$$\int_F \Omega_\lambda(z)\overline{\Omega_{\lambda'}(z)}\mathrm{d}F = 0, \quad \text{where } \lambda, \lambda' \in P^+ \text{ and } \lambda \neq \lambda', \tag{4.15}$$

is a consequence of the orthogonality of characters of irreducible representations and the decomposability of products (4.10) of C-functions. Indeed, let the zero weight be denoted 0 for any rank. Because $W0=0$, one has $\Omega_0(z)=1$ for every group and all $z \in \mathbb{R}^n$. Setting $\lambda'=0$ in (4.15), we have

$$\int_F \Omega_\lambda(z)\mathrm{d}F = 0, \quad \text{for any } 0 \neq \lambda \in P^+. \tag{4.16}$$

Complex conjugate $\overline{\Omega_\lambda}$ is a C-function with another (contragredient) dominant weight, say $\overline{\lambda'}$. Therefore $\Omega_\lambda(z)\overline{\Omega_{\lambda'}(z)}$ decomposes according to (4.10). The decomposition contains Ω_0 precisely if $\overline{\lambda'}=\overline{\lambda}$. Therefore, only in that case, the integral (4.15) is not zero.

K. Eigenfunctions of the Laplace operator

Consider the differential operator

$$L=(\alpha_1\partial_1+\alpha_2\partial_2+\cdots+\alpha_n\partial_n)^2. \tag{4.17}$$

Since the matrix of scalar products of simple roots is positive definite, by a suitable choice of basis, the operator can be brought to the sum of second derivatives with positive coefficients. Hence, one is justified in calling L the Laplace operator.

Subsequently, we will verify the validity of the eigenvalue equation[17]

$$L\Omega_\lambda(z)=-4\pi\langle\lambda|\lambda\rangle\Omega_\lambda(z),\quad \text{for all } \lambda\in P^+ \text{ and } z\in\mathbb{R}^n. \tag{4.18}$$

From (4.7) it is clear that C-functions are continuous functions with continuous derivatives of all orders in $\mathbb{R}^n$. Then it follows from (4.9) that their derivatives, normal to the boundary of the fundamental region, must be equal to zero (Newmann boundary value condition).

V. THE CASE $A_1\times A_1$

This is a simple concatenation of two cases of A_1 described in Sec. III.

A. Roots and weights

Relative length and angles of the simple roots are given by the scalar products,

$$\langle\alpha_1|\alpha_2\rangle=0,\quad \langle\alpha_1|\alpha_1\rangle=\langle\alpha_2|\alpha_2\rangle=2.$$

The Cartan matrix and its inverse are the following:

$$C=\begin{pmatrix}2&0\\0&2\end{pmatrix}\quad\text{and } C^{-1}=\begin{pmatrix}\frac{1}{2}&0\\0&\frac{1}{2}\end{pmatrix}.$$

Consequently, $\alpha_1=2\omega_1$ and $\alpha_2=2\omega_2$. Their duals $\hat{\alpha}_k$ and $\hat{\omega}_j$ coincide with α_k and ω_j. The root system $\Delta=\{\pm\alpha_1,\pm\alpha_2\}$ geometrically represents the vertices of a square of a side length $2\sqrt{2}$.

B. Weyl group orbits

Suppose $\lambda=a\omega_1+b\omega_2\in P$. Then the Weyl group orbit W_λ is given by

$$W_\lambda\equiv W_{(a,b)}=\begin{cases}\{(0,0)\}, & \text{if } a,b=0,\\ \{\pm(a,0)\}, & \text{if } a\neq 0 \text{ and } b=0,\\ \{\pm(0,b)\}, & \text{if } a=0 \text{ and } b\neq 0,\\ \{\pm(a,b),\pm(a,-b)\}, & \text{if } a,b\neq 0.\end{cases}$$

C. C-functions

The C-functions of $A_1\times A_1$, with $\lambda=a\omega_1+b\omega_2$ and $z=x\omega_1+y\omega_2$, are products of two A_1 C-functions,

$$\Omega_{a.b}(x,y)=\Omega_a(x)\Omega_b(y).$$

They are the following:

$$\Omega_{(0,0)}(x,y)=1,$$

$$\Omega_{(a,0)}(x,y) = 2\cos(\pi a x),$$

$$\Omega_{(0,b)}(x,y) = 2\cos(\pi b y),$$

$$\Omega_{(a,b)}(x,y) = 4\cos(\pi a x)\cos(\pi b y). \tag{5.1}$$

The C-functions, normalized as in (4.8), are written for all $a,b \in \mathbb{Z}^{\geqslant 0}$ in one expression,

$$\Phi_{(a,b)}(x,y) = 4\cos(\pi a x)\cos(\pi b y).$$

D. Orthogonality of C-functions

The fundamental region of $A_1 \times A_1$ here is

$$F(A_1 \times A_1) = \{x\omega_1 + y\omega_2 \mid 0 \leqslant x,y \leqslant 1\},$$

its vertices being 0, ω_1, ω_2, and ω_1, ω_2 (see Fig. 1). Hence its sides have length $|\omega_1| = |\omega_2| = 1/\sqrt{2}$.

Orthogonality of the functions is readily verified directly,

$$\int_F \Omega_{(a,b)}(x,y)\Omega_{(c,d)}(x,y)\mathrm{d}F = \frac{1}{2}\int_0^1 \mathrm{d}x \int_0^1 \Omega_{(a,b)}(x,y)\Omega_{(c,d)}(x,y)\mathrm{d}y$$
$$= \begin{cases} 0, & \text{if } a \neq c \text{ and } b \neq d, \\ \frac{1}{2}, & \text{if } a = b = c = d = 0, \\ 1, & \text{if } a = c > 0 \text{ and } b = d = 0, \\ & \text{or } a = c = 0 \text{ and } b = d > 0, \\ 2, & \text{if } a = b > 0 \text{ and } c = d > 0. \end{cases} \tag{5.2}$$

E. Laplace operator

The Laplace operator in this case is

$$L = 2\partial_{xx} + 2\partial_{yy}.$$

The C-functions are its eigenfunctions, and

$$L\Omega_\lambda = -4\pi^2\langle\lambda|\lambda\rangle\Omega_\lambda = -2\pi^2(a^2+b^2)\Omega_\lambda,$$

where the scalar product for $\lambda = a\omega_1 + b\omega_2$ is computed using the inverse Cartan matrix C^{-1}:

$$\langle\lambda|\lambda\rangle = (a\ b)C^{-1}\begin{pmatrix} a \\ b \end{pmatrix} = \frac{1}{2}(a^2+b^2).$$

VI. THE CASE C_2

A. Roots and weights

Relative length and angles of the simple roots of C_2 are given by

$$\langle\alpha_1|\alpha_2\rangle = -1, \quad \langle\alpha_1|\alpha_1\rangle = 1, \quad \langle\alpha_2|\alpha_2\rangle = 2.$$

The Cartan matrix and its inverse are

$$C=\begin{pmatrix}2 & -1\\ -2 & 2\end{pmatrix} \quad \text{and } C^{-1}=\begin{pmatrix}1 & \frac{1}{2}\\ 1 & 1\end{pmatrix}.$$

Consequently,

$$\alpha_1=2\omega_1-\omega_2,\quad \omega_1=\alpha_1+\tfrac{1}{2}\alpha_2,\quad \hat{\alpha}_1=2\alpha_1,\quad \hat{\omega}_1=\hat{\alpha}_1+\hat{\alpha}_2,$$

$$\alpha_2=-2\omega_2+2\omega_2,\quad \omega_2=\alpha_1+\alpha_2,\quad \hat{\alpha}_2=\alpha_2,\quad \hat{\omega}_2=\tfrac{1}{2}\hat{\alpha}_1+\hat{\alpha}_2.$$

The root system $\Delta=\{\pm\alpha_1,\pm\alpha_2,\pm(\alpha_1+\alpha_2),\pm(2\alpha_1+\alpha_2)\}$ geometrically represents the vertices and midpoints of a square. The highest root is $\xi_h=2\alpha_1+\alpha_2$.

B. Weyl group orbits

Let $\lambda=a\omega_1+b\omega_2\in P^+$. Then the Weyl group orbit $W_\lambda\equiv W_{(a,b)}$ contains one, four, or eight points. More precisely,

$$W_{(a,b)}=\begin{cases}\{(0,0)\}, & \text{if } a=b=0,\\ \{\pm(a,0),\pm(-a,a)\}, & \text{if } a\neq 0 \text{ and } b=0,\\ \{\pm(0,b),\pm(2b,-b)\}, & \text{if } a=0 \text{ and} b\neq 0,\\ \{\pm(a,b),\pm(-a,a+b),\pm(a+2b,-b),\pm(a+2b,-a-b)\}, & \text{if } a,b\neq 0.\end{cases}$$

In particular, $\Delta=W_{(2,0)}\cup W_{(0,1)}$.

C. C-functions

The C-functions of C_2, with $\lambda=a\omega_1+b\omega_2$ and $z=x\hat{\omega}_1+y\hat{\omega}_2$, are the following:

$$\Omega_{(0,0)}(x,y)=1,$$

$$\Omega_{(a,0)}(x,y)=2\cos(\pi ay)+2\cos(\pi a(2x+y)),$$

$$\Omega_{(0,b)}(x,y)=2\cos(2\pi bx)+2\cos(2\pi b(x+y)),$$

$$\begin{aligned}\Omega_{(a,b)}(x,y)&=2\cos(\pi(2bx+(a+2b)y))+2\cos(\pi((2a+2b)x+(a+2b)y))\\ &\quad+2\cos(\pi(ay+(2a+2b)x))+2\cos(\pi(2bx-ay)),\quad \text{where } a,b>0.\end{aligned}\tag{6.1}$$

C-functions, normalized as in (4.8), are written for all $a,b\in\mathbb{Z}^{\geqslant 0}$ in one expression,

$$\begin{aligned}\Phi_{(a,b)}(x,y)&=2\cos(\pi(2bx+(a+2b)y))+2\cos(\pi((2a+2b)x+(a+2b)y))\\ &\quad+2\cos(\pi(ay+(2a+2b)x))+2\cos(\pi(2bx-ay)).\end{aligned}$$

D. Decomposition of products of C-functions

Products of the C-functions decompose into sums of C-functions (4.10). For example, one has

$$\Omega_{(0,a)}\Omega_{(0,b)}=\Omega_{(0,a+b)}+\Omega_{(2a,b-a)}+\Omega_{(0,b-a)},\quad \text{when } a<b,$$

$$\Omega_{(0,a)}\Omega_{(b,0)}=\Omega_{(b,a)}+\Omega_{(2a-b,b-a)},\quad \text{when } a<b<2a,$$

$$\Omega_{(a,0)}\Omega_{(0,b)}=\Omega_{(a,b)}+\Omega_{(a,b-2a)},\quad \text{when } b>2a.$$

It is possible to build up recursively the higher C-functions, starting from the lowest three, namely, $\Omega_{(0,0)}, \Omega_{(1,0)}$, and $\Omega_{(0,1)}$,

$$\Omega_{(1,1)} = \Omega_{(1,0)}\Omega_{(0,1)} - 2\Omega_{(1,0)},$$

$$\Omega_{(2,0)} = \Omega_{(1,0)}\Omega_{(1,0)} - 4\Omega_{(0,0)} - 2\Omega_{(0,1)},$$

$$\Omega_{(0,2)} = \Omega_{(0,1)}\Omega_{(0,1)} - 4\Omega_{(0,0)} - 2\Omega_{(2,0)},$$

$$\Omega_{(2,1)} = \Omega_{(0,1)}\Omega_{(2,0)} - 2\Omega_{(0,1)},$$

$$\Omega_{(3,0)} = \Omega_{(1,0)}\Omega_{(2,0)} - \Omega_{(1,0)} - \Omega_{(1,1)},$$

$$\Omega_{(1,2)} = \Omega_{(0,1)}\Omega_{(1,1)} - 2\Omega_{(1,0)} - \Omega_{(1,1)} - 2\Omega_{(3,0)},$$

$$\cdots .$$

E. Orthogonality of C-functions

The fundamental region $F(C_2)$ is defined as follows:

$$F(C_2) = \{x\hat{\omega}_1 + y\hat{\omega}_2 \mid x,y \geqslant 0 \text{ and } 2x + y \leqslant 1\}.$$

Therefore, its vertices are 0, $\hat{\omega}_1/2$, and $\hat{\omega}_2$. Geometrically it is a triangle with angles $\pi/2, \pi/4$, and $\pi/4$ (see Fig. 1).

Orthogonality of C-functions of C_2 can be verified, if somewhat laboriously, by using (6.1) in (4.15),

$$\int_F \Omega_{(a,b)}(x,y)\Omega_{(c,d)}(x,y)\mathrm{d}F = \int_0^{\frac{1}{2}} \mathrm{d}x \int_0^{1-2x} \Omega_{(a,b)}(x,y)\Omega_{(c,d)}(x,y)\mathrm{d}y$$
$$= \begin{cases} 0, & \text{if } a \neq c \text{ and } b \neq d, \\ \frac{1}{4}, & \text{if } a = b = c = d = 0, \\ 1, & \text{if } a = c > 0 \text{ and } b = d = 0, \\ & \text{or } a = c = 0 \text{ and } b = d > 0, \\ 2, & \text{if } a = c > 0 \text{ and } b = d > 0. \end{cases} \tag{6.2}$$

In particular, we have for any $(a,b) \neq (0,0)$ and $(c,d) = (0,0)$

$$\int_F \Omega_{(a,b)}(x,y)\mathrm{d}F = 0.$$

F. Laplace operator

The Laplace operator (4.17) specializes to C_2 as follows:

$$L = (\alpha_1\partial_x + \alpha_2\partial_y)^2 = \partial_{xx} - 2\partial_{xy} + 2\partial_{yy}.$$

Applying L to C-functions, we see that they are its eigenfunctions,

TABLE II. Examples of the decomposition of C-functions of C_2 (left column) into C-functions of the maximal subgroup $A_1\times A_1^{\subset}$ (middle column) and of the maximal subjoint group $A_1\times A_1^{<}$ (right column).

C_2	$A_1\times A_1^{\subset}$	$A_1\times A_1^{<}$
$\Omega_{(0,0)}$	$\Omega_{(0,0)}$	$\Omega_{(0,0)}$
$\Omega_{(1,0)}$	$\Omega_{(1,0)}+\Omega_{(0,1)}$	$\Omega_{(1,1)}$
$\Omega_{(0,1)}$	$\Omega_{(1,1)}$	$\Omega_{(2,0)}+\Omega_{(0,2)}$
$\Omega_{(2,0)}$	$\Omega_{(2,0)}+\Omega_{(0,2)}$	$\Omega_{(2,2)}$
$\Omega_{(1,1)}$	$\Omega_{(2,1)}+\Omega_{(1,2)}$	$\Omega_{(3,1)}+\Omega_{(1,3)}$
$\Omega_{(0,2)}$	$\Omega_{(2,2)}$	$\Omega_{(4,0)}+\Omega_{(0,4)}$
$\Omega_{(3,0)}$	$\Omega_{(3,0)}+\Omega_{(0,3)}$	$\Omega_{(3,3)}$
$\Omega_{(2,1)}$	$\Omega_{(3,1)}+\Omega_{(1,3)}$	$\Omega_{(4,2)}+\Omega_{(2,4)}$
$\Omega_{(1,2)}$	$\Omega_{(3,2)}+\Omega_{(2,3)}$	$\Omega_{(5,1)}+\Omega_{(1,5)}$
$\Omega_{(0,3)}$	$\Omega_{(3,3)}$	$\Omega_{(6,0)}+\Omega_{(0,6)}$
$\Omega_{(4,0)}$	$\Omega_{(4,0)}+\Omega_{(0,4)}$	$\Omega_{(4,4)}$

$$L\Omega_\lambda = -4\pi^2\langle\lambda|\lambda\rangle\Omega_\lambda = -2\pi^2(a^2+2ab+2b^2)\Omega_\lambda,$$

where the scalar product $\langle\lambda|\lambda\rangle$ is computed for $\lambda=(a\omega_1+b\omega_2)\equiv(a\ b)$, using the quadrature matrix Q,

$$\langle\lambda|\lambda\rangle = \lambda Q\lambda^T = \frac{1}{2}(a\ b)\begin{pmatrix}1 & 1\\ 1 & 2\end{pmatrix}\begin{pmatrix}a\\ b\end{pmatrix} = \frac{1}{2}a^2+ab+b^2.$$

G. The branching rules for C-functions of C_2 to the subgroup $A_1\times A_1$

The problem considered here is to calculate the "branching rules" for C-functions. There are two rather different ways how a semisimple Lie group of rank 2 is related to C_2. In both cases the group is of type $A_1\times A_1$. In order to distinguish the two cases we use the notations $A_1\times A_1^{\subset}$ and $A_1\times A_1^{<}$. The C-functions of C_2 are completely reducible with respect to either of $A_1\times A_1$. The possibility of such reduction is a direct consequence of the corresponding reduction of W orbits.[15]

The first case is the maximal subgroup $A_1\times A_1^{\subset}$ of C_2. Its root system is the subset of long roots of C_2. In the second case, $A_1\times A_1^{<}$ is not a subgroup. It is the maximal subjoint group $A_1\times A_1$ to C_2. Its root system consists of the short roots of C_2. For more about subjoining, see Refs. 18 and 19.

Using the matrices

$$B_1 = \begin{pmatrix}0 & \frac{1}{2}\\ 1 & -\frac{1}{2}\end{pmatrix} \quad \text{and } B_2 = \begin{pmatrix}1 & -1\\ 0 & 1\end{pmatrix}$$

to transform the variables in the C-functions of C_2, we can obtain the decompositions of C_2 C-functions into C-functions of its subgroup and subjoint group, demonstrated in Table II. The general rules for such decompositions are given by

$$[\Omega_{(a,b)}]_{C_2} = [\Omega_{(a+b,b)} + (1-\delta_{a,0})\Omega_{(b,a+b)}]_{A_1\times A_1^{\subset}} \tag{6.3}$$

and

$$[\Omega_{(a,b)}]_{C_2} = [\Omega_{(a+2b,a)} + (1-\delta_{b,0})\Omega_{(a,a+2b)}]_{A_1\times A_1^{<}}. \tag{6.4}$$

VII. DISCRETIZATION OF TWO-DIMENSIONAL TRANSFORMS

In this section we describe all the necessary tools, which allow one to decompose a function $f(s)$, given by its values on points s of certain two-dimensional grids F_M, $M=1,2,\ldots<\infty$, in terms of finite series of C-functions. Such decomposition is possible, due to the discrete orthogonality of C-functions on the points of F_M, i.e., its coefficients can be computed.

A. Equidistant grids of points in the fundamental region

The fundamental region F can be used to tile the entire plane by its copies, $W^{\text{aff}}F=\mathbb{R}^2$. Our next task is to describe grids F_M of discrete points in F of any density, specified by a positive integer M, which extends into a lattice with the tiling of $\mathbb{R}^2$ by copies of F.

The points s of F_M are conveniently described in barycentric coordinates. That is, by three non-negative integers, $[s_0,s_1,s_2]$. A point s belongs the grid F_M, provided

$$s=\frac{s_1}{M}\hat{\omega}_1+\frac{s_2}{M}\hat{\omega}_2, \quad \text{where } s_0,s_1,s_2\in\mathbb{Z}^{\geqslant 0} \text{ and } M=s_0+q_1s_1+q_2s_2>0. \tag{7.1}$$

Here q_1 and q_2 are positive integers, specific for each Lie group. They are the coefficients of the highest root of Δ in α basis. Equivalently, we write

$$F_M\overset{\text{def}}{=}\left\{\left(\frac{s_1}{M},\frac{s_2}{M}\right)\mid s_0,s_1,s_2\in\mathbb{Z}^{\geqslant 0},s_0+q_1s_1+q_2s_2=M>0\right\}. \tag{7.2}$$

B. Bilinear form on F_M

Given the set of points F_M in the fundamental region, and two functions $f(s)$ and $h(s)$, given by their values at the points $s\in F_M$, one defines a Hermitian form as follows:[3]

$$\langle f|h\rangle_M\overset{\text{def}}{=}\sum_{s\in F_M}c_sf(s)\overline{h(s)}. \tag{7.3}$$

The line over $h(s)$ stands for complex conjugation. The coefficients c_s are positive integer numbers for each Lie group. They are given below for the groups of rank 2, for a general case, see Ref. 3.

C. Discrete orthogonality of C-functions

For a fixed value of $M\in\mathbb{N}$, the discrete orthogonality of C-functions on $F_M\subset F$ is crucial for this study,

$$\langle\Phi_{(a,b)}|\Phi_{(a',b')}\rangle_M=\sum_{s\in F_M}c_s\Phi_{(a,b)}(s)\overline{\Phi_{(a',b')}(s)}=\delta_{a,a'}\delta_{b,b'}\langle\Phi_{(a,b)}|\Phi_{(a,b)}\rangle_M. \tag{7.4}$$

The orthogonality (7.4) holds for $\Phi_{(a,b)},\Phi_{(a',b')}$ from a finite subset S_M of C-functions.

In general, for all cases of rank 2, we can construct (infinitely many) such subsets S_M by using the following:

$$S_M\overset{\text{def}}{=}\left\{\Phi_{(a,b)}|\left(\frac{b}{M},\frac{a}{M}\right)=r\left(\frac{s_1}{M},\frac{s_2}{M}\right),\ \text{where}\left(\frac{s_1}{M},\frac{s_2}{M}\right)\in F_M \text{ and } r\in W^{\text{aff}}\right\}. \tag{7.5}$$

As an easy example, one can obtain the set of the lowest $\Phi_{(a,b)}\in S_M$, by taking $r=1$ and a,b that satisfy the inequality

$$aq_2+bq_1\leqslant M\Rightarrow\Phi_{(a,b)}\in S_M, \tag{7.6}$$

where q_1,q_2 are the same as in (4.11).

From the definition of S_M it is easy to see that

$$|S_M| = |F_M|.$$

The numbers $\langle \Phi_{(a,b)} | \Phi_{(a,b)} \rangle_M$ in (7.4) take only a few integer values for each M. Subsequently, we will provide them for all $0 \leqslant a,b < \infty$, for all the cases considered in this paper.

D. Decomposition into C-functions and continuous extension

A function $f(s)$, with known values on points of the grid F_M, can be decomposed as follows:

$$f(s) = \sum_{\Phi_{(a,b)} \in S_M} d_{(a,b)} \Phi_{(a,b)}(s), \quad s \in F_M. \tag{7.7}$$

Orthogonality (7.4) makes it possible to compute the coefficients $d_{(a,b)}$ from

$$d_{(a,b)} = \frac{\langle f | \Phi_{(a,b)} \rangle_M}{\langle \Phi_{(a,b)} | \Phi_{(a,b)} \rangle_M}, \quad \text{where } \langle f | \Phi_{(a,b)} \rangle_M = \sum_{s \in F_M} c_s f(s) \overline{\Phi_{(a,b)}(s)}. \tag{7.8}$$

After $d_{(a,b)}$ have been calculated, one can replace s in (7.7) by the continuous variables x and y,

$$f_{\text{cont}}(x,y) \overset{\text{def}}{=} \sum_{\Phi_{(a,b)} \in S_M} d_{(a,b)} \Phi_{(a,b)}(x,y), \quad x,y \in \mathbb{R}. \tag{7.9}$$

The function $f_{\text{cont}}(x,y)$ is the continuous extension of the decomposition (7.7). Both functions coincide at the points $(x,y) = (s_1/M, s_2/M) = s \in F_M$.

E. Discretization in the case of $A_1 \times A_1$

The fundamental region in the case of $A_1 \times A_1$ is a Cartesian product of two fundamental regions of A_1. It forms a square described by the following:

$$F = \{ x\omega_1 + y\omega_2 \mid 0 \leqslant x,y \leqslant 1 \}.$$

A square lattice F_M of order M is a Cartesian product of two lattices $F_M(A_1)$, built on F the following way:

$$F_M \overset{\text{def}}{=} \left\{ \left(\frac{s_1}{M}, \frac{s_2}{M} \right) \mid s_1, s_2 \in \mathbb{Z}^{\geqslant 0}, \quad s_1, s_2 \leqslant M \in \mathbb{N} \right\}.$$

Coefficients c_s are in this case

$$c_s \equiv c_{(s_1/M, s_2/M)} = \begin{cases} 1, & \text{if } s_2 = s_2 = 0, \\ & \quad \text{or } s_1 = s_2 = M, \\ & \quad \text{or } s_1 = 0 \text{ and } s_2 = M, \\ & \quad \text{or } s_1 = M \text{ and } s_2 = 0, \\ 2, & \text{if } s_1 = 0 \text{ and } 0 < s_2 < M, \\ & \quad \text{or } s_2 = 0 \text{ and } 0 < s_1 < M, \\ & \quad \text{or } s_1 = M \text{ and } 0 < s_2 < M, \\ & \quad \text{or } s_2 = M \text{ and } 0 < s_1 < M, \\ 4, & \text{if } 0 < s_1, s_2 < M. \end{cases}$$

The C-functions are orthogonal,

$$\langle \Phi_{(a,b)} | \Phi_{(a',b')} \rangle_M = 0, \quad \text{if } a \neq a' \text{ and } b \neq b',$$

otherwise, for the set of the lowest pairwise orthogonal normalized C-functions,

$$\langle\Phi_{(a,b)}|\Phi_{(a,b)}\rangle_M = 16M^2 \times \begin{cases} 1, & \text{if } 0 < a,b < M, \\ 2, & \text{if } 0 < a < M \text{ and } b = 0, \\ & \text{or } a = 0 \text{ and } 0 < b < M, \\ & \text{or } 0 < a < M \text{ and } b = M, \\ & \text{or } a = M \text{ and } 0 < b < M, \\ 4, & \text{if } a = b = 0, \\ & \text{or } a = 0 \text{ and } b = M, \\ & \text{or } a = M \text{ and } b = 0, \\ & \text{or } a = b = M, \end{cases}$$

with the higher C-functions repeating the values of the lowest ones. (See Fig. 2.)

For example, F_2 consists of the nine points given as $[s_1,s_2]=(s_1/2,s_2/2)$,

$$[0,0]=(0,0), \quad [0,1]=\left(0,\tfrac{1}{2}\right), \quad [0,2]=(0,1),$$

$$[1,0]=\left(\tfrac{1}{2},0\right), \quad [1,1]=\left(\tfrac{1}{2},\tfrac{1}{2}\right), \quad [1,2]=\left(\tfrac{1}{2},1\right), \tag{7.10}$$

$$[2,0]=(1,0), \quad [2,1]=\left(1,\tfrac{1}{2}\right), \quad [2,2]=(1,1),$$

while F_1 has only four points,

$$[0,0]=(0,0), \quad [0,1]=(0,1), \quad [1,0]=(1,0), \quad [1,1]=(1,1).$$

F. Discretization in the case of C_2

The highest root of C_2 is $2\alpha_1+\alpha_2$. Therefore,

$$F_M \overset{\text{def}}{=} \left\{ \left(\frac{s_1}{M}, \frac{s_2}{M} \right) \mid s_0,s_1,s_2 \in \mathbb{Z}^{\geqslant 0}, \quad s_0 + 2s_1 + s_2 = M > 0 \right\}.$$

Vertices of F are (0,0), (0,1), $\left(\frac{1}{2},0\right)$, relative to $\hat{\omega}$ basis. (See Fig. 3.) Coefficients c_s are in this case,

$$c_s \equiv c_{(s_1/M,s_2/M)} = \begin{cases} 1, & \text{if } s_1 = 0 \text{ and } s_2 = 0, \\ & \text{or } s_1 = 0 \text{ and } s_2 = M, \\ 2, & \text{if } s_1 = 0 \text{ and } s_2 = \frac{M}{2}, \\ 4, & \text{if } s_1 = 0 \text{ and } 0 < s_2 < M, \\ & \text{or } s_2 = 0 \text{ and } 0 < s_1 < M, \\ & \text{or } s_1,s_2 > 0 \text{ and } 2s_1 + s_2 = M, \\ 8, & \text{if } s_1,s_2 > 0 \text{ and } 2s_1 + s_2 < M. \end{cases} \tag{7.11}$$

The discrete orthogonality,

$$\langle\Phi_{(a,b)}|\Phi_{(a',b')}\rangle_M = 0, \quad \text{if } a \neq a' \text{ and } b \neq b',$$

otherwise, for the set of the lowest pairwise orthogonal normalized C-functions,

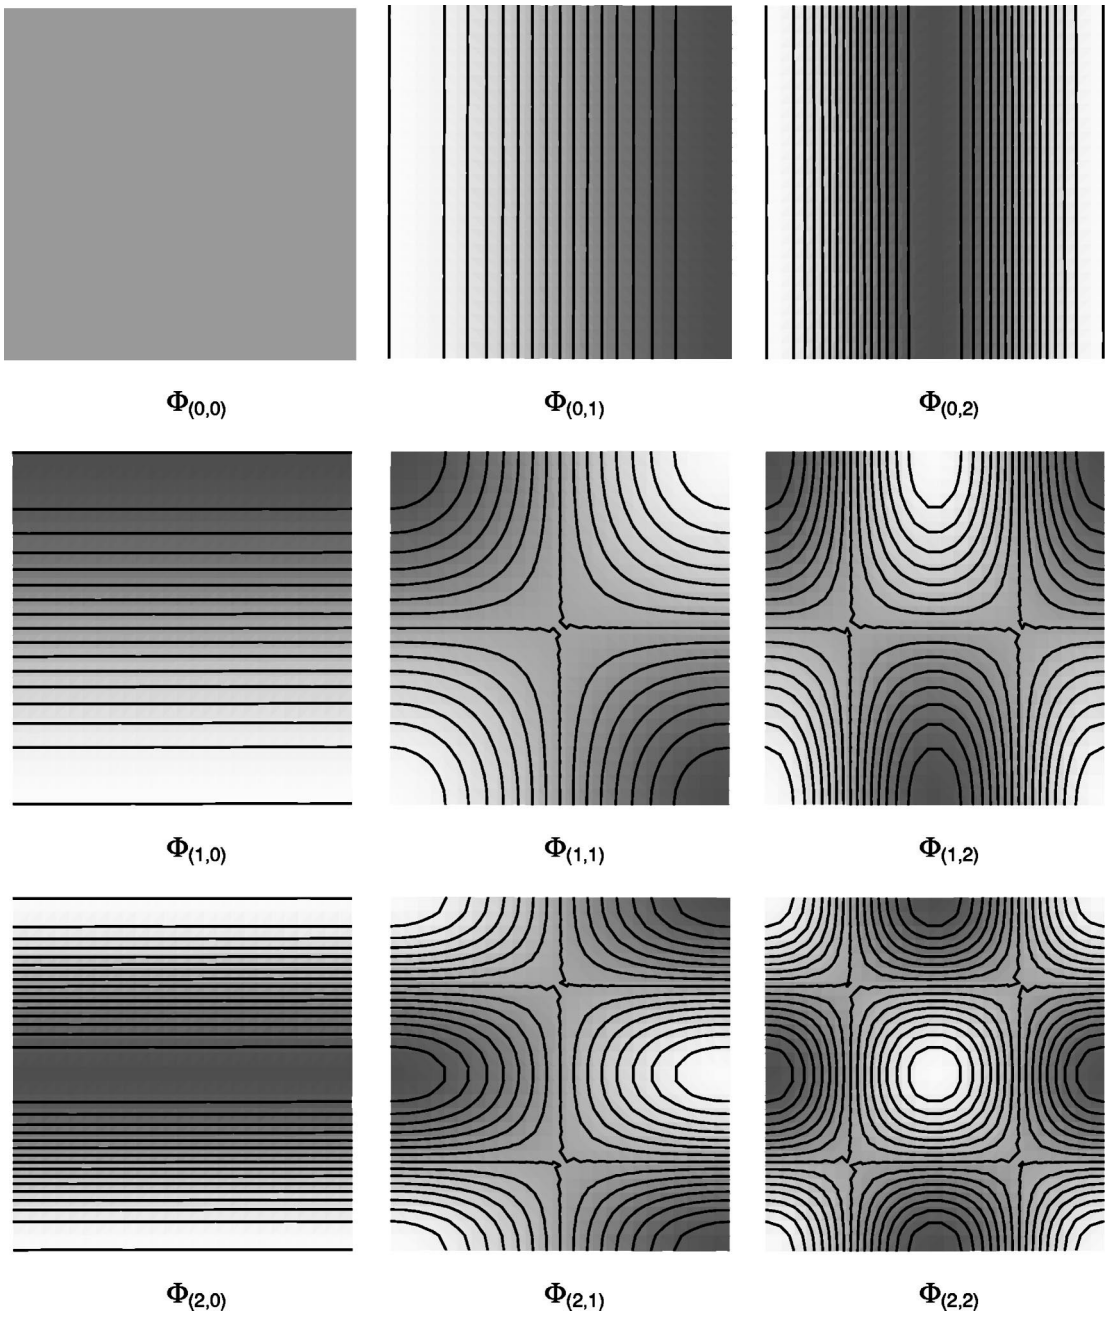

FIG. 2. The set of nine lowest pairwise orthogonal normalized C-functions of $A_1 \times A_1$ for the grid F_2.

$$\langle \Phi_{(a,b)} | \Phi_{(a,b)} \rangle_M = 16M^2 \times \begin{cases} 1, & \text{if } 0 < a,b \text{ and } a + 2b < M, \\ 2, & \text{if } 0 < a < M \text{ and } b = 0, \\ & \quad \text{or } a = 0 \text{ and } 0 < 2b < M, \\ & \quad \text{or } 0 < a,b \text{ and } a + 2b = M, \\ 4, & \text{if } a = 0 \text{ and } 2b = M, \\ 8, & \text{if } a = b = 0, \\ & \quad \text{or } a = M \text{ and } b = 0, \end{cases}$$

with the higher C-functions repeating the values of the lowest ones. (See Fig. 4.)

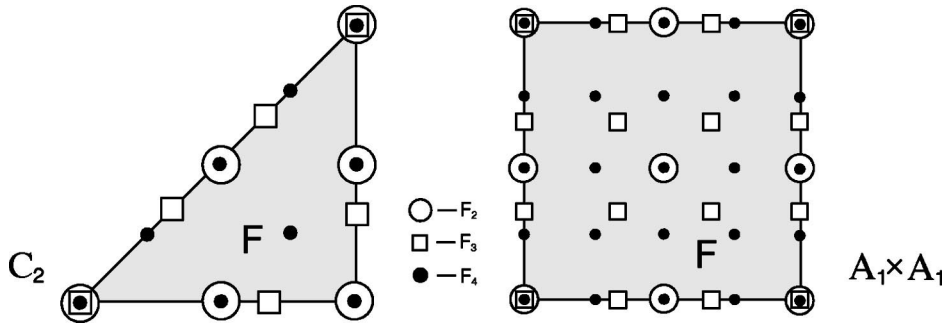

FIG. 3. The lattice points of F_2, F_3, and F_4 in the fundamental region F for the cases C_2 and $A_1 \times A_1$.

For example, F_3 consists of the six points given as $[s_0, s_1, s_2] = (s_1/M, s_2/M)$,

$$[1,0,0] = (0,0), \quad [0,0,1] = (0,1), \quad [1,1,0] = \left(\tfrac{1}{3}, 0\right),$$
$$[0,1,1] = \left(\tfrac{1}{3}, \tfrac{1}{3}\right), \quad [1,0,2] = \left(0, \tfrac{2}{3}\right), \quad [2,0,1] = \left(0, \tfrac{1}{3}\right), \tag{7.12}$$

while F_2 has only four points,

$$[1,0,0] = (0,0), \quad [0,0,1] = (0,1), \quad [0,1,0] = \left(\tfrac{1}{2}, 0\right), \quad [1,0,1] = \left(0, \tfrac{1}{2}\right).$$

As an example, the values of C_2 normalized orbit functions on the grid F_3 are given in Table III.

VIII. MOTIVATING EXAMPLES

Comparison of expansions of into series of both groups considered here, as well as the two additional groups of Ref. 1, will require further study. Related questions are illustrated by the following examples.

There are two examples shown in this section, involving decomposition of the same function $f(x,y)$ into series of C-functions of $A_1 \times A_1$ and C_2. Goal of the examples is (i) to illustrate discrete decomposition of a given function followed by the continuous extension, and (ii) to compare the continuous extensions in both cases.

We choose for $f(x,y)$ the square step function with sharp edges,

$$f(x,y) = \begin{cases} 1 & \text{for } 0.30 < x < 0.45, \quad \text{and } 0.05 < y < 0.20, \\ 0 & \text{elsewhere in } F. \end{cases} \tag{8.1}$$

In order to make the comparison, we set up the vertices of the two fundamental regions as follows (relative to an orthonormal basis):

$$F(A_1 \times A_1) = \left\{(0,0), \left(\tfrac{1}{2}, 0\right), \left(0, \tfrac{1}{2}\right), \left(\tfrac{1}{2}, \tfrac{1}{2}\right)\right\}, \tag{8.2}$$

$$F(C_2) = \left\{(0,0), \left(\tfrac{1}{2}, 0\right), \left(\tfrac{1}{2}, \tfrac{1}{2}\right)\right\}. \tag{8.3}$$

Thus $F(C_2)$ is exactly half of $F(A_1 \times A_1)$ with three vertices in common. In order to have the grid of the same density in both regions, one must make sure that there is the same number of points along the edges of sides of F adjacent to angle $\pi/2$.

Suppose M is fixed. Then each side of $F(A_1 \times A_1)$ contains $M+1$ points each. For a given M', the $F(C_2)$-edge $(0,0)$, $\left(\tfrac{1}{2}, 0\right)$ contains $[M'/2]$ points, where $[M'/2]$ stands for the integer part of $M'/2$. Consequently, to have the same density of the grid in both cases, we have to have $M+1 = [M'/2]$.

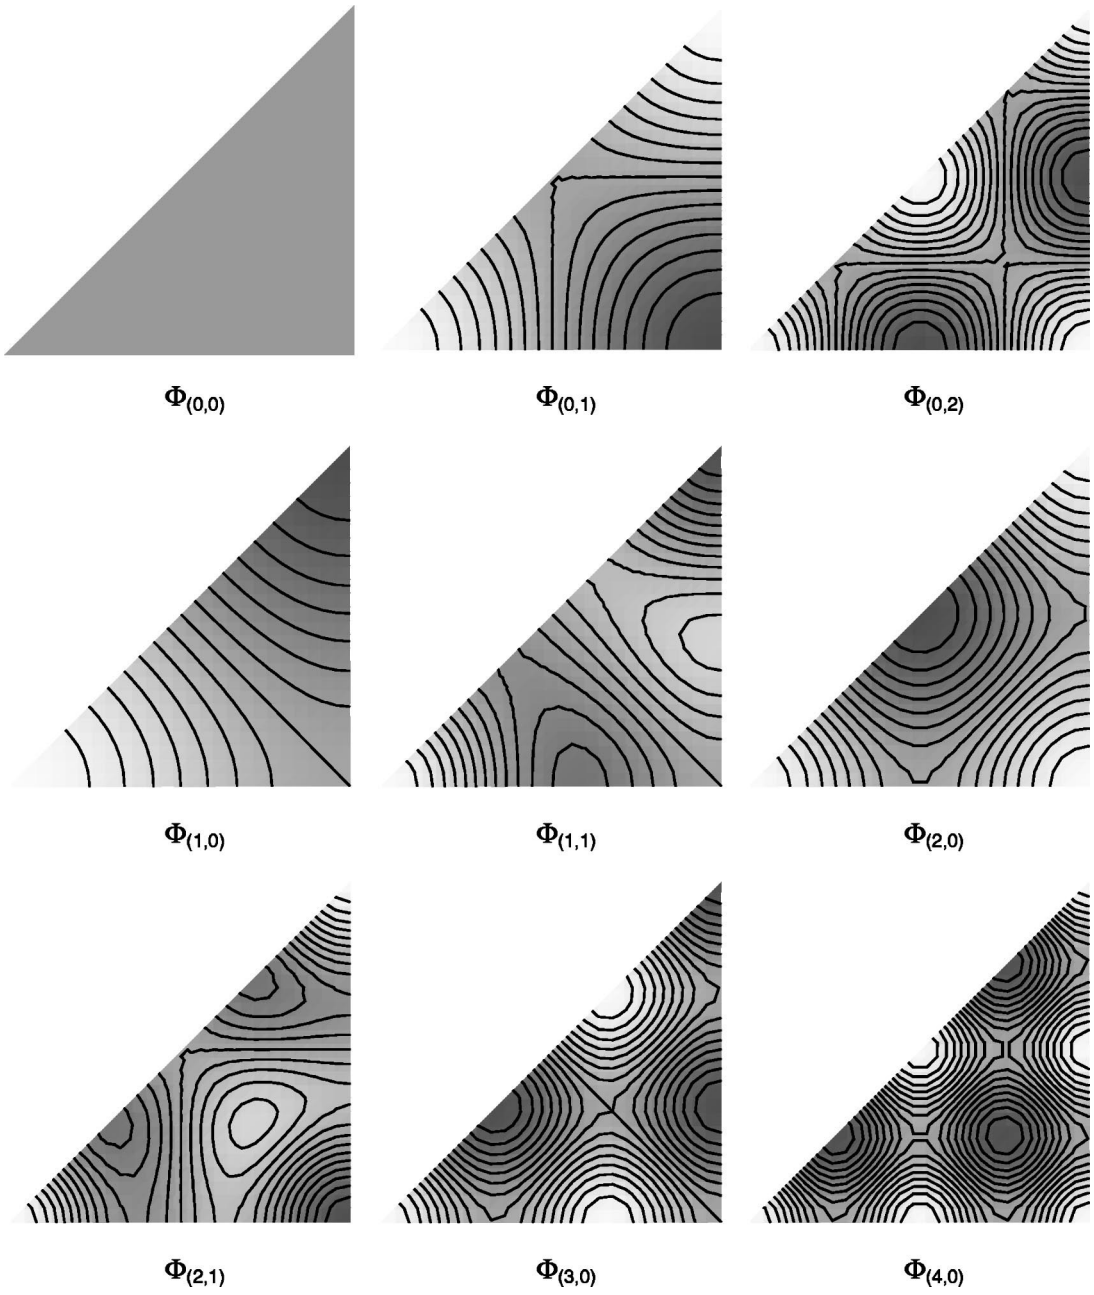

FIG. 4. The set of nine lowest pairwise orthogonal normalized C-functions of C_2 for the grid F_4.

Figures 5 and 6 contain results of our two examples. The same function $f(x,y)$ of (8.1) is placed into the fundamental regions F of the two groups, their values are sampled at the points s of the grids F_M (7.2) and taken as our digital data $f(s)$. Then the functions are expanded (7.7) into C-functions of $A_1 \times A_1$ and of C_2 on the corresponding grid F_M, i.e., expansion coefficients are calculated (7.8). After that, continuous extensions of the discrete expansions of $f(s)$ are made (7.9) by replacing the C-functions of the discrete argument s in the expansions by the same functions of the continuous argument, while keeping the expansion coefficients unchanged. Each figure shows the function $f_{\text{cont}}(x,y)$ resulting from the continuous extension of discrete expansions. More precisely, four different continuous extensions are shown in each figure. They differ by the densities

TABLE III. Values of several normalized C-functions of C_2 at the points of the grid F_3. Note that only the first six C-functions are pairwise orthogonal. The higher ones repeat the values of the lowest six. The c_s are the coefficients from ((7.11)).

of the grid F_M, namely $M=4$, 8, 16, and 32, from which the continuous extension is made. For the same value of M, the densities of grids of $A_1 \times A_1$ and C_2 are the same. The points of the grids are not shown in the figures.

Inspecting and comparing the two figures, one readily observes the following:

(i) Increasing density of the grid, i.e., increasing the value of M, makes the continuous extension to match more closely the given model function $f(x,y)$ of (8.1).

(ii) Quality of the extension, i.e., the match between the continuous extension $f_{\text{cont}}(x,y)$ and the original function $f(x,y)$, is comparable for the same density of the grid in both cases, though C_2 expansion may be slightly superior, as noticeable by comparing the two at $M=32$.

The observations have important consequences.

The number of points of $F_M(A_1 \times A_1)$ and $F_M(C_2)$ are approximately in the ratio 2:1, due to the ration of the areas of the fundamental regions (see Fig. 1) and to the equal density of the points in both cases.

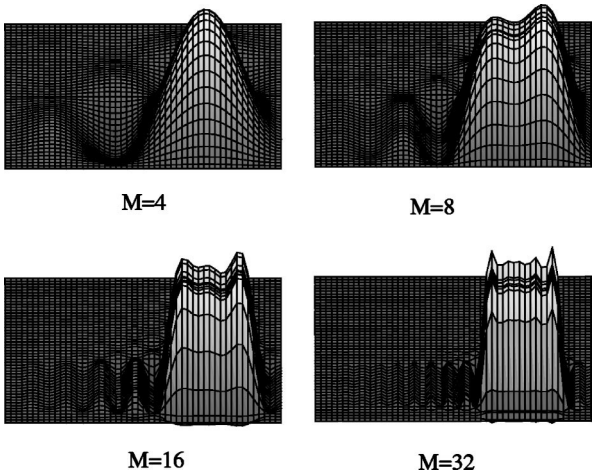

FIG. 5. Decomposition and continuous extension of a square step function placed in the fundamental region of $A_1 \times A_1$ on the grids of orders $M=4$, 8, 16, and 32.

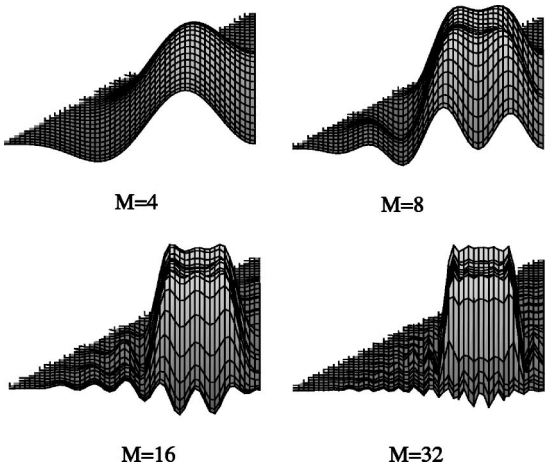

FIG. 6. Decomposition and continuous extension of a square step function placed in the fundamental region of C_2 on the grids of orders $M=4$, 8, 16, and 32.

The number of terms in the expansions equals the number of points in the corresponding F_M. Hence the C_2 expansions are half as long as those of $A_1\times A_1$ for the same quality of continuous expansion.

Consequently, as much as one can draw a conclusion from an example of using only one function $f(x,y)$, it appears that the C_2 expansions are considerably more efficient than the $A_1\times A_1$ ones.

In a way of objection to the conclusion just made, one may point out that C-functions of C_2 are formed as sums of twice as many exponential functions (up to eight), in comparison with C-functions of $A_1\times A_1$ (sums of up to four exponentials). Consequently, computing the values of more complicated C-functions of C_2 on half as many points of its grid, may require comparable computational efforts to those for the simpler C-functions of $A_1\times A_1$ on larger number of points. Although such an objection is undoubtedly true, it is hardly pertinent. Indeed, in any extensive computations of the expansions, the values of C-functions at the grid points would be calculated in advance, and used as a look-up table during the actual expansions. Size of such a look-up table is given by the number of points in F_M, and by, what is the same, the number of discretely orthogonal C-functions in the set S_M. Moreover, the same table should be used for expansion of any function on the same grid.

IX. CONCLUDING REMARKS

(1) In general terms, the families of C- and S-functions, based on any compact semisimple Lie group, have all the properties of traditional special functions, and more.[12] Indeed, discretization, as demonstrated in this paper and generally in Ref. 3, is not a standard feature of traditional special functions.

(2) The application, which mostly motivated our interest in rank-2 group transforms, like the two considered in this paper, is the decomposition of functions sampled on two-dimensional lattices into finite sums of discretized C-functions. The remaining two cases, the groups A_2 and G_2, are considered in a similar manner in Ref. 1.

(3) Recently it was recognized[4] that the continuous extension of the decompositions on the grid F_M is particularly useful. Once coefficients of a discrete expansion are found, one replaces in the expansion the C-functions, sampled on F_M, by their continuous versions. Unlike similar extension of conventional Fourier expansions, continuous extensions of C-function expansions smoothly interpolate between grid points of F_M. This property is likely to turn out extremely useful for various methods of image enhancement and data compression.[4,8]

(4) In parallel with cosine transform, there exists a sine transform (see for example, Ref. 20). Similarly, as C-function transforms generalize cosine transform to any compact semisimple

Lie group, the sine transforms generalize as S-function transforms[2] (continuous and discrete). Most of the properties of C-transforms carry over as properties of S-transforms, one of the noticeable differences being their behaviors at the boundary of F.

(5) In our opinion, independent interest represents the construction of the lattices in $\mathbb{R}^n$ through the grids in F_M, even without the problem of expansion of functions on F,. The flexibility and uniformity of its construction for any density specified by just one natural number M, should be exploited in other applications. Let us also single out the fact that the grid F_M, for any M, is group-theoretically defined. It represents an Abelian subgroup of the maximal torus generated by the elements of order M. Each point $s \in F_M$ is a representative of a conjugacy class of elements of finite order in the Lie group.

(6) Among problems of interest related to this paper and to Refs. 1 and 2, one can point out the following ones:

(i) The fact, that the C- and S-functions are the eigenfunctions of the Laplace operator with known eigenvalues and known value at the boundary of F, should find a number of useful applications in physics. That property, along with their relative simplicity, distinguishes them from the irreducible characters. Equally useful should prove to be the fact that they form bases for lattice problems.

(ii) Also, we are interested in the question of identification of the types of functions on F, which are most efficiently decomposed into C- and/or S-function series for each of the four semisimple Lie groups of rank 2. Examples of comparison are given in Sec. VIII and in Ref. 1, but more conclusive and more definite results would be interesting.

(iii) Practical processing of two-dimensional digital data often involves grids with millions of points. The question of computational efficiency in large scale applications needs to be investigated. Furthermore, rational coordinates of points $s \in F_M$ make C-functions into linear combinations of Mth roots of unity. It was shown in Ref. 3 that some, even very large, decomposition problems can be reformulated and done entirely in integers, for example, Ref. 14.

(iv) There exists a similarity to fast Fourier transform, which merits further investigation. Indeed, one has the freedom to work with series of gradually refining grids, for example, $F_2 \subset F_{2^2} \subset \cdots \subset F_{2^k} \subset \cdots$.

(7) Every C- or S-function is a sum of a finite number of exponential functions. In rank 2, that is

$$e^{2\pi i\langle \lambda | z\rangle} = e^{2\pi i(A/|C|)\theta_1 + 2\pi i(B/|C|)\theta_2},$$

where A and B are integers and $|C|$ is the determinant of the corresponding Cartan matrix. The substitution

$$e^{2\pi i(\theta_1/|C|)} \to x, \quad e^{2\pi i(\theta_2/|C|)} \to y$$

transforms any C- and S-function into a polynomial in x and y. Indeed, one gets $e^{2\pi i\langle \lambda | z\rangle} = x^A y^B$.

Thus, C- and S-functions are families of orthogonal polynomials, each related to a particular semisimple Lie group and to a particular W orbit, in as many variables as is the rank of the group.

Continuous spin representations from group contraction

Abu M. Khan[a] and Pierre Ramond[b]
Institute for Fundamental Theory, Department of Physics, University of Florida, Gainesville, Florida 32611

(Received 11 October 2004; accepted 3 March 2005; published online 27 April 2005; publisher error corrected 28 June 2005)

We consider how the continuous spin representation (CSR) of the Poincaré group in four dimensions can be generated by dimensional reduction. The analysis uses the front-form little group in five dimensions, which must yield the Euclidean group $E(2)$, the little group of the CSR. We consider two cases, one is the single spin massless representation of the Poincaré group in five dimensions, the other is the infinite component Majorana equation, which describes an infinite tower of massive states in five dimensions. In the first case, the double singular limit $j, R \to \infty$, with j/R fixed, where R is the Kaluza–Klein radius of the fifth dimension, and j is the spin of the particle in five dimensions, yields the CSR in four dimensions. It amounts to the Inönü–Wigner contraction, with the inverse Kaluza–Klein radius as contraction parameter. In the second case, the CSR appears only by taking a triple singular limit, where an internal coordinate of the Majorana theory goes to infinity, while leaving its ratio to the Kaluza–Klein radius fixed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897663]

I. INTRODUCTION

As shown in Wigner's classic work[1] in four dimensions, there are four types of irreducible representations of the Poincaré group. Two describe massless and massive elementary particles with definite helicity and spin, respectively. However, nature does not seem to use the other two, one that describes particles with spacelike momenta,[2] tachyons which move faster than the speed of light, and the others that describe massless states with an infinite number of integer or half-odd integer unit-spaced helicities, dubbed by Wigner continuous spin representations (CSRs).

When tachyons occur in field and string theories, it is as symptoms of an unstable theory, a malady whose cure is known, by shifting the vacuum through spontaneous symmetry breaking as in field and string field theory, or by extending to supersymmetry as in string theory.

There is no analogous cure for the CSR, for which the obstacles are indeed formidable, negative norm states, nonlocality, and acausality,[3] and according to Wigner himself,[4] infinite heat capacity of the vacuum.

The bosonic CSR necessarily contains one massless graviton, but accompanied by an infinite tower of massless helicity states. Therefore it should be viewed in the context of theories that extend general relativity, such as M- or string theories, where a naive application of the infinite slope limit to their spectrum leads to an infinite array of massless states with unit-spaced helicities. Like the tachyonic representation, the CSR may also be symptomatic of a diseased theory, but is there a cure for it?

Such considerations merit further studies. In a previous paper,[5] Wigner's bosonic and fermionic CSR in four dimensions were found to be supersymmetric partners of one another. Interestingly, the supersymmetric CSR does not have infinite heat capacity as it cancels between bosons

[a]Electronic mail: amas@phys.ufl.edu
[b]Electronic mail: ramond@phys.ufl.edu

and fermions. We also showed how to generalize them to higher dimensions by using Dirac's front form (also known as light cone) where the CSRs are linked to representations of the Euclidian group in the transverse plane in any dimensions.

The purpose of this paper is to seek CSR's in familiar mathematical structures which contain the Poincaré group in four dimensions: the conformal group SO(4,2), the Poincaré group in higher dimensions, and in the de Sitter and anti-de Sitter groups in five dimensions. The latter require group contraction, introduced by Inönü and Wigner (IW),[6] in order to generate the Euclidean group from the rotation group. We show that, while the CSR do not appear as representations of the conformal group,[7,8] they can be generated from the five-dimensional Poincaré group by a combination of group contraction and Kaluza–Klein[9] dimensional reduction. We apply the same procedure to a more complicated theory, Majorana's infinite component wave equation[10] in five dimensions. We do not consider how string theories in higher dimension can yield CSR's in lower dimensions, our considerations indicate a connection between group contraction and their infinite slope limit.

II. FRONT FORMS OF THE POINCARÉ AND CONFORMAL ALGEBRAS

In this section, we briefly review the light-cone forms of the Poincaré and conformal algebras in arbitrary dimensions.

A. Poincaré algebra

In d dimensions, the generators of the Poincaré algebra satisfy the commutation relations

$$[P^\mu, P^\nu] = 0,$$

$$[M^{\mu\nu}, P^\sigma] = i(\eta^{\mu\sigma}P^\nu - \eta^{\nu\sigma}P^\mu),$$

$$[M^{\mu\nu}, M^{\alpha\beta}] = i(\eta^{\mu\alpha}M^{\nu\beta} + \eta^{\alpha\nu}M^{\beta\mu} + \eta^{\nu\beta}M^{\mu\alpha} + \eta^{\beta\mu}M^{\alpha\nu}),$$

where $\eta_{\mu\nu}=(-1,1,\ldots,1)$ and $\mu,\nu,\alpha,\beta=0,\ldots,(d-1)$.

Introduce the light-cone coordinates,[11,5]

$$x^\pm = \frac{1}{\sqrt{2}}(t \pm x^{d-1}) \quad \text{and } p^\pm = \frac{1}{\sqrt{2}}(p^0 \pm p^{d-1}),$$

where $i,j=1,2,\ldots,(d-2)$ are the transverse directions. The commutation relations satisfied by the momenta and positions are

$$[x^-, p^+] = -i \quad \text{and } [x^i, p^j] = i\eta^{ij}.$$

Following Dirac, we set $x^+=0$ and use the mass-shell condition to express its conjugate variable p^- in terms of the remaining variables. The translation generators become

$$P^- = \frac{p^i p^i + M^2}{2p^+}, \quad P^+ = p^+, \quad P^i = p^i;$$

P^- is called the light-cone Hamiltonian. The Lorentz generators are given by

$$M^{+i} = -x^i p^+, \tag{1}$$

$$M^{+-} = -x^- p^+, \tag{2}$$

$$M^{ij} = x^i p^j - x^j p^i + S^{ij}, \tag{3}$$

$$M^{-i} = x^- p^i - \frac{1}{2}\{x^i, P^-\} + \frac{1}{p^+}(T^i - p^j S^{ij}). \tag{4}$$

The generators, S^{ij}, form the SO$(d-2)$ transverse light-cone little group and obey,

$$[S^{ij}, S^{kl}] = i(\eta^{ik}S^{jl} + \eta^{kj}S^{li} + \eta^{jl}S^{ik} + \eta^{li}S^{kj}). \tag{5}$$

The T^i's transform as SO$(d-2)$ vectors, called the light-cone translation vectors and satisfy

$$[S^{ij}, T^k] = i(\eta^{ik}T^j - \eta^{jk}T^i), \tag{6}$$

$$[T^i, T^j] = iM^2 S^{ij}. \tag{7}$$

The difference between the various representations is easily understood in terms of these variables.

(i) When $M \neq 0$, we can divide Eq. (7) by M, so that

$$S^{ij} \quad \text{and} \quad \frac{T^i}{M}$$

generate the massive little group SO$(d-1)$. The representations are therefore labelled by the massive little group.

(ii) When $M=0$, the T^i's are still SO$(d-2)$ vectors, but they commute with one another. This leads us to consider two cases.

(1) $T^i=0$, yields the regular massless representation labelled by a representation of the SO$(d-2)$ little group generated by S^{ij}, with a finite number of helicity states.

(2) $T^i \neq 0$. In this case, the S^{ij} and T^i's form the inhomogeneous light-cone little group in $(d-2)$ dimensions, which has infinite-dimensional representations, yielding the continuous spin massless representations of the Poincaré group.

B. Conformal algebra

The Poincaré group is a subgroup of the conformal group SO$(d,2)$ which contains dilatation and conformal transformations. The concept of mass makes sense in the conformal sense only if it is zero, to preserve scale invariance. Thus one expects massless representations of the Poincaré group to appear naturally in those of the conformal group.

It has been known[7,8] for some time that the CSR do not appear in this decomposition. We can show it elegantly using light-cone coordinates, and expressing the generators of the conformal algebra using the same variables as for the Poincaré algebra. We need to add to the Poincaré generators the dilatation generator

$$D = \tfrac{1}{2}(x \cdot p + p \cdot x), \tag{8}$$

for the scale transformation and the special conformal transformations generated by

$$K^\mu = 2x_\nu M^{\mu\nu} + x^2 p^\mu = 2x^\mu D - x^2 p^\mu + 2x^\nu S^{\mu\nu}, \tag{9}$$

where $\mu=0,1,\ldots(d-1)$, and

$$M^{\mu\nu} = x^\mu p^\nu - x^\nu p^\mu + S^{\mu\nu}. \tag{10}$$

In addition to those of the Poincaré algebra, these two generators satisfy the following commutation relations:

$$[M^{\mu\nu}, D] = 0, \quad [D, p^\mu] = ip^\mu, \quad [D, K^\mu] = -iK^\mu,$$

$$[M^{\mu\nu},K^{\alpha}]=i(\eta^{\mu\alpha}K^{\nu}-\eta^{\nu\alpha}K^{\mu}),\quad [p^{\mu},K^{\nu}]=-2i(\eta^{\mu\nu}D-M^{\mu\nu}).$$

To obtain the light-cone forms of the dilatation and the conformal translation generators, we first express the dilation and conformal generators in light-cone coordinates,

$$D=\tfrac{1}{2}(-\{x^{-},p^{+}\}-\{x^{+},p^{-}\}+\{x^{i},p^{i}\}),$$

$$K^{+}=-2x^{+}M^{+-}+x^{2}p^{+}+2x^{i}M^{+i},$$

$$K^{-}=2x^{-}M^{+-}+2x^{i}M^{-i}+x^{2}p^{-},$$

$$K^{i}=2x^{-}M^{+i}+2x^{+}M^{-i}+2x^{j}M^{ij}+x^{2}p^{i},$$

where $i,j=1,\ldots,(d-2)$. Using the light-cone forms of the Poincaré generators from Eqs. (1)–(4) and setting $x^{+}=0$, K^{-}, and K^{i} can be written as

$$K^{-}=2x^{-}(-x^{-}p^{+}+x^{i}p^{i})-x^{i}x^{i}p^{-}+\frac{2}{p^{+}}(x^{i}T^{i}-x^{i}p^{j}S^{ij}), \tag{11}$$

$$K^{i}=2x^{i}(-x^{-}p^{+}+x^{i}p^{i})-x^{j}x^{j}p^{i}+2x^{j}S^{ij}. \tag{12}$$

To check if these satisfy the algebra, we calculate the commutators $[P^{-},K^{i}]$ and $[p^{i},K^{-}]$. Substituting the light-cone forms, we find

$$[P^{-},K^{i}]=2i\left(x^{-}p^{i}-\frac{1}{2}\{x^{i},P^{-}\}-\frac{p^{j}}{p^{+}}S^{ij}\right), \tag{13}$$

$$-[p^{i},K^{-}]=2i\left(x^{-}p^{i}-\frac{1}{2}\{x^{i},P^{-}\}+\frac{1}{p^{+}}(T^{i}-p^{j}S^{ij})\right). \tag{14}$$

But to satisfy the conformal algebra, these two commutators must be equal, requiring $T^{i}=0$. Therefore, the front forms of the conformal generators are

$$K^{+}=-x^{i}x^{i}p^{+},\quad K^{i}=2x^{i}D-x^{j}x^{j}p^{i}+2x^{j}S^{ij}, \tag{15}$$

$$K^{-}=2x^{-}D-x^{i}x^{i}p^{-}-\frac{2}{p^{+}}x^{i}p^{j}S^{ij}, \tag{16}$$

$$D=\tfrac{1}{2}(-\{x^{-},p^{+}\}+\{x^{i},p^{i}\}). \tag{17}$$

This shows that $T^{i}=0$, which imply regular massless representations, not the CSR.

We conclude that in order to generate a CSR by embedding the Poincaré algebra into larger algebraic structures, we must consider singular limits. The CSRs require the transverse little group to be the Euclidean group $E(2)$, the semidirect product of translations and rotations. It is the very same group that Inönü and Wigner[6] obtained by contracting the homogeneous SO(3) group. As this group is the massless transverse little group in five dimensions, we are led to consider dimensional reduction as well as group contraction of the Poincaré group in higher dimensions.

III. KALUZA–KLEIN REDUCTION OF THE 5D POINCARÉ ALGEBRA

Kaluza and Klein[9] reduced one dimension by setting it on to a circle of finite radius. We apply it to the five-dimensional Poincaré algebra, by setting the third direction on to a circle of radius R,

$$x^3 = x^3 + 2\pi R.$$

The generators act on functions of the form

$$\Phi(x) = \sum_n \Phi_n(x^\mu) e^{inx^3/R}, \tag{18}$$

where $\mu = +, -, 1, 2$ and n is the mode number. The momentum along the third direction is quantized

$$p^3 = \frac{n}{R}, \tag{19}$$

and the light-cone Hamiltonian becomes

$$P^- = \frac{p^i p^i + (p^3)^2 + M^2}{2p^+} \equiv \frac{p^i p^i + M_n^2}{2p^+}, \tag{20}$$

where

$$M_n^2 = M^2 + \frac{n^2}{R^2}, \tag{21}$$

is the Kaluza–Klein (KK) mass. The single state of mass M in five dimensions generates an equally spaced tower of states of mass M_n. To find their spin, observe that the two transverse boost generators are

$$M^{-i} = x^- p^i - \frac{1}{2}\{x^i, P^-\} + \frac{1}{p^+}\left(T^i + \frac{n}{R} S^{3i} - p^j S^{ij}\right), \tag{22}$$

for $i = 1, 2$, leading us to define new light-cone translation vectors

$$\hat{T}^i = T^i + \frac{n}{R} S^{3i}, \tag{23}$$

which satisfy the algebra

$$[S^{ij}, \hat{T}^k] = i(\eta^{jk}\hat{T}^j - \eta^{jk}\hat{T}^i), \quad [\hat{T}^i, \hat{T}^j] = iM_n^2 S^{ij}. \tag{24}$$

The generators

$$S^{12}, \quad \frac{\hat{T}^i}{M_n},$$

form the SO(3) light-cone little group in four dimensions. Analyzing the mass term, the mass M_n increases with the mode number and gives the well-known infinite (KK) tower of masses starting at $M_0 = M$. The remaining Lorentz generators of the four-dimensional group, M^{+-}, M^{12}, and M^{+i} for $i = 1, 2$ are not changed. Note that when evaluated at $x^3 = 2\pi R$, the generators that rotate into the third direction become (for large R) like the momenta

$$\frac{M^{-3}}{R} = \frac{n}{R^2} x^- - 2\pi p^- + \frac{1}{Rp^+}(T^3 - p^i S^{3i}), \tag{25}$$

$$\frac{M^{3i}}{R} = 2\pi p^i - \frac{nx^i}{R^2} + \frac{1}{R} S^{3i}, \tag{26}$$

$$\frac{M^{+3}}{R} = -2\pi p^{+}. \tag{27}$$

When the starting representation is massive ($M \neq 0$), the KK procedure yields massive representations in lower dimensions, but even if $M=0$, the ground floor of a KK tower is the usual massless representation in four dimensions, not the CSR. In the simple limit $R \to \infty$, the KK mass tower collapses without any sign of a CSR.

IV. INÖNÜ–WIGNER CONTRACTION

This section presents the original Inönü–Wigner[6] contraction procedure. Starting from the homogeneous SO(3) group, they generated the Euclidean group $E(2)$, in a singular limit with an arbitrary contraction parameter that tends to zero. They considered the algebra's generators, identifying those which are well defined under contraction, as well as to the two-dimensional wave function on which the Euclidean translation vectors act, which they show to be Bessel's functions J_n.

They begin with the SO(3) generators L_i in the $(2l+1)$-dimensional representation, which satisfy

$$[L_i, L_j] = i\epsilon_{ijk}L_k, \quad L_iL_i = l(l+1), \quad L_3 = m.$$

They introduce a contraction parameter ϵ and the vectors

$$T_i \equiv \epsilon L_i. \tag{28}$$

They observe that in the limit $\epsilon \to 0$, these, together with L_3, satisfy the commutation relations of the Euclidean algebra

$$[L_3, T_i] = \epsilon_{ij}T_j, \quad [T_i, T_j] = 0. \tag{29}$$

Multiplying the Casimir operator with ϵ^2 yields

$$(\epsilon m)^2 + T_1^2 + T_2^2 = \epsilon^2 l(l+1). \tag{30}$$

The Inönü–Wigner contraction is the double limit

$$l \to \infty, \quad \epsilon \to 0, \quad \epsilon l \equiv \Xi \text{ fixed}, \tag{31}$$

in which the Euclidean translations have a finite length

$$T_1^2 + T_2^2 = \Xi^2. \tag{32}$$

In their original paper, Inönü and Wigner applied their method to the Poincaré group, using the inverse of the speed of light as a contraction parameter, and find it to contract to the nonrelativistic Galilei group (*but only if the starting point is the tachyonic representation*).

The representation function of $E(2)$ in a space labelled by the polar coordinates ρ and θ are of the form

$$\sum_n c_n J_n(\Xi\rho)e^{in\theta}. \tag{33}$$

In the Appendix we show how to obtain these results directly by imposing periodic boundary conditions à la Kaluza–Klein.

V. THE CSR À LA KALUZA–KLEIN–INÖNÜ–WIGNER

The results of the preceding two sections hints on how to proceed. The contraction parameter ϵ is simply the inverse of the Kaluza–Klein radius. We start from the usual massless Poincaré group in five dimensions, and apply the KK procedure to the third direction. The dynamical boosts are

$$M^{-i} = x^- p^i - \frac{1}{2}\{x^i, P^-\} + \frac{1}{p^+}\left(\frac{n}{R}S^{3i} - p^j S^{ij}\right). \tag{34}$$

Comparison with the results of the preceding section leads us to identify the IW contraction parameter as

$$\epsilon = \frac{n}{R}. \tag{35}$$

This yields the CSR boosts, where the translations are given by

$$\hat{T}^i = \frac{n}{R}S^{3i}. \tag{36}$$

We mimic the IW procedure and consider the Casimir operator of the SO(3) light-cone little group, where j is the spin of the massless particle in five dimensions,

$$(S^{12})^2 + (S^{23})^2 + (S^{31})^2 = j(j+1).$$

Dividing both sides by R^2, we obtain

$$(\hat{T}^1)^2 + (\hat{T}^2)^2 = \frac{n^2 j^2}{R^2} \equiv \Xi^2 \neq 0. \tag{37}$$

The length of the translation vector is nothing but the Pauli–Lubanski Casimir operator of the Poincaré group. This shows that it is possible to generate the CSR as long as one takes the double limit

$$R \to \infty, \quad j \to \infty, \quad \frac{j}{R} \text{ fixed}. \tag{38}$$

In the next section, we apply the same method to a more complicated theory.

VI. CSR FROM MAJORANA'S THEORY

In this section, we consider the contraction of the five-dimensional massive representations. A simple, yet nontrivial model for the massive relativistic particle is the infinite component Majorana theory, introduced by Majorana long ago.[10] Its spectrum can be inferred from Poincaré generators with a massive SO(4) little group. Amusingly the mathematics of this SO(4) are exactly the same as those of Bohr's nonrelativistic hydrogen atom. We want to apply contraction to this theory and investigate under what circumstances a CSR can be generated.

In the following, we construct the mass operator and other generators of the little group in terms of internal coordinates. This can be thought of as the nonlinear realization of the homogeneous SO(4) group. We start with applying the contraction to the SO(4) little group algebra and find the Casimirs in five and four dimensions which label the representations. We will then find the conditions necessary for the existence of the CSRs. We will also find the representation of the wave functions in four dimensions and compare with the IW paper.

A. Majorana's theory

We start with the five dimensional light-cone realization of the dynamical Poincaré boosts

$$M^{-i} = x^- p^i - \frac{1}{2}\{x^i, P^-\} + \frac{1}{p^+}(T^i - p^j S^{ij}),$$

with $i, j = 1,2,3$.

The little group generators are built in terms of three "internal variables" η^j and their conjugates π^j,

$$[\eta^j, \pi^j] = i\delta^{ij}, \quad i,j = 1,2,3, \tag{39}$$

in the form

$$S^{ij} = \epsilon^{ijk} L^k = \eta^i \pi^j - \eta^j \pi^i, \tag{40}$$

and with the nonlinear Laplace–Runge–Lenz (LRL) vectors

$$T^i = \epsilon^{ijk} \pi^j L^k - \mu \frac{\eta^j}{\eta} - i\pi^j, \tag{41}$$

where $\eta = \sqrt{\eta^j \eta^j}$ and μ is a mass parameter (we have set the "electron charge" to one). They obey the commutation relations

$$[T^i, T^j] = i(-2\mu H)\epsilon^{ijk} L^k, \tag{42}$$

where H is the same as Bohr's Hamiltonian

$$H = \frac{\pi^i \pi^i}{2\mu} - \frac{1}{\eta}. \tag{43}$$

[In Bohr's case, of course, the SO(4) generators are written in terms of coordinates and momenta in real three-dimensional space.]

Comparison between Eqs. (7) and (42) yields the mass squared operator

$$M^2 = -2\mu H, \tag{44}$$

which must then appear in the light-cone Hamiltonian,

$$P^- = \frac{p^i p^i + M^2}{2p^+} = \frac{p^i p^i - 2\mu H}{2p^+}.$$

Each mass level has the same degeneracy as that of the hydrogen atom. Two commuting SO(3)'s are generated by the combinations

$$\frac{1}{2}\left(L^k + \frac{T^k}{\sqrt{-2\mu H}}\right), \quad \frac{1}{2}\left(L^k - \frac{T^k}{\sqrt{-2\mu H}}\right),$$

corresponding to $\mathrm{SO}(4) \sim \mathrm{SO}(3) \times \mathrm{SO}(3)$. Since

$$L^k T^k = T^k L^k = 0, \tag{45}$$

they have the same Casimir operator

$$C_2 = \frac{1}{4}\left(L^k L^k - \frac{T^k T^k}{2\mu H}\right) = j(j+1), \tag{46}$$

where j is related to the mass operator by

$$M_j^2 = \frac{\mu^2}{4C_2 + 1} = \frac{\mu^2}{(2j+1)^2}, \tag{47}$$

so that $(2j+1)$ is Bohr's principal quantum number. At each mass level, these states assemble in a representation of SO(4) and generate the spectrum of the infinite component Majorana wave equation. Since $\mathrm{SO}(4) \supset \mathrm{SO}(3) \supset \mathrm{SO}(2)$, we need to contract at least twice to obtain a CSR in four dimensions. One contraction parameter is of course the inverse radius of the compactified direction and the other one is not yet defined. There are two ways to proceed with the contractions.

(1) We contract, staying in five dimensions first, and then use KK reduction and contract to four dimensions, i.e.,

$$\mathrm{SO}(4) \xrightarrow[\text{contraction}]{\text{1st}} E(3) \xrightarrow[\text{reduction}]{\text{KK}} \mathrm{SO}(3) \xrightarrow[\text{contraction}]{\text{2nd}} E(2).$$

(2) We apply the KK reduction first and then contract, i.e.,

$$\mathrm{SO}(4) \xrightarrow[\text{reduction}]{\text{KK}} \mathrm{SO}(3) \xrightarrow[\text{contraction}]{\text{Double}} E(2).$$

We consider both cases in the following and find the conditions for these procedures to lead to the CSR in four dimensions.

1. Case 1: Contraction to E(3)

In the Majorana theory, the degeneracy at each mass level is generated by the addition of two angular momenta j. The states are eigenstates of their SO(3) diagonal subgroup (the angular momentum in Bohr's model), so that

$$L^k L^k = l(l+1), \tag{48}$$

where $l = 0, 1, 2, \ldots, 2j$. This is the analog of the magnetic quantum number in the $\mathrm{SO}(3) \to E(2)$ contraction process, its range goes to infinity while its value remains finite. This leads us to consider the contraction where all three L^k that generate SO(3) remain finite as $j \to \infty$.

In that limit, the mass vanishes and the T^k become commuting translations

$$M_j = \frac{\mu}{2j+1} \to 0, \quad [T^i, T^k] \to 0, \tag{49}$$

producing $E(3)$, the Euclidean group in three dimensions. This contraction of the transverse little group yields a CSR in five dimensions. To see this explicitly, we multiply the SO(4) Casimir operator by the contraction parameter ϵ,

$$(\epsilon L^k)(\epsilon L^k) + \frac{\epsilon^2}{M_j^2} T^k T^k = 4\epsilon^2 j(j+1).$$

As $\epsilon \to 0$ and $j \to \infty$, for fixed ϵj we get

$$T^k T^k = \mu^2, \tag{50}$$

so that the length of the translation vector is fixed.

In five dimensions, the Poincaré group has three Casimir operators, the momentum squared (zero in this case),

$$W_{\mu\nu} W^{\mu\nu} \quad \text{and } W = \epsilon_{\rho\mu\nu\sigma\lambda} P^\rho M^{\mu\nu} M^{\sigma\lambda}, \tag{51}$$

where

$$W_{\mu\nu} = \epsilon_{\mu\nu\rho\sigma\lambda} P^{\rho} M^{\sigma\lambda}. \tag{52}$$

In this case,

$$W_{\mu\nu} W^{\mu\nu} = \mu^2 \quad \text{and } W = T_k L_k = 0. \tag{53}$$

These two Casimirs characterize a unique CSR in five dimensions. The dimensionality of space–time does not change, but the contraction parameter ϵ does not have an obvious physical meaning.

We can use this contracted theory as a starting point to obtain a four-dimensional theory. So we apply the KK reduction to the $E(3)$ algebra to get down to four dimensions. The mass operator and the light-cone vector now takes the following form:

$$M_n^2 = \frac{n^2}{R^2} \quad \text{and } \hat{T}^a = T^a + \frac{n}{R} S^{3a}, \quad a = 1,2, \tag{54}$$

which can be checked by analyzing the light-cone Hamiltonian and the dynamical boosts, respectively. The generators S^{12} and $\hat{T}^a$ now form SO(3), the massive little group in four dimensions. The contraction parameter is now $\epsilon' = 1/R$. Let $\tilde{j}(\tilde{j}+1)$ be the eigenvalue of this SO(3) angular momentum algebra. It is quite clear that to get a CSR, we take the limits,

$$R \to \infty, \quad \tilde{j} \to \infty \quad \text{with } \frac{\tilde{j}}{R} \text{ fixed}.$$

Therefore we obtain,

$$\hat{T}^a \hat{T}^a = \frac{n^2 \tilde{j}^2}{R^2} \equiv \tilde{\Xi}^2, \tag{55}$$

which is the Casimir of the $E(2)$ algebra. The other Casimir is of course the mass squared which is zero. These two uniquely determines the CSR in four dimensions.

Notice that the first contraction parameter could have been identified with $1/j$ or μ; both would have yielded a zero mass, but it is only the first case that leads to the CSR; the other $\mu \to 0$ generates a normal massless representation of definite helicity.

2. Case 2: KK reduction first

In this case, we apply the KK reduction first. The massive SO(4) little group in five dimensions now reduces to the massive little group in four dimensions. The light-cone Hamiltonian becomes

$$P^- = \frac{1}{2p^+}(p^a p^a + M_{jn}^2), \tag{56}$$

for $a = 1, 2$, with

$$M_{jn}^2 = \frac{\mu^2}{(2j+1)^2} + \frac{n^2}{R^2}, \tag{57}$$

using Eq. (19). The generators of the SO(3) little group are

$$L^3 \quad \text{and } \hat{T}^a = \left(T^a + \frac{n}{R} S^{3a} \right), \quad a = 1,2 \tag{58}$$

deduced by looking at M^{-a}.

The quadratic Casimir is

$$(L^3)^2 + \frac{1}{M_{jn}^2}\left(T^a + \frac{n}{R}S^{3a}\right)\left(T^a + \frac{n}{R}S^{3a}\right) = j'(j'+1). \tag{59}$$

The mass operator in Eq. (57) clearly shows that we need to take the double limit $j,R\to\infty$ to obtain the massless case. However this is not enough to get a CSR, because from Eq. (59), it is also clear that the ratio j'/R must also remain finite and nonzero. To see it explicitly, we divide Eq. (59) by R^2 and rearrange to get

$$\hat{T}^a\hat{T}^a = \left(\frac{\mu^2}{(2j+1)^2/R^2} + n^2\right)\left(\frac{j'}{R}\right)^2 - M_{jn}^2 m^2, \tag{60}$$

where we have used $L^3 = m$. The double limit certainly does not give any nonzero value, but the following triple limit,

$$j,j',R\to\infty, \quad \text{such that } \frac{j}{R},\frac{j'}{R} \text{ remain finite (nonzero)}, \tag{61}$$

does give a finite value. Therefore, in this triple limit, we find,

$$(\hat{T}^a)^2 = \left(\frac{\mu^2}{(2j/R)^2} + n^2\right)\left(\frac{j'}{R}\right)^2 \equiv \Xi'^2, \tag{62}$$

which is the Casimir in four dimensions. This and the mass squared (which is zero) uniquely labels the representation. The difference between Case 1 and Case 2 is the length of the light-cone vector. This feature is what we expected, because the generator S^{12} was not affected by any of the reduction and/or contraction processes. The contraction only affected the quadratic Casimir eigenvalues which sets the range of quadratic Casimir of its maximal subgroup. Therefore, the representations of the contracted algebra of these two cases should differ by the length of the light-cone vectors and that is what we have found. These representations are also consistent with Inönü and Wigner's result with different lengths of the Euclidean light-cone vectors.

B. Representation of the wave function

Since we have the form of the T^i's in terms of the internal variables, we can explicitly find the representation of the wave function for the light-cone vectors $\hat{T}^a$. First note that in $\hat{T}^a$ the contraction parameter j is not explicitly present. Therefore if we apply the contraction it will only include the $R\to\infty$ limit, not the $j\to\infty$. As a result we will not obtain a commuting vector which is required to obtain the CSR. Since the contraction parameter j appears through the Hamiltonian when it acts on the wave function, we rewrite T^i in terms of the Hamiltonian as in the following:

$$T^i = \epsilon_{ijk}\pi^j L^k - \frac{\mu\eta^i}{\eta} - i\pi^i = \eta^i\left(2\mu H + \frac{\mu}{\eta}\right) - (\eta\cdot\pi - i)\pi^i, \tag{63}$$

where we used H as given by Eq. (43). Therefore the light-cone vector, $\hat{T}^a$, can be expressed as

$$\hat{T}^a = \left(2\mu\eta^a H + \frac{\mu\eta^a}{\eta} - \frac{n}{R}\eta^a\pi^3 - \mu[\eta^a,H]\right) + (y + 2i - \eta\cdot\pi)\pi^a, \tag{64}$$

where

$$y = \frac{n\eta^3}{R}. \tag{65}$$

The first term is dependent on the contraction parameters whereas the second term is independent and also both terms are separately Hermitian. Since $H\sim\mathcal{O}(1/j^2)$ and $1/\eta\sim\mathcal{O}(1/R)$, the first term vanishes as $j,\ R\to\infty$.

It should be noted that if we evaluate the commutator in the first term in Eq. (64) and then consider the contraction, the resulting light-cone vector becomes non-Hermitian and the whole analysis becomes physically meaningless. It is not well understood why this happens, but to maintain the hermiticity, we must consider the contraction without computing the commutator. Using

$$\eta \cdot \pi = \eta^a \pi^a - iy\frac{\partial}{\partial y},$$

and dropping the first term, the light-cone vector becomes

$$\hat{T}^a = \left(y + 2i + iy\frac{\partial}{\partial y} - \eta^b \pi^b\right)\pi^a. \tag{66}$$

It can be easily checked that the above form satisfies the $E(2)$ algebra,

$$[\hat{T}^a, \hat{T}^b] = 0 \quad \text{and } [S^{ab}, \hat{T}^c] = i(\eta^{ac}\hat{T}^b - \eta^{bc}\hat{T}^a),$$

which is required to obtain any CSR in four dimensions. We now find the representation of the wave function for this $E(2)$ algebra.

The square of the light-cone vector is

$$(\hat{T}^a)^2 = \left[(\eta^b \pi^b)^2 - i\eta^b \pi^b\left(-2iy + 5 + 2y\frac{d}{dy}\right) - \left(y^2\frac{d^2}{dy^2} - (2iy^2 - 6y)\frac{d}{dy} - (y^2 + 6iy - 6)\right)\right](\pi^2).$$

On a wave function of the form,

$$\Phi(\eta^i) = e^{iy}\phi(\eta^a, y),$$

this gives the following form of the differential equation:

$$\left[(\eta^b \pi^b)^2 - i\eta^b \pi^b\left(5 + 2y\frac{d}{dy}\right) - \left(y^2\frac{d^2}{dy^2} + 6y\frac{d}{dy} + 6\right)\right](\pi^2) = \Xi^2, \tag{67}$$

where $\Xi = \tilde{\Xi}$ or Ξ' corresponding to Case 1 and Case 2, respectively. To solve the above equation, let

$$(\pi^a)^2 = \Pi^2(y) \tag{68}$$

when it acts on $\phi(\eta^a, y)$, that is the representation of the η^a dependent part of the wave function is the Bessel function, namely,

$$\phi(\eta^a, y) = J_m(\Pi(y)\rho)e^{im\theta}F(y),$$

where $F(y)$ is a real function and we used the polar coordinates, $\eta^1 = \rho\cos\theta$ and $\eta^2 = \rho\sin\theta$. In polar coordinates, we use,

$$-i\eta^a \pi^a = -\rho\frac{d}{d\rho},$$

$$(\eta^a \pi^a)^2 = -\left(\rho^2\frac{d^2}{d\rho^2} + \rho\frac{d}{d\rho}\right),$$

and we rewrite Eq. (67) as

$$\left[\rho^2\frac{d^2}{d\rho^2}+\left(6+2y\frac{d}{dy}\right)\rho\frac{d}{d\rho}+\left(y^2\frac{d^2}{dy^2}+6y\frac{d}{dy}+6\right)\right](\Pi^2 J_m F)=-\Xi^2 J_m F. \tag{69}$$

Making use of the following identities:

$$\frac{d}{d\rho}J_m(\Pi(y)\rho)=\frac{\Pi}{2}(J_{m-1}-J_{m+1}), \tag{70}$$

$$\frac{d}{dy}J_m(\Pi(y)\rho)=\frac{\rho}{2}\frac{d\Pi}{dy}(J_{m-1}-J_{m+1}), \tag{71}$$

and after straightforward algebra, the left-hand side of Eq. (69) can be expressed as a linear combination of Bessel function of different orders,

$$\begin{aligned}
&\left(\frac{\rho^2\Pi^4 F}{4}+\frac{\rho^2 y\Pi^3\Pi' F}{2}+\frac{\rho^2 y^2\Pi^2\Pi'^2 F}{4}\right)(J_{m-2}+J_{m+2})\\
&+\left(3\rho\Pi^3 F+6\rho y\Pi^2\Pi' F+\rho y\Pi^3 F'+2\rho y^2\Pi\Pi'^2 F+\rho y^2\Pi^2\Pi' F'+\frac{\rho y^2\Pi^2\Pi'' F}{2}\right)(J_{m-1}-J_{m+1})\\
&+\left(-\frac{\rho^2\Pi^4 F}{2}-\rho^2 y\Pi^3\Pi' F+2y^2\Pi'^2 F+2y^2\Pi\Pi\Pi'' F+4y^2\Pi\Pi' F'+y^2\Pi^2 F''\right.\\
&\left.-\frac{\rho^2 y^2\Pi^2\Pi'^2 F}{2}+12y\Pi\Pi' F+6y\Pi^2 F'+6\Pi^2 F\right)J_m,
\end{aligned}$$

where the prime denotes derivative with respect to the argument. By matching the coefficients of Bessel functions of different order with the right-hand side of Eq. (69), we get three constraints. Equating the coefficient of $J_{m\pm2}$ to zero gives the first constraint,

$$\frac{\rho^2\Pi^2}{4}\left(\Pi^2+2y\Pi\frac{d\Pi}{dy}+y^2\left(\frac{d\Pi}{dy}\right)^2\right)F(y)=0,$$

which is satisfied if

$$\Pi^2+2y\Pi\frac{d\Pi}{dy}+y^2\left(\frac{d\Pi}{dy}\right)^2=0. \tag{72}$$

The solution to this equation is given by

$$\Pi(y)=\frac{\Pi_0}{y}, \tag{73}$$

where Π_0 is a constant. The constraint obtained by equating the coefficients of $J_{m\pm1}$ provides no new result. Finally the remaining constraint is from the coefficients of J_m which gives a differential equation for $F(y)$,

$$\frac{d^2F}{dy^2}+\frac{2}{y}\frac{dF}{dy}+\frac{\Xi^2}{\Pi_0^2}F=0, \tag{74}$$

where we used $\Pi(y)=\Pi_0/y$ and its derivatives. The solution is given by

$$F(y)=\frac{1}{y}\left(A\sin\left(\frac{\Xi y}{\Pi_0}\right)+B\cos\left(\frac{\Xi y}{\Pi_0}\right)\right), \tag{75}$$

where A and B are constants, and the regularity condition at $y=0$ implies $B=0$. Therefore the complete wave function can be written as

$$\Phi(\rho,\theta,y)=\sum_m N_m\left(\frac{e^{iy}}{y}\sin\left(\frac{\Xi y}{\Pi_0}\right)\right)e^{im\theta}J_m\left(\frac{\Pi_0\rho}{y}\right), \tag{76}$$

where N_m is the overall normalization constant.

In their paper,[6] IW found the following wave function for the $E(2)$ algebra,

$$\Phi_{\mathrm{IW}}(\rho,\theta)=\sum_m c_m e^{im\theta}J_m(\Xi\rho), \tag{77}$$

where Ξ^2, the square of the Pauli–Lubanski vector, is the second Casimir of the Poincaré group, and labels the CSR in four dimensions. The Euclidean vector is linear in π^a and as a result its length appeared as a scale factor in the Bessel function. In four dimensions there are only two types of CSRs, fermionic and bosonic types corresponding to half-odd and integer values of m. The amplitude is also constant.

Although similar in form, there are differences between Eq. (76) and the IW form in Eq. (77). In our case, the internal momentum [Eq. (73)] and amplitude are not constant, but functions of y which is the ratio of the internal and external coordinates. It is due to the fact that the Euclidean light-cone vector $\hat{T}^a$ is not linear in π^a (in addition to the y dependence). Moreover, unlike the IW case, the length of the light-cone vector does not appear as a scale factor in the Bessel function, even though it is the CSR. To find how our CSR is related to IW's CSR, we must find a relation between Π and Ξ. Let us assume $\Pi=\Xi=\Pi_0/y$. The only solution we get, following Eq. (72), is $\Xi=0$ which corresponds to the regular massless representation, not the CSR. Therefore $\Pi\neq\Xi$ is the only possibility and these are quite new. On the other hand, we may assume that, instead of Π, $\Pi_0=\Xi$. Substituting this into Eq. (76) and setting $y=1$, the solution becomes exactly the same as that of Wigner's CSR apart from the overall phase factor which has no physical effect (the overall constant factor can be absorbed into the normalization factor). For any other values of y, we have a different kind of CSR because of the nonequality between the scale factor and length of the Euclidean vector. There is no physical reason for Π_0 and Ξ to be equal and $y=1$, but this is the only condition to obtain IW's result.

Finally, the raising and lowering operators are defined as

$$\hat{T}^{\pm}=\hat{T}^1\pm i\hat{T}^2.$$

In polar coordinates, these become

$$\hat{T}^{+}=e^{i\theta}\left(2+y\frac{d}{dy}+\rho\frac{d}{d\rho}\right)\left(\frac{d}{d\rho}+\frac{i}{\rho}\frac{d}{d\theta}\right), \tag{78}$$

$$\hat{T}^{-}=e^{-i\theta}\left(2+y\frac{d}{dy}+\rho\frac{d}{d\rho}\right)\left(\frac{d}{d\rho}-\frac{i}{\rho}\frac{d}{d\theta}\right), \tag{79}$$

which acts on $\phi(\rho,\theta,y)$. It is quite obvious that the states $\hat{T}^{+}|>$ and $\hat{T}^{-}|>$ have helicities $(m+1)$ and $(m-1)$, respectively. The remaining generator T^3/R becomes

$$\frac{T^3}{R}=(\pi^a)^2,$$

under contraction. The complete Poincaré wave function is

$$\Phi(x^{+},x^{a};\rho,\theta,y)=\sum_m N_m\frac{e^{iy}}{y}\sin\left(\frac{\Xi y}{\Pi_0}\right)e^{-i(x^{-}p^{+}-x^{a}p^{a})}e^{im\theta}J_m\left(\frac{\Pi_0\rho}{y}\right).$$

The physical meaning of the new parameter y is not clear to us, but it links the external to the internal coordinates of the Majorana theory. This type of limit links the internal structure to that of

space–time. If we view, as we have, the Majorana theory as a warm-up for string theory, it may correspond to compactifying a string with its vibrational modes stuck along an extra dimension. This may help define the infinite slope limit of string theory.

VII. CONCLUSION

In this paper, we showed that if we dimensionally reduce from five to four dimensions, the compactified algebra is the regular representation of the Poincaré group in four dimensions with mass M_n for all modes. For the infinite radius limit, we find that the KK mass spectra collapses to the lowest mass state and gives the regular representation of the Poincaré group in four dimensions. Only for nonzero modes and infinite radius limit, we obtain CSR if the j/R remains constant as $R\to\infty$, otherwise we will get the regular representation.

We constructed explicitly the representation of the Euclidean group in a system with periodic boundary condition for internal coordinates and found the condition to obtain nonzero Euclidean vectors using IW contraction method. We found that for nonzero and finite Euclidean vector, the eigenvalue of the uncontracted group must be proportional to the radius of the compactified direction. This condition is similar to that of the CSR where the spin is proportional to the radius, apart from the mode number. Therefore finding the representations of any Euclidean group provides the representations of the inhomogeneous light-cone little group which is the CSR.

We have applied the contraction technique to both regular massless and massive representations in five dimensions. In the regular massless case, the contraction yields the $E(2)$ little group under the double limits j, $R\to\infty$, keeping j/R finite and nonzero.

The massive case is not as straightforward as the regular massless case. We have considered Majorana theory as a model in the five-dimensional massive case. We have found that the double limits are not enough to get a CSR, even though the mass operator vanishes. We must consider triple singular limits j, j', $R\to\infty$ such that both j/R and j'/R remain fixed and nonzero. There are two ways to consider the contraction limits, in the sequence of contraction, KK reduction and contraction, or KK reduction and double contraction. Both of these yield the CSR in four dimensions. The difference is in the length of the light-cone vector. The representation wave function of the contracted algebra is the Bessel function, however as in Wigner's solution, the length of the light cone vector does not appear as a scale factor in the Bessel factor. In our case both the amplitude and the scale factor are a function of the parameter y which is a ratio of the internal and external coordinates. We have found that the contracted algebra is identical to that of Wigner's CSR only if Π_0 which is the magnitude of the internal momenta at $y=1$, equals the length of the light-cone vector (apart from an overall phase factor).

Thus, the CSR can arise in the Majorana theory, but with an extra variable. Its physical interpretation may provide clues when we apply our techniques to string theory in the hope of identifying the CSR with its infinite slope limit.

Our technique may also prove useful when the starting point is curved space in higher dimensions, particularly anti-de-Sitter. There the starting group is the conformal, not the Poincaré group. This possibility, though interesting in its own right, will not be discussed here.

APPENDIX: INÖNÜ–WIGNER À LA KALUZA–KLEIN

In this Appendix we reproduce their results by a different method. We consider the full SO(3) algebra which acts on three-dimensional vector space with periodic boundary condition along one direction The contraction parameter is in the inverse radius of that direction. After the contraction, the three-dimensional wave function reduces to Bessel functions in the radial coordinate. In the following we retrace IW's steps, stressing the geometrical picture of the contraction procedure.

The IW contraction of SO(3) to $E(2)$ amounts to the study of a dynamical system with SO(3) symmetry restrained to a space whose boundary condition breaks that symmetry. We switch to cylindrical coordinates, and seek solutions which are periodic in z,

$$z \to z + 2\pi R, \tag{A1}$$

$$\Phi(\rho, \theta, z) = \sum_n \Phi_n(\rho, \theta) e^{inz/R}, \tag{A2}$$

where n is the mode number. In the following we will use $1/R$ as the contraction parameter. The angular momentum operators are given by

$$S^{12} = -i\frac{\partial}{\partial \theta}, \tag{A3}$$

$$S^{23} = -i\left(-z\sin\theta\frac{\partial}{\partial \rho} + \rho\sin\theta\frac{\partial}{\partial z} - \frac{z\cos\theta}{\rho}\frac{\partial}{\partial \theta}\right), \tag{A4}$$

$$S^{31} = -i\left(z\cos\theta\frac{\partial}{\partial \rho} - \rho\cos\theta\frac{\partial}{\partial z} - \frac{z\sin\theta}{\rho}\frac{\partial}{\partial \theta}\right). \tag{A5}$$

Acting on the wave function, the factor $\partial/\partial z$ can be replaced by in/R. When R is very large (ultimately we will take it to ∞), we drop all terms proportional to $\partial/\partial z$, yielding

$$S^{31} \to -iz\left(\cos\theta\frac{\partial}{\partial \rho} - \frac{\sin\theta}{\rho}\frac{\partial}{\partial \theta}\right), \tag{A6}$$

$$S^{32} \to iz\left(-\sin\theta\frac{\partial}{\partial \rho} - \frac{\cos\theta}{\rho}\frac{\partial}{\partial \theta}\right). \tag{A7}$$

However z is no longer well defined on the wave function. The Casimir operator now becomes

$$(S^{12})^2 + (S^{31})^2 + (S^{32})^2 = j(j+1), \tag{A8}$$

$$\to -z^2\left(\frac{\partial^2}{\partial \rho^2} + \frac{1}{\rho}\frac{\partial}{\partial \rho} + \left(\frac{1}{\rho^2} + \frac{1}{z^2}\right)\frac{\partial^2}{\partial \theta^2}\right). \tag{A9}$$

The wave function on which this differential operator acts is of the form

$$\Phi(\rho, \theta) = \mathcal{R}(\rho)\Theta(\theta),$$

with eigenvalue s^2. Since there is no mode dependence, we have dropped the subscript n from the wave function. For the above form of the wave function, the angular part decouples from the radial part and can be written as

$$\frac{1}{\Theta}\frac{\mathrm{d}^2\Theta}{\mathrm{d}\theta^2} \equiv -m^2, \tag{A10}$$

where m, the azimuthal quantum number, is an integer or half-odd integer depending on whether the wave function is single or double valued. Let us also define the dimensionless variable

$$\tilde{\rho} = \frac{\sqrt{s^2 - m^2}}{z}\rho \equiv q(s,m)\rho.$$

Substituting the angular part, the eigenvalue equation for the differential operator in Eq. (A9) becomes Bessel's differential equation

$$\tilde{\rho}^2 \frac{\mathrm{d}^2\mathcal{R}}{\mathrm{d}\tilde{\rho}^2} + \tilde{\rho}\frac{\mathrm{d}\mathcal{R}}{\mathrm{d}\tilde{\rho}} + (\tilde{\rho}^2 - m^2)\mathcal{R} = 0, \tag{A11}$$

whose solutions are well known. The regularity condition at the origin implies that the physically relevant solution is the Bessel function $J_m(\tilde{\rho})$. Therefore the wave functions for the $E(2)$ group are linear combinations of the form

$$\Phi(\rho,\theta) = J_m(q\rho)e^{im\theta}. \tag{A12}$$

We let

$$T^a \equiv \lim_{R\to\infty} \frac{S^{3a}}{R}, \tag{A13}$$

that is

$$T^1 = \left(\cos\theta\frac{\partial}{\partial\rho} - \frac{\sin\theta}{\rho}\frac{\partial}{\partial\theta}\right), \quad T^2 = \left(-\sin\theta\frac{\partial}{\partial\rho} - \frac{\cos\theta}{\rho}\frac{\partial}{\partial\theta}\right).$$

It can easily be checked that the T^a, $a=1, 2$, commute and that they transform as a 2-vector under S[12], forming a representation of the $E(2)$ algebra. The length of the Euclidean vector is now

$$\xi^2 \equiv T^a T^a = -\left(\frac{\partial^2}{\partial\rho^2} + \frac{1}{\rho}\frac{\partial}{\partial\rho} + \frac{1}{\rho^2}\frac{\partial^2}{\partial\theta^2}\right). \tag{A14}$$

The wave function for the above differential equation is the same as in Eq. (A12) with scale factor q defined as

$$q(\xi) = \frac{\xi}{z/R}. \tag{A15}$$

Since in the infinite radius limit these two scale factors are the same, the eigenvalues, ξ and s, must be related by

$$\xi = 2\pi q = \frac{s}{R}. \tag{A16}$$

This solution is of course the same as that of Inönü and Wigner, because s and j are the same when both are large. The generalization of the above construction to any dimensions is also quite straightforward.

Quantum integrability of classical integrable systems given by quadratic Killing tensors on curved configuration spaces is investigated. It is proven that, using a "minimal" quantization scheme, quantum integrability is ensured for a large class of classic examples. © *2005 American Institute of Physics.*

I. INTRODUCTION

One of the main goals of this paper is to present a somewhat general framework for the quantization of classical observables on a cotangent bundle which are polynomials at most cubic in momenta. This approach enables us to investigate the quantization of classically Poisson-commuting observables, and hence to tackle the problem of quantum integrability for a reasonably large class of dynamical systems.

What should actually be the definition of quantum integrability is a long standing issue, see, e.g., Ref. 37. The point of view espoused in this paper is the following. Start with a complete set of independent Poisson-commuting classical observables, and use some quantization rule to get a corresponding set of quantum observables; if these operators appear to be still in involution with respect to the commutator, the system will be called integrable at the quantum level.

Our work can be considered as a sequel to earlier and pioneering contributions[11,4,5,22,34] that provide worked examples of persistence of integrability from the classical to the quantum regime. The general approach we deal with in this paper helps us to highlight the general structure of quantum corrections and to show that the latter actually vanish in most, yet not all, interesting examples.

Returning to the general issue of quantization, let us mention that our choice of quantization procedure, which we might call "minimal," does not stem from first principles, e.g., from invariance or equivariance requirements involving some specific symmetry. Although this "minimal" quantization only applies to low degree polynomials on cotangent bundles, it has the virtue of leading automatically to the simplest symmetric operators that guarantee quantum integrability in many cases. In order to provide the explicit form of the quantization scheme, hence of the quantum corrections, we need a symmetric linear connection to be given on the base of our cotangent bundle. In most examples where a (pseudo-)Riemannian metric is considered from the outset, this connection will be chosen as the Levi-Civita connection.

To exemplify our construction, we consider a number of examples of classical integrable systems together with their quantization. For instance, our approach for dealing with quantum

integrability in somewhat general terms allowed us to deduce the quantum integrability of the Hamiltonian flow for the generalized Kerr–Newman solution of the Einstein–Maxwell equations with a cosmological constant first discovered by Carter.[9–11] Also our quantization scheme leads us to an independent proof of the quantum integrability for Stäckel systems originally due to Benenti, Chanu, and Rastelli.[4,5]

The paper is organized as follows. In Sec. II we gather the definitions of the Schouten bracket of symmetric contravariant tensor fields on configuration space, M. We make use of Souriau's procedure to present, in a manifestly gauge invariant fashion, the minimal coupling to an external electromagnetic field; this enables us to provide a geometric definition of the so-called Schouten–Maxwell bracket. The related definitions of Killing and Killing–Maxwell tensors follow naturally and will be used throughout the rest of the article. We recall the basics of classical integrable systems, with emphasis on the Stäckel class. The main objective of the present section is then to revisit some classic examples of integrable systems involving Killing tensors. Naturally starting with the Jacobi system on the ellipsoid, we prove, *en passant*, that it is locally of the Stäckel type, even allowing for an extra harmonic potential. This extends previous work of Benenti[3] related to the geodesic flow of the ellipsoid. Similarly, we show that the Neumann system is also locally Stäckel. A number of additional examples, not of Stäckel type, e.g., the Di Pirro system, and the geodesic flow on various (pseudo-)Riemannian manifolds such as the Kerr–Newman–de Sitter solution and the multi-center solution are also considered.

We introduce, in Sec. III, a specific "minimal" quantization scheme for observables at most cubic in momenta on the cotangent bundle T^*M of a smooth manifold M endowed with a symmetric connection ∇, extending a previous proposal.[11] This quantization mapping is shown to be equivariant with respect to the affine group of (M,∇). The computation of the commutators of quantum observables is then carried out and yields explicit expressions for quantum corrections. We also provide the detailed analysis of quantum integrability for a wide class of examples within the above-mentioned list.

The concluding section includes a discussion and brings together several remarks about the status of the "minimal" quantization that has been abstracted from the various examples dealt with in this paper. It also opens some prospects for future investigations related to quantum integrability in the spirit of this work.

II. CLASSICAL INTEGRABLE SYSTEMS

A. Killing tensors

Let us start with the definition of the Schouten bracket of two polynomial functions on the cotangent bundle $(T^*M,\omega=\mathrm{d}\xi_i\wedge\mathrm{d}x^i)$ of a smooth manifold M. Consider two such homogeneous polynomials $P=P^{i_1\ldots i_k}(x)\xi_{i_1}\ldots\xi_{i_k}$ and $Q=Q^{i_1\ldots i_\ell}(x)\xi_{i_1}\ldots\xi_{i_\ell}$ of degree k and ℓ, respectively; we will identify these polynomials with the corresponding smooth symmetric contravariant tensor fields $P^\sharp=P^{i_1\ldots i_k}(x)\partial_{i_1}\otimes\cdots\otimes\partial_{i_k}$ and $Q^\sharp=Q^{i_1\ldots i_\ell}(x)\partial_{i_1}\otimes\cdots\otimes\partial_{i_\ell}$.

The Schouten bracket $[P^\sharp,Q^\sharp]_S$ of the two contravariant symmetric tensors $P^\sharp$ and $Q^\sharp$ (of degree k and ℓ, respectively) is the symmetric contravariant $(k+\ell-1)$-tensor corresponding to the Poisson bracket of P and Q, namely

$$[P^\sharp,Q^\sharp]_S=\{P,Q\}^\sharp. \tag{2.1}$$

Using the Poisson bracket $\{P,Q\}=\partial_{\xi_i}P\partial_iQ-\partial_{\xi_i}Q\partial_iP$, and (2.1), we readily get the local expression of the Schouten bracket of $P^\sharp$ and $Q^\sharp$. If the manifold M is endowed with a symmetric connection ∇, the latter can be written as

$$[P^\sharp,Q^\sharp]_S^{i_1\ldots i_{k+\ell-1}}=kP^{i(i_1\ldots i_{k-1}}\nabla_iQ^{\,i_k\ldots i_{k+\ell-1})}-\ell Q^{i(i_1\ldots i_{\ell-1}}\nabla_iP^{\,i_\ell\ldots i_{k+\ell-1})}. \tag{2.2}$$

[In this paper the round (respectively, square) brackets will denote symmetrization (respectively, skew-symmetrization) with the appropriate combinatorial factor.] If M is, in addition, equipped with a (pseudo-)Riemannian metric, g, we denote by

$$H = \tfrac{1}{2} g^{ij} \xi_i \xi_j \tag{2.3}$$

the Hamiltonian function associated with this structure. The Hamiltonian flow associated with H is nothing but the geodesic flow on T^*M.

A symmetric contravariant tensor field $P^\sharp$ of degree k satisfying $\{H,P\}=0$ is called a Killing (or Killing–Stäckel) tensor; now using the Levi-Civita connection ∇ in (2.2), this condition reads

$$\nabla^{(i} P^{i_1 \dots i_k)} = 0. \tag{2.4}$$

B. Killing–Maxwell tensors

1. Souriau's coupling

In the presence of an electromagnetic field, F, Souriau[33] has proposed to replace the canonical symplectic structure, ω, of T^*M by the twisted symplectic structure $\omega_F = \mathrm{d}\xi_i \wedge \mathrm{d}x^i + \frac{1}{2} F_{ij} \mathrm{d}x^i \wedge \mathrm{d}x^j$. The (gauge-invariant) Poisson bivector now reads

$$\pi_F = \partial_{\xi_i} \wedge \partial_i - \tfrac{1}{2} F_{ij} \partial_{\xi_i} \wedge \partial_{\xi_j}.$$

The Poisson bracket of two observables P, Q of T^*M is now

$$\{P,Q\}_F = \pi_F(dP, dQ) = \partial_{\xi_i} P \partial_i Q - \partial_{\xi_i} Q \partial_i P - F_{ij} \partial_{\xi_i} P \wedge \partial_{\xi_j} Q, \tag{2.5}$$

and the Schouten–Maxwell bracket of two polynomials P and Q is then defined by

$$[P^\sharp, Q^\sharp]_{S,F} = \{P,Q\}_F^\sharp.$$

If the manifold M is endowed with a symmetric connection ∇, the Schouten–Maxwell bracket takes on the following form:

$$[P^\sharp, Q^\sharp]_{S,F} = [P^\sharp, Q^\sharp]_S^{i_1 \dots i_{k+\ell-1}} \partial_{i_1} \otimes \cdots \otimes \partial_{i_{k+\ell-1}} - k\ell F_{ij} P^{i(i_1 \dots i_{k-1}} Q^{i_k \dots i_{k+\ell-2})j} \partial_{i_1} \otimes \cdots \otimes \partial_{i_{k+\ell-2}} \tag{2.6}$$

with the expression (2.2) of the Schouten bracket $[\cdot,\cdot]_S$.

Suppose now that the manifold M is endowed with a metric g; the Hamiltonian vector field on (T^*M, ω_F) for the Hamiltonian H given by (2.3) yields the Lorentz equations of motions for a charged test particle moving on (M,g) under the influence of an external electromagnetic field F.

A symmetric contravariant tensor field $P^\sharp$ of degree k on (M,g) is now called a Killing–Maxwell tensor if $\{H,P\}_F=0$. The Killing–Maxwell equations then read, using (2.6),

$$\nabla^{(i} P^{i_1 \dots i_k)} = 0, \quad P^{i(i_1 \dots i_{k-1}} F_i^{\ i_k)} = 0, \tag{2.7}$$

where $F_i^j = g^{jm} F_{mi}$, in accordance with previous results[11] obtained with a slightly different standpoint.

The conditions (2.7) are of special importance for proving the classical and quantum integrability of the equations of motion of a charged test particle in the generalized Kerr–Newman background.

2. Standard electromagnetic coupling

A more traditional, though equivalent, means to deal with the coupling to an electromagnetic field, $F=\mathrm{d}A$ (locally), is to keep the canonical one-form, $\alpha = \xi_i \mathrm{d}x^i$, on T^*M unchanged, and hence to work with the original Poisson bracket $\{\cdot,\cdot\}$, but to replace the Hamiltonian (2.3) by

$$\tilde{H} = \tfrac{1}{2} \mathrm{g}^{ij} (\xi_i - A_i)(\xi_j - A_j), \tag{2.8}$$

where the tilde makes it clear that the expressions to consider are actually polynomials in the variables $\xi_i - A_i$, for $i=1,\dots,n$; for example, if $P = P^{i_1 \cdots i_k} \xi_{i_1} \dots \xi_{i_k}$, then

$$\widetilde{P} = P^{i_1\cdots i_k}(\xi_{i_1} - A_{i_1}) \ldots (\xi_{i_k} - A_{i_k}). \tag{2.9}$$

The equations of motion given by the Hamiltonian vector field for the Hamiltonian (2.8) on $(T^*M, \mathrm{d}\alpha)$ are, again, the Lorentz equations of motion.

The Schouten–Maxwell brackets and Schouten brackets for the electromagnetic coupling are related as follows via the corresponding Poisson brackets, viz.

$$\{P,Q\}_F = \{\widetilde{P},\widetilde{Q}\}.$$

In this framework, a Killing–Maxwell tensor, $P^\sharp$, of degree k on (M,g) is defined by the equation $\{\widetilde{H},\widetilde{P}\}=0$. The resulting constraints are, again, given by (2.7).

From now on, and in order to simplify the notation, we will omit the $\sharp$-superscript and use the same symbol for symmetric contravariant tensors and the corresponding polynomial functions on T^*M.

C. General definition of classical integrability

Let us recall that a dynamical system $(\mathcal{M},\omega,H)$ is (Liouville) integrable if there exist $n = \frac{1}{2}\dim\mathcal{M}$ independent Poisson-commuting functions $P_1,\ldots,P_n \in C^\infty(\mathcal{M})$—that is $\mathrm{d}P_1\wedge\cdots\wedge\mathrm{d}P_n \neq 0$ and $\{P_k,P_\ell\}=0$ for all $k,\ell=1,\ldots,n$—such that $P_1=H$.

We will, in the sequel, confine considerations to the case of cotangent bundles, $(\mathcal{M}=T^*M,\omega=\mathrm{d}\theta)$ where θ is the canonical one-form, and of polynomial functions, $P_1,\ldots,P_n$, on T^*M, that is to the case of n Schouten-commuting Killing tensors. Moreover, all examples that we will consider will be given by polynomials of degree two or three.

D. The Stäckel systems

These systems on $(T^*M,\omega=\mathrm{d}\xi_i\wedge\mathrm{d}x^i)$ are governed by the Hamiltonians

$$H = \sum_{i=1}^{n} a^i(x)\left(\tfrac{1}{2}\xi_i^2 + f_i(x^i)\right) \tag{2.10}$$

where the ith function f_i depends on the coordinate x^i only, and the functions a^i are defined as follows. Let B denote a $\mathrm{GL}(n,\mathbf{R})$-valued function defined on M and such that

$$B(x) = (B_1(x^1)B_2(x^2)\ldots B_n(x^n)),$$

where the ith column $B_i(x^i)$ depends on x^i only $(i=1,\ldots,n)$; such a matrix will be called a Stäckel matrix. Then take

$$a(x) = \begin{pmatrix} a^1(x) \\ \vdots \\ a^n(x) \end{pmatrix}$$

to be the first column $A_1(x)$ of the matrix $A(x)=B(x)^{-1}$.

The integrability of such a system follows from the existence of n quadratic polynomials

$$I_\ell = \sum_{i=1}^{n} A^i_\ell(x)\left(\tfrac{1}{2}\xi_i^2 + f_i(x^i)\right), \quad \ell = 1,\ldots,n, \quad H = I_1. \tag{2.11}$$

We call Stäckel potential every function of the form

$$U_\ell(x) = \sum_{i=1}^{n} A_\ell^i(x) f_i(x^i), \quad \ell = 1, \ldots, n; \tag{2.12}$$

the potential appearing in the Hamiltonian is just U_1.

One can check (see, e.g., Ref. 28, p. 101) that the n independent quantities I_ℓ are such that

$$\{I_\ell, I_m\} = \sum_{s,t=1}^{n} (A_\ell^s \partial_s A_m^t - A_m^s \partial_s A_\ell^t) \xi_s \left(\frac{1}{2} \xi_t^2 + f_t \right), \quad \ell \neq m.$$

The relation $A = B^{-1}$, gives the useful identity (the Einstein summation convention is not used)

$$\partial_k A_j^i = - C_k^i A_j^k, \quad C_k^i = \sum_{s=1}^{n} A_s^i \frac{dB_k^s}{dx^k}, \tag{2.13}$$

which implies

$$A_\ell^s \partial_s A_m^t - A_m^s \partial_s A_\ell^t = 0, \quad \ell \neq m, \quad s,t = 1, \ldots, n \tag{2.14}$$

and therefore the so-defined Stäckel systems are classically integrable.

Remark 2.1: Let us mention an interesting result due to Pars (see Ref. 28, p. 102): for a system whose Hamiltonian is of the form (2.10), the Hamilton–Jacobi equation is separable if and only if this system is Stäckel.

Although these systems constitute quite a large class of integrable systems, they do not exhaust the full class. A simple example of a non-Stäckel integrable system was produced by Di Pirro (see Sec. II I).

E. The Jacobi integrable system on the ellipsoid

Let $\mathcal{E} \subset \mathbf{R}^{n+1}$ be the n-dimensional ellipsoid defined by the equation $Q_0(y,y) = 1$ where we define, for $y, z \in \mathbf{R}^{n+1}$,

$$Q_\lambda(y,z) = \sum_{\alpha=0}^{n} \frac{y_\alpha z_\alpha}{a_\alpha - \lambda}, \tag{2.15}$$

with $0 < a_0 < a_1 < \ldots < a_n$; the equations $Q_\lambda(y,y) = 1$ define a family of confocal quadrics.

It has been proved by Jacobi (in the case $n=2$) that the differential equations governing the geodetic motions on the ellipsoid, $\mathcal{E}$, form an integrable system. The same remains true if a quadratic potential is admitted (see Ref. 27). The Hamiltonian of the system, prior to reduction, reads

$$H(p,y) = \frac{1}{2} \sum_{\alpha=0}^{n} p_\alpha^2 + \frac{a}{2} \sum_{\alpha=0}^{n} y_\alpha^2 \tag{2.16}$$

where $p, y \in \mathbf{R}^{n+1}$ and a is some real parameter.

Moser has shown[26] that the following polynomial functions

$$F_\alpha(p,y) = p_\alpha^2 + a y_\alpha^2 + \sum_{\beta \neq \alpha} \frac{(p_\alpha y_\beta - p_\beta y_\alpha)^2}{a_\alpha - a_\beta} \quad \text{with} \quad \alpha = 0,1, \ldots, n, \tag{2.17}$$

are in involution on $(T^*\mathbf{R}^{n+1}, \Sigma_{\alpha=0}^n \mathrm{d}p_\alpha \wedge \mathrm{d}y_\alpha)$. Those will generate the commuting first integrals of the Jacobi dynamical system on the cotangent bundle $T^*\mathcal{E}$ of the ellipsoid.

Our goal is to deduce from the knowledge of (2.17) the independent quantities in involution $I_1, \ldots, I_n$ on $(T^*\mathcal{E}, \mathrm{d}\xi_i \wedge \mathrm{d}x^i)$ from the symplectic embedding

$$\iota: T^*\mathcal{E} \hookrightarrow T^*\mathbf{R}^{n+1}$$

given by $Z_1(p,y)=Q_0(y,y)-1=0$ and $Z_2(p,y)=Q_0(p,y)=0$.

Proposition 2.2: The restrictions $F_\alpha|_{T^*\mathcal{E}}=F_\alpha\circ\iota$ *of the functions (2.17) Poisson-commute on* $T^*\mathcal{E}$.

Proof: We get, using Dirac brackets,

$$\{F_\alpha|_{T^*\mathcal{E}}, F_\beta|_{T^*\mathcal{E}}\} = \{F_\alpha,F_\beta\}|_{T^*\mathcal{E}} - \frac{1}{\{Z_1,Z_2\}}[\{Z_1,F_\alpha\}\{Z_2,F_\beta\} - \{Z_1,F_\beta\}\{Z_2,F_\alpha\}]|_{T^*\mathcal{E}} \tag{2.18}$$

for second-class constraints. Now, the denominator $\{Z_1,Z_2\}=-2\Sigma_{\alpha=0}^n(y_\alpha/a_\alpha)^2$ does not vanish while $\{Z_1,F_\alpha\}=4(p_\alpha y_\alpha/a_\alpha)Z_1-4(y_\alpha^2/a_\alpha)Z_2$ is zero on $T^*\mathcal{E}$, for all $\alpha=0,\ldots,n$. The fact that $\{F_\alpha,F_\beta\}=0$ completes the proof. □

The reduced Hamiltonian for the Jacobi system on the ellipsoid $\mathcal{E}$ is plainly

$$H=\frac{1}{2}\sum_{\alpha=0}^n (p_\alpha^2+ay_\alpha^2)|_{T^*\mathcal{E}} = \frac{1}{2}\sum_{\alpha=0}^n F_\alpha|_{T^*\mathcal{E}}. \tag{2.19}$$

In order to provide explicit expressions for the function in involution $I_1,\ldots,I_n$, we resort to Jacobi ellipsoidal coordinates $x^1,\ldots,x^n$ on $\mathcal{E}$. Those are defined by

$$Q_\lambda(y,y) = 1 - \frac{\lambda U_x(\lambda)}{V(\lambda)}, \tag{2.20}$$

where

$$U_x(\lambda)=\prod_{i=1}^n(\lambda-x^i), \quad V(\lambda)=\prod_{\alpha=0}^n(\lambda-a_\alpha) \tag{2.21}$$

and are such that $a_0<x^1<a_1<x^2<\ldots<x^n<a_n$. The induced metric, $g=\Sigma_{i,j=1}^n g_{ij}(x)\mathrm{d}x^i\mathrm{d}x^j$, of the ellipsoid $\mathcal{E}$ is given by

$$g_{ij}(x)=\frac{1}{4}\sum_{\alpha=0}^n\frac{y_\alpha^2}{(a_\alpha-x^i)(a_\alpha-x^j)}$$

and retains the form[26]

$$g=\sum_{i=1}^n g_i(x)(\mathrm{d}x^i)^2 \quad \text{where} \quad g_i(x)=-\frac{x^i}{4}\frac{U_x'(x^i)}{V(x^i)}, \tag{2.22}$$

which is actually Riemannian because of the previous inequalities. We put for convenience $g^i(x)=1/g_i(x)$.

Using (2.20) and (2.21), we find the local expressions $y_\alpha(x)$ via the formula

$$y_\alpha^2 = a_\alpha\frac{\prod_{i=1}^n(a_\alpha-x^i)}{\prod_{\beta\neq\alpha}(a_\alpha-a_\beta)} \tag{2.23}$$

and then obtain the constrained coordinate functions

$$p_\alpha(\xi,x) = -\frac{1}{2}y_\alpha\sum_{i=1}^n\frac{g^i(x)\xi_i}{(a_\alpha-x^i)} \tag{2.24}$$

given by the induced canonical one-form $\Sigma_{i=1}^n\xi_i\mathrm{d}x^i=\iota^*(\Sigma_{\alpha=0}^n p_\alpha\mathrm{d}y_\alpha)$.

The Hamiltonian (2.19) on $(T^*\mathcal{E}, \mathrm{d}\xi_i \wedge \mathrm{d}x^i)$ is then found to be

$$H = \frac{1}{2}\sum_{i=1}^{n} g^i(x)\xi_i^2 + \frac{a}{2}\left[\sum_{\alpha=0}^{n} a_\alpha - \sum_{i=1}^{n} x^i\right]. \tag{2.25}$$

Note that the potential term is obtained from the large λ behavior

$$Q_\lambda(y,y) \sim \frac{1}{\lambda}\sum_{\alpha=0}^{n} y_\alpha^2 + \frac{1}{\lambda^2}\sum_{\alpha=0}^{n} a_\alpha y_\alpha^2 + \cdots,$$

which can be computed using relation (2.20). One gets

$$Q_\lambda(y,y) \sim \frac{1}{\lambda}\left[\sum_{\alpha=0}^{n} a_\alpha - \sum_{i=1}^{n} x^i\right] + \cdots .$$

One relates the conserved quantities (2.17) to their reduced expressions on $T^*\mathcal{E}$ by computing, using (2.24) and (2.23), the expression of $F_\alpha|_{T^*\mathcal{E}}$. One gets

Proposition 2.3: The Moser conserved quantities $(F_\alpha|_{T^*\mathcal{E}})_{\alpha=0,\ldots,n}$ *retain the form*

$$F_\alpha|_{T^*\mathcal{E}} = \frac{a_\alpha G_{a_\alpha}(\xi,x)}{\prod_{\beta\neq\alpha}(a_\alpha - a_\beta)}$$

where

$$G_\lambda(\xi,x) = \sum_{i=1}^{n} g^i(x)\prod_{j\neq i}(\lambda - x^j)\xi_i^2 + a\prod_{i=1}^{n}(\lambda - x^i). \tag{2.26}$$

It is useful to introduce the notation $\sigma_k^i(x)$ for the symmetric functions of order $k = 0,1,\ldots,n-1$ of the variables $(x^1,\ldots,x^n)$, with the exclusion of index i, namely

$$\prod_{j\neq i}(\lambda - x^j) = \sum_{k=1}^{n}(-1)^{k-1}\lambda^{n-k}\sigma_{k-1}^i(x). \tag{2.27}$$

We note that, from the above definition, $\sigma_0^i(x) = 1$.

It is also worthwhile to introduce other symmetric functions, $\sigma_k(x)$, via

$$\prod_{j=1}^{n}(\lambda - x^j) = \sum_{k=0}^{n}(-1)^k\lambda^{n-k}\sigma_k(x). \tag{2.28}$$

We thus have

$$G_\lambda(\xi,x) = \sum_{i=1}^{n}(-1)^{i-1}\lambda^{n-i}I_i(\xi,x) + a(-\lambda)^n, \tag{2.29}$$

where the independent functions I_i $(i = 1,\ldots,n)$ are in involution and can be written as

$$I_i(\xi,x) = \sum_{j=1}^{n} A_i^j(x)\xi_j^2 - a\sigma_i(x) \quad \text{with} \quad A_i^j(x) = g^j(x)\sigma_{i-1}^j(x). \tag{2.30}$$

In the case $i = 1$, we recover the Hamiltonian (2.25), i.e.,

$$H = \frac{1}{2}I_1 + \frac{a}{2}\sum_{\alpha=0}^{n} a_\alpha.$$

Proposition 2.4: The Jacobi system on $T^\star\mathcal{E}$ defines a Stäckel system, with Stäckel matrix

$$B_k^i(x^k) = (-1)^i \frac{(x^k)^{n+1-i}}{4V(x^k)} \tag{2.31}$$

and potential functions

$$f_k(x^k) = a\frac{(x^k)^{n+1}}{4V(x^k)} \tag{2.32}$$

for $i,k=1,\ldots,n$.

Proof: It is obvious from its definition that B is a Stäckel matrix. We just need to prove that $A=B^{-1}$. To this aim we first prove a useful identity. Let us consider the integral in the complex plane

$$\frac{1}{2i\pi}\int_{|z|=R} \frac{z^{n-i}}{(z-\lambda)}\frac{U_x(\lambda)}{U_x(z)}\mathrm{d}z.$$

When $R\to\infty$ the previous integral vanishes because the integrand vanishes as $1/R^2$ for large R. We then compute this integral using the theorem of residues and we get the identity

$$\sum_{k=1}^{n} \frac{(x^k)^{n-i}}{U_x'(x^k)}\prod_{j\neq k}(\lambda - x^j) = \lambda^{n-i}. \tag{2.33}$$

Equipped with this identity let us now prove that

$$\sum_{k=1}^{n} B_k^i A_j^k = \delta_j^i.$$

Multiplying this relation by $(-1)^{j-1}\lambda^{n-j}$ and summing over j from 1 to n, we get the equivalent relation

$$\sum_{k=1}^{n} B_k^i \sum_{j=1}^{n} (-1)^{j-1}\lambda^{n-j}A_j^k = (-1)^{i-1}\lambda^{n-i},$$

which becomes, using (2.30) and (2.27):

$$\sum_{k=1}^{n} B_k^i g^k(x)\prod_{j\neq k}(\lambda - x^j) = (-1)^{i-1}\lambda^{n-i}.$$

Using the explicit form of $g^k(x)$ given in (2.22) and of the matrix B, this relation reduces to the identity (2.33) and this completes the derivation of (2.31).

In order to get the functions $f_i(x^i)$ as in (2.10), let us resort to (2.30) and solve, for the unknown f_i, the following

$$-a\sigma_i(x) = \sum_{j=1}^{n} A_i^j(x) f_j.$$

Multiplying both sides by B_k^i, summing over i from 1 to n, and using (2.31) we get

$$f_k = -a\sum_{i=1}^{n} B_k^i\sigma_i(x) = -\frac{a}{4V(x^k)}\sum_{i=1}^{n}(-1)^i(x^k)^{n+1-i}\sigma_i(x) = -\frac{a}{4V(x^k)}\left[\sum_{i=0}^{n}(-1)^i(x^k)^{n+1-i}\sigma_i(x) - (x^k)^{n+1}\right].$$

In view of (2.28), we have $\Sigma_{i=0}^{n}(-1)^i(x^k)^{n-i}\sigma_i(x) = \Pi_{j=1}^{n}(x^k - x^j) = 0$, which completes the proof. □

Remark 2.5: 1. The fact that the geodesic flow on $T^\star\mathcal{E}$ is a Stäckel system was first proved by

Benenti in Ref. 3. We have given here a new derivation, which makes the link between Moser's conserved quantities on $T^*\mathbf{R}^{n+1}$ and the Stäckel conserved quantities on $T^*\mathcal{E}$. We have extended this link to the case where Jacobi's potential is admitted.

2. Checking that the unconstrained observables I_i are in involution is most conveniently done using their generating function (2.26). Indeed it is easy to verify the relation

$$\{G_\lambda(\xi,x),G_\mu(\xi,x)\}=0, \quad \lambda,\mu\in\mathbf{R},$$

which implies, via (2.29), and upon expansion in powers of λ and μ, the relations $\{I_i,I_j\}=0$ for any $i,j=1,\ldots,n$.

3. Some authors[2,22] have quantized the full set of commuting observables for the geodesic flow of the ellipsoid $\mathcal{E}\subset\mathbf{R}^{n+1}$ in its unconstrained form, namely on $T^*\mathbf{R}^{n+1}$. Notice though that in the reduction process from $T^*\mathbf{R}^{n+1}$ to $T^*\mathcal{E}$ quantum corrections may prove necessary in order to ensure self-adjointness of the quantized observables. Our point of view will be to perform the classical reduction in the first place and then to quantize the observables directly on $T^*\mathcal{E}$ via a specific procedure that will be described in Sec. III.

F. The Neumann system

The Neumann Hamiltonian on $(T^*\mathbf{R}^{n+1},\Sigma_{\alpha=0}^n \mathrm{d}p_\alpha\wedge\mathrm{d}y_\alpha)$ is[1]

$$H=\frac{1}{2}\sum_{\alpha=0}^{n}(p_\alpha^2+a_\alpha y_\alpha^2) \tag{2.34}$$

with the real parameters $0<a_0<a_1<\ldots<a_n$. Under the symplectic reduction, with the second class constraints

$$Z_1(p,y)=\sum_{\alpha=0}^{n}y_\alpha^2-1=0, \quad Z_2(p,y)=\sum_{\alpha=0}^{n}p_\alpha y^\alpha=0, \tag{2.35}$$

it becomes a dynamical system on $(T^*S^n,\mathrm{d}\xi_i\wedge\mathrm{d}x^i)$.

This system is classically integrable, with the following commuting first integrals of the Hamiltonian flow in $T^*\mathbf{R}^{n+1}$:

$$F_\alpha(p,y)=y_\alpha^2+\sum_{\beta\neq\alpha}\frac{(p_\alpha y_\beta-p_\beta y_\alpha)^2}{a_\alpha-a_\beta} \quad \text{with} \quad \alpha=0,1,\ldots,n. \tag{2.36}$$

The symplectic embedding

$$\iota:T^*S^n\hookrightarrow T^*\mathbf{R}^{n+1}$$

given by $Z_1(p,y)=0$ and $Z_2(p,y)=0$ preserves the previous conservation laws. Indeed the Poisson brackets of the restrictions $F_\alpha|_{T^*\mathcal{E}}=F_\alpha\circ\iota$ of the functions F_α are still given by the Dirac brackets (2.18) of the second class constraints (2.35). This time we have

$$\{Z_1,Z_2\}=-2\sum_{\alpha=0}^{n}y_\alpha^2\neq 0, \quad \{Z_1,F_\alpha\}=0,$$

which gives again

$$\{F_\alpha|_{T^*\mathcal{E}},F_\beta|_{T^*\mathcal{E}}\}=0.$$

Let us introduce an adapted coordinate system on $(T^*S^n,\mathrm{d}\xi_i\wedge\mathrm{d}x^i)$ much in the same manner as for the ellipsoid.

We start with the following definition[26] of a coordinate system $(x^1,\ldots,x^n)$ on S^n:

$$Q_\lambda(y,y) = \sum_{\alpha=0}^{n} \frac{y_\alpha^2}{a_\alpha - \lambda} = -\frac{\prod_{i=1}^{n}(\lambda - x^i)}{\prod_{\alpha=0}^{n}(\lambda - a_\alpha)}.$$

The following inequalities hold: $0 < a_0 < x^1 < a_1 < \ldots < x^n < a_n$. We get, in the same way as before,

$$y_\alpha^2 = \frac{\prod_{i=1}^{n}(a_\alpha - x^i)}{\prod_{\beta\neq\alpha}(a_\alpha - a_\beta)} \tag{2.37}$$

together with the following expression of the round metric $g = \Sigma_{\alpha=0}^{n} \mathrm{d}y_\alpha^2|_{S^n}$ in terms of the newly introduced coordinates, namely

$$g = \sum_{i=1}^{n} g_i(x)(\mathrm{d}x^i)^2 \quad \text{with } \mathrm{g}_i(x) = -\frac{U_x'(x^i)}{4V(x^i)} \tag{2.38}$$

with the notation (2.21). Again, we put for convenience $g^i(x) = 1/g_i(x)$.

Our goal is to deduce from the knowledge of (2.36) the independent quantities in involution $I_1, \ldots, I_n$ on $(T^*S^n, \mathrm{d}\xi_i \wedge \mathrm{d}x^i)$. The formula (2.24) relating unconstrained and constrained momenta still holds and yields

Proposition 2.6: The Neumann system $(F_\alpha|_{T^*S^n})_{\alpha=0,\ldots,n}$ *retains the following form:*

$$F_\alpha|_{T^*S^n} = -\frac{G_{a_\alpha}(\xi,x)}{\prod_{\beta\neq\alpha}(a_\alpha - a_\beta)},$$

where

$$G_\lambda(\xi,x) = \sum_{i=1}^{n} g^i(x) \prod_{j\neq i} (\lambda - x^j)\xi_i^2 + \prod_{j=1}^{n} (\lambda - x^j).$$

Let us, again, posit

$$G_\lambda(\xi,x) = \sum_{i=1}^{n} (-1)^{i-1} \lambda^{n-i} I_i(\xi,x) + \lambda^n$$

where the independent functions I_i $(i = 1, \ldots, n)$ are in involution and can be written as

$$I_i(\xi,x) = \sum_{j=1}^{n} A_i^j(x)\xi_j^2 - \sigma_i(x) \quad \text{with } A_i^j(x) = g^j(x)\sigma_{i-1}^j(x), \tag{2.39}$$

where the symmetric functions $\sigma_i(x)$ are as in (2.28).

Using the relations

$$\sigma_1(x) = \sum_{i=1}^{n} x^i, \quad \sum_{\alpha=0}^{n} a_\alpha y_\alpha^2 = \sum_{\alpha=0}^{n} a_\alpha - \sum_{i=1}^{n} x^i,$$

one can check that the Hamiltonian (2.34) is $H = \frac{1}{2} I_1$.

Proposition 2.7: The Neumann flow on (T^*S^n, H) *defines a Stäckel system, with Stäckel matrix*

$$B_k^i(x^k) = (-1)^i \frac{(x^k)^{n-i}}{4V(x^k)}$$

and potential functions

$$f_k(x^k) = \frac{(x^k)^n}{4V(x^k)} \tag{2.40}$$

for $i,k=1,\ldots,n$.

Proof: To check that $A=B^{-1}$, it is enough to use the identity (2.33). The computation of the potential functions f_k proceeds along the same lines as in the proof of Proposition 2.4. □

Remark 2.8: The involution property $\{I_i,I_j\}=0$ for $i,j=1,\ldots,n$, similar to the case of the ellipsoid, is seen to follow from the relation $\{G_\lambda(\xi,x),G_\mu(\xi,x)\}=0$.

G. Test particles in generalized Kerr–Newman background

Plebanski and Demianski have constructed in Refs. 29 and 30 a class of metrics generalizing the Kerr–Newman solution in four-dimensional space-time. The former are also known as the Kerr–Newman–Taub–NUT–de Sitter solutions of the Einstein–Maxwell equations. The metric, in the coordinate system $(x^1,x^2,x^3,x^4)=(p,q,\sigma,\tau)$, retains the form

$$g = \frac{X}{p^2+q^2}(\mathrm{d}\tau + q^2\mathrm{d}\sigma)^2 - \frac{Y}{p^2+q^2}(\mathrm{d}\tau - p^2\mathrm{d}\sigma)^2 + \frac{p^2+q^2}{X}\mathrm{d}p^2 + \frac{p^2+q^2}{Y}\mathrm{d}q^2 \tag{2.41}$$

with

$$X = \gamma - g^2 + 2np - \epsilon p^2 - \frac{\Lambda}{3}p^4, \quad Y = \gamma + e^2 - 2mq + \epsilon q^2 - \frac{\Lambda}{3}q^4, \tag{2.42}$$

where (m,γ) are related to the mass and angular momentum of the Kerr black hole, (e,g) to the electric and magnetic charge; n is the NUT charge, and Λ the cosmological constant. The remaining parameter ϵ can be scaled out to ± 1 or 0.

This metric, g, together with the electromagnetic field, locally given by $F=dA$ where

$$A = \frac{1}{p^2+q^2}[(eq+gp)\mathrm{d}\tau + pq(gq-ep)\mathrm{d}\sigma], \tag{2.43}$$

provide an exact solution of the Einstein–Maxwell equations with cosmological constant Λ. Let us notice for further use that

$$\nabla_i A^i = 0. \tag{2.44}$$

Upon defining the one-forms

$$K = \sqrt{\frac{Y}{2(p^2+q^2)}}(\mathrm{d}\tau - p^2\mathrm{d}\sigma) + \sqrt{\frac{p^2+q^2}{2Y}}\mathrm{d}q,$$

$$L = \sqrt{\frac{Y}{2(p^2+q^2)}}(\mathrm{d}\tau - p^2\mathrm{d}\sigma) - \sqrt{\frac{p^2+q^2}{2Y}}\mathrm{d}q,$$

$$M_1 = \sqrt{\frac{p^2+q^2}{X}}\mathrm{d}p,$$

$$M_2 = \sqrt{\frac{X}{p^2+q^2}}(\mathrm{d}\tau + q^2\mathrm{d}\sigma),$$

one constructs the two-form

$$\mathcal{Y} = pK \wedge L - qM_1 \wedge M_2. \tag{2.45}$$

One can check that the twice-symmetric tensor $P=-\mathcal{Y}^2$, namely $P_{ij}=-\mathcal{Y}_{ik}\mathcal{Y}_{\ell j}\mathrm{g}^{k\ell}$, is a Killing–Maxwell tensor [see (2.7)], given by

$$P = p^2(K\otimes L + L\otimes K) + q^2(M_1\otimes M_1 + M_2\otimes M_2). \tag{2.46}$$

We thus recover Carter's result[11] about the integrability of the Hamiltonian flow for a charged test particle in the generalized Kerr–Newman background in a different manner.

Remark 2.9: The two-form $\mathcal{Y}$ in (2.45) defines what is usually called a Killing–Yano tensor.[20,8]

The four conserved quantities in involution for the generalized Kerr–Newman system are, respectively,

$$\widetilde{H} = \tfrac{1}{2}g^{ij}(\xi_i - A_i)(\xi_j - A_j), \quad \widetilde{P} = P^{ij}(\xi_i - A_i)(\xi_j - A_j) \tag{2.47}$$

where P is as in (2.46), and

$$\widetilde{S} = \xi_3 - A_3, \quad \widetilde{T} = \xi_4 - A_4. \tag{2.48}$$

H. The multi-center geodesic flow

The class of multi-center Euclidean metrics in four dimensions retain, in a local coordinate system $(x^i)=(t,(y^a)) \in \mathbf{R}\times\mathbf{R}^3$, the form

$$\mathrm{g} = \frac{1}{V(y)}(\mathrm{d}t + A_a(y)\mathrm{d}y^a)^2 + V(y)\gamma \tag{2.49}$$

with $\gamma=\delta_{ab}\mathrm{d}y^a\mathrm{d}y^b$ the flat Euclidean metric in three-space, and $\mathrm{d}V=\pm\star(\mathrm{d}A)$ where $\star$ is the Hodge star for γ. These conditions ensure that the metric (2.49) is Ricci-flat.

For some special potentials $V(y)$, the geodesic flow is integrable as shown in Refs. 21, 13, and 35. The four conserved quantities in involution are given by

$$H = \tfrac{1}{2}\mathrm{g}^{ij}\xi_i\xi_j, \quad K = K^i\xi_i, \quad L = L^i\xi_i, \quad P = P^{ij}\xi_i\xi_j, \tag{2.50}$$

where K and L are two commuting Killing vectors and P a Killing two-tensor whose expressions can be found in the previous references.

I. The Di Pirro system

Di Pirro has proved (see, e.g., Ref. 28, p. 113) that the Hamiltonian on $T^*\mathbf{R}^3$,

$$H = \frac{1}{2(\gamma(x^1,x^2)+c(x^3))}[a(x^1,x^2)\xi_1^2 + b(x^1,x^2)\xi_2^2 + \xi_3^2] \tag{2.51}$$

admits one and only one additional first integral given by

$$P = \frac{1}{(\gamma(x^1,x^2)+c(x^3))}[c(x^3)(a(x^1,x^2)\xi_1^2 + b(x^1,x^2)\xi_2^2) - \gamma(x^1,x^2)\xi_3^2]. \tag{2.52}$$

In the case where the metric defined by H in (2.51) possesses a Killing vector, the system becomes integrable though not of Stäckel type. This happens, e.g., if (i) $c(x^3)=$const., or (ii) $a=b$ and γ depend on $r=\sqrt{(x^1)^2+(x^2)^2}$ only.

III. A QUANTIZATION SCHEME FOR INTEGRABLE SYSTEMS

We wish to deal now with the quantum version of the preceding examples. Let us start with some preliminary considerations:

1. There is no universally accepted procedure of quantization, i.e., of a linear identification, $\mathcal{Q}$, of a space of classical observables with some space of linear symmetric operators on a Hilbert space. One—among many—of the pathways to construct such a quantization mapping has been to demand that the mapping $\mathcal{Q}$ be equivariant with respect to some Lie group of symplectomorphisms of classical phase space.
2. Similarly, there is no universally accepted notion of quantum integrability. However, given a classical integrable system $P_1,\ldots,P_n$ on a symplectic manifold $(\mathcal{M},\omega)$, and a quantization mapping $\mathcal{Q}:P_i\mapsto\hat{P}_i$, we will say that such a system is integrable in the quantum sense if $[\hat{P}_i,\hat{P}_j]=0$ for all $i,j=1,\ldots,n$.
3. A large number of integrable systems involve *quadratic* observables. We will thus choose to concentrate on this important—yet very special—case, both from the classical and quantum viewpoint.
4. Among all possible quantization procedures, the search for integrability-preserving ones (if any) should be of fundamental importance. The quantization of quadratic observables we will present in the following might serve as a starting point for such a program.

A. Quantizing quadratic and cubic observables

Let us recall that the space $\mathcal{F}_\lambda(M)$ of λ-densities on M is defined as the space of sections of the complex line bundle $|\Lambda^n T^*M|^\lambda\otimes\mathbf{C}$. In the case where the configuration manifold is orientable, (M,vol), such a λ-density can be, locally, cast into the form $\phi=f|\mathrm{vol}|^\lambda$ with $f\in C^\infty(M)$ which means that ϕ transforms under the action of $a\in\mathrm{Diff}(M)$ according to $f\mapsto a_*f|(a_*\mathrm{vol})/\mathrm{vol}|^\lambda$.

The completion $\mathcal{H}(M)$ of the space of compactly supported half-densities, $\lambda=\frac{1}{2}$, is a Hilbert space canonically attached to M that will be used throughout this paper. The scalar product of two half-densities reads

$$\langle\phi,\psi\rangle=\int_M\overline{\phi}\psi,$$

where the bar stands for complex conjugation.

We will assume that configuration space is endowed with a (pseudo-)Riemannian structure, (M,g); and denote by $|\mathrm{vol}_g|$ the corresponding density and by Γ^k_{ij} the associated Christoffel symbols.

The quantization now introduced is a linear invertible mapping from the space of quadratic observables $P=P_2^{jk}(x)\xi_j\xi_k+P_1^j(x)\xi_j+P_0(x)$ to the space of second-order differential operators on $\mathcal{H}(M)$, viz. $A=\hat{P}=A_2^{jk}(x)\nabla_j\nabla_k+A_1^j(x)\nabla_j+A_0(x)\mathbf{1}$ where the covariant derivative of half-densities $\nabla_j\phi=\partial_j\phi-\frac{1}{2}\Gamma^k_{jk}\phi$ (or, locally, $\nabla_j\phi=(\partial_j f)|\mathrm{vol}_g|^{1/2}$) has been used. We furthermore require that the principal symbol be preserved [see in the following (3.1)–(3.3)], and that $\hat{P}$ be formally self-adjoint, i.e., $\langle\phi,\hat{P}\psi\rangle=\langle P\phi,\psi\rangle$ for all compactly supported $\phi,\psi\in\mathcal{F}_{1/2}(M)$.

The quantization reads

$$A_2^{jk}=-P_2^{jk}, \tag{3.1}$$

$$A_1^j=iP_1^j-\nabla_kP_2^{jk}, \tag{3.2}$$

$$A_0 = P_0 + \frac{i}{2}\nabla_j P_1^j \tag{3.3}$$

and admits the alternative form

$$P = -\nabla_j \circ P_2^{\mathrm{jk}} \circ \nabla_k + \frac{i}{2}(P_1^j \circ \nabla_j + \nabla_j \circ P_1^j) + P_0\mathbf{1}, \tag{3.4}$$

which makes clear the symmetry of the quantum operators.

Remark 3.1: The formula (3.4) was originally used by Carter[11] for proving the quantum integrability of the equations of motion of charged test particles in the Kerr–Newman solution.

Remark 3.2: It is worth mentioning that formula (3.4) actually corresponds at the same time to the projectively equivariant quantization[24,17] and to the conformally equivariant quantization[15,16] $\mathcal{Q}_{0,1}(P):\mathcal{F}_0(M)\to\mathcal{F}_1(M)$ restricted to quadratic polynomials.

One can check the relations:

$$[\hat{P}_0,\hat{Q}_1] = i[P_0,Q_1]_S = i\widehat{\{P_0,Q_1\}}, \tag{3.5}$$

$$[\hat{P}_0,\hat{Q}_2] = -\tfrac{1}{2}(\nabla_j \circ [P_0,Q_2]_S^j + [P_0,Q_2]_S^j \circ \nabla_j) = i\widehat{\{P_0,Q_2\}}, \tag{3.6}$$

$$[\hat{P}_1,\hat{Q}_1] = -\tfrac{1}{2}(\nabla_j \circ [P_1,Q_1]_S^j + [P_1,Q_1]_S^j \circ \nabla_j) = i\widehat{\{P_1,Q_1\}}. \tag{3.7}$$

Quantum corrections appear explicitly whenever $k+\ell>2$, as can be seen from the next commutators:

$$[\hat{P}_1,\hat{Q}_2] = i\widehat{\{P_1,Q_2\}} + i\hat{A}_{P_1,Q_2} \tag{3.8}$$

where

$$A_{P_1,Q_2} = \tfrac{1}{2}\nabla_j \circ Q_2^{jk} \circ \nabla_k(\nabla_\ell P_1^\ell) \tag{3.9}$$

is a scalar quantum correction that may vanish in some special instances, e.g., if the vector-field P_1 is divergence-free (in particular if it is a Killing vector-field).

The previous formulas can be found, in a different guise, in Ref. 11. Here, we will go one step further and compute the commutators $[\hat{P}_2,\hat{Q}_2]$ which involve third-order differential operators. To that end, we propose to quantize homogeneous cubic polynomials according to

$$\hat{P}_3 = -\frac{i}{2}(\nabla_j \circ P_3^{jk\ell} \circ \nabla_k \circ \nabla_l + \nabla_j \circ \nabla_k \circ P_3^{jk\ell} \circ \nabla_\ell) \tag{3.10}$$

as a "minimal" choice to ensure the symmetry of the resulting operator.

Remark 3.3: The formula (3.10) precisely coincides with the projectively equivariant quantization[7] $\mathcal{Q}_{0,1}(P):\mathcal{F}_0(M)\to\mathcal{F}_1(M)$ restricted to cubic polynomials.

The previously mentioned commutator is actually given by

$$[\hat{P}_2,\hat{Q}_2] = [P_2,Q_2]_S^{jk\ell}\nabla_j \circ \nabla_k \circ \nabla_\ell + \tfrac{3}{2}(\nabla_j[P_2,Q_2]_S^{jk\ell})\nabla_k \circ \nabla_\ell + \left[\tfrac{1}{2}(\nabla_j\nabla_k[P_2,Q_2]_S^{jk\ell}) + \tfrac{2}{3}(\nabla_k B_{P_2,Q_2}^{k\ell})\right]\nabla_\ell, \tag{3.11}$$

where the skew-symmetric tensor

$$B^{jk}_{P,Q} = P^{\ell[j}\,\nabla_\ell\nabla_m Q^{\,k]m} + P^{\ell[j}\,R^{\,k]}_{m,n\ell}Q^{mn} - (P \leftrightarrow Q) - \nabla_\ell P^{m[j}\,\nabla_m Q^{\,k]\ell} - P^{\ell[j}\,R_{\ell m}Q^{\,k]m} \tag{3.12}$$

satisfies, in addition, $B_{P,Q}=-B_{Q,P}$. We have used the following convention for the Riemann and Ricci tensors, viz. $R^{\ell}_{\ i,jk}=\partial_j\Gamma^{\ell}_{ik}-(j\leftrightarrow k)+\ldots$, and $R_{ij}=R^{k}_{\ i,kj}$.

We can rewrite the commutator (3.11) with the help of the quantization prescription (3.4) and (3.10) as

$$[\hat{P}_2,\hat{Q}_2] = i\widehat{\{P_2,Q_2\}} + i\hat{A}_{P_2,Q_2} \tag{3.13}$$

where

$$A_{P_2,Q_2} = -\tfrac{2}{3}(\nabla_k B^{k\ell}_{P_2,Q_2})\xi_\ell \tag{3.14}$$

is a divergence-free vector-field associated with the tensor (3.12) and providing the potential quantum correction for quadratic polynomials; recall that, according to (3.4), one has $\hat{A}_{P_2,Q_2}=(i/2)(A^{\ell}_{P2,Q2}\circ\nabla_\ell+\nabla_{\ell}\circ A^{\ell}_{P_2,Q_2})$.

We thus have

Proposition 3.4: The commutator of the quantum operators $\hat{P}$ and $\hat{Q}$ associated with two general quadratic polynomials $P=P_2+P_1+P_0$ and $Q=Q_2+Q_1+Q_0$ reads

$$\frac{1}{i}[\hat{P},\hat{Q}] = \widehat{\{P,Q\}} + \hat{A}_{P_2,Q_2} + \hat{A}_{P_1,Q_2} - \hat{A}_{Q_1,P_2} \tag{3.15}$$

where the third-order differential operator $\widehat{\{P,Q\}}$ is given by (3.10).

Proof: The formula (3.15) results trivially from the previously computed commutators and from collecting the anomalous terms appearing in (3.8) and (3.13) only. □

Remark 3.5: In the special case where $Q_2=H$ as given by (2.3), the anomalous tensor (3.12) takes the form

$$B^{jk}_{P,H} = -\tfrac{1}{2}\nabla^{[j}\,\nabla_\ell P^{\,k]\ell} - P^{\ell[j}\,R^{\,k]}_{\ell}$$

and reduces to

$$B^{jk}_{P,H} = -\,P^{\ell[j}\,R^{\,k]}_{\ell} \tag{3.16}$$

if P is a Killing tensor.[11]

Remark 3.6. In the particular case where $H=\frac{1}{2}g^{jk}(\xi_j-eA_j)(\xi_k-eA_k)$ is the Hamiltonian of the electromagnetic coupling, our quantum commutator (3.15) reduces to Carter's formula (6.16) in Ref. 11.

The purpose of our paper is, indeed, to study, using explicit examples, how classical integrability behaves under the "minimal" quantization rules proposed in Ref. 11 and somewhat extended here. The next section will be devoted to the computation of the quantum corrections in (3.8) and (3.13) for all the examples that have been previously introduced.

B. The equivariance Lie algebra

So far, the transformation property of the quantization rules (3.4) and (3.10) under a change of coordinates has been put aside. It is mandatory to investigate if these rules are consistent with the map $\mathcal{Q}:P\mapsto\hat{P}$ (which has been defined for cubic polynomials, $P=\Sigma_{k=0}^{3}P^{i_1\cdots i_k}\xi_{i_1}\ldots\xi_{i_k}$, only) being equivariant with respect to some Lie subgroup of the group of diffeomorphisms of configuration space, M.

Restricting considerations to the infinitesimal version of the sought equivariance, we will therefore look for the set $\mathfrak{g}$ of all vector fields X with respect to which our quantization is

equivariant, namely $L_X\mathcal{Q}=0$. From its very definition, $\mathfrak{g}$ is a Lie subalgebra of the Lie algebra, Vect(M), of vector fields of M. The previous condition means that, for each polynomial P, the following holds:

$$L_X(\mathcal{Q}(P)\phi) - \mathcal{Q}(L_XP)\phi - \mathcal{Q}(P)L_X\phi = 0, \tag{3.17}$$

where $L_X\phi$ denotes the Lie derivative of the half-density ϕ of M with respect to the vector field $X \in \mathfrak{g}$ and $L_XP=\{X,P\}$ is the Poisson bracket of $X=X^i\xi_i$ and P.

Let us recall that, putting locally $\phi=f|\mathrm{vol}|^{1/2} \in \mathcal{F}_{1/2}$ with $f \in C^\infty(M)$, we get the following expression for the Lie derivative: $L_X\phi=(Xf+1/2\mathrm{div}(X)f)|\mathrm{vol}|^{1/2}$, or with a slight abuse of notation, $L_X\phi=X^j\nabla_j\phi+\frac{1}{2}(\nabla_jX^j)\phi=\frac{1}{2}(X_j\circ\nabla_j+\nabla_j\circ X^j)\phi$, that is

$$L_X\phi = \frac{1}{i}\hat{X}\phi \tag{3.18}$$

for any $X \in \mathrm{Vect}(M)$.

The equivariance condition (3.17) must hold for any $\phi \in \mathcal{F}_{1/2}$ and thus translates into

$$[\hat{X},\hat{P}] = i\widehat{\{X,P\}} \tag{3.19}$$

for any $X \in \mathfrak{g}$ and any cubic polynomial P. The condition (3.19) characterizes the Lie algebra $\mathfrak{g}$ we are looking for. We will consider successively the case of polynomials of increasing degree:

(i) Returning to the previous relations (3.5) and (3.7) together with $X=P_1$ and $P=Q_0+Q_1$, we readily find that the Lie algebra $\mathfrak{g}_1$ spanned by the solutions of (3.19) restricted to polynomials P of degree one is $\mathfrak{g}_1=\mathrm{Vect}(M)$.

(ii) Let us now proceed to the case of quadratic polynomials $P=P^{jk}\xi_j\xi_k$. The relations (3.7) and (3.9) give, in that case, the following equivariance defect:

$$[\hat{X},\hat{P}] - i\widehat{\{X,P\}} = \frac{i}{2}\nabla_j\circ P^{jk}\circ\nabla_k(\nabla_\ell X^\ell)\mathbf{1}. \tag{3.20}$$

This defect vanishes for any such P iff $\nabla_k(\nabla_\ell X^\ell)=0$, i.e.,

$$d(\mathrm{div}(X)) = 0. \tag{3.21}$$

The vector fields X with constant divergence now span a subspace $\mathfrak{g}_2 \subset \mathfrak{g}_1$ which is, indeed, an infinite dimensional Lie subalgebra of Vect(M). The "minimal" quantization restricted to quadratic polynomials is therefore equivariant with respect to the group of all diffeomorphisms which preserve the volume up to a multiplicative nonzero constant.

(iii) Let us finally consider homogeneous cubic polynomials $P=P^{jk\ell}\xi_j\xi_k\xi_\ell$ and compute the equivariance defect in this case. A tedious calculation leads to

$$[\hat{X},\hat{P}] - i\widehat{\{X,P\}} = i\hat{Z}, \quad Z = Z^j\xi_j, \tag{3.22}$$

with

$$Z^j = \nabla_k[P^{jk\ell}\nabla_\ell\,\mathrm{div}(X) - P^{\ell m[j}\,L_X\Gamma^{\,k]}_{\ell m}] \tag{3.23}$$

where

$$L_X\Gamma^k_{\ell m} = \nabla_\ell\nabla_m X^k - R^k{}_{m,n\ell}X^n \tag{3.24}$$

is the Lie derivative of the symmetric linear connection ∇ with respect to the vector field X.

Proposition 3.7: The Lie algebra $\mathfrak{g} \subset \mathrm{Vect}(M)$ *with respect to which the "minimal" quantization* (3.4) and (3.10) *is equivariant is* $\mathrm{aff}(M,\nabla)$, *the Lie algebra of affine vector fields of* (M,∇).

Proof: The equivariance condition (3.19), defining the Lie algebra $\mathfrak{g}_3$ we are looking for, is

equivalent to $Z=0$ in (3.22) for all symmetric tensor fields $P^{jk\ell}$, i.e., thanks to (3.23) to

$$T_k^{jk\ell}\nabla_\ell \operatorname{div}(X) - T_k^{\ell m[j} L_X \Gamma^{k]}_{\ell m} = 0$$

for all tensor fields $T_k^{\ell mj} = T_k^{(\ell mj)}$. This readily implies that

$$2\delta^j_{(i}\,\delta^k_\ell \nabla_{m)} \operatorname{div}(X) + \delta^j_{(i} L_X \Gamma^k{}_{\ell m)} - \delta^k_{(i} L_X \Gamma^j{}_{\ell m)} = 0.$$

Summing over $i=j$, one gets

$$2n\delta^k_m \nabla_\ell \operatorname{div}(X) + 4\delta^k_\ell \nabla_m \operatorname{div}(X) + (n+1) L_X \Gamma^k_{\ell m} - \delta^k_m L_X \Gamma^i_{\ell i} - \delta^k_\ell L_X \Gamma^i_{mi} = 0,$$

where $n=\dim(M)$, hence $\nabla_i \operatorname{div}(X)=0$ and $L_X\Gamma^k_{ij} = \delta^k_i \varphi_j + \delta^k_j \varphi_i$ for some one-form φ depending upon the (projective) vector field X. The expression (3.24) of the Lie derivative of the symmetric connection ∇ then yields $L_X\Gamma^j_{ij} = (n+1)\varphi_i = 0$ since we have found that $\nabla_i \nabla_j X^j = 0$. This entails $L_X \Gamma^k_{ij} = 0$, proving that $\mathfrak{g} = \mathfrak{g}_3$ is nothing but the Lie algebra $\mathrm{aff}(M, \nabla)$ of affine vector fields. □

We thus obtain the nested equivariance Lie algebras

$$\mathfrak{g} = \mathrm{aff}(M, \nabla) \subset \mathfrak{g}_2 \subset \mathfrak{g}_1 = \mathrm{Vect}(M),$$

where $\mathfrak{g}_2$ is the Lie algebra of vector fields with constant divergence. (Note that if M is compact without boundary, $\mathfrak{g}_2$ reduces to the Lie algebra of divergence-free vector fields.)

Conspicuously, our quantization scheme turns out to be equivariant with respect to a rather small Lie subgroup of $\mathrm{Diff}(M)$, namely of the affine group of (M, ∇). It would be interesting to investigate to what extent the equivariance under the sole affine group, $\mathrm{GL}(n, \mathbf{R}) \ltimes \mathbf{R}^n$, of a flat affine structure (M, ∇) allows one to uniquely extend to the whole algebra of polynomials the quantization scheme we have devised for cubic polynomials.

C. The quantum Stäckel system

The quantization of the general Stäckel system (see Sec. II D) has first been undertaken by Benenti, Chanu, and Rastelli in Refs. 4 and 5. We will derive here the covariant expression of the quantum correction associated to the "minimal" quantization, with the help of the results obtained in Sec. III A.

Denote by $I_i = I_{2,i} + I_{0,i}$ the ith Stäckel conserved quantity, $i=1,\ldots,n$, in (2.11) where the indices 0 and 2 refer to the degree of homogeneity with respect to the coordinates ξ. Applying (3.15) with $P_1 = Q_1 = 0$, $P_2 = I_{2,i}$, and $Q_2 = I_{2,j}$ one gets

$$[\hat{I}_i, \hat{I}_j] = [\hat{I}_{2,i}, \hat{I}_{2,j}] = i\hat{A}_{I_{2,i}, I_{2,j}} = \tfrac{2}{3}\left(\nabla_k B^{k\ell}_{I_{2,i}, I_{2,j}}\right)\nabla_\ell.$$

Remark 3.8: This result shows that there are no quantum corrections produced by the potential term. More generally, start with a system defined by independent, homogeneous, quadratic observables $H_1, \ldots, H_n$ which is integrable at the classical and quantum levels. Consider a new set of observables $H_1 + U_1, \ldots, H_n + U_n$ obtained by adding potential terms $U_1, \ldots, U_n$; if the new system is classically integrable, it will remain integrable at the quantum level.

We are now in position to prove the following

Proposition 3.9: The quantum correction (3.12) *of a general Stäckel system, with commuting conserved quantities* $I_1, \ldots, I_n$ *defined by* (2.11), *retains the form*

$$B^{k\ell}_{I_{2,i}, I_{2,j}} = -2 I^{s[k}_{2,i} R_{st} I^{\ell]t}_{2,j} \tag{3.25}$$

for $i, j = 1, \ldots, n$, *where* R_{st} *denotes the components of the Ricci tensor of the metric associated with the Hamiltonian* I_1.

Proof: As a preliminary remark, let us observe that the Stäckel metric, given by (2.10), needs not be Riemannian. So we will write it

$$g = \sum_{i=1}^{n} \frac{(dx^i)^2}{A_1^i(x)} = \sum_{a=1}^{n} \eta_a (\theta^a)^2, \tag{3.26}$$

where $(\theta^a = \mathrm{d}x^a / \sqrt{|A_1^a|})_{a=1,\ldots,n}$ is the orthonormal moving coframe and the signature of g is given by $\eta_a = \mathrm{sign}(A_1^a)$. We will denote by $(e_a = \sqrt{|A_1^a|}\partial_a)_{a=1,\ldots,n}$ the associated orthonormal frame with respect to the metric $\eta_{ab} = \eta_a \delta_{ab}$ used to raise and lower frame indices.

Let us recall, in order to fix the notation, that the connection form ω satisfies the structure equation $\mathrm{d}\theta^a + \omega^a{}_b \wedge \theta^b = 0$ and the associated curvature form, Ω, given by $\Omega^a{}_b = \mathrm{d}\omega^a{}_b + \omega^a{}_c \wedge \omega^c{}_b$, is expressed in terms of the Riemann tensor by $\Omega^a{}_b = \frac{1}{2} R^a{}_{b,cd} \theta^c \wedge \theta^d$. The indices $a, \ldots, d$ run from 1 to n and the Einstein summation convention is used when no ambiguity arises. Denoting by $R^\ell{}_{i,jk}$ the local components of the Riemann tensor, we have $R^a{}_{b,cd} = \theta^a_\ell R^\ell{}_{i,jk} e^i_b e^j_c e^k_d$.

We start off with the calculation of the connection form, ω, and of some components of the curvature form, Ω. Straightforward computation, using relation (2.13), then yields for the nonvanishing components of the connection

$$\omega_{ab,a} = \tfrac{1}{2} \eta_b C_b^a \frac{|A_1^b|^{3/2}}{|A_1^a|}, \quad a \neq b, \quad \omega_{ab,c} = \omega_{ab}(e_c),$$

the other nontrivial components $\omega_{ab,b}$ are obtained accordingly. For the curvature, a lengthy computation gives the special components

$$R_{ac,cb} = 3(-\eta_a \omega_{ca,c} \omega_{ab,a} - \eta_b \omega_{cb,c} \omega_{ba,b} + \eta_c \omega_{ca,c} \omega_{cb,c}), \quad a \neq b, \tag{3.27}$$

which will be needed in the sequel.

Two last ingredients are the introduction of the frame components of various objects. We will denote the Killing tensor $I_{2,i}$ (respectively, $I_{2,j}$) as P (respectively, Q). Their frame components $P = P^{bc} e_b \otimes e_c$, and similarly for Q, will be

$$P^{bc} = p_b \delta_{bc}, \quad p_b = \frac{A_i^b}{2|A_1^b|}, \quad Q^{bc} = q_b \delta_{bc}, \quad q_b = \frac{A_j^b}{2|A_1^b|}. \tag{3.28}$$

The covariant derivative will have the frame components

$$\mathcal{D}_c P_{ab} = e_c(P_{ab}) - \omega^s{}_{a,c} P_{sb} - \omega^s{}_{b,c} P_{as}.$$

The equations which express that P^{ab} is a Killing tensor are now

$$\begin{aligned} e_b(p_a) &= 2\omega_{ab,a}(\eta_a p_a - \eta_b p_b), \quad a \neq b, \\ e_a(p_a) &= 0, \end{aligned} \tag{3.29}$$

where the repeated indices are not summed over. One can check that they hold true using the explicit form of p_a given in (3.28) and the identity (2.13).

Using all of the previous information one can compute the frame components of the various pieces appearing in the tensor $B^{ij}_{P,Q}$. We have successively

$$\begin{aligned} P^{s[i} \nabla_s \nabla_t Q^{j]t} - (P \leftrightarrow Q) = \sum_{l \neq i,j} & (4\omega_{li,l}\omega_{lj,l} - 3\eta_l \eta_i \omega_{li,l}\omega_{ij,i} - 3\eta_l \eta_j \omega_{lj,l}\omega_{ji,j}) \\ & \times [p_i q_j - \eta_l p_l \eta_i q_j + \eta_i q_l \eta_i p_j - (i \leftrightarrow j)] \end{aligned}$$

and

$$\nabla_s P^{t[i} \nabla_t Q^{j]s} = \tfrac{1}{2} \sum_l \omega_{li,l}\omega_{lj,l} [p_i q_j - \eta_l p_l \eta_i q_j + \eta_l q_l \eta_i p_j - (i \leftrightarrow j)].$$

Combining these relations, and using (3.27), we get

$$P^{s[i}\nabla_s\nabla_t Q^{j]t} - (P \leftrightarrow Q) - \nabla_s P^{t[i}\nabla_t Q^{j]s} = \tfrac{1}{2}\sum_l \eta_l R_{il,lj}[p_i q_j - \eta_l p_l \eta_i q_j + \eta_l q_l \eta_i p_j - (i \leftrightarrow j)].$$

Let us then compute

$$P^{s[i}R^{j]}{}_{u,vs}Q^{uv} - (P \leftrightarrow Q) = \tfrac{1}{2}\sum_l \eta_l R_{il,lj}[\eta_l p_l \eta_i q_j - \eta_l q_l \eta_i p_j - (i \leftrightarrow j)].$$

Collecting all the pieces leaves us with

$$P^{s[i}\nabla_s\nabla_t Q^{j]t} + P^{s[i}R^{j]}{}_{u,vs}Q^{uv} - (P \leftrightarrow Q) - \nabla_s P^{t[i}\nabla_t Q^{j]s} = \tfrac{1}{2}\sum_l \eta_l R_{il,lj}(p_i q_j - p_j q_i). \tag{3.30}$$

The last sum is nothing but the frame components of the tensor $-P^{s[i}R_{st}Q^{j]t}$, so that we have obtained the tensorial relation

$$P^{s[i}\nabla_s\nabla_t Q^{j]t} + P^{s[i}R^{j]}{}_{u,vs}Q^{uv} - (P \leftrightarrow Q) - \nabla_s P^{t[i}\nabla_t Q^{j]s} = -P^{s[i}R_{st}Q^{j]t}, \tag{3.31}$$

which implies

$$B^{ij}{}_{P,Q} = -2P^{s[i}R_{st}Q^{j]t}, \tag{3.32}$$

in agreement with Ref. 5. This ends the proof of Proposition 3.9. □

Now we can come to the central point of our analysis: is a Stäckel system integrable at the quantum level? The answer is given by the following

Corollary 3.10: (Refs. 4 and 5) *A Stäckel system is integrable at the quantum level iff*

$$R_{ij} = 0 \quad \text{for } i \neq j, \quad \text{where } i,j = 1,\ldots,n, \tag{3.33}$$

in the special coordinates which are constituent to this system.

Proof: The Killing tensors $I_{2,i}$ are diagonal, for $i=1,\ldots,n$, in the Stäckel coordinate system, and the proof follows from (3.25). □

The conditions (3.33) are known as the Robertson conditions,[31] as interpreted by Eisenhart.[18] Quite recently, Benenti *et al.*[4] have refined the definition of the separability of the Schrödinger equation and shown that, for Stäckel systems, the Robertson conditions are necessary and sufficient for the separability of the Schrödinger equation. As mentioned in Remark 2.1, the classical integrability is equivalent to the separability of the Hamilton–Jacobi equation; the situation for these systems can therefore be summarized by the following diagram:

$$\begin{array}{ccccc} \text{Classical integrability} & \Leftrightarrow & \text{separable Hamilton-Jacobi} \\ \Downarrow & \text{provided} & R_{ij}=0\ (i\neq j) \\ \text{Quantum integrability} & \Leftrightarrow & \text{separable Schrödinger.} \end{array}$$

D. The quantum ellipsoid and Neumann systems

It is now easy to prove that the ellipsoid geodesic flow (see Sec. II E), including the potential given in (2.16), is integrable at the quantum level. Using the coordinates (x^i) and the (Riemannian) metric given by (2.22), one can check that the Ricci tensor has components

$$R_{ij} = \frac{\mathcal{N}}{x^i}\sum_{s\neq i}\frac{1}{x^s}g_{ij}, \quad \mathcal{N} = \frac{a_0 a_1 \cdots a_n}{x^1 \cdots x^n},$$

and therefore satisfies the Robertson conditions. As already emphasized, the occurrence of an additional potential is irrelevant for the quantum analysis since the potential terms do not generate quantum corrections (see Remark 3.8).

Similarly we get the quantum integrability for the Neumann system (see Sec. II F) using the metric on S^n given by (2.38). The Ricci tensor being given by

$$R_{ij} = (n-1)g_{ij},$$

the Robertson conditions are again satisfied.

E. The quantum generalized Kerr–Newman system

The quantization of the four commuting observables (2.47) and (2.48) is straightforward.

In view of the relations given in Sec. III all quantum commutators vanish except for $[\hat{\tilde{H}}, \hat{\tilde{P}}]$; this is due to the fact that the conserved quantities $\tilde{S}$ and $\tilde{T}$ [see (2.48)] are Killing–Maxwell vector fields.

The anomalous terms in the previous commutator are A_{P_2,H_2}, A_{P_1,H_2}, and A_{P_2,H_1} where $P_2 = P^{ij}\xi_i\xi_j$, $H_2 = \frac{1}{2}g^{ij}\xi_i\xi_j$, $P_1 = -2P^{ij}\xi_i A_j$, and $H_1 = -g^{ij}\xi_i A_j$.

The vector field A_{P_2,H_2} given by (3.14) actually vanishes because, cf. (3.16), $B^{jk}_{P_2,H_2} = -P^{\ell[j}R_\ell^{\ k]} = 0$ as a consequence of (2.7); indeed the tensor P anti-commutes with the electromagnetic field strength F, implying that it commutes with the stress-energy electromagnetic tensor, hence with the Ricci tensor in view of the Einstein–Maxwell equations.[11]

The two other anomalous terms (3.9) also vanish as it turns out that $\nabla_j A^j = 0$ [see (2.44)] and $\nabla_j(P^{jk}A_k) = 0$.

This derivation reproduces and extends Carter's results to the generalized Kerr–Newman solution, in a somewhat shorter manner.

Remark 3.11: Our analysis of quantum integrability for the generalized Kerr-Newman solution in four dimensions can be carried over into recent work[19,23,32] dealing with five-dimensional black holes. In these cases, classical integrability follows from the existence of three Killing vectors and one quadratic Killing tensor, besides the Hamiltonian. These metrics being Einstein, the above arguments given for the generalized Kerr–Newman case apply just as well, ensuring quantum integrability. This fact is in agreement with the separability of the Laplace operator.

F. The quantum multi-center system

For this example too, the quantization is straightforward. The single point to be checked for quantum integrability is just the commutator $[\hat{H}, \hat{P}]$, with the possible quantum correction (3.16) given by $-P^{\ell[j}R_\ell^{\ k]}$. Here it vanishes trivially since these metrics are Ricci-flat.

G. The quantum Di Pirro system

As seen in Sec. II I, the classical integrability of this system is provided by three commuting observables: on the one hand H, P, respectively, given by (2.51) and (2.52), and $T = \xi_3$ if $c(x^3) = \text{const.}$, and on the other hand H, P and $J = \xi_1 x^2 - \xi_2 x^1$ if $a = b$, γ depend on r only.

At the quantum level, the Killing vectors $\hat{T}$ and $\hat{J}$ do commute with $\hat{H}$ according to (3.8) and (3.9). As for the commutator $[\hat{P}, \hat{H}]$ of the quantized Killing tensors, it is given by (3.16), namely $B_{P,H} = -\frac{1}{2}P^{\ell[j}R_\ell^{\ k]}\partial_j \wedge \partial_k$, and one finds

$$B_{P,H} = -\frac{3}{16}\frac{c'(x^3)}{(\gamma(x^1,x^2) + c(x^3))^3}(a(x^1,x^2)\partial_1\gamma(x^1,x^2)\partial_1 \wedge \partial_3 + b(x^1,x^2)\partial_2\gamma(x^1,x^2)\partial_2 \wedge \partial_3).$$

For the system (H,P,T), this quantum correction vanishes since $c'(x^3) = 0$, implying quantum integrability. However, for the system (H,P,J), in the generic case $\gamma \neq \text{const.}$, we get $B_{P,H} \neq 0$, showing that the minimal quantization rules may produce quantum corrections.

IV. DISCUSSION AND OUTLOOK

It would be worthwhile to get insight into the status of our "minimal" quantization rules and to their relationship with other bona fide quantization procedures. Among the latter, let us mention those obtained by geometric means, and more specifically by imposing equivariance of the quantization mapping, $\mathcal{Q}$, with respect to some symmetry group, G, e.g., a group of automorphisms of a certain geometric structure on configuration space, M. We refer to Refs. 24, 15–17, and 6 for a detailed account on equivariant quantization. The two main examples are, respectively, the projectively, $G=SL(n+1,\mathbf{R})$, and conformally, $G=O(p+1,q+1)$, equivariant quantizations which have been shown to be uniquely determined.[24,15–17] For instance, the conformally equivariant quantization $\mathcal{Q}_{1/2}:\mathcal{F}_{1/2}(M)\to\mathcal{F}_{1/2}(M)$ has been explicitly computed for quadratic[16] and cubic[25] observables; for example, if $P=P^{ij}\xi_i\xi_j$ we then have

$$\mathcal{Q}_{1/2}(P)=\hat{P}+\beta_3\nabla_i\nabla_j(P^{ij})+\beta_4 g^{ij}g_{k\ell}\nabla_i\nabla_j(P^{k\ell})+\beta_5 R_{ij}P^{ij}+\beta_6 R g_{ij}P^{ij} \tag{4.1}$$

where the "minimal" quantum operator

$$\hat{P}=-\nabla_i\circ P^{ij}\circ\nabla_j \tag{4.2}$$

is given by (3.4), together with $\beta_3=-n/(4(n+1))$, $\beta_4=-n/(4(n+1)(n+2))$, $\beta_5=n^2/(4(n-2)(n+1))$, $\beta_6=-n^2/(2(n^2-4)(n^2-1))$, assuming $n=\dim(M)>2$. In (4.1) we denote by R_{ij} the components of the Ricci tensor and by R the scalar curvature. The formula (4.1) provides a justification of the term "minimal" for the mapping $P\mapsto\hat{P}$ given by (3.4) and (3.10).

We have checked that, in the special instance of the geodesic flow of the ellipsoid discussed in Sec. II E, the quantum commutators of the observables I_i defined in (2.30), namely $[\mathcal{Q}_{1/2}(I_i),\mathcal{Q}_{1/2}(I_j)]$, fail to vanish for $i\neq j=1,\ldots,n$. Had we started from the expression (4.1) with adjustable coefficients $\beta_3,\ldots,\beta_6$, the requirement that the latter commutator be vanishing imposes $\beta_3=\ldots=\beta_6=0$, leading us back to the minimal quantization rule (4.2).

Despite their nice property of preserving, to a large extent, integrability (from classical to quantum), the "minimal" quantization rules still remain an ad hoc procedure, defined for observables at most cubic in momenta, and do not follow from any sound constructive principle, be it of a geometric or an algebraic nature. The quest for a construct leading unambiguously to a genuine "minimal" quantization procedure remains an interesting challenge. As discussed in Sec. III B, the equivariance assumption with respect to the affine group might be helpful for determining the sought "minimal" quantization of polynomials of higher degree. This analysis is required for the quantization of, e.g., the newly discovered integrable systems[14] which involve cubic Killing tensors.

Another field of applications of the present work could be the search for quantum integrability of the geodesic flow on the higher dimensional generalizations of the Kerr metric which have been under intense study lately.[19,12,36]

Still another perspective for future work would be to generalize the previous computation of quantum corrections to the case of classical integrability in the presence of an electromagnetic field in a purely gauge invariant manner. In particular the approach presented in Sec. II B should be further extended at the quantum level via the quantization of the Schouten–Maxwell brackets.

ACKNOWLEDGMENTS

We are indebted to Daniel Bennequin for several very interesting remarks, and to Brandon Carter for fruitful correspondence. Special thanks are due to Valentin Ovsienko for a careful reading of the manuscript together with a number of most enlightening suggestions.

We present Noether's second theorem for graded Lagrangian systems of even and odd variables on an arbitrary body manifold X in a general case of BRST symmetries depending on derivatives of dynamic variables and ghosts of any finite order. As a preliminary step, Noether's second theorem for Lagrangian systems on fiber bundles $Y \to X$ possessing gauge symmetries depending on derivatives of dynamic variables and parameters of arbitrary order is proved. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1899988]

I. INTRODUCTION

Different variants of Noether's second theorem state that, if a Lagrangian admits symmetries depending on parameters, its variational derivatives obey certain relations, called the Noether identities. We present Noether's second theorem in the case of BRST transformations depending on derivatives (jets) of dynamic variables and ghosts of arbitrary order. In particular, this is the case of the field-antifield BRST theory and BV quantization.[1,2] Special attention is paid to global aspects of Noether's second theorem as a preliminary step of the global analysis of BV quantization.[3,4]

We start with a classical Lagrangian system on a fiber bundle $Y \to X$ subject to even gauge transformations depending on even dynamic variables, even parameters, and their derivatives of any order. For this purpose, we consider Lagrangian formalism on the composite fiber bundle $E \to Y \to X$, where $E \to Y$ is a vector bundle of gauge parameters. Accordingly, gauge transformations are represented by a linear differential operator υ on E taking its values in the vertical tangent bundle VY of $Y \to X$ (Sec. II). The Noether identity for a Lagrangian L is defined as a differential operator Δ on the fiber bundle (13) which takes its values in the density-dual

$$E^* \underset{Y}{\otimes} \overset{n}{\wedge} T^*X, \quad n = \dim X, \tag{1}$$

of E and whose kernel contains the image of the Euler–Lagrange operator δL of L, i.e., $\Delta \circ \delta L = 0$ (Definition 4). Expressed in these terms, Noether's second theorem (Sec. III, Theorem 5) follows at once from the properties of differential operators on dual fiber bundles (Appendix A, Theorem 16). Namely, there exists the intertwining operator $\eta(\upsilon) = \Delta$, $\eta(\Delta) = \upsilon$ such that

$$\eta(\eta(\upsilon)) = \upsilon, \quad \eta(\eta(\Delta)) = \Delta, \tag{2}$$

[b)]Electronic mail: giovanni.giachetta@unicam.it
[c)]Electronic mail: luigi.mangiarotti@unicam.it
[d)]Electronic mail: sard@grav.phys.msu.su

$$\eta(v \circ v') = \eta(v') \circ \eta(v), \quad \eta(\Delta' \circ \Delta) = \eta(\Delta) \circ \eta(\Delta'). \tag{3}$$

The appropriate notions of reducible Noether identities and gauge symmetries are formulated, and their equivalence with respect to the intertwining operator η is proved (Sec. IV).

This formulation of Noether's second theorem is generalized to the case of graded Lagrangian systems of even and odd variables and BRST symmetries (Sec. VII, Theorem 15). We describe odd variables and their jets on an arbitrary smooth manifold X as generating elements of the structure ring of a graded manifold whose body is X.[4,5] This definition differs from that of jets of a graded fiber bundle,[6] but reproduces the heuristic notion of jets of ghosts in the above-mentioned field–antifield BRST theory.[1,7]

We consider BRST symmetries of a graded Lagrangian, i.e., its nilpotent odd symmetries depending on ghosts as parameters (Sec. VI). In particular, BRST symmetries come from the above-mentioned gauge symmetries by replacement of even parameters with odd ghosts (Example 5). In this case, the nilpotency condition implies that original gauge symmetries form an algebra.

The key point is that, in order to define the Noether identity associated to BRST symmetries, one should introduce antifields and the Koszul–Tate differential. If a Noether identity is reducible, $(0 \leqslant k)$-stage ghosts and antighosts are called into play (Sec. VIII), and we come to the complete tuple of fields, ghosts, and antifields in the field–antifield BRST theory.[1] We, however, leave this theory outside the scope of the present work, and keep an original graded Lagrangian independent of ghosts and antifields.

II. GAUGE SYSTEMS ON FIBER BUNDLES

Recall that an r-order Lagrangian on a fiber bundle $Y \to X$ is defined as a density

$$L = \mathcal{L}\omega : J^r Y \to \overset{n}{\wedge} T^* X, \quad \omega = dx^1 \wedge \cdots \wedge dx^n, \tag{4}$$

on the r-order jet manifold $J^r Y$ of sections of $Y \to X$. Jet manifolds of $Y \to X$ make up the inverse system

$$X \overset{\pi}{\leftarrow} Y \overset{\pi_0^1}{\leftarrow} J^1 Y \leftarrow \cdots J^{r-1} Y \overset{\pi_{r-1}^r}{\leftarrow} J^r Y \leftarrow \cdots. \tag{5}$$

In the sequel, the index $r=0$ stands for Y. Accordingly, we have the direct system

$$\mathcal{O}^* X \overset{\pi^*}{\to} \mathcal{O}^* Y \overset{\pi_0^{1*}}{\to} \mathcal{O}_1^* Y \to \cdots \mathcal{O}_{r-1}^* Y \overset{\pi_{r-1}^{r*}}{\to} \mathcal{O}_r^* Y \to \cdots \tag{6}$$

of graded differential algebras (henceforth GDAs) $\mathcal{O}_r^* Y$ of exterior forms on jet manifolds $J^r Y$ with respect to the pull-back monomorphisms π_{r-1}^{r*}. Its direct limit $\mathcal{O}_\infty^* Y$ is a GDA consisting of all exterior forms on finite order jet manifolds modulo the pull-back identification.

The projective limit $(J^\infty Y, \pi_r^\infty : J^\infty Y \to J^r Y)$ of the inverse system (5) is a Fréchet manifold.[8] A bundle atlas $\{(U_Y; x^\lambda, y^i)\}$ of $Y \to X$ yields the coordinate atlas

$$\{((\pi_0^\infty)^{-1}(U_Y); x^\lambda, y^i_\Lambda)\}, \quad y'^i_{\lambda+\Lambda} = \frac{\partial x^\mu}{\partial x'^\lambda} d_\mu y'^i_\Lambda, \quad 0 \leqslant |\Lambda|, \tag{7}$$

of $J^\infty Y$, where $\Lambda = (\lambda_k \ldots \lambda_1)$ is a symmetric multi-index, $\lambda + \Lambda = (\lambda \lambda_k \ldots \lambda_1)$, and

$$d_\lambda = \partial_\lambda + \sum_{0 \leqslant |\Lambda|} y^i_{\lambda+\Lambda} \partial_i^\Lambda, \quad d_\Lambda = d_{\lambda_r} \circ \cdots \circ d_{\lambda_1} \tag{8}$$

are the total derivatives. There is the restriction epimorphism $\mathcal{O}_\infty^* Y \to \mathcal{O}_\infty^* U_Y$. Therefore, $\mathcal{O}_\infty^* Y$ can be written in a coordinate form where the horizontal one-forms $\{dx^\lambda\}$ and the contact one-forms $\{\theta^i_\Lambda = dy^i_\Lambda - y^i_{\lambda+\Lambda} dx^\lambda\}$ are generating elements of the $\mathcal{O}_\infty^0 U_Y$-algebra $\mathcal{O}_\infty^* U_Y$. Though $J^\infty Y$ is not a smooth manifold, elements of $\mathcal{O}_\infty^* Y$ are exterior forms on finite order jet manifolds and, therefore, their coordinate transformations are smooth.

There is the canonical decomposition $\mathcal{O}^*_\infty Y = \oplus \mathcal{O}^{k,m}_\infty Y$ of $\mathcal{O}^*_\infty Y$ into $\mathcal{O}^0_\infty Y$-modules $\mathcal{O}^{k,m}_\infty Y$ of k-contact and m-horizontal forms together with the corresponding projectors $h_k: \mathcal{O}^*_\infty Y \to \mathcal{O}^{k,*}_\infty Y$ and $h^m: \mathcal{O}^*_\infty Y \to \mathcal{O}^{*,m}_\infty Y$. Accordingly, the exterior differential on $\mathcal{O}^*_\infty Y$ is split into the sum $d = d_H + d_V$ of the nilpotent total and vertical differentials

$$d_H(\phi) = dx^\lambda \wedge d_\lambda \phi, \quad d_V(\phi) = \theta^i_\Lambda \wedge \partial^\Lambda_i \phi, \quad \phi \in \mathcal{O}^*_\infty Y.$$

One also introduces the $\mathbb{R}$-module projector

$$\varrho = \sum_{0<k} \frac{1}{k} \overline{\varrho} \circ h_k \circ h^n, \quad \overline{\varrho}(\phi) = \sum_{0 \leqslant |\Lambda|} (-1)^{|\Lambda|} \theta^i \wedge [d_\Lambda(\partial^\Lambda_i \rfloor \phi)], \quad \phi \in \mathcal{O}^{>0,n}_\infty Y, \tag{9}$$

of $\mathcal{O}^*_\infty Y$ such that $\varrho \circ d_H = 0$, and the nilpotent variational operator $\delta = \varrho \circ d$ on $\mathcal{O}^{*n}_\infty Y$. Let us put $\mathbf{E}_k = \varrho(\mathcal{O}^{k,n}_\infty Y)$. Then the GDA $\mathcal{O}^*_\infty Y$ is split into the well-known variational bicomplex.[4,8–10] Here, we are concerned with its variational subcomplex

$$0 \to \mathbb{R} \to \mathcal{O}^0_\infty Y \xrightarrow{d_H} \mathcal{O}^{0,1}_\infty Y \cdots \xrightarrow{d_H} \mathcal{O}^{0,n}_\infty Y \xrightarrow{\delta} \mathbf{E}_1 \xrightarrow{\delta} \mathbf{E}_2 \to \cdots \tag{10}$$

and the subcomplex of one-contact forms

$$0 \to \mathcal{O}^{1,0}_\infty Y \xrightarrow{d_H} \mathcal{O}^{1,1}_\infty Y \cdots \xrightarrow{d_H} \mathcal{O}^{1,n}_\infty Y \xrightarrow{\varrho} \mathbf{E}_1 \to 0. \tag{11}$$

They possess the following cohomology.[3,4,11]

Theorem 1: The cohomology of the variational complex (10) equals the de Rham cohomology of Y.

Theorem 2: The complex (11) is exact.

Any finite order Lagrangian L (4) is an element of $\mathcal{O}^{0,n}_\infty Y$, while

$$\delta L = \mathcal{E}_i \theta^i \wedge \omega = \sum_{0 \leqslant |\Lambda|} (-1)^{|\Lambda|} d_\Lambda(\partial^\Lambda_i \mathcal{L}) \theta^i \wedge \omega \in \mathbf{E}_1 \tag{12}$$

is its Euler–Lagrange operator taking the values in the vector bundle

$$T^*Y \underset{Y}{\wedge} (\overset{n}{\wedge} T^*X) = V^*Y \underset{Y}{\otimes} \overset{n}{\wedge} T^*X. \tag{13}$$

The components $\mathcal{E}_i$ of δL are called the variational derivatives. We further abbreviate $A \approx 0$ with an equality which holds on-shell. This means that A is an element of a module over the ideal I_L of the ring $\mathcal{O}^0_\infty Y$ which is locally generated by the variational derivatives $\mathcal{E}_i$ (12) and their total derivatives $d_\Lambda \mathcal{E}_i$. Thus, I_L is a differential ideal.

By virtue of Theorem 1, every δ-closed Lagrangian $L \in \mathcal{O}^{0,n}_\infty Y$ is the sum

$$L = h_0 \psi + d_H \sigma, \quad \sigma \in \mathcal{O}^{0,n-1}_\infty Y, \tag{14}$$

where ψ is a closed n-form on Y. Theorem 2 provides the $\mathbb{R}$-module decomposition

$$\mathcal{O}^{1,n}_\infty Y = \mathbf{E}_1 \oplus d_H(\mathcal{O}^{1,n-1}_\infty Y).$$

Given a Lagrangian $L \in \mathcal{O}^{0,n}_\infty Y$, we have the corresponding decomposition

$$dL = \delta L - d_H \Xi \tag{15}$$

where $\Xi_L = \Xi + L$ is a Lepagean equivalent of L.

Let $\mathfrak{d}\mathcal{O}^0_\infty Y$ be the $\mathcal{O}^0_\infty Y$-module of derivations of the $\mathbb{R}$-ring $\mathcal{O}^0_\infty Y$. Any $\vartheta \in \mathfrak{d}\mathcal{O}^0_\infty Y$ yields the graded derivation (the interior product) $\vartheta \rfloor \phi$ of the GDA $\mathcal{O}^*_\infty Y$ given by the relations

$$\vartheta \rfloor df = \vartheta(f), \quad f \in \mathcal{O}^0_\infty Y,$$

$$\vartheta(\phi\wedge\sigma)=(\vartheta\rfloor\phi)\wedge\sigma+(-1)^{|\phi|}\phi\wedge(\vartheta\rfloor\sigma),\quad \phi,\sigma\in\mathcal{O}^*_\infty Y,$$

and its derivation (the Lie derivative)

$$\begin{aligned}&\mathbf{L}_\vartheta\phi=\vartheta\rfloor d\phi+d(\vartheta\rfloor\phi),\quad \phi\in\mathcal{O}^*_\infty Y,\\ &\mathbf{L}_\vartheta(\phi\wedge\phi')=\mathbf{L}_\vartheta(\phi)\wedge\phi'+\phi\wedge\mathbf{L}_\vartheta(\phi').\end{aligned}\tag{16}$$

Relative to an atlas (7), a derivation $\vartheta\in\mathfrak{d}\mathcal{O}^0_\infty Y$ reads[4]

$$\vartheta=\vartheta^\lambda\partial_\lambda+\vartheta^i\partial_i+\sum_{|\Lambda|>0}\vartheta^i_\Lambda\partial^\Lambda_i,\tag{17}$$

where the tuple of derivations $\{\partial_\lambda,\partial^\Lambda_i\}$ is defined as the dual of the set $\{dx^\lambda,dy^i_\Lambda\}$ of generating elements for the $\mathcal{O}^0_\infty Y$-algebra $\mathcal{O}^*_\infty Y$ with respect to the interior product $\rfloor$, and local functions ϑ^λ, ϑ^i, $\vartheta^i_\Lambda\in\mathcal{O}^0_\infty Y$ obey the transformation law

$$\vartheta'^\lambda=\frac{\partial x'^\lambda}{\partial x^\mu}\vartheta^\mu,\quad \vartheta'^i_\Lambda=\sum_{|\Sigma|\leqslant|\Lambda|}\frac{\partial y'^i_\Lambda}{\partial y^j_\Sigma}\vartheta^j_\Sigma+\frac{\partial y'^i_\Lambda}{\partial x^\mu}\upsilon^\mu.\tag{18}$$

Note that the tuple of derivations $\{\partial^\Lambda_i\}$ is the dual of the basis $\{\theta^i_\Lambda\}$ of contact forms.

A derivation ϑ is called contact if the Lie derivative $\mathbf{L}_\vartheta$ (16) preserves the contact ideal of the GDA $\mathcal{O}^*_\infty Y$ generated by contact forms. A derivation ϑ (17) is contact iff

$$\vartheta^i_\Lambda=d_\Lambda(\vartheta^i-y^i_\mu\vartheta^\mu)+y^i_{\mu+\Lambda}\vartheta^\mu,\quad 0<|\Lambda|.\tag{19}$$

Any contact derivation admits the horizontal splitting

$$\vartheta=\vartheta_H+\vartheta_V=\vartheta^\lambda d_\lambda+\left(\upsilon^i\partial_i+\sum_{0<|\Lambda|}d_\Lambda\upsilon^i\partial^\Lambda_i\right),\quad \upsilon^i=\vartheta^i-y^i_\mu\vartheta^\mu,\tag{20}$$

relative to the canonical connection $\nabla=dx^\lambda\otimes d_\lambda$ on the $C^\infty(X)$-ring $\mathcal{O}^0_\infty Y$.[5,12] Its vertical part ϑ_V is completely determined by the first summand

$$\upsilon=\upsilon^i(x^\lambda,y^i_\Lambda)\partial_i,\quad 0\leqslant|\Lambda|\leqslant k.\tag{21}$$

This is a section of the pull-back $VY\underset{Y}{\times}J^kY\to J^kY$ of the vertical tangent bundle $VY\to Y$ onto J^kY,[13] i.e., υ (21) is a k-order VY-valued differential operator on Y (see Appendix A). One calls this differential operator the *generalized vector field* on Y.

Proposition 3: It follows from the splitting (15) that the Lie derivative of a Lagrangian L (4) along a contact derivation ϑ (20) fulfills the first variational formula

$$\mathbf{L}_\vartheta L=\upsilon\rfloor\delta L+d_H(h_0(\vartheta\rfloor\Xi_L))+\mathcal{L}d_V(\vartheta_H\rfloor\omega),\tag{22}$$

where Ξ_L is a Lepagean equivalent of L.[4]

A contact derivation ϑ (20) is called variational if the Lie derivative (22) is d_H-exact, i.e., $\mathbf{L}_\vartheta L=d_H\sigma$, $\sigma\in\mathcal{O}^{0,n-1}_\infty$. A glance at the expression (22) shows that: (i) a contact derivation ϑ is variational only if it is projected onto X (i.e., its components ϑ^λ depend only on coordinates on X), (ii) ϑ is variational iff its vertical part ϑ_V is variational, (iii) it is variational if $\upsilon\rfloor\delta L$ is d_H-exact.

By virtue of item (ii), we can restrict our consideration to vertical contact derivations $\vartheta=\vartheta_V$. A generalized vector field υ (21) is called a *variational symmetry* of a Lagrangian L if it generates a variational vertical contact derivation.

One can also consider locally variational contact derivations when the Lie derivative (22) is δ-closed, but any locally variational gauge symmetry is always variational (see Remark 1 in the following).

Turn now to the notion of a gauge symmetry. A Lagrangian system on a fiber bundle $Y \to X$ is said to be a gauge theory if its Lagrangian L admits a family of variational symmetries parametrized by elements of a vector bundle $E \to Y$ as follows.

Let $E \to Y$ be a vector bundle coordinated by (x^λ, y^i, ξ^r). Given a Lagrangian L on Y, let us consider its pull-back, say again L, onto E. Let ϑ_E be a vertical contact derivation of the $\mathbb{R}$-ring $\mathcal{O}^0_\infty E$ whose restriction

$$\vartheta = \vartheta_E|_{\mathcal{O}^0_\infty Y} = \sum_{0 \leqslant |\Lambda|} d_\Lambda v^i \partial^\Lambda_i \tag{23}$$

to $\mathcal{O}^0_\infty Y \subset \mathcal{O}^0_\infty E$ is linear in coordinates ξ^r_Ξ. It is determined by a generalized vector field (i.e., a VE-valued differential operator) v_E on E whose canonical projection

$$v: J^k E \overset{v_E}{\to} VE \to E \underset{Y}{\times} VY$$

[see the exact sequence (35) below] is a linear VY-valued differential operator

$$v = \sum_{0 \leqslant |\Xi| \leqslant m} v^{i,\Xi}_r(x^\lambda, y^i_\Sigma) \xi^r_\Xi \partial_i \tag{24}$$

on E. Let ϑ_E be a variational symmetry of a Lagrangian L on E, i.e.,

$$v_E \rfloor \delta L = v \rfloor \delta L = d_H \sigma. \tag{25}$$

Then one says that v (24) is a *gauge symmetry* of a Lagrangian L on Y.

Remark 1: As was mentioned above, any locally variational gauge symmetry ϑ_E, when the Lie derivative $\mathbf{L}_{\vartheta_E} L$ is δ-closed, is variational. By virtue of Theorem 1, $\mathbf{L}_{\vartheta_E} L$ takes the form (14) where ψ is a closed form on E. Since $E \to Y$ is a vector bundle, Y is a strong deformation retract of E and, consequently, the de Rham cohomology of E equals that of Y. Then any closed form on E is the sum of the pull-back of a closed form on Y and an exact form on E. The former is independent of fiber coordinates ξ^r on $E \to Y$. Since the Lie derivative $\mathbf{L}_\vartheta L$ is linear in ξ^r_Λ, it is always d_H-exact, i.e., ϑ_E is variational.

III. NOETHER'S SECOND THEOREM I

Let us start with the notion of the Noether identity.

Definition 4: Given a Lagrangian L (4) and its Euler–Lagrange operator δL (12), let $E \to Y$ be a vector bundle and Δ a linear differential operator of order $0 \leqslant m$ on the vector bundle (13) with the values in the density-dual $\overline{E}^*$ (1) of E such that

$$\Delta \circ \delta L = 0. \tag{26}$$

This condition is called the *Noether identity*, and Δ is the *Noether operator*.

Given bundle coordinates $(x^\lambda, y^i, \overline{y_i})$ on the fiber bundle (13) and (x^λ, y^i, ξ^r) on E, a Noether operator Δ in Definition 4 is represented by the density

$$\Delta = \Delta_r \xi^r \omega = \sum_{0 \leqslant |\Lambda| \leqslant m} \Delta^{i,\Lambda}_r(x^\lambda, y^j_\Sigma) \overline{y}_{\Lambda i} \xi^r \omega \in \mathcal{O}^{0,n}_\infty [E \underset{Y}{\times} V^* Y], \quad 0 \leqslant |\Sigma| \leqslant m, \tag{27}$$

(see Appendix A). Then the Noether identity (26) takes the coordinate form

$$\left[\sum_{0 \leqslant |\Lambda| \leqslant m} \Delta^{i,\Lambda}_r d_\Lambda \mathcal{E}_i \right] \xi^r \omega = 0, \tag{28}$$

where $\mathcal{E}_i$ are variational derivatives (12).

Remark 2: We further use the relations

$$\sum_{0\leqslant|\Lambda|\leqslant k} B^\Lambda d_\Lambda A' = \sum_{0\leqslant|\Lambda|\leqslant k} (-1)^{|\Lambda|} d_\Lambda(B^\Lambda) A' + d_H\sigma, \tag{29}$$

$$\sum_{0\leqslant|\Lambda|\leqslant k} (-1)^{|\Lambda|} d_\Lambda(B^\Lambda A) = \sum_{0\leqslant|\Lambda|\leqslant k} \eta(B)^\Lambda d_\Lambda A, \tag{30}$$

$$\eta(B)^\Lambda = \sum_{0\leqslant|\Sigma|\leqslant k-|\Lambda|} (-1)^{|\Sigma+\Lambda|} C^{|\Sigma|}_{|\Sigma+\Lambda|} d_\Sigma B^{\Sigma+\Lambda}, \quad C^a_b = \frac{b!}{a!(b-a)!}, \tag{31}$$

$$(\eta\circ\eta)(B)^\Lambda = B^\Lambda, \tag{32}$$

for any exterior forms $A'\in\mathcal{O}^{*,n}_\infty Z$, $A\in\mathcal{O}^*_\infty z$ and any local function $B^\Lambda\in\mathcal{O}^0_\infty Z$ on jet manifolds of a fiber bundle $Z\to X$.

Theorem 5: If a Lagrangian L (4) admits a gauge symmetry υ (24), its Euler–Lagrange operator obeys the Noether identity (28) where

$$\Delta^{i,\Lambda}_r = \eta(\upsilon)^{i,\Lambda}_r = \sum_{0\leqslant|\Sigma|\leqslant m-|\Lambda|} (-1)^{|\Sigma+\Lambda|} C^{|\Sigma|}_{|\Sigma+\Lambda|} d_\Sigma \upsilon^{i,\Sigma+\Lambda}_r. \tag{33}$$

Conversely, if the Euler–Lagrange operator of a Lagrangian L obeys the Noether identity (28), this Lagrangian admits a gauge symmetry υ (24) where

$$\upsilon^{i,\Lambda}_r = \eta(\Delta)^{i,\Lambda}_r = \sum_{0\leqslant|\Sigma|\leqslant m-|\Lambda|} (-1)^{|\Sigma+\Lambda|} C^{|\Sigma|}_{|\Sigma+\Lambda|} d_\Sigma \Delta^{i,\Sigma+\Lambda}_r. \tag{34}$$

The relations (2) hold.

Proof: Given a differential operator υ (24), the operator $\Delta=\eta(\upsilon)$ expressed in the coordinate form (33) is defined in accordance with Theorem 16. Since the density

$$\upsilon \rfloor \delta L = \upsilon^i \mathcal{E}_i\omega = \sum_{0\leqslant|\Xi|\leqslant m} \upsilon^{i,\Xi}_r \xi^r_\Xi \mathcal{E}_i\omega$$

is d_H-exact, the Noether identity

$$\delta(\upsilon \rfloor \delta L) = \eta(\upsilon)\circ\delta L = 0$$

holds. Conversely, any Noether operator Δ (27) defines the VY-valued differential operator $\upsilon=\eta(\Delta)$ on E expressed in the coordinate form (34). This differential operator gives rise to a VE-valued differential operator (i.e., a generalized vector field) υ_E on E and, thus, defines a contact derivation ϑ_E of $\mathcal{O}^0_\infty E$. Indeed, let us consider the exact sequence of vector bundles

$$0\to V_Y E\to VE\to E\underset{Y}{\times} VY\to 0, \tag{35}$$

where $V_Y E$ is the vertical tangent bundle of $E\to Y$. Any splitting Γ of this exact sequence lifts υ to the generalized vector field $\upsilon_E=\Gamma\circ\upsilon$ on E, but the Lie derivative $\mathbf{L}_{\vartheta_E}L$ is independent of the choice of a splitting Γ. Due to the Noether identity (28), we obtain

$$\begin{aligned} 0 &= \sum_{0\leqslant|\Lambda|\leqslant m} \xi^r \Delta^{i,\Lambda}_r d_\Lambda \mathcal{E}_i\omega = \sum_{0\leqslant|\Lambda|\leqslant m} (-1)^{|\Lambda|} d_\Lambda(\xi^r\Delta^{i,\Lambda}_r)\mathcal{E}_i\omega + d_H\sigma \\ &= \sum_{0\leqslant|\Xi|\leqslant m} \upsilon^{i,\Xi}_r \xi^r_\Xi \mathcal{E}_i\omega + d_H\sigma = \upsilon\rfloor\delta L + d_H\sigma, \end{aligned}$$

i.e., υ is a gauge symmetry of L. Due to the equality (32), the relations (2) hold.

Example 3: If a gauge symmetry

$$v = (v_r^i \xi^r + v_r^{i,\mu} \xi_\mu^r)\partial_i \tag{36}$$

is of first jet order in parameters, the corresponding Noether operator and Noether identity read

$$\Delta_r^i = v_r^i - d_\mu v_r^{i,\mu}, \quad \Delta_r^{i,\mu} = -v_r^{i,\mu}, \tag{37}$$

$$[v_r^i \mathcal{E}_i - d_\mu (v_r^{i,\mu} \mathcal{E}_i)]\xi^r \omega = 0. \tag{38}$$

Any Lagrangian L has gauge symmetries. In particular, there always exist trivial gauge symmetries

$$v = \sum_\Lambda \eta(M)_r^{i,\Lambda} \xi_\Lambda^r, \quad M_r^{i,\Lambda} = \sum_\Sigma T^{i,j,\Lambda,\Sigma} d_\Sigma \mathcal{E}_j, \quad T_r^{j,i,\Lambda,\Sigma} = -T_r^{i,j,\Sigma,\Lambda},$$

corresponding to the trivial Noether identity

$$\sum_{\Sigma,\Lambda} T_r^{j,i,\Lambda,\Sigma} d_\Sigma \mathcal{E}_j d_\Lambda \mathcal{E}_i = 0.$$

Furthermore, given a gauge symmetry v (24), let h be a linear differential operator on some vector bundle $E' \to Y$, coordinated by (x^λ, y^i, ξ'^s), with values in the vector bundle E. Then the composition

$$v_0' = v \circ h = v_s'^{i,\Lambda} \xi_\Lambda'^s \partial_i, \quad v_s'^{i,\Lambda} = \sum_{\Xi+\Xi'=\Lambda} \sum_{0 \leqslant |\Sigma| \leqslant m-|\Xi|} v_r^{i,\Xi+\Sigma} d_\Sigma h_s^{r,\Xi'},$$

is a variational symmetry of the pull-back onto E' of a Lagrangian L on Y, i.e., a gauge symmetry of L. In view of this ambiguity, we agree to say that a gauge symmetry v (24) of a Lagrangian L is complete if a different gauge symmetry v_0' of L factors through v as

$$v_0' = v \circ h + T, \quad T \approx 0.$$

A complete gauge symmetry always exists, but the vector bundle of its parameters need not be finite-dimensional.

Accordingly, given the Noether operator (27), let H be a linear differential operator on $\overline{E}^*$ with values in the density-dual $\overline{E'}^*$ (1) of some vector bundle $E' \to Y$. Then the composition $\Delta' = H \circ \Delta$ is also a Noether operator. We agree to call the Noether operator (27) complete if a different Noether operator Δ' factors through Δ as

$$\Delta' = H \circ \Delta + F, \quad F \approx 0.$$

Proposition 6: A gauge symmetry v of a Lagrangian L is complete iff so is the associated Noether operator.

Proof: The proof follows at once from Proposition 17 in Appendix A. Given a gauge symmetry v of L, let v_0' be a different gauge symmetry. If $\eta(v)$ is a complete Noether operator, then

$$\eta(v_0') = H \circ \eta(v) + F, \quad F \approx 0,$$

and, by virtue of the relations (3), we have

$$v_0' = v \circ \eta(H) + \eta(F),$$

where $\eta(F) \approx 0$ because I_L is a differential ideal. The converse is similarly proved.

Example 4: Let us consider the gauge theory of principal connections on a principal bundle $P \to X$ with a structure Lie group G.[12] These connections are represented by sections of the quotient

$$C = J^1P/G \to X, \tag{39}$$

called the bundle of principal connections. This is an affine bundle coordinated by (x^λ, a^r_λ) such that, given a section A of $C \to X$, its components $A^r_\lambda = a^r_\lambda \circ A$ are coefficients of the familiar local connection form (i.e., gauge potentials). Let $J^\infty C$ be the infinite order jet manifold of $C \to X$ coordinated by $(x^\lambda, a^r_{\Lambda\lambda})$, $0 \leqslant |\Lambda|$. We consider the GDA $\mathcal{O}^*_\infty C$. Infinitesimal generators of local one-parameter groups of automorphisms of a principal bundle P are G-invariant projectable vector fields on $P \to X$. They are associated to sections of the vector bundle $T_G P = TP/G \to X$. This bundle is endowed with the coordinates $(x^\lambda, \tau^\lambda = \dot{x}^\lambda, \xi^r)$ with respect to the fiber bases $\{\partial_\lambda, e_r\}$ for $T_G P$, where $\{e_r\}$ is the basis for the right Lie algebra $\mathfrak{g}$ of G such that $[e_p, e_q] = c^r_{pq} e_r$. If

$$u = u^\lambda \partial_\lambda + u^r e_r, \quad v = v^\lambda \partial_\lambda + v^r e_r, \tag{40}$$

are sections of $T_G P \to X$, their bracket reads

$$[u,v] = (u^\mu \partial_\mu v^\lambda - v^\mu \partial_\mu u^\lambda)\partial_\lambda + (u^\lambda \partial_\lambda v^r - v^\lambda \partial_\lambda u^r + c^r_{pq} u^p v^q) e_r. \tag{41}$$

Any section u of the vector bundle $T_G P \to X$ yields the vector field

$$u_C = u^\lambda \partial_\lambda + (c^r_{pq} a^p_\lambda u^q + \partial_\lambda u^r - a^r_\mu \partial_\lambda u^\mu)\partial^\lambda_r \tag{42}$$

on the bundle of principal connections C (39). It is an infinitesimal generator of a one-parameter group of automorphisms of C.[12] Let us consider the bundle product

$$E = C \underset{X}{\times} T_G P, \tag{43}$$

coordinated by $(x^\lambda, \tau^\lambda, \xi^r, a^r_\lambda)$. It can be provided with the generalized vector field

$$v_E = v = (c^r_{pq} a^p_\lambda \xi^q + \xi^r_\lambda - a^r_\mu \tau^\mu_\lambda - \tau^\mu a^r_{\mu\lambda})\partial^\lambda_r. \tag{44}$$

For instance, this is a gauge symmetry of the global Chern–Simons Lagrangian.[14] Let us consider a subbundle $V_G P = VP/G \to X$ of the vector bundle $T_G X$ coordinated by (x^λ, ξ^r). Its sections $u = u^r e_r$ are infinitesimal generators of vertical automorphisms of P. Let us restrict the bundle product (43) to

$$E = C \underset{X}{\times} V_G P. \tag{45}$$

It is provided with the generalized vector field

$$v_E = v = (c^r_{pq} a^p_\lambda \xi^q + \xi^r_\lambda)\partial^\lambda_r. \tag{46}$$

This is a gauge symmetry of the Yang–Mills Lagrangians,[14] and yields the well-known Noether identity

$$[c^r_{pq} a^p_\lambda \mathcal{E}^\lambda_r - d_\lambda(\mathcal{E}^\lambda_q)]\xi^q \omega = 0.$$

IV. REDUCIBLE GAUGE THEORIES

Recall that the notion of a reducible Noether identity has come from that of a reducible constraint,[15] but it involves differential relations.

Definition 7: A complete Noether operator $\Delta \neq 0$ (27) and the corresponding Noether identity (26) are said to be *N-stage reducible* ($N = 0, 1, \ldots$) if there exist vector bundles $E_k \to Y$ and differential operators Δ_k, $k = 0, \ldots, N$, such that:

(i) Δ_k is a linear differential operator on the density-dual $\overline{E^*_{k-1}}$ of E_{k-1} with values in the density-dual $\overline{E^*_k}$ of E_k, where $E_{-1} = E$;
(ii) $\Delta_k \neq 0$ for all $k = 0, \ldots, N$;

(iii) $\Delta_k \circ \Delta_{k-1} \approx 0$ for all $k=0,\ldots,N$, where $\Delta_{-1}=\Delta$;
(iv) if Δ'_k is another differential operator possessing these properties, then it factors through Δ_k on-shell.

In particular, a zero-stage reducible Noether operator is called reducible. In this case, given bundle coordinates $(x^\lambda, y^i, \overline{\xi_r})$ on $\overline{E^*}$ and $(x^\lambda, y^i, \xi^{r_0})$ on E_0, a differential operator Δ_0 reads

$$\Delta_0 = \sum_{0\leqslant|\Xi|\leqslant m_0} \Delta^{r,\Xi}_{r_0} \overline{\xi_{\Xi r}} \xi^{r_0}\omega. \tag{47}$$

Then the reduction condition $\Delta_0 \circ \Delta \approx 0$ takes the coordinate form

$$\sum_{0\leqslant|\Xi|\leqslant m_0} \Delta^{r,\Xi}_{r_0} d_\Xi \left(\sum_{0\leqslant|\Lambda|\leqslant m} \Delta^{i,\Lambda}_r \overline{y_{\Lambda i}} \right) \xi^{r_0}\omega \approx 0, \tag{48}$$

i.e., the left-hand side of this expression takes the form

$$\sum_{0\leqslant|\Sigma|\leqslant m_0+m} M^{i,\Sigma}_{r_0} \overline{y_{\Sigma i}} \xi^{r_0} \otimes \omega,$$

where all the coefficients $M^{i,\Sigma}_{r_0}$ belong to the ideal I_L.

Definition 8: A complete gauge symmetry $v \not\approx 0$ (24) is said to be N-stage reducible if there exist vector bundles E_k and differential operators v^k, $k=0,\ldots,N$, such that:

(i) v^k is a linear differential operator on the vector bundle E_k with values in the vector bundle E_{k-1};
(ii) $v_k \not\approx 0$ for all $k=0,\ldots,N$;
(iii) $v^{k-1} \circ v^k \approx 0$ for all $k=0,\ldots,N$, where v^k, $k=-1$, stands for v;
(iv) if v'^k is another differential operator possessing these properties, then v^k factors through v'^k on-shell.

Theorem 9: A gauge symmetry v is N-stage reducible iff so is the associated Noether identity.

Proof: The proof follows at once from Theorem 16 and Proposition 17. Let us put $\Delta_k = \eta(v^k)$, $k=0,\ldots,N$. If $v^k \approx 0$, then $\eta(v^k) \approx 0$ because I_L is a differential ideal. By the same reason, if v^{k-1} and v^k obey the reduction condition $v^{k-1} \circ v^k \approx 0$, then

$$\eta(v^{k-1} \circ v^k) = \eta(v^k) \circ \eta(v^{k-1}) \approx 0.$$

The converse is justified in the same way. The equivalence of the conditions in items (iv) of Definitions 7 and 8 is proved similarly to that in Proposition 6.

V. GRADED LAGRANGIAN SYSTEMS

Recall that, by virtue of Batchelor's theorem,[16] any graded manifold $(\mathcal{U}, X)$ with a body X is isomorphic to the one whose structure sheaf $\mathcal{U}_Q$ is formed by germs of sections of the exterior product

$$\wedge Q^* = \mathbb{R} \underset{X}{\oplus} Q^* \underset{X}{\oplus} \overset{2}{\wedge} Q^* \underset{X}{\oplus} \cdots, \tag{49}$$

where Q^* is the dual of some real vector bundle $Q \to X$ of fiber dimension m. In field models, a vector bundle Q is usually given from the beginning. Therefore, we consider graded manifolds $(X, \mathcal{U}_Q)$ where Batchelor's isomorphism is fixed, and call $(X, \mathcal{U}_Q)$ the simple graded manifold constructed from Q. The structure ring $\mathcal{A}_Q$ of sections of $\mathcal{U}_Q$ consists of sections of the exterior bundle (49) called graded functions. Given bundle coordinates (x^λ, q^a) on Q with transition functions $q'^a = \rho^a_b q^b$, let $\{c^a\}$ be the corresponding fiber bases for $Q^* \to X$, together with transition functions $c'^a = \rho^a_b c^b$. Then (x^λ, c^a) is called the local basis for the graded manifold $(X, \mathcal{U}_Q)$. With respect to this basis, graded functions read

$$f = \sum_{k=0}^{m} \frac{1}{k!} f_{a_1 \cdots a_k} c^{a_1} \cdots c^{a_k},$$

where $f_{a_1 \cdots a_k}$ are local smooth real functions on X, and we omit the symbol of the exterior product of elements c^a.

Given a graded manifold $(X, \mathcal{U}_Q)$, let $\mathfrak{d}\mathcal{A}_Q$ be the $\mathcal{A}_Q$-module of $\mathbb{Z}_2$-graded derivations of the $\mathbb{Z}_2$-graded ring of $\mathcal{A}_Q$, i.e.,

$$u(ff') = u(f)f' + (-1)^{[u][f]} f u(f'), \quad u \in \mathfrak{d}\mathcal{A}_Q, \quad f, f' \in \mathcal{A}_Q,$$

where $[.]$ denotes the Grassmann parity. Its elements are called $\mathbb{Z}_2$-graded (or, simply, graded) vector fields on $(X, \mathcal{U}_Q)$. Due to the canonical splitting $VQ = Q \times Q$, the vertical tangent bundle $VQ \to Q$ of $Q \to X$ can be provided with the fiber bases $\{\partial_a\}$ which is the dual of $\{c^a\}$. Then a graded vector field takes the local form $u = u^\lambda \partial_\lambda + u^a \partial_a$, where u^λ, u^a are local graded functions. It acts on $\mathcal{A}_Q$ by the rule

$$u(f_{a \ldots b} c^a \cdots c^b) = u^\lambda \partial_\lambda (f_{a \ldots b}) c^a \cdots c^b + u^d f_{a \ldots b} \partial_d \rfloor (c^a \cdots c^b). \tag{50}$$

This rule implies the corresponding transformation law

$$u'^\lambda = u^\lambda, \quad u'^a = \rho^a_j u^j + u^\lambda \partial_\lambda (\rho^a_j) c^j.$$

Then one can show[5,12] that graded vector fields on a simple graded manifold can be represented by sections of the vector bundle $\mathcal{V}_Q \to X$ which is locally isomorphic to the vector bundle $\wedge Q^* \otimes_X (Q \oplus_X TX)$.

Using this fact, we can introduce graded exterior forms on the simple graded manifold $(X, \mathcal{U}_Q)$ as sections of the exterior bundle $\wedge \mathcal{V}^*_Q$, where $\mathcal{V}^*_Q \to X$ is the $\wedge Q^*$-dual of $\mathcal{V}_Q$. They are characterized both by the Grassmann parity and the familiar form degree. Relative to the dual local bases $\{dx^\lambda\}$ for T^*X and $\{dc^b\}$ for Q^*, graded one-forms read

$$\phi = \phi_\lambda dx^\lambda + \phi_a dc^a, \quad \phi'_a = \rho^{-1b}_a \phi_b, \quad \phi'_\lambda = \phi_\lambda + \rho^{-1b}_a \partial_\lambda (\rho^a_j) \phi_b c^j,$$

where dx^λ are even and dc^b are odd. The duality morphism is given by the interior product

$$u \rfloor \phi = u^\lambda \phi_\lambda + (-1)^{[\phi_a]} u^a \phi_a.$$

Graded exterior forms constitute the bigraded differential algebra (henceforth BGDA) $\mathcal{C}^*_Q$ with respect to the bigraded exterior product

$$\phi \wedge \phi' = (-1)^{|\phi||\phi'| + [\phi][\phi']} \phi' \wedge \phi, \quad \phi, \phi' \in \mathcal{C}^*_Q,$$

and the exterior differential

$$d(\phi \wedge \phi') = d\phi \wedge \phi' + (-1)^{|\phi|} \phi \wedge d\phi', \quad \phi, \phi' \in \mathcal{C}^*_Q.$$

Since the jet bundle $J^r Q \to X$ of a vector bundle $Q \to X$ is a vector bundle, let us consider the simple graded manifold $(X, \mathcal{U}_{J^r Q})$ constructed from $J^r Q \to X$. Its local basis is $\{x^\lambda, c^a_\Lambda\}$, $0 \leq |\Lambda| \leq r$, together with the transition functions

$$c'^a_{\lambda+\Lambda} = d_\lambda (\rho^a_j c^j_\Lambda), \quad d_\lambda = \partial_\lambda + \sum_{|\Lambda| < r} c^a_{\lambda+\Lambda} \partial^\Lambda_a, \tag{51}$$

where the graded derivations ∂^Λ_a are the duals of c^a_Λ. Let $\mathcal{C}^*_{J^r Q}$ be the BGDA of graded exterior forms on the graded manifold $(X, \mathcal{U}_{J^r Q})$. A linear bundle morphism $\pi^r_{r-1} : J^r Q \to J^{r-1} Q$ yields the corresponding monomorphism of BGDAs $\mathcal{C}^*_{J^{r-1} Q} \to \mathcal{C}^*_{J^r Q}$. Hence, there is the direct system of BGDAs

$$\mathcal{C}^*_Q \xrightarrow{\pi_0^{1*}} \mathcal{C}^*_{J^1Q} \cdots \xrightarrow{\pi_{r-1}^{r*}} \mathcal{C}^*_{J^rQ} \to \cdots. \tag{52}$$

Its direct limit $\mathcal{C}^*_\infty Q$ consists of graded exterior forms on graded manifolds $(X, \mathcal{U}_{J^rQ})$, $r \in \mathbb{N}$, modulo the pull-back identification, and it inherits the BGDA operations intertwined by the monomorphisms π^{r*}_{r-1}. It is locally a free $C^\infty(X)$-algebra locally generated by the elements $(1, c^a_\Lambda, dx^\lambda, \theta^a_\Lambda = dc^a_\Lambda - c^a_{\lambda+\Lambda} dx^\lambda)$, $0 \leqslant |\Lambda|$, where c^a_Λ and θ^a_Λ are odd.

In order to regard even and odd dynamic variables on the same footing, let $Y \to X$ hereafter be an affine bundle, and let $\mathcal{P}^*_\infty Y \subset \mathcal{O}^*_\infty Y$ be the $C^\infty(X)$-subalgebra of exterior forms whose coefficients are polynomial in the fiber coordinates on jet bundles $J^rY \to X$. This notion is intrinsic since any element of $\mathcal{O}^*_\infty Y$ is an exterior form on some finite order jet manifold and all jet bundles $J^rY \to X$ are affine. One can think of the GDA $\mathcal{P}^*_\infty Y$ as being the BGDA whose elements are even. Let us consider the product

$$\mathcal{S}^*_\infty[Q;Y] = \mathcal{C}^*_\infty Q \wedge \mathcal{P}^*_\infty Y \tag{53}$$

of bigraded algebras $\mathcal{C}^*_\infty Q$ and $\mathcal{P}^*_\infty Y$ over their common graded subalgebra $\mathcal{O}^*X$ of exterior forms on X.[4] It consists of the elements

$$\sum_i \psi_i \otimes \phi_i, \quad \sum_i \phi_i \otimes \psi_i, \quad \psi \in \mathcal{C}^*_\infty Q, \quad \phi \in \mathcal{P}^*_\infty Y,$$

modulo the commutation relations

$$\begin{gathered} \psi \otimes \phi = (-1)^{|\psi||\phi|} \phi \otimes \psi, \quad \psi \in \mathcal{C}^*_\infty Q, \quad \phi \in \mathcal{P}^*_\infty Y, \\ (\psi \wedge \sigma) \otimes \phi = \psi \otimes (\sigma \wedge \phi), \quad \sigma \in \mathcal{O}^*X. \end{gathered} \tag{54}$$

These elements are endowed with the total form degree $|\psi \otimes \phi| = |\psi| + |\phi|$ and the total Grassmann parity $[\psi \otimes \phi] = [\psi]$. Their multiplication

$$(\psi \otimes \phi) \wedge (\psi' \otimes \phi') := (-1)^{|\psi'||\phi|} (\psi \wedge \psi') \otimes (\phi \wedge \phi') \tag{55}$$

obeys the relation

$$\varphi \wedge \varphi' = (-1)^{|\varphi||\varphi'| + [\varphi][\varphi']} \varphi' \wedge \varphi, \quad \varphi, \varphi' \in \mathcal{S}^*_\infty[Q;Y],$$

and makes $\mathcal{S}^*_\infty[Q;Y]$ (53) into a bigraded $C^\infty(X)$-algebra. For instance, elements of the ring $\mathcal{S}^0_\infty[Q;Y]$ are polynomials of odd c^a_Λ and even y^i_Λ with coefficients in $C^\infty(X)$.

The algebra $\mathcal{S}^*_\infty[Q;Y]$ is provided with the exterior differential

$$d(\psi \otimes \phi) := (d_{\mathcal{C}} \psi) \otimes \phi + (-1)^{|\psi|} \psi \otimes (d_{\mathcal{P}} \phi), \quad \psi \in \mathcal{C}^*_\infty Q, \quad \phi \in \mathcal{P}^*_\infty Y, \tag{56}$$

where $d_{\mathcal{C}}$ and $d_{\mathcal{P}}$ are exterior differentials on the differential algebras $\mathcal{C}^*_\infty Q$ and $\mathcal{P}^*_\infty Y$, respectively. It obeys the relations

$$d(\varphi \wedge \varphi') = d\varphi \wedge \varphi' + (-1)^{|\varphi|} \varphi \wedge d\varphi', \quad \varphi, \varphi' \in \mathcal{S}^*_\infty[Q;Y],$$

and makes $\mathcal{S}^*_\infty[Q;Y]$ into a BGDA, which is locally generated by the elements

$$(1, c^a_\Lambda, y^i_\Lambda, dx^\lambda, \theta^a_\Lambda = dc^a_\Lambda - c^a_{\lambda+\Lambda} dx^\lambda, \theta^i_\Lambda = dy^i_\Lambda - y^i_{\lambda+\Lambda} dx^\lambda), \quad 0 \leqslant |\Lambda|,$$

where c^a_Λ, θ^a_Λ are odd and y^i_Λ, dx^λ, θ^i_Λ are even. The cohomology of its de Rham complex

$$0 \to \mathbb{R} \to \mathcal{S}^0_\infty[Q;Y] \xrightarrow{d} \mathcal{S}^1_\infty[Q;Y] \cdots \xrightarrow{d} \mathcal{S}^k_\infty[Q;Y] \to \cdots \tag{57}$$

equals the de Rham cohomology $H^*(X)$ of X.[4] We agree to call elements of $\mathcal{S}^*_\infty[Q;Y]$ the *graded exterior forms* on X.

Hereafter, let the collective symbols s^A_Λ and θ^A_Λ stand for both even and odd generating elements c^a_Λ, y^i_Λ, θ^a_Λ, θ^i_Λ of the $C^\infty(X)$-algebra $\mathcal{S}^*_\infty[Q;Y]$ which, thus, is locally generated by $(1, s^A_\Lambda, dx^\lambda, \theta^A_\Lambda)$, $|\Lambda| \geqslant 0$. Since $s^A_\Lambda = d_\Lambda s^A$ and $\theta^A_\Lambda = ds^A_\Lambda + s^A_{\lambda+\Lambda} dx^\lambda$, the BGDA $\mathcal{S}^*_\infty[Q;Y]$ is completely specified by the elements s^A together with their transition functions. Therefore, we agree to call $\{s^A\}$ the *local basis* for $\mathcal{S}^*_\infty[Q;Y]$.

Similarly to $\mathcal{O}^*_\infty Y$, the BGDA $\mathcal{S}^*_\infty[Q;Y]$ is decomposed into $\mathcal{S}^0_\infty[Q;Y]$-modules $\mathcal{S}^{k,r}_\infty[Q;Y]$ of k-contact and r-horizontal graded forms together with the corresponding projections h_k and h^r. Accordingly, the exterior differential d (56) on $\mathcal{S}^*_\infty[Q;Y]$ is split into the sum $d = d_H + d_V$ of the total and vertical differentials

$$d_H(\phi) = dx^\lambda \wedge d_\lambda(\phi), \quad d_V(\phi) = \theta^A_\Lambda \wedge \partial^\Lambda_A \phi, \quad \phi \in \mathcal{S}^*_\infty[Q;Y].$$

The projection endomorphism ϱ of $\mathcal{S}^*_\infty[Q;Y]$ is given by

$$\varrho = \sum_{k>0} \frac{1}{k} \overline{\varrho} \circ h_k \circ h^n, \quad \overline{\varrho}(\phi) \sum_{0 \leqslant |\Lambda|} (-1)^{|\Lambda|} \theta^A \wedge [d_\Lambda(\partial^\Lambda_A \rfloor \phi)], \quad \phi \in \mathcal{S}^{>0,n}_\infty[Q;Y],$$

similar to (9). The graded variational operator $\delta = \varrho \circ d$ is introduced. Then the BGDA $\mathcal{S}^*_\infty[Q;Y]$ is split into the $\mathbb{Z}_2$-graded variational bicomplex analogous to the above-mentioned variational bicomplex of $\mathcal{O}^*_\infty Y$.

We restrict our consideration to the short variational subcomplex

$$0 \to \mathbb{R} \to \mathcal{S}^0_\infty[Q;Y] \overset{d_H}{\to} \mathcal{S}^{0,1}_\infty[Q;Y] \cdots \overset{d_H}{\to} \mathcal{S}^{0,n}_\infty[Q;Y] \overset{\delta}{\to} \mathbf{E}_1 \tag{58}$$

and the subcomplex of one-contact graded forms

$$0 \to \mathcal{S}^{1,0}_\infty[Q;Y] \overset{d_H}{\to} \mathcal{S}^{1,1}_\infty[Q;Y] \cdots \overset{d_H}{\to} \mathcal{S}^{1,n}_\infty[Q;Y] \overset{\varrho}{\to} \mathbf{E}_1 \to 0, \tag{59}$$

of the BGDA $\mathcal{S}^*_\infty[Q;Y]$. They possess the following cohomology.[4]

Theorem 10: The cohomology of the complex (58) equals the de Rham cohomology $H^*(X)$ of X.

Theorem 11: The complex (59) is exact.

One can think of the elements

$$L = \mathcal{L}\omega \in \mathcal{S}^{0,n}_\infty[Q;Y], \quad \delta L = \theta^A \wedge \mathcal{E}_A \omega = \sum_{0 \leqslant |\Lambda|} (-1)^{|\Lambda|} \theta^A \wedge d_\Lambda(\partial^\Lambda_A L)\omega \in \mathbf{E}_1 \tag{60}$$

of the complexes (58)–(59) as being a *graded Lagrangian* and its Euler–Lagrange operator, respectively. The components $\mathcal{E}_A$ of δL are graded variational derivatives.

By virtue of Theorem 10, every δ-closed graded Lagrangian L (60) is the sum

$$\phi = \psi + d_H \xi, \quad \xi \in \mathcal{S}^{0,n-1}_\infty[Q;Y], \tag{61}$$

where ψ is a nonexact n-form on X.

The global exactness of the complex (59) at the term $\mathcal{S}^{1,n}_\infty[Q;Y]$ results in the following.[4]

Proposition 12: Given a graded Lagrangian $L = \mathcal{L}\omega$, there is the decomposition

$$dL = \delta L - d_H \Xi, \quad \Xi \in \mathcal{S}^{1,n-1}_\infty[Q;Y], \tag{62}$$

$$\Xi = \sum_{s=0} \theta^A_{\nu_s \cdots \nu_1} \wedge F^{\lambda \nu_s \cdots \nu_1}_A \omega_\lambda, \quad F^{\nu_k \cdots \nu_1}_A = \partial^{\nu_k \cdots \nu_1}_A \mathcal{L} - d_\lambda F^{\lambda \nu_k \cdots \nu_1}_A + h^{\nu_k \cdots \nu_1}_A, \tag{63}$$

where local graded functions h obey the relations $h^\upsilon_a = 0$, $h^{(\nu_k \nu_{k-1}) \cdots \nu_1}_a = 0$.

Proposition 12 states the existence of a global finite order Lepagean equivalent $\Xi_L = \Xi + L$ of any graded Lagrangian L. Locally, one can always choose Ξ (63) where all functions h vanish.

VI. BRST SYMMETRIES

A graded derivation $\vartheta \in \mathfrak{d}\mathcal{S}^0_\infty[Q;Y]$ of the $\mathbb{R}$-ring $\mathcal{S}^0_\infty[Q;Y]$ is said to be contact if the Lie derivative $\mathbf{L}_\vartheta$ preserves the ideal of contact graded forms of the BGDA $\mathcal{S}^*_\infty[Q;Y]$. With respect to the local basis $\{s^A\}$ for the BGDA $\mathcal{S}^*_\infty[Q;Y]$, any contact graded derivation takes the form

$$\vartheta = \vartheta_H + \vartheta_V = \vartheta^\lambda d_\lambda + \left(\vartheta^A \partial_A + \sum_{|\Lambda|>0} d_\Lambda \vartheta^A \partial^\Lambda_A\right), \tag{64}$$

where tuple of graded derivations $\{\partial_\lambda, \partial^\Lambda_A\}$ is defined as the dual of the tuple $\{dx^\lambda, ds^A_\Lambda\}$ of generating elements of the $\mathcal{S}^0_\infty[Q;Y]$-algebra $\mathcal{S}^*_\infty[Q;Y]$, and ϑ^λ, ϑ^A are local graded functions.[4] The interior product $\vartheta \rfloor \phi$ and the Lie derivative $\mathbf{L}_\vartheta \phi$, $\phi \in \mathcal{S}^*_\infty[Q;Y]$, are defined by the same formulas

$$\vartheta \rfloor \phi = \vartheta^\lambda \phi_\lambda + (-1)^{[\phi_A]} \vartheta^A \phi_A, \quad \phi \in \mathcal{S}^1_\infty[Q;Y],$$

$$\vartheta \rfloor (\phi \wedge \sigma) = (\vartheta \rfloor \phi) \wedge \sigma + (-1)^{|\phi|+[\phi][\vartheta]} \phi \wedge (\vartheta \rfloor \sigma), \quad \phi, \sigma \in \mathcal{S}^*_\infty[Q;Y],$$

$$\mathbf{L}_\vartheta \phi = \vartheta \rfloor d\phi + d(\vartheta \rfloor \phi), \quad \mathbf{L}_\vartheta(\phi \wedge \sigma) = \mathbf{L}_\vartheta(\phi) \wedge \sigma + (-1)^{[\vartheta][\phi]} \phi \wedge \mathbf{L}_\vartheta(\sigma),$$

as those on a graded manifold. One can justify that any vertical contact graded derivation ϑ (64) satisfies the relations

$$\vartheta \rfloor d_H \phi = -d_H(\vartheta \rfloor \phi), \quad \mathbf{L}_\vartheta(d_H \phi) = d_H(\mathbf{L}_\vartheta \phi), \quad \phi \in \mathcal{S}^*_\infty[Q;Y]. \tag{65}$$

Proposition 13: It follows from the splitting (12) that the Lie derivative $\mathbf{L}_\vartheta L$ of a Lagrangian L along a contact graded derivation ϑ (64) fulfills the first variational formula

$$\mathbf{L}_\vartheta L = \vartheta_V \rfloor \delta L + d_H(h_0(\vartheta \rfloor \Xi_L)) + d_V(\vartheta_H \rfloor \omega)\mathcal{L}, \tag{66}$$

where $\Xi_L = \Xi + L$ is a Lepagean equivalent of L given by the coordinate expression (63).[4]

A contact graded derivation ϑ is said to be variational if the Lie derivative (66) is d_H-exact. A glance at the expression (66) shows that: (i) a contact graded derivation ϑ is variational only if it is projected onto X, (ii) ϑ is variational iff its vertical part ϑ_V is variational.

Therefore, we restrict our consideration to vertical contact graded derivations

$$\vartheta = \sum_{0 \leqslant |\Lambda|} d_\Lambda v^A \partial^\Lambda_A, \tag{67}$$

where the tuple of graded derivations $\{\partial^\Lambda_A\}$ is defined as the dual of the tuple $\{\theta^\Lambda_A\}$ of contact graded forms. Such a derivation is completely determined by its first summand

$$v = v^A(x^\lambda, s^A_\Lambda)\partial_A, \quad 0 \leqslant |\Lambda| \leqslant k, \tag{68}$$

which is also a graded derivation of $\mathcal{S}^0_\infty[Q;Y]$. It is called the *generalized graded vector field.* A glance at the first variational formula (66) shows that ϑ (67) is variational iff $v \rfloor \delta L$ is d_H-exact.

A vertical contact graded derivation ϑ (67) is said to be nilpotent if

$$\mathbf{L}_v(\mathbf{L}_v \phi) = \sum_{|\Sigma| \geqslant 0, |\Lambda| \geqslant 0} \left(v^B_\Sigma \partial^\Sigma_B(v^A_\Lambda)\partial^\Lambda_A + (-1)^{[s^B][v^A]} v^B_\Sigma v^A_\Lambda \partial^\Sigma_B \partial^\Lambda_A\right)\phi = 0 \tag{69}$$

for any horizontal graded form $\phi \in \mathcal{S}^{0,*}_\infty[Q;Y]$. One can show[4] that ϑ is nilpotent only if it is odd and iff the equality

$$\mathbf{L}_\vartheta(v^A) = \sum_{|\Sigma| \geqslant 0} v^B_\Sigma \partial^\Sigma_B(v^A) = 0 \tag{70}$$

holds for all v^A.

Example 5: Let $Y \to X$ be an affine bundle, L (4) a Lagrangian of a gauge theory on Y and υ (24) its gauge symmetry where

$$E = Y \underset{X}{\times} V$$

is the pull-back onto Y of a vector bundle $V \to X$ coordinated by (x^λ, ξ^r). Let us consider the BGDA $\mathcal{S}^*_\infty[V;Y] = \mathcal{C}^*_\infty V \wedge \mathcal{P}^*_\infty Y$ possessing a local basis $\{c^r, y^i\}$. Let $L \in \mathcal{O}^{0,n}_\infty Y$ be a polynomial in y^i_Λ, $0 \leqslant |L|$. Then it is a graded Lagrangian $L \in \mathcal{P}^{0,n}_\infty Y \subset \mathcal{S}^{0,n}_\infty[V;Y]$ in $\mathcal{S}^*_\infty[V;Y]$. Since $E \to Y$ is the pull-back bundle, a gauge symmetry υ (24) gives rise to the generalized vector field $\upsilon_E = \upsilon$ on E, and the latter defines the generalized graded vector field υ (68) by the formula

$$\upsilon = \sum_{0 \leqslant |\Xi| \leqslant m} \upsilon^{i,\Xi}_r(x^\lambda, y^i_\Sigma) c^r_\Xi \partial_i. \tag{71}$$

It is easily justified that the vertical contact graded derivation ϑ (67) generated by υ (71) is variational for the graded Lagrangian L. It is odd, but need not be nilpotent. However, one can try to find a nilpotent contact graded derivation generated by some generalized graded vector field

$$\upsilon = \sum_{0 \leqslant |\Lambda| \leqslant m} \upsilon^{i,\Lambda}_r c^r_\Lambda \partial_i + u^r \partial_r \tag{72}$$

which coincides with ϑ on $\mathcal{P}^*_\infty Y$. In this case, the nilpotency conditions (70) read

$$\sum_\Sigma d_\Sigma \left(\sum_\Xi \upsilon^{i,\Xi}_r c^r_\Xi \right) \sum_\Lambda \partial^\Sigma_i (\upsilon^{j,\Lambda}_s) c^s_\Lambda + \sum_\Lambda d_\Lambda(u^r) \upsilon^{j,\Lambda}_r = 0, \tag{73}$$

$$\sum_\Lambda \left(\sum_\Xi d_\Lambda(\upsilon^{i,\Xi}_r c^r_\Xi) \partial^\Lambda_i + d_\Lambda(u^r) \partial^\Lambda_r \right) u^q = 0 \tag{74}$$

for all indices j and q. They are equations for graded functions $u^r \in \mathcal{S}^0_\infty[V;Y]$. Since these functions are polynomials

$$u^r = u^r_{(0)} + \sum_\Gamma u^{r,\Gamma}_{(1)p} c^p_\Gamma + \sum_{\Gamma_1,\Gamma_2} u^{r,\Gamma_1\Gamma_2}_{(2)p_1p_2} c^{p_1}_{\Gamma_1} c^{p_2}_{\Gamma_2} + \cdots \tag{75}$$

in c^s_Λ, Eqs. (73) and (74) take the form

$$\sum_\Sigma d_\Sigma \left(\sum_\Xi \upsilon^{i,\Xi}_r c^r_\Xi \right) \sum_\Lambda \partial^\Sigma_i (\upsilon^{j,\Lambda}_s) c^s_\Lambda + \sum_\Lambda d_\Lambda(u^r_{(2)}) \upsilon^{j,\Lambda}_r = 0, \tag{76}$$

$$\sum_\Lambda d_\Lambda(u^r_{(k\neq 2)}) \upsilon^{j,\Lambda}_r = 0, \tag{77}$$

$$\sum_\Lambda \sum_\Xi d_\Lambda(\upsilon^{i,\Xi}_r c^r_\Xi) \partial^\Lambda_i u^q_{(k-1)} + \sum_{m+n-1=k} d_\Lambda(u^r_{(m)}) \partial^\Lambda_r u^q_{(n)} = 0. \tag{78}$$

One can think of equalities (76) and (78) [and, consequently, the nilpotency conditions (73) and (74)] as being the generalized commutation relations and generalized Jacobi identities of gauge transformations, respectively.[17] For instance, let us consider a gauge system on a principal bundle and the generalized vector field υ (44) in Example 4. Following the procedure above, we replace parameters ξ^r and τ^λ with the odd ghosts C^r and C^λ, respectively, and obtain the generalized graded vector field

$$v = (c^r_{pq} a^p_\lambda C^q + C^r_\lambda - a^r_\mu C^\mu_\lambda - C^\mu a^r_{\mu\lambda})\partial^\lambda_r + \left(-\tfrac{1}{2} c^r_{pq} C^p C^q - C^\mu C^r_\mu\right)\partial_r + C^\lambda_\mu C^\mu \partial_\lambda \tag{79}$$

such that the vertical contact graded derivation (67) generated by v (79) is nilpotent. In the case of the vertical gauge symmetry (46), we obtain the familiar BRST transformation

$$v = (c^r_{pq} a^p_\lambda C^q + C^r_\lambda)\partial^\lambda_r - \tfrac{1}{2} c^r_{pq} C^p C^q \partial_r \tag{80}$$

of Yang–Mills theory.

Generalizing Example 5, we describe BRST symmetries in a general setting as follows.

Let $\mathcal{S}^*_\infty[Q;Y]$ be the BGDA (53) and $L \in \mathcal{S}^{0,n}_\infty[Q;Y]$ a graded Lagrangian. We agree to call generating elements s^A of $\mathcal{S}^*_\infty[Q;Y]$ the fields. Let $V \to X$ be a vector bundle coordinated by (x^λ, ξ^r). By analogy with $\mathcal{S}^*_\infty[Q;Y]$, we consider the BGDA,

$$\mathcal{S}^*_\infty[QV;Y] = \mathcal{C}^*_\infty[Q \underset{X}{\times} V] \wedge \mathcal{P}^*_\infty Y, \tag{81}$$

whose local basis is $\{s^A, c^r\}$. Obviously, L is also a graded Lagrangian in $\mathcal{S}^*_\infty[QV;Y]$. Let

$$\vartheta = \sum_{0 \leqslant |\Lambda|} (d_\Lambda v^A \partial^\Lambda_A + d_\Lambda v^r \partial^\Lambda_r) \tag{82}$$

be a graded contact derivation of the $\mathbb{R}$-ring $\mathcal{S}^0_\infty[QV;Y]$ generated by an odd generalized graded vector field

$$v = v^A \partial_A + v^r \partial_r \tag{83}$$

whose restriction to $\mathcal{S}^*_\infty[Q;Y]$ is linear in c^r_Λ, i.e.,

$$v = \sum_{0 \leqslant |\Xi| \leqslant m} c^r_\Xi v^{A,\Xi}_r(x^\lambda, s^B_\Sigma)\partial_A + v^r \partial_r. \tag{84}$$

If ϑ (82) is variational for L and nilpotent, we say that v (84) is a *BRST symmetry* of L. Following the terminology of BRST theory, we agree to call generating elements c^r of $\mathcal{S}^*[QV;Y]$ the *ghosts.*

VII. NOETHER'S SECOND THEOREM II

In order to introduce Noether identities in the case of BRST symmetries, let us extend the BGDA $\mathcal{S}^*[QV;Y]$ (81) to the BGDA

$$S^*_\infty[Q\overline{Y^*}V; Y\overline{Q^*}] = \mathcal{C}^*_\infty[Q \underset{X}{\times} \overline{Y^*} \underset{X}{\times} V] \wedge \mathcal{P}^*_\infty[Y \underset{X}{\times} \overline{Q^*}], \tag{85}$$

where $\overline{Q^*}$ is the density-dual of Q and $\overline{Y^*}$ is the density dual of the vector bundle $\widetilde{Y} \to X$ which the affine bundle Y is modeled on (e.g., $\widetilde{Y} = Y$ if Y is a vector bundle). The local basis for the BGDA $\mathcal{S}^*_\infty[Q\overline{Y^*}V; Y\overline{Q^*}]$ is $\{s^A, c^r, \overline{s_A}\}$. Following the terminology of the field–antifield BRST theory, we call generating elements $\overline{s_A}$ of $\mathcal{S}^*_\infty[Q\overline{Y^*}V; Y\overline{Q^*}]$ the *antifields*. Their Grassmann parity is $[\overline{s_A}] = ([s^A]+1) \bmod 2$.

The BGDA $\mathcal{S}^*_\infty[Q\overline{Y^*}V; Y\overline{Q^*}]$ (85) is provided with the *Koszul–Tate differential* defined as the nilpotent contact graded derivation

$$\overline{\delta} = \sum_{0 \leqslant |\Lambda|} \overleftarrow{\partial}^{\Lambda A} d_\Lambda \mathcal{E}_A, \tag{86}$$

where $\mathcal{E}_A$ are the graded variational derivatives (60) and the tuple of graded right derivations $\overleftarrow{\partial}^{\Lambda A}$ is the dual of the tuple of contact graded forms $\{\theta_{\Lambda A}\}$, i.e.,

$$\theta_{\Lambda A}\rfloor\overleftarrow{\partial}^{\Sigma B} = \delta^{\Sigma}_{\Lambda}\delta^{A}_{B},$$

where multi-indices Σ and Λ are regard modulo permutations. Because of the expression (60) for δL, it is convenient to describe the Koszul–Tate differential as a graded derivation acting on graded functions and forms ϕ on the right by the rule

$$\overline{\delta}(\phi) = \mathrm{d}\phi\rfloor\overline{\delta} + \mathrm{d}(\phi\rfloor\overline{\delta}), \quad \overline{\delta}(\phi\wedge\phi') = (-1)^{[\phi']}\overline{\delta}(\phi)\wedge\phi' + \phi\wedge\overline{\delta}(f').$$

Definition 14: Given a graded Lagrangian $L\in\mathcal{S}^{*}_{\infty}[Q;Y]\subset\mathcal{S}^{*}_{\infty}[Q\overline{Y^{*}}V;Y\overline{Q^{*}}]$ (60), we say that its Euler–Lagrange operator δL (60) obeys a Noether identity if there exists a $\overline{\delta}$-closed even graded density

$$\Delta = c^{r}\Delta_{r}\omega = \sum_{0\leqslant|\Lambda|\leqslant m} c^{r}\Delta^{A,\Lambda}_{r}(x^{\lambda},s^{B}_{\Sigma})\overline{s_{\Lambda A}}\omega \in \mathcal{S}^{0,n}_{\infty}[Q\overline{Y^{*}}V;Y\overline{Q^{*}}], \tag{87}$$

which is linear both in ghosts c^{r} and antifields $\overline{s_{A}}$ and their jets $\overline{s_{\Lambda A}}$. The above-mentioned *Noether identity* reads

$$\overline{\delta}(\Delta) = c^{r}\left[\sum_{0\leqslant|\Lambda|\leqslant m}\Delta^{A,\Lambda}_{r}d_{\Lambda}\mathcal{E}_{A}\right]\omega = 0. \tag{88}$$

Then Noether's second theorem for BRST symmetries is formulated as follows.

Theorem 15: If v (84) is a BRST symmetry of a graded Lagrangian L, then

$$\begin{aligned}\Delta = \eta(v) &= \sum_{0\leqslant|\Lambda|\leqslant m} c^{r}\eta(v)^{A,\Lambda}_{r}\overline{s_{\Lambda A}}\omega,\\ \eta(v)^{A,\Lambda}_{r} &= \sum_{0\leqslant|\Sigma|\leqslant m-|\Lambda|}(-1)^{|\Sigma+\Lambda|}\mathcal{C}^{|\Sigma|}_{|\Sigma+\Lambda|}d_{\Sigma}v^{A,\Sigma+\Lambda}_{r},\end{aligned} \tag{89}$$

is a $\overline{\delta}$-closed graded density (87). Conversely, if a $\overline{\delta}$-closed graded density Δ (87) exists, the generalized graded vector field

$$\begin{aligned}v = \eta(\Delta) &= \sum_{0\leqslant|\Xi|\leqslant m} c^{r}_{\Xi}\eta(\Delta)^{A,\Xi}_{r}\partial_{A},\\ \eta(\Delta)^{A,\Lambda}_{r} &= \sum_{0\leqslant|\Sigma|\leqslant m-|\Lambda|}(-1)^{|\Sigma+\Lambda|}\mathcal{C}^{|\Sigma|}_{|\Sigma+\Lambda|}d_{\Sigma}\Delta^{A,\Sigma+\Lambda}_{r},\end{aligned} \tag{90}$$

generates a contact graded derivation (82) which is variational for the graded Lagrangian L, but it need not be nilpotent. The relations (2) hold.

Proof: The first summand of the generalized vector field (84) defines the graded function

$$v = \sum_{0\leqslant|\Xi|\leqslant m} c^{r}_{\Xi}v^{A,\Xi}_{r}(x^{\lambda},s^{B}_{\Sigma})s_{A} \in \mathcal{S}^{*}_{\infty}[QQ^{*}V;Y\widetilde{Y}^{*}], \tag{91}$$

and *vice versa*. Then the proof follows from Theorem 18 in Appendix B. By virtue of this theorem, the graded function (91) yields the graded density (89). Since the graded density $v\rfloor\delta L$ is d_{H}-exact, we obtain the equality

$$\delta(v\rfloor\delta L) = \overline{\delta}(\eta(v)) = 0.$$

Conversely, the graded density (87) yields the graded function (91) where $v^{A,\Xi}_{r} = \eta(\Delta)^{A,\Xi}_{r}$. Since Δ (87) is $\overline{\delta}$-closed, we have

$$0 = \sum_{0\leqslant|\Lambda|\leqslant m} c^r\Delta_r^{A,\Lambda} d_\Lambda \mathcal{E}_A\omega = \sum_{0\leqslant|\Lambda|\leqslant m} (-1)^{|\Lambda|} d_\Lambda(c^r\Delta_r^{A,\Lambda})\mathcal{E}_A\omega + d_H\sigma$$
$$= \sum_{0\leqslant|\Xi|\leqslant m} c^r_\Xi v_r^{A,\Xi}\mathcal{E}_A\omega + d_H\sigma = v \rfloor \delta L + d_H\sigma,$$

i.e., the graded contact derivation generated by v (90) is variational for L. Due to the equality (32), the relations (2) hold.

Bearing in mind the field–antifield BRST theory and BV quantization, the Noether identity (88) can be rewritten as follows. Let us consider the BGDA $\mathcal{S}^*_\infty[Q\overline{Y}^*V; Y\overline{Q}^*\overline{V}^*]$ possessing the local basis $\{s^A, c^r, \overline{s_A}, \overline{c_r}\}$, where even elements $\overline{c_r}$ are called *antighosts* of the ghosts c^r. Clearly, the graded density Δ (87) is an element of $\mathcal{S}^*_\infty[Q\overline{Y}^*V; V\overline{Q}^*\overline{V}^*]$. Then this BGDA is provided with the contact graded right derivation

$$\overline{\delta_c} = \sum_{0\leqslant|\Lambda|} \left(\overleftarrow{\partial}^{\Lambda A} d_\Lambda \mathcal{E}_A + \overleftarrow{\partial}^{\Lambda r} d_\Lambda \Delta_r\right), \tag{92}$$

where the tuple of graded right derivations $\overleftarrow{\partial}^{\Lambda r}$ is the dual of $\theta_{\Lambda r}$. It is easily justified that the graded density Δ (87) obeys the Noether identity (88) iff the graded right derivation $\overline{\delta_c}$ (92) is nilpotent. It is the extension of the Koszul–Tate differential (86) to antighosts. For instance, the graded density Δ is always $\overline{\delta_c}$-exact.

VIII. REDUCIBLE BRST SYMMETRIES

The notion of a reducible Noether identity in Sec. IV is straightforwardly generalized to BRST symmetries, but we formulate it in terms of the Koszul–Tate differential. We say that the Noether identity (88) is N-stage reducible if the following conditions hold.

(a) There exists a set of vector bundles $V_{-1}=V, V_0, \ldots, V_N$ over X, and we consider the BGDA

$$\overline{\mathcal{S}}^*_\infty\{N\} = \mathcal{S}^*_\infty[Q\overline{Y}^*VV_1\ldots V_{2k-1}\ldots\overline{V}^*_0\ldots\overline{V}^*_{2k}\ldots; Y\overline{Q}^*V_0\ldots V_{2k}\ldots\overline{V}^*\overline{V}^*_1\ldots\overline{V}^*_{2k-1}\ldots]. \tag{93}$$

It possesses a local basis

$$\{s^A, \overline{s_A}, c^r, c^{r_0}, \ldots, c^{r_N}, \overline{c_r}, \overline{c_{r_0}}, \ldots, \overline{c_{r_N}}\}, \quad [c^{r_k}] = k \bmod 2, \tag{94}$$

where c^{r_k} and $\overline{c_{r_k}}$ are called the k-stage ghosts and antighosts, respectively..

(b) The BGDA (93) contains the graded density Δ (87) and a set of even graded densities

$$\Delta_{(k)} = c^{r_k}\Delta_{r_k}\omega = \sum_\Lambda c^{r_k}\Delta_{r_k}^{r_{k-1},\Lambda}(x^\lambda, s^B_\Sigma)\overline{c}_{\Lambda r_{k-1}}\omega, \quad k=0,\ldots,N, \tag{95}$$

such that the contact graded derivation

$$\overline{\delta_N} = \sum_{0\leqslant|\Lambda|} (\overleftarrow{\partial}^{\Lambda A} d_\Lambda \mathcal{E}_A + \overleftarrow{\partial}^{\Lambda r} d_\Lambda \Delta_r + \overleftarrow{\partial}^{\Lambda r_0} d_\Lambda \Delta_{r_0} + \cdots + \overleftarrow{\partial}^{\Lambda r_N} d_\Lambda \Delta_{r_N}) \tag{96}$$

is weakly nilpotent, i.e., $\overline{\delta_N}(\overline{\delta_N}(f))$ is $\overline{\delta}$-exact for any graded function $f\in\overline{\mathcal{S}}^0_\infty\{N\}$. This nilpotency condition is equivalent to the requirement that all the compositions

$$\sum_\Xi c^{r_k}\Delta_{r_k}^{r_{k-1},\Xi} d_\Xi\left(\sum_\Lambda \Delta_{r_{k-1}}^{r_{k-2},\Lambda}\overline{c}_{\Lambda r_{k-2}}\right), \quad k=1,\ldots,N, \tag{97}$$

are $\overline{\delta}$-exact. The graded derivation $\overline{\delta_N}$ (96) is called the *N-stage Koszul–Tate differential.*

(c) No graded density Δ, $\Delta_{(k)}$, $k=0,\ldots,N$, is $\overline{\delta}$-exact. Let $V'_0,\ldots,V'_{N'}$, be another set of vector bundles such that $V'_{k\leqslant N}$ contains V_k as a direct summand. Then the corresponding BGDA $\overline{\mathcal{S}}^*_\infty\{N'\}$ (93) contains the graded densities Δ (87), $\Delta_{(k)}$ (95), $k=0,\ldots,N$, and it is provided with the contact

graded derivation $\overline{\delta}_N$ (96). If there exists another set $\Delta'_{(k)}$, $k=0,\ldots,N'$, of graded densities obeying the conditions in item (b), then any graded density $\Delta'_{(k)}$ of this set is $\overline{\delta}_N$-exact.

Note, that following the arguments in Sec. III, one can say that the Noether identity (88) is complete if it obeys the condition (c).

If the Noether identity (88) is reducible, the associated BRST symmetry (90) is reducible as follows.

Let us consider the BGDA

$$\mathcal{S}^*_\infty\{N\} = \mathcal{S}^*_\infty[QQ^*VV^*V_1V_1^*\ldots V_{2k-1}V_{2k-1}^*\ldots;Y\tilde{Y}^*V_0V_0^*\ldots V_{2k}V_{2k}^*\ldots], \tag{98}$$

possessing the local basis $\{s^A, s_A, c^r, c^{r_0}, \ldots, c^{r_N}, c_r, c_{r_0}, \ldots, c_{r_N}\}$. By virtue of Theorem 18, each graded density $\Delta_{(k)}$ (95), $k=0,\ldots,N$, defines the graded function

$$v_{(k)} = \sum_\Xi c^{r_k}_\Xi \eta(\Delta_{(k)})^{r_{k-1},\Xi}_{r_k} c_{r_{k-1}} \in \mathcal{S}^0_\infty(\{N\}$$

and, consequently, the generalized graded vector field

$$v_{(k)} = \sum_\Xi c^{r_k}_\Xi \eta(\Delta_{(k)})^{r_{k-1},\Xi}_{r_k} \partial_{r_{k-1}} \in \mathcal{S}^0_\infty\{N\}, \tag{99}$$

which yields a contact graded derivation of the BGDA $\overline{\mathcal{S}}^*_\infty\{N\}$. Similar to the proof of Theorem 9, one can show that they possess the following properties.

(a′) Contact graded derivations ϑ and $\vartheta_{(k)}$ generated by the generalized graded vector fields v (90) and $v_{(k)}$ (99) are not weakly $\overline{\delta}$-exact, i.e., $\vartheta(f)$ and $\vartheta_{(k)}(f)$ are not $\overline{\delta}$-exact for some graded function $f \in \overline{\mathcal{S}}^*_\infty\{N\}$.

(b′) Contact graded derivations generated by the generalized graded vector fields

$$\sum_\Lambda d_\Lambda\left(\sum_\Xi c^{r_0}_\Xi \eta(\Delta_{(0)})^{r,\Xi}_{r_0}\right)\eta(\Delta)^{A,\Lambda}_r \partial_A, \tag{100}$$

$$\sum_\Lambda d_\Lambda\left(\sum_\Xi c^{r_k}_\Xi \eta(\Delta_{(k)})^{r_{k-1},\Xi}_{r_k}\right)\eta(\Delta_{(k-1)})^{r_{k-2},\Lambda}_{r_{k-1}} \partial_{r_{k-2}}, \quad k=1,\ldots,N, \tag{101}$$

are weakly $\overline{\delta}$-exact. This condition can be reformulated as follows. Let us consider the BGDA

$$\mathcal{S}^*_\infty[QQ\overline{Y}^*VV_1\ldots V_{2k-1}\ldots\overline{V}_0^*\ldots\overline{V}_{2k}^*\ldots;Y\tilde{Y}\overline{Q}^*V_0\ldots V_{2k}\ldots\overline{V}^*\overline{V}_1^*\ldots\overline{V}_{2k-1}^*\ldots]$$

whose basis consists of elements (94) and the elements s'^A associated to the additional bundles Q and $\tilde{Y}$. Let us replace the generalized graded vector field v (90) with

$$v' = \sum_{0\leq|\Xi|\leq m} c^r_\Xi \eta(\Delta)^{A,\Xi}_r(x^\lambda, s^B_\Sigma)\partial'_A, \tag{102}$$

where the graded derivations ∂'_A are dual of the basis elements s'^A. Then the contact graded derivation generated by the generalized graded vector field

$$v_N = v' + v_{(0)} + \cdots + v_{(N)} \tag{103}$$

is weakly nilpotent.

(c′) Let $v_{N'}$ be the generalized graded vector field (103) defined by the graded densities $\Delta'_{(k)}$ in item (c) above. Then there exists some generalized graded vector field u such that $v_{N'} - [u, v_N]$ is weakly $\overline{\delta}$-exact.

Conversely, one can show the following. Let v (90) be a BRST symmetry of a graded Lagrangian L. Let us assume that there exists a set of generalized graded vector fields

$$v_{(k)} = \sum_{\Xi} c^{r_k}_{\Xi} v^{r_{k-1},\Xi}_{r_k} \partial_{r_{k-1}} \in \mathcal{S}^0_\infty\{N\}, \tag{104}$$

which obey the conditions in items (a′)–(c′). Then the graded density (15) defines a complete reducible Noether identity where the graded densities

$$\Delta_{(k)} = \sum_{\Lambda} c^{r_k} \eta(v_{(k)})^{r_{k-1},\Lambda}_{r_k}(x^\lambda, s^B_\Sigma)\overline{c}_{\Lambda r_{k-1}}$$

obey the conditions in items (a)–(c).

In contrast with the generalized graded vector field v_N (103), the contact graded derivation generated by the generalized graded vector field $v + v_{(0)} + \cdots + v_{(N)}$ need not be weakly nilpotent. Its extension to the nilpotent one provides a BRST symmetry of the field–antifield BRST theory whose Lagrangian depends on ghosts and antifields.

APPENDIX A

A k-order differential operator on a fiber bundle $Y \to X$ with values in a fiber bundle $Z \to X$ is defined as a section Δ of the fiber bundle

$$J^k Y \underset{X}{\times} Z \to J^k Y.$$

It admits an m-order jet prolongation $\Delta^{(m)}$ as a section of the fiber bundle

$$J^{m+k} Y \underset{X}{\times} J^m Z \to J^{m+k} Y.$$

By a differential operator throughout is meant its appropriate finite order jet prolongation. Given bundle coordinates (x^λ, y^i) on Y and (x^λ, z^A) on Z, a differential operator Δ reads

$$z^A \circ \Delta = \Delta^A(x^\lambda, y^i_\Lambda), \quad z^A_\Sigma \circ \Delta^{(m)} = d_\Sigma \Delta^A, \quad 0 \leqslant |\Lambda| \leqslant k, \quad 0 \leqslant |\Sigma| \leqslant m.$$

If Z is a composite fiber bundle $\pi \circ \pi_{ZY}: Z \to Y \to X$ and the relation $\pi_{ZY} \circ \Delta = \pi^k_0$ holds, a differential operator Δ is identified to a section of the fiber bundle

$$J^k Y \underset{Y}{\times} Z \to J^k Y$$

or, equivalently, a bundle morphism

$$J^k Y \underset{Y}{\to} Z.$$

Let $E \to Y$ and $Q \to Y$ be vector bundles. A k-order Q-valued differential operator v on $E \to X$ is called linear on $E \to Y$ (or, simply, linear) if $v: J^k E \to Q$ is a morphism of the vector bundle $J^k E \to J^k Y$ to the vector bundle $Q \to Y$ over $\pi^k_0: J^k Y \to Y$. Given bundle coordinates (x^λ, y^i, ξ^r) on E and (x^λ, y^i, q^a) on Q, such an operator is represented by the function

$$v = v^a q_a = \sum_{0 \leqslant |\Lambda| \leqslant m} v^{a,\Lambda}_r(x^\lambda, y^i_\Sigma)\xi^r_\Lambda q_a \in \mathcal{O}^0_\infty[E \underset{Y}{\times} Q^*], \quad 0 \leqslant |\Sigma| \leqslant m. \tag{A1}$$

Let us consider the density-dual $\overline{E^*}$ (1) of a vector bundle $E \to Y$ and that $\overline{Q^*}$ of $Q \to Y$ coordinated by $(x^\lambda, y^i, \overline{q_a})$. Let Δ be a linear $\overline{E^*}$-valued differential operator on $\overline{Q^*}$. It is represented by the density

$$\Delta = \Delta_r \xi^r \omega = \sum_{0 \leqslant |\Lambda| \leqslant m} \Delta^{a,\Lambda}_r(x^\lambda, y^i_\Sigma)\overline{q}_{\Lambda a}\xi^r \omega \in \mathcal{O}^{0,n}_\infty[E \underset{Y}{\times} Q^*], \quad 0 \leqslant |\Sigma| \leqslant m. \tag{A2}$$

Theorem 16: Any linear Q-valued differential operator v (A1) on E yields the linear $\overline{E}^*$-valued differential operator

$$\eta(v) = \sum_{0\leqslant|\Lambda|\leqslant m} \eta(v)_r^{a,\Lambda}\overline{q}_{\Lambda a}\xi^r\omega,$$
$$\eta(v)_r^{a,\Lambda} = \sum_{0\leqslant|\Sigma|\leqslant m-|\Lambda|} (-1)^{|\Sigma+\Lambda|}C_{|\Sigma+\Lambda|}^{|\Sigma|}d_\Sigma(v_r^{a,\Sigma+\Lambda}), \tag{A3}$$

on $\overline{Q}^*$. Conversely, any linear $\overline{E}^*$-valued differential operator Δ (A2) on $\overline{Q}^*$ defines the linear Q-valued differential operator

$$\eta(\Delta) = \sum_{0\leqslant|\Lambda|\leqslant m} \eta(\Delta)_r^{a,\Lambda}\xi_\Lambda^r q_a,$$
$$\eta(\Delta)_r^{a,\Lambda} = \sum_{0\leqslant|\Sigma|\leqslant m-|\Lambda|} (-1)^{|\Sigma+\Lambda|}C_{|\Sigma+\Lambda|}^{|\Sigma|}d_\Sigma(\Delta_r^{a,\Sigma+\Lambda}), \tag{A4}$$

on E. The relations (2) hold.

Proof: The function v (A1) defines the density

$$\overline{v} = \sum_{0\leqslant|\Lambda|\leqslant m} v_r^{a,\Lambda}\xi_\Lambda^r\overline{q}_a\omega \in \mathcal{O}_\infty^{0,n}[\underset{Y}{E\times}Q^*]. \tag{A5}$$

Its Euler–Lagrange operator

$$\delta(\overline{v}) = \mathcal{E}_i dy^i\wedge\omega + \mathcal{E}_r d\xi^r\wedge\omega + \mathcal{E}^a d\overline{q}_a\wedge\omega$$

takes its values in the fiber bundle

$$V^*(\underset{Y}{E\times}Q^*)\underset{\underset{Y}{E\times}Q^*}{\otimes}\overset{n}{\wedge}T^*X, \tag{A6}$$

where

$$V^*(\underset{Y}{E\times}Q^*)$$

is the vertical cotangent bundle of the fiber bundle

$$\underset{Y}{E\times}Q^*\to X.$$

Let

$$\alpha_E: V^*(\underset{Y}{E\times}Q^*)\to V_Y^*(\underset{Y}{E\times}Q^*)\to V_Y^*E \tag{A7}$$

be the canonical projection of

$$V^*(\underset{Y}{E\times}Q^*)$$

onto the vertical cotangent bundle

$$V_Y^*(\underset{Y}{E\times}Q^*)$$

of the fiber bundle

$$E\underset{Y}{\times}Q^* \to Y$$

and, afterwards, onto the vertical cotangent bundle V_Y^*E of $E \to Y$. Then we obtain a differential operator $(\alpha_E \circ \delta)(\overline{v})$ on

$$E\underset{Y}{\times}Q^*$$

with values in the fiber bundle

$$V_Y^*E \underset{E}{\otimes} \overset{n}{\wedge} T^*X.$$

It reads

$$(\alpha_E \circ \delta)(\overline{v}) = \mathcal{E}_r \overline{\mathrm{d}\xi^r} \otimes \omega = \sum_{0 \leq |\Lambda| \leq m} (-1)^{|\Lambda|} d_\Lambda (v_r^{a,\Lambda} \overline{q_a}) \overline{\mathrm{d}\xi^r} \otimes \omega,$$

where $\{\overline{\mathrm{d}\xi^r}\}$ is the fiber basis for $V_Y^*E \to E$. Due to the canonical isomorphism

$$V_Y^*E = E^*\underset{Y}{\times}E,$$

this operator defines the density

$$\sum_{0 \leq |\Lambda| \leq m} (-1)^{|\Lambda|} d_\Lambda (v_r^{a,\Lambda} \overline{q_a}) \xi^r \omega \in \mathcal{O}_\infty^{0,n}[E\underset{Y}{\times}Q^*]$$

and, by virtue of the formula (30), the desired differential operator (A3). Conversely, the Euler–Lagrange operator of the density (A2) takes its values in the fiber bundle (A6) and reads

$$\delta(\overline{v}) = \mathcal{E}_i dy^i \wedge \omega + \mathcal{E}_r d\xi^r \wedge \omega + \mathcal{E}^a d\overline{q_a} \wedge \omega. \tag{A8}$$

In order to repeat the above-mentioned procedure, let us consider a volume form $J\omega$ on X and substitute $\mathrm{d}\overline{q_a} \wedge \omega = J\mathrm{d}q_a \wedge \omega$ into expression (A8). Using the projection

$$\alpha_Q : V^*(E\underset{Y}{\times}Q^*) \to V_Y^*Q^*$$

similar to α_E (A7) and the canonical isomorphism

$$V_Y^*Q^* = Q\underset{Y}{\times}Q^*,$$

we come to the density

$$\sum_{0 \leq |\Lambda| \leq m} (-1)^{|\Lambda|} d_\Lambda (\Delta_r^{a,\Lambda} \xi^r) q_a J\omega \in \mathcal{O}_\infty^{0,n}[E\underset{Y}{\times}Q^*]$$

and, hence, the function

$$\sum_{0 \leq |\Lambda| \leq m} (-1)^{|\Lambda|} d_\Lambda (\Delta_r^{a,\Lambda} \xi^r) q_a \in \mathcal{O}_\infty^{0,n}[E\underset{Y}{\times}Q^*],$$

defining the desired operator (A4). The relations (2) result from the relation (32).

Relations (2) show that the intertwining operator η (A3) and (A4) provides a bijection between the sets $\mathrm{Diff}(E,Q)$ and $\mathrm{Diff}(\overline{Q^*},\overline{E^*})$ of differential operators (A1) and (A2).

Proposition 17: Compositions of operators $v \circ v'$ and $\Delta' \circ \Delta$ obey the relations (3).

Proof: It suffices to prove the first relation. Let $v \circ v' \in \mathrm{Diff}(E',Q)$ be a composition of differ-

ential operators $v \in \mathrm{Diff}(E,Q)$ and $v' \in \mathrm{Diff}(E',E)$. Given fiber coordinates (ξ^r) on $E \to Y$, (ϵ^p) on $E' \to Y$ and $(\overline{q_a})$ on $\overline{Q}^* \to Y$, this composition defines the density (A5)

$$\overline{v \circ v'} = \sum_{\Lambda} v_r^{a,\Lambda} d_\Lambda \left(\sum_{\Sigma} v_p'^{r,\Sigma} \epsilon_\Sigma^p \right) \overline{q_a} \omega.$$

Following the relation (29), one can bring this density into the form

$$\sum_{\Sigma} v_p'^{r,\Sigma} \epsilon_\Sigma^p \sum_{\Lambda} (-1)^{|\Lambda|} d_\Lambda (v_r^{a,\Lambda} \overline{q_a}) \omega + d_H \sigma = \sum_{\Sigma} v_p'^{r,\Sigma} \epsilon_\Sigma^p \sum_{\Lambda} \eta(v)_r^{a,\Lambda} \overline{q}_{\Lambda a} \omega + d_H \sigma.$$

Its Euler–Lagrange operator projected to $V_Y^* E' \underset{E'}{\otimes} T^* X$ is

$$\sum_{\Sigma} (-1)^{|\Sigma|} d_\Sigma \left(v_p'^{r,\Sigma} \sum_{\Lambda} \eta(v)_r^{a,\Lambda} \overline{q}_{\Lambda a} \right) \overline{d\epsilon}^p \otimes \omega = \sum_{\Sigma} \eta(v')_p^{r,\Sigma} d_\Sigma \left(\sum_{\Lambda} \eta(v)_r^{a,\Lambda} \overline{q}_{\Lambda a} \right) \overline{d\epsilon}^p \otimes \omega,$$

which leads to the desired composition $\eta(v') \circ \eta(v)$.

APPENDIX B

The following is a graded counterpart of Theorem 16.

Let $T \to X$ and $W \to X$ be vector bundles, W^* the dual of W, and $\overline{W}^*$ the density-dual (1) of W. Given the BGDA $\mathcal{S}_\infty^*[Q;Y]$ (53), let us consider its extensions to a BGDA $\mathcal{S}_\infty^*[T,W^*]$ with the local basis $\{s^A, t^r, w_a\}$, where elements t^r and w_a are either even or odd, and to a BGDA $\mathcal{S}_\infty^*[T,\overline{W}^*]$ possessing the local basis $\{s^A, t^r, \overline{w}_a\}$, where $[\overline{w}_a] = ([w_a]+1) \bmod 2$.

Theorem 18: Given a graded function

$$v = \sum_{0 \leq |\Lambda| \leq m} t_\Lambda^r v_r^{a,\Lambda}(x^\lambda, s_\Sigma^A) w_a \in \mathcal{S}_\infty^0[T,W^*], \tag{B1}$$

linear in t_Λ^r and w_a, there exists a graded density

$$\begin{aligned} \eta(v) &= \sum_{0 \leq |\Lambda| \leq m} t^r \eta(v)_r^{a,\Lambda} \overline{w}_{\Lambda a} \omega \in \mathcal{S}_\infty^{0,n}[T,\overline{W}^*], \\ \eta(v)_r^{a,\Lambda} &= \sum_{0 \leq |\Sigma| \leq m-|\Lambda|} (-1)^{|\Sigma+\Lambda|} C_{|\Sigma+\Lambda|}^{|\Sigma|} d_\Sigma (v_r^{a,\Sigma+\Lambda}), \end{aligned} \tag{B2}$$

linear in t^r and $\overline{w}_{\Lambda_a}$. Conversely, such a density

$$\Delta = \sum_{0 \leq |\Lambda| \leq m} t^r \Delta_r^{a,\Lambda} \overline{w}_{\Lambda a} \omega \tag{B3}$$

defines the graded function

$$\begin{aligned} \eta(\Delta) &= \sum_{0 \leq |\Lambda| \leq m} t_\Lambda^r \eta(\Delta)_r^{a,\Lambda} w_a \in \mathcal{S}_\infty^0[T,W^*], \\ \eta(\Delta)_r^{a,\Lambda} &= \sum_{0 \leq |\Sigma| \leq m-|\Lambda|} (-1)^{|\Sigma+\Lambda|} C_{|\Sigma+\Lambda|}^{|\Sigma|} d_\Sigma (\Delta_r^{a,\Sigma+\Lambda}), \end{aligned} \tag{B4}$$

linear in t_Λ^r and w_a.

Proof: The graded function v (B1) defines the graded density

$$\overline{v} = \sum_{0\leqslant|\Lambda|\leqslant m} t^r_\Lambda v^{a,\Lambda}_r(x^\lambda, s^A_\Sigma)\overline{w}_a\omega \in \mathcal{S}^0_\infty[T, \overline{W}^*].$$

Its Euler–Lagrange operator $\delta(\overline{v})$ (60) contains the summand

$$\mathcal{E}_r\theta^r \wedge \omega = \sum_{0\leqslant|\Lambda|\leqslant m} (-1)^{|\Lambda|}\theta^r \wedge d_\Lambda(v^{a,\Lambda}_r\overline{w}_a)\omega,$$

which defines the graded density

$$\sum_{0\leqslant|\Lambda|\leqslant m} (-1)^{|\Lambda|}t^r d_\Lambda(v^{a,\Lambda}_r\overline{w}_a)\omega$$

owing to the canonical isomorphism $V^*T = T^* \times T$. Using the relation (30), we come to the formula (B2). The converse is proved similarly to the proof of Theorem 16.

(Received 3 December 2004; accepted 7 March 2005; published online 9 May 2005)

In the spirit of some earlier work on the construction of vector coherent states (VCS) over matrix domains, we compute here such states associated to some physical Hamiltonians. In particular, we construct vector coherent states of the Gazeau–Klauder type. As a related problem, we also suggest a way to handle degeneracies in the Hamiltonian for building coherent states. Specific physical Hamiltonians studied include a single photon mode interacting with a pair of fermions, a Hamiltonian involving a single boson and a single fermion, a charged particle in a three-dimensional harmonic force field and the case of a two-dimensional electron placed in a constant magnetic field, orthogonal to the plane which contains the electron. In this last example, which is related to the fractional quantum Hall effect, an interesting modular structure emerges for two underlying von Neumann algebras, related to opposite directions of the magnetic field. This leads to the existence of coherent states built out of Kubo-Martin-Schwinger (KMS) states for the system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1901343]

I. INTRODUCTION

In some earlier work,[4,20] a fairly systematic method has been introduced for constructing vector coherent states (VCS) over various types of matrix domains. The construction included earlier types of vector coherent states, arising mainly in nuclear physical problems, under the additional assumption of the existence of a resolution of the identity. (A detailed discussion of this point, as well as an exhaustive reference to the earlier literature is given in Ref. 4.) In the present paper we apply the method developed in Refs. 4 and 20 to construct vector coherent states arising from various physical Hamiltonians. The kind of coherent states we generate are thus vectorial generalizations of the Gazeau–Klauder type[10] of coherent states. Some of the Hamiltonians we consider have degenerate spectra and in order to deal with this situation, we attempt a second generalization of the Gazeau–Klauder formalism. There have been earlier attempts in the literature for handling degeneracies when constructing coherent states associated to Hamiltonians.[8,15] The method we suggest here is somewhat different from the one suggested in Ref. 15 and radically different from that suggested in Ref. 8. However, we feel that the present method is more economical in the introduction of additional parameters defining the coherent states—we only need one additional parameter. We also look at situations where the degeneracy is countably infinite. In this context, in the case of a two-dimensional electron placed in a constant magnetic field, orthogonal to the plane which contains the electron, we encounter a highly interesting modular

[a)]Electronic mail: stali@mathstat.concordia.ca
[b)]Electronic mail: bagarell@unipa.it; www.unipa.it/~bagarell

algebraic structure generated by the observables of the problem, leading to the rather unexpected appearance of equilibrium statistical mechanical states of the well-known Kubo-Martin-Schwinger (KMS) type.[14] It is worth recalling that this model, while well known even from textbooks on quantum mechanics, is of additional interest in that it is the building block for writing down the many-body Hamiltonian for the fractional quantum Hall effect, see Ref. 7 and references therein. It is well known that the eigenspectrum of the single electron Hamiltonian can be found explicitly, and that there exists an infinite degeneracy for each eigenvalue (the so-called *Landau levels*).[5]

The rest of this paper is organized as follows: In Sec. II we review the Gazeau–Klauder construction within the framework of reproducing kernel Hilbert spaces. This general framework is then used in Sec. III to construct vector coherent states of the Gazeau–Klauder type. We illustrate the method with a couple of physical examples. Section generalizes the treatment to Hamiltonians with degeneracies. We treat the cases of finite and infinite degeneracies separately and illustrate the finite situation with a number of physical examples. In Section V we work out, in detail, a physical example in which infinite degeneracies occur. In this example we also observe the existence of a modular algebraic structure and the appearance of KMS states, familiar from equilibrium statistical mechanics. Finally, in the Appendix we collect together explicit computations of some of the more unfamiliar formulas in Secs. IV A and V.

II. THE GAZEAU–KLAUDER SCHEME REVISITED

The Gazeau–Klauder scheme[10] is a method for constructing coherent states $|J,\gamma\rangle$, where $J \geqslant 0$ and $\gamma \in \mathbb{R}$, associated to physical Hamiltonians H, which have discrete nondegenerate spectra. The states must satisfy the following properties:

(i) *Continuity*, the mapping $(J,\gamma) \to |J,\gamma\rangle$ is continuous in some appropriate topology.
(ii) *Resolution of the identity*, $\int |J,\gamma\rangle\langle J,\gamma| \mathrm{d}m(J,\gamma) = I$, where I is the identity in the Hilbert space and dm is some appropriate measure.
(iii) *Temporal stability*, $e^{-iHt}|J,\gamma\rangle = |J,\gamma+\omega t\rangle$, for some constant ω.
(iv) *Action identity*, $\langle J,\gamma|H|J,\gamma\rangle = \omega J$.

Their construction, which we shall review below, works if H has no degenerate eigenstates and, furthermore, if the lowest eigenvalue is exactly zero. This second requirement can always be imposed for reasonable physical systems, since all physically relevant Hamiltonians H must be bounded from below, in order to admit a ground state. This means that there exists a lowest eigenvalue $E_{\min} > -\infty$, so that we can define a new Hamiltonian, $\widetilde{H} = H - E_{\min} I$, whose lowest eigenvalue is clearly zero. Furthermore H and $\widetilde{H}$ have *exactly* the same dynamical content, since they obey the same commutation relations with all the observables of the system. For such a Hamiltonian, in the Gazeau–Klauder scheme, one writes the eigenvalues as $E_n = \omega\epsilon_n$ by introducing a sequence of dimensionless quantities $\{\epsilon_n\}$ ordered as $0 = \epsilon_0 < \epsilon_1 < \epsilon_2 < \cdots$. Then, the Gazeau–Klauder coherent states are defined as

$$|J,\gamma\rangle := \mathcal{N}(J)^{-1/2} \sum_{k=0}^{\infty} \frac{J^{n/2} e^{-i\varepsilon_n \gamma}}{\sqrt{\rho_n}} |n\rangle, \tag{2.1}$$

where $\mathcal{N}$ is a normalization factor, which turns out to be dependent on J only, the $|n\rangle$ are the eigenstates of H and the ρ_n are positive numbers, which are fixed by the requirement of the action identity to be $\rho_n = \epsilon_1 \epsilon_2 \cdots \epsilon_n$.

In the rest of this section we recapitulate the Gazeau–Klauder construction, with the aim of putting the discussion in a somewhat more general context, which will also enable us to extend the construction to include vector coherent states and to cases where each energy level is (a) finitely degenerate and (b) infinitely degenerate. The essential mathematical ingredient in the construction is a reproducing kernel Hilbert space. Although this concept is a familiar one, both in the physical and the mathematical literature, we summarize below some essential features, putting them in the context of the present discussion.

A. Some generalities

Recall that a reproducing kernel Hilbert space (see, for example, Refs. 2, 6, and 16 for detailed discussions) $\mathfrak{H}_{\text{ker}}$, consists of functions $f: X \to \mathbb{C}$ on some topological space X, with the property that, for all $x \in X$, the evaluation map E_x: $\mathfrak{H}_{\text{ker}} \to \mathbb{C}$, $E_x(f) = f(x)$, is continuous. Such a space may or may not be an L^2-space or a subspace of an L^2-space and its scalar product, which we denote by $\langle \cdot | \cdot \rangle_{\text{ker}}$, may be given in more general ways. (Although the space $\mathfrak{H}_{\text{ker}}$ could be finite or infinite dimensional, we shall only be interested in the infinite dimensional case here.) The continuity of the evaluation map implies that for each $x \in X$, there exists a vector $\xi_x \in \mathfrak{H}_{\text{ker}}$ such that

$$f(x) = \langle \xi_x | f \rangle_{\text{ker}}, \quad \text{for any } f \in \mathfrak{H}_{\text{ker}}. \tag{2.2}$$

The vectors ξ_x, $x \in X$, are total in $\mathfrak{H}_{\text{ker}}$ (i.e., their linear span is dense in the space), as can be easily seen. Furthermore, they can be used to define the reproducing kernel, $K: X \times X \to \mathbb{C}$, for this space,

$$K(y,x) := \langle \xi_y | \xi_x \rangle_{\text{ker}} = \xi_x(y), \tag{2.3}$$

the second equality following from (2.2). If now $\{\Psi_n\}_{n=0}^{\infty}$ is an orthonormal basis of $\mathfrak{H}_{\text{ker}}$, then writing

$$\xi_x = \sum_{n=0}^{\infty} \lambda_n(x) \Psi_n, \quad \lambda_n(x) = \langle \Psi_n | \xi_x \rangle_{\text{ker}} = \overline{\Psi_n(x)},$$

and taking account of (2.3), we get

$$K(x,y) = \sum_{n=0}^{\infty} \Psi_n(x) \overline{\Psi_n(y)}. \tag{2.4}$$

It should be noted that the above equation is true for any orthonormal basis, so that the kernel $K(x,y)$ is independent of the basis chosen to express it. An equivalent condition for the existence of a reproducing kernel is that there be an orthonormal basis for which,

$$\sum_{n=0}^{\infty} |\Psi_n(x)|^2 < \infty, \quad \text{for all } x \in X. \tag{2.5}$$

If we *symbolically* write the scalar product of $\mathfrak{H}_{\text{ker}}$ as

$$\langle f | g \rangle_{\text{ker}} = \int_X \overline{f(x)} g(x) \mathrm{d}\mu(x),$$

then using (2.2) and (2.3) we may also write

$$\langle \xi_x | \xi_y \rangle_{\text{ker}} = \int_X \overline{\xi_x(z)} \xi_y(z) \mathrm{d}\mu(z) = \int_X \langle \xi_x | \xi_z \rangle_{\text{ker}} \langle \xi_z | \xi_y \rangle_{\text{ker}} \, \mathrm{d}\mu(z).$$

Referring again to (2.3) and noting that the vectors ξ_x are total in $\mathfrak{H}_{\text{ker}}$, the above equation may be re-expressed either as

$$K(x,y) = \int_X K(x,y) K(z,y) \mathrm{d}\mu(z), \tag{2.6}$$

or as

$$\int_X |\xi_x\rangle\langle\xi_z| \mathrm{d}\mu(z) = I_{\text{ker}}, \tag{2.7}$$

where $I_{\ker}$ is the identity operator on $\mathfrak{H}_{\ker}$. Thus, these equations appear now as the well-known *reproducing property* for the kernel $K(x,y)$ and the *resolution of the identity* generated by the vectors ξ_x, respectively. Once more we emphasize that in general, Eqs. (2.6) and (2.7) only have symbolic meaning. However, if in fact $\mathfrak{H}_{\ker}$ is an L^2 space with respect to some real measure $\mathrm{d}\mu$ on X (or a subspace of such a space), then the above equations do make literal sense. In view of equations (2.6) and (2.7), we may call the vectors ξ_x the *coherent states* defined by the kernel $K(x,y)$ and they in fact characterize the reproducing kernel Hilbert space $\mathfrak{H}_{\ker}$. However, since $\|\xi_x\|^2 = K(x,x)$, these states are generally not normalized. If $K(x,x) \neq 0$, we may define the normalized vectors $\zeta_x = [K(x,x)]^{-1/2}\xi_x$, for which we would have the "resolution of the identity"

$$\int_X |\zeta_z\rangle\langle\zeta_z| K(z,z)\mathrm{d}\mu(z) = I_{\ker}.$$

Coherent states, of all types appearing in the physical literature, can be built by simply transporting the above structure to some other appropriate Hilbert space by a basis change. To see this, let $\mathfrak{H}$ be an abstract (separable, complex) Hilbert space and $\{\phi_n\}_{n=0}^{\infty}$ an orthonormal basis of it. Define the unitary map, $V: \mathfrak{H}_{\ker} \to \mathfrak{H}$ by $V|\Psi_n\rangle = |\phi_n\rangle$, $n = 0, 1, 2, \ldots$. Then the vectors

$$|\eta_x\rangle := V|\xi_x\rangle = \sum_{n=0}^{\infty} \overline{\Psi_n(x)}|\phi_n\rangle, \tag{2.8}$$

define (non-normalized) coherent states on $\mathfrak{H}$. They are associated to the same reproducing kernel as the ξ_x since,

$$K(x,y) = \langle \eta_x | \eta_y \rangle_{\mathfrak{H}} = \langle \xi_x | \xi_y \rangle_{\ker}$$

and satisfy a "resolution of the identify" similar to (2.7):

$$\int_X |\eta_z\rangle\langle\eta_z| \mathrm{d}\mu(z) = I_{\mathfrak{H}},$$

where again, this equation is to be generally interpreted in the sense of (2.6). Furthermore, for arbitrary $\phi \in \mathfrak{H}$, the function $f(x) = \langle \eta_x | \phi \rangle_{\mathfrak{H}}$ defines a vector in $\mathfrak{H}_{\ker}$ and it is easy to see that the inverse of the isometry V is given by this relation, i.e., $(V^{-1}\phi)(x) = \langle \eta_x | \phi \rangle_{\mathfrak{H}}$. Usually, in the physical literature one works with the normalized vectors

$$|x\rangle = [K(x,x)]^{-1/2}|\eta_x\rangle = [K(x,x)]^{-1/2} \sum_{n=0}^{\infty} \overline{\Psi_n(x)}|\phi_n\rangle. \tag{2.9}$$

It will later become apparent that the above coherent states coincide with $|J,\gamma\rangle$ in (2.1) upon identifying $\Psi_n(x)$ with $J^{n/2}e^{i\epsilon_n\gamma}/\sqrt{\rho_n}$, ρ_n with $\epsilon_1\epsilon_2\cdots\epsilon_n = \epsilon_n!$ and $\mathcal{N}(J)$ with $K(x,x)$.

To summarize the preceding discussion, coherent states are linear superpositions of the elements of a basis in a Hilbert space, the components in the expansion being the values taken at a point by a set of vectors forming a basis in a reproducing kernel Hilbert space. Alternatively, referring to (2.5), we may identify the reproducing kernel Hilbert space $\mathfrak{H}_{\ker}$ with a subspace of ℓ^2 generated by the infinite sequences, $\{\Psi_0(x), \Psi_1(x), \Psi_2(x), \ldots, \Psi_n(x), \ldots\}$, $x \in X$. An associated family of coherent states is then simply given by the vectors, $\{\overline{\Psi_0(x)}, \overline{\Psi_1(x)}, \overline{\Psi_2(x)}, \ldots, \overline{\Psi_n(x)}, \ldots\}$, $x \in X$, in this subspace. To see that this way of looking at coherent states does indeed include all the standard types of coherent states, let us assume that we are given a family of coherent states, $|\lambda\rangle$, $\lambda \in \Lambda$, on some Hilbert space $\mathfrak{R}$. The parameter space Λ is assumed to be a topological space. Being coherent states means that the vectors either satisfy a resolution of the identity,

$$\int_{\Lambda} |\lambda\rangle\langle\lambda| \mathrm{d}w(\lambda) = I_{\mathfrak{R}},$$

with respect to some measure dw defined on Λ, or else that the mapping $\phi \to f$, with $f(\lambda) = \langle\lambda|\phi\rangle$, where ϕ runs through $\mathfrak{R}$, is an isometry between $\mathfrak{R}$ and a reproducing kernel Hilbert space $\mathfrak{R}_{\mathrm{ker}}$ of functions on Λ. (In fact the first case implies the second.) In either case, if we choose an orthonormal basis $\{\phi_n\}_{n=0}^{\infty}$ in $\mathfrak{R}$ and expand the coherent states in this basis,

$$|\lambda\rangle = \sum_{n=0}^{\infty} \overline{f_n(\lambda)}|\phi_n\rangle, \quad f_n(\lambda) = \langle\lambda|\phi_n\rangle,$$

then the functions f_n are easily seen to form a basis for the Hilbert space $\mathfrak{R}_{\mathrm{ker}}$ with reproducing kernel $K(\lambda,\lambda') = \langle\lambda|\lambda'\rangle$.

The above considerations can also be generalized to the case where $\mathfrak{H}_{\mathrm{ker}}$ is a space of vector valued functions and the kernel $K(x,y)$ is matrix valued, yielding vector coherent states (see Refs. 4 and 20).

B. The Gazeau–Klauder situation

In the light of the preceding discussion, in order to develop a systematic method for generating coherent states and vector coherent states of the Gazeau–Klauder type, we begin by defining a Hilbert space, $\mathfrak{H}_{\mathrm{ns}}$, of functions $f: \mathbb{R} \to \mathbb{C}$, which is complete with respect to the scalar product

$$\langle f|g\rangle_{\mathrm{ns}} = \lim_{T\to\infty} \frac{1}{2T} \int_{-T}^{T} \overline{f(\gamma)} g(\gamma) \mathrm{d}\gamma. \tag{2.10}$$

The vectors f_x, $x \in \mathbb{R}$,

$$f_x(\gamma) = e^{ix\gamma}, \tag{2.11}$$

are of unit norm and for any two distinct numbers x, x', the corresponding vectors f_x and $f_{x'}$ are orthogonal. This also means that the space $\mathfrak{H}_{\mathrm{ns}}$ is nonseparable. Although this space is not an L^2 space, by abuse of notation we shall still symbolically write the scalar product as

$$\langle f|g\rangle_{\mathrm{ns}} = \lim_{T\to\infty} \frac{1}{2T} \int_{-T}^{T} \overline{f(\gamma)} g(\gamma) \mathrm{d}\gamma := \int_{\mathbb{R}} \overline{f(\gamma)} g(\gamma) \mathrm{d}\mu_{\mathcal{B}}(\gamma), \tag{2.12}$$

(d$\mu_{\mathcal{B}}$ is usually referred to as the *Bohr measure*). If $\{\epsilon_n\}_{n=0}^{\infty}$ is a sequence of numbers in $\mathbb{R}$ (we assume that $\epsilon_n \neq \epsilon_m$ if $n \neq m$), then the set of vectors

$$f_n(\gamma) = e^{i\epsilon_n\gamma}, \quad n = 0,1,2,\ldots, \tag{2.13}$$

forms a countable orthonormal set and hence the closure of their linear span is a separable subspace of $\mathfrak{H}_{\mathrm{ns}}$. We denote this subspace by $\mathfrak{H}_{\mathrm{ang}}$ and it is such subspaces of $\mathfrak{H}_{\mathrm{ns}}$ that we shall use for constructing coherent states. The reason for the subscript will become clear presently. Suppose next, that the sequence $\{\epsilon_n\}_{n=0}^{\infty}$ is so chosen that the following conditions are satisfied:

(1) $\epsilon_0=0$ and the series

$$\sum_{n=0}^{\infty}\frac{J^n}{\epsilon_n!},\quad J\in\mathbb{R}^+,\quad \epsilon_n!=\epsilon_1\epsilon_2\epsilon_3\cdots\epsilon_n,\quad \epsilon_0!=1,$$

has a radius of convergence $L>0$.

(2) There exists a measure $\mathrm{d}\nu$ on $\mathbb{R}^+$ which solves the moment problem

$$\int_0^L J^n\,\mathrm{d}\nu(J)=\epsilon_n!,\quad \int_0^L \mathrm{d}\nu(J)=1.$$

Then the vectors r_n, $n=0,1,2,\ldots$, in $L^2((0,L),\mathrm{d}\nu)$ defined by

$$r_n(J)=\frac{J^{n/2}}{\sqrt{\epsilon_n!}},\tag{2.14}$$

are of unit norm and span the space. Thus the vectors

$$\Psi_n=r_n\otimes f_n,\quad \Psi_n(J,\gamma)=\frac{J^{n/2}e^{i\epsilon_n\gamma}}{\sqrt{\epsilon_n!}},\quad n=0,1,2,3,\ldots,\tag{2.15}$$

form an *orthonormal basis* in the Hilbert space $\mathfrak{H}_{\text{ac-ang}}=L^2((0,L),\mathrm{d}\nu)\otimes\mathfrak{H}_{\text{ang}}$. Since the vectors Ψ_n satisfy the condition [analogous to (2.5)],

$$\sum_{n=0}^{\infty}|\Psi_n(J,\gamma)|^2=\sum_{n=0}^{\infty}\frac{J^n}{\epsilon_n!}:=\mathcal{N}(J)<\infty,\tag{2.16}$$

for all $(J,\gamma)\in(0,L)\times\mathbb{R}^+$, the space $\mathfrak{H}_{\text{ac-ang}}$ is a reproducing kernel Hilbert space with kernel

$$K(J,\gamma;J',\gamma')=\sum_{n=0}^{\infty}\Psi_n(J,\gamma)\overline{\Psi_n(J',\gamma')}=\sum_{n=0}^{\infty}\frac{(JJ')^{n/2}e^{i\epsilon_n(\gamma-\gamma')}}{\epsilon_n!}.\tag{2.17}$$

By (2.3), the (non-normalized) coherent states, $\xi_{J,\gamma}$, defined on $\mathfrak{H}_{\text{ac-ang}}$ and associated to this kernel are then

$$\xi_{J,\gamma}(J'\gamma')=K(J',\gamma';J,\gamma)=\langle\xi_{J',\gamma'}|\xi_{J,\gamma}\rangle_{\text{ac-ang}},\tag{2.18}$$

while for any $\Psi\in\mathfrak{H}_{\text{ac-ang}}$, we have the relation,

$$\langle\xi_{J,\gamma}|\Psi\rangle_{\text{ac-ang}}=\Psi(J,\gamma).$$

Adopting the notation of (2.12), we may also symbolically write a resolution of the identity as

$$\int_0^L\left[\int_{-\infty}^{\infty}|\xi_{J,\gamma}\rangle\langle\xi_{J,\gamma}|\mathrm{d}\mu_{\mathcal{B}}(\gamma)\right]\mathrm{d}\nu(J)=I_{\text{ac-ang}},\tag{2.19}$$

where $I_{\text{ac-ang}}$ denotes the identity in $\mathfrak{H}_{\text{ac-ang}}$. The above equation is to be understood in the sense that for arbitrary Φ, $\Psi\in\mathfrak{H}_{\text{ac-ang}}$,

$$\int_0^L\left[\int_{-\infty}^{\infty}\langle\Psi|\xi_{J,\gamma}\rangle\langle\xi_{J,\gamma}|\Phi\rangle\mathrm{d}\mu_{\mathcal{B}}(\gamma)\right]\mathrm{d}\nu(J)=\int_0^L\left[\lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{T}\overline{\Psi(J,\gamma)}\Phi(J,\gamma)\mathrm{d}\gamma\right]\mathrm{d}\nu(J)=\langle\Psi|\Phi\rangle.$$

In the Gazeau–Klauder construction of coherent states, related to Hamiltonians with discrete spectra, one assumes that the Hamiltonian is given on some abstract Hilbert space $\mathfrak{H}$ in the orthonormal basis $\{\phi_n\}_{n=0}^{\infty}$ by

$$H = \omega \sum_{n=0}^{\infty} \epsilon_n |\phi_n\rangle\langle\phi_n|, \quad \epsilon_0 = 0, \tag{2.20}$$

where ω is a constant with the dimensions of energy (we take $\hbar = 1$). The variable J is then generally identified with the classical action and γ with the conjugate angle. It is this identification that prompted our choice of the subscripts for the Hilbert spaces $\mathfrak{H}_{\text{ang}}$ and $\mathfrak{H}_{\text{ac-ang}}$.

Following (2.8) we can now construct the *non-normalized* Gazeau–Klauder-type coherent states in $\mathfrak{H}$ using the vectors (2.15),

$$|\eta_{J,\gamma}\rangle = \sum_{n=0}^{\infty} \overline{\Psi_n(J,\gamma)} |\phi_n\rangle = \sum_{n=0}^{\infty} \frac{J^{n/2} e^{-i\epsilon_n \gamma}}{\sqrt{\epsilon_n!}} |\phi_n\rangle. \tag{2.21}$$

Once again, the map

$$W: \mathfrak{H} \to \mathfrak{H}_{\text{ac-ang}}, \quad (W\phi)(J,\gamma) = \langle \eta_{J,\gamma}|\phi\rangle_{\mathfrak{H}},$$

is unitary. If instead, we use the normalized vectors,

$$|J,\gamma\rangle = \mathcal{N}(J)^{-1/2} |\eta_{J,\gamma}\rangle, \tag{2.22}$$

with $\mathcal{N}$ as in (2.16), the resolution of the identity becomes

$$\int_0^L \left[\int_{\mathbb{R}} |J,\gamma\rangle\langle J,\gamma| \mathcal{N}(J) \mathrm{d}\mu_{\mathcal{B}}(\gamma) \right] \mathrm{d}\nu(J) = I_{\mathfrak{H}}. \tag{2.23}$$

We also have the formal reconstruction formula,

$$|\phi\rangle = \int_0^L \left[\int_{\mathbb{R}} \Phi(J,\gamma) |J,\gamma\rangle \mathcal{N}(J) \mathrm{d}\mu_{\mathcal{B}}(\gamma) \right] \mathrm{d}\nu(J), \quad \Phi(J,\gamma) = \langle J,\gamma|\phi\rangle_{\mathfrak{H}}, \tag{2.24}$$

which easily follows from (2.23).

The Gazeau–Klauder coherent states are characterized by the *temporal stability* property,

$$e^{-iHt}|J,\gamma\rangle = |J,\gamma+\omega t\rangle, \tag{2.25}$$

and the *action identity*,

$$\langle J,\gamma|H|J,\gamma\rangle_{\mathfrak{H}} = \omega J. \tag{2.26}$$

If for a given Hamiltonian, $\epsilon_0 \neq 0$, then as discussed in Sec. II, we work with the shifted Hamiltonian $H' = H - \omega\epsilon_0 I_{\mathfrak{H}}$, and use $\varepsilon_n = \epsilon_n - \epsilon_0$ to construct coherent states. In this case,

$$\begin{aligned} e^{-iHt}|J,\gamma\rangle &= e^{-iH't} e^{-i\omega\epsilon_0 t}|J,\gamma\rangle = e^{-i\omega\epsilon_0 t}|J,\gamma+\omega t\rangle, \\ \langle J,\gamma|H|J,\gamma\rangle_{\mathfrak{H}} &= \langle J,\gamma|H' + \omega\epsilon_0|J,\gamma\rangle_{\mathfrak{H}} = \omega J + \omega\epsilon_0. \end{aligned} \tag{2.27}$$

One final comment about coherent states of the type (2.21), there are two probability densities naturally associated with them. The first is the one associated with the measure $\mathrm{d}\nu$ (over the interval $[0,J]$). The second is the discrete density associated with the "event" $\{\phi_n\}$, given by

$$|\langle \phi_n|J,\gamma\rangle|^2 = \frac{J^n}{\epsilon_n! \mathcal{N}(J)}.$$

The physical meaning of these and their inter-relation are discussed in detail in Ref. 11.

III. VECTOR COHERENT STATES OF THE GAZEAU–KLAUDER TYPE

Suppose now that the Hamiltonian H (acting on the Hilbert space $\mathfrak{H}$) has a discrete positive spectrum and that the eigenvectors ϕ_{jk}, $j=1,2,3,\ldots,N<\infty$, $k=0,1,2,3,\ldots,\infty$, can be grouped into N families, each containing an infinite number of vectors. (Such a situation could arise, for example, through the lifting of an N-fold degeneracy in the energy spectrum, by an interaction. Therefore k labels the *main* energy levels while j labels the *sublevels* generated by, e.g., a small perturbation.) Furthermore, assume that the corresponding eigenvalues $E_{jk}=\omega\epsilon_{jk}$ satisfy $\epsilon_{j0}=0$, $j=1,2,3,\ldots,N$, and $\epsilon_{jk}\neq\epsilon_{j'\ell}$ if $k\neq\ell$ and $\forall j,j'$. Denote by $\mathfrak{H}_j$ the subspace of $\mathfrak{H}$ spanned by the vectors ϕ_{jk}, $k=0,1,2,\ldots,\infty$, and by $\mathbb{P}_j$ the projection operator onto this subspace. Then $H=\oplus_{j=1}^{N}H_j$, with $H_j=\omega\Sigma_{k=0}^{\infty}\epsilon_{jk}|\phi_{jk}\rangle\langle\phi_{jk}|$, which leaves $\mathfrak{H}_j$ stable. We will give an example of such a decomposition in the first application below. In $\mathfrak{H}_j$ we define the coherent states,

$$|J_j,\gamma_j\rangle=\mathcal{N}(J_j)^{-1/2}\sum_{k=0}^{\infty}\frac{J_j^{k/2}e^{-i\epsilon_{jk}\gamma_j}}{\sqrt{\epsilon_{j1}\epsilon_{j2}\ldots\epsilon_{jk}}}|\phi_{jk}\rangle. \tag{3.1}$$

Here $-\infty<\gamma_j<\infty$ and $0\leqslant J_j<L_j=\lim_{k\to\infty}\epsilon_{jk}$, and we assume that $L_j>0$. The normalization factor $\mathcal{N}(J_j)$ is chosen so that

$$\langle J_j,\gamma_j|J_k,\gamma_k\rangle=\delta_{jk}. \tag{3.2}$$

These states also satisfy

$$e^{-iH_jt}|J_j,\gamma_j\rangle=|J_j,\gamma_j+\omega t\rangle,\quad \langle J_j,\gamma_j|H_k|J_k,\gamma_k\rangle=\omega J_j\delta_{jk}, \tag{3.3}$$

and the "partial resolution of the identity"

$$\int_0^{L_j}\left[\int_{\mathbb{R}}|J_j,\gamma_j\rangle\langle J_j,\gamma_j|\mathcal{N}(J_j)\mathrm{d}\mu_{\mathcal{B}}(\gamma_j)\right]\mathrm{d}\nu_j(J_j)=\mathbb{P}_j, \tag{3.4}$$

where $\mathrm{d}\mu_{\mathcal{B}}$ is as in (2.12) and the measure $\mathrm{d}\nu_j(J_j)$ is defined through the moment problem

$$\int_0^{L_j}J^n\,\mathrm{d}\nu_j(J)=\epsilon_{j1}\epsilon_{j2}\cdots\epsilon_{jn},\quad \int_0^{L_j}\mathrm{d}\nu_j(J)=1. \tag{3.5}$$

Next, introducing the diagonal matrices,

$$\begin{gathered}\mathbf{J}=\mathrm{diag}(J_1,J_2,\ldots,J_N),\quad \boldsymbol{\epsilon}_k=\mathrm{diag}(\epsilon_{1k},\epsilon_{2k},\ldots,\epsilon_{Nk}),\\ \boldsymbol{\gamma}=\mathrm{diag}(\gamma_1,\gamma_2,\ldots,\gamma_N),\quad \boldsymbol{\epsilon}_k!=\boldsymbol{\epsilon}_1,\boldsymbol{\epsilon}_2\cdots\boldsymbol{\epsilon}_k,\end{gathered} \tag{3.6}$$

and the vectors

$$|\boldsymbol{\Phi}_k;j\rangle=\begin{pmatrix}0\\ \vdots\\ |\phi_{jk}\rangle\\ \vdots\\ 0\end{pmatrix},\quad j=1,2,\ldots,N,\quad k=0,1,2,\ldots, \tag{3.7}$$

we may rewrite the vectors (3.1) as

$$|\mathbf{J},\boldsymbol{\gamma};j\rangle := \mathcal{N}(J_j)^{-1/2}\sum_{n=0}^{\infty}[\boldsymbol{\varepsilon}_k!]^{-1/2}\mathbf{J}^{k/2}\exp[-i\boldsymbol{\varepsilon}_k\gamma]|\boldsymbol{\Phi}_k;j\rangle = \begin{pmatrix} 0 \\ \vdots \\ |J_j,\gamma_j\rangle \\ \vdots \\ 0 \end{pmatrix}. \tag{3.8}$$

We call these states *vector coherent states* for the Hamiltonian H. Note that, in this representation, H is a diagonal operator, $H=\mathrm{diag}\,(H_1,H_2,\ldots,H_N)$, each H_j being an infinite diagonal matrix with eigenvalues $\omega\boldsymbol{\epsilon}_{jk}$, $k=0,1,2,\ldots$.

$$e^{-iHt}|\mathbf{J},\boldsymbol{\gamma};j\rangle = |\mathbf{J},\boldsymbol{\gamma}+\omega t\mathbf{d}_j;j\rangle, \quad \langle\mathbf{J},\boldsymbol{\gamma};j|H|\mathbf{J},\boldsymbol{\gamma};j\rangle = \omega J_j, \tag{3.9}$$

where $\mathbf{d}_j$ is the diagonal matrix with one in the jj position and zeroes elsewhere. Furthermore, we have the resolution of the identity on $\mathfrak{H}$,

$$\sum_{j=0}^{N}\int_0^{L_N}\cdots\int_0^{L_1}\left[\int_{\mathbb{R}^N}|\mathbf{J},\boldsymbol{\gamma};j\rangle\langle\mathbf{J},\boldsymbol{\gamma};j|\mathcal{N}(J_j)\mathrm{d}\mu_{\mathcal{B}}(\gamma)\right]\mathrm{d}\nu(\mathbf{J}) = I_{\mathfrak{H}}, \tag{3.10}$$

with

$$\mathrm{d}\nu(\mathbf{J}) = \mathrm{d}\nu(J_1)\mathrm{d}\nu(J_2)\cdots\mathrm{d}\nu(J_N), \quad \mathrm{d}\mu_{\mathcal{B}}(\boldsymbol{\gamma}) = \mathrm{d}\mu_{\mathcal{B}}(\gamma_1)\mathrm{d}\mu_{\mathcal{B}}(\gamma_2)\cdots\mathrm{d}\mu_{\mathcal{B}}(\gamma_N).$$

In view of the fact that [see also (3.2)]

$$\langle\mathbf{J},\boldsymbol{\gamma};j|\mathbf{J},\boldsymbol{\gamma};\ell\rangle = \delta_{j\ell}, \tag{3.11}$$

a general vector coherent state for such a system may be written as a linear combination,

$$|\mathbf{J},\boldsymbol{\gamma}\rangle = \sum_{j=0}^{N} c_j|\mathbf{J},\boldsymbol{\gamma};j\rangle.$$

However, such a state would, in general, not be of the Gazeau–Klauder type, unless the levels $\boldsymbol{\epsilon}_{jk}$, $j=1,2,\ldots,N$, are degenerate for all k. Associated to the vector coherent states (3.8) is the *matrix-valued* reproducing kernel, $\mathbf{K}(\mathbf{J},\boldsymbol{\gamma},\mathbf{J}',\boldsymbol{\gamma}')$, with matrix elements

$$\mathbf{K}(\mathbf{J},\boldsymbol{\gamma};\mathbf{J}',\boldsymbol{\gamma}')_{j\ell} = \langle\mathbf{J},\boldsymbol{\gamma};\mathbf{j}|\mathbf{J}',\boldsymbol{\gamma};\ell\rangle. \tag{3.12}$$

This kernel has the properties,

$$\mathbf{K}(\mathbf{J},\boldsymbol{\gamma};\mathbf{J},\boldsymbol{\gamma})_{jj} = \||\mathbf{J},\boldsymbol{\gamma};j\rangle\|^2 > 0, \quad \mathbf{K}(\mathbf{J},\boldsymbol{\gamma};\mathbf{J}',\boldsymbol{\gamma}')_{j\ell} = \overline{\mathbf{K}(\mathbf{J}',\boldsymbol{\gamma}';\mathbf{J},\boldsymbol{\gamma})_{\ell j}},$$

$$\sum_{j'=0}^{N}\int_0^{L_N}\cdots\int_0^{L_1}\left[\int_{\mathbb{R}^N}\mathbf{K}(\mathbf{J},\boldsymbol{\gamma};\mathbf{J}'',\boldsymbol{\gamma}'')_{jj'}\mathbf{K}(\mathbf{J}'',\boldsymbol{\gamma}'';\mathbf{J}',\boldsymbol{\gamma}')_{j'\ell}\mathcal{N}(J_\ell)\mathrm{d}\mu_{\mathcal{B}}(\boldsymbol{\gamma}'')\right]\mathrm{d}\nu(\mathbf{J}'') = \mathbf{K}(\mathbf{J},\boldsymbol{\gamma};\mathbf{J}',\boldsymbol{\gamma}')_{j\ell}. \tag{3.13}$$

Some examples: Let us consider a model described by the Hamiltonian

$$H = \omega a^\dagger a + \boldsymbol{\epsilon}_1 c_1^\dagger c_1 + \boldsymbol{\epsilon}_2 c_2^\dagger c_2 + (g_1 c_1^\dagger c_1 + g_2 c_2^\dagger c_2)(a + a^\dagger), \tag{3.14}$$

where the following commutation rules hold:

$$[a,a^\dagger] = \{c_1,c_1^\dagger\} = \{c_2,c_2^\dagger\} = I \tag{3.15}$$

and

$$[a^{\sharp}, a_i^{\sharp}] = \{c_1, c_1\} = \{c_2, c_2\} = 0, \tag{3.16}$$

where $a^{\#}$ stands for a or $a^{\dagger}$, $[A,B]=AB-BA$ and $\{A,B\}=AB+BA$. This model, which describes an interaction between a single mode, $(a,a^{\dagger})$, of the radiation field with two Fermi-type modes, has been analyzed quite recently in Ref. 17.

A convenient feature of the above Hamiltonian is that its spectrum can be obtained explicitly, as well as its eigenvectors. In fact, considering the *fermionic* part, it is clear that all the eigenstates of H must be of the following form:

$$\Phi = \varphi \otimes \Psi_{kl}, \quad \text{where } \Psi_{kl} = (c_1^{\dagger})^k (c_2^{\dagger})^l \Psi_{00}, \tag{3.17}$$

with $k,l=0,1$, and where $\Psi_{0,0}$ is the fermionic vacuum, $c_j\Psi_{00}=0$, for $j=1,2$. The vector φ must still be determined, but it is clear that it cannot, in general, be proportional to $(a^{\dagger})^n\cdot\varphi_0$, where $a\varphi_0=0$, since the interaction part of H is not diagonal on these vectors. However it is a rather simple exercise to check that

$$H(\varphi \otimes \Psi_{00}) = \omega a^{\dagger} a (\varphi \otimes \Psi_{00}),$$

$$\begin{aligned} H(\varphi \otimes \Psi_{10}) &= (\omega a^{\dagger} a + \epsilon_1 + g_1(a + a^{\dagger}))(\varphi \otimes \Psi_{10}), \\ H(\varphi \otimes \Psi_{01}) &= (\omega a^{\dagger} a + \epsilon_2 + g_2(a + a^{\dagger}))(\varphi \otimes \Psi_{01}), \end{aligned} \tag{3.18}$$

$$H(\varphi \otimes \Psi_{11}) = (\omega a^{\dagger} a + \epsilon_1 + \epsilon_2 + (g_1 + g_2)(a + a^{\dagger}))(\varphi \otimes \Psi_{11}).$$

To proceed further, we observe that in each of the four cases above, φ is an eigenvector of a self-adjoint operator of the type,

$$B_{kl} = \omega A_{kl}^{\dagger} A_{kl} + \left(\varepsilon_{kl} - \frac{g_{kl}^2}{\omega}\right) I, \quad A_{kl} = a + \frac{g_{kl}}{\omega}, \quad [A_{kl}, A_{kl}^{\dagger}] = 1, \quad k,l = 0,1, \tag{3.19}$$

where,

$$\varepsilon_{kl} = l\varepsilon_1 + k\varepsilon_2, \quad g_{kl} = lg_1 + kg_2, \quad l,k = 0,1.$$

We know, however, that

$$A_{kl} = \exp\left[i\sqrt{2}\frac{g_{kl}}{\omega} P \right] a \exp\left[-i\sqrt{2}\frac{g_{kl}}{\omega} P \right], \quad \text{where } P = \frac{a - a^{\dagger}}{i\sqrt{2}}.$$

Thus, the eigenvectors of B_{kl} are,

$$|\Phi_n^{kl}\rangle = \exp\left[i\sqrt{2}\frac{g_{kl}}{\omega} P \right] |n\rangle = \frac{(A_{kl}^{\dagger})^n}{\sqrt{n!}} |\Phi_0^{kl}\rangle, \tag{3.20}$$

where $|n\rangle = a^n/\sqrt{n!}|0\rangle$ are the eigenvectors of the usual number operator $N=a^{\dagger}a$.

The diagonalization of H is now complete. Our results can be summarized as follows:
eigenstates of H, $\{\varphi_n^{kl} := \Phi_n^{kl} \otimes \Psi_{kl}$, where $n=0,1,2,\ldots$, and $k,l=0,1\}$,
eigenvalues of H, $\{E_n^{kl}$, with $n=0,1,2,\ldots$, and $k,l=0,1\}$,

where the relevant quantities are shown in the following table.

k, l	$E_n^{kl}=$	$\Psi_{kl}=$	$\Phi_n^{kl}=$	where	and
0, 0	ωn	Ψ_{00}	$\frac{(a^\dagger)^n}{\sqrt{n!}}\Phi_0^{00}$	$a\Phi_0^{00}=0$	
1, 0	$\omega n+\epsilon_1-\frac{g_1^2}{\omega}$	$c_1^\dagger\Psi_{00}$	$\frac{(A_{10}^\dagger)^n}{\sqrt{n!}}\Phi_0^{10}$	$A_{10}\Phi_0^{10}=0$	$A_{10}=a+\frac{g_1}{\omega}$
0, 1	$\omega n+\epsilon_2-\frac{g_2^2}{\omega}$	$c_2^\dagger\Psi_{00}$	$\frac{(A_{01}^\dagger)^n}{\sqrt{n!}}\Phi_0^{01}$	$A_{01}\Phi_0^{01}=0$	$A_{01}=a+\frac{g_2}{\omega}$
1, 1	$\omega n+\epsilon_1+\epsilon_2-\frac{(g_1+g_2)^2}{\omega}$	$c_1^\dagger c_2^\dagger\Psi_{00}$	$\frac{(A_{11}^\dagger)^n}{\sqrt{n!}}\Phi_0^{11}$	$A_{11}\Phi_0^{11}=0$	$A_{11}=a+\frac{g_1+g_2}{\omega}$

From (3.20) it is also clear that the vectors Φ_0^{kl} are just the well-known canonical coherent states $|z\rangle$, with $z=-g_{kl}/\omega$. Thus, in the position space representation these vectors are shifted Gaussians,

$$\Phi_0^{kl}(x)\simeq e^{-1/2(x+\sqrt{2}g_{kl})^2},\quad k=0,1.$$

In order to build Gazeau–Klauder type of coherent states for this Hamiltonian, we see now that it breaks up into four orthogonal parts,

$$H=\oplus_{k,l=0,1}H_{kl},\quad \text{where } H_{kl}=\sum_{n=0}^{\infty}E_n^{kl}|\varphi_n^{kl}\rangle\langle\varphi_n^{kl}|. \tag{3.21}$$

Since the lowest eigenvalue E_0^{kl}, for the component Hamiltonian H_{kl}, is zero only for $k=l=0$, we work with $H'=\oplus_{k,l=0,1}H'_{kl}$, where $H'_{kl}=\Sigma_{n=0}^{\infty}(E_n^{kl}-E_0^{kl})|\varphi_n^{kl}\rangle\langle\varphi_n^{kl}|$. But $E_n^{kl}-E_0^{kl}=\omega n$. (Note that H and H' commute.) Thus, the vector coherent states of the present model are 4-component vectors, involving the standard canonical coherent states, $|z_{kl}\rangle$, $k,l=0,1$, $z_{kl}\in\mathbb{C}$, built on the bosonic vacuum state Φ_0^{kl}. Thus, introducing the diagonal matrix $\mathfrak{Z}=\mathrm{diag}(z_{00},z_{10},z_{01},z_{11})$, we can write the vectors (3.8) for the present case as

$$|\mathfrak{Z};kl\rangle=|z_{kl}\rangle|\Psi_{kl}\rangle=e^{-|z_{kl}|^2/2}\sum_{n=0}^{\infty}\frac{\mathfrak{Z}^n}{\sqrt{n!}}|\Psi_{kl}\rangle|\Phi_n^{kl}\rangle,\quad j,k=1,2, \tag{3.22}$$

where in the present representation, the vectors Ψ_{kl} form the canonical basis of $\mathbb{C}^4$,

$$\Psi_{00}=\begin{pmatrix}1\\0\\0\\0\end{pmatrix},\quad \Psi_{10}=\begin{pmatrix}0\\1\\0\\0\end{pmatrix},\quad \Psi_{01}=\begin{pmatrix}0\\0\\1\\0\end{pmatrix},\quad \Psi_{11}=\begin{pmatrix}0\\0\\0\\1\end{pmatrix}.$$

These then are the Gazeau–Klauder-type vector coherent states for the Hamiltonian (3.14). Equations (3.9) and (3.10) have obvious transcriptions for these states.

One could also consider the following variant of the Hamiltonian (3.14):

$$H = \omega a^\dagger a + \epsilon_1 c_1^\dagger c_1 + \epsilon_2 c_2^\dagger c_2 + \sum_{i,j=1}^{2} g_{ij} c_i^\dagger c_j (a + a^\dagger), \tag{3.23}$$

where the same commutation rules (3.15) and (3.16) are assumed and

$$g = \begin{pmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{pmatrix}$$

is a 2×2 Hermitian matrix, $g=\overline{g}^T$. Let V be the unitary matrix which diagonalizes g,

$$VgV^{-1} = g_d := \begin{pmatrix} g_1 & 0 \\ 0 & g_2 \end{pmatrix},$$

so that, defining

$$d = \begin{pmatrix} d_1 \\ d_2 \end{pmatrix} = Vc = V\begin{pmatrix} c_1 \\ c_2 \end{pmatrix},$$

and $d^\dagger = c^\dagger V^\dagger = (d_1^\dagger, d_2^\dagger)$, the operators d_j again obey the same anticommutation relations as the c_j. Also, $\Sigma_{i,j=1}^2 g_{ij} c_i^\dagger c_j = g_1 d_1^\dagger d_1 + g_2 d_2^\dagger d_2$. However, if $\epsilon_1 \neq \epsilon_2$, this change of variables would make the free fermionic Hamiltonian $\epsilon_1 c_1^\dagger c_1 + \epsilon_2 c_2^\dagger c_2$ no longer diagonal, while if $\epsilon_1 = \epsilon_2 = \epsilon$ we get

$$H = \omega a^\dagger a + \epsilon d_1^\dagger d_1 + \epsilon d_2^\dagger d_2 + (g_1 d_1^\dagger d_1 + g_2 d_2^\dagger d_2)(a + a^\dagger),$$

for which the entire analysis performed above can be repeated.

Remark: A possible method for describing a nondegenerate two-level atom (i.e., $\epsilon_1 \neq \epsilon_2$), which is the one considered in Ref. 17, can be obtained by adapting the previous procedure as follows: we consider a fictitious three-level atom interacting with the radiation field in the following way:

$$H = \omega a^\dagger a + \epsilon (c_1^\dagger c_1 + c_2^\dagger c_2 + c_3^\dagger c_3) + \sum_{i,j=1}^{3} g_{ij} c_i^\dagger c_j (a + a^\dagger),$$

where now $\{g_{ij}\}$ is a 3×3 Hermitian matrix. We recover a two-level system by considering a subspace of the complete Hilbert space spanned by the vectors $\Psi_{kl} \otimes \Phi_n^{kl}$, where the Φ_n^{kl} are constructed by trivially extending the foregoing procedure. Next we take $\Psi_0^{00} = \Psi_0$ to be the ground state of c_j, $j=1,2,3$ and set $\Psi_{10} = c_1^\dagger \Psi_0$, $\Psi_{01} = c_2^\dagger c_3^\dagger \Psi_0$, and $\Psi_{11} = c_1^\dagger c_2^\dagger c_3^\dagger \Psi_0$. (The interpretation is clear, Ψ_0 corresponds to both levels of our atom being empty, while Ψ_{10}, Ψ_{01}, and Ψ_{11} correspond, respectively, to the first, second, and both levels being occupied.)

If it is now possible to ensure that the resulting energy spectrum E_n^{kl}, $n=0,1,2,\ldots$, $k,l=0,1$, has no degeneracies, we could build Grazeau–Klauder-type coherent states for this system. On the other hand, it is easily verified that degeneracy will be avoided if the physical constants of the model satisfy the following inequalities:

$$0 < \epsilon_1 - \frac{g_1^2}{\omega} < \epsilon_2 - \frac{g_2^2}{\omega} < \epsilon_1 + \epsilon_2 - \frac{(g_1^2 + g_2^2)}{\omega} < \omega.$$

In this case we set $E_0 = E_0^{00} = 0$, $E_1 = E_0^{10} = \epsilon_1 - g_1^2/\omega$, $E_2 = E_0^{01} = \epsilon_2 - g_2^2/\omega$, $E_3 = E_0^{11} = \epsilon_1 + \epsilon_2 - [(g_1^2 + g_2^2)/\omega]$, $E_4 = E_1^{00} = \omega$, and so on and write, for the corresponding eigenstates $\varphi_0 = \varphi_0^{00}$, $\varphi_1 = \varphi_0^{10}$, $\varphi_2 = \varphi_0^{01}$, $\varphi_3 = \varphi_0^{11}$, $\varphi_4 = \varphi_1^{00}$, and so on. Finally, defining $\epsilon_n = E_n/\omega$, we recover a sequence of quantities satisfying the inequalities $0 = \epsilon_0 < \epsilon_1 < \epsilon_2 < \cdots$, as required in Ref. 10. Thus we obtain the coherent states $|J, \gamma\rangle = N(J)^{-1/2} \Sigma_{n=0}^{\infty} [(J^{n/2} e^{-i\gamma\epsilon_n})/\sqrt{\epsilon_n!}] \varphi_n$, with all the required properties.

IV. HAMILTONIANS WITH DEGENERACIES

Here we extend the preceding construction to the situation in which some (or perhaps all) of the eigenvalues of the given Hamiltonian have degeneracies. We will consider two situations, first, where all the degeneracies are finite and second, where they are all countably infinite. In the first case, we will show that a natural way to recover all the required properties of the Gazeau–Klauder-type coherent states, such as the resolution of the identity, temporal stability, and the action identity, among others, is to introduce a third parameter into the definition of the coherent states, replacing $|J,\gamma\rangle$ by $|J,\gamma,\theta\rangle$. The extension we are proposing is somewhat different from that suggested in Refs. 8 and 15, since it only involves one extra parameter. Moreover, as we will demonstrate, our method can also be adapted to the case of infinite degeneracies.

A. Finite degeneracies

Let us now consider a Hamiltonian H, the eigenvalues of which are all discrete with the lowest eigenvalue being again zero. Assume that the nth level, $E_n=\omega\epsilon_n$, has a degeneracy $d(n)$, in general different from 1. We assume $d(n)<\infty$, for all n. Denote by $|n,j\rangle$, $n=0,1,2,\ldots$, $j=1,2,\ldots,d(n)$, the eigenvectors of the Hamiltonian H so that $H|n,j\rangle=E_n|n,j\rangle$, with n labeling the level and j counting the degeneracy. As usual we introduce the dimensionless quantity ϵ_n and again, without loss of generality, arrange them in the sequence $0=\epsilon_0<\epsilon_1<\epsilon_2<\cdots$. This means that the Hamiltonian is $H=\omega\Sigma_{n=0}^{\infty}\Sigma_{j=1}^{d(n)}\epsilon_n|n,j\rangle\langle n,j|$. We next introduce the parameter $\theta\in[0,2\pi)$ and define

$$|J,\gamma,\theta\rangle := \mathcal{N}(J)^{-1/2}\sum_{n=0}^{\infty}\sum_{j=1}^{d(n)}\frac{J^{n/2}e^{-i\epsilon_n\gamma}e^{-ij\theta}}{\sqrt{\rho_n}}|n,j\rangle, \tag{4.1}$$

with J and γ as before. We now prove that, for appropriate choice of ρ_n, these states satisfy the following properties, which naturally generalize the analogous ones stated at the beginning of Sec. II:

(i) *Continuity*, if $(J,\gamma,\theta)\to(J',\gamma',\theta')$ then $|J,\gamma,\mu\rangle\to|J',\gamma',\mu'\rangle$.
(ii) *Resolution of the identity*, $\int|J,\gamma,\theta\rangle\langle J,\gamma,\theta|\mathrm{d}m(J,\gamma,\theta)=I$, for some appropriately chosen measure dm.
(iii) *Temporal stability*, $e^{-iHt}|J,\gamma,\theta\rangle=|J,\gamma+\omega t,\theta\rangle$, for some constant ω.
(iv) *Action identity*, $\langle J,\gamma,\theta|H|J,\gamma,\theta\rangle=\omega J$.

Indeed, continuity follows automatically from the definition itself. As for normalization, we observe that

$$\langle J,\gamma,\theta|J,\gamma,\theta\rangle=\mathcal{N}(J)^{-1}\sum_{n,m=0}^{\infty}\sum_{j=1}^{d(n)}\sum_{l=0}^{d(m)}\frac{J^{n/2+m/2}e^{-i(\epsilon_n-\epsilon_m)\gamma}e^{-i(j-l)\theta}}{\sqrt{\rho_n\rho_m}}\langle m,l|n,j\rangle=\mathcal{N}(J)^{-1}\sum_{n=0}^{\infty}\sum_{j=1}^{d(n)}\frac{J^n}{\rho_n}$$
$$=\mathcal{N}(J)^{-1}\sum_{n=0}^{\infty}\frac{J^n d(n)}{\rho_n},$$

from which we conclude that $\langle J,\gamma,\theta|J,\gamma,\theta\rangle=1$ if and only if

$$\mathcal{N}(J)=\sum_{n=0}^{\infty}\frac{J^n d(n)}{\rho_n}. \tag{4.2}$$

Of course, this is a power series in J and we assume that it has a radius of convergence $L>0$.

The proof of temporal stability is easy,

$$e^{-iHt}|J,\gamma,\theta\rangle = e^{-iHt}\mathcal{N}(J)^{-1/2}\sum_{n=0}^{\infty}\sum_{j=1}^{d(n)}\frac{J^{n/2}e^{-i\epsilon_n\gamma}e^{-ij\theta}}{\sqrt{\rho_n}}|n,j\rangle = \mathcal{N}(J)^{-1/2}\sum_{n=0}^{\infty}\sum_{j=1}^{d(n)}\frac{J^{n/2}e^{-i\epsilon_n\gamma}e^{-ij\theta}}{\sqrt{\rho_n}}e^{-i\omega\epsilon_n t}|n,j\rangle$$
$$= |J,\gamma+\omega t,\theta\rangle.$$

In order for the action identity to be satisfied, we need a condition on the ρ_n. Since $\epsilon_0=0$, we get

$$\langle J,\gamma,\theta|H|J,\gamma,\theta\rangle = \omega J\left[\mathcal{N}(J)^{-1}\sum_{n=1}^{\infty}\frac{\epsilon_n J^{n-1}d(n)}{\rho_n}\right].$$

Thus, in order for the action identity to hold the expression within the square brackets must equal one. This can be achieved if we require that

$$\frac{\epsilon_n d(n)}{\rho_n} = \frac{d(n-1)}{\rho_{n-1}}, \quad n=1,2,3,\ldots,$$

for then

$$\rho_n = \epsilon_n\frac{d(n)}{d(n-1)}\rho_{n-1} = \cdots = \epsilon_n!\frac{d(n)}{d(0)}\rho_0, \quad \text{by iteration.}$$

We choose $\rho_0=d(0)$ so that

$$\rho_n = \epsilon_n! d(n), \quad n=0,1,2,\ldots, \quad \text{and} \quad \mathcal{N}(J)=\sum_{n=0}^{\infty}\frac{J^n}{\epsilon_n!}. \tag{4.3}$$

Thus the coherent states (4.1) become

$$|J,\gamma,\theta\rangle := \mathcal{N}(J)^{-1/2}\sum_{n=0}^{\infty}\sum_{j=1}^{d(n)}\frac{J^{n/2}e^{-i\epsilon_n\gamma}e^{-ij\theta}}{\sqrt{\epsilon_n! d(n)}}|n,j\rangle. \tag{4.4}$$

It remains only to determine the measure dm in order for the resolution of the identity to be satisfied. Proceeding as in Sec. II, and assuming that the measure dν solves the moment problem

$$\int_0^L J^n\,\mathrm{d}\nu(J) = \epsilon_n! d(n), \quad n=0,1,2,\ldots, \tag{4.5}$$

we take

$$\mathrm{d}m(J,\gamma,\theta) = \frac{\mathcal{N}(J)}{2\pi}\mathrm{d}\nu(J)\mathrm{d}\mu_{\mathcal{B}}(\gamma)\mathrm{d}\theta, \tag{4.6}$$

where d$\mu_{\mathcal{B}}$ is the symbolic measure defined in (2.12). Then, we prove exactly as in Sec. II, the identity [see (2.23)]

$$\frac{1}{2\pi}\int_0^L\left\{\int_2^{2\pi}\left[\int_{\mathbb{R}}|J,\gamma,\theta\rangle\langle J,\gamma,\theta|\mathcal{N}(J)\mathrm{d}\mu_{\mathcal{B}}(\gamma)\right]\mathrm{d}\theta\right\}\mathrm{d}\nu(J) = I_{\mathfrak{H}}. \tag{4.7}$$

Remark: If $d(n)=1$ for all n, the above coherent states coincide, apart from an inessential overall phase $e^{-i\theta}$, with the usual Gazeau–Klauder coherent states (2.1). However, when the Hamiltonian H has a nontrivial degeneracy, it is interesting to notice the presence of $d(n)$ in the denominator of the expression for the coherent states in (4.4), which implies that the radius of convergence L depends not only on the eigenvalues of the Hamiltonian but also on their degen-

eracies. Similarly, the measure $d\nu$, solving the moment problem (4.5) and appearing in the resolution of the identity, depends on the degeneracy.

Example 1: Consider the following simple example, consisting of a single boson and a single fermion: $H=\omega(a^\dagger a+c^\dagger c)$, where $[a,a^\dagger]=\{c,c^\dagger\}=I$ and $[a^\#,c^\#]=0$, $x^\#$ being x or $x^\dagger$. Introducing the vacuum Φ_0 of a, and Ψ_0 of c and taking, as usual $\Phi_n=[(a^\dagger)^n/\sqrt{n!}]\Phi_0$, $n=0,1,2,\ldots$, and $\Psi_j=(c^\dagger)^j\Psi_0$, $j=0,1$, we can write the eigenvectors of H as $\varphi_{n,j}=\Phi_0\otimes\Psi_0$ if $n=j=0$, and $\varphi_{n,j}=\Phi_{n-j}\otimes\Psi_j$, if $n=1,2,3,\ldots$, and $j=0,1$. The corresponding eigenvalues are $E_{n,j}=n\omega$, so that they turn out to be degenerate in j. In particular we have $d(0)=1$ and $d(n)=2$ for all $n\geqslant 1$. The normalization can be computed using (4.2), and we get

$$\mathcal{N}(J)=\sum_{n=0}^{\infty}\frac{J^n d(n)}{\rho_n}=1+2\sum_{n=1}^{\infty}\frac{J^n}{\rho_n}=1+\sum_{n=1}^{\infty}\frac{J^n}{n!}=e^J.$$

Definition (4.1) yields therefore,

$$|J,\gamma,\theta\rangle\coloneqq e^{-J/2}\left[e^{-i\theta}|\varphi_{00}\rangle+\sum_{n=1}^{\infty}\sum_{j=1}^{2}\frac{J^{n/2}e^{-in\gamma}e^{-ij\theta}}{\sqrt{2n!}}|\varphi_{nj}\rangle\right]. \tag{4.8}$$

Actually, this time we can restrict the variable γ to the interval $[0,2\pi)$ and use the measure $d\mu_{\mathcal{B}}(\gamma)=(1/2\pi)d\gamma$ in (4.6) instead of the one in (2.12). Furthermore, $0\leqslant J<\infty$ and the measure $d\nu(J)$ must solve the moment problem

$$\int_0^{\infty}J^n\,d\nu(J)=\begin{cases}1, & \text{if } n=0,\\ 2n!, & \text{if } n\geqslant 1.\end{cases}$$

It is then easily seen that $d\nu(J)=[2e^{-J}-\delta(J)]dJ$. Thus, writing

$$dm(J,\gamma,\theta)=\frac{e^J}{4\pi^2}[2e^{-J}-\delta(J)]dJ\,d\gamma\,d\theta,$$

we can prove the resolution of the identity,

$$\int|J,\gamma,\theta\rangle\langle J,\gamma,\theta|dm(J,\gamma,\theta)=I.$$

Finally, introducing the complex variable $z=re^{-i\gamma}=J^{1/2}e^{-i\gamma}$, $z\in\mathbb{C}$, we can rewrite (4.8) as

$$|z,\theta\rangle=e^{-|z|^2/2}\left[e^{-i\theta}|\varphi_{00}\rangle+\sum_{n=1}^{\infty}\sum_{j=1}^{2}\frac{z^n e^{-ij\theta}}{\sqrt{2n!}}|\varphi_{nj}\rangle\right]. \tag{4.9}$$

Example 2: As a second example consider a particle of mass m constrained to move on the xy plane and subject to the force $\vec{F}=(-kx-by,-ky-bx,0)$, derivable from the potential $V(x,y)=\frac{1}{2}k(x^2+y^2)+bxy$. In the rotated coordinates $\xi_\pm=(1/\sqrt{2})(x\pm y)$, this potential assumes the form $V(\xi_+,\xi_-)=\frac{1}{2}m(\omega_+^2\xi_+^2+\omega_-^2\xi_-^2)$, where $\omega_\pm^2=(1/m)(k\pm b)$. The Hamiltonian looks like a two-dimensional harmonic oscillator since, in an obvious notation, we also have $p_x^2+p_y^2=p_+^2+p_-^2$. Introducing finally the creation and annihilation operators for the $\pm$ modes and adding an inessential constant we get $H=\omega_+a_+^\dagger a_++\omega_-a_-^\dagger a_-$. The eigenvalues are therefore $E_{n_+,n_-}=\omega_+n_++\omega_-n_-$ and the corresponding eigenstates are $\varphi_{n_+,n_-}=[(a_+^\dagger)^{n_+}(a_-^\dagger)^{n_-}/\sqrt{n_+!n_-!}]\varphi_{00}$, where $a_-\varphi_{00}=a_+\varphi_{00}=0$. Let us now take, as a concrete example, $b=3k/5$. Then the eigenvalues can be written as $E_{n_+,n_-}=\omega_-(2n_++n_-)$ and the degeneracy can be simply deduced, we notice that the spectrum is ω_-n, $n=2n_++n_-=0,1,2,\ldots$, and $d(2n)=d(2n+1)=n+1$. Therefore, since $\rho_{2n}=(2n)!(n+1)$ and $\rho_{2n+1}=(2n+1)!(n+1)$, we may write

$$|J,\gamma,\theta\rangle = e^{-J/2}\sum_{l=0}^{\infty}\sum_{j=1}^{l+1}\frac{J^l e^{-2i\gamma l}e^{-i\theta j}}{\sqrt{(2l)!(l+1)}}\left[|\Psi_{2l,j}\rangle + \frac{\sqrt{J}e^{-i\gamma}}{\sqrt{2l+1}}|\Psi_{2l+1,j}\rangle\right], \tag{4.10}$$

where we have introduced the states $\Psi_{n,j}$, $n=0,1,2,\ldots$, and $j=1,2,\ldots,d(n)$, in order to keep track of the degeneracy of H. It is trivial to check that these states display temporal stability and the action identity, while it does not seem to be an easy task to find an explicit expression for a measure with respect to which a resolution of the identity would be satisfied. However, as we will discuss in the Appendix, it is possible to find weight functions, which are not necessarily everywhere positive, with respect to which a resolution of the identity could be defined in a *weak* sense.

Example 3: Let us consider now a particle of mass m and electric charge e, subject to a three-dimensional harmonic force $\vec{F}=-k(x,y,z)$ and placed in a uniform magnetic field, oriented along the z axis and given by the vector potential $\vec{A}=(B/2)(-y,x,0)$. The Hamiltonian

$$H = \frac{1}{2m}\left(p_x + \frac{eB}{2}y\right)^2 + \frac{1}{2m}\left(p_y - \frac{eB}{2}x\right)^2 + \frac{1}{2m}p_z^2 + \frac{1}{2}k(x^2+y^2+z^2),$$

can be rewritten as

$$H = N_+(\tilde{\omega}+\Omega) + N_-(\tilde{\omega}-\Omega) + N_z\omega,$$

where we have introduced

$$\Omega = \frac{eB}{2m}, \quad \omega^2 = \frac{k}{m}, \quad \tilde{\omega}^2 = \Omega^2+\omega^2,$$

$$a_u = \frac{1}{\sqrt{2}}\left(\sqrt{m\tilde{\omega}}u + \frac{i}{\sqrt{m\tilde{\omega}}}p_u\right), \quad u=x,y, \quad a_z = \frac{1}{\sqrt{2}}\left(\sqrt{m\omega}z + \frac{i}{\sqrt{m\omega}}p_z\right),$$

$$a_\pm = \frac{a_x \pm i a_y}{\sqrt{2}}, \quad N_\pm = a_\pm^\dagger a_\pm, \quad N_z = a_z^\dagger a_z.$$

The eigenvalues and the eigenstates of H are easily found to be

$$E_{n_+,n_-,n_z} = n_+(\tilde{\omega}+\Omega) + n_-(\tilde{\omega}-\Omega) + n_z\omega,$$

$$\varphi_{n_+,n_-,n_z} = \frac{(a_+^\dagger)^{n_+}(a_-^\dagger)^{n_-}(a_z^\dagger)^{n_z}}{\sqrt{n_+!n_-!n_z!}}\varphi_{000},$$

where $a_-\varphi_{000}=a_+\varphi_{000}=a_z\varphi_{000}=0$. In order to simplify the computation of the degeneracy of this Hamiltonian we assume that $\Omega \ll \omega$. In this approximation H can be written as $H \simeq \omega(N_+ + N_- + N_z)$, which means that the eigenvalues really depend only on $n=n_+ + n_- + n_z$. As in the previous examples we can introduce the eigenvalues $E_n=\omega n$ while the degeneracy of the nth energy level is $d(n)=\Sigma_{k=1}^{n+1}k=\frac{1}{2}(n+1)(n+2)$. If we denote the corresponding eigenstates by Ψ_{nj}, $n=0,1,2,\ldots$, $j=1,2,\ldots,d(n)$, we find

$$|J,\gamma,\theta\rangle := \sqrt{2}e^{-J/2}\sum_{n=0}^{\infty}\sum_{j=1}^{d(n)}\frac{J^{n/2}e^{-in\gamma}e^{-ij\theta}}{\sqrt{(n+2)!}}|\Psi_{nj}\rangle. \tag{4.11}$$

Once again, in this case we may introduce the complex variable $z=re^{-i\gamma}=J^{1/2}e^{-i\gamma}$, $z\in\mathbb{C}$, and write these coherent states as

$$|z,\theta\rangle = \sqrt{2}e^{-|z|^2/2}\sum_{n=0}^{\infty}\sum_{j=1}^{d(n)}\frac{z^n e^{-ij\theta}}{\sqrt{(n+2)!}}|\Psi_{nj}\rangle. \tag{4.12}$$

In this case the resolution of the identity takes the form,

$$\frac{1}{4\pi^2}\int_0^{\infty}\int_0^{2\pi}\int_0^{2\pi}|z,\theta\rangle\langle z,\theta|r^5\,\mathrm{d}\gamma\,\mathrm{d}\theta\,\mathrm{d}r = I. \tag{4.13}$$

It is trivial to check that all the other stated properties are satisfied as well. We should mention here that coherent states for this Hamiltonian have been constructed before (see Refs. 9 and 12). However the treatment there is somewhat different, in that the authors obtain multidimensional coherent states which allow them to study the Berezin–Lieb inequalities for the associated thermodynamic potential.

B. Infinite degeneracies

We are now in a position to construct coherent states for Hamiltonians with infinite degeneracies. Let $\tilde{\mathfrak{H}}$ be an abstract Hilbert space and $\{\phi_{k\ell}\}_{k,\ell=0}^{\infty}$ an orthonormal basis in it,

$$\langle\phi_{k\ell}|\phi_{k'\ell'}\rangle = \delta_{kk'}\delta_{\ell\ell'}.$$

Using these and the basis vectors Ψ_n [see (2.15)] of $\mathfrak{H}_{\text{ac-ang}}$ we now build several families of coherent states on $\tilde{\mathfrak{H}}$

(1) Vector coherent states, VCS1.
These are infinite component vector coherent states,

$$|J,\gamma;\ J'\gamma';\ \ell\rangle^1 = \frac{\Psi_\ell(J',\gamma')}{[\mathcal{N}(J)\mathcal{N}(J')]^{1/2}}\sum_{n=0}^{\infty}\overline{\Psi_n(J,\gamma)}|\phi_{n\ell}\rangle = \frac{J'^{\ell/2}e^{i\epsilon_\ell\gamma'}}{[\mathcal{N}(J)\mathcal{N}(J')]^{1/2}}\sum_{n=0}^{\infty}\frac{J^{n/2}e^{-i\epsilon_n\gamma}}{[\epsilon_\ell!\,\epsilon_n!]^{1/2}}|\phi_{n\ell}\rangle, \tag{4.14}$$

with components $\ell=0,1,2,\ldots$, where $\mathcal{N}(J)=\Sigma_{n=0}^{\infty}(J^n/\epsilon_n!)$. These vectors satisfy the normalization

$$\sum_{\ell=0}^{\infty}{}^1\langle J,\gamma;\ J',\gamma';\ \ell|J,\gamma;\ J',\gamma';\ \ell\rangle^1 = 1$$

(note that according to our present convention, the individual vectors are not normalized) and the resolution of identity condition,

$$\sum_{\ell=0}^{\infty}\int_{\mathbb{R}}\int_{\mathbb{R}}\left[\int_0^L\int_0^L|J,\gamma;\ J',\gamma';\ \ell\rangle^{11}\langle J,\gamma;\ J',\gamma';\ \ell|\right.$$
$$\left.\times\,\mathrm{d}\mu_{\mathcal{B}}(\gamma)\mathrm{d}\mu_{\mathcal{B}}(\gamma')\right]\mathcal{N}(J)\mathcal{N}(J')\mathrm{d}\nu(J)\mathrm{d}\nu(J') = I_{\tilde{\mathfrak{H}}}. \tag{4.15}$$

Notice that $\Psi_\ell(J',\gamma')\overline{\Psi_n(J,\gamma)}$ in (4.14) could be replaced by $\overline{\Psi_\ell(J',\gamma')}\Psi_n(J,\gamma)$ without affecting any of the results stated here, this would simply amount to replacing γ and γ' by $-\gamma$ and $-\gamma'$. The same remark also holds for formulas (4.22) and (4.25) below. However, a deeper significance of this interplay between the two options will emerge when we discuss modular structures in Sec. V below.
Consider now the Hamiltonian

$$H_1 = \sum_{n,\ell=0}^{\infty} \omega\epsilon_n |\phi_{n\ell}\rangle\langle\phi_{n\ell}| = \omega A_1^\dagger A_1, \tag{4.16}$$

where A_1, $A_1^\dagger$ are the operators

$$A_1\phi_{n\ell} = \sqrt{\epsilon_n}\phi_{n-1\ell}, \quad A_1^\dagger\phi_{n\ell} = \sqrt{\epsilon_{n+1}}\phi_{n+1\ell}. \tag{4.17}$$

Each level $\omega\epsilon_n$ of this Hamiltonian is infinitely degenerate, with ℓ counting the degeneracy. Thus the states (4.14) are Gazeau–Klauder-type vector coherent states for this Hamiltonian. Indeed, they satisfy the time stability condition,

$$e^{-iH_1 t}|J,\gamma;\ J'\gamma';\ \ell\rangle^1 = |J,\gamma+\omega t;\ J'\gamma';\ \ell\rangle^1, \tag{4.18}$$

and an action identity, which we could write either as

$$\frac{{}^1\langle J,\gamma;\ J'\gamma';\ \ell|H_1|J,\gamma;\ J'\gamma';\ \ell\rangle^1}{\|\|J,\gamma;\ J'\gamma';\ \ell\rangle^1\|^2} = \omega J, \tag{4.19}$$

or as

$$\sum_{\ell=0}^{\infty} {}^1\langle J,\gamma;\ J',\gamma';\ \ell|H_1|J,\gamma;\ J',\gamma';\ \ell\rangle^1 = \omega J, \tag{4.20}$$

where we have summed over the degenerate levels.

Note that we could just as well have constructed vector coherent states in this example, using an orthonormal basis $\{\Psi_n\}_{n=0}^{\infty}$ in an arbitrary reproducing kernel Hilbert space $\mathfrak{H}_{\rm ker}$,

$$|J,\gamma;\ x;\ \ell\rangle = \frac{\Psi_\ell(x)}{[K(x,x)\mathcal{N}(J')]^{1/2}}\sum_{n=0}^{\infty}\frac{J^{n/2}e^{-i\epsilon_n\gamma}}{[\epsilon_\ell!\,\epsilon_n!]^{1/2}}|\phi_{n\ell}\rangle, \tag{4.21}$$

with $K(x,x)$ as in (2.5) and the degeneracies would again be handled as before. However, the special choice made in (4.14) enables us to write down the related family of vector coherent states, appearing in (4.22) below, which are the coherent states of a second Hamiltonian, acting on the degeneracy levels.

(2) Vector coherent states, VCS2.

These are a second set of similar vector coherent states

$$|J,\gamma;\ J'\gamma';\ n\rangle^2 = \frac{\overline{\Psi_n(J,\gamma)}}{[\mathcal{N}(J)\mathcal{N}(J')]^{1/2}}\sum_{\ell=0}^{\infty}\Psi_\ell(J',\gamma')|\phi_{n\ell}\rangle = \frac{J^{n/2}e^{-i\epsilon_n\gamma}}{[\mathcal{N}(J)\mathcal{N}(J')]^{1/2}}\sum_{\ell=0}^{\infty}\frac{J'^{\ell/2}e^{i\epsilon_\ell\gamma'}}{[\epsilon_\ell!\,\epsilon_n!]^{1/2}}|\phi_{n\ell}\rangle, \tag{4.22}$$

with components $n=0,1,2,\ldots$. Defining a second Hamiltonian,

$$H_2 = \sum_{n,\ell=0}^{\infty} \omega\epsilon_\ell |\phi_{n\ell}\rangle\langle\phi_{n\ell}| = \omega A_2^\dagger A_2, \tag{4.23}$$

where A_2, $A_2^\dagger$ are the operators

$$A_2\phi_{n\ell} = \sqrt{\epsilon_\ell}\phi_{n\ell-1}, \quad A_2^\dagger\phi_{n\ell} = \sqrt{\epsilon_{\ell+1}}\phi_{n\ell+1}, \tag{4.24}$$

we see that the states (4.22) are Kazeau–Klauder-type coherent states for this Hamiltonian. The two Hamiltonians H_1 and H_2 commute and, in fact, H_2 lifts the degeneracy of H_1 and vice versa.

Finally, we can define a third set of coherent states as below.

(3) Bicoherent states, BCS.

These are basically the summed-over versions of the previous two

$$|J,\gamma;\ J',\gamma'\rangle^{\mathrm{BCS}} = \frac{1}{[\mathcal{N}(J)\mathcal{N}(J')]^{1/2}} \sum_{n,\ell=0}^{\infty} \overline{\Psi_n(J,\gamma)}\Psi_\ell(J',\gamma')|\phi_{n\ell}\rangle$$

$$= \frac{1}{[\mathcal{N}(J)\mathcal{N}(J')]^{1/2}} \sum_{n,\ell=0}^{\infty} \frac{J^{n/2}J'^{\ell/2}e^{-i(\epsilon_n\gamma-\epsilon_\ell\gamma')}}{[\epsilon_n!\epsilon_\ell!]^{1/2}}|\phi_{n\ell}\rangle, \tag{4.25}$$

which can be considered as being the multidimensional coherent states (see Ref. 12) of the Hamiltonian,

$$H = H_1 - H_2 = \sum_{n,\ell=0}^{\infty} \omega(\epsilon_n - \epsilon_\ell)|\phi_{n\ell}\rangle\langle\phi_{n\ell}| = \omega[A_1^\dagger A_1 - A_2^\dagger A_2]. \tag{4.26}$$

These coherent states are normalized to unity; they satisfy the resolution of the identity,

$$\int_{\mathbb{R}}\int_{\mathbb{R}}\left[\int_0^L\int_0^L |J,\gamma;\ J',\gamma'\rangle^{\mathrm{BCS}\ \mathrm{BCS}}\langle J,\gamma;\ J',\gamma'|\mathrm{d}\mu_{\mathcal{B}}(\gamma)\mathrm{d}\mu_{\mathcal{B}}(\gamma')\right]\mathcal{N}(J)\mathcal{N}(J')\mathrm{d}\nu(J)\mathrm{d}\nu(J') = I_{\tilde{\mathfrak{H}}}, \tag{4.27}$$

temporal stability condition,

$$e^{-iHt}|J,\gamma;\ J',\gamma'\rangle^{\mathrm{BCS}} = |J,\gamma+\omega t;\ J',\gamma'+\omega t\rangle^{\mathrm{BCS}}, \tag{4.28}$$

and the action identity,

$${}^{\mathrm{BCS}}\langle J,\gamma;\ J',\gamma'|H|J,\gamma;\ J',\gamma'\rangle^{\mathrm{BCS}} = \omega(J-J'). \tag{4.29}$$

A physical example of a Hamiltonian admitting such infinite degeneracies is worked out in the following section.

V. ELECTRON IN A MAGNETIC FIELD

A single electron of unit charge, placed in the *xy* plane and subjected to a constant magnetic field, pointing along the negative *z* direction, has the classical Hamiltonian,

$$H_{\mathrm{elec}} = \frac{1}{2}(\vec{p}+\vec{A})^2 = \frac{1}{2}\left(p_x + \frac{y}{2}\right)^2 + \frac{1}{2}\left(p_y - \frac{x}{2}\right)^2, \tag{5.1}$$

where we have chosen the magnetic vector potential to be $\vec{A}=\frac{1}{2}(y,-x,0)$, using the convenient units introduced in Ref. 7. In this reference it is shown that H_{elec} is the single-electron free Hamiltonian related to the so-called *fractional quantum Hall effect*, FQHE, whose static and dynamical behaviors are yet to be fully understood.[13] In particular, different copies of H_{elec} are used to build up the free Hamiltonian for the *N*-electron system as follows: $H_0^{(N)}=\Sigma_{i=1}^N H_{\mathrm{elec}}(i)$. The many-body model of the FQHE consists, then, of a two-dimensional electron gas, 2DEG (that is a gas of electrons constrained to a two-dimensional layer) in a positive uniform background and subjected to a uniform magnetic field along *z*, whose Hamiltonian (for *N* electrons) is (Ref. 7) $H^{(N)}=H_0^{(N)}+\lambda(H_C^{(N)}+H_B^{(N)})$, with $H_0^{(N)}$ as above, $H_C^{(N)}$ is the canonical Coulomb interaction between charged particles, $H_C^{(N)}=\frac{1}{2}\Sigma_{i\neq j}^N(1/|r_i-r_j|)$, and $H_B^{(N)}$ is the interaction of the charges with the positive background.

One usually considers $\lambda(H_C^{(N)}+H_B^{(N)})$ as a perturbation on the free Hamiltonian $H_0^{(N)}$, and looks for the eigenstates of $H_0^{(N)}$ in the form of a Slater determinant built up with single electron wave functions, the eigenstates of H_{elec}. Already, the solution of this static problem is very hard and many proposals exist in literature. Moreover, a completely satisfactory explanation of the plateau observed for the resistivity tensor is still far from being at hand. For these reasons all possibilities for getting a deeper understanding of this phenomenon would appear relevant. With this in mind we study below a modular structure associated with the single electron model and construct vector

coherent states for the associated Hamiltonians. In a later publication we intend to report on results, using these coherent states, which shed light on the FQHE. We might add, however, that the appearance of this rather sophisticated mathematical structure in this context, is in itself interesting.

On $\tilde{\mathfrak{H}}=L^2(\mathbb{R}^2,\mathrm{d}x\,\mathrm{d}y)$ we introduce the quantized observables,

$$p_x+\frac{y}{2}\to Q_1=-i\frac{\partial}{\partial x}+\frac{y}{2};\quad p_y-\frac{x}{2}\to P_1=-i\frac{\partial}{\partial y}-\frac{x}{2}, \tag{5.2}$$

which satisfy $[Q_1,P_1]=iI_{\tilde{\mathfrak{H}}}$ and in terms of which the quantum Hamiltonian, corresponding to H_{elec} becomes

$$H_1=\tfrac{1}{2}(P_1^2+Q_1^2). \tag{5.3}$$

This is just the oscillator Hamiltonian in one dimension, with eigenvalues $E_n=\omega\left(n+\frac{1}{2}\right)$, $n=0,1,2,\ldots,\infty$. Each level is infinitely degenerate, and we will denote the corresponding normalized eigenvectors by $\Psi_{n\ell}$, $\ell=0,1,2,\ldots,\infty$. If the magnetic field were aligned along the positive z axis [with $\vec{A}=\frac{1}{2}(-y,x,0)$], the corresponding quantum Hamiltonian would have been

$$H_2=\tfrac{1}{2}(P_2^2+Q_2^2). \tag{5.4}$$

with

$$Q_2=-i\frac{\partial}{\partial y}+\frac{x}{2},\quad P_2=-i\frac{\partial}{\partial x}-\frac{y}{2}, \tag{5.5}$$

and $[Q_2,P_2]=iI_{\bar{\mathfrak{H}}}$. The two sets of operators $\{Q_i,P_i\}$, $i=1,2$, mutually commute,

$$[Q_1,Q_2]=[Q_1,P_2]=[P_1,Q_2]=[P_1,P_2]=0. \tag{5.6}$$

(Note that at the classical level, the transformation $(x,y,p_x,p_y)\to[x'=p_x+(y/2),y'=p_y+(x/2),p_{x'}=p_y-(x/2),p_{y'}=p_y-(y/2)]$ is canonical, i.e., $\mathrm{d}x\wedge\mathrm{d}p_x+\mathrm{d}y\wedge\mathrm{d}p_y=\mathrm{d}x'\wedge\mathrm{d}p_{x'}+\mathrm{d}y'\wedge\mathrm{d}p_{y'}$.**)** Thus, $[H_1,H_2]=0$ and the eigenvectors $\Psi_{n\ell}$ of H_1 can be so chosen that they are also the eigenvectors of H_2 in the manner

$$H_1\Psi_{n\ell}=\omega\left(n+\tfrac{1}{2}\right)\Psi_{n\ell},\quad H_2\Psi_{n\ell}=\omega\left(\ell+\tfrac{1}{2}\right)\Psi_{n\ell}, \tag{5.7}$$

so that H_2 lifts the degeneracy of H_1 and vice versa. We shall assume that this has been done.

While we shall follow the technique outlined in the preceding section to construct vector coherent states for the above two Hamiltonians, we shall first analyze the algebraic structures generated by these operators, to get a deeper insight into the nature of the resulting coherent states. In the process we shall display some von Neumann algebraic properties, the appearance of KMS states and, as stated earlier, a certain *modular structure* carried by the above model. The appearance of KMS states in the present context is interesting since, as is well known, KMS states are equilibrium states for infinite-dimensional quantum systems and the associated modular structures, being linked to the (effective) Hamiltonian of the system, are closely related to their dynamical behavior Both these aspects may therefore shed additional light on some still unclear aspects of the FQHE. Details of the mathematical theory underlying modular these structures may be found in Refs. 2, 3, 14, 18, and 19.

On $\mathfrak{H}=L^2(\mathbb{R})$ let Q and P be the usual position and momentum operators in the Schrödinger representation. Denote by $\mathcal{B}_2(\mathfrak{H})\simeq\mathfrak{H}\otimes\bar{\mathfrak{H}}$ the space of Hilbert–Schmidt operators on $\mathfrak{H}$. This is again a Hilbert space, with the scalar product $\langle X|Y\rangle_2=\mathrm{Tr}[X^*Y]$. Let $\{\phi_n\}_{n=0}^{\infty}$ be the orthonormal basis of $\mathfrak{H}$ consisting of the eigenvectors of the oscillator Hamiltonian $H_{\mathrm{osc}}=\frac{1}{2}(P^2+Q^2)$, i.e., $H_{\mathrm{osc}}\phi_n=\omega\left(n+\frac{1}{2}\right)\phi_n$, $n=0,1,2,\ldots$. Then,

$$\phi_{n\ell} := |\phi_n\rangle\langle\phi_\ell|, \quad n,\ell = 0,1,2,\ldots,\infty, \tag{5.8}$$

is an orthonormal basis for $\mathcal{B}_2(\mathfrak{H})$. On $\mathfrak{H}$ define the unitary operators,

$$U(x,y) = e^{-i(xQ+yP)}, \quad (U(x,y)\phi)(\xi) = e^{-ix[\xi-(y/2)]}\phi(\xi - y), \quad (x,y) \in \mathbb{R}^2, \quad \phi \in \mathfrak{H}. \tag{5.9}$$

Then, it is well known (see, for example, Ref. 2) that the map,

$$\mathcal{W}:\mathcal{B}_2(\mathfrak{H}) \to L^2(\mathbb{R}^2, \mathrm{d}x\mathrm{d}y) = \tilde{\mathfrak{H}}, \quad (\mathcal{W}X)(x,y) = \frac{1}{(2\pi)^{1/2}}\mathrm{Tr}[U(x,y)^* X], \tag{5.10}$$

is unitary. Next, if A and B are two operators on $\mathfrak{H}$, we define by $A \vee B$ the operator

$$A \vee B(X) = AXB^*, \quad X \in \mathcal{B}_2(\mathfrak{H}).$$

For a large class of operators A, B (in particular when A and B are both bounded operators), $A \vee B$ defines a linear operator on $\mathcal{B}_2(\mathfrak{H})$. Then straightforward computations (as shown in the Appendix) yield,

$$\mathcal{W}\begin{pmatrix} Q \vee I_{\mathfrak{H}} \\ P \vee I_{\mathfrak{H}} \end{pmatrix}\mathcal{W}^{-1} = \begin{pmatrix} Q_1 \\ P_1 \end{pmatrix}, \quad \mathcal{W}\begin{pmatrix} I_{\mathfrak{H}} \vee Q \\ I_{\mathfrak{H}} \vee P \end{pmatrix}\mathcal{W}^{-1} = \begin{pmatrix} P_2 \\ Q_2 \end{pmatrix}, \tag{5.11}$$

and

$$\mathcal{W}\begin{pmatrix} H_{\mathrm{osc}} \vee I_{\mathfrak{H}} \\ I_{\mathfrak{H}} \vee H_{\mathrm{osc}} \end{pmatrix}\mathcal{W}^{-1} = \begin{pmatrix} H_1 \\ H_2 \end{pmatrix}, \quad \mathcal{W}\phi_{n\ell} = \Psi_{n\ell}, \tag{5.12}$$

where the $\phi_{n\ell}$ are the basis vectors defined in (5.8) and the $\Psi_{n\ell}$ are the normalized eigenvectors defined in (5.7). This also means that these latter vectors form a basis of $\tilde{\mathfrak{H}} = L^2(\mathbb{R}^2, \mathrm{d}x\,\mathrm{d}y)$.

In the sequel we shall also need the thermal equilibrium state, at inverse temperature β, corresponding to the Hamiltonian H_{osc}. This is the density matrix,

$$\rho_\beta = \frac{e^{-\beta H_{\mathrm{osc}}}}{\mathrm{Tr}[e^{-\beta H_{\mathrm{osc}}}]} = (1 - e^{-\omega\beta})\sum_{n=0}^{\infty} e^{-n\omega\beta}|\phi_n\rangle\langle\phi_n|. \tag{5.13}$$

On $\tilde{\mathfrak{H}}$, for each $(x,y) \in \mathbb{R}^2$, define the operators

$$U_1(x,y) = \mathcal{W}[U(x,y) \vee I_{\mathfrak{H}}]\mathcal{W}^{-1}, \quad U_2(x,y) = \mathcal{W}[I_{\mathfrak{H}} \vee U(x,y)^*]\mathcal{W}^{-1}, \tag{5.14}$$

and let $\mathfrak{A}_i$ $i=1,2$, be the von-Neumann algebra (see, e.g., Ref. 19) generated by the unitary operators $\{U_i(x,y)\,|\,(x,y) \in \mathbb{R}^2\}$. Then using the unitary map $\mathcal{W}$, the following modular structure can easily be inferred for the pair of von Neumann algebras $\mathfrak{A}_1$ and $\mathfrak{A}_2$ (for details on modular structures see Ref. 18 and for the particular type of algebras appearing here, see Refs. 2 and 3).

(1) The algebra $\mathfrak{A}_1$ is the commutant of the algebra $\mathfrak{A}_2$ and vice versa and $\mathfrak{A}_1 \cap \mathfrak{A}_2 = \mathbb{C}I_{\tilde{\mathfrak{H}}}$.
(2) If $\{\lambda_n\}_{n=0}^{\infty}$ is a sequence of nonzero positive numbers such that $\Sigma_{n=0}^{\infty}\lambda_n = 1$, then the vector $\Phi = \Sigma_{n=0}^{\infty}\lambda_n^{1/2}\Psi_{nn}$ is cyclic and separating for $\mathfrak{A}_1$. In particular, we shall work with the vector $\Phi = \Phi_\beta$, for which the λ_n correspond to the thermal state ρ_β in (5.13):

$$\Phi_\beta = [1 - e^{-\omega\beta}]^{1/2}\sum_{n=0}^{\infty} e^{-n\omega\beta/2}\Psi_{nn}, \quad \text{i.e., } \lambda_n = (1 - e^{-i\omega\beta})e^{-n\omega\beta}. \tag{5.15}$$

(3) The map

$$S_\beta:\tilde{\mathfrak{H}} \to \tilde{\mathfrak{H}}, \quad S_\beta[U_1(x,y)\Phi_\beta] = U_1(x,y)^*\Phi_\beta, \tag{5.16}$$

is closable and has the polar decomposition,

$$S_\beta = J_\beta \Delta_\beta^{1/2}, \tag{5.17}$$

where J_β is the *antiunitary* operator:

$$J_\beta \Psi_{n\ell} = \Psi_{\ell n}, \quad J_\beta^2 = I_{\tilde{\mathfrak{H}}}, \quad J_\beta \Phi_\beta = \Phi_\beta, \tag{5.18}$$

so that $J_\beta \mathfrak{A}_1 J_\beta = \mathfrak{A}_2$, and Δ_β is the self-adjoint operator,

$$\Delta_\beta = \sum_{n,\ell=0}^{\infty} \frac{\lambda_n}{\lambda_\ell} |\Psi_{n\ell}\rangle\langle\Psi_{n\ell}| = e^{-\beta H} \quad \text{where } H = H_1 - H_2, \tag{5.19}$$

the Hamiltonians H_1 and H_2 being as in (5.7). [We reproduce the derivation of (5.17)–(5.19) in the Appendix.] The operator Δ_β defines a one parameter group of evolution, $t \to \alpha_\beta(t)$ on the algebra $\mathfrak{A}_1$,

$$\alpha_\beta(t)[A] = \Delta_\beta^{-it/\beta} A \Delta_\beta^{it/\beta} = e^{itH} A e^{-itH} = e^{itH_1} A e^{-itH_1}, \quad A \in \mathfrak{A}_1. \tag{5.20}$$

(4) The state φ_β, defined on the algebra $\mathfrak{A}_1$ by the vector Φ_β,

$$\langle \varphi_\beta; A\rangle = \langle \Phi_\beta | A\Phi_\beta\rangle_{\tilde{\mathfrak{H}}}, \quad A \in \mathfrak{A}_1, \tag{5.21}$$

is a faithful normal vector state which is invariant under the evolution α_β,

$$\langle \varphi_\beta; \alpha_\beta(t)[A]\rangle = \langle \varphi_\beta; A\rangle. \tag{5.22}$$

Furthermore, φ_β is a KMS state[14,18] in the following sense: for $A, B \in \mathfrak{A}_1$, define the function $F_{A,B}$ of the real variable t,

$$F_{A,B}(t) = \langle \varphi_\beta; A\alpha_\beta(t)[B]\rangle. \tag{5.23}$$

Then this function has an analytic extension to the open strip $\{z = t + iv \,|\, 0 < v < \beta\}$ and furthermore,

$$F_{A,B}(t + i\beta) = \langle \varphi_\beta; \alpha_\beta(t)[B]A\rangle. \tag{5.24}$$

Going back now to the problem of constructing coherent states for this system we can immediately write down three types of states, in analogy with (4.14), (4.22), and (4.25).

(1) Vector coherent states of the Hamiltonian $H_1 - (\omega/2) I_{\tilde{\mathfrak{H}}}$.
These are the states on $\tilde{\mathfrak{H}} = L^2(\mathbb{R}^2, \mathrm{d}x\, \mathrm{d}y)$,

$$|z, \overline{z'}; \ell\rangle^1 = e^{-(|z|^2 + |z'|^2)/2} \overline{z'}^{\ell} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{n!\ell!}} |\Psi_{n\ell}\rangle, \quad \ell = 0, 1, 2, \ldots, \infty. \tag{5.25}$$

They are obtained by replacing $J^{n/2} e^{-i\epsilon_n \gamma}$ by $z^n = r^n e^{in\theta}$ and $J'^{\ell/2} e^{-i\epsilon_\ell \gamma'}$ by $z'^{\ell} = r'^{\ell} e^{i\ell\theta'}$ in (4.14), with $z, z' \in \mathbb{C}$. The resolution of the identity now takes the form

$$\frac{1}{(2\pi)^2} \sum_{\ell=0}^{\infty} \int_{\mathbb{C}\times\mathbb{C}} |z, \overline{z'}; \ell\rangle^{11} \langle z, \overline{z'}; \ell| \mathrm{d}x\, \mathrm{d}x'\, \mathrm{d}y\, \mathrm{d}y' = I_{\tilde{\mathfrak{H}}}, \tag{5.26}$$

where $z = (1/\sqrt{2})(y - ix)$ and $z' = (1/\sqrt{2})(y' - ix')$. Let us introduce the operators,

$$A_\ell = \frac{1}{\sqrt{2}}(Q_\ell + iP_\ell), \quad A_\ell^\dagger = \frac{1}{\sqrt{2}}(Q_\ell - iP_\ell), \quad H_\ell = A_\ell^\dagger A_\ell + \frac{\omega}{2}, \quad \ell = 1, 2. \tag{5.27}$$

Then, it is not hard to see that,

$$U_1(z) := U_1(x,y) = e^{zA_1^\dagger - \overline{z}A_1} = e^{-\frac{1}{2}|z|^2} e^{zA_1^\dagger} e^{-\overline{z}A_1}. \tag{5.28}$$

Also, since

$$A_1|\Psi_{n\ell}\rangle = \sqrt{n}|\Psi_{n-1\ell}\rangle, \quad A_1^\dagger|\Psi_{n\ell}\rangle = \sqrt{n+1}|\Psi_{n+1\ell}\rangle,$$

it easily follows that,

$$|z,\overline{z}';\ell\rangle^1 = e^{-|z'|^2/2}\frac{\overline{z}'^\ell}{\sqrt{\ell!}}U_1(z)|\Psi_{0\ell}\rangle. \tag{5.29}$$

(2) Vector coherent states of the Hamiltonian $H_2-(\omega/2)I_{\tilde{\mathfrak{H}}}$.
Following (4.22), we have the analogous set of vector coherent states

$$|z,\overline{z}';n\rangle^2 = e^{-(|z|^2+|z'|^2)/2}z^n\sum_{\ell=0}^{\infty}\frac{\overline{z}'^\ell}{\sqrt{n!\ell!}}|\Psi_{n\ell}\rangle = e^{-|z|^2/2}\frac{z^n}{\sqrt{n!}}U_2(z')|\Psi_{n0}\rangle, \quad n=0,1,2,\ldots,\infty, \tag{5.30}$$

with $U_2(z')=\mathcal{W}[I_{\mathfrak{H}}\vee U(z')^*]\mathcal{W}^{-1}$ [see (5.14)], which satisfy a resolution of the identity similar to (5.26).

(3) Coherent states of the Hamiltonian $H=H_1-H_2$.
These are the "bicoherent states," analogous to (4.25),

$$|z,\overline{z}'\rangle^{\mathrm{BCS}} = e^{-(|z|^2+|z'|^2)/2}\sum_{n,\ell=0}^{\infty}\frac{z^n\overline{z}'^\ell}{\sqrt{n!\ell!}}|\Psi_{n\ell}\rangle = U_1(z)U_2(z')|\Psi_{00}\rangle. \tag{5.31}$$

(4) Coherent states built from the thermal equilibrium state.
As yet another example related to this system, we build coherent states, starting with the thermal state Φ_β [see (5.15) and (5.21)]. We define these states as

$$|z,\overline{z},\beta\rangle^{\mathrm{KMS}} = U_1(z)|\Phi_\beta\rangle = e^{zA_1^\dagger-\overline{z}A_1}|\Phi_\beta\rangle. \tag{5.32}$$

In view of the fact that for any normalized vector $\phi\in\mathfrak{H}$, the vectors $U(z)\phi$, $z\in\mathbb{C}$, where $U(z):=U(x,y)$ [see (5.9)], satisfy

$$\frac{1}{2\pi}\int_{\mathbb{C}}|U(z)\phi\rangle\langle U(z)\phi|\mathrm{d}x\,\mathrm{d}y = I_{\mathfrak{H}},$$

we deduce, using the isometry $\mathcal{W}$ in (5.10) that the coherent states (5.32) satisfy the resolution of the identity condition

$$\frac{1}{2\pi}\int_{\mathbb{C}}|z,\overline{z},\beta\rangle^{\mathrm{KMS\ KMS}}\langle z,\overline{z},\beta|\mathrm{d}x\,\mathrm{d}y = I_{\tilde{\mathfrak{H}}}. \tag{5.33}$$

Also, since

$$U_1(z)|\Psi_{nn}\rangle = \frac{1}{\sqrt{n!}}(A_1^\dagger-\overline{z}I_{\tilde{\mathfrak{H}}})^nU_1(z)|\Psi_{0n}\rangle = \frac{1}{\sqrt{n!}}\left(\frac{\partial}{\partial z}-\frac{\overline{z}}{z}I_{\tilde{\mathfrak{H}}}\right)^nU_1(z)|\Psi_{0n}\rangle, \tag{5.34}$$

which follows from the fact that

$$(A_1^\dagger)^n|\Psi_{0n}\rangle = \sqrt{n!}|\Psi_{nn}\rangle \quad \text{and } U_1(z)|\Psi_{0n}\rangle = e^{-|z|^2/2}\sum_{k=0}^{\infty}\frac{(zA_1)^k}{k!}|\Psi_{0n}\rangle,$$

we may rewrite (5.32) as

$$|z,\overline{z},\beta\rangle^{\mathrm{KMS}} = [1-e^{-\omega\beta}]^{1/2}\sum_{n=0}^{\infty}\sqrt{n!}e^{-n\omega\beta/2}\left(\frac{\partial}{\partial z}-\frac{\overrightarrow{\overline{z}}}{2}\right)^n|z;n\rangle, \tag{5.35}$$

where we have set

$$|z;n\rangle = U_1(z)|\Psi_{0n}\rangle.$$

Furthermore, using the fact that

$$(A_2^\dagger)^n|\Psi_{n0}\rangle = \sqrt{n!}|\Psi_{nn}\rangle,$$

we may also write

$$|z,\overline{z},\beta\rangle^{\mathrm{KMS}} = [1-e^{-\omega\beta}]^{1/2}\sum_{n=0}^{\infty}e^{-n\omega\beta/2}\left(\frac{\partial}{\partial z}-\frac{\overrightarrow{\overline{z}}}{2}\right)^n A_2^n|z;0\rangle. \tag{5.36}$$

It should be pointed out that the coherent states (5.32) are not of the Gazeau–Klauder type. States of the type

$$\left(\frac{\partial}{\partial z}-\frac{\overrightarrow{\overline{z}}}{2}\right)^n|z;n\rangle = (A_1^\dagger-\overline{z}\tilde{I_{\mathfrak{H}}})^n|z;n\rangle,$$

are finite linear combinations of *photon-added coherent states* (see Ref. 1), which have been studied extensively in the optical literature. Note that

$$\langle z;n|z';m\rangle = e^{-(|z|^2+|z'|^2)/2}e^{\overline{z}z'}\delta_{nm}. \tag{5.37}$$

Finally, note that since $U_1(x,y)^* = U_1(-x,-y)$, using (5.16) we can get another family of coherent states built on the thermal state Φ_β:

$$S_\beta|z,\overline{z},\beta\rangle^{\mathrm{KMS}} = |-z,-\overline{z},\beta\rangle^{\mathrm{KMS}}.$$

Obviously, these also satisfy the same resolution of the identity as (5.33).

We shall consider in more detail the relationship between the above algebraic structure and the different kinds of coherent states discussed here, as well as their use in the analysis of the quantum Hall effect, in a subsequent paper.

APPENDIX

We work out here some of the results quoted in the preceding two sections.

The measure in Example 2 of Sec. IV A

The proof of the existence of the measure in Example 2 of Sec. IV A will be considered as a particular case of a more general situation.

We are looking for a "density" $f(x)$ such that, given a sequence of numbers ρ_n, the following equation holds:

$$\int_0^\infty f(x)x^n\,\mathrm{d}x = \rho_n, \quad n = 0,1,2,\ldots .$$

It is convenient to introduce a new function $\tilde{f}(x)$ as $f(x)=e^{-x}\tilde{f}(x)$ and restate the problem as follows: we are looking for a function $\tilde{f}(x)$ such that

$$\int_0^\infty \tilde{f}(x)x^n(e^{-x}\,\mathrm{d}x) = \rho_n, \quad n = 0,1,2,\ldots . \tag{A1}$$

As is well known, the orthonormalization procedure in $L^2(\mathbb{R}^+, e^{-x}\,\mathrm{d}x)$ for x^n produces the Laguerre polynomials,

$$x^n \to L_n(x) = \sum_{k=0}^{n} \binom{n}{n-k} \frac{(-1)^k}{k!} x^k, \tag{A2}$$

and $\langle L_n | L_l \rangle = \delta_{nl}$, where the scalar product is, of course, the one in $L^2(\mathbb{R}^+, e^{-x}\,\mathrm{d}x)$. If we consider the linear combination of (A1) with the coefficients given in (A2) we get

$$\int_0^\infty \tilde{f}(x)L_n(x)(e^{-x}\,\mathrm{d}x) = \sum_{k=0}^{n} \binom{n}{n-k} \frac{(-1)^k}{k!}\rho_k =: d_n. \tag{A3}$$

It is clear then that we must take $\tilde{f}(x)=\Sigma_{n=0}^{\infty} d_n L_n(x)$, provided this sum converges and consequently, the required "density" is $f(x)=e^{-x}[\Sigma_{n=0}^{\infty} d_n L_n(x)]$. Note however, that this function is not everywhere positive.

We can say more on the coefficients d_n by recalling that $\rho_{2n}=(2n)!(n+1)$ and $\rho_{2n+1}=(2n+1)!(n+1)$. It is an easy exercise to check that

$$d_n = \sum_{l=0}^{[n/2]} \binom{n}{n-2l}(l+1) - \sum_{l=0}^{[(n-1)/2]} \binom{n}{n-(2l+1)}(l+1),$$

where $[r]$ stands for the integer part of the rational number r. This implies that $d_1=0$ and $d_n = 2^{n-2}$ for all $n \geqslant 2$, so that $\tilde{f}(x)$ cannot be a square-integrable function. However, if we consider the sequence $\{\tilde{f}_N | N \in \mathbb{N}\}$, where $\tilde{f}_N(x)=\Sigma_{n=0}^{N} d_n L_n(x)$, it is possible to show that it converges with respect to a certain family of test functions. For that we define

$$\mathcal{D}_b = \left\{ f \in \mathcal{D}([0,1]) \,\middle|\, \int_0^1 \left| \frac{d^k}{\mathrm{d}x^k} f(x) \right| \mathrm{d}x \leqslant 1, \ \forall\, k = 0,1,2,\ldots \right\}. \tag{A4}$$

This is a nonempty subset of $\mathcal{D}([0,1])$. We can check that

$$I_{NM} := \int_0^\infty (\tilde{f}_N(x) - \tilde{f}_M(x))\varphi(x)\mathrm{d}x \to 0, \tag{A5}$$

as $N, M \to \infty$ for all $\varphi \in \mathcal{D}_b$. This follows from the fact that

$$L_n(x) = \frac{1}{n!} e^x \frac{d^n}{\mathrm{d}x^n}(e^{-x}x^n)$$

and from the properties of $\mathcal{D}_b$. Thus, using integration by parts

$$|I_{NM}| \leqslant \sum_{n=M+1}^{N} \frac{|d_n|}{n!} \int_0^1 \left| x^n \left(1 + \frac{d}{dx}\right)^n \varphi(x) \right| dx \leqslant \sum_{n=M+1}^{N} \frac{2^{n-2} \cdot 2^n}{n!} \to 0,$$

as $N, M \to \infty$.

It may be worth remarking that the set $\mathcal{D}_b$ could be replaced by some larger set without affecting the final result. However, the estimates above would have been harder to obtain. Thus, since such a stronger result would not be very relevant in the present context, we will not consider this generalization here.

Proof of (5.11)

We only demonstrate the first two relations in (5.11), since the other two follow in an entirely analogous manner. Moreover, (5.12) is a direct consequence of (5.11). Consider $X \in \mathcal{B}_2(\mathfrak{H})$ of the type $X = |\phi\rangle\langle\psi|$, such that both ϕ and ψ are in the domains of the operators Q and P, are differentiable and vanish at infinity. Then,

$$(\mathcal{W}X)(x,y) = \frac{1}{(2\pi)^{1/2}} \mathrm{Tr}[U(x,y)^* X] = \frac{1}{(2\pi)^{1/2}} \langle U(x,y)\psi | \phi \rangle_{\mathfrak{H}} = \frac{1}{(2\pi)^{1/2}} \int_{\mathbb{R}} e^{ix[\xi - (y/2)]} \overline{\psi(\xi - y)} \phi(\xi) d\xi.$$

Thus,

$$\begin{aligned}(\mathcal{W}Q \vee I_{\mathfrak{H}}(X))(x,y) &= \frac{1}{(2\pi)^{1/2}} \langle U(x,y)\psi | Q\phi \rangle_{\mathfrak{H}} = \frac{1}{(2\pi)^{1/2}} \int_{\mathbb{R}} e^{ix[\xi - (y/2)]} \overline{\psi(\xi - y)} \xi \phi(\xi) d\xi \\ &= \left(-i \frac{\partial}{\partial x} + \frac{y}{2} \right) \\ &\quad \times \left[\frac{1}{(2\pi)^{1/2}} \int_{\mathbb{R}} e^{ix[\xi - (y/2)]} \overline{\psi(\xi - y)} \phi(\xi) d\xi \right],\end{aligned}$$

implying

$$(\mathcal{W}Q \vee I_{\mathfrak{H}}(X))(x,y) = \left(-i \frac{\partial}{\partial x} + \frac{y}{2} \right) (\mathcal{W}X)(x,y).$$

Extending by linearity on appropriate domains, we get

$$\mathcal{W}Q \vee I_{\mathfrak{H}} \mathcal{W}^{-1} = -i \frac{\partial}{\partial x} + \frac{y}{2} = Q_1.$$

Next,

$$(\mathcal{W}P \vee I_{\mathfrak{H}}(X))(x,y) = \frac{1}{(2\pi)^{1/2}} \langle U(x,y)\psi | P\phi \rangle_{\mathfrak{H}} = \frac{1}{(2\pi)^{1/2}} \int_{\mathbb{R}} e^{ix[\xi - (y/2)]} \overline{\psi(\xi - y)} \left(-i \frac{\partial}{\partial \xi} \right) \phi(\xi) d\xi.$$

Now,

$$\begin{aligned}-i \frac{\partial}{\partial \xi} [e^{ix[\xi - (y/2)]} \overline{\psi(\xi - y)} \phi(\xi)] &= x e^{ix[\xi - (y/2)]} \overline{\psi(\xi - y)} \phi(\xi) + e^{ix[\xi - (y/2)]} \left(-i \frac{\partial}{\partial \xi} \right) \overline{\psi(\xi - y)} \phi(\xi) \\ &\quad + e^{ix[\xi - (y/2)]} \overline{\psi(\xi - y)} \left(-i \frac{\partial}{\partial \xi} \right) \phi(\xi).\end{aligned}$$

Integrating both sides of this equation with respect to ξ from $-\infty$ to ∞ and noting that $\psi(\xi)$, $\phi(\xi) \to 0$ as $\xi \to \pm\infty$, and $(\partial/\partial\xi)\psi(\xi - y) = -(\partial/\partial y)\psi(\xi - y)$, we get

$$0 = \frac{x}{(2\pi)^{1/2}} \int_{\mathbb{R}} e^{ix[\xi-(y/2)]} \overline{\psi(\xi-y)}\, \phi(\xi) + \frac{1}{(2\pi)^{1/2}} \int_{\mathbb{R}} e^{ix[\xi-(y/2)]} \left(i \frac{\partial}{\partial y} \right) \overline{\psi(\xi-y)}\, \phi(\xi)$$
$$+ \frac{1}{(2\pi)^{1/2}} \int_{\mathbb{R}} e^{ix[\xi-(y/2)]} \overline{\psi(\xi-y)} \left(- i \frac{\partial}{\partial \xi} \right) \phi(\xi).$$

Thus,

$$(\mathcal{W}P \vee I_{\mathfrak{H}}(X))(x,y) = \left(- i \frac{\partial}{\partial y} - \frac{x}{2} \right) (\mathcal{W}X)(x,y),$$

and again, extending by linearity on appropriate domains we get

$$\mathcal{W}P \vee I_{\mathfrak{H}} \mathcal{W}^{-1} = - i \frac{\partial}{\partial y} - \frac{x}{2} = P_1.$$

Proof of (5.17)–(5.19)

Since the vectors Ψ_{jk}, $j,k=0,1,2,\ldots,\infty$, form a basis of $\tilde{\mathfrak{H}}[=L^2(\mathbb{R}^2, \mathrm{d}x\, \mathrm{d}y)]$, we may write

$$U_1(x,y)\Phi_\beta = \sum_{i=0}^{\infty} \lambda_i^{1/2} U_1(x,y)\Psi_{ii} = \sum_{i,j,k=0}^{\infty} \lambda_i^{1/2} \langle \Psi_{jk} | U_1(x,y)\Psi_{ii} \rangle_{\tilde{\mathfrak{H}}} \Psi_{jk}.$$

Now, using the isometry $\mathcal{W}\phi_{jk} = \mathcal{W}(|\phi_j\rangle\langle\phi_k|) = \Psi_{jk}$ [see (5.8) and (5.12)], the first relation in (5.14) and the fact that the vectors ϕ_i, $i=0,1,2,\ldots,\infty$, form an orthonormal basis of $\mathfrak{H}$, we obtain

$$\langle \Psi_{jk} | U_1(x,y)\Psi_{ii} \rangle_{\tilde{\mathfrak{H}}} = \mathrm{Tr}[|\phi_k\rangle\langle\phi_j| U(x,y) |\phi_i\rangle\langle\phi_i|] = \langle \phi_j | U(x,y)\phi_i \rangle \delta_{ik} = (2\pi)^{1/2} \overline{\Psi_{ji}(x,y)}\, \delta_{ik},$$

the second equality following from (5.10). Thus,

$$U_1(x,y)\Phi_\beta = (2\pi)^{1/2} \sum_{i,j=0}^{\infty} \lambda_i^{1/2} \overline{\Psi_{ji}(x,y)} \Psi_{ji}. \tag{A6}$$

Similarly,

$$U_1(x,y)^* \Phi_\beta = (2\pi)^{1/2} \sum_{i,j=0}^{\infty} \lambda_j^{1/2} \Psi_{ij}(x,y)\Psi_{ji} = (2\pi)^{1/2} \sum_{i,j=0}^{\infty} \lambda_j^{1/2} \Psi_{ji}(x,y)\Psi_{ij}. \tag{A7}$$

Next, applying the operator S_β to both sides of (A6) and taking account of the fact that this operator is antilinear, we get

$$S_\beta[U_1(x,y)\Phi_\beta] = U_1(x,y)^* \Phi_\beta = (2\pi)^{1/2} \sum_{i,j=0}^{\infty} \lambda_i^{1/2} \Psi_{ji}(x,y) S_\beta \Psi_{ji}.$$

Comparing this equation with (A7) we immediately see that

$$S_\beta \Psi_{ji} = \left[\frac{\lambda_j}{\lambda_i} \right]^{1/2} \psi_{ij},$$

from which (5.17)–(5.19) follow directly.

(Received 2 November 2004; accepted 7 March 2005; published online 9 May 2005)

Universal Drinfeld twists are inner automorphisms which relate the coproduct of a quantum enveloping algebra to the coproduct of the undeformed enveloping algebra. Even though they govern the deformation theory of classical symmetries and have appeared in numerous applications, no twist for a semisimple quantum enveloping algebra has ever been computed. It is argued that universal twists can be reconstructed from their well-known representations. A method to reconstruct an arbitrary element of the enveloping algebra from its irreducible representations is developed. For the twist this yields an algebra valued generating function to all orders in the deformation parameter, expressed by a combination of basic and ordinary hypergeometric functions. It is shown how the generating function can be expanded to the formal power series of the twist. An explicit expression for the universal twist of su(2) is given up to third order. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1901344]

I. INTRODUCTION

Quantum enveloping algebras are formal deformations of the enveloping Hopf algebras of Lie algebras.[1] While the notion of quantum enveloping algebras is very general, comprising arbitrary deformations, the most famous examples are the Drinfeld–Jimbo deformations[2,3] which act as natural symmetry structures on quantum spaces.[4–6] Drinfeld observed that every quantum enveloping algebra is related to the corresponding undeformed enveloping algebra by an inner automorphism which he called universal twist[7] and which now bears his name. Given the universal Drinfeld twist one can reconstruct the corresponding quantum enveloping algebra up to isomorphism. In this sense, the twist contains all information on the quantum deformation of a classical symmetry.[8]

Due to their pivotal role for the deformation theory of symmetries, universal Drinfeld twists have found numerous important applications beyond the structure theory of quantum enveloping algebras, such as to quantum statistics on quantum spaces,[9] quantum spin chains,[10,11] noncommutative quantum field theory,[12] or to algebraic geometry,[13] just to name a few recent examples. Our original motivation was the observation that certain twists yield a covariant realization of quantum spaces by a star product[14,15] within the framework of deformation quantization.[16] Such a description of noncommutative spaces by formal deformations of algebras[17] has appeared naturally in the context of string theory,[18] the construction of gauge theories on noncommutative spaces,[19,20] and the subsequent development of noncommutatvie quantum field theories. (For reviews of noncommutative field theories see Refs. 21 and 22.)

The noncommutative geometry on which so far most noncommutative quantum field theories have been constructed is defined by constant commutators of the space–time observables. Such a noncommutativity breaks Lorentz symmetry, which had to be expected because the constant commutator can be viewed as due to a constant background field, in string theory a constant *B*-field on a D-brane. It was hoped that a small noncommutativity would lead to an equally small violation of Lorentz symmetry. However, on the level of regularization of loop diagrams an

interdependence of ultraviolet and infrared cutoff scales appears[23,24] which seems to put even large scale Lorentz symmetry and weakened notions of locality of noncommutative quantum field theory into doubt,[25] indicating that the breaking of symmetries is not under good control—at least for the case of constant noncommutativity. These serious deficiencies seem to be reason enough to reconsider such deformations, for which the symmetry structure can be deformed together with the space, so that covariance is preserved. That is, quantum spaces[4–6] which carry a covariant representation of the Drinfeld–Jimbo deformation[2,3] of the enveloping symmetry algebra. Three particularly important quantum spaces, the quantum plane, quantum Euclidean 4-space, and quantum Minkowski space, have been shown to be realizable as deformation quantization[8,14] by universal Drinfeld twists.[15] (For more information on the relation between quantum groups and deformation quantization we refer the reader to Ref. 26.)

While the quantum enveloping algebra can be reconstructed rather easily given the universal Drinfeld twist, there is no general soution for the inverse problem of calculating the Drinfeld twist for a given quantum deformation. The existence of twists is proved by homological methods which are inherently nonconstructive. To our best knowledge, no universal Drinfeld twist for the Drinfeld–Jimbo deformation of a semisimple Lie algebra has ever been computed successfully, not even for the simplest possible case of su_2. (In Refs. 27 and 28 the nonsemisimple case of the Heisenberg algebra was studied.) It could be argued that the universal twist is more or less the square root of the universal $\mathcal{R}$-matrix, so that Drinfeld's ingenious but simple construction of the $\mathcal{R}$-matrix by the dual pairing of the Borel–Hopf subalgebras might be used. For the case of triangular deformations this reasoning appears to lead, indeed, to a method to construct the twist.[29] For the nontriangular Drinfeld–Jimbo deformations, however, this argument falls short, as is confirmed by the complexity of the expressions derived in Ref. 30. But even though there are no closed form expressions or simple constructions for the twist, one might expect that a brute force calculation by means of a computer algebra system should be possible up to an order of the perturbation parameter high enough for all reasonable applications. However, it turns out that the naive attempt of an algebraic order by order calculation quickly runs into overwhelming combinatorial problems, as it was described in Ref. 30 where the authors did not go beyond the second order.

A closer inspection of the brute force approach reveals, first, that the number of operations which must be carried out increases at least exponentially with the order of the perturbation parameter, so the algorithm is certainly nonpolynomial. Second, the results expressed in terms of the Poincaré–Birkhoff–Witt basis of the enveloping algebra are extremely lengthy and do not appear to provide any structural insight. Third, it is unclear how to implement the algorithm such that it yields the particular twist which realizes the star product of quantum spaces. In conclusion, it is fair to say that the calculation of universal Drinfeld twists turns out to be a computational problem in any respect.

While little is known about the calculation of universal twists in the enveloping algebra, their representations are well understood and have been computed explicitly. They are essentially given by a contraction of deformed and undeformed Clebsch–Gordan coefficients as it was first observed in Ref. 31. For the Drinfeld–Jimbo q-deformation the Clebsch–Gordan coefficients are known explicitly, so we obtain the representations of the twist in a closed form, expressed by basic and ordinary hypergeometric functions. The approach to the calculation of universal twists presented here is to reconstruct the twists from their representations. The obvious advantage of this approach is that, rather than starting with algebraic calculations from scratch, it builds on the computational effort which has gone into the calculation of q-Clebsch–Gordan coefficients. The explicit calculations in this paper are carried out for $\mathcal{U}_q(\mathrm{su}_2)$ although the methods will be seen to be generic.

We will proceed as follows: In order to make this paper reasonably self-contained we will start in Sec. II with a short introduction to universal Drinfeld twists, giving some basic results which will be referred to in the following. Moreover, we briefly explain why universal twists appear naturally in the context of star products. In Sec. III we will develop a method to reconstruct an element in the enveloping algebra from its irreducible representations. From Lie theory it is clear that in the semisimple case the representations determine the algebra element uniquely. But how

do we actually compute it? The key to developing a constructive method is the choice of a suitable basis of $\mathcal{U}_q(\mathrm{su}_2)$. We will choose the basis of tensor operators because the matrix elements satisfy useful orthogonality relations, which then lead to the desired reconstruction method. The results are given in Proposition 2 and Eq. (27). In Sec. IV we apply the reconstruction method to the representations of the universal Drinfeld twist. This leads to the main result presented here, a formula for the the universal Drinfeld twist, given in Eq. (46) by an algebra-valued generating function in $q=e^{\hbar}$. In order to obtain the twist to each order in the perturbation parameter $\hbar$, we yet need to expand the generating function in powers of $\hbar$. Surprisingly, the problem of perturbative expansion of basic hypergeometric functions has recieved little attention in the literature. In particular, no closed formulas for such expansions have been derived as yet. While a thorough study of this problem is beyond the scope of this paper, we present the first few steps in this direction which suffice to make the order of order expansion of the generating function of the twist accessible to efficient computer algebra calculations. This is exemplified in Eq. (59) where the universal twist of $\mathcal{U}_\hbar(\mathrm{su}_2)$ was computed up to third order. In Sec. V we concludingly assess the computational value of the generating function of the twist and indicate how the approach presented here will be naturally continued.

II. BRIEF INTRODUCTION TO DRINFELD TWISTS

For the reader's convenience we briefly review how Drinfeld twists appear naturally in the study of formal deformations of algebras and Hopf algebras. The approach and the results described here are essentially due to Gerstenhaber[17] and Drinfeld.[1,7] The formal perturbation parameter is $\hbar$, the completion of a complex vector space or algebra A with respect to the $\hbar$-adic topology by formal power series is denoted as usual by $A[[\hbar]]$.

An $\hbar$-adic algebra A' is called a deformation of an algebra A if $A'/\hbar A'$ and A are isomorphic as algebras. Analogously, an $\hbar$-adic Hopf algebra H' is called a deformation of a Hopf algebra H if $H'/\hbar H'$ and H are isomorphic as Hopf algebras. Recall, that $\mathcal{U}(\mathfrak{g})$ is a Hopf algebra with the canonical Lie–Hopf structure defined on the generators $g\in\mathfrak{g}$ by the coproduct $\Delta(g)=g\otimes 1+1\otimes g$, counit $\varepsilon(g)=0$, and antipode $S(g)=-g$. The Drinfeld–Jimbo algebra $\mathcal{U}_\hbar(\mathfrak{g})$ is a deformation of this Hopf algebra $\mathcal{U}(\mathfrak{g})$. This can be seen by developing the commutation relations and the Hopf structure of $\mathcal{U}_\hbar(\mathfrak{g})$ as formal power series in $\hbar$ and keeping only the zeroth order terms, which yields the commutation relations and the Lie–Hopf structure of $\mathcal{U}(\mathfrak{g})$.

Gerstenhaber has shown[17] that whenever the second Hochschild cohomology of A with coefficients in A is zero, $H^2(A,A)=0$, then all deformations of A are trivial up to isomorphism. That is, any deformation A' of A is isomorphic to the $\hbar$-adic completion of the undeformed algebra, $A'\cong A[[\hbar]]$. Algebras with this property are called rigid. The second Whitehead lemma states that the second Lie algebra cohomology of a semisimple Lie algebra $\mathfrak{g}$ and, hence, the second Hochschild cohomology of its enveloping algebra is zero. Therefore, the enveloping algebra $\mathcal{U}(\mathfrak{g})$ of a semisimple Lie algebra $\mathfrak{g}$ is rigid. In particular, there is an isomorphism of algebras $\alpha:\mathcal{U}_\hbar(\mathfrak{g})\to\mathcal{U}(\mathfrak{g})[[\hbar]]$, by which the the Hopf structure Δ', ε', S' of $\mathcal{U}_\hbar(\mathfrak{g})$ can be transfered to $\mathcal{U}(\mathfrak{g})[[\hbar]]$,

$$\Delta_\hbar := (\alpha\otimes\alpha)\circ\Delta'\circ\alpha^{-1},\quad \varepsilon_\hbar := \varepsilon'\circ\alpha^{-1},\quad S_\hbar := \alpha\circ S'\circ\alpha^{-1}, \tag{1}$$

such that α becomes an isomorphism of Hopf algebras from $\mathcal{U}_\hbar(\mathfrak{g})$ to $\mathcal{U}(\mathfrak{g})[[\hbar]]$ with this deformed Hopf structure. Let α' be another such isomorphism and $\Delta'_\hbar$, $\varepsilon'_\hbar$, $S'_\hbar$ be defined as in Eq. (1) with α' instead of α. Then α' is an isomorphism of Hopf algebras from $\mathcal{U}_\hbar(\mathfrak{g})$ to $\mathcal{U}(\mathfrak{g})[[\hbar]]$ with the primed Hopf structure,

$$(\mathcal{U}(\mathfrak{g})[[\hbar]],\Delta_\hbar,\varepsilon_\hbar,S_\hbar)\xleftarrow{\alpha}\mathcal{U}_\hbar(\mathfrak{g})\xrightarrow{\alpha'}(\mathcal{U}(\mathfrak{g})[[\hbar]],\Delta'_\hbar,\varepsilon'_\hbar,S'_\hbar), \tag{2}$$

hence, $\alpha'\circ\alpha^{-1}$ is an isomorphism of Hopf algebras. We conclude that, while the Hopf structure (1) may depend on the isomorphism α, it is unique up to an isomorphism of Hopf algebras.

As a consequence of the first Whitehead lemma, the first Hochschild cohomology of the enveloping algebra $\mathcal{U}(\mathfrak{g})$ of a semisimple Lie algebra is zero. This implies, that the two homomorphisms Δ and $\Delta_\hbar$ from $\mathcal{U}(\mathfrak{g})[[\hbar]]$ to $(\mathcal{U}(\mathfrak{g})\otimes\mathcal{U}(\mathfrak{g}))[[\hbar]]$ with $\Delta_\hbar=\Delta+\mathcal{O}(\hbar)$ are related by an inner automorphism, as it was observed by Drinfeld.[1,7]

Theorem 1 (Drinfeld): *Let $\mathfrak{g}$ be a semisimple Lie algebra, and let $\Delta_\hbar$ be defined as in Eq. (1). Then there is an invertible element $\mathcal{F}\in(\mathcal{U}(\mathfrak{g})\otimes\mathcal{U}(\mathfrak{g}))[[\hbar]]$ such that $\Delta_\hbar(g)=\mathcal{F}\Delta(g)\mathcal{F}^{-1}$, which is called a Drinfeld twist from Δ to $\Delta_\hbar$.*

It can be shown that such a Drinfeld twist not only relates the deformed and undeformed coproducts but also the counits and antipodes. Hence, a universal Drinfeld twist uniquely determines the corresponding quantum enveloping algebra. In that sense the twist contains the entire structural information on a quantum deformation of an enveloping algebra. The twist of Theorem 1 is not unique. For a given quantum enveloping algebra any two twists are related by a noncommutative 2-coboundary in the sense of Ref. 32.

Drinfeld has shown, that the isomorphism of $\mathcal{U}(\mathfrak{g})[[\hbar]]$ and $\mathcal{U}_\hbar(\mathfrak{g})$ can be chosen to leave a given Cartan subalgebra invariant.

Theorem 2 (Drinfeld,[1] Proposition 4.3): *Let $\mathfrak{g}$ be a semisimple Lie algebra and $\mathfrak{h}\subset\mathfrak{g}$ a Cartan subalgebra. Then there exists an isomorphism of $\hbar$-adic algebras $\alpha:\mathcal{U}_\hbar(\mathfrak{g})\to\mathcal{U}(\mathfrak{g})[[\hbar]]$ such that $\alpha=\mathrm{id}+\mathcal{O}(\hbar)$ and $\alpha|_\mathfrak{h}=\mathrm{id}_\mathfrak{h}$.*

The important consequence of this theorem for representation theory is that weight vectors and weight spaces of representations of the deformed and underformed algebras can be identified. While in this sense, the irreducible representations of quantum alebras are equivalent to the usual representations, the nonequivalent coproducts on the enveloping algebra and its quantum deformation lead to different tensor representation in the deformed and undeformed case. For Drinfeld–Jimbo deformations $\mathcal{U}_\hbar(\mathrm{su}_2)$, which are the Hopf duals of quantum groups, the reduction of tensor representations are given by q-deformed Clebsch–Gordan coefficients. As the deformed and undeformed coproducts are related by a Drinfeld twist, it was quickly realized[31] that the representations of Drinfeld twists ought to be given by a combination of deformed and undeformed Clebsch–Gordan coefficients. Indeed, one can rigorously prove the following proposition.[15]

Proposition 1: *There is a universal Drinfeld twist $\mathcal{F}$ from $\mathcal{U}(\mathrm{su}_2)$ to $\mathcal{U}_\hbar(\mathrm{su}_2)$, the inverse of which has the matrix elements*

$$\langle j_1,m_1';j_2,m_2'|\mathcal{F}^{-1}|j_1,m_1;j_2,m_2\rangle=\sum_{j,m}\left(\begin{array}{cc|c} j_1 & j_2 & j\\ m_1' & m_2' & m\end{array}\right)_q\left(\begin{array}{cc|c} j_1 & j_2 & j\\ m_1 & m_2 & m\end{array}\right) \tag{3}$$

in an irreducible representation of $\mathcal{U}(\mathrm{su}_2)\otimes\mathcal{U}(\mathrm{su}_2)$ with weights j_1, j_2 and basis $|j_1,m_1;j_2,m_2\rangle := |j_1,m_1\rangle\otimes|j_2,m_2\rangle$, where the expressions in parentheses denote the q-deformed and undeformed Clebsch–Gordan coefficients.

Here, we gave the formula for the representations of the inverse of the twist, because the inverse realizes the covariant star product of the corresponding quantum space: Recall that the action of an enveloping algebra $\mathcal{U}(\mathfrak{g})$ on an algebra $\mathcal{X}$ is called covariant if for all x, $y\in\mathcal{X}$ and $g\in\mathcal{U}(\mathfrak{g})$,

$$g\triangleright(xy)=(g_{(1)}\triangleright x)(g_{(2)}\triangleright y), \tag{4}$$

using the Sweedler notation $g_{(1)}\otimes g_{(2)}\equiv\Delta_\hbar(g)$ for the coproduct. In mathematical terminology $\mathcal{X}$ is called a module algebra. For the undeformed coproduct Eq. (4) simply means that the elements of the Lie algebra $\mathfrak{g}\subset\mathcal{U}(\mathfrak{g})$ act as derivations on $\mathcal{X}$. A quantum space, which is by definition a module algebra of the quantum deformation $\mathcal{U}_\hbar(\mathfrak{g})$, is realized by a star product on a function algebra in a covariant manner only if the analogous condition

$$g\triangleright(x\star y)=(g_{(1_\hbar)}\triangleright x)\star(g_{(2_\hbar)}\triangleright y) \tag{5}$$

holds, where $g_{(1_\hbar)}\otimes g_{(2_\hbar)}\equiv\Delta_\hbar(g)$ is the Sweedler notation for the deformed coproduct. If we define the star product map by

$$x \star y := (\mathcal{F}^{-1}_{[1]} \triangleright x)(\mathcal{F}^{-1}_{[2]} \triangleright y), \tag{6}$$

where we use the Sweedler-type notation $\mathcal{F}^{-1}_{[1]} \otimes \mathcal{F}^{-1}_{[2]} \equiv \mathcal{F}^{-1}$, covariance condition (5) is satisfied because $\Delta_\hbar(g) = \mathcal{F}\Delta(g)\mathcal{F}^{-1}$. But are there twists for which Eq. (6) also defines an associative product, thus realizing the algebra of a quantum space? It turns out that the twist of Proposition 1 realizes the quantum plane and, essentially, also quantum Euclidean 4-space, and quantum Minkowski space.[15]

III. THE RECONSTRUCTION METHOD

A. The tensor operator basis

We want to find a method to reconstruct elements of the enveloping algebra $\mathcal{U}(\mathrm{su}_2)$ from their irreducible representations. Consider the Cartan–Weyl basis $\{E, H, F\}$ of su_2 with commutation relations

$$[H,E] = 2E, \quad [H,F] = -2F, \quad [E,F] = H, \tag{7}$$

the compact real form being given by the $*$-structure $E^* = F$, $H^* = H$, $F^* = E$. For our purposes the usual Poincare–Birkhoff–Witt basis of ordered monomials of the generators

$$\mathcal{B}_{\mathrm{PBW}} = \{E^i H^j F^k | i,j,k \in \mathbb{N}_0\} \tag{8}$$

turns out to be not particularly convenient. The irreducible representations of the ordered monomials do not satisfy any obvious orthogonality relations which would allow us to draw immediate conclusions from the representations of a given algebra element to its coefficients with respect to this basis. Recall that for each half-integer weight $j \in \frac{1}{2}\mathbb{N}_0$ there is one irreducible unitary representation of $\mathcal{U}(\mathrm{su}_2)$ defined on the orthonormal weight-j (or spin-j) basis $\{|j,m\rangle, m = -j, -j+1, \ldots, j\}$ by

$$E|j,m\rangle = \sqrt{(j+m+1)(j-m)}\,|j,m+1\rangle,$$

$$F|j,m\rangle = \sqrt{(j+m)(j-m+1)}\,|j,m-1\rangle,$$

$$H|j,m\rangle = 2m|j,m\rangle. \tag{9}$$

The structure homomorphism $\rho^j : \mathcal{U}(\mathrm{su}_2) \to \mathrm{End}(\mathbb{C}^{2j+1})$ is given by the matrix elements, $\rho^j(g)^{m'}{}_m := \langle j,m'|g|j,m\rangle$. Since the Lie algebra su_2 is simple, any representation of $\mathcal{U}(\mathrm{su}_2)$ can be decomposed into a direct sum of irreducible subrepresentations, each of which is isomorphic to a representation given by (9). This is in particular true for the adjoint action of $\mathcal{U}(\mathrm{su}_2)$ on itself which is defined on the generators as

$$\mathrm{ad}\, g \triangleright u := [g,u], \quad g \in \mathrm{su}_2 \subset \mathcal{U}(\mathrm{su}_2), \quad u \in \mathcal{U}(\mathrm{su}_2). \tag{10}$$

Let $\{T^j_m \in \mathcal{U}(\mathrm{su}_2) \,|\, m = -j, \ldots, j\}$ be a weight basis of a weight-j subrepresentation of the adjoint representation, that is,

$$[g, T^j_m] = \sum_{m'} T^j_{m'} \rho^j(g)^{m'}{}_m \equiv \sum_{m'} T^j_{m'} \langle j,m'|g|j,m\rangle \tag{11}$$

for all $g \in \mathrm{su}_2$. Such a basis $\{T^j_m\}$ is called a weight-j tensor operator of su_2. The set of all weight-0 operators is the center of $\mathcal{U}(\mathrm{su}_2)$. As commutative algebra, the center is generated by the canonical quadratic Casimir element $C := 2\Sigma_{ij} g_i g_j K^{ij}$, where $\{g_i\}$ is a basis of the Lie algebra, K^{ij} is the inverse of the Killing metric $K_{ij} := \mathrm{tr}(\mathrm{ad}\, g_i\, \mathrm{ad}\, g_j)$, and where the factor 2 was insterted for convenience. In the Cartan–Weyl basis we obtain

$$C = \tfrac{1}{2}EF + \tfrac{1}{2}FE + \tfrac{1}{4}H^2 = EF + \tfrac{1}{4}H(H-2), \tag{12}$$

such that the polynomial algebra $\mathbb{C}[C]$ is the center of $\mathcal{U}(\mathrm{su}_2)$. The representations of the Casimir element,

$$C|j,m\rangle = j(j+1)|j,m\rangle, \tag{13}$$

show that C is the ususal square of angular momentum.

By definition, T^j_j is the highest weight vector of a weight-j subrepresentation of the adjoint representation, so $(\mathrm{ad}\,E)\triangleright T^j_j \equiv [E,T^j_j]=0$ and $(\mathrm{ad}\,C)\triangleright T^j_j = j(j+1)T^j_j$. From these two equalities it follows, that $T^j_j = zE^j$, where z is some element of the center. If we pick z from the number field we get the tensor operators

$$T^J_J := \alpha E^J, \quad \alpha \in \mathbb{C}, \tag{14}$$

from which all other tensor operators can be obtained by multiplication by a central element. Here α is a normalization constant, which will later be chosen for convenience. From now on we denote by T^J_M always the tensor operator which is generated by αE^J. We use capital letters for the indices in order to allow in the formulas which we will derive below for a clear disctinction of the weights pertaining to the adjoint action from those pertaining to matrix representations. The fact that, as module with respect to the adjoint action, $\mathcal{U}(\mathrm{su}_2)$ can be completely decomposed into irreducible submodules implies that

$$\mathcal{B}_{\mathrm{tensor}} = \{C^k T^J_M | k,J \in \mathbb{N}_0, M = -J, -J+1, \ldots, J\} \tag{15}$$

is a basis of $\mathcal{U}(\mathrm{su}_2)$, which we will call the tensor basis. The fact that (15) is a basis of $\mathcal{U}(\mathrm{su}_2)$ means that the tensor operators are a basis of $\mathcal{U}(\mathrm{su}_2)$ as free module over its center. Thus, every element $a \in \mathcal{U}(\mathrm{su}_2)$ can be written uniquely as

$$a = \sum_{J,M} a^J_M T^J_M, \quad a^J_M \in \mathbb{C}[C], \tag{16}$$

where the sum runs over a finite subset of all allowed integer values of J and M. Reconstructing the element a from its representations now amounts to finding the polynomials a^J_M.

B. The reconstruction method

Let us compute the irreducible representations of Eq. (16). First, we consider the central coefficients a^J_M. Since a^J_M is a polynomial in the Casimir, the matrix element is a polynomial of the weight j of the representation,

$$\langle j,m|a^J_M|j,m\rangle =: a^J_M(j) \in \mathbb{C}[j]. \tag{17}$$

Due to Eq. (13) this polynomial satisfies

$$a^J_M = a^J_M(-j-1), \tag{18}$$

since it is actually a polynomial in $j(j+1)$ or, equivalently, a quadratic polynomial in $j+\frac{1}{2}$. Conversely, given a polynomial $p(j) \in \mathbb{C}[j]$ which satisfies $p(j)=p(-j-1)$ there exists a unique polynomial in the Casimir which has $p(j)$ as its matrix elements. For an intuitive notation we will denote this polynomial by $p(\hat{j}) \in \mathbb{C}[C]$, such that its defining equation takes the suggestive form

$$\langle j,m|p(\hat{j})|j,m\rangle = p(j). \tag{19}$$

The map $p(j) \mapsto p(\hat{j})$ could be viewed as substitution

$$j \mapsto \hat{j} = \tfrac{1}{2}(\sqrt{4C+1} - 1), \tag{20}$$

where the relation $p(j)=p(-j-1)$ guarantees that the square roots drop out such that $p(\hat{j})$ is a polynomial in C only. We emphasize that we do not add such a square root of the Casimir to the algebra, though. We view $p(\hat{j})$ merely as a suggestive notation for the element of the center which is uniquely defined by Eq. (19).

The matrix elements of the tensor operators are given by the Wigner–Eckhart theorem,

$$\langle j,m'|T^J_M|j,m\rangle = \langle j\|T^J\|j\rangle \left(\begin{array}{cc|c} J & j & j \\ M & m & m' \end{array} \right), \tag{21}$$

where the reduced matrix element $\langle j\|T^J\|j\rangle$ does not depend on m, m', or M, and where the expression in parentheses denotes the Clebsch–Gordan coeffient. The explicit form and some properties of Clebsch–Gordan coefficients and their q-deformations can be found for example in Ref. 33. The reduced matrix elements will be computed below.

The irreducible representations of Eq. (16) now take the form

$$\langle j,m'|a|j,m\rangle = \sum_{J,M} a^J_M(j)\langle j\|T^J\|j\rangle \left(\begin{array}{cc|c} J & j & j \\ M & m & m' \end{array} \right). \tag{22}$$

The main advantage of using the tensor basis (15) instead of the Poincaré–Birkhoff–Witt basis (8) is the fact, that the Clebsch–Gordan coefficients satisfy orthogonality relations which can be used in order to solve Eq. (22) for $a^J_M(j)$. Using the well-known orthogonality relation

$$\sum_{m,m'} \left(\begin{array}{cc|c} J & j & j \\ M & m & m' \end{array} \right) \left(\begin{array}{cc|c} J' & j & j \\ M' & m & m' \end{array} \right) = \frac{2j+1}{2J+1} \delta_{JJ'} \delta_{MM'} \tag{23}$$

we thus arrive at the following.

Proposition 2: *Let $a \in \mathcal{U}(\mathrm{su}_2)$ be an element of the enveloping algebra with matrix elements $\langle j,m'|a|j,m\rangle$ with respect to the irreducible representations defined in Eqs. (9). Let $T^J_M \in \mathcal{U}(\mathrm{su}_2)$ be the minimal degree tensor operators generated by $T^J_J \sim E^J$ and $\langle j\|T^J\|j\rangle$ their reduced matrix elements. Then we have the following*:

(i) *For all integers $J \geqslant 0$ and $M, |M| \leqslant J$ the expression*

$$a^J_M(j) := \frac{(2J+1)}{(2j+1)\langle j\|T^J\|j\rangle} \sum_{m,m'} \left(\begin{array}{cc|c} J & j & j \\ M & m & m' \end{array} \right) \langle j,m'|a|j,m\rangle \tag{24}$$

defines a polynomial in j which is nonzero for only a finite number of values of J and M.

(ii) *The polynomials $a^J_M(j)$ are quadratic in $j+\frac{1}{2}$, the substitution*

$$(j_1 + \tfrac{1}{2})^2 \mapsto C + \tfrac{1}{4} \tag{25}$$

yielding polynomials in the Casimir element C which are denoted by $a^J_M(\hat{j})$.

(iii) *The element a can be written as*

$$a = \sum_{J,M} a^J_M(\hat{j}) T^J_M. \tag{26}$$

This reconstruction method can be readily generalized to the tensor product $\mathcal{U}(\mathrm{su}_2) \otimes \mathcal{U}(\mathrm{su}_2)$. Let $a \in \mathcal{U}(\mathrm{su}_2) \otimes \mathcal{U}(\mathrm{su}_2)$ be an element of the tensor product, let $\langle j_1, m_1'; j_2, m_2'|a|j_1, m_1; j_2, m_2\rangle$ denote its matrix elements with respect to irreducibles representation of each tensor factor. First we need to calculate

$$a^{J_1J_2}_{M_1M_2}(j_1,j_2) := \frac{(2J_1+1)(2J_2+1)}{(2j_1+1)(2j_2+1)\langle j_1\|T^{J_1}\|j_1\rangle\langle j_2\|T^{J_2}\|j_2\rangle}\sum_{\substack{m_1,m_1'\\ m_2,m_2'}}\left(\begin{array}{cc|c} J_1 & j_1 & j_1\\ M_1 & m_1 & m_1'\end{array}\right)\left(\begin{array}{cc|c} J_2 & j_2 & j_2\\ M_2 & m_2 & m_2'\end{array}\right)$$

$$\times\langle j_1,m_1';j_2,m_2'|a|j_1,m_1;j_2,m_2\rangle, \tag{27}$$

which defines polynomials, which are quadratic in $\left(j_1+\frac{1}{2}\right)$ and $\left(j_2+\frac{1}{2}\right)$. Then we substitute

$$(j_1+\tfrac{1}{2})^2\mapsto(C+\tfrac{1}{4})\otimes 1,\quad (j_2+\tfrac{1}{2})^2\mapsto 1\otimes(C+\tfrac{1}{4}) \tag{28}$$

in order to obtain the unique central elements

$$a^{J_1J_2}_{M_1M_2}(\hat{j}_1,\hat{j}_2)\in\mathbb{C}[C\otimes 1,1\otimes C], \tag{29}$$

the representations of which are given by the polynomials (27). Finally, reconstruct the element of the tensor algebra by

$$a=\sum_{\substack{J_1,M_1\\ J_2,M_2}} a^{J_1J_2}_{M_1M_2}(\hat{j}_1,\hat{j}_2)T^{J_1}_{M_1}\otimes T^{J_2}_{M_2}. \tag{30}$$

We will now apply this reconstruction method to the Drinfeld twist (3).

IV. RECONSTRUCTION OF THE UNIVERSAL DRINFELD TWIST

A. Calculation of the tensor basis

In order to obtain explicit formulas from the reconstruction method of Proposition 2 we need to calculate the tensor operators T^J_M in terms of the Poincaré–Birkhoff–Witt basis as well as the reduced matrix elements $\langle j\|T^J\|j\rangle$. We start with the reduced matrix elements.

From Eq. (9) we can derive the representation of powers of the generators

$$E^J|j,m\rangle=\sqrt{(-1)^J(j+m+1)_J(m-j)_J}|j,m+J\rangle,$$

$$F^J|j,m\rangle=\sqrt{(-1)^J(j-m+1)_J(-m-j)_J}|j,m-J\rangle, \tag{31}$$

where

$$(x)_J := (x)(x+1)\cdots(x+J-1) \tag{32}$$

denotes the Pochhammer symbol. From Eqs. (31) we obtain for the irreducible representations of the tensor operator (14) on the one hand,

$$\langle j,j|T^J_J|j,j-J\rangle=\langle j,j|\alpha E^J|j,j-J\rangle=\alpha\sqrt{\frac{(2j)!J!}{(2j-J)!}} \tag{33}$$

for $J\leqslant 2j$. On the other hand, we have due to the Wigner–Eckhart theorem (21),

$$\langle j,j|T^J_J|j,j-J\rangle=\langle j\|T^J\|j\rangle\left(\begin{array}{cc|c} J & j & j\\ J & j-J & j\end{array}\right)=\langle j\|T^J\|j\rangle\sqrt{\frac{(2j+1)!(2J)!}{(2j+J+1)!J!}}, \tag{34}$$

where we have inserted the explicit expression for the Clebsch–Gordan coefficient. We conclude that

$$\langle j\|T^J\|j\rangle=\alpha\sqrt{\frac{(2j+J+1)!J!J!}{(2j+1)(2j-J)!(2J)!}}. \tag{35}$$

For our purposes, it is convenient to choose the normalization constant α such that

$$\langle J \| T^J \| J \rangle = 1, \tag{36}$$

for which we must set

$$\alpha := \sqrt{\frac{(2J+1)!}{(3J+1)!J!}}. \tag{37}$$

From now on we will assume this choice of α, for which the value of the reduced matrix element (35) becomes

$$\langle j \| T^J \| j \rangle = \sqrt{\frac{(2J+1)(2j+J+1)!J!}{(2j+1)(3J+1)!(2j-J)!}}. \tag{38}$$

From the heighest weight vector T^J_J we obtain the weight basis by repeated action of the lowering operator $\mathrm{ad}\, F$. More precisely, from Eq. (31) we conclude that

$$T^J_M = [(-1)^{J-M}(J-M)!(-2J)_{J-M}]^{-1/2} (\mathrm{ad}\, F)^{J-M} \triangleright T^J_J = \sqrt{\frac{(2J+1)(J+M)!}{(3J+1)!J!(J-M)!}} (\mathrm{ad}\, F)^{J-M} \triangleright E^J \tag{39}$$

for $|M| \leqslant J$. The remaining computational problem for an explicit expression of T^j_m in terms of the Poincaré–Birkhoff–Witt basis is the lexicographic reordering of $(\mathrm{ad}\, F)^{J-M} \triangleright E^J$. Details of the computation are provided in Appendix A. As result we obtain

$$T^J_M = (-1)^{J+M} \sqrt{\frac{(2J+1)J!(J-M)!(J+M)!}{(3J+1)!}} \times \sum_{p=0}^{p \leqslant (J-M)/2} \frac{(-1)^p}{p!(p+M)!} E^{p+M} \binom{J+H-1}{J-M-2p} F^p \quad \text{for } M \geqslant 0, \tag{40a}$$

$$T^J_M = (-1)^{J-M} \sqrt{\frac{(2J+1)J!(J-M)!(J+M)!}{(3J+1)!}} \times \sum_{p=0}^{p \leqslant (J+M)/2} \frac{(-1)^p}{p!(p-M)!} E^{p} \binom{J+H-1}{J+M-2p} F^{p-M} \quad \text{for } M < 0, \tag{40b}$$

where the algebra valued binomial coefficient is defined by

$$\binom{X}{k} := \frac{(-1)^k (-X)_k}{k!}, \tag{41}$$

denoting a polynomial in X. For a complete expansion in terms of ordered monomials we yet must expand the binomials in powers of H,

$$\binom{J+H-1}{J \pm M - 2p} = \sum_{n=0}^{J \pm M - 2p} H^n \sum_{k=n}^{J-M \pm 2p} \frac{1}{k!} \binom{J-1}{J \pm M - 2p - k} s(k,n), \tag{42}$$

where $s(k,n)$ are Stirling numbers of the first kind.

B. The generating function for the Drinfeld twist

We will now apply the reconstruction method of Sec. III to the inverse of the universal Drinfeld twist $\mathcal{F}^{-1}$ of Proposition 1. Inserting the representations (3) of the twist into Eq. (27) the inverse twist can be expressed according to Eq. (30) as

$$\mathcal{F}^{-1}=\sum_{\substack{J_1,M_1\\J_2,M_2}}\frac{(2J_1+1)(2J_2+1)}{(2\hat{j}_1+1)(2\hat{j}_2+1)\langle\hat{j}_1\|T^{J_1}\|\hat{j}_1\rangle\langle\hat{j}_2\|T^{J_2}\|\hat{j}_2\rangle}\sum_{\substack{m_1,m_1'\\m_2,m_2'}}\begin{pmatrix}J_1 & \hat{j}_1 & \hat{j}_1\\ M_1 & m_1 & m_1'\end{pmatrix}\begin{pmatrix}J_2 & \hat{j}_2 & \hat{j}_2\\ M_2 & m_2 & m_2'\end{pmatrix}$$
$$\times\sum_{j,m}m_2\,m_2\begin{pmatrix}\hat{j}_1 & \hat{j}_2 & j\\ m_1' & m_2' & m\end{pmatrix}\begin{pmatrix}\hat{j}_1 & \hat{j}_2 & j\\ m_1 & m_2 & m\end{pmatrix}_q T^{J_1}_{M_1}\otimes T^{J_2}_{M_2}, \tag{43}$$

where we recall that the hats on $\hat{j}_1$ and $\hat{j}_2$ indicate that the coefficients of the tensor operators are polynomials in $C\otimes 1$ and $1\otimes C$ which we obtain after substitution (28). Equation (43) does in general not yield an element of $\mathcal{U}(\mathrm{su}_2)\otimes\mathcal{U}(\mathrm{su}_2)$ for any fixed value of q. It must be understood as algebra valued generating function in $q=\mathrm{e}^{\hbar}$ which produces in each order of $\hbar$ an element of $\mathcal{U}(\mathrm{su}_2)\otimes\mathcal{U}(\mathrm{su}_2)$ proper. An explicit expansion up to third order in $\hbar$ will be given in the next section.

Note that while the entire dependence on $\hbar$ is contained in the q-deformed Clebsch–Gordan coefficient, the arguments of the latter are contracted with the arguments of undeformed Clebsch–Gordan coefficients. We can confine the $\hbar$-dependence further by using the following identity for the Clebsch–Gordan coefficients which is derived in Appendix B:

$$\begin{pmatrix}J_1 & j_1 & j_1\\ M_1 & m_1 & m_1'\end{pmatrix}\begin{pmatrix}J_2 & j_2 & j_2\\ M_2 & m_2 & m_2'\end{pmatrix}\begin{pmatrix}j_1 & j_2 & j\\ m_1' & m_2' & m\end{pmatrix}$$
$$=\sum_{J,j'}\beta\begin{Bmatrix}J_1 & j_1 & j_1\\ J_2 & j_2 & j_2\\ J & j' & j\end{Bmatrix}\begin{pmatrix}J_1 & J_2 & J\\ M_1 & M_2 & M\end{pmatrix}\begin{pmatrix}j_1 & j_2 & j'\\ m_1 & m_2 & m'\end{pmatrix}\begin{pmatrix}J & j' & j\\ M & m' & m\end{pmatrix}, \tag{44}$$

where the expression in braces denotes the $9j$ symbol, the factor β is defined as

$$\beta:=\sqrt{(2J+1)(2j'+1)(2j_1+1)(2j_2+1)}, \tag{45}$$

and $m_1'=M_1+m_1$, $m_2'=M_2+m_1$, $M=M_1+M_2$, $m'=m_1+m_2$. Inserting Eq. (44) into Eq. (43) we obtain

$$\mathcal{F}^{-1}=\sum_{J_1,J_2,J}\sum_{j,j'}\frac{(2J_1+1)(2J_2+1)}{\langle\hat{j}_1\|T^{J_1}\|\hat{j}_1\rangle\langle\hat{j}_2\|T^{J_2}\|\hat{j}_2\rangle}\sqrt{\frac{(2J+1)(2j'+1)}{(2\hat{j}_1+1)(2\hat{j}_2+1)}}\begin{Bmatrix}J_1 & \hat{j}_1 & \hat{j}_1\\ J_2 & \hat{j}_2 & \hat{j}_2\\ J & j' & j\end{Bmatrix}$$
$$\times\sum_m\begin{pmatrix}J & j'\\ 0 & m\end{pmatrix}\begin{pmatrix}j\\ m\end{pmatrix}\sum_{m_1,m_2}\begin{pmatrix}\hat{j}_1 & \hat{j}_2 & j'\\ m_1 & m_2 & m\end{pmatrix}\begin{pmatrix}\hat{j}_1 & \hat{j}_2 & j\\ m_1 & m_2 & m\end{pmatrix}_q\sum_M\begin{pmatrix}J_1 & J_2 & J\\ M & -M & 0\end{pmatrix}T^{J_1}_M\otimes T^{J_2}_{-M}, \tag{46}$$

where we have used that from condition $m_1'+m_2'=m=m_1+m_2$ in Eq. (43) it follows that $M=0$ and $m'=m$.

In the form of Eq. (46) the generating function gives us some insight into the structure of the the twist. The first line of Eq. (46) and the first Clebsch–Gordan coefficient on the second line do not depend on the deformation parameter $\hbar$ and contain only well-known functions, the $9j$ symbol and the Clebsch–Gordan coefficient essentially being given by hypergeometric functions.

The summation over M in the last line eliminates the dependence on the magnetic quantum numbers M_1 and M_2 of the tenor operator basis. The fact that the magnetic quantum number of the tensor operators $T^{J_1}_{M_1}\otimes T^{J_2}_{M_2}$ which appear in the Drinfeld twist add up to zero, $M_1+M_2=M=0$, can also be understood on a more abstract level. Up to isomorphism, the quantum deformation of an enveloping algebra does not affect the Cartan subalgebra as it was stated in Theorem 2. For the Drinfeld–Jimbo deformation $\mathcal{U}_\hbar(\mathrm{su}_2)$ which we consider here this means that

$$\Delta(H) = \Delta_\hbar(H) = H \otimes 1 + 1 \otimes H, \tag{47}$$

which implies that the Drinfeld twist $\mathcal{F}$ must commute with $\Delta(H)$. From

$$[\Delta(H), T^{J_1}_{M_1} \otimes T^{J_2}_{M_2}] = 2(M_1 + M_2)(T^{J_1}_{M_1} \otimes T^{J_2}_{M_2}) \tag{48}$$

we conclude that only those products of tensor operators can appear in $\mathcal{F}$ and $\mathcal{F}^{-1}$ for which $M_1 + M_2 = 0$.

The dependence of Eq. (46) on the deformation parameter is contained in the contraction of the deformed and undeformed Clebsch–Gordan coefficient over m_1 and m_2 in the second line. The representation theoretic interpretation of this term is the following: We can use both, the undeformed and the deformed coproduct, to define a tensor product representation of two irreducible representations with weights j_1 and j_2, defining the undeformed and deformed structure maps as

$$\rho^{j_1 \otimes j_2} := (\rho^{j_1} \otimes \rho^{j_2}) \circ \Delta \quad \text{and} \quad \rho^{j_1 \otimes j_2}_\hbar := (\rho^{j_1} \otimes \rho^{j_2}) \circ \Delta_\hbar. \tag{49}$$

Both representations can be reduced into irreducible components. Denoting the basis vectors of the irreducible weight-j subrepresentation of the undeformed and deformed tensor representation by $|j_1, j_2 \to j, m\rangle$ and $|j_1, j_2 \to j, m\rangle_\hbar$, respectively, we obtain

$$\langle j_1, j_2 \to j', m | j_1, j_2 \to j, m \rangle_\hbar = \sum_{m_1, m_2} \left(\begin{matrix} j_1 & j_2 \\ m_1 & m_2 \end{matrix} \middle| \begin{matrix} j' \\ m \end{matrix} \right) \left(\begin{matrix} j_1 & j_2 \\ m_1 & m_2 \end{matrix} \middle| \begin{matrix} j \\ m \end{matrix} \right)_q. \tag{50}$$

In other words the deformation is now expressed as the change of basis from the irreducible components of tensor representations with respespect to the undeformed coproduct Δ to those with respect to the deformed coproduct $\Delta_\hbar$. Again, the expression on the right-hand side of Eq. (50) is to be understood as generating function. While the q-Clebsch–Gordan coefficient are well-known functions for a given value of q, little is known about its perturbative expansion in powers of $\hbar$.

C. Perturbative expansion

Ideally, we would like to find a closed form expression for the Drinfeld twist in each order of $\hbar$. This would require a closed form expansion of Eq. (50), which is essentially given by a sum of the product of the ordinary hypergeometric function ${}_3F_2$ and its basic (q-deformed) counterpart ${}_3\varphi_2$. To our best knowledge such hybrid combinations of ordinary and basic hypergeometric functions have not been studied in the literature yet and little is known about the perturbative expansion of basic hypergeometric functions in powers of $\hbar = \ln q$ or other possible perturbation parameters such as $q - q^{-1}$ and $q - 1$. Studying the general problem of perturbative expansion of basic hypergeometric functions is beyond the scope of this paper. This is ongoing research and will be presented elsewhere. Here we will only expand the q-deformed Pochhammer symbol, which is the building block of basic hypergeometric functions. This will enable us to carry out the explicit calculation of each order of the Drinfeld twist by a Taylor series expansion of the generating functions (43) and (46).

For our purposes it is convenient to consider the q-Pochhammer symbol $[x]_n$ which is defined by symmetric quantum numbers $[x]$,

$$[x]_n := [x] \cdot [x+1] \cdots [x+n-1], \quad [x] = \frac{e^{x\hbar} - e^{-x\hbar}}{e^{\hbar} - e^{-\hbar}} = \frac{\sinh x\hbar}{\sinh \hbar}. \tag{51}$$

Considering the logarithm of the Pochhammer symbols will turn the product of the q-numbers into the sum of their logarithms. Using the well-known formula

$$\ln\frac{\sinh x}{x}=\sum_{k=1}^{\infty}\frac{2^{2k-1}B_{2k}}{k(2k)!}x^{2k}, \tag{52}$$

where B_{2k} are Bernoulli numbers, we obtain for the expansion of the logarithm of a quantum number

$$\ln\frac{[x]}{x}=\sum_{k=1}^{\infty}\frac{2^{2k-1}B_{2k}}{k(2k)!}(x^{2k}-1)\hbar^{2k}. \tag{53}$$

The Pochhammer symbol can then be expressed as exponential of the sum of this power series,

$$\frac{[x]_n}{(x)_n}=\exp\left(\sum_{k=1}^{\infty}\frac{2^{2k-1}B_{2k}}{k(2k)!}\sum_{j=0}^{n-1}\{(x+j)^{2k}-1\}\hbar^{2k}\right). \tag{54}$$

The sum is carried out using

$$\sum_{j=0}^{n-1}(x+j)^{2k}=\frac{B_{2k+1}(x+n)-B_{2k+1}(x)}{2k+1}, \tag{55}$$

where $B_k(x)$ denotes Bernoulli polynomials. We thus get

$$\frac{[x]_n}{(x)_n}=\exp\left(\sum_{k=1}^{\infty}\frac{2^{2k-1}B_{2k}}{k(2k)!}\left\{\frac{B_{2k+1}(x+n)-B_{2k+1}(x)}{2k+1}-n\right\}\hbar^{2k}\right). \tag{56}$$

This formula could serve as starting point for a perturbative expansion of general q-hypergeometric functions. Here it suffices to deduce from Eq. (56) the expansion of the Pochhammer symbol in $\hbar$. Up to third order we obtain

$$\begin{aligned}\frac{[x]_n}{(x)_n}&=1+\frac{1}{3}B_2\{B_3(x+n)-B_3(x)-3n\}\hbar^2+\mathcal{O}(\hbar^4)\\&=1+\frac{1}{36}(-5n-3n^2+2n^3-6nx+6n^2x+6nx^2)\hbar^2+\mathcal{O}(\hbar^4).\end{aligned} \tag{57}$$

This expression is polynomial in n and x to each order of $\hbar$. Inserting it into Eq. (27) yields the searched-for polynomials in $C\otimes 1$ and $1\otimes C$. From the generating functions (43) or (46) we then obtain the universal Drinfeld twist up to third order in $\hbar$.

Each order $\mathcal{F}_k^{-1}$ of the expansion $\mathcal{F}^{-1}=\Sigma_k\mathcal{F}_k^{-1}\hbar^k$ is alternatingly symmetric or antisymmetric with respect to the exchange of tensor factors by the transpose $\tau(a\otimes b)=b\otimes a$ according to

$$\tau(\mathcal{F}_k^{-1})=(-1)^k\mathcal{F}_k^{-1}. \tag{58}$$

This property can be derived from the fact that the transpose of the deformed coproduct amounts to a change of sign of the perturbation parameter, from which it follows that $\tau(\mathcal{F}^{-1}(\hbar))=\mathcal{F}^{-1}(-\hbar)$. Alternatively, it can be derived from the symmetry properties of the q-Clebsch–Gordan coefficients with respect to the transformation $q\mapsto q^{-1}$. The explicit expressions for the first three orders of the twist we finally obtain are

$$\mathcal{F}_1^{-1}=2(T_{-1}^1\otimes T_1^1-T_{-1}^1\otimes T_1^1)=2T_{-1}^1\otimes T_1^1-\text{transpose}, \tag{59a}$$

$$\mathcal{F}_2^{-1}=-\frac{1}{18}C\otimes C+\frac{\sqrt{14}}{6}T_0^2\otimes C+\frac{\sqrt{21}}{6}(T_1^1\otimes T_{-1}^2-T_{-1}^1\otimes T_1^2)+\frac{21}{2}T_{-2}^2\otimes T_2^2-\frac{7}{4}T_0^2\otimes T_0^2+\text{transpose}, \tag{59b}$$

$$\mathcal{F}_3^{-1} = \frac{\sqrt{2}}{180}(3-4C)T_0^1 \otimes C + \frac{\sqrt{7}}{30}T_0^2 \otimes (9-2C)T_0^1 + \frac{1}{75}[7-21(C\otimes 1 + 1\otimes C) - 12C\otimes C]T_{-1}^1 \otimes T_1^1$$
$$+ \frac{7}{2}T_{-2}^2 \otimes T_2^2 + \frac{\sqrt{6}}{3}T_0^3 \otimes C + \frac{2\sqrt{2}}{5}[T_1^3 \otimes (1-3C)T_{-1}^1 - T_{-1}^3 \otimes (1-3C)T_1^1] + \sqrt{21}T_0^2 \otimes T_0^3$$
$$+ \sqrt{105}(T_{-2}^3 \otimes T_2^2 + T_2^3 \otimes T_{-2}^2) + 18(5T_{-3}^3 \otimes T_2^3 + T_{-1}^3 \otimes T_1^3) - \text{transpose}, \tag{59c}$$

where "transpose" is shorthand for the tensor transpose of all preceding terms such that each expression becomes symmetric or antisymmetric, respectively. One can use Eqs. (40) in order to express the result in terms of the Poincaré–Birkhoff–Witt basis. However, this yields expressions which are much longer than those of Eqs. (59), indicating that the tensor operator basis seems to be the better choice within the context of Drinfeld twists.

The calculations leading to Eqs. (59) are elementary but lengthy and are best carried out using computer algebra. With the expansion (56) of the q-Pochhammer symbol at hand the Taylor series expansion of the generating function (43) is reduced to addition and multiplication of polynomials, operations which are implemented efficiently by all common computer algebra systems. Hence, the explicit calculation of the Drinfeld twist to third order is not significantly limited by computing resources in any way. In any case, by the method presented here it is possible to compute the twist explicitly to orders which are high enough for the applications of Drinfeld twists to mathematical physics which we had in mind.

V. CONCLUSION

Although the existence of universal Drinfeld twists can be proved rather easily, their calculation is a notoriously difficult and long standing problem. While we still did not derive a closed form for each order in the perturbation parameter of the universal twist of $\mathcal{U}_\hbar(\mathrm{su}_2)$, significant progress towards this goal was presented here. In Eq. (46) we have given a generating function for the twist to all orders which can be easily expanded in powers of $\hbar$, as demonstrated in Eq. (59). Moreover, the generating function, which is expressed in terms of basic and ordinary hypergeometric functions, gives new insight into the general structure of the twist.

It is not difficult to understand why the proof of existence of the twist is so easy but the computation is so hard. The existence proof relies mainly on the fact that the first Hochschild cohomolgy of the enveloping algebra is zero. This means that every 1-cocycle is the coboundary of a 0-cocycle or, in other words, every derivation is inner. But we do not know how to compute this 0-cocycle. If in analogy to differential forms we view the inversion of the coboundary operator as a sort of integration, then the nonconstructive existence proof uses integrability but does not tell us how to actually integrate. Just as in differential calculus, this cohomological type of integration turns out to be a difficult problem. In contrast, the series expansion of the generating function (46) in powers of $\hbar$ is a problem of differentiation. While integration is an art, differentiation is a simple technique which can be left to a computer algebra system. This is the reason why we consider the availability of a generating function as significant progress.

The computer algebra expansion of the generating function is computationally cheap and produces expansions of the twist which will suffice for many applications. However, it is not completely satisfactory as it produces expansion formulas like Eq. (59) containing a lot of "magical" combinatorial numbers which cannot be explained any further. In Eq. (46) the dependence of the twist on the perturbation parameter is entirely confined to the q-Clebsch–Gordon coefficient, that is, essentially to the basic hypergeometric function ${}_3\varphi_2$ with basis $q=e^\hbar$. Hence, the remaining problem which still separates us from a truly closed form expression for the universal twist is the perturbative expansion of this basic hypergeometric function in powers of $\hbar$. To our best knowledge, the question of perturbative expansion of basic hypergeometric functions, which seems so obvious in the context of quantum groups, has so far not recieved any systematic treatment in the special functions literature. Therefore, we had to make in Sec. IV C our own first step in this direction, computing a closed form expression for the q-deformed Pochhammer symbol in Eq.

(56). We believe that, further pursuing this approach, a closed form expansion of basic hypergeometric functions and, hence, a closed form of the universal Drinfeld twist of $\mathcal{U}_\hbar(\mathrm{su}_2)$ can be achieved.

ACKNOWLEDGMENTS

The author would like to thank Daniel Sternheimer for pointing out to me previous work on this subject. The author is grateful to Petr Kulish for an illuminating discussion on the calculation of universal twists in the triangular case. The author is also indebted to Hjalmar Rosengren for discussing aspects of the present work from the viewpoint of the theory of basic hypergeometric functions.

APPENDIX A: CALCULATION OF THE TENSOR OPERATOR BASIS

Expressing the tensor operator basis in terms of the Poincaré–Birkhoff–Witt basis amounts to the normal ordering of Eq. (39). While it is possible to carry out the normal ordering using the commutation relations of $\mathcal{U}(\mathrm{su}_2)$, this turns out to be surpisingly cumbersome. Therefore, we present an alternative approach which is much more in the spirit of this paper: We deduce the normal ordered expression from the representations of the tensor operators.

Let us assume that $M \geqslant 0$. Starting from the Wigner–Eckart theorem (21), using (38) for the reduced matrix elements and the well-known explicit formula

$$\begin{aligned}\left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right) &= (-1)^{m_1-j_1}\sqrt{\frac{(2j+1)(j_1+j_2-j)!}{(j_1+j_2+j+1)!(j_1-j_2+j)!(j_2-j_1+j)!}} \\ &\times \frac{(j_2+j-m_1)!}{(j_2-j+m_1)!}\sqrt{\frac{(j_1+m_1)!(j_2-m_2)!(j+m)!}{(j_1-m_1)!(j_2+m_2)!(j-m)!}} \\ &\times {}_3F_2\left(\begin{matrix} m_1-j_1, j_1+m_1+1, m-j \\ j_2-j+m_1+1, -j-j_2+m_1 \end{matrix}\right)\end{aligned} \tag{A1}$$

for the Clebsch–Gordan coefficients,[33] we derive for the matrix elements of the tensor operators

$$\begin{aligned}\langle j,m'|T^J_M|j,m\rangle &= (-1)^{J+M}\sqrt{\frac{(2J+1)(J-M)!}{(3J+1)!(J)!\,(J+M)!}}\,\delta_{m',m+M}\sqrt{(-1)^M(j+m+1)_M(-j+m)_M} \\ &\times \sum_k (-1)^k\binom{J+M}{k}(-j-m-k)_J(j+1-m-k)_J.\end{aligned} \tag{A2}$$

We want to deduce the element of the algebra in the Poincaré–Birkhoff–Witt basis from these representations. Towards this end we will compare Eq. (A2) with the matrix elements of monomials

$$\begin{aligned}\langle j,m'|E^pF^p|j,m\rangle &= \delta_{m'm}(-1)^p(-j-m)_p(j-m+1)_p, \\ \langle j,m'|E^M|j,m\rangle &= \delta_{m',m+M}\sqrt{(-1)^M(j+m+1)_M(-j+m)_M}.\end{aligned} \tag{A3}$$

We immediately see that the second line of Eq. (A2) is the matrix element of E^M. The last line has yet to be written in a different form. For this, we need a variant of the Pfaff–Saalschütz summation formula

$$(a-c)_n(b-c)_n = \sum_{p=0}^{n}\binom{n}{p}(-c)_{n-p}(a+b-c+p)_{n-p}(a)_p(b)_p, \tag{A4}$$

from which we get for $a=-j-m$, $b=j-m+1$, $c=k$, $n=J$,

$$(-j-m-k)_J(j-m+1-k)_J=\sum_{p=0}^{J}\binom{J}{p}(-k)_{J-p}(-2m+1-k+p)_{J-p}(-j-m)_p(j-m+1)_p, \tag{A5}$$

and a variant of the Vandermonde summation formula

$$\sum_{k=0}^{n}(-1)^k\binom{n}{k}(-k)_q(-k-x)_q=(-1)^n n!\binom{q}{n-q}(-x-q)_{2q-n}. \tag{A6}$$

Inserting first Eq. (A5) and then Eq. (A6) into the last line of Eq. (A2) we obtain

$$\sum_{k=0}^{J+M}(-1)^k\binom{J+M}{k}(-j-m-k)_J(j+1-m-k)_J=\sum_{p=0}^{p\leqslant J-M/2}\frac{J!(J+M)!}{p!(M+p)!}\binom{2m-2p+J-1}{J-M-2p}\times(-j-m)_p(j-m+1)_p, \tag{A7}$$

Comparing this with the matrix element (A3), we obtain the equality of matrix elements,

$$\langle j,m'|T^J_M|j,m\rangle=(-1)^{J+M}\sqrt{\frac{(2J+1)J!\,(J-M)!\,(J+M)!}{(3J+1)!}}\sum_{p=0}^{p\leqslant J-M/2}\frac{(-1)^p}{p!(M+p)!}\langle j,m'|E^{p+M}\binom{J+H-1}{J-M-2p}F^p|j,m\rangle, \tag{A8}$$

from which we can deduce Eq. (40a). The analogous calculations for $M\leqslant 0$ lead to Eq. (40b).

APPENDIX B: DERIVATION OF EQ. (44)

In order to derive Eq. (44) we recall that, while the Clebsch–Gordan coefficients reduce tensor representations, this reduction is neither commutative nor associative. Let us denote by D^j the irreducible weight-j representation. The isomorphism which corresponds to the exchange of the order in a product representation, $D^{j_1}\otimes D^{j_2}\to D^{j_1}\otimes D^{j_2}$, is given by a change of sign

$$\left(\begin{array}{cc|c} j_1 & j_2 & j\\ m_1 & m_2 & m\end{array}\right)=(-1)^{j-j_1-j_2}\left(\begin{array}{cc|c} j_2 & j_1 & j\\ m_2 & m_1 & m\end{array}\right), \tag{B1}$$

where j_1+j_2-j is always an integer. The associator which corresponds to changing the order of reduction of a product of three irreducible representations, $D^{j_1}\otimes(D^{j_2}\otimes D^{j_3})_{j_{23}}\to(D^{j_1}\otimes D^{j_2})_{j_{12}}\otimes D^{j_2}$ is by definition given by the Racah coefficients,

$$\left(\begin{array}{cc|c} j_2 & j_3 & j_{23}\\ m_2 & m_3 & m_{23}\end{array}\right)\left(\begin{array}{cc|c} j_1 & j_{23} & j\\ m_1 & m_{23} & m\end{array}\right)=\sum_{j_{12}}\left(\begin{array}{cc|c} j_1 & j_2 & j_{12}\\ m_1 & m_2 & m_{12}\end{array}\right)\left(\begin{array}{cc|c} j_{12} & j_3 & j\\ m_{12} & m_3 & m\end{array}\right)\mathbf{R}^{j_1j_2j_3}_{j_{12}j_{23}j}, \tag{B2}$$

where $m_{12}=m_1+m_2$, $m_{23}=m_2+m_3$. Using Eqs. (B1) and (B2) the change of the reduction of a tensor product of four representations according to

$$(D^{j_1}\otimes D^{j_2})_{j_{12}}\otimes(D^{j_1}\otimes D^{j_1})_{j_{34}}\to((D^{j_1}\otimes D^{j_2})_{j_{12}}\otimes D^{j_3})_{j'}\otimes D^{j_4}\to(D^{j_3}\otimes(D^{j_1}\otimes D^{j_2})_{j_{12}})_{j'}\otimes D^{j_4}\to((D^{j_3}\otimes D^{j_1})_{j_{13}}\otimes D^{j_2})_{j'}\otimes D^{j_4}\to(D^{j_1}\otimes D^{j_3})_{j_{13}}\otimes(D^{j_2}\otimes D^{j_4})_{j_{24}} \tag{B3}$$

is then expressed as

$$
\begin{aligned}
&\left(\begin{array}{cc|c} j_1 & j_2 & j_{12} \\ m_1 & m_2 & m_{12} \end{array}\right)\left(\begin{array}{cc|c} j_3 & j_4 & j_{34} \\ m_3 & m_4 & m_{34} \end{array}\right)\left(\begin{array}{cc|c} j_{12} & j_{34} & j \\ m_{12} & m_{34} & m \end{array}\right) \\
&\quad=\sum_{j'}\left(\begin{array}{cc|c} j_1 & j_2 & j_{12} \\ m_1 & m_2 & m_{12} \end{array}\right)\left(\begin{array}{cc|c} j_{12} & j_3 & j' \\ m_{12} & m_3 & m' \end{array}\right)\left(\begin{array}{cc|c} j' & j_4 & j \\ m' & m_4 & m \end{array}\right)\mathbf{R}^{j_{12}j_3j_4}_{j'j_{34}j} \\
&\quad=\sum_{j'}\left(\begin{array}{cc|c} j_1 & j_2 & j_{12} \\ m_1 & m_2 & m_{12} \end{array}\right)\left(\begin{array}{cc|c} j_3 & j_{12} & j' \\ m_3 & m_{12} & m' \end{array}\right)\left(\begin{array}{cc|c} j' & j_4 & j \\ m' & m_4 & m \end{array}\right)\mathbf{R}^{j_{12}j_3j_4}_{j'j_{34}j}(-1)^{j'-j_{12}-j_3} \\
&\quad=\sum_{j_{13},j'}\left(\begin{array}{cc|c} j_3 & j_1 & j_{13} \\ m_3 & m_1 & m_{13} \end{array}\right)\left(\begin{array}{cc|c} j_{13} & j_2 & j' \\ m_{13} & m_2 & m' \end{array}\right)\left(\begin{array}{cc|c} j' & j_4 & j \\ m' & m_4 & m \end{array}\right)\mathbf{R}^{j_3j_1j_2}_{j_{13}j_{12}j'}\mathbf{R}^{j_{12}j_3j_4}_{j'j_{34}j}(-1)^{j'-j_{12}-j_3} \\
&\quad=\sum_{j_{13},j_{24}}\left(\begin{array}{cc|c} j_1 & j_3 & j_{13} \\ m_1 & m_3 & m_{13} \end{array}\right)\left(\begin{array}{cc|c} j_2 & j_4 & j_{24} \\ m_2 & m_4 & m_{24} \end{array}\right)\left(\begin{array}{cc|c} j_{13} & j_{24} & j \\ m_{13} & m_{24} & m \end{array}\right) \\
&\qquad\times\sum_{j'}\mathbf{R}^{j_{13}j_2j_4}_{j'j_{24}j}\mathbf{R}^{j_3j_1j_2}_{j_{13}j_{12}j'}\mathbf{R}^{j_{12}j_3j_4}_{j'j_{34}j}(-1)^{j'-j_{12}+j_{13}-j_1-2j_3},
\end{aligned}
\tag{B4}
$$

where $m_{ij}=m_i+m_j$ for $i,j\in\{1,2,3,4\}$, $i<j$. Next we express the Racah coefficients in terms of $6j$ symbols,

$$
\mathbf{R}^{j_1j_2j_3}_{j_{12}j_{13}j}=(-1)^{j_1+j_2+j_3+j}\sqrt{(2j_{12}+1)(2j_{13}+1)}\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j & j_{13} \end{Bmatrix}. \tag{B5}
$$

Using the symmetries of the $6j$ symbol and the definition of the $9j$ symbol we can rewrite the last line of Eq. (B4) as

$$
\begin{aligned}
&\sum_{j'}\mathbf{R}^{j_{13}j_2j_4}_{j'j_{24}j}\mathbf{R}^{j_3j_1j_2}_{j_{13}j_{12}j'}\mathbf{R}^{j_{12}j_3j_4}_{j'j_{34}j}(-1)^{j'-j_{12}+j_{13}-j_1-2j_3} \\
&\qquad=\alpha\sum_{j'}(-1)^{2j'}(2j'+1)\begin{Bmatrix} j_{13} & j_2 & j' \\ j_4 & j & j_{24} \end{Bmatrix}\begin{Bmatrix} j_3 & j_1 & j_{13} \\ j_2 & j' & j_{12} \end{Bmatrix} \\
&\qquad\quad\times\begin{Bmatrix} j_{12} & j_3 & j' \\ j_4 & j & j_{34} \end{Bmatrix}=\alpha\sum_{j'}(-1)^{2j'}(2j'+1) \\
&\qquad\quad\times\begin{Bmatrix} j_3 & j_{13} & j_1 \\ j_2 & j_{12} & j' \end{Bmatrix}\begin{Bmatrix} j_4 & j_{24} & j_2 \\ j_{13} & j' & j \end{Bmatrix}\begin{Bmatrix} j_{34} & j & j_{12} \\ j' & j_3 & j_4 \end{Bmatrix} \\
&\qquad=\alpha\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j_4 & j_{34} \\ j_{13} & j_{24} & j \end{Bmatrix},
\end{aligned}
\tag{B6}
$$

where the factor α is defined as

$$
\alpha:=(-1)^{2j}\sqrt{(2j_{12}+1)(2j_{34}+1)(2j_{13}+1)(2j_{24}+1)}. \tag{B7}
$$

From Eqs. (B4) and (B6) we finally obtain

$$
\begin{aligned}
&\left(\begin{array}{cc|c} j_1 & j_2 & j_{12} \\ m_1 & m_2 & m_{12} \end{array}\right)\left(\begin{array}{cc|c} j_3 & j_4 & j_{34} \\ m_3 & m_4 & m_{34} \end{array}\right)\left(\begin{array}{cc|c} j_{12} & j_{34} & j \\ m_{12} & m_{34} & m \end{array}\right) \\
&\quad=\sum_{j_{13},j_{24}}\alpha\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j_4 & j_{34} \\ j_{13} & j_{24} & j \end{Bmatrix}\left(\begin{array}{cc|c} j_1 & j_3 & j_{13} \\ m_1 & m_3 & m_{13} \end{array}\right)\left(\begin{array}{cc|c} j_2 & j_4 & j_{24} \\ m_2 & m_4 & m_{24} \end{array}\right)\left(\begin{array}{cc|c} j_{13} & j_{24} & j \\ m_{13} & m_{24} & m \end{array}\right).
\end{aligned}
\tag{B8}

(Received 11 January 2005; accepted 9 March 2005; published online 10 May 2005)

We study bifurcations of eigenvalues from the endpoints of the essential spectrum in the linearized nonlinear Schrödinger problem in three dimensions. We show that a resonance and an eigenvalue of positive energy at the endpoint may bifurcate only to a real eigenvalue of positive energy, while an eigenvalue of negative energy at the endpoint may also bifurcate to complex eigenvalues. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1901345]

I. INTRODUCTION

We consider the nonlinear Schrödinger (NLS) equation in three dimensions,

$$i\psi_t = -\Delta\psi + U(x)\psi + F(|\psi|^2)\psi, \tag{1.1}$$

where $(x,t) \in \mathbb{R}^3 \times \mathbb{R}$ and $\psi \in \mathbb{C}$. For suitable functions $U(x)$ and $F(|\psi|^2)$, the NLS equation (1.1) possesses special solutions,

$$\psi = \phi(x)e^{i\omega t}, \quad \omega > 0, \tag{1.2}$$

where $\phi(x)$ is an exponentially decreasing solution of the elliptic problem,

$$-\Delta\phi + \omega\phi + U(x)\phi + F(\phi^2)\phi = 0, \tag{1.3}$$

such that $\phi: \mathbb{R}^3 \to \mathbb{R}$ and $\phi \in C^\infty$. Linearization of the nonlinear Schrödinger equation (1.1) with the ansatz,

$$\psi = (\phi(x) + \varphi(x)e^{iz t} + \overline{\theta}(x)e^{-i\overline{z}t})e^{i\omega t}, \tag{1.4}$$

leads to the spectral problem,

$$\mathcal{L}\boldsymbol{\psi} = z\boldsymbol{\psi}, \tag{1.5}$$

where $\boldsymbol{\psi} = (\varphi, \theta)^T$ and the linear operator $\mathcal{L}$ on $L^2(\mathbb{R}^3 \mapsto \mathbb{C}^2)$ takes the form $\mathcal{L} = \sigma_3\mathcal{H}$, where

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \mathcal{H} = \begin{pmatrix} -\Delta + \omega + f(x) & g(x) \\ g(x) & -\Delta + \omega + f(x) \end{pmatrix}, \tag{1.6}$$

and

$$f(x) = U(x) + F(\phi^2) + F'(\phi^2)\phi^2, \quad g(x) = F'(\phi^2)\phi^2.$$

We assume that $U(x) \in C^\infty$ is exponentially decreasing and $F \in C^\infty, F(0) = 0$, such that $f, g: \mathbb{R}^3 \to \mathbb{R}$ are exponentially decaying C^∞-functions.

We denote the point spectrum of $\mathcal{L}$ as $\sigma_p(\mathcal{L})$ and the essential spectrum of $\mathcal{L}$ as $\sigma_e(\mathcal{L})$. We have shown in Cuccagna *et al.* (2005) that the spectrum of $\mathcal{L}$ is associated to the sign of the energy functional defined in $H^1(\mathbb{R}^3 \mapsto \mathbb{C}^2)$,

$$h = \langle \psi, \mathcal{H}\psi \rangle. \tag{1.7}$$

In particular, an eigenvalue is of positive (respectively, negative) energy if $h>0$ (respectively, $h<0$). We showed in Cuccagna *et al.* (2005) that the nonsingular part of $\sigma_e(\mathcal{L})$ has always positive energy. We also proved that an embedded eigenvalue z of positive energy $h>0$ disappears under a generic perturbation in the context of operator $\mathcal{L}$, while one of negative energy $h<0$ bifurcates into isolated complex eigenvalues of $\sigma_p(\mathcal{L})$. The latter result generalizes an older work by Grillakis (1990), while the former one is new and consistent with the theory of embedded eigenvalues for standard Schrödinger operators.

In this paper we apply a generic perturbation to $\mathcal{L}$ in the case when the points $z=\pm\omega$, that are thresholds of $\sigma_e(\mathcal{L})$, are either eigenvalues or resonances of rank one. We show how the resonance or eigenvalue can either disappear in a different sheet of the Riemann surface associated to the resolvent of $\mathcal{L}$ or move away from the essential spectrum becoming an isolated real eigenvalue, or a pair of isolated complex eigenvalues. Furthermore we study the dependence of this singularity on the perturbation, obtaining an analogue of the similar work by Klaus and Simon (1980) on standard Schrödinger operators. We note that the resonance and eigenvalues at the endpoints are typically eliminated by hypothesis in the analysis of the NLS equation (1.1) and the linearized NLS problem (1.5) [Cuccagna (2001), Perelman (2004), Schlag (2004)]

One application of our result is the analysis of the NLS equation (1.1) in the case when operator $H_0=-\Delta+U(x)$ supports $-\mu_1<\cdots<-\mu_N$ negative eigenvalues and when the threshold 0 is either a resonance or an eigenvalue. It is well known [Tsai and Yau (2002)] that the NLS equation (1.1) admits then nonlinear standing wave solutions of form (1.2) with ω close to μ_n for any preassigned n and these standing wave solutions are small. Their stability properties depend crucially on the spectral properties of the related $\mathcal{L}$ which turns out to be a small perturbation of $\sigma_3(H_0+\omega)$ by the smallness of the standing wave. In the case of $n=1$, the discrete spectrum of $\mathcal{L}$ is close to that of $\sigma_3(H_0+\omega)$, in particular has at least $2N$ elements with the point 0 of multiplicity 2. Our paper can be used to track the threshold singularity of operator $\mathcal{L}$ under perturbation.

Another possible application occurs when we add a small nonlinear perturbation $\epsilon\delta F(|\psi|^2)\psi$ to the main equation (1.1). Under appropriate conditions, the ground state can be shown to depend smoothly on ϵ. Now, if for $\epsilon=0$ and a given value of ω operator $\mathcal{L}$ has resonances or eigenvalues at the thresholds, one can ask what happens to these singularities for nearby $\epsilon\neq 0$. The present paper gives a tool for analysis, avoiding details of specific applications.

For earlier work on "edge bifurcations," which is the name for bifurcations of resonances from the endpoints, see Kapitula and Sandstede [(2002), (2004)] where the main tool is the Evans function. Since the Evans function seems better suited to one-dimensional (1D) problems, our present work is based on theory by Jensen and Kato (1979) for scalar Schrödinger operators, applied here to the linearized NLS problem (1.5). Notice that our work is more general than Kapitula and Sandstede [(2002), (2004)] since it allows also eigenvalues at the endpoints and it does not depend on whether the solution $\phi(x)$ is a ground state. Furthermore we answer to a specific question [see Corollary 5.4 in Kapitula *et al.* (2004)] by showing that it is impossible for a resonant pole to become an unstable (complex) eigenvalue.

Our paper is structured as follows. The formalism of operator resolvent near the endpoints is exposed in Sec. II. Bifurcations of a simple resonance and a simple eigenvalue from the endpoint are described in Secs. III and IV, respectively. Section V gives the proof of Lemma 4.7.

II. OPERATOR RESOLVENT NEAR THE ENDPOINTS

Using standard Pauli matrices σ_2 and σ_3, we write $\mathcal{L}$ explicitly as

$$\mathcal{L} = (-\Delta + \omega + f(x))\sigma_3 + ig(x)\sigma_2, \tag{2.1}$$

such that $\sigma_3\mathcal{L}\sigma_3=\mathcal{L}^*$. We also decompose the operator $\mathcal{L}$ into the unbounded differential part $\mathcal{L}_0$ and bounded potential part $V(x)$ as $\mathcal{L}=\mathcal{L}_0+V(x)$, where $\mathcal{L}_0=(-\Delta+\omega)\sigma_3$ and $V(x)=f(x)\sigma_3$

$+ig(x)\sigma_2$. We assume that $V(x)$ is continuous, exponentially decaying matrix-valued function, such that

$$|V_{i,j}(x)| \leqslant Ce^{-\alpha|x|}, \quad \forall\, x \in \mathbb{R}^3, \quad 1 \leqslant i,j \leqslant 2, \tag{2.2}$$

for some $\alpha > 0, C > 0$. In these notations, the spectral problem (1.5) is rewritten as

$$(\mathcal{L}_0 - z)\boldsymbol{\psi} = -V(x)\boldsymbol{\psi}. \tag{2.3}$$

We use the weighted H^τ_s and L^2_s spaces defined as

$$H^\tau_s = \left\{f:(\omega - \Delta)^{r/2} f \in L^2_s\right\}, \tag{2.4}$$

$$L^2_s = \left\{f:(1 + |x|^2)^{s/2} f \in L^2\right\}. \tag{2.5}$$

We also use the standard Fourier transform in L^2,

$$f(p) = \frac{1}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} f(x) e^{ipx}\, dx, \quad f(x) = \frac{1}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} f(p) e^{-ipx}\, dp. \tag{2.6}$$

We denote the operator resolvent as $\mathcal{R}(z) = (\mathcal{L} - z)^{-1}$ and $\mathcal{R}_0(z) = (\mathcal{L}_0 - z)^{-1}$, such that

$$\mathcal{R}(z) = (I + \mathcal{R}_0(z)V)^{-1}\mathcal{R}_0(z). \tag{2.7}$$

The domain of the essential spectrum $\sigma_e(\mathcal{L})$ is located at $\mathcal{D}_e = (-\infty, -\omega] \cup [\omega, \infty)$, such that the points $z = \pm\omega$ are endpoints of $\sigma_e(\mathcal{L})$.

Let us consider bifurcations from the endpoint $z = \omega$, since bifurcations from the other endpoint $z = -\omega$ are obtained from the symmetry of the problem (2.3). When $z \notin \mathcal{D}_e$ but $|z - \omega|$ is small, we introduce the parametrization,

$$z = \omega - \zeta^2, \quad \operatorname{Re} \zeta > 0, \tag{2.8}$$

and consider the kernel of $R_0(\zeta) \equiv \mathcal{R}_0(\omega - \zeta^2), \operatorname{Re} \zeta > 0$ in the explicit form

$$R_0(\zeta) = \frac{\sigma_3}{4\pi|x-y|} \begin{bmatrix} e^{-\zeta|x-y|} & 0 \\ 0 & e^{-\sqrt{2\omega - \zeta^2}|x-y|} \end{bmatrix}. \tag{2.9}$$

When $\zeta \to 0$, the resolvent $R_0(\zeta)$ has the Taylor series expansion in $\mathcal{B}(H^{-1}_s, H^1_{-s}), s > \frac{3}{2}$,

$$R_0(\zeta) = R_0 - \zeta R_1 + \zeta^2 R_2 - \zeta^3 R_3 + \mathrm{O}(\zeta^4), \quad \operatorname{Re} \zeta > 0, \tag{2.10}$$

where

$$R_0 = \frac{\sigma_3}{4\pi|x-y|} \begin{bmatrix} 1 & 0 \\ 0 & e^{-\sqrt{2\omega}|x-y|} \end{bmatrix}, \quad R_1 = \frac{1}{4\pi} \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \tag{2.11}$$

$$R_2 = \frac{\sigma_3}{8\pi} \begin{bmatrix} |x-y| & 0 \\ 0 & \dfrac{e^{-\sqrt{2\omega}|x-y|}}{\sqrt{2\omega}} \end{bmatrix}, \quad R_3 = \frac{1}{24\pi} \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} |x-y|^2. \tag{2.12}$$

If the function $\boldsymbol{\psi}(x)$ solves the problem (2.3) for $z = \omega$, the components $\psi_1(x)$ and $\psi_2(x)$ satisfy the equations

$$\Delta\psi_1 = f\psi_1 + g\psi_2, \tag{2.13}$$

$$(\Delta - 2\omega)\psi_2 = g\psi_1 + f\psi_2. \tag{2.14}$$

Define

$$C_0 = \int_{\mathbb{R}^3} (f\psi_1 + g\psi_2)\mathrm{d}x. \tag{2.15}$$

The bounded linear operator $(I+R_0V)$ is defined in $L^2_{-s}, s>\frac{1}{2}$. When it has a kernel, then $|C_0|<\infty$ for the function $\boldsymbol{\psi}(x)$. The following two cases are different: (i) $C_0\neq 0$ and (ii) $C_0=0$. The first case is referred to as the resonance and the second case is referred to as the eigenvalue of the linearized NLS problem (2.3).

Since $(f\psi_1+g\psi_2)\in H^2_s, s>0$ and $f(x), g(x)$ decay exponentially, it follows from (2.14) that $\psi_2(x)$ decays exponentially too, such that $\psi_2\in H^2_s, s>0$. When $C_0\neq 0, \psi_1(x)$ decays algebraically as $1/|x|$, such that $\psi_1\in H_{-s}, s>\frac{1}{2}$. When $C_0=0, \psi_1(x)$ decays more rapidly as $1/|x|^2$, such that $\psi_1\in H_{-s}, s>-\frac{1}{2}$, including the energy space $H^1_0\subset L^2$. We summarize that

$$C_0 \neq 0, \quad \mathrm{Ker}(I+R_0V)\in H^1_{-s}, \quad s>\tfrac{1}{2}, \tag{2.16}$$

$$C_0 = 0, \quad \mathrm{Ker}(I+R_0V)\in H^1_{-s}, \quad s>\tfrac{1}{2}. \tag{2.17}$$

In either case, we study the kernel of the adjoint operator $\mathrm{Ker}(I+V^*R_0)$ and the generalized kernel $N_g(I+R_0V)=\cup_{n=1}^{\infty}\mathrm{Ker}(I+R_0V)^n$ in the following two lemmas.

Lemma 2.1: Let $\boldsymbol{\psi}\in\mathrm{Ker}(I+R_0V), \boldsymbol{\psi}\in H^1_{-s}, s>\frac{1}{2}$. *Then,* $\boldsymbol{\phi}=V^*\sigma_3\boldsymbol{\psi}\in\mathrm{Ker}(I+V^*R_0), \boldsymbol{\phi}\in H^{-1}_s, s>\frac{1}{2}$, *such that* $V^*\sigma_3$ *is an injection of* $\mathrm{Ker}(I+R_0V)$ *to* $\mathrm{Ker}(I+V^*R_0)$.

Proof: It follows from direct computations for $\boldsymbol{\psi}\neq\mathbf{0}$ that

$$(I+V^*R_0)V^*\sigma_3\boldsymbol{\psi} = V^*(I+R_0V^*)\sigma_3\boldsymbol{\psi} = V^*\sigma_3(I+R_0V)\boldsymbol{\psi} = \mathbf{0},$$

such that $\boldsymbol{\phi}=V^*\sigma_3\boldsymbol{\psi}\in\mathrm{Ker}(I+V^*R_0)$ and $\boldsymbol{\phi}\in H^{-1}_s, s>\frac{1}{2}$. We show that $\boldsymbol{\phi}\neq\mathbf{0}$. Since $V^*\sigma_3=\sigma_3V$, then $\boldsymbol{\phi}=\sigma_3V\boldsymbol{\psi}=\mathbf{0}$ implies that $V\boldsymbol{\psi}=\mathbf{0}$ and $(\mathcal{L}_0-\omega)\boldsymbol{\psi}=\mathbf{0}$, or equivalently, $\Delta\psi_1=0$ and $(\Delta-2\omega)\psi_2=0$. However, if $\boldsymbol{\psi}\in H^1_{-s}, s>\frac{1}{2}$, then the latter equations imply that $\boldsymbol{\psi}=\mathbf{0}$, which is impossible. ■

Lemma 2.2: The generalized kernel $N_g(I+R_0V)$ *in* $H^1_{-s}, s>\frac{1}{2}$, *coincides with* $\mathrm{Ker}(I+R_0V)$.

Proof: Let $\boldsymbol{\psi}\in\mathrm{Ker}(I+R_0V)$. The generalized kernel $N_g(I+R_0V)$ is bigger than the kernel $\mathrm{Ker}(I+R_0V)$ iff there exists a solution of the derivative equation,

$$(I+R_0V)\boldsymbol{\psi}_1 = \boldsymbol{\psi}, \quad \boldsymbol{\psi}_1\in H^1_{-s}, \quad s>\tfrac{1}{2}. \tag{2.18}$$

Then,

$$\langle\boldsymbol{\psi}, V^*\sigma_3\boldsymbol{\psi}\rangle = \langle(I+R_0V)\boldsymbol{\psi}_1, V^*\sigma_3\boldsymbol{\psi}\rangle = \langle\boldsymbol{\psi}_1, V^*(I+R_0V^*)\sigma_3\boldsymbol{\psi}\rangle = \langle\boldsymbol{\psi}_1, V^*\sigma_3(I+R_0V)\boldsymbol{\psi}\rangle = 0,$$

such that $\langle\boldsymbol{\psi}, \sigma_3V\boldsymbol{\psi}\rangle = -\langle\boldsymbol{\psi}, \sigma_3(\mathcal{L}_0-\omega)\boldsymbol{\psi}\rangle = 0$. Since $\sigma_3(\mathcal{L}_0-\omega) = -\Delta+\omega-\omega\sigma_3$ and $\boldsymbol{\psi}\neq\mathbf{0}$, the quadratic form $\langle\boldsymbol{\psi}, \sigma_3V\boldsymbol{\psi}\rangle$ is nonzero for $\boldsymbol{\psi}\in H^1_{-s}, s>\frac{1}{2}$, such that no solution $\boldsymbol{\psi}_1(x)$ exists in the problem (2.18). ■

Since geometric and algebraic dimensions of the kernel of $(I+R_0V)$ coincide in $H^1_{-s}, s>\frac{1}{2}$, we introduce a natural splitting,

$$H^1_{-s} = \mathrm{Ker}(I+R_0V)\oplus[\mathrm{Ker}(I+V^*R_0)]^{\perp}, \tag{2.19}$$

$$H^{-1}_s = [\mathrm{Ker}(I+R_0V)]^{\perp}\oplus\mathrm{Ker}(I+V^*R_0), \tag{2.20}$$

where $\perp$ is defined in terms of the pairing of H^1_{-s} and H^{-1}_s. We denote $\mathcal{S}_0$ as the projection of H^1_{-s} to $\mathrm{Ker}(I+R_0V)$, associated to the splitting (2.19), and $\mathcal{S}_0^*$ as the dual projection in the dual space

H_s^{-1}, associated to the splitting (2.20). In what follows, we assume that the dimension of $\mathrm{Ker}(I+R_0V)$ is one. The two cases in (2.16) and (2.17) are considered separately in Secs. III and IV.

III. BIFURCATION OF A SIMPLE RESONANCE

Here we assume that $\mathrm{Ker}(I+R_0V)\subsetneq H_0^1$, such that $z=\omega$ is a resonance of $\sigma_e(\mathcal{L})$ but not an eigenvalue. It is clear from (2.13) in the case of $C_0\neq 0$ that there is only one eigenvector $\boldsymbol{\psi}(x)$ which decays as $1/|x|$ and belongs to $H^1_{-s}, s>\frac{1}{2}$. Therefore, the resonance at $z=\omega$ is always simple, such that the dimension of $\mathrm{Ker}(I+R_0V)$ in $H^1_{-s}, s>\frac{1}{2}$ is one. Since $C_0\neq 0$, we normalize the eigenvector $\boldsymbol{\psi}\in\mathrm{Ker}(I+R_0V)$ by the condition

$$\int_{\mathbb{R}^3}(f\psi_1+g\psi_2)\mathrm{d}x=\sqrt{4\pi}, \tag{3.1}$$

such that

$$R_1V\boldsymbol{\psi}=\frac{1}{\sqrt{4\pi}}\mathbf{e}_1, \quad \mathbf{e}_1=\begin{bmatrix}1\\0\end{bmatrix}.$$

By Lemma 2.2, we have $\langle\boldsymbol{\psi},V^*\sigma_3\boldsymbol{\psi}\rangle\neq 0$, such that the spectral projection, associated with the splitting (2.19), is

$$\mathcal{S}_0=\boldsymbol{\psi}\frac{\langle\cdot,V^*\sigma_3\boldsymbol{\psi}\rangle}{\langle\boldsymbol{\psi},V^*\sigma_3\boldsymbol{\psi}\rangle}. \tag{3.2}$$

Following the analysis of Jensen and Kato (1979), we study the Taylor series expansions of $(I+R_0(\zeta)V)$ near $z=\omega$, or equivalently $\zeta=0$.

Lemma 3.1: Let $\mathcal{S}=\mathcal{I}-\mathcal{S}_0$. The following statements are true:

(i) *Operator $\mathcal{S}(I+R_0V)\mathcal{S}$ is invertible in $\mathcal{B}(\mathcal{S}H^1_{-s},\mathcal{S}H^1_{-s})$ with the inverse denoted by $\mathcal{K}$.*
(ii) *Operator $\mathcal{S}_0^*V^*\sigma_3R_1V\mathcal{S}_0=\mathcal{S}_0^*V^*R_1V\mathcal{S}_0$ is invertible in $\mathcal{B}(\mathcal{S}_0H^1_{-s},\mathcal{S}_0^*H_s^{-1})$ with the inverse $\boldsymbol{\psi}\langle\cdot,\boldsymbol{\psi}\rangle$.*

Proof: To prove (i), we notice that the splitting in (2.19) and (2.20) is invariant for $(I+R_0V)$, such that $\mathcal{S}(I+R_0V)\mathcal{S}$ is the restriction of $(I+R_0V)$ on $[\mathrm{Ker}(I+V^*R_0)]^\perp$. Since it has an empty kernel and R_0V is compact, the statement (i) follows from the Fredholm alternative theorem.

To prove (ii), we denote the dual of $\boldsymbol{\psi}$ as $\boldsymbol{\phi}\in\mathcal{S}_0^*H_s^{-1}\subseteq\mathrm{Ker}(I+V^*R_0)$, such that $\langle\boldsymbol{\psi},\boldsymbol{\phi}\rangle=1$. Then $\mathcal{S}_0^*=\boldsymbol{\phi}\langle\cdot,\boldsymbol{\psi}\rangle$ and

$$\mathcal{S}_0^*V^*R_1V\mathcal{S}_0\boldsymbol{\psi}=\frac{1}{\sqrt{4\pi}}\mathcal{S}_0^*V^*\mathbf{e}_1=\frac{1}{\sqrt{4\pi}}\boldsymbol{\phi}\langle\mathbf{e}_1,V\boldsymbol{\psi}\rangle=\boldsymbol{\phi},$$

where the last equality is due to normalization (3.1). Therefore, $\mathcal{S}_0^*V^*R_1V\mathcal{S}_0=\boldsymbol{\phi}\langle\cdot,\boldsymbol{\phi}\rangle$, which has the inverse $\boldsymbol{\psi}\langle\cdot,\boldsymbol{\psi}\rangle$. ■

Lemma 3.2: The following expansion is valid in $\mathcal{B}(H^1_{-s},H^1_{-s})$ for $s>\frac{5}{2}$ near $\zeta=0$:

$$(I+R_0(\zeta)V)^{-1}=-\zeta^{-1}\boldsymbol{\psi}\langle\cdot,V^*\sigma_3\boldsymbol{\psi}\rangle+\mathcal{K}+\mathrm{O}(\zeta), \quad \mathrm{Re}\,\zeta>0. \tag{3.3}$$

Proof: Let

$$\mathcal{X}=\mathcal{S}H^1_{-s}\oplus\mathcal{S}_0H^1_{-s}=H^1_{-s}, \quad \mathcal{Y}=\mathcal{S}H^1_{-s}\oplus\mathcal{S}_0^*H_s^{-1}$$

and

$$\mathcal{B} = \begin{bmatrix} \mathcal{S} & 0 \\ 0 & \zeta^{-\frac{1}{2}}\mathcal{S}_0 \end{bmatrix}, \quad \mathcal{C} = \begin{bmatrix} \mathcal{S} & 0 \\ 0 & \zeta^{-\frac{1}{2}}\mathcal{S}_0^* V^* \sigma_3 \end{bmatrix}.$$

If $\mathcal{S}\mathbf{u}=\mathbf{0}$, then $\mathbf{u}\in\mathcal{S}_0 H^1_{-s}$ and $\mathcal{S}_0^* V^* \sigma_3$ is injective by Lemma 2.1 and definition of $\mathcal{S}_0^*$. As a result, $\mathcal{B}:\mathcal{X}\mapsto H^1_{-s}$ is an isomorphism, while $\mathcal{C}:H^1_{-s}\mapsto\mathcal{Y}$ is injective. Let $\mathcal{A}\equiv\mathcal{C}(I+R_0(\zeta)V)\mathcal{B}$. Then,

$$\mathcal{A} = \mathcal{C}(I+R_0V)\mathcal{B} - \zeta\mathcal{C}R_1V\mathcal{B} + \mathrm{O}(\zeta^2) = \begin{bmatrix} \mathcal{S}(I+R_0V)\mathcal{S} & 0 \\ 0 & -\mathcal{S}_0^* V^* \sigma_3 R_1 V \mathcal{S}_0 \end{bmatrix} + \mathrm{O}(\zeta).$$

If $\mathcal{A}$ is invertible, $\mathcal{B}$ is surjective, and $\mathcal{C}$ is injective, then, by Lemma 3.12 of Jensen and Kato (1979), we have

$$(I+R_0(\zeta)V)^{-1} = \mathcal{B}\mathcal{A}^{-1}\mathcal{C},$$

such that the expansion (3.3) holds by the Neumann expansion argument. ■

Using (2.7), (2.10), and (3.3), we have the following result.

Corollary 3.3: The following expansion is valid in $\mathcal{B}(H^{-1}_s, H^1_{-s})$ for $s>\frac{5}{2}$ near $\zeta=0$:

$$R(\zeta) = \zeta^{-1}\langle\cdot,\sigma_3\boldsymbol{\psi}\rangle\boldsymbol{\psi} + \mathrm{O}(1), \quad \mathrm{Re}\,\zeta>0. \tag{3.4}$$

In order to work in L^2 rather than in a weighted space $L^2_{-s}, s>\frac{1}{2}$, we use the Birman–Schwinger formulation of the spectral problem (2.3) for $V=B^*A$ [Cuccagna *et al.* (2005)];

$$(I+\mathcal{Q}_0(z))\boldsymbol{\Psi} = \mathbf{0}, \quad \mathcal{Q}_0(z) = A\mathcal{R}_0(z)B^*, \quad z\in\mathbb{C}\setminus\mathcal{D}_e, \tag{3.5}$$

where

$$\boldsymbol{\Psi} = -A\boldsymbol{\psi}, \quad \boldsymbol{\psi} = \mathcal{R}_0(z)B^*\boldsymbol{\Psi}. \tag{3.6}$$

It is clear from (2.9) that $Q_0(\zeta)\equiv\mathcal{Q}_0(\omega-\zeta^2)$, initially defined for $\mathrm{Re}\,\zeta>0$, admits an analytical extension in an open set around $\zeta=0$ with values in $\mathcal{B}(L^2,H^2)$, such that $Q_0=Q(0)$ is well defined. Moreover, for any positive integer n, the map $\boldsymbol{\psi}\mapsto -A\boldsymbol{\psi}$ is an isomorphism,

$$\mathrm{Ker}(I+R_0V)^n \subset L^2_{-s} \mapsto \mathrm{Ker}(I+Q_0)^n \subset L^2, \quad s>\tfrac{1}{2}, \tag{3.7}$$

such that the inverse map is $\boldsymbol{\Psi}\mapsto R_0B^*\boldsymbol{\Psi}$. By Lemma 2.2, there exists an $(I+Q_0)$-invariant splitting,

$$L^2 = \mathrm{Ker}(I+Q_0)\oplus[\mathrm{Ker}(I+Q_0^*)]^\perp. \tag{3.8}$$

We denote $\mathcal{P}_0$ by the projection of L^2 on $\mathrm{Ker}(I+Q_0)$ and $\mathcal{P}_0^*$ by the dual projection.

With the use of Corollary 3.3, we consider the family of operators $\mathcal{L}_1=\mathcal{L}+\epsilon V_1$, where the perturbation potential $V_1(x)$ satisfies the same assumption as the potential $V(x)$, while the unperturbed operator $\mathcal{L}$ has a simple resonance. Let $\mathcal{R}_1(z)=(\mathcal{L}_1-z)^{-1}$ and define $\mathcal{Q}(z)=A_1\mathcal{R}(z)B_1^*$ and $\mathcal{Q}_1(z)=A_1\mathcal{R}_1(z)B_1^*=(I+\epsilon\mathcal{Q}(z))^{-1}\mathcal{Q}(z)$, where $V_1=B_1^*A_1$. We can always factorize V_1 so that $A_1=A$. It follows from (2.7) with $A_1=A$ that

$$\mathcal{Q}(z) = (I+A\mathcal{R}_0(z)B_1^*)^{-1}A\mathcal{R}_0(z)B_1^* = (I+\mathcal{Q}_0(z))^{-1}A\mathcal{R}_0(z)B_1^*.$$

We again use parametrization (2.8) and denote $Q(\zeta)\equiv\mathcal{Q}(\omega-\zeta^2), \mathrm{Re}\,\zeta>0$. Since $(I+Q_0(\zeta))^{-1}$ can be extended meromorphically from $\mathrm{Re}\,\zeta>0$ to $\mathrm{Re}\,\zeta\leqslant 0$, then $Q(\zeta)$ is a meromorphic function of $\zeta\in\mathbb{C}$. Similarly, $Q_1(\zeta)$ is also a meromorphic function of $\zeta\in\mathbb{C}$.

The main results of this section are formulated in the following two propositions.

Proposition 3.4: Let ϵ be a small positive parameter. If $\langle\psi,V_1^*\sigma_3\psi\rangle<0$, then $\sigma_p(\mathcal{L}_1)$ includes a real eigenvalue $z(\epsilon), z(\epsilon)<\omega$, such that

$$z(\epsilon) = \omega - \epsilon^2\langle\boldsymbol{\psi},V_1^*\sigma_3\boldsymbol{\psi}\rangle^2 + \mathrm{o}(\epsilon^2). \tag{3.9}$$

If $\langle \psi, V_1^* \sigma_3 \psi \rangle > 0$, *then* $\sigma_p(\mathcal{L}_1)$ *does not include an eigenvalue in the neighborhood of* $z=\omega$. *In both cases, resonance at* $z=\omega$ *disappears at* $\epsilon \neq 0$.

Proof: It follows from Corollary 3.3 that

$$Q(\zeta) = \zeta^{-1} A\psi \langle \cdot, B_1 \sigma_3 \psi \rangle + Q_c(\zeta),$$

where $Q_c(\zeta)$ is bounded for small $|\zeta|$. Then for Re $\zeta > 0$, we have

$$Q_1(\zeta) = [I + \epsilon \zeta^{-1}(I + \epsilon Q_c(\zeta))^{-1} A\psi \langle \cdot, B_1 \sigma_3 \psi \rangle]^{-1} (I + \epsilon Q_c(\zeta))^{-1} Q(\zeta), \tag{3.10}$$

which can be extended meromorphically from Re $\zeta > 0$ to Re $\zeta \leqslant 0$. By Fredholm theorem, the first factor on the right-hand side of (3.10) has singularities at $\zeta = \zeta(\epsilon)$, where $\zeta(\epsilon)$ is the solution of the linear equation,

$$\zeta + \epsilon \langle \psi, V_1^* \sigma_3 \psi \rangle - \epsilon^2 \langle Q_c(0) A\psi, B_1 \sigma_3 \psi \rangle + \mathrm{O}(\epsilon^3) = 0. \tag{3.11}$$

By implicit function theorem, there is a unique solution $\zeta = \zeta(\epsilon)$ for small ϵ, such that

$$\zeta(\epsilon) = -\epsilon \langle \psi, V_1^* \sigma_3 \psi \rangle + 0(\epsilon^2). \tag{3.12}$$

The map $\zeta = \sqrt{\omega - z}$ transforms the domain $\mathcal{D} = \{z \in \mathbb{C} : z \notin [\omega, \infty)\}$ into the first sheet of the Riemann surface $\mathcal{D}_1 = \{\zeta \in \mathbb{C} : \mathrm{Re}\, \zeta > 0\}$, which is connected with the second sheet $\mathcal{D}_2 = \{\zeta \in \mathbb{C} : \mathrm{Re}\, \zeta < 0\}$. When the root of (3.11) belongs to $\mathcal{D}_1$, the corresponding point $z \in \mathcal{D}$ is the eigenvalue of $\mathcal{L}_1$, at least for small ϵ, since the singularities of $\mathcal{Q}_1(z) = A\mathcal{R}_1(z)B_1^*$ coincide with the singularities of $\mathcal{R}_1(z)$. When the root of (3.11) belongs to $\mathcal{D}_2$, the corresponding point z belongs to the compliment of the closure of $\mathcal{D}$ in the Riemann surface, which continues $\mathcal{D}$ across $z \in [\omega, \infty)$. As a result, it does not belong to the closure of $\mathcal{D}$, such that it is not an eigenvalue. ■

Proposition 3.5: If $\epsilon > 0$ *and* $\langle \psi, V_1^* \sigma_3 \psi \rangle < 0$, *the new eigenvalue* $z(\epsilon)$ *with the corresponding eigenvector* $\psi_\epsilon(x)$ *has the positive energy norm* (1.7), *such that*

$$\langle \psi_\epsilon, \mathcal{H} \psi_\epsilon \rangle > 0, \quad \forall\ \epsilon > 0. \tag{3.13}$$

Proof: Using (3.5), we look for a solution of the problem:

$$(I + AR_0(\zeta(\epsilon))(B^* + \epsilon B_1^*))(\Psi + \tilde{\Psi}_\epsilon) = 0,$$

where $\Psi = -A\psi$ and $\tilde{\Psi}_\epsilon \in [\mathrm{Ker}(I + Q_0^*)]^\perp$. Projecting the equation on $[\mathrm{Ker}(I + Q_0^*)]^\perp$ with operator $\mathcal{P}_0^*$, we have the problem,

$$F(\tilde{\Psi}_\epsilon, \epsilon) = \mathcal{P}_0^*(I + AR_0(\zeta(\epsilon))(B^* + \epsilon B_1^*))\tilde{\Psi}_\epsilon + \epsilon \mathcal{P}_0^* A R_0(\zeta(\epsilon)) B_1^* \Psi + \mathcal{P}_0^* A[R_0(\zeta(\epsilon)) - R_0] B^* \Psi = 0,$$

where $F(0,0) = 0$ and

$$\frac{\partial F}{\partial \tilde{\Psi}_\epsilon}(0,0) = \mathcal{P}_0^*(I + Q_0^*).$$

Since $\mathcal{P}_0^*(I + Q_0^*)$ is an isomorphism in $[\mathrm{Ker}(I + Q_0^*)]^\perp$, the function $\tilde{\Psi}_\epsilon$ is a smooth function of ϵ, by implicit function theorem. Therefore, we define

$$\psi_\epsilon = R_0(\zeta(\epsilon))(B^* + \epsilon B_1^*)(\Psi + \tilde{\Psi}_\epsilon).$$

Since $R_0(\zeta(\epsilon)) \in B(L_s^2, H_{-s}^2)$ and $(B^* + \epsilon B_1^*)(\Psi + \tilde{\Psi}_\epsilon) \in L_s^2, s > \frac{1}{2}$ are continuous in ϵ at $\epsilon = 0$, we conclude that

$$\lim_{\epsilon\to 0^+} \boldsymbol{\psi}_\epsilon(x) = \boldsymbol{\psi}(x), \quad \boldsymbol{\psi}_\epsilon \in L^2_{-s}, \quad s > \tfrac{1}{2}.$$

It follows from the system (2.13) and (2.14) in the case (2.16) that $\psi_1 \notin L^2(\mathbb{R})$ and $\psi_2 \in L^2(\mathbb{R})$. By Fatou lemma, we have the limit

$$\lim_{\epsilon\to 0} \langle \boldsymbol{\psi}_\epsilon, \mathcal{H}\boldsymbol{\psi}_\epsilon\rangle = \omega\|\psi_1\|^2_{L^2} - \omega\|\psi_2\|^2_{L^2} = +\infty.$$

By continuity, the inequality (3.13) holds for $\epsilon > 0$. ■

IV. BIFURCATION OF A SIMPLE EIGENVALUE

Here we assume that $\mathrm{Ker}(I+R_0V) \subseteq H^1_0$, such that $z=\omega$ is an eigenvalue of $\sigma_p(\mathcal{L})$. Let $\psi \in \mathrm{Ker}(\mathcal{L}-\omega) \subset L^2$ and we assume that $\dim \mathrm{Ker}(\mathcal{L}-\omega) = 1$. Let $\mathcal{P}_0$ be the spectral projection in L^2 onto $\mathrm{Ker}(\mathcal{L}-\omega)$, such that

$$\mathcal{P}_0 = \boldsymbol{\psi}\frac{\langle \cdot, \sigma_3\boldsymbol{\psi}\rangle}{\langle \boldsymbol{\psi}, \sigma_3\boldsymbol{\psi}\rangle}. \tag{4.1}$$

It is proved in Cuccagna *et al.* (2005), Sec. III that a simple eigenvalue has non zero energy (1.7) such that $\langle \boldsymbol{\psi}, \sigma_3\boldsymbol{\psi}\rangle \neq 0$. Since $C_0=0$ in (2.15), it is clear that $R_1V\boldsymbol{\psi}=\mathbf{0}$. Furthermore, we have the following result.

Lemma 4.1: Let $\mathbf{u},\mathbf{v}$ *be two functions in* $H^{-1}_s, s>\frac{5}{2}$, *such that* $R_1\mathbf{u}=R_1\mathbf{v}=0$ *and* $\langle \mathbf{e}_1,\mathbf{u}\rangle = \langle \mathbf{e}_1,\mathbf{v}\rangle = 0$, *where* $\mathbf{e}_1=(1,0)^T$. *Then,*

$$\langle R_2\mathbf{u},\mathbf{v}\rangle = -\langle R_0\mathbf{u}, R_0\mathbf{v}\rangle. \tag{4.2}$$

Proof: The proof is given with a direct computation

$$\langle R_2\mathbf{u},\mathbf{v}\rangle = \lim_{\zeta\to 0} \zeta^{-2}\langle [R_0(\zeta)-R_0]\mathbf{u},\mathbf{v}\rangle = \lim_{\zeta\to 0} \zeta^{-2}\left\langle \sigma_3 \begin{bmatrix} \frac{1}{p^2+\zeta^2} - \frac{1}{p^2} & 0 \\ 0 & \frac{1}{p^2+2\omega-\zeta^2} - \frac{1}{p^2+2\omega} \end{bmatrix} \hat{\mathbf{u}}, \hat{\mathbf{v}} \right\rangle$$

$$= -\left\langle \begin{bmatrix} \frac{1}{p^4} & 0 \\ 0 & \frac{1}{(p^2+2\omega)^2} \end{bmatrix} \hat{\mathbf{u}}, \hat{\mathbf{v}} \right\rangle = -\langle R_0\mathbf{u}, R_0\mathbf{v}\rangle,$$

where $\hat{\mathbf{u}}(p)$ is the Fourier transform of $\mathbf{u}(x)$, defined by (2.6). ■

We apply the splitting of $H^1_{-s}, s>-\frac{1}{2}$, defined by (2.19), with projection $\mathcal{S}_0$ to $\mathrm{Ker}(I+R_0V)$, such that $\mathcal{S}=\mathcal{I}-\mathcal{S}_0$.

Lemma 4.2: The following statements are true:

(i) $\mathcal{P}_0^*V^*R_2\sigma_3V\mathcal{P}_0 = -\mathcal{P}_0^*\sigma_3\mathcal{P}_0$ *and* $\mathcal{S}_0^*V^*\sigma_3R_2V\mathcal{S}_0 = -\mathcal{S}_0^*\sigma_3\mathcal{S}_0$.
(ii) *Operator* $\mathcal{S}_0^*\sigma_3\mathcal{S}_0$ *is invertible in* $\mathcal{B}(\mathcal{S}_0H^1_{-s}, \mathcal{S}_0^*H^{-1}_s)$, *with the inverse* $\mathcal{P}_0\sigma_3$.

Proof: To prove (i), we note that $\sigma_3V\mathcal{P}_0\mathbf{u}$ and $V\mathcal{P}_0\mathbf{v}$ for any $\mathbf{u},\mathbf{v} \in H^1_{-s}, s>-\frac{1}{2}$ satisfy assumptions of Lemma 4.1 and, therefore,

$$\langle R_2\sigma_3 V\mathcal{P}_0\mathbf{u}, V\mathcal{P}_0\mathbf{v}\rangle = -\langle R_0\sigma_3 V\mathcal{P}_0\mathbf{u}, R_0 V\mathcal{P}_0\mathbf{v}\rangle = -\langle \sigma_3\mathcal{P}_0\mathbf{u}, \mathcal{P}_0\mathbf{v}\rangle = -\langle \mathcal{P}_0^*\sigma_3\mathcal{P}_0\mathbf{u}, \mathbf{v}\rangle.$$

The second part of (i) follows from the relations $\mathcal{P}_0\mathcal{S}_0=\mathcal{S}_0$ and $\mathcal{S}_0^*\mathcal{P}_0^*=\mathcal{S}_0^*$.

To prove (ii), let $\boldsymbol{\phi}\in\mathcal{S}_0^*H_s^{-1}\subseteq\mathrm{Ker}(I+V^*R_0)$ be the dual of $\boldsymbol{\psi}$, such that $\langle\boldsymbol{\psi},\boldsymbol{\phi}\rangle=1$. Therefore,

$$\mathcal{S}_0=\boldsymbol{\psi}\langle\cdot,\boldsymbol{\phi}\rangle,\quad \mathcal{S}_0^*=\boldsymbol{\phi}\langle\cdot,\boldsymbol{\psi}\rangle,\quad \mathcal{S}_0^*\sigma_3\mathcal{S}_0=\boldsymbol{\phi}\langle\cdot,\boldsymbol{\phi}\rangle\langle\boldsymbol{\psi},\sigma_3\boldsymbol{\psi}\rangle,$$

such that

$$(\mathcal{S}_0^*\sigma_3\mathcal{S}_0)^{-1}=\boldsymbol{\psi}\frac{\langle\cdot,\boldsymbol{\psi}\rangle}{\langle\boldsymbol{\psi},\sigma_3\boldsymbol{\psi}\rangle}=\mathcal{P}_0\sigma_3.$$

■

Lemma 4.3: The following expansion is valid in $\mathcal{B}(H^1_{-s},H^1_{-s})$ for $s>\frac{5}{2}$ near $\zeta=0$:

$$(I+R_0(\zeta)V)^{-1}=-\zeta^{-2}\mathcal{P}_0V+\zeta^{-1}\mathcal{P}_0VR_3V\mathcal{P}_0V+\mathrm{O}(1),\quad \mathrm{Re}\,\zeta>0. \tag{4.3}$$

Proof: The proof is similar to that of Lemma 3.2. Let

$$\mathcal{X}=\mathcal{S}H^1_{-s}\oplus\mathcal{S}_0H^1_{-s}=H^1_{-s},\quad \mathcal{Y}=\mathcal{S}H^1_{-s}\oplus\mathcal{S}_0^*H_s^{-1}$$

and

$$\mathcal{B}=\begin{bmatrix}\mathcal{S} & 0\\ 0 & \zeta^{-1}\mathcal{S}_0\end{bmatrix},\quad \mathcal{C}=\begin{bmatrix}\mathcal{S} & 0\\ 0 & \zeta^{-1}\mathcal{S}_0^*V^*\sigma_3\end{bmatrix}.$$

If $\mathcal{S}\mathbf{u}=\mathbf{0}$, then $\mathbf{u}\in\mathrm{Ker}(I+R_0V)$ and $V^*\sigma_3$ is injective in $\mathrm{Ker}(I+V^*R_0)$ by Lemma 2.1. As a result, $\mathcal{B}:\mathcal{X}\mapsto\mathcal{X}$ is surjective, while $\mathcal{C}:\mathcal{X}\mapsto\mathcal{Y}$ is injective. Let $\mathcal{A}\equiv\mathcal{C}(I+R_0(\zeta)V)\mathcal{B}$. Using the Taylor series expansion (2.10), we have

$$\mathcal{A}=\mathcal{A}_0-\zeta\mathcal{A}_1+\mathrm{O}(\zeta^2),$$

where

$$\mathcal{A}_0=\begin{bmatrix}\mathcal{S}(I+R_0V)\mathcal{S} & 0\\ 0 & \mathcal{S}_0^*V^*\sigma_3R_2V\mathcal{S}_0\end{bmatrix},\quad \mathcal{A}_1=\begin{bmatrix}\mathcal{S}R_1V\mathcal{S} & 0\\ 0 & \mathcal{S}_0^*V^*\sigma_3R_3V\mathcal{S}_0\end{bmatrix}.$$

By Neumann expansions, we have $\mathcal{A}^{-1}=\mathcal{A}_0^{-1}+\zeta\mathcal{A}_0^{-1}\mathcal{A}_1\mathcal{A}_0^{-1}+\mathrm{O}(\zeta^2)$, such that

$$\mathcal{A}^{-1}=\begin{bmatrix}\mathcal{K}_0 & 0\\ 0 & -(\mathcal{S}_0^*\sigma_3\mathcal{S}_0)^{-1}\end{bmatrix}+\zeta\begin{bmatrix}\mathcal{K}_0\mathcal{S}R_1V\mathcal{S}\mathcal{K}_0 & 0\\ 0 & (\mathcal{S}_0^*\sigma_3\mathcal{S}_0)^{-1}\mathcal{S}_0^*V^*\sigma_3R_3V\mathcal{S}_0(\mathcal{S}_0^*\sigma_3\mathcal{S}_0)^{-1}\end{bmatrix}+\mathrm{O}(\zeta^2),$$

where $\mathcal{K}_0=(\mathcal{S}(I+R_0V)\mathcal{S})^{-1}$. Since $(I+R_0(\zeta)V)^{-1}=\mathcal{B}\mathcal{A}^{-1}\mathcal{C}$, the expansion (4.3) holds. ■

Using (2.7), (2.10), and (4.3), as well as $\mathcal{P}_0VR_0=-\mathcal{P}_0$ and $\mathcal{P}VR_1=0$, we have the following result.

Corollary 4.4: The following expansion is valid in $\mathcal{B}(H_s^{-1},H^1_{-s})$ for $s>\frac{5}{2}$ near $\zeta=0$:

$$R(\zeta)=\zeta^{-2}\mathcal{P}_0-\zeta^{-1}\mathcal{P}_0VR_3V\mathcal{P}_0+\mathrm{O}(1),\quad \mathrm{Re}\,\zeta>0. \tag{4.4}$$

Similar to Sec. III, we use Corollary 4.4 and consider the family of operators $\mathcal{L}_1=\mathcal{L}+\epsilon V_1(x)$, where the perturbation potential $V_1(x)$ satisfies the same assumption as the potential $V(x)$, while the unperturbed operator $\mathcal{L}$ has a simple eigenvalue. Let $\mathcal{R}_1(z)=(\mathcal{L}_1-z)^{-1}$ and define $\mathcal{Q}(z)=A\mathcal{R}(z)B_1^*$ and $\mathcal{Q}_1(z)=A\mathcal{R}_1(z)B_1^*=(I+\epsilon\mathcal{Q}(z))^{-1}\mathcal{Q}(z)$, where $V_1=B_1^*A$. As in Sec. III, functions $Q(\zeta)$ and $Q_1(\zeta)$ can be meromorphically extended from $\mathrm{Re}\,\zeta>0$ to $\mathrm{Re}\,\zeta\leqslant 0$. The main result of this section is formulated in the following proposition.

Proposition 4.5: Let ϵ be a small positive parameter and let $\langle R_3V\boldsymbol{\psi},V^*\sigma_3\boldsymbol{\psi}\rangle\neq 0$. Then,

(i) *eigenvalue at $z=\omega$ disappears as $\epsilon\neq 0$.*

(ii) *Let* $\langle \psi, \sigma_3 \psi \rangle < 0$. *Then* $\sigma_p(\mathcal{L}_1)$ *near* $z=\omega$ *includes one real eigenvalue* $z(\epsilon) < \omega$ *if* $\langle \psi, V_1^* \sigma_3 \psi \rangle > 0$ *and two complex eigenvalues* $z_{1,2}(\epsilon)$ *if* $\langle \psi, V_1^* \sigma_3 \psi \rangle < 0$. *Asymptotic approximations of the eigenvalues* $z(\epsilon)$ *and* $z_{1,2}(\epsilon)$ *are given by*

$$z(\epsilon) = \omega + \epsilon \frac{\langle \psi, V_1^* \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle} + \mathrm{O}(\epsilon^{3/2}) \tag{4.5}$$

and

$$\mathrm{Re}(z_{1,2}(\epsilon)) = \omega + \epsilon \frac{\langle \psi, V_1^* \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle} + \mathrm{O}(\epsilon^2), \tag{4.6}$$

$$\mathrm{Im}(z_{1,2}(\epsilon)) = \pm \epsilon^{3/2} \sqrt{\frac{\langle \psi, V_1^* \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle}} \frac{\langle R_3 V \psi, V^* \sigma_3 \psi \rangle \langle \psi, V_1^* \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle^2} + \mathrm{O}(\epsilon^2). \tag{4.7}$$

(iii) *Let* $\langle \psi, \sigma_3 \psi \rangle > 0$. *Then* $\sigma_p(\mathcal{L}_1)$ *near* $z=\omega$ *includes one real eigenvalue* $z(\epsilon) < \omega$, *given by* (4.5), *if* $\langle \psi, V_1^* \sigma_3 \psi \rangle < 0$ *and no eigenvalues if* $\langle \psi, V_1^* \sigma_3 \psi \rangle > 0$.

The proof of Proposition is based on the following elementary result.

Lemma 4.6: Consider a quadratic equation,

$$\zeta^2 - \epsilon \zeta F(\epsilon, \zeta) + \epsilon G(\epsilon, \zeta) = 0, \tag{4.8}$$

where $F(\epsilon, \zeta)$ *and* $G(\epsilon, \zeta)$ *are analytic in* ϵ *and* ζ *at the point* (0, 0), *such that* $G(0,0) \neq 0$ *and*

$$\left. \frac{\partial F(0,\zeta)}{\partial \zeta} \right|_{\zeta=0} = \left. \frac{\partial G(0,\zeta)}{\partial \zeta} \right|_{\zeta=0} = 0. \tag{4.9}$$

Then, for small ϵ, *the quadratic equation* (4.8) *has exactly two solutions* $\zeta_{1,2}(\epsilon)$, *such that* $|\zeta_j(\epsilon) - \zeta_{j0}(\epsilon)| = \mathrm{O}(\epsilon^{3/2})$, *where* $\zeta_{j0}(\epsilon), j=1, 2$, *are solutions of the quadratic equation*

$$\zeta^2 - \epsilon \zeta F(0,0) + \epsilon G(0,0) = 0. \tag{4.10}$$

Proof: Let $\mu = \epsilon^{1/2}$ and substitute $\zeta = \mu \xi$. Introducing another parameter λ, we rewrite the quadratic equation (4.8) in the form,

$$\xi^2 - \mu \xi F(\lambda \mu^2, \lambda \mu \xi) + G(\lambda \mu^2, \lambda \mu \xi) = 0. \tag{4.11}$$

The case $\lambda = 1$ gives (4.8), while the case $\lambda = 0$ gives (4.10). Since $G(0,0) \neq 0$ by assumption, there exist two analytical solutions of (4.11), by the implicit function theorem, which are defined for small $\mu > 0$ and $\lambda \in [0,1]$. Since

$$\xi(1,\mu) - \xi(0,\mu) = \int_0^1 \partial_\lambda \xi(\lambda, \mu) \mathrm{d}\lambda,$$

we apply implicit differentiation of (4.11) and find that

$$\begin{aligned} &[2\xi - \mu F(\lambda \mu^2, \lambda \mu \xi) - \lambda \mu^2 \xi \partial_2 F(\lambda \mu^2, \lambda \mu \xi) + \lambda \mu \partial_2 G(\lambda \mu^2, \lambda \mu \xi)] \partial_\lambda \xi - \mu^3 \xi \partial_1 F(\lambda \mu^2, \lambda \mu \xi) \\ &\quad - \mu^2 \xi^2 \partial_2 F(\lambda \mu^2, \lambda \mu \xi) + \mu^2 \partial_1 G(\lambda \mu^2, \lambda \mu \xi) + \mu \xi \partial_2 G(\lambda \mu^2, \lambda \mu \xi) = 0, \end{aligned}$$

where ∂_1 and ∂_2 are derivatives in the first and second arguments. Under constraints (4.9), we have $\partial_\lambda \xi = \mathrm{O}(\mu^2)$, such that $|\zeta(1,\mu) - \zeta(0,\mu)| = \mathrm{O}(\mu^3)$. ■

Proof of Proposition 4.5: It follows from Corollary 4.4 that

$$Q(\zeta) = \zeta^{-2} A \mathcal{P}_0 B_1^* - \zeta^{-1} A \mathcal{P}_0 V R_3 V \mathcal{P}_0 B_1^* + Q_c(\zeta), \tag{4.12}$$

where $Q_c(\zeta)$ is bounded for small ζ. As a result, for $\mathrm{Re}\, \zeta > 0$, we have

$$Q_1(\zeta) = [I + \epsilon(I + \epsilon Q_c(\zeta))^{-1}[\zeta^{-2}A\mathcal{P}_0B_1^* - \zeta^{-1}A\mathcal{P}_0VR_3V\mathcal{P}_0B_1^*]]^{-1}(I + \epsilon Q_c(\zeta))^{-1}Q(\zeta),$$

which can be extended meromorphically for Re $\zeta \leqslant 0$. Singularities of $Q_1(\zeta)$ near $\zeta = 0$ correspond to zeros of

$$\det\left[\zeta^2 + \epsilon(I + \epsilon Q_c(\zeta))^{-1}\left(A\psi\frac{\langle B_1^*\cdot, \sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle} - \zeta A\psi\frac{\langle R_3V\mathcal{P}_0B_1^*\cdot, V^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle}\right)\right].$$

The determinant equation can be written as the quadratic equation (4.8), where $F(\epsilon, \zeta)$ and $G(\epsilon, \zeta)$ are defined for Re $\zeta > 0$ as

$$F(\epsilon, \zeta) = \frac{\langle R_3V\psi, V^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle^2}\langle B_1^*(I + \epsilon Q_c(\zeta))^{-1}A\psi, \sigma_3\psi\rangle, \tag{4.13}$$

$$G(\epsilon, \zeta) = \frac{1}{\langle\psi, \sigma_3\psi\rangle}\langle B_1^*(I + \epsilon Q_c(\zeta))^{-1}A\psi, \sigma_3\psi\rangle, \tag{4.14}$$

and they can be analytically continued to Re $\zeta \leqslant 0$. It is clear from (4.13) and (4.14) that

$$F(0, \zeta) = \frac{\langle R_3V\psi, V^*\sigma_3\psi\rangle\langle\psi, V_1^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle^2}, \quad G(0, \zeta) = \frac{\langle\psi, V_1^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle},$$

such that the condition (4.9) is satisfied. By Lemma 4.6, there exist two solutions of (4.8) in the $O(\epsilon^{3/2})$-neighborhood of solutions of (4.10), when $\langle\psi, V_1^*\sigma_3\psi\rangle \neq 0$. Solutions of (4.10) are expanded as

$$\zeta_{\pm 0}(\epsilon) = \pm\epsilon^{1/2}\sqrt{-\frac{\langle\psi, V_1^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle}} + \frac{\epsilon}{2}\frac{\langle R_3V\psi, V^*\sigma_3\psi\rangle\langle\psi, V^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle^2} + O(\epsilon^{3/2}). \tag{4.15}$$

When $\langle\psi, V_1^*\sigma_3\psi\rangle/\langle\psi, \sigma_3\psi\rangle < 0$, there is a unique real eigenvalue of operator $\mathcal{L}_1$ in the neighborhood of $z = \omega$, such that $z = \omega - \zeta_{+0}^2 + O(\epsilon^{3/2})$, which results in (4.5). The other solution $\zeta_{-0}(\epsilon)$ corresponds to Re $\zeta < 0$ and, by arguments in the proof of Proposition 3.4, it does not correspond to an eigenvalue of operator $\mathcal{L}_1$.

When $\langle\psi, V_1^*\sigma_3\psi\rangle/\langle\psi, \sigma_3\psi\rangle > 0$, we have to consider the $O(\epsilon)$ term of the asymptotic expansion (4.15). Due to the constraint $C_0 = 0$ in (2.15), we have

$$\langle R_3V\psi, V^*\sigma_3\psi\rangle = -\frac{1}{12\pi}\sum_{j=1}^{3}|(x_j, f\psi_1 + g\psi_2)|^2 \leqslant 0. \tag{4.16}$$

Since $\langle R_3V\psi, V^*\sigma_3\psi\rangle \neq 0$, then $\langle R_3V\psi, V^*\sigma_3\psi\rangle < 0$. Therefore, it follows from (4.15) that

$$\text{Im } \zeta_{\pm 0}(\epsilon) = \pm\epsilon^{1/2}\sqrt{\frac{\langle\psi, V_1^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle}} + O(\epsilon^{3/2}),$$

$$\text{Re } \zeta_{\pm 0}(\epsilon) = \frac{\epsilon}{2}\frac{\langle R_3V\psi, V^*\sigma_3\psi\rangle\langle\psi, V_1^*\sigma_3\psi\rangle}{\langle\psi, \sigma_3\psi\rangle^2} + O(\epsilon^{3/2}).$$

In the case $\langle\psi, \sigma_3\psi\rangle > 0$ and $\langle\psi, \mathbf{V}_1^*\sigma_3\psi\rangle > 0$, we have Re $\zeta_{\pm 0} < 0$, such that no eigenvalues of $\mathcal{L}_1$ exist in the neighborhood of $z = \omega$. In the case $\langle\psi, \sigma_3\psi\rangle < 0$ and $\langle\psi, V_1^*\sigma_3\psi\rangle < 0$, we have Re $\zeta_{\pm 0} > 0$, such that two complex eigenvalues of $\mathcal{L}_1$ exist in the neighborhood of $z = \omega$, with the asymptotic approximations (4.6) and (4.7). ■

A more special result occurs in the case when $\langle R_3V\psi, V^*\sigma_3\psi\rangle = 0$, which includes spherically

symmetric potential $V(x)$ with spherically symmetric eigenvector $\boldsymbol{\psi}(x)$, see (4.16). In order to study this special case, we need to extend the theory of wave operators from Kato (1966) and Cuccagna *et al.* (2005). Following Cuccagna *et al.* (2005), we consider a decomposition of L^2 into the $\mathcal{L}$-invariant Jordan blocks:

$$L^2 = \sum_{z \in \sigma_p(\mathcal{L})} N_g(\mathcal{L} - z) \oplus X_c(\mathcal{L}), \quad X_c(\mathcal{L}) = \left[\sum_{z \in \sigma_p(\mathcal{L})} N_g(\mathcal{L}^* - z) \right]^{\perp}, \tag{4.17}$$

and, equivalently,

$$L^2 = \sum_{z \in \sigma_p(\mathcal{L})} N_g(\mathcal{L}^* - z) \oplus X_c(\mathcal{L}^*), \quad X_c(\mathcal{L}^*) = \left[\sum_{z \in \sigma_p(\mathcal{L})} N_g(\mathcal{L} - z) \right]^{\perp}, \tag{4.18}$$

where $\sigma_p(\mathcal{L}) = \sigma_p(\mathcal{L}^*)$ and $N_g(\mathcal{L} - z) = \cup_{n=1}^{+\infty} \mathrm{Ker}(\mathcal{L} - z)^n$. The invariant splittings (4.17) and (4.18) hold in the assumption that $\sigma_p(\mathcal{L}) \cap \sigma_e(\mathcal{L})$ is a union of simple eigenvalues, such that $N_g(\mathcal{L} - z) = \mathrm{Ker}(\mathcal{L} - z)$ for $z \in \mathcal{D}_e$. The action of $\mathcal{L}$ in $X_c(\mathcal{L})$ is given by the scattering theory of wave operators Kato (1966), which is based on the following existence result.

Lemma 4.7: Let $A(x)$ and $B(x)$ be exponentially decaying potentials and $\sigma_p(\mathcal{L}) \cap \sigma_e(\mathcal{L})$ be a union of simple eigenvalues, which includes the endpoints $z = \pm\omega$ without resonance. Let $\langle R_3 V \boldsymbol{\psi}, V^* \sigma_3 \boldsymbol{\psi} \rangle = 0$. There exist isomorphisms $W: L^2 \mapsto X_c(\mathcal{L})$ and $Z: X_c(\mathcal{L}) \mapsto L^2$, which are inverse of each other, defined as follows:

$$\forall u \in L^2, \forall v \in X_c(\mathcal{L}^*), \langle Wu, v \rangle = \langle u, v \rangle + \lim_{\epsilon \to 0^+} \frac{1}{2\pi i} \int_{-\infty}^{+\infty} \langle A(\mathcal{L}_0 - \lambda - i\epsilon)^{-1} u, B(\mathcal{L}^* - \lambda + i\epsilon)^{-1} v \rangle \mathrm{d}\lambda, \tag{4.19}$$

and

$$\forall u \in X_c(\mathcal{L}), \forall v \in L^2, \langle Zu, v \rangle = \langle u, v \rangle + \lim_{\epsilon \to 0^+} \frac{1}{2\pi i} \int_{-\infty}^{+\infty} \langle A(\mathcal{L} - \lambda - i\epsilon)^{-1} u, B(\mathcal{L}_0 - \lambda + i\epsilon)^{-1} v \rangle \mathrm{d}\lambda. \tag{4.20}$$

We prove this result in Sec. V. Using Lemma 4.7, we consider bifurcation of the simple eigenvalue in the special case when $\langle R_3 V \boldsymbol{\psi}, V^* \sigma_3 \boldsymbol{\psi} \rangle = 0$.

Proposition 4.8: Let ϵ be a small positive parameter and $\langle R_3 V \boldsymbol{\psi}, V^* \sigma_3 \boldsymbol{\psi} \rangle = 0$. Then, Proposition 4.5 holds, but the asymptotic expansion (4.7) *is modified as follows*:

$$\mathrm{Im}(z_{1,2}(\epsilon)) = \pm \epsilon^{5/2} \frac{2\pi^2 |\hat{\psi}_1(0)|^2}{\langle \boldsymbol{\psi}, \sigma_3 \boldsymbol{\psi} \rangle} \sqrt{\frac{\langle \boldsymbol{\psi}, V_1^* \sigma_3 \boldsymbol{\psi} \rangle}{\langle \boldsymbol{\psi}, \sigma_3 \boldsymbol{\psi} \rangle}} + \mathrm{O}(\epsilon^3), \tag{4.21}$$

where $\tilde{\boldsymbol{\psi}} = Z \mathcal{P}_c V_1 \boldsymbol{\psi}$ and $\hat{\boldsymbol{\psi}}(p)$ is the Fourier transform of $\tilde{\boldsymbol{\psi}}(x)$.

Proof: We use the splittings (4.17) and (4.18) and define operator $\mathcal{P}_c$ as the projection of L^2 on $X_c(\mathcal{L})$. It is clear from (4.12) that

$$Q_c(\zeta) = A(\mathcal{I} - \mathcal{P}_0) R(\zeta) B_1^* = \sum_{z \in \sigma_p(\mathcal{L}) \setminus \{\omega\}} A \mathcal{P}_z R(\zeta) B_1^* + A P_c \mathcal{R}(\zeta) B_1^*.$$

In the special case $\langle R_3 V \boldsymbol{\psi}, V^* \sigma_3 \boldsymbol{\psi} \rangle = 0$, the quadratic equation (4.8) has $F(\epsilon, \zeta) = 0$ and

$$G(\epsilon, \zeta) = G(0, \zeta) + \epsilon \partial_1 G(0, \zeta) + \mathrm{O}(\epsilon^2),$$

where

$$G(0,\zeta) = \frac{\langle \psi, V_1^* \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle},$$

and

$$\partial_1 G(0,\zeta) = -\frac{\langle B_1^* Q_c(\zeta) A\psi, \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle} = -\frac{\langle (\mathcal{I} - \mathcal{P}_0) R(\zeta) V_1 \psi, V_1^* \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle}.$$

The term $\partial_1 G(0,\zeta)$ consists of the contribution from all eigenvalues of $\sigma_p(\mathcal{L})$ different from $z = \omega$ and from the contribution from $X_c(\mathcal{L})$. The first contribution can be estimated as follows:

$$\mathrm{Im} \sum_{z \in \sigma_p(\mathcal{L}) \setminus \{\omega\}} \langle \mathcal{P}_z R(\zeta) V_1 \psi, V_1^* \sigma_3 \psi \rangle = \mathrm{O}(\zeta^2).$$

This estimate is based on the expansion for real-valued $V_1(x)$ and $\psi(x)$ [see Cuccagna *et al.* (2005)],

$$\sum_{z \in \sigma_p(\mathcal{L}) \setminus \{\omega\}} \langle \mathcal{P}_z \mathcal{R}(z) V_1 \psi, V_1^* \sigma_3 \psi \rangle = \sum_{z_j \in \mathbb{R}} (z - z_j)^{-1} \langle P_{z_j} V_1 \psi, V^* \sigma_3 \psi \rangle + \sum_{z_j \in \mathbb{C}} [(z - z_j)^{-1} \langle P_{z_j} V_1 \psi, V^* \sigma_3 \psi \rangle + (z - \overline{z_j})^{-1} \langle P_{\overline{z_j}} V_1 \psi, V^* \sigma_3 \psi \rangle]. \tag{4.22}$$

Since $\mathcal{P}_{z_j} \sigma_3$ is self-adjoint for $z_j \in \mathbb{R}$, the factor $\langle P_{z_j} V_1 \psi, V^* \sigma_3 \psi \rangle$ is real. Then, the first term in (4.22) has the imaginary part of order $\mathrm{O}(\mathrm{Im}\, z)$ or $\mathrm{O}(\zeta^2)$ for $z = \omega - \zeta^2$. Similarly, the operator $(\mathrm{Re}\, z - z_j)^{-1} \mathcal{P}_{z_j} \sigma_3 + (\mathrm{Re}\, z - \overline{z_j})^{-1} \mathcal{P}_{\overline{z_j}} \sigma_3$ is self-adjoint for $z_j \in \mathbb{C}$, such that the second term in (4.22) has the imaginary part of order $\mathrm{O}(\mathrm{Im}\, z)$ or $\mathrm{O}(\zeta^2)$. The second contribution in $\partial_1 G(0,\zeta)$ can be estimated by using wave operators, which satisfy the following identities [Cuccagna *et al.* (2005)]:

$$P_c^* \sigma_3 = \sigma_3 P_c, \quad W^* \sigma_3 = \sigma_3 Z, \quad Z^* \sigma_3 = \sigma_3 W, \quad Z\mathcal{L} = \mathcal{L}_0 Z. \tag{4.23}$$

Since $\mathcal{P}_c V_1 \psi \in X_c(\mathcal{L})$, there exists $\tilde{\psi} \in L^2$, such that $\mathcal{P}_c V_1 \psi = W \tilde{\psi}$. As a result, we have

$$\langle \mathcal{P}_c R(\zeta) V_1 \psi, V_1^* \sigma_3 \psi \rangle = \langle R(\zeta) V_1 \psi, \sigma_3 W \tilde{\psi} \rangle = \langle Z R(\zeta) V_1 \psi, \sigma_3 \tilde{\psi} \rangle = \langle R_0(\zeta) \tilde{\psi}, \sigma_3 \tilde{\psi} \rangle.$$

Since $\langle R_0 \tilde{\psi}, \sigma_3 \tilde{\psi} \rangle$ and $\langle R_1 \tilde{\psi}, \sigma_3 \tilde{\psi} \rangle$ are real valued, we finally have

$$\mathrm{Im}\, \partial_1 G(0,\zeta) = \frac{\langle R_1 \tilde{\psi}, \sigma_3 \tilde{\psi} \rangle}{\langle \psi, \sigma_3 \psi \rangle} \mathrm{Im}\, \zeta + \mathrm{O}(\zeta^2). \tag{4.24}$$

The quadratic equation (4.8) is now read as follows

$$\zeta^2 + \epsilon G(\epsilon, \zeta) = 0. \tag{4.25}$$

In the case $G(0,0) > 0$, we have from Lemma 4.6 that

$$\mathrm{Im}\, \zeta_{1,2}(\epsilon) = \pm \epsilon^{1/2} \sqrt{\frac{\langle \psi, V_1^* \sigma_3 \psi \rangle}{\langle \psi, \sigma_3 \psi \rangle}} + \mathrm{O}(\epsilon^{3/2}),$$

in addition, by expansion (4.24), we have from (4.25) that $2\, \mathrm{Re}\, \zeta\, \mathrm{Im}\, \zeta = -\epsilon^2\, \mathrm{Im}\, \zeta \partial_1 \partial_2 G(0,0) + \mathrm{O}(\epsilon^3, \epsilon^2 \zeta^2)$, such that

$$\mathrm{Re}\, \zeta_{1,2}(\epsilon) = -\frac{\epsilon^2}{2} \frac{\langle R_1 \tilde{\psi}, \sigma_3 \tilde{\psi} \rangle}{\langle \psi, \sigma_3 \psi \rangle} + \mathrm{O}(\epsilon^{5/2}).$$

Direct computations from (2.11) show that

$$\langle R_1\tilde{\boldsymbol{\psi}}, \sigma_3\tilde{\boldsymbol{\psi}}\rangle = \frac{1}{4\pi}\left(\int_{\mathbb{R}^3}\tilde{\psi}_1\,dx\right)\left(\int_{\mathbb{R}^3}\tilde{\psi}_1^*\,dx\right) = 2\pi^2|\hat{\psi}_1(0)|^2 \geqslant 0,$$

where $\hat{\psi}_1(p)$ is the Fourier transform of $\psi_1(x)$, defined by (2.6). Again, we have $\mathrm{Re}\,\zeta_{1,2}(\epsilon) > 0$ in the case $\langle \boldsymbol{\psi}, \sigma_3\boldsymbol{\psi}\rangle < 0$ and $\hat{\psi}_1(0) \neq 0$, such that two complex eigenvalues of $\mathcal{L}_1$ exist in the neighborhood of $z = \omega$, with the asymptotic approximations (4.6) and (4.21). ■

V. PROOF OF LEMMA 4.7

According to Kato (1966), Lemma 4.7 is valid if we can prove that there exists $c > 0$ such that $\forall \epsilon \neq 0$, the following bounds are true:

$$\int_{-\infty}^{\infty} \|A(\mathcal{L}_0 - i\epsilon - \lambda)^{-1}\mathbf{u}\|^2\,d\lambda \leqslant c\|\mathbf{u}\|^2, \quad \mathbf{u} \in L^2, \tag{5.1}$$

$$\int_{-\infty}^{\infty} \|B(\mathcal{L}_0 - i\epsilon - \lambda)^{-1}\mathbf{u}\|^2\,d\lambda \leqslant c\|\mathbf{u}\|^2, \quad \mathbf{u} \in L^2, \tag{5.2}$$

$$\int_{-\infty}^{\infty} \|B(\mathcal{L}^* - i\epsilon - \lambda)^{-1}\mathbf{u}\|^2\,d\lambda \leqslant c\|\mathbf{u}\|^2, \quad \forall\, \mathbf{u} \in X_c(\mathcal{L}^*), \tag{5.3}$$

$$\int_{-\infty}^{\infty} \|A(\mathcal{L} - i\epsilon - \lambda)^{-1}\mathbf{u}\|^2\,d\lambda \leqslant c\|\mathbf{u}\|^2, \quad \forall\, \mathbf{u} \in X_c(\mathcal{L}). \tag{5.4}$$

The bounds (5.1) and (5.2) are proved in Corollary to Theorem XIII.25 in Reed and Simon (1978). We prove the bound (5.4), while the bound (5.3) can be proved similarly. Following Cuccagna *et al.* (2005), we write

$$A(\mathcal{L} - z)^{-1}\mathbf{v} = (I + \mathcal{Q}_0^+(z))^{-1}A(\mathcal{L}_0 - z)^{-1}\mathbf{v}, \quad \mathbf{v} \in X_c(\mathcal{L}), \tag{5.5}$$

where $\mathcal{Q}_0^+(z)$ is continuation of $Q_0(z)$ from $\mathrm{Im}\,z > 0$ to $\mathrm{Im}\,z \geqslant 0$. The operator $(I + \mathcal{Q}_0^+(z))^{-1}$ is uniformly bounded in z away from the eigenvalues of $\sigma_p(\mathcal{L})$. It has pole singularities at the eigenvalues of $\sigma_p(\mathcal{L})$, which were considered in Cuccagna *et al.* (2005), Lemma 4.3. The endpoint eigenvalues $z = \pm\omega$ were excluded from Cuccagna *et al.* (2005). Here we shall consider the eigenvalue $z = \omega$. We need to show that $A(\mathcal{L} - z)^{-1}\mathbf{v}$ has L^2-norm which is uniformly bounded in $\epsilon > 0$, for $\mathrm{Im}\,z = \epsilon$ and $\mathrm{Re}\,z \approx \omega$. Near $z = \omega$, we have the following expansion in the space of operators $L^2 \to L^2$:

$$(I + \mathcal{Q}_0^+(z))^{-1} = \frac{1}{\omega - z}A\mathcal{P}_0B^* + \mathrm{O}(1).$$

Due to the bounds (5.1) and (5.2), we only need to study $(\omega - z)^{-1}A\mathcal{P}_0V\mathcal{R}_0(z)\mathbf{v}$, for $\mathbf{v} \in X_c(\mathcal{L})$ near $z = \omega$. We use the relation

$$\langle VR_0\mathbf{v}, \sigma_3\boldsymbol{\psi}\rangle = -\langle \mathbf{v}, \sigma_3\boldsymbol{\psi}\rangle = 0, \quad \forall\, \mathbf{v} \in X_c(\mathcal{L}).$$

As a result,

$$\frac{1}{\omega - z}\mathcal{P}_0V\mathcal{R}_0(z)\mathbf{v} = \frac{\boldsymbol{\psi}}{\omega - z}\frac{\langle V\mathcal{R}_0(z)\mathbf{v}, \sigma_3\boldsymbol{\psi}\rangle}{\langle \boldsymbol{\psi}, \sigma_3\boldsymbol{\psi}\rangle} = \frac{\boldsymbol{\psi}}{\omega - z}\frac{\langle V|\mathcal{R}_0(z) - R_0|\mathbf{v}, \sigma_3\boldsymbol{\psi}\rangle}{\langle \boldsymbol{\psi}, \sigma_3\boldsymbol{\psi}\rangle} = -\boldsymbol{\psi}\frac{\langle VR_0\mathcal{R}_0(z)\mathbf{v}, \sigma_3\boldsymbol{\psi}\rangle}{\langle \boldsymbol{\psi}, \sigma_3\boldsymbol{\psi}\rangle}$$

$$= \boldsymbol{\psi}\frac{\langle \mathcal{R}_0(z)\mathbf{v}, \sigma_3\boldsymbol{\psi}\rangle}{\langle \boldsymbol{\psi}, \sigma_3\boldsymbol{\psi}\rangle}.$$

We need to show that $\langle \mathcal{R}_0(z)\mathbf{v}, \sigma_3 \boldsymbol{\psi} \rangle$ is in Hardy space H^2 for $\mathrm{Im}\, z > 0$, which is true if $\boldsymbol{\psi}(x)$ belong to the space of Rollnick potentials,

$$\int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|\boldsymbol{\psi}(x)||\boldsymbol{\psi}(x)|}{|x-y|^2} \mathrm{d}x\mathrm{d}y < \infty. \tag{5.6}$$

It is clear from (2.14) that $\psi_2(x)$ decays exponentially as $|x| \to \infty$. Since $C_0 = 0$ in (2.15) and $(x_j, f\psi_1 + g\psi_2) = 0, j = 1, 2, 3$ in (4.16), it follows from (2.13) that $\psi_1(x)$ decays algebraically as $|x|^{-3}$. As a result, the eigenvector $\boldsymbol{\psi}(x)$ satisfies the condition (5.6).

[DOI: 10.1063/1.1884887]

We have identified three minor errors in our paper, none of which affects the overall logical structure.

First, the differential equation for $\nu(s,R)$ in Theorem 2 contains a sign error. The correct equation is

$$\frac{d\nu(s,R)}{ds} = \frac{1}{2}\left[\frac{\partial^2 \nu}{\partial R^2} + (d-1)\frac{\cosh R}{\sinh R}\frac{\partial \nu}{\partial R}\right].$$

The above equation is the one used in the proof of Theorem 2; compare Lemma 4.

Second, on page 1227, in the proof of Theorem 2, we assert that the operators J_{a}^2 and $J_{\overline{\mathrm{a}}}^2$ are self-adjoint. This is not correct. However, $J_{\mathrm{a}}^2 + J_{\overline{\mathrm{a}}}^2$ *is* self-adjoint, and this is all that is needed in the proof.

Third, in Sec. IX, we assert that the action of the little group is trivial if and only if Eq. (57) holds. This assertion is not correct in the case $d=1$. What we actually prove is that (for all $d \geqslant 1$) the action of the Lie algebra of the little group is trivial if and only if Eq. (57) holds. When $d \geqslant 2$, the little group is connected and so the triviality of the action of the Lie algebra implies the triviality of the action of the little group itself. When $d=1$, however, the little group is disconnected and its action may be nontrivial even when the action of the Lie algebra is trivial.

In the case $d=1$, our results hold under the stronger assumption that the action of the little group is trivial. This assumption implies (but is not implied by) Eq. (57).

We thank Boonyong Sriponpaew for pointing out the first error and Wicharn Lewkeeratiyutkul and Areerak Kaewthep for pointing out the second error.

Scattering kernel for polyatomic molecules

J. Gilbert Méolans[a] and S. Kokou Dadzie[b]
Université de Provence, UMR CNRS 6595, Département de Mécanique Energétique, 5 rue Enrico Fermi 13453, Marseille Cedex 13, France

(Received 8 July 2004; accepted 11 March 2005; published online 12 May 2005)

A polyatomic scattering kernel phenomenologically presented in a previous paper is derived from an integral operator formulation. The five parameters involved in the scattering kernel expression are shown to be equal to the accommodation coefficients of various fluxes at the wall, namely, the fluxes of the three components of the momentum and the fluxes of the rotational and vibrational energies of molecules. Under its present form the model is especially convenient for the diatomic molecules. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904703]

I. INTRODUCTION

During the last 20 years a need of new knowledge appeared concerning the interaction of gases with solid surfaces in order to formulate realistic boundary conditions in rarefied gas dynamics.[1–4] In spatial research the challenge was especially to predict correct heat fluxes and drag forces on engines reentering in planetary atmospheres. With the recent developments of the gaseous microflows, where the flow fields are characterized by moderately high Knudsen numbers, this topic acquired still more interest. This paper is devoted to the derivation of realistic laws linking the distribution functions of the reflected and the incoming particles at the wall. As it is well known such laws may be used as boundary conditions in order to resolve the Boltzmann equation. Moreover, in the slip regime, these laws also allow us to obtain more accurate velocity slip and temperature jumps at the wall, so the validity domain of the continuum equations is extended up to higher Knudsen numbers when these equations are associated to the correct boundary conditions.

In a previous paper[5] we developed a model of a scattering kernel for unstructured molecules using an integral operator formulation as illustrated by Cercignani.[6,7] At the end of this previous work the proposed scattering kernel was extended to the case of molecules with internal structure on the basis of brief phenomenological arguments. In the present paper, the integral operator formulation is generalized to a polyatomic gas, then the polyatomic scattering kernel is methodologically derived from the study of an eigenvalue equation and the meaning of the five parameters introduced in the kernel is clarified.

In Sec. II we deduced the polyatomic scattering kernel, investigating the associated integral operator. In its fully developed form the scattering kernel appears as a linear combination of 32 partial kernels declining all the possible associations of, respectively, diffusive and specular processes (according to three directions) and elastic or inelastic processes (for the internal modes). The 32 coefficients of this combination are the weight of the various accommodation processes and they depend on five basic parameters. These five parameters are shown to be, respectively, equal to the accommodation coefficients of the momentum components and of the internal energies. In Sec. III, we present a general comment on this method of integral operator in the framework of scattering kernel derivation.

II. POLYATOMIC SCATTERING KERNEL DERIVATION

We consider the problem of finding the scattering kernel,

$$B(V',E_{ir'},E_{iv'},g_{ir'},V,E_{ir},E_{iv},g_{ir}),$$

governing the reflection of polyatomic molecules at the wall. V' is the velocity of the impinging gas particle referred to the wall, $V'=(V'_x,V'_y,V'_z)\in\{\Omega'=\Omega'_x\times\Omega'_y\times\Omega'_z=\mathbb{R}_-\times\mathbb{R}\times\mathbb{R}\}$ and V the velocity of the reflected one referred to the wall, $V=(V_x,V_y,V_z)\in\{\Omega=\Omega_x\times\Omega_y\times\Omega_z=\mathbb{R}_+\times\mathbb{R}\times\mathbb{R}\}$. These velocities reduce to the peculiar velocities when the slip velocity at the wall is neglected. V_R is defined as $V_R=(-V_x,V_y,V_z)$, and (x,y,z) are the three spatial coordinates with x the normal axis to the wall oriented from the wall towards the gas. $E_{ir'}$ and $E_{iv'}$ are, respectively, the rotational energy and the vibrational energy of an incident particle at the wall. Similarly E_{ir} and E_{iv} are, respectively, the rotational energy and the vibrational energy of a reflected particle at the wall. Then the subscripts ir and iv are the quantum numbers related to the internal energy of a particle, hence they are integers; g_{ir} is the weight of the rotational degeneracy and will be taken here equal to $(2ir+1)$. The kernel B, which is the density of probability that a molecule in a state $(V',E_{ir'},E_{iv'})$ hitting the wall at any point X of the wall is reflected at the same point in a state (V,E_{ir},E_{iv}), must satisfy the following conditions detailed in Ref. 5:[1–3] the non-negativity,

$$B(V',E_{ir'},E_{iv'},g_{ir'},V,E_{ir},E_{iv},g_{ir})\geqslant 0, \tag{1}$$

the normalization,

$$\sum_{ir,iv}\int_{\Omega}B(V',E_{ir'},E_{iv'},g_{ir'},V,E_{ir},E_{iv},g_{ir})d_V=1, \tag{2}$$

and the reciprocity relation,

$$\begin{aligned}&|V'_x|e^{-\|V'\|^2/C_w^2}e^{-\varepsilon_{ir'}}e^{-\varepsilon_{iv'}}g_{ir'}B(V',E_{ir'},E_{iv'},V,E_{ir},E_{iv})\\&\quad=V_xe^{-\|V\|^2/C_w^2}e^{-\varepsilon_{ir}}e^{-\varepsilon_{iv}}g_{ir}B(-V,E_{ir},E_{iv},-V',E_{ir'},E_{iv'}),\end{aligned} \tag{3}$$

where

$$\varepsilon_{ir}=\frac{E_{ir}}{kT_w},\quad \varepsilon_{iv}=\frac{E_{iv}}{kT_w} \tag{4}$$

with k the Boltzmann constant and T_w the wall temperature.

A. Analytical derivation from integral operator

Let us write the transformation

$$\begin{aligned}K(V,E_{ir},E_{iv},g_{ir},V',E_{ir'},E_{iv'},g_{ir'})&=[|V'_x|f_0(V',E_{ir'},E_{iv'})]^{1/2}[|V_x|f_0(V,E_{ir},E_{iv})]^{-1/2}\\&\quad\times B(V'_R,E_{ir'},E_{iv'},g_{ir'},V,E_{ir},E_{iv},g_{ir}),\end{aligned} \tag{5}$$

where $f_0(V,E_{ir},E_{iv})$ is the local equilibrium distribution function at the temperature T_w of the wall, defined by

$$f_0(V,E_{ir},E_{iv})=\frac{n}{(C_w\sqrt{\pi})^3}e^{-\|V\|^2/C_w^2}\frac{g_{ir}e^{-\varepsilon_{ir}}e^{-\varepsilon_{iv}}}{Q_rQ_v} \tag{6}$$

with

$$Q_r = \sum_{ir} g_{ir} e^{-\varepsilon_{ir}}, \quad Q_v = \sum_{iv} e^{-\varepsilon_{iv}}, \quad C_w^2 = \frac{2kT_w}{m}. \tag{7}$$

Since f_0 is a known function the problem of finding B is equivalent to finding K. The normalization condition and the non-negativity conditions on B imply obviously the same conditions on K.

Note F_r the set of the rotational energy states E_{ir}, and F_v the set of the vibrational energy states E_{iv}. Consider the five elementary Hilbert spaces of states $L^2(\Omega_\kappa)_{\kappa=x,y,z}$, $L^2(F_r)$, and $L^2(F_v)$ of square summable functions with their corresponding usual scalar product

$$\langle \varphi_{\kappa 1}, \varphi_{\kappa 2} \rangle_\kappa = \int_{\Omega_\kappa} \varphi_{\kappa 1}(V) \varphi_{\kappa 2}(V) d_V \quad \text{for all } \varphi_{\kappa 1}, \varphi_{\kappa 2} \in L^2(\Omega_\kappa), \quad \kappa = x,y,z,$$

$$\langle \varphi_{r1}, \varphi_{r2} \rangle_r = \sum_{ir} \varphi_{r1}(E_{ir}) \varphi_{r2}(E_{ir}) \quad \text{for all } \varphi_{r1}, \varphi_{r2} \in L^2(F_r),$$

$$\langle \varphi_{v1}, \varphi_{v2} \rangle_v = \sum_{iv} \varphi_{v1}(E_{iv}) \varphi_{v2}(E_{iv}) \quad \text{for all } \varphi_{v1}, \varphi_{v2} \in L^2(F_v).$$

Consider the tensor product $\mathcal{L} = L^2(\Omega_x) \otimes L^2(\Omega_y) \otimes L^2(\Omega_z) \otimes L^2(F_r) \otimes L^2(F_v)$ of the five Hilbert spaces of states. Let us remark that this tensor product of Hilbert space $\mathcal{L}$ is dense in the Hilbert space $\mathcal{H} = L^2(\Omega) \otimes L^2(F_r) \otimes L^2(F_v)$ where the scalar product is defined by

$$\langle \varphi_1, \varphi_2 \rangle = \sum_{ir,iv} \int_\Omega \varphi_1(V, E_{ir}, E_{iv}) \varphi_2(V, E_{ir}, E_{iv}) d_V \text{ for all } \varphi_1, \varphi_2 \in \mathcal{H}. \tag{8}$$

Instead of studying the problem of the kernel K, we study the linear integral associated operator A defined on $\mathcal{H}$ by

$$A(\psi) = \sum_{ir',iv'} \int_{\Omega'} K(V, E_{ir}, E_{iv}, g_{ir}, V', E_{ir'}, E_{iv'}, g_{ir'}) \psi(V', E_{ir'}, E_{iv'}, g_{ir'}) d_{V'}. \tag{9}$$

Assume that the operator A has a purely discrete spectrum, and assume that its eigenfunctions are all in the Hilbert space $\mathcal{L}$. The kernel K can be written in the form

$$\begin{aligned} K = \sum_{j_x,j_y,j_z,j_r,j_v=0}^{\infty} & \lambda_{j_x,j_y,j_z,j_r,j_v} \psi_{j_x}(V_x) \psi_{j_y}(V_y) \psi_{j_z}(V_z) \psi_{j_r}(E_{ir}) \psi_{j_v}(E_{iv}) \\ & \times \psi_{j_x}(V_x') \psi_{j_y}(V_y') \psi_{j_z}(V_z') \psi_{j_r}(E_{ir'}) \psi_{j_v}(E_{iv'}), \end{aligned} \tag{10}$$

where the functions $\psi_{j_x}(V_x) \psi_{j_y}(V_y) \psi_{j_z}(V_z) \psi_{j_r}(E_{ir}) \psi_{j_v}(E_{iv})$ are the eigenfunctions of A with their corresponding eigenvalues $\lambda_{j_x,j_y,j_z,j_r,j_v}$. According to the non-negativity and the normalization conditions, the eigenvalues must satisfy $\lambda_{j_x,j_y,j_z,j_r,j_v} \in [0,1]$ for all $j_x, j_y, j_z, j_r, j_v \in \mathbb{N}$. Moreover, one can see that, in the tensor product space $\mathcal{L}$, the scalar product (8) equals the scalar product defined in this tensor product space $\mathcal{L}$ by the product of the five elementary scalar products (8). So, we can suppose that the eigenvalues have the form $\lambda_{j_x} \lambda_{j_y} \lambda_{j_z} \lambda_{j_r} \lambda_{j_v}$ and that the set of functions $\psi_{j_\chi}(M_\chi), j_\chi \in \mathbb{N}$, is a function basis of the χ corresponding Hilbert space $\chi = x,y,z,r,v$. Therefore, the expression (10) can be written as a product of five infinite sums,

$$K = \prod_{\chi \in \{x,y,z,r,v\}} \sum_{j=0}^{\infty} \lambda_{j_\chi} \psi_{j_\chi}(M_\chi) \psi_{j_\chi}(M_\chi'), \quad M_\chi = V_x, V_y, V_z, E_{ir}, E_{iv}. \tag{11}$$

Define $\psi_0 = \psi_{0_x} \psi_{0_y} \psi_{0_z} \psi_{0_r} \psi_{0_v}$ by

$$\psi_{0_x}(V_x) = \frac{\sqrt{2}}{C_w}|V_x|^{1/2}e^{-V_x^2/2C_w^2}, \quad \psi_{0_y}(V_y) = (C_w\sqrt{\pi})^{-1/2}e^{-V_y^2/2C_w^2},$$

$$\psi_{0_z}(V_z) = (C_w\sqrt{\pi})^{-1/2}e^{-V_z^2/2C_w^2}, \quad \psi_{0_r}(E_{ir}) = \sqrt{\frac{g_{ir}}{Q_r}}e^{-1/2\epsilon_{ir}}, \quad \psi_{0_v}(E_{iv}) = \frac{e^{-1/2\epsilon_{iv}}}{\sqrt{Q_v}}.$$

Let us prove that ψ_0 is an eigenfunction of A. Mathematically, the normalization condition can be also written

$$\sum_{ir',iv'} \int_{\Omega'} B(-V,E_{ir},E_{iv},g_{ir},-V'_R,E_{ir'},E_{iv'},g_{ir'})d_{V'} = 1, \tag{12}$$

from this relation (12), the reciprocity relation (3) leads to

$$\sum_{ir',iv'} \int_{\Omega'} |V'_x|f_0(V',E_{ir'},E_{iv'})B(V'_R,E_{ir'},E_{iv'},g_{ir'},V,E_{ir},E_{iv},g_{ir})d_{V'} = |V_x|f_0(-V,E_{ir},E_{iv}). \tag{13}$$

Using the relation (13), the calculation of $A(\psi_0)$ gives $A(\psi_0)=\psi_0$. Consequently $\psi_0=\psi_{0_x}\psi_{0_y}\psi_{0_z}\psi_{0_r}\psi_{0_v}$ is an eigenfunction of the operator A associated to the eigenvalue 1.

Now, following the five state parameters, let us introduce five parameters related to the eigenvalues as follows: $\lambda_{0_\chi}=1$, and for $j\neq 0, \lambda_{j_\chi}=(1-\alpha_\chi)$ for all $\chi=x,y,z,r,v$. The relation (11) becomes

$$K = \prod_{\chi\in\{x,y,z,r,v\}} \left[\psi_{0_\chi}(M_\chi)\psi_{0_\chi}(M'_\chi) + (1-\alpha_\chi)\sum_{j=1}^{\infty} \psi_{j_\chi}(M_\chi)\psi_{j_\chi}(M'_\chi) \right]$$

which may be written

$$K = \prod_{\chi\in\{x,y,z,r,v\}} \left[\alpha_\chi\psi_{0_\chi}(M_\chi)\psi_{0_\chi}(M'_\chi) + (1-\alpha_\chi)\sum_{j=1}^{\infty} \psi_{j_\chi}(M_\chi)\psi_{j_\chi}(M'_\chi) \right].$$

Finally, using the following property,

$$\sum_{j=0}^{\infty} \psi_{j_\chi}(M_\chi)\psi_{j_\chi}(M'_\chi) = \delta(M_\chi - M'_\chi),$$

where δ is the dirac function, it is obtained

$$\begin{aligned} K = {} & \{\alpha_x\psi_{0_x}(V_x)\psi_{0_x}(V'_x) + (1-\alpha_x)\delta(V_x-V'_x)\}\{\alpha_y\psi_{0_y}(V_y)\psi_{0_y}(V'_y) + (1-\alpha_y)\delta(V_y-V'_y)\} \\ & \times\{\alpha_z\psi_{0_z}(V_z)\psi_{0_z}(V'_z) + (1-\alpha_z)\delta(V_z-V'_z)\}\{\alpha_r\psi_{0_r}(V_r)\psi_{0_r}(V'_r) + (1-\alpha_r)\delta(V_r-V'_r)\} \\ & \times\{\alpha_v\psi_{0_v}(V_v)\psi_{0_v}(V'_v) + (1-\alpha_v)\delta(V_v-V'_v)\}. \end{aligned} \tag{14}$$

Applying inversely the transformation (5), the operator B corresponding to the kernel K above [relationship (14)] is

$$B(V',E_{ir'},E_{iv'},g_{ir'},V,E_{ir},E_{iv},g_{ir}) = \left\{(1-\alpha_x)\,\delta(V_x'+V_x)+\alpha_x\frac{2V_x}{C_w^2}e^{-V_x^2/C_w^2}\right\}$$
$$\times\left\{(1-\alpha_y)\,\delta(V_y'-V_y)+\alpha_y\frac{1}{C_w\sqrt{\pi}}e^{-V_y^2/C_w^2}\right\}$$
$$\times\left\{(1-\alpha_y)\,\delta(V_z'-V_z)+\alpha_z\frac{1}{C_w\sqrt{\pi}}e^{-V_z^2/C_w^2}\right\}$$
$$\times\left\{(1-\alpha_r)\,\delta(E_{ir'}-E_{ir})+\alpha_r\frac{g_{ir}}{Q_r}e^{-\epsilon_{ir}}\right\}$$
$$\times\left\{(1-\alpha_v)\,\delta(E_{iv'}-E_{iv})+\alpha_v\frac{1}{Q_v}e^{-\epsilon_{iv}}\right\}. \tag{15}$$

In the further calculations, we will note the scattering kernel (15) simply as

$$B = P_x P_y P_z P_r P_v,$$

where P_x, P_y, P_z, P_r, P_v correspond, respectively, to the five factors of the expression (15). It would be seen that these five factors satisfy

$$\int_0^{+\infty} P_x d_{V_x} = \int_{-\infty}^{+\infty} P_y d_{V_y} = \int_{-\infty}^{+\infty} P_z d_{V_z} = \sum_{ir} P_r = \sum_{iv} P_v = 1. \tag{16}$$

On the other hand when developing the expression (15) one obtains the kernel B as combination of 32 elementary scattering kernels where the coefficients are functions of the α_χ.

B. On the coefficient α_χ

In this section we prove that the five coefficients α_χ involved in the scattering kernel equal, respectively, the accommodation coefficients of the various fluxes of the five microscopic state parameters ($M_\chi = V_x, V_y, V_z, E_{ir}, E_{iv}$).

The accommodation coefficient β_χ of a physical property M_χ at the wall is defined through the relation[3,4,8]

$$\beta_\chi = \frac{\Phi_\chi^- - \Phi_\chi^+}{\Phi_\chi^- - \Phi_\chi^e}, \tag{17}$$

where Φ_χ^- is the incoming flux at the wall of the property M_χ, Φ_χ^+ is the corresponding reflected flux, and Φ_χ^e is the reflected flux in the hypothetical situation of perfect accommodation to the wall. These various fluxes are written

$$\Phi_\chi^- = \sum_{ir',iv'} \int_{\Omega'} m|V_x'|M_\chi' f^-(V',E_{ir'},E_{iv'},g_{ir'})\,d_{V'}, \tag{18}$$

$$\Phi_\chi^+ = \sum_{ir,iv} \int_{\Omega} m|V_x|M_\chi f^+(V,E_{ir},E_{iv},g_{ir})\,d_V, \tag{19}$$

where f^- and f^+ are, respectively, the incident and the reflected distribution functions linked by the relation

$$|V_x| f_i^+(V,E_{ir},g_{ir},E_{iv}) = \sum_{ir',iv'} \int_{\Omega'} |V_x'| f^-(V',E_{ir'},g_{ir'},E_{iv'}) B(V',E_{ir'},g_{ir'},E_{iv'},V,E_{ir},g_{ir},E_{iv}) d_{V'}. \tag{20}$$

Accounting for (20), the reflected flux Φ_χ^+ [expression (19)] may be rewritten as

$$\Phi_\chi^+ = \sum_{ir',iv'} \int_{\Omega'} m|V_x'| f^-(V',E_{ir'},g_{ir'},E_{iv'}) \left[\sum_{ir,iv} \int_{\Omega} M_\chi P_x P_y P_z P_r P_v d_V \right] d_{V'} \tag{21}$$

and the reflected flux in the case of perfect accommodation is written as

$$\Phi_\chi^e = \sum_{ir',iv'} \int_{\Omega'} m|V_x'| f^-(V',E_{ir'},g_{ir'},E_{iv'}) \left[\sum_{ir,iv} \int_{\Omega} M_\chi B_e d_V \right] d_{V'}, \tag{22}$$

where B_e, the perfect accommodation scattering kernel, is defined by

$$B_e = \frac{2g_{ir}}{Q_r Q_v C_w^4 \pi} V_x e^{-\|V\|^2/C_w^2} e^{-\epsilon_{ir}} e^{-\epsilon_{iv}}. \tag{23}$$

1. Calculation of β_y and β_z

The tangential accommodation coefficient, β_y is obtained by substituting $M_\chi = V_y$ in the definition relation (17). In this case it is easily seen that $\Phi_y^e = 0$. Then accounting for the property (16) the expression (21) leads to

$$\Phi_y^+ = (1-\alpha_y) \sum_{ir',iv'} \int_{\Omega'} m V_y' |V_x'| f^-(V',E_{ir'},g_{ir'},E_{iv'}) d_{V'}.$$

It results immediately from expression (17)

$$\beta_y = 1 - \frac{\Phi_y^+}{\Phi_y^-} = \alpha_y.$$

Similarly it is found,

$$\beta_z = 1 - \frac{\Phi_z^+}{\Phi_z^-} = \alpha_z.$$

2. Calculation of β_x

The normal accommodation coefficient is obtained by substituting $M_\chi = |V_x|$ in the definition (17). In this case, accounting for the property (16) and the expressio of the partial operator P_x, it is obtained

$$\sum_{ir,iv} \int_{\Omega} |V_x| P_x P_y P_z P_r P_v d_V = -(1-\alpha_x) V_x' + \alpha_x \frac{C_w \sqrt{\pi}}{2}$$

then the expression (21) yields.

$$\Phi_x^+ - \Phi_x^- = \alpha_x \sum_{ir',iv'} \int_{\Omega'} m|V_x'| f^-(V',E_{ir'},E_{iv'},g_{ir'}) \left(V_x' + \frac{C_w \sqrt{\pi}}{2} \right) d_{V'}.$$

The calculation of Φ^e leads easily to

$$\Phi_x^e - \Phi_x^- = \sum_{ir',iv'} \int_{\Omega'} m|V_x'| f^-(V', E_{ir'}, E_{iv'}, g_{ir'}) \left(V_x' + \frac{C_w\sqrt{\pi}}{2} \right) d_{V'}.$$

Consequently we obtained from the relation (17),

$$\beta_x = \alpha_x.$$

3. Calculation of β_r and β_v

Now substitute $M_\chi = g_{ir}E_{ir}$ in the relation (17). Accounting for the property (16) it is obtained

$$\sum_{ir,iv} \int_{\Omega} g_{ir}E_{ir}P_xP_yP_zP_rP_v d_V = \sum_{ir} g_{ir}E_{ir}P_r = (1-\alpha_r) g_{ir'}E_{ir'} + \alpha_r \frac{Q_r^*}{Q_r},$$

where we have noted

$$Q_r^* = \sum_{ir} g_{ir}^2 E_{ir} e^{-\varepsilon_{ir}}.$$

Then the expression of Φ^+ leads to

$$\Phi_{E_{ir}}^- - \Phi_{E_{ir}}^e = \alpha_r \sum_{ir',iv'} \int_{\Omega'} m|V_x'| f^-(V', E_{ir'}, E_{iv'}, g_{ir'}) \left(g_{ir'}E_{ir'} - \frac{Q_r^*}{Q_r} \right) d_{V'}.$$

Using the expression (23) of B_e, we obtain

$$\sum_{ir,iv} \int_{\Omega} g_{ir}E_{ir}B_e d_V = \frac{Q_r^*}{Q_r}$$

and then

$$\Phi_{E_{ir}}^- - \Phi_{E_{ir}}^e = \sum_{ir',iv'} \int_{\Omega'} m|V_x'| f^-(V', E_{ir'}, E_{iv'}, g_{ir'}) \left(g_{ir'}E_{ir'} - \frac{Q_r^*}{Q_r} \right) d_{V'}$$

consequently,

$$\beta_r = \alpha_r.$$

In the same way, substituting $M_\chi = E_{iv}$, it is found

$$\beta_v = \alpha_v.$$

In conclusion, the five parameters α_χ involved in the scattering kernel (15) are the accommodation coefficients corresponding to the five state parameters, namely the three momentum components and the two internal energy degrees.

III. COMMENT ON THE METHOD USED IN SCATTERING KERNEL DERIVATION

The $\mathcal{H}$ Hilbert space corresponds generally to the Hilbert space used in the framework of the modelling of the Boltzmann equation in polyatomic gases. Following the quantum mechanic concept, the wall and then the boundary conditions can be represented by an operator defined on this $\mathcal{H}$ Hilbert space.[4,6,8,9] Therefore the problem of boundary condition for the Boltzmann equation can be basically formulated through the integral operator (9), so this formulation is convenient for solving the linearized Boltzmann equation. The reciprocity relation assumption globally means that the local equilibrium distribution function must be invariant by the kernel B.[8,9] This last condition, which contains thermodynamic properties is the most important condition. In addition, it is the only one condition containing physical meaning. This condition leads to the first eigen-

function representation ψ_0. The other eigenfunctions remain unknown. At this step of the scattering kernel construction, one should suggest to choose the set of the other eigenfunctions[10] or a finite number of them. But, such a way would be a purely mathematical construction without real physical justifications.[4,7]

Then, another way consists to analyze physically the accommodation process. Let us consider the couple gas/surface characterized by its macroscopic properties. It seems convenient to assume that for each microscopic property p of the molecules, the solid surface behaves in a way perfectly defined in the accommodation process. In other worlds, in a gas/surface configuration, physically and geometrically given, for each microscopic property there is a linear relation between the amount of the p flux accommodated by the wall and the amount of the p incoming flux. So the accommodation at the wall of any physical microscopic property provides a physical information through a corresponding accommodation coefficient. Thus, five elementary accommodation coefficients associated to the five basic parameters defining the molecule states (the three momentum components, rotational energy, vibrational energy) are naturally introduced completely describing the molecules behavior in the reflection process. In this way, the present construction of the polyatomic scattering kernel is based on five accommodation coefficients, and corresponds to an integral operator partially degenerated involving 32 different eigenvalues in its expansion: from our point of view, this construction appears physically founded and completely describing the reflection process.

IV. CONCLUDING REMARKS

We have established a scattering kernel for structured molecules involving one rotational and one vibrational energy mode. A convenient integral operator formulation is used assuming a purely discrete spectrum and assuming eigenvalues depending on five basic parameters in respect to the five state parameters of the molecules (and then assuming a partial degeneracy of the integral operator). These five basic parameters are shown to be the accommodation coefficients of, respectively, the three momentum accommodation coefficients and the accommodation coefficients of the two internal energy modes.

Under its factorized form (15), the proposed scattering kernel is easy to use in analytical calculations or to be implemented in numerical modelling. In order to show its physical meaning, the expression (15) may be developed. Under its developed form, the scattering kernel appears as a linear combination of 32 elementary scattering kernels (listed in the Appendix). All these elementary kernels correspond to various situations of accommodation at the wall which have been described in Ref. 5. The linear combination coefficients, which represent the weight of the various types of accommodation in the reflection process, are combinations of the factors α_χ and $(1-\alpha_\chi)$ (see the Appendix). In each elementary kernel each molecule state accommodates independently from the others. So the new kernel allows us to take into account the interplay between the molecule freedom degrees when interacting at the wall.[11] Up to now, the data available concerning the whole set of accommodation coefficients involved in the proposed scattering kernel are rare; that makes a complete validation of the model difficult.

Finally, let us add that, in the form presented here, the scattering kernel accounts for a single rotational and a single vibrational mode. This description is sufficient in any condition for diatoms. In the case of more complex polyatomic structures, involving various vibrational (or rotational) modes, the present form of scattering kernel remains directly usable, as long as the various vibrational (or rotational) modes remain in the same thermodynamics state (i.e., in local equilibrium the ones with the others). In a contrary situation (for example, in strong vibrational nonequilibrium conditions) it may be pertinent—depending on the considered time scale—to distinguish various vibrational (or rotational) accommodation coefficients to describe the reflection process. In such a case, the scattering kernel should be written in the same way as previously, but it should involve more than five state parameters, and thus more than five accommodation coefficients.

APPENDIX: DIFFERENT WRITING OF THE SCATTERING KERNEL *B* OF RELATION (15)

Let

$$\tilde{P}_0 = \delta(E_{ir'} - E_{ir})\,\delta(E_{iv'} - E_{iv}), \quad \tilde{P}_{rv} = \frac{e^{-\varepsilon_{ir}}}{Q_r} g_{ir} \frac{e^{-\varepsilon_{iv}}}{Q_v},$$

$$\tilde{P}_v = \delta(E_{ir'} - E_{ir}) \frac{e^{-\varepsilon_{iv}}}{Q_v}, \quad \tilde{P}_r = \frac{e^{-\varepsilon_{ir}}}{Q_r} g_{ir}\,\delta(E_{iv'} - E_{iv}). \tag{A1}$$

Develop partially the expression (15). The scattering kernel can be written in the form presented in Ref. 5, as follows:

$$B = \left(\sum_{\kappa} \mu_\kappa B_\kappa(V', V) \right) (1 - \alpha_r)(1 - \alpha_v)\tilde{P}_0 + \alpha_v(1 - \alpha_r)\tilde{P}_v + \alpha_r(1 - \alpha_v)\tilde{P}_r + \alpha_v\alpha_r\tilde{P}_{rv}, \tag{A2}$$

where B_κ the elementary scattering kernels, and μ_κ their corresponding coefficients in the case of unstructured molecule given in Ref. 5, are recalled below,

$$B_0(V', V) = \delta(V_x + V'_x)\,\delta(V_y - V'_y)\,\delta(V_z - V'_z),$$

$$B_{yz}(V', V) = \frac{1}{\pi C_w^2}\,\delta(V_x + V'_x) e^{-V_y^2/C_w^2} e^{-V_z^2/C_w^2},$$

$$B_{xz}(V', V) = \frac{2}{C_w^3\sqrt{\pi}} V_x\,\delta(V_y - V'_y) e^{-V_x^2/C_w^2} e^{-V_z^2/C_w^2},$$

$$B_{xy}(V', V) = \frac{2}{C_w^3\sqrt{\pi}} V_x\,\delta(V_z - V'_z) e^{-V_x^2/C_w^2} e^{-V_y^2/C_w^2},$$

$$B_{xyz}(V', V) = \frac{2}{\pi C_w^4} V_x e^{-V_x^2/C_w^2} e^{-V_y^2/C_w^2} e^{-V_z^2/C_w^2},$$

$$B_z(V', V) = \frac{1}{C_w\sqrt{\pi}}\,\delta(V_x + V'_x)\,\delta(V_y - V'_y) e^{-V_z^2/C_w^2},$$

$$B_y(V', V) = \frac{1}{C_w\sqrt{\pi}}\,\delta(V_x + V'_x)\,\delta(V_z - V'_z) e^{-V_y^2/C_w^2},$$

$$B_x(V', V) = \frac{2}{C_w^2} V_x\,\delta(V_y - V'_y)\,\delta(V_z - V'_z) e^{-V_x^2/C_w^2},$$

and

$$\mu_{xz} = \alpha_x\alpha_z(1 - \alpha_y), \quad \mu_{xy} = \alpha_x\alpha_y(1 - \alpha_z), \quad \mu_{yz} = \alpha_y\alpha_z(1 - \alpha_x), \quad \mu_x = \alpha_x(1 - \alpha_y)(1 - \alpha_z), \quad \mu_{xyz} = \alpha_x\alpha_y\alpha_z, \quad \mu_0 = (1 - \alpha_x)(1 - \alpha_y)(1 - \alpha_z), \quad \mu_y = \alpha_y(1 - \alpha_x)(1 - \alpha_z), \quad \mu_z = \alpha_z(1 - \alpha_x)(1 - \alpha_y).$$

A complete development of expression (15) yields the scattering kernel written as a sum of 32 elementary polyatomic scattering kernels $B_\kappa\tilde{P}_{in}$ as follows:

$$B = \sum_{\kappa,in} \mu_\kappa \mu_{in} B_\kappa \tilde{P}_{in},$$

where $\tilde{P}_{in}$ refers to the four partial operators $\tilde{P}_0, \tilde{P}_v, \tilde{P}_r, \tilde{P}_{rv}$ defined in the relationship (A1) and μ_{in} to their respective coefficients in the formula (A2). In this developed form it is clear that this scattering kernel describes various types of accommodation processes at the wall. Each of the partial scattering kernels $B_\kappa \tilde{P}_{in}$ corresponds to a particular type of accommodation. There are exactly 32 types.

The quantum effects for a physical system can be described by the set $\mathcal{E}(\mathcal{H})$ of positive operators on a complex Hilbert space $\mathcal{H}$ that are bounded above by the identity operator. While a general effect may be unsharp, the collection of sharp effects is described by the set of orthogonal projections $\mathcal{P}(\mathcal{H})\subseteq\mathcal{E}(\mathcal{H})$. Under the natural order, $\mathcal{E}(\mathcal{H})$ becomes a partially ordered set that is not a lattice if $\dim\mathcal{H}\geqslant 2$. A physically significant and useful characterization of the pairs $A,B\in\mathcal{E}(\mathcal{H})$ such that the infimum $A\wedge B$ exists is called the infimum problem. We show that $A\wedge P$ exists for all $A\in\mathcal{E}(\mathcal{H})$, $P\in\mathcal{P}(\mathcal{H})$ and give an explicit expression for $A\wedge P$. We also give a characterization of when $A\wedge(I-A)$ exists in terms of the location of the spectrum of A. We present a counterexample which shows that a recent conjecture concerning the infimum problem is false. Finally, we compare our results with the work of Ando on the infimum problem. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904704]

I. INTRODUCTION

A quantum mechanical measurement with just two values 1 and 0 (or yes and no) is called a *quantum effect*. These elementary measurements play an important role in the foundations of quantum mechanics and quantum measurement theory.[3–5,7,14,16,18] We shall follow the Hilbert space model for quantum mechanics in which effects are represented by positive operators on a complex Hilbert space $\mathcal{H}$ that are bounded above by the identity operator I. In this way the set of effects $\mathcal{E}(\mathcal{H})$ becomes

$$\mathcal{E}(\mathcal{H})=\{A\in\mathcal{B}(\mathcal{H}):0\leqslant A\leqslant I\}.$$

The set of orthogonal projections $\mathcal{P}(\mathcal{H})\subseteq\mathcal{E}(\mathcal{H})$ corresponds to sharp effects while a general $A\in\mathcal{E}(\mathcal{H})$ may be unsharp (fuzzy, imprecise). Employing the usual order $A\leqslant B$ for the set of bounded self-adjoint operators $\mathcal{S}(\mathcal{H})$ on $\mathcal{H}$, we see that $(\mathcal{E}(\mathcal{H}),\leqslant)$ is a partially ordered set. It is well known that $(\mathcal{E}(\mathcal{H}),\leqslant)$ is not a lattice if $\dim\mathcal{H}\geqslant 2$. However, if the infimum $A\wedge B$ of $A,B\in\mathcal{E}(\mathcal{H})$ exists then $A\wedge B$ has the important property of being the largest effect that physically implies both A and B. It would thus be of interest to give a physically significant and useful characterization of when $A\wedge B$ exists. This so-called infimum problem has been considered for at least 10 years.[2,10–12,17,19]

Before discussing the progress that has been made toward solving the infimum problem, let us compare the situation with that of the partially ordered set $(\mathcal{S}(\mathcal{H}),\leqslant)$. Of course, if A,B

$\in \mathcal{S}(\mathcal{H})$ are comparable, that is, $A \leqslant B$ or $B \leqslant A$, then $A \wedge B$ exists and is the smaller of the two. A surprising result of Kadison[15] states that the converse holds. Thus, for $A, B \in \mathcal{S}(\mathcal{H})$, $A \wedge B$ exists in $\mathcal{S}(\mathcal{H})$ if and only if A and B are comparable. We conclude that $(\mathcal{S}(\mathcal{H}), \leqslant)$ is an antilattice which is as far from being a lattice as possible. The situation is quite different in $(\mathcal{E}(\mathcal{H}), \leqslant)$. In fact it is well known that $P \wedge Q$ exists in $\mathcal{E}(\mathcal{H})$ for all $P, Q \in \mathcal{P}(\mathcal{H})$. More generally, we shall show that $A \wedge P$ exists in $\mathcal{E}(\mathcal{H})$ for all $A \in \mathcal{E}(\mathcal{H})$, $P \in \mathcal{P}(\mathcal{H})$ and give an explicit expression for $A \wedge P$. The existence of $A \wedge P$ has already been proved in Ref. 18 but we present a different proof here.

For $A, B \in \mathcal{E}(\mathcal{H})$ let $P_{A,B}$ be the orthogonal projection onto the closure of $\mathrm{Ran}(A^{1/2}) \cap \mathrm{Ran}(B^{1/2})$. It is shown in Ref. 19 that if $\dim \mathcal{H} < \infty$ then $A \wedge B$ exists in $\mathcal{E}(\mathcal{H})$ if and only if $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$ are comparable and in this case $A \wedge B$ is the smaller of the two. This was considered to be a solution to the infimum problem for the case $\dim \mathcal{H} < \infty$ and it was conjectured in Ref. 19 that this result also holds in general. One of our main results is that this conjecture is false. We shall present an example of a pair $A, B \in \mathcal{E}(\mathcal{H})$ with $\dim \mathcal{H} = \infty$ for which $A \wedge B$ exists in $\mathcal{E}(\mathcal{H})$ but $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$ are not comparable. In addition, we prove that, assuming $A \wedge B$ exists, $P_{A,B}$ is the smallest of all orthogonal projections P having the property that $(A \wedge P) \wedge (B \wedge P)$ exists and $(A \wedge P) \wedge (B \wedge P) = A \wedge B$. Combined with the counter-example as described before, this means that, in the infinite dimensional case, there is no orthogonal projection to replace $P_{A,B}$ and have a positive solution to the infimum problem.

The *negation* A' of an effect A is defined to be the effect $A' = I - A$. Physically, A' is the effect A with its values 1 and 0 reversed. We also present a simple spectral characterization of when $A \wedge A'$ exists in $\mathcal{E}(\mathcal{H})$. The result is essentially the same as Theorem 2 in Ref. 2, with the difference that we express the condition in terms of the location of the spectrum of A and the proof is based on the matrix representations obtained in the preceding section.

Ando has given a solution to the infimum problem in terms of a generalized shorted operator.[2] However, in our opinion, these shorted operators do not have a physical significance in contrast to the operationally defined operators $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$. Finally, we discuss the relationship between our work and that of Ando. First, we show that the shorted operator of A by B is always smaller than $A \wedge P_{A,B}$. Actually, it is the fact, that in the infinite dimensional case, the shorted operator of A by B can be strictly smaller than $A \wedge P_{A,B}$, that is responsible for the failure of a solution of the infimum problem similar to the finite dimensional case. This can be viewed from the counter-example as before, but we record also a simpler one that illustrates this situation.

We now briefly discuss connections between the infimum problem and physics. Quantum effects have been studied by mathematicians and physicists for over 40 years.[5,16,17] Besides the applications of effect-valued measures in quantum measurement theory, many researchers consider effects to be the basic elements of important quantum structures. In recent times quantum effects have been organized into a structure called an effect algebra[7,10] and their order properties have been studied.[11,12,17] Among other things, the effect algebra $\mathcal{E}(\mathcal{H})$ is a partially ordered set and if $A \wedge B$ exists for $A, B, \in \mathcal{E}(\mathcal{H})$, then this effect has important physical properties. In particular, among all the effects that have a smaller probability of occurring than both A and B, $A \wedge B$ has the largest probability. Thus if $A \wedge B$ exists, then $A \wedge B$ has a crucial physical significance. In the case where A and B are sharp, A and B are projections, $A \wedge B$ always exists and is the projection onto the intersection of their ranges. But if A and B are not sharp, the situation is much more complicated. An interesting special case is when $A \in \mathcal{E}(\mathcal{H})$ and $P \in \mathcal{P}(\mathcal{H})$. In this case $A \wedge P$ always exists and if A and P commute (are compatible) then $A \wedge P = AP$. However, if A and P do not commute an explicit closed form expression for $A \wedge P$ has been difficult to obtain and is now presented in Theorem 2.2. We can now define conditional probabilities

$$\mathrm{prob}(A|P) = \mathrm{prob}(A \wedge P)/\mathrm{prob}(P)$$

and conditional measurements and these may have useful physical applications. Finally, our Example 4.2 gives a surprising phenomenon that does not occur in finite dimensional Hilbert spaces. The existence of effects such as those in this example may have interesting physical significance.

II. INFIMUM OF A QUANTUM EFFECT AND A SHARP EFFECT

We first record a parametrization of bounded positive 2×2 matrices with operator entries, in terms of operator balls.

In the following we make use of the *Frobenius-Schur factorization*: for T, X, Y, Z bounded operators on appropriate spaces and T boundedly invertible, we have

$$\begin{bmatrix} T & X \\ Y & Z \end{bmatrix} = \begin{bmatrix} I & 0 \\ YT^{-1} & I \end{bmatrix} \begin{bmatrix} T & 0 \\ 0 & Z - YT^{-1}X \end{bmatrix} \begin{bmatrix} I & T^{-1}X \\ 0 & I \end{bmatrix}. \tag{2.1}$$

For instance, by using Frobenius–Schur factorizations and a perturbation argument one can obtain the following classical result of Shmulyan.[21]

Theorem 2.1: *Let $A \in \mathcal{B}(\mathcal{H})$ be self-adjoint and $\mathcal{H}=\mathcal{H}_1 \oplus \mathcal{H}_2$ an orthogonal decomposition of $\mathcal{H}$. Then $A \geqslant 0$ if and only if it has a matrix representation of the following form:*

$$A = \begin{bmatrix} A_1 & A_1^{1/2}\Gamma A_2^{1/2} \\ A_2^{1/2}\Gamma^* A_1^{1/2} & A_2 \end{bmatrix} \quad \text{with respect to } \mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2, \tag{2.2}$$

where $A_1 \in \mathcal{B}(\mathcal{H}_1)^+$, $A_2 \in \mathcal{B}(\mathcal{H}_2)^+$, and $\Gamma \in \mathcal{B}(\mathcal{H}_2, \mathcal{H}_1)$ is contractive.

In addition, the operator Γ can be chosen in such a way that $\mathrm{Ker}(\Gamma) \supseteq \mathrm{Ker}(A_2)$ *and* $\mathrm{Ker}(\Gamma^*) \supseteq \mathrm{Ker}(A_1)$, *and in this case it is unique.*

For two effects $A, B \in \mathcal{E}(\mathcal{H})$ we denote by $A \wedge B$, the *infimum*, equivalently, the *greatest lower bound*, of A and B over the partially ordered set $(\mathcal{E}(\mathcal{H}), \leqslant)$, if it exists. To be more precise, $A \wedge B$ is an operator in $\mathcal{E}(\mathcal{H})$ uniquely determined by the following properties: $A \wedge B \leqslant A$, $A \wedge B \leqslant B$, and an arbitrary operator $D \in \mathcal{E}(\mathcal{H})$ satisfies both $D \leqslant A$ and $D \leqslant B$ if and only if $D \leqslant A \wedge B$. Characterizations of the existence of infimum for positive operators have been obtained for the finite-dimensional case in Ref. 19, and in general in Ref. 2.

In Theorem 4.4 of Ref. 19 it is proved that the infimum $A \wedge P$ exists for any $A \in \mathcal{E}(\mathcal{H})$ and $P \in \mathcal{P}(\mathcal{H})$. As a consequence of Theorem 2.1 we can obtain an explicit description of $A \wedge P$, together with another proof of the existence.

Theorem 2.2: *For any $A \in \mathcal{E}(\mathcal{H})$ and $P \in \mathcal{P}(\mathcal{H})$ the infimum $A \wedge P$ exists, more precisely, if A has the matrix representation as in* (2.2) *with respect to the orthogonal decomposition $\mathcal{H}$* $=\mathrm{Ran}(P) \oplus \mathrm{Ker}(P)$, *where* $A_1 \in \mathcal{E}(\mathrm{Ran}(P))$, $A_2 \in \mathcal{E}(\mathrm{Ker}(P))$, *and* $\Gamma \in \mathcal{B}(\mathrm{Ker}(P), \mathrm{Ran}(P))$, *with* $\|\Gamma\| \leqslant 1$, $\mathrm{Ker}(\Gamma) \supseteq \mathrm{Ker}(A_2)$ *and* $\mathrm{Ker}(\Gamma^*) \supseteq \mathrm{Ker}(A_1)$, *then*

$$A \wedge P = \begin{bmatrix} A_1^{1/2}(I - \Gamma\Gamma^*)A_1^{1/2} & 0 \\ 0 & 0 \end{bmatrix} \quad \text{with respect to } \mathcal{H} = \mathrm{Ran}(P) \oplus \mathrm{Ker}(P). \tag{2.3}$$

Proof: Let $A \in \mathcal{E}(\mathcal{H})$ and $P \in \mathcal{P}(\mathcal{H})$. In the following we consider the orthogonal decomposition $\mathcal{H}=\mathrm{Ran}(P) \oplus \mathrm{Ker}(P)$. By Theorem 2.1 A has a matrix representation as in (2.2), with $A_1 \in \mathcal{B}(\mathrm{Ran}(P))^+$, $A_2 \in \mathcal{B}(\mathrm{Ker}(P))^+$, and $\Gamma \in \mathcal{B}(\mathrm{Ker}(P), \mathrm{Ran}(P))$, with $\|\Gamma\| \leqslant 1$, $\mathrm{Ker}(\Gamma) \supseteq \mathrm{Ker}(A_2)$ and $\mathrm{Ker}(\Gamma^*) \supseteq \mathrm{Ker}(A_1)$. Since $A \leqslant I$ it follows that $A_1 \leqslant I_{\mathrm{Ran}(P)}$ and $A_2 \leqslant I_{\mathrm{Ker}(P)}$. Consider the operator $D \in \mathcal{B}(\mathcal{H})$, defined by the matrix in (2.3). Clearly $0 \leqslant D \leqslant P$, in particular $D \in \mathcal{E}(\mathcal{H})$. In addition,

$$A - D = \begin{bmatrix} A_1^{1/2}\Gamma\Gamma^* A_1^{1/2} & A_1^{1/2}\Gamma A_2^{1/2} \\ A_2^{1/2}\Gamma^* A_1^{1/2} & A_2 \end{bmatrix} = [\Gamma^* A_1^{1/2} A_2^{1/2}]^* [\Gamma^* A_1^{1/2} A_2^{1/2}] \geqslant 0,$$

hence $A \geqslant D$.

Let $C \in \mathcal{E}(\mathcal{H})$ be such that $C \leqslant A, P$. From $C \leqslant P$ it follows that $CP=PC=C$ and hence

$$C = \begin{bmatrix} C_1 & 0 \\ 0 & 0 \end{bmatrix} \quad \text{with respect to } \mathcal{H} = \mathrm{Ran}(P) \oplus \mathrm{Ker}(P).$$

Then

$$0 \leqslant A - C = \begin{bmatrix} A_1 - C_1 & A_1^{1/2}\Gamma A_2^{1/2} \\ A_2^{1/2}\Gamma^* A_1^{1/2} & A_2 \end{bmatrix}. \tag{2.4}$$

The matrix with operator entries in (2.4) can be factored as

$$\begin{bmatrix} I_{\mathrm{Ran}(P)} & 0 \\ 0 & A_2^{1/2} \end{bmatrix} \begin{bmatrix} A_1 - C_1 & A_1^{1/2}\Gamma \\ \Gamma^* A_1^{1/2} & I_{\mathrm{Ker}(P)} \end{bmatrix} \begin{bmatrix} I_{\mathrm{Ran}(P)} & 0 \\ 0 & A_2^{1/2} \end{bmatrix}. \tag{2.5}$$

Note that by $\mathrm{Ker}(\Gamma) \supseteq \mathrm{Ker}(A_2)$ or, equivalently, $\overline{\mathrm{Ran}(\Gamma^*)} \subseteq \overline{\mathrm{Ran}(A_2)}$, $A - C$ and each of the factors of (2.5) map the subspace $\mathcal{H}' = \mathrm{Ran}(P) \oplus \overline{\mathrm{Ran}(A_2)}$ into itself. Since $\mathrm{diag}(I_{\mathrm{Ran}(P)} A_2^{1/2})$ regarded as an operator on $\mathcal{H}'$, is symmetric and has dense range, $A - C \geqslant 0$ implies that the middle term in (2.5) regarded as an operator in $\mathcal{H}'$ is non-negative. By performing a Frobenius–Schur factorization of this middle term, we find $A_1^{1/2}\Gamma\Gamma^* A_1^{1/2} \leqslant A_1 - C_1$, that is, $C_1 \leqslant A_1^{1/2}(I_{\mathrm{Ran}(P)} - \Gamma\Gamma^*)A_1^{1/2}$, or, equivalently, $C \leqslant D$.

We thus proved that $A \wedge P$ exists and has the matrix representation as in (2.3). □

Remark 2.3: If $A \in \mathcal{E}(\mathcal{H})$, E_A is the spectral function of A and Δ is a Borel subset of $[0, 1]$, then $A \wedge E_A(\Delta) = AE_A(\Delta)$. This is an immediate consequence of Theorem 2.2. The second to last sentence in the proof of Theorem 2.2 can also be demonstrated by using the well-known fact that any operator matrix of the form

$$\begin{bmatrix} A & B \\ B^* & I \end{bmatrix} \tag{2.6}$$

is positive if and only if $A \geqslant 0$ and $BB^* \leqslant A$.

Let $A, B \in \mathcal{E}(\mathcal{H})$. By $P_{A,B}$ we denote the orthogonal projection onto the closure of $\mathrm{Ran}(A^{1/2}) \cap \mathrm{Ran}(B^{1/2})$. As mentioned in the introduction, the infimum problem for a finite dimensional space $\mathcal{H}$ was solved in Ref. 19 by showing that $A \wedge B$ exists if and only if $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$ are comparable, and that $A \wedge B$ is the smaller of $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$. The following proposition shows that for $\dim \mathcal{H} = \infty$ the infimum problem for A and B can be reduced to the same problem for the "smaller" operators $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$. In Sec. IV we will see that in this case the infimum problem cannot be solved in the same fashion, as conjectured in Ref. 19.

Proposition 2.4: Let $A, B \in \mathcal{E}(\mathcal{H})$. Then $A \wedge B$ exists if and only if $(A \wedge P_{A,B}) \wedge (B \wedge P_{A,B})$ exists. In this case $A \wedge B = (A \wedge P_{A,B}) \wedge (B \wedge P_{A,B})$.

Proof: Note first that the operators $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$ exist, e.g., by Theorem 2.2.

Let us assume that $(A \wedge P_{A,B}) \wedge (B \wedge P_{A,B})$ exists and let $C \in \mathcal{E}(\mathcal{H})$ be such that $C \leqslant A, B$, thus we have $\mathrm{Ran}(C^{1/2}) \subseteq \mathrm{Ran}(A^{1/2}) \cap \mathrm{Ran}(B^{1/2}) \subseteq \mathrm{Ran}(P_{A,B})$ and hence $C \leqslant P_{A,B}$. Therefore, $C \leqslant A \wedge P_{A,B}$ and $C \leqslant B \wedge P_{A,B}$ and hence, by the majorization theorem as in Ref. 6, $C \leqslant (A \wedge P_{A,B}) \wedge (B \wedge P_{A,B})$. Taking into account that $(A \wedge P_{A,B}) \wedge (B \wedge P_{A,B}) \leqslant A, B$ it follows that $A \wedge B$ exists and equals $(A \wedge P_{A,B}) \wedge (B \wedge P_{A,B})$.

Conversely, let us assume that $A \wedge B$ exist. Then, $A \wedge B \leqslant P_{A,B}$. This relation and $A \wedge B \leqslant A, B$ give $A \wedge B \leqslant A \wedge P_{A,B}$, $A \wedge B \leqslant B \wedge P_{A,B}$. Let $C \in \mathcal{E}(\mathcal{H})$ be such that $C \leqslant A \wedge P_{A,B}$, $B \wedge P_{A,B}$. Then $C \leqslant A$, B, $P_{A,B}$ and, in particular, $C \leqslant A \wedge B$. □

One may ask for which orthogonal projections P except $P_{A,B}$ the statement of Proposition 2.4 is true. It turns out that $P_{A,B}$ is the infimum of the set of those projections P.

Theorem 2.5: *Let $A, B \in \mathcal{E}(\mathcal{H})$ such that $A \wedge B$ exists. Let $\Pi_{A,B}$ be the set of all orthogonal projections subject to the properties that $(A \wedge P) \wedge (B \wedge P)$ exists and $(A \wedge P) \wedge (B \wedge P) = A \wedge B$. Then*

$$\Pi_{A,B} = \{P \in \mathcal{P}(\mathcal{H}) | P_{A,B} \leqslant P\}.$$

In order to prove the above stated proposition, we first consider the connection of parallel sum with the infimum of quantum effects (see also Ref. 2). To see this, instead of giving the original definition as in Ref. 8, we prefer to introduce the parallel sum of two quantum effects by means of the characterization of Pekarev–Shmulyan,[20]

$$\langle (A:B)h,h\rangle = \inf\{\langle Aa,a\rangle + \langle Bb,b\rangle | h = a + b\}, \text{for all } h \in \mathcal{H}. \tag{2.7}$$

Theorem 2.6: (Refs. 8 and 20) *Let* $A,B \in \mathcal{B}(\mathcal{H})^+$. *Then*

(i) $0 \leqslant A: B \leqslant A, B$,
(ii) $A:B = B:A$,
(iii) $\mathrm{Ran}((A:B)^{1/2}) = \mathrm{Ran}(A^{1/2}) \cap \mathrm{Ran}(B^{1/2})$,
(iv) *if* $A_1, B_1 \in \mathcal{B}(\mathcal{H})^+$ *are such that* $A \leqslant A_1$ *and* $B \leqslant B_1$, *then* $A:B \leqslant A_1:B_1$,
(v) *if* $A+B$ *is boundedly invertible, then* $\|A:B\| = A(A+B)^{-1}B$,
(vi) *If* $A_n \searrow A$ *and* $B_n \searrow B$ *strongly, then* $A_n:B_n \searrow A:B$ *strongly*.

In view of the properties of the parallel sum listed above, a moment of thought shows that if $P,Q \in \mathcal{P}(\mathcal{H})$, that is, P and Q are orthogonal projections in $\mathcal{H}$, then $P \wedge Q$ over $\mathcal{E}(\mathcal{H})$ always exists and coincides with the orthogonal projection onto $\mathrm{Ran}(P) \cap \mathrm{Ran}(Q)$. By Theorem 4.3 in Ref. 8 we also have $P \wedge Q = 2(P:Q)$.

Lemma 2.7: Let $A,B \in \mathcal{E}(\mathcal{H})$ *be such that* $A \wedge B$ *exists. Then*

(i) $\mathrm{Ran}((A \wedge B)^{1/2}) = \mathrm{Ran}((A:B)^{1/2})$,
(ii) $(A \wedge B)^{1/2} = (A:B)^{1/2}V$ *for some boundedly invertible operator* $V \in \mathcal{B}(\mathcal{H})$,
(iii) $A:B \leqslant A \wedge B \leqslant \gamma(A:B)$, *for some* $\gamma > 0$.

Proof: Since $A \wedge B \leqslant A$ it follows that $\mathrm{Ran}((A \wedge B)^{1/2}) \subseteq \mathrm{Ran}(A^{1/2})$. Similarly we have $\mathrm{Ran}((A \wedge B)^{1/2}) \subseteq \mathrm{Ran}(B^{1/2})$, hence $\mathrm{Ran}((A \wedge B)^{1/2}) \subseteq \mathrm{Ran}(A^{1/2}) \cap \mathrm{Ran}(B^{1/2}) = \mathrm{Ran}((A:B)^{1/2})$.

For the converse inclusion, note that $A:B \leqslant A$ and $A:B \leqslant B$; since $A:B \leqslant A:I = A(A+I)^{-1} \leqslant A$. Thus, by the definition of $A \wedge B$, it follows that $A:B \leqslant A \wedge B$. In particular, this proves that $\mathrm{Ran}((A \wedge B)^{1/2}) \supseteq \mathrm{Ran}((A:B)^{1/2})$, and hence (i) is proved.

The assertions (ii) and (iii) are consequences of (i) and the majorization theorem as in Ref. 6. □

Lemma 2.8: If $A,B \in \mathcal{E}(\mathcal{H})$ *and* $A \wedge B$ *exists, then* $A \wedge B \leqslant P_{A,B}$ *and* $\mathrm{Ran}(A \wedge B)$ *is dense in* $\mathrm{Ran}(P_{A,B})$.

Proof: This is a consequence of Theorem 2.6 and Lemma 2.7. □

We now come back to Theorem 2.5.

Proof of Theorem 2.5: Let $P \in \Pi_{A,B}$. Then $A \wedge B \leqslant P$ and hence $\overline{\mathrm{Ran}(A \wedge B)} \subseteq \mathrm{Ran}(P)$. Therefore, by Lemma 2.8 $\mathrm{Ran}(P_{A,B}) \subseteq \mathrm{Ran}(P)$, that is, $P_{A,B} \leqslant P$.

Assume that $P \geqslant P_{A,B}$. We claim that then $(A \wedge P) \wedge (B \wedge P)$ exists and it coincides with $(A \wedge P_{A,B}) \wedge (B \wedge P_{A,B})$. Evidently, $(A \wedge P_{A,B}) \wedge (B \wedge P_{A,B}) \leqslant A \wedge P, B \wedge P$. Let $C \in \mathcal{E}(\mathcal{H})$ with $C \leqslant A \wedge P$, $B \wedge P$. Then $C \leqslant A \wedge B \leqslant P_{A,B}$ and hence,

$$C \leqslant (A \wedge P_{A,B}) \wedge (B \wedge P_{A,B}).$$

Therefore, $(A \wedge P) \wedge (B \wedge P)$ exists and, by Proposition 2.4 it coincides with $A \wedge B$. □

III. INFIMUM OF A QUANTUM EFFECT AND ITS NEGATION

The *negation* A' of an effect A is defined to be the effect $A' = I - A$. Physically, A' is the effect A with its values 1 and 0 reversed. In the following we present a characterization of when $A \wedge A'$ exists in $\mathcal{E}(\mathcal{H})$ in terms of the location of the spectrum of A. The theorem essentially coincides with the result of Ando (Ref. 2, Theorem 2), the difference consists on that we express the condition with the help of the spectrum of A and the proof is based on the matrix representations as in Sec. II. There is also a similar characterization in Ref. 13.

Theorem 3.1: *Let* A *be a quantum effect on the Hilbert space* $\mathcal{H}$. *Then the following assertions are equivalent:*

(i) $A \wedge (I - A)$ *exists*,
(ii) $\sigma(A)$, *the spectrum of* A, *is contained either in* $\{0\} \cup \left[\frac{1}{2}, 1\right]$ *or in* $\left[0, \frac{1}{2}\right] \cup \{1\}$,
(iii) $A \wedge P_{A,I-A}$ *and* $(I-A) \wedge P_{A,I-A}$ *are comparable, that is, either* $A \wedge P_{A,I-A} \leqslant (I-A) \wedge P_{A,I-A}$ *or* $(I-A) \wedge P_{A,I-A} \leqslant A \wedge P_{A,I-A}$.

In addition, if either of the above holds, letting $g \in C([0,1])$ *be the function*

$$g(t) = \min(t, 1-t) = \begin{cases} t, & 0 \leqslant t \leqslant \frac{1}{2}, \\ 1-t, & \frac{1}{2} \leqslant t \leqslant 1, \end{cases} \tag{3.1}$$

we have, by continuous functional calculus, $A \wedge (I-A) = g(A)$.

Proof: Let E_A denote the spectral function of A. In view of Proposition 2.4, $A \wedge (I-A)$ exists if and only if $(A \wedge P_{A,I-A}) \wedge ((I-A) \wedge P_{A,I-A})$ exists. A moment of thought shows that $P_{A,I-A} = E_A((0,1))$ and hence, by Remark 2.3, we have that $A \wedge P_{A,I-A} = AE_A((0,1))$ and $(I-A) \wedge P_{A,I-A} = (I-A)E_A((0,1))$. Thus, without restricting the generality, we can and will assume in the following that 0 and 1 are not eigenvalues of A. Now, the equivalence of (ii) with (iii) is a matter of elementary spectral theory for selfadjoint operators, hence we will prove only the equivalence of (i) and (ii).

To prove that (ii) implies (i), let us assume that $\sigma(A)$ is contained either in $\{0\} \cup [\frac{1}{2}, 1]$ or in $[0, \frac{1}{2}] \cup \{1\}$. To make a choice, let us assume that $\sigma(A) \subseteq \{0\} \cup [\frac{1}{2}, 1]$. Since, by assumption, 0 is not an eigenvalue of A, it follows that $\sigma(A) \subseteq [\frac{1}{2}, 1]$. Then $A \geqslant I-A$ and clearly $A \wedge (I-A) = I-A = g(A)$, where the function g is defined as in (3.1). A similar argument holds in case we assume $\sigma(A) \subseteq [0, \frac{1}{2}] \cup \{1\}$; in this case $A \wedge (I-A) = A = g(A)$.

Conversely, let us assume that $A \wedge (I-A) = D$, the infimum of A and $I-A$ over $\mathcal{E}(\mathcal{H})$, exists. Using the spectral measure E_A of A, let $E_1 = E_A([0,1/2])$, $A_1 = A|E_1\mathcal{H}$, $E_2 = E_A((1/2,1])$, $A_2 = A|E_2\mathcal{H}$. We write D as an operator matrix with respect to the decomposition $\mathcal{H} = E_1\mathcal{H} \oplus E_2\mathcal{H}$,

$$D = \begin{bmatrix} D_1 & D_1^{1/2}\Gamma D_2^{1/2} \\ D_2^{1/2}\Gamma^* D_1^{1/2} & D_2 \end{bmatrix},$$

with contractive $\Gamma \in \mathcal{B}(E_2\mathcal{H}, E_1\mathcal{H})$, cf. Theorem 2.1. Since $g(A) \leqslant A, I-A$, by the definition of D we have

$$0 \leqslant D - g(A) = \begin{bmatrix} D_1 - A_1 & D_1^{1/2}\Gamma D_2^{1/2} \\ D_2^{1/2}\Gamma^* D_1^{1/2} & D_2 - (I_2 - A_2) \end{bmatrix}. \tag{3.2}$$

Therefore, $0 \leqslant D_1 - A_1$ while taking into account that $D \leqslant A$ it follows that $D_1 \leqslant A_1$, hence $D_1 = A_1$. Similarly, $0 \leqslant D_2 - (I_2 - A_2)$ and, since $D \leqslant I-A$ it follows $D_2 \leqslant I_2 - A_2$, hence $D_2 = I_2 - A_2$. Thus, the main diagonal of the matrix in (3.2) is null, hence (e.g., by Theorem 2.1) it follows that $D = g(A)$.

Further, let $\varepsilon \in (0, 1/4)$, and consider the operators

$$E_{\varepsilon,1} = E_A((\varepsilon, -\varepsilon + 1/2)), \quad E_{\varepsilon,2} = E_A((\varepsilon + 1/2, 1 - \varepsilon)). \tag{3.3}$$

Denote $E_\varepsilon = E_{\varepsilon,1} + E_{\varepsilon,2}$ and $A_\varepsilon = A|E_\varepsilon\mathcal{H}$. We show that $A_\varepsilon \wedge (I - A_\varepsilon)$ exists. To see this, we remark that, as proven before, $g(A) = A \wedge (I-A)$, so we actually show that $D_\varepsilon = D|E_\varepsilon\mathcal{H} = g(A_\varepsilon)$ coincides with $A_\varepsilon \wedge (I - A_\varepsilon)$. Indeed, assume that for some $C_\varepsilon \in \mathcal{E}(E_\varepsilon\mathcal{H})$ we have $C_\varepsilon \leqslant A_\varepsilon, I - A_\varepsilon$. Then, letting $C = C_\varepsilon E_\varepsilon \in \mathcal{E}(\mathcal{H})$ it follows that $C \leqslant A, I-A$. Since $D = A \wedge (I-A)$ this implies $C \leqslant D$ and hence $C_\varepsilon \leqslant D_\varepsilon$. Therefore, D_ε coincides with $A_\varepsilon \wedge (I - A_\varepsilon)$.

We finally prove that (i) implies (ii). Assume that (i) holds and (ii) is not true. Then there exists $\varepsilon \in (0, 1/4)$ such that $E_{\varepsilon,1} \neq 0$ and $E_{\varepsilon,2} \neq 0$, where we use the notation as in (3.3). Letting

$$A_{\varepsilon,1} = A|E_{\varepsilon,1}\mathcal{H}, \quad A_{\varepsilon,2} = A|E_{\varepsilon,2}\mathcal{H},$$

and $d = \varepsilon(1 + \sqrt{3})^{-1}$, consider an arbitrary contraction $T \in \mathcal{B}(E_{\varepsilon,2}\mathcal{H}, E_{\varepsilon,1}\mathcal{H})$. In the following all operator matrices are understood with respect to the decomposition $E_{\varepsilon,1}\mathcal{H} \oplus E_{\varepsilon,2}\mathcal{H}$. Then, letting

$$C = \begin{bmatrix} A_{\varepsilon,1} - \mathrm{d}I_{\varepsilon,1} & \sqrt{3}\,\mathrm{d}T \\ \sqrt{3}\,\mathrm{d}T^* & I_{\varepsilon,2} - A_{\varepsilon,2} - \mathrm{d}I_{\varepsilon,2} \end{bmatrix} = \begin{bmatrix} A_{\varepsilon,1} - \varepsilon I_{\varepsilon,1} + \sqrt{3}\,\mathrm{d}I_{\varepsilon,1} & \sqrt{3}\mathrm{d}T \\ \sqrt{3}\,\mathrm{d}T^* & I_{\varepsilon,2} - A_{\varepsilon,2} - \varepsilon I_{\varepsilon,2} + \sqrt{3}\,\mathrm{d}I_{\varepsilon,2} \end{bmatrix}$$
$$= \begin{bmatrix} A_{\varepsilon,1} - \varepsilon I_{\varepsilon,1} & 0 \\ 0 & I_{\varepsilon,2} - A_{\varepsilon,2} - \varepsilon I_{\varepsilon,2} \end{bmatrix} + \sqrt{3}d \begin{bmatrix} I_{\varepsilon,1} & T \\ T^* & I_{\varepsilon,2} \end{bmatrix} \geqslant 0,$$

we have

$$A_\varepsilon - C = \begin{bmatrix} \mathrm{d}I_{\varepsilon,1} & -\sqrt{3}\,\mathrm{d}T \\ -\sqrt{3}\,\mathrm{d}T^* & 2A_{\varepsilon,2} - I_{\varepsilon,2} + \mathrm{d}I_{\varepsilon,2} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 2A_{\varepsilon,2} - I_{\varepsilon,2} - 2\,\mathrm{d}I_{\varepsilon,2} \end{bmatrix} + d \begin{bmatrix} I_{\varepsilon,1} & -\sqrt{3}T \\ -\sqrt{3}T^* & 3I_{\varepsilon,2} \end{bmatrix} \geqslant 0$$

and

$$I - A_\varepsilon - C = \begin{bmatrix} I_{\varepsilon,1} - 2A_{\varepsilon,1} + \mathrm{d}I_{\varepsilon,1} & -\sqrt{3}T \\ -\sqrt{3}\,\mathrm{d}T^* & \mathrm{d}I_{\varepsilon,2} \end{bmatrix} = \begin{bmatrix} I_{\varepsilon,1} - 2A_{\varepsilon,1} - 2\,\mathrm{d}I_{\varepsilon,1} & 0 \\ 0 & 0 \end{bmatrix} + d \begin{bmatrix} 3I_{\varepsilon,1} & -\sqrt{3}T \\ -\sqrt{3}\,\mathrm{d}T^* & I_{\varepsilon,2} \end{bmatrix}$$
$$\geqslant 0.$$

But, the operator

$$(A_\varepsilon \wedge (I_\varepsilon - A_\varepsilon)) - C = g(A_\varepsilon) - C = d \begin{bmatrix} I_{\varepsilon,1} & -\sqrt{3}T \\ -\sqrt{3}T^* & I_{\varepsilon,2} \end{bmatrix}$$

is not non-negative for some choices of T, unless at least one of the spectral projections $E_{\varepsilon,1}$ and $E_{\varepsilon,2}$ is trivial. Since ε is arbitrarily small, it follows that A cannot simultaneously have spectral points in $(0,1/2)$ and $(1/2,1)$. Therefore, (i) implies (ii). □

IV. TWO EXAMPLES

In this section we answer in the negative a question raised in Ref. 19. First we recall how the problem of the existence of the infimum of A and B in $\mathcal{E}(\mathcal{H})$ can be reduced to the infimum problem for some quantum effects and their negations. Assume, in addition, that $\mathrm{Ker}(A+B)=0$. Let f_{A+B} be the affine (that is, linear on convex combinations) mapping defined as in Ref. 9 by

$$f_{A+B}:\{C|0 \leqslant C \leqslant A+B\} \to \{D|0 \leqslant D \leqslant P_{A+B}\}, \tag{4.1}$$

with $C=(A+B)^{1/2}f_{A+B}(C)(A+B)^{1/2}$. By Theorem 2.2 in Ref. 9, f_{A+B} is well defined. Since f_{A+B} is an affine isomorphism, $A\wedge B$ exists if and only if $f_{A+B}(A)\wedge f_{A+B}(B)$ exists. As

$$f_{A+B}(A) + f_{A+B}(B) = f_{A+B}(A+B) = I$$

we are in the situation of Theorem 3.1.

Actually, the following more general fact holds.

Lemma 4.1: Let $A \in \mathcal{E}(\mathcal{H})$, $0 \leqslant C$, $D \leqslant A$, and consider the mapping f_A as defined in (4.1). *Then $C\wedge D$ exists if and only if $f_A(C)\wedge f_A(D)$ exists and, in this case, we have*

$$f_A(C \wedge D) = f_A(C) \wedge f_A(D).$$

Proof: This is a consequence of Theorem 2.5 in Ref. 9. □

By Proposition 2.4, the infimum of A and B exists if and only if the infimum of $A\wedge P_{A,B}$ and $B\wedge P_{A,B}$ exists or, equivalently, the infimum of the restrictions $\widetilde{A} := A\wedge P_{A,B}|P_{A,B}\mathcal{H}$ and $\widetilde{B} := B\wedge P_{A,B}|P_{A,B}\mathcal{H}$ exists. Since $\mathrm{Ker}(\widetilde{A}+\widetilde{B})=\{0\}$, $\widetilde{A}\wedge\widetilde{B}$ exists if and only if $f_{\widetilde{A}+\widetilde{B}}(\widetilde{A})\wedge f_{\widetilde{A}+\widetilde{B}}(\widetilde{B})$ exists, and for the pair $f_{\widetilde{A}+\widetilde{B}}(\widetilde{A}), f_{\widetilde{A}+\widetilde{B}}(\widetilde{B})$ we observe that Theorem 3.1 applies. Therefore, under the additional assumptions that 0 and 1 are not eigenvalues of $f_{\widetilde{A}+\widetilde{B}}(\widetilde{A})$ and $f_{\widetilde{A}+\widetilde{B}}(\widetilde{B})$, $\widetilde{A}\wedge\widetilde{B}$ exists if and only if $A\wedge P_{A,B}$ and $B\wedge P_{A,B}$ are comparable; in this case, $A\wedge B$ coincides with the smaller of the

$A \wedge P_{A,B}$ and $B \wedge P_{A,B}$. For a finite dimensional Hilbert space it was proven in Ref. 19 that the infimum of the operators $A \wedge P_{A,B}$ and $B \wedge P_{A,B}$ exists if and only if they are comparable.

The next example shows that, contrary to the finite dimensional case, we may have two quantum effects B_1 and B_2 for which $B_1 \wedge B_2$ exists, but $(B_1 \wedge P_{B_1,B_2})$ and $(B_2 \wedge P_{B_1,B_2})$ are not comparable.

Example 4.2: Let $\mathcal{H}=L^2[-1,1]$ and A be the operator of multiplication with the square of the independent variable on $\mathcal{H}$, $(Ax)(t)=t^2x(t)$, for all $x \in L^2[-1,1]$. Then A is a non-negative contraction on $\mathcal{H}$, that is, a quantum effect, and the same is its square root $A^{1/2}$, that is, $(A^{1/2}x)(t) = |t|x(t)$, $x \in L^2[-1,1]$. Note that A, and hence $A^{1/2}$, are injective.

Let $\mathbf{1}$ be the constant function equal to 1 on $[-1,1]$, $\theta(t) := \operatorname{sgn}(t)$, and $\chi_\pm := \frac{1}{2}(\mathbf{1} \pm \theta)$, the characteristic functions of $[0, 1]$ and, respectively, $[-1,0]$. All these functions are in $L^2[-1,1]$. Note that $\mathbf{1}$ and θ span the same two dimensional space as $\chi_\pm$. Denote

$$\mathcal{H}_0 = \mathcal{H} \ominus \operatorname{span}\{\mathbf{1}, \theta\} = \mathcal{H} \ominus \operatorname{span}\{\chi_+, \chi_-\}.$$

With respect to the decomposition

$$\mathcal{H} = \mathbb{C}\mathbf{1} \oplus \mathbb{C}\ \theta \oplus \mathcal{H}_0$$

consider two quantum effects C_1 and C_2 on $\mathcal{H}$ defined by

$$C_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{2}I_0 \end{bmatrix}, \quad C_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \frac{1}{2}I_0 \end{bmatrix},$$

where I_0 is the identity operator on $\mathcal{H}_0$. Clearly we have $C_1 + C_2 = I$ and letting

$$B_1 = A^{1/2}C_1A^{1/2}, \quad B_2 = A^{1/2}C_2A^{1/2},$$

we have

$$B_1 + B_2 = A.$$

Comparing the spectra of C_1 and C_2 and using Theorem 3.1, it follows that $C_1 \wedge C_2$ exists, but C_1 and C_2 are not comparable. Therefore, using Lemma 4.1, it follows that $B_1 \wedge B_2$ exists, but B_1 and B_2 are not comparable. In the following we will prove that $P_{B_1,B_2} = I$, that is, $\operatorname{Ran}(B_1^{1/2}) \cap \operatorname{Ran}(B_2^{1/2})$ is dense in $\mathcal{H}$. We divide the proof in several steps.

Step 1: $A^{1/2}\mathcal{H}_0$ is dense in $\mathcal{H}$.

Indeed, let $f \in \mathcal{H} = L^2[-1,1]$ be a function such that for all $h_0 \in \mathcal{H}_0$ we have

$$0 = \langle A^{1/2}h_0, f\rangle = \langle h_0, A^{1/2}f\rangle.$$

Then $A^{1/2}f$ is a linear combination of the functions $\mathbf{1}$ and θ, that is, there exist scalars α and β such that

$$|t|f(t) = \alpha + \beta \operatorname{sgn}(t), \quad t \in [-1,1]$$

and hence

$$f(t) = \frac{\alpha + \beta \operatorname{sgn}(t)}{|t|} = \begin{cases} \dfrac{\alpha+\beta}{t}, & 0 < t \leqslant 1, \\ \dfrac{\beta-\alpha}{t}, & -1 \leqslant t < 0. \end{cases}$$

Since $f \in L^2[-1,1]$ this shows that $f=0$ and the claim is proven.

Let us consider the following linear manifolds in $\mathcal{H}$:

$$\mathcal{F} := \{f \in L^2[-1,1] | f \text{ piecewise constant}\},$$

$$\mathcal{F}_0 := \{f \in \mathcal{F} | \exists\ \varepsilon > 0 \text{ s.t. } f|(-\varepsilon,\varepsilon) = 0, \langle f, \chi_- \rangle = \langle f, \chi_+ \rangle = 0\}.$$

Step 2: $\mathcal{F}_0$ is dense in $\mathcal{H}_0$.

Indeed, to see this, let us first note that $\mathcal{F}_0 \subset \mathcal{H}_0$. If h_0 is an arbitrary vector in $\mathcal{H}_0$ and $\varepsilon > 0$, there exists $f_1 \in \mathcal{F}$ such that

$$\|h_0 - f_1\| \leqslant \frac{\varepsilon}{8} \text{ hence } |\langle h_0 - f_1, \chi_\pm \rangle| \leqslant \frac{\varepsilon}{8}. \tag{4.2}$$

Moreover, there exists $f_2 \in \mathcal{F}$ such that it is zero in a neighbourhood of zero and

$$\|f_1 - f_2\| \leqslant \frac{\varepsilon}{8}. \tag{4.3}$$

Consequently,

$$\|h_0 - f_2\| \leqslant \frac{\varepsilon}{4} \quad \text{and hence } |\langle h_0 - f_2, \chi_\pm \rangle| \leqslant \frac{\varepsilon}{4}. \tag{4.4}$$

Let

$$f_3 = f_2 + 2\chi_{[1/2,1]}\langle h_0 - f_2, \chi_+ \rangle + 2\chi_{[-1,-1/2]}\langle h_0 - f_2, \chi_- \rangle.$$

Then, from the choice of f_2 it follows

$$\langle f_3, \chi_+ \rangle = \langle f_2, \chi_+ \rangle + \langle h_0 - f_2, \chi_+ \rangle = \langle h_0, \chi_+ \rangle = 0$$

and

$$\langle f_3, \chi_- \rangle = \langle f_2, \chi_- \rangle + \langle h_0 - f_2, \chi_- \rangle = \langle h_0, \chi_- \rangle = 0,$$

hence $f_3 \in \mathcal{F}_0$. Finally, from (4.2), (4.3), and (4.4) we get

$$\|h_0 - f_3\| \leqslant \|h_0 - f_1\| + \|f_1 - f_2\| + \|f_2 - f_3\| \leqslant \varepsilon,$$

and the claim is proven.

Finally, we prove the following.

Step 3: $P_{B_1,B_2} = I$, that is, $\mathrm{Ran}(B_1^{1/2}) \cap \mathrm{Ran}(B_2^{1/2})$ is dense in $\mathcal{H}$.

In the following we are using the inverse operator $A^{-1/2}$ on its range. By the preceding claim, $A^{1/2}(A^{-1/2}\mathcal{F}_0)$ is a linear submanifold in $\mathcal{H}_0$ and dense in it. Since the restrictions of C_1 and C_2 to $\mathcal{H}_0$ coincide with $\frac{1}{2}I_0$, it follows that the linear manifolds $C_1A^{1/2}(A^{-1}\mathcal{F}_0)$ and $C_2A^{1/2}(A^{-1}\mathcal{F}_0)$ coincide and are dense in $\mathcal{H}_0$. Consequently, the linear manifolds $A^{1/2}C_1A^{1/2}(A^{-1}\mathcal{F}_0)$ and $A^{1/2}C_2A^{1/2}(A^{-1}\mathcal{F}_0)$ coincide and, by Step 1 and Step 2, they are dense in $\mathcal{H}$. Thus, the linear manifold,

$$\mathcal{L} = B_1(A^{-1/2}\mathcal{F}_0) = B_2(A^{-1/2}\mathcal{F}_0) \subseteq \mathrm{Ran}(B_1) \cap \mathrm{Ran}(B_2) \subseteq \mathrm{Ran}(B_1^{1/2}) \cap \mathrm{Ran}(B_2^{1/2}),$$

is dense in $\mathcal{H}$. This concludes the proof of the last step, and the example.

In order to explain the connection with the characterization of the existence of infimum obtained by Ando in Ref. 2 we consider the comparison of $A \wedge P_{A,B}$ with the *generalized shorted* operator, as considered in Ref. 2.

Lemma 4.3: Let $A, B \in \mathcal{E}(\mathcal{H})$. Then, for any sequence α_n of positive numbers that converge increasingly to infinity, we have

$$\text{SO-}\lim_{n\to\infty}(A:\alpha_n B) \leqslant A \wedge P_{A,B}, \tag{4.5}$$

and the limit does not depend on the sequence (α_n).

Proof: First note that the sequence of positive operators $A:\alpha_n B$ is nondecreasing and bounded by A, cf. Ref. 8. Consequently, the strong operator limit exists and does not depend on the sequence α_n increasing to infinity. We thus can take $\alpha_n=n$. Since the parallel sum is strongly continuous in the second variable with respect to nondecreasing sequences, cf. Theorem 2.6, we have $A:nB\leqslant A$ and, since $\mathrm{Ran}((A:nB)^{1/2})=\mathrm{Ran}(A^{1/2})\cap\mathrm{Ran}(B^{1/2})$ it follows $A:nB\leqslant P_{A,B}$ and hence (4.5) holds. □

Given two positive operators A and B, the *generalized shorted operator* $[B]A$ is defined (see Ref. 1) by

$$[B]A=\lim_{n\to\infty} A:(nB).$$

The main result in Ref. 2 states that the infimum $A\wedge B$ exists if and only $[B]A$ and $[A]B$ are comparable and, in this case, $A\wedge B$ is the smaller of $[A]B$ and $[B]A$. In view of this result and our Example 4.2, it follows that, in general, (4.5) cannot be improved to equality. Here we have a simpler example emphasizing this fact.

Example 4.4: Let $\mathcal{H}=L^2[0,1]$ and A the operator of multiplication with the function t^2. Then A is bounded, contractive, and positive. In addition, $A^{1/2}$ is the operator of multiplication with the independent variable t. Note that both A and $A^{1/2}$ are injective.

Further, let **1** be the function constant 1 in $L^2[0,1]$ and note that it does not belong to the range of either A or $A^{1/2}$. Let C be a non-negative contraction in $\mathcal{H}$ with kernel $\mathbb{C}1$ and define $B=A^{1/2}CA^{1/2}$. Then the operator B is injective and hence its range is dense in $\mathcal{H}$. Since $\mathrm{Ran}(B)\subseteq\mathrm{Ran}(B^{1/2})$ and, by construction, $\mathrm{Ran}(B)\subseteq\mathrm{Ran}(A^{1/2})$ as well, it follows that $\mathrm{Ran}(A^{1/2})\cap\mathrm{Ran}(B^{1/2})$ is dense in $\mathcal{H}$, hence $P_{A,B}=I$.

For each $n\geqslant 1$ consider the function $v_n\in L^2[0,1]$ defined by

$$v_n(t)=\begin{cases}0, & 0\leqslant t\leqslant 1/n,\\ 1/t & 1/n<t\leqslant 1.\end{cases}$$

Note that $A^{1/2}v_n=\chi_{(1/n,1]}$, the characteristic function of the interval $(1/n,t]$. Taking into account that the sequence of functions $\chi_{(1/n,1]}$ converges in norm to the function **1**, it follows that

$$\langle Bv_n,v_n\rangle=\langle CA^{1/2}v_n,A^{1/2}v_n\rangle=\langle C\chi_{(1/n,1]},\chi_{(1/n,1]}\rangle\to\langle C\mathbf{1},\mathbf{1}\rangle=0.$$

Let α_n be a sequence of positive numbers increasing to $+\infty$ and such that $\alpha_n\langle Bv_n,Bv_n\rangle$ converges to 0. It is easy to see that this is always possible. Then using the characterization of the parallel sum as in Theorem 2.6.(vi), for arbitrary $n\geqslant m>2$ we have

$$\begin{aligned}\langle(A:\alpha_nB)v_mv_m\rangle&=\inf\{\langle Au,u\rangle+\alpha_n\langle Bv,v\rangle|v_m=u+v\}=\inf\{\langle A(v_m-v),v_m-v\rangle+\alpha_n\langle Bv,v\rangle|v\in\mathcal{H}\}\\&=\inf\{\langle Av_m,v_m\rangle-2\,\mathrm{Re}\langle Av_m,v\rangle+\langle Av,v\rangle+\alpha_n\langle Bv,v\rangle|v\in\mathcal{H}\}\leqslant\langle Av_m,v_m\rangle\\&\quad-2\,\mathrm{Re}\langle Av_m,v_n\rangle+\langle Av_n,v_n\rangle+\alpha_n\langle Bv_n,v_n\rangle=1-\frac{1}{m}-2+\frac{2}{m}+1-\frac{1}{n}+\alpha_n\langle Bv_n,v_n\rangle\\&=\frac{1}{m}-\frac{1}{n}+\alpha_n\langle Bv_n,v_n\rangle\to\frac{1}{m}<\frac{1}{2}\ \text{as}\ n\to\infty.\end{aligned}$$

On the other hand,

$$\langle Av_m,Av_m\rangle=1-\frac{1}{m}\geqslant\frac{1}{2}.$$

Hence, we have strict inequality in (4.5).

Distinguishing bipartitite orthogonal states using LOCC: Best and worst cases

Michael Nathanson[a)]
Department of Mathematics, Northeastern University, Boston Massachusetts 02115

(Received 7 December 2004; accepted 16 March 2005; published online 16 May 2005)

Two types of results are presented for distinguishing pure bipartite quantum states using local operations and classical communications. We examine sets of states that can be perfectly distinguished, in particular showing that any three orthogonal maximally entangled states in $C^3 \otimes C^3$ form such a set. In cases where orthogonal states cannot be distinguished, we obtain upper bounds for the probability of error using LOCC taken over all sets of k orthogonal states in $C^n \otimes C^m$. In the process of proving these bounds, we identify some sets of orthogonal states for which perfect distinguishability is not possible. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1914731]

I. INTRODUCTION

There is much interest in understanding what can and cannot be achieved using local operations and classical communications (LOCC) on a composite quantum system, pursued with an eye towards applications in communication and cryptography. One of the first and most basic problems in LOCC is that of distinguishing orthogonal quantum states. While some direct applications of this problem do exist (for instance, data hiding[13] and corrected channels[8,9]), these are limited by the usual assumption that no additional entanglement exists between the two parties. However, the problem of LOCC discrimination has proved a fertile area for attempts to better understand the relationship between entanglement and locality, the mysterious interplay that underlies virtually all quantum communication and cryptography protocols. It is in this spirit that the current work is undertaken.

The setup for bipartite LOCC is quite simple: Two parties (by convention Alice and Bob) are physically separate but share a quantum state. Each may perform local quantum operations on his/her piece of the system, but the two may only communicate through a classical channel. In this paper, we will suppose that Alice and Bob share one of a known set of orthogonal states; their task is to determine the identity of this state (even if it is destroyed in the process). Since the possible states are orthogonal, they clearly could be distinguished and preserved were global operations permitted.

The most fundamental and surprising results in this area are those of Walgate *et al.*,[15] that *any* two orthogonal states can be locally distinguished; and of Bennett *et al.*,[2] that there exists a basis of product states that cannot be distinguished with LOCC. These two facts demonstrate that there is no simple relationship between entanglement and locality, which has led to further exploration, e.g., Refs. 10 and 14.

Following the definitive result for two states,[15] work has been done to identify larger sets of orthogonal states that can and cannot be perfectly distinguished with LOCC. Both Refs. 5 and 6 looked at generalized Bell bases in $C^n \otimes C^n$. Fan[5] showed that any k such states can be perfectly distinguished if n is prime and $k(k-1) \leqslant 2n$, in particular, in the case $k=n=3$. The question was posed in Ref. 6 whether *any* three maximally entangled states could be distinguished; we answer this question in the affirmative. We also also give a sufficient condition for perfect distinguish-

[a)]Electronic mail: nathanson.m@neu.edu

ability among maximally entangled states in $C^n \otimes C^n$ using unbiased bases, thus providing an alternative proof of the result in Ref. 5.

It not always possible to perfectly distinguish k orthogonal vectors when $k>2$. For instance, Ghosh *et al.* showed that k generalized Bell states in $C^n \otimes C^n$ cannot be distinguished with LOCC if $k>n$.[6,7] In the second part of this paper we establish lower bounds on the effectiveness of probabilistic LOCC discrimination of orthogonal vectors. If Alice and Bob share one of k arbitrary orthogonal vectors in $C^n \otimes C^n$, what is their guaranteed minimal probability of correctly identifying it? And which sets of states achieve this minimum? These questions have an immediate application to a data hiding setup, as described in Ref. 13 in which a "Boss" can clear prior entanglement between Alice and Bob before giving them pieces of a secret quantum state to work on.

It is shown that for $2 \leqslant k \leqslant 4$, k arbitrary orthogonal vectors in $C^m \otimes C^n$ can be correctly identified with probability at least $2/k$, and this bound is tight. An interesting fact is that this does not depend on the dimension of the overall space—the worst case occurs when the states are embedded in a $C^2 \otimes C^2$ subspace. Our final result translates these ideas into the more familiar language of mutual information and recovers a bound implied by Ref. 1.

The bounds from these propositions identify sets of vectors for which perfect distinguishability is impossible. In particular, we generalize Ref. 6 to show that no k maximally entangled states can be perfectly distinguished if $k>n$. The bounds also lead to the well-known result of Horodecki *et al.*[10] that a complete basis of perfectly distinguishable vectors must be a product basis.

As a final comment, we note the distinction made in Ref. 4 between LOCC protocols that have so-called infinite resources and those that use a finite number of rounds of communication and remain in finite-dimensional ancillary spaces. The results in this paper are established under the assumption that all protocols terminate with probability one and that each ancillary system is finite dimensional.

The paper is organized as follows: In Sec. II we state the results and give the necessary background, and in Secs. III and IV we provide the proofs.

II. STATEMENT OF RESULTS

Following the result in Ref. 15, we would like to identify sets of k orthogonal vectors that can be perfectly distinguished with LOCC for $k>2$. For instance, it is immediate that any three orthogonal states can be perfectly distinguished if two of them are product states. Also, from Ref. 5, any 3 states of a generalized Bell basis of $C^n \otimes C^n$ can be distinguished if $n \geqslant 3$; the question for general maximally entangled vectors in $C^3 \otimes C^3$ is noted but not answered in Ref. 6.

Proposition 1: Any three orthogonal maximally entangled states in $C^3 \otimes C^3$ can be perfectly distinguished using LOCC.

It is not clear whether any 3 orthogonal maximally entangled states are distinguishable in $C^n \otimes C^n$. However, the following proposition gives a sufficient condition for distinguishing maximally entangled states using the idea of mutually unbiased bases, which arise in several areas of quantum information (see, for instance Refs. 11 and 16). The more general notion of a common unbiased basis is not well studied but is defined here for convenience.

Definition 2: Let $\mathcal{A}=\{\mathcal{A}_i : i \in \mathcal{I}\}$ be a family of orthonormal bases of C^n, with $\mathcal{A}_i = \{|a_{i1}\rangle, |a_{i2}\rangle, \ldots, |a_{in}\rangle\}$ and $\mathcal{I}$ some indexing set.

A basis $\mathcal{B}$ of C^n is a common unbiased basis for $\mathcal{A}$ if, for all $|b\rangle \in \mathcal{B}$ and for all $i \in \mathcal{I}$, $1 \leqslant j \leqslant n$:

$$|\langle b|a_{ij}\rangle|^2 = \frac{1}{n}. \tag{1}$$

So, a set of bases $\mathcal{A}$ is mutually unbiased if and only if for all $i \in \mathcal{I}$, $\mathcal{A}_i$ is a common unbiased basis for $\mathcal{A}-\{\mathcal{A}_i\}$.

In the following proposition, we write our states in terms of a (noncanonical) standard maximally entangled state of $C^n \otimes C^n$:

$$|ME_n\rangle := \frac{1}{\sqrt{n}}\sum_{j=0}^{n-1}|j\rangle|j\rangle. \tag{2}$$

Proposition 3: Let $|\Psi_1\rangle, |\Psi_2\rangle, \ldots, |\Psi_k\rangle$ *be orthogonal, maximally entangled vectors in* $C^n \otimes C^n$, *with* $|\Psi_i\rangle = (I \otimes B_i)|ME_n\rangle$.

For each pair (i,j), *let* $\mathcal{A}_{ij}$ *be a basis of eigenvectors of* $B_i^\dagger B_j$, *and let*

$$\mathcal{A} = \{\mathcal{A}_{ij}: 1 \leqslant i < j \leqslant k\}.$$

If the family $\mathcal{A}$ *has a common unbiased basis, then the k states can be perfectly distinguished by LOCC.*

The result is actually more general—we do not require that the states be maximally entangled, only that the matrices $B_i^\dagger B_j$ be diagonalizable. For instance, we could use the same proof to show that any simultaneously diagonalizable orthogonal states can be locally distinguished. These are sets of the form

$$\left\{ |\varphi_i\rangle = \sum_{j=0}^{n-1} u_{ij}|jj\rangle, 1 \leqslant i \leqslant n \right\}, \tag{3}$$

where u is an $n \times n$ unitary matrix.

The main result of Ref. 5 follows from Proposition 3. It involves the generalized Pauli matrices $Z = \Sigma_j e^{2\pi i j/n}|j\rangle\langle j|$ and $X = \Sigma_j |j\rangle\langle j+1|$ and the generalized Bell basis,

$$\mathrm{BB}_n := \{(I \otimes X^m Z^l)|ME_n\rangle : 0 \leqslant m,l \leqslant n-1\} \subset C^n \otimes C^n. \tag{4}$$

Corollary 4 (H. Fan): Let $|\Psi_1\rangle, |\Psi_2\rangle, \ldots, |\Psi_k\rangle$ *be orthogonal, maximally entangled vectors in* $C^n \otimes C^n$, *with n prime and* $|\Psi_i\rangle \in \mathrm{BB}_n$.

Then if $k(k-1)/2 \leqslant n$, *the k vectors can be perfectly distinguished by LOCC.*

Proof: This follows from the fact that for n prime, the eigenbases of $\{X^m Z^l : 0 \leqslant l,m < n\}$ form a maximum set of $(n+1)$ mutually unbiased bases in C^n.[11] Up to a global phase,

$$(X^{m_i}Z^{l_i})^\dagger (X^{m_j}Z^{l_j}) \equiv X^{m_j - m_i} Z^{l_j - l_i}, \tag{5}$$

so the eigenbases of the pairwise products also belong to the set of mutually unbiased bases. As long as the number of pairs (i,j) is less than the number of mutually unbiased bases, then there exists a common unbiased basis and the proposition can be applied. But this is the condition that $k(k-1)/2 < n+1$.

It is not always possible to distinguish maximally entangled states (Ref. 7), which raises the question of how bad it can be (or conversely, what minimal level of success is guaranteed). When perfect discrimination is not possible, one possible strategy is unambiguous discrimination, in which either the correct identity of the state is discovered or else a generic error message is returned. Another strategy is minimum error discrimination, in which the protocol always produces one of the possible states, but this identification might be incorrect. The challenge in this case is to find a protocol that minimizes the probability of error. It is this problem of minimum error discrimination that we will consider throughout the rest of the paper.

Suppose Alice and Bob share one of the orthogonal vectors $\{|\Psi_i\rangle\}$ with *a priori* probabilities $\{p_i\}$. They apply a LOCC protocol, which produces a best guess as to the identity of their state. Define $P(\{|\Psi_i\rangle\}, \{p_i\})$ as the probability that Alice and Bob correctly identify which vector they share, assuming an optimal strategy is used. We are interested in the worst case scenario–what ensembles of k orthogonal vectors are hardest to distinguish using LOCC? Initially, we restrict ourselves to maximally entangled states and define

$$f_{\mathrm{me}}(k,n) := \min_{\{|\Psi_i\rangle\},\{p_i\}} P(\{|\Psi_i\rangle\},\{p_i\}), \tag{6}$$

where the minimum is taken over probability distributions p_i and sets of orthogonal maximally entangled states $\{|\Psi_1\rangle,\ldots,|\Psi_k\rangle\}\subset C^n\otimes C^n$.

We immediately observe that f_{me} is a nonincreasing function in both k and n; as k and n increase, the minimum is taken over larger nested sets. We note that for all n, $f_{\mathrm{me}}(2,n)=1$, since two orthogonal states can always be distinguished by LOCC.[15] Proposition 1 is equivalent to the fact that $f_{\mathrm{me}}(3,3)=1$.

But there are limitations to what can be done if the number of vectors is bigger than the dimension.

Proposition 5: For all $2\leqslant n\leqslant k\leqslant n^2$,

$$\frac{2}{k}\leqslant f_{\mathrm{me}}(k,n)\leqslant\frac{n}{k}. \tag{7}$$

In the case $n=3\leqslant k\leqslant 9$,

$$f_{\mathrm{me}}(k,3)=\frac{3}{k}. \tag{8}$$

.

We can also define a more general function in which we remove the assumption that the states are maximally entangled,

$$f(k,n) := \min_{\{|\Psi_i\rangle\},\{p_i\}} P(\{|\Psi_i\rangle\},\{p_i\}), \tag{9}$$

where the minimum is taken over probability distributions p_i and *all* sets of orthogonal states $\{|\Psi_1\rangle,\ldots,|\Psi_k\rangle\}\subset C^n\otimes C^n$.

Again, f is nonincreasing with respect to n and k and $f(2,n)=1$. Also, for $k\leqslant m^2\leqslant n^2$, k maximally entangled vectors in $C^m\otimes C^m$ can be embedded in $C^n\otimes C^n$, so $f(k,n)\leqslant f_{\mathrm{me}}(k,m)$. The previous results for f_{me} imply bounds on f.

Proposition 6: For $2\leqslant n\leqslant k\leqslant n^2$,

$$\frac{2}{k}\leqslant f(k,n)\leqslant\frac{\lceil\sqrt{k}\rceil}{k}. \tag{10}$$

In particular,

$$f(3,n)=\frac{2}{3},\quad f(4,n)=\frac{1}{2}. \tag{11}$$

.

The function $f(k,n)$ is defined only when the two spaces have the same dimension. We could just as easily have defined $f(k,m,n)$ for k vectors in $C^m\otimes C^n$ and applied Lemma 8 to that. However, we have discovered no bounds on this that do not follow from inclusion; that is, for $m\leqslant n$, the best we can say is

$$f(k,n)\leqslant f(k,m,n)\leqslant f(k,m),\quad k\leqslant m^2, \tag{12}$$

$$f(k,n)\leqslant f(k,m,n)\leqslant\frac{n}{k},\quad m^2<k\leqslant mn. \tag{13}$$

.

We note that for $k \leqslant 4$, $f(k,n)$ is independent of n; the k vectors are most difficult to distinguish when they are squeezed into the smallest possible space. It seems entirely possible that $f(k,n)$ will remain independent of n, even for higher values of k.

Propositions 5 and 6 are proved using the following lemmas. In fact, most of the work goes into the proof of Lemma 8, as it requires us to analyze Alice and Bob's protocol in detail.

Lemma 7: For all $2 \leqslant j \leqslant k \leqslant n^2$,

$$\frac{j}{k} f_{\mathrm{me}}(j,n) \leqslant f_{\mathrm{me}}(k,n), \tag{14}$$

$$\frac{j}{k} f(j,n) \leqslant f(k,n). \tag{15}$$

Lemma 8: Given k equally probable vectors $\{|\Psi_1\rangle, \ldots, |\Psi_k\rangle\} \subset C^m \otimes C^n$, $n \leqslant k \leqslant mn$, *with the property that for each i,* $|\Psi_i\rangle = (I \otimes U_i)|\Psi_1\rangle$ *for* U_i *unitary. Then the k vectors can be distinguished using LOCC with probability that is at most* n/k.

The assumption in Lemma 8 is equivalent to the fact that the C^n party can unilaterally transform $|\Psi_i\rangle$ into $|\Psi_j\rangle$ for any i,j. The lemma includes the special case in which all the states are maximally entangled. Also, note that there is no assumption here that the states are orthogonal, though this is clearly the most interesting case.

Examples: Given a basis of four orthogonal maximally entangled states in $C^2 \otimes C^2$, one naive notion is to ignore two of the possible states and perfectly distinguish the remaining two, thus achieving the lower bound in Lemma 7. Lemma 8 states that this, in fact, is an optimal strategy for identifying the given state. Proposition 6 combines the lemmas to say that this is the worst case for trying to distinguish four orthogonal states.

Likewise, given $k > 3$ orthogonal maximally entangled states in $C^3 \otimes C^3$, one can discard all but three of them and then perfectly distinguish those that remain using Proposition 1. Again, the lemma states that this is optimal. However, for $k=4$ or $k=5$, this succeeds with probability greater than $\frac{1}{2}$ and so is no longer the worst case in $C^3 \otimes C^3$. A worse case would be four equally probable maximally entangled states in a $C^2 \otimes C^2$ subspace.

Finally, we look at an example using the generalized Bell basis BB_n defined in (4). Suppose we wish to distinguish the states in a set $T \subset \mathrm{BB}_n$ with $|T| = k$. If n is prime, then the argument in Ref. 5 implies that Alice and Bob can correctly identify their vectors with probability n/k; Lemma 8 shows that this is in fact optimal.

The following modification of Lemma 8 establishes a necessary condition to distinguish a set of states.

Proposition 9: Given k equally probable vectors $\{|\Psi_1\rangle, \ldots, |\Psi_k\rangle\} \subset C^m \otimes C^n$ *and let* λ_M *be the largest Schmidt coefficient in any of the* $|\Psi_i\rangle$. *Then the k vectors can be distinguished using LOCC with probability that is at most* $\lambda_M mn/k$.

In particular, if k vectors can be perfectly distinguished with LOCC, then $\lambda_M \geqslant k/mn$.

It is interesting to note that in the case of perfect distinguishability, this proposition gives a lower bound on the maximal Schmidt coefficient, while the result of Chen and Li[3] gives an upper bound on the number of nonzero Schmidt coefficients.

The following generalizes the work of Ref. 6 by setting $\lambda_M = 1/n$ above.

Corollary 10: No k maximally entangled states in $C^n \otimes C^n$ *can be perfectly distinguished with LOCC if* $k > n$.

Both Proposition 9 and the result in Ref. 3 imply the fundamental result of Horodecki *et al.*, that a distinguishable basis must be a product basis.[10]

Corollary 11 (Horodecki et al): Let $\{|\Psi_1\rangle, \ldots, |\Psi_{mn}\rangle\}$ *be an orthonormal basis of* $C^m \otimes C^n$, *and suppose these vectors can be perfectly distinguished using LOCC. Then each of the vectors is a product vector*.

To see this as a consequence of Proposition 9, suppose we have have one of the $|\Psi_i\rangle$ with equal probability. Then clearly $\lambda_M = k/mn = 1$. Examining the proof of Proposition 9 reveals that if $|\Psi_i\rangle$ has maximal Schmidt coefficient $\lambda_i < \lambda_M$, then either $P(Z=i)=0$ or else the inequality on $P(Z=V)$ is strict. Neither of these is possible with perfect distinguishability, which means $\lambda_i = \lambda_M = 1$ and $|\Psi_i\rangle$ is a product state for all i.

These types of results are useful in that they allow us to identify classes of sets of k vectors in $C^m \otimes C^n$ that cannot be perfectly distinguished. Also, they provide an upper bound on the probabilities and allow us to deduce optimal strategies for correct identification.

The function $f(k,n)$ is one way of assessing how much information Alice and Bob can gain from LOCC measurements on their vectors. Another approach would be to use the classical mutual information between the identity V of the vector sent and the outcomes of Alice and Bob's measurements. (This idea was explored, for instance, with reference to the specific nine-state ensemble in Ref. 2.) Let Y represent the outcomes of the first $r-1$ measurements and Z indicate the final measurement, i.e., the conclusion as to the value of V, and write

$$I(V;YZ) = H(V) - H(V|YZ), \tag{16}$$

where H is the Shannon entropy.

As we defined $f(k,n)$, we define a function $g(k,n)$ based on mutual information. Assuming that Alice and Bob use optimal measurements, we can consider $I(V;YZ)$ to be the optimal mutual information between the input vector V and the measurement results:

$$g(k,n) \coloneqq \min_{\{|\Psi_i\rangle\}} I(V;YZ). \tag{17}$$

Note that we now assume that all the k vectors are equally likely; there is no sensible lower bound if the entropy of the *a priori* probability distribution is allowed to approach zero.

Proposition 12: The function $g(k,n)$ defined above for $1 < k \leqslant n^2$ satisfies the following bounds:

$$\frac{2}{k}\log 2 \leqslant g(k,n) \leqslant \log\lceil\sqrt{k}\rceil. \tag{18}$$

This proposition is proved as a consequence of Lemma 8. The same upper bound can be seen as a consequence of the following inequality given in Ref. 1:

$$I_{acc}^{\mathrm{LOCC}} \leqslant S(\rho_A) + S(\rho_B) - \sum_i p_i S(\rho_A^i), \tag{19}$$

where I_{acc}^{LOCC} is the classical mutual accessible information using LOCC, S is the von Neumann entropy, $\rho = \Sigma p_i |\Psi_i\rangle\langle\Psi_i|$, and ρ_A and ρ_B are the partial traces.

Let the $|\Psi_i\rangle$ be maximally entangled states in $C^n \otimes C^n$. Then

$$\rho_A^i = \rho_A = \rho_B = \frac{1}{n} I_n, \quad \forall\, i, \tag{20}$$

$$I_{acc}^{\mathrm{LOCC}} \leqslant S(\rho_A) + S(\rho_B) - \sum_i p_i S(\mathrm{Tr}_A(|\Psi_i\rangle\langle\Psi_i|)), \tag{21}$$

$$\leqslant \log n + \log n - \sum_i p_i S(\mathrm{Tr}_A(|\Psi_i\rangle\langle\Psi_i|)) = \log n. \tag{22}$$

This gives another way to see that k maximally entangled states in $C^n \otimes C^n$ cannot be distinguished if $k > n$.

Example: Recall the set BB_n defined in (4); it is a generalized Bell basis for $C^n \otimes C^n$. Suppose Alice and Bob share a state $|\Psi\rangle = (I \otimes X^m Z^l)|\mathrm{ME}_n\rangle$, uniformly chosen from BB_n. Each measures in the standard basis, allowing them to perfectly determine the value of m but giving no information about l.

If at this point they make a guess as to the value of l, they will be correct with probabilty $1/n$, which saturates the inequality in Lemma 8, and hence is optimal for $P(Z=V)$.

Perhaps more surprising, this protocol is also optimal with respect to classical mutual information, as $I(V;YZ) = \log n$ and the proof of the upper bound in Proposition 12 shows that this is maximal.

III. PROOFS OF PROPOSITIONS FOR DISTINGUISHING MAXIMALLY ENTANGLED STATES

A. Preliminaries

As has been previously noted (for instance in Ref. 12), there is one-to-one correspondence between states $|\Psi\rangle \in C^n \otimes C^m$ and $m \times n$ complex matrices B given by $|\Psi\rangle = (I \otimes B)|\mathrm{ME}_n\rangle$, where $|\mathrm{ME}_n\rangle$ is the standard maximally entangled $C^n \otimes C^n$ state defined in (2). Throughout the paper, we will use the following property, which was noted in Ref. 12 and implicitly used in Ref. 15.

Lemma 13: For any $m \times n$ matrix A written in the standard basis,

$$\sqrt{n}(I \otimes A)|\mathrm{ME}_n\rangle = \sqrt{m}(A^T \otimes I)|\mathrm{ME}_m\rangle. \tag{23}$$

In particular, setting $m=1$,

$$\sqrt{n}(I \otimes \langle v|)|\mathrm{ME}_n\rangle = |\overline{v}\rangle \otimes I, \tag{24}$$

where $|\overline{v}\rangle$ denotes the entrywise complex conjugate of $|v\rangle$ in the standard basis.

We adopt the convention of associating states $|\Psi\rangle$ with $\langle\Psi|\Psi\rangle = 1$ and $m \times n$ matrices B with $\mathrm{Tr}\, B^\dagger B = n$. This correspondence has the following immediate properties:

(1) If $|\Psi_i\rangle = (I \otimes B_i)|\mathrm{ME}_n\rangle$ for $i=1,2$, then $\langle\Psi_1|\Psi_2\rangle = 1/n\ \mathrm{Tr}\, B_1^\dagger B_2$.
(2) $\|B^\dagger B\|_\infty = n\lambda_M$, where λ_M is the largest Schmidt coefficient of $|\Psi\rangle$.
(3) $|\Psi\rangle = (I \otimes B)|\mathrm{ME}_n\rangle \in C^n \otimes C^n$ is maximally entangled if and only if B is unitary.

We will use this correspondence throughout what follows.

B. Proof of proposition 1

For $i=1,2,3$, write $|\Psi_i\rangle = (I \otimes B_i)|\mathrm{ME}_3\rangle$ with B_i unitary and $\mathrm{Tr}\, B_i^\dagger B_j = 3\delta_{ij}$. The matrix $B_2^\dagger B_1$ is a traceless 3×3 unitary matrix, so its eigenvalues are $\{1, \omega, \omega^2\}$, with $\omega = e^{i2\pi/3}$. The same is also true for $B_3^\dagger B_2$. We write these matrices in terms of their eigenvectors:

$$B_2^\dagger B_1 = \sum_{i=0}^{2} \omega^i |e_i\rangle\langle e_i|, \quad B_3^\dagger B_2 = \sum_{i=0}^{2} \omega^i |f_i\rangle\langle f_i|. \tag{25}$$

Given $|\Psi_i\rangle$, for i unknown, choose a unitary U and measure the first system in the basis $\{\overline{U}|j\rangle : j = 0,1,2\}$, where $\overline{U}$ indicates the entrywise complex conjugate of U. If the outcome of the measurement is $x \in \{0,1,2\}$, then Lemma 13 implies the state now looks like

$$(\overline{U}|x\rangle\langle x|U^T \otimes I)|\Psi_i\rangle = (\overline{U}|x\rangle\langle x|U^T \otimes B_i)|\mathrm{ME}_n\rangle, \tag{26}$$

$$= (\overline{U}|x\rangle \otimes B_i)(\langle x|U^T \otimes I)|\mathrm{ME}_n\rangle, \tag{27}$$

$$= \frac{1}{\sqrt{n}}(\overline{U}|x\rangle \otimes B_i)(I \otimes U|x\rangle), \tag{28}$$

$$= \frac{1}{\sqrt{n}}\overline{U}|x\rangle \otimes B_i U|x\rangle. \tag{29}$$

In particular, after normalization, the second system is in the state

$$B_i U|x\rangle. \tag{30}$$

We want to show that for an appropriate choice of U, the vectors $\{B_1U|x\rangle, B_2U|x\rangle, B_3U|x\rangle\}$ are orthogonal for all x. The proof is constructive and is achieved in three steps:

(1) Observe that the quantity $|\langle e_i|f_j\rangle|^2$ depends only on $(j-i) \bmod 3$.
(2) Show that we can adjust the phases of the $|e_i\rangle$ and $|f_j\rangle$ so that we may assume that $\langle e_i|f_j\rangle$ depends only on $(j-i) \bmod 3$.
(3) Let our unitary U be the Fourier matrix in the basis $\{|e_i\rangle\}$ and show that the vectors $\{B_1U|x\rangle, B_2U|x\rangle, B_3U|x\rangle\}$ are orthogonal for all x.

The proof of each step is given below. Note that all operations on indices are assumed to be taken modulo 3.

(1) Since $\mathrm{Tr}\, B_3^\dagger B_1 = 0$:

$$0 = \mathrm{Tr}\, B_3^\dagger B_2 B_2^\dagger B_1 = \sum_{i,j} \omega^{i+j}|\langle e_i|f_j\rangle|^2 = \sum_{i,k} \omega^k|\langle e_i|f_{k-i}\rangle|^2. \tag{31}$$

For any $a_k \geqslant 0$, $\Sigma_{k=0}^2 \omega^k a_k = 0$ implies that all the a_k are the same. Therefore,

$$\sum_i |\langle e_i|f_{-i}\rangle|^2 = \sum_i |\langle e_i|f_{1-i}\rangle|^2 = \sum_i |\langle e_i|f_{2-i}\rangle|^2. \tag{32}$$

Combining with the normalization conditions for any i, j,

$$\sum_k |\langle e_k|f_j\rangle|^2 = \sum_k |\langle e_i|f_k\rangle|^2 = 1 \tag{33}$$

gives a linear system of seven independent equations in the nine unknowns $|\langle e_i|f_j\rangle|^2$ whose solutions look like this:

$$(|\langle e_i|f_j\rangle|^2)_{ij} = \begin{pmatrix} |a|^2 & |c|^2 & |b|^2 \\ |b|^2 & |a|^2 & |c|^2 \\ |c|^2 & |b|^2 & |a|^2 \end{pmatrix}. \tag{34}$$

That is, the quantity $|\langle e_i|f_j\rangle|^2$ depends only on $(j-i) \bmod 3$.

(2) Let V be the unitary matrix whose (i,j) entry is given by $\langle e_i|f_j\rangle$. From above, $|V_{i,j}|$ depends only on $(j-i) \bmod 3$. We would like to have $V_{i,j}$ itself depend only on $(j-i) \bmod 3$. We accomplish this by adjusting the phases of $|e_i\rangle$ and $|f_j\rangle$, which is equivalent to finding diagonal unitaries U_1 and U_2 such that

$$V' = U_1 V U_2^\dagger = \begin{pmatrix} a & c & b \\ b & a & c \\ c & b & a \end{pmatrix}, \tag{35}$$

for some $a, b, c \in C$. Write $m_{ij} = \arg(\langle e_i | f_j \rangle)$ and

$$U_1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & e^{i\alpha} & 0 \\ 0 & 0 & e^{i\beta} \end{pmatrix}, \quad U_2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & e^{i\gamma} & 0 \\ 0 & 0 & e^{i\delta} \end{pmatrix}.$$

Solving a system of three linear equations in the phases of the first two columns of V allows us to set

$$\gamma = \frac{1}{3} \sum_{j=0}^{2} (m_{1j} - m_{0j}), \tag{36}$$

$$\alpha = m_{00} - m_{11} + \gamma, \tag{37}$$

$$\beta = m_{01} - m_{20} - \gamma. \tag{38}$$

Put these values into U_1 and U_2 and choose δ to adjust the top right corner, which gets our matrix into the form

$$V' = \begin{pmatrix} a & c & b \\ b & a & ce^{i\delta_1} \\ c & b & ae^{i\delta_2} \end{pmatrix}. \tag{39}$$

The fact that V' is unitary implies its columns are orthogonal, yielding the three equations:

$$\begin{pmatrix} 1 & 1 & 1 \\ e^{i\delta_1} & 1 & e^{i\delta_2} \\ e^{-i\delta_2} & e^{-i\delta_1} & 1 \end{pmatrix} \begin{pmatrix} \overline{ac} \\ \overline{cb} \\ \overline{ba} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}. \tag{40}$$

The determinant of the above matrix cannot be zero unless $e^{i\delta_1} = e^{i\delta_2} = 1$, which means that in fact V' is already in the desired form (35).

Adjusting our matrix V was equivalent to adjusting the phases of the vectors $|e_i\rangle$ and $|f_j\rangle$. Therefore, without loss of generality, we assume that $\langle e_i | f_j \rangle$ depends only on $(j-i) \bmod 3$ and define

$$A_k := \langle e_i | f_{k+i} \rangle, \tag{41}$$

which is independent of i.

(3) For $x \in \{0, 1, 2\}$ define

$$U|x\rangle = \frac{1}{\sqrt{3}} \sum_{i=0}^{2} \omega^{ix} |e_i\rangle. \tag{42}$$

Explicit calculation shows that for all x, the vectors $B_1 U|x\rangle$, $B_2 U|x\rangle$, $B_3 U|x\rangle$ are pairwise orthogonal:

$$3\langle x|U^\dagger B_2^\dagger B_1 U|x\rangle = \sum_k \omega^{-kx}\omega^k\omega^{kx} = 0, \tag{43}$$

$$3\langle x|U^\dagger B_3^\dagger B_2 U|x\rangle = \sum_{k,i,l} \omega^{-kx}\omega^i\omega^{lx}\langle e_k|f_i\rangle\langle f_i|e_l\rangle, \tag{44}$$

$$= \sum_{k,i,l} \omega^{(l-k)x}\omega^i A_{i-k}\overline{A_{i-l}}, \tag{45}$$

$$= \sum_{k',l'} (\omega^{(k'-l')x}A_{k'}\overline{A_{l'}})\sum_i \omega^i = 0, \tag{46}$$

$$3\langle x|U^\dagger B_3^\dagger B_1 U|x\rangle = \langle x|U^\dagger B_3^\dagger B_2 B_2^\dagger B_1 U|x\rangle, \tag{47}$$

$$= \sum_{k,i,l} \omega^{(l-k)x}\omega^{i+l}A_{i-k}\overline{A_{i-l}}, \tag{48}$$

$$= \sum_{k',l'} (\omega^{(k'-l')x}\omega^{-l'}A_{k'}\overline{A_{l'}})\sum_i \omega^{2i} = 0. \tag{49}$$

This proves that, for all x, the vectors $B_1U|x\rangle$, $B_2U|x\rangle$, $B_3U|x\rangle$ are orthogonal and hence can be perfectly distinguished.

C. Proof of proposition 3

Let $\mathcal{B}=\{|b_1\rangle,\ldots|b_n\rangle\}$ be the common unbiased basis. We need to show that for any $i\neq j$ and any k, the vectors $B_i|b_k\rangle$ and $B_j|b_k\rangle$ are orthogonal. Using the eigenbasis $\mathcal{A}_{ij}$, write

$$B_i^\dagger B_j = \sum_s \lambda_s|e_s\rangle\langle e_s|. \tag{50}$$

Then for all k,

$$\langle b_k|B_i^\dagger B_j|b_k\rangle = \sum_s \lambda_s|\langle b_k|e_s\rangle|^2, \tag{51}$$

$$= \frac{1}{n}\sum_s \lambda_s, \tag{52}$$

$$= \frac{1}{n}\mathrm{Tr}\, B_i^\dagger B_j = 0. \tag{53}$$

IV. PROOFS ON THE WORST CASES FOR DISTINGUISHING ORTHOGONAL STATES

Throughout what follows, let V be the true identity of the vector $|\Psi_i\rangle$, and let Z be Alice and Bob's best guess of the value of V, which we assume is also the outcome of the final measurement. Their goal, then, is to maximize $P(Z=V)$.

A. Proof of propositions 5 and 6 using the lemmas

Setting $j=2$ in Lemma 7 gives us the desired lower bounds, since $f_{\mathrm{me}}(2,n)=f(2,n)=1$. As long as $k\leqslant n^2$, there exist k orthogonal maximally entangled vectors in $C^n\otimes C^n$, so Lemma 8 implies that $f_{\mathrm{me}}(k,n)\leqslant n/k$. In the case $k\leqslant 9$, we know $f_{\mathrm{me}}(3,3)=1$ so

$$\frac{3}{k}=\frac{3}{k}f_{\mathrm{me}}(3,3)\leqslant f_{\mathrm{me}}(k,3)\leqslant\frac{3}{k}, \tag{54}$$

so $f_{\mathrm{me}}(k,3)=3/k$. Similarly, if $k\leqslant m^2\leqslant n^2$, then $f(k,n)\leqslant f_{\mathrm{me}}(k,m)$, since we can embed maximally entangled $C^m\otimes C^m$ vectors into $C^n\otimes C^n$. The minimum value of m for which we can do this is $\lceil\sqrt{k}\rceil$, which implies

$$f(k,n)\leqslant\frac{\lceil\sqrt{k}\rceil}{k}. \tag{55}$$

In the case $2\leqslant k\leqslant 4$, $\lceil\sqrt{k}\rceil=2$ and

$$\frac{2}{k}=\frac{2}{k}f(2,n)\leqslant f(k,n)\leqslant\frac{2}{k}, \tag{56}$$

which implies

$$f(k,n)=\frac{2}{k}. \tag{57}$$

B. Proof of lemma 7

We prove the lemma for the function $f(k,n)$; the proof for f_{me} is identical. Given any orthogonal vectors $|\Psi_i\rangle\in\{|\Psi_1\rangle,\ldots,|\Psi_k\rangle\}$ with probabilities $p_1\geqslant p_2\geqslant\cdots\geqslant p_k$. There exists an algorithm that can distinguish the first j of these vectors with probability that is at least $f(j,n)$. Applying this algorithm to the received vector $|\Psi_i\rangle$ cannot succeed if $i>j$, but clearly

$$P(Z=V)\geqslant P(Z=V,i\leqslant j), \tag{58}$$

$$=P(i\leqslant j)P(Z=V|i\leqslant j), \tag{59}$$

$$\geqslant\frac{j}{k}f(j,n), \tag{60}$$

which gives the desired lower bound on $f(k,n)$.

C. Proof of lemma 8

For this proof, we will need to examine the measurement process more closely. As mentioned earlier, we will assume that the protocol terminates with probability 1. In fact, through the calculation, we will assume there exists an r such that the protocol terminates after at most r rounds of communication. Completing the argument for arbitrary r is sufficient. Let R be the actual number of rounds needed to complete to protocol and let p_r be the probability that more than r rounds are needed. Then

$$P(Z=V) = (1-p_r)P(Z=V|R \leqslant r) + p_r P(Z=V|R > r), \tag{61}$$

$$\leqslant P(Z=V|R \leqslant r) + p_r. \tag{62}$$

Our proof will show that for any r, $P(Z=V|R \leqslant r) \leqslant n/k$. Taking the limit as $r \to \infty$, p_r gets arbitrarily small and we can bound $P(Z=V)$ by n/k.

The actions of Alice and Bob will consist of adding ancilla systems, performing unitary operations, and performing measurements. All of these can be encoded into a POVM. Alice measures first; we write her POVM as $\mathcal{X}^T = \{X_1^T, X_2^T, \ldots, X_{k_1}^T\}$. (Because we will eventually apply Lemma 13 to show the effect of Alice's POVM on Bob's system, we write it in terms of the transpose.) Suppose Alice gets the result j_1; then Bob uses a POVM that depends on j_1: $\mathcal{E}_{j_1} = \{E(j_1)_1, E(j_1)_2, \ldots, E(j_1)_{k_2}\}$. Alice then measures in a POVM that depends on j_1 and j_2, and so on. After r rounds of measurement, Alice and Bob have effectively measured, using the POVM,

$$\{(\mathcal{X}^T_{j_1,j_2,\ldots j_{r-1}} \otimes \mathcal{E}_{j_1,j_2,\ldots j_r}) : j_1, j_2, \ldots, j_r \geqslant 0\}, \tag{63}$$

which are defined recursively as in Ref. 2:

$$\begin{aligned} \mathcal{X}^T_{j_1,j_2,\ldots j_{r-1}} &= X^T(j_1, j_2, \ldots, j_{r-2})_{j_{r-1}} \mathcal{X}^T_{j_1,j_2,\ldots j_{r-3}}, \\ \mathcal{E}_{j_1,j_2,\ldots j_r} &= E(j_1, j_2, \ldots, j_{r-1})_{j_r} \mathcal{E}_{j_1,j_2,\ldots j_{r-2}}. \end{aligned} \tag{64}$$

The subscripts show that each measurement depends on the previous outcomes. Here each $X^T(m_0)$ and $E(m_1)$ is a POVM, where m_0 is a vector encoding an even number of previous outcomes and m_1 encodes an odd number. This corresponds to the fact that Alice and Bob alternate measurements, so Alice's action will always depend on an even number of previous results while's Bob's will always depend on an odd number. As usual, we have the normalization

$$\sum_i (X(m_0)_i^T)^\dagger X(m_0)_i^T = I_{d_A(m_0)} = \sum_i X(m_0)_i X(m_0)_i^\dagger, \tag{65}$$

$$\sum_i E(m_1)_i^\dagger E(m_1)_i = I_{d_B(m_1)}, \tag{66}$$

where $d_A(m_0)$ and $d_B(m_1)$ are sufficiently large dimensions to include any ancilla spaces.

Alice and Bob start with the state $|\Psi_i\rangle = (I \otimes B_i)|\mathrm{ME}_n\rangle$ and then apply the POVM above, getting results $m = (j_1, j_2, \ldots, j_{r-1})$ and j_r, for r an even number. Then, using Lemma 13, their state now looks like

$$(\mathcal{X}_m^T \otimes \mathcal{E}_{m,j_r})(I \otimes B_i)|\mathrm{ME}_n\rangle = I \otimes (\mathcal{E}_{m,j_r} B_i \mathcal{X}_m)|\mathrm{ME}_n\rangle. \tag{67}$$

This state is not normalized—its magnitude indicates the probability of this outcome. Without loss of generality, we assume that the final measurement identifies the best guess of the value of V. This gives us a more formal definition of our optimal measurement, where we sum over all outcomes with the final output equal to the correct state identity:

$$P(\{|\Psi_i\rangle\}, \{p_i\}) \coloneqq \sup_{\mathcal{X},\mathcal{E}} P(Z=V), \tag{68}$$

$$P(Z=V)=\sum_i P(Z=V=i), \tag{69}$$

$$=\sum_{i,m} p_i\langle\Psi_i|(\overline{\mathcal{X}}_m\mathcal{X}_m^T\otimes\mathcal{E}_{m,i}^\dagger\mathcal{E}_{m,i}\ |\Psi_i\rangle, \tag{70}$$

$$=\sum_{i,m} p_i\langle \mathrm{ME}_n|(I\otimes\mathcal{X}_m^\dagger B_i^\dagger\mathcal{E}_{m,i}^\dagger\mathcal{E}_{m,i}B_i\mathcal{X}_m\ |\mathrm{ME}_n\rangle \tag{71}$$

$$=\frac{1}{n}\sum_{i,m} p_i\ \mathrm{Tr}(X_m^\dagger B_i^\dagger\mathcal{E}_{m,i}^\dagger\mathcal{E}_{m,i}B_iX_m). \tag{72}$$

The measurements might make use of ancilla systems, so we write P_A and P_B as the projections back onto our original Alice and Bob spaces; since each B_i maps Alice's space to Bob's, we see that $P_BB_i=B_iP_A=B_i$. Recall also that $\mathrm{Tr}\,B_i^\dagger B_i=n$ by assumption.

We may now turn to the lemma, which assumes that $|\Psi_i\rangle=(I\otimes U_iB)|\mathrm{ME}_n\rangle$ with U_i unitary and B fixed. Suppose Alice and Bob make r measurements with the POVMs described in (64). We assume that r is even so Bob measures last—we can always append a trivial measurement to make this so. Suppose that the first $r-2$ measurement outcomes are contained in the vector $m=(j_1,j_2,\ldots,j_{r-2})$. For simplicity we write j_{r-1} as j and assume that $Z=V$ if and only if Bob's final measurement $j_r=i$. Plugging this into (72) and setting $p_i=1/k$ yields

$$P(Z=V)=\frac{1}{kn}\sum_{m,j,i}\mathrm{Tr}(X_m^\dagger B_i^\dagger\mathcal{E}_{m,i}^\dagger\mathcal{E}_{m,i}B_iX_m), \tag{73}$$

$$=\frac{1}{kn}\sum_{m,j,i}\mathrm{Tr}(X_m^\dagger B_i^\dagger P_B\mathcal{E}_{m,i}^\dagger\mathcal{E}_{m,i}P_BB_iX_m), \tag{74}$$

$$\leqslant\frac{1}{kn}\sum_{m,j,i}(\mathrm{Tr}\,P_B\mathcal{E}_{m,j,i}^\dagger\mathcal{E}_{m,j,i}P_B)(\mathrm{Tr}\,B_i\mathcal{X}_{m,j}\mathcal{X}_{m,j}^\dagger B_i^\dagger), \tag{75}$$

$$=\frac{1}{kn}\sum_{m,j,i}(\mathrm{Tr}\,P_B\mathcal{E}_{m,j,i}^\dagger\mathcal{E}_{m,j,i})(\mathrm{Tr}\,B^\dagger B\mathcal{X}_{m,j}\mathcal{X}_{m,j}^\dagger). \tag{76}$$

In (75), we use the fact that for matrices $A,B\geqslant 0$, $\mathrm{Tr}\,AB\leqslant(\mathrm{Tr}\,A)(\mathrm{Tr}\,B)$, and in (76) we use the assumption of the lemma that $B_i=U_iB$. The key observation now is that there is no i in the second term of (76); rewriting the first term as in (64) shows that summing the first term over i yields the identity matrix on the inside, allowing us to drop two subscripts, not just one:

$$\mathrm{Tr}\left(\sum_i P_B\mathcal{E}_{m,j,i}^\dagger\mathcal{E}_{m,j,i}\right)=\mathrm{Tr}\left(\sum_i P_B\mathcal{E}_m^\dagger E(m,j)_i^\dagger E(m,j)_i\mathcal{E}_m\right), \tag{77}$$

$$=\mathrm{Tr}(P_B\mathcal{E}_m^\dagger\mathcal{E}_m). \tag{78}$$

This corresponds to the fact that Alice does nothing during Bob's measurement phase. We now have

$$P(Z=V) \leqslant \frac{1}{kn}\sum_{m,j} (\mathrm{Tr}\, P_B \mathcal{E}_m^\dagger \mathcal{E}_m)(\mathrm{Tr}\, B^\dagger B \mathcal{X}_{m,j} \mathcal{X}_{m,j}^\dagger). \tag{79}$$

Now, there is no j in the first term, only in the second, so we can likewise sum to get the identity on the inner term. Alternating in this way, we can count back through the measurements until they all sum to the identity and we are left with

$$P(Z=V) \leqslant \frac{1}{kn}\mathrm{Tr}(P_B)\mathrm{Tr}(B^\dagger B) = \frac{1}{kn}(n)(n) = \frac{n}{k}. \tag{80}$$

This shows that even if Alice and Bob add ancilla systems to do their measurements, the relevant bound comes from the dimension of Bob's system. This proves the lemma.

D. Proof of proposition 9

In Eq. (75), we insert the projection onto Alice's space P_A and use Hölder's inequality to note that

$$\mathrm{Tr}\, B_i \mathcal{X}_{m,j} \mathcal{X}_{m,j}^\dagger B_i^\dagger = \mathrm{Tr}\, B_i P_A \mathcal{X}_{m,j} \mathcal{X}_{m,j}^\dagger P_A B_i^\dagger, \tag{81}$$

$$\leqslant \|B_i^\dagger B_i\|_\infty \,\mathrm{Tr}\, P_A \mathcal{X}_{m,j} \mathcal{X}_{m,j}^\dagger P_A, \tag{82}$$

$$\leqslant n\lambda_M \,\mathrm{Tr}\, P_A \mathcal{X}_{m,j} \mathcal{X}_{m,j}^\dagger P_A, \tag{83}$$

since $\|B_i^\dagger B_i\|_\infty \leqslant \max_i \|B_i^\dagger B_i\|_\infty = n\lambda_M$. Aside from the new factor of $n\lambda_M$, the rest of the calculation from Lemma 8 remains unchanged, inserting P_A for B so that (80) becomes

$$P(Z=V) \leqslant \frac{1}{kn}(n\lambda_M)\mathrm{Tr}(P_B)\mathrm{Tr}(P_A) = \frac{\lambda_M}{k}(n)(m) = \frac{\lambda_M mn}{k}. \tag{84}$$

E. Proof of proposition 12

The lower bound comes from the idea of tossing out all but two of the vectors and distinguishing them perfectly. At worst, this process gives you $(2/k)\log 2$ bits of information. The upper bound arises in the case of k states to which Lemma 8 applies. The joint probability distribution on (V,Y,Z) must have two properties. First, that the marginal distribution on V is uniform, since the states are equally likely. Second, by relabeling in Lemma 8, we see that for any permutation $\sigma \in S_k$, $P(Z=\sigma(V)) \leqslant n/k$. The set of distributions with these properties is a convex set on which the mutual information is convex. The extreme points of this set are distributions for which Z takes on only n values and Y is a function of Z. Hence the maximum happens at an extreme point and

$$I(V;YZ) \leqslant H(YZ) = H(Z) \leqslant \log n. \tag{85}$$

This implies that the maximum mutual information in this case is $\log n$. Making n as small as possible, we see that

$$g(k,n) \leqslant \log\lceil \sqrt{k} \rceil. \tag{86}$$

V. CONCLUSION

In summary, we have demonstrated that several classes of maximally entangled states that can be distinguished using LOCC. By examining the measurement process itself, we have explored bounds on both the success probability and the mutual information and shown that the well-understood $C^2 \otimes C^2$ Bell basis provides the worst case of three or four vectors with respect to either of these measures. In the process, we have identified some sets of states that cannot be

perfectly distinguished. It is hoped that through better understanding best and worst cases of the distinguishing problem, we can further our understanding of the interplay between locality and entanglement.

On pure states of n quantum bits, the *concurrence entanglement monotone* returns the norm of the inner product of a pure state with its spin-flip. The monotone vanishes for n odd, but for n even there is an explicit formula for its value on mixed states, i.e., a closed-form expression computes the minimum over all ensemble decompositions of a given density. For n even a matrix decomposition $\nu=k_1ak_2$ of the unitary group is explicitly computable and allows for study of the monotone's dynamics. The side factors k_1 and k_2 of this concurrence canonical decomposition (CCD) are concurrence symmetries, so the dynamics reduce to consideration of the a factor. This unitary a phases a basis of entangled states, and the concurrence dynamics of u are determined by these relative phases. In this work, we provide an explicit numerical algorithm computing $\nu=k_1ak_2$ for n odd. Further, in the odd case we lift the monotone to a two-argument function. The *concurrence capacity* of ν according to the double argument lift may be nontrivial for n odd and reduces to the usual concurrence capacity in the literature for n even. The generalization may also be studied using the CCD, leading again to maximal capacity for most unitaries. The capacity of $\nu\otimes I_2$ is at least that of ν, so odd-qubit capacities have implications for even-qubit entanglement. The generalizations require considering the spin-flip as a time reversal symmetry operator in Wigner's axiomatization, and the original Lie algebra homomorphism defining the CCD may be restated entirely in terms of this time reversal. The polar decomposition related to the CCD then writes any unitary evolution as the product of a time-symmetric and time-antisymmetric evolution with respect to the spin-flip. En route we observe a Kramers' nondegeneracy: the existence of a nondegenerate eigenstate of any *time reversal symmetric* n-qubit Hamiltonian demands (i) n even and (ii) maximal concurrence of said eigenstate. We provide examples of how to apply this work to study the kinematics and dynamics of entanglement in spin chain Hamiltonians. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1900293]

I. INTRODUCTION

The entanglement theory of two quantum bits is now well understood. Let ρ be a mixed two-qubit quantum state, described by a 4×4 Hermitian density matrix. Hill and Wootters[22] describe all classes of ρ up to evolution by unitaries in terms of the concurrence. This concurrence

[a)]Electronic mail: stephen.bullock@nist.gov
[b)]Electronic mail: gavin.brennen@nist.gov
[c)]Electronic mail: oleary@cs.umd.edu

is explicitly a function of the eigenvalues of $\rho(\sigma^y)^{\otimes 2}\overline{\rho}(\sigma^y)^{\otimes 2}$, where the factor $\tilde{\rho}=(\sigma^y)^{\otimes 2}\overline{\rho}(\sigma^y)^{\otimes 2}$ may be interpreted as the spin-flip of ρ. Further, for pure states the entropy of the partial trace to either one-qubit subsystem is a one-to-one function of the concurrence, so that both measures agree as to which two-qubit states are more or less entangled. Local states (tensors) are unentangled, while states locally equivalent to Bell states have maximal entropy and concurrence.

For other systems, entanglement theory is more complicated. Even for two *d*-level systems (qudits) it is not typical to use a single function to quantify entanglement,[45] and research into generalized concurrences continues.[20] Instead we focus on the multi-partite qubit case. The key point is that it is not sensible in *n*-qubits to speak of a *unique* maximally entangled state. More precisely, suppose now ρ is a $2^n\times 2^n$ Hermitian density matrix describing a mixed *n*-qubit state. A unitary evolution is given by a $2^n\times 2^n$ unitary matrix, say ν, with the evolution being $\rho\mapsto\nu\rho\nu^\dagger$. A partial ordering of such ρ as more or less entangled follows by stipulating that (i) for $\nu=\otimes_{j=1}^n\nu_j$ local unitary, ρ and $\nu\rho\nu^\dagger$ are equally entangled, while (ii) the ρ becomes no more entangled on average after applying any sequence of local measurements and local unitaries, i.e., after applying local completely positive maps.[23] More entangled is a partial order which has distinct maximal elements for $n\geqslant 3$. For example, in three qubits, two states which are maximally entangled yet locally inequivalent are given as follows:[16]

$$|GHZ\rangle=(1/\sqrt{2})[|000\rangle+|111\rangle],\quad |W\rangle=(1/\sqrt{3})[|001\rangle+|010\rangle+|100\rangle]. \tag{1}$$

There are nine distinct maxima of the partial order in four qubits,[44] and strong theoretical evidence suggests that the number of such *entanglement types* grows quite rapidly with *n* (e.g., Ref. 33).

To quantify multi-partite entanglement, one often uses functions known as entanglement monotones.[3,45] All such monotones must vanish on any local state. A monotone might also vanish on certain entangled states but definitively reports that a state is not local should its value be nonzero. The value on a mixed state ρ is defined to be the minimum over all ensemble decompositions of ρ of the ensemble weighted-average. A monotone is convex on density matrices, since entanglement does not increase under mixing of states. Monotones are also nonincreasing *on average* under local quantum operations and classical communication. Among popular monotones are Meyer's *Q*-measure,[6,32] the Schmidt measure,[18] and certain polynomial invariants[3] of eigenvalues of density matrices representing stochastic mixtures of pure data states.

The *n*-qubit concurrence is an entanglement monotone. To define the monotone, we first note that *throughout* υ refers to the spin-flip of the *n*-qubit state space. Concurrence for a pure state[48] is the component on a pure state of its spin-flip:

$$C_n(|\psi\rangle)=|\langle\psi|\upsilon|\psi\rangle|/\langle\psi|\psi\rangle,$$

where

$$\upsilon|\psi\rangle=\overline{(-i\sigma^y)^{\otimes n}|\psi\rangle}=(-i\sigma^y)^{\otimes n}\overline{|\psi\rangle}. \tag{2}$$

The concurrence of an *n* qubit state with *n* odd vanishes identically. This monotone is noteworthy for two reasons. First, there is an explicit, computable closed-form expression for the minimum $C_n(\rho)$ which is again defined in terms of the eigenvalues of $\rho\tilde{\rho}=\rho(\sigma^y)^{\otimes n}\overline{\rho}(\sigma^y)^{\otimes n}$.[7,42] Second, in the context of concurrence dynamics we may study entanglement dynamics. This paper concerns itself with the latter topic, and we henceforth consider only pure states and unitary maps.

The primary mathematical tool used in this paper is the concurrence canonical decomposition (CCD). This is discussed in detail in Sec. II. Briefly, it is a way to decompose a unitary on *n* qubits into a factor that changes concurrence and factors that do not. Let $\nu:\mathcal{H}_n\rightarrow\mathcal{H}_n$ be a unitary evolution. Consider the CCD $\nu=k_1ak_2$.[8] Now k_1 and k_2 are symmetries of the concurrence, reducing concurrence dynamics to the second factor. This *a* factor applies relative phases to a basis of *GHZ*-like states. Such phases are not unique due to choices of diagonalization while computing the CCD, but the spectrum spec(a^2) is uniquely determined by ν. Moreover, the two-qubit test for maximal entanglement capacity[49] generalizes to *n* qubit concurrence capacities if *n* is even:

Let $\nu = k_1 a k_2$ be a CCD of ν. Consider spec(a^2) as a subset of the unit circle. Then for $n = 2p$, there is a $|\psi\rangle \in \mathcal{H}_n$ with $C_n(|\psi\rangle) = 0$ and $C_n(\nu|\psi\rangle) = 1$ if and only if 0 is within the convex hull of spec(a^2).[8,49]

Also, for even n there is an explicit numerical algorithm for computing the CCD and hence spec(a^2).[8]

This work presents three new results. The first is an extension of concurrence capacities to the case n odd. For n even, the concurrence symmetry group K to which k_1, k_2 belong is up to a similarity transform an orthogonal group. For n odd, K is not orthogonal but symplectic, a has repeat eigenvalues, and $C_{2p-1}(|\psi\rangle) = 0$ for all $|\psi\rangle$. Nonetheless, we define a two-argument lift of the usual concurrence, say $\mathcal{C}(|\phi\rangle, |\psi\rangle)$. [See Eq. (7).] Suppose we define the amount of concurrence an odd-qubit unitary ν creates to be

$$\kappa(\nu) = \max\{\mathcal{C}(\nu|\phi\rangle, \nu|\psi\rangle); \mathcal{C}(|\phi\rangle, |\psi\rangle) = 0\}. \tag{3}$$

This generalized capacity has the following properties:

- For n even, the one-argument concurrence capacity and the two-argument capacity of ν coincide.
- For n odd, often $\kappa_n(\nu) \neq 0$ for the pairwise capacity despite $C_n(|\psi\rangle) \equiv 0$. Further, $\kappa_n(\nu) = 1$ if and only if 0 lies within the convex hull of spec(a^2) for any CCD by $\nu = k_1 a k_2$.
- *Concurrence capacity monotonicity:* Using double argument capacities, the capacity of $\nu \otimes I_2$ is always at least that of ν.

Hence there exists a theory of odd-qubit concurrence dynamics, even though concurrence vanishes identically (on the diagonal) in odd qubits.

Second, we present an explicit numerical algorithm for computing the odd-qubit CCD. Various matrix logarithms must be computed, after which one invokes work in the numerical analysis literature[15] to diagonalize a time reversal symmetric Hamiltonian using symplectic matrices.

We close with the third observation, which we will refer to as *Kramers' nondegeneracy:*

On the n-quantum bit state space, suppose that a υ-time reversal symmetric Hamiltonian H has a nondegenerate eigenstate $|\lambda\rangle$. Then (i) n is even and (ii) $C_n(|\lambda\rangle) = 1$. In particular, $|\lambda\rangle$ is entangled, i.e. $|\lambda\rangle \neq \otimes_{j=1}^{n} |\psi_j\rangle$.

The proof follows from viewing υ as a time reversal symmetry operator in Wigner's axiomatization, a point of view which also simplifies the derivation of the CCD. Kramers' nondegeneracy leads one to wonder whether useful entangled states may be produced by cooling the system of qubits coupled to a υ-time reversal symmetric Hamiltonian. We consider the perturbative stability of this entanglement while breaking the time reversal symmetry here, while the thermal stability of the Kramers' nondegeneracy for the quantum XY model is considered elsewhere.[7]

II. BACKGROUND AND PRIOR WORK

Since our key tool is a generalized canonical decomposition,[8] we review the canonical decomposition literature. The two-qubit canonical decomposition (CD) states that any two-quantum bit unitary evolution ν, i.e., any 4×4 unitary matrix ν, may be written:

$$\nu = e^{i\varphi}(u_1 \otimes u_2) a (u_3 \otimes u_4). \tag{4}$$

Here u_1, u_2, u_3, u_4 are one-qubit (2×2) unitary matrices, which may be chosen to have determinant one. The unitary a is diagonal in the Bell basis and may be thought of as applying relative phases to this basis. However, it is better computationally to think of a as phasing the *magic basis*[4,29] instead:

$$|\mathrm{m}0\rangle = (|00\rangle + |11\rangle)/\sqrt{2}, \quad |\mathrm{m}1\rangle = (|01\rangle - |10\rangle)/\sqrt{2},$$

$$|\mathrm{m}2\rangle = (i|00\rangle - i|11\rangle)/\sqrt{2}, \quad |\mathrm{m}3\rangle = (i|01\rangle + i|10\rangle)/\sqrt{2}. \tag{5}$$

Let E be defined by $E|j\rangle = |\mathrm{m}j\rangle$, and let $\mathrm{SU}(2^n)$ denote the Lie group of determinant one $2^n \times 2^n$ unitary matrices, $\mathrm{SO}(2^n)$ denotes determinant one orthogonal matrices, and $\mathrm{D}(2^n)$ denotes the diagonal $2^n \times 2^n$ unitary matrices. A diagonalization argument shows $\mathrm{SU}(4) = \mathrm{SO}(4)\mathrm{D}(4)\mathrm{SO}(4)$. Moreover, the magic basis has the property that $E^\dagger \mathrm{SU}(2) \otimes \mathrm{SU}(2) E = \mathrm{SO}(4)$, i.e., *determinant one* tensors have real matrix coefficients in the basis. Thus the canonical decomposition may be computed by transforming the diagonalization through E:

$$\mathrm{SU}(4) = [E\mathrm{SO}(4)E^\dagger][E\mathrm{D}(4)E^\dagger][E\mathrm{SO}(4)E^\dagger] = \mathrm{SU}(2) \otimes \mathrm{SU}(2)(E\mathrm{D}(4)E^\dagger)\mathrm{SU}(2) \otimes \mathrm{SU}(2). \tag{6}$$

We next provide a brief account and references for the best known applications and generalizations of the CD.

Makhlin[31] anticipates the canonical decomposition by directly computing that the double cosets $[\mathrm{SU}(2) \otimes \mathrm{SU}(2)] \backslash \mathrm{SU}(4) / [\mathrm{SU}(2) \otimes \mathrm{SU}(2)]$ are parametrized by three real parameters, the number of parameters in a given $\det(a) = 1$. The CD appears explicitly in Kraus and Cirac.[28] In an important paper, Khaneja, Brockett, and Glaser point out that one may view the CD as an example of the $G = KAK$ decomposition theorem for $G = \mathrm{SU}(4)$, $K = \mathrm{SU}(2) \otimes \mathrm{SU}(2)$, and $A = \Delta$ the commutative Lie group that phases the magic (or Bell) basis.[24] They also consider the matrix factorization from the point of view of control theory in order to compute minimum times for applying a given two-qubit unitary evolution. Zhang, Vala, Sastry, and Whaley made use of this observation to describe which 4×4 unitaries ν are equivalent up to tensors of one-qubit rotations. The factor $a \in \Delta$ is not unique but depends on choices of diagonalization, and these are described geometrically using Weyl chambers. Specifically, the Weyl group orbit of any a produces all possible a, and each orbit intersects the Weyl chamber once. For $G = \mathrm{SU}(4)$, the Weyl chamber is a tetrahedron.[49] The terms canonical decomposition and magic basis are by now standard, and there are published surveys (e.g., Ref. 13, Sec. II.B). Moreover, explicit control sequences for two-qubit unitary evolution have been mapped using the CD [Ref. 37, Eq. (B2)].[14] The timing arguments of Khaneja *et al.*[24] have been recently verified in liquid-state NMR.[35]

There are many applications of the two-qubit CD. In addition to timing as above, they include (i) studying the entanglement capacity of two-qubit operations,[49] (ii) building efficient (small) quantum circuits in two qubits,[10,41,43,46] and (iii) classifying which two-qubit computations require fewer than average multiqubit interactions.[41,46]

Besides the CCD,[8] there is another n-qubit generalization of the canonical decomposition due to Khaneja and Glaser.[25] It is also defined in terms of a $G = KAK$ decomposition. Label $N = 2^n$ for the remainder. The type of a $G = KAK$ decomposition follows from a classification theorem of Cartan involutions and determines the groups K and A up to Lie isomorphism. [The classification appears in Helgason (Ref. 21, p. 518, see the same for details).] Given $G = \mathrm{SU}(N)$, the three possible types demand $K \cong \mathrm{SO}(N)$ (type **AI**), $K \cong \mathrm{Sp}(N/2)$ a symplectic group (type **AII**), or $K \cong \mathrm{S}[\mathrm{U}(p) \oplus \mathrm{U}(q)]$ for $p+q=N$ a block unitary (type **AIII**). In the **AII** case, the structure of the A group also demands any $a \in A$ has even-degenerate eigenvalues. The two-qubit canonical decomposition is type **AI**, and indeed the similarity transform by E shows $\mathrm{SU}(2) \otimes \mathrm{SU}(2) \cong \mathrm{SO}(4)$. The CCD alternates **AI** and **AII** as n is even or odd. The KGD of Khaneja and Glaser technically contains two $G = KAK$ decompositions, the first of which is type **AIII** for $n > 2$. In fact, the KGD is similar to the cosine sine decomposition (CSD) of numerical linear algebra[11] and so may be computed numerically. Physically, the $K \cong \mathrm{S}[\mathrm{U}(N/2) \oplus \mathrm{U}(N/2)]$ group of the KGD may be viewed as those unitaries commuting with measurements in the z basis of the least significant qubit, i.e., commuting with $I_{N/2} \otimes \sigma^z$.

We next recall notation from quantum computing. The one-qubit state space is $\mathcal{H}_1 = \mathbb{C}\{|0\rangle\} \oplus \mathbb{C}\{|1\rangle\}$. For n quantum bits, $\mathcal{H}_n = (\mathcal{H}_1)^{\otimes n} = \mathcal{H}_1 \otimes \cdots \otimes \mathcal{H}_1$. (See Ref. 36.) A local state $|\psi\rangle$ is any state which may be written as $\otimes_{j=1}^n |\psi_j\rangle$ for $|\psi_j\rangle \in \mathcal{H}_1$, while an *entangled* state is any state which is not local. Notations such as, e.g., $|7\rangle$ refer not to the state of a qudit but rather to a multiqubit

state, e.g., $|7\rangle = |1\rangle \otimes |1\rangle \otimes |1\rangle$. The *n*-concurrence of Eq. (2) is an entanglement monotone.[8] Besides the well-known two-qubit concurrence,[22] even qubit concurrences *n*-qubits [Ref. 48, Ref. 40—Eq. (62), Ref. 8] have also been studied. Since the single-argument concurrence vanishes for *n* odd, we introduce a two-argument generalization.

For υ per Eq. (2), the *concurrence bilinear form*[8] is the map $\mathcal{C}_n: \mathcal{H}_n \times \mathcal{H}_n \to \mathbb{C}$ given by

$$\mathcal{C}_n(|\phi\rangle, |\psi\rangle) = \overline{\langle \phi | \upsilon | \psi \rangle}. \tag{7}$$

The complex conjugate forces the two-argument function to be complex bilinear rather than complex bi-antilinear, and the concurrence monotone is the norm of the form on the diagonal: $\mathcal{C}_n(|\phi\rangle) = |\mathcal{C}_n(|\phi\rangle, |\phi\rangle)|$. The bilinear form $\mathcal{C}_n$ is symmetric for *n* even and antisymmetric for *n* odd, which causes vanishing of the monotone *but not the form* in the odd-qubit case.

The CD is an example of the $G = KAK$ decomposition theorem (Ref. 21, Theorem 8.6, Sec. VII.8) for $G = \mathrm{SU}(N)$. This theorem produces a decomposition of a reductive Lie group *G* for any θ, $\mathfrak{a}$ as follows:

- The map $\theta: \mathfrak{g} \to \mathfrak{g}$ for $\mathfrak{g} = \mathrm{Lie}(G)$ is a Cartan involution (Ref. 21, Sec. X.6.3, p. 518). By definition,[50] (i) $\theta^2 = \mathbf{1}_{\mathfrak{g}}$ and (ii) $\theta[X, Y] = [\theta X, \theta Y]$ for all $X, Y \in \mathfrak{g}$. As is standard, we write $\mathfrak{g} = \mathfrak{p} \oplus \mathfrak{k}$ for the decomposition of $\mathfrak{g}$ into the -1 and $+1$ eigenspace of θ.
- Given θ, $\mathfrak{a} \subset \mathfrak{p}$ is a commutative subalgebra which is maximal commutative in $\mathfrak{p}$.

Note that $\mathfrak{k}$ is closed under the Lie bracket, while this is trivially true for $\mathfrak{a}$. Thus the exponential of each is a group. Label $K = \exp \mathfrak{k}$, $A = \exp \mathfrak{a}$, where for linear $G \subset GL(n, \mathbb{C})$ the exponential may be interpreted as a matrix exponential. The theorem then asserts that $G = KAK = \{k_1 a k_2; k_1, k_2 \in K, a \in A\}$.

The CD is seen to be an example as follows, cf. Ref. 24. Take $\theta: \mathfrak{su}(4) \to \mathfrak{su}(4)$ by $\theta(X) = (-i\sigma^y)^{\otimes 2} \overline{X} (-i\sigma^y)^{\otimes 2}$ and $\mathfrak{a} = \mathrm{span}_{\mathbb{R}}\{i|0\rangle\langle 0| - i|1\rangle\langle 1| - i|2\rangle\langle 2| + i|3\rangle\langle 3|, i|0\rangle\langle 3| + i|3\rangle\langle 0|, i|1\rangle\langle 2| + i|2\rangle\langle 1|\}$. Extending these choices to *n* qubits produces the CCD:

Definition II.1: [CCD, Ref. 8] Define $\theta: \mathfrak{su}(N) \to \mathfrak{su}(N)$ by $\theta(X) = [(-i\sigma^y)^{\otimes n}]^\dagger \overline{X} (-i\sigma^y)^{\otimes n}$. Then $\mathfrak{k}$ denotes the $+1$-eigenspace of θ while $\mathfrak{p}$ denotes the -1-eigenspace. Finally, in case *n* is even we define

$$\begin{aligned}\mathfrak{a} = \mathrm{span}_{\mathbb{R}}(&\{i|j\rangle\langle j| + i|N-j-1\rangle\langle N-j-1| - i|j+1\rangle\langle j+1| - i|N-j-2\rangle\langle N-j-2|; \quad 0 \leqslant j \leqslant 2^{n-1} \\ &- 2\} \sqcup \{i|j\rangle\langle N-j-1| + i|N-j-1\rangle\langle j|; 0 \leqslant j \leqslant 2^{n-1} - 1\},)\end{aligned} \tag{8}$$

with $A = \exp \mathfrak{a}$. In case *n* odd, we drop the second set:

$$\begin{aligned}\mathfrak{a} = \mathrm{span}_{\mathbb{R}}(&\{i|j\rangle\langle j| + i|N-j-1\rangle\langle N-j-1| - i|j+1\rangle\langle j+1| - i|N-j-2\rangle\langle N-j-2|; \\ &0 \leqslant j \leqslant 2^{n-1} - 2\}).\end{aligned} \tag{9}$$

The *concurrence canonical decomposition (CCD)* in *n*-qubits is the resulting matrix decomposition $\mathrm{SU}(N) = KAK$. Note that *n* may be even or odd.

In an earlier work,[8] computations in Dirac (bra-ket) notation show that $\theta(X)$ is a Cartan involution and $\mathfrak{a}$ is maximal-commutative in $\mathfrak{p}$. The $G = KAK$ theorem (Ref. 21, Theorem 8.6, Sec. VII.8) then shows that the CCD exists. Further, the CCD may be computed numerically in the even qubit case.[8]

The CCD is a useful tool for studying concurrence capacities since $K = \exp(\mathfrak{k})$ consists of symmetries of the concurrence form of Eq. (7), where $\mathfrak{k}$ is given per Definition II.1,[8]

$$(\nu \in K) \Leftrightarrow [\mathcal{C}_n(\nu|\phi\rangle, \nu|\psi\rangle) = \mathcal{C}_n(|\phi\rangle, |\psi\rangle) \text{ for all } |\phi\rangle, |\psi\rangle \in \mathcal{H}_n]. \tag{10}$$

In particular, the above may be used to verify that $\mathrm{SU}(2)^{\otimes n} \subseteq K$ as a subgroup of large codimension. One explanation for the fact that *K* alternates between orthogonal and symplectic groups is to note that the form $\mathcal{C}_n$ is symmetric or antisymmetric as *n* is even or odd.[8] Another outlook,

illustrated in Sec. V, is that the spin-flip υ is a bosonic or fermionic time reversal symmetry operator as n is even or odd, i.e., $\upsilon^{-1}=(-1)^n\upsilon$.

III. ODD-QUBIT CONCURRENCE CAPACITIES

The main results of this section are summarized in Theorem III.11. Each is proven in turn.

A. Double-argument capacities generalize single-argument capacities

To begin, we introduce a pairwise concurrence capacity $\kappa_n(\nu)$ and denote earlier concurrence capacities[8] with a tilde,

$$\begin{aligned}\tilde{\kappa}_n(\nu) &= \max\{\mathcal{C}_n(\nu|\psi\rangle);\langle\psi|\psi\rangle = 1,\mathcal{C}_n(|\psi\rangle) = 0\},\\ \kappa_n(\nu) &= \max\{|\mathcal{C}_n(\nu|\phi\rangle,\nu|\psi\rangle)|;\langle\phi|\phi\rangle = \langle\psi|\psi\rangle = 1,\mathcal{C}_n(|\phi\rangle,|\psi\rangle) = 0\}.\end{aligned} \tag{11}$$

Due to Eq. (10), any CCD of a unitary $\nu=k_1ak_2$ implies $\tilde{\kappa}_n(\nu)=\tilde{\kappa}_n(a)$[8] and $\kappa_n(\nu)=\kappa_n(a)$.

Proposition III.1: Suppose $n=2p$ is an even number of qubits. Then $\kappa_n(\nu)=\tilde{\kappa}_n(\nu)$.

The proof requires certain results from the literature.[8,49]

- There is an $n=2p$ qubit entangler E_0 so that for any $k\in K$, $E_0kE_0^\dagger$ is a real unitary matrix, i.e., orthogonal. The columns of E_0 resemble $|GHZ\rangle$ states.
- For this E_0, any CCD $\nu=k_1ak_2$ moreover has $d=E^\dagger aE$ for $d=\Sigma_{j=0}^{N-1}d_j|j\rangle\langle j|$ diagonal. As d is unitary diagonal, each d_j is on the unit circle within $\mathbb{C}$.
- The concurrence spectrum becomes $\lambda_c(\nu)=\{d_j^2\}_{j=0}^{N-1}$. Then $\tilde{\kappa}_{2n}(\nu)=1$ if and only if $0\in\mathbb{C}$ lies within the convex hull of $\lambda_c(\nu)$, a subset of the unit circle (Ref. 8, Lemma III.2).
- A corollary (Ref. 8, Scho. 2.18) of the symmetry group theorem shows that E_0 also translates between $\mathcal{C}_n(-,-)$ and a simpler bilinear form: $\mathcal{C}_n(E_0z_1,E_0z_2)=z_1^Tz_2$.

Example III.2: We use the CD to compute a two-qubit concurrence capacity. Consider a family of controlled-phase gates, e.g., $\nu(t)=e^{-it}|0\rangle\langle 0|+e^{-it}|1\rangle\langle 1|+e^{-it}|2\rangle\langle 2|+e^{3it}|3\rangle\langle 3|$ with $\det[\nu(t)]=1$. A possible CD is:

$$\nu(t) = (e^{-it\sigma^z}\otimes I_2)e^{it\sigma^z\otimes\sigma^z}(I_2\otimes e^{-it\sigma^z}). \tag{12}$$

The central factor is a valid choice for a in $\nu(t)=k_1ak_2$, since $e^{it\sigma^z\otimes\sigma^z}$ is also diagonal in the magic basis. Thus $\lambda_c[\nu(t)]=\mathrm{spec}(e^{2it\sigma^z\otimes\sigma^z})=\{e^{2it},e^{2it},e^{-2it},e^{-2it}\}$. Only for $t\in\pi/4\mathbb{Z}$ do we have 0 within the convex hull of $\lambda_c[\nu(t)]$, and the convex hull theorem asserts $\tilde{\kappa}_2[\nu(\pi/4)]=1$. Indeed, up to phase $\nu(\pi/4)=|0\rangle\langle 0|+|1\rangle\langle 1|+|2\rangle\langle 2|-|3\rangle\langle 3|$. Moreover, if

$$H=\frac{1}{\sqrt{2}}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}$$

is the Hadamard gate,[36] a standard identity converts $\nu(\pi/4)$ into the quantum controlled-not:

$$\mathrm{CNOT} = |00\rangle\langle 00| + |01\rangle\langle 01| + |10\rangle\langle 11| + |11\rangle\langle 10| = (I_2\otimes H)\,\nu(\pi/4)(I_2\otimes H). \tag{13}$$

Thus $\nu(\pi/4)$ carries an unentangled state to a maximally entangled state, since $\mathrm{CNOT}(H\otimes I_2)|00\rangle=\mathrm{CNOT}(1/\sqrt{2})(|00\rangle+|10\rangle)=(1/\sqrt{2})(|00\rangle+|11\rangle)$. More intricate examples in two-qubits[41,49] and an even number of qubits[9] are available in the literature.

Lemma III.3: Suppose the number of qubits is even. Let $z_1=\Sigma_{j=0}^{N-1}a_j|j\rangle$, $z_2=\Sigma_{j=0}^{N-1}b_j|j\rangle$, and $z_3=\Sigma_{j=0}^{N-1}c_j|j\rangle$ throughout, and let $\lambda_c(\nu)=\{\lambda_j\}_{j=0}^{N-1}$. Then we have the following:

$$\tilde{\kappa}_n(\nu) = \max\left\{\left|\sum_{j=0}^{N-1}c_j^2\lambda_j\right|;z_3^\dagger z_3 = 1, z_3^Tz_3 = 0\right\},$$

$$\kappa_n(\nu) = \max\left\{ \left| \sum_{j=0}^{N-1} a_j b_j \lambda_j \right| ; z_1^\dagger z_1 = z_2^\dagger z_2 = 1, z_1^T z_2 = 0 \right\}. \tag{14}$$

Proof of Lemma III.3: The first equation appears in Ref. 8; cf. Ref. 49. For the second, take vectors z_1, z_2 and label $x=E_0z_1$, $y=E_0z_2$. Then

$$[\mathcal{C}_n(x,y)=0] \Leftrightarrow [\mathcal{C}_n(E_0z_1,E_0z_2)=0] \Leftrightarrow [z_1^T z_2 = 0]. \tag{15}$$

Moreover, without loss of generality by choice of z_1, z_2, and symmetry we may suppose $\nu = E_0 d E_0^\dagger$ for $d^2=\Sigma_{j=0}^{N-1}\lambda_j|j\rangle\langle j|$. Then $\mathcal{C}_n(E_0dE_0^\dagger x, E_0dE_0^\dagger y)=\mathcal{C}_n(E_0dz_1, E_0dz_2)=(z_1^T d^T)dz_2=\Sigma_{j=0}^{N-1}a_jb_j\lambda_j$.

Proof of Proposition III.1: Let a_j, b_j be chosen so as to maximize the expression for $\kappa_n(\nu)$ per Lemma III.3, i.e., $\kappa_n(\nu)=|\Sigma_{j=0}^{N-1}a_jb_j\lambda_j|$. Now choose complex numbers c_j so that $c_j^2=a_jb_j$, and put $z_3=\Sigma_{j=0}^{N-1}c_j|j\rangle$. We note that $z_3^Tz_3=0$. Moreover, $z_3^\dagger z_3 \leqslant 1$, for

$$\sum_{j=0}^{N-1}|c_j|^2 = \sum_{j=0}^{N-1}|c_j^2| = \sum_{j=0}^{N-1}|a_jb_j| \leqslant \sum_{j=0}^{N-1}\frac{1}{2}|a_j|^2 + \frac{1}{2}|b_j|^2 = 1. \tag{16}$$

Label $t^2=z_3^\dagger z_3$, noting $t^2\leqslant 1$. Then $(t^{-1}z_3)^\dagger(t^{-1}z_3)=1$, so by definition of $\tilde{\kappa}_{2p}(\nu)$ we have

$$\kappa_n(\nu) \geqslant \tilde{\kappa}_n(\nu) \geqslant \left| \sum_{j=0}^{N-1} t^{-2}c_j^2\lambda_j \right| = t^{-2}\left| \sum_{j=0}^{N-1} a_jb_j\lambda_j \right| = t^{-2}\kappa_n(\nu). \tag{17}$$

Thus $t=1$ and hence $\kappa_n(\nu)=\tilde{\kappa}_n(\nu)$. □

B. Monotonicity

We next demonstrate concurrence capacity monotonicity, i.e., that $j\mapsto\kappa_{n+j}(\nu\otimes I_2^{\otimes j})$ is monotonic. It provides another justification for odd-qubit concurrence capacities, despite $\mathcal{C}_{2p-1}\equiv 0$. For if $\kappa_{2p-1}(\nu)>0$, then there is a $2p$-qubit state $|\psi\rangle$ with $C_{2p}(|\psi\rangle)=0$ while $C_{2p}[(\nu\otimes I_2)|\psi\rangle] \geqslant \kappa_{2p-1}(\nu)$.

Proposition III.4: Let n be either even or odd, $\nu\in \mathrm{SU}(N)$ an n-qubit computation, and let I_2 denote the trivial one-qubit computation. Then $\kappa_{n+1}(\nu\otimes I_2)\geqslant\kappa_n(\nu)$.

Proof: Choose $|\phi\rangle$, $|\psi\rangle$ such that $\kappa_n(\nu)=\mathcal{C}_n(\nu|\phi\rangle,\nu|\psi\rangle)$ while $\mathcal{C}_n(|\phi\rangle,|\psi\rangle)=0$. Then $|\phi\rangle\otimes|0\rangle$ and $|\psi\rangle\otimes|1\rangle$ are a null-concurrent pair of $(n+1)$-qubit states:

$$\mathcal{C}_{n+1}(|\phi\rangle\otimes|0\rangle,|\psi\rangle\otimes|1\rangle) = \overline{(\langle\phi|\otimes\langle 0|)}(-i\sigma^y)^{\otimes n+1}(|\psi\rangle\otimes|1\rangle) = [\mathcal{C}_n(|\phi\rangle,|\psi\rangle)](\overline{\langle 0|}(-i\sigma^y)|1\rangle). \tag{18}$$

Now $\overline{\langle 0|}(-i\sigma^y)|1\rangle=1$, so the above expression is $[0](1)=0$. A similar argument demonstrates that

$$\mathcal{C}_{n+1}[(\nu\otimes I_2)(|\phi\rangle\otimes|0\rangle),(\nu\otimes I_2)(|\psi\rangle\otimes|1\rangle)] = [\mathcal{C}_n(\nu|\phi\rangle,\nu|\psi\rangle)][\mathcal{C}_1(|0\rangle,|1\rangle)]. \tag{19}$$

The second term of the product is one, while the first is $\kappa_n(\nu)$. Thus we have exhibited a pair for which $\nu\otimes I_2$ raises the pairwise concurrence by at least $\kappa_n(\nu)$. Since $\kappa_{n+1}(\nu\otimes I_2)$ is the maximum over all null-concurrent pairs, while $|\phi\rangle\otimes|0\rangle$, $|\psi\rangle\otimes|1\rangle$ is such, we see $\kappa_{n+1}(\nu\otimes I_2)\geqslant\kappa_n(\nu)$. □

C. Parity-independent concurrence spectra

We extend the maximal concurrence capacity condition of Zhang *et al.* and Bullock, Brennen[8] to odd-qubit systems. The first step is a definition valid in either parity.

Definition III.5: Let $\nu\in\mathrm{SU}(N)$, $N=2^n$. For n of either parity, the concurrence spectrum $\lambda_c(\nu)$ is the set $\lambda_c(\nu)=\mathrm{spec}([(-i\sigma^y)^{\otimes n}]^\dagger\nu(-i\sigma^y)^{\otimes n}\nu^T)$. Viewing ν as an $\mathbb{R}$-linear map, equivalently $\lambda_c(\nu)=\mathrm{spec}(\nu\upsilon\nu^\dagger\upsilon^{-1})$.

We briefly show this coincides with the definition of the even-qubit concurrence spectrum of the literature.[8] The definition ibid. states that the concurrence spectrum is the spectrum of $(E_0^\dagger \nu E_0)(E_0^\dagger \nu E_0)^T$. Indeed, given $E_0 E_0^T = (-i\sigma^y)^{\otimes n}$ per the classification of E with $E\mathrm{SO}(N)E^\dagger = K$ ibid.,

$$\mathrm{spec}(E_0^\dagger \nu E_0)(E_0^\dagger \nu E_0)^T = \mathrm{spec}(E_0^\dagger \nu E_0 E_0^T \overline{E_0}) = \mathrm{spec}[(E_0 E_0^T)^\dagger \nu E_0 E_0^T \nu^T] = \mathrm{spec}[(-i\sigma^y)^{\otimes n} \nu (-i\sigma^y)^{\otimes n} \nu^T]. \tag{20}$$

In fact, the same argument shows that $\lambda_c(\nu)$ is the spectrum $(E^\dagger \nu E)(E^\dagger \nu E)^T$ for any E as above, cf. Ref. 31.

The odd-qubit case requires different similarity matrices, say F,[8] which translate K not into an orthogonal group but rather a symplectic group per Eq. (22). For the concurrence form $\mathcal{C}_n(-,-)$ n-odd is antisymmetric, and symplectic rather than orthogonal groups are the appropriate symmetries of antisymmetric bilinear forms (i.e., two-forms). For a standard similarity matrix, we take

$$F_0 = \sum_{j=0}^{N/2-1} |j\rangle\langle j| + |N-j-1\rangle\langle j| + \iota_j(|j\rangle\langle N/2+j| - |N-j-1\rangle\langle N/2+j|),$$

where

$$\{\iota_j\}_{j=0}^{N/2-1} \subset \{\pm 1\} \text{ by } (-i\sigma^y)^{\otimes n} = \sum_{j=0}^{N/2-1} \iota_j(|N-j-1\rangle\langle j| - |j\rangle\langle N-j-1|). \tag{21}$$

Also, label throughout $J_N = (-i\sigma^y) \otimes I_{N/2}$. Before showing that F_0 translates K into the standard symplectic group, we show that F_0 carries $\mathcal{C}(-,-)$ to the standard two-form $\mathcal{A}(-,-)$.

Lemma III.6: For $\mathcal{A}(|\phi\rangle, |\psi\rangle) = \overline{\langle\phi|}\, J_N |\psi\rangle$, $\mathcal{C}_n(F_0|\phi\rangle, F_0|\psi\rangle) = \mathcal{A}(|\phi\rangle, |\psi\rangle)$ *for all* $|\phi\rangle, |\psi\rangle \in \mathcal{H}_n$.

Proof: $\mathcal{C}_n(F_0|\phi\rangle, F_0|\psi\rangle) = \overline{\langle\phi|} F_0^T (-i\sigma^y)^{\otimes n} F_0 |\psi\rangle$. Now $F_0 J_N F_0^T = (-i\sigma^y)^{\otimes n}$ [Ref. 8, Proposition II.14], whence $F_0^T (-i\sigma^y)^{\otimes n} F_0 = J_N$. □

Now $\mathrm{Sp}(N/2)$ is that copy of the symplectic group which embeds within $\mathrm{SU}(N)$ as the symmetries of $\mathcal{A}(-,-)$, i.e., satisfying $\mathcal{A}(\nu|\phi\rangle, \nu|\psi\rangle) = \mathcal{A}(|\phi\rangle, |\psi\rangle)$ for all $|\phi\rangle, |\psi\rangle \in \mathcal{H}_n$. In block form:

$$\begin{aligned} \mathrm{Sp}(N/2) &= \{\nu \in \mathrm{SU}(N); \nu^T J_N \nu = J_N\} \\ &= \left\{ \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \mathrm{SU}(N); \begin{matrix} A^T C \text{ is symmetric}, B^T D \text{ is symmetric}, \\ A^T D - C^T B = I \end{matrix} \right\} \end{aligned} \tag{22}$$

As $E_0 \mathrm{SO}(N)\ E_0^\dagger = K_{2p}$, so too $F_0 \mathrm{Sp}(N/2)\ F_0^T = K_{2p-1}$.

We next associate $\lambda_c(\nu)$ to $\mathrm{spec}(a^2)$ for $\nu = k_1 a k_2$ in the odd-qubit case. Suppose we label D to be the following diagonal subalgebra of $\mathrm{SU}(N)$:

$$D = \left\{ \sum_{j=0}^{N/2-1} d_j(|j\rangle\langle j| + |N/2+j\rangle\langle N/2+j|);\ \prod_{j=0}^{N/2-1} d_j = \pm 1 \right\}. \tag{23}$$

Now there is a standard $\mathrm{SU}(N) = KAK$ decomposition which follows from $\theta_{\mathbf{AII}}(iH) = J_N(-iH^T)J_N^\dagger$ (Ref. 21, Sec. X.2, p. 452) and $\mathfrak{a} = \log D$ as above. Given a $\nu \in \mathrm{SU}(2^{2p-1})$, it writes $\nu = \omega_1 d \omega_2$, with $\omega_j \in \mathrm{Sp}(N/2)$, $j = 1,2$ and $d \in D$.

Suppose given $\nu \in \mathrm{SU}(2^{2p-1})$, we then write $F_0^T \nu F_0 = \omega_1 d \omega_2$, with $\omega_j \in \mathrm{Sp}(N/2)$, $j = 1,2$ and $d \in D$. The odd-qubit CCD again follows by a similarity transform: $\nu = (F_0 \omega_1 F_0^T)(F_0 d F_0^T) \times (F_0 \omega_2 F_0^T)$ with $a = F_0 d F_0^T \in A$, $k_j = F_0 \omega_j F_0^T \in K$, $j = 1,2$ is a CCD. Note that a is diagonal on the *GHZ*-like basis states $\{F_0|j\rangle\}$.

Lemma III.7: Let $n = 2p-1$. *Then for* $\nu = (F_0 \omega_1 F_0^T)(F_0 d F_0^T)(F_0 \omega_2 F_0^T)$ *the CCD as above with* $d = \sum_{j=0}^{N/2-1} d_j(|j\rangle\langle j| + |N/2+j\rangle\langle N/2+j|)$ *diagonal and determinant one, we have* $\lambda_c(\nu) = \{d_j^2\}_{j=0}^{N/2-1} \sqcup \{d_j^2\}_{j=0}^{N/2-1}$ (*counted with multiplicity*.)

Proof: Given A, B, invertible, $\mathrm{spec}(AB)=\mathrm{spec}(BA)$. Also, Eq. (10) is equivalent to a matrix equation $k^T(-i\sigma^y)^{\otimes n}k=(-i\sigma^y)^{\otimes n}$ for all $k\in K$. Recall $F_0J_NF_0^T=(-i\sigma^y)^{\otimes n}$. Then

$$\begin{aligned}\lambda_c(\nu) &= \mathrm{spec}([(-i\sigma^y)^{\otimes n}]^\dagger \nu(-i\sigma^y)^{\otimes n}\nu^T) = \mathrm{spec}([(-i\sigma^y)^{\otimes n}]^\dagger k_1 a k_2(-i\sigma^y)^{\otimes n}k_2^T a^T k_1^T)\\ &= \mathrm{spec}(k_1^T[(-i\sigma^y)^{\otimes n}]k_1 a k_2[(-i\sigma^y)^{\otimes n}]^T k_2^T a^T) = \mathrm{spec}(k_1^T[(-i\sigma^y)^{\otimes n}]k_1 a[k_2^T(-i\sigma^y)^{\otimes n}k_2]^T a^T)\\ &= \mathrm{spec}([(-i\sigma^y)^{\otimes n}]a[(-i\sigma^y)^{\otimes n}]^T a^T) = \mathrm{spec}(-[F_0J_NF_0^T]F_0 d F_0^T[F_0J_NF_0^T]F_0 d^T F_0^T)\\ &= \mathrm{spec}(-F_0J_N d J_N d^T F_0^T) = \mathrm{spec}(-J_N d J_N d) = \mathrm{spec}(d^2). \end{aligned} \tag{24}$$

The last equality makes use of $d\in D$ repeat diagonal. □

D. A convex hull argument in odd qubits

Definition III.8: Suppose $n=2p-1$. The *reduced concurrence spectrum* $\tilde{\lambda}_c(\nu)$ of $\nu\in \mathrm{SU}(N)$ is the set $\{\lambda_j\}_{j=0}^{N/2-1}$ for $\nu=k_1(F_0dF_0^T)k_2$ a canonical decomposition of ν and $d=\Sigma_{j=0}^{N/2-1}\sqrt{\lambda_j}(|j\rangle\langle j|+|N/2+j\rangle\langle N/2+j|)$. The *convex hull* $\mathrm{CH}[\tilde{\lambda}_c(\nu)]$ of $\tilde{\lambda}_c(\nu)$ is the set of convex linear combinations of the points of $\tilde{\lambda}_c(\nu)$, i.e.,

$$\mathrm{CH}[\tilde{\lambda}_c(\nu)] = \left\{ \sum_{j=0}^{N/2-1} t_j\lambda_j; 0\leqslant t_j\leqslant 1,\ \sum_{j=0}^{N/2-1} t_j = 1, \lambda_j\in\tilde{\lambda}_c(\nu)\right\}. \tag{25}$$

Proposition III.9: Suppose $n=2p-1$ is an odd number of qubits. Throughout, label $z_1=\Sigma_{j=0}^{N-1}a_j|j\rangle$, $z_2=\Sigma_{j=0}^{N-1}b_j|j\rangle$, and $\tilde{\lambda}_c(\nu)=\{\lambda_j\}_{j=0}^{N/2-1}$. Then the following hold:

- $\kappa_n(\nu)=\max\{|\Sigma_{j=0}^{N/2-1}\lambda_j(a_{N/2+j}b_j-a_jb_{N/2+j})|; z_1^TJ_Nz_2=0, z_1^\dagger z_1=z_2^\dagger z_2=1\}$,
- $(\kappa_n(\nu)=1)\Leftrightarrow(0\in\mathrm{CH}[\tilde{\lambda}_c(\nu)])$.

Proof: The first item follows from Lemma III.6, substituting $x=F_0z_1$, $y=F_0z_2$. We continue to the next item.

For the second item, we first prove $\Rightarrow$. If $\kappa_n(\nu)=1$, then we may choose z_1, z_2 so that

$$\begin{aligned} 1 &= \left|\sum_{j=0}^{N/2-1}\lambda_j(a_{N/2+j}b_j-a_jb_{N/2+j})\right| \leqslant \sum_{j=0}^{N/2-1}|a_{N/2+j}b_j-a_jb_{N/2+j}|\\ &\leqslant \sum_{j=0}^{N/2-1}\sqrt{|a_j|^2+|a_{N/2+j}|^2}\sqrt{|b_j|^2+|b_{N/2+j}|^2}\leqslant 1. \end{aligned} \tag{26}$$

Here, note that the second inequality is an iterate of $\mathcal{C}_1(|\phi\rangle,|\psi\rangle)\leqslant\sqrt{\langle\phi|\phi\rangle\langle\psi|\psi\rangle}$, for all $|\phi\rangle,|\psi\rangle\in\mathcal{H}_1$. The last inequality in Eq. (26) is the Schwarz inequality.

Now label $\alpha_j=a_{N/2+j}b_j-a_jb_{N/2+j}$, for $0\leqslant j\leqslant N/2-1$. Then by Eq. (26),

$$1 = \left|\sum_{j=0}^{N/2-1}\lambda_j\alpha_j\right| = \sum_{j=0}^{N/2-1}|\lambda_j\alpha_j| = \sum_{j=0}^{N/2-1}|\alpha_j|. \tag{27}$$

Thus there must exist some $z\in\mathbb{C}$, $z\bar{z}=1$, so that $\lambda_j\alpha_j=z|\alpha_j|$, and moreover $\Sigma_{j=0}^{N/2-1}|\alpha_j|=1$. On the other hand, $z_1^TJ_Nz_2=0$ demands that $0=\Sigma_{j=0}^{N/2-1}\alpha_j=z\Sigma_{j=0}^{N/2-1}|\alpha_j|\bar{\lambda}_j$. Multiplying by $\bar{z}$ and taking the complex conjugate, $0=\Sigma_{j=0}^{N/2-1}|\alpha_j|\lambda_j$ which given $\Sigma_{j=0}^{N/2-1}|\alpha_j|=1$ by Eq. (27) demands $0\in\mathrm{CH}[\tilde{\lambda}_c(\nu)]$.

Consider now the converse case, i.e., $0\in\mathrm{CH}[\tilde{\lambda}_c(\nu)]$. Then there exist t_j real, non-negative so that $0=\Sigma_{j=0}^{N/2-1}t_j\lambda_j$. For $0\leqslant j\leqslant N/2-1$, label complex numbers $\alpha_j=t_j\bar{\lambda}_j$, so that we have $1=\Sigma_{j=0}^{N/2-1}|\alpha_j|$ and moreover $0=\bar{0}=\Sigma_{j=0}^{N/2-1}t_j\bar{\lambda}_j=\Sigma_{j=0}^{N/2-1}\alpha_j$. We are reduced to the following question: May we choose $\{a_j\}_{j=0}^{N-1}$, $\{b_j\}_{j=0}^{N-1}$ so that

$$\alpha_j = a_{N/2+j}b_j - a_j b_{N/2+j}, \quad \sum_{j=0}^{N-1} |a_j|^2 = \sum_{j=0}^{N/2-1} |b_j|^2 = 1. \tag{28}$$

To do this, write $\alpha_j = |\alpha_j| e^{i \arg \alpha_j}$, and take $a_j = \sqrt{|\alpha_j|}$, $a_{N/2+j} = 0$, $b_j = 0$, and $b_{N/2+j} = -e^{i \arg \alpha_j}\sqrt{|\alpha_j|}$. Then we see that $a_{N/2+j}b_j - a_j b_{N/2+j} = \alpha_j$. Moreover,

$$|a_j|^2 + |a_{N/2+j}|^2 = |\alpha_j|, \quad |b_j|^2 + |b_{N/2+j}|^2 = |\alpha_j|, \quad \sum_{j=0}^{N/2-1} |\alpha_j| = 1. \tag{29}$$

Thus the vectors z_1, z_2 per the statement of the proposition are normalized to be norm one. □

Hence, as in the even-qubit case, a convex hull criterion on the middle factor of the CCD determines which odd-qubit unitaries ν have concurrence capacity equal to the maximal possible capacity, i.e., one. The new feature, doubly degenerate eigenvalues in $\lambda_c(\nu)$ arising from the D above required for type **AII** will *a posteriori* be an instance of Kramers' degeneracy; see Sec. V.

Corollary III.10: For $n = 2p-1$, $\lim_{p\mapsto\infty} da(\{a \in A; \kappa_n(a) = 1\}) = 1$.

The proof of the Corollary follows by considering probability density functions on the unit circle,[8] given that the number of concurrence eigenvalues grows exponentially with n. Thus most unitary evolutions for large n (of either parity) are maximally entangling as measured by concurrence. It would be interesting but technically challenging to restate this in terms of Haar measure du on SU(N). The difficulty is that the pullback measure from the $K \times A \times K$ to SU(N) is singular, namely singular near the set where the A factor is an identity. For future reference, we summarize the concurrence capacity results of this section.

Theorem III.11: *Let* $\kappa_n(\nu)$, $\tilde{\kappa}_n(\nu)$ *be the pairwise concurrence capacity and concurrence capacity, respectively*.

1. *The pairwise capacity and the capacity are equal in any even number of qubits. Thus,*

$$\tilde{\kappa}_n(\nu) = \begin{cases} \kappa_n(\nu), & n = 2p \text{ even} \\ 0, & n = 2p-1 \text{ odd}. \end{cases} \tag{30}$$

2. *For n either even or odd, any CCD by* $\nu = k_1 a k_2$ *satisfies* $\kappa_n(\nu = k_1 a k_2) = \kappa_n(a)$.
3. *For any n, we must have* $\kappa_{n+1}(\nu \otimes I_2) \geqslant \kappa_n(\nu)$.
4. *Suppose* $n = 2p-1$ *is odd. Then for da the Haar measure on A,*

$$\lim_{p\mapsto\infty} \mathrm{Prob}(\kappa_n(a) = 1) = \lim_{p\mapsto\infty} da(\{a \in A; \kappa_n(a) = 1\}) = 1. \tag{31}$$

IV. AN ALGORITHM COMPUTING THE ODD-QUBIT CCD

In this section, we close a gap in the literature. Specifically, we present an algorithm for computing the CCD when the number of qubits is odd. We make use of an algorithm[15] by Dongarra, Gabriel, Koelling, and Wilkinson cited in a survey[12] of diagonalization arguments. The algorithm,[15] which appears in the numerical matrix analysis literature, improves the numerical stability and computational efficiency of the earlier work on time reversal by Dyson.[17]

Recall from Sec. III C that it suffices to compute the standard type **AII** *KAK* decomposition given by SU(N) = Sp($N/2$)DSp($N/2$) with D the repeat diagonal subgroup of SU(N). For given $\nu \in \mathrm{SU}(2^{2p-1})$ for which we wish to compute the CCD, suppose we obtain $F_0^T \nu F_0 = \omega_1 d \omega_2$, with $\omega_j \in \mathrm{Sp}(N/2)$, $j = 1, 2$ and $d \in D$. Then ν will have CCD $\nu = k_1 a k_2 = (F_0 \omega_1 F_0^T)(F_0 d F_0^T)(F_0 \omega_2 F_0^T)$. Before computing SU($N$) = Sp($N/2$)$D$Sp($N/2$), we make one new definition.

Definition IV.1: Let $H \in \mathbb{C}^{N\times N}$ be Hermitian. Recall $J_N = (-i\sigma^y) \otimes I_{N/2}$. We say that the Hamiltonian H is J_N*-skew symmetric* iff $HJ_N - J_N H^T = 0$.

Remark IV.2: In Ref. 15, the above is the definition of "H has a time reversal symmetry." Indeed, time reversal symmetry follows for the operator $\Theta = J_N \tau$, (τ complex conjugation) per the upcoming Definition V.1. Moreover, for the standard type **AII** Cartan involution (Ref. 21, p. 452)

$\theta_{\mathbf{AII}}(X)=J_N\overline{X}J_N^T$, let $\mathfrak{su}(N)=\mathfrak{p}_{\mathbf{AII}}\oplus\mathfrak{k}_{\mathbf{AII}}$ for the corresponding Cartan decomposition into -1 and $+1$ eigenspaces. Then H is J_N skew-symmetric if and only if $iH\in\mathfrak{p}_{\mathbf{AII}}$. Indeed on $\mathfrak{su}(N)$, $\overline{X}=-X^T$. Hence $-iH=J_N\overline{iH}J_N^T=-J_NiH^TJ_N^T$ if and only if $HJ_N=J_NH^T$.

A. Algorithm for the standard AII *KAK* decomposition, SU(*N*)=Sp(*N*/2)*D*Sp(*N*/2)

The outline below for computing the standard $\mathrm{SU}(N)=KAK$ decomposition of type **AII** (see Sec. III C) is similar to the **AI** case used in Ref. 8 to compute the even-qubit CCD. The added difficulties are (i) a more complicated formula for p^2 and (ii) a more delicate diagonalization argument for p^2 once computed. In fact, the latter requires the symplectic diagonalization argument referenced above.

Lemma IV.3: Suppose $\nu\in\mathrm{SU}(N)$ *with* $\nu=pk$ *for* $p=\exp(iH)$ *with H a* J_N *skew-symmetric Hamiltonian and* $k\in\mathrm{Sp}(N/2)$. *Then* $p^2=-\nu J_N\nu^TJ_N$.

Proof: We have $H^T=-J_NHJ_N$, given $J_N^\dagger=J_N^T=-J_N$. Thus for any $t\in\mathbb{R}$, $[\exp(iHt)]^T=J_N^\dagger\exp(iHt)J_N=-J_N\exp(iHt)J_N$. This holds in particular for p. Now put $w=\nu^\dagger$, so that $w=\tilde{k}\tilde{p}$ for $\tilde{k}=k^\dagger$, $\tilde{p}=p^\dagger$. Thus $\tilde{p}^T=J_N^\dagger\tilde{p}J_N$. Moreover, $k\in\mathrm{Sp}(N/2)$ demands $\tilde{k}^TJ_N\tilde{k}=J_N$, as $\mathrm{Sp}(N/2)$ is a group. Thus $-J_Nw^TJ_Nw=\tilde{p}^2$. Taking the adjoint of each side produces the result. □

With this lemma, we now present the algorithm for computing the standard type **AII** decomposition.

1. Suppose $\nu=pk$ per Lemma IV.3. Compute $p^2=-\nu J_N\nu^TJ_N$.
2. We may write $p=\exp(iH)$ for some J_N skew-symmetric Hamiltonian H. Compute a logarithm of $p^2=\exp(2iH)$. The diagonalizing matrix implicit in computing the matrix log need not be symplectic, and generic logarithms will take the form $2iH$ for some $(2)H$ which is J_N skew-symmetric.
3. Compute a symplectic matrix $\omega_1\in\mathrm{Sp}(N/2)$ so that $iH_2=\omega_1^\dagger(iH)\omega_1$ is repeat diagonal, per Sec. IV B.
4. Label $p=\omega_1\exp(iH_2)\omega_1^\dagger$ and $d=\exp(iH_2)$. Compute $\omega_3=p^\dagger\nu$. Then $\omega_3\in\mathrm{Sp}(N/2)$.
5. Put $\omega_2=\omega_1^\dagger\omega_3\in\mathrm{Sp}(N/2)$. Note that $\omega_1d\omega_1^\dagger=p$. Thus the type **AII** decomposition is $\nu=[\omega_1]\times[d][\omega_1^\dagger\omega_3]=\omega_1d\omega_2$.

This concludes the overview of computing $\mathrm{SU}(N)=\mathrm{Sp}(N/2)D\mathrm{Sp}(N/2)$. The next section details step 3.

B. Symplectic diagonalization

In this section we address the problem of finding the eigendecomposition of a matrix H which is J_N skew-symmetric. Generically, these techniques work on any square matrix with an even number of rows and columns, and there are no simplifications when the size is a power of two. Thus we describe the generic case where

$$J_{2\ell}=\begin{pmatrix}\mathbf{0} & -I_\ell\\ I_\ell & \mathbf{0}\end{pmatrix}$$

and $H=H^\dagger$ is also $J_{2\ell}$ skew symmetric.

Explicitly, $J_{2\ell}$-skew symmetric means

$$H=\begin{pmatrix}A & B\\ -\overline{B} & \overline{A}\end{pmatrix},$$

where $A=A^\dagger$ and $B=-B^T$ are $\ell\times\ell$ matrices. We will construct a unitary skew-symmetric Hamiltonian matrix ω of the form

$$\omega = \begin{pmatrix} U & V \\ -\overline{V} & \overline{U} \end{pmatrix},$$

so that the columns of ω are the (right) eigenvectors of H. Each eigenvalue λ_k for $k=1,\ldots,\ell$ of H is real and of multiplicity 2. In particular, both the kth and the $(\ell+k)$th columns of ω are eigenvectors of H corresponding to λ_k. Also, given the block form, $\omega \in \mathrm{Sp}(N/2)$ up to global phase.

The algorithm of Dongarra *et al.*[15] proceeds in two major steps. First we reduce H to block diagonal form using a similarity transformation, and then we use the QR algorithm to find the eigenvalues of the blocks. We consider each of these phases in turn.

First, we construct a skew-symmetric Hamiltonian unitary matrix Q of the form

$$Q = \begin{pmatrix} Q_1 & Q_2 \\ -\overline{Q_2} & \overline{Q_1} \end{pmatrix}$$

so that

$$QHQ^\dagger = \begin{pmatrix} T & 0 \\ 0 & T \end{pmatrix}$$

where T is real, symmetric, and tridiagonal. We initialize Q to be the $2\ell \times 2\ell$ identity matrix. In order to preserve the structure, we construct Q as the product of two simple types of matrices:

- The product of 2×2 skew-symmetric Hamiltonian matrices is also skew-symmetric Hamiltonian, and if we let $r^2=|a|^2+|b|^2$, then a matrix of the form

$$\begin{pmatrix} \overline{a}/r & -b/r \\ \overline{b}/r & a/r \end{pmatrix}$$

  is unitary. In addition,

$$\begin{pmatrix} \overline{a}/r & -b/r \\ \overline{b}/r & a/r \end{pmatrix}\begin{pmatrix} a & b \\ -\overline{b} & \overline{a} \end{pmatrix} = \begin{pmatrix} r & 0 \\ 0 & r \end{pmatrix}$$

  so the unitary matrix can be used to introduce zeros. Choose j between 1 and ℓ and construct a matrix R as the $2\ell\times 2\ell$ identity matrix except that entries $R_{\ell+j,\ell+j}=\overline{R_{j,j}}=a/r$ and $R_{j,\ell+j}=-\overline{R_{\ell+j,\ell+j}}=-b/r$. Then the product RH is equal to H except that the entries in rows j and $\ell+j$ become

$$\begin{pmatrix} (RH)_{j,k} & (RH)_{j,\ell+k} \\ (RH)_{\ell+j,k} & (RH)_{\ell+j,\ell+k} \end{pmatrix} = \begin{pmatrix} \overline{a}/r & -b/r \\ \overline{b}/r & a/r \end{pmatrix}\begin{pmatrix} A_{j,k} & B_{j,k} \\ -\overline{B_{j,k}} & \overline{A_{j,k}} \end{pmatrix}, \tag{32}$$

  $k=1,\ldots,\ell$. Since this product is skew-symmetric Hamiltonian, so is RH, and it can be shown in a similar way that $(RH)R^\dagger$ is skew-symmetric Hamiltonian. Thus we can use R as a similarity transformation that preserves the structure.
- Let S be a real orthogonal matrix of dimension $\ell\times\ell$. Then

$$\begin{pmatrix} S & 0 \\ 0 & S \end{pmatrix}\begin{pmatrix} A & B \\ -\overline{B} & \overline{A} \end{pmatrix}\begin{pmatrix} S^\dagger & 0 \\ 0 & S^\dagger \end{pmatrix} = \begin{pmatrix} SAS^\dagger & SBS^\dagger \\ -\overline{SBS^\dagger} & \overline{SAS^\dagger} \end{pmatrix} \tag{33}$$

  is skew-symmetric Hamiltonian.

Using these matrices, our construction takes $\ell-1$ steps. We describe the first step in detail.

The first step places zeros in the first column of the matrix in rows 3 through 2ℓ. To put a zero in position $(\ell+j,1)$ $(j=1,\ldots,n)$, we construct an R matrix involving rows j and $\ell+j$. If $r_j^2=|A_{j,1}|^2+|B_{j,1}|^2$, then this matrix R_j is the identity matrix except that entries $R_{\ell+j,\ell+j}=\overline{R_{j,j}}=A_{j,1}/r_j$ and $R_{j,\ell+j}=-R_{\ell+j,\ell+j}=-B_{j,1}/r_j$. We replace H by $(RH)R^\dagger$ and update Q by premultiplying by R_j, repeating this for $j=1,\ldots,\ell$.

We complete the first step by putting zeros in rows 3 through ℓ of column 1. Note that these elements are now real, since elements 2 through ℓ are just the values r_j. Thus we can construct a real orthogonal reflection (Householder) matrix of the form $S=I-2ss^T$ where $\hat{s}=[0,r_2+\|r\|,r_3,\ldots,r_n]^T$ and $s=\hat{s}/\|\hat{s}\|$. A similarity transformation of H by

$$\begin{pmatrix} S & 0 \\ 0 & S \end{pmatrix}$$

produces the required zeros, and Q is updated by premultiplying by this matrix.

Steps 2 through $\ell-1$ are similar; in step k we first put zeros in the B portion of column k using R matrices and then zero elements $k+2$ through ℓ of the A portion using a reflection matrix. The final result is that the transformed H has a real tridiagonal matrix T in place of A and $\overline{A}$ and zeros elsewhere.

The QR algorithm is considered to be the algorithm of choice for determining all of the eigenvalues and eigenvectors of a real symmetric tridiagonal matrix. We use the algorithm to form X, the matrix of eigenvectors of T. Implementation of the algorithm requires care, and high quality implementations are available, for example, in LAPACK.[2] Other codes are available at http://www.netlib.org.

We construct the eigenvector matrices U and V as $U=Q_1^\dagger X$ and $V=Q_2{}^T X$. Note that most implementations of the QR algorithm do not guarantee that the eigenvalues are ordered, so a final sort of the eigenvalues and the columns of U and V should be done at the end if desired.

V. TIME REVERSAL, THE CCD, AND KRAMERS' NONDEGENERACY

The section presents three topics, all following from an interpretation of υ from Eq. (2) as a time reversal symmetry operator. First, the Cartan involution defining the CCD may be rewritten entirely in terms of the spin-flip, and the eigenspaces of $\theta(iH)$ are associated to time symmetric and antisymmetric Hamiltonians H in a natural way. Second, a well-known procedure exists to convert any $G=KAK$ decomposition into a polar decomposition, and the polar decomposition associated to the CCD writes a unitary $\nu\in \mathrm{SU}(N)$ as a product of two factors, one evolution by a time symmetric Hamiltonian and one evolution by a time anti-symmetric Hamiltonian. Third, we demonstrate the entangled eigenstates of Kramers' nondegeneracy as described in the introduction and consider the perturbative stability of this entanglement under time reversal symmetry breaking.

A. Spin-flips as time reversal symmetry operators

Recall the *Bloch sphere* (e.g., Ref. 36), which provides a picture of the data space of one qubit. As a remark, the Bloch sphere may be thought of as a parametrization of the complex projective line $\mathbb{CP}^1$ (e.g., Ref. 34, Sec. 40). Briefly, $\mathbb{CP}^1$ is the set of all equivalence classes of vectors in $\mathbb{C}^2$ up to multiple by a nonzero complex scalar. To associate such a class with a Bloch vector, normalize $|\psi\rangle$ as above so as to write $|\psi\rangle=re^{it}[\cos(\theta/2)|0\rangle+e^{i\varphi}\sin(\theta/2)|1\rangle]$. The Bloch sphere vector of $|\psi\rangle$, say $[|\psi\rangle]$, is given in spherical coordinates by $(1,\theta,\varphi)$ (Ref. 36, p. 15). Recall also that the north pole is $[|0\rangle]$ and $[|1\rangle]$ is the south pole.

Now let $\vec{b}\in(\mathbb{F}_2)^n$ be an n-bit string. The typical procedure when quantizing a classical computation is to extend the classical outputs linearly without phases. Thus, a reasonable interpretation of quantum bit-flip would be $(\sigma^x)^{\otimes n}$. This is the common interpretation, but note that in one qubit

σ^x is not reflection on the Bloch sphere and indeed has a fixed state, $(1/\sqrt{2})(|0\rangle+|1\rangle)$. Rather, the odd reflection of a single qubit under the Bloch parametrization of $\mathbb{CP}^1$ is the spin-flip $|\psi\rangle\mapsto\overline{(-i\sigma^y)|\psi\rangle}=(-i\sigma^y)\overline{|\psi\rangle}$.

The appropriate physical interpretation of the spin-flip is as a time reversal symmetry operator (Ref. 47, Chap. 26, Ref. 19, pp. 314–322, Refs. 27 and 39). Wigner defined a generic time reversal symmetry operator Θ as any $\mathbb{R}$-linear involutive map of the quantum Hilbert space which is antiunitary, i.e., complex anti-linear $(\Theta(\alpha|\psi_1\rangle+\beta|\psi_2\rangle)=\overline{\alpha}\Theta|\psi_1\rangle+\overline{\beta}\Theta|\psi_2\rangle)$, and orthogonal in the induced real inner-product on $\mathbb{R}^{2p}\cong\mathbb{C}^p$. Generic time reversal symmetry operators are usually denoted by a capital Θ; we ask the reader's forebearance in distinguishing this from the lower-case θ describing a Cartan involution.

Such a time reversal symmetry operator Θ maps the state of a system to its motion-reversed state, so that momentum eigenstates transform as $\Theta|\mathbf{p}\rangle=|-\mathbf{p}\rangle$. In particular, if our qubit is a spin $\frac{1}{2}$ particle, e.g., with $|0\rangle=|\uparrow\rangle$ and $|1\rangle=|\downarrow\rangle$, then υ per Eq. (2) reverses the one-qubit spin vector on the Bloch sphere and so is the natural quantum angular momentum reversal in n-qubits. Indeed, the total spin angular momentum, $\vec{S}=\Sigma_{j=1}^n\vec{\sigma}_j$, is inverted under time reversal: $\upsilon\vec{S}\upsilon^{-1}=-\vec{S}$. Spin-flip operators may be defined for d-level systems (qudits) but may not both preserve pure states and commute with local unitaries.[38]

We note in passing that the spin-flip picture also allows one to quickly rederive one of the monotone properties. Namely, antipodal points in the Bloch sphere parametrization of the complex projective line $\mathbb{CP}^1$ correspond to Hermitian-orthogonal states of $\mathcal{H}_1$. Hence, $C_n(|\psi\rangle)=|\langle\psi|\upsilon|\psi\rangle|=0$ if $|\psi\rangle=\otimes_{j=1}^n|\psi_j\rangle$ (the monotone property,) since in this event $\langle\psi|\upsilon|\psi\rangle$ has a factor $\langle\psi_j|\upsilon|\psi_j\rangle=0$. More generally $C_n(|\psi\rangle)=0$ whenever $|\psi\rangle=|\psi_1\rangle\otimes|\psi_2\rangle$ for $|\psi_1\rangle\in\mathcal{H}_{n-1}$ and $[|\psi_2\rangle]$ a point on the Bloch sphere. However, the latter is not an equivalence for n even. Consider $|\mathrm{W}_4\rangle=(1/2)\times(|0001\rangle+|0010\rangle+|0100\rangle+|1000\rangle)$.

B. Time reversal and the CCD Cartan involution

We next show that physically, the eigenspaces of the Cartan involution producing the CCD correspond to υ-time symmetric and υ-time antisymmetric Hamiltonians. They are then explicitly described in the Pauli-tensor basis of $\mathfrak{su}(N)$ in much more compact form than in Dirac notation.[8]

Definition V.1: Consider H a Hamiltonian on a finite dimensional Hilbert space $\mathcal{H}$, i.e., H is self-adjoint within $\mathrm{End}_{\mathbb{C}}(\mathcal{H})\subset\mathrm{End}_{\mathbb{R}}(\mathcal{H})$. Then H is time reversal symmetric with respect to Θ iff $H=\Theta H\Theta^{-1}$ as elements of $\mathrm{End}_{\mathbb{R}}(\mathcal{H})$. A Hamiltonian is time reversal anti-symmetric with respect to Θ iff $H=-\Theta H\Theta^{-1}$.

Proposition V.2: Let $\theta(X)$ per Definition II.1. Label $\mathfrak{su}(N)=\mathfrak{p}\oplus\mathfrak{k}$ as the -1 and $+1$-eigenspaces of θ. Let υ be the spin-flip. Then (i) for H a traceless Hamiltonian, so that $iH\in\mathfrak{su}(N)$, $\theta(iH)=\upsilon(iH)\upsilon^{-1}$, with the right-hand side viewed as a composition of $\mathbb{R}$-linear maps. Also (ii) (H has time reversal symmetry with respect to υ) $\Leftrightarrow(iH\in\mathfrak{p})$, and (iii) ($H$ has time reversal anti-symmetry with respect to υ) $\Leftrightarrow(iH\in\mathfrak{k})$.

Proof: Let τ denote the complex conjugation operator $|\psi\rangle\mapsto\overline{|\psi\rangle}$. Then $\upsilon=(-i\sigma^y)^{\otimes n}\tau=\tau(-i\sigma^y)^{\otimes n}$, given $-i\sigma^y$ real. So $\upsilon^{-1}=\tau[(-i\sigma^y)^{\otimes n}]^\dagger$. Moreover, $[(-i\sigma^y)^{\otimes n}]^\dagger=(-I_N)^n(-i\sigma^y)^{\otimes n}$. Finally, $\tau(iH)\tau=\overline{iH}$. Thus,

$$\upsilon(iH)\upsilon^{-1}=(-i\sigma^y)^{\otimes n}\tau(iH)\tau[(-i\sigma^y)^{\otimes n}]^\dagger=(-I_N)^n(-i\sigma^y)^{\otimes n}\overline{(iH)}[(-i\sigma^y)^{\otimes n}]=\theta(iH). \quad (34)$$

The latter two items follow at once. □

With the above proposition, we may describe the infinitesimal Cartan decomposition $\mathfrak{su}(n)=\mathfrak{p}\oplus\mathfrak{k}$ directly in terms of tensors of Pauli operators. Let j denote either 0, x, y, or z, with $\sigma^j=I_2$ in case $j=0$ and Pauli matrices σ^x, σ^y, or σ^z as appropriate otherwise. A multi-index $J=j_1j_2\cdots j_k\cdots j_n$ denotes a string of length n, and J will be said to be nonzero if some $j_k\neq 0$. Finally, let $i\sigma^{\otimes J}$ denote $i\otimes_{k=1}^n(\sigma^{j_k})$. Then $\mathfrak{su}(N)=\oplus_{\text{all nonzero }J}\mathbb{R}\{i\sigma^{\otimes J}\}$. We have the following corollary, discovered independently by Bremner *et al.* (Ref. 5, Theorem 5) which has recently reappeared in a different context (Ref. 1, p. 243).

Corollary V.3: Continue the convention of the previous paragraph, and write

$$\mathfrak{su}(N) = \left(\bigoplus_{\#J=0 \bmod 2} \mathbb{R}\{i\sigma^{\otimes J}\} \right) \oplus \left(\bigoplus_{\#J=1 \bmod 2} \mathbb{R}\{i\sigma^{\otimes J}\} \right). \tag{35}$$

The above is the infinitesimal Cartan decomposition of $\theta(iH)$, *i.e.,* $\mathfrak{p} = \oplus_{\#J=0 \bmod 2} \mathbb{R}\{i\sigma^{\otimes J}\}$, and $\mathfrak{k} = \oplus_{\#J=1 \bmod 2} \mathbb{R}\{i\sigma^{\otimes J}\}$. *In particular, K is the Lie group of those unitaries which are exponentials of Hamiltonians with time reversal anti-symmetry with respect to* υ.

Proof: Distinct Pauli matrices anti-commute, each has $(\sigma^j)^2 = I_2$, and σ^y is purely imaginary while σ^x, σ^z, and I_2 are real. Considering the tensors case by case completes the proof. □

C. A time reversal polar decomposition

We next consider the polar decomposition which may be derived from the CCD. In most treatments, the polar decomposition of a general Cartan involution is proven and then a $G = KAK$ theorem is derived from it. We next use the CCD to produce a polar decomposition for time reversal symmetry. This practical decision avoids rearguing the $G = KAK$ theorem for compact groups (Ref. 21, Theorem 8.6, Sec. VII.8).

Corollary V.4: Suppose $\nu \in \mathrm{SU}(N)$ *is a phase normalized quantum computation in n qubits. Then we may write* $\nu = \exp(iH_\mathfrak{p})\exp(iH_\mathfrak{k})$ *for some Hamiltonians* $H_\mathfrak{p}$, $H_\mathfrak{k}$ *such that* $H_\mathfrak{p}$ *has time reversal symmetry and* $H_\mathfrak{k}$ *has time reversal anti-symmetry with respect to the spin-flip* υ.

Proof: Let $\nu = k_1 a k_2$ be the CCD of $\nu \in \mathrm{SU}(N)$. Then in particular $\nu = (k_1 a k_1^\dagger)(k_1 k_2)$. Since K is a group, $k_1 k_2$ is a time antisymmetric evolution by Proposition V.2. Moreover, let $a = \exp iH$ for $iH \in \mathfrak{a} \subset \mathfrak{p}$ a time symmetric Hamiltonian. As $iH \in \mathfrak{p}$, we have $\theta(iH) = [(-i\sigma^y)^{\otimes n}]^\dagger \overline{(iH)}(-i\sigma^y)^{\otimes n} = -iH$. Moreover, $k \in K$ is a symmetry of the concurrence form [Eq. (10)] which as a matrix equation demands $k^T(-i\sigma^y)^{\otimes n}k = (-i\sigma^y)^{\otimes n}$. Hence $k_1^T(-i\sigma^y)^{\otimes n} = (-i\sigma^y)^{\otimes n}k_1^\dagger$, and for $k_1 iHk_1^\dagger \in \mathfrak{p}$:

$$\theta(k_1 iHk_1^\dagger) = [(-i\sigma^y)^{\otimes n}]^\dagger \overline{k_1}\,\overline{(iH)}k_1^T(-i\sigma^y)^{\otimes n} = k_1[(-i\sigma^y)^{\otimes n}]^\dagger \overline{(iH)}(-i\sigma^y)^{\otimes n}k_1^\dagger = -k_1(iH)k_1^\dagger. \tag{36}$$

Thus $k_1(iH)k_1^\dagger$ has time reversal symmetry, and the usual matrix exponential formula [valid since $\mathrm{SU}(N)$ is linear] shows $k_1 a k_1^\dagger = \exp[k_1(iH)k_1^\dagger]$. □

Remark V.5: Note that the vector space decomposition $\mathfrak{su}(N) = \mathfrak{p} \oplus \mathfrak{k}$ makes clear any such ν may be approximated by rapid pulsing of the time symmetric and anti-symmetric factors, by applying the Trotter formula (e.g., Ref. 36, Sec. 4.7.2). However, the decomposition above requires no such pulsing of the time-symmetric and time-antisymmetric Hamiltonians.

D. Kramers' nondegeneracy

Finally, we rederive Kramers' degeneracy in the case of υ and note a further, υ-specific nondegeneracy property. Recall Kramers' degeneracy[26,27] proves that the eigenstates of a collection of an odd number of spin $\frac{1}{2}$ electrons become doubly degenerate in the exclusive presence of a time-reversal-symmetric interaction, such as an electric field. The degeneracy is broken with the introduction of a magnetic field. In terms of an energy Hamiltonian H of the system, the degeneracy corresponds to 2 or greater dimensional eigenspace for energy eigenstates.

Lemma V.6: Suppose that $|\psi\rangle \in \mathcal{H}_n$ *is an eigenstate of some traceless Hamiltonian H which has time reversal symmetry, with eigenvalue* $\lambda \in \mathbb{R}$. *Then the spin-flip* $\upsilon|\psi\rangle$ *is also an eigenstate of eigenvalue* λ.

Proof: Since iH has time reversal symmetry, $\theta(iH) = -iH$. Thus $(-i\sigma^y)^{\otimes n}(iH) + \overline{(iH)}(-i\sigma^y)^{\otimes n} = 0$, and taking a complex conjugate produces $(-i\sigma^y)^{\otimes n}\overline{(iH)} + (iH)(-i\sigma^y)^{\otimes n} = 0$. Now $(iH)|\psi\rangle = \lambda|\psi\rangle$, so that

$$(iH)\upsilon|\psi\rangle = (iH)(-i\sigma^y)^{\otimes n}\overline{|\psi\rangle} = -(-i\sigma^y)^{\otimes n}\overline{(iH)|\psi\rangle} = -(-i\sigma^y)^{\otimes n}\overline{i\lambda|\psi\rangle} = i\lambda\upsilon|\psi\rangle. \tag{37}$$

This concludes the proof. □

Theorem V.7 [cf. Kramers' degeneracy—Refs. 26, 27, and 39 (p. 281)]. *Let H be a traceless Hamiltonian on some number n of quantum-bits. Suppose H has time reversal symmetry with respect to* υ. *Let* λ *be a fixed eigenvalue of H. Then either (i)* λ *is degenerate with even multiplicity*

or (ii) the normalized eigenstate $|\lambda\rangle$ *has* $C_n(|\lambda\rangle)=1$. *For n odd, case (i) holds: all* λ *are degenerate with even multiplicity*.

Proof: Let λ_j be some eigenvalue of H. By Lemma V.6, both $|\lambda_j\rangle$ and $\upsilon|\lambda_j\rangle$ are energy eigenstates. Should these two states be linearly independent, then λ_j is degenerate. If any eigenvalue is nondegenerate, say λ_k, then by antiunitarity of υ, we must have $\upsilon|\lambda_k\rangle=e^{i\varphi}|\lambda_k\rangle$ for some global phase φ. Using $C_n(|\lambda_k\rangle)=|\langle\lambda_k|\upsilon|\lambda_k\rangle|$ we see that this eigenstate must have concurrence one.

Suppose in particular $n=2p-1$. Then $\mathcal{C}_n(-,-)$ is antisymmetric and vanishes on the diagonal, implying $\langle\lambda_j|\upsilon|\lambda_j\rangle=0$ for all j. Consequently, $|\lambda_j\rangle$ and $\upsilon|\lambda_j\rangle$ are Hermitian orthogonal and may not be dependent, implying case (i). □

Thus, for the spin-flip υ there is in addition to the Kramers' degeneracy a Kramers' nondegeneracy. As always, if n is odd so that the total n-qubit system is a fermion, then a time reversal symmetric Hamiltonian implies that all energy eigenstates are degenerate. Yet moreover in the specific case of υ and *n even*, a nondegenerate eigenstate must also have maximal concurrence and hence be entangled.

We provide some illustrative examples. First note that there are many systems endowed with time reversal symmetric Hamiltonians. In particular, any system with (exclusively) pairwise nearest neighbor coupling between qubits has $iH\in\mathfrak{p}$, by Corollary V.3. An example of an interaction that occurs in many solid state systems is the quantum XYZ model:

$$H_{\mathrm{XYZ}}=\sum_{\langle j,k\rangle}J_x\sigma_j^x\sigma_k^x+J_y\sigma_j^y\sigma_k^y+J_z\sigma_j^z\sigma_k^z \tag{38}$$

with $J_{x,y,z}\in\mathbb{R}$ where the sum is taken over all nearest neighbor pairs and the boundaries may be fixed or periodic. In one dimension, these nearest neighbor coupled systems are known as spin chains. Spin chain Hamiltonians are of great theoretical interest, for under the appropriate parameter regime they exhibit long range classical correlations near a quantum phase transition.[30] We can characterize the dynamics of entanglement in spin chains using the concurrence capacity. With this goal in mind we observe the following useful fact:

Proposition V.8: Let $\mathfrak{p}$, $\mathfrak{k}$ *be as in Corollary V.3. If* $iH\in\mathfrak{p}$ *and* $H\in\mathbb{R}^{N\times N}$, *then* $\lambda_c(u=e^{-iHt})=\{e^{-2i\lambda_j t}\}$ *where* $t\in\mathbb{R}$ *parameterizes time and* $\lambda_j\in\mathbb{R}$ *are the eigenvalues of H*.

Proof: By Definition III.5 the concurrence spectrum of the unitary generated by iH, $u=e^{-iHt}$ is

$$\begin{aligned}\lambda_c(u)&=\mathrm{spec}[(-i\sigma^y)^{\otimes n\dagger}e^{iHt}(-i\sigma^y)^{\otimes n}(e^{-iHt})^T]=\mathrm{spec}(e^{-iHt}e^{-iH^Tt})\\&=\mathrm{spec}(e^{-2iHt})\qquad\qquad=\{e^{-2i\lambda_j t};\lambda_j\in\mathrm{spec}(H)\}.\end{aligned} \tag{39}$$

We have used $(-i\sigma^y)^{\otimes n\dagger}\overline{iH}(-i\sigma^y)^{\otimes n}=-iH$ and therefore $(-i\sigma^y)^{\otimes n\dagger}H(-i\sigma^y)^{\otimes n}=H$ because H is real. The third line is a consequence of H being Hermitian. □

The quantum XYZ Hamiltonian has time reversal symmetry with respect to the spin-flip υ. We next demonstrate how to build up entanglement with such a system. Consider a collection of n qubits laid out in a cyclic array interacting under the Ising class of Hamiltonians given by H_{XYZ} with $J_x=J_y=0$: $H_{Is}=\Sigma_{j=1}^n J_z\sigma_j^z\sigma_{j+1}^z$, where we identify $\sigma_{n+1}^z=\sigma_1^z$.

The eigenvalues are given by $\{\lambda_j\}=\{J_z(n-2\Sigma_k j_k\oplus j_{k+1});j=j_1j_2\ldots j_n\}$,[30] where the addition is done modulo 2 over the components j_k of the binary expansion of j. For n even, each eigenvalue λ_j is paired with another of opposite sign and in particular, $\lambda_0=-\lambda_{N-1}$ with $|\lambda_0|=n|J_z|=\lambda^{\max}$. The concurrence spectrum of $u=e^{-iH_{Is}t}$ is composed of complex conjugate pairs and the concurrence capacity $\tilde{\kappa}_n(u)$ may be computed explicitly. Then $\tilde{\kappa}_n(u)=\max\{|\Sigma_{j=0}^{N-1}a_j^2e^{-2i\lambda_j t}|;z^\dagger z=1,z^Tz=0\}$ where $z=\Sigma_{j=0}^{N-1}a_j|j\rangle$, per Eq. (14). Maximum capacity is obtained when the convex hull condition is satisfied which occurs precisely when the concurrence spectrum extends outside the right half of the complex plane. The minimum time at which this occurs is given by $e^{-2i\lambda^{\max}t_{\min}}=i$ or $t_{\min}=\pi/4|\lambda_0|=\pi/4n|J_z|$.

The existence of a time reversal symmetry in the interaction between qubits gives us important information about the nature of quantum correlations in the energy eigenstates. Applying Theorem V.7, we immediately find that the ground state of a Hamiltonian H with time reversal symmetry has maximum n-concurrence if it is unique. Examples of interactions satisfying these

conditions are the XYZ Hamiltonian with $(J_x=J_y=J_z=J>0)$, denoted the XXX Hamiltonian, and the XY Hamiltonian $(J_x=J_y, J_z=0)$.[30] In particular, the XXX Hamiltonian with $J>0$ has been shown to have nondegenerate ground states in any number of dimensions, with or without periodic boundary conditions, provided the underlying lattice has a reflection symmetry about some plane (ibid.).

To illustrate this phenomenon we consider what happens when the time reversal symmetry is broken by adding a time-antisymmetric term to the XY Hamiltonian:

$$H=\sum_{j=1}^{n} J\left(\frac{1+g}{4}\sigma_j^x\sigma_{j+1}^x+\frac{1-g}{4}\sigma_j^y\sigma_{j+1}^y\right)+\frac{h_z}{2}\sigma_j^z, \tag{40}$$

where $\sigma_{n+1}^{\alpha}\equiv\sigma_1^{\alpha}$. The presence of the linear term proportional to the total spin projection operator $S_z=\Sigma_{j=1}^{n}\sigma_j^z$, breaks the time reversal symmetry so that $iH\notin\mathfrak{p}$ when $h_z\neq 0$. For zero magnetic field and $0\leqslant g<1$, the Hamiltonian is time reversal symmetric and the ground state is nondegenerate meaning the concurrence is maximal. In the isotropic case $(g=0)$, the Hamiltonian commutes with S_z and eigenstates are independent of h_z. For magnetic field strengths below some critical value, $|h|<h_{\text{crit}}$ the ground state corresponds to an eigenstate with eigenvalue $s_z=0$ of the operator S_z. This ground state has maximal concurrence. For $|h_z|>h_{\text{crit}}$, the ground state corresponds to an eigenvalue $s_z\neq 0$ and the concurrence is zero.[7]

VI. CONCLUSIONS

We show that the odd-qubit concurrence canonical decomposition admits generalizations of all constructions studied on the even qubit CCD. In particular, a generalized pairwise concurrence capacity may be defined, and the operators for which this is maximal are characterized by a convex hull condition on the concurrence spectrum. Again for an odd number of qubits, we find that for large odd *n* most unitaries have maximal concurrence capacities. Moreover, we provide an explicit algorithm for computing the odd-qubit CCD.

These advances are complemented by new interpretation of the original inputs to the $G=KAK$ theorem which define the CCD. Specifically, they may be rewritten in terms of time reversal symmetry υ which is the spin-flip in *n* quantum bits, and the CCD is best understood in terms of such symmetries. For example, the odd-qubit CCD is a type **AII** *KAK* decomposition, and as such must have degenerate eigenvalues. In fact, this recaptures Kramers' degeneracy for the odd-qubit spin-flip, and a more careful study of the arguments reveals a Kramers' nondegeneracy: Nondegenerate eigenstates of υ time reversal symmetric Hamiltonians only exist when the number of quantum bits is even and *moreover* must be highly entangled. Specifically, such $|\lambda\rangle$ are highly entangled in the sense that the concurrence $C_n(|\lambda\rangle)=|\langle\lambda|\upsilon|\lambda\rangle|=1$. Finally, the polar decomposition extracted from the CCD in the usual way accomplishes the following: any unitary *n*-qubit evolution is a product of precisely one time reversal symmetric and one time reversal antisymmetric evolution.

[50] Some authors only use the term Cartan involution in the case that $\mathfrak{g}$ is a noncompact Lie algebra. In their terminology, this definition of a Cartan involution on the Lie algebra of a compact group, e.g., $\mathfrak{su}(N)$, is the image of a Cartan involution of a noncompact Lie algebra through symmetric duality $(\mathfrak{g}=\mathfrak{k}\oplus\mathfrak{p})\leftrightarrow(\mathfrak{g}^{\mathrm{dual}}=\mathfrak{k}\oplus i\mathfrak{p})$.

An isoperimetric problem for leaky loops and related mean-chord inequalities

Pavel Exner[a)]
Department of Theoretical Physics, Nuclear Physics Institute, Academy of Sciences, 25068 Řež near Prague, Czechia, and Doppler Institute, Czech Technical University, Břehová 7, 11519 Prague, Czechia

(Received 26 January 2005; accepted 15 March 2005; published online 17 May 2005)

We consider a class of Hamiltonians in $L^2(\mathbb{R}^2)$ with attractive interaction supported by piecewise C^2 smooth loops Γ of a fixed length L, formally given by $-\Delta - \alpha\delta(x-\Gamma)$ with $\alpha>0$. It is shown that the ground state of this operator is locally maximized by a circular Γ. We also conjecture that this property holds globally and show that the problem is related to an interesting family of geometric inequalities concerning mean values of chords of Γ. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1914728]

I. INTRODUCTION

There is a small number of topics which can be regarded as a trademark for mathematical physics. One of them without any doubt concerns relations between geometric properties of constraints and/or interaction and extremal values of a spectral quantity; classical examples are the Faber–Krahn inequality[12,14] or the PPW conjecture proved by Ashbaugh and Benguria.[3]

A common feature of these and analogous problems is that the extremum is reached by shapes having a rotational symmetry. At the same time, the nature of the extremum may be different. While a ball *minimizes* the principal eigenvalue of the Dirichlet Laplacian among regions of a fixed volume, for nonsimply connected regions like annular strips or layers considered in Refs. 8 and 13, built over a curve (surface) of a fixed length (area), the circular shape is on the contrary a *maximizer*. A natural topological way to understand this difference becomes smeared, however, when the particle is not localized by boundary conditions but by a potential, a regular or a singular one.

In this paper we consider such a problem associated with a class of operators in $L^2(\mathbb{R}^2)$ which are given formally by the expression

$$H_{\alpha,\Gamma} = -\Delta - \alpha\delta(x-\Gamma), \tag{1.1}$$

where $\alpha>0$ and Γ is a C^2 loop in the plane (see below for exact assumptions) having a fixed length $L>0$. A motivation to study these operators comes from the theory of *leaky quantum graphs*—see Refs. 5 and 9 and related papers, a bibliography can be found in Ref. 1—aiming at a more realistic model of quantum wire structures which would take quantum tunneling into account.

Our aim is to show that the ground-state energy of $H_{\alpha,\Gamma}$ is (sharply) maximized when Γ is a circle. We will be able to prove that this property holds *locally* conjecturing its global validity. There are several reasons why one may expect this result to be valid. On one hand, we know from Ref. 11 that in the limit of strong coupling, $\alpha\to\infty$, the ground-state dependence on Γ is given in the leading order by the lowest eigenvalue of the operator $-\mathrm{d}^2/\mathrm{d}s^2-\frac{1}{4}\gamma(s)^2$ on $L^2([0,L])$ with periodic boundary conditions where γ is the curvature of Γ, and the latter is easily seen to be globally sharply maximized when γ is constant along Γ. On the other hand, by Ref. 10 the

a)Electronic mail: exner@ujf.cas.cz

operator $H_{\alpha,\Gamma}$ can be approximated in the strong resolvent sense by point interaction Hamiltonians with the point interactions equidistantly spaced along Γ and properly chosen coupling constants, and from Ref. 7 we know that the ground state of such an operator is locally maximized by a regular polygon.

Needless to say, neither of the above observations proves the desired result. The first one is global, but it holds only asymptotically and we do not know whether the error term will not spoil the inequality. The second argument holds for any $\alpha>0$, suggesting the local validity, but the polygons approximating the circle do not have exactly the same lengths.

Our main tools in this paper are the generalized Birman–Schwinger principle in combination with the convexity of the Green's function. They allow us to reformulate the problem in a purely geometric way, in terms of *mean value of chords* of arc segments of Γ. Since such geometric inequalities are of an independent interest, we discuss them in Sec. IV separately in a broader context, including the discrete version which arose in connection with the polygon problem treated in Ref. 7. Before doing that, we will formulate in the next section the problem and state our main result, Theorem 2.1, and provide the mentioned reformulation in Sec. III. After the discussion of the inequalities we will finish the proof of Theorem 2.1 and present some concluding remarks.

II. FORMULATION AND THE MAIN RESULT

We will assume throughout that $\Gamma:[0,L]\to\mathbb{R}^2$ is *a closed curve*, $\Gamma(0)=\Gamma(L)$, *parametrized by its arclength, which is* C^1*-smooth, piecewise* C^2*, and has no cusps.* (There are, of course, no local cusps under the C^1 assumption, but we have not excluded self-intersections, so the last requirement means that the curve meets itself at such a point at a nonzero angle. In fact, our main result can be pushed through under a slightly weaker regularity assumption, namely that $\dot{\Gamma}$ is absolutely continuous.) Unless stated otherwise, we will mean by the curve Γ for simplicity both the above-mentioned function and its image in the plane. Furthermore, we introduce the equivalence relation: Γ and Γ' belong to the same equivalence class if one can be obtained from the other by a Euclidean transformation of the plane. Spectral properties of the corresponding $H_{\alpha,\Gamma}$ and $H_{\alpha,\Gamma'}$ are obviously the same, and we will usually speak about a curve Γ having in mind the corresponding equivalence class. It is clear that the stated regularity assumptions are satisfied, in particular, by the circle, say $\mathcal{C}:=\{((L/2\pi)\cos s,(L/2\pi)\sin s):s\in[0,L]\}$, and its equivalence class.

First of all we have to give a rigorous meaning to the operator (1.1). Following Refs. 4 and 5, we can do that in two ways. The more general one is to consider a positive Radon measure m on $\mathbb{R}^2$ and $\alpha>0$ such that

$$(1+\alpha)\int_{\mathbb{R}^2}|\psi(x)|^2\,\mathrm{d}m(x)\leqslant a\int_{\mathbb{R}^2}|\nabla\psi(x)|^2\,\mathrm{d}x+b\int_{\mathbb{R}^2}|\psi(x)|^2\,\mathrm{d}x, \tag{2.1}$$

holds for all ψ from the Schwartz space $\mathcal{S}(\mathbb{R}^2)$ and some $a<1$ and b. The map I_m defined on $\mathcal{S}(\mathbb{R}^2)$ by $I_m\psi=\psi$ extends by density uniquely to

$$I_m:W^{1,2}(\mathbb{R}^2)\to L^2(m):=L^2(\mathbb{R}^2,\mathrm{d}m); \tag{2.2}$$

abusing notation we employ the same symbol for a continuous function and the corresponding equivalence classes in both $L^2(\mathbb{R}^2)$ and $L^2(m)$. The inequality (2.1) extends to $W^{1,2}(\mathbb{R}^2)$ with ψ replaced by $I_m\psi$ at the left-hand side. This makes it possible to introduce the following quadratic form:

$$\mathcal{E}_{-\alpha m}(\psi,\phi):=\int_{\mathbb{R}^2}\overline{\nabla\psi(x)}\,\nabla\phi(x)\mathrm{d}x-\alpha\int_{\mathbb{R}^2}(I_m\overline{\psi})(x)(I_m\phi)(x)\mathrm{d}m(x), \tag{2.3}$$

with the domain $W^{1,2}(\mathbb{R}^2)$; it is straightforward to see that under the condition (2.1) it is closed and below bounded, with $C_0^\infty(\mathbb{R}^2)$ as a core, and thus associated with a unique self-adjoint operator. Furthermore, (2.1) is satisfied with any $a>0$ provided m belongs to the generalized Kato class,

$$\lim_{\epsilon\to 0}\sup_{x\in\mathbb{R}^2}\int_{B(x,\epsilon)}|\ln|x-y||\mathrm{d}m(y)=0, \tag{2.4}$$

where $B(x,\epsilon)$ is the ball of radius ϵ and center x. Choosing now for m the Dirac measure supported by the curve one can check easily that the condition (2.4) is satisfied under our assumptions about Γ, hence we may identify the above mentioned self-adjoint operator with the formal one given by (1.1).

The described definition applies naturally to a much wider class of perturbations than we need here. Since Γ is supposed to be smooth, with the normal defined everywhere, we can define $H_{\alpha,\Gamma}$ alternatively through boundary conditions. Specifically, it acts as $-\Delta\psi$ on any ψ from the domain consisting of functions which belong to $W^{2,2}(\mathbb{R}^2\setminus\Gamma)$, they are continuous at the curve Γ and their normal derivatives have a jump there,

$$\frac{\partial\psi(x)}{\partial n_+}-\frac{\partial\psi(x)}{\partial n_-}=-\alpha\psi(x),\quad \text{for } x=\Gamma(s),\quad \forall\, s\in[0,L].$$

It is straightforward to check that such an operator is e.s.a. and its closure can be identified with (1.1) defined in the above described way.[4] The advantage of the second definition is that it has an illustrative meaning which corresponds well to the concept of a δ interaction in the cross cut of the curve.

Since the curve is finite, by Refs. 4 and 5 we have $\sigma_{\mathrm{ess}}(H_{\alpha,\Gamma})=[0,\infty)$ while the discrete spectrum is nonempty and finite, so that

$$\epsilon_1\equiv\epsilon_1(\alpha,\Gamma):=\inf\sigma(-\Delta_{\alpha,\Gamma})<0;$$

we ask for which Γ the principal eigenvalue is maximal. The main result of this paper is a partial answer to this question, namely, the following.

Theorem 1: *Within the specified class of curves, $\epsilon_1(\alpha,\Gamma)$ is for any fixed $\alpha>0$ and $L>0$ locally sharply maximized by a circle.*

While we do not give a general answer here, we suggest what it should be.

Conjecture 2.2: The circle is a sharp global maximizer, even under weaker regularity assumptions.

III. BIRMAN–SCHWINGER REFORMULATION

For operators associated with the quadratic form (2.3), one can establish a generalized Birman–Schwinger principle—we refer to Ref. 4 for a detailed discussion. In particular, if k^2 belongs to the resolvent set of $H_{\alpha,\Gamma}$ we put $R^k_{\alpha,\Gamma}:=(H_{\alpha,\Gamma}-k^2)^{-1}$. The free resolvent R^k_0 is defined for $\mathrm{Im}\,k>0$ as an integral operator in $L^2(\mathbb{R}^2)$ with the kernel

$$G_k(x-y)=\frac{i}{4}H_0^{(1)}(k|x-y|).$$

Next we have to introduce embedding operators associated with R^k_0. Let μ,ν be arbitrary positive Radon measures on $\mathbb{R}^2$ with $\mu(x)=\nu(x)=0$ for any $x\in\mathbb{R}^2$. By $R^k_{\nu,\mu}$ we denote the integral operator from $L^2(\mu):=L^2(\mathbb{R}^2,\mathrm{d}\mu)$ to $L^2(\nu)$ with the kernel G_k, in other words, we suppose that

$$R^k_{\nu,\mu}\phi=G_k*\phi\mu,$$

holds ν—a.e. for all $\phi\in D(R^k_{\nu,\mu})\subset L^2(\mu)$. In our case the two measures will be the Dirac measure supported by Γ, denoted by m if necessary, and the Lebesgue measure $\mathrm{d}x$ on $\mathbb{R}^2$, in different combinations. With this notation one can express the generalized BS principle as follows.

Proposition 3.1: (i) There is a $\kappa_0>0$ such that the operator $I-\alpha R^{i\kappa}_{m,m}$ on $L^2(m)$ has a bounded inverse for any $\kappa\geqslant\kappa_0$.

(ii) Let $\mathrm{Im}\, k>0$. *Suppose that* $I-\alpha R^k_{m,m}$ *is invertible and the operator*

$$R^k := R^k_0 + \alpha R^k_{\mathrm{d}x,m}[I-\alpha R^k_{m,m}]^{-1}R^k_{m,\mathrm{d}x}$$

from $L^2(\mathbb{R}^2)$ *to* $L^2(\mathbb{R}^2)$ *is everywhere defined. Then* k^2 *belongs to* $\rho(H_{\alpha,\Gamma})$ *and* $(H_{\alpha,\Gamma}-k^2)^{-1}=R^k$.

(iii) $\dim\ker(H_{\alpha,\Gamma}-k^2)=\dim\ker(I-\alpha R^k_{m,m})$ *for any* k *with* $\mathrm{Im}\, k>0$.

(iv) An eigenfunction of $H_{\alpha,\Gamma}$ *associated with such an eigenvalue* k^2 *can be written as*

$$\psi(x)=\int_0^L R^k_{\mathrm{d}x,m}(x,s)\,\phi(s)\mathrm{d}s,$$

where ϕ *is the corresponding eigenfunction of* $\alpha R^k_{m,m}$ *with the eigenvalue one.*

Proof of (i)–(iii) is given in Ref. 4, for (iv) see Ref. 15. ■

Denoting conventionally $k=i\kappa$ with $\kappa>0$ as corresponding to the bound-state energy $-\kappa^2$, we can thus rephrase our problem as a search for solutions to the integral-operator equation,

$$\mathcal{R}^\kappa_{\alpha,\Gamma}\phi=\phi,\quad \mathcal{R}^\kappa_{\alpha,\Gamma}(s,s') := \frac{\alpha}{2\pi}K_0(\kappa|\Gamma(s)-\Gamma(s')|), \tag{3.1}$$

on $L^2([0,L])$, where K_0 is the Macdonald function. Referring again to Refs. 4 and 15 we find that the operator-valued function $\kappa\mapsto\mathcal{R}^\kappa_{\alpha,\Gamma}$ is strictly decreasing in $(0,\infty)$ and $\|\mathcal{R}^\kappa_{\alpha,\Gamma}\|\to 0$ as $\kappa\to\infty$. In fact, the two properties can be checked also directly. The first one follows from the one-to-one correspondence of the eigenvalue branches (as functions of κ) to those of $H_{\alpha,\Gamma}$ which are obviously strictly monotonous as functions of α; the second one in turn comes from the explicit form of the kernel together with the dominated convergence theorem.

Next we use the fact that the maximum eigenvalue of $\mathcal{R}^\kappa_{\alpha,\Gamma}$ is simple. This conclusion results from the following considerations: the kernel of the operator is by (3.1) strictly positive, so $\mathcal{R}^\kappa_{\alpha,\Gamma}$ is positivity improving. It further means that for any nonzero $\phi,\chi\geqslant 0$ the functions $\mathcal{R}^\kappa_{\alpha,\Gamma}\phi$, $\mathcal{R}^\kappa_{\alpha,\Gamma}\chi$ are also strictly positive. Hence $(\phi,(\mathcal{R}^\kappa_{\alpha,\Gamma})^2\chi)\neq 0$, and as a consequence, $\mathcal{R}^\kappa_{\alpha,\Gamma}$ is ergodic; then the claim follows from Theorem XIII.43 of Ref. 16. In view of Proposition 3.1(iii) the ground state of $H_{\alpha,\Gamma}$ is, of course, also simple.

If Γ is a circle the operator $H_{\alpha,\mathcal{C}}$ has a full rotational symmetry, so the corresponding eigenspace supports a one-dimensional representation of the group $O(2)$. Let us denote the ground-state eigenfunction of $H_{\alpha,\mathcal{C}}$ as $-\tilde\kappa_1^2$ (we will use an overtilde to distinguish quantities referring to the circle). The correspondence between the eigenfunctions given by Proposition 3.1(iv) then requires that the respective eigenfunction of $\mathcal{R}^{\tilde\kappa_1}_{\alpha,\mathcal{C}}$ corresponding to the unit eigenvalue is constant; we can choose it as $\tilde\phi_1(s)=L^{-1/2}$. Then we have

$$\max\sigma(\mathcal{R}^{\tilde\kappa_1}_{\alpha,\mathcal{C}})=(\tilde\phi_1,\mathcal{R}^{\tilde\kappa_1}_{\alpha,\mathcal{C}}\tilde\phi_1)=\frac{1}{L}\int_0^L\int_0^L\mathcal{R}^{\tilde\kappa_1}_{\alpha,\mathcal{C}}(s,s')\mathrm{d}s\,\mathrm{d}s',$$

and, on the other hand, for the same quantity referring to a general Γ a simple variational estimate gives

$$\max\sigma(\mathcal{R}^{\tilde\kappa_1}_{\alpha,\Gamma})\geqslant(\tilde\phi_1,\mathcal{R}^{\tilde\kappa_1}_{\alpha,\Gamma}\tilde\phi_1)=\frac{1}{L}\int_0^L\int_0^L\mathcal{R}^{\tilde\kappa_1}_{\alpha,\Gamma}(s,s')\mathrm{d}s\,\mathrm{d}s'.$$

Hence to check that the circle is a maximizer it sufficient to show that

$$\int_0^L\int_0^L K_0(\kappa|\Gamma(s)-\Gamma(s')|)\mathrm{d}s\,\mathrm{d}s'\geqslant\int_0^L\int_0^L K_0(\kappa|\mathcal{C}(s)-\mathcal{C}(s')|)\mathrm{d}s\,\mathrm{d}s', \tag{3.2}$$

holds *for all* $\kappa>0$ and Γ of the considered class, or at least for Γ in the vicinity of $\mathcal{C}$ to prove the local result in Theorem 2.1. Since the kernel is symmetric with respect to the two variables, we

can replace the double integral by $2\int_0^L \mathrm{d}s \int_0^s \mathrm{d}s'$. By another simple change of variables we find that the above claim is equivalent to positivity of the functional

$$F_\kappa(\Gamma) := \int_0^{L/2} \mathrm{d}u \int_0^L \mathrm{d}s [K_0(\kappa|\Gamma(s+u)-\Gamma(s)|) - K_0(\kappa|\mathcal{C}(s+u)-\mathcal{C}(s)|)],$$

where the second term in the integrand is, of course, independent of s being equal to $K_0((\kappa L/\pi)\sin(\pi u/L))$. Now we employ the (strict) convexity of K_0 which yields by means of the Jensen inequality the following estimate:

$$\frac{1}{L}F_\kappa(\Gamma) \geqslant \int_0^{L/2} \left[K_0\left(\frac{\kappa}{L}\int_0^L |\Gamma(s+u)-\Gamma(s)|\mathrm{d}s \right) - K_0\left(\frac{\kappa L}{\pi}\sin\frac{\pi u}{L} \right) \right] \mathrm{d}u,$$

where the inequality is sharp unless $\int_0^L |\Gamma(s+u)-\Gamma(s)|\mathrm{d}s$ is independent of s. Finally, we observe that K_0 is decreasing in $(0,\infty)$; hence it is sufficient to check the inequality

$$\int_0^L |\Gamma(s+u)-\Gamma(s)|\mathrm{d}s \leqslant \frac{L^2}{\pi}\sin\frac{\pi u}{L}, \tag{3.3}$$

for all $u \in (0, \frac{1}{2}L]$ and to show that is sharp unless Γ is a circle.

IV. MEAN-CHORD INEQUALITIES

The inequality (3.3) to which we have reduced our problem can be regarded as an element of a wider family which we are now going to describe. Let $\Gamma\colon [0,L] \to \mathbb{R}^2$ be again a loop in the plane; for the moment we do not specify its regularity properties. Let us consider all the arcs of Γ having length $u \in (0, \frac{1}{2}L]$. The mentioned inequalities are the following:

$$C_L^p(u)\colon \int_0^L |\Gamma(s+u)-\Gamma(s)|^p \,\mathrm{d}s \leqslant \frac{L^{1+p}}{\pi^p}\sin^p\frac{\pi u}{L}, \quad p>0, \tag{4.1}$$

$$C_L^{-p}(u)\colon \int_0^L |\Gamma(s+u)-\Gamma(s)|^{-p} \,\mathrm{d}s \geqslant \frac{\pi^p L^{1-p}}{\sin^p\frac{\pi u}{L}}, \quad p>0. \tag{4.2}$$

They have also a discrete counterpart for an equilateral polygon $\mathcal{P}_N$ of N vertices and side length $l>0$. Let $\{y_n\}$ be the family of its vertices, where the index values are identified modulo N; then we introduce

$$D_{N,l}^p(m)\colon \sum_{n=1}^N |y_{n+m}-y_n|^p \leqslant \frac{Nl^p \sin^p\frac{\pi m}{N}}{\sin^p\frac{\pi}{N}}, \quad p>0, \tag{4.3}$$

$$D_{N,l}^{-p}(m)\colon \sum_{n=1}^N |y_{n+m}-y_n|^{-p} \geqslant \frac{N\sin^p\frac{\pi}{N}}{l^p \sin^p\frac{\pi m}{N}}, \quad p>0, \tag{4.4}$$

for any $m=1,\ldots,\lfloor \frac{1}{2}N \rfloor$, where $[\cdot]$ denotes as usual the entire part.

In all the cases the right-hand side corresponds, of course, to the case with maximal symmetry, i.e., to the circle and regular polygon $\widetilde{\mathcal{P}}_N$, respectively. *We conjecture* that without regularity

restrictions $C_L^{\pm p}(u)$ *holds for any* $p \leq 2$ *and the same is true for* $D_{N,l}^{\pm p}(m)$, and furthermore, we expect the inequalities *to be sharp unless* $\Gamma = \mathcal{C}$ *or* $\mathcal{P}_N = \widetilde{\mathcal{P}}_N$, *respectively*. In the polygon case it is clear that the claim may not be true for $p > 2$ as the example of a rhomboid shows: $D_{4,l}^p(2)$ is equivalent to $\sin^p \phi + \cos^p \phi \leq 2^{1-p/2}$ for $0 < \phi < \pi$. We are unable at this moment to demonstrate the inequalities (4.1)–(4.4) in full generality; below we will present a few particular cases.

It is obvious that the inequalities have a scaling property, so without loss of generality one can assume, e.g., $L = 1$ and $l = 1$; in such a case we drop the corresponding symbol from the label. If necessary we can include also the case $p = 0$ when the inequalities turn into trivial identities.

Proposition 4.1: $C_L^p(u) \Rightarrow C_L^{p'}(u)$ *and* $D_{N,l}^p(m) \Rightarrow D_{N,l}^{p'}(m)$ *if* $p > p' > 0$.

Proof: The claim follows from the convexity of $x \mapsto x^\alpha$ in $(0, \infty)$ for $\alpha > 1$,

$$\frac{L^{1+p}}{\pi^p} \sin^p \frac{\pi u}{L} \geq \int_0^L (|\Gamma(s+u) - \Gamma(s)|^{p'})^{p/p'} \, \mathrm{d}s \geq L \left(\frac{1}{L} \int_0^L |\Gamma(s+u) - \Gamma(s)|^{p'} \, \mathrm{d}s \right)^{p/p'}.$$

It is now sufficient to take both sides to the power p'/p; in the same way one checks the second implication. ∎

Proposition 4.2: $C_L^p(u) \Rightarrow C_L^{-p}(u)$ *and* $D_{N,l}^p(m) \Rightarrow D_{N,l}^{-p}(m)$ *for any* $p > 0$.

Proof: The Schwarz inequality implies

$$\int_0^L |\Gamma(s+u) - \Gamma(s)|^{-p} \, \mathrm{d}s \geq \frac{L^2}{\int_0^L |\Gamma(s+u) - \Gamma(s)|^p \, \mathrm{d}s} \geq \frac{L^2 \pi^p}{L^{1+p} \sin^p \frac{\pi u}{L}},$$

and similarly for the polygon case. ∎

These simple relations mean that to check the above stated conjecture one needs only to verify $C^2(u)$ and $D_N^2(m)$. We will address the continuous case in the next section; here we notice that the results of Ref. 7 in combination with the last two propositions leads to the following conclusions.

Theorem 4.3: *(a)* $D_{N,l}^1(m)$ *holds locally for any* N *and* $m = 1, \ldots, \lceil \frac{1}{2} N \rceil$, *i.e., in a vicinity of the regular polygon, and, consequently,* $D_{N,l}^{\pm p}(m)$ *holds locally for any* $p \in (0, 1]$.

(b) $D_{N,l}^1(2)$ *holds globally for any* N, *and so does* $D_{N,l}^{\pm p}(2)$ *for each* $p \in (0, 1]$.

V. PROOF OF THEOREM 2.1

After this interlude let us return to our main problem. Notice first that our regularity hypothesis allows us to characterize Γ by its (signed) curvature $\gamma := \dot{\Gamma}_2 \ddot{\Gamma}_1 - \dot{\Gamma}_1 \ddot{\Gamma}_2$ which is by assumption a piecewise continuous function in $[0, L]$. The advantage is that γ specifies uniquely the equivalence class related by Euclidean transformations which can be represented by

$$\Gamma(s) = \left(\int_0^s \cos \beta(s') \mathrm{d}s', \int_0^s \sin \beta(s') \mathrm{d}s' \right), \tag{5.1}$$

where $\beta(s) := \int_0^s \gamma(s') \mathrm{d}s'$ is the bending angle relative to the tangent at the chosen initial point, $s = 0$. To ensure that the curve is closed, the conditions

$$\int_0^L \cos \beta(s') \mathrm{d}s' = \int_0^L \sin \beta(s') \mathrm{d}s' = 0, \tag{5.2}$$

must be satisfied. Using this parametrization we can rewrite the left-hand side of the inequality (4.1) in the form

$$\int_0^L \left[\left(\int_s^{s+u} \cos \beta(s') \mathrm{d}s' \right)^2 + \left(\int_s^{s+u} \sin \beta(s') \mathrm{d}s' \right)^2 \right]^{p/2} \mathrm{d}s := c_\Gamma^p(u),$$

or, equivalently,

$$c_\Gamma^p(u) = \int_0^L \mathrm{d}s \left[\int_s^{s+u} \mathrm{d}s' \int_s^{s+u} \mathrm{d}s'' \cos(\beta(s') - \beta(s'')) \right]^{p/2}.$$

By Proposition (4.1) it is sufficient to check that the quantity $c_\Gamma^2(u)$ is maximized by the circle, i.e., by $\beta(s) = 2\pi s/L$. Rearranging the integrals we get

$$\begin{aligned} c_\Gamma^2(u) &= \int_0^L \mathrm{d}s' \int_{s'-u}^{s'+u} \mathrm{d}s'' \int_{\max\{s'-u, s''-u\}}^{\min\{s', s''\}} \mathrm{d}s \cos(\beta(s') - \beta(s'')) \\ &= \int_0^L \mathrm{d}s' \int_{s'-u}^{s'+u} \mathrm{d}s''[\min\{s', s''\} - \max\{s' - u, s'' - u\}]\cos(\beta(s') - \beta(s'')), \end{aligned}$$

or

$$c_\Gamma^2(u) = \int_0^L \mathrm{d}s' \int_{s'-u}^{s'+u} \mathrm{d}s''[u - |s' - s''|]\cos(\beta(s') - \beta(s'')).$$

Next, we change the integration variables to $x := s' - s''$ and $z := \frac{1}{2}(s' + s'')$,

$$c_\Gamma^2(u) = \int_{-u}^{u} \mathrm{d}x(u - |x|) \int_0^L \mathrm{d}z \cos\left(\beta\left(z + \frac{1}{2}x \right) - \beta\left(z - \frac{1}{2}x \right) \right),$$

and since the functions involved are even w.r.t. x we finally get

$$c_\Gamma^2(u) = 2\int_0^u \mathrm{d}x(u - x) \int_0^L \mathrm{d}z \cos\left(\int_{z-1/2x}^{z+1/2x} \gamma(s)\mathrm{d}s \right). \tag{5.3}$$

As a certain analogy to Theorem 4.3b we can prove the sought global inequality in the case when the curve arcs in question are sufficiently short and/or the tangent vector direction does change too fast.

Proposition 5.1: Suppose that Γ *has no self-intersections and the inequality* $\beta(z + \frac{1}{2}u) - \beta(z - \frac{1}{2}u) \leqslant \frac{1}{2}\pi$ *is valid for all* $z \in [0, L]$, *then* $C_L^2(u)$ *holds.*

Proof: We employ concavity of cosine in $(0, \frac{1}{2}\pi)$ obtaining

$$\begin{aligned} c_\Gamma^2(u) &\leqslant 2L \int_0^u \mathrm{d}x(u - x)\cos\left(\frac{1}{L}\int_0^L \mathrm{d}z \int_{z-(1/2)x}^{z+(1/2)x} \gamma(s)\mathrm{d}s \right) \\ &= 2L \int_0^u \mathrm{d}x(u - x)\cos\left(\frac{1}{L}\int_0^L \mathrm{d}s\gamma(s) \int_{s-(1/2)x}^{s+(1/2)x} \mathrm{d}z \right) \\ &= 2L \int_0^u \mathrm{d}x(u - x)\cos\frac{2\pi x}{L} = \frac{L^3}{\pi^2}\sin^2\frac{\pi u}{L}, \end{aligned}$$

since $\int_0^L \gamma(s)\mathrm{d}s = \pm 2\pi$ for a curve without self-intersections. Moreover, the function $z \mapsto \int_{z-(1/2)x}^{z+(1/2)x} \gamma(s)\mathrm{d}s$ is constant for $x \in (0, u)$ *iff* $\gamma(\cdot)$ is constant; hence the circle corresponds to a sharp maximum. ■

This result, however, does not help us with our main problem, because we need the inequality to be valid for all arclengths. As indicated before, we can prove a local result which will imply Theorem 2.1.

Theorem 5.2: *Under the regularity assumptions of Sec. III, the inequality* $C_L^2(u)$ *holds locally for any* $L > 0$ *and* $u \in (0, \frac{1}{2}L]$, *and, consequently,* $C_L^{\pm p}(u)$ *holds locally for any* $p \in (0, 2]$.

Proof: Gentle deformations of a circle can be characterized by the curvature

$$\gamma(s) = \frac{2\pi}{L} + g(s),$$

where g is a piecewise continuous functions which is small in the sense that $\|g\|_\infty \ll L^{-1}$ and satisfies the condition $\int_0^L g(s)\mathrm{d}s = 0$. The function in the last integral of (5.3) can be then expanded as

$$\cos\frac{2\pi x}{L} - \sin\frac{2\pi x}{L}\int_{z-(1/2)x}^{z+(1/2)x} g(s)\mathrm{d}s - \frac{1}{2}\cos\frac{2\pi x}{L}\left(\int_{z-(1/2)x}^{z+(1/2)x} g(s)\mathrm{d}s\right)^2 + \mathcal{O}(g^3),$$

where the error term is a shorthand for $\mathcal{O}(\|Lg\|_\infty^3)$. Substituting this expansion into (5.3) we find that the term linear in g vanishes, because

$$\int_0^L \mathrm{d}z \int_{z-(1/2)x}^{z+(1/2)x} g(s)\mathrm{d}s = \int_0^L \mathrm{d}s\, g(s)\int_{s-(1/2)x}^{s+(1/2)x} \mathrm{d}z = 0,$$

and thus

$$c_\Gamma^2(u) = \frac{L^3}{\pi^2}\sin^2\frac{\pi u}{L} - I_g(u) + \mathcal{O}(g^3), \tag{5.4}$$

where

$$I_g(u) := \int_0^u \mathrm{d}x(u-x)\cos\frac{2\pi x}{L}\int_0^L \mathrm{d}z\left(\int_{z-(1/2)x}^{z+(1/2)x} g(s)\mathrm{d}s\right)^2.$$

We need to show that $I_g(u) > 0$ unless $g = 0$ identically. Notice that for $u \leqslant \frac{1}{4}L$ this property holds trivially. For $u \in (\frac{1}{4}L, \frac{1}{2}L]$ we use the fact that g is periodic and piecewise continuous, so we can write it through its Fourier series,

$$g(s) = \sum_{n=1}^{\infty}\left(a_n \sin\frac{2\pi n s}{L} + b_n\cos\frac{2\pi n s}{L}\right),$$

with the zero term missing, where $\Sigma_n(a_n^2 + b_n^2)$ is finite (and small). Using

$$\int_{z-(1/2)x}^{z+(1/2)x} g(s)\mathrm{d}s = \frac{L}{\pi}\sum_{n=1}^{\infty}\frac{1}{n}\left(a_n\sin\frac{2\pi n z}{L} + b_n\cos\frac{2\pi n z}{L}\right)\sin\frac{\pi n x}{L},$$

together with the orthogonality of the Fourier basis we find

$$I_g(u) = \int_0^u \mathrm{d}x(u-x)\cos\frac{2\pi x}{L}\sum_{n=1}^{\infty}\frac{L^3}{2\pi^2}\frac{a_n^2+b_n^2}{n^2}\sin\frac{\pi n x}{L}.$$

Since the summation and integration can be obviously interchanged, we have

$$I_g(u) = \frac{L^5}{2\pi^4}\sum_{n=1}^{\infty}\frac{a_n^2+b_n^2}{n^2}F_n\left(\frac{\pi u}{L}\right), \tag{5.5}$$

where

$$F_n(v) := \int_0^v (v-y)\cos 2y \sin ny\,\mathrm{d}y.$$

These integrals are equal to

$$F_1(v) = \frac{1}{18}(9\sin v - \sin 3v - 6v),$$

$$F_2(v) = \frac{1}{32}(4v - \sin 4v),$$

$$F_n(v) = \frac{nv}{n^2-4} - \frac{\sin(n-2)v}{2(n-2)^2} - \frac{\sin(n+2)v}{2(n+2)^2}, \quad n \geqslant 3.$$

Using the fact that $\sin x < x$ for $x > 0$ we see immediately that $F_n(v) > 0$ for $v > 0$ and $n \geqslant 2$. On the other hand, $F_1(v)$ has in the interval $(0, \pi/2)$ a single positive maximum, at some $v > \pi/4$, from which it decreases to the value $F_1(\pi/2) = \frac{1}{18}(10-3\pi) > 0$. Summing up this argument, we have found that the quantity (5.5) is positive unless all the coefficients a_n, b_n are zero. ■

Remark 5.3: One may wonder what happened with the closedness requirement (5.2). As the argument shows we were able to demonstrate the claim using only the weaker property that $\beta(0) = \beta(L)$. This is possible, of course, for small deformations only! As an illustration, consider Γ in the form of an "overgrown paperclip" which satisfies the condition $\beta(0) = \beta(L)$ but not (5.2), i.e., a line segment with two U turns at the ends. Making the latter short one can get $c_\Gamma^2(\frac{1}{2}L)$ arbitrarily close to $\frac{1}{3}L^3$ which is larger than L^3/π^2.

VI. EXTENSIONS AND CONCLUSIONS

To support our expectations that the result given in Theorem 2.1 holds globally and under weaker regularity assumptions, consider a simple example.

Example 6.1: Let Γ be a curve consisting of two circular segments of radius $R > L/4\pi$, i.e., it is given by the equations

$$\left(x \pm R\cos\frac{L}{2R}\right)^2 + y^2 = R^2, \quad \text{for } \pm x \geqslant 0. \tag{6.1}$$

For $R > L/2\pi$ it is "lens shaped," for $L/4\pi < R < L/2\pi$ "apple shaped;" it is not smooth except in the trivial case of a circle, $R = L/2\pi$. The curvature of this Γ equals

$$\gamma(s) = \frac{1}{R} + \left(\pi - \frac{L}{2R}\right)(\delta(s) + \delta(s - L/2));$$

hence

$$c_\Gamma^2(u) = 2\int_0^u \mathrm{d}x(u-x)\left[(L-2x)\cos\frac{x}{R} - 2x\cos\frac{L-2x}{2R}\right]\mathrm{d}x,$$

and evaluating the integral, we arrive at

$$c_\Gamma^2(u) = 8R^3\left\{\frac{L}{2R}\sin^2\frac{u}{2R} + 4\left(\frac{u}{2R}\cos\frac{u}{2R} - \sin\frac{u}{2R}\right)\cos\frac{L}{4R}\cos\frac{L-2u}{4R}\right\}.$$

This function has for each $u \in (0, \frac{1}{2}L]$ a maximum at $R = L/2\pi$ and one can check directly that its value is smaller for any other R. In particular, in the limit $R \to \infty$ we have $c_\Gamma^2(u) \to Lu^2 - \frac{4}{3}u^3$ as one can find also directly with the "lens" degenerate into a double line segment; this value is less than $(L^3/\pi^2)\sin^2(\pi u/L)$ because $\sin^2 x > x^2 - (4/3\pi)x^3$ holds in $(0, \pi/2)$.

To summarize our discussion, to prove Conjecture 2.2 it is sufficient to verify the inequality $C_L^p(u)$ for some $p \geqslant 1$ under appropriate regularity hypothesis. Naturally, one can ask also about the ground-state maximizer in smaller families of curves Γ which do not contain the circle; examples could be polygonal loops with a fixed or limited number of vertices, or various pre-

scribed compositions of arcs belonging to specific classes, circular, elliptic, parabolic, etc. Obviously a reasonable strategy is to look first for curves as close to the circle as possible within the given class. Sometimes one expects that the answer will be the curve with maximum symmetry as in the polygon case, in other situations it may not be true.

Another, and maybe more important extension of the present problem concerns a maximizer for the generalized Schrödinger operator in $\mathbb{R}^3$ with an attractive δ interaction supported by a closed surface of a fixed area A, and its generalization to closed hypersurfaces of codimension one in $\mathbb{R}^d$, $d>3$. In the case of $d=3$ we have a heuristic argument relying on Refs. 6 and 8 similar to that used in the Introduction, which suggests that the problem is solved by the sphere, provided the discrete spectrum is not empty, of course, which is a nontrivial assumption in this case—for properties of the corresponding operators, see Ref. 2. The Birman–Schwinger reduction of the problem similar to that of Sec. III can be performed again and the task is thus reduced to verification of a geometric inequality analogous to (4.1) which we can label as $C_A^{d,p}(u)$. We will discuss this problem in a following paper.

We define and study a fidelity criterion for quantum channels, which we term the *minimax fidelity*, through a noncommutative generalization of maximal Hellinger distance between two positive kernels in classical probability theory. Like other known fidelities for quantum channels, the minimax fidelity is well defined for channels between finite-dimensional algebras, but it also applies to a certain class of channels between infinite-dimensional algebras (explicitly, those channels that possess an operator-valued Radon-Nikodym density with respect to the trace in the sense of Belavkin-Staszewski) and induces a metric on the set of quantum channels that is topologically equivalent to the CB-norm distance between channels, precisely in the same way as the Bures metric on the density operators associated with statistical states of quantum-mechanical systems, derived from the well-known fidelity ("generalized transition probability") of Uhlmann, is topologically equivalent to the trace-norm distance. © *2005 American Institute of Physics.*

I. INTRODUCTION

Many problems in quantum information science,[1,2] both in theory and in experiment, involve finding a set of quantum-mechanical states or channels that solve some sort of an optimization problem, typically formulated in terms of a numerical criterion that measures how close a given pair of states or operations are to each other. (Many such criteria have been proposed to date, each defined with specific theoretical or experimental considerations in mind; see Ref. 3 for a recent comprehensive survey.)

Let us first consider the case of quantum states, i.e., density operators. Let $\mathfrak{h}$ be a complex separable Hilbert space associated to a quantum-mechanical system. Given a pair of density operators ρ,σ, i.e., positive trace-class operators with unit trace, one can use either the *fidelity*[4–7]

$$F(\rho,\sigma) := \mathrm{Tr}[(\rho^{1/2}\sigma\rho^{1/2})^{1/2}] \tag{1}$$

or the *trace-norm (half-) distance*

[c)]E-mail address: maxim@ece.northwestern.edu

$$D(\rho,\sigma) := \tfrac{1}{2}\|\rho-\sigma\|_{\mathrm{T}}, \tag{2}$$

where $\|\rho\|_{\mathrm{T}} := \mathrm{Tr}|\rho|$ and $|\rho| := (\rho^{\dagger}\rho)^{1/2}$.[8,9] Loosely speaking, two states ρ and σ are close to each other if $F(\rho,\sigma)$ is large, or if $D(\rho,\sigma)$ is small. In fact, as follows from the key inequality[5,10]

$$1-F(\rho,\sigma) \leqslant D(\rho,\sigma) \leqslant \sqrt{1-F^2(\rho,\sigma)}, \tag{3}$$

the fidelity and the trace-norm distance are equivalent in the sense that any two density operators that are close to one another in the sense of (1) are also close in the sense of (2), and vice versa.

As for *quantum channels*, i.e., normal completely positive unital mappings from an operator algebra $\mathcal{B}=\mathcal{B}(\mathfrak{h})$ into another algebra $\mathcal{A}=\mathcal{B}(\mathfrak{g})$, where $\mathfrak{g}$ and $\mathfrak{h}$ are complex separable Hilbert spaces, things get somewhat complicated. Consider, for instance, the case when $\mathfrak{g}$ is finite-dimensional, and let $m := \dim \mathfrak{g}$. Fix an orthonormal basis $\{|j\rangle\}_{j=1}^{m}$ of $\mathfrak{g}$, and let $|\psi\rangle := m^{-1/2}\Sigma_{j=1}^{m}|j\rangle \otimes |j\rangle$ be the normalized maximally entangled vector in the product space $\mathfrak{g}\otimes\mathfrak{g}$. Given two quantum channels $\Phi,\Psi:\mathcal{B}\to\mathcal{A}$, one can measure their closeness in terms of the fidelity of the states on $\mathcal{B}\otimes\mathcal{A}$, obtained from the maximally entangled state $\pi=|\psi\rangle\langle\psi|$ by applying the predual channels Φ_{T} and Ψ_{T} (cf. Sec. II for precise definitions) to the first factor in the tensor product:

$$\Phi_{\mathrm{T}}\otimes\mathrm{id}(\pi) = \frac{1}{m}\sum_{i=1}^{m}\sum_{k=1}^{m}\Phi_{\mathrm{T}}(|i\rangle\langle k|)\otimes|i\rangle\langle k| \equiv \rho,$$

$$\Psi_{\mathrm{T}}\otimes\mathrm{id}(\pi) = \frac{1}{m}\sum_{i=1}^{m}\sum_{k=1}^{m}\Psi_{\mathrm{T}}(|i\rangle\langle k|)\otimes|i\rangle\langle k| \equiv \sigma.$$

The fidelity $F(\rho,\sigma)$, taken as the *channel fidelity*

$$\mathcal{F}(\Phi,\Psi) := F(\Phi_{\mathrm{T}}\otimes\mathrm{id}(\pi),\quad \Psi_{\mathrm{T}}\otimes\mathrm{id}(\pi)), \tag{4}$$

by Raginsky in Ref. 11, enjoys many properties parallel to those of the fidelity (1) for quantum states. Alternatively, one can adopt the (half-) distance[1,12,13]

$$\mathcal{D}(\Phi,\Psi) := \tfrac{1}{2}\|\Phi-\Psi\|_{\mathrm{CB}}, \tag{5}$$

where $\|\cdot\|_{\mathrm{CB}}$ denotes the so-called *norm of complete boundedness* (or CB-norm for short; cf. Sec. II C for details). We note that the CB-norm half-distance (5) can be given in terms of the trace-norm distance (2) between density operators by means of the variational expression[1,12,13]

$$\mathcal{D}(\Phi,\Psi) = \sup_{\pi} D(\Phi_{\mathrm{T}}\otimes\mathrm{id}(\pi),\quad \Psi_{\mathrm{T}}\otimes\mathrm{id}(\pi)), \tag{6}$$

where the supremum is taken over all density operators π on the tensor product space $\mathfrak{g}\otimes\mathfrak{g}$. By analogy with density operators of the states, we are tempted to say that two quantum channels, Φ and Ψ, are close either if $\mathcal{F}(\Phi,\Psi)$ is large or if $\mathcal{D}(\Phi,\Psi)$ is small. However, in addition to the finite-dimension restriction $\dim\mathfrak{g}<\infty$ [the only case under which the definition (4) of the channel fidelity makes sense], we encounter the following difficulty. It turns out[11] that, as a criterion of closeness, the CB-norm distance (5) is strictly stronger than the fidelity measure (4) in the sense that even when $\mathcal{D}(\Phi,\Psi)$ is large, $\mathcal{F}(\Phi,\Psi)$ may be quite large as well, and may even become equal to one in the limit $\dim\mathfrak{g}\to\infty$. Consider, for instance, the case $\Psi=\mathrm{id}$. Then one can show[11] that

$$1-\mathcal{D}(\Phi,\mathrm{id}) \leqslant \mathcal{F}(\Phi,\mathrm{id}) \leqslant \sqrt{1-(1/4)\mathcal{D}^2(\Phi,\mathrm{id})}, \tag{7}$$

and we immediately see that when Φ is such that $\mathcal{D}(\Phi,\mathrm{id})$ attains its maximum value of unity, the fidelity $\mathcal{F}(\Phi,\mathrm{id})$ is still bounded between 0 and $\sqrt{3}/2$. To make matters worse, the only bound on (5) in terms of (4) known so far is

$$1 \geqslant \mathcal{D}(\Phi,\Psi) \geqslant 1 - \mathcal{F}(\Phi,\Psi), \tag{8}$$

as follows readily from Eqs. (3) and (6). Furthermore, one can easily find sequences $\{\Phi_m\}$, $\{\Psi_m\}$ of channels $\Phi_m,\Psi_m:\mathcal{B}(\mathbb{C}^m)\to\mathcal{B}(\mathbb{C}^m)$, such that $\mathcal{D}(\Phi_m,\Psi_m)\neq 0$ for all m, while

$$\lim_{m\to\infty} \mathcal{F}(\Phi_m,\Psi_m) = 1.$$

Indeed, consider the unitarily implemented channels

$$\Phi_m(B) = U_m^\dagger B U_m, \quad \Psi(B) = V_m^\dagger B V_m$$

with the unitaries U_m, V_m chosen in such a way that $U_m \neq V_m$ but

$$\lim_{m\to\infty} \frac{1}{m} \mathrm{Tr}(U_m^\dagger V_m) = 1.$$

Thus, the channel fidelity (4), apart from being applicable only in finite-dimensional settings, has the distinct disadvantage of not being equivalent to the CB-norm distance, in contrast to the case of the Uhlmann fidelity (1) and the trace-norm distance (2) on the state space of a quantum-mechanical system.

The goal of this paper is to define and study a new fidelity criterion for quantum channels, which we term the *minimax fidelity* and which is a noncommutative generalization of maximal Hellinger distance between two positive kernels in classical probability theory. Unlike the channel fidelity (4) of Ref. 11, the minimax fidelity is not only well defined for channels between finite-dimensional algebras, but also applies to a certain class of channels between infinite-dimensional algebras (explicitly, those channels that possess an operator-valued Radon-Nikodym density with respect to the trace in the sense of Belavkin-Staszewski[14]) and is equivalent to the CB-norm distance, echoing the way the Uhlmann fidelity (1) for density operators is equivalent to the trace-norm distance (2).

Apart from these technical features, the minimax fidelity $f(\Phi,\Psi)$ between two quantum channels Φ,Ψ has a direct *operational* meaning: intuitively, it is defined as the minimum overlap of output states (density operators) of the predual channels $\Phi_\mathsf{T},\Psi_\mathsf{T}$, when the operator-sum decompositions[2] of the latter are chosen to be maximally overlapping; this is spelled out in precise terms in Sec. IV E. Our central result (Theorem 1) demonstrates that the minimax fidelity is independent of the order of these two optimizations. Furthermore, the equivalence of our minimax fidelity to the CB-norm distance, which is stated precisely in Sec. V in terms of *dimension-free* bounds, is a promising avenue for the study and characterization of dimension-free bounds (whenever they exist) on other operationally meaningful distance measures for quantum operations[3] in terms of the CB-norm distance. As pointed out in Ref. 15, such bounds are crucial for a successful generalization of the usual quantum capacity of a channel[1,2] (i.e., with respect to the identity channel) to the case of comparing quantum channels to an arbitrary reference channel. We plan to pursue these matters further in a future publication.

The paper is organized as follows. In Sec. II we fix the definitions and notation used throughout the paper. The minimax fidelity is then introduced in Sec. III. Section IV is devoted to the evaluation of the minimax fidelities in the various mathematical settings that arise in quantum information theory. Next, in Sec. V, we list key properties of the minimax fidelity. Finally, in Sec. VI we sketch some example applications of the minimax fidelity to several problems of quantum information theory.

II. PRELIMINARIES, DEFINITIONS, NOTATION

A. Pairings, states, operations

Let $\mathfrak{h}$ be a complex separable Hilbert space; let $\mathcal{B}$ denote the Banach algebra $\mathcal{B}(\mathfrak{h})$ of all bounded linear operators on $\mathfrak{h}$ with the usual operator norm $\|\cdot\|$; and let $\mathcal{B}_\mathsf{T}$ denote the Banach space $\mathcal{B}_\mathsf{T}(\mathfrak{h})$ of trace-class operators on $\mathfrak{h}$ with the trace norm $\|\cdot\|_\mathsf{T}$. The set of normal states on $\mathcal{B}$,

i.e., ultraweakly continuous positive unital linear functionals on $\mathcal{B}$, will be denoted by $\mathcal{S}(\mathcal{B})$ or, whenever we need to exhibit the underlying Hilbert space explicitly, by $\mathcal{S}(\mathfrak{h})$. Generic elements of $\mathcal{S}(\mathcal{B})$ will be denoted by the stylized Greek letters $\varpi, \varrho, \varsigma$. Note that the operator norm on $\mathcal{B}$ can be written as $\|B\| = \sup\{\varrho(|B|) : \varrho \in \mathcal{S}(\mathcal{B})\}$.

We equip $\mathfrak{h}$ (and shall equip all Hilbert spaces introduced in the sequel) with an isometric involution $J = J^\dagger$, $J^2 = \mathbb{1}_\mathfrak{h}$, having the properties of complex conjugation,

$$J\sum_j \lambda_j \eta_j = \sum_j \overline{\lambda_j} J\eta_j, \quad \forall\, \lambda_j \in \mathbb{C},\ \eta_j \in \mathfrak{h}.$$

We can thus define the *transpose* of any $B \in \mathcal{B}$ as $\widetilde{B} := JB^\dagger J$, as well as introduce the trace pairing[16]

$$(B, \rho) := \mathrm{Tr}(B\widetilde{\rho}) = \mathrm{Tr}(\widetilde{B}\rho), \quad \forall\, B \in \mathcal{B},\ \rho \in \mathcal{B}_\mathsf{T} \tag{9}$$

of $\mathcal{B}$ and $\mathcal{B}_\mathsf{T}$. Under this pairing, which differs from the usual one in that $B \in \mathcal{B}$ is paired with the transpose of $\rho \in \mathcal{B}_\mathsf{T}$ rather than directly with ρ, normal linear functionals on $\mathcal{B}$ are in a one-to-one correspondence with the elements of $\mathcal{B}_\mathsf{T}$. Thus to each normal state ϱ we associate a unique positive trace-class operator with unit trace, denoted by the standard Greek letter ρ and referred to as the *density operator* corresponding to ϱ, via $\varrho(B) = (B, \rho)$ for all $B \in \mathcal{B}$. Similarly, density operators corresponding to states denoted by ϖ and ς will be denoted by π and σ, respectively.

Apart from natural arguments from standard representation theory of operator algebras, one reason why we chose to pair B with the transposed operator $\widetilde{\rho} = J\rho^\dagger J$, rather than with ρ, is to be able to keep all notations conveniently parallel to the classical (commutative) case, as will be amply demonstrated throughout the paper. Note also that we can fix a complete orthonormal basis $\{|j\rangle\}$ of $\mathfrak{h}$ and express the pairing (9) in terms of the matrix elements of B and ρ as

$$(B, \rho) = \sum_{j,k} \langle j|B|k\rangle \cdot \langle j|\rho|k\rangle \equiv \sum_{j,k} B_{jk}\rho^{jk},$$

where we have used the covariant indices for the matrix elements of bounded operators in $\mathcal{B}$ and the contravariant indices for the matrix elements of trace-class operators in $\mathcal{B}_\mathsf{T}$, when the latter are identified via the pairing (9) with normal linear functionals on $\mathcal{B}$. Yet another reason to opt for the pairing of B with the transposed operator $\widetilde{\rho}$, further elaborated upon in Sec. II B, is that then the density operator ρ of a normal state ϱ will coincide with the operational density of ϱ, understood as a quantum operation from $\mathcal{B}$ into the Abelian algebra $\mathbb{C}$.

Introducing another Hilbert space $\mathfrak{g}$, the algebra $\mathcal{A} := \mathcal{B}(\mathfrak{g})$, and the trace class $\mathcal{A}_\mathsf{T} := \mathcal{B}_\mathsf{T}(\mathfrak{g})$, let us consider *quantum operations*, i.e., the completely positive normal linear mappings $\Phi : \mathcal{B} \to \mathcal{A}$ such that $\Phi(\mathbb{1}_\mathfrak{h}) \leqslant \mathbb{1}_\mathfrak{g}$; if $\Phi(\mathbb{1}_\mathfrak{h}) = \mathbb{1}_\mathfrak{g}$, then Φ is referred to as a *quantum channel*. Any quantum operation Φ possesses a unique *predual* $\Phi_\mathsf{T} : \mathcal{A}_\mathsf{T} \to \mathcal{B}_\mathsf{T}$, defined as the transpose of Φ with respect to the trace pairing (9), i.e.,

$$(\Phi(B), \rho) = (B, \Phi_\mathsf{T}(\rho)), \quad \forall\, B \in \mathcal{B},\ \rho \in \mathcal{A}_\mathsf{T}. \tag{10}$$

Conversely, given a normal completely positive linear map $\Phi : \mathcal{A}_\mathsf{T} \to \mathcal{B}_\mathsf{T}$ such that $\mathrm{Tr}_\mathfrak{h}\Phi(\rho) \leqslant \mathrm{Tr}_\mathfrak{g}\rho$ for all $\rho \in \mathcal{A}_\mathsf{T}$, we define its *dual* with respect to the trace pairing (9) as the unique mapping $\Phi^\mathsf{T} : \mathcal{B} \to \mathcal{A}$ for which

$$(B, \Phi(\rho)) = (\Phi^\mathsf{T}(B),\ \rho), \quad \forall\, B \in \mathcal{B}, \rho \in \mathcal{A}_\mathsf{T}. \tag{11}$$

Using these definitions, one readily obtains that $\Phi_\mathsf{T}^\mathsf{T} = \Phi$ for any normal completely positive map $\Phi : \mathcal{B} \to \mathcal{A}$. Alternatively, one may define the predual of a normal completely positive map $\Phi : \mathcal{B} \to \mathcal{A}$ as the unique normal completely positive map $\Phi_\mathsf{T} : \mathcal{A}_\mathsf{T} \to \mathcal{B}_\mathsf{T}$ such that $\Phi_\mathsf{T}^\mathsf{T} = \Phi$.

If Φ is given in the Kraus form[17] $\Phi(B) = \Sigma F_j^\dagger B F_j$, or more generally as an integral

$$\Phi(B) = \int_Z F(z)^\dagger B F(z) \mathrm{d}\mu(z), \tag{12}$$

with respect to a positive measure μ on a measurable space $(Z, \mathcal{B}_Z)$, where the integration is understood in the sense of Bochner,[18] then the predual map Φ_T has the transposed integral form

$$\Phi_\mathsf{T}(\rho) = \int_Z F_\mathsf{T}(z)^\dagger \rho F_\mathsf{T}(z) \mathrm{d}\mu(z),$$

where $\mathfrak{g} \ni \xi \mapsto \langle \xi | F_\mathsf{T}(z)$ are Hilbert-transposed to the operators $\mathfrak{h} \ni \eta \mapsto \langle \eta | F(z)$, that is $F_\mathsf{T}(z) = \widetilde{F(z)}$ for all $z \in Z$.

Any normal state $\varrho \in \mathcal{S}(\mathcal{B})$ is automatically a quantum channel from $\mathcal{B}$ into the Abelian algebra $\mathbb{C}$, and it is readily seen that the density operator ρ of ϱ, understood as acting on $\lambda \in \mathbb{C}$ on the right, $\mathbb{C} \ni \lambda \mapsto \lambda\rho$, is precisely the predual $\varrho_\mathsf{T}: \mathbb{C} \to \mathcal{B}_\mathsf{T}$. Indeed, given $B \in \mathcal{B}$ and $\lambda \in \mathbb{C}$, we have

$$(\varrho(B), \lambda) = (B, \lambda\rho) = (B, \varrho_\mathsf{T}(\lambda)),$$

which proves our claim that $\rho = \varrho_\mathsf{T}$. Thus we also have that $\varrho = \varrho_\mathsf{T}^\mathsf{T} = \rho^\mathsf{T}$.

B. Operational densities

In order to avoid technicalities involving unbounded operators, we shall henceforth assume that all quantum operations we deal with are *completely majorized* by the trace, considered as the map $\tau(\sigma) = \mathbb{1}_\mathfrak{g} \mathrm{Tr}\, \sigma$ of $\mathcal{B}_\mathsf{T}$ into $\mathcal{A} = \mathcal{B}(\mathfrak{g})$, in the sense[14] that there exists a constant $\lambda > 0$ such that the difference $\lambda\tau - \Phi$ is a completely positive map $\mathcal{B}_\mathsf{T} \to \mathcal{A}$. For example, this condition is satisfied by all quantum operations between finite-dimensional algebras.[19] As was proven in Ref. 14, in this case there exists a unique positive operator Φ_τ on the Hilbert space $\mathcal{H} := \mathfrak{g} \otimes \mathfrak{h}$, called the *density* of Φ with respect to the trace τ, such that

$$\Phi(B) = \mathrm{Tr}_\mathfrak{h}[(\mathbb{1}_\mathfrak{g} \otimes \widetilde{B})\Phi_\tau], \tag{13}$$

where $\mathrm{Tr}_\mathfrak{h}\, Y$, $Y \in \mathcal{B}(\mathcal{H})$, denotes the partial trace of Y with respect to $\mathfrak{h}$,

$$(\mathrm{Tr}_\mathfrak{h} Y, \rho) = (Y, \rho \otimes \mathbb{1}_\mathfrak{h}), \quad \forall\, \rho \in \mathcal{B}_\mathsf{T}(\mathfrak{g}).$$

Moreover, Φ_τ as a linear operator on $\mathcal{H}$ is bounded and majorized by $\lambda: 0 \leqslant \Phi_\tau \leqslant \lambda \mathbb{1}_\mathcal{H}$, and the operation is unital, $\Phi(\mathbb{1}_\mathfrak{h}) = \mathbb{1}_\mathfrak{g}$ [contractive, $\Phi(\mathbb{1}_\mathfrak{h}) \leqslant \mathbb{1}_\mathfrak{g}$] if and only if $\mathrm{Tr}_\mathfrak{h}\, \Phi_\tau = \mathbb{1}_\mathfrak{g}$ ($\mathrm{Tr}_\mathfrak{h}\, \Phi_\tau \leqslant \mathbb{1}_\mathfrak{g}$). This is equivalent to saying that the predual map $\Phi_\mathsf{T}: \mathcal{A}_\mathsf{T} \to \mathcal{B}_\mathsf{T}$, which, using Eqs. (10) and (13), can be written as

$$\Phi_\mathsf{T}(\rho) = \mathrm{Tr}_\mathfrak{g}[\Phi_\tau(\widetilde{\rho} \otimes \mathbb{1}_\mathfrak{h})], \tag{14}$$

is trace preserving (trace decreasing).

As an example, consider a normal state ϱ on $\mathcal{B}$, which, being a quantum channel into $\mathbb{C}$, satisfies the complete majorization condition with $\lambda = \|\rho\|$, where ρ is the density operator of ϱ. Furthermore, it is easy to see that $\varrho_\tau = \rho$. Indeed, we can write

$$\varrho(B) = (B, \rho) = \mathrm{Tr}(B\widetilde{\rho}) = \mathrm{Tr}(\widetilde{B}\rho) = \mathrm{Tr}_\mathfrak{h}[(\mathbb{1}_\mathbb{C} \otimes \widetilde{B})\rho],$$

and the desired result follows upon comparing this with Eq. (13). This provides additional justification for our definition of the trace pairing in Eq. (9), since we then have that $\varrho_\mathsf{T} = \rho = \varrho_\tau$ for any normal state ϱ.

If the operation $\Phi: \mathcal{B} \to \mathcal{A}$ is given in the generalized Kraus form (12), we can write down its operational density Φ_τ explicitly. To this end, suppose that all operators $F(z)$ are determined by generalized bra-vectors $\Gamma(z) = (F(z)|$, densely defined as the linear functionals

$$\Gamma(z)|\xi\otimes\eta\rangle = \langle\xi|F(z)|\eta\rangle \equiv (F(z)||\xi\otimes\eta\rangle)$$

on the linear span of the ket-vectors $|\xi\otimes\eta\rangle \equiv \widetilde{\xi\otimes\eta}$ in $\mathcal{H}=\mathfrak{g}\otimes\mathfrak{h}$, where $\xi\in\mathfrak{g}$ is also treated as a bra-vector such that $J\xi=\langle\xi|$ and $|\xi\rangle=\tilde{\xi}$. Then the operational density Φ_τ of Φ is given by the corresponding decomposition

$$\Phi_\tau = \int \Gamma(z)^\dagger\Gamma(z)\mathrm{d}\mu(z) \equiv \Gamma^\dagger\Gamma, \tag{15}$$

where the integral is, again, understood in the sense of Bochner.

C. Completely bounded maps

Completely positive linear maps between operator algebras are a special case of *completely bounded* maps.[20] Consider, as before, the algebras $\mathcal{B}=\mathcal{B}(\mathfrak{h})$ and $\mathcal{A}=\mathcal{B}(\mathfrak{g})$. For each $n\in\mathbb{N}$ define the *n*th *matrix level* $\mathcal{M}_n(\mathcal{B})\simeq\mathcal{B}\otimes\mathcal{M}_n$, where $\mathcal{M}_n$ denotes the algebra of $n\times n$ matrices with complex entries. That is, $\mathcal{M}_n(\mathcal{B})$ is the space of $n\times n$ matrices with $\mathcal{B}$-valued entries,

$$\mathcal{M}_n(\mathcal{B}) := \{[B_{ij}]: B_{ij}\in\mathcal{B}, 1\leqslant i,j\leqslant n\}.$$

Analogous construction can also be applied to $\mathcal{A}$ to yield the matrix levels $\mathcal{M}_n(\mathcal{A})$. Each matrix level $\mathcal{M}_n(\mathcal{B})$ inherits a *-algebra structure from $\mathcal{B}$ through

$$[B_{ij}][C_{ij}] := \left[\sum_{k=1}^{n} B_{ik}C_{kj}\right], \quad [B_{ij}]^\dagger := [B_{ij}^\dagger].$$

In fact, by identifying $\mathcal{M}_n(\mathcal{B})$ via a natural *-isomorphism with the algebra $\mathcal{B}(\mathfrak{h}^{(n)})$ of bounded linear operators on $\mathfrak{h}^{(n)}$, the direct sum of *n* copies of $\mathfrak{h}$, one can make $\mathcal{M}_n(\mathcal{B})$ into a C^*-algebra. Thus, each matrix level of $\mathcal{B}$ possesses a unique C^*-norm.

Now, for any $n\in\mathbb{N}$ a linear map $\Lambda:\mathcal{B}\to\mathrm{A}$ induces the map $\Lambda^{(n)}:=\Lambda\otimes\mathrm{id}_n$ from $\mathcal{M}_n(\mathcal{B})$ into $\mathcal{M}_n(\mathcal{A})$, defined by $\Lambda^{(n)}:[B_{ij}]\mapsto[\Lambda(B_{ij})]$. Let us define the *norm of complete boundedness* (or CB-norm) by $\|\Lambda\|_{\mathrm{CB}}:=\sup\{\|\Lambda^{(n)}\|:n\in\mathbb{N}\}$, where

$$\|\Lambda^{(n)}\| := \sup_{B\in\mathcal{M}_n(\mathcal{B}),\|B\|\leqslant 1}\|\Lambda^{(n)}(B)\|$$

is the usual operator norm of $\Lambda^{(n)}$. A linear map $\Lambda:\mathcal{B}\to\mathcal{A}$ is called *completely bounded* if $\|\Lambda\|_{\mathrm{CB}}<\infty$. Every completely positive map $\Phi:\mathcal{B}\to\mathcal{A}$ is automatically completely bounded, with $\|\Phi\|_{\mathrm{CB}}=\|\Phi(1_\mathfrak{h})\|$. For a general completely bounded map Λ, one has, by definition, $\|\Lambda(1_\mathfrak{h})\|\leqslant\|\Lambda\|\leqslant\|\Lambda\|_{\mathrm{CB}}$.

Passing to the predual map $\Lambda_\mathsf{T}:\mathcal{A}_\mathsf{T}\to\mathcal{B}_\mathsf{T}$, we can similarly define induced maps $\Lambda_\mathsf{T}^{(n)}:\mathcal{M}_n(\mathcal{A}_\mathsf{T})\to\mathcal{M}_n(\mathcal{B}_\mathsf{T})$, $n\in\mathbb{N}$, and the predual CB-norm

$$\|\Lambda\|_{\mathrm{CB}}^{\mathsf{T}} := \sup_{n\in\mathbb{N}}\|\Lambda^{(n)}\|_\mathsf{T},$$

where

$$\|\Lambda^{(n)}\|_\mathsf{T} := = \sup_{\rho\in\mathcal{M}_n(\mathcal{A}_\mathsf{T}):\|\rho\|_\mathsf{T}\leqslant 1}\|\Lambda^{(n)}(\rho)\|_\mathsf{T}.$$

It is easy to see that $\|\Lambda^{(n)}\|=\|\Lambda_\mathsf{T}^{(n)}\|_\mathsf{T}$ for all $n\in\mathbb{N}$, so that $\|\Lambda\|_{\mathrm{CB}}=\|\Lambda_\mathsf{T}\|_{\mathrm{CB}}^{\mathsf{T}}$. It is also straightforward to see that the "unstabilized" norms $\|\cdot\|$ and $\|\cdot\|_\mathsf{T}$ are tensor supermultiplicative (i.e., $\|\Lambda_1\otimes\Lambda_2\|\geqslant\|\Lambda_1\|\,\|\Lambda_2\|$), whereas the corresponding CB-norms are tensor multiplicative (i.e., $\|\Lambda_1\otimes\Lambda_2\|_{\mathrm{CB}}=\|\Lambda_1\|_{\mathrm{CB}}\|\Lambda_2\|_{\mathrm{CB}}$).

There is also a useful nonvariational formula for the CB-norm of a map $\Lambda:\mathcal{B}\to\mathcal{A}$. Namely, let ℓ^2 denote the Hilbert space of square-summable infinite sequences of complex numbers, and let $\mathcal{K}(\ell^2)$ denote the space of compact operators on ℓ^2. Then $\|\Lambda\|_{\mathrm{CB}}=\|\Lambda\otimes\mathrm{id}_{\mathcal{K}(\ell^2)}\|$. Since we have

assumed that $\mathcal{B}=\mathcal{B}(\mathfrak{h})$ with $\mathfrak{h}$ a complex separable Hilbert space, and since all complex separable Hilbert spaces are canonically isomorphic to ℓ^2, we may also write $\|\Lambda\|_{\mathrm{CB}}=\|\Lambda\otimes \mathrm{id}_{\mathcal{K}(\mathfrak{h})}\|$.

D. Miscellany

Any positive operator $B\in\mathcal{B}(\mathfrak{h})$ has a unique positive square root, denoted by $B^{1/2}$ and defined as the positive operator $X\in\mathcal{B}(\mathfrak{h})$ such that $B=X^2$. This definition can be extended to any operator A that is similar to a positive operator $\Delta\in\mathcal{B}(\mathfrak{h})$, in the sense that there exists an operator $S\in\mathcal{B}(\mathfrak{h})$ such that $A=S\Delta S^+$, where S^+ is the pseudoinverse of S, equal to S^{-1} on ran S and to 0 on ker S. In that case, we may *define* $\sqrt{A}:=S\Delta^{1/2}S^+$. From now on, in order to distinguish this extended definition of the square root from the usual one, we shall always use the square root symbol $\sqrt{\cdot}$ for this extended definition, and reserve the exponent notation $\cdot^{1/2}$ for the usual definition.

Consider now two positive operators $A,B\in\mathcal{B}(\mathfrak{h})$. It is easy to see that their product AB is similar to $A^{1/2}BA^{1/2}$ with $S=A^{1/2}$. Note that the operator AB is positive when restricted to the closure of ran A, when the latter is equipped with the weighted inner product $\langle v|\chi\rangle_A:=\langle A^{-1/2}v|A^{-1/2}\chi\rangle$:

$$\langle v|ABv\rangle_A=\langle A^{-1/2}v|A^{-1/2}ABv\rangle=\langle v|Bv\rangle\geqslant 0,\qquad \forall\, v\in\overline{\mathrm{ran}A}.$$

Thus we may define $\sqrt{AB}:=S(A^{1/2}BA^{1/2})S^+$ with $S=A^{1/2}$.

This notation, again, allows for a convenient parallelism between the classical (commutative) formalism and the quantum (noncommutative) one. Indeed, consider two mutually commuting positive trace-class operators ρ, σ, let $\{|x\rangle\}$ denote the set of their common eigenvectors, and let $\rho_x\equiv\langle x|\rho|x\rangle$, $\sigma_x\equiv\langle x|\sigma|x\rangle$ denote the corresponding eigenvalues. Then $\sqrt{\rho\sigma}$ is also trace-class, and

$$\mathrm{Tr}\sqrt{\rho\sigma}=\sum_x\sqrt{\rho_x\sigma_x}.$$

If $\mathrm{Tr}\,\rho=1=\mathrm{Tr}\,\sigma$, then $P:=\{\rho_x\}$ and $Q:=\{\sigma_x\}$ are probability distributions, and $\mathrm{Tr}\,\sqrt{\rho\sigma}$ then gives the classical fidelity (also known as the *Bhattacharyya coefficient*)[10] $F(P,Q)$ between P and Q.

Our main technical tool in this paper is given by the following:

Lemma 1: Let $\mathcal{H}$ be a complex separable Hilbert space, and let R, $S\in\mathcal{B}(\mathcal{H})$ be positive operators such that $R^{1/2}SR^{1/2}$ is trace class. Then the supremum

$$\sup_{X,Y\in\mathcal{B}(\mathcal{H})}\{\mathrm{Tr}(X^\dagger Y+Y^\dagger X):X^\dagger X=R,Y^\dagger Y=S\}=2\,\mathrm{Tr}\sqrt{RS}\tag{16}$$

is achieved on any $X\in\mathcal{B}(\mathcal{H})$ satisfying the condition $X^\dagger X=R$, say $X=R^{1/2}$, and $Y=Y_o$ satisfying the equation

$$Y_oX^\dagger=(XSX^\dagger)^{1/2}=XY_o^\dagger.\tag{17}$$

Proof: To prove the lemma one can use either the polar decomposition or the method of Lagrange multipliers. We shall use the latter. Fixing an X satisfying $X^\dagger X=R$, we can write the Lagrange function as

$$\mathsf{L}=\mathrm{Tr}(X^\dagger Y+Y^\dagger X-Y^\dagger YL),$$

where $L=L^\dagger\in\mathcal{B}(\mathcal{H})$ is the operator-valued Lagrange multiplier corresponding to the hermiticity condition $S=Y^\dagger Y=S^\dagger$. At the stationary point

$$\delta\mathsf{L}=\mathrm{Tr}(X^\dagger-LY^\dagger)\,\delta Y+(X-YL)\,\delta Y^\dagger=0,$$

so $Y=Y_o$ must satisfy the equation $YL=X$ (the other equation, $LY^\dagger=X^\dagger$, corresponding to $Y^\dagger=Y_o^\dagger$, is obtained by taking the Hermitian adjoint). Thus $Y_o=XL^{-1}$, where L^{-1} should be determined from $L^{-1}X^\dagger XL^{-1}=S$. Multiplying this on the left by X and on the right by $X^\dagger$ yields $(XL^{-1}X^\dagger)^2=XSX^\dagger$, or

$XL^{-1}X^\dagger=(XSX^\dagger)^{1/2}$. Thus, we indeed have that $Y_oX^\dagger=(XSX^\dagger)^{1/2}=XY_o^\dagger$, and therefore that

$$\mathrm{Tr}(Y_oX^\dagger + XY_o^\dagger) = 2\,\mathrm{Tr}((XSX^\dagger)^{1/2}). \tag{18}$$

This extremal value is precisely the maximal value due to convexity of the function being maximized in Eq. (16). Note that, since $(U^\dagger XSX^\dagger U)^{1/2}=U^\dagger(XSX^\dagger)^{1/2}U$ for any unitary U, the value of the supremum in Eq. (16), which coincides with Eq. (18), does not depend on the choice of X satisfying $X^\dagger X=R$. Indeed, by virtue of the polar decomposition $X=UR^{1/2}$,

$$2\,\mathrm{Tr}(XSX^\dagger)^{1/2} = 2\,\mathrm{Tr}(U^\dagger(XSX^\dagger)^{1/2}U) = 2\,\mathrm{Tr}((R^{1/2}SR^{1/2})^{1/2}).$$

Rewriting this trace in the equivalent form $2\,\mathrm{Tr}(X^\dagger Y_o)$ with

$$X^\dagger Y_o = R^{1/2}(R^{1/2}SR^{1/2})^{1/2}R^{-1/2} \equiv \sqrt{RS}$$

corresponding to $X=R^{1/2}$, we obtain the extremal value in Eq. (16). □

We shall also need the following simple, but useful, result:

Lemma 2: Let S be a compact subset of a complex Banach space V, such that $x\in S$ implies $\lambda x\in S$ for all $\lambda\in\mathbb{C}$ with $|\lambda|=1$. Let $f:V\to\mathbb{C}$ be a continuous function which is homogeneous of order 1, i.e., $f(\lambda x)=\lambda f(x)$ for all $\lambda\in\mathbb{C}$ and all $x\in V$. Then

$$\sup_{x\in S}|f(x)| = \sup_{x\in S}\mathrm{Re}\, f(x). \tag{19}$$

Proof: Let $x^*\in S$ be such that $|f(x^*)|=\sup_{x\in S}|f(x)|$, with $f(x^*)=|f(x^*)|e^{i\arg f(x^*)}$. Let $x^{**}:=e^{-i\arg f(x^*)}x^*$. By the homogeneity of f,

$$f(x^{**}) = e^{-i\arg f(x^*)}f(x^*) = |f(x^*)|.$$

But then $|f(x^{**})|=f(x^{**})=\mathrm{Re}\, f(x^{**})$. Since $\mathrm{Re}\,\lambda\leqslant|\lambda|$ for all $\lambda\in\mathbb{C}$, the lemma is proved. □

III. OPERATIONAL FIDELITIES AND DISTANCES

A. Classical kernel fidelity

The fidelity distinguishing different quantum operations without the restriction on the Hilbert space dimensionality was suggested by Belavkin in Ref. 21 on the basis of a noncommutative generalization of the maximal Hellinger distance between two positive kernels. Namely, given a locally compact space X and a measure space $(Y,\mathcal{B}_Y,\mu)$, where μ is a positive measure, let us denote by $\mathcal{A}$ the algebra $\mathcal{C}(X)$ of bounded continuous functions on X, and by $\mathcal{B}_\mathsf{T}\equiv\mathcal{C}_\mathsf{T}(Y)$ the space of absolutely μ-integrable complex functions on Y. A *positive kernel* $\mathbf{P}$ is then given in terms of a function $p(\cdot|\cdot):Y\times X\to\mathbb{R}^+$, such that $P_x:=p(\cdot|x)\in\mathcal{B}_\mathsf{T}$ for all $x\in X$, while $P:=\int_Y p(y|\cdot)\mathrm{d}\mu(y)\in\mathcal{A}$. Given two positive kernels $\mathbf{P}$ and $\mathbf{Q}$, the squared pointwise Hellinger distance

$$d_H^2(P_x,Q_x) := \frac{1}{2}\int(\sqrt{p(y|x)}-\sqrt{q(y|x)})^2\mathrm{d}\mu(y) = \int\left[\frac{1}{2}(p(y|x)+q(y|x)) - \sqrt{p(y|x)q(y|x)}\right]\mathrm{d}\mu(y) \tag{20}$$

is well defined and finite for each $x\in X$, so that we can define

$$d_H^2(\mathbf{P},\mathbf{Q}) := \frac{1}{2}\sup_{x\in X}\int(\sqrt{p(y|x)}-\sqrt{q(y|x)})^2\mathrm{d}\mu(y) \equiv \|d_H^2(P_x,Q_x)\|, \tag{21}$$

the last expression indicating the fact that $d_H^2(\mathbf{P},\mathbf{Q})$ is given by the supremum of the squared pointwise Hellinger distance (20) over all $x\in X$. Note that the squared Hellinger distance $d_H^2(P,Q)$ between two positive distributions $P=p(\cdot)$ and $Q=q(\cdot)$ is the minimal mean quadratic distance

$$d_H^2(P,Q) = \frac{1}{2}\inf_{\chi,\psi\in C(Y)}\left\{\int |\chi(y)-\psi(y)|^2 \mathrm{d}\mu(y) : |\chi(\cdot)|^2 = p(\cdot), |\psi(\cdot)|^2 = q(\cdot)\right\}$$

$$= \left(1, \tfrac{1}{2}(P+Q)\right) - \sup_{\psi:|\psi(\cdot)|^2=q(\cdot)} \int \sqrt{p(y)}\,\mathrm{Re}\,\psi(y)\mathrm{d}\mu(y), \tag{22}$$

where $(f,P)=\int f(y)p(y)d\mu(y)$ denotes the integral pairing of $f\in\mathcal{C}(Y)$ with $P\in\mathcal{C}_{\mathrm{T}}(Y)$. The *relative fidelity*

$$f(P,Q) = \frac{1}{\sqrt{(1,P)(1,Q)}} \sup_{\psi:|\psi(\cdot)|^2=q(\cdot)} \int \sqrt{p(y)}\,\mathrm{Re}\,\psi(y)\mathrm{d}\mu(y) = \frac{(1,\sqrt{PQ})}{\sqrt{(1,P)(1,Q)}} \tag{23}$$

of the distributions P and Q is obviously related to the distance (22) by

$$d_H^2(P,Q) + \sqrt{(1,P)(1,Q)}f(P,Q) = \left(1, \tfrac{1}{2}(P+Q)\right). \tag{24}$$

If $P_x := p(\cdot|x)$ and $Q_x := q(\cdot|x)$ are conditional distributions with constant integrals $(1,P_x)$ and $(1,Q_x)$, e.g., normalized to unity, this relation also remains valid for the minimal fidelity

$$f(\mathbf{P},\mathbf{Q}) = \inf_{x\in X} f(P_x,Q_x),$$

which can alternatively be defined by the minimax formula

$$f(\mathbf{P},\mathbf{Q}) = \inf_{x\in X} \sup_{\psi:|\psi(\cdot|x)|^2=Q_x(\cdot)} \frac{(1,\sqrt{P_x}\,\mathrm{Re}\,\psi(\cdot|x))}{\sqrt{(1,P_x)(1,Q_x)}}, \tag{25}$$

where the supremum is achieved on $\psi(\cdot|x)\equiv\psi_\circ(\cdot|x)$ satisfying $\psi(y|x)=\sqrt{q(y|x)}$. In particular, if $\mathbf{P}$ and $\mathbf{Q}$ are probability kernels, $(1,P_x)=1=(1,Q_x)$ for all $x\in X$, then

$$d_H^2(\mathbf{P},\mathbf{Q}) = 1 - \inf_{x\in X}\int \sqrt{p(y|x)q(y|x)}\mathrm{d}\mu(y) \equiv 1 - f(\mathbf{P},\mathbf{Q}),$$

where

$$f(\mathbf{P},\mathbf{Q}) = \inf_{x\in X}\int \sqrt{p(y|x)q(y|x)}\mathrm{d}\mu(y) \equiv \inf_{x\in X}(1,\sqrt{P_xQ_x}) \tag{26}$$

is the minimax fidelity of the classical channels described by these kernels.

B. Quantum operational fidelity

Generalizing Eq. (21), one can define the squared Hellinger distance between quantum operations Φ and Ψ with the respective operational densities $\Phi_\tau,\Psi_\tau\in\mathcal{B}(\mathcal{H})$, $\mathcal{H}=\mathfrak{g}\otimes\mathfrak{h}$, as

$$d_H^2(\Phi,\Psi) = \tfrac{1}{2}\inf_{\Gamma,\Upsilon\in\mathcal{B}(\mathcal{H})}\{\|\mathrm{Tr}_{\mathfrak{h}}(\Gamma-\Upsilon)^\dagger(\Gamma-\Upsilon)\| : \Gamma^\dagger\Gamma=\Phi_\tau, \Upsilon^\dagger\Upsilon=\Psi_\tau\}. \tag{27}$$

The operators $\Gamma,\Upsilon\in\mathcal{B}(\mathcal{H})$, such that $\Gamma^\dagger\Gamma=\Phi_\tau$ and $\Upsilon^\dagger\Upsilon=\Psi_\tau$, are naturally thought of as the *purifications* of Φ_τ and Ψ_τ, respectively. This means that we can fix an orthonormal basis $\{|j\rangle\}$ of $\mathcal{H}$, say the product basis $|j\rangle=|i\rangle\otimes|k\rangle\equiv|i,k\rangle$, where $\{|i\rangle\}$ and $\{|k\rangle\}$ are some fixed orthonormal bases of $\mathfrak{g}$ and $\mathfrak{h}$, respectively, and represent any such Γ and Υ as strongly convergent sums

$$\Gamma = \sum_j |j\rangle\langle j|\Gamma \equiv \sum_j |j\rangle(F_j|, \quad \Upsilon = \sum_j |j\rangle\langle j|\Upsilon \equiv \sum_j |j\rangle(V_j|, \tag{28}$$

where the generalized bra-vectors $(F_j|$ define the bounded operators $F_j,V_j:\mathfrak{g}\to\mathfrak{h}$ through

$$\langle k|F_j|i\rangle = (F_j|(|i\rangle \otimes |k\rangle) = \langle j\|\Gamma|i,k\rangle, \quad \langle k|V_j|i\rangle = (V_j|(|i\rangle \otimes |k\rangle) = \langle j\|\Upsilon|i,k\rangle.$$

As seen directly from this definition, the mapping $(F|\mapsto F$ is linear: $(aF+bG|\mapsto aF+bG$. Using Eq. (28), we may write

$$\Phi_\tau = \sum_j |F_j)(F_j| \equiv \Gamma^\dagger\Gamma, \quad \Psi_\tau = \sum_j |V_j)(V_j| \equiv \Upsilon^\dagger\Upsilon, \tag{29}$$

where the sums converge in the strong operator topology. This determines the Kraus decompositions[17] $\Phi(B)=\Sigma_j F_j^\dagger B F_j$, $\Psi(B)=\Sigma_j V_j^\dagger B V_j$ of the maps $\Phi,\Psi:\mathcal{B}\to\mathcal{A}$. Analogously, upon defining the mappings $F,V:\mathfrak{g}\to\mathfrak{h}\otimes\mathcal{H}$ by

$$F\upsilon := \sum_j F_j\upsilon \otimes |j\rangle, \quad V\upsilon := \sum_j V_j\upsilon \otimes |j\rangle,$$

we can write the maps Φ,Ψ in the Stinespring form[22] as $\Phi(B)=F^\dagger(B\otimes\mathbb{1}_\mathcal{H})F$ and $\Psi(B)=V^\dagger(B\otimes\mathbb{1}_\mathcal{H})V$.

Taking into account the fact that $\|A^\dagger A\|=\sup_{\varrho\in\mathcal{S}(\mathfrak{g})}\varrho(A^\dagger A)$ and defining the positive function

$$c(\cdot;\cdot):\mathcal{B}(\mathcal{H})\times\mathcal{B}_\mathsf{T}(\mathfrak{g})\to\mathbb{R},$$

$$c(A;\rho) := \tfrac{1}{2}\mathrm{Tr}(A(\rho\otimes\mathbb{1}_\mathfrak{h})A^\dagger),$$

we can rewrite the fidelity distance (27) in the following minimax form:

$$d_H^2(\Phi,\Psi) = \inf_{\Gamma,\Upsilon\in\mathcal{B}(\mathcal{H})}\left\{\sup_{\varrho\in\mathcal{S}(\mathfrak{g})} c(\Gamma-\Upsilon;\rho):\Gamma^\dagger\Gamma=\Phi_\tau,\Upsilon^\dagger\Upsilon=\Psi_\tau\right\}. \tag{30}$$

On the other hand, generalizing Eq. (20) to quantum operations, we can define the squared pointwise distance

$$d_H^2(\Phi,\Psi)(\varrho) := \inf_{\Gamma,\Upsilon\in\mathcal{B}(\mathcal{H})}\{c(\Gamma-\Upsilon;\rho):\Gamma^\dagger\Gamma=\Phi_\tau,\Upsilon^\dagger\Upsilon=\Psi_\tau\} \tag{31}$$

between Φ and Ψ on the set $\mathcal{S}(\mathfrak{g})$ of all normal states on $\mathcal{A}=\mathcal{B}(\mathfrak{g})$. Just as with the probability kernels in the commutative setting described in the preceding section, $d_H^2(\Phi,\Psi)$ coincides with the supremum of $d_H^2(\Phi,\Psi)(\varrho)$ over all normal states $\varrho\in\mathcal{S}(\mathfrak{g})$ whenever Φ and Ψ are (proportional to) quantum channels:

Theorem 1: *Let $\Phi,\Psi:\mathcal{B}\to\mathcal{A}$ be quantum operations with the respective operational densities $\Phi_\tau,\Psi_\tau\in\mathcal{B}(\mathcal{H})$. Suppose that for all $\varrho\in\mathcal{S}(\mathfrak{g})$ the pairings*

$$(\Phi_\tau,\rho\otimes\mathbb{1}_\mathfrak{h}) \equiv \varrho[\Phi(\mathbb{1}_\mathfrak{h})], \quad (\Psi_\tau,\rho\otimes\mathbb{1}_\mathfrak{h}) \equiv \varrho[\Psi(\mathbb{1}_\mathfrak{h})] \tag{32}$$

are constant. Then

$$d_H^2(\Phi,\Psi) = \sup_{\varrho\in\mathcal{S}(\mathfrak{g})} d_H^2(\Phi,\Psi)(\varrho). \tag{33}$$

Furthermore, then we have that

$$d_H^2(\Phi,\Psi) + \sqrt{\|\Phi\|\,\|\Psi\|}f(\Phi,\Psi) = \tfrac{1}{2}(\|\Phi\|+\|\Psi\|), \tag{34}$$

where

$$f(\Phi,\Psi) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\sup_{\Upsilon\in\mathcal{B}(\mathcal{H}):\Upsilon^\dagger\Upsilon=\Psi_\tau}\frac{\mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2}\Upsilon(\rho\otimes\mathbb{1}_\mathfrak{h})]}{\sqrt{\varrho[\Phi(\mathbb{1}_\mathfrak{h})]}\sqrt{\varrho[\Psi(\mathbb{1}_\mathfrak{h})]}} \tag{35}$$

is the minimax fidelity *between Φ and Ψ.*

Proof: Fix an arbitrary $\varrho\in\mathcal{S}(\mathfrak{g})$. From Eq. (32) it follows that

$$\|\Phi\| = \sup_{\varrho \in \mathcal{S}(\mathfrak{g})} \varrho[\Phi(\mathbb{1}_{\mathfrak{h}})] = \varrho[\Phi(\mathbb{1}_{\mathfrak{h}})],$$

and the same goes for Ψ. Therefore, given any pair $\Gamma, \Upsilon \in \mathcal{B}(\mathcal{H})$ such that $\Gamma^\dagger\Gamma = \Phi_\tau$ and $\Upsilon^\dagger\Upsilon = \Psi_\tau$, we can write

$$\begin{aligned} c(\Gamma - \Upsilon; \rho) &= \tfrac{1}{2}\mathrm{Tr}((\Gamma - \Upsilon)^\dagger(\Gamma - \Upsilon)(\rho \otimes \mathbb{1}_{\mathfrak{h}})) = \tfrac{1}{2}\mathrm{Tr}((\Phi_\tau + \Psi_\tau)(\rho \otimes \mathbb{1}_{\mathfrak{h}}) - (\Gamma^\dagger\Upsilon + \Gamma\Upsilon^\dagger)(\rho \otimes \mathbb{1}_{\mathfrak{h}})) \\ &= \tfrac{1}{2}(\|\Phi\| + \|\Psi\| - \mathrm{Tr}[(\Gamma^\dagger\Upsilon + \Gamma\Upsilon^\dagger)(\rho \otimes \mathbb{1}_{\mathfrak{h}})]), \end{aligned}$$

whence it follows that

$$d_H^2(\Phi, \Psi)(\varrho) = \inf_{\substack{\Gamma:\Gamma^\dagger\Gamma = \Phi_\tau \\ \Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau}} c(\Gamma - \Upsilon; \rho) = \tfrac{1}{2}\left(\|\Phi\| + \|\Psi\| - \sup_{\substack{\Gamma:\Gamma^\dagger\Gamma = \Phi_\tau \\ \Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau}} \mathrm{Tr}[(\Gamma^\dagger\Upsilon + \Gamma\Upsilon^\dagger)(\rho \otimes \mathbb{1}_{\mathfrak{h}})]\right).$$

Taking the supremum of both sides over all $\varrho \in \mathcal{S}(\mathfrak{g})$, we obtain

$$\sup_{\varrho \in \mathcal{S}(\mathfrak{g})} d_H^2(\Phi, \Psi)(\varrho) = \tfrac{1}{2}\left(\|\Phi\| + \|\Psi\| - \inf_{\varrho \in \mathcal{S}(\mathfrak{g})} \sup_{\substack{\Gamma:\Gamma^\dagger\Gamma = \Phi_\tau \\ \Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau}} \mathrm{Tr}[(\Gamma^\dagger\Upsilon + \Gamma\Upsilon^\dagger)(\rho \otimes \mathbb{1}_{\mathfrak{h}})]\right). \tag{36}$$

On the other hand,

$$d_H^2(\Phi, \Psi) = \inf_{\substack{\Gamma:\Gamma^\dagger\Gamma = \Phi_\tau \\ \Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau}} \sup_{\varrho \in \mathcal{S}(\mathfrak{g})} c(\Gamma - \Upsilon; \rho) = \tfrac{1}{2} \inf_{\substack{\Gamma:\Gamma^\dagger\Gamma = \Phi_\tau \\ \Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau}} \sup_{\varrho \in \mathcal{S}(\mathfrak{g})} (\|\Phi\| + \|\Psi\| - \mathrm{Tr}[(\Gamma^\dagger\Upsilon + \Gamma\Upsilon^\dagger)(\rho \otimes \mathbb{1}_{\mathfrak{h}})]),$$

which yields

$$d_H^2(\Phi, \Psi) = \tfrac{1}{2}\left(\|\Phi\| + \|\Psi\| - \sup_{\substack{\Gamma:\Gamma^\dagger\Gamma = \Phi_\tau \\ \Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau}} \inf_{\varrho \in \mathcal{S}(\mathfrak{g})} \mathrm{Tr}[(\Gamma^\dagger\Upsilon + \Gamma\Upsilon^\dagger)(\rho \otimes \mathbb{1}_{\mathfrak{h}})]\right). \tag{37}$$

Note that the right-hand sides of Eqs. (36) and (37) differ only in the order of the extrema. Thus, establishing the validity of Eq. (33) amounts to justifying the interchange of the extrema.

According to Lemma 1, the supremum over Γ and Υ in Eq. (36) can be evaluated by fixing $\Gamma = \Phi_\tau^{1/2}$ first and then varying only over all $\Upsilon \in \mathcal{B}(\mathcal{H})$ such that $\Upsilon^\dagger\Upsilon = \Psi_\tau$. By the polar decomposition, any such Υ has the form $U\Psi_\tau^{1/2}$ for some partial isometry U. Thus we have

$$\begin{aligned} \sup_{\substack{\Gamma:\Gamma^\dagger\Gamma = \Phi_\tau \\ \Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau}} \mathrm{Tr}[(\Gamma^\dagger\Upsilon + \Gamma\Upsilon^\dagger)(\rho \otimes \mathbb{1}_{\mathfrak{h}})] &= 2 \sup_{\Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau} \mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2}\Upsilon(\rho \otimes \mathbb{1}_{\mathfrak{h}})] \\ &= 2 \sup_U \mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2}U\Psi_\tau^{1/2}(\rho \otimes \mathbb{1}_{\mathfrak{h}})], \end{aligned} \tag{38}$$

where the supremum in Eq. (38) is taken over all partial isometries U such that

$$\Psi_\tau^{1/2}U^\dagger U\Psi_\tau^{1/2} = \Psi_\tau.$$

Since the expression being minimized is linear in U and the isometries are the extreme points of the unit ball $\mathsf{B}_1(\mathcal{H}) := \{X \in \mathcal{B}(\mathcal{H}) : \|X\| \leqslant 1\}$ of all bounded operators,[23] we may instead take the supremum over the entire unit ball:

$$\sup_{\Upsilon:\Upsilon^\dagger\Upsilon = \Psi_\tau} \mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2}\Upsilon(\rho \otimes \mathbb{1}_{\mathfrak{h}})] = \sup_{X \in \mathsf{B}_1(\mathcal{H})} \mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2}X\Psi_\tau^{1/2}(\rho \otimes \mathbb{1}_{\mathfrak{h}})]. \tag{39}$$

Since the expression being maximized in the right-hand side of Eq. (39) is affine in both X and ρ, and since $\mathsf{B}_1(\mathcal{H})$ and $\mathcal{S}(\mathfrak{g})$ are closed convex subsets of $\mathcal{B}(\mathcal{H})$ and $\mathcal{B}_\mathsf{T}(\mathfrak{g})$, respectively, it follows from standard minimax arguments[24] that we can indeed interchange the extrema to obtain $f_-(\Phi, \Psi) = f_+(\Phi, \Psi)$, where

$$f_-(\Phi,\Psi) := \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \sup_{X\in\mathsf{B}_1(\mathcal{H})} \mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2} X \Psi_\tau^{1/2}(\rho\otimes\mathbb{1}_\mathfrak{h})]$$

$$f_+(\Phi,\Psi) := \sup_{X\in\mathsf{B}_1(\mathcal{H})} \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2} X \Psi_\tau^{1/2}(\rho\otimes\mathbb{1}_\mathfrak{h})],$$

which proves the claim of Eq. (33). The rest is straightforward. □

As seen immediately from Theorem 1, when Φ and Ψ are quantum channels, then

$$d_H^2(\Phi,\Psi) + f(\Phi,\Psi) = 1,$$

with the minimax fidelity given by

$$f(\Phi,\Psi) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \sup_{Y:Y^\dagger Y=\Psi_\tau} \mathrm{Re}\,\mathrm{Tr}[\Phi_\tau^{1/2} Y(\rho\otimes\mathbb{1}_\mathfrak{h})]. \tag{40}$$

IV. EVALUATING THE FIDELITY DISTANCES

A. Fidelities for quantum states and quantum effects

Consider two normal states ϱ,ς on $\mathcal{B}=\mathcal{B}(\mathfrak{h})$ as quantum channels from $\mathcal{B}$ into the Abelian algebra $\mathcal{A}=\mathcal{B}(\mathfrak{g})$ with $\mathfrak{g}\simeq\mathbb{C}$. In this case, the operational densities $\varrho_\tau,\varsigma_\tau$ of ϱ,ς coincide with the corresponding density operators ρ,σ: $\varrho_\tau=\rho$ and $\varsigma_\tau=\sigma$. The predual maps $\varrho_\mathsf{T},\varsigma_\mathsf{T}:\mathcal{A}_\mathsf{T}\simeq\mathbb{C}\to\mathcal{B}_\mathsf{T}$ can then be thought of as the *state creation operations*, $\varrho_\mathsf{T}(\lambda)=\lambda\rho$ and $\varsigma_\mathsf{T}(\lambda)=\lambda\sigma$ for $\lambda\in\mathbb{C}$.

In order to compute the minimax fidelity $f(\varrho,\varsigma)$, we have to consider all $\chi,\psi\in\mathcal{B}$ that give the decompositions $\rho=\chi^\dagger\chi$ and $\sigma=\psi^\dagger\psi$. Note that we can always write these decompositions as purifications

$$\rho=\sum_j |\chi_j\rangle\langle\chi_j|, \quad \sigma=\sum_j |\psi_j\rangle\langle\psi_j|,$$

where $|\chi_j\rangle := \chi|j\rangle, |\psi_j\rangle := \psi|j\rangle$ with respect to a fixed orthonormal basis $\{|j\rangle\}$ of $\mathfrak{h}$. We then have the minimum quadratic distance

$$d_H^2(\varrho,\varsigma) = \tfrac{1}{2} \inf_{\substack{\chi\in\mathcal{B}:\chi^\dagger\chi=\rho\\ \psi\in\mathcal{B}:\psi^\dagger\psi=\sigma}} \sup_{\varpi\in\mathcal{S}(\mathfrak{g})} \varpi[(\chi-\psi)^\dagger(\chi-\psi)] \equiv \tfrac{1}{2} \inf_{\substack{\chi\in\mathcal{B}:\chi^\dagger\chi=\rho\\ \psi\in\mathcal{B}:\psi^\dagger\psi=\sigma}} \mathrm{Tr}[(\chi-\psi)^\dagger(\chi-\psi)],$$

where the last equality is due to the fact that $\dim\mathfrak{g}=1$. Expanding the product under the trace, we can write

$$d_H^2(\varrho,\varsigma) = \tfrac{1}{2}\Big[\mathrm{Tr}(\rho+\sigma) - \sup_{\chi,\psi\in\mathcal{B}} \{\mathrm{Re}\,\mathrm{Tr}(\chi^\dagger\psi): \chi^\dagger\chi=\rho, \psi^\dagger\psi=\sigma\}\Big] \tag{41}$$

$$= 1 - \sup_{\substack{\chi\in\mathcal{B}:\chi^\dagger\chi=\rho\\ \psi\in\mathcal{B}:\psi^\dagger\psi=\sigma}} \mathrm{Re}\,\mathrm{Tr}(\chi^\dagger\psi) \tag{42}$$

$$\equiv 1 - f(\varrho,\varsigma). \tag{43}$$

According to Lemma 1, the supremum in Eq. (42) is attained at any $\chi\in\mathcal{B}$ satisfying the condition $\chi^\dagger\chi=\rho$, say $\chi=\rho^{1/2}$, and $\psi=\psi_\circ$ satisfying the equation $\psi_\circ\chi^\dagger=(\chi\sigma\chi^\dagger)^{1/2}=\chi\psi_\circ^\dagger$:

$$f(\varrho,\varsigma) = \sup_{\substack{\chi\in\mathcal{B}:\chi^\dagger\chi=\rho\\ \psi\in\mathcal{B}:\psi^\dagger\psi=\sigma}} \mathrm{Re}\,\mathrm{Tr}(\chi^\dagger\psi) = \sup_{\psi\in\mathcal{B}(\mathfrak{h})} \{\mathrm{Re}\mathrm{Tr}(\rho^{1/2}\psi): \psi^\dagger\psi=\sigma\} = \mathrm{Tr}\,\sqrt{\rho\sigma}.$$

Observe that the standard Uhlmann fidelity between the density operators ρ and σ, $F(\rho,\sigma)$ in Eq. (1), can be written as $F(\rho,\sigma)=\|\rho^{1/2}\sigma^{1/2}\|_\mathsf{T}=\mathrm{Tr}\,\sqrt{\rho\sigma}$. Thus the minimax fidelity between two normal

states ϱ and ς on $\mathcal{B}$, or, equivalently, between the state creation operations $\varrho_{\mathsf{T}}, \varsigma_{\mathsf{T}}: \mathbb{C} \to \mathcal{B}_{\mathsf{T}}(\mathfrak{h})$, agrees with the Uhlmann fidelity between the respective density operators ρ and σ of ϱ and ς.

Next we turn to the other extreme case, namely that of the *state annihilation operations* Φ, Ψ with the preduals $\Phi_{\mathsf{T}}(\rho) = (\Phi_\tau, \rho), \Psi_{\mathsf{T}}(\rho) = (\Psi_\tau, \rho)$, corresponding to $\dim \mathfrak{h} = 1$. They are completely specified by the *effects*, i.e., the positive operators $\Phi_\tau, \Psi_\tau \in \mathcal{B}(\mathfrak{g})$ satisfying $0 \leqslant \Phi_\tau, \Psi_\tau \leqslant \mathbb{1}_{\mathfrak{g}}$, which can be purified as in (29), where $\Gamma_j = \langle j|\Gamma, \Upsilon_j = \langle j|\Upsilon$ are the bra-vectors corresponding to an orthonormal basis $\{|j\rangle\}$ in $\mathfrak{g}$. The squared pointwise minimax distance between the state annihilation operations Φ, Ψ, or, equivalently between the effects Φ_τ, Ψ_τ, on the set $\mathcal{S}(\mathfrak{g})$ of normal states $\varrho = \rho^{\mathsf{T}}$ on $\mathcal{B}(\mathfrak{g})$ is given by the minimum

$$d_H^2(\Phi, \Psi)(\varrho) = \tfrac{1}{2} \inf_{\Gamma, \Upsilon \in \mathcal{B}(\mathfrak{g})} \{\mathrm{Tr}[(\Gamma - \Upsilon)^\dagger (\Gamma - \Upsilon)\rho] : \Gamma^\dagger \Gamma = \Phi_\tau, \Upsilon^\tau \Upsilon = \Psi_\tau\}$$

of the quadratic distance between their purifications $\Gamma, \Upsilon \in \mathcal{B}(\mathfrak{g})$. The solution of this problem is likewise given by Lemma 1 with $R = \Phi_\tau$ and $S = \rho \Psi_\pi \rho$. Thus the optimum

$$d_H^2(\Phi, \Psi)(\varrho) = \tfrac{1}{2} \mathrm{Tr}[(\Phi_\tau + \Psi_\tau)\rho] - \mathrm{Tr} \sqrt{\Phi_\tau (\rho \Psi_\pi \rho)}$$

is attained at any $\Gamma \in \mathcal{B}$ satisfying the condition $\Gamma^\dagger \Gamma = \Phi_\tau$, say $\Gamma = \Phi_\tau^{1/2}$, and the corresponding $\Upsilon = \Upsilon_\circ$ satisfying the equation $\Upsilon_\circ \rho \Gamma^\dagger = \sqrt{\Gamma \rho \Psi_\pi \rho \Gamma^\dagger} = \Gamma \rho \Upsilon_\circ^\dagger$. The maximum of this distance over all states,

$$\begin{aligned} d_H^2(\Phi, \Psi) &= \sup_{\varrho \in \mathcal{S}(\mathfrak{g})} d_H^2(\Phi, \Psi)(\varrho) \\ &\equiv \sup_{\varrho \in \mathcal{S}(\mathfrak{g})} \left(\tfrac{1}{2} \mathrm{Tr}[(\Phi_\tau + \Psi_\tau)\rho] - \mathrm{Tr} \sqrt{\Phi_\tau (\rho \Psi_\pi \rho)} \right) \\ &= \sup_{\varrho \in \mathcal{S}(\mathfrak{g})} \inf_{\Gamma, \Upsilon \in \mathcal{B}(\mathfrak{g})} \{Tr[(\Gamma - \Upsilon)^\dagger (\Gamma - \Upsilon)\rho] : \Gamma^\dagger \Gamma = \Phi_\tau, \Upsilon^\dagger \Upsilon = \Psi_\tau\}, \end{aligned}$$

is given by the minimax quadratic distance

$$d_H^2(\Phi, \Psi) = \tfrac{1}{2} \inf_{\Gamma, \Upsilon \in \mathcal{B}(\mathfrak{g})} \{\|\Gamma - \Upsilon\|^2 : \Gamma^\dagger \Gamma = \Phi_\tau, \Upsilon^\dagger \Upsilon = \Psi_\tau\},$$

interchange of the extrema following from standard minimax arguments,[24] and the fact that all Γ, Υ satisfying, respectively, $\Gamma^\dagger \Gamma = \Phi_\tau$ and $\Upsilon^\dagger \Upsilon = \Psi_\tau$ are contained in the unit ball of $\mathcal{B}(\mathfrak{g})$.

B. Semiclassical fidelity

It is straightforward to extend the formalism of Sec. III A involving the commutative Hellinger distance between two positive kernels to the case of mappings from a set X into positive trace-class operators on the Hilbert space $\mathfrak{h}$, i.e., $\boldsymbol{\rho}: x \in X \mapsto \rho(x) \in \mathcal{B}_{\mathsf{T}}(\mathfrak{h})$ and $\boldsymbol{\sigma}: x \in X \mapsto \sigma(x) \in \mathcal{B}_{\mathsf{T}}(\mathfrak{h})$ with $\rho(x), \sigma(x) \geqslant 0$ for all $x \in X$. We thus have the pointwise Hellinger distance

$$d_H^2(\rho(x), \sigma(x)) = \left(\mathbb{1}, \tfrac{1}{2}[\rho(x) + \sigma(x)]\right) - \sqrt{(\mathbb{1}, \rho(x))(\mathbb{1}, \sigma(x))} f(\rho(x), \sigma(x))$$

in terms of the trace pairing $(B, \rho) = \mathrm{Tr}(B\widetilde{\rho})$ of $B \in \mathcal{B} = \mathcal{B}(\mathfrak{h})$ and $\rho \in \mathcal{B}_{\mathsf{T}} = \mathcal{B}_{\mathsf{T}}(\mathfrak{h})$, where

$$f(\rho(x), \sigma(x)) = \frac{(\mathbb{1}, \sqrt{\rho(x)\sigma(x)})}{\sqrt{(\mathbb{1}, \rho(x))(\mathbb{1}, \sigma(x))}} = \frac{\mathrm{Tr} \sqrt{\rho(x)\sigma(x)}}{\sqrt{\mathrm{Tr}\, \rho(x) \mathrm{Tr}\, \sigma(x)}}.$$

The semi-classical operational distance between $\boldsymbol{\rho} = \rho(\cdot)$ and $\boldsymbol{\sigma} = \sigma(\cdot)$ can then be defined as

$$d_H^2(\boldsymbol{\rho}, \boldsymbol{\sigma}) = \sup_{x \in X} d_H^2(\rho(x), \sigma(x)) \equiv \|d_H^2(\rho(\cdot), \sigma(\cdot))\|. \tag{44}$$

When $\mathrm{Tr}\, \rho(x) = 1 = \mathrm{Tr}\, \sigma(x)$ for all $x \in X$, i.e., when $\boldsymbol{\rho}$ and $\boldsymbol{\sigma}$ are *classical-to-quantum*, c-q (or *semiclassical*), channels, Eq. (44) can be written as $d_H^2(\boldsymbol{\rho}, \boldsymbol{\sigma}) = 1 - f(\boldsymbol{\rho}, \boldsymbol{\sigma})$, where

$$f(\boldsymbol{\rho},\boldsymbol{\sigma}) = \inf_{x\in X} \mathrm{Tr}[\rho(x)^{1/2}\sigma(x)\rho(x)^{1/2}]^{1/2} = \inf_{x\in X} \mathrm{Tr}\sqrt{\rho(x)\sigma(x)} \equiv \inf_{x\in X} F(\rho(x),\sigma(x))$$

is the minimax fidelity of $\boldsymbol{\sigma}$ relative to $\boldsymbol{\rho}$.

C. Semiquantum fidelity

Next we consider the opposite of semiclassical operations—namely, the *semiquantum operations* which correspond to quantum measurements as quantum-to-classical (q-c) channels. Such operations are given as

$$\Phi(b) = \int_Y b(y)\Phi_\tau(y)\mathrm{d}\mu(y) \equiv (b,\Phi_\tau)$$

on the algebra $\mathcal{B}=\mathcal{C}(Y)$ of continuous bounded functions $b: Y\to\mathbb{C}$, where $(Y,\mathcal{B}_Y,\mu)$ is a measure space, by specifying the positive operator-valued Bochner μ-integrable functions $\Phi_\tau: Y\to\mathcal{A}=\mathcal{B}(\mathfrak{g})$. If

$$\Phi(1) = (1,\Phi_\tau) = \mathbb{1}_\mathfrak{g},$$

the predual maps $\mathcal{A}\ni\rho\mapsto\Phi_\mathsf{T}(\rho)(\cdot)\in\mathcal{C}_\mathsf{T}(Y)$,

$$\Phi_\mathsf{T}(\rho)(y) := (\Phi_\tau(y),\rho) \equiv \varrho[\Phi_\tau(y)],$$

define for each input quantum state $\varrho\in\mathcal{S}(\mathfrak{g})$ a classical probability density on $(Y,\mathcal{B}_Y,\mu)$, that is, they describe quantum measurements by the positive operator-valued measures (POVMs) $M(\mathrm{d}y)=\Phi_\tau(y)\mathrm{d}\mu(y)$.

In order to avoid technicalities in defining the semi-quantum fidelity distance between two q-c channels $\Phi,\Psi:\mathcal{B}\to\mathcal{A}$, we shall assume that $\Phi_\tau(y),\Psi_\tau(y)$ are weakly continuous bounded functions on Y. Then the squared distance $d_H^2(\Phi,\Psi)$ can be written as

$$\mathrm{d}_H^2(\Phi,\Psi) = \inf_{\Gamma,\Upsilon:\Gamma^\dagger\Gamma=\Phi_\tau,\Upsilon^\dagger\Upsilon=\Psi_\tau} \left\| \int (\Gamma(y)-\Upsilon(y))^\dagger(\Gamma(y)-\Upsilon(y))\mathrm{d}\mu(y) \right\|, \tag{45}$$

where the decompositions $\Gamma^\dagger\Gamma=\Phi_\tau$ and $\Upsilon^\dagger\Upsilon=\Psi_\tau$ are understood in the pointwise sense as

$$\Phi_\tau(y) = \Gamma(y)^\dagger\Gamma(y), \quad \Psi_\tau(y) = \Upsilon(y)^\dagger\Upsilon(y), \quad \forall\, y\in Y.$$

The infimum in Eq. (45) is achieved at any $\Gamma\in\mathcal{A}\otimes\mathcal{C}_\mathsf{T}(Y)$ satisfying the condition $\Gamma^\dagger\Gamma=\Phi_\tau$, say $\Gamma(y)=\Phi_\tau(y)^{1/2}$, and the corresponding $\Upsilon=\Upsilon_\mathrm{o}$ satisfying the equation

$$\Upsilon_\mathrm{o}(y)\rho\Gamma(y)^\dagger = [\Gamma(y)\rho\Psi_\tau(y)\rho\Gamma(y)^\dagger]^{1/2} = \Gamma(y)\rho\Upsilon_\mathrm{o}(y)^\dagger.$$

The maximum of this minimal distance over all states,

$$\mathrm{d}_H^2(\Phi,\Psi) = \sup_{\varrho\in\mathcal{S}(g)} \int \left(\frac{1}{2}\mathrm{Tr}[(\Phi_\tau(y)+\Psi_\tau(y))\rho] - \mathrm{Tr}\sqrt{\Phi_\tau(y)(\rho\Psi_\tau(y)\rho)}\right)\mathrm{d}\mu(y),$$

is equal to $d_H^2(\Phi,\Psi)=1-f(\Phi,\Psi)$ in the measurement operation case $\Phi(1)=\mathbb{1}_\mathfrak{g}=\Psi(1)$, where

$$f(\Phi,\Psi) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \int \mathrm{Tr}\sqrt{\Phi_\tau(y)(\rho\Psi_\tau(y)\rho)}\mathrm{d}\mu(y). \tag{46}$$

D. Operational fidelity formula

Now we can easily evaluate the minimax formula (30) for the fidelity of two general quantum operations $\Phi,\Psi:\mathcal{B}\to\mathcal{A}$, $\mathcal{B}=\mathcal{B}(\mathfrak{h})$, $\mathcal{A}=\mathcal{B}(\mathfrak{g})$. The solution of this problem is also given by Lemma 1 with $R=\Phi_\tau$ and $S=(\rho\otimes\mathbb{1}_\mathfrak{h})\Psi_\tau(\rho\otimes\mathbb{1}_\mathfrak{h})$. For a given $\varrho\in\mathcal{S}(\mathfrak{g})$, the supremum in

$$d_H^2(\Phi,\Psi)(\varrho)=\tfrac{1}{2}(\mathrm{Tr}[(\Phi_\tau+\Psi_\tau)(\rho\otimes\mathbb{1}_\mathfrak{h})]-2\sup_{\Gamma,\Upsilon\in\mathcal{B}(\mathcal{H})}\{\mathrm{Re}\,\mathrm{Tr}[\Gamma^\dagger\Upsilon(\rho\otimes\mathbb{1}_\mathfrak{h})]:\Gamma^\dagger\Gamma=\Phi_\tau,\Upsilon^\dagger\Upsilon=\Psi_\tau\})$$

is equal to $\mathrm{Tr}\sqrt{\Phi_\tau[(\rho\otimes\mathbb{1}_\mathfrak{h})\Psi_\tau(\rho\otimes\mathbb{1}_\mathfrak{h})]}$, and is achieved at any $\Gamma\in\mathcal{B}(\mathcal{H})$ satisfying the condition $\Gamma^\dagger\Gamma=\Phi_\tau$, say $\Gamma=\Phi_\tau^{1/2}$, and the corresponding $\Upsilon=\Upsilon_\mathrm{o}$ satisfying the equation

$$\Upsilon_\mathrm{o}(\rho\otimes\mathbb{1}_\mathfrak{h})\Gamma^\dagger=[\Gamma(\rho\otimes\mathbb{1}_\mathfrak{h})\Psi_\tau(\rho\otimes\mathbb{1}_\mathfrak{h})\Gamma^\dagger]^{1/2}=\Gamma(\rho\otimes\mathbb{1}_\mathfrak{h})\Upsilon_\mathrm{o}^\dagger.$$

When Φ,Ψ are quantum channels, or, equivalently, when the preduals $\Phi_\mathsf{T},\Psi_\mathsf{T}$ are trace preserving, Theorem 1 says that the maximum of this distance over all states,

$$d_H^2(\Phi,\Psi)=\sup_{\varrho\in\mathcal{S}(\mathfrak{g})}\mathrm{Tr}\Big(\tfrac{1}{2}(\Phi_\tau+\Psi_\tau)(\rho\otimes\mathbb{1}_\mathfrak{h})-\sqrt{\Phi_\tau[(\rho\otimes\mathbb{1}_\mathfrak{h})\Psi_\tau(\rho\otimes\mathbb{1}_\mathfrak{h})]}\Big),\tag{47}$$

can be written as $d_H^2(\Phi,\Psi)=1-f(\Phi,\Psi)$, where

$$f(\Phi,\Psi)=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\mathrm{Tr}\sqrt{\Phi_\tau[(\rho\otimes\mathbb{1}_\mathfrak{h})\Psi_\tau(\rho\otimes\mathbb{1}_\mathfrak{h})]}\tag{48}$$

is the minimax fidelity between Φ and Ψ.

E. Operational fidelity in terms of Kraus and Stinespring decompositions

Consider, as before, two quantum channels $\Phi,\Psi:\mathcal{B}\to\mathcal{A}$, where $\mathcal{B}=\mathcal{B}(\mathfrak{h})$ and $\mathcal{A}=\mathcal{B}(\mathfrak{g})$. Given the minimax fidelity

$$f(\Phi,\Psi)=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\sup_{\substack{\Gamma:\Gamma^\dagger\Gamma=\Phi_\tau\\ \Upsilon:\Upsilon^\dagger\Upsilon=\Psi_\tau}}\mathrm{Re}\,\mathrm{Tr}[\Gamma^\dagger\Upsilon(\rho\otimes\mathbb{1}_\mathfrak{h})]=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\sup_{\substack{\Gamma:\Gamma^\dagger\Gamma=\Phi_\tau\\ \Upsilon:\Upsilon^\dagger\Upsilon=\Psi_\tau}}|\mathrm{Tr}[\Gamma^\dagger\Upsilon(\rho\otimes\mathbb{1}_\mathfrak{h})]|$$

between Φ and Ψ, where the second equality follows from Lemma 2, the supremum over all Γ and Υ satisfying, respectively, $\Gamma^\dagger\Gamma=\Phi_\tau$ and $\Upsilon^\dagger\Upsilon=\Psi_\tau$ can be replaced with the supremum over all Kraus decompositions of Φ and Ψ, i.e., over all collections $\{F_j\}$, $\{V_j\}$ of bounded operators $\mathfrak{g}\to\mathfrak{h}$, determined from Φ_τ,Ψ_τ via Eqs. (29) and (28):

$$f(\Phi,\Psi)=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\sup_{\{F_j\},\{V_j\}}\left|\sum_j\varrho(F_j^\dagger V_j)\right|.\tag{49}$$

Just as in the proof of Theorem 1, we may restrict ourselves only to those Γ,Υ that can be written as $\Gamma=U\Phi_\tau^{1/2},\Upsilon=V\Psi_\tau^{1/2}$ for some isometries U,V. Thus, if we write $\Phi_\tau^{1/2}$ and $\Psi_\tau^{1/2}$ in the form of Eq. (28) as

$$\Phi_\tau^{1/2}=\sum_j|j\rangle\langle\hat{F}_j|,\quad\Psi_\tau^{1/2}=\sum_j|j\rangle\langle\hat{V}_j|,$$

then it follows that, given isometries U, we can write

$$\Gamma=U\Phi_\tau^{1/2}=\sum_j|j\rangle\left(\sum_\ell U_{j\ell}\hat{F}_\ell\right|\equiv\sum_j|j\rangle\langle\hat{F}_j(U)|,$$

and similarly for $\Upsilon=V\Psi_\tau^{1/2}$. Thus

$$f(\Phi,\Psi)=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\sup_{U,V}\left|\sum_j\varrho[\hat{F}_j(U)^\dagger\hat{V}_j(V)]\right|=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\sup_U\left|\sum_j\varrho[\hat{F}_j(U)^\dagger\hat{V}_j]\right|.$$

Turning now to the infimum over all normal states ϱ on $\mathcal{A}\equiv\mathcal{B}(\mathfrak{g})$, we may equivalently consider all pairs $\{\varphi,\mathcal{K}\}$, where φ is a normal $*$-representation of $\mathcal{A}$ on a Hilbert space $\mathcal{K}$:

$$f(\Phi,\Psi) := \inf_{\{\varphi,\mathcal{K}\};\upsilon\in\mathcal{K},\|\upsilon\|=1} \sup_{U} \left| \sum_j \langle \upsilon|\varphi[\hat{F}_j(U)^\dagger \hat{V}_j]|\upsilon\rangle \right|.$$

Since all normal $*$-representations of the full operator algebra $\mathcal{B}(\mathfrak{g})$ are unitarily equivalent to an amplification $B\mapsto B\otimes 1_{\mathfrak{k}}$ for some Hilbert space $\mathfrak{k}$, we can write

$$f(\Phi,\Psi) := \inf_{\upsilon\in\mathfrak{g}\otimes\mathfrak{k};\|\upsilon\|=1} \sup_{U} \left| \sum_j \langle \upsilon|\hat{F}_j(U)^\dagger \hat{V}_j \otimes 1_{\mathfrak{k}}|\upsilon\rangle \right|. \tag{50}$$

Introducing the vectors $|\upsilon,\Phi\rangle, |\upsilon,\Psi\rangle \in \mathfrak{g}\otimes\mathfrak{k}\otimes\mathcal{H}$, defined by

$$|\upsilon,\Phi\rangle := \sum_j (\hat{F}_j \otimes 1_{\mathfrak{k}})\upsilon \otimes |j\rangle, \quad |\upsilon,\Psi\rangle := \sum_j (\hat{V}_j \otimes 1_{\mathfrak{k}})\upsilon \otimes |j\rangle,$$

we obtain yet another form of the minimax fidelity:

$$f(\Phi,\Psi) = \inf_{\upsilon\in\mathfrak{g}\otimes\mathfrak{k}} \sup_{U} |\langle \upsilon,\Phi|1_{\mathfrak{g}\otimes\mathfrak{k}} \otimes U|\upsilon,\Psi\rangle|. \tag{51}$$

For a fixed $\upsilon\in\mathfrak{g}\otimes\mathfrak{k}$, taking the supremum over U is tantamount to taking the supremum of $|\langle\chi|\xi\rangle|$ over all pairs of unit vectors $\chi,\xi\in\mathfrak{g}\otimes\mathfrak{k}\otimes\mathcal{H}$ such that

$$\mathrm{Tr}_{\mathcal{H}}|\chi\rangle\langle\chi| = \sum_j (\widetilde{F_j}\otimes 1_{\mathfrak{k}})|\upsilon\rangle\langle\upsilon|(\widetilde{F_j}\otimes 1_{\mathfrak{k}})^\dagger \equiv \Phi_{\mathsf{T}} \otimes \mathrm{id}(|\upsilon\rangle\langle\upsilon|),$$

$$\mathrm{Tr}_{\mathcal{H}}|\xi\rangle\langle\xi| = \sum_j (\widetilde{V_j}\otimes 1_{\mathfrak{k}})|\upsilon\rangle\langle\upsilon|(\widetilde{V_j}\otimes 1_{\mathfrak{k}})^\dagger \equiv \Psi_{\mathsf{T}} \otimes \mathrm{id}(|\upsilon\rangle\langle\upsilon|),$$

which, in conjunction with the standard results on the Uhlmann fidelity (1) between density operators,[6,7] finally yields

$$f(\Phi,\Psi) = \inf_{\upsilon\in\mathfrak{g}\otimes\mathfrak{k}:\|\upsilon\|=1} F(\Phi_{\mathsf{T}} \otimes \mathrm{id}(|\upsilon\rangle\langle\upsilon|), \Psi_{\mathsf{T}} \otimes \mathrm{id}(|\upsilon\rangle\langle\upsilon|)) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g}\otimes\mathfrak{k})} F(\Phi_{\mathsf{T}} \otimes \mathrm{id}(\rho), \Psi_{\mathsf{T}} \otimes \mathrm{id}(\rho)).$$

Note that we may always take $\mathfrak{k}$ isomorphic to $\mathfrak{g}$:

$$f(\Phi,\Psi) = \inf_{\upsilon\in\mathfrak{g}\otimes\mathfrak{g},\|\upsilon\|=1} F(\Phi_{\mathsf{T}} \otimes \mathrm{id}(|\upsilon\rangle\langle\upsilon|), \Psi_{\mathsf{T}} \otimes \mathrm{id}(|\upsilon\rangle\langle\upsilon|)). \tag{52}$$

Given some Kraus decompositions $\{F_j\}$, $\{V_j\}$ of Φ and Ψ, respectively, we may define the operators

$$F\xi := \sum_j F_j\xi \otimes |j\rangle, \quad V\xi := \sum_j V_j\xi \otimes |j\rangle$$

from $\mathfrak{g}$ into $\mathfrak{h}\otimes\mathcal{H}$ and express Φ and Ψ in the Stinespring form $\Phi(B)=F^\dagger(B\otimes 1_{\mathcal{H}})F$, $\Psi(B)=V^\dagger(B\otimes 1_{\mathcal{H}})V$ (cf. Sec. III B). Then we may rewrite Eq. (49) as

$$f(\Phi,\Psi) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \sup_{F,V} |\mathrm{Tr}(F\rho V^\dagger)|,$$

where the supremum is over all $F,V:\mathfrak{g}\to\mathfrak{h}\otimes\mathcal{H}$ giving the Stinespring decompositions of Φ and Ψ, respectively. We may, as before, fix F and V, say, by considering the "canonical" Kraus decompositions $\{\hat{F}_j\}$, $\{\hat{V}_j\}$, and instead take the supremum over all unitaries $U\in\mathsf{U}(\mathcal{H})$:

$$f(\Phi,\Psi) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \sup_{U} |\mathrm{Tr}[(1_{\mathfrak{h}}\otimes U)F\rho V^\dagger]| = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \sup_{U} |\mathrm{Tr}[U\,\mathrm{Tr}_{\mathfrak{h}}(F\rho V^\dagger)]|,$$

which yields another useful formula

$$f(\Phi,\Psi) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \|\mathrm{Tr}_{\mathfrak{h}}(F\rho V^{\dagger})\|_{\mathsf{T}} \tag{53}$$

for the minimax fidelity between the channels Φ,Ψ. It is, in fact, not hard to show that the right-hand side of Eq. (53) does not depend on the particular choice of the Stinespring operators F,V, as long as we agree to dilate the input Hilbert space $\mathfrak{h}$ by the "canonical" auxiliary Hilbert space $\mathcal{H}=\mathfrak{g}\otimes\mathfrak{h}$.

We note that the constructions of this section are valid more generally for channels given in terms of the continual Kraus decompositions

$$\Phi(B) = \int_Z F(z)^{\dagger}BF(z)\mathrm{d}\mu(z), \quad \Psi(B) = \int_Z V(z)^{\dagger}BV(z)\mathrm{d}\nu(z),$$

provided that the measures μ and ν are equivalent, i.e., absolutely continuous with respect to each other. Then Eq. (49) is a special instance of the more general expression

$$f(\Phi,\Psi) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \sup_{\{F(z)\},\{V(z)\}} \left| \varrho\left(\int_Z \sqrt{\mathrm{d}\nu/\mathrm{d}\mu}F(z)^{\dagger}V(z)\mathrm{d}\mu(z) \right) \right|,$$

where $\mathrm{d}\nu/\mathrm{d}\mu$ is the Radon-Nikodym derivative of ν with respect to μ, for the case when both μ and ν are counting measures, $\mathrm{d}\mu=\mathrm{d}\nu=1$, on a finite or countably infinite set.

V. PROPERTIES OF THE OPERATIONAL FIDELITY

In this section we establish several key properties of the minimax fidelity between quantum operations. These properties follow almost immediately from the corresponding properties enjoyed by the fidelity (1) on density operators:

(F.1) F is symmetric, $F(\rho,\sigma)=F(\sigma,\rho)$, bounded between 0 and 1, and $F(\rho,\sigma)=1$ if and only if $\rho=\sigma$.

(F.2) F is jointly concave over all pairs of density operators.

(F.3) F is unitarily invariant, i.e., $F(\rho,\sigma)=F(U\rho U^{\dagger},U\sigma U^{\dagger})$ for any unitary U.

(F.4) F is monotone with respect to quantum channels: $F(\Phi_{\mathsf{T}}(\rho),\Phi_{\mathsf{T}}(\sigma))\geqslant F(\rho,\sigma)$ for every quantum channel Φ.

(F.5) The *Bures distance* $d_B(\cdot,\cdot):=\sqrt{1-F(\cdot,\cdot)}$ is topologically equivalent to the trace-norm half-distance $D(\cdot,\cdot)$:

$$2^{-1/2}D(\rho,\sigma) \leqslant d_B(\rho,\sigma) \leqslant \sqrt{D(\rho,\sigma)}$$

[cf. Eq. (3)]. Property (F.2), in fact, follows from *strong concavity* of F,[2] i.e.,

$$F\left(\sum_i p_i\rho_i, \sum_i q_i\sigma_i\right) \geqslant \sum_i \sqrt{p_iq_i}F(\rho_i,\sigma_i) \tag{54}$$

for all $0\leqslant p_i,q_i\leqslant 1$ such that $\Sigma_i p_i=1=\Sigma_i q_i$.

Using Eq. (52), we can immediately obtain for the minimax fidelity $f(\cdot,\cdot)$ on pairs of quantum channels the following analogs of properties (F.1)–(F.4) of the fidelity $F(\cdot,\cdot)$ on pairs of density operators:

(f.1) f is symmetric, bounded between 0 and 1, and $f(\Phi,\Psi)=1$ if and only if $\Phi=\Psi$.

(f.2) f is jointly concave over all pairs of channels.

(f.3) f is invariant under both left and right composition with unitarily implemented channels, i.e.,

$$f(\Theta_U\circ\Phi,\Theta_U\circ\Psi) = f(\Phi,\Psi)$$

and

$$f(\Phi \circ \Theta_V, \Psi \circ \Theta_V) = f(\Phi, \Psi)$$

for any two channels $\Phi, \Psi : \mathcal{B}(\mathfrak{h}) \to \mathcal{B}(\mathfrak{g})$ and any two unitaries $U \in \mathsf{U}(\mathfrak{g})$, $V \in \mathsf{U}(\mathfrak{h})$, where $\Theta_U(B) := U^\dagger B U$, and Θ_V is defined analogously.

(f.4) f is monotone with respect to both left and right composition with quantum channels, i.e., $f(\Phi \circ \Phi_1, \Psi \circ \Phi_1) \geqslant f(\Phi, \Psi)$ and $f(\Phi_2 \circ \Phi, \Phi_2 \circ \Psi) \geqslant f(\Phi, \Psi)$ for any two channels $\Phi, \Psi : \mathcal{B} \to \mathcal{A}$, all channels Φ_1 into $\mathcal{B}$, and all channels Φ_2 on $\mathcal{A}$. Just as in the case of the fidelity between density operators, the minimax fidelity f possesses the strong concavity property

$$f\left(\sum_i p_i \Phi_i, \sum_i q_i \Psi_i\right) \geqslant \sum_i \sqrt{p_i q_i} f(\Phi_i, \Psi_i). \tag{55}$$

On the other hand, deriving for the minimax fidelity f an analog of property (F.5) of the Uhlmann fidelity F requires a bit more work. To this end, let us consider two channels $\Phi, \Psi : \mathcal{B} \to \mathcal{A}, \mathcal{B} = \mathcal{B}(\mathfrak{h}), \mathcal{A} = \mathcal{B}(\mathfrak{g})$. Suppose first that $\mathfrak{g}$ is infinite dimensional and separable. Then $\mathfrak{g} \simeq \ell^2$, and we can rewrite Eq. (55) as

$$f(\Phi, \Psi) = \inf_{v \in \mathfrak{g} \otimes \ell^2 : \|v\| = 1} F(\Phi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|), \Psi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|)).$$

The space ℓ^2 contains, as a dense subset, the pre-Hilbert space ℓ_0^2 of all infinite sequences of complex numbers with all but finitely many components equal to zero. Using this fact and the continuity property (F.5) of the fidelity F, we obtain

$$f(\Phi, \Psi) = \inf_{v \in \mathfrak{g} \otimes \ell_0^2 : \|v\| = 1} F(\Phi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|), \Psi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|)).$$

Using this expression in conjunction with Eq. (3), we get the bounds

$$f(\Phi, \Psi) \geqslant 1 - \sup_{v \in \mathfrak{g} \otimes \ell_0^2 : \|v\| = 1} D(\Phi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|), \Psi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|)), \tag{56}$$

$$f^2(\Phi, \Psi) \leqslant 1 - \sup_{v \in \mathfrak{g} \otimes \ell_0^2 : \|v\| = 1} D^2(\Phi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|) - \Psi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|)). \tag{57}$$

Now, for any completely bounded map $\Lambda : \mathcal{B}(\mathfrak{h}) \to \mathcal{B}(\mathfrak{g})$, the image of the set $\{|v\rangle\langle v| : v \in \mathfrak{g} \otimes \ell_0^2, \|v\| = 1\}$ under the predual map $\Lambda_\mathsf{T} \otimes \mathrm{id} : \mathcal{B}_\mathsf{T}(\mathfrak{g} \otimes \ell_0^2) \to \mathcal{B}_\mathsf{T}(\mathfrak{h} \otimes \ell_0^2)$ is contained in the trace-norm closure of the linear span of $\{|\xi\rangle\langle\xi| : \xi \in \mathfrak{h} \otimes \ell_0^2, \|\xi\| = 1\}$, which is dual to the tensor product $\mathcal{B}(\mathfrak{h}) \otimes \mathcal{K}(\ell^2)$, where $\mathcal{K}(\ell^2)$ is the space of compact operators on ℓ^2. Thus, by duality we have

$$\sup_{v \in \mathfrak{g} \otimes \ell_0^2 : \|v\| = 1} D(\Phi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|), \Psi_\mathsf{T} \otimes \mathrm{id}(|v\rangle\langle v|)) = \tfrac{1}{2} \|(\Phi - \Psi) \otimes \mathrm{id}_{\mathcal{K}(\ell^2)}\| \equiv \mathcal{D}(\Phi, \Psi),$$

where $\mathcal{D}(\Phi, \Psi)$ denotes the CB-norm half-distance $\frac{1}{2}\|\Phi - \Psi\|_{\mathrm{CB}}$, and the last equality follows from the formula $\|\Lambda\|_{\mathrm{CB}} = \|\Lambda \otimes \mathrm{id}_{\mathcal{K}(\ell^2)}\|$ for any completely bounded map Λ.

On the other hand, when $\dim \mathfrak{g} = m < \infty$, we can use the fact[20] that, for any completely bounded map Λ into $\mathcal{B}(\mathfrak{g})$,

$$\|\Lambda\|_{\mathrm{CB}} = \|\Lambda \otimes \mathrm{id}_{\mathcal{M}_m}\| = \|\Lambda_\mathsf{T} \otimes \mathrm{id}_{\mathcal{M}_m}\|_\mathsf{T},$$

where $\mathcal{M}_m$ denotes the algebra of $m \times m$ complex matrices, it follows that

$$\sup_{v \in \mathfrak{g} \otimes \mathfrak{g} : \|v\| = 1} D(\Phi_\mathsf{T} \otimes \mathbb{1}(|v\rangle\langle v|), \Psi_\mathsf{T} \otimes \mathbb{1}(|v\rangle\langle v|)) = \mathcal{D}(\Phi, \Psi).$$

In either case, we immediately derive the inequality

$$1 - \mathcal{D}(\Phi,\Psi) \leqslant f(\Phi,\Psi) \leqslant \sqrt{1 - \mathcal{D}^2(\Phi,\Psi)}, \tag{58}$$

which, when expressed in terms of the Hellinger distance $d_H(\cdot,\cdot) := \sqrt{1-f(\cdot,\cdot)}$ as

$$2^{-1/2}\mathcal{D}(\Phi,\Psi) \leqslant d_H(\Phi,\Psi) \leqslant \sqrt{\mathcal{D}(\Phi,\Psi)}, \tag{59}$$

yields the desired property

(f.5) the Hellinger distance $d_H(\cdot,\cdot) := \sqrt{1-f(\cdot,\cdot)}$ is topologically equivalent to the CB-norm distance [cf. Eq. (59)].

This completes our survey of the basic properties of the minimax fidelity f.

VI. SOME EXAMPLES AND APPLICATIONS

The expressions for the minimax fidelity, derived in Sec. IV for different kinds of quantum operations encountered in quantum information theory, share the common feature of being set up as variational problems, namely, as minimizations of a concave functional over a convex set. This feature of the minimax fidelity renders the problem of computing it amenable to robust numerical methods (see Ref. 3 for detailed discussion of numerical optimization methods for the calculation of fidelitylike measures in quantum information theory). However, there are instances in which the minimax fidelity between two quantum channels can be written down in a more explicit form. In this section we sketch some examples of such instances.

Before we proceed, we would like to remind the reader of the assumption we made in Sec. II B, namely that all the channels we deal with are completely majorized by the trace in the sense of Ref. 14. This assumption, while allowing us to circumvent certain technicalities involving unbounded operators, is somewhat restrictive, as one can easily find examples of quantum channels between infinite-dimensional algebras (e.g., unitarily or isometrically implemented channels; see Ref. 21 for details) that do not satisfy this condition of complete majorization. However, owing to the CB-continuity of the minimax fidelity (cf. Sec. V), we may always regard such channels as CB-limits of sequences of channels with finite-dimensional output algebras. Thus, given a channel $\Phi:\mathcal{B}\to\mathcal{A}, \mathcal{B}=\mathcal{B}(\mathfrak{h}), \mathcal{A}=\mathcal{B}(\mathfrak{g})$ with $\dim\mathfrak{g}=\infty$, we consider a sequence $\{P_n\}$ of finite-dimensional projections such that $P_n\to\mathbb{1}_g$ strongly, and the corresponding sequence $\{\Phi_n\}$ of quantum operations $\Phi_n(B) := P_n\Phi(B)P_n$, so that $\Phi_n(B)\to\Phi(B)$ uniformly as $n\to\infty$ for each $B \in \mathcal{B}$, and each Φ_n is a channel from $\mathcal{B}$ into $P_n\mathcal{A}P_n$, with $\lim_{n\to\infty}\|\Phi-\Phi_n\|_{\mathrm{CB}}=0$.

With this in mind, in the examples below we shall not worry about the issue of bounded versus unbounded operational densities.

A. Unitary maps

In the case of channels Θ_U,Θ_V implemented by the unitaries $U,V:\mathfrak{h}\to\mathfrak{h}$, i.e., $\Theta_U(B) = U^\dagger BU$ and $\Theta_V(B)=V^\dagger BV$, the minimax fidelity $f(\Phi,\Psi)$ is easily evaluated using Eq. (49):

$$f(\Theta_U,\Theta_V) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} |\varrho(W)|,$$

where we have defined $W := U^\dagger V$. Let $\mathrm{Sp}(W)$ denote the spectrum of W, which is a closed compact subset of the unit circle $\mathbb{T}$ in the complex plane, and let $E^W(\mathrm{d}z)$ denote the corresponding spectral measure of W. Then we can write

$$f(\Theta_U,\Theta_V) = \inf_{\varrho\in\mathcal{S}(\mathfrak{g})} \left| \int_{\mathrm{Sp}(W)} z M^{W,\varrho}(\mathrm{d}z) \right|,$$

where $M^{W,\varrho}(\mathrm{d}z)$ is the probability measure $\varrho[E^W(\mathrm{d}z)] \equiv (E^W(\mathrm{d}z),\rho)$. Thus

$$f(\Theta_U,\Theta_V) = \mathrm{dist}(0,\overline{\mathrm{co}\,\mathrm{Sp}(W)}), \tag{60}$$

where $\overline{\mathrm{co}\,\mathrm{Sp}(W)}$ denotes the closed convex hull of $\mathrm{Sp}(W)$, and $\mathrm{dist}(z,S) := \inf\{|z-z'| : z' \in S\}$ for any $z \in \mathbb{C}$ and $S \subset \mathbb{C}$. Clearly, $f(\Theta_U,\Theta_V)=1$ if and only if $\overline{\mathrm{co}\,\mathrm{Sp}\,W} \subset \mathbb{T}$, i.e., if and only if $W = \lambda \mathbb{1}_{\mathfrak{h}}$ with $|\lambda|=1$, which is equivalent to $\Theta_U=\Theta_V$.

When $\dim \mathfrak{h} < \infty$, $\mathrm{Sp}(W)$ is a finite subset of $\mathbb{T}$, so that $\overline{\mathrm{co}\,\mathrm{Sp}(W)}$ is a polygon in the complex plane, and Eq. (60) shows that $f(\Theta_U,\Theta_V)$ is simply the distance d from this polygon to the origin. On the other hand, recalling the formula[12] $\mathcal{D}(\Theta_U,\Theta_V)=\sqrt{1-d^2}$, we see that the upper bound in Eq. (58) is saturated by the unitarily implemented channels.

B. Random unitary channels

Continuing with the setup from the preceding example, let us consider channels of the form

$$\Phi(B) = \sum_i p_i \Theta_{U_i}(B), \quad \Psi(B) = \sum_i q_i \Theta_{U_i}(B), \tag{61}$$

where Θ_{U_i} are unitarily implemented channels and $\mathbf{p} \equiv \{p_i\}$, $\mathbf{q} \equiv \{q_i\}$ are probability distributions. It then follows immediately from the strong concavity property (55) of the minimax fidelity that

$$f(\Phi,\Psi) \geqslant \sum_i \sqrt{p_i q_i} \equiv F(\mathbf{p},\mathbf{q}). \tag{62}$$

When $\dim \mathfrak{h} < \infty$, the inequality in (62) becomes equality when the unitaries U_i are orthogonal in the Hilbert-Schmidt sense, $\mathrm{Tr}\, U_i^\dagger U_k = \dim \mathfrak{h} \cdot \delta_{ik}$. On the other hand, when $\mathfrak{h}$ is infinite dimensional, this orthogonality condition does not make sense unless we consider channels given in terms of continual Kraus decompositions, so that the sums in Eq. (62) are replaced with integrals with respect to some positive measure μ, and agree to understand orthogonality in the sense of operator-valued Schwartz distributions. As an example, consider the following.

Let $\mathfrak{h}=\mathcal{F}$, the boson Fock space, let a and $a^\dagger$ be the field annihilation and creation operators, and let $D(z) := \exp(za^\dagger - \overline{z}a)$, $z \in \mathbb{C}$, be the unitary displacement operators obeying the Weyl relation $D(z)D(z') = \mathrm{e}^{\mathrm{i}\,\mathrm{Im}\, zz'} D(z+z')$. Given a function $f \in L^2(\mathbb{C}, \mathrm{d}z)$, where $\mathrm{d}z := \mathrm{d}(\mathrm{Re}\, z)\mathrm{d}(\mathrm{Im}\, z)$, we define its *Weyl-Fourier transform* as $D(f) := \pi^{-1/2}\int_{\mathbb{C}} f(z)D(z)\mathrm{d}z$. Since f is square integrable, $D(f)$ is a Hilbert-Schmidt operator, and it can be easily shown that

$$\mathrm{Tr}[D(f)^\dagger D(g)] = \int_{\mathbb{C}} \overline{f(z)} g(z)\mathrm{d}z \equiv \langle f,g\rangle_{L^2(\mathbb{C})}, \quad \forall\, f,g \in L^2(\mathbb{C})$$

so that $\mathrm{Tr}[D(z)^\dagger D(z')] = \pi\delta^{(2)}(z-z')$, $z,z' \in \mathbb{C}$, where $\delta^{(2)}(\lambda) := \delta(\mathrm{Re}\,\lambda)\delta(\mathrm{Im}\,\lambda)$ is the Dirac δ-function in the complex plane.

With this in mind, consider the family of channels $\Gamma^{(\mu)} : \mathcal{B}(\mathcal{F}) \to \mathcal{B}(\mathcal{F})$, $\mu \in \mathbb{R}^+$, with the preduals given by

$$\Gamma_*^{(\mu)}(\rho) := \frac{1}{\pi\mu}\int_{\mathbb{C}} D(z)\rho D(z)^\dagger \exp(-|z|^2/\mu)\mathrm{d}z$$

(in quantum optics these channels model the so-called *Gaussian displacement noise*[25]). Then the minimax fidelity between $\Gamma^{(\mu)}$ and $\Gamma^{(\nu)}$ is given by

$$f(\Gamma^{(\mu)},\Gamma^{(\nu)}) = \frac{(\mu\nu)^{1/2}}{\frac{1}{2}(\mu+\nu)}. \tag{63}$$

Owing to the inequality between the geometric and the arithmetic means, the right-hand side of Eq. (63) is always bounded between 0 and 1, and the maximum value of 1 is attained if and only

if $\mu=\nu$, i.e., $\Gamma^{(\mu)}=\Gamma^{(\nu)}$. This, of course, agrees with the properties of the minimax fidelity (cf. Sec. V).

C. Master equation

Consider a strongly continuous semigroup of channels $\{\Phi^{(t)}:\mathcal{B}(\mathfrak{h})\to\mathcal{B}(\mathfrak{h})\}_{t\in\mathbb{R}^+}$, with the preduals $\Phi_{\mathrm{T}}^{(t)}$ satisfying the Lindblad master equation[26]

$$\frac{\mathrm{d}\Phi_{\mathrm{T}}^{(t)}(\rho)}{\mathrm{d}t}=X\rho X^\dagger-\frac{1}{2}(X^\dagger X\rho+\rho X^\dagger X) \tag{64}$$

for some $X\in\mathcal{B}(\mathfrak{h})$. Introducing the dilating Hilbert space $\mathcal{H}=\mathfrak{h}\otimes\mathfrak{h}$ with the basis $\{|0\rangle,|1\rangle,\ldots\}$, we can, for an infinitesimal time $t=\varepsilon$, write the predual of the channel $\Phi^{(\varepsilon)}$ in the Stinespring form

$$\Phi_{\mathrm{T}}^{(\varepsilon)}(\rho)=\mathrm{Tr}_{\mathcal{H}}A_\varepsilon\rho A_\varepsilon^\dagger, \tag{65}$$

where the map $A_\varepsilon:\mathfrak{h}\to\mathfrak{h}\otimes\mathcal{H}$ is given by

$$A_\varepsilon\upsilon:=\left(\mathbb{1}_{\mathfrak{h}}-\tfrac{1}{2}\varepsilon X^\dagger X\right)\upsilon\otimes|0\rangle+\sqrt{\varepsilon}X\upsilon\otimes|1\rangle+O(\varepsilon^2), \tag{66}$$

$O(\varepsilon^2)$ indicating terms with norm bounded from above by $M\varepsilon^2$ for some constant $M\geqslant 0$. Note that $A_0\upsilon=\upsilon\otimes|0\rangle$, so that $T^{(0)}=\mathrm{id}$. We can then evaluate the partial trace

$$\mathrm{Tr}_{\mathfrak{h}}[A_\varepsilon\rho A_0^\dagger]=\left(1-\tfrac{1}{2}\varepsilon\langle X^\dagger X\rangle_\rho\right)|0\rangle\langle 0|+\sqrt{\varepsilon}\langle X\rangle_\rho|1\rangle\langle 0|+O(\varepsilon^2), \tag{67}$$

where $\langle B\rangle_\rho:=\mathrm{Tr}(B\rho)$ for $B\in\mathcal{B}(\mathfrak{h})$. Then, again up to an additive term of operator norm $O(\varepsilon^2)$,

$$\mathrm{Tr}_{\mathfrak{h}}[A_\varepsilon\rho A_0^\dagger]^\dagger\mathrm{Tr}_{\mathfrak{h}}[A_\varepsilon\rho A_0^\dagger]\approx\left[\left(1-\tfrac{1}{2}\varepsilon\langle X^\dagger X\rangle_\rho\right)^2+\varepsilon|\langle X\rangle_\rho|^2\right]|0\rangle\langle 0|, \tag{68}$$

which allows us to compute, up to $O(\varepsilon^2)$, the minimax fidelity between the channel $T^{(\varepsilon)}$ after an infinitesimal time ε and the identity map. Using Eq. (53), we obtain

$$f(T^{(\epsilon)},\mathrm{id})=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}\|\mathrm{Tr}_{\mathfrak{h}}[A_\varepsilon\rho A_0^\dagger]\|_{\mathrm{T}}\approx\sqrt{1-\varepsilon C}, \tag{69}$$

where

$$C=\inf_{\varrho\in\mathcal{S}(\mathfrak{g})}(\langle X^\dagger X\rangle_\rho-|\langle X\rangle_\rho|^2). \tag{70}$$

D. Impossibility of quantum bit commitment

The statement of topological equivalence of the noncommutative Hellinger distance and the CB-norm distance between a pair of quantum channels, i.e., Eq. (59), is essentially the "continuity argument" at the heart of a proof of "impossibility of quantum bit commitment (QBC)."[27] Quantum bit commitment is a cryptographic objective in which one party, Alice, commits a bit to another party, Bob, in such a way that the corresponding protocol is *concealing* (i.e., Bob is not able to retrieve the bit before the opening) and *binding* (i.e., Alice cannot change the bit after the commitment). The impossibility proof asserts that if the protocol is perfectly concealing, then it is necessarily not binding, and invokes a continuity argument for "asymptotically" concealing protocols, stating that Alice's probability of successful cheating approaches unity, while Bob's cheating probability becomes close to the value $\frac{1}{2}$ (pure guessing). (The reader should be aware that the impossibility proof in Ref. 27 is valid for a restricted class of protocols, i.e., those that are nonaborting and have a single commitment step. For wider classes of protocols, it is still a matter of debate whether a secure QBC protocol exists.[28]) In this example we derive the continuity argument from the expression of Alice's and Bob's respective cheating probabilities as a consequence of the topological equivalence between the Hellinger distance and the CB-norm distance in Eq. (59).

From the point of view of Bob, Alice's action of committing the bit is equivalent to a channel $\Phi_{\mathbf{A}^{(b)}}$ on an algebra $\mathcal{B}(\mathfrak{h})$, $\dim \mathfrak{h} < \infty$, for each value of the committed bit $b=0,1$, where $\mathbf{A}^{(b)} \equiv \{A_j^{(b)}\}_{j=1}^k$ is a collection of operators satisfying the Kraus condition $\Sigma_{j=1}^k A_j^{(b)\dagger} A_j^{(b)} = \mathbb{1}$, and $\Phi_{\mathbf{A}^{(b)}}$ denotes the channel induced by this Kraus decomposition. At the opening, Alice informs Bob about which element of the Kraus decomposition $\mathbf{A}^{(b)}$ she actually used in the commitment. However, prior to unveiling the label j, Alice can perform an *EPR attack* with the purpose of changing the Kraus decomposition to another equivalent decomposition $\mathbf{A}^{(b)}(V) \equiv \{A_j^{(b)}(V)\}$, where $A_j^{(b)}(V) := \Sigma_\ell A_l^{(b)} V_{j\ell}$ for some $V \in \mathsf{U}(\mathbb{C}^k)$. The EPR attack is achieved by Alice via the unitary transformation V on an ancillary k-dimensional space $\mathcal{H}$. The conditional probability that Alice can cheat successfully by convincing Bob that she has committed, say, $b=1$, while having successfully committed $b=0$ instead, is given by

$$P_c^A(V,\upsilon) = \sum_j \frac{|\langle \upsilon | A_j^{(0)\dagger}(V) A_j^{(1)} \otimes \mathbb{1}_{\mathcal{H}} | \upsilon \rangle|^2}{\|(A_j^{(1)} \otimes \mathbb{1}_{\mathcal{H}})\upsilon\|^2}, \tag{71}$$

where $\|(A_j^{(0)} \otimes \mathbb{1}_{\mathcal{H}})\upsilon\|^2$ is the probability that the jth Kraus element is unveiled. Which V should Alice use? Without any knowledge of $|\upsilon\rangle$, the best she can do is to adopt a conservative strategy of choosing the V that will maximize her cheating probability in the worst-case scenario, namely for the anonymous state $|\upsilon\rangle$ chosen by Bob to minimize $P_c^A(V,\upsilon)$. This is the *minimax* choice of V, corresponding to the cheating probability

$$\overline{P_c^A} := \sup_{V \in \mathsf{U}(\mathbb{C}^k)} \inf_{\upsilon \in \mathfrak{h} \otimes \mathcal{H}; \|\upsilon\|=1} P_c^A(V,\upsilon). \tag{72}$$

On the other hand, for equiprobable bit values $b \in \{0,1\}$ Bob's optimal probability of cheating is given by the probability of error in discriminating between the corresponding output states, more precisely

$$\overline{P_c^B} = \tfrac{1}{2} + \tfrac{1}{4} \sup_{\upsilon \in \mathfrak{h} \otimes \mathcal{H}; \|\upsilon\|=1} \left\| \rho_{\mathbf{A}^{(0)}}^{\upsilon} - \rho_{\mathbf{A}^{(1)}}^{\upsilon} \right\|_1 = \tfrac{1}{2}[1 + \mathcal{D}(\Phi_{\mathbf{A}^{(0)}}, \Phi_{\mathbf{A}^{(1)}})], \tag{73}$$

where we have defined $\rho_{\mathbf{A}}^{\upsilon} := \Phi_{\mathbf{A}} \otimes \mathrm{id}(|\upsilon\rangle\langle\upsilon|)$. Using Jensen's inequality, we can bound Alice's cheating probability $P_c^A(V,\upsilon)$ from below as

$$P_c^A(V,\upsilon) \geqslant \left| \sum_j |\langle \upsilon | A_j^{(0)}(V)^\dagger A_j^{(1)} \otimes \mathbb{1}_{\mathcal{H}} | \upsilon \rangle| \right|^2. \tag{74}$$

Note that the value of the max-min in Eq. (72) will not change if we perform the maximization over the closed convex hull of $\mathsf{U}(\mathbb{C}^k)$, i.e., the set $\mathsf{K}(\mathbb{C}^k)$ of all linear contractions on $\mathbb{C}^k$, and the minimization over the closed convex hull of the pure states on $\mathfrak{h} \otimes \mathcal{H}$, i.e., the set $\mathcal{S}(\mathfrak{h} \otimes \mathcal{H})$ of states on $\mathcal{B}(\mathfrak{h} \otimes \mathcal{H})$, thus completing the domain of the max-min to the product $\mathsf{K}(\mathbb{C}^k) \times \mathcal{S}(\mathfrak{h} \otimes \mathcal{H})$ of compact convex sets. Now, the functional

$$F(V,\rho) := \sum_j \mathrm{Re}\, \mathrm{Tr}\{\rho [A_j^{(0)}(V)^\dagger A_j^{(1)} \otimes \mathbb{1}_{\mathcal{H}}]\} \tag{75}$$

is affine in both $V \in \mathsf{K}(\mathbb{C}^k)$ and $\rho \in \mathcal{S}(\mathfrak{h} \otimes \mathcal{H})$, so that we can use standard minimax arguments[24] to justify the interchange of extrema in Eq. (72), and then apply Lemma 2 to obtain

$$\sup_{V \in \mathsf{U}(\mathbb{C}^k)} \inf_{\upsilon \in \mathfrak{h} \otimes \mathcal{H}} |F(V, |\upsilon\rangle\langle\upsilon|)| = \sup_{V \in \mathsf{K}(\mathbb{C}^k)} \inf_{\varrho \in \mathcal{S}(\mathfrak{h} \otimes \mathcal{H})} |F(V,\rho)| \tag{76}$$

$$= \inf_{\varrho \in \mathcal{S}(\mathfrak{h} \otimes \mathcal{H})} \sup_{V \in \mathsf{K}(\mathbb{C}^k)} |F(V,\rho)| \tag{77}$$

$$= \inf_{v \in \mathfrak{h} \otimes \mathcal{H}; \|v\|=1} \sup_{V \in \mathrm{U}(k)} |F(V, |v\rangle\langle v|)|. \tag{78}$$

Now, since a monotone function does not affect the saddle point, we can use Eqs. (50), (72), (74), and (78) to obtain

$$\overline{P}_c^A \geqslant f^2(\Phi_{\mathbf{A}^{(0)}}, \Phi_{\mathbf{A}^{(1)}}).$$

Using Eq. (59) and then Eq. (73), we finally obtain the chain of estimates

$$\overline{P}_c^A \geqslant f^2(\Phi_{\mathbf{A}^{(0)}}, \Phi_{\mathbf{A}^{(1)}}) \geqslant [1 - \mathcal{D}(\Phi_{\mathbf{A}^{(0)}}, \Phi_{\mathbf{A}^{(1)}})]^2 \geqslant [1 - 2(\overline{P}_c^B - 1/2)]^2,$$

where it follows that, for "asymptotically" concealing protocols, i.e., those for which $\overline{P}_c^B \to \frac{1}{2}$, Alice's probability of cheating will approach unity, and the protocol will not be binding.

Generalized density functional theories using the *k*-electron densities: Development of kinetic energy functionals

Paul W. Ayers[a)]
Department of Chemistry, McMaster University, Hamilton, Ontario, L8S 4M1, Canada

(Received 24 June 2004; accepted 24 March 2005; published online 26 May 2005)

Several explicit formulas for the kinetic energy of a many-electron system as a functional of the *k*-electron density are derived, with emphasis on the electron pair density. The emphasis is on general techniques for deriving approximate kinetic energy functionals and features generalized Weisacker bounds and methods using density-matrix reconstruction. Adapting results from statistical mechanics, a hierarchy of equations is derived that links electron pairs, triplets, quadruplets, etc.; this may be used to derive more accurate approximations. Several methods for defining the exact kinetic energy functional are presented, including the generalizations of the Levy and Lieb formulations of density-functional theory. Together with *N*-representability constraints on the *k*-density, this paper provides the basis for "generalized density functional theories" based on the electron pair density. There are also implications for conventional density-functional theory, notably regarding the development of more accurate density functionals for the kinetic energy. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1922071]

I. INTRODUCTION

Due to the prohibitive cost associated with accurate solutions to the many-electron Schrödinger equation, most computational modeling of many-electron systems does not use the many-electron wave function. Instead, one typically considers some simpler descriptor of the system, typically a few-electron Green's function, density-matrix, or electron density.[1–3] For systems with more than a hundred electrons, these approaches provide the basis for almost every study of many-electron phenomenon. While some of these techniques are exact in principle, practical applications always use approximations, commonly neglecting or approximating certain aspects of electron correlation. One particularly popular method, especially for systems containing hundreds (or even thousands!) of electrons, is density-functional theory.[4,5] In density-functional theory, the electron density is the fundamental descriptor of the system. While there exists an exact formulation of density-functional theory,[6–8] all practical calculations use approximations to the kinetic energy of and the electron–electron repulsion energy between the electrons. Finding accurate approximate functionals is very important, but also very difficult.

Partly motivated by the difficulties one encounters when approximating the kinetic energy and electron–electron repulsion energy in terms of the electron density, there has been recent interest in "higher-order" density-functional theories,[4,5] in which either the first-order reduced density matrix[7,9–31] or the electron pair density[28,32–40] (hereafter called the 2-density) is used as the fundamental variable. In the first case, the kinetic energy functional is known exactly, leaving only the electron–electron repulsion energy to be approximated. When the 2-density

[a)]Electronic mail: ayers@mcmaster.ca

$$\rho_2(\boldsymbol{x}_1,\boldsymbol{x}_2) \equiv \left\langle \Psi \left| \sum_{i=1}^{N} \sum_{j\neq i}^{N} \delta(\boldsymbol{r}_i - \boldsymbol{x}_1)\,\delta(\boldsymbol{r}_j - \boldsymbol{x}_2) \right| \Psi \right\rangle \tag{1}$$

is used as the fundamental variable, the electron–nuclear attraction and electron–electron repulsion energies are known exactly,

$$V_{ne}[\rho_2,v] = \int\int \rho_2(\boldsymbol{x}_1,\boldsymbol{x}_2)\frac{[v(\boldsymbol{x}_1)+v(\boldsymbol{x}_2)]}{2(N-1)}\mathrm{d}\boldsymbol{x}_1\mathrm{d}\boldsymbol{x}_2, \tag{2}$$

$$V_{ee}[\rho_2] = \frac{1}{2}\int\int \frac{\rho_2(\boldsymbol{x}_1,\boldsymbol{x}_2)}{|\boldsymbol{x}_1-\boldsymbol{x}_2|}\mathrm{d}\boldsymbol{x}_1\mathrm{d}\boldsymbol{x}_2, \tag{3}$$

but no explicit expression for the kinetic energy functional is known. However, because the electron–electron repulsion energy is known exactly, there is no need for an adiabatic connection formalism in 2-density functional theory (2-DFT), and the kinetic energy functional of the pair density is homogeneous of degree two with respect to coordinate scaling:[28]

$$T[\rho_2(\boldsymbol{x}_1,\boldsymbol{x}_2)] = \gamma^2 T[\rho_2(\gamma\boldsymbol{x}_1,\gamma\boldsymbol{x}_2)]. \tag{4}$$

Equation (4) is to be contrasted with the much more complicated scaling behavior of the exchange-correlation energy with respect to the electron density.[41]

The kinetic energy component of the exchange-correlation energy, $T_c[\rho]$, also has a very complicated scaling with respect to the electron density.[41] This implies that it may be much easier to develop accurate and robust kinetic energy functionals for the 2-density than it is to develop kinetic energy functionals of the 1-density.[42] (The 1-density is the usual electron density used in density-functional theory.)

There is another obstacle, however, in developing computational methods based on the electron pair density, and that is the N-representability problem: given a kinetic energy functional, the energy and ground state 2-density may be obtained using the variational principle

$$\begin{aligned} E_u^{\mathrm{gs}} &= \min_{\rho_2\in\mathcal{N}}[T[\rho_2] + V_{ee}[\rho_2] + V_{ne}[\rho_2,v]], \\ \rho_2^{\mathrm{gs}}(\boldsymbol{x},\boldsymbol{x}') &= \arg\min_{\rho_2\in\mathcal{N}}[T[\rho_2] + V_{ee}[\rho_2] + V_{ne}[\rho_2,v]], \end{aligned} \tag{5}$$

but the search is restricted to 2-densities that are N-representable. The studies of Davidson,[43] Samveylan,[34] and Pistol[38] demonstrate that forcing the N-representability constraints is not a trivial matter. (Note, in particular, that the explicit constructions of Samveylan and Pistol scale exponentially with the number of electrons.[34,38])

There has been some recent progress in characterizing the ensemble-N-representability constraints for the k-electron spin-densities (hereafter referred to as the k-density), $\rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)$. $\rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{x}_1,\ldots,\boldsymbol{x}_k)$ denotes the probability that there is a σ_1-spin electron at $\boldsymbol{x}_1$, a σ_2-spin electron at $\boldsymbol{x}_2,\ldots$, and a σ_k-spin electron at $\boldsymbol{x}_N$. Thus,

$$\rho_k^{\sigma_1\sigma_2\cdots\sigma_k}(\boldsymbol{x}_1,\boldsymbol{x}_2,\ldots,\boldsymbol{x}_k) \equiv \left\langle \Psi \left| \sum_{i_k\neq i_1,i_2,\ldots,i_{k-1}}^{N} \cdots \sum_{i_2\neq i_1}^{N}\sum_{i_1=1}^{N}\prod_{j=1}^{k} \delta_{s_{i_j},\sigma_j}\delta(\boldsymbol{r}_{i_j}-\boldsymbol{x}_j) \right| \Psi \right\rangle. \tag{6}$$

If $\rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{x}_1,\ldots,\boldsymbol{x}_k)$ is ensemble-N-representable, then there is an "ensemble average" of electronic states,

$$\Gamma_N^{(N)}(\boldsymbol{z}_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_N;\boldsymbol{z}_1',\boldsymbol{z}_2',\ldots,\boldsymbol{z}_N') \equiv \sum_\nu w_\nu \Psi_\nu(\boldsymbol{z}_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_N)\Psi_\nu^*(\boldsymbol{z}_1',\boldsymbol{z}_2',\ldots,\boldsymbol{z}_N') \tag{7}$$

$(0 \leqslant w_\nu \leqslant 1;\ \Sigma_\nu w_\nu = 1)$, such that

$$\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{x}_1,\ldots,\boldsymbol{x}_k) = \sum_\nu w_\nu \left\langle \Psi_\nu \left| \sum_{i_k\neq i_1,i_2,\ldots,i_{k-1}}^{N} \cdots \sum_{i_2\neq i_1}^{N} \sum_{i_1=1}^{N} \prod_{j=1}^{k} \delta_{s_{i_j},\sigma_j}\delta(\boldsymbol{r}_{i_j}-\boldsymbol{x}_j) \right| \Psi_\nu \right\rangle. \tag{8}$$

In Eq. (7) and in the following, $\boldsymbol{z}$ is often used as a shorthand for the spatial and spin coordinates of an electron, $\boldsymbol{z}_i=(\boldsymbol{r}_i,\sigma_i)$.

Even if the N-representability problem for the k-density was solved, the problem of constructing the kinetic energy as a functional of the k-density, however, still remains. This paper addresses this issue by presenting approximate functionals, developing general techniques for deriving new functionals, deriving useful bounds for the kinetic energy, and revealing the links between this problem and other, more conventional, approaches to many-body quantum mechanics. To this end, in Sec. II we prove that exact kinetic energy functionals exist. The construction is explicit (albeit computationally intractable), and is modeled after Levy's and Lieb's constructions of exact functionals in density-functional theory.[7,8] The Levy-constrained search approach has been presented before,[38] but the approach using Lieb's search is new. Section III is concerned with approximate functionals and proving bounds for the kinetic energy. Specificially, two different approaches to the kinetic energy functional are developed, one of which generalizes the Weisacker bounds from density-functional theory[39,40,44] and the other of which is based on density-matrix reconstruction, recovering in a special case the results of March and Santamaria.[45] Section IV points out connections between this approach and other methods in the literature, with emphasis on how extensions to the Lee–Jackson–Feenberg hierarchy of equations can be used to systematically obtain more accurate functionals. Implications for practical computational approaches, including density-functional theory, are discussed in Sec. V.

II. EXACT FUNCTIONALS FROM THE CONSTRAINED-SEARCH AND LEGENDRE-TRANSFORM PROCEDURES

Perhaps the simplest approaches to the kinetic energy functional of the k-density are obtained by extending the methods used to define density-functionals in density-functional theory. For instance, adapting Valone's[17] constrained search[7,46] over ensemble-N-representable density matrices, we have[37]

$$T[\rho_k^{\sigma_1\ldots\sigma_k}] \equiv \underbrace{\min}_{\Gamma_N^{(N)}\to\rho_k^{\sigma_1\ldots\sigma_k}} \mathrm{Tr}(\hat{T}\Gamma_N^{(N)}), \tag{9}$$

where $\Gamma_N^{(N)}$ is a convex sum or "ensemble" of antisymmetric N-electron wave functions [cf. Eq. (7)] and the notation indicates that the search includes only the density matrices that satisfy Eq. (8). This approach to the kinetic energy functional was presented, over a decade ago, in a prescient paper by Ziesche.[39,40]

Note that the electron–nuclear and electron–electron energies are explicit functionals of the k-density, and do not depend on the particular N-electron state with which the k-density is associated; Eq. (9) is then derived directly from the variational principle for the energy, Eq. (5). Note that we can only write Eq. (9) for k-densities that are ensemble-N-representable, as otherwise there will be no $\Gamma_N^{(N)}$ consistent with the k-density in question.

Equivalent to Eq. (9) is the generalization of Lieb's Legendre transform spin-density functional,[8,47] which we state only for the 2-density

$$T[\rho_2] \equiv \underbrace{\sup_{v^\sigma(\boldsymbol{r}),V_r^{\sigma\sigma'}(\boldsymbol{r}_1,\boldsymbol{r}_2)}}\left[E[\{v^\sigma,V_r^{\sigma\sigma'}\};N_\alpha,N_\beta] - \sum_{\sigma,\sigma'=\alpha,\beta}\left(\begin{array}{l}\frac{1}{2}\int\int \rho_2^{\sigma\sigma'}(\boldsymbol{x}_1,\boldsymbol{x}_2)V_r^{\sigma\sigma'}(\boldsymbol{x}_1,\boldsymbol{x}_2)\mathrm{d}\boldsymbol{x}_1\mathrm{d}\boldsymbol{x}_2 \\ -\int\int \rho_2^{\sigma\sigma'}(\boldsymbol{x}_1,\boldsymbol{x}_2)\frac{[v^\sigma(\boldsymbol{x}_1)+v^{\sigma'}(\boldsymbol{x}_2)]}{2(N-1)}\mathrm{d}\boldsymbol{x}_1\mathrm{d}\boldsymbol{x}_2\end{array}\right)\right] \tag{10}$$

where $E[\{v^\sigma,V_r^{\sigma\sigma'}\};N]$ is the energy of an N-electron system with spin-dependent external potentials $\{v^\sigma(\boldsymbol{r})\}_{\sigma=\alpha,\beta}$ and interelectronic interaction potentials $\{V_r^{\sigma\sigma'}(\boldsymbol{r}_1,\boldsymbol{r}_2)\}_{\sigma,\sigma'=\alpha,\beta}$,

$$E[\{v^\sigma,V_r^{\sigma\sigma'}\};N_\alpha,N_\beta] \equiv \underbrace{\min_{\Psi}}\frac{\left\langle \Psi \left| \sum_{\sigma,\sigma'}\sum_{i=1}^{N}\left(\begin{array}{l}-\frac{\nabla_i^2}{2}+|\sigma_i\rangle\frac{v^\sigma(\boldsymbol{r}_i)}{2}\langle\sigma_i|+|\sigma_i'\rangle\frac{v^{\sigma'}(\boldsymbol{r}_i)}{2}\langle\sigma_i'| \\ +\sum_{j>i}^{N}|\sigma_i\rangle|\sigma_j'\rangle V_r(\boldsymbol{r}_i,\boldsymbol{r}_j)\langle\sigma_j'|\langle\sigma_i|\end{array}\right)\right| \Psi \right\rangle}{\langle\Psi|\Psi\rangle}. \tag{11}$$

The Legendre-transform approach to the k-density with $k>2$ is similar, but complicated by the fact that the supremum must include k-body potentials. For this reason we will only derive Eq. (10) in the present work. The spin-free analogues of Eqs. (9) and (10) are perhaps more useful for formal theory: such functionals depend on the components of the spin-resolved 2-density only through

$$\rho_2(\boldsymbol{x},\boldsymbol{x}') = \sum_{\sigma,\sigma'}\rho_2^{\sigma\sigma'}(\boldsymbol{x},\boldsymbol{x}'). \tag{12}$$

The derivation of Eq. (10) will be familiar to density-functional aficionados but, for the sake of completeness, the proof follows. Suppose we are given two systems, with external potentials $v(\boldsymbol{z})\neq\tilde{v}(\boldsymbol{z})$ and interelectron potentials $V_r(\boldsymbol{z},\boldsymbol{z}')\neq\tilde{V}_r(\boldsymbol{z},\boldsymbol{z}')$, where it is understood that external potentials and/or the interelectronic potentials differ by more than just an additive constant. Given the 2-density, $\rho_2^{\sigma\sigma'}(\boldsymbol{z},\boldsymbol{z}')$ of the former system, it follows from the variational principle that

$$T[\rho_2^{\sigma\sigma'}] + \int\int \rho_2(\boldsymbol{z}_1,\boldsymbol{z}_2)\frac{[v(\boldsymbol{z}_1)+v(\boldsymbol{z}_2)]}{2(N-1)}\mathrm{d}\boldsymbol{z}_1\mathrm{d}\boldsymbol{z}_2 + \frac{1}{2}\int\int \rho_2(\boldsymbol{z}_1,\boldsymbol{z}_2)V_r(\boldsymbol{z}_1,\boldsymbol{z}_2)\mathrm{d}\boldsymbol{z}_1\mathrm{d}\boldsymbol{z}_2 > E[\tilde{v},\tilde{V}_r;N_\sigma]. \tag{13}$$

Clearly, then, the maximum value in Eq. (10) is obtained when the search over potentials finds the potentials appropriate to $\rho_2(\boldsymbol{z},\boldsymbol{z}')$, namely $v(\boldsymbol{z})$ and $V_r(\boldsymbol{z},\boldsymbol{z}')$. At the maximum, then, Eq. (10) is an identity,

$$T[\rho_2] \equiv E[v,V_r;N_\sigma] - \int\int \rho_2(\mathbf{z}_1,\mathbf{z}_2)\frac{[v(\mathbf{z}_1)+v(\mathbf{z}_2)]}{2(N-1)}d\mathbf{z}_1 d\mathbf{z}_2 - \frac{1}{2}\int\int \rho_2(\mathbf{z}_1,\mathbf{z}_2)V_2(\mathbf{z}_1,\mathbf{z}_2)d\mathbf{z}_1 d\mathbf{z}_2, \tag{14}$$

which established the exactness of the generalized Lieb functional, Eq. (10).

Just as some N-representable electron densities are not ensemble-v-representable,[8,48] some ensemble-N-representable 2-pair densities will not be ensemble-(v,V_r)-representable. [A 2-density is not ensemble-(v,V_r)-representable if there are no potentials, $(v(\mathbf{z}),V_r(\mathbf{z},\mathbf{z}'))$ for which the 2-density can be expressed as a convex sum of degenerate N-electron ground state(s).] For such states, the maximum in Eq. (10) does not exist, and is replaced by a supremum. (The supremum exists because the kinetic energy of any ensemble-N-representable density-matrices is finite.) Because a supermum is never achieved, if $\tilde{\rho}_2(\mathbf{z},\mathbf{z}')$ is not ensemble-(v,V_r)-representable, then

$$E_{v,V_r}[\tilde{\rho}_2^{nv}] > E[v,V_r;N]. \tag{15}$$

Because 2-densities that are not ensemble-(v,V_r)-representable do not minimize the energy for any choice of potentials, the generalized Lieb functional is consistent with the variational principle. Just as with their density-functional analogues, the constrained search functional, Eq. (9), and the Legendre-transform functional, Eq. (10), are equivalent.[8] The proof, however, is rather more involved than the preceding analysis.

III. APPROXIMATE KINETIC ENERGY FUNCTIONALS

A. Kinetic energy from the *N*-electron distribution function

For real-valued wave functions and pure states, the kinetic energy of the N-electron distribution function,

$$n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N) = (\Psi(\mathbf{z}_1,\ldots,\mathbf{z}_N))^2 \tag{16}$$

is given by[49,50]

$$\begin{aligned} T[n_N^{(N)}] &= \sum_{i=1}^{N}\left\langle \frac{\nabla_i n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)\cdot\nabla_i n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)}{8n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)}\right\rangle_{1\ldots N} \\ &= -\sum_{i=1}^{N}\left\langle \frac{n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)\nabla_i^2[\ln n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)]}{8}\right\rangle_{1\ldots N}, \end{aligned} \tag{17}$$

where $\langle\ \rangle_{1\ldots N}$ is a convenient shorthand for the integration over the coordinates of electrons $1,2,\ldots,N$. For $n_N^{(N)}$ that do not correspond to pure states, the kinetic energy functional is significantly more complicated, requiring a constrained search over ensemble-N-representable density matrices, $\Gamma_N^{(N)}$,

$$T[n_N^{(N)}] \equiv \min_{\Gamma_N^{(N)}\to n_N^{(N)}} \mathrm{Tr}[\hat{T}\Gamma_N^{(N)}]. \tag{18}$$

If one naively applies Eq. (17) to an $n_N^{(N)}$ that is ensemble-N-representable, one obtains a lower bound to the true answer,

$$T[n_N^{(N)}] \equiv \min_{\Gamma_N^{(N)}\to n_N^{(N)}} \mathrm{Tr}[\hat{T}\Gamma_N^{(N)}] \geqslant \sum_{i=1}^{N}\left\langle \frac{\nabla_i n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)\cdot\nabla_i n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)}{8n_N^{(N)}(\mathbf{z}_1,\ldots,\mathbf{z}_N)}\right\rangle_{1\ldots N}. \tag{19}$$

Equation (19) follows directly from the triangle inequality for the Sobolev ($\mathbb{H}^1$) norm. For completeness, however, an elementary proof of this inequality is provided in the Appendix.

The importance of Eq. (17) [and even Eq. (18)] is that one can *reconstruct* the N-electron density from the 2-density by a variety of methods: cluster expansion techniques, hierarchies of

equations, etc. Though such methods are not practical computational techniques for large numbers of electrons, their mere existence is important, suggesting ways to construct systematically improvable families of approximations to the exact kinetic-energy functional. In particular, methods originally developed for statistical-mechanical simulations of fermions[51] may be profitably applied to computing the kinetic energy of molecular systems.

It is frequently convenient to consider an alternative k-electron density, $n_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)$, which is normalized to one,

$$n_k^{(N)}(\boldsymbol{z}_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k) \equiv \int\int\int \cdots \int\int\int \Gamma_N^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N;\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)\mathrm{d}\boldsymbol{z}_{k+1}\ldots\mathrm{d}\boldsymbol{z}_N. \tag{20}$$

To obtain the k-density from $n_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)$, one simply multiplies by the appropriate normalization factor, obtaining

$$\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{x}_1,\boldsymbol{x}_2,\ldots,\boldsymbol{x}_k) = \left(\frac{N_\alpha!N_\beta!}{(N_\alpha-m_\alpha)!(N_\beta-m_\beta)!}\right) n_k^{(N)}(\sigma_1,\boldsymbol{x}_1;\ldots;\sigma_k,\boldsymbol{x}_k), \tag{21}$$

where N_α and N_β are the number of α-spin and β-spin electrons and m_α and m_β are the number of α-spin and β-spin indices in $\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{x}_1,\boldsymbol{x}_2,\ldots,\boldsymbol{x}_k)$,

$$m_\sigma \equiv \sum_{i=1}^{k} \delta_{\sigma\sigma_i}. \tag{22}$$

B. Generalized-Weisacker bounds for the kinetic energy

Using Eq. (17), one expects approximations to the kinetic energy may be obtained from the k-density. To this end, we write $n_N^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)$ in terms of $n_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)$ using Bayes' theorem,

$$f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N) \equiv \frac{n_N^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)}{n_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)}. \tag{23}$$

Because $f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots\boldsymbol{z}_N)$ represents the probability of observing electrons at $(\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)$ given that there are electrons at $(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)$,

$$\int\int\ldots\int f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)\mathrm{d}\boldsymbol{z}_{k+1}\ldots\mathrm{d}\boldsymbol{z}_N = 1: \tag{24}$$

that is, the probability of observing electrons $k+1,k+2,\ldots,N$ *somewhere* is unity. [Alternatively, Eq. (24) follows directly from the definitions, Eqs. (20) and (23).] With this background we can prove the following theorem:

Theorem 1: *(Lower bounds on the kinetic energy of pure states.)* If $\{\rho_k^{\sigma_1\ldots\sigma_k}\}_{k=1}^N$ are N-representable, the Weisacker-type bounds,

$$T_w^{(k)}[\rho] \equiv \sum_{\sigma_1=\alpha,\beta}\left[N_{\sigma_1}\left(\frac{(N_\alpha-m_\alpha)!(N_\beta-m_\beta)!}{N_\alpha!N_\beta!}\right)\times\max_{\sigma_2,\sigma_3,\ldots,\sigma_k}\int\int\cdots\int\frac{\nabla_1\rho_k^{\sigma_1\ldots\sigma_N}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)\nabla_1\rho_k^{\sigma_1\ldots\sigma_N}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)}{8\rho_k^{\sigma_1\ldots\sigma_N}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)}\mathrm{d}\boldsymbol{r}_1,\ldots,\mathrm{d}\boldsymbol{r}_k\right] \tag{25}$$

provide a nondecreasing set of bounds on the true kinetic energy of the system,

$$T_w^{(1)}[\rho_1^{\sigma_1}] \leqslant T_w^{(2)}[\rho_2^{\sigma_1\sigma_2}] \leqslant \cdots \leqslant T_w^{(N)}[\rho_N^{\sigma_1\ldots\sigma_N}] \leqslant T_{\text{exact}}. \tag{26}$$

The inequalities are strict unless $f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots\boldsymbol{z}_N)$ is constant for all $\boldsymbol{z}_1$ for some $k<N$, in which case $T_w^{(k)}=T_w^{(k+1)}=\cdots=T_w^{(N)}$. [In Eq. (25), it is understood that the variation over spin states

is restricted by the multiplicity of the system. That is, the number of σ-spin electrons, m_σ, in Eq. (25) cannot exceed the total number of electrons with this spin, N_σ.]

Proof: The Weisacker functional can be shown to be a lower bound to the true kinetic energy using the Cauchy–Schwarz inequality,[52] and Eq. (26) follows from a straightforward generalization of that argument. A more elementary method of proof will suffice here, however. Substituting the definition of $f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)$ into Eq. (17), we can write[49,53]

$$
\begin{aligned}
T[n_N^{(N)}] &= \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \left\langle \frac{|\nabla_1 (n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k) f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N))|^2}{8 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k) f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)} \right\rangle_{2\ldots N} \mathrm{d}\boldsymbol{r}_1 \\
&= \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \left\langle \frac{|\nabla_1 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k)|^2}{8 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k)} f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N) \right\rangle_{2\ldots N} \mathrm{d}\boldsymbol{r}_1 \\
&\quad + \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \frac{1}{4} \langle \nabla_1 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k) \cdot \nabla_1 f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N) \rangle_{2\ldots N} \mathrm{d}\boldsymbol{r}_1 \\
&\quad + \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \left\langle \frac{n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k)}{8 f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)} \cdot \right. \\
&\qquad \left. \times |\nabla_1 f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)|^2 \right\rangle_{2\ldots N} \mathrm{d}\boldsymbol{r}_1 \\
&= \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \left\langle \frac{|\nabla_1 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k)|^2}{8 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k)} \right\rangle_{2\ldots k} \mathrm{d}\boldsymbol{r}_1 \\
&\quad + \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \frac{1}{4} \langle \nabla_1 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k) \cdot \nabla(1) \rangle_{2\ldots k} \mathrm{d}\boldsymbol{r}_1 \\
&\quad + \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \left\langle n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k) \frac{|\nabla_1 f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)|^2}{8 f_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)} \right\rangle_{2\ldots N} \mathrm{d}\boldsymbol{r}_1 .
\end{aligned}
\tag{27}
$$

The normalization of $f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)$ [Eq. (24)] is used to make the second simplification in Eq. (27). Note that the last term in Eq. (27), as a product of two non-negative functions, will be positive unless $f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)$ is a constant, independent with respect to changes in $\boldsymbol{z}_1$, so that $\nabla_1 f_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k|\boldsymbol{z}_{k+1},\ldots,\boldsymbol{z}_N)=0$. For this reason,

$$
T[n_N^{(N)}] \geqslant \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \int \left\langle \frac{|\nabla_1 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k)|^2}{8 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_k)} \right\rangle_{2\ldots k} \mathrm{d}\boldsymbol{r}_1 . \tag{28}
$$

Next, note that the result is independent of the spins of electrons $2\ldots N$, provided the total number of α-spin electrons and β-spin electrons in Eq. (27) are N_α and N_β, respectively. That is, due to the symmetry of $n_N^{(N)}$ with respect to interchange of electronic coordinates (both space and spin), we need not sum over spin in evaluating the angular brackets in Eqs. (17), (27), and (28) (provided we renormalize $n_k^{(N)}$ so that $\langle n_k^{(N)} \rangle_{1\ldots k}=1$). It follows from the derivation, then, that Eq. (28) holds regardless how we choose the spins of electrons $2\ldots N$. Choosing the spins to make the bound as tight as possible gives

$$T[n_N^{(N)}] \geqslant \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \underbrace{\max}_{\sigma_2,\sigma_3,\ldots,\sigma_k} \left\langle \frac{|\nabla_1 n_k^{(N)}(\boldsymbol{r}_1,\sigma_1;\boldsymbol{r}_2,\sigma_2,\ldots,\boldsymbol{r}_k,\sigma_k)|^2}{8n_k^{(N)}(\boldsymbol{r}_1,\sigma_1;\boldsymbol{r}_2,\sigma_2,\ldots,\boldsymbol{r}_k,\sigma_k)} \right\rangle_{1\ldots k}. \tag{29}$$

Equation (25) follows from the relation between n_k^N and $\rho_k^{\sigma_1\cdots\sigma_k}$,. Noting that $T_w^{(1)}[\rho_1^{\sigma_1}]$ is the Weisacker bound on the kinetic energy,[44] we call $T_w^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}]$ the *k*th-Weisacker bound.[44] Since $T_w^{(N)}[\rho_N^{\sigma_1\cdots\sigma_N}]$ is given by Eq. (17), the *N*th-Weisacker bound is a lower bound for ensemble-*N* representable $\rho_k^{\sigma_1\cdots\sigma_k}$, and exact for pure-state-*N*-representable $\rho_k^{\sigma_1\cdots\sigma_k}$.

It remains to show that the Weisacker bounds, $T_w^k[\rho_k^{\sigma_1\cdots\sigma_k}]$, are an increasing sequence of approximations to the true kinetic energy. Defining

$$b_{k-1}^{(k)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_{k-1}|\boldsymbol{z}_k) \equiv \frac{n_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)}{n_{k-1}^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_{k-1})} \tag{30}$$

and repeating the argument in Eq. (27), we find that

$$T_w^{(k-1)}[\rho_{k-1}^{\sigma_1,\ldots\sigma_{k-1}}] \leqslant T_w^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}] \tag{31}$$

with the equality holding only if

$$\sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \left\langle n_{k-1}^{(N)}(\boldsymbol{r}_1,\sigma_1,\ldots,\boldsymbol{r}_{k-1},\sigma_{k-1}) \frac{|\nabla_1 b_{k-1}^{(k)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_{k-1}|\boldsymbol{z}_k)|^2}{8b_{k-1}^{(k)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_{k-1}|\boldsymbol{z}_k)} \right\rangle_{1\ldots k} = 0 \tag{32}$$

for some choice of the electron spins, $\{\sigma_i\}_{i=2}^k$. But this would indicate that

$$b_{k-1}^{(k)} = \frac{f_{k-1}^{(N)}}{f_k^{(N)}}$$

is constant with respect to changes in any of the first $k-1$ electronic coordinates. Because $f_{k-1}^{(N)}$ has the coordinate of the $(k-1)$st electron as a variable, while $f_k^{(N)}$ does not, this implies that $f_{k-1}^{(N)}$ (and hence $f_k^{(N)}$) is also constant with respect to changes in any of the first $k-1$ electronic coordinates. That the Weisacker bounds form an increasing sequence immediately follows. □

We conclude this section by discussing the accuracy of the Weisacker bounds. Clearly, the Weisacker bound from the 2-density will be tighter than that from the usual electron density. That is, just because the Weisacker kinetic energy functional is not suitable for density-functional theory does not mean that $T_w^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}]$ is similarly poor. In particular, the derivation of Eq. (27) shows that the error in $T_w^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}]$ is caused by neglecting the correlated motions between groupings containing more than *k* electrons. While assuming that electrons act totally independently is a poor assumption, we might expect that except for those rare instances where more than two electrons are close together, the effect of correlations between three (or more) electrons can be safely neglected. It is reasonable to hope that $T_w^{(2)}[\rho_2^{\sigma_1\sigma_2}]$ is already a good approximation to the kinetic energy and, by the same argument, that the quality of the Weisacker bounds rapidly improves with increasing *k*.

Another perspective on the Weisacker bounds is obtained by considering the *N*-representability of the underlying density matrices. $T_w^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}]$ can be derived by assuming that the *k*th order reduced density matrix,

$$\Gamma_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k') = \sum_{i=1}^{\infty} \omega_i^{(k,N)} \psi_i^{(k,N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k) \psi_i^{(k,N)}(\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k') \tag{33}$$

has only one occupied "natural" *k*-electron function, $\psi_i^{(k,N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k) \equiv \sqrt{n_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)}$. That is,

$$\Gamma_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k') \approx \sqrt{n_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)}\sqrt{n_k^{(N)}(\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k')}. \tag{34}$$

Note that the maximum (in this case, only) occupation number of $\Gamma_k^{(N)}$ is 1, which violates an N-representability condition on the occupation numbers, $\{\omega_i^{(k,N)}\}_{i=1}^{\infty}$ of the kth-order reduced density matrix,[54–57]

$$\max_i \omega_i^{(k,N)} \leqslant \frac{1}{N-k+1}, \tag{35}$$

unless $k=N$. That is, the Pauli exclusion principle prevents all the electrons in an N-electron system for being described by the same k-electron state.

We may profitably construct approximate kinetic energy functionals based on the analysis in Eq. (27). For instance, one may consider

$$T[\rho_k^{\sigma_1\cdots\sigma_k}] \approx T_w^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}] + \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1}\left(\frac{(N_\alpha-m_\alpha)!(N_\beta-m_\beta)!}{N_\alpha!N_\beta!}\right) \times\left\langle \rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)\frac{|\nabla_1\tilde{f}_k^{(N)}(\boldsymbol{r}_1,\sigma_1;,\ldots;\boldsymbol{r}_k,\sigma_k|\boldsymbol{r}_{k+1},\sigma_{k+1};,\ldots;\boldsymbol{r}_N\sigma_N)|^2}{8\tilde{f}_k^{(N)}(\boldsymbol{r}_1,\sigma_1;,\ldots;\boldsymbol{r}_k,\sigma_k|\boldsymbol{r}_{k+1},\sigma_{k+1};,\ldots;\boldsymbol{r}_N\sigma_N)}\right\rangle_{1\ldots N}, \tag{36}$$

where $\tilde{f}_k^{(N)}$ denotes an approximation to the exact conditional probability distribution function defined by Eq. (23). Since Eq. (36) requires performing a $3N$-dimensional integration, it will probably be more practical to settle for approximations of a high-order Weisacker approximation. For example, a functional of the form

$$T_w^{(n)}[\rho_n^{\sigma_1\cdots\sigma_n}] \approx T_w^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}] + \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1}\left(\frac{(N_\alpha-m_\alpha)!(N_\beta-m_\beta)!}{N_\alpha!N_\beta!}\right) \times\left\langle \rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)\frac{|\nabla_1\tilde{b}_k^{(n)}(\boldsymbol{r}_1,\sigma_1;,\ldots;\boldsymbol{r}_k,\sigma_k|\boldsymbol{r}_{k+1},\sigma_{k+1};,\ldots;\boldsymbol{r}_n\sigma_n)|^2}{8\tilde{b}_k^{(n)}(\boldsymbol{r}_1,\sigma_1;,\ldots;\boldsymbol{r}_k,\sigma_k|\boldsymbol{r}_{k+1},\sigma_{k+1};,\ldots;\boldsymbol{r}_n\sigma_n)}\right\rangle_{1\ldots n}, \tag{37}$$

where $\tilde{b}_k^{(n)}$ approximates the conditional distribution function defined by Eq. (30), could be significantly more accurate than the kth-order Weisacker approximation. Based on the preceding arguments, one expects functionals like Eq. (37) will typically underestimate the kinetic energy of a system.

C. Weisacker functionals for the kinetic energy of the 2-density

The form of the Weisacker functional for the 2-density is of special interest in the present work, as the 2-density is the simplest quantity for which the electron–electron repulsion energy can be evaluated exactly. Define the pair correlation function,

$$g_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) \equiv \frac{\rho_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)}{\rho_1^{\sigma_1}(\boldsymbol{r}_1)\rho_1^{\sigma_2}(\boldsymbol{r}_2)}, \tag{38}$$

and the hole correlation function,

$$h_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) \equiv g_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) - 1. \tag{39}$$

Recalling the normalization of the exchange-correlation hole,

$$\int \rho_1^{\sigma_2}(\boldsymbol{r}_2) h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)\mathrm{d}\boldsymbol{r}_2 = -\,\delta_{\sigma_1\sigma_2}, \tag{40}$$

$T_w^2[\rho_2^{\sigma_1\sigma_2}]$ can be simplified to

$$T_w^{(2)}[\rho] \equiv \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1} \cdot \underbrace{\max_{\sigma_2=\alpha,\beta}}\left[\left(\frac{(N_\alpha-\delta_{\alpha\sigma_1}-\delta_{\alpha\sigma_2})!(N_\beta-\delta_{\beta\sigma_1}-\delta_{\beta\sigma_2})!}{N_\sigma!N_\beta!}\right)\right.$$
$$\left.\times\int\int \frac{\nabla_1\rho_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)\cdot\nabla_1\rho_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)}{8\rho_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)}\mathrm{d}\boldsymbol{r}_1\mathrm{d}\boldsymbol{r}_2\right]$$
$$=\sum_{\sigma_1=\alpha,\beta}\left[T_w^{(1)}[\rho_1^{\sigma_1}]+\underbrace{\max_{\sigma_2=\alpha,\beta}}\left[\left(\frac{N_{\sigma_1}(N_\alpha-\delta_{\alpha\sigma_1}-\delta_{\alpha\sigma_2})!(N_\beta-\delta_{\beta\sigma_1}-\delta_{\beta\sigma_2})!}{N_\alpha!N_\beta!}\right)\right.\right.$$
$$\left.\left.\times\int\int\rho_1^{\sigma_1}(\boldsymbol{r}_1)\rho_1^{\sigma_2}(\boldsymbol{r}_2)\frac{\nabla_1 h_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)\cdot\nabla_1 h_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)}{8(1+h_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2))}\mathrm{d}\boldsymbol{r}_1\mathrm{d}\boldsymbol{r}_2\right]\right]$$
$$\leqslant T_{\mathrm{exact}}[\rho_2]. \tag{41}$$

Corrections to the second-order Weisacker functional can be constructed using Eq. (37). Since relatively simple methods for constructing the 3-density and 4-density from the 2-density are known (see, for example, Secs. III G and III H), approximations to $T_w^{(3)}$ and $T_w^{(4)}$ should be feasible.

After this paper was submitted, results equivalent to those of this section were published by Furche.[40] There is also a strong connection between this model for the kinetic-energy of the 2-density and the equations for $\sqrt{\rho_2(\boldsymbol{r}_1,\boldsymbol{r}_2)}$ proposed by Nagy[32,39] (and later by Furche[40]); the "uncorrected" kinetic energy computed in such theories is implicitly identical to Eq. (41) (albeit without the maximization over the choice of spins). The derivations and explanation in these references offer an instructive perspective that is often complementary to that presented here.

D. Kinetic energy from reduced density matrices

To this point we have focused on the idea that the kinetic energy can be computed (either approximately or exactly) from the k-density. A more common approach, however, is to use the kth-order reduced density matrix, $\Gamma_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k')$ [cf. Eq. (34)].[54,55] From the definition of the reduced density matrix,

$$T[\Gamma_k^{(N)}] \equiv \sum_{\sigma_1=\alpha,\beta} N_{\sigma_1}\int\int\int\left(\begin{array}{l}\delta(\boldsymbol{r}_1-\boldsymbol{r}_1')\\ \times-\dfrac{\nabla_1^2}{2}\Gamma_k^{(N)}(\boldsymbol{r}_1,\sigma_1;\ldots;\boldsymbol{r}_k,\sigma_k;\boldsymbol{r}_1',\sigma_1;\boldsymbol{r}_2,\sigma_2;\ldots;\boldsymbol{r}_k,\sigma_k)\end{array}\right)\mathrm{d}\boldsymbol{r}_1\ldots\mathrm{d}\boldsymbol{r}_k\mathrm{d}\boldsymbol{r}_1'. \tag{42}$$

That is, we need only evaluate the kinetic energy of a single electron (all electrons are identical), with the kinetic energy appropriately weighted by the number of electrons of each spin. From Eq. (42), just the first-order density matrix is sufficient to compute the kinetic energy,

$$T[\Gamma_1^{(N)}] \equiv \sum_{\sigma=\alpha,\beta} N_\sigma\int\int\delta(\boldsymbol{x}-\boldsymbol{x}')\left(-\frac{\nabla_x^2}{2}\right)\Gamma_1^{(N)}(\boldsymbol{x},\sigma;\boldsymbol{x}',\sigma)\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{x}'. \tag{43}$$

The importance of Eq. (43) arises from the existence of methods for constructing the reduced density matrices and Green's functions (of which the reduced density matrices can be regarded as initial values) from k-densities. The first-order reduced density matrix is of special interest: not only is Eq. (43) an especially simple functional, but also because the known ensemble-N-representability conditions for $\Gamma_1^{(N)}$ constrain the derivation of methods for constructing approximate first-order density matrices from 2-densities.

Even though exact reconstruction is probably computationally impracticable, approximate reconstructions may be useful insofar as the reduced density matrices so constructed should be "close to" ensemble-*N*-representable," in the sense that the (unknown and/or unenforced) *N*-representability constraints will be only "slightly" violated. (Similar considerations presumably underlie the computational utility of the contracted Schrödinger equation, whereby the interrelations between the density matrices seems to help solve the *N*-representability problem by severely restricting the number of permissible density matrices.)[58–63]

The significance of the preceding abstract discussion is bolstered by the existence of a general method for constructing the $(k-1)$-order reduced density matrix from the k-density. To this end, write the cumulant expansion for $\Gamma_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k')$ in terms of reduced density matrices of lower order plus a "connected piece," $\Delta_k^{(N)}(\boldsymbol{z}_1,\ldots\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k')$, correcting this form.[64–66] The sequential relation between the density matrices,

$$\Gamma_j^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_j;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_j') = \int\int\int \Gamma_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k')\mathrm{d}\boldsymbol{z}_{j+1}\ldots\mathrm{d}\boldsymbol{z}_k, \tag{44}$$

allows us to write the lower-order density matrices in the cumulant expansion in terms of $\Gamma_{k-1}^{(N)}$, so that the cumulant expansion equation can be written in the form

$$\Gamma_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k') = f(\Gamma_{k-1}^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_{k-1};\boldsymbol{z}_1',\ldots,\boldsymbol{z}_{k-1}')) + \Delta_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k'). \tag{45}$$

The connected piece, $\Delta_k^{(N)}$, is either neglected or approximated using the k-density and/or the $(k-1)$-order density matrix. Setting the primed variables equal to the unprimed variables in Eq. (45) gives a nonlinear equation for $\Gamma_{k-1}^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_{k-1};\boldsymbol{z}_k,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_{k-1})$ in terms of the k-density. $\Gamma_{k-1}^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_{k-1};\boldsymbol{z}_k,\boldsymbol{z}_2,\ldots,\boldsymbol{z}_{k-1})$ can then be used to approximate the kinetic energy,

$$\begin{aligned} T_{\mathrm{DM}}^{(k)}[\rho_k^{\sigma_1\cdots\sigma_k}] &\equiv \sum_{s=\alpha,\beta} N_s \int\int\int \left(\begin{array}{l} \delta(\boldsymbol{r}_1-\boldsymbol{r}_k) \\ \times\left(-\frac{\nabla_1^2}{2}\right)\Gamma_{k-1}^{(N)}(\boldsymbol{r}_1,s;\boldsymbol{r}_2,\sigma_2;\ldots,\boldsymbol{r}_{k-1},\sigma_{k-1};\boldsymbol{r}_k,s;\boldsymbol{r}_2,\sigma_2;\ldots,\boldsymbol{r}_{k-1},\sigma_{k-1}) \end{array} \right) \mathrm{d}\boldsymbol{r}_1\cdots\mathrm{d}\boldsymbol{r}_k \\ &\approx T_{\mathrm{exact}}[\rho_k^{\sigma_1\cdots\sigma_k}]. \end{aligned} \tag{46}$$

For $k>2$, the kinetic energy constructed using this procedure, $T_{\mathrm{DM}}^{(k)}[\rho_k]$, is an upper bound on the true kinetic energy if

- the k-density and the $(k-1)$-order density matrix constructed therefrom have the same 2-density and $\Gamma_{k-1}^{(N)}$ is ensemble-*N*-representable
  or
- there exists an ensemble-*N*-representable $(k-1)$-order density matrix with the correct 2-density and a lower kinetic energy than the $\Gamma_{k-1}^{(N)}$ determined from Eq. (45).

The second condition is sufficient to ensure that the kinetic energy functional using the first-order density matrix, $T_{\mathrm{DM}}^{(1)}[\rho_2]$, will be an upper bound to the true kinetic energy.

E. Density-matrix functionals for the kinetic energy of the 2-density

In general, there is no explicit solution to Eq. (45), which must then be solved numerically. However, when the 2-density is used, the cumulant expansion takes a simple form, namely

$$\gamma_2^{\sigma_1\sigma_1'\sigma_2\sigma_2'}(\boldsymbol{r}_1,\boldsymbol{r}_2;\boldsymbol{r}_1',\boldsymbol{r}_2') = \gamma_1^{\sigma_1\sigma_1'}(\boldsymbol{r}_1;\boldsymbol{r}_1')\gamma_1^{\sigma_2\sigma_2'}(\boldsymbol{r}_2;\boldsymbol{r}_2') - \gamma_1^{\sigma_1\sigma_2}(\boldsymbol{r}_1;\boldsymbol{r}_2')\gamma_1^{\sigma_1'\sigma_2'}(\boldsymbol{r}_1';\boldsymbol{r}_2) + \mathcal{D}_2^{\sigma_1\sigma_1'\sigma_2\sigma_2'}(\boldsymbol{r}_1,\boldsymbol{r}_2;\boldsymbol{r}_1',\boldsymbol{r}_2'), \tag{47}$$

where, for convenience, we have used density matrices,

$$\gamma_k^{\sigma_1\ldots\sigma_k\sigma_1'\ldots\sigma_k'}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k;\boldsymbol{r}_1',\ldots,\boldsymbol{r}_k') \equiv \left(\frac{N_\alpha! N_\beta!}{(N_\alpha - m_\alpha)!(N_\beta - m_\beta)!}\right)\Gamma_k^{(N)}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k;\boldsymbol{z}_1',\ldots,\boldsymbol{z}_k'), \tag{48}$$

with the same normalization as the k-densities. [The relationship between $\Gamma_k^{(N)}$ and $\gamma_k^{\sigma_1\ldots\sigma_k'}$ is directly analogous to that between $n_k^N(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_k)$ and $\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)$, cf. Eq. (21).]

Setting the primed and unprimed variables equal in Eq. (47), and using the definition of the hole correlation function [Eq. (39)], one finds

$$\rho_1^{\sigma_1}(\boldsymbol{r}_1)\rho_1^{\sigma_2}(\boldsymbol{r}_2)h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) = -\left|\gamma_1^{\sigma_1\sigma_2}(\boldsymbol{r}_1;\boldsymbol{r}_2)\right|^2 + \mathcal{D}_2^{\sigma_1\sigma_2\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2;\boldsymbol{r}_1,\boldsymbol{r}_2). \tag{49}$$

Renewed interest in natural orbital functional theories has seen the proliferation of a variety of expressions for $\mathcal{D}_2^{\sigma_1\sigma_2\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2;\boldsymbol{r}_1,\boldsymbol{r}_2)$ in terms of the natural orbitals of the first-order density matrix,[13,15,20,21,26]

$$\gamma_1^{\sigma}(\boldsymbol{r}_1;\boldsymbol{r}_1') \equiv \sum_{i=1}^{\infty} \pi_{i,\sigma}^{(1)}\chi_{i,\sigma}^{(1)}(\boldsymbol{r})(\chi_{i,\sigma}^{(1)}(\boldsymbol{r}'))^*. \tag{50}$$

[Comparing Eq. (50) to Eq. (34), we see that

$$\begin{aligned}\chi_{i,\sigma}^{(1)}(\boldsymbol{r}) &\equiv \psi_i^{(1)}(\boldsymbol{z}),\\ \pi_{i,\sigma}^{(1)} &\equiv N_\sigma \cdot \omega_{i,\sigma}^{(1)},\end{aligned} \tag{51}$$

so the ensemble-N-representability constraints on the natural orbital populations is simply $0 \leqslant \pi_{i,\sigma}^{(1)} \leqslant 1$.[12,29,55–57,67]] While these approximations seem to have severe shortcomings when they are used to approximate the hole-correlation function (and thereby the electron–electron repulsion energy),[14,22,25,27,31,68] the approximation might provide adequate accuracy for the kinetic energy when the procedure is inverted, with a given 2-density used to compute the natural orbitals and their occupation numbers or, equivalently, the first-order density matrix.

Equation (49) can be solved exactly when the connected piece is ignored, recovering the independent particle result,

$$\rho_1^{\sigma_1}(\boldsymbol{r}_1)\rho_1^{\sigma_2}(\boldsymbol{r}_2)h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) \equiv -\left|\gamma_1^{\sigma_1\sigma_2}(\boldsymbol{r}_1;\boldsymbol{r}_2)\right|^2. \tag{52}$$

It follows that

$$h^{\alpha\beta}(\boldsymbol{r},\boldsymbol{r}') \equiv 0 \tag{53}$$

and

$$h^{\sigma\sigma}(\boldsymbol{r},\boldsymbol{r}') \leqslant 0, \quad \sigma = \alpha,\beta. \tag{54}$$

Unless Eqs. (53) and (54) are satisfied, Eq. (52) does not have a solution. If Eq. (52) does have a solution and the resulting density matrix is ensemble-N-representable, then the kinetic energy from $\gamma_1^{\sigma\sigma}(\boldsymbol{r},\boldsymbol{r}')$ is an upper bound to the exact kinetic functional defined by Eqs. (9) and (10).

Because Eq. (52) gives an expression for the squared magnitude of the density matrix, rather than the density matrix itself, it is useful to derive a kinetic energy functional for $\left|\gamma_1^{\sigma_1\sigma_2}(\boldsymbol{r}_1;\boldsymbol{r}_2)\right|^2$. Selecting the phase of the natural orbitals so that the first-order density matrix is real, one obtains[45]

$$T_{\mathrm{MS}}[\gamma_1] \equiv \sum_{\sigma=\alpha,\beta} \int\int \frac{\nabla_{\boldsymbol{r}}(\gamma_1^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2))^2 \cdot \nabla_{\boldsymbol{r}}(\gamma_1^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2))^2}{8(\gamma_1^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2))^2} \mathrm{d}\boldsymbol{r}_1 \mathrm{d}\boldsymbol{r}_2$$

$$= \sum_{\sigma=\alpha,\beta} \sum_{i=1}^{\infty} (\pi_{i,\sigma}^{(1)})^2 \int \nabla \psi_{i,\sigma}^{(1)}(\boldsymbol{r}) \cdot \nabla \psi_{i,\sigma}^{(1)}(\boldsymbol{r}) \mathrm{d}\boldsymbol{r}$$

$$\leqslant \sum_{\sigma=\alpha,\beta} \sum_{i=1}^{\infty} (\pi_{i,\sigma}^{(1)}) \int \nabla \psi_{i,\sigma}^{(1)}(\boldsymbol{r}) \cdot \nabla \psi_{i,\sigma}^{(1)}(\boldsymbol{r}) \mathrm{d}\boldsymbol{r} \equiv T_{\mathrm{exact}}[\gamma_1], \tag{55}$$

where the equality holds only in the independent particle model, where all the natural orbital occupations are zero or one. Substituting Eq. (52) into Eq. (55), one obtains the result of March and Santamaria,[45]

$$T_{\mathrm{MS}}[\rho_2^{\sigma\sigma}] \equiv \sum_{\sigma=\alpha,\beta} \left(-\frac{1}{8}\right) \int\int \frac{\nabla_1 \rho_1^{\sigma}(\boldsymbol{r}_1)\rho_1^{\sigma}(\boldsymbol{r}_2)h^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2) \cdot \nabla_1 \rho_1^{\sigma}(\boldsymbol{r}_1)\rho_1^{\sigma}(\boldsymbol{r}_2)h^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2)}{8\rho_1^{\sigma}(\boldsymbol{r}_1)\rho_1^{\sigma}(\boldsymbol{r}_2)h^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2)} \mathrm{d}\boldsymbol{r}_1 \mathrm{d}\boldsymbol{r}_2$$

$$= \sum_{\sigma=\alpha,\beta} \left[T_w^{(1)}[\rho_1^{\sigma}] - \frac{1}{8} \int\int \rho_1^{\sigma}(\boldsymbol{r}_1)\rho_1^{\sigma}(\boldsymbol{r}_2) \frac{\nabla_1 h^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2) \cdot \nabla_1 h^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2)}{h^{\sigma\sigma}(\boldsymbol{r}_1,\boldsymbol{r}_2)} \mathrm{d}\boldsymbol{r}_1 \mathrm{d}\boldsymbol{r}_2 \right]. \tag{56}$$

Equation (56) is similar to the second Weisacker approximation, Eq. (41), and recalls the form of many previous "full Weisacker plus correction" results in density-functional theory.[49,53,69–72] Equation (56) can be applied even when Eq. (54) does not hold. However, the March–Santamaria functional is not generally a rigorous upper bound to the true kinetic energy. Because Eq. (56) is an exact expression for the noninteracting kinetic energy if the exchange-hole is used instead of the exchange-correlation hole in Eq. (56), and because the noninteracting kinetic energy is only slightly less than the true kinetic energy,[73–75] Eq. (56) should provide the basis for quantitative approximations to the true kinetic energy.

F. A tool for checking the accuracy of approximate functionals

Suppose one has, using the variational principle or some other means, arrived at an approximate 2-density for the electronic system with external potential $v(\boldsymbol{r})$. Were the 2-density exact, the virial theorem would imply that

$$2T[\rho] + V_{ee}[\rho_2] = \int \rho(\boldsymbol{r}) \boldsymbol{r} \cdot \nabla v(\boldsymbol{r}) \mathrm{d}\boldsymbol{r}, \tag{57}$$

where $V_{ee}[\rho_2]$ is given by Eq. (3) and the electron density is given by

$$\rho(\boldsymbol{r}) \equiv \rho_1^{\alpha}(\boldsymbol{r}) + \rho_1^{\beta}(\boldsymbol{r}). \tag{58}$$

For an approximate 2-density and/or an approximate kinetic energy functional, Eq. (57) will usually not be exactly satisfied, and so can be used to estimate the error in the approximation. [Equation (57) will, however, be satisfied if the kinetic energy functional has the appropriate scaling; cf. Eq. (4). The author thanks Mel Levy for making this important observation.] It should be noted that the same approach could be used to assess the accuracy of electron–electron repulsion functionals in theories based on the first-order reduced density matrix. In all cases, however, Eq. (57) is not a practical functional, since it requires knowledge of the external potential for which the given 2-density is the ground state. This is impossible to find for non-v-representable densities and, even when a density is v-representable, it is difficult to construct the external potential computationally.[76]

IV. FROM THE 2-DENSITY TO THE KINETIC ENERGY

A. Survey of the literature

Accurately calculating the kinetic energy of a given 2-density, $\rho_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)$, seems to require expressions relating the 2-density to the many-electron distributions of higher order (Sec. II B) and/or expressions for the cumulants of the reduced density-matrices. Both problems have been explored in many different contexts over a long period of time, and so a concise and selective survey of the literature is appropriate.

The first methods for constructing the *k*-density from the 2-density were in classical statistical mechanics, where both exact expressions[77–80] and accurate approximate representations[50,80–87] have been extensively explored. The possibility of extending the classical results to quantum mechanical systems was recognized by Abe in his 1959 paper,[78] with early published results from De Dominiciis and Martin.[88–92] Concurrently, researchers were developing sequential relations between the Green's functions in quantum physics and statistical mechanics.[93–95] Insofar as the density matrices can be regarded as initial values of the Green's functions, we recognize relationships between the first-order Green's function and the higher-order Green's functions have implications for constructing kinetic energy functionals using the approach of Secs. III D and III E [cf. Eqs. (45) and (47)]. The early work of Martin and Schwinger is directly relevant.[95] Bridging the gap between these two lines of research is the work of Lee and Yang, who showed how a system of fermions can be modeled as a collection of classical particles subject to additional one-body, two-body, …, and *N*-body potentials.[96] Motivated by the success of hierarchies of equations and diagrammatic expansion techniques for the closures thereof in simulations of classical systems, analogues to these results were derived for quantum systems. One may cite the work on the family of Fermi-hypernetted chain approximations[97–103] and the Chakravarty–Woo equations[104–107] as representative examples.

Foreshadowing the Hohenberg–Kohn theorem,[6] the preceding results are typically derived by using a Legendre transformation to change the variables of the system from the one- and two-body potentials to the one- and two-body distribution functions, density matrices, or Green's functions. Then, known expressions for the properties of a system in terms of the potentials were converted to expressions in terms of the appropriate distribution functions. Later researchers derived exact expressions for higher-order Green's functions in terms of the lower order Green's functions, proved the Legendre transform existed, and proved that the theoretical results can be derived without making unwarranted assumptions about the convergence of various perturbation series.[108–114]

These threads of research continue at present. For example, recent studies where electronic systems are treated as classical systems with an effective "Pauli repulsion potential"[51,103,115] and "classical temperature"[116,117] can be viewed as approximations to the Lee–Yang quantum-classical mapping. The contracted Schrödinger equation and the methods employed for constructing higher-order density matrices from their lower-order counterparts[64,118,119] recall the equation-of-motion method[95] and the similar closures used therein.

The relevance of this prior work to constructing approximations for the kinetic energy from the 2-density places computational techniques based on the 2-density into context, and allow us to draw on these related results in further development of this theory. In particular, developing accurate kinetic energy functionals of the *k*-density using the general techniques in Secs. III B and III D should be a relatively straightforward theoretical exercise. Finding functionals that are both accurate and computationally efficient, so that the resulting theory compares favorably to traditional ways of addressing electron correlation, is expected to be more difficult, and some suggestions along these lines follow.

B. The Hierarchy of Lee, Jackson, and Feenberg

Given a 2-density, $\rho_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)$, constructing an accurate kinetic energy functional using either the Weisacker-based functionals or the density-matrix based approach will often rely on expressing the *k*-density (with $k>2$) as a functional of the 2-density, so that higher-order kinetic energy

functionals like Eq. (25) or (46) can be used. This problem is similar to the problem of constructing closures in statistical mechanics. For example, one might employ the convolution approximation for the 3-density,

$$\rho_{3,\mathrm{conv}}^{\sigma_1\sigma_2\sigma_3}(\boldsymbol{r}_1,\boldsymbol{r}_2,\boldsymbol{r}_3) \equiv \rho_1^{\sigma_1}(\boldsymbol{r}_1)\rho_1^{\sigma_2}(\boldsymbol{r}_2)\rho_1^{\sigma_3}(\boldsymbol{r}_3)\left(\begin{array}{l} 1 + h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) + h^{\sigma_1\sigma_3}(\boldsymbol{r}_1,\boldsymbol{r}_3) + h^{\sigma_2\sigma_3}(\boldsymbol{r}_2,\boldsymbol{r}_3) \\ + h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)h^{\sigma_2\sigma_3}(\boldsymbol{r}_2,\boldsymbol{r}_3) + h^{\sigma_1\sigma_3}(\boldsymbol{r}_1,\boldsymbol{r}_3)h^{\sigma_3\sigma_2}(\boldsymbol{r}_3,\boldsymbol{r}_2) \\ + h^{\sigma_3\sigma_1}(\boldsymbol{r}_3,\boldsymbol{r}_1)h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) \\ + \int \rho^{\sigma'}(\boldsymbol{x}')h^{\sigma_1\sigma'}(\boldsymbol{r}_1,\boldsymbol{x}')h^{\sigma_2\sigma'}(\boldsymbol{r}_2,\boldsymbol{x}')h^{\sigma_3\sigma'}(\boldsymbol{r}_3,\boldsymbol{x}')\mathrm{d}\boldsymbol{x}' \end{array}\right) \tag{59}$$

or the superposition approximation,

$$\rho_{3,\mathrm{sup}}^{\sigma_1\sigma_2\sigma_3}(\boldsymbol{r}_1,\boldsymbol{r}_2,\boldsymbol{r}_3) \equiv \rho_1^{\sigma_1}(\boldsymbol{r}_1)\rho_1^{\sigma_2}(\boldsymbol{r}_2)\rho_1^{\sigma_3}(\boldsymbol{r}_3)\left(\begin{array}{l} 1 + h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) + h^{\sigma_1\sigma_3}(\boldsymbol{r}_1,\boldsymbol{r}_3) + h^{\sigma_2\sigma_3}(\boldsymbol{r}_2,\boldsymbol{r}_3) \\ + h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)h^{\sigma_2\sigma_3}(\boldsymbol{r}_2,\boldsymbol{r}_3) + h^{\sigma_1\sigma_3}(\boldsymbol{r}_1,\boldsymbol{r}_3)h^{\sigma_3\sigma_2}(\boldsymbol{r}_3,\boldsymbol{r}_2) \\ + h^{\sigma_3\sigma_1}(\boldsymbol{r}_3,\boldsymbol{r}_1)h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2) \\ + h^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)h^{\sigma_2\sigma_3}(\boldsymbol{r}_2,\boldsymbol{r}_3)h^{\sigma_3\sigma_1}(\boldsymbol{r}_3,\boldsymbol{r}_1) \end{array}\right). \tag{60}$$

As noted by Lee, Jackson, and Feenberg,[50] however, neither of these approximations is entirely satisfactory. In particular, the convolution approximation does not always satisfy the electron coalescence N-representability condition,

$$\rho_3^{\sigma_1,\sigma_2,\sigma_3}(\boldsymbol{r},\boldsymbol{r},\boldsymbol{r}) = 0. \tag{61}$$

The superposition approximation satisfies Eq. (61), but it does not generally satisfy the sequential relations,

$$\rho_{k-1}^{\sigma_1\sigma_2\cdots\sigma_{k-1}}(\boldsymbol{x}_1,\ldots,\boldsymbol{x}_{k-1}) = \left(\frac{1}{N_{\sigma_k} - m_{\sigma_k}}\right)\int \rho_k^{\sigma_1\sigma_2\cdots\sigma_k}(\boldsymbol{x}_1,\ldots,\boldsymbol{x}_k)\mathrm{d}\boldsymbol{x}_k \tag{62}$$

[m_{σ_k} was defined in Eq. (22)]. (The convolution approximation does satisfy the sequential relations.)[50] Unfortunately, the author knows of no closed form (series solutions are available[50,77,78,120]) that satisfies both the sequential relations and the electron coalescence criterion. Still, one might hope that the 3-densities constructed using the convolution approximation [Eq. (59)] or the superposition approximation [Eq. (60)] "inherit" near-N-representability from their underlying 2-density, so that kinetic energy formulas employing Eqs. (59) and (60) might, at least, provide some improvement over forms in which the 3-density was never constructed. It should be noted that higher-order convolution approximations[50] and superposition approximations[81] are available.

Without an acceptable closed form for the closure, one might explore the possibility of using a hierarchy of equations to determine $\rho_{k>2}^{\sigma_1\cdots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)$ from $\rho_2^{\sigma_1\sigma_2}(\boldsymbol{r}_1,\boldsymbol{r}_2)$. The following analysis adapts one hierarchy of this type, derived by Lee, Jackson, and Feenberg for quantum fluids in the absence of an external electrostatic potential,[50] to the electronic structure problem. From the Schrödinger equation for the ground state wave function, $\Psi(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)$,

$$0 = \Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)\left(\sum_{i=1}^{N} -\frac{\nabla_i^2}{2} + \sum_{i=1}^{N}\left(v(\boldsymbol{r}_i) + \sum_{j=i+1}^{N}\frac{1}{|\boldsymbol{r}_i - \boldsymbol{r}_j|}\right) - E_0\right)\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N), \tag{63}$$

where E_0 is the ground state energy. To express the ground state energy and the ground state wave function in terms of the k-densities, we start by writing Eq. (63) in terms of $|\Psi_0|^2$, using the identity [cf. Eq. (17)]

$$\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)\frac{\nabla_i^2}{2}\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N) \equiv \frac{\nabla_i^2}{8}(\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2 + (\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2\frac{\nabla_i^2}{8}\ln(\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2, \tag{64}$$

where it is assumed that the wave function is real. Substituting Eq. (64) into Eq. (63), one obtains

$$\sum_{i=1}^{N}\frac{\nabla_i^2}{8}(\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2 = (\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2 \times\sum_{i=1}^{N}\left(-\frac{\nabla_i^2}{8}\ln(\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2 + v(\boldsymbol{r}_i) + \sum_{j=i+1}^{N}\frac{1}{|\boldsymbol{r}_i-\boldsymbol{r}_j|} - E_0\right). \tag{65}$$

In order to eliminate the dependence on the energy and obtain a hierarchy reminiscent of those from the classical theory of fluids, we introduce a function reminiscent of the partition function,

$$Q(\beta) \equiv \langle\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)|e^{-\beta\mathcal{W}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)}|\Psi(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)\rangle, \tag{66}$$

where

$$\mathcal{W}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_n) \equiv \sum_{i=1}^{N}\left(-\frac{\nabla_i^2}{8}\ln(\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2 + v(\boldsymbol{r}_i) + \sum_{j=i+1}^{N}\frac{1}{|\boldsymbol{r}_i-\boldsymbol{r}_j|}\right). \tag{67}$$

Equation (65) can then be rewritten as

$$\sum_{i=1}^{N}\frac{\nabla_i^2}{8}(\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2 = \left.\frac{\partial}{\partial\beta}\left(\frac{(\Psi_0(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N))^2 e^{-\beta\mathcal{W}(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)}}{Q(\beta)}\right)\right|_{\beta=0}. \tag{68}$$

The kth order in the hierarchy is obtained by defining, in analogy to Eq. (8),

$$\rho_k^{\sigma_1\sigma_2\ldots\sigma_k}(\boldsymbol{x}_1,\boldsymbol{x}_2,\ldots,\boldsymbol{x}_k,\beta) = \frac{\left\langle\Psi\left|\left(\sum_{i_k\neq i_1,i_2,\ldots,i_{k-1}}^{N}\cdots\sum_{i_2\neq i_1}^{N}\sum_{i_1=1}^{N}\prod_{j=1}^{k}\delta_{s_{i_j},\sigma_j}\delta(\boldsymbol{r}_{i_j}-\boldsymbol{x}_j)\right)e^{-\beta\mathcal{W}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_N)}\right|\Psi\right\rangle}{Q(\beta)}. \tag{69}$$

Then, from Eq. (68)

$$\sum_{i=1}^{k}\frac{\nabla_i^2}{8}\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k,0) = \left.\frac{\partial\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{x}_1,\ldots,\boldsymbol{x}_k,\beta)}{\partial\beta}\right|_{\beta=0}, \tag{70}$$

where $\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k,0)$ is just the usual k-density, $\rho_k^{\sigma_1\ldots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)$. In deriving Eq. (70) it is helpful to remember that

$$0 = \int\frac{\nabla_i^2}{2}|\Psi(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)|^2\mathrm{d}\boldsymbol{r}_i = \lim_{r_i\to\infty}\int_0^{2\pi}\int_0^{\pi}(\nabla_i|\Psi(\boldsymbol{z}_1,\ldots,\boldsymbol{z}_N)|^2\cdot\hat{\boldsymbol{r}}_i)r_i^2\sin\theta_i\mathrm{d}\theta_i\mathrm{d}\phi_i; \tag{71}$$

the surface of integration is a sphere whose radius, r_i, tends to infinity.

The reason Eq. (70) constitutes a hierarchy of equations is because it is difficult to evaluate

$$\left.\frac{\partial \rho_k^{\sigma_1 \ldots \sigma_k}(\boldsymbol{r}_1, \ldots, \boldsymbol{r}_k, \beta)}{\partial \beta}\right|_{\beta=0}$$

directly from the definition Eq. (69). However, suppose one is given an expression for the k-density, $\rho_k^{\sigma_1 \ldots \sigma_k}(\boldsymbol{r}_1, \ldots, \boldsymbol{r}_k, \beta)$, in terms of the l-densities ($l<k$). Using the chain rule for functional derivatives, Eq. (70) yields

$$\begin{aligned}\sum_{i=1}^{k} \nabla_i^2 \rho_k^{\sigma_1 \ldots \sigma_k}(\boldsymbol{r}_1, \ldots, \boldsymbol{r}_k, 0) &= 8 \sum_{l=1}^{k-1} \int \int \int \left(\frac{\delta \rho_k^{\sigma_1 \ldots \sigma_k}(\boldsymbol{r}_1, \ldots, \boldsymbol{r}_k, \beta)}{\delta \rho_l^{s_1 \ldots s_l}(\boldsymbol{x}_1, \ldots, \boldsymbol{x}_l, \beta)} \times \left. \frac{\partial \rho_l^{s_1 \ldots s_l}(\boldsymbol{x}_1, \ldots, \boldsymbol{x}_l, \beta)}{\partial \beta} \right|_{\beta=0} \right) \mathrm{d}\boldsymbol{x}_1 \ldots \mathrm{d}\boldsymbol{x}_l \\ &= \sum_{l=1}^{k-1} \int \int \int \frac{\delta \rho_k^{\sigma_1 \ldots \sigma_k}(\boldsymbol{r}_1, \ldots, \boldsymbol{r}_k, \beta)}{\delta \rho_l^{s_1 \ldots s_l}(\boldsymbol{x}_1, \ldots, \boldsymbol{x}_l, \beta)} \left(\sum_{i=1}^{l} \nabla_i^2 \rho_l^{s_1 \ldots s_l}(\boldsymbol{r}_1, \ldots, \boldsymbol{r}_l, 0) \right) \mathrm{d}\boldsymbol{x}_1 \ldots \mathrm{d}\boldsymbol{x}_l. \end{aligned} \tag{72}$$

Equation (72) will not be satisfied by an inexact closure. However, if one proposes a general form of the closure, wherein the weight or functional form of various terms depends on some parameters, one may regard Eq. (72) as a nonlinear equation for those parameters, with the "optimal" choice of parameters being that which minimizes the residual error in Eq. (72).

The most important cases of Eq. (72) are probably the case where $k=2$,

$$(\nabla_1^2 + \nabla_2^2) \rho_2^{\sigma_1 \sigma_2}(\boldsymbol{r}_1, \boldsymbol{r}_2, 0) = \int \frac{\delta \rho_2^{\sigma_1 \sigma_2}(\boldsymbol{r}_1, \boldsymbol{r}_2, \beta)}{\delta \rho_1^{s}(\boldsymbol{x})} (\nabla_{\boldsymbol{x}}^2 \rho_1^{s}(\boldsymbol{x})) \mathrm{d}\boldsymbol{x} \tag{73}$$

(which might be useful for deriving hole-correlation functionals for use in density-functional theory) and $k=3$,

$$(\nabla_1^2 + \nabla_2^2 + \nabla_3^2) \rho_3^{\sigma_1 \sigma_2 \sigma_3}(\boldsymbol{r}_1, \boldsymbol{r}_2, \boldsymbol{r}_3, 0) = \int \frac{\delta \rho_3^{\sigma_1 \sigma_2 \sigma_3}(\boldsymbol{r}_1, \boldsymbol{r}_2, \boldsymbol{r}_3, \beta)}{\delta \rho_2^{s_1 s_2}(\boldsymbol{x}_1, \boldsymbol{x}_2, \beta)} [(\nabla_{\boldsymbol{x}_1}^2 + \nabla_{\boldsymbol{x}_2}^2) \rho_2^{s_1 s_2}(\boldsymbol{x}_1, \boldsymbol{x}_2)] \mathrm{d}\boldsymbol{x}_1 \mathrm{d}\boldsymbol{x}_2, \tag{74}$$

which is useful for approximating the 3-density in terms of the 2-density. One might, for example, seek to find the linear combination of the convolution and superposition approximations, Eqs. (59) and (60), which minimizes the residual error in Eq. (74).

V. DISCUSSION

A. Implications for computational methods based on the *k*-density

In combination with N-representability conditions on the k-density, the path to accurate kinetic energy functionals developed in this paper provides the basis for computational approaches to quantum chemistry using the k-density ($k \geqslant 2$). This approach, based on the minimization of the energy as a functional of the k-density subject to the constraints imposed by ensemble-N-representability, is sketched in Sec. I, with Eq. (5) encapsulating the essence of the approach for the case that is probably most important, with $k=2$. Such methods may be termed k-density-functional theory, and constitute a hierarchy of methods bridging the gap between the usual density-functional theory ($k=1$) and direct approaches to the Schrödinger equation ($k=N$). Just as Sham, Görling, Levy, Bartlett, and others have shown how the exact exchange-correlation density-functional can be constructed by adapting standard approaches to the quantum many-body problem,[113,114,121–124] the techniques in Secs. III and IV show how existing approaches to the quantum many-body problem can inform the construction of an accurate kinetic energy functional. The computational demands and accuracy of such approaches will necessarily resemble the many-body methods on which they are based, limiting the utility of such approaches. However, insights gleaned from these well-understood techniques can guide the development of more practical and efficient methods. In particular, just as a combination of physical insight and parameter-fitting has

rendered density-functional theory the method of choice for quantum mechanical simulations of large systems, one may expect physical insights from exact and systematic formulations of the kinetic-energy functionals, possibly coupled with limited fitting of parameters, to produce accurate kinetic-energy functionals of the *k*-density.

When one restricts oneself to the 2-density, there is the prospect of using one of the simpler kinetic-energy functionals presented in Secs. III C and III E. In this case, the resulting theory will be approximate, but as argued in those sections, there are reasons to believe the errors may be small. In addition, because the 2-density is a function of only two spatial coordinates, such methods should be competitive with methods based on the first-order density matrix and, implicitly, not much more expensive than Kohn–Sham density-functional theory,[125] which can also be considered a first-order density matrix method.

B. Implications for density-functional theory

One of the most important outstanding problems in density-functional theory is the lack of a satisfactory kinetic-energy density functional for atoms and molecules.[42] Present functionals give poor results when used for variational all-electron calculations on atoms and molecules, presumably because the *N*-representability constraints on the first-order density matrix implicit in such functionals are insufficient.[126,127] In addition, as first pointed out by Levy, Perdew, Parr, and Balduz, if the total energy functional employed in a calculation can be functionally differentiated, then the dissociation of molecules into fragments will be described incorrectly (since the number of electrons in the fragments will be noninteger).[128–131] The Kohn–Sham kinetic energy is similarly nondifferentiable,[132] but present orbital-free approximations to the Kohn–Sham kinetic-energy violate this constraint.

All these issues are surmounted in the Kohn–Sham implementation of density-functional theory: by using the kinetic energy of the Kohn–Sham reference system of noninteracting fermions, $T_s[\rho]$, the *N*-representability constraints and derivative discontinuity are largely accounted for, with residual errors confined to the small correlation-kinetic energy correction, $T_c[\rho] \equiv T[\rho] - T_s[\rho]$.[125] The computational cost of this ansatz is the self-consistent determination of the first-order density matrix for the Kohn–Sham reference system, which renders Kohn–Sham calculations much more costly than calculations based on orbital-free functionals for the kinetic energy. From this perspective, one can consider the Kohn–Sham kinetic energy to be a composite functional of the electron density: the Kohn–Sham kinetic energy is an explicit functional of the Kohn–Sham orbitals (or Kohn–Sham density matrix), which is determined implicitly from the electron density via the Kohn–Sham equations.

The development in Sec. III shows that the kinetic energy is readily approximated from the 2-density. Hence, by formulating an approach whereby the 2-density is generated from the electron density, one could construct kinetic energy functionals using the 2-density as an "auxiliary functional" of the electron density. An added benefit of this approach is that the unknown, but less problematic, electron–electron repulsion energy density functional is supplanted by the exact expression, Eq. (3). That is, by using the 2-density as an intermediary between the electron density and the kinetic-energy and electron–electron repulsion energy, one can avoid the ubiquitous Kohn–Sham reference system, leading to an entirely new perspective on practical methods for density-functional theory computation. Insofar as the March–Santamaria form for the kinetic energy, Eq. (56), is exact for the noninteracting reference system, even the simplest kinetic-energy functionals of the 2-density may be expected to give accuracy approaching that of conventional Kohn–Sham DFT.

The outstanding problem is that the 2-density must be expressed as functional of the 1-density. Such a pursuit can be guided by the Lee–Jackson–Feenberg hierarchy, cf. Eq. (73). The author's work along these lines will be communicated separately.

C. Summary

In constructing an approach to quantum chemistry based on the k-density, there are two main requirements. First of all, one must know the ensemble-N-representability constraints on the k-density, $\rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k)$. With these constraints either known or effectively approximated, one can minimize an energy functional of the k density over the set of ensemble-representable k-densities, and obtain

$$E_v^{\mathrm{gs}} = \min_{\rho_k^{\sigma_1\cdots\sigma_k}\in\mathcal{N}} [T[\rho_k^{\sigma_1\cdots\sigma_k}] + V_{ee}[\rho_k^{\sigma_1\cdots\sigma_k}] + V_{ne}[\rho_k^{\sigma_1\cdots\sigma_k},v]],$$
$$\rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{r}_1,\ldots,\boldsymbol{r}_k) = \arg\min_{\rho_k^{\sigma_1\cdots\sigma_k}\in\mathcal{N}}[T[\rho_k^{\sigma_1\cdots\sigma_k}] + V_{ee}[\rho_k^{\sigma_1\cdots\sigma_k}] + V_{ne}[\rho_k^{\sigma_1\cdots\sigma_k},v]], \tag{75}$$

where the notation has the same meaning as that in Eq. (5). In order to use Eq. (75), one has to express the kinetic energy as a functional of the k-density. In Sec. II, exact approaches based on the Levy–Valone constrained search [Eq. (9)] and Lieb's generalized Legendre transform [Eq. (10)] are presented. While these do not represent practical approaches to the kinetic energy functional, they do set the standard by which all approximate functionals must be judged, and can be used to establish analytic constraints on the properties of the exact functional.

Unlike exact approaches based on the constrained-search or Legendre-transform, the emphasis in Sec. III is on controlled and systematic approximations to the kinetic energy functionals. Section III B develops a series of lower bounds on the kinetic energy of pure states; these are essentially generalizations of the Weisacker functional for density-functional theory. Section III C applies this analysis to the 2-density, deriving the simple working formula, Eq. (41), which is a lower bound to the true kinetic energy. The leading order correction to Eq. (41), involves three-electron correlations; these terms could be considered analogous to triple-excitations in conventional multi-configuration approaches to the electron correlation problem, and might be suspected to be negligible except when three or more electrons are close together. For this reason, we may hope that Eq. (41) is a reasonably tight lower bound to the true kinetic energy.

Section III D uses the technique of density-matrix reconstruction to construct a different kinetic energy functional—one that is often an upper bound. Section III E uses this technique to derive a simple kinetic energy functional of the 2-density, Eq. (56). Equation (56) is exact for a system of noninteracting electrons. Because the correction to the noninteracting kinetic energy (often called the correlation-kinetic energy and denoted $T_c[\rho]$) is small and readily approximated using density-functionals, we suspect that Eq. (56) can be used as the basis for practical computational methods based on the 2-density.

The easiest way to improve these functionals for the kinetic energy in terms of the k-density is to introduce information about l-electron correlations, which can be done by constructing $\rho_{l>k}^{\sigma_1\cdots\sigma_l}(\boldsymbol{x}_1\ldots\boldsymbol{x}_l)$ as a functional of $\rho_k^{\sigma_1\cdots\sigma_k}(\boldsymbol{x}_1\ldots\boldsymbol{x}_k)$. Techniques for this reconstruction are analogous to methods used in wave-function-based quantum chemistry and statistical mechanics, and are reviewed in Sec. IV A. Section IV B discusses the possibility of constructing the l-density using approximate closures and hierarchies of equations. Together with the results from Secs. III B and III D, this leads to families of systematically improvable kinetic energy functionals, so that one can construct a kinetic energy functional of any desired accuracy. At present, it is unclear whether the reconstruction of higher-order electron densities is preferable to a direct treatment using the higher-order densities; this, as well as computational implementation of the ideas contained herein, is a topic for further research.

ACKNOWLEDGMENTS

Helpful discussions with Julius Lucks (Harvard University) and Professor Mel Levy (North Carolina A&T University) are acknowledged. Funding was provided by McMaster University, the National Sciences and Engineering Research Council of Canada, and the Canada Research Chairs.

Some of the results were first presented in the author's Ph.D. proposal of November, 1998, which was prepared under the tutelage of Professor Robert G. Parr (University of North Carolina at Chapel Hill). His guidance is gratefully acknowledged. Most of the results on kinetic energy functionals and the bounds thereto were presented at the conference "Computer modeling of atoms, molecules and materials using approximate functionals of the kinetic energy" held at the Centre Européen de Calcul Atomique et Moléculaire in July 2002.

APPENDIX: DERIVATION OF EQ. (19)

Suppose that $n_N^{(N)}$ is not pure-state N-representable, but can be represented in terms of an ensemble with only two components,

$$n_N^{(N)}(\mathbf{z}_1, \ldots, \mathbf{z}_N) \equiv w_1(\Psi_1(\mathbf{z}_1, \ldots, \mathbf{z}_N))^2 + w_2(\Psi_2(\mathbf{z}_1, \ldots, \mathbf{z}_N))^2. \tag{A1}$$

(For ensembles with more than two components, the argument proceeds by induction from the two-component case.) In this case, the exact kinetic energy can be written as

$$\begin{aligned} T_{\text{exact}}[n_N^{(N)}] &\equiv \frac{1}{2}\langle \nabla \sqrt{w_1(\Psi_1)^2} \cdot \nabla \sqrt{w_1(\Psi_1)^2} \rangle + \frac{1}{2}\langle \nabla \sqrt{w_2(\Psi_2)^2} \cdot \nabla \sqrt{w_2(\Psi_2)^2} \rangle \\ &\geqslant T_w^{(N)}[\rho_N^{\sigma_1 \ldots \sigma_N}] \equiv \frac{1}{2}\langle \nabla \sqrt{n_N^{(N)}} \cdot \nabla \sqrt{n_N^{(N)}} \rangle. \end{aligned} \tag{A2}$$

In Eq. (A2), the gradient is evaluated in $3N$-dimensions. The inequality on the second line of Eq. (A2) is the statement we wish to prove.

To derive Eq. (A2), merely note that

$$\begin{aligned} &\frac{1}{2}\langle \nabla \sqrt{f} \cdot \nabla \sqrt{f} \rangle + \frac{1}{2}\langle \nabla \sqrt{g} \cdot \nabla \sqrt{g} \rangle - \frac{1}{2}\langle \nabla \sqrt{f+g} \cdot \nabla \sqrt{f+g} \rangle \\ &= \left\langle \frac{\nabla f \cdot \nabla f}{8f} \right\rangle + \left\langle \frac{\nabla g \cdot \nabla g}{8g} \right\rangle - \left\langle \frac{\nabla (f+g) \cdot \nabla (f+g)}{8(f+g)} \right\rangle \\ &= \left\langle g^2 \frac{\nabla f \cdot \nabla f}{8fg(f+g)} \right\rangle + \left\langle f^2 \frac{\nabla g \cdot \nabla g}{8fg(f+g)} \right\rangle - 2\left\langle fg \frac{\nabla (f+g) \cdot \nabla (f+g)}{8fg(f+g)} \right\rangle \\ &= \left\langle \frac{g^4}{8fg(f+g)} \nabla \left(\frac{f}{g}\right) \cdot \nabla \left(\frac{f}{g}\right) \right\rangle \geqslant 0 \end{aligned} \tag{A3}$$

Identifying $f = w_1(\Psi_1)^2$ and $g = w_2(\Psi_2)^2$, Eq. (A2) immediately follows. Excepting the trivial cases where (a) w_1 or w_2 is zero or (b) $(\Psi_1)^2 = (\Psi_2)^2$, the inequality is strict—the kinetic energy is strictly larger than the N-electron Weisacker approximation, $T_w^{(N)}[\rho_N^{\sigma_1 \ldots \sigma_N}]$.

We solve the Schrödinger equation for a quark–antiquark system interacting via a Coulomb-plus-linear potential, and obtain the wave functions as power series, with their coefficients given in terms of the combinatorics functions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1931041]

I. INTRODUCTION

The Coulomb-plus-linear potential, $V(r)=-a/r+br$, also known as the Cornell potential, has received a great deal of attention both in particle physics, more precisely in the context of meson spectroscopy where it is used to describe systems of quark and antiquark bound states, and in atomic and molecular physics where it represents a radial Stark effect in hydrogen.

The Coulomb-plus-linear potential was used with considerable success in models describing systems of bound heavy quarks.[1–5] It was introduced as a mathematically simple potential incorporating characteristics of interquark interactions and accounting for the features of the spectrum of charmed quark–antiquark bound states. The potential includes the short distance Coulombic interaction of quarks, known from perturbative quantum chromodynamics (QCD), and the large distance quark confinement, known from lattice QCD, via the linear term in a simple form. It is also in good agreement with the central part of the static heavy quark potential derived from dual QCD (Ref. 6) and from lattice QCD.[7,8]

Solutions of the Schrödinger equation for the Coulomb-plus-linear potential have been investigated with a large number of techniques and also as a special case of the generalized Killingbeck potential, $V(r)=-a/r+br+cr^2$.

In the context of perturbation theory, Mehta and Patil[9] showed that the eigenvalues of the Coulomb-plus-linear potential have an asymptotic perturbation series in the linear coupling parameter b. Killingbeck[10] showed how the hypervirial theorem could be used to calculate the perturbation series for the energy of spherically symmetric ($l=0$) states without calculation of the perturbed wave functions. Padé approximants to the divergent energy series were used to obtain the eigenvalues. Austin[11] extended the calculation of the perturbation series to higher order and to a broader range of values of the perturbation parameter. Using the same technique, Lai and Lin[12] obtained the eigenvalues for different values of the orbital angular momentum quantum number.

In the framework of the WKB approximation, Seetharaman *et al.*[13] obtained a nonperturbative approximate analytic expression for the energy in terms of complete elliptic integrals. Thidé and Linnaeus[14] and Brau[15] also obtained approximate analytical results for the eigenvalues using, respectively, higher-order phase integral quantization and Bohr–Sommerfeld quantization.

Chhajlany and Letov[16] obtained exact results for the Coulomb-plus-linear potential for specific values of the coupling parameters following a technique used by Saxena and Varma[17] to find exact solutions for the problem of a Coulomb potential with a polynomial radial perturbation $2\lambda r+2\lambda^2 r^2$. The technique works by searching a solution in the form of a product of an interpolating function and two functions with the correct endpoint behavior. If the coefficients of the power series of the interpolating function are related by a Nth order recursion relation, then the

eigenvalues are obtained by requiring that the interpolating function be a polynomial of degree n, i.e., by explicitly setting N successive coefficients of its power series to zero. This arbitrary condition also results in the quantization of some of the coupling parameters of the potential. The eigenvalues found converge to the true eigenvalues as the degree of the polynomial goes to infinity.

In Ref. 16, this technique is applied to the case of a Coulomb potential with a radial perturbation $\mu r+\alpha^2 r^2$. The requirement that the solution be polynomial leads to the quantization of the quadratic coupling α which now depends on the linear coupling μ and on the orbital angular momentum quantum number. The eigenvalues of the Coulomb-plus-linear potential are recovered because α goes to zero as the degree of the polynomial goes to infinity, letting the generalized Killingbeck potential go to the desired potential.

Solutions for the Coulomb-plus-linear potential have also been investigated using the Hill determinant method by Chaudhuri *et al.*[18] where the eigenvalues are obtained as the zeros of an infinite dimensional determinant associated with the infinite system of linear equations relating the coefficients of the power series of the solution.

Fulcher *et al.*[19] showed that analytic expressions for the eigenvalues of the low-lying states can be obtained by expanding the radial part of the wave function in a basis of functions given by the product of a centrifugal barrier, an exponential function, and a Laguerre polynomial. Their approach transforms the problem of the Schrödinger equation for the Coulomb-plus-linear potential to a matrix diagonalization problem where the matrix elements are given by analytic expressions. The eigenvalues of the matrix converge to the true eigenvalues when the size of the basis becomes sufficiently large.

The solutions of the Schrödinger equation for a central polynomial type potential $V(r)=\Sigma_{i=1}^{I} a_i r^{\nu_i}$ with $\nu_i \geqslant -1$ can be written as the product of a spherical harmonic, a centrifugal barrier r^l, a decreasing exponential function and an unknown function $\eta(r)$ that admits a power series expansion. The factor r^l dominates near the origin, the exponential factor is the function with the correct asymptotic behavior and $\eta(r)$ is the solution that dominates at intermediate distances. Explicit solutions in terms of special functions exist in only two special cases of the potential, $\nu_1=-1$ and $\nu_1=2$ both with $I=1$. This is due to the fact that, only in these two cases, are the expansion coefficients of the function $\eta(r)$ related by a two-term recursion relation. In all other cases they are related by a three- or more-term recursion relation.

The usual method used to solve multiterm linear recursion relations with nonconstant coefficients is to compute the first terms of the series, guess the general solution and prove it by mathematical induction. While this is easily achieved for two term recursion relations, it is almost impossible for recursion relations with three or more terms. Antippa and Phares developed a general formalism for solving linear multiterm recursion relations with nonconstant coefficients[20] in terms of algebraic combinatorial expressions called combinatorics functions. The first application of this formalism to the solution of the Schrödinger equation with polynomial type central potentials was to the case of the linear potential.[21,22] The wave functions were obtained as power series expansions with their coefficients given in terms of functionals called structure functions, a special kind of combinatorics function. The energy eigenvalue equation was obtained by requiring that the asymptotic behavior of the wave function be that of the asymptotic solution of the Schrödinger equation for the linear potential. The eigenvalues were given by the roots of an infinite order polynomial.

The series solution of the Schrödinger equation for the Coulomb-plus-linear potential leads to a four-term recursion relation with nonconstant coefficients. The same method used to solve the Schrödinger equation for the linear potential can be used to obtain a solution for the Coulomb-plus-linear potential. The purpose of this paper is to obtain an analytic expression for the nonrelativistic Schrödinger wave functions of the Coulomb-plus-linear potential.

The organization of the paper is as follows: in Sec. II we set up the problem and obtain the coefficients of the power series expansion of the wave functions in terms of structure functions, in

Sec. III we derive recursion relations for the structure functions and in Sec. IV we present the general expression for the wave functions of the Coulomb-plus-linear potential and give explicit expressions for the first six coefficients of the power series.

II. RADIAL EQUATION

A. Dimensionless radial equation

Consider a quark-antiquark system interacting via a Coulomb-plus-linear potential,

$$V(r) = V_0 + \kappa r - \frac{\alpha}{r}. \tag{1}$$

Since the potential has spherical symmetry, then the solutions of the time-independent Schrödinger equation are of the form

$$\psi_{nlm}(\vec{r}) = R_{nl}(r)Y_l^m(\theta,\phi), \tag{2}$$

where $R_{nl}(r)=u_{nl}(r)/r$, and $u_{nl}(r)$ is a solution of the radial Schrödinger equation,

$$\left[-\frac{\hbar^2}{2\mu}\frac{d^2}{\mathrm{d}r^2} + \frac{l(l+1)\hbar^2}{2\mu r^2} + V(r)\right]u_{nl}(r) = E_{nl}u_{nl}(r). \tag{3}$$

Inserting the expression for the potential as given by Eq. (1), into Eq. (3), leads to

$$\left[-\frac{\hbar^2}{2\mu}\frac{d^2}{\mathrm{d}r^2} + \frac{l(l+1)\hbar^2}{2\mu r^2} + V_0 + \kappa r - \frac{\alpha}{r}\right]u_{nl}(r) = E_{nl}u_{nl}(r). \tag{4}$$

Applying the scale transformation $x=ar$ to the above equation, and dividing through by $-\hbar^2a^2/2\mu$, leads further to

$$\left[\frac{d^2}{\mathrm{d}x^2} - \frac{l(l+1)}{x^2} - \frac{2\mu\kappa x}{\hbar^2a^3} + \frac{2\mu\alpha}{\hbar^2 ax} + \frac{2\mu}{\hbar^2a^2}(E_{nl}-V_0)\right]u_{nl}(x) = 0. \tag{5}$$

Setting the parameter a to

$$a = \left(\frac{2\mu\kappa}{\hbar^2}\right)^{1/3} \tag{6}$$

gives it the dimensions of inverse length, and consequently x becomes dimensionless. Substituting the above expression for a, into Eq. (5) reduces this latter to

$$\left[\frac{d^2}{\mathrm{d}x^2} - \frac{l(l+1)}{x^2} - x + \frac{1}{x}\left(\frac{4\mu^2\alpha^3}{\hbar^4\kappa}\right)^{1/3} + \left(\frac{\sqrt{2\mu}}{\hbar\kappa}\right)^{2/3}(E_{nl}-V_0)\right]u_{nl}(x) = 0. \tag{7}$$

By defining the dimensionless coupling constant ρ and the dimensionless energy parameter t_{nl}, respectively, by

$$\rho = \left(\frac{4\mu^2}{\hbar^4\kappa}\right)^{1/3}\alpha \tag{8}$$

and

$$t_{nl} = \left(\frac{2\mu}{\hbar^2\kappa^2}\right)^{1/3}(E_{nl}-V_0) \tag{9}$$

we finally obtain the radial Schrödinger equation in terms of dimensionless parameters, as

$$\left[\frac{d^2}{dx^2} - \frac{l(l+1)}{x^2} - x + \frac{\rho}{x} + t_{nl}\right] u_{nl}(x) = 0. \tag{10}$$

Solving the Schrödinger Eq. (1), for the Coulomb-plus-linear potential, has thus been reduced to solving the radial equation (10), for the functions $u_{nl}(x)$.

B. Series solutions for $u_{nl}(x)$

Equation (10) has the generic form

$$\frac{d^2u_{nl}}{dx^2} + p(x)\frac{du_{nl}}{dx} + q(x)u_{nl} = 0 \tag{11}$$

with

$$p(x) = 0, \tag{12}$$

$$q(x) = -\frac{l(l+1)}{x^2} - x + \frac{\rho}{x} + t_{nl}. \tag{13}$$

Since $xp(x)$ and $x^2q(x)$ are entire functions, then Eq. (10) has a series solution with an infinite radius of convergence, of the form[23]

$$v_{nl}(x,s) = \sum_{i=0}^{\infty} a_i(s)x^{i+s} \tag{14}$$

with the coefficients $a_i(s)$ given by the recursion relation

$$F(s+i)a_i(s) + \sum_{j=0}^{i-1}[(j+s)p_{i-j} + q_{i-j}]a_j(s) = 0, \tag{15}$$

where $F(s)$ is defined by

$$F(s) = s(s-1) + p_0 s + q_0 \tag{16}$$

and p_k and q_k are the coefficients of the power series expansions of $xp(x)$ and $x^2q(x)$, respectively. That is

$$p_k = \frac{1}{k!}\left.\frac{d^k(xp(x))}{dx^k}\right|_{x=0}, \tag{17}$$

$$q_k = \frac{1}{k!}\left.\frac{d^k(x^2q(x))}{dx^k}\right|_{x=0}. \tag{18}$$

Independent solutions of Eq. (11) are obtained, via Eq. (14), by setting the value of s equal to the roots

$$s_{\pm} = \frac{(1-p_0) \pm \sqrt{(1-p_0)^2 - 4q_0}}{2} \tag{19}$$

of the indicial equation

$$F(s) = 0. \tag{20}$$

From Eqs. (12) and (13) we see that in the case of the second order differential equation (11), $p_k=0$ for $k=0,1,2,\ldots,\infty$ and $q_k=0$ for $k=4,5,6,\ldots,\infty$, while the nonzero values of q_k are

$$q_0 = -l(l+1), \quad q_1 = \rho, \quad q_2 = t_{nl}, \quad q_3 = -1. \tag{21}$$

Consequently, the recursion relation (15) reduces to

$$F(s+i)a_i(s) + \rho a_{i-1}(s) + t_{nl}a_{i-2}(s) - a_{i-3}(s) = 0 \tag{22}$$

with $a_i = 0$ for $i < 0$. The function $F(s)$ as given by Eq. (16) takes the special form

$$F(s) = s(s-1) - l(l+1). \tag{23}$$

The roots, as given by Eq. (19), of the indicial equation (20), reduce to the simple form

$$s_+ = l+1 \quad \text{and } s_- = -l. \tag{24}$$

When the above values for the indices are used with Eq. (23), they lead, respectively, to

$$F(s_+ + i) = i(i+2l+1) \tag{25}$$

and

$$F(s_- + i) = i(i-2l-1). \tag{26}$$

Since the roots of the indicial equation differ by an integer then the general solution of Eq. (11) is given by[23]

$$h_{nl}(x) = Au_{nl}(x) + Bw_{nl}(x), \tag{27}$$

where

$$u_{nl}(x) = v_{nl}(x, s_+) = x^{l+1}\sum_{m=0}^{\infty} b_m x^m, \quad b_m = a_m(s)\big|_{s=l+1} \tag{28}$$

and

$$w_{nl}(x) = u_{nl}(x)\ln x + v_{nl}(x, s_-) = x^{l+1}\ln x \sum_{m=0}^{\infty} b_m x^m + x^{-l}\sum_{m=0}^{\infty} c_m x^m, \quad c_m = a_m(s)\big|_{s=-l}. \tag{29}$$

For $R_{nl}(r)$ to be regular at the origin, $h_{nl}(x)/x$ must be regular at the origin. At threshold $u_{nl}(x)/x \sim_{x\to 0} x^l$ and is regular for all non-negative values of l. On the other hand, the first term in $w_{nl}(x)/x$ has a threshold behavior $[w_{nl}(x)]_1/x \sim_{x\to 0} x^l \ln x$ and has a logarithmic singularity at the origin, while the second term of $w_{nl}(x)/x$ has a threshold behavior $[w_{nl}(x)]_2/x \sim_{x\to 0} x^{-l-1}$, and has an $l+1$ order pole at the origin for all non-negative values of l. Consequently, the regularity of $R_{nl}(r)$ at the origin requires setting $B=0$, and the solution of Eq. (11) with the boundary conditions imposed is $Au_{nl}(x)$. Since the recursion relation does not determine b_0, then the coefficient A can be absorbed in b_0. Hence the solution of Eq. (11) which is regular at the origin is given by

$$u_{nl}(x) = x^{l+1}\sum_{m=0}^{\infty} b_m x^m \tag{30}$$

with the coefficients $b_m = a_m(s_+)$ determined by the recursion relation (22) with $s = s_+$. Combining Eqs. (22) and (25) we obtain the recursion relation for b_m as

$$m(m+2l+1)b_m + \rho b_{m-1} + t_{nl}b_{m-2} - b_{m-3} = 0 \quad m = 0,1,2,\ldots,\infty \tag{31}$$

subject to the boundary conditions $b_m = \lambda_0 \delta_{m0}$ for $m \leqslant 0$. Hence, the solution of the radial equation (10) for the function $u_{nl}(x)$ has been reduced to the solution of the recursion relation (31) for the coefficients b_m.

C. Solution of the recursion relation

We define the function $f(m,l)$ by

$$f(m,l) = \frac{1}{F(s_+ + m)} = \frac{1}{m(m+2l+1)} \tag{32}$$

so that the above recursion relation can be rewritten as

$$b_m = -\rho f(m,l) b_{m-1} - t_{nl} f(m,l) b_{m-2} + f(m,l) b_{m-3}. \tag{33}$$

Furthermore, we define

$$f_1(m) = -\rho f(m,l), \quad f_2(m) = -t_{nl} f(m,l), \quad f_3(m) = f(m,l) \tag{34}$$

to obtain

$$b_m = f_1(m) b_{m-1} + f_2(m) b_{m-2} + f_3(m) b_{m-3}, \quad m = 0,1,2,\ldots,\infty \tag{35}$$

subject to the boundary conditions

$$b_m = \lambda_0 \delta_{m0} \quad \text{for } m \leqslant 0. \tag{36}$$

The recursion relation (35), subject to boundary conditions (36), is cast in standard form.[20]

Equation (35) is a four-term linear recursion relation with variable coefficients. A solution of this equation in terms of the special combinatorics functions can be obtained using the method introduced by Antippa *et al.*[20] The solution of a linear recursion relation of the form

$$b_m = \sum_{k=1}^{N} f_{a_k}(m) b_{m-a_k} \quad \text{for } m > j_0 \tag{37}$$

with boundary conditions

$$b_{j_0 - i} = \lambda_i \quad \text{for } i = 0,1,2,\ldots,a_N - 1, \tag{38}$$

is[20]

$$b_m = \sum_{i=0}^{a_N - 1} \lambda_i \overline{C}_2(j_0 - i, m, i), \tag{39}$$

where $\overline{C}_2(m_1,m_2,d)$ is a constrained combinatorics function of the second kind. The solution of the recursion relation (35) has thus been reduced to the evaluation of the combinatorics function $\overline{C}_2(j_0 - i, m, i)$.

D. The combinatorics functions

The constrained combinatorics function of the second kind $\overline{C}_2(m_1,m_2,d)$ is a discrete functional defined over the ordered partitions of the interval $[m_1,m_2]$ with the first part of the ordered partition constrained to be of length greater than d. The parts a_i available for partitioning, are the elements of a set $\mathcal{A}$,

$$\mathcal{A} = \{a_1, a_2, \ldots, a_N\}, \quad 0 < a_1 < a_2 < \cdots < a_N. \tag{40}$$

The subintervals of an ordered partition are denoted by δ_j, and a possible ordered partition is represented by $(\delta_1, \delta_2, \ldots, \delta_n)$, where $\delta_j \in \mathcal{A}$. The points at which subintervals end are denoted by s_j,

$$s_0 = m_1, \quad s_j = m_1 + \sum_{i=1}^{j} \delta_i, \quad s_n = m_2. \tag{41}$$

The building blocks from which the combinatorics functions are constructed are the functionals $F_n^q(m_1, m_2)$ defined over the qth ordered partition of the interval $[m_1, m_2]$ into n parts belonging to the set $\mathcal{A}$, according to[20]

$$F_n^q(m_1, m_2) = \prod_{j=1}^{n} f_{\delta_j}(s_j). \tag{42}$$

The special combinatorics functions of the first kind, $C_1(m_1, m_2, n)$, are obtained by summing the $F_n^q(m_1, m_2)$ over the ordered partitions of the interval $[m_1, m_2]$ into n parts,

$$C_1(m_1, m_2, n) = \sum_{q=1}^{q_{\max}(m_1, m_2, n)} F_n^q(m_1, m_2). \tag{43}$$

The special combinatorics functions of the second kind are obtained by summing the special combinatorics functions of the first kind over the possible values of n,

$$C_2(m_1, m_2) = \sum_{n \in \mathcal{N}(m_2 - m_1)} C_1(m_1, m_2, n), \tag{44}$$

where the set $\mathcal{N}(m_2 - m_1)$ is the set of all the number of parts n into which an interval of length $m_2 - m_1$ can be partitioned. The special combinatorics functions of the second kind can thus be expressed as the sum of the $F_n^r(m_1, m_2)$ over all ordered partitions of the interval $[m_1, m_2]$,

$$C_2(m_1, m_2) = \sum_{r=1}^{r_{\max}(m_1, m_2)} F_{n(r)}^r(m_1, m_2), \tag{45}$$

where the number of parts $n(r)$ is now a function of the partition number r. The constrained combinatorics functions of the second kind are related to the special combinatorics functions of the second kind by[24]

$$\overline{C_2}(m_1, m_2, d) = \sum_{\substack{a_k \in \mathcal{A} \\ a_k > d}} f_{a_k}(m_1 + a_k) C_2(m_1 + a_k, m_2). \tag{46}$$

In the special case of $d = 0$, the above equation reduces to

$$\overline{C_2}(m_1, m_2, 0) = \sum_{a_k \in \mathcal{A}} f_{a_k}(m_1 + a_k) C_2(m_1 + a_k, m_2) \tag{47}$$

but the special combinatorics functions obey the recursion relation[25]

$$C_2(m_1, m_2) = \sum_{a_k \in \mathcal{A}} f_{a_k}(m_1 + a_k) C_2(m_1 + a_k, m_2). \tag{48}$$

Hence combining (47) and (48),

$$\overline{C_2}(m_1, m_2, 0) = C_2(m_1, m_2). \tag{49}$$

Note that Eq. (49) is also a coherence condition which can be derived directly from the respective definitions of the special and constrained combinatorics functions of the second kind.

E. Reduction of the combinatorics functions

In the case of Eq. (35), the set $\mathcal{A}$ of allowed parts is given by (see Ref. 20)

$$\mathcal{A} = \{1,2,3\}. \tag{50}$$

Thus $N=3$, $a_1=1$, $a_2=2$, and $a_3=3$. Furthermore, the boundary conditions are given by

$$b_m = \lambda_0 \delta_{m0} \quad \text{for } m \leqslant 0 \tag{51}$$

thus $j_0=0$. Hence, in the case of Eq. (35) subject to boundary conditions (36), the solution for b_m as given by Eq. (39) reduces to

$$b_m = \sum_{i=0}^{2} b_{-i}\overline{C}_2(-i,m,i) = \sum_{i=0}^{2} \lambda_0 \delta_{-i0}\overline{C}_2(-i,m,i) = \lambda_0 \overline{C}_2(0,m,0) \tag{52}$$

and using Eq. (49),

$$b_m = \lambda_0 C_2(0,m). \tag{53}$$

The special combinatorics functions of the second kind $C_2(0,m)$ are given, via Eq. (45), in terms of the functionals $F^r_{n(r)}(m_1,m_2)$. So we need to evaluate these latter functionals.

We define the triplet (p_1,p_2,p_3) representing the number of parts of lengths (1, 2, 3) for a possible ordered partition r of an interval $[0,m]$ into n parts, where p_i is the number of parts of length i. Examining Eq. (34) we notice that the $f_{\delta_j}(s_j)$ are equal to a constant times $f(m,l)$. The number of times these constants will appear in expression (42) as multiplicative factors is related to the number of parts of length 1 for $-\rho$, the number of parts of length 2 for $-t_{nl}$ and the number of parts of length 3 for 1. In order to simplify the notation, we will, from now on, drop the subscripts n and l on t. The $F^r_{n(r)}(0,m)$ can therefore be expressed as

$$F^r_{n(r)}(0,m) = (-\rho)^{p_1}(-t)^{p_2}\prod_{j=1}^{n(r)} f(s_j,l), \tag{54}$$

while the special combinatorics functions of the second kind become[26]

$$C_2(0,m) = \sum_{r=1}^{r_{\max}(0,m)} (-\rho)^{p_1}(-t)^{p_2}\prod_{j=1}^{n(r)} f(s_j,l) \tag{55}$$

leading, via Eq. (53), to the following expression for b_m:

$$b_m = \lambda_0 \sum_{r=1}^{r_{\max}(0,m)} (-\rho)^{p_1}(-t)^{p_2}\prod_{j=1}^{n(r)} f(s_j,l), \tag{56}$$

where s_j is given by Eq. (41), and $f(s_j,l)$ is given, via Eq. (32) as

$$f(s_j,l) = \frac{1}{s_j(s_j+2l+1)}. \tag{57}$$

Evaluating the product over $f(s_j,l)$ in Eq. (56) is an algebraic combinatorial ordered partitioning problem, and so is the sum over r.

F. Partitions

A partition $p(m,n)=1^{p_1}2^{p_2}3^{p_3}$ of an interval of length m into n parts belonging to the set {1, 2, 3} is subject to the constraints

$$p_1 + p_2 + p_3 = n, \tag{58a}$$

TABLE I. Relations between m, n, p_1, p_2, and p_3.

λ	1	2	3
$\Sigma_{i=1}^{3}(\lambda-i)p_i=\lambda n-m$	$p_2+2p_3=m-n$	$p_3-p_1=m-2n$	$2p_1+p_2=3n-m$
$n=\lambda^{-1}(m+\Sigma_{i=1}^{3}(\lambda-i)p_i)$	$n=m-p_2-2p_3$	$n=\lfloor(m+p_1-p_3)/2\rfloor$	$n=\lfloor(m+2p_1+p_2)/3\rfloor$
$m=\lambda n-\Sigma_{i=1}^{3}(\lambda-i)p_i$	$m=n+p_2+2p_3$	$m=2n+p_3-p_1$	$m=3n-2p_1-p_2$
$(\lambda-j)\,p_j\vert_{j=(\lambda+1)\bmod 3}=\lambda n-m-(\lambda-j)\,p_j\vert_{j=(\lambda+2)\bmod 3}$	$p_2=m-n-2p_3$	$p_3=m-2n+p_1$	$p_1=\lfloor(3n-m-p_2)/2\rfloor$
$(\lambda-j)\,p_j\vert_{j=(\lambda+2)\bmod 3}=\lambda n-m-(\lambda-j)\,p_j\vert_{j=(\lambda+1)\bmod 3}$	$p_3=\lfloor(m-n-p_2)/2\rfloor$	$p_1=2n-m+p_3$	$p_2=3n-m-2p_1$

$$p_1 + 2p_2 + 3p_3 = m. \tag{58b}$$

Subtracting (58b) from λ times (58a) we obtain

$$\sum_{i=1}^{3} (\lambda - i)p_i = \lambda n - m. \tag{59}$$

By setting λ successively equal to 1, 2, and 3 we eliminate p_i, for $i=1,2,3$, respectively, from the equations, leading to

$$(\lambda - j)p_j|_{j=(\lambda+1)\bmod 3} + (\lambda - j)p_j|_{j=(\lambda+2)\bmod 3} = \lambda n - m \tag{60}$$

from which we obtain the results presented in Table I. The results of Table I will be used throughout. For example, from the fourth row of the table we see that an interval $[0,m]$ can be partitioned into n parts belonging to {1, 2} if and only if $m=n+p_2$ or $m=2n-p_1$. Similarly it can be partitioned into n parts belonging to {2, 3} if and only if $m=2n+p_3$ or $m=3n-p_2$. Finally it can be partitioned into n parts belonging to {1, 3} if and only if $m=n+2p_3$ or $m=3n-2p_1$.

Equation (58) imposes two linear constraints on the five parameters m, n, p_1, p_2, and p_3, and hence only three of them are independent. Thus, given m, knowledge of any two other parameters, uniquely determines the partition $p(m,n)=1^{p_1}2^{p_2}3^{p_3}$. This result is also explicitly evident from Table I. Specifically, given m, p_2 and p_3 uniquely determine the partition $p(m,n)=1^{p_1}2^{p_2}3^{p_3}$. From Table I, the number of parts n is then given by

$$n(m,p_2,p_3) = m - p_2 - 2p_3 \tag{61}$$

while the number of parts of length 1 is given by

$$p_1(m,p_2,p_3) = m - 2p_2 - 3p_3. \tag{62}$$

G. The sum over *r*

The results obtained in Sec. II F allow us to evaluate the sum over ordered partitions (sum over r) appearing in Eqs. (55) and (56) of Sec. II E.

Let $\mathcal{O}(m_1,m_2)$ designate the set of *ordered partitions* of an interval $[m_1,m_2]$ into parts belonging to {1, 2, 3}, and let $\mathcal{O}_{p_3}(m_1,m_2)$ designate a subset of $\mathcal{O}(m_1,m_2)$, all of whose elements have exactly p_3 parts of length 3. Since the minimum number of parts of length 3 is 0 and the maximum is $\lfloor(m_2-m_1)/3\rfloor$ then the set $\mathcal{O}(m_1,m_2)$ can be expanded as

$$\mathcal{O}(m_1,m_2) = \bigcup_{p_3=0}^{\lfloor(m_2-m_1)/3\rfloor} \mathcal{O}_{p_3}(m_1,m_2). \tag{63}$$

Furthermore, let $\mathcal{O}_{p_3,p_2}(m_1,m_2)$ designate a subset of $\mathcal{O}_{p_3}(m_1,m_2)$, all of whose elements have exactly p_3 parts of length 3 and p_2 parts of length 2. The minimum number of parts of length 2 is

0 and since the partitions contain p_3 parts of length 3 then the maximum is $\lfloor (m_2-m_1-3p_3)/2 \rfloor$. Hence the set of ordered partitions of the interval $[m_1,m_2]$ containing exactly p_3 parts of length 3 can be expanded as

$$\mathcal{O}_{p_3}(m_1,m_2) = \bigcup_{p_2=0}^{\lfloor (m_2-m_1-3p_3)/2 \rfloor} \mathcal{O}_{p_3,p_2}(m_1,m_2) \tag{64}$$

leading, via Eq. (63), to

$$\mathcal{O}(m_1,m_2) = \bigcup_{p_3=0}^{\lfloor (m_2-m_1)/3 \rfloor} \bigcup_{p_2=0}^{\lfloor (m_2-m_1-3p_3)/2 \rfloor} \mathcal{O}_{p_3,p_2}(m_1,m_2). \tag{65}$$

The ordered partitions of the set $\mathcal{O}_{p_3,p_2}(m_1,m_2)$ all correspond to the same partition $p(m,n) = 1^{p_1}2^{p_2}3^{p_3}$ since knowledge of the length of the interval and of p_2 and p_3 completely specifies it. Furthermore the different subsets $\mathcal{O}_{p_3,p_2}(m_1,m_2)$ are disjoint

$$\mathcal{O}_{p_3,p_2}(m_1,m_2) \cap \mathcal{O}_{p_3',p_2'}(m_1,m_2) = \emptyset \quad \text{for } p_3 \neq p_3' \text{ or } p_2 \neq p_2'. \tag{66}$$

Hence

$$\sum_{o \in \mathcal{O}(m_1,m_2)} = \sum_{p_3=0}^{\lfloor (m_2-m_1)/3 \rfloor} \sum_{p_2=0}^{\lfloor (m_2-m_1-3p_3)/2 \rfloor} \sum_{o \in \mathcal{O}_{p_3,p_2}(m_1,m_2)}. \tag{67}$$

The sum over r (the sum over ordered partitions) appearing in Eqs. (55) and (56) of Sec. II E can thus be evaluated as follows:

$$\sum_{r=1}^{r_{\max}(0,m)} = \sum_{p_3=0}^{\lfloor m/3 \rfloor} \sum_{p_2=0}^{\lfloor (m-3p_3)/2 \rfloor} \sum_{o \in \mathcal{O}_{p_3,p_2}(m_1,m_2)}. \tag{68}$$

Let $o_{\max}(p)$, be the number of ordered partitions corresponding to a given partition $p(m,n) = 1^{p_1}2^{p_2}3^{p_3}$ [the cardinality of $\mathcal{O}_{p_3,p_2}(m_1,m_2)$], then[27]

$$o_{\max}(p) = \frac{n!}{p_1!p_2!p_3!}, \quad n = p_1 + p_2 + p_3. \tag{69}$$

Furthermore, let $\mathcal{O}_{p_2}(m_1,m_2,n)$ be the set of ordered partitions of the interval $[m_1,m_2]$ into n parts corresponding to the partition $1^{p_1}2^{p_2}3^{p_3}$. Note that since any three parameters of Eqs. (58) uniquely determines the partition $p(m,n) = 1^{p_1}2^{p_2}3^{p_3}$, then

$$\mathcal{O}_{p_3,p_2}(m_1,m_2) = \mathcal{O}_{p_2}(m_1,m_2,n)\big|_{n=m_2-m_1-p_2-2p_3}. \tag{70}$$

Making use of Eqs. (68) and (70), the combinatorics function given by Eq. (55) can be rewritten as

$$C_2(0,m) = \sum_{p_3=0}^{\lfloor m/3 \rfloor} \sum_{p_2=0}^{\lfloor (m-3p_3)/2 \rfloor} \left(\sum_{o \in \mathcal{O}_{p_2}(0,m,n)} (-\rho)^{p_1}(-t)^{p_2} \prod_{j=1}^{n} f(s_j,l) \right), \tag{71}$$

where n and p_1 are, respectively, given by Eqs. (61) and (62). Since p_1 and p_2 do not depend on ordering (on o), then they can be taken outside the second summation to obtain

$$C_2(0,m) = \sum_{p_3=0}^{\lfloor m/3 \rfloor} \sum_{p_2=0}^{\lfloor (m-3p_3)/2 \rfloor} (-\rho)^{p_1}(-t)^{p_2} \left(\sum_{o \in \mathcal{O}_{p_2}(0,m,n)} \prod_{j=1}^{n} f(s_j,l) \right). \tag{72}$$

In analogy with the structure functions introduced in Ref. 21, we introduce the structure functions $\beta_l(m_1,m_2;n,p_2)$ defined over the ordered partitions of the interval $[m_1,m_2]$ into n parts, p_2 of which are of length 2, as

$$\beta_l(m_1,m_2;n,p_2)=\sum_{o\in\mathcal{O}_{p_2}(m_1,m_2,n)}\prod_{j=1}^{n}f(s_j,l) \tag{73}$$

so that Eq. (72) may be expressed as, replacing p_1 and n by their respective expressions in terms of m, p_2 and p_3 [Eqs. (61) and (62)],

$$C_2(0,m)=\sum_{p_3=0}^{\lfloor m/3\rfloor}\sum_{p_2=0}^{\lfloor (m-3p_3)/2\rfloor}(-\rho)^{m-2p_2-3p_3}(-t)^{p_2}\beta_l(0,m;m-p_2-2p_3,p_2). \tag{74}$$

Inserting the above expression for the combinatorics function of the second kind in Eq. (53) and rearranging we finally find that the coefficients b_m are given by

$$b_m=\lambda_0(-1)^m\sum_{j=0}^{\lfloor m/3\rfloor}(-1)^j\sum_{i=0}^{\lfloor (m-3j)/2\rfloor}(-1)^i\beta_l(0,m;m-2j-i,i)\rho^{m-3j-2i}t^i. \tag{75}$$

The coefficients b_m are polynomials in t of order $m/2$ if m is even or $(m-1)/2$ if m is odd.

III. STRUCTURE FUNCTIONS

A. Fundamental cases

The $\beta_l(m_1,m_2;n,p_2)$ are, in general, complicated expressions. However, in three particular cases, they can be expressed compactly. These cases are $\beta_l(m_1,m_1+n;n,0)$, $\beta_l(m_1,m_1+2n;n,n)$, and $\beta_l(m_1,m_1+3n;n,0)$. They all have in common the fact that $o_{\max}(p)=1$, that is, there is only one possible ordered partition for each partition p. The three structure functions $\beta_l(m_1,m_1+n;n,0)$, $\beta_l(m_1,m_1+2n;n,n)$, and $\beta_l(m_1,m_1+3n;n,0)$ correspond to the values $p_1=n$, $p_2=n$, and $p_3=n$, respectively.

1. Segments of length 1 ($m=n$ and $p_1=n$)

In the case of $\beta_l(m_1,m_1+n;n,0)$, the length of the interval to be partitioned is $m=n$, and $p_2=0$. Hence from Table I, we have $p_1=n$ and $p_3=0$, and that is the interval is partitioned exclusively into segments of unite length. Thus $o_{\max}(p)=1$ and $s_j=m_1+j$ leading to

$$\beta_l(m_1,m_1+n;n,0)=\sum_{o\in\mathcal{O}_{p_2=0}(m_1,m_1+n,n)}\prod_{j=1}^{n}f(s_j,l)=\prod_{j=1}^{n}f(m_1+j,l) \tag{76}$$

and using Eq. (32), we have

$$\beta_l(m_1,m_1+n;n,0)=\prod_{j=1}^{n}\frac{1}{(m_1+j)}\prod_{j=1}^{n}\frac{1}{(m_1+2l+1+j)}. \tag{77}$$

Making use of the Pochhammer notation (see Appendix A), the above equation can be rewritten as

$$\beta_l(m_1,m_1+n;n,0)=\{(m_1+1)^{[n]}(m_1+2l+2)^{[n]}\}^{-1}. \tag{78}$$

2. Segments of length 2 ($m=2n$ and $p_2=n$)

In the case of $\beta_l(m_1,m_1+2n;n,n)$, the length of the interval to be partitioned is $m=2n$, and $p_2=n$. Hence from Table I, we have $p_1=0$ and $p_3=0$, that is the interval is partitioned exclusively into segments of length 2. Thus $o_{\max}(p)=1$ and $s_j=m_1+2j$ leading to

$$\beta_l(m_1,m_1+2n;n,n) = \sum_{o\in\mathcal{O}_{p_2=n}(m_1,m_1+2n,n)} \prod_{j=1}^{n} f(s_j,l) = \prod_{j=1}^{n} f(m_1+2j,l)$$
$$= \prod_{j=1}^{n} \frac{1}{(m_1+2j)} \prod_{j=1}^{n} \frac{1}{(m_1+2j+2l+1)}$$
$$= \frac{1}{2^{2n}} \prod_{j=1}^{n} \frac{1}{(m_1/2+j)} \prod_{j=1}^{n} \frac{1}{((m_1+1)/2+l+j)}. \tag{79}$$

The above equation can be rewritten as

$$\beta_l(m_1,m_1+2n;n,n) = \{2^{2n}[(m_1+2)/2]^{[n]}[(m_1+2l+3)/2]^{[n]}\}^{-1}. \tag{80}$$

3. Segments of length 3 ($m=3n$ and $p_3=n$)

In the case of $\beta_l(m_1,m_1+3n;n,0)$, the length of the interval to be partitioned is $m=3n$, and $p_2=0$. Hence from Table I, we have $p_3=n$ and $p_1=0$, in other words the interval is partitioned exclusively into segments of length 3. Thus $o_{\max}(p)=1$ and $s_j=m_1+3j$ leading to

$$\beta_l(m_1,m_1+3n;n,0) = \{3^{2n}[(m_1+3)/3]^{[n]}[(m_1+2l+4)/3]^{[n]}\}^{-1}. \tag{81}$$

B. Recursion relations for the structure functions

To determine the structure functions, we proceed in two steps. First, using the results of the preceding section as initial conditions, we establish a recursive procedure for determining $\beta_l(m_1,m_2;n,0)$. Next, we use these values of $\beta_l(m_1,m_2;n,0)$ as initial conditions, and determine a recursive expression for $\beta_l(m_1,m_2;n,p_2)$ in the case $p_2\neq 0$.

1. Structure functions of the form $\beta_l(m_1,m_2;n,0)$

Following the procedure of Ref. 21, the structure functions of the form $\beta_l(m_1,m_2;n,0)$ will be determined recursively by establishing a relation between the structure functions $\beta_l(m_1,m_2;n,0)$ corresponding to partitions with p_3 parts of length 3, and the structure functions $\beta_l(m_1,m_2';n',0)$ corresponding to partitions with a smaller number of parts of length 3.

Let $\mathcal{T}(m_1,m_2,n)$ be the set of all *ordered partitions*, of $[m_1,m_2]$ into n parts, corresponding to the *partition* $1^{p_1}2^0 3^{p_3}$. Since, given m_1, m_2, and n, the value of p_2 uniquely determines the partition $p(m_2-m_1,n)=1^{p_1}2^{p_2}3^{p_3}$, then

$$\mathcal{T}(m_1,m_2,n) = \mathcal{O}_{p_2=0}(m_1,m_2,n) \tag{82}$$

and

$$\sum_{o\in\mathcal{O}_{p_2=0}(m_1,m_2,n)} = \sum_{\pi\in\mathcal{T}(m_1,m_2,n)}. \tag{83}$$

Let $\mathcal{T}_i(m_1,m_2,n)$, $i=0,1,2,\ldots,p_3$, be a subset of $\mathcal{T}(m_1,m_2,n)$ whose elements satisfy two additional constraints: (i) the last i parts of the ordered partition are of length 3 and (ii) the $(n-i)$th part of the ordered partition is of length 1 (see Fig. 1). Note that

$$\mathcal{T}(m_1,m_2,n) = \bigcup_{i=0}^{p_3} \mathcal{T}_i(m_1,m_2,n) \tag{84}$$

and that the subsets $\mathcal{T}_i(m_1,m_2,n)$ are disjoint,

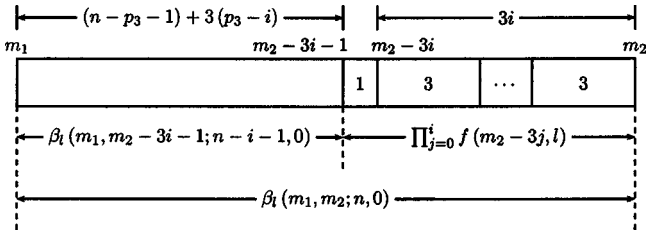

FIG. 1. Graphical representation of the partitions which are elements of the set $\mathcal{T}_i(m_1,m_2,n)$ and their corresponding structure functions.

$$\mathcal{T}_i(m_1,m_2,n) \cap \mathcal{T}_j(m_1,m_2,n) = \emptyset \quad \text{for } i \neq j, \tag{85}$$

hence

$$\sum_{\pi \in \mathcal{T}(m_1,m_2,n)} = \sum_{i=0}^{p_3} \sum_{\pi \in \mathcal{T}_i(m_1,m_2,n)} . \tag{86}$$

Combining Eqs. (83) and (86) we have the summation equation,

$$\sum_{o \in \mathcal{O}_{p_2=0}(m_1,m_2,n)} = \sum_{i=0}^{p_3} \sum_{\pi \in \mathcal{T}_i(m_1,m_2,n)} . \tag{87}$$

Note also (see Fig. 1), that there is a one-to-one correspondence between the elements of $\mathcal{T}_i(m_1,m_2,n)$ and the elements of $\mathcal{O}_{p_2=0}(m_1,m_2-3i-1,n-i-1)$,

$$\mathcal{T}_i(m_1,m_2,n) \leftrightarrow \mathcal{O}_{p_2=0}(m_1,m_2-3i-1,n-i-1), \tag{88}$$

hence

$$\sum_{\pi \in \mathcal{T}_i(m_1,m_2,n)} = \sum_{o \in \mathcal{O}_{p_2=0}(m_1,m_2-3i-1,n-i-1)} . \tag{89}$$

The structure function $\beta_l(m_1,m_2;n,0)$ is given via Eq. (73) as

$$\beta_l(m_1,m_2;n,0) = \sum_{o \in \mathcal{O}_{p_2}(m_1,m_2,n)} \prod_{j=1}^{n} f(s_j,l) \tag{90}$$

and due to Eq. (87), it can be rewritten as

$$\beta_l(m_1,m_2;n,0) = \sum_{i=0}^{p_3} \left(\sum_{\pi \in \mathcal{T}_i(m_1,m_2,n)} \prod_{j=1}^{n} f(s_j,l) \right). \tag{91}$$

Now

$$\prod_{j=1}^{n} f(s_j,l) = \left(\prod_{j=1}^{n-i-1} f(s_j,l) \right) \left(\prod_{j=n-i}^{n} f(s_j,l) \right) \tag{92}$$

and since all partitions belonging to the set $\mathcal{T}_i(m_1,m_2,n)$ have their last i parts of length 3, then from Eq. (41), with $\delta_j=3$ for $n-i+1 \leqslant j \leqslant n$, and $s_{n-i}=m_2-3i$ we have

$$s_{n-i+j'} = s_{n-i} + 3j' = m_2 - 3(i-j') \quad \text{for } j' = 1,2,\ldots,i \tag{93}$$

and consequently

$$\prod_{j=n-i}^{n} f(s_j,l) = \prod_{j'=0}^{i} f(s_{n-i+j'},l) = \prod_{j'=0}^{i} f(m_2 - 3(i-j'),l) = \prod_{j=0}^{i} f(m_2 - 3j,l). \tag{94}$$

Combining Eqs. (89), (92), and (94), Eq. (91) can be rewritten as

$$\beta_l(m_1,m_2;n,0) = \sum_{i=0}^{p_3} \left(\prod_{j=0}^{i} f(m_2 - 3j,l) \sum_{o \in \mathcal{O}_{p_2=0}(m_1,m_2-3i-1,n-i-1)} \prod_{j=1}^{n-i-1} f(s_j,l) \right). \tag{95}$$

But

$$\sum_{o \in \mathcal{O}_{p_2=0}(m_1,m_2-3i-1,n-i-1)} \prod_{j=1}^{n-i-1} f(s_j,l) = \beta_l(m_1,m_2-3i-1;n-i-1,0). \tag{96}$$

Hence Eq. (95) becomes

$$\beta_l(m_1,m_2;n,0) = \sum_{i=0}^{p_3} \beta_l(m_1,m_2-3i-1;n-i-1,0) \prod_{j=0}^{i} f(m_2-3j,l). \tag{97}$$

The fourth cell of the fourth row of Table I gives an expression for the length of an interval in terms of n, p_2, and p_3. Setting $p_2=0$, we obtain the length of intervals that can be partitioned into n parts belonging to $\{1, 3\}$ as $m_2-m_1=n+2p_3$. Inserting this results in Eq. (97), we obtain

$$\beta_l(m_1,m_1+n+2p_3;n,0) = \sum_{i=0}^{p_3} \beta_l(m_1,m_1+n+2p_3-3i-1;n-i-1,0) \prod_{j=0}^{i} f(m_1+n+2p_3-3j,l). \tag{98}$$

The product can be expressed as

$$\begin{aligned} \prod_{j=0}^{i} f(m_1+n+2p_3-3j,l) &= \prod_{j=0}^{i} \frac{1}{(m_1+n+2p_3-3j)} \prod_{j=0}^{i} \frac{1}{(m_1+n+2p_3-3j+2l+1)} \\ &= \frac{1}{3^{2(i+1)}} \prod_{j=0}^{i} \frac{1}{((m_1+n+2p_3)/3-j)} \prod_{j=0}^{i} \frac{1}{((m_1+n+2p_3+2l+1)/3-j)} \end{aligned} \tag{99}$$

or in Pochhammer notation

$$\prod_{j=0}^{i} f(m_1+n+2p_3-3j,l) = \frac{3^{-2(i+1)}}{[(m_1+n+2p_3)/3]^{(i+1)}[(m_1+n+2p_3+2l+1)/3]^{(i+1)}}. \tag{100}$$

Substituting this result in Eq. (98), we finally obtain

$$\beta_l(m_1,m_1+n+2p_3;n,0) = \sum_{i=0}^{p_3} \frac{3^{-2(i+1)} \beta_l(m_1,m_1+n+2p_3-3i-1;n-i-1,0)}{[(m_1+n+2p_3)/3]^{(i+1)}[(m_1+n+2p_3+2l+1)/3]^{(i+1)}}. \tag{101}$$

The recursion equation (101), can alternatively be written as a recursion relation in p_1, by making use of the relation $p_3=n-p_1$ to obtain

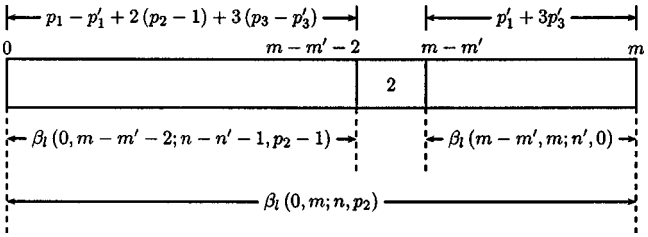

FIG. 2. Graphical representation of the relation between the partitions which are elements of the set $\mathcal{O}_{p_2-1}(0,m-m'-2,n-n'-1)$ and the partitions which are elements of the sets $\mathcal{O}_{p_2=0}(m-m',m,n')$ and $\mathcal{S}_{p_2}^{n',m'}(0,m,n)$, as well as their corresponding structure functions.

$$\beta_l(m_1,m_1+3n-2p_1;n,0)=\sum_{i=0}^{n-p_1}\frac{3^{-2(i+1)}\beta_l(m_1,m_1+3n-2p_1-3i-1;n-i-1,0)}{[(m_1+3n-2p_1)/3]^{(i+1)}[(m_1+3n-2p_1+2l+1)/3]^{(i+1)}}. \tag{102}$$

In the appendix we evaluate the above Eq. (102) for $p_1=n$ and reproduce Eq. (78).

2. Structure functions of the form $\beta_l(0,m;n,p_2)$

In this section, we derive a recursion relation for the structure functions $\beta_l(0,m;n,p_2)$, evaluated over the ordered partitions of the interval $[0,m]$ into n parts belonging to {1, 2, 3}, and corresponding to the partition $1^{p_1}2^{p_2}3^{p_3}$.

To this end we note that the structure functions $\beta_l(m_1,m_2;n,p_2)$ are combinatorics functions (see Secs. II C and II D) evaluated over the set of ordered partitions $\mathcal{O}_{p_2}(m_1,m_2,n)$, with the set of parts $\mathcal{A}=\{a_1,a_2,\ldots,a_N\}$ given by $\mathcal{A}=\{1,2,3\}$, and the corresponding variable coefficients, $f_{a_i}(m)$ for $a_i=1,2,3$, given by

$$f_1(m)=f_2(m)=f_3(m)=f(m,l), \tag{103}$$

where $f(m,l)$ is given by Eq. (32). Hence, $\beta_l(m_1,m_2;n,p_2)$ is obtained from $\mathcal{O}_{p_2}(m_1,m_2,n)$ by a homomorphism H from $(\mathcal{O}^*,\cup,\otimes)$ to $(R,+,\times)$, where the $*$ indicates the power set (see Ref. 25 Sec. II C, or Ref. 28 Sec. III A, or Ref. 29 Sec. 2.2.1):

$$(\mathcal{O}^*,\cup,\otimes)\overset{H}{\rightarrow}(R,+,\times) \tag{104}$$

and Eq. (90) can be rewritten as

$$\beta_l(m_1,m_2;n,p_2)=H(\mathcal{O}_{p_2}(m_1,m_2,n)). \tag{105}$$

Let $\mathcal{S}_{p_2}^{n',m'}(0,m,n)$ be the set of ordered partitions of the interval $[0,m]$ into n parts (p_1,p_2,p_3) (with $p_2\geqslant 1$ and $m\geqslant 2$), subject to the following constraints (i) the last n' parts are not of length 2, (ii) the $(n-n')$th part is of length 2, and (iii) the total length of the last n' parts is m'. Thus

$$n'=p_1'+p_3', \tag{106}$$

$$m'=p_1'+3p_3', \tag{107}$$

where p_1' and p_3' are the number of parts of lengths 1 and 3, respectively, to the right of the $(n-n')$th part of length 2. Their ranges are $0\leqslant p_1'\leqslant p_1$ and $0\leqslant p_3'\leqslant p_3$. The ordered partitions of the set $\mathcal{S}_{p_2}^{n',m'}(0,m,n)$ are presented in Fig. 2.

The set $\mathcal{S}_{p_2}^{n',m'}(0,m,n)$ can be expressed as follows (see Fig. 2):

$$\mathcal{S}_{p_2}^{n',m'}(0,m,n) = \mathcal{O}_{p_2-1}(0,m-m'-2,n-n'-1) \otimes \{m-m'-2,m-m'\} \otimes \mathcal{O}_{p_2=0}(m-m',m,n'). \tag{108}$$

Furthermore, the set of all ordered partitions of the interval $[0,m]$ into n parts (p_1,p_2,p_3) (with $p_2 \geqslant 1$ and $m \geqslant 2$) is given by the union of the sets $\mathcal{S}_{p_2}^{n',m'}(0,m,n)$ over all possible values of n' and m', that is,

$$\mathcal{O}_{p_2}(0,m,n) = \cup_{n'}\left(\cup_{m'} \mathcal{S}_{p_2}^{n',m'}(0,m,n)\right). \tag{109}$$

Combining Eqs. (108) and (109) we have

$$\mathcal{O}_{p_2}(0,m,n) = \cup_{n'}\cup_{m'} \mathcal{O}_{p_2-1}(0,m-m'-2,n-n'-1) \otimes \{m-m'-2,m-m'\} \otimes \mathcal{O}_{p_2=0}(m-m',m,n'). \tag{110}$$

Applying the homomorphism H to Eq. (110) leads to

$$H(\mathcal{O}_{p_2\geqslant 1}(0,m,n)) = \sum_{n'}\sum_{m'} H(\mathcal{O}_{p_2-1}(0,m-m'-2,n-n'-1)) \times H(\{m-m'-2,m-m'\})H(\mathcal{O}_{p_2=0}(m-m',m,n')) \tag{111}$$

which evaluates to

$$\beta_l(0,m;n,p_2) = \sum_{n'}\sum_{m'} \beta_l(0,m-m'-2;n-n'-1,p_2-1) f_2(m-m') \beta_l(m-m',m;n',0) \tag{112}$$

and due to Eq. (103) becomes

$$\beta_l(0,m;n,p_2) = \sum_{n'}\sum_{m'} \frac{\beta_l(0,m-m'-2;n-n'-1,p_2-1)\beta_l(m-m',m;n',0)}{(m-m')(m-m'+2l+1)}. \tag{113}$$

Making use of Eqs. (106) and (107), the double sum over the values of m' and n' can be converted into a double sum over p_1' and p_3', ranging, respectively, from 0 to p_1 and from 0 to p_3, and we finally obtain

$$\beta_l(0,m;n,p_2) = \sum_{p_1'=0}^{p_1}\sum_{p_3'=0}^{p_3} \frac{\beta_l(m-p_1'-3p_3',m;p_1'+p_3',0)}{(m-p_1'-3p_3')(m-p_1'-3p_3'+2l+1)} \times \beta_l(0,m-p_1'-3p_3'-2;n-p_1'-p_3'-1,p_2-1). \tag{114}$$

IV. THE WAVE FUNCTIONS

In this section we use the results of the preceding sections to obtain the wave functions of the Coulomb-plus-linear potential and then proceed to calculate the first six coefficients of the power series expansion of the wave functions.

A. General expression for the wave functions

The wave functions for the Coulomb-plus-linear potential are given by Eq. (2) as

$$\psi_{nlm}(\vec{r}) = r^{-1}u_{nl}(r)Y_l^m(\theta,\phi). \tag{115}$$

The functions $u_{nl}(r)$ are given by Eq. (30), with $x=(2\mu\kappa/\hbar^2)^{1/3}r$, leading to

$$u_{nl}(r) = r^{l+1}\sum_{k=0}^{\infty} b_k \left(\frac{2\mu\kappa}{\hbar^2}\right)^{(k+l+1)/3} r^k. \tag{116}$$

Substituting the above expression for $u_{nl}(r)$ in Eq. (115), inserting the expression for the coefficients b_k [Eq. (75)] and replacing ρ and t by Eqs. (8) and (9), respectively, we finally find that the wave functions for the Coulomb-plus-linear potential are given by

$$\psi_{nlm}(\vec{r}) = \lambda_0 Y_l^m(\theta,\phi) r^l \left(\frac{2\mu\kappa}{\hbar^2}\right)^{(l+1)/3} \sum_{k=0}^{\infty} (-1)^k \sum_{j=0}^{\lfloor k/3 \rfloor} (-1)^j \sum_{i=0}^{\lfloor (k-3j)/2 \rfloor} (-1)^i \times \left(\frac{2\mu}{\hbar^2}\right)^{k-2j-i} \beta_l(0,k;k-2j-i,i)\kappa^j \alpha^{k-3j-2i} (E_{nl}-V_0)^i r^k. \tag{117}$$

B. Explicit expressions for the power series coefficients

We now give expressions for the first six coefficients b_m, $m=1,2,3,4,5,6$ of the power series. The computation of a coefficient proceeds in the following way: (i) Eq. (75) is used to obtain an expression for the coefficient b_m in terms of structure functions. (ii) Recursion relations (102) and (114), obtained in Sec. III B, are used to bring the expression for the coefficient to a form containing only fundamental structure functions, that is, structure functions of the form $\beta_l(m_1,m_1+n;n,0)$ or $\beta_l(m_1,m_1+2n;n,n)$ or $\beta_l(m_1,m_1+3n;n,0)$. The upper summation limits of Eq. (114) are obtained using Table I. (iii) The fundamental structure functions can then be evaluated using Eqs. (78), (80), and (81).

The coefficient b_0 was arbitrarily chosen as λ_0 and we can verify that Eq. (75) with $m=0$ leads to

$$b_0 = \lambda_0 \beta_l(0,0;0,0) = \lambda_0. \tag{118}$$

The coefficients b_1 to b_6 are given by

$$b_1 = -\lambda_0 \beta_l(0,1;1,0)\rho, \tag{119}$$

$$b_2 = \lambda_0[\beta_l(0,2;2,0)\rho^2 - \beta_l(0,2;1,1)t], \tag{120}$$

$$b_3 = \lambda_0[-\beta_l(0,3;3,0)\rho^3 + \beta_l(0,3;2,1)\rho t + \beta_l(0,3;1,0)], \tag{121}$$

$$b_4 = \lambda_0[\beta_l(0,4;4,0)\rho^4 - \beta_l(0,4;3,1)\rho^2 t + \beta_l(0,4;2,2)t^2 - \beta_l(0,4;2,0)\rho], \tag{122}$$

$$b_5 = -\lambda_0[\beta_l(0,5;5,0)\rho^5 - \beta_l(0,5;4,1)\rho^3 t + \beta_l(0,5;3,2)\rho t^2 - \beta_l(0,5;3,0)\rho^2 + \beta_l(0,5;2,1)t], \tag{123}$$

$$b_6 = \lambda_0[\beta_l(0,6;6,0)\rho^6 - \beta_l(0,6;5,1)\rho^4 t + \beta_l(0,6;4,2)\rho^2 t^2 - \beta_l(0,6;3,3)t^3 - \beta_l(0,6;4,0)\rho^3 + \beta_l(0,6;3,1)\rho t + \beta_l(0,6;2,0)]. \tag{124}$$

Evaluating the structure functions we find that

$$b_1 = -\lambda_0 \frac{\rho}{(2l+2)^{[1]}}, \tag{125}$$

$$b_2 = \frac{\lambda_0}{2!(2l+2)^{[2]}}[\rho^2 - (2l+2)t], \tag{126}$$

$$b_3 = \frac{\lambda_0}{3!(2l+2)^{[3]}}\{-\rho^3 + [2(2l+3) + (2l+2)]\rho t + 2(2l+2)^{[2]}\}, \tag{127}$$

$$b_4 = \frac{\lambda_0}{4!(2l+2)^{[4]}}\{\rho^4 - [3(2l+4) + 2(2l+3) + (2l+2)]\rho^2 t + 3(2l+2)(2l+4)t^2 - [2(2l+2)^{[2]} + 6(2l+3)^{[2]}]\rho\}, \tag{128}$$

$$b_5 = \frac{-\lambda_0}{5!(2l+2)^{[5]}}\{\rho^5 - [4(2l+5) + 3(2l+4) + 2(2l+3) + (2l+2)]\rho^3 t + [8(2l+3)(2l+5) + 4(2l+2)(2l+5) + 3(2l+2)(2l+4)]\rho t^2 - [2(2l+2)^{[2]} + 6(2l+3)^{[2]} + 12(2l+4)^{[2]}]\rho^2 + [8(2l+2)^{[2]}(2l+5) + 12(2l+2)(2l+4)^{[2]}]t\}, \tag{129}$$

$$b_6 = \frac{\lambda_0}{6!(2l+2)^{[6]}}\{\rho^6 - [5(2l+6) + 4(2l+5) + 3(2l+4) + 2(2l+3) + (2l+2)]\rho^4 t + \{5(2l+6)[3(2l+4) + 2(2l+3) + (2l+2)] + 4(2l+5)[2(2l+3) + (2l+2)] + 3(2l+4)(2l+2)\}\rho^2 t^2 - 15(2l+2)(2l+4)(2l+6)t^3 - [2(2l+2)^{[2]} + 6(2l+3)^{[2]} + 12(2l+4)^{[2]} + 20(2l+5)^{[2]}]\rho^3 + \{5(2l+6) \times [2(2l+2)^{[2]} + 6(2l+3)^{[2]}] + 8(2l+2)^{[2]}(2l+5) + 12(2l+2)(2l+4)^{[2]} + 20[(2l+2) + 2(2l+3)](2l+5)^{[2]}\}\rho t + 40(2l+2)^{[2]}(2l+5)^{[2]}\}. \tag{130}$$

In the $\alpha \to 0$ limit, the Coulomb-plus-linear potential, parametrized as in (1), reduces to the linear potential. A consistency check would be to reproduce, in this limit, the coefficients obtained in the case of the linear potential. Setting $\alpha = 0$ in the potential corresponds, via Eq. (8), to setting $\rho = 0$ in the expressions for the coefficients. In the case $\rho = 0$, Eqs. (119)–(124) reduce to

$$b_1|_{\rho=0} = 0, \tag{131}$$

$$b_2|_{\rho=0} = -\lambda_0 \beta_l(0,2;1,1)t, \tag{132}$$

$$b_3|_{\rho=0} = \lambda_0 \beta_l(0,3;1,0), \tag{133}$$

$$b_4|_{\rho=0} = \lambda_0 \beta_l(0,4;2,2)t^2, \tag{134}$$

$$b_5|_{\rho=0} = -\lambda_0 \beta_l(0,5;2,1)t, \tag{135}$$

$$b_6|_{\rho=0} = \lambda_0[-\beta_l(0,6;3,3)t^3 + \beta_l(0,6;2,0)]. \tag{136}$$

Note that the structure functions appearing in these expressions are all of the form $\beta_l(0,m;n,3n-m)$, that is, they are defined over partitions containing only parts of length 2 or 3 (see Table I). Since the structure functions $\beta_l(0,m;n,p_2)$ and the structure functions $\beta_l(0,m;n)$ of Ref. 21 are defined in an analogous manner [see Eq. (73) of this paper and (3.14a) of Ref. 21] and since the $f(m,l)$ function [Eq. (57) of this paper and Eq. (3.3b) of Ref. 21] is the same in both cases, then the structure functions $\beta_l(0,m;n,3n-m)$ are equal to the structure functions $\beta_l(0,m;n)$ of Ref. 21. With this in mind, it can easily be checked that the above expressions reproduce the coefficients given by Eqs. (3.17a) and (3.17b) of Ref. 21, repeated here for convenience

$$b_{2k}^{\mathrm{lin}} = \lambda_0 \sum_{j=0}^{\lfloor k/3 \rfloor} \beta_l(0,2k;k-j)(-t)^{k-3j} \quad (k \geqslant 1), \tag{137}$$

$$b_{2k+1}^{\mathrm{lin}} = \lambda_0 \sum_{j=0}^{\lfloor (k-1)/3 \rfloor} \beta_l(0,2k+1;k-j)(-t)^{k-1-3j} \quad (k \geqslant 1). \tag{138}$$

V. CONCLUSION

We solved the Schrödinger equation for a quark–antiquark system interacting via a Coulomb-plus-linear potential. The series solution of the Schrödinger equation involved a four-term recursion relation relating the coefficients of the power series expansion of the wave function. This recursion relation was solved in terms of *combinatorics functions* which were then reduced to *structure functions*. Finally, recursion relations were derived to explicitly calculate these *structure functions*. The present work on the wave functions of the Schrödinger equation for the Coulomb-plus-linear potential lays the mathematical framework necessary to formulate and solve the corresponding eigenvalue equation.

APPENDIX A: POCHHAMMER SYMBOLS

The following notation is used for the Pochammer symbols:[30]

$$x^{(n)} = x(x-1)\cdots(x-n+1) = \prod_{i=1}^{n}(x+1-i) = \frac{\Gamma(x+1)}{\Gamma(x-n+1)}, \tag{A1}$$

$$x^{[n]} = x(x+1)\cdots(x+n-1) = \prod_{i=1}^{n}(x-1+i) = \frac{\Gamma(x+n)}{\Gamma(x)}, \tag{A2}$$

where $x^{(n)}$ is the descending Pochhammer symbol (or falling factorial) and $x^{[n]}$ is the ascending Pochammer symbol (or rising factorial). An ascending Pochammer can be converted to a descending Pochhammer, and vice versa, via

$$x^{(n)} = (x-n+1)^{[n]}, \quad x^{[n]} = (x+n-1)^{(n)}. \tag{A3}$$

Furthermore, the Pochhammer symbols can be factorized using the following properties:

$$x^{(n)} = x^{(i)}(x-i)^{(n-i)}, \quad x^{[n]} = x^{[i]}(x+i)^{[n-i]}. \tag{A4}$$

APPENDIX B: THE RECURSIVE RELATION FOR $\beta_l(m_1,m_2;n,0)$

In this appendix we demonstrate that the recursive relation for the structure function $\beta_l(m_1,m_2;n,0)$, as given by Eq. (102), in the special case of $p_1=n$, reduces to the expression of the fundamental structure function in which all parts are of unit length [Eq. (78)]. Setting $p_1=n$ in Eq. (102), we obtain

$$\beta_l(m_1,m_1+n;n,0) = \frac{\beta_l(m_1,m_1+n-1;n-1,0)}{3^2[(m_1+n)/3]^{(1)}[(m_1+n+2l+1)/3]^{(1)}} \tag{B1}$$

$$= \frac{\beta_l(m_1, m_1 + n - 1; n - 1, 0)}{(m_1 + n)(m_1 + n + 2l + 1)} \tag{B2}$$

but

$$\beta_l(m_1, m_1 + n - 1; n - 1, 0) = \{(m_1 + 1)^{[n-1]}(m_1 + 2l + 2)^{[n-1]}\}^{-1}. \tag{B3}$$

Hence

$$\beta_l(m_1, m_1 + n; n, 0) = \{(m_1 + n)(m_1 + 1)^{[n-1]}(m_1 + n + 2l + 1)(m_1 + 2l + 2)^{[n-1]}\}^{-1} \tag{B4}$$

leading to

$$\beta_l(m_1, m_1 + n; n, 0) = \{(m_1 + 1)^{[n]}(m_1 + 2l + 2)^{[n]}\}^{-1} \tag{B5}$$

which is identical to Eq. (78).

Solvable $\mathcal{PT}$-symmetric model with a tunable interspersion of nonmerging levels

Miloslav Znojil[a)]
Nuclear Physics Institute, Academy of Sciences of the Czech Republic, 250 68 Řež, Czech Republic

(Received 1 November 2004; accepted 7 April 2005; published online 27 May 2005)

We study the spectrum in such a $\mathcal{PT}$-symmetric square well (of a diameter $L \leqslant \infty$) where the "strength of the non-Hermiticity" is controlled by the two parameters, viz., by an imaginary coupling ig and by the distance $\ell < L$ of its onset from the origin. We solve this problem and confirm that the spectrum is discrete and real in a nonempty interval of $g \leqslant g_0(\ell, L)$. Surprisingly, a specific distinction between the bound states is found in their asymptotic stability/instability with respect to an unlimited growth of g beyond $g_0(\ell, L)$. In our model, *all* of the low-lying levels remain asymptotically unstable at the small $\ell \ll L$ and finite L while only the stable levels survive near $\ell \approx L < \infty$ *or* in the purely imaginary force limit with $0 < \ell < L = \infty$. In between these two extremes, an unusual and tunable, variable pattern of the interspersed "robust" and "fragile" subspectra of the real levels is obtained. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1925249]

I. INTRODUCTION

Around 1992, Bessis succeeded in attracting attention of a few people to a certain toy Hamiltonian (with some relevance in quantum field theory) which appeared to produce the real and discrete spectrum of energies in spite of being manifestly non-Hermitian.[1] A few years later, Bender and Boettcher returned to his mind-boggling problem and published a numerical study[2] of the whole class of the perceivably more general one-dimensional Schrödinger equations

$$\left[-\frac{d^2}{dx^2} + V(x) + iW(x) \right] \psi(x) = E\psi(x), \tag{1}$$

where, in our present perspective, the real component of the potential was assumed spatially symmetric while its Hermiticity-violating partner was chosen as spatially antisymmetric,

$$\mathcal{P}V(x)\mathcal{P} = V(-x) = +V(x), \quad \mathcal{P}W(x)\mathcal{P} = W(-x) = -W(x).$$

The latter study confirmed that the similar models [exhibiting, obviously, the parity ($\mathcal{P}$) times time-reversal ($\mathcal{T}$) symmetry] may possess *both* the purely real and partially (or, perhaps, completely) complex spectra. The Bender's and Boettcher's Fig. 1 (*loc. cit.*) illustrated the existence of the spectrum which proved "robustly real," i.e., real in a wide range of parameters of their "massless" $\mathcal{PT}$-symmetric model. In contrast, a merely slightly modified "massive" $\mathcal{PT}$-symmetric model of their Fig. 3 (*loc. cit.*) behaved quite differently. The values of many of its energy levels proved extremely sensitive to the very small variations of the parameters and, moreover, even the very reality of some energies proved "fragile" in the sense that after a very small change of a parameter of the model, certain energy pairs merged and disappeared forming, presumably, the complex conjugate pairs. At present, many more similar and more or less purely numerical examples exists (cf., e.g., the recent paper[3] for a sample of references).

a)Electronic mail; znojil@ujf.cas.cz

The recent progress in our understanding of the various $\mathcal{PT}$-symmetric quantum Hamiltonians H may be briefly summarized as an observation that their symmetry is important. First, it was established that the time-reversal-type antilinear operator factor $\mathcal{T}$ merely mediates the Hermitian conjugation $A \to A^{\dagger}$.[4,5] The role of parity $\mathcal{P}$ is more subtle and seems to offer the main mathematical key to the study of the $\mathcal{PT}$-symmetric quantum Hamiltonians H within the so-called Krein-space theory (cf., e.g., Ref. 6 for a nice as well as concise introduction to this language).

On the background of these *mathematical* observations, the formalism lost its originally highly enigmatic features in the context of *physics*. During the last two or three years, the use of the $\mathcal{PT}$-symmetric quantum models has in fact been accepted as just opening new horizons within the standard quantum mechanics. At present, virtually all the people active in the field would agree that it is only necessary to make the resulting physical picture complete by a revitalization of its probabilistic contents and tractability. This is being achieved via an introduction of the "missing" (and, in fact, quite nontrivial) metric $\eta \neq I$ in the Hilbert space of states.[6–8]

The temporary doubts and puzzles related, typically, to the applicability of the formalism look, at least roughly, clarified. One feels urged to return to many recently neglected and apparently evasive and mathematically more subtle questions like the problems of the robustness/fragility of the individual energies or of a global typology of the spectra. We believe that it is time for their deeper and more technical study via, say, simplified and, first of all, *non-numerically tractable* models. A new one, with rather surprising properties and descriptive features of the spectrum, is to be proposed and analyzed in what follows.

A. Non-Hermitian square-well-type models

Within $\mathcal{PT}$-symmetric quantum mechanics a one-parametric non-Hermitian square well (NSW) model has been described in Ref. 9. A key merit of the NSW model lies in a combination of its straightforward mathematical solvability with an exceptional transparency of its applications. In this way, the NSW model was able to offer an insight into the mechanism of the spontaneous $\mathcal{PT}$-symmetry breaking.[10] Next, due to its elementary character, the NSW model has been selected by Bagchi *et al.*[11] as a starting point of a systematic supersymmetric generation of solvable non-Hermitian Hamiltonians with $\mathcal{PT}$-symmetry and real spectra. Last but not least, Mostafazadeh and Batal[7] choose the NSW model in their very recent illustrative application of the $\mathcal{PT}$-symmetric quantum mechanics in its present, mathematically as well as physically more or less consistent updated form (readers may consult some of the available reviews for more details.[12])

In our recent paper[13] we revealed that a certain "hidden" shortcoming of the NSW model may be seen in its "fragility," i.e., in an instability of all the higher energy levels with respect to a certain highly speculative form of a complex-coordinate perturbation. Although such an observation does not have any *immediate* impact on the applications of the NSW model in Refs. 7, 10, and 11, certain doubts survive concerning the possible manifestations of some more serious instabilities in some of the generalized, NSW-type (NSWT) models.

For our present purposes let us vaguely characterize the latter NSWT potentials as piecewise constant. Then we may immediately recollect the existence of several "user-friendly" NSWT examples incorporating square-well models on a compact domain[14] or systems based on the use of point interactions.[15] Unfortunately, even within this class, the expectations concerning the stability of the spectrum are not always fulfilled. One may recollect, e.g., a spontaneous complexification of the high-lying part of many NSWT spectra as detected in very early numerical studies of certain particular potentials in Ref. 16. The phenomenon looks puzzling and makes all the NSWT models worth a more detailed non-numerical study.

B. The choice of a specific example

In applied quantum mechanics the construction of the majority of phenomenological models relies quite heavily on the correspondence principle which tries to connect each quantum model with its classical predecessor. $\mathcal{PT}$-symmetric quantum mechanics offers a weakening of this connection.[17] The operator of parity $\mathcal{P}$ is indefinite so that, as we already mentioned, the formal-

ism requires an explicit *additional* construction of a Hamiltonian-dependent positively definite metric $\eta>0$ in Hilbert space. Equivalently, this may be mediated by the construction of a quasiparity $\mathcal{Q}$ (Ref. 18) or charge $\mathcal{C}$,[19] both defined as a product $\eta\mathcal{P}$. In practical calculations this means that the metric is often being introduced in a suitably factorized form.[20]

It is worth adding that the quasiparity in $\eta=\mathcal{QP}$ is easily defined in some exactly solvable examples[18] while the charge in $\eta=\mathcal{CP}$ has immediate connotations in field theory.[19] In between these two extremes the authors of Ref. 7 revealed that the application of the formalism to the particular NSW model proves facilitated by a perturbative connection between the NSW model and a Hermitian square well. Their construction of $\eta^{(\mathrm{NSW})}$ profited from the existence of a finite-dimensional matrix approximation of the non-Hermitian part of the NSW Hamiltonian. A transition to the extended NSWT class of models looks promising and comotivates also our present project.

Within such a framework we intend to pay attention to the family of Schrödinger equations (1) where the interaction is non-Hermitian but manifestly $\mathcal{PT}$-symmetric. For the sake of definiteness we shall contemplate the less interesting real part of the potential just in the most elementary infinitely deep square-well form,

$$V(x)=\begin{cases}+\infty\\ 0\\ +\infty\end{cases}\quad\text{for}\quad\begin{cases}x>L,\\ -L<x<L,\\ x<-L.\end{cases}\tag{2}$$

This means that all our wave functions must vanish at its walls,

$$\psi(-L)=\psi(L)=0.\tag{3}$$

By adding any imaginary interaction we break the Hermiticity of the Hamiltonian. By doing so in the $\mathcal{PT}$-symmetric manner we preserve a chance and good hope of having the energies real.[2]

For the sake of definiteness and in a way generalizing the NSW model of Ref. 9 we shall assume that the Hermiticity-breaking term W is composed of two purely imaginary steps which both vanish inside a subinterval $(-\ell,\ell)$ of the interval $(-L,L)$,

$$W(x)=\begin{cases}+ig,\\ 0\\ -ig\end{cases}\quad\text{for}\quad\begin{cases}\mathrm{Re}\,x>\ell>0,\\ \mathrm{Re}\,x\in(-\ell,\ell),\\ \mathrm{Re}\,x<-\ell.\end{cases}\tag{4}$$

A priori, the strength of the Hermiticity-violating imaginary force may be expected proportional to the coupling $g>0$ and inversely proportional to $\ell<L$.

Our interest in the particular two-parametric model (4) results from the obvious need of an enhancement of flexibility of its one-parametric NSW predecessor and also from the lasting possibility of its rigorous mathematical description by means of the efficient moving-lattice method of Ref. 13 (reviewed also briefly in Appendix A below). Among additional purposes of the study of the similar NSWT models one may list a search for reliable comparisons between different potentials revealing, hopefully, some new, unnoticed characteristic features of their spectra. One would like to understand, e.g., how the details of the shape of $W(x)$ could influence the stability of the spectrum, or how one could control the domain of parameters where all the energies remain real.

Some of the NSWT studies have been motivated by their potential capacity of mimicking the properties of unsolvable models and, in particular, of one of the most popular $\mathcal{PT}$-symmetric toy interactions $W(x)=ix^3$.[21] Some parallels are definitely there since in the latter unsolvable case the spectrum was proved real, non-negative and discrete.[22] Of course, there are always good reasons for an introduction of more parameters in NSW. Thus, the new freedom of a weakening of the non-Hermiticity by the choice of $\ell>0$ might simulate analogies with the Bender's and Boettcher's

generalized $\mathcal{PT}$-symmetric family $W(x)=-(ix)^{3-\mu}$ characterized by an abrupt change of its spectral properties at $\mu=1$ and by the spontaneous complexification of all the sufficiently high-lying energies inside the interval $\mu\in(1,2)$ of the shape parameter.[2]

The possibility of the latter correspondence passes an easy test at $\ell=0$ and $L=\infty$ when the general solutions of our Schrödinger Eq. (1) are mere exponentials at any real $g>0$. Once we demand that they vanish in infinity we have

$$\psi(x)=\begin{cases} B_+\exp(-\sigma x), & \sigma^2=ig-E, \qquad \mathcal{R}e\,\sigma>0, \quad x\in(0,\infty), \\ B_-\exp(\sigma' x), & \sigma'^2=-ig-E, \quad \mathcal{R}e\,\sigma'>0, \quad x\in(-\infty,0). \end{cases} \tag{5}$$

When $x\to 0^{\pm}$ the coincidence of the right and left limit of $\psi(x)$ itself specifies the normalization, $B_+=B_-$, while the second matching rule $\psi'(0^+)=\psi'(0^-)$ implies that $\sigma=-\sigma'$, i.e., Eq. (5) has no solutions at $g>0$. It is of no avail to admit that $\mathcal{R}e\,\sigma\to 0$ and $\mathcal{R}e\,\sigma'\to 0$ and to employ the scattering boundary conditions since, unless $g=0$, the matching-compatible states remain always incompatible with our differential Schrödinger equation on a half-line.

We may conclude that both the discrete and continuous spectra are empty at $\ell=0$ for $g>0$ and $L=\infty$. This reconfirms our above expectations since the emptiness of the spectrum also characterizes the Bender's and Boettcher's toy interaction $W(x)=-(ix)^{3-\mu}$ at the Herbst's extreme shape parameter $\mu=2$.[23] At the same time, the spectrum abruptly ceases to be empty at $\mu<2$ (Ref. 2) as well as at $\ell>0$ while $L=\infty$ (cf. the proof of this assertion as given in Appendix B below).

II. THE METHOD

A. Wave functions and their matching

As long as our potential is piecewise constant at $0<\ell<L<\infty$ we may postulate

$$\psi(x)=\begin{cases} \psi_-(x)=B_-\sinh\kappa^*(L+x), & x\in(-L,-\ell), \\ \psi_0(x)=C\cos kx+iD\sin kx, & x\in(-\ell,\ell), \\ \psi_+(x)=B_+\sinh\kappa(L-x), & x\in(\ell,L), \end{cases} \tag{6}$$

where $\kappa=s+it$, $E=k^2=t^2-s^2$, $g=2st>0$ and where s, t, and k are assumed real and, for the sake of definiteness, positive. In other words, we assume that within a not yet specified nonempty domain of parameters g and ℓ the $\mathcal{PT}$-symmetry of the wave functions remains unbroken. In the way proposed in Ref. 9 we prescribe the phase,

$$\psi(x)=\text{real symmetric}+\text{imaginary antisymmetric}$$

and deduce that C and D are real. Next, we differentiate

$$\psi'(x)=\begin{cases} \psi'_-(x)=\kappa^*B_-\cosh\kappa^*(L+x), & x\in(-L,-\ell), \\ \psi'_0(x)=-kC\sin kx+ikD\cos kx, & x\in(-\ell,\ell), \\ \psi'_+(x)=-\kappa B_+\cosh\kappa(L-x), & x\in(\ell,L), \end{cases}$$

and write down the following four matching conditions:

$$\psi_-(-\ell)=\psi_0(-\ell), \quad \text{i.e., } B_-\sinh\kappa^*(L-\ell)=C\cos k\ell-iD\sin k\ell,$$

$$\psi'_-(-\ell)=\psi'_0(-\ell), \quad \text{i.e., } \kappa^*B_-\cosh\kappa^*(L-\ell)=kC\sin k\ell+ikD\cos k\ell,$$

$$\psi_+(\ell)=\psi_0(\ell), \quad \text{i.e., } B_+\sinh\kappa(L-\ell)=C\cos k\ell+iD\sin k\ell,$$

$$\psi_+'(\ell) = \psi_0'(\ell), \quad \text{i.e.,} \quad -\kappa B_+ \cosh \kappa(L-\ell) = -kC \sin k\ell + ikD \cos k\ell .$$

Two of them define the (complex) values of $B_\pm$ so that we are left with the pair of the matching constraints,

$$(kC \sin k\ell + ikD \cos k\ell)\sinh \kappa^*(L-\ell) = (C \cos k\ell - iD \sin k\ell)\kappa^* \cosh \kappa^*(L-\ell),$$

$$(kC \sin k\ell - ikD \cos k\ell)\sinh \kappa(L-\ell) = (C \cos k\ell + iD \sin k\ell)\kappa \cosh \kappa(L-\ell).$$

These two relations are complex conjugate of each other so that we must consider just one of them, say,

$$(kC \sin k\ell - ikD \cos k\ell)\sinh(s+it)(L-\ell) = (C \cos k\ell + iD \sin k\ell)\kappa \cosh(s+it)(L-\ell) \quad (7)$$

with $k \geqslant 0$.

B. Matching equations in the $\sigma-\tau-\varrho$ space

After we abbreviate $\sigma = s(L-\ell)$, $\tau = t(L-\ell)$, and $\varrho = k\ell$, Eq. (7) reads

$$\varrho(L-\ell)(C \sin \varrho - iD \cos \varrho)[\sinh \sigma \cos \tau + i \cosh \sigma \sin \tau] = \ell(\sigma + i\tau)(C \cos \varrho + iD \sin \varrho) \times [\cosh \sigma \cos \tau + i \sinh \sigma \sin \tau]. \quad (8)$$

We must keep in mind that

$$\tau^2 = \sigma^2 + \frac{(L-\ell)^2}{\ell^2}\varrho^2$$

while the respective real and imaginary parts of Eq. (8) must be treated as independent equations

$$\begin{aligned} &\varrho(L-\ell)(C \sin \varrho \sinh \sigma \cos \tau + D \cos \varrho \cosh \sigma \sin \tau) \\ &\quad = \ell[\sigma(C \cos \varrho \cosh \sigma \cos \tau - D \sin \varrho \sinh \sigma \sin \tau) \\ &\qquad - \tau(C \cos \varrho \sinh \sigma \sin \tau + D \sin \varrho \cosh \sigma \cos \tau)] \end{aligned} \quad (9)$$

and

$$\begin{aligned} &\varrho(L-\ell)(C \sin \varrho \cosh \sigma \sin \tau - D \cos \varrho \sinh \sigma \cos \tau) \\ &\quad = \ell[\sigma(C \cos \varrho \sinh \sigma \sin \tau + D \sin \varrho \cosh \sigma \cos \tau) \\ &\qquad + \tau(C \cos \varrho \cosh \sigma \cos \tau - D \sin \varrho \sinh \sigma \sin \tau)]. \end{aligned} \quad (10)$$

In the next step we notice that the latter equations form a linear algebraic homogeneous set for the two coefficients C and D. They possess a nontrivial solution if and only if the secular determinant $\mathcal{D}$ vanishes. After we abbreviate $\Omega = \tan \varrho$ (= a quickly oscillating function of ϱ), $T = \tan \tau$ (= a quickly oscillating function of τ) and $\Sigma = \tanh \sigma$ (= a monotonous and bounded function of σ) we can evaluate $\mathcal{D}$. After a lengthy calculation the secular condition $\mathcal{D} = 0$ acquires the following compact form:

$$X(\sigma) + Y(\tau) + F(R)[x(\sigma) + y(\tau)] = 0, \quad (11)$$

where

$$X(\sigma) = \frac{1+\Sigma^2}{1-\Sigma^2}\sigma^2 = \sigma^2 \cosh 2\sigma,$$

$$Y(\tau)=\frac{1-T^2}{1+T^2}\tau^2=\tau^2\cos 2\tau,$$

$$x(\sigma)=\frac{\Sigma}{1-\Sigma^2}\sigma=\frac{1}{2}\sigma\sinh 2\sigma,$$

$$y(\tau)=\frac{T}{1+T^2}\tau=\frac{1}{2}\tau\sin 2\tau,$$

$$F(R)=\frac{1-\Omega^2}{\Omega}R=\frac{2R}{\tan 2\varrho},\quad \varrho=\varrho(R)=\frac{\ell}{L-\ell}R.$$

We may rescale our coupling $g=2Z/(L-\ell)^2$ and conclude that our Z-independent secular equation (11),

$$\sin 2\varrho(R)[\sigma^2\cosh 2\sigma+\tau^2\cos 2\tau]+R\cos 2\varrho(R)[\sigma\sinh 2\sigma+\tau\sin 2\tau]=0 \tag{12}$$

only must be complemented by the two trivial constraints,

$$\sigma\tau=Z,\quad \tau^2-\sigma^2=R^2. \tag{13}$$

The triplets of roots R_n, σ_n, and τ_n of this triplet of equations with $n=0,1,\ldots$ define all the bound-state energies E_n by the elementary formula

$$E_n=\frac{1}{(L-\ell)^2}R_n^2\equiv\frac{1}{(L-\ell)^2}(\tau_n^2-\sigma_n^2). \tag{14}$$

In an indirect check of the recipe we may recollect its $\ell\to 0$ (i.e., $\varrho\to 0$) limit and conclude that our present Eq. (12) degenerates smoothly and correctly back to the known secular $\ell=0$ equation [cf. Eq. (9) in Ref. 9].

C. Matching in the moving-lattice representation

The basic tool for a rigorous analysis of the form of the solutions of our matching constraints is the moving-lattice method of Ref. 13 as reviewed in Appendix A below. Skipping the majority of details let us only note that for an analysis of this type, one of the recommended techniques seems to be the reduction of the problem to $\sigma-\tau$ plane. Preserving the definition of $\tau=\tau(N,t)$ of Appendix A and replacing the definition of $\sigma=\sigma(N,t)$ by another formula,

$$\sigma=\sigma(N,t,K,r)=\pi\times\sqrt{[N+t]^2+\left[\frac{L-\ell}{2\ell}(K+r)\right]^2},$$

we eliminate the coordinate R. A shortcoming of this approach is that our matching condition (12) transferred into the $\sigma-\tau$ plane must be understood as the following quadratic equation for τ:

$$\Phi_t\tau^2+\omega_{K,r,t}\tau+\Omega_{K,r,t}(\sigma)=0, \tag{15}$$

where we abbreviated

$$\omega_{K,r,t}=\frac{(L-\ell)\pi\Psi_t}{2\ell\Xi_r}(K+r),\quad \Omega_{K,r,t}(\sigma)=\Xi_r\left[\sigma^2\cosh 2\sigma+\frac{\omega_{K,r,t}}{\Psi_t}\sigma\sinh 2\sigma\right].$$

This defines $\tau=\tau_{K,r,t}(N)$ on the lattice, the "motion" of which will be controlled not only by t and r but also, not so strongly, by K. Technically, the price to be paid is still reasonable—we get the closed form of the matching-compatible function $\tau=\tau(\sigma)$ as the two well-known root formulas

from Eq. (15). Nevertheless, significant simplifications of the resulting picture may be mediated by the direct inspection of the equations in question.

III. SOLUTIONS

A. Matching equations in the $\sigma-\tau$ plane

Building far-reaching analogies with the $\ell=0$ special case would be misleading because the form of our matching constraint (12) is discontinuous in the limit $\ell\to 0$. Thus, let us assume that $\ell\neq 0$ and study Eq. (12) in its full-fledged form. First, we abbreviate $\mathcal{M}(\sigma,\tau)=\sigma\sinh 2\sigma+\tau\sin 2\tau$ and $\mathcal{N}(\sigma,\tau)=\sigma^2\cosh 2\sigma+\tau^2\cos 2\tau$ and rewrite our matching constraint (12) as the secular equation

$$\mathcal{D}(\sigma,\tau,R)=Q(\sigma,\tau)+\frac{\tan 2\varrho(R)}{R}=0,\quad Q(\sigma,\tau)=\frac{\mathcal{M}(\sigma,\tau)}{\mathcal{N}(\sigma,\tau)}. \tag{16}$$

This enables us to formulate several obvious observations.

[O1] The shape of both the functions $\mathcal{M}(\sigma,\tau)$ and $\mathcal{N}(\sigma,\tau)$ of two variables is easily deduced using their separability, $\mathcal{X}(\sigma,\tau)=\mathcal{X}(\sigma,0)+\mathcal{X}(0,\tau)$, $\mathcal{X}=\mathcal{M},\mathcal{N}$.

[O2] The smoothness of the σ and τ dependence of the denominator $\mathcal{N}(\sigma,\tau)$ facilitates also the determination of the shape of $\mathcal{F}(\sigma,\tau)=1/\mathcal{N}(\sigma,\tau)$.

[O3] In $\sigma-\tau$ plane we may visualize the shape of the second fraction in (16) as a function which is constant along hyperbolas $R(\sigma,\tau)=\sqrt{\tau^2-\sigma^2}=\text{fixed}$.

All these innocent-looking observations have several far-reaching though not always obvious consequences and form in fact a background for a rigorous analysis of the spectrum.

B. A rigorous graphical interpretation of $Q(\sigma,\tau)$

In more detail, observation [O1] means that the surfaces defined by the two non-negative function(s) $\mathcal{X}(\sigma,0)\geqslant 0$ have the form of the two only slightly different parabolic valleys with the same degenerate minimum (=zero) which coincides with the axis $\sigma=0$. The pertaining second components $\mathcal{X}(0,\tau)$ differ more from each other but both are adding a structurally similar perpendicular set of infinitely many parallel hills and valleys possessing a steadily increasing (though always finite) amplitude. As an obvious result of the superposition, both the resulting surfaces $\mathcal{X}(\sigma,\tau)$ cross the zero plane merely along certain ovals $O_n^{\mathcal{X}}$, and both of them only get negative in their interior.

The precise shape of these ovals (numbered by $n=0,1,\ldots$) may fully rigorously be determined using the moving-lattice method (cf. Appendix A) but even without any use of the moving lattices the qualitative character of their shape is obvious and we may conclude that the zero lines of $\mathcal{M}(\sigma,\tau)$ and $\mathcal{N}(\sigma,\tau)$ form the families of ovals $O_n^{\mathcal{M}}$ and $O_n^{\mathcal{N}}$ located within the stripes of $\tau\in[(n+1/2)\pi,(n+1)\pi]$ and $\tau\in[(n+1/4)\pi,(n+3/4)\pi]$, respectively. All of them are symmetric with respect to the reflection $\sigma\to-\sigma$ and their size in the σ direction increases with τ.

Examples of these structures may be found in both Refs. 9 and 13 and another illustration appears in Fig. 1 here. In fact, the figure displays another surface $Q(\sigma,\tau)=\mathcal{M}(\sigma,\tau)/\mathcal{N}(\sigma,\tau)$ (within a narrow window of $0\leqslant Q\leqslant 0.05$) but the shape of the curve where $\mathcal{M}$ vanishes ($O_1^{\mathcal{M}}\equiv V_1$) appears there clearly since the denominator $\mathcal{F}(\sigma,\tau)=1/\mathcal{N}(\sigma,\tau)$ has its zeros, generically, elsewhere (cf. observation [O2]). Besides the oval V_1 (and a part of $O_0^{\mathcal{M}}\equiv V_0$) the picture displays another oval $O_1^{\mathcal{N}}\equiv D_1$ of the zeros of the denominator $\mathcal{N}$. Incidentally it lies within the chosen interval of $\tau\in(3,7)$ and remains visible due to a numerical artifact of a spurious projection of an infinite discontinuity of the function $\mathcal{F}(\sigma,\tau)$.

Although the visibility of the discontinuities reflects just an imperfection of the graphical representation of the surface, it will prove useful in what follows.

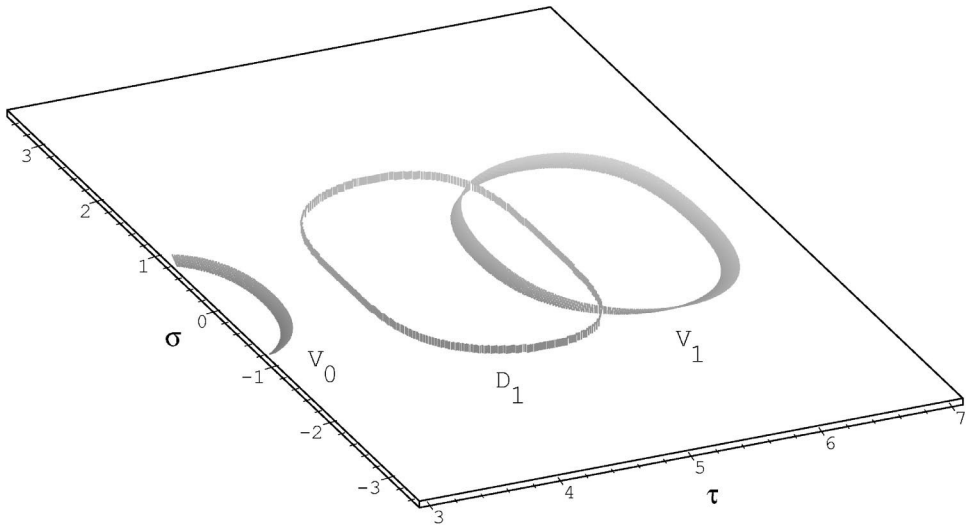

FIG. 1. A thin slice through the surface $Q(\sigma,\tau)=\mathcal{M}/\mathcal{N}$.

C. The role of the second component of $\mathcal{D}[\sigma,\tau,R(\sigma,\tau)]$

The presence of the subsurface generated by the second, R-dependent component $\mathcal{D}_{(R)}[R(\sigma,\tau)]$ in Eq. (16) does not violate the separation between σ and τ too much (cf. observation [O3]). At the smallest absolute values of σ we may safely return to the approximation of $\mathcal{D}_{(R)}[R(\sigma,\tau)]$ by a function of a single variable, $[\tan 2\varrho(R)]/R\approx[\tan 2\ell\tau/(L-\ell)]/\tau$. This picture only becomes deformed, at the larger σ, by being bent to the right, i.e., along hyperbolas $R(\sigma,\tau)=$constant.

A clear understanding of the τ-dependence of the whole surface $\mathcal{D}[\sigma,\tau,R(\sigma,\tau)]$ will be obtained when we distinguish between the domain of the "small τ" **(**where $[\tan 2\ell\tau/(L-\ell)]/\tau\approx 2\ell/(L-\ell)$ is positive and virtually constant**)**, "medium τ" **(**with the repeated quick growth of the curve $[\tan 2\ell\tau/(L-\ell)]/\tau$ from minus infinity up to plus infinity within each interval of the constant length $\Delta\tau=\pi(L-\ell)/2\ell$**)** and "large τ" **(**where the values of $\mathcal{D}_{(R)}[R(\sigma,\tau)]\approx 1/\tau$ become very small up to the very thin layers near the singularity hyperbolas H_n**)**. Due to the local dominance of the latter singularities H_n at any $n=0,1,\ldots$ it is easy to imagine that the sign of the whole function $\mathcal{D}[\sigma,\tau,R(\sigma,\tau)]$ is positive and negative in their left and right vicinity, respectively. This "rule of thumb" enables us to deduce the sign of the whole function $\mathcal{D}[\sigma,\tau,R(\sigma,\tau)]$ in all our figures.

D. The left-moving hyperbolic discontinuities H_n

In the domain of the small shifts $\ell\ll 1$ the numerical values of the R-dependent component $\mathcal{D}_{(R)}[R(\sigma,\tau)]$ of Eq. (16) remain almost constant and small. In this regime the above-mentioned "small-τ" constraint $\tau\ll(L-\ell)/\ell$ is not particularly restrictive so that the matching-compatible roots of equation $\mathcal{D}=0$ remain very similar to their $\ell=0$ predecessors in quite a large leftmost portion of the $\sigma-\tau$ plane. In our notation, the first few ovals $O_n^{\mathcal{D}}\equiv V_n$ of the zeros of the secular determinant stay only perturbatively shifted and deformed by an increase of $\ell\ll 1$.

With the growth of ℓ or $\lambda=\ell/(L-\ell)$ the leftmost discontinuity-hyperbola H_0 of the surface $\mathcal{D}[\sigma,\tau,R(\sigma,\tau)]$ moves to the left and emerges in the right half of Fig. 2 where we choose the scale-independent parameter $\lambda=11/40$ which corresponds to $\ell=11L/51$. This means that we are just leaving the domain of the small shifts $\ell\ll 1$ so that the deformation of the nodal oval $O_1^{\mathcal{D}}\equiv V_1$ becomes perceivable, caused by the closeness of H_0 to the ℓ-independent discontinuity oval $D_1\equiv O_1^{\mathcal{N}}$ inherited from the never-vanishing factor $\mathcal{F}(\sigma,\tau)=1/\mathcal{N}(\sigma,\tau)$.

In a way which generalizes the illustrative Fig. 2, each hyperbolic singularity H_k [defined by the equation $R(\sigma,\tau)=(L-\ell)(k+1/2)\pi/\ell$ with $k=0,1,\ldots$] moves to the left with the growth of ℓ

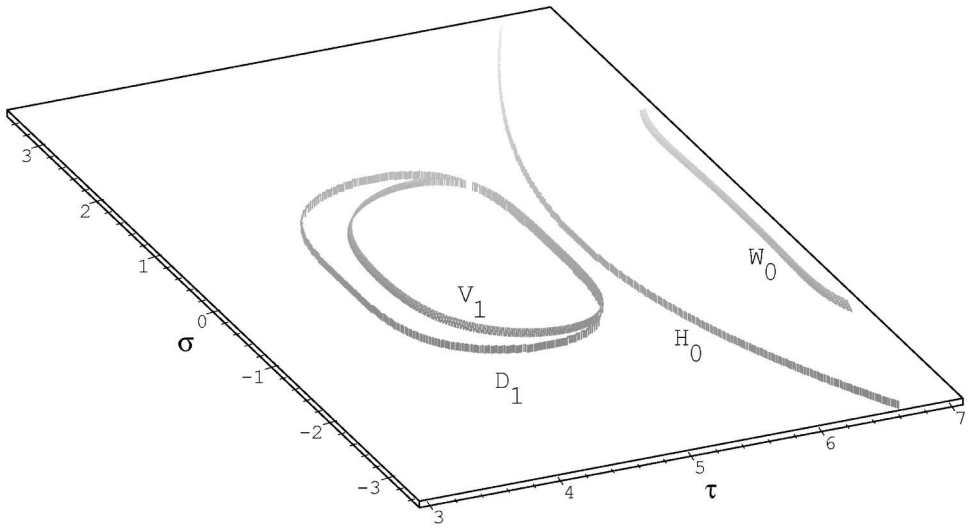

FIG. 2. A thin slice through the surface of the secular determinant $\mathcal{D}(\sigma,\tau)$ at $\lambda=\ell/(L-\ell)=0.275$.

and λ. Once it gets close to the Nth singularity oval D_{N-1}, it touches it at a point with the coordinates $\sigma_{(\mathrm{in})}^{(N,k)}=0$ and $\tau_{(\mathrm{in})}^{(N,k)}=(N-1/4)\pi$ at the critical value $\lambda=2\ell/(L-\ell)=(4k+2)/(4N-1)\equiv\lambda_{(\mathrm{in})}^{(N,k)}$ of the shift.

With the further growth of λ the intersection of the hyperbola with the standing oval moves to the left and disappears, curiously enough, at a certain pair of points with the "last-contact" $|\sigma|=|\sigma_{(\mathrm{out})}^{(N,k)}|>0$ and $\tau=\tau_{(\mathrm{out})}^{(N,k)}<(N-3/4)\pi$. The latter value lies slightly below the oval's end. Let us skip here the proof of this subtlety as not too relevant.

E. A completion of the list of the nodal lines

We are now prepared to detect *all* the nodal curves of $\mathcal{D}[\sigma,\tau,R(\sigma,\tau)]$ and to determine their qualitative ℓ-dependence in all the interval of $\ell\in(0,L)$ and/or of $\lambda=\lambda(\ell)\in(0,\infty)$. For the first inspiration we return to Fig. 2 where the oval of zeros $O_1^{\mathcal{D}}\equiv V_1$ cannot be interpreted as a mere small perturbation of $O_1^{\mathcal{M}}$ in spite of the fact that the singularity hyperbola H_0 still did not touch the singularity oval $O_1^{\mathcal{N}}\equiv D_1$ since $\lambda=0.275<\lambda_{(\mathrm{in})}^{(2,1)}=2/7\approx0.286$.

Still, the much more important observation made in Fig. 2 concerns the emergence of the new curve W_0 of the new zeros of the function $\mathcal{D}$. At the chosen λ this curve just entered Fig. 2 at its right side. Our next Fig. 3 confirms that the new nodal curve W_0 moves to the left and gets deformed in a way reflecting the presence of a steep oval dip in $Q(\sigma,\tau)$ below $\tau=2\pi$. We choose $\lambda=0.355$ which is still safely smaller than the lower estimate $(4k-2)/(4N-3)=0.4$ of the singularity hyperbola's "jumped-over" parameter $\lambda_{(\mathrm{out})}^{(2,1)}\approx0.403$.

The "next-step snapshot" of Fig. 4 at $\lambda=0.395$ shows how the same dip deforms the shape of the oval $O_1^{\mathcal{D}}\equiv V_1$ in the domain where the function of R is small. In the subsequent Fig. 5 we finally see how the two curves of the zeros merge while a topologically new situation is created and sampled at $\lambda=0.415>\lambda_{(\mathrm{out})}^{(2,1)}$.

We may summarize that for the growing λ the motion of the singular component $\tan 2\varrho(R)/R$ of our secular determinant $\mathcal{D}(\sigma,\tau)$ to the left gives a clear guide how to keep the ℓ dependence of its zero lines under full control. The emergence and the asymptotically hyperbolic shape of the new (and, in fact, not quite expected) nonoval curves W_m of zeros follows immediately from the asymptotic smallness of the positive component $Q(\sigma,\tau)\sim1/\sigma^2$ of $\mathcal{D}(\sigma,\tau)$ at the larger $|\sigma|\gg1$.

Due to the reasonably elementary character of the function $\mathcal{D}(\sigma,\tau)$ we are able to understand

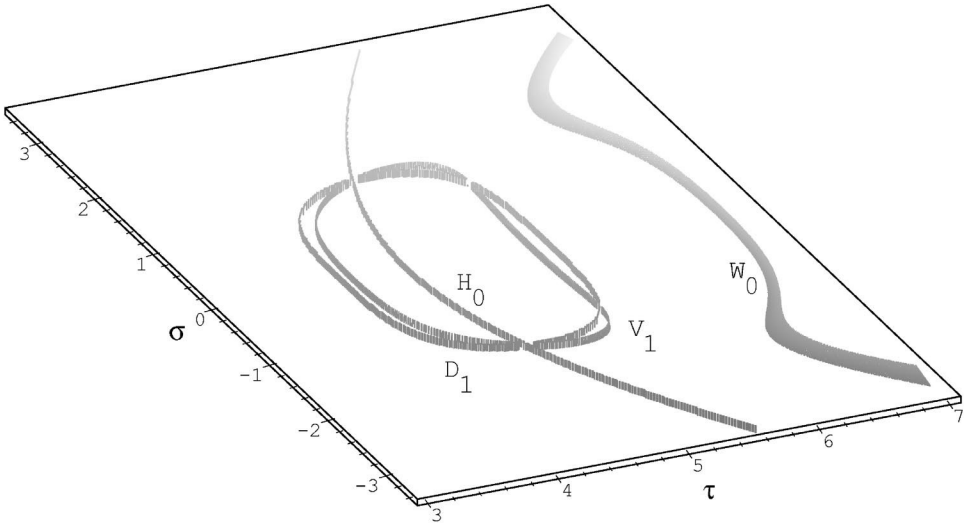

FIG. 3. Same as Fig. 2, $\lambda = 0.355$.

that the pattern sampled by Figs. 2–5 is entirely universal. Always, step by step, the nodal ovals V_n as well as their asymptotically hyperbolic nodal-line partners W_m become deformed by the existence of the dip in the numerator function $\mathcal{M}(\sigma, \tau)$.

Of course, after the hyperbola of singularities H_k as well as its strongly deformed trailing nodal curve W_k "creep" over the fixed singularity oval D_j (as well as over its attached and strongly deformed zero curve V_j), the smoother shapes of both the nodal curves W_k and V_j are more or less recovered, and only their ordering remains permanently reversed. In spite of the apparent nonlinearity of the "creeping-over" effects, their details might again be analyzed algebraically, using an adapted version of the moving-lattice method of Sec. II C.

The most important reward compensating an increase in complexity of the latter recipe is that one becomes able to treat one of the two roots of Eq. (15), say, as a "nonperturbative" solution at the small ℓ. The most important example of its role are the hyperbolic nodal curves W_m which move to the right in τ with the decrease of ℓ and which disappear in infinity in the NSW limit of $\ell \to 0$.

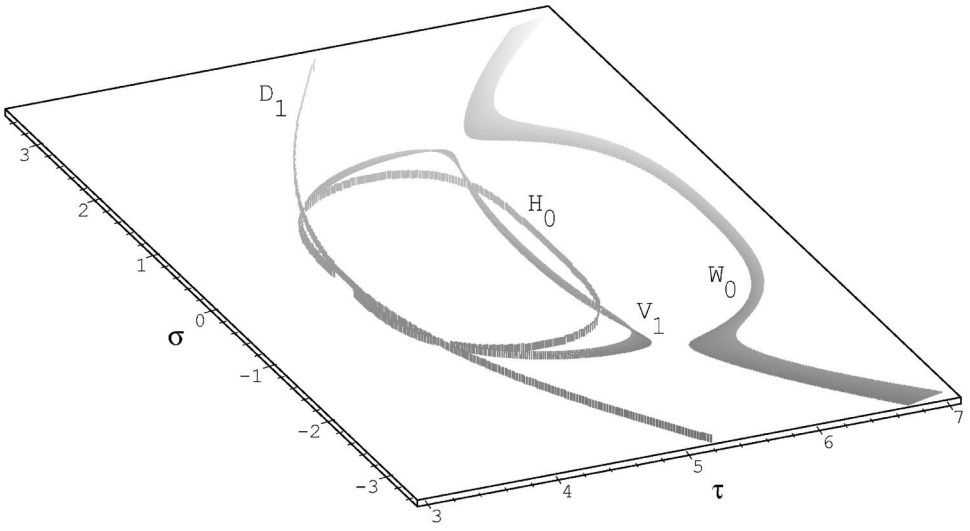

FIG. 4. Same as Fig. 2, $\lambda = 0.395$.

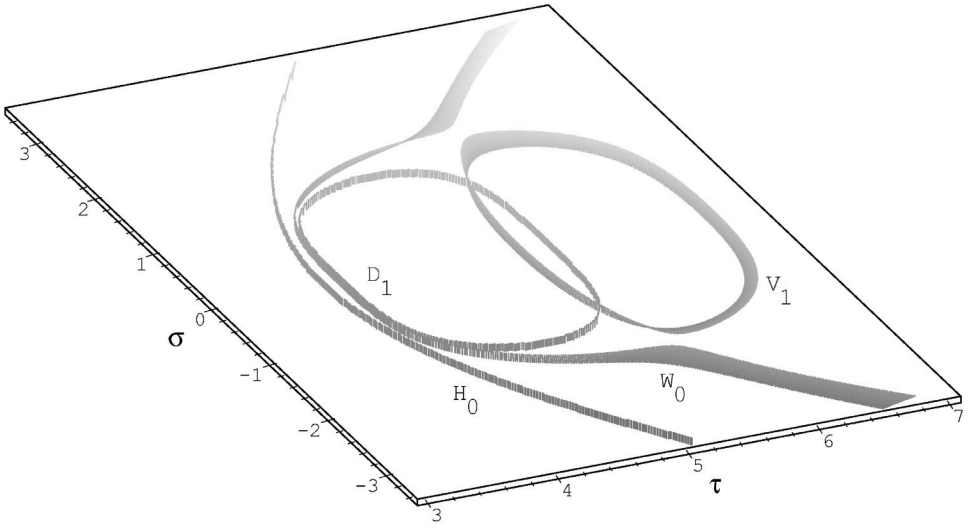

FIG. 5. Same as Fig. 2, $\lambda = 0.415$.

IV. ENERGIES

A. Graphical representation and classification

On the background of the preceding material, what remains for us to do is a combination of the above-described knowledge of the nodal lines of $\mathcal{D}[\sigma, \tau, R(\sigma, \tau)]$ with the coupling-dependence constraint $\sigma \times \tau = Z = (L-\ell)^2 g/2$. A sample of the intersections of this type (i.e., of a typical final solution) is offered in Fig. 6 where $\lambda = 2.40$ is neither small nor large and where we choose $Z = Z^{(a)} = 1.00$ and $Z = Z^{(b)} = 2.24$ (= the critical "exceptional-point" value of Ref. 9) for illustration. The conclusions which are illustrated by this graph have a general validity:

(i) We always have $\tau > \sigma > 0$ which means that all the real bound-state energies E_n remain positive at $Z > 0$.

(ii) Some of the energies remain real at *any* value of $Z > 0$. They correspond to the intersections of the hyperbola $\sigma = Z/\tau$ with the hyperbolic nodal lines W_m and may be called "stable," $E = E_m^{(s)}$.

(iii) All the other energies $E = E_n^{(u)}$ correspond to the intersections of the hyperbola $\sigma = Z/\tau$ with the nodal ovals V_k. At a sufficiently small Z the latter intersections remain real [see the line (a) with $Z = 1$ in Fig. 6].

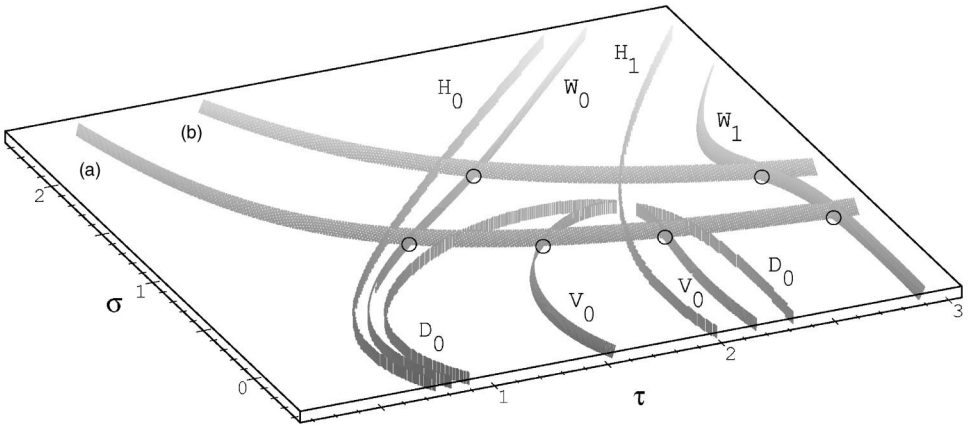

FIG. 6. Solutions at $Z^{(a)} = 1.00$ and $Z^{(b)} = 2.24$, intersections marked by circles, $\lambda = 2.4$.

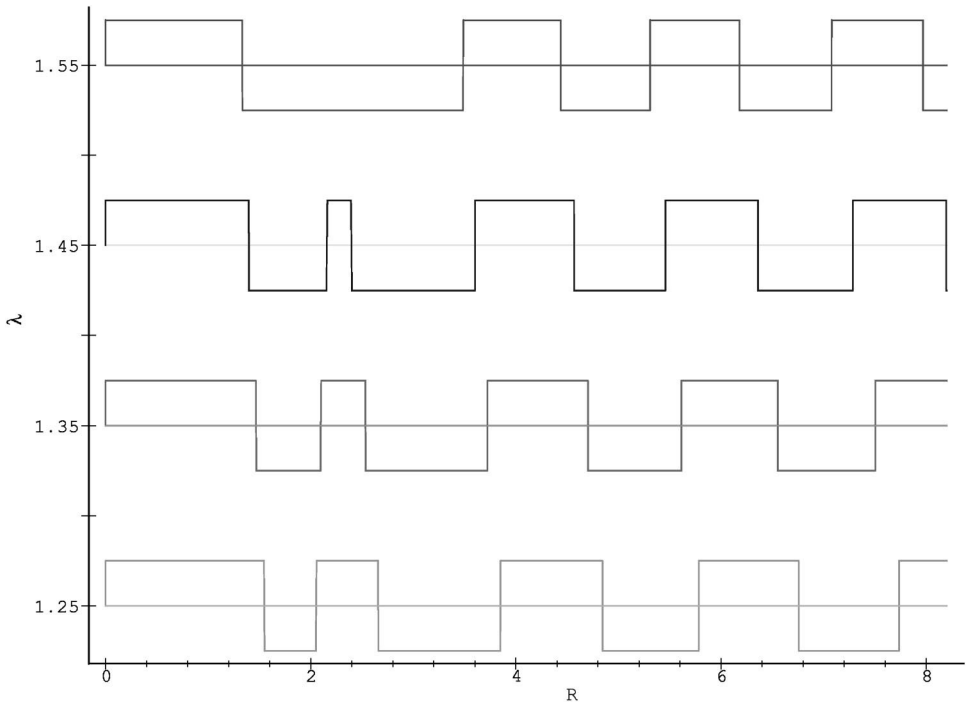

FIG. 7. Four rescaled graphs of the function $\hat{\mathcal{D}}(R)$.

(iv) We may call the latter energies "unstable" as they merge in pairs and form complex conjugate doublets[4] beyond certain "exceptional-point"[24] values of ℓ and Z [illustration, the line (b) in Fig. 6].

The decomposition of the spectrum into its stable and unstable parts varies with ℓ or $\lambda = \ell/(L-\ell)$ in an obvious manner. Hence, the stability pattern in the spectrum will be entirely different at the small and large λ since in the former case the hyperbolic curves W_n only generate the high-lying energies and *vice versa*.

B. Numerical construction

After all our previous detailed analysis of the qualitative features of the spectrum the numerical determination of energies becomes fully routine. Indeed, as long as we know $\tau = Z/\sigma$, the rule $\tau^2 - \sigma^2 = R^2$ leads immediately to the definition of

$$\sigma = \sigma(R) = \sqrt{\frac{2Z^2}{R^2 + \sqrt{R^4 + 4Z^2}}}. \tag{17}$$

In parallel to such an introduction of the closed function $\sigma = \sigma(R)$ of R we may return once more to the recipe $\tau = Z/\sigma(R)$ and re-read it as another explicit definition of the second auxiliary function $\tau(R) = Z/\sigma(R)$ of R.

In such a setting, the purely numerical determination of the bound-state energies is reduced to the search for the roots R_n of Eq. (12), i.e., of the zeros of the secular determinant,

$$\hat{\mathcal{D}}(R) = [\sigma^2(R)\cosh 2\sigma(R) + \tau^2(R)\cos 2\tau(R)]\sin 2\lambda R + R[\sigma(R)\sinh 2\sigma(R) + \tau(R)\sin 2\tau(R)]\cos 2\lambda R \tag{18}$$

converted now in the function of the single variable $R \sim \sqrt{E}$. An illustration of such a search is given in Fig. 7 at a fixed choice of $Z = 2$. The quadruplet of the graphs of the secular determinant

$\hat{\mathcal{D}}(R)=\mathcal{D}[\sigma(R),\tau(R),R]$ is presented there at the four different values 1.25, 1.35, 1.45, and 1.55 of λ (indicated along the vertical axis). In each of these graphs we magnified the vertical units near $\hat{\mathcal{D}}(R)\approx 0$ and compressed them to a single point representing all the bigger values of $|\hat{\mathcal{D}}(R)|\geqslant\varepsilon$. In this way the picture samples the left-hand side of Eq. (18) solely near its zeros. Our magnification of the vertical dimension marks these zeros by the virtually straight parts of the curve which are seen as practically perpendicular to the horizontal axis.

The set of graphs in Fig. 7 illustrates the λ dependence of the bound-state roots R_n. We see that a pair of the unstable energies may merge and cease to be real after a fine-tuned growth of λ. This illustrates the complexification of the unstable energies which is *not* caused by the growth of Z but rather by the growth of λ. At the first sight this phenomenon looks like a paradox because we are now *weakening* the non-Hermiticity in fact. Fortunately, this paradox is still easily understood once we imagine (and check, say, in the spirit of Figs. 2 and 3) that the growth of λ "pushes" *all* the zeros (including of course also the nodal oval in question) to the left. Of course, this oval cannot get prolonged in the σ direction because the function $\mathcal{M}(\sigma,\tau)$ itself grows too quickly with σ. This implies that the two real intersections of the oval with the hyperbola $\sigma=Z/\tau$ disappear because the latter curve grows to the left.

In the light of an additional scaling in Eq. (14) one may only admire the subtlety of the phenomenon, the verification of which very much profits from the exact solvability of the model. An independent confirmation of the absence of any contradictions may be also offered via a further simplification of mathematics. This inspires us to pay particular attention to the "most counterintuitive" limiting case where $L\to\infty$. Such an analysis may be of an independent interest as it simulates, very roughly, the shape of the most popular antisymmetric and purely imaginary potential $V(x)\sim ix^3$ with real spectrum.[22] As long as this discussion already lies somewhat beyond the scope of the present text, it is moved to Appendix B.

V. CONCLUSIONS

After more than 10 years of an intensive research many people now seem to believe that we now better understand the key problems related to the so-called $\mathcal{PT}$-symmetric as well as to many other similar non-Hermitian models or, in the more rigorous terminology, to all the models where the metric remains nontrivial, $\eta\neq I$.[25] By the way, not all the related results are new. For example, Scholz *et al.*[26] (inspired, presumably, by a few earlier mathematical as well as physical publications) studied the similar $\eta\neq I$ models more than 10 years ago and coined the name "quasi-Hermitian" for them.

Still, one cannot deny that during the last 7 years, a new and intensive excitement has been caused by the discoveries of the reality of the spectra in many $\mathcal{PT}$-symmetric models. The emphasis of the research has been shifted, typically, to the explicit constructions of the charge $\mathcal{C}$ (Ref. 20) or to the more detailed analysis of what happens at the "exceptional" points where the reality of the spectrum is being lost.[24,27] A few unusual features exhibited by our present model seem to offer another welcome and clear intuitive guidance in this area.

We found our results interesting since the merger and subsequent spontaneous complexification of some "twin" pairs $E^{(\pm\text{twin})}$ of the energies cannot be easily described within the usual textbook models where the metric is "trivial," $\eta_{(\text{trivial})}=I$. It is also in this context where considerations based on our present model could lead to a deeper insight in the underlying mechanisms and mathematics, not only because our model is solvable but also because it proves able to provide different "twin-merging" patterns in the spectrum. Indeed, by the choice of the shape parameter ℓ we may, up to a large extent, prescribe *which* particular excitations (say, in the low-lying spectrum) should remain robustly stable and which ones should form the unstable, fragile "twins" merging at some sufficiently large couplings $g_{(\text{critical})}$.

In the similar constructions and studies, one might feel hesitant whether his/her models should be simpler or more realistic. We believe that one should transfer the insight gained in the solvable models (like in the present one) to all the more realistic applications where just some approximate

methods can be used. In this sense we already mentioned a parallelism between the role of the shift ℓ in our solvable model and of the exponent μ in the power-law potentials with $\mathcal{PT}$-symmetry.

It is encouraging to see that a certain nontrivial enrichment of the merging pattern has been detected, more or less in parallel, within the class of the power-law forces.[27] In this comparison, our present model's merit lies in its exact solvability. Definitely, it proves able to offer a comparably rich pattern of the mergers of the levels.

This being said, the *key* phenomenological and "model-building" specific merit of our present new version of the $\mathcal{PT}$-symmetric square-well model is still to be seen in the "global" structure of its spectrum. There, one observes that the "fragile" and the "robust" levels seem to form the two sets which may be moved with respect to each other as a whole. Thus, the *whole* spectrum becomes "almost completely robust" in one extreme (which is "almost Hermitian") and "almost all fragile" in another extreme which is, near $\ell \approx 0$, "maximally non-Hermitian."

APPENDIX A: THE METHOD OF MOVING LATTICE

Secular Eq. (12) and its descendants contain quickly oscillating trigonometric functions of arguments 2τ and 2ϱ. In the spirit of Ref. 13 it makes sense to reparametrize both these variables according to the rules

$$\tau = \tau(N,t) = \pi N + \pi t, \quad N = 0,1,\ldots, \quad t \in (0,1),$$

$$\varrho = \pi K + \pi r, \quad K = 0,1,\ldots, \quad r \in (0,1)$$

which separate their "large" change (by an integer multiple of the period 2π so that the trigonometric function itself remains unchanged) from a "small" change [within one period $(0,2\pi)$]. Thus, once we define

$$\Psi = \sin 2\tau = \sin 2\pi t, \quad \Phi = \cos 2\tau = \cos 2\pi t,$$

$$\Xi = -\tan 2\varrho = -\tan \pi r,$$

all our trigonometric functions in question become independent of both the integer variables. Thus, once we decide to work, say, in the $\sigma - R$ plane, we simply introduce a lattice $\mathcal{L}_{t,r}$ of points with coordinates

$$\sigma = \sigma(N,t) = \frac{Z}{\tau(\sigma)} = \frac{Z}{\pi N + \pi t}$$

and

$$R = \frac{L-\ell}{\ell}\varrho(R) = \frac{\pi(L-\ell)}{2\ell}(K+r),$$

where $t \in (0,1)$ and $r \in (0,1)$ are fixed while $N = 0,1,\ldots$ and $K = 0,1,\ldots$ remain variable. Our secular equation (12) then becomes more easily analyzed at the fixed $t \in (0,1)$ and $r \in (0,1)$ when it may be re-read as a simplified mapping $\sigma \to R$ with

$$R = R_{t,r}(\sigma) = \Xi_r \times \frac{\sigma^4 \cosh 2\sigma + Z^2 \Phi_t}{\sigma^3 \sinh 2\sigma + \sigma Z \Psi_t}, \tag{A1}$$

i.e., $R_{t,r} \approx \Xi_r |\sigma|$ at $|\sigma| \gg 1$ while

$$R_{t,r} \approx \frac{Z}{\sigma} \times \frac{\Phi_t \Xi_r}{\Psi_t}$$

at $|\sigma| \ll 1$, etc. In the subsequent step, remembering that the latter formulas hold on the lattice $\mathcal{L}(t,r)$ only, we must let this lattice move with the variation of t and/or r. Within each box numbered by the pair (N,K) of non-negative integers we would be able to rederive all the qualitative geometric considerations of Sec. III in an alternative, quantitative manner.

APPENDIX B: SHALLOW WELL

In the infinite-size limit $L \to \infty$ our model degenerates to a purely imaginary square well with asymptotic boundary conditions

$$\psi(\pm\infty) = 0 \tag{B1}$$

and with the $\mathcal{PT}$-symmetric matching conditions in the origin,

$$\psi(0) = 1, \quad \partial_x \psi(0) = iG. \tag{B2}$$

This means that we have the general solution

$$\psi(x) = \begin{cases} \cos kx + B \sin kx, & x \in (0,\ell), \quad k^2 = E, \\ (L + iN)\exp(-\sigma x), & x \in (\ell,\infty), \quad \sigma^2 = iT^2 - k^2, \end{cases} \tag{B3}$$

with $T = \sqrt{g}$ and with the the purely imaginary constant $B = iG/k$.

1. Matching conditions at $x = \ell$

Let us split $\sigma = p + iq$ in its real and imaginary part with $p, q \geqslant 0$. This gives the rules $p^2 + k^2 = q^2$ and $2pq = T^2$, easily reparametrized in terms of a single variable α,

$$p = q \cos \alpha, \quad k = q \sin \alpha, \quad q = \frac{T}{\sqrt{2 \cos \alpha}}, \quad \alpha \in (0, \ell/2). \tag{B4}$$

The standard matching at the point of discontinuity is immediate,

$$\cos k\ell + B \sin k\ell = (L + iN)\exp(-\sigma\ell),$$

$$-\sin k\ell + B \cos k\ell = -\frac{\sigma}{k}(L + iN)\exp(-\sigma\ell).$$

After we abbreviate $\sigma/k = -\tan \Omega\ell$, we get an elementary complex condition of the matching of logarithmic derivatives at $x = \ell$,

$$G = -ik \tan(k + \Omega)\ell. \tag{B5}$$

Its real part defines our first unknown parameter, $G = G(\alpha)$. Due to our normalization conventions, the imaginary part of the right-hand-side expression must vanish, $\mathrm{Re}[\tan(k+\Omega)\ell] = 0$. An elementary rearrangement of such an equation acquires the form of an elementary quadratic algebraic equation for $X = \tan k\ell$. Its two explicit solutions read

$$X_1 = \frac{p + q}{k}, \quad X_2 = \frac{p - q}{k} \tag{B6}$$

or, after all the insertions,

$$\tan\left[\frac{\ell T \sin \alpha^{(+)}}{\sqrt{2 \cos \alpha^{(+)}}}\right] = \tan\left[\frac{\ell - \alpha^{(+)}}{2}\right], \tag{B7}$$

$$\tan\left[\frac{\ell T \sin\alpha^{(-)}}{\sqrt{2\cos\alpha^{(-)}}}\right] = \tan\left[-\frac{\alpha^{(-)}}{2}\right]. \tag{B8}$$

These equations specify, in implicit manner, the two respective infinite series of the appropriately bounded real roots $\alpha=\alpha_n^{(\pm)}\in(0,\ell/2)$.

2. Energies

For $\alpha\in(0,\ell/2)$ the left-hand-side arguments in Eqs. (B7) and (B8) run from zero to infinity and the functions oscillate infinitely many times from minus infinity to plus infinity. In contrast, the limited variation of the argument α makes both the right-hand side functions monotonic, very smooth and bounded, $\tan[(\ell-\alpha^{(+)})/2]\in(1,\infty)$ and $\tan[\alpha^{(-)}/2]\in(0,1)$. This indicates that our roots $k=k(\alpha_n^{(\pm)})$ will all lie within well determined intervals,

$$k_n^{(+)}\in\left(n+\frac{1}{4},n+\frac{1}{2}\right),\quad n=0,1,\ldots,$$

$$k_m^{(-)}\in\left(m+\frac{3}{4},m+1\right),\quad m=0,1,\ldots.$$

An additional merit of parametrization (B4) lies in an unambiguous removal of the tangens operators from both Eqs. (B7) and (B8). This gives

$$k_n^{(+)}=n+\frac{1}{2}-\frac{\omega_n^{(+)}}{4},\quad k_m^{(-)}=m+1-\frac{\omega_m^{(-)}}{4},\quad \omega_n^{(\pm)}=\frac{2\alpha_n^{(\pm)}}{\ell}\in(0,1).$$

After a change of notation with $\omega_n^{(+)}=\omega_{2n}$ and $\omega_n^{(-)}=\omega_{2n+1}$, we may finally combine the latter two rules in the single secular equation

$$\sin\left(\frac{\ell}{2}\omega_N\right)=\frac{2N+2-\omega_N}{4T}\cdot\sqrt{2\cos\left(\frac{\ell}{2}\omega_N\right)},\quad N=0,1,\ldots. \tag{B9}$$

In a graphical interpretation this equation represents an intersection of a tangenslike curve with the infinite family of parallel lines. This is illustrated in Fig. 8. The equation generates, therefore, an infinite number of real roots $\omega_N\in(0,1)$ at all the non-negative integers $N=0,1,\ldots$. The discrete spectrum is unbounded from above and remains constrained by the inequalities

$$\frac{(N+1/2)^2}{4}\leqslant E_N\leqslant\frac{(N+1)^2}{4} \tag{B10}$$

independently of the coupling T.

3. Wave functions

Equation (B5) in combination with Eqs. (B7) and (B8) determines the real parameter

$$G=G^{(\pm)}=-\frac{k^2}{q\pm p} \tag{B11}$$

responsible for the behavior of the wave functions near the origin [remember that $B=iG/k$ in Eq. (B3)]. For its deeper analysis let us first introduce an auxiliary linear function of ω and N,

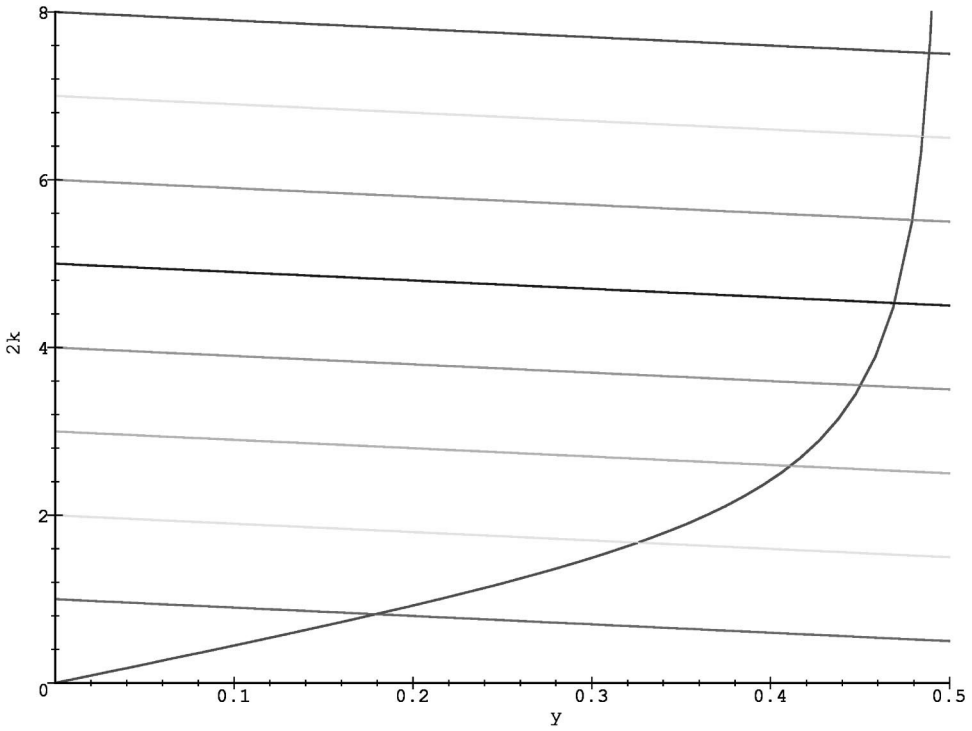

FIG. 8. Graphical solution of Eq. (B9) ($y=\omega_N/2, T=1$)

$$\sqrt{R(\omega_N,N)} = \frac{2N+2-\omega_N}{4T} \in \left(\frac{N+1/2}{2T}, \frac{N+1}{2T}\right)$$

and reinterpret our secular Eq. (B9) as an algebraic quadratic equation with the unique positive solution,

$$\cos\left(\frac{\ell}{2}\omega_N\right) = \frac{1}{R(\omega_N,N)+\sqrt{R^2(\omega_N,N)+1}}. \tag{B12}$$

This is an amended implicit definition of the sequence ω_N. As long as the right-hand side expression is very smooth and never exceeds one, the latter formula reverifies that the root ω_N is always real and bounded as required.

In the weak coupling regime (i.e., in the domain of the large and almost constant $R \gg 1$ with the small square-well height T or at the higher excitations), our new secular equation (B12) gives a better picture of our bound-state parameters $\omega_N = 1-\eta_N$ which all lie very close to one. The estimate

$$\frac{\ell}{2}\eta_N = \arcsin\frac{1}{R+\sqrt{R^2+1}} \approx \frac{1}{2R} - \frac{5}{48R^3} + \cdots$$

represents also a quickly convergent iterative algorithm for the efficient numerical evaluation of the roots ω_N. One can conclude that in a way compatible with our *a priori* expectations, the value of $p=p_N=\mathrm{Re}\,\sigma \approx q/2R$ is very close to zero and, as a consequence, the asymptotic decrease of our wave functions remains slow. We have $q=q_N=\mathrm{Im}\,\sigma \approx k$ so that, asymptotically, our wave functions very much resemble free waves $\exp(-ikx)$. In the light of Eq. (B11) we have also $\psi(x) \approx \exp(-ikx)$ near the origin.

In the strong coupling regime (i.e., for very small R representing, say, the low-lying excitations in a deep well with $T \gg 1$) we get an alternative estimate

$$\frac{\ell}{4}\omega_N = \arcsin\sqrt{\frac{1}{2}[R-(\sqrt{1+R^2}-1)]} \approx \frac{1}{2}R - \frac{1}{4}R^2 + \cdots \ll \frac{\ell}{4}.$$

In the extreme of $R \to 0$ the present spectrum of energies moves towards (and precisely coincides with) the well-known levels of the infinitely deep Hermitian square well of the same width $I=(-\ell,\ell)$. In this sense, the "complex-rotation" transition from the Hermitian well to its present non-Hermitian $\mathcal{PT}$-symmetric alternative proves amazingly smooth.

The wave functions exhibit the similar tendency. In the outer region, they are proportional to $\exp(-px)$ and decay very quickly since $p=\mathcal{O}(R^{-1/2})$. The parameter $G^{(\pm)}$ becomes strongly superscript dependent,

$$G^{(+)} = -\frac{k^2}{q+p} = \mathcal{O}(R^{3/2}), \quad G^{(-)} = -(q+p) = \mathcal{O}(R^{-1/2}).$$

This means that in the interior domain of $x \in (-\ell,\ell)$, the wave functions with the superscript $^{(+)}$ and $^{(-)}$ become dominated by their spatially even and odd components $\cos kx$ and $\sin kx$, respectively. In this sense, the superscript mimics (or at least keeps the trace of) the quantum number of the slightly broken spatial parity $\mathcal{P}$.

(Received 20 August 2004; accepted 17 February 2005; published online 31 May 2005)

In the hydrodynamic formulation of the scale relativity theory one shows that a stable vortices distribution of bipolaron type induces superconducting pairs by means of the quantum potential. Then, usual mechanisms (as, for example, the exchange interaction used in the bipolaron theory) are reduced to the coherence on the subquantum medium, the superconducting pairs resulting as a one-dimensional projection of a fractal. The temperature dependences of the superconducting parameters (coherence length, critical speed, pair breaking time, carriers concentration, penetration depth, critical field, critical current) and the concordance with the experimental data and other theories are analyzed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904163]

I. INTRODUCTION

One of the modern theories which deals with high-temperature superconductivity is the bipolaron theory.[1,2] The bipolarons are pairs of spin polarons with zero total spin like the Cooper pairs from the Bardeen–Cooper–Schrieffer (BCS) theory,[3] but unlike the Cooper pairs, the spin polarons form pairs in the real space and not only close to the energy interval Δ centered on the Fermi level. The bonding forces acting between the spin-polarons constituting the boson (bipolaron) are exchange-type forces. Under these circumstances Δ corresponds to the superconducting gap, and T_C is the temperature for Bose–Einstein gas to become degenerate. As an example, between the Cu–O planes spin polarons are formed, and they consist of holes and electrons; the holes originate from O–2*p* and the electrons from the Cu–3*d* orbitals. They become ordered as in Fig. 1(a).[1,2] The exchange mechanism between the spin-polarons leads to a stable distribution—the bipolarons [Fig. 1(b)] which endow the material with superconducting properties.

More recently, some superconducting properties have been explained by considering the charge carriers (electrons and holes) are quantized vortexlike objects, ordered in two vortex streets having antiparallel vortices.[4] The interaction between these vortexlike objects is mediated by a subquantum level with superfluid properties. For superconducting matter the status of such a medium is imposed by the hydrodynamic formulation of the scale relativity (SR) theory,[5] a unique mechanism inducing superconductivity, by means of a fractal string (a string in a fractal space–time).

Having in view these results, in the present paper we suggest new mechanisms for approaching superconductivity. Accordingly, once given the distribution from Fig. 1(a) we substitute the

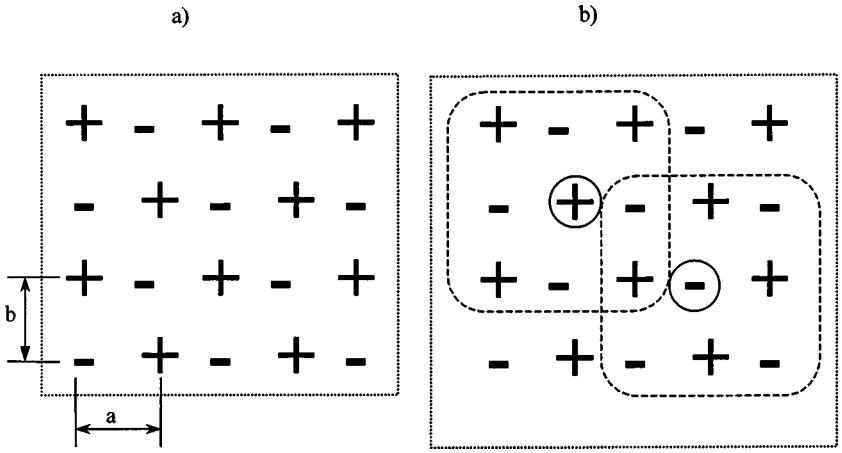

FIG. 1. (a) The holes and electrons distribution between the Cu–O planes associated to the distribution of zeros and poles of the potential (63). (b) The bipolarons distribution induced by means of the exchange mechanism.

exchange interaction (used in the bipolaron theory) by the sub quantum medium interaction. Superconducting pairs result, as being a one-dimensional (1D) projections of a fractal and the temperature dependences of the superconducting parameters.

II. SCALE RELATIVITY HYDRODYNAMIC EQUATIONS, QUANTUM POTENTIAL, DYNAMIC AND STATIC STATES

The SR theory extends Einstein's principle of relativity to scale transformation of resolution. It is based on the giving up of the axiom of differentiability of the space–time continuum. Three consequences arise from this withdrawal[5] (for details see Appendix A): (i) The geodesics of a nondifferentiable space–time are fractal and in infinite number, this leads one to use a fluidlike description $v=v[x(t),t]$ and implies adding new terms in the differential equations of the mean motion; (ii) the geometry of space–time become fractal, i.e., explicitly resolution dependent; this allows one to describe a nondifferentiable physics in terms of differential equation acting in the scale space. The requirement that these equations satisfy the principle of SR leads to introduce scale laws having a Galilean form (constant fractal dimension), then a log-Lorentzian form. In this framework, the Planck length-time scale becomes minimal impassable scale, invariant under dilatations, and the cosmic length scale (related to the cosmological constant) a maximal one. Recent measurements of the cosmological constant have confirmed the theoretical predicted value.[6] Then we attempt to construct a generalized SR, which includes nonlinear scale transformations and scale-motion coupling. In this last framework, one can interpret gauge invariance as scale invariance on the internal resolutions. This approach allowed us to make theoretical predictions concerning coupling constants and elementary particle masses (electron, Higgs boson, vacuum energy of Higgs field). These predictions are successfully checked using recently improved experimental values. Each elementary displacement is then described in terms of the sum, $dX=dx+d\xi$, of a mean classical displacement $dx=v\,dt$ and of a fractal fluctuation $d\xi$, whose behavior satisfies the principle of SR. It is such that $\langle d\xi\rangle=0$ and $\langle d\xi^2\rangle=2D\,dt$. The existence of this fluctuation implies introducing new second order terms in the differential equation of motion; (iii) time reversibility is broken at the infinitesimal level, this can be described in terms of a two-valuedness of the velocity vector, for which we use a complex representation, $\mathbf{V}=(v_+ + v_-)/2 - i(v_+ - v_-)/2$.

These three effects can be combined to construct a complex time-derivative operator

$$\delta/dt = \partial_t + \mathbf{V}\cdot\nabla - iD\Delta, \tag{1}$$

where the mean velocity $\mathbf{V}=dx/dt$ is now complex, and D is a parameter characterizing the fractal behavior of trajectories (for details of this problem see Appendix A).

Let us consider the covariant derivative (1) and the **V** complex velocity[5]

$$\mathbf{V} = -2iD\nabla \ln \psi \tag{2}$$

Applying the $\delta/\mathrm{d}t$ covariant derivative to the **V** complex velocity, we obtain

$$(\delta/\mathrm{d}t)\mathbf{V} = -2iD[\partial_t(\nabla \ln \psi) - 2iD(\nabla \ln \psi \cdot \nabla)(\nabla \ln \psi) - iD\Delta(\nabla \ln \psi)] \tag{3}$$

or still, considering the identity[5]

$$\begin{gathered}\nabla(\Delta\psi/\psi) = \Delta(\nabla \ln \psi) + 2(\nabla \ln \psi \cdot \nabla)(\nabla \ln \psi), \\ (\delta/\mathrm{d}t)\mathbf{V} = -2D\nabla[i(\partial_t\psi/\psi) + D(\Delta\psi/\psi)].\end{gathered} \tag{4}$$

For a fractal space–time, Newton's second principle takes the form

$$m(\delta/\mathrm{d}t)\mathbf{V} = -\nabla U \tag{5}$$

or explicitly

$$\nabla U = [2imD(\partial_t\psi/\psi) + 2mD^2(\Delta\psi/\psi)] \tag{6}$$

with U the potential.

Integrating this equation yields

$$D^2\Delta\psi + iD\partial_t\psi = \frac{U}{2m}\psi \tag{7}$$

up to an arbitrary phase factor $\alpha(t)$ which may be set to zero by a suitable choice of the phase of ψ. If there is no external fied, $U=0$, the convariance is explicit, since Newton's equation of inertial motion

$$(\delta/\mathrm{d}t)\mathbf{V} = 0.$$

The hydrodynamic model in the nondifferentiable space–time is built, replacing the complex velocity $\mathbf{V} = -2iD\nabla \ln(Ae^{iS})$ (A the amplitude and S the phase), i.e.,

$$\mathbf{V} = \mathbf{v} + i\mathbf{u}, \tag{8a}$$

$$\mathbf{v} = 2D\nabla S, \tag{8b}$$

$$\mathbf{u} = -iD\nabla \ln \rho, \tag{8c}$$

$$\rho = A^2 \tag{8d}$$

in (3) and replacing it in (5). It first follows that

$$-m^{-1}\nabla \cdot U = \{\partial_t(\mathbf{v} - iD\nabla \ln \rho) + [(\mathbf{v} - iD\nabla \ln \rho)\cdot\nabla](\mathbf{v} - iD\nabla \ln \rho) - iD\Delta(\mathbf{v} - iD\nabla \ln \rho)\}. \tag{9}$$

Using the identities

$$\Delta\nabla = \nabla\Delta, \tag{10a}$$

$$(\nabla f \cdot \nabla)(\nabla f) = 2^{-1}\nabla(\nabla f)^2, \tag{10b}$$

$$f^{-1}\Delta f = \Delta \ln f + (\nabla \ln f)^2, \tag{10c}$$

and separating in (9) the real and the imaginary parts [up to an arbitrary phase factor $\beta(t)$ which may be set to zero by a suitable choice of the phase of ψ] we obtain

$$m(\partial_t \mathbf{v} + (\mathbf{v}\cdot\nabla)\mathbf{v}) = -\nabla(U-Q), \tag{11a}$$

$$\partial_t \rho + \nabla\cdot(\rho\mathbf{v}) = 0, \tag{11b}$$

where Q is the quantum potential and has the expression[7]

$$Q = -2mD^2\frac{\nabla^2\sqrt{\rho}}{\sqrt{\rho}}. \tag{12}$$

Another form of (12), i.e.,

$$Q = -mD\nabla\cdot\mathbf{u} - \tfrac{1}{2}m\mathbf{u}^2 \tag{13}$$

is obtained combining the imaginary part **u**, (8c) of the complex velocity (8a), with the relation (12) using the identity (10c). Thus, the quantum potential depends only on the imaginary part of the complex velocity. Since **u** arises of nondifferertiability according to the nondifferentiable space model of quantum mechanics, it might be stressed that the quantum potential comes from the nondifferentiability of the quantum space–time (subquantum medium).

The wave function of $\Psi(\mathbf{r},t)$ is invariant when its phase changes by an integer multiple of 2π. Indeed, Eq. (8b) gives

$$\oint m\mathbf{v}\,\mathrm{d}r = 2mD\oint \mathrm{d}S = 4\pi nmD, \quad n = 0, \pm 1, \pm 2, \ldots \tag{14}$$

a condition of compatibility between the SR hydrodynamic model and the wave mechanics.[8]

For $D=\hbar/2m^*$ with $m^*=2m_e$ the mass of the Cooper pair the relation (14) becomes $\oint \mathbf{p}\cdot\mathrm{d}\mathbf{r} = nh$. This result can be identified with the quantification law of the gravitomagnetic flux $\phi_g = n\phi_{0g}$ with $\phi_{0g}=h/2m_e$ the gravitational fluxoid. Indeed, the generalized momentum of the Cooper pair in the gravitomagnetic field $\mathbf{B}_g=\nabla\times\mathbf{A_g}$ with $\mathbf{A_g}$ the potential vector of the gravitomagnetic field, $\mathbf{P}_g=2m_e\mathbf{v}+2m_e\mathbf{A}_g=\hbar\nabla S+2m_e\mathbf{A}_g$ is null, i.e., $\mathbf{P}_g\equiv 0$.[9]

Through integration we obtain

$$\hbar\oint \nabla S = \pm 2\pi n\hbar = 2m_e\oint \mathbf{A}_g\cdot\mathrm{d}\mathbf{r} = 2m_e\int\int_{\partial\Sigma}\mathbf{B}_g\cdot\mathrm{d}\mathbf{O} = 2m_e\phi_g,$$

i.e.,[9]

$$\phi_g = n\phi_{0g}, \quad \phi_{0g} = h/2m_e.$$

In the magnetic field $\mathbf{B}=\nabla\times\mathbf{A}$ with **A** the potential vector of the electromagnetic field, the generalized momentum of the Cooper pair $\mathbf{P}=\hbar\nabla S+2e\mathbf{A}$ is null, i.e., $\mathbf{P}=0$.[2] From here, by means of integration follows that

$$\hbar\oint \nabla S = \pm 2\pi n\hbar = 2e\oint \mathbf{A}\,\mathrm{d}\mathbf{r} = 2e\int\int_{\partial\Sigma}\mathbf{B}\cdot\mathrm{d}\mathbf{O} = 2e\phi_e.$$

the quantization law of the magnetic flux,[2]

$$\phi_e = n\phi_{0e}, \quad \phi_{0e} = h/2e,$$

with ϕ_{0e} the magnetic fluxoid.

The set of Eqs. (11a) and (11b) represents a complete system of differential equations for the fields $\rho(\mathbf{r},t)$ and $\mathbf{v}(r,t)$; relation (14) relates each solution $(\rho,\mathbf{v})_n$ with the wave solution Ψ in a unique way.

The field $\rho(\mathbf{r},t)$ is a probability distribution, namely the probability of finding the particle in the vicinity d$\mathbf{r}$ of the point $\mathbf{r}$ at time t,

$$d\mathbf{P} = \rho\, dr, \tag{15a}$$

$$\iiint \rho\, dr = 1, \tag{15b}$$

the space integral being extended over the entire area of the system. Any time variation of the probability density $\rho(\mathbf{r},t)$ is accompanied by a probability current $\rho\mathbf{v}$ pointing towards or outward from the corresponding field point $\mathbf{r}$ [Eq. (11b)].

The position probability of the real velocity field $\mathbf{v}(r,t)$ [Eq. (11a)], varies with space and time similar to a hydrodynamic fluid placed in the force field of an external potential $U(\mathbf{r},t)$ and a quantum potential (12). The fluid (in the sense of a statistical particles ensemble) exhibits, however, an essential difference compared to an ordinary fluid, in a rotation motion $\mathbf{v}(r,t)$ increases (decreases) with the decreasing (increasing) distance $\mathbf{r}$ from the center [Eq. (14)].

The expectation values for the real velocity field and the velocity operator $\hat{\mathbf{v}} = -2iD\nabla$ (Ref. 5) of wave mechanics are equal,

$$\langle \mathbf{v} \rangle = \iiint \rho \mathbf{v}\, dr = \iiint \Psi^* \hat{\mathbf{v}} \Psi\, dr = \langle \hat{\mathbf{v}} \rangle_{WM}, \tag{16}$$

but in the higher order, $|n| > 2$, similar identities are invalid, namely $\langle \mathbf{v}^n \rangle \neq \langle \mathbf{v}^n \rangle_{WM}$. The expectation for the quantum force vanishes at all times (theorem of Ehrenfest[8]), i.e.,

$$\langle -\nabla Q \rangle = \iiint \rho(-\nabla Q) d\mathbf{r} = 0 \tag{17}$$

or explicitly

$$2mD^2 \iiint \rho \nabla \left(\frac{\nabla^2 \sqrt{\rho}}{\sqrt{\rho}} \right) d\mathbf{r} = mD^2 \oint (\rho \nabla \nabla \ln \rho) \cdot d\mathbf{\acute{o}} = 0. \tag{18}$$

Two types of fractal stationary states are to be distinguished. (i) Dynamic states. For $\partial/\partial t = 0$ and $\mathbf{v} \neq 0$, Eqs. (11a) and (11b) give

$$\nabla \left(\frac{1}{2} m\mathbf{v}^2 + U - 2mD^2 \frac{\nabla^2 \sqrt{\rho}}{\sqrt{\rho}} \right) = 0, \tag{19a}$$

$$\nabla(\rho \mathbf{v}) = 0, \tag{19b}$$

namely

$$\frac{1}{2} m\mathbf{v}^2 + U - 2mD^2 \frac{\nabla^2 \sqrt{\rho}}{\sqrt{\rho}} = E, \tag{20a}$$

$$\rho \mathbf{v} = \nabla \times \mathrm{F}. \tag{20b}$$

Consequently, inertia $m\mathbf{v} \cdot \nabla \mathbf{v}$, exterior forces $(-\nabla U)$, and quantum forces $(-\nabla Q)$ are in balance at every field point [Eq. (19a)]. The sum of the kinetic energy $m\mathbf{v}^2/2$, external (U), and quantum potential energy (Q) is invariant, i.e., equal to the integration constant $E \neq E(\mathbf{r})$ [Eq. (20a)]. $E \equiv \langle E \rangle$ represents the total energy of the dynamic system. The probability flow density $\rho\mathbf{v}$ has no sources [Eq. (19b)], i.e., its streamlines are closed [Eq. (20b)]. (ii) Static states. For $\partial/\partial t = 0$ and $\mathbf{v} = 0$, Eqs. (11a) and (11b) give

$$\nabla\left(U-2mD^2\frac{\nabla^2\sqrt{\rho}}{\sqrt{\rho}}\right)=0, \tag{21}$$

i.e.,

$$U-2mD^2\frac{\nabla^2\sqrt{\rho}}{\sqrt{\rho}}=E. \tag{22}$$

The exterior force $(-\nabla U)$ is balanced by the quantum force $(-\nabla Q)$ at any field point [Eq. (21)]. The sum of the exterior (U) and interior (Q) potential energy is invariant, i.e., equal to the integration constant $E\neq E(\mathbf{r})$ [Eq. (22)]. $E\equiv<E>$ represents the total energy of the fractal static system.

In the general case, making $U=0$ in Eq. (11a), multiplying it by ρ and taking into account (11b), it becomes[10]

$$\partial_t(m\rho v_k)+\partial_{x_i}(m\rho v_i v_k)=-\rho\partial_{x_k}[2mD^2\rho^{-1/2}\partial_{x_l}\partial_{x_l}\rho^{1/2}]. \tag{23}$$

Using the notation[10]

$$\pi_{ik}=m\rho\mathbf{v}_i\mathbf{v}_k-\sigma_{ik}, \tag{24a}$$

$$\sigma_{ik}=m\rho D^2\partial_{x_l}\partial_{x_k}(\ln\rho), \tag{24b}$$

Eq. (23) takes the simple form[10]

$$\partial_t(m\rho\mathbf{v}_k)=-\partial_{x_l}\pi_{ik}. \tag{25}$$

The analogy with classical fluid mechanics works will if one introduces the cinematic[10]

$$\nu=D/2 \tag{26}$$

and dynamic

$$\eta=\tfrac{1}{2}mD\rho \tag{27}$$

viscosities. Under these circumstances π_{ik} defines the momentum flux density tensor and σ_{ik} the internal stress tensor

$$\sigma_{ik}=\eta(\partial_{x_k}u_i+\partial_{x_l}u_k). \tag{28}$$

Since from (24a) and (24b) one can see that the internal stress tensor is built using the quantum potential, the equations of hydrodynamic model in the nondifferentiable space–time are nothing but a system of equations of the Navier–Stokes type where the quantum potential plays the role of an internal stress tensor. Then the dynamical regime implies the system of equations of Navier–Stokes type, a system which is generally difficult to be solved.

III. STATIC STATES AND KINK TYPE SOLUTIONS

Assimilating the coherent quantum fluid particle (of superfluid or superconducting type) with the vortex type objects, one finds that $U=A\rho$ with $A=A(\Gamma,\hat{\sigma})=\text{const}$—see Appendix B (for details on this problem see also Ref. 8). First, from (22) it results

$$\Delta(\rho)^{1/2}+\frac{E}{2mD^2}\rho^{1/2}-\frac{A}{2mD^2}\rho^{3/2}=0 \tag{29}$$

and with the substitutions

$$\xi = (E/2mD^2)^{-1/2}, \tag{30a}$$

$$f = (A\rho/E)^{1/2}, \tag{30b}$$

$$x_r = (x/\xi), \tag{30c}$$

$$y_r = (y/\xi), \tag{30d}$$

$$z_r = (z/\xi), \tag{30e}$$

it results in the non linear differential equation

$$\Delta f + f(1 - f^2) = 0. \tag{31}$$

We will restrict to the (1D) case, this is

$$\frac{d^2 f}{dx_r^2} = f^3 - f, \tag{32}$$

Multiplying both sides of Eq. (32) by (df/dx_r), and performing integration over x_r we obtain

$$\frac{df}{dx_r} = \sqrt{\frac{1}{2}f^4 - f^2 + C}, \tag{33}$$

where

$$C = \left[\left(\frac{df}{dx_r}\right)^2 - \frac{1}{2}f^4 + f^2\right]_{x=x_r^0}. \tag{34}$$

Equation (34) is obviously a restriction imposed on the order parameter, f, showing the boundary conditions. A further integration of Eq. (33) leads to

$$\frac{x_r - x_r^0}{\sqrt{2}} = \int_0^f \frac{df}{\sqrt{(f_1^2 - f^2)(f_2^2 - f^2)}}, \tag{35}$$

where

$$f_{1,2}^2 = 1 \mp \sqrt{1 - 2C}. \tag{36}$$

By the change of variable $\varphi = f/f_1$, Eq. (35) becomes

$$f_2 \frac{x_r - x_r^0}{\sqrt{2}} = \int_0^{f/f_1} \frac{d\varphi}{\sqrt{(1 - \varphi^2)(1 - k^2\varphi^2)}}, \tag{37}$$

where we made the notation

$$k \equiv f_1/f_2. \tag{38}$$

Writing f_1 and f_2 in terms of k, $f_1^2 = (2k^2/1+k^2)$, $f_2^2 = (2/1+k^2)$, Eq. (37) becomes

$$\frac{x_r - x_r^0}{\sqrt{1 + k^2}} = \int_0^{\varphi_1} \frac{d\varphi}{\sqrt{(1 - \varphi^2)(1 - k^2\varphi^2)}}, \tag{39}$$

where the superior limit is

$$\varphi_1 = f\sqrt{\frac{1+k^2}{2k^2}}.$$

We distinguish two cases, (i) $k \leqslant 1$ and (ii) $k \geqslant 1$. In both cases, Eq. (39) can be solved in the terms of the Jacobian elliptic functions, $\mathrm{sn}(u|k)$, of argument u and modulus k.[11]

(i) For $k \leqslant 1$, the class of solutions of Eq. (39) becomes

$$f = \sqrt{\frac{2k^2}{1+k^2}}\mathrm{sn}\left(\left.\frac{x_r - x_r^0}{\sqrt{1+k^2}}\right| k\right). \tag{40}$$

In the limit $k \to 0$, Eq. (40) can be approximated as

$$f = \sqrt{\frac{2k^2}{1+k^2}}\sin\left(\frac{x_r - x_r^0}{\sqrt{1+k^2}}\right) \to 0 \tag{41}$$

and for $k \to 1$ one obtains the kink solution

$$f = \sqrt{\frac{2k^2}{1+k^2}}\mathrm{th}\left(\frac{x_r - x_r^0}{\sqrt{1+k^2}}\right). \tag{42}$$

It is well known that the Ginzburg–Landau model (GLM) also supports two solutions, zero and hyperbolic tangent which correspond to the Cooper pair.[2]

(ii) If $k > 1$, by the substitution $\eta = f\varphi$, Eq. (39) becomes

$$k\frac{x_r - x_r^0}{\sqrt{1+k^2}} = \int_0^{\eta_1} \frac{\mathrm{d}\eta}{\sqrt{(1-\eta^2/k^2)(1-\eta^2)}} \tag{43}$$

with

$$\eta_1 = f\sqrt{\frac{1+k^2}{2}}$$

which gives the class of solutions

$$f = \sqrt{\frac{2}{1+k^2}}\mathrm{sn}\left(\left.\frac{x_r - x_r^0}{\sqrt{1+k^2}}k\right| \frac{1}{k}\right). \tag{44}$$

We are able now to get the expressions of some superconducting parameters. Thus, from Eqs. (39) and (43), by integration and using the relation which defines the relative coherence length,[2] it results in

$$\xi_r = \begin{cases} (1+k^2)^{1/2}K(k), & k \leqslant 1, \quad (45a) \\ k^{-1}(1+k^2)^{1/2}K(1/k), & k > 1, \quad (45b) \end{cases}$$

where $K(k)$ is the complete elliptic integral of the first kind,[11] $K(k) = \int_0^{\pi/2}(1-k^2\sin^2\varphi)^{-1/2}\,\mathrm{d}\varphi$.

The relative critical speed

$$v_r = \begin{cases} (1+k^2)^{-1/2}K^{-1}(k), & k \leqslant 1, \quad (46a) \\ k(1+k^2)^{-1/2}K^{-1}(1/k), & k > 1, \quad (46b) \end{cases}$$

and the relative pair breaking time

$$\tau_r = \begin{cases} (1+k^2)K^2(k), & k \leqslant 1, \quad (47a) \\ k^{-2}(1+k^2)K^2(1/k), & k > 1 \quad (47b) \end{cases}$$

are deduced from (45a) and (45b) and the relations which define these parameters.[2]

In the 1D case, we can express the relative superconducting carrier concentration as

$$n_r = |f|^2 = \begin{cases} \dfrac{2k^2}{1+k^2}\mathrm{sn}^2\left(\dfrac{x_r - x_r^0}{\sqrt{1+k^2}}\middle| k\right), & k \leqslant 1, \quad (48a) \\ \dfrac{2}{1+k^2}\mathrm{sn}^2\left(\dfrac{k(x_r - x_r^0)}{\sqrt{1+k^2}}\middle| \dfrac{1}{k}\right), & k > 1. \quad (48b) \end{cases}$$

In order to establish a direct connection with experimental observations in the physical systems, the acquired spatial dependence of n_r can be cancelled by averaging $|f|^2$ on a period, $2K$,

$$n_r = \begin{cases} \dfrac{2}{1+k^2}\left(1 - \dfrac{E(k)}{K(k)}\right), & k \leqslant 1, \quad (49a) \\ \dfrac{2}{k(1+k^2)}\left(1 - \dfrac{E(1/k)}{K(1/k)}\right), & k > 1, \quad (49b) \end{cases}$$

where $E(k)$ is the complete elliptic integral of the second kind of modulus k (Ref. 11) $E(k) = \int_0^{\pi/2}(1-k^2\sin^2\varphi)^{1/2}\,\mathrm{d}\varphi$.

By using Eqs. (49a) and (49b) and the London definition of the penetration depth,[2] we obtain the relative penetration depth in the case of spatial gradients

$$\lambda_r = \begin{cases} \left[\dfrac{2}{1+k^2}\left(1 - \dfrac{E(k)}{K(k)}\right)\right]^{-1/2}, & k \leqslant 1, \quad (50a) \\ \left[\dfrac{2}{k(1+k^2)}\left(1 - \dfrac{E(1/k)}{K(1/k)}\right)\right]^{-1/2}, & k > 1. \quad (50b) \end{cases}$$

For the relative critical field, we derive the expression

$$B_r = \begin{cases} \dfrac{2}{1+k^2}\sqrt{2\left(1 - \dfrac{E(k)}{K(k)}\right)}, & k \leqslant 1, \quad (51a) \\ \dfrac{2}{k(1+k^2)}\sqrt{2\left(1 - \dfrac{E(1/k)}{K(1/k)}\right)}, & k > 1. \quad (51b) \end{cases}$$

The relative critical current density

$$j_r = \begin{cases} \dfrac{2}{(1+k^2)^{3/2}}\left(\dfrac{1}{K(k)} - \dfrac{E(k)}{K^2(k)}\right), & k \leqslant 1, \quad (52a) \\ \dfrac{2}{(1+k^2)^{3/2}}\left(\dfrac{1}{K(1/k)} - \dfrac{E(1/k)}{K^2(1/k)}\right), & k > 1 \quad (52b) \end{cases}$$

is obtained from (46a), (46b), (49a), and (49b) and the expression which defines j_r.

The important characteristics of the material versus k are illustrated in Figs. 2(a)–2(g). One can notice a clear discontinuity at $k=1$ for all superconducting parameters. This leads to the idea that the point $k=1$, could be associated with the transition from superconducting into normal state.

IV. TEMPERATURE DEPENDENCES OF THE SUPERCONDUCTING PARAMETERS

Probably the most important physical consideration which concerns our results, from the applicative point of view, is that we need to introduce the temperature dependences of the superconducting parameters. Taking into account that all the superconducting parameters suffer a discontinuity for $k=1$ [as can been seen in Figs. 2(a)–2(g)], one can admit the following functional dependence of the modulus of the elliptic function on the reduced temperature:

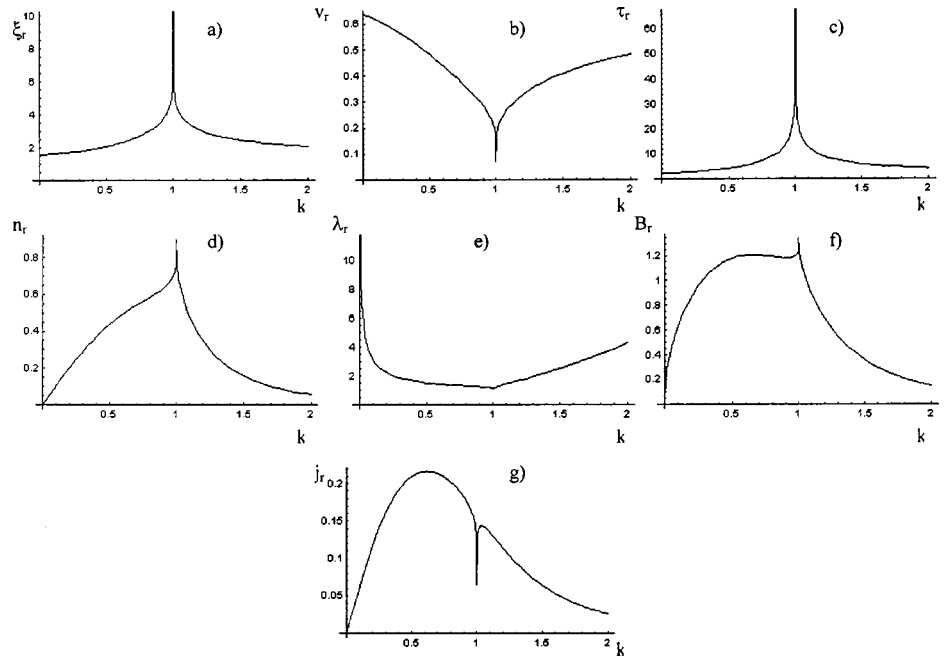

FIG. 2. (a) The k dependence of the relative coherence length. (b) The k dependence of the relative critical speed. (c) The k dependences of the relative pair breaking time. (d) The k dependences of the average relative concentration. (e) The k dependences of the relative penetration depth. (f) The k dependences of the relative critical field. (g) The k dependences of the relative critical current density.

$$k = t = T/T_C. \tag{53}$$

To avoid the confusion and to obtain the exact temperature dependences of the superconducting parameters, we will admit adequate normalizations of these parameters and the restriction $k<1$. Thus, the dependence on t of the coherence length is

$$(\xi(t)/\xi(0)) = (2/\pi)(1+t^2)^{1/2}K(t). \tag{54}$$

Figure 3(a) shows the relation (54) in comparison with the one given by the BCS theory,[2] i.e., $(\xi(t)/\xi(0))=(1-t^2)^{-1/2}$ (dashed line). In the relation (54) $K(t)=\int_0^{\pi/2}(1-t^2\sin^2\varphi)^{-1/2}\,d\varphi$.

The dependence on t of the critical speed is

$$(v_C(t)/v_C(0)) = (\pi/2)(1+t^2)^{-1/2}K^{-1}(t). \tag{55}$$

In Fig. 3(b) one can see the comparison between the (55) dependence and the one given by the BCS theory,[2] i.e., $(v_C(t)/v_C(0))=(1-t^2)^{1/2}$ (dashed line).

The dependence on t of the pair breaking time is

$$(\tau(t)/\tau(0)) = (4/\pi^2)(1+t^2)K^2(t). \tag{56}$$

Figure 3(c) presents together the dependence (56) and the one given by BCS theory,[2] i.e., $(\tau(t)/\tau(0))=(1-t^2)^{-1}$ (dashed line).

Comparing with the BCS theory,[2] similar behaviors of the coherence length [Fig. 3(a)], critical speed [Fig. 3(b)] and pair breaking time [Fig. 3(c)] can be observed.

In order to get the dependence of the concentration on t one admits first that

$$(n(t)/n(0)) = \rho = (E/A)f^2 \approx (\xi(0)/\xi(t))^2 f^2 = 3.7\cdot(1+t^2)^{-1}K^{-2}(t)f^2 \tag{57}$$

with

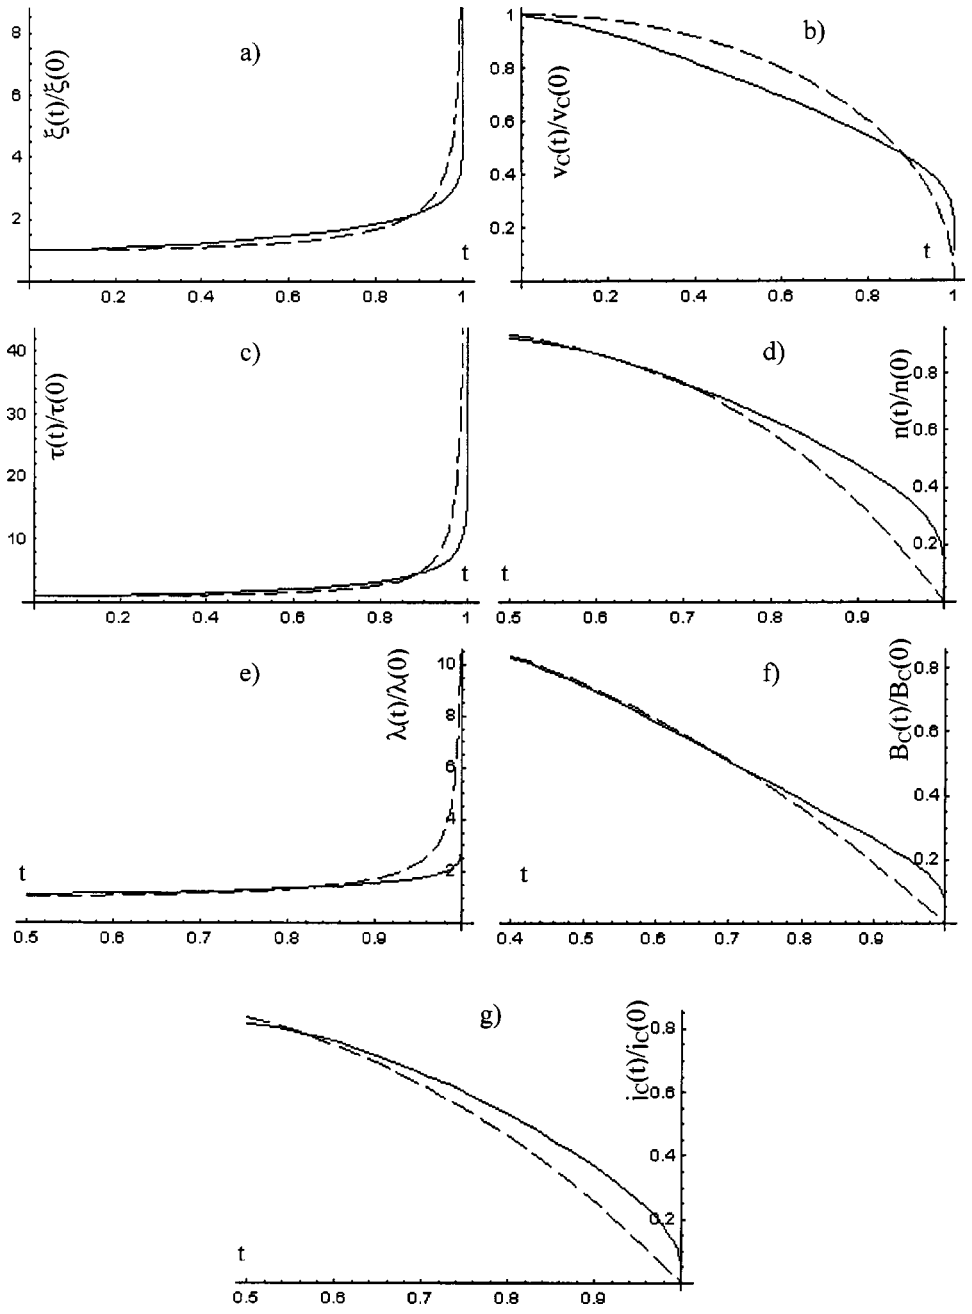

FIG. 3. (a) The t dependence of the relative coherence length in comparison with the one given by BCS theory. (b) The t dependences of the relative critical speed in comparison with the one given by BCS theory. (c) The t dependence of the relative pair breaking time in comparison with the one given by BCS theory. (d) The t dependence of the average relative concentration in comparison with the experimental one. (e) The t dependence of the relative penetration depth in comparison with the one given by bifluid model. (f) The t dependences of the relative critical field in comparison with the one given by BCS theory. (g) The t dependence of the relative critical current density in comparison with the one given by BCS theory.

$$(2mD^2/A) = \xi^2(0), \tag{58a}$$

$$(2mD^2/E) = \xi^2(t). \tag{58b}$$

By inserting Eq. (49a) in Eq. (57) one finds

$$(n(t)/n(0)) = 3.7 \cdot (1+t^2)^{-2}K^{-2}(t)[1-(E(t)/K(t))]. \tag{59}$$

The concordance with the experimental data described by $(n(t)/n(0))=(1-t^4)$ (Ref. 2) (dashed line) is good in the limits $0.5<t<1$, as can be seen in Fig. 3(d). As temperature decreases, the superconducting concentration is recovered. Consequently, our equation can describe the superconducting behavior starting from temperatures equal to $0.5T_c$ until the critical temperature.

The reduced temperature dependence of the penetration depth

$$(\lambda(t)/\lambda(0)) = 0.55 \cdot (1+t^2)K(t)[1-(E(t)/K(t))]^{-1/2} \tag{60}$$

is in agreement with the data of the bifluid model $(\lambda(t)/\lambda(0))=(1-t^4)^{-1/2}$ [2] [dashed line, Fig. 3(e)], for $0.5<t<1$.

In the case of the critical field,

$$(B_C(t)/B_C(0)) = 7.67 \cdot (1+t^2)^{-2}K^{-2}(t)[1-(E(t)/K(t))]^{1/2} \tag{61}$$

the concordance with the experimental data, which is well described by $(B_C(t)/B_C(0))=(1-t^2)^2$ (dashed line), can be seen in Fig. 3(f), where Eq. (61) fits data for $0.4<t<1$.

The dependence on t of the critical current density is

$$(j_C(t)/j_C(0)) = 26.7 \cdot (1+t^2)^{-3/2}K^{-3}(t)[1-(E(t)/K(t))]. \tag{62}$$

In Fig. 3(g) one can see the comparison between the (62) dependence and the one given by the BCS theory,[2] i.e., $(j_C(t)/j_C(0))=(1-t^2)^{1/2}(1-t^4)^{1/2}$ (dashed line). The concordance is good in the limits $0.5<t<1$.

Summarizing this section, we would emphasize that the derived expressions of the superconducting parameters $(n(t),\lambda(t),B_C(t),j_C(t))$ are amendable to experimental verifications in the range about $0.5<t<1$. At the same time, $\xi(t),v_C(t),\tau(t)$ have similar behaviors for $0<t<1$.

V. NONDIFFERENTIABILITY AND SUPERCONDUCTIVITY

The choice $U=A\rho$—see Sec. III, induces nondifferentiability through the imaginary speed **u**. In particular, for $k\to 0$, $x^0/\xi \equiv K(k)$ and an adequate normalization, from (40), (44), and (8c) it results $u=D\partial_x \ln(\mathrm{cn}(x_r))=(D/\xi)(\mathrm{sn}(x_r)\mathrm{dn}(x_r)/\mathrm{cn}(x_r))$. From here, the two-dimensional (2D) generalization of the real speed field, $\Omega=\ln(u\xi/D)$, i.e.,

$$\Omega = \Gamma \ln\left[\frac{\mathrm{sn}(\underline{u})\mathrm{dn}(\underline{u})}{\mathrm{cn}(\underline{u})}\right] \tag{63}$$

with

$$\underline{u} = \frac{K}{a}\underline{z}, \tag{64a}$$

$$\underline{z} = x + iy, \tag{64b}$$

$$K/K' = b/a, \tag{64c}$$

$$K = \int_0^{\pi/2} (1-k^2\sin^2\varphi)^{-1/2}\,\mathrm{d}\varphi, \tag{64d}$$

$$K' = \int_0^{\pi/2} (1-k'^2\sin^2\varphi)^{-1/2}\,\mathrm{d}\varphi, \tag{64e}$$

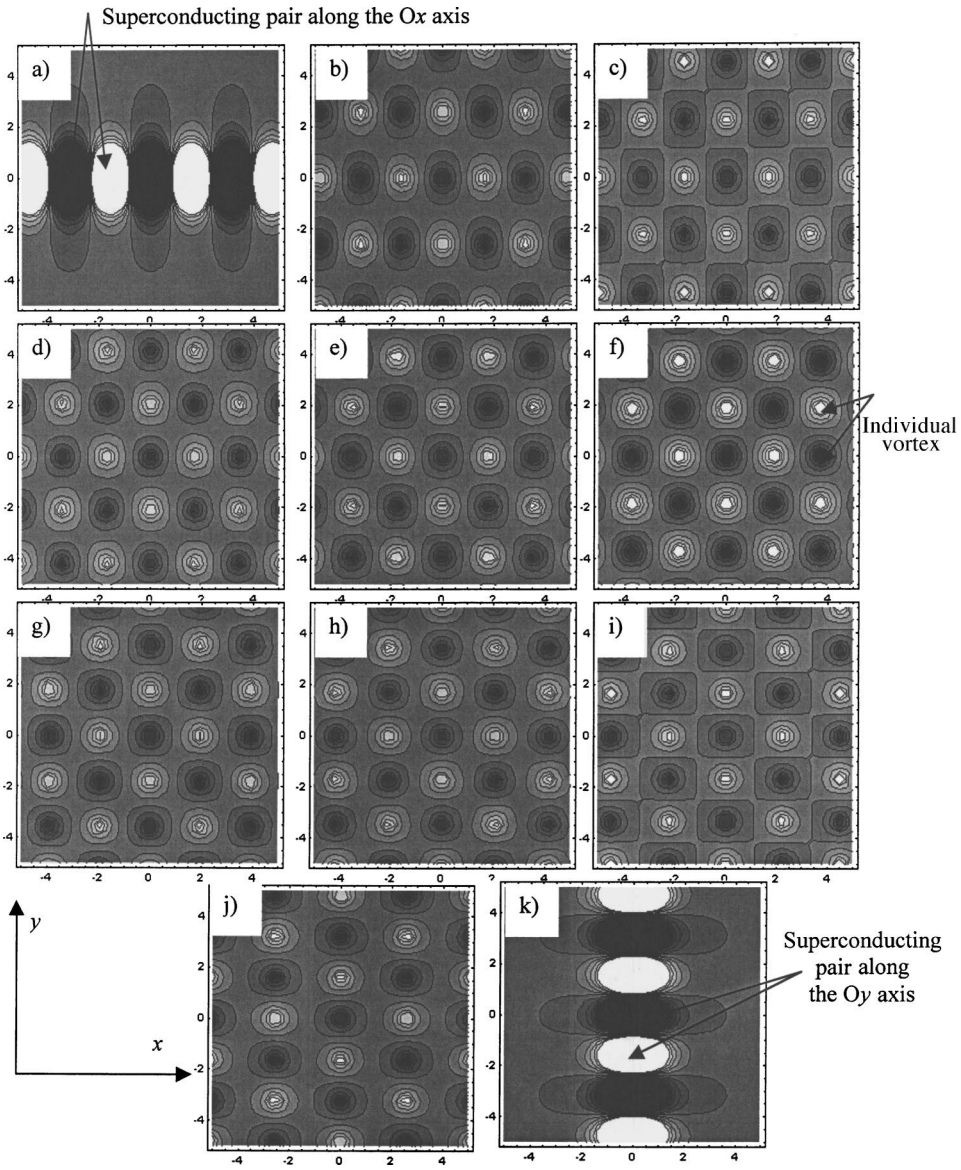

FIG. 4. (a)–(k) The k dependences, of the equipotential lines corresponding to the real part of the complex potential (63). Superconducting pairs along the Ox and Oy axes.

$$k^2 + k'^2 = 1 \tag{64f}$$

describes the stable distribution—the bipolarons[1,2,12] from Fig. 1(b).

In relations (63) and (64a)–(64d) cn, dn are the Jacobi elliptic functions,[11] K, K' the complete elliptic integrals of first kind of k modulus,[11] a, b the lattice constants along Ox and Oy axis, respectively, and Γ the vortex constant.[13] In Figs. 4(a)–4(k) one shows the equipotential curves $\mathrm{Re}\,\Omega = 0$ for $k = 0$–1 and in Fig. 5 the corresponding fractal dimension $\mathbf{D}$ (Ref. 14) dependence with k, i.e., $\mathbf{D} = \mathbf{D}(k)$. The following aspects result.

(i) The parameter k gives the vortices coherence in the lattice (the phase and amplitude correlation of the vortices[13,15]). For $k = 0$ and $k = 1$ the coherence is maximum through vortex pairs forming, along Ox axis [Fig. 4(a)] or Oy axis [Fig. 4(k)], respectively. For $k = 0.5$ the coherence is minimum through vortex individualizing [Fig. 4(f)].

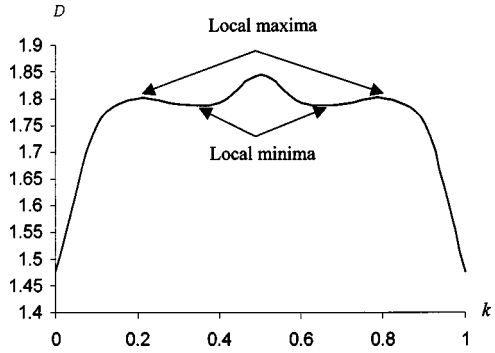

FIG. 5. The k dependence of the fractal dimension. It results that through k the fractal dimension is a measure of the coherence degree.

Mathematically, the vortices coherence implies $\Omega(u)=\Omega(u')$. Such a relation occurs if, and only if, between u and u' it exists the homography

$$u=\frac{au'+b}{cu'+d},$$

where $a, b, c, d \in \mathrm{N}$, $ad-bc\equiv 1$, $u=\omega_2/\omega_1$, $u'=\omega_2'/\omega_1'$, (ω_2/ω_1) and (ω_2'/ω_1') being the fundamental period pairs of a two equivalent elliptic function $(\mathrm{sn}\cdot\mathrm{dn}/\mathrm{cn})$—the equivalence theorem of elliptic functions.[11] In particular, for $c=1$ and $d=0$, the vortices coherence is generated by the $\varepsilon^{(\infty)}$ space–time[16]—see Appendix C. Therefore, the vortices amplitude and phase correlations in the lattice are of Cantorian type [for example, in the vortices synchronization by frequency looking, the frequency ratio is $v=1/(2n+1)$ (Ref. 2)]. Such result implies the fractionar statistics, i.e., the anyonic mechanism.[2]

(ii) The $\mathbf{D}=\mathbf{D}(k)$ curve symmetry shows the simultaneous coherence extension along this two axis, i.e., in plane. Besides, for the high temperature superconductivity, the coherence in the superconducting pairs form is achieved only in Cu–O planes.[2,17]

(iii) The fractal dimension varies from the minimum $\mathbf{D}\approx 1.445$, and local minima $\mathbf{D}\approx 1.755$, to maxima $\mathbf{D}\approx 1.850$ and local maxima $\mathbf{D}\approx 1.80$, respectively. Moreover, the observations superconducting pair–superconducting pair correlations can be associated with a (limited) fractal with dimension of $\mathbf{D}\approx 1.80$.[2,14] This fractal dimension represents a manifestation of the fact that the observed fractal should have emerged from two-dimensional sheetlike objects (superconductivity is a property characterizing 2D objects[2,17]).

(iv) Figures 4(a) and 4(k) correspond to the final structures developed in the coherence process and Figs. 4(e)–4(g) to the initial ones. Furthermore, the time evolution of the coherence process given by the iterated map of the $(\mathrm{sn}\,\mathrm{dn}/\mathrm{cn})$ function shows that this is generated by means of a fractal (superconducting fractal) (Fig. 6) [its fractal dimension (or Hausdorff–Besicovich dimension[14]), $\mathbf{D}\approx 2.4$ is greater than the topological one $\mathbf{D}\approx 2$] In such a context, the structures described by Figs. 4(a)–4(k), i.e., the coherence sequences, are projections of the superconducting fractal.

VI. ONE-DIMENSIONAL PROJECTION OF A SUPERCONDUCTING FRACTAL: COOPER PAIRS

Let us demonstrate that the superconducting pairs are 1D projections of the superconducting fractal from Fig. 6. Having this aim in view, let us consider the potential projection along Ox axis, i.e.,

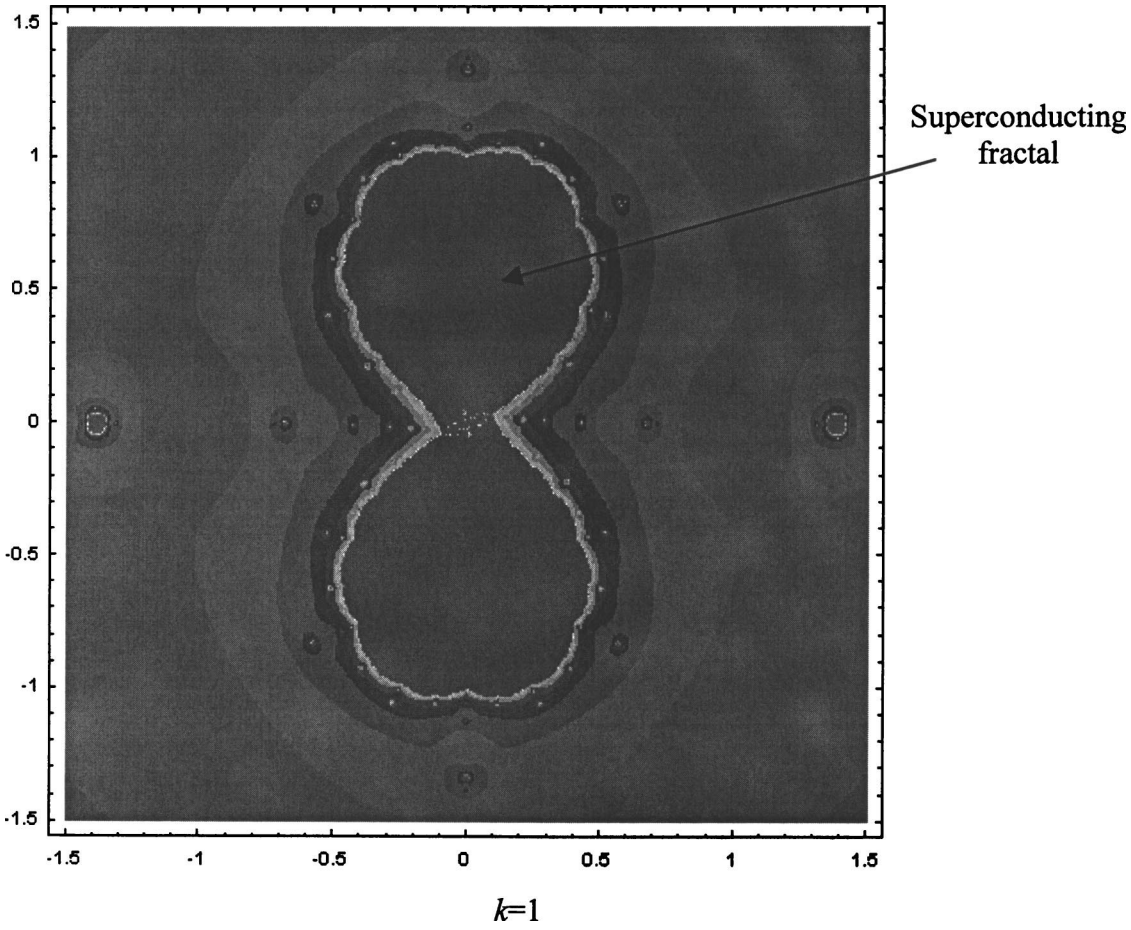

FIG. 6. The superconducting fractal given by an iterated map of the (sn dn/cn) function.

$$\Omega(x;k) = \Gamma \ln\left[\frac{\mathrm{sn}\left(\frac{K}{a}x;k\right)\mathrm{dn}\left(\frac{K}{a}x;k\right)}{\mathrm{cn}\left(\frac{K}{a}x;k\right)}\right]. \tag{65}$$

The quantum states, being stationary and with $E=0$ (for details see Refs. 8 and 17), Eq. (22), with $U=\Omega(x;k)$ and substitutions

$$\sqrt{\rho} = f, \tag{66a}$$

$$(Kx/a) = u \tag{66b}$$

takes the form

$$\frac{d^2f}{dx^2} - \left(\frac{\Gamma}{2mD}\right)\ln\left(\frac{\mathrm{sn}(u)\mathrm{dn}(u)}{\mathrm{cn}(u)}\right)f = 0, \tag{67}$$

The nonlinear Helmholtz like Eq. (67) can be solved only approximately. Using the WKBJ method[8,12] we get

$$f \sim \frac{A}{\sqrt{p}} e^{\mp \int p \, dx}, \tag{68a}$$

$$A = \text{const} \tag{68b}$$

with

$$p^2 = \frac{1}{\Lambda^2} \ln\left(\frac{\text{sn}(u)\text{dn}(u)}{\text{cn}(u)}\right) \tag{69a}$$

$$\frac{1}{\Lambda^2} \equiv \frac{\Gamma}{2mD^2}, \tag{69b}$$

Λ being a dissipation characteristic length (Kolmogorov model),[14] i.e., the minimal dimension of a vortexlike particle. Then, the density of probability ρ becomes

$$\tilde{n} \approx \frac{A^2 \ddot{E}^2}{\ln\left(\frac{\text{sn}(u)\text{dn}(u)}{\text{cn}(u)}\right)} \exp\left[\mp \frac{2a}{\ddot{E}K(k)} \int \sqrt{\ln\left(\frac{\text{sn}(u)\text{dn}(u)}{\text{cn}(u)}\right)} du \right]. \tag{70}$$

The integral from Eq. (70) can be rewritten in the form

$$\Im = \int \sqrt{\ln\left(\frac{\text{sn}(u)\text{dn}(u)}{\text{cn}(u)}\right)} du = \mp \frac{1}{2} \int \frac{\sqrt{\mu}\, d\mu}{\sqrt{\cosh^2 \mu - k^2}}, \tag{71}$$

for

$$\mu = \ln\left(\frac{\text{sn}(u)\text{dn}(u)}{\text{cn}(u)}\right). \tag{72}$$

In the general case this integral cannot be evaluated. However, for $k=0$ the integral (71) takes the form

$$\Im = \mp \frac{1}{2} \sum_{n=0}^{\infty} \frac{E_{2n}}{(2n)\left(2n+\frac{3}{2}\right)} \mu^{(2n+3/2)} \quad \left(|\mu| < \frac{\partial}{2}\right) \tag{73}$$

with E_{2n} the Euler constants ($E_0=1, E_1=0, E_2=-1, E_3=0$). Finally, substituting in the integral (71)

$$\text{sn}(u,0) = \sin u, \quad \text{cn}(u,0) = \cos u, \quad \text{dn}(u,0) = 1, \quad K(0) = \partial/2, \tag{74}$$

the density ρ becomes

$$\tilde{n} \approx \frac{A\ddot{E}^2}{\ln\left[\text{tg}\left(\frac{\partial x}{2a}\right)\right]} \exp\left\{ \mp \frac{2a}{\partial x} \sum_{n=0}^{\infty} \frac{E_{2n}}{(2n)\left(2n+\frac{3}{2}\right)} \left[ln\left(\text{tg}\frac{\partial x}{2a}\right)\right]^{(2n+3/2)} \right\}. \tag{75}$$

The relation (75) works only with the restriction

$$\frac{1}{p}\frac{d}{dx}(\ln p) \ll 1 \tag{76}$$

that is true for domains closed to the zeros of the same sign of the potential (63) (for details see Ref. 15). In the relation (75) we can consider only the first four series terms because the others are negligible—Fig. 7. In Fig. 8 the density ρ is plotted as a function of x and a/Λ. One notices that for a/Λ ratio values greater than 10^3, the density splits into two parts, signifying the formation of

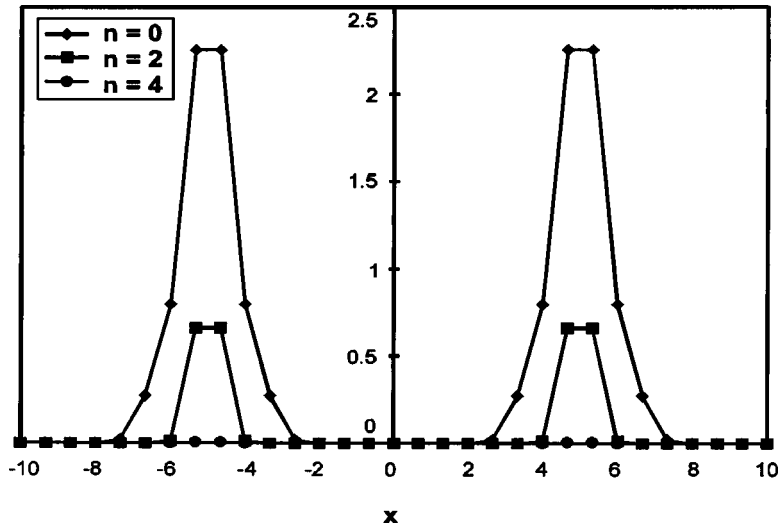

FIG. 7. The representation of the first four series terms of (75).

the superconducting pairs. In such a context, if $\Lambda \approx \Lambda_C \approx 3.8 \times 10^{-13}$ m (the minimal dimension of the vortexlike particle is the electron wavelength[2,17]) than $a > 3.8 \times 10^{-10}$ m. Such a value corresponds to the minimum distance between two vortices to form a pair (coherence length—for details see Refs. 2 and 17).

The case $k=1$ is presented in Figs. 9(a) and 9(b). It also results the superconducting pair (Cooper pair) forming—the states density is symmetric on $x=0$ and increases toward $k=1$.

VII. CONCLUSIONS

The main conclusions of the present paper are as follows.

(i) In the hydrodynamic formulation of the SR theory one obtains the conservation equations of momentum and probability density.

(ii) Through momentum conservation law one introduces the quantum potential as a measure of nondifferentiability of the quantum space–time. In such a frame, the quantum space–time is identified with a subquantum medium of superfluid properties.

(iii) One finds the compatibility relation between the SR hydrodynamic model and the wave mechanics and one defines the dynamic and static states.

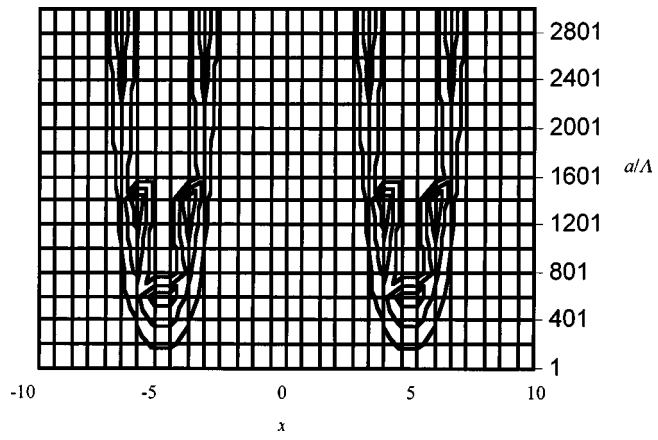

FIG. 8. 2D dependence of the density (75) on x and a/Λ.

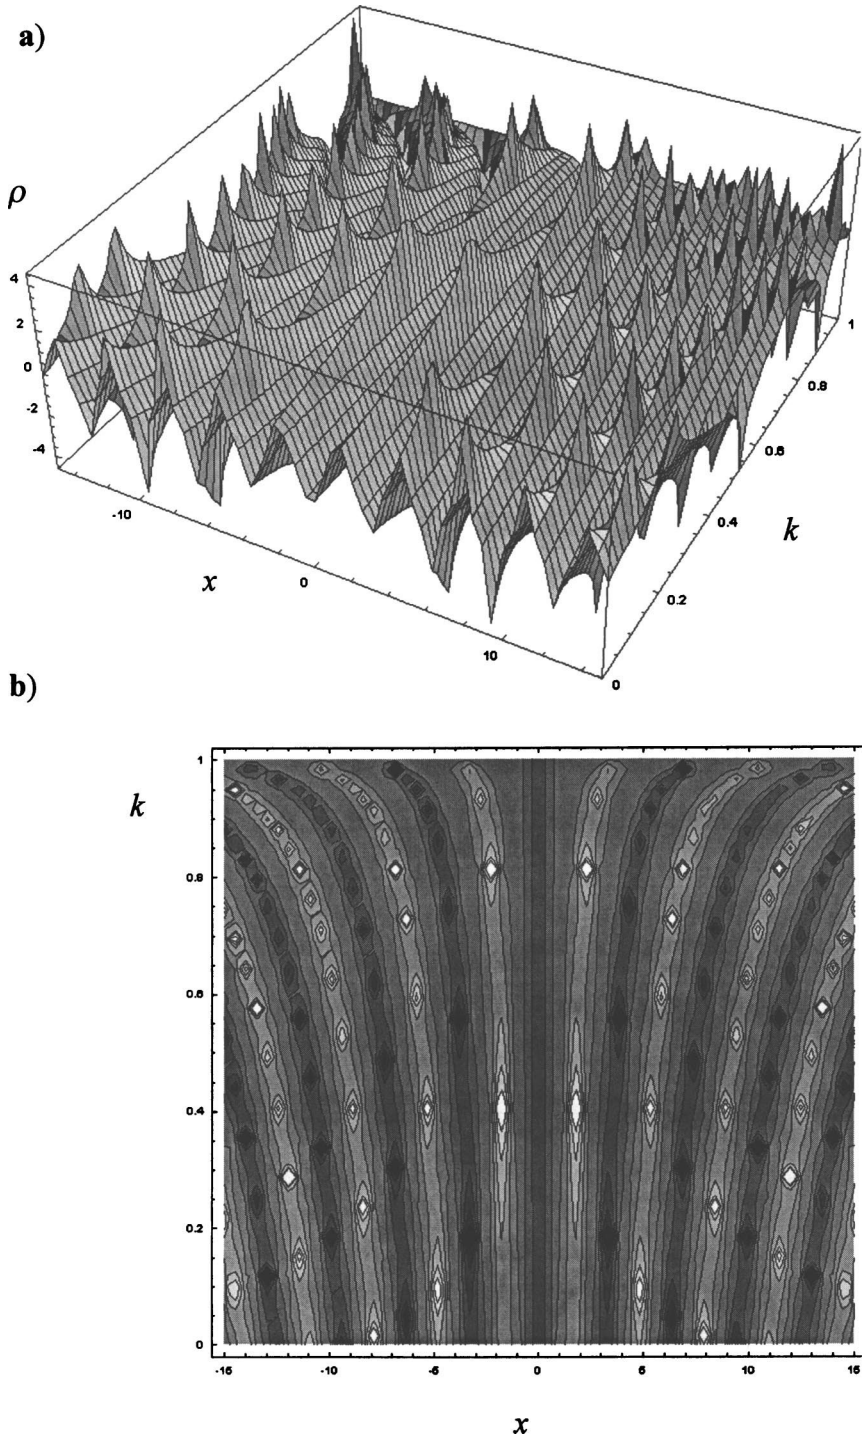

FIG. 9. (a) 3D dependence of the density (75) on x and k. (b) 2D dependence of the density (75) on x and k.

(iv) One defines a stable vortex lattice of bipolaron type by means of the potential (63) and one specifies some of its properties (the equipotential curves, the fractal dimensions variation, etc). In such a context, by an iterated map, one builds the superconducting fractal.

(v) One demonstrates that the superconducting pairs are 1D projections of this fractal. Mathematically, the problem resumes to the determination of the probability field obtained by identi-

fying the quantum potential (12) with the projection on Ox axis of complex potential (63). It results the splitting of the probability field that in our opinion corresponds to a superconducting pair (Cooper pair). In such a context, one gives an evaluation of the coherence length.

(vi) The superconductivity in such structures is achieved through the coherence on the subquantum medium.

(vii) The temperature dependences of the superconducting parameters are given and the concordances with experimental data and other theories are analyzed.

(viii) If $S=\text{const}$ and $\nabla\cdot\mathbf{u}=\Delta\ln\rho=0$ (the quantum fluid is incompressible), the 1D Eq. (22) admits for $E=A=\text{const}$ the speed fields

$$u_x = i[(2A/m)(1-\rho)]^{1/2}.$$

Then, the quantum potential takes a very simple expression which is proportional to the density of states of the Cooper pairs, i.e.,

$$Q = -(mu_x^2/2) = A(1-\rho).$$

When the density of states of the Cooper pairs becomes zero (i.e., the material is normal) the quantum potential takes a finite value, A, and when it becomes 1 (i.e., the entire material becomes superconducting), the quantum potential turns to zero—the entire quantity of energy from the subquantic medium transfers to the superconducting pairs. Consequently, one can assume the energy from the background subquantic medium can be stoked by transforming all the particles from the environment into Cooper pairs and then "freezing" them. The superconductor acts like a subquantic medium energy accumulator.

(ix) In the SR theory the space–time of quantum mechanics is continuous and nondifferentiable. Nondifferentiability is induced by means of the fractal, a global mechanism when explaining superconductivity, the 2D projection of the fractal generates the mechanism responsible of the type II superconductivity (the anyonic mechanism[2]) and the 1D projection the mechanism responsible of the type I superconductivity (the Cooper pairs). In such a context, by means of the generalized coherence of the quantum fluid the superconducting parameters occur as intrinsic properties of this fluid.

APPENDIX A

Strictly, the nondifferentiability of the coordinates means that the velocity $V=\mathrm{d}X/\mathrm{d}t$ is no longer defined. However, continuity and nondifferentiability implies scale divergence.[5,14] Therefore, the basis of the method consists in replacing the classical velocity by a function that explicitly depends on the resolution, $V=V(\varepsilon)$. Only $V(\varepsilon)$ is undefined, while $V(\varepsilon)$ is now defined for any nonzero ε. The scale dependence of the velocity forces one to complete the standard equations of physics by differential equations of scale. The simplest possible equation that one can write for V is a first order, renormalization-group-like differential equation, written in terms of the dilatation operator $d/d\ln\varepsilon$,[5] in which the infinitesimal scale dependence of V is determined by the field V itself, namely,

$$\frac{\mathrm{d}V}{d\ln\varepsilon} = \Gamma(V). \tag{A1}$$

The -function here is *a priori* unknown, but we can use the fact that $V<1$ (in motion-relativistic units) to expand it in terms of a Taylor expansion. One obtains

$$\frac{dV}{d\ln\varepsilon} = a + bV + O(V^2), \tag{A2}$$

where a and b are constants (independent of ε, but possibly dependent on the space–time coordinates). Setting $b=-\delta$ and $a=r\delta$, we obtain the solution of this equation under the form

$$V = v + k\varepsilon^{-\delta}, \tag{A3}$$

where k is an integration constant (independent of ε). From the dimensional analysis, we can write it under the form $k=\zeta\lambda^{\delta}$, with $\_=\_(t)$ dimensionless, $\langle\zeta^2\rangle=1$ and $\_$ a constant length scale. We get

$$V = v + \zeta\left(\frac{\lambda}{\varepsilon}\right)^{\delta}. \tag{A4}$$

We recognize here a typical fractal behavior with fractal dimension $\mathbf{D}=\mathbf{D}_{\tau}+\delta$, where $\mathbf{D}_{\tau}$ is the topological dimension (=1 here, since the description concerns displacements along geodesical curves). However, at large scales $\varepsilon \gg \lambda$, the velocity shows a classical (i.e., scale independent) behavior, $V\approx v$, while at small scales $\varepsilon ll \lambda$, it shows a power law, scale divergent behavior $V \approx \zeta(\lambda\varepsilon^{-1})^{\delta}$. The transition scale $\_$ (that will be interpreted in what follows as the Compton scale) thus stands out as a fractal–nonfractal transition scale (that takes place not in space, but in the new resolution dimension).

The resolution ε in the above formula is a space resolution, $\varepsilon=\delta X$. We can relate it to time resolution by writing (A4) in the asymptotic domain $\varepsilon<\lambda$ under the form

$$\frac{\delta X}{c\,\delta t} \approx \left(\frac{\lambda}{\delta X}\right)^{\mathbf{D}-1}. \tag{A5}$$

This provides us with a fundamental, well-known formula on fractals,

$$\delta X^{\mathbf{D}} = \lambda^{\mathbf{D}-1} c\,\delta t. \tag{A6}$$

By reinserting this result in (A4), we obtain the following expression (where we have reinserted the indices) for the elementary displacement in terms of time-resolution:[5]

$$dX^i = v\,dt + \lambda^{l-1/\mathbf{D}}\zeta^i (c\,dt)^{1/\mathbf{D}}, \tag{A7}$$

where we have identified the time resolution with the time differential element.

As we shall see in what follows, the first terms yields classical physics while the second is one of the sources of quantum behavior. They are both present whatever the scale, but the classical term is dominant at large scales while the quantum term is dominant at small scales. Then, the quantum and classical laws are irreducible to each other, but they both find their origin in a single, more profound, scale-dependent description whose equations take the form given by (A1) in the simplest case. In the special case of fractal dimension $\mathbf{D}=2$, the time transition is easily identified with the de Broglie time scale $\tau\approx c\lambda/v^2=\hbar/mv^2$, by writing (A7) under the form

$$dX = v\,dt\left[-\zeta(c\lambda/v^2\,dt)^{1/2}\right], \tag{A8}$$

The nondifferentiable nature of space–time implies an even more dramatic consequence, namely, a breaking of differential time reflection invariance. Let us consider indeed the usual definition of the derivative of a given function with respect to time

$$\left(\frac{df}{dt}\right) = \lim_{dt\to 0}\frac{f(t+dt)-f(t)}{dt} = \lim_{dt\to 0}\frac{f(t)-f(t-dt)}{dt}. \tag{A9}$$

The two definitions are equivalent in the differentiable case. One passes from one to the other by the transformation $dt\to -dt$ (time reflection invariance at the infinitesimal level). In the nondiffer-

entiable situation considered here, both definitions fail, since the limits are no longer defined. The scale-relativistic method solves this problem in the following way.

We attribute to the differential element dt the new meaning of a variable, identified with a time resolution, $dt=\delta t$ (substitution principle). The passage to the limit $dt\to 0$ is actually devoid of physical meaning (an infinite energy would be needed to really perform a measurement at zero time resolution interval). The physics is now in the behavior of the function during the zoom operation on dt. The two functions f'_+ and f'_- are now defined as explicit functions of t and of dt,

$$f'_+(t,dt)=\frac{f(t+dt)-f(t)}{dt},$$
$$f'_-(t,dt)=\frac{f(t)-f(t-dt)}{dt}. \tag{A10}$$

When applied to the space variable, we get for each geodesic two velocities that are fractal functions of resolution, $v_+(t,dt)$ and $v_-(t,dt)$. In order to go back to the classical microscopic domain, we smooth out each geodesic with balls of radius larger than _ (the fractal/nonfractal transition), then we take the average on the whole set of geodesics. We get two mean velocities $v_+(t)=\langle v_+(t,dt\gg\tau)\rangle$ and $v_-(t)=\langle v_-(t,dt\gg\tau)\rangle$, but after this double averaging process, there is no reason for these two velocities to be equal, contrarily to what happens in the classical, differentiable case.[5]

In summary, while the concept of velocity was classically a single concept, we must introduce, if space–time is nondifferentiable, two velocities instead of one even when going back to the classical domain. Such a two valuedness of the velocity vector is a specific consequence of nondifferentiability that has no standard counterpart (in the sense of differential physics), since it finds its origin in a breaking of the symmetry ($dt\to -dt$). Such a symmetry was considered self-evident up to now in physics (since the differential element dt disappears when passing to the limit), so that it has not been analyzed on the same footing as the other well-known symmetries. Note that it is actually different from the time reflection symmetry T, even though infinitesimal irreversibility implies global irreversibility.

Now, at the level of our description, we have no way to favor v_+ rather than v_-. Both choices are equally qualified for the description of the laws on nature. The only solution to this problem is to consider both the forward ($dt>0$) and backward ($dt<0$) processes together. The number of degrees of freedom is doubled with respect to the classical, differentiable description (six velocity components instead of three).

A simple and natural way to account for this doubling of the needed information consists in complex number and the complex product. As we shall recall hereafter, this is the origin of the complex nature of the wave function in quantum mechanics, since the probability amplitude is defined in terms of the complex action that is naturally introduced in such a theory. But one can demonstrate that the complex calculus is nothing but a particular choice of representation that achieves the simplest description. Namely, using a different product would introduce additional terms in the Schrödinger equation.[5] Note also that the new complex process, as a whole, recovers the fundamental property of microscopic reversibility.

We then can write

$$dX^i_\pm = dx^i_\pm + d\xi^i_\pm, \tag{A11}$$

respectively, for the forward process (+) and backward process (−). From our above discussion, the fluctuation $d\zeta_\pm$ is written

$$\left\langle \frac{\mathrm{d}\xi_{\pm}^{i}}{\mathrm{d}t}\frac{\mathrm{d}\xi_{\pm}^{j}}{\mathrm{d}t}\right\rangle = \pm\,\delta^{ij}c^{2}\left(\frac{\lambda}{c\,\mathrm{d}t}\right)^{2-2/\mathbf{D}}. \tag{A12}$$

This relation is invariant under translations and rotations in space between Cartesian coordinate systems. In the special, Galilean scale-relativistic case that we consider here, the scale invariant is the fractal dimension itself. The fractal dimension of typical quantum mechanical paths is $\mathbf{D}=2$. We shall reduce our discussion in what follows to this particular case. When $\mathbf{D}=2$, (A12) becomes

$$\left\langle \mathrm{d}\xi_{\pm}^{i}\mathrm{d}\xi_{\pm}^{j}\right\rangle = \pm\,\lambda\delta^{ij}c\,\mathrm{d}t. \tag{A13}$$

We can now jump to the second step of the fractal-space description, by constructing the covariant derivative that describes the combined effects of the new displacement laws and scale laws. We define mean forward (+) and backward (−) derivatives, which, once applied to x', yield the above forward and backward mean velocities

$$\frac{d_{+}x^{i}(t)}{\mathrm{d}t} = v_{+}^{i}, \tag{A14a}$$

$$\frac{d_{-}x^{i}(t)}{\mathrm{d}t} = v_{-}^{i}. \tag{A14b}$$

The averaging is here taken on the family of geodesics. As a consequence, the Born statistical interpretation of quantum mechanics will be ensured from the very beginning of our construction, since the particle can be identified with one random geodesic among their infinite set (more generally, with the subset of the geodesics that share the geometric properties that correspond to a given measurement result). The forward and backward derivatives of (A14a) and (A14b) can be combined in terms of a complex derivative operator,[5]

$$\frac{\delta}{\mathrm{d}t} = \frac{(d_{+}+d_{-})-i(d_{+}-d_{-})}{2\,\mathrm{d}t} \tag{A15}$$

which, when applied to the position vector, yields a complex velocity

$$\mathbf{V}^{i} = \frac{\delta}{\mathrm{d}t}x^{i} = \mathbf{V}^{i} - iU^{i} = \frac{v_{+}^{i}+v_{-}^{i}}{2} - i\frac{v_{+}^{i}-v_{-}^{i}}{2}. \tag{A16}$$

Consider a function $f(X,t)$, and expand its total differential to second order. We get

$$\frac{\mathrm{d}f}{\mathrm{d}t} = \frac{\partial f}{\partial t} + \nabla f\cdot\frac{\mathrm{d}X}{\mathrm{d}t} + \frac{1}{2}\sum_{i,j}\frac{\partial^{2}f}{\partial x_{i}\,\partial x_{j}}\frac{\partial X_{i}\,\partial X_{j}}{\mathrm{d}t}. \tag{A17}$$

We may now compute the forward and backward derivatives of f. In this averaging procedure, the mean value of $\mathrm{d}X_{i}/\mathrm{d}t$ amount to $d_{\pm}x_{i}/\mathrm{d}t = v_{\pm i}$, while $\langle \mathrm{d}X_{i}\,\mathrm{d}X_{j}\rangle$ reduces to $\langle \mathrm{d}\xi_{\pm i}\,\mathrm{d}\xi_{\pm j}\rangle$, so that the last term of (A17) amounts to a Laplacian thanks to (A13). We obtain

$$d_{\pm}f/\mathrm{d}t = \partial/\partial t + v_{\pm}\tfrac{1}{2}\lambda c\Delta. \tag{A18}$$

By combining them we get our final expression for the complex scale-covariant derivative,

$$\frac{\delta}{\mathrm{d}t} = \frac{\partial}{\partial t} + \mathbf{V}\cdot\nabla - i\frac{1}{2}\lambda c\Delta. \tag{A19}$$

We now apply the principle of scale covariance, and postulate that the passage from classical (differentiable) mechanics to the new nondifferentiable mechanics that is considered here can be implemented by replacing the standard time derivative $d/\mathrm{d}t$ by the complex operator $\delta/\mathrm{d}t$. As a

consequence, we are now able to write the equation of geodesics of the fractal space under its covariant form,

$$\frac{\delta^2}{dt^2}x^i = 0. \tag{A20}$$

In the present paper between λ and D measures,

$$D = \tfrac{1}{2}\lambda c. \tag{A21}$$

APPENDIX B

Let us consider a quantum fluid of identical particles. To each particle of fluid one can associate by means of its spin the vector potential $\mathbf{A}$ and the vortex field $\mathbf{\Omega}$,

$$\mathbf{A} = \mathrm{curl}(\Gamma\hat{\sigma}/r), \tag{B1a}$$

$$\mathbf{U} = \mathrm{curl}\,\mathbf{A}, \tag{B1b}$$

and by self-interaction the potential

$$W = -\Gamma\hat{\sigma}\cdot\grave{\mathbf{U}} = \Gamma^2[\hat{\sigma}\,\mathrm{curl}\,\mathrm{curl}(\hat{\sigma}/r)] = \Gamma^2[(\hat{\sigma}\cdot\nabla)(\hat{\sigma}\cdot\nabla)(1/r) - (\hat{\sigma}\cdot\hat{\sigma})\nabla^2(1/r)]. \tag{B2}$$

Since

$$(\hat{\sigma}\cdot\nabla)(\hat{\sigma}\cdot\nabla) = (1/3)(\hat{\sigma}\cdot\hat{\sigma})\nabla^2, \tag{B3a}$$

$$\nabla^2(1/r) = -4\pi\delta(r), \tag{B3b}$$

one gets

$$W = (8\pi/3)\Gamma^2(\hat{\sigma}\cdot\hat{\sigma})\delta(r). \tag{B4}$$

Then, the mean value of the potential is

$$U = \langle W\rangle = \frac{8\pi}{3}\Gamma^2(\hat{\sigma}\cdot\hat{\sigma})\int \psi^*\delta(r)\psi d^3x = A(\Gamma,\hat{\sigma})|\psi(0)|^2. \tag{B5}$$

In the previous relations, $\mathbf{i}=\Gamma\hat{\sigma}$ is the vortex momentum, Γ is the vortex constant, and $A(\Gamma,\hat{\sigma})$ is a constant. Consequently, assimilating the quantum fluid particles with vortex type objects, the potential U will be proportional with the concentration of the particles.

APPENDIX C

$\underline{\Omega}(u)=\underline{\Omega}(u')$ if and only if between u and u' it exists the transformation $u=(au'+b)/(cu'+d), a,b,c,d\in N, ad-bc=1$, with $u=(\omega_2/\omega_1), u'=(\omega'_2/\omega'_1)$, and $(\omega_1,\omega_2)(\omega'_1,\omega'_2)$ the fundamental periods pairs of a two equivalent elliptic function (sn dn/cn) (the equivalence theorem of elliptic functions[7]).

Let us consider a transformation element in the matrix form

$$M = \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

Under the special conditions $c=1, d=0$ we can calculate the eigenvalues as follows: The characteristic equation of this matrix is

$$\begin{pmatrix} a-\lambda & b \\ 1 & -\lambda \end{pmatrix} = 0,$$

$$\lambda^2 - a\lambda - b = 0, \quad \lambda_{1,2} = \tfrac{1}{2}[a \pm (a^2 + 4b)^{1/2}].$$

For different values of a and b we obtain members which are irrational numbers. Let us begin with the quadratic equations and $b=1$ or $b=-1$. In this case, the quadratic equations are of the following type: $x^2-a_nx-1=0, x^2-a_nx+1=0$ or $x^2-a_nx+(-1)^n=0$. For $a_1=1, a_2=3, a_3=4, a_4=7$ one finds

$$a_1 = 1, \quad x^2 - 1x - 1 = 0, \quad x_1^{(1)} = -\phi, \quad x_2^{(1)} = 1/\phi = (1 + \phi),$$

$$a_2 = 3, \quad x^2 - 3x + 1 = 0, \quad x_1^{(2)} = \phi^2, \quad x_2^{(2)} = 1/\phi^2 = (3 - \phi^2),$$

$$a_3 = 4, \quad x^2 - 4x - 1 = 0, \quad x_1^{(3)} = -\phi^3, \quad x_2^{(3)} = 1/\phi^3 = (4 + \phi^3),$$

$$a_2 = 7, \quad x^2 - 7x + 1 = 0, \quad x_1^{(4)} = \phi^4, \quad x_2^{(4)} = 1/\phi^4 = (7 - \phi^4).$$

Consequently, one can write that for $a_n=a_{n-2}+a_{n-1}, a_1=1, a_2=3, n>2$, one finds $x^2-a_nx+(-1)^n=0, x_1^{(n)}=(-\phi)^n, x_2^{(n)}=1/\phi^n=(a_{n-2}+a_{n-1})+(-1)^{n-1}\phi^n$.

Under these special conditions we obtain the irrational roots, $x_1^{(n)}=(-\phi)^n, x_2^{(n)}=(1/\phi)^n$ which are contained in the limit set. This clearly shows the connection between the geometry induced by the previous transformation, KAM theorem, the VAK and El Naschie's $\varepsilon^{(\infty)}$ theory for determining the mass spectrum of high elementary particles as a function of the golden mean $\phi=(\sqrt{5}-1)/2$.[16] Consequently, the vortex coherence in the lattice implies the $\varepsilon^{(\infty)}$ space.

Representation of the contextual statistical model by hyperbolic amplitudes

Andrei Khrennikov[a)]
MSI, University of Växjö, S-35195, Sweden

(Received 6 September 2004; accepted 18 April 2005; published online 6 June 2005)

We continue the development of a so-called contextual statistical model (here context has the meaning of a complex of physical conditions). It is shown that, besides contexts producing the conventional trigonometric cos-interference, there exist contexts producing the hyperbolic cos-interference. Starting with the corresponding interference formula of total probability we represent such contexts by hyperbolic probabilistic amplitudes or in the abstract formalism by normalized vectors of a hyperbolic analogue of the Hilbert space. There is obtained a hyperbolic Born's rule. Incompatible observables are represented by noncommutative operators. This paper can be considered as the first step towards hyperbolic quantum probability. We also discuss possibilities of experimental verification of hyperbolic quantum mechanics: in physics of elementary particles, string theory as well as in experiments with nonphysical systems, e.g., in psychology, cognitive sciences, and economy. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1931042]

I. INTRODUCTION

In Ref. 1 there was presented a so-called contextual viewpoint of the origin of quantum (conditional) probabilities (here a *context* has the meaning of a complex of physical conditions). Such an approach gives the possibility to unify classical Kolmogorov (measure theoretical) and quantum (Hilbert space) probability theories by constructing a natural representation of the Kolmogorov model in a complex Hilbert space. Thus in the contextual approach quantum probabilistic behavior (in particular, *interference of probabilities*) is simply a consequence of a very special representation of Kolmogorov probabilities—by complex amplitudes (vectors in a complex Hilbert space). Each representation is based on a fixed pair of observables (Kolmogorov random variables) *a* and *b—reference observables*—which produce the contextual image of a Kolmogorov probability space in a complex Hilbert space. The crucial point is that all Kolmogorov probabilities should be considered as conditional (or better to say contextual) probabilities, cf. Accardi,[2–4] Ballentine,[5,6] W. De Muynck,[7,8] S. Gudder,[9,10] A. Lande,[11] G. Mackey.[12]

In Ref. 1 we introduced a class $\mathcal{C}^{\mathrm{tr}}$ of contexts ("trigonometric contexts") which can be represented by complex probabilistic amplitudes inducing the representation in the complex Hilbert space. The $\mathcal{C}^{\mathrm{tr}}$ consists of context producing the conventional trigonometric cos-interference. However, in general the set of contexts is not reduced to the class of trigonometric contexts $\mathcal{C}^{\mathrm{tr}}$. There exist contexts producing the hyperbolic cosh-interference. The set of hyperbolic contexts is denoted by the symbol $\mathcal{C}^{\mathrm{hyp}}$.

In this paper we show that it is possible to represent contexts belonging to $\mathcal{C}^{\mathrm{hyp}}$ by so-called *hyperbolic amplitudes*. Such amplitudes take values in the set of "hyperbolic numbers" (two-dimensional Clifford algebra). It will be demonstrated that in the hyperbolic framework we can proceed quite far in the same directions as in the trigonometric framework. We obtain hyperbolic analogues of the interference of probabilities, probability amplitudes, Born's rule, representation

of incompatible observables by noncommuting operators. The crucial difference between two representations is that in the hyperbolic case the principle of superposition is violated.

II. CONTEXTUAL VIEWPOINT TO THE KOLMOGOROV MODEL AND INTERFERENCE OF PROBABILITIES

In this section we repeat the main points of contextual measure-theoretical approach to interference of probabilities, see Ref. 1 for details.

Let $(\Omega,\mathcal{F},\mathbf{P})$ be a Kolmogorov probability space: Ω is an arbitrary set, $\mathcal{F}$ is a σ-field of subsets of Ω and $\mathbf{P}$ is a countably additive measure on $\mathcal{F}$ taking values in $[0, 1]$ and normalized by one (Kolmogorov probability). By the standard Kolmogorov axiomatics sets $A\in\mathcal{F}$ represent *events*. In our simplest model of *contextual probability* (which can be called the Kolmogorov contextual space) the same system of sets, $\mathcal{F}$, is used to represent complexes of experimental physical conditions—*contexts*.

Thus depending on circumstances a set $O\in\mathcal{F}$ will be interpreted either as event or as context. We shall sharply distinguish events and contexts on phemenological level, but we shall use the same mathematical object $\mathcal{F}$ to represent both events and contexts in a mathematical model. In principle, in a mathematical model events and contexts can be represented by different families of sets, e.g., in Renye's model. We will not do this from the beginning. But later we will fix families of contexts, e.g., $\mathcal{C}^{\text{tr}}$ or $\mathcal{C}^{\text{hyp}}$, which are proper subfamilies of $\mathcal{F}$.

The conditional probability is mathematically defined by the Bayes' formula: $\mathbf{P}(A/C)=\mathbf{P}(AC)/\mathbf{P}(C)$, $P(C)\neq 0$. In our contextual model this probability has the meaning of the probability of occurrence of the event A under the complex of physical conditions C. Thus it would be more natural to call $\mathbf{P}(A/C)$ a *contextual probability* and not *conditional probability*. Roughly speaking to find $\mathbf{P}(A/C)$ we should find parameters ω^A favoring for the occurrence of the event A among parameters ω^C describing the complex of physical conditions C.

Let $\mathcal{A}=\{A_n\}$ be finite or countable *complete group of disjoint contexts* (or in the event-terminology—complete group of disjoint events),

$$A_iA_j=\emptyset,\quad i\neq j,\quad \cup_i A_i=\Omega.$$

Let $B\in\mathcal{F}$ be an event and $C\in\mathcal{F}$ be a context and let $\mathbf{P}(C)>0$. We have the standard *formula of total probability:* $\mathbf{P}(B/C)=\Sigma_n\mathbf{P}(A_n/C)\mathbf{P}(B/A_nC)$. Let $a=a_1,\ldots,a_n$ and $b=b_1,\ldots,b_n$ be discrete random variables. Then

$$\mathbf{P}(b=b_i/C)=\sum_n \mathbf{P}(a=a_n/C)\mathbf{P}(b=b_i/a=a_n,C). \tag{1}$$

We remark that sets

$$B_x=\{\omega\in\Omega: b(\omega)=x\}\quad \text{and } A_y=\{\omega\in\Omega: a(\omega)=y\} \tag{2}$$

have two different interpretations. On the one hand, these sets represent events corresponding to occurrence of the values $b=x$ and $a=y$, respectively. On the other hand, they represent contexts (complexes of physical conditions) corresponding to selections of physical systems with respect to values $b=x$ and $a=y$, respectively. The main problem with the formula of total probability is that in general it is impossible to construct a context "A_yC" corresponding to a selection with respect to the value $a=y$ which would not disturb systems prepared by the context C. But only in the absence of disturbance we can use the set theoretical operation of intersection. This paper would like to modify the formula of total probability by eliminating sets "A_yC" which in general do not represent physically realizable contexts.

A set C belonging to $\mathcal{F}$ is said to be a *nondegenerate context* with respect to $\mathcal{A}=\{A_n\}$ if $\mathbf{P}(A_nC)\neq 0$ for all n. We denote the set of such contexts by the symbol $\mathcal{C}_{\mathcal{A},\text{nd}}$.

Let $\mathcal{A}=\{A_n\}$ and $\mathcal{B}=\{B_n\}$ be two complete groups of disjoint contexts. They are said to be *incompatible* if $\mathbf{P}(B_nA_k)\neq 0$ for all n and k. Thus $\mathcal{B}$ and $\mathcal{A}$ are incompatible iff every B_n is a nondegenerate context with respect to $\mathcal{A}$ and vice versa. Random variables a and b inducing, see

(2), incompatible complete groups $\mathcal{A}=\{A_n\}$ and $\mathcal{B}=\{B_n\}$ of disjoint contexts are said to be *incompatible random variables.*

Theorem 2.1: (Interference formula of total probability) *Let* $\mathcal{A}=\{A_1,A_2=\Omega\backslash A_1\}$ *and* $\mathcal{B}=\{B_1,B_2=\Omega\backslash B_1\}$ *be incompatible and let a context* $C\in\mathcal{C}_{\mathcal{A},\mathrm{nd}}$. *Then, for any* $B\in\mathcal{B}$,

$$\mathbf{P}(B/C)=\sum_{j=1}^{2}\mathbf{P}(A_j/C)\mathbf{P}(B/A_j)+2\lambda(B/\mathcal{A},C)\sqrt{\prod_{j=1}^{2}\mathbf{P}(A_j/C)\mathbf{P}(B/A_j)},$$

where

$$\lambda(B/\mathcal{A},C)=\frac{\mathbf{P}(B/C)-\sum_{j=1}^{2}\mathbf{P}(B/A_j)\mathbf{P}(A_j/C)}{2\sqrt{\mathbf{P}(A_1/C)\mathbf{P}(B/A_1)\mathbf{P}(A_2/C)\mathbf{P}(B/A_2)}}.$$

To prove the theorem, we set the expression for λ into the sum and obtain identity. In fact, this formula is just a representation of the probability $\mathbf{P}(A/C)$ in a special way. The $\lambda(B/\mathcal{A},C)$ are called *coefficients of statistical disturbance.* We shall use at few occasions the following result:

Lemma 2.1: *Let conditions of Theorem 2.1 hold true. Then*

$$\sum_{k}\lambda(B_k/\mathcal{A},C)\sqrt{\mathbf{P}(A_1/C)\mathbf{P}(A_2/C)\mathbf{P}(B_k/A_1)\mathbf{P}(B_k/A_2)}=0. \tag{3}$$

Proof: We have

$$1=\sum_{k}\mathbf{P}(B_k/C)=\sum_{k}\sum_{n}\mathbf{P}(A_n/C)\mathbf{P}(B_k/A_n)+\sum_{k}\lambda(B_k/\mathcal{A},C)\sqrt{\mathbf{P}(A_1/C)\mathbf{P}(A_2/C)\mathbf{P}(B_k/A_1)\mathbf{P}(B_k/A_2)}.$$

But $\Sigma_n(\Sigma_k\mathbf{P}(B_k/A_n))\mathbf{P}(A_n/C)=1$.

(1) Suppose that for every $B\in\mathcal{B}$, $|\lambda(B/\mathcal{A},C)|\leqslant 1$. In this case we can introduce statistical parameters $\theta(B/\mathcal{A},C)\in[0,2\pi]$ and represent the coefficients of statistical disturbance in the trigonometric form, $\lambda(B/\mathcal{A},C)=\cos\theta(B/\mathcal{A},C)$. Parameters $\theta(B/\mathcal{A},C)$ are said to be *relative phases* of an event B with respect to $\mathcal{A}$ (in the context C). We have the following interference formula of total probability,

$$\mathbf{P}(B/C)=\sum_{j=1}^{2}\mathbf{P}(A_j/C)\mathbf{P}(B/A_j)+2\cos\theta(B/\mathcal{A},C)\sqrt{\prod_{j=1}^{2}\mathbf{P}(A_j/C)\mathbf{P}(B/A_j)}.$$

This is nothing other than the famous *formula of interference of probabilities.*

In Ref. 1 there was shown that by starting with this formula we can construct the representation of the set of trigonometric contexts

$$\mathcal{C}^{\mathrm{tr}}=\{C\in\mathcal{C}_{a,\mathrm{nd}}:|\lambda(B_j/a,c)|\leqslant 1,j=1,2\}$$

in the complex Hilbert space, obtain Born's rule and represent incompatible variables a and b by (noncommutative) operators.

(2) Suppose that for every $B\in\mathcal{B}$, $|\lambda(B/\mathcal{A},C)|\geqslant 1$. In this case we can introduce statistical parameters $\theta(B/\mathcal{A},C)\in(-\infty,+\infty)$ and represent the coefficients of statistical disturbance in the trigonometric form, $\lambda(B/\mathcal{A},C)=\pm\cosh\theta(B/\mathcal{A},C)$. Parameters $\theta(B/\mathcal{A},C)$ are said to be hyperbolic *relative phases.* In this case we obtain the formula of total probability with hyperbolic cosh-interference,

$$\mathbf{P}(B/C)=\sum_{j=1}^{2}\mathbf{P}(A_j/C)\mathbf{P}(B/A_j)\pm 2\cosh\theta(B/\mathcal{A},C)\sqrt{\prod_{j=1}^{2}\mathbf{P}(A_j/C)\mathbf{P}(B/A_j)}. \tag{4}$$

The aim of this paper is to show that by starting with this formula we can construct the representation of the set of hyperbolic contexts,

$$\mathcal{C}^{\text{hyp}} = \{C \in \mathcal{C}_{a,\text{nd}} : |\lambda(B_j/a,c)| \geqslant 1, j = 1,2\}$$

in the hyperbolic Hilbert space, obtain an analogue of Born's rule and represent incompatible variables a and b by (noncommutative) operators.

We can also consider the case of mixed hypertrigonometric behavior, one of the coefficients is larger than 1 and one is smaller than 1. However, in this paper we shall discuss only the case of the hyperbolic interference.

In our further considerations the complete groups of disjoint contexts $\mathcal{A}$ and $\mathcal{B}$ will correspond to some incompatible random variables a and b. We shall use the symbols $\lambda(b=x/a,C)$ instead of $\lambda(b=x/\mathcal{A},C)$.

III. REPRESENTATION OF CONTEXTS BY HYPERBOLIC AMPLITUDES, HYPERBOLIC HILBERT SPACE REPRESENTATION

Everywhere below we study contexts producing the hyperbolic interference for incompatible dichotomous random variables $a=a_1$, a_2, $b=b_1$, b_2. This pair of variables will be fixed. We call such variables reference variables. For each pair a, b of reference variables we construct a representation of the set of contexts $\mathcal{C}^{\text{hyp}}$ in hyperbolic Hilbert space ("quantumlike representation").

A. Hyperbolic algebra

Instead of the field complex numbers **C**, we shall use so-called hyperbolic numbers, namely the two-dimensional Clifford algebra, **G**. We call this algebra *hyperbolic algebra*.

Remark 3.1: Of course, it is rather dangerous to invent an own name for a notion established almost as firm as complex numbers. We use a new name, hyperbolic algebra, for the well-known algebraic object, the two-dimensional Clifford algebra, by the following reasons. First we explain why we dislike to use the standard notion Clifford algebra in this particular case. The standard Clifford machinery was developed around noncommutative features of general Clifford algebras. The two-dimensional Clifford algebra, hyperbolic algebra in our terminology, is commutative. Commutativity of **G** is very important in our considerations. We now explain why we propose the name hyperbolic algebra. Hyperbolic functions are naturally related to the algebraic structure of **G** through a hyperbolic generalization of Euler's formula for the complex numbers. This is the crucial point of our considerations—the possibility to use this algebraic structure to represent some special transformations for hyperbolic functions.

Denote by the symbol j the generator of the algebra **G** of hyperbolic numbers,

$$j^2 = 1.$$

The algebra **G** is the two-dimensional real algebra with basis $e_0=1$ and $e_1=j$. Elements of **G** have the form $z=x+jy$, $x, y \in \mathbf{R}$. We have $z_1+z_2=(x_1+x_2)+j(y_1+y_2)$ and $z_1z_2=(x_1x_2+y_1y_2)+j(x_1y_2+x_2y_1)$. This algebra is commutative. It is not a field—not every element has the inverse one.

We introduce an involution in **G** by setting $\overline{z}=x-jy$ and set $|z|^2=z\overline{z}=x^2-y^2$. We remark that $|z|=\sqrt{x^2-y^2}$ is not well defined for an arbitrary $z \in \mathbf{G}$. We set $\mathbf{G}_+=\{z \in \mathbf{G}: |z|^2 \geqslant 0\}$. We remark that $\mathbf{G}_+$ is a multiplicative semigroup as follows from the equality

$$|z_1z_2|^2 = |z_1|^2|z_2|^2.$$

Thus, for $z_1, z_2 \in \mathbf{G}_+$, we have that $|z_1z_2|$ is well defined and $|z_1z_2|=|z_1||z_2|$. We define a hyperbolic exponential function by using a hyperbolic analogue of the Euler's formula,

$$e^{j\theta} = \cosh\theta + j\sinh\theta, \theta \in \mathbf{R}.$$

We remark that

$$e^{j\theta_1}e^{j\theta_2} = e^{j(\theta_1+\theta_2)}, \quad \overline{e^{j\theta}} = e^{-j\theta}, \quad |e^{j\theta}|^2 = \cosh^2\theta - \sinh^2\theta = 1.$$

Hence, $z = \pm e^{j\theta}$, always belongs to $\mathbf{G}_+$. We also have

$$\cosh\theta = \frac{e^{j\theta}+e^{-j\theta}}{2}, \quad \sinh\theta = \frac{e^{j\theta}-e^{-j\theta}}{2j}.$$

We set $\mathbf{G}_+^* = \{z \in \mathbf{G}_+ : |z|^2 > 0\}$. Let $z \in \mathbf{G}_+^*$. We have

$$z = |z|(x/|z|) + j(y/|z|) = \operatorname{sign} x|z|\left(\frac{x \operatorname{sign} x}{|z|} + j\frac{y \operatorname{sign} x}{|z|}\right).$$

As $(x^2/|z|^2) - (y^2/|z|^2) = 1$, we can represent $x \operatorname{sign} x = \cosh\theta$ and $y \operatorname{sign} x = \sinh\theta$, where the phase θ is unequally defined. We can represent each $z \in \mathbf{G}_+^*$ as

$$z = \operatorname{sign} x|z|e^{j\theta}.$$

By using this representation we can easily prove that $\mathbf{G}_+^*$ is a multiplicative group. Here $1/z = -(\operatorname{sign} x/|z|)e^{-j\theta}$. The unit circle in $\mathbf{G}$ is defined as $S_1 = \{z \in \mathbf{G} : |z|^2 = 1\} = \{z = \pm e^{j\theta}, \theta \in (-\infty, +\infty)\}$. It is a multiplicative subgroup of $\mathbf{G}_+^*$.

To construct a $\mathbf{G}$-linear representation of the set $\mathcal{C}^{\mathrm{hyp}}$ of hyperbolic contexts, we shall use the following elementary formula:

$$D = A + B \pm 2AB\cosh\theta = |\sqrt{A} \pm e^{j\theta}\sqrt{B}|^2, \tag{5}$$

for real coefficients $A, B > 0$.

B. Hyperbolic probability amplitude, hyperbolic Born's rule

We set $Y = \{a_1, a_2\}$, $X = \{b_1, b_2\}$ ("spectra" of random variables a and b). Let $C \in \mathcal{C}^{\mathrm{hyp}}$. We set

$$p_C^a(y) = \mathbf{P}(a = y/C), \quad p_C^b(x) = \mathbf{P}(b = x/C), \quad p(x/y) = \mathbf{P}(b = x/a = y),$$

$x \in X$, $y \in Y$. The interference formula of total probability (4) can be written in the following form:

$$p_C^b(x) = \sum_{y \in Y} p_C^a(y)p(x/y) \pm 2\cosh\theta_C(x)\sqrt{\Pi_{y\in Y}p_C^a(y)p(x/y)}, \tag{6}$$

where $\theta_C(x) = \theta(b = x/a, C) = \pm\operatorname{arccosh}|\lambda(b = x/a, C)|$, $x \in X$, $C \in \mathcal{C}^{\mathrm{hyp}}$. Here the coefficient λ is defined by

$$\lambda(b = x/a, C) = \frac{p_C^b(x) - \sum_{y\in Y} p_C^a(y)p(x/y)}{2\sqrt{\Pi_{y\in Y}p_C^a(y)p(x/y)}}. \tag{7}$$

By using (5) we can represent the probability $p_C^b(x)$ as the square of the hyperbolic amplitude,

$$p_C^b(x) = |\varphi_C(x)|^2, \tag{8}$$

where

$$\varphi(x) \equiv \varphi_C(x) = \sqrt{p_C^a(a_1)p(x/a_1)} + \epsilon_C(x)e^{j\theta_C(x)}\sqrt{p_C^a(a_2)p(x/a_2)}. \tag{9}$$

Here $\epsilon_C(x) = \operatorname{sign}\lambda(x/a, C)$. We remark that by Lemma 2.1,

$$\sum_{x\in X} \epsilon_C(x) = 0. \tag{10}$$

Thus we have a *hyperbolic generalization of Born's rule* for the b variable, see (8).

C. Hyperbolic Hilbert space

Hyperbolic Hilbert space is **G**-linear space (module) **E** with a **G**-linear scalar product, a map $(\cdot,\cdot) : \mathbf{E}\times\mathbf{E}\to\mathbf{G}$ that is

(1) linear with respect to the first argument, $(az+bw,u)=a(z,u)+b(w,u)$, $a, b\in\mathbf{G}$, $z, w, u\in\mathbf{E}$;
(2) symmetric, $(z,u)=\overline{(u,z)}$;
(3) nondegenerate, $(z,u)=0$ for all $u\in\mathbf{E}$ iff $z=0$.

Remark 3.2: If we consider **E** as just a **R**-linear space, then $(\cdot,\cdot)$ is a bilinear form which is not positive defined. In particular, in the two-dimensional case we have the signature $(+,-,+,-)$.

D. Hyperbolic Hilbert space representation

We introduce the space $\Phi(X,\mathbf{G})$ of functions, $\varphi: X\to\mathbf{G}$. Since $X=\{b_1,b_2\}$, the $\Phi(X,\mathbf{G})$ is the two-dimensional **G** module. We define the **G**-scalar product by

$$(\varphi,\psi)=\sum_{x\in X}\varphi(x)\overline{\psi}(x) \tag{11}$$

with conjugation in the algebra **G**. The system of Dirac δ-functions $\{e_x^b\equiv\delta_x\}_{x\in X}$ is an orthonormal basis in the hyperbolic Hilbert space $H^{\mathrm{hyp}}=(\Phi(X,\mathbf{G}),(\cdot,\cdot))$. Thus we have the hyperbolic analogue of the Born's rule in H^{hyp},

$$p_C^b(x)=|(\varphi_C,e_x^b)|^2. \tag{12}$$

Let $X\subset R$. By using the hyperbolic Hilbert space representation (12) of the Born's rule we obtain the hyperbolic Hilbert space representation of the expectation of the (Kolmogorovian) random variable b,

$$E(b/C)=\sum_{x\in X}xp_C^b(x)=\sum_{x\in X}x|\varphi_C(x)|^2=\sum_{x\in X}x(\varphi_C,e_x^b)\overline{(\varphi_C,e_x^b)}=(\hat{b}\varphi_C,\varphi_C), \tag{13}$$

where the (self-adjoint) operator $\hat{b}: H^{\mathrm{hyp}}\to H^{\mathrm{hyp}}$ is determined by its eigenvectors, $\hat{b}e_x^b=xe_x^b$, $x\in X$. This is the multiplication operator in the space of **G**-valued functions $\Phi(X,\mathbf{G})$,

$$\hat{b}\varphi(x)=x\varphi(x).$$

By (13) the conditional expectation of the Kolmogorovian random variable b is represented with the aid of the self-adjoint operator $\hat{b}$.

Thus we constructed a **G**-linear representation of the contextual Kolmogorov model,

$$J^{b/a}:\mathcal{C}^{\mathrm{hyp}}\to H^{\mathrm{hyp}}.$$

We set $S_{\mathcal{C}^{\mathrm{hyp}}}=J^{b/a}(\mathcal{C}^{\mathrm{hyp}})$. This is a subset of the unit sphere S of the Hilbert space H^{hyp}. We introduce the coefficients

$$u_j^a=\sqrt{p_C^a(a_j)},\quad u_j^b=\sqrt{p_C^b(b_j)},\quad p_{ij}=p(b_j/a_i),\quad u_{ij}=\sqrt{p_{ij}},\quad \theta_j=\theta_C(b_j), \tag{14}$$

and $\epsilon_i=\epsilon(b_i)$. We remark that the coefficients u_j^a, u_j^b depend on a context C; so $u_j^a=u_j^a(C)$, $u_j^b=u_j^b(C)$. We also consider the *matrix of transition probabilities* $\mathbf{P}^{b/a}=(p_{ij})$. It is always a *stochastic matrix*, $p_{i1}+p_{i2}=1$, $i=1,2$. In further considerations we shall also consider *double stochastic matrices*, $p_{1j}+p_{2j}=1$, $j=1,2$.

We represent a state φ_C by $\varphi_C=v_1^be_1^b+v_2^be_2^b$, where $v_i^b=u_1^au_{1i}+\epsilon_iu_2^au_{2i}e^{j\theta_i}$. So

$$p_C^b(b_i) = |v_i^b|^2 = |u_1^a u_{1i} + \epsilon_i u_2^a u_{2i} e^{j\theta_i}|^2.$$

This is the **G**-linear representation of the hyperbolic interference of probabilities. This formula can also be derived in the formalism of the hyperbolic Hilbert space, see Sec. IV. We remark that here the **G**-linear combination $u_1^a u_{1i} + \epsilon_i u_2^a u_{2i} e^{j\theta_i}$ belongs to $\mathbf{G}_+^*$.

Thus for any context $C_0 \in \mathcal{C}^{\text{hyp}}$ we can represent φ_{C_0} in the form

$$\varphi_{C_0} = u_1^a e_1^a + u_2^a e_2^a,$$

where

$$e_1^a = (u_{11}, u_{12}), \quad e_2^a = (\epsilon_1 e^{j\theta_1} u_{21}, \epsilon_2 e^{j\theta_2} u_{22}).$$

As in the **C** case,[1] we introduce the matrix V with coefficients $v_{11} = u_{11}$, $v_{21} = u_{21}$, and $v_{12} = \epsilon_1 e^{j\theta_1} u_{21}$, $v_{22} = \epsilon_2 e^{j\theta_2} u_{22}$. We remark that here coefficients $v_{ij} \in \mathbf{G}_+^*$. In the same way as in the complex case the Born's rule

$$p_{C_0}^a(a_i) = |(\varphi_{C_0}, e_i^a)|^2 \tag{15}$$

holds true in the a-basis iff $\{e_i^a\}$ is an orthonormal basis in H^{hyp}. The latter is equivalent to the **G** unitary of the matrix V (corresponding to the transition from $\{e_i^b\}$ to $\{e_i^a\}$): $\overline{V^*} V = I$, or

$$\overline{v}_{11} v_{11} + \overline{v}_{21} v_{21} = 1, \quad \overline{v}_{12} v_{12} + \overline{v}_{22} v_{22} = 1, \tag{16}$$

$$\overline{v}_{11} v_{12} + \overline{v}_{21} v_{22} = 0. \tag{17}$$

Thus $1 = u_{11}^2 + u_{21}^2 = p(b_1/a_1) + p(b_1/a_2)$ and $1 = u_{12}^2 + u_{22}^2 = p(b_2/a_1) + p(b_2/a_2)$. Thus the first two equations of the **G** unitary are equivalent to the double stochasticity of $\mathbf{P}^{b/a}$ (as in the **C** case[1]). We remark that the equations (16) can be written as

$$|v_{11}|^2 + |v_{21}|^2 = 1, \quad |v_{12}|^2 + |v_{22}|^2 = 1, \tag{18}$$

cf. Sec. IV. The third unitarity equation (17) can be written as

$$u_{11} u_{12} \epsilon_1 e^{-j\theta_2} + u_{21} \epsilon_2 e^{-j\theta_2} u_{22} = 0. \tag{19}$$

By using double stochasticity of $\mathbf{P}^{a/b}$ we obtain $e^{j\theta_1} = e^{j\theta_2}$. Thus

$$\theta_1 = \theta_2. \tag{20}$$

Lemma 3.1: *Let a and b be incompatible random variables and let* $\mathbf{P}^{b/a}$ *be double stochastic. Then*

$$\cosh \theta_C(b_2) = \cosh \theta_C(b_1) \tag{21}$$

for any context $C \in \mathcal{C}^{\text{hyp}}$.

Proof: By Lemma 2.1 we have

$$\sum_x \epsilon(x) \cosh \theta_C(x) \sqrt{\Pi_y p_C^a(y) p(x/y)} = 0.$$

Double stochasticity of $\mathbf{P}^{b/a}$ implies (21).

The constraint (21) induced by double stochasticity can be written as the constraint to phases

$$\theta_C(b_2) = \pm \theta_C(b_1). \tag{22}$$

To obtain unitary of the matrix V of transition $\{e_i^b\} \to \{e_i^a\}$ we should choose phases according to (20). And by (22) we can always do this for a double stochastic matrix of transition probabilities.

By choosing such a representation we obtain the hyperbolic generalization of the Born's rule for the a variable,

$$p_C^a(a_j) = |(\varphi, e_j^a)|^2. \tag{23}$$

We now investigate the possibility to use one fixed basis $\{e_j^a \equiv e_j^a(C_0)\}$, $C_0 \in \mathcal{C}^{\text{hyp}}$, for all states φ_C, $C \in \mathcal{C}^{\text{hyp}}$. For any $C \in \mathcal{C}^{\text{hyp}}$ we would like to have the representation

$$\phi_C = v_1^a(C)e_1^a(C_0) + v_2^a(C)e_2^a(C_0), \quad \text{where } |v_j^a(C)|^2 = p_C^a(a_j). \tag{24}$$

We have

$$\phi_C(b_1) = u_1^a(C)v_{11}(C_0) + \epsilon_C(b_1)\epsilon_{C_0}(b_1)e^{j[\theta_C(b_1)-\theta_{C_0}(b_1)]}u_2^a(C)v_{12}(C_0),$$

$$\phi_C(b_2) = u_1^a(C)v_{21}(C_0) + \epsilon_C(b_2)\epsilon_{C_0}(b_2)e^{j[\theta_C(b_2)-\theta_{C_0}(b_2)]}u_2^a(C)v_{22}(C_0).$$

Thus to obtain (24) we should have

$$\epsilon_C(b_1)\epsilon_{C_0}(b_1)e^{j[\theta_C(b_1)-\theta_{C_0}(b_1)]} = \epsilon_C(b_2)\epsilon_{C_0}(b_2)e^{j[\theta_C(b_2)-\theta_{C_0}(b_2)]}.$$

Thus

$$\theta_C(b_1) - \theta_{C_0}(b_1) = \theta_C(b_2) - \theta_{C_0}(b_2), \text{ or } \theta_C(b_1) - \theta_C(b_2) = \theta_{C_0}(b_1) - \theta_{C_0}(b_2).$$

By choosing the representation with (20) we satisfy the above condition.

Theorem 3.1: *We can construct the quantumlike (Hilbert space) representation of a contextual Kolmogorov space such that the hyperbolic Born's rule holds true for both reference variables a and b iff the matrix of transition probabilities* $\mathbf{P}^{b/a}$ *is double stochastic.*

We remark that basic contexts $B_x = \{\omega \in \Omega : b(\omega) = x\}$, $x \in X$, always belong to $\mathcal{C}^{\text{hyp}}$, so $\varphi_{B_x} \in H^{\text{hyp}}$; and $B_x \in \mathcal{C}^{\text{tr}} \cap \mathcal{C}^{\text{hyp}}$ iff a and b are uniformly distributed ($\mathbf{P}^{a/b}$ and $\mathbf{P}^{b/a}$ are double stochastic).

IV. HYPERBOLIC QUANTUM MECHANICS

As in the ordinary quantum formalism, we represent physical states by normalized vectors of a hyperbolic Hilbert space $\mathbf{E} : \varphi \in \mathbf{E}$ and $(\varphi, \varphi) = 1$. We shall consider only dichotomous physical variables and quantum states belonging to the two-dimensional Hilbert space. Thus everywhere below $\mathbf{E}$ denotes the two-dimensional space. Let $a = a_1$, a_2 and $b = b_1$, b_2 be two physical variables. We represent them by $\mathbf{G}$-linear operators, $\hat{a} = a_1|a_1\rangle\langle a_1| + a_2|a_2\rangle\langle a_2|$ and $\hat{b} = b_1|b_1\rangle\langle b_1| + b_2|b_2\rangle\langle b_2|$, where $\{|a_i\rangle\}_{i=1,2}$ and $\{|b_i\rangle\}_{i=1,2}$ are two orthonormal bases in $\mathbf{E}$. The latter condition plays the fundamental role in hyperbolic quantum mechanics. This is an analogue of the representation of physical observables by self-adjoint operators in the conventional quantum mechanics (in the complex Hilbert space).

Let φ be a state (normalized vector belonging to $\mathbf{E}$). We can perform the following operation (which is well defined from the mathematical point of view). We expend the vector φ with respect to the basis $\{|b_i\rangle\}_{i=1,2}$,

$$\varphi = v_1^b|b_1\rangle + v_2^b|b_2\rangle, \tag{25}$$

where the coefficients (coordinates) v_i^b belong to $\mathbf{G}$. We remark that we consider the two-dimensional $\mathbf{G}$-Hilbert space. There exists (by definition) a basis consisting of two vectors. As the basis $\{|b_i\rangle\}_{i=1,2}$ is orthonormal, we have (as in the complex case) that

$$|v_1^b|^2 + |v_2^b|^2 = 1. \tag{26}$$

However, we could not automatically use Born's probabilistic interpretation for normalized vectors in the hyperbolic Hilbert space, it may be that $v_i^b \notin \mathbf{G}_+$ and hence $|v_i^b|^2 < 0$ (in fact, in the

complex case we have $\mathbf{C}=\mathbf{C}_+$; thus there is no problem with positivity). Since we do not want to consider negative probabilities, in such a case we cannot use the hyperbolic version of Born's probability interpretation.

Definition 4.1: *A state φ is decomposable with respect to the system of states $\{|b_i\rangle\}_{i=1,2}$ (b-decomposable) if*

$$v_i^b \in \mathbf{G}_+. \tag{27}$$

In such a case we can use generalization of Born's probabilistic interpretation for a hyperbolic Hilbert space. Numbers

$$p_\varphi^b(b_i) = |v_i^b|^2, \quad i = 1,2,$$

are interpreted as probabilities for values $b=b_i$ for the **G**-quantum state φ.

We remark that in this framework (here we started with a hyperbolic Hilbert space and not with a contextual statistical model, cf. Sec. III) a hyperbolic generalization of Born's rule is a postulate.

Thus decomposability is not a mathematical notion. This is not just linear algebraic decomposition of a vector with respect to a basis. This is a physical notion describing the possibility of probability interpretation of a measurement over a state. As it was already mentioned, in hyperbolic quantum mechanics a state $\varphi\in\mathbf{E}$ is not always decomposable. Thus for an observable b there can exist a state φ such that the probabilities $p_\varphi^b(b_i)$ are not well defined. One of the reasons for this can be the impossibility to perform the b-measurement for systems in the state φ. Such a situation is quite natural from the experimental viewpoint. Moreover, it looks surprising that in ordinary quantum (as well as classical) theory we can measure any observable in any state. I think that this is just a consequence of the fact that there was fixed the set of states corresponding to a rather special class of physical observables. Thus in the hyperbolic quantum formalism for each state $\varphi\in\mathbf{E}$ there exists its own set of observables $\mathcal{O}(\varphi)$. And in general $\mathcal{O}(\varphi)\neq\mathcal{O}(\psi)$. We cannot exclude another possibility. The set of observables $\mathcal{O}$ does not depend on a state φ. And the result of an individual measurement of any $b\in\mathcal{O}$ is well defined for any state φ. But relative frequencies of realizations of the value $b=b_k$ do not converge to any limit. Therefore probabilities are not well defined. Thus the principle of the statistical stabilization should be violated, cf. Ref. 13.

Let $\mathcal{K}$ be a Kolmogorov probability model and let $\varphi\in S_{\mathcal{C}^{\text{hyp}}}$. Thus $\varphi=\varphi_C$ for some context $C\in\mathcal{C}^{\text{hyp}}$. Let the matrix of transition probabilities $\mathbf{P}^{b/a}$ be double stochastic. Then φ is decomposable with respect to both reference variables b and a. Moreover, basis vectors $e_i^b=|b_i\rangle$ are a decomposable and vice versa.

We now start the derivation of the hyperbolic probabilistic rule by using the hyperbolic Hilbert space formalism. Suppose that a state $\varphi\in\mathbf{E}$ is a decomposable,

$$\varphi = v_1^a|a_1\rangle + v_2^a|a_2\rangle$$

and the coefficients $v_i^a\in\mathbf{G}_+$.

We also suppose that each state $|a_i\rangle$ is decomposable with respect to the system of states $\{|b_i\rangle\}_{i=1,2}$. We have

$$|a_1\rangle = v_{11}|b_1\rangle + v_{12}|b_2\rangle, \quad |a_2\rangle = v_{21}|b_1\rangle + v_{22}|b_2\rangle, \tag{28}$$

where the coefficients v_{ik} belong to $\mathbf{G}_+$. We have (since both bases are orthonormal)

$$|v_{11}|^2 + |v_{12}|^2 = 1, \quad |v_{21}|^2 + |v_{22}|^2 = 1, \tag{29}$$

cf. (18). We can use the probabilistic interpretation of numbers $p_{ik}=|v_{ik}|^2$, namely $p_{ik}=p_{|a_i\rangle}(b_k)$ is the probability for $b=b_k$ in the state $|a_i\rangle$.

Let us consider matrix $V=(v_{ik})$. As in the complex case, the matrix V is unitary, since vectors $|a_1\rangle=(v_{11},v_{12})$ and $|a_2\rangle=(v_{21},v_{22})$ are orthonormal. Hence we have normalization conditions (29) and the orthogonality condition,

$$v_{11}\overline{v_{21}} + v_{12}\overline{v_{22}} = 0, \tag{30}$$

cf. (17). It must be noticed that in general unitarity does not imply that $v_{ik} \in \mathbf{G}_+$. The latter condition is the additional constraint on the unitary matrix V. Let us consider the matrix $\mathbf{P}^{b/a} = (p_{ik})$. This matrix is double stochastic (since V is unitary).

By using the **G**-linear space calculation (the change of the basis) we get $\varphi = v_1^b|b_1\rangle + v_2^b|b_2\rangle$, where $v_1^b = v_1^a v_{11} + v_2^a v_{21}$ and $v_2^b = v_1^a v_{12} + v_2^a v_{22}$.

We remark that decomposability is not transitive. In principle φ may not be decomposable with respect to $\{|b_i\rangle\}_{i=1,2}$, despite the decomposability of φ with respect to $\{|a_i\rangle\}_{i=1,2}$ and the decomposability of the latter system with respect to $\{|b_i\rangle\}_{i=1,2}$.

The possibility of decomposability is based on two (totally different) conditions, (26), normalization, and (27), positivity. Any **G**-unitary transformation preserves the normalization condition. Thus we get automatically that $|v_1^b|^2 + |v_2^b|^2 = 1$. However, the condition of positivity in general is not preserved, it can be that $v_i^b \notin \mathbf{G}_+$ even if we have $v_i^a \in \mathbf{G}_+$ and the matrix V is **G** unitary.

Finally, suppose that φ is decomposable with respect to $\{|b_i\rangle\}_{i=1,2}$. Thus $v_k^b \in \mathbf{G}_+$. Therefore coefficients $p_\varphi^b(b_i) = |v_i^b|^2$ can be interpreted as probabilities for $b = b_k$ for the **G**-quantum state φ.

Let us consider states such that coefficients v_i^a, v_{ik} belong to $\mathbf{G}_+^*$. We can uniquely represent them as

$$v_i^a = \pm\sqrt{p_\varphi^a(a_i)}e^{j\xi_i}, \quad v_{ik} = \pm\sqrt{p_{ik}}e^{j\gamma_{ik}}, \quad i,k, = 1,2.$$

We find that

$$p_\varphi^b(b_1) = p_\varphi^a(a_1)p_{11} + p_\varphi^a(a_2)p_{21} + 2\epsilon_1 \cosh\,\theta_1\sqrt{p_\varphi^a(a_1)p_{11}p_\varphi^a(a_2)p_{21}}, \tag{31}$$

$$p_\varphi^b(b_2) = p_\varphi^a(a_1)p_{12} + p_\varphi^a(a_2)p_{22} + 2\epsilon_2 \cosh\,\theta_2\sqrt{p_\varphi^a(a_1)p_{12}p_\varphi^a(a_2)p_{22}}, \tag{32}$$

where $\theta_i = \eta + \gamma_i$ and $\eta = \xi_1 - \xi_2$, $\gamma_1 = \gamma_{11} - \gamma_{21}$, $\gamma_1 = \gamma_{12} - \gamma_{22}$, and $\epsilon_i = \pm$. To find the right relation between signs of the last terms in equations (31) and (32), we use the normalization condition

$$|v_2^b|^2 + |v_2^b|^2 = 1 \tag{33}$$

(which is a consequence of the normalization of φ and orthonormality of the system $\{|b_i\rangle\}_{i=1,2}$).

We remark that the normalization condition (33) can be reduced to relations between coefficients of the transition matrix V. So it does not depend on the original a-decomposition of φ, namely coefficients v_i^a. Condition of positivity, $|v_i^b|^2 \geqslant 0$, could not be written by using only coefficients of V. We also need to use coefficients v_i^a. Therefore it seems to be impossible to find such a class of linear transformations V that would preserve condition of positivity, "decomposition group" of operators.

Equation (33) is equivalent to the equation

$$\sqrt{p_{12}p_{22}}\cosh\,\theta_2 \pm \sqrt{p_{11}p_{21}}\cosh\,\theta_2 = 0. \tag{34}$$

Thus we must choose opposite signs in Eqs. (31) and (32). Unitarity of V also implies that $\theta_1 - \theta_2 = 0$, so $\gamma_1 = \gamma_2$. We recall that in the ordinary quantum mechanics we have similar conditions, but trigonometric functions are used instead of hyperbolic and phases γ_1 and γ_2 are such that $\gamma_1 - \gamma_2 = \pi$.

Finally, we get that unitary linear transformations in the **G**-Hilbert space (in the domain of decomposable states) represent the following transformation of probabilities:

$$p_{\varphi}^{b}(b_1) = p_{\varphi}^{a}(a_1)p_{11} + p_{\varphi}^{a}(a_2)p_{21} \pm 2\epsilon_1 \cos\theta_1 \sqrt{p_{\varphi}^{a}(a_1)p_{11}p_{\varphi}^{a}(a_2)p_{21}}, \tag{35}$$

$$p_{\varphi}^{b}(b_2) = p_{\varphi}^{a}(a_1)p_{12} + p_{\varphi}^{a}(a_2)p_{22} \mp 2\epsilon_2 \cosh\theta_2 \sqrt{p_{\varphi}^{a}(a_1)p_{12}p_{\varphi}^{a}(a_2)p_{22}}. \tag{36}$$

This is hyperbolic interference. In Sec. II it was derived from the contextual statistical model and then in Sec. III by using interference formulas we obtained the hyperbolic Hilbert space representation for contexts. In this section we started directly from the hyperbolic Hilbert space representation and derived interference of probabilities.

V. EXPERIMENTAL VERIFICATION OF HYPERBOLIC QUANTUM MECHANICS

This paper contains an important experimental prediction.

In statistical experiments with physical (micro as well as macro) systems there could be produced not only the ordinary trigonometric, but also the hyperbolic interference picture.

We start with the general description of interference experiments for discrete observables. There are considered two dichotomous observables, a, "slit number;" and b, "position of a particle on the registration screen." The observable a is measured in the following way. Particle detectors are placed behind the screen having two open slits. The observable $a=j$ if the detector behind the jth slit clicks. To define another observable, we choose some domain D on the registration screen and we set $b=1$ if a particle is registered inside D and $b=0$ if outside. The complex of physical conditions under consideration (context) C is screen with two open slits and the registration screen. We find frequency probabilities $p_C^b(1)$ and $p_C^b(0)$ by counting the number of particles inside and outside the domain D on the registration screen. Then we perform the measurement of the a variable by placing detectors behind the first screen. We find frequency probabilities $p_C^a(1)$ and $p_C^a(2)$ by counting the numbers of particles passing through the first screen and the second screen, respectively [if the source is located symmetrically with respect to screens, then $p_C^a(a=1)=p_C^a(a=2)=1/2$]. We also find transition probability $p^{b/a}(i/j)$ by closing the jth slit and performing the b measurement under this complex of physical conditions. For systems described by classical (noncontextual) probability theory we get the well-known formula of total probability,

$$p_C^b(x) = p_C^a(1)p^{b/a}(x/1) + p_C^a(2)p^{b/a}(x/2).$$

Here the coefficient of statistical disturbance $\lambda(b=x/a,C)=0$. For systems described by quantum probability, we get the interference formula,

$$p_C^b(x) = p_C^a(1)p^{b/a}(x/1) + p_C^a(2)p^{b/a}(x/2) + 2\cos\theta\sqrt{p_C^a(1)p^{b/a}(x/1)p_C^a(2)p^{b/a}(x/2)}.$$

This formula is usually derived in the Hilbert space formalism. In the book of Feynman and Hibs[14] violation of the formula of total probability was considered as the most important exhibition of difference between probabilistic laws for classical and quantum systems. However, in papers of some authors, e.g., Refs. 2, 5–8, and 13 there was pointed out that violation of the formula of total probability is just an exhibition of contextuality of quantum probabilities.

In this paper we predict that contextual statistics produced by experiments of two slit type is not reduced to classical and quantum. Besides the absence of interference and the quantum trigonometric interference, we predict a type of interference—the hyperbolic interference. In our approach it is very easy to find the type of interference of probabilities. In a statistical test for some context C we calculate the coefficient

$$\lambda(a=x/b,C) = \frac{p_C^b(x) - p_C^a(1)p^{b/a}(x/1) - p_C^a(2)p^{b/a}(x/2)}{2\sqrt{p_C^a(1)p^{b/a}(x/1)p_C^a(2)p^{b/a}(x/2)}}.$$

An empirical situation with $\lambda(a=x/b,C)>1$ would yield evidence for quantumlike hyperbolic behavior. The coefficient $\lambda(a=x/b,C)$ can be easily calculated on the basis of statistical data.

Thus our hyperbolic quantum mechanics predicts a testable result, namely the hyperbolic interference, that ordinary quantum mechanics does not.

We wrote about experiments of "two slit type." They need not be precisely experiments with space variables. The a and b can be any pair of incompatible observables. Incompatibility is understood as the impossibility to escape mutual disturbances in the process of measurement. The coefficient $\lambda(a=x/b,C)$ gives the measure of statistical disturbance. Classical measurements are characterized by (statistically) negligibly small mutual disturbances, so here $\lambda(b=x/a,C)=0$ (and we have the conventional formula of total probability). Quantum measurements are characterized by mutual disturbances which are not negligible (statistically). Here $\lambda(b=x/a,C)\in(0,1]$. The conventional formula of total probability is violated and we have the conventional trigonometric interference. However, the quantum case, i.e., $\lambda(b=x/a,C)\in(0,1]$, does not describe all nonclassical measurements. There can exist incompatible observables which produce mutual disturbances which are (statistically) essentially larger than the conventional quantum disturbances. In such a case $\lambda(a=x/b,C)>1$. As in the quantum case, the conventional formula of total probability is violated, but we have nonconventional hyperbolic interference.

Thus hyperbolic interference might be found in experiments with systems which are essentially more sensitive to disturbance effects of measurement devices than quantum systems. So to find such an interference we should go to scales of space, time, and energy, distances and time intervals which are essentially smaller than approached in the conventional quantum experiments. One may speculate that there can be some connections with string theory and cosmology. It may be that quantum mechanics for string theory and cosmology is hyperbolic quantum mechanics.

Another possibility to find hyperbolic interference (which looks more realizable at the present technological level) is to look for observables on ordinary quantum or classical systems which would produce very strong statistical disturbances.

Since we derived the hyperbolic (as well as the conventional trigonometric) interference in the general contextual probabilistic approach, our formalism can be applied to any kind of system, for example, cognitive systems. Experiments of the two slit type can be done for cognitive systems, e.g., human beings. Here observables a and b are given in the form of questions. It might be that cognitive systems can produce hyperbolic interference and should be described by hyperbolic quantum mechanics.

Lifting Bell inequalities

Stefano Pironio[a)]
Institute for Quantum Information, California Institute of Technology, Pasadena, California 91125

(Received 6 April 2005; accepted 20 April 2005; published online 10 June 2005)

A Bell inequality defined for a specific experimental configuration can always be extended to a situation involving more observers, measurement settings, or measurement outcomes. In this article, such "liftings" of Bell inequalities are studied. It is shown that if the original inequality defines a facet of the polytope of local joint outcome probabilities then the lifted one also defines a facet of the more complex polytope. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1928727]

I. INTRODUCTION

In a typical Bell experiment, two or more entangled particles are distributed to separate observers. Each observer measures on his particle one from a set of possible observables and obtains some outcome. One of the most striking features of quantum mechanics is that the resulting joint outcome probabilities can violate a Bell inequality,[1] indicating that quantum mechanics is not, in Bell's terminology, locally causal. This prediction has been confirmed, up to some loopholes, in numerous laboratory experiments.[2,3] The implications of nonlocality for our fundamental description of nature[4,5] have long been discussed; more recently, nonlocality has also acquired a significance in quantum information science.[6–12] From this perspective, being able to decide whether a joint probability distribution can be reproduced with classical randomness only, or whether entanglement is necessary, is an important issue.

For a given number of observers, measurement settings, and measurement outcomes, the set of joint probabilities accessible to locally causal theories is a convex polytope.[13] It is therefore completely characterized by a finite number of linear inequalities that these probabilities must satisfy—that is, by a finite number of Bell inequalities. Each of these inequalities corresponds to a *facet* of the local polytope. Note, however, that not every Bell inequality represents a facet. Facet inequalities are the ones which characterize precisely the border between the local and the nonlocal region. They form a minimal and complete set of Bell inequalities.

In the simple situation where they are only two observers, two measurement choices, and two outcomes per measurement, all the facet inequalities are known:[14,15] up to permutation of the outcomes, they correspond to the Clauser–Horne–Shimony–Holt (CHSH) inequality.[16] Beyond this, little is known. It is in principle possible to obtain all the facet inequalities of an arbitrary Bell polytope using specific algorithms. In practice this only allows one to extend the range of solved cases to a few more observers, measurements, or outcomes,[17,18] as these algorithms are excessively time-consuming. The problem of listing all facet inequalities has in fact been demonstrated to be NP-complete;[19] it is therefore unlikely that it could be solved in full generality. Discouraging as this result may seem, it nevertheless leaves open several possibilities. First, complete sets of facet inequalities may be obtained for particular classes of Bell polytopes or for simplified versions of them. For instance, in the case where "full correlation functions" are considered instead of complete joint probability distributions, all facet inequalities are known for Bell scenarios consisting of an arbitrary number of parties with two measurement choices and two outcomes.[20,21]

[a)]Electronic mail: spironio@caltech.edu

Second, in more complicated situations it may still be possible to obtain partial lists of facets. For instance, families of facet inequalities are known for arbitrary number of measurements[19] or outcomes.[22]

Further progress in the derivation of Bell inequalities would certainly benefit from a better characterization of the general properties of Bell polytopes. This is the motivation behind the present article. The question that we will investigate is how, and to what extent, the facial structure of a Bell polytope determines the facial structure of more complex polytopes. More specifically consider a bipartite Bell experiment characterized by the probability $p_{k_1k_2|j_1j_2}$ for the first observer to obtain outcome k_1 and for the second one to obtain outcome k_2, given that the first observer measures j_1 and the second one j_2. Suppose that each observer chooses one from two dichotomic observables, that is, $k_1, k_2 \in \{1,2\}$ and $j_1, j_2 \in \{1,2\}$. A necessary condition for this experiment to be reproducible by a local model is that the joint probabilities satisfy the CHSH inequality

$$p_{11|11} + p_{11|12} + p_{11|21} - p_{11|22} + p_{22|11} + p_{22|12} + p_{22|21} - p_{22|22} \geqslant 0. \tag{1}$$

Although this inequality is defined for the specific Bell scenario that we have just described, it also constrains the set of local joint probabilities involving more observers, measurements, and outcomes. Indeed, as was noted by Peres[23] there are obvious ways to extend Bell inequalities to more complex situations, or to *lift* them following the terminology of polytope theory. As an illustration, let us consider the following three possible extensions of our CHSH scenario.

(i) *More observers*. Consider a tripartite Bell experiment with joint probability distribution $p_{k_1k_2k_3|j_1j_2j_3}$, where $k_1, k_2, k_3 \in \{1,2\}$ and $j_1, j_2, j_3 \in \{1,2\}$. A necessary condition for this tripartite distribution to be local is that the probabilities $\tilde{p}_{k_1k_2|j_1j_2}$ for the first two observers to measure j_1 and j_2 and to obtain outcomes k_1 and k_2 *conditional* on the third observer measuring $j_3=1$ and obtaining $k_3=1$ satisfy the CHSH inequality. These conditional probabilities are given by $\tilde{p}_{k_1k_2|j_1j_2}=p_{k_1k_21|j_1j_21}/p_{1_3|1_3}$, where the marginal $p_{1_3|1_3}=\sum_{k_1,k_2}p_{k_1k_21|j_1j_21}$ is independent of j_1 and j_2 by no signaling (see Sec. III A). Inserting these probabilities in (1) and multiplying both sides by $p_{1_3|1_3}$ leads to

$$p_{111|111} + p_{111|121} + p_{111|211} - p_{111|221} + p_{221|111} + p_{221|121} + p_{221|211} - p_{221|221} \geqslant 0, \tag{2}$$

a natural extension of the CHSH inequality to three parties.

(ii) *More measurements*. Consider our original bipartite Bell scenario, but assume that the second observer may choose between three different measurement settings $j_2 \in \{1,2,3\}$. Clearly, a necessary condition for the corresponding joint distribution to be reproducible by a local model is that, when restricted to the probabilities involving $j_2 \in \{1,2\}$, it satisfies the CHSH inequality. Therefore, inequality (1) is, as such, a valid Bell inequality for this three-measurement scenario.

(iii) *More outcomes*. Suppose now that the measurement apparatus of the second observer may output one out of three distinct values $k_2 \in \{1,2,3\}$. Merging the outcomes $k_2=2$ and $k_2=3$, we obtain an effective two-outcomes distribution with probabilities $\tilde{p}_{k_11|j_1j_2}=p_{k_11|j_1j_2}$ and $\tilde{p}_{k_12|j_1j_2}=p_{k_12|j_1j_2}+p_{k_13|j_1j_2}$. The existence of a local model for the original distribution obviously implies a model for the coarse-grained one. Expressing the fact that the $\tilde{p}_{k_1k_2|j_1j_2}$ should satisfy (1), we thus deduce the following lifting

$$p_{11|11} + p_{11|12} + p_{11|21} - p_{11|22} + p_{22|11} + p_{22|12} + p_{22|21} - p_{22|22} + p_{23|11} + p_{23|12} + p_{23|21} - p_{23|22} \geqslant 0 \tag{3}$$

of the CHSH inequality to three outcomes.

These three examples can be combined and used sequentially to lift the CHSH inequality to an arbitrary number of observers, measurements, and outcomes. It is also straightforward to generalize them to other Bell inequalities than the CHSH one. How strong are the constraints on the joint probabilities obtained in this way? We will show that if the original inequality describes a facet of the original polytope, then the lifted one is also a facet of the more complex polytope. This implies, for instance, that the CHSH inequality is a facet of every Bell polytope since it is a facet of the simplest one.

This article is organized as follows. Section II introduces the concepts and notations that will be used in the remainder of the paper. In particular, we briefly review the definition of Bell polytopes and elementary notions of polytope theory. In Sec. III, we derive some basic properties of Bell polytopes that are necessary to prove our main results concerning the lifting of facet inequalities. These results are presented in Sec. IV. We conclude with a discussion and some open questions in Sec. V.

II. DEFINITIONS

A. Bell scenario

Consider n systems and assume that on each system i a measurement $j \in \{1,\ldots,m_i\}$ is made, yielding an outcome $k \in \{1,\ldots,v_{ij}\}$. Note that the number of possible measurements m_i may be different for each system i, and that the number of possible outcomes v_{ij} may be different for each measurement j on system i. Such a Bell scenario is thus characterized by the triple (n,m,v) where $m=(m_1,\ldots,m_n)$ specifies the number of possible measurements per system, and where the table $v=[(v_{11},\ldots,v_{1m_1});\ldots;(v_{n1},\ldots,v_{nm_n})]$ specifies the number of possible outcomes per measurement on each system. When notations such as $(n,2,v)$ are used, it should be understood that $m_i=2$ for all i.

The joint probability of obtaining the outcomes $(k_1,\ldots,k_n)$ given the measurement settings $(j_1,\ldots,j_n)$ will be denoted $p_{k_1\ldots k_n|j_1\ldots j_n}$. We will view these $t=\Pi_{i=1}^{n}(\Sigma_{j=1}^{m_i}v_{ij})$ probabilities as forming the components of a vector p in $\mathbb{R}^t$. For a given observer $i \in \{1,\ldots,n\}$, measurement $j \in \{1,\ldots,m_i\}$ and outcome $k \in \{1,\ldots,v_{ij}\}$, we will often be interested in the subset of the components of p that have the indices k_i and j_i corresponding to observer i fixed, and equal, respectively, to k and j. In other words, we will be interested in the variables $p_{k_1\ldots k_{i-1}k\,k_{i+1}\ldots k_n|j_1\ldots j_{i-1}j\,j_{i+1}\ldots j_n}$. The restriction of p to these components will be denoted $p(i,j,k)$.

B. Bell polytopes

The set $\mathcal{B}\subseteq\mathbb{R}^t$ of correlations reproducible within a locally causal model is the set of correlations p satisfying

$$p_{k_1\ldots k_n|j_1\ldots j_n}=\int \mathrm{d}\mu q(\mu)P(k_1|j_1,\mu)\ldots P(k_n|j_n,\mu),$$

where $q(\mu)\geqslant 0$, $\int \mathrm{d}\mu\, q(\mu)=1$, and $P(k_i|j_i,\mu)$ is the probability of obtaining the measurement outcome k_i given the setting j_i and the hidden-variable μ.[1,4] From this definition it is easily deduced (see Ref. 13 for instance) that p is generated by specifying probabilities for every assignment of one of the possible outcomes to each of the measurement settings. More precisely, let the table $\lambda=[(\lambda_{11},\ldots,\lambda_{1m_1});\ldots;(\lambda_{n1},\ldots,\lambda_{nm_n})]$ assign to each measurement j on system i the outcome λ_{ij}. The (finite) set of all such possible assigmenents will be denoted Λ. Let

$$p^{\lambda}_{k_1\ldots k_n|j_1\ldots j_n}=\begin{cases}1 & \text{if } \lambda_{1j_1}=k_1,\ldots,\lambda_{nj_n}=k_n\\ 0 & \text{otherwise}\end{cases} \tag{4}$$

be the deterministic vector corresponding to the assignment λ. Then

$$\mathcal{B}=\left\{p\in\mathbb{R}^t \middle| p=\sum_{\lambda\in\Lambda} q_\lambda p^\lambda, q_\lambda\geqslant 0, \sum_{\lambda\in\Lambda} q_\lambda = 1\right\}. \tag{5}$$

The set $\mathcal{B}$ of local correlations is thus the convex hull of a finite number of points, i.e., it is a polytope. The deterministic vectors $\{p^\lambda|\lambda\in\Lambda\}$ form the extreme points of this polytope.

C. Notions of polytope theory

We review in this section some elementary notions of polytope theory. For more detailed introductions, see Refs. 24–26.

The points $p_1,\ldots,p_n$ in $\mathbb{R}^t$ are said to be affinely independent if the unique solution to $\Sigma_i\mu_i p_i=0$, $\Sigma_i\mu_i=0$ is $\mu_i=0$ for all i, or equivalently, if the points $p_2-p_1,\ldots,p_n-p_1$ are linearly independent. They are affinely dependent otherwise. The affine hull of a set of points is the set of all their affine combinations. An affine set has dimension D, if the maximum number of affinely independent points it contains is $D+1$.

Let $\mathcal{B}\subseteq\mathbb{R}^t$ be a polytope defined as in (5). Let $(b,b_0)\in\mathbb{R}^{t+1}$ define the inequality $b\cdot p\geqslant b_0$. If this inequality is satisfied for all $p\in\mathcal{B}$, it is called a valid inequality for the polytope $\mathcal{B}$, or a Bell inequality in the context of Bell polytopes. Note that to check whether an inequality is a valid inequality, it is sufficient, by convexity, to check whether it is satisfied by the extreme points $\{p^\lambda|\lambda\in\Lambda\}$. Given the valid inequality $b\cdot p\geqslant b_0$, the set $F=\{p\in\mathcal{B}|b\cdot p=b_0\}$ is called a face of $\mathcal{B}$ and the inequality is said to support F. If $F\neq\emptyset$ and $F\neq\mathcal{B}$, it is a proper face. The dimension of F is the dimension of its affine hull. Proper faces clearly satisfy $\dim F\leqslant\dim\mathcal{B}-1$. Proper faces of maximal dimension are called facets. An inequality $b\cdot p\geqslant b_0$ thus supports a facet of $\mathcal{B}$ if and only if $\dim\mathcal{B}$ affinely independent of $\mathcal{B}$ satisfy it with equality.

A fundamental result in polyhedral theory, known as Minkowski–Weyl's theorem, states that a polytope represented as the convex hull of a finite number of points, as in (5), can equivalently be represented as the intersection of finitely many half-spaces:

$$\mathcal{B}=\{p\in\mathbb{R}^t|b^i\cdot p\geqslant b_0^i,\ \text{for all } i\in I\}, \tag{6}$$

where $\{b^i\cdot p\geqslant b_0^i, i\in I\}$ is a finite set of inequalities. The inequalities supporting facets of $\mathcal{B}$ provide a minimal set of such inequalities.[27] In particular, any valid inequality for $\mathcal{B}$ can be derived from the facet inequalities.

Given a Bell scenario (n,m,v), the task of finding all the Bell inequalities is thus the problem of finding all the facets of the convex polytope $\mathcal{B}(n,m,v)$ defined by (4) and (5). This connection between the search for optimal Bell inequalities and polyhedral geometry was observed by different authors.[14,23,28,29] For discussions on the complexity of this facet enumeration task see Refs. 19 and 30. For the instances for which this problem has been partially or completely solved, see Refs. 14, 15, 17–22, 31, and 32.

III. BASIC PROPERTIES OF BELL POLYTOPES

A. Affine hull

Local correlations $p\in\mathcal{B}$ satisfy the following equality constraints: *the normalization conditions*

$$\sum_{k_1\ldots k_n} p_{k_1\ldots k_n|j_1\ldots j_n}=1 \tag{7}$$

for all $j_1,\ldots,j_n$; *and the no signaling conditions*

$$\sum_{k_i} p_{k_1\ldots k_i\ldots k_n|j_1\ldots j_i\ldots j_n}=\sum_{k_i} p_{k_1\ldots k_i\ldots k_n|j_1\ldots j_i'\ldots j_n} \tag{8}$$

for all i, $k_1,\ldots k_{i-1}$, $k_{i+1},\ldots,k_n$ and $j_1,\ldots j_{i-1}$, j_i,j_i', $j_{i+1},\ldots,j_n$.

The no signaling conditions imply that for each subset $\{i_1,\ldots,i_q\}$ of size q of the observers, the q-marginals $p_{k_{i_1}\ldots k_{i_q}|j_{i_1}\ldots j_{i_q}}=\Sigma_{k_{i_{q+1}}}\ldots\Sigma_{k_{i_n}}p_{k_1\ldots k_n|j_1\ldots j_n}$ are well-defined, that is, are independent of the precise value of the measurement settings $j_{i_{q+1}}\ldots j_{i_n}$.

The two conditions (7) and (8) also imply that the polytope $\mathcal{B}$ is not full dimensional in $\mathbb{R}^t$, i.e., it is contained in an affine subspace. The following theorem generalizes results given in Refs. 22 and 19.

Theorem 1: *The constraints* (7) and (8) *fully determine the affine hull of* $\mathcal{B}$ *and*

$$\dim \mathcal{B}=\prod_{i=1}^{n}\left(\sum_{j=1}^{m_i}(v_{ij}-1)+1\right)-1. \tag{9}$$

Proof: Consider the marginals $p_{k_{i_1}\ldots k_{i_q}|j_{i_1}\ldots j_{i_q}}$ as defined above for all possible subsets $\{i_1,\ldots,i_q\}$ of size q, and for all $q=1,\ldots,n$. Of these marginals retain only the ones such that $k_i\neq 1$ for all $i\in\{i_1,\ldots,i_q\}$. These probabilities define in total $D=\Pi_{i=1}^{n}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)-1$ numbers. It is straightforward to check that their knowledge is sufficient to reconstruct, using the normalization and no signaling conditions, the original $p_{k_1\ldots k_n|j_1\ldots j_n}$. This implies that the affine subspace defined by (7) and (8) is of dimension $\leqslant D$.

Let us now show that $\dim\mathcal{B}\geqslant D$, or equivalently that $\mathcal{B}$ contains $D+1$ affinely independent points. For this, note that the definition (4) implies that an extreme point p^{λ} can be written as the product $p^{\lambda}_{k_1\ldots k_n|j_1\ldots j_n}=p^{\lambda}_{k_1|j_1}\ldots p^{\lambda}_{k_n|j_n}$, where $p^{\lambda}_{k_i|j_i}$ is a vector of length $\Sigma_{j=1}^{m_i}v_{ij}$ such that

$$p^{\lambda}_{k_i|j_i}=\begin{cases}1 & \text{if } \lambda_{ij_i}=k_i\\ 0 & \text{otherwise.}\end{cases} \tag{10}$$

For fixed i, consider, for each $j_i'\in\{1,\ldots,m_i\}$ and for each $k_i'\in\{2,\ldots,v_{ij_i'}\}$, the points $p^{\lambda}_{k_i|j_i}$ defined by $\lambda_{ij_i}=1$ for all $j_i\neq j_i'$ and $\lambda_{ij_i'}=k_i'$. In addition, consider the vector $p^{\lambda}_{k_i|j_i}$ defined by $\lambda_{ij_i}=1$ for all j_i. These $\Sigma_{j=1}^{m_i}(v_{ij}-1)+1$ points are linearly independent. The products $p^{\lambda}_{k_1\ldots k_n|j_1\ldots j_n}=p^{\lambda}_{k_1|j_1}\ldots p^{\lambda}_{k_n|j_n}$ of all these points thus define $\Pi_{i=1}^{n}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)=D+1$ linearly independent extreme points of $\mathcal{B}$, which are therefore also affinely independent. □

Since $\mathcal{B}$ is not full dimensional, it follows that there is no unique way to write down a valid inequality for $\mathcal{B}$. More specifically, the inequalities $b\cdot p\geqslant b_0$ and $(b+\mu c)\cdot p\geqslant(b+\mu c_0)$, where $\mu\in\mathbb{R}$ and where $c\cdot p=c_0$ is a linear combination of the equalities (7) and (8), impose the same constraints on $\mathcal{B}$. In particular, it is always possible to use the normalization conditions to rewrite an inequality such that its lower bound is 0, that is, in the form $b\cdot p\geqslant 0$. This fact will be used later on.

B. Trivial facets and nontrivial polytopes

In addition to the normalization and no signaling conditions, $\mathcal{B}$ also satisfy the following *positivity conditions*:

$$p_{k_1\ldots k_n|j_1\ldots j_n}\geqslant 0 \tag{11}$$

for all $k_1,\ldots,k_n$ and $j_1,\ldots,j_n$.

Theorem 2: *The positivity conditions support facets of* $\mathcal{B}$.

Proof: Without loss of generality, suppose that $p_{k_1\ldots k_n|j_1\ldots j_n}\geqslant 0$ is such that the $k_1,\ldots,k_n$ are all different than 1. Then, in the proof of Theorem 1, we enumerated $\dim\mathcal{B}+1$ affinely independent points, $\dim\mathcal{B}$ of which satisfy $p_{k_1\ldots k_n|j_1\ldots j_n}=0$. □

The normalization, no signaling, and positivity conditions are obviously not only satisfied by local probabilities, but also by all no signaling nonlocal ones, and in particular by quantum ones. The only useful constraints that separate the local region from the nonlocal thus correspond to the facets of $\mathcal{B}$ that are not of the form (11).

Let us also note that when determining the facets of a Bell polytope, we can always assume that n, m_i and v_{ij} are all $\geqslant 2$ because otherwise all the corresponding facets are trivial or belong to simpler polytopes. Indeed,

(i) the only facet inequalities of one-partite polytopes are the positivity constraints,
(ii) all the facet inequalities of a polytope where $m_i=1$ for some party i are equivalent to the facet inequalities of the polytope obtained by discarding that party,
(iii) a polytope with $v_{ij}=1$ for some measurement j of party i is equivalent to the polytope obtained by discarding that measurement choice.

Point (i) is easily established. To show (ii), assume that $\mathcal{B}$ is a polytope such that for party i the only measurement choice is $j \in \{1\}$. A valid inequality for $\mathcal{B}$ can thus be written as

$$\sum_k b_k \cdot p(i,j,k) \geqslant 0, \tag{12}$$

where, without loss of generality, the right-hand side is equal to zero. It then follows that for all $k \in \{1,\ldots,v_{ij}\}$ the following inequalities

$$b_k \cdot p(i,j,k) \geqslant 0 \tag{13}$$

are also valid for $\mathcal{B}$. Indeed, for each extreme point p^λ, either the assignment λ is such that $\lambda_{ij}=k$ and (12) and (13) impose the same constraints on p^λ, or $\lambda_{ij} \neq k$ and (13) gives the trivial inequality $0 \geqslant 0$. Every extreme point satisfying (12) thus also satisfies (13). Note further that every extreme point satisfying (12) with equality also satisfies (13) with equality. This implies that the face supported by (12) cannot be—unless (12) is itself equivalent to one of the inequalities (13)—a facet of $\mathcal{B}$, because it lies in the intersection of the faces supported by (13) and is therefore of dimension $<\dim \mathcal{B}-1$. We can thus assume that all facet inequalities of $\mathcal{B}$ are of the form (13). It will be shown in Sec. IV A that all these facet inequalities are equivalent to facet inequalities of the polytope obtained by discarding party i. Finally, point (iii) follows immediately when we notice that a polytope with $v_{ij}=1$ for some measurement j of party i and the polytope obtained by discarding that measurement have the same dimension and have their extreme points in one-to-one correspondence.

C. A useful lemma

As we have reminded earlier an inequality defines a facet of a polytope $\mathcal{B}$ if and only if it is satisfied by $\dim B$ affinely independent points of $\mathcal{B}$. To prove the results of the next section concerning the lifting of facet inequalities, we will then need to count the number of affine points that a facet contains. The following lemma will be our main tool to achieve this task.

Lemma 3: *Let the inequality $b \cdot p \geqslant b_0$ support a facet of $\mathcal{B}(n,m,v)$. Let $i' \in \{1,\ldots,n\}$, $j' \in \{1,\ldots,m_{i'}\}$ and $k' \in \{1,\ldots,v_{i'j'}\}$. Then there are at exactly r extreme points p^λ of $\mathcal{B}$ such that $b \cdot p^\lambda = b_0$, $\lambda_{i'j'}=k'$, and such that the r restrictions $p^\lambda(i',j',k')$ are affinely independent, where*

(i) $r=\Pi_{i\neq i'}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)-1$, *if $b \cdot p \geqslant b_0$ is equivalent to an inequality of the form $c \cdot p(i',j',k') \geqslant 0$;*
(ii) $r=\Pi_{i\neq i'}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)$, *otherwise.*

Proof: Let $\{p^\delta \mid \delta \in \Delta \subseteq \Lambda\}$ be $\dim \mathcal{B}$ affinely independent extreme points which belong to the facet supported by $b \cdot p \geqslant b_0$. Among these, let $\{p^\gamma \mid \gamma \in \Gamma \subseteq \Delta\}$ be the extreme points satisfying $\gamma_{i'j'}=k'$ and such that their restrictions $\{p^\gamma(i',j',k') \mid \gamma \in \Gamma\}$ are affinely independent.

Consider the polytope $\mathcal{B}^{n-1}$ obtained from $\mathcal{B}$ by discarding party i'. The components of $p \in \mathcal{B}^{n-1}$ are thus of the form $p_{k_1\ldots k_{i'-1}k_{i'+1}\ldots k_n|j_1\ldots j_{i'-1}j_{i'+1}\ldots j_n}$. Given that $p^\gamma(i',j',k')$ corresponds to the components of p^γ where the indices associated to the i'th party are fixed and satisfy $k_{i'}=k'$, $j_{i'}=j'$, given that $\gamma_{i'j'}=k'$, and given definition (4), it follows that each $p^\gamma(i',j',k')$ can be identified with an extreme point of the $(n-1)$-partite polytope $\mathcal{B}^{n-1}$ [and conversely, each extreme point of $\mathcal{B}^{n-1}$ can be identified with the restriction $p^\gamma(i',j',k')$ of some extreme point $p^\gamma \in \mathcal{B}$

satisfying $\gamma_{i'j'}=k']$. Thus no more than dim $\mathcal{B}^{n-1}$ of the $p^{\gamma}(i',j',k')$ can be affinely independent, and $r \leqslant \dim \mathcal{B}^{n-1}+1=\Pi_{i\neq i'}(\Sigma_{i=1}^{m_i}(v_{ij}-1)+1)$. Alternatively, one could have deduced the same result starting from the fact that the p^{γ} satisfy the implicit equalities (7) and (8), and counting the number of constraints that these equalities impose on the $p^{\gamma}(i',j',k')$.

Suppose that $r<\dim \mathcal{B}^{n-1}+1$. Then the $\{p^{\gamma}|\,\gamma\in\Gamma\}$ satisfy at least one constraint

$$c\cdot p(i',j',k')=0 \tag{14}$$

linearly independent from the implicit equalities of $\mathcal{B}$. Following the remark at the end of Sec. III A, we have not lost generality by taking the right-hand side of (14) equal to zero. Note that the constraint (14) is in fact satisfied by all $\{p^{\delta}|\,\delta\in\Delta\}$. Indeed, either $\delta_{i'j'}\neq k'$ and (14) gives the trivial equation $0=0$, or $p^{\delta}(i',j',k')$ is affinely dependent from the $p^{\gamma}(i',j',k')$, which satisfy (14).

As the $\{p^{\delta}|\,\delta\in\Delta\}$ form a set of dim $\mathcal{B}$ independent extreme points, they can satisfy at most one constraint linearly independent from the implicit equalities of $\mathcal{B}$, i.e., there can only be one constraint of the form (14). Thus at most $r=\dim \mathcal{B}^{n-1}=\Pi_{i\neq i'}(\Sigma_{i=1}^{m_i}(v_{ij}-1)+1)-1$. Furthermore, as the $\{p^{\delta}|\,\delta\in\Delta\}$ already satisfy the equality $b\cdot p=b_0$, this can only be the case if (14) is equivalent to $b\cdot p=b_0$, that is if $b\cdot p\geqslant b_0$ is equivalent either to $c\cdot p(i',j',k')\geqslant 0$ or $(-c)\cdot p(i',j',k')\geqslant 0$. □

IV. LIFTING BELL INEQUALITIES

We now move on to study the liftings of Bell inequalities that we have presented in Sec. I and their natural generalizations. We will prove that these liftings are facet-preserving. It was already shown in Ref. 19 that a Bell inequality that supports a facet of $\mathcal{B}(2,m,2)$ also supports a facet of $\mathcal{B}(2,m',2)$ for all $m'\geqslant m$. Furthermore, in Ref. 33 liftings of "partial constraint satisfaction polytopes" (polytopes encountered in certain optimization problems) were considered. Although such liftings were studied independently from any potential relation to Bell inequalities, it turns out that partial constraint satisfaction polytopes over a complete bipartite graph are bipartite Bell polytopes (in particular, the "4-cycle inequality" introduced in Ref. 33 corresponds to the CHSH inequality). The results presented in Ref. 33 then imply that an inequality that supports a facet of $\mathcal{B}(2,m,v)$ also supports a facet of $\mathcal{B}(2,m',v')$ for all $m'\geqslant m$, $v'\geqslant v$. It is in fact these results that inspired the ones that are presented here.

In Secs. IV A–IV C, we will see that the lifting of an arbitrary inequality to a situation involving, respectively, one more observer, one more measurement outcome, and one more measurement setting are facet-preserving. Combined together these results imply that a Bell inequality that supports a facet of a Bell polytope $\mathcal{B}(n,m,v)$, also supports, when lifted in the appropriate way, a facet of any higher dimensional polytope $\mathcal{B}(n',m',v')$ with $n'\geqslant n$, $m'\geqslant m$, $v'\geqslant v$.

A. One more observer

Consider a polytope $\mathcal{B}\equiv\mathcal{B}(n,m,v)$, where the n parties are labeled $\{1,\ldots,i'-1,i'+1\ldots,n+1\}$ for some value i'. Let the inequality

$$b\cdot p\geqslant 0 \tag{15}$$

be valid for $\mathcal{B}$. Note that we have taken, without loss of generality, the right-hand side of (15) to be equal to 0. Let us extend the polytope $\mathcal{B}$ by inserting an additional observer in position i'. The resulting $(n+1)$-partite polytope will be denoted $\mathcal{B}^{n+1}$.

Given a point $p\in\mathcal{B}^{n+1}$, remember that $p(i',j',k')$ represents the probabilities of p for which the indices corresponding to the measurement setting and the outcome of party i' are fixed, and are equal, respectively, to j' and k'. Therefore $p(i',j',k')/p_{k'_{i'}|j'_{i'}}$, where $p_{k'_{i'}|j'_{i'}}$ denotes the marginal probability for observer i' to measure j' and obtain k', is the joint outcome probability distribution for the n observers $\{1,\ldots,i'-1,i'+1,\ldots n+1\}$ conditional on party i' measuring j' and obtaining k'. Either this conditional probability is equal to zero, or it corresponds to a point of $\mathcal{B}$. In both cases, it satisfies (15). It thus follows immediately that the following inequality

$$b \cdot p(i',j',k') \geqslant 0 \tag{16}$$

is valid for $\mathcal{B}^{n+1}$. Further, this lifting is facet-preserving.

Theorem 4: *The inequality* (15) *supports a facet of* $\mathcal{B}$ *if and only if* (16) *supports a facet of* $\mathcal{B}^{n+1}$.

Proof: As we have noted in the proof of Lemma 3, the restriction $p^{\lambda}(i',j',k')$ of an extreme point p^{λ} of $\mathcal{B}^{n+1}$ satisfying $\lambda_{i'j'}=k'$ can be identified with an extreme point of $\mathcal{B}$, and conversely. Moreover, it is clear that if $p^{\lambda}(i',j',k')$ satisfy (16) with equality the corresponding extreme point of $\mathcal{B}$ satisfy (15) with equality, and the other way around.

Assume that (16) supports a facet of $\mathcal{B}^{n+1}$. Then it follows from Lemma 3 that they are $\Pi_{i\neq i'}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)-1=\dim \mathcal{B}$ extreme points of $\mathcal{B}^{n+1}$ that satisfy (16) with equality, such that $\lambda_{i'j'}=k'$ and for which the restrictions $p^{\lambda}(i',j',k')$ are affinely independent. By the above remark, these extreme points define $\dim \mathcal{B}$ affinely independent extreme points of $\mathcal{B}$ that satisfy (15) with equality, hence this inequality supports a facet of $\mathcal{B}$.

To prove the converse statement, suppose now that (15) defines a facet of $\mathcal{B}$, that is, there exist $\dim \mathcal{B}$ affinely independent extreme points of $\mathcal{B}$ that satisfy it with equality. By the above remark, there thus exist $\dim \mathcal{B}$ extreme points of $\mathcal{B}^{n+1}$ that satisfy (16) with equality, such that $\lambda_{i'j'}=k'$ and for which the restrictions $p^{\lambda}(i',j',k')$ are affinely independent. To show that (16) defines a facet of $\mathcal{B}^{n+1}$, it thus remains to find $\dim \mathcal{B}^{n+1}-\dim \mathcal{B}$ affinely independent points satisfying it with equality. For this, consider[34] the extreme points of $\mathcal{B}^{n+1}$ with $\lambda_{i'j'}\neq k'$. They form an affine subspace of dimension $\dim \mathcal{B}^{n+1}-\Pi_{i\neq i'}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)=\dim \mathcal{B}^{n+1}-\dim \mathcal{B}-1$ since they can be identified with the extreme points of the polytope involving one outcome less than $\mathcal{B}^{n+1}$ for the measurement j'. Moreover, because they verify $p^{\lambda}(i',j',k')=0$, they satisfy (16) with equality, and are affinely independent from the extreme points for which $\lambda_{i'j'}=k'$. □

We thus have just shown that any facet inequality of an n-partite polytope can be extended to a facet inequality for a situation involving $n+1$ parties. This result can be used sequentially so that facets of n-party polytopes are lifted to $(n+k)$-partite polytopes. For instance, the positivity conditions (11) can be viewed as the successive lifting of 1-party inequalities.

The result holds in the other direction as well, since any facet inequality of the form (16) is the lifting of an n-partite inequality. When studying Bell polytopes, it is thus in general sufficient to consider *genuinely n-partite inequalities*, that is, inequalities that cannot be written in a form that involves only probabilities associated with one specific measurement setting j' and one specific outcome k' for some party i'. Note that we can extend this definition to also exclude all inequalities such as (12) that involve only probabilities associated to one measurement setting (but possibly several outcomes corresponding to this measurement). Indeed, we have noted at the end of Sec. III B that such inequalities cannot be stronger than inequalities of the form (16).

B. One more measurement outcome

Consider a polytope $\mathcal{B}\equiv\mathcal{B}(n,m,v)$, where for measurement j' of party i' the $v_{i'j'}$ outcomes are labeled $\{1,\ldots,k'-1,k'+1,\ldots,v_{i'j'}+1\}$ for some k'. Let

$$b \cdot p \geqslant b_0 \tag{17}$$

be a genuinely n-partite inequality valid for $\mathcal{B}$. Let us consider the polytope $\mathcal{B}^{v+1}$ obtained from $\mathcal{B}$ by allowing an extra outcome k' for the measurement j' of party i'. To lift the inequality $b\cdot p \geqslant b_0$ to the polytope $\mathcal{B}^{v+1}$, we can merge the additional outcome k' with some other outcome $k^* \in\{1,\ldots,k'-1,k'+1,\ldots,v_{i'j'}+1\}$, and insert the resulting probability distribution in (15). This results in the inequality

$$b \cdot p + b(i',j',k^*) \cdot p(i',j',k') \geqslant b_0. \tag{18}$$

Theorem 5: *If the genuinely n-partite inequality* (15) *supports a facet of* $\mathcal{B}$, *then* (18) *supports a facet of* $\mathcal{B}^{v+1}$.

Proof: The dimension of $\mathcal{B}^{v+1}$ equals $\dim \mathcal{B}+\Pi_{i\neq i'}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)$. The extreme points of $\mathcal{B}$

that belong to the facet $b\cdot p\geqslant b_0$ provide $\dim \mathcal{B}$ affinely independent points satisfying (18) with equality. By Lemma 3, there exist $\Pi_{i\neq i'}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)$ extreme points p^{λ} with $\lambda_{i'j'}=k^*$ that saturate (15), and thus (18), and for which the $p^{\lambda}(i',j',k^*)$ are affinely independent. Replace k^* by k' in these extreme points. These new extreme points still satisfy (18) with equality and are affinely independent with all the previous ones, since they are the unique extreme points with $p^{\lambda}(i',j',k')\neq 0$. In total, we thus enumerated $\dim \mathcal{B}^{v+1}=\dim \mathcal{B}+\Pi_{i\neq i'}(\Sigma_{j=1}^{m_i}(v_{ij}-1)+1)$ affinely independent point satisfying (18) with equality. □

C. One more measurement setting

Consider a polytope $\mathcal{B}\equiv\mathcal{B}(n,m,v)$, where for party i' the $m_{i'}$ measurements are labeled $\{1,\ldots,j'-1,j'+1,\ldots,m_{i'}+1\}$ for some j'. Let the polytope $\mathcal{B}^{m+1}$ be the polytope obtained from $\mathcal{B}$ by allowing the additional measurement setting j' for party i'. An inequality $b\cdot p\geqslant b_0$ valid for $\mathcal{B}$ is also clearly valid for $\mathcal{B}^{m+1}$. Moreover, the following stronger result holds.

Theorem 6: *Let $b\cdot p\geqslant b_0$ be a genuinely n-partite inequality supporting a facet of $\mathcal{B}$. Then it is also support a facet of $\mathcal{B}^{m+1}$.*

Proof: Consider the polytope $\tilde{\mathcal{B}}^{m+1}$ defined as $\mathcal{B}^{m+1}$ but such that for the measurement j' of party i' is associated a single possible outcome, i.e., $v_{i'j'}=1$. The inequality $b\cdot p\geqslant b_0$ is a valid genuinely n-partite inequality for $\tilde{\mathcal{B}}^{m+1}$. Further, since $\tilde{\mathcal{B}}^{m+1}$ and $\mathcal{B}$ have the same dimension, it is also facet defining for $\tilde{\mathcal{B}}^{m+1}$. Following the procedure to lift an inequality to more outcomes delineated in Sec. IV B, this inequality can be lifted from $\tilde{\mathcal{B}}^{m+1}$ to $\mathcal{B}^{m+1}$. Since $b\cdot p\geqslant b_0$ does not involve components associated with the measurement j' of party i', this results in the inequality $b\cdot p\geqslant b_0$ itself. By Theorem 5, this inequality is facet defining for $\mathcal{B}^{m+1}$. □

V. CONCLUSION

We have shown that the facial structure of Bell polytopes is organized in a hierarchical way, with all the facets of a given polytope inducing, through their respective liftings, facets of more complex polytopes. Instead of considering the entire set of facets of a Bell polytope, it is thus in general sufficient to characterize the ones that do not belong to simpler polytopes. It would be interesting to investigate whether this fact could be exploited to improve the efficiency of the algorithms used to list facet inequalities or to simplify analytical derivations of Bell inequalities.

Note that for certain polytopes, the complete set of facet inequalities is constituted entirely by inequalities lifted from more elementary polytopes. For instance for Bell scenarios involving two observers, the first having a choice between two dichotomic measurements and the second one between an arbitrary number of them, all the facet-defining inequalities correspond to liftings of the CHSH inequality.[18,31] A natural extension of the results reported in this article would then be to investigate more generally when inequalities lifted from simpler polytopes describe complete sets of facets. Progress along this line would allow one to narrow down the class of Bell scenarios that have to be considered to find new Bell inequalities. Following this approach, all the polytopes for which the only facets correspond to liftings of the CHSH inequality have recently been characterized.[35]

Finally, let us note that while the facet-preserving liftings that we have considered are interesting because they throw light on the structure of Bell polytopes, the inequalities obtained in this way are not essentially different from the original ones, they are merely re-expressions of these inequalities adapted to more general scenarios. However, it is also in principle possible to consider more complicated generalizations of Bell inequalities that alter significantly their intrinsic structure. For instance, the family of Bell inequalities introduced in Ref. 36 can be understood as being generated by successive nontrivial liftings of the CHSH inequality. Studying such liftings, as well as the other possible extensions of our results, seems a promising path toward a more accurate characterization of the constraints that separate the set of local joint probabilities from the set of nonlocal ones.

(Received 6 February 2004; accepted 29 March 2005; published online 13 May 2005)

We argue that a semi-infinite D6-brane ending on an NS5-brane can be obtained from the condensation of the tachyon on the unstable D9-brane of type IIA theory. The construction uses a combination of the descriptions of these branes as solitons of the worldvolume theory of the D9-brane. The NS5-brane, in particular, involves a gauge bundle which is operator valued, and hence is better thought of as a gerbe. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1922069]

I. INTRODUCTION

In type IIA string theory a D6-brane can end on a Neveu–Schwarz (NS) fivebrane in a supersymmetric configuration.[1] The simplest way to see this is to start from a fundamental string ending on a D5-brane in type IIB theory. Indeed this defines a *Dirichlet* fivebrane. Now by S-duality followed by T-dualities along all the spatial directions of the worldvolume of the resulting NS5-brane we reach the desired configuration. Recall that this system (and its T-dual cousins) are essential ingredients in "brane engineering" of gauge theory dynamics following Ref. 2.

Naively a semi-infinite brane in a flat space cannot exist by charge conservation. There is a quantized charge of a D6-brane through a two-sphere enclosing it. However, in case of a semi-infinite brane this S^2 can just be "slipped off" the end and collapsed, leading to an apparent contradiction. This argument fails because we are in a situation with a nontrivial Neveu–Schwarz B-field provided by the fivebrane. The gauge-invariant field strength is not simply the curvature of the RR one-form gauge field.[3] The NS B-field also couples to the Chan–Paton gauge field modifying the Bianchi identity[4] to $dF \sim H$.

We would like to obtain the semi-infinite D6-brane ending on a NS5-brane via tachyon condensation on the unstable D9-brane. According to Sen,[5] all D-branes in type IIA string theory arise as solitons of the worldvolume theory on the D9-branes. (For early work on tachyon condensation in string theory, see Ref. 6.) In particular, the stable D6-brane is an 't Hooft-Polyakov monopole of the gauge field-tachyon system on at least two D9-branes.[7] The situation is more complicated in the presence of the nontrivial B-field due to the fivebrane (see Ref. 8 where many configurations involving D-branes and the NS5-brane were discussed). Any configuration must satisfy the modified Bianchi identity. In our case, the relation $dF \sim H$ must hold for both the final D6-NS5-brane configuration *after* the tachyon condensation, as well as *before* it, for the D9-NS5-brane system. The problem of tachyon condensation in the presence of an H field whose quantized charges are $\mathbf{Z}_n$ valued was analyzed in Ref. 4. This was generalized to the usual integrally quantized case in Ref. 9, which argues that in this situation one needs to consider the group of unitary operators in a Hilbert space as the gauge group on the D9-brane. Operator valued gauge fields appear in a natural way in the solitons of noncommutative gauge theory.[10,11] Indeed, Harvey and Moore[12] have suggested a configuration to describe a NS5-brane as a noncommutative soliton

of open string theory (see also Ref. 13). We present our arguments in this setup.

It turns out that our construction is related to one version of what is called a *gerbe*,[14] one in which it is described by operator valued gauge fields. (Let us note parenthetically that in their study of the antisymmetric tensor gauge fields, Freund and Nepomechie[15] discovered gerbes in string theory. Some recent applications to string theory may be found in Refs. 16 and 17.) As a matter of fact, the NS5-D6-brane configuration has been obtained as a stable solution of massive type IIA supergravity,[16] in the language of gerbes. However, a different description of gerbes in terms of local U(1) bundles was used in Ref. 16, which did not discuss tachyon condensation either.

II. FIELD THEORY ANALOG

It is instructive to look at a simpler field theory model, in four space–time dimension, which share the essential features of the brane configuration we wish to obtain after tachyon condensation. This model consists of a semi-infinite Nielsen–Olesen vortex of the Abelian Higgs model ending on a Dirac monopole. We can think of this monopole as a singular limit of the 't Hooft-Polyakov monopole in the SO(3) Georgi–Glashaw model. With the Higgs field pointed radially outwards in the field space, this is a nonsingular solution to the equations of motion with mass proportional to M_W/g_{YM}^2. The Nielsen–Olesen vortex, on the other hand, has constant finite energy per unit length. A semi-infinite vortex ending on a monopole is then an infinite energy configuration. To minimize its energy, the vortex will reduce its length thereby pulling the monopole along all the way to infinity. Hence the semi-infinite vortex string ending on a monopole is unstable.

There exists a remarkable way to stabilize this configuration by putting the monopole inside an accelerating black hole.[18] Here we begin with the Abelian Higgs model coupled to gravity. This model has cosmic string, i.e., Nielsen–Olesen vortex solution as well as, say, a Schwarzschild black hole solution. Let us consider a configuration in which the vortex ends on a black hole. In this case one finds an axisymmetric metric with a conical singularity on the accelerating Schwarzschild black hole, whose metric up to a conformal factor is (see the third reference in Ref. 19),

$$\mathrm{d}s^2 = f(r)\mathrm{d}t^2 - f^{-1}(r)\mathrm{d}r^2 - r^2\mathrm{d}\theta^2 - r^2(1-\alpha)^2\sin^2\theta\,\mathrm{d}\phi^2, \tag{1}$$

where

$$f(r) = \left(1 - \frac{2M}{r} - A^2r^2\right)$$

and A is the acceleration of the black hole. The deficit angle of the conical singularity is proportional to α. This is a reflection of the fact that the vortex is piercing the black hole horizon. The Schwarzschild black hole horizon has the topology of a two sphere. Suppose in the frame of an asymptotic observer the vortex ends on the south pole of the horizon, then we can take a loop on the horizon around the south pole and measure the magnetic flux of the vortex. For one vortex configuration, the *angle valued* Higgs field Φ winds once around this loop. Now, by deforming this loop we can shrink it at the north pole. Since the vortex pierces the horizon only once, the shrinking of the loop at the north pole seems to lead to a contradiction. However, this result is misleading as the value of Φ is gauge dependent. The vortex is also accompanied by a topologically nontrivial gauge field configuration. A consistent solution corresponds to defining the Hopf fibration over S^2. This can be achieved by defining two charts on S^2,

$$\mathcal{U}_N = \{\theta, \phi: \theta < \pi\}, \quad \mathcal{U}_S = \{\theta, \phi: \theta > 0\}. \tag{2}$$

On the overlap, the fields are related by the transition function $g_{\mathrm{NS}} = \exp(-i\phi)$ as

$$\exp(i\Phi_N) = g_{NS}\exp(i\Phi_S), \quad A_{N\mu} = A_{S\mu} + ig_{NS}^{-1}\partial_\mu g_{NS}. \tag{3}$$

Since the vortex is on the lower hemisphere, we can take $\Phi_N=0$ and $A_N=0$ on the northern hemisphere and connect it to the vortex configuration on the southern hemisphere via the topologically nontrivial transition function. This configuration makes sense as long as the S^2 horizon does not shrink to zero size. This is ensured by the fact that the extended Schwarzschild geometry in the Kruskal coordinates is a wormhole with topology $S^2\times\mathbf{R}$, the minimum radius of the sphere being $2GM$. In the extended geometry, absence of the vortex in the northern hemisphere can be explained in the following manner. As the vortex approached the south pole of the horizon it goes down the throat of the wormhole and reappears through the horizon in the other asymptotic region.

Let us now get back to the winding number of Φ. This quantity is not gauge invariant in the presence of a nontrivial gauge field configuration. The field Φ is also not single valued everywhere on the sphere. We can, however, define a quantity

$$\mathcal{A} = d\Phi - A, \tag{4}$$

which is both gauge invariant and single valued. In the northern hemisphere we have chosen $\Phi_N=0$ and $A_N=0$, which implies even in the southern hemisphere the net winding charge should vanish. Clearly $\mathcal{A}$ being single valued has zero winding charge. On the other hand, we saw that a vortex solution near the south pole has $d\Phi$ winding number one. Hence we conclude that the integral of A around the loop near the south pole also has unit winding charge.

III. NEVEU–SCHWARZ FIVEBRANE IN OPEN STRING THEORY

The NS5-brane is a soliton of the closed string theory. Therefore one does not expect to see detailed features of it in open string theory. Nevertheless, it turns out that some topological aspect of the NS5-brane can be captured in terms of open strings. Harvey and Moore[12] have a configuration with the right H-flux. In fact they have argued that the NS5-brane may be thought of as a particular soliton in the noncommutative gauge theory of the unstable D9-brane in type IIA theory. This is inspired by the idea of a noncommutative tachyon.[11]

We will now review this construction. In Ref. 12, the space–time topology is chosen to be $\mathbf{R}^{1,4}\times\mathbf{R}^2_{NC}\times S^2\times S^1$ and the H-flux is through the 3-cycle $S^2\times S^1$. This is based on an example in Ref. 20. We will work, however, with $\mathbf{R}^{1,4}\times\mathbf{R}^2_{NC}\times S^3$, which is the space–time topology, at least in the near horizon limit, of the NS5-brane.[21] There is a *constant* NS B-field along $\mathbf{R}^2_{NC}$. It should be emphasized that this is not the B-field that contributes to the H-flux, but has the effect of making the (the $\mathbf{R}^2_{NC}$ part of) space–time noncommutative. Therefore we may treat the tachyon, gauge, and other fields as operator valued on $\mathbf{R}^{1,4}\times S^3$. Henceforth we will concentrate only on the S^3 part.

In Refs. 9 and 22, it was argued that the gauge group in noncommutative gauge theory is $\mathrm{U}_{\mathrm{cpt}}(\mathcal{H})$, a subgroup of unitary operators in a Hilbert space $\mathcal{H}$ of the form $u=\mathbf{1}+K$, where $K\in\mathcal{K}(\mathcal{H})$ is a compact operator. Conjugation by elements of the group $\mathrm{U}(\mathcal{H})$ are automorphisms of the corresponding Lie algebra $\mathcal{K}(\mathcal{H})$ of compact operators. However, since the U(1) center of $\mathrm{U}(\mathcal{H})$ acts trivially, the automorphism of $\mathcal{K}(\mathcal{H})$, [and hence of $\mathrm{U}_{\mathrm{cpt}}(\mathcal{H})$], is really $\mathrm{PU}(\mathcal{H})=\mathrm{U}(\mathcal{H})/\mathrm{U}(1)$. The Lie algebra valued gauge field and the tachyon which transform in the adjoint representation are therefore valued in $\mathcal{K}(\mathcal{H})$. A nontrivial gauge bundle may be constructed with a twist by an element of $\mathrm{Aut}(\mathcal{K}(\mathcal{H}))=\mathrm{PU}(\mathcal{H})$. The proposal of Ref. 12 is that an appropriate nontrivial $\mathrm{PU}(\mathcal{H})$ bundle on S^3, with the tachyon field at the maximum of the potential, represents a D9-brane and a NS5-brane. Moreover, when the tachyon condenses to a minimum of the potential, there is only a NS5-brane as the D9-brane ought to have disappeared according to Sen's conjecture.[5]

The key to the construction of this $\mathrm{PU}(\mathcal{H})$ bundle is the fact that $\pi_2(\mathrm{PU}(\mathcal{H}))=\mathbf{Z}$. It is then possible to patch together trivial bundles on local coordinate charts of S^3 along their overlaps. This is a one higher dimensional generalization of the construction of a monopole on S^2, which used the fact that $\pi_1(\mathrm{U}(1))=\mathbf{Z}$. As we have mentioned before, the base space in Ref. 12 is $S^2\times S^1$. The Hopf fibration $S^3\to S^2$ and the covering space of the fiber $\mathbf{R}\to S^1$ defines a natural $S^1\times\mathbf{Z}$ bundle

on it. This is embedded in PU($\mathcal{H}$) by lifting the circle coordinate to an angle valued position operator $\hat{\Omega}$ and its (integrally quantized) conjugate momentum $\hat{L}$ satisfying a Heisenberg algebra

$$[\hat{\Omega},\hat{L}] = i\hat{1}. \tag{5}$$

Let us review some details of this construction following Ref. 20. One starts with a principle U(1) bundle $P(\mathrm{U}(1))$ over a base manifold X and the universal covering space $\mathbf{R}$ of S^1. This defines a principle $P(\mathrm{U}(1)\times\mathbf{Z})$ bundle over the base space $X\times S^1$. In the following we will consider the specific example of the Hopf bundle $X=S^2$ and $P(\mathrm{U}(1))=S^3$. Given a (vector) space V on which the group G acts, it is possible to define a fiber bundle $E_V\to X\times S^1$ associated to the principle G bundle by the quotient $(P(G)\times V)/G$. The fiber of this bundle [recall that in the associated bundle the sections coming from a quotient action of G on $G\times V$ are identified as $(s,v)\sim(sg,g^{-1}v)$ providing a twist] is isomorphic to V. The frame bundle and the tangent bundle to a manifold is an example of such a pair. Another natural association is one in which V is the Lie algebra $\hat{g}$ of G or any of its representations. The G action on V, in turn, induces an adjoint action on the space of linear operators $\mathcal{L}(V)$ on V. One can, therefore, construct an associated "bundle" whose fiber is $\mathcal{L}(V)$ and the transition functions g_{ij} act by adjoint action (with the center acting trivially). In particular, our objective will be to construct a bundle whose fiber consists of operators in the Hilbert space $\mathcal{H}$ of square integrable functions $L^2(S^1)$ of a projective representation of the Heisenberg group H, which is a central extension of the group $S^1\times\mathbf{Z}$.

In order to specify the bundle, it will be sufficient to give a local trivialization over open sets $\mathcal{U}_i$, in which we specify the Hilbert space of functions and provide the transition functions. Let $(x=(\psi,\theta),\phi)$ be points in $S^2\times S^1$ and

$$p{:}S^3\times\mathbf{R}\to S^2\times S^1$$

be the projection map of the smaller bundle with which the construction proceeds. The fiber $p^{-1}(x)$ is a circle S^1_x without any fixed base point. The universal cover $\tilde{S}^1_x\sim\mathbf{R}_x$ is ambiguous up to the cyclic group generated by T which shifts the coordinate of $\mathbf{R}_x$ by (2π times) an integer. Consider the Hilbert space of functions

$$\mathcal{H}_{(x,\phi)} = \{f{:}\mathbf{R}_x\to\mathbf{R}_x | f(T(\xi)) = e^{i\phi}\cdot f(\xi), \tilde{\xi}\in\mathbf{R}_x\}. \tag{6}$$

Of course, the space depends on the choice of coordinates on the universal cover, but the ambiguity is up to an action of T, which acts as multiplication by a scalar leading to a unique projective Hilbert space. Let S^1 be a circle which we can identify with the fiber S^1_x. With an abuse of notation we will use the same angular coordinate ξ on both these circles. Consider the square integrable functions $f(\xi)$ on the circle satisfying the following property under the isomorphism $\lambda_{(x,\phi)}{:}L^2(S^1)\sim\mathcal{H}_{(x,\phi)}$:

$$\lambda_{(x,\phi)}(f(\xi)) = \exp\left(\frac{i}{2\pi}\xi\phi\right)f(\xi).$$

This specifies the local trivialization. It is easy to check that the above satisfies the property required of $\mathcal{H}_{(x,\phi)}$ defined above.

The Lie algebra $\hat{\mathfrak{h}}$ of the group H has generators

$$(\hat{L},\hat{1}) = \left(-i\frac{\mathrm{d}}{\mathrm{d}\xi},\hat{1}\right).$$

Since the spectrum of the angular momentum $\hat{L}$ is discrete, there is no Lie algebra associated with the generator $\hat{\Omega}$ of the Heisenberg algebra (5). Rather $\exp(2\pi i\hat{\Omega})\sim T$ is the generator of the automorphism discussed earlier. The group H acts by adjoint action on $\hat{\mathfrak{h}}$. While the action of the center and the shift in S^1 generated by $\hat{L}$ is trivial, the $\mathbf{Z}$ acts nontrivially as follows:

$$e^{2\pi i\ell\hat{\Omega}}\hat{L}e^{-2\pi i\ell\hat{\Omega}} = \hat{L} - 2\pi\ell\hat{1}. \tag{7}$$

The sections of the associated PU($\mathcal{H}$) bundle are vectors $v(x,\phi)$ in $\hat{\mathsf{h}}$ satisfying

$$v(x,\phi + 2\pi\ell) = e^{2\pi i\ell\hat{\Omega}}v(x,\phi)e^{-2\pi i\ell\hat{\Omega}}.$$

Writing v in terms of the basis elements as $v=v_1(x,\phi)\hat{1}+v_2(x,\phi)\hat{L}$, we get: $v_1(x,\phi+2\pi\ell) = v_1(x,\phi)-2\pi\ell v_2(x,\phi)$ and $v_2(x,\phi+2\pi\ell)=v_2(x,\phi)$.

The final ingredient is a linear function from the PU($\mathcal{H}$) bundle to $\mathbf{R}$. In order to motivate this, let us start with the exact sequence of vector spaces V_C (generated by $\hat{1}$), $\hat{\mathsf{h}}$ and $V_{\hat{L}}$ (generated by $\hat{L}$). The exact sequence of bundles

$$E_{\mathbf{R}} \to E_{\hat{\mathsf{h}}} \to E_{V_{\hat{L}}}$$

follows from it, moreover, $E_{\mathbf{R}} \sim \mathbf{R}\times(S^2\times S^1)$ is a trivial bundle. However, while in the former sequence $\hat{\mathsf{h}}$ cannot be written as a direct sum of V_C and $V_{\hat{L}}$, it is possible to do so in the latter (although the Lie algebra will not be respected in the process). The linear function, which we will call "tr,"

$$\mathrm{tr}: E_{\hat{\mathsf{h}}} \to \mathbf{R},$$

provides this decomposition. For a vector $v\in\hat{\mathsf{h}}$, which can be written in terms of the basis elements as $v=v_1(x,\phi)\hat{1}+v_2(x,\phi)\hat{L}$, we define

$$\mathrm{tr}(v) = (v_1(x,\phi) - \phi v_2(x,\phi)). \tag{8}$$

It is clear from (7) that the function tr is well defined on the PU($\mathcal{H}$) bundle. In particular, when $v_1=0$, $v_2=1$, we have

$$\mathrm{tr}(\hat{L}) = \phi.$$

We will use this in a moment.

In order to specify a connection on this bundle, we start with a connection on the priciple U(1) bundle $p:S^3\to S^2$, which is the familiar monopole gauge field configuration $A^{(M)}$. The gauge field of this bundle is a one-form on S^2 valued in the Lie algebra generated by $-i(\mathrm{d}/\mathrm{d}\xi)$. The gauge connection of the PU($\mathcal{H}$) bundle is a one-form valued in $\hat{\mathsf{h}}$ and is taken to be $A^{(M)}$. Since $\hat{\mathsf{h}}$ is Abelian, the curvature of this connection is a two-form,

$$F^{(M)} = dA^{(M)}\hat{L},$$

where we have displayed the $\hat{\mathsf{h}}$ dependent part explicitly (this is the same as writing $F=F^aT^a$ in YM theories). Acting with the linear function tr, we obtain $\mathrm{tr}\,F^{(M)}=\mathrm{d}A^{(M)}\phi$. This is called the "scalar curvature" in Ref. 20. It is a two-form which is not closed, rather $\mathrm{d}\,\mathrm{tr}\,F^{(M)}\sim\mathrm{vol}(S^2\times S^1)$.

In case of the S^3 base, once again we use the Hopf fibration, however, this time, following Ref. 23 the U(1) action along the fiber is lifted to a U(1) action in PU($\mathcal{H}$) with the help of a cocycle. Let us consider S^3 as the unit sphere defined by $x_1^2+x_2^2+x_3^2+x_4^2=1$, which may be written as

$$|z_0|^2 + |z_1|^2 = 1,$$

in terms of complex coordinates of $\mathbf{C}^2[x_1+ix_2, x_3+ix_4]$. Let us cover S^3 by charts

$$\mathcal{U}_0 = \{(z_0, z_1) \in S^3 : |z_0| \geqslant |z_1|\},$$
$$\mathcal{U}_1 = \{(z_0, z_1) \in S^3 : |z_0| \leqslant |z_1|\}. \tag{9}$$

Each $\mathcal{U}_i$ is topologically a disc times S^1 and they overlap on a two-torus

$$\mathcal{U}_0 \cap \mathcal{U}_1 = T^2 = \{(z_0, z_1) \in S^3 : |z_0| = |z_1| = 1/\sqrt{2}\}. \tag{10}$$

The simplest way to see that S^3 has this topological structure is to think $S^3 = \mathbf{R}^3 \cup \{\infty\}$. Now, if we remove a solid torus from $\mathbf{R}^3$, what remains, together with the point at infinity, is also a solid torus. Introduce coordinates (ψ, θ, ϕ) on S^3 such that $z_0 = \cos(\psi/2) e^{i(\phi+\theta)/2}$ and $z_1 = \sin(\psi/2) e^{i(\phi-\theta)/2}$. The bundle structure of Hopf fibration is given by the local trivializations

$$\mathcal{U}_0 \sim \left(\frac{z_1}{z_0}, \frac{z_0}{|z_0|}\right), \quad \mathcal{U}_1 \sim \left(\frac{z_0}{z_1}, \frac{z_1}{|z_1|}\right), \tag{11}$$

along with the transition function z_0/z_1 on the overlap. The U(1) action

$$(z_0, z_1) \to (e^{-i\omega} z_0, e^{-i\omega} z_1) \tag{12}$$

along the fiber is an isometry of S^3. [The metric in these coordinates is $ds^2 = \frac{1}{4}(d\psi^2 + \sin^2\psi\, d\theta^2 + (d\phi + \cos\psi\, d\theta)^2)$.]

The PU($\mathcal{H}$) bundle on S^3 is specified by a map

$$g_{01} : \mathcal{U}_0 \cap \mathcal{U}_1 = T^2 \to \mathrm{PU}(\mathcal{H}). \tag{13}$$

Local trivializations

$$f_0 : \mathcal{U}_0 \to \mathcal{K}(\mathcal{H}), \quad f_1 : \mathcal{U}_1 \to \mathcal{K}(\mathcal{H})$$

are related by $f_0 = g_{01}(f_1) = g_{01} f_1 g_{01}^{-1}$ on the overlap. The topological properties of the bundle are characterized by the homotopy class of g_{01}, an element of maps from T^2 to PU($\mathcal{H}$). Now since $\pi_n(\mathrm{U}(\mathcal{H})) = 0$ for all n,[24] we have $\pi_{n-1}(\mathrm{U}(1)) = \pi_n(\mathrm{PU}(\mathcal{H}))$, hence the only nonvanishing homotopy group of PU($\mathcal{H}$) is π_2 and this is $\mathbf{Z}$. The homotopy classes of maps g_{01} of interest is therefore isomorphic to $H^2(T^2, \mathbf{Z})$ (see, for example, Ref. 25 Chap. 1). Now, using the relation[26] between the differential complexes on $\mathcal{U}_0$, $\mathcal{U}_1$, $\mathcal{U}_0 \cup \mathcal{U}_1 = S^3$ and $\mathcal{U}_0 \cap \mathcal{U}_1 = T^2$, we have $H^2(T^2, \mathbf{Z}) = H^3(S^3, \mathbf{Z}) = \mathbf{Z}$.

Let us define the U(1) action (12) on the PU($\mathcal{H}$) bundle as

$$\Omega_\omega : (f_0, f_1) \to (f_0^\omega, f_1^\omega),$$
$$\text{where,} \quad f_0^\omega(z_0, z_1) = f_0(e^{-i\omega} z_0, e^{-i\omega} z_1), \tag{14}$$
$$f_1^\omega(z_0, z_1) = h(\omega, z_0, z_1)(f_1(e^{-i\omega} z_0, e^{-i\omega} z_1)),$$

for a function $h(\omega, z_0, z_1) : S^1 \times \mathcal{U}_1 \to \mathrm{PU}(\mathcal{H})$ which satisfy

$$h(\omega, z_0, z_1) = g_{01}^{-1}(z_0, z_1) g_{01}(e^{-i\omega} z_0, e^{-i\omega} z_1) \quad \text{for } (z_0, z_1) \in \mathcal{U}_0 \cap \mathcal{U}_1,$$
$$h(\omega_1 + \omega_2, z_0, z_1) = h(\omega_1, z_0, z_1) h(\omega_2, e^{-i\omega_1} z_0, e^{-i\omega_1} z_1) \quad \text{for } (z_0, z_1) \in \mathcal{U}_1. \tag{15}$$

The first of the conditions (15) ensures that the patching condition given by (13) is respected. In other words, Ω_ω is an automorphism of the triple $(f_0, f_1; g_{01})$ used to define the PU($\mathcal{H}$) bundle. The second condition is a group homomorphism that identifies an S^1 in PU($\mathcal{H}$). The existence of Ω_ω with the required properties is proven in Ref. 23. [The PU($\mathcal{H}$) bundle on S^3 has also been defined through local trivializations $S^3 = D_+^3 \cup D_-^3$, $D_+^3 \cap D_-^3 = S^2$ at the equator.[27] The topological

properties of the bundle are characterized by maps from S^2 to PU($\mathcal{H}$). This, however, does not seem suitable for our purpose as there is no natural U(1) action.]

We will use the above to propose a construction along the lines of Ref. 12, with Ω_ω playing the role of $\hat{\Omega}$ in (5). We cannot identify $\hat{L}$ explicitly in PU($\mathcal{H}$), but proceed with the assumption that there is one such $\hat{L}$ such that (5) is true. This assumption is not untenable since the size of the fiber in Hopf fibration is fixed, namely 4π, therefore the spectrum of $\hat{L}$ is discrete. Motivated by the construction in $S^2 \times S^1$ and the Hopf bundle description of S^3 outlined above, we propose the following expression for the gauge fields using the two charts (11) of $S^{2'}$.

$$A_0 = +\frac{i}{2}(1-\cos\psi)\mathrm{d}\theta\cdot\hat{L},$$
$$A_1 = -\frac{i}{2}(1+\cos\psi)\mathrm{d}\theta\cdot\hat{L}, \tag{16}$$

where we have displayed the algebra generator explicitly. Recall the charts overlap for $\psi=\pi/2$, where the transition functions $(\psi,\theta)\to(\pi-\psi,-\theta)$ of the Hopf bundle ensures that A_0 and A_1 differ by a gauge transformation.

The "scalar curvature" of the gauge field (16) is obtained by taking the tr:

$$\mathrm{tr}\,F = \frac{i}{2}\sin\psi\,\mathrm{d}\psi\wedge\mathrm{d}\theta(\phi+\theta),$$

where, in analogy with (8), we have used $\mathrm{tr}\,\hat{L}=\phi+\theta$, the value of the coordinate of the Hopf fiber of the base space. Notice that this is a well-defined two-form. Finally,

$$\mathrm{d}\,\mathrm{tr}\,F = \frac{i}{2}\sin\psi\,\mathrm{d}\psi\wedge\mathrm{d}\theta\wedge\mathrm{d}\phi \tag{17}$$

is the volume form on S^3 yielding a unit three-form flux through it. It is assumed here that the tachyon is trivial, it is zero corresponding to the maximum of the potential. In other words, this gauge field configuration describes the unstable D9-brane in presence of the NS5-brane.

The NS5-brane so constructed has its worldvolume along $\mathbf{R}^{1,4}$ as well as along one of the noncommutative dimensions in $\mathbf{R}^2_{NC}$. We refer to Ref. 12 for some subtleties with this description.

Finally, although we have been talking about a PU($\mathcal{H}$) bundle, the above construction is not a bundle in the usual sense. In the Appendix, we show how it satisfies the conditions required of a gerbe.

IV. SEMI-INFINITE D6-BRANE AND NS FIVEBRANE

In Sec. III we have constructed a configuration of the operator valued gauge fields in the noncommutative worldvolume theory of the unstable D9-brane of type IIA theory. This configuration carries a unit H-flux through S^3, and satisfies the modified Bianchi $\mathrm{d}\,\mathrm{tr}\,F=H$. It is argued[12] that for the tachyon at the maximum of the potential, this configuration describes the D9-NS5-brane system, while at a minimum there is only a NS5-brane. One expects that, when the tachyon is nontrivial, we should have a configuration of the NS5-brane together with a D-brane of appropriate codimension.

Recall, that in the absence of any H-flux (no NS5-brane), all the stable Dp-branes may be obtained as odd codimension soliton solutions of the tachyon and gauge field theory. In particular the D6-brane is the 't Hooft-Polyakov monopole of the U(2) theory on two D9-branes.[7] Let (x_1,x_2,x_3) be the space transverse to the would be D6-brane. Identifying $\mathrm{SU}(2)\subset\mathrm{U}(2)$ with the (covering space) of the SO(3) group of rotations, the configuration is

$$T \sim x_i \sigma^j,$$
$$A_i \sim \epsilon_{ijk} x^j \sigma^k, \tag{18}$$

where σ^i are the Pauli matrices. There should also be some convergence factors on the right-hand side. One important feature of this construction is that it is local, i.e., it relies only on coordinates in a small neighborhood of the origin where the D6-brane is located.

The configuration we would like to obtain is that of a semi-infinite D6-brane that ends on the NS5-brane. The fivebrane shares all its worldvolume dimensions with the D6-brane, whose additional dimension has a boundary on which the NS5-brane lies. Let us put the NS-brane at the origin of its transverse $\mathbf{R}^4$ directions. This space is foliated by S^3 of varying radii, with the size finally saturating to give the "throat" geometry.[21] The D6-brane appears to be a string which pierces the S^3's at, say, the south pole. Although, to an observer far away from the origin, it would seem that the D6-brane ends on the NS5-brane at the origin, it would be more correct to say that it goes down the "throat." Actually for our case, where there are two noncommutative dimensions and the D6-brane worldvolume extends along both, this picture is an extrapolation from the commutative limit. In particular, the radial direction in $\mathbf{R}^4$, i.e., the direction transverse to S^3 is one of the noncommutative directions.

We would like to argue that the situation is different *after* tachyon condensation. The operator $\hat{\Omega}$ is a shift along the Hopf fiber of S^3. The process of tachyon condensation selects a special point, which we may choose to be the south pole. The fields are localized around this point, in particular, also along the Hopf fiber through it. This in turn, determines the value of the operator $\hat{\Omega}$ to be, say, zero, to an accuracy $\Delta\Omega \sim \varepsilon$. As a result, there is a large uncertainty in the value of the conjugate variable $\hat{L}$: $\Delta L \sim 1/\varepsilon$. This, in effect, makes the spectrum of $\hat{L}$ continuous for sufficiently small ε. Therefore, after the tachyon has condensed, it should be possible to shift $\hat{L}$ by an arbitrary amount. This is in contrast to the previous section in which the fields are not localized in S^3.

We can follow the field theory example in Sec. II and use continuous gauge transformation of the form $\exp(ix\hat{\Omega})$ (for any real x) available now to propose the following gauge field configurations:

$$A_0 = +\frac{i}{2}(1-\cos\psi)\mathrm{d}\theta \cdot \hat{L},$$
$$A_1 = -\frac{i}{2}(1+\cos\psi)\mathrm{d}\theta \cdot (\hat{L} + (\phi-\theta)\hat{1}). \tag{19}$$

At the overlap, an operator valued U(1) gauge transformation,

$$A_1 = e^{-i(\phi-\theta)\hat{\Omega}} A_0 e^{i(\phi-\theta)\hat{\Omega}}, \tag{20}$$

relates the gauge configurations from the chart $\mathcal{U}_0$ to $\mathcal{U}_1$.

An operator valued U(1) gauge transformation is in fact equivalent to the gauge transformation of the B field (see the Appendix and Ref. 17). The field configuration (19) has the property that in the chart $\mathcal{U}_0$, $\mathrm{d}\,\mathrm{tr}\,F_0 \sim \mathrm{vol}(S^3)$ as before, but in $\mathcal{U}_1$, $\mathrm{tr}\,F_1$ and hence $\mathrm{d}\,\mathrm{tr}\,F_1$ vanish. Hence there is a NS H-flux through $\mathcal{U}_0$ but none through $\mathcal{U}_1$.

Continuing to follow the field theory example, we now need to show that the operator valued U(1) gauge field configuration (19) arises from a configuration of the tachyon and gauge fields (in the S^3 part of the worldvolume of the non-BPS D9-brane). This ought to localize the energy around the south pole of S^3, which we assume is at the origin of $\mathcal{U}_0$. Unfortunately, we are not able to write this explicitly. However, the operator corresponding to the tachyon field is expected to be of the form

$$T \sim \int \mathrm{d}\varphi |\varphi\rangle\langle\varphi| e^{-\varphi^2/\varepsilon^2}, \tag{21}$$

which is a projection operator. Interestingly, in Ref. 7, it is shown that the configuration (18) can also be thought of as a two step process of a vortex and a kink. This seems more natural in the present situation as the local symmetry group around the south pole is $\mathrm{SO}(2)\times\mathbf{R}$, since $\mathcal{U}_0$ has the topology of a cylinder $D_0^2\times S^1$, which naturally accommodates this break up.

V. BIANCHI IDENTITIES AND CHARGE CONSERVATION

In Ref. 16 the NS5-D6-brane configuration described in Sec. IV was shown, following a construction in Ref. 14, to be a solution of type IIA supergravity using a description of gerbes as local line bundles. There the various charge conservation conditions are discussed in detail. Briefly, consider an S^2 surrounding the D6-brane. There is a flux of the RR one-form gauge field $C^{(1)}_{\mathrm{RR}}$ through it. In the absence of any H-flux, this measures the quantized RR charge of the D6-brane. This arises from the Chern–Simons couplings, ($\mathrm{d}T\wedge F_{CP}\wedge C^{(7)}$, $\mathrm{d}T\wedge\mathrm{d}T\wedge\mathrm{d}T\wedge C^{(7)}$, etc.), on the D9-brane. When a NS B-field is present, the correct gauge invariant field strength for this field is[3]

$$G^{(2)}_{\mathrm{RR}} = \mathrm{d}C^{(1)}_{\mathrm{RR}} + mB, \tag{22}$$

where B is the NS two-form and m is the mass parameter. Similarly,

$$\mathcal{F} = dA_{CP} - B \tag{23}$$

is a gauge invariant combination of the field strength involving the Chan–Paton gauge field.

In our description, the flux is through a two-cycle T^2 at the overlap of $\mathcal{U}_0$ and $\mathcal{U}_1$. This is assumed to enclose D6-brane at the south pole of S^3. Since the D6-brane is semi-infinite, there is no Chan–Paton gauge field flux through the chart $\mathcal{U}_1$. We can also choose to set $B=0$ here. This means $\mathcal{F}=0$ in $\mathcal{U}_1$, and in particular, there is no $\mathcal{F}$-flux through it. Notice that $\mathcal{F}$ is gauge invariant and therefore $\mathcal{F}$-flux must vanish everywhere. The overlap T^2 is the boundary of a three-space $\mathcal{U}_0$, which is that part of the S^3 through which there is a nontrivial H-flux. The anomalous Bianchi identity[3] from (22) ensures that there is no net six-brane charge. By drawing analogy with the field theory example, it now follows that the net monopole charge through a T^2 (at the overlap of $\mathcal{U}_0$ and $\mathcal{U}_1$ or any deformation of it in $\mathcal{U}_0$), enclosing the south pole of S^3 should also vanish. Since $\mathcal{F}$-flux through T^2 vanishes and the flux of $\mathrm{d}A_{CP}$ does not, we conclude that the monopole charge evaluated by integrating $\mathrm{d}A_{CP}$ over a T^2 enclosing the south pole is equal to the boundary value of the H-flux through the three-space $D_0^2\times S^1$ enclosed by T^2, i.e.,

$$\oint_{T^2} \mathrm{d}A_{CP} = \int_{D_0^2\times S^1} H = \oint_{T^2} B. \tag{24}$$

This in effect implies a modified Bianchi identity

$$\mathrm{d}F_{CP} = H \tag{25}$$

for the NS5-D6-brane configuration.

VI. DISCUSSION

We have argued how to realize a configuration in which a semi-infinite D6-brane ends on a NS5-brane via condensation of the tachyon field on the worldvolume of unstable D9-branes. Both the five- as well as the six-brane are solitonic configurations in the noncommutative field theory on the D9-brane. Let us emphasize that although the six-brane by itself is a solution of this field theory, the NS5-brane is only a configuration. In the framework of open string theory, it is as yet unclear in what sense a solitonic object of closed string theory can be realized as a solution. Some

topological aspect of the NS5-brane can, however, be reproduced. Our intersecting brane configuration, in which we have combined features of Refs. 7 and 12, is also not a solution of the open string equations of motion.

The geometrical description we have used is strictly valid for large values of NS5-brane charge, or far away from the core of the fivebrane. Moreover, two of the longitudinal directions of our D6-brane carry a constant B field. This is the B field introduced to have a noncommutative worldvolume theory. The Chern–Simons coupling $B\wedge C^{(5)}_{\mathrm{RR}}$ therefore results in an induced D4-brane charge in the configuration.

Let us end by some speculative remarks on D3-branes in SU(2) WZW model. In this case, it is well-known that the symmetries allow only D2-branes and D0-branes along conjugacy classes of the group manifold.[28] These are S^2's at some fixed "latitudes" of S^3. On the other hand, Ref. 29 argued in favor of D3-branes which wrap almost all of S^3 except for a set of points. More recently, based on consistency with T-duality, Ref. 30 showed that there should be D3-branes which are "fat" D-strings. These have the topology of a cylinder reminiscent of the coordinate charts we have used in our construction of the NS5-D9-brane configuration. While a single fat string cannot cover the entire group manifold without having a singularity, it seems possible for a configuration of two fat D-strings "linked" together to do so. A nontrivial linking should capture the fact that this configuration is a gerbe. This may be possible with operator valued gauge fields on the fat strings.

ACKNOWLEDGMENTS

It is a pleasure to acknowledge fruitful discussions with Rajesh Gopakumar, Gautam Mandal, Dipendra Prasad, Volker Schomerus, Ashoke Sen, David Tong, Spenta Wadia, and especially Indranil Biswas, who patiently explained gerbes to us. The work of M.K. was supported in part by the FWF under Grant No. P15553.

APPENDIX: GERBES

Gerbes are generalization of U(1) bundles (more generally line bundles) on a manifold. This appendix contains a quick description of gerbes. Further details and references can be found in the expository article by Hitchin.[14] Reference 17 is an incomplete list of their applications in string theory.

Consider a manifold $\mathcal{M}$ and a set of open charts $\{\mathcal{U}_i\}$ that covers it: $\mathcal{M}=\cup_i\mathcal{U}_i$. We will assume, for simplicity, that each $\mathcal{U}_i$ is contractible. A *1-gerbe* $\mathcal{G}$ on $\mathcal{M}$ is defined by a set of U(1) bundles $\mathcal{L}_{ij}$ on each (ordered) overlap $\mathcal{U}_i\cap\mathcal{U}_j$, satisfying the following conditions

(i) $\mathcal{L}_{ji}=\mathcal{L}_{ij}^*$, (where $\mathcal{L}^*$ is the bundle dual to $\mathcal{L}$),
(ii) on triple overlaps $\mathcal{U}_i\cap\mathcal{U}_j\cap\mathcal{U}_k$, the tensor product bundle $\mathcal{L}_{ij}\otimes\mathcal{L}_{jk}\otimes\mathcal{L}_{ki}$ has a nowhere vanishing section s_{ijk},
(iii) on quadruple overlaps $\mathcal{U}_i\cap\mathcal{U}_j\cap\mathcal{U}_k\cap\mathcal{U}_l$, the section $s_{ijk}\otimes s^*_{ijl}\otimes s_{ikl}\otimes s^*_{jkl}=1$.

Notice that in the last condition, the tensor product of the sections is that of a trivial bundle $\mathcal{M}\times\mathrm{U}(1)$, as follows from the other two conditions. Let us also note that if we take $\mathcal{L}_{ij}=\mathcal{L}_i\otimes\mathcal{L}_j^*$, where $\mathcal{L}_i$ are U(1) bundles on $\mathcal{U}_i$, then all the conditions are trivially satisfied. Therefore this is called a trivial gerbe.

The above may be generalized to k-gerbes by defining line bundles on $(k+1)$-fold overlaps with appropriate conditions. An ordinary line bundle is a 0-gerbe from this point of view. It should be noted that (except for $k=0$) the "total space" of a gerbe is not a manifold, as the definition involves conditions on more than two overlaps.

A *connection* on a 1-gerbe is specified by connections A_{ij} for each $\mathcal{L}_{ij}$ and a two-form B_i on each chart $\mathcal{U}_i$, such that

(i) $A_{ij}=-A_{ji}$,
(ii) s_{ijk} is flat with respect to the induced connection,
(iii) on $\mathcal{U}_i\cap\mathcal{U}_j$, we have $B_i-B_j=dA_{ij}$.

The "curvature" $H=dB$ of this connection is independent of the chart and hence makes sense globally. The cohomology of H is characterized by $H^3(\mathcal{M},\mathbf{Z})$. The quantization is analogous to the case of usual U(1) gauge fields.[31]

As an example, let us describe the "NS5-brane." Consider space–time of the form $\mathbf{R}^{1,5}\times\mathbf{R}\times S^3$, the geometry of the NS5-brane. The only relevant part of it is S^3, on which we will construct a gerbe such that it carries an H-flux. This example is due to Hitchin[14] (and has been used in Ref. 16). First, we cover S^3 with two open 3-discs $D^3_{\pm}$, which overlap around a region around the equatorial S^2. The overlap $D^3_+\cap D^3_-$ has the topology of a "cylinder" $S^2\times\mathbf{R}$. For the U(1) bundle on the overlap, we take the monopole bundle on S^2 (more precisely, the pull-back of this bundle). Let A_{+-} be the gauge field and $F=dA_{+-}$ be its curvature. In order to give their concrete forms, let us introduce coordinates (α,β,γ) on S^3, such that the metric is

$$ds^2 = d\alpha^2 + \sin^2\alpha(d\beta^2 + \sin^2\beta\, d\gamma^2).$$

The overlap region is $\pi/2-\epsilon<\alpha<\pi/2+\epsilon$, and $F_{+-}\sim\sin\beta\, d\beta\wedge d\gamma$. We need to specify the gerbe connections $B_{\pm}$. To this end, consider a partition of unity $\varphi_{\pm}$. Recall that these are functions with supports, respectively, in $D^3_{\pm}$, such that $0\leqslant\varphi_{\pm}\leqslant 1$ and $\varphi_+ + \varphi_- = 1$ at each point. We write,

$$B_{\pm} = \pm\,\varphi_{\pm}F_{+-},$$

which satisfy the condition $B_+ - B_- = F_{+-}$. It is easy to check that the curvature $H=dB$ is independent of the chart. In fact it equals $F_{+-}\wedge d\varphi_+$, which is supported on the overlap. Therefore, using the quantization of the monopole field F_{+-}, we see that the H-flux through S^3 is integrally quantized. It is curious that the gerbe defining an NS5-brane is roughly like a monopole (F part) times a kink (φ part), quite similar to, say, the soliton description of D6-brane in Ref. 7. Reference 16 describes the NS5- and semi-infinite D6-brane configuration in this language.

Finally, let us show how the $\mathcal{K}(\mathcal{H})$ valued gauge fields patched together by $\mathrm{Aut}(\mathcal{K}(\mathcal{H}))=\mathrm{PU}(\mathcal{H})$ satisfy the axioms of a gerbe. In the construction of Sec. III, we have only two coordinate charts, so there is not much to check. Consider, instead, a general setup where we have local trivializations given by maps

$$f_i:\mathcal{U}_i\to\mathcal{K}(\mathcal{H}),$$

which satisfy $f_i=g_{ij}(f_j)=g_{ij}f_jg_{ij}^{-1}$, for $g_{ij}\in\mathrm{PU}(\mathcal{H})$, on twofold overlaps. Hence, on triple overlaps $h_{ijk}=g_{ij}g_{jk}g_{ki}$ must be an element of U(1), [since action of the U(1) center of U($\mathcal{H}$) is trivial]. These h_{ijk}'s may be taken as the sections s_{ijk}'s of (trivial) U(1) bundles on threefold overlaps. It is also easy to check that the conditions on fourfold overlaps is satisfied.

Boundary conditions play a nontrivial role in string theory. For instance, the rich structure of D-branes is generated by choosing appropriate combinations of Dirichlet and Neumann boundary conditions. Furthermore, when an antisymmetric background is present at the string end points (corresponding to mixed boundary conditions) space time becomes noncommutative there. We show here how to build up normal ordered products for bosonic string position operators that satisfy both equations of motion and open string boundary conditions at the quantum level. We also calculate the equal time commutator of these normal ordered products in the presence of an antisymmetric tensor background. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1914727]

I. INTRODUCTION

Recent progress in string theory[1] indicates a scenario where our four-dimensional space-time should correspond to a D-brane[2] representing the boundary of a larger manifold. This idea also proved useful indicating a possible explanation for the hierarchy problem.[3,4] One important consequence of such a model is the noncommutativity of space-time coordinates in our four-dimensional world.[5–7] The reason is that D-branes correspond to the space where open string end points are located and where the corresponding string boundary conditions must be satisfied. In the presence of an antisymmetric tensor background these conditions are incompatible with commuting coordinates.

Since antisymmetric fields show up in the massless spectrum of closed strings living on the D-branes it is reasonable to suspect that our physical world could be noncommutative at very small length scales. This is one of the reasons for the increasing interest in studying many aspects of noncommutative quantum field theories as can be seen, for example, in Refs. 7,8. Furthermore, this fact illustrates the nontrivial role of boundary conditions in string theory and the importance of taking them into account when considering the quantization of open strings.

In quantum field theory, products of quantum fields at the same space-time points are, in general, singular objects. The same thing happens in string theory if one multiplies position operators, that can be taken as conformal fields on the world sheet. This situation is well known and one can remove the singular part of the operator products by defining normal ordered well-behaved objects.[9] This is important, for example, when one builds up the generators of conformal transformations and investigate the realization, at the quantum level, of the classical symmetries.

Normal ordered products of operators are usually defined so as to satisfy the classical equations of motion at quantum level. Our purpose in this article is to define normal ordered products for open string position operators that additionally satisfy the boundary conditions. This way we will define a normal ordering that will be valid also at string end points. We will also investigate the relation between this new definition for normal ordering and the noncommutativity of space-time coordinates.

II. STRING POSITION OPERATOR PRODUCTS

The classical action for a bosonic string in the presence of a constant antisymmetric background taking a world sheet with a Euclidean signature is

$$S = \frac{1}{4\pi\alpha'}\int_{\Sigma} d^2\sigma(g^{ab}\eta_{\mu\nu}\partial_a X^\mu\,\partial_b X^\nu - i\epsilon^{ab}B_{\mu\nu}\,\partial_a X^\mu\,\partial_b X^\nu), \tag{1}$$

where X^μ are the space-time string coordinates and $B_{\mu\nu}$ is the antisymmetric field. The string world sheet Σ is represented by the parameters $\sigma_1 \equiv \tau, \sigma_2 \equiv \sigma$ with, as usual, the boundary (string end points) at $\sigma = 0, \pi$. The Euclidean world sheet metric is $g^{\tau\tau} = g^{\sigma\sigma} = 1$ and the antisymmetric tensor is chosen by $\epsilon^{\tau\sigma} = 1$.

The variation of the action gives us a volume term that vanishes imposing the equations of motion,

$$(\partial_\tau^2 + \partial_\sigma^2)X^\mu = 0, \tag{2}$$

plus a boundary term that vanishes if we additionally impose that the string coordinates satisfy the boundary conditions

$$(\eta_{\mu\nu}\,\partial_\sigma X^\nu + iB_{\mu\nu}\,\partial_\tau X^\nu)\big|_{\sigma=0} = 0,$$

$$(\eta_{\mu\nu}\,\partial_\sigma X^\nu + iB_{\mu\nu}\,\partial_\tau X^\nu)\big|_{\sigma=\pi} = 0. \tag{3}$$

These boundary conditions, when imposed at the quantum level, are responsible for the noncommutativity of the position operators.[5,7] We can infer this result by realizing that these conditions represent constraints in phase space relating position and conjugate momenta.

It is convenient, for studying the quantum operators, to introduce complex world sheet coordinates: $z = \tau + \imath\sigma$, $\bar{z} = \tau - \imath\sigma$; $\partial_z = 1/2(\partial_\tau - \imath\partial_\sigma)$, $\partial_{\bar{z}} = 1/2(\partial_\tau + \imath\partial_\sigma)$.

The action takes the form

$$S = \frac{1}{2\pi\alpha}\int dz^2[\,\eta_{\mu\nu}\,\partial_z X^\mu\,\partial_{\bar{z}} X^\nu - B_{\mu\nu}\,\partial_z X^\mu\,\partial_{\bar{z}} X^\nu], \tag{4}$$

while classical equations of motion and boundary conditions take the form

$$\partial_{\bar{z}}\partial_z X^i = 0, \tag{5}$$

$$(\eta_{\mu\nu}(\partial_z - \partial_{\bar{z}}) + B_{\mu\nu}(\partial_z + \partial_{\bar{z}}))X^\nu\big|_{z=\bar{z}} = 0,$$

$$(\eta_{\mu\nu}(\partial_z - \partial_{\bar{z}}) + B_{\mu\nu}(\partial_z + \partial_{\bar{z}}))X^\nu\big|_{z=\bar{z}+2\pi i} = 0. \tag{6}$$

We can study the properties of quantum operators by considering the expectation values of the corresponding classical objects. Defining the expectation value of an operators $\mathcal{F}$ as[9]

$$\langle \mathcal{F}[X] \rangle = \int [dX] \exp(-S[X]) \mathcal{F}[X], \tag{7}$$

and using the fact that the path integral of a total derivative vanishes one finds that the equations of motion and boundary conditions are realized for the expectation values of string coordinates X^ν,

$$0 = \int [dX] \frac{\delta}{\delta X^\nu(z',\bar{z}')} \exp(-S[X]) = \left\langle \frac{1}{\pi\alpha'} \partial_{\bar{z}'} \partial_{z'} X_\nu(z',\bar{z}') \right\rangle + \frac{1}{2\pi\alpha'} \oint_{\partial\Sigma} \delta^2(z-z') \langle (\eta_{\nu\mu}(\partial_z - \partial_{\bar{z}}) + B_{\nu\mu}(\partial_z + \partial_{\bar{z}})) X^\mu(z,\bar{z}) dz \rangle = 0. \tag{8}$$

The last (singular) term is integrated over the boundary, where $dz = d\bar{z}$. This equation implies that both string equations of motion and the boundary condition hold as expectation values. So the corresponding quantum position operators satisfy the equivalent conditions (as long as they are not multiplied by other operators located at the same world sheet point)

$$\partial_{\bar{z}} \partial_z \hat{X}^\nu(z,\bar{z}) = 0, \tag{9}$$

$$(\eta_{\nu\mu}(\partial_z - \partial_{\bar{z}}) + B_{\nu\mu}(\partial_z + \partial_{\bar{z}})) \hat{X}^\mu \Big|_{z=\bar{z}} = 0,$$

$$(\eta_{\nu\mu}(\partial_z - \partial_{\bar{z}}) + B_{\nu\mu}(\partial_z + \partial_{\bar{z}})) \hat{X}^\mu \Big|_{z=\bar{z}+2\pi i} = 0. \tag{10}$$

Products of operators at the same point will have a singular behavior. We can see this by calculating

$$0 = \int [dX] \frac{\delta}{\delta X^\nu(z',\bar{z}')} \exp(-S[X]) X^\rho(z'',\bar{z}'') = \left\langle \delta^2(z'-z'') \delta^\rho_\nu + \left(\frac{1}{\pi\alpha'} \partial_{\bar{z}'} \partial_{z'} X_\nu(z',\bar{z}') X^\rho(z'',\bar{z}'') + \frac{1}{2\pi\alpha'} \oint_{\partial\Sigma} \delta^2(z-z') (\eta_{\nu\mu}(\partial_z - \partial_{\bar{z}}) + B_{\nu\mu}(\partial_z + \partial_{\bar{z}})) X^\mu(z,\bar{z}) X^\rho(z'',\bar{z}'') dz \right\rangle = 0. \tag{11}$$

The volume term gives an extra singular term to the equation of motion for a product of two fields,

$$\frac{1}{\pi\alpha'} \langle \partial_{z'} \partial_{\bar{z}'} X^\mu(z',\bar{z}') X^\nu(z'',\bar{z}'') \rangle = -\eta^{\mu\nu} \langle \delta^2(z'-z'',\bar{z}'-\bar{z}'') \rangle, \tag{12}$$

while the boundary terms vanishes if this product of two fields satisfies the same boundary condition as the single field

$$\langle (\eta_{\nu\mu}(\partial_{z'} - \partial_{\bar{z}'}) + B_{\nu\mu}(\partial_{z'} + \partial_{\bar{z}'})) X^\mu(z',\bar{z}') X^\rho(z'',\bar{z}'') \Big|_{\text{Bound.}} \rangle = 0, \tag{13}$$

where Bound. means that we are taking this condition both at $z = \bar{z}$ and at $z = \bar{z} + 2\pi i$. Thus the products of operators will satisfy

$$\partial_{\bar{z}'} \partial_{z'} \hat{X}^\mu(z',\bar{z}') \hat{X}^\nu(z'',\bar{z}'') = -\pi\alpha' \eta^{\mu\nu} \delta^2(z'-z'',\bar{z}'-\bar{z}''), \tag{14}$$

$$(\eta_{\nu\mu}(\partial_{z'} - \partial_{\bar{z}'}) + B_{\nu\mu}(\partial_{z'} + \partial_{\bar{z}'})) \hat{X}^\mu(z',\bar{z}') \hat{X}^\rho(z'',\bar{z}'') \Big|_{\text{Bound.}} = 0. \tag{15}$$

If we define a normal ordered product of two position operators in the standard way,[9]

$$:\hat{X}^\mu(z,\bar{z}) \hat{X}^\nu(z',\bar{z}'): = \hat{X}^\mu(z,\bar{z}) \hat{X}^\nu(z',\bar{z}') + \frac{\alpha'}{2} \eta^{\mu\nu} \ln|z-z'|^2, \tag{16}$$

it satisfies the equation of motion at the quantum level:

$$\partial_{\bar{z}}\partial_z:\hat{X}^\mu(z,\bar{z})\hat{X}^\nu(z',\bar{z}'):=0, \tag{17}$$

but fails to satisfy the boundary conditions. So we will introduce a different kind of normal ordered product satisfying both the equation of motion and boundary conditions.

The mathematical problem posed by defining the normal ordering is related to that of calculating the Green's functions.[10–13] The normal ordered product is defined by subtracting out the corresponding Green's functions. So we can find normal ordered products satisfying open string boundary condition using the solutions to open the string Green's functions.

At this point it is more convenient to choose world sheet coordinates that simplify the representation of the boundary. In the present coordinates the boundary $\sigma=0$ corresponds to $z=\bar{z}$, and $\sigma=\pi$ to $z=\bar{z}+2\pi i$. Introducing

$$w=e^{\tau+i\sigma}; \quad \bar{w}=e^{\tau-i\sigma},$$

the complete boundary corresponds just to the region $w=\bar{w}$. On the other hand, the factor $w\bar{w}$ in $\partial_z\partial_{\bar{z}}=w\bar{w}\partial_w\partial_{\bar{w}}$ cancel out precisely the Jacobian of the coordinate transformation in such a way that the action in terms of $w,\bar{w}$ has still the same form as in Eq. (4). The boundary conditions take the form

$$(\eta_{\mu\nu}(w\partial_w-\bar{w}\partial_{\bar{w}})+B_{\mu\nu}(w\partial_w+\bar{w}\partial_{\bar{w}}))\hat{X}^\nu\big|_{w=\bar{w}}=(\eta_{\mu\nu}(\partial_w-\partial_{\bar{w}})+B_{\mu\nu}(\partial_w+\partial_{\bar{w}}))\hat{X}^\nu\big|_{w=\bar{w}}=0. \tag{18}$$

This implies that starting with a solution in coordinates $z,\bar{z}$ that satisfies the boundary conditions just at $\sigma=0$ and replacing everywhere $z,\bar{z}$ by $w,\bar{w}$ we get a new solution that satisfies the boundary conditions both at $\sigma=0$ and $\sigma=\pi$.

So our new normal ordering is defined as

$$:\hat{X}^\mu(w,\bar{w})\hat{X}^\nu(w',\bar{w}'):=\hat{X}^\mu(w,\bar{w})\hat{X}^\nu(w',\bar{w}')+\frac{\alpha'}{2}\eta^{\mu\nu}\ln|w-w'|^2+\frac{\alpha'}{2}([\eta+B]^{-1}[\eta-B])^{\mu\nu}\ln(w-\bar{w}')+\frac{\alpha'}{2}([\eta+B][\eta-B]^{-1})^{\mu\nu}\ln(\bar{w}-w')+\alpha' D^{\mu\nu}, \tag{19}$$

where $D^{\mu\nu}$ is a constant that may depend on B but not on the coordinates.

It is important to note that even when the antisymmetric tensor background is not present ($B_{\mu\nu}=0$) the normal ordering of expression (19) does not reduce to the standard normal ordering of Eq. (16), discussed in the literature. This is a new result: for open strings one must always use the normal ordering (19) rather than (16) otherwise the boundary conditions will not be satisfied.

III. EQUAL TIME COMMUTATORS

It is important to investigate the effect of this normal ordering on the commutators of position operators to check if the noncommutativity of space-time coordinates in the presence of the antisymmetric tensor background is changed. We can rewrite Eq. (19) in a more convenient form for calculating the commutators:

$$:\hat{X}^\mu(w,\bar{w})\hat{X}^\nu(w',\bar{w}'):=\hat{X}^\mu(w,\bar{w})\hat{X}^\nu(w',\bar{w}')+\frac{\alpha'}{2}\eta^{\mu\nu}\ln|w-w'|^2-\alpha'\eta^{\mu\nu}\ln|w-\bar{w}'|+\alpha' G^{\mu\nu}\ln|w-\bar{w}'|^2+\frac{1}{2\pi}\Theta^{\mu\nu}\ln\left(\frac{w-\bar{w}'}{\bar{w}-w'}\right)+\alpha' D^{\mu\nu}, \tag{20}$$

where we introduced

$$G^{\mu\nu} = ([\eta + B]^{-1}\eta[\eta - B]^{-1})^{\mu\nu},$$

$$\Theta^{\mu\nu} = -2\pi\alpha'([\eta + B]^{-1}B[\eta - B]^{-1})^{\mu\nu}. \tag{21}$$

Now we calculate the normal ordered commutator at boundary points $w = \overline{w} = \tau, w' = \overline{w'} = \tau'$ using the same choice for the constant $D^{\mu\nu}$ and the same procedure as in Ref. 7,

$$:[\hat{X}^{\mu}(\tau),\hat{X}^{\nu}(\tau')]: \equiv :\hat{X}^{\mu}(\tau)\hat{X}^{\nu}(\tau'):- :\hat{X}^{\nu}(\tau')\hat{X}^{\mu}(\tau): = [\hat{X}^{\mu}(\tau),\hat{X}^{\nu}(\tau')] + \alpha' G^{\mu\nu}\ln((\tau-\tau')^2)$$
$$-\frac{i}{2}\Theta^{\mu\nu}\epsilon(\tau-\tau') - \alpha' G^{\nu\mu}\ln((\tau'-\tau)^2) + \frac{i}{2}\Theta^{\nu\mu}\epsilon(\tau'-\tau) = [\hat{X}^{\mu}(\tau),\hat{X}^{\nu}(\tau')]. \tag{22}$$

So the commutator does not get any extra contribution from the new normal ordering prescription. The equal time commutator thus keeps the same form calculated in Ref. 7 (see also Refs. 14,15):

$$:[\hat{X}^{\mu}(\tau),\hat{X}^{\nu}(\tau)]: = i\Theta^{\mu\nu}. \tag{23}$$

This is a nontrivial result. The commutator of position operators was calculated by Seiberg and Witten[7] using the open string Green's function. Here we have defined a normal ordering by subtracting precisely this Green's function from the product of position operators. So one could think that the commutator of two normal ordered products would be zero. However, we have shown that this is not the case because the extra terms cancel and the commutator is unchanged.

Concluding, the new normal ordering for position operators that is consistent with both equations of motion and boundary conditions at the quantum level does not spoil the previous results related to the noncommutativity of space-time coordinates.

Bose–Einstein condensate and spontaneous breaking of conformal symmetry on Killing horizons

Valter Moretti[a] and Nicola Pinamonti[b]
Department of Mathematics, Faculty of Science, University of Trento, via Sommarive 14, I-38050 Povo (TN), Italy

(Received 17 January 2005; accepted 28 March 2005; published online 18 May 2005)

Local scalar quantum field theory (in Weyl algebraic approach) is constructed on degenerate semi-Riemannian manifolds corresponding to Killing horizons in spacetime. Covariance properties of the C^*-algebra of observables with respect to the conformal group $\mathrm{PSL}(2,\mathbb{R})$ are studied. It is shown that, in addition to the state studied by Guido, Longo, Roberts, and Verch for bifurcated Killing horizons, which is conformally invariant and KMS at Hawking temperature with respect to the Killing flow and defines a conformal net of von Neumann algebras, there is a further wide class of algebraic (coherent) states representing spontaneous breaking of $\mathrm{PSL}(2,\mathbb{R})$ symmetry. This class is labeled by functions in a suitable Hilbert space and their GNS representations enjoy remarkable properties. The states are nonequivalent extremal KMS states at Hawking temperature with respect to the residual one-parameter subgroup of $\mathrm{PSL}(2,\mathbb{R})$ associated with the Killing flow. The KMS property is valid for the two local subalgebras of observables uniquely determined by covariance and invariance under the residual symmetry unitarily represented. These algebras rely on the physical region of the manifold corresponding to a Killing horizon cleaned up by removing the unphysical points at infinity [necessary to describe the whole $\mathrm{PSL}(2,\mathbb{R})$ action]. Each of the found states can be interpreted as a different thermodynamic phase, containing Bose–Einstein condensate, for the considered quantum field. It is finally suggested that the found states could describe different black holes. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1917310]

I. INTRODUCTION

In a remarkable paper,[11] among other results, Guido, Longo, Roberts, and Verch show that, in a globally hyperbolic spacetime containing a bifurcate Killing horizon,[17] the local algebra of observables (realized as bounded operators associated to bounded space–time regions in a suitable Hilbert space) may induce a local algebra of observables localized at the horizon itself with interesting properties. In fact, the induced local algebra turns out to be covariant with respect to a unitary representation of Möbius group of the circle $\mathrm{PSL}(2,\mathbb{R}) := \mathrm{SL}(2,\mathbb{R})/\{\pm I\}$ defined in the Hilbert space of the system. The covariance property is referred to the geometric action of the Möbius group of the circle on the horizon as explained below. The work, on one hand, uses general theorems due to Wiesbrock[39,40] establishing the existence of $\mathrm{SL}(2,\mathbb{R})$ representations related to modular operators of von Neumann algebras. On the other hand, it enjoys some interplay with several "holographic" ideas (including LightFront Holography) in quantum field theory (QFT).[34,25–27]

The central mathematical object employed in Ref. 11 is a net of von Neumann algebras built upon a certain state which is assumed to exist and satisfy the following requirement. Its restriction

[a]Istituto Nazionale di Alta Matematica "F.Severi," unità locale di Trento. Electronic mail: moretti@science.unitn.it
[b]Istituto Nazionale di Fisica Nucleare, Gruppo Collegato di Trento. Electronic mail: pinamont@science.unitn.it

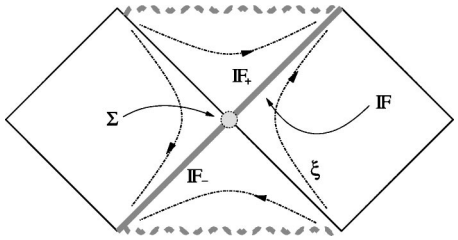

FIG. 1. Carter–Penrose conformal diagram of Kruskal space–time.

to the subnet of observables which are localized at the horizon, must be KMS at Hawking temperature for the Killing flow. In that case, the net of observables localized at the future horizon $\mathbb{F}$ (see Fig. 1) is shown to support a unitary representation of $\mathrm{PSL}(2,\mathbb{R})$ giving rise to a *conformal net* (see for instance Refs. 4, 8, 10, and 5, and references therein).

It is worth noticing that the full $\mathrm{PSL}(2,\mathbb{R})$-covariance of the observables of the conformal net is apparent when one extends the future Killing horizon $\mathbb{F}$ by adding points at infinity obtaining a manifold $\mathbb{S}^1\times\Sigma$, Σ being the transverse manifold at the bifurcation of horizons. $\mathbb{S}^1$ represents nothing but the history $\mathbb{R}$ of a particle of light living on the future horizon compactified into a circle by means of the addition of a point at infinity. The addition of points at infinity is necessary because $\mathrm{PSL}(2,\mathbb{R})$ acts properly as a subgroup of the diffeomorphisms of the circle $\mathbb{S}^1$ and not the line $\mathbb{R}$. In particular the action of $\mathrm{PSL}(2,\mathbb{R})$ on $\mathbb{S}^1$ includes arbitrary rotations of the circle itself which shift the point at infinity in the physical region $\mathbb{R}$.

From a physical point of view these transformations have no meaning. So it seems that the found covariance of the observables localized at the horizon under the full group $\mathrm{PSL}(2,\mathbb{R})$ is actually too large. The problem could be traced back to the state used to construct the von Neumann net of observables.

In spite of this drawback, the results proved in Ref. 11 show the existence of a nice interplay of Killing horizons, thermal states at the correct physical temperature, and conformal symmetry. This result is strongly remarkable in its own right.

In the first part of this paper we give an explicit procedure to build up a local algebra of observables localized on a degenerate semi-Riemannian manifold $\mathbb{M}:=\mathbb{S}^1\times\Sigma$ (obtained from future or past Killing horizons in particular) based on Weyl quantization procedure. This is done without referring to external (bulk) algebras and states and restriction procedures. We find, in fact, a conformal net of observables relying on a $\mathrm{PSL}(2,\mathbb{R})$-invariant vacuum λ. At algebraic level there is a representation α of $\mathrm{PSL}(2,\mathbb{R})$ made of $*$-automorphisms of the Weyl algebra $\mathcal{W}(\mathbb{M})$ and there is a state λ on $\mathcal{W}(\mathbb{M})$ which is invariant under α. In the GNS representation of λ,α is implemented covariantly by a unitary representation U of $\mathrm{PSL}(2,\mathbb{R})$. Moreover it is shown that λ is KMS at Hawking temperature, with respect to the generator of conformal dilatations, in suitable regions $\mathbb{F}_\pm$ of $\mathbb{M}$ (see Fig. 1). $\mathbb{F}_\pm$ do not include points at infinity and are the two disjoint regions in $\mathbb{F}$, respectively, in the past and in the future of the bifurcation surface.

In the second part we try to solve the problem focused above concerning the physical inappropriateness of the full $\mathrm{PSL}(2,\mathbb{R})$ covariance whenever $\mathbb{M}$ is realized by adding (unphysical) points at infinity to a future Killing horizon $\mathbb{F}$.

To this end, it is proven that it is possible to get rid of the unphysical action of $\mathrm{PSL}(2,\mathbb{R})$ and single out the physical part of the horizon at *quantum level, i.e., in Hilbert space*, through a sort of *spontaneous breaking of* $\mathrm{PSL}(2,\mathbb{R})$ *symmetry*. In fact, we establish the existence of other, unitarily inequivalent, GNS representations of $\mathcal{W}(\mathbb{M})$ based on new coherent KMS states λ_ζ at Hawking temperature. Here ζ denotes any functions in $L^2(\Sigma)$. Those states are no longer invariant under the whole representation α and in particular they are not invariant under the unphysical transformations of $\mathrm{PSL}(2,\mathbb{R})$. However the residual symmetry still is covariantly and unitarily implementable and singles out the algebras $\mathcal{A}(\mathbb{F}_+)$ and $\mathcal{A}(\mathbb{F}_-)$ as unique invariant subalgebras. The states λ_ζ represent different *thermodynamical phases* with respect to λ (this is because the states

λ_ζ are extremal KMS states) at Hawking temperature. Those states have different properties in relation with the appearance of a Bose–Einstein condensate localized at the horizon. Finally we suggest that these states could, in fact, denote different black holes. In this view the bosonic field ϕ generating the Weyl representations could represent a noncommutative coordinate in the physical regions $\mathbb{F}_\pm$, whereas its mean value represents the classical coordinate describing the parameter of integral curves of the Killing vector restricted to the horizon.

Several comments concerning the representation of the whole group $\mathrm{Diff}^+(\mathbb{S}^1)$ and in particular its Lie algebra in the presence of the transverse manifold Σ, are spread throughout the work.

II. SCALAR FREE QFT ON DEGENERATE SEMI-RIEMANNIAN MANIFOLDS

A. Basic definitions and notation

In this paper we deal with metric-degenerate semi-Riemannian manifolds of the product form $\mathbb{S}^1\times\Sigma$, where Σ is a connected oriented d-dimensional manifold equipped with a positive metric. $\mathbb{S}^1$ is assumed to be oriented and endowed with the null metric. $\mathbb{S}^1\times\Sigma$ itself is oriented by the orientation induced from those of $\mathbb{S}^1$ and Σ. $\mathbb{S}^1\times\Sigma$ will be called degenerate manifold in the following and it will be denoted by $\mathbb{M}$ throughout. A standard frame θ on the factor $\mathbb{S}^1$ of $\mathbb{M}$ is a positive-oriented local coordinate patch on $\mathbb{S}^1$ which maps $\mathbb{S}^1\backslash\{\infty\}$ bijectively to the segment $-\pi<\theta<\pi$, ∞ being a point of $\mathbb{S}^1$. Throughout $C_c^\infty(\mathbb{M};\mathbb{R})$ and $C_c^\infty(\mathbb{M};\mathbb{C})$ denote the space of compactly supported real-valued, respectively, complex-valued, smooth functions on $\mathbb{M}$ and ω_Σ is the volume form on Σ induced by the metric of Σ. $C_c^\infty(\mathbb{M};\mathbb{C})$ is endowed with a natural symplectic (i.e., bilinear and antisymmetric) form given by, if ψ, $\psi'\in C_c^\infty(\mathbb{M};\mathbb{C})$,

$$\Omega(\psi,\psi') := \int_{\mathbb{M}} \psi'\epsilon_\psi - \psi\epsilon_{\psi'}, \quad \text{where } \epsilon_\psi := \mathrm{d}\psi\wedge\omega_\Sigma. \tag{1}$$

Concerning KMS states we adopt the Definition 5.3.1 in Ref. 2 (see also Chap. V of Ref. 13 where the σ-weak topology used in the definition above in the case of a von Neumann algebra is called *weak $*$-topology*, also known as *ultraweak topology*).

The symbol $\mathbb{N}$ denotes the set of natural numbers $\{0,1,2,\ldots\}$, whereas $\mathbb{N}'$ means $\mathbb{N}\backslash\{0\}$.

B. Bifurcate Killing horizon and Kruskal cases

A simple example of three-dimensional degenerate manifold can be obtained from a submanifold of Kruskal manifold. However, everything that follows is valid, more generally, for any $(d+2)$-dimensional globally hyperbolic space–time containing a bifurcate Killing horizon[17] if replacing $\mathbb{S}^2$ with a generic d-dimensional spacelike submanifold Σ. A basis of Killing vector fields of Kruskal space–time is made of three fields: two generating the $\mathbb{S}^2$ symmetry and ξ generating the time evolution in the two static open wedges where ξ is timelike. The region where $(\xi,\xi)=0$ is made of the union of two three-dimensional submanifolds, $\mathbb{P}$ and $\mathbb{F}$, which we call, respectively, the past and the future Killing horizon of the manifold in reference to Fig. 1. $\mathbb{P}\cap\mathbb{F}$ is the *bifurcation surface*, i.e., a spacelike two-dimensional oriented submanifold where $\xi=0$, given by $\mathbb{S}^2$ equipped with the Euclidean standard metric of a two-sphere with radius given by a Schwarzschild one r_s. That metric is induced from the space–time metric. $\mathbb{F}$ is isometric to the degenerate manifold $\mathbb{R}\times\mathbb{S}^2$. $\mathbb{R}$ is made of the orbits of the null Killing vector ξ restricted to $\mathbb{F}$. We assume that the origin of $\mathbb{R}$ is arranged to belong to the bifurcation manifold $\mathbb{S}^2$. The metric induced on $\mathbb{F}$ is degenerate along $\mathbb{R}$ and invariant under $\mathbb{R}$ displacements. A degenerate manifold $\mathbb{M}=\mathbb{S}^1\times\Sigma$ can, obviously, be obtained from $\mathbb{F}$ by adding a point at infinity ∞ to $\mathbb{R}$ producing $\mathbb{S}^1$. In this case $\mathbb{M}=\mathbb{S}^1\times\mathbb{S}^2$. Orientation of $\mathbb{S}^1$ is that induced by $\mathbb{R}$. Then $\theta(V)=2\tan^{-1}V$, with $V\in\mathbb{R}$, is a standard frame on $\mathbb{S}^1$.

Other examples of degenerate manifold arise from the event horizon of topological black-holes,[36,21] where Σ is replaced by a compact two-dimensional manifold of arbitrary nonnegative genus.

C. Weyl/symplectic approach

In Refs. 25–27 we have considered the limit case of a degenerate manifold $\mathbb{M}=\mathbb{S}^1$ where $\mathbb{M}\backslash\{\infty\}$ is as part of its boundary made of a bifurcate Killing horizon in two-dimensional (2D) Minkowski space–time. In that case local QFT can be induced on $\mathbb{M}$, by means of a suitable restriction procedure of standard linear QFT in the bulk space–time. This restriction actually enjoys some holographic properties because it preserves information about bulk quantum field theory. Here we construct QFT on a general degenerate manifold $\mathbb{M}=\mathbb{S}^1\times\Sigma$ without referring to any restriction procedure. The restriction procedure with holographic properties could be generalized to more complicated manifolds (Kruskal manifold in particular) and this issue will be investigated elsewhere. The formulation of real scalar QFT on a degenerate manifold $\mathbb{M}$ we present here is an adaptation of the theory of fields obeying linear field equations in globally hyperbolic space–times.[2,17,37,38] (In this paper, barring few differences, we make use of conventions and notation of Ref. 38.) The starting point of QFT is the real vector space of wave functions $\mathcal{S}(\mathbb{M}) \coloneqq C_c^\infty(\mathbb{M};\mathbb{R})/\sim$, where $\psi\sim\psi'$ iff $\epsilon_\psi=\epsilon_{\psi'}$. Ω induces a symplectic form on $\mathcal{S}(\mathbb{M})$ still indicated by Ω and defined by, if $[\psi]$, $[\psi']\in\mathcal{S}(\mathbb{M})$,

$$\Omega([\psi],[\psi']) \coloneqq \Omega(\psi,\psi'). \tag{2}$$

Remarks:

(1) Two facts hold, (a) $\psi\sim\psi'$ iff $\partial(\psi-\psi')/\partial\rho=0$ everywhere, and (b) $\epsilon_\psi=(\partial\psi/\partial\rho)\mathrm{d}\rho\wedge\omega_\Sigma$, ρ being any (local) coordinate on $\mathbb{S}^1$. Using (a) and (b) one proves straightforwardly that $\Omega([\psi],[\psi'])$ is well defined, that is it does not depend on the representatives ψ, ψ' chosen in the classes $[\psi]$, $[\psi']$.

(2) Ω is *nondegenerate* on $\mathcal{S}(\mathbb{M};\mathbb{R})$, that is $\Omega([\psi],[\psi'])=0$ for all $[\psi']\in\mathcal{S}(\mathbb{M})$ implies $[\psi]=0$. The definition $\mathcal{S}(\mathbb{M}) \coloneqq C_c^\infty(\mathbb{M};\mathbb{R})/\sim$ gets rid of the degenerateness of Ω on $C_c^\infty(\mathbb{M};\mathbb{R})$ due to functions constant in $\mathbb{S}^1$. Nondegenerateness allows the use of standard procedure to build up QFT within the Weyl formalism as explained below. Another possibility to remove degenerateness is to define $\mathcal{S}(\mathbb{M})$ as the space of $C_c^\infty(\mathbb{M};\mathbb{R})$ functions with vanishing integral with respect to some measure $\mathrm{d}\rho$ induced by a coordinate ρ on $\mathbb{S}^1$. Such a definition, different to that given above, would break invariance under orientation-preserving diffeomorphisms of $\mathbb{S}^1$, which is a natural physical requirement due to the absence of a metric on $\mathbb{S}^1$. Breaking diffeomorphism invariance will enter the theory through the choice of a reference quantum state.

(3) *Henceforth we indicate a wave function* $[\psi]$ *by* ψ *if the notation is not misunderstandable.*

"Wave function" is quite an improper term, due to the absence of any equation of motion on $\mathbb{M}$, nevertheless the "wave functions" introduced here play a role similar to that of the smooth solutions of Klein–Gordon equation in a globally hyperbolic space–time. As $\mathcal{S}(\mathbb{M})$ is a real vector space equipped with a *nondegenerate* symplectic form Ω, there exist a complex C^*-algebra (Theorem 5.2.8 in Ref. 2) generated by elements, $W(\psi)$ with $\psi\in\mathcal{S}(\mathbb{M})$ satisfying, for all ψ, $\psi'\in\mathcal{S}(\mathbb{M})$,

$$\text{(W1)}\quad W(-\psi)=W(\psi)^*,\quad \text{(W2)}\quad W(\psi)W(\psi')=e^{i\Omega(\psi,\psi')/2}W(\psi+\psi').$$

That C^*-algebra, indicated by $\mathcal{W}(\mathbb{M})$, is unique up to (isometric) $*$-isomorphisms (Theorem 5.2.8 in Ref. 2). As consequences of (W1) and (W2), $\mathcal{W}(\mathbb{M})$ admits unit $I=W(0)$, each $W(\psi)$ is unitary and, from the nondegenerateness of Ω, $W(\psi)=W(\psi')$ if and only if $\psi=\psi'$. $\mathcal{W}(\mathbb{M})$ is called Weyl algebra associated with $\mathcal{S}(\mathbb{M})$ and Ω whereas the $W(\psi)$ are called symplectically smeared (abstract) Weyl operators. The formal interpretation of elements $W(\psi)$ is $W(\psi)\equiv e^{i\Omega(\psi,\hat{\phi})}$ where $\Omega(\psi,\hat{\phi})$ are symplectically smeared scalar fields as we shall see shortly.

D. Implementing locality: Fields smeared with forms

In a globally hyperbolic space–time X the *local* smearing is obtained employing real compactly supported functions f instead of solutions of field equations[38] to smear field operator. In particular one gives a rigorous meaning to

$$\hat{\phi}(f) = \int_X \hat{\phi}(x) f(x) \mathrm{d}\mu(x), \tag{3}$$

μ being the measure induced by the metric of X. The support of the smearing function f gives a suitable notion of support of the associated observable $\hat{\phi}(f)$. In this way locality can be implemented by stating that observables with causally disjoint supports commute. In our case it is impossible to assign a unique support to a class of equivalence $[\psi]$ and thus implementation of locality is not very straightforward in the symplectic approach. Furthermore, there is no natural measure μ on $\mathbb{M}$ as that present in (3) because $\mathbb{S}^1$ is metrically degenerate. Both problems can be solved by using compactly supported forms instead of compactly supported functions. Let us indicate by $\mathcal{D}(\mathbb{M})$ the space of real forms ϵ_ψ [see (1)] with $\psi \in C_c^\infty(\mathbb{M};\mathbb{R})$. In a globally hyperbolic space–time[38] the relation between wave functions and smooth compactly supported functions [now elements of $\mathcal{D}(\mathbb{M})$] used in (3), is implemented by the *causal propagator*, $E:\mathcal{D}(\mathbb{M}) \to \mathcal{S}(\mathbb{M})$.[38] It is a $\mathbb{R}$-linear surjective map which associates a smooth function with wave functions (supported in the causal set generated by the support of the smooth function) and satisfies several properties. The crucial property describing the interplay of E and Ω reads, if $E(\omega,\omega') := \int_{\mathbb{M}} E(\omega)\omega'$,

$$\Omega(E\omega, E\omega') = E(\omega,\omega') \quad \text{for all } \omega,\omega' \in \mathcal{D}(\mathbb{M}). \tag{4}$$

In our case (4) and surjectivity determine E uniquely on $\mathbb{M}$.

Proposition 2.1: *On a degenerate manifold $\mathbb{M} := \mathbb{S}^1 \times \Sigma$ there is a unique surjective $\mathbb{R}$-linear map $E:\mathcal{D}(\mathbb{M}) \to \mathcal{S}(\mathbb{M})$ satisfying (4). Moreover the following facts hold.*

(a) *If θ is a standard frame on $\mathbb{S}^1$ and $\omega \in \mathcal{D}(\mathbb{M})$ is realized as a 2π-periodic form in θ viewed as positive-oriented coordinate $\mathbb{R}$ and $s \in \Sigma$, E admits the representation*

$$(E(\omega))(\theta,s) = \left[\frac{1}{4} \int_{\theta' \in [-\pi,\pi] s' \in \Sigma} \left(\mathrm{sign}(\theta') - \frac{\theta'}{\pi} \right) \delta(s,s') \omega(\theta - \theta', s') \right]. \tag{5}$$

(b) *E is* bijective *and in particular, for $\psi \in \mathcal{S}(\mathbb{M})$, $\omega \in \mathcal{D}(\mathbb{M})$, one has*

$$E(\epsilon_\psi) = \tfrac{1}{2}\psi \quad \textit{and} \quad \epsilon_{E(\omega)} = \tfrac{1}{2}\omega. \tag{6}$$

Thus $(\omega,\omega') \mapsto E(\omega,\omega')$ is a nondegenerate symplectic form on $\mathcal{D}(\mathbb{M})$.

Proof: The fact that E defined in (5) satisfies (4) can be proved straightforwardly by direct computation. Direct computation shows also the validity of (6) proving injectivity and surjectivity. Any linear surjective map E satisfying (4) fulfills also $\Omega(\psi, E\omega') = \int_{\mathbb{M}} \psi\omega'$ for every $\psi \in \mathcal{S}(\mathbb{M})$ and $\omega' \in \mathcal{D}(\mathbb{M})$. If E, E' are surjective linear maps satisfying (4), one has $\Omega(\psi, E\omega - E'\omega) = \int_{\mathbb{M}} \psi(\omega - \omega) = 0$ for every $\psi \in \mathcal{S}(\mathbb{M})$. Ω is nondegenerate and thus $E\omega - E'\omega = 0$ for every $\omega \in \mathcal{D}(\mathbb{M})$. Hence $E = E'$. The final statement is now obvious. □

We shall call the bijective map E in (5) causal propagator, regardless of the partial inappropriateness of the name due to the lack of field equations. In space–times, existence of field equations is responsible for the failure of the injectivity of the causal propagator. $\delta(s,s')$ in (5) has an evident physical meaning if $(\mathbb{S}^1 \setminus \{\infty\}) \times \Sigma$ is thought as the future Kruskal Killing horizon and E is interpreted as the limit case of a properly defined causal propagator. As the boundary of a causal set $J(S)$, for $S \subset \Sigma$, is made of portions of the factor $\mathbb{S}^1$, causal separation of sets S, $S' \subset \Sigma$ assigned at different "times" of $\mathbb{S}^1 \setminus \{\infty\}$, is equivalent to $S \cap S' = \emptyset$.

As in space–times, if $\omega \in \mathcal{D}(\mathbb{M})$, the form-smeared (abstract) Weyl field is defined as

$$V(\omega) := W(E\omega). \tag{7}$$

With this definition one immediately gets Weyl relations once again. For all $\omega,\ \eta \in \mathcal{D}(\mathbb{M})$,

$$\text{(V1)} \quad V(-\omega) = V(\omega)^*, \quad \text{(V2)} \quad V(\omega)V(\eta) = e^{iE(\omega,\eta)/2}V(\omega+\eta).$$

Since E is injective, differently from the extent in a space–time, $V(\omega)=V(\omega')$ if and only if $\omega=\omega'$. A notion of *locality* on $\mathbb{M}$ (in a straightforward extension of an original idea due to Sewell[35]) can be introduced at this point by the following proposition (the proof is in the Appendix).

Proposition 2.2: $[V(\omega),V(\omega')]=0$ *for* $\omega,\ \omega' \in \mathcal{D}(\mathbb{M})$ *if one of the conditions is fulfilled:*

(a) *there are two open disjoint segments* $I,\ I' \subset \mathbb{S}^1$ *with supp* $\omega \subset I\times\Sigma$ *and supp* $\omega' \subset I'\times\Sigma$,
(b) *there are two open disjoint sets* $S,\ S' \subset \Sigma$ *with supp* $\omega \subset \mathbb{S}^1\times S$ *and supp* $\omega' \subset \mathbb{S}^1\times S'$.

The $*$-algebra $\mathcal{W}(\mathbb{M})$ is *local* in the sense stated in the thesis of Proposition 2.2. Notice that supp $\omega \cap$ supp $\omega' = \varnothing$ does not imply commutativity of $V(\omega)$ and $V(\omega')$ in general.

E. Fock representations

Breaking invariance under orientation-preserving $\mathbb{S}^1$-diffeomorphisms, Fock representations of $\mathcal{W}(\mathbb{M})$ can be introduced as follows generalizing part of the construction presented in 2.4 of Ref. 12 and in Ref. 27. From a physical point of view, the procedure resembles quantization with respect to Killing time in a static space–time. Fix a standard frame θ on $\mathbb{S}^1$. Any representative ψ of $[\psi] \in \mathcal{S}(\mathbb{M})$ can be expanded in Fourier series in the parameter θ, where $\mathbb{N}' := \mathbb{N}\backslash\{0\}$,

$$\psi(\theta,s) \sim \sum_{n\in\mathbb{N}'} \frac{e^{-in\theta}\widetilde{\psi(s,n)_+}}{\sqrt{4\pi n}} + \sum_{n\in\mathbb{N}'} \frac{e^{in\theta}\overline{\widetilde{\psi(s,n)_+}}}{\sqrt{4\pi n}} = \psi_+(\theta,s) + \overline{\psi_+(\theta,s)}. \tag{8}$$

ψ_+ is the θ-positive frequency part of ψ. The term with $n=0$ was discarded due to the equivalence relation used defining $\mathbb{S}(\mathbb{M})$, the remaining terms depend on $[\psi]$ only. $\Sigma \ni s \mapsto \widetilde{\psi(s,n)_+}$ is smooth, supported in a compact set of Σ independent from n and, using integration by parts, for any $\gamma>0$, there is $C_\gamma \geqslant 0$ with $\|\widetilde{\psi(\cdot,n)_+}\|_\infty \leqslant C_\gamma n^{-\gamma}$ for $n \in \mathbb{N}'$ so that the series in (8) converges uniformly and θ-derivative operators can be interchanged with the symbol of summation. The found estimation and Fubini's theorem entail that the sesquilinear form

$$\langle \psi'_+, \psi_+ \rangle := -i\Omega(\overline{\psi'_+}, \psi_+) \tag{9}$$

on the space of complex linear combinations of θ-positive frequency parts satisfies

$$\langle \psi'_+, \psi_+ \rangle = \sum_{n=1}^{\infty} \int_\Sigma \overline{\widetilde{\psi'(s,n)_+}}\widetilde{\psi(s,n)_+}\omega_\Sigma(s) = \int_\Sigma \sum_{n=1}^{\infty} \overline{\widetilde{\psi'(s,n)_+}}\widetilde{\psi(s,n)_+}\omega_\Sigma(s). \tag{10}$$

Thus it is positive and defines a Hermitian scalar product. The one-particle space $\mathcal{H}$ is now defined as the completion with respect to $\langle\cdot,\cdot\rangle$ of the space of positive θ-frequency parts ψ_+ of wave functions. Due to (10), $\mathcal{H}$ is isomorphic to $\ell^2(\mathbb{N})\otimes L^2(\Sigma,\omega_\Sigma)$. [The construction of $\mathcal{H}$ is equivalent to that performed in the approach of Ref. 38 (see also Ref. 17) using the real scalar product on $\mathcal{S}(\mathbb{M})$, $\mu(\psi,\psi') := -\mathrm{Im}\,\Omega(\psi_+,\psi'_+)$ and the map $K:\mathcal{S}(\mathbb{M}) \ni \psi \mapsto \psi_+ \in \mathcal{H}$.] $\mathfrak{F}_+(\mathcal{H})$ is the symmetrized Fock space with vacuum state Ψ and one-particle space $\mathcal{H}$. The field operator symplectically smeared with $\psi \in \mathcal{S}(\mathbb{M})$ and the field operator smeared with the form $\omega \in \mathcal{D}(\mathbb{M})$ are, respectively, the operators

$$\Omega(\psi,\hat{\phi}) := ia(\overline{\psi_+}) - ia^\dagger(\psi_+) \quad \text{and} \quad \hat{\phi}(\omega) := \Omega(E\omega,\hat{\phi}), \tag{11}$$

where the operators $a^\dagger(\psi_+)$ and $a(\overline{\psi_+})$ ($\mathbb{C}$-linear in $\overline{\psi_+}$), respectively, create and annihilate the state ψ_+. The common invariant domain of all the involved operators is the dense linear manifold $F(\mathcal{H})$ spanned by the vectors with finite number of particle. $\Omega(\psi,\hat{\phi})$ and $\hat{\phi}(\omega)$ are essentially self-

adjoint on $F(\mathcal{H})$ [they are symmetric and $F(\mathcal{H})$ is dense and made of analytic vectors] and satisfy bosonic commutation relations (CCR),

$$[\Omega(\psi,\hat{\phi}),\Omega(\psi',\hat{\phi})] = -i\Omega(\psi,\psi')I \quad \text{and} \quad [\hat{\phi}(\omega),\hat{\phi}(\omega')] = -iE(\omega,\omega')I.$$

The definition $\hat{\phi}(\omega) := \Omega(E\omega,\hat{\phi})$ is here nothing but a rigorous interpretation of the formula $\hat{\phi}(\omega) = \int_{\mathbb{M}} \hat{\phi}(x)\omega(x)$. Finally the unitary operators

$$\hat{W}(\psi) := e^{i\overline{\Omega(\psi,\hat{\phi})}} \quad \text{and, equivalently,} \quad \hat{V}(\omega) := \hat{W}(E\omega) = e^{i\overline{\hat{\phi}(\omega)}} \tag{12}$$

enjoy properties (W1), (W2) and, respectively (V1), (V2), so that they define a unitary representation $\hat{\mathcal{W}}(\mathbb{M})$ of $\mathcal{W}(\mathbb{M})$ which is also irreducible. The proof of these properties follows from Propositions 5.2.3 and 5.2.4 in Ref. 2. [There the symplectic form is $\sigma = -2\Omega$ and the field operator $\Phi(\underline{\psi_+})$ of Proposition 5.2.3 of Ref. 2 is $\Phi(\psi_+) = 2^{-1/2}\Omega(J\psi,\hat{\phi})$ where $J\psi = -i\psi_+ + i\overline{\psi_+}$ if $\psi = \psi_+ + \underline{\psi_+}$. Notice that $J(\mathcal{S}(\mathbb{M})) \subset \mathcal{S}(\mathbb{M})$, that is false in general with other definitions of $\mathcal{S}(\mathbb{M})$!]

If $\Pi : \mathcal{W}(\mathbb{M}) \to \hat{\mathcal{W}}(\mathbb{M})$ denotes the unique (Ω being nondegenerate) C^*-algebra isomorphism between those two Weyl representations, $(\mathfrak{F}_+(\mathcal{H}),\Pi,\Psi)$ coincides, up to unitary transformations, with the GNS triple associated with the algebraic pure state λ on $\mathcal{W}(\mathbb{M})$ uniquely defined by the requirement (see the Appendix)

$$\lambda(W(\psi)) := e^{-\langle\psi_+,\psi_+\rangle/2}. \tag{13}$$

III. CONFORMAL NETS ON DEGENERATE MANIFOLDS

A. Diff$^+$($\mathbb{S}^1$), PSL(2,$\mathbb{R}$) and associated $*$-automorphisms on $\mathbb{M}$

We recall here some basic notions of conformal representations on $\mathbb{S}^1$. Let Vect($\mathbb{S}^1$) be the infinite-dimensional Lie algebra of the infinite-dimensional Lie group (see Milnor[23]) of orientation-preserving smooth diffeomorphisms of the circle Diff$^+$($\mathbb{S}^1$). Vect($\mathbb{S}^1$) is the real linear space of smooth vector fields on $\mathbb{S}^1$ whose associated one-parameter diffeomorphisms preserve the orientation of $\mathbb{S}^1$. Vect$^{\mathbb{C}}$($\mathbb{S}^1$) denotes the complex Lie algebra Vect($\mathbb{S}^1$) $\oplus\, i$ Vect($\mathbb{S}^1$) with usual Lie brackets $\{\cdot,\cdot\}$ and involution $\imath : X \mapsto -\overline{X}$ for $X \in$ Vect$^{\mathbb{C}}$($\mathbb{S}^1$), so that $\imath(\{X,Y\}) = \{\imath(Y),\imath(X)\}$. Vect($\mathbb{S}^1$) is the (real) sub-Lie-algebra of Vect$^{\mathbb{C}}$($\mathbb{S}^1$) of anti-Hermitian elements with respect to $\imath$. $\mathfrak{a}$ denotes the Lie subalgebra of Vect$^{\mathbb{C}}$($\mathbb{S}^1$) whose elements have a finite number of Fourier component with respect to a standard frame θ which is supposed to be fixed from now on. A basis for $\mathfrak{a}$ is made of fields

$$\mathfrak{L}_n := ie^{in\theta}\partial_\theta \quad \text{with } n \in \mathbb{Z}. \tag{14}$$

They enjoy the so-called *Hermiticity condition*, $\imath(\mathfrak{L}_n) = \mathfrak{L}_{-n}$ and the well-known *Virasoro commutation rules* with vanishing central charge, $[\mathfrak{L}_n,\mathfrak{L}_m] = (n-m)\mathfrak{L}_{n+m}$.

We remind that SL(2,$\mathbb{R}$) and SU(1,1) are isomorphic through the map SL(2,$\mathbb{R}$) $\ni h \mapsto g \in$ SU(1,1) where

$$g := \begin{pmatrix} \zeta & \overline{\eta} \\ \eta & \overline{\zeta} \end{pmatrix}, \quad h = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}, \quad \text{and} \quad \zeta := \frac{\alpha+\delta+i(\beta-\gamma)}{2}, \quad \eta := \frac{\delta-\alpha-i(\beta+\gamma)}{2}.$$

Diff$^+$($\mathbb{S}^1$) includes the Möbius group of the circle PSL(2,$\mathbb{R}$) := SU(1,1)/$\{\pm I\}$ as a finite-dimensional subgroup: Thinking $\mathbb{S}^1$ as the unit complex circle parametrized by θ, an element $g \in$ PSL(2,$\mathbb{R}$) is injectively associated with the diffeomorphism $g \in$ Diff$^+$($\mathbb{S}$),

$$g{:}e^{i\theta}\mapsto \frac{\zeta e^{i\theta}+\overline{\eta}}{\eta e^{i\theta}+\overline{\zeta}} \quad \text{with } \theta\in[-\pi,\pi]. \tag{15}$$

The corresponding inclusion of Lie algebras is illustrated by the fact that the three $\imath$-anti-Hermitian linearly independent elements of $\mathfrak{a}$,

$$\mathcal{K}:=i\mathfrak{L}_0=-\partial_\theta,\quad \mathcal{S}:=i\frac{\mathfrak{L}_1+\mathfrak{L}_{-1}}{2}=-\cos\theta\partial_\theta,\quad \mathcal{D}:=i\frac{\mathfrak{L}_1-\mathfrak{L}_{-1}}{2}=-\sin\theta\partial_\theta \tag{16}$$

enjoy the commutation rules of the elements k, s, d of the basis of the Lie algebra $\mathrm{sl}(2,\mathbb{R})$ with

$$k=\frac{1}{2}\begin{bmatrix}0 & 1\\ -1 & 0\end{bmatrix},\quad s=\frac{1}{2}\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix},\quad d=\frac{1}{2}\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}. \tag{17}$$

In particular k is the generator of the subgroup of rotations $\mathrm{SO}(2)/\pm I\subset\mathrm{PSL}(2,\mathbb{R})$ given by dispacements in θ. $\mathrm{Diff}^+(\mathbb{S}^1)$ acts naturally as a group of *isometries* on the semi-Riemannian manifold $\mathbb{M}=\mathbb{S}^1\times\Sigma$. If $g\in\mathrm{Diff}^+(\mathbb{S}^1)$, we shall use the same symbol to indicate the associated diffeomorphism of $\mathbb{M}$.

B. Invariance with respect to PSL(2,$\mathbb{R}$)

From now on we use the following notation. If $g\in\mathrm{Diff}^+(\mathbb{S}^1)$ and $\psi\in C_c^\infty(\mathbb{M};\mathbb{C})$, $\psi^{(g)}:=\psi\circ g$. If $[\psi]\in\mathcal{S}(\mathbb{M})$, the element $[\psi]^{(g)}:=[\psi^{(g)}]$ is well defined and it will be indicated by $\psi^{(g)}$ simply if the meaning is clear from the context. The usual pull-back action on forms $\omega\in\mathcal{D}(\mathbb{M})$ will be denoted similarly, $\omega^{(g)}:=g^*\omega$. Notice that g^* leaves $\mathcal{D}(\mathbb{M})$ fixed. Using (6), it results that if $\psi=E\omega$ with $\omega\in\mathcal{D}(\mathbb{M})$ then $\omega^{(g)}=2\epsilon_{\psi^{(g)}}\in\mathcal{D}(\mathbb{M})$. Ω and E are *invariant* under $\mathrm{Diff}^+(\mathbb{S}^1)$. That is, for all ψ, $\phi\in C_c^\infty(\mathbb{M};\mathbb{C})$, $g\in\mathrm{Diff}^+(\mathbb{S}^1)$ and ω, $\eta\in\mathcal{D}(\mathbb{M})$,

$$\Omega(\psi,\phi)=\Omega(\psi^{(g)},\phi^{(g)}),\quad \text{and}\quad E(\omega,\eta)=E(\omega^{(g)},\eta^{(g)}). \tag{18}$$

Therefore, as a consequence of general results [(4) in Theorem 5.2.8 of Ref. 2], $\mathrm{Diff}^+(\mathbb{M})$ admits a representation $\alpha{:}g\mapsto\alpha_g$ made of $*$-automorphisms of the algebra $\mathcal{W}(\mathbb{M})$ induced by

$$\alpha_g(V(\omega)):=V(\omega^{(g^{-1})}). \tag{19}$$

In the following we employ only *the restriction* of the representation α to the Möbius group of the circle $\mathrm{PSL}(2,\mathbb{R})\ni g\mapsto\alpha_g$ in terms of $*$-automorphisms of $\mathcal{W}(\mathbb{M})$.

The definition of the state λ (13) is not $\mathrm{Diff}^+(\mathbb{S}^1)$ invariant since it relies upon the choice of a preferred standard frame θ. Let us show that actually a different standard frame θ' produces the same λ provided the coordinate transformation $\theta'=\theta'(\theta)$ belongs to $\mathrm{PSL}(2,\mathbb{R})$.

Theorem 3.1: *Let θ be a standard frame on $\mathbb{S}^1$ of $\mathbb{M}:=\mathbb{S}^1\times\Sigma$, consider the state on $\mathcal{W}(\mathbb{M})$, λ (13) and the representation α of PSL$(2,\mathbb{R})$ defined above. The following hold.*

(a) *λ is invariant under α, that is $\lambda(\alpha_g(w))=\lambda(w)$ for all $g\in PSL(2,\mathbb{R})$ and $w\in\mathcal{W}(\mathbb{M})$.*
(b) *If θ' is another standard frame $\mathbb{S}^1$ such that the coordinate transformation $\theta'=\theta'(\theta)$ belongs to PSL$(2,\mathbb{R})$, then $\lambda'=\lambda$ where λ' is the analog of λ referred to θ'.*

The proof arises from (13) using the invariance of Ω under $\mathrm{Diff}^+(\mathbb{S}^1)$ and the following lemma.

Lemma 3.1: *Let θ be a standard frame on $\mathbb{S}^1$ of $\mathbb{M}:=\mathbb{S}^1\times\Sigma$. The action of PSL$(2,\mathbb{R})\subset\mathrm{Diff}^+(\mathbb{S}^1)$ preserves positive frequency parts. That is, if $g\in PSL(2,\mathbb{R})$, $\psi\in\mathcal{S}(\mathbb{M})$, $\omega\in\mathcal{D}(\mathbb{M})$,*

$$(\psi^{(g)})_+=(\psi_+\circ g)\quad\text{and}\quad(\omega^{(g)})_+=g^*\omega_+, \tag{20}$$

*where $\omega_+:=\epsilon_{\phi_+}$ is called the θ-*positive-frequency part *of any form $\omega:=\epsilon_\phi$ in $\mathcal{D}(\mathbb{M})$.*

Proof: From *Remark* on p. 271 of Ref. 27 one finds that $(\psi^{(g)})_+=(\psi_+\circ g)$ for all $g\in \mathrm{PSL}(2,\mathbb{R})$ and $\psi\in\mathcal{S}(\mathbb{M})$. The result straightforwardly extends to $\omega\in\mathcal{D}(\mathbb{M})$ using the definition of $\mathcal{D}(\mathbb{M})$. □.

We stress that (20) does *not* hold for generic diffeomorphisms $g\in \mathrm{Diff}^+(\mathbb{S}^1)$.

C. Virasoro representations and conformal nets

Let us investigate on the existence of operator representations of Virasoro algebra and the real subalgebra $\mathrm{sl}(2,\mathbb{R})$ in the Fock space $\mathfrak{F}_+(\mathcal{H})$ introduced above focusing, in particular, on the relationship with the algebra $\hat{\mathcal{W}}(\mathbb{M})$. Fix a standard frame θ on $\mathbb{S}^1$ and build up the associated Fock space and the Weyl representation. It is possible to introduce in $\mathfrak{F}_+(\mathcal{H})$ a new class of operators which generalizes chiral currents straightforwardly. If $\mathbb{N}':=\{1,2,3,\ldots\}$ and $\{u_j\}_{j\in\mathbb{N}'}$ is a Hilbert basis of $L^2(\Sigma,\omega_\Sigma)$ the vectors

$$Z_{jn}(\theta,s):=\frac{u_j(s)e^{-in\theta}}{\sqrt{4\pi n}}$$

define a Hilbert basis of the one-particle space $\mathcal{H}$. We can always reduce to the case of *real* vectors u_j and we assume that henceforth. [$L^2(\Sigma,\omega_\Sigma)$ is separable since the Borel measure induced by ω_Σ is σ-finite and the Borel σ-algebra of Σ is countably generated (the topology of Σ being second countable by definition of manifold). If $\{u_j\}$ is a Hilbert basis $\{\overline{u_j}\}$ is such. Orthonormalization procedure of a maximal set of linearly independent generators in the set of all $u_j+\overline{u_j}, i(u_j-\overline{u_j})$ yields a real Hilbert basis.] The functions $\mathcal{D}(\mathbb{M})\ni\omega\mapsto a(E\omega)$ and $\mathcal{D}(\mathbb{M})\ni\omega\mapsto a^\dagger(E\omega)$, where the operators work on the domain $F(\mathcal{H})$, can be proved to be distributions using the strong-operator topology [to show it essentially use (1) in Proposition 5.2.3 in Ref. 2] and the usual test-function topology on $\mathcal{D}(\mathbb{M})$ induced by families of seminorms referred to derivatives (of any order) in coordinates of components of forms ω (see 2.8 in Ref. 7). $\mathcal{D}(\mathbb{M})\ni\omega\mapsto\hat{\phi}(\omega)$ admits the distributional kernel

$$\hat{\phi}(\theta,s)=\frac{1}{i\sqrt{4\pi}}\sum_{(n,j)\in\mathbb{Z}\times\mathbb{N}'}\frac{u_j(s)e^{-in\theta}}{n}J_n^{(j)}, \tag{21}$$

where the (generalized) chiral currents $J_n^{(j)}:F(\mathcal{H})\to F(\mathcal{H})$ are defined as follows:

$$J_0^{(j)}=0,\quad J_n^{(j)}=i\sqrt{n}a(\overline{Z_{jn}})\quad\text{if } n>0\quad\text{and}\quad J_n^{(j)}=-i\sqrt{-n}a^\dagger(Z_{j,-n})\quad\text{if } n<0.$$

They satisfy on $F(\mathcal{H})$ both the Hermiticity condition $J_n^{(j)\dagger}\restriction_{F(\mathcal{H})}=J_{-n}^{(j)}$ and the oscillator commutation relations $[J_n^{(j)},J_m^{(i)}]=n\delta^{ij}\delta_{n,-m}I$. Introducing the usual normal order prescription $:\cdots:$ "operators $J_p^{(j)}$ with negative index p must precede those with positive index p," one can try to define the linearly independent operators, with $c\in\mathbb{N}'\cup\{\infty\}$,

$$L_k^{(c)}:=\frac{1}{2}\sum_{n\in\mathbb{Z},j\leqslant c}:J_n^{(j)}J_{k-n}^{(j)}:,\quad L_k:=L_k^{(\infty)} \tag{22}$$

on some domain in $\mathfrak{F}_+(\mathcal{H})$. We shall denote the complex infinite-dimensional algebra spanned by $L_k^{(c)}$ by $\hat{d}_c$. One can formally show that L_k have two equivalent geometric expressions

$$L_k=\frac{1}{2i}:\Omega(\hat{\phi},\mathfrak{L}_k(\hat{\phi})):, \tag{23}$$

$$L_k = \int_{\mathbb{M}} :\partial_\theta \hat{\phi} \partial_\theta \hat{\phi}: (\theta, s) e^{ik\theta} \, \mathrm{d}\theta \wedge \omega_\Sigma, \tag{24}$$

$\mathfrak{L}_k(\hat{\phi})$ is the "scalar field" obtained by the action of the differential operator $\mathfrak{L}_k$ (naturally extended from $\mathbb{S}^1$ to the product $\mathbb{M}=\mathbb{S}^1\times\Sigma$) on the "scalar field" ϕ. The same formulas hold if replacing $L_k^{(c)}$ for L_k and replacing $\hat{\phi}$ with $\hat{\phi}^{(c)}$ given by the right-hand side of (21) with the sum over j restricted to the set $\{1,2,\ldots, c\}$. If c is finite the following proposition can be proved by direct inspection.

Proposition 3.1: *Fix a standard frame θ on $\mathbb{S}^1$ of $\mathbb{M}=\mathbb{S}^1\times\Sigma$, take $c\in\mathbb{N}'$ and consider the real vector space $\hat{\mathfrak{a}}_c$ generated by the operators $L_n^{(c)}$ in* (22) *equipped with the commutator $[\cdot,\cdot]$ and the involution $\hat{\mathfrak{a}}_c \ni a \mapsto a^\dagger{\restriction}_{F(\mathcal{H})}$). The following holds.*

(a) *The elements of $\hat{\mathfrak{a}}_c$ are well defined on $F(\mathcal{H})$ which is a dense invariant space of common analytic vectors.*

(b) *$(\hat{\mathfrak{a}}_c, [\cdot,\cdot], \cdot^\dagger{\restriction}_{F(\mathcal{H})})$ is a central representation, with central charge c, of the algebra $(\mathfrak{a}, \{\cdot,\cdot\}, \imath)$ (that is a unitarizable Virasoro representation) since the following relations hold:*

$$L_{-n}^{(c)} = L_n^{(c)\dagger}{\restriction}_{F(\mathcal{H})}, \tag{25}$$

$$[L_n^{(c)}, L_m^{(c)}] = (n-m)L_{n+m}^{(c)} + \frac{(n^3-n)c}{12}\delta_{n+m,0} I. \tag{26}$$

(c) *The representation is* positive energy, *i.e., the generators of rotations $L_0^{(j)}$ is non-negative.*

(d) *Each operator $L_n^{(c)}$ does not depend on the choice for the real base $\{u_j\}_{j\leq c}$ (but depends on the finite dimensional subspace spanned by those vectors).*

Notice that the found Virasoro representations are strongly reducible.[15] Once they are decomposed into unitarizable irreducible highest-weight representations,[15] they can be exponentiated (Refs. 9, 18, and 5) obtaining unitary strongly continuous representations of $\mathrm{Diff}^+(\mathbb{S}^1)$.

In general there is no physical reason to single out a Hilbert basis $\{u_j\}$ or equivalently a sequence $\cdots\mathcal{H}_k\subset\mathcal{H}_{k+1}\cdots$ of finite dimensional subspace of$L^2(\Sigma, \omega_\Sigma)$. In the presence of particular symmetries for Σ a class of finite dimensional subspaces can be picked out referring to the invariant subspaces with respect to a unitary representation on $L^2(\Sigma, \omega_\Sigma)$ of the symmetry group. For instance, think of $\Sigma=\mathbb{S}^2$, in that case one may decompose $\psi\in L^2(\mathbb{S}^2)$ using (real and imaginary parts of) spherical harmonics Y_m^l. Hence a suitable class of finite dimensional subspaces are those with fixed angular momentum $l=0, 1, 2, \ldots$. The sphere $\mathbb{S}^2$ is reconstructed as a sequence of *fuzzy spheres* (Ref. 20) with greater and greater angular momentum l. The associated Virasoro representations have central charges $c_l=2l+1$.

In the absence of symmetries only the case $c=\infty$ seems to be physically interesting. Let us turn attention on this case. Serious problems arise when trying to give a rigorous meaning to all the operators L_n. First of all (26) becomes meaningless due to $c=\infty$ in the right-hand side. Furthermore, by direct inspection one finds that, if $n<-1$, the domain of L_n cannot include any vector of $F(\mathcal{H})$ due to an evident divergence (this drawback would arise also for $|n|=1$ if $J_0^{(j)}=0$ were false). However, by direct inspection, one finds that L_n with $n\geqslant -1$ are well defined on $F(\mathcal{H})$ which is, in fact, a common invariant dense domain made of analytic vectors, moreover $L_n\Psi=0$. The central charge does not appear considering commutators of those operators. The complex space (finitely) spanned by those vectors is closed with respect to the commutator but, unfortunately, it is *not* with respect to the Hermitian conjugation so that they cannot represent a Lie algebra of observables. However, restricting to the case $|n|\leqslant 1$ everything goes right and one gets a Lie algebra closed with respect to the Hermitian conjugation. Anti-Hermitian linearly independent operators generating that Lie algebra are

$$iK := iL_0, \quad iS := i\frac{L_1 + L_{-1}}{2}, \quad iD := \frac{L_1 - L_{-1}}{2}. \tag{27}$$

They enjoy the commutation rules of the elements k,s,d of the basis of the Lie algebra $\mathrm{sl}(2,\mathbb{R})$ (17). As a consequence a representation $R:\mathrm{sl}(2,\mathbb{R}) \to \mathfrak{L}(F(\mathcal{H}))$ can be realized by assuming $iK = R(k), iS = R(s), iD = R(d)$ and $R:\alpha k + \beta s + \gamma d \mapsto \alpha iK + \beta iS + \gamma iD$ for all $\alpha,\beta,\gamma \in \mathbb{R}$. One expects that this representation is associated, via exponentiation, with a strongly continuous (projective) unitary representation of the universal covering of $\mathrm{SL}(2,\mathbb{R})$, $\widetilde{\mathrm{SL}(2,\mathbb{R})}$. Let us prove that such a representation does exist and enjoys remarkable properties.

Theorem 3.2: *Fix a standard frame θ on $\mathbb{S}^1$ of $\mathbb{M} = \mathbb{S}^1 \times \Sigma$ and construct the GNS (Fock) realization of $\mathcal{W}(\mathbb{M})$ associated with the state λ in* (13) *and the representation R. It turns out that the Hermitian operators $iR(x)$, with $x \in sl(2,\mathbb{R})$, are essentially self-adjoint on $F(\mathcal{H})$ and there is a unique strongly continuous representation $PSL(2,\mathbb{R}) \ni g \mapsto U(g):\mathfrak{F}_+(\mathcal{H}) \to \mathfrak{F}_+(\mathcal{H})$ with*

$$U(\exp(tx)) = e^{t\overline{iR(x)}} \quad \textit{for all } x \in sl(2,\mathbb{R}) \textit{ and } t \in \mathbb{R}. \tag{28}$$

The following further facts hold.

(a) *U is a positive-energy representation of $PSL(2,\mathbb{R})$—that is the self-adjoint generator $\overline{K}$ of the subgroup of rotations, has non-negative spectrum—and furthermore $\sigma(\overline{K}) = \{0,1,2,\ldots\}$.*
(b) *U and its generators do not depend on the choice of the basis $\{u_j\}_{j\in\mathbb{Z}} \subset L^2(\Sigma,\omega_\Sigma)$. In particular, U is the tensorialization of $U\restriction_{\mathcal{H}}$. Referring to the factorization of the one-particle space $\mathcal{H} = \ell^2(\mathbb{C}) \otimes L^2(\Sigma,\omega_\Sigma)$, it holds $U\restriction_{\mathcal{H}} = V \otimes I$, where V is the restriction to the one-particle space of the representation U in the simplest case $\mathbb{M} = \mathbb{S}^1$.*
(c) *Each subspace of $\mathfrak{F}_+(\mathcal{H})$ with finite number of particles is invariant under U.*
(d) *The GNS representative of λ, Ψ, is invariant under U and it is the only unit vector of $\mathfrak{F}_+(\mathcal{H})$ invariant under $\{e^{it\overline{D}}\}_{t\in\mathbb{R}}$ up to phases.*

The proof of the theorem is given in the Appendix. The following further theorem states that $\hat{\mathcal{W}}(\mathbb{M})$ transform covariantly under this representation with respect to the action of the diffeomorphisms of $\mathrm{PSL}(2,\mathbb{R}) \subset \mathrm{Diff}^+(\mathbb{S}^1)$ seen in Sec. II B.

Theorem 3.3: *With hypotheses and notation of Theorem 3.2, the following holds.*

(a) *U is $PSL(2,\mathbb{R})$ covariant. In other words it implements unitarily the representation α of* $\mathrm{PSL}(2,\mathbb{R})$ *defined in Theorem 3.2: For all $g \in PSL(2,\mathbb{R})$,*

$$U(g) w U(g)^\dagger = \alpha_g(w) \quad \textit{for all } w \in \hat{\mathcal{W}}(\mathbb{M}). \tag{29}$$

(b) *The one-parameter group of $*$-automorphisms associated with the one-parameter group of diffeomorphisms, respectively, generated by vector fields $\mathcal{K}$, $\mathcal{S}$, $\mathcal{D}$ correspond, through (29), to the one-parameter unitary subgroups of U, respectively, generated by iK, iS, iD.* [Sign conventions should be clear, anyway to fix them notice that formally $[iK, \hat{\phi}(\theta,s)] = -\partial_\theta \hat{\phi}(\theta,s)$.]

The proof of the theorem is given in the Appendix. Theorems 3.2 and 3.3 have a remarkable consequence concerning the existence of a so-called *conformal net on* $\mathbb{S}^1$ associated with the algebra $\hat{\mathcal{W}}(\mathbb{M})$. This fact has a wide spectrum of relevant consequences in physics and in mathematics, see for instance Refs. 4, 8, 10, and 5, and references therein. We remind the reader that any weakly closed $*$-subalgebra of the unital C^*-algebra of all bounded operators on a Hilbert space is called *von Neuman algebra* if it contains the unit operator. For several theoretical reasons (see Ref. 13) the largest set of bounded observables of a quantum system represented in a Hilbert space may be assumed to be made of the self-adjoint elements of a suitable von Neumann algebra. If X is a $*$-algebra of bounded operators over a Hilbert space, X' denotes the algebra of the bounded operators which commute with each element of X and it results that[13] X is a von

Neumann algebra if and only if $X=(X')'$. In any case, $X'':=(X')'$ is the minimal von Neumann algebra which contains X. It is called the *von Neumann algebra generated by X*.

Definition 3.1: *Let $\mathcal{I}$ be the set of nonempty, nondense, open intervals of $\mathbb{S}^1$. Assume that $\mathbb{S}^1$ is equipped with a standard coordinate frame θ. A* conformal net on $\mathbb{S}^1$ *is any triple $(\mathcal{A},\Psi,U)$ where $\mathcal{A}$ is any family $\{\mathcal{A}(I)|I\in\mathcal{I}\}$ of von Neumann algebras on an infinite-dimensional separable complex Hilbert space $\mathcal{H}_{\mathcal{A}}$, and the following properties hold.*

(C1) ***Isotony:*** *$\mathcal{A}(I)\subset\mathcal{A}(J)$, if $I\subset J$ with $I,J\in\mathcal{I}$.*
(C2) ***Locality:*** *$\mathcal{A}(I)\subset\mathcal{A}(J)'$, if $I\cap J=\emptyset$ with $I,J\in\mathcal{I}$.*
(C3) ***Möbius covariance:*** *$U(g)\mathcal{A}(I)U(g)^\dagger=\mathcal{A}(gI)$, $I\in\mathcal{I}$, $g\in PSL(2,\mathbb{R})$, where U is a strongly continuous unitary representation of $PSL(2,\mathbb{R})$ in $\mathcal{H}_{\mathcal{A}}$ and g denotes the Möbius transformation (15) associated with θ.*
(C4) ***Positivity of the energy:*** *The representation U is a positive-energy representation.*
(C5) ***U-invariance and uniqueness of the vacuum:*** *$\Psi\in\mathcal{H}_{\mathcal{A}}$ is the unique (up to phases) unit vector invariant under U.*
(C6) ***Cyclicity of the vacuum:*** *Ψ is cyclic for the algebra $\mathcal{A}(\mathbb{S}^1):=\vee_{I\in\mathcal{I}}\mathcal{A}(I)$.*

We have the following theorem.

Theorem 3.4: *Fix a standard frame θ on $\mathbb{S}^1$ of $\mathbb{M}=\mathbb{S}^1\times\Sigma$ and define the associated Weyl algebra $\hat{\mathcal{W}}(\mathbb{M})$ in the Fock space $\mathfrak{F}_+(\mathcal{H})$ with vacuum state Ψ and the representation of $PSL(2,\mathbb{R})$, U of Theorems 3.2 and 3.3. With those hypotheses the family*

$$\mathcal{A}=\{\mathcal{A}(I)|I\in\mathcal{I}\}\quad \text{with } \mathcal{A}(I)=\{\hat{V}(\omega)|\text{supp }\omega\subset I\times\Sigma\}'', \tag{30}$$

together with Ψ and U form a conformal net on $\mathbb{S}^1$ such that $\hat{\mathcal{W}}(\mathbb{M})\subset\mathcal{A}(\mathbb{S}^1)$.

Proof: (C1), (C2), and (C3) are straightforward consequences of the definition (30) using the fact that (von Neumann's density theorem) $\mathcal{A}(K)$ is the closure with respect to the strong operator topology of the $*$-algebra generated by the elements in $\{\hat{W}(\omega)|\text{supp }\omega\subset K\times\Sigma\}$, employing Proposition 2.2 concerning (C2) and Theorem 3.3 concerning (C3). (C4) and (C5) are part of Theorem 3.2. (C6) is a consequence of the fact that Ψ is cyclic with respect to $\hat{\mathcal{W}}(\mathbb{M})$ (see the Appendix) and $\hat{\mathcal{W}}(\mathbb{M})\subset\mathcal{A}(\mathbb{S}^1)$. This inclusion is a consequence of the fact that, if I, $J\in\mathcal{I}$ and $\mathbb{S}^1=I\cup J$, then, due to (W2), each element of $\hat{\mathcal{W}}(\mathbb{M})$ has the form $c\hat{W}(\omega)\hat{W}(\omega')$ where supp $\omega\subset I\times\Sigma$, supp $\omega'\subset J\times\Sigma$ and $|c|=1$, so that $\hat{\mathcal{W}}(\mathbb{M})\subset\mathcal{A}(I)\vee\mathcal{A}(J)\subset\mathcal{A}(\mathbb{S}^1)$. □

Remarks:

(1) Our construction of a conformal net for, in particular, a bifurcate Killing horizon in a globally hyperbolic space–time, is explicit in giving the effective form of the unitary representation of $\mathrm{PSL}(2,\mathbb{R})$ and the relationship with the whole Virasoro algebra. It does not require any assumption on the existence of any algebra of observables in the space–time where $(\mathbb{S}^1\setminus\{\infty\})\times\Sigma$ can be viewed to be embedded, or any KMS state on that algebra. A different approach was presented in Ref. 11 where it is shown that, in a globally hyperbolic space–time containing a bifurcate Killing horizon, a conformal net can be obtained by restriction to the horizon of a local algebra in the space–time realized using a GNS representation with cyclic vector which satisfies the KMS condition with respect to the Killing time flow. The unitary representation of $\mathrm{PSL}(2,\mathbb{R})$ was obtained there making use of relevant results by Weisbrock *et al.*[40,39,12] on the interplay of modular theory and conformal theory. It seems plausible that our construction can be recovered also using the approach of Ref. 11 defining a bulk algebra of observables and a KMS state appropriately. This topic will be investigated elsewhere.
(2) Conformal nets enjoy relevant properties.[4,8,10,5]
Reeh–Schlieder property: Ψ is cyclic and separating for every $\mathcal{A}(I)$.
Bisognano–Wichmann property: The modular operator Δ_I associated with every $\mathcal{A}(I)$ satisfies $\Delta_I^{it}=U(\exp(2\pi\mathcal{D}_I))$ for every $t\in\mathbb{R}$, $\{\exp(t\mathcal{D}_I)\}_{t\in\mathbb{R}}\subset\mathrm{PSL}(2,\mathbb{R})$ being the one-parameter subgroup which leaves I invariant [with $\mathcal{D}_I$ defined as in remark (2) after Theorem 4.1

below] so that Ψ is a KMS state for $\mathcal{A}(I)$ at inverse temperature 2π with respect to $-\mathcal{D}_I$ for $\mathcal{A}((0,\pi))$.
Haag duality: $\mathcal{A}(I)' = \mathcal{A}(\mathrm{Int}(\mathbb{S}^1 \backslash I))$ for every $\mathcal{A}(I)$.
Irreducibility: $\mathcal{A}(\mathbb{S}^1)$ includes all of bounded operators on $\mathcal{H}_{\mathcal{A}}$.
Factoriality: Each $\mathcal{A}(I)$ is a type III_1 factor.
Additivity: For every $\mathcal{A}(I)$, it holds $\mathcal{A}(I) \subset \vee_{J\in S}\mathcal{A}(J)$ if $\cup_{J\in S} J \supset I$.

(3) With obvious changes, Theorems 3.2, 3.3, and 3.4 are still valid if one considers operators $L_n^{(c)}$ with $c<\infty$, $|n|\leqslant 1$ and the real basis u_j is made of smooth functions with $j \leqslant c$.

IV. SPONTANEOUS BREAKING OF SL(2,$\mathbb{R}$) SYMMETRY AND THERMAL STATES

A. Back to physics

Consider the degenerate manifold $\mathbb{M} = \mathbb{S}^1 \times \mathbb{S}^2$ obtained by the future Killing horizon $\mathbb{F} \equiv \mathbb{R} \times \mathbb{S}^2$ of the Kruskal manifold as discussed in Sec. II A. (However what we say can be generalized to globally hyperbolic space–times with a bifurcate Killing horizon.) In particular the orientation of $\mathbb{S}^1 = \mathbb{R} \cup \{\infty\}$ is that induced on $\mathbb{R}$ from time orientation of the space–time. Let θ be a standard frame on $\mathbb{S}^1$ such that, with $\mathcal{D}$ given in (16),

$$\xi\restriction_{\mathbb{F}} = -\kappa\mathcal{D}, \tag{31}$$

ξ being the global Killing field defining Schwarzschild time in both static wedges and κ being the *surface gravity* which is constant on the Killing horizon $\mathbb{F}$, $\kappa = (4GM)^{-1}$, M being the mass of the black hole.[37,38] *Equation (31) does not fix a standard frame uniquely. However the remaining freedom does not affect the construction we present as a consequence of Theorem 4.3 below*. The requirement (31) implies that the *adimensional* parameter $v \in \mathbb{R}$ of the integral curves of $-\mathcal{D}$ on $\mathbb{F}$ coincides, up the factor κ^{-1} and the choice for the origin, with the usual light-coordinate [this fact is evident using well-known global Kruskal null coordinates U, V (Ref. 37)]: $v = \kappa(t + r_*)$. There r_* is the usual *Regge–Wheeler tortoise coordinate* and t the Schwarzschild time, that is the parameter of the integral curves of ξ in any Schwarzschild wedge. In our picture the point ∞ of $\mathbb{S}^1 = \mathbb{R} \cup \{\infty\}$ corresponds to $\theta = \pi$ whereas $\theta = 0$ corresponds to the bifurcation surface of $\mathbb{F}$ (see Sec. II A).

Let us illustrate the physical consequences of the choice (31) for bosonic QFT built up on the future Horizon together with a Möbius-covariant representation of PSL(2,$\mathbb{R}$) everything associated with the preferred choice for the coordinate θ on $\mathbb{S}^1$.

A celebrated result by Kay and Wald[17] states that any globally defined quasifree state on a globally hyperbolic space–time with a bifurcate Killing horizon (Kruskal manifold in particular) which is invariant under ξ and satisfies some further requirement (*Hadamard condition* imposed on the two-point function of the quasifree state in particular)[17] must be unique and KMS with respect to ξ with the *Hawking inverse temperature* $\beta_H = 2\pi/\kappa$. From a physical point of view, one expects that the system of the field defined on the horizon be in thermal equilibrium with the state in the bulk. More precisely, since $\partial_{\kappa t}$ reduces to $-\mathcal{D}$ on the future horizon due to (31), one might assume that the natural state on the Killing horizon is a KMS state with respect to $-\mathcal{D}$ at the inverse temperature 2π: That coincides with Hawking inverse temperature referred to the adimensional "time" v on $\mathbb{F}$. A first-glance candidate for such a state is just the restriction to λ to the algebra of observables supported in the future Killing horizon (omitting the unphysical points $\{\infty\} \times \mathbb{S}^2$). This is because λ enjoys the very inverse temperature 2π referred to as $-\mathcal{D}$. On the other hand, there are physical reasons to reject that candidate. Indeed, the circle $\mathbb{S}^1 = \mathbb{R} \cup \{\infty\}$ admits two physically distinguishable points: The point at infinity, which cannot be reached physically because it corresponds to a surface which does not belong to the Kruskal manifold. The other point corresponds to the bifurcation manifold where ξ vanishes. (In the general case $\mathbb{M} := \mathbb{S}^1 \times \Sigma$ considered in this work, $\mathbb{M}$ itself cannot represent a portion of space–time due to the presence of closed causal curves lying in $\mathbb{S}^1$ and thus one point of $\mathbb{S}^1$ at least must be removed to make contact with physics.) The remaining points of $\mathbb{S}^1$ are physically equivalent barring the fact that they are

either in the past or in the future of $\theta=0$. This determines two regions $\mathbb{F}_- \equiv (-\pi,0)\times\mathbb{S}^2$ and $\mathbb{F}_+ \equiv (0,\pi)\times\mathbb{S}^2$ in the physical part $\mathbb{R}\times\mathbb{S}^1$, of the manifold $\mathbb{S}^1\times\mathbb{S}^2$, corresponding to, respectively, the future and past part—with respect to the bifurcation manifold—of the future Killing horizon of Kruskal space–time. Conversely, the whole $\mathrm{PSL}(2,\mathbb{R})$ unitary representation, referred to the Fock space $\mathfrak{F}_+(\mathcal{H})$ built upon λ, which, in turn, is invariant under the whole representation U, cannot select those physical regions. In particular $\mathrm{PSL}(2,\mathbb{R})$ includes arbitrary displacements of the coordinate θ. Those transformations connect the physical regions with the points at infinity. For these reasons λ seems not to be completely satisfactory from the point of view of physics in spite of its relevant thermal properties.

Once a reference state μ is fixed on $\mathcal{W}(\mathbb{M})$, the physical regions $\mathbb{F}_\pm$ correspond to von Neumann algebras $\mathcal{A}(\mathbb{F}_+)$ and $\mathcal{A}(\mathbb{F}_-)$ (based upon the GNS representation of μ) representing the observables in those regions.

In the following we show that it is possible to single out those physical regions at *quantum, i.e., Hilbert space, level* through a sort of *spontaneous breaking of* $\mathrm{SL}(2,\mathbb{R})$ *symmetry* referring to a new state $\lambda_\zeta \neq \lambda$ which *preserves* the relevant thermal properties. We mean that the following facts, actually valid for any manifold $\mathbb{M}=\mathbb{S}^1\times\Sigma$, hold true. At algebraic level there is a representation α of Möbius group of the circle $\mathrm{PSL}(2,\mathbb{R})$ made of $*$-automorphisms of the Weyl algebra $\mathcal{W}(\mathbb{M})$. Moreover, we have seen in Theorems 3.2 and 3.3 that there is a state λ on $\mathcal{W}(\mathbb{M})$ which is invariant under α and, in the GNS representation of λ, α is implemented unitarily and covariantly by a representation U of $\mathrm{PSL}(2,\mathbb{R})$. We show below that there are other, unitarily inequivalent, GNS representations of $\mathcal{W}(\mathbb{M})$ based on new states λ_ζ which are no longer invariant under the whole α, but such that, the residual symmetry is still covariantly and unitarily implementable and singles out the algebras $\mathcal{A}(\mathbb{F}_+)$ and $\mathcal{A}(\mathbb{F}_-)$ as unique invariant algebras. We show also that every λ_ζ enjoys the same thermal (KMS) properties as λ and it represents a different thermodynamical phase with respect to λ.

B. Symmetry breaking

We need some definitions to go on. Coming back to the general case $\mathbb{M}=\mathbb{S}^1\times\Sigma$ where Σ is any Riemannian manifold, fix a standard frame $\theta\in(-\pi,+\pi)$ on $\mathbb{S}^1$. The regions $\mathbb{F}_\pm$ are defined as those containing the points $(0,\pi)\times\Sigma$ and $(-\pi,0)\times\Sigma$, respectively. Consider the one-parameter subgroup of Möbius transformations $\mathbb{R}\ni t\to\exp(t\mathcal{D})$ where $\mathcal{D}:=-\sin\theta(\partial/\partial\theta)$ in $\mathbb{M}$. It admits 0 and π as unique fixed points. On the other hand, it is simply proven that (up to nonvanishing factors) $\mathcal{D}$ is the unique nonzero vector field in the representation of $\mathrm{sl}(2,\mathbb{R})$ which vanishes at 0 and π. As a consequence that subgroup is the unique (up to rescaling of the parameter) nontrivial one-parameter subgroup of $\mathrm{PSL}(2,\mathbb{R})$ which admits $(0,\pi)$ and $(-\pi,0)$ as invariant segments. The origin of the parameter v of the integral curves of $-\mathcal{D}$ can be arranged in order that

$$v=\Gamma(\theta):=\ln\left|\tan\frac{\theta}{2}\right|, \tag{32}$$

where v ranges monotonically in $\mathbb{R}$ with $\mathrm{d}v/\mathrm{d}\theta>0$ for $\theta\in(0,\pi)$, whereas it ranges monotonically in $\mathbb{R}$ with $\mathrm{d}v/\mathrm{d}\theta<0$ for $\theta\in(-\pi,0)$. In spite of its singularity at $\theta=0$, the function Γ in (32) is locally integrable. Thus for any fixed function $\zeta\in L^2(\Sigma,\omega_\Sigma)$, $\Lambda_\zeta(V(\omega)):=\lambda(V(\omega))e^{i\int_{\mathbb{M}}\Gamma(\zeta\omega_+ +\overline{\zeta\omega_+})}$ is well defined if $\omega\in\mathcal{D}(\mathbb{M})$. Let us show that Λ_ζ extends to a state on $\mathcal{W}(\mathbb{M})$. It holds $\Lambda_\zeta(V(0))=1$. Using (V1), (V2) and imposing linearity, Λ_ζ defines a linear functional on the $*$-algebra generated by all objects of $V(\omega)$. As λ is positive, Λ_ζ turns out to be positive too, finally $\mathbb{R}\ni t\mapsto\Lambda_\zeta(V(\omega))$ is continuous. For known theorems[19] there is a unique extension λ_ζ of Λ_ζ to a state on $\mathcal{W}(\mathbb{M})$: If the real function $\zeta\in L^1_{\mathrm{loc}}(\Sigma,\omega_\Sigma)$ is fixed, it is the unique state satisfying,

$$\lambda_\zeta(V(\omega))=\lambda(V(\omega))e^{i\int_{\mathbb{M}}\Gamma(\zeta\omega_+ +\overline{\zeta\omega_+})} \tag{33}$$

for all $\omega\in\mathcal{D}(\mathbb{M})$. Similar states, obtained by linear deformation of the vacuum state of a Fock representation of Weyl algebra, are known in the literature as *coherent states*. They were studied in Ref. 33 for photons in flat space–time and in Ref. 22 (see also Ref. 32). Several propositions

presented in those works could be readapted to our case with some effort. We think anyway that the shortest way consists of giving independent proofs based on more modern general results of local quantum physics[13] as the proofs of our propositions are not very complicated. Similar states for free QFT defined in globally hyperbolic spacetimes containing a bifurcate Killing horizon give rise to the failure of the uniqueness property proven in Ref. 17 (see the first footnote on p. 70 in Ref. 17).

λ_ζ and its GNS triple $(\mathfrak{H}_\zeta, \Pi_\zeta, \Psi_\zeta)$ enjoy the remarkable properties stated in the theorems below.

Theorem 4.1: *Fix a standard frame θ on $\mathbb{S}^1$ of $\mathbb{M}=\mathbb{S}^1\times\Sigma$, define $\mathcal{D}$ as in (16) and the group of $*$-automorphisms α representing PSL$(2,\mathbb{R})$ as in Theorem 3.1, $\{\alpha_t^{(\mathcal{X})}\}_{t\in\mathbb{R}}$ being any one-parameter subgroup associated with the vector field $\mathcal{X}$. If $\zeta\in L^2(\Sigma,\omega_\Sigma)$ and λ_ζ is the state defined in (33) with GNS triple $(\mathfrak{H}_\zeta,\Pi_\zeta,\Psi_\zeta)$, the following holds:*

(a) *The map $V(\omega)\mapsto V(\omega)e^{i\int_{\mathbb{M}}\Gamma(\zeta\omega_+ + \overline{\zeta\omega_+})}$, $\omega\in\mathcal{D}(\mathbb{M})$, uniquely extends to a $*$-automorphism γ_ζ on $\mathcal{W}(\mathbb{M})$ and*

$$\lambda_\zeta(w)=\lambda(\gamma_\zeta w), \quad \text{for all } w\in\mathcal{W}(\mathbb{M}), \tag{34}$$

$$\gamma_\zeta\circ\alpha_t^{(\mathcal{D})}=\alpha_t^{(\mathcal{D})}\circ\gamma_\zeta, \quad \text{for all } t\in\mathbb{R}. \tag{35}$$

(b) (i) *λ_ζ is pure,* (ii) *if $\zeta\neq\zeta'$ i.e., λ_ζ and $\lambda_{\zeta'}$ are not quasiequivalent,* (iii) *λ_ζ is invariant under $\{\alpha_t^{(\mathcal{D})}\}_{t\in\mathbb{R}}$, but it is not under any other one-parameter subgroup of α (barring those associated with $c\mathcal{D}$ for $c\in\mathbb{R}$ constant) when $\zeta\neq 0$ almost everywhere.*

(c) *$\mathfrak{H}_\zeta$ identifies with a Fock space $\mathfrak{F}_+(\mathcal{H}_\zeta)$ with vacuum vector Ψ_ζ and, for all $\omega\in\mathcal{D}(\mathbb{M})$,*

$$\Pi_\zeta: V(\omega)\mapsto\hat{V}_\zeta(\omega):=e^{i\overline{\hat{\phi}_\zeta(\omega)}}, \quad \text{where } \hat{\phi}_\zeta(\omega):=\hat{\phi}_0(\omega)+\left\{\int_{\mathbb{M}}\Gamma\left(\zeta\omega_+ + \overline{\zeta\omega_+}\right)\right\}I, \tag{36}$$

$\hat{\phi}_0(\omega)$ being here the standard field operator in the Fock space $\mathfrak{F}_+(\mathcal{H}_\zeta)$ as in Sec. II E.

(d) *There is a strongly continuous one-parameter group of unitary operators $\{U_\zeta^{(\mathcal{D})}(t)\}_{t\in\mathbb{R}}$ with*

$$\alpha_t^{(\mathcal{D})}(w)=U_\zeta^{(\mathcal{D})}(t)wU_\zeta^{(\mathcal{D})\dagger}(t) \quad \text{for all } t\in\mathbb{R} \quad \text{and } w\in\hat{\mathcal{W}}_\zeta(\mathbb{M}):=\Pi_\zeta(\mathcal{W}_\zeta(\mathbb{M})). \tag{37}$$

Moreover (the derivative is performed in the strong sense where it exists)

$$\left.\frac{d}{dt}\right|_{t=0}U_\zeta^{(\mathcal{D})}(t)=\frac{-i}{2}\overline{:\Omega(\hat{\phi}_0,\mathcal{D}\hat{\phi}_0):}\,. \tag{38}$$

The proof is in the Appendix.

Theorem 4.2: *In the hypotheses of Theorem 4.1 the following holds for net of von Neumann algebras,*

$$\mathcal{A}_\zeta=\{\mathcal{A}_\zeta(I)|I\in\mathcal{I}\}, \quad \text{with } \mathcal{A}_\zeta(I)=\{\hat{V}_\zeta(\omega)|\text{supp }\omega\subset I\times\Sigma\}''. \tag{39}$$

(a) *$\mathcal{A}_\zeta\supset\hat{\mathcal{W}}_\zeta(\mathbb{M})$ and it enjoys the following properties:* (i) *isotony,* (ii) *locality,* (iii) *$\{\exp(t\mathcal{D})\}_{t\in\mathbb{R}}$-covariance,* (iv) *$U_\zeta^{(\mathcal{D})}$-invariance and uniqueness of the vacuum Ψ_ζ,* (v) *cyclicity of the vacuum Ψ_ζ,* (vi) *Reeh–Schlieder,* (vii) *Haag duality,* (viii) *factoriality,* (ix) *irreducibility,* (x) *additivity.*

(b) *If $\zeta\neq 0$ i.e., $\mathcal{A}_\zeta(\mathbb{F}_+):=\mathcal{A}_\zeta((0,\pi))$ and $\mathcal{A}_\zeta(\mathbb{F}_-):=\mathcal{A}_\zeta((-\pi,0))$ are the unique $\{U_t^{(\mathcal{D})}\}_{t\in\mathbb{R}}$-invariant algebras in $\mathcal{A}_\zeta$.*

(c) *If Δ is the modular operator associated with $\mathcal{A}_\zeta(\mathbb{F}_+)$ then*

$$\Delta^{it}=U_\zeta^{(\mathcal{D})}(2\pi t), \quad \text{for all } t\in\mathbb{R}. \tag{40}$$

Thus λ_ζ is a KMS state on $\mathcal{A}_\zeta(\mathbb{F}_+)$ with temperature $T=1/2\pi$, with respect to $\{\alpha_t^{(-\mathcal{D})}\}_{t\in\mathbb{R}}$ [extended to σ-weak one-parameter group of $*$-automorphisms of $\mathcal{A}_\zeta(\mathbb{F}_+)$ through (37)].

Proof: (a) and (c) Since the difference between $\hat{V}_\zeta(\omega)$ and $e^{i\overline{\hat{\phi}_0(\omega)}}$ amounts to a phase only, each algebra $\mathcal{A}_\zeta(I)$ of $\mathcal{A}_\zeta$ coincides with the analog constructed starting from operators $e^{i\overline{\hat{\phi}_0(\omega)}}$ and using the same $I\in\mathcal{I}$. Hence Theorem 3.4 and subsequent Remark (2) hold using the field $\hat{\phi}_0$, replacing Ψ with Ψ_ζ and employing the representation U of $\mathrm{PSL}(2,\mathbb{R})$ which leaves Ψ_ζ unchanged. Notice that U does not implement α! In this way all the properties cited in the thesis turn out to be automatically proved with the exception of (iii) and (iv). However using (35) and (38) and (d) of Theorem 3.2 also those properties can be immediately proved. The proof of (c) is straightforward. $\mathcal{A}_\zeta((0,\pi))$ coincides with the analog constructed starting from operators $e^{i\overline{\hat{\phi}_0(\omega)}}$. In that case the thesis holds with respect to the subgroup of U, $e^{t:\Omega(\hat{\phi}_0,\mathcal{D}(\hat{\phi}_0)):/2}$ [Remark (2) after Theorem 3.4]. Now (38) implies the validity of the thesis in our case.

(b) Since $\mathcal{D}$ admits the only zeros at $\theta=0$ and $\theta=\pi\equiv-\pi$, the only open nonempty and nondense intervals of $\mathbb{S}^1$ which are invariant under the one-parameter group $\{g_t^{(\mathcal{D})}\}_{t\in\mathbb{R}}$ generated by $\mathcal{D}$ are $(0,\pi)$ and $(-\pi,0)$. $\mathcal{D}$-covariance reads $U_\zeta^{(\mathcal{D})}(t)\mathcal{A}_\zeta(I)U_\zeta^{(\mathcal{D})\dagger}(t)=\mathcal{A}_\zeta(g_t^{(\mathcal{D})}(I))$ and thus $\mathcal{A}_\zeta((0,\pi))$ and $\mathcal{A}_\zeta((-\pi,0))$ are invariant under $\{U_\zeta^{(\mathcal{D})}(t)\}_{t\in\mathbb{R}}$. Let us prove their uniqueness. Consider the case of $I=(a,b)$ with $0\leqslant a<b<\pi$. There are $t'>0$ and $a'>0$, with $a'<b$ and such that $g_{t'}^{(\mathcal{D})}(a',b)\cap(a,b)=\varnothing$. Therefore, by locality it holds $[U_\zeta^{(\mathcal{D})}(t')\mathcal{A}_\zeta((a',b))U_\zeta^{(\mathcal{D})\dagger}(t'),\mathcal{A}_\zeta((a,b))]=0$, i.e. $[\mathcal{A}_\zeta((a',b)),U_\zeta^{(\mathcal{D})}(-t')\mathcal{A}_\zeta((a,b))U_\zeta^{(\mathcal{D})\dagger}(-t')]=0$. If $\mathcal{A}_\zeta((a,b))$ were invariant under $\{U_\zeta^{(\mathcal{D})}(t)\}_{t\in\mathbb{R}}$, the latter identity above would imply that $[\mathcal{A}_\zeta((a',b)),\mathcal{A}_\zeta((a,b))]=0$, and thus in particular $\mathcal{A}_\zeta((a',b))\subset\mathcal{A}_\zeta((a',b))'$ which is trivially false because elements $\hat{V}_\zeta(\omega)\in\mathcal{A}_\zeta((a',b))$ generally do not commute. All the remaining cases can be reduced to that studied above with obvious adaptations. □

Remarks:

(1) (c) in the last theorem is valid also replacing $\mathbb{F}_-$ for $\mathbb{F}_+$ and $\mathcal{D}$ for $-\mathcal{D}$ as well. Theorems 4.1 and 4.2 hold in particular for $\Sigma=\mathbb{S}^2$ and $\mathbb{M}=\mathbb{S}^1\times\mathbb{S}^2$. In that case one finds easily that λ_ζ *is invariant under the group of $*$-automorphisms induced by the action of SO*(3) *as isometry group on $\mathbb{S}^2$ if and only if ζ is constant i.e. on $\mathbb{S}^2$.*
Generic Σ do not admit SO(3) as a group of isometries, in that case λ_ζ is invariant under the relevant isometry group of Σ provided ζ is so. Finally we notice that the hypotheses $\zeta\in L^2(\Sigma,\omega_\Sigma)$ can be relaxed in $\zeta\in L^1_{\mathrm{loc}}(\Sigma,\omega_\Sigma)$ (the space of locally integrable functions on Σ with respect to ω_Σ) both in Theorems 4.1 and 4.2, the only result that could fail to hold is (ii) in (b) of Theorem 4.1.

(2) Theorems 4.1 and 4.2 refer to the pair of segments $(0,\pi)$ and $(-\pi,0)$ in the circle realized as the segment $[-\pi,\pi]$ with $-\pi\equiv\pi$. From a physical point of view there is no way to distinguish between the pair of regions $(0,\pi)$, $(-\pi,0)$ and any other pair of open nonempty segments I, $J\subset\mathbb{S}^1$ such that $J=\mathrm{int}(\mathbb{S}^1\setminus I)$. This is because there is no way to measure segments on $\mathbb{S}^1$ as the metric is degenerate therein. In fact the theorem can be stated for any pair of such segments. To prove it we notice that there exists a Möbius diffeomorphism $g:\mathbb{S}^1\to\mathbb{S}^1$ with $I=g((0,\pi))$ and $J=g((-\pi,0))$. [Assume that, in coordinates θ, I has length equal or shorter than J. The diffeomorphism g^{-1} is the composition of a rigid rotation generated by $\mathcal{K}$ which maps the center of I in 0, a dilatation generated by $\mathcal{D}$ which enlarges the transformed I up to $(-\pi/2,\pi/2)$ and another anticlockwise rigid rotation of $\pi/2$.] Hence, Theorems 4.1 and 4.2 can be restated replacing $(0,\pi)$ and $(-\pi,0)$ with, respectively, I and J, replacing the state (33) with the state and assuming to have fixed some $\zeta\in L^2(\Sigma,\omega_\Sigma)$,

$$\lambda_I(V(\omega)):=\lambda(V(\omega))e^{i\Gamma_I(\omega)},\quad\text{with }\Gamma_I(\omega):=\int_{\mathbb{M}}\Gamma(\zeta g^*\omega_+ + \overline{\zeta g^*\omega_+})$$

and replacing $\mathcal{D}$ with the generator $\mathcal{D}_I$ of the one-parameter subgroup of $\mathrm{PSL}(2,\mathbb{R})$ $\mathbb{R}\ni t\mapsto\exp(t\mathcal{D}_I):=g\circ\exp(t\mathcal{D})\circ g^{-1}$ which leaves invariant I and J ($\mathcal{D}_I$ does not depend on

the choice of g).

Notice also that if I, J is a pair of segments as said above and h is any Möbius transformation, $h(I)$, $h(J)$ still is a pair of open nonempty segments with $h(J)=\mathrm{int}(\mathbb{S}^1\backslash h(I))$ and it holds (using also Lemma 3.1)

$$\lambda_{h(I)}(V(\omega)) = \lambda_I(V(h^*\omega)).$$

This fact means that the PSL(2,$\mathbb{R}$) symmetry, broken at Hilbert-space level, is restored at an algebraic level by considering the whole class of states λ_I. The residual Virasoro representation after breaking PSL(2,$\mathbb{R}$) symmetry is analyzed in the Appendix.

(3) Considering again the particular case of the Kruskal manifold, the requirement (31), that is $-\sin\theta\partial_\theta = -\kappa^{-1}\xi|_{\mathbb{F}}$, fixes the standard frame only up to a coordinate transformation $\theta' = \theta'(\theta)$, where θ' being any other positive oriented coordinate frame on $\mathbb{S}^1$ satisfying $\sin\theta'\partial_{\theta'} = \sin\theta\partial_\theta$. Since our construction of quantum field theory on $\mathbb{M}$ relies upon the choice of a standard frame on $\mathbb{S}^1$, a natural question is the following: *Are quantum field theories based on* λ_ζ *and its analog* λ'_ζ *with obvious notation, unitarily equivalent?* (Notice that ζ is the same for both states). The answer is strongly positive because of the following general result.

Theorem 4.3: *With the same hypotheses as in Theorem 4.1, let* θ' *be another standard frame on* $\mathbb{S}^1$. *Referring to the coordinate frame* θ', *let* $\mathcal{D}'$ *be the vector field analog of* $\mathcal{D}$ *and let* λ'_ζ *be the state analog of* λ_ζ [*both states defined on* $\mathcal{W}(\mathbb{M})$]. *If* $\mathcal{D}'=\mathcal{D}$ *then, for any* $\zeta \in L^2(\Sigma, \omega_\Sigma)$,

$$\lambda'_\zeta = \lambda_\zeta. \tag{41}$$

Proof: In our hypotheses $\theta'(\theta) = 2\tan^{-1}(e^c \tan(\theta/2))$ for some $c \in \mathbb{R}$. The transformation $\theta \to \theta'(\theta)$ *interpreted as an active diffeomorphism* is nothing but the action of the element $\alpha^{(\mathcal{D})}_{-c}$ of the one-parameter group generated by $\mathcal{D}$. Since λ_ζ is invariant under that group [(b) in Theorem 4.1] the thesis is true. □

V. TOWARDS PHYSICAL INTERPRETATIONS

Consider the case of $\mathbb{M}$ constructed by the future Killing horizon of Kruskal manifold (however Theorem 5.1 below holds true for a generic degenerate manifold $\mathbb{M}=\mathbb{S}^1\times\Sigma$). As is well known the complete maximal Kruskal solution of Einstein equation describes a space–time with an eternal pair of black hole–white hole. However, some features (e.g., Hawking radiation) of real black holes produced by collapse can be modelled by using the right Schwarzschild wedge and the region containing the future singularity in Kruskal manifold, the region about $\mathbb{F}_+$ (see Refs. 37 and 38) in particular. $\mathbb{F}_+$ itself can be considered as (an extension of the) actual event horizon of a physical black hole. The space–time of a physical black hole obtained by stellar collapse has no white hole neither Killing bifurcate horizon. Nevertheless, in the sense stated below a physical black hole will asymptotically approach such a space–time (at least a space–time including a bifurcate Killing horizon). Indeed, in Ref. 31 Racz and Wald considered a globally hyperbolic, stationary space–time containing a black hole but no white hole, assuming, further, that the event horizon $\mathbb{E}$ of the black hole is a Killing horizon with compact cross sections. With those hypotheses they proved that if surface gravity is nonzero and constant throughout the horizon, one can globally extend the initial space–time so that the image of $\mathbb{E}$ is a proper subset of a regular bifurcate Killing horizon in the enlarged space–time. In that paper they also provided necessary and sufficient conditions for the extendibility of matter fields to the enlarged space–time. These results support the view that any space–time representing the asymptotic final state of a black hole formed by gravitational collapse may be assumed to possess a bifurcate Killing horizon (see Ref. 31 for details). Therefore, from a physical point of view, it is worth investigating the physical meaning for the theory referred to as the GNS representation of λ_ζ when restricting to the region $\mathbb{F}_+$.

A. Extremal KMS states: Existence of different thermodynamical phases

By construction λ_ζ are KMS states on the C^*-algebra $\mathcal{W}(\mathbb{F}_+)$, the Weyl algebra generated by Weyl operators $V(\omega)$ with supp $\omega \subset \mathbb{F}_+$ which is contained in $\mathcal{A}_\zeta(\mathbb{F}_+)$. As states on $\mathcal{W}(\mathbb{F}_+)$, λ_ζ and $\lambda_{\zeta'}$ can be compared also if $\zeta \neq \zeta'$ [they do not belong to a common folium if (ii) in (b) of Theorem 4.1 holds, so they cannot be compared on a common von Neumann algebra of observables in that case]. The next theorem, valid for the general case $\mathbb{M}=\mathbb{S}^1\times\Sigma$, shows that $\{\lambda_\zeta\}_{\zeta\in L^2(\Sigma,\omega_\Sigma)}$ is a family of extremal states in the convex space of KMS states over $\mathcal{W}(\mathbb{F}_+)$ at inverse temperature 2π with respect to $-\mathcal{D}$.

Theorem 5.1: *With the same hypotheses as in Theorem 4.1 the following holds*.

(a) *Any state* λ_ζ [*with* $\zeta \in L^2(\Sigma, \omega_\Sigma)$] *defines an extremal state in the convex set of KMS states on the* C^**-algebra* $\mathcal{W}(\mathbb{F}_+)$ *at inverse temperature* 2π *with respect to* $\{\alpha_t^{(-\mathcal{D})}\}_{t\in\mathbb{R}}$.

(b) *Different choices of* ζ *individuate different states on* $\mathcal{W}(\mathbb{F}_+)$ *which are not unitarily equivalent as well*.

Proof: Let $(\mathfrak{H}_\zeta, \Pi_\zeta, \Psi_\zeta)$ be the GNS representations of λ_ζ. The GNS representations of $\lambda_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)}$ must be (up to unitary equivalences) $(\mathfrak{H}_\zeta, \Pi_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)}, \Psi_\zeta)$ due to Reeh–Schlieder property [(a) in Theorem 4.2] of $\mathcal{A}_\zeta(\mathbb{F}_+)$. Since $\mathcal{A}_\zeta(\mathbb{F}_+) = \Pi_\zeta\restriction''_{\mathcal{W}(\mathbb{F}_+)}$ is a (type III_1) factor, the state $\lambda_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)}$—namely $\Pi_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)}$—is primary (see Sec. III.2.2 in Ref. 13). As a consequence, by Theorem 1.5.1 in Ref. 13, the KMS state $\lambda_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)}$ is extremal in the space of KMS states on $\mathcal{W}(\mathbb{F}_+)$ with respect to $\alpha_t^{(-\mathcal{D})}$ at the temperature of $\lambda_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)}$ itself. Obviously $\lambda_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)} \neq \lambda_{\zeta'}\restriction_{\mathcal{W}(\mathbb{F}_+)}$ because, if $\zeta-\zeta'$ is not zero almost everywhere, the integrals in the exponentials defining λ_ζ and $\lambda_{\zeta'}$ produce different results when applied to $V(\omega)$ with supp $\omega \subset \mathbb{F}_+$ with a suitable choice of ω. The proof of nonequivalence is the same as done (see the Appendix) for the states defined in the whole von Neumann algebras. □

The natural interpretation of this fact is that the states λ_ζ, restricted to the observables in the physical region $\mathbb{F}_+$, are nothing but *different thermodynamical phases* of the same system at the Hawking temperature (see Sec. V.1.5 in Ref. 13).

B. Bose–Einstein condensate and states λ_ζ with ζ real

In the following we assume that ζ is real. Let us examine some features of the generators $\hat{\phi}_\zeta$ of the Weyl representation associated with λ_ζ when restricted to the physical region $\mathbb{F}_+$. Consider $\omega \in \mathcal{D}(\mathbb{M})$ such that supp $\omega \subset \mathbb{F}_+$ and such that $\omega(v,s)$ can be rewritten as $[\partial\psi(v,s)/\partial v]\mathrm{d}v\wedge\omega_\Sigma$ where ψ is smooth and compactly supported in $\mathbb{F}_+$. Similar "wave functions" ψ have been considered in Ref. 26 building up scalar QFT on a Killing horizon ($\mathbb{F}_+$ in our case). Using (32) we can write the formal expansion

$$\hat{\phi}_\zeta(\omega) = \int_{\mathbb{F}_+} \hat{\phi}_0(\theta_+(v))\omega(v,s) + \int_{\mathbb{F}_+} \zeta(s) v\, \omega(v,s). \tag{42}$$

In terms of wave functions, if $\Omega_{\mathbb{F}_+}$ is the restriction of the right-hand side of the definition of Ω given in (1) to real smooth functions compactly supported in $\mathbb{F}_+$, it holds

$$\Omega(\psi, \hat{\phi}_\zeta) = \Omega_{\mathbb{F}_+}(\psi, \hat{\phi}_0) - \int_\Sigma \left(\int_{-\infty}^{+\infty} \psi(v,s)\mathrm{d}v \right) \zeta(s)\omega_\Sigma(s). \tag{43}$$

The group of elements $e^{itH_\zeta} := U_\zeta^{(-\mathcal{D})}(t), t\in\mathbb{R}$ generates displacements $v \mapsto v-t$ in the variable v in the argument of the wave functions ψ, since v is just the parameter of the integral curves of $-\mathcal{D}$ which takes the form $\partial/\partial v$ in $\mathbb{F}_+$. Using Fourier transformation with respect to v we can write down

$$\psi(v,s) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}_+} \mathrm{d}E\, \widetilde{\psi_+(E,s)} e^{-iEv} + \overline{\widetilde{\psi_+(E,s)}} e^{iEv}. \tag{44}$$

In heuristic sense H_ζ acts on the wave functions ψ as the multiplicative operator $\widetilde{\psi_+(E,s)} \mapsto E\widetilde{\psi_+(E,s)}$. Physically speaking, thermal properties of λ_ζ are referred just to the energy notion associated with that Hamiltonian. Actually, as is well known, this interpretation must be handled with great care, the interpretation of $\widetilde{\psi_+}$ as a representative of a one-particle quantum state can be done in a Fock space whose vacuum state does not coincide with the KMS state λ_ζ (see Sec. V.1.4 and the discussion on p. 219 of Ref. 13.) Using (44) and (43) can be rewritten as

$$\Omega(\psi, \hat{\phi}_\zeta) = \Omega_{\mathbb{F}_+}(\psi, \hat{\phi}_0) - \sqrt{2\pi} \int_\Sigma \zeta(s) \widetilde{\psi(0,s)}_+ \omega_\Sigma(s). \tag{45}$$

From (45) it is apparent that $\hat{\phi}_\zeta$ gets contributions from *zero-energy modes* ($E=0$) as it happens in *Bose–Einstein condensate*. To this end see Chap. 6 of Ref. 30 and 5.2.5 of Ref. 2, especially p. 72, where in the decomposition of the KMS state ω (after the thermodynamical limit) in $\mathbb{R}^\nu$-ergodic states, the mathematical structure of the latter states resemble that of the states λ_ζ. The decomposition of the field operator (42) into a "quantum" (with vanishing expectation value) and a "classical" (i.e., commuting with all the elements of the algebra) part is typical of the theoretical description of a boson system containing a Bose–Einstein condensate; the classical part plays the role of an *order parameter*.[6,30]

Let us focus attention on the generator of $U_\zeta^{(-\mathcal{D})}(t) = e^{itH_\zeta}$ in the representation of a state λ_ζ. Using Theorem 4.1 we find [both sides are supposed to be restricted to the core $F(\mathcal{H}_\zeta)$]

$$H_\zeta = \int_{\mathbb{M}} \sin(\theta) : \frac{\partial \hat{\phi}_\zeta}{\partial \theta} \frac{\partial \hat{\phi}_\zeta}{\partial \theta} : (\theta, s) \mathrm{d}\theta \wedge \omega_\Sigma(s).$$

Indeed, if $\theta_\pm(v) = \pm 2 \tan^{-1}(e^v)$ are the inverse functions of $v = \Gamma(\theta)$ in $\mathbb{F}_+$ and $\mathbb{F}_-$, respectively, passing from coordinates (θ, s) to coordinates (v, s) and employing the field $\hat{\phi}_0$ the right-hand side of the formula above can be rearranged as

$$\begin{aligned} H_\zeta = \lim_{N \to +\infty} \Bigg\{ & \int_{\mathbb{F}_+} \chi_N(v) : \frac{\partial \hat{\phi}_0}{\partial v} \frac{\partial \hat{\phi}_0}{\partial v} : (\theta_+(v), s) \mathrm{d}v \wedge \omega_\Sigma(s) + \|\zeta\|^2 \int_{\mathbb{R}} \chi_N(v) \mathrm{d}v \\ & - \int_{\mathbb{F}_-} \chi_N(v) : \frac{\partial \hat{\phi}_0}{\partial v} \frac{\partial \hat{\phi}_0}{\partial v} : (\theta_-(v), s) \mathrm{d}v \wedge \omega_\Sigma(s) - \|\zeta\|^2 \int_{\mathbb{R}} \chi_N(v) \mathrm{d}v \Bigg\}, \end{aligned}$$

where the function χ_N is smooth with compact support in $[-N, N]$ and becomes the constant function 1 for $N \to +\infty$. The two constant terms in brackets cancel out each other, they have the opposite sign, and the final form of H_ζ is just that in (d) of Theorem 4.1. The normal ordering prescription used in the integrals is defined by subtracting $(\Psi, \hat{\phi}_0(\theta', s') \hat{\phi}_0(\theta, s) \Psi)$ before applying derivatives and then smoothing with a product of delta in θ, θ' and s, s'. We do not enter into mathematical details here which are quite standard procedures of applied microlocal analysis similar to that used in Hadamard regularization.[3,14,24]

From the decomposition of H_ζ written above, we see that it is made of two contributions $H_\zeta^{(-)}$, $H_\zeta^{(+)}$, respectively, localized at the two disjoint regions of $\mathbb{F}$, $\mathbb{F}_-$, and $\mathbb{F}_+$. The two terms have the same value with opposite sign as one expects from the indefiniteness of the self-adjoint generator D (corresponding to the fact that the Killing vector $-\mathcal{D}$ changes orientation passing from $\mathbb{F}_+$ to $\mathbb{F}_-$). Let us concentrate on the second term in the contribution $H_\zeta^{(+)}$ to H_ζ due to $\mathbb{F}_+$. It is a volume divergence

$$E_\zeta := \|\zeta\|^2 \int_{\mathbb{R}} \mathrm{d}v\,.$$

This can be interpreted as the energy of the BE condensate localized at $\mathbb{F}_+$ whose density is *finite* and amounts to $\|\zeta\|^2$.

C. Conclusions: Can the condensate describe physical properties of a black hole?

Here, to conclude, we try to give some hints to relate the properties of the condensate with space–time, i.e., Schwarzschild black hole, properties. To do it we start from a deeper point of view. The only difference between two different Schwarzschild black holes concerns their masses, that is their Schwarzschild radii. Since we want to ascribe this difference to a feature of a state, the background and the system supporting the state must be independent from the black-hole radius. In this way the states λ_ζ must be referred to as a quantum field theory on an abstract manifold $\mathbb{M}=\mathbb{S}^1\times\mathbb{S}^2$ with a metric on $\mathbb{S}^2$ which does not coincide with the actual metric of a particular black hole. We assume the hypothesis of spherical symmetry so that the metric on $\mathbb{S}^2$ is determined by fixing the value of an adimensional parameter only (the radius rate for instance). In this view a state λ_ζ on the scalar field $\hat{\phi}$ must fix the geometry of the black hole under the constraints of the presence of a Killing horizon and spherical symmetry. Since we are in fact dealing with quantum gravity we adopt natural Planck units ($\hbar=c=G=1$) so that we can employ pure numbers in the following. In particular, the pure number defining the radius of $\mathbb{S}^2$ will be denoted by r_0.

The idea that the assignment of a (classical) scalar field fixes the metric of a space–time (solution of Einstein equations) when other constraints are given on the metric is not new, the so-called dimensional-reduction theory for gravitation leads to such a scenario (e.g., see Ref. 29 with cited references) where the scalar field is related to the dilation field. Now we adopt a similar point of view but, in addition, we assume also that the assignment of the configuration of the scalar field is due to the assignment of a quantum state of that field. Let us see how this idea can be implemented from the following remark.

Spherical symmetry implies that ζ must be constant on $\mathbb{S}^2$ [see Remark (1) after Theorem 4.2]. Since the considered states are coherent the field admits a nonvanishing averaged value. Formally it holds

$$\lambda_\zeta(\hat{\phi}_\zeta(\theta,s)) = v_\zeta(\theta)\,. \tag{46}$$

(See remarks below.) Hence the mean value of $\hat{\phi}_\zeta$ with respect to λ_ζ picks out a preferred coordinate frame along the light lines of $\mathbb{F}_+$. So, up to the choice of the origin, the mean value of the field $\hat{\phi}_\zeta$ defines a preferred coordinate v_ζ in the physical region $\mathbb{F}_+$. Now the natural hypotheses is that v_ζ is the parameter of the Killing field $\xi\restriction_{\mathbb{F}_+}$ of the considered black hole as in Sec. IV A. In other words we are saying that ζ determines a black hole in the class of Schwarzschild ones by determining its surface gravity through the identity (both sides are pure numbers since we are employing natural Planck units),

$$\zeta = \kappa^{-1}. \tag{47}$$

Such a black hole must have horizon surface $S_\zeta = \pi\zeta^2$. As a consequence we find that

$$\|\zeta\|^2 = 4\pi\zeta^2 r_0^2 \tag{48}$$

scales as the actual surface of the black hole horizon (and it is exactly the measure of the surface provided $r_0=1/2$). This provides some clues for an interpretation of $\|\zeta\|^2$ that is, equivalently, the *density of energy* of the condensate $E_\zeta/\int_{\mathbb{R}}\mathrm{d}v$.

Remarks: A pair of mathematical remarks are necessary to interpret (46).

(1) $\lambda_\zeta(\hat{\phi}_\zeta(\theta,s))$ is not well defined and it could be thought of as the weak limit of a sequence $\lambda_\zeta(\hat{\phi}_\zeta(\omega_n))$ where the forms ω_n regularize Dirac' s delta centered in $(\theta,s)\in\mathbb{F}$.

(2) Furthermore, one must take into account that the allowable forms have the shape $\omega_n(\theta,s)=[\partial f_n(\theta,s)/\partial\theta]\mathrm{d}\theta\wedge\omega_\Sigma$ where f_n is *periodic* in θ. It is not possible to produce a regularization sequence for $\delta(s,s')[\partial\delta(\theta'-\theta)/\partial\theta]\mathrm{d}\theta\wedge\omega_\Sigma$ in this way due to the periodic constraint. The drawback can easily be skipped by fixing an origin $v_{\zeta 0}$ for v_ζ (corresponding to some θ_0) for the coordinate x. In other words one considers a sequence of forms $\omega_n^{(\theta,s)}$ induced by smooth θ-periodic functions $f_n^{(\theta,s)}(\theta')=\delta_n(s'-s)[\Theta_n(\theta-\theta')+\Theta_n(\theta'-\theta_0)]$, where $\{\delta_n(s')\}$ regularize $\delta(s')$ and $\{\Theta_n(\theta')\}$ regularize the step distribution whose derivative is just $\delta(\theta')$. In this sense

$$\lim_{n\to+\infty}\lambda_\zeta(\hat{\phi}_\zeta(\omega_n^{(\theta,s)}))=v_\zeta(\theta)-v_{\zeta 0}.$$

The presented results could lead to an interesting scenario which deserves future investigation. The Kruskal space–time could be a classical object arising by spontaneous breaking of SL(2,$\mathbb{R}$) symmetry as well as Bose–Einstein condensation due to a state of a local QFT defined on a certain conformal net. In particular the abstract field operator ϕ can be seen as a noncommutative coordinate on $\mathbb{F}_+$. [Obviously noncommutativity arises from canonical commutation relations $[\phi(\theta,s),\phi(\theta',s')]=iE(\theta,s,\theta',s')$.] Commutativity is restored under the choice of an appropriate coherent state on that $*$-algebra considering the averaged values of the field. This state also fixes the actual black hole. (A recent remarkable application of some ideas of noncommutative geometry to conformal net theory and black holes appears in Ref. 16.) With a pair of fields ϕ defined on $\mathbb{F}$ and the other defined on the past Killing horizon $\mathbb{P}$ we may define, through the outlined way, global null coordinates in the complete r, t section of right Schwarzschild wedge. A subject deserving future investigation concerns the issue if, in addition to the null coordinates in the plane r, t, it is possible to give a quantum interpretation to the transverse coordinate and the whole metric of the Kruskal manifold.

APPENDIX

A.1. Fock representation and GNS theorem: The interplay of the Fock representation presented in Sec. III and GNS theorem[13,1] is simply sketched. Using notation introduced therein, if $\Pi:\mathcal{W}(\mathbb{M})\to\hat{\mathcal{W}}(\mathbb{M})$ denotes the unique (Ω being nondegenerate) C^*-algebra isomorphism between those two Weyl representations, it turns out that $(\mathfrak{F}_+(\mathcal{H}),\Pi,\Psi)$ is the GNS triple associated with a particular pure algebraic state λ (quasifree[1,17] and invariant under the automorphism group associated with ∂_θ) on $\mathcal{W}(\mathbb{M})$ we go to introduce. Define

$$\lambda(W(\psi)):=e^{-\langle\psi_+,\psi_+\rangle/2}$$

then extend λ to the $*$-algebra finitely generated by all the elements $W(\psi)$ with $\psi\in\mathcal{S}(\mathbb{M})$, by linearity and using (W1), (W2). It is simply proven that, $\lambda(\mathbb{I})=1$ and $\lambda(a^*a)\geqslant 0$ for every element a of that $*$-algebra so that λ is a state. As the map $\mathbb{R}\ni t\mapsto\lambda(W(t\psi))$ is continuous, known theorems[19] imply that λ extends uniquely to a state λ on the complete Weyl algebra $\mathcal{W}(\mathbb{M})$. On the other hand, by direct computation, one finds that $\lambda(W(\psi))=\langle\Psi,\hat{W}(\psi)\Psi\rangle$. Since a state on a C^* algebra is continuous, this relation can be extended to the whole algebras by linearity and continuity and using (W1), (W2) so that a general GNS relation is verified,

$$\lambda(a)=\langle\Psi,\Pi(a)\Psi\rangle\quad\text{for all } a\in\mathcal{W}(\mathbb{M}).\tag{A1}$$

To conclude, it is sufficient to show that Ψ is cyclic with respect to Π. Let us show it. If $\hat{\mathcal{F}}(\mathbb{M})$ denotes the $*$-algebra generated by field operators $\Omega(\psi,\hat{\phi})$, $\psi\in\mathcal{S}(\mathbb{M})$, defined on $F(\mathcal{H})$, $\hat{\mathcal{F}}(\mathbb{M})\Psi$

is dense in the Fock space (see Proposition 5.2.3 in Ref. 2). Let $\Phi \in \mathfrak{F}_+(\mathcal{H})$ be a vector orthogonal to both Ψ and to all the vectors $\hat{W}(t_1\psi_1)\cdots\hat{W}(t_n\psi_n)\Psi$ for $n=1,2,\ldots$ and $t_i \in \mathbb{R}$ and $\psi_i \in \mathcal{S}(\mathbb{M})$. Using Stone theorem to differentiate in t_i for $t_i=0$, starting from $i=n$ and proceeding backwards up to $i=1$, one finds that Φ must also be orthogonal to all of the vectors $\Omega(\psi_1,\hat{\phi})\cdots\Omega(\psi_n,\hat{\phi})\Psi$ and thus vanishes because $\hat{\mathcal{F}}(\mathbb{M})\Psi$ is dense. This result means that $\Pi(\mathcal{W}(\mathbb{M}))\Psi$ is dense in the Fock space too, i.e., Ψ is cyclic with respect to Π. Since Ψ satisfies also (A1), the uniqueness of the GNS triple proves that the triple $(\mathfrak{F}_+(\mathcal{H}), \Pi, \Psi)$ is just (up to unitary transformations) the GNS triple associated with λ. Since the Fock representation is irreducible, λ is pure.

A.2. Residual Virasoro representation after breaking PSL$(2,\mathbb{R})$ *symmetry:* The complex Lie algebra $(\mathfrak{a},\{\cdot,\cdot\},\imath)$ of vector field on $\mathbb{S}^1$ (see discussion in Sec. III A) is made of vector fields on $\mathbb{S}^1$ whose diffeomorphism groups, generated by their real and imaginary parts, do not admit (in general) $\mathbb{F}_\pm$ as invariant regions, when extended to $\mathbb{M}=\mathbb{S}^1\times\Sigma$. This happens in particular for generators $\mathcal{L}_n=ie^{in\theta}\partial_\theta$. However, it is possible to rearrange that basis in order to partially overcome the problem. Consider the equivalent basis of $\mathfrak{a}$ made of the following real vector fields $-i\mathcal{L}_0$, $\mathcal{E}_n := (1-\cos((2n)\theta))\partial_\theta$, $\mathcal{O}_n := (1+\cos((2n+1)\theta))\partial_\theta$, $\mathcal{G}_n := -\sin(n\theta)\partial_\theta$ with $n=1,2,\ldots$. Barring $-i\mathcal{L}_0$ and $\mathcal{O}_n$, the other fields admit $\mathbb{F}_\pm$ as invariant regions. Moreover the fields $\mathcal{G}_n$ define a Lie algebra with respect to the usual Lie bracket whereas $\mathcal{E}_n$, or $\mathcal{E}_n$ together $\mathcal{G}_n$, do not. However allowing infinite linear combinations of vector fields—using for instance L^2-convergence for the components of vector fields with respect to ∂_θ (the same result holds anyway using stronger notions of convergence as uniform convergence of functions and their derivatives up to some order)—one sees that each $\mathcal{E}_n$ can be expanded as an infinite linear combination of $\mathcal{G}_n$. From these considerations one might expect, at least, that fields $\mathcal{E}_n$, but *not the vectors* $\mathcal{L}_n$ *and* $\mathcal{O}_n$, admit some operator representation in $\mathfrak{H}_\zeta$ in terms of the field operator $\hat{\phi}_\zeta$. In fact this is the case if ζ is a real function in $L^2(\Sigma,\mathrm{d}\Sigma)$. If one tries to define operators $L^{(c)}_{\zeta n}$ as in (23) with $\hat{\phi}^{(c)}$ replaced with $\hat{\phi}^{(c)}_\zeta := \hat{\phi}^{(c)}+\zeta\Gamma$, one immediately faces ill-definiteness of those operators due to infinite additive terms and the same problem arises for formal operators $O^{(c)}_n := L^{(c)}_{\zeta 0}+(L^{(c)}_{\zeta 2n+1}+L^{(c)}_{\zeta -2n-1})/2$ and also for $E^{(c)}_n := L^{(c)}_{\zeta 0}-(L^{(c)}_{\zeta 2n}+L^{(c)}_{\zeta -2n})/2$. However these terms cancel out if considering the operators $G^{(c)}_n := (L^{(c)}_{\zeta -n}-L^{(c)}_{\zeta n})/(2i)$ with $n=1,2,\ldots$, which are well defined and essentially self-adjoint on $F(\mathcal{H}_\zeta)$. Moreover, the operators $G^{(c)}_n$ define a Lie algebra with respect to the commutator. [Direct inspection shows that if $c=\infty$ none of the considered operators is well defined on $F(H_\zeta)$.] It is plausible that operators $\overline{G^{(c)}_n}$ define one-parameter groups which implement covariance with respect to analogous groups of diffeomorphisms generated by associated vector fields $\mathcal{G}_n$, and that the exponentiation of the algebra of $G^{(c)}_n$ produces a unitary representation of a (perhaps the) subgroup of $\mathrm{Diff}^+(\mathbb{S}^1)$ of the diffeomorphisms which leaves $\mathbb{F}_\pm$ invariant. However, it is worth stressing that, barring the case $\overline{G^{(c)}_1}$ which generates just $U^{(\mathcal{D})}_\zeta(t)$, Ψ_ζ is not invariant under the remaining unitary groups.

A.3. Proofs of some theorems:

Proof of Proposition 2.2: Let θ be a standard frame on $\mathbb{S}^1$. Assume the condition (a) holds. We can write $\omega=\epsilon_f$ and $\omega'=\epsilon_{f'}$ for some functions f, $f' \in \mathbb{C}^\infty(\mathbb{S}^1\times\Sigma;\mathbb{C})$. To use these facts we notice that, in the general case, it holds $E(\epsilon_f,\epsilon_{f'})=\Omega(f,f')/4$ by Proposition 2.1. Therefore, by (V2), to conclude the proof it is sufficient to show that $\Omega(f,f')=0$. Let us prove it. In our hypotheses f' is constant in the variable θ in $I\times\Sigma$ since $\partial f'(\theta,s)/\partial\theta=0$ therein and $I\times\Sigma$ is connected by paths with s constant. Moreover, if t, t' are the endpoints of I, it must hold $f(t,s)=f(t',s)$ for every $s \in \Sigma$. Indeed $\partial f(\theta,s)/\partial\theta=0$ vanishes outside $I\times\Sigma$—and thus f is constant in θ in that set as before—and f is periodic in θ at s fixed by hypotheses. Integrating by parts in the right-hand side of the definition of Ω given in (1) with f and f' in place of ψ and ψ',

$$\Omega(f,f') = 2\int_\Sigma \omega_\Sigma(s)\int_{\mathbb{S}^1} f'(\theta,s)\frac{\partial f}{\partial\theta}(\theta,s)\mathrm{d}\theta = 2\int_\Sigma \omega_\Sigma(s)\int_I f'(\theta,s)\frac{\partial f}{\partial\theta}(\theta,s)\mathrm{d}\theta.$$

f' is constant in θ in $I\times\Sigma$ and $f(t',s)=f(t,s)$, t, t' being the extreme points of I, so that

$$\frac{1}{2}\Omega(f,f') = \int_I f'(\theta,s)\frac{\partial f}{\partial\theta}(\theta,s)\mathrm{d}\theta = f'(s)\int_I \frac{\partial f}{\partial\theta}(\theta,s)\mathrm{d}\theta = f'(s)(f(t',s) - f(t,s)) = 0.$$

Now suppose that (b) holds true. In this case one has

$$i\Omega(f,f') = 2\int_\Sigma \omega_\Sigma(s)\int_{\mathbb{S}^1} f'(\theta,s)\frac{\partial f}{\partial\theta}(\theta,s)\mathrm{d}\theta = 2\int_S \omega_\Sigma(s)\int_{\mathbb{S}^1} f'(\theta,s)\frac{\partial f}{\partial\theta}(\theta,s)\mathrm{d}\theta.$$

Since $\partial f'(\theta,s)/\partial\theta = 0$ in the set $\mathbb{S}^1\times S$ which is connected by paths with s constant, f' does not depend on θ in that set and thus

$$\frac{1}{2}\Omega(f,f') = 2\int_S \omega_\Sigma(s)f'(s)\int_{\mathbb{S}^1}\frac{\partial f}{\partial\theta}(\theta,s)\mathrm{d}\theta = 2\int_S \omega_\Sigma(s)f'(s) = 0.$$

Finally (W2) or equivalently (V2) entails the thesis. □

Proof of Theorem 3.2: The operator $L := K^2+S^2+D^2$ is essentially self–adjoint on $F(\mathcal{H})$ since the dense invariant space $F(\mathcal{H})$ is made of analytic vectors. The proof is straightforward by direct estimation of $\|L^n\Psi\|$ with $\Psi\in F(\mathcal{H})$ (there is a constant $C_\Psi\geqslant 0$ with $\|L^n\Psi\|\leqslant C_\Psi^n$). As a consequence of some results by Nelson (Theoem 5.2, Corellary 9.1, Lemma 9.1, and Lemma 5.1 in Ref. 28) the Hermitean operators $iR(x)$ with $x\in \mathrm{sl}(2,\mathbb{R})$ are essentially self-adjoint on $F(\mathcal{H})$ and there is a unique strongly continuous representation $\mathrm{SL}(2,\mathbb{R})\ni g\mapsto \mathrm{U}(g):\mathfrak{F}_+(\mathcal{H})\to\mathfrak{F}_+(\mathcal{H})$ such that (28) holds true.

(a) k generates the one-parameter subgroup $\mathbb{S}^1$ in $\mathrm{SL}(2,\mathbb{R})$—that is $\mathbb{R}\ni t\mapsto\exp(tk)$ with period 4π—as well as the one-parameter subgroup $\mathbb{R}\ni t\mapsto l(t)$ isomorphic to $\mathbb{R}$ in $\mathrm{SL}(2,\mathbb{R})$. From the general theory of $\mathrm{SL}(2,\mathbb{R})$ representations, a representation $\mathrm{SL}(2,\mathbb{R})\ni g\mapsto V(g)$ is in fact a representation of $\mathrm{SL}(2,\mathbb{R})$ if $t\mapsto V(l(t))$ has period $4\pi/k$ for some integer $k\neq 0$. It is simply proved that the operator K is the tensorialization of the operator defined on $\ell^2(\mathbb{C})\otimes L^2(\Sigma,\omega_\Sigma)$ by extending

$$\{C_n\}_{n=1,2,\ldots}\otimes u_j \mapsto \{nC_n\}_{n=1,2,\ldots}\otimes u_j$$

by linearity. As a consequence the spectrum of $\overline{K}$ is the set $\sigma(\overline{K})=\{0,1,2,\ldots\}$ where the eigenspace with eigenvalue 0 is one dimensional and it is generated by the vacuum state Ψ. This implies that $\mathbb{R}\ni t\mapsto e^{it\overline{K}}=\mathrm{U}(l(t))$ has period 2π. As a first consequence U is a proper representation of $\mathrm{SL}(2,\mathbb{R})$. Furthermore, since $\sigma(\overline{K})$ is non-negative, the representation is a positive-energy representation. Finally, notice that $-I=e^{2\pi k}$ and thus $\mathrm{U}(-I)=e^{i2\pi\overline{K}}=I$ and so U is a representation of $\mathrm{PSL}(2,\mathbb{R}) := \mathrm{SL}(2,\mathbb{R})/\pm I$.

(b) and (c). From direct inspection one sees that the operators K, S, D are tensorializations of the respective operators $K\restriction_{\mathcal{H}}$, $S\restriction_{\mathcal{H}}$, $D\restriction_{\mathcal{H}}$, in particular their restriction to the space generated by the vacuum vector coincide with the operator 0. Moreover, decomposing $\mathcal{H}=\ell^2(\mathbb{C})\otimes L^2(\Sigma,\omega_\Sigma)$, one finds

$$K\restriction_{\mathcal{H}} = K_0\otimes 0, \quad S\restriction_{\mathcal{H}} = S_0\otimes 0, \quad D\restriction_{\mathcal{H}} = D_0\otimes 0,$$

where K_0, S_0, and D_0 are obtained by restricting to the one-particle space the operators K, S, and D defined in the case $\mathbb{M}=\mathbb{S}^1$ (without transverse manifold). Using again Nelson results these operators give rise to a representation $\mathrm{SL}(2,\mathbb{R})\ni g\mapsto V(g)\otimes I$ in $\mathcal{H}$. (This representation is, in fact, an irreducible representation of $\mathrm{SL}(2,\mathbb{R})$, see Ref. 27.) By tensorialization this representation extends to a representation U′ in the whole Fock space. By construction, the generators iK', iS', iD' of this representation ad associated with k, s, d, respectively, coincides with iK, iS, iD, on $F(\mathcal{H})$, respectively. Nelson's uniqueness property implies that $\mathrm{U}'=\mathrm{U}$. By construction U (=U′) admits every space with finite number of particles as invariant space, including the space with zero particles spanned by the vacuum state.

(d) First of all, as said above, U leaves invariant the space generated by the vacuum vector Ψ so that it is an invariant vector up to a phase. Let us show that this is the only unit vector with this property. By (b), the operator $\overline{D}$ is the tensorialization of $\overline{D_0 \oplus I} = \overline{D_0 \oplus I}$ where the generator of V, $\overline{D_0}$, is defined on the one-particle space in the case of the absence of Σ, $\ell^2(\mathbb{C})$, and I acts on $L^2(\Sigma, \omega_\Sigma)$. In Refs. 26 and 27 the representation V has been studied, realized, under a suitable Hilbert space isomorphism, in the space $L^2(\mathbb{R}^+, \mathrm{d}E)$. In that space $\overline{D_0}$ is the closure of the essentially self-adjoint operator $-i(Ed/\mathrm{d}E + 1/2)$. The original dense, invariant domain of $-i(Ed/\mathrm{d}E + 1/2)$ is a core for D_0 made of smooth functions on $(0, +\infty)$ (see Ref. 26 for details) of the form $\sqrt{E}e^{-\beta E}P(E)$ with $\beta > 0$ a constant not depending on the considered function and P any polynomial. Under the unitary transformation U, which takes the form $(\mathrm{U}\psi)(x) := (2\pi)^{-1/2}\int_0^{+\infty} e^{-ix \ln E}\psi(E)/\sqrt{E}\,\mathrm{d}E$ on the domain of $-i(Ed/\mathrm{d}E + 1/2)$, this operator becomes the operator position X [i.e., $(X\psi)(x) = x\psi(x)$] on $L^2(\mathbb{R}, \mathrm{d}x)$ restricted to a core contained in the Schwartz space. As a consequence $\sigma(\overline{D_0}) = \sigma_c(\overline{D_0}) = \sigma(X) = \mathbb{R}$ and, similarly, $\sigma(\overline{D_0 \oplus I}) = \sigma_c(\overline{D_0 \oplus I}) = \mathbb{R}$. Therefore, passing to the tensorialization, $\sigma(\overline{D}) = \mathbb{R}$ and $\sigma_p(\overline{D}) = \{0\}$ with, up to phases, unique eigenvector given by the vacuum vector Ψ. If Φ is a unit vector which is up-to-phases invariant under U, it must be in particular $e^{itX}\Phi = u_X(t)\Phi$ where X is any real linear combination of K, S, D and $|u_X| = 1$. As the domain of X is dense, it contains a vector Φ' with $\langle \Phi', \Phi\rangle \neq 0$ and thus $u_X(t) = \langle e^{-itX}\Phi', \Phi\rangle / \langle \Phi', \Phi\rangle$ is differentiable at $t = 0$ by Stones' theorem. As a consequence, the left-hand side $e^{itX}\Phi = u_X(t)\Phi$ must be differentiable at $t = 0$. By Stone theorem Φ belongs to the domain of $\overline{X}$ and it holds $\overline{X}\Phi = \lambda_X\Phi$ where $\lambda_X = -i\,\mathrm{d}u_X/\mathrm{d}t|_{t=0}$. Specializing the identity to $X = D$, from the spectral structure of $\overline{D}$, one concludes that it must be $\lambda_D = 0$ and, up to phases, $\Phi = \Psi$. □

Proof of Theorem 3.3: (a) and (b) To establish (29) it is sufficient to prove those identities for $w = \hat{V}(\omega)$ with $\omega \in \mathcal{D}(\mathbb{M})$ and $g \in PSL(2, \mathbb{R})$. Actually, with the said choices for w,

$$\mathrm{U}(g)a\mathrm{U}^\dagger(g) = \alpha'_g(a) \quad \text{for all } a \in \hat{\mathcal{F}}(\mathbb{M}). \tag{A2}$$

implies (29). For if (A2) holds, taking the adjoint twice for both sides one gets the relations for self-adjoint field operators $U(g)\hat{\phi}(\omega)U^\dagger(g) = \hat{\phi}(\omega^{(g^{-1})})$. Then (12) implies (29) for $w = \hat{V}(\omega)$ via standard spectral theory. To conclude the proof of (a) it is now sufficient to show the validity of (A2) with $a = \hat{\phi}(\omega)$ or of the equivalent statement

$$\mathrm{U}(g)\Omega(\psi, \hat{\phi})\mathrm{U}^\dagger(g) = \Omega(\psi^{(g^{-1})}, \hat{\phi}) \quad \text{for all } \psi \in \mathcal{S}(\mathbb{M}) \quad \text{and} \quad g \in \mathrm{PSL}(2, \mathbb{R}). \tag{A3}$$

In turn, using the fact that U preserves the vacuum vector and is the tensorialization of $\mathrm{U}\restriction_{\mathcal{H}}$ (Theorem 3.2) as well as (11) one sees that (A3) is equivalent to

$$\psi^{(g)} = \mathrm{U}(g^{-1})\restriction_{\mathcal{H}}\psi_+ + \overline{\mathrm{U}(g^{-1})\restriction_{\mathcal{H}}\psi_+} \quad \text{for all } \psi \in \mathcal{S}(\mathbb{M}) \quad \text{and} \quad g \in \mathrm{PSL}(2, \mathbb{R}). \tag{A4}$$

Let us prove (A4). If $\psi \in \mathcal{S}(\mathbb{M})$ and $g \in \mathrm{Diff}^+(\mathbb{S}^1)$ the map $\psi \mapsto \psi^{(g)}$ induces a $\mathbb{R}$-linear map from the space of θ-positive frequency parts ψ_+ to the same space given by

$$\psi_+ \mapsto S(g)\psi_+ := ((\psi_+ + \overline{\psi_+})^{(g^{-1})})_+.$$

In this way the action of g on the wave function ψ is equivalent to the action of $S(g)$ on its positive frequency part ψ_+:

$$\psi^{(g^{-1})} = S(g)\psi_+ + \overline{S(g)\psi_+}. \tag{A5}$$

However, in general, $S(g)$ is not $\mathbb{C}$-linear (and thus it cannot be seen as a map $\mathcal{H} \to \mathcal{H}$) since, using $\chi_+ := i\psi_+$ above, one gets $S(g)(i\psi_+) = ((i\psi_+ - i\overline{\psi_+})^{(g^{-1})})_+ = i((\psi_+ - \overline{\psi_+})^{(g^{-1})})_+ \neq i((\psi_+ + \overline{\psi_+})^{(g^{-1})})_+ = iS(g)\psi_+$. Actually, if $g \in \mathrm{PSL}(2, \mathbb{R})$, it turns out that $(\overline{\psi_+} \circ g^{-1})_+ = 0$ so that $S(g)\psi_+ = (\psi_+ \circ g^{-1})_+$ and S is $\mathbb{C}$-linear. This nontrivial result was proven in Lemma (i) 3.1. To conclude the proof it is

sufficient to show that $S(g)=\mathrm{U}(g)\restriction_{\mathcal{H}}$ for all $g\in \mathrm{PSL}(2,\mathbb{R})$. To establish such an identity we first notice that $S(g):\mathcal{H}\to\mathcal{H}$ is a unitary representation of $\mathrm{PSL}(2,\mathbb{R})$. The only fact non-self-evident is that $S(g)$ preserve the scalar product. It is however true because, if $\chi:=i\psi_+-i\overline{\psi_+}$, it holds

$$\langle\psi_+,\psi'_+\rangle=-i\Omega(\overline{\psi_+},\psi'_+)=\frac{-i}{2}(\Omega(\psi,\psi')+i\Omega(\chi,\psi'))$$

now, due to (A5) we can replace the arguments ψ_+,ψ'_+ by, respectively, $S(g)\psi_+$, $S(g)\psi'_+$ and the arguments ψ, ψ', χ, by $\psi^{(g^{-1})}$, $\psi'^{(g^{-1})}$, $\chi^{(g^{-1})}$, respectively, obtaining a similar identity; finally, since the action of positive-oriented diffeomorphisms of $\mathbb{S}^1$ preserves the symplectic form, one has $\Omega(\psi^{(g^{-1})},\psi'^{(g^{-1})})+i\Omega(\chi^{(g^{-1})},\ \psi'^{(g^{-1})})=\Omega(\psi,\psi')+i\Omega(\chi,\psi')$ and thus $\langle S(g)\psi_+,S(g)\psi'_+\rangle=\langle\psi_+,\psi'_+\rangle$. To conclude the proof it is sufficient to notice that, by direct inspection making use of Stone theorem one finds (details are very similar to those in the corresponding part of Theorem 2.4 in Ref. 27) that, if $\psi_{nj}=\{\delta_{np}\}_{p=1,2,\ldots}\otimes u_j\in\ell^2(\mathbb{C})\otimes L^2(\Sigma,\omega_\Sigma)=\mathcal{H}$,

$$iX\psi_{nj}=\frac{d}{\mathrm{d}t}S(\exp(tx))\psi_{nj},$$

where $X=K$, S, D, and, respectively, $x=k$, s, d [k, d, s being the basis of $\mathrm{sl}(2,\mathbb{R})$ introduced above]. On the other hand, the same result holds, by construction, for the representation $\mathrm{U}\restriction_{\mathcal{H}}$

$$iX\psi_{nj}=\frac{d}{\mathrm{d}t}\mathrm{U}(\exp(tx))\psi_{nj}.$$

Since the elements ψ_{nj} span a dense space of analytic vectors for $K\restriction^2_{\mathcal{H}}+S\restriction^2_{\mathcal{H}}+D\restriction^2_{\mathcal{H}}$, by the results by Nelson cited in the proof of Theorem 3.2, $S=\mathrm{U}\restriction_{\mathcal{H}}$. Now (A5) implies (A4) and this concludes the proof. □

Proof of Theorem 4.1: (a) Consider the closure $\mathcal{W}_\zeta(\mathbb{M})$ of the $*$-algebra in $\mathcal{W}(\mathbb{M})$ spanned elements $V_\zeta(\omega):=V(\omega)e^{i\int_{\mathbb{M}}\Gamma(\zeta\omega_++\overline{\zeta\omega_+})}$ with $\omega\in\mathcal{D}(\mathbb{M})$. Obviously the obtained C^*-algebra coincides with $\mathcal{W}(\mathbb{M})$ itself. On the other hand, its generators $V_\zeta(\omega)$ satisfy (V1) and (V2) and thus, by Theorem 5.8.8 in Ref. 2 there is a unique $*$-isomorphism $\gamma_\zeta:\mathcal{W}(\mathbb{M})\to\mathcal{W}_\zeta(\mathbb{M})=\mathcal{W}(\mathbb{M})$ with $\gamma_\zeta(V(\omega))=V(\omega)e^{i\int_{\mathbb{M}}\Gamma(\zeta\omega_++\overline{\zeta\omega_+})}$. Finally, by construction $\lambda(\gamma_\zeta(V(\omega)))=\lambda_\zeta(V(\omega))$ and thus, linearity and continuity imply (33). Let us proof (35). Due to linearity and continuity, it is sufficient to show the validity of the relation when restricting to elements $V_\zeta(\omega)$. In turn, since $V(\omega)$ is invariant under $g_t:=\exp(t\mathcal{D})$ and using Lemma 3.1, the validity of (35) for those elements is a consequence of the invariance of the integral $\int_{\mathbb{M}}\zeta\Gamma\omega_+$ under the action of g_t^* on the argument ω_+ which we go to prove. If $\mathcal{D}(\mathbb{M})\ni\omega=[\partial f(\theta,s)/\partial\theta]\mathrm{d}\theta\wedge\omega_\Sigma(s)$ and defining $\theta_\pm(v)=\pm2\tan^{-1}(e^v)$, direct computation yields

$$\int_{\mathbb{M}}\zeta\Gamma\omega_+=-\lim_{N\to+\infty}\int_{-N}^{N}\mathrm{d}v\int_\Sigma\omega_\Sigma(s)\zeta(s)[f_+(\theta_+(v),s)-f_+(\theta_-(v),s)]+\text{boundary terms}.$$

Using periodicity of f_+ in θ, boundary terms can be rearranged into a term

$$\lim_{\Theta\nearrow\pi}\left[(\Theta-\pi)\ln\left(\left|\tan\frac{\Theta}{2}\right|\right)\int_\Sigma\zeta(s)\frac{f_+(\Theta,s)-f_+(\pi,s)}{\Theta-\pi}\omega_\Sigma\right]$$

and three other similar terms where $-\pi$ or 0 replaces π. The last integral can be bounded uniformly in Θ using Lagrange theorem since $\partial f_+/\partial\theta$ is continuous and compactly supported. As a consequence the limit vanishes and the boundary terms can be dropped. Finally, using the fact that v is the parameter of the integral curves of $\mathcal{D}$ one has,

$$\int_{\mathbb{M}} \zeta\Gamma g_t^* \omega_+ = -\lim_{N\to+\infty}\int_{-N}^{N} \mathrm{d}v \int_\Sigma \omega_\Sigma(s)\zeta(s)[f_+(\theta_+(v-t),s) - f_+(\theta_-(v-t),s)]$$

$$= -\lim_{N\to+\infty}\int_{-N+t}^{N+t} \mathrm{d}v \int_\Sigma \omega_\Sigma(s)\zeta(s)[f_+(\theta_+(v),s) - f_+(\theta_-(v),s)] = \int_{\mathbb{M}} \zeta\Gamma\omega_+,$$

so that the invariance of the integral functional under $\exp(t\mathcal{D})$ is evident.

(b) Let us start from the bottom. Since λ is invariant under the whole $\mathrm{PSL}(2,\mathbb{R})$ group, invariance (noninvariance) of λ_ζ is equivalent to invariance (noninvariance) of the integral functional in the right-hand side of (33). Let us study that integral. Take $\omega(\theta,s) = [\partial f(\theta)/\partial v]h(s)\mathrm{d}\theta\wedge\omega_\Sigma(s)$ where s are coordinates on Σ and the real functions f and h are smooth with the latter compactly supported as well. Assume $\zeta\neq 0$ almost everywhere. We can fix h such that $\int_\Sigma \zeta h = e^{i\alpha}$. In this case

$$\int_{\mathbb{M}} \Gamma(\zeta\omega_+ + \overline{\zeta\omega_+}) = \int_{\mathrm{S}^1} \Gamma(\theta)\left(e^{i\alpha}\frac{\partial f_+}{\partial\theta}\mathrm{d}\theta + \mathrm{c.c.}\right).$$

As a consequence, if $\{g_t\}_{t\in\mathbb{R}}$ denotes the one-parameter subgroup of $\mathrm{PSL}(2,\mathbb{R})$ generated by $X = (a+b\cos\theta + c\sin\theta)\partial_\theta$, with $a,b,c\in\mathbb{R}$, one has

$$\left.\frac{d}{\mathrm{d}t}\right|_{t=0}\int_{\mathbb{M}} \Gamma(\zeta g_t^*\omega_+ + \overline{\zeta g_t^*\omega_+}) = \int_{\mathrm{S}^1}\Gamma(\theta)\left(e^{i\alpha}\frac{\partial}{\partial\theta}\left((a+b\cos\theta+c\sin\theta)\frac{\partial f_+}{\partial\theta}\right)\mathrm{d}\theta + \mathrm{c.c.}\right).$$

The invariance of the integral implies that the left-hand must vanish no matter the choice of f

$$\int_{\mathrm{S}^1}\Gamma(\theta)\frac{\partial}{\partial\theta}\left((a+b\cos\theta+c\sin\theta)\frac{\partial e^{i\alpha}f_+}{\partial\theta}\right)\mathrm{d}\theta + \mathrm{c.c.} = 0.$$

Using $f(\theta) := \cos(\theta-\alpha)$ one finds that it must be $a=0$ as a consequence of the identity above. Then using $f(\theta) := \cos(2\theta-\alpha)$ one finds that it must also be $b=0$. We conclude that the integral functional is invariant at most under the group generated by $c\sin\theta\partial/\partial\theta = -c\mathcal{D}$. On the other hand, the proof of such an invariance arises directly from (34) and (35) using the fact that λ is invariant under $\alpha_t^{(\mathcal{D})}$ as stated in (c) in Theorem 3.4.

The fact that λ_ζ is pure (that is extremal) is an immediate consequence of (33) using the fact that γ_ζ is bijective and λ is pure. As the λ_ζ are pure their GNS representations are irreducible. Therefore the proof of the fact that λ_ζ and $\lambda_{\zeta'}$ are not quasiequivalent if $\zeta\neq\zeta'$, almost everywhere, reduces to the proof that, if $\zeta\neq\zeta'$ almost everywhere, there is no unitary transformation $\mathrm{U}:\mathfrak{F}_+(\mathcal{H}_\zeta)\to\mathfrak{F}_+(\mathcal{H}_{\zeta'})$ such that $\mathrm{U}\hat{V}_\zeta(\omega)U^{-1} = \hat{V}_{\zeta'}(\omega)$ for all $\omega\in\mathcal{D}(\mathbb{M})$. We shall make use of the first statement in (c) which will be proved independently from the following. Suppose that there is such a unitary transformation for some choice of $\zeta\neq\zeta'$. As a consequence one also gets the identity $\mathrm{U}\hat{V}_\zeta(\omega)e^{-i(\int_{\mathbb{M}}\zeta\Gamma\omega_+ + \mathrm{c.c.})}\mathrm{U}^{-1} = \hat{V}_{\zeta'}(\omega)e^{-i(\int_{\mathbb{M}}\zeta\Gamma\omega_+ + \mathrm{c.c.})}$. That is, redefining $\zeta'-\zeta\to\zeta\neq 0$, one has $\mathrm{U}e^{i\hat{\phi}_\zeta(\omega)}\mathrm{U}^\dagger = e^{i\hat{\phi}_0(\omega)}$ where we have also identified the one-particle Hilbert spaces $\mathcal{H}_0$ and $\mathcal{H}_\zeta$ with the one-particle space $\mathcal{H}$ of the GNS representation of λ (and thus the Fock spaces). Via Stone theorem (using above $\omega = t\omega$ and $t\in\mathbb{R}$) one gets $\mathrm{U}\hat{\phi}_\zeta(\omega) = \hat{\phi}_0(\omega)\mathrm{U}$, that is $i\mathrm{U}a(\overline{\psi_+}) - a^\dagger(\psi_+) + (\int_{\mathbb{M}}\zeta\Gamma\epsilon_{\psi_+} + \mathrm{c.c.})\mathrm{U} = ia(\overline{\psi_+}) - a^\dagger(\psi_+)\mathrm{U}$ where $\psi_+ = E\omega_+$ according with (b) in Proposition 2.1. Using the analogous relation for $\psi' := i\psi_+ - i\overline{\psi_+}$ one gets in the end

$$\mathrm{U}[\overline{a(\overline{\psi_+}) - a^\dagger(\psi_+)} + \overline{a(\overline{\psi_+}) + a^\dagger(\psi_+)}] - \left(4i\int_{\mathbb{M}}\overline{\zeta\Gamma\epsilon_{\overline{\psi_+}}}\right)\mathrm{U} = [\overline{a(\overline{\psi_+}) - a^\dagger(\psi_+)} + \overline{a(\overline{\psi_+}) + a^\dagger(\psi_+)}]\mathrm{U}.$$

Applying both sides to the vacuum state Ψ_ζ and computing the scalar product of the resulting vectors with Ψ_ζ itself, the identity above implies that

$$-\left(2i\int_{\mathbb{M}}\overline{\zeta\Gamma\epsilon_{\overline{\psi_+}}}\right)\langle\Psi_\zeta, U\Psi_\zeta\rangle = \langle a^\dagger(\psi_+)\Psi_\zeta, U\Psi_\zeta\rangle.$$

If $\{\psi_{+m}\}_{m\in\mathbb{N}'}$ is a Hilbert base of $\mathcal{H}_\zeta$, iteration of the procedure sketched above produces

$$\langle\Psi_\zeta, U\Psi_\zeta\rangle\prod_n \frac{\lambda_m^{N_m}}{\sqrt{N_m!}} = \langle N_1, N_2, \ldots, N_m, \ldots|U\Psi_\zeta\rangle \tag{A6}$$

for any vector with finite number of particles $|N_1, N_2, \ldots, N_m, \ldots\rangle$, N_m being the occupation number of the state ψ_{+m} and where $\lambda_m := -2i\int_{\mathbb{M}}\overline{\zeta\Gamma\epsilon_{\overline{\psi_{+m}}}}$. It must be $\langle\Psi_\zeta, \mathrm{U}\Psi_\zeta\rangle \neq 0$, otherwise all components of $U\Psi_\zeta$ would vanish producing $\mathrm{U}\Psi_\zeta = 0$ which is impossible since U is unitary. Conversely, as $\|\Psi_\zeta\|^2 = 1$, it must hold $\|\mathrm{U}\Psi_\zeta\|^2 = 1$. This identity can be expanded with the basis of states $|N_1, N_2, \ldots, N_m, \ldots\rangle$ and a straightforward computation which employs (A6) produces

$$\|\mathrm{U}\Psi_\zeta\|^2 = |\langle\Psi_\zeta, U\Psi_\zeta\rangle|^2 \exp\left(\sum_{m=1}^{+\infty}|\lambda_m|^2\right). \tag{A7}$$

The series can explicitly be computed using a basis $\psi_{(n,j)}(\theta, s) = u_j(s)(e^{-in\theta}/\sqrt{4\pi n})$, where u_j is any basis of $L^2(\Sigma, \omega_\Sigma)$ made of compactly supported real smooth functions. [The space $\mathcal{C}$ of smooth compactly supported functions on Σ is dense in $L^2(\Sigma, \omega_\Sigma)$. As the latter is separable $\mathcal{C}$ contains a countable subset $\mathcal{C}'$ still dense in $L^2(\Sigma, \omega_\Sigma)$. In turn one may extract from $\mathcal{C}'$ a subset $\mathcal{C}''$ of linearly independent elements which span the same dense space as $\mathcal{C}'$. Usual orthonormalization procedure applied to $\mathcal{C}''$ gives a Hilbert basis for $L^2(\Sigma, \omega_\Sigma)$ made of smooth compactly supported functions. One obtains the wanted basis of u_j.] In that case $\int_\Sigma\overline{\zeta u_j}\omega_\Sigma \neq 0$ for some $j = j_0$ [otherwise the function ζ on Σ would have $L^2(\Sigma, \omega_\Sigma)$-norm zero]. One finds $|\lambda_{2n+1,j_0}|^2 = C|\int_\Sigma\zeta u_{j_0}\omega_\Sigma|^2(2n+1)^{-1}$ with $C > 0$ so that the series in (A7) diverges and the found contradiction shows that U cannot exist.

(c) By direct inspection one finds that the operators $V_\zeta(\omega)$ enjoy (V1) and (V2). Therefore, (Theorem 5.2.8, in Ref. 2) the C^*-algebra $\hat{\mathcal{W}}_\zeta(\mathbb{M})$ given by the closure of the $*$-algebra generated by $V_\zeta(\omega)$ is a representation of Weyl algebra and there is a $*$-algebra isomorphism of C^* algebras, $\Pi_\zeta : \mathcal{W}(\mathbb{M}) \to \hat{\mathcal{W}}_\zeta(\mathbb{M})$ which satisfies (36). The vacuum vector of $\mathfrak{H}_\zeta = \mathfrak{F}_+(\mathcal{H}_\zeta)$ is cyclic with respect to Π_ζ because $\hat{\mathcal{W}}_\zeta(\mathbb{M})\Psi_\zeta$ is the same space as the dense space (see part A.1 of this Appendix) spanned by vectors $e^{i\overline{\hat{\phi}(\omega_1)}}\ldots e^{i\overline{\hat{\phi}(\omega_n)}}\Psi_\zeta$, $n = ,1,2,\ldots$. Finally it holds

$$\begin{aligned}\lambda_\zeta(V(\omega)) &= \lambda(V(\omega))e^{i(\int_{\mathbb{M}}\zeta\Gamma\omega_+ + \mathrm{c.c.})} = \langle\Psi_\zeta, e^{i\overline{\hat{\phi}(\omega)}}\Psi_\zeta\rangle e^{i(\int_{\mathbb{M}}\zeta\Gamma\omega_+ + \mathrm{c.c.})} = \langle\Psi_\zeta, e^{\overline{i(\hat{\phi}(\omega) + \int_{\mathbb{M}}\zeta\Gamma\omega_+ + \mathrm{c.c.})}}\Psi_\zeta\rangle \\ &= \langle\Psi_\zeta, \hat{V}_\zeta(\omega)\Psi_\zeta\rangle,\end{aligned}$$

that is $\lambda_\zeta(V(\omega)) = \langle\Psi_\zeta, \Pi_\zeta(V(\omega))\Psi_\zeta\rangle$. By linearity and continuity this relation extends to the whole algebras, $\lambda_\zeta(w) = \langle\Psi_\zeta, \Pi_\zeta(w)\Psi_\zeta\rangle$, $w \in \mathcal{W}(\mathbb{M})$. We conclude that $(\mathfrak{F}_+(\mathcal{H}_\zeta), \Pi_\zeta, \Psi_\zeta)$ is the (unique, up to unitary transformations) GNS triple for λ_ζ.

(d) Let us denote by $\{g_t\}_{t\in\mathbb{R}}$ the one-parameter group of Möbius transformations generated by $\mathcal{D}$. The statements (a) and (b) in Theorem 3.3 imply that if D is defined as $(1/2i) : \Omega(\hat{\phi}_0, \mathcal{D}(\hat{\phi}_0))$: then $e^{itD}e^{i\overline{\hat{\phi}_0(\omega)}}e^{-itD} = e^{i\overline{\hat{\phi}_0(g_t^{-1^*}\omega)}}$. Since $\int_{\mathbb{M}}\zeta\Gamma\omega_+ + \mathrm{c.c.}$ is invariant under the action of g_t on ω as seen in the proof of (a), we have also

$$e^{itD}e^{i\overline{\hat{\phi}_0(\omega)}}e^{i(\int_{\mathbb{M}}\zeta\Gamma\omega_+ + \text{c.c.})}e^{-itD} = e^{i\overline{\hat{\phi}_0(g_t^{-1*}\omega)}}e^{i\left(\int_{\mathbb{M}}\zeta\Gamma g_t^{-1*}\omega + \text{c.c.}\right)}$$

that can be rewritten as $e^{itD}\hat{V}_\zeta(\omega)e^{-itD} = \hat{V}_\zeta(\omega^{(g_t^{-1})})$ and thus extends to the whole Weyl algebra proving (37). □

The Epstein–Glaser approach to perturbative quantum field theory: graphs and Hopf algebras

Alexander Lange[a)]
Max-Planck-Institut für Mathematik in den Naturwissenschaften, Inselstrasse 22-26, 04103 Leipzig, Germany

(Received 8 August 2004; accepted 17 February 2005; published online 20 May 2005)

The paper aims at investigating perturbative quantum field theory in the approach of Epstein and Glaser (EG) and, in particular, its formulation in the language of graphs and Hopf algebras (HAs). Various HAs are encountered, each one associated with a special combination of physical concepts such as normalization, localization, pseudounitarity, causal regularization, and renormalization. The algebraic structures, representing the perturbative expansion of the *S*-matrix, are imposed on operator-valued distributions equipped with appropriate graph indices. Translation invariance ensures the algebras to be analytically well defined and graded total symmetry allows to formulate bialgebras. The algebraic results are given embedded in the corresponding physical framework, covering the two EG versions by Fredenhagen and Scharf that differ with respect to the concrete recursive implementation of causality. Besides, the ultraviolet divergences occurring in Feynman's representation are mathematically reasoned. As a final result, the change of the renormalization scheme in the context of EG is modeled via a HA and interpreted as the EG analog of Kreimer's HA. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1893215]

I. INTRODUCTION

In perturbative quantum field theory (pQFT) interaction of elementary particles is modeled to describe the outcomes of scattering experiments. In the approach of Epstein and Glaser (EG) the scattering matrix is investigated as a formal power series,

$$S(a\tau)=\sum_{n=0}^{\infty}\frac{a^n}{n!}T_n(\tau^{\otimes n}),\qquad \begin{cases} a & \text{coupling (constant)},\\ \tau & \text{infrared regularization (test function)}, \end{cases} \tag{1}$$

representing an operator-valued distribution acting on the Fock space of free quantum fields, where in the adiabatic limit, $\tau\to 1$, the square of the corresponding scalar product, $|\langle final|S(a\tau)|initial\rangle|^2$, is supposed to yield the scattering probability. Based on the interaction term T_1, which is assumed to be local, the higer order terms T_n, $n>1$, of the perturbative expansion can be deduced by "only" applying causality. In general the series does not converge in any norm, but in a few cases it is at least Borel summable (cf. Ref. 1, Sec. 41.4). Despite this fact, conceptually, the theory is determined only up to the so-called renormalization freedom. However, renormalization in the usual sense, as a subtraction of counterterms, does not have to be performed. This actually reflects the original motivation of EG,[2] namely, to give a proof of locality (i.e., renormalizability by local counterterms) just by proceeding the sketched way which can be seen as a parallel road to the well-known BPHZ approach[3–5] although, referring to the abstract intial setting (1), coming from the same junction.

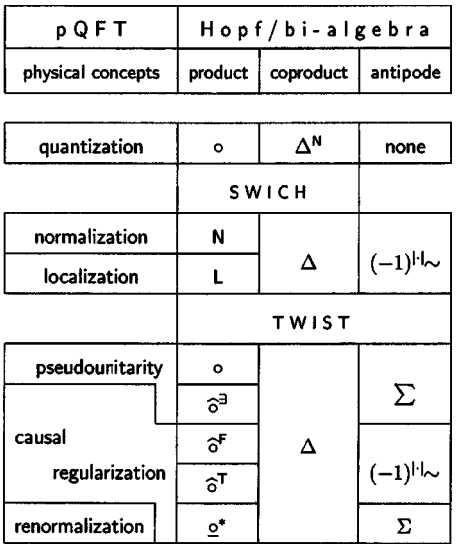

FIG. 1. Hopf algebras modeling pQFT in the EG approach.

The specified title of this paper refers to terminology which so far has not properly been implemented into the considered approach. Graphs do not appear in the EG framework and its recent versions,[6,7] and Hopf algebras (HAs), from the perspective of physics, constitute a well-developed concept only in the subject of quantum groups, having decent applications in statistical physics (cf. Ref. 8, Secs. 3.7, 7.6, 8.7). Here, graphs serve as indices for the n-point distributions T_n, and the inductive method to obtain the latter is modeled by various HAs.

In 1997, Kreimer[9] discovered that the counterterms in Zimmermann's forest formula,[5] which underlies renormalization in the Feyman graph approach, can be interpreted as an antipode condition of a HA. By then one has obviously overcome the mathematical lack which had been associated with renormalization before. But the finding of the mathematical structure alone could not fully eliminate the mysticism involved—the occurance of a combinatorial HA in this context requires further explanation. The method developed by EG would give a closer look at the physics involved. From a similar point of view (cf. Ref. 10, p. 689), in 2000, Kreimer[11] formulated the research problem of investigating the EG approach under the aspect of HAs; the content of Ref. 12 was not considered as the solution.

The brief history of contributions to the topic of EG-relevant HAs in pQFT starts in 2000 when Fauser[13] describes a HA that combines normal and time ordering. In the same year, based on the work of Fredenhagen and co-workers,[7,14–16] Pinter[17] discusses the question of uniqueness of EG's n-point distributions to establish a link to Kreimer's HA. In 2002, Brouder *et al.*[18,19] have taken up the previous two results again; they revive the work of Rota and Stein[20,21] about combinatorial HAs and present a link to quantum groups. Recent publications along this line are Refs. 22 and 23.

In the present paper, which uses a very general formulation of pQFT, Kreimer's HA is reconstructed in the EG approach via a scheme of HAs associated with different physical concepts such as normalization (referring to the normal product construction), localization, pseudounitarity, causality and an associated regularization, and eventually renormalization, cf. Fig. 1. The overall strategy has been to represent iterated solutions (e.g., of the pertubative expansion) in terms of antipode conditions. At the beginning of this project, which was the topic of the author's thesis,[24] it was not clear what the involved physical instances would be and neither whether one would be able to realize the aimed correspondence at all.

According to recent results, the starting point for the construction of the sketched HAs can be fixed by a bialgebra which most naturally models the quantum character of the considered physical objects. The algebra formalizes products of free quantum fields and the coalgebra normal products

of the latter. By switching the coalgebra into an algebra and adding a shuffling coalgebra which respects graded total symmetry (GTS) one can easily construct a HA which encodes normal ordering. Going over to a ring of scalars containing delta distributions, one can as well include the concept of localization. Extending this ring by propagators that satisfy the spectral condition and by translation invariant (TI) distributions, one obtains an algebra which formalizes the Wick expansion. The product is again the composition, i.e., the circle product, which defines a so-called twist with respect to the localized normal product. With the shuffling coproduct and an antipode given by Schmitt's formula, which implements pseudounitarity, the resulting Laplace[25] HA models the perturbative expansion. This structure must be extended again to explicitly implement causality. In accordance with the well-known ultraviolet problems of pQFT, causality requires an adequate regularization. For the three considered approches, i.e., the two recent EG versions of Fredenhagen (EGF) and Scharf (EGS) as well as the Feynman approach of Bogoliubov–Shirkov (BS), which vary with respect to the concrete product and antipode, this is realized by localization on causally determined space–time regions. In order to finally reestablish the concept of renormalization in the language of HAs one must consider graded commutative versions of the causally regularizing HAs. Then one can, in analogy to Kreimer's achievements, via some kind of deformation, describe the change of the renormalization scheme in terms of HAs.

The content has been arranged according to the items just given. This organizes the paper as follows. Free quantum fields and their algebraic structures with respect to normalization and localization are introduced in Sec. II. Including interaction, Sec. III continues with the formal expansion of the *S*-matrix and the construction of associated (Hopf) algebras. In Sec. IV, causality and renormalization get explicitly implemented into pQFT, leading to various HAs. More detailed explanation is given at the beginning of the sections.

Some technical remarks: Independent of its mathematical importance, only propositions which immediately refer to the table of Fig. 1 are called theorems. To keep the number of pages in reasonable bounds, most of the proofs are only sketched, especially when they can be found in Ref. 24 or in some other reference. The remaining calculations are provided in Appendix A. Furthermore, one finds appended examples illustrating the text and a list of symbols and abbreviations that are less standard.

II. LOCAL INTERACTION OF FREE QUANTIZED FIELDS

A. Free quantized fields

The basic physical objects in pQFT, the free quantized fields, are given here in a rather abstract way, emphasizing on physical aspects such as the causal and the spectral condition but also on mathematical ones. For instance, free fields are shown to form a bialgebra where the normal product serves as a coproduct.

1. The physical setup

The inner product of the one particle Hilbert space $\mathcal{H}_p$,

$$\frac{1}{i\hbar}(f,g)_p^+ \propto \Delta_p^+(f,g) := (\Delta_p^+ * g)(f^*), \quad f,g \in \mathcal{D}_p, \tag{2}$$

is induced by the fundamental solutions of a wave (i.e., a TI and relativistically covariant linear hyperbolic) operator, where Δ_p^+, given via Fourier transformation $(F\Delta_p^+)(k) = \theta(k^0)(F\Delta_p)(k)$, is the positive frequency part of the difference $\Delta_p = \Delta_p^R - \Delta_p^A$ between the retarded and advanced Green's functions [fulfilling $\operatorname{supp} \Delta_p^{R|A}(\cdot - y) \subseteq y + \overline{V}_{+|-}$, $\forall y \in \mathbb{R}^{1+d}$, where $\overline{V}_{+|-}$ is the closed forward|backward lightcone, i.e., $\overline{V}_+ = \{x \in \mathbb{R}^{1+d} \,|\, \sqrt{x_1^2 + \cdots + x_d^2} \leqslant x_0\} = -\overline{V}_-$]. The appropriate test function space, of Schwartz class say, is denoted by $\mathcal{D}_p$. In addition to the adjoint f^* of a test function $f \in \mathcal{D}_p$, one will also have to apply the transposed of the former, $\tilde{f} := f^{*t}$. Notice, Planck's constant $\hbar$ has been implemented and the velocity of light $c := 1$.

Following a notation similar to Ref. 26 (e.g., covariance is not simulated here), general indices ν (and μ, respectively) are supposed to determine derived (anti)particles, $p=[\![\nu]\!]$ (and $\tilde{p}=[\![\mu]\!]$, respectively), representing propagators including derivatives in terms of the Pauli Jordan function, i.e.,

$$\Delta_p = (\Delta^{\nu\mu})_{[\![\nu]\!]=p,[\![\mu]\!]=\tilde{p}}, \quad \text{where } \Delta^{\nu\mu} \overset{\partial\cdots}{\sim} D_{m_\nu} = D^+_{m_\nu} + D^-_{m_\nu} \tag{3}$$

and $D^\pm_{m_\nu}(x) = \pm[i/(2\pi)^{1+\mathrm{d}}]\int \mathrm{d}\vec{k}[e^{\mp ikx}/2\omega_\nu(\vec{k})]$ where $\omega_\nu(\vec{k}) = \sqrt{\vec{k}^2 + (m_\nu^2/\hbar^2)}$. *Antiparticles* $\tilde{p}=[\![\tilde{\nu}]\!]$ are always assumed to exist, at least formally, defined by

$$\Delta^+_{\tilde{p}}(x) = -s_p \Delta^-_p(-x)^t, \quad \text{where } s_p := (-1)^{2\,\mathrm{spin}(p)} \tag{4}$$

and where Δ^-_p symbolizes the negative frequency part.

Quantum fields φ_p associated with particles p are defined as operators on (the dense subspace of) Fock space $\mathcal{D}^{\mathrm{F}}_p = \oplus_{n\geqslant 0} S^{\sigma_p}_n \mathcal{D}^{\otimes n}_p \subset \mathcal{H}^{\mathrm{F}}_p$, i.e., in terms of annihilation and creation operators,

$$\begin{pmatrix} \varphi_p(f) \\ \varphi_{\tilde{p}}(\tilde{f}) \end{pmatrix} = A^-_p \begin{pmatrix} a_p(f) \\ a_{\tilde{p}}(\tilde{f}) \end{pmatrix} + A^+_p \begin{pmatrix} a^*_p(f) \\ a^*_{\tilde{p}}(\tilde{f}) \end{pmatrix}, \quad f \in \mathcal{D}_p, \tag{5}$$

where for the considered theories

$$A^-_p = \begin{pmatrix} 1 & 0 \\ 0 & \gamma_p \end{pmatrix} \quad \text{and } A^+_p = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{6}$$

so that by the choice of $\gamma_p = -1 \in \{\pm 1\}$ one can also model ghost fields. As usual, on $\mathcal{D}^{\mathrm{F}}_p \ni |h\rangle = (h_0, h_1(\cdot), h_2(\cdot,\cdot), \ldots)$,

$$(a_p(f)|h\rangle)_n = \sqrt{n+1}(f, h_{n+1}(\cdot,\ldots))^+_p, \tag{7}$$

$$(a^*_p(f)|h\rangle)_n = \sqrt{n} S^{\sigma_p}_n (f \otimes h_{n-1}), \tag{8}$$

where (anti)symmetrization characterizes bosons (fermions, respectively),

$$S^{\sigma_p}_n h_n = \frac{1}{n!} \sum_{\pi \in S_n} \sigma_p(\pi) h_n \circ \pi, \tag{9}$$

and $\sigma_p(\cdot)$ defines the *grading* with respect to the statistics σ_p,

$$\sigma_p(\pi) = \begin{cases} 1 \\ (\mathrm{sgn}\ \pi) \end{cases} \quad \text{if } \sigma_p = \begin{cases} +1 \\ (-1, \text{ respectively}). \end{cases} \tag{10}$$

Derived fields $\varphi_{p'} = \partial\cdots\varphi_p$ are as well, in order to be treated as free, considered to be given by *derived particles* $p' \in A'(p)$,

$$\left(\bigcirc_{\mu\in I} \partial^\mu\right)\varphi^\nu(f) := \varphi_\nu\left((-1)^{|I|}\left(\bigcirc_{\mu\in I}\partial^\mu\right)f\right), \quad I \text{ depends on } (\nu, p'). \tag{11}$$

The graded commutators of free fields have been defined to fulfill the *causal property*, i.e., $\gamma_p = 1/s_p\sigma_p \equiv s_p\sigma_p$, which imposes them,

$$[\varphi^\nu(f), \varphi^\mu(\tilde{g})]^\circ_{\sigma_p} := \varphi^\nu(f) \circ \varphi^\mu(\tilde{g}) - \sigma_p \varphi^\mu(\tilde{g}) \circ \varphi^\nu(f) \tag{12}$$

$$= i\hbar\gamma_p \Delta^{\nu\mu}(f,g)\mathrm{id}_{\mathcal{F}} =: i\hbar\Delta^{\nu\mu}_\gamma(f,g), \tag{13}$$

to have a causal support, i.e.,

$$[\varphi^{\nu}(f),\varphi^{\mu}(\tilde{g})]^{\circ}_{\sigma_p}=0 \quad \text{if supp } f\subseteq\mathbb{R}^{1+\mathrm{d}}\setminus(\text{supp } g+(\overline{V_+}\cup\overline{V_-})), \tag{14}$$

where $[\![\nu]\!]=p$ and $[\![\mu]\!]=\tilde{p}'$. Whenever spin and statistics do not coincide the particle is a ghost, cf. Ref. 27. The annihilation and creation part commutators read (i.e., in density notation, with $x,y\in\mathbb{R}^{1+\mathrm{d}}$)

$$[\varphi^{\nu}_{\mp}(x),\varphi^{\mu}_{\pm}(y)]^{\circ}_{\sigma_p}=i\hbar\Delta^{\nu\mu}_{\pm\gamma}(x-y). \tag{15}$$

The upper case, representing the positive frequency part, reflects the *spectral condition* which, applied by Wick's theorem later in the text, ensures the propagators' multiplication as distributions to be well defined. Namely, as $F\Delta^{+}_{i}\in\mathcal{S}'(\overline{V_+})$, i.e.,

$$\text{supp } F\Delta^{+}_{i}\subseteq\overline{V_+},\quad \forall\, i\leqslant n, \tag{16}$$

the so-called Fourier product[28]

$$\prod_{i\leqslant n}\Delta^{+}_{i}(x):=F^{-1}(F(\Delta^{+}_{1}(x))*\ldots*F(\Delta^{+}_{n}(x)))\in\mathcal{S}'(\mathbb{R}^{1+\mathrm{d}}). \tag{17}$$

Moreover, as the associative and commutative convolution lies in $\mathcal{S}'(\overline{V_+})$ again,[29] the resulting product satisfies the spectral condition as well.

The relevant counter example is *Feynman's (time-ordered) propagator*

$$\Delta^{\mathrm{F}}:=\mathsf{T}\Delta^{+}. \tag{18}$$

Applying the causality condition, this leads to the well-known representation,

$$\Delta^{\mathrm{F}\gamma}_{p}(x)=\mathsf{T}\Delta^{+\gamma}_{p}(x):=\theta(x^0)\Delta^{+\gamma}_{p}(x)+\sigma_p\theta(-x^0)\Delta^{+\gamma}_{\tilde{p}}(-x) \tag{19}$$

$$=\theta(x^0)\Delta^{+\gamma}_{p}(x)-\theta(-x^0)\Delta^{-\gamma}_{p}(x), \tag{20}$$

which shows that the spectral condition does not hold true.

2. The initial bialgebra

Starting the algebraic considerations for an arbitrarily chosen pQFT, let P denote the finite set of particles and $A'(p)$ the class of derived particles associated with $p\in\mathrm{P}$. Then the common Fock space is formed by a symmetrized tensor product, $\mathcal{H}^{\mathrm{F}}_{\mathrm{P}}:=(S_{|\mathrm{P}|}\otimes_{p\in\mathrm{P}})(\otimes_{q\in A'(p)}\mathcal{H}^{\mathrm{F}}_{q})$. Compatible with this definition, the composition of field operators $\mathcal{F}_{\mathrm{p}}:=\{\phi^{i}\equiv\varphi_{\mathrm{p}_i}(x_i)\,|\,i\in\mathbb{N}\}$, that are fixed by a given surjective map $\mathrm{p}:\mathbb{N}\ni i\mapsto\mathrm{p}_i\in\mathrm{P}$ which models the whole scattering scenario, is commutative only, cf. (13), if the associated particles do not belong to the same class of derived particles, i.e., $[\varphi_{\mathrm{p}_1}(x_1),\varphi_{\mathrm{p}_2}(x_2)]^{\circ}=0$ if $\mathrm{p}_2\notin A'(\mathrm{p}_1)$.

The admissible compositions $\mathcal{F}=\mathbb{C}\langle\mathcal{F}_{\mathrm{p}},+,\circ\rangle/(\cdots\circ\phi\circ\cdots\circ\phi\circ\cdots)$ of field operators $\mathcal{F}_{\mathrm{p}}$, where multiple occurances are excluded, generate an algebra $(\mathcal{F},\mathbb{C},+,\circ,\eta)$ with unity (map $\eta:=\cdot\,\mathrm{id}_{\mathcal{H}^{\mathrm{F}}_{\mathrm{p}}}$). In accordance with the following rule of resolving brackets, "$\bigcirc_{i\leqslant n}\phi^{i}$ with brackets" $=\phi^{1}\circ(\cdots\circ(\phi^{n-1}\circ\phi^{n})\cdots)$, the composition is always assumed to be associative. In a similar spirit, as these field operators act linearly on their domain, which is a dense subspace of the Fock space $\mathcal{H}^{\mathrm{F}}_{\mathrm{p}}$, distributivity is implemented. However, repeating the statement above, the composition algebra of free fields is not graded commutative.

To model local interaction, as the following example shows, the composition is not a good product. In the limit of coinciding space–time points the vacuum expectation is not defined,

$$\langle 0|\varphi^{\nu}(x)\circ\varphi^{\mu}(y)|0\rangle=\underbrace{\langle 0|\varphi^{\nu}(x)\,\mathsf{N}\,\varphi^{\mu}(y)|0\rangle}_{=0,\ \forall x,y}+i\hbar\underbrace{\Delta^{\nu\mu}_{+\gamma}(x-y)}_{\to_{x\to y}(?)}\equiv 0+(?). \tag{21}$$

The vanishing expectation, i.e., the first expression on the right-hand side (rhs) is induced by the so-called normal product,

$$\varphi^{\nu}(x) \,\mathsf{N}\, \varphi^{\mu}(y) = \varphi^{\nu}_{+}(x) \circ \varphi^{\mu}_{-}(y) + \sigma_p \varphi^{\mu} + (y) \circ \varphi^{\nu}_{-}(x). \tag{22}$$

As already applied in (15), left-hand side (lhs), the subscript sign $+|-$ denotes the projection $\mathrm{pr}_{\pm}: \phi \mapsto \phi_{\pm}$ onto the creation|annihilation part, cf. (5). For more than two factors the normal product is defined by

$$\mathsf{N}\phi^{\otimes J} := \sum_{J_+ \in \mathcal{P}_2^0(J)} \sigma_J(J_{\pm}) \bigcirc \phi_+^{\otimes J+} \circ \bigcirc \phi_-^{\otimes J-}, \tag{23}$$

where σ_J denotes the grading sign formulated on tuples $\otimes J \equiv (J_1, \ldots, J_n) \in \mathbb{N}_{\neq}^n$ of $n \in \mathbb{N}$ distinct numbers (i.e., $J_i \neq J_j$ if $i \neq j$, $\forall i,j \leqslant n$) that represent (indices of) particles p_{Ji}, where $J_{\pm} = (J_+, J_-) \in \mathcal{P}_2^{(0)}(J)$ denotes a 2-partition of J (respectively, including empty parts), and where $\phi^{\otimes J} := \bigotimes_{j \in J} \phi^j$. The grading $\sigma: S_n \to \mathbb{Z}_2$, $(J \mapsto K) = \pi \mapsto \sigma(\pi) = \sigma_J(K)$ is a representation of the permutation group $(S_n, \circ)$ on $(\mathbb{Z}_2, \cdot)$. In accordance with the definition of the common Fock space $\mathcal{H}_{\mathrm{P}}^{\mathrm{F}}$ it can be given in terms of the statistical coefficients σ_p, i.e.,

$$\sigma(\pi) := \prod_{p \in \mathrm{P}} \sigma_p(\pi|_p) = \prod_{\substack{p \in \mathrm{P} \\ \mathrm{sgn}(x|_p) = \sigma_p = -1}} \sigma_p(\pi|_p) \quad \text{and } \sigma_p(\varnothing) := 1, \tag{24}$$

where $\pi|_p: J|_p \mapsto \pi(J|_p)$ denotes a subpermutation of π which exclusively applies to derived particles $A'(p)$ with respect to p, defined on the subtuple $J|_p := (J_i)_{(\exists i \leqslant n) p_{J_i} \in A'(p)}$.

Important for the (Hopf/bi-) algebraic scenario going to be presented is the fact that the normal product can be denoted with the help of a coproduct,

$$\Delta^{\mathsf{N}} := (\mathrm{pr}_+ \otimes \mathrm{pr}_-) \circ \Delta, \tag{25}$$

which is based on the graded shuffling coproduct,

$$\Delta(\phi^{\bigcirc J}) = \sum_{J_{\pm} \in P_2^0(J)} \sigma_J(J_{\pm}) \phi^{\bigcirc J+} \otimes \phi^{\bigcirc J-}. \tag{26}$$

Immediately one observes that

$$\mathsf{N} = \bigcirc \circ \Delta^{\mathsf{N}} \circ \bigcirc, \tag{27}$$

and Lemma A.2 in the appendix verifies the implicit claim about Δ and Δ^{N} being coproducts. Therefore, as one easily verifies, $(\mathcal{F}, \mathbb{C}, +, \Delta^{(\mathsf{N})})$ forms a (non)cocommutative coalgebra (respectively) where only Δ comes with a counit,

$$\varepsilon(\phi) = \begin{cases} c & \text{if } \phi = c1, \\ 0 & \text{otherwise}. \end{cases} \tag{28}$$

Moreover, $\Delta^{(\mathsf{N})}$ as well as ε, can be shown to define homomorphisms with respect to the composition product. This leads to the main result of this section.

Theorem 2.1: $(\mathcal{F}, \mathbb{C}, +, \circ, \eta, \Delta^{(\mathsf{N})}, \varepsilon)$ *forms a bialgebra (without counit, respectively).*

Proof: All that is left to show is an immediate consequence of Lemma A.3. □

Remark 2.2: Because of (21), only the structure in parentheses is relevant for local pQFT.

Furthermore, one observes that the latterly introduced objects are equipped with the very quantum theoretic property of GTS, which models indistinguishable particles governed by particular statistics.

Proposition 2.3: *The normal product* N, *as well as the associated (and, respectively, the shuffling) coproduct* $\Delta^{(\mathsf{N})}$, *and the Feynman propagator* Δ^{F} *are all GTS.*

Proof: GTS of $\Delta^{(\mathsf{N})}$, which holds true because of Lemma A.1, immediately implies GTS of N. Applying (19), one gets

$$\Delta_p^{\mathsf{F}\gamma}(x) = \sigma_p \Delta_{\tilde{p}}^{\mathsf{F}\gamma}(-x) \tag{29}$$

which, due to the propagator's TI, just expresses GTS. □

B. Normalization and localization

The composition algebra of free fields does not provide an adequate algebraic structure for modeling local interaction. As only the normal product is suitable for such a purpose, indicated by (21), the bialgebraic structure must be modified again.

1. An appropriate weakening of structure

In fact, one drops the "co" again and *switches* the previously constructed coalgebra into an algebra. As Δ^{N} is coassociative the normal product N is associative, and therefore, the normal $\mathbb{C}$-compositions $\mathcal{N} := \{\bigcirc \circ \Delta^{\mathsf{N}}(\phi) \,|\, \phi \in \mathcal{F}\}$ constitute a graded commutative algebra with unity, i.e., $(\mathcal{N}, \mathbb{C}, +, \mathsf{N}, \eta)$. Notice, graded cocommutativity has switched to graded commutativity. Because of its shared GTS property, the right candidate for an additional coalgebra is the one with the shuffling coproduct, i.e., $(\mathcal{N}, \mathbb{C}, +, \Delta, \epsilon)$. Together with an appropriate antipode the structure of normally ordered free field operators $\mathcal{N}$ turns out to be a HA.

Theorem 2.4: *$(\mathcal{N}, \mathsf{N}, \eta, \Delta, \varepsilon)$ forms [both] a graded [co]commutative bialgebra which moreover, with the antipode $\mathsf{S} := (-1)^{|\cdot|}\sim$, i.e.,*

$$\mathsf{S}(\phi^{\mathsf{N}J}) = (-1)^n \phi^{\mathsf{N}\tilde{J}}, \quad \forall\, J \in \mathbb{N}^n_{\neq}, \quad \forall\, n \in \mathbb{N} \tag{30}$$

[where $\tilde{J} := (J_n, \ldots, J_1)$], defines a HA.

Proof: The bialgebra part follows from Lemma A.3. Notice that graded [co]commutativity is nothing else than GTS, thus realized for N (and Δ^{N}, respectively). It remains to prove the *antipode condition*, i.e., $\mathsf{N} \circ (\mathsf{S} \otimes \mathrm{id}) \circ \Delta = \eta \circ \varepsilon = \mathsf{N} \circ (\mathrm{id} \otimes \mathsf{S}) \circ \Delta$. For the nontrivial case, i.e., $n > 0$, where $\eta \circ \varepsilon = 0$, one can write the rhs (and similarly the lhs) as a sum over vanishing pairs,

$$\begin{aligned} \mathsf{N} \circ (\mathrm{id} \otimes \mathsf{S}) \circ \Delta(\phi^{\bigcirc J}) &= \sum_{\substack{J_\pm \in \mathcal{P}_2^0(J) \\ |J_-| \text{ odd}}} (\sigma_J(J_\pm)\phi^{\bigcirc J_+} \mathsf{N}(-1)\phi^{\bigcirc \tilde{J}_-} + \underbrace{\sigma_J(K_\pm)\phi^{\bigcirc K_+} \mathsf{N}\phi^{\bigcirc \tilde{K}_-}}) \\ &= \ldots + \underbrace{\sigma_J(K_\pm)\sigma_{J_\pm}(K_\pm)}_{=\sigma_J(J_\pm)} \phi^{\bigcirc J_+} \mathsf{N}\, \phi^{\bigcirc \tilde{J}_-} = 0, \end{aligned}$$

where $K_+ := J'_+ \otimes (j) \otimes J''_+$ and $K_- := J'_- \otimes J''_-$ provided $J_+ = J'_+ \otimes J''_+$ and $J_- = J'_- \otimes (j) \otimes J''_-$. The first brace results from GTS of N and the second from the composition laws of the grading σ being a group representation. □

Going over from the bialgebra of free field operators to the bialgebra of normally ordered field operators, i.e., $\mathcal{F} \to \mathcal{N}$,

$$\phi^{\bigcirc J} \mapsto \phi^{\mathsf{N}J}, \quad \bigcirc \mapsto \mathsf{N} \quad \text{and } \Delta^{\mathsf{N}} \mapsto \Delta \tag{31}$$

(as well as $\eta \mapsto \eta$), referred to as *normalization* here, this defines a functor that switching from a non[co]commutative to a graded [co]commutative bialgebra weakens the considered algebraic structure.

2. Another ring of scalars

In order to model local interaction one must describe different free particles localized at the same space–time point. In the chosen mathematical context of distributions this is done by applying Dirac's delta distributions. The implementation of the latter within the (Hopf) algebraic formalism can be realized by changing to another ring of scalars.

With tuples $J\in\mathbb{N}^n$ of $n\in\mathbb{N}$ numbers representing particles one associates the following products of delta distributions:

$$\delta^{\Pi J}\equiv\prod\delta^{\otimes J}:=\begin{cases}\prod_{i<n}\delta(x_{J_{i+1}}-x_{J_i}) & \text{if } J\in\mathbb{N}^n_{\neq},\\ 0, & \text{otherwise.}\end{cases}\tag{32}$$

Generated by these distributions and its derivatives, one obtains an algebra of localizing scalars,

$$\mathbb{L}:=\mathbb{C}\oplus\mathbb{C}\langle\{\partial^\beta\delta^K|\beta\in\mathbb{N}^2,K\in\mathbb{N}^2_{\neq}\},+,\cdot\rangle/(\delta^K\cdot\partial^\beta\delta^K,\delta^K-\delta^{\tilde{K}}),\tag{33}$$

i.e., having excluded multiple occurances of $\delta^{\Pi J}$, even with respect to permuations of its indices, and added the unity. The localized quantum field operators $\phi^{\mathsf{L}J}:=\delta^{\Pi J}\phi^{\mathsf{N}J}$ are introduced as a $\mathbb{C}$-submodule,

$$\mathcal{L}:=\bigoplus_{J\in\mathbb{N}^n_{\neq},n\geqslant 0}\mathbb{C}\{\phi^{\mathsf{L}J}|\phi^j\in\mathcal{F}_{\mathrm{p}},\forall j\in J\},\tag{34}$$

of $\mathbb{L}\otimes\mathcal{N}=:\mathcal{N}_{\mathbb{L}}$ equipped with an (associative and distributive) product, $\mathsf{L}:\phi^{\mathsf{L}J}\otimes\phi^{\mathsf{L}K}\mapsto\phi^{\mathsf{L}(J\otimes K)}$, which varies from the one that is naturally given on $\mathcal{N}_{\mathbb{L}}$ i.e., $\Pi\otimes\mathsf{N}\circ(\mathrm{id}\otimes\tau\otimes\mathrm{id})=:\mathsf{N}$, where $\tau:J\otimes K\mapsto K\otimes J$ denotes the flip operation. The latter two spaces as well carry the all over announced stucture.

Theorem 2.5: $(\mathcal{N}_{\mathbb{L}},\mathbb{L},+,\mathsf{N},\eta,\Delta,\varepsilon,\mathrm{S})$ *and its substructure* $(\mathcal{L},\mathbb{C},+,\mathsf{L},\eta,\Delta,\varepsilon,\mathrm{S})$ *form graded [co]commutative HAs over the ring* $\mathbb{L}$ *and, respectively, the field* $\mathbb{C}$.

Proof: Except for the explained modifications, this is again the content of Theorem 2.4. □

C. Interaction

Utilizing EG's language of distributions, interaction of quantum fields naturally implements the concept of classical background fields. The Hamiltonian modeling local interaction is formed by the adiabatic limit of coupled localized field operators. The presentation concludes this preliminary section. Throughout the paper, only polynomial interaction is considered, leading to the well-known identification of graphs as applied to the EG approach in the two subsequent sections.

1. Monomial couplings and the adiabatic limit

In the considered physical setup the coupling Σ_b is given by a monomial in $\mathcal{L}$. Let $M\in\mathbb{N}^m_{\neq}$ symbolize a tuple of $m\in\mathbb{N}$ particles. Then

$$\Sigma_b(\phi^{\mathsf{L}M})=\sum_{\bar{\mu}\in M}\sum_{|\alpha|\leqslant\omega_b}b^{\alpha,\bar{\mu}}(\partial^\alpha\delta^{\Pi\bar{\mu}})\phi^{\mathsf{N}\bar{\mu}}\tag{35}$$

formalizes a coupling monomial, b labels the associated coupling coefficients $b^{\alpha,\bar{\mu}}\in\mathbb{C}$ where α serves as a suitable multi-index, and $\omega_b\geqslant 0$ denotes the order of singularity. Spelled out explicitly, $\Sigma_b\phi^{\mathsf{L}M}\equiv\Sigma_b\varphi^{\mathsf{L}M}(x)$ formally depends on m space–time variables $x\equiv(x_1,\ldots,x_m)\in\mathbb{R}^{(1+\mathrm{d})\times m}$, even though (because of the localization which uses delta distributions) only one of them is independent.

The adiabatic limit replaces those m variables by a single one, i.e.,

$$\mathsf{A}_{x_i}\Sigma_b\phi^{\mathsf{L}M}:=\lim_{\tau\to 1}\langle\Sigma_b\varphi^{\mathsf{L}M}(x),\tau(x_1,\ldots,x_{i-1},x_{i+1},\ldots,x_m)\rangle_{m-1}\tag{36}$$

$$=\langle \Sigma_b \varphi^{\mathsf{L}M}(\ldots,x_i,\ldots),1(x_1,\ldots,x_{i-1},x_{i+1},\ldots,x_m)\rangle_{m-1}, \tag{37}$$

where, as well as in general, $\langle t(x),\tau(x)\rangle_m := \int_{\mathbb{R}^{(1+\mathrm{d})\times m}} t(x)\tau(x)\mathrm{d}x_1\cdots\mathrm{d}x_m$ denotes the distributions' dual bracket and $1(x)$ symbolizes an arbitrary test function in $\mathcal{D}^{\otimes}_{\mathrm{p}_M} := \bigotimes_{i\leqslant m}\mathcal{D}_{\mathrm{p}_{M_i}}$ with value "1" in a neighborhood of the origin $x=0\in\mathbb{R}^{(1+\mathrm{d})\times m}$. Of course, one may introduce another variable $x_\bullet\in\mathbb{R}^{1+\mathrm{d}}$. Then

$$\mathsf{A}_{x_\bullet}\Sigma_b\phi^{\mathsf{L}M} = \delta(x_\bullet) * \mathsf{A}_{x_1}\Sigma_b\phi^{\mathsf{L}M} = \langle \delta(x_\bullet - x_1)\Sigma_b\varphi^{\mathsf{L}M}(x), 1^{\Pi M}(x)\rangle_m, \tag{38}$$

which yields the prototype of a so-called interaction Hamiltonian.

In the algebraic context of normalization and localization the composition of monomial couplings and adiabatic limits is quite straightforward. For any $i\leqslant n$, let $\overline{M_i}\in\mathbb{N}^{m_i}_{\neq}$ denote an $m_i\in\mathbb{N}$ tuple of particles and b_i the associated coupling of order $\overline{\omega_{b_i}}$. Furthermore, form tuples of the latter objects and let $y\in\mathbb{R}^{(1+\mathrm{d})\times n}$. Then

$$\mathsf{N}_{i\leqslant n}\mathsf{A}_{y_i}\Sigma_{b_i}\phi^{\mathsf{L}\overline{M_i}} = \mathsf{A}_y^{\otimes\overline{M}}\Sigma_{\Pi b}\phi^{\mathsf{N}\circ\mathsf{L}\overline{M}}, \tag{39}$$

where $\mathsf{A}_y^{\otimes\overline{M}} = \mathsf{A}_{y_1}^{\overline{M_1}}\cdots\mathsf{A}_{y_n}^{\overline{M_n}}$ specifies the application of the adiabatic limit (in the obvious way) and

$$\Sigma_{\Pi b}\phi^{\mathsf{N}\circ\mathsf{L}\overline{M}} = \sum_{\hat{\mu}\in\overline{M}}\sum_{|\overline{\alpha}|\leqslant\overline{\omega}_b}\prod_{i\leqslant n} b_i^{\overline{\alpha}_i,\hat{\mu}_i}(\partial^{\Pi\overline{\alpha}}\delta^{\Pi^2\hat{\mu}})\phi^{\mathsf{N}^{\circ 2}\hat{\mu}}. \tag{40}$$

2. Physical supplements

To make a coupling monomial a physical magnitude it might be supplemented by another coupling constant, and to get a reasonable physical theory some of those prototype Hamiltonians with vanishing order of singularity might be additively combined.

Moreover, the concrete physical model, fixed by the interaction Hamiltonian, contains classical background fields that are given by scalar (e.g., real or Grassmann) valued test functions $\tau_p\in\mathcal{D}_p$, supposed to smear the operator valued distributions. Those are nonquantized fields that, in order to be equipped with the required indices, are as well labeled by particles $p\in\mathrm{C}\equiv\mathrm{P}\setminus\mathrm{Q}$, referred to as virtual ones. The particles considered so far are renamed $\mathrm{Q}\subseteq\mathrm{P}$. Notice that virtual particles $p\neq(\emptyset)\in\mathrm{C}$, if not just representing a nonindexed real valued test function $\tau_{(\emptyset)}$, may also have to follow nontrivial statistics.

Let the disjoint union $\mathcal{I}=\mathcal{C}\dot{\cup}\mathcal{Q}\subset\mathcal{P}(\mathbb{N})$ denote a system of subsets of basic indices, i.e., $\{c_j\}\in\mathcal{C}$ and $\mathcal{Q}_j\in\mathcal{Q}$ where $j\leqslant m\in\mathbb{N}$, which is supposed to specify virtual particles $p_j=\mathrm{p}_{c_j}\in\mathrm{C}$, that label associated couplings a_{p_j}, b_{p_j}, as well as tuples of particles $Q_j=(\mathrm{p}_i)_{i\in\mathcal{Q}_j}\subset\mathrm{Q}$ and their coordinates, x_{c_j} and $x_{Q_j}=(x_i)_{i\in\mathcal{Q}_j}$. Then the smeared abstract interaction Hamiltonian reads

$$H_{\mathcal{I}}(\tau^{\oplus\mathcal{C}}) = \sum_{j\leqslant m} a_{p_j}\left\langle \mathsf{A}_{x_{c_j}}\left(\Sigma_{b_{p_j}}\varphi^{\mathsf{L}Q_j}(x_{Q_j})\right),\tau_{c_j}(x_{c_j})\right\rangle_1. \tag{41}$$

Example 2.6: Quantum electrodynamics (QED) in an external electromagnetic field is, using the conventional notions (e.g., $\overline{\psi}$, ψ for the spinorial positron and electron, A^{cl}, A for the classical and quantized electromagnetic field, all equipped with localized space–time indices, and colons for the normal product), described by the interaction Hamiltonian, $(e/i\hbar)\,{:}\overline{\psi}(x)\gamma^\mu\psi(x){:}\,(A_\mu(x)+A^{\mathrm{cl}}_\mu(x))$. Therefore, one must identify $a=e/i\hbar$, $c=\gamma$, and $\varphi\in\{\overline{\psi},\psi,A\}$. The two sorts of test functions are real and Grassmann valued, i.e., $\tau\in\{\tau_{(\emptyset)},A^{\mathrm{cl}}\}$.

III. PERTURBATIVE EXPANSION

Underlying the expansion of the *S*-matrix, there is a HA whose antipode condition represents the property of pseudounitarity, cf. Fig. 1. This result will be achieved at the end of the section

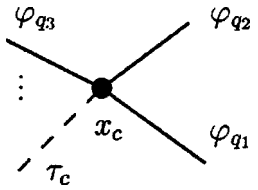

FIG. 2. A vertex.

having constructed an algebra of operator-valued distributions modeling Wick-expansion without explicit implementation of causality enriched by a graded shuffling coalgebra and an antipode given by Schmitt's formula.

A. The concept of graphs

In addition to vertex tuples and rather unusual for the EG approach, graphs and their GTS versions are chosen as indices for the *n*-point distributions, constructed to provide a direct correspondence with the configuration space variables that determine the support of the latter.

1. Vertices and graphs

The elements of the index set $\mathcal{I}$ in Sec. II C 2, and correspondingly the prototype interaction Hamiltonians, are interpreted as vertices, cf. Fig. 2.

Starting from an initial set U of vertices, the perturbative expansion leads to objects that can be interpreted as graphs $\mathrm{G_U}=\mathcal{G}(\mathrm{U})$ formed by these vertices. Renormalization then allows, by forgetting about the inner graph structure, to reinterpret graphs as vertices, i.e., $\Omega:\mathrm{G_U}\to\mathrm{W}$, which produces new vertices in $\mathrm{W}\backslash\mathrm{U}$. With all these vertices one as well forms graphs in $\mathrm{G_W}=\mathcal{G}(\mathrm{W})$ that can again be *shrunken* to vertices via the map $\Omega:\mathrm{G_W}\to\mathrm{W}$. This rough description of the vertex-generating induction, illustrated in Fig. 3, must be supplemented by the remark that physical conditions such as symmetries, discussed in Sec. IV B 2, restrict the number of physically relevant vertices, to $\mathrm{V}\subseteq\mathrm{W}$ say.

Formally, the pairs $v\equiv(P,b)\in Q^n\times\mathbb{C}^{|\mathcal{P}_n(\omega_b)|\times\Pi|P|}$ of particle tuples $P=\mathrm{P}(v)$ and coupling coefficients $b=\mathrm{b}(v)$, where $\mathcal{P}_n(\omega_b)=\{\alpha\in\mathbb{N}^n\,|\,\Sigma_{i\leqslant n}\alpha_i\equiv|\alpha|\leqslant\omega_b\}$ and $n\equiv|P|$, are supposed to define vertices $v\in\{\mathrm{U},\mathrm{V},\mathrm{W}\}$. Graphs are defined as pairs $\Gamma\equiv(\overline{v},l)$ of a vertex tuple $\overline{v}=\mathrm{V}(\Gamma)$ and a $|\overline{v}|\times|\overline{v}|$ matrix $l=\mathrm{l}(\Gamma)$ of (sets of internal) lines $l_{rs}\subseteq\{(i,j)\in\mathbb{N}_{|\overline{p}|}\times\mathbb{N}_{|\overline{q}|}\,|\,\gamma_{\overline{p_iq_j}}\neq0,\overline{p}\equiv\overline{v_r},\overline{q}\equiv\overline{v_s}\}$ that form a collection of index pairs representing two matching particles where so-called tadpoles are excluded, i.e., $l_{rr}=\emptyset$.

Keeping the notations, the iterated tuple $\mathrm{I}(\Gamma)\equiv(I_r)_{r\leqslant|\overline{v}|}$ of particles that support the internal lines of a graph Γ, referred to as representing the internal half-lines, can be reobtained by $I_r=(\mathrm{P}_i(\overline{v_r}))_{i\in\mathrm{l}_r}$ where $\mathrm{l}_r=\{\mathrm{pr}_1\,\lambda\,|\,\lambda\in l_{rs},s\leqslant|\overline{v}|\}$. Hence, the tuple $\mathrm{E}(\Gamma)\equiv(E_r)_{r\leqslant|\overline{v}|}$ representing the external half-lines is given by $E_r=(\mathrm{P}_i(\overline{v_r}))_{i\in\overline{\mathrm{l}_r}}$, where $\overline{\mathrm{l}_r}=\mathbb{N}_{|\mathrm{P}(\overline{v_r})|}\backslash\mathrm{l}_r$.

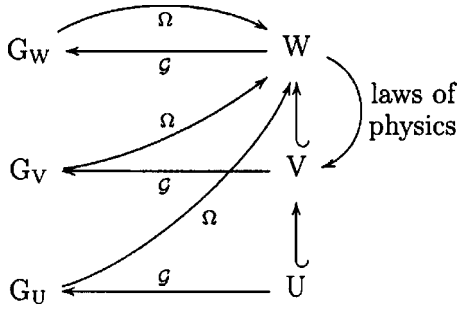

FIG. 3. Generation of graphs and of (new) vertices.

In order to introduce graph related cardinalities Euler's formula is stated, i.e.,

$$|\Gamma| = \#\Gamma - |l| + |\overline{v}|, \quad \text{where} \quad \begin{cases} |\Gamma| \\ \#\Gamma \text{ denotes the} \\ |l| \text{ number of} \\ |\overline{v}| \end{cases} \quad \begin{cases} \text{connected components,} \\ \text{independent loops,} \\ \text{(internal) lines,} \\ \text{vertices.} \end{cases} \tag{42}$$

The number of lines can be obtained by $|l| = \Sigma_{r<s\leqslant|\overline{v}|}|l_{rs}|$.

The map p which identifies particles p_i via basic indices $i \in I \subset \mathbb{N}$ and thus provides a correspondence with space–time variables $x_i \in \mathbb{R}^{1+\mathrm{d}}$ can consistently be extended to identify vertex tuples and associated classes of graphs as well. One must only consider a bigger system $\mathcal{J} := \mathcal{C} \dot{\cup} \mathcal{Q} \subseteq \mathcal{P}(\mathbb{N})$ of subsets of indices than $\mathcal{I}$ in Sec. II C 2, i.e., $c_J := \dot{\cup}_{j\in J}\{c_j\}$ and $Q_J := \dot{\cup}_{j\in J} Q_j$ satisfying $c_J \cap c_K = \emptyset$ and $Q_J \cap Q_K = \emptyset$, for $J, K \in \mathcal{P}(\mathbb{N})$.

Lemma 3.1: *There are a system* $\mathcal{J}$ *and a surjective map* $\mathrm{p}: \mathbb{N} \to \mathrm{P}$,

$$n \mapsto \begin{cases} \mathrm{p}^{\mathrm{C}}_n \in \mathrm{C} \\ \mathrm{p}^{\mathrm{Q}}_n \in \mathrm{Q} \end{cases} \quad \textit{if } n \in \begin{cases} \mathbb{N}_{\mathrm{C}}, \\ \mathbb{N}_{\mathrm{Q}}, \end{cases} \quad \textit{where } \mathbb{N}_{\mathrm{C}} \cap \mathbb{N}_{\mathrm{Q}} = \emptyset, \quad \textit{such that}$$

$(\forall \overline{v} \in \cup_{n\geqslant 0} W^n)(\exists J \in \mathbb{N}^n_{\neq})(\forall j \in J)(\mathrm{b}(\overline{v_j}) = b_{\mathrm{p}^{\mathrm{C}}(c_j)} \wedge \mathrm{P}(\overline{v_j}) = (\mathrm{p}^{\mathrm{Q}}(i))_{i\in Q_j})$.

Proof: Decompose the operation of forming graphs, i.e., $\mathcal{G} = \cup_{n\leqslant 0}\mathcal{G}_n$, so that $\mathcal{G}_n : \mathcal{P}(W) \to \mathcal{P}(\mathrm{G_W})$, $\mathrm{W}_k \mapsto \mathcal{G}_n(\mathrm{W}_k)$ yields graphs Γ with $n = |\mathrm{V}(\Gamma)|$ vertices, $\mathrm{V}(\Gamma) \in \mathrm{W}_k^{\times n}$. Then the existence of $\mathcal{J}$ and p is guaranteed by the inductive construction of $\mathrm{W} = \cup_{k>1}\mathrm{W}_k$, and thus $\mathrm{G_W} = \cup_{\mathrm{n}\geqslant 1}\mathcal{G}_{\mathrm{n}}(\mathrm{W_n})$, from finite sets $\mathrm{W}_{k+1} = \{\Omega(\Gamma) \in \mathrm{W} \,|\, \Gamma \in \mathcal{G}_k(\mathrm{W}_k)\}$ starting with $\mathrm{W}_1 = \mathrm{U}$. □

Consequently, p^{C} realizes the announced correspondence. As vertices of tuples $\overline{v}$ or of graphs $\Gamma \equiv (\overline{v}, l)$ are now associated with virtual particles, $\overline{v_j} = \Gamma_j \sim \mathrm{p}^{\mathrm{C}}_i$, the former are associated with space–time variables x_i as well, i.e.,

$$x_\cdot : \overline{v_j} \mapsto x_{v_j} := x_i \quad \text{and} \quad \Gamma_j \mapsto x_{\Gamma_j} := x_i, \text{ respectively.} \tag{43}$$

This will be essential to incorporate causality, cf. Sec. IV.

2. Algebras of graphs

For the algebraic considerations graphs are always assumed to form a complex vector space which respects the $\mathbb{N}$-grading corresponding to the number of vertices, i.e., $(\mathrm{G_V}, \mathbb{C}, +)$ where $\mathrm{G_V} = \oplus_{n\geqslant 0}\mathbb{C}\mathcal{G}_n(\mathrm{V})$.

Let $\Gamma^i \equiv (\overline{v^i}, l^i)$, for $i \leqslant 2$, denote two graphs. Then there are $|\overline{v^1}| \times |\overline{v^2}|$ matrices $l^{12} \in \mathbb{M}_{|\overline{v^1}|\times|\overline{v^2}|}(\mathcal{P}(\mathbb{N}^{\times 2}))$ yielding a new graph by combining the former (cf. Example B.1), i.e.,

$$\Gamma^1 \sqcup_{l^{12}} \Gamma^2 := \left(\overline{v^1} \otimes \overline{v^2}, \begin{pmatrix} l^1 & l^{12} \\ \widetilde{l}^{\,12} & l^2 \end{pmatrix} \right), \tag{44}$$

so that the required symmetry, $l_{rs} = \widetilde{l}_{sr} := \{(\mathrm{pr}_2\lambda, \mathrm{pr}_1\lambda) \,|\, \lambda \in l_{sr}\}$, is realized. The admissible ones, i.e., $l^{12} \in 1(\Gamma^1, \Gamma^2)$, are called concatenation matrices. In contrast to the matrices of lines, $l^{12} = \Sigma_{r\leqslant|\overline{v^1}|, s\leqslant|\overline{v^2}|}|l^{12}_{rs}|$.

The previous composition defines the Wick product of graphs, i.e., $\sqcup_\Sigma = \Sigma_{l^{12}\in 1(\cdot,\cdot)} \circ \sqcup_{l^{12}}$. Respectively, by linear extension one considers GTS versions of graphs, $\sqcup\Gamma := (1/n!)\Sigma_{\pi\in S_n}\sigma(\pi)\pi(\Gamma) \in \oplus_{n\geqslant 0} S^\sigma_n \mathbb{C}\mathcal{G}_n(\mathrm{V}) =: \mathrm{G}^\sigma_{\mathrm{V}}$, where the permutation $\pi(\Gamma) := (\pi(\overline{v}), \pi(l))$ acts on the vertex tuple as well as on the matrix of lines, i.e., $\pi(\overline{v}) := (\overline{v}_{\pi(r)})_{r\leqslant n}$ and $\pi(l) := (l_{\pi(r)\pi(s)})_{r,s\leqslant n}$, and the grading is reduced to the graph's vertex tuple, i.e., $\sigma_\Gamma(\pi(\Gamma)) := \sigma_{\mathrm{V}(\Gamma)}(V \circ \pi(\Gamma))$, discussed right below in Sec. III B 1.

Lemma 3.2: $(\mathrm{G}^{[\sigma]}_{\mathrm{V}}, \mathbb{C}, +, \sqcup_\Sigma, \emptyset)$ *forms an algebra [in both cases] where the empty graph serves as unity.*

Proof: Compare Sec. 3.2.2 in Ref. 24, pp. 75ff. □

Associativity can be illustrated introducing the inverse concept of concatenation, i.e., separation into subgraphs that, with respect to the reference graph, are completely determined by their vertices. Let $(\Gamma^1,\ldots,\Gamma^k)\in\mathcal{P}_k^{(0)}(\Gamma)$ denote a k-partition (with possibly empty subgraphs, respectively) of the graph $\Gamma\in \mathrm{G}_{\mathrm{V}}^{[\sigma]}$ iff there are a permutation $\pi\in S_k$ and appropriate concatenation matrices, $l^1,\ldots,l^{k-1}$, such that $\pi(\Gamma)=\Gamma^1\sqcup_{l^1}(\cdots\sqcup_{l^{k-1}}\Gamma^k)\cdots)$ [appropriately extended, respectively].

Let $\Gamma\in \mathrm{G}_{\mathrm{V}}^{(\sigma)}$. Then $\mathrm{G}_{\Gamma}^{[\sigma]}:=\mathcal{P}(\Gamma)=\{\Gamma'\,|\,(\Gamma',\ldots)\in\mathcal{P}_2^0(\Gamma)\}\subset \mathrm{G}_{\mathrm{V}}^{[\sigma]}$ denotes the power set which contains all subgraphs of Γ. Graphs in $\mathrm{G}_{\mathrm{V}}^{[\sigma]}$ can be composed as Γ-restricted graphs, i.e., via $\sqcup_\Gamma=(\sigma_\Gamma^0\circ\sqcup_\Sigma)\sqcup_\Sigma$, where

$$\sigma_\Gamma^0:\mathrm{G}_{\mathrm{V}}^{[\sigma]}\to\{-1,0,1\},\quad \Gamma'\mapsto\begin{cases}\sigma_\Gamma(\Gamma') & \text{if } \Gamma'\in G_\Gamma^{[\sigma]},\\ 0 & \text{otherwise,}\end{cases}\tag{45}$$

and $\sigma_\Gamma(\Gamma')=\sigma_{\Gamma'}(\Gamma)\equiv\sigma(\pi)$, regarding $\pi:\Gamma'\mapsto\Gamma$ as a permutation in $S_{|\mathrm{V}(\Gamma')|}$.

Proposition 3.3: $(\mathrm{G}_{\mathrm{V}}^{[\sigma]},\mathbb{C},+,\sqcup_\Gamma,\emptyset)$ *forms an algebra, and* $(\mathrm{G}_\Gamma^{[\sigma]},\ldots)$ *identifies its largest zero divisor free subalgebra* $(\mathrm{G}_{\Gamma'}^{\sigma},\ldots)$, $\Gamma'\in\mathrm{G}_{\mathrm{V}}^{[\sigma]}$.

Proof: Associativity of $\sqcup_\Sigma$ implies associativity of $\sqcup_\Gamma$. The other statements required are rather obvious, cf. Ref. 24, Sec. 3.2.2. □

B. The expansion of the *S*-matrix

In the EG approach the S-matrix is expanded in terms of operator-valued GTS n-point distributions. In contrast to the conventional approach, Wick and time ordering are not mixed. This allows to construct analytically well-defined algebras (relevant for the distribution's scalar parts) ensured alone by the presumed physical properties, i.e., TI and the spectral condition.

1. Infrared regularization, the ansatz, and GTS

The S-matrix is supposed to depend on coupling constants a_p and normalized test functions $\tau_p\in\mathcal{D}_p$ [i.e., $\tau_p(0)=1$] that, representing external classical fields $p\in\mathrm{C}$, serve as an infrared regularization. To obtain concrete physical quantities, the following adiabatic limit must be taken:

$$S\big((a\tau)_C^{\oplus}\big)=\lim_{\epsilon\to0}S\big((a\tau_\epsilon)_C^{\oplus}\big),\quad \forall\,\tau:\tau\circ\epsilon\equiv\tau_\epsilon\xrightarrow{L^\infty(K)}{}_{\epsilon\to0}1,\quad \forall\,K\Subset\mathbb{R}^{1+\mathrm{d}}.\tag{46}$$

This task, however, will not be regarded in this paper. Notice, as the vertices in V correspond to the set $\mathcal{C}$ in Sec. II C 2, which specifies the virtual particles $\mathrm{C}=\{\mathrm{p}_i\,|\,i\in\mathcal{C}\}$, the former are used as indices as well.

The expansion of the S-matrix is given with respect to a renormalization scheme $\mathcal{R}$ (only discussed in Sec. IV B) and the (somehow related) set V of vertices. The ansatz, chosen in accordance with the original ones of Bogoliubov and Shirkov (BS),[30] EG, and Scharf,[31] reflects the Dyson series (cf. Example B.2), i.e.,

$$S_{\mathrm{V}}^{\mathcal{R}}\big((a\tau)^{\oplus\mathrm{V}}\big)=\sum_{n\geqslant0}\frac{1}{n!}\sum_{\overline{v}\in\mathrm{V}^n}a^{\Pi\overline{v}}\Big\langle T_{\overline{v}}^{\mathcal{R}}(y),\tau^{\sqcap\overline{v}}(y)\Big\rangle_n,\tag{47}$$

where $T_{\overline{v}}\in C(S'_{|\overline{v}|}\mathcal{D}_{\overline{v}}^{\otimes},\mathcal{H}_{\mathrm{P}}^{\mathrm{F}})$ are operator-valued n-point distributions, i.e., strongly continuous mappings, indexed by vertices. The interaction Hamiltonian prototypes can be reidentified as $H_p=i\hbar a_pT_{(p)}$.

The vertex distributions are assumed to be GTS, i.e., $T_{\overline{v}}=\sigma(\pi)T_{\pi(\overline{v})}\circ\pi$, $\forall\pi\in S_n$. Here, σ symbolizes the grading on vertex tuples, given again by (24), but $\pi|_p:\overline{v}|_p\mapsto\pi(\overline{v}|_p)$ denotes a subpermutation of π defined on $\overline{v}|_p=(\overline{v_k})_{k'\mathrm{odd}}$, where $k'=\Sigma_{q\in A'(p)}1_{q=v_i\wedge v=\overline{v_k}}$ (cf. Ref. 24, p. 45). This is again a representation of $\mathcal{S}_n$ on $\mathbb{Z}_2$; and one also writes $\sigma_U(V):=\sigma(U\mapsto V)$, for vertex tuples $U,V\in\mathbb{N}_{\neq}^n$.

Lemma 3.4: *The two definitions of* σ *are consistent, i.e.,* $\sigma_U(V)=\sigma_{[U]}([V])$ *where, only here,*

$[\cdot]$ *symbolizes the formal transfer from a vertex tuple into a particle tuple by simply omitting brackets and couplings.*

Proof: Compare Lemma 2.1.7 in Ref. 24, p. 45. □

Of course, the test functions associated with vertex tuples are GTS as well, $\tau^{\sqcap\overline{v}} \equiv \tau^{\sqcap\overline{c}} := S_n^\sigma \tau^{\otimes\overline{c}} \in S_n^\sigma \mathcal{D}_{\overline{c}}^{\otimes} \equiv S_n^\sigma \mathcal{D}_{\overline{v}}^{\otimes}$, where $\overline{c} \in \mathrm{C}_{\neq}^n$ denotes the corresponding tuple of virtual particles. Again, the definitions are consistent.

Lemma 3.5: $\sigma_{\overline{v}}(\pi(\overline{v})) = \sigma_{\overline{c}}(\pi(\overline{c}))$, $\forall \pi \in \mathcal{S}_n$.

Proof: Applying the permutation π to both sides of the dual brackets in (47), this results in $\sigma_{\overline{v}}(\pi(\overline{v}))\sigma_{\overline{c}}(\pi(\overline{c})) = 1$. Therefore, the statement is due to the fact that $\sigma(\pi) \in \{\pm 1\}$. □

2. Algebras of n-point distributions

Founded on Wick's theorem, referring to the expansion rule of normal products with respect to the composition product (also regarded as twist or Cliffordization), one constructs an algebra of graph distributions over a carefully chosen ring of TI scalar distributions. Those TI distributions $t^J \in \mathcal{S}'(\mathbb{R}^{(1+\mathrm{d})\times n})$, $J \in \mathbb{N}_{\neq}^n$, i.e.,

$$t^J \equiv t_J(\tau) = t_J(\tau(\cdot - z^{\times n})), \quad \forall\, \tau \in \mathcal{S}(\mathbb{R}^{(1+\mathrm{d})\times n}), \quad \forall\, z \in \mathbb{R}^{1+\mathrm{d}}, \tag{48}$$

are supposed to form an $\mathbb{N}$-graded algebra with respect to the direct product,

$$\mathbb{T} := \mathbb{C} \oplus \mathbb{C}\langle\{t^K | K \in \mathbb{N}_{\neq}^n, n \in \mathbb{N}\}, +, \cdot\rangle / (t^{(\ldots,k,\ldots)} \cdot t^{(\ldots,k,\ldots)}), \tag{49}$$

covering the (algebra of) localizing scalars $\mathbb{L}$ as well as the positive frequency part propagators with derivatives $\Delta_+^J \equiv \Delta_{\mathrm{p}_{J_1}}^{+\gamma}(x_{J_1} - x_{J_2})$, i.e.,

$$\mathbb{P} := \mathbb{C} \oplus \mathbb{C}\langle\{\partial^\beta \Delta_+^K | \beta \in \mathbb{N}^2, K \in \mathbb{N}_{\neq}^2, \gamma_K \neq 0\}, +, \cdot\rangle / (\tilde{\Delta_+^K} \cdot \partial^\beta \Delta_+^K), \tag{50}$$

that, with respect to the Fourier product and in accordance with the spectral condition (cf. end of Sec. II A 1), form an algebra as well. Notice, $\mathbb{L}$ and $\mathbb{P}$ are ideals in $\mathbb{T}$. Combining the two previously defined algebras, one gets another commutative algebra,

$$\mathbb{T}_{\mathrm{P}} := \mathbb{T} \otimes \mathbb{P} / (t \otimes p - p \otimes t, \cdots \underbrace{t^{(\ldots,K_{1|2},\ldots,K_{2|1},\ldots)}}_{\neq t^{(\ldots,K_{1|2},\ldots)} t^{(\ldots,K_{1|2},\ldots)}} \otimes \cdots \Delta_+^K) \tag{51}$$

which, on the level of distributions, encodes the Fourier and the direct product, and additionally, the well-defined product of distributions with continuous functions. Including localization, the related commutative algebra $(\mathbb{T}_{\mathrm{PL}}, \mathbb{C}, +, \cdot, 1)$ is given by

$$\mathbb{T}_{\mathrm{PL}} := \mathbb{T}_{\mathrm{P}} \otimes \mathbb{L} / (t \otimes l - l \otimes t, \cdots \underbrace{t^{(\ldots,K_{1|2},\ldots,K_{2|1},\ldots)}}_{\text{irreducible in } \mathbb{T}_{\mathrm{P}}} \otimes \cdots \delta^K - \cdots \otimes \cdots \delta^K). \tag{52}$$

Again, the substructures are ideals, i.e., $\mathbb{T}_{\mathrm{PL}} \subset \mathbb{T}_{\mathrm{P}} \subset \mathbb{T}$. Similar to Sec. II B 2, those algebras will mainly be applied as rings.

Turning to the operator side, let $\mathcal{T}_{\mathrm{V}} := \oplus_{n\geqslant 0} \cup \{\mathcal{T}_\Gamma | \Gamma \in \mathrm{G}_{\mathrm{V}}, |\mathrm{V}(\Gamma)| = n\}$ be the $\mathbb{N}$-graded space of graph-indexed n-point distributions

$$\mathcal{T}_\Gamma = \{\Sigma_{\mathrm{b}(\Omega\Gamma)} t_{\mathrm{I}(\Gamma)}(\bullet) \mathsf{A}_\bullet^{\otimes \mathrm{V}(\Gamma)} \phi^{\mathrm{N}\circ\mathrm{LE}(\Gamma)} \in \mathcal{C}(S_n^\sigma \mathcal{D}_{\mathrm{V}(\Gamma)}^{\otimes}, \mathcal{H}_{\mathrm{P}}^{\mathrm{F}}) | t_{\mathrm{I}(\Gamma)} \in \mathbb{T}\}, \tag{53}$$

where, in terms of the couplings at the vertices of $\mathrm{V}(\Gamma)$, the coupling at the vertex $\Omega\Gamma$ reads

$$\mathrm{b}(\Omega\Gamma) = \prod_{r<s\leqslant n} \prod_{(i,j)\in \mathrm{l}_{rs}(\Gamma)} \sum_{\substack{\mu \\ [\![\mu]\!]\in P_{ri}}} \sum_{\substack{\nu \\ [\![\nu]\!]\in P_{sj}}} \prod_{k\leqslant n} b_{\mathrm{V}_k(\Gamma)}^{\alpha_k, P_k}. \tag{54}$$

Then $\mathcal{T}_{\mathrm{V}}$ is obviously a submodule of $\mathbb{T}_{\mathrm{PL}} \otimes \mathcal{N}$, and it is algebraically closed with respect to the composition product.

Proposition 3.6: $(\mathcal{T}_{\mathrm{V}}, \mathbb{T}_{\mathrm{PL}}, +, \circ, \eta)$ *forms an algebra*.

Proof: This is the content of Proposition 3.3.2 in Ref. 24, p. 85, which in the presented approach serves as the alternative to EG's Theorem 0 in Ref. 2, p. 229. In order to illustrate the crucial points, let $T^i \in \mathcal{T}_{\Gamma^i}$ with scalars $t^i \equiv t_{\mathrm{I}(\Gamma^i)} \in \mathbb{T}$, for $\Gamma^i \in \mathrm{G}_{\mathrm{V}}$ and $i \leqslant 2$, and use the abbreviation $N(\bullet) := \mathsf{A}^{\otimes \mathrm{V}(\bullet)}_{\chi^{\otimes}_{\mathrm{V}(\bullet)}} \phi^{\mathsf{N} \circ \mathrm{LE}(\bullet)}$. Then

$$T^1 \circ T^2 = \sum_{l \in 1(\Gamma^1, \Gamma^2)} (i\hbar)^{|l|} \Sigma_{\mathrm{b}(\Omega(\Gamma^1 \sqcup_l \Gamma^2))} t^l N(\Gamma^1 \sqcup_l \Gamma^2) \in \mathcal{T}_{\mathrm{V}}, \tag{55}$$

having a well-defined associated scalar distribution that is again TI, i.e.,

$$t^l(y^1 \otimes y^2) = t^1(y^1) t^2(y^2) \amalg^l_{(\Gamma^1, \Gamma^2)}(y^1, y^2) \in \mathbb{T}_{\mathrm{P}}. \tag{56}$$

The most rhs expression abbreviates a certain product of positive frequency propagators (also referred to as Wick contractions, cf. below),

$$\amalg^l_{(\Gamma^1, \Gamma^2)}(y^1, y^2) := \prod_{r \leqslant |P^1|, s \leqslant |P^2|} \prod_{(i,j) \in l_{rs}} \Delta^{P^1_{ri} P^2_{sj}}_{+\gamma}(y^1_r - y^2_s) \in \mathbb{P}, \tag{57}$$

which is well defined due to the spectral condition (16). Besides TI, for the analytical part, the proof of the algebraic part rests upon the following. □

Lemma 3.7: (Wick's theorem.) *Keeping the notations, then*

$$N(\Gamma^1) \circ N(\Gamma^2) = \sum_{l \in 1(\Gamma^1, \Gamma^2)} (i\hbar)^{|l|} \amalg^l_{(\Gamma^1, \Gamma^2)} N(\Gamma^1 \sqcup_l \Gamma^2). \tag{58}$$

Proof: On the level of free field operators, and provided $[\cdot, \cdot]^{\otimes}_{\sigma} \propto \mathrm{id}_{\mathcal{H}^{\mathrm{F}}_{\mathrm{P}}}$, the expansion reads

$$\phi^{\mathsf{N}I} \otimes \phi^{\mathsf{N}J} = \sum_{\Lambda \subseteq \mathbb{N}_{|I|} \times \mathbb{N}_{|J|}} \left(\prod_{\lambda \in \Lambda} [\phi^{I_{\lambda_1}}_-, \phi^{J_{\lambda_2}}_+]^{\otimes}_{\sigma} \right) \phi^{\mathsf{N}(I \otimes_\Lambda J)}, \tag{59}$$

where $I \otimes_\Lambda J = (I_i)_{i \in \mathbb{N}_{|I|} \setminus \{\lambda_1 | \lambda \in \Lambda\}} \otimes (J_i)_{i \in \mathbb{N}_{|J|} \setminus \{\lambda_2 | \lambda \in \Lambda\}}$, for tuples I, J. This is proven by successive insertion of Wick contractions,

$$\phi^i_- \otimes \phi^j_+ = [\phi^i_-, \phi^j_+]^{\otimes}_{\sigma} + \sigma_{(i,j)}((j,i)) \phi^j_+ \otimes \phi^i_-,$$

moving the ϕ^j_+'s to the left and the ϕ^i_-'s to the right. Due to (15), the brackets in (59) can be replaced by propagators. In accordance with the definition of $\mathbb{T}_{\mathrm{PL}}$, the localizing delta distribution's are supposed to dominate (i.e., erase) the propagators, which reduces (58) and (59). □

Remark 3.8: Associativity of the algebra, i.e., $N(\Gamma^1) \circ (N(\Gamma^2) \circ N(\Gamma^3)) = (N(\Gamma^1) \circ N(\Gamma^2)) \circ N(\Gamma^3)$, is equivalent to the 2-cocycle condition for $\amalg$, i.e., $\amalg_{(\Gamma^1, \Gamma^2 \sqcup_\Gamma \Gamma^3)} \amalg_{(\Gamma^2, \Gamma^3)} = \amalg_{(\Gamma^1, \Gamma^2)} \amalg_{(\Gamma^1 \sqcup_\Gamma \Gamma^2, \Gamma^3)}$, $\forall \Gamma^i \in \mathrm{G}_\Gamma$, $i \leqslant 3$, which is obviously fulfilled. In the context of Refs. 20 and 21, $\amalg_{(\cdot,\cdot)}$ is called a *Laplace pair* and the relation (58), regarded as a so-called *twist* (cf. Ref. 22), is understood as *Cliffordization*.

3. Graph and vertex distributions

In the present context the physically relevant solution of the perturbation expansion is assumed to be given—formally, without having introduced the essential concepts of their derivation yet, cf. Sec. IV.

Graph distributions $\mathcal{R}^{\mathsf{T}}_{\mathrm{G_V}} := \oplus_{n \geqslant 0} \mathbb{C}\{T^{\mathcal{R}}_\Gamma \,|\, \Gamma \in \mathrm{G_V}, |\mathrm{V}(\Gamma)| = n\}$, supposed to solve the perturbative expansion by respecting causality, are introduced via a vector space homomorphism,

$$T^{\mathcal{R}}_{\bullet}:\mathrm{G_V}\to T_\Gamma,\quad \Gamma\mapsto T^{\mathcal{R}}_\Gamma:=(i\hbar)^{\#\Gamma-|\Gamma|}\Sigma_{\mathrm{b}(\Omega\Gamma)}t^{\mathcal{R}}_{\mathrm{I}(\Gamma)}N(\Gamma), \tag{60}$$

fixing the associated scalar valued n-point distributions $t^{\mathcal{R}}_{\mathrm{I}(\Gamma)}\in S^{\sigma}_n\mathcal{D}^{\otimes}_{\mathrm{V}(\Gamma)}\subset\mathbb{T}$, that are supposed to be given with respect to a renormalization scheme $\mathcal{R}$, and via a GTS requirement,

$$T^{\mathcal{R}}_{\pi(\Gamma)}=\sigma(\pi)T^{\mathcal{R}}_\Gamma,\quad \forall\ \pi\in\mathcal{S}_{|\mathrm{V}(\Gamma)|} \tag{61}$$

(which can only be motivated in Sec. IV cf. Remark 4.17).

Remark 3.9: According to GTS, one may alternatively have introduced $T^{\mathcal{R}}_{\bullet}$ as a vector space isomorphism, $\mathrm{G}^{\sigma}_{\mathrm{V}}\to T_\Gamma$.

Lemma 3.10: *Let* Γ^1, Γ^2 *be independent, i.e.,* $\nexists c\in\mathbb{C}$ *s.t.* $\sqcap\Gamma^1=c\sqcap\Gamma^2$. *Then* $c_1T_{\Gamma^1}+c_2T_{\Gamma^2}=0$, $\forall c_1, c_2\in\mathbb{C}$, *implies that* $T^{\mathcal{R}}_{\Gamma^1}=T^{\mathcal{R}}_{\Gamma^2}=0$.

Proof: This is an immediate consequence of the previous remark. □

Defining the homomorphism $T^{\mathcal{R}}_{\bullet}$ only for graphs $\mathrm{G}_\Gamma\subset\mathrm{G_V}$, this leads to the vector space $\mathcal{R}^{\mathsf{T}}_{\mathrm{G}_\Gamma}$ of Γ-restricted graph distributions with a finite grading. On this space, a product is given by

$$\circ^{\mathsf{T}}_\Gamma:T^{\mathcal{R}}_{\Gamma^1}\otimes T^{\mathcal{R}}_{\Gamma^2}\mapsto T^{\mathcal{R}}_{\Gamma^1\sqcup_\Gamma\Gamma^2}. \tag{62}$$

Lemma 3.11: *Let* $\Gamma,\Gamma'\in\mathrm{G_V}$ *and* $*\in\{\mathrm{V},\Gamma'\}$. *Then* $(\mathcal{R}^{\mathsf{T}}_{\mathrm{G}_*},\mathbb{C},+,\circ^{\mathsf{T}}_\Gamma,\eta)$ *forms an algebra (which is free of zero divisors only if* $*\subseteq\Gamma$*).*

Proof: Obviously, $T^{\mathcal{R}}_{\bullet}:\mathrm{G}_*\to\mathcal{R}^{\mathsf{T}}_{\mathrm{G}_*}$ defines an algebra homomorphism. [Compare (45), if $\Gamma^1\not\subseteq\Gamma$ or $\Gamma^2\not\subseteq\Gamma$ then $T_{\Gamma^1}\circ^{\mathsf{T}}_\Gamma T_{\Gamma^2}\equiv T_{\Gamma^1\sqcup_\Gamma\Gamma^2}=T_0\equiv 0$.] □

Consider the following restrictions of the composition product obtained by redefining the right-hand side of (55):

$$T^1\circ T^2=:\sum_{l\in 1(\Gamma^1,\Gamma^2)}T^1\circ_l T^2=:\sum_{\Upsilon\in\mathrm{G_V},(\Gamma^1,\Gamma^2)\in\mathcal{P}^0_2(\Upsilon)}T^1\circ_\Upsilon T^2, \tag{63}$$

where $T^1\circ_l T^2=T^1\circ_\Upsilon T^2$ iff $\exists\pi\in\mathcal{S}_{|\Upsilon|}$ s.t. $l=(\mathbb{I}\ \emptyset)\cdot 1(\pi\circ\Upsilon)\cdot(\emptyset\ \mathbb{I})^t$. For any fixed graph $\Gamma\in\mathrm{G_V}$, this induces a Γ-restricted product on the TI distributions $\mathcal{T}_\mathrm{V}$, i.e., $\circ_\Gamma:\mathcal{T}_{\Gamma^1}\otimes\mathcal{T}_{\Gamma^2}\to\mathcal{T}_{\Gamma^1\sqcup_\Gamma\Gamma^2}$,

$$T^1\circ_\Gamma T^2:=\begin{cases}\sigma_\Upsilon(\Gamma)T^1\circ_\Upsilon T^2 & \text{if } \exists!\Upsilon\in\mathcal{P}(\Gamma)\text{s.t.}(\Gamma^1,\Gamma^2)\in\mathcal{P}^0_2(\Upsilon),\\ 0, & \text{otherwise}.\end{cases} \tag{64}$$

Then $\mathcal{R}_{\mathrm{G}_\Gamma}:=\oplus_{n\geqslant 0}\mathbb{C}\{\bigcirc_\Gamma\oplus_{i\leqslant r}T^{\mathcal{R}}_{\Gamma^i}|\Gamma^i\in\mathrm{G}_\Gamma,\Sigma_{i\leqslant r}|\mathrm{V}(\Gamma^i)|=n\}$ denotes the corresponding space of distributions defining a $\mathbb{C}$-submodule of $\mathcal{T}_\mathrm{V}$ and thus a $\mathbb{C}$-algebra, $(\mathcal{R}_{\mathrm{G}_\Gamma},\mathbb{C},+,\circ_\Gamma,\eta)$.

Remark 3.12: The consistency of the choice of the scalar $(i\hbar)^{\#\Gamma-|\Gamma|}$ in (60) can be checked with the help of Euler's formula (42), cf. Corollary 3.3.8 in Ref. 24, p. 90.

Now, the vertex distributions used in Ansatz (47) reappear as a sum over graph distributions,

$$T^{\mathcal{R}}_{\overline{v}}=\sum_{\Gamma\in\mathrm{G_V},\mathrm{V}(\Gamma)=\overline{v}}T^{\mathcal{R}}_\Gamma,\quad \forall\,\overline{v}\in\mathrm{V}, \tag{65}$$

so that the space of vertex distributions, $\mathcal{R}^{\mathsf{T}}_\mathrm{V}:=\oplus_{n\geqslant 0}\mathbb{C}\{T^{\mathcal{R}}_{\overline{v}}|\overline{v}\in\mathrm{V},|\overline{v}|=n\}$, can be introduced by restricting the homomorphism $T^{\mathcal{R}}_{\bullet}$ to be defined on the vector space of vertex tuples, i.e., $\oplus_{n\geqslant 0}\mathbb{C}\{\overline{v}\,||\overline{v}|=n\}\equiv\mathrm{V}\to\mathcal{T}_\mathrm{V}$, $\overline{v}\mapsto T^{\mathcal{R}}_{\overline{v}}$.

Lemma 3.13: *Let* $\circ^{\mathsf{T}}:T^{\mathcal{R}}_{\overline{v}^1}\otimes T^{\mathcal{R}}_{\overline{v}^2}\to T^{\mathcal{R}}_{\overline{v}^1\otimes\overline{v}^2}$. *Then* $(\mathcal{R}^{\mathsf{T}}_\mathrm{V},\mathbb{C},+,\circ^{\mathsf{T}},\eta)$ *forms an algebra.*

Proof: Obviously, $T^{\mathcal{R}}_{\bullet}:\mathrm{V}\to\mathcal{T}_\mathrm{V}$ defines an algebra homomorphism. □

Furthermore, $\mathcal{R}_\mathrm{V}:=\oplus_{n\geqslant 0}\mathbb{C}\{\bigcirc_{i\leqslant r}T^{\mathcal{R}}_{\overline{v}^i}|\overline{v^i}\in\mathrm{V},\Sigma_{i\leqslant r}|\overline{v^i}|=n\}$ denotes the space of vertex distributions which defines a $\mathbb{C}$-submodule of $\mathcal{T}_\mathrm{V}$ and thus a $\mathbb{C}$-algebra, $(\mathcal{R}_\mathrm{V},\mathbb{C},+,\circ,\eta)$.

4. HAs underlying pseudounitarity

The perturbative expansion can now be modeled by a HA. In accordance with the power series ansatz (47), let

$$\sum_{n\geqslant 0}\frac{1}{n!}\sum_{\overline{v}\in \mathrm{V}^n} a^{\Pi\overline{v}}\left\langle \widetilde{T}^{\mathcal{R}}_{\overline{v}}(y),\tau^{\sqcap\overline{v}}(y)\right\rangle_n := S^{\mathcal{R}}_{\mathrm{V}}\left((a\tau)^{\oplus \mathrm{V}}\right)^{-1}, \tag{66}$$

where the inverse n-point distributions $\widetilde{T}_{\overline{v}}\in C(S^{\sigma}_{|\overline{v}|}\mathcal{D}^{\otimes}_{\overline{v}},\mathcal{H}^{\mathrm{F}}_{\mathrm{p}})$, supposed to be GTS as well, are denoted by a tilde. Formally, the inverse of the S-matrix is characterized by the *relation of pseudounitarity*, i.e.,

$$S^{\mathcal{R}}_{\mathrm{V}}(\xi)^{-1}\circ S^{\mathcal{R}}_{\mathrm{V}}(\xi)=\mathrm{id}_{\mathcal{H}^{\mathrm{F}}_{\mathrm{p}}}=S^{\mathcal{R}}_{\mathrm{V}}(\xi)\circ S^{\mathcal{R}}_{\mathrm{V}}(\xi)^{-1},\quad \forall\ \xi\in\mathcal{D}^{\oplus}_{\mathrm{V}}(\mathbb{R}^{1+\mathrm{d}}). \tag{67}$$

Remark 3.14: The probabilistic interpretation of quantum theory is ensured by requiring unitarity. But, for gauge theories and their unphysical states, unitarity can only be pseudo (i.e., true on a subspace of the Fock space $\mathcal{H}^{\mathrm{F}}_{\mathrm{p}}$), i.e., $S(\xi)^{-1}=S(\xi)^{K}$, where K is a pseudoadjoint (i.e., adjoint for a subdomain). Questions of that kind were investigated extensively by Scharf and collaborators in the 1990s, cf. Refs. 32–34.

In terms of n-point distributions the relation of pseudounitarity reads as follows.

Lemma 3.15: *Let T_Y, $T_Z\in\mathcal{R}_{\mathrm{V}}$, where Y, $Z\in\mathrm{V}$, and let $\emptyset\neq X\in\mathrm{V}$. Then*

$$\sum_{(Y,Z)\in\mathcal{P}^0_2(X)}\sigma_X(Y\otimes Z)\widetilde{T}_Y\circ T_Z=0=\sum_{(Y,Z)\in\mathcal{P}^0_2(X)}\sigma_X(Y\otimes Z)T_Y\circ\widetilde{T}_Z. \tag{68}$$

Moreover, $\widetilde{T}_Y$, $\widetilde{T}_Z\in\mathcal{R}_{\mathrm{V}}$ and therefore the inverse distributions are GTS.

Proof: To obtain (68), perform the power expansion (cf. Lemma 3.3.15 in Ref. 24, p. 94). The other claim is a side result. □

This statement can be rewritten assuming the tilde to be linear, i.e., assigning the tilde to graph distributions in the following straightforward manner:

$$\sum_{\Gamma\in\mathrm{G}_{\mathrm{V}},\mathrm{V}(\Gamma)=\overline{v}}\widetilde{T}^{\mathcal{R}}_{\Gamma}:=\widetilde{T}^{\mathcal{R}}_{\overline{v}}. \tag{69}$$

Corollary 3.16: *Let $\emptyset\neq\Gamma'\in\mathrm{G}_{\Gamma}$ and $\Gamma\in\mathrm{G}_{\mathrm{V}}$. Then*

$$\sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}^0_2(\mathrm{Y})}\sigma_{\Gamma}(\Gamma^1\sqcup_{\Gamma}\Gamma^2)\widetilde{T}^{\mathcal{R}}_{\Gamma^1}\circ_{\Gamma}T^{\mathcal{R}}_{\Gamma^2}=0=\sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}^0_2(\mathrm{Y})}\sigma_{\Gamma}(\Gamma^1\sqcup_{\Gamma}\Gamma^2)T^{\mathcal{R}}_{\Gamma^1}\circ_{\Gamma}\widetilde{T}^{\mathcal{R}}_{\Gamma^2}. \tag{70}$$

Proof: Insert the expansions (65) and (69) into (68) and apply Lemma 3.10 (cf. Corollary 3.3.17 in Ref. 24, p. 97).

The previous two equations, if interpreted as antipode conditions, motivate to consider $\mathcal{R}_{\mathrm{V}}$ and $\mathcal{R}_{\mathrm{G}_{\Gamma}}$, respectively, as HAs.

Theorem 3.17: $(\mathcal{R}_*,\mathbb{C},+,\circ_{(\Gamma)},\eta,\Delta,\varepsilon,\mathrm{S}_{(\circ_{\Gamma})})$, *where $*=\mathrm{V}$ (respectively, $=\mathrm{G}_{\Gamma}$, for any $\Gamma\in\mathrm{G}_{\mathrm{V}}$), forms a HA. The tilde serves as antipode, i.e., $\mathrm{S}_{(\circ_{\Gamma})}T:=\widetilde{T}$, which, e.g., in $\mathcal{R}_{\mathrm{G}_{\Gamma}}$, is explicitely given by*

$$\mathrm{S}_{\circ_{\Gamma}}T^{\mathcal{R}}_{\Gamma'}=\sum_{r=1}^{|\mathrm{V}(\Gamma')|}(-1)^r\sum_{(\Gamma^1,\ldots,\Gamma^r)\in\mathcal{P}_r(\Gamma')}\sigma_{\Gamma}(\Gamma^1\sqcup_{\Gamma}\cdots\sqcup_{\Gamma}\Gamma^r)T^{\mathcal{R}}_{\Gamma^1}\circ_{\Gamma}\cdots\circ_{\Gamma}T^{\mathcal{R}}_{\Gamma^r}. \tag{71}$$

Proof: It only remains to show the representation of the antipode. This will be done by induction over the number of vertices. Assume (71) is fulfilled for $|\mathrm{V}(\Gamma')|=n$, which is true for $n=1$. Then, starting with the antipode condition, one reproduces (71),

$$
\begin{aligned}
S_{\circ_\Gamma} T^{\mathcal{R}}_{\Upsilon} &= -T^{\mathcal{R}}_{\Upsilon} - \sum_{(\Gamma',\Gamma'')\in\mathcal{P}_2(\Upsilon)} \sigma_\Gamma(\Gamma' \sqcup_\Gamma \Gamma'') S_{\circ_\Gamma} T^{\mathcal{R}}_{\Gamma'} \circ_\Gamma T^{\mathcal{R}}_{\Gamma''} \\
&= -T^{\mathcal{R}}_{\Upsilon} - \sum_{r=1}^{n} (-1)^r \sum_{(\Gamma',\Gamma'')\in\mathcal{P}_2(\Upsilon)} \sum_{(\Gamma^1,\ldots,\Gamma^r)\in\mathcal{P}_r(\Gamma')} \\
&\quad \times \sigma_\Gamma(\Gamma' \sqcup_\Gamma \Gamma'') \sigma_\Gamma(\Gamma^1 \sqcup_\Gamma \cdots \sqcup_\Gamma \Gamma^r) T^{\mathcal{R}}_{\Gamma^1} \circ_\Gamma \cdots \circ_\Gamma T^{\mathcal{R}}_{\Gamma^r} \circ_\Gamma T^{\mathcal{R}}_{\Gamma''} \\
&= -\sum_{r=0}^{n} (-1)^r \sum_{(\Gamma',\ldots,\Gamma^r,\Gamma'')\in\mathcal{P}_{r+1}(\Upsilon)} \sigma_\Gamma(\Gamma^1 \sqcup_\Gamma \cdots \sqcup_\Gamma \Gamma^r \sqcup_\Gamma \Gamma'') \cdots = \sum_{r=1}^{n+1} (-1)^r \sum_{(\Gamma^1,\ldots,\Gamma^r,\Gamma'')\in\mathcal{P}_r(\Upsilon)} \cdots,
\end{aligned}
$$

for the graph Υ with $|V(\Upsilon)| = n+1$ and hence for any such graph. □

Remark 3.18: Rota and Stein[20,21] have obtained this kind of antipode for their *plethystic HAs* and refer to the general version of (71) as *Schmitt formula* (indicated by "Σ" in Fig. 1).

IV. RENORMALIZED CAUSAL pQFT

This section provides an algebraic formalism for the main qualities determining the *S*-matrix in the considered framework of pQFT, i.e., causality and renormalization. As the EG approach is a recursive method it is free of subdivergences. A change of the renormalization scheme, however, indicates all the structure contained in Kreimer's HA. In contrast to most of the existing work on EG and following the preceding section, the presentation here is given in terms of graph instead of vertex distributions.

A. Causal regularization

Causality defines the graph distributions only outside the so-called diagonals. The required regularization, performed as a localization on the corresponding causally determined space–time region in configuration space, allows a characterization in terms of HAs. In addition to two EG versions, that vary with respect to the concrete but recursive implementation of causality, Feynman's approach to pQFT is recalled, which due to the mixing of Wick with time ordering yields an explicit representation of graph distributions. However, the unavoidable coarse localization reasons the occurrence of subdivergences.

1. Causality

Preparing the two EG versions, two relations of causality are formulated for sets of space–time points, $X, Y \subseteq \mathbb{R}^{1+d}$, i.e., *causal ordering* $\precsim$, given by

$$
X \cap (Y + \overline{V_+}) = \emptyset \Leftrightarrow : X \precsim Y \Leftrightarrow Y \succsim X, \tag{72}
$$

and *weak causal ordering* $\precsim^{\exists} (\supseteq \precsim)$, given by

$$
\exists (x,y) \in X \times Y \text{ s.t. } \{x\} \precsim \{y\} \Leftrightarrow : X \precsim^{\exists} Y \Leftrightarrow Y \succsim^{\exists} X. \tag{73}
$$

Both these relations are not reflexive, i.e., $\exists X \not\precsim^{(\exists)} X$. Coinciding space–time points cannot be compared with respect to causality. This fact reasons the necessity of renormalization and makes it look acceptable from the physics' point of view.

Accordingly, one distinguishes two sorts of configuration space regions. For the one sort, the *causal cones*, the space–time points are causally related, whereas for the other, the *diagonals*, that model coinciding space–time points, they are not. Let $P \in \mathcal{P}_r(\Gamma)$ where $\Gamma \in G_V$ and $r \leqslant n \equiv |V(\Gamma)|$. Then

$$\mathrm{cone}_P^{(\exists)} := \{y \in \mathbb{R}^{(1+d)\times n} | \{y_{P_1}^{\otimes}\} \gtrsim^{(\exists)} \cdots \gtrsim^{(\exists)} \{y_{P_r}^{\otimes}\}\} \tag{74}$$

define (respectively, two) TI open cones on the configuration space $\mathbb{R}^{(1+d)\times n} := \times_{i\leqslant n}\mathbb{R}^{1+d}$. Furthermore, the sets of r coinciding points,

$$\mathrm{diag}_P := \{y \in \mathbb{R}^{(1+d)\times n} | y_i = y_j,\ \forall\, i,j \in P_s,\ \forall\, s \leqslant r\}, \tag{75}$$

are called the (sub)diagonals with respect to P [if $P \neq (\Gamma)$, respectively]. Subtracting

$$\mathrm{diag}_r^n := \bigcup_{s<r} \bigcup_{P\in\mathcal{P}_s(I)} \mathrm{diag}_P \tag{76}$$

from the configuration space, one obtains the *causally determined region* which contains at least r noncoinciding space–time points, i.e.,

$$\mathbb{R}_{r\neq}^{(1+d)\times n} := \mathbb{R}^{(1+d)\times n} \setminus \mathrm{diag}_r^n. \tag{77}$$

One uses the following abbreviations, $\mathbb{R}_{\times}^{(1+d)\times n} := \mathbb{R}_{2\neq}^{(1+d)\times n}$ and $\mathbb{R}_{\neq}^{(1+d)\times n} := \mathbb{R}_{n\neq}^{(1+d)\times n}$.

Lemma 4.1: *Let* $\Gamma \in \mathrm{G_V}$ *and* $r \leqslant n \equiv |\mathrm{V}(\Gamma)|$. *Then*

$$\bigcup_{P\in\mathcal{P}_r(\Gamma)} \mathrm{cone}_P = \mathbb{R}_{r\neq}^{(1+d)\times n}. \tag{78}$$

Let Γ, Γ_1, $\Gamma'' \in \mathrm{G_V}$ *where* $(\Gamma_1, \Gamma'') \in \mathcal{P}_2(\Gamma)$ *and* $|V(\Gamma_1)| = 1$. *Then*

$$\mathrm{cone}_{(\Gamma_1,\Gamma'')}^{\exists} \cup \mathrm{cone}_{(\Gamma'',\Gamma_1)}^{\exists} = \mathbb{R}_{\times}^{(1+d)\times n}, \tag{79}$$

where the two cones are represented by

$$\mathrm{cone}^{\exists}_{\begin{cases}(\Gamma_1,\Gamma'')\\(\Gamma'',\Gamma_1)\end{cases}} = \bigcup_{(\Gamma_Q,\Gamma_P)\in\mathcal{P}_2(\Gamma),\Gamma_1\subseteq\begin{cases}\Gamma_Q\\\Gamma_P\end{cases}} \mathrm{cone}_{(\Gamma_Q,\Gamma_P)}. \tag{80}$$

Proof: These (four) relations follow immediately from the definitions above. □

Utilizing only the causal relation, the S-matrix is called causal iff,

$$\mathrm{supp}\ \xi^1 \gtrsim \mathrm{supp}\ \xi^2 \Rightarrow S_{\mathrm{V}}^{\mathcal{R}}(\xi^1 + \xi^2) = S_{\mathrm{V}}^{\mathcal{R}}(\xi^1) \circ S_{\mathrm{V}}^{\mathcal{R}}(\xi^2), \tag{81}$$

$\forall\, \xi^i \in \mathcal{D}_{\mathrm{V}}^{\oplus}(\mathbb{R}^{1+d})$, $i \leqslant 2$. There is an equivalent characterization in terms of graph distributions.

Proposition 4.2: *The S-matrix is causal iff* $\mathrm{supp}\ \xi^1 \gtrsim \mathrm{supp}\ \xi^2$ *implies*

$$T_{\Gamma'}^{\mathcal{R}}(\xi^1 \sqcap \xi^2) = \sigma_{\Gamma'}(\Gamma^1 \sqcup_{\Gamma} \Gamma^2) T_{\Gamma^1}^{\mathcal{R}}(\xi^1) \circ_{\Gamma} T_{\Gamma^2}^{\mathcal{R}}(\xi^2), \tag{82}$$

$\forall (\Gamma^1, \Gamma^2) \in \mathcal{P}_2(\Gamma')$, $\forall \Gamma' \subseteq \Gamma \in \mathrm{G_V}$, *and* $\forall\, \xi^i \in \mathcal{D}_{\mathrm{V}(\Gamma^i)}^{\otimes}$, $i \leqslant 2$.

Proof: This is due to power expansion (cf. Lemma 4.1.4 in Ref. 24, p. 103). □

In the EG approach, i.e., in the sequel, the S-matrix is assumed to be causal.

2. Regularization of two EG versions

EG's method is an implicit induction over subgraphs where the implementation of causality leads to localized n-point distributions (being GTS and having TI scalar parts) of the form $T_{\Gamma'}^{r\neq} := T_{\Gamma'}^{\mathcal{R}}|_{\mathbb{R}_{r\neq}^{(1+d)\times n}} \in \mathcal{R}_{\mathrm{G}_\Gamma}^{\mathsf{T}}(\mathbb{R}_{r\neq}^{(1+d)\times n})$, for $r \leqslant n \equiv |\mathrm{V}(\Gamma')|$, $\Gamma' \in \mathcal{P}(\Gamma)$, and $\Gamma \in \mathrm{G_V}$.

EG à la Fredenhagen (EGF): For each graph Γ and each $r \leqslant n$ one chooses a partition of unity $(\chi_P)_{P\in\mathcal{P}_r(\Gamma)}$ of class C^{∞} subordinate to the finite open covering $(\mathrm{cone}_P)_{P\in\mathcal{P}_r(\Gamma)}$ of the metric space $\mathbb{R}_{r\neq}^{(1+d)\times n}$, i.e.,

$$\sum_{P\in\mathcal{P}_r(\Gamma)} \chi_P(x) = 1, \quad \forall\, x \in \mathbb{R}_{r\neq}^{(1+d)\times n}, \tag{83}$$

$$\text{where} \quad 0 \leqslant \chi_P \in C^\infty(\mathbb{R}^{(1+d)\times n}_{r\neq}) \tag{84}$$

$$\text{and} \quad \operatorname{supp}\chi_P \subset \operatorname{cone}_P. \tag{85}$$

It is well known that partitions of this kind exist (e.g., cf. Ref. 35, p. 214).

Proposition 4.3: *The graph distributions are (uniquely) determined by*

$$T^\chi_{\Gamma'} := \sum_{(\Gamma^1,\ldots,\Gamma^r)\in\mathcal{P}_r(\Gamma')} \chi_{(\Gamma^1,\ldots,\Gamma^r)}\sigma_\Gamma(\Gamma^1\sqcup_\Gamma\ldots\sqcup_\Gamma\Gamma^r)T^{\mathcal{R}}_{\Gamma^1}\circ_\Gamma\ldots\circ_\Gamma T^{\mathcal{R}}_{\Gamma^r} \tag{86}$$

(independently of χ), i.e., $T^{r\neq}_{\Gamma'} = T^\chi_{\Gamma'}|_{\mathbb{R}^{(1+d)\times n}_{r\neq}} \in \mathcal{R}^{\mathsf{T}}_{G_\Gamma}(\mathbb{R}^{(1+d)\times n}_{r\neq})$.

Proof: By applying (78) one can straightforwardly generalize Ref. 7 where only the case of $r=2$ is considered (cf. Proposition 4.2.6 in Ref. 24, p. 110). □

EG à la Scharf (EGS): The genuine approach is based on two expressions,

$$\text{the} \quad \begin{cases}\text{retarded}\\ \text{advanced}\end{cases} \quad \text{distribution} \quad \begin{cases} R_{(\Gamma_1,\Gamma'')} := T_{\Gamma'} + R'_{(\Gamma_1,\Gamma'')},\\ A_{(\Gamma_1,\Gamma'')} := T_{\Gamma'} + A'_{(\Gamma_1,\Gamma'')},\end{cases} \tag{87}$$

where, applying Scharf's notation,

$$R'_{(\Gamma_1,\Gamma'')} := \sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}_2(\Gamma'),\Gamma_1\subseteq\Gamma^1} \sigma_\Gamma(\Gamma^1\sqcup\Gamma^2)T^{\mathcal{R}}_{\Gamma^1}\circ_\Gamma\tilde{T}^{\mathcal{R}}_{\Gamma^2}, \tag{88}$$

$$A'_{(\Gamma_1,\Gamma'')} := \sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}_2(\Gamma'),\Gamma_1\subseteq\Gamma^2} \sigma_\Gamma(\Gamma^1\sqcup\Gamma^2)\tilde{T}^{\mathcal{R}}_{\Gamma^1}\circ_\Gamma T^{\mathcal{R}}_{\Gamma^2}. \tag{89}$$

These expressions vanish when restricted to appropriate cones.

Lemma 4.4: *Let* Γ, Γ_1, $\Gamma''\in G_V$ *where* $(\Gamma_1,\Gamma'')\in\mathcal{P}_2(\Gamma)$ *and* $|V(\Gamma_1)|=1$. *Then*

$$A_{(\Gamma_1,\Gamma'')}|_{\operatorname{cone}^\exists_{(\Gamma'',\Gamma_1)}} = 0 = \mathcal{R}_{(\Gamma_1,\Gamma'')}|_{\operatorname{cone}^\exists_{(\Gamma_1,\Gamma'')}}. \tag{90}$$

Proof: One must apply the property (80) of cones of weak causality, cf. Lemma 4.2.12 in Ref. 24, pp. 113ff. □

Again, but formally varying from the named version (cf. Remark 4.7 below), one considers a partition of unity. For each triple of graphs Γ, Γ_1, $\Gamma''\in G_V$ where $(\Gamma_1,\Gamma'')\subset\mathcal{P}_2(\Gamma)$ and $|V(\Gamma_1)|=1$ one chooses a partition of unity $(\chi^\exists_s)$, $s\leqslant 2$ of class C^∞ subordinate to the finite open covering $\operatorname{cone}^\exists := (\operatorname{cone}^\exists_{(\Gamma_1,\Gamma'')}, \operatorname{cone}^\exists_{(\Gamma'',\Gamma_1)})$ of the metric space $\mathbb{R}^{(1+d)\times n}_\times$, i.e.,

$$\chi^\exists_1(x) + \chi^\exists_2(x) = 1, \quad \forall\, x\in\mathbb{R}^{(1+d)\times n}_\times, \tag{91}$$

$$\text{where} \quad 0\leqslant\chi^\exists_s\in C^\infty(\mathbb{R}^{(1+d)\times n}_\times) \tag{92}$$

$$\text{and} \quad \operatorname{supp}\chi^\exists_s\subset\operatorname{cone}^\exists_s, \quad s\leqslant 2. \tag{93}$$

Example 4.5: One may use the partitions of unity χ introduced for the EGF approach to define such a $\chi^\exists$, i.e., $\chi^\exists_s := \Sigma_{P\in\mathcal{P}_2(\Gamma'),\Gamma_1\subseteq P_s}\chi_P$, $s\leqslant 2$.

Proposition 4.6: *The graph distributions are (uniquely) determined by*

$$T^\exists_{\Gamma'} := -\chi^\exists_1 R'_{(\Gamma_1,\Gamma'')} - \chi^\exists_2 A'_{(\Gamma_1,\Gamma'')} \tag{94}$$

(independently of $\chi^\exists$), i.e., $T^\times_{\Gamma'} = T^\exists_{\Gamma'}|_{\mathbb{R}^{(1+d)\times n}_\times} \in \mathcal{R}^{\mathsf{T}}_{G_\Gamma}(\mathbb{R}^{(1+d)\times n}_\times)$.

Proof: This is a consequence of (80) and Lemma 4.4 (cf. Prop. 4.2.15 in Ref. 24, p. 116). □

Remark 4.7: In the original EGS version the *n*-point distribution is obtained actually via a

so-called *splitting* of the *causal distribution* $D:=R'-A'=R-A$. Here, the mapping $D\mapsto\chi_2^{\exists}D$ defines a regularized splitting, i.e.,

$$T^{\times}_{\Gamma'} = \chi_2^{\exists}D_{(\Gamma_1,\Gamma'')}\big|_{\mathbb{R}^{(1+d)\times n}_{\times}} - R'_{(\Gamma_1,\Gamma'')}\big|_{\mathbb{R}^{(1+d)\times n}_{\times}}. \tag{95}$$

3. Regularizing HAs

As causal regularization is understood to be a localization of distributions on subregions of noncoinciding space–time points in configuration space it can be modeled algebraically via A^0-modules $\overline{A}=A^0\overline{1}\oplus\bigoplus_{n\geqslant 0}\overline{A^n}$ that are extensions of $\mathbb{N}$-graded (configuration space depending) modules $A=\bigoplus_{n\geqslant 0}A^n$, where $\overline{A^n}=\bigoplus_{r\leqslant n}A^n(\mathbb{R}^{(1+d)\times n}_{r\neq})$ and $\overline{1}$ denotes the formally defined unity. In concrete cases they will be used as algebras. The instances of those modules (respectively, algebras) are the (algebra of) n-point distributions $\mathcal{R}_{G_\Gamma}$ as well as the tensor product structure $C^\infty\otimes\mathcal{R}_{G_\Gamma}$, with C^∞ functions multiplied pointwise.

The regularization for the EGF (respectively, EGS) version is given as a subalgebra of $\overline{C^\infty\otimes\mathcal{R}_{G_\Gamma}}$ which is isomorphic to $\overline{\mathcal{R}}_{G_\Gamma}$ as an algebra, i.e., $\big(\hat{\mathcal{R}}^{(\exists)}_{G_\Gamma},\mathbb{C},+,\hat{\circ}^{(\exists)}_{\Gamma},\overline{1}\big)$, where

$$\overline{\mathcal{R}}_{G_\Gamma}\overset{\iota}{\cong}\hat{\mathcal{R}}^{(\exists)}_{G_\Gamma}\overset{\vartheta^{(\exists)}}{\hookrightarrow}\overline{C^\infty\otimes\mathcal{R}_{G_\Gamma}} \tag{96}$$

and, for at least $r\in\mathbb{N}$ noncoinciding space–time points, the embedding algebra homomorphism

$$\vartheta^{(\exists)}:\hat{\bigcirc}^{(\exists)}_{\Gamma}\iota\big(T^{\otimes}_P|_{\mathbb{R}^{(1+d)\times n}_{r\neq}}\big)=:\hat{\bigcirc}^{(\exists)}_{\Gamma}\hat{T}^{\otimes}_P\mapsto\vartheta^{(\exists)}_P\otimes\bigcirc_\Gamma T^{\otimes}_P|_{\mathbb{R}^{(1+d)\times n}_{r\neq}} \tag{97}$$

is realized via functions $\vartheta^{(\exists)}_P\in C^\infty(\mathbb{R}^{(1+d)\times n}_{r\neq})$ indexed with r-partitions $P\in\mathcal{P}^0_r(\Gamma')$ of graphs $\Gamma'\in G_\Gamma$, where $r\leqslant n\equiv|V(\Gamma')|$. Those *causally ordering functions* will be used to model the considered regularizing algebra. One of their general properties is according to the defining isomorphism, i.e., $\vartheta^{(\exists)}_{(\Gamma')}=1$, $\forall\Gamma'\in G_\Gamma$. The costructure is introduced by the graded shuffling coproduct, where $\Delta(\overline{1})=\overline{1}\otimes\overline{1}$ and $\varepsilon(\overline{1})=1$. Moreover, the (respectively, two) algebras above define bialgebras $\big(\hat{\mathcal{R}}^{(\exists)}_{G_\Gamma},\mathbb{C},+,\hat{\circ}^{(\exists)}_{\Gamma},\eta,\Delta,\varepsilon\big)$.

Notice, one always applies the following abbreviation, $T_{\Gamma'}=\hat{T}_{(\Gamma')}\in\hat{\mathcal{R}}^{(\exists)}_{G_\Gamma}$.

Modeling EGF: The causally ordering functions are given in terms of the partition of unity,

$$\vartheta_p:=\tfrac{1}{2}\chi_{\check{P}},\quad\forall P\in\mathcal{P}^0_r(\Gamma'),\quad\forall\Gamma'\in G_\Gamma,\quad\forall r\leqslant|V(\Gamma')|, \tag{98}$$

where $\check{P}\in\mathcal{P}_s(\Gamma')$, for $s\leqslant r$, denotes the tuple P reduced by empty graph entries. This motivates a further general property of ϑ, i.e.,

$$\vartheta_P=\vartheta_Q\quad\text{if}\quad\check{P}=\check{Q}\quad\text{and}\quad|P|=|Q|. \tag{99}$$

Theorem 4.8: $(\hat{\mathcal{R}}_{G_\Gamma},\mathbb{C},+,\hat{\circ}_\Gamma,\eta,\Delta,\varepsilon,S^{\hat{\circ}_\Gamma})$ *forms a HA where*

$$S^{\hat{\circ}_\Gamma}T_{\Gamma'}=\begin{cases}T_\varnothing & \text{if }\Gamma'=\varnothing,\\ -T_{\Gamma'}, & \text{otherwise.}\end{cases} \tag{100}$$

Proof: It remains to check the antipode condition. This can be done by rewriting EGF's induction (Proposition 4.3), i.e., $0=\frac{1}{2}T^{\times}_{\Gamma'}-T^{\chi/2}_{\Gamma'}$. Let $L:=\mathbb{R}^{(1+d)\times n}_{\times}$, then

$$
\begin{aligned}
0 = & \left(1-\frac{1}{2}\right)\chi_{(\Gamma')}T_{\Gamma'}\Big|_L - \frac{1}{2}\sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}_2(\Gamma')}\chi_{(\Gamma^1,\Gamma^2)}\sigma_{\Gamma'}(\Gamma^1\sqcup_\Gamma\Gamma^2)T_{\Gamma^1}\circ_\Gamma T_{\Gamma^2}\Big|_L \\
= & \ \vartheta_{(\Gamma',\varnothing)}\otimes T_{\Gamma'}|_L - \vartheta_{(\varnothing,\Gamma')}\otimes T_{\Gamma'}|_L - \sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}_2(\Gamma')}\vartheta_{(\Gamma^1,\Gamma^2)}\otimes\sigma_{\Gamma'}(\cdots)\cdots\Big|_L \\
= & \ T_{\Gamma'}\hat{\circ}_\Gamma T_\varnothing + T_\varnothing\hat{\circ}_\Gamma(-T_{\Gamma'}) + \sum_{(\Gamma^1,\Gamma^2)\in P_2(\Gamma')}\sigma_{\Gamma'}(\Gamma^1\sqcup_\Gamma\Gamma^2)T_{\Gamma^1}\hat{\circ}_\Gamma(-T_{\Gamma^2}) \\
= & \ \hat{\bigcirc}_\Gamma\circ(\mathrm{id}\otimes \mathrm{S}_{\hat{\circ}_\Gamma})\circ\Delta T_{\Gamma'}.
\end{aligned}
$$

The other side of the antipode condition follows similarly. □

Modeling EGS: There are two extra properties of $\vartheta^\exists$, i.e.,

$$
\vartheta^\exists_P = \begin{cases} \vartheta^\exists_{(\cdots\sqcup_\Gamma P_{i-1},P_i,P_{i+1}\sqcup_\Gamma\cdots)} & \text{if } \exists\,\Gamma_1\subseteq P_i \text{ s.t. } y_1 = x_{\Gamma_1}, \\ \vartheta^\exists_{\sqcup_\Gamma P}, & \text{otherwise,} \end{cases} \tag{101}
$$

and

$$
\vartheta^\exists_p = \begin{cases} \vartheta^\exists_{(\Gamma_1,\Gamma'')} \\ \vartheta^\exists_{(\Gamma'',\Gamma_1)} \end{cases} \quad \text{if} \quad \exists\,\Gamma_1\subseteq\begin{cases} P_1 \\ P_r \end{cases} \text{s.t. } y_1 = x_{\Gamma_1}, \tag{102}
$$

so that the causally ordering functions can also be given in terms of the partition of unity,

$$
\vartheta^\exists_P := \begin{cases} \chi^\exists_s & \text{if } \exists\,\Gamma_1\subseteq P_s \text{ s.t. } y_1 = x_{\Gamma_1} \text{ and } P\in\mathcal{P}_2(\Gamma'), \\ 0, & \text{otherwise,} \end{cases}
$$

$\forall P\in\mathcal{P}^0_r(\Gamma')$, $\Gamma'\in\mathrm{G}_\Gamma$, $r\leqslant|\mathrm{V}(\Gamma')|$.

Theorem 4.9: $(\hat{\mathcal{R}}^\exists_{\mathrm{G}_\Gamma},\mathbb{C},+,\hat{\circ}^\exists_\Gamma,\eta,\Delta,\varepsilon,\mathrm{S}_{\hat{\circ}^\exists_\Gamma})$ *forms a HA where*

$$
\mathrm{S}_{\hat{\circ}^\exists_\Gamma}T_{\Gamma'} = \begin{cases} 0 & \text{if } \exists\,\Gamma_1\subseteq\Gamma' \text{ s.t. } y_1 = x_{\Gamma_1}, \\ \mathrm{S}_{\circ_\Gamma}T_{\Gamma'}, & \text{otherwise.} \end{cases} \tag{103}
$$

Proof: Again, it remains to check the antipode condition. By rewriting the *R*-part of EGS' induction (cf. Lemma 4.4), i.e., $0=\chi^\exists_1 R_{(\Gamma_1,\Gamma'')}|_L = \chi^\exists_1 T^\exists_{\Gamma'} + \chi^\exists_1 R'_{(\Gamma_1,\Gamma'')}|_L$, where $L:=\mathbb{R}^{(1+d)\times n}_\times$, one obtains

$$
\begin{aligned}
0 = & \ \chi^\exists_1 T_{\Gamma'}|_L + \chi^\exists_1\sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}_2(\Gamma'),\Gamma_1\subseteq\Gamma^1}\sigma_\Gamma(\Gamma^1\sqcup_\Gamma\Gamma^2)T_{\Gamma^1}\circ_\Gamma\mathrm{S}_{\circ_\Gamma}T_{\Gamma^2}\Big|_L \\
= & \ \vartheta^\exists_{(\Gamma',\theta)}\otimes T_{\Gamma'}|_L + \sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}_2(\Gamma'),\Gamma_1\subseteq\Gamma^1}\vartheta^\exists_{(\Gamma^1,\Gamma^2)}\otimes\sigma_{\Gamma'}(\Gamma^1\sqcup_\Gamma\Gamma^2)T_{\Gamma^1}\circ_\Gamma\mathrm{S}_{\circ_\Gamma}T_{\Gamma^2}\Big|_L \\
= & \sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}^0_2(\Gamma'),\Gamma_1\subseteq\Gamma^1}\vartheta^\exists_{(\Gamma^1,\Gamma^2)}\otimes\sigma_{\Gamma'}(\Gamma^1\sqcup_\Gamma\Gamma^2)T_{\Gamma^1}\circ_\Gamma\mathrm{S}_{\circ_\Gamma}T_{\Gamma^2}\Big|_L \\
= & \sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}^0_2(\Gamma')}\sigma_{\Gamma'}(\Gamma^1\sqcup_\Gamma\Gamma^2)T_{\Gamma'}\hat{\circ}^\exists_\Gamma\,\mathrm{S}_{\hat{\circ}^\exists_\Gamma}T_{\Gamma^2} \equiv \hat{\bigcirc}^\exists_\Gamma\circ(\mathrm{id}\otimes\mathrm{S}_{\hat{\circ}^\exists_\Gamma})\circ\Delta T_{\Gamma'}.
\end{aligned}
$$

Similarly, the other side of the antipode condition follows from the *A*-part.

4. BS' Feynman approach

The conventional approach to pQFT is written in terms of Feynman propagators. This leads to an explicit representation of graph distributions in momentum space which, without iterated renormalization as indicated below, suffers from so-called ultraviolet subdivergences. When going over

to configuration space this means that the distributions are determined only on $L:=\mathbb{R}^{(1+d)\times n}_{\neq}$. Even if the aspect of causality has already been investigated by BS[30] only the work of BPHZ[3–5] could verify the correctness of the common method of curing subdivergences via renormalization over so-called forests of subgraphs (which is the main application of Kreimer's HA[9]).

Lemma 4.10: *Let $\Gamma'=\Gamma^1\sqcup_l\Gamma^2$ be a graph and $P'\equiv P^1\otimes P^2=(P\circ \mathrm{V}_i(\Gamma'))_{i\leqslant n}$, $n\equiv|V(\Gamma')|$, the associated tuples of particles. Localized on L, time-ordered [cf. (B2) in the Appendix B] Wick contractions can be represented by Feynman contractions, i.e.,*

$$(\mathrm{T}\amalg)^l_{(\Gamma^1,\Gamma^2)}\Big|_L=\prod\nolimits^l_{(\Gamma^1,\Gamma^2)}\Big|_L,\quad \textit{where}\ \prod\nolimits^l_{(\Gamma^1,\Gamma^2)}:=\prod_{\substack{(i,j)\in l_{rs}\\ r\leqslant|P^1|,s\leqslant|P^2|}}\Delta_{F\gamma}^{P^1_{ri}P^2_{sj}}. \tag{104}$$

Proof: As chronological cycles $C\subset M$ can be excluded by localization on L, one confirms

$$\begin{aligned}\prod\nolimits^l_{(\Gamma^1,\Gamma^2)}\Big|_L&=\prod_{\substack{(i,j)\in l_{rs}\\ r\leqslant|P^1|,s\leqslant|P^2|}}(\theta_{(r,s)}\Delta_{+\gamma}^{P^1_{ri}P^2_{sj}}+\sigma\theta_{(s,r)}\Delta_{+\gamma}^{P^2_{sj}P^1_{ri}})\Big|_L=\sum_{\substack{M\subseteq M^{12}\cup M^{21}\\ (u,v)\in M\Leftrightarrow(v,u)\notin M}}\prod_{\substack{(i,j)\in\overline{l}_{uv}\\ (u,v)\in M}}\theta_{(u,v)}\sigma_{\mathrm{I}(\Gamma')}\\ &\times(P'_u,P'_v)\Delta_{+\gamma}^{P'_{ui}P'_{vj}}\Big|_L=\sum_{\substack{M\subseteq M^{12}\cup M^{21}\\ \nexists C\subset M\text{cycle}}}\prod_{(u,v)\in M}\theta_{(u,v)}\sigma_{I(\Gamma')}(\Gamma'_u\sqcup_\varnothing\Gamma'_v)\amalg^{\overline{l}_{uv}}_{(\Gamma'_u,\Gamma'_v)}\Big|_L\\ &=\sum_{\pi\in S_n}\theta_{\pi(\Gamma')}\sigma_{\mathrm{I}(\Gamma^1\sqcup_l\Gamma^2)}(\pi(\Gamma'))\prod_{i<j\leqslant n}\prod\nolimits^{\overline{\pi\circ l_{ij}}}_{(\pi\circ\Gamma'_i,\pi\circ\Gamma'_j)}\Big|_L=(\mathrm{T}\amalg)^l_{(\Gamma^1,\Gamma^2)}\Big|_L,\end{aligned}$$

where the omitted variables in $\Delta^{**}_{+\gamma}(y_{**})$ are related as follows:

$$y_{uv}:=y'_u-y'_v=\begin{cases}y_r-y_s=:y_{rs}\\ y_s-y_r=:y_{sr}\end{cases}\quad\text{if }(u,v)=\begin{cases}(\tau,s+|\nu^1|),\\ (s+|\nu^1|,r).\end{cases}$$

The sets $\left\{\begin{smallmatrix}M^{12}\\ M^{21}\end{smallmatrix}\right.$ collect the corresponding pairs $(u,v)\in\mathbb{N}_n\times\mathbb{N}_n$ of indices, and the bar over the concatenation matrix $l\in\mathrm{l}(\Gamma^1,\Gamma^2)$ denotes its conversion into a matrix of lines, $\overline{l}:=\left(\begin{smallmatrix}\varnothing & l\\ \tilde{l} & \varnothing\end{smallmatrix}\right)$. □

Remark 4.11: Restricted to $x_{uv}\in\mathbb{R}^{1\times n}_{\neq}\times\mathbb{R}^{d\times n}\subset L$, the products of step functions vanish whenever their variables form a chronological cycle C, i.e.,

$$\prod_{(u,v)\in C}\theta_{(u,v)}(x_{uv})\equiv\prod_{(u,v)\in C}\theta(x^0_{uv})=0\ \text{if}\ \sum_{(u,v)\in C}x^0_{uv}=0.$$

The localization on L is sufficient, namely $\operatorname{supp}\Delta^{**}_{+\gamma}\subseteq\overline{V}_+\cup\overline{V}_-=:\overline{V}$, yielding $\operatorname{supp}\theta_{(*,*)}\Delta^{**}_{+\gamma}\subseteq L\cap\overline{V}\subset\mathbb{R}^{1\times n}_{\neq}\times\mathbb{R}^{d\times n}$.

Without localization, a simple consideration about the role of cycles, that correspond to so-called loops in Feyman diagrams, motivates the phenomenon of renormalization freedom.

Example 4.12: Let (r,s,t) be a cycle, i.e., $\theta(x^0_{rs})\theta(x^0_{st})\theta(x^0_{tr})|_{\mathbb{R}^{1\times3}_{\neq}\times\mathbb{R}^{d\times3}}=0$, and apply TI. Then, on the subspace generated by $x_r=x_t$,

$$\theta(x^0)\theta(-x^0)\big|_{(\mathbb{R}\setminus\{0\})\times\mathbb{R}^d}=0,\quad\text{where } x:=x_{rs}=-x_{st}.$$

The restriction cannot be dropped, as one realizes by applying the 1hs to certain distributions t. For example, let $t=\delta$ be the Dirac distribution, and let the product be defined via a regularization of θ, e.g., $\theta_n(x^0):=\frac{1}{2}(1+\tanh(nx^0))$. Then, induced by this particular regularization,

$$\theta(x^0)\theta(-x^0)t(x):=\lim_{n\to\infty}\theta_n(x^0)\theta_n(-x^0)t(x)=\tfrac{1}{4}\delta(x^0),$$

which obviously spoils associativity (i.e., the algebraic structure),

$$\tfrac{1}{4}\delta(x)=\theta(x^0)\theta(-x^0)\delta(x)\neq(\theta(x^0)\theta(-x^0))\delta(x)=0\,\delta(x).$$

This is consistent with the no-go theorem of Schwartz.[36]

Proposition 4.13: *Localized on L, graph distributions can be represented by time-ordered products* $T^{\neq}_{\Gamma'}=T^{\mathcal{R}}_{\Gamma^1}\circ^{\mathsf{T}}_{\Gamma}\cdots\circ^{\mathsf{T}}_{\Gamma}T^{\mathcal{R}}_{\Gamma^r}\big|_L\in\mathcal{R}^{\mathsf{T}}_{\mathrm{G}_\Gamma}(L)$, *where*

$$T^{\neq}_{\Gamma'}=(i\hbar)^{\#\Gamma'-|\Gamma'|}\Sigma_{b(\Omega\Gamma')}t^{\mathcal{R}}_{\mathrm{I}(\Gamma^1)}t^{\mathcal{R}}_{\mathrm{I}(\Gamma^2)}\prod_{(\Gamma^1,\Gamma^2)}^{l}N(\Gamma^l)\Bigg|_L, \tag{105}$$

for $r:=2$ *and* $\Gamma'\equiv\Gamma^1\sqcup_l\Gamma^2$.

Proof: The scalar part rests upon Lemma 4.10 and the structural part upon the following. □

Lemma 4.14: (Wick's theorem of time ordering.) *Keeping the notations*,

$$N(\Gamma^1)\circ^{\mathsf{T}}_{\Gamma}N(\Gamma^2)_L=\sum_{\substack{l\in\mathrm{l}(\Gamma^1,\Gamma^2)\\ \Gamma^1\sqcup_l\Gamma^2=\Gamma^1\sqcup_\Gamma\Gamma^2}}(i\hbar)^{|l|}\prod_{(\Gamma^1,\Gamma^2)}^{l}N(\Gamma^1\sqcup_l\Gamma^2)\Bigg|_L. \tag{106}$$

Proof: This follows from (58) and (104) (cf. Lemma 4.2.25 in Ref. 24, p. 122). □

Remark 4.15: Associativity of $\circ^{\mathsf{T}}_{\Gamma}$ corresponds with $\Pi_{(\cdot,\cdot)}$ being a 2-cocyle. In addition to $\amalg$, also Π can be considered as a Laplace pairing.

Explicitly, the graph distributions (60) can be characterized by the following.

Proposition 4.16: (Feynman diagrams) *Localized on L, graph distributions are (uniquely) determined by their scalar parts*,

$$t^{\mathcal{R}}_{\mathrm{I}(\Gamma')}\big|_L=\Pi^{\Gamma}_{\Gamma'}\big|_L,\quad \textit{where}\ \Pi^{\Gamma}_{\Gamma'}=\prod_{r<s\leqslant n}\prod_{\Gamma'_r\sqcup_\Gamma\Gamma'_s\in\mathcal{P}(\Gamma')}\Pi^{\mathrm{l}(\Gamma')_{rs}}_{(\Gamma'_r,\Gamma'_s)} \tag{107}$$

(independent of the renormalization scheme $\mathcal{R}$*).*

Proof: This is a consequence of Proposition 4.13. The calculation of (107) is similar to the one in the proof of Lemma 4.10 [cf. (4.139) in Ref. 24, p. 127].

Remark 4.17: Immediately, (29), (104), and (107) imply GTS of $t_{\mathrm{I}(\Gamma')}|_L$.

For completion, one can as well present an algebraic formulation of the BS regularization in the sense of Sec. IV A 3. The corresponding causally ordering functions read

$$\vartheta^{\mathsf{T}}:\hat{\bigcirc}^{\mathsf{T}}_{\Gamma}\hat{T}^{\otimes}_P\mapsto\vartheta^{\mathsf{T}}_P\otimes\bigcirc^{\mathsf{T}}_{\Gamma}T^{\otimes}_P|_L,\quad\text{where}\ \ \vartheta^{\mathsf{T}}_P:=1|_L, \tag{108}$$

$\forall P\in\mathcal{P}^0_r(\Gamma')$, $\forall\Gamma'\in\mathrm{G}_\Gamma$, $\forall r\leqslant|\mathrm{V}(\Gamma')|$.

Theorem 4.18: $\big(\hat{\mathcal{R}}^{\mathsf{T}}_{\mathrm{G}_\Gamma},\mathbb{C},+,\hat{\circ}^{\mathsf{T}}_{\Gamma},\eta,\Delta,\varepsilon,\mathrm{S}_{\hat{\circ}^{\mathsf{T}}_{\Gamma}}\big)$ *forms a HA where*

$$\mathrm{S}_{\hat{\circ}^{\mathsf{T}}_{\Gamma}}T_{\Gamma'}=(-1)^{|\mathrm{V}(\Gamma')|}T_{\tilde{\Gamma}'}. \tag{109}$$

Proof: It remains to check the antipode condition. Due to the claimed form of the antipode, the calculation is analogous to the one that proves Theorem 2.4. Formally, one would only have to substitute $\mathsf{N}:=\mathsf{T}$ and $\phi^{\bigcirc_J}:=T_{\Gamma'}$. □

B. Renormalization

For both EG versions the concept of renormalization can be implemented using EGF's method[7] of extending localized distributions to the smallest diagonal. For the remaining text, let $*\in\{\mathsf{F},\exists,\mathsf{T}\}$ symbolize the reference to one of the three causal regularizations where, to include EGF, $\hat{\mathcal{R}}^{\mathsf{F}}_{\mathrm{G}_\Gamma}:=\hat{\mathcal{R}}_{\mathrm{G}_\Gamma}$ and $\hat{\circ}^{\mathsf{F}}_{\Gamma}:=\hat{\circ}_{\Gamma}$.

1. Implementation via an extension of distributions

Renormalization can be understood as a method to (re)obtain elements of $\hat{\mathcal{R}}^{*}_{G_\Gamma}$ which are not determined by causality, introduced here without reference to the concrete regularization via a projective map,

$$\hat{\text{ren}} \equiv \hat{} \circ \text{ren}: \hat{\mathcal{R}}^{*n}_{G_\Gamma}(\mathbb{R}^{(1+d)\times n}_{r\neq}) \to \mathcal{R}^{*n}_{G_\Gamma} \hookrightarrow \hat{\mathcal{R}}^{*n}_{G_\Gamma}, \quad \hat{\text{ren}}|_{\hat{\mathcal{R}}^{*n}_{G_\Gamma}(\mathbb{R}^{(1+d)\times n})} = \text{id}. \tag{110}$$

In particular, when performing the causally regularizing induction step, this map is supposed to implement the renormalization scheme $\mathcal{R}$ depending on the underlying graph Γ',

$$\text{ren}^{\mathcal{R}}_{\Gamma'}: T^{r\neq}_{\Gamma'} \mapsto T^{\mathcal{R}}_{\Gamma'}, \quad \forall\, r \leqslant n. \tag{111}$$

For both EG versions, renormalization is performed as an extension of the considered graph distribution [i.e., (86) and (94), where $r:=2$] to the diagonal diag^n_2, performed on its scalar part [cf. (60)], i.e.,

$$T^{\mathcal{R}}_{\Gamma'} := \text{ren}^{\mathcal{R}}_{\Gamma'} T^{\times}_{\Gamma'} \equiv (i\hbar)^{\#\Gamma' - |\Gamma'|} \Sigma_{b(\Omega\Gamma')} \text{ext}^{\varrho,k}_{\Gamma'}(t^{\times}_{I(\Gamma)}) N(\Gamma'), \tag{112}$$

where reflecting the involved renormalization freedom (i.e., ambiguity), the extension $\text{ext}^{\varrho,k}_{\Gamma'}: \mathcal{D}'^{\otimes}_{I(\Gamma')}(\mathbb{R}^{(1+d)\times n}_{\times}) \to \mathcal{D}'^{\otimes}_{I(\Gamma')}$ is indexed by an auxiliary function $\varrho \in \mathcal{S}(\mathbb{R}^{(1+d)\times n})$ and a set (abbreviated by k) of complex constants $k^{\alpha, I(\Gamma')}_{\Gamma'}$, for $|\alpha| \leqslant \omega_{\Gamma'}$. Depending on the associated graph Γ', the instances for ϱ and k can up to a few restrictions be chosen arbitrarily. The concrete choice of $(\varrho_{\Gamma'}, k_{\Gamma'})$ fixes a particular renormalization scheme, i.e., $\mathcal{R} = \{(\varrho_{\Gamma'}, k_{\Gamma'}) | \Gamma' \text{ divergent}\}$. According to the assumed property of TI, the relevant dimension reduces to $\dim = (1+d)(n-1)$, and hence, the diagonal $\text{diag}^n_2 \subset \mathbb{R}^{(1+d)\times n}$ goes over into the origin $\{0\} \subset \mathbb{R}^{\dim}$.

For the BS approach, renormalization can only be given formally due to its coarse regularization, i.e., $T^{\mathcal{R}}_{\Gamma'} := \text{ren}^{\mathcal{R}}(T^{\mathcal{R}}_{\Gamma^1} \hat{\circ}_\Gamma T^{\mathcal{R}}_{\Gamma^2}) \equiv \mathcal{T}^{\mathcal{R}}_{\Gamma^1} \circ^{\mathsf{T}}_\Gamma T^{\mathcal{R}}_{\Gamma^2}$ where $\Gamma' \equiv \Gamma^1 \sqcup_\Gamma \Gamma^2$. For a concrete realization one must apply EG.

In the EG framework renormalization is as well based on power counting. This can be realized, as in the EGF version, via the so-called scaling degree,

$$\text{sd}(t) := \inf\left\{\rho \middle| \lim_{\lambda\to 0} \lambda^{\rho-\dim} t(\tau(\lambda^{-1}\cdot)) = 0,\ \forall\ \tau \in \mathcal{D}(\mathbb{R}^{\dim})\right\}, \tag{113}$$

which counts the inverse power of distributions $t \in \mathcal{D}'(\mathbb{R}^{\dim})$ at the origin of $\mathbb{R}^{\dim}$, i.e., $t(x) = O(|x|^{\text{sd}})$ as $|x| \to 0$. Then the extension of distributions is characterized as follows.

Proposition 4.19: *Let $t^{\times} \in \mathcal{S}(\mathbb{R}^{\dim}\backslash\{0\})$ with scaling degree $\rho := \text{sd}(t^{\times}) < \infty$. Then there exist extensions $t^{\varrho,k} \equiv \text{ext}^{\varrho,k}(t^{\times}) \in \mathcal{S}(\mathbb{R}^{\dim})$ with the same finite scaling degree* $\text{sd}(t^{\varrho,k}) = \rho$, *i.e., $t^{\varrho,k}(\tau^{\times}) = t^{\times}(\tau^{\times})$, $\forall \tau^{\times} \in \mathcal{S}(\mathbb{R}^{\dim}\backslash\{0\})$. Two cases have to be distinguished. If the distribution $t^{\times}$ is not singular, i.e., if its singular order ω is negative, then the extended distribution $t^{\varrho,k}$ is uniquely determined. Otherwise, if the* singular order $\omega := \rho - \dim \geqslant 0$, *uniqueness is violated. Then the extension depends, first, on an arbitrarily chosen tempered function $\varrho \in \mathcal{S}(\mathbb{R}^{\dim})$ which satisfies $\varrho(0) = 1$ and $\partial^\alpha \varrho(0) = 0$, and second, on an arbitrary set of constants $k^\alpha \in \mathbb{C}$ which defines the extended distribution on a set of test functions, $x \mapsto x^\alpha \varrho(x)$, i.e., $t^{\varrho,k}(\cdot^\alpha \varrho(\cdot)) = k^\alpha$, $\forall \alpha$, $|\alpha| \leqslant \omega$.*

Proof: Compare Theorems 5.2 and 5.3 in Ref. 7, pp. 645ff. □

Remark 4.20: More precisely, the extended distribution reads

$$t^{\varrho,k}(\tau) = t^{\times}(W_{\omega,\varrho}\tau) + \sum_{|\alpha|\leqslant\omega} \frac{k^\alpha}{\alpha!} \partial^\alpha \tau(0), \tag{114}$$

so that in the *second case*, where an associated graph would be called *divergent*, the following projection cannot be the identity, $W_{\omega,\varrho}: \mathcal{S}(\mathbb{R}^{\dim}) \to \mathcal{S}_\omega(\mathbb{R}^{\dim})$, $\tau \mapsto W_{\omega,\varrho}\tau$ where $(W_{\omega,\varrho}\tau)(x) = \tau(x) - \Sigma_{|\alpha|\leqslant\omega}(\partial^\alpha \tau(0)/\alpha!) x^\alpha \varrho(x)$, and where $\mathcal{S}_\omega = \{\xi \in \mathcal{S} | \partial^\alpha \xi(0) = 0, |\alpha| \leqslant \omega\}$ denotes test function space appropriate for the unique extension t in the *first case*, i.e., $t(\tau^{\times}_\omega) = t^{\times}(\tau^{\times}_\omega)$, $\forall \tau^{\times}_\omega \in \mathcal{S}_\omega(\mathbb{R}^{\dim}\backslash\{0\})$.

As the singular order is supposed to be preserved by the extension, (114) and the following lemma allow to describe the difference of the scalar distributions $t^{\mathcal{R}_i}_{\mathrm{I}(\Gamma)} := t^{\varrho,k_i}_{\mathrm{I}(\Gamma)}$ with respect to renormalization schemes $\mathcal{R}_i$, $i \leqslant 2$, by a polynomial in derivatives of the delta distribution, i.e.,

$$t^{\mathcal{R}_2}_{\mathrm{I}(\Gamma)} - t^{\mathcal{R}_1}_{\mathrm{I}(\Gamma)} = \sum_{|\alpha| \leqslant \omega_\Gamma} k_\Gamma^{\alpha,\mathrm{I}(\Gamma)} \partial^\alpha \delta^{\Pi \mathrm{V}(\Gamma)}, \tag{115}$$

with coefficients $k^\alpha = k_2^\alpha - k_1^\alpha$ formed by the difference of the renormalization constants in $\mathcal{R}_2$ and $\mathcal{R}_1$, provided that ϱ has been fixed.

Lemma 4.21: *Let* $t \in \mathcal{S}'(\mathbb{R}^{\dim})$ *and* $\operatorname{supp} t = \{0\}$. *Then* $\exists ! \{k^\alpha \in \mathbb{C} \,|\, |\alpha| \leqslant \omega \equiv [\mathrm{sd}(t)]\}$ *s.t.* $t(x) = \Sigma_{|\alpha| \leqslant \omega} k^\alpha \Pi_{i \leqslant \dim} \partial^{\alpha_i} \delta(x_i)$.

Proof: Compare a textbook on distributions, e.g., Ref. 37, Sec. 8.4. □

2. On the physical meaning

The diagram in Fig. 3, especially the "laws of physics" arrow, will now be supplemented with more detail.

Classification of theories: By applying the scaling degree's additive properties that, based on the scaling degree $2\rho_{p'} := \mathrm{sd}(\Delta^{+\gamma}_{p'}) \leqslant 2|p'| + \mathrm{sd}(\Delta^{+\gamma}_{p})$ of the propagator $\Delta^{+\gamma}_{p'} \equiv (-1)^{|p'|} \partial_{p'} \partial_{\tilde{p}'} \Delta^{+\gamma}_{p}$, lead to

$$\rho_v = \sum_{i \leqslant |P(v)|} \rho_{P_i(v)} \quad \text{and} \quad \rho_\Gamma = \sum_{k \leqslant |\mathrm{I}(\Gamma)|} \rho_{\mathrm{I}_k(\Gamma)}, \tag{116}$$

one determines the singular order $\omega_\Gamma = \rho_\Gamma - \dim$ of the graph Γ, i.e.,

$$\omega_\Gamma = \sum_{k \leqslant |\mathrm{V}(\Gamma)|} \omega_{\mathrm{V}_k(\Gamma)} - \omega_{\Omega(\Gamma)}, \quad \text{where } \omega_v := \rho_v - (1 + \mathrm{d}). \tag{117}$$

Power counting therefore reproduces the well-known classes, called

$$\begin{cases} \text{nonrenormalizable} \\ \text{renormalizable} \\ \text{super-renormalizable} \end{cases} \text{if} \quad \begin{cases} (\exists v \in \mathrm{U})\, \omega_v > 0, \\ (\forall v \in \mathrm{U})\, \omega_v \leqslant 0, (\exists v \in \mathrm{U})\, \omega_v = 0, \\ (\forall v \in \mathrm{U})\, \omega_v < 0, \end{cases} \tag{118}$$

or as usual, in numbers of divergent graphs $\mathrm{G}_{\mathrm{div}}$ and vertices $\mathrm{V}_{\mathrm{div}}$,

$$\text{if} \begin{cases} |\mathrm{V}_{\mathrm{div}}| \begin{cases} = \infty, \\ < \infty, \end{cases} & \text{where} \quad \mathrm{V}_{\mathrm{div}} = \{v \in \mathrm{W} | (\exists \Gamma \in \mathrm{G}_{\mathrm{div}}) v = \Omega\Gamma\}, \\ |\mathrm{G}_{\mathrm{div}}| < \infty, & \mathrm{G}_{\mathrm{div}} = \{\Gamma \in \mathrm{G}_{\mathrm{W}} | \omega_\Gamma \geqslant 0\}. \end{cases} \tag{119}$$

This is illustrated for a "toy pQFT" with $|\mathrm{U}| = 1$ initial vertex which couples m scalar fields ϕ.

Example 4.22: Let $H_{\mathcal{I}} \propto :\phi^m:$. Since $\Delta^+_\phi(x) = O(|x|^{-2})$ as $x \to 0$, $\rho_\phi = 1$, and $\rho_{\phi^m} = m$. Then, for a graph Γ consisting (exclusively) of ϕ^m vertices,

$$\omega_\Gamma = |\mathrm{V}(\Gamma)|(m - (1 + \mathrm{d})) - |\mathrm{E}(\Gamma)| + (1 + \mathrm{d}). \tag{120}$$

Depending on the considered space–time dimension $1 + \mathrm{d}$, i.e.,

$$\begin{cases} < m, \\ = m, \\ > m, \end{cases} \quad \text{so that} \quad \begin{cases} \mathrm{V}_{\mathrm{div}} = \mathrm{W}, \\ \mathrm{V}_{\mathrm{div}} = \{v \in \mathrm{W} |\, |\mathrm{P}(v)| \leqslant m\}, \\ \mathrm{G}_{\mathrm{div}} \subseteq \left\{\Gamma \in \mathrm{G}_{\mathrm{W}} |\, |\mathrm{V}(\Gamma)| \leqslant \frac{1+\mathrm{d}}{1+\mathrm{d}-m}\right\}, \end{cases} \tag{121}$$

one reproduces the above classes of renormalizable theories.

Renormalization freedom: Besides TI, which was implemented explicitly, k_Γ must satisfy other symmetries. For instance, GTS is ensured by the condition $k_\Gamma^{\alpha,\mathrm{I}(\Gamma)} = \sigma_\Gamma(\mathrm{I}(\pi \circ \Gamma)) k_{\pi(\Gamma)}^{\pi(\alpha),\mathrm{I}(\pi\circ\Gamma)}$,

$\forall \alpha$, $|\alpha| \leqslant \omega_\Gamma$. The requirements for Lorentz invariance are investigated in Ref. 38. Moreover, the physicists' strategy of selecting new vertices produced by renormalization is to implement further (physical) symmetries, e.g., C,P,T, invariance, pseudounitarity, and gauge invariance; Scharf[6] calls this *the principle of perturbative gauge invariance.*

Example 4.23: (Scalar QED) Let $H_{\mathcal{I}} = e : \phi^*(\partial^\mu \phi) A_\mu : - e : (\partial^\mu \phi^*) \phi A_\mu :$. Then there are two initial vertices,

$u_1 =$  , $u_2 =$  .

Consider d=3. Then $\omega_\Gamma = -\omega_{\Omega(\Gamma)} \equiv 1 + d - \rho_{\Omega(\Gamma)}$, i.e., a graph Γ is divergent only if $E(\Gamma) \leqslant 4$ and "$\partial\phi$" $\notin E(\Gamma)$. Therefore, three candidates $V \backslash U \subseteq V_{\text{div}}$ of new physical vertices are generated by renormalization,

$v_1 =$  , $v_2 =$  , $w_1 =$  .

However, only v_1 and v_2 are relevant (cf. Ref. 31, pp. 335ff). In accordance with pseudounitarity, $T_{(v_1)}(x) = : \phi^{*2}(x) \phi^2(x) :$, where $a_{v_1} = \lambda \in i\mathbb{R}$, and in accordance with gauge and C invariance, $T_{(v_2)}(x) = (1/i\hbar) g^{\mu\nu} : \phi^*(x) \phi(x) A_\mu(x) A_\nu(x) :$ where $a_{v_2} = e^2/i\hbar$. In the conventional approach, one would then rewrite the interaction Hamiltonian by summing over V, i.e., $H_{\mathcal{I}} = i\hbar \Sigma_{v \in V} a_v T_v$.

3. EG counterparts of Kreimer's HA

The goal is to model the change of the renormalization scheme via a HA similar to Kreimer's.[9] Formally, this is in contrast with the literature[12,17] where it has been claimed having extracted Kreimer's HA of renormalization in the EG approach (which should be impossible). In fact, similar to Kreimer's approach in Ref. 11, one can deform graded commutative versions of (the three) causally regularizing HAs in order to construct the aimed HA. However, the resulting HAs are still coassociative. This is in contrast with Kreimer's structure, which is noncoassociative and precisely referred to as a quasi-HA.

Graded commutative versions of the causally regularizing HAs are given as quotient algebras, $\underline{\mathcal{R}}^*_{G_\Gamma} = \hat{\mathcal{R}}^*_{G_\Gamma} / {}^*_\Gamma[\cdot,\cdot]^\otimes_\sigma$, divided by the ideal which is generated by the graded commutator, i.e., $(\underline{\mathcal{R}}^*_{G_\Gamma}, \mathbb{C}, +, \underline{\circ}^*_\Gamma, \eta, \Delta, \varepsilon, S_{\underline{\circ}^*_\Gamma})$ where the product reads

$$\underline{T}_{\Gamma^1} \underline{\circ}^*_\Gamma \underline{T}_{\Gamma^2} = \tfrac{1}{2} [\hat{T}_{\Gamma^1}, \hat{T}_{\Gamma^2}]^{\hat{\circ}^*_\Gamma}_{-\sigma}, \quad \forall\, T_{\Gamma^1}, T_{\Gamma^2} \in \mathcal{R}^{\mathsf{T}}_{G_\Gamma}. \tag{122}$$

Again, one abbreviates the new representatives by the former notation, $T_{\Gamma'} = \underline{T}_{(\Gamma')} \in \underline{\mathcal{R}}^*_{G_\Gamma}$. Notice, due to graded commutativity, $\underline{\mathcal{R}}^{\mathsf{T}}_{G_\Gamma} = \hat{\mathcal{R}}^{\mathsf{T}}_{G_\Gamma}$ and $\underline{\circ}^{\mathsf{T}}_\Gamma = \hat{\circ}^{\mathsf{T}}_\Gamma$.

As another prerequisite one introduces the algebra of tuples of strongly decreasing graphs, $(\mathcal{G}^{\supset}_\Gamma, \mathbb{C}, +, \cdot, \varnothing)$, which is defined as the quotient of the tensor algebra of graphs divided by an ideal of nondecreasing graphs,

$$\mathcal{G}^{\supset}_\Gamma = \bigoplus_{n \geqslant 0} G^{\otimes n}_\Gamma \Big/ \big((\ldots, \Gamma^2) \otimes (\Gamma^1, \ldots),\ \sqcap \Gamma^2 \not\supseteq \sqcap \Gamma^1, \tag{123}$$

$$(\ldots, \Gamma^2, \Gamma^1, \ldots) - (\ldots, \Gamma^1, \ldots),\ \sqcap \Gamma^2 = \sqcap \Gamma^1 \big). \tag{124}$$

The EG counterpart of Kreimer's HA, providing the transition $(\mathcal{R} \to \mathcal{R}') =: \mathcal{K}$ of renormalization schemes, is a HA $\underline{\mathcal{K}}^*_{G_\Gamma}$ which defines an extension of $\underline{\mathcal{R}}^*_{G_\Gamma}$. This HA can be constructed in complete analogy to the latter, starting with the counterpart of $\mathcal{R}^{\mathsf{T}}_{G_\Gamma}$, i.e., $\mathcal{K}^{\mathsf{T}}_{G_\Gamma}$

$:=\oplus_{n\geqslant 0}\mathbb{C}\{k_{\overline{\Gamma'}}T^{\mathcal{R}}_{\Gamma'}\,|\,\overline{\Gamma'}\in\mathcal{G}^{\supset}_{\Gamma},\overline{\Gamma'}_{|\overline{\Gamma'}|}=\Gamma',|\mathrm{V}(\Gamma')|=n\}$ where, analogous to (60),

$$k_{\overline{\Gamma'}}T^{\mathcal{R}}_{\Gamma'}:=(i\hbar)^{\#\Gamma'-|\Gamma'|}\Sigma_{\mathrm{b}(\Omega\Gamma')}k_{\overline{\Gamma'}}t^{\mathcal{R}}_{\mathrm{I}(\Gamma')}N(\Gamma') \tag{125}$$

which, chosen in accordance with (115), is determined by its scalar part,

$$\mathbb{T}\ni k_{\overline{\Gamma'}}t^{\mathcal{R}}_{\mathrm{I}(\Gamma')}:=\begin{cases} t^{\mathcal{R}}_{\mathrm{I}(\Gamma')} & \text{if } \overline{\Gamma'}=\emptyset,\\ \displaystyle\sum_{|\alpha|\leqslant\omega_{\Gamma'}} k^{\alpha,\mathrm{I}(\Gamma')}_{\overline{\Gamma'}\cdot(\Gamma')}\partial^{\alpha}\delta^{\mathrm{IV}(\Gamma')}, & \text{otherwise}. \end{cases} \tag{126}$$

The complex constants $k^{\alpha,\mathrm{I}(\Gamma')}_{\overline{\Gamma'}\cdot(\Gamma')}$ with multi-index α and particle indices $\mathrm{I}(\Gamma')$, depending on the product of the graph Γ' with an appropriate tuple of decreasing graphs $\overline{\Gamma'}$, fix the transition $\mathcal{K}$. As an empty sums is zero, $k_{\overline{\Gamma'}}T^{\mathcal{R}}_{\Gamma'}$ vanishes for nondivergent graphs Γ', i.e., if $\omega_{\Gamma'}<0$.

The additional structure in $\mathcal{K}_{\mathrm{G}_\Gamma}$ (i.e., the HA analogous to $\mathcal{R}_{\mathrm{G}_\Gamma}$) can be introduced as an action of an algebra, $k_\bullet:\mathcal{G}^{\supset}_{\Gamma}\to\mathrm{End}(\mathcal{K}_{\mathrm{G}_\Gamma})$ ($k_{\overline{\Gamma'}}T^{\mathcal{R}}_{\Gamma'}=0$ if $\sqcup\overline{\Gamma'}_{|\overline{\Gamma'}|}\not\supseteq\sqcap\Gamma'$), i.e., $k_{\overline{\Gamma^2}}\circ k_{\overline{\Gamma^1}}=k_{\overline{\Gamma^1}\cdot\overline{\Gamma^2}}$, $\forall\overline{\Gamma^1},\overline{\Gamma^2}\in\mathcal{G}^{\supset}_{\Gamma}$, so that, $\forall\overline{\Gamma'}\in\mathcal{G}^{\supset}_{\Gamma}$, $k_{\overline{\Gamma'}}$ defines a HA homomorphism, i.e., $k_{\overline{\Gamma'}}\circ\bigcirc_\Gamma=\bigcirc_\Gamma\circ(k_{\overline{\Gamma'}}\otimes k_{\overline{\Gamma'}})$, $\Delta\circ k_{\overline{\Gamma'}}=(k_{\overline{\Gamma'}}\otimes k_{\overline{\Gamma'}})\circ\Delta$, and $\mathrm{S}_{\circ_\Gamma}\circ k_{\overline{\Gamma'}}=k_{\overline{\Gamma'}}\circ\mathrm{S}_{\circ_\Gamma}$. Along this line, starting with Sec. III B 3, one repeats all the algebraic constructions for $\mathcal{K}$. As far as renormalization is involved, the scheme is still $\mathcal{R}$. One must only require that transition and renormalization exchange, i.e., $k_{\overline{\Gamma'}}\circ\mathrm{ren}^{\mathcal{R}}_{\Gamma'}:=\mathrm{ren}^{\mathcal{R}}_{\Gamma'}\circ k_{\overline{\Gamma'}}$, whenever $\overline{\Gamma'}_{|\overline{\Gamma'}|}\supset\sqcup\Gamma'$.

Theorem 4.24: *$(\underline{\mathcal{K}}^*_{\mathrm{G}_\Gamma},\mathbb{C},+,\underline{\circ}^*_{\Gamma'},\eta,\Delta,\epsilon,\mathrm{S}_{\underline{\circ}^*_\Gamma})$ forms a HA which extends $\mathcal{R}^*_{\mathrm{G}_\Gamma}$, and $k_\bullet:\mathcal{G}^{\supset}_{\Gamma}\to\mathrm{End}(\mathcal{K}^*_{\mathrm{G}_\Gamma})$ defines an action of an algebra where, $\forall\overline{\Gamma'}\in\mathcal{G}^{\supset}_{\Gamma}$, $k_{\overline{\Gamma'}}$ is a HA homomorphism. More precisely, $(\forall T'\in\underline{\mathcal{K}}^*_{\mathrm{G}_\Gamma})$ $(\exists!T\in\underline{\mathcal{R}}^*_{\mathrm{G}_\Gamma})$ $(\exists!\overline{\Gamma'}\in\mathcal{G}^{\supset}_{\Gamma})$ s.t. $k_{\overline{\Gamma'}}T=T'$, i.e., $k_\bullet:\mathcal{G}^{\supset}_{\Gamma}\to\mathrm{Hom}(\underline{\mathcal{R}}^*_{\mathrm{G}_\Gamma},\underline{\mathcal{K}}^*_{\mathrm{G}_\Gamma})$ where $T'\in\underline{\mathcal{R}}^*_{\mathrm{G}_\Gamma}\subset\underline{\mathcal{K}}^*_{\mathrm{G}_\Gamma}$ requires $T=T'\equiv k_\emptyset T$.*

Proof: This is the result of the constructions in the preceding sections, but in the context of $\mathcal{K}$ instead of $\mathcal{R}$. □

The theorem gets meaning when claiming the concrete embedding of the new scheme $\mathcal{R}'$, i.e., $\underline{\mathcal{R}}^*_{\mathrm{G}_\Gamma}\overset{\iota}{\cong}\underline{\mathcal{R}}'^*_{\mathrm{G}_\Gamma}\subset\underline{\mathcal{K}}^*_{\mathrm{G}_\Gamma}$,

$$\iota:T^{\mathcal{R}}_{\Gamma'}\mapsto T^{\mathcal{R}'}_{\Gamma'}:=T^{\mathcal{R}}_{\Gamma'}+\mathrm{S}^{k\geqslant 1}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}\quad\forall\,\Gamma'\in\mathrm{G}_\Gamma, \tag{127}$$

where $\mathrm{S}^{k}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}\equiv k_\bullet\circ\mathrm{S}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}:=\mathrm{S}_{\underline{\circ}^*_\Gamma}(k_{(\Gamma')}T^{\mathcal{R}}_{\Gamma'})$, $n\equiv|\mathrm{V}(\Gamma')|$, and $\mathrm{S}^{k\geqslant 1}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}=\mathrm{S}^{k}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}$, except for $n=1$, where $\mathrm{S}^{k\geqslant 1}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}=0$. The correctness of this setting rests upon the requirement that $\mathrm{supp}(T^{\mathcal{R}'}_{\Gamma'}-T^{\mathcal{R}}_{\Gamma'})\subseteq\mathrm{diag}^n_n$, which is guaranteed by the following fact.

Lemma 4.25: $\mathrm{supp}(\mathrm{S}^{k\geqslant 1}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'})\subseteq\mathrm{diag}^n_n$.

Proof: This can be shown by expansion of the antipode, i.e.,

$$\mathrm{S}^{k}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}=\mathrm{ren}^{\mathcal{R}}_{(\Gamma')}\circ k_{(\Gamma')}\Bigg(-T^{\mathcal{R}}_{\Gamma'}-\sum_{(\Gamma^1,\Gamma^2)\in\mathcal{P}_2(\Gamma')}\sigma_\Gamma(\Gamma^1\sqcup_\Gamma\Gamma^2)\mathrm{S}^{k}_{\underline{\circ}^*_\Gamma}T^{\mathcal{R}}_{\Gamma'}\,\underline{\circ}^*_\Gamma\,T^{\mathcal{R}}_{\Gamma^2}\Bigg), \tag{128}$$

and applying an adequate induction argument. For example, if $\underline{\mathcal{K}}^*_{\mathrm{G}_\Gamma}$ and $\mathrm{supp}\,K^i\subseteq\mathrm{diag}^{n_i}_{n_i}$, $i\leqslant 2$, where $n=n_1+n_2$, then $\mathrm{supp}(K^1\underline{\circ}^*_\Gamma K^2)\subseteq\mathrm{diag}^n_n$. □

For the case, $*=\mathsf{T}$, one can state the transition between the schemes explicitly.

Example 4.26: Let $P\in\mathcal{P}_r(\Gamma')$, $r\leqslant n$. Then R is called a P-tree iff $R\in\mathcal{G}^{\supset\times r}_{\Gamma}$, $(\forall j<r)$ $(R_{ij})_{i\leqslant j}\in\mathcal{P}_j(\Gamma')$ and $\exists!\,i_j\in\{i_{j-1},i_{j-1}+1\}$s.t.$(R_{i_jj+1},R_{i_j+1j+1})\in\mathcal{P}_2(R_{i_jj})$ where $i_1=1$, and $(R_{ir})_{i\leqslant r}=P$. Applying this notation, one obtains

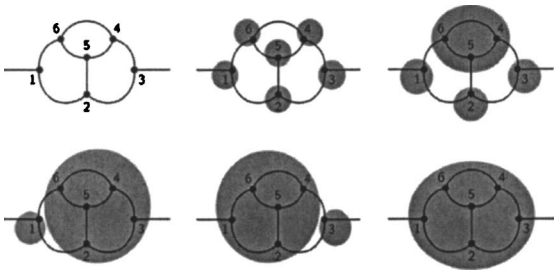

FIG. 4. A sample graph of ϕ^3 theory and its (five) partitions P of divergent subgraphs.

$$T^{\mathcal{R}'}_{\Gamma'} = T^{\mathcal{R}}_{\Gamma'} + \sum_{r<n} \sum_{P\in\mathcal{P}_r(\Gamma')} \sigma_{\Gamma'}(P) \sum_{R\ P-\text{tree}} \bigcirc^{\mathsf{T}}_{i\leqslant r} k_{R_i} T^{\mathcal{R}}_{P_i}. \tag{129}$$

For the (most) trivial transition (in this context), i.e., $k_{\overline{\Gamma'}} := k_{(\Gamma)}$, $\forall \overline{\Gamma'} \in \mathcal{G}^{\supset}_{\Gamma}$, this reduces to

$$T^{\mathcal{R}'}_{\Gamma'} = T^{\mathcal{R}}_{\Gamma'} + \sum_{r<n} \sum_{P\in\mathcal{P}_r(\Gamma')} \sigma_{\Gamma'}(P) \bigcirc^{\mathsf{T}}_{i\leqslant r} k_{P_i} T^{\mathcal{R}}_{P_i}, \tag{130}$$

corresponding to Pinter's result, cf. Eq. (14) in Ref. 17, p. 6.

Starting the comparison with the conventional approach, the following two examples illustrate how overlapping divergences are treated in the EG framework.

Example 4.27: Consider $H_{\mathcal{I}} \propto \phi^3$ for $\mathrm{d}=2$ and, especially, the graph in Fig. 4. Then the singular order of the divergent subgraphs $\Upsilon = P_i$ is given by $\omega_\Upsilon = 3 - |\mathrm{E}(\Upsilon)|$, i.e.,

$$\omega_\Upsilon = \begin{cases} 1 & \text{if } \mathrm{V}(\Upsilon) \in \{(4,5,6),(1,\ldots,6)\}, \\ 0, & \text{otherwise}. \end{cases}$$

Notice, the two subgraphs with loops, i.e., $((1,2,5,6),\ldots)$ and $((2,3,4,5),\ldots)$, which because of their 4 (>3) external lines are not divergent, do not contribute to the so-called forest formula (129).

Here, loops obviously do not play the distinguished role they play in the conventional approach (cf. Example 4.12). That holds true for tree graphs as well.

Example 4.28: Consider scalar QED for $\mathrm{d}=3$ and, especially, the graph in Fig. 5. Then the singular order of the divergent subgraphs $\Upsilon = P_i$ is given by $\omega_\Upsilon = 4 - |\mathrm{E}(\Upsilon)| = 0$. Notice, also tree graphs, i.e., $((1,2),\ldots)$ and $((3,4),\ldots)$, do represent divergent subgraphs.

Even if the structure of graphs presented here varies from Kreimer's (which is only pre-Lie), one can identify the following connection.

Remark 4.29: Let R be Kreimer's map which is supposed to leave the short distance singularities unaltered, e.g., if $\mathrm{reg}(\varepsilon) = \sum_{n=-p}^{\infty} c_n \varepsilon^n, p>0$, denotes a regularization for $\varepsilon \to 0$ then

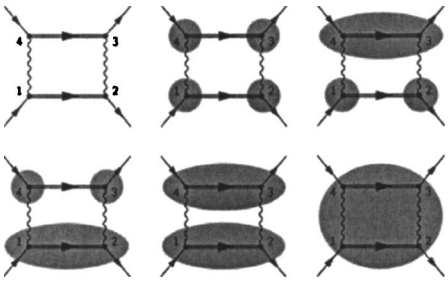

FIG. 5. A sample graph of scalar QED and its (five) partitions P of divergent subgraphs.

$R:\mathrm{reg}(\varepsilon)\mapsto\mathrm{reg}(\varepsilon)-\Sigma_{n\leqslant 0}c'_n\varepsilon^n$. Then one observes the following correspondence between the presented and Kreimer's HA:

$$k_\bullet \leftrightarrow R \text{ (i.e., } S^{k_\bullet}_{\circ^*_\Gamma} \leftrightarrow S_R) \quad \text{and} \quad \mathrm{ren}^{\mathcal{R}} \leftrightarrow \mathrm{id}-R, \tag{131}$$

reflecting the algebraic structure and, respectively, the function of renormalization.

In order to ensure that the deformed antipode S_R defines a homomorphism (which, for $S_{\circ^*_\Gamma}$, is fulfilled for free) the map R, and thus $\mathrm{id}-R$, have to satisfy a multiplicativity constraint, i.e.,

$$R(XY)+R(X)R(Y)=R(XR(Y))+R(R(X)Y), \tag{132}$$

the so-called Rota–Baxter relation, cf. Ref. 39.

Moreover, one can motivate the quasiness of Kreimer's deformed HA.

Remark 4.30: In the spirit of Kreimer's presentation, e.g., in Ref. 11, one may interpret the functor $\mathrm{Hom}(\underline{\mathcal{R}}^*_{G_\Gamma},\underline{\mathcal{K}}^*_{G_\Gamma})$ as a deformation of HAs induced by deforming,

$$\text{either the antipode,} \quad S_{\circ^*_\Gamma} \mapsto S^{k_\bullet}_{\circ^*_\Gamma} \equiv k_\bullet \circ S_{\circ^*_\Gamma}, \tag{133}$$

$$\text{or the coproduct,} \quad \Delta \mapsto \Delta^k \equiv (k_\bullet \otimes k_\bullet)\circ\Delta, \tag{134}$$

while keeping the coproduct or antipode, respectively, fixed. Then it is obvious why the deformed HA in Kreimer's original approach is only quasi (i.e., noncoassociative). Namely, $(\mathrm{id}\otimes\Delta^k)\circ\Delta^k T^{\mathcal{R}}_{\Gamma'}=(\Delta^k\circ\mathrm{id})\circ\Delta^k T^{\mathcal{R}}_{\Gamma'}$ is true only if the transition $k_\bullet$ is trivial.

A more detailed presentation of the content of this section will be given elsewhere.[40]

V. CONCLUSIONS AND OUTLOOK

About 10 years ago HAs entered the framework of pQFT. At that time Wick and Feynman contractions (i.e., $\sqcup\!\!\sqcup$ and $\sqcap$) have been identified, by Rota and Stein,[20,21] as examples for Laplace pairs in the context of combinatorial HAs. Since then, the formal perturbative expansion could have been considered as given by a Laplace HA. However, only recently has this been done, cf. Refs. 13 and 22. The knowledge about it did not get that popular among physicists as Kreimer's Hopf algebraic description of renormalization[9] in the late 1990s.

In this paper, both these HA approaches to pQFT (i.e., Entries 4 and 7 and, respectively, Entry 8 in the table of Fig. 1) get represented in the EG framework. The causally regularizing HAs (Entries 5–7) can therefore be regarded as a bridge between them. Furthermore, as an EG only feature, the HAs modeling normalization and localization of free fields (Entries 2–3) appear as the stucture that Cliffordization twists into the Laplace HA representing the perturbative expansion.

Topics for further research supplementing and extending the presented scenario of HAs, which apparently underlies the EG approach to pQFT, could read as follows (enumerated from the physical to the mathematical one):

i In the spirit of Kreimer's more recent work,[41,42] one might also think about implementing Scharf's principle[6] of perturbative gauge invariance into the HA context.

ii As Laplace pairs can be interpreted as objects in the theory of quantum groups (cf. Refs. 18, 19, and 22), namely as so-called R-forms (cf. Ref. 43, Sec. VIII.5), investigations in this direction, e.g., incorporating broader algebraic concepts as done in Ref. 23, still seem to be fruitful.

iii Following an idea of Kontsevich,[44] one might try to understand renormalization as a dual procedure to the compactification of the configuration space;[45] see also Ref. 46.

ACKNOWLEDGMENTS

The author would like to thank Professor Dirk Kreimer for the invitation to Boston University in fall 2003. The author profited a lot from the discussions with him and with Kurush Ebrahimi-

Fard. Moreover, the author would like to thank the Max Planck Institute MIS in Leipzig for financial support and especially Professor Eberhard Zeidler for his interest in the topic.

APPENDIX A: CALCULATIONS

Lemma A.1: $\Delta^{(\mathsf{N})}$, *i.e.,* Δ *and* Δ^{N}, *are GTS.*

Proof: The two claims can be proven at once, where the possible empty alternative is symbolized by brackets. Let $X\subseteq \mathrm{P}^n$, $n\in\mathbb{N}$, and let $\pi\in S_n$ be a permutation on X. Then

$$\Delta^{(\mathsf{N})}(\varphi^{\bigcirc\pi(X)}) = \sum_{P_\pm\in\mathcal{P}_2^0(\pi(X))} \sigma_{\pi(X)}(P_\pm)\cdots$$

$$= \sum_{P_\pm\in\mathcal{P}_2^0(X)} \sigma_{\pi(X)}(X)\sigma_X(P_\pm)\cdots = \sigma(\pi)\Delta^{(\mathsf{N})}(\varphi^{\bigcirc X}),$$

where the following identity for sets of partitions, i.e., $\mathcal{P}_2^0=\mathcal{P}_2^0\circ\pi$, $\forall\pi\in S_n$, and following the group representation rule for the grading sign, $\sigma_Y(Z)=\sigma_Y(X)\sigma_X(Z)$, $\forall X, Y, Z\in\mathrm{P}^n$, were used. □

Lemma A.2: Δ *and* Δ^{N} *are coassociative where, for the first coproduct,* ε *also satisfies the counit property.*

Proof: The three calculations below verify the claims. Let $X\in\mathrm{P}^n$, $n\in\mathbb{N}$. First,

$$(\mathrm{id}\otimes\Delta)\circ\Delta(\varphi^{\bigcirc X}) = \sum_{P\in\mathcal{P}_2^0(X)} \sigma_X(P)\varphi^{\bigcirc P_1}\otimes\Delta(\varphi^{\bigcirc P_2})$$

$$= \sum_{P\in\mathcal{P}_2^0(X)} \sigma_X(P)\varphi^{\bigcirc P_1}\otimes \sum_{Q\in\mathcal{P}_2^0(P_2)} \sigma_{P_2}(Q)\varphi^{\bigcirc Q_1}\otimes\varphi^{\bigcirc Q_2}$$

$$= \sum_{(P_1,Q_1,Q_2)\in\mathcal{P}_3^0(X)} \sigma_X(P_1,Q_1,Q_2)\varphi^{\bigcirc P_1}\otimes\varphi^{\bigcirc Q_1}\otimes\varphi^{\bigcirc Q_2}$$

$$\cdots$$

$$=(\Delta\otimes\mathrm{id})\circ\Delta(\varphi^{\bigcirc X}),$$

second

$$(\mathrm{id}\otimes\varepsilon)\circ\Delta(\varphi^{\bigcirc X}) = \sum_{P\in\mathcal{P}_2^0(X)} \sigma_X(P)\varphi^{\bigcirc P_1}\otimes\varepsilon(\varphi^{\bigcirc P_2})$$

$$=\sigma_X(X\otimes\emptyset)\varphi^{\bigcirc X}\otimes 1=\varphi^{\bigcirc X}$$

$$\cdots$$

$$=(\varepsilon\otimes\mathrm{id})\circ\Delta(\varphi^{\bigcirc X}),$$

which have been rather standard, and third,

$$(\mathrm{id}\otimes\Delta^{\mathsf{N}})\circ\Delta^{\mathsf{N}}(\varphi^{\bigcirc X}) = \sum_{P\in\mathcal{P}_2^0(X)} \sigma_X(P)\mathrm{pr}_+\circ\varphi^{\bigcirc P_1}\otimes\mathrm{pr}_-\circ\Delta^{\mathsf{N}}(\varphi^{\bigcirc P_2})$$

$$= \sum_{P\in\mathcal{P}_2^0(X)} \sigma_X(P)\varphi_+^{\bigcirc P_1} \otimes \sum_{Q\in\mathcal{P}_2^0(P_2)} \sigma_{P_2}(Q)\mathrm{pr}_- \circ \varphi_+^{\bigcirc Q_1} \otimes \mathrm{pr}_- \circ \varphi_-^{\bigcirc Q_2}$$

$$= \sum_{P\in\mathcal{P}_2^0(X)} \sigma_X(P)\varphi_+^{\bigcirc P_1} \otimes \sigma_{P_2}(\varnothing \otimes P_2)1 \otimes \varphi_-^{\bigcirc P_2}$$

$$= \sum_{P\in\mathcal{P}_2^0(X)} \sigma_X(P)\varphi_+^{\bigcirc P_1} \otimes 1 \otimes \varphi_-^{\bigcirc P_2}$$

$$\cdots$$

$$= (\Delta^{\mathsf{N}} \otimes \mathrm{id}) \circ \Delta^{\mathsf{N}}(\varphi^{\bigcirc X}),$$

where the projection properties, $\mathrm{pr}_\pm^2 = \mathrm{pr}_\pm$ and $\mathrm{pr}_\mp \circ \mathrm{pr}_\pm = 0$, were applied. □

Lemma A.3: *$\Delta^{(\mathsf{N})}$ and ε define homomorphisms with respect to the products $\square \in \{\circ, \mathsf{N}\}$.*

Proof: Let X^1, $X^2 \subset \mathrm{P}^n$, $n \in \mathbb{N}$. Then

$$\varepsilon(\varphi^{\square X^1} \square \varphi^{\square X^2}) \equiv \varepsilon(\varphi^{\square X^1})\varepsilon(\varphi^{\square X^2}) = \begin{cases} 1 & \text{if } X^1 = X^2 = \varnothing, \\ 0, & \text{otherwise,} \end{cases} \tag{A1}$$

and

$$\Delta^{(\mathsf{N})}(\varphi^{\square X^1} \square \varphi^{\square X^2}) = \sum_{P\in P_2^0(X^1\otimes X^2)} \sigma_{X^1\otimes X^2}(P)\varphi_{(+)}^{\square P_1} \otimes \varphi_{(-)}^{\square P_2}$$

$$= \sum_{\substack{P\in P_2^0(X^1\otimes X^2) \\ P_i = P_i^1 \otimes P_i^2, i\leqslant 2 \\ P_i^j \in P_2^0(X^j), j\leqslant 2}} \sigma_{X^1}(P^1)\sigma_{X^2}(P^2) \underbrace{\varphi_{(+)}^{\square P_1^1} \circ \varphi_{(+)}^{\square P_1^2} \otimes \varphi_{(-)}^{\square P_2^1} \circ \varphi_{(-)}^{\square P_2^2}}_{=\left(\varphi_{(+)}^{\square P_1^1} \otimes \varphi_{(-)}^{\square P_2^1}\right) \square \left(\varphi_{(+)}^{\square P_1^2} \otimes \varphi_{(-)}^{\square P_2^2}\right)}$$

$$= \Delta^{(\mathsf{N})}(\varphi^{\square X^1}) \square \Delta^{(\mathsf{N})}(\varphi^{\square X^2}),$$

where a decomposition of the grading sign based on the group representation were applied. □

APPENDIX B: ILLUSTRATIONS

Example B.1: Illustrated for two graphs of QED (cf. Example 2.6), e.g., for

$\Gamma^1 \equiv (X^1, \Lambda^1) =$  , $\Gamma^2 \equiv (X^2, \Lambda^2) =$ 
with vertices $(\overline{\psi}, \psi, A)$, except of $X_2^2 = (\overline{\psi}, \psi, A^{\mathrm{cl}})$, and matrices of lines

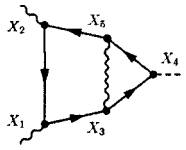
$$\Lambda^1 = \begin{pmatrix} \varnothing & \{(1,2)\} \\ \{(2,1)\} & \varnothing \end{pmatrix}, \quad \Lambda^2 = \begin{pmatrix} \varnothing & \{(2,1)\} & \{(3,3)\} \\ \{(1,2)\} & \varnothing & \{(2,1)\} \\ \{(3,3)\} & \{(1,2)\} & \varnothing \end{pmatrix},$$

the concatenation with the matrix

$$\Lambda^{12} = \begin{pmatrix} \{(2,1)\} & \varnothing & \varnothing \\ \varnothing & \varnothing & \{(1,2)\} \end{pmatrix},$$

yields the graph

$$\Gamma^1 \sqcup_{\Lambda^{12}} \Gamma^2 \equiv \left(X, \begin{pmatrix} \Lambda^1 & \Lambda^{12} \\ \tilde{\Lambda}^{12} & \Lambda^2 \end{pmatrix} \right) =$$



Example B.2: Consider the following quantum model, where the time evolution is determined by the Schrödinger equation, $i\hbar\partial_t\varphi(t,\vec{x}) = H(t)\varphi(t,\vec{x})$, and an interaction Hamiltonian, $H(t) = \int_{\mathbb{R}^d} dx\, H(t,\vec{x})$. The S-matrix $S = \lim_{t_\pm \to \pm\infty} U(t_+,t_-)$ is the limit of an unitary operator U which describes the time evolution of an incoming free field. By repeatedly applying the integrated Schrödinger equation, $\varphi(t,\vec{x}) = \varphi(s,\vec{x}) - (i/\hbar)\int_s^t dt_1\, H(t_1)\varphi(t_1,\vec{x})$, one obtains the so-called *Dyson series*,

$$U(t,s) = 1 + \sum_{n=1}^{\infty} \frac{(-i)^n}{\hbar^n} \int_s^t dt_1 \cdots \int_s^{t_{n-1}} dt_n H(t_1)\cdots H(t_n).$$

By inserting the time-ordering operation, i.e.,

$$\mathsf{T}(h(t_1,\ldots,t_n)) = \sum_{\pi\in S_n} \theta_{(t_{\pi_1},\ldots,t_{\pi_n})}\sigma(\pi)h(t_{\pi_1},\ldots,t_{\pi_n}), \tag{B1}$$

where

$$\theta_{(t_1,\ldots,t_n)} := \theta(t_1 - t_2)\cdots\theta(t_{n-1} - t_n) = \begin{cases} 1 & \text{if } t_1 > \cdots > t_n, \\ 0, & \text{otherwise} \end{cases} \tag{B2}$$

denotes a product of step functions, the limit can be performed,

$$S = 1 + \sum_{n=1}^{\infty} \frac{1}{n!(i\hbar)^n} \int_{\mathbb{R}^{1+d}} dt_1\, dx_1 \cdots \int_{\mathbb{R}^{1+d}} dt_n\, dx_n\, \mathsf{T}(H(t_1,\vec{x}_1)\cdots H(t_n,\vec{x}_n)).$$

APPENDIX C: SYMBOLS AND ABBREVIATIONS

GTS	graded total symmetry (symmetric, respectively)
TI	translation invariance (invariant, respectively)
$\phi^{\square_J}$, $\phi_J^{\square}$	$\phi^{\square_J} := \square_{j\in J}\phi^j$ and $\phi_J^{\square} := \square_{j\in J}\phi_j$, for any kind of product "$\square$"
$[\cdot,\cdot]_\sigma^{\otimes}$	graded commutator, cf. (12)
N	normal product, cf. (27) and (39)
L	localization, cf. (34)
$\Sigma_{\ldots}$	coupling monomial, cf. (35), (41), and (54)
$\Omega: G_V \to V$	shrinking of graphs G_v to vertices V, cf. Sec. III A 1
$\sqcup_\Gamma$	composition of graphs with Γ being a reference graph, cf. (44)
U	Wick contractions, cf. (57); in accordance with BS' notation: $\mathsf{U}_{(i,j)} := \mathsf{N}(\ldots\otimes\phi^i\otimes\cdots\otimes\phi^j\otimes\ldots) = [\phi_-^i,\phi_+^j]_\sigma^{\otimes}\mathsf{N}(\ldots\otimes\cdots\otimes\ldots)$
$\circ_\Gamma^*$	product of distributions with Γ being a reference graph, cf. (62) and (64)
$\mathrm{cone}_P^{(\exists)}$	(weak) causal cone with respect to a partition P, cf. (74)
$\mathbb{R}^{\dim}_{\neq r}$	causally determined spacetime region, cf. (77)
$\hat{\circ}_\Gamma^*$	product of causally regularized distributions, cf. (97)

Π Feynman contractions, cf. (104); in accordance with BS' notation:
$\Pi_{(i,j)} := \mathsf{N}(\cdots \otimes \phi^i \otimes \cdots \otimes \phi^j \otimes \cdots) = \mathsf{T}[\phi^i_-, \phi^j_+]^{\otimes}_{\sigma} \mathsf{N}(\cdots \otimes \cdots \otimes \cdots)$
$\circ^*_\Gamma$ graded commutative product of regularized distributions, cf. (122)
$* = \exists, \mathsf{F}, \mathsf{T}$ referring to the method of EGS, EGF, BS, respectively

(Received 10 March 2005; accepted 30 March 2005; published online 25 May 2005)

We derive classical particle, string, and membrane motion equations from a rigorous asymptotic analysis of the Born–Infeld nonlinear electromagnetic theory. We first add to the Born–Infeld equations the corresponding energy-momentum conservation laws and write the resulting system as a nonconservative symmetric 10×10 system of first-order PDEs. Then we show that four rescaled versions of the system have smooth solutions existing in the (finite) time interval where the corresponding limit problems have smooth solutions. Our analysis is based on a continuation principle previously formulated by Yong for (singular) limit problems. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1925248]

I. INTRODUCTION

The Born–Infeld (BI) equations were originally introduced in Ref. 1 as a nonlinear correction to the standard linear Maxwell equations for electromagnetism. They form a 6×6 system of conservation laws, together with two solenoidal constraints on the magnetic field and electric displacement. This system has many remarkable physical and mathematical features. Introduced in 1934, the BI model was designed to cure the classical divergence of the electrostatic field generated by point charges, by introducing an absolute limit to it (just like the speed of light is an absolute limit for the particle velocity in special relativity). The value of the absolute field was fixed by Born and Infeld according to physical considerations. As a result, for moderate electromagnetic fields, the discrepancy between the BI model and the classical Maxwell equations is noticable only at subatomic scales (10^{-15} meters). However, for very large values of the field, the BI model gets very different from the Maxwell model and, as will be rigorously established in this paper, rather describes the evolution of point particles along straight lines, or vibrating strings or vibrating membranes, depending on the considered scales.

Although the BI model was rapidly given up due to the emergence of quantum electrodynamics (QED) in the 1940s, there has been a lot of recent interest in it. In high energy physics, D-branes can be modelled according to a generalization of the BI model.[14,5] In differential geometry, the BI equations are closely related to the study of extremal surfaces in the Minkowski space. From the partial differential equations (PDEs) viewpoint, the initial value problem (IVP) has been recently investigated by Lindblad (in the "scalar case" of extremal surfaces[12]) and by Chae and Huh.[3] They show the existence of global smooth solutions, for small initial data (in a regime sufficiently close to the Maxwell limit), using Klainerman's null forms and energy estimates. In mathematical physics, QED has recently been revisited by Kiessling who used a quantization technique well suited to nonlinear PDEs, involving a relativistic version of the Fisher information.[9]

b)Electronic mail: yong.wen-an@iwr.uni-heidelberg.de

In Ref. 2, Brenier exploited the fact that the energy density and the Poynting vector satisfy certain additional conservation laws and lifted the Born–Infeld model to a 10×10 system of conservation laws, by using the energy density and the Poynting vector as new unknown variables. The resulting ABI (augmented Born–Infeld) system provides a set of equations coupling the electromagnetic field and a virtual fluid having the electromagnetic energy as mass and the Poynting vector as momentum. It was pointed out that the ABI system has some remarkable structural properties like existence of a strictly convex entropy, Galilean invariance of fluid mechanics, and full linear degeneracy.

Moreover, three asymptotic regimes of the ABI system are studied in Ref. 2, using Dafermos' relative entropy method[4] to analyze the resulting (singular) limit problems. With such analysis, the linear Maxwell equations are derived for low fields, some pressureless MHD equations, describing vibrating strings, for high fields, and pressureless gas equations for very high fields. Unfortunately, these results postulate the existence of global weak solutions for the ABI system (although they do not require *a priori* bounds on them). This is a major weakness, since the global existence of weak solutions to the IVP remains an outstanding open problem for essentially all multidimensional system of nonlinear hyperbolic conservation laws.

The goal of this paper is to use the framework of smooth solutions and energy estimates to get definite asymptotic results, using a nonconservative form of the ABI system. It will be shown that IVPs of the rescaled ABI systems have smooth solutions existing in the (finite) time interval where the corresponding reduced problems have smooth solutions. The analysis is based on a continuation principle previously formulated in Ref. 17 for (singular) limit problems, and combines formal asymptotic expansions with error estimates of energy type for symmetrizable hyperbolic systems. We also consider a high field regime, involving vibrating membranes, which was disregarded in Ref. 2.

The use of the continuation principle makes our analysis quite different from the classical one due to Klainerman and Majda.[10,11,13] With the latter, one shows the existence in a scaling-independent time interval, which may be properly contained in the time interval where the corresponding reduced problems have smooth solutions. The difference of the two approaches makes significant sense when the reduced problems have global smooth solutions. Such an example is given in Sec. VI D for low fields. See also Sec. III.

As a by-product and first step of our analysis, we observe that the nonconservation form of the ABI equations constitutes a *symmetric* (not only *symmetrizable*) hyperbolic system. Thus, the local well-posedness of the ABI system becomes obvious. Note that the symmetry does not follow directly from the existence of a strictly convex entropy proved in Ref. 2, since the latter involves the solenoidal constraints and thus the entropy is not that in the usual sense. About this point see also Serre.[15] Moreover, we show that the solenoidal constraints are compatible with the symmetric hyperbolic systems and point out a few possibly important structural properties thereof. In addition, the nonconservative ABI system, remarkably enough, is well defined for all states in $\mathbb{R}^{10}$, in sharp contrast with the conservative version, which requires the density field h to be non-negative. Indeed, the nonconservative system involves the inverse density field τ, which substitutes for h^{-1} and can take any real values, negative, positive, or null. As a consequence, the previously mentioned asymptotic results trivially follow from the symmetry of the nonconservative ABI system, at least for short time intervals. So an important technical issue of this paper is to extend these time intervals according to the existence time interval of the solutions to the limit equations, by using the method discussed above.

The paper is organized as follows. In Sec. II, we introduce the nonconservative augmented Born–Infeld equations and point out some of its structural properties. In Sec. III, we introduce three high field limits of the ABI equations and show that they, respectively, describe particle, string, and membrane motions. In Sec. IV, a crude asymptotic analysis is performed just by using the symmetric structure of the nonconservative ABI system. In Sec. V, an abstract theorem is established for the rescaled ABI systems. This theorem is applied to four concrete asymptotic regimes in Sec. VI to get sharper results. The paper ends with an appendix, which contains the continuation principle for (singular) limit problems of symmetrizable hyperbolic systems.

Notation: Let $\Omega=\mathbb{R}^d$ or $\mathbb{T}^d$ (the d-dimensional torus). L^2 is the space of square integrable (vector- or matrix-valued) functions on Ω and its norm is denoted by $\|\cdot\|$. In case A depends on another variable t as well as on $x\in\Omega$, we write $\|A(t)\|$ or $\|A(\cdot,t)\|$ to recall that the norm is taken with respect to x while t is viewed as a parameter. Similar notation will be adopted for the function spaces introduced below. For a non-negative integer k, the Sobolev space $H^k=H^k(\Omega)$ is defined as the space of functions whose distributional derivatives of order $\leqslant k$ are all in L^2. We use $\|\cdot\|_k$ to denote the norm of H^k. Furthermore, $C(J,H^k)$ denotes the space of continuous functions on the interval J with values in H^k. Finally, partial time derivatives will be frequently denoted by u_t, instead of $\partial_t u$.

II. THE BORN–INFELD SYSTEM AND ITS NONCONSERVATIVE AUGMENTED VERSION

Let B and D be time-dependent vector fields in $\mathbb{R}^3$. The Born–Infeld (BI) equations read (see, e.g., Ref. 2)

$$B_t+\nabla\times\left(\frac{B\times V+D}{h}\right)=0,\quad D_t+\nabla\times\left(\frac{D\times V-B}{h}\right)=0,\quad \operatorname{div}B=\operatorname{div}D=0, \tag{2.1}$$

where

$$h=\sqrt{1+|B|^2+|D|^2+|D\times B|^2},\quad V=D\times B, \tag{2.2}$$

and $|\cdot|$ stands for the Euclidean norm. Immediately notice that the classical (homogeneous) Maxwell equations

$$B_t+\nabla\times D=0,\quad D_t-\nabla\times B=0,\quad \operatorname{div}B=\operatorname{div}D=0 \tag{2.3}$$

can be seen as the limit of the BI equations for weak fields $B,D\ll 1$.

In Ref. 2, Brenier exploited the fact that, for smooth solutions of the BI system, the energy density h and the Poynting vector V satisfy additional conservation laws—the first two lines in (2.4) below, and used h and V as unknown variables to augment the BI model as a 10×10 system of conservation laws. Set

$$v=V/h,\quad b=B/h,\quad d=D/h.$$

The ABI (augmented Born–Infeld) system can be written as

$$\begin{aligned}
&h_t+\operatorname{div}(hv)=0,\\
&(hv)_t+\operatorname{div}(hv\otimes v-hb\otimes b-hd\otimes d)=\nabla h^{-1},\\
&(hb)_t+\operatorname{div}(hb\otimes v-hv\otimes b)+\nabla\times d=0,\\
&(hd)_t+\operatorname{div}(hd\otimes v-hv\otimes d)-\nabla\times b=0
\end{aligned} \tag{2.4}$$

along with

$$\operatorname{div}(hb)=\operatorname{div}(hd)=0. \tag{2.5}$$

See Ref. 2 for further discussions about this ABI system.

Here we only consider smooth solutions to the ABI system. Therefore, we may focus on the nonconservative form of (2.4) with (2.5). Set $\tau=h^{-1}$. By using the identity

$$\operatorname{div}(d\otimes b)=(b\cdot\nabla+\operatorname{div}b)d,$$

we can easily verify that smooth solutions to (2.4) with (2.5) satisfy

$$\begin{aligned} &\tau_t + v \cdot \nabla \tau - \tau \operatorname{div} v = 0, \\ &v_t + v \cdot \nabla v - b \cdot \nabla b - d \cdot \nabla d - \tau \nabla \tau = 0, \\ &b_t + v \cdot \nabla b - b \cdot \nabla v + \tau \nabla \times d = 0, \\ &d_t + v \cdot \nabla d - d \cdot \nabla v - \tau \nabla \times b = 0. \end{aligned} \tag{2.6}$$

This is a symmetric hyperbolic system,

$$W_t + \sum_{j=1}^{3} A_j(W) W_{x_j} = 0 \tag{2.7}$$

for $W=(\tau, v^T, b^T, d^T)^T$, with homogeneous quadratic nonlinearities. Here the superscript "T" denotes the transpose operation and the coefficient matrix is

$$A_j(W) = v_j I_{10} + \begin{pmatrix} 0 & -\tau e_j^T & 0_3^T & 0_3^T \\ -\tau e_j & 0_{3\times 3} & -b_j I_3 & -d_j I_3 \\ 0_3 & -b_j I_3 & 0_{3\times 3} & \tau e_j \times \\ 0_3 & -d_j I_3 & -\tau e_j \times & 0_{3\times 3} \end{pmatrix} \tag{2.8}$$

with v_j the jth component of v, I_k the unit matrix of order k, e_j the jth column of I_3, 0_3 the origin of $\mathbb{R}^3$, and $0_{3\times 3}$ the origin of $\mathbb{R}^{3\times 3}$. Notice that (2.7) makes sense for all states

$$W = (\tau, v^T, b^T, d^T)^T \in \mathbb{R}^{10}, \tag{2.9}$$

not only for $\tau > 0$ and even if the solenoidal constraints (2.5) do not hold.

It is remarkable that the coefficient matrix $A_j(W)$ *linearly* depends on W and the symmetry is independent of the solenoidal constraints, which are needed in Ref. 2 to show the existence of a strictly convex entropy function.

Also notice that, in the original BI equations, B, D, h, and V are linked together by the algebraic relations (2.2). This means that the original BI equations exactly correspond to the nonconservative formulation (2.6), with the further restriction that $W=(\tau, v^T, b^T, d^T)^T$ must be valued in the "BI manifold" defined by

$$\tau > 0, \quad \tau^2 + b^2 + d^2 + v^2 = 1, \quad \tau v = d \times b. \tag{2.10}$$

Of course, as for the original ABI system, the BI manifold is an invariant set for system (2.6).

The equivalence of (2.6) and (2.4) with (2.5) is illustrated here.

Proposition 2.1: If initial data for (2.6) satisfy the constraints in (2.5), then the corresponding smooth solutions to (2.6) satisfy (2.4) as well as (2.5).

Proof: It suffices to verify (2.5). To do this, we notice that the smooth solutions to (2.6) satisfy $h_t + \operatorname{div}(hv) = 0$ and

$$(hb)_t + \nabla \times (hb \times v) + \nabla \times d + \operatorname{div}(hb) v = 0,$$

where $h = \tau^{-1}$. Thus, we have

$$(\operatorname{div}(hb))_t + v \cdot \nabla (\operatorname{div}(hb)) + \operatorname{div}(hb) \operatorname{div} v = 0.$$

Since $\operatorname{div}(hb) = 0$ initially, we have $\operatorname{div}(hb) = 0$ for all t. Similarly, we can show $\operatorname{div}(hd) = 0$. This completes the proof. □

Furthermore, we point out the following important property of the symmetric hyperbolic system (2.6) or (2.7) with (2.8).

Proposition 2.2: Let $W=(\tau, v^T, b^T, d^T)^T$ be a smooth solution to (2.6) with $\tau > 0$. Then

$$\partial_t(hI_{10}) + \sum_j \partial_{x_j}(hA_j(W)) = \mathrm{div}(hb)C_1 + \mathrm{div}(hd)C_2$$

holds with C_1 and C_2 constant symmetric matrices and $h=\tau^{-1}$. In particular, if intial data for (2.6) satisfy the solenoidal constraints in (2.5), then

$$\partial_t(hI_{10}) + \sum_j \partial_{x_j}(hA_j(W)) = 0.$$

Proof: From the explicit expression of the coefficient matrix given in (2.8) it follows that

$$\partial_t(hI_{10}) + \sum_j \partial_{x_j}(hA_j(W)) = (h_t + \mathrm{div}(hv))I_{10} + \sum_j \partial_{x_j}\begin{pmatrix} 0 & -e_j^T & 0_3^T & 0_3^T \\ -e_j & 0_{3\times 3} & -hb_jI_3 & -hd_jI_3 \\ 0_3 & -hb_jI_3 & 0_{3\times 3} & e_j\times \\ 0_3 & -hd_jI_3 & -e_j\times & 0_{3\times 3} \end{pmatrix}$$

$$= -\begin{pmatrix} 0 & 0_3^T & 0_3^T & 0_3^T \\ 0_3 & 0_{3\times 3} & \mathrm{div}(hb)I_3 & \mathrm{div}(hd)I_3 \\ 0_3 & \mathrm{div}(hb)I_3 & 0_{3\times 3} & 0_{3\times 3} \\ 0_3 & \mathrm{div}(hd)I_3 & 0_{3\times 3} & 0_{3\times 3} \end{pmatrix}.$$

This completes the proof. □

III. HIGH FIELD LIMITS: PARTICLE, STRING, AND MEMBRANE MOTIONS

Observe that, for the nonconservative system (2.6), the states $W=(0,v^T,b^T,d^T)^T$, for which $\tau=0$, are not singular, while, for the conservative ABI system (2.4), they correspond to fields (B,D) of infinite intensity. (Indeed $\tau=h^{-1}$.) (Let us recall that, for classical gas dynamics equations, the state $\tau=0$ is always singular.)

Due to the special structure of (2.6), the corresponding "reduced" states $(v^T,b^T,d^T)^T$ solve the following "reduced" system

$$\begin{aligned} &v_t + v\cdot\nabla v - b\cdot\nabla b - d\cdot\nabla d = 0, \\ &b_t + v\cdot\nabla b - b\cdot\nabla v = 0, \\ &d_t + v\cdot\nabla d - d\cdot\nabla v = 0. \end{aligned} \tag{3.1}$$

A further reduction is obtained as $d=0$, which leads to

$$\begin{aligned} &v_t + v\cdot\nabla v - b\cdot\nabla b = 0, \\ &b_t + v\cdot\nabla b - b\cdot\nabla v = 0. \end{aligned} \tag{3.2}$$

Finally, $\tau=0$ and $b=d=0$ reduce (2.6) to a single equation

$$v_t + v\cdot\nabla v = 0. \tag{3.3}$$

Notice the parallel reduction of the BI manifold (2.10) to the following reduced manifolds

$$b^2 + d^2 + v^2 = 1, \quad d\times b = 0, \quad v\cdot b = v\cdot d = 0, \tag{3.4}$$

$$b^2 + v^2 = 1, \quad v\cdot b = 0, \tag{3.5}$$

$$v^2 = 1, \tag{3.6}$$

respectively, associated to (3.1)–(3.3).

These three sets of "high field" equations have a simple physical and geometrical interpretation. Indeed, system (3.3) describes a continuum of particles moving along straight lines with constant speed, as well known. If, in addition, (3.6) holds true, these particles can be interpreted as massless particles with unit velocities. System (3.2) is more subtle and describes collections of vibrating strings, as will be shown below. Condition (3.5) guarantees that these strings are genuine relativistic strings. Notice that (3.2) can also be interpreted as a shallow water MHD equation (without gravity terms), following Ref. 6. Similarly, system (3.1) describes vibrating membranes. These statements follow from the following observation.

Proposition 3.1: Let $(s,r,u) \in \mathbb{R}^3 \to X(t,s,r,u)$ *be a smooth family of diffeomorphisms of* $\mathbb{R}^3$, *depending on* $t \in [-T,T]$. *Let* λ, μ *be two non-negative real constants. Assume that*

$$\partial_{tt} X = \lambda \partial_{ss} X + \mu \partial_{rr} X \tag{3.7}$$

holds true. Implicitly define

$$b(t,X(t,s,r,u)) = \partial_s X(t,s,r,u), \tag{3.8}$$

$$d(t,X(t,s,r,u)) = \partial_r X(t,s,r,u), \tag{3.9}$$

$$v(t,X(t,s,r,u)) = \partial_t X(t,s,r,u). \tag{3.10}$$

Then (b,d,v), *respectively, is a smooth solution to system (3.1) if* $\lambda = \mu = 1$, *system (3.2) if* $\lambda = 1$ and $\mu = 0$, *and equation (3.3) if* $\lambda = \mu = 0$.

Proof: The proof is a straightforward application of the chain rule: differentiate (3.8)–(3.10) with respect to t, use Eq. (3.7) and get the desired equations (3.1)–(3.3).

Geometrical interpretation: According to (3.7), in the case $\lambda = \mu = 0$, each trajectory $t \to X(t,r,s,u)$ is a straight line, as (r,s,u) varies in $\mathbb{R}^3$. In the case $\lambda = 1$ and $\mu = 0$, each surface $(t,s) \to X(t,r,s,u)$ solves the wave equation

$$\partial_{tt} X = \partial_{ss} X,$$

and describes a vibrating string, as (r,u) varies in $\mathbb{R}^2$. Notice that the algebraic constraint (3.5) reads

$$\partial_t X^2 + \partial_s X^2 = 1, \quad \partial_t X \cdot \partial_s X = 0,$$

which, together with the wave equation, means that these strings are genuinely relativistic (i.e., they are extremal surfaces in the Minkowski space). Similarly, in the case $\lambda = \mu = 1$, each $(t,s,r) \to X(t,r,s,u)$ describes a vibrating membrane as u varies along the real line.

Global smooth solutions to the string system (3.2). From Proposition 3.1, we see that the high field equation (3.2) has nontrivial global smooth solutions for smooth initial conditions sufficiently close to suitable trivial solutions. Any constant vector $B_0 \neq 0$ provides a trivial solution $b = B_0$, $v = 0$ and a corresponding family of diffeomorphisms is $X(t,s,r,u) = sB_0 + rD_0 + uB_0 \times D_0$, where $D_0 \neq 0$ is arbitrarily chosen such that $B_0 \cdot D_0 = 0$. Then, for any initial condition (b,v) chosen sufficiently close to the trivial solution, Eq. (3.2) has a global smooth solution. Indeed, it is enough to (i) introduce an initial diffeomorphism $X(0,s,r,u)$ implicitly defined by

$$\partial_s X(0,s,r,u) = b(0,X(0,s,r,u)),$$

(ii) for each fixed (s,u) solve the wave equation (3.7) with $\mu = 0$ and

$$\partial_t X(0,s,r,u) = v(0,X(0,s,r,u)),$$

(iii) ensure that, for all t, $(s,r,u)\to X(t,s,r,u)$ still is a diffeomorphism of $\mathbb{R}^3$, by choosing initial data $(b,v)(0,x)$ sufficiently close to $(B_0,0)$, (iv) globally define a solution (b,v) to (3.2) by

$$\partial_s X(t,s,r,u) = b(t,X(t,s,r,u)), \quad \partial_t X(t,s,r,u) = v(t,X(t,s,r,u)).$$

So, we see that the high field limit equations formally derived from the ABI system do have global smooth solutions in the neighborhood of some trivial solutions. This is also true for the original BI equations, as shown by Chae and Huh.[3] We conjecture the same property for the ABI system. (Concerning the existence of global classical solutions for the gas dynamics equations, we refer to Ref. 7.)

IV. A CRUDE ASYMPTOTIC ANALYSIS

According to well-known results on symmetric system of first-order PDEs,[13] there is a positive continuous function θ attached to system (2.6) such that, for all initial conditions W_0 belonging to the (homogeneous) Sobolev space H^s, where $s>3/2+1$ is fixed (say $s=3$), there is a unique strong solution $t\to W(t)$ to (2.6) such that $W(0)=W_0$, defined at least in the time interval $[-T,T]$ where $T=\theta(\|W_0\|_s)$. In addition, this solution depends continuously on W_0 in the space $C^0([-T,T],H^{s'})$ for all $s'<s$. Thus, we get without effort the following asymptotic result.

Theorem 4.1: *Let $\epsilon\in]0,1]$. Let $W_{0\epsilon}=(\tau_{0\epsilon},v_{0\epsilon},b_{0\epsilon},d_{0\epsilon})$ be a smooth initial condition, depending on ϵ, uniformly bounded in H^s for some $s>3/2+1$, distant from $W_0=(0,v_0,b_0,d_0)$ by ϵ in $H^{s'}$ norm for some $s'<s$. Then, there is a time interval $[-T,T]$, where $T>0$ does not depend on ϵ, such that systems (2.6) and (3.1) both have a unique strong solution $W^\epsilon=(\tau^\epsilon,v^\epsilon,b^\epsilon,d^\epsilon)$ and (v,b,d), with respective initial condition $W_{0\epsilon}$ and (v_0,b_0,d_0) on $[-T,T]$. Moreover, their distance in $C^0([-T,T],H^s)$ norm is of order ϵ.*

Of course, in the special case when $d_0=0$, the limit equation (3.1) reduces to the "string equation" (3.2). Similarly, as $b_0=d_0$, (3.1) reduces to (3.3). Let us point out that this result is obtained without effort, because of the remarkable structure of the nonconservative augmented version of the BI equations. A direct asymptotic analysis of the *original* BI equations (2.1) would have been considerably more difficult.

Need for refined asymptotic results: The main weakness of Theorem 4.1 is that the uniform existence time T is not at all optimal. Indeed, T depends on the H^s norm of the initial conditions, which is very far from being sharp. As a matter of fact, in many situations the optimal existence times T^* for the limit systems (3.1)–(3.3) can be explicitly computed. Therefore, we want a sharper existence time of form $T=T^*+O(\epsilon)$. This goal will be achieved in the next section through more refined arguments.

V. REFINED ASYMPTOTIC ANALYSIS

Consider IVPs of the ABI system (2.6) [or (2.7) with (2.8)] with initial data $W_{0\epsilon}$, which depends on ϵ in a certain topological space. Suppose an approximate smooth solution $W_\epsilon=W_\epsilon(x,t)$ has been constructed (see the next section) and is well defined for $(x,t)\in\Omega\times[0,T_*]$ with a certain $T_*>0$. Here Ω stands for the three-dimensional torus (for simplicity, we consider periodic initial data only). Define *the residual* of W_ϵ as

$$R=R(W_\epsilon) := W_{\epsilon t}+\sum_{j=1}^{3} A_j(W_\epsilon)W_{\epsilon x_j}. \tag{5.1}$$

This section is devoted to the proof of the following general result.

Theorem 5.1: *Let $s\geqslant 3$ be an integer. Suppose $W_{0\epsilon}\in H^s$ for each ϵ different from a certain singular point* (*say* 0), *$W_\epsilon(\cdot,t)\in H^{s+1}$, and*

$$\delta := \|W_{0\epsilon} - W_\epsilon(\cdot,0)\|_s^2 + \int_0^{T_*} \|R(\cdot,t)\|_s^2 \, dt \to 0$$

as ϵ approaches to the singular point 0. *Moreover, suppose there is a* 10×10*-matrix* L_ϵ*, which is bounded and invertible for* $\epsilon \neq 0$*, such that* $|L_\epsilon^{-1}|\sqrt{\delta} \to 0$ *as* $\epsilon \to 0$, $\sup_\epsilon \|L_\epsilon^{-1} W_{0\epsilon}\|_s < \infty$, *and* $\sup_{t,\epsilon} \|L_\epsilon^{-1} W_\epsilon(\cdot,t)\|_{s+1} < \infty$.

Then there is a neighborhood of $\epsilon = 0$ *such that, for all* ϵ *in the neighborhood, the ABI system (2.6) with initial data* $W_{0\epsilon}$ *has a unique classical solution*

$$W^\epsilon \in C([0,T_*], H^s).$$

Moreover, the error estimate

$$\|W^\epsilon(\cdot,t) - W_\epsilon(\cdot,t)\|_s \leqslant K\sqrt{\delta}, \quad \forall\, t \in [0,T_*], \tag{5.2}$$

holds with K a constant independent of ϵ.

Proof: Set $U_\epsilon = L_\epsilon^{-1} W_\epsilon$ for $\epsilon \neq 0$. Then (5.1) becomes

$$U_{\epsilon t} + \sum_{j=1}^{3} A_j(U_\epsilon, \epsilon) U_{\epsilon x_j} = L_\epsilon^{-1} R \tag{5.3}$$

with

$$A_j(U,\epsilon) = L_\epsilon^{-1} A_j(L_\epsilon U) L_\epsilon.$$

Accordingly, we consider the following IVP

$$U_t + \sum_j A_j(U,\epsilon) U_{x_j} = 0,$$

$$U(x,0) = \overline{U}(x,\epsilon) := L_\epsilon^{-1} W_{0\epsilon}. \tag{5.4}$$

This is a symmetrizable hyperbolic system with $A_0(U,\epsilon) := L_\epsilon^T L_\epsilon$ as its symmetrizer.

Since $\sup_\epsilon \|\overline{U}(\cdot,\epsilon)\|_s < \infty$ and $\sup_{t,\epsilon} \|U_\epsilon(\cdot,t)\|_{s+1} < \infty$ with $s \geqslant 3$, we deduce from the Sobolev embedding theorem that both $\overline{U}$ and U_ϵ take values in a bounded subset of the state space $\mathbb{R}^{10}$. Namely, there is an open set G such that

$$\bigcup_{x,t,\epsilon} \{\overline{U}(x,\epsilon), U_\epsilon(x,t)\} \subset G \subset\subset \mathbb{R}^{10}.$$

Thus, we can choose G_1 so that

$$G \subset\subset G_1 \subset\subset \mathbb{R}^{10}.$$

For each fixed $\epsilon (\neq 0)$, since $\overline{U}(x,\epsilon) \in G \subset\subset G_1$ for all $x \in \Omega$ and $\overline{U}(\cdot,\epsilon) \in H^s$ with $s \geqslant 3$, it follows from the local-in-time existence theory[13] for IVPs of symmetrizable hyperbolic systems that there is a maximal time $T_\epsilon = T_\epsilon(G_1) > 0$ so that the rescaled problem (5.4) has a unique classical solution

$$U^\epsilon \in C([0,T_\epsilon), H^s) \quad \text{and } U^\epsilon(x,t) \in G_1 \ \ \forall\, (x,t) \in \Omega \times [0,T_\epsilon).$$

Thus we only need to show $T_\epsilon > T_*$ and the error estimate in (5.2). Moreover, it suffices to prove the estimate (5.2) for $t \in [0, \min\{T_*, T_\epsilon\})$, thanks to the continuation principle (Lemma 9.1 in Ref. 17, see also the Appendix of this paper) and $|L_\epsilon^{-1}|\sqrt{\delta} \to 0$ as $\epsilon \to 0$.

Now we turn to derive the error estimate (5.2) for $t \in [0, \min\{T_*, T_\epsilon\})$. Notice that, in that time interval, both U^ϵ and U_ϵ are regular. We compute from (5.3) and (5.4) that $E = W_\epsilon - W^\epsilon = L_\epsilon(U_\epsilon - U^\epsilon)$ satisfies

$$E_t + \sum_j A_j(W^\epsilon)E_{x_j} = R - \sum_j A_j(E)W_{\epsilon x_j}.$$

Here we have used the linearity of $A_j = A_j(W)$ with respect to W. Differentiating this equation with ∂^α for a multi-index α satisfying $|\alpha| \leqslant s$ and setting $E_\alpha = \partial^\alpha E$, we get

$$E_{\alpha t} + \sum_j A_j(W^\epsilon)E_{\alpha x_j} = R_\alpha + F^\alpha. \tag{5.5}$$

Here

$$F^\alpha = \sum_j [A_j(W^\epsilon), \partial^\alpha]E_{x_j} - \left\{ \sum_j A_j(E)W_{\epsilon x_j} \right\}_\alpha .$$

Recall that $A_j(W^\epsilon)(j=1,2,\ldots,d)$ are all symmetric. Multiplying the equation (5.5) with E_α^T from the left, we get

$$(|E_\alpha|^2)_t + \sum_j \{E_\alpha^T A_j(W^\epsilon)E_\alpha\}_{x_j} = 2\,\mathrm{Re}\,E_\alpha^T(R_\alpha + F^\alpha) + E_\alpha^T\left\{ \sum_j \frac{\partial A_j(W^\epsilon)}{\partial x_j} \right\}E_\alpha. \tag{5.6}$$

The right-hand side of (5.6) is treated as follows:

$$\begin{aligned} &2\,\mathrm{Re}\,E_\alpha^T(R_\alpha + F^\alpha) \leqslant 2|E_\alpha|^2 + |R_\alpha|^2 + |F^\alpha|^2, \\ &\sum_j \frac{\partial A_j(W^\epsilon)}{\partial x_j} \leqslant C\sum_j |W^\epsilon_{x_j}| \leqslant C\|W^\epsilon\|_s, \end{aligned} \tag{5.7}$$

where C is a generic constant and the well-known Sobolev inequality has been used. Moreover, we apply the Moser-type calculus inequalities in Sobolev spaces[13] to F^α and obtain

$$\begin{aligned} \|F^\alpha\| &\leqslant C\|W_{\epsilon x_j}\|_s\|E\|_{|\alpha|} + C\|W^\epsilon\|_s\|E_{x_j}\|_{|\alpha|-1} \\ &\leqslant C\|W_\epsilon\|_{s+1}\|E\|_{|\alpha|} + C(\|W_\epsilon\|_s + \|E\|_s)\|E\|_{|\alpha|} \leqslant C(1 + \|E\|_s)\|E\|_{|\alpha|}. \end{aligned} \tag{5.8}$$

Here the boundedness of $\|W_\epsilon\|_{s+1}$ is used. Integrating (5.6) over $(x,t) \in \Omega \times [0,T]$ with $T < \min\{T_\epsilon, T_*\}$ and using (5.7) and (5.8) yields

$$\|E_\alpha(T)\|^2 \leqslant \|E_\alpha(0)\|^2 + \int_0^T \|R_\alpha(t)\|^2\,\mathrm{d}t + C\int_0^T (1 + \|E(t)\|_s^2)\|E(t)\|_{|\alpha|}^2\,\mathrm{d}t. \tag{5.9}$$

Summing up (5.9) for all multi-indices α with $|\alpha| \leqslant s$, we get

$$\|E(T)\|_s^2 \leqslant \|E(0)\|_s^2 + \int_0^T \|R(t)\|_s^2\,\mathrm{d}t + C\int_0^T (1 + \|E(t)\|_s^2)\|E(t)\|_s^2\,\mathrm{d}t \leqslant \delta + C\int_0^T (1 + \|E(t)\|_s^2)\|E(t)\|_s^2\,\mathrm{d}t.$$

Applying the Gronwall lemma to the last inequality yields

$$\|E(T)\|_s^2 \leqslant \delta \exp\left[C\int_0^T (1 + \|E(t)\|_s^2)\mathrm{d}t \right] \equiv \Phi(T). \tag{5.10}$$

Thus, we have

$$\Phi'(t) = C(1 + \|E(t)\|_s^2)\Phi(t) \leqslant C\Phi(t) + C\Phi^2(t).$$

Applying the nonlinear Gronwall-type inequality in Ref. 16 to the last inequality yields

$$\|E(t)\|_s^2 \leqslant \Phi(t) \leqslant \exp(CT_*) \tag{5.11}$$

for $t \in [0, \min\{T_\epsilon, T_*\})$ if $\Phi(0) = \delta < \exp(-CT_*)$. From (5.10) and (5.11) it follows that

$$\|E(t)\|_s \leqslant K\sqrt{\delta}$$

for all $t \in [0, \min\{T_\epsilon, T_*\})$. This completes the proof. □

We conclude this section with a remark.

Remark 5.1: In case $W_\epsilon(x,t)$ is defined globally in time and the conditions of Theorem 5.1 hold for $T_* = \infty$, we actually prove the following existence result for the ABI system (2.6): For any $T < \infty$, there is a neigborhood of $\epsilon = 0$ such that, for all ϵ in the neighborhood, the ABI system (2.6) with initial data $W_{0\epsilon}$ has a unique classical solution

$$W^\epsilon \in C([0,T], H^s).$$

Moreover, the error estimate in (5.2) holds for $t \leqslant T$ and the constant K depends on T.

VI. ASYMPTOTIC REGIMES

In this section, we apply Theorem 5.1 to four concrete asymptotic regimes. For simplicity, we will always take

$$W_{0\epsilon}(x) = W_\epsilon(x,0).$$

In addition, we do not make remarks parallel to Remark 5.1.

A. Membrane motion equations

Let ϵ be a small parameter. If the ABI system (2.6) is solved with initial data of the form

$$\tau(x,0) = O(\epsilon), \quad v(x,0) = O(1), \quad b(x,0) = O(1), \quad d(x,0) = O(1),$$

it is natural to take

$$L_\epsilon = \mathrm{diag}(\epsilon, I_3, I_3, I_3)$$

in Theorem 5.1. This L_ϵ is bounded for $\epsilon \leqslant 1$, invertible for $\epsilon \neq 0$ and $|L_\epsilon^{-1}| = \epsilon^{-1}$. This is a high field regime disregarded in Ref. 2. It might be incompatible with the BI regime (2.10), contrary to the other ones to be discussed in the following subsections. The rescaled system (5.4) reads

$$\begin{aligned}
&\tilde{\tau}_t + \tilde{v} \cdot \nabla \tilde{\tau} - \tilde{\tau} \,\mathrm{div}\, \tilde{v} = 0, \\
&\tilde{v}_t + \tilde{v} \cdot \nabla \tilde{v} - \tilde{b} \cdot \nabla \tilde{b} - \tilde{d} \cdot \nabla \tilde{d} - \epsilon^2 \tilde{\tau} \nabla \tilde{\tau} = 0, \\
&\tilde{b}_t + \tilde{v} \cdot \nabla \tilde{b} - \tilde{b} \cdot \nabla \tilde{v} + \epsilon \tilde{\tau} \nabla \times \tilde{d} = 0, \\
&\tilde{d}_t + \tilde{v} \cdot \nabla \tilde{d} - \tilde{d} \cdot \nabla \tilde{v} - \epsilon \tilde{\tau} \nabla \times \tilde{b} = 0.
\end{aligned} \tag{6.1}$$

Here $\tilde{\tau}$, $\tilde{v}$, $\tilde{b}$, and $\tilde{d}$ denote the components of the scaled variable $U = L_\epsilon^{-1} W = (\tilde{\tau}, \tilde{v}^T, \tilde{b}^T, \tilde{d}^T)^T$.

In order to apply Theorem 5.1 to this regime, we drop the tildes in (6.1) and seek an approximate solution W_ϵ of the form

$$W_\epsilon = L_\epsilon U_\epsilon, \quad U_\epsilon = U_0(x,t) + \epsilon U_1(x,t)$$

with the first component of U_1 being 0. Plugging this ansatz into (6.1), we see that $U_0 = (\tau_0, v_0, b_0, d_0)$ solves

$$\tau_t + v \cdot \nabla \tau - \tau \operatorname{div} v = 0,$$

$$v_t + v \cdot \nabla v - b \cdot \nabla b - d \cdot \nabla d = 0,$$

$$b_t + v \cdot \nabla b - b \cdot \nabla v = 0, \tag{6.2}$$

$$d_t + v \cdot \nabla d - d \cdot \nabla v = 0$$

and $U_1 = (0, v_1, b_1, d_1)$ satisfies

$$v_t + v_0 \cdot \nabla v - b_0 \cdot \nabla b - d_0 \cdot \nabla d = - v \cdot \nabla v_0 + b \cdot \nabla b_0 + d \cdot \nabla d_0,$$

$$b_t + v_0 \cdot \nabla b - b_0 \cdot \nabla v = b \cdot \nabla v_0 - v \cdot \nabla b_0 - \tau_0 \nabla \times d_0, \tag{6.3}$$

$$d_t + v_0 \cdot \nabla d - d_0 \cdot \nabla v = d \cdot \nabla v_0 - v \cdot \nabla d_0 + \tau_0 \nabla \times b_0.$$

Notice that the last three equations in (6.2) are just (3.1).

Now we solve (6.2) and (6.3) to obtain U_0 and U_1. Note that the last three equations in (6.2) form a symmetric hyperbolic system of nonlinear equations. By the local existence theory[8,13] for IVPs of symmetrizable hyperbolic systems, if $(v_0, b_0, d_0)(\cdot, 0) \in H^s$ with $s \geqslant 3$, then there is $T_* > 0$ such that the corresponding IVP has a unique classical solution $(v_0, b_0, d_0) \in C([0, T_*], H^s)$. With v_0 thus obtained, we obtain $\tau_0 \in C([0, T_*], H^{s-1})$ by solving the first equation in (6.2):

$$\tau_t + v_0 \cdot \nabla \tau - \tau \operatorname{div} v_0 = 0,$$

which is a linear equation, with $\tau(\cdot, 0) \in H^{s-1}$. Similarly, by using the existence theory[8] for IVPs of linear symmetrizable hyperbolic systems, we obtain $U_1 = (0, v_1, b_1, d_1) \in C([0, T_*], H^{s-1})$ by solving (6.3) with appropriate initial data.

With $U_\epsilon = U_0 + \epsilon U_1 \in C([0, T_*], H^{s-1})$ thus obtained, it is easy to see that the residual R, defined in (5.1), satisfies

$$R = \epsilon^2 O(1) \in C([0, T_*], H^{s-2}).$$

Thus, we deduce the following conclusion from Theorem 5.1, together with Corollary 1 of Theorem 2.2 in Ref. 13—a continuation principle.

Corollary 6.1: Let $s \geqslant 3$ be an integer. Assume $W_{0\epsilon}(x) = W_\epsilon(x, 0) \in H^{s+2}$. Then there exists $T_* > 0$ and $\epsilon_0 > 0$ such that, for each $\epsilon \in (0, \epsilon_0]$, the ABI system (2.6) with initial data $W_{0\epsilon}$ has a unique classical solution

$$W^\epsilon = (\tau^\epsilon, v^\epsilon, b^\epsilon, d^\epsilon) \in C([0, T_*], H^{s+2}).$$

Moreover, the error estimates

$$\| (\tau^\epsilon - \epsilon\tau_0, v^\epsilon - v_0 - \epsilon v_1, b^\epsilon - b_0 - \epsilon b_1, d^\epsilon - d_0 - \epsilon d_1)(\cdot, t) \|_s \leqslant K\epsilon^2,$$

for $t \in [0, T_*]$, hold with K a constant independent of ϵ. In particular, we have

$$\| (\tau^\epsilon, v^\epsilon - v_0, b^\epsilon - b_0, d^\epsilon - d_0)(\cdot, t) \|_s = \epsilon O(1).$$

Remark 6.1: Theorem 5.1 claims that $W^\epsilon \in C([0, T_*], H^s)$. Since $W_{0\epsilon} = W_\epsilon(\cdot, 0) \in H^{s+2}$, it follows from Corollary 1 of Theorem 2.2 in Ref. 13 that this solution W^ϵ has better regularity, that is,

$$W^\epsilon \in C([0, T_*], H^{s+2}).$$

This argument applies to Corollaries 6.2–6.4 in the following subsections.

B. String motion equations

Consider the ABI system (2.6) with initial data of the form

$$\tau(x,0)=O(\epsilon),\quad v(x,0)=O(1),\quad b(x,0)=O(1),\quad d(x,0)=O(\epsilon)$$

with $\epsilon \ll 1$. This is the high field regime considered in Ref. 2. As in the preceding subsection, we take

$$L_\epsilon = \mathrm{diag}(\epsilon, I_3, I_3, \epsilon I_3)$$

in Theorem 5.1. This L_ϵ is bounded for $\epsilon \ll 1$, invertible for $\epsilon \neq 0$ and $|L_\epsilon^{-1}| = \epsilon^{-1}$. Then the rescaled system (5.4) reads

$$\begin{aligned}
&\tau_t + v\cdot\nabla\tau - \tau\,\mathrm{div}\, v = 0,\\
&v_t + v\cdot\nabla v - b\cdot\nabla b - \epsilon^2 d\cdot\nabla d - \epsilon^2\tau\nabla\tau = 0,\\
&b_t + v\cdot\nabla b - b\cdot\nabla v + \epsilon^2\tau\nabla\times d = 0,\\
&d_t + v\cdot\nabla d - d\cdot\nabla v - \tau\nabla\times b = 0.
\end{aligned} \tag{6.4}$$

Dropping the ϵ^2 terms, we obtain

$$\begin{aligned}
&\tau_t + v\cdot\nabla\tau - \tau\,\mathrm{div}\, v = 0,\\
&v_t + v\cdot\nabla v - b\cdot\nabla b = 0,\\
&b_t + v\cdot\nabla b - b\cdot\nabla v = 0,\\
&d_t + v\cdot\nabla d - d\cdot\nabla v - \tau\nabla\times b = 0.
\end{aligned} \tag{6.5}$$

Notice that the second and third equations in (6.5) are just (3.2).

To solve (6.5), we note that the second and third equations in (6.5) form a symmetric hyperbolic system of nonlinear equations. Thus, if $(v,b)(\cdot,0)\in H^s$ with $s\geqslant 3$, then there is $T_*>0$ such that the corresponding IVP has a unique classical solution $(v_0,b_0)\in C([0,T_*],H^s)$. With v_0 and b_0 thus obtained, we see from the existence theory[8] for linear problems that the decoupled hyperbolic system of linear equations,

$$\begin{aligned}
&\tau_t + v_0\cdot\nabla\tau - \tau\,\mathrm{div}\, v_0 = 0,\\
&d_t + v_0\cdot\nabla d - d\cdot\nabla v_0 - \tau\nabla\times b_0 = 0,
\end{aligned}$$

with appropriate initial data, has a unique classical solution $(\tau_0,d_0)\in C([0,T_*],H^{s-1})$.

Now we take $W_\epsilon = L_\epsilon U_\epsilon$ in Theorem 5.1 with U_ϵ obtained above. It is clear that the residual R, defined in (5.1), satisfies

$$\sup_t \|\epsilon^{-2}R(\cdot,t)\|_{s-2} < \infty.$$

Thus we deduce the following conclusion from Theorem 5.1, together with Corollary 1 of Theorem 2.2 in Ref. 13.

Corollary 6.2: Let $s\geqslant 3$ be an integer. Assume $W_{0\epsilon}=W_\epsilon(\cdot,0)\in H^{s+2}$. Then there is $\epsilon_0>0$ such that, for all $\epsilon\in(0,\epsilon_0]$, the ABI system (2.6) with initial data $W_{0\epsilon}$ has a unique classical solution

$$W^\epsilon = (\tau^\epsilon, v^\epsilon, b^\epsilon, d^\epsilon) \in C([0,T_*],H^{s+2}).$$

Moreover, the error estimates

$$\|(\tau^\epsilon - \epsilon\tau_0, v^\epsilon - v_0, b^\epsilon - b_0, d^\epsilon - \epsilon d_0)(\cdot,t)\|_s \leqslant K\epsilon^2, \quad \forall\, t \in [0,T_*],$$

hold with K a constant independent of ϵ.

The interested reader can derive Corollary 6.2 directly from Corollary 6.1 with initial data satisfying $(v_1, b_1, d_0)(x,0) = 0$.

C. Particle motion equations

Now we consider the ABI system (2.6) with initial data of the form

$$\tau(x,0) = O(\epsilon^2), \quad v(x,0) = O(1), \quad b(x,0) = O(\epsilon), \quad d(x,0) = O(\epsilon)$$

with $\epsilon \ll 1$. This is the very high field regime considered in Ref. 2. As in the preceding subsections, we take

$$L_\epsilon = \mathrm{diag}(\epsilon^2, I_3, \epsilon I_3, \epsilon I_3)$$

in Theorem 5.1. This L_ϵ is bounded for $\epsilon \ll 1$, invertible for $\epsilon \neq 0$ and $|L_\epsilon^{-1}| = \epsilon^{-2}$. Then the rescaled system (5.4) reads

$$\begin{gathered}
\tau_t + v \cdot \nabla\, \tau - \tau\, \mathrm{div}\, v = 0, \\
v_t + v \cdot \nabla\, v - \epsilon^2 b \cdot \nabla\, b - \epsilon^2 d \cdot \nabla\, d - \epsilon^4 \tau \nabla\, \tau = 0, \\
b_t + v \cdot \nabla\, b - b \cdot \nabla\, v + \epsilon^2 \tau \nabla \times d = 0, \\
d_t + v \cdot \nabla\, d - d \cdot \nabla\, v - \epsilon^2 \tau \nabla \times b = 0.
\end{gathered} \tag{6.6}$$

In order to see what Theorem 5.1 means for this rescaled system, we look for an approximate solution W_ϵ of the form

$$W_\epsilon = L_\epsilon U_\epsilon, \quad U_\epsilon = (\tau_0, v_0 + \epsilon^2 v_1, b_0, d_0)(x,t).$$

Plugging this ansatz into (6.6), we see that (τ_0, v_0, b_0, d_0) should solve

$$\begin{gathered}
\tau_t + v \cdot \nabla\, \tau - \tau\, \mathrm{div}\, v = 0, \\
v_t + v \cdot \nabla\, v = 0, \\
b_t + v \cdot \nabla\, b - b \cdot \nabla\, v = 0, \\
d_t + v \cdot \nabla\, d - d \cdot \nabla\, v = 0
\end{gathered} \tag{6.7}$$

and v_1 should satisfy

$$v_t + v_0 \cdot \nabla\, v + v \cdot \nabla\, v_0 = b_0 \cdot \nabla\, b_0 + d_0 \cdot \nabla\, d_0. \tag{6.8}$$

Notice that the second equation in (6.7) is just (3.3).

As in the preceding subsections, Eqs. (6.7) and (6.8) can be solved by using the local-in-time existence theorey[8,13] for IVPs of quasilinear and linear symmetrizable hyperbolic systems. In particular, if initial data for (6.7) satisfy $v_0(\cdot,0) \in H^{s+3}$ and $(\tau_0, b_0, d_0)(\cdot,0) \in H^{s+2}$, then there exists $T_* > 0$ so that the corresponding IVP has a unique classical solution (τ_0, v_0, b_0, d_0) satisfying

$$v_0 \in C([0,T_*], H^{s+3}), \quad (\tau_0, b_0, d_0) \in C([0,T_*], H^{s+2}).$$

Moreover, if $v_1(\cdot,0) \in H^{s+1}$, then the IVP of (6.8) has a unique classical solution

$$v_1 \in C([0,T_*],H^{s+1}).$$

With W_ϵ thus obtained, it is easy to see that the residual R, defined in (5.1), satisfies

$$R = \epsilon^3 \operatorname{diag}(\epsilon, \epsilon I_3, I_3, I_3) O(1) \in C([0,T_*],H^s).$$

Thus we have $\|R(\cdot,t)\|_s = \epsilon^3 O(1)$ and the following corollary from Theorem 5.1 together with Corollary 1 of Theorem 2.2 in Ref. 13.

Corollary 6.3: Let $s \geqslant 3$ be an integer. Assume $W_{0\epsilon} = W_\epsilon(\cdot,0) \in H^{s+3}$. Then there is $\epsilon_0 > 0$ such that, for all $\epsilon \in (0,\epsilon_0]$, the ABI system (2.6) with initial data $W_{0\epsilon}$ has a unique classical solution

$$W^\epsilon = (\tau^\epsilon, v^\epsilon, b^\epsilon, d^\epsilon) \in C([0,T_*],H^{s+3}).$$

Moreover, the error estimates

$$\|(\tau^\epsilon - \epsilon^2\tau_0, v^\epsilon - v_0 - \epsilon^2 v_1, b^\epsilon - \epsilon b_0, d^\epsilon - \epsilon d_0)(\cdot,t)\|_s \leqslant K\epsilon^3,$$

for $t \in [0,T_*]$, hold with K a constant independent of ϵ.

D. The Maxwell equations

Finally, we consider the ABI system (2.6) with initial data of the form

$$\tau(x,0) = 1 + O(\epsilon^2), \quad v(x,0) = O(\epsilon^2), \quad b(x,0) = O(\epsilon), \quad d(x,0) = O(\epsilon)$$

with $\epsilon \ll 1$. This is the low field regime considered in Ref. 2. As in the preceding subsections, we take

$$L_\epsilon = \operatorname{diag}(1, \epsilon^2 I_3, \epsilon I_3, \epsilon I_3)$$

in Theorem 5.1. This L_ϵ is bounded for $\epsilon \ll 1$, invertible for $\epsilon \neq 0$ and $|L_\epsilon^{-1}| = \epsilon^{-2}$. Then the rescaled system (5.4) reads

$$\begin{aligned}
&\tau_t + \epsilon^2 v \cdot \nabla \tau - \epsilon^2 \tau \operatorname{div} v = 0,\\
&v_t + \epsilon^2 v \cdot \nabla v - b \cdot \nabla b - d \cdot \nabla d - \epsilon^{-2}\tau \nabla \tau = 0,\\
&b_t + \epsilon^2 v \cdot \nabla b - \epsilon^2 b \cdot \nabla v + \tau \nabla \times d = 0,\\
&d_t + \epsilon^2 v \cdot \nabla d - \epsilon^2 d \cdot \nabla v - \tau \nabla \times b = 0.
\end{aligned} \tag{6.9}$$

In order to apply Theorem 5.1 to this case, we seek an approximate solution W_ϵ of the form

$$W_\epsilon = L_\epsilon U_\epsilon, \quad U_\epsilon = (1 + \epsilon^2 \tau_1, v_0, b_0, d_0).$$

Plugging this ansatz into (6.9), we see that (v_0, b_0, d_0) solves

$$\begin{aligned}
&v_t - b \cdot \nabla b - d \cdot \nabla d - \nabla \tau_1 = 0,\\
&b_t + \nabla \times d = 0,\\
&d_t - \nabla \times b = 0
\end{aligned} \tag{6.10}$$

and τ_1 satisfies

$$\tau_t - \operatorname{div} v_0 = 0. \tag{6.11}$$

Having (6.10) and (6.11), we determine U_ϵ as follows. By solving the last two lines in (6.10) (the standard linear Maxwell equations), we obtain b_0 and d_0. Then v_0 and τ_1 solve the inhomogeneous linear hyperbolic system

$$v_t - \nabla \tau = b_0 \cdot \nabla b_0 + d_0 \cdot \nabla d_0,$$

$$\tau_t - \operatorname{div} v = 0.$$

Note that here solved are only hyperbolic systems of linear equations with constant coefficients.

Assume $(b_0, d_0, v_0, \tau_1)(\cdot, 0) \in H^s$. It is easy to see that $W_\epsilon \in C([0,\infty), H^{s-1})$ and the residual R satisfies

$$R = \epsilon^3 \operatorname{diag}(\epsilon, \epsilon I_3, I_3, I_3) O(1) \in C([0,\infty), H^{s-2}).$$

Thus $\|R(\cdot,t)\|_{s-2} = \epsilon^3 O(1)$. In conclusion, from Theorem 5.1 and Corollary 1 of Theorem 2.2 in Ref. 13 we have the following.

Corollary 6.4: Let $s \geqslant 3$ be an integer. Assume $W_{0\epsilon} = W_\epsilon(\cdot, 0) \in H^{s+2}$. Then for any $T > 0$ there is $\epsilon_0 > 0$ such that, for each $\epsilon \in (0, \epsilon_0]$, the ABI system (2.6) with initial data $W_{0\epsilon}$ has a unique classical solution

$$W^\epsilon = (\tau^\epsilon, v^\epsilon, b^\epsilon, d^\epsilon) \in C([0,T], H^{s+2}).$$

Moreover, the error estimates

$$\|(\tau^\epsilon - 1 - \epsilon^2 \tau_1, v^\epsilon - \epsilon^2 v_0, b^\epsilon - \epsilon b_0, d^\epsilon - \epsilon d_0)(\cdot, t)\|_s \leqslant K \epsilon^3,$$

for $t \in [0,T]$, hold with K a constant independent of ϵ but dependent on T.

APPENDIX: A CONTINUATION PRINCIPLE FOR SINGULAR LIMIT PROBLEMS

For the convenience of the reader, we present in this appendix the convergence-stability lemma previously formulated (Yong thanks Heinrich Freistühler and Denis Serre for pointing out two errors in an earlier version of this formulation. Thanks also go to Ya-Guang Wang for valuable discussions which improve the presentation) by Yong in Ref. 17 for IVPs of quasilinear symmetrizable hyperbolic systems depending (singularly) on parameters

$$U_t + \sum_{j=1}^{d} A_j(U, \epsilon) U_{x_j} = Q(U, \epsilon) \tag{A.1}$$

for $x \in \Omega = \mathbb{R}^d$ or $\mathbb{T}^d$ (the d-dimensional torus). Here ϵ represents a parameter in a *topological space*, $A_j(U,\epsilon)(j = 1, 2, \ldots, d)$ and $Q(U,\epsilon)$ are (matrix- or vector-valued) smooth functions of $U \in G \subset \mathbb{R}^n$ (state space) for each ϵ (possible) different from a certain singular point, say 0.

For each fixed $\epsilon (\neq 0)$, consider the IVP of (A.1) with initial data $\bar{U}(x,\epsilon)$. Assume $\bar{U}(x,\epsilon) \in G_0 \subset\subset G$ for all $x \in \Omega$ and $\bar{U}(\cdot,\epsilon) \in H^s$ with $s > d/2 + 1$ an integer. Let G_1 be a subset of the state space and satisfy $G_0 \subset\subset G_1$ [see (A.3) below]. According to the local-in-time existence theory for IVPs of symmetrizable hyperbolic systems (see Theorem 2.1 in Ref. 13), there exists $T > 0$ so that (A.1) with initial data $\bar{U}(x,\epsilon)$ has a unique classical solution,

$$U^\epsilon \in C([0,T], H^s) \quad \text{and } U^\epsilon(x,t) \in G_1 \ \ \forall\, (x,t) \in \Omega \times [0,T].$$

Define

$$T_\epsilon = \sup\{T > 0 : U^\epsilon \in C([0,T], H^s) \quad \text{and } U^\epsilon(x,t) \in G_1 \ \ \forall\, (x,t) \in \Omega \times [0,T]\}. \tag{A.2}$$

Namely, $[0, T_\epsilon)$ is the maximal time interval for the existence of H^s-solutions with values in G_1. Note that $T_\epsilon = T_\epsilon(G_1)$ depends on G_1 and may tend to zero as ϵ approaches to the singular point 0.

In order to show that $\underline{\lim}_{\epsilon \to 0} T_\epsilon > 0$, we make the following assumption.

Convergence assumption: there exists $T_* > 0$ and $U_\epsilon = U_\epsilon(x,t)$ defined for $(x,t) \in \Omega \times [0, T_*]$ and $\epsilon (\neq 0)$, satisfying

$$\bigcup_{x,t,\epsilon} \{U_\epsilon(x,t)\} \subset\subset G, \quad U_\epsilon(\cdot,t) \in H^s, \quad \text{and } \sup_{t,\epsilon} \|U_\epsilon(\cdot,t)\|_s < \infty,$$

such that for $t \in [0, \min\{T_*, T_\epsilon\})$,

$$\sup_{x,t} |U^\epsilon(x,t) - U_\epsilon(x,t)| = o(1),$$

$$\sup_{t} \|U^\epsilon(\cdot,t) - U_\epsilon(\cdot,t)\|_s = O(1),$$

as ϵ goes to the singular point.

Under this assumption, we slightly modify the argument in Ref. 16 to prove the following.

Lemma 6.5: Suppose $\overline{U}(x,\epsilon) \in G_0 \subset\subset G$ *for all* $x \in \Omega$ *and* $\epsilon (\neq 0)$, $\overline{U}(\cdot,\epsilon) \in H^s$ *with* $s > d/2 + 1$ *an integer, and the convergence assumption holds. Then, for each* G_1 *satisfying*

$$G_0 \cup \bigcup_{x,t,\epsilon} \{U_\epsilon(x,t)\} \subset\subset G_1 \subset G, \tag{A.3}$$

there is a neighborhood of the singular point such that

$$T_\epsilon(G_1) > T_*$$

for all ϵ *in the neighborhood.*

Proof: Otherwise, there is a G_1 satisfying (A.3) and a sequence $\{\epsilon_k\}_{k \geq 1}$ such that $\lim_{k \to \infty} \epsilon_k = 0$ and $T_{\epsilon_k} = T_{\epsilon_k}(G_1) \leq T_*$. Thanks to (A.3) and the convergence assumption, there exists $\widetilde{G}$, satisfying $\cup_{x,t,\epsilon} \{U_\epsilon(x,t)\} \subset\subset \widetilde{G} \subset\subset G_1$, and a certain k such that $U^{\epsilon_k}(x,t) \in \widetilde{G}$ for all $(x,t) \in \Omega \times [0, T_{\epsilon_k})$. On the other hand, we deduce from

$$\|U^\epsilon(\cdot,t)\|_s \leq \|U^\epsilon(\cdot,t) - U_\epsilon(\cdot,t)\|_s + \|U_\epsilon(\cdot,t)\|_s$$

and the convergence assumption that $\|U^{\epsilon_k}(\cdot,t)\|_s$ is bounded uniformly with respect to $t \in [0, T_{\epsilon_k})$. Now we could apply Theorem 2.1 in Ref. 13, beginning at a time t less than T_{ϵ_k} (k is fixed here), to continue the solution beyond $T_{\epsilon_k}(G_1)$. This contradicts the definition of $T_{\epsilon_k}(G_1)$ in (A.2) and, hence, the proof is complete. □

To our knowledge, such a sharp continuation principle has not appeared explicitly in the published literature other than Ref. 17. Thanks to this lemma, the study of the singular limit problems is reduced to find a $U_\epsilon(x,t)$ such that the convergence assumption holds. In verifying the two error estimates in the convergence assumption, we often take G_1 satisfying $G_1 \subset\subset G$ and being convex. Furthermore, we notice that, in the time interval $[0, \min\{T_*, T_\epsilon\})$, both U^ϵ and U_ϵ are regular and take values in the precompact subset G_1.

Remark: Similar lemmas can be easily formulated for other evolution differential equations. In fact, such a lemma can be regarded as a part of the local-in-time existence theory of any evolution equations.

(Received 28 June 2004; accepted 3 December 2004; published online 26 May 2005)

We discuss the asymptotic behavior of regulated field commutators for linearly polarized, cylindrically symmetric gravitational waves and the mathematical techniques needed for this analysis. We concentrate our attention on the effects brought about by the introduction of a physical cutoff in the study of the microcausality of the model and describe how the different physically relevant regimes are affected by its presence. Specifically we discuss how genuine quantum gravity effects can be disentangled from those originating in the introduction of a regulator. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1864251]

I. INTRODUCTION

Linearly polarized cylindrical waves, also known as Einstein-Rosen waves,[1,2] provide a symmetry reduction of general relativity that can be used as a test bed for the quantization of the theory. This system displays several interesting features that contribute to its relevance. On one hand, it has an infinite number of local degrees of freedom and, hence, it is a genuine quantum field theory (in contradistinction to other symmetry reductions, such as Bianchi models, that have a finite number of global degrees of freedom). On the other, the system is tractable both classically and quantum mechanically, thus allowing us to derive exact consequences independent of any approximation scheme.[3–8] The main reason behind this success and tractability is the fact that the gravitational degrees of freedom of the model are encoded in a free, massless, axially symmetric, scalar field that evolves in an auxiliary Minkowskian background.

In previous papers we have analyzed the issue of microcausality in this system; in particular, we have studied in detail the smearing of light cones owing to the quantization of the gravitational field.[7,8] The main tool for this type of analysis is the study *in vacuo* of the field commutator evaluated at different space–time points. As is well known, the commutator of quantum fields reflects the causal structure of space–time (Minkowskian space–time in ordinary perturbative quantum field theory) in the sense that the quantum fields in spatially separated space–time points commute. This is true for all standard types of quantum fields, i.e., scalar, fermion, or vector fields, though issues related to gauge invariance must be carefully considered in this last case. In the specific model that we are interested in, gauge invariance has been discussed in Ref. 9. The authors of that paper conclude that it is correct to use the Ashtekar-Pierri gauge fixed action, written in terms of the axially symmetric scalar field, to derive gauge invariant information about the model.

In a recent work[8] we discussed the situation when no cutoff is introduced in the system, studying the unregulated commutator. The main results reached were the following. First, one can clearly see that light cones are smeared by quantum gravity effects; in fact it is possible to obtain a quantitative measure of this smearing and show how sharp light cones are recovered in the limit of large distances as compared to the natural length scale of the model, the Planck length. It is also interesting to point out that the asymptotic behavior of the commutator in the different physically relevant regimes strongly depends on the causal relationship between the different space–time points involved. Second, one finds a singularity structure in the commutator that differs from that of the free theory; in particular, the field commutator for equal values of the radial coordinate R is singular. Finally, one observes that, in the case when one of the space–time points that appear in the commutator corresponds to the symmetry axis, there are quantum effects that persist for large values of the difference of the time coordinates. This effect is reminiscent of the large quantum gravity effects first discussed by Ashtekar.[4,6,10,11]

The purpose of this paper is to study how the conclusions of Ref. 8 are changed by the introduction of a cutoff. As is well known, regulators are generally necessary in order to have well-defined quantum field theories. One can justify its use, for example, by noticing that the action of the field operator on the vacuum in a Fock space is not a vector in the Hilbert space because it has infinite norm. In order to have a well-defined action of the field operator one regulates it by introducing smearing functions that render the norms of these states finite. The problem then consists in removing these regulators (or rather showing that the physical results are independent of them).

In principle, it is possible to argue that the results derived in the absence of regulators somehow approximate those derived after their introduction; this is straightforward to see in the case of cutoffs. In the presence of a cutoff Λ, the improper integrals that define the field commutator become proper because the integration region is a closed interval $[0,\Lambda]$. For a given value of the parameters that appear in the integral (involving the values of the space–time coordinates of the quantum fields and the gravitational constant) it is always possible to choose a value for Λ such that the integral with the cutoff is well approximated by the integral extended to $[0,\infty)$.

Of course it is conceivable that the cutoff is not just a mathematical device but rather a physical scale defining a fundamental limit for the resolution of our measurements. If space–time becomes discrete at short distances (such as the Planck length), the continuum space–time picture breaks down and, certainly, it would be difficult to justify the extension of the integrals involved in the definition of field commutators (or S matrix elements, for that matter) to infinite intervals in momenta (inverse length). Our point of view here is that the introduction of a cutoff can mimic some of the effects appearing after a successful quantization of gravity (for example, in the loop quantum gravity approach), and hence we plan to study its effect within the consistent framework provided by the Einstein-Rosen waves. It is also interesting to point out here that the cutoff by itself can produce some of the effects expected from quantum gravity. In particular, it is possible to show that light cones are also smeared by cutoffs.[12] In our opinion this makes it necessary to study in detail how the effects of the cutoff and quantum gravity can be disentangled.

The paper is organized as follows. After this introduction, we briefly review the main results about microcausality in quantum cylindrical gravitational waves and introduce the commutators that we will discuss in the rest of the paper. We will then study the field commutators in the presence of a cutoff with the help of the asymptotic techniques already employed in Ref. 8. Here the situation is simpler because we will only have to consider integrals over closed intervals. We will discuss one by one the asymptotic behaviors in the different parameters involved. In Sec. VI we will derive a power series expansion in the gravitational constant for the commutator in the presence of a cutoff in the spirit of ordinary perturbative quantum field theory, and discuss the uniform convergence of this series under appropriate conditions on the cutoff in Sec. VII. We end the paper with a discussion of our results and our conclusions.

II. THE FIELD COMMUTATOR

Einstein-Rosen waves describe topologically trivial space–times with two linearly independent, commuting, spacelike, and hypersurface orthogonal Killing vector fields[1,2,13] endowed with a metric that can be written as

$$ds^2 = e^{\gamma-\psi}(-dT^2 + dR^2) + e^{-\psi}R^2 d\theta^2 + e^{\psi}dZ^2. \tag{1}$$

Here we use the coordinates (T,R,θ,Z), $T\in\mathbb{R}$, $R\in[0,\infty)$, $\theta\in[0,2\pi)$, $Z\in\mathbb{R}$, and ψ and γ are functions only of R and T. The Einstein field equations are very simple. The scalar field ψ satisfies the wave equation for a massless, axially symmetric scalar field in three dimensions,

$$\partial_T^2\psi - \partial_R^2\psi - \frac{1}{R}\partial_R\psi = 0,$$

and the function γ can be expressed in terms of this field[3,6] as

$$\gamma(R) = \frac{1}{2}\int_0^R d\overline{RR}[(\partial_T\psi)^2 + (\partial_{\overline{R}}\psi)^2].$$

We will use in the following a system of units such that $c=\hbar=1$ and define $G\equiv\hbar G_3$, where G_3 denotes the gravitational constant per unit length in the direction of the symmetry axis.[14] The function $\gamma(R)$ (apart from a factor of $8G$) has a simple physical interpretation: it is the energy of the scalar field in a ball of radius R whereas γ_∞ denotes $\lim_{R\to\infty}\gamma(R)$ (the energy of the whole two-dimensional flat space). It is also possible to show[3,7] that $\gamma_\infty/(8G)$ coincides with the Hamiltonian H_0 of the system obtained by a linearization of the metric (1).

In order to have a unit asymptotic timelike Killing vector and a physical notion of energy (per unit length) we introduce the coordinates (t,R,θ,Z) defined by $T=e^{-\gamma_\infty/2}t$. In these coordinates the metric takes the form[2,13]

$$ds^2 = e^{\gamma-\psi}(-e^{-\gamma_\infty}dt^2 + dR^2) + e^{-\psi}R^2 d\theta^2 + e^{\psi}dZ^2.$$

By taking a sufficiently fast fall-off for ψ as $R\to\infty$, this metric describes asymptotically flat cylindrical space–times such that ∂_t is a unit timelike Killing vector in the asymptotic region. In the $2+1$-dimensional framework these space–times are asymptotically flat at spacelike and null infinities[15,16] (the appropriate introduction of null infinity will be needed in order to study the S matrix of the model). It is also worthwhile noting that these space–times have a nonzero deficit angle.

The Einstein field equations can be obtained from a Hamiltonian action principle.[13,17,18] A remarkable (and useful) feature of the physical Hamiltonian H (associated with the physical time t) is the fact that it is a function of the Hamiltonian corresponding to the free scalar field, H_0:

$$H = E(H_0) = \frac{1}{4G}(1 - e^{-4GH_0}).$$

In terms of the T-time and imposing regularity at the axis $R=0$[3], the classical solutions for the field ψ can be written as

$$\psi(R,T) = \sqrt{4G}\int_0^\infty dk J_0(Rk)[A(k)e^{-ikT} + A^\dagger(k)e^{ikT}],$$

where $A(k)$ and its complex conjugate $A^\dagger(k)$ are fixed by the initial conditions. The free Hamiltonian H_0 can be written now as

$$\frac{\gamma_\infty}{8G} = H_0 = \int_0^\infty dk k A^\dagger(k) A(k).$$

Using this expression, we obtain the t-evolution of the field

$$\psi_E(R,t) = \sqrt{4G}\int_0^\infty dk J_0(Rk)[A(k)e^{-ikte^{-\gamma_\infty/2}} + A^\dagger(k)e^{ikte^{-\gamma_\infty/2}}].$$

The quantization can be carried out in the usual way by introducing a Fock space where $\hat{\psi}(R,0)$, the quantum counterpart of $\psi(R,0)$, is the operator-valued distribution[19] given by[20]

$$\hat{\psi}(R,0;\Lambda=\infty) = \hat{\psi}_E(R,0;\Lambda=\infty) = \sqrt{4G}\int_0^\infty dk J_0(Rk)[\hat{A}(k) + \hat{A}^\dagger(k)]. \tag{2}$$

Its action on Fock space is determined by those of $\hat{A}(k)$ and $\hat{A}^\dagger(k)$, the annihilation and creation operators, with nonvanishing commutators given by $[\hat{A}(k_1),\hat{A}^\dagger(k_2)] = \delta(k_1,k_2)$.

We can regulate the field by introducing suitable functions $g(k)$ that render finite the norms of the states obtained by acting with the quantum field on Fock space vectors. In the following we will make the simplest choice $g(k) = \chi_{[0,\Lambda_k]}(k)$ (here $\chi_{[a,b]}$ denotes the characteristic function of the interval $[a,b]$). By doing this the integration region in (2) becomes compact and we have

$$\hat{\psi}(R,0) = \hat{\psi}_E(R,0) = \sqrt{4G}\int_0^{\Lambda_k} dk J_0(Rk)[\hat{A}(k) + \hat{A}^\dagger(k)]. \tag{3}$$

Evolution in T is given by the unitary operator $\hat{U}_0(T) = \exp(-iT\hat{H}_0)$, where

$$\hat{H}_0 = \int_0^\infty dk k \hat{A}^\dagger(k)\hat{A}(k)$$

is the quantum Hamiltonian operator of a three-dimensional, axially symmetric scalar field. The cutoff-regulated quantum scalar field in the Heisenberg picture is hence given by

$$\hat{\psi}(R,T) = \hat{U}_0^\dagger(T)\hat{\psi}(R,0)\hat{U}_0(T) = \sqrt{4G}\int_0^{\Lambda_k} dk J_0(Rk)[\hat{A}(k)e^{-ikT} + \hat{A}^\dagger(k)e^{ikT}].$$

If we describe the evolution in our model in terms of the physical time t, the quantum Hamiltonian is $\hat{H} = E(\hat{H}_0) = (1-e^{-4G\hat{H}_0})/(4G)$ and unitary evolution is given by $\hat{U}(t) = \exp(-it\hat{H})$. With this time evolution the annihilation and creation operators in the Heisenberg picture are

$$\hat{A}_E(k,t) \equiv \hat{U}^\dagger(t)\hat{A}(k)\hat{U}(t) = \exp[-itE(k)e^{-4G\hat{H}_0}]\hat{A}(k),$$

$$\hat{A}_E^\dagger(k,t) = \hat{A}^\dagger(k)\exp[itE(k)e^{-4G\hat{H}_0}],$$

where $E(k) = (1-e^{-4Gk})/(4G)$, and the regulated field operator evolved with the physical Hamiltonian [that we denote as $\hat{\psi}_E(R,t)$] is given by

$$\hat{\psi}_E(R,t) = \sqrt{4G}\int_0^{\Lambda_k} dk J_0(Rk)[\hat{A}_E(k,t) + \hat{A}_E^\dagger(k,t)].$$

The field commutator $[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]$ can be computed from these expressions.[7] Since we are dealing with an effectively interacting theory this operator is not proportional to the identity in the Fock space basis that we are using and, hence, we have to consider its matrix elements. As in

previous work we will concentrate on the vacuum expectation value. If a cutoff Λ_k is introduced, this is given by

$$\frac{1}{8iG}\langle 0|[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]|0\rangle = \int_0^{\Lambda_k} dk J_0(R_1k)J_0(R_2k)\sin\left[\frac{t_2-t_1}{4G}(1-e^{-4Gk})\right], \tag{4}$$

which can be seen to depend on the time coordinates only through their difference t_2-t_1, which we will assume in the following to be positive. Notice that it depends symmetrically on R_1 and R_2. The functional dependence in G is less trivial, a fact that requires special attention when studying the limit in which the relevant lengths and time differences are much larger than the Planck length.[8]

It is convenient to refer the dimensional parameters of these integrals to another length scale, which we choose as R_1. We hence introduce $R_2=\rho R_1$, $t_2-t_1=R_1\tau$, and $\lambda=R_1/4G$ and rewrite (4) as

$$\frac{1}{8iG}\langle 0|[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]|0\rangle = \frac{\lambda}{R_1}\Im\left\{\int_0^{\Lambda_q} dq J_0(\lambda q)J_0(\rho\lambda q)e^{i\tau\lambda(1-e^{-q})}\right\} \tag{5}$$

after introducing the new variable $k=q/(4G)$. Here $\Im$ denotes the imaginary part and $\Lambda_q=4G\Lambda_k$.

Physically, the cutoff Λ_k (which in principle has the dimensionality of an inverse length) could be interpreted as having its origin in the existence of a minimum length. This comes out naturally in loop quantum gravity where space is discrete and the area and volume operators have minimum eigenvalues of the order of the Planck area and volume, respectively. In fact, the existence of a minimum length (of the size of the Planck scale) can be considered a generic feature of essentially every quantum theory.[21] The interpretation of the adimensional cutoff Λ_q would follow from that of Λ_k, so it may be reasonable to expect that it be a number of order unity; nevertheless we will treat it as a free parameter in the following.

III. ASYMPTOTIC BEHAVIOR IN ρ

Let us start by considering the behavior of (5) when the parameter ρ grows to infinite or approaches $\rho=0$. This integral can be written as a standard h-transform[22] by the change of variables $t=q\lambda$. The most convenient way to get its asymptotic behavior in $\rho\to\infty$ is by rewriting it in the form

$$\frac{1}{R_1}\Im\left[\int_0^{\infty} dt J_0(\rho t)J_0(t)e^{i\tau\lambda(1-e^{-t/\lambda})} - \int_{R_1\Lambda_k}^{\infty} dt J_0(\rho t)J_0(t)e^{i\tau\lambda(1-e^{-t/\lambda})}\right]. \tag{6}$$

One can then use the asymptotic behavior obtained for the first integral in Ref. 8, and find the asymptotics of the second integral by standard integration by parts [employing the fact that[23] $J_0(k)=-J_0'(k)/k-J_0''(k)$]. By doing this one gets the following two contributions:

$$\frac{1}{R_1}\left[\frac{\tau}{2\lambda\rho^3}+\frac{1}{\rho^5}\left(\frac{9\tau}{8\lambda}-\frac{3\tau}{8\lambda^3}+\frac{9\tau^2}{2\lambda}\right)\right]+O\left(\frac{1}{\rho^7}\right),$$

$$\frac{1}{\rho R_1}\Im[J_1(\Lambda_k R_1\rho)J_0(\Lambda_k R_1)e^{i\tau\lambda(1-e^{-\Lambda_k R_1/\lambda})}]+O\left(\frac{1}{\rho^{5/2}}\right).$$

The first one is cutoff independent but subdominant with respect to the second, hence we see that the presence of a cutoff changes the asymptotic behavior in ρ. This is the kind of behavior that one would expect even in a Lorentz covariant theory after the introduction of a cutoff because of the breaking of the Lorentz symmetry. The novel feature here is the presence of cutoff independent terms. Although the cutoff-dependent one dominates in the asymptotic limit, there may be a transient regime, whose onset will be controlled by the value of Λ_k, in which the asymptotic behavior is given by the first term. This will be most evident when $\Lambda_k\to\infty$.

In the $\rho \to 0$ limit we get

$$\frac{1}{R_1}\Im\int_0^{R_1\Lambda_k} dt J_0(t) e^{i\tau\lambda(1-e^{-t/\lambda})} + O(\rho) = \frac{\lambda}{R_1}\Im\int_0^{\Lambda_q} dq J_0(\lambda q) e^{i\tau\lambda(1-e^{-q})} + O(\rho), \tag{7}$$

as a result of the continuity at $\rho=0$ of the integral defining the commutator (5).

IV. ASYMPTOTIC BEHAVIOR IN τ

The integral in (5) has the convenient form of an *h*-transform and, hence, it can be studied by standard Mellin transform methods[22] if the asymptotic parameter is chosen to be ρ; however, this is no longer true if the asymptotic parameter is taken to be τ (which corresponds to considering large separations in the time coordinates). This fact introduces some mathematical difficulties in the asymptotic analysis. In this case one has to consider the cases $\rho=0$ and $\rho\neq 0$ separately.

If $\rho=0$, one finds that the asymptotic behavior when $\tau\to\infty$ without the cutoff is given by[8]

$$\frac{1}{R_1}\sqrt{\frac{\lambda}{2\pi\log\tau}}\Im\{e^{i[(\pi/4)+\tau\lambda-\lambda\log(\tau\lambda)]}e^{(\pi/2)\lambda}\Gamma(i\lambda) + e^{-i[(\pi/4)-\tau\lambda-\lambda\log(\tau\lambda)]}e^{-(\pi/2)\lambda}\Gamma(-i\lambda)\} + O\left(\frac{1}{\log\tau}\right), \tag{8}$$

whereas for $\rho\neq 0$ we get

$$\begin{aligned}
&\frac{1}{2\pi R_1\sqrt{\rho}\log\tau}\Im\{e^{i[(\pi/2)+\tau\lambda-\lambda(1+\rho)\log(\tau\lambda)]}e^{(\pi/2)\lambda(1+\rho)}\Gamma[i\lambda(1+\rho)]\\
&+ e^{-i[(\pi/2)-\tau\lambda-\lambda(1+\rho)\log(\tau\lambda)]}e^{-(\pi/2)\lambda(1+\rho)}\Gamma[-i\lambda(1+\rho)]\\
&+ e^{i[\tau\lambda-\lambda(1-\rho)\log(\tau\lambda)]}e^{(\pi/2)\lambda(1-\rho)}\Gamma[i\lambda(1-\rho)]\\
&+ e^{i[\tau\lambda-\lambda(\rho-1)\log(\tau\lambda)]}e^{(\pi/2)\lambda(\rho-1)}\Gamma[i\lambda(\rho-1)]\} + O\left(\frac{1}{(\log\tau)^2}\right).
\end{aligned} \tag{9}$$

The most interesting feature of these expressions is their unusual dependence on the asymptotic parameter τ; in fact, the dependence on inverse powers of logarithms (especially on the inverse square root of $\log\tau$) cannot be obtained by direct application of the usual asymptotic expressions derived by Mellin transform techniques.[8] It is also remarkable how slowly the commutator decays in τ, in particular in the axis $\rho=0$, a fact that is suggestive of the large quantum gravity effects discussed by Ashtekar.[4] Outside the axis the decay is faster but still quite slow. A consequence of the different asymptotic behaviors in τ for $\rho=0$ and $\rho\neq 0$ is the impossibility to recover (8) as the limit when $\rho\to 0$ of (9). As we can see, the frequency of the oscillations of the commutator in τ is controlled by λ (proportional to the inverse of G) in such a way that although the amplitude of the oscillations decays very slowly, they will average to zero on scales larger than the Planck length.

When we introduce a cutoff Λ_k, the above asymptotic expressions change to

$$\frac{1}{R_1}\Im\left\{\frac{i}{\tau}[1-e^{i\tau\lambda(1-e^{-\Lambda_k R_1/\lambda})}e^{\Lambda_k R_1/\lambda}J_0(\Lambda_k R_1)J_0(\rho\Lambda_k R_1)]\right\} + O\left(\frac{1}{\tau^2}\right), \tag{10}$$

valid both for $\rho=0$ and $\rho\neq 0$. This can be obtained by straightforward integration by parts. An interesting situation develops at this point because the asymptotic behavior of the integral in τ behaves in a discontinuous way in the cutoff. In the analysis carried out to study the asymptotic behavior in ρ we found out that the cutoff-dependent term, in spite of being dominant, goes to zero in the limit $\Lambda_k\to\infty$. Here the situation is different: taking now $\Lambda_k\to\infty$ in (10) does not lead to the asymptotic expressions corresponding to $\Lambda_k=\infty$. That is, the asymptotic behavior of the improper integral in (4) is not the limit when $\Lambda_k\to\infty$ of (5). As in the case of the asymptotics in ρ, one expects that there must be a transient regime in which the behavior in τ of (5) is given by (8) and

(9). We will not consider here a precise characterization of this transient behavior for arbitrary values of the relevant parameters because its main properties can be conveniently discussed, at least for large λ, by looking at the $\lambda\to\infty$ asymptotics of the commutator in the (ρ,τ) plane.

The $\tau\to 0$ limit is easy to analyze. In fact what we find, both with and without the cutoff, is that the series obtained by expanding $e^{i\pi\lambda(1-e^{-t/\lambda})}$ in powers of $e^{-t/\lambda}$, exchanging integration and infinite sum, and computing the resulting integrals gives a series that converges to the value of the commutator.

V. ASYMPTOTIC BEHAVIOR IN λ

The asymptotic behavior in λ is studied by following the procedure described in Ref. 8. It is worth remarking that the limit $\lambda\to\infty$ of the regulated field commutator cannot be identified with that in which the gravitational constant G vanishes if one admits that the dimensionful cutoff $\Lambda_k<\infty$ is kept constant in principle. On the contrary, the two limits could be considered equivalent only under the assumption that Λ_k increases as the inverse of G for small gravitational constant, so that its dimensionless counterpart $\Lambda_q=4G\Lambda_k$ may remain fixed.

The analysis of the asymptotics in λ when the cutoff is present is simultaneously simpler in some respects and more complicated in others compared with the case when no cutoff is introduced. It is simpler because the lengthy analysis needed to discuss the asymptotics of the improper integral is not necessary now. It is more complicated in the sense that the final asymptotic expressions contain additional terms and also because the number of regions with different λ-asymptotic regimes in the (ρ,τ) plane increases.

We have to consider now the cases $\rho=0$ and $\rho\neq 0$ separately. Let us consider first $\rho=0$ and write the rhs of (5) as[8]

$$\Im\left\{-\frac{i\lambda e^{i\tau\lambda}}{2\pi R_1}\int_0^{\Lambda_q}dq\oint_\gamma dt\frac{1}{t}e^{\lambda[(q/2)(t-1/t)-i\tau e^{-q}]}\right\},\tag{11}$$

after using the usual integral representation for the Bessel functions J_n $(n=0,1,\ldots)$,

$$J_n(z)=\frac{1}{2\pi i}\oint_\gamma\frac{dt}{t^{n+1}}e^{(z/2)(t-1/t)},$$

where γ is a closed, positively oriented, simple path in the complex plane surrounding the origin. Notice that we are integrating an integrable function in a compact region, so we can write the integrals in any order we want. The asymptotic analysis of (11) can be carried out by following the same steps as in Ref. 8. As we did there, it is useful to introduce neutralizers to split the integral in three pieces I_j, $j=1,2,3$, and choose appropriate contours for each of them. These integrals are

$$I_j\equiv\Im\left\{-\frac{i\lambda e^{i\tau\lambda}}{2\pi R_1}\int_0^{\Lambda_q}dq\oint_\gamma dt\nu_j(q)\frac{1}{t}e^{\lambda[(q/2)(t-1/t)-i\tau e^{-q}]}\right\},$$

where we have introduced the neutralizer functions $\nu_j(q)$, $j=1,2,3$, satisfying $\nu_1+\nu_2+\nu_3=1$ in $[0,\Lambda_q]$ and

$$\nu_1(q)=1 \text{ if } q\in[0,\alpha_1],$$

$$\nu_1(q)=0 \text{ if } q\in[\alpha_2,\Lambda_q],$$

$$\nu_2(q)=0 \text{ if } q\in[0,\alpha_1]\cup[\beta_2,\Lambda_q],$$

$$\nu_2(q)=1 \text{ if } q\in[\alpha_2,\beta_1],$$

$$\nu_3(q) = 0 \text{ if } q \in [0, \beta_1],$$

$$\nu_3(q) = 1 \text{ if } q \in [\beta_2, \Lambda_q],$$

with $0 < \alpha_1 < \alpha_2 < \beta_1 < \beta_2 < \Lambda_q$ (these parameters are chosen as in Ref. 8). By doing this the effective integration regions in q are $[0, \alpha_2]$, $[\alpha_1, \beta_2]$, and $[\beta_1, \Lambda_q]$ and the boundary $q=0$ appears only in the first.

The asymptotics in λ of the integral I_1 is best obtained by choosing an integration contour satisfying $\Re(t - 1/t) \leqslant 0$ (that passes necessarily through $t=i$ and $t=-i$). By using the same method of Ref. 8 we see that the first two relevant terms are given by the contour integrals

$$\frac{1}{\pi R_1} \Im \left\{ i \oint_\gamma \frac{dt}{t^2 + 2i\pi t - 1} \right\},$$

$$- \frac{1}{2\pi R_1} \Im \left\{ \frac{i}{\lambda} \oint_\gamma dt \frac{8i\pi t^2}{(t^2 + 2i\pi t - 1)^3} \right\},$$

whose sum gives

$$\frac{1}{R_1 \sqrt{\tau^2 - 1}} \text{ for } \tau > 1$$

and

$$\frac{\pi(1 + 2\tau^2)}{2R_1 \lambda (1 - \tau^2)^{5/2}} \text{ for } \tau < 1.$$

Although the second term will be subdominant with respect to some of the contributions coming from I_2 and I_3, it improves the approximation of the full commutator obtained from the asymptotics in λ in the region $\tau < 1$.

The contribution of I_3 to the asymptotics in λ is obtained from the contour integral (corresponding to the boundary at $q = \Lambda_q$)

$$\Im \left\{ \frac{ie^{i\tau\lambda}}{2\pi R_1} \oint_\gamma dt \frac{2}{t} \frac{(t - 1/t + 2i\tau e^{-\Lambda_q}) e^{(\lambda\Lambda_q/2)(t-1/t) - i\tau e^{-\Lambda_q}}}{\Lambda_q^2 (t + 1/t)^2 - (t - 1/t + 2i\tau e^{-\Lambda_q})^2} \right\}.$$

The asymptotics in λ of this integral can be easily studied by using the method of steepest descents. This gives

$$\Im \left\{ \frac{2ie^{i\tau\lambda(1 - e^{-\Lambda_q})}}{R_1 (\tau^2 e^{-2\Lambda_q} - 1) \sqrt{2\pi\lambda\Lambda_q}} \left[i\tau e^{-\Lambda_q} \sin\left(\lambda\Lambda_q - \frac{\pi}{4} \right) - \cos\left(\lambda\Lambda_q - \frac{\pi}{4} \right) \right] \right\}.$$

Finally, the integral I_2 (for which we choose for γ the curve $|t| = 1$) only contributes when the stationary points of the exponent are in the integration region. This happens only when $1 < \tau < e^{\Lambda_q}$. The contribution to the first relevant order in λ is[8]

$$\Im \left\{ \frac{1}{R_1} \frac{e^{i\lambda(\tau - \log \tau - 1)}}{\sqrt{\log \tau}} \right\}.$$

Adding up the different terms we get

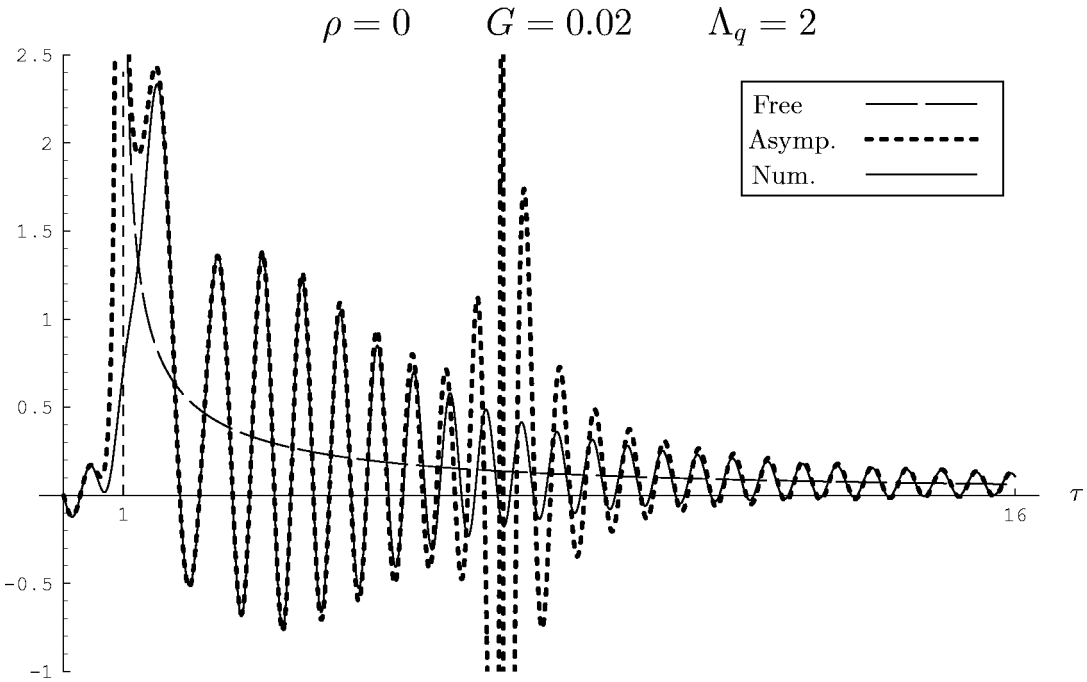

FIG. 1. Asymptotic approximation in λ for the field commutator over $8iG$ as a function of τ for $\rho=0$, $G=0.02$, and $\Lambda_q=2$. We compare it both with a numerical computation of the integral that defines it and with the unregulated free commutator. As we can see, the approximation is good except at the points where the asymptotic behavior changes ($\tau=1$ and $\tau=e^{\Lambda_q}$). Notice the difference in the amplitude of the oscillations for $\tau<e^{\Lambda_q}$ and $\tau>e^{\Lambda_q}$.

$$\theta(1-\tau)\frac{\tau(1+2\tau^2)}{2R_1\lambda(1-\tau^2)^{5/2}}+\theta(\tau-1)\frac{1}{R_1\sqrt{\tau^2-1}}+\theta(\tau-1)\,\theta(e^{\Lambda_q}-\tau)\Im\left\{\frac{1}{R_1}\frac{e^{i\lambda(\tau-\log\,\tau-1)}}{\sqrt{\log\,\tau}}\right\}$$
$$+\Im\left\{\frac{2ie^{i\tau\lambda(1-e^{-\Lambda_q})}}{R_1(\tau^2e^{-2\Lambda_q}-1)\sqrt{2\pi\lambda\Lambda_q}}\left[i\tau e^{-\Lambda_q}\sin\left(\lambda\Lambda_q-\frac{\pi}{4}\right)-\cos\left(\lambda\Lambda_q-\frac{\pi}{4}\right)\right]\right\}, \tag{12}$$

where θ denotes the step function.

We see that the final result consists of several contributions: the free commutator for an infinite cutoff, a $1/\lambda$ correction for $\tau<1$, the term with the $1/\sqrt{\log\,\tau}$ dependence for $1<\tau<e^{\Lambda_q}$, and a cutoff-dependent contribution for all values of τ that fall off to zero when $\Lambda_q\to\infty$. If the cutoff goes to infinity, the commutator can be approximated by the one obtained in Ref. 8; however, if it is of order one (as would be the case if it is defined by the Planck length), then that approximation is no longer valid. Notice that the values of $\tau\in(1,e^{\Lambda_q})$ are those for which the asymptotics provided by the unregulated commutator are a correct approximation. This is roughly the transient region in the τ parameter mentioned in the previous subsection.

Figures 1–3 show the behavior of the field commutator (over $8iG$) when $\rho=0$ as a function of τ for several values of Λ_q. As we can see, the asymptotic approximation becomes singular between regions with different asymptotic regimes, but approximates well the exact value of the commutator (obtained by numerical methods) for the remaining values of τ. Notice that the singularity at $\tau=e^{\Lambda_q}$ of the asymptotic expansion lies outside the plotted region in Figs. 2 and 3.

In order to study the $\rho\neq0$ case we start by writing the rhs of (5) as

$$\Im\left\{-\frac{\lambda e^{i\tau\lambda}}{4\pi^2R_1}\int_0^{\Lambda_q}dq\oint_{\gamma_1}dt_1\oint_{\gamma_2}dt_2\frac{1}{t_1t_2}e^{\lambda[(q)(t_1-1/t_1)/2+\rho q(t_2-1/t_2)/2-i\tau e^{-q}]}\right\} \tag{13}$$

after employing the usual integral representation for the Bessel functions J_n ($n=0,1,\ldots$). Again it is helpful to introduce the same neutralizers as above to split the integral in three pieces I_j, $j=1,2,3$.

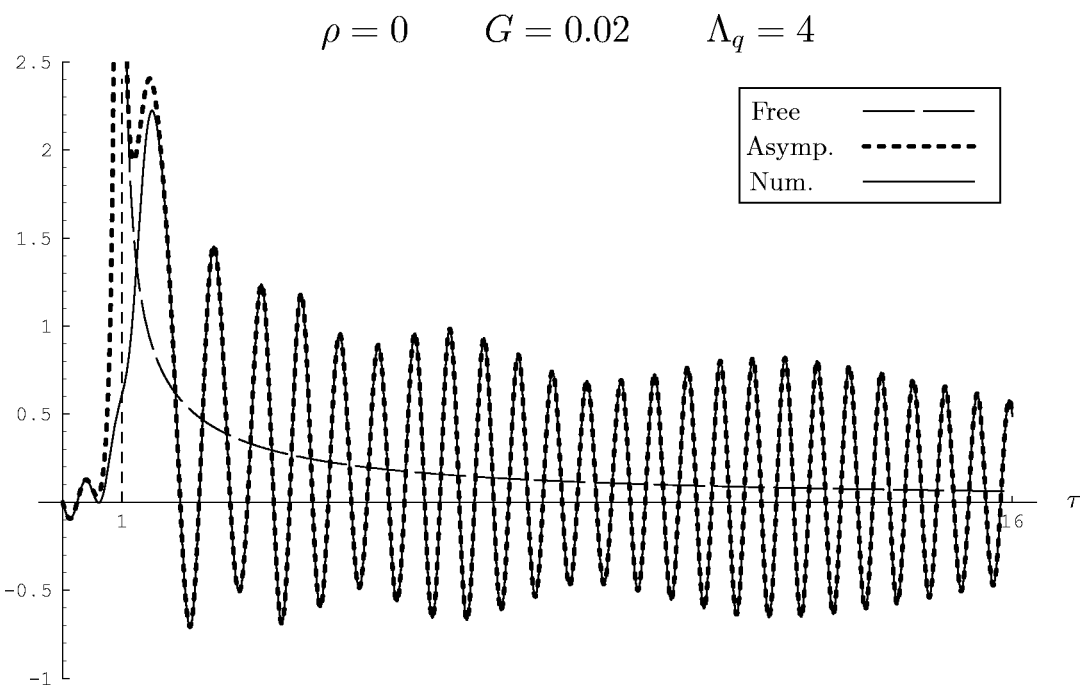

FIG. 2. Asymptotic approximation in λ for the field commutator over $8iG$ as a function of τ for $\rho=0$, $G=0.02$, and $\Lambda_q=4$ (compared both with a numerical computation of the integral that defines it and with the unregulated free commutator). As we can see, the asymptotic approximation is good except at $\tau=1$. Notice that the cutoff introduces a modulation of the amplitude in the region $1<\tau<e^{\Lambda_q}$. The singularity of the asymptotic approximation at $\tau=e^{\Lambda_q}$ lies outside the plotted region.

The integral I_1 gives the following two contributions:

$$\Im\left\{\frac{1}{2\pi^2 R_1}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{1}{\rho t_1(t_2^2-1)+t_2(t_1^2+2i\pi t_1-1)}\right\} \tag{14}$$

and

$$\Im\left\{-\frac{2i\tau}{\pi^2 R_1 \lambda}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{t_1^2 t_2^2}{[\rho t_1(t_2^2-1)+t_2(t_1^2+2i\pi t_1-1)]^3}\right\}. \tag{15}$$

Both integrals can be computed exactly[8] in terms of complete elliptic integrals of first and second kinds. The first one gives the contribution of the unregulated free commutator (i.e., with infinite cutoff).

In order to describe it we define regions I, II, and III by $0<\tau<|\rho-1|$, $|\rho-1|<\tau<\rho+1$, and $\rho+1<\tau$, respectively. They are shown in Fig. 4. In region I the free commutator is zero, whereas in regions II and III it is given by

region II,

$$\frac{1}{\pi R_1\sqrt{\rho}} K\left(\sqrt{\frac{\tau^2-(\rho-1)^2}{4\rho}}\right),$$

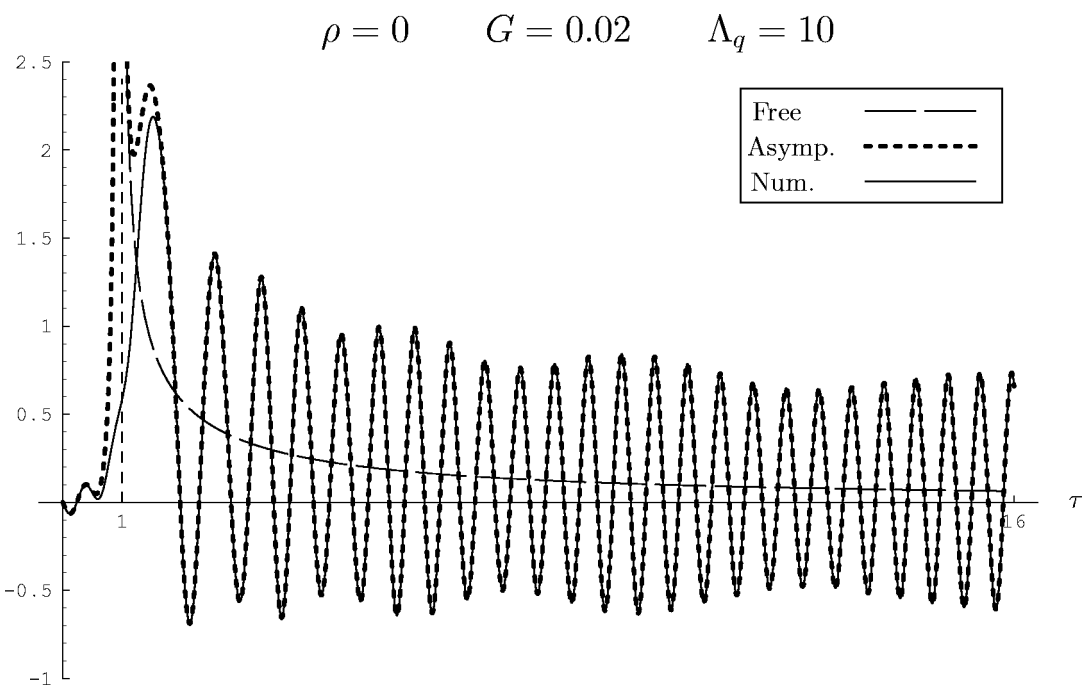

FIG. 3. Asymptotic approximation in λ for the field commutator over $8iG$ as a function of τ for $\rho=0$, $G=0.02$, and $\Lambda_q=10$ (compared both with a numerical computation of the integral that defines it and with the unregulated free commutator). As we can see, the asymptotic approximation is good except at $\tau=1$. The asymptotic approximation obtained in Ref. 8 is good in a large region in the τ axis. The singularity of the asymptotic approximation at $\tau=e^{\Lambda_q}$ lies outside the plotted region.

region III,

$$\frac{2}{\pi R_1}\frac{1}{\sqrt{\tau^2-(1-\rho)^2}}K\left(\sqrt{\frac{4\rho}{\tau^2-(1-\rho)^2}}\right).$$

The second contribution (15) can be computed by the method outlined in Appendix IV of Ref. 8, obtaining

region I,

$$\frac{\tau}{2\pi R_1\lambda}\left\{\frac{2[1+\rho^4+2\tau^2-3\tau^4+2\rho^2(\tau^2-1)]\sqrt{(1+\rho)^2-\tau^2}}{(1+\rho-\tau)^2(1-\rho+\tau)^2(-1+\rho+\tau)^2(1+\rho+\tau)^2}E\left(\sqrt{\frac{4\rho}{(1+\rho)^2-\tau^2}}\right)\right.$$
$$\left.-\frac{2\tau^2}{[\rho^4+(\tau^2-1)^2-2(1+\tau^2)\rho^2]\sqrt{(1+\rho)^2-\tau^2}}K\left(\sqrt{\frac{4\rho}{(1+\rho)^2-\tau^2}}\right)\right\}, \tag{16}$$

region II,

$$\frac{\tau}{2\pi R_1\lambda}\left\{\frac{1-2\rho^2+\rho^4+\tau^2-2\rho\tau^2+\rho^2\tau^2-2\tau^4}{\sqrt{\rho}[(1-\rho)^2-\tau^2][(1+\rho)^2-\tau^2]^2}K\left(\sqrt{\frac{(1+\rho)^2-\tau^2}{4\rho}}\right)\right.$$
$$\left.+\frac{4\sqrt{\rho}[1-2\rho^2+\rho^4+2\tau^2-3\tau^4+2\rho^2\tau^2]}{[\rho^4+(\tau^2-1)^2-2(1+\tau^2)\rho^2]^2}E\left(\sqrt{\frac{(1+\rho)^2-\tau^2}{4\rho}}\right)\right\}. \tag{17}$$

The value of (15) in region III is zero.

The integral I_3, on the other hand, can also be studied by the methods described in Ref. 8. The first relevant term to its asymptotic expansion in inverse powers of λ is derived from the double contour integral

$$\Im\left\{\frac{e^{i\tau\lambda}}{4\pi^2 R_1}\oint_{\gamma_1} dt_1 \oint_{\gamma_2} dt_2 \frac{2}{t_1 t_2}\frac{[t_1 - 1/t_1 + \rho(t_2 - 1/t_2) + 2i\tau e^{-\Lambda_q}]e^{\lambda[(\Lambda_q/2)(t_1-1/t_1)+\rho(\Lambda_q/2)(t_2-1/t_2)-i\tau e^{-\Lambda_q}]}}{\Lambda_q^2[(t_1+1/t_1)^2+\rho^2(t_2+1/t_2)^2]-[t_1-1/t_1+\rho(t_2-1/t_2)+2i\tau e^{-\Lambda_q}]^2}\right\}, \tag{18}$$

corresponding to $q=\Lambda_q$ and whose asymptotic behavior can be determined by employing standard techniques for multiple integrals.[22] In this way we obtain the following contribution:

$$\frac{1}{2\pi R_1 \Lambda_q \lambda\sqrt{\rho}}\left\{\frac{\sin[\lambda\Lambda_q(1+\rho)-\tau\lambda(1-e^{-\Lambda_q})]}{1+\rho-\tau e^{-\Lambda_q}} - \frac{\sin[\lambda\Lambda_q(1+\rho)+\tau\lambda(1-e^{-\Lambda_q})]}{1+\rho+\tau e^{-\Lambda_q}}\right.$$
$$\left. + \frac{\cos[\lambda\Lambda_q(1-\rho)-\tau\lambda(1-e^{-\Lambda_q})]}{1-\rho-\tau e^{-\Lambda_q}} - \frac{\cos[\lambda\Lambda_q(1-\rho)+\tau\lambda(1-e^{-\Lambda_q})]}{1-\rho+\tau e^{-\Lambda_q}}\right\}. \tag{19}$$

Finally, the integral I_2 is written in terms of a neutralizer that vanishes at $q=0$ and $q=\Lambda_q$. This integral is best studied by choosing the unit circumference centered in the origin of the complex plane as the integration contour γ. The contributions of this integral to the asymptotics of (13) come from the stationary points of the exponent in the integrand whenever they are within the integration region. This fact is controlled by the value of the cutoff Λ_q. The result is

$$\{\theta(\tau-\rho+1)\theta[(\rho-1)e^{\Lambda_q}-\tau]\theta(\rho-1)$$
$$+\theta(\tau+\rho-1)\theta[(1-\rho)e^{\Lambda_q}-\tau]\theta(1-\rho)\}\Im\left\{\frac{e^{-i\pi/4}e^{i\lambda[\tau+|\rho-1|(1+\log\tau/|\rho-1|)]}}{R_1\sqrt{2\pi\lambda\rho|1-\rho|}\log\tau/|1-\rho|}\right\}$$
$$+\theta(\tau-\rho-1)\theta[(\rho+1)e^{\Lambda_q}-\tau]\Im\left\{\frac{e^{i\pi/4}e^{i\lambda[\tau+(\rho+1)(\log 1+\rho/\tau-1)]}}{R_1\sqrt{2\pi\lambda\rho(1+\rho)}\log\tau/1+\rho}\right\},$$

where the step functions define the regions where the different stationary points contribute. As we can see and it is explained in Fig. 5, there are two contributions in some parts of the (ρ,τ) plane,

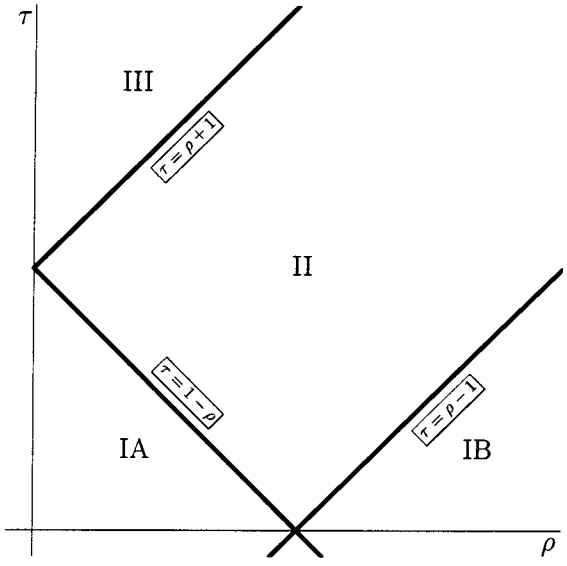

FIG. 4. Regions in the (ρ,τ) plane used in the discussion of the λ asymptotics and the free commutator. Region I is defined by $0<\tau<|\rho-1|$, region II by $|\rho-1|<\tau<\rho+1$, and region III by $\rho+1<\tau$.

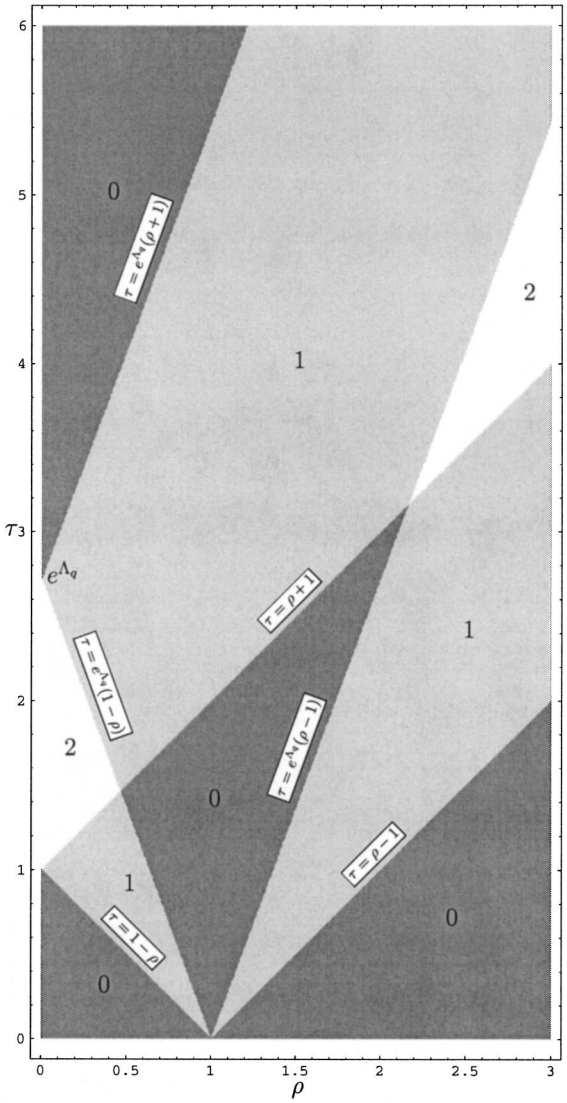

FIG. 5. Regions in the (ρ, τ) plane used in the discussion of the λ asymptotics in the presence of a cutoff $\Lambda_q = 1$. The label of each region indicates how many critical points contribute to the asymptotic expansion in λ.

only one in some other parts, and no contribution in the remaining ones. Notice that, whenever they differ from zero, these contributions are dominant with respect to those coming from the other integrals.

Several points are now in order. First it is interesting to realize that the singularity at $\rho = 1$ that exists when the cutoff is taken to be infinite (and is obviously absent now) shows up as the region defined by the lines $\tau = e^{\Lambda_q}(1-\rho)$, $\tau = e^{\Lambda_q}(\rho-1)$, and $\tau = e^{\Lambda_q}(\rho+1)$ shrinks with growing Λ_q. Another interesting feature of the commutator when the cutoff is present is the appearance of some regions where the leading asymptotic behavior is not given by the expressions obtained in Ref. 8 for infinite cutoff, namely the regions with $\tau > |1-\rho|$ labeled 0 in Fig. 5 and the region labeled 1 that connects them. On the contrary, there are two regions where two stationary points contribute to the asymptotics just as in the $\Lambda_q \to \infty$ case, showing the characteristic slow decay in the τ direction.[24] Of these two regions, the one closer to the axis is bounded, whereas the second one

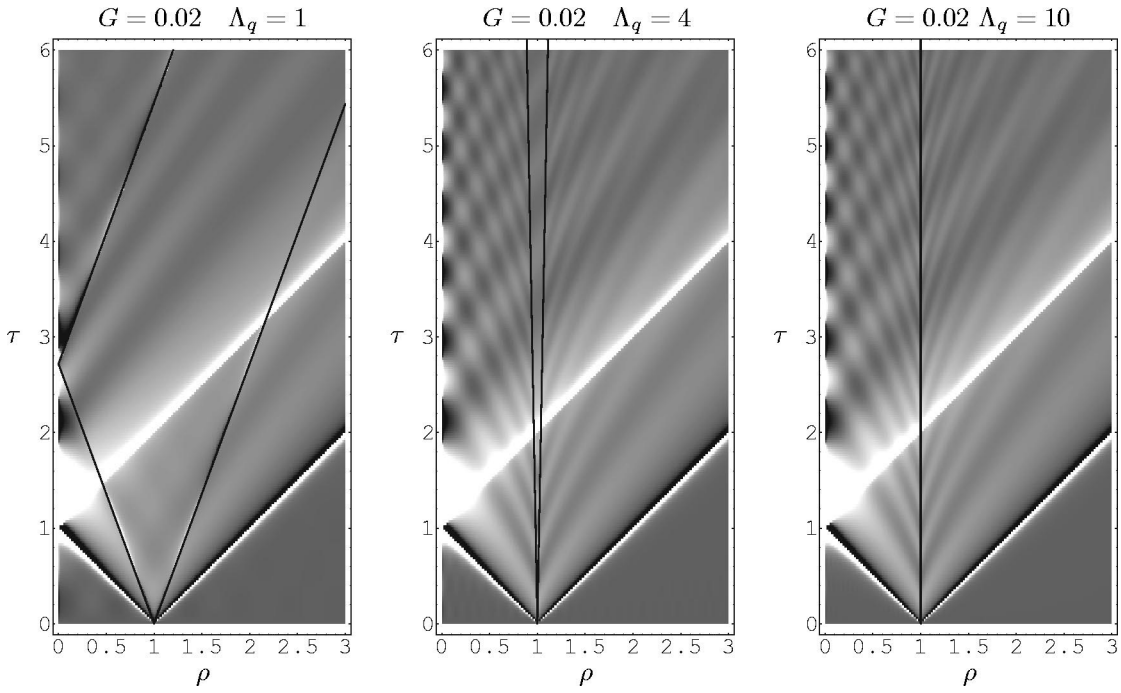

FIG. 6. Density plots of the commutator for $G=0.02$ and different values of Λ_q. Comparing the results with those of Ref. 8, we can see that the commutator in the regions labeled 2 in Fig. 4 is essentially equal to the one corresponding to an infinite cutoff. Notice also the process by which the singularity at R_1 appears.

[defined by the lines $\tau=e^{\Lambda_q}(\rho-1)$ and $\tau=\rho+1$] is not. The effect of the symmetry axis is evident in the sense that it is precisely there where one of the lines that limits the boundary of this region starts, namely $\tau=\rho+1$.

As we can see, the influence of the cutoff is important in some parts of the (ρ,τ) plane, but there are others where the asymptotic behavior is described at leading order(s) by the unregulated $\lambda\to\infty$ limit. The consideration of these different regions helps in describing the intermediate regimes where the infinite cutoff approximation is expected to work, at least for large values of λ. Finally, we want to point out that the most dramatic quantum effect observed when the cutoff is infinite, the very slow falloff of the commutator at the axis in the τ direction, is no longer present after introducing a regulator. This casts some doubts about the "observability" of large quantum gravitational fluctuations at the axis. These behaviors can be visually appreciated in Figs. 6–9.

VI. POWER EXPANSION IN *G*

In the above sections we have discussed the asymptotics of the regulated field commutator as a function of ρ, λ, and τ. These are dimensionless parameters obtained by using R_1 as a length scale. We want to discuss now the possibility of expanding this commutator as a power series in G. The main motivation to consider this issue is that one would expect to arrive at an expansion of this kind when adopting a standard perturbative approach for the treatment of the problem. As we will see, this can be done in a rather straightforward way if a cutoff is introduced in the system. However, our description breaks down when the cutoff is removed.

Let us analyze then the expansion of the vacuum expectation value of the commutator in powers of the quantum gravitational constant[25] $G=G_3\hbar$. To this end we rewrite (4) as

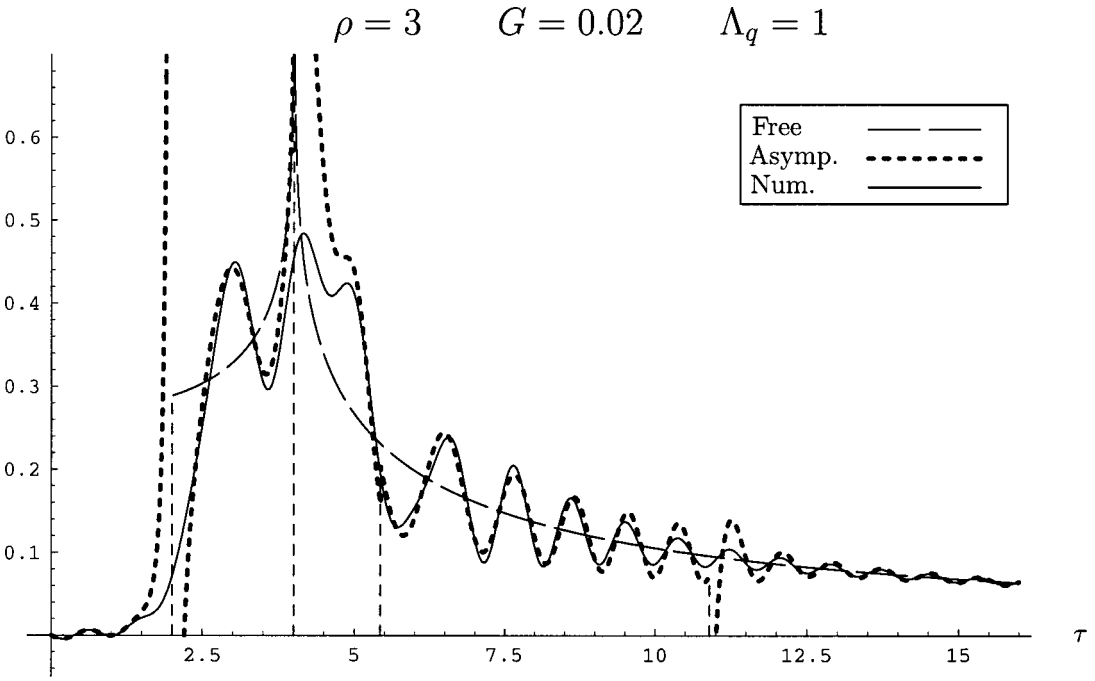

FIG. 7. Asymptotic approximation in λ for the field commutator over $8iG$ as a function of τ for $G=0.02$, $\rho=3$, and $\Lambda_q=1$ compared with a numerical approximation. The regions with different asymptotic regimes are shown. The asymptotic approximation is good except at the boundaries between these regions. The different types of behavior are also evident.

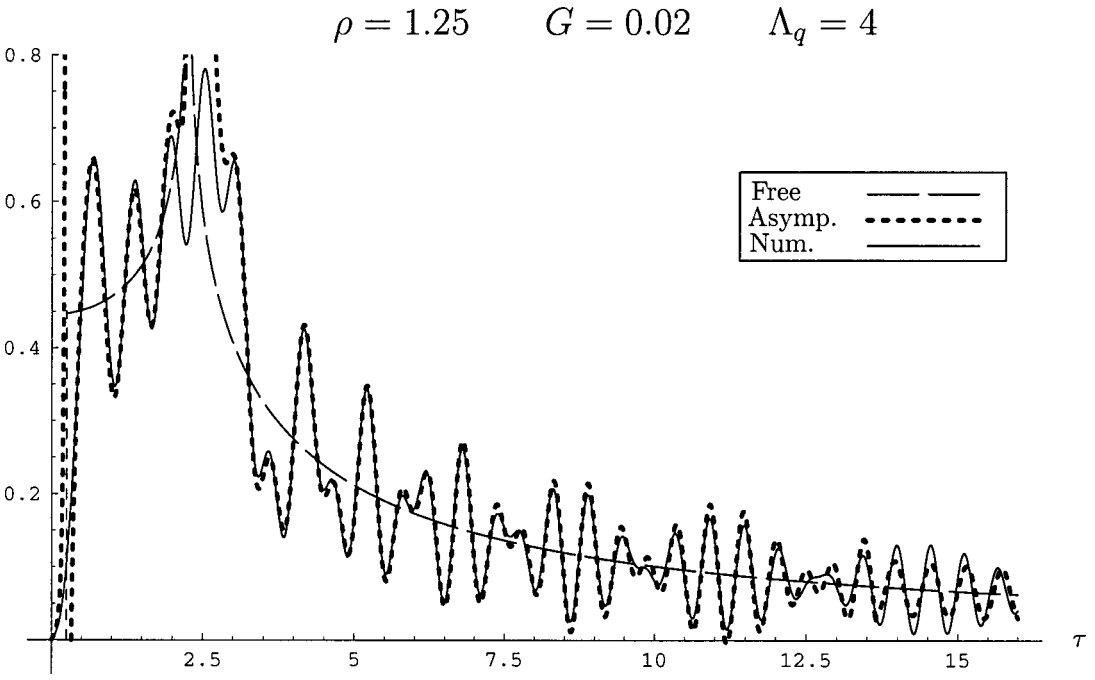

FIG. 8. Asymptotic approximation in λ for the field commutator over $8iG$ as a function of τ for $G=0.02$, $\rho=1.25$, and $\Lambda_q=4$ compared with a numerical approximation.

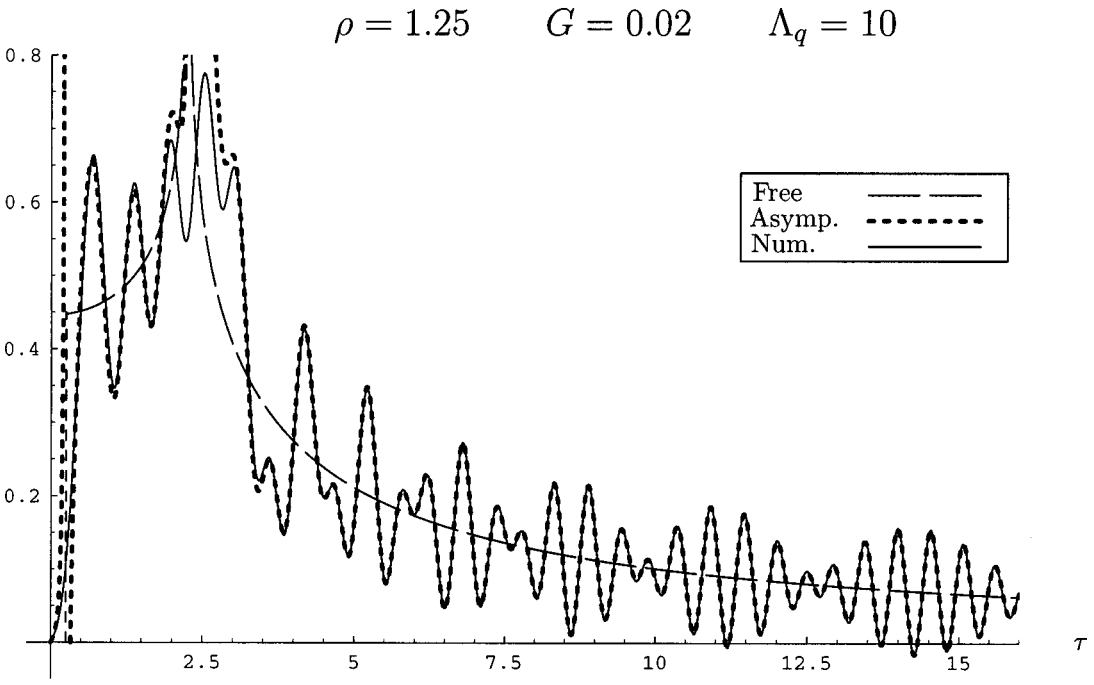

FIG. 9. Asymptotic approximation in λ for the field commutator over $8iG$ as a function of τ for $G=0.02$, $\rho=1.25$, and $\Lambda_q=10$ compared with a numerical approximation.

$$\frac{1}{8iG}\langle 0|[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]|0\rangle = \int_0^{\Lambda_k} dk J_0(R_1k)J_0(R_2k)\sin\left[kR_1\tau\frac{(1-e^{-q})}{q}\right]. \tag{20}$$

With our conventions, both $kR_1\tau$ and $q=Gk$ are dimensionless, whereas k can be regarded to have dimensions of an inverse length. Note that all the dependence on G is contained in q, accepting that the cutoff Λ_k is fixed. Thus, in order to arrive at the desired series, we will expand the integrand in powers of the variable q. At this point, it is worth remarking that, had we described the regulated commutator by means of the dimensionless cutoff $\Lambda_q=4G\Lambda_k$ as in previous sections,[26] it would not have been possible to single out the dependence on the gravitational constant via that on q.

We will use the following formulas for the Taylor expansion of the functions involved in our expression (20) and the composition of the resulting series, assuming for the moment their convergence:

$$g(q) := \frac{1-q-e^{-q}}{q} = \sum_{n=1}^{\infty}\frac{(-q)^n}{(n+1)!}, \tag{21}$$

$$\sin(kR_1\tau+y) = \sin(kR_1\tau)\sum_{m=0}^{\infty}(-1)^m\frac{y^{2m}}{(2m)!} + \cos(kR_1\tau)\sum_{m=0}^{\infty}(-1)^m\frac{y^{2m+1}}{(2m+1)!}, \tag{22}$$

$$[g(q)]^m = \left[\sum_{n=1}^{\infty}\frac{(-q)^n}{(n+1)!}\right]^m = \sum_{p=m}^{\infty}a_p[m](-q)^p, \tag{23}$$

$$a_p[m] := \sum_{\sigma(p|m)} \prod_{i=1}^{m} \frac{1}{(n_i+1)!}, \tag{24}$$

where the range of the last sum extends to the sets of m integers n_i given by

$$\sigma(p|m) := \left\{ n_i \geqslant 1; \sum_{i=1}^{m} n_i = p \right\}. \tag{25}$$

Interchanging the sum and integration orders, one then obtains the formal series

$$\frac{1}{8iG}\langle 0|[\hat{\psi}_E(R_1,t_1),\hat{\psi}_E(R_2,t_2)]|0\rangle = \sum_{p=0}^{\infty} \int_0^{\Lambda_k} dk J_0(R_1k)J_0(R_2k)(-4Gk)^p F_p(kR_1\tau), \tag{26}$$

with

$$F_p(kR_1\tau) := \sin(kR_1\tau) \sum_{m=1}^{\mathrm{int}[p/2]} \frac{(-1)^m}{(2m)!} a_p[2m](kR_1\tau)^{2m} + \cos(kR_1\tau) \sum_{m=0}^{\mathrm{int}[(p-1)/2]} \frac{(-1)^m}{(2m+1)!} a_p[2m+1](kR_1\tau)^{2m+1}, \quad p \geqslant 1,$$

$$F_0(kR_1\tau) := \sin(kR_1\tau). \tag{27}$$

Here, the function int$[x]$ is the integer part of x, and the sum over m that multiplies the function $\sin(kR_1\tau)$ is understood to vanish when $p=1$. Note that, in the case of infinite cutoff, the first ($p=0$) term reproduces the commutator of the free-field theory. Moreover, then all the $p \geqslant 1$ additions to the free field contribution are integrals over $[0,\infty)$ of oscillating, nonbounded functions and, hence, at best conditionally convergent. So, in the unregulated theory ($\Lambda_k=\infty$), the above expansion should be taken only as a formal expression, and therefore we expect that the corresponding vacuum expectation value of the field commutator is not analytic in G.

Of course these problems disappear when we admit the existence of a finite cutoff $0<\Lambda_k<\infty$. Taking into account that all the functions $F_p(kR_1\tau)$ are analytic in k around the positive real axis, because F_p is a finite combination of products of analytic functions, and that so are the zeroth-order Bessel functions that appear in the integrals of (26), it is easy to conclude that all those integrals are well defined when they are restricted to a compact interval $[0,\Lambda_k]$. Thus, each term in the power series (26) is finite for any finite positive value of Λ_k.

In the rest of this section, we will discuss the formal manipulations that we have carried out with infinite sums in order to deduce the above expansion. First, notice that the Taylor series in (21), which is obtained from that of the exponential function, has an infinite convergence radius. When this series is substituted in (20), one obtains a trigonometric function similar to that on the lhs of (22), but with $y=kR_1\tau g(q)$ expanded in powers of q. On the other hand, relation (22) is just the formula for the sine of the sum of two angles, with the resulting functions $\sin y$ and $\cos y$ replaced with their Taylor expansion. The series compositions $\sin[kR_1\tau g(q)]$ and $\cos[kR_1\tau g(q)]$ can then be rearranged without problems employing for $[g(q)]^m$ the value given in (23) because $g(q)$ (which we recall that converges for all $q \in \mathbb{R}^+$) is always smaller than the convergence radii of the sine and cosine series, which are in fact infinite.

In this way, one arrives at an expectation value of the regulated commutator that is equal to an integral over the interval $k \in [0,\Lambda_k]$ of the series of functions $\Sigma_p f_p(k|R_1,R_2,\tau)$, with

$$f_p(k|R_1,R_2,\tau) := J_0(R_1k)J_0(R_2k)(-4Gk)^p F_p(kR_1\tau). \tag{28}$$

Since the functions $f_p(k)$ are clearly continuous in $k \in [0,\Lambda_k]$ (for all allowed values of R_1, R_2, and τ) and this interval is compact, they are all integrable in that region. As a consequence, it is

sufficient that the considered series of functions converges uniformly in $k \in [0, \Lambda_k]$ to guarantee that the integration can be interchanged with the infinite sum. We will postpone to the next section the proof of this uniform convergence, at least for a convenient choice of the cutoff.

In conclusion, we have seen that the field commutator *in vacuo*, regulated with a (dimensionful) fixed cutoff, can be expanded as a power series in the gravitational constant G, each term in the series being finite. Besides, all the manipulations performed to deduce this series are rigorously justified provided that the cutoff is chosen so that the series $\Sigma_p f_p(k|R_1, R_2, \tau)$ converges uniformly in $k \in [0, \Lambda_k]$. Furthermore, in fact, this requirement of uniform convergence automatically ensures that the corresponding integrated power series (26) converges, and that it does so to the actual value of the expectation value of the regulated commutator.

VII. UNIFORM CONVERGENCE

We want to demonstrate that there exists a nonzero value of the cutoff for which the series $\Sigma_p f_p(k|R_1, R_2, \tau)$ converges uniformly in $k \in [0, \Lambda_k]$ for any fixed non-negative value of R_1, R_2, and τ. Let us start by finding a convenient upper bound for the coefficients $a_p[m]$, with $m \geqslant 1$, defined in (24). First, note that $a_p[m] = 0$ unless $p \geqslant m$, because no set of the form $\sigma(p|m)$ exists with $n_i \geqslant 1$ if $\Sigma_{i=1}^m n_i = p < m$. In addition, since $(n_i + 1)! \geqslant 2$ for $n_i \geqslant 1$, we have that

$$a_p[m] \leqslant \frac{1}{2^m} \sum_{\sigma(p|m)} 1. \tag{29}$$

From our definition (25), the last sum equals the different ways to arrange $p - m$ nondistinguishable elements [namely, the excess about its minimum of the sum of m elements $n_i \geqslant 1$, which equals $p - m$ for $\sigma(p|m)$] between m different sets (which correspond to the m integers n_i). The result is given by the permutations of $(p - m) + m - 1$ elements (the latter $m - 1$ elements representing movable delimiters between the m sets) with possible repetition in $p - m$ (the genuine, nondistinguishable elements) and in $m - 1$ (the imaginary delimiters). Thus,

$$a_p[m] \leqslant \frac{1}{2^m} \frac{(p-1)!}{(p-m)!(m-1)!} \leqslant \frac{1}{2^m} \frac{p!}{(p-m)!}. \tag{30}$$

In the last inequality we have employed that $(m - 1)! p \geqslant 1$ for all $p \geqslant m \geqslant 1$.

Using that the absolute value of the sine and the cosine is never greater than the unity, it is not difficult then to deduce from (27) the following bound for $F_p(kR_1\tau)$, with $p \geqslant 1$:

$$|F_p(kR_1\tau)| \leqslant \sum_{m=1}^{p} \frac{k^m R_1 \tau^m}{m!} a_p[m] \leqslant \sum_{m=1}^{p} \left(\frac{kR_1\tau}{2}\right)^m \binom{p}{m} = \left(1 + \frac{kR_1\tau}{2}\right)^p - 1. \tag{31}$$

In the last step, we have employed the formula of the binomial expansion. Likewise, since the zeroth-order Bessel function is bounded by the unity in the positive real axis, we get that, for all non-negative values of R_1 and R_2,

$$|f_p(k|R_1, R_2, \tau)| \leqslant (4Gk)^p \left[\left(1 + \frac{kR_1\tau}{2}\right)^p - 1\right] \leqslant \left[4Gk\left(1 + \frac{kR_1\tau}{2}\right)\right]^p. \tag{32}$$

The last inequality is trivial, given that $4Gk \geqslant 0$. Note also that the bound on the rhs is valid even in the case $p = 0$, taking into account (28).

Finally, since $4Gk(1 + kR_1\tau/2)$ is a strictly increasing function of k in $[0, \Lambda_k]$, we obtain a bound independent of the variable k in the interval considered:

$$|f_p(k|R_1, R_2, \tau)| \leqslant \left[4G\Lambda_k\left(1 + \frac{\Lambda_k R_1\tau}{2}\right)\right]^p. \tag{33}$$

To obtain the desired convergence properties, it will suffice to require that

$$4G\Lambda_k\left(1+\frac{\Lambda_k R_1\tau}{2}\right)<1. \tag{34}$$

We then get that both $|f_p(k|R_1,R_2,\tau)|$ and its integral over $[0,\Lambda_k]$ are small corrections for large p, which tend to zero in the limit $p\to\infty$.

In order to prove the uniform convergence of the series $\Sigma_p f_p(k|R_1,R_2,\tau)$, we have to check that, for each $\epsilon>0$, there exists an integer P such that, for every $k\in[0,\Lambda_k]$,

$$\left|\sum_{p=P}^{\infty} f_p(k|R_1,R_2,\tau)\right|\leqslant\epsilon. \tag{35}$$

Taking into account inequality (34), it is clear that, given $\epsilon>0$, we can always find a sufficiently large integer P for which

$$\left[4G\Lambda_k\left(1+\frac{\Lambda_k R_1\tau}{2}\right)\right]^P<\epsilon\left[1-4G\Lambda_k\left(1+\frac{\Lambda_k R_1\tau}{2}\right)\right]. \tag{36}$$

Note that the choice of this P depends only on the values of ϵ, Λ_k, G, and $R_1\tau$. Using (33), we then have

$$\left|\sum_{p=P}^{\infty} f_p(k|R_1,R_2,\tau)\right|\leqslant\sum_{p=P}^{\infty}\left[4G\Lambda_k\left(1+\frac{\Lambda_k R_1\tau}{2}\right)\right]^p=\frac{[4G\Lambda_k(1+\Lambda_k R_1\tau/2)]^P}{1-4G\Lambda_k(1+\Lambda_k R_1\tau/2)}\leqslant\epsilon.$$

So, inequality (35) is valid for all k in the considered interval $[0,\Lambda_k]$, as we wanted to prove.

We have thus shown that, for a given τ, every choice of the cutoff $\Lambda_k>0$ that satisfies condition (34) leads to a convergent power series in the gravitational constant G for the expectation vacuum of the regulated commutator, regardless of the radial coordinates R_1 and R_2. Moreover, the power expansion converges indeed to the true value of this regulated commutator *in vacuo*.

VIII. CONCLUSIONS AND COMMENTS

We have studied in this paper the issue of microcausality for quantum Einstein-Rosen waves after a suitable cutoff is introduced to regulate the quantum fields. In more detail, we have considered the introduction of a momentum cutoff Λ_k (or its dimensionless counterpart Λ_q). We have discussed first the asymptotic expansions in terms of the dimensionless parameters ρ, τ, and λ along the lines of Ref. 8. Owing to the fact that these parameters are defined with the help of R_1, in principle one does not need to make explicit the dependence of the cutoff Λ_k on G in this case. On physical grounds, one could view this cutoff, for example, as the inverse of the Planck length.

We have seen that the introduction of a finite cutoff modifies some of the conclusions obtained in Ref. 8. In particular we have seen that some of the most dramatic effects present when the cutoff is infinite (in particular the behavior of the field commutators in the symmetry axis) are now somewhat mitigated. Nevertheless, we have been able to show that the approximation provided by the unregulated field commutator is a good one in some regions of the (ρ,τ) plane, and, in fact, there is an unbounded region where that approximation prevails. This indicates that, even though the influence of the cutoff is felt in some regions of the parameter space, it is irrelevant in others.

In Secs. VI and VII, on the other hand, we have considered the expansion of the field commutator in terms of the gravitational constant G. We notice, nonetheless, that condition (34) on the cutoff Λ_k, which guarantees the convergence of the series, depends on G. At this stage, one possibility would be to admit that the cutoff depends on the gravitational constant; however, the expansion obtained would then fail to provide a genuine power series in G, because this parameter would also enter the different terms in the series via the implicit dependence of Λ_k on it. Another possibility that indeed respects the interpretation of our expansion as a power series in G is the following. Employing that condition (34) is an inequality equation for Λ_k given in terms of a

function of G that is strictly increasing, it is easy to see that the inequality is satisfied for all values of G in a certain interval $[0,G_M]$ if and only if it is satisfied for G_M. Something similar happens with respect to the dependence on the value of $R_1\tau=|t_2-t_1|$, so that if we want to consider a whole time interval of the form $|t_2-t_1|\in[0,t_M]$, we only have to evaluate our condition at the maximum time lapse. In other words, to ensure the convergence of the series for $G\in[0,G_M]$ and any time difference in $[0,t_M]$, we only have to demand the requirement (34) at $G=G_M$ and $R_1\tau=t_M$, because then

$$4G\Lambda_k\left(1+\frac{\Lambda_k R_1\tau}{2}\right)<4G_M\Lambda_k\left(1+\frac{\Lambda_k t_M}{2}\right)<1. \tag{37}$$

In this way we arrive at a cutoff that is independent of the particular values considered for $|t_2-t_1|$ and the gravitational constant (in the commented intervals), and our expansion becomes a true power series in G. The above inequality leads to the following positive upper bound for Λ_k:

$$\Lambda_k\leqslant\frac{1}{t_M}\left(\sqrt{1+\frac{t_M}{2G_M}}-1\right). \tag{38}$$

Therefore, with a cutoff that satisfies this condition, the power series (26) converges in the interval $[0,G_M]$ for all radial positions R_1 and R_2 and $R_1\tau=|t_2-t_1|\in[0,t_M]$.

When t_M is small, the bound on Λ_k is approximately $1/(4G_M)$, whereas for large t_M it is nearly equal to $1/\sqrt{2G_Mt_M}$. In particular, with this bound the cutoff would have to be vanishingly small if we want a good convergent behavior in an infinitely large time interval ($t_M\to\infty$). An open question is whether it is possible or not to find a different, nonzero time-independent cutoff such that the expansion of the regulated commutator converges for any value of the time elapsed, i.e., for all $|t_2-t_1|\in\mathbb{R}^+$. We expect to encounter convergence problems when the time interval is unbounded; for instance, one can prove that the series (26) does not converge uniformly in $\tau\in\mathbb{R}^+$ with any choice of the cutoff Λ_k (for generic R_1 and R_2). Nonetheless, one can in fact consider a kind of semi-classical limit in which G_M tends to zero (and hence so does the value of the gravitational constant, which had been restricted to $[0,G_M]$), while the time interval where the convergence is granted reaches infinity.

In order to do this, one only needs to allow a dependence of t_M on G_M, so that the assumed maximum value of the time difference varies with that of the gravitational constant. Suppose, let us say, that $t_M(G_M)=G_M^{-\alpha}$ with $0<\alpha<1$. Then, the bound (38) on the cutoff becomes

$$\Lambda_k\leqslant G_M^{\alpha}\left(\sqrt{1+\frac{1}{2G_M^{(\alpha+1)}}}-1\right). \tag{39}$$

Thus, when G_M tends to zero, we get the asymptotic behavior $\Lambda_k\leqslant G_M^{(\alpha-1)/2}/\sqrt{2}$. Since $G_M^{(\alpha-1)/2}$ and $G_M^{-\alpha}$ diverge for vanishing G_M, because $0<\alpha<1$, we therefore conclude that the cutoff can be removed in the limit $G_M\to0$ while ensuring that the time interval $[0,t_M(G_M)]$, where the expansion is well defined, covers the positive real axis.

We finally discuss the physical interpretation of this type of cutoff. It turns out to be intimately related to the maximum resolution that can be reached for the physical time when a certain perturbative approach is adopted to describe the quantum dynamics.[27] In such an approach, one expands the evolution generator in powers of G and regards the free-field Hamiltonian as the dominant contribution, with the higher powers seen as corrections. The auxiliary time T, associated with the free-field Hamiltonian, then plays the role of evolution parameter in the quantum theory, whereas the physical time becomes an operator. It was shown in Ref. 27 that, under these circumstances, a resolution limit Δt emerges for the physical time,

$$[\Delta t]^2\geqslant 4G^2+4GT. \tag{40}$$

Employing the inequality $\sqrt{1+x}\leqslant x/(\sqrt{1+x}-1)$ for $x>0$, evaluated at $x=t_M/(2G)$, one can easily check from condition (38) that the inverse of the cutoff satisfies

$$\Lambda_k^{-1} \geqslant \sqrt{4G_M^2 + 2G_M t_M}. \tag{41}$$

Therefore, the bound on Λ_k^{-1} equals that on the time resolution Δt for a value $G=G_M$ of the gravitational constant and a time elapsed $T=2t_M$ (and thus of the same order as t_M). In this sense, one can assign to Λ_k^{-1} the interpretation of a genuine resolution limit in the physical time.

The future prospects for this line of work will focus on the issue of deriving and obtaining meaningful physical information from the S matrix of the model. We feel that the mathematical techniques employed here to study the asymptotics of field commutators, with and without a cutoff, will also be helpful in analyzing this issue. We plan to concentrate on this problem in the future.

[23] The appearance of $1/k$ terms forces us to split the original integral in two as in (6) to avoid singularities at $k=0$.
[24] Notice that the other contributions are subdominant with respect to this one.
[25] In previous papers[7,8] we chose to expand $\sin[kt(1-e^{-q})/q]$ as a power series in e^{-q}. This yielded a convergent series representation for the commutator. Nonetheless, the complicated dependence of this expansion in G did not allow us to obtain a power series in the gravitational constant.
[26] Let us comment that one can always make dimensionless the cutoff Λ_k (as well as k and $1/G$) by multiplication with an arbitrary, fixed length scale independent of the gravitational constant, so that no spurious dependence on G is introduced in the process. In this sense, one may always view Λ_k either as a G-independent dimensionful cutoff or equivalently as a fixed dimensionless parameter.

(Received 7 March 2005; accepted 12 April 2005; published online 13 June 2005)

We investigate a one-parameter family of quantum Harish–Chandra modules of $U_q\mathfrak{sl}_{2n}$. This family is an analog of the holomorphic discrete series of representations of the group $\mathrm{SU}(n,n)$ for the quantum group $U_q\mathfrak{su}_{n,n}$. We introduce a *q*-analog of "the wave" operator (a determinant-type differential operator) and prove certain covariance property of its powers. This result is applied to the study of some quotients of the above-mentioned quantum Harish–Chandra modules. We also prove an analog of a known result by J. Faraut and A. Koranyi on the expansion of reproducing kernels which determines the analytic continuation of the holomorphic discrete series. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1927077]

I. INTRODUCTION

We start with recalling classical known results about analytic continuation of the weighted Bergman spaces in the unit disk and their explicit realization.

Recall that the group $\mathrm{SU}_{1,1}$ acts on the unit disk by fractional-linear transformations. Many important representations of the group are realized geometrically in various functional spaces on the disk and on the unit circle. In particular, representations of the discrete series admit a realization of that kind. Namely, consider the kernel $(1-z\overline{w})^{-\lambda}$ in the unit disk. For $\lambda>1$ it is the reproducing kernel for the so-called weighted Bergman space consisting of holomorphic functions that are square integrable with the weight $(1-|z|^2)^{\lambda-2}dm(z)$ [here $dm(z)$ is the normalized Lebesgue measure]. The group $\mathrm{SU}_{1,1}$ acts in the space via change of variable and a multiplier:

$$\pi_\lambda(g)(f(z)) = f(g^{-1}z)\cdot(cz+d)^{-\lambda}, \quad g^{-1}=\begin{pmatrix} a & b \\ c & d \end{pmatrix} \tag{1.1}$$

(for noninteger λ's one should consider the universal covering $\widetilde{\mathrm{SU}}_{1,1}$ instead of $\mathrm{SU}_{1,1}$). Thus obtained unitary representation belongs to the discrete series and is said to be a representation of the holomorphic discrete series for $\mathrm{SU}_{1,1}$ or $\widetilde{\mathrm{SU}}_{1,1}$.

The reproducing kernel $(1-z\overline{w})^{-\lambda}$ has analytic continuation in the parameter λ. This is obtained from the formula

$$(1-z\overline{w})^{-\lambda} = \sum_{m=0}^{\infty} (\lambda)_m \frac{(z\overline{w})^m}{m!}, \quad (\lambda)_m = \lambda\cdot(\lambda+1)\cdot\ \cdots\ \cdot(\lambda+m-1). \tag{1.2}$$

[a)]Electronic mail: shklyarov@math.ksu.edu
[b)]Electronic mail: genkai@math.chalmers.se

For $\lambda > 0$ the kernel is still positive definite, and the $SU_{1,1}$-action (1.1) in the associated Hilbert space is also unitary. For $\lambda = 1$, the Hilbert space is the Hardy space of holomorphic function on the closed disk whose boundary values are square integrable on the circle.

For further study of the previous representations, it is convenient to pass to the corresponding Harish–Chandra modules. Consider the space $\mathbb{C}[z]$ of polynomials on $\mathbb{C}$. The representation π_λ induces a representation of $\mathfrak{sl}_2(\mathbb{C}) = \mathfrak{su}_{1,1} \otimes \mathbb{C}$ on $\mathbb{C}[z]$ which may be defined for any $\lambda \in \mathbb{R}$ (and even for $\lambda \in \mathbb{C}$). Let us denote by $\mathcal{P}_\lambda$ the space $\mathbb{C}[z]$ endowed with the above-mentioned action of $\mathfrak{sl}_2(\mathbb{C})$. $\mathcal{P}_\lambda$ is irreducible for all positive λ's. However, if $\lambda = 1 - l$ for some positive integer l then $\mathcal{P}_\lambda = \mathcal{P}_{1-l}$ has the following composition series:

$$\{0\} \subset \mathcal{P}^{(0)}_{1-l} \subset \mathcal{P}_{1-l}, \tag{1.3}$$

where $\mathcal{P}^{(0)}_{1-l}$ is the submodule of polynomials of degree $\leqslant l-1$. The natural problem is to study the quotient $\mathcal{P}_{1-l}/\mathcal{P}^{(0)}_{1-l}$. This is the point where covariant differential operators appear on the scene. They play an important role in an explicit realization of the quotient. Namely, one checks that the differential operator $(\partial/\partial z)^l$ intertwines the actions π_{1-l} and π_{1+l}:

$$\left(\frac{\partial}{\partial z}\right)^l \cdot \pi_{1-l}(\xi) = \pi_{1+l}(\xi) \cdot \left(\frac{\partial}{\partial z}\right)^l, \quad \xi \in \mathfrak{sl}_2(\mathbb{C}). \tag{1.4}$$

Clearly, $(\partial/\partial z)^l$ induces an isomorphism from $\mathcal{P}_{1-l}/\mathcal{P}^{(0)}_{1-l}$ into $\mathcal{P}_{1+l}$, and this, in particular, proves unitarizability of the former module.

The unit disk is the simplest example of a bounded symmetric domain.[1] The above-mentioned results admit appropriate generalization for any such domain (of course, the group $SU_{1,1}$ is replaced by the group of biholomorphic automorphisms of the domain under consideration).

For the so-called tube domains, some generalizations of the covariance property (1.4) have been obtained by Shimura,[19] Arazy,[1] Jakobsen,[9] Jakobsen and Vergne,[13] and Jakobsen and Harris.[12] For example, in the case of the tube domain of type $I_{n,n}$ (the unit ball in the space of complex $n \times n$ matrices) the analog of (1.4) is a statement about an intertwining property of powers of the operator $\Box = \det(\partial/\partial z^\alpha_a)_{a,\alpha=1,\ldots,n}$ with respect to certain "twisted" action of the group $SU_{n,n}$ analogous to (1.1).

The generalized covariance property (1.4) has turned out to be useful beyond the problems we mentioned previously. It has been applied also to computing the Harish–Chandra homomorphism of invariant differential operators.[28]

Now for symmetric bounded domains the expansion (1.2) has been found by Ørsted[18] for type *I* matrix domains and in a general case by Faraut and Koranyi.[5] From this expansion one can read off the composition series analogous to (1.3); the covariant property of the intertwining operators is related to the classical Cayley–Capelli type formula. We note that the unitarity of the highest weight modules had been classified earlier by Jakobsen[8] using algebraic method; however the analytic approach as in Refs. 18 and 5 generated some other interesting analytic subjects and is related to many problems in special functions and orthogonal polynomials. For quantum groups the classification of unitary highest weight representations has also been done recently,[11] and we believe however that an analytic and concrete approach deserves pursuing.

In the present article we obtain analogs of (1.2), (1.3), and (1.4) for a quantum matrix ball, an analog of the tube domain of type $I_{n,n}$ which has been defined in framework of quantum group theory by Vaksman *et al.*[21]

In Ref. 22, the authors defined analogs of the weighted Bergman spaces on the quantum matrix ball. Also, they constructed analogs of the corresponding reproducing kernels and the twisted unitary action of the group $SU_{n,n}$. From the representation theoretic point of view, Ref. 22 presents a *q*-analog of the holomorphic discrete series of the group $SU_{n,n}$ (more precisely, analogs of the associated Harish–Chandra modules).

The natural problem now is to investigate those representations, particularly, to define their

"analytic continuation" and to study composition series of the resulting Harish–Chandra modules. In the case $n=2$, these problems were treated in Ref. 23. In the present paper, we deal with the case of arbitrary n.

The role of covariant differential operators in the classical theory of bounded symmetric domains and related Harish–Chandra modules is very well known.[9,12,13,19] Our intention is to bring covariant q-differential operators into the study of quantum Harish–Chandra modules and thus to demonstrate their importance in the quantum setting as well [note that similar questions have been already treated in the literature (see Ref. 3 and, especially, Ref. 10)]. We introduce a determinant-type q-differential operator similar to $\Box$ and prove a q-analog of the covariance property. In the last section, this result is applied to investigation of certain quotients of the above quantum Harish–Chandra modules.

Another goal of the paper is to obtain an analog of the aforementioned result by Faraut and Koranyi[5] which has allowed them to solve the problem of analytic continuation of the holomorphic discrete series in the classical setting.

As we already mentioned, there is a complete classification of unitarizable highest-weight modules over quantum groups (see Ref. 11). Thus, neither the holomorphic discrete series of the quantum group $\mathrm{SU}(n,n)$, constructed in Ref. 22, nor its analytic continuation, obtained in the present paper, give us a new family of unitary modules. The principal aim of the present paper, as well as other papers,[22,23] is to develop an "analytic and geometric" framework for studying quantum Harish–Chandra modules related to quantum Cartan domains, particularly, to show that there are substantial generalizations of known classical constructions and results connected with the holomorphic discrete series.

The paper is organized as follows. Sections II and III contain some preliminary material. In Sec. II, we recall some basic notions and results of quantum group theory (particularly, the notion of quantum space of matrices and of the quantized universal enveloping algebra $U_q\mathfrak{sl}_n$). This is done mainly for the purpose to set the notation we use further. Also, we recall certain hidden quantum $U_q\mathfrak{sl}_{2n}$ symmetry of the quantum matrix space discovered in Ref. 25. (This hidden symmetry was one of the first hints that there should be a substantial theory of q-bounded symmetric domains. These objects were invented a little later in Ref. 24). In the end of Sec. II we describe a twisted action (depending on a parameter λ) of $U_q\mathfrak{sl}_{2n}$ on the quantum matrix space. For λ large enough the corresponding Harish–Chandra modules are unitarizable representations of $U_q\mathfrak{su}_{n,n}$, which we call the holomorphic discrete series due to the previous motivation. Section III is devoted to q-differential operators. We recall there the notion of a q-differential operator with constant coefficients and describe certain properties of the algebra of such operators. Also, we introduce an analog of the operator $\Box$ and derive its "obvious" quantum symmetry which amounts to an intertwining property of the operator with an action of Hopf subalgebra $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n \subset U_q\mathfrak{sl}_{2n}$. This obvious symmetry is extended to a large hidden symmetry, namely, the intertwining property of the operator (and of its powers) with the twisted $U_q\mathfrak{sl}_{2n}$ actions. This covariance property is formulated and proved in Sec. IV. In the course of the proof, we use a number of results from the theory of quantum bounded symmetric domains, in particular, those obtained in Ref. 20 and, especially, results of Ref. 27. To keep the size of the paper reasonable, we have to be more sketchy in this part of the paper. We omit proofs of those results giving appropriate references instead. In the last section of the paper we investigate the holomorphic discrete series for $U_q\mathfrak{su}_{n,n}$. First of all, we use computations of Sec. IV to produce an analog of the result by Faraut and Koranyi[5] we mentioned earlier. Then we derive some applications of the covariance property.

II. QUANTUM SPACE OF MATRICES AND ITS SYMMETRIES

In this paper, the parameter q is supposed to be a number from the interval (0, 1).

A. Quantum space of matrices

Let us start with the definition of the algebra $\mathbb{C}[M_n]_q$ of polynomials on the quantum matrix space. It is the unital algebra given by its generators z_a^α (here, $a,\ \alpha=1,\ldots,n$, a is the column index and α is the row index) and the following relations:

$$z_a^\alpha z_b^\beta = \begin{cases} qz_b^\beta z_a^\alpha, & a=b \quad \text{and} \quad \alpha<\beta \quad \text{or} \quad a<b \quad \text{and} \quad \alpha=\beta \\ z_b^\beta z_a^\alpha, & a<b \quad \text{and} \quad \alpha>\beta \\ z_b^\beta z_a^\alpha + (q-q^{-1}) z_a^\beta z_b^\alpha, & a<b \quad \text{and} \quad \alpha<\beta. \end{cases} \tag{2.1}$$

These commutation relations, along with the relation

$$\det_q(\mathbf{z}) = \sum_{s\in S_n} (-q)^{l(s)} z_{a_1}^{\alpha_{s(1)}} z_{a_2}^{\alpha_{s(2)}} \cdots z_{a_n}^{\alpha_{s(n)}} = 1, \tag{2.2}$$

appeared for the first time in Ref. 4 as the relations between generators in the algebra $\mathbb{C}[SL_n]_q$ of regular functions on the quantum SL_n. It was suggested in Ref. 6 to discard (2.2) from the list of relations and to regard (2.1) as the defining relations of the algebra of polynomials on the quantum space of matrices. The algebra $\mathbb{C}[SL_n]_q$ is then the quotient of $\mathbb{C}[M_n]_q$ by the two-sided ideal generated by the element $\det_q(\mathbf{z})-1$ {note that the q-determinant $\det_q(\mathbf{z})$ belongs to the center of $\mathbb{C}[M_n]_q$ ([2, Sec. VII C 2])}. Also, the algebra $\mathbb{C}[M_n]_q$ is used to define the algebra of regular functions on the quantum GL_n. The latter is just the localization of the former with respect to the multiplicative system $\det_q(\mathbf{z})^m$, $m=1,2,\ldots$.

The crucial observation concerning the algebra $\mathbb{C}[M_n]_q$ was the discovery of the comultiplication

$$\mathbb{C}[M_n]_q \to \mathbb{C}[M_n]_q \otimes \mathbb{C}[M_n]_q, \quad z_a^\alpha \mapsto \sum_j z_a^j \otimes z_j^\alpha$$

which, along with the initial multiplication, makes $\mathbb{C}[M_n]_q$ into a bialgebra. The comultiplication maps the q-determinant $\det_q(\mathbf{z})$ to $\det_q(\mathbf{z})\otimes\det_q(\mathbf{z})$ and thus induces a comultiplication on the algebra $\mathbb{C}[SL_n]_q$. The latter, along with certain antipode and counit, makes $\mathbb{C}[SL_n]_q$ into a Hopf algebra.

All the above structures allow one to produce q-analogs of the left and right actions

$$L(g): f(\mathbf{z}) \mapsto f(g^{-1}\cdot\mathbf{z}), \quad R(g): f(\mathbf{z}) \mapsto f(\mathbf{z}\cdot g)$$

of SL_n in $\mathbb{C}[M_n]$. These q-analogs are usually described in terms of comodule algebras.[2] However, it is more convenient for us to use an "infinitesimal" version of those actions which is based on the notion of the quantum universal enveloping algebra $U_q\mathfrak{sl}_n$ due to Drinfeld[4] and Jimbo.[15]

First, we recall the definition of $U_q\mathfrak{sl}_n$ (we follow the notation of Ref. 14). The quantum universal enveloping algebra $U_q\mathfrak{sl}_n$ is the unital algebra generated by the elements E_i, F_i, $K_i^{\pm1}$, $i=1,\ldots,n$, which satisfy the relations

$$K_iK_j = K_jK_i, \quad K_iK_i^{-1} = K_i^{-1}K_i = 1,$$

$$K_iE_j = q^{a_{ij}}E_jK_i, \quad K_iF_j = q^{-a_{ij}}F_jK_i,$$

$$E_iF_j - F_jE_i = \delta_{ij}(K_i - K_i^{-1})/(q-q^{-1}),$$

$$E_i^2E_j - (q+q^{-1})E_iE_jE_i + E_jE_i^2 = 0, \quad |i-j|=1$$

$$F_i^2F_j - (q+q^{-1})F_iF_jF_i + F_jF_i^2 = 0, \quad |i-j|=1$$

$$[E_i,E_j]=[F_i,F_j]=0, \quad |i-j|\neq 1$$

with (a_{ij}) being the Cartan matrix of type A_{n-1}. Moreover, $U_q\mathfrak{sl}_n$ is a Hopf algebra. The comultiplication Δ, the antipode S, and the counit ε are determined by

$$\Delta(E_i)=E_i\otimes 1+K_i\otimes E_i, \quad \Delta(F_i)=F_i\otimes K_i^{-1}+1\otimes F_i, \quad \Delta(K_i)=K_i\otimes K_i, \tag{2.3}$$

$$S(E_i)=-K_i^{-1}E_i, \quad S(F_i)=-F_iK_i, \quad S(K_i)=K_i^{-1}, \tag{2.4}$$

$$\varepsilon(E_i)=\varepsilon(F_i)=0, \quad \varepsilon(K_i)=1. \tag{2.5}$$

It is observed in Ref. 4 that the Hopf algebras $U_q\mathfrak{sl}_n$ and $\mathbb{C}[SL_n]_q$ are dual to each other. This, in particular, allows one to use the language of $U_q\mathfrak{sl}_n$-module algebras instead of that of $\mathbb{C}[SL_n]_q$-comodule algebras mentioned previously. This is what we do in the present paper.

Let us recall now what the terminology "$U_q\mathfrak{sl}_n$-module algebra" means. Let A be a Hopf algebra. A unital algebra F is said to be an A-module algebra if F is an A-module, the unit of F is A-invariant [which means $\xi(1)=\varepsilon(\xi)\cdot 1$ for any $\xi\in A$], and, finally, the multiplication $F\otimes F\to F$ intertwines the A-actions (we recall that for any A-modules V_1, V_2 their tensor product is endowed with an A-module structure via the comultiplication $\Delta: A\to A\otimes A$).

Remark: In the sequel, we shall sometimes consider Hopf algebras with an additional structure, namely, Hopf $*$-algebras (a Hopf $*$-algebra is a pair $(A,*)$ where A is a Hopf algebra and $*$ is an involution in A with certain properties; see Ref. 2). In the case of Hopf $*$-algebras the above-mentioned definition includes an additional requirement. Namely, let $A_0=(A,*)$ be a Hopf $*$-algebra and F an algebra. Then F is said to be an A_0-module algebra if, first, F is an A-module algebra in the previous sense, and, second, F is involutive and the involutions in A and F agree as follows:

$$(\xi(f))^*=S(\xi)^*(f^*), \quad \xi\in A, f\in F. \tag{2.6}$$

[The notion of module algebras can be clarified in the classical setting of a Lie group G acting on a smooth G-space X. Denote by $\mathfrak{g}$ the Lie algebra of G. Then the universal enveloping algebra $U\mathfrak{g}$ acts on the space $C^\infty(X)$ via differential operators. The usual Leibnitz rule means that $C^\infty(X)$ is a $U\mathfrak{g}$-module algebra.]

Let us turn back to the quantum space of matrices. Now we are in position to describe the very well known "infinitesimal version" of the left and right actions of the quantum group SL_n in $\mathbb{C}[M_n]_q$. Note, however, that the left action we present below is not an analog of the classical one, mentioned earlier. It is more convenient for us to use an action that differs from the usual left one by a simple automorphism of $U_q\mathfrak{sl}_n$.

Proposition 2.1:

(i) *There exists a unique structure of $U_q\mathfrak{sl}_n$-module algebra in $\mathbb{C}[M_n]_q$ such that*

$$R(K_i)z_a^\alpha=\begin{cases} qz_a^\alpha, & a=i \\ q^{-1}z_a^\alpha, & a=i+1 \\ z_a^\alpha, & \text{otherwise}, \end{cases} \tag{2.7}$$

$$R(F_i)z_a^\alpha=\begin{cases} q^{1/2}z_{a+1}^\alpha, & a=i \\ 0, & \text{otherwise}, \end{cases} \qquad R(E_i)z_a^\alpha=\begin{cases} q^{-1/2}z_{a-1}^\alpha, & a=i+1 \\ 0, & \text{otherwise}. \end{cases} \tag{2.8}$$

(ii) *There exists a unique structure of $U_q\mathfrak{sl}_n$-module algebra in $\mathbb{C}[M_n]_q$ such that*

$$L(K_j)z_a^\alpha = \begin{cases} qz_a^\alpha, & \alpha = n-j \\ q^{-1}z_a^\alpha, & \alpha = n-j+1 \\ z_a^\alpha, & \text{otherwise}, \end{cases} \tag{2.9}$$

$$L(F_j)z_a^\alpha = \begin{cases} q^{1/2}z_a^{\alpha+1}, & \alpha = n-j \\ 0, & \text{otherwise}, \end{cases} \qquad L(E_j)z_a^\alpha = \begin{cases} q^{-1/2}z_a^{\alpha-1}, & \alpha = n-j+1 \\ 0, & \text{otherwise}. \end{cases} \tag{2.10}$$

(iii) *For any* $\xi, \eta \in U_q\mathfrak{sl}_n$ *the endomorphisms* $R(\xi)$, $L(\eta)$ *commute*

$$R(\xi)L(\eta)f = L(\eta)R(\xi)f, \quad f \in \mathbb{C}[M_n]_q.$$

Note that by statement (iii) in the above-mentioned proposition, the algebra $\mathbb{C}[M_n]_q$ is acted upon by the tensor product $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$:

$$\xi \otimes \eta(f) = R(\xi)L(\eta)f.$$

One can check that the q-determinant $\det_q(\mathbf{z})$ (2.2) is invariant with respect to both left and right $U_q\mathfrak{sl}_n$-actions, i.e.,

$$R(\xi)\det_q(\mathbf{z}) = L(\xi)\det_q(\mathbf{z}) = \varepsilon(\xi)\cdot\det_q(\mathbf{z})$$

for any $\xi \in U_q\mathfrak{sl}_n$. Thus the formulas from Proposition 2.1 define left and right $U_q\mathfrak{sl}_n$-actions in $\mathbb{C}[SL_n]_q$. By analogy with the classical case, one has the following proposition (see Ref. 2).

Proposition 2.2: *The* $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$*-module* $\mathbb{C}[SL_n]_q$ *splits into direct sum of simple pairwise nonisomorphic submodules whose lowest vectors are given via q-minors as follows:*

$$(z_n^n)^{a_1}(\mathbf{z}^{\wedge 2\{n-1,n\}}_{\{n-1,n\}})^{a_2}(\mathbf{z}^{\wedge 3\{n-2,n-1,n\}}_{\{n-2,n-1,n\}})^{a_3}\cdots(\mathbf{z}^{\wedge (n-1)\{2,\ldots,n\}}_{\{2,\ldots,n\}})^{a_{n-1}}.$$

We recall that the q-minors are defined by

$$(\mathbf{z}^{\wedge k})^{\{\alpha_1,\alpha_2,\ldots,\alpha_k\}}_{\{a_1,a_2,\ldots,a_k\}} \overset{\text{def}}{=} \sum_{s\in S_k}(-q)^{l(s)}z_{a_1}^{\alpha_{s(1)}}z_{a_2}^{\alpha_{s(2)}}\cdots z_{a_k}^{\alpha_{s(k)}} \tag{2.11}$$

with $\alpha_1 < \alpha_2 < \cdots < \alpha_k$, $a_1 < a_2 < \cdots < a_k$, and $l(s)$ being the length of $s \in S_k$. In particular, $\det_q(\mathbf{z}) = (\mathbf{z}^{\wedge n})^{\{1,2,\ldots,n\}}_{\{1,2,\ldots,n\}}$.

Let us denote the tensor product $U_q\mathfrak{sl}_n \otimes U_q\mathfrak{sl}_n$ with the canonical Hopf algebra structure by $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$. Thus, $\mathbb{C}[M_n]_q$ is a $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-module algebra. It follows from the definition of the quantum universal enveloping algebra $U_q\mathfrak{sl}_n$ that there is an embedding of Hopf algebras $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n) \hookrightarrow U_q\mathfrak{sl}_{2n}$ determined by

$$1 \otimes E_i \mapsto E_i, \quad 1 \otimes F_i \mapsto F_i, \quad 1 \otimes K_i^{\pm 1} \mapsto K_i^{\pm 1}, \quad i = 1,\ldots,n-1,$$

$$E_i \otimes 1 \mapsto E_{n+i}, \quad F_i \otimes 1 \mapsto F_{n+i}, \quad K_i^{\pm 1} \otimes 1 \mapsto K_{n+i}^{\pm 1}, \quad i = 1,\ldots,n-1.$$

This is a q-analog of the embedding $SL_n \times SL_n \hookrightarrow SL_{2n}$ given, in the matrix realization, by

$$(A,B) \mapsto \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}.$$

In the next subsection we shall extend the above $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-module algebra structure in $\mathbb{C}[M_n]_q$ to a structure of $U_q\mathfrak{sl}_{2n}$-module algebra.

B. A structure of $U_q\mathfrak{sl}_{2n}$-module algebra on $\mathbb{C}[M_n]_q$

In this subsection we describe a "hidden" $U_q\mathfrak{sl}_{2n}$-module algebra structure in $\mathbb{C}[M_n]_q$. It was discovered in Ref. 25. Its classical counterpart comes from an embedding of the matrix space M_n into the Grassmannian $\mathrm{Gr}_n(\mathbb{C}^{2n})$ as the affine cell $U\subset \mathrm{Gr}_n(\mathbb{C}^{2n})$ defined by the inequality $t\neq 0$ with t being a distinguished Plücker coordinate. A q-version of the embedding is described in Ref. 25, Proposition 0.7 (see also Proposition 5.4 from Ref. 21).

Let us turn to the quantum case. The following statement was proved in Ref. 21, Sec. 2.

***Proposition 2.3**: There exists a unique $U_q\mathfrak{sl}_{2n}$-module algebra structure in $\mathbb{C}[M_n]_q$ given on the Hopf subalgebra $U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)$ by the formulas from Proposition 2.1 and on the remaining generators $K_n^{\pm 1}$, F_n, E_n by*

$$K_n z_a^\alpha=\begin{cases} q^2 z_a^\alpha, & a=n \quad \text{and} \quad \alpha=n \\ q z_a^\alpha, & a=n \quad \text{and} \quad \alpha\neq n \quad \text{or} \quad a\neq n \quad \text{and} \quad \alpha=n \\ z_a^\alpha, & \text{otherwise,}\end{cases} \tag{2.12}$$

$$F_n z_a^\alpha=q^{1/2}\begin{cases}1, & a=n \quad \text{and} \quad \alpha=n\\ 0, & \text{otherwise,}\end{cases} \qquad E_n z_a^\alpha=-q^{1/2}\begin{cases} q^{-1} z_a^m z_n^\alpha, & a\neq n \quad \text{and} \quad \alpha\neq n\\ (z_n^m)^2, & a=n \quad \text{and} \quad \alpha=n\\ z_n^m z_a^\alpha, & \text{otherwise.}\end{cases} \tag{2.13}$$

Let us point out some straightforward but essential properties of this $U_q\mathfrak{sl}_{2n}$-action in $\mathbb{C}[M_n]_q$. Denote by $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$ the Hopf subalgebra in $U_q\mathfrak{sl}_{2n}$ derived from $U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)$ by adding the generators $K_n^{\pm 1}$. Clearly, elements of $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$ preserve the natural $\mathbb{Z}_+$-grading in $\mathbb{C}[M_n]_q$ given by powers of monomials. It is also obvious, that the generators F_n, E_n act in $\mathbb{C}[M_n]_q$ as endomorphisms of degrees -1 and 1, respectively. All this may be derived also from the following convenient description of the $\mathbb{Z}_+$-grading in $\mathbb{C}[M_n]_q$:

$$\deg f=N \Leftrightarrow \hat{K} f=q^{2N} f, \tag{2.14}$$

where $\hat{K}$ is the element of the center of $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$ given by

$$\hat{K}=(K_n)^n\cdot\prod_{j=1}^{n-1}(K_j K_{2n-j})^j. \tag{2.15}$$

For computational purposes, it is important to understand the structure of $\mathbb{C}[M_n]_q$ as a $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-module in greater detail. The following statement is a straightforward consequence of Proposition 2.2.

***Proposition 2.4**: The $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-module $\mathbb{C}[M_n]_q$ splits into direct sum of simple pairwise non-isomorphic submodules $\mathbb{C}[M_n]_q^{(k_1,k_2,\ldots,k_n)}$, $k_1\geqslant k_2\geqslant\cdots\geqslant k_n\geqslant 0$, whose lowest vectors are given by*

$$(z_n^n)^{k_1-k_2}\left(\mathbf{z}^{\wedge 2^{\{n-1,n\}}_{\{n-1,n\}}}\right)^{k_2-k_3}\left(\mathbf{z}^{\wedge 3^{\{n-2,n-1,n\}}_{\{n-2,n-1,n\}}}\right)^{k_3-k_4}\cdots(\det_q\mathbf{z})^{k_n}.$$

In what follows, the above $U_q\mathfrak{sl}_{2n}$-action in $\mathbb{C}[M_n]_q$ will be sometimes called "the initial" one, in contrast to a twisted action described in the next subsection.

Let us present another view on the above $U_q\mathfrak{sl}_{2n}$-action in $\mathbb{C}[M_n]_q$. The point is that the corresponding classical $U\mathfrak{sl}_{2n}$-action is well known in the theory of bounded symmetric domains (see, for instance, Ref. 1). In framework of this theory, it is constructed as follows. The vector space M_n contains the so-called matrix ball (the boundary symmetric domain of type $I_{n,n}$)

$$\mathcal{D} = \{\mathbf{z} \in M_n | \mathbf{z}\mathbf{z}^* < 1\}$$

(with $*$ being the hermitian conjugation and 1 the unit matrix). It is known that the real simple Lie group $\mathrm{SU}_{n,n}$ acts on $\mathcal{D}$ via biholomorphic automorphisms, and $S(U_n \times U_n) \subset \mathrm{SU}_{n,n}$ is the isotropy subgroup of the center $0 \in \mathcal{D}$. Thus elements of the universal enveloping algebra $U\mathfrak{su}_{n,n}$, and hence elements of its complexification $U\mathfrak{sl}_{2n}$, act on the space of holomorphic functions on $\mathcal{D}$ via differential operators. These differential operators have polynomial coefficients and, thus, preserve $\mathbb{C}[M_n]$. The resulting $U\mathfrak{sl}_{2n}$-action in $\mathbb{C}[M_n]$ is what we call the initial one. In framework of this approach, the result of Proposition 2.4 is just a q-analog of the famous Hua–Schmid decomposition[1] whereas the quantum enveloping algebra $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$ itself is an analog of the universal enveloping algebra of the complexified Lie algebra of the isotropy subgroup $S(U_n \times U_n)$.

C. A twisted $U_q\mathfrak{sl}_{2n}$-action on $\mathbb{C}[M_n]_q$

In this subsection we introduce a one-parameter family π_λ, $\lambda \in \mathbb{R}$, of $U_q\mathfrak{sl}_{2n}$-actions in $\mathbb{C}[M_n]_q$ such that the initial $U_q\mathfrak{sl}_{2n}$-action, defined in the previous subsection, corresponds to $\lambda = 0$. In the classical case the corresponding twisted $U\mathfrak{sl}_{2n}$-action π_λ for $\lambda \in \mathbb{Z}$ can be produced by trivializing the homogeneous line bundle $\mathcal{O}(-\lambda)$ on the Grassmannian $\mathrm{Gr}_n(\mathbb{C}^{2n})$ over the affine cell U. Namely, we identify the space of polynomials on M_n with the space of sections $\Gamma(U, \mathcal{O}(-\lambda))$ by $f(\mathbf{z}) \sim f(\mathbf{z}) \cdot t^{-\lambda}$ (here t is the distinguished Plücker coordinate mentioned at the beginning of the previous subsection) and define the $U\mathfrak{sl}_{2n}$-action π_λ as follows:

$$(\pi_\lambda(\xi)f) \cdot t^{-\lambda} = \xi(f \cdot t^{-\lambda}), \quad \xi \in U\mathfrak{sl}_{2n}. \tag{2.16}$$

Note that, among the actions π_λ, the initial action π_0 is the only one which makes $\mathbb{C}[M_n]$ into a $U\mathfrak{sl}_{2n}$-*module algebra*. This is true in the q-setting as well.

Let us define a quantum version of the $U\mathfrak{sl}_{2n}$-action (2.16)

Proposition 2.5: *For any* $\lambda \in \mathbb{R}$ *the formulas*

$$\pi_\lambda(K_j^{\pm 1})f = \begin{cases} K_j^{\pm 1} f, & j \neq n \\ q^{\pm\lambda} K_n^{\pm 1} f, & j = n, \end{cases}$$

$$\pi_\lambda(F_j)f = \begin{cases} F_j f, & j \neq n \\ q^{-\lambda} F_n f, & j = n, \end{cases} \qquad \pi_\lambda(E_j)f = \begin{cases} E_j f, & j \neq n \\ E_n f - q^{1/2}\dfrac{1-q^{2\lambda}}{1-q^2}(K_n f) z_n^n, & j = n \end{cases}$$

define a $U_q\mathfrak{sl}_{2n}$*-action in* $\mathbb{C}[M_n]_q$ (*in the right-hand sides the initial* $U_q\mathfrak{sl}_{2n}$*-action is used*).

This proposition was proved in Ref. 22 (Proposition 6.2). Note that π_0 coincides with the initial $U_q\mathfrak{sl}_{2n}$-action. For brevity, we shall denote the $U_q\mathfrak{sl}_{2n}$-module, corresponding to λ, by $\mathcal{P}_\lambda$, namely $\mathcal{P}_\lambda = (\mathbb{C}[M_n]_q, U_q\mathfrak{sl}_{2n}, \pi_\lambda)$.

The classical counterpart of the above twisted $U_q\mathfrak{sl}_{2n}$-action is also well known in the theory of bounded symmetric domains. The corresponding $\mathrm{SU}_{n,n}$-action (more precisely, the action of the universal covering $\widetilde{\mathrm{SU}}_{n,n}$) is defined by

$$\pi_\lambda(g): f(\mathbf{z}) \mapsto f(g^{-1}\mathbf{z}) \cdot J_{g^{-1}}(\mathbf{z})^{\lambda/2n} \tag{2.17}$$

with $J_{g^{-1}}(\mathbf{z})$ being the Jacobian of the biholomorphic map $\mathbf{z} \mapsto g^{-1}\mathbf{z}$ (see Ref. 1 for details). For $\lambda > 2n-1$ the action π_λ on a weighted Bergman space defines a holomorphic discrete scries representation of $\widetilde{SU}_{n,n}$. In the last section of the paper we will describe a unitary structure on $\mathcal{P}_\lambda$ which formally tends to the classical setting as $q \to 1$.

III. SOME q-DIFFERENTIAL OPERATORS

A. Basic definitions

One of our results is connected with a q-analog of the wave operator

$$\Box = \det\left(\frac{\partial}{\partial z_a^\alpha}\right).$$

We start with some general consideration of q-differential operators with constant coefficients.

To produce q-analogs of the partial derivatives, we use certain known first order differential calculus over $\mathbb{C}[M_n]_q$, see Ref. 2. Let $\Omega^1(M_n)_q$ be the $\mathbb{C}[M_n]_q$-bimodule given by its generators dz_a^α, $a,\alpha=1,\ldots,n$, and the relations

$$z_b^\beta dz_a^\alpha = \sum_{\alpha',\beta'=1}^{n} \sum_{a',b'=1}^{n} R_{\beta\alpha}^{\beta'\alpha'} R_{ba}^{b'a'} dz_{a'}^{\alpha'} \cdot z_{b'}^{\beta'},$$

with

$$R_{ba}^{b'a'} = \begin{cases} q^{-1}, & a=b=a'=b' \\ 1, & a\neq b \text{ and } a=a' \text{ and } b=b' \\ q^{-1}-q, & a<b \text{ and } a=b' \text{ and } b=a' \\ 0, & \text{otherwise}. \end{cases}$$

The map $d: z_a^\alpha \mapsto dz_a^\alpha$ can be extended to a linear operator $d:\mathbb{C}[M_n]_q \to \Omega^1(M_n)_q$ satisfying the Leibnitz rule $d(f_1f_2)=d(f_1)f_2+f_1d(f_2)$. The pair $(\Omega^1(M_n)_q, d)$ is the first order differential calculus over $\mathbb{C}[M_n]_q$ we need.

The calculus itself has been known for a long time.[2] However, its hidden $U_q\mathfrak{sl}_{2n}$-symmetry was observed much later in Ref. 25. To be more precise, it is proved in Ref. 27 that there exists a unique structure of a $U_q\mathfrak{sl}_{2n}$-module in $\Omega^1(M_n)_q$ such that, first, the map d is a morphism of $U_q\mathfrak{sl}_{2n}$-modules, and, second, the left and right multiplications

$$\mathbb{C}[M_n]_q \otimes \Omega^1(M_n)_q \to \Omega^1(M_n)_q, \quad \Omega^1(M_n)_q \otimes \mathbb{C}[M_n]_q \to \Omega^1(M_n)_q$$

are morphisms of $U_q\mathfrak{sl}_{2n}$-modules. This is usually expressed by saying that the first order differential calculus $(\Omega^1(M_n)_q, d)$ is $U_q\mathfrak{sl}_{2n}$-covariant. Before Ref. 25 appeared, only $U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)$-covariance of the calculus was known.

The first order differential calculus allows us to define the q-analogs of partial derivatives as follows: Set

$$\mathrm{d}f = \sum_{a=1}^{n} \sum_{\alpha=1}^{n} \frac{\partial f}{\partial z_a^\alpha} \cdot dz_a^\alpha, \quad f \in \mathbb{C}[M_n]_q.$$

Here the left-hand side defines the right-hand one.

It is quite reasonable to regard the unital subalgebra in $\mathrm{End}(\mathbb{C}[M_n]_q)$ generated by all the derivatives as an analog of the algebra of differential operators with constant coefficients. This algebra seems to be interesting in itself. First of all, it admits a very explicit description. Namely, it is observed in Ref. 20 (Section 2) that the map $z_a^\alpha \mapsto \partial/\partial z_a^\alpha$ may be extended to an algebra homomorphism $\Upsilon:\mathbb{C}[M_n]_q \to \mathrm{End}(\mathbb{C}[M_n]_q)$ which means that the operators $\partial/\partial z_a^\alpha$ satisfy the same commutation relations as the generators z_a^α of $\mathbb{C}[M_n]_q$ do. Further, the algebra is invariant with respect to a certain natural $U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)$-action in $\mathrm{End}(\mathbb{C}[M_n]_q)$ defined via a q-analog of the commutator. Let us describe this latter observation in full detail.

Endow the space $\mathrm{End}(\mathbb{C}[M_n]_q)$ with a structure of $U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)$-module as follows: For $\xi \in U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)$, $T\in\mathrm{End}(\mathbb{C}[M_n]_q)$ put

$$\xi(T) = \sum_j \xi_j'' \cdot T \cdot S^{-1}(\xi_j'),$$

where $\Sigma_j \xi_j' \otimes \xi_j'' = \Delta(\xi)$ [here Δ denotes the comultiplication in $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$], S is the antipode of $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$, and the elements in the right-hand side are multiplied within $\mathrm{End}(\mathbb{C}[M_n]_q)$. It is explained in Ref. 20 that the $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-covariance of the first order differential calculus $(\Omega^1(M_n)_q, d)$ and the explicit formulas for the $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-action in $\mathbb{C}[M_n]_q$, presented in Proposition 2.1, allow one to prove $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-invariance of the linear span of all $\partial/\partial z_a^\alpha$ in $\mathrm{End}(\mathbb{C}[M_n]_q)$ and to describe the $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-action on the partial derivatives explicitly. The explicit description is based on the following intertwining property of the homomorphism Υ

$$\Upsilon(\xi f) = \omega(\xi)\Upsilon(f), \quad \forall\, \xi \in U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n), \quad \forall\, f \in \mathbb{C}[M_n]_q$$

with ω being the automorphism of $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$ (the "Chevalley involution") given by

$$\omega(E_i) = -F_i, \quad \omega(F_i) = -E_i, \quad \omega(K_i^{\pm 1}) = K_i^{\mp 1}.$$

B. A *q*-wave operator

Here we apply the results from the previous subsection to study the q-wave operator given by

$$\Box_q = \sum_{s \in S_n} (-q)^{l(s)} \cdot \frac{\partial}{\partial z_1^{s(1)}} \cdot \frac{\partial}{\partial z_2^{s(2)}} \cdot \ \cdots \ \cdot \frac{\partial}{\partial z_n^{s(n)}}.$$

Clearly, the q-wave operator belongs to the center of the algebra of quantum differential operators with constant coefficients since $\Box_q = \Upsilon(\det_q(\mathbf{z}))$. The latter formula, together with $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-invariance of the q-determinant and the above intertwining property of Υ, implies also that the operator $\Box_q$ commutes with the action of $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$ in $\mathbb{C}[M_n]_q$. Also, we can easily prove that

$$K_n \cdot \Box_q = q^{-2} \Box_q \cdot K_n. \tag{3.1}$$

Indeed, the degree of the operator $\Box_q$ in $\mathbb{C}[M_n]_q$ is equal to $-n$ which means $\hat{K} \cdot \Box_q = q^{-2n} \cdot \Box_q \cdot \hat{K}$ [see (2.14)]. The latter equality implies (3.1) since $\Box_q$ commutes with all the $K_i^{\pm 1}$'s for $i \neq n$.

IV. A COVARIANCE PROPERTY

A. Formulation

The intertwining properties of the q-wave operator derived above may be written in a unified way as follows:

$$\Box_q^l \cdot \pi_{n-l}(\xi) = \pi_{n+l}(\xi) \cdot \Box_q^l, \quad \xi \in U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n). \tag{4.1}$$

It turns out that this obvious symmetry of the operator $\Box_q^l$ is a part of a large hidden symmetry.

Theorem 4.1: *For any $l \in \mathbb{N}$ the linear operator $\Box_q^l : \mathbb{C}[M_n]_q \to \mathbb{C}[M_n]_q$ intertwines the $U_q\mathfrak{sl}_{2n}$-actions π_{n-l} and π_{n+l}:*

$$\Box_q^l \cdot \pi_{n-l}(\xi) = \pi_{n+l}(\xi) \cdot \Box_q^l, \quad \xi \in U_q\mathfrak{sl}_{2n}$$

(in other words, the map $\Box_q^l : \mathcal{P}_{n-1} \to \mathcal{P}_{n+1}$ is a morphism of $U_q\mathfrak{sl}_{2n}$-modules).

We will prove Theorem 4.1 in Sec. IV E. The proof uses some results from the theory of quantum bounded symmetric domains which we recall in the subsequent three subsections. Very briefly, the idea is as follows (compare with Ref. 1): We use the q-Cauchy-Szegö integral formula to rewrite the operator $\Box_q^l$ as a q-integral operator; then, using some standard technique, we prove that the q-integral operator intertwines the $U_q\mathfrak{sl}_{2n}$-actions π_{n-l} and π_{n+l}.

B. A q-analog of the Cauchy-Szegö integral representation

For any bounded symmetric domain there is a multivariable generalization of the famous Cauchy formula, the so-called Cauchy-Szegö integral representation.[1,7] This integral formula restores a holomorphic function on the domain from its boundary value on the Shilov boundary. In the case of the unit matrix ball the Cauchy-Szegö formula looks as follows:

$$f(\mathbf{z}) = \int_{S(\mathcal{D})} \frac{f(\boldsymbol{\zeta})}{\det(1-\mathbf{z}\boldsymbol{\zeta}^*)^n} \mathrm{d}\nu(\boldsymbol{\zeta}).$$

Here $S(\mathcal{D})$ is the Shilov boundary of the unit matrix ball $\mathcal{D} \in M_n$

$$S(\mathcal{D}) = \{\mathbf{z} \in M_n | \mathbf{z}\mathbf{z}^* = 1\},$$

and $\mathrm{d}\nu$ is the unique U_n-invariant normalized measure on $S(\mathcal{D})$ which, of course, coincides with the Haar measure under the identification $S(\mathcal{D}) = U_n$.

A q-analog of this formula was found in Ref. 27 in framework of quantum bounded symmetric domain theory. Particularly, in that paper q-analogs of the Shilov boundary $S(\mathcal{D})$, the measure $\mathrm{d}\nu$, and the kernel $\det(1-\mathbf{z}\boldsymbol{\zeta}^*)^{-n}$ were found. In this subsection we recall all these results. We omit proofs. An interested reader might want to look into Ref. 27 which is the main reference for this section.

The q-analog of the Shilov boundary is described by a (noncommutative) $*$-*algebra* of functions on it. It is also natural to require the quantum Shilov boundary to be a homogeneous space of the *quantum* group $\mathrm{SU}_{n,n}$. Here is an explicit construction.

The localization of $\mathbb{C}[M_n]_q$ with respect to the multiplicative system $\det_q(\mathbf{z})^{\mathbb{N}}$ is called the algebra of regular functions on the quantum GL_n and is denoted by $\mathbb{C}[GL_n]_q$ (see Sec. II A). It was observed in Ref. 27 (Lemma 2.1) that there exists a unique involution $*$ in $\mathbb{C}[GL_n]_q$ such that

$$(z_a^\alpha)^* = (-q)^{a+\alpha-2n} \det_q(\mathbf{z})^{-1} \cdot \mathbf{z}^{\wedge(n-1)J_\alpha}_{J_a}, \tag{4.2}$$

with $J_c \overset{\text{def}}{=} \{1,2,\ldots,n\}\backslash\{c\}$ [here we use the notation (2.11)]. The $*$-algebra $\mathrm{Pol}(S(\mathcal{D}))_q = (\mathbb{C}[GL_n]_q, *)$ is a q-analog of the polynomial algebra on the Shilov boundary of the matrix ball $\mathcal{D}$. Note that

$$\det_q(\mathbf{z})\det_q(\mathbf{z})^* = \det_q(\mathbf{z})^*\det_q(\mathbf{z}) = q^{-n(n-1)}. \tag{4.3}$$

Let's describe a structure of homogeneous space of the quantum group $\mathrm{SU}_{n,n}$ on the quantum Shilov boundary. Recall that the q-determinant $\det_q(\mathbf{z})$ belongs to the center of $\mathbb{C}[M_n]_q$ and is a "relative invariant" with respect to the $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-action:

$$\xi\det_q(\mathbf{z}) = \varepsilon(\xi) \cdot \det_q(\mathbf{z}), \quad \xi \in U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n), \quad K_n\det_q(\mathbf{z}) = q^2\det_q(\mathbf{z}). \tag{4.4}$$

Using (4.4), one can make $\mathrm{Pol}(S(\mathcal{D}))_q$ into a $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-module algebra. [More precisely, we can use the above formulas to define a $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-action on negative powers of $\det_q(\mathbf{z})$ which suffices to extend the $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-action from $\mathbb{C}[M_n]_q$ to $\mathrm{Pol}(S(\mathcal{D}))_q$.]

In fact [see Ref. 27 (Section 2)], the above $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-module algebra structure in $\mathrm{Pol}(S(\mathcal{D}))_q$ may be extended to a structure of $U_q\mathfrak{sl}_{2n}$-module algebra which coincides on the subspace $\mathbb{C}[M_n]_q \subset \mathrm{Pol}(S(\mathcal{D}))_q$ with the $U_q\mathfrak{sl}_{2n}$-module algebra structure described in Proposition 2.3.

Let us recall the definition of the "real form" $U_q\mathfrak{su}_{n,n}$ of the quantum universal enveloping algebra $U_q\mathfrak{sl}_{2n}$. $U_q\mathfrak{su}_{n,n}$ is simply the pair $(U_q\mathfrak{sl}_{2n}, *)$ with $*$ being an involution in $U_q\mathfrak{sl}_{2n}$ determined by

$$E_n^* = -K_nF_n, \quad F_n^* = -E_nK_n^{-1}, \quad (K_n^{\pm 1})^* = K_n^{\pm 1},$$

$$E_j^* = K_j F_j, \quad F_j^* = E_j K_j^{-1}, \quad (K_j^{\pm 1})^* = K_j^{\pm 1}, \quad \text{for } j \neq n.$$

It is not difficult to verify that $U_q\mathfrak{su}_{n,n} = (U_q\mathfrak{sl}_{2n}, *)$ is a Hopf $*$-algebra (see Ref. 2 for definitions). Evidently, the involution $*$ keeps the Hopf subalgebras $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$ and $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$ invariant, and we shall denote the corresponding Hopf $*$-subalgebras in $U_q\mathfrak{su}_{n,n}$ by $U_q(\mathfrak{su}_n \times \mathfrak{su}_n)$ and $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_n)$, respectively.

The crucial property of the involution (4.2) is the following observation: it makes $\mathrm{Pol}(S(\mathcal{D}))_q$ into a $U_q\mathfrak{su}_{n,n}$-module algebra (this is explained in Ref. 27 after Proposition 2.7). It is in this sense that the quantum Shilov boundary is a homogeneous space of the quantum group $\mathrm{SU}_{n,n}$.

To define a q-analog of the measure $\mathrm{d}\nu$ on $S(\mathcal{D})$, we note [see Ref. 27 (Section 3)] that the $*$-algebra $\mathrm{Pol}(S(\mathcal{D}))_q$ is closely related to the $*$-algebra $\mathbb{C}[U_n]_q = (\mathbb{C}[GL_n]_q, \star)$ of regular functions on the quantum group U_n where, we recall, the involution $\star$ is defined by $(z_a^\alpha)^\star = (-q)^{a-\alpha}(\det_q \mathbf{z})^{-1} \cdot \mathbf{z}^{\wedge(n-1)J_\alpha}_{J_a}$. (The quantum group U_n is one of the most well studied objects in quantum group theory. We refer to Ref. 16 for basic definitions and facts about this quantum group. Of course, there are many other good references.)

It is easy to check that $* = \theta^{-1} \cdot \star \cdot \theta$ where $\theta: \mathbb{C}[GL_n]_q \to \mathbb{C}[GL_n]_q$ is an automorphism given by $\theta: z_a^\alpha \mapsto q^{\alpha - n} z_a^\alpha$. It is known that the compact quantum group U_n possesses a unique normalized invariant integral, an analog of the Haar integral. The isomorphism θ of $*$-algebras $\mathrm{Pol}(S(\mathcal{D}))_q \to \mathbb{C}[U_n]_q$ allows us to "transfer" the invariant integral onto $\mathrm{Pol}(S(\mathcal{D}))_q$. In this way we get a positive $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-invariant linear functional $\mathrm{Pol}(S(\mathcal{D}))_q \to \mathbb{C}$, $f \mapsto \int_{S(\mathcal{D})_q} f \mathrm{d}\nu$ which is the analog of the integral with respect to $\mathrm{d}\nu$. The $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-invariance means

$$\int_{S(D)_q} \xi f \mathrm{d}\nu = \varepsilon(\xi) \cdot \int_{S(\mathcal{D})_q} f \mathrm{d}\nu, \quad \forall\, \xi \in U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n). \tag{4.5}$$

Finally let us describe the analog of the Cauchy-Szegö kernel $\det(1 - \mathbf{z}\boldsymbol{\zeta}^*)^{-n}$.

Consider the algebra $\mathrm{Pol}(M_n \times S(\mathcal{D}))_q = \mathbb{C}[M_n]_q^{\mathrm{op}} \otimes \mathrm{Pol}(S(\mathcal{D}))_q$ with "op" indicating the change of the multiplication to the opposite one. Equip it with a $\mathbb{Z}_+$-grading by setting $\deg(z_a^\alpha \otimes f) = 1$ for any $f \in \mathrm{Pol}(S(\mathcal{D}))_q$. Its completion with respect to this grading is denoted by $\mathrm{Fun}(M_n \times S(\mathcal{D}))_q$. The elements of $\mathrm{Fun}(M_n \times S(\mathcal{D}))_q$ are q-analogs of kernels of integral operators, while the elements of the subalgebra $\mathrm{Pol}(M_n \times S(\mathcal{D}))_q$ are q-analogs of polynomial kernels.

Let us comment on the replacement of the multiplication law in the first tensor multiplier in the definition of the algebra $\mathrm{Pol}(M_n \times S(\mathcal{D}))_q$. Given a Hopf algebra A and two A-module algebras F_1, F_2, A-invariant elements in $F_1 \otimes F_2$ *do not* form a subalgebra. However, they do form a subalgebra in $F_1^{\mathrm{op}} \otimes F_2$.[26] Almost all the kernels we encounter in the present paper are $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-invariant in $\mathrm{Pol}(M_n \times S(\mathcal{D}))_q$ or $\mathrm{Fun}(M_n \times S(\mathcal{D}))_q$ and so, as we have explained, form a subalgebra.

Let us explain now why we are interested in $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-invariant kernels. It is not difficult to prove that there is a one-to-one correspondence between $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-invariant elements in $\mathrm{Fun}(M_n \times S(\mathcal{D}))_q$ and endomorphisms of the $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-module $\mathbb{C}[M_n]_q$, explicitly given as follows: the element $K \in \mathrm{Fun}(M_n \times S(\mathcal{D}))_q$ defines the morphism $f \mapsto (1 \otimes \int_{S(\mathcal{D})_q})(K \cdot (1 \otimes f))$. In other words, a linear operator on $\mathbb{C}[M_n]_q$ intertwines the $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-action if and only if it is a q-integral operator with an invariant kernel.

It is convenient to choose some generators of $\mathrm{Pol}(M_n \times S(\mathcal{D}))_q$ and express all other invariant kernels from $\mathrm{Pol}(M_n \times S(\mathcal{D}))_q$ or $\mathrm{Fun}(M_n \times S(\mathcal{D}))_q$ as (finite or formal) series in those generators.

Consider the elements $\chi_k \in \mathrm{Pol}(M_n \times S(\mathcal{D}))_q$, $k = 1, \ldots, n$, given by

$$\chi_k = \sum \mathbf{z}^{\wedge k}_{J''}{}^{J'} \otimes (\mathbf{z}^{\wedge k}_{J''}{}^{J'})^* \tag{4.6}$$

where the sum is taken over the pairs of subsets $J', J'' \subset \{1, 2, \ldots, n\}$ of cardinality k. It turns out that the elements χ_k are pairwise commuting and $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-invariant [Ref. 22 (Section 10)].

Proposition 4.2: *The elements $\chi_1, \ldots, \chi_n$ generate the subalgebra of $U_q\mathfrak{s}(\mathfrak{gl}_n \times \mathfrak{gl}_n)$-invariant kernels in $\mathrm{Pol}(M_n \times S(\mathcal{D}))_q$ (which is therefore a commutative algebra).*

Sketch of a proof: Recall (see Proposition 2.4) that the $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-module $\mathbb{C}[M_n]_q$ splits into direct sum of simple pairwise nonisomorphic submodules $\mathbb{C}[M_n]_q^{\mathbf{k}}$ with $\mathbf{k}=(k_1,k_2,\ldots,k_n)$, $k_1\geqslant k_2\geqslant\cdots\geqslant k_n\geqslant 0$. Thus, any endomorphism of the $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-module $\mathbb{C}[M_n]_q$ is a (in general infinite) series of the form $\Sigma_{\mathbf{k}}c_{\mathbf{k}}\cdot\mathbf{P}^{\mathbf{k}}$ where $\mathbf{P}^{\mathbf{k}}$ stands for the projection in $\mathbb{C}[M_n]_q$ onto $\mathbb{C}[M_n]_q^{\mathbf{k}}$ parallel to the sum of other $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-submodules and $c_{\mathbf{k}}$ are complex numbers. It is sufficient to show that each projection $\mathbf{P}^{\mathbf{k}}$ is a q-integral operator whose kernel is a function of $\chi_1,\ldots,\chi_n$. This may be done by using well known orthogonality relations for the quantum group U_n (see Ref. 16) and the precise relation between the quantum Shilov boundary and the quantum U_n described previously. ■

The projection $\mathbf{P}^{\mathbf{k}}$ can be written as a q-integral operator with a kernel $P^{\mathbf{k}}\in\mathrm{Pol}(M_n\times S(\mathcal{D}))_q$. Namely, let $u^{\mathbf{k}}$ be a polynomial such that $P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*)=u^{\mathbf{k}}(\chi_1,\chi_2,\ldots,\chi_n)$. Consider the isomorphism

$$\mathrm{Fun}(M_n\times S(\mathcal{D}))_q^{U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)}\to\mathbb{C}[[x_1,x_2,\ldots,x_n]]^{S_n},\quad \chi_k\mapsto\sigma_k,\quad k=1,2,\ldots n \tag{4.7}$$

from the subalgebra $\mathrm{Fun}(M_n\times S(\mathcal{D}))_q^{U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)}$ of $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-invariants in $\mathrm{Fun}(M_n\times S(\mathcal{D}))_q$ to the algebra of symmetric formal series of the variables $x_1,x_2,\ldots,x_n$, where σ_k is the ith elementary symmetric polynomial in $x_1,x_2,\ldots,x_n$. The image of $u^{\mathbf{k}}(\chi_1,\chi_2,\ldots,\chi_n)$ under the above isomorphism differs only by a constant from the so-called Schur polynomial $s_{\mathbf{k}}$ associated to the partition $\mathbf{k}$ (see Ref. 17) viz.

$$u^{\mathbf{k}}(\sigma_1,\sigma_2,\ldots,\sigma_n)=C(\mathbf{k})\cdot s_{\mathbf{k}}(x_1,x_2,\ldots,x_n). \tag{4.8}$$

We compute the coefficients $C(\mathbf{k})$ in the next subsection.

From now on, for a kernel $K\in\mathrm{Fun}(M_n\times S(\mathcal{D}))_q$ we shall sometimes write

$$K(\mathbf{z},\boldsymbol{\zeta}^*),\quad \int_{S(\mathcal{D})_q}K(\mathbf{z},\boldsymbol{\zeta}^*)\cdot f(\boldsymbol{\zeta})\mathrm{d}\nu(\boldsymbol{\zeta}),$$

instead of K and $(1\otimes\int_{S(\mathcal{D})_q})(K\cdot(1\otimes f))$, respectively.

Now we are ready to present the q-analog of the Cauchy-Szegö integral formula found in Ref. 27. In short, it represents the identity operator on $\mathbb{C}[M_n]_q$ in the form of a q-integral operator.

Theorem 4.3: [*Ref.* 27 (*Sec.* 5)] *For any element* $f\in\mathbb{C}[M_n]_q$ *one has*

$$f(\mathbf{z})=\int_{S(\mathcal{D})_q}C_q(\mathbf{z},\boldsymbol{\zeta}^*)f(\boldsymbol{\zeta})\mathrm{d}\nu(\boldsymbol{\zeta})$$

where $C_q=\Pi_{j=0}^{n-1}(1+\Sigma_{k=1}^{n}(-q^{2j})^k\chi_k)^{-1}$ (*a q-analog of the Cauchy-Szegö kernel*).

C. q-analogs of the kernels $\det(1-\mathbf{z}\boldsymbol{\zeta}^*)^{-N}$

Consider the family K_N, $N=1$, 2, …, of $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-invariant kernels given by

$$K_N=\prod_{j=0}^{N-1}\left(1+\sum_{k=1}^{n}(-q^{2j})^k\chi_k\right)^{-1}. \tag{4.9}$$

Clearly, the q-Cauchy-Szegö kernel C_q defined in the previous subsection coincides with K_n. One also has

$$\lim_{q\to 1}K_N(\mathbf{z},\boldsymbol{\zeta}^*)=\det(1-\mathbf{z}\boldsymbol{\zeta}^*)^{-N}$$

(the limit should be understood formally). The aim of this subsection is to study these kernels and the associated q-integral operators in detail.

Let $\mathbf{K}_N$ be the $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-intertwining q-integral operator corresponding to the kernel K_N:

$$\mathbf{K}_N f(\mathbf{z}) = \int_{S(\mathcal{D})_q} K_N(\mathbf{z}, \boldsymbol{\zeta}^*) \cdot f(\boldsymbol{\zeta}) \mathrm{d}\nu(\boldsymbol{\zeta}).$$

Then

$$\mathbf{K}_N = \sum_{\mathbf{k}} c_N^{\mathbf{k}} \cdot \mathbf{P}^{\mathbf{k}} \tag{4.10}$$

where $\mathbf{P}^{\mathbf{k}}$ stands for the projection defined in the previous subsection (see the proof of Proposition 4.2). We are interested in an explicit formula for the coefficients $c_N^{\mathbf{k}}$.

One may write (4.10) as an equality of kernels:

$$K_N(\mathbf{z}, \boldsymbol{\zeta}^*) = \sum_{\mathbf{k}} c_N^{\mathbf{k}} \cdot P^{\mathbf{k}}(\mathbf{z}, \boldsymbol{\zeta}^*). \tag{4.11}$$

This approach, along with formula (4.8), allows us to use some identities for the Schur functions[17] to compute $c_N^{\mathbf{k}}$.

Our first step toward computing the coefficients in (4.10) consists in computing the constants $C(\mathbf{k})$ in (4.8). For that purpose, we note that

$$K_n(\mathbf{z}, \boldsymbol{\zeta}^*) = \sum_{\mathbf{k}} P^{\mathbf{k}}(\mathbf{z}, \boldsymbol{\zeta}^*)$$

(this is just another way to formulate Theorem 4.3). In view of the explicit form of the q-Cauchy-Szegö kernel (Theorem 4.3) and the isomorphism (4.7), the latter can be written as follows:

$$\prod_{j=0}^{n-1} \left(1 + \sum_{k=1}^{n} (-q^{2j})^k \sigma_k \right)^{-1} = \sum_{\mathbf{k}} u^{\mathbf{k}}(\sigma_1, \sigma_2, \ldots, \sigma_n),$$

or, by taking into account (4.8)

$$\prod_{j=0}^{n-1} \left(1 + \sum_{k=1}^{n} (-q^{2j})^k \sigma_k \right)^{-1} = \sum_{\mathbf{k}} C(\mathbf{k}) \cdot s_{\mathbf{k}}(x_1, x_2, \ldots, x_n). \tag{4.12}$$

Recall, for any integer $N \geqslant 0$, the q-Pochhammer symbol $(x;q^2)_N = \Pi_{j=0}^{N-1}(1 - xq^{2j})$. We have then,

$$\prod_{j=0}^{N-1} \left(1 + \sum_{k=1}^{N} (-q^{2j})^k \sigma_k \right)^{-1} = \prod_{j=0}^{N-1} \left(\prod_{i=1}^{n} (1 - q^{2j} x_i) \right)^{-1} = \prod_{i=1}^{n} \frac{1}{(x_i; q^2)_N};$$

in particular for $N = n$ the equality (4.12) reads

$$\prod_{i=1}^{n} \frac{1}{(x_i; q^2)_n} = \sum_{\mathbf{k}} C(\mathbf{k}) \cdot s_{\mathbf{k}}(x_1, x_2, \ldots, x_n).$$

Now we are in position to make use of the following formula from:[17]

$$\prod_{i=1}^{n} \frac{(a x_i; q^2)_\infty}{(x_i; q^2)_\infty} = \sum_{\mathbf{k}} C(\mathbf{k}; a) \cdot s_{\mathbf{k}}(x_1, x_2, \ldots, x_n) \tag{4.13}$$

where

$$C(\mathbf{k};a)=\prod_{i=1}^{n}\frac{(aq^{2-2i};q^2)_{k_i}\cdot q^{2(i-1)k_i}}{(q^2;q^2)_{k_i+n-i}}\cdot\prod_{1\leqslant i<j\leqslant n}(1-q^{2k_i-2k_j-2i+2j}). \tag{4.14}$$

In our case $a=q^{2n}$ and thus the equality (4.8) acquires the form

$$u^{\mathbf{k}}(\sigma_1,\sigma_2,\ldots,\sigma_n)=C(\mathbf{k};q^{2n})\cdot s_{\mathbf{k}}(x_1,x_2,\ldots,x_n), \tag{4.15}$$

where

$$C(\mathbf{k};q^{2n})=\prod_{i=1}^{n}\frac{q^{2(i-1)k_i}}{(q^2;q^2)_{n-i}}\cdot\prod_{1\leqslant i<j\leqslant n}(1-q^{2k_i-2k_j-2i+2j}).$$

We turn back now to computing the coefficients in (4.10). Identifying K_N with its image under the isomorphism (4.7), we have, in view of (4.9),

$$K_N=\prod_{j=0}^{N-1}\left(1+\sum_{k=1}^{n}(-q^{2j})^k\sigma_k\right)^{-1}=\prod_{i=1}^{n}\frac{1}{(x_i;q^2)_N}.$$

By (4.13) and (4.15)

$$K_N=\sum_{\mathbf{k}}C(\mathbf{k};q^{2N})\cdot s_{\mathbf{k}}(x_1,x_2,\ldots,x_n)=\sum_{\mathbf{k}}\frac{C(\mathbf{k};q^{2N})}{C(\mathbf{k};q^{2n})}u^{\mathbf{k}}(\sigma_1,\sigma_2,\ldots,\sigma_n). \tag{4.16}$$

We have thus obtained the following proposition

Proposition 4.4: *The coefficients in* (4.10) *are given by*

$$c_N^{\mathbf{k}}=\frac{C(\mathbf{k};q^{2N})}{C(\mathbf{k};q^{2n})}=\prod_{i=1}^{n}\frac{(q^{2N+2-2i};q^2)_{k_i}}{(q^{2n+2-2i};q^2)_{k_i}}.$$

D. A *q*-analog of the Fock inner product

The aim of this subsection is to describe some results on a q-analog of the Fock inner product in $\mathbb{C}[M_n]$ obtained in Ref. 20. At the end of the subsection we shall prove a q-analog of one known result by Faraut and Koranyi[5] which compares the Fock inner product with the one in the Hilbert space of square-integrable functions on the Shilov boundary of the matrix ball.

Recall that the Fock inner product in the space $\mathbb{C}[M_n]$ is defined by

$$(f_1,f_2)_F=\int_{M_n}f_1(\mathbf{z})\overline{f_2(\mathbf{z})}e^{-\mathrm{tr}(\mathbf{z}\mathbf{z}^*)}\mathrm{d}\mathbf{z} \tag{4.17}$$

with $\mathrm{d}\mathbf{z}$ being the Lebesgue measure on M_n normalized so that $(1,1)_F=1$. The inner product possesses the following remarkable property:

$$\left(\frac{\partial f_1}{\partial z_a^\alpha},f_2\right)_F=(f_1,z_a^\alpha f_2)_F,\qquad\forall\, a,\alpha. \tag{4.18}$$

This property, along with $S(U_n\times U_n)$-invariance of the inner product, is quite useful in explicit computations of various norms.

Below we present a q-analog of the Fock inner product. But first we have to explain what is understood by an invariance of an inner product in the q-setting.

Let $A_0=(A,*)$ be a Hopf $*$-algebra. An inner product $(,)$ on an A-module V is said to be A_0-invariant if for all $v_1,v_2\in V$ and any $\xi\in A$

$$(\xi v_1,v_2)=(v_1,\xi^* v_2).$$

The following is one of the main results of Ref. 20.

Proposition 4.5: *There exists a (unique)* $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_n)$*-invariant inner product* $(\cdot,\cdot)_F$ *in* $\mathbb{C}[M_n]_q$ *satisfying the properties*

$$(1,1)_F=1,$$

$$\left(\frac{\partial f_1}{\partial z_a^\alpha},f_2\right)_F=(f_1,f_2\cdot z_a^\alpha)_F,\quad \forall\, a,\alpha.$$

Let $(\cdot,\cdot)_{S(\mathcal{D})}$ be the inner product in $\mathbb{C}[M_n]_q$ defined via the $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-invariant integral on the quantum Shilov boundary

$$(f_1,f_2)_{S(\mathcal{D})}=\int_{S(\mathcal{D})_q} f_2(\boldsymbol{\zeta})^* f_1(\boldsymbol{\zeta})\mathrm{d}\nu(\boldsymbol{\zeta}).$$

Clearly, the inner product is $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_n)$-invariant. This is a consequence of (4.5) and the condition (2.6). Since $(\cdot,\cdot)_F$ and $(\cdot,\cdot)_{S(\mathcal{D})}$ are $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_n)$-invariant, the subspaces $\mathbb{C}[M_n]_q^{\mathbf{k}}$ are pairwise orthogonal with respect to both inner products, and the corresponding norms are proportional by the Schur lemma. The proportionality constant is computed in the classical setting by Faraut and Koranyi [Ref. 5 (Corollary 3.5)]. Here we present a q-analog of their result.

Proposition 4.6:

$$(f_1,f_2)_F=\frac{\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_{k_i}}{(1-q^2)^{k_1+k_2+\ldots+k_n}}\cdot(f_1,f_2)_{S(\mathcal{D})},\quad f_1,f_2\in\mathbb{C}[M_n]_q^{\mathbf{k}}. \tag{4.19}$$

Proof: To prove the proposition, we need an explicit description of the inner product $(\cdot,\cdot)_F$.

Consider the algebra $\mathbb{C}[M_n\times M_n]_q=\mathbb{C}[M_n]_q\otimes\mathbb{C}[M_n]_q$. Equip it with the natural bigrading by setting $\deg(f_1\otimes f_2)=(\deg(f_1),\deg(f_2))$ for any $f_1,f_2\in\mathbb{C}[M_n]_q$. Its completion with respect to this bigrading is denoted by $\mathbb{C}[[M_n\times M_n]]_q$.

Let

$$\hat{\chi}_k=\sum_{\substack{J',J''\subset\{1,2,\ldots,n\}\\ \mathrm{card}(J')=\mathrm{card}(J'')=k}}\mathbf{z}^{\wedge k}{}_{J''}^{J'}\otimes\mathbf{z}^{\wedge k}{}_{J''}^{J'}\in\mathbb{C}[M_n\times M_n]_q,\quad k=1,\ldots,n.$$

Note that $\hat{\chi}_k$ are similar to the kernels χ_k defined in (4.6). Since the latter pairwise commute, the elements $\hat{\chi}_k$ pairwise commute as well. Put

$$\hat{K}_\infty=\prod_{j=0}^{\infty}\left(1+\sum_{k=1}^{n}(-q^{2j})^k\hat{\chi}_k\right)^{-1}\in\mathbb{C}[[M_n\times M_n]]_q.$$

Let $\langle\cdot,\cdot\rangle$ be the inner product in $\mathbb{C}[M_n]_q$ so that $\hat{K}_\infty$ is the reproducing kernel, namely, writing $\hat{K}_\infty=\Sigma_j k_j'\otimes k_j''$ we have then

$$f=\sum_j k_j'\cdot\langle f,k_j''\rangle$$

Lemma 4.7:

$$\left\langle\frac{\partial f_1}{\partial z_a^\alpha},f_2\right\rangle=\frac{1}{1-q^2}\cdot\langle f_1,f_2\cdot z_a^\alpha\rangle,\quad \forall\, a,\alpha.$$

Sketch of a proof: The inner product $\langle\cdot,\cdot\rangle$ is described in a slightly different way in Ref. 20

(Theorem 6.1). The equivalence of the two definitions may be deduced from Theorem 9.1 in Ref. 22 via the limit $\lambda \to \infty$. ■

The above lemma allows us to express the inner product $\langle \cdot, \cdot \rangle$ via the q-Fock one

$$\langle f_1, f_2 \rangle = (1 - q^2)^k \cdot (f_1, f_2)_F \tag{4.20}$$

for f_1, f_2 homogeneous of degree k. Thus, to prove the theorem it suffices to show that

$$\langle f_1, f_2 \rangle = \prod_{i=1}^{n} (q^{2n+2-2i}; q^2)_{k_i} \cdot (f_1, f_2)_{S(\mathcal{D})}, \quad f_1, f_2 \in \mathbb{C}[M_n]_q^{\mathbf{k}}.$$

It follows from the q-Cauchy-Szegö formula (Theorem 4.3) that the inner product $(\cdot, \cdot)_{S(\mathcal{D})}$ is the one associated to the kernel

$$\hat{K}_n = \prod_{j=0}^{n-1} \left(1 + \sum_{k=1}^{n} (-q^{2j})^k \hat{\chi}_k \right)^{-1} \in \mathbb{C}[[M_n \times M_n]]_q$$

in the same sense as described above for $\hat{K}_\infty$. It remains to use the same arguments as in the previous subsection and to compare the coefficients $C(\mathbf{k}; 0)$ and $C(\mathbf{k}; q^{2n})$ [see (4.14)]. ■

In the last section of the present paper we shall present a more general result which is due to Ørsted,[18] and Faraut and Koranyi[5] in the classical setting.

E. Proof of the covariance property

Now we are in position to prove Theorem 4.1.

In view of Theorem 4.3, $\Box_q^l$ is the integral operator with the kernel $\Box_q^l K_n(\mathbf{z}, \boldsymbol{\zeta}^*)$ (here and further we assume that the operator $\Box_q$ acts on a kernel in the first argument $\mathbf{z}$). We are going to compute the kernel explicitly.

Recall the notation $P^{\mathbf{k}}(\mathbf{z}, \boldsymbol{\zeta}^*)$ for the kernel of the q-integral operator $\mathbf{P}^{\mathbf{k}}: \mathbb{C}[M_n]_q \to \mathbb{C}[M_n]_q^{\mathbf{k}}$ (see Sec. IV C)

$$\mathbf{P}^{\mathbf{k}} f(\mathbf{z}) = \int_{S(\mathcal{D})_q} P^{\mathbf{k}}(\mathbf{z}, \boldsymbol{\zeta}^*) f(\boldsymbol{\zeta}) \mathrm{d}\nu(\boldsymbol{\zeta}).$$

By Theorem 4.3,

$$C_q(\mathbf{z}, \boldsymbol{\zeta}^*) = \sum_{\mathbf{k}} P^{\mathbf{k}}(\mathbf{z}, \boldsymbol{\zeta}^*).$$

Thus to compute the kernel $\Box_q^l C_q(\mathbf{z}, \boldsymbol{\zeta}^*)$ it suffices to compute $\Box_q^l P^{\mathbf{k}}(\mathbf{z}, \boldsymbol{\zeta}^*)$. We observe that

$$\Box_q(\mathbb{C}[M_n]_q^{\mathbf{k}}) = \begin{cases} \mathbb{C}[M_n]_q^{\mathbf{k}-1}, & k_n \geqslant 1 \\ \{0\}, & \text{otherwise}. \end{cases} \tag{4.21}$$

[We use the notation $\mathbf{k} - l = (k_1 - l, k_2 - l, \ldots, k_n - l)$.] Indeed, the operator $\Box_q$ is, in particular, a morphism of $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-modules, and all $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-modules, isomorphic to $\mathbb{C}[M_n]_q^{\mathbf{k}}$, have the form $\mathbb{C}[M_n]_q^{\mathbf{k}+m}$ for some (positive or negative) m. The left-hand side is then a subspace of right-hand side by (3.1). On the other hand, if $k_n \geqslant 1$ and $\Box_q(\mathbb{C}[M_n]_q^{\mathbf{k}}) \subsetneqq \mathbb{C}[M_n]_q^{\mathbf{k}-1}$ then $\Box_q(\mathbb{C}[M_n]_q^{\mathbf{k}}) = \{0\}$ since $\mathbb{C}[M_n]_q^{\mathbf{k}}$ and $\mathbb{C}[M_n]_q^{\mathbf{k}-1}$ are simple isomorphic $U_q(\mathfrak{sl}_n \times \mathfrak{sl}_n)$-modules. This, however, contradicts positive definiteness of the q-Fock inner product: we have $\Box_q(\det_q(\mathbf{z}) \cdot f) = 0$ for arbitrary element $f \in \mathbb{C}[M_n]_q^{\mathbf{k}-1}$ and so

$$0 = (\Box_q(\det_q(\mathbf{z}) \cdot f), f)_F = (\det_q(\mathbf{z}) \cdot f, \det_q(\mathbf{z}) \cdot f)_F.$$

The equality (4.21), together with (4.3) and (4.4), implies that for certain constant $c(\mathbf{k}, l)$

$$\square_q^l P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*) = c(\mathbf{k},l) P^{\mathbf{k}-l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}.$$

Indeed, the q-integral operators with the kernels $\square_q^l P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*)$ and $P^{\mathbf{k}-l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}$ belong to

$$\mathrm{Hom}_{U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)}(\mathbb{C}[M_n]_q^{\mathbf{k}},\mathbb{C}[M_n]_q^{\mathbf{k}-l}),$$

and thus differ by a constant (the latter space is one-dimensional since $\mathbb{C}[M_n]_q^{\mathbf{k}}$ and $\mathbb{C}[M_n]_q^{\mathbf{k}-l}$ are isomorphic irreducible $U_q(\mathfrak{sl}_n\times\mathfrak{sl}_n)$-modules). Our immediate aim is to compute $c(\mathbf{k},l)$.

Given an inner product $(\cdot,\cdot)$ in $\mathbb{C}[M_n]_q$ and a kernel $P(\mathbf{z},\boldsymbol{\zeta}^*)=\Sigma_j p_j'\otimes p_j''\in \mathrm{Pol}(M_n\times S(\mathcal{D}))_q$ we shall write $(f(\mathbf{z}),P(\mathbf{z},\boldsymbol{\zeta}^*))$ instead of $\Sigma_j(f,p_j')\cdot(p_j'')^*$.

Recall the notation $(\cdot,\cdot)_{S(\mathcal{D})}$ for the inner product defined in Sect. IV D via the invariant integral on the q-Shilov boundary. It is not difficult to observe that the reproducing property of the kernel $P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*)$ is equivalent to

$$(f(\mathbf{z}),P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*))_{S(\mathcal{D})} = f, \quad \forall\, f\in\mathbb{C}[M_n]_q^{\mathbf{k}}.$$

We have

$$\square_q^l P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*) = c(\mathbf{k},l) P^{\mathbf{k}-l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}$$

or

$$(f(\mathbf{z}),\square_q^l P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*))_{S(\mathcal{D})} = c(\mathbf{k},l)\cdot(f(\mathbf{z}),P^{\mathbf{k}-l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l})_{S(\mathcal{D})},$$

for any $f\in\mathbb{C}[M_n]_q^{\mathbf{k}-l}$. By Theorem 4.6

$$\frac{(1-q^2)^{k_1+k_2+\ldots+k_n-2l_n}}{\prod_{i=1}^n (q^{2n+2-2i};q^2)_{k_i-l}}(f(\mathbf{z}),\square_q^l P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*))_F = c(\mathbf{k},l)\cdot f(\boldsymbol{\zeta})\cdot\det_q(\boldsymbol{\zeta})^l,$$

and, due to the main property of the q-Fock product,

$$\frac{(1-q^2)^{k_1+k_2+\ldots+k_n-2l_n}}{\prod_{i=1}^n (q^{2n+2-2i};q^2)_{k_i-l}}(f(\mathbf{z})\det_q(\mathbf{z})^l,P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*))_F = c(\mathbf{k},l)\cdot f(\boldsymbol{\zeta})\cdot\det_q(\boldsymbol{\zeta})^l.$$

Apply Theorem 4.6 once again:

$$\frac{\prod_{i=1}^n (q^{2n+2-2i};q^2)_{k_i}}{(1-q^2)^{2ln}\cdot\prod_{i=1}^n (q^{2n+2-2i};q^2)_{k_i-l}}(f(\mathbf{z})\det_q(\mathbf{z})^l,P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*))_{S(\mathcal{D})} = c(\mathbf{k},l)\cdot f(\boldsymbol{\zeta})\cdot\det_q(\boldsymbol{\zeta})^l.$$

The reproducing property of the kernel $P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*)$ implies that

$$\frac{\prod_{i=1}^n (q^{2n+2-2i};q^2)_{k_i}}{(1-q^2)^{2ln}\cdot\prod_{i=1}^n (q^{2n+2-2i};q^2)_{k_i-l}}\cdot f(\boldsymbol{\zeta})\cdot\det_q(\boldsymbol{\zeta})^l = c(\mathbf{k},l)\cdot f(\boldsymbol{\zeta})\cdot\det_q(\boldsymbol{\zeta})^l,$$

consequently,

$$c(\mathbf{k},l)=\frac{\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_{k_i}}{(1-q^2)^{2ln}\cdot\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_{k_i-l}}.$$

We then get

$$\Box_q^l K_n(\mathbf{z},\boldsymbol{\zeta}^*)=\sum_{\mathbf{k}:k_n\geqslant l}\frac{\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_{k_i}}{(1-q^2)^{2ln}\cdot\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_{k_i-l}}\cdot P^{\mathbf{k}-l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}$$

$$=\sum_{\mathbf{k}}\frac{\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_{k_{i+l}}}{(1-q^2)^{2ln}\cdot\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_{k_i}}\cdot P^{\mathbf{k}}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}.$$

Finally, Proposition 4.4 implies

$$\Box_q^l K_n(\mathbf{z},\boldsymbol{\zeta}^*)=\frac{\prod_{i=1}^{n}(q^{2n+2--2i};q^2)_l}{(1-q^2)^{2ln}}\cdot K_{n+l}(\mathbf{z},\boldsymbol{\zeta}^*)\cdot\det_q(\boldsymbol{\zeta})^{*l}.$$

We have thus obtained

Proposition 4.8: *For any element $f\in\mathbb{C}[M_n]_q$ one has*

$$\Box_q^l f(\mathbf{z})=\frac{\prod_{i=1}^{n}(q^{2n+2-2i};q^2)_l}{(1-q^2)^{2ln}}\cdot\int_{S(\mathcal{D})_q}K_{n+l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}f(\boldsymbol{\zeta})\mathrm{d}\nu(\boldsymbol{\zeta}).$$

Proposition 4.8 reduces the statement of Theorem 4.1 to the following proposition.

Proposition 4.9: *The integral operator*

$$f(\mathbf{z})\mapsto\int_{S(\mathcal{D})_q}K_{n+l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}f(\boldsymbol{\zeta})d\nu(\boldsymbol{\zeta})$$

intertwines the $U_q\mathfrak{sl}_{2n}$-actions π_{n-l} and π_{n+l}.

Proof: We shall use a quantum version of the description (2.16) of the twisted action π_λ.

Let us extend the algebra $\mathbb{C}[M_n]_q$ by adding one more generator t [an analog of the distinguished Plücker coordinate t in (2.16)] such that

$$tz_a^\alpha=q^{-1}z_a^\alpha t,\quad a,\alpha=1,2,\ldots,n.$$

The localization of the resulting algebra with respect to the multiplicative system $t^{\mathbb{N}}$ will be denoted by $\mathbb{C}[M_n]_{q,t}$. It was noted in Ref. 21 that there exists a unique extension of the $U_q\mathfrak{sl}_{2n}$-module algebra structure in $\mathbb{C}[M_n]_q$ to the one in $\mathbb{C}[M_n]_{q,t}$ such that

$$E_jt=F_jt=(K_j^{\pm1}-1)t=0\quad(j\neq n),\quad F_nt=(K_n^{\pm1}-q^{\mp1})t=0,\quad E_nt=q^{-1/2}tz_n^n.\tag{4.22}$$

It is clear that the subspace $\mathbb{C}[M_n]_q\cdot t^{-\lambda}\subset\mathbb{C}[M_n]_{q,t}$ is $U_q\mathfrak{sl}_{2n}$-invariant for any $\lambda\in\mathbb{Z}$. The following is an equivalent definition of the $U_q\mathfrak{sl}_{2n}$-action π_λ:

$$(\pi_\lambda(\xi)f)\cdot t^{-\lambda}=\xi(f\cdot t^{-\lambda}),\quad \xi\in U_q\mathfrak{sl}_{2n},\quad f\in\mathbb{C}[M_n]_q.$$

In other words, the linear map

$$\mathbb{C}[M_n]_q\to\mathbb{C}[M_n]_q\cdot t^{-\lambda},\quad f\mapsto f\cdot t^{-\lambda}$$

intertwines the $U_q\mathfrak{sl}_{2n}$-action π_λ and the natural $U_q\mathfrak{sl}_{2n}$-action in $\mathbb{C}[M_n]_q\cdot t^{-\lambda}$.

We also need certain extension of the algebra $\mathrm{Pol}(S(\mathcal{D}))_q$. Let us add to $\mathrm{Pol}(S(\mathcal{D}))_q$ two generators t, t^* such that

$$tt^*=t^*t,\quad tz_a^\alpha=q^{-1}z_a^\alpha t,\quad t^*z_a^\alpha=q^{-1}z_a^\alpha t^*,\quad a,\alpha=1,2,\ldots,n.$$

Denote this new algebra by $\mathrm{Pol}(\hat{S}(\mathcal{D}))_q$ and its localization with respect to the multiplicative system $(tt^*)^{\mathbb{N}}$ by $\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}$. The involution in $\mathrm{Pol}(S(\mathcal{D}))_q$ can be extended to an involution in $\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}$ by setting $*:t\mapsto t^*$. It is proved in [Ref. 27 (Sec. 2)] that there exists a unique structure of $U_q\mathfrak{su}_{n,n}$-module algebra in $\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}$ which coincides with the original one on $\mathrm{Pol}(S(\mathcal{D}))_q\subset\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}$ and satisfies (4.22). Following [Ref. 27 (Sec. 3)], we equip $\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}$ with a bigrading:

$$\deg t=(0,1),\quad \deg t^*=(1,0),\quad \deg(z_a^\alpha)=\deg(z_a^\alpha)^*=(0,0),\quad a,\alpha=1,2,\ldots,n.$$

Obviously, the homogeneous components

$$\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(i,j)}=\{f\in\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}|\deg f=(i,j)\}=t^{*i}\cdot\mathrm{Pol}(S(\mathcal{D}))_q\cdot t^j$$

are submodules of the $U_q\mathfrak{sl}_{2n}$-module $\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}$.

Proposition 4.9 is an immediate consequence of the following statement.

Lemma 4.10: *The linear operator from* $\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(0,l-n)}$ *to* $\mathbb{C}[M_n]_q\cdot t^{-l-n}$ *given by*

$$f\cdot t^{l-n}\mapsto\left(\int_{S(\mathcal{D})_q}K_{n+l}(\mathbf{z},\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}f(\boldsymbol{\zeta})\mathrm{d}\nu(\boldsymbol{\zeta})\right)\cdot t^{-l-n}$$

is a morphism of $U_q\mathfrak{sl}_{2n}$*-modules*.

Proof of the lemma: The proof may be easily reduced to the following three statements:

(i) The linear map

$$\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(0,l-n)}\to\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(l,-n)},\quad f(\boldsymbol{\zeta})\cdot t^{l-n}\mapsto\det_q(\boldsymbol{\zeta})^{*l}f(\boldsymbol{\zeta})\cdot t^{*l}t^{-n}\qquad(4.23)$$

is a morphism of $U_q\mathfrak{sl}_{2n}$-modules. This statement follows from the results of Secs. II and III in Ref. 27.

(ii) Let $K_{n+l}(\mathbf{z},\boldsymbol{\zeta}^*)=\Sigma_j k_j'(\mathbf{z})\otimes k_j''(\boldsymbol{\zeta}^*)$. Then the element

$$\sum_j k_j'(\mathbf{z})\cdot t^{-l-n}\otimes t^{*(-l-n)}\cdot k_j''(\boldsymbol{\zeta}^*)\in(\mathbb{C}[M_n]_q\cdot t^{-l-n})\hat{\otimes}\,\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(-l-n,0)}$$

is a $U_q\mathfrak{sl}_{2n}$-invariant (here the symbol $\hat{\otimes}$ has the same meaning as the one in the equality $\mathbb{C}[M_n]_q\hat{\otimes}\mathrm{Pol}(S(\mathcal{D}))_q=\mathrm{Fun}(M_n\times S(\mathcal{D}))_q$). The statement is a consequence of results of Sec. 8 in Ref. 22. This, together with statement (i), implies that the map

$$\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(0,l-n)}\to(\mathbb{C}[M_n]_q\cdot t^{-l-n})\hat{\otimes}\,\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(-n,-n)},$$

$$f(\boldsymbol{\zeta})\cdot t^{l-n}\mapsto\sum_j k_j'(\mathbf{z})\cdot t^{-l-n}\otimes t^{*(-l-n)}\cdot k_j''(\boldsymbol{\zeta}^*)\det_q(\boldsymbol{\zeta})^{*l}f(\boldsymbol{\zeta})\cdot t^{*l}t^{-n}\qquad(4.24)$$

is a morphism of $U_q\mathfrak{sl}_{2n}$-modules.

(iii) The linear functional

$$\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(-n,-n)} \to \mathbb{C}, \quad t^{*(-n)} \cdot f \cdot t^{-n} \mapsto \int_{S(\mathcal{D})_q} f(\boldsymbol{\zeta}) \mathrm{d}\nu(\boldsymbol{\zeta})$$

is a $U_q\mathfrak{sl}_{2n}$-invariant integral. This is proved in Sec. III of Ref. 27. As a consequence of this statement and statements (i) and (ii) we get: the linear operator from $\mathrm{Pol}(\hat{S}(\mathcal{D}))_{q,x}^{(0,l-n)}$ to $\mathbb{C}[M_n]_q \cdot t^{-l-n}$ given by

$$f(\boldsymbol{\zeta}) \cdot t^{l-n} \mapsto \sum_j k_j'(\mathbf{z}) \cdot t^{-l-n} \cdot \int_{S(\mathcal{D})_q} \Theta_i(k_j''(\boldsymbol{\zeta}^*)\det{}_q(\boldsymbol{\zeta})^{*l} f(\boldsymbol{\zeta})) \mathrm{d}\nu(\boldsymbol{\zeta}) \tag{4.25}$$

is a morphism of $U_q\mathfrak{sl}_{2n}$-modules (here Θ_l means the automorphism of the algebra $\mathrm{Pol}(S(\mathcal{D}))_q$ given by $f \mapsto t^{*(-l)} \cdot f \cdot t^{*l}$).

Lemma 4.10 follows from the latter statement and the equality

$$\int_{S(\mathcal{D})_q} \Theta_l(f(\boldsymbol{\zeta})) \mathrm{d}\nu(\boldsymbol{\zeta}) = \int_{S(\mathcal{D})_q} f(\boldsymbol{\zeta}) \mathrm{d}\nu(\boldsymbol{\zeta}), \quad \forall\, f$$

which is due to the simple observation that the functional $\int_{S(\mathcal{D})_q} f(\boldsymbol{\zeta}) \mathrm{d}\nu(\boldsymbol{\zeta})$ "picks up" the constant term of f and the constant terms of $\Theta_l(f)$ and f are the same. ■

Proposition 4.9, consequently Theorem 4.1, is now proved. ■

V. HOLOMORPHIC DISCRETE SERIES FOR $U_q\mathfrak{su}_{n,n}$

In this last section we study the holomorphic discrete series representations for $U_q\mathfrak{su}_{n,n}$ and study their analytic continuation.

After giving a definition of the holomorphic discrete series for $U_q\mathfrak{su}_{n,n}$, we prove an analog of a classical known result by Faraut and Koranyi[5] which allows one to express the inner product in a module of the holomorphic discrete series via the Fock inner product. We use the result to prove unitarizability of the modules $\mathcal{P}_\lambda$ with $\lambda > n-1$; the discrete series parameters are $\lambda > 2n-1$. We apply then the covariance property, proved earlier, to studying certain quotients of the modules $\mathcal{P}_\lambda$.

A. Definition of the holomorphic discrete series

We start by recalling the definition of the holomorphic discrete series for $\mathrm{SU}_{n,n}$. Fix $\lambda > 2n-1$ and consider the Hilbert space of holomorphic functions on the unit matrix ball $\mathcal{D}$ which are square integrable with respect to the measure $\det(1-\mathbf{z}\mathbf{z}^*)^{\lambda-2n}\mathrm{d}\mathbf{z}$ (here $\mathrm{d}\mathbf{z}$ is the normalized Lebesgue measure: $\int_{\mathcal{D}} \mathrm{d}\mathbf{z} = 1$). It is known[1] that the operators (2.17) are unitary on that Hilbert space. The corresponding representation of $\widetilde{\mathrm{SU}}_{n,n}$ is said to be a representation of the holomorphic discrete series.

Now let us turn to the quantum setting. Suppose $A_0 = (A, *)$ is a Hopf $*$-algebra. An A-module V is said to be a unitarizable A_0-module if there exists an inner product $(,)$ on V such that for all $v_1, v_2 \in V$ and any $\xi \in A$

$$(\xi v_1, v_2) = (v_1, \xi^* v_2)$$

(that is, V possesses an A_0-invariant inner product, see Sec. IV D).

Unitarizable $U_q\mathfrak{su}_{n,n}$-modules substitute unitary representations of $\mathrm{SU}_{n,n}$ (or $\widetilde{\mathrm{SU}}_{n,n}$) in the quantum setting. The following statement was proved in Ref. 22 (Corollary 6.5).

Proposition 5.1: *For $\lambda > 2n-1$ there exists a unique inner product $(,)_\lambda$ in $\mathcal{P}_\lambda$ such that for all $f_1, f_2 \in \mathcal{P}_\lambda$ and $\xi \in U_q\mathfrak{sl}_{2n}$*

$$(\pi_\lambda(\xi)f_1,f_2)_\lambda=(f_1,\pi_\lambda(\xi^*)f_2)_\lambda,$$

with the normalization $(1,1)_\lambda=1$.

Clearly, the unitarizable $U_q\mathfrak{su}_{n,n}$-modules $\mathcal{P}_\lambda$, $\lambda>2n-1$, are q-analogs of unitary representation of the holomorphic discrete series for $\widetilde{\mathrm{SU}}_{n,n}$.

The inner product $(,)_\lambda$ may be described explicitly as follows. Let us use the notation from the proof of Proposition 4.6. Consider the element

$$\hat{K}_\lambda=\frac{\prod_{j=0}^{\infty}\left(1+\sum_{k=1}^{m}(-q^{2(\lambda+j)})^k\hat{\chi}_k\right)}{\prod_{j=0}^{\infty}\left(1+\sum_{k=1}^{m}(-q^{2j})^k\hat{\chi}_k\right)}\in\mathbb{C}[[M_n\times M_n]]_q. \tag{5.1}$$

Then the inner product $(,)_\lambda$ is the one associated with the previous element, i.e.,

$$f=\sum_j k_j'\cdot(f,k_j'')_\lambda \tag{5.2}$$

provided $\hat{K}_\lambda=\Sigma_j k_j'\otimes k_j''$ (see Theorem 9.1 in Ref. 22).

B. A *q*-analog of a result by Faraut and Koranyi (Ref. 5)

In this subsection, we present a q-analog of Corollary 3.7 in Ref. 5 where (in the classical setting) the Fock inner product and the inner products $(,)_\lambda$ are compared. We then apply the result to the problem of analytic continuation of the holomorphic discrete series for $U_q\mathfrak{su}_{n,n}$.

Using the arguments preceding Proposition 4.6 we deduce that the inner product $(,)_\lambda$ and the q-Fock inner product on a particular simple $U_q\mathfrak{s}(\mathfrak{gl}_n\times\mathfrak{gl}_n)$-submodule $\mathbb{C}[M_n]_q^{\mathbf{k}}\subset\mathbb{C}[M_n]_q$ are proportional. The proportionality constant is given by the following formula.

Proposition 5.2: *Let* $\lambda>2n-1$. *Then*

$$(f_1,f_2)_F=\frac{\prod_{i=1}^{n}(q^{2\lambda+2-2i};q^2)_{k_i}}{(1-q^2)^{k_1+k_2+\cdots+k_n}}\cdot(f_1,f_2)_\lambda,\quad f_1,f_2\in\mathbb{C}[M_n]_q^{\mathbf{k}}. \tag{5.3}$$

Proof: Consider the reproducing kernel

$$K_\lambda=\frac{\prod_{j=0}^{\infty}\left(1+\sum_{k=1}^{m}(-q^{2(\lambda+j)})^k\chi_k\right)}{\prod_{j=0}^{\infty}\left(1+\sum_{k=1}^{m}(-q^{2j})^k\chi_k\right)}$$

associated to the element (5.1). The image of this kernel under the isomorphism (4.7) is given by

$$\prod_{i=1}^{n}\frac{(q^{2\lambda}x_i;q^2)_\infty}{(x_i;q^2)_\infty}.$$

By repeating the computation from Sec. IV C, one gets

$$(f_1,f_2)_{S(\mathcal{D})}=\prod_{i=1}^{n}\frac{(q^{2\lambda+2-2i};q^2)_{k_i}}{(q^{2n+2-2i};q^2)_{k_i}}\cdot(f_1,f_2)_\lambda,\quad f_1,f_2\in\mathbb{C}[M_n]_q^{\mathbf{k}}.$$

What remains is to apply Proposition 4.6. ■

The result of the above proposition has an important application to the problem of analytic continuation of the holomorphic discrete series. The point is that (5.3) allows one to define the sesquilinear form $(,)_\lambda$ on $\mathbb{C}[M_n]_q$ for any $\lambda \in \mathbb{R}$ for which all the multipliers $\Pi_{i=1}^n (q^{2\lambda+2-2i};q^2)_{k_i}$ are nonzero. It is not difficult to prove that the resulting form is still $U_q\mathfrak{su}_{n,n}$-invariant with respect to the corresponding twisted action. Indeed, the invariance is equivalent to the infinitely many equalities of the form

$$(\pi_\lambda(\xi)f_1,f_2)_\lambda = (f_1,\pi_\lambda(\xi^*)f_2)_\lambda, \quad \xi \in U_q\mathfrak{sl}_{2n}, f_1,f_2 \in \mathbb{C}[M_n]_q.$$

After simple transformations, each equality becomes an equality of two Laurent polynomials in q^λ which is known to hold for $\lambda > 2n-1$ by Proposition 5.1, and, thus, for any λ. It is natural to pose the problem of finding those λ's for which the corresponding sesquilinear form is positive definite, i.e. the corresponding $U_q\mathfrak{su}_{n,n}$-modules are unitarizable. In the classical setting, such λ's are said to belong to the continuous part of the Wallach set.[1]

The above-mentioned proposition implies positive definiteness of the inner product $(f_1,f_2)_\lambda$ for any $\lambda > n-1$:

Corollary 5.3: *The $U_q\mathfrak{su}_{n,n}$-modules $\mathcal{P}_\lambda$ are unitarizable for $\lambda > n-1$.*

For $n=2$, this statement was obtained in Ref. 23 (see Proposition 6.1).

C. Some consequences of the covariance property

In the previous subsection, we were able to deduce some irreducibility and unitarity property of $U_q\mathfrak{sl}_{2n}$-modules $\mathcal{P}_\lambda$ for any λ from the results obtained earlier. We will not pursue all the details here. It is immediate that $\mathcal{P}_\lambda$ is reducible for $\lambda = n-1, n-2,\ldots$ for the following obvious reason: by the covariance property, $\mathcal{P}_{n-l}^{(0)} = \mathrm{Ker}\,\Box_q^l$ is a submodule in $\mathcal{P}_{n-l}$. A related application of the covariance property is the following.

Proposition 5.4: *For any $l \in \mathbb{N}$ $\mathcal{P}_{n-l}/\mathcal{P}_{n-l}^{(0)}$ is a unitarizable $U_q\mathfrak{su}_{n,n}$-module isomorphic to $\mathcal{P}_{n+l}$.*

Proof: Unitarizability follows from the covariance property, Corollary 5.3, and injectivity of the induced morphism $\mathcal{P}_{n-1}/\mathcal{P}_{n-1}^{(0)} \to \mathcal{P}_{n+l}$ of $U_q\mathfrak{sl}_{2n}$-modules. Actually, this latter morphism is an isomorphism. To prove this, it suffices to show that the operator

$$\Box_q^l : \mathbb{C}[M_n]_q \to \mathbb{C}[M_n]_q$$

is surjective. In turn, it suffices to prove the latter statement for $l=1$, i.e. to show that $\Box_q$ is surjective. But this follows from (4.21). ■

Energy transport in the Vaidya system

J. P. Krisch and E. N. Glass
Department of Physics, University of Michigan, Ann Arbor, Michigan 48109

(Received 15 February 2005; accepted 18 March 2005; published online 16 May 2005)

Energy transport mechanisms can be generated by imposing relations between null tetrad Ricci components. Several kinds of mass and density transport generated by these relations are studied for the generalized Vaidya system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1915290]

I. INTRODUCTION

The Vaidya[1] space–time generalized the Schwarzschild vacuum solution by allowing mass parameter m_0 to be a function of retarded time. The extension created a spherically symmetric null fluid atmosphere. Glass and Krisch[2] pointed out that allowing the mass function to also depend on the radial coordinate created a more complex atmosphere containing an anisotropic string fluid in addition to Vaidya radiation.

The fluid parameters for the Vaidya atmosphere $\{\rho, p_r, p_\perp\}$ all depend on time through their relationship to the time-dependent mass function $m(u,r)$; they control the motion of matter through the atmosphere. The Ricci tensor null tetrad components (i.e., Ricci spinor components), Φ_{11} and Φ_{22}, for the generalized Vaidya space–time also depend on both spatial and time derivatives of the mass function. If we impose relations between these components then those relations will, in turn, impose matter transport in the Vaidya system. Conversely, if a particular mode of matter transport were assumed for the mass or one of the fluid parameters, it would contain within it a Ricci relation. Relating Ricci components is a way of imposing and classifying a range of atmospheric matter transport mechanisms. In this paper we consider the generalized Vaidya metric,[2,3] and examine how functional relations between Φ_{11} and Φ_{22} lead to mass transport described by the diffusion equation, by the wave equation, and by a dissipative transport equation of Telegrapher type.

In studying fluid transport, the transport equations are often reducible to ordinary differential equations by introducing a similarity variable; a well-known example of this is the diffusion variable, $\eta \sim r/\sqrt{t}$, suggested by Boltzmann[4] in 1894. All the transport equations studied in this paper have similarity solutions. The physical similarity of matter fields has been discussed by many authors.[5–8] The matter transport considered here is in the atmosphere around a compact object or an already existing black hole. By examining the similarity structure of the mass solution to the transport equations, we are able to relate the function of proportionality between the Ricci components to the spatial part of a similarity variable.

The paper is structured as follows: In the next section we briefly review the generalized Vaidya space–time. Matter transport mechanisms and their similarity structure are discussed in Sec. III. Some explicit examples are given in Sec. IV. Metric and tetrad details are provided in the Appendix.

Our sign conventions are $2A_{\nu;[\alpha\beta]}=A_\mu R^\mu{}_{\nu\alpha\beta}$, $R_{\mu\nu}=R^\alpha{}_{\mu\nu\alpha}$, and metric signature $(+,-,-,-)$. Greek indices range over $(0,1,2,3)=(u,r,\vartheta,\varphi)$. $\dot{m}$ abbreviates $\partial m/\partial u$, m' abbreviates $\partial m/\partial r$, with another prime for each higher derivative. Overhead carets denote unit vectors. Field equations are $G_{\mu\nu}=-8\pi T_{\mu\nu}$.

II. GENERALIZED VAIDYA SPACE–TIME

The Vaidya metric generalizes vacuum Schwarzschild when $m_0 \to m(u)$,

$$g^{\mathrm{vad}}_{\alpha\beta}\,\mathrm{d}x^{\alpha}\,\mathrm{d}x^{\beta} = A^{\mathrm{vad}}\,\mathrm{d}u^2 + 2\,\mathrm{d}u\,\mathrm{d}r - r^2(\mathrm{d}\vartheta^2 + \sin^2\vartheta\,\mathrm{d}\varphi^2), \tag{1}$$

where $A^{\mathrm{vad}}=1-2m(u)/r$. The only nonzero Weyl null tetrad component is $\Psi_2=-m(u)/r^3$. The Ricci tensor, with $l_\alpha\,\mathrm{d}x^\alpha=\mathrm{d}u$, is

$$R^{\mathrm{vad}}_{\alpha\beta} = \frac{2\dot{m}}{r^2} l_\alpha l_\beta.$$

The Vaidya metric has been generalized so that $m(u)\to m(u,r)$ and $A^{\mathrm{vad}}\to A^{\mathrm{gv}}=1-2m(u,r)/r$,

$$g^{\mathrm{gv}}_{\alpha\beta}\,\mathrm{d}x^{\alpha}\,\mathrm{d}x^{\beta} = A^{\mathrm{gv}}\,\mathrm{d}\,u^2 + 2\,\mathrm{d}u\,\mathrm{d}r - r^2(\mathrm{d}\vartheta^2 + \sin^2\vartheta\,\mathrm{d}\varphi^2). \tag{2}$$

The metric is Petrov type **D** with l_μ and n_μ principal null vectors (details are in the Appendix),

$$l_\mu\,\mathrm{d}x^\mu = \mathrm{d}u, \tag{3a}$$

$$n_\mu\,\mathrm{d}x^\mu = (A^{\mathrm{gv}}/2)\mathrm{d}u + \mathrm{d}r, \tag{3b}$$

$$m_\mu\,\mathrm{d}x^\mu = -(r/\sqrt{2})(\mathrm{d}\vartheta + i\sin\vartheta\,\mathrm{d}\varphi). \tag{3c}$$

Basis vectors for the generalized Vaidya metric are the unit vector set $(\hat{v}_\mu,\hat{r}_\mu,\hat{\vartheta}_\mu,\hat{\varphi}_\mu)$ and the related null set $(l_\mu,n_\mu,m_\mu,\overline{m}_\mu)$ such that

$$g^{\mathrm{gv}}_{\mu\nu} = \hat{v}_\mu\hat{v}_\nu - \hat{r}_\mu\hat{r}_\nu - \hat{\vartheta}_\mu\hat{\vartheta}_\nu - \hat{\varphi}_\mu\hat{\varphi}_\nu = l_\mu n_\nu + n_\mu l_\nu - m_\mu\overline{m}_\nu - \overline{m}_\mu m_\nu. \tag{4}$$

In terms of the basis vectors, metric g^{gv} has energy-momentum[2]

$$-8\pi T^{\mathrm{gv}}_{\mu\nu} = \psi l_\mu l_\nu + \rho\hat{v}_\mu\hat{v}_\nu + p_r\hat{r}_\mu\hat{r}_\nu + p_\perp(\hat{\vartheta}_\mu\hat{\vartheta}_\nu + \hat{\varphi}_\mu\hat{\varphi}_\nu) \tag{5}$$

with components

$$4\pi\psi = -\dot{m}/r^2, \tag{6a}$$

$$4\pi\rho = -4\pi p_r = m'/r^2, \tag{6b}$$

$$8\pi p_\perp = -m''/r. \tag{6c}$$

The Einstein tensor is computed from g^{gv} and given by

$$G^{\mathrm{gv}}_{\mu\nu} = -2\Phi_{11}(l_\mu n_\nu + n_\mu l_\nu + m_\mu\overline{m}_\nu + \overline{m}_\mu m_\nu) - 2\Phi_{22} l_\mu l_\nu - (\mathcal{R}/4)g^{\mathrm{gv}}_{\mu\nu}, \tag{7}$$

with components

$$\Phi_{11} = (2m' - rm'')/(4r^2) = 2\pi(p_\perp - p_r), \tag{8a}$$

$$\Phi_{22} = -\dot{m}/r^2, \tag{8b}$$

$$\mathcal{R} = 2(rm'' + 2m')/r^2 = -16\pi(p_\perp + p_r). \tag{8c}$$

An inspection of Eq. (8) shows that a relation between Φ_{11} and Φ_{22} will generate matter transport.

$S_{\mu\nu}=\frac{1}{2}\left(R^{\mathrm{gv}}_{\mu\nu}-\frac{1}{4}\mathcal{R}^{\mathrm{gv}}g_{\mu\nu}\right)$ is the trace-free Ricci tensor. Its eigenspectrum determines the Segre type of metric $g^{\mathrm{gv}}_{\mu\nu}$. The characteristic equation, $\det[S-\lambda I]=0$, is

$$\lambda^4 - (\Phi_{22})\lambda^3 - 2(\Phi_{11}^2)\lambda^2 + (\Phi_{11}^2\Phi_{22})\lambda + \Phi_{11}^4 = 0, \tag{9}$$

with factors

$$(\lambda - \Phi_{11})(\lambda + \Phi_{11})(\lambda^2 - \Phi_{22}\lambda - \Phi_{11}^2). \tag{10}$$

This set corresponds to Segre type [2,(11)]. The Ricci relations established below will not change the Segre type.

III. GEOMETRY AND TRANSPORT OF MATTER

A. Mass diffusion from fluid relations

The fluid components of the energy-momentum in Eq. (6) depend on both time and spatial derivatives, so matter transport will occur. Implicit in these equations is the relation

$$4\pi r^2\dot{\rho} = \partial_r\dot{m}.$$

If one also assumes

$$\dot{m} = 4\pi D_0 r^2 \partial_r \rho$$

then both the mass and density obey diffusion equations, the mass diffusing in a space whose determinant is dual to Vaidya,[2]

$$\dot{\rho} = D_0\nabla^2\rho, \tag{11a}$$

$$\dot{m} = D_0\nabla^{-2}m \tag{11b}$$

with $\nabla^2 = r^{-2}(\partial/\partial r)r^2(\partial/\partial r)$, $\nabla^{-2} = r^2(\partial/\partial r)r^{-2}(\partial/\partial r)$, and D_0 the diffusion constant. Equating the nonzero Ricci components will also produce motion of the mass and density.

B. Mass diffusion from Ricci components

Consider the quantities $(4r\Phi_{11})$ and $(r^2\Phi_{22})$. Equations (8a) and (8b) (with no assumptions) allow the relation between these quantities to be written as

$$\partial_u(4r\Phi_{11}) = r^2\partial_r\left[\frac{\partial_r(r^2\Phi_{22})}{r^2}\right]. \tag{12}$$

If there is a general linear relation between Φ_{11} and Φ_{22} such as

$$\Phi_{22} = h_d(r)\Phi_{11}, \tag{13}$$

then both Ricci components will evolve diffusively. We will show in the next section that $h_d(r)$ is related to a spatial similarity variable for the diffusion equation. For exact solutions mass is a more physical quantity and, if we impose this relation and examine mass transport, Eqs. (8a) and (8b) imply

$$\Phi_{11} = -(r/4)\partial_r(m'/r^2), \tag{14a}$$

$$\Phi_{22} = -\dot{m}/r^2 = -(rh_d/4)\partial_r(m'/r^2). \tag{14b}$$

The linear relation (13) together with (14b) yields

$$\dot{m} = (r^3h_d/4)\partial_r(m'/r^2) \tag{15}$$

and so the mass will also move diffusively.

The homogeneous solution of Eq. (15) is

$$m = r^3 c_1(u) + c_2(u), \quad \dot{c}_2 + r^3 \dot{c}_1 = 0,$$

$$8\pi\rho = -8\pi p_r = 6c_1(u), \tag{16}$$

$$p_r = p_\perp.$$

Equation $\dot{c}_2 + r^3\dot{c}_1 = 0$ is satisfied only for c_1 and c_2 both constant.

C. Mass transport by wave motion

The basic relation between the Ricci components, Eq. (12), is

$$\partial_u(4r\Phi_{11}) = r^2\partial_r\left[\frac{\partial_r(r^2\Phi_{22})}{r^2}\right].$$

If one assumes the Ricci components are related by

$$\partial_u\Phi_{22} = h_w(r)\Phi_{11} \tag{17}$$

then $r^2\Phi_{22}$ will evolve as a wave equation solution. Focusing again on the mass behavior, Eq. (8a) for Φ_{11} and Eq. (8b) for Φ_{22} provide a wave equation for the mass,

$$\ddot{m} - (h_w/4)r^3 m = 0$$

or

$$\ddot{m} - (h_w/4)r^5\partial_r(r^{-2}\partial_r m) = 0. \tag{18}$$

Classical wave motion provides shape preserving traveling solutions to the wave equations for functions with argument $(kr - \omega t)$. Therefore, consider a variable of the form $\eta = R(r) - T(u)$. The wave equation becomes

$$[\dot{T}^2 - (h_w/4)r^3(R')^2]m_{\eta\eta} - [\ddot{T} + (h_w/4)(r^3R'' - 2r^2R')]m_\eta = 0. \tag{19}$$

The transport equation is

$$\alpha m_{\eta\eta} - \beta m_\eta = 0,$$

$$\dot{T}^2 - (h_w/4)r^3(R')^2 = \alpha,$$

$$\ddot{T} + (h_w/4)(r^3R'' - 2r^2R') = \beta.$$

The simplest solutions require α and β to be separately zero. These are

$$h_w = \frac{4c_1}{r^3(R')^2}, \quad R = c_2r^3 + c_3, \quad T = T_0u + T_1, \tag{20}$$

and, as in diffusive transport, the proportionality function between the Ricci components is related to the similarity variable. The mass is given by any function of argument η, $m = F(\eta)$.

D. Dissipative transport

It is clear that the mode of matter transport depends on the relation chosen between Φ_{22} and Φ_{11}. Dissipative waves obey a Telegrapher equation,[9] combining both wave and diffusive elements,

$$\ddot{\chi} - c_0^2 \nabla^2 \chi + c_1 \dot{\chi} = 0, \tag{21}$$

where $\nabla^2 \chi = (1/r^2)\partial_r (r^2 \partial_r \chi)$. The relationship

$$(\partial_u + \alpha_0)\Phi_{22} + h_t(r)\Phi_{11} = 0 \tag{22}$$

will generate an equation of Telegrapher form for mass,

$$\ddot{m} - (h_t/4) r \nabla^{-2} m + \alpha_0 \dot{m} = 0. \tag{23}$$

This form of causal dissipative transport provides a richer tool for modeling than a pure diffusion equation, since it avoids the infinite propagation speeds associated with parabolic diffusion equations.[10] Causal transport has recently been discussed by Herrera and Santos.[11] As before, the function of proportionality h_t is related to a similarity variable.

E. Similarity and h_d

To see the relation of the proportionality function to the similarity structure of the diffusion equation, assume a mass solution and similarity variable with forms

$$m - m_0 = T(u)F(\eta),$$

$$\eta = R(r)/L(u).$$

Rewriting the mass diffusion equation (15), with $F_\eta = \mathrm{d}F/\mathrm{d}\eta$ results in

$$F_{\eta\eta} + F_\eta \left[L \left\{ \frac{R''}{(R')^2} - \frac{2}{rR'} \right\} + \frac{4R}{h_d r (R')^2} \dot{L} \right] - \left[\frac{4}{h_d r (R')^2} L^2 \frac{\dot{T}}{T} \right] F = 0. \tag{24}$$

This diffusion equation should have similarity form[4]

$$F_{\eta\eta} + 2\alpha\eta F_\eta - \beta F = 0.$$

We look for solutions with the same similarity form, and so the coefficients impose constraints. The coefficient of F relates β and $h_d(r)$,

$$\beta = \frac{4}{h_d r (R')^2} L^2 \frac{\dot{T}}{T}. \tag{25}$$

Removing r-dependence provides the relation between $R(r)$ and $h_d(r)$,

$$h_d = \frac{4c_0}{r(R')^2}. \tag{26}$$

With this h_d constraint, the u-dependent part of the coefficient β implies

$$L^2 \frac{\dot{T}}{T} = \beta c_0. \tag{27}$$

This allows Eq. (24) to be written as

$$F_{\eta\eta} + F_\eta \left[L \left\{ \frac{R''}{(R')^2} - \frac{2}{rR'} \right\} + (R/c_0)\dot{L} \right] - \beta F = 0.$$

The coefficient of F_η requires

$$2\alpha\eta = 2\alpha(R/L) = L\left[\frac{R''}{(R')^2} - \frac{2}{rR'}\right] + (R/c_0)\dot{L}. \tag{28}$$

Solutions of this equation depend on the value of α. Some example solutions will be given in Sec. IV. We note here that the choice $R=R_0r^3+R_1$, which solves

$$R''/R' - 2/r = 0, \tag{29}$$

provides an analog of the Boltzman similarity variable. For this choice Eq. (28) yields

$$L^2 = 4c_0\alpha u + L_0^2$$

with similarity variable $R(r)/L(u)$

$$\eta = \frac{R_0r^3 + R_1}{\sqrt{4c_0\alpha u + L_0^2}}$$

and proportionality function

$$h_d = \frac{4c_0}{r^5R_0^2}.$$

If $c_0=D_0R_0^2$ then $h_d=4D_0/r^5$. This choice yields a simple diffusion equation for mass.

F. Similarity and h_t

Assuming a mass and similarity variable of the form

$$m - m_0 = T(u)F(\eta), \quad \eta = R(r)/L(u)$$

we find

$$\left[\frac{\dot{L}^2}{L^2}\frac{R^2}{T} - \left(\frac{h_t}{4}\right)r(R')^2\right]F_{\eta\eta} - \left[R\left(2\dot{L}\frac{\dot{T}}{T} + \ddot{L} - 2\frac{\dot{L}^2}{L} + \alpha_0\dot{L}\right) + \left(\frac{h_t}{4}\right)L(rR'' - 2R')\right]F_\eta + \left[L^2\left(\frac{\ddot{T}}{T} + \alpha_0\frac{\dot{T}}{T}\right)\right]F = 0.$$

The relationship of h_t to the scaling variable in this similarity equation depends on the form of the time scaling function. The example that we shall use in the next section has $L=L_0$, and for this choice the similarity equation becomes

$$-\frac{h_t}{4}r(R')^2F_{\eta\eta} + L_0\frac{h_t}{4}(2R' - rR'')F_\eta + L_0^2\left(\frac{\ddot{T}}{T} + \alpha_0\frac{\dot{T}}{T}\right)F = 0. \tag{30}$$

For this choice of L, we see the diffusive relation between the proportionality function and the spatial scaling function again emerges as

$$h_t = \frac{4c_0}{r(R')^2}. \tag{31}$$

Telegrapher transport could allow many other relations to be imposed, reflecting the richer solution structure of this transport mechanism. In the next section we give some examples.

IV. TRANSPORT EXAMPLES

A. Similarity solutions

As an example of the mass transport solutions based on similarity, we consider a single scenario to which we apply all three transport mechanisms. The physical setting considered is a compact object of mass $m(u,\eta)$ with an atmosphere in which transport is occurring. We use solutions where the scale variable R and proportionality function $h(r)$ are the same for all transports,

$$R=\frac{R_0}{3}r^3, \quad L=L_0, \quad h(r)=\frac{4c_0}{R_0^2 r^5}. \tag{32}$$

In simple diffusion problems, the choice $L=L_0$ is applied to bounded systems where L_0 can be identified with a natural physical scale. For the Vaidya black hole, the Schwarzschild radius provides a physical distance scale and we could identify L_0 with an associated distance.

1. Diffusive transport

For diffusive transport with the choices above, the equations describing the evolution of the mass function are

$$F_{\eta\eta}-\beta F=0, \quad \dot{T}/T=\beta c_0/L_0^2. \tag{33}$$

The mass function, with time parameter $\tau_0^{-1}=\beta D_0 R_0^2/L_0^2$, will be given by

$$\begin{gathered} m=m_0+T_0 e^{u/\tau_0}F(\eta), \\ F(\eta)=F_0\sin(\sqrt{|\beta|}\,\eta+\delta), \quad \beta<0=F_0\sinh(\sqrt{\beta}\,\eta+\delta), \quad \beta>0. \end{gathered} \tag{34}$$

For $\beta<0$, the atmosphere is decaying in time as the Vaidya photons carry energy out of the system, while for $\beta>0$, mass is accreting. From the field equations, the density of the atmosphere is described by

$$\rho=\rho_0 e^{-u/\tau_0}\cos(\sqrt{|\beta|}\,\eta+\delta)=\rho_0 e^{u/\tau_0}\cosh(\sqrt{\beta}\,\eta+\delta), \tag{35}$$

where we have identified the initial atmospheric density and a time constant for the accretion or decay

$$\rho_0=\frac{T_0 F_0\sqrt{|\beta|}}{2\pi L_0}. \tag{36}$$

The similarity variable in this example is simply a distance coordinate. The decaying solution could describe a bounded atmosphere whose density decreases with distance away from the surface. There is zero radial pressure outer boundary described by $\sqrt{|\beta|}\,\eta_B+\delta=\pi/2$. In the decaying solutions, the atmosphere will go asymptotically to zero leaving a compact object of mass m_0. Because of the outgoing Vaidya radiation, there is no vacuum match until the atmosphere is gone. For the accreting solution, there is no zero radial pressure boundary. Since the accreting mass is entering the atmosphere from the exterior, this is expected. The density profile depends strongly on the phase δ. For $\delta=0$, the density increases as one looks upward from the core surface. For nonzero δ, the density decreases going up from the surface, reaching a minimum value which might be identified with the boundary between the atmosphere and the source of the accreting mass.

2. Telegrapher transport

The equations for Telegrapher transport with the scaling functions chosen are

$$F_{\eta\eta} - \beta F = 0,$$

$$\frac{L_0^2}{c_0}\left(\frac{\ddot{T}}{T} + \alpha_0 \frac{\dot{T}}{T}\right) = \beta.$$

Telegrapher transport has a wider set of solutions for the scaling choice than pure diffusive transport. One solution, using $\beta = 0$, is

$$T = T_0 e^{-\alpha_0 u},$$

$$F = F_0 \eta, \tag{37}$$

$$m = m_0 + \rho_1 r^3 e^{-\alpha_0 u}, \quad \rho_1 = T_0 F_0 / L_0.$$

The atmospheric density is related to the mass through the field equations by $\rho = m'/(4\pi r^2)$. The density for this case does not vary with radial distance from the black hole but does reflect the atmospheric decay, approaching zero as the atmosphere vanishes and the mass becomes m_0,

$$\rho = \rho_0 e^{-\alpha_0 u}, \quad \rho_0 = 3R_0\rho_1/4\pi. \tag{38}$$

The $\beta \neq 0$ solutions are similar to the diffusive solutions,

$$T = T_0 e^{\gamma u}, \quad \beta = (L_0^2/c_1)(\gamma^2 + \alpha_0 \gamma),$$

$$F = F_0 \sin(\sqrt{|\beta|}\,\eta + \delta), \quad \beta < 0,$$
$$F = F_0 \sinh(\sqrt{\beta}\,\eta + \delta), \quad \beta > 0, \tag{39}$$

$$m = m_0 + T(u)F(\eta).$$

B. A diffusively evaporating atmosphere

(a) *The boundary behavior:* In this example, we consider a compact object whose atmosphere is diffusively evaporating. An exact mass solution, given in Ref. 2, is

$$m = m_0 + (4\pi/3)r^3\rho_0 - (4\pi/3)k_2(r^5/10 + \mathfrak{D}_0 u r^3). \tag{40}$$

For this example the proportionality function follows directly from the diffusion equation:

$$h_d = 4D_0/r.$$

The atmospheric density associated with this mass is

$$\rho = \rho_0 - k_2(r^2/6 + \mathfrak{D}_0 u). \tag{41}$$

A boundary can be defined by requiring the radial pressure (and density, from the equation of state) to be zero. Solving the density equation for a boundary radius gives the boundary as a function of retarded time,

$$R_b^2 = \frac{6}{k_2}(\rho_0 - k_2 \mathfrak{D}_0 u).$$

Let the boundary move inward as the atmosphere evaporates until the atmosphere is gone and the radius is at the compact object boundary, R_c. This happens in time u_0, thus

$$R_c^2 = \frac{6}{k_2}(\rho_0 - k_2 \mathfrak{D}_0 u_0). \tag{42}$$

It follows that

$$R_b^2(u) = R_c^2 + 6\mathfrak{D}_0(u_0 - u). \tag{43}$$

The bounding surface of the core is parametrized as $R_c = 2m_0\alpha$. Substituting into (43) provides

$$R_b^2(u) = 4m_0^2\alpha^2 + 6\mathfrak{D}_0(u_0 - u). \tag{44}$$

The mass function places a constraint on the parameters. From Eq. (42) at time u_0,

$$(\alpha - 1)m_0 = \frac{128}{45} k_2 \pi m_0^5 \alpha^5. \tag{45}$$

Using Eqs. (42) and (45), the time for the evaporation process to complete is

$$\mathfrak{D}_0 u_0 = \frac{2}{3}\alpha^2 m_0^2 \left[\frac{64\pi\rho_0 m_0^2 \alpha^3}{15(\alpha - 1)} - 1 \right]. \tag{46}$$

The density and mass evolve as

$$\rho = \frac{k_2}{6}(R_c^2 - R_b^2) + k_2 \mathfrak{D}_0(u_0 - u), \tag{47}$$

$$m = m_0 + \frac{4\pi k_2}{45} R_b^5 + \frac{4\pi}{3} k_2 R_b^3 \left[\frac{R_c^2 - R_b^2}{6} + \mathfrak{D}_0(u_0 - u) \right]. \tag{48}$$

(b) *Extremal case:* The time at which the evaporation of the atmosphere is complete has an extremal value. Extremising Eq. (46) one finds

$$\frac{2(\alpha - 1)^2}{\alpha^3(4\alpha - 5)} = \frac{64\pi\rho_0 m_0^2}{15}.$$

The extremal time for the evaporation is

$$\mathfrak{D}_0 u_0 = \frac{2}{3}\alpha^2 m_0^2 \left[\frac{3 - 2\alpha}{4\alpha - 5} \right]. \tag{49}$$

The second derivative shows this is a minimum. For positive times, we require

$$1.25 < \alpha < 1.5.$$

(c) *Time estimates:* Take m_0 to be a solar size, $m_0 \sim 1.5 \times 10^3$ m. The diffusivity constant $\mathfrak{D}_0$ is related to the constancy of the jump distance (L) and frequency (f).[4] $\mathfrak{D}_0$ can be estimated as

$$\mathfrak{D}_0 \sim L^2 f.$$

For example, if the Debye frequency in a solid is the same as the jump frequency, we would have $f \sim 10^{13}$ Hz and the jump distance could be of the order of an angstrom, so that an estimate for the diffusivity is

$$\mathfrak{D}_0 \sim 10^{-7}\ \mathrm{m}^2/\mathrm{s}.$$

Using these estimates, the time for the atmosphere to vanish by diffusion is roughly

$$u_0 = 10^7\left(\frac{2}{3}\right)\alpha^2 \times 2.25 \times 10^6\left[\frac{3-2\alpha}{4\alpha-5}\right] \sim 1.5 \times 10^{13}\left[\frac{3-2\alpha}{4\alpha-5}\right]\alpha^2.$$

For $\alpha=1.4$, the time is about $10^{13}\ \mathrm{s} \sim 10^5$ years. The diffusivity is much larger than is normally measured since not all atomic oscillations will have an associated jump. A smaller diffusivity would increase the time.

V. DISCUSSION

In this paper we have examined some of the atmospheric matter transport mechanisms introduced by imposing a relation between Ricci components of the generalized Vaidya space–time. We found that diffusive, wave, and general Telegrapher-type transport can all follow from such a relation. Imposing a Ricci relation is a way of unifying matter transport mechanisms; if one started with a particular transport mechanism then a Ricci relation would emerge.

Examples of the matter transport mechanisms were given. All of the exact solutions describe atmospheres that are either accreting or decaying. The first two examples had the same similarity function but the density profiles in each solution were very different. The first Telegrapher solution describes a core object with a decaying atmospheric density varying only with time, and whose tangential and radial stress are all spatially constant tensions. In the pure diffusive solution, the densities vary with both distance from the core surface and time. The decaying atmospheres could be bounded by an exterior fluid of Vaidya radiation. The accreting solutions were surrounded by the source of accreting matter and Vaidya radiation. The third example, with a different proportionality function, examined a diffusing atmosphere around a core object of radius R_c in the range $2.5m_0 < R_c < 3m_0$. For an $R_c = 2.8m_0$ object with a diffusivity based on a solid Debye frequency there was a minimum evaporation time of about 10^5 years. Jump frequencies based on the actual atmospheric fluid would increase this time. Apart from the actual size of the evaporation time for a specific object, the model predicts that atmospheres around smaller core objects, near the lower end of the range, will take very much longer to diffusively evaporate than the atmospheres of larger core objects. This can be understood by looking at the initial size of the atmosphere. Using Eq. (44) at $u=0$, Eq. (49), and the parametrized boundary surface $R_c = 2m_0\alpha$, the initial atmospheric radius is

$$R_b^2|_{u=0} = 2R_c^2\left[\frac{\alpha-1}{4\alpha-5}\right], \quad 1.25 < \alpha < 1.5.$$

The smaller core objects have larger atmospheric envelopes, taking longer to evaporate. The smaller core has an extended atmosphere because its gravitational field is not strong enough to hold the atmosphere compactly.

Some additional insights into the meaning of the proportionality function can be seen for diffusive and wave transport by writing the transport equations in terms of variable $w = r^3$. The diffusive and wave transport equations become

$$\dot{m} = \left(\frac{9r^5 h_d}{4}\right) m_{ww},$$

$$\ddot{m} = \left(\frac{9r^5 h_w}{4}\right) m_{ww}.$$

In each case we can find the functional form of $h(r)$ that will produce the simplest transport and can relate that value to the diffusion constant or the wave velocity. Our example solutions include this simple case and a case where the mass and density evolution are more complex.

The choice $h_d(r)=4D_0/r^5$ yields a simple (u,w) diffusion equation for mass. From the Ricci relations and the field equations we see that

$$\dot{m}/r^2 = 2\pi h_d(p_r - p_\perp)$$

indicating that, with the Ricci relations, mass transport is driven by the pressure anisotropy. This also illustrates a drawback of the mass transport ansatz. Φ_{11} is certainly zero for isotropic pressures with a string equation of state [Eq. (8a) with $p_\perp=p_r$]. The assumed relation, $\Phi_{22}=h_d(r)\Phi_{11}$, then says that there is no time variation in the mass for isotropic pressures. In general, when the two Ricci components are not related, the mass can vary with time, even in the case of isotropic pressures.

We list the assumptions that lead to matter transport. For diffusion the specific choice $h_d=4D_0/r^5$ is used.

Assumption	Transport
$\dot{m}=4\pi D_0 r^2\partial_r\rho$	$\dot{m}-D_0\nabla^{-2}m=0,\ \dot{\rho}-D_0\nabla^2\rho=0$
$\Phi_{22}=(4D_0/r^5)\Phi_{11}$	$\dot{m}-D_0\nabla^{-2}m=0$
$\partial_u\Phi_{22}=h_w(r)\Phi_{11}$	$\ddot{m}-(h_w/4)r^3\nabla^{-2}m=0$
$(\partial_u+\alpha_0)\Phi_{22}+h_t(r)\Phi_{11}=0$	$\ddot{m}-(h_t/4)r\nabla^{-2}m+\alpha_0\dot{m}=0$

We have seen that imposing a Ricci relation provides a broad arena to investigate a range of atmospheric transport processes in the generalized Vaidya space–time and is a rich source of new analytic mass solutions. The mass solutions that we presented focused on the growth or depletion of an atmosphere around a central object. They can be used to describe the behavior, for example, of isolated black hole atmospheres but also offer simple models of galaxies with a massive black hole at the center. The relationships we imposed on the Ricci components were investigated in terms of mass transport although the fundamental relationships described the evolution of the Ricci components themselves. The Ricci evolution is an interesting avenue for further investigation as they are input functions for the Riemann invariants. The evolution of the invariants and their syzigies will be discussed elsewhere.

APPENDIX: GENERALIZED VAIDYA PRINCIPAL NULL FRAME

The principal null frame Eq. (3) of the Petrov type **D** metric $g^{\rm gv}_{\mu\nu}$ obeys

$$l_{\mu;\nu} = (A'_{\rm gv}/2)l_\mu l_\nu - (1/r)(m_\mu\overline{m}_\nu + \overline{m}_\mu m_\nu), \tag{A1a}$$

$$n_{\mu;\nu} = -(A'_{\rm gv}/2)n_\mu l_\nu + (A^{\rm gv}/2r)(m_\mu\overline{m}_\nu + \overline{m}_\mu m_\nu), \tag{A1b}$$

$$m_{\mu;\nu} = (A^{\rm gv}/2r)l_\mu m_\nu - (1/r)n_\mu m_\nu + (\cot\vartheta/\sqrt{2}r)(m_\mu m_\nu - m_\mu\overline{m}_\nu). \tag{A1c}$$

with both principal null vectors l_μ and n_μ geodesic.

For tetrad $\{\hat{v},\hat{r},\hat{\vartheta},\hat{\varphi}\}$ and metric $g^{\rm gv}_{\mu\nu}=\hat{v}_\mu\hat{v}_\nu-\hat{r}_\mu\hat{r}_\nu-\hat{\vartheta}_\mu\hat{\vartheta}_\nu-\hat{\varphi}_\mu\hat{\varphi}_\nu$, the basis vectors are related by

$$\hat{v}_\mu\,{\rm d}x^\mu = A^{1/2}_{\rm gv}\,{\rm d}u + A^{-1/2}_{\rm gv}\,{\rm d}r = A^{-1/2}_{\rm gv}[n_\mu + (A_{\rm gv}/2)l_\mu]{\rm d}x^\mu, \tag{A2a}$$

$$\hat{r}_\mu\,{\rm d}x^\mu = A^{-1/2}_{\rm gv}\,{\rm d}r = A^{-1/2}_{\rm gv}[n_\mu - (A_{\rm gv}/2)l_\mu]{\rm d}x^\mu, \tag{A2b}$$

$$\hat{\vartheta}_\mu\,{\rm d}x^\mu = r\,{\rm d}\vartheta = (1/\sqrt{2})(m_\mu + \overline{m}_\mu){\rm d}x^\mu, \tag{A2c}$$

$$\hat{\varphi}_\mu \, \mathrm{d}x^\mu = r \sin\vartheta \, \mathrm{d}\varphi = -(i/\sqrt{2})(m_\mu - \overline{m}_\mu)\mathrm{d}x^\mu. \tag{A2d}$$

The kinematics of the $\hat{v}$ flow, acceleration, expansion, and shear, are described by

$$\hat{v}^\mu{}_{;\nu} = a^\mu \hat{v}_\nu + \sigma^\mu{}_\nu - (\Theta/3)(\hat{r}^\mu \hat{r}_\nu + \hat{\vartheta}^\mu \hat{\vartheta}_\nu + \hat{\varphi}^\mu \hat{\varphi}_\nu), \tag{A3}$$

where

$$a^\mu = [\dot{m}/r + A_{\mathrm{gv}} \partial_r (m/r)] A_{\mathrm{gv}}^{-3/2} \hat{r}^\mu, \tag{A4a}$$

$$\sigma^\mu{}_\nu = (\Theta/3)(-2\hat{r}^\mu \hat{r}_\nu + \hat{\vartheta}^\mu \hat{\vartheta}_\nu + \hat{\varphi}^\mu \hat{\varphi}_\nu), \tag{A4b}$$

$$\Theta = (\dot{m}/r) A_{\mathrm{gv}}^{-3/2}. \tag{A4c}$$

Spherical symmetry allows the function $m(u,r)$ to be identified as the mass within two surfaces of constant u and r, and invariantly defined from the sectional curvature of those surfaces,

$$-2m/r^3 = R_{\alpha\beta\mu\nu} \hat{\vartheta}^\alpha \hat{\varphi}^\beta \hat{\vartheta}^\mu \hat{\varphi}^\nu. \tag{A5}$$

New College of Florida, Sarasota, Florida 34243

(Received 16 April 2004; accepted 11 March 2005; published online 19 May 2005)

We study a collection of Markov chains with values in the collection of partial orderings of the natural numbers. These systems arise naturally in the causal set approach to discrete quantum gravity and include the well-studied random partial orders of Alon, Bollobas, Brightwell, and Janson [Ann. Appl. Probab. **4**, 108–123 (1994)]. We prove that under the dynamics associated to Markov chains in our collection, posts occur infinitely often, almost surely. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1922070]

I. INTRODUCTION

The causal set approach to quantum gravity posits that the deep structure of space–time should be modeled on discrete structures admitting a causal order (cf. Bombelli *et al.*, 1987; Brightwell *et al.*, 2002a, 2002b; Dou and Sorkin, 2003; Martin *et al.*, 2002; Rideout and Sorkin, 2000; Sorkin, 2000, 1997, and references therein). Such discrete structures are called *causets*, and much work has been done to construct stochastic classical dynamics for causet evolution in hopes that this might serve as a guide to developing corresponding quantum dynamics. There is an attractive classification for possible stochastic dynamics for causets which satisfy a discrete version of covariance and relativistic causality: such dynamics are given by Markov chains which are defined by a sequence of coupling constants, t_n, $n \geqslant 0$, where $t_0 = 1$ and $t_n \geqslant 0$ for all $n > 0$ (cf. Rideout and Sorkin, 2000). Such dynamics are collectively referred to as "classical sequential growth models" (CSG).

In seeking to understand the possible role of CSG models in dealing with problems involving the unexplained "large numbers" in cosmology related to the size of the universe and its high degree of homogeneity and isotropy, Sorkin (2000) relates such problems to the number of cycles of contraction and re-expansion through which the universe has gone to date. He then notes that contraction followed by re-expansion has the effect of "renormalizing" the coupling constants of a CSG model in a definite manner [cf. (2.13) below], and argues that this observation provides a possible method for isolating a collection of dynamical laws which might play a distinguished physical role: those CSG models which are attractors under cycles of contraction and re-expansion. A study of such models was undertaken by Dou (1999) and further developed in Martin *et al.* (2002), where the authors note that the question of *which dynamical laws lead to cycles of contraction followed by re-expansion* is very much open.

The results of the above-mentioned studies suggest a natural avenue for further constraining the coupling constants defining the class of CSG models: consider those models which are stable "under cycles of contraction and re-expansion." A representation theorem for the corresponding class of Markov chains [which we call *GCD chains* (cf. Definition 2.4)] was established in Ash and McDonald (2003). This paper continues the study of GCD chains.

[a)]Electronic mail: avner.ash@bc.edu
[b)]Electronic mail: ptm@virtu.sar.usf.edu

The fixed points under renormalization play a fundamental role in understanding GCD chains and their relation to general CSG models. Every such fixed point is represented by the much-studied random graph process investigated by Barak and Erdós twenty years ago and known in the physics literature as *transitive percolation*.

Transitive percolation, the standard model for producing random partial orders on the natural numbers, is easy to describe inductively: Fix $0<p<1$ and suppose that we already have our randomly chosen partial order on n nodes labeled $0,1,\ldots,n-1$ (which is always assumed to be consistent with the natural ordering given by the node labelings). Introduce a new node (labeled n) and with probability p introduce an edge directed to the new node from each of the existing nodes, the addition of each edge being independent of all other edges. Finally, take the transitive closure of the partial order obtained once the random edges are determined (cf. Sec. II for examples).

A great deal is known about transitive percolation; the associated literature falls under a number of titles related to "random graphs" and there are many applications [cf. Bollobás and Brightwell (1997), and references therein]. Our interest is primarily directed toward the existence of *posts* which are defined to be nodes in a partial order of $\mathbb{N}$ which are ordered with respect to every other node in $\mathbb{N}$.

Posts were introduced by Alon, Bollobás, Brightwell, and Janson in (1994) where their properties with respect to transitive percolation were first studied. In particular, it was shown in Alon, Bollobás, Brightwell, and Janson (1994) that, under transitive percolation with any fixed p, an infinite number of posts occur, almost surely. Our main goal is to establish the same result for each of a certain dense family of GCD chains. Postponing the technicalities to Sec. II, we can give a statement of our main result:

Theorem 1.1: *Let M be a Markov chain taking values in the partial orderings on the natural numbers. Suppose that M exhibits general covariance, Bell causality and renormalizability (cf. Definition 2.1, Definition 2.3). Suppose further that the support of M (cf. Definition 2.6) is compact and that the supremum of the support is isolated. Then under the dynamics generated by M, an infinite number of posts occur, almost surely.*

In addition to providing new examples of dynamics which produce an infinite number of posts, almost surely, our result indicates that our notion of CSG models is consistent: If the dynamical laws are renormalizable (which follows from a hypothetical past with infinitely many cycles of contraction and re-expansion), then they will generate cycles of contraction and re-expansion infinitely often in the future. We expect our result to have a number of applications both in physics (discrete universes satisfying the hypotheses of our theorem will have an infinite number of cycles of expansion and contraction, almost surely) and in mathematics (various other properties of transitive percolation should also be inherited by random partial orders which satisfy the hypotheses of our theorem).

The paper is organized as follows: In Sec. II we provide the necessary background information and notation, including a mathematical introduction to causet dynamics and a discussion of the notion of "posts" in random partial orders. In Sec. III we provide a proof of our main result, Theorem 1.1.

In Sec. IV we prove a related theorem about the asymptotic behavior of GCD chains. Namely, in a sense made precise there, any GCD chain approaches a transitive percolation in the limit of large time. This result is illustrative of our viewpoint: We view transitive percolations as the building blocks of GCD chains and, in the limit of large time (again, in a sense made precise in Sec. IV), the behavior of any given GCD chain will be given by a transitive percolation associated to this chain. Unfortunately, this asymptotic property appears to be too weak in itself to imply the existence of infinitely many (or even just one) posts, almost surely.

Throughout the paper we usually work with *labeled* causets. In particular, references to "time" are usually references to a "gauge time" associated to a particular Markov chain and not to the physical time of space–time. Similarly, references to the "state of the system" involve references to the state of a particular Markov chain and not to the state of the physical universe at a particular time.

II. BACKGROUND

Let $[n]$ denote the set $\{0,1,2,\ldots,n\}$ with the natural partial order denoted by $<$. Let $\mathcal{C}_n$ be the collection of all subgraphs of the complete graph on the vertex set $[n]$. Suppose that $\mathcal{C} \in \mathcal{C}_n$ has an edge, ij, given by vertices i and j with $i<j$. We introduce a direction along edges by requiring that ij be directed from i to j. The graph C with edges so directed induces a partial order on $[n]$; we say $i<j$ if there is a directed edge in C from i to j. This provides an identification of a subset of the directed graphs on $[n]$ (those with edge directions consistent with the natural labeling of the vertices) with the collection of partial orders on $[n]$ which are extendible to the natural order on $[n]$. Allowing n to vary we define a set

$$\mathcal{C} = \bigcup_{n \in \mathbb{N}} \mathcal{C}_n. \tag{2.1}$$

We call elements of $\mathcal{C}$ *labeled causets*. We call any equivalence class of labeled causets under (order preserving) isomorphisms a *causet*. We will denote the equivalence classes by a tilde (for example, $\tilde{\mathcal{C}}$ is the set of all causets). In the calculations which follow, we usually work with labeled causets.

It is clear that for $m<n$, there is a natural inclusion $\mathcal{C}_m \subset \mathcal{C}_n$ which induces a partial order on $\mathcal{C}$. This partial order extends to causets, two causets being ordered if they admit representatives in $\mathcal{C}_n$, and $\mathcal{C}_m$ with $n<m$ and there exists an order preserving function $f: C \to D$ such that $f(C)$ is an initial segment of D. We will denote the partial order on both causets and labeled causets with the symbol $\prec\prec$.

Recall, a *link* in a partially ordered set is an irreducible relation (i.e., a relation that contains no other relation). A *path* in a partially ordered set is a sequence of elements of the set, each related to the next by a link.

Given $C \in \mathcal{C}$ and an element $x \in C$, we define the past of x by

$$\text{past}_C(x) = \{y \in C : y \prec x\}. \tag{2.2}$$

We will regard $\text{past}_c(x)$ as a poset with partial order given by the partial order of C. Similarly, the future of an element $x \in C$ is defined to be

$$\text{future}_C(x) = \{y \in C : x \prec y\}. \tag{2.3}$$

Given $C \in \mathcal{C}_n$, we will define the family of C, denoted $F(C)$, as those elements $D \in \mathcal{C}_{n+1}$ such that $C \prec\prec D$:

$$F(C) = \{D \in \mathcal{C}_{n+1} : C \prec\prec D\}. \tag{2.4}$$

Given $C \in \mathcal{C}_n$ and $D \in F(C)$, the *precursor set of the transition* $C \to D$, denoted $\text{Prec}(C,D)$, is the past of the element $x \in D \setminus C$:

$$\text{Prec}(C,D) = \text{past}_D(x) \subset C. \tag{2.5}$$

Note that $\text{Prec}(C,D)$ is a poset with partial order given by its description as the past of an element $x \in D$. The collection of *maximal elements associated to the transition* $C \to D$ is the collection of elements of C with links to the element x:

$$\max(C,D) = \{y \in D : y \text{ linked to } x,\ \{x\} = D \setminus C\}. \tag{2.6}$$

While the above-mentioned material is described in the context of labeled causets, a completely parallel development can be given for causets.

Before giving the formal definition of the Markov chains upon which our work will focus, we give an informal description of the processes with which we will deal.

Initially, the state of our system is given by the trivial poset consisting of a single point. At each increment of time, an element comes into existence as the "offspring" of elements already in existence. That is, at the beginning of the nth increment of time we have an element $C \in \mathcal{C}_n$ which

we evolve to an element $D \in \mathcal{C}_{n+1}$ by adding an element to C together with relations between the new element and a subset of elements of C (those elements in the past of the new element, i.e., those which bear some causal relationship to the new element). The new relations are determined randomly; the probability that any given collection of relations is added is given by a collection of transition probabilities which define the process.

We define a collection of Markov chains with state space $\mathcal{C}$ as follows:

Definition 2.1: We say that a Markov chain M with state space $\mathcal{C}$ belongs to the collection $\mathcal{M}$ if the transition probabilities of M satisfy:

(1) Given $C \in \mathcal{C}_n$, let $\mathrm{Prob}(C \to D)$ denote the transition probability corresponding to an evolution from causet C to causet D. Then $\mathrm{Prob}(C \to D) = 0$ if $D \notin F(C)$ and $\Sigma_{D \in F(C)} \mathrm{Prob}(C \to D) = 1$.

(2) (General Covariance) Let $\tilde{C} \in \tilde{\mathcal{C}}_n$. Suppose $\mathcal{P}_1$ and $\mathcal{P}_2$ are two paths from the trivial causet consisting of a single point to $\tilde{C}$ and write $\mathcal{P}_I = \{l_{i1}, \ldots, l_{in}\}$ where the l_{ij} are the links defining the path $\mathcal{P}_i$. Then

$$\prod_{k=1}^{n} \mathrm{Prob}(l_{1k}) = \prod_{k=1}^{n} \mathrm{Prob}(l_{2k}).$$

(3) (Causality) Suppose that $C \in \mathcal{C}_n$ and for $i = 1, 2$, suppose that $C_i \in F(C)$. Let $B \in \mathcal{C}_m$, $m \leqslant n$, be defined by

$$B = \mathrm{Prec}(C, C_1) \cup \mathrm{Prec}(C, C_2)$$

with poset structure induced by that of C. Let $B_i \in \mathcal{C}_{m+1}$ be B with an element added in the same manner as in the transitions $C \to C_i$. Then we require

$$\frac{\mathrm{Prob}(C \to C_1)}{\mathrm{Prob}(C \to C_2)} = \frac{\mathrm{Prob}(B \to B_1)}{\mathrm{Prob}(B \to B_2)}. \tag{2.7}$$

For a detailed discussion of these restrictions and results related to the corresponding dynamics, see Rideout and Sorkin (2000) and Dou (1999).

A special role in the theory will be played by those causets with no relations. We will denote the element of $\mathcal{C}_n$ with no relations by A_n. We note that there is a unique path in $\mathcal{C}$ of length n from A_0 to A_n.

Definition 2.2: Let $M \in \mathcal{M}$ and suppose that A_n is the causet on n nodes with no relations. Associate to M a sequence of positive constants $\{q_n\}_{n=0}^{\infty}$ defined by

$$q_0 = 1, \tag{2.8}$$

$$q_n = \mathrm{Prob}(A_n \to A_{n+1}), \tag{2.9}$$

where, as above, the expression appearing on the right-hand side of (2.9) denotes the probability of transition from A_n to A_{n+1}. We call the sequence $\{q_n\}$ *defining probabilities for the chain M*. If $q_n > 0$ for all n we say that the chain M is *generic*.

Rideout and Sorkin (2000) prove that for generic M, the sequence $\{q_n\}_{n=0}^{\infty}$ completely determines the theory associated to M. More precisely, given an element $C \in \mathcal{C}_n$, and $D \in F(C)$ [cf. (2.4)], let m be the number of maximal elements associated to the transition $C \to D$ [cf. (2.6)] and let ρ be the cardinality of the precursor set of the transition $C \to D$ [cf. (2.5)]. Then the transition probability for the evolution $C \to D$ is given by (cf. Rideout and Sorkin, 2000)

$$\mathrm{Prob}(C \to D) = q_n \sum_{k=0}^{m} (-1)^k \binom{m}{k} \frac{1}{q_{\rho-k}}. \tag{2.10}$$

Following Rideout and Sorkin (2000), we define a sequence t_n by

$$t_n = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} \frac{1}{q_k}. \tag{2.11}$$

Then we can recover the probabilities q_n from the sequence of t_n:

$$\frac{1}{q_n} = \sum_{k=0}^{n} \binom{n}{k} t_k. \tag{2.12}$$

We call the collection $\{t_n\}$ the *coupling constants* of the associated Markov chain. We note that if $\mathcal{S}_1$ is the collection of sequences of non-negative real numbers $T=\{t_n\}_{n=0}^{\infty}$ such that $t_0=1$, then there is a bijection between generic elements of $\mathcal{M}$ and elements of $\mathcal{S}_1$ given by associating to each element of $\mathcal{S}_1$ the associated collection of defining probabilities $\{q_n\}_{n=0}^{\infty}$ given by (2.12).

We constrain the class of Markov chains defined by Definition 2.1 further by requiring that they be *renormalizable under cycles of expansion and contraction*. We can state this requirement concisely in terms of a renormalization operator $\mathcal{R}:\mathcal{S}_1 \to \mathcal{S}_1$ defined by

$$(\mathcal{R}(T))_n = \frac{t_{n+1} + t_n}{t_0 + t_1}. \tag{2.13}$$

We define the stable set of the operator $\mathcal{R}$ by

$$\mathrm{Stab}(\mathcal{R}) = \left\{ T \in \mathcal{S}_1 : T \in \bigcap_{n \in \mathbb{N}} \mathcal{R}^n(\mathcal{S}_1) \right\}. \tag{2.14}$$

Definition 2.3: Let M be a Markov chain with coupling constants T satisfying $T \in \mathcal{S}_1$. We say that M is renormalizable if $T \in \mathrm{Stab}(\mathcal{R})$.

Using Definition 2.3 we define the Markov chains upon which we will focus:

Definition 2.4: Suppose that $M \in \mathcal{M}$ has coupling constants $T \in \mathcal{S}_1$. If M is renormalizable, we say that M defines a *generic causet dynamics* or *GCD chain*. We denote the collection of systems which are GCD chains by $\mathbb{M}$.

We denote by $\mathbb{S}$ the collection of coupling constants given by

$$\mathbb{S} = \mathcal{S}_1 \cap \mathrm{Stab}(\mathcal{R}). \tag{2.15}$$

From the relevant definitions it is clear that there is a bijection between elements of $\mathbb{M}$ and elements of $\mathbb{S}$ afforded by restricting the identification between $\mathcal{M}$ and $\mathcal{S}_1$.

The main result of Ash and McDonald (2003) is the following more subtle characterization of GCD chains:

Theorem 2.5: [*cf.* Ash and McDonald (2003)] *Suppose that $M \in \mathcal{M}$ has associated coupling constants $T=\{t_n\}$. Then $M \in \mathbb{M}$ if and only if there is a non-decreasing function $\alpha:\mathbb{R}^+ \to \mathbb{R}$ such that*

$$t_n = \int_0^{\infty} s^n d\alpha(s). \tag{2.16}$$

Definition 2.6: Let M be a GCD chain defined by coupling constants $\{t_n\}$. If $\alpha:\mathbb{R}^+ \to \mathbb{R}$ is a nondecreasing function satisfying (2.16) we say that α *represents* M. If $M \in \mathbb{M}$ is represented by α, we define the support of M to be the support of the measure $d\alpha$.

We can use Theorem 2.5 to give a second definition of transitive percolation:

Definition 2.7: Fix p, $0<p<1$. Transitive percolation is the GCD chain whose defining probabilities and coupling constants are given by

$$q_n = (1-p)^n \tag{2.17}$$

$$t_n = \left(\frac{p}{1-p}\right)^n.$$

Setting $d = p/(1-p) \in \mathbb{R}^+$, we see from (2.17) and (2.16) that transitive percolation corresponds to choosing α in Theorem 2.5 to be given by the appropriate Heaviside function:

$$\alpha(x) = \begin{cases} 0 & \text{if } x < d \\ 1 & \text{if } x \geqslant d. \end{cases} \tag{2.18}$$

It is a corollary of Theorem 2.5 [cf. Ash and McDonald (2003)] that for any GCD chain, we can write the transition probability for an arbitrary evolution using a representation. More precisely, given $C \in \mathcal{C}_n$ and $D \in F(C)$, evolution from C to D is effected by the addition of a new vertex, x_D, and a number of new edges. The transition probability for evolution from C to D under the GCD chain represented by α is given by [cf. Ash and McDonald (2003)]

$$\text{Prob}(C \to D) = \frac{\displaystyle\int_0^\infty s^m (1+s)^{\rho-m} d\alpha(s)}{\displaystyle\int_0^\infty (1+s)^n d\alpha(s)}, \tag{2.19}$$

where m is the number of maximal elements in the past of x_D [cf. (2.6)] and ρ is the number of elements in the past of x_D [cf. (2.5)]. In particular, for transitive percolation as given in Definition 2.7, the transition probabilities associated to the evolution $\mathcal{C}_n \ni C \to D \in F(C)$ given by (2.19) are given by

$$\text{Prob}(C \to D) = d^m (1+d)^{\rho-m-n}. \tag{2.20}$$

In the sequel we will have use for the measure space machinery associated to a Markov chain. To fix notation, we recall the standard constructions:

Let Ω be the collection of paths in $\mathcal{C}$. Thus, if $f \in \Omega$, then f is a function from $\mathbb{N}$ to $\mathcal{C}$ and for each $n \in \mathbb{N}$, $f(n)$ is linked to $f(n+1)$.

Given a finite collection of sets of causets, $\{A_1, A_2, \ldots, A_n\}$ with $A_j \subset \mathcal{C}_{i_j}$, we define a subset $A_{i_1,\ldots,i_n} \subset \Omega$ by

$$A_{i_1,\ldots,i_n} = \{S \in \Omega : S(i_j) \in A_j\}. \tag{2.21}$$

We call $A_{i_1,\ldots,i_n}$ the cylinder set defined by the sequence $A_1, A_2, \ldots, A_n$. We let Σ denote the sigma algebra generated by the collection of cylinder sets.

Let M be a GCD chain, $M(k)$ the state of the system at time k. Given a cylinder set $A = A_{i_1,\ldots,i_n}$, we can associate a probability to A:

$$\mathbb{P}_M(A) = \text{Prob}(M(j) \in A_j \text{ for } j = i_1, \ldots, i_n). \tag{2.22}$$

More generally, given $C \in \mathcal{C}_m$, we can regard C as an initial segment of a path generated by M (we call such an initial segment a *stem*). Given a cylinder set $A = A_{i_1,\ldots,i_n}$ we can consider starting the process at C and associate a probability to A,

$$\mathbb{P}_M^C(A) = \text{Prob}(M(j) \in A_j | M(m) = C \text{ for } j = i_1, \ldots, i_n). \tag{2.23}$$

By standard arguments, $\mathbb{P}_M^C$ extends to a probability measure on (Ω, Σ). When $D \in F(C)$ we can think of D as a cylinder set and the above convention gives

$$\mathbb{P}_M^C(D) = \text{Prob}(C \to D). \tag{2.24}$$

When $C = \{0\} \in \mathcal{C}_0$ we will, as above, drop the reference to C and write $\mathbb{P}_M^C = \mathbb{P}_M$ (*cf.* Brightwell *et*

al. (2002) for further study of this sigma algebra and measure and their invariance properties under relabeling the vertices of the causets).

Let

$$\mathcal{H} = \{f \in \Omega : f(0) \in \mathcal{C}_0, f(n+1) \in F(f(n))\}.$$

We call elements of $\mathcal{H}$ *histories* and we note that the measures constructed above charge the collection of histories. Given an element $H \in \mathcal{H}$, we can define a partial order on $\mathbb{N}$ by constructing a formal limit. More precisely, given $i, j \in \mathbb{N}$, we say that $i < j$ with respect to $\lim H$ if for all n sufficiently large, $i < j$ with respect to $H(n)$. This partial order facilitates discussion of posts:

Definition 2.8: The vertex i is a post in the history $H \in \mathcal{H}$ if every vertex $j \neq i$ satisfies $i < j$ with respect to $\lim H$ or $j < i$ with respect to $\lim H$.

Note that the sets

$$\mathcal{P}_i = \{H \in \mathcal{H} : i \text{ is a post in } H\} \tag{2.25}$$

are in the sigma algebra Σ generated by the cylinder sets. Let $\mathcal{P}_\infty$ be the event that an infinite number of posts occur. Then

$$\mathcal{P}_\infty = \cap_{n=1}^{\infty} \cup_{i=n}^{\infty} \mathcal{P}_i. \tag{2.26}$$

We note that it is a theorem of Alon, Bollobas, Brightwell, and Janson (1994) that for any transitive percolation M with associated parameter $d > 0$,

$$\mathbb{P}_M(\mathcal{P}_\infty) = 1.$$

Our goal is to extend this result to a large family of GCD chains.

III. PROOF OF THE MAIN RESULT

Suppose that $0 < x_1 < x_2 < \ldots < x_L < \infty$ and let δ_{x_i} be the delta mass concentrated at x_i. Let μ be a convex combination of the δ_{x_i}:

$$\mu = \sum_{i=1}^{L} \gamma_i \delta_{x_i}, \tag{3.1}$$

where $0 \leqslant \gamma_i \leqslant 1$ and $\Sigma_{i=1}^{L} \gamma_i = 1$. Then by Theorem 2.5 and Definition 2.7, μ represents a GCD chain.

Lemma 3.1: Let $\epsilon > 0$. Suppose that μ is as given in (3.1). Then there exists N such that for any $\overline{N} \geqslant N$, and any causet $C_{\overline{N}}$ on $\overline{N}$ elements, the probability that a post develops after time $\overline{N}$ under dynamics generated by μ, given stem $C_{\overline{N}}$, is greater than $1-\epsilon$.

Proof: Let $\epsilon > 0$ and suppose that μ is as given in (3.1). Let C_n be a causet on n elements. Let C_{n+1} be in the family of C_n and suppose that the transition $C_n \to C_{n+1}$ is characterized by m maximal elements and a precursor set of size ρ. By (2.19), under the dynamics generated by μ,

$$\mathbb{P}_\mu^{C_n}(C_{n+1}) = \frac{\sum_{i=1}^{L} \gamma_i x_i^m (1+x_i)^{\rho-m}}{\sum_{i=1}^{L} \gamma_i (1+x_i)^n}.$$

Let $\Gamma_i = (1+x_i)/(1+x_L)$. Then

$$\mathbb{P}_\mu^{C_n}(C_{n+1}) = \frac{\sum_{i=1}^{L-1} \gamma_i x_i^m (1+x_i)^{\rho-m}}{\sum_{i=1}^{L} \gamma_i (1+x_i)^n} + \frac{\mathbb{P}_{x_L}^{C_n}(C_{n+1})}{1 + \sum_{i=1}^{L-1} \frac{\gamma_i}{\gamma_L} \Gamma_i^n},$$

where $\mathbb{P}_{x_L}$ denotes probability with respect to transitive percolation with delta mass at x_L. Thus,

$$\mathbb{P}_{\mu}^{C_n}(C_{n+1}) \geqslant \mathbb{P}_{x_L}^{C_n}(C_{n+1}) \frac{1}{1+\sum_{i=1}^{L-1} \frac{\gamma_i}{\gamma_L} \Gamma_i^n}. \tag{3.2}$$

Given $C_N \in \mathcal{C}_N$, let S_{C_N} be the collection of histories with stem C_N which develop a post after time N. For $k > N$, let $S_{C_N}(k) \subset S_{C_N}$ be the collection of histories with stem C_N that develop their first post after time greater than N at vertex k. Given $N' > N$, let $S_{C_N}(k, N')$ be the cylinder set consisting of those histories which coincide with an element of $S_{C_N}(k)$ up to time N'. Thus, for $N' \geqslant k$, elements of $S_{C_N}(k, N')$ consist of histories of the form $C_N \to C_{N+1} \to \cdots \to C_{N'} \to \cdots$ where the node labeled k is ordered with respect to all other nodes in C_j, $j \leqslant k \leqslant N'$ and k is the least integer in $(N, N']$ with that property. It follows easily that

$$S_{C_N}(k) = \bigcap_{N' > N} S_{C_N}(k, N')$$

and for any GCD chain ν,

$$\mathbb{P}_{\nu}^{C_N}(S_{C_N}(k)) = \lim_{N' \to \infty} \mathbb{P}_{\nu}^{C_N}(S_{C_N}(k, N')). \tag{3.3}$$

We can write $\mathbb{P}_{\mu}^{C_N}(S_{C_N}(k, N'))$ as a sum of products:

$$\mathbb{P}_{\mu}^{C_N}(S_{C_N}(k, N')) = \sum_{S_{C_N}(k, N')} \prod_{n=N}^{N'-1} \mathbb{P}_{\mu}^{C_n}(C_{n+1}), \tag{3.4}$$

where the notation indicates that the sum is over all paths from C_N to $C_{N'}$ which develop a first post at node k, $N < k \leqslant N'$. We estimate each term in the product using (3.2). Thus,

$$\begin{aligned} \mathbb{P}_{\mu}^{C_N}(S_{C_N}(k)) &\geqslant \lim_{N' \to \infty} \sum_{S_{C_N}(k, N')} \prod_{n=N}^{N'-1} \mathbb{P}_{x_L}^{C_n}(C_{n+1}) \frac{1}{1+\sum_{i=1}^{L-1} \frac{\gamma_i}{\gamma_L} \Gamma_i^n} \\ &= \lim_{N' \to \infty} \sum_{S_{C_N}(k, N')} \left(\prod_{n=N}^{N'-1} \mathbb{P}_{x_L}^{C_n}(C_{n+1}) \right) \left(\prod_{n=N}^{N'-1} \frac{1}{1+\sum_{i=1}^{L-1} \frac{\gamma_i}{\gamma_L} \Gamma_i^n} \right). \end{aligned} \tag{3.5}$$

For $0 \leqslant z < 1$ and γ positive, the infinite product

$$\prod_{n=1}^{\infty} \frac{1}{1+\gamma z^n}$$

converges. Choose N so large that

$$\prod_{n=N}^{\infty} \frac{1}{1+\sum_{i=1}^{L-1} \frac{\gamma_i}{\gamma_L} \Gamma_i^n} \geqslant 1 - \epsilon. \tag{3.6}$$

From (3.4)–(3.6) we have for any $\overline{N} \geqslant N$, for $k > \overline{N}$ and for any causet $C_{\overline{N}}^{-} \in \mathcal{C}_{\overline{N}}^{-}$,

$$\mathbb{P}_{\mu}^{C_N}(S_{C_N^-}(k)) \geqslant (1-\epsilon) \lim_{N' \to \infty} \sum_{S_{C_N^-}(k,N')} \prod_{n=\overline{N}}^{N'-1} \mathbb{P}_{x_L}^{C_n}(C_{n+1}). \tag{3.7}$$

By (3.3) the limit on the right-hand side of (3.7) is the probability that a first post occurs at node k, given stem $C_{\overline{N}}^-$, under transitive percolation. Since identification of the first post after time $\overline{N}$ partitions $S_{C_N^-}$, we have

$$\begin{aligned}\mathbb{P}_{\mu}^{C_N}(S_{C_N^-}) &= \sum_{k \geqslant \overline{N}} \mathbb{P}_{\mu}^{C_N}(S_{C_N^-}(k)) \geqslant (1-\epsilon) \sum_{k \geqslant \overline{N}} \lim_{N' \to \infty} \sum_{S_{C_N^-}(k,N')} \prod_{n=\overline{N}}^{N'-1} \mathbb{P}_{x_L}^{C_n}(C_{n+1}) \\ &= (1-\epsilon) \sum_{k \geqslant \overline{N}} \lim_{N' \to \infty} \mathbb{P}_{x_L}^{C_N}(S_{C_N^-}(k,N')). \end{aligned} \tag{3.8}$$

It follows from the work of Alon, Bollobas, Brightwell, and Janson (1994) that the sum on the right-hand side of (3.8) is equal to one, which finishes the proof of the lemma. □

Lemma 3.2: Suppose that μ is as in (3.1) and let $\mathbb{P}_{\mu}$ be the associated probability measure. Let $\mathcal{P}_{\infty}$ be the event that an infinite number of posts occur [cf. (2.26)]. Then

$$\mathbb{P}_{\mu}(\mathcal{P}_{\infty}) = 1.$$

Proof: Let $\epsilon > 0$. As in (2.25), let $\mathcal{P}_i$ be the collection of histories which develop a post at node i. Given $C_N \in \mathcal{C}_N$, let S_{C_N} be as in the proof of Lemma 3.1. By Lemma 3.1, there exists N such that for all $\overline{N} \geqslant N$, for all histories H,

$$\mathbb{P}_{\mu}^{H(\overline{N})}(S_{H(\overline{N})}^-) \geqslant 1-\epsilon.$$

Since

$$\bigcup_{H \in \mathcal{H}} S_{H(\overline{N})}^- \subset \bigcup_{i=\overline{N}}^{\infty} \mathcal{P}_i \tag{3.9}$$

we conclude that

$$\mathbb{P}_{\mu}\left(\bigcup_{i=\overline{N}}^{\infty} \mathcal{P}_i \right) \geqslant 1-\epsilon. \tag{3.10}$$

Since ϵ was arbitrary, we conclude that for all n,

$$\mathbb{P}_{\mu}\left(\bigcup_{i=n}^{\infty} \mathcal{P}_i \right) = 1.$$

Noting that $\mathcal{P}_{\infty} = \liminf \mathcal{P}_i$ [cf. (2.26)], the proof is complete. □

The proof of Lemma 3.2 uses only the conclusion of Lemma 3.1. This being the case, we have:

Corollary 3.3: Suppose that ν is a GCD chain and let $\mathbb{P}_{\nu}$ be the associated probability measure. Suppose for every $\epsilon > 0$ there exists N such that for every $\overline{N} \geqslant N$ and every $C_{\overline{N}}^- \in \mathcal{C}_{\overline{N}}^-$, the probability that a post develops after time $\overline{N}$ under the dynamics associated to ν, given stem C_N, is greater than or equal to $(1-\epsilon)$. Let $\mathcal{P}_{\infty}$ be the event that an infinite number of posts occur. Then

$$\mathbb{P}_{\nu}(\mathcal{P}_{\infty}) = 1.$$

Proof of Theorem 1.1: Suppose that M is a compactly supported GCD chain represented by $\alpha: \mathbb{R}^+ \to \mathbb{R}$. Let $\epsilon > 0$ and write

$$c = \inf\{x : x \in \text{support}(d\alpha)\},$$

$$d = \sup\{x : x \in \text{support}(d\alpha)\}.$$

Choose a partition $I=\{x_i\}_{i=0}^{L}$, $c=x_0<x_1<\ldots,<x_L=d$ and set $\gamma_i=\alpha(x_i)-\alpha(x_{i-1})$. Then, since $d\alpha$ is a probability measure and α is nondecreasing, we have $0\leqslant\gamma_i\leqslant 1$ and $\Sigma_{i=1}^{L}\gamma_i=1$. With notation as in (3.1), let μ_I be defined by

$$\mu_I = \sum_{i=1}^{L} \gamma_i \delta_{x_i}. \tag{3.11}$$

Then μ_I is a GCD chain.

Given $C_n \in \mathcal{C}_n$ and $C_{n+1} \in F(C_n)$ we use (2.19) and we approximate

$$\mathbb{P}_M^{C_n}(C_{n+1}) = \frac{\int s^m (1+s)^{\rho-m} d\alpha}{\int (1+s)^n d\alpha} \tag{3.12}$$

by

$$\mathbb{P}_{\mu_I}^{C_n}(C_{n+1}) = \frac{\sum_{i=1}^{L} \gamma_i x_i^m (1+x_i)^{\rho-m}}{\sum_{i=1}^{L} \gamma_i (1+x_i)^n}. \tag{3.13}$$

As in the proof of Lemma 3.1, choose N so large that

$$\prod_{n=N}^{\infty} \frac{1}{1+\sum_{i=1}^{L-1} \frac{\gamma_i}{\gamma_L}\left(\frac{1+x_i}{1+d}\right)^n} \geqslant 1-\frac{\epsilon}{8}. \tag{3.14}$$

Let I' be a refinement of I, $I'=\{x_i'\}_{i=0}^{L'}$, with $x'_{L'-1}=x_{L-1}$. For $x_i' \in I'$, write $\gamma_i'=\alpha(x_i')-\alpha(x_{i-1}')$. Writing $x_{L-2}=x'_{L'-k}$, we note that for all j, $1<j\leqslant k$, $x'_{L'-j}<x'_{L'-1}$ and thus

$$\begin{aligned}
\sum_{i=L'-k+1}^{L'-1} \gamma_i' \left(\frac{1+x_i'}{1+d}\right)^n &\leqslant \sum_{i=L'-k+1}^{L'-1} \gamma_i' \left(\frac{1+x'_{L'-1}}{1+d}\right)^n \\
&= (\alpha(x'_{L'-1}) - \alpha(x'_{L'-k}))\left(\frac{1+x'_{L'-1}}{1+d}\right)^n \\
&= \gamma_{L-1}\left(\frac{1+x_{L-1}}{1+d}\right)^n.
\end{aligned}$$

Continuing inductively we conclude

$$\frac{1}{1+\sum_{i=1}^{L-1} \frac{\gamma_i}{\gamma_L}\left(\frac{1+x_i}{1+d}\right)^n} \leqslant \frac{1}{1+\sum_{i=1}^{L'-1} \frac{\gamma_i'}{\gamma_L}\left(\frac{1+x_i'}{1+d}\right)^n}. \tag{3.15}$$

Thus, the estimate (3.14) is uniform in N under refinements of the partition I which do not affect the last subinterval of the partition I. With S_{C_N}, $S_{C_N}(k)$, and $S_{C_N}(k,N')$ as defined in the proof of Lemma 3.1, we thus obtain that there exists N such that for all refinements I' of I which do not affect the last subinterval of I and all $k>N$, we have, for all $N'>k$,

$$\mathbb{P}_{\mu_{I'}}^{C_N}(S_{C_N}(k,N')) \geqslant \left(1-\frac{\epsilon}{6}\right) \sum_{S_{C_N}(k,N')} \prod_{n=N}^{N'-1} \mathbb{P}_d^{C_n}(C_{n+1}). \tag{3.16}$$

Because the sum on the right-hand side of (3.16) is $\mathbb{P}_d(S_{C_N}(k,N'))$, we have that there exists N such that for all refinements I' of I which do not affect the last subinterval of I,

$$\mathbb{P}_{\mu_{I'}}^{C_N}(S_{C_N}(k,N')) \geqslant \left(1-\frac{\epsilon}{6}\right)\mathbb{P}_d^{C_N}(S_{C_N}(k,N')) \tag{3.17}$$

for all $C_N \in \mathcal{C}_N$ and all $k>N$, all $N'>k$. Using the fact that the sets $S_{C_N}(k)$ partition S_{C_N} and that $\mathbb{P}_d^{C_N}(S_{C_N})=1$, we choose J so large that

$$\mathbb{P}_M^{C_N}(S_{C_N}) - \sum_{k=N}^{J} \mathbb{P}_M^{C_N}(S_{C_N}(k)) \leqslant \frac{\epsilon}{6}, \tag{3.18}$$

$$\sum_{k=N}^{J} \mathbb{P}_d^{C_N}(S_{C_N}(k)) \geqslant 1-\frac{\epsilon}{8}. \tag{3.19}$$

Having chosen J, choose N' so large that for all k, $N\leqslant k\leqslant J$, for all $N''\geqslant N'$,

$$\mathbb{P}_M^{C_N}(S_{C_N}(k)) - \mathbb{P}_M^{C_N}(S_{C_N}(k,N'')) \leqslant \frac{\epsilon}{6(J-N)}, \tag{3.20}$$

$$\sum_{k=N}^{J} \mathbb{P}_d^{C_N}(S_{C_N}(k,N'')) \geqslant 1-\frac{\epsilon}{6}. \tag{3.21}$$

Now suppose that d is an isolated point of support and choose an open interval $\mathcal{I}$ containing d such that $(\mathcal{I}\backslash\{d\})\cap \text{support}(d\alpha)$ is empty. Choose a partition I which includes a single point in $\mathcal{I}\backslash\{d\}$. Then, by the above, there exists N such that for all $C_N \in \mathcal{C}_N$, for all $k>N$, for all J and all N' large enough, and all partitions I' refining I, (3.17)–(3.21) hold.

Having chosen J and N' as above, note that under refinement (3.13) converges to (3.12). Choose a refinement I' such that for all k, $N\leqslant k\leqslant J$,

$$|\mathbb{P}_M^{C_N}(S_{C_N}(k,N')) - \mathbb{P}_{\mu_{I'}}^{C_N}(S_{C_N}(k,N'))| \leqslant \frac{\epsilon}{6(J-N)}. \tag{3.22}$$

Then

$$\begin{aligned}\mathbb{P}_M^{C_N}(S_{C_N}) &= \left(\mathbb{P}_M^{C_N}(S_{C_N}) - \sum_{k=N}^{J} \mathbb{P}_M^{C_N}(S_{C_N}(k))\right) + \left(\sum_{k=N}^{J} \mathbb{P}_M^{C_N}(S_{C_N}(k)) - \sum_{k=N}^{J} \mathbb{P}_M^{C_N}(S_{C_N}(k,N'))\right) \\ &\quad + \left(\sum_{k=N}^{J} \mathbb{P}_M^{C_N}(S_{C_N}(k,N')) - \sum_{k=N}^{J} \mathbb{P}_{\mu_{I'}}^{C_N}(S_{C_N}(k,N'))\right) + \sum_{k=N}^{J} \mathbb{P}_{\mu_{I'}}^{C_N}(S_{C_N}(k,N')) \\ &= T_1 + T_2 + T_3 + \sum_{k=N}^{J} \mathbb{P}_{\mu_{I'}}^{C_N}(S_{C_N}(k,N')).\end{aligned}$$

Using (3.18) we see that $|T_1|<\epsilon/6$. Using (3.20) we see that $|T_2|<\epsilon/6$. Using (3.22) we see that $|T_3|<\epsilon/6$. Thus,

$$\mathbb{P}_M^{C_N}(S_{C_N}) \geqslant \sum_{k=N}^{J} \mathbb{P}_{\mu_{I'}}^{C_N}(S_{C_N}(k,N')) - \frac{\epsilon}{2}.$$

Using (3.17) we conclude

$$\mathbb{P}_M^{C_N}(S_{C_N}) \geqslant \left(1 - \frac{\epsilon}{6}\right) \sum_{k=N}^{J} \mathbb{P}_d^{C_N}(S_{C_N}(k,N')) - \frac{\epsilon}{2}. \tag{3.23}$$

From (3.21) and (3.23), we conclude

$$\mathbb{P}_M^{C_N}(S_{C_N}) \geqslant \left(1 - \frac{\epsilon}{6}\right)\left(1 - \frac{\epsilon}{6}\right) - \frac{\epsilon}{2} \geqslant (1 - \epsilon).$$

Thus, we have proven that there exists N such that for all $C_N \in \mathcal{C}_N$, given stem C_N, a post develops after time N under the dynamics generated by M with probability one. From our proof it is clear that for any $\overline{N} \geqslant N$, for any $C_{\overline{N}} \in \mathcal{C}_{\overline{N}}$, the probability that a post develops after time $\overline{N}$ under the dynamics generated by M, given stem $C_{\overline{N}}$, is one. Given Corollary 3.3, this proves the theorem.

IV. RENORMALIZATION FLOW

In this section we study the behavior of sequences of coupling constants associated to systems described in Sec. II. In particular, we study the asymptotic behavior of such sequences under the repeated action of the operator $\mathcal{R}$ (the so-called renormalization flow). We show that in the limit of large time, the transition probabilities approach those of a transitive percolation.

Theorem 4.1: *Suppose that $T \in \mathcal{S}_1$ defines the coupling constants for a GCD chain. Let $\alpha: \mathbb{R}^+ \to \mathbb{R}$ be a nondecreasing function representing T as in (2.16). Suppose that $\{q_n\}_{n=0}^{\infty}$ are the defining probabilities given in (2.9). Then*

(1) *If the support of the measure $d\alpha$ is compact with*

$$t = \sup\{x : x \in \text{support}(d\alpha)\}, \tag{4.1}$$

then

$$\lim_{m\to\infty} \frac{q_{m+n}}{q_m} = \frac{1}{(1+t)^n}. \tag{4.2}$$

(2) *If the support of the measure $d\alpha$ is not compact, then*

$$\lim_{m\to\infty} \frac{q_{m+n}}{q_m} = \begin{cases} 1 & \text{if } n = 0 \\ 0 & \text{if } n \neq 0. \end{cases} \tag{4.3}$$

Proof: We denote by $L^q(\mathbb{R}^+, d\alpha)$ the Banach space with norm

$$\|f\|_q = \left(\int_0^{\infty} f^q d\alpha\right)^{1/q}.$$

Since $d\alpha$ is a probability measure, the function $g(x) = 1$ is in $L^q(\mathbb{R}^+, d\alpha)$ for all q. Let k be positive, $m > k$. Let q be defined by

$$\frac{1}{q} + \frac{k}{m} = 1.$$

By Hölder's inequality,

$$\|(1+s)\|_k \leqslant \|(1+s)\|_m. \tag{4.4}$$

Since α is nondecreasing and the function $(1+s)^k$ is continuous and strictly increasing on $\mathbb{R}^+$, there is a unique positive real number τ_k such that

$$\int_0^\infty (1+s)^k d\alpha = (1+\tau_k)^k. \tag{4.5}$$

From (4.4) and (4.5), the sequence $\{\tau_k\}$ is increasing.

Suppose that the support of the measure $d\alpha$ is compact with t as in (4.1). Suppose $\lim_{k\to\infty} \tau_k = \tau_*$ with $\tau_* < t$. Choose τ^* satisfying $\tau_* < \tau^* < t$. Then

$$\int_0^\infty (1+s)^k d\alpha = \int_0^{\tau^*} (1+s)^k d\alpha + \int_{\tau^*}^t (1+s)^k d\alpha.$$

As in (4.5) we can find unique $\mu_k \in [0, \tau^*)$ and $\nu_k \in [\tau^*, t]$ such that

$$\int_0^\infty (1+s)^k d\alpha = (1+\mu_k)^k \int_0^{\tau^*} d\alpha + (1+\nu_k)^k \int_{\tau^*}^t d\alpha.$$

By the argument used to establish that the τ_k are increasing, we have that the μ_k and the ν_k are increasing. By assumption, $d\alpha$ is supported near t and thus, $\int_{\tau^*}^t d\alpha \neq 0$ and, for k large enough and ϵ small enough, $\nu_k \geqslant \tau^* + \epsilon$. From this we conclude that $\int_0^\infty (1+s)^k d\alpha$ is, for large k, at least of the order of $(1+\tau^*+\epsilon)^k$, contradicting (4.5) and the choice of τ^*. We conclude that $\tau_* = t$, which proves the first claim of the theorem.

To prove the second claim of the theorem, note that either the sequence $\{\tau_k\}$ converges to a real number or it does not. If it does not converge to a real number, then it converges to ∞, and we are done. If we assume that it does converge to a real number, the construction of the sequences μ_k and ν_k lead to a contradiction. □

Wyman's solution, self-similarity, and critical behavior

G. Oliveira-Neto[a] and F. I. Takakura[b]

(Received 10 February 2005; accepted 30 March 2005; published online 24 May 2005)

The Wyman solution depends on two parameters, the mass M and the scalar charge Σ. If one fixes M to a positive value, say M_0, and lets Σ^2 take values along the real line, we show that this solution exhibits a type of critical behavior, in analogy with the nonstatic massless scalar field solutions. For $\Sigma^2>0$ the space-times have naked singularities, for $\Sigma^2=0$ one has a Schwarzschild black hole of mass M_0 and finally for $-M_0^2\leqslant\Sigma^2<0$ one has "wormhole-like" solutions. We also show that the Wyman solution is not self-similar, i.e., it does not admit a homothetic Killing vector. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1920308]

I. INTRODUCTION

The four-dimensional space-time generated by a minimally coupled, spherically symmetric, static, massless scalar field has been studied by many authors.[1–5] The general solution was found by Wyman in Ref. 2. From a particular case of the general Wyman's solution, Roberts showed how to construct a time-dependent solution.[3] The Roberts' solution has an important physical interest because it may represent the gravitational collapse of a scalar field. Later, Brady, and independently Oshiro *et al.*,[6] showed that Roberts' solution could be derived from the appropriated, time-dependent, Einstein-scalar equations by using a continuous self-similarity. They also showed that the Roberts' solution exhibits a critical behavior qualitatively identical to the one found numerically by Choptuik,[7] studying the same system of equations.

Using a discrete self-similarity of the system, Choptuik explicitly showed that the collapse results in two families of solutions depending on the value of a certain parameter p, which characterizes the scalar charge. In the first family, when $p<p_c$, the scalar field collapses up to a certain surface and then disperses. In the other family, when $p>p_c$, the scalar field collapses to form a black hole. The critical value p_c separates the two end states of the collapse. The critical solution ($p=p_c$) represents a naked singularity. Therefore, since it is given by a single value of the parameter, it has zero measure in the parameter space. In fact, the above results confirmed early studies of Christodoulou, who pioneered analytical studies of that model.[8]

The Wyman solution is not usually thought to be of great importance for the issue of gravitational collapse because it is static and the naked singularities derived from it are unstable against spherically symmetric linear perturbations of the system.[4,5] On the other hand, as we saw above, from a particular case of the Wyman solution one may derive the Roberts' one, which is of great importance for the issue of gravitational collapse. Also, it was shown that there are nakedly singular solutions to the static, massive scalar field equations which are stable against spherically symmetric linear perturbations.[5] Therefore, we think it is of great importance to gather as much information as we can about the Wyman solution for it may be helpful to better understand the scalar field collapse.

Self-similarity is an important symmetry that has been extensively used in order to study Einstein's equations describing the gravitational collapse. As was mentioned above, Roberts'

[a]Electronic mail: gilneto@fisica.ufjf.br
[b]Electronic mail: takakura@fisica.ufjf.br

solution admits a homothetic Killing vector; one may wonder if the Wyman solution also has this property. In the present work, we would like to show that the Wyman solution is not self-similar, i.e., it does not admit a homothetic Killing vector.

Wyman's solution depends on two parameters, the mass M and the scalar charge Σ. As we have seen above, Choptuik found a critical behavior in the solutions to the Einstein-scalar equations in terms of the parameter describing the scalar charge. Therefore, one may try to find critical behavior in Wyman's solution by fixing M and letting Σ vary. We would like to show that, if one fixes M to a positive value, say M_0, and let Σ^2 take values along the real line, this solution exhibits a type of critical behavior, in analogy with the nonstatic massless scalar field solutions.

In Sec. II, we demonstrate that the Wyman's solution is not self-similar, or, in other words, it does not admit a homothetic Killing vector.

In Sec. III, we show that Wyman's solution exhibits a type of critical behavior, in analogy with the nonstatic massless scalar field solutions.

Finally, in Sec. IV, we summarize the main points and results of the paper.

II. WYMAN'S SOLUTION AND CONTINUOUS SELF-SIMILARITY

In the present paper we work with the double-null coordinates (u,v); therefore, our starting point is Wyman's line element given in Eq. (14) of Ref. 3

$$ds^2 = -\left(1-\frac{2\eta}{r}\right)^{M/\eta} dv\, du + \left(1-\frac{2\eta}{r}\right)^{1-M/\eta} r^2 d\Omega^2, \tag{1}$$

where M is the mass parameter, $\eta^2 = M^2 + \Sigma^2$, and Σ is the scalar charge. The function $r(v,u)$ may be obtained if we integrate the following equation:

$$dv - du = 2\left(1-\frac{2\eta}{r}\right)^{-M/\eta} dr. \tag{2}$$

The above equation was derived by combining Eq. (10) of Ref. 3 with the analogous one for the coordinate u, for advanced null coordinates.

Let us now demonstrate that the Wyman solution is not self-similar, or, in other words, it does not admit a homothetic Killing vector. In order to do that, we start writing the most general form of a "radial" homothetic Killing vector for a spherically symmetric space-time in double null coordinates

$$\xi^a = \xi^v \delta^a_v + \xi^u \delta^a_u, \tag{3}$$

where ξ^v and ξ^u are both functions of v and u. Now, the condition for self-similarity is given by the equation $\mathcal{L}_\xi g = a_0 g$, where $\mathcal{L}_\xi$ denotes the Lie derivative with respect to ξ, g is the space-time metric, ξ is a vector field, and a_0 is a real constant. This last equation may, equivalently, be written in the following way:

$$\xi_{a;b} + \xi_{b;a} = a_0 g_{ab}, \tag{4}$$

where [;] means covariant differentiation.

With the aid of Eqs. (1)–(3), the condition (4) leads us to the following set of equations:

$$r_{,v}\xi^v + r_{,u}\xi^u = \frac{a_0}{2}\frac{r^2(1-2\eta/r)}{r-M-\eta}, \tag{5}$$

$$\xi^v{}_{,v} + \xi^u{}_{,u} + \frac{2M}{r^2(1-2\eta/r)}(r_{,v}\xi^v + r_{,u}\xi^u) = a_0, \tag{6}$$

$$\xi^u{}_{,v} = 0, \tag{7}$$

$$\xi^{v}{}_{,u} = 0. \tag{8}$$

The solutions to Eqs. (7) and (8) are, respectively

$$\xi^{v} = \xi^{v}(v) \text{ and } \xi^{u} = \xi^{u}(u), \tag{9}$$

where ξ^{v} depends only on v, and ξ^{u} depends only on u.

Now, introducing the right-hand side of Eq. (5) in Eq. (6), we may write

$$\xi^{v}{}_{,v} + \xi^{u}{}_{,u} = a_0 \frac{r - 2M - \eta}{r - M - \eta}. \tag{10}$$

We may obtain independently the expressions for $\xi^{v}{}_{,v}$ and $\xi^{u}{}_{,u}$ and introduce them in the left-hand side of Eq. (10). The resulting equation should be an identity, if the system of Eqs. (5)–(8) admits the solutions given in Eq. (9).

In order to obtain $\xi^{v}{}_{,v}$ and $\xi^{u}{}_{,u}$, we start using Eq. (2) to find

$$r_{,v} = \frac{1}{2}\left(1 - \frac{2\eta}{r}\right)^{M/\eta} = -r_{,u}. \tag{11}$$

Now, we introduce both values of $r_{,v}$ and $r_{,u}$ of Eq. (11) in Eq. (5) and write

$$\xi^{v} - \xi^{u} = a_0 \frac{r^2}{r - M - \eta}\left(1 - \frac{2\eta}{r}\right)^{1-(M/\eta)}. \tag{12}$$

Then, we may differentiate Eq. (12) with respect to v and, using the information from Eq. (9), we derive the following expression for $\xi^{v}{}_{,v}$:

$$\xi^{v}{}_{,v} = a_0 \frac{r_{,v}}{(r - M - \eta)^2} \frac{1}{(1 - 2\eta/r)^{M/\eta}} (r^2 - 4Mr - 2\eta r + 4M\eta + 2\eta^2 + 2M^2). \tag{13}$$

Proceeding in an analogous manner, we derive the following expression for $\xi^{u}{}_{,u}$:

$$\xi^{u}{}_{,u} = -a_0 \frac{r_{,u}}{(r - M - \eta)^2} \frac{1}{(1 - 2\eta/r)^{M/\eta}} (r^2 - 4Mr - 2\eta r + 4M\eta + 2\eta^2 + 2M^2). \tag{14}$$

Finally, introducing the values of $\xi^{v}{}_{,v}$ and $\xi^{u}{}_{,u}$ coming, respectively, from Eqs. (13) and (14) in the left-hand side of Eq. (10), we find

$$-Mr + M\eta + \eta^2 = 0. \tag{15}$$

This equation is not an identity; therefore, we may conclude that there are no self-similar solutions for the system (5)–(8). In fact, this result was expected since the case $\Sigma = 0$ is the Schwarzschild space-time,[3] which is not a self-similar solution.

III. WYMAN'S SOLUTION AND CRITICAL BEHAVIOR

Depending on the value of the parameters M and Σ, Wyman's solution may represent different static, asymptotically flat space-times.[1,3] When one sets $\Sigma = 0$, the scalar field (Φ) vanishes, as can be seen from Eq. (9) of Ref. 3

$$\Phi = \frac{\Sigma}{2\eta} \ln\left(1 - \frac{2\eta}{r}\right), \tag{16}$$

and one obtains the Schwarzschild solution with a mass M. Therefore, it is usual to consider M positive. It is important to introduce the function R

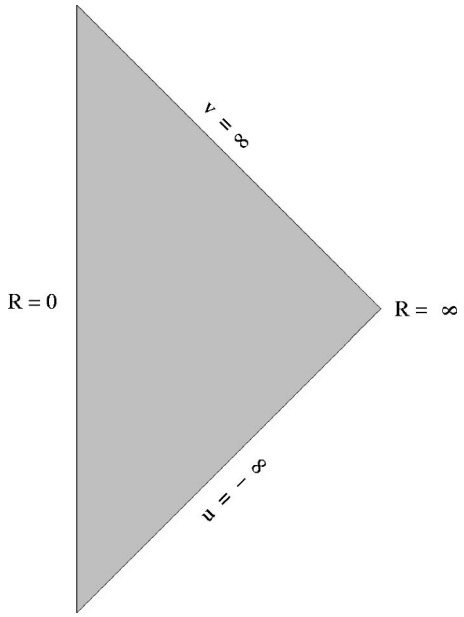

FIG. 1. Conformal diagram for a typical element of the set N. The time-like singularity lies at $R=0$ and spatial infinity at $R\to\infty$ $(v-u\to\infty)$.

$$R^2=\left(1-\frac{2\eta}{r}\right)^{1-M/\eta}r^2, \tag{17}$$

which is a function of r and, from Eq. (1), the quantity $4\pi R^2$ represents the proper area of each two-dimensional sphere obtained by fixing t and r. R can be written as a function of v and u with the aid of r, which is a function of v and u; $r(u,v)$ is obtained by the integration of Eq. (2).

For positive M one may let Σ^2 take values over the real line. For $\Sigma^2>0$, the solution represents space-times with a naked time-like singularity located at $R=0$ $(r=2\eta)$. This singularity is sometimes called a "central singularity" and is similar to that appearing in the "extreme" Reissner–Nordstrøm black hole and in the negative mass Schwarzschild space-time (see Fig. 1). From Eq. (16), the scalar field vanishes asymptotically, $R\to\infty$ (which is equivalent to $r\to\infty$ in the present case), and diverges at the singularity. For $\Sigma^2<0$, one considers the domain: $-M^2\leqslant\Sigma^2<0$, because if $\Sigma^2<-M^2$ from Eq. (1) the metric gets complex. The case $\Sigma^2=-M^2$ is well known in the literature as the Yilmaz–Rosen space-time.[9] In the space-times with $-M^2\leqslant\Sigma^2<0$, R is never zero. If one starts with a large value of R it diminishes, as we let it vary as a function of r, until it reaches a minimum value $\{R_{\min}=[(M-\eta)/(M+\eta)]^{1-M/\eta}(M+\eta)^2\}$. Then, it starts to increase again without limit, giving rise to a new asymptotically flat region. An important property of this space-time is that the scalar field equation (16) is imaginary. The imaginary scalar field also known as the ghost Klein–Gordon field[10] is an example of the type of matter called *exotic* by some authors.[11] It violates most of the energy conditions and is repulsive. This property helps explain why the collapsing scalar field never reaches $R=0$. Recently, the exotic matter has been in evidence due to the discovery that the universe is expanding at an accelerated rate.[12] This implies that the universe must be filled with matter which violates at least the strong energy condition.[12] This is the type of matter associated with the formation and stability of traversible wormholes.[11,13] In particular, the ghost Klein–Gordon field has been used as one of the first specific *exotic* matter models to explain the formation and stability of traversible wormholes.[10] Besides the above motivations for the use of *exotic* matter, which involve classical fields, one must not forget about the negative energy densities very common in quantum field theories.[14] We may interpret this case $-M^2\leqslant\Sigma^2<0$ as a "wormhole-like" solution.

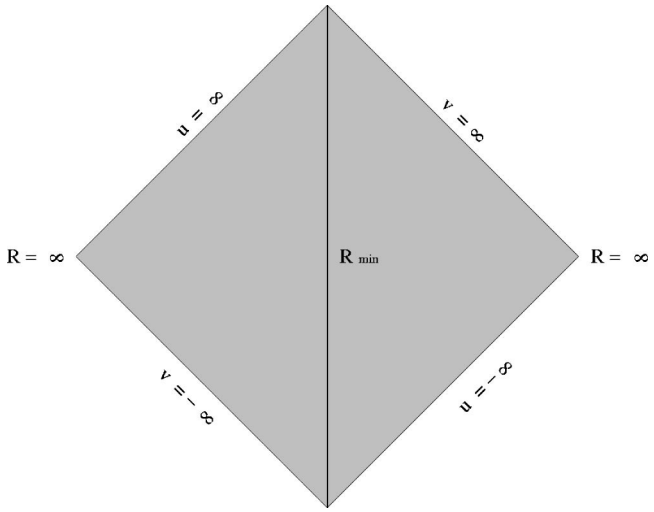

FIG. 2. Conformal diagram for a typical element of the set W. The $R_{\min}$, which may be identified as the wormhole throat, and the two spatial infinities $R\to\infty$ ($v-u\to\infty$ and $v-u\to-\infty$), one for each asymptotically flat region, are shown.

Based on the above properties of Wyman's solution, and taking in account the results of Refs. 6–8, on critical behavior in the spherical symmetric, massless, scalar field collapse, we conclude that Wyman's solution also shows a type of critical behavior, in analogy with the nonstatic massless scalar field solutions. Although the critical solution is of a different kind from the one discovered in the above-mentioned references, one may proceed here in the same way as the authors there, in order to show the critical behavior. One fixes the mass parameter M and considers the scalar charge Σ as the only free parameter. In the present case, as discussed above, we fix M to a positive value, say M_0. Σ^2 may take values in the domain, $(-M_0^2,\infty)$. For Σ^2 positive ($0<\Sigma^2<\infty$), we have a set (N) of solutions representing asymptotically flat, time-like, naked singularities. We show the conformal diagram of a typical element of the set N in Fig. 1. For Σ^2 negative ($-M_0^2<\Sigma^2<0$), we have a set (W) of solutions representing asymptotically flat, wormhole-like space-times. Figure 2 shows the conformal diagram of a typical element of the set W. Finally, for $\Sigma^2=0$, we obtain the critical solution. For fixed M this solution is a point in the parameter space of solutions and represents the Schwarzschild black hole with mass M_0.

IV. CONCLUSIONS

In the present work, we showed that the Wyman's solution is not self-similar or, in other words, it does not admit a homothetic Killing vector. We also showed that Wyman's solution exhibits a type of critical behavior in analogy with the dynamical massless scalar field case. We did that by fixing the mass M to a positive value, say M_0, and letting Σ^2 takes values along the real line. For $\Sigma^2>0$ the space-times have naked singularities; for $\Sigma^2=0$ one has a Schwarzschild black hole of mass M_0, and finally for $-M_0^2\leqslant\Sigma^2<0$ one has wormhole-like solutions. Here, the critical solution is a Schwarzschild black hole. Although this behavior is very different from the one discovered by Choptuik, one may have other kinds of critical solutions in the Einstein-scalar system, as demonstrated by Brady in Ref. 15.

An exact solution of the five-dimensional Einstein equations with four-dimensional de Sitter-like expansion

Tomáš Liko[a] and Paul S. Wesson[b]
Department of Physics, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1

(Received 25 February 2005; accepted 13 April 2005; published online 1 June 2005)

We present an exact solution to the Einstein field equations which is Ricci and Riemann flat in five dimensions, but in four dimensions is a good model for the early vacuum-dominated universe. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1926168]

I. INTRODUCTION

There has recently been an uprising in interest in finding exact solutions of the Kaluza–Klein field equations in five dimensions (5D) which reproduce and extend known solutions of the Einstein field equations in four dimensions (4D).[1–5] Particular interest revolves around solutions which are not only Ricci flat ($R_{AB}=0; A,B,\ldots\in\{0,1,2,3,4\}$ where R_{AB} is the 5D Ricci tensor), but also Riemann flat ($R_{ABCD}=0$, where the vanishing of the Riemann–Christoffel tensor means that we are considering the analog of the Minkowski metric in 5D).[6–11] This is because it is possible to have a flat 5D manifold which contains a curved 4D submanifold, as implied by Campbell's embedding theorem.[12–18] So, the universe may be "empty" and simple in 5D, but contain matter of complicated forms in 4D.[19,20] (This idea has been extended to higher-dimensional manifolds that are not Ricci flat, in particular manifolds with nonzero cosmological constant,[21,22] scalar field sources,[23] as well as manifolds with an arbitrary nondegenerate Ricci tensor.[24] In addition, the Campbell–Magaard theorem has been used to study the embedding of Randall–Sundrum-type branes in 5D manifolds,[25] suggesting that the curvature of any given brane is not necessarily determined by its stress-energy content.)

Despite the physical appeal of this idea, it is mathematically nontrivial to realize. This is because solutions of the flat and empty Einstein equations in 5D which correspond to solutions of $G_{\alpha\beta}=T_{\alpha\beta}(\alpha,\beta,\ldots\in\{0,1,2,3\})$ in 4D with acceptable physics, are rare. (Here $G_{\alpha\beta}$ is the 4D Einstein tensor and $T_{\alpha\beta}$ is the induced stress-energy tensor obtained via the standard reduction of the 5D equations to their 4D counterparts; see Ref. 20. We use units throughout which render the speed of light and Newton's gravitational constant invisible via $c=1, 8\pi G=1$.) In what follows, we present and derive the properties of an exact 5D solution which provides a good 4D model for the vacuum-dominated early universe.

II. A NEW SOLUTION AND ITS PROPERTIES

Consider the five-dimensional line element with coordinates t, r, θ, ϕ, ℓ such that

$$dS^2 = \frac{\ell^2}{L^2}dt^2 - \left[\ell \sinh\left(\frac{t}{L}\right)\right]^2 d\sigma_3^2 - d\ell^2$$

[a]Electronic mail: tliko@astro.uwaterloo.ca
[b]Tel: (519) 885-1211 ext. 2215; fax: (519) 746-8115; Webpage: http://astro.uwaterloo.ca/~wesson

$$\mathrm{d}\sigma_3^2 = \left(1 + \frac{kr^2}{4}\right)^{-2} (\mathrm{d}r^2 + r^2\,\mathrm{d}\theta^2 + r^2 \sin^2\theta\,\mathrm{d}\phi^2) \quad \text{and } k = -1. \tag{1}$$

In five dimensions this defines a manifold $(\mathcal{M}, g_{AB})$ that is indeed both Ricci flat and Riemann flat, thus giving Minkowski space $\mathbb{M}^5$ in a different coordinate system. That (1) satisfies the Ricci-flat equations $R_{AB}=0$ may be shown by tedious algebra (e.g., using the equations of Ref. 20), and confirmed by computer (e.g., using the program GRTensor of Ref. 26). The only humanly practical way to show that (1) also satisfies the Riemann-flat equations $R_{ABCD}=0$ is by computer, as may be verified.

The physical properties of the matter associated with (1) may, again, be derived either analytically or computationally. The basic procedure, in either approach, is to separate the purely 4D terms in $R_{AB}=0$ from the other ones, compare with $G_{\alpha\beta}=T_{\alpha\beta}$, and thereby obtain $T_{\alpha\beta} = T_{\alpha\beta}(x^4, \partial g_{AB}/\partial x^C)$. Since the Einstein equations $G_{AB}=0$ in empty 5D are equivalent to $R_{AB}=0$ by straight algebra, what we are doing here is simply solving in effect the 5D Einstein equations, comparing the results to the 4D Einstein equations, and thereby evaluating the stress-energy tensor $T_{\alpha\beta}$ necessary to balance the latter set of equations.

This procedure has in recent years been much used. A review of the algebraic technique and a list of applications is available.[20] Here we note that the procedure has been applied to cosmologies of the Friedmann–Robertson–Walker (FRW) type,[27] 3D spherically symmetric solutions,[28] solutions with off-diagonal metrics,[29] Gödel-type space–times,[30] and solutions containing a big bounce.[31–35] General theorems have also been proven, having to do with the field equations,[36] dynamics[37] and the algebraic classification of 5D solutions with their associated 4D stress-energy tensors.[38] However, there is the constraint that the $T_{\alpha\beta}$ given by algebra should correspond to the properties of matter indicated by observational cosmology. For the early universe, this means that the equation of state for the matter should be close to that of the "classical vacuum." Here, the sum of the density ρ and pressure p is zero, as in inflationary cosmology.[39] We now proceed to this and other consequences of metric (1), to investigate its physical acceptability.

The line element (1) can be written in the useful "canonical" form[40] such that

$$\mathrm{d}S^2 = \frac{\ell^2}{L^2}\left[\mathrm{d}t^2 - \left[L \sinh\left(\frac{t}{L}\right)\right]^2 \mathrm{d}\sigma_3^2\right] - \mathrm{d}\ell^2. \tag{2}$$

So with the 4D space–time metric

$$\begin{gathered} g_{\alpha\beta} = \mathrm{diag}[1, -\mathcal{F}_k(t,r), -r^2\mathcal{F}_k(t,r), -r^2\sin^2\theta\mathcal{F}_k(t,r)], \\ \mathcal{F}_k(t,r) = \left[L \sinh\left(\frac{t}{L}\right)\right]^2 \left(1 + \frac{kr^2}{4}\right)^{-2}, \end{gathered} \tag{3}$$

we find the components of the stress-energy tensor $T_{\alpha\beta}=G_{\alpha\beta}$ to be $T_0^0=3/L^2, T_1^1=T_2^2=T_3^3=3/L^2$. In comoving coordinates this defines an energy density $\rho=T_0^0=3/L^2$ and pressure $p=-(T_1^1+T_2^2+T_3^3)/3=-3/L^2$ for a vacuum with cosmological constant $\Lambda=3/L^2$ and equation of state $\rho+p=0$. The 4D Ricci scalar is $R=R_{\alpha\beta}g^{\alpha\beta}=12/L^2$, and the 4D curvature scalar is $K=R_{\alpha\beta\gamma\delta}R^{\alpha\beta\gamma\delta}=24/L^4$. This latter scalar implies that there are no singularities in the manifold because the constant $L \neq 0$.

Let us now look at (1), viewing its 4D part as describing an FRW model. The 4D hypersurfaces $\ell=$constant therefore describe cosmologies with scale factor given by $\mathcal{S}=\mathcal{S}(t)=L\sinh(t/L)$. Here the Hubble parameter $H \equiv \dot{\mathcal{S}}/\mathcal{S}$ and deceleration parameter $q \equiv -\mathcal{S}\ddot{\mathcal{S}}/\dot{\mathcal{S}}^2$ (with $\dot{\mathcal{S}}=\mathrm{d}\mathcal{S}/\mathrm{d}t$) are found to be

$$H = \frac{1}{L \tanh\left(\frac{t}{L}\right)} \quad \text{and} \quad q = -\tanh^2\left(\frac{t}{L}\right). \tag{4}$$

We note that H is infinite at $t=0$ and goes to $1/L=\sqrt{\Lambda/3}$ as $t\to\infty$, which is the Hubble parameter for de Sitter space–time. Also, q starts at zero when $t=0$ and goes to -1 for $t\to\infty$. This is in line with astrophysical data which currently constrain the deceleration parameter to $-1\leqslant q\leqslant 1$. Thus we conclude that our solution (1) describes an inflationary space–time on $\ell=$constant hypersurfaces, where the vacuum has repulsive properties.

The preceding paragraphs show that (1) has physical properties consistent with those of inflationary cosmology. However, the motivating factor for the latter approach to cosmology is that the (4D) horizon should grow fast enough to resolve certain problems of astrophysical nature, primarily to do with the 3 Kelvin microwave background.[41,42] First, we recall that the horizon distance at time t for any FRW model can be defined[43] such that

$$\int_r^0 \mathrm{d}r\left(1+\frac{kr^2}{4}\right)^{-1} = \int_0^t \frac{\mathrm{d}t'}{\mathcal{S}(t')}. \tag{5}$$

Multiplying both sides by the scale factor $\mathcal{S}(t)$ then gives

$$d_{PH} = \mathcal{S}(t)\int_r^0 \mathrm{d}r\left(1+\frac{kr^2}{4}\right)^{-1} = \mathcal{S}(t)\int_0^t \frac{\mathrm{d}t'}{\mathcal{S}(t')}, \tag{6}$$

which defines the proper distance to the particle horizon at time t. For the space–time (3) this is

$$d_{PH} = 2L\sinh\left(\frac{t}{L}\right)\left[\operatorname{arctanh}(1) - \operatorname{arctanh}\left(\exp\left(\frac{t}{L}\right)\right)\right]. \tag{7}$$

Here we see that d_{PH} is infinite because arctanh(1) is infinite. This means that during the inflationary period that the solution (1) describes on $\ell=$constant hypersurfaces, the entire universe is in causal contact. This is in line with the apparent isotropy of the microwave background.

Finally, we would like to point out an interesting coordinate transformation of the solution (1). Recall that $\sinh(t)=(\exp(t)-\exp(-t))/2$, which with the coordinate change $t\to tL$ in (1) gives

$$\mathrm{d}S^2 = \ell^2\,\mathrm{d}t^2 - \frac{1}{4}\ell^2(e^t+ke^{-t})^2\,\mathrm{d}\sigma_3^2 - \mathrm{d}\ell^2 \quad \text{with } k=-1. \tag{8}$$

This form of the metric resembles a solution noted by McManus.[9] For the solution (8), all 4D physical quantities are the same as those calculated for the solution (1), but with the replacement $L\to\ell$. The 4D space–time contained in (8) therefore still describes an inflationary vacuum with equation of state $\rho+p=0$. An important difference is that the 4D curvature scalar for (8) is $K=24/\ell^4$, which implies that the space–time in (8) has a singularity at the point where $\ell=0$. This is in contrast to the solution (1), for which all physical quantities of spacetime were calculated to be (finite) constants. Evidently the simple coordinate transformation $t\to tL$ casts (1) into a form where the vacuum evolves in accordance with how $x^4=\ell$ is determined by the extra component of the geodesic equation. This issue from the mathematical side has to do with whether we take the whole of the 4D part of the 5D manifold as defining the geometry of space–time, or whether we take the 4D part of the 5D manifold without its prefactor. This 5D issue resembles the 4D one in scalar-tensor theory, where it manifests itself as a choice between what are commonly called the Jordan and Einstein frames. From the physical side, the choice has to do with how we define space–time as a 4D slice of a 5D manifold; and we suggest that since the two choices only become differentiated over cosmological time scales, that it is essentially one of observation to decide.

Dixon's multipoles for a system of N relativistic positive-energy scalar particles are evaluated in the rest-frame instant form of dynamics. The Wigner hyperplanes (intrinsic rest frame of the isolated system) turn out to be the natural framework for describing multipole kinematics. Classical concepts like the *barycentric tensor of inertia* turn out to be extensible to special relativity only by means of the quadrupole moments of the isolated system. Two new applications of the multipole technique are worked out for systems of interacting particles and fields. In the rest frame of the isolated system of either free or interacting positive energy particles it is possible to define a unique world line which embodies the properties of the most relevant centroids introduced in the literature as candidates for the collective motion of the system. This is no longer true, however, in the case of open subsystems of the isolated system. While effective mass, 3-momentum and angular momentum in the rest frame can be calculated from the definition of the *subsystem energy-momentum tensor*, the definitions of effective center of motion and effective intrinsic spin of the subsystem are not unique. Actually, each of the previously considered centroids corresponds to a different world line in the case of open systems. The pole–dipole description of open subsystems is compared to their description as effective extended objects. Hopefully, the technique developed here could be instrumental for the relativistic treatment of binary star systems in metric gravity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897841]

I. INTRODUCTION

An important area of research is nowadays the construction of templates for gravitational waves emitted by binary systems. Analytically, this can be done within the framework of post-Newtonian (PN) approximations by means of essentially nonrelativistic multipole expansions for compact bodies. On the other hand, since the main emission are supposed to take place in a region where the PN approximation fails, it would be desirable to have at disposal a relativistic treatment of multipolar expansions as a preliminary kinematical tool for dealing with open gravitating systems. This paper focuses just on the construction of a suitable relativistic kinematical background by exploiting an N-body system as a tool. A preliminary extension of the results of this paper to special relativistic perfect fluids is given in Ref. 1. Then using the framework of the

[a)]Electronic mail: alba@fi.infn.it
[b)]Electronic mail: lusanna@fi.infn.it
[c)]Electronic mail: pauri@pr.infn.it

rest-frame instant form of tetrad gravity developed in Refs. 2,3, the relativistic perfect fluids will be coupled to tetrad gravity and the relativistic multipolar expansion will be used in the weak field Hamiltonian linearization[3] leading to background-independent gravitational waves.[4]

The description of either extended or point-particle classical relativistic systems by means of multipolar expansions both in special and general relativity began at the end of the 1930s[5–10] and after many developments[11–19] was set in a final form by Dixon. His special[20] and general[21] relativistic formulation has been the reference standard for recent improvements.[22–24] Then, because of the difficulties in actual evaluations of general relativistic multipoles,[21] the studies of gravitational radiation in the PN regime led to the introduction of the more manageable irreducible symmetric trace-free Cartesian tensors (STF tensors).[25–28]

The multipolar expansion has been mainly used to make *pole–dipole* approximations of extended objects and to replace their equations of motion with the Papapetrou–Dixon–Souriau equations of motion[11,20–22,24] for the 4-momentum and the spin tensor of the objects. However, since in all these approaches the multipoles are defined as moments of the energy-momentum tensor of the system with respect to the world line of an arbitrary *centroid* (the *center of motion*), the intrinsic weakness of multipolar expansions lies in the absence of a *constitutive relation* connecting the 4-velocity of the centroid to the 4-momentum of the system. As a consequence, both from a practical and a theoretical point of view it is not known which is the most convenient choice for the definition of center of motion among, e.g., Pirani centroid,[14] Tulczyjew centroid,[15,18,23] Møller center of energy,[29] Corinaldesi–Papapetrou centroid,[12] Fokker–Pryce center of inertia (or of spin)[30–32] and many other possible centroids.

In this paper we will face these problems in the framework of special relativity from a viewpoint which can be generalized and adapted to the new canonical formulation of metric and tetrad gravity of Refs. 2 and 3. Our starting point are the results recently obtained[33] about a complete treatment of the kinematics of the relativistic *N*-body problem in the *rest-frame instant form of dynamics*.[34–37] This program required a reformulation of the theory of isolated relativistic systems and was essentially grounded upon Dirac's reformulation[38] of classical field theory (suitably extended to particles) on arbitrary spacelike hypersurfaces.[39,40] For each isolated system (containing any combination of particles, strings and fields) one obtains in this way a reformulation of the standard theory as a parametrized Minkowski theory.[34,37] This program contains the extra bonus of being naturally prepared for the coupling to gravity in its ADM formulation. The price to be paid is that the functions $z^\mu(\tau,\vec{\sigma})$ describing the embedding of the spacelike hypersurface in Minkowski space–time become configuration variables in the action principle. Since the action is invariant under separate τ-reparametrizations and space diffeomorphisms, first class constraints emerge ensuring the independence of the description of the choice of the $3+1$ splitting. The embedding configuration variables $z^\mu(\tau,\vec{\sigma})$ are thus the *gauge* variables associated with this particular kind of general covariance.[41]

In parametrized Minkowski theories in the case of particles, each particle must have *a well defined sign of the energy*, since the intersection of a timelike world line with a spacelike hypersurface corresponding to a value τ of the time parameter is identified by three numbers $\vec{\sigma}=\vec{\eta}(\tau)$ instead of four. Therefore, the two topologically disjoint branches of the mass hyperboloid cannot be simultaneously described as in the standard manifestly Lorentz-covariant theory, so that no mass-shell constraint appears. Each particle with a definite sign of the energy is described by the canonical coordinates $\vec{\eta}_i(\tau),\vec{\kappa}_i(\tau)$ while the 4-position of the particles are given by $x_i^\mu(\tau)=z^\mu(\tau,\vec{\eta}_i(\tau))$. The following 4-momenta $p_i^\mu(\tau)$ are $\vec{\kappa}_i$-dependent solutions of $p_i^2-m_i^2=0$ with the chosen sign of the energy.

In order to exploit the separate spatial and time reparametrization invariances of parametrized Minkowski theories, we can first of all restrict the foliation to spacelike *hyperplanes* as leaves. For each configuration of the isolated system with timelike 4-momentum, we further restrict to the special leaves defined by hyperplanes orthogonal to the conserved system 4-momentum (*Wigner hyperplanes*). This foliation is fully determined by the configuration of the isolated system. One gets in this way[34] the definition of the *Wigner-covariant rest-frame instant form of dynamics* for any isolated system whose configurations have well defined and finite Poincaré generators with

timelike total 4-momentum (see Ref. 42 for the traditional forms of dynamics). Finally, this formulation casts new light on the long standing problem of defining a relativistic center of mass. As well known, no definition of this concept can enjoy all the properties of its nonrelativistic counterpart. See Refs. 30–32, 43, and 44 for a partial bibliography of all the existing attempts.

We summarize here the main previous results necessary to understand all the subsequent technical developments (further details can be found in Appendix A of Ref. 33 and Sec. II):

(a) The Wigner hyperplanes are described by the embedding $z^\mu(\tau,\vec{\sigma}) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\sigma^r$, where $x_s^\mu(\tau) = z^\mu(\tau,\vec{0})$ is an arbitrary centroid (origin of the 3-coordinates $\vec{\sigma}$) playing the role of the *center of motion* for multipolar expansions.

(b) The canonical variables describing the remaining freedom in the embedding are a *noncovariant canonical so-called external 4-center-of-mass* configurational variable $\tilde{x}_s^\mu(\tau) \neq x_s^\mu(\tau)$ and the conjugate 4-momentum p_s^μ, weakly equal to the total 4-momentum of the isolated system and orthogonal to the Wigner hyperplanes. The timelike unit vector $u^\mu(p_s) = p_s^\mu/\sqrt{p_s^2}$ $[p_{s\mu}\epsilon_r^\mu(u(p_s)) = 0]$ describes the orientation of Wigner hyperplanes in the chosen inertial system. These canonical variables describe a decoupled free point (*point particle clock*).

(c) The mathematical time τ is identified with the Lorentz scalar time $T_s = \tilde{x}_s \cdot p_s/\sqrt{p_s^2} = x_s \cdot p_s/\sqrt{p_s^2}$ of this decoupled point by means of the gauge fixing $T_s - \tau \approx 0$, which implies $\epsilon_s = \sqrt{p_s^2} = M_{\rm sys}, \dot{\tilde{x}}_s^\mu(\tau) = u^\mu(p_s)$ and $\dot{x}_s^\mu(\tau) = u^\mu(p_s) + \epsilon_r^\mu(u(p_s))\lambda_r(\tau)$ [$\lambda_r(\tau)$ are three arbitrary Dirac multipliers]. Here $M_{\rm sys}$ is the invariant mass of the isolated system. The decoupled point is now described by canonical 3-coordinates $\vec{z}_s = \epsilon_s[\vec{\tilde{x}}_s - (\vec{p}_s/p_s^o)\tilde{x}^o]$ (the *external 3-center of mass*) and $\vec{k}_s = \vec{p}_s/\epsilon_s$.[45]

(d) There is an *external* realization of the Poincaré group, whose Lorentz transformations (change of the inertial observer) induce a *Wigner rotation* of the 3-vectors inside each Wigner hyperplane. As shown in Ref. 33, the *external* Poincaré generators allow to define three concepts of the *external* collective variable, (i) the *external* noncovariant canonical *4-center of mass* (also named *4-center of spin*) $\tilde{x}_s^\mu$ (with 3-location $\vec{\tilde{\sigma}}$); (ii) the *external* noncovariant noncanonical Møller *4-center of energy* R_s^μ (with 3-location $\vec{\sigma}_R$); (iii) the *external* covariant noncanonical Fokker–Pryce *4-center of inertia* Y_s^μ (with 3-location $\vec{\sigma}_Y$). Only the canonical noncovariant center of mass $\tilde{x}_s^\mu(\tau)$ is relevant to the Hamiltonian treatment with Dirac constraints, while only the Fokker–Pryce Y_s^μ is a 4-vector by construction. See Ref. 33 for the construction of the *4-centers* starting from the corresponding *3-centers* (3-center of spin,[31] 3-center of energy,[29] 3-center of inertia[30,31]), which are group-theoretically defined in terms of generators of the external Poincaré group.

(e) Inside the Wigner hyperplanes the particles are described by Wigner spin-1 canonical 3-vectors $\vec{\eta}_i(\tau), \vec{\kappa}_i(\tau)$ restricted by the three first class constraints (the *rest-frame conditions*) $\vec{\kappa}_+ = \Sigma_{i=1}^N \vec{\kappa}_i \approx 0$, whose associated Dirac multipliers $\lambda_r(\tau)$ describe the freedom in the choice of the centroid $x_s^\mu(\tau)$. The rest-frame conditions imply that an *internal* 3-center-of-mass variable $\vec{\sigma}_{\rm c.m.}$ is a *gauge variable*, whose elimination through a gauge fixing[46] is equivalent to a definite choice of the world-line $x_s^\mu(\tau)$ of the centroid. Inside Wigner hyperplanes there is an unfaithful *internal* realization of the Poincaré algebra, the total *internal* 3-momentum of the isolated system vanishes due to the rest-frame conditions. The *internal* energy and angular momentum are the invariant mass $M_{\rm sys}$ and the spin [the angular momentum with respect to $\tilde{x}_s^\mu(\tau)$] of the isolated system, respectively. By means of the *internal* realization of the Poincaré algebra we can define three *internal* 3-centers of mass, the *internal* canonical 3-center of mass (or 3-center of spin) $\vec{q}_+$, the *internal* Møller 3-center of energy $\vec{R}_+$, and the *internal* Fokker–Pryce 3-center of inertia $\vec{y}_+$. However, because of the rest-frame condition $\vec{\kappa}_+ \approx 0$, *they all coincide*, $\vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+$. As a natural gauge fixing to the rest-frame conditions, we can add the vanishing of the *internal* Lorentz boosts $\vec{K}$ (recall that they are equal to $-\vec{R}_+/M_{\rm sys}$). This is equivalent to locate the internal canonical 3-center of mass $\vec{\sigma}_{\rm c.m.} = \vec{q}_+$ in $\vec{\sigma} = 0$, i.e., in the centroid $x_s^\mu(\tau) = z^\mu(\tau,\vec{0})$. Upon such gauge fixings, the world-line $x_s^\mu(\tau)$

becomes uniquely determined except for the arbitrariness in the choice of $x_s^\mu(0)$,

$$x_s^{(\vec{q}_+)\mu}(\tau) = x_s^\mu(0) + u^\mu(p_s)T_s, \tag{1.1}$$

and, modulo $x_s^\mu(0)$, it coincides with the *external* covariant noncanonical Fokker–Pryce 4-center of inertia, $x_s^\mu(\tau) = x_s^\mu(0) + Y_s^\mu$.[33]

In the gauge where $\epsilon_s \equiv M_{\rm sys}$, and $T_s \equiv \tau$, the canonical basis $\vec{z}_s, \vec{k}_s, \vec{\eta}_i, \vec{\kappa}_i$ is restricted by the three pairs of second class constraints $\vec{\kappa}_+ = \Sigma_{i=1}^N \vec{\kappa}_i \approx 0$, $\vec{q}_+ \approx 0$, so that $6N$ canonical variables describe the N particles as in the nonrelativistic case. We still need a canonical transformation $\vec{\eta}_i, \vec{\kappa}_i \mapsto \vec{q}_+[\approx 0], \vec{\kappa}_+[\approx 0], \vec{\rho}_a, \vec{\pi}_a$ $[a = 1, \ldots, N-1]$ identifying a set of relative canonical variables. The final $6N$-dimensional canonical basis is $\vec{z}_s, \vec{k}_s, \vec{\rho}_a, \vec{\pi}_a$. To get this result we need a highly nonlinear canonical transformation,[33] which can be obtained by exploiting the Gartenhaus–Schwartz singular transformation.[47]

At the end we obtain *the Hamiltonian for the relative motions as a sum of N square roots*, each one containing a squared mass and a quadratic form in the relative momenta, which goes into the nonrelativistic Hamiltonian for relative motions in the limit $c \to \infty$. This fact has the following implications.

(a) If one tries to make the inverse Legendre transformation to find the associated Lagrangian, it turns out that, due to the presence of square roots, the Lagrangian is a hyperelliptic function of $\dot{\vec{\rho}}_a$ already in the free case. A closed form exists only for $N=2$, $m_1 = m_2 = m$, $L = -m\sqrt{4 - \dot{\vec{\rho}}^2}$. This exceptional case already shows that the existence of the limiting velocity c forbids a linear relation between the spin (center-of-mass angular momentum) and the angular velocity.

(b) The N quadratic forms in the relative momenta appearing in the relative Hamiltonian *cannot be simultaneously diagonalized*. The Hamiltonian is anyway a sum of square roots, so that concepts like *reduced masses, Jacobi normal relative coordinates*, and *tensor of inertia* cannot be extended to special relativity. As a consequence, for example, a relativistic static orientation-shape SO(3) principal bundle approach[48,49] can be implemented only by using non-Jacobi relative coordinates.

(c) The best way of studying rotational kinematics, *viz.* the non-Abelian rotational symmetry associated with the conserved *internal* spin, is based on the concept of *canonical spin bases* with the associated concepts of *spin frames* and *dynamical body frames* introduced in Ref. 33. It is a remarkable fact that they can be built, just as in the nonrelativistic case,[50] starting from the canonical basis $\vec{\rho}_a, \vec{\pi}_a$.

As anticipated at the outset, our aim is to complete the study of relativistic kinematics for the N-body system by first evaluating the rest-frame Dixon multipoles[20] and then by analyzing the role of Dixon's multipoles for *open subsystems*. The basic technical tool will be the standard definition of the *energy momentum tensor* of the N positive-energy *free* particles on the Wigner hyperplane. It will be seen that, in order to get a sensible extension of this definition to open subsystems, a physically significant convention is required. On the whole, it turns out that the Wigner hyperplane is the natural framework for reorganizing a lot of kinematics connected with multipoles, but only when the gauge fixing $T_s - \tau \approx 0$ identifies the mathematical time τ with the rest-frame scalar time T_s. Only in this way, moreover, a concept like the *barycentric tensor of inertia* can be introduced in special relativity, specifically by means of the quadrupole moments.

A first application of the formalism is done for an isolated system of N positive-energy particles with *mutual action-at-a-distance interactions*. The formalism is then applied to the case of an *open* $n < N$ *particle subsystem* of an isolated system consisting of N charged positive-energy particles (with Grassmann-valued electric charges introduced to regularize the Coulomb self-energies) plus the electromagnetic field.[36] In the rest frame of the isolated system, a *suitable* definition of the energy-momentum tensor of the open subsystem allows to define its effective mass, 3-momentum, and angular momentum.

Then we evaluate the rest-frame Dixon multipoles of the energy-momentum tensor of the

open subsystem with respect to various centroids describing possible *collective centers of motion*. Unlike the case of isolated systems, each centroid generates a different world line and there are many candidates as effective centers of motion and effective intrinsic spin. Two centroids (namely the so-called *center of energy* and Tulczyjew centroid) show particularly interesting properties. The case $n=2$ is studied explicitly. It is also shown that the pole–dipole description of the two-particle cluster can be replaced by a description of the cluster as an extended system (its effective spin frame can be evaluated). This can be done, however, at the price of introducing an explicit dependence on the action of the external electromagnetic field upon the cluster. By comparing the effective parameters of an open cluster of n_1+n_2 particles to the effective parameters of the two clusters with n_1 and n_2 particles, it turns out in particular that only the effective *center of energy* appears to be a viable center of motion for studying the interactions of open subsystems.

For the sake of simplicity, we shall omit many explicit calculations. The interested reader may find them in an extended version of this paper given in Ref. 51.

A review of the rest-frame instant form of dynamics for N scalar free positive-energy particles and some new original results on the canonical transformation to the internal center of mass and relative variables are given in Sec. II.

In Sec. III we evaluate the energy momentum tensor in the Wigner hyperplanes.

Dixon's multipoles are introduced in Sec. IV. A special study of monopole, dipole, and quadrupole moments is given and the multipolar expansion is defined.

After the extension of the previous results to isolated systems with mutual action-at-a-distance interactions, in Sec. V we study the behavior of open subsystems of isolated systems, the centroids which are good candidates for the description the collective center of motion, and discuss the determination of the effective parameters (mass, spin, momentum, variables relative to the center of motion) for the open subsystem.

Some comments about standing problems are given in the Conclusions.

The Gartenhaus–Schwartz transformation is summarized in the Appendix.

II. REVIEW OF THE REST-FRAME INSTANT FORM

We briefly review the treatment of N free scalar positive-energy particles in the framework of parametrized Minkowski theory (see Appendixes A and B and Sec. II of Ref. 33).

The foliation associated to a $3+1$ splitting of Minkowski space–time is defined by an embedding $R\times\Sigma\to M^4$, $\sigma^A=(\tau,\vec{\sigma})\mapsto z^\mu(\tau,\vec{\sigma})$, with Σ an abstract 3-surface diffeomorphic to R^3. Σ_τ is the Cauchy surface of *equal time*. The 4-metric induced on Σ_τ is $g_{AB}[z]=z^\mu_A\eta_{\mu\nu}z^\nu_B$, a functional of z^μ, and the embedding coordinates $z^\mu(\tau,\vec{\sigma})$ are considered as independent fields. The $z^\mu_A(\sigma)=\partial z^\mu(\sigma)/\partial\sigma^A$ are flat cotetrad fields on Minkowski space–time with the z^μ_r's tangent to Σ_τ. The vectors $z^\mu_r(\tau,\vec{\sigma})$ are tangent to Σ_τ, whose unit normal field is $l^\mu(\tau,\vec{\sigma})=\epsilon^\mu{}_{\alpha\beta\gamma}[z^\alpha_1 z^\beta_2 z^\gamma_3]\times(\tau,\vec{\sigma})_1/\sqrt{\gamma(\tau,\vec{\sigma})}$. The dual tetrad fields are $z^A_\mu(\sigma)=\partial\sigma^A(z)/\partial z^\mu$, $z^A_\mu(\tau,\vec{\sigma})z^\mu_B(\tau,\vec{\sigma})=\delta^A_B$. The inverse of the 3-metric g_{rs} is denoted γ^{rs}, $\gamma^{ru}g_{us}=\delta^r_s$. While in Ref. 33 we used the metric convention $\eta_{\mu\nu}=\epsilon(+---)$ with $\epsilon=\pm$, in this paper we shall use $\epsilon=1$ like in Ref. 34.

Each particle is described by a configuration 3-vector $\vec{\eta}_i(\tau)$. The particle world line is $x^\mu_i(\tau)=z^\mu(\tau,\vec{\eta}_i(\tau))$, where $z^\mu(\tau,\vec{\sigma})$ are the embedding configuration variables describing the spacelike hypersurface Σ_τ.

The system of configuration variables $z^\mu(\tau,\vec{\sigma})$, $\vec{\eta}_i(\tau)$, is described by the action[34–36]

$$S=\int \mathrm{d}\tau\, d^3\sigma\, \mathcal{L}(\tau,\vec{\sigma})=\int \mathrm{d}\tau\, L(\tau),$$

$$\mathcal{L}(\tau,\vec{\sigma})=-\sum_{i=1}^{N}\delta^3(\vec{\sigma}-\vec{\eta}_i(\tau))m_i\sqrt{g_{\tau\tau}(\tau,\vec{\sigma})+2g_{\tau r}(\tau,\vec{\sigma})\dot{\eta}^r_i(\tau)+g_{rs}(\tau,\vec{\sigma})\dot{\eta}^r_i(\tau)\dot{\eta}^s_i(\tau)}. \tag{2.1}$$

The action is invariant under separate τ and $\vec{\sigma}$ reparametrizations. Therefore the canonical momenta $\rho_\mu(\tau,\vec{\sigma})=-\partial\mathcal{L}(\tau,\vec{\sigma})/\partial z^\mu_\tau(\tau,\vec{\sigma})$ and $\kappa_{ir}(\tau)=-\partial L(\tau)/\partial\dot{\eta}^r_i(\tau)$ satisfy the primary first class constraints

$$\mathcal{H}_\mu(\tau,\vec{\sigma}) = \rho_\mu(\tau,\vec{\sigma}) - l_\mu(\tau,\vec{\sigma})\sum_{i=1}^{N}\delta^3(\vec{\sigma}-\vec{\eta}_i(\tau))\sqrt{m_i^2-\gamma^{rs}(\tau,\vec{\sigma})\kappa_{ir}(\tau)\kappa_{is}(\tau)}$$

$$-z_{r\mu}(\tau,\vec{\sigma})\gamma^{rs}(\tau,\vec{\sigma})\sum_{i=1}^{N}\delta^3(\vec{\sigma}-\vec{\eta}_i(\tau))\kappa_{is}\approx 0, \tag{2.2}$$

so that the Dirac Hamiltonian is $H_D=\int d^3\sigma\,\lambda^\mu(\tau,\vec{\sigma})\mathcal{H}_\mu(\tau,\vec{\sigma})$, where $\lambda^\mu(\tau,\vec{\sigma})$ are Dirac multipliers. The standard particle 4-momentum is the following solution of $p_i^2-m_i^2=0$: $p_i^\mu(\tau)=l^\mu(\tau,\vec{\eta}_i(\tau))\sqrt{m_i^2-\gamma^{rs}(\tau,\vec{\eta}_i(\tau))\kappa_{ir}(\tau)\kappa_{is}(\tau)}+z^\mu(\tau,\vec{\eta}_i(\tau))\gamma^{rs}(\tau,\vec{\eta}_i(\tau))\kappa_{is}(\tau)$.

The conserved Poincaré generators are (the suffix "s" denotes the hypersurface Σ_τ)

$$p_s^\mu=\int d^3\sigma\,\rho^\mu(\tau,\vec{\sigma}),$$

$$J_s^{\mu\nu}=\int d^3\sigma[z^\mu(\tau,\vec{\sigma})\rho^\nu(\tau,\vec{\sigma})-z^\nu(\tau,\vec{\sigma})\rho^\mu(\tau,\vec{\sigma})]. \tag{2.3}$$

After the restriction to *Wigner hyperplane*,[52] $z^\mu(\tau,\vec{\sigma})=x_s^\mu(\tau)+\epsilon_r^\mu(u(p_s))\sigma^r$, the independent degrees of freedom of the embedding are reduced to the canonical coordinates x_s^μ, $p_s^\mu=\epsilon_s u^\mu(p_s)$ of a point particle and we have the following constraints and Dirac Hamiltonian[34,36] (the symbol $\overset{\circ}{=}$ means evaluated on the solutions of the equations of motion):

$$\tilde{\mathcal{H}}^\mu(\tau)=u^\mu(p_s)\left[\epsilon_s-\sum_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2}\right]+\epsilon_r^\mu(u(p_s))\sum_{i=1}^{N}\kappa_{ir}\approx 0,$$

or

$$\epsilon_s-M_{\rm sys}\approx 0,\quad M_{\rm sys}=\sum_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2},\quad \vec{p}_{\rm sys}=\vec{\kappa}_+=\sum_{i=1}^{N}\vec{\kappa}_i\approx 0,$$

$$H_D=\lambda^\mu(\tau)\tilde{\mathcal{H}}_\mu(\tau)=\lambda(\tau)[\epsilon_s-M_{\rm sys}]-\vec{\lambda}(\tau)\sum_{i=1}^{N}\vec{\kappa}_i,$$

$$\dot{x}_s^\mu(\tau)\overset{\circ}{=}\{x_s^\mu(\tau),H_D\}\approx -\lambda^\mu(\tau)=-\lambda(\tau)u^\mu(p_s)+\epsilon_r^\mu(u(p_s))\lambda_r(\tau),$$

$$\Rightarrow x_s^\mu(\tau)=x_s^\mu(0)-u^\mu(p_s)\int_0^\tau d\tau_1\lambda(\tau_1)+\epsilon_r^\mu(u(p_s))\int_0^\tau d\tau_1\lambda_r(\tau_1). \tag{2.4}$$

While the Dirac multiplier $\lambda(\tau)$ is determined by the gauge fixing $T_s-\tau\approx 0$, implying $\epsilon_s\equiv M_{\rm sys}$, and the value $\lambda(\tau)=-1$, the three Dirac's multipliers $\vec{\lambda}(\tau)$ describe the classical Zitterbewegung of the centroid $x_s^\mu(\tau)=z^\mu(\tau,\vec{0})$ which is the origin of the 3-coordinates on the Wigner hyperplane. Each gauge-fixing $\vec{\chi}(\tau)\approx 0$ to the three first class constraints $\vec{\kappa}_+\approx 0$ (defining the *internal rest-frame* 3-center of mass $\vec{\sigma}_{\rm c.m.}$) gives a different determination of the multipliers $\vec{\lambda}(\tau)$.[53] Therefore each gauge-fixing identifies a different world line for the covariant noncanonical centroid $x_s^{(\vec{\chi})\mu}(\tau)$. Of course, inside the Wigner hyperplane, three degrees of freedom of the isolated system become gauge variables. The natural gauge fixing for eliminating the first class constraints $\vec{\kappa}_+\approx 0$ is $\vec{\chi}(\tau)=\vec{\sigma}_{\rm c.m.}=\vec{q}_+\approx 0$ [vanishing of the location of the internal canonical 3-center of mass, see after Eq. (2.12)]. We have that $\vec{q}_+\approx 0$ implies $\lambda_r(\tau)=0$: in this way the *internal* 3-center of mass is located in a unique centroid $x_s^{(\vec{q}_+)\mu}(\tau)=z^\mu(\tau,\vec{\sigma}=0)$ $[\dot{x}_s^{(\vec{q}_+)\mu}=\dot{\tilde{x}}_s^\mu=u^\mu(p_s)]$.

Note that the constant $x_s^\mu(0)$ [and, therefore, also $\tilde{x}_s^\mu(0)$] is arbitrary, reflecting the arbitrariness

in the absolute location of the origin of the *internal* coordinates on each hyperplane in Minkowski space–time. The centroid $x_s^\mu(\tau)$ corresponds to the unique special relativistic center-of-mass-type world line for isolated systems of Refs. 54–56, which unifies previous proposals of Synge, Møller, and Pryce.

The only remaining canonical variables describing the Wigner hyperplane in the final Dirac brackets are a noncovariant canonical coordinate $\tilde{x}_s^\mu(\tau)$ (Ref. 57) and p_s^μ. The point with coordinates $\tilde{x}_s^\mu(\tau)$ is the decoupled canonical *external 4-center of mass* of the isolated system, which can be interpreted as a decoupled observer with his parametrized clock (*point particle clock*). Its velocity $\dot{\tilde{x}}_s^\mu(\tau)$ is parallel to p_s^μ, so that it has no classical Zitterbewegung.

The relation between $x_s^\mu(\tau)$ and $\tilde{x}_s^\mu(\tau)$ ($\vec{\tilde{\sigma}}$ is its 3-location on the Wigner hyperplane) is[33,34]

$$\tilde{x}_s^\mu(\tau) = (\tilde{x}_s^o(\tau); \vec{\tilde{x}}_s(\tau)) = z^\mu(\tau, \vec{\tilde{\sigma}}) = x_s^\mu(\tau) - \frac{1}{\epsilon_s(p_s^o + \epsilon_s)} \left[p_{s\nu} S_s^{\nu\mu} + \epsilon_s \left(S_s^{o\mu} - S_s^{o\nu} \frac{p_{s\nu} p_s^\mu}{\epsilon_s^2} \right) \right], \tag{2.5}$$

and we get $\dot{\tilde{x}}_s^\mu(\tau) = \{\tilde{x}_s^\mu(\tau), H_D\} = -\lambda(\tau) u^\mu(p_s)$ [$= u^\mu(p_s)$ when $\lambda(\tau) = -1$]. After the separation of the relativistic canonical noncovariant *external* 4-center of mass $\tilde{x}_s^\mu(\tau)$, the N particles are described on the Wigner hyperplane by the $6N$ Wigner spin-1 3-vectors $\vec{\eta}_i(\tau), \vec{\kappa}_i(\tau)$ restricted by the rest-frame condition $\vec{\kappa}_+ = \sum_{i=1}^N \vec{\kappa}_i \approx 0$.

The various spin tensors and vectors are[34]

$$J_s^{\mu\nu} = x_s^\mu p_s^\nu - x_s^\nu p_s^\mu + S_s^{\mu\nu} = \tilde{x}_s^\mu p_s^\nu - \tilde{x}_s^\nu p_s^\mu + \tilde{S}_s^{\mu\nu},$$

$$S_s^{\mu\nu} = [u^\mu(p_s)\epsilon_r^\nu(u(p_s)) - u^\nu(p_s)\epsilon_r^\mu(u(p_s))]\overline{S}_s^{\tau r} + \epsilon_r^\mu(u(p_s))\epsilon_s^\nu(u(p_s))\overline{S}_s^{rs} \equiv [\epsilon_r^\mu(u(p_s))u^\nu(p_s) - \epsilon_r^\nu(u(p_s))u^\mu(p_s)] \sum_{i=1}^N \eta_i^r \sqrt{m_i^2 c^2 + \vec{\kappa}_i^2} + [\epsilon_r^\mu(u(p_s))\epsilon_s^\nu(u(p_s)) - \epsilon_r^\nu(u(p_s))\epsilon_s^\mu(u(p_s))] \sum_{i=1}^N \eta_i^r \kappa_i^s,$$

$$\overline{S}_s^{AB} = \epsilon_\mu^A(u(p_s))\epsilon_\nu^B(u(p_s))S_s^{\mu\nu},$$

$$\overline{S}_s^{rs} \equiv \sum_{i=1}^N (\eta_i^r \kappa_i^s - \eta_i^s \kappa_i^r), \quad \overline{S}_s^{\tau r} \equiv -\sum_{i=1}^N \eta_i^r \sqrt{m_i^2 c^2 + \vec{\kappa}_i^2},$$

$$\tilde{S}_s^{\mu\nu} = S_s^{\mu\nu} + \frac{1}{\sqrt{p_s^2}(p_s^o + \sqrt{p_s^2})} [p_{s\beta}(S_s^{\beta\mu} p_s^\nu - S_s^{\beta\nu} p_s^\mu) + \sqrt{p_s^2}(S_s^{o\mu} p_s^\nu - S_s^{o\nu} p_s^\mu)],$$

$$\tilde{S}_s^{ij} = \delta^{ir}\delta^{js}\overline{S}_s^{rs}, \quad \tilde{S}_s^{oi} = -\frac{\delta^{ir}\overline{S}_s^{rs} p_s^s}{p_s^o + \sqrt{p_s^2}},$$

$$\vec{\overline{S}} = \sum_{i+1}^N \vec{\eta}_i \times \vec{\kappa}_i \approx \sum_{i=1}^N \vec{\eta}_i \times \vec{\kappa}_i - \vec{\eta}_+ \times \vec{\kappa}_+ = \sum_{a=1}^{N-1} \vec{\rho}_a \times \vec{\pi}_a. \tag{2.6}$$

Note that while $L_s^{\mu\nu} = x_s^\mu p_s^\nu - x_s^\nu p_s^\mu$ and $S_s^{\mu\nu}$ are not constants of the motion due to the classical Zitterbewegung [when $\vec{\lambda}(\tau) \neq 0$], both $\tilde{L}_s^{\mu\nu} = \tilde{x}_s^\mu p_s^\nu - \tilde{x}_s^\nu p_s^\mu$ and $\tilde{S}_s^{\mu\nu}$ are conserved.

The canonical variables $\tilde{x}_s^\mu, p_s^\mu$ for the *external* 4-center of mass, can be replaced by the canonical pairs[58]

$$T_s = \frac{p_s \cdot \tilde{x}_s}{\epsilon_s} = \frac{p_s \cdot x_s}{\epsilon_s}, \quad \epsilon_s = \pm\sqrt{p_s^2}, \quad \vec{z}_s = \epsilon_s\left(\vec{\tilde{x}}_s - \frac{\vec{p}_s}{p_s^o}\tilde{x}_s^o\right), \quad \vec{k}_s = \frac{\vec{p}_s}{\epsilon_s},$$

$$\tilde{x}_s^o = \sqrt{1+\vec{k}_s^2}\left(T_s + \frac{\vec{k}_s \cdot \vec{z}_s}{\epsilon_s}\right), \quad \vec{\tilde{x}}_s = \frac{\vec{z}_s}{\epsilon_s} + \left(T_s + \frac{\vec{k}_s \cdot \vec{z}_s}{\epsilon_s}\right)\vec{k}_s, \quad p_s^o = \epsilon_s\sqrt{1+\vec{k}_s^2},$$

$$\vec{p}_s = \epsilon_s \vec{k}_s, \tag{2.7}$$

which make explicit the interpretation of it as a *point particle clock*.

This nonpoint canonical transformation can be summarized as $[\epsilon_s - M_{\rm sys} \approx 0,\ \vec{\kappa}_+ = \Sigma_{i=1}^N \vec{\kappa}_i \approx 0]$

$$\begin{array}{|c|c|}\hline \tilde{x}_s^\mu & \vec{\eta}_i \\ \hline p_s^\mu & \vec{\kappa}_i \\ \hline \end{array} \longrightarrow \begin{array}{|c|c|c|}\hline \epsilon_s & \vec{z}_s & \vec{\eta}_i \\ \hline T_s & \vec{k}_s & \vec{\kappa}_i \\ \hline \end{array}. \tag{2.8}$$

After the addition of the gauge-fixing $T_s - \tau \approx 0$, the invariant mass $M_{\rm sys}$ of the system, which is also the *internal* energy of the isolated system, replaces the nonrelativistic Hamiltonian $H_{\rm rel}$ for the relative degrees of freedom: this reminds of the frozen Hamilton–Jacobi theory, in which the time evolution can be reintroduced by using the energy generator of the Poincaré group as Hamiltonian.

After the gauge fixings $T_s - \tau \approx 0$, the final Hamiltonian, the embedding of the Wigner hyperplane into Minkowski space–time and the Hamilton equations become

$$H_D = M_{\rm sys} - \vec{\lambda}(\tau) \cdot \vec{\kappa}_+,$$

$$z^\mu(\tau, \vec{\sigma}) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\sigma^r = x_s^\mu(0) + u^\mu(p_s)\tau + \epsilon_r^\mu(u(p_s))\left(\sigma^r + \int_o^\tau d\tau_1 \lambda_r(\tau_1)\right),$$

$$\dot{\vec{\eta}}_i(\tau) \stackrel{\circ}{=} \frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2 + \vec{\kappa}_i^2(\tau)}} - \vec{\lambda}(\tau), \quad \Rightarrow \vec{\kappa}_i(\tau) \stackrel{\circ}{=} m_i \frac{\dot{\vec{\eta}}_i(\tau) + \vec{\lambda}(\tau)}{\sqrt{1 - [\dot{\vec{\eta}}_i(\tau) + \vec{\lambda}(\tau)]^2}},$$

$$\dot{\vec{\kappa}}_i(\tau) \stackrel{\circ}{=} 0. \tag{2.9}$$

The particles' world lines in Minkowski space–time and the associated momenta are

$$x_i^\mu(\tau) = z^\mu(\tau, \vec{\eta}_i(\tau)) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\,\eta_i^r(\tau),$$

$$p_i^\mu(\tau) = \sqrt{m_i^2 + \vec{\kappa}_i^2(\tau)}u^\mu(p_s) + \epsilon_r^\mu(u(p_s))\kappa_{ir}(\tau) \Rightarrow p_i^2 = m_i^2. \tag{2.10}$$

The *external* rest-frame instant form realization of the Poincaré generators[59] with nonfixed invariants $p_s^2 = \epsilon_s^2 \approx M_{\rm sys}^2$, $-p_s^2\vec{S}_s^2 \approx M_{\rm sys}^2\vec{S}^2$, is obtained from Eq. (2.6):

$$p_s^\mu = \sum_{i=1}^N p_i^\mu, \quad J_s^{\mu\nu} = \tilde{x}_s^\mu p_s^\nu - \tilde{x}_s^\nu p_s^\mu + \tilde{S}_s^{\mu\nu},$$

$$p_s^o = \sqrt{\epsilon_s^2 + \vec{p}_s^2} = \epsilon_s\sqrt{1+\vec{k}_s^2} \approx \sqrt{M_{\rm sys}^2 + \vec{p}_s^2} = M_{\rm sys}\sqrt{1+\vec{k}_s^2},$$

$$\vec{p}_s = \epsilon_s \vec{k}_s \approx M_{\rm sys}\vec{k}_s,$$

$$J_s^{ij} = \tilde{x}_s^i p_s^j - \tilde{x}_s^j p_s^i + \delta^{ir}\delta^{js}\sum_{i=1}^{N}(\eta_i^r \kappa_i^s - \eta_i^s \kappa_i^r) = z_s^i k_s^j - z_s^j k_s^i + \delta^{ir}\delta^{js}\epsilon^{rsu}\overline{S_s^u},$$

$$K_s^i = J_s^{oi} \approx \tilde{x}_s^o p_s^i - \tilde{x}_s^i \sqrt{M_{\rm sys}^2 + \vec{p}_s^{\,2}} - \frac{\delta^{ir} p_s^s \epsilon^{rsu}\overline{S_s^u}}{M_{\rm sys} + \sqrt{M_{\rm sys}^2 + \vec{p}_s^{\,2}}}. \tag{2.11}$$

On the other hand the *internal* realization of the Poincaré algebra is built inside the Wigner hyperplane by using the expression of $\overline{S_s^{AB}}$ given by Eq. (2.6) (II and W^2 are the two nonfixed invariants of this realization)

$$M_{\rm sys} = H_M = \sum_{i=1}^{N}\sqrt{m_i^2 + \vec{\kappa}_i^2}, \quad \vec{\kappa}_+ = \sum_{i=1}^{N}\vec{\kappa}_i \ (\approx 0),$$

$$\vec{J} = \sum_{i=1}^{N}\vec{\eta}_i \times \vec{\kappa}_i, \quad J^r = \overline{S^r} = \tfrac{1}{2}\epsilon^{ruv}\overline{S^{uv}} \equiv \overline{S_s^r},$$

$$\vec{K} = -\sum_{i=1}^{N}\sqrt{m_i^2 + \vec{\kappa}_i^2}\,\vec{\eta}_i = -M_{\rm sys}\vec{R}_+, \quad K^r = J^{or} = \overline{S_s^{\tau r}},$$

$$\Pi = M_{\rm sys}^2 - \vec{\kappa}_+^2 \approx M_{\rm sys}^2 > 0, \quad W^2 = -(M_{\rm sys}^2 - \vec{\kappa}_+^2)\vec{\overline{S_s^2}} \approx -M_{\rm sys}^2 \vec{\overline{S_s^2}}. \tag{2.12}$$

The constraints $\epsilon_s - M_{\rm sys} \approx 0, \vec{\kappa}_+ \approx 0$ have the following meaning.

(i) The constraint $\epsilon_s - M_{\rm sys} \approx 0$ is the bridge connecting the *external* and the *internal* realizations [the external spin coincides with the internal angular momentum due to Eq. (A11) of Ref. 33].

(ii) The constraints $\vec{\kappa}_+ \approx 0$, together with $\vec{K} \approx 0$ (i.e., $\vec{R}_+ \approx \vec{q}_+ \approx \vec{y}_+ \approx 0$), lead to an unfaithful *internal* realization, in which the only nonzero generators are the conserved energy and spin of an isolated system.

The determination of $\vec{q}_+$ for the N particle system has been carried out by the group theoretical methods of Ref. 60 in Sec. III of Ref. 33. As said in the Introduction there are three internal position variables $\vec{q}_+, \vec{R}_+, \vec{y}_+$, which can be defined in terms of the internal Poincaré generators (2.12). It can be shown[33] that, due to $\vec{\kappa}_+ \approx 0$, they all *coincide*, $\vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+$.

Therefore the gauge fixings $\vec{\chi}(\tau) = \vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+ \approx 0$ imply $\vec{\lambda}(\tau) \approx 0$ and identify the special centroid (1.1). As shown in Sec. IV, the addition of the gauge fixings $\vec{\chi}(\tau) = \vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+ \approx 0$ also implies that the Dixon center of mass of an extended object[20] and the Pirani[14] and Tulczyjew[15,18,23] centroids[61–63] all simultaneously coincide with the centroid $x_s^{(\vec{q}_+)\mu}(\tau)$.

The *external* realization (2.11) allows to build the analogous *external* 3-variables $\vec{q}_s, \vec{R}_s, \vec{Y}_s$. Equation (4.4) of Ref. 33 shows the construction of the associated *external* 4-variables $\tilde{x}_s^\mu, Y_s^\mu, R_s^\mu$ and their locations $\vec{\tilde{\sigma}}, \vec{\sigma}_Y, \vec{\sigma}_R$ on the Wigner hyperplane. The relevant point is that the *external* Fokker–Pryce noncanonical covariant 4-center of inertia Y_s^μ coincides with the centroid Eq. (1.1).

Finally, in Ref. 33 there is the definition of the following sequence of canonical transformations:

$$\boxed{\begin{array}{c}\vec{\eta}_i \\ \vec{\kappa}_i\end{array}} \longrightarrow \boxed{\begin{array}{cc}\vec{\eta}_+ & \vec{\rho}_a \\ \vec{\kappa}_+ & \vec{\pi}_a\end{array}} \longrightarrow \boxed{\begin{array}{cc}\vec{q}_+ & \vec{\rho}_{qa} \\ \vec{\kappa}_+ & \vec{\pi}_{qa}\end{array}}, \ a = 1,\ldots,N-1, \tag{2.13}$$

leading to the canonical separation of the internal 3-center of mass $(\vec{q}_+, \vec{\kappa}_+)$ from the internal relative variables $\vec{\rho}_{qa}, \vec{\pi}_{qa}$. Since the rest-frame condition $\vec{\kappa}_+ \approx 0$ implies[33] $\vec{\rho}_{qa} \approx \vec{\rho}_a$, $\vec{\pi}_{qa} \approx \vec{\pi}_a$, in the gauge $\vec{q}_+ \approx 0$ and in terms of the associated Dirac brackets we get an internal reduced phase space whose canonical basis is $\vec{\rho}_{qa} \equiv \vec{\rho}_a$, $\vec{\pi}_{qa} \equiv \vec{\pi}_a$, $a = 1, \ldots, N-1$.

The intermediate linear point canonical transformation in (2.13) is [actually this is a family of canonical transformations, since the γ_{ai}'s are any set of numbers satisfying $\Sigma_i \gamma_{ai} = 0$, $\Sigma_a \gamma_{ai} \gamma_{aj} = \delta_{ij} - (1/N)$, $\Sigma_i \gamma_{ai} \gamma_{bi} = \delta_{ab}$]

$$\vec{\eta}_i = \vec{\eta}_+ + \frac{1}{\sqrt{N}} \sum_a \gamma_{ai} \vec{\rho}_a,$$

$$\vec{\kappa}_i = \frac{1}{N} \vec{\kappa}_+ + \sqrt{N} \sum_a \gamma_{ai} \vec{\pi}_a,$$

$$\vec{\eta}_+ = \frac{1}{N} \sum_i \vec{\eta}_i, \quad \vec{\rho}_a = \sqrt{N} \sum_i \gamma_{ai} \vec{\eta}_i,$$

$$\vec{\kappa}_+ = \sum_i \vec{\kappa}_i, \quad \vec{\pi}_a = \frac{1}{\sqrt{N}} \sum_i \gamma_{ai} \vec{\kappa}_i. \tag{2.14}$$

The second canonical transformation has been defined in Sec. V of Ref. 33 by using a singular Gartenhaus–Schwartz transformation (see the Appendix), but there it was not written explicitly for $\vec{\kappa}_+ \neq 0$. For completeness its explicit form has been found and it is given at the end of the Appendix of this paper.

III. THE ENERGY-MOMENTUM TENSOR ON THE WIGNER HYPERPLANE

The Euler–Lagrange equations associated with the Lagrangian (2.1) are

$$\left(\frac{\partial \mathcal{L}}{\partial z^\mu} - \partial_A \frac{\partial \mathcal{L}}{\partial z^\mu_A} \right)(\tau, \vec{\sigma}) = \eta_{\mu\nu} \partial_A [\sqrt{g} T^{AB} z^\nu_B](\tau, \vec{\sigma}) \stackrel{\circ}{=} 0,$$

$$\frac{\partial L}{\partial \vec{\eta}_i} - \partial_\tau \frac{\partial L}{\partial \dot{\vec{\eta}}_i} = - \left[\frac{1}{2} \frac{T^{AB}}{\sqrt{g}} \right] \Bigg|_{\vec{\sigma} = \vec{\eta}_i} \frac{\partial g_{AB}}{\partial \vec{\eta}_i} - \partial_\tau \frac{g_{\tau r} + g_{rs} \dot{\eta}^s_i}{\sqrt{g_{\tau\tau} + 2 g_{\tau u} \dot{\eta}^u_i + g_{uv} \dot{\eta}^u_i \dot{\eta}^v_i}} \Bigg|_{\vec{\sigma} = \vec{\eta}_i} \stackrel{\circ}{=} \partial \dot{\vec{\eta}}_i$$

where we have introduced the energy-momentum tensor [here $\dot{\eta}^A_i(\tau) = (1; \dot{\vec{\eta}}_i(\tau))$],

$$T^{AB}(\tau, \vec{\sigma}) = - \left[\frac{2}{\sqrt{g}} \frac{\delta S}{\delta g_{AB}} \right](\tau, \vec{\sigma}) = - \sum_{i=1}^N \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \frac{m_i \dot{\eta}^A_i(\tau) \dot{\eta}^B_i(\tau)}{\sqrt{g_{\tau\tau} + 2 g_{\tau u} \dot{\eta}^u_i + g_{uv} \dot{\eta}^u_i \dot{\eta}^v_i}}(\tau, \vec{\sigma}). \tag{3.2}$$

Because of the delta functions, the Euler–Lagrange equations for the fields $z^\mu(\tau, \vec{\sigma})$ are trivial $(0 \stackrel{\circ}{=} 0)$ everywhere except at the positions of the particles. They may be rewritten in a form valid for every isolated system as

$$\partial_A T^{AB} z^\mu_B \stackrel{\circ}{=} - \frac{1}{\sqrt{g}} \partial_A [\sqrt{g} z^\mu_B] T^{AB}. \tag{3.3}$$

When $\partial_A [\sqrt{g} z^\mu_B] = 0$, as it happens on the Wigner hyperplanes in the gauge $\vec{q}_+ \approx 0$ and $T_s - \tau \approx 0$, we get the conservation of the energy-momentum tensor T^{AB}, i.e., $\partial_A T^{AB} \stackrel{\circ}{=} 0$. Otherwise, there is a compensation coming from the dynamics of the surface.

On the Wigner hyperplane the energy-momentum tensor $T^{AB}(\tau, \vec{\sigma})$ takes the form

$$T^{\tau\tau}(\tau,\vec{\sigma}) = -\sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \frac{m_i}{\sqrt{\dot{x}_s^2(\tau) + 2\dot{x}_{s\mu}(\tau)\epsilon_r^\mu(u(p_s)) - \dot{\vec{\eta}}_i^2(\tau)}},$$

$$T^{\tau r}(\tau,\vec{\sigma}) = -\sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \frac{m_i \dot{\eta}_i^r(\tau)}{\sqrt{\dot{x}_s^2(\tau) + 2\dot{x}_{s\mu}(\tau)\epsilon_r^\mu(u(p_s)) - \dot{\vec{\eta}}_i^2(\tau)}},$$

$$T^{rs}(\tau,\vec{\sigma}) = -\sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \frac{m_i \dot{\eta}_i^r(\tau)\dot{\eta}_i^s(\tau)}{\sqrt{\dot{x}_s^2(\tau) + 2\dot{x}_{s\mu}(\tau)\epsilon_r^\mu(u(p_s)) - \dot{\vec{\eta}}_i^2(\tau)}}. \tag{3.4}$$

With the position $x^\mu = z^\mu(\tau,\vec{\sigma})$, the same form is obtained from the energy momentum tensor of the standard manifestly Lorentz covariant theory with Lagrangian $S_S = \int d\tau L_S(\tau) = -\sum_{i=1}^N m_i \int d\tau \sqrt{\dot{x}_i^2(\tau)}$, restricted to positive energies[64]

$$T^{\mu\nu}(z(\tau,\vec{\sigma})) = -\left(\frac{2}{\sqrt{g}}\frac{\delta S_S}{\delta g_{\mu\nu}}\right)\Bigg|_{x=z(\tau,\vec{\sigma})} = \sum_{i=1}^{N} m_i \int d\tau_1 \frac{\dot{x}_i^\mu(\tau_1)\dot{x}_i^\nu(\tau_1)}{\sqrt{\dot{x}_i^2(\tau_1)}} \delta^4(x_i(\tau_1) - z(\tau,\vec{\sigma}))$$

$$= \sum_{i=1}^{N} \frac{1}{m_1} \int d\tau_1 \sqrt{\dot{x}_i^2(\tau_1)} p_i^\mu(\tau_1) p_i^\nu(\tau_1) \delta^4(x_i(\tau_1) - z(\tau,\vec{\sigma})) = \epsilon_A^\mu(u(p_s))\epsilon_B^\nu(u(p_s)) T^{AB}(\tau,\vec{\sigma}). \tag{3.5}$$

As shown explicitly in Ref. 51, on Wigner hyperplanes but only with $\tau \equiv T_s$ [so that $\dot{x}_s^\mu(\tau) = u^\mu(p_s) + \epsilon_r^\mu(u(p_s))\lambda_r(\tau)$ and $x_s^\mu(\tau) = x_s^\mu(0) + \tau u^\mu(p_s) + \epsilon_r^\mu(u(p_s))\int_0^\tau d\tau_1\, \lambda_r(\tau_1)$], we get for every value of the Dirac multiplier $\vec{\lambda}(\tau)$,

$$T^{\mu\nu}[x_s^\beta(T_s) + \epsilon_u^\beta(u(p_s))\sigma^\mu] = \epsilon_A^\mu(u(p_s))\epsilon_B^\nu(u(p_s)) T^{AB}(T_s,\vec{\sigma}) = \sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(T_s))$$

$$\times \Bigg[\sqrt{m_i^2 + \vec{\kappa}_i^2(T_s)} u^\mu(p_s) u^\nu(p_s) + k_i^r(T_s)(u^\mu(p_s)\epsilon_r^\nu(u(p_s))$$

$$+ u^\nu(p_s)\epsilon_r^\mu(u(p_s))) + \frac{\kappa_i^r(T_s)\kappa_i^s(T_s)}{\sqrt{m_i^2 + \vec{\kappa}_i^2(T_s)}} \epsilon_r^\mu(u(p_s))\epsilon_s^\nu(u(p_s)) \Bigg],$$

$$T^{\tau\tau}(T_s,\vec{\sigma}) = \sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(T_s)) \sqrt{m_i^2 + \vec{\kappa}_i^2(T_s)},$$

$$T^{\tau r}(T_s,\vec{\sigma}) = \sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(T_s)) \kappa_i^r(T_s),$$

$$T^{rs}(T_s,\vec{\sigma}) = \sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(T_s)) \frac{\kappa_i^r(T_s)\kappa_i^s(T_s)}{\sqrt{m_i^2 + \vec{\kappa}_i^2(T_s)}},$$

$$P_T^\mu = \int d^3\sigma\, T^{\mu\nu}[x_s^\beta(T_s) + \epsilon_u^\beta(u(p_s))\sigma^\mu] u_\nu(p_s) = p_s^\mu = M_{\rm sys} u^\mu(p_s) + \epsilon_r^\mu(u(p_s))\kappa_+^r \approx M_{\rm sys} u^\mu(p_s),$$

$$M_{\rm sys} = P_T^\mu u_\mu(p_s) = \sum_{i=1}^N \sqrt{m_i^2 c^2 + \vec{\kappa}_i^2(T_s)}, \tag{3.6}$$

where P_T^μ and $M_{\rm sys}$ are the total 4-momentum and the invariant mass of the isolated N-body system.

IV. DIXON'S MULTIPOLES FOR FREE PARTICLES ON THE WIGNER HYPERPLANE

In this section we will define the special relativistic Dixon multipoles on the Wigner hyperplane with $T_s - \tau \equiv 0$ for the N-body problem [see Eqs. (2.9) with $x_s^\mu(\tau) = x_o^\mu + u^\mu(p_s)T_s + \epsilon_r^\mu(u(p_s))$ $\int_o^\tau d\tau_1\, \lambda_r(\tau_1) = \vec{x}_s^{(q_+)\mu}(\tau) + \int_o^\tau d\tau_1\, \lambda_r(\tau_1)$]. By comparison, a list of the *nonrelativistic multipoles* for N free particles is given in Appendix A of Ref. 51.

Consider an arbitrary timelike world-line $w^\mu(\tau) = z^\mu(\tau, \vec{\eta}(\tau)) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\,\eta^r(\tau)$ $= x_s^{(\vec{q}_+)\mu}(\tau) + \epsilon_r^\mu(u(p_s))\,\tilde{\eta}^r(\tau)$ [$\tilde{\eta}^r(\tau) = \eta^r(\tau) + \int_o^\tau d\tau_1\, \lambda_r(\tau_1)$] and evaluate the Dixon multipoles[20] on the Wigner hyperplanes in the natural gauge with respect to the given world line. A generic point will be parametrized by

$$\begin{aligned} z^\mu(\tau,\vec{\sigma}) &= x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\sigma^r = x_s^{(\vec{q}_+)\mu}(\tau) + \epsilon_r^\mu(u(p_s))\left[\sigma^r + \int_0^\tau d\tau_1\, \lambda_r(\tau_1)\right] \\ &= w^\mu(\tau) + \epsilon_r^\mu(u(p_s))[\sigma^r - \eta^r(\tau)] \overset{\rm def}{=} w^\mu(\tau) + \delta z^\mu(\tau,\vec{\sigma}), \end{aligned} \tag{4.1}$$

so that $\delta z_\mu(\tau,\vec{\sigma})u^\mu(p_s) = 0$.

While for $\vec{\tilde{\eta}}(\tau) = 0$ [$\vec{\tilde{\eta}}(\tau) = \int_o^\tau d\tau_1\, \lambda_r(\tau_1)$] we get the multipoles relative to the centroid $x_s^\mu(\tau)$, for $\vec{\eta}(\tau) = 0$ we get those relative to the centroid $x_s^{(\vec{q}_+)\mu}(\tau)$. In the gauge $\vec{R}_+ \approx \vec{q}_+ \approx \vec{y}_+ \approx 0$, where $\vec{\lambda}(\tau) = 0$, it follows that $\vec{\eta}(\tau) = \vec{\tilde{\eta}}(\tau) = 0$ identifies the *barycentric* multipoles with respect to the centroid $x_s^{(\vec{q}_+)\mu}(\tau)$, which now carries the internal 3-center of mass.

A. Dixon's multipoles

Lorentz covariant *Dixon's multipoles* and their Wigner covariant counterparts on the Wigner hyperplanes are then defined as

$$\begin{aligned} t_T^{\mu_1\cdots\mu_n\mu\nu}(T_s,\vec{\eta}) &= t_T^{(\mu_1\cdots\mu_n)(\mu\nu)}(T_s,\vec{\eta}) = \epsilon_{r_1}^{\mu_1}(u(p_s))\cdots\epsilon_{r_n}^{\mu_n}(u(p_s))\epsilon_A^\mu(u(p_s))\epsilon_B^\nu(u(p_s))q_T^{r_1\cdots r_n AB}(T_s,\vec{\eta}) \\ &= \int d^3\sigma\, \delta z^{\mu_1}(T_s,\vec{\sigma})\cdots\delta z^{\mu_n}(T_s,\vec{\sigma})T^{\mu\nu}[x_s^{(\vec{q}_+)\beta}(T_s) + \epsilon_u^\beta(u(p_s))\sigma^\mu] \\ &= \epsilon_A^\mu(u(p_s))\epsilon_B^\nu(u(p_s)) \int d^3\sigma\, \delta z^{\mu_1}(T_s,\vec{\sigma})\cdots\delta z^{\mu_n}(T_s,\vec{\sigma})T^{AB}(T_s,\vec{\sigma}), \end{aligned}$$

$$\begin{aligned} q_T^{r_1\cdots r_n AB}(T_s,\vec{\eta}) = \int d^3\sigma[\sigma^{r_1} - \eta^{r_1}(T_s)]\cdots[\sigma^{r_n} - \eta^r(\tau_s)]T^{AB}(T_s,\vec{\sigma}) &= \delta_\tau^A\delta_\tau^B \sum_{i=1}^N [\eta_i^{r_1}(T_s) \\ - \eta^{r_1}(T_s)]\cdots[\eta_i^{r_n}(T_s) - \eta^{r_n}(T_s)]\sqrt{m_i^2 + \vec{k}_i^2(T_s)} &+ \delta_u^A\delta_v^B \sum_{i=1}^N [\eta_i^{r_1}(T_s) \\ - \eta^{r_1}(T_s)]\cdots[\eta_i^{r_n}(T_s) - \eta^{r_n}(T_s)]\frac{\kappa_i^u(T_s)\kappa_i^v(T_s)}{\sqrt{m_i^2 + \vec{\kappa}_i^2(T_s)}} &+ (\delta_\tau^A\delta_u^B + \delta_u^A\delta_\tau^B)\sum_{i=1}^N [\eta_i^{r_1}(T_s) \\ - \eta^{r_1}(T_s)]\cdots[\eta_i^{r_n}(T_s) - \eta^{r_n}(T_s)]\kappa_i^r(T_s), & \end{aligned}$$

$$u_{\mu_1}(p_s)t_T^{\mu_1\cdots\mu_n\mu\nu}(T_s,\vec{\eta})=0. \tag{4.2}$$

Related multipoles are

$$\begin{aligned}
p_T^{\mu_1\cdots\mu_n\mu}(T_s,\vec{\eta}) &= t_T^{\mu_1\cdots\mu_n\mu\nu}(T_s,\vec{\eta})u_\nu(p_s)=\epsilon_{r_1}^{\mu_1}(u(p_s))\cdots\epsilon_{r_n}^{\mu_n}(u(p_s))\epsilon_A^{\mu}(u(p_s))q_T^{r_1\cdots r_nA\tau}(T_s,\vec{\eta})\\
&=\epsilon_{r_1}^{\mu_1}(u(p_s))\cdots\epsilon_{r_n}^{\mu_n}(u(p_s))\sum_{i=1}^{N}[\eta_i^{r_1}(T_s)-\eta^{r_1}(T_s)]\cdots[\eta_i^{r_n}(T_s)-\eta^{r_n}(T_s)]\\
&\quad\times[\sqrt{m_i^2+\vec{\kappa}_i^2(\tau)}u^\mu(p_s)+k_i^r(T_s)\epsilon_r^\mu(u(p_s))],\ u_{\mu_1}(p_s)p_T^{\mu_1\cdots\mu_n\mu}(T_s,\vec{\eta})=0,\\
&\quad p_T^{\mu_1\cdots\mu_n\mu}(T_s,\vec{\eta})u_\mu(p_s)=\tilde{t}_T^{\mu_1\cdots\mu_n}(T_s,\vec{\eta}),
\end{aligned}$$

$$n=0\Rightarrow p_T^\mu(T_s,\vec{\eta})=\epsilon_A^\mu(u(p_s))q_T^{A\tau}(T_s)=P_T^\mu\approx p_s^\mu. \tag{4.3}$$

The inverse formulas, giving the *multipolar expansion*, are

$$\begin{aligned}
T^{\mu\nu}[w^\beta(T_s)+\delta z^\beta(T_s,\vec{\sigma})] &= T^{\mu\nu}[x_s^{(\vec{q}_+)\beta}(T_s)+\epsilon_r^\beta(u(p_s))\sigma^r]=\epsilon_A^\mu(u(p_s))\epsilon_B^\nu(u(p_s))T^{AB}(T_s,\vec{\sigma})\\
&=\epsilon_A^\mu(u(p_s))\epsilon_B^\nu(u(p_s))\sum_{n=0}^{\infty}(-1)^n\frac{q_T^{r_1\cdots r_nAB}(T_s,\vec{\eta})}{n!}\frac{\partial^n}{\partial\sigma^{r_1}\cdots\partial\sigma^{r_n}}\delta^3(\vec{\sigma}-\vec{\eta}(T_s))\\
&=\sum_{n=0}^{\infty}(-1)^n\frac{t_T^{\mu_1\cdots\mu_n\mu\nu}(T_s,\vec{\eta})}{n!}\epsilon_{r_1\mu_1}(u(p_s))\cdots\epsilon_{r_n\mu_n}(u(p_s))\frac{\partial^n}{\partial\sigma^{r_1}\cdots\partial\sigma^{r_n}}\\
&\quad\delta^3(\vec{\sigma}-\vec{\eta}(T_s)).
\end{aligned} \tag{4.4}$$

Note however that, as pointed out by Dixon,[20] the distributional equation (4.4) is valid only if analytic test functions are used, defined on the support of the energy-momentum tensor.

The quantities $q_T^{r_1\cdots r_n\tau\tau}(T_s,\vec{\eta})$, $q_T^{r_1\cdots r_nr\tau}(T_s,\vec{\eta})=q_T^{r_1\cdots r_n\tau r}(T_s,\vec{\eta})$, $q_T^{r_1\cdots r_nuv}(T_s,\vec{\eta})$ are the *mass density, momentum density, and stress tensor multipoles* with respect to the world-line $w^\mu(T_s)$ (barycentric for $\vec{\eta}=\tilde{\eta}=0$).

B. Monopoles

The *monopoles* correspond to $n=0$ and have the following expression[65] (see the Appendix for the definition of $\to_{\alpha\to\infty}$):

$$\begin{aligned}
q_T^{AB}(T_s,\vec{\eta}) &= \delta_\tau^A\delta_\tau^BM+\delta_u^A\delta_v^B\sum_{i=1}^{N}\frac{\kappa_i^u\kappa_i^v}{\sqrt{m_i^2+\vec{\kappa}_i^2}}+(\delta_\tau^A\delta_u^B+\delta_u^A\delta_\tau^B)\kappa_+^u\approx\\
&\to_{\alpha\to\infty}\delta_\tau^A\delta_\tau^B\sum_{i=1}^{N}\sqrt{m_i^2+N\sum_{de}\gamma_{di}\gamma_{ei}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}+\delta_u^A\delta_v^BN\sum_{i=1}^{N}\frac{\sum_{ab}^{1\cdots N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}}{\sqrt{m_i^2+N\sum_{de}\gamma_{di}\gamma_{ei}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}}
\end{aligned}$$

$$q_T^{\tau\tau}(T_s,\vec{\eta})\to_{c\to\infty}\sum_{i=1}^{N}m_ic^2+\frac{1}{2}\sum_{ab}^{1\cdots N-1}\sum_{i=1}^{N}\frac{N\gamma_{ai}\gamma_{bi}}{m_i}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}+O(1/c)=\sum_{i=1}^{N}m_ic^2+H_{\mathrm{rel},nr}+O(1/c),$$

$$q_T^{r\tau}(T_s,\vec{\eta})=\kappa_+^r\approx 0,\ \textit{rest-frame condition(also at the non relativistic level)},$$

$$q_T^{uv}(T_s,\vec{\eta}) \to_{c\to\infty} \sum_{ab}^{1\cdots N-1} \sum_{i=1}^{N} \frac{N\gamma_{ai}\gamma_{bi}}{m_i} \pi_{qa}^u \pi_{qb}^v + O(1/c) = \sum_{ab}^{1\cdots N-1} k_{ab}^{-1} \pi_{qa}^u \pi_{qb}^v + O(1/c) = \sum_{ab}^{1\cdots N-1} k_{ab} \dot{\rho}_a^u \dot{\rho}_b^v + O(1/c) \tag{4.5}$$

where we have exploited Eqs. (5.10), (5.11) of Ref. 33 to obtain the expression in terms of the internal relative variables.

Therefore, independently of the choice of the world-line $w^\mu(\tau)$, in the rest-frame instant form the *mass monopole* $q_T^{\tau\tau}$ is the invariant mass $M_{\rm sys}=\Sigma_{i=1}^N \sqrt{m_i^2+\vec{\kappa}_i^2}$, while the *momentum monopole* $q_T^{r\tau}$ vanishes and q_T^{uv} is the *stress tensor monopole*.

C. Dipoles

The mass, momentum, and stress tensor *dipoles* correspond to $n=1$,

$$q_T^{rAB}(T_s,\vec{\eta}) = \delta_\tau^A \delta_\tau^B M_{\rm sys}[R_+^r(T_s) - \eta^r(T_s)] + \delta_u^A \delta_v^B \left[\sum_{i=1}^N \frac{\eta_i^r \kappa_i^u \kappa_i^v}{\sqrt{m_i^2+\vec{\kappa}_i^2}}(T_s) - \eta^r(T_s) q_T^{uv}(T_s,\vec{\eta}) \right] + (\delta_\tau^A \delta_u^B + \delta_u^A \delta_\tau^B) \left[\sum_{i=1}^N [\eta_i^r \kappa_i^u](T_s) - \eta^r(T_s)\kappa_+^u \right]. \tag{4.6}$$

The vanishing of the *mass dipole* $q_T^{r\tau\tau}$ implies $\vec{\eta}(\tau)=\vec{\tilde{\eta}}(\tau)-\int_0^\tau d\tau_1 \vec{\lambda}(\tau_1)=\vec{R}_+$ and identifies the world-line $w^\mu(\tau)=x_s^{(\vec{q}_+)\mu}(\tau)+\epsilon_r^\mu(u(p_s))$ $[R_+^r+\int_0^\tau d\tau_1 \lambda_r(\tau_1)]$. In the gauge $\vec{R}_+\approx\vec{q}_+\approx\vec{y}_+\approx 0$, where $\vec{\lambda}(\tau)=0$, this is the world-line $w^\mu(\tau)=x_s^{(\vec{q}_+)\mu}(\tau)$ of the centroid associated with the *internal Møller 3-center of energy* and, as a consequence of the rest-frame condition, also with the *rest-frame internal 3-center of mass* $\vec{q}_+$. Therefore we get the implications following from the vanishing of the barycentric [i.e., $\vec{\lambda}(\tau)=0$] mass dipole:

$$q_T^{r\tau\tau}(T_s,\vec{\eta}) = \epsilon_{\mu_1}^{r_1}(u(p_s))\tilde{t}_T^{\mu_1}(T_s,\vec{\eta}) = M_{\rm sys}[R_+^r(T_s) - \eta^r(T_s)] = 0, \text{ and } \vec{\lambda}(\tau)=0,$$

$$\Rightarrow \vec{\eta}(T_s) = \vec{\tilde{\eta}}(T_s) = \vec{R}_+ \approx \vec{q}_+ \approx \vec{y}_+. \tag{4.7}$$

In the gauge $\vec{R}_+\approx\vec{q}_+\approx\vec{y}_+\approx 0$, Eq. (4.7) with $\vec{\eta}=\vec{\tilde{\eta}}=0$ implies the vanishing of the time derivative of the barycentric mass dipole, this identifies the *center-of-mass momentum-velocity relation* (the so-called *constitutive equation*) for the system

$$\frac{dq_T^{r\tau\tau}(T_s,\vec{\eta})}{dT_s} \stackrel{\circ}{=} \kappa_+^r - M_{\rm sys}\dot{R}_+^r = 0. \tag{4.8}$$

The expression of the barycentric dipoles in terms of the internal relative variables, when $\vec{\eta}=\vec{\tilde{\eta}}=\vec{R}_+\approx\vec{q}_+\approx 0$ and $\vec{\kappa}_+\approx 0$, is obtained by using the results of the Appendix,

$$q_T^{r\tau\tau}(T_s,\vec{R}_+) = 0,$$

$$q_T^{ru\tau}(T_s,\vec{R}_+) = \sum_{i=1}^N \eta_i^r \kappa_i^u - R_+^r \kappa_+^u = \sum_{a=1}^{N-1} \rho_a^r \pi_a^u + (\eta_+^r - R_+^r)\kappa_+^u \to_{\alpha\to\infty} \sum_{a=1}^{N-1} \rho_{qa}^r \pi_{qa}^u \to_{c\to\infty} \sum_{a=1}^{N-1} \rho_a^r \pi_{qa}^u = \sum_{ab}^{1\cdots N-1} k_{ab} \rho_a^r \dot{\rho}_b^u,$$

$$q_T^{ruv}(T_s,\vec{R}_+)=\sum_{i=1}^{N}\eta_i^r\frac{\kappa_i^u\kappa_i^v}{H_i}-R_+^r\sum_{i=1}^{N}\frac{\kappa_i^u\kappa_i^v}{H_i}=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\sum_{a=1}^{N-1}\gamma_{ai}\rho_a^r\frac{\kappa_i^u\kappa_i^v}{H_i}+(\eta_+^r-R_+^r)\sum_{i=1}^{N}\frac{\kappa_i^u\kappa_i^v}{H_i}$$

$$\rightarrow_{\alpha\rightarrow\infty}\sum_{a=1}^{N-1}\left(c\sqrt{N}\sum_{ij}^{1\cdots N}(\gamma_{ai}-\gamma_{aj})\frac{\sqrt{m_j^2+N\sum_{de}\gamma_{dj}\gamma_{ej}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}}{\sqrt{m_i^2+N\sum_{de}\gamma_{di}\gamma_{ei}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}}\right.$$

$$\left.\times\frac{\sum_{bc}^{1\cdots N-1}\gamma_{bi}\gamma_{ci}\pi_{qb}^u\pi_{qc}^v}{\sum_{k=1}^{N}\sqrt{m_k^2+N\sum_{de}\gamma_{dk}\gamma_{ek}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}}\right)\rho_{qa}^r$$

$$=\rightarrow_{c\rightarrow\infty}\sum_{ij}^{1\cdots N}\sum_{a=1}^{N-1}\frac{\gamma_{ai}-\gamma_{aj}}{\sqrt{N}}\rho_a^r\frac{m_jN}{m_im}\sum_{bc}^{1\cdots N-1}\gamma_{bi}\gamma_{ci}\pi_{qb}^u\pi_{qc}^v+O(1/c)$$

$$=\frac{1}{\sqrt{N}}\sum_{abc}^{1\cdots N-1}\left[N\sum_{i=1}^{N}\frac{\gamma_{ai}\gamma_{bi}\gamma_{ci}}{m_i}-\frac{\sum_{j=1}^{N}m_j\gamma_{aj}}{m}\right]\rho_a^r\pi_{qb}^u\pi_{qc}^v+O(1/c).\tag{4.9}$$

The antisymmetric part of the related dipole $p_T^{\mu_1\mu}(T_s,\vec{\eta})$ identifies the *spin tensor*. Indeed, the *spin dipole* is

$$S_T^{\mu\nu}(T_s)[\vec{\eta}]=2p_T^{[\mu\nu]}(T_s,\vec{\eta})=2\epsilon_r^{[\mu}(u(p_s))\epsilon_A^{\nu]}(u(p_s))q_T^{rA\tau}(T_s,\vec{\eta})=M_{\rm sys}[R_+^r(T_s)-\eta^r(T_s)]$$

$$\times[\epsilon_r^\mu(u(p_s))u^\nu(p_s)-\epsilon_r^\nu(u(p_s))u^\mu(p_s)]+\sum_{i=1}^{N}[\eta_i^r(T_s)-\eta^r(T_s)]\kappa_i^s(T_s)[\epsilon_r^\mu(u(p_s))\epsilon_s^\nu(u(p_s))$$

$$-\epsilon_r^\nu(u(p_s))\epsilon_s^\mu(u(p_s))],$$

$$m_{u(p_s)}^\nu(T_s,\vec{\eta})=u_\mu(p_s)S_T^{\mu\nu}(T_s)[\vec{\eta}]=-\epsilon_r^\nu(u(p_s))[\overline{S_s^{\tau r}}-M_{\rm sys}\eta^r(T_s)]=-\epsilon_r^\nu(u(p_s))M_{\rm sys}[R_+^r(T_s)-\eta^r(T_s)]$$

$$=-\epsilon_r^\nu(u(p_s))q_T^{r\tau\tau}(T_s,\vec{\eta}),$$

$$\Rightarrow u_\mu(p_s)S_T^{\mu\nu}(T_s)[\vec{\eta}]=0,\quad\Rightarrow\vec{\eta}=\vec{R}_+,$$

$$\Downarrow barycentric\ spin\ for\ \vec{\eta}=\vec{\tilde{\eta}}=0,\ see\ Eq.\ (2.9),$$

$$S_T^{\mu\nu}(T_s)[\vec{\eta}=0]=S_s^{\mu\nu}\overset{\circ}{=}\sum_{i=1}^{N}\frac{m_i\eta_i^r(T_s)}{\sqrt{1-\dot{\vec{\eta}}_i^2(T_s)}}[\epsilon_r^\mu(u(p_s))u^\nu(p_s)-\epsilon_r^\nu(u(p_s))u^\mu(p_s)]$$

$$+\sum_{i=1}^{N}\frac{m_i\eta_i^r(T_s)\dot{\eta}_i^s(T_s)}{\sqrt{1-\dot{\vec{\eta}}_i^2(T_s)}}[\epsilon_r^\mu(u(p_s))\epsilon_s^\nu(u(p_s))-\epsilon_r^\nu(u(p_s))\epsilon_s^\mu(u(p_s))]$$

$$\overset{\circ}{=}\sum_i\eta_i^r(T_s)\sqrt{m_i^2+\vec{\kappa}_i^2}[\epsilon_r^\mu(u(p_s))u^\nu(p_s)-\epsilon_r^\nu(u(p_s))u^\mu(p_s)]+\epsilon^{rsu}\overline{S_s^u}\epsilon_r^\mu(u(p_s))\epsilon_s^\nu(u(p_s)).\tag{4.10}$$

This explains why $m_{u(p_s)}^\mu(T_s,\vec{\eta})$ is also called the *mass dipole moment*.

We find, therefore, that in the gauge $\vec{R}_+\approx\vec{q}_+\approx\vec{y}_+\approx0$ with $P_T^\mu=M_{\rm sys}\,u^\mu(p_s)=M_{\rm sys}\,\dot{x}_s^{(\vec{q}_+)\mu}(T_s)$ the Møller and barycentric centroid $x_s^{(\vec{q}_+)\mu}(T_s)$ is simultaneously the *Tulczyjew centroid*[15,18,23] [defined by $S_T^{\mu\nu}(T_s)[\vec{\eta}]P_{T_\nu}=0$, namely by $S_s^{or}=0$ in the momentum rest frame] and also the *Pirani centroid*[14]

[defined by $S_T^{\mu\nu}(T_s)[\vec{\eta}]\dot{x}_{s\nu}^{(\vec{q}_+)}=0$, namely by $S_s^{or}=0$ in the instantaneous-velocity rest frame]. In general, lacking a relation between 4-momentum and 4-velocity, they are different centroids.[66]

Note that noncovariant centroids could also be connected with the noncovariant external center of mass $\tilde{x}_s^\mu$ and the noncovariant external Møller center of energy.

D. Quadrupoles and the barycentric tensor of inertia

The *quadrupoles* correspond to $n=2$,

$$q_T^{r_1r_2AB}(T_s,\vec{\eta}) = \delta_\tau^A\delta_\tau^B\sum_{i=1}^N [\eta_i^{r_1}(T_s)-\eta^{r_1}(T_s)][\eta_i^{r_2}(T_s)-\eta^{r_2}(T_s)]\sqrt{m_i^2+\vec{\kappa}_i^2(T_s)} + \delta_u^A\delta_v^B\sum_{i=1}^N [\eta_i^{r_1}(T_s) - \eta^{r_1}(T_s)][\eta_i^{r_2}(T_s)-\eta^{r_2}(T_s)]\frac{\kappa_i^u\kappa_i^v}{\sqrt{m_i^2+\vec{\kappa}_i^2}}(T_s) + (\delta_\tau^A\delta_u^B+\delta_u^A\delta_\tau^B)\sum_{i=1}^N [\eta_i^{r_1}(T_s)-\eta^{r_1}(T_s)] \times[\eta_i^{r_2}(T_s)-\eta^{r_2}(T_s)]\kappa_i^u(T_s). \tag{4.11}$$

When the mass dipole vanishes, i.e., $\vec{\eta}=\vec{R}_+=\Sigma_i\vec{\eta}_i\sqrt{m_i^2+\vec{\kappa}_i^2}/M_{\rm sys}$, we get

$$q_T^{r_1r_2\tau\tau}(T_s,\vec{R}_+) = \sum_{i=1}^N (\eta_i^{r_1}-R_+^{r_1})(\eta_i^{r_2}-R_+^{r_2})\sqrt{m_i^2+\vec{\kappa}_i^2(T_s)},$$

$$q_T^{r_1r_2u\tau}(T_s,\vec{R}_+) = \sum_{i=1}^N (\eta_i^{r_1}-R_+^{r_1})(\eta_i^{r_2}-R_+^{r_2})\kappa_i^u,$$

$$q_T^{r_1r_2uv}(T_s,\vec{R}_+) = \sum_{i=1}^N (\eta_i^{r_1}-R_+^{r_1})(\eta_i^{r_2}-R_+^{r_2})\frac{\kappa_i^u\kappa_i^v}{\sqrt{m_i^2+\vec{\kappa}_i^2(T_s)}} = \frac{1}{N}\sum_{ijk}^{1\cdots N}\sum_{ab}^{1\cdots N-1}(\gamma_{ai}-\gamma_{aj}). \tag{4.12}$$

Following the nonrelativistic pattern, Dixon starts from the *mass quadrupole*,

$$q_T^{r_1r_2\tau\tau}(T_s,\vec{R}_+) = \sum_{i=1}^N [\eta_i^{r_1}\eta_i^{r_2}\sqrt{m_i^2+\vec{\kappa}_i^2}](T_s) - M_{\rm sys}\,R_+^{r_1}R_+^{r_2}, \tag{4.13}$$

and defines the following *barycentric tensor of inertia:*

$$I_{\rm Dixon}^{r_1r_2}(T_s) = \delta^{r_1r_2}\sum_u q_T^{uu\tau\tau}(T_s,\vec{R}_+) - q_T^{r_1r_2\tau\tau}(T_s,\vec{R}_+) = \sum_{i=1}^N [(\delta^{r_1r_2}(\vec{\eta}_i-\vec{R}_+)^2 - (\eta_i^{r_1}-R_+^{r_1})(\eta_i^{r_2} - R_+^{r_2}))\sqrt{m_i^2+\vec{\kappa}_i^2}](T_s) = \to_{\alpha\to\infty} \sum_{ab}^{1\cdots N-1}\left(\frac{1}{N}\sum_{ijk}^{1\cdots N}(\gamma_{ai}-\gamma_{aj})(\gamma_{bi}-\gamma_{bk}) \times \frac{\sqrt{m_i^2+N\sum_{de}\gamma_{di}\gamma_{ei}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}}{\left(\sum_{h=1}^N\sqrt{m_h^2+N\sum_{de}\gamma_{dh}\gamma_{eh}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}\right)^2}\right.$$

$$\times \sqrt{m_j^2 + N\sum_{de} \gamma_{dj}\gamma_{ej}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}\sqrt{m_k^2 + N\sum_{de} \gamma_{dk}\gamma_{ek}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}\Bigg)[\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\delta^{r_1r_2} - \rho_{qa}^{r_1}\rho_{qb}^{r_2}]$$

$$\to_{c\to\infty} \sum_{ab}^{1\cdots N-1}\sum_{ijk}^{1\cdots N}\frac{m_i m_j m_k}{Nm^2}(\gamma_{ai}-\gamma_{aj})(\gamma_{bi}-\gamma_{bk})\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\delta^{r_1r_2} - \rho_{qa}^{r_1}\rho_{qb}^{r_2}$$

$$\times\Bigg[1+\frac{1}{c}\Bigg(\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{ci}\gamma_{di}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{2m_i^2}+\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{cj}\gamma_{dj}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{2m_j^2}+\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{ck}\gamma_{dk}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{2m_k^2}$$

$$-\frac{1}{m}\sum_{h=1}^{N}\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{ch}\gamma_{dh}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{m_h}\Bigg)+O(1/c^2)\Bigg] = \sum_{ab}^{1\cdots N-1} k_{ab}[\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\delta^{r_1r_2} - \rho_{qa}^{r_1}\rho_{qb}^{r_2}]$$

$$+O(1/c) = I^{r_1r_2}[\vec{q}_{nr}] + O(1/c). \tag{4.14}$$

Note that in the nonrelativistic limit we recover the *tensor of inertia* of Eqs. (A11) of Appendix A of Ref. 51.

On the other hand, Thorne's definition of *barycentric tensor of inertia*[27] is

$$I^{r_1r_2}_{\text{Thorne}}(T_s) = \delta^{r_1r_2}\sum_u q_T^{uuA}{}_A(T_s,\vec{R}_+) - q_T^{r_1r_2A}{}_A(T_s,\vec{R}_+)$$

$$= \sum_{i=1}^{N}\frac{m_i^2(\delta^{r_1r_2}(\vec{\eta}_i-\vec{R}_+)^2-(\eta_i^{r_1}-R_+^{r_1})(\eta_i^{r_2}-R_+^{r_2}))}{\sqrt{m_i^2+\vec{\kappa}_i^2}}(T_s)\to_{\alpha\to\infty}\sum_{ab}^{1\cdots N-1}\Bigg(\frac{c}{N}\sum_{ijk}^{1\cdots N}(\gamma_{ai}-\gamma_{aj})$$

$$\times(\gamma_{bi}-\gamma_{bk})\frac{m_i^2\sqrt{m_j^2+N\sum_{de}\gamma_{dj}\gamma_{ej}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}\sqrt{m_k^2+N\sum_{de}\gamma_{dk}\gamma_{ek}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}}{\sqrt{m_i^2+N\sum_{de}\gamma_{di}\gamma_{ei}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}\Big(\sum_{h=1}^{N}\sqrt{m_h^2+N\sum_{de}\gamma_{dh}\gamma_{eh}\vec{\pi}_{qd}\cdot\vec{\pi}_{qe}}\Big)^2}\Bigg)$$

$$\times[\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\delta^{r_1r_2} - \rho_{qa}^{r_1}\rho_{qb}^{r_2}] = \to_{c\to\infty}\sum_{ab}^{1\cdots N-1}\sum_{ijk}^{1\cdots N}\frac{m_i m_j m_k}{Nm^2}(\gamma_{ai}-\gamma_{aj})(\gamma_{bi}-\gamma_{bk})\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\delta^{r_1r_2}$$

$$-\rho_{qa}^{r_1}\rho_{qb}^{r_2}\times\Bigg[1+\frac{1}{c}\Bigg(-\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{ci}\gamma_{di}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{2m_i^2}+\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{cj}\gamma_{dj}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{2m_j^2}$$

$$+\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{ck}\gamma_{dk}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{2m_k^2}-\frac{1}{m}\sum_{h=1}^{N}\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{ch}\gamma_{dh}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{m_h}\Bigg)+O(1/c^2)\Bigg]$$

$$= \sum_{ab}^{1\cdots N-1} k_{ab}[\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\delta^{r_1r_2} - \rho_{qa}^{r_1}\rho_{qb}^{r_2}] + O(1/c) = I^{r_1r_2}[\vec{q}_{nr}] + O(1/c). \tag{4.15}$$

In this case too we recover the *tensor of inertia* of Eq. (A11) of Appendix A of Ref. 51.

Note that the Dixon and Thorne barycentric tensors of inertia differ at the post-Newtonian level

$$I^{r_1r_2}_{\rm Dixon}(T_s) - I^{r_1r_2}_{\rm Thorne}(T_s) = \frac{1}{c}\sum_{ab}^{1\cdots N-1}\sum_{ijk}^{1\cdots N}\frac{m_j m_k}{Nm^2}(\gamma_{ai}-\gamma_{aj})(\gamma_{bi}-\gamma_{bk})[\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\delta^{r_1r_2} - \rho^{r_1}_{qa}\rho^{r_2}_{qb}]\frac{N\sum_{cd}^{1\cdots N-1}\gamma_{ci}\gamma_{di}\vec{\pi}_{qc}\cdot\vec{\pi}_{qd}}{m_i} + O(1/c^2).$$

E. The multipolar expansion

By further exploiting the types of Dixon's multipoles analyzed in Appendix D of Ref. 51 (where there is also the proof of some basic formulas of Ref. 20 along the lines of this paper) as well as the consequences of Hamilton equations for an isolated system (equivalent to $\partial_\mu T^{\mu\nu}\overset{\circ}{=}0$), it turns out that the *multipolar expansion* (4.4) can be rearranged in the following form:

$$\begin{aligned}T^{\mu\nu}[x_s^{(\vec{q}_+)\beta}(T_s)+\epsilon^\beta_r(u(p_s))\sigma^r] &= T^{\mu\nu}[w^\beta(T_s)+\epsilon^\beta_r(u(p_s))(\sigma^r-\eta^r(T_s))] = u^{(\mu}(p_s)\epsilon_A^{\nu)}(u(p_s))[\delta^A_\tau M_{\rm sys}\\ &+\delta^A_u\kappa^u_+]\delta^3(\vec{\sigma}-\vec{\eta}(T_s))+\frac{1}{2}S_T^{\rho(\mu}(T_s)[\vec{\eta}]u^{\nu)}(p_s)\epsilon^r_\rho(u(p_s))\frac{\partial}{\partial\sigma^r}\\ &\delta^3(\vec{\sigma}-\vec{\eta}(T_s))\\ &+\sum_{n=2}^{\infty}\frac{(-1)^n}{n!}I_T^{\mu_1\cdots\mu_n\mu\nu}(T_s,\vec{\eta})\epsilon^{r_1}_{\mu_1}(u(p_s))\cdots\epsilon^{r_n}_{\mu_n}(u(p_s))\\ &\frac{\partial^n}{\partial\sigma^{r_1}\cdots\partial\sigma^{r_n}}\delta^3(\vec{\sigma}-\vec{\eta}(T_s)),\end{aligned}\tag{4.16}$$

where, for $n\geqslant 2$ and $\vec{\eta}=0$, $I_T^{\mu_1\cdots\mu_n\mu\nu}(T_s)=\frac{4(n-1)}{n+1}J_T^{(\mu_1\cdots\mu_{n-1}|\mu|\mu_n)\nu}(T_s)$, with $J_T^{\mu_1\cdots\mu_n\mu\nu\rho\sigma}(T_s)$ being the Dixon 2^{2+n}-*pole inertial moment tensors* given in Eqs. (D10) of Ref. 51. With this form of the multipolar expansion, the quadrupole term ($n=2$) takes the form [see Eq. (D11) of Ref. 51]

$$\begin{aligned}&\tfrac{1}{2}\Big(\tfrac{5}{3}u^\mu(p_s)u^\nu(p_s)q_F^{r_1r_2\tau\tau}(T_s,\vec{\eta})+\tfrac{1}{2}[u^\mu(p_s)\epsilon^\nu_u(u(p_s))+u^\nu(p_s)\epsilon^\mu_u(u(p_s))]q_T^{r_1r_2u\tau}(T_s,\vec{\eta})\\ &+\epsilon^\mu_{u_1}(u(p_s))\epsilon^\nu_{u_2}(u(p_s))\Big[q_T^{r_1r_2u_1u_2}(T_s,\vec{\eta})-\tfrac{3}{2}(q_T^{(r_1r_2u_1)u_2}(T_s,\vec{\eta})+q_T^{(r_1r_2u_2)u_1}(T_s,\vec{\eta}))+q_T^{(r_1r_2u_1u_2)}(T_s,\vec{\eta})\Big]\Big).\end{aligned}$$

Note that, as said in Appendix D of Ref. 51, Eq. (4.16) holds only if the multipoles are evaluated with respect to world-lines $w^\mu(\tau)=z^\mu(\tau,\vec{\eta}(\tau))$ with $\vec{\eta}(\tau)=\vec{\eta}=$const, namely with respect to one of the integral lines of the vector field $z^\mu_\tau(\tau,\vec{\sigma})\partial_\mu$.

On the Wigner hyperplane, the content of these 2^{n+2}-*pole inertial moment tensors* is replaced by the *Euclidean Cartesian tensors* $q_T^{r_1\cdots r_n\tau\tau}, q_T^{r_1\cdots r_n r\tau}, q_T^{r_1\cdots r_n rs}$. As shown in Appendix B of Ref. 51, we can decompose these Cartesian tensors in their irreducible STF (symmetric trace free) parts (the *STF tensors*).

For an isolated system described by the multipoles appearing in Eq. (4.16) [this is not true for those in Eq. (4.4)] the equations $\partial_\mu T^{\mu\nu}\overset{\circ}{=}0$ [see Eqs. (D4) and (D7) of Ref. 51] imply no more than the following *Papapetrou–Dixon–Souriau equations of motion*[11,21,22,24] for the total momentum $P^\mu_T(T_s)=\epsilon^\mu_A(u(p_s))q_T^{A\tau}(T_s)\approx p_s^\mu$ and the spin tensor $S_T^{\mu\nu}(T_s)[\vec{\eta}=0]$,

$$\frac{{\rm d}P^\mu_T(T_s)}{{\rm d}T_s}\overset{\circ}{=}0,$$

$$\frac{dS_T^{\mu\nu}(T_s)[\vec{\eta}=0]}{dT_s} \overset{\circ}{=} 2P_T^{[\mu}(T_s)u^{\nu]}(p_s) = 2\kappa_+^u \epsilon_u^{[\mu}(u(p_s))u^{\nu]}(p_s) \approx 0,$$

$$\text{or } \frac{dM_{\text{sys}}}{dT_s} \overset{\circ}{=} 0, \quad \frac{d\vec{\kappa}_+}{dT_s} \overset{\circ}{=} 0, \quad \frac{dS_s^{\mu\nu}}{dT_s} \overset{\circ}{=} 0. \tag{4.17}$$

For *open systems*, subsystems of an isolated system like in Sec. V, we have $\partial_\nu T^{\mu\nu} \overset{\circ}{=} F^\mu \neq 0$, with F^μ an external force. As shown in Ref. 20 for the case in which $F^\mu = -F^{\mu\nu}J_\nu (\partial_\mu J^\mu \overset{\circ}{=} 0)$ is the Lorentz force, the multipolar expansion (4.16) is still valid, while the equations of motion (4.17) become (P^μ and T_s are the conserved 4-momentum and the rest-frame time of the global isolated system)

$$\frac{dP_c^\mu(T_s)}{dT_s} \overset{\circ}{=} \int d^3\sigma\, F^\mu(T_s,\vec{\sigma}),$$

$$\frac{dS_c^{\mu\nu}(T_s)[\vec{\eta}=0]}{dT_s} \overset{\circ}{=} 2p_c^{[\mu}(T_s)u^{\nu]}(P) - \int d^3\sigma\, \sigma^r [\epsilon_r^\mu(u(P))F^\nu(T_s,\vec{\sigma}) - \epsilon_r^\nu(u(P))F^\mu(T_s,\vec{\sigma})]. \tag{4.18}$$

V. DIXON'S MULTIPOLES AND RELEVANT CENTROIDS FOR CLOSED AND OPEN SYSTEMS OF INTERACTING RELATIVISTIC PARTICLES

In this section we present new applications of the multipolar expansion to interacting systems of particles and fields. We first deal with the case of an isolated system of positive-energy relativistic particles with mutual action-at-a-distance interaction (see Sec. VIII of Ref. 33 and Sec. VI of Ref. 36); then we deal with the case of an *open particle subsystem* of an isolated system consisting of N charged positive-energy relativistic particles (with Grassmann-valued electric charges to regularize the Coulomb self-energies) plus the electromagnetic field.[36]

A. An isolated system of positive-energy particles with action-at-a-distance interactions

As mentioned in Sec. VIII of Ref. 33, the most general expression of the internal energy for an isolated system of N positive-energy particles with mutual action-at-a-distance interactions, in the rest-frame instant form, is

$$M = \sum_i \sqrt{m_i^2 + U_i + (\vec{\kappa}_i - \vec{V}_i)^2} + V, \tag{5.1}$$

where all the potentials $U_i, \vec{V}_i, V$ are functions of $\vec{\kappa}_i \cdot \vec{\kappa}_j, |\vec{\eta}_i - \vec{\eta}_j|, \vec{\kappa}_k \cdot (\vec{\eta}_i - \vec{\eta}_j)$. On the other hand, as shown at the end of Sec. II, in the free case we have

$$M_{(\text{free})} = \sum_i \sqrt{m_i^2 + \vec{\kappa}_i^2} = \sqrt{\mathcal{M}_{(\text{free})}^2 + \vec{\kappa}_+^2} \approx \mathcal{M}_{(\text{free})} = \sum_i \sqrt{m_i^2 + N\sum_{ab} \gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}}. \tag{5.2}$$

Since the 3-centers $\vec{R}_+$ and $\vec{q}_+$ become interaction dependent, in the interacting case we do not know the final canonical basis $\vec{q}_+, \vec{\kappa}_+, \vec{\rho}_{qa}, \vec{\pi}_{qa}$ explicitly. For an isolated system, however, we have $M = \sqrt{\mathcal{M}^2 + \vec{\kappa}_+^2} \approx \mathcal{M}$ with $\mathcal{M}$ independent of $\vec{q}_+$ ($\{M, \vec{\kappa}_+\} = 0$ in the internal Poincaré algebra). This suggests that also in the interacting case the same result should hold true. Indeed, by its very definition, the Gartenhaus–Schwartz transformation gives $\vec{\rho}_{qa} \approx \vec{\rho}_a, \vec{\pi}_{qa} \approx \vec{\pi}_a$ also in presence of interactions, so that we get

$$M|_{\vec{\kappa}_{+=0}} = \left(\sum_i \sqrt{m_i^2 + U_i + (\vec{\kappa}_i - \vec{V}_i)^2} + V \right) \Bigg|_{\vec{\kappa}_+=0} = \sqrt{\mathcal{M}^2 + \vec{\kappa}_+^2}|_{\vec{\kappa}_+} = \mathcal{M}|_{\vec{\kappa}_+=0}$$

$$= \sum_i \sqrt{m_i^2 + \tilde{U}_i + (\vec{\kappa}_i - \vec{\tilde{V}}_i)^2} + \tilde{V}, \tag{5.3}$$

where the potentials $\tilde{U}_i, \vec{\tilde{V}}_i, \tilde{V}$ are now functions of $\vec{\pi}_{qa} \cdot \vec{\pi}_{qb}, \vec{\pi}_{qa} \cdot \vec{\rho}_{qb}, \vec{\rho}_{qa} \cdot \vec{\rho}_{qb}$.

A relevant example of this type of isolated system has been studied in Ref. 36 starting from the isolated system of N charged positive-energy particles (with Grassmann-valued electric charges $Q_i = \theta^* \theta$, $Q_i^2 = 0$, $Q_i Q_j = Q_j Q_i \neq 0$ for $i \neq j$) plus the electromagnetic field. After a Shanmugadhasan canonical transformation, this system can be expressed only in terms of transverse Dirac observables corresponding to a radiation gauge for the electromagnetic field. The expression of the energy-momentum tensor in this gauge will be shown in the next section. In the semiclassical approximation of Ref. 36, the electromagnetic degrees of freedom are reexpressed in terms of the particle variables by means of the Lienard–Wiechert solution in the framework of the rest-frame instant form. In this way it has been possible to derive the exact semiclassical relativistic form of the action-at-a-distance Darwin potential in the reduced phase space of the particles. Note that this form is independent of the choice of the Green function in the Lienard–Wiechert solution. In Ref. 36 the associated energy-momentum tensor for the case $N=2$ [Eqs. (6.48)] is also given. The internal energy is $M = \sqrt{\mathcal{M}^2 + \vec{\kappa}_+^2} \approx \mathcal{M} = \Sigma_{i=1}^2 \sqrt{m_i^2 + \vec{\pi}^2} + (Q_1 Q_2 / 4\pi\rho)[1 + \tilde{V}(\vec{\pi}^2, \vec{\pi} \cdot (\vec{\rho}/\rho))]$ where $\tilde{V}$ is given in Eqs. (6.34), (6.35) [in Eqs. (6.36), (6.37) for $m_1 = m_2$]. The internal boost $\vec{\mathcal{K}}$ [Eq. (6.46)] allows the determination of the 3-center of energy $\vec{R}_+ = -\vec{\mathcal{K}}/M \approx \vec{q}_+ \approx \vec{y}_+$ in the present interacting case.

The knowledge of the energy-momentum tensor $T^{AB}(\tau, \vec{\sigma})$ and of $\vec{R}_+ \approx \vec{q}_+$ allows to apply our formalism to find the *barycentric multipoles of this interacting case*. It turns out that, in the gauge $\vec{R}_+ \approx \vec{q}_+ \approx \vec{y}_+ \approx 0$, all the formal properties studied in the preceding section (like the coincidence of all the relevant centroids) are reproduced in presence of mutual action-at-a-distance interactions.

B. Open subsystem of the isolated system of *N* positive-energy particles with Grassmann-valued electric charge plus the electromagnetic field

Let us now consider an open subsystem of the isolated system of N charged positive-energy particles plus the electromagnetic field in the radiation gauge. The energy-momentum tensor and the Hamilton equations on the Wigner hyperplane of the isolated system are ($\vec{\kappa}_+ = \Sigma_i \vec{\kappa}_i$; to avoid degenerations we assume that all the masses m_i are different)

$$T^{\tau\tau}(\tau, \vec{\sigma}) = \sum_{i=1}^N \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \sqrt{m_i^2 + [\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau, \vec{\eta}_i(\tau))]^2} + \frac{1}{2} \Bigg[\left(\vec{\pi}_\perp + \sum_{i=1}^N Q_i \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \right)^2$$

$$+ \vec{B}^2 \Bigg](\tau, \vec{\sigma}) = \sum_{i=1}^N \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \sqrt{m_i^2 + [\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau, \vec{\eta}_i(\tau))]^2} + \sum_{i=1}^N Q_i \vec{\pi}_\perp(\tau, \vec{\sigma})$$

$$\times \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) + \frac{1}{2} [\vec{\pi}_\perp^2 + \vec{B}^2](\tau, \vec{\sigma}) + \frac{1}{2} \sum_{i,k,i \neq k}^{1 \cdots N} Q_i Q_k \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \cdot \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_k(\tau)),$$

$$T^{\tau\tau}(\tau, \vec{\sigma}) = \sum_{i=1}^N \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) [\kappa_i^r(\tau) - Q_i A_\perp^r(\tau, \vec{\eta}_i(\tau))] + \left[\left(\vec{\pi}_\perp + \sum_{i=1}^N Q_i \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \right) \times \vec{B} \right]^r (\tau, \vec{\sigma}),$$

$$T^{rs}(\tau,\vec{\sigma}) = \sum_{i=1}^{N} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \frac{[\kappa_i^r(\tau) - Q_i A_\perp^r(\tau,\vec{\eta}_i(\tau))][\kappa_i^s(\tau) - Q_i A_\perp^s(\tau,\vec{\eta}_i(\tau))]}{\sqrt{m_i^2 + [\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i(\tau))]^2}}$$
$$- \left[\frac{1}{2}\delta^{rs} \left[\left(\vec{\pi}_\perp + \sum_{i=1}^{N} Q_i \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \right)^2 + \vec{B}^2 \right] - \left[\left(\vec{\pi}_\perp + \sum_{i=1}^{N} Q_i \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \right)^r \right.$$
$$\left. \times \left(\vec{\pi}_\perp + \sum_{i=1}^{N} Q_i \frac{\vec{\partial}}{\Delta} \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)) \right)^s + B^r B^s \right] \Bigg] (\tau,\vec{\sigma}), \tag{5.4}$$

$$\dot{\vec{\eta}}_i(\tau) \stackrel{\circ}{=} \frac{\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i(\tau))}{\sqrt{m_i^2 + (\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i(\tau)))^2}},$$

$$\dot{\vec{\kappa}}_i(\tau) \stackrel{\circ}{=} \sum_{k\neq i} \frac{Q_i Q_k (\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau))}{4\pi |\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau)|^3} + Q_i \dot{\eta}_i^u(\tau) \frac{\partial}{\partial \vec{\eta}_i} A_\perp^u(\tau,\vec{\eta}_i(\tau)),$$

$$\dot{A}_{\perp r}(\tau,\vec{\sigma}) \stackrel{\circ}{=} -\pi_{\perp r}(\tau,\vec{\sigma}),$$

$$\dot{\pi}_\perp^r(\tau,\vec{\sigma}) \stackrel{\circ}{=} \Delta A_\perp^r(\tau,\vec{\sigma}) - \sum_i Q_i P_\perp^{rs}(\vec{\sigma}) \dot{\eta}_i^s(\tau) \delta^3(\vec{\sigma} - \vec{\eta}_i(\tau)),$$

$$\vec{\kappa}_+(\tau) + \int d^3\sigma [\vec{\pi}_\perp \times \vec{B}](\tau,\vec{\sigma}) \approx 0 \quad (\textit{rest-frame condition}). \tag{5.5}$$

Let us note that in this reduced phase space there are only either particle-field interactions or action-at-a-distance two-body interactions.

The particle world lines are $x_i^\mu(\tau) = x_o^\mu + u^\mu(p_s)\tau + \epsilon_r^\mu(u(p_s))\eta_i^r(\tau)$, while their 4-momenta are $p_i^\mu(\tau) = \sqrt{m_i^2 + [\vec{\kappa}_i - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i)]^2} u^\mu(p_s) + \epsilon_r^\mu(u(p_s))[\kappa_i^r - Q_i A_\perp^r(\tau,\vec{\eta}_i)]$.

The generators of the internal Poincaré group are

$$\mathcal{P}^\tau_{(\mathrm{int})} = M = \sum_{i=1}^{N} \sqrt{m_i^2 + (\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i(\tau)))^2} + \frac{1}{2} \sum_{i\neq j} \frac{Q_i Q_j}{4\pi |\vec{\eta}_i(\tau) - \vec{\eta}_j(\tau)|} + \int d^3\sigma \frac{1}{2} [\vec{\pi}_\perp^2 + \vec{B}^2](\tau,\vec{\sigma}),$$

$$\vec{\mathcal{P}}_{(\mathrm{int})} = \vec{\kappa}_+(\tau) + \int d^3\sigma [\vec{\pi}_\perp \times \vec{B}](\tau,\vec{\sigma}) \approx 0,$$

$$\mathcal{J}^r_{(\mathrm{int})} = \sum_{i=1}^{N} (\vec{\eta}_i(\tau) \times \vec{\kappa}_i(\tau))^r + \int d^3\sigma (\vec{\sigma} \times [\vec{\pi}_\perp \times \vec{B}]^r(\tau,\vec{\sigma}),$$

$$\mathcal{K}^r_{(\mathrm{int})} = -\sum_{i=1}^{N} \eta_i^r(\tau) \sqrt{m_i^2 + [\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i(\tau))]^2} + \frac{1}{2} \left[Q_i \sum_{i=1}^{N} \sum_{j\neq i}^{1\cdots N} Q_j \int d^3\sigma\, \sigma^r \vec{c}(\vec{\sigma} - \eta_i^r(\tau)) \right.$$
$$\left. \cdot \vec{c}(\vec{\sigma} - \eta_j^r(\tau)) + Q_i \int d^3\sigma\, \pi_\perp^r(\tau,\vec{\sigma}) c(\vec{\sigma} - \eta_i^r(\tau)) \right] - \frac{1}{2} \int d^3\sigma\, \sigma^r (\vec{\pi}_\perp^2 + \vec{B}^2)(\tau,\vec{\sigma}), \tag{5.6}$$

with $c(\vec{\eta}_i - \vec{\eta}_j) = 1/(4\pi|\vec{\eta}_j - \vec{\eta}_i|)$ [$\Delta c(\vec{\sigma}) = \delta^3(\vec{\sigma})$, $\Delta = -\vec{\partial}^2$, $\vec{c}(\vec{\sigma}) = \vec{\partial}\, c(\vec{\sigma}) = \vec{\sigma}/(4\pi|\vec{\sigma}|^3)$].

Note that $\mathcal{P}^\tau_{(\mathrm{int})} = q^{\tau\tau}$ and $\mathcal{P}^r_{(\mathrm{int})} = q^{r\tau}$ are the mass and momentum monopoles, respectively.

For the sake of simplicity, consider the subsystem formed by the two particles of mass m_1 and m_2. Our considerations may be extended to any cluster of particles both in this case and in the case discussed in the preceding section. This subsystem is *open*, besides their mutual interaction, the two particles share Coulomb interaction with the other $N-2$ particles and are acted upon by the transverse electromagnetic fields.

By using the multipoles we select a set of *effective parameters* (mass, 3-center of motion, 3-momentum, spin) describing the two-particle cluster as a global entity subject to external forces in the global rest-frame instant form. This was the original motivation of the multipolar expansion in general relativity, replacing an extended object (an open system due to the presence of the gravitational field) with a set of multipoles concentrated on a center of motion. In the rest-frame instant form it is then possible to show that, unlike the case of isolated systems where, in the rest frame $\vec{\kappa}_+ \approx 0$, different conventions identify the same centroid, in the case of an open system different conventions lead to different centers of motion, although a preferred choice seems to stand out on the basis of some reasonable properties.

Given the energy-momentum tensor $T^{AB}(\tau,\vec{\sigma})$ (5.4) of the isolated system, it would seem natural to define *the energy-momentum tensor* $T^{AB}_{c(n)}(\tau,\vec{\sigma})$ *of an open subsystem composed by a cluster of* $n \leqslant N$ *particles* as the sum of all the terms in Eq. (5.4) containing a dependence on the variables $\vec{\eta}_i, \vec{\kappa}_i$, of the particles of the cluster. Besides kinetic terms, this tensor would contain internal mutual interactions as well as external interactions of the cluster particles with the environment composed by the other $N-n$ particles and by the transverse electromagnetic field. An ambiguity, however, appears, why should we attribute *all the external interactions with the other* $N-n$ *particles* to the cluster (note that no such ambiguity exists for the interaction with the electromagnetic field)? Since we have two-body interactions, it seems more reasonable to attribute only *half* of these external interactions to the cluster and consider the other half as a property of the remaining $N-n$ particles. In particular, according to the first choice if we consider two clusters composed by two nonoverlapping sets of n_1 and n_2 particles, respectively, we would get $T^{AB}_{c(n_1+n_2)} \neq T^{AB}_{c(n_1)} + T^{AB}_{c(n_2)}$, since the mutual Coulomb interactions between the two clusters are present in both $T^{AB}_{c(n_1)}$ and $T^{AB}_{c(n_2)}$. On the other hand according to the second choice we get $T^{AB}_{c(n_1+n_2)} = T^{AB}_{c(n_1)} + T^{AB}_{c(n_2)}$. Since this property is important for studying the mutual relative motion of two clusters in actual cases, we will adopt *the convention that the energy-momentum tensor of a n particle cluster contains only half of the external interaction with the other* $N-n$ *particles*.

Let us remark that, in the case of k-body forces, this convention should be replaced by the following rule: (i) for each particle m_i of the cluster and each k-body term in the energy-momentum tensor involving this particle, write $k = h_i + (k-h_i)$, where h_i is the number of particles of the cluster participating to this particular k-body interaction; (ii) only the fraction h_i/k of this particular k-body interaction term containing m_i must be attributed to the cluster.

Consider now the cluster composed by the two particles with mass m_1 and m_2. The knowledge of $T^{AB}_c \overset{\text{def}}{=} T^{AB}_{c(2)}$ on the Wigner hyperplane of the global rest-frame instant form allows to find the following 10 *nonconserved* charges [due to $Q_i^2 = 0$ we have $\sqrt{m_i^2 + [\vec{\kappa}_i - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i)]^2} = \sqrt{m_i^2 + \vec{\kappa}_1^2} - Q_i[\vec{\kappa}_i \cdot \vec{A}_\perp(\tau,\vec{\eta}_i)/\sqrt{m_i^2+\vec{\kappa}_i^2}]$]:

$$M_c = \int d^3\sigma\, T_c^{\tau\tau}(\tau,\vec{\sigma}) = \sum_{i=1}^{2} \sqrt{m_i^2 + [\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau,\vec{\eta}_i(\tau))]^2} + \frac{Q_1 Q_2}{4\pi |\vec{\eta}_1(\tau) - \vec{\eta}_2(\tau)|^2}$$

$$+ \frac{1}{2} \sum_{i=1}^{2} \sum_{k \neq 1,2} \frac{Q_i Q_k}{4\pi |\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau)|^2} = M_{c(\text{int})} + M_{c(\text{ext})},$$

$$M_{c(\text{int})} = \sum_{i=1}^{2} \sqrt{m_i^2 + \vec{\kappa}_i^2} - \frac{Q_1 Q_2}{4\pi |\vec{\eta}_1(\tau) - \vec{\eta}_2(\tau)|^2},$$

$$\vec{\mathcal{P}}_c = \left\{ \int d^3\sigma\, T_c^{r\tau}(\tau,\vec{\sigma}) \right\} = \vec{\kappa}_1(\tau) + \vec{\kappa}_2(\tau),$$

$$\vec{\mathcal{J}}_c = \left\{ \epsilon^{ruv} \int d^3\sigma [\sigma^u T_c^{v\tau} - \sigma^v T_c^{u\tau}](\tau,\vec{\sigma}) \right\} = \vec{\eta}_i(\tau) \times \vec{\kappa}_1(\tau) + \vec{\eta}_2(\tau) \times \vec{\kappa}_2(\tau),$$

$$\vec{\mathcal{K}}_c = -\int d^3\sigma\, \vec{\sigma} T_c^{\tau\tau}(\tau,\vec{\sigma}) = -\sum_{i=1}^{2} \vec{\eta}_i(\tau) \sqrt{m_i^2 + [\vec{\kappa}_i(\tau) - Q_i \vec{A}_\perp(\tau, \vec{\eta}_i(\tau))]^2} - \sum_{i=1}^{2} Q_i \int d^3\sigma\, \vec{\pi}_\perp(\tau,\vec{\sigma})$$
$$\times c(\vec{\sigma} - \vec{\eta}_i(\tau)) - Q_1 Q_2 \int d^3\sigma\, \vec{\sigma} \vec{c}(\vec{\sigma} - \vec{\eta}_1(\tau)) \cdot \vec{c}(\vec{\sigma} - \vec{\eta}_2(\tau)) - \frac{1}{2} \sum_{i=1}^{2} Q_i \sum_{k \neq 1,2} Q_k$$
$$\times \int d^3\sigma\, \vec{\sigma} \vec{c}(\vec{\sigma} - \vec{\eta}_i(\tau)) \cdot \vec{c}(\vec{\sigma} - \vec{\eta}_k(\tau)) = \vec{\mathcal{K}}_{c(\mathrm{int})} + \vec{\mathcal{K}}_{c(\mathrm{ext})},$$

$$\vec{\mathcal{K}}_{c(\mathrm{int})} = -\sum_{i=1}^{2} \vec{\eta}_i(\tau) \sqrt{m_i^2 + \vec{\kappa}_i^2} - Q_1 Q_2 \int d^3\sigma\, \vec{\sigma} \vec{c}(\vec{\sigma} - \vec{\eta}_1(\tau)) \cdot \vec{c}(\vec{\sigma} - \vec{\eta}_2(\tau)), \tag{5.7}$$

which do *not* satisfy the algebra of an internal Poincaré group because of the openess of the system. Since we are working in an instant form of dynamics, only the cluster internal energy and boosts depend on the (internal and external) interactions. Again $M_c = q_c^{\tau\tau}$ and $\mathcal{P}_c^r = q_c^{r\tau}$ are the mass and momentum monopoles of the cluster.

Another needed quantity is the momentum dipole

$$p_c^{ru} = \int d^3\sigma\, \sigma^r T_c^{u\tau}(\tau,\vec{\sigma}) = \sum_{i=1}^{2} \eta_i^r(\tau) \kappa_i^u(\tau) - \sum_{i=1}^{2} Q_i \int d^3\sigma\, c(\vec{\sigma} - \vec{\eta}_i(\tau)) [\partial^r A_\perp^s + \partial^s A_\perp^r](\tau,\vec{\sigma}),$$

$$p_c^{ru} + p_c^{ur} = \sum_{i=1}^{2} [\eta_i^r(\tau) \kappa_i^u(\tau) + \eta_i^u(\tau) \kappa_i^r(\tau)] - 2 \sum_{i=1}^{2} Q_i \int d^3\sigma\, c(\vec{\sigma} - \vec{\eta}_i(\tau)) [\partial^r A_\perp^s + \partial^s A_\perp^r](\tau,\vec{\sigma}),$$

$$p_c^{ru} - p_c^{ur} = \epsilon^{ruv} \mathcal{J}_c^v. \tag{5.8}$$

The time variation of the 10 charges (5.7) can be evaluated by using the equations of motion (5.5),

$$\frac{\mathrm{d}M_c}{\mathrm{d}\tau} = \sum_{i=1}^{2} Q_i \left(\frac{\vec{\kappa}_i(\tau) \cdot \vec{\pi}_\perp(\tau, \vec{\eta}_i(\tau))}{\sqrt{m_i^2 + \vec{\kappa}_i^2}} + \frac{1}{2} \sum_{k \neq 1,2} Q_k \left[\frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2 + \vec{\kappa}_i^2}} + \frac{\vec{\kappa}_k(\tau)}{\sqrt{m_k^2 + \vec{\kappa}_k^2}} \right] \cdot \frac{\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau)}{4\pi |\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau)|^3} \right),$$

$$\frac{\mathrm{d}\mathcal{P}_c^r}{\mathrm{d}\tau} = \sum_{i=1}^{2} Q_i \left(\frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2 + \vec{\kappa}_i^2}} \cdot \frac{\partial A_\perp^r(\tau, \vec{\eta}_i(\tau))}{\partial \vec{\eta}_i} + \sum_{k \neq 1,2} Q_k \frac{\eta_i^r(\tau) - \eta_k^r(\tau)}{4\pi |\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau)|^3} \right),$$

$$\frac{\mathrm{d}\vec{\mathcal{J}}_c}{\mathrm{d}\tau} = \sum_{i=1}^{2} Q_i \left(\frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2 + \vec{\kappa}_i^2}} \times \vec{A}_\perp(\tau, \vec{\eta}_i(\tau)) + \vec{\eta}_i(\tau) \times \left[\frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2 + \vec{\kappa}_i^2}} \cdot \frac{\partial}{\partial \vec{\eta}_i} \right] \vec{A}_\perp(\tau, \vec{\eta}_i(\tau)) \right.$$
$$\left. - \sum_{k \neq i} Q_k \frac{\vec{\eta}_i(\tau) \times \vec{\eta}_k(\tau)}{4\pi |\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau)|^3} \right),$$

$$
\begin{aligned}
\frac{d\mathcal{K}_c^r}{d\tau} &= -\mathcal{P}_c^r - \sum_{i=1}^{2} Q_i \eta_i^r(\tau) \frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2+\vec{\kappa}_i^2(\tau)}} \cdot \left[\vec{\pi}_\perp(\tau,\eta_i^r(\tau)) + \sum_{k\neq i} Q_k \vec{c}(\eta_i^r(\tau)-\eta_k^r(\tau)) \right] \\
&+ \sum_{i=1}^{2} Q_i \left[\sum_{k\neq i} Q_k \frac{\vec{\kappa}_k(\tau)}{\sqrt{m_k^2+\vec{\kappa}_k^2(\tau)}} c(\eta_i^r(\tau)-\eta_k^r(\tau)) - \int d^3\sigma\, \vec{\pi}_\perp(\tau,\vec{\sigma}) \frac{\vec{\kappa}_i(\tau)\cdot\vec{c}(\vec{\sigma}-\eta_i^r(\tau))}{\sqrt{m_i^2+\vec{\kappa}_i^2(\tau)}} \right] \\
&+ \sum_{i=1}^{2} Q_i \sum_{k\neq 1} Q_k \int d^3\sigma\, c(\vec{\sigma}-\eta_i^r(\tau)) \left(\frac{\vec{\kappa}_k(\tau)}{\sqrt{m_k^2+\vec{\kappa}_k^2(\tau)}} \cdot \vec{\partial} \right) \vec{c}(\vec{\sigma}-\eta_k^r(\tau)) \\
&= Q_1 Q_2 \int d^3\sigma\, \vec{\sigma} \left(\left[\left(\frac{\vec{\kappa}_1(\tau)}{\sqrt{m_1^2+\vec{\kappa}_1^2(\tau)}} \cdot \vec{\partial} \right) \vec{c}(\vec{\sigma}-\eta_1^r(\tau)) \right] \cdot \vec{c}(\vec{\sigma}-\eta_2^r(\tau)) \right. \\
&+ \vec{c}(\vec{\sigma}-\vec{\eta}_1(\tau)) \cdot \left[\left(\frac{\vec{\kappa}_2(\tau)}{\sqrt{m_2^2+\vec{\kappa}_2^2(\tau)}} \cdot \vec{\partial} \right) \vec{c}(\vec{\sigma}-\eta_2^r(\tau)) \right] \\
&- \frac{1}{2} \sum_{i=1}^{2} Q_i \sum_{k\neq 1,2} Q_k \int d^3\sigma\, \vec{\sigma} \left(\left[\left(\frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2+\vec{\kappa}_i^2(\tau)}} \cdot \vec{\partial} \right) \vec{c}(\vec{\sigma}-\eta_i^r(\tau)) \right] \cdot \vec{c}(\vec{\sigma}-\eta_k^r(\tau)) \right. \\
&+ \left. \vec{c}(\vec{\sigma}-\eta_i^r(\tau)) \cdot \left[\left(\frac{\vec{\kappa}_k(\tau)}{\sqrt{m_k^2+\vec{\kappa}_k^2(\tau)}} \cdot \vec{\partial} \right) \vec{c}(\vec{\sigma}-\eta_k^r(\tau)) \right] \right). \qquad (5.9)
\end{aligned}
$$

Let us remark that, if we have two clusters of n_1 and n_2 particles, respectively, our definition of cluster energy-momentum tensor implies

$$
\begin{aligned}
M_{c(n_1+n_2)} &= M_{c(n_1)} + M_{c(n_2)}, \\
\vec{\mathcal{P}}_{c(n_1+n_2)} &= \vec{\mathcal{P}}_{c(n_1)} + \vec{\mathcal{P}}_{c(n_2)}, \\
\vec{\mathcal{J}}_{c(n_1+n_2)} &= \vec{\mathcal{J}}_{c(n_1)} + \vec{\mathcal{J}}_{c(n_2)}, \\
\vec{\mathcal{K}}_{c(n_1+n_2)} &= \vec{\mathcal{K}}_{c(n_1)} + \vec{\mathcal{K}}_{c(n_2)}. \qquad (5.10)
\end{aligned}
$$

Then the main problem is the determination of an effective center of motion $\zeta_c^r(\tau)$ with world-line $w_c^\mu(\tau)=x_o^\mu+u^\mu(p_s)\tau+\epsilon_r^\mu(u(p_s))\zeta_c^r(\tau)$ in the gauge $T_s\equiv\tau$, $\vec{q}_+=\vec{R}_+=\vec{y}_+\equiv 0$ of the isolated system. The unit 4-velocity of this center of motion is $u_c^\mu(\tau)=\dot{w}_c^\mu(\tau)/\sqrt{1-\dot{\vec{\zeta}}_c^2(\tau)}$ with $\dot{w}_c^\mu(\tau)=u^\mu(p_s)+\epsilon_r^\mu(u(p_s))\dot{\zeta}_c^r(\tau)$. By using $\delta z^\mu(\tau,\vec{\sigma})=\epsilon_r^\mu(u(p_s))(\sigma^r-\zeta^r(\tau))$ we can define the multipoles of the cluster with respect to the world-line $w_c^\mu(\tau)$,

$$
q_c^{r_1\cdots r_n AB}(\tau) = \int d^3\sigma [\sigma^{r_1}-\zeta_c^{r_1}(\tau)]\cdots[\sigma^{r_n}-\zeta_c^{r_n}(\tau)] T_c^{AB}(\tau,\vec{\sigma}). \qquad (5.11)
$$

The mass and momentum monopoles and the mass, momentum, and spin dipoles are

$$
\begin{aligned}
q_c^{\tau\tau} &= M_c, \quad q_c^{r\tau} = \mathcal{P}_c^r, \\
q_c^{r\tau\tau} &= -\mathcal{K}_c^r - M_c\zeta_c^r(\tau) = M_c(R_c^r(\tau)-\zeta_c^r(\tau)), \\
q_c^{ru\tau} &= p_c^{ru}(\tau) - \zeta_c^r(\tau)\mathcal{P}_c^u,
\end{aligned}
$$

$$S_c^{\mu\nu} = [\epsilon_r^\mu(u(p_s))u^\nu(p_s) - \epsilon_r^\nu(u(p_s))u^\mu(p_s)]q_c^{r\tau\tau} + \epsilon_r^\mu(u(p_s))\epsilon_u^\nu(u(p_s))(q_c^{ru\tau} - q_c^{ur\tau}) = [\epsilon_r^\mu(u(p_s))u^\nu(p_s) - \epsilon_r^\nu(u(p_s))u^\mu(p_s)]M_c(R_c^r - \zeta_c^r) + \epsilon_r^\mu(u(p_s))\epsilon_u^\nu(u(p_s))[\epsilon^{ruv}\mathcal{J}_c^v - (\zeta_c^r\mathcal{P}_c^u - \zeta_c^u\mathcal{P}_c^r)],$$

$$\Rightarrow m_{c(p_s)}^\mu = -S_c^{\mu\nu}u_\nu(p_s) = -\epsilon_r^\mu(u(p_s))q_c^{r\tau\tau}. \tag{5.12}$$

Let us now consider the following possible definitions of effective centers of motion (many others are possible).

(1) *Center of energy*[29] *as center of motion*, $\vec{\zeta}_{c(E)}(\tau) = \vec{R}_c(\tau)$, where $\vec{R}_c(\tau)$ is *a 3-center of energy* for the cluster built by means of the standard definition

$$\vec{R}_c = -\frac{\vec{\mathcal{K}}_c}{M_c}. \tag{5.13}$$

It is determined by the requirement that either the mass dipole vanishes, $q_c^{r\tau\tau} = 0$ or the mass dipole moment with respect to $u^\mu(p_s)$ vanishes, $m_{c(p_s)}^\mu = 0$.

The center of energy seems to be the only center of motion enjoying the simple composition rule

$$\vec{R}_{c(n_1+n_2)} = \frac{M_{c(n_1)}\vec{R}_{c(n_1)} + M_{c(n_2)}\vec{R}_{c(n_2)}}{M_{c(n_1+n_2)}}. \tag{5.14}$$

The constitutive relation between $\vec{\mathcal{P}}_c$ and $\dot{\vec{R}}_c(\tau)$, see Eq. (4.8), is

$$0 = \frac{dq_c^{r\tau\tau}}{d\tau} = -\dot{\mathcal{K}}_c^r - \dot{M}_c R_c^r - M_c\dot{R}_c^r,$$

$$\Downarrow$$

$$\begin{aligned}
\vec{\mathcal{P}}_c = {} & M_c\dot{\vec{R}}_c + \dot{M}_c\vec{R}_c - \sum_{i=1}^2 Q_i\vec{\eta}_i(\tau)\frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2 + \vec{\kappa}_i^2(\tau)}}\cdot\left[\vec{\pi}_\perp(\tau,\vec{\eta}_i(\tau)) + \sum_{k\neq i}Q_k\vec{c}(\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau))\right] \\
& + \sum_{i=1}^2 Q_i\left[\sum_{k\neq i}Q_k\frac{\vec{\kappa}_k(\tau)}{\sqrt{m_k^2 + \vec{\kappa}_k^2(\tau)}}c(\vec{\eta}_i(\tau) - \vec{\eta}_k(\tau)) - \int d^3\sigma\,\vec{\pi}_\perp(\tau,\vec{\sigma})\frac{\vec{\kappa}_i(\tau)\cdot\vec{c}(\vec{\sigma} - \vec{\eta}_i(\tau))}{\sqrt{m_i^2 + \vec{\kappa}_i^2(\tau)}}\right] \\
& + \sum_{i=1}^2 Q_i\sum_{k\neq i}Q_k\int d^3\sigma\, c(\vec{\sigma} - \vec{\eta}_i(\tau))\left(\frac{\vec{\kappa}_k(\tau)}{\sqrt{m_k^2 + \vec{\kappa}_k^2(\tau)}}\cdot\vec{\partial}\right)\vec{c}(\vec{\sigma} - \vec{\eta}_k(\tau)) \\
= {} & Q_1Q_2\int d^3\sigma\,\vec{\sigma}\left(\left[\left(\frac{\vec{\kappa}_1(\tau)}{\sqrt{m_1^2 + \vec{\kappa}_1^2(\tau)}}\cdot\vec{\partial}\right)\vec{c}(\vec{\sigma} - \vec{\eta}_1(\tau))\right]\cdot\vec{c}(\vec{\sigma} - \vec{\eta}_2(\tau))\right. \\
& \left. + \vec{c}(\vec{\sigma} - \vec{\eta}_1(\tau))\cdot\left[\left(\frac{\vec{\kappa}_2(\tau)}{\sqrt{m_2^2 + \vec{\kappa}_2^2(\tau)}}\cdot\vec{\partial}\right)\vec{c}(\vec{\sigma} - \vec{\eta}_2(\tau))\right]\right) \\
& - \frac{1}{2}\sum_{i=1}^2 Q_i\sum_{k\neq 1,2}Q_k\int d^3\sigma\,\vec{\sigma}\left(\left[\left(\frac{\vec{\kappa}_i(\tau)}{\sqrt{m_i^2 + \vec{\kappa}_i^2(\tau)}}\cdot\vec{\partial}\right)\vec{c}(\vec{\sigma} - \vec{\eta}_i(\tau))\right]\cdot\vec{c}(\vec{\sigma} - \vec{\eta}_k(\tau))\right.
\end{aligned}$$

$$+\vec{c}(\vec{\sigma}-\vec{\eta}_i(\tau))\cdot\left[\left(\frac{\vec{\kappa}_k(\tau)}{\sqrt{m_k^2+\vec{\kappa}_k^2(\tau)}}\cdot\vec{\partial}\right)\vec{c}(\vec{\sigma}-\vec{\eta}_k(\tau))\right]\Bigg). \tag{5.15}$$

From Eq. (4.10) the associated cluster spin tensor is

$$S_c^{\mu\nu}=\epsilon_r^\mu(u(p_s))\epsilon_u^\nu(u(p_s))[q_c^{ru\tau}-q_c^{ur\tau}]=\epsilon_r^\mu(u(p_s))\epsilon_u^\nu(u(p_s))\epsilon^{ruv}[\mathcal{J}_c^v-(\vec{R}_c\times\vec{\mathcal{P}}_c)^v]. \tag{5.16}$$

(2) *Pirani centroid* $\vec{\zeta}_{c(P)}(\tau)$ (Ref. 14) *as center of motion*. It is determined by the requirement that the mass dipole moment with respect to 4-velocity $\dot{w}_c^\mu(\tau)$ vanishes (it involves the antisymmetric part of p_c^{ur})

$$m^\mu_{c(\dot{w}_c)}=-S_c^{\mu\nu}\dot{w}_{c\nu}=0,\quad \Rightarrow \dot{\vec{\zeta}}_{c(P)}\cdot\vec{\zeta}_{c(P)}=\dot{\vec{\zeta}}_{c(P)}\cdot\vec{R}_c,$$

$$\Downarrow$$

$$\vec{\zeta}_{c(P)}(\tau)=\frac{1}{M_c-\vec{\mathcal{P}}_c\cdot\dot{\vec{\zeta}}_{c(P)}(\tau)}[M_c\vec{R}_c-\vec{R}_c\cdot\dot{\vec{\zeta}}_{c(P)}(\tau)\vec{\mathcal{P}}_c-\dot{\vec{\zeta}}_{c(P)}(\tau)\times\vec{\mathcal{J}}_c]. \tag{5.17}$$

Therefore this centroid is implicitly defined as the solution of these three coupled first order ordinary differential equations.

(3) *Tulczyjew centroid* $\vec{\zeta}_{c(T)}(\tau)$ (Refs. 15,18, and 23) *as center of motion*. If we define the cluster 4-momentum $P_c^\mu=M_cu^\mu(p_s)+\mathcal{P}_c^s\epsilon_s^\mu(u(p_s))$ $[P_c^2=M_c^2-\vec{\mathcal{P}}_c^2\overset{\text{def}}{=}\mathcal{M}_c^2]$, its definition coincides with requiring the vanishing of the mass dipole moment with respect to P_c^μ (it involves the antisymmetric part of p_c^{ur})

$$m^\mu_{c(P_c)}=-S_c^{\mu\nu}P_{c\nu}=0,\quad \Rightarrow \vec{\mathcal{P}}_c\cdot\vec{\zeta}_{c(T)}=\vec{\mathcal{P}}_c\cdot\vec{R}_c,$$

$$\Downarrow$$

$$\vec{\zeta}_{c(T)}(\tau)=\frac{1}{M_c^2-\vec{\mathcal{P}}_c^2}[M_c^2\vec{R}_c-\vec{\mathcal{P}}_c\cdot\vec{R}_c\vec{\mathcal{P}}_c-\vec{\mathcal{P}}_c\times\vec{\mathcal{J}}_c]. \tag{5.18}$$

Let us show that this centroid satisfies the free particle relation as constitutive relation,

$$\vec{\mathcal{P}}_c=M_c\dot{\vec{\zeta}}_{c(T)},$$

$$\Downarrow$$

$$P_c^\mu=M_c[u^\mu(p_s)+\dot{\zeta}^s_{c(T)}\epsilon_s^\mu(u(p_s))],$$

$$q^{r\tau\tau}_{c(T)}=\frac{M_c}{M_c^2-\vec{\mathcal{P}}_c^2}[\vec{\mathcal{P}}_c^2\vec{R}_c+\vec{\mathcal{P}}_c\cdot\vec{R}_c\vec{\mathcal{P}}_c+\vec{\mathcal{P}}_c\times\vec{\mathcal{J}}_c],$$

$$S_c^{\mu\nu} = [\epsilon_r^\mu(u(p_s))u^\nu(p_s) - \epsilon_r^\nu(u(p_s))u^\mu(p_s)]q_{c(T)}^{r\tau\tau} + \epsilon_r^\mu(u(p_s))\epsilon_u^\nu(u(p_s))\epsilon^{ruv}[\mathcal{I}_c^v - (\vec{\zeta}_{c(T)} \times \vec{\mathcal{P}}_c)^v]. \tag{5.19}$$

If we use Eq. (5.17) to find a Pirani centroid such that $\dot{\vec{\zeta}}_c = \vec{\mathcal{P}}_c / M_c$, it turns out that the condition (5.17) becomes Eq. (5.18) and this implies Eq. (5.19).

The equations of motion,

$$M_c(\tau)\ddot{\vec{\zeta}}_{c(T)}(\tau) = \dot{\vec{\mathcal{P}}}_c(\tau) - \dot{M}_c(\tau)\dot{\vec{\zeta}}_{c(T)}(\tau), \tag{5.20}$$

contain both internal and external forces. In spite of the nice properties (5.19) and (5.20) of the Tulczyjew centroid, this effective center of motion suffers the drawback of lacking a simple composition property. The relation among the Tulczyjew centroids of clusters with n_1, n_2 and n_1+n_2 particles, respectively, is much more complicated of the composition (5.14) of the centers of energy.

All the previous centroids coincide for an isolated system in the rest-frame instant form with $\vec{\mathcal{P}}_c = \vec{\kappa}_+ \approx 0$ in the gauge $\vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+ \approx 0$.

(4) The *Corinaldesi–Papapetrou centroid*[12] *with respect to a timelike observer with, 4-velocity* $v^\mu(\tau), \zeta_{c(\mathrm{CP})}^{(v)}(\tau)$ *as center of motion.*

$$m_{c(v)}^\mu = -S_c^{\mu\nu} v_\nu = 0. \tag{5.21}$$

Clearly these centroids are unrelated to the previous ones being dependent on the choice of an arbitrary observer.

(5) The *Pryce center of spin*[30–32] *or classical canonical Newton–Wigner centroid* $\vec{\zeta}_{c(\mathrm{NW})}$. It defined as the solution of the differential equations implied by the requirement $\{\zeta_{c(\mathrm{NW})}^r, \zeta_{c(\mathrm{NW})}^s\} = 0$, $\{\zeta_{c(\mathrm{NW})}^r, \mathcal{P}_c^s\} = \delta^{rs}$. Note that, being in an instant form of dynamics, we have $\{\mathcal{P}_c^r, \mathcal{P}_c^s\} = 0$ also for an open system.

The two effective centers of motion which look more useful for applications seems to be the center of energy $\vec{\zeta}_{c(E)}(\tau)$ and Tulczyjew's centroid $\vec{\zeta}_{c(T)}(\tau)$, with $\vec{\zeta}_{c(E)}(\tau)$ preferred for the study of the mutual motion of clusters due to Eq. (5.14).

Therefore, in the spirit of the multipolar expansion, our two-body cluster may be described by an effective nonconserved internal energy (or mass) $M_c(\tau)$, by the world-line $w_c^\mu = x_o^\mu + u^\mu(p_s)\tau + \epsilon_r^\mu(u(p_s))\ \zeta_{c(E \text{ or } T)}^r(\tau)$ associated with the effective center of motion $\vec{\zeta}_{c(E \text{ or } T)}(\tau)$ and by the effective 3-momentum $\vec{\mathcal{P}}_c(\tau)$, with $\vec{\zeta}_{c(E \text{ or } T)}(\tau)$ and $\vec{\mathcal{P}}_c(\tau)$ forming a noncanonical basis for the collective variables of the cluster. A noncanonical effective spin for the cluster in the (1) and (3) cases is defined by the following:

(a) case of the center of energy,

$$\vec{\mathcal{S}}_{c(E)}(\tau) = \vec{\mathcal{J}}_c(\tau) - \vec{R}_c(\tau) \times \vec{\mathcal{P}}_c(\tau),$$

$$\frac{\mathrm{d}\vec{\zeta}_{c(E)}(\tau)}{\mathrm{d}\tau} = \frac{\mathrm{d}\vec{\mathcal{J}}_c(\tau)}{\mathrm{d}\tau} - \frac{\mathrm{d}\vec{R}_c(\tau)}{\mathrm{d}\tau} \times \vec{\mathcal{P}}_c(\tau) - \vec{R}_c(\tau) \times \frac{\mathrm{d}\vec{\mathcal{P}}_c(\tau)}{\mathrm{d}\tau},$$

(b) case of the Tulczyjew centroid,

$$\vec{\mathcal{S}}_{c(T)}(\tau) = \vec{\mathcal{J}}_c(\tau) - \vec{\zeta}_{c(T)}(\tau) \times \vec{\mathcal{P}}_c(\tau) = \frac{M_c^2(\tau)\vec{\mathcal{S}}_{c(E)}(\tau) - \vec{\mathcal{P}}_c(\tau) \cdot \vec{\mathcal{J}}_c(\tau)\vec{\mathcal{P}}_c(\tau)}{M_c^2(\tau) - \vec{\mathcal{P}}_c^2(\tau)},$$

$$\frac{\mathrm{d}\vec{\zeta}_{c(T)}(\tau)}{\mathrm{d}\tau} = \frac{\mathrm{d}\vec{\mathcal{J}}_c(\tau)}{\mathrm{d}\tau} - \vec{\zeta}_{c(T)}(\tau) \times \frac{\mathrm{d}\vec{\mathcal{P}}_c(\tau)}{\mathrm{d}\tau}. \tag{5.22}$$

Since our cluster contains only two particles, this pole–dipole description concentrated on the world-line $w_c^\mu(\tau)$ is equivalent to the original description in terms of the canonical variables $\vec{\eta}_i(\tau), \vec{\kappa}_i(\tau)$ (all higher multipoles are not independent quantities in this case).

Then, let us see whether it is possible to replace the description of the two-body system as an effective pole–dipole system, by a description of it as an effective extended two-body system obtained by introducing two noncanonical relative variables $\vec{\rho}_{c(E \text{ or } T)}(\tau)$, $\vec{\pi}_{c(E \text{ or } T)}(\tau)$ through the following definitions:

$$\vec{\eta}_1 \overset{\text{def}}{=} \vec{\zeta}_{c(E \text{ or } T)} + \tfrac{1}{2}\vec{\rho}_{c(E \text{ or } T)}, \quad \vec{\zeta}_{c(E \text{ or } T)} = \tfrac{1}{2}(\vec{\eta}_1 + \vec{\eta}_2),$$

$$\vec{\eta}_2 \overset{\text{def}}{=} \vec{\zeta}_{c(E \text{ or } T)} - \tfrac{1}{2}\vec{\rho}_{c(E \text{ or } T)}, \quad \vec{\rho}_{c(E \text{ or } T)} = \vec{\eta}_1 - \vec{\eta}_2,$$

$$\vec{\kappa}_1 \overset{\text{def}}{=} \tfrac{1}{2}\vec{\mathcal{P}}_c + \vec{\pi}_{c(E \text{ or } T)}, \quad \vec{\mathcal{P}}_c = \vec{\kappa}_1 + \vec{\kappa}_2,$$

$$\vec{\kappa}_2 \overset{\text{def}}{=} \tfrac{1}{2}\vec{\mathcal{P}}_c - \vec{\pi}_{c(E \text{ or } T)}, \quad \vec{\pi}_{c(E \text{ or } T)} = \tfrac{1}{2}(\vec{\kappa}_1 - \vec{\kappa}_2),$$

$$\vec{\mathcal{J}}_c = \vec{\eta}_1 \times \vec{\kappa}_1 + \vec{\eta}_2 \times \vec{\kappa}_2 = \vec{\zeta}_{c(E \text{ or } T)} \times \vec{\mathcal{P}}_c + \vec{\rho}_{c(E \text{ or } T)} \times \vec{\pi}_{c(E \text{ or } T)},$$

$$\Rightarrow \vec{\mathcal{S}}_{c(E \text{ or } T)} = \vec{\rho}_{c(E \text{ or } T)} \times \vec{\pi}_{c(E \text{ or } T)}. \tag{5.23}$$

Note that, even if it is suggested by a canonical transformation, the above transformation is in fact *not* a canonical transformation and it can only be defined since we are working in an instant form of dynamics, in which both $\vec{\mathcal{P}}_c$ and $\vec{\mathcal{J}}_c$ do not depend upon the interactions.

Note finally that we know everything about this new basis except for the unit vector $\vec{\rho}_{c(E \text{ or } T)}/|\vec{\rho}_{c(E \text{ or } T)}|$ and the momentum $\vec{\pi}_{c(E \text{ or } T)}$. However, this relevant lacking information can be extracted from the symmetrized momentum dipole $p_c^{ru} + p_c^{ur}$, which is a known effective quantity since Eq. (5.9) has the following expression in terms of the variables (5.23):

$$p_c^{ru} + p_c^{ur} + 2\sum_{i=1}^{2} Q_i \int d^3\sigma\, c(\vec{\sigma} - \vec{\eta}_i(\tau))[\partial^r A_\perp^s + \partial^s A_\perp^r](\tau, \vec{\sigma}) = \sum_{i=1}^{2} (\eta_i^r \kappa_i^u + \eta_i^u \kappa_i^r) = \zeta_{c(E \text{ or } T)}^r \mathcal{P}_c^u$$
$$+ \zeta_{c(E \text{ or } T)}^r \mathcal{P}_c^r + \rho_{c(E \text{ or } T)}^r \pi_{c(E \text{ or } T)}^u + \rho_{c(E \text{ or } T)}^u \pi_{c(E \text{ or } T)}^r. \tag{5.24}$$

A strategy for working out this information explicitly is provided by the construction of a *spin frame* which, following Ref. 33 for the $N-2$ case, is defined by $\hat{\mathcal{S}}_{c(E \text{ or } T)} = \vec{\mathcal{S}}_{c(E \text{ or } T)}/|\vec{\mathcal{S}}_{c(E \text{ or } T)}|$, $\hat{\mathcal{R}}_{c(E \text{ or } T)}$, $\hat{\mathcal{V}}_{c(E \text{ or } T)} = \hat{\mathcal{R}}_{c(E \text{ or } T)} \times \hat{\mathcal{S}}_{c(E \text{ or } T)}$, with $\hat{\mathcal{S}}_{c(E \text{ or } T)} \cdot \hat{\mathcal{R}}_{c(E \text{ or } T)} = 0$, $\hat{\mathcal{S}}_{c(E \text{ or } T)}^2 = \hat{\mathcal{R}}_{c(E \text{ or } T)}^2 = \hat{\mathcal{V}}_{c(E \text{ or } T)}^2 = 1$. Then we get the following decomposition ($\mathcal{S}_{c(E \text{ or } T)} = |\vec{\mathcal{S}}_{c(E \text{ or } T)}|$):

$$\vec{\rho}_{c(E \text{ or } T)} = \rho_{c(E \text{ or } T)} \hat{\mathcal{R}}_{c(E \text{ or } T)}, \quad \rho_{c(E \text{ or } T)} = |\vec{\eta}_1 - \vec{\eta}_2|,$$

$$\vec{\pi}_{c(E \text{ or } T)} = \tilde{\pi}_{c(E \text{ or } T)} \hat{\mathcal{R}}_{c(E \text{ or } T)} - \frac{\mathcal{S}_{c(E \text{ or } T)}}{\rho_{c(E \text{ or } T)}} \hat{\mathcal{V}}_{c(E \text{ or } T)}, \quad \tilde{\pi}_{c(E \text{ or } T)} = \vec{\pi}_{c(E \text{ or } T)} \cdot \frac{\vec{\rho}_{c(E \text{ or } T)}}{\rho_{c(E \text{ or } T)}}, \tag{5.25}$$

where $\rho_{c(E \text{ or } T)}$ is just the relative variable appearing in the Coulomb potential. Equations (5.25) show that only the three variables $\tilde{\pi}_{c(E \text{ or } T)}$ and $\hat{\mathcal{R}}_{c(E \text{ or } T)} = \vec{\rho}_{c(E \text{ or } T)} / \rho_{c(E \text{ or } T)}$ are still unknown. Then from Eqs. (5.23) and (5.24) we obtain

$$\begin{aligned} \rho^r_{c(E \text{ or } T)} \pi^u_{c(E \text{ or } T)} + \rho^u_{c(E \text{ or } T)} \pi^r_{c(E \text{ or } T)} &= 2\, \rho_{c(E \text{ or } T)} \tilde{\pi}_{c(E \text{ or } T)} \hat{\mathcal{R}}^r_{c(E \text{ or } T)} \hat{\mathcal{R}}^u_{c(E \text{ or } T)} - \mathcal{S}_{c(E \text{ or } T)} \\ &\times (\hat{\mathcal{R}}^r_{c(E \text{ or } T)} \hat{\mathcal{V}}^u_{c(E \text{ or } T)} + \hat{\mathcal{R}}^u_{c(E \text{ or } T)} \hat{\mathcal{V}}^r_{c(E \text{ or } T)}) = p^{ru}_c + p^{ur}_c \\ &- (\zeta^r_{c(E \text{ or } T)} \mathcal{P}^u_c + \zeta^u_{c(E \text{ or } T)} \mathcal{P}^r_c) + 2 \sum_{i=1}^{2} Q_i \int d^3\sigma\, c(\vec{\sigma} - \vec{\eta}_i(\tau)) \\ &\times [\partial^r A^u_\perp + \partial^u A^r_\perp](\tau, \vec{\sigma}) \overset{\text{def}}{=} F^{ru}_{c(E \text{ or } T)}, \end{aligned}$$

$$F^{ru}_{c(E \text{ or } T)} \mathcal{S}^u_{c(E \text{ or } T)} \equiv 0. \tag{5.26}$$

Now, these are three independent equations for $\tilde{\pi}_{c(E \text{ or } T)}$ and for the two degrees of freedom in the unit vector $\hat{\mathcal{R}}_{c(E \text{ or } T)}$ in terms of the known quantities $F^{ru}_{c(E \text{ or } T)}, \mathcal{S}_{c(E \text{ or } T)}$, $\rho_{c(E \text{ or } T)} = |\vec{\eta}_1 - \vec{\eta}_2|$. For instance we get $\tilde{\pi}_{c(E \text{ or } T)} = (\Sigma_r F^{rr}_{c(E \text{ or } T)})/2\, \rho_{c(E \text{ or } T)}$, which is independent of the vector potential because of the transversality of the latter. In conclusion, the external electromagnetic potential $\vec{A}_\perp$ enters only in the determination of the axis $\hat{\mathcal{R}}_{c(E \text{ or } T)}$ of the spin frame.

This completes the construction of the effective relative variables and of the effective spin frame using the extra input of the 3-momentum dipole. *In this way we get a description of the two-body cluster as an effective two-body system instead of a pole–dipole system.* The weak point of this description of the open system as an extended object is that, whatever definition of effective center of motion one exploits, the symmetrized momentum dipole $p^{ru}_c + p^{ur}_c$ *does not depend* on the cluster properties *only* but *also* on the external electromagnetic transverse vector potential at the particle positions, as shown by Eq. (5.8). As a consequence the spin frame, or equivalently the three Euler angles associated with the internal spin, depends upon the external fields.

If we accept this drawback, it is reasonable to expect that, taking into account higher multipoles, be possible to give a description of a cluster of $n \geqslant 3$ particles in terms of as many effective n-body systems as effective dynamical body frames following the scheme of Ref. 33.

This would open the possibility of obtaining effective descriptions of two clusters of n_1 and n_2 particles, respectively, and comparing it with the effective description of the cluster composed by the same $n_1 + n_2$ particles. Then it should be possible to find the relations among the three centers of motion of the $(n_1 + n_2)$, n_1, and n_2 clusters and the relative motion of the two n_1 and n_2 clusters. With this in view, adopting *the center of energy as center of motion* seems unavoidable because of the simple composition law (5.14). Whatever choice one adopts, however, it turns out that the relative motion of the two clusters depends on the external fields besides the effective parameters of the clusters.

These techniques can be extended to relativistic perfect fluids, if described in the rest-frame instant form as done in Ref. 1. Moreover, they are needed for the determination of the post-Minkowskian approximation to the quadrupole formula for the emission of gravitational waves (resummation of the post-Newtonian approximations) in the background-independent Hamiltonian linearization of tetrad gravity plus a perfect fluid.[4]

VI. CONCLUSIONS

A relativistic description of open systems like binary stars embedded in the gravitational field would be nowadays an important achievement in view of the construction of templates for the gravitational radiation. Even by approximating such description by means of a multipolar expansion in a way suitable for actually doing either analytical or numerical calculations, a big amount of kinematical technical preliminaries is needed anyway. With this in view, we had in mind to develop methods which could be useful in general relativity with relativistic perfect fluids as matter, where single or binary stars could be described by open fluid subsystems of the isolated system formed by the gravitational field plus the fluid in the rest-frame instant form of either metric or tetrad gravity.[2–4]

To pursue our program, in the present paper we have first of all completed the study of the relativistic kinematics of the system of N free scalar positive-energy particles in the rest-frame instant form of dynamics on Wigner hyperplanes, initiated in Ref. 33.

Then, we have evaluated the energy momentum tensor of the system on the Wigner hyperplane and then determined Dixon's multipoles for the N-body problem with respect to the *internal* 3-center of mass located at the origin of the Wigner hyperplane. For an isolated system most of the existing definitions of a collective centroid identify a unique world line, associated with the internal canonical 3-center of mass. In the rest-frame instant form these multipoles are *Cartesian (Wigner-covariant) Euclidean tensors*. While the study of the *monopole* and *dipole* moments in the rest frame gives information on the mass, the spin and the *internal* center of mass, the *quadrupole* moment provides the only (though not unique) way of introducing the concept of *barycentric tensor of inertia* for extended systems in special relativity.

By exploiting the *canonical spin bases* of Refs. 33 and 50 after the elimination of the internal 3-center of mass ($\vec{q}_+ = \vec{\kappa}_+ = 0$), the Cartesian multipoles $q_T^{r_1 \cdots r_n AB}$ can be expressed in terms of six *orientational* variables (the *spin vector* and the three *Euler angles* identifying the *dynamical body frame*) and of $6N-6$ (*rotational scalar*) *shape* variables, i.e., in terms of the canonical pairs of a canonical spin basis.

Having completed the discussion of the isolated system of N positive energy free scalar particles the formalism has been applied to an isolated system of N positive-energy particles with *mutual action-at-a-distance interactions*. Here again we find a unique world line describing the collective motion of the system.

On the other hand, in the case of an *open* $n < N$ *particle subsystem* of an isolated system consisting of N charged positive-energy particles plus the electromagnetic field a more complex description surfaces. In the rest frame of the isolated system a suitable definition of the energy-momentum tensor of the open subsystem allows to define its *effective mass, 3-momentum, and angular momentum*. However, unlike the case of isolated systems, each centroid putatively describing the *collective centers of motion*, gives rise to a different world line. Starting from the evaluation of the rest-frame Dixon multipoles of the energy-momentum tensor of the open subsystem with respect to various centroids, we get thereby *many candidates for the effective center of motion and the effective intrinsic spin*. Two centroids (viz. the center of energy and Tulczyjew's centroid) stand out because of their specific properties. In the case $n=2$ the pole–dipole description of the two-particle cluster can be replaced by a description of the cluster as an extended system (whose effective spin frame can be evaluated) at the price of introducing an explicit dependence on the cluster in the action of the external electromagnetic field.

Finally, by comparing the effective parameters of an open cluster of n_1+n_2 particles with the effective parameters of the two clusters with n_1 and n_2 particles, it is shown that only the effective *center of energy* can in fact play the role of a useful center of motion,

The kinematical concepts we have defined for closed and open N-body systems are sufficient for the treatment of relativistic continua like relativistic fluids. In Ref. 1 a preliminary extension to closed relativistic fluids is given.

APPENDIX: THE GARTENHAUS–SCHWARTZ TRANSFORMATION

In Ref. 33 we defined canonical internal relative variables with respect to the internal 3-center of mass $\vec{q}_+$ by exploiting a *Gartenhaus–Schwartz* canonical transformation. Let us stress that *while at the nonrelativistic level the transformation is a point-transformation both in the coordinates and the momenta, in the relativistic case we get a point-transformation only in the momenta*.

The canonical generator of the transformation is

$$G = \vec{q}_+ \cdot \vec{\kappa}_+, \tag{A1}$$

so that the finite transformation, depending on a parameter α, on a generic function F on the phase space is

$$F(\alpha) = F + \int_0^\infty d\overline{\alpha}\{F(\overline{\alpha}), G(\overline{\alpha})\}. \tag{A2}$$

In particular we have

$$\lim_{\alpha\to\infty} \vec{\kappa}_+(\alpha) = 0, \quad \lim_{\alpha\to\infty} \vec{q}_+(\alpha) = \infty. \tag{A3}$$

As mentioned in Sec. II, if we define the canonical transformation (2.14), then the quantities

$$\vec{\pi}_{qa} = \lim_{\alpha\to\infty} \vec{\pi}_a(\alpha), \quad \vec{\rho}_{qa} = \lim_{\alpha\to\infty} \vec{\rho}_a(\alpha), \tag{A4}$$

are well defined and the transformation

$$\vec{\eta}_i, \vec{\kappa}_i \to \vec{\kappa}_+, \vec{q}_+, \vec{\rho}_{qa}, \vec{\pi}_{qa}, \tag{A5}$$

is a canonical transformation

$$\{q_+^r, \kappa_+^s\} = \delta^{rs}, \quad \{\rho_{qa}^r, \pi_{qb}^s\} = \delta^{rs}\delta_{ab}, \tag{A6}$$

as said in Eq. (2.13).

The quantities $\vec{\rho}_{qa}, \vec{\pi}_{qa}$ are the searched internal relative variables, they describe the system after the gauge fixing $\vec{q}_+ \approx 0, \vec{\kappa}_+ \approx 0$. We have also

$$\vec{\kappa}_+ \approx 0 \Rightarrow \vec{\rho}_{qa} \approx \vec{\rho}_a, \quad \vec{\pi}_{qa} \approx \vec{\pi}_a. \tag{A7}$$

Thanks to these results, we can calculate a function F independent of $\vec{q}_+$ on the phase space, under the constraint $\vec{\kappa}_+ \approx 0$, by simply performing the limit

$$F|_{\vec{\kappa}_+\approx 0}(\vec{\rho}_{qa}, \vec{\pi}_{qa}) = \lim_{\alpha\to\infty} F(\alpha). \tag{A8}$$

This method is applied in Sec. IV for calculating the multipoles after the gauge fixing $\vec{q}_+ \approx 0, \vec{\kappa}_+ \approx 0$. These multipoles depend on $\vec{\kappa}_i$, so that (see Ref. 33)

$$\lim_{\alpha\to\infty} \vec{\kappa}_i(\alpha) = \sqrt{N} \sum_{a=1}^{N-1} \gamma_{ai} \vec{\pi}_{qa}, \tag{A9}$$

and on $(\vec{\eta}_i - \vec{R}_+)$, so that

$$\vec{\eta}_i - \vec{R}_+ = \sum_j (\vec{\eta}_i - \vec{\eta}_j) \frac{\sqrt{m_j^2 + \vec{\kappa}_j^2}}{\sum_k \sqrt{m_k^2 + \vec{\kappa}_k^2}} = \sum_j \sum_a \sqrt{N}(\gamma_{ai} - \gamma_{aj}) \vec{\rho}_a \frac{\sqrt{m_j^2 + \vec{\kappa}_j^2}}{\sum_k \sqrt{m_k^2 + \vec{\kappa}_k^2}}. \tag{A10}$$

Then using (A9) and (A4) we have

$$\lim_{\alpha\to\infty}(\vec{\eta}_i(\alpha)-\vec{R}_+(\alpha))=\sum_j\sum_a\sqrt{N}(\gamma_{ai}-\gamma_{aj})\vec{\rho}_{qa}\frac{\sqrt{m_j^2+N\Sigma_{ab}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}\gamma_{aj}\gamma_{bj}}}{\Sigma_k\sqrt{m_k^2+N\Sigma_{ab}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}\gamma_{ak}\gamma_{bk}}}. \tag{A11}$$

The following notation is used to denote the limits (A8):

$$F\to_{\alpha\to\infty}F|_{\vec{\kappa}_+\approx 0}(\vec{\rho}_{qa},\vec{\pi}_{qa}). \tag{A12}$$

For example, Eqs. (A9) and (A11) become

$$\vec{\kappa}_i\to_{\alpha\to\infty}\sqrt{N}\sum_{a=1}^{N-1}\gamma_{ai}\vec{\pi}_{qa},$$

$$\vec{\eta}_i-\vec{R}_+\to_{\alpha\to\infty}\sum_j\sum_a\sqrt{N}(\gamma_{ai}-\gamma_{aj})\vec{\rho}_{qa}\frac{\sqrt{m_j^2+N\Sigma_{ab}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}\gamma_{aj}\gamma_{bj}}}{\Sigma_k\sqrt{m_k^2+N\Sigma_{ab}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}\gamma_{ak}\gamma_{bk}}}. \tag{A13}$$

The closed form (A16)–(A18) of the canonical transformation (A5) was not given in Ref. 33, but it can derived from the following two equations of that paper [its Eq. (5.13) and (5.24)]:

$$\vec{\pi}_a(\alpha)=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\gamma_{ai}\vec{\kappa}_i(\alpha),$$

$$\begin{aligned}\vec{\pi}_{qa}&\overset{\text{def}}{=}\vec{\pi}_a(\infty)=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\vec{\kappa}_i(\infty)\\&=\vec{\pi}_a+\frac{\vec{n}_+}{\mathcal{M}}[(M_{\text{sys}}-\mathcal{M})\vec{n}_+\cdot\vec{\pi}_a-|\vec{\kappa}_+|H_a]\\&=\vec{\pi}_a-\frac{\vec{\kappa}_+}{\sqrt{M_{\text{sys}}^2-\vec{\kappa}_+^2}}\left[H_a-\frac{M_{\text{sys}}-\sqrt{M_{\text{sys}}^2-\vec{\kappa}_+^2}}{\vec{\kappa}_+^2}\vec{\kappa}_+\cdot\vec{\pi}_a\right]\approx\vec{\pi}_a,\end{aligned}$$

$$H_a=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\gamma_{ai}H_i=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\gamma_{ai}\sqrt{m_i^2+\vec{\kappa}_i^2},$$

$$\vec{\kappa}_i(\infty)=\sqrt{N}\sum_{a=1}^{N-1}\gamma_{ai}\vec{\pi}_{qa},$$

$$H_{(\text{rel})i}=H_i(\infty)=\sqrt{m_i^2+N\sum_{ab}^{1\ldots N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}},$$

$$M_{\text{sys}}=\sum_{i=1}^{N}H_i=\sqrt{\mathcal{M}^2+\vec{\kappa}_+^2}\approx H_{(\text{rel})}=H_M(\infty)=\mathcal{M}=\sum_{i=1}^{N}H_i(\infty)=\sum_{i=1}^{N}\sqrt{m_i^2+N\sum_{ab}^{1\ldots N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}}, \tag{A14}$$

$$\vec{\rho}_{qa} \overset{\text{def}}{=} \vec{\rho}_a(\infty) = \vec{\rho}_a - \sum_{i,j=1}^{N} \sum_{b=1}^{N-1} \gamma_{aj}(\gamma_{bi} - \gamma_{bj}) \frac{H_i}{M_{\text{sys}}} \left[\frac{|\vec{\kappa}_+| \vec{\kappa}_j(\infty)}{H_j(\infty)\sqrt{\Pi}} + \left(\frac{M_{\text{sys}}}{\sqrt{\Pi}} - 1 \right) \vec{n}_+ \right] \vec{n}_+ \cdot \vec{\rho}_b$$

$$= \vec{\rho}_a - \sum_{i,j=1}^{N} \sum_{b=1}^{N-1} \gamma_{aj}(\gamma_{bi} - \gamma_{bj}) \frac{H_i}{M_{\text{sys}}} \frac{\vec{\kappa}_j(\infty)}{H_j(\infty)\sqrt{\Pi}} \vec{\kappa}_+ \cdot \vec{\rho}_b \approx \vec{\rho}_a. \tag{A15}$$

Let us end by giving the explicit expression of the second canonical transformation (2.13). By using Eqs. (A14) and (A15) we get the following results.

(1) For $N=2(\gamma_{11}=-\gamma_{12}=1/\sqrt{2})$ we have

$$\vec{\eta}_1 = \vec{\eta}_+ + \tfrac{1}{2}\vec{\rho}, \quad \vec{\kappa}_1 = \tfrac{1}{2}\vec{\kappa}_+ + \vec{\pi},$$

$$\vec{\eta}_2 = \vec{\eta}_+ - \tfrac{1}{2}\vec{\rho}, \quad \vec{\kappa}_2 = \tfrac{1}{2}\vec{\kappa}_+ - \vec{\pi},$$

$$\vec{\eta}_+ = \tfrac{1}{2}(\vec{\eta}_1 + \vec{\eta}_2), \quad \vec{\kappa}_+ = \vec{\kappa}_1 + \vec{\kappa}_2,$$

$$\vec{\rho} = \vec{\eta}_1 - \vec{\eta}_2, \quad \vec{\pi} = \tfrac{1}{2}(\vec{\kappa}_1 - \vec{\kappa}_2),$$

$$\vec{J} = \vec{\eta}_1 \times \vec{\kappa}_1 + \vec{\eta}_2 \times \vec{\kappa}_2 = \vec{\eta}_+ \times \vec{\kappa}_+ + \vec{S} = \vec{q}_+ \times \vec{\kappa}_+ + \vec{S}_q, \quad \vec{S} = \vec{\rho} \times \vec{\pi}, \quad \vec{S}_q = \vec{\rho}_q \times \vec{\pi}_q,$$

$$\vec{R}_+ = \frac{\sqrt{m_1^2 + \vec{\kappa}_1^2}\,\vec{\eta}_1 + \sqrt{m_2^2 + \vec{\kappa}_2^2}\,\vec{\eta}_2}{\sqrt{m_1^2 + \vec{\kappa}_1^2} + \sqrt{m_2^2 + \vec{\kappa}_2^2}} = \vec{\eta}_+ + \frac{1}{2}\frac{\sqrt{m_1^2 + \vec{\kappa}_1^2} - \sqrt{m_2^2 + \vec{\kappa}_2^2}}{\sqrt{m_1^2 + \vec{\kappa}_1^2} + \sqrt{m_2^2 + \vec{\kappa}_2^2}}\vec{\rho},$$

$$\vec{q}_+ = \vec{R}_+ + \frac{\vec{S}_q \times \vec{\kappa}_+}{(\sqrt{m_1^2 + \vec{\kappa}_1^2} + \sqrt{m_2^2 + \vec{\kappa}_2^2})\left(\sqrt{m_1^2 + \vec{\kappa}_1^2} + \sqrt{m_2^2 + \vec{\kappa}_2^2} + \sqrt{(\sqrt{m_1^2 + \vec{\kappa}_1^2} + \sqrt{m_2^2 + \vec{\kappa}_2^2})^2 - \vec{\kappa}_+^2}\right)}. \tag{A16}$$

Then after some straightforward algebra we get (note that in Ref. 33 we used the notation $M_{(\text{free})}=M_{\text{sys}}$ and $\mathcal{M}^2_{(\text{free})}=\Pi$)

$$\sqrt{m_i^2 + \vec{\kappa}_i^2} = \frac{1}{2}\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}_+^2}\left(1 + (-)^{i+1}\frac{m_1^2 - m_2^2}{\mathcal{M}^2_{(\text{free})}}\right) + (-)^{i+1}\frac{\vec{\pi}_q \cdot \vec{\kappa}_+}{\mathcal{M}_{(\text{free})}},$$

$$M_{(\text{free})} = \sqrt{m_1^2 + \vec{\kappa}_1^2} + \sqrt{m_2^2 + \vec{\kappa}_2^2} = \sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}_+^2} \approx \mathcal{M}_{(\text{free})} \overset{\text{def}}{=} \sqrt{m_1^2 + \vec{\pi}_q^2} + \sqrt{m_2^2 + \vec{\pi}_q^2},$$

$$\sqrt{m_1^2 + \vec{\kappa}_1^2} - \sqrt{m_2^2 + \vec{\kappa}_2^2} = \frac{2\vec{\pi}_q \cdot \vec{\kappa}_+}{\mathcal{M}_{(\text{free})}} + \frac{m_1^2 - m_2^2}{\mathcal{M}^2_{(\text{free})}}\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}_+^2} \overset{\text{def}}{=} E,$$

$$\vec{\pi} = \vec{\pi}_q + \frac{\vec{\kappa}_+}{\mathcal{M}_{(\text{free})}\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}_+^2}}\left[\vec{\pi}_q \cdot \vec{\kappa}_+\left(1 - (\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}_+^2} - \mathcal{M}_{(\text{free})})\frac{\mathcal{M}_{(\text{free})}}{\vec{\kappa}_+^2}\right)\right.$$

$$\left. + (m_1^2 - m_2^2)\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}_+^2}\right] \overset{\text{def}}{=} \vec{\pi}_q + F\vec{\kappa}_+,$$

$$\vec{\rho} = \vec{\rho}_q - \frac{A}{B}\frac{\vec{\kappa}_+ \cdot \vec{\rho}_q \vec{\pi}_q}{\mathcal{M}_{(\text{free})}\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+}} \stackrel{\text{def}}{=} \vec{\rho}_q + C\vec{\pi}_q,$$

$$A = \frac{\sqrt{m_1^2 + \vec{\kappa}_1^2}}{\sqrt{m_2^2 + \vec{\pi}_q^2}} + \frac{\sqrt{m_2^2 + \vec{\kappa}_2^2}}{\sqrt{m_1^2 + \vec{\pi}_q^2}}, \quad B = 1 + \frac{A\vec{\pi}_q \cdot \vec{\kappa}_+}{\mathcal{M}_{(\text{free})}\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+}},$$

$$\vec{\pi}_q = \vec{\pi} - \frac{\vec{\kappa}_+}{\sqrt{M^2_{(\text{free})} - \vec{\kappa}^2_+}}\left(\frac{1}{2}(\sqrt{m_1^2 + \vec{\kappa}_1^2} - \sqrt{m_2^2 + \vec{\kappa}_2^2}) - \frac{\vec{\kappa}_+ \cdot \vec{\pi}}{\vec{\kappa}^2_+}[M_{(\text{free})} - \sqrt{M^2_{(\text{free})} - \vec{\kappa}^2_+}]\right) \stackrel{\text{def}}{=} \vec{\pi} - D\vec{\kappa}_+,$$

$$\vec{\rho}_q = \vec{\rho} + \frac{A\vec{\kappa}_+ \cdot \vec{\rho}}{M_{(\text{free})}\sqrt{M^2_{(\text{free})} - \vec{\kappa}^2_+}}\vec{\pi}_q,$$

$$\vec{S}_q = \vec{S} - D\vec{\rho} \times \vec{\kappa}_+,$$

$$\vec{q}_+ = \vec{R}_+ + G\vec{S}_q \times \vec{\kappa}_+,$$

$$G = \frac{1}{M_{(\text{free})}(M_{(\text{free})} + \sqrt{M^2_{(\text{free})} - \vec{\kappa}^2_+})} = \frac{1}{\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+}(\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+} + \mathcal{M}_{(\text{free})})},$$

$$\vec{\eta}_+ = \vec{q}_+ - \frac{E}{2\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+}}[\vec{\rho}_q + C\vec{\pi}_q] - G\vec{S}_q \times \vec{\kappa}_+,$$

$$\vec{\eta}_i = \vec{q}_+ + \frac{1}{2}\left((-)^{i+1} - \frac{E}{\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+}}\right)(\vec{\rho}_q + C\vec{\pi}_q) - G\vec{S}_q \times \vec{\kappa}_+,$$

$$\vec{\kappa}_i = \left(\tfrac{1}{2} + (-)^{i+1}F\right)\vec{\kappa}_+ + (-)^{i+1}\vec{\pi}_q. \tag{A17}$$

(2) For $N > 2$ the results concerning the coordinates (and also $\vec{q}_+$) are much more involved due to the complexity of Eqs. (A15) so that we give only the following results for the momenta:

$$M(\text{free}) = \sum_i \sqrt{m_i^2 + \vec{\kappa}_i^2} = \sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+} \approx \mathcal{M}_{(\text{free})} = \sum_i \sqrt{m_i^2 + N\sum_{ab} \gamma_{ai}\gamma_{bi}\vec{\pi}_{qa} \cdot \vec{\pi}_{qb}},$$

$$\sqrt{m_i^2 + \vec{\kappa}_i^2} = \frac{1}{\mathcal{M}_{(\text{free})}}\left(\sqrt{N}\sum_a \gamma_{ai}\vec{\kappa}_+ \cdot \vec{\pi}_{qa} + \sqrt{m_i^2 + N\sum_{ab} \gamma_{ai}\gamma_{bi}\vec{\pi}_{qa} \cdot \vec{\pi}_{qb}}\sqrt{\mathcal{M}^2_{(\text{free})} + \vec{\kappa}^2_+}\right),$$

$$\vec{\kappa}_i = \frac{\vec{\kappa}_+}{N} + \sqrt{N}\sum_a \gamma_{ai}\left[\vec{\pi}_{qa} + \left(\frac{M_{(\text{free})}}{\mathcal{M}_{(\text{free})}} - 1\right)\frac{\vec{\kappa}_+ \cdot \vec{\pi}_{qa}}{\vec{\kappa}^2_+}\vec{\kappa}_+ + \frac{\vec{\kappa}_+}{\mathcal{M}_{(\text{free})}\sqrt{N}}\sum_i \gamma_{ai}\sqrt{m_i^2 + N\sum_{ab} \gamma_{ai}\gamma_{bi}\vec{\pi}_{qa} \cdot \vec{\pi}_{qb}}\right]. \tag{A18}$$

[39] Such hypersurfaces are the leaves of a foliation of Minkowski space–time, associated with one among its admissible $3+1$ splittings. They are both Cauchy surfaces for the dynamics and simultaneity surfaces corresponding to a convention for the synchronization of distant clocks. For more details see Ref. 40.
[40] D. Alba and L. Lusanna, submitted to Gen. Relativ. Gravit., (gr-qc/0311058).
[41] As shown in Ref. 40 this implies that the change of the convention on clock synchronization becomes a gauge transformation in parametrized Minkowski theories.

[45] $\vec{z}_s/\epsilon_s$ is the classical analogue of the Newton–Wigner 3-position operator, only covariant under the Euclidean subgroup of the Poincaré group.
[46] For instance $\vec{q}_+ \approx 0$ implies that the internal 3-center of mass is set in the centroid $x^\mu_s(\tau)=z^\mu(\tau,\vec{\sigma}=0)$, origin of the 3-coordinates on the Wigner hyperplanes.

(Received 23 February 2005; accepted 15 March 2005; published online 13 May 2005)

We give a definition and discuss main properties of the asymptotic Hopf invariant, or helicity, for Hamiltonian systems. The definition relies on a technical construction which is a definition of a relative Hopf invariant for divergence-free vector fields in multiconnected domains of the following type: (flat domain in $\mathbb{R}^2$) $\times$(circle). We prove correctness of the definitions, and discuss ergodic interpretation of the Hamiltonian Hopf invariant, together with its relation with the Calabi invariant. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1904511]

I. INTRODUCTION

The asymptotic Hopf invariant, or helicity of a divergence-free vector field (which, for example, can be a magnetic field) is an invariant, known in fluid dynamics and plasma physics. Being an invariant means that the helicity integral is preserved under an action on the vector field by an arbitrary volume-preserving diffeomorphism. Helicity was introduced in Refs. 14 and 15 and has been widely studied thereafter, see e.g., Ref. 3. One of the important applications of helicity is that it provides a lower bound for the magnetic energy, see, e.g., Ref. 5, and we also refer to Ref. 9 for explicit estimates for the lower bound for the energy, as well as a discussion of the geometry of the extremal vector fields.

We briefly remind the definition of helicity see, e.g., Ref. 3. Let M be a simply connected three-dimensional Riemannian manifold with boundary ∂M, let a 3-form μ be a volume form on M, and let ξ be a divergence-free vector field on M, tangent to the boundary ∂M. Consider a 2-form $\Omega_\xi = i_\xi \mu$. As M is simply connected, the form Ω_ξ is exact.

By definition, the *asymptotic Hopf invariant*, or *helicity* of the field ξ on M is an integral

$$\mathcal{H}(\xi) = \int_M \Omega_\xi \wedge d^{-1}\Omega_\xi. \tag{1}$$

Topological properties of helicity were discovered in Ref. 2, given a vector field on a three-dimensional simply connected domain, its helicity measures the average linking of the trajectories of this field. This property is also referred to as *ergodic*, as the proofs rely on Birkhoff's ergodic theorem. The topological description has also been generalized to higher dimensions, see, e.g., Refs. 16, 12, 13, and 6.

It is natural to try to extend the asymptotic Hopf invariant to Hamiltonian systems, indeed, one notices that in the extended phase space, a Hamiltonian vector field is a *curl* of a 1-form $p\,\mathrm{d}q - H\,\mathrm{d}t$, see, e.g., Ref. 1. Thus one can at least formally write down the same helicity integral as (1) (see Ref. 10). The problem is that Hamiltonian systems have no bounded simply connected invariant manifolds in the extended phase space (while multiconnected invariant manifolds certainly exist, for example, KAM-tori in Hamiltonian systems, close to integrable ones), while the asymptotic Hopf invariant does not exist for vector fields on multi-connected manifolds.[3]

First we define a *relative* Hopf invariant and a relative cross-helicity invariant for divergence-free vector fields in multiconnected domains of the type (flat domain in $\mathbb{R}^2$) $\times$(circle). Note that the simplest multiconnected manifold, invariant for a Hamiltonian system, is a solid torus, and it is clearly of the above type. The invariant we define describes the asymptotic linking of trajectories of these vector fields for some proper embedding of this domain into a sphere, assuming that

the domain itself is unlinked. We also discuss generalizations, when linking of the domain itself can be nontrivial. Then we consider Hamiltonian systems and discuss the relation of this invariant with the Calabi invariant.[8]

II. THE RELATIVE HOPF INVARIANT

As noted above, for vector fields in multiconnected manifolds (i.e., with nontrivial first homology group) there is no asymptotic Hopf invariant, the value of the integral (1) depends on a choice of a potential 1-form $d^{-1}\Omega_\xi$. We show that this choice can be made in some natural way for one case, important for applications.

Let a set V be a direct product of a circle (base) S^1 and a ring $R^2 \in \mathbb{R}^2$. Let μ be a volume 3-form, and let ξ be a divergence-free vector field, tangent to the boundary ∂V. Consider a 2-form $\Omega^2_\xi = i_\xi \mu$. This form is closed, since ξ is divergence-free (thus the Lie derivative $L_\xi \mu = d i_\xi \mu = 0$), and one can see that it is also exact (thus any divergence-free field tangent to the boundary ∂V is *null-homologious*). Indeed, the 2-cycle, on which the values of closed 2-forms are defined, is a two-torus, obtained by shrinking the ring R^2 to a circle. Integral of any closed 2-form over this torus equals the integral over any component of the boundary. But our 2-form Ω^2_ξ is identically zero on the boundary ∂V, as the field ξ is tangent to it.

We assume that in polar coordinates r, ϕ (mod 2π) the ring R^2 is given by $r \in [r_1, r_2]$. We take r, ϕ (mod 2π), t (mod 2π) as local coordinates on V.

Let γ_1 be a closed curve on the boundary ∂V, given by conditions $t = \text{const}$, $r = r_1$, and let a closed curve γ_2 be given by condition $\phi = \text{const}$, $r = r_2$.

We *choose* a 1-form $\omega^1_\xi = d^{-1}\Omega^2_\xi$ such that

$$\int_{\gamma_1} \omega^1_\xi = 0, \quad \int_{\gamma_2} \omega^1_\xi = 0. \tag{2}$$

Note that conditions (2) define a coset of 1-forms $[\omega^1_\xi]$, i.e., a 1-form modulo differential (as they define the values of a 1-form ω^1 on the fundamental group).

Definition 1: We call an integral

$$\mathcal{H}(\xi) = \int_V \Omega^2_\xi \wedge \omega^1_\xi,$$

a *relative Hopf invariant for the field ξ in V*.

Let another divergence-free vector field η be given on V, also being tangent to the boundary ∂V.

Definition 2: We call an integral

$$\mathcal{H}(\xi, \eta) = \int_V \Omega^2_\xi \wedge \omega^1_\eta,$$

where 1-form ω^1_η satisfies condition (2), a *relative cross-helicity of the fields ξ, η*. This choice of the potential 1-form is explained by the following crucial observation.

Assume that V is embedded into a sphere S^3, V is unlinked, and assume that the volume form $\mu = r\, \mathrm{d}r \wedge \mathrm{d}\phi \wedge \mathrm{d}t$. Let $r = r_1$, $\xi = (0,1,0)$ on the inner component of the boundary, and $r = r_2$, $\xi = (0,0,1)$ on the outer component.

Consider a set $\tilde{V} = \tilde{R}^2 \times S^1$, where the ring $\tilde{R}^2 \in \mathbb{R}^2$ is given by condition $r \in [\tilde{r}_1, \tilde{r}_2]$, where $r_1 > \tilde{r}_1$ and $r_2 < \tilde{r}_2$. We continue the volume form μ and the field ξ on $\tilde{V}$ (where the same local coordinates can be introduced as above) such, that μ remains the same, while $\xi \equiv (0,1,0)$ at $r < r_1$ and $\xi \equiv (0,0,1)$ at $r > r_2$.

As none of the trajectories of the field ξ in the domain $\tilde{V}\backslash V$ is linked with the trajectories of the field ξ in the domain $\tilde{V}$, we should expect that for a well-defined invariant, the relative helicities in domains V and $\tilde{V}$ are equal.

Proposition 1: Integrals

$$\int_V \Omega_\xi^2 \wedge \omega_\xi^1 = \int_{\tilde{V}} \Omega_\xi^2 \wedge \omega_\xi^1$$

for any $\tilde{r}_1$, $\tilde{r}_2$ *if and only if conditions* (2) *are satisfied.*

Proof: We consider the case when $\tilde{r}_1 = r_1$, $\tilde{r}_2 \neq r_2$, the general case is similar. In the domain $\tilde{V}\backslash V$, the 2-form $\Omega_\xi^2 = r\,\mathrm{d}r \wedge \mathrm{d}\phi$, thus $\omega_\xi^1 = (r^2/2 + f(\phi))\mathrm{d}\phi + g(t)\mathrm{d}t$ for some 2π-periodic functions f, g. Condition (2) means that $\int_0^{2\pi} g(t)\mathrm{d}t = 0$. However, this integral is zero if and only if

$$\int_{\tilde{V}\backslash V} \Omega_\xi^2 \wedge \omega_\xi^1 = \pi(\tilde{r}_2^2 - r_2^2) \int_0^{2\pi} g(t)\mathrm{d}t = 0.$$

□

Remarks: The condition for the ring R^2 being *flat* is of uttermost importance, if we drop this condition, then for different embeddings of the ring into $\mathbb{R}^2$ the same vector field may have different asymptotic linkings. A fiber can be more complicated, say, a disk with some number of holes, and the set V itself can be a nontrivial fibration over S^1. One can show that still any divergence-free vector field, tangent to the boundary, is null-homologious, as the corresponding 2-form is zero on every component of the boundary. As the fundamental group becomes more complicated, the number of conditions of the type (2) will grow.

It follows from Proposition 1 that condition (2) is *necessary* such that the relative Hopf invariant could be equal to asymptotic linking of the trajectories under an "appropriate" embedding of the set V into S^3, namely, the boundary torus should not be linked and the measure should be continued to the whole sphere. One can prove that this condition is also *sufficient*, say, by realizing this embedding. Instead, we demonstrate in an example that under our choice of a coset $[\omega_\xi^1]$ the relative Hopf invariant equals the asymptotic linking of the vector field ξ.

Let the field ξ be the Hopf vector field on a sphere S^3, in coordinates $x_1, x_2, x_3, x_4 \in \mathbb{R}^4$, where the sphere is given by relation $x_1^2 + x_2^2 + x_3^2 + x_4^2 = 1$, it is given by $\xi = (x_2, -x_1, x_4, -x_3)$.

Consider a solid torus V, $x_1^2 + x_2^2 \leqslant a^2$. We introduce local coordinates in the solid torus V [x_1, x_2, t (mod 2π)]. In these coordinates the Hopf field is $\xi = (x_2, -x_1, 1)$. As the volume form we take, as above, the 3-form $\mu = \mathrm{d}x_1 \wedge \mathrm{d}x_2 \wedge \mathrm{d}t$.

Proposition 2: Asymptotic linking of the Hopf field in the solid torus $x_1^2 + x_2^2 \leqslant a^2$, $a^2 < 1$ *equals the relative Hopf invariant* $\mathcal{H}(\xi)$.

Proof: The asymptotic linking of any two trajectories equals $1/4\pi^2$, see Ref. 3, example 4.5, the linking number for any two trajectories is 1, and all trajectories are periodic with the period 2π. Thus the asymptotic linking of the Hopf field in the solid torus V equals $\lambda_\xi = \mathrm{vol}(V)^2/4\pi^2 = \pi^2 a^4$. Now one can check by direct calculation that $\mathcal{H}(\xi) = \pi^2 a^4 = \lambda_\xi$. □

Remark: The asymptotic Hopf invariant for a vector field in a solid torus is usually calculated inserting the solid torus into a three-dimensional sphere, and setting the field being zero outside of the solid torus, see, e.g., Ref. 3 (as above the boundary torus should not be linked itself). However the *integral form* of such an invariant with condition (2) to the best of our knowledge has not been used before.

III. CORRECTNESS OF DEFINITIONS

Having justified the choice of the potential 1-forms, we now prove that the definitions above are consistent.

Lemma 1: The values of the relative Hopf invariant and the relative cross-helicity do not depend on a choice of 1-forms ω_ξ^1, ω_η^1, *that satisfy condition* (2).

Proof: Conditions (2) define a coset of 1-forms $[\omega^1]$, i.e., if $\omega^1+\alpha^1=d^{-1}\Omega^2$, then α^1 is exact. Now, the integral

$$\int_V \Omega^2 \wedge \alpha^1 = \int_V d(F\Omega^2) = \int_{\partial V} F\Omega^2 = 0.$$

□

From Lemma 1 we have the following.

Theorem 1: The relative Hopf invariant and the relative cross-helicity do not change under the action on the fields ξ, η of a volume-preserving diffeomorphism that maps the boundary ∂V on itself.

Proof: By Lemma 1, the definition of the integral $\mathcal{H}$ is invariant under coordinate transformations. □

Let now two divergence-free fields ξ_1, ξ_2 be given.

Theorem 2: Relative cross-helicities are symmetric, $\mathcal{H}(\xi_1,\xi_2)=\mathcal{H}(\xi_2,\xi_1)$.

Proof: We denote the 2-forms $\Omega_i^2=i_{\xi_i}\mu$, $\omega_i^1=d^{-1}\Omega_i^2$, $i=1,2$. Let, as above, r,ϕ,t be the coordinates in V, and let the volume form be $\mu=r\,\mathrm{d}r\wedge\mathrm{d}\phi\wedge\mathrm{d}t$ (note that this can be done by a variable change).

We first note that cross-helicities for an arbitrary field ξ and fields $\eta=(0,1,0)$ [and thus $\eta^*=(0,0,1)$] are symmetric. Proof relies on direct computation, one just has to check that

$$\int_V \Omega_\xi^2 \wedge \omega_\eta^1 - \int_V \Omega_\eta^2 \wedge \omega_\xi^1 = \int_{\partial V} \omega_\xi^1 \wedge \omega_\eta^1 = 0.$$

We next prove the following.

Lemma 2: Suppose that the integrals of the 2-forms Ω_1^2 and Ω_2^2 are equal over the surfaces $\Sigma_t=\{t=0\}$ and $\Sigma_\phi=\{\phi=0\}$. Then relative cross-helicities of the fields ξ_1 and ξ_2 are symmetric.

Proof of Lemma 2: Consider a 1-form $\omega_1^1-\omega_2^1$ on the boundary ∂V, which consists of two tori, $\partial V_1=\{r=r_1\}$ and $\partial V_2=\{r=r_2\}$. This form is closed, as each of the 2-forms Ω_1^2 and Ω_2^2 equal zero on both components of the boundary ∂V. Besides, the value of the 1-form $\omega_1^1-\omega_2^1$ on cycles γ_1, γ_2 is zero [by condition (2)], and on cycles $\sigma_1=\partial\Sigma_t\setminus\gamma_1$, $\sigma_2=\partial\Sigma_\phi\setminus\gamma_2$ is zero by the condition of the lemma. Thus the 1-form $\omega_1^1-\omega_2^1$ is *exact* both on ∂V_1 and ∂V_2. But the integral

$$\int_{\partial V} \omega_1^1 \wedge \mathrm{d}F = -\int_{\partial V} d(F\omega^1) = 0$$

for any function F. Thus,

$$\int_V \Omega_1^2 \wedge \omega_2^1 - \int_V \Omega_2^2 \wedge \omega_1^1 = 0.$$

To prove the theorem in the general case, it is sufficient to represent the field ξ_2 as a sum, $\xi_2=\xi_2^*+\eta_1+\eta_2$ where the fields $\eta_1=(0,0,c_1)$, $\eta_2=(0,c_2,0)$, $c_{1,2}=\mathrm{const}$ are such that the fields ξ_1 ξ_2^* satisfy condition of Lemma 2. □

Remark: The above results remain true if one replaces zero in the *second* condition (2) by an arbitrary constant,

$$\int_{\gamma_2} \omega^1 = k.$$

This can be done to relate the relative Hopf invariant with the asymptotic linking of the vector field, realizing nontrivial embeddings of the solid torus into the sphere S^3 (note that in Proposition 2 this embedding was trivial).

IV. THE HOPF INVARIANT FOR HAMILTONIAN SYSTEMS

Let M be a smooth $2n$-dimensional *exact* symplectic manifold (possibly unbounded). The condition for M to be exact means, that the symplectic 2-form Ω^2 is globally a differential of some 1-form. For example, one can consider cotangent bundles with a natural symplectic structure, see, e.g., Ref. 1.

Let p,q be local coordinates on M: $\Omega^2=\mathrm{d}p\wedge\mathrm{d}q$. Consider a Hamiltonian system that is given by a function $H(p,q,t)$, that is 2π-periodic in time t, on the extended phase space $M\times S^1$ $[t\ (\mathrm{mod}\ 2\pi)\in S^1]$. The corresponding Hamiltonian vector field in the extended phase space $\xi=(-\partial H/\partial q,\partial H/\partial p,1)$ annihilates the 2-form $\Omega_H=\Omega^2-\mathrm{d}H\wedge\mathrm{d}t$, $i_\xi\Omega_H=0$. Hamilton's equations are written in the standard form

$$\dot{p}=-\frac{\partial H}{\partial q},\quad \dot{q}=\frac{\partial H}{\partial p}. \tag{3}$$

Let a 1-form $\omega_H=d^{-1}\Omega_H$. In local coordinates p,q one can write it as $\omega_H=p\,\mathrm{d}q-H\,\mathrm{d}t$. The form ω_H is defined globally on $M\times S^1$, up to a closed 1-form. Note that having a Hamiltonian vector field, the corresponding Hamilton function cannot be uniquely reconstructed either, for example, add a constant to the function H, and the values of the 1-form ω_H 1-cycles will be changed.

Let, as above, $V\subset M\times S^1$ be a direct product of a ring and a circle, $V=R^2\times S^1$, $R^2\subset M$ is a 2-disk, $S^1=\{t\ (\mathrm{mod}\ 2\pi)\}$. Assume that V is an invariant set for the Hamiltonian system (3). Then on the boundary ∂V the 2-form $\Omega_H=0$. These invariant sets exist in Hamiltonian systems with one-and-a-half degrees of freedom, both integrable ones and close to integrable. We will assume that the restriction of the symplectic 2-form to R^2 is nondegenerate.

We define a coset of 1-forms $[\omega_H]$ by the following conditions:

$$\int_{\gamma_1}\omega_H=0,\quad \int_{\gamma_2}\omega_H=0, \tag{4}$$

where $\gamma_{1,2}\in\partial V$ are the cycles defined for conditions (2) in Sec. II.

Definition 3: We call an integral

$$\mathcal{H}(H)=\int_V\omega_H\wedge\Omega_H,$$

where ω_H satisfies condition (4), an *asymptotic Hopf invariant for the Hamiltonian vector field* with a Hamiltonian H.

Definition 4: An integral

$$\mathcal{H}(H,F)=\int_V\omega_H\wedge\Omega_F,$$

where ω_H, ω_F satisfies condition (4), will be referred to as a *cross-helicity of Hamiltonian vector fields* with Hamiltonians H, F.

Remarks: Instead of the volume form μ we use here the 3-form $\mu=\mathrm{d}p\wedge\mathrm{d}q\wedge\mathrm{d}t$. As in Sec. II, one can define the Hamiltonian Hopf invariants for fibrations over a circle with multiconnected fibers.

As a consequence of the corresponding results for the relative Hopf invariant (Sec. III), we get their symplectic versions.

Theorem 3: The values $\mathcal{H}(H)$, $\mathcal{H}(H,F)$ do not depend on a choice of the 1-form ω_H from the coset $[\omega_H]$, and they are invariant under symplectic diffeomorphisms, given by a single-valued generating function on V and sending the boundary to itself.

Proof: Take an invariant 3-form $\mu=\mathrm{d}p\wedge\mathrm{d}q\wedge\mathrm{d}t$, then $\Omega_H=i_\xi\mu$ and we can use Theorem 1. Note that since under symplectic coordinate transformation $p,q\to P=P(p,q,t)$, $Q=Q(p,q,t)$ with a generating function S the new Hamiltonian equals $H_1(P,Q,t)=H(p(P,Q,t),q(P,Q,t),t)$

$+\partial S/\partial t$, the 1-form ω_H will become $p\,\mathrm{d}q - H\,\mathrm{d}t = P\,\mathrm{d}Q - H_1\,\mathrm{d}t + dS(P,Q,t)$. Thus the form $P\,\mathrm{d}Q - H_1\,\mathrm{d}t$ belongs to the same coset $[\omega_H]$ and the value of the integral

$$\mathcal{H} = \int_V (P\,\mathrm{d}Q - H_1\,\mathrm{d}t) \wedge (\mathrm{d}P \wedge \mathrm{d}Q - \mathrm{d}H_1 \wedge \mathrm{d}t)$$

does not change. In a similar way, the integral $\mathcal{H}(H,F)$ can be treated. □

Corollary: The Hamiltonian Hopf invariant $\mathcal{H}(H)$ is a symplectic invariant of the Hamiltonian system with the Hamiltonian H.

The comparison of these two systems must be done in the following way. Let us compare two systems with invariant domains D_1^2 and D_2^2 (homotopically equivalent, i.e., disks with the same number of holes) in the phase space M, such that the areas of these domains coincide. Then, if the Hamiltonian Hopf invariants for these two systems are different, the systems are not symplectomorphic.

Remark: This invariant is finer than, say, the topological invariants of integrable Hamiltonian systems:[7] for example, it separates systems with proportional Hamiltonians, even if the relation of the Hamiltonians is a constant. This is clear from the invariant construction: as the Hamiltonian is multiplied by a constant, an asymptotic linking of the trajectories is changed.

An immediate corollary of Theorem 2 is the following.

Theorem 4: Hamiltonian cross-helicities are symmetric, $\mathcal{H}(H,F) = \mathcal{H}(F,H)$.

Note that both integrals of the 2-forms Ω_H, Ω_F upon the section $\Sigma = \{t=0\}$ are equal to the sum of the areas of the projection of Σ to 2-planes p_i, q_i.

V. THE HAMILTONIAN HOPF INVARIANT AND THE CALABI INVARIANT

The choice of condition (4) makes it possible to give a simple form for the relation of the asymptotic linking invariant in a solid torus with the Calabi invariant.[8]

We first remind the definition of the Calabi invariant. Let ϕ be a symplectic diffeomorphism of the 2-disk D^2, equipped with an area form μ, identical near the boundary ∂D. Take a 1-form α, such that $\mu = \mathrm{d}\alpha$. As the 1-form $\phi^*\alpha - \alpha$ is closed and vanishes near the boundary, there is a function $h(\phi): D^2 \to \mathbb{R}$, which vanishes near the boundary ∂D and satisfies

$$\mathrm{d}h(\phi) = \phi^*\alpha - \alpha.$$

By definition, the *Calabi invariant* of the area-preserving diffeomorphism ϕ is the integral,

$$\int_{D^2} h(\phi)\mu,$$

see Ref. 11. This definition also extends to higher dimensions, see, e.g., Ref. 3.

One can show[3] that, provided the symplectic diffeomorphism ϕ is defined by a Poincaré mapping of a period 2π for a Hamiltonian system (3), the Calabi invariant equals

$$2n \int_0^{2\pi} \int_{D^{2n}} H(p,q,t)(\Omega^2)^n\,\mathrm{d}t.$$

We will see that it is the latter definition that provides the relation of the Calabi invariant with the relative asymptotic Hopf invariant.

Let V be a solid torus.

Proposition 3: Let the differential dH be identically zero in a neighborhood of the boundary ∂V. Then under condition (4) the Hamiltonian Hopf invariant $\mathcal{H}$ equals (minus) the Calabi invariant of the symplectic diffeomorphism of the 2-disk $D^2 \subset M$, defined by a Poincaré mapping of a period 2π for the Hamiltonian system (3).

Proof: Assume first that the dimension $\dim M = 2$. Let the differential $\mathrm{d}H$ be identically zero in

a neighborhood of the boundary ∂V. Then $H=\text{const}$ on ∂V. Condition (4) means that this constant must be equal to zero. Consider now an integral

$$\mathcal{H} = \int_V \omega_H \wedge \Omega_H = -\int_V H\,\mathrm{d}p \wedge \mathrm{d}q \wedge \mathrm{d}t - \int_V p\,\mathrm{d}q \wedge \mathrm{d}H \wedge \mathrm{d}t = -2\int_V H\,\mathrm{d}p \wedge \mathrm{d}q \wedge \mathrm{d}t + \int_{\partial V} Hp\,\mathrm{d}q \wedge \mathrm{d}t.$$

The last integral equals zero, as $H=0$ on the boundary ∂V. The integral,

$$2\int_V H\,\mathrm{d}p \wedge \mathrm{d}q \wedge \mathrm{d}t,$$

is exactly the Calabi invariant.

Suppose now that the dimension $\dim M=2n>2$. As we assumed above, the restriction of the symplectic 2-form on the invariant set D^2 is nondegenerate. Then one can show that the restriction of the original Hamiltonian system to $V=D^2\times\{t \pmod{2\pi}\}$ is a Dirac constrained Hamiltonian system, cf. Ref. 4. Namely, the Hamiltonian vector field ξ in the solid torus V is given by the standard condition $i_\xi\omega^2=\mathrm{d}F$, where ω^2 is the restriction of the symplectic 2-form, and the function F is the restriction of the Hamiltonian on V. □

An important corollary of this observation is related to ergodic properties of the Calabi invariant, this invariant describes *relative asymptotic linking of the trajectories of the Hamiltonian vector field in the solid torus*, cf. Proposition 2.

In higher-dimensional cases, ergodic properties of the Calabi invariant can be deduced from general results on higher-dimensional analogues of the asymptotic Hopf invariant, see, e.g., Ref. 13.

Let α be an exact 2-form of rank 2 in a simply connected domain M (thus it defines a foliation of codimension 2). Let the vector field ξ be chosen by the condition $i_\xi\mu=\beta$, where μ is the volume form, and the form β is exact. Then an integral,

$$lk_\xi(\mathcal{F}) = \int_M d^{-1}\alpha \wedge \beta,$$

equals the average linking of the foliation $\mathcal{F}$, defined by the 2-form α, and the vector field ξ, see Refs. 3 and 13.

The forms α and β are easily defined for the Calabi invariant: the 2-form α is $\mathrm{d}H\wedge\mathrm{d}t$ (while the 1-form $d^{-1}\alpha=H\,\mathrm{d}t$), and $\beta=(\Omega^2)^n$. One can see that rank $\mathrm{d}H\wedge\mathrm{d}t=2$. Thus, as in the 3-dimensional case, the Calabi invariant equals *relative asymptotic linking of the foliation*, defined by the 2-form $\mathrm{d}H\wedge\mathrm{d}t$, *with the vector field* ξ, which in canonical coordinates $(p_1,q_1,\ldots,p_n,q_n,t)$ looks like $\xi=(0,\ldots,0,1)$. Note that instead of the vector field ξ one can take the Hamiltonian vector field with the Hamiltonian H, the form β certainly changes, but the value of the integral $lk_\xi(\mathcal{F})$ is preserved.

Remark: If the phase space is two dimensional, one can give another definition of the Calabi invariant in terms of the average orbit braiding, see, e.g., Ref. 11. Let $\{\phi_t\}$, $t\in[0,1]$ be a Hamiltonian isotopy of the two-disk D^2 to itself. Consider the map

$$\mathrm{Ang}_\phi: (D^2\times D^2)\setminus\Delta \to \mathbb{R}^2$$

(where Δ is the diagonal), that associates to any pair of points $x\neq y$ the angular variation of the vector from $\phi_t(x)$ to $\phi_t(y)$, when t goes from 0 to 1. Then the Calabi invariant is the integral of this function:

$$\mathcal{H}(\phi) = \int \int_{D^2 \times D^2} \mathrm{Ang}_{\phi}(x,y)\mu_x \mu_y,$$

where μ is the area 2-form on the disk D^2. Our construction shows that the average orbit braiding in this case equals the average linking of the trajectories. However, while a higher-dimensional analog of the angular definition of the Calabi invariant is unknown, its ergodic definition in terms of average linking of the field with the foliation is straightforward, as shown above.

VI. CONCLUSION AND ACKNOWLEDGMENTS

In this paper we considered a generalization of the asymptotic and cross-Hopf invariants for divergence-free vector fields in multiconnected domains of the type (flat domain) $\times S^1$. For a vector field in a solid torus one must choose a potential 1-form such that its integral along the torus meridian equals zero. Under this choice the value of the relative Hopf invariant becomes well-defined, and one can show that for the "correct" embedding of the solid torus into a 3-sphere it coincides with asymptotic linking of this field. For Hamiltonian vector fields the relative Hopf invariant is equal to the Calabi invariant, under the condition that the differential $\mathrm{d}H=0$ on the boundary of the domain. Ergodic properties of the Calabi invariant follow from this observation: the Calabi invariant describes relative asymptotic linking of the trajectories of the Hamiltonian vector field with the Hamiltonian H with the foliation, defined by the 2-form $\mathrm{d}H \wedge \mathrm{d}t$.

(Received 16 December 2004; accepted 28 March 2005; published online 18 May 2005)

We study the presence of a logarithmic time scale in discrete approximations of sawtooth maps on the 2-torus. The techniques used are suggested by quantum mechanical similarities, and are based on a particular class of states on the torus, that fulfill dynamical localization properties typical of quantum coherent states. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1917283]

I. INTRODUCTION

Under the term of quantum chaos goes a rich phenomenology of behaviors[1–3] proper to quantum systems whose classical limit presents typical chaotic features as positive Lyapunov exponents (hyperbolic regime).[4–6]

The footprints of classical chaos are usually studied semiclassically when a suitable "$\hbar$"-like quantization parameter goes to zero; one then examines the differences between quantum and classical behaviors. In the hyperbolic case, quantum chaos reveals itself through the presence of a time scale, over which quantum and classical motions mimic each other, that increases as $-\log\hbar$.[1–3,7–9] This peculiar logarithmic time scale has to be compared with the scaling $\hbar^{-\alpha}$, $\alpha>0$, which is proper of quantum systems with regular classical limit.[1]

Heuristical explanations of the logarithmic time scale already indicate that the phenomenon is not exclusive of quantum systems, and thus of noncommutativity, but that it should also be present when the classical dynamics is looked at as the continuous limit of a family of discrete classical systems.[10]

Intrinsically discrete systems[11] and discretized classical continuous systems[12–14] have recently been objects of numerical analysis concerning the entropy production and the presence of a logarithmic time scale, whereas the ergodic properties of discretized discontinuous maps have been addressed in Ref. 15.

In the following, we shall rigorously show this fact to be true for sawtooth maps on the two-dimensional torus:[16–18] this will be done by forcing them to move on a square lattice and by retrieving the continuous dynamics when the lattice spacing goes to zero. Because of the analogies between quantization and discretization, we will make use of technologies strictly resembling the so-called *anti-Wick* quantization.[19]

We shall prove that a time-scale logarithmic in the lattice spacing appears; in comparison to previous results obtained studying numerically the entropy production,[14] a rigorous continuous limit is established that succeeds in controlling the discontinuities of sawtooth maps. Despite their classical nature, the entropy previously investigated was quantum mechanical; somewhat analo-

b)Electronic mail: valerio.cappellini@ts.infn.it

gously, in this article, sawtooth maps will be studied by means of states, which play a role similar to quantum coherent states, whose choice is naturally provided by the lattice structure of discretized sawtooth maps. They will be shown to satisfy a *dynamical localization property* that makes them remain localized around the trajectories of the continuous dynamics, but only on a logarithmic time scale.

II. CLASSICAL DYNAMICAL SYSTEMS

Classical dynamics is usually described by means of a measure space χ, the phase space, endowed with the Borel σ algebra and a normalized measure μ, $\mu(\chi)=1$. The "volumes"

$$\mu(E)=\int_E \mu(\mathrm{d}\mathbf{x})$$

of measurable subsets $E\subseteq\chi$ represent the probabilities that a phase-point $\mathbf{x}\in\chi$ belong to them: the measure μ defines the statistical properties of the system and represents a possible state, which is taken to be an equilibrium state with respect to the given dynamics.

In such a scheme, a reversible discrete time dynamics amounts to an invertible measurable map $S:\chi\mapsto\chi$ such that $\mu\circ S=\mu$ and to its iterates $\{S^k|k\in\mathbb{Z}\}$: phase trajectories passing through $\mathbf{x}\in\chi$ at time 0 are then sequences $\{S^k\mathbf{x}\}_{k\in\mathbb{Z}}$.[6]

Classical dynamical systems are thus conveniently described by triplets (χ,μ,S); in the present work, we shall focus upon the following choices:

χ: the two-dimensional torus $\mathbb{T}^2=\mathbb{R}^2/\mathbb{Z}^2=\{\mathbf{x}=(x_1,x_2)\in\mathbb{R}^2 \pmod 1\}$;

μ: the Lebesgue measure, $\mu(\mathrm{d}\mathbf{x})=\mathrm{d}x_1\mathrm{d}x_2$, on $\mathbb{T}^2$;

S: an invertible measurable transformation on $\mathbb{T}^2$ that preserves the Lebesgue measure.

It is convenient to associate an algebraic triple $(\mathcal{M},\omega,\Theta)$ to the measure-theoretic triple $(\mathbb{T}^2,\mu,S)$, consisting of

$\mathcal{M}$: the (Abelian) Von Neumann $*$-algebra $L^\infty_\mu(\mathbb{T}^2)$ of essentially bounded functions on $\mathbb{T}^2$.[20,21]

ω_μ: the state (expectation) on $\mathcal{M}$, given by

$$\omega_\mu: L^\infty_\mu(\mathbb{T}^2)\ni f\mapsto \omega_\mu(f):=\int_{\mathbb{T}^2}\mu(\mathrm{d}\mathbf{x})f(x)\in\mathbb{R}^+. \tag{1}$$

Θ: the automorphism of $\mathcal{M}$ such that $\Theta(f)=f\circ S$, $\omega\circ\Theta=\omega$.

In the following, we shall consider a discretized version of $(\mathbb{T}^2,\mu,S)$ which arises by forcing the continuous classical system to live on a square lattice $L_N\subseteq\mathbb{T}^2$ of spacing $1/N$:

$$L_N:=\left\{\left.\frac{\mathbf{p}}{N}\right|\mathbf{p}\in(\mathbb{Z}/N\mathbb{Z})^2\right\}, \tag{2}$$

where $(\mathbb{Z}/N\mathbb{Z})$ denotes the residual class (mod N), that is $0\leqslant p_i\leqslant N-1$.

Taking the N^2 points as labels of the elements $\{|\ell\rangle\}_{\ell\in(\mathbb{Z}/N\mathbb{Z})^2}$ of an orthonormal basis (o.n.b.) of the $\mathcal{N}$-dimensional Hilbert space $\mathcal{H}_\mathcal{N}$, $\mathcal{N}:=N^2$, we will consider discrete algebraic triples $(\mathcal{D}_\mathcal{N},\tau_\mathcal{N},\Theta_\mathcal{N})$, consisting of

$\mathcal{D}_\mathcal{N}$: an $\mathcal{N}\times\mathcal{N}$ matrix algebra diagonal in the orthonormal basis introduced previously;

$\tau_\mathcal{N}$: the uniform state (expectation) on $D_\mathcal{N}$ defined by

$$\tau_\mathcal{N}:\mathcal{D}_\mathcal{N}\ni D\mapsto\tau_\mathcal{N}(D):=\frac{1}{\mathcal{N}}\mathrm{Tr}(D)\in\mathbb{R}^+; \tag{3}$$

$\Theta_\mathcal{N}$: an automorphism of $D_\mathcal{N}$ suitably reproducing Θ when $N\to\infty$ (see Sec. IV B).

Remark 2.1: As it will become evident in the following, up to a certain extent, discretization resembles quantization; in the latter case, instead of $\mathcal{D}_\mathcal{N}$, one deals with noncommutative matrix algebras, the typical instance being the finite dimensional quantization of the Arnold cat map.[22,23]

III. DISCRETIZATION OF PHASE SPACE

As sketched in the previous Remark, we proceed now to setup a discretization procedure close to the so-called anti-Wick quantization.[19]

Given the classical algebraic triple $(L^\infty_\mu(\mathbb{T}^2), \omega_\mu, \Theta)$, the aim of a discretization–dediscretization procedure (specifically an $\mathcal{N}$-dimensional discretization) is twofold:

- finding a pair of $*$-morphisms, $\mathcal{J}_{\mathcal{N},\infty}$ mapping $L^\infty_\mu(\mathbb{T}^2)$ into the abelian finite dimensional algebra $\mathcal{D}_\mathcal{N}$ and $\mathcal{J}_{\infty,\mathcal{N}}$ mapping backward $\mathcal{D}_\mathcal{N}$ into $L^\infty_\mu(\mathbb{T}^2)$;
- providing an automorphism $\Theta_\mathcal{N}$, the discrete dynamics, acting on $\mathcal{D}_\mathcal{N}$ such that it approximates the continuous one, Θ, on $L^\infty_\mu(\mathbb{T}^2)$ as follows:

$$\mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_\mathcal{N} \circ \mathcal{J}_{\mathcal{N},\infty} \xrightarrow[N\to\infty]{} \Theta^j. \tag{4}$$

The latter requirement can be seen as a modification of the so-called Egorov's property (see Ref. 24). Intuitively, a discrete description of the measure-theoretic triple $(\mathbb{T}^2, \mu, S)$ becomes finer when we increase N, the number of points per linear dimension on the grid L_N in (2): this corresponds to enlarging the dimension of the Hilbert space $\mathcal{H}_\mathcal{N}$ associated to the corresponding algebraic triple $(\mathcal{D}_\mathcal{N}, \tau_\mathcal{N}, \Theta_\mathcal{N})$. In this sense, the lattice spacing $a := 1/N$ of the grid L_N is a natural "discretization parameter" playing an analogous role to the quantization parameter $\hbar$.

The difficulty is to find convenient $*$-morphisms $\mathcal{J}_{\mathcal{N},\infty}$ and $\mathcal{J}_{\infty,\mathcal{N}}$ that set up a rigorous asymptotic (in N) correspondence, of functions on $L^\infty_\mu(\mathbb{T}^2)$ and matrices in $\mathcal{D}_\mathcal{N}$ and, above all, between the discrete dynamics $\Theta_\mathcal{N}$ and the continuous one Θ.

Due to the similarities with quantization, we shall consider a discretization procedure based on states that we shall refer to as lattice states (LS for short) which mimic the use of coherent states in the study of the semiclassical limit. In the next section we will give a suitable definition of LS belonging to the Hilbert space $\mathcal{H}_\mathcal{N}$, that we shall use to discretize $(L^\infty_\mu(\mathbb{T}^2), \omega_\mu, \Theta)$.

A. Lattice states on $\mathbb{T}^2$

In analogy with the properties of quantum coherent states, we shall look for a class $\{|C_\mathcal{N}(\mathbf{x})\rangle \,|\, \mathbf{x} \in \mathbb{T}^2\} \in \mathcal{H}_\mathcal{N}$ of vectors, indexed by points $\mathbf{x} \in \mathbb{T}^2$, satisfying the following conditions which are borrowed from analogous quantum ones.[25]

Properties 3.1:

1. Measurability: $\mathbf{x} \mapsto |C_\mathcal{N}(\mathbf{x})\rangle$ is measurable on $\mathbb{T}^2$;
2. Normalization: $\|C_\mathcal{N}(\mathbf{x})\|^2 = 1$, $\mathbf{x} \in \mathbb{T}^2$;
3. Completeness: $\mathcal{N} \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{x}) |C_\mathcal{N}(\mathbf{x})\rangle\langle C_\mathcal{N}(\mathbf{x})| = \mathbb{1}$;
4. Localization: given $\epsilon > 0$ and $d_0 > 0$, there exists $N_0(\epsilon, d_0)$ such that for $N \geqslant N_0(\epsilon, d_0)$ and $d_{\mathbb{T}^2}(\mathbf{x}, \mathbf{y}) \geqslant d_0$ one has

$$\mathcal{N} |\langle C_\mathcal{N}(\mathbf{x}), C_\mathcal{N}(\mathbf{y})\rangle|^2 \leqslant \epsilon.$$

The symbol $d_{\mathbb{T}^2}(\mathbf{x}, \mathbf{y})$ used in the localization property stands for the length of the shorter segment connecting the two points $\mathbf{x}, \mathbf{y} \in \mathbb{T}^2$, namely

Definition 3.1: We shall denote by $d_{\mathbb{T}^2}(\mathbf{x}, \mathbf{y}) := \min_{\mathbf{n} \in \mathbb{Z}^2} \|\mathbf{x} - \mathbf{y} + \mathbf{n}\|_{\mathbb{R}^2}$ the distance on $\mathbb{T}^2$.

We shall now construct a family of $|C_\mathcal{N}(\mathbf{x})\rangle$. Let $\lfloor \cdot \rfloor$ denote the integer part of a real number, namely $x - 1 < \lfloor x \rfloor \leqslant x$ is the largest integer smaller than x; further, let $\langle \cdot \rangle$ denote the fractional parts, that is $\langle x \rangle := x - \lfloor x \rfloor$. Thus we will write

$$\mathbb{T}^2 \ni \mathbf{x} = \left(\frac{\lfloor N x_1 \rfloor}{N}, \frac{\lfloor N x_2 \rfloor}{N} \right) + \left(\frac{\langle N x_1 \rangle}{N}, \frac{\langle N x_2 \rangle}{N} \right),$$

or, more compactly,

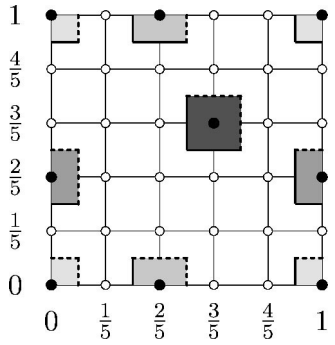

FIG. 1. All points in the shadowed square $I_{(3/5,3/5)} := \left[\frac{5}{10},\frac{7}{10}\right)\times\left[\frac{5}{10},\frac{7}{10}\right)\subset\mathbb{T}^2$ are associated with the grid point $\left(\frac{3}{5},\frac{3}{5}\right)$ (black dot). Thus, for all $\mathbf{x}\in I_{(3/5,3/5)}$, it turns out that $|C_{\mathcal{N}}(\mathbf{x})\rangle = |(3,3)\rangle \in \mathcal{H}_{\mathcal{N}}$.

$$\mathbf{x} = \frac{\lfloor N\mathbf{x}\rfloor}{N} + \frac{\langle N\mathbf{x}\rangle}{N}.$$

We proceed by associating to points of $\mathbb{T}^2$ specific lattice points.

Definition 3.2 (lattice states): Given $\mathbf{x}\in\mathbb{T}^2$, we shall denote by $\hat{\mathbf{x}}_N$ the element of $(\mathbb{Z}/N\mathbb{Z})^2$ given by

$$\hat{\mathbf{x}}_N = (\hat{x}_{N,1},\hat{x}_{N,2}) := \left(\left\lfloor Nx_1 + \tfrac{1}{2}\right\rfloor,\left\lfloor Nx_2 + \tfrac{1}{2}\right\rfloor\right), \tag{5}$$

and call lattice states on $\mathbb{T}2$ the vectors $|C_{\mathcal{N}}(\mathbf{x})\rangle$ defined by

$$\mathbb{T}^2 \ni \mathbf{x} \mapsto |C_{\mathcal{N}}(\mathbf{x})\rangle := |\hat{\mathbf{x}}_N\rangle \in \mathcal{H}_{\mathcal{N}}. \tag{6}$$

Remark 3.1: The family of states $|C_{\mathcal{N}}(\mathbf{x})\rangle$ is constructed by choosing, for each $\mathbf{x}\in\mathbb{T}^2$, that element of the basis of $\mathcal{H}_{\mathcal{N}}$ which is labeled by the closest element of L_N to $\mathbf{x}$.

Figure 1 represents a square lattice (L_5) of spacing $\frac{1}{5}$ by circles and connecting lines.

Proposition 3.1: The family of LS $\{|C_{\mathcal{N}}(\mathbf{x})\}$ *satisfies Properties 3.1.*

Proof: Measurability and normalization are straightforward. Completeness can be expressed as

$$\mathcal{N}\int_{\mathbb{T}^2}\mu(\mathrm{d}\mathbf{x})\langle\boldsymbol{\ell}|C_{\mathcal{N}}(\mathbf{x})\rangle\langle C_{\mathcal{N}}(\mathbf{x})|\mathbf{m}\rangle = \delta^{(N)}_{\boldsymbol{\ell},\mathbf{m}}, \quad \forall\,\boldsymbol{\ell},\mathbf{m}\in(\mathbb{Z}/N\mathbb{Z})^2,$$

where we have introduced the periodic Kronecker delta, that is $\delta^{(N)}_{\mathbf{n},\mathbf{0}}=1$ if and only if $\mathbf{n}\equiv\mathbf{0}$ (mod N). This is proved as follows:

$$\begin{aligned}
&\mathcal{N}\int_{\mathbb{T}^2}\mu(\mathrm{d}\mathbf{x})\langle\boldsymbol{\ell}|C_{\mathcal{N}}(\mathbf{x})\rangle\langle C_{\mathcal{N}}(\mathbf{x})|\mathbf{m}\rangle\\
&\quad= \mathcal{N}\int_0^1\mathrm{d}x_1\int_0^1\mathrm{d}x_2\langle\boldsymbol{\ell}|\hat{\mathbf{x}}_N\rangle\langle\hat{\mathbf{x}}_N|\mathbf{m}\rangle\\
&\quad= \mathcal{N}\delta^{(N)}_{\ell_1,m_1}\delta^{(N)}_{\ell_2,m_2}\left[\int_0^1\mathrm{d}x_1\,\delta^{(N)}_{\ell_1,\lfloor Nx_1+1/2\rfloor}\right]\left[\int_0^1\mathrm{d}x_2\,\delta^{(N)}_{\ell_2,\lfloor Nx_2+1/2\rfloor}\right]\\
&\quad= \mathcal{N}(\delta^{(N)}_{\ell_1,m_1}\delta^{(N)}_{\ell_2,m_2})\left[\int_{\ell_1-1/2/N}^{\ell_1+1/2/N}\mathrm{d}x_1\right]\left[\int_{\ell_2-1/2/N}^{\ell_2+1/2/N}\mathrm{d}x_2\right] = N^2\delta^{(N)}_{\boldsymbol{\ell},\mathbf{m}}\frac{1}{N^2} = \delta^{(N)}_{\boldsymbol{\ell},\mathbf{m}}.
\end{aligned}$$

Localization comes as follows: from Definition 3.2 (see Remark 3.1 and Fig 1), it turns out that $|C_{\mathcal{N}}(\mathbf{x})\rangle$ is orthogonal to every basis element labeled by a point of L_N whose toral distance $d_{\mathbb{T}^2}$ (see

Definition 3.1) from $\mathbf{x}$ is greater than $1/N\sqrt{2}$. As a consequence, the quantity $\langle C_{\mathcal{N}}(\mathbf{x}), C_{\mathcal{N}}(\mathbf{y})\rangle = 0$ if the distance on the torus between $\mathbf{x}$ and $\mathbf{y}$ is greater than $\sqrt{2}/N$. Thus, given $d_0 > 0$, it is sufficient to choose $N_0(\epsilon, d_0) > \sqrt{2}/d_0$, to have

$$N > N_0(\epsilon, d_0) \Rightarrow \mathcal{N}\langle C_{\mathcal{N}}(\mathbf{x}), C_{\mathcal{N}}(\mathbf{y})\rangle = 0.$$

■

Remarks 3.2:

(1) The last result in the previous proposition amounts to an even stronger localization property than Property 3.1.4; this is due to our particular choice of lattice states, which, as we shall see, is suited to the task of controlling sawtooth maps. In general, one can hardly hope to achieve orthogonality and must be content with the weaker localization condition 3.1.4.

(2) Although the set of LS of Definition 3.2 fulfill Properties 3.1, which are typical of coherent states, LS differ from them in that the context we are considering is commutative. In spite of this, it is convenient to adopt the formalism of quantum mechanics; in particular the set of LS is interpreted as a Hilbert orthonormal basis of Dirac kets, whose corresponding projectors form a partition of unit into indicator functions having support on small squares of the torus, as in Figure 1, whose side scales as $1/N$.

B. Anti-Wick discretization and its continuous limit on $\mathbb{T}^2$

In order to study the continuous limit and, more generally, the quasicontinuous behavior of $(\mathcal{D}_{\mathcal{N}}, \tau_{\mathcal{N}}, \Theta_{\mathcal{N}})$ when $N \to \infty$, we follow the semiclassical technique known as anti-Wick quantization. The other standard quantization technique, namely the Weyl procedure, despite being more straightforward and less technically heavy, is nevertheless more suited to smooth spaces of functions and was indeed instrumental in the study of discretized cat maps.[14] Instead, in our case, the anti-Wick procedure is a better choice due to the discontinuous character of the dynamics, as it will clearly appear in the next section.

We start choosing concrete discretization/de-discretization $*$-morphisms.

Definitions 3.3: Given the family $\{|C_{\mathcal{N}}(\mathbf{x})\rangle\}$ of lattice states in $\mathcal{H}_{\mathcal{N}}$, the anti-Wick-like discretization scheme (AW, for short) will be described by a one parameter family of (completely) positive unital map $\mathcal{J}_{\mathcal{N},\infty}: L^{\infty}_{\mu}(\mathbb{T}^2) \to \mathcal{D}_{\mathcal{N}}$

$$L^{\infty}_{\mu}(\mathbb{T}^2) \ni f \mapsto \mathcal{N}\int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{x}) f(\mathbf{x}) |C_{\mathcal{N}}(\mathbf{x})\rangle\langle C_{\mathcal{N}}(\mathbf{x})| =: \mathcal{J}_{\mathcal{N},\infty}(f) \in \mathcal{D}_{\mathcal{N}}.$$

The corresponding de-discretization operation will be described by the (completely) positive unital map $\mathcal{J}_{\infty,\mathcal{N}}: \mathcal{D}_{\mathcal{N}} \to L^{\infty}_{\mu}(\mathbb{T}^2)$

$$\mathcal{D}_{\mathcal{N}} \ni X \mapsto \langle C_{\mathcal{N}}(\mathbf{x}), X C_{\mathcal{N}}(\mathbf{x})\rangle =: \mathcal{J}_{\infty,\mathcal{N}}(X)(\mathbf{x}) \in L^{\infty}_{\mu}(\mathbb{T}^2).$$

Remarks 3.3: (i) Both maps are identity preserving (unital) because of the conditions satisfied by the family of lattice states and are completely positive, since both $L^{\infty}_{\mu}(\mathbb{T}^2)$ and $\mathcal{D}_{\mathcal{N}}$ are commutative algebras. One can also check that

$$\|\mathcal{J}_{\infty,\mathcal{N}} \circ \mathcal{J}_{\mathcal{N},\infty}(g)\|_{\infty} \leqslant \|g\|_{\infty}, \quad g \in L^{\infty}_{\mu}(\mathbb{T}^2).$$

(ii) Definition 3.3 yields $\tau_{\mathcal{N}} \circ \mathcal{J}_{\mathcal{N},\infty} = \omega_{\mu}$, with $\tau_{\mathcal{N}}$ given in (3).

In Appendix A, more operative details are presented, whereas in the following we prove some simple properties that incorporate minimal requests for rigorously defining the sense in which the discrete dynamical systems $(\mathcal{D}_{\mathcal{N}}, \tau_{\mathcal{N}}, \Theta_{\mathcal{N}})$ tends to $(L^{\infty}_{\mu}(\mathbb{T}^2), \omega_{\mu}, \Theta)$, when $1/N \to 0$.

Proposition 3.2:

(1) For all $f \in L^{\infty}_{\mu}(\mathbb{T}^2)$ and $X \in \mathcal{D}_{\mathcal{N}}$,

$$\omega_{\mu}(\overline{g}\mathcal{J}_{\infty,\mathcal{N}}(X)) = \tau_{\mathcal{N}}(\mathcal{J}_{\mathcal{N},\infty}(g)^* X);$$

(2) For all $f,g \in L^{\infty}_{\mu}(\mathbb{T}^2)$

$$\lim_{N\to\infty} \tau_{\mathcal{N}}(\mathcal{J}_{\mathcal{N},\infty}(f)^{*}\mathcal{J}_{\mathcal{N},\infty}(g)) = \omega_{\mu}(\overline{fg}) = \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{x})\overline{f(\mathbf{x})}g(\mathbf{x});$$

(3) For all $X \in \mathcal{D}_{\mathcal{N}}$, and for all $N \in \mathbb{N}^{+}$,

$$\mathcal{J}_{\mathcal{N},\infty} \circ \mathcal{J}_{\infty,\mathcal{N}}(X) = X;$$

(4) For all $f \in L^{\infty}_{\mu}(\mathbb{T}^2)$

$$\lim_{N\to\infty} \mathcal{J}_{\infty,\mathcal{N}} \circ \mathcal{J}_{\mathcal{N},\infty}(f) = f \ \mu - \text{a.e.}$$

Proof: The first two statements in the above proposition directly follow from Definitions 3.3 together with (6); the latter two are equivalent and their proof can be found in Ref. 25, the only difference being the dimension $\mathcal{N}$ of the Hilbert space $H_{\mathcal{N}}$, here $\mathcal{N}=N^2$, there $\mathcal{N}=N$. ■

Remark 3.4: Properties 1 and 2 in the previous proposition show how (GNS) scalar products in the discrete, respectively continuous limit, are related; Properties 3 and 4 concern instead the direct-inverse relations between the discretization and the de-discretization maps.

IV. DISCRETIZATION OF THE DYNAMICS

A. Classical description of sawtooth maps

We shall now focus on a special class of automorphisms of the torus, namely the sawtooth maps[16,17] (SM for short), that is on triples $(\mathbb{T}^2,\mu,S_{\alpha})$ where

$$S_{\alpha}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 1+\alpha & 1 \\ \alpha & 1 \end{pmatrix}\begin{pmatrix} \langle x_1 \rangle \\ x_2 \end{pmatrix} \ (\mathrm{mod}\ 1), \quad \alpha \in \mathbb{R} = \begin{pmatrix} \langle (1+\alpha)\langle x_1\rangle + x_2 \rangle \\ \langle \alpha \langle x_1 \rangle + x_2 \rangle \end{pmatrix}. \tag{7}$$

Remarks 4.1

i. In the following, a point $\mathbf{x}$ of the torus, will correspond to an equivalence class of $\mathbb{R}^2$ points whose coordinates differ by integer values;

ii. without the fractional part, (7) is not well defined on $\mathbb{T}^2$ for noninteger α; indeed, the same point $\mathbf{x}=\mathbf{x}+\mathbf{n} \in \mathbb{T}^2, \mathbf{n} \in \mathbb{Z}^2$, would have (in general) $S_{\alpha}(\mathbf{x}) \neq S_{\alpha}(\mathbf{x}+\mathbf{n})$. Of course, $\langle\cdot\rangle$ is not necessary when $\alpha \in \mathbb{Z}$;

iii. the Lebesgue measure on $\mathbb{T}^2$ is *invariant* for all $\alpha \in \mathbb{R}$;

iv. if $\alpha \notin \mathbb{Z}$, the S_{α} are known as sawtooth maps;

v. when $\alpha \in \mathbb{Z}$, we shall write T_{α} instead of S_{α}. $T_1=\left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ is the Arnold cat map.[6] In general, $T_1 \in \{T_{\alpha}\}_{\alpha\in\mathbb{Z}} \subset \mathrm{SL}_2(\mathbb{Z}) \subset \mathrm{GL}_2(\mathbb{Z}) \subset \mathrm{M}_2(\mathbb{Z})$ where $\mathrm{M}_2(\mathbb{Z})$ is the subset of 2×2 matrices with integer entries, $\mathrm{GL}_2(\mathbb{Z})$ the subset of invertible matrices and $\mathrm{SL}_2(\mathbb{Z})$ the subset of matrices with determinant one: the dynamics generated by $T_{\alpha} \in \mathrm{SL}_2(\mathbb{Z})$ is called *Unimodular Group*[6] (UMG for short);

vi. after identifying $\mathbf{x}$ with canonical coordinates (q,p) and imposing the (mod 1) condition on both of them, the previous dynamics reads

$$\begin{aligned} q' &= q + p' \\ p' &= p + \alpha\langle q \rangle \end{aligned} \ (\mathrm{mod}\ 1). \tag{8}$$

This is nothing but the Chirikov standard map[3] in which $-(1/2\pi)\sin(2\pi q)$ is replaced by $\langle q\rangle$. The dynamics in (8) can also be thought of as generated by the (singular) Hamiltonian

$$H(q,p,t) = \frac{p^2}{2} - \alpha\frac{\langle q\rangle^2}{2}\delta_p(t),$$

where $\delta_p(t)$ is the periodic Dirac delta which makes the potential act through periodic kicks with period 1;[26]

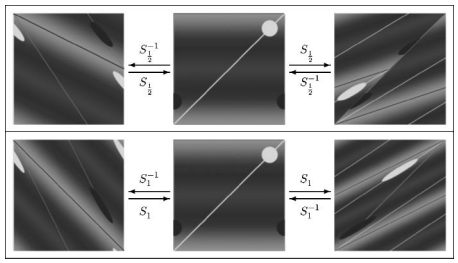

FIG. 2. In the upper row, we depict the effects of the discontinuities of a SM with $\alpha=\frac{1}{2}$; the picture in the middle shows the discontinuity lines γ_0 and γ_{-1}, whereas those on the right and left show how they evolve backward and forward in time. The different parallel bands help the reader to figure out the toral periodicity and the discontinuous character of the map, also highlighted by the aperiodic splits of two spots. Further, for sake of comparison, the lower row presents the same case of the upper one but for the continuous dynamics ($\alpha=1$).

vii. Sawtooth maps are invertible and the inverse is given by the expression

$$S_\alpha^{-1}\begin{pmatrix}x_1\\x_2\end{pmatrix}=\begin{pmatrix}1 & 0\\ -\alpha & 1\end{pmatrix}\left\langle\begin{pmatrix}1 & -1\\0 & 1\end{pmatrix}\begin{pmatrix}x_1\\x_2\end{pmatrix}\right\rangle \ (\mathrm{mod}\ 1)=\begin{pmatrix}\langle x_1-x_2\rangle\\ \langle\langle x_2\rangle-\alpha\langle x_1-x_2\rangle\rangle\end{pmatrix} \tag{9}$$

or, in other words,

$$\begin{aligned} q&=q'-p'\\ p&=-\alpha q+p' \end{aligned} \ (\mathrm{mod}\ 1).$$

It can indeed be checked that $S_\alpha(S_\alpha^{-1}(\mathbf{x}))=S_\alpha^{-1}(S_\alpha(\mathbf{x}))=\mathbf{x}$, $\forall\mathbf{x}\in\mathbb{T}^2$.

Further, S_α^{-1} preserves the Lebesgue measure on $\mathbb{T}^2$.

We now list a set of properties[16–18] of sawtooth maps that will be used in the following.

Properties 4.1 (of sawtooth maps)

(1) Sawtooth maps $\{S_\alpha\}$ are *discontinuous* on the subset $\gamma_0:=\{\mathbf{x}=(0,p),p\in\mathbb{T}\}\in\mathbb{T}^2$: two points close to γ_0, $A:=(\varepsilon,p)$ and $B:=(1-\varepsilon,p)$, have images that differ, in the $\varepsilon\to 0$ limit, by a vector $d^{(1)}_{S_\alpha}(A,B)=(\alpha,\alpha)$ (mod 1).

(2) Inverse sawtooth maps $\{S_\alpha^{-1}\}$ are *discontinuous* on the subset $\gamma_{-1}:=S_\alpha(\gamma_0)=\{\mathbf{x}=(p,p),p\in\mathbb{T}\}\in\mathbb{T}^2$: two points close to γ_{-1}, namely $A:=(p+\varepsilon,p-\varepsilon)$ and $B:=(p-\varepsilon,p+\varepsilon)$, have images that differ, in the $\varepsilon\to 0$ limit, by a vector $d^{(1)}_{S_\alpha^{-1}}(A,B)=(0,\alpha)$ (mod 1).

(3) The maps T_α and T_α^{-1} are *continuous*: $\alpha\in\mathbb{Z}\Rightarrow d^{(1)}_{T_\alpha}(A,B)=d^{(1)}_{T_\alpha^{-1}}(A,B)=(0,0)$ (mod 1).

(4) The eigenvalues of the matrix $S_\alpha=\left(\begin{smallmatrix}1+\alpha & 1\\ \alpha & 1\end{smallmatrix}\right)$ are $(\alpha+2\pm\sqrt{(\alpha+2)^2-4})/2$. They are conjugate complex numbers if $\alpha\in[-4,0]$, whereas one eigenvalue $\lambda>1$ if $\alpha\notin[-4,0]$. In this case, distances are stretched along the direction of the eigenvector $|\mathbf{e}_+\rangle$, $S_\alpha|\mathbf{e}_+\rangle=\lambda|\mathbf{e}_+\rangle$, contracted along that of $|\mathbf{e}_-\rangle$, $S_\alpha|\mathbf{e}_-\rangle=\lambda^{-1}|\mathbf{e}_-\rangle$: $\log\lambda$ is a (positive) *Lyapunov exponent*.

For such α's all periodic points are hyperbolic (see Fig. 2).[18]

Remarks 4.2: Because of the presence of the fractional part in (7) and (9), we have to distinguish the action of S_α and S_α^{-1} from a mere matrix action. We shall adopt the following notations.

i. With S_α the matrix $\left(\begin{smallmatrix}1+\alpha & 1\\ \alpha & 1\end{smallmatrix}\right)$ in Property 3.1.4, the expression $S_\alpha(\mathbf{x})$ will denote the action represented by (7), whereas $S_\alpha\cdot\mathbf{x}$ will denote the matrix action of S_α on the vector $\mathbf{x}$.

ii. When the dynamics arises from the action of the UMG (see Remark 4.1.v.), so, in particular, when $\{T_\alpha\}_{\alpha\in\mathbb{Z}}$ is the family of toral automorphisms, Eq. (7) assumes the simpler form $T_\alpha(\mathbf{x})=T_\alpha\cdot\mathbf{x}$ (mod 1).

iii. Analogously, expressions like $T_\alpha\cdot\mathbf{x}$, $T_\alpha^{\mathrm{tr}}\cdot\mathbf{x}$, $T_\alpha^{-1}\cdot\mathbf{x}$, and $(T_\alpha^{\mathrm{tr}})^{-1}\cdot\mathbf{x}$, will denote the actions by T_α itself, its transposed, its inverse, and the inverse of the transposed, respectively.

B. Algebraic description of continuous and discretized sawtooth maps

In this section we make use of the commutative (Von Neumann) algebra $L^\infty_\mu(\mathbb{T}^2)$ introduced in Sec. II and consider the algebraic description of sawtooth maps by triples $(L^\infty_\mu(\mathbb{T}^2), \omega_\mu, \Theta_\alpha)$, where ω_μ has been defined in (1) and $\Theta_\alpha: L^\infty_\mu(\mathbb{T}^2) \mapsto L^\infty_\mu(\mathbb{T}^2)$ is the discrete-time dynamics generated as follows:

$$\Theta_\alpha(f)(\mathbf{x}) := f(S_\alpha(\mathbf{x})), \quad \alpha \in \mathbb{R}.$$

The maps Θ^j_α, $j \in \mathbb{Z}$ are automorphisms of $L^\infty_\mu(\mathbb{T}^2)$ and leave the state ω_μ invariant.

Our aim is now to define a suitable discrete evolution $\Theta_{\mathcal{N},\alpha}$ on $\mathcal{D}_\mathcal{N}$, such that the discretized triplets $(\mathcal{D}_\mathcal{N}, \tau_\mathcal{N}, \Theta_{\mathcal{N},\alpha})$ converge to the continuous SM.

We start by introducing two different kinds of maps: the first ones, $U^{\pm j}_\alpha$, $j \in \mathbb{Z}$, are defined on the torus $\mathbb{T}^2([0,N)^2)$, namely $[0,N)\times[0,N)$ (mod N), and given by

$$\mathbb{T}^2([0,N)^2) \ni \mathbf{x} \mapsto U^0_\alpha(\mathbf{x}) := \mathbf{x} = NS^0_\alpha\left(\frac{\mathbf{x}}{N}\right) \in \mathbb{T}^2([0,N)^2), \tag{10a}$$

$$\mathbb{T}^2([0,N)^2) \ni \mathbf{x} \mapsto U^{\pm 1}_\alpha(\mathbf{x}) := NS^{\pm 1}_\alpha\left(\frac{\mathbf{x}}{N}\right) \in \mathbb{T}^2([0,N)^2), \tag{10b}$$

$$\mathbb{T}^2([0,N)^2) \ni \mathbf{x} \mapsto U^{\pm j}_\alpha(\mathbf{x}) := \underbrace{U^{\pm 1}_\alpha(U^{\pm 1}_\alpha(\cdots U^{\pm 1}_\alpha(U^{\pm 1}_\alpha}_{j \text{ times}}(\mathbf{x}))\cdots)), \quad j \in \mathbb{N}^+,$$

$$= NS^{\pm j}_\alpha\left(\frac{\mathbf{x}}{N}\right) \in \mathbb{T}^2([0,N)^2). \tag{10c}$$

The second class consists of maps $V^{\pm j}_\alpha$ from $\mathbb{T}^2([0,N)^2)$ onto its subset $(\mathbb{Z}/N\mathbb{Z})^2$, whose actions are as follows:

$$\mathbb{T}^2([0,N)^2) \ni \mathbf{x} \mapsto V^0_\alpha(\mathbf{x}) := \lfloor \mathbf{x} \rfloor = \pm\lfloor \pm U^0_\alpha(\lfloor \mathbf{x} \rfloor)\rfloor \in (\mathbb{Z}/N\mathbb{Z})^2, \tag{11a}$$

$$\mathbb{T}^2([0,N)^2) \ni \mathbf{x} \mapsto V^{\pm 1}_\alpha(\mathbf{x}) := \pm\lfloor \pm U^{\pm 1}_\alpha(\lfloor \mathbf{x} \rfloor)\rfloor \in (\mathbb{Z}/N\mathbb{Z})^2, \tag{11b}$$

$$\mathbb{T}^2([0,N)^2) \ni \mathbf{x} \mapsto V^{\pm j}_\alpha(\mathbf{x}) := \underbrace{V^{\pm 1}_\alpha(V^{\pm 1}_\alpha\ (\cdots V^{\pm 1}_\alpha\ (V^{\pm 1}_\alpha}_{j \text{ times}}\ (\lfloor \mathbf{x} \rfloor))\cdots)), \quad j \in \mathbb{N}^+,$$

$$= \underbrace{\pm\lfloor \pm U^{\pm 1}_\alpha\ (\pm\lfloor \pm U^{\pm 1}_\alpha(\cdots \pm\ \lfloor \pm U^{\pm 1}_\alpha\ (\pm\lfloor \pm U^{\pm 1}_\alpha}_{j \text{ times}}(\lfloor \mathbf{x} \rfloor)\rfloor)\rfloor\cdots)\rfloor)\rfloor \in (\mathbb{Z}/N\mathbb{Z})^2. \tag{11c}$$

Remark 4.3: The maps U^j_α are extensions of the S^j_α on the enlarged torus $\mathbb{T}^2([0,N)^2)$; however, they do not map the lattice L_N into itself, therefore we are forced to use the maps V^j_α to define a consistent discretized dynamics.

Definition 4.1: $\Theta_{\mathcal{N},\alpha}$ will denote the map:

$$\mathcal{D}_\mathcal{N} \ni X \mapsto \Theta_{\mathcal{N},\alpha}(X) := \sum_{\ell \in (\mathbb{Z}/N\mathbb{Z})^2} X_{V_\alpha(\ell),V_\alpha(\ell)} |\ell\rangle\langle\ell| \in \mathcal{D}_\mathcal{N}. \tag{12}$$

$\Theta_{\mathcal{N},\alpha}$ is a $*$-automorphism of $\mathcal{D}_\mathcal{N}$; indeed, the map

$$(\mathbb{Z}/N\mathbb{Z})^2 \ni \ell \mapsto V_\alpha(\ell) \in (\mathbb{Z}/N\mathbb{Z})^2$$

is a bijection, so that (12) can be rewritten in the more convenient form

$$\Theta_{\mathcal{N},\alpha}(X) = \sum_{\ell \in (\mathbb{Z}/N\mathbb{Z})^2} X_{V_\alpha(\ell),V_\alpha(\ell)} |\ell\rangle\langle\ell| = \sum_{V^{-1}_\alpha(\mathbf{s}) \in (\mathbb{Z}/N\mathbb{Z})^2} X_{\mathbf{s},\mathbf{s}} |V^{-1}_\alpha(\mathbf{s})\rangle\langle V^{-1}_\alpha(\mathbf{s})|$$

$$(\text{see Remark 4 . 4iii . }) = W_{\alpha N}\left(\sum_{\substack{\text{all equiv.}\\ \text{classes}}} X_{\mathbf{s},\mathbf{s}}|\mathbf{s}\rangle\langle\mathbf{s}|\right)W^*_{\alpha,N} = W_{\alpha,N}XW^*_{\alpha,N}, \tag{13}$$

where the operators $W_{\alpha,N}$, defined by linearly extending the maps

$$\mathcal{H}_{\mathcal{N}} \ni |\ell\rangle \mapsto W_{\alpha,N}|\ell\rangle := |V_\alpha^{-1}(\ell)\rangle \in \mathcal{H}_{\mathcal{N}}, \tag{14}$$

to $\mathcal{H}_{\mathcal{N}}$, are unitary: $W^*_{\alpha,N}|\ell\rangle := |V_\alpha(\ell)\rangle$.

For the same reason the state $\tau_{\mathcal{N}}$ is $\Theta_{\mathcal{N},\alpha}$-invariant and V_α is invertible too. Note that $\Theta^j_{\mathcal{N},\alpha} := \underbrace{\Theta_{\mathcal{N},\alpha}\circ\cdots\circ\Theta_{\mathcal{N},\alpha}}_{j \text{ times}}$ is implemented by $V^j_\alpha(\ell)$ given in (11c).

Remarks 4.4:

i. The double $\pm$ sign in front and within every floor function in equations (11) is needed in order to have $V^{\pm j}_\alpha(V^{\mp j}_\alpha(\mathbf{x})) = V^0_\alpha(\mathbf{x})$ (the identity when $\mathbf{x} \in (\mathbb{Z}/N\mathbb{Z})^2$); the reason is that, in general, $\lfloor -x\rfloor \neq -\lfloor x\rfloor$, for $x \notin \mathbb{Z}$ (see Ref. 27).

ii. When $\alpha \in \mathbb{Z}$, $(\mathbb{Z}/N\mathbb{Z})^2 \ni \ell \mapsto V_\alpha(\ell) = T_\alpha \cdot \ell \in (\mathbb{Z}/N\mathbb{Z})^2$, namely the action of the map V_α becomes that of a matrix (mod N). Moreover, in that case, U_α and V_α coincide.

iii. Since $\ell \mapsto V_\alpha(\ell)$ is a bijection, in (13) one can sum over the equivalence classes.

V. CONTINUOUS LIMIT OF THE DYNAMICS

One of the main issues in the semiclassical analysis is to compare if and how the quantum and classical time evolutions mimic each other when a suitable quantization parameter goes to zero.

In this article we are instead considering the possible agreement between the dynamics of continuous classical systems and that of a class of discrete approximants. In practice, in our case, we will study the difference

$$\Theta^j_\alpha - \mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty} \tag{15}$$

which represents how much the discrete dynamics at timestep j differs from the continuous one at the same timestep.

For quantum systems, whose classical limit is chaotic, the situation is strikingly different from those with regular classical limit. In the former case, classical and quantum mechanics agree, that is a difference as in (15) is negligible, only over times j which scale logarithmically (and not as a power law) in the quantization parameter.

As we shall see, such a type of scaling is not exclusively related with noncommutativity; in fact, the quantization-like procedure developed so far, exhibits a similar behavior when $N \to \infty$ and we recover $(L^\infty_\mu(\mathbb{T}^2), \omega_\mu, \Theta_\alpha)$ as a continuous limit of $(\mathcal{D}_{\mathcal{N}}, \tau_{\mathcal{N}}, \Theta_{\mathcal{N},\alpha})$.

A. Continuous limit for sawtooth maps

Later on we shall show that the difference in (15) goes to zero in a suitable topology; for the moment we just note that the major difficulties in the proof are due to the discontinuous character of the fractional part that appears in (7).

It is therefore important to briefly discuss the discontinuities of the maps S_α.[16–18]

As already noted in Property 4.1.1, S_α is discontinuous on the circle γ_0; therefore S^n_α will be discontinuous on the preimages

$$\gamma_m := S^{-m}_\alpha(\gamma_0) \quad \text{for } 0 \leqslant m < n, \tag{16a}$$

whereas the discontinuities of S^{-n}_α lie on the sets

$$\gamma_{-m} := S^m_\alpha(\gamma_0) \quad \text{for } 0 < m \leqslant n. \tag{16b}$$

Apart from γ_{-1}, whose projection on the $[0,1)^2$ square is its diagonal (see Fig. 5), each set of the type γ_m (for γ_{-m} the argument is similar) is the (disjoint) union of segments parallel to each other

whose endpoints lie either on the same segment belonging to γ_p, $p<m$, or on two different segments belonging to γ_p and $\gamma_{p'}$, with $p' \leqslant p < m$.[17] It proves convenient to introduce the *discontinuity set* of S^n_α,

$$\mathbb{T}^2 \supset \Gamma_n := \bigcup_{p=0}^{n-1} \gamma_p, \tag{17}$$

and its complementary set, $G_n := \mathbb{T}^2 \backslash \Gamma_n$.

We now enlarge the previous definition from continuous sawtooth maps, to discretized ones.

Definitions 5.1: We shall call, "segment," denoted by (A,B), the shortest curve joining $A,B \in \mathbb{T}^2$, by $l(\gamma_p)$ the length of the curve γ_p and by

$$\overline{\gamma_p}(\varepsilon) := \{\mathbf{x} \in \mathbb{T}^2 | d_{\mathbb{T}^2}(\mathbf{x}, \gamma_p) \leqslant \varepsilon\} \tag{18}$$

the strip around γ_p of width ε, where the distance $d_{\mathbb{T}^2}(\cdot,\cdot)$ on the torus has been introduced in Definition 3.1.

Further, we shall denote by

$$\overline{\Gamma_n}(\varepsilon) := \bigcup_{p=0}^{n-1} \overline{\gamma_p}(\varepsilon) \tag{19}$$

the union of the strips up to $p=n-1$ and by $G^N_n(\varepsilon)$ the subset of points

$$G^N_n(\varepsilon) := \left\{ \mathbf{x} \in \mathbb{T}^2 \,\middle|\, \frac{\hat{\mathbf{x}}_N}{N} \notin \overline{\Gamma}_n(\varepsilon) \right\}, \tag{20}$$

where the lattice points $\hat{\mathbf{x}}_N$ have been introduced in Definition 3.2.

As already observed, in order to prove that the discretized SM tend to continuous SM when $N \to \infty$, the main problem is to control the discontinuities. It proves convenient to subdivide the lattice points into a *good* and *bad* set and show that, on the former, $V^q_\alpha \simeq U^q_\alpha$, at least on a certain time scale (see Remark 4.3). This will not turn out to be true for the bad set, however we shall show that the latter tends with N to a set of zero Lebesgue measure and thus becomes ineffective.

Following this strategy, we shall concretely show that the difference (15) goes to zero with $N \to \infty$ in the strong topology over the Hilbert space $L^2_\mu(\mathbb{T}^2)$. More precisely, we have the following theorem.

Theorem 1:

Let $(\mathcal{D}_\mathcal{N}, \tau_\mathcal{N}, \Theta_{\mathcal{N},\alpha})$ be a sequence of discretized SM as defined in Sect. IV: for all $\gamma > 3$,

$$\forall f \in L^\infty_\mu(\mathbb{T}^2), \qquad \underset{\substack{j,N \to \infty \\ j < 1/\gamma(\log N/\log \eta)}}{\text{s-lim}} (\Theta^j_\alpha - \mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty})(f) = 0, \tag{21}$$

where the limit is in the strong topology over the Hilbert space $L^2_\mu(\mathbb{T}^2)$ and $\eta > \sqrt{2}$ is the largest eigenvalue of the matrix $|S_\alpha| := \sqrt{S^\dagger_\alpha S_\alpha}$, with S_α defined in Property 4.1.4.

The previous theorem indicates that the time limit and the continuous limit do not commute. In particular, the difference between the discretized dynamics and the continuous one can be made small by increasing N, while it becomes large beyond the time scale $j \simeq (1/\gamma)(\log N/\log \eta)$. This phenomenon is the same as in quantum chaos and points to discretization of phase space (in the traditional semi-classical treatment of quantum systems), rather than to noncommutativity, as the source of the so-called *logarithmic breaking time*. The constant γ is a *form factor*, which reflects the fine structure of the dynamics: for instance, in the case of quantum cat maps,[25] $\gamma = 2$.

Remark 5.1: The parameter $\gamma > 3$ in Theorem 1 may seem overestimated if compared with the case of the quantum cat map, where $\gamma = 2$. As we shall see (in particular in the next Proposition), the upper bound for γ is dictated by the discontinuities of the sawtooth maps, and not by commutativity. The corresponding exponent assumes the lower value $\gamma > 1$ in the case of discretized cat maps, that include sawtooth maps with integer α. This result will be presented in a forthcoming

paper,[28] in which we study the breaking time $\tau_B(N)$, here $(1/\gamma)(\log N/\log \eta)$, relative to the chaotic or nonchaotic properties of the dynamics. In particular, in the hyperbolic regime, the parameter $\log \eta$ of Theorem 1 is replaced by the Lyapunov exponent $\log \lambda$ whereas, in the elliptic regime, the two limits $j, N \to \infty$ do commute and in the parabolic one, the breaking time is given by $\tau_B(N) = N^{1/\gamma}$.

The proof of Theorem 1 consists of several steps, among which the most important is a property, satisfied by our choice of lattice states, which we shall call *dynamical localization.*

We give a full proof that our choice of lattice states satisfies such property, since it represents a natural request that should be fulfilled by any consistent discretization/de-discretization (quantization/de-quantization) scheme.

Remarks 5.2:

(1) In analogy to the quantum case, dynamical localization is what one expects from a good choice of states suited to the study of the continuous limit: in fact, it essentially amounts to asking that LS remain decently localized around the continuous trajectories while evolving with the corresponding discrete evolution. As we shall see this is the case only on logarithmic time scales. Informally, when $N \to \infty$, the quantities

$$K_j(\mathbf{x}, \mathbf{y}) := \langle C_{\mathcal{N}}(\mathbf{x}), W^j_{\alpha,N} C_{\mathcal{N}}(\mathbf{y}) \rangle$$

should behave as if $\mathcal{N}|K_j(\mathbf{x}, \mathbf{y})|^2 \simeq \delta(S^j_\alpha \mathbf{x} - \mathbf{y})$: this would make the discretization analogous to the notion of *regular quantization* described in Sec. V of Ref. 29. Actually, with our choice of LS, the quantity $K_j(\mathbf{x}, \mathbf{y})$ is a Kronecker delta.

(2) In quantum chaos, instead of seeking for the dynamical localization, one can study the *dynamical spreading* of coherent states. Consider for instance the classical function f over the phase space, its corresponding quantum observable $\mathrm{Op}_\hbar(f)$ and a coherent state $|C_\hbar(\mathbf{x})\rangle$ centered at the point $\mathbf{x}$. The time needed for the quantum mechanical expectation $\langle C_\hbar(\mathbf{x}), \mathrm{Op}_\hbar(f) C_\hbar(\mathbf{x}) \rangle$ to converge to the average of f over a suitable invariant measure can be explicitly analyzed. Recent work [7,9] shows also that this time scales logarithmically in $\hbar$, at least for the automorphisms on the 2-torus.

(3) The constraint $j \leqslant C \log \mathcal{N}$ is typical of *hyperbolic* behavior with Lyapunov exponent $\log \lambda$ and comes heuristically as follows: the expansion of an initial small distance δ can be exponential until the distance becomes the largest possible, namely $\delta \lambda^{T_B} \simeq 1$. After discretization, the minimal distance gives $\delta = 1/N$, therefore one estimates $T_B \simeq \log N / \log \lambda$, which is called *breaking time* and sets the time scale over which continuous and discretized dynamics mimic each other.

(4) In quantum chaos, the semiclassical analysis leads to an estimate of T_B exactly as above; further, the logarithmic dependence on $\hbar$ of T_B is a signature of the hyperbolic character of the classical limit. Conversely, if the classical limit is regular, then the time scale when quantum and classical behaviors are more or less indistinguishable goes as $\hbar^{-b}, b > 0$. Another interpretation of the breaking time is given in Ref. 8, where it is related to the shortest time needed for the system to transfer all scales $1 \geqslant \ell \geqslant \hbar$ down to the "quantum scale" $\hbar$. Indeed, this is the scale at which the differences among quantum and classical mechanics come up. Regarding the SM, the hyperbolic case corresponds to S_α with eigenvalue $\lambda > 1$, whereas the regular cases are the *elliptic* one (two complex eigenvalues) and the *parabolic* one (only one eigenvalue $= 1$).

(5) The dynamical localization property has fruitfully been used in several quantum contexts;[25] however, to our knowledge, this is the first instance, though not properly quantal, where dynamical localization is fully exposed.

Before proceeding with the proof of Theorem 1, it is important to notice that in its statement the Lyapunov exponent $\log \lambda$ does not appear but $\log \eta$, instead; of course λ and η are related for λ is eigenvalue of S_α, and η of $\sqrt{S^\dagger_\alpha S_\alpha}$ (see Remark 5.1).

As will become clear during the proof, the use of η and not of λ is required by the discontinuous character of SM. In fact, the discontinuities do not allow us to control the difference between the nth iterates of the discretized and the continuous dynamics, but instead force us to estimate that difference at each single time step up to n and to put all the estimates together. In the single time-step estimate, independently of whether the map is continuous or not, one must use η,

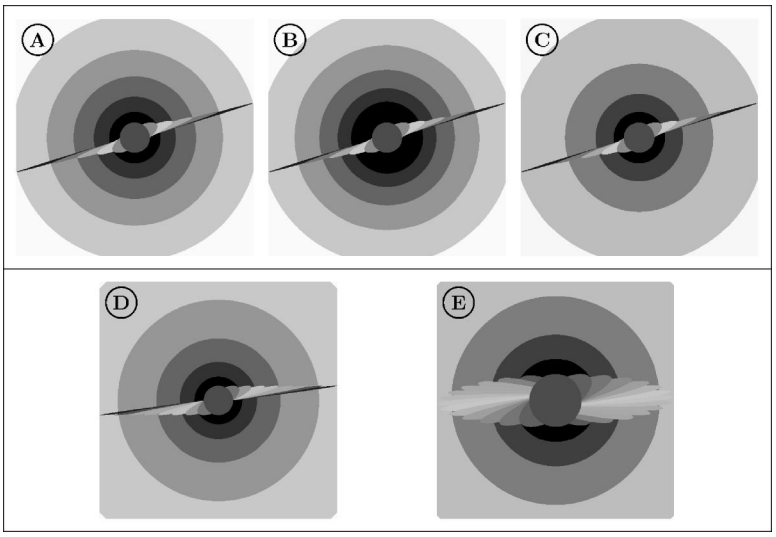

FIG. 3. In plots A, B, and C we compare the estimates of the (maximum) stretching given by the action of the SM $S_{1/10}$ and its temporal iterates $S^n_{1/10}$ ($n \leqslant 5$) given by λ, respectively η, on a small ball $B^0_{\mathbf{v}}$ of radius $\mathbf{v}$, centered in $(\frac{1}{2},\frac{1}{2}) \in \mathbb{T}^2$. The five evolved images of the ball, namely $\{B^n_{\mathbf{v}}, 1<n\leqslant 5\}$, are plotted together with $B^0_{\mathbf{v}}$, using different colors. In A we surround every evolved ball $B^n_{\mathbf{v}}$ with the smallest circle containing it. We compare that plot with B and C, in which the surrounding circles have radii proportional to $\lambda^n\mathbf{v}$, respectively, $\eta^n\mathbf{v}$; in both cases the correct radii of A are overestimated although, on the long run, circles in B provide a good approximation. The fake hyperbolicity given by η is clearly shown in D and E, where a parabolic SM S_0 and an elliptic one $S_{-1/20}$ are presented: in the first case the maximum spreading grows linearly, whereas in the second one it remains confined, and the estimate given by the surrounding circles of radii growing as powers of η is inappropriate. Note that in all examples C–E, the black circles of radii $\eta\mathbf{v}$ rightly surround $B^1_{\mathbf{v}}$.

which coincides with λ only when the dynamical matrix S_α is symmetric. Indeed, Fig. 3 shows that the eigenvalue η correctly describes how volumes behave under a single application of the dynamics, whereas λ underestimates it. On the contrary, it is λ^n which asymptotically controls the stretching, whereas η^n largely overestimates it. In the regular elliptic case, where $\lambda=0$ and $\eta \geqslant \sqrt{2}$, the use of η gives the impression of hyperbolic stretching, whereas the elliptic motion is confined: from the lower strip in Fig. 3 it is apparent that such hyperbolicity is spurious.

Theorem 2 (Dynamical localization with $\{|\mathbf{C}_{\mathcal{N}}(\mathbf{x})\rangle\}$ states):

For $\alpha \in \mathbb{R}$, $\beta \in \mathbb{R}^+\setminus(0,2]$ and $d_0>0$, there exists $N_0=N_0(\alpha,\beta,d_0) \in \mathbb{N}^+$ with the following property: if $N>N_0$ and $n<(1/\beta)(\log N/\log \eta)$, then

$$d_{\mathbb{T}^2}(S^n_\alpha(\mathbf{x}),\mathbf{y}) \geqslant d_0 \Rightarrow \langle C_{\mathcal{N}}(\mathbf{x}) \; | W^n_{\alpha,N} C_{\mathcal{N}}(\mathbf{y})\rangle = 0,$$

for all $\mathbf{y} \in \mathbb{T}^2$ and $\mathbf{x} \in G^N_n(\tilde{N}/2N)$, where $W^n_{\alpha,N}$ is the unitary operator defined in (14), *$\tilde{N} = 2\sqrt{2}(\sqrt{2}+1)\eta^{2n}$ and $G^N_n(\varepsilon)$ has been introduced in Definitions 5.1.*

In order to prove Theorem 2, we need the following result, whose proof can be found in Appendix B.

Proposition 5.1: With the notation of Definitions 3.1 and 5.1, and with $[E]^\circ$ denoting the complement of $E \subseteq \mathbb{T}^2$, $[E]^\circ := \mathbb{T}^2\setminus E$, the following inclusions hold:

$$\left[\overline{\Gamma}_n\left(\varepsilon + \frac{1}{\sqrt{2}N}\right)\right]^\circ \subseteq G^N_n(\varepsilon) \subseteq \left[\overline{\Gamma}_n\left(\varepsilon - \frac{1}{\sqrt{2}N}\right)\right]^\circ. \tag{22}$$

Further, for $\alpha \in \mathbb{R}$ and $n \in \mathbb{N}^+$, if

$$N > \tilde{N} = 2\sqrt{2}(\sqrt{2}+1)\eta^{2n}$$

and

$$\mathbf{x} \in G_n^N\left(\frac{\tilde{N}}{2N}\right)$$

then

$$d_{\mathbb{T}^2}\left(\frac{U_\alpha^p(N\mathbf{x})}{N}, \frac{V_\alpha^p(\hat{\mathbf{x}}_N)}{N}\right) \leqslant \frac{\sqrt{2}}{N}\left(\frac{\eta^{p+1}-1}{\eta-1}\right), \quad \forall\, p \leqslant n. \tag{23}$$

Proof of Theorem 2: Using the definition of $\{|C_{\mathcal{N}}(\mathbf{x})\rangle\}$ in (6), we easily compute

$$\langle C_{\mathcal{N}}(\mathbf{x}) \,|W_{\alpha,N}^n C_{\mathcal{N}}(\mathbf{y})\rangle = \langle \hat{\mathbf{x}}_N \,|V_\alpha^{-n}(\hat{\mathbf{y}}_N)\rangle = \delta^{(N)}_{V_\alpha^n(\hat{\mathbf{x}}_N),\hat{\mathbf{y}}_N}. \tag{24}$$

Using the triangular inequality, we get:

$$d_{\mathbb{T}^2}\left(\frac{U_\alpha^n(N\mathbf{x})}{N}, \mathbf{y}\right) \leqslant d_{\mathbb{T}^2}\left(\frac{U_\alpha^n(N\mathbf{x})}{N}, \frac{V_\alpha^n(\hat{\mathbf{x}}_N)}{N}\right) + d_{\mathbb{T}^2}\left(\frac{V_\alpha^n(\hat{\mathbf{x}}_N)}{N}, \frac{\hat{\mathbf{y}}_N}{N}\right) + d_{\mathbb{T}^2}\left(\frac{\hat{\mathbf{y}}_N}{N}, \mathbf{y}\right)$$

or equivalently, using the definitions (10),

$$d_{\mathbb{T}^2}\left(\frac{V_\alpha^n(\hat{\mathbf{x}}_N)}{N}, \frac{\hat{\mathbf{y}}_N}{N}\right) \geqslant d_{\mathbb{T}^2}(S_\alpha^n(\mathbf{x}), \mathbf{y}) - d_{\mathbb{T}^2}\left(\frac{U_\alpha^n(N\mathbf{x})}{N}, \frac{V_\alpha^n(\hat{\mathbf{x}}_N)}{N}\right) - d_{\mathbb{T}^2}\left(\frac{\hat{\mathbf{y}}_N}{N}, \mathbf{y}\right).$$

Now, since $d_{\mathbb{T}^2}(S_\alpha^n(\mathbf{x}), \mathbf{y}) \geqslant d_0$ by hypothesis, using (B1) in Appendix B and observing that $\mathbf{x} \in G_n^N(\tilde{N}/2N)$ permits us to use (23) in Proposition 5.1, namely that

$$N > \tilde{N} \Rightarrow d_{\mathbb{T}^2}\left(\frac{U_\alpha^n(N\mathbf{x})}{N}, \frac{V_\alpha^n(\hat{\mathbf{x}}_N)}{N}\right) \leqslant \frac{\sqrt{2}}{N}\left(\frac{\eta^{n+1}-1}{\eta-1}\right), \tag{25}$$

we can derive

$$d_{\mathbb{T}^2}\left(\frac{V_\alpha^n(\hat{\mathbf{x}}_N)}{N}, \frac{\hat{\mathbf{y}}_N}{N}\right) \geqslant d_0 - \frac{\sqrt{2}}{N}\left(\frac{\eta^{n+1}-1}{\eta-1}\right) - \frac{1}{\sqrt{2}N}.$$

The r.h.s. of the previous inequality can always be made strictly larger than $1/N$,

$$d_{\mathbb{T}^2}\left(\frac{V_\alpha^n(\hat{\mathbf{x}}_N)}{N}, \frac{\hat{\mathbf{y}}_N}{N}\right) > \frac{1}{N}, \tag{26}$$

by choosing an N larger than

$$N_{\mathsf{M}}(n) = \max\left\{\frac{1}{d_0}\left[1 + \sqrt{2}\left(\frac{\eta^{n+1}-1}{\eta-1}\right) + \frac{1}{\sqrt{2}}\right], \quad \tilde{N} = 2\sqrt{2}(\sqrt{2}+1)\,\eta^{2n}\right\}, \tag{27}$$

so that the condition on the l.h.s. of (25) is also satisfied. From (24) and (26), we have

$$N > N_{\mathsf{M}}(n) \Rightarrow \langle C_{\mathcal{N}}(\mathbf{x}) \,|W_{\alpha,N}^n C_{\mathcal{N}}(\mathbf{y})\rangle = 0. \tag{28}$$

Indeed, if the toral distance between two points $(\mathbf{z}, \mathbf{w})$ exceeds $1/N$, then the corresponding grid points $(\hat{\mathbf{z}}_N, \hat{\mathbf{w}}_N)$ are different and then the periodic Kronecker delta in (24) vanishes.

Since the (nondecreasing) function N_{M} in (27) is eventually bounded by $\eta^{\beta n}$ (β being strictly greater than two), we define $\overline{n}$ as the time when $N_{\mathsf{M}}(\overline{n}) = \eta^{\beta\overline{n}} =: N_0$, and choose $N > N_0$, $\mathbf{x} \in G_n^N(\tilde{N}/2N)$. Thus, if $0 < n < \overline{n}$, then $N > N_0 = N_{\mathsf{M}}(\overline{n}) > N_{\mathsf{M}}(n)$, whereas if $\overline{n} \leqslant n < (1/\beta)(\log N/\log \eta)$, then $N > \eta^{\beta n} > N_{\mathsf{M}}(n)$ and (28) holds for all $0 < n < (1/\beta)(\log N/\log \eta)$. ■

In order to proceed with the proof of Theorem 1, we need another auxiliary result which is proved in Appendix C.

Proposition 5.2: With the notation of Definition 5.1, the following relations hold for all $p \in \mathbb{N}$, $n \in \mathbb{N}^+$ and $\varepsilon \in \mathbb{R}^+$:

$$l(\gamma_p) \leqslant \eta^p, \tag{29a}$$

$$\mu(\overline{\gamma}_p(\varepsilon)) \leqslant 2\varepsilon\eta^p + \pi\varepsilon^2, \tag{29b}$$

$$\mu(\overline{\Gamma}_n(\varepsilon)) \leqslant 2(\sqrt{2}+1)\varepsilon\eta^n + \pi n\varepsilon^2. \tag{29c}$$

Moreover, if $N \in \mathbb{N}^+$ and $\widetilde{N} = 2\sqrt{2}(\sqrt{2}+1)\eta^{2n}$ [cfr. Eq. (23) in Proposition 5.1]:

$$N > \widetilde{N} \Rightarrow \mu\left(\left[G_n^N\left(\frac{\widetilde{N}}{2N}\right)\right]^\circ\right) \leqslant \frac{38\eta^{3n}}{N}. \tag{29d}$$

We are finally in position to conclude with

Proof of Theorem 1: We subdivide the proof in two steps: in the first we concentrate on continuous f, that is $f \in \mathcal{C}^0(\mathbb{T}^2)(\subset L^2_\mu(\mathbb{T}^2))$; in the second one we extend the result to essentially bounded function by applying the following corollary of Lusin's theorem:[21,30,31]

Given $f \in L^\infty_\mu(\chi)$, with χ compact, there exists a sequence $\{f_n\}$ of continuous functions on χ such that $|f_n| \leqslant \|f\|_\infty$ and converging to f μ—almost everywhere.

(1) Let $f \in \mathcal{C}^0(\mathbb{T}^2)$ and $\mathrm{Op}_{j,N}(f) := (\Theta^j_\alpha - \mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\alpha})\,(f)$: notice that $\mathrm{Op}_{j,N}(f)$ is a multiplication operator on $L^2_\mu(\mathbb{T}^2)$, but also an $L^\infty_\mu(\mathbb{T}^2)$ (and thus also an $L^2_\mu(\mathbb{T}^2)$) function. According to (21), we must show that

$$\forall g \in L^2_\mu(\mathbb{T}^2), \qquad \lim_{\substack{j,N\to\infty \\ j<\frac{1}{\gamma}\frac{\log N}{\log \eta}}} \|\mathrm{Op}_{j,N}(f)g\|_2 = 0.$$

Using Schwartz's inequality first with g in the class of *simple functions* and then using their density in $L^2_\mu(\mathbb{T}^2)$, we have to show only that

$$\lim_{\substack{j,N\to\infty \\ j<\frac{1}{\gamma}\frac{\log N}{\log \eta}}} \|\mathrm{Op}_{j,N}(f)\|_2 = 0.$$

Explicitly, using (1), we write:

$$\begin{aligned}\|\mathrm{Op}_{j,N}(f)\|_2^2 = \omega_\mu(\mathrm{Op}_{j,N}(f)^*\mathrm{Op}_{j,N}(f)) &= \omega_\mu[(\Theta^j_\alpha f)^*(\Theta^j_\alpha f)] \\ &+ \omega_\mu[(\mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty})(f)^*(\mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty})(f)] \\ &- 2\,\mathrm{Re}\{\omega_\mu[(\Theta^j_\alpha f)^*(\mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty})(f)]\},\end{aligned}$$

which via Proposition 3.2.1, becomes

$$\begin{aligned}\omega_\mu[\Theta^j_\alpha(\overline{f})\Theta^j_\alpha(f)] - 2\,\mathrm{Re}\{\tau_{\mathcal{M}}[\mathcal{J}_{\mathcal{N},\infty}(\Theta^j_\alpha f)^*(\Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty})(f)]\} \\ + \tau_{\mathcal{M}}[(\mathcal{J}_{\mathcal{N},\infty} \circ \mathcal{J}_{\infty,\mathcal{N}} \circ \Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty})(f)^*(\Theta^j_{\mathcal{N},\alpha} \circ \mathcal{J}_{\mathcal{N},\infty}) \\ \times(f)],\end{aligned}$$

that, using Proposition 3.2.3, can be recast as

$$
\begin{aligned}
&(\omega_\mu \circ \Theta_\alpha^j)(\overline{ff}) + \tau_{\mathcal{M}}[(\Theta_{\mathcal{N},\alpha}^j \circ \mathcal{J}_{\mathcal{N},\infty})(f)^*(\Theta_{\mathcal{N},\alpha}^j \circ \mathcal{J}_{\mathcal{N},\infty})(f)] \\
&\quad - 2\,\mathrm{Re}\{\tau_{\mathcal{M}}[(\mathcal{J}_{\mathcal{N},\infty} \circ \Theta_\alpha^j)(f)^*(\Theta_{\mathcal{N},\alpha}^j \circ \mathcal{J}_{\mathcal{N},\infty})(f)]\} \\
&\quad = \omega_\mu(|f|^2) + (\tau_{\mathcal{N}} \circ \Theta_{\mathcal{N},\alpha}^j)[\mathcal{J}_{\mathcal{N},\infty}(f)^* \mathcal{J}_{\mathcal{N},\infty}(f)] - 2\,\mathrm{Re}(I_{j,N}(f)),
\end{aligned}
$$

with

$$
\begin{aligned}
I_{j,N}(f) &:= \tau_{\mathcal{M}}[(\mathcal{J}_{\mathcal{N},\infty} \circ \Theta_\alpha^j)(f)^*(\Theta_{\mathcal{N},\alpha}^j \circ \mathcal{J}_{\mathcal{N},\infty})(f)] \\
&= \mathcal{N} \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{x}) \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) \overline{f(\mathbf{y})} f(S_\alpha^j \mathbf{x}) |\langle C_{\mathcal{N}}(\mathbf{x}), W_{\alpha,N}^j C_{\mathcal{N}}(\mathbf{y})\rangle|^2.
\end{aligned}
$$

Now, Proposition 3.2.2 yields

$$
(\tau_{\mathcal{N}} \circ \Theta_{\mathcal{N},\alpha}^j)[\mathcal{J}_{\mathcal{N},\infty}(f)^* \mathcal{J}_{\mathcal{N},\infty}(f)] = \tau_{\mathcal{M}}[\mathcal{J}_{\mathcal{N},\infty}(f)^* \mathcal{J}_{\mathcal{N},\infty}(f)] \xrightarrow[N\to\infty]{} \omega_\mu(|f|^2),
$$

so that the strategy is to prove also that $I_{j,N}(f)$ goes to $\omega_\mu(|f|^2) = \int_{\mathbb{T}^2} \mu(d\mathbf{x}) |f(\mathbf{x})|^2$ when $j, N \to \infty$ with $j < (1/\gamma)(\log N / \log \eta)$.

Resorting to $G_n^N(\hat{N}/2N)$ in Definition 5.1, and to its complementary set $[G_n^N(\tilde{N}/2N)]^\circ = \mathbb{T}^2 \backslash G_n^N(\tilde{N}/2N)$, we can write

$$
\begin{aligned}
&\left| I_{j,N}(f) - \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) |f(\mathbf{y})|^2 \right| \\
&\quad = \left| \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{x}) \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) \overline{f(\mathbf{y})} (f(S_\alpha^j \mathbf{x}) - f(\mathbf{y})) \mathcal{N} |\langle C_{\mathcal{N}}(\mathbf{x}), W_{\alpha,N}^j C_{\mathcal{N}}(\mathbf{y})\rangle|^2 \right| \\
&\quad \leqslant \left| \int_{[G_n^N(\tilde{N}/2N)]^\circ} \mu(\mathrm{d}\mathbf{x}) \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) \overline{f(\mathbf{y})} (f(S_\alpha^j \mathbf{x}) - f(\mathbf{y})) \mathcal{N} |\langle C_{\mathcal{N}}(\mathbf{x}), W_{\alpha,N}^j C_{\mathcal{N}}(\mathbf{y})\rangle|^2 \right| \\
&\quad + \left| \int_{G_n^N(\tilde{N}/2N)} \mu(\mathrm{d}\mathbf{x}) \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) \overline{f(\mathbf{y})} (f(S_\alpha^j \mathbf{x}) - f(\mathbf{y})) \mathcal{N} |\langle C_{\mathcal{N}}(\mathbf{x}), W_{\alpha,N}^j C_{\mathcal{N}}(\mathbf{y})\rangle|^2 \right|. \qquad (30)
\end{aligned}
$$

For the first integral in the r.h.s. of the previous expression we have

$$
\begin{aligned}
&\left| \int_{[G_n^N(\tilde{N}/2N)]^\circ} \mu(\mathrm{d}\mathbf{x}) \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) \overline{f(\mathbf{y})} (f(S_\alpha^j \mathbf{x}) - f(\mathbf{y})) \mathcal{N} |\langle C_{\mathcal{N}}(\mathbf{x}), W_{\alpha,N}^j C_{\mathcal{N}}(\mathbf{y})\rangle|^2 \right| \\
&\quad \leqslant 2(\|f\|_\infty)^2 \int_{[G_n^N(\tilde{N}/2N)]^\circ} \mu(\mathrm{d}\mathbf{x}) \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) \mathcal{N} |\langle (W_{\alpha,N}^*)^j C_{\mathcal{N}}(\mathbf{x}), C_{\mathcal{N}}(\mathbf{y})\rangle|^2 \\
&\quad \leqslant 2(\|f\|_\infty)^2 \mu\left(\left[G_n^N\left(\frac{\tilde{N}}{2N} \right) \right]^\circ \right) \leqslant \frac{76\eta^{3j}}{N} (\|f\|_\infty)^2
\end{aligned}
$$

where we have used completeness and normalization Properties 3.1 and Eq. (29d) from Proposition 5.2; this term becomes negligible for large $N > \tilde{N}$ iff $j < (1/\gamma)(\log N / \log \eta)$, with $\gamma > 3$.

Now it remains to prove that the second term in (30) is also negligible for large N: selecting a ball $B(S_\alpha^j \mathbf{x}, d_0)$, one derives

$$\left|\int_{G_n^N(\tilde{N}/2N)}\mu(\mathrm{d}\mathbf{x})\int_{\mathbb{T}^2}\mu(\mathrm{d}\mathbf{y})\overline{f(\mathbf{y})}(f(S_\alpha^j\mathbf{x})-f(\mathbf{y}))\mathcal{N}|\langle C_\mathcal{N}(\mathbf{x}),W_{\alpha,N}^jC_\mathcal{N}(\mathbf{y})\rangle|^2\right|$$
$$\leqslant\left|\int_{G_n^N(\tilde{N}/2N)}\mu(\mathrm{d}\mathbf{x})\int_{B(S_\alpha^j\mathbf{x},d_0)}\mu(\mathrm{d}\mathbf{y})\overline{f(\mathbf{y})}(f(S_\alpha^j\mathbf{x})-f(\mathbf{y}))\mathcal{N}|\langle C_\mathcal{N}(\mathbf{x}),W_{\alpha,N}^jC_\mathcal{N}(\mathbf{y})\rangle|^2\right|$$
$$+\left|\int_{G_n^N(\tilde{N}/2N)}\mu(\mathrm{d}\mathbf{x})\int_{\mathbb{T}^2\setminus B(S_\alpha^j\mathbf{x},d_0)}\mu(\mathrm{d}\mathbf{y})\overline{f(\mathbf{y})}(f(S_\alpha^j\mathbf{x})-f(\mathbf{y}))\mathcal{N}|\langle C_\mathcal{N}(\mathbf{x}),W_{\alpha,N}^jC_\mathcal{N}(\mathbf{y})\rangle|^2\right|.$$

Applying the mean value theorem in the first double integral, we get that $\exists\mathbf{c}\in B(S_\alpha^j\mathbf{x},d_0)$ such that

$$\left|\int_{G_n^N(\tilde{N}/2N)}\mu(\mathrm{d}\mathbf{x})\int_{\mathbb{T}^2}\mu(\mathrm{d}\mathbf{y})\overline{f(\mathbf{y})}(f(S_\alpha^j\mathbf{x})-f(\mathbf{y}))\mathcal{N}|\langle C_\mathcal{N}(\mathbf{x}),W_{\alpha,N}^jC_\mathcal{N}(\mathbf{y})\rangle|^2\right|$$
$$\leqslant\int_{G_n^N(\tilde{N}/2N)}\mu(\mathrm{d}\mathbf{x})|\overline{f(\mathbf{c})}(f(S_\alpha^j\mathbf{x})-f(\mathbf{c}))|\int_{B(S_\alpha^j\mathbf{x},d_0)}\mu(\mathrm{d}\mathbf{y})\mathcal{N}|\langle(W_{\alpha,N}^*)^jC_\mathcal{N}(\mathbf{x}),C_\mathcal{N}(\mathbf{y})\rangle|^2$$
$$+2\|f\|_\infty^2\int_{G_n^N(\tilde{N}/2N)}\mu(\mathrm{d}\mathbf{x})\int_{\mathbb{T}^2\setminus B(S_\alpha^j\mathbf{x},d_0)}\mu(\mathrm{d}\mathbf{y})\mathcal{N}|\langle C_\mathcal{N}(\mathbf{x}),W_{\alpha,N}^jC_\mathcal{N}(\mathbf{y})\rangle|^2.$$

Finally, using completeness and normalization (Properties 3.1), we arrive at the upper bound

$$\leqslant\|f\|_\infty\sup_{\substack{\mathbf{z}\in\mathbb{T}^2\\ \mathbf{c}\in B(\mathbf{z},d_0)}}|(f(\mathbf{z})-f(\mathbf{c}))|+2\|f\|_\infty^2\,\mathcal{N}\sup_{\substack{\mathbf{x}\in G_n^N(\tilde{N}/2N)\\ \mathbf{y}\notin B(S_\alpha^j\mathbf{x},d_0)}}|\langle C_\mathcal{N}(\mathbf{x}),W_{\alpha,N}^jC_\mathcal{N}(\mathbf{y})\rangle|^2.$$

By uniform continuity, the first term can be made arbitrarily small, provided we choose d_0 small enough. For the second integral, we use Theorem 2, which provides us with $N_0=N_0(d_0)$ depending on the same d_0, such that the second term vanishes for all $N>N_0$ and for all $j<(1/\gamma)(\log N/\log\eta)$.

(2) In order to extend the result of point (1) to $f\in L_\mu^\infty(\mathbb{T}^2)$, we use the corollary of Lusin's theorem, choose a sequence $\{f_n\}_n$ as in its statement and estimate

$$\lim_{\substack{j,N\to\infty\\ j<(1/\gamma)(\log N/\log\eta)}}\|\mathrm{Op}_{j,N}(f)\|_2\leqslant\lim_{\substack{j,N\to\infty\\ j<(1/\gamma)(\log N/\log\eta)}}\|\mathrm{Op}_{j,N}(f-f_n)\|_2+\lim_{\substack{j,N\to\infty\\ j<(1/\gamma)(\log N/\log\eta)}}\|\mathrm{Op}_{j,N}(f_n)\|_2.$$

Using point (1), the second term in the r.h.s. of the previous equation can be bounded by arbitrarily small ε, indeed $f_n\in\mathcal{C}^0(\mathbb{T}^2)$.

For the first term we proceed as follows: using Definition 4.1 together with Eqs. (A5) and (A6) of Appendix A, we find

$$(\mathcal{J}_{\infty,\mathcal{N}}\circ\Theta_{\mathcal{N},\alpha}^j\circ\mathcal{J}_{\mathcal{N},\infty})(g)(\mathbf{x})=\sum_{\ell\in(\mathbb{Z}/N\mathbb{Z})^2}\Gamma_N(g)\left(\frac{V_\alpha(\ell)}{N}\right)\mathcal{X}_{Q_N(\ell/N)}(\mathbf{x}),\tag{31}$$

where g is any measurable function on $\mathbb{T}^2$. Then, because of how the running average operator (RAO) Γ_N is defined, for all $g\in L_\mu^1(\mathbb{T}^2)$ it follows that

$$\|(\mathcal{J}_{\infty,\mathcal{N}}\circ\Theta_{\mathcal{N},\alpha}^j\circ\mathcal{J}_{\mathcal{N},\infty})(g)\|_1\leqslant\|(\mathcal{J}_{\infty,\mathcal{N}}\circ\Theta_{\mathcal{N},\alpha}^j\circ\mathcal{J}_{\mathcal{N},\infty})(|g|)\|_1=\|g\|_1,$$

where $\|\cdot\|_1$ denotes the $L_\mu^1(\mathbb{T}^2)$-norm, and that

$$\|(\mathcal{J}_{\infty,\mathcal{N}}\circ\Theta^j_{\mathcal{N},\alpha}\circ\mathcal{J}_{\mathcal{N},\infty})(g)\|_\infty=\sup_{\ell\in(\mathbb{Z}/N\mathbb{Z})^2}\left\{\left|\Gamma_N(g)\left(\frac{\ell}{N}\right)\right|\right\}\leqslant\|\Gamma_N(g)\|_0\leqslant\|g\|_\infty.$$

Indeed, the first equality in the last formula comes from the definition of essential norm[21] (which in this case amounts to the greater absolute value assumed by the simple function $\mathcal{J}_{\infty,\mathcal{N}}\circ\Theta^j_{\mathcal{N},\alpha}\circ\mathcal{J}_{\mathcal{N},\infty}$), whereas the first inequality is a consequence of the continuity of Γ_N and the last one from Proposition A.1. Putting last two inequalities together, we obtain

$$\|(\mathcal{J}_{\infty,\mathcal{N}}\circ\Theta^j_{\mathcal{N},\alpha}\circ\mathcal{J}_{\mathcal{N},\infty})(g)\|_2\leqslant\|g\|_\infty\|g\|_1,$$

whence, setting $g=f-f_n$,

$$\begin{aligned}\|\mathrm{Op}_{j,N}(f-f_n)\|_2&=\|\Theta^j_\alpha(f-f_n)-\mathcal{J}_{\infty,\mathcal{N}}\circ\Theta^j_{\mathcal{N},\alpha}\circ\mathcal{J}_{\mathcal{N},\infty}(f-f_n)\|_2\\&\leqslant\|f-f_n\|_2+\|f-f_n\|_\infty\|f-f_n\|_1,\quad\forall\, j,N.\end{aligned}\tag{32}$$

Now convergence follows from Lusin's corollary. ■

VI. CONCLUSIONS

In this article we have considered discrete approximants of sawtooth maps on the torus and we have studied them in an algebraic framework modeled on the so-called anti-Wick quantization. In fact, finite-dimensional discretization and quantization can be seen as similar procedures in that they map an abelian Von Neumann algebra (of essentially bounded functions on phase space) into finite-dimensional matrix subalgebras, the only difference being whether the latter are diagonal (commutative) or not.

In the semiclassical analysis of classically chaotic quantum systems, the correspondence classical/quantum is usually observed only on time scales that are logarithmic in the quantization parameter $\hbar$. The motivation of our study was to show that the same phenomenon arises when a hyperbolic classical system is discretized, namely forced to move on a lattice, and afterwards the lattice spacing is set to zero.

Previous results[14] based on the numerical investigation of the entropy production indicate that it should indeed be so; however, these results were not supported by a solid framework where to analyze the continuous limit of the family of discrete approximants. This is the content of this article.

The major difficulty was represented by the need of controlling the discontinuous character of sawtooth maps, which was made possible by an appropriate choice of lattice states. In fact, similarly to the entropic approach which, despite the dynamics being classical, was based on a quantum dynamical entropy, the discretization/de-discretization procedure we set up is based on quantum tools.

The choice of lattice states was naturally pointed to by the lattice structure of the discrete phase-space and turned out to possess the right localization properties for mastering the discontinuities. The result is the appearance of a logarithmic time scale when the discrete hyperbolic SM tend to their continuous limit; namely, the continuous and discrete dynamics agree up to a *breaking time* which is proportional to the logarithm of the lattice spacing.

The proportionality constant does not involve the Lyapunov exponent, that is the eigenvalue $\lambda>1$ of the dynamical matrix S_α, rather the largest eigenvalue, η, of $\sqrt{S^\dagger_\alpha S_\alpha}$. In the case of elliptic SM, $|\lambda|=1$, $\eta>\sqrt{2}$; however the resulting breaking time is a spurious effect, while when $\lambda>1$, the presence of η in the breaking time seems to be an unavoidable consequence of the discontinuous dynamics.

APPENDIX A: ANTI-WICK DISCRETIZATION OF $L^\infty_\mu(\mathbb{T}^2)$

In this appendix we will apply Definitions 3.3 and discretize $L^\infty_\mu(\mathbb{T}^2)$ by means of the LS set $\{|C_\mathcal{N}(\mathbf{x})\rangle\,|\,\mathbf{x}\in\mathbb{T}^2\}\in\mathcal{H}_\mathcal{N}$ introduced in Sec. III A.

In this framework, the discretizing/de-discretizing operators of Definitions 3.3 read:

$$L^{\infty}_{\mu}(\mathbb{T}^2) \ni f \mapsto N^2 \int_{\mathbb{T}^2} \mu(d\mathbf{x}) f(\mathbf{x}) |\hat{\mathbf{x}}_N\rangle\langle\hat{\mathbf{x}}_N| =: \mathcal{J}_{\mathcal{N},\infty}(f) \in \mathcal{D}_{\mathcal{N}}, \tag{A1}$$

$$D_{\mathcal{N}} \ni \chi \mapsto \langle\hat{\mathbf{x}}_N|X|\hat{\mathbf{x}}_N\rangle =: \mathcal{J}_{\infty,\mathcal{N}}(X)(\mathbf{x}) \in \mathcal{S}(\mathbb{T}^2) \subset L^{\infty}_{\mu}(\mathbb{T}^2), \tag{A2}$$

where $\mathcal{S}(\mathbb{T}^2)$ denotes the set of *simple functions*[21] on the torus. The matrix elements of $\mathcal{J}_{\mathcal{N},\infty}(f)$ are as follows:

$$\begin{aligned} M^{(f)}_{\boldsymbol{\ell},\mathbf{m}} &:= \langle\boldsymbol{\ell}|\mathcal{J}_{\mathcal{N},\infty}(f)|\mathbf{m}\rangle = N^2 \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{x}) f(\mathbf{x}) \langle\boldsymbol{\ell}|\hat{\mathbf{x}}_N\rangle\langle\hat{\mathbf{x}}_N|\mathbf{m}\rangle \\ &= N^2 \int_0^1 \mathrm{d}x_1 \int_0^1 \mathrm{d}x_2 f(\mathbf{x}) \delta^{(N)}_{\ell_1,\hat{x}_{N,1}} \delta^{(N)}_{\ell_2,\hat{x}_{N,2}} \delta^{(N)}_{m_1,\hat{x}_{N,1}} \delta^{(N)}_{m_2,\hat{x}_{N,2}} \\ &= N^2 \delta^{(N)}_{\ell_1,m_1} \delta^{(N)}_{\ell_2,m_2} \int_0^1 \mathrm{d}x_1 \int_0^1 \mathrm{d}x_2 f(\mathbf{x}) \delta^{(N)}_{\ell_1,\lfloor Nx_1+1/2\rfloor} \delta^{(N)}_{\ell_2,\lfloor Nx_2+1/2\rfloor}. \end{aligned}$$

This implies

$$M^{(f)}_{\boldsymbol{\ell},\mathbf{m}} = N^2 \delta^{(N)}_{\boldsymbol{\ell},\mathbf{m}} \int_{\ell_1-1/2N}^{\ell_1+1/2N} \mathrm{d}x_1 \int_{\ell_2-1/2N}^{\ell_2+1/2N} \mathrm{d}x_2 f(\mathbf{x}), \tag{A3}$$

so that varying $f \in L^{\infty}_{\mu}(\mathbb{T}^2)$ yields Ran $(\mathcal{J}_{\mathcal{N},\infty}) = \mathcal{D}_{\mathcal{N}}$. In order to recast (A3) into a nicer expression, we introduce

Definition A.1 (Running Average Operator): Let $Q_N(\mathbf{x})$ denote the square of side $1/N$, oriented parallel to the axis of the torus and centered around $\mathbf{x}$; then, the running average operator $\Gamma_N : L^{\infty}_{\mu}(\chi) \mapsto \mathcal{C}^0(\mathbb{T}^2)$, is defined by

$$L^{\infty}_{\mu}(\mathbb{T}^2) \ni f(\mathbf{x}) \mapsto \Gamma_N(f)(\mathbf{x}) =: N^2 \int_{Q_N(\mathbf{x})} \mu(\mathrm{d}\mathbf{y}) f(\mathbf{y}) \in \mathcal{C}^0(\mathbb{T}^2).$$

Proposition A.1: Given $f \in L^{\infty}_{\mu}(\mathbb{T}^2)$, the function $f^{(Q)}_N := \Gamma_N(f)$ is uniformly continuous on $\mathbb{T}^2$; moreover, the running average operator has norm

$$\|\Gamma_N\|_{\mathcal{B}} := \sup_{f \in L^{\infty}_{\mu}(\mathbb{T}^2)} \frac{\|\Gamma_N(f)\|_0}{\|f\|_{\infty}} = 1. \tag{A4}$$

Proof: Let $\mathbf{x}_0 \in \mathbb{T}^2$, $\mathbf{x} \in Q_N(\mathbf{x}_0)$ and χ_E denote the characteristic function of $E \subset \mathbb{T}^2$. By Definition A.1:

$$\begin{aligned} |f^{(Q)}_N(\mathbf{x}_0) - f^{(Q)}_N(\mathbf{x})| &= N^2 \left| \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) f(\mathbf{y}) (\chi_{Q_N(\mathbf{x}_0)}(\mathbf{y}) - \chi_{Q_N(\mathbf{x})}(\mathbf{y})) \right| \\ &\leqslant N^2 \|f\|_{\infty} \int_{\mathbb{T}^2} \mu(\mathrm{d}\mathbf{y}) |\chi_{Q_N(\mathbf{x}_0)}(\mathbf{y}) - \chi_{Q_N(\mathbf{x})}(\mathbf{y})| \\ &= N^2 \|f\|_{\infty} [\mu(Q_N(\mathbf{x}_0) \cup Q_N(\mathbf{x})) - \mu(Q_N(\mathbf{x}_0) \cap Q_N(\mathbf{x}))]. \end{aligned}$$

According to our hypothesis, $\mathbf{x} \in Q_N(\mathbf{x}_0)$, thus geometrical considerations lead to:

$$\mu(Q_N(\mathbf{x}_0) \cup Q_N(\mathbf{x})) \leqslant \left(\frac{1}{N} + |x_1 - x_{01}|\right)\left(\frac{1}{N} + |x_2 - x_{02}|\right)$$

$$\mu(Q_N(\mathbf{x}_0) \cap Q_N(\mathbf{x})) = \left(\frac{1}{N} - |x_1 - x_{01}|\right)\left(\frac{1}{N} - |x_2 - x_{02}|\right)$$

$$\mu(Q_N(\mathbf{x}_0) \cup Q_N(\mathbf{x})) - \mu(Q_N(\mathbf{x}_0) \cap Q_N(\mathbf{x})) \leqslant \frac{2}{N}(|x_1 - x_{01}| + |x_2 - x_{02}|) \leqslant \frac{2\sqrt{2}}{N}\|\mathbf{x}_0 - \mathbf{x}\|,$$

so that $|f_N^{(Q)}(\mathbf{x}_0) - f_N^{(Q)}(\mathbf{x})| \leqslant 2\sqrt{2}N\|f\|_\infty\|\mathbf{x}_0 - \mathbf{x}\|$, which proves the continuity of $f_N^{(Q)}$, while uniform continuity comes from $\mathbb{T}^2$ being compact.

Concerning the norm in (A4), the upper bound $\|\Gamma_N\|_{\mathcal{B}} \leqslant 1$ is clear and the maximum is reached by choosing f constant. ■

By means of the running average operator (RAO), the discretization operator in (A1) can be conveniently written as

$$\mathcal{J}_{\mathcal{N},\infty}(f) = \sum_{\boldsymbol{\ell} \in (\mathbb{Z}/N\mathbb{Z})^2} f_N^{(Q)}\left(\frac{\boldsymbol{\ell}}{N}\right)|\boldsymbol{\ell}\rangle\langle\boldsymbol{\ell}|. \tag{A5}$$

Analogously, the de-discretization operator in (A2) can be recast as

$$\mathcal{J}_{\infty,\mathcal{N}}(X)(\mathbf{x}) = \sum_{\boldsymbol{\ell} \in (\mathbb{Z}/N\mathbb{Z})^2} X_{\boldsymbol{\ell},\boldsymbol{\ell}}\delta^{(N)}_{\boldsymbol{\ell},\hat{\mathbf{x}}_N} = \sum_{\boldsymbol{\ell} \in (\mathbb{Z}/N\mathbb{Z})^2} X_{\boldsymbol{\ell},\boldsymbol{\ell}}\chi_{Q_N(\boldsymbol{\ell}/N)}(\mathbf{x}), \tag{A6}$$

thus proving that Ran $(\mathcal{J}_{\infty,\mathcal{N}}) = \mathcal{S}(\mathbb{T}^2)$.

Moreover, combining equations (A5) and (A6), we explicitly get the simple function arising from $f \in L^\infty_\mu(\mathbb{T}^2)$, via AW discretization/de-discretization:

$$(\mathcal{J}_{\infty,\mathcal{N}} \circ \mathcal{J}_{\mathcal{N},\infty})(f)(\mathbf{x}) = \sum_{\boldsymbol{\ell} \in (\mathbb{Z}/N\mathbb{Z})^2} \Gamma_N(f)\left(\frac{\boldsymbol{\ell}}{N}\right)\chi_{Q_N(\boldsymbol{\ell}/N)}(\mathbf{x}). \tag{A7}$$

The action of the operator $\mathcal{J}_{\infty,\mathcal{N}} \circ \mathcal{J}_{\mathcal{N},\infty}$ can be seen in Figs. 4 and 5.

APPENDIX B: PROOF OF PROPOSITION 4.1

We start by proving the inclusions (22).

For every real number t, we have $0 \leqslant \langle Nt + 1/2\rangle = Nt + 1/2 - \lfloor Nt + 1/2\rfloor < 1$, so that

$$\left| t - \frac{\left\lfloor Nt + \frac{1}{2}\right\rfloor}{N}\right| \leqslant \frac{1}{2N}, \quad \forall\, t \in \mathbb{R}.$$

From (5) in Definition 3.2, we derive

$$d_{\mathbb{T}^2}\left(\mathbf{x}, \frac{\hat{\mathbf{x}}_N}{N}\right) \leqslant \frac{1}{\sqrt{2}N}, \quad \forall\, \mathbf{x} \in \mathbb{T}^2. \tag{B1}$$

Then, let us consider the triangular inequality

$$d_{\mathbb{T}^2}(\mathbf{x},\mathbf{y}) \leqslant d_{\mathbb{T}^2}\left(\mathbf{x}, \frac{\hat{\mathbf{x}}_N}{N}\right) + d_{\mathbb{T}^2}\left(\frac{\hat{\mathbf{x}}_N}{N}, \mathbf{y}\right), \quad \forall\, \mathbf{y} \in \mathbb{T}^2, \tag{B2}$$

and let us take the infimum over the set $\mathbf{y} \in \Gamma_n$ defined in (17)

$$d_{\mathbb{T}^2}\left(\frac{\hat{\mathbf{x}}_N}{N}, \Gamma_n\right) \geqslant d_{\mathbb{T}^2}(\mathbf{x}, \Gamma_n) - d_{\mathbb{T}^2}\left(\mathbf{x}, \frac{\hat{\mathbf{x}}_N}{N}\right) \geqslant d_{\mathbb{T}^2}(\mathbf{x}, \Gamma_n) - \frac{1}{\sqrt{2}N},$$

where we used (B1). Therefore, considering the complement $[\overline{\Gamma}_n(\varepsilon)]^\circ$ of the union of strip of width ε, $\overline{\Gamma}_n(\varepsilon)$ defined in (19), we get that

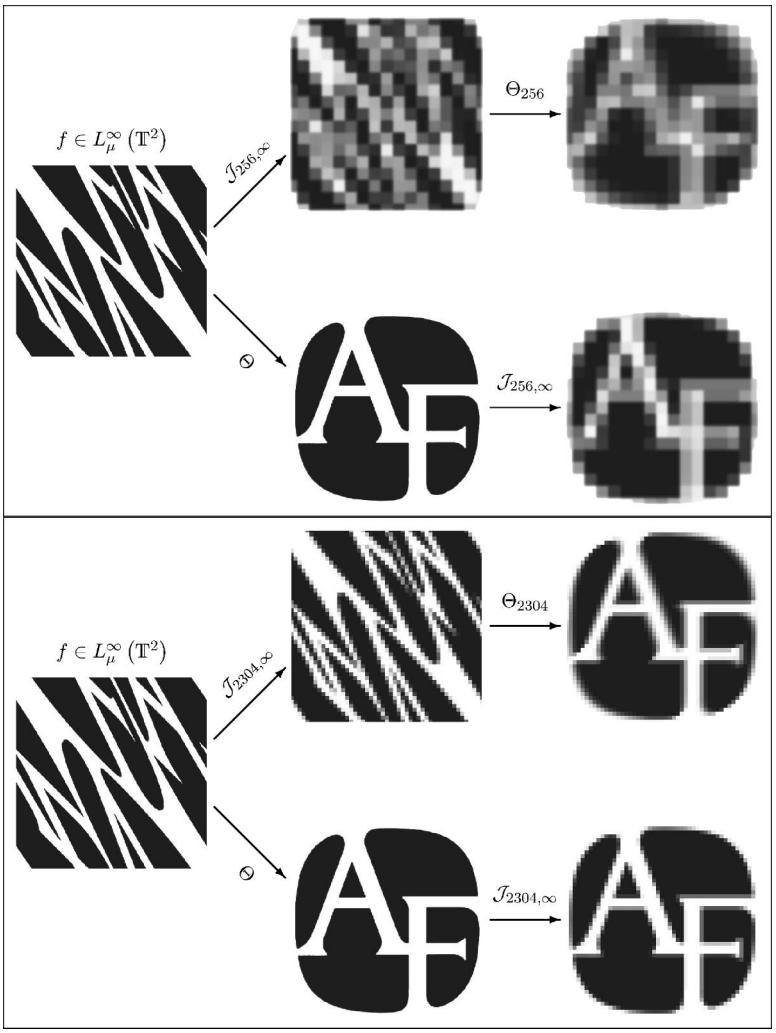

FIG. 4. These two plots show how the difference between $\mathcal{J}_{\mathcal{N},\infty}\circ\Theta_\alpha$ and $\Theta_{\mathcal{N},\alpha}\circ\mathcal{J}_{\mathcal{N},\infty}$ becomes smaller with N. For the continuous SM, Θ_1, the actions $\mathcal{J}_{\mathcal{N},\infty}\circ\Theta_1$ and $\Theta_{\mathcal{N},1}\circ\mathcal{J}_{\mathcal{N},\infty}$ on $f\in L^\infty_\mu(\mathbb{T}^2)$ (left part of both plots) are plotted for two different N: $N=16$ (top) and $N=48$ (bottom). The resulting matrices are mapped back, together with the function $\Theta_1(f)$, on the unfolded torus, by means of the de-discretization operator $\mathcal{J}_{\infty,\mathcal{N}}$.

$$\mathbf{x}\in[\overline{\Gamma}_n(\varepsilon)]^\circ \Rightarrow \frac{\hat{\mathbf{x}}_N}{N}\in\left[\overline{\Gamma}_n\left(\varepsilon-\frac{1}{\sqrt{2}N}\right)\right]^\circ.$$

Further, from (20), it follows that, if the lattice point $\hat{\mathbf{x}}_N/N$ does not belong to $\overline{\Gamma}_n(\varepsilon-1/\sqrt{2}N)$, then the corresponding point $\mathbf{x}\in\mathbb{T}^2$ must belong to $G_n^N(\varepsilon-1/\sqrt{2}N)$. Changing $\varepsilon-1/\sqrt{2}N\mapsto\varepsilon$ we obtain the first inclusion relation in Eq. (22); the second one follows by interchanging the role played by $\hat{\mathbf{x}}_N/N$ and $\mathbf{x}$ in (B2).

In order to prove (23), we start by considering the matrices $S_\alpha=\left(\begin{smallmatrix}1+\alpha & 1\\ \alpha & 1\end{smallmatrix}\right)$ and its inverse $S_\alpha^{-1}=\left(\begin{smallmatrix}1 & -1\\ -\alpha & 1+\alpha\end{smallmatrix}\right)$. Let η be the largest (positive) eigenvalue of $\sqrt{S_\alpha^\dagger S_\alpha}$; its characteristic polynomial for η is $\eta^4-(2\alpha^2+2\alpha+3)\eta^2+1=0$, where η attains its minimum $\eta_{\min}=\sqrt{2}$ at $\alpha=-\frac{1}{2}$. Then, we set $\widetilde{N}:=2\sqrt{2}(\sqrt{2}+1)\eta^{2n}$, $n\in\mathbb{N}$, choose $N>\widetilde{N}$ and proceed by induction.

$\boldsymbol{p}=\mathbf{0}$: from definitions (10) and (11), it follows

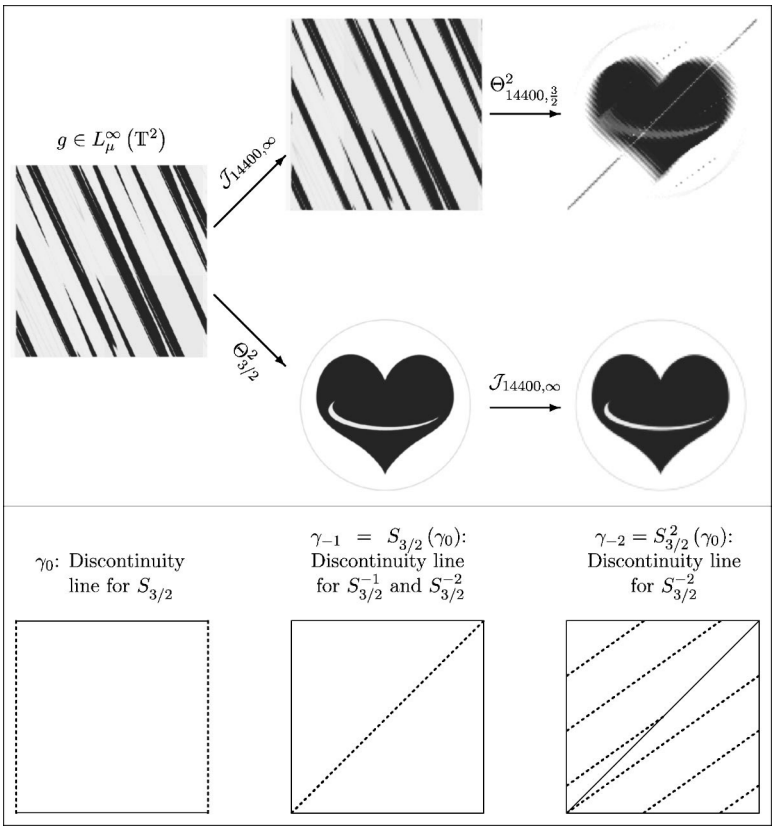

FIG. 5. Here, the same picture as in Fig. 4, is represented, with a finer discretization given by $N=120$ and a different function $g \in L^{\infty}_{\mu}(\mathbb{T}^2)$, for a discontinuous SM, $\Theta_{3/2}$, acting two times. Choosing a function g with sharp variation across γ_0, the preimage of γ_{-1}, the discontinuity of $\Theta_{3/2}$ makes it evident how the differences between $\mathcal{J}_{14\,400,\infty}\circ\Theta^2_{\alpha}$ and $\Theta^2_{14\,400,\alpha}\circ\mathcal{J}_{14\,400,\infty}$ are the greater the closer they are to the discontinuity line γ_{-1}. Of course, the longer the temporal evolution, the worse the correspondence, in the sense that several new discontinuity lines come to play a role. In the case at hand, the map acts twice, and γ_{-2} is felt by $\Theta^2_{14400,\alpha}\circ\mathcal{J}_{14400,\infty}$, as expected.

$$d_{\mathbb{T}^2}\left(\frac{U^0_{\alpha}(N\mathbf{x})}{N},\frac{V^0_{\alpha}(\hat{\mathbf{x}}_N)}{N}\right)=d_{\mathbb{T}^2}\left(\mathbf{x},\frac{\hat{\mathbf{x}}_N}{N}\right)<\frac{1}{\sqrt{2}N}<\frac{\sqrt{2}}{N},$$

where the first inequality follows from (B1), thus relation (23) holds for $p=0$.

$\boldsymbol{p=q-1}$, $\mathbf{1}\leqslant\boldsymbol{q}\leqslant\boldsymbol{n}$: since

$$d_{\mathbb{T}^2}\left(\frac{U^q_{\alpha}(N\mathbf{x})}{N},\frac{V^q_{\alpha}(\hat{\mathbf{x}}_N)}{N}\right)\leqslant d_{\mathbb{T}^2}\left(\frac{U_{\alpha}(U^{q-1}_{\alpha}(N\mathbf{x}))}{N},\frac{U_{\alpha}(V^{q-1}_{\alpha}(\hat{\mathbf{x}}_N))}{N}\right)+d_{\mathbb{T}^2}\left(\frac{U_{\alpha}(V^{q-1}_{\alpha}(\hat{\mathbf{x}}_N))}{N},\frac{V_{\alpha}(V^{q-1}_{\alpha}(\hat{\mathbf{x}}_N))}{N}\right),$$

using (10) in the first term and noting that, from definitions (10) and (11), the second term is less or equal to $\sqrt{2}/N$, we get

$$d_{\mathbb{T}^2}\left(\frac{U^q_{\alpha}(N\mathbf{x})}{N},\frac{V^q_{\alpha}(\hat{\mathbf{x}}_N)}{N}\right)\leqslant d_{\mathbb{T}^2}\left(S_{\alpha}\left(\frac{U^{q-1}_{\alpha}(N\mathbf{x})}{N}\right),S_{\alpha}\left(\frac{V^{q-1}_{\alpha}(\hat{\mathbf{x}}_N)}{N}\right)\right)+\frac{\sqrt{2}}{N}.$$

By the induction hypothesis we have

$$d_{\mathbb{T}^2}\left(\frac{U^{q-1}_{\alpha}(N\mathbf{x})}{N},\frac{V^{q-1}_{\alpha}(\hat{\mathbf{x}}_N)}{N}\right)\leqslant\frac{\sqrt{2}}{N}\left(\frac{\eta^q-1}{\eta-1}\right)\leqslant\frac{\sqrt{2}}{N}\frac{1}{\sqrt{2}-1}\eta^q \tag{B3}$$

$$(\eta > \sqrt{2}, 1 \leqslant q \leqslant n \Rightarrow) < \frac{1}{2}\eta^{q-2n} < \frac{1}{2}\eta^{-1}. \tag{B4}$$

Now we set $\varepsilon = \tilde{N}/2N$, taking into account that $n \geqslant \sqrt{2}$ and use the right inclusion in (22) to deduce that

$$\mathbf{x} \in G_n^N\left(\frac{\tilde{N}}{2N}\right) \Rightarrow \mathbf{x} \notin \overline{\Gamma}_n\left(\frac{\tilde{N}}{2N} - \frac{1}{\sqrt{2}N}\right).$$

At this point, we make use of the following result, which shall be proven in Lemma B.1.3: it states that if a point does not belong to $\overline{\Gamma}_n(\varepsilon)$, the union of the the strips of width $\varepsilon \leqslant \frac{1}{2}$ up to time n, then its orbit under S_α up to time $n-1$ is farther away than $\varepsilon\eta^{-q}$, $0 \leqslant q < n$ from the discontinuity line γ_0. Explicitly

$$\mathbf{x} \notin \overline{\Gamma}_n(\varepsilon) \Rightarrow d_{\mathbb{T}^2}(S_\alpha^q(\mathbf{x}), \gamma_0) > \varepsilon\eta^{-q}, \quad \forall\, 0 \leqslant q < n,$$

where

$$d_{\mathbb{T}^2}\left(\frac{U_\alpha^{q-1}(N\mathbf{x})}{N}, \gamma_0\right) > \left(\frac{\tilde{N}}{2N} - \frac{1}{\sqrt{2}N}\right)\eta^{1-q} > \frac{\sqrt{2}}{N}\left(\frac{\eta^{2n-1} - \eta^{q-1}}{\eta - 1}\right)\eta^{1-q} \geqslant \frac{\sqrt{2}}{N}\left(\frac{\eta^q - 1}{\eta - 1}\right), \tag{B5}$$

where the second inequality comes from $\eta \geqslant \sqrt{2}$, the relation $(\eta^n - 1)/(\eta - 1) \leqslant [1/(\sqrt{2} - 1)]\eta^n$ and the following estimates:

$$\left(\frac{\tilde{N}}{2N} - \frac{1}{\sqrt{2}N}\right) = \frac{\sqrt{2}}{N}\left((\sqrt{2}+1)\eta^{2n} - \frac{1}{2}\right) \geqslant \frac{\sqrt{2}}{N}\left[(\sqrt{2}+1)(\sqrt{2}-1)\frac{\eta^{2n} - \eta + \eta - 1}{\eta - 1} - \frac{1}{2}\right]$$
$$\geqslant \frac{\sqrt{2}}{N}\left[\eta\frac{\eta^{2n-1} - 1}{\eta - 1} + \frac{1}{2}\right] \geqslant \frac{\sqrt{2}}{N}\left(\frac{\eta^{2n-1} - \eta^{q-1}}{\eta - 1}\right).$$

Therefore, comparing (B5) with (B3)

$$d_{\mathbb{T}^2}\left(\frac{U_\alpha^{q-1}(N\mathbf{x})}{N}, \frac{V_\alpha^{q-1}(\hat{\mathbf{x}}_N)}{N}\right) < d_{\mathbb{T}^2}\left(\frac{U_\alpha^{q-1}(N\mathbf{x})}{N}, \gamma_0\right), \quad \forall\, q \leqslant n.$$

As a consequence, the segment $(U_\alpha^{q-1}(N\mathbf{x})/N, V_\alpha^{q-1}(\hat{\mathbf{x}}_N)/N)$ cannot cross the line γ_0. This condition, together with (B4), allows us to use another result proven in Lemma B.1.1b, which states that if a segment (A,B) on the torus does not cross the discontinuity line γ_0 then $d_{\mathbb{T}^2}(S_\alpha(A), S_\alpha(B)) \leqslant \eta d_{\mathbb{T}^2}(A,B)$. We can finally conclude with

$$d_{\mathbb{T}^2}\left(\frac{U_\alpha^q(N\mathbf{x})}{N}, \frac{V_\alpha^q(\hat{\mathbf{x}}_N)}{N}\right) \leqslant \eta\frac{\sqrt{2}}{N}\left(\frac{\eta^q - 1}{\eta - 1}\right) + \frac{\sqrt{2}}{N} = \frac{\sqrt{2}}{N}\left(\frac{\eta^{q+1} - 1}{\eta - 1}\right).$$

■

The following Lemma, which has been used in the proof of the previous proposition, deals with the geometrical properties of the sawtooth dynamics.

Lemma B.1: With η the largest (positive) eigenvalue of $\sqrt{S_\alpha^\dagger S_\alpha}$ and A, $B \in \mathbb{T}^2$ such that $d_{\mathbb{T}^2}(A,B) < \frac{1}{2}\eta^{-1}$, it follows:

(1a) If the segment (A,B) does not cross γ_{-1}, then

$$d_{\mathbb{T}^2}(S_\alpha^{-1}(A), S_\alpha^{-1}(B)) \leqslant \eta d_{\mathbb{T}^2}(A,B). \tag{B6a}$$

(1b) If (A,B) does not cross γ_0, then

$$d_{\mathbb{T}^2}(S_\alpha(A), S_\alpha(B)) \leqslant \eta d_{\mathbb{T}^2}(A,B). \tag{B6b}$$

(2) For any given $\alpha \in \mathbb{R}$, $p \in \mathbb{N}^+$ and $0 \leqslant \varepsilon \leqslant \frac{1}{2}\eta^{-1}$,

$$\mathbf{x} \in \overline{\gamma}_{p-1}(\varepsilon) \Rightarrow S_\alpha^{-1}(\mathbf{x}) \in (\overline{\gamma}_p(\eta\varepsilon) \cup \overline{\gamma}_0(\eta\varepsilon)).$$

(3) For any given $\alpha \in \mathbb{R}$, $n \in \mathbb{N}^+$ and $0 \leqslant \varepsilon \leqslant \frac{1}{2}$, with U_α^q as in (10),

$$\mathbf{x} \notin \overline{\Gamma}_n(\varepsilon) \Rightarrow d_{\mathbb{T}^2}\left(\frac{U_\alpha^q(N\mathbf{x})}{N}, \gamma_0\right) > \varepsilon\eta^{-q}, \quad \forall\, 0 \leqslant q < n.$$

Proof: In the course of the proof, we shall use that

$$\|S_\alpha^{\pm 1} \cdot \mathbf{v}\|_{\mathbb{R}^2} \leqslant \eta \|\mathbf{v}\|_{\mathbb{R}^2}, \tag{B7a}$$

$$\|S_\alpha^{\pm 1} \cdot \mathbf{v}\|_{\mathbb{R}^2} \geqslant \eta^{-1} \|\mathbf{v}\|_{\mathbb{R}^2}, \tag{B7b}$$

which directly follows from the definition of η, where $\mathbf{v}$ is any two-dimensional real vector.
