leqslant s = 1,\ldots,n, \quad e_{lm} + e_{2m,m+l}, e_{l,2m+n+p} + e_{2m+p,m+l}, e_{2m,2m+n+p} + e_{2m+p,m}, \quad l = 1,\ldots,m-1, \quad p = 1,\ldots,n\}; \tag{6.3}$$

and for $m+n$:

$$G_{-1} = \mathrm{span}\{e_{j,m+k} - e_{k,m+j}, \quad j < k = 1,\ldots,m, \quad e_{2m+p,2m+n+s} + e_{2m+s,2m+n+p}, \quad p \leqslant s = 1,\ldots,n, \quad e_{j,2m+n+l} + e_{2m+l,m+j}, \quad j = 1,\ldots,m, \quad l = 1,\ldots,n\}. \tag{6.4}$$

Both cases have $N=(m+n)(m+n+1)/2-m$, and they are isomorphic.

Step 3. Upon deleting two nodes i and j (except $i=m+n-1, j=m+n$) or more from the

distinguished Dynkin diagram of $D(m|n)$, the corresponding $\mathbb{Z}$-gradings no longer have the required property (there are nonzero G_i with $|i|>2$).

Step 4. Delete node $m+n-1$ and $m+n$ from the distinguished Dynkin diagram. We have $G_0=H+sl(m-1|n)$. There are six simple G_0-modules. All the possible combinations of these modules give rise to gradings of the form (2.3). There are essentially three different ways in which these G_0-modules can be combined. To characterize these three cases, it is sufficient to give only G_{-1}:

$$G_{-1}=\mathrm{span}\{e_{jm}-e_{2m,m+j},e_{j,2m}-e_{m,m+j},e_{m,2m+k}-e_{2m+n+k,2m},e_{m,2m+n+k}+e_{2m+k,2m};\\ j=1,\ldots,m-1,\quad k=1,\ldots,n\},\tag{6.5}$$

with $N=2(m+n-1)$;

$$G_{-1}=\mathrm{span}\{e_{jm}-e_{2m,m+j},e_{2m,2m+n+k}+e_{2m+k,m},e_{m+j,l}-e_{m+l,j},e_{m+j,2m+k}-e_{2m+n+k,j},e_{2m+n+k,2m+p}\\ +e_{2m+n+p,2m+k};\quad j=1,\ldots,m-1,\quad k=1,\ldots,n,\quad j<l=1,\ldots,m-1,\quad k\leqslant p=1,\ldots,n\},\tag{6.6}$$

with $N=(m+n)(m+n+1)/2-m$;

$$G_{-1}=\mathrm{span}\{e_{j,m+l}-e_{l,m+j},e_{j,2m+n+k}+e_{2m+k,m+j},e_{2m+k,2m+n+p}+e_{2m+p,2m+n+k},e_{m+j,m}-e_{2m,j},e_{2m,2m+k}\\ -e_{2m+n+k,m};\quad j=1,\ldots,m-1,\quad k=1,\ldots,n,\quad j<l=1,\ldots,m-1,\quad k\leqslant p=1,\ldots,n\},\tag{6.7}$$

with $N=(m+n)(m+n+1)/2-m$. The cases (6.6) and (6.7) are isomorphic.

Step 5. Delete node i, $i=0,1,\ldots,n+m$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0=D(m|n),A_1\oplus D(m|n-1),C_2\oplus D(m|n-2),\ldots,C_{n-1}\oplus D(m|1),C_n\oplus D_m,C(n+1)\oplus D_{m-1},D(2|n)\oplus D_{m-2},\ldots,D(m-2|n)\oplus A_1\oplus A_1,D(m|n),D(m|n)$. In all these cases there is only one G_0-module, so there are no contributions to the classification.

Step 6. Delete the adjacent nodes $(i-1)$ and i, $i=2,3,\ldots,n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=A_1\oplus D(m|n-2)$ for $i=2$, of $\tilde{G}_0=C_{i-1}\oplus D(m|n-i)$ for $i=3,\ldots,n-1$ and of $\tilde{G}_0=C_{n-1}\oplus D_m$ for $i=n$. In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0\equiv H+D(m|n-1)$. Now there are four G_0-modules and $D(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{2m+k,2m+n+i}+e_{2m+i,2m+n+k},e_{2m+i,2m+k}-e_{2m+n+k,2m+n+i},\quad i\neq k=1,\ldots,n,\\ e_{l,2m+n+i}+e_{2m+i,m+l},e_{m+l,2m+n+i}+e_{2m+i,l},\quad l=1,\ldots,m\},$$

$N=2(m+n-1)$ and $G_{-2}=\mathrm{span}\{e_{2m+i,2m+n+i}\}$. All these cases are isomorphic to that of Step 1 with $i=1$.

Step 7. Delete the adjacent nodes $(i-1)$ and i, $i=n+1,\ldots,m+n-1$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=C_n\oplus D_{m-1}$ for $i=n+1$, of $\tilde{G}_0=C(n+1)\oplus D_{m-2}$ for $i=n+2$, of $\tilde{G}_0=D(i-n-1|n)\oplus D_{m+n-i}$ for $i=n+3,\ldots,m+n-3$, of $\tilde{G}_0=D(m-3|n)\oplus A_1\oplus A_1$ for $i=m+n-2$ and of $\tilde{G}_0=D(m-2|n)\oplus A_1$ for $i=m+n-1$. In each case there are five $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0\equiv H+D(m-1|n)$. Now there are two G_0-modules and $D(m|n)=G_{-1}\oplus G_0\oplus G_{+1}$ with

$$G_{-1}=\mathrm{span}\{e_{i-n,2m+n+j}+e_{2m+j,m+i-n},e_{i-n,2m+j}-e_{2m+n+j,m+i-n},\quad j=1,\ldots,n,\\ e_{k,m+i-n}-e_{i-n,m+k},e_{i-n,k}-e_{m+k,m+i-n},\quad i-n\neq k=1,\ldots,m\}\tag{6.8}$$

and $N=2(m+n-1)$. All these cases are mutually isomorphic.

Step 8. Delete the adjacent nodes $m+n-1$ and $m+n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0 \equiv D(m-1|n)$. There are two G_0-modules and $D(m|n)=G_{-1}\oplus G_0\oplus G_{+1}$ with

$$G_{-1}=\mathrm{span}\{e_{m,2m+n+j}+e_{2m+j,2m},e_{m,2m+j}-e_{2m+n+j,2m},\quad j=1,\ldots,n,$$
$$e_{k,2m}-e_{m,m+k},e_{m,k}-e_{m+k,2m},\quad k=1,\ldots,m-1\},\tag{6.9}$$

with $N=2(m+n-1)$. This case and all cases from Step 7 are isomorphic.

Step 9. Delete the nonadjacent nodes $i,j,\quad i<j-1,\ j=3,\ldots,n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=C_i\oplus sl(j-i)\oplus D(m|n-j)$ (for $i=1$ instead of C_i we have A_1). In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0 \equiv H+sl(j-i)\oplus D(m|n-j+i)$. Now there are four G_0-modules and $D(m|n)=G_{-2}\oplus G_{-1}\oplus G_0 \oplus G_{+1}\oplus G_{+2}$. All these cases are isomorphic to those of Step 1 with $i=2,\ldots,n-1$.

Step 10. Delete the nonadjacent nodes $i,j,\ i=1,\ldots,n,\ j=n+1,\ldots,n+m-2$ [but $(i,j)\neq(n,n+1)$] from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=C_i \oplus sl(j-n|n-i)\oplus D_{m+n-j}$ (for $j=n+m-2$ instead of D_{n+m-j} we have $A_1\oplus A_1$). In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0\equiv H+sl(j-n|n-i)\oplus D(m+n-j|i)$. Now there are four G_0-modules and $D(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{kl}-e_{m+l,m+k},e_{k,m+l}-e_{l,m+k},e_{r,2m+n+s}+e_{2m+s,m+r},e_{m+l,2m+n+p}+e_{2m+p,l},$$
$$e_{k,2m+q}-e_{2m+n+q,m+k},e_{2m+q,2m+n+p}+e_{2m+p,2m+n+q},e_{2m+p,2m+q}-e_{2m+n+q,2m+n+p},$$
$$k=1,\ldots,j-n,\quad l=j-n+1,\ldots,m,\quad r=1,\ldots,m,\quad s=1,\ldots,n,\quad q=1,\ldots,i,\quad p=i+1,\ldots,n\},\tag{6.10}$$

with $N=2(j-i)(m+n-j+i)$.

Step 11. Delete the nonadjacent nodes $i,j,\quad i=1,\ldots,n$, and $j=n+m-1$ or $n+m$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0=C_i\oplus sl(m|n-i)$. There are four G_0-modules and $D(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{k,2m+p}-e_{2m+n+p,m+k},e_{k,2m+n+p}+e_{2m+p,m+k},e_{2m+p,2m+n+q}+e_{2m+q,2m+n+p},e_{2m+q,2m+p}$$
$$-e_{2m+n+p,2m+n+q};\quad k=1,\ldots,m,\quad p=1,\ldots,i,\quad q=i+1,\ldots,n\}\tag{6.11}$$

for $j=m+n$ and a similar expression for $j=m+n-1$. Naturally, both cases are isomorphic and $N=2i(m+n-i)$.

Step 12. Delete the nonadjacent nodes $i,j,\ i=n+1,\ldots,m+n-2,\ j=n+m-1$ or $n+m$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0=D(i-n|n)\oplus sl(m+n-i)$ (if $i=n+1$ instead of $D(i-n|n)$ we have $C(n+1)$). There are four G_0-modules and $D(m|n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{kl}-e_{m+l,m+k},e_{m+k,l}-e_{m+l,k},e_{m+l,2m+n+p}+e_{2m+p,l};e_{m+l,2m+p}-e_{2m+n+p,l},$$
$$k=1,\ldots,i-n,\quad l=i-n+1,\ldots,m,\quad p=1,\ldots,n\},\tag{6.12}$$

for $j=m+n$ and a similar expression for $j=m+n-1$, both having $N=2i(m+n-i)$. The cases here and in Step 10 with one and the same G_0 and N are isomorphic.

Step 13. Delete the nonadjacent nodes $i,j,\ i<j-1,\ i=n+1,\ldots,n+m-4,\ j=n+3,\ldots,n+m-2$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=D(i-n|n)\oplus sl(j-i)\oplus D_{m+n-j}$ [for $i=n+1$ instead of $D(i-n|n)$ we have $C(n+1)$, for $j=m+n-2$ instead of D_{m+n-j} we have $A_1\oplus A_1$]. In each case there are seven $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0=H+\tilde{G}_0+g_1$, and in each case one finds G_0

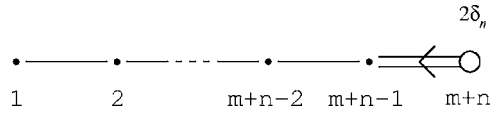
$\equiv H+sl(j-i)\oplus D(m-j+i|n)$. Now there are four G_0-modules and $D(m|n)=G_{-2}\oplus G_{-1}\oplus G_0 \oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{kl}-e_{m+l,m+k},e_{m+k,l}-e_{m+l,k},e_{m+l,2m+n+q}+e_{2m+q,l},e_{m+l,2m+q}-e_{2m+n+q,l},$$
$$k=1,\ldots,i-n,j-n+1,\ldots,m,\quad l=i-n+1,\ldots,j-n,\quad q=1,\ldots,n\}$$

with $N=2(j-i)(m+n-j+i)$. All of these are isomorphic to cases in Step 12.

Step 14. If we delete three or more nodes from the extended distinguished Dynkin diagram, the corresponding $\mathbb{Z}$-grading of $D(m|n)$ has no longer the required properties (i.e., there are non-zero subspaces G_i with $|i|>2$).

Step 15. Also here, we have considered all the nondistinguished Dynkin diagrams and their extensions, following Ref. 17. Repeating our procedure for all of them leads again to a lot of case studies, most of which are isomorphic to results of the previous steps. There is, however, one extra case that is not covered in the previous steps, and that we shall briefly describe. Consider the nondistinguished Dynkin diagrams of $D(m|n)$ of the following form:



In this diagram, each dot stands for a white or gray circle, depending upon whether the corresponding simple root is even or odd. All these other simple roots are of the form $\eta-\eta'$, where η and η' can be a ϵ_i or a δ_j. For example, root $m+n-1$ is either $\delta_{n-1}-\delta_n$ (in which case the circle is white) or $\epsilon_m-\delta_n$ (in which case it is gray). Deleting node i ($i=1,\ldots,m+n-2$) yields the (nondistinguished) Dynkin diagram of $G_0=sl(k|l)\oplus D(m-k|n-l)$. Most of these cases are isomorphic to those already found in Step 10 or 11. However, the case $G_0=H+sl(m-1|l)\oplus D(1|n-l)=H+sl(m-1|l)\oplus C(n-l+1)$ ($l=0,\ldots,n-1$) did not occur before. This adds a new case to the classification, for which the length of the grading is 5. From a detailed analysis, it follows that this is the only extra case that can be obtained from the nondistinguished Dynkin diagrams (extended or not).

VII. THE LIE SUPERALGEBRAS $C(n)$

Let $G=C(n)=D(1|n-1)=osp(2|2n-2)$. For a description of the root vectors, we refer to Sec. VI. The even roots are of the form $\pm\delta_j\pm\delta_k(j,k=1,\ldots,n-1)$ and the odd roots are $\pm\epsilon\pm\delta_k(k=1,\ldots,n-1)$. This Lie superalgebra is treated separately from $D(m|n)$ because its distinguished Dynkin diagram is different (see Table I), and its structure is also different (it is a type I Lie superalgebra[4]).

Step 1. Delete node 1 from the distinguished Dynkin diagram. Then the corresponding diagram is that of $G_0=C_{n-1}$. There are only two G_0-modules and $C(n)$ has the grading $C(n)=G_{-1}\oplus G_0\oplus G_{+1}$, where

$$\begin{aligned}G_{-1}&=\mathrm{span}\{e_{1,i+2}-e_{n+1+i,2},e_{1,n+1+i}+e_{i+2,2},\quad i=1,\ldots,n-1\},\\ G_{+1}&=\mathrm{span}\{e_{2,n+1+i}+e_{i+2,1},e_{2,i+2}-e_{n+1+i,1},\quad i=1,\ldots,n-1\},\end{aligned}\tag{7.1}$$

with $N=2(n-1)$. Putting

$$c^-_{-,i}=e_{1,2+i}-e_{n+1+i,2},\quad c^-_{+,i}=e_{1,n+1+i}+e_{2+i,2},$$

$$c^+_{-,i}=e_{2,n+1+i}+e_{2+i,1},\quad c^+_{+,i}=e_{2,2+i}-e_{n+1+i,1},$$

the operators $c^{\pm}_{\xi i},\xi=\pm,i=1,\ldots,n-1$, satisfy the following relations:

$$[\{c^-_{\xi i},c^+_{\eta j}\},c^+_{\epsilon k}]=\xi\delta_{\xi\eta}\delta_{ij}c^+_{\epsilon k}-\epsilon\delta_{\xi\epsilon}\delta_{ik}c^+_{\eta j}+\eta\delta_{-\eta\epsilon}\delta_{jk}c^+_{-\xi i},$$

$$[\{c^-_{\xi i},c^+_{\eta j}\},c^-_{\epsilon k}]=-\xi\delta_{\xi\eta}\delta_{ij}c^-_{\epsilon,k}+\eta\delta_{\eta\epsilon}\delta_{jk}c^-_{\xi i}+\epsilon\delta_{-\xi\epsilon}\delta_{ik}c^-_{-\eta j},$$

$$\{c^-_{-i},c^+_{+j}\}=\{c^-_{-j},c^+_{+i}\},\quad \{c^-_{+i},c^+_{-j}\}=\{c^-_{+j},c^+_{-i}\},$$

$$\{c^-_{\xi i},c^-_{\eta j}\}=\{c^+_{\xi i},c^+_{\eta j}\}=0. \tag{7.2}$$

(Here and throughout, by convention, ξ,η,ϵ are written as $\pm$ when used as subscripts, and as ±1 when used algebraically as multipliers.)

Step 2. Delete node i, $i=2,\ldots,n-1$, from the distinguished Dynkin diagram. The corresponding diagram is the Dynkin diagram of $G_0=H+sl(1|i-1)\oplus C_{n-i}$ (if $i=n-1, C_{n-i}=A_1$). There are four simple G_0-modules and $C(n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ where

$$G_{-1}=\mathrm{span}\{e_{j+2,k+2}-e_{n+1+k,n+1+j},e_{j+2,n+1+k}+e_{k+2,n+1+j},e_{1,k+2}-e_{n+1+k,2},e_{1,n+1+k}+e_{k+2,2},;$$
$$j=1,\ldots,i-1,\ k=i,\ldots,n-1\}, \tag{7.3}$$

with $N=2i(n-i)$. An interesting case is that with $i=n-1$ and $N=2(n-1)$.

Step 3. Delete node n from the distinguished Dynkin diagram. Then the corresponding diagram is that of $G_0=sl(1|n-1)$. There are only two G_0-modules and $C(n)$ has grading $C(n)=G_{-1}\oplus G_0\oplus G_{+1}$, where

$$G_{-1}=\mathrm{span}\{e_{k+2,n+1+l}+e_{l+2,n+1+k},\quad k\leqslant l=1,\ldots,n-1,\quad e_{1,n+1+j}+e_{j+2,2},\quad j=1,\ldots,n-1\}. \tag{7.4}$$

This is also an interesting case, since there are

$$N=\frac{n(n+1)}{2}-1$$

supercommuting annihilation (respectively, creation) operators.

Step 4. Upon deleting two nodes i and j (except $i=1,j=n$) or more from the distinguished Dynkin diagram of $C(n)$, the corresponding $\mathbb{Z}$-gradings no longer have the required property (there are nonzero G_i with $|i|>2$).

Step 5. Delete node 1 and n from the distinguished Dynkin diagram. We have $G_0=H+sl(n-1)$. There are six simple G_0-modules. All the possible combinations of these modules give rise to gradings of the form $C(n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$. There are essentially three different ways in which these G_0-modules can be combined. To characterize these three cases, it is sufficient to give only G_{-1}:

$$G_{-1}=\mathrm{span}\{e_{j+2,n+k+1}+e_{k+2,n+j+1},\quad j\leqslant k=1,\ldots,n-1,\quad e_{1,i+2}-e_{n+i+1,2},\ i=1,\ldots,n-1\}, \tag{7.5}$$

with $N=n(n+1)/2-1$;

$$G_{-1}=\mathrm{span}\{e_{1,k+2}-e_{n+k+1,2},e_{2,k+2}-e_{n+k+1,1},\quad k=1,\ldots,n-1\}, \tag{7.6}$$

with $N=2(n-1)$;

$$G_{-1}=\mathrm{span}\{e_{1,n+k+1}+e_{k+2,2},\quad k=1,\ldots,n-1,\ e_{n+l+1,p+2}+e_{n+p+1,l+2},\quad l\leqslant p=1,\ldots,n-1\}, \tag{7.7}$$

with $N=n(n+1)/2-1$. It is interesting to give the algebraic relations for (7.6), since the number of creation and annihilation operators is $N=2(n-1)$. One can label the CAOs as follows ($k=1,\ldots,n-1$):

$$c^-_{-k}=e_{1,k+2}-e_{n+k+1,2},\quad c^-_{+k}=e_{2,k+2}-e_{n+k+1,1},$$

$$c^+_{-k} = e_{2,n+k+1} + e_{k+2,1}, \quad c^+_{+k} = e_{1,n+k+1} + e_{k+2,2}.$$

The CAOs $c^{\pm}_{\xi k}, \xi = \pm, k = 1, \ldots, n-1$, satisfy the relations ($\xi, \eta, \epsilon = \pm$ or $\pm 1; j, k, l = 1, \ldots, n-1$):

$$\{c^{\eta}_{\xi j}, c^{\eta}_{\xi k}\} = \{c^-_{-j}, c^+_{+k}\} = \{c^-_{+j}, c^+_{-k}\} = 0,$$

$$\{c^-_{+j}, c^+_{+k}\} = \{c^-_{-j}, c^+_{-k}\}, \quad j \neq k,$$

$$\{c^{\xi}_{\xi j}, c^{\xi}_{-\xi k}\} = \{c^{\xi}_{\xi k}, c^{\xi}_{-\xi j}\},$$

$$[\{c^{\gamma}_{\xi j}, c^{\gamma}_{\eta k}\}, c^{\gamma}_{\epsilon l}] = 0,$$

$$[\{c^{\xi}_{\xi j}, c^{\xi}_{-\xi k}\}, c^{-\xi}_{\epsilon l}] = -\xi \delta_{kl} c^{\xi}_{-\epsilon j} - \xi \delta_{jl} c^{\xi}_{-\epsilon k},$$

$$[\{c^-_{\xi j}, c^+_{\xi k}\}, c^-_{\eta l}] = -\delta_{kl} c^-_{\eta j} - (-1)^{\delta_{\xi\eta}} \delta_{jk} c^-_{\eta l},$$

$$[\{c^-_{\xi j}, c^+_{\xi k}\}, c^+_{\eta l}] = (-1)^{\delta_{\xi\eta}} \delta_{jk} c^+_{\eta l} + \delta_{jl} c^+_{\eta k}. \tag{7.8}$$

Step 6. Delete node i, $i = 0, 1, \ldots, n$, from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0 = C(n), C(n), sl(2|1) \oplus C_{n-2}, C(3) \oplus C_{n-3}, \ldots, C_{n-1} \oplus A_1, C(n)$. In all these cases there is only one G_0-module, so there are no contributions to the classification.

Step 7. Delete the adjacent nodes i and $i+1$, $i = 2, 3, \ldots, n-2$, from the extended distinguished Dynkin diagram. The remaining diagram is that of $\widetilde{G}_0 = H + sl(2|1) \oplus C_{n-3}$ for $i = 2$ and of $\widetilde{G}_0 = H + C(i) \oplus C_{n-i-1}$ for $i = 3, \ldots, n-2$. In each case there are seven $\widetilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0 = H + \widetilde{G}_0 + g_1$, and in each case one finds $G_0 \equiv H + C(n-1)$. Now there are four G_0-modules and $C(n) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$ with

$$G_{-1} = \operatorname{span}\{e_{i+2,n+k+1} + e_{k+2,n+i+1}, e_{i+2,k+2} - e_{n+k+1,n+i+1}, e_{1,n+i+1} + e_{i+2,2}, e_{2,n+i+1} + e_{i+2,1};$$
$$k \neq i = 1, \ldots, n-1\} \tag{7.9}$$

and $N = 2(n-1)$. All these cases are mutually isomorphic.

*Step 8.*Delete the adjacent nodes $n-1$ and n from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0 \equiv H + C(n-1)$. This case turns out to be isomorphic to those of Step 7.

Step 9. Delete the nonadjacent nodes i, $i = 2, 3, \ldots, n-2$, and $j = n$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $G_0 = H + C(i) \oplus sl(n-i)$ [for $i = 2$ instead of $C(i)$ we have $sl(2|1)$]. In each case there are four G_0-modules and $C(n) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$ with

$$G_{-1} = \operatorname{span}\{e_{k+2,l+2} - e_{n+1+l,n+1+k}, e_{n+1+k,l+2} + e_{n+l+1,k+2}, e_{1,l+2} - e_{n+l+1,2}, e_{2,l+2} - e_{n+l+1,1};$$
$$l = i, \ldots, n-1, \quad k = 1, \ldots, i-1\} \tag{7.10}$$

and $N = 2i(n-i)$. These are all new cases.

Step 10. Delete the nonadjacent nodes $i < j-1$, $i = 2, 3, \ldots, n-2$, $j = 4, \ldots, n-1$ from the extended distinguished Dynkin diagram. The remaining diagram is that of $\widetilde{G}_0 = H + C(i) \oplus sl(j-i) \oplus C_{n-j}$ [for $i = 2$ instead of $C(i)$ we have $sl(2|1)$, for $j = n-1$ instead of C_{n-j} we have A_1]. In each case there are seven $\widetilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one has to put $G_0 = H + \widetilde{G}_0 + g_1$, and in each case one finds $G_0 \equiv H + sl(j-i) \oplus C(n-j+i)$. Now there are four G_0-modules and $C(n) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$ with

$$G_{-1} = \mathrm{span}\{e_{k+2,l+2} - e_{n+1+l,n+1+k}, e_{n+1+k,l+2} + e_{n+l+1,k+2}, e_{1,l+2} - e_{n+l+1,2}, e_{2,l+2} - e_{n+l+1,1};$$
$$l = i,\ldots,j-1, \quad k = 1,\ldots,i-1, \quad j,\ldots,n-1\} \tag{7.11}$$

and $N=2(j-i)(n-j+i)$. All these cases are amongst those of Step 10.

Step 11. Upon deleting three or more nodes from the extended distinguished Dynkin diagram of $C(n)$, the corresponding $\mathbb{Z}$-gradings no longer have the required property (there are nonzero G_i with $|i|>2$).

The other nondistinguished choices for the simple root systems give no new results.

VIII. SUMMARY AND CONCLUSIONS

Our analysis has led to a complete classification of all GQS associated with the basic classical Lie superalgebras. Some cases in our classification have appeared earlier as examples, e.g., para-Bose statistics (5.1), A-superstatistics (3.4) in Refs. 11 and 15, and the combined para-Bose/para-Fermi case (4.7) in Ref. 19. Some other examples are also rather simple, e.g., the alternatives to A-superstatistics in (3.5), a statistics with two kinds of particles in (3.6), and the statistics related to $C(n)$ superalgebras (7.2) and (7.8).

Although the detailed analysis in the previous sections was necessary to present the complete solution, it is convenient to summarize the final results in a table. Table II recapitulates the classification of all GQS. From this table, it follows that many of the earlier cases can be somewhat unified in a simple form, provided one makes use of the common isomorphisms for Lie algebras and Lie superalgebras [such as $D_1=C_1=A_1, D_2=A_1\oplus A_1, B(m|0)=B_m, D(1|1)=C(2)=sl(1|2)$ etc.]. For $A(m|n)$, there are essentially two distinct cases. Either $G_0=H+sl(k|l)\oplus sl(p|q)$, in which case the grading has length 3 and $G_{\pm1}$ is fixed by G_0. Or else $G_0=H+sl(k|l)\oplus sl(p|q)\oplus sl(r|s)$, in which case the grading has length 5. In this second case, there are always three ways of combining the G_0-modules in order to give some G_{-1}. For $B(m|n)$, all the cases are characterized by a G_0 of the form $G_0=H+sl(k|l)\oplus B(m-k,n-l)$. This includes cases such as $sl(l)\oplus B(m|n-l), sl(k|n)\oplus B_{m-k}$ (Step 1), $B(m|n-1)$ (Step 4) and $B(m-1|n)$ (Step 5). Also the results for the remaining Lie superalgebras can be neatly summarized. Note that for $D(m|n)$ [and for $C(n)=D(1|n-1)$] there is one G_0 which gives rise not only to different possibilities for G_{-1} but even for N.

A striking property, see Table II, is that all basic classical Lie superalgebras, except $B(0|n)$, allow a GQS with a grading of length 3; in other words, a GQS with supercommuting creation and annihilation operators.

Note that a set of CAOs together with a complete set of relations $\mathcal{R}$ unambiguously describes the Lie superalgebra. So each case of our classification also gives the description of a Lie superalgebra in terms of a number of generators subject to certain relations. This can also be reformulated in terms of the notion of Lie supertriple systems.[20] In fact, in our case the subspace $G_{-1}\oplus G_{+1}$ (i.e., the subspace spanned by all CAOs) is a Lie supertriple system for the universal enveloping algebra $U(G)$.

Just as in Ref. 2, we have dealt only with a mathematical definition of generalized quantum statistics. In order to talk about a quantum statistics in the physical sense, one should take into account additional requirements for the CAOs, related to certain quantization postulates.[8] These conditions are related to the existence of state spaces (Fock spaces), in which the CAOs act in such a way that the corresponding observables are Hermitian operators. We refer to Sec. VII of Ref. 2 for a discussion on this. We hope that some cases of our classification will yield interesting GQS also from this point of view.

As a second application, we mention the possible solutions of Wigner quantum systems.[21] Roughly speaking, the compatibility conditions (CCs) to be satisfied by a Wigner quantum oscillator system [see formula (3.7) in Ref. 22) are written in terms of certain odd operators $A_i^{\pm}$; furthermore, these CCs are special triple relations. So it is of importance to investigate which triple relations $\mathcal{R}$ of our current classification of GQS could provide special solutions of these CCs. It is known, for instance, that there is a $sl(1|n)$ solution[21–23] or a $sl(n|3)$ solution.[24] Obvi-

TABLE II. Summary of the classification: all nonisomorphic GQS associated with a classical Lie superalgebra (LSA) are given. For each GQS, we list: the subalgebra G_0 (each G_0 contains the complete Cartan subalgebra H, so we only list the remaining part of $G_0=H+\cdots$); the length ℓ of the Z-grading; the number N of annihilation operators; the equation in the text where (an example of) G_{-1} can be found.

LSA	$G_0=H+\cdots$	ℓ	N	G_{-1}
$A(m\|n)$	$sl(k\|l)\oplus sl(p\|q)$ $(k+p=m+1, l+q=n+1, k+l\neq 0, p+q\neq 0)$	3	$(k+l)(p+q)$	(3.2) and (3.12)
	$sl(k\|l)\oplus sl(p\|q)\oplus sl(r\|s)$	5	$(k+l)(p+q+r+s)$	(3.7) and (3.13)
	$(k+p+r=m+1$	5	$(p+q)(k+l+r+s)$	(3.8) and (3.14)
	$l+q+s=n+1, k+l\neq 0, p+q\neq 0, r+s\neq 0)$	5	$(r+s)(k+l+p+q)$	(3.9) and (3.15)
$B(m\|n)$	$sl(k\|l)\oplus B(m-k\|n-l)$ $(k=0,\ldots,m; l=0,\ldots,n; (k,l)\notin\{(0,0),(1,0)\})$	5	$(k+l)(2m-2k+2n-2l+1)$	(4.2) and (4.3), (4.11) and (4.12)
	$B(m-1\|n)[(k,l)=(1,0)]$	3	$2m+2n-1$	(4.10)
$B(0\|n)$	$sl(i)\oplus B(0\|n-i)$ $(i=1,\ldots,n)$	5	$i(2n-2i+1)$	(5.1)
$D(m\|n)$	$sl(k\|l)\oplus D(m-k\|n-l)$ $(k=0,1,\ldots,m; l=0,1,\ldots,n; (k,l)\notin\{(0,0),(1,0),(m-1,n),(m,n)\})$	5	$2(k+l)(m+n-k-l)$	(6.10) and (6.11), (6.1) and (6.2), (6.12)
	$D(m-1\|n)[(k,l)=(1,0)]$	3	$2(m+n-1)$	(6.8) and (6.9)
	$sl(m\|n)[(k,l)=[m,n)]$	3	$(m+n)(m+n+1)/2-m$	(6.3) and (6.4)
	$sl(m-1\|n)[(k,l)=(m-1,n)]$	5	$(m+n)(m+n+1)/2-m$	(6.6) and (6.7)
	$sl(m-1\|n)[(k,l)=(m-1,n)]$	5	$2(m+n-1)$	(6.5)
$C(n)$	$sl(k\|l)\oplus D(1-k\|n-1-l)$ $(k=0,1; l=1,\ldots,n-2)$	5	$2(k+l)(n-k-l)$	(7.3) and (7.9), (7.10) and (7.11)
	$C_{n-1}[(k,l)=(1,0)]$	3	$2(n-1)$	(7.1)
	$sl(1\|n-1)[(k,l)=(1,n-1)]$	3	$n(n+1)/2-1$	(7.4)
	$sl(n-1)[(k,l)=(0,n-1)]$	5	$n(n+1)/2-1$	(7.5) and (7.7)
	$sl(n-1)[(k,l)=(0,n-1)]$	5	$2(n-1)$	(7.6)

ously, for a possible candidate solution all the CAOs of $\mathcal{R}$ should be odd operators. Let us briefly describe the GQSs of the current classification which have only odd CAOs. Then G_{-1} and G_{+1} are odd subspaces, and by the grading condition it follows automatically that the GQS grading (2.3) is *consistent* with the $\mathbb{Z}_2$-grading. So our problem reduces to selecting those GQS from our classification with a consistent $\mathbb{Z}$-grading. This is not too difficult.

For $A(m|n)$, one can consider $i=m+1$ in Step 1. Then all elements of G_{-1} in (3.2) are odd; $G_0=H+sl(m+1)\oplus sl(n+1)$, and the grading has length 3 (the case $m=0$ corresponds to Refs. 11 and 21–23). Alternatively, one can consider the cases $(i,j)=(i,m+1)$ or $(i,j)=(m+1,j)(i<j)$ of Step 2. In the case $(i,j)=(i,m+1)$, the elements of G_{-1} given by (3.9) are all odd, and $G_0=H+sl(i)\oplus sl(m+1-i)\oplus sl(n+1)$. In the case $(i,j)=(m+1,j)$, the elements of G_{-1} given by (3.8) are all odd, and $G_0=H+sl(m+1)\oplus sl(k)\oplus sl(n+1-k)$ with $k=j-m-1$. For $B(m|n)$, the case $i=n$ in Step 1 leads to a G_{-1} with only odd elements in (4.2). Note that in this case $G_0=H+sl(n)\oplus B_m$. For $B(0|n)$, this corresponds to taking $i=n$ in Step 1, so that G_{-1} in (5.1) has odd elements only and $G_0=H+sl(n)$ (this is the para-Bose case). For $D(m|n)$, the case $i=n$ in Step 1 leads to a G_{-1} in (6.1) with odd elements only, and with $G_0=H+sl(n)\oplus D_m$. There is a second solution here, namely the case $i=n$ in Step 11; then G_{-1}, given by (6.11) has odd elements only and $G_0=H+sl(m)\oplus C_n$. Finally for $C(n)$ the solution provided in Step 1 has only odd elements for G_{-1}, see (7.1),

with $G_0=H+C_{n-1}$. Also here there is a second solution given in Step 5 with G_{-1} of the form (7.6) and $G_0=H+sl(n-1)$. To conclude, all the basic classical Lie superalgebras have GQSs with odd CAOs only. Whether all these cases provide special solutions to the CCs of the Wigner quantum oscillator will be treated elsewhere.

Properly specializing the parameters in "Schnizer modules," for types A,B,C, and D, we get its unique primitive vector. Then we show that the module generated by the primitive vector is an irreducible highest weight module of finite dimensional classical quantum groups at roots of unity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2107307]

I. INTRODUCTION

The representation theory of quantum groups at roots of unity are divided into the following two types: one is for U_ε defined by DeConcini-Kac (=nonrestricted type)[3] and the other is for $U_\varepsilon^{\mathrm{res}}$ defined by Lusztig(=restricted type).[6] In the latter case, the classification of irreducible modules is the same as the generic case, that is, they are classified by highest weights.[6,7] In the former case, however, most irreducible modules are no longer highest or lowest weight modules and they are characterized by several continuous parameters.[3] For type A, such modules are constructed very explicitly in Ref. 2, which are called maximal cyclic representations. For any simple Lie algebra, Schnizer introduced an alternative construction of such modules in Refs. 9 and 10, which we also call maximal cyclic representations or "Schnizer modules."

In Ref. 8, T. N. found that for type A_n-case if the continuous parameters in a maximal cyclic representation are specialized properly, then there exists a unique primitive vector and the submodule generated by the primitive vector is irreducible as a module of finite dimensional quantum group at roots of unity(denoted by $U_\varepsilon^{\mathrm{fin}}$). In this paper, we shall show that this method is applicable to the Schnizer modules of types A_n, B_n, C_n, and D_n.

In order to explain what we shall do in this paper, let us see A_n-case explicitly: Let $N=\frac{1}{2}n(n+1)$ be the number of positive roots, l be an odd integer greater than 3, and ε be the primitive lth root of unity. Set $V:=(\mathbb{C}^l)^{\otimes N}$ and for each $a\in(\mathbb{C}^\times)^N, b\in\mathbb{C}^N$, and $\lambda\in\mathbb{C}^n$, we can define a $U_\varepsilon(\mathsf{sl}(n+1,\mathbb{C}))$-module structure on V as follows.

Theorem 1.1 (Ref. 10): *For any* $a=(a_{i,j})_{1\leqslant i\leqslant j\leqslant n}\in(\mathbb{C}^\times)^N, b=(b_{i,j})_{1\leqslant i\leqslant j\leqslant n}\in\mathbb{C}^N, \lambda=(\lambda_1,\cdots,\lambda_n)\in\mathbb{C}^n$, *we obtain a* $U_\varepsilon(sl(n+1,\mathbb{C}))$*-module structure on* $V:\Phi_\lambda: U_\varepsilon(sl(n+1,\mathbb{C}))\to End(V)$. *For any* $i\in I$,

$$\Phi_\lambda(f_i)(u(m))=\sum_{j=i}^{n}[m_{i,j}-m_{i+1,j}+b_{i,j}-b_{i+1,j}-\mu_{i,j-1}^{m,b}]u(m+\epsilon_{i,j}),$$

$$\Phi_\lambda(t_i)(u(m))=\varepsilon^{\mu_{i,n}^{m,b}}u(m),$$

[a)] In memory of W. A. Schnizer

[b)] Electronic Mail: yu-abe@hoffman.cc.sophia.ac.jp

[c)] Supported in part by JSPS Grants in Aid for Scientific Research, electronic-mail: toshiki@mm.sophia.ac.jp

$$\Phi_\lambda(e_i)(u(m)) = \sum_{j=1}^{i} [m_{j-1,n-i+j} - m_{j,n-i+j} + b_{j-1,n-i+j} - b_{j,n-i+j}]$$
$$\times a_{j,n-i+j}^{-1} \prod_{k=j+1}^{i} (a_{k-1,n-i+k} a_{k,n-i+k}^{-1}) u(m + \sum_{k=j+1}^{i} (\epsilon_{k-1,n-i+k} - \epsilon_{k,n-i+k}) - \epsilon_{j,n-i+j}),$$

where

$$\mu_{i,j}^{m,b} = \lambda_i + m_{i-1,i-1} + b_{i-1,i-1} + \sum_{k=i}^{j} (m_{i-1,k} - 2m_{i,k} + m_{i+1,k} + b_{i-1,k} - 2b_{i,k} + b_{i+1,k}),$$

$$(1 \leqslant i \leqslant n, i-1 \leqslant j \leqslant n),$$

and we understand that $m_{i,j} := 0$ *if the index* (i,j) *is out of range and* $\Sigma_{j=k}^{i}(\cdots) := 0, \Pi_{j=k}^{i}(\cdots) := 1$ *for* $k > i$.

Let us define $a^{(0)} = (a_{i,j}^{(0)})_{1 \leqslant i \leqslant j \leqslant n} \in (\mathbb{C}^\times)^N, b^{(0)} = (b_{i,j}^{(0)})_{1 \leqslant i \leqslant j \leqslant n} \in \mathbb{C}^N$, by

$$a_{i,j}^{(0)} = 1, \quad b_{i,j}^{(0)} = 0, \quad (1 \leqslant i \leqslant j \leqslant n).$$

For any $\lambda \in \mathbb{C}^n$, let us denote by $V(\lambda)$ the $U_\varepsilon(\mathsf{sl}(n+1,\mathbb{C}))$-module defined by $(\Phi_{a^{(0)},b^{(0)},\lambda}, V)$.

Proposition 1.2: For any $\lambda \in \mathbb{C}^n$, *there exists a unique (up to nonzero scalar multiplication) nonzero vector* $u_{\mathbf{0}}$, *such that* $e_i u = 0$ *in* $V(\lambda)$ *for any* $i \in I$.

Finally, it turns out that the submodule $U_\varepsilon u_{\mathbf{0}} \subset V(\lambda)$ is an irreducible highest weight $U_\varepsilon^{\mathrm{fin}}$-module. By this method, we obtain all finite dimensional irreducible $U_\varepsilon^{\mathrm{fin}}$-modules:

Theorem 1.3: *Let* $\lambda \in \mathbb{Z}_l^n (\mathbb{Z}_l := \{0,1,\cdots,l-1\})$. *Then* $U_\varepsilon u_{\mathbf{0}}$ *is a finite dimensional irreducible* $U_\varepsilon^{\mathrm{fin}}(sl(n+1,\mathbb{C}))$*-module of type* 1 *with highest weight* λ.

The proofs of the above-noted statements are done in a similar way to the ones in Ref. 8.

The organization of the paper is as follows: in Sec. II, we prepare notations and review the theory of quantum groups at roots of unity briefly. In Sec. III, we introduce Schnizer modules and show the uniqueness of primitive vectors. In the last two sections, we show that the submodule generated by the primitive vector is regarded as a module for the finite dimensional quantum group at roots of unity $U_\varepsilon^{\mathrm{fin}}$ of types (A), B, C, and D. At last, we obtain that such submodule is an irreducible $U_\varepsilon^{\mathrm{fin}}$-module and all finite dimensional irreducible $U_\varepsilon^{\mathrm{fin}}$-modules are obtained as such modules.

II. QUANTUM ENVELOPING ALGEBRA $U_q(\ )$

A. Definition of quantum enveloping algebra

In this section, we define the quantum enveloping algebra $U_q(\mathfrak{g})$ for a generic q. Let $\mathbb{C}(q)$ be the rational function field in an indeterminate q. Define

$$[a]_{q^d} := \frac{q^{da} - q^{-da}}{q^d - q^{-d}}, \quad [a] := [a]_q,$$

$$[a]_{q^d}! := [a]_{q^d}[a-1]_{q^d} \cdots [1]_{q^d}, \quad [0]! := 1,$$

for any $a, d \in \mathbb{Z}_+ := \{0,1,2,\ldots\}$. Let $\mathfrak{g}$ be a finite dimensional simple Lie algebra over $\mathbb{C}$ of rank n and $\{\alpha_1,\ldots,\alpha_n\}$ be the set of simple roots, $I := \{1,2,\ldots,n\}, \Delta$ be the set of roots (respectively, Δ_+ be the set of positive roots). Define the root lattice $Q = \oplus_{i=1}^n \mathbb{Z}\alpha_i$ (respectively, $Q_+ = \oplus_{i=1}^n \mathbb{Z}_+\alpha_i$). Let $(\mathsf{a}_{ij})_{i,j=1}^n$ be the Cartan matrix associated with $\mathfrak{g}$, and $d = (d_1,\ldots,d_n)$ be an element in $\mathbb{N}^n$ such that $d_i \mathsf{a}_{i,j} = d_j \mathsf{a}_{j,i}$ for any $i,j \in I$ and g.c.d $(d_1,\cdots,d_n) = 1$. In particular, $d = (1,\cdots,1)$ for $\mathfrak{g} = \mathsf{sl}(n+1,\mathbb{C}), \mathsf{so}(2n,\mathbb{C}), d = (1,\ldots,1,2)$ for $\mathfrak{g} = \mathsf{sp}(2n,\mathbb{C}), d = (2,\cdots,2,1)$ for $\mathfrak{g} = \mathsf{so}(2n+1,\mathbb{C})$, We denote

the Weyl group of $\mathfrak{g}$ by W which is generated by the simple reflections $\{s_1,\ldots,s_n\}$. Now, we define the quantum enveloping algebra $U_q(\mathfrak{g})$ over $\mathbb{C}(q)$.

Definition 2.1.: Quantum enveloping algebra $U_q(\mathfrak{g})$ is an associative $\mathbb{C}(q)$-algebra generated by $\{e_i,f_i,t_i^{\pm 1}\,|\,i\in I\}$ with the relations

$$t_it_i^{-1}=t_i^{-1}t_i=1,\quad t_it_j=t_jt_i,$$

$$t_ie_jt_i^{-1}=q_i^{\mathsf{a}_{ij}}e_j,$$

$$t_if_jt_i^{-1}=q_i^{-\mathsf{a}_{ij}}e_j,$$

$$e_if_j-f_je_i=\delta_{ij}\{t_i\}_{q_i},$$

$$\sum_{k=0}^{1-\mathsf{a}_{ij}}(-1)^k e_i^{(k)}e_je_i^{(1-\mathsf{a}_{ij}-k)}=\sum_{k=0}^{1-\mathsf{a}_{ij}}(-1)^k f_i^{(k)}f_jf_i^{(1-\mathsf{a}_{ij}-k)}=0\quad (i\neq j),$$

where

$$q_i:=q^{d_i},e_i^{(k)}:=\frac{1}{[k]_{q^{d_i}}!}e_i^k,f_i^{(k)}:=\frac{1}{[k]_{q^{d_i}}!}f_i^k,\{t_i\}_{q_i}:=\frac{t_i-t_i^{-1}}{q_i-q_i^{-1}}.$$

Let $U_q^+(\mathfrak{g})$ [respectively, $U_q^-(\mathfrak{g}),U_q^0(\mathfrak{g})$] be the $\mathbb{C}(q)$-subalgebra of $U_q(\mathfrak{g})$ generated by $\{e_i\}_{i=1}^n$ (respectively, $\{f_i\}_{i=1}^n,\{t_i^{\pm 1}\}_{i=1}^n$).

B. Non restricted specialization

In this section, we define the non restricted specializations U_ε for a root of unity ε.

Definition 2.2.: Let $A:=\mathbb{C}[q,q^{-1}]$ be the Laurent polynomial ring, U_A be the A-subalgebra of $U_q(\mathfrak{g})$ generated by $\{e_i,f_i,t_i^{\pm 1},\{t_i\}_{q_i}\}_{i=1}^n,l$ be an odd integer greater than 3, and ε be a primitive lth root of unity such that $\varepsilon^{2d_i}\neq 1$ for any $i\in I$. We regard $\mathbb{C}$ as A-algebra by $f(q)c:=f(\varepsilon)\cdot c$ for any $f(q)\in A,c\in\mathbb{C}$ and we denote it by $\mathbb{C}_\varepsilon$. Now we define

$$U_\varepsilon:=U_A\otimes_A\mathbb{C}_\varepsilon,$$

and we call U_ε "non-restricted specialization of $U_q(\mathfrak{g})$." By a similar manner to Definition 2.1, we define $U_\varepsilon^+,U_\varepsilon^-$, and U_ε^0, and we denote $u\otimes 1$ as u for any $u\in U_A$.

Remark. (Ref. 3): One can also describe U_ε in terms of generators and relations. That is, U_ε is an associative $\mathbb{C}$-algebra generated by $\{e_i,f_i,t_i^{\pm 1}\}_{i=1}^n$ with the relations of Definition 2.1 replacing q by ε.

C. Root vectors

In this section, we introduce the root vectors and their properties.

Proposition 2.3 (Refs. 3 and 4): (i) For any $i\in I$, there exists an automorphism of U_ε, denoted by T_i, such that

$$T_i(e_i)=-f_it_i,\quad T_i(e_j)=\sum_{s=0}^{-a_{ij}}(-1)^{s-a_{ij}}q_i^{-s}e_i^{(-a_{ij}-s)}e_je_i^{(s)}\quad (i\neq j),$$

$$T_i(f_i)=-t_i^{-1}e_i,\quad T_i(f_j)=\sum_{s=0}^{-a_{ij}}(-1)^{s-a_{ij}}q_i^{s}f_i^{(s)}f_jf_i^{(-a_{ij}-s)}\quad (i\neq j),$$

$$T_i(t_j)=t_jt_i^{-a_{ij}}.$$

(ii) For $w\in W$, let $w=s_{i_1}\cdots s_{i_r}$ be a reduced expression of w, and set $T_w:=T_{i_1}\cdots T_{i_r}$. Then T_w

is well-defined (that is, T_w does not depend on a choice of reduced expression of w).

Definition 2.4.: Let w_0 be the longest element of $W, w_0=s_{i_1}\cdots s_{i_N}$ be a reduced expression of w_0, and we set

$$\beta_1 := \alpha_{i_1}, \beta_2 := s_{i_1}(\alpha_{i_2}), \ldots, \beta_N := s_{i_1}\cdots s_{i_{N-1}}(\alpha_{i_N})$$

(by the theory of the classical Lie algebra, $\Delta_+=\{\beta_1,\cdots,\beta_N\}$) and

$$e_{\beta_k} := T_{i_1}\cdots T_{i_{k-1}}(e_{i_k}), f_{\beta_k} := T_{i_1}\cdots T_{i_{k-1}}(f_{i_k}) \quad (1 \leqslant k \leqslant N).$$

We call these e_{β_k}, f_{β_k} "root vectors of U_ε."

Definition 2.5.: Set $\deg(e_i) := \alpha_i, \deg(f_i) := -\alpha_i, \deg(t_i) := 0$.

These are compatible with the relations of U_ε. Therefore, we can regard U_ε as Q-graded algebra and we have

$$U_\varepsilon = \bigoplus_{\alpha\in Q} (U_\varepsilon)_\alpha, \quad (U_\varepsilon)_\alpha (U_\varepsilon)_{\alpha'} \subset (U_\varepsilon)_{\alpha+\alpha'},$$

for any $\alpha, \alpha' \in Q$, where $(U_\varepsilon)_\alpha := \{u \in U_\varepsilon \,|\, \deg(u)=\alpha\}$. We also use the following propositions later.

Proposition 2.6: (Ref. 4): We have $e_\alpha \in U_\varepsilon^+ \cap (U_\varepsilon)_\alpha, f_\alpha \in U_\varepsilon^- \cap (U_\varepsilon)_{-\alpha}$ $(\alpha \in \Delta_+)$.

Proposition 2.7 (Ref. 3):Let $Z(U_\varepsilon)$ be the center of U_ε. We have $e_\alpha^l, f_\alpha^l, t_i^l \in Z(U_\varepsilon)$ for any $\alpha \in \Delta_+, 1 \leqslant i \leqslant n$.

Next, we introduce the PBW theorem and the triangular decomposition. They will be used in the subsequent sections. Let $\{\beta_1,\ldots,\beta_N\}$ be as in Definition 2.4, then $\Delta_+=\{\beta_1,\ldots,\beta_N\}$.

Theorem 2.8 (Ref. 3): *(i) $\{e_{\beta_1}^{m_1}\cdots e_{\beta_N}^{m_N} | m_1,\ldots,m_N \in \mathbb{Z}_+\}$ is a $\mathbb{C}$-basis of U_ε^+.*

(ii) $\{f_{\beta_1}^{m_1}\cdots f_{\beta_N}^{m_N} | m_1,\ldots,m_N \in \mathbb{Z}_+\}$ is a $\mathbb{C}$-basis of U_ε^-.

(iii) $\{k_1^{m_1}\cdots k_n^{m_n} | m_1,\ldots,m_n \in \mathbb{Z}\}$ is a $\mathbb{C}$-basis of U_ε^0.

(iv) Let ϕ be the multiplication map $\phi: U_\varepsilon^- \otimes U_\varepsilon^0 \otimes U_\varepsilon^+ \to U_\varepsilon (u_- \otimes u_0 \otimes u_+ \mapsto u_- u_0 u_+)$. Then ϕ is an isomorphism of $\mathbb{C}$-vector space.

III. PRIMITIVE VECTORS

We keep the settings and notations as in Sec. II.

A. Schnizer modules

In this section, we introduce the Schnizer modules of $U_\varepsilon(\mathsf{sp}(2n,\mathbb{C}))$, $U_\varepsilon(\mathsf{so}(2n+1,\mathbb{C}))$ and $U_\varepsilon(\mathsf{so}(2n,\mathbb{C}))$.

First, we fix the following notations. Let N be the number of positive roots, that is, $N=n^2$ for $\mathfrak{g}=\mathsf{sp}(2n,\mathbb{C}), \mathsf{so}(2n+1,\mathbb{C})$, and $N=(n-1)n$ for $\mathfrak{g}=\mathsf{so}(2n,\mathbb{C})$. We set

$$M := \{m=(m_{i,j})_{1\leqslant i\leqslant (N/n), 1\leqslant j\leqslant n} \in \mathbb{Z}^N | 0 \leqslant m_{i,j} \leqslant l-1 \text{ for any } i,j\}.$$

Let V be the l^N-dimensional $\mathbb{C}$-vector space with the basis $\{u(m) | m \in M\}$ and $\epsilon_{i,j} (1 \leqslant i \leqslant N/n, 1 \leqslant j \leqslant n)$ be an element in $\mathbb{Z}^N$ such that the (i,j)-component of $\epsilon_{i,j}$ is 1 and the other components of $\epsilon_{i,j}$ are 0. [We regard $u(-\epsilon_{i,j})$ as $u((l-1)\epsilon_{i,j})$.] For any $a=(a_{i,j})_{i,j} \in (\mathbb{C}^\times)^N, b=(b_{i,j})_{i,j} \in \mathbb{C}^N$, and $m=(m_{i,j})_{i,j} \in \mathbb{Z}^N$, we define

$$a(m) = \prod_{i,j} a_{i,j}^{m_{i,j}}, \quad m^b = (m_{i,j}^b)_{i,j} := (m_{i,j}+b_{i,j})_{i,j}. \tag{3.1}$$

Theorem 3.1 (Ref. 9 Theorem 3.8): *Let $\mathfrak{g}=sp(2n,\mathbb{C})$ $(n \geqslant 2)$. For any $a=(a_{i,j})_{i,j=1}^n \in (\mathbb{C}^\times)^N, b=(b_{i,j})_{i,j=1}^n \in \mathbb{C}^N$, and $\lambda=(\lambda_1,\ldots,\lambda_n) \in \mathbb{C}^n$, we obtain the U_ε-module structure on V by*

the following algebra homomorphism $\Phi_{a,b,\lambda}: U_\varepsilon \to End(V)$. *We call these modules "Schnizer module." For any* $m=(m_{i,j})_{i,j=1}^n \in M$,

$$\begin{aligned}\Phi_{a,b,\lambda}(e_j)u(m) = a(\alpha_{j,j})[-m^b_{j,j}]_{\varepsilon_j} u(m+\alpha_{j,j}) + \sum_{i=1}^{j-1} a(\alpha_{i,j})\{[m^b_{i,j-1}-m^b_{i,j}]_{\varepsilon_j} u(m+\alpha_{i,j}) \\ + a_{i,j-1}a_{j,i}^{-1}[m^b_{j+1,i}-m^b_{j,i}]_{\varepsilon_j} u(m+\alpha_{i,j}+\epsilon_{i,j-1}-\epsilon_{j,i})\} \quad (1\le j\le n-1),\end{aligned} \tag{3.2}$$

$$\begin{aligned}\Phi_{a,b,\lambda}(e_n)u(m) = a(\alpha_{n,n})[-m^b_{n,n}]_{\varepsilon_n} u(m+\alpha_{n,n}) + \sum_{i=1}^{n-1} a(\alpha_{i,n})\{[m^b_{i,n}-m^b_{n,i}]_{\varepsilon_n} u(m+\alpha_{i,n}) \\ + a_{i,n-1}a_{n,i}^{-1}[m^b_{i,n-1}-m^b_{n,i}]_{\varepsilon_n} u(m+\alpha_{i,n}+\epsilon_{i,n-1}-\epsilon_{n,i}) \\ + a^2_{i,n-1}a^{-2}_{n,i}[m^b_{i,n}-m^b_{n,i}]_{\varepsilon_n} u(m+\alpha_{i,n}+2\epsilon_{i,n-1}-2\epsilon_{n,i})\},\end{aligned} \tag{3.3}$$

$$\Phi_{a,b,\lambda}(t_j)u(m) = \varepsilon_j^{-\mu^{m^b}_{1,j}+\lambda_j} u(m) \quad (1\le i\le n), \tag{3.4}$$

$$\begin{aligned}\Phi_{a,b,\lambda}(f_j)u(m) = \sum_{i=1}^{j}\{a_{i,j}[\eta^{m^b}_{i,j}+\mu^{m^b}_{i+1,j}-\lambda_j]_{\varepsilon_j} u(m+\epsilon_{i,j}) \\ + a_{j+1,i}[\eta^{m^b}_{j+1,i}+\mu^{m^b}_{i+1,j}-\lambda_j]_{\varepsilon_j}\}u(m+\epsilon_{j+1,i}) \quad (1\le j\le n-1),\end{aligned} \tag{3.5}$$

$$\Phi_{a,b,\lambda}(f_n)u(m) = \sum_{i=1}^{n} a_{i,n}[\eta^{m^b}_{i,n}+\mu^{m^b}_{i+1,n}-\lambda_n]_{\varepsilon_n} u(m+\epsilon_{i,n}). \tag{3.6}$$

Here we set

$$\begin{aligned}\alpha_{i,j} &= -\epsilon_{i,j} + \sum_{k=1}^{i-1}(-\epsilon_{j,k}+\epsilon_{j+1,k}-\epsilon_{k,j}+\epsilon_{k,j-1}) \quad (1\le i\le j\le n-1), \\ \alpha_{i,n} &= -\epsilon_{i,n} + 2\sum_{k=1}^{i-1}(-\epsilon_{n,k}+\epsilon_{k,n-1}) \quad (1\le i\le n),\end{aligned} \tag{3.7}$$

$$\mu^{m^b}_{i,j} = \sum_{k=i}^{j} \nu^{m^b}_{k,j} \quad (1\le i\le j\le n), \tag{3.8}$$

where

$$\begin{aligned}\nu^{m^b}_{i,j} &= -m^b_{i,j-1}+2m^b_{i,j}-m^b_{i,j+1}-m^b_{j+2,i}+2m^b_{j+1,i}-m^b_{j,i} \quad (1\le i<j\le n-2), \\ \nu^{m^b}_{j,j} &= 2m^b_{j,j}-m^b_{j,j+1}-m^b_{j+2,j}+2m^b_{j+1,j}-m^b_{j+1,j+1}-m^b_{j+2,j+1} \quad (1\le j\le n-2), \\ \nu^{m^b}_{i,n-1} &= -m^b_{i,n-2}+2m^b_{i,n-1}-2m^b_{i,n}-2m^b_{n,i}-m^b_{n-1,i} \quad (1\le i<n-1), \\ \nu^{m^b}_{n-1,n-1} &= 2m^b_{n-1,n-1}-2m^b_{n-1,n}+2m^b_{n,n-1}-2m^b_{n,n},\end{aligned} \tag{3.9}$$

$$\nu^{m^b}_{i,n} = -m^b_{i,n-1} + 2m^b_{i,n} - m^b_{n,i} \quad (1 \leqslant i < n) \quad \nu^{m^b}_{n,n} = 2m^b_{n,n},$$

$$\eta^{m^b}_{i,j} = -m^b_{i,j+1} - m^b_{j+2,i} + 2m^b_{j+1,i} - m^b_{j,i} + m^b_{i,j},$$

$$\eta^{m^b}_{j+1,i} = -m^b_{j,i} + m^b_{j+1,i} \quad (1 \leqslant i < j \leqslant n-2),$$

$$\eta^{m^b}_{j,j} = m^b_{j,j} - m^b_{j,j+1} - m^b_{j+2,j} + 2m^b_{j+1,j} - m^b_{j+1,j+1} - m^b_{j+2,j+1},$$
$$\eta^{m^b}_{j+1,j} = m^b_{j+1,j} - m^b_{j+1,j+1} - m^b_{j+2,j+1} \quad (1 \leqslant j \leqslant n-2), \tag{3.10}$$

$$\eta^{m^b}_{i,n-1} = -2m^b_{i,n} - m^b_{i,n-1} + 2m^b_{n,i} - m^b_{n-1,i}, \quad \eta^{m^b}_{n,i} = -m^b_{n-1,i} + m^b_{n,i} \quad (1 \leqslant i < n-1),$$

$$\eta^{m^b}_{n-1,n-1} = m^b_{n-1,n-1} - 2m^b_{n-1,n} + 2m^b_{n,n-1} - 2m^b_{n,n}, \quad \eta^{m^b}_{n,n-1} = m^b_{n,n-1} - 2m^b_{n,n},$$

$$\eta^{m^b}_{i,n} = m^b_{i,n} - m^b_{n,i}, \quad (1 \leqslant i < n), \quad \eta^{m^b}_{n,n} = m^b_{n,n},$$

where we understand that $\mu_{i,j} = \eta_{i,j} = 0$ if the index (i,j) is out of the range.

Theorem 3.2 (Ref. 9 Theorem 3.10): *Let* $\mathfrak{g} = so(2n+1, \mathbb{C})$ $(n \geqslant 3)$. *For any* $a = (a_{i,j})^n_{i,j=1} \in (\mathbb{C}^\times)^N, b = (b_{i,j})^n_{i,j=1} \in \mathbb{C}^N$, *and* $\lambda = (\lambda_1, \ldots, \lambda_n) \in \mathbb{C}^n$, *we obtain the* U_ε*-module structure on* V *by the following algebra homomorphisms* $\Phi_{a,b,\lambda}: U_\varepsilon \to End(V)$. $\Phi_{a,b,\lambda}(e_j), (1 \leqslant j \leqslant n-1), \Phi_{a,b,\lambda}(t_j), \Phi_{a,b,\lambda}(f_j), (1 \leqslant j \leqslant n)$, *as in (3.2) and (3.4)–(3.6)), and for any* $m = (m_{i,j})^n_{i,j=1} \in M$,

$$\nu_{i,n}^{m^b} = -m_{i,n-2}^b + 2m_{i,n}^b - m_{n-1,i}^b, \quad (1 \leqslant i < n-1), \quad \nu_{n-1,n}^{m^b} = 2m_{n-1,n}^b. \tag{3.21}$$

$\eta_{i,j}^{m^b}$, $\eta_{j+1,i}^{m^b} (1 \leqslant i \leqslant j \leqslant n-3)$, *as in (3.10), and*

$$\eta_{i,n-2}^{m^b} = m_{i,n-2}^b - m_{i,n-1}^b - m_{i,n}^b + 2m_{n-1,i}^b - m_{n-2,i}^b,$$
$$\eta_{n-1,i}^{m^b} = m_{n-1,i}^b - m_{n-2,i}^b, \quad (1 \leqslant i \leqslant n-3),$$
$$\eta_{n-2,n-2}^{m^b} = m_{n-2,n-2}^b - m_{n-2,n-1}^b - m_{n-2,n}^b + 2m_{n-1,n-2}^b - m_{n-1,n-1}^b - m_{n-1,n}^b,$$
$$\eta_{n-1,n-2}^{m^b} = m_{n-1,n-2}^b - m_{n-1,n-1}^b - m_{n-1,n}^b,$$
$$\eta_{i,n-1}^{m^b} = m_{i,n-1}^b - m_{n-1,i}^b, \quad \eta_{n-1,n-1}^{m^b} = m_{n-1,n-1}^b,$$
$$\eta_{i,n}^{m^b} = m_{i,n}^b - m_{n-1,i}^b, \quad (1 \leqslant i \leqslant n-2), \quad \eta_{n-1,n}^{m^b} = m_{n-1,n}^b, \tag{3.22}$$

where we understand that $\mu_{i,j} = \eta_{i,j} = 0$ *if the index* (i,j) *is out of the range.*

B. Existence and uniqueness of primitive vector in *V*

In this section, we show the existence and uniqueness of primitive vector in the specialized Schnizer modules.

We define $a^{(0)}=(a_{i,j}^{(0)})_{i,j}\in(\mathbb{C}^{\times})^N, b^{(0)}=(b_{i,j}^{(0)})_{i,j}\in\mathbb{C}^N$, by

$$a_{i,j}^{(0)}=1,\quad b_{i,j}^{(0)}=0\quad (1\leqslant i\leqslant N/n, 1\leqslant j\leqslant n). \tag{3.23}$$

Obviously, by (3.1), for any $c\in\mathbb{Z}^N$ and $m\in M$, we have

$$a^{(0)}(c)=1,\quad m^b=m,\quad m_{i,j}^b=m_{i,j}. \tag{3.24}$$

For any $\lambda\in\mathbb{C}$, we denote the U_ε-module defined by $(\Phi_{a^{(0)},b^{(0)},\lambda},V)$ by $V(\lambda)$.

Proposition 3.4: Let $\mathfrak{g}=sp(2n,\mathbb{C})(n\geqslant 2)$ *and* $\lambda=(\lambda_1,\ldots,\lambda_n)\in\mathbb{C}^n$. *A vector* $u\in V(\lambda)$ *satisfies that* $e_iu=0$ *for any* $i\in I$ *if and only if* $u\in\mathbb{C}u_0$, *where* $u_0=u(0,\ldots,0)\in V(\lambda)$. *(We call these vectors "primitive vectors.")*

Proof: "If part" is obvious by (3.2) and (3.3). So we prove "only if part." First, we define $\{r_i\}_{1\leqslant i\leqslant n^2}(=I\times I)$ inductively as follows: $r_1:=(1,1)$ and if $r_s=(i,j)$, then

$$\begin{aligned} r_{s+1}&:=(n,i)\quad (1\leqslant i<j=n),\\ r_{s+1}&:=(i-1,j)\quad (1\leqslant j<i\leqslant n,\text{and } i-1\neq j),\\ r_{s+1}&:=(i,j+1)\quad (\text{otherwise}). \end{aligned} \tag{3.25}$$

And we define $M_s:=\{m\in M\,|\,m_{r_1}=m_{r_2}\cdots=m_{r_s}=0\}(1\leqslant s\leqslant n^2)$. So we have

$$\{(0)\}=M_{n^2}\subset M_{n^2-1}\subset\cdots\subset M_1\subset M.$$

Now, assume that $e_iu=0$ for any $i\in I$ and set $u=\Sigma_{m\in M}c_mu(m)\in V(c_m\in\mathbb{C})$. We shall prove that $u=\Sigma_{m\in M_s}c_mu(m)$ for any $1\leqslant s\leqslant n^2$ by the induction on s. Indeed, if we can prove this, then we have $u=\Sigma_{m\in M_{n^2}}c_mu(m)=c_0u_0\in\mathbb{C}u_0$.

Since $e_1u=0$, by (3.2), we have $0=\Sigma_{m\in M}c_m[-m_{1,1}]u(m-\epsilon_{1,1})$. Since the vectors $\{u(m-\epsilon_{1,1})\,|\,m\in M\}$ are linearly independent, $c_m[-m_{1,1}]=0$ for any $m\in M$. Therefore if $0\neq m_{1,1}(=m_{r_1})$, then $c_m=0$. Hence $u=\Sigma_{m\in M_1}c_mu(m)$. Now we assume that $u=\Sigma_{m\in M_s}c_mu(m)$ for $1\leqslant s<n^2$, and $r_s=(i_s,j_s)$.

Case 1: $1\leqslant i_s\leqslant j_s\leqslant n-2$: In this case $r_{s+1}=(i_s,j_s+1)$. Let $m\in M_s$ then

$$m_{i,j_s}=m_{i,j_s+1}=m_{j_s+2,i}=m_{j_s+1,i}=0(1\leqslant i\leqslant i_s-1).$$

Hence, by (3.2), we have

$$\begin{aligned} 0=e_{j_s+1}u&=\sum_{m\in M_s}c_m[-m_{j_s+1,j_s+1}]_{\varepsilon_{j_s+1}}u(m+\alpha_{j_s+1,j_s+1})+\sum_{m\in M_s}\sum_{i=i_s}^{j_s}c_m[m_{i,j_s}-m_{i,j_s+1}]_{\varepsilon_{j_s+1}}u(m+\alpha_{i,j_s+1})\\ &+\sum_{m\in M_s}\sum_{i=i_s}^{j_s}c_m[m_{j_s+2,i}-m_{j_s+1,i}]_{\varepsilon_{j_s+1}}u(m+\alpha_{i,j_s+1}+\epsilon_{i,j_s}-\epsilon_{j_s+1,i}). \end{aligned} \tag{3.26}$$

On the other hand, by (3.7), for any $m\in M_s$, we have

$$\begin{aligned} (m+\alpha_{j_s+1,j_s+1})_{i_s,j_s}&=\left(m-\epsilon_{j_s+1,j_s+1}+\sum_{k=1}^{j_s}(-\epsilon_{j_s+1,k}+\epsilon_{j_s+2,k}-\epsilon_{k,j_s+1}+\epsilon_{k,j_s})\right)_{i_s,j_s}\\ &=(m+\epsilon_{i_s,j_s})_{i_s,j_s}=m_{i_s,j_s}+1=1. \end{aligned}$$

Similarly , for any $i(i_s\leqslant i\leqslant j_s)$, we have

$$(m+\alpha_{i,j_s+1})_{i_s,j_s}=(m-\epsilon_{i,j_s+1}+\sum_{k=1}^{i-1}(-\epsilon_{j_s+1,k}+\epsilon_{j_s+2,k}-\epsilon_{k,j_s+1}+\epsilon_{k,j_s}))_{i_s,j_s}=1-\delta_{i,i_s},$$

$$(m+\alpha_{i,j_s+1}+\epsilon_{i,j_s}-\epsilon_{j_s+1,i})_{i_s,j_s}=(1-\delta_{i,i_s})+\delta_{i,i_s}=1,$$

where $\delta_{i,j}$ is the Kronecker's delta. Thus

$$\sum_{m\in M_s}\sum_{i=i_s}^{j_s+1}\mathbb{C}u(m+\alpha_{i,j_s+1})+\sum_{m\in M_s}\sum_{i=i_s}^{j_s}\mathbb{C}u(m+\alpha_{i,j_s+1}+\epsilon_{i,j_s}-\epsilon_{j_s+1,i})$$
$$=\{\bigoplus_{m\in M_s}\mathbb{C}u(m+\alpha_{i_s,j_s+1})\}$$
$$\oplus\{\sum_{m\in M_s}\sum_{i=i_s+1}^{j_s+1}\mathbb{C}u(m+\alpha_{i,j_s+1})+\sum_{m\in M_s}\sum_{i=i_s}^{j_s}\mathbb{C}u(m+\alpha_{i,j_s+1}+\epsilon_{i,j_s}-\epsilon_{j_s+1,i})\}.$$

Then, by (3.26), we have that

$$0=c_m[m_{i_s,j_s}-m_{i_s,j_s+1}]=c_m[-m_{i_s,j_s+1}]$$

for any $m\in M_s$, which implies if $0\neq m_{i_s,j_s+1}=m_{r_{s+1}}$ then $c_m=0$. Therefore $u=\Sigma_{m\in M_{s+1}}c_m u(m)$.
Case 2—$1\leqslant i_s\leqslant j_s=n-1$: In this case , $r_{s+1}=(i_s,n)$. Let $m\in M_s$ then

$$m_{i,n}=m_{n,i}=m_{i,n-1}=0\quad(1\leqslant i\leqslant i_s-1).$$

Thus, by (3.3),

$$0=e_n u=\sum_{m\in M_s}c_m[-m_{n,n}]_{\varepsilon_n}u(m+\alpha_{n,n})+\sum_{m\in M_s}\sum_{i=i_s}^{n-1}c_m[m_{i,n}-m_{n,i}]_{\varepsilon_n}u(m+\alpha_{i,n})+\sum_{m\in M_s}\sum_{i=i_s}^{n-1}c_m[m_{i,n-1}$$
$$-m_{n,i}]_{\varepsilon_n}u(m+\alpha_{i,n}+\epsilon_{i,n-1}-\epsilon_{n,i})+\sum_{m\in M_s}\sum_{i=i_s}^{n-1}c_m[m_{i,n}-m_{n,i}]_{\varepsilon_n}u(m+\alpha_{i,n}+2\epsilon_{i,n-1}-2\epsilon_{n,i}).$$

On the other hand, in a similar way to Case 1, for any $i(i_s\leqslant i\leqslant n)$, we have

$$(m+\alpha_{i,n})_{i_s,n-1}=2-2\delta_{i,i_s},\quad(m+\alpha_{i,n}+\epsilon_{i,n-1}-\epsilon_{n,i})_{i_s,n-1}=2-\delta_{i,i_s},$$

$$(m+\alpha_{i,n}+2\epsilon_{i,n-1}-2\epsilon_{n,i})_{i_s,n-1}=2.$$

Thus, $(m+\alpha_{i_s,n})_{i_s,n-1}=0,(m+\alpha_{i_s,n}+\epsilon_{i_s,n-1}-\epsilon_{n,i_s})_{i_s,n-1}=1$, and the others are 2. Hence, by the linearly independence, we have that

$$0=c_m[m_{i_s,n}-m_{n,i_s}]_{\varepsilon_n}=c_m[m_{i_s,n-1}-m_{n,i_s}]_{\varepsilon_n}=c_m[-m_{n,i_s}]_{\varepsilon_n}$$

for any $m\in M_s$. Therefore $u=\Sigma_{m\in M_{s+1}}c_m u(m)=\Sigma_{m\in M_{s+2}}c_m u(m)$.

Case 3—$1\leqslant i_s\leqslant j_s=n$. This case is already shown in Case 2.

Case 4—$1\leqslant j_s<i_s\leqslant n$ and $j_s\neq i_s-1$: In this case $r_{s+1}=(i_s-1,j_s)$. For $m\in M_s$, we have

$$m_{j,i_s-2}=m_{j,i_s-1}=0\quad(1\leqslant j\leqslant j_s),\quad m_{i_s,j}=m_{i_s-1,j}=0\quad(1\leqslant j\leqslant j_s-1).$$

Thus, by (3.2),

$$0 = e_{i_s-1}u = \sum_{m\in M_s} c_m[-m_{i_s-1,i_s-1}]_{\varepsilon_{i_s-1}} u(m+\alpha_{i_s-1,i_s-1})$$
$$+ \sum_{m\in M_s}\sum_{j=j_s+1}^{i_s-2} c_m[m_{j,i_s-2}-m_{j,i_s-1}]_{\varepsilon_{i_s-1}} u(m+\alpha_{j,i_s-1})$$
$$+ \sum_{m\in M_s}\sum_{j=j_s}^{i_s-2} c_m[m_{i_s,j}-m_{i_s-1,j}]_{\varepsilon_{i_s-1}} u(m+\alpha_{j,i_s-1}+\epsilon_{j,i_s-2}-\epsilon_{i_s-1,j}).$$

On the other hand,

$$(m+\alpha_{j,i_s-1})_{i_s,j_s} = 1 \quad (j_s+1 \leqslant j \leqslant i_s-1),$$

$$(m+\alpha_{j,i_s-1}+\epsilon_{j,i_s-2}-\epsilon_{i_s-1,j})_{i_s,j_s} = 1-\delta_{j,j_s} \quad (j_s \leqslant j \leqslant i_s-2).$$

Thus, by the linearly independence, $0=c_m[m_{i_s,j_s}-m_{i_s-1,j_s}]=c_m[-m_{i_s-1,j_s}]=0$ for any $m\in M_s$. Therefore $u=\Sigma_{m\in M_{s+1}}c_m u(m)$.

Case 5—$1\leqslant j_s<i_s\leqslant n$ and $j_s=i_s-1$: In this case $r_{s+1}=(i_s,i_s)$. For any $m\in M_s$, we have

$$m_{j,i_s-1}=m_{j,i_s}=m_{i_s,j}=m_{i_s+1,j}=0 \quad (1\leqslant j\leqslant i_s-1).$$

Thus, by (3.2) and (3.3),

$$0 = e_{i_s}u = \sum_{m\in M_s} c_m[-m_{i_s,i_s}]_{\varepsilon_{i_s}} u(m+\alpha_{i_s,i_s}).$$

Hence, $c_m[-m_{i_s,i_s}]=0$ for any $m\in M_s$. Therefore $u=\Sigma_{m\in M_{s+1}}c_m u(m)$. □

In a similar way to the proof of Proposition 3.4, we can prove the following propositions.

Proposition 3.5: Let $\mathfrak{g}=so(2n+1,\mathbb{C}), so(2n,\mathbb{C})$, *and* $\lambda=(\lambda_1,\cdots,\lambda_n)\in\mathbb{C}^n$. *A vector* $u=\Sigma_{m\in M}c_m u(m)\in V(\lambda)(c_m\in\mathbb{C})$ *satisfies the condition* $e_i u=0$ *for any* $i\in I$ *if and only if* $u\in\mathbb{C}u_0$.

In the case of $\mathfrak{g}=\mathsf{so}(2n,\mathbb{C})$, the proof of Proposition 3.5 is slightly different from the one of Proposition 3.4.

Proof: ($\mathsf{so}(2n,\mathbb{C})$-*case*): "If part" is obvious from (3.2) and (3.15)–(3.18). So we prove "only if part." We define $\{r_i\}_{i=1}^{(n-1)n}$ by a similar way to the previous cases: $r_1:=(1,1)$ and if $r_s=(i,j)$, then

$$r_{s+1}:=(n-1,i) \quad (1\leqslant i<j=n),$$

$$r_{s+1}:=(i-1,j) \quad (1\leqslant j<i\leqslant n-1, i-1\neq j),$$

$$r_{s+1}:=(i,j+1) \quad (\text{otherwise}).$$

We set $M_s=\{m\in M\,|\,m_{r_1}=\cdots=m_{r_s}=0\}$ for any $s(1\leqslant s\leqslant(n-1)n)$.

Now we shall prove that $u=\Sigma_{m\in M_s}c_m u(m)$ for any $1\leqslant s\leqslant(n-1)n$ by the induction on s. By using $e_1u=0$, we can prove $u=\Sigma_{m\in M_1}c_m u(m)$. Next, we assume that $u=\Sigma_{m\in M_s}c_m u(m)$ for $s(1\leqslant s<(n-1)n)$, and $r_s=(i_s,j_s)$. Then we prove by a similar manner to the proof of Proposition 3.4.

In case $j_s\neq n-2,n-1,n$, we only use $e_{j_s}(1\leqslant j\leqslant n-2)$ to prove $u=\Sigma_{m\in M_{s+1}}c_m u(m)$. Since the action of e_j is the same as the one of $\mathfrak{g}=\mathsf{sp}(2n,\mathbb{C})$ for $1\leqslant j\leqslant n-2$, the proof is also the same. So we prove the case of $j_s=n-2,n-1,n$.

Let $1\leqslant i_s\leqslant j_s=n-2$. In this case, $r_{s+1}=(i_s,n-1), r_{s+2}=(i_s,n)$ and $r_{s+3}=(n-1,i_s)$. We assume that $i_s=2i_s'-1, n=2n'(i',n'\in\mathbb{Z})$. Then, for any $m\in M_s$,

$$m_{2i-1,n-2}-m_{2i-1,n-1}=m_{2i-1,n}-m_{n-1,2i-1}=m_{2i,n-2}-m_{2i,n}=m_{2i,n-1}-m_{n-1,2i}=0 \quad (1\leqslant i<i_s').$$

Thus, by (3.15),

$$e_{n-1}u = \sum_{m\in M_s} c_m[-m_{n-1,n-1}]u(m+\alpha_{2n'-1,n-1}) + \sum_{m\in M_s}\sum_{i=i'_s}^{n'-1} c_m\{[m_{2i-1,n-2}-m_{2i-1,n-1}]u(m+\alpha_{2i-1,n-1})$$
$$+[m_{2i-1,n}-m_{n-1,2i-1}]u(m+\alpha_{2i-1,n-1}+\epsilon_{2i-1,n-2}-\epsilon_{n-1,2i-1})+[m_{2i,n-2}-m_{2i,n}]u(m+\alpha_{2i,n})$$
$$+[m_{2i,n-1}-m_{n-1,2i}]u(m+\alpha_{2i,n}+\epsilon_{2i,n-2}-\epsilon_{n-1,2i})\},$$

On the other hand, by (3.20),

$$(\beta_{2i-1,n-1})_{2i'_s-1,n-2}=1-\delta_{i,i'_s},\quad (\beta_{2i,n})_{2i'_s-1,n-2}=0,\quad (i'_s\leqslant i\leqslant n').$$

Hence, by (3.19),

$$(\alpha_{2i-1,n-1})_{2i'_s-1,n-2}=1-\delta_{i,i'_s},\quad (\alpha_{2i-1,n-1}+\epsilon_{2i-1,n-2}-\epsilon_{n-1,2i-1})_{2i'_s-1,n-2}=1,$$

$$(\alpha_{2i,n})_{2i'_s-1,n-2}=1,\quad (\alpha_{2i,n}+\epsilon_{2i,n-2}-\epsilon_{n-1,2i})_{2i'_s-1,n-2}=1,\quad (i'_s\leqslant i\leqslant n').$$

So $(\alpha_{2i'_s-1,n-1})_{2i'_s-1,n-1}=0$, and the others are 1. Thus, for any $m\in M_s$ we have

$$0=c_m[m_{2i'_s-1,n-2}-m_{2i'_s-1,n-1}]=c_m[m_{i_s,n-2}-m_{i_s,n-1}]=c_m[-m_{i_s,n-1}].$$

Therefore $u=\Sigma_{m\in M_{s+1}}c_m u(m)$.

Furthermore, for any $m\in M_s$, we have

$$m_{2i,n-2}-m_{2i,n-1}=m_{2i,n}-m_{n-1,2i}=m_{2i-1,n-2}-m_{2i-1,n}=m_{2i-1,n-1}-m_{n-1,2i-1}=0\quad (1\leqslant i<i'_s).$$

Thus, by (3.16),

$$e_n u = \sum_{m\in M_s} c_m[-m_{n-1,n}]u(m+\alpha_{2n'-1,n}) + \sum_{m\in M_s}\sum_{i=i'_s}^{n'-1} c_m\{[m_{2i,n-2}-m_{2i,n-1}]u(m+\alpha_{2i,n-1})+[m_{2i,n}$$
$$-m_{n-1,2i}]u(m+\alpha_{2i,n-1}+\epsilon_{2i,n-2}-\epsilon_{n-1,2i})+[m_{2i-1,n-2}-m_{2i-1,n}]u(m+\alpha_{2i-1,n})+[m_{2i-1,n-1}$$
$$-m_{n-1,2i-1}]u(m+\alpha_{2i-1,n}+\epsilon_{2i-1,n-2}-\epsilon_{n-1,2i-1})\}.$$

On the other hand, by (3.20),

$$(\beta_{2i,n-1})_{2i'_s-1,n-2}=0,\quad (\beta_{2i-1,n})_{2i'_s-1,n-2}=1-\delta_{i,i'_s},\quad (i'_s\leqslant i\leqslant n').$$

Hence, by (3.19),

$$(\alpha_{2i,n-1})_{2i'_s-1,n-2}=1,\quad (\alpha_{2i,n-1}+\epsilon_{2i,n-2}-\epsilon_{n-1,2i})_{2i'_s-1,n-2}=1,$$

$$(\alpha_{2i-1,n})_{2i'_s-1,n-2}=1-\delta_{i,i'_s},\quad (\alpha_{2i-1,n}+\epsilon_{2i-1,n-2}-\epsilon_{n-1,2i-1})_{2i'_s-1,n-2}=1,\quad (i'_s\leqslant i\leqslant n').$$

So $(\alpha_{2i'_s-1,n})_{2i'_s-1,n-2}=0$, and the others are 1. Thus, for any $m\in M_s$ we have

$$0=c_m[m_{2i'_s-1,n-2}-m_{2i'_s-1,n}]=c_m[m_{i_s,n-2}-m_{i_s,n}]=c_m[-m_{i_s,n}].$$

Therefore $u=\Sigma_{m\in M_{s+2}}c_m u(m)$. Then,

$$e_n u = \sum_{m\in M_{s+2}} c_m[-m_{n-1,n}]u(m+\alpha_{2n'-1,n}) + \sum_{m\in M_{s+2}} \sum_{i=i'_s}^{n'-1} c_m\{[m_{2i,n-2}-m_{2i,n-1}]u(m+\alpha_{2i,n-1})$$
$$+[m_{2i,n}-m_{n-1,2i}]u(m+\alpha_{2i,n-1}+\epsilon_{2i,n-2}-\epsilon_{n-1,2i})+[m_{2i-1,n-1}-m_{n-1,2i-1}]u(m+\alpha_{2i-1,n}$$
$$+\epsilon_{2i-1,n-2}-\epsilon_{n-1,2i-1})\}+\sum_{m\in M_{s+2}}\sum_{i=i'_s+1}^{n'-1} c_m[m_{2i-1,n-2}-m_{2i-1,n}]u(m+\alpha_{2i-1,n}).$$

On the other hand, by (3.20),

$$(\beta_{2i,n-1})_{2i'_s-1,n}=0,\quad (\beta_{2i-1,n})_{2i'_s-1,n}=1-\delta_{i,i'_s},\quad (i'_s\leqslant i\leqslant n').$$

Hence, by (3.19),

$$(\alpha_{2i,n-1})_{2i'_s-1,n}=1,\quad (\alpha_{2i,n-1}+\epsilon_{2i,n-2}-\epsilon_{n-1,2i})_{2i'_s-1,n}=1,$$

$$(\alpha_{2i-1,n}+\epsilon_{2i-1,n-2}-\epsilon_{n-1,2i-1})_{2i'_s-1,n}=1-2\delta_{i,i'_s},\quad (i'_s\leqslant i\leqslant n'),$$

$$(\alpha_{2i-1,n})_{2i'_s-1,n}=1,\quad (i_s+1\leqslant i\leqslant n').$$

So $(\alpha_{2i'_s-1,n}+\epsilon_{2i'_s-1,n-2}-\epsilon_{n-1,2i'_s-1})_{2i'_s-1,n}=-1$, and the others are 1. Thus, for any $m\in M_{s+2}$ we have

$$0=c_m[m_{2i'_s-1,n-1}-m_{n-1,2i'_s-1}]=c_m[m_{i_s,n-1}-m_{n-1,i_s}]=c_m[-m_{n-1,i_s}].$$

Therefore $u=\Sigma_{m\in M_{s+3}}c_m u(m)$. So we also obtain the case $1\leqslant i_s\leqslant n-2, j_s=n-1,n, (n=2n', i_s=2i'_s-1)$.

Similarly, we can prove the cases $(n=2n', i_s=2i'_s), (n=2n'+1, i_s=2i'_s-1)$ and $(n=2n'+1, i_s=2i'_s)$.

The remaining cases are $(i_s,j_s)=(n-1,n-2),(n-1,n-1)$. But these cases are proved similarly. □

IV. IRREDUCIBLE $U_\varepsilon^{\mathrm{fin}}$-MODULE $U_\varepsilon u_0$

We keep the settings and notations as in Secs. II and III.

A. Restricted specializations

In this section, we introduce the restricted specializations and their properties.

Definition 4.1: Let $A:=\mathbb{C}[q,q^{-1}]$ and U_A^{res} be the A-subalgebra of $U_q(\mathsf{g})$ generated by $\{e_i^{(k)}, f_i^{(k)}, t_i^{\pm 1} \mid i\in I, k\in\mathbb{Z}_+\}$. Let l be an odd integer greater than 3 and ε be a primitive lth root of unity such that $\varepsilon^{2d_i}\neq 1$ for any $i\in I$. We regard $\mathbb{C}$ as A-algebra by $f(q).c:=f(\varepsilon)\cdot c$ for any $f(q)\in A, c\in\mathbb{C}$ and we denote it by $\mathbb{C}_\varepsilon$. We define

$$U_\varepsilon^{\mathrm{res}} := U_A^{\mathrm{res}}\otimes_A \mathbb{C}_\varepsilon,$$

which is called "restricted specialization of $U_q(\mathsf{g})$." Similarly, we define $(U_\varepsilon^{\mathrm{res}})^+, (U_\varepsilon^{\mathrm{res}})^-, (U_\varepsilon^{\mathrm{res}})^0$. We denote $u\otimes 1$ by u for any $u\in U_A^{\mathrm{res}}$. Let $U_\varepsilon^{\mathrm{fin}}$ be the subalgebra of $U_\varepsilon^{\mathrm{res}}$ generated by $\{e_i, f_i, t_i^{\pm 1}\}_{i=1}^n$. (Similarly, we define $(U_\varepsilon^{\mathrm{fin}})^+, (U_\varepsilon^{\mathrm{fin}})^-$ and $(U_\varepsilon^{\mathrm{fin}})^0$).

Next we review the representation theory of $U_\varepsilon^{\mathrm{res}}$.

Definition 4.2: Let L be a finite dimensional $U_\varepsilon^{\mathrm{res}}$-module. If $t_i^l v=v$ for any $v\in L, i\in I$ (that is, t_i^l is the identity map), we call L "$U_\varepsilon^{\mathrm{res}}$-module of type 1."

Remark (Ref. 1): In general, finite dimensional irreducible $U_\varepsilon^{\mathrm{res}}$-modules are divided into 2^n types according to $\{\sigma: Q\to\{\pm 1\}$; homomorphism of group $\}$. Without a loss of generality, we may assume that finite dimensional irreducible $U_\varepsilon^{\mathrm{res}}$-modules are of type 1.

Definition 4.3: For $\lambda=(\lambda_1,\ldots,\lambda_n)\in\mathbb{Z}_+^n$, let I_λ be the left ideal of $U_q(\mathfrak{g})$ generated by $\{e_i, f_i^{\lambda_i+1}, t_i-q_i^{\lambda_i} \mid i\in I\}$ and $L(\lambda):=U_q(\mathfrak{g})/\mathsf{I}_\lambda$. We set $v_\lambda=1+\mathsf{I}_\lambda\in L(\lambda)$. Let $V_A^{\mathrm{res}}(\lambda)$ be the U_A^{res}-submodule of $L(\lambda)$ generated by v_λ, $V_\varepsilon^{\mathrm{res}}(\lambda):=V_A^{\mathrm{res}}(\lambda)\otimes_A\mathbb{C}_\varepsilon$, and $W_\varepsilon^{\mathrm{res}}(\lambda)$ be the maximal proper $U_\varepsilon^{\mathrm{res}}$-submodule of $V_\varepsilon^{\mathrm{res}}(\lambda)$. We define

$$L_\varepsilon^{\mathrm{res}}(\lambda):=V_\varepsilon^{\mathrm{res}}(\lambda)/W_\varepsilon^{\mathrm{res}}(\lambda).$$

Theorem 4.4 (Refs. 6 and 7): *(i) For any $\lambda\in\mathbb{Z}_+^n$, $L_\varepsilon^{\mathrm{res}}(\lambda)$ is a finite dimensional irreducible $U_\varepsilon^{\mathrm{res}}$-module of type 1 (We call λ "highest weight of $L_\varepsilon^{\mathrm{res}}(\lambda)$").*

(ii) Let L be a finite dimensional irreducible $U_\varepsilon^{\mathrm{res}}$-module of type 1. Then, there exists a unique element $\lambda\in\mathbb{Z}_+^n$ such that $L\cong L_\varepsilon^{\mathrm{res}}(\lambda)$.

(iii) Let $\lambda'=(\lambda_1',\ldots,\lambda_n')\in\mathbb{Z}_l^n(\mathbb{Z}_l:=\{0,1,\ldots,l-1\})$, $\lambda''\in\mathbb{Z}_+^n$, and $\lambda:=\lambda'+l\lambda''$. Then we have

$$L_\varepsilon^{\mathrm{res}}(\lambda)\cong L_\varepsilon^{\mathrm{res}}(\lambda')\otimes L_\varepsilon^{\mathrm{res}}(l\lambda'').$$

Next, we give the relation between the representations of $U_\varepsilon^{\mathrm{res}}$ and $U_\varepsilon^{\mathrm{fin}}$.

Proposition 4.5 (Ref. 6 and 7): (i) For any $\lambda=(\lambda_1,\ldots,\lambda_n)\in\mathbb{Z}_l^n$, we regard $L_\varepsilon^{\mathrm{res}}(\lambda)$ as $U_\varepsilon^{\mathrm{fin}}$-module and denote it by $L_\varepsilon^{\mathrm{fin}}(\lambda)$. Then $L_\varepsilon^{\mathrm{fin}}(\lambda)$ is a finite dimensional irreducible $U_\varepsilon^{\mathrm{fin}}$-module of type 1. Conversely, let L be any finite dimensional irreducible $U_\varepsilon^{\mathrm{fin}}$-module of type 1, then there exists a unique element $\lambda=(\lambda_1,\ldots,\lambda_n)\in\mathbb{Z}_l^n$ such that $L\cong L_\varepsilon^{fin}(\lambda)$.

(ii) Let $U(\mathfrak{g})$ be the universal enveloping algebra of $\mathfrak{g}$. Then for any $\lambda\in\mathbb{Z}_+^n$, we can regard $L_\varepsilon^{\mathrm{res}}(l\lambda)$ as a finite dimensional irreducible $U(\mathfrak{g})$-module of the highest weight λ.

B. Finite dimensional quantum algebra $U_\varepsilon^{\mathrm{fin}}$

In this section, we introduce the properties of $U_\varepsilon^{\mathrm{fin}}$ to prove Theorem 4.10 below. First, we introduce PBW theorem and the triangular decomposition of $U_\varepsilon^{\mathrm{fin}}$.

Theorem 4.6 (Ref. 7): Let $\beta_1,\ldots,\beta_N$ *be as in Definition 2.4* ($\Delta_+=\{\beta_1,\ldots,\beta_N\}$). *We assume that $l\not\equiv 0$ (mod 3) if $\mathfrak{g}$ is type G_2. Then we have*

(i) $\{e_{\beta_1}^{m_1}\cdots e_{\beta_N}^{m_N} \mid 0\le m_i\le l-1$ *for any* $1\le i\le N\}$ *is a $\mathbb{C}$-basis of* $(U_\varepsilon^{\mathrm{fin}})^+$.
(ii) $\{f_{\beta_1}^{m_1}\cdots f_{\beta_N}^{m_N} \mid 0\le m_i\le l-1$ *for any* $1\le i\le N\}$ *is a $\mathbb{C}$-basis of* $(U_\varepsilon^{\mathrm{fin}})^-$.
(iii) $\{t_1^{m_1}\cdots t_n^{m_n} \mid 0\le m_i\le 2l-1$ *for any* $1\le i\le n\}$ *is a $\mathbb{C}$-basis of* $(U_\varepsilon^{\mathrm{fin}})^0$.
(iv) *Let ϕ be the multiplication map*

$$\phi:(U_\varepsilon^{\mathrm{fin}})^-\otimes(U_\varepsilon^{\mathrm{fin}})^0\otimes(U_\varepsilon^{\mathrm{fin}})^+\to U_\varepsilon^{\mathrm{fin}}\quad u_-\otimes u_0\otimes u_+\quad\mapsto\quad u_-u_0u_+.$$

Then ϕ is an isomorphism of $\mathbb{C}$-vector space.

By Theorem 4.6, we know that the dimension of $U_\varepsilon^{\mathrm{fin}}$ is $2^n l^{n+2N}$.

Proposition 4.7(Ref. 1): We have $e_\alpha^l=f_\alpha^l=0$ *in* $U_\varepsilon^{\mathrm{fin}}$ *for any* $\alpha\in\Delta_+$, *and* $t_i^{2l}=1$ *in* $U_\varepsilon^{\mathrm{fin}}$ *for any* $i\in I$.

Lemma 4.8: We assume that $l\not\equiv 0$ (mod 3) if $\mathfrak{g}$ is type G_2. Let J be the two-sided ideal of U_ε generated by $\{e_\alpha^l, f_\alpha^l \mid \alpha\in\Delta_+\}\cup\{t_i^{2l}-1 \mid i\in I\}$. Then we have $U_\varepsilon^{\mathrm{fin}}\cong U_\varepsilon/\mathrm{J}$.
