It is difficult to produce interesting worked examples in the current state of the theory. The problem is that in almost all theories of physical significance, the canonical endomorphisms ρ_γ are not known explicitly, and so one cannot check the compatibility conditions with the constraints explicitly (cf. Corollary 4.3). Here we give an example which is extracted from QED, so it may have some physical interest. It consists of a fermion in an Abelian gauge potential. Since the global gauge group $\mathcal{G}$ is Abelian, the superselection theory simplifies radically. However, we have explicit endomorphisms ρ_γ and can check the compatibility conditions with the constraints. Nevertheless, even at this simple level, it is not possible to verify all the conditions of regularity. We will not treat the issue of dynamics.

A. Constraint structure of QED

We start with a discussion of the setup of QED in order to motivate our subsequent example. The starting point for QED, is a fermion field ψ in $\mathbb{R}^4$ satisfying the free CARs, and a U(1)-gauge potential A in $\mathbb{R}^4$ satisfying free CCRs, and initially these are assumed to commute. So the appropriate C*-algebraic framework at this initial level is

$$\mathcal{B} := \mathrm{CAR}(\mathcal{H}) \otimes \mathrm{CCR}(S,B),$$

where $\mathcal{H} = L^2(\mathbb{R}^4,\mathbb{C}^4)$, $S = \mathcal{S}(\mathbb{R}^4,\mathbb{R}^4)/\mathrm{Ker}\, B$, and B denotes the symplectic form for QEM, coming from the Jordan-Wigner distribution, cf. Sec. 5 of Ref. 5. [Note that the tensor product $\mathcal{B}$ is unique because $\mathrm{CAR}(\mathcal{H})$ is a nuclear algebra.] There is a global charge Q acting on $\mathrm{CAR}(\mathcal{H})$ and there are constraints in the heuristic theory,

$$A_\mu{}^{,\mu}(x) := 0 \quad \text{(Lorentz condition)}$$

and

$$\Box A_\mu := j_\mu \quad \text{(Maxwell equation)},$$

where $j_\mu := -e\tilde{\psi}\gamma_\mu\psi$ is the electron current, and we denote $\tilde{\psi} := \psi^*\gamma_0$. The Lorentz condition has been treated in the C*-algebra context (cf. Ref. 5) and it needs special treatment, e.g., indefinite metric or nonregular states, but it is not very interesting for us, since it only affects the electromagnetic field $\mathrm{CCR}(S,B)$, hence is independent of the charge Q. The Maxwell equation is more interesting, since it involves both factors of $\mathcal{B}$ and it expresses part of the interaction between the two fields. It is however very difficult to enforce in the C*-algebra context (and ultimately leads to the conclusion that $\mathcal{B}$ is too small an algebra to do this in). Naively, it seems that we can easily realize both sides of the Maxwell equation in the present C*-setting, smear the left-hand side over $\mathcal{S}(\mathbb{R}^4,\mathbb{R}^4)$,

$$\int \Box A_\mu(x) f^\mu(x)\mathrm{d}x = \int A_\mu \Box f^\mu \,\mathrm{d}x = A(\Box f)$$

then this is realized in $\mathrm{CCR}(S,B)$ through the identification of the generating Weyl unitaries δ_h with the heuristic $\exp iA(h)$ where $h = \Box f$. If we smear the right-hand side of the Maxwell equation

$$j(f) = -e \int \tilde{\psi}(x)\gamma_\mu \psi(x) f^\mu(x) \mathrm{d}x,$$

then $j(f)$ generates a Bogoliubov transformation T_f on $L^2(\mathbb{R}^4, \mathbb{C}^4)$ by

$$\mathrm{Ad}(\exp ij(f))\psi(g) := (\exp i \,\mathrm{ad}\, j(f))(\psi(g)) = \psi(T_f g) =: \alpha_{T_f}(\psi(g)),$$

where α_{T_f} is its associated automorphism on CAR($\mathcal{H}$) (we will calculate T_f explicitly in a simplified setting below). Let $G \subset \mathrm{Aut}\,\mathcal{B}$ be the discrete group generated in Aut $\mathcal{B}$ by

$$\{\beta_f := \alpha_{T_f} \otimes \iota | f \in \mathcal{S}(\mathbb{R}^4, \mathbb{R}^4)\}$$

and let ν denote its action on $\mathcal{B}$. Define the crossed product

$$\mathcal{E} := \mathcal{G} \underset{\nu}{\times} \mathcal{B} = \mathrm{C}^*\{\mathcal{B}, U_g | U_g^* = U_g^{-1}, \nu_g = \mathrm{Ad}\, U_g, U_g U_h = U_{gh}, g, h \in G\}$$

then we identify the heuristic objects $\exp ij(f)$ with the implementing unitaries U_{β_f}. So each side of the Maxwell equation has a C*-realization, and we only need to decide how to impose the constraint equation. Heuristically, the Maxwell equations are imposed as state conditions, $A(\Box f)\phi = j(f)\phi$ for vectors ϕ in the representing Hilbert (or Krein) space. If we take instead the stronger condition $A(\Box f)^n \phi = j(f)^n \phi$ for $n \in \mathbb{N}$, then we can rewrite the constraint conditions in the form $e^{iA(\Box f)}\phi = e^{if(f)}\phi$. This suggests that we choose constraint unitaries $V_f := U_{-\beta_f} \cdot \delta_{\Box f}$ in $\mathcal{E}$ and thus select our Dirac states ω on $\mathcal{E}$ by

$$\omega(V_f) = 1 \quad \forall f \in \mathcal{S}(\mathbb{R}^4, \mathbb{R}^4).$$

As one expects from the interaction, this program encounters problems.

(1) We always have that $\Box f \in \mathrm{Ker}\, B$, hence $\Box f$ corresponds to zero in S (since we factor out by Ker B). This can be remedied by changing S to $\mathcal{S}(\mathbb{R}^4, \mathbb{R}^4)$, in which case (S, B) is a degenerate symplectic space. This problem is connected to the fact that the heuristic smearing formula

$$A(f) = \int_{C_+} (a_\mu(\mathbf{p})\hat{f}^\mu(p) + a_\mu^+(\mathbf{p})\bar{\hat{f}}^\mu(p)) \frac{d^3p}{p_0}$$

cannot be correct for the interacting theory, since it implies that $A(\Box f) = 0$, in contradiction with the Maxwell equation.

(2) Interaction mixes the fermions and bosons, so it is unrealistic to expect that the interacting fermion and boson fields will commute (as in the tensor product structure of $\mathcal{B}$). In fact, if one assumes that the bosons and fermions commute, then the Maxwell equation forces the local charges to become central, in which case only neutral local fields are allowed, which is too restrictive for QED. Even worse, perturbation theory suggests that the interacting fields need not be canonical, so the assumption of the CCR and CAR relations for the interacting bosons and fermions is problematic.

B. Model for the interacting Maxwell constraint

Inspired by the observations above, we now propose an example which is a simplified version of the Maxwell constraint. Heuristically, we want to impose a constraint of the form

$$a^*(x)a(x) = LA(x),$$

where $a(x)$ is a fermion field on $\mathbb{R}^4$, A is a boson field and L is a linear differential operator on $\mathcal{S}(\mathbb{R}^4)$. To realize this, together with a superselection structure in a suitable C*-algebra setting, we present our construction in six steps.

Step 1: For the fermion field, let $\mathcal{H}=L^2(\mathbb{R}^4)$ and define $\mathrm{CAR}(\mathcal{H})$ in Araki's self-dual form (cf. Ref. 24) as follows. On $\mathcal{K}:=\mathcal{H}\oplus\mathcal{H}$ define an antiunitary involution Γ by $\Gamma(h_1\oplus h_2):=\bar{h}_2\oplus\bar{h}_1$. Then $\mathrm{CAR}(\mathcal{H})$ is the unique simple C^*-algebra with generators $\{\Phi(k)\,|\,k\in\mathcal{K}\}$ such that $k\to\Phi(k)$ is antilinear, $\Phi(k)^*=\Phi(\Gamma k)$, and

$$\{\Phi(k_1),\Phi(k_2)^*\}=(k_1,k_2)\mathbb{1},\quad k_i\in\mathcal{K}.$$

The correspondence with the heuristic creators and annihilators of fermions is given by $\Phi(h_1\oplus h_2)=a(h_1)+a^*(\bar{h}_2)$, where

$$a(h)=\int a(x)\overline{h(x)}d^4x,\quad a^*(h)=\int a^*(x)h(x)d^4x.$$

Step 2: For the boson field, let $S=\mathcal{S}(\mathbb{R}^4,\mathbb{R})$, and let $K:S\to L^2(M,\mu)$ be a linear map, where (M,μ) is a fixed measure space. Define a symplectic form on S by $B(f,g):=\mathrm{Im}(Kf,Kg)$, where $(\cdot,\cdot)$ is the inner product of $L^2(M,\mu)$. Note that B is degenerate if $\mathrm{Ker}\,K$ is nonzero. Define then $\mathrm{CCR}(S,B)=C^*\{\delta_f|f\in S\}$ where the δ_f are unitaries satisfying the Weyl relations

$$\delta_f\cdot\delta_g=\delta_{f+g}\exp[iB(f,g)/2],$$

i.e., $\mathrm{CCR}(S,B)$ is the σ-twisted discrete group algebra of S with respect to the two-cocycle $\sigma(f,g):=\exp[iB(f,g)/2]$.

Step 3: To combine the bosons and fermions in one C^*-algebra, we want to allow for the possibility that they may not commute with each other, hence we will not take the tensor algebra $\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)$. However, we do not know what form their commutators should take, so we start with the free C^*-algebra $\mathcal{E}$ generated by $\mathrm{CAR}(\mathcal{H})$ and $\mathrm{CCR}(S,B)$. The free C^*-algebra $\mathcal{E}$ seems to be big enough to allow for possible interactions, but it is also likely to contain redundant elements.

To be explicit, let $\mathcal{L}$ be the linear space spanned by all monomials of the form $A_0B_0A_1B_1\cdots A_nB_n$ where $A_i\in\mathrm{CAR}(\mathcal{H})$ and $B_i\in\mathrm{CCR}(S,B)$. Note that $\mathcal{L}$ is an algebra with respect to concatenation. Factor out by the ideal generated by $\mathbb{1}_{\mathrm{CAR}}-\mathbb{1}_{\mathrm{CCR}}$ and replace concatenation by multiplication for any two elements in a monomial which are in the same algebra (either CAR or CCR) after the factorization. Note that this will now produce all possible monomials of elements in $\mathrm{CAR}(\mathcal{H})$ and $\mathrm{CCR}(S,B)$, just consider those monomials in $\mathcal{L}$ with A_0 or B_n the identity to obtain all other monomials. Now the resultant algebra $\mathcal{N}$ is a *-algebra with the involution given by

$$(A_0B_0\cdots A_nB_n)^*=B_n^*A_n^*\cdots B_0^*A_0^*.$$

Form the enveloping C^*-algebra $\mathcal{E}$ of $\mathcal{N}$, i.e., let

$$\mathcal{I}_0:=\cap\{\mathrm{Ker}\,\pi|\pi\in\text{Hilbert space representations of }\mathcal{N}\}$$

and set $\mathcal{E}:=\overline{\mathcal{N}/\mathcal{I}_0}$ where the closure is with respect to the enveloping C^*-norm, i.e.,

$$\|A\|:=\sup\{\|\pi(A)\|\,|\,\pi\in\text{Hilbert space representations of }\mathcal{N}\}.$$

That $\mathcal{E}$ is nontrivial, follows from the fact that any tensor product representation of $\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)$ defines a Hilbert space representation of $\mathcal{N}$, hence it follows that $\mathcal{E}$ is nonzero and that $\mathrm{CAR}(\mathcal{H})$ and $\mathrm{CCR}(S,B)$ are faithfully embedded in $\mathcal{E}$ (as the images under the factorization maps of the original generating algebras in the construction). Note that we have a surjective homomorphism $\zeta:\mathcal{E}\to\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)$ given by

$$\zeta(A_0B_0\cdots A_nB_n) \coloneqq (A_0\cdots A_n)\otimes(B_0\cdots B_n), \quad A_i\in \mathrm{CAR}(\mathcal{H}), \quad B_i\in \mathrm{CCR}(S,B).$$

Clearly the ideal $\mathcal{I}_T$ of $\mathcal{E}$ generated by the commutators $[\mathrm{CAR}(\mathcal{H}), \mathrm{CCR}(S,B)]$ is in Ker ζ. Since $\mathcal{E}$ probably contains redundant elements, we do not require it to be simple. ζ will be important in proofs below.

Step 4: Next, we would like to model in the curent C*-setting, the global and local heuristic charges,

$$Q=\int a^*(x)a(x)d^4x, \quad Q(f)=\int a^*(x)a(x)f(x)d^4x, \quad f\in\mathcal{S}(\mathbb{R}^4,\mathbb{R}).$$

Let us calculate the Bogoliubov transformations which they induce,

$$\begin{aligned}
[Q(f),\Phi(h_1\oplus h_2)] &= \int\int [a^*(x)a(x)f(x),a(y)\overline{h_1(y)}+a^*(y)\overline{h_2(y)}]d^4x\,d^4y\\
&= \int\int f(x)\{(a^*(x)a(x)a(y)-a(y)a^*(x)a(x))\overline{h_1(y)}\\
&\quad +(a^*(x)a(x)a^*(y)-a^*(y)a^*(x)a(x))\overline{h_2(y)}\}d^4x\,d^4y\\
&= \int\int f(x)\{-\{a^*(x),a(y)\}a(x)\overline{h_1(y)}+(a^*(x)(\delta(x-y)-a^*(y)a(x))\\
&\quad -a^*(y)a^*(x)a(x))\overline{h_2(y)}\}d^4x\,d^4y\\
&= \int\int f(x)\{-\delta(x-y)\overline{h_1(y)}a(x)+\delta(x-y)a^*(x)\overline{h_2(y)}\}d^4x\,d^4y\\
&= -a(\overline{f}\cdot h_1)+a^*(f\cdot\overline{h_2})=\Phi(-\overline{f}\cdot h_1\oplus\overline{f}\cdot h_2)=\Phi(f(-h_1\oplus h_2))
\end{aligned}$$

since f is real. For the global charge Q, just set $f=1$ in the last calculation. Thus

$$(\mathrm{ad}\,Q(f))^n(\Phi(h_1\oplus h_2))=\Phi(f^n\cdot((-1)^nh_1\oplus h_2)),$$

hence,

$$\begin{aligned}
(\mathrm{Ad}(\exp iQ(f)))(\Phi(h_1\oplus h_2)) &= (\exp i\,\mathrm{ad}\,Q(f))(\Phi(h_1\oplus h_2))\\
&= \sum_{n=0}^{\infty}\frac{(i\,\mathrm{ad}\,Q(f))^n}{n!}(\Phi(h_1\oplus h_2))\\
&= \sum_{n=0}^{\infty}\frac{i^n}{n!}\Phi(f^n((-1)^nh_1\oplus h_2))=\Phi(e^{-if}h_1\oplus e^{if}h_2)\eqqcolon\Phi(T_f(h_1\oplus h_2)).
\end{aligned}$$

Now T_f is unitary on $\mathcal{K}$, and satisfies $[T_f,\Gamma]=0$, hence it is a Bogoliubov transformation (cf. p. 43 in Ref. 24), and so we can define automorphisms on $\mathrm{CAR}(\mathcal{H})$ by

$$\tilde{\gamma}_f(\Phi(k))\coloneqq\Phi(T_fk).$$

It is clear that $T_fT_g=T_{f+g}$, hence that $\tilde{\gamma}:\mathcal{S}(\mathbb{R}^4)+\mathbb{R}\to\mathrm{Aut}(\mathrm{CAR}(\mathcal{H}))$ is a homomorphism. We extend these automorphisms to maps γ_f on $\mathcal{E}$ by setting

$$\gamma_f\restriction\mathrm{CAR}(\mathcal{H})=\tilde{\gamma}_f, \quad \text{and} \quad \gamma_f\restriction\mathrm{CCR}(S,B)=\iota,$$

where ι is the identity map. The only relations between $\mathrm{CAR}(\mathcal{H})$ and $\mathrm{CCR}(S,B)$ in the free construction of $\mathcal{E}$, is $\mathbb{1}_{\mathrm{CAR}}=\mathbb{1}_{\mathrm{CCR}}$, so since the definition of γ_f preserves this relation, it will extend to a well-defined map on the free *-algebra $\mathcal{N}$. In fact, since γ_f replaces $\mathrm{CAR}(\mathcal{H})$ by an isomor-

phic one in a free construction, it will be an automorphism on $\mathcal{N}$, and so will define an automorphism on the enveloping algebra $\mathcal{E}$.

Let G denote the Abelian group generated in Aut $\mathcal{E}$ by $\{\gamma_f | f \in \mathcal{S}(\mathbb{R}^4) \cup \mathbb{R}\}$ and equip it with the discrete topology. Denote its action by $\beta: G \to \text{Aut}\,\mathcal{E}$, and define the algebra

$$\mathcal{A} := \mathcal{G} \underset{\beta}{\times} \mathcal{E},$$

then we identify the implementing unitaries $U_{\gamma_f} \in \mathcal{A}$ of $\gamma_f \in \text{Aut}\,\mathcal{E}$ with the heuristic objects $\exp iQ(f)$, $f \in \mathcal{S}(\mathbb{R}^4) \cup \mathbb{R}$ [in the case that $f = t \in \mathbb{R}$, we denote $Q(t) = tQ$]. Now γ is a surjective homomorphism $\gamma: \mathcal{S}(\mathbb{R}^4) + \mathbb{R} \to G$ and from the definitions above, it is clear that its kernel is $2\pi\mathbb{Z} \subset \mathbb{R}$, hence the discrete group G is isomorphic to $\mathcal{S}(\mathbb{R}^4) \times \mathbb{T}$. Of course $\mathbb{T}$ will be our global gauge group below.

Step 5: Next, we would like to realize in $\mathcal{E}$ the heuristic constraints

$$Q(f)^n \psi = A(Lf)^n \psi \quad \forall\, f \in \mathcal{S}(\mathbb{R}^4), \quad n \in \mathbb{N},$$

where $L: S \to \text{Ker}\, K \subseteq \text{Ker}\, B$ is a given linear map. First write the heuristic constraints in bounded form

$$e^{iQ(f)}\psi = e^{iA(Lf)}\psi, \quad \text{i.e.,}\ e^{-iA(Lf)}e^{iQ(f)}\psi = \psi.$$

So, given the identifications with heuristic objects above, we define our constraint unitaries to be

$$\mathcal{U} := \{\delta_{-Lf} \cdot U_{\gamma_f} =: V_f | f \in \mathcal{S}(\mathbb{R}^4, \mathbb{R})\} \subset \mathcal{A}.$$

Proposition 5.1: $\mathcal{U}$ is first class.

The proof is in the next section. The heuristic constraint conditions now correspond to the application of the T-procedure to $\mathcal{U}$.

Step 6: Now we will specify the superselection structure associated with the global charge Q using the fact that Q must take integer values on the vacuum state. Recall that the global gauge transformations γ_t, $t \in \mathbb{R}$ are implemented by the unitaries $U_{\gamma_t} \in \mathcal{A}$ which we identify with the heuristic objects $\exp itQ$ (cf. Step 3). For the superselection sectors we need to find cyclic representations (π, Ω) such that

$$\pi(U_{\gamma_t})\Omega = e^{itn}\Omega \quad \forall\, t \in \mathbb{R}$$

and some $n \in \mathbb{Z}$ (the heuristic corresponding conditions are $Q\Omega = n\Omega$). We recognize these as constraint conditions for Dirac states of the constraint unitaries,

$$\mathcal{V}_n := \{V_t^{(n)} := e^{-itn} U_{\gamma_t} | t \in \mathbb{R}\}.$$

Denote the sets of these Dirac states by

$$\mathfrak{S}_D^{(n)} := \{\omega \in \mathfrak{S}(\mathcal{A}) | \omega(V_t^{(n)}) = 1 \ \ \forall\, t \in \mathbb{R}\}.$$

These folia of states will be our superselection sectors.

Lemma 5.2: With notation as above, we have

(i) $\mathfrak{S}_D^{(n)} \cap \mathfrak{S}_D^{(m)} = \emptyset$ *if* $n \neq m$,

(ii) $\mathfrak{S}_D^{(0)} \neq \emptyset$.

Proof: (i) If there is a $\omega \in \mathfrak{S}_D^{(n)} \cap \mathfrak{S}_D^{(m)}$ for $n \neq m$, then

$$\omega(e^{-itn}U_{\gamma_t}) = 1 = \omega(e^{-itm}U_{\gamma_t}),$$

so

$$\omega(U_{\gamma_t}) = e^{itn} = e^{itm} \quad \forall\, t$$

which contradicts $n \neq m$.

(ii) In the proof of Lemma 5.1 we constructed a state $\omega_3 \in \mathfrak{S}(\mathcal{A})$ satisfying $\omega_3(U_g) = 1$ for all $g \in G$. If we take $g = \gamma_t$, then this implies that $\omega_3 \in \mathfrak{S}_D^{(0)}$. ■

To connect with the usual machinery for superselection used above, we need to exhibit the canonical endomorphisms (automorphisms in the Abelian case). We construct an action $\rho: \mathbb{Z} \to \mathrm{Aut}\,\mathcal{A}$ such that its dual action on $\mathcal{A}^*$ satisfies $\rho_k^*(\mathfrak{S}_D^{(n)}) = \mathfrak{S}_D^{(n+k)}$.

Definition 5.3: For each $k \in \mathbb{Z}$ define a $*$-automorphism ρ_k of $\mathcal{A}$ by

$$\rho_k(A) = A \quad \forall\, A \in \mathcal{E}, \quad \rho_k(U_{\gamma_t}) = e^{itk} U_{\gamma_t} \quad \forall\, t \in \mathbb{R},$$

$$\rho_k(U_{\gamma_f}) = U_{\gamma_f} \quad \forall\, f \in \mathcal{S}(\mathbb{R}^4).$$

Lemma 5.4: ρ_k is well-defined, and $\rho_k \in \mathrm{Aut}\,\mathcal{A}$.

The proof is in the next section. Recall that for any $\alpha \in \mathrm{Aut}\,\mathcal{A}$ we define its dual $\alpha^*: \mathcal{A}^* \to \mathcal{A}^*$ by $\alpha^*(f) := f \circ \alpha$ for all functionals $f \in \mathcal{A}^*$.

Proposition 5.5: With notation as above, we have $\rho_k^*(\mathfrak{S}_D^{(n)}) = \mathfrak{S}_D^{(n+k)}$ and $\mathfrak{S}_D^{(n)} \neq \emptyset$ for all $n \in \mathbb{Z}$.

Proof: Let $\omega \in \rho_k^*(\mathfrak{S}_D^{(n)})$, i.e., $\omega = \omega_n \circ \rho_k$ for some $\omega_n \in \mathfrak{S}_D^{(n)}$. Thus

$$\omega(e^{-it(n+k)} U_{\gamma_t}) = \omega_n(e^{-it(n+k)} \rho_k(U_{\gamma_t})) = \omega_n(e^{-itn} U_{\gamma_t}) = 1,$$

i.e., $\omega \in \mathfrak{S}_D^{(n+k)}$. Conversely, for any $\omega \in \mathfrak{S}_D^{(n+k)}$ there is a $\omega_n \in \mathfrak{S}_D^{(n)}$ for which $\omega = \omega_n \circ \rho_k$ and it is obviously $\omega_n = \omega \circ \rho_{-k}$. Thus $\rho_k^*(\mathfrak{S}_D^{(n)}) = \mathfrak{S}_D^{(n+k)}$. Since we have that $\mathfrak{S}_D^{(0)} \neq \emptyset$, it is now immediate that $\mathfrak{S}_D^{(n)} = \rho_k^*(\mathfrak{S}_D^{(0)}) \neq \emptyset$. ■

Recall from our earlier discussions that the canonical automorphisms (Abelian case) must necessarily be outer on $\mathcal{A}$.

Proposition 5.6: With notation as above, $\rho_k \in \mathrm{Out}\,\mathcal{A}$ if $k \neq 0$.

The proof of this is long, and is in the next section.

From the action $\rho: \mathbb{Z} \to \mathrm{Out}\,\mathcal{A}$ we construct a Hilbert extension (cf. Sec. II F). First set

$$\Lambda := \{\mathrm{Ad}\, U \circ \rho_k | U \in \mathcal{A} \text{ unitary}, k \in \mathbb{Z}\}$$

so $\mathbb{Z} \cong \Lambda / \mathrm{Inn}\,\mathcal{A}$. So the class of $k \in \mathbb{Z}$ in $\Lambda / \mathrm{Inn}\,\mathcal{A}$ is $\chi_k := \{\mathrm{Ad}\, U \circ \rho_k \,|\, U \in \mathcal{A}_u\}$. Take the monomorphic section $\chi_k \to k$, then it has a trivial cocycle $\sigma(n,m) = 1$ for all $n, m \in \mathbb{Z}$. Define $\mathcal{F} := \mathbb{Z} \times_{\rho} \mathcal{A}$, then it has the dense $*$-algebra

$$\mathcal{F}_0 := \left\{ \sum_{n \in F} A_n U^n | A_n \in \mathcal{A}, F \subset \mathbb{Z} \text{ finite} \right\},$$

where $U \in \mathcal{F}$ is the unitary which implements ρ_1, i.e., $\rho_1 = \mathrm{Ad}\, U \restriction \mathcal{A}$. Fix $t \in \mathbb{T} = \hat{\mathbb{Z}}$ and define an action $\alpha: \mathbb{T} \to \mathrm{Aut}\,\mathcal{F}$ by

$$\alpha_t\left(\sum_{n \in F} A_n U^n \right) := \sum_{n \in F} A_n t^n U^n \quad \text{on } \mathcal{F}_0.$$

Then the fixed point algebra of α is $\mathcal{A}$. We verify the compatibility condition in Corollary 4.3.

Proposition 5.7: $\rho_k(\mathcal{D}) \sim \mathcal{D}$ for all $k \in \mathbb{Z}$.

Proof: The constraint unitaries from which we define $\mathcal{D}$ are $V_f := \delta_{-Lf} \cdot U_{\gamma_f}$, $f \in \mathcal{S}(\mathbb{R}^4)$. By Definition 5.3 we have $\rho_k \restriction \mathcal{E} = \iota$, hence $\rho_k(\delta_{-Lf}) = \delta_{-Lf}$. Also $\rho_k(U_{\gamma_f}) = U_{\gamma_f}$ for all $f \in \mathcal{S}(\mathbb{R}^4)$, hence $\rho_k(V_f) = V_f$ for all $f \in \mathcal{S}(\mathbb{R}^4)$. Thus ρ_k preserves the Dirac states $\mathfrak{S}_D$ and hence $\rho_k(\mathcal{D}) = \mathcal{D}$ for all $k \in \mathbb{Z}$. ■

It remains to show that this Hilbert system is regular and minimal. However, at this stage we do not have a proof because little is known about the ideal $\mathcal{I}_0$ factored out in Step 3.

VI. PROOFS

Proof of Theorem 4.1: (i) We have that $\beta_g := g \restriction \mathcal{O}_\mathcal{F}$. The pointwise norm-continuity of $\beta_\mathcal{G}$ follows from the pointwise norm-convergence topology of $\mathcal{G}$. So $\{\mathcal{O}_\mathcal{F}, \mathcal{G}, \beta\}$ is a C*-dynamical system. Since $\mathcal{A}$ is the fixed point algebra of $\mathcal{G}$, the fixed point algebra of $\beta_\mathcal{G}$ is $\mathcal{O}_\mathcal{F} \cap \mathcal{A}$. By Theorem 3.7 we have that $\mathcal{O}_\mathcal{F} \cap \mathcal{A} = \mathcal{O}$.

If $A \in Z(\mathcal{A})$, then $[A, \mathcal{C}] = 0$, hence $A \in \mathcal{O}$ by Theorem 3.3 (iii), and from this it follows that $Z(\mathcal{A}) \subseteq Z(\mathcal{O})$.

(ii) Now let $\mathcal{H}_\gamma \subset \Pi_\gamma \mathcal{F}$. If there is a unit vector $\Phi \in \mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F}$, then by invariance of $\mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F}$ under $\mathcal{G}$, we also have $\mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F} \supset$ span $(\mathcal{G}\Phi) = \mathcal{H}_\gamma$, where the last equality follows from irreducibility of the action of $\mathcal{G}$ on $\mathcal{H}_\gamma$. Thus $\mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F} \neq \{0\}$ implies that $\mathcal{H}_\gamma \subset \mathcal{O}_\mathcal{F}$, hence $\mathcal{H}_\gamma \subset \Pi_\gamma \mathcal{O}_\mathcal{F}$.

To prove that $\Pi_\gamma \mathcal{O}_\mathcal{F} = \text{clo-span}(\mathcal{O}\mathcal{H}_\gamma)$ we follow the proof of Lemma 10.1.3 in Ref. 3. First, since $\mathcal{O} = \Pi_\iota \mathcal{O}_\mathcal{F}$, it follows that $\mathcal{O}\mathcal{H}_\gamma \subseteq \Pi_\gamma \mathcal{O}_\mathcal{F}$ by Remark 2.5 (v).

By Evans and Sund,[11] $\Pi_\gamma \mathcal{O}_\mathcal{F}$ is the closed span of all the $\mathcal{G}$-invariant subspaces $\mathcal{E} \subset \mathcal{O}_\mathcal{F}$ such that $\beta_\mathcal{G}$ acts on $\mathcal{E}$ as an element of $\gamma \in \widehat{\mathcal{G}/\mathcal{K}}$. So for the reverse inclusion, $\Pi_\gamma \mathcal{O}_\mathcal{F} \subseteq$ clo-span$\{\mathcal{O}\mathcal{H}_\gamma\}$, it suffices to show that span $\{\mathcal{O}\mathcal{H}_\gamma\}$ contains all $\mathcal{G}$-invariant subspaces $\mathcal{E} \subset \mathcal{O}_\mathcal{F}$ such that $\mathcal{G}$ acts on $\mathcal{E}$ as an element of γ. Let $\{\Psi_1, \ldots, \Psi_d\}$, $d = \dim \gamma$ be a basis of such an $\mathcal{E}$ under which the matrix representation of the action of $\mathcal{G}$ is an element of γ, i.e.,

$$g\Psi_i = \sum_j \lambda_{ji}(g)\Psi_j,$$

where the matrix $(\lambda_{ji}(g))$ is a unitary matrix representation of $\mathcal{G}$ of the type γ. Choose an orthonormal basis $\{\Phi_1, \ldots, \Phi_d\}$ of $\mathcal{H}_\gamma$ which also transforms under $\mathcal{G}$ according to $(\lambda_{ji}(g))$. Consider now the element $A := \Sigma_j \Psi_j \Phi_j^* \in \mathcal{O}_\mathcal{F}$. Then

$$g(A) = \sum_j g(\Psi_j \Phi_j^*) = \sum_{i,k} \left(\sum_j \lambda_{ij}(g)\overline{\lambda_{kj}(g)} \right) \Psi_i \Phi_k^* = \sum_{i,k} \delta_{ik} \Psi_i \Phi_k^* = \sum_j \Psi_j \Phi_j^* = A.$$

Thus $A \in \mathcal{O}$, and hence all $\Psi_i = A\Phi_i \in \mathcal{O}\mathcal{H}_\gamma$, i.e., $\mathcal{E} \subset$ span $(\mathcal{O}\mathcal{H}_\gamma)$.

(iii) Let $\mathcal{H}_\sigma$ have an orthonormal basis $\{\Phi_1, \ldots, \Phi_d\}$ hence $\rho_\sigma(F) = \Sigma_{j=1}^d \Phi_j F \Phi_j^*$ for $F \in \mathcal{F}$, $\rho_\sigma \restriction \mathcal{A} = \sigma$. Since $\{\Phi_j\} \subset \mathcal{O}_\mathcal{F} = M(\mathcal{D}_\mathcal{F})$ it is clear that ρ_σ preserves both $\mathcal{D}_\mathcal{F}$ and $\mathcal{O}_\mathcal{F}$. Since ρ_σ also preserves $\mathcal{A}$, it preserves $\mathcal{D} = \mathcal{D}_\mathcal{F} \cap \mathcal{A}$ and $\mathcal{O} = \mathcal{O}_\mathcal{F} \cap \mathcal{A}$, where these equalities come from Theorem 3.7.

Proof of Theorem 4.2: (i) Let $\mathcal{H} \subset \mathcal{O}_\mathcal{F}$ have an orthonormal basis $\{\Phi_j\}$. By the same proof as for Theorem 4.1 (iii) we have that $\rho_\mathcal{H}(\mathcal{D}) \subseteq \mathcal{D}$.

Since $\mathcal{O}_\mathcal{F}$ is a *-algebra and the relative multiplier algebra of $\mathcal{D}_\mathcal{F} \supset \mathcal{D}$, we have that

$$[\Phi_j^*, D] \in \mathcal{D}_\mathcal{F} \quad \text{for all } D \in \mathcal{D}, j.$$

Thus

$$\Phi_j[\Phi_j^*, D] \in \Phi_j \mathcal{D}_\mathcal{F} = \rho_\mathcal{H}(\mathcal{D}_\mathcal{F})\Phi_j \subset \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F})\mathcal{F}),$$

i.e.,

$$D - \rho_\mathcal{H}(D) = \sum_j (\Phi_j \Phi_j^* D - \Phi_j D \Phi_j^*) \in \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F})\mathcal{F}).$$

So

$$D \in \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F})\mathcal{F}) \quad \text{for all } D \in \mathcal{D}.$$

Thus we have shown that $\mathcal{D} \subset \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F})\mathcal{F})$, and now we would like to show that clo-span$(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F})\mathcal{F}) = \text{clo-span}(\rho_\mathcal{H}(\mathcal{D})\mathcal{F})$. We have that

$$\text{clo-span}(\mathcal{C}\mathcal{F}) = \text{clo-span}(\mathcal{D}\mathcal{F}) = \text{clo-span}(\mathcal{D}_{\mathcal{F}}\mathcal{F}),$$

so if we apply $\rho_{\mathcal{H}}$ to both sides of the last equation, multiply by $\mathcal{F}$ on the right and take closed span, we get

$$\text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D})\rho_{\mathcal{H}}(\mathcal{F})\mathcal{F}) = \text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D}_{\mathcal{F}})\rho_{\mathcal{H}}(\mathcal{F})\mathcal{F}),$$

i.e.,

$$\text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D}_{\mathcal{F}})\mathcal{F}) = \text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D})\mathcal{F}).$$

Thus

$$\mathcal{D} \subset \text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D})\mathcal{F}) \quad \text{and since } \mathcal{D} \text{ is a * -algebra in } \mathcal{A},$$

$$\mathcal{D} \subseteq \text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D})\mathcal{F}) \cap \text{clo-span}(\mathcal{F}\rho_{\mathcal{H}}(\mathcal{D})) \cap \mathcal{A} \subseteq \text{clo-span}(\mathcal{D}\mathcal{F}) \cap \text{clo-span}(\mathcal{F}\mathcal{D}) \cap \mathcal{A} = \mathcal{D},$$

where we used $\mathcal{D}_{\mathcal{F}} \cap \mathcal{A} = \mathcal{D}$. Thus,

$$\mathcal{D} = \text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D})\mathcal{F}) \cap \text{clo-span}(\mathcal{F}\rho_{\mathcal{H}}(\mathcal{D})) \cap \mathcal{A} = \text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D})\mathcal{A}) \cap \text{clo-span}(\mathcal{A}\rho_{\mathcal{H}}(\mathcal{D}))$$

which also follows from Theorem 3.7, treating $\rho_{\mathcal{H}}(\mathcal{D}) \subseteq \mathcal{D}$ as a second constraint set. Thus $\mathcal{D} \sim \rho_{\mathcal{H}}(\mathcal{D})$ in $\mathcal{A}$.

For the converse, let $\mathcal{D} \sim \rho_{\mathcal{H}}(\mathcal{D})$ and take $\Phi \in \mathcal{H}$. From the equation $\Phi D = \rho_{\mathcal{H}}(D)\Phi$ for all $D \in \mathcal{D}$, we conclude that

$$\Phi \cdot \text{clo-span}(\mathcal{D}\mathcal{F}) \subset \text{clo-span}(\rho_{\mathcal{H}}(\mathcal{D})\mathcal{F}) = \text{clo-span}(\mathcal{D}\mathcal{F})$$

using $\mathcal{D} \sim \rho_{\mathcal{H}}(\mathcal{D})$. Since we have trivially that $\Phi \cdot \text{clo-span}(\mathcal{F}\mathcal{D}) \subset \text{clo-span}(\mathcal{F}\mathcal{D})$, it follows that

$$\Phi\mathcal{D}_{\mathcal{F}} = \Phi(\text{clo-span}(\mathcal{F}\mathcal{D}) \cap \text{clo-span}(\mathcal{D}\mathcal{F})) \subset \mathcal{D}_{\mathcal{F}}$$

so Φ is in the left multiplier of $\mathcal{D}_{\mathcal{F}}$. We also have that

$$\text{clo-span}(\mathcal{F}\mathcal{D})\Phi = \text{clo-span}(\mathcal{F}\rho_{\mathcal{H}}(\mathcal{D}))\Phi = \text{clo-span}(\mathcal{F}\Phi\mathcal{D}) \subseteq \text{clo-span}(\mathcal{F}\mathcal{D}).$$

Since trivially $\text{clo-span}(\mathcal{D}\mathcal{F})\Phi \subseteq \text{clo-span}(\mathcal{D}\mathcal{F})$, it follows that

$$\mathcal{D}_{\mathcal{F}}\Phi = (\text{clo-span}(\mathcal{F}\mathcal{D}) \cap \text{clo-span}(\mathcal{D}\mathcal{F}))\Phi \subset \mathcal{D}_{\mathcal{F}}$$

and hence Φ is in the relative multiplier algebra of $\mathcal{D}_{\mathcal{F}}$, i.e., $\Phi \in \mathcal{O}_{\mathcal{F}}$ by Theorem 3.3 (ii).

(ii) Let $\mathcal{H}_\sigma \subset \mathcal{O}_{\mathcal{F}} \supset \mathcal{H}_\tau$, hence by (i) $\mathcal{D} \sim \sigma(\mathcal{D}) \sim \tau(\mathcal{D})$.

First let $X \in (\sigma, \tau)_{\mathcal{A}} \cap \mathcal{O}$, i.e., $X \in \mathcal{O}$ and $X\sigma(A) = \tau(A)X$ for all $A \in \mathcal{A}$. By letting A range over only $\mathcal{O} \subset \mathcal{A}$, we immediately get that $X \in (\sigma\restriction\mathcal{O}, \tau\restriction\mathcal{O})_{\mathcal{O}}$, making use of Theorem 4.1 (iii). Therefore, it suffices to prove that $(\sigma, \tau)_{\mathcal{A}} \subset \mathcal{O}$.

Let $X \in (\sigma, \tau)_{\mathcal{A}}$, i.e., $X \in \mathcal{A}$ and $X\sigma(A) = \tau(A)X$ for all $A \in \mathcal{A}$. Thus

$$X \cdot \text{clo-span}(\mathcal{D}\mathcal{A}) = X \cdot \text{clo-span}(\sigma(\mathcal{D})\mathcal{A}) = \text{clo-span}(X\sigma(\mathcal{D})\mathcal{A}) \subseteq \text{clo-span}(\tau(\mathcal{D})X\mathcal{A})$$

$$\subseteq \text{clo-span}(\tau(\mathcal{D})\mathcal{A}) = \text{clo-span}(\mathcal{D}\mathcal{A}).$$

Since we have trivially that $X \cdot \text{clo-span}(\mathcal{A}\mathcal{D}) \subseteq \text{clo-span}(\mathcal{A}\mathcal{D})$, it follows that

$$X\mathcal{D} \subseteq \text{clo-span}(\mathcal{A}\mathcal{D}) \cap \text{clo-span}(\mathcal{D}\mathcal{A}) = \mathcal{D},$$

i.e., X is in the left multiplier of $\mathcal{D}$. Likewise,

$$\text{clo-span}(\mathcal{AD})\cdot X=\text{clo-span}(\mathcal{A}\tau(\mathcal{D}))\cdot X=\text{clo-span}(\mathcal{A}\tau(\mathcal{D})X)$$
$$\subseteq \text{clo-span}(\mathcal{A}X\sigma(\mathcal{D}))\subseteq \text{clo-span}(\mathcal{A}\sigma(\mathcal{D}))=\text{clo-span}(\mathcal{AD}).$$

Since trivially $\text{clo-span}(\mathcal{DA})\cdot X\subseteq\text{clo-span}(\mathcal{DA})$, we have

$$\mathcal{D}\cdot X\subseteq \text{clo-span}(\mathcal{AD})\cap\text{clo-span}(\mathcal{DA})=\mathcal{D},$$

and hence X is in the relative multiplier of $\mathcal{D}$, i.e., $X\in\mathcal{O}$.

Proof of Proposition 4.5: (i) According to the decomposition

$$\sigma(\cdot)=\sum_j V_j\rho_{\gamma_j}(\cdot)V_j^*,\quad V_j\in(\rho_{\gamma_j},\sigma)_{\mathcal{A}},$$

we have $\mathcal{H}_\sigma=\Sigma_j V_j\mathcal{K}_j'$ where $\rho_{\gamma_j}=\rho_{\mathcal{K}_j'}$ and the $\mathcal{K}_j'$ are irreducible with respect to $\mathcal{G}$ carrying the representation $\gamma_j\in\hat{\mathcal{G}}$. Moreover supp $\mathcal{K}_j'=1$.

Set $E_j:=V_jV_j^*$. Then $\Sigma_jE_j=1$. Since $V_j\mathcal{K}_j'\subset\mathcal{H}_\sigma\subset\mathcal{O}_\mathcal{F}$ it follows that

$$E_j=\text{supp}\ V_j\mathcal{K}_j'\in\mathcal{O}$$

for all j. Therefore, by assumption, there are isometries $W_j\in\mathcal{O}$ with $E_j=W_jW_j^*$. Now we set

$$\mathcal{K}_j:=W_j^*V_j\mathcal{K}_j'\subset\mathcal{O}_\mathcal{F}.$$

Then $\mathcal{K}_j$ is an algebraic Hilbert space with supp $\mathcal{K}_j=1$, carrying the representation γ_j and we have $V_j\mathcal{K}_j'=W_j\mathcal{K}_j$. Hence $\mathcal{H}_\sigma=\Sigma_jW_j\mathcal{K}_j$ and

$$\sigma(\cdot)=\sum_j W_j\rho_{\mathcal{K}_j}(\cdot)W_j^*,\quad W_j\in(\rho_{\mathcal{K}_j},\sigma)_{\mathcal{O}}$$

follows.

(ii) This follows from (i) using the existence of subobjects.

Proof of Theorem 4.8: Let $\mathcal{H}\subset\mathcal{F}$ be an arbitrary algebraic Hilbert space. Then $\xi(\mathcal{H})\subset\mathcal{L}$ is also an algebraic Hilbert space, with support 1. To see this, let $\{\Phi_j\}_j$ be an orthonormal basis of $\mathcal{H}$, i.e., $\Phi_j^*\Phi_k=\delta_{j,k}1$ and $\Sigma_j\Phi_j\Phi_j^*=1$ then the same relations are true for the system $\{\xi(\Phi_j)\}_j$. In particular ξ is injective on $\mathcal{H}$. Moreover, if $\mathcal{H}$ is $\mathcal{G}$-invariant and $g(\Phi_j)=\Sigma_ku_{k,j}(g)\Phi_k$ then $g^\xi(\xi(\Phi_j))=\Sigma_ku_{k,j}(g)\xi(\Phi_k)$, i.e., $\xi(\mathcal{H})$ carries the same representation as $\mathcal{H}$. In particular, if $\mathcal{H}_\gamma$ carries γ, i.e., $\mathcal{H}_\gamma\subset\Pi_\gamma\mathcal{F}$ then $\xi(\mathcal{H}_\gamma)\subset\Pi_\gamma^\xi\mathcal{L}$. This proves (ii) and (i).

Let $\mathcal{N}_\gamma$ be an orthonormal basis for $\xi(\mathcal{H}_\gamma)$, then by the first part it is the image under ξ of an orthonormal basis $\{\Phi_{\gamma,j}\}_j$ of $\mathcal{H}_\gamma$. Let $F=\Sigma A_{\gamma,j}\Phi_{\gamma,j}\in\mathcal{F}_{\text{fin}}$ such that $\xi(F)=0=\Sigma\xi(A_{\gamma,j})\xi(\Phi_{\gamma,j})$. By applying $\mathcal{G}^\xi$ to this equality, and using the relation $g^\xi(\xi(\Phi_{\gamma,j}))=\Sigma_ku_{k,j}(g)\xi(\Phi_{\gamma,k})$ we get $\Sigma_{\gamma,j,k}u_{k,j}^\gamma(g)\xi(A_{\gamma,j})\xi(\Phi_{\gamma,k})=0$ for all $g\in\mathcal{G}$. Now the orthogonality relations for the matrix elements of the irreducible representations of $\mathcal{G}$ imply $\xi(A_{\gamma,j})\xi(\Phi_{\gamma,k})=0$ for all $\gamma\in\hat{\mathcal{G}},j,k$. Hence $\xi(A_{\gamma,j})=0$ follows. This proves (iii). From $\xi\circ\Pi_\gamma=\Pi_\gamma^\xi\circ\xi$ (iv) follows.

For (v) observe that the homomorphic images of isometries $V_i\in\mathcal{A}$ with $V_1V_1^*+V_2V_2^*=1$ produces a pair of isometries in $\xi(\mathcal{A})$ satisfying the same relation. So Property B for $\mathcal{A}$ implies Property B for $\xi(\mathcal{A})$.

Proof of Corollary 4.9: (i) Let λ be generated by $\mathcal{H}$, i.e., let $\lambda=\rho_\mathcal{H}$ such that $\lambda(A)=\Sigma_j\Phi_jA\Phi_j^*$ where $\{\Phi_j\}_j$ is an orthonormal basis of $\mathcal{H}$. Then $\xi(\lambda(A))=\Sigma_j\xi(\Phi_j)\xi(A)\xi(\Phi_j)^*$ and $\xi(A)=0$ implies $\xi(\lambda(A))=0$. Furthermore, $\lambda^\xi(\xi(A))=\rho_{\xi(\mathcal{H})}(\xi(A))$.

(ii) $\lambda(\cdot)=\Sigma_jW_j\lambda_j(\cdot)W_j^*$ implies $\lambda^\xi(\cdot)=\Sigma_j\xi(W_j)\lambda_j^\xi(\cdot)\xi(W_j)^*$ and $(\lambda\circ\sigma)^\xi=\lambda^\xi\circ\sigma^\xi$. Further, if $\sigma(\cdot)=V^*\lambda(\cdot)V$ where $V\in(\sigma,\lambda)$, i.e., $V\sigma(\cdot)=\lambda(\cdot)V$ then $\xi(V)\sigma^\xi(\cdot)=\lambda^\xi(\cdot)\xi(V)$ and $\sigma^\xi(\cdot)=\xi(V)^*\lambda^\xi(\cdot)\xi(V)$.

In particular, if $\lambda\cong\sigma$ then $\lambda^\xi\cong\sigma^\xi$.

Proof of Theorem 4.10: (i) Let $\sigma\in\text{Ob}\,\mathcal{T}^\xi$. Then there is a $\mathcal{G}$-invariant algebraic Hilbert space $\mathcal{H}\subset\mathcal{L}$ such that $\sigma(X)=\Sigma_j\Psi_jX\Psi_j^*$, $X\in\xi(\mathcal{A})$, where $\{\Psi_j\}_j$ denotes an orthonormal basis of $\mathcal{H}$. On

the other hand, there is a corresponding $\mathcal{G}$-invariant Hilbert space $\mathcal{K}\subset\mathcal{F}$ such that $\mathcal{H}$ and $\mathcal{K}$ carry unitarily equivalent representations of $\mathcal{G}$. In $\mathcal{K}$ we choose an orthonormal basis $\{\Phi_j\}_j$ such that the representation matrix of $\mathcal{G}$ in $\mathcal{H}$ with respect to $\{\Psi_j\}_j$ coincides with that in $\mathcal{K}$ with respect to $\{\Phi_j\}_j$. Then $\xi(\mathcal{K})$ transforms under $\mathcal{G}$ with respect to $\{\xi(\Phi_j)\}_j$ with the same representation matrix. Now we set

$$V := \sum_j \Psi_j \xi(\Phi_j)^* \in \mathcal{L}.$$

Obviously, V is unitary and $g^\xi(V)=V$ for all $g\in\mathcal{G}$, i.e., $V\in\xi(\mathcal{A})$. Then $V\xi(\Phi_j)=\Psi_j$ or $\mathcal{H}=V\xi(\mathcal{K})$ and $\sigma=\mathrm{Ad}\,V\circ\rho_{\mathcal{K}}^\xi$.

(ii) According to Corollary 4.9 and $(\mathrm{Ob}\,\mathcal{T})^\xi\subseteq\mathrm{Ob}\,\mathcal{T}^\xi$ the image $\mathcal{C}^\xi$ of an equivalence class $\mathcal{C}\subset\mathrm{Ob}\,\mathcal{T}$ is contained in a unique equivalence class of $\mathrm{Ob}\,\mathcal{T}^\xi$. But (i) says that every equivalence class $\mathcal{E}$ of $\mathrm{Ob}\,\mathcal{T}^\xi$ is an image $\mathcal{E}=\mathcal{C}^\xi$.

Proof of Lemma 4.11: Let $A\in(\sigma,\tau)_{\mathcal{A}}$, then it follows immediately from $A\sigma(B)=\tau(B)A$, $B\in\mathcal{A}$ that $\xi(A)\sigma^\xi(\xi(B))=\tau^\xi(\xi(B))\xi(A)$ for all $B\in\mathcal{A}$. Recall that $\xi(\mathcal{A})$ is the fixed point algebra of $\mathcal{G}^\xi$.

Proof of Proposition 4.12: (i) This is obvious because the union $\cup_\gamma\mathcal{N}_\gamma$ of orthonormal bases $\mathcal{N}_\gamma$ of $\mathcal{H}_\gamma$ is an $\mathcal{A}$-left module basis of $\mathcal{F}_{\mathrm{fin}}$.

(ii) By a straightforward calculation one obtains for all $F\in\mathcal{F}$ that

$$\langle\xi(F),\xi(F)\rangle_{\xi(\mathcal{A})}=\xi(\langle F,F\rangle_{\mathcal{A}})$$

and

$$|\xi(F)|_{\xi(\mathcal{A})}=\|\xi(\langle F,F\rangle_{\mathcal{A}})\|^{1/2}\leqslant\|\langle F,F\rangle_{\mathcal{A}}\|^{1/2}=|F|_{\mathcal{A}},$$

i.e., ξ is continuous with respect to the norm $|\cdot|_{\mathcal{A}}$. Now let $F\in\mathrm{clo}_{|\cdot|_{\mathcal{A}}}(\mathrm{Ker}\,\xi\cap\mathcal{F}_{\mathrm{fin}})$, hence there is a sequence $\{F_n\}\subset\mathrm{Ker}\,\xi\cap\mathcal{F}_{\mathrm{fin}}$ such that $|F_n-F|_{\mathcal{A}}\to 0$. Then $\xi(F)=0$ follows. Conversely, let $F\in\mathrm{Ker}\,\xi$. Recall $\xi\circ\Pi_\gamma=\Pi_\gamma^\xi\circ\xi$ which implies $\Pi_\gamma F\in\mathrm{Ker}\,\xi$. Now, according to Remark 2.5 (iv) we have $F=\Sigma_\gamma\Pi_\gamma F$ with respect to the $|\cdot|_{\mathcal{A}}$-norm convergence. This implies

$$F\in\mathrm{clo}_{|\cdot|_{\mathcal{A}}}(\mathrm{Ker}\,\xi\cap\mathcal{F}_{\mathrm{fin}}).$$

Proof of Theorem 4.14: (i) Since $\{\mathcal{F},\mathcal{G}\}$ is minimal and regular, there exists an assignment $\sigma\to\mathcal{H}_\sigma$ such that an admissible (DR-) subcategory $\mathcal{T}_{\mathbb{C}}$ can be defined by

$$(\sigma,\tau)_{\mathcal{A},\mathbb{C}} := (\mathcal{H}_\sigma,\mathcal{H}_\tau),$$

cf. Theorem 2.25. Now we use the morphism ξ to define a corresponding subcategory $\mathcal{T}_{\mathbb{C}}^\xi$ for $\xi(\mathcal{T})$. Recall $\mathrm{Ob}\,\xi(\mathcal{T})=(\mathrm{Ob}\,\mathcal{T})^\xi\subset\mathrm{Ob}\,\mathcal{T}^\xi$. We set

$$\mathrm{Ob}\,\mathcal{T}_{\mathbb{C}}^\xi := \mathrm{Ob}\,\xi(\mathcal{T}).$$

Let $\lambda,\sigma\in\mathrm{Ob}\,\mathcal{T}$. Then λ^ξ, $\sigma^\xi\in\mathrm{Ob}\,\xi(\mathcal{T})$ and the arrows are defined by

$$(\sigma^\xi,\tau^\xi)_{\xi(\mathcal{A}),\mathbb{C}} := \xi((\sigma,\tau)_{\mathcal{A},\mathbb{C}})=(\xi(\mathcal{H}_\sigma),\xi(\mathcal{H}_\tau)).$$

Then

$$(\iota^\xi,\iota^\xi)_{\xi(\mathcal{A}),\mathbb{C}}=\xi((\iota,\iota)_{\mathcal{A},\mathbb{C}})=\xi(\mathbb{C}\,\mathbb{I})=\mathbb{C}\xi(\mathbb{I}).$$

It is straightforward to show that $\mathcal{T}_{\mathbb{C}}^\xi$ has direct sums and subobjects [in the latter case note that if F is a nontrivial projection from $(\sigma^\xi,\sigma^\xi)_{\xi(\mathcal{A}),\mathbb{C}}$ then there is a nontrivial projection $E\in(\sigma,\sigma)_{\mathcal{A},\mathbb{C}}$ such that $F=\xi(E)$ because the ($\mathcal{G}$ -invariant) matrix $\{p_{j,k}\}_{j,k}$ of F with respect to $\{\xi(\Phi_{\sigma,j})\}_j$, where the $\Phi_{\sigma,j}$ form an orthonormal basis of $\mathcal{H}_\sigma$, can be used to define a corresponding E in $(\sigma,\sigma)_{\mathcal{A},\mathbb{C}}$]. Furthermore, the permutation and conjugation structures of $\mathcal{T}_{\mathbb{C}}$ survive the morphism ξ. Thus $\mathcal{T}_{\mathbb{C}}^\xi$ is

a DR-category. We use the notation $\mathcal{T}^{\xi}_{\mathbb{C}}=\xi(\mathcal{T}_{\mathbb{C}})$. [This result means, the Hilbert system $\{\xi(\mathcal{F}),\mathcal{G}\}$ is regular.]

(ii) First let $\xi(\mathcal{A})'\cap\xi(\mathcal{F})=\xi(Z(\mathcal{A}))$. Then, according to Theorem 2.25, property P.2 can be fulfilled by an appropriate subcategory of the form described before. Second, let property P.2 be satisfied. Then $\xi(\mathcal{T}_{\mathbb{C}})$ is an admissible (DR-) subcategory of $\xi(\mathcal{T})$. Therefore, according to Theorem 2.27 there is a corresponding minimal and regular Hilbert extension $\widetilde{\mathcal{F}}$ of $\xi(\mathcal{A})$. The uniqueness part of Theorem 2.27 gives that $\widetilde{\mathcal{F}}$ and $\xi(\mathcal{F})$ are $\mathcal{A}$-module isomorphic, hence $\xi(\mathcal{A})'\cap\xi(\mathcal{F})=Z(\xi(\mathcal{A}))$ is also true.

(iii) The inclusion $\supseteq$ is obvious (see Lemma 4.11). The assertion is

$$(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A})}\subseteq\xi((\sigma,\tau)_{\mathcal{A}}). \tag{9}$$

First we prove this inclusion for the admissible subcategory, i.e., we assert

$$(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A}),\mathbb{C}}\subseteq\xi((\sigma,\tau)_{\mathcal{A}}).$$

This is obvious by

$$(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A}),\mathbb{C}}=\xi((\sigma,\tau)_{\mathbb{C}})\subset\xi((\sigma,\tau)_{\mathcal{A}}).$$

Second, recall that $\xi((\sigma,\tau)_{\mathcal{A}})$ is a right module with respect to $\sigma^{\xi}(\xi(Z(\mathcal{A})))$ and a left module with respect to $\tau^{\xi}(\xi(Z(\mathcal{A})))$. On the other hand, $(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A})}$ is a right module with respect to $\sigma^{\xi}(Z(\xi(\mathcal{A})))$ and a left module with respect to $\tau^{\xi}(Z(\xi(\mathcal{A})))$. Further, according to P.2. $(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A}),\mathbb{C}}$ is a generating subset for this module. Since, by assumption, $Z(\xi(\mathcal{A}))$ and $\xi(Z(\mathcal{A}))$ coincide, the inclusion (9) follows.

(iv) This follows directly from $\xi(\mathcal{A})'\cap\xi(\mathcal{F})=Z(\xi(\mathcal{A}))$ and the fact that the unitary equivalence classes of $\mathcal{T}^{\xi}$ and $\xi(\mathcal{T})$ coincide.

Proof of Theorem 4.15: Since $\mathcal{T}_{\mathbb{C}}$ is an admissible (DR-) subcategory of $\mathcal{T}$ we can apply Theorem 2.27, i.e., there is a corresponding minimal and regular Hilbert extension $\{\mathcal{F},\mathcal{G}\}$ of $\mathcal{A}$. Therefore the arrows of the category $\mathcal{T}_{\mathbb{C}}$ are given by

$$(\sigma,\tau)_{\mathcal{A},\mathbb{C}}=(\mathcal{H}_{\sigma},\mathcal{H}_{\tau}), \tag{10}$$

where the Hilbert spaces $\mathcal{H}_{\sigma}$, $\mathcal{H}_{\tau}$ generate the endomorphisms σ, τ, respectively.

Now it is not hard to show that the morphism ξ can be extended to a morphism of $\mathcal{F}$ by setting

$$\xi(\Phi_{\lambda,j}):=\Phi_{\lambda,j}, \tag{11}$$

where λ runs through a complete system of irreducible and mutually disjoint endomorphisms and $\{\Phi_{\lambda,j}\}$ denotes an orthonormal basis of the Hilbert space $\mathcal{H}_{\lambda}$ which generates λ (recall and use Proposition 4.12). This morphism satisfies the assumptions of Theorem 4.8. The corresponding Hilbert system is denoted by $\{\mathcal{F}^{\xi},\mathcal{G}\}$ (recall that $\mathcal{G}^{\xi}\cong\mathcal{G}$). Equations (10) and (11) imply

$$\sigma^{\xi}(\xi(\mathcal{A}))=\sum_{j}\Phi_{\lambda,j}\xi(A)\Phi^{*}_{\lambda,j}\quad\text{and}\quad\xi((\sigma,\tau)_{\mathcal{A},\mathbb{C}})=(\sigma,\tau)_{\mathcal{A},\mathbb{C}}.$$

By assumption (iii) we have $\xi((\sigma,\tau)_{\mathcal{A}})=(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A})}$. Since $(\sigma,\tau)_{\mathcal{A},\mathbb{C}}\subset(\sigma,\tau)_{\mathcal{A}}$ we have $\xi((\sigma,\tau)_{\mathcal{A},\mathbb{C}})\subset(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A})}$. Therefore the subcategory $\mathcal{T}^{\xi}_{\mathbb{C}}$ of $\xi(\mathcal{T})$ defined by

$$(\sigma^{\xi},\tau^{\xi})_{\xi(\mathcal{A}),\mathbb{C}}:=\xi((\sigma,\tau)_{\mathcal{A},\mathbb{C}}=(\sigma,\tau)_{\mathcal{A},\mathbb{C}}$$

is a DR-category.

Now we prove property P.2 for $\mathcal{T}^{\xi}_{\mathbb{C}}$. We must show

$$\sigma^{\xi}(Z(\xi(\mathcal{A})))(\lambda^{\xi},\sigma^{\xi})_{\xi(\mathcal{A}),\mathbb{C}}\lambda^{\xi}(Z(\xi(\mathcal{A})))=(\lambda^{\xi},\sigma^{\xi})_{\xi(\mathcal{A})}.$$

The left-hand side equals

$$\sigma^{\xi}\xi(Z(\mathcal{A}))(\lambda^{\xi},\sigma^{\xi})_{\xi(\mathcal{A}),\mathbb{C}}\lambda^{\xi}(\xi(Z(\mathcal{A}))) = \xi(\sigma(Z(\mathcal{A})))(\lambda^{\xi},\sigma^{\xi})_{\xi(\mathcal{A}),\mathbb{C}}\xi(\lambda(Z(\mathcal{A})))$$
$$= \xi(\sigma(Z(\mathcal{A})))\xi((\lambda,\sigma)_{\mathcal{A},\mathbb{C}})\xi(\lambda(Z(\mathcal{A})))$$
$$= \xi(\sigma(Z(\mathcal{A}))(\lambda,\sigma)_{\mathcal{A},\mathbb{C}}\lambda(Z(\mathcal{A}))) = \xi((\lambda,\sigma)_{\mathcal{A}})$$

and this coincides, by assumption, with the right-hand side.

Now we can apply Theorem 2.27 to obtain a further Hilbert extension $\{\tilde{\mathcal{F}}^{\xi},\mathcal{G}^{\xi}\}$ where again $\mathcal{G}^{\xi}\cong\mathcal{G}$. Using the uniqueness part of Theorem 2.27 we obtain that both Hilbert extensions are $\xi(\mathcal{A})$-module isomorphic.

Proof of Proposition 5.1: It suffices to show that there is one Dirac state, i.e., a state $\omega \in \mathfrak{S}(\mathcal{A})$ with $\omega(\mathcal{U})=1$. Recall the homomorphism $\zeta:\mathcal{E}\to\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)$. Let $\omega_0 \in \mathfrak{S}(\mathrm{CAR}(\mathcal{H}))$ be that quasifree state which is zero on any normal-ordered monomial of $a(f)$ and $a^*(h)$ of degree greater or equal to 1. Then ω_0 is invariant with respect to $\tilde{\gamma}_f$ for all $f \in \mathcal{S}(\mathbb{R}^4)\cup\mathbb{R}$. Moreover, since $L(S)\subset\mathrm{Ker}\,B$, there is a state $\omega_1\in\mathfrak{S}(\mathrm{CCR}(S,B))$ such that $\omega_1(\delta_{Lf})=1$ for all $f\in S$. Then $\omega_2 := \omega_0\otimes\omega_1 \in \mathfrak{S}(\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B))$ is a $\tilde{\gamma}_f\otimes\iota$-invariant state on $\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)$ such that $\omega_2(\mathbb{I}\otimes\delta_{Lf})=1$ for all $f\in S$. From this we define a state on $\mathcal{E}$ by $\tilde{\omega}_2 := \omega_2\circ\zeta$ and since $\zeta\circ\beta_{\gamma_f}=\tilde{\gamma}_f\otimes\iota$, it follows that $\tilde{\omega}_2$ is β_G-invariant on $\mathcal{E}$. Thus $\tilde{\omega}_2$ extends to a state ω_3 on $\mathcal{A}=G\times_{\beta}\mathcal{E}$ by $\omega_3(U_g)=1$ for all $g\in G$, where U_g denotes the unitary implementer for β_g. So $\omega_3\in\mathfrak{S}(\mathcal{A})$ is a Dirac state with respect to the unitaries $U_G\cup\delta_{LS}$. Since the maximal set of constraint unitaries for a Dirac state is a group, it follows that for the products $V_f=\delta_{-Lf}\cdot U_{\gamma_f}$ we have $\omega_3(V_f)=1$ for all f, i.e., ω_3 is a Dirac state with respect to $\mathcal{U}$, hence $\mathcal{U}$ is first class.

Proof of Lemma 5.4: Note that ρ_k on the unitary implementers $\rho_k:U_G\to\mathcal{A}$ is a faithful group homomorphism. This is because it is the pointwise product of the identity map ι with the character $\chi_k:U_G\to\mathbb{C}$ given by $\chi_k(U_{\gamma_{f+t}}) := e^{itk}$, $t\in\mathbb{R}$, $f\in\mathcal{S}(\mathbb{R}^4)$. Furthermore, $\mathcal{A}=C^*(\rho_k(U_G)\cup\mathcal{E})$. Thus the pair $\{\rho_k(U_G),\mathcal{E}\}$ is also a covariant system for the action $\beta:G\to\mathrm{Aut}\,\mathcal{E}$ (cf. Step 3), hence by the universal property of cross products (cf. Ref. 25) there is a *-homomorphism $\theta:\mathcal{A}\to\mathcal{A}$ such that $\theta(A)=A$ for $A\in\mathcal{A}$, and $\theta(U_g)=\rho_k(U_g)\equiv$ implementing unitary of the second system. Then θ coincides with the definition of ρ_k on the generating elements, so it follows that ρ_k extends uniquely to a homomorphism. Since it is clear that ρ_k is bijective (its inverse is ρ_{-k}) it follows that ρ_k is an automorphism of $\mathcal{A}$.

Proof of Proposition 5.6: Proof by contradiction. Let $k\neq 0$ and assume $\rho_k\in\mathrm{Inn}\,\mathcal{A}$, i.e., $\rho_k=\mathrm{Ad}\,V$ for some unitary $V\in\mathcal{A}$. Recall the homomorphism

$$\zeta:\mathcal{E}\to\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)$$

encountered in Step 3. Since (S,B) is degenerate, $\zeta(\mathcal{E})$ is not simple which will be inconvenient in the proof below. Choose therefore a maximal ideal $\mathcal{I}$ of $\mathrm{CCR}(S,B)$ [necessarily associated with a character of the center $Z(\mathrm{CCR}(S,B))$], and let

$$\eta:\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)\to\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)/\mathcal{I}$$

be the factorization by the ideal $\mathbb{I}\otimes\mathcal{I}$. Then the composition

$$\xi := \eta\circ\zeta:\mathcal{E}\to\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)/\mathcal{I}$$

is a homomorphism of which the image is a simple algebra.

Now the action $\beta:G\to\mathrm{Aut}\,\mathcal{E}$ (Step 4) only affects $\mathrm{CAR}(\mathcal{H})$ in $\mathcal{E}$, so preserves the ideal generated by the commutators $[\mathrm{CAR}(\mathcal{H}),\mathrm{CCR}(S,B)]$ in $\mathcal{E}$ as well as the ideal $\mathbb{I}\otimes\mathcal{I}$. Thus each β_g can be taken through the homomorphism ξ to define an action $\beta^{\xi}:G\to\mathrm{Aut}(\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)/\mathcal{I})$ and it is just $\beta^{\xi}_{\gamma_f}=\tilde{\gamma}_f\otimes\iota$. Thus we can extend ξ from $\mathcal{E}$ to $\mathcal{A}=G\overset{\times}{_{\beta}}\mathcal{E}$ to get a surjective homomorphism

$$\xi:\mathcal{A}\to \underset{\beta^{\xi}}{G\times}(\mathrm{CAR}(\mathcal{H})\otimes \mathrm{CCR}(S,B)/\mathcal{I}).$$

Now $\rho_k\in \mathrm{Aut}\,\mathcal{A}$ only affects U_G, leaving $\mathcal{E}$ invariant, hence it preserves $\mathrm{Ker}\,\xi\subset\mathcal{A}$. Thus ρ_k can be factored through ξ to obtain the automorphisms $\rho_k^{\xi}\in \mathrm{Aut}\,\xi(\mathcal{A})$ by

$$\rho_k^{\xi}(\xi(A)) := \xi(\rho_k(A)) \quad \forall\, A\in\mathcal{A}, \quad \text{and so } \rho_k^{\xi}=\mathrm{Ad}\,\xi(V). \tag{12}$$

Recall now that each element of the discrete crossed product $\xi(\mathcal{A})=G\underset{\beta^{\xi}}{\times}\xi(\mathcal{E})$ [with $\xi(\mathcal{E})=\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,R)/\mathcal{I}$] can be written as a C*-norm convergent series $\Sigma_{n=1}^{\infty}B_nU_{g_n}$ where $B_n\in\xi(\mathcal{E})$ and $g_n\in G$ (with g_n distinct for different n) and that the unitaries U_G form a left $\xi(\mathcal{E})$-module basis. In particular, for the implementing unitaries $\xi(V)$ of ρ_k^{ξ} we have a series $\xi(V)=\Sigma_{n=1}^{\infty}B_nU_{g_n}$, $B_n\in\xi(\mathcal{E})\backslash 0$. Since $\rho_k\restriction\mathcal{E}=\iota$, it follows from Eq. (12) that $\xi(V)A=A\xi(V)$ for all $A\in\xi(\mathcal{E})$, i.e.,

$$A\xi(V)=\sum_{n=1}^{\infty}AB_nU_{g_n}=\xi(V)A=\sum_{n=1}^{\infty}B_nU_{g_n}A=\sum_{n=1}^{\infty}B_n\beta_{g_n}^{\xi}(A)U_{g_n}$$

for all $A\in\xi(\mathcal{E})$. So by the basis property of U_G we have

$$AB_n=B_n\beta_{g_n}^{\xi}(A) \quad \forall\, A\in\xi(\mathcal{E})=\mathrm{CAR}(\mathcal{H})\otimes\mathrm{CCR}(S,B)/\mathcal{I}. \tag{13}$$

Since $\beta_{g_n}^{\xi}\restriction\mathrm{CCR}(S,B)/\mathcal{I}=\iota$, this implies that $B_n\in(\mathrm{CCR}(S,B)/\mathcal{I})'$. From the fact that $\mathrm{CCR}(S,B)/\mathcal{I}$ is simple (hence has trivial center) this means that $B_n\in\mathrm{CAR}(\mathcal{H})\otimes\mathbb{1}$, and hence Eq. (13) claims that B_n is a nonzero intertwiner between ι and $\beta_{g_n}^{\xi}$ in $\mathrm{CAR}(\mathcal{H})$. We next prove that B_n is invertible, in which case $\beta_{g_n}^{\xi}$ becomes inner on $\mathrm{CAR}(\mathcal{H})$.

Let $\pi:\mathrm{CAR}(\mathcal{H})\to\mathcal{B}(\mathcal{L})$ be any faithful irreducible representation of $\mathrm{CAR}(\mathcal{H})$ on a Hilbert space $\mathcal{L}$, e.g., the Fock representation, and let $\psi\in\mathrm{Ker}\,\pi(B_n)$. Then by (13),

$$\pi(B_nA)\psi=\pi(\beta_{g_n^{-1}}(A))\pi(B_n)\psi=0 \quad \forall\, A\in\mathrm{CAR}(\mathcal{H}).$$

Thus $\pi(\mathrm{CAR}(\mathcal{H}))\psi\subseteq\mathrm{Ker}\,\pi(B_n)$. However, in an irreducible representation every nonzero vector is cyclic, so either $\psi=0$ or $\pi(B_n)=0$, and the latter case is excluded by $B_n\neq 0$, π faithful. Thus $\psi=0$, i.e., we have shown that $\mathrm{Ker}\,\pi(B_n)=\{0\}$. Moreover by Eq. (13) we have

$$\pi(A)\pi(B_n)\varphi=\pi(B_n)\pi(\beta_{g_n}(A))\varphi \quad \forall\,\varphi\in\mathcal{L}\backslash 0, \quad A\in\mathrm{CAR}(\mathcal{H}),$$

hence $\pi(\mathrm{CAR}(\mathcal{H}))(\pi(B_n)\varphi)\subseteq\mathrm{Ran}\,\pi(B_n)$ for all $\varphi\in\mathcal{L}\backslash 0$. Now $\pi(B_n)\varphi\neq 0$ [by $\mathrm{Ker}\,\pi(B_n)=\{0\}$] and so by Dixmier 2.8.4 (Ref. 26) we have that $\pi(\mathrm{CAR}(\mathcal{H}))(\pi(B_n)\varphi)=\mathcal{L}$ (no closure is necessary). Thus $\mathrm{Ran}\,\pi(B_n)=\mathcal{L}$, i.e., $\pi(B_n)$ is invertible, and so since π is faithful (hence preserves the spectrum of an element) it follows that B_n is also invertible in $\mathrm{CAR}(\mathcal{H})$.

Using the fact that B_n is invertible, Eq. (13) becomes $\beta_{g_n}(A)=B_n^{-1}AB_n$ for all $A\in\mathrm{CAR}(\mathcal{H})$. Since β_{g_n} is a *-homomorphism, this implies that $B_n^{-1}A^*B_n=B_n^*A^*(B_n^{-1})^*$, i.e., $B_nB_n^*A^*=A^*B_nB_n^*$ for all $A\in\mathrm{CAR}(\mathcal{H})$, and since $\mathrm{CAR}(\mathcal{H})$ has trivial center, this means $B_nB_n^*\in\mathbb{C}\,\mathbb{1}$. Set $B_nB_n^*=:t_n$ (necessarily $t_n>0$) then $U_n:=B_n/\sqrt{t_n}$ satisfies $U_nU_n^*=\mathbb{1}$. By substituting A by $\beta_{g_n^{-1}}(A)$ in (13) we also obtain $B_n^*B_n\in\mathbb{C}\,\mathbb{1}$ by the above argument, then using $t_n=\|B_nB_n^*\|=\|B_n\|^2=\|B_n^*B_n\|=B_n^*B_n$ we get also $U_n^*U_n=\mathbb{1}$. Thus

$$\beta_{g_n}(A)=B_n^{-1}AB_n=\left(\frac{B_n}{\sqrt{t_n}}\right)^{-1}A\left(\frac{B_n}{\sqrt{t_n}}\right)=U_n^*AU_n$$

for $A\in\mathrm{CAR}(\mathcal{H})$, i.e., β_{g_n} is inner on $\mathrm{CAR}(\mathcal{H})$. Recall however, that on $\mathrm{CAR}(\mathcal{H})$, β_{g_n} is just an automorphism $\tilde{\gamma}_{f_n}$ for some $f_n\in\mathcal{S}(\mathbb{R}^4)+\mathbb{R}$, coming from a Bogoliubov transformation, $\tilde{\gamma}_{f_n}(\Phi(k)):=\Phi(T_{f_n}k)$ (cf. Step 4). So for β_{g_n} to be inner on $\mathrm{CAR}(\mathcal{H})$, this means that either of

$I \pm T_{f_n}$ must be trace-class (cf. Theorem 4.1, p. 48 of Ref. 24 or Theorem 4.1.4 in Ref. 27). However,

$$T_{f_n}(h_1 \oplus h_2) := e^{-if_n} h_1 \oplus e^{if_n} h_2 \quad \forall\, h_i \in \mathcal{H} = L^2(\mathbb{R}^4).$$

Now for any f_n such that $T_{f_n} \neq I$, it is clear that the multiplication operators on $L^2(\mathbb{R}^4)$ by $(I \pm e^{\pm if_n})$ cannot be trace-class. This contradicts our finding that β_{g_n} is inner if $g_n \neq e$, hence only $g_n = e$ is possible in the series $\xi(V) = \Sigma_{n=1}^{\infty} B_n U_{g_n}$, i.e., $\xi(V) = B \cdot U_e$, $B \in \xi(\mathcal{E}) \backslash 0$. But in this case, Eq. (13) becomes $AB = BA$ for all $A \in \xi(\mathcal{E})$ and so since $\xi(\mathcal{E})$ is simple, $B \in \mathbb{C}\,\mathbb{I}$. This however implies that $\iota = \mathrm{Ad}\ \xi(V) = \rho_k^{\xi}$ which cannot be because $\rho_k(U_{\gamma_t}) = e^{ikt} U_{\gamma_t}$ factors unchanged through ξ. From this contradiction, it follows that our initial assumption $\rho_k \in \mathrm{Inn}\ \mathcal{A}$ is false.

VII. CONCLUSIONS

In this paper, we studied the question of under what conditions, and how much of the superselection structures will survive the constraining procedure. We did this in the context of DR theory (extended to the case of nontrivial center of the observable algebra), and the method of the T-procedure for enforcing constraints.

Since the T-procedure involves a restriction and a factoring, this meant that we had to analyze for Hilbert systems their behavior first, with respect to restriction, and then with respect to general morphisms (this seems to be of independent interest). Finally, in Sec. IV E we combined these to obtain conditions for a Hilbert system to pass through a constraining. We also obtained conditions for the preservation of the regularity property, and partial conditions for the preservation of the minimality property as well as Property B.

In Sec. V we developed an example based on the Maxwell constraint of interacting QED. In this setting the superselection structure came explicitly from the usual global electromagnetic charge, and we could verify the basic compatibility conditions on the endomorphisms, but not the additional conditions of regularity, minimality and Property B.

Our results suggest the following further directions: to solve the compatibility problem of minimality and Property B with respect to constraining; to obtain a physically convincing example with a non-Abelian global gauge group where supersymmetry passes through the constraining.

There is also another possible line of analysis; since the initial constraint system contains nonphysical information, the supersymmetry structures need not be precisely defined as in the DR theory, indeed one can ask for a "weak" supersymmetry structure, with the only requirement on it, that after constraining it produces the usual DR structures on the physical algebra. (This line of thought is parallel to the development of "weak" Haag-Kastler axioms in Ref. 5.) This will enlarge the set of examples of systems with both supersymmetry and constraints.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 082304 (2005)

Operator product expansions as a consequence of phase space properties

Henning Bostelmann[a)]
Institut für Theoretische Physik, Universität Göttingen, 37077 Göttingen, Germany

(Received 6 March 2005; accepted 27 June 2005; published online 19 August 2005)

The paper presents a model-independent, nonperturbative proof of operator product expansions in quantum field theory. As an input, a recently proposed phase space condition is used that allows a precise description of point field structures. Based on the product expansions, we also define and analyze normal products (in the sense of Zimmermann). © *2005 American Institute of Physics.* [DOI: 10.1063/1.2007567]

I. INTRODUCTION

Quantum fields, representing observables sharply localized in space–time, generally are quite singular objects.[1] In particular, their products at coinciding space–time points are ill-defined and lead to divergences. Since such products play a vital role in the definition and classification of models (by means of path integrals or field equations), a thorough understanding and precise description of their singularities is of considerable interest.

A step toward this goal was taken by Wilson,[2] who proposed that a product of two fields $\phi(x)$ and $\phi'(y)$ should be expandable into a series,

$$\phi(x)\cdot\phi'(y)=\sum_j c_j(x-y)\phi_j\left(\frac{x+y}{2}\right), \tag{1.1}$$

where $\phi_j(\cdot)$ are local fields as well, and $c_j(\cdot)$ are (generalized) functions which show singularities at the origin. This operator product expansion should then be valid at short distances, i.e., in the limit $x\to y$.

The operator product expansion provides a detailed description of the product's singular behavior. It may furthermore serve to define "normal products" of fields, in generalization of the Wick product. Any field ϕ_j in Eq. (1.1) whose coefficient $c_j(\cdot)$ does not vanish in the limit may be taken as a candidate for such a normal product.[3]

However, it remains to clear up in which sense and under which conditions Eq. (1.1) holds precisely. The expansion has originally been proposed in perturbation theory[2,3] and has widely been used as a tool in Lagrangian field theory.[4] Investigations in the framework of axiomatic field theory[5] aimed at a rigorous proof; it seems that the Wightman axioms are too weak to ensure existence of the expansion structure, and that additional conditions are needed. Unfortunately, these conditions could not be connected directly to physical properties of the theory. More detailed results are available in conformal field theory,[6] especially in $1+1$-dimensional models.[7] Here the expansion is a consequence of conformal symmetry. These methods cannot be carried over to physically more realistic situations, though.

This paper presents an approach that explains operator product expansions in a model-independent way, based on physically motivated assumptions. We make use of the theory's phase space behavior, which has recently been shown to have a strong impact on the field content.[8,9] A phase space condition proposed in Ref. 9 can be taken as a physically natural assumption to ensure

[a)]Electronic mail: bostelm@theorie.physik.uni-goettingen.de

a regular short distance behavior. On these grounds, we will establish operator product expansions rigorously in the sense of an asymptotic series. Furthermore, we will define normal products of fields and investigate their properties.

In Sec. II, we recall the relevant facts and results on the point field structure established in Ref. 9, which lie at the root of our investigation. Section III defines products of pointlike fields and gives a proof of their product expansion. Normal products and their properties are discussed in Sec. IV. We end with a brief outlook on the classification of models in Sec. V.

The present work is based on the author's thesis;[10] it presents an abbreviated and partially improved version of material developed there. The reader is referred to the original text for a more detailed exposition, especially regarding mathematical aspects and the development of proofs.

II. POINTLIKE FIELDS AND PHASE SPACE PROPERTIES

It has been outlined in Refs. 8 and 11 that a strong connection exists between the phase space properties of a quantum field theory and its point field structure. A natural phase space condition, similar but not identical to the usual compactness or nuclearity conditions,[12] was proposed in Ref. 9 and shown to allow a precise description of the theory's field content. We will give a brief review of the results established in Ref. 9, mainly to fix our notation.

We start from a quantum field theory in the framework of local quantum physics[13] in the vacuum sector, i.e., given by a net of observable algebras $\mathcal{O}\mapsto\mathfrak{A}(\mathcal{O})$, where $\mathcal{O}\subset\mathcal{M}:=\mathbb{R}^{s+1}$ are open bounded regions in Minkowski space of $s+1$ space–time dimensions, and $\mathfrak{A}(\mathcal{O})$ are W^*-algebras acting on some common Hilbert space $\mathcal{H}$. We assume the standard axioms: isotony, locality, covariance with respect to some strongly continuous unitary representation $U(x,\Lambda)$ of the connected Poincaré group $\mathfrak{P}_+^\uparrow$, and the spectrum condition (positivity of energy). We will denote the elements of the translation subgroup of $\mathfrak{P}_+^\uparrow$ as $U(x)=\exp(iP_\mu x^\mu)$, where $H:=P_0$ is the Hamiltonian; its spectral projections will be written as $P_H(E)$. Σ stands for the predual space of $\mathfrak{B}(\mathcal{H})$, i.e. the space of weak-$*$-continuous linear functionals on $\mathfrak{B}(\mathcal{H})$, the positive normed elements of which represent the physical states of the system.

As we restrict our attention to point fields fulfilling polynomial H-bounds (cf. Ref. 1), we consider the space

$$\mathcal{C}^\infty(\Sigma):=\bigcap_{\ell>0} R^\ell\Sigma R^\ell, \quad \text{where } R=(1+H)^{-1}, \tag{2.1}$$

equipped with the topology of simultaneous convergence in the norms $\|\sigma\|^{(\ell)}:=\|R^{-\ell}\sigma R^{-\ell}\|$, $\ell>0$. We also make use of its dual space $\mathcal{C}^\infty(\Sigma)^*$, equipped with the weak topology; its elements are linear forms ϕ which fulfill

$$\|\phi\|^{(\ell)}:=\|R^\ell\phi R^\ell\|<\infty \quad \text{for some } \ell>0. \tag{2.2}$$

For linear maps $\alpha:\mathcal{C}^\infty(\Sigma)^*\to\mathcal{C}^\infty(\Sigma)^*$, we sometimes consider

$$\|\alpha\|^{(\ell,\ell')}:=\|R^{\ell'}\alpha(R^{-\ell}\cdot R^{-\ell})R^{\ell'}\| \quad (\ell,\ell'>0) \tag{2.3}$$

in case this expression is finite.

Let Ψ be the space of linear continuous maps from $\mathcal{C}^\infty(\Sigma)$ to Σ, where Σ is equipped with the norm topology. For our setup, the inclusion map $\Xi\in\Psi$ plays a central role,

$$\Xi:\mathcal{C}^\infty(\Sigma)\to\Sigma, \quad \sigma\mapsto\sigma. \tag{2.4}$$

In order to analyze this map in the short distance limit, we refer to the algebras $\mathfrak{A}(r):=\mathfrak{A}(\mathcal{O}_r)$, where $\mathcal{O}_r$ is the standard double cone of radius $r>0$ centered at the origin, then define for $\psi\in\Psi$,

$$\|\psi\|_r^{(\ell)}:=\|\psi\lceil\mathfrak{A}(r)\|^{(\ell)}=\sup_{\sigma\in\Sigma}\sup_{A\in\mathfrak{A}(r)}\frac{|\psi(R^\ell\sigma R^\ell)(A)|}{\|\sigma\|\,\|A\|}, \tag{2.5}$$

which is finite for sufficiently large $\ell>0$, and for $\gamma\geqslant 0$ consider the pseudometrics,

$$\delta_\gamma(\psi) := \begin{cases} 0 & \text{if } r^{-\gamma}\|\psi\|_r^{(\ell)} \underset{r\to 0}{\to} 0 \quad \text{for some } \ell > 0, \\ 1 & \text{otherwise.} \end{cases} \tag{2.6}$$

We say that the net $\mathfrak{A}$ fulfills the *microscopic phase space condition* if for every $\gamma \geqslant 0$, there exists a map $\psi \in \Psi$ of finite rank such that

$$\delta_\gamma(\Xi - \psi) = 0. \tag{2.7}$$

It is not overly difficult to see that this condition holds for a wide range of free theories (see the Appendix of Ref. 9), and it seems plausible that the same condition is fulfilled in any model with a sufficiently regular short distance behavior. Its consequences are the following: There exists an increasing sequence of finite-dimensional vector spaces $\Phi_\gamma \subset \mathcal{C}^\infty(\Sigma)^*$, $\gamma \geqslant 0$, the elements of which are Wightman fields located at $x=0$. Their union $\cup_\gamma \Phi_\gamma =: \Phi_{\mathrm{FH}}$ exhausts the field content of the theory as investigated by Fredenhagen and Hertel.[1] Given $\phi \in \Phi_{\mathrm{FH}}$, we can find a sequence $A_r \in \mathfrak{A}(r)$ $(r>0)$ such that

$$\|\phi - A_r\|^{(\ell)} = O(r), \quad \|A_r\| = O(r^{-k}) \tag{2.8}$$

as $r \to 0$, where $k, \ell > 0$ can be chosen uniformly for all $\phi \in \Phi_\gamma$, with γ being fixed. If $p_\gamma : C^\infty(\Sigma)^* \to C^\infty(\Sigma)^*$ is any continuous projection onto Φ_γ, and $p_{\gamma *}$ its predual, then we find

$$\delta_\gamma(\Xi - \Xi \circ p_{\gamma *}) = 0. \tag{2.9}$$

[Note that a continuous projection can be found for any given finite-dimensional subspace $V \subset \mathcal{C}^\infty(\Sigma)^*$. We will require all such projections considered in the following to be continuous and refrain from noting this fact repeatedly.]

Every Φ_γ is invariant under a certain class of symmetry transformations, including Lorentz transformations, dilations and inner symmetries, provided that they exist as symmetries of the underlying net $\mathfrak{A}$. Linear differential operators act as maps $\Phi_{\mathrm{FH}} \to \Phi_{\mathrm{FH}}$ as well, but typically map Φ_γ into some larger space $\Phi_{\gamma'}$.

III. PRODUCT EXPANSIONS

Our task will now be to establish operator product expansions, assuming that the theory under discussion fulfills the microscopic phase space condition. We will prove the expansion in the form

$$\phi(x) \cdot \phi'(y) = \sum_j c_j(x,y)\phi_j(0) \quad (x,y \to 0), \tag{3.1}$$

which can easily be transformed into the more familiar form (1.1) and vice versa.

The proof is based on the following heuristic idea: Let $A, A' \in \mathfrak{A}(r)$ be two bounded localized observables, and $A(x) := U(x)AU(x)^*$, etc. Choosing a projector p_γ onto Φ_γ, the phase space property (2.9) can roughly be expressed as $\Xi \approx \Xi \circ p_{\gamma *}$ at small distances. This means

$$A(x)A'(y) \approx p_\gamma(A(x)A'(y)) \tag{3.2}$$

if x, y, and r are small enough. Expanding $p_\gamma = \Sigma_j \sigma_j(\cdot)\phi_j$ in a finite basis, this reads

$$A(x)A'(y) \approx \sum_j \sigma_j(A(x)A'(y))\phi_j \tag{3.3}$$

in the limit $x,y,r \to 0$. If now $A \approx \phi$ and $A' \approx \phi'$ in this limit, we can define $c_j(x,y) := \sigma_j(A(x)A'(y))$ and arrive at the expansion (3.1).

In order to transfer this heuristic idea into a rigorous expression for the product of pointlike fields, we will first define the product of two fields [the left-hand side of Eq. (3.1)] for spacelike-separated x and y, namely by means of approximating them with bounded observables; this is

done in Sec. III A. On these grounds, we will then establish the product expansion in Sec. III B. Some generalizations, such as products of more than two factors and products for non-spacelike-separated arguments, will be discussed in Sec. III C.

A. Spacelike products

In the following, let $\phi, \phi' \in \Phi_{\mathrm{FH}}$ be fixed. As a first step towards the expansion (3.1), we will give meaning to the *a priori* ill-defined product $\phi(x)\cdot\phi'(y)$. This is certainly possible in a distributive sense (as a product of smeared Wightman fields); however, we shall use a more direct approach here. For $(x-y)^2<0$, we will define $\phi(x)\cdot\phi'(y)$ as an element of $\mathcal{C}^\infty(\Sigma)^*$, i.e., as a sesquilinear form.

This will be achieved by an approximation with bounded operators. We choose sequences $A_r \to \phi$, $A'_r \to \phi'$ as specified in Eq. (2.8). Then it seems natural to define

$$\phi(x)\cdot\phi'(y) := \lim_{r\to 0} A_r(x)A'_r(y), \quad (x-y)^2<0. \tag{3.4}$$

We will use methods from complex analysis to establish the existence of this limit and to control the convergence dependent on x and y.

To this end, let $\sigma=(\xi|\cdot|\xi')$ be an energy-bounded functional, i.e., $\xi^{(\prime)}\in P_H(E)\mathcal{H}$ for some $E>0$. We assume $\|\sigma\|=1$. Leaving x fixed for the moment, we consider the function

$$f_r(z) = \sigma(U(x)A_rU(z)A'_rU(-x-z)), \quad z\in\mathcal{M}. \tag{3.5}$$

f is the boundary value of a function analytic on $\mathcal{M}+i\mathcal{V}_+$, where $\mathcal{V}_+$ denotes the open forward light cone. This is seen from

$$f_r(z) = \sigma(U(x)A_r\exp(iP_\mu z^\mu)A'_rU(x)^*\exp(-iP_\mu z^\mu)), \tag{3.6}$$

using the spectrum condition and the strong continuity of translations. [Note that the factor $\exp(-iP_\mu z^\mu)$ does not disturb analyticity here, since σ is energy bounded.] We can estimate the modulus of f_r on $\mathcal{M}+i\mathcal{V}_+$ as

$$|f_r(z)| \leqslant \|P_H(E)R^{-\ell}\|\,\|R^\ell A_r R^\ell\|\,\|R^{-\ell}\exp(iP_\mu z^\mu)R^{-\ell}\|\,\|R^\ell A'_r R^\ell\|\,\|R^{-\ell}P_H(E)\|\,\|P_H(E)\exp(-iP_\mu z^\mu)\|. \tag{3.7}$$

Here $\|R^\ell A_r^{[\prime]} R^\ell\|$ stays bounded in the limit $r\to 0$ if ℓ is sufficiently large. A straightforward calculation shows that

$$\|R^{-2\ell}\exp(iP_\mu z^\mu)\| \leqslant \|\mathrm{Im}\, z\|^{-2\ell}\cdot c_1, \quad \|P_H(E)\exp(-iP_\mu z^\mu)\| \leqslant e^{c_2 E\|\mathrm{Im}\, z\|} \quad \text{for } \|\mathrm{Im}\, z\|\leqslant 1, \tag{3.8}$$

where $c_1, c_2>0$ can be chosen constant if $\mathrm{Im}\, z$ varies over some open convex cone $\mathcal{C}$ with $\bar{\mathcal{C}}\subset\mathcal{V}_+$, which we keep fixed in the following. (All c_i will be positive constants in what follows.) Thus we have

$$|f_r(z)| \leqslant (1+E)^{2\ell}e^{c_2E\|\mathrm{Im}\, z\|}\|\mathrm{Im}\, z\|^{-2\ell}\cdot c_3 \quad \text{for } r\leqslant 1, \quad \mathrm{Im}\, z\in\mathcal{C}, \quad \|\mathrm{Im}\, z\|\leqslant 1. \tag{3.9}$$

By these and similar arguments, it follows in particular that $\{f_r\}_{r\leqslant 1}$ is a normal family of analytic functions on $\mathcal{M}+i\mathcal{V}_+$, i.e., uniformly bounded on compact subsets.

In just the same way, we may represent

$$\hat{f}_r(z) = \sigma(U(x+z)A'_rU(-z)A_rU(-x)) \tag{3.10}$$

as a boundary value of functions analytic on $\mathcal{M}-i\mathcal{V}_+$; similar bounds as in Eq. (3.9) can be established. If we choose z real and spacelike, the operators A_r and $A'_r(z)$ will commute for small r, hence we find

$$f_r(z) = \hat{f}_r(z) \quad \text{for } z \text{ real}, \quad z^2 < 0, \quad \text{and small } r. \tag{3.11}$$

This allows us to apply the edge of the wedge theorem to f_r and $\hat{f}_r$: They are parts of a single function f_r analytic on $\mathcal{M} \pm i\mathcal{V}_+$ and on some complex neighborhood of those real points where (3.11) holds.

Let us investigate this common analytic continuation more closely. We choose some fixed $v \in \mathcal{M}$, $u \in \mathcal{C}$ with $v^2 < 0$, $\|u\| = 1$. For r small enough, the function

$$f_{r,v,u}(t) = \begin{cases} f_r(v + tu) & \text{if } \operatorname{Im} t \geqslant 0, \\ \hat{f}_r(v + tu) & \text{if } \operatorname{Im} t < 0 \end{cases} \tag{3.12}$$

is analytic on $\mathbb{C}\backslash\mathbb{R}$ and continuous on some real neighborhood of $t=0$, which is, e.g., given by

$$|t| < \tfrac{1}{2} d(v), \quad \text{where } d(v) := \min\{1, \operatorname{dist}(v, \partial\mathcal{V}_+ \cup -\partial\mathcal{V}_+)\}, \tag{3.13}$$

assuming $r < \frac{1}{4} d(v)$. Applying Painlevé's theorem,[14] we see that $f_{r,v,u}$ is indeed analytic on $\mathbb{C}\backslash\{t \,|\, \operatorname{Im} t = 0, |t| \geqslant \frac{1}{2} d(v)\}$. From Eq. (3.9), we can derive the estimate

$$|f_{r,v,u}(t)| \leqslant c_4 (1+E)^{2\ell} e^{c_2 E |\operatorname{Im} t|} |\operatorname{Im} t|^{-2\ell} \quad \text{if } |t| < \tfrac{1}{2} d(v), \quad r \leqslant 1. \tag{3.14}$$

A Phragmén-Lindelöf-type of argument (cf. Lemma 5.7 of Ref. 10) then leads us to

$$|f_{r,v,u}(t)| \leqslant c_5 (1+E)^{2\ell} e^{\lambda c_2 E} \lambda^{-2\ell} \quad \text{for } r < \tfrac{1}{4} d(v), \quad |t| < \lambda, \quad \text{and any } \lambda \leqslant \tfrac{1}{4} d(v), \tag{3.15}$$

where c_5 depends neither on v nor on u. Choosing t to be purely imaginary, this means

$$|f_r(v + iu)| \leqslant c_5 (1+E)^{2\ell} e^{\lambda c_2 E} \lambda^{-2\ell} \quad \text{for } v^2 < 0, \quad u \in \mathcal{C}, \quad \|u\| < \lambda, \quad \lambda \leqslant \tfrac{1}{4} d(v), \quad r < \tfrac{1}{4} d(v). \tag{3.16}$$

The same estimate holds at the real points ($u=0$), setting $t=0$ in Eq. (3.15).

As mentioned above, f_r possesses an analytic continuation to a complex neighborhood of any real spacelike z, provided that r is sufficiently small for z. This continuation is known very explicitly (see the proof of the edge of the wedge theorem in Ref. 14 for details); in fact, the domain of holomorphy depends only on the geometry of $\mathcal{C}$, and the estimate (3.16) can be carried over to the continued function, showing that $\{f_r\}_{r \leqslant 1}$ is a normal family throughout its domain.

We are now in the position to control the limit $r \to 0$. Since $\|R^{-2\ell} \exp(iP_\mu z^\mu)\| < \infty$ for $\operatorname{Im} z \in \mathcal{V}_+$, the expression

$$f(z) := \sigma(U(x) \phi U(z) \phi' U(-x-z)) \tag{3.17}$$

is well-defined for $z \in M + i\mathcal{V}_+$. Using the approximation properties (2.8) of A_r and A_r', and applying the same methods that lead to Eq. (3.14), we can establish the estimate

$$\begin{gathered} |f(z) - f_r(z)| \leqslant c_6 (1+E)^{2\ell} e^{c_2 E |\operatorname{Im} t|} |\operatorname{Im} t|^{-2\ell} \cdot r \\ \text{for } z = v + itu, \quad v \in \mathcal{M}, \quad u \in \mathcal{C}, \quad \|u\| = 1, |t| < \tfrac{1}{2} d(v), \quad r \leqslant 1. \end{gathered} \tag{3.18}$$

Combined with similar estimates for $\|\operatorname{Im} z\| > 1$, we see in particular that $f_r(z) \to f(z)$ for $z \in \mathcal{M} + i\mathcal{V}_+$. In analogy to (3.10), we may define $f(z)$ on $\mathcal{M} - i\mathcal{V}_+$; pointwise convergence $f_r \to f$ and estimates of the form (3.18) hold there, too. Now, since $\{f_r\}_{r \leqslant 1}$ is a normal family, we know that f_r converges to some analytic limit throughout its domain, where the convergence is uniform on compact subsets; so f has an analytic continuation to that region, and $f_r \to f$ holds in particular at the real points. Thus the limit

$$\sigma(\phi(x)\cdot\phi'(y)) := \lim_{r\to 0} f_r(y-x) \tag{3.19}$$

is well-defined and—cf. Eq. (3.17)—independent of the choice of sequences A_r, A'_r. This definition obviously is linear in σ; so $\phi(x)\cdot\phi'(y)$ is a well-defined linear form on $P_H(E)\Sigma P_H(E)$ for any E. In view of Eq. (3.16), the following estimate holds:

$$\|P_H(E)\phi(x)\cdot\phi'(y)P_H(E)\| \leqslant c_5(1+E)^{2\ell}e^{\lambda c_2 E}\lambda^{-2\ell} \quad \text{for } (x-y)^2<0, \quad \lambda \leqslant \tfrac{1}{4}d(x-y). \tag{3.20}$$

Applying this result with $\lambda=(c_2E)^{-1}$ for $(c_2E)^{-1}<\frac{1}{4}d(x-y)$, and with $\lambda=\frac{1}{4}d(x-y)$ otherwise, we obtain a $c_7>0$ such that

$$\|P_H(E)\phi(x)\cdot\phi'(y)P_H(E)\| \leqslant c_7(1+E)^{4\ell}d(x-y)^{-2\ell} \quad \text{for any } E>0. \tag{3.21}$$

Using the spectral representation of R, one can show on these grounds that $\phi(x)\cdot\phi'(y)\in\mathcal{C}^\infty(\Sigma)^*$, and

$$\|\phi(x)\cdot\phi'(y)\|^{(4\ell+1)} \leqslant c_8 d(x-y)^{-2\ell}. \tag{3.22}$$

The same methods can be applied to quantify the convergence $A_r(x)A'_r(y)\to\phi(x)\cdot\phi'(y)$. Starting from Eq. (3.18) and using the arguments that lead to Eqs. (3.16) and (3.21), we arrive at the estimate

$$\|\phi(x)\cdot\phi'(y)-A_r(x)A'_r(y)\|^{(4\ell+1)} \leqslant c_9 d(x-y)^{-2\ell}r \quad \text{for } r<\tfrac{1}{4}d(x-y). \tag{3.23}$$

To summarize, we have established the following result:

Theorem 3.1: *For $\phi,\phi'\in\Phi_{\mathrm{FH}}$, there exist linear forms*

$$\phi(x)\cdot\phi'(y)\in\mathcal{C}^\infty(\Sigma)^* \quad \text{for } x,y\in\mathcal{M}, \quad (x-y)^2<0,$$

with the following properties: Given γ, we can choose constants $\ell,m>0$, and for any fixed ϕ, $\phi'\in\Phi_\gamma$ another constant $c>0$ such that

$$\|\phi(x)\cdot\phi'(y)\|^{(m)} \leqslant c d(x-y)^{-2\ell}.$$

If A_r, $A'_r\in\mathfrak{A}(r)$ are sequences of operators with $\|\phi^{[r]}-A_r^{[r]}\|^{(\ell)}=O(r)$, then

$$\|\phi(x)\cdot\phi'(y)-A_r(x)A'_r(y)\|^{(m)} \leqslant O(r)d(x-y)^{-2\ell},$$

where the estimate $O(r)$ is uniform in x,y, given that $r<\frac{1}{4}d(x-y)$.

Note that the spacelike product usually diverges as $x\to y$, say, on a straight line, but that the singularity is bounded by an inverse power of $d(x-y)$.

B. Proof of the expansion

Based on the detailed results established for the spacelike product $\phi(x)\cdot\phi'(y)$, we are now going to prove the operator product expansion for this case, making use of the phase space approximation

$$\delta_\gamma(\Xi-\Xi\circ p_{\gamma*})=0. \tag{3.24}$$

We follow the heuristic motivation given at the beginning of this section. To be precise, let $\gamma\geqslant 0$ be given, and let $\phi,\phi'\in\Phi_\gamma$. As before, we choose approximating sequences A_r, $A'_r\in\mathfrak{A}(r)$ with

$$\|\phi^{[r]}-A_r^{[r]}\|^{(\ell)}=O(r), \quad \|A_r^{[r]}\|=O(r^{-k}), \tag{3.25}$$

where $k,\ell>0$ are suitably chosen; note that we can choose them dependent on γ only.

First of all, we will approximate the bounded product $A_r(x)A_r'(y)$. Let $\gamma'>0$ (its value will be specified later), and fix a projector $p_{\gamma'}$ onto $\Phi_{\gamma'}$. Since $A_r(x)A_r'(y)\in\mathfrak{A}(r+2\|x\|+2\|y\|)$, it follows from Eqs. (3.24) and (3.25) that for some $m>0$ (dependent on γ),

$$\|p_{\gamma'}(A_r(x)A_r'(y))-A_r(x)A_r'(y)\|^{(m)}\leqslant(r+2\|x\|+2\|y\|)^{\gamma'}O(r^{-2k}). \tag{3.26}$$

Since $\Phi_{\gamma'}$ is finite dimensional, we can find $m'\geqslant m$ such that $\|p_{\gamma'}\|^{(m,m')}<\infty$; in fact, this choice depends on γ' only. Now on the left-hand side of Eq. (3.26), $A_r(x)A_r'(y)$ converges to $\phi(x)\cdot\phi'(y)$ in the limit $r\to 0$: In view of Theorem 3.1, one sees that

$$\|p_{\gamma'}(\phi(x)\cdot\phi'(y))-\phi(x)\cdot\phi'(y)\|^{(m')}\leqslant(r+2\|x\|+2\|y\|)^{\gamma'}O(r^{-2k})+d(x-y)^{-2\ell}O(r), \tag{3.27}$$

given that $r<\frac{1}{4}d(x-y)$.

We will now consider the limit $x,\ y\to 0$, where we assume that

$$d(x-y)\geqslant(\|x\|+\|y\|)\cdot\text{const}, \tag{3.28}$$

i.e., we demand that $x-y$ does not approach the light cone too fast. We will refer to this approximation as the *spacelike limit* and denote it by $\to^{\text{sp}}$. Now given some $\beta>0$, we set

$$r(x,y):=(\|x\|+\|y\|)^{1+\beta+2\ell}, \tag{3.29}$$

which fulfills $r<\frac{1}{4}d(x-y)$ for small x,y due to Eq. (3.28). If now γ' was chosen sufficiently large (dependent on β), we see that (3.27) vanishes faster than $(\|x\|+\|y\|)^{\beta}$ in the spacelike limit. Thus, we have achieved the following.

Theorem 3.2: *Let $\gamma>0$, $\beta>0$ be given. We can find constants $\gamma'>0$ and $\ell>0$ such that for any ϕ, $\phi'\in\Phi_\gamma$ and any projection $p_{\gamma'}$ onto $\Phi_{\gamma'}$:*

$$(\|x\|+\|y\|)^{-\beta}\|\phi(x)\cdot\phi'(y)-p_{\gamma'}(\phi(x)\cdot\phi'(y))\|^{(\ell)}\overset{\text{sp}}{\to}0.$$

This establishes the operator product expansion—as explained at the beginning of this section, we may expand $p_{\gamma'}$ in a basis in order to pass to the more explicit form (3.1). In mathematical terms, product expansions are asymptotic series; while with increasing β we will usually have to increase γ', to any finite approximation order β a finite "number of approximation terms" will suffice. Note that the approximation terms are not unique (since $p_{\gamma'}$ is not); however, the ambiguities are restricted to terms that vanish rapidly in the limit, so at least the singular structure of an operator product expansion can be understood as an intrinsic property of the theory. It is also worth noting that the approximation is not only valid in the weak sense, as originally proposed in Ref. 2, but holds uniformly for all states of sufficiently regular high energy behavior.

Furthermore, the coefficients of the product expansion are simply matrix elements of the spacelike product $\phi(x)\cdot\phi'(y)$; thus, we can apply Theorem 3.1 directly, which shows that their divergences at $x=y=0$ are bounded by an inverse power of $d(x-y)$.

C. Further directions

The results established in Secs. III A and III B can be generalized in many ways. For the sake of brevity, we will just sketch these findings; the reader is referred to Chap. 5 of Ref. 10 for details of the construction.

First, we may consider products of arbitrary many factors; though we restricted ourselves to the case of two factors in the above, our methods carry over quite directly. In the following, let $n\in\mathbb{N}$ and $\gamma\geqslant 0$ be given. It seems natural not only to consider n-fold products, but also their linear combinations; by the same methods as outlined in Sec. III A, we may define spacelike products

$$\Pi(x) = \sum_k c_k \phi_k^{(1)}(x^{(1)}) \cdot \cdots \cdot \phi_k^{(n)}(x^{(n)}) \in \mathcal{C}^\infty(\Sigma)^*, \quad \text{where } c_k \in \mathbb{C}, \quad \phi_k^{(j)} \in \Phi_\gamma. \tag{3.30}$$

This expression is multilinear in the fields $\phi_k^{(j)}$ [note that the products $\phi(x)\cdot\phi'(y)$ were bilinear in ϕ,ϕ' by definition], so we can formally obtain the products from a map $\Pi \mapsto \Pi(x)$ which is well-defined on the tensor product space $\Phi_\gamma^{\otimes n}$. In Eq. (3.30), we must demand that the components of $x=(x^{(1)},\ldots,x^{(n)}) \in \mathcal{M}^n$ are (pairwise) spacelike separated. More abstractly, let

$$\mathcal{M}^n_{\mathrm{sp}} := \{x \in \mathcal{M}^n | (x^{(i)} - x^{(j)})^2 < 0 \ \forall\ 1 \leqslant i < j \leqslant n\}, \tag{3.31}$$

and define

$$d(x) := \min\{1, \mathrm{dist}(x, \partial\mathcal{M}^n_{\mathrm{sp}})\}; \tag{3.32}$$

we then demand of the spacelike limit $x \to^{\mathrm{sp}} 0$ that

$$x \in \mathcal{M}^n_{\mathrm{sp}}, \quad \|x\| \leqslant d(x) \cdot \mathrm{const}, \quad x \to 0, \tag{3.33}$$

where $\|x\|$ stands for the Euclidean norm of x in $\mathcal{M}^n = \mathbb{R}^{n(s+1)}$. Following the line of arguments given in Sec. III A, the divergence of the spacelike products can be estimated as

$$\|\Pi(x)\|^{(n\cdot m)} = O(d(x)^{-n\cdot\ell}) \quad (x \overset{\mathrm{sp}}{\to} 0), \tag{3.34}$$

where m,ℓ depend on γ only. Finally, we may obtain the following analog of Theorem 3.2.

Theorem 3.3: *Let $\gamma>0$, $\beta>0$, $n\in\mathbb{N}$ be given. We can find constants $\gamma'>0$ and $\ell>0$ such that for any $\Pi\in\Phi_\gamma^{\otimes n}$ and any projection $p_{\gamma'}$ onto $\Phi_{\gamma'}$,*

$$\|x\|^{-\beta} \|\Pi(x) - p_{\gamma'}\Pi(x)\|^{(\ell)} \overset{\mathrm{sp}}{\to} 0.$$

Hence product expansions exist for products of an arbitrary (finite) number of fields.

Moreover, similar expansions can be established for arbitrary (not necessarily spacelike) distances of arguments. Here the field products are defined in the sense of distributions only, i.e., we replace $\Pi(x)$ with $\Pi(f)\in\mathcal{C}^\infty(\Sigma)^*$, where $f\in\mathcal{S}(\mathcal{M}^n)$ is a test function with compact support. Theorem 3.3 holds in an analogous way, where $\|x\|$ is substituted with

$$d(f) := \sup\{\|x\| \mid x \in \mathrm{supp}\, f\}; \tag{3.35}$$

instead of the spacelike limit, we consider the limit $d(f)\to 0$, and we must require that for every multi-index μ, a constant c_μ exists such that

$$\|\partial^\mu f\|_{L_1} \leqslant d(f)^{-|\mu|} c_\mu \quad \text{as } d(f) \to 0. \tag{3.36}$$

So the product expansions can be extended to the non-space-like region, where their coefficients are no longer functions, but rather tempered distributions.

Furthermore, one may investigate the action of symmetry transformations on the products and their expansions, demanding that these transformations are compatible with translations and with the product structure on $\mathfrak{B}(\mathcal{H})$ (in a suitably defined way—see Chap. 5.4 of Ref. 10; these conditions are, e.g., fulfilled for Lorentz transforms, dilations and inner symmetries). The results are compatible with what is expected from perturbation theory.[15]

IV. ZIMMERMANN'S NORMAL PRODUCTS

In the preceding section, we have defined and analyzed products of fields at different (spacelike separated) space–time points, and investigated their divergences at small distances. However, with possible applications in mind, one would like to develop some substitute for the ill-defined product at coinciding points in the sense of a local field (i.e., an element of Φ_{FH}). In free field

theory, such a substitute is given by means of the Wick product, e.g., the normal ordered square $:\phi^2:(x)$ of a real scalar field. According to Wick's theorem,[16] it can be constructed from spacelike products by subtraction of divergent terms,

$$:\phi^2:(0) = \lim_{x,y\to 0} (\phi(x)\cdot\phi(y) - (\Omega|\phi(x)\cdot\phi(y)|\Omega)\mathbb{1}). \tag{4.1}$$

In interacting theories, one would not expect such a limit to exist; nevertheless, similar "subtraction methods" combined with a suitable "renormalization factor" can be used at least in a perturbative context to justify the existence of local field equations.[17,18] Zimmermann[3] used operator product expansions to derive these constructions more generally: For any field ϕ_k occuring in the expansion (1.1), one obtains heuristically

$$\phi_k(0) = \lim_{x,y\to 0} \frac{1}{c_k(x-y)}\left(\phi(x)\cdot\phi'(y) - \sum_{j\neq k} c_j(x-y)\,\phi_j\left(\frac{x+y}{2}\right)\right), \tag{4.2}$$

provided that the coefficient c_k does not vanish in the limit. So every "composite field operator" ϕ_k that appears in the expansion can serve as a candidate for a normal product.

Let us see how this can be formalized in our context. We fix a product $\Pi\in\Phi_{\mathrm{FH}}^{\otimes n}$ and try to collect all "relevant" terms in its product expansion. To this end, we make the following definition: We say that a finite-dimensional subspace $V\subset\mathcal{C}^\infty(\Sigma)^*$ is spacelike approximating for Π if for some projection p_V onto V and some $\ell>0$,

$$\|\Pi(x) - p_V\Pi(x)\|^{(\ell)} \overset{\mathrm{sp}}{\to} 0. \tag{4.3}$$

It can easily be seen, using the triangle inequality, that then the same is true for any projection p_V onto V. In view of Theorem 3.3, Φ_γ always is spacelike approximating (sp-app) for Π if γ is chosen sufficiently large. Moreover, a short calculation shows that if V and W are two spaces which are sp-app for Π, then the same holds for $V\cap W$; this is easily extended to the intersection $\cap_{i\in I}V_i$ of an arbitrary family $\{V_i\}_{i\in I}$ of sp-app spaces, even if I is infinite. (Note that all spaces in question are finite dimensional.) That justifies the following definition.

Definition 4.1: *Let* $\Pi\in\Phi_{\mathrm{FH}}^{\otimes n}$. *The finite-dimensional space*

$$N[\Pi] := \bigcap_{V\text{sp-app for }\Pi} V \subset \Phi_{\mathrm{FH}}$$

is called the normal product space *of* Π. *It is the smallest space that is spacelike approximating for* Π.

Let p be a projection onto $N[\Pi]$, and choose a basis $\{\phi_j\}_{j=1}^J$ of $N[\Pi]$. Since $N[\Pi]\subset\Phi_{\mathrm{FH}}$, the basis elements ϕ_j are local Wightman fields. Expanding p in this basis, we find functions $c_j(x)$ such that

$$p\Pi(x) = \sum_{j=1}^{J} c_j(x)\,\phi_j. \tag{4.4}$$

Due to the minimality of $N[\Pi]$, none of the coefficients $c_j(x)$ vanishes in the spacelike limit. Thus for every $k\in\{1,\ldots,J\}$, we can find a sequence (x_n) with $x_n\to^{\mathrm{sp}} 0$ such that

$$\phi_k = \lim_{n\to\infty} \frac{1}{c_k(x_n)}\left(\Pi(x_n) - \sum_{j\neq k} c_j(x_n)\,\phi_j\right) \tag{4.5}$$

with respect to some norm $\|\cdot\|^{(\ell)}$; we have recovered Zimmermann's approximation formula.

$N[\Pi]$ is a normal product not in the sense of a single field, but as a vector space containing all possible candidates for such a normal product field. In the case of a real scalar free field $\phi(x)$, one obtains the result (cf. Chap. 5.7 of Ref. 10)

$$N[\phi \otimes \phi] = \mathrm{span}\{\mathbb{1}, :\phi^2:\}, \tag{4.6}$$

so the normal product space gives us some generalization of the Wick product. In free field theory, it is possible to choose a distinct element $:\phi^2: \in N[\phi \otimes \phi]$ by virtue of "normal ordering" or of Eq. (4.1). This structure is lost in the general case, as is suggested by perturbation theory and low-dimensional integrable models. Certainly, for specific applications, there may be additional restrictions on the choice of a normal product field. One can try to isolate a "most divergent term" in the product expansion, seek for specific representations of the Lorentz group[19] (see also below), or use field equations as selection criteria.[18] Still, some ambiguities may remain;[20] in our general setting, it does not seem possible to establish a full substitute for the Wick product.

We can slightly modify the methods developed above in order to define "extended" normal product spaces $N[\Pi]_\beta$ for $\beta \geqslant 0$, requiring that the left-hand side of Eq. (4.3) vanishes faster than $\|x\|^\beta$ in the limit. That provides us with an increasing sequence of vector spaces $N[\Pi]_0 \subset N[\Pi]_1 \subset \cdots$ containing higher and higher order composite field operators of some fixed product Π. This construction has recently found application in a characterization of nonequilibrum thermodynamical states.[21]

We shall now investigate the behavior of $N[\Pi]$ under Lorentz transformations or other symmetries and under differential operators. All these cases will be treated within a single concept. We consider a transformation α which acts in three different ways (denoted by the same symbol for simplicity),

(i) a linear, continuous map $\alpha: \mathcal{C}^\infty(\Sigma)^* \to \mathcal{C}^\infty(\Sigma)^*$,
(ii) linear maps $\alpha: \Phi_{\mathrm{FH}}^{\otimes n} \to \Phi_{\mathrm{FH}}^{\otimes n}$ (for every n),
(iii) an invertible action $x \mapsto \alpha.x$ on $\mathcal{M}^n$ (for every n)

with the following properties:

(1) $\alpha(\Pi(x)) = (\alpha\Pi)(\alpha.x)\ \forall \Pi \in \Phi_{\mathrm{FH}}^{\otimes n}, \quad n \in \mathbb{N}, \quad x \in \mathcal{M}^n$,
(2) $\alpha.x \to^{\mathrm{sp}} 0 \Leftrightarrow x \to^{\mathrm{sp}} 0$,
(3) $\|\alpha\|^{(\ell,\ell')} < \infty$ for any $\ell > 0$ and appropriate $\ell' > 0$ (dependent on ℓ).

We shall show that under these conditions, one has $\alpha N[\Pi] = N[\alpha\Pi]$; applications of this "covariance property" will be discussed below. As a first step, we shall prove the following lemma:

Lemma 4.2: *Let $V \subset \mathcal{C}^\infty(\Sigma)^*$ be a finite-dimensional subspace. There exist projections p onto V and p' onto αV such that*

$$\alpha \circ p = p' \circ \alpha.$$

Proof: Let $K := \ker \alpha \cap V$. Choose a space $\hat{V}$ such that $V = K \oplus \hat{V}$. Furthermore, choose projections p_K onto K such that $p_K \restriction \hat{V} = 0$, and p' onto $\alpha V = \alpha\hat{V}$. (This is certainly possible, since V is finite dimensional.) Denote the inverse of $\alpha: \hat{V} \to \alpha V$ by $\hat{\alpha}^{-1}$. We define

$$p := p_K + \hat{\alpha}^{-1} \circ p' \circ \alpha. \tag{4.7}$$

A short calculation shows $p^2 = p$, $\mathrm{img}\, p = V$, $\alpha \circ p = p' \circ \alpha$, so p has the properties desired. ■

Now we are in the position to prove the "covariance" of $N[\Pi]$.

Theorem 4.3: *Let α fulfill the conditions (1) to (3) listed above. Then*

$$N[\alpha\Pi] = \alpha N[\Pi] \quad \forall\, \Pi \in \Phi_{\mathrm{FH}}^{\otimes n}, \quad n \in \mathbb{N}.$$

Proof: Let $V \subset \mathcal{C}^\infty(\Sigma)^*$ be sp-app for Π, and p, p' projections as in Lemma 4.2. Then for sufficiently large ℓ, ℓ', we have

$$\|(\alpha\Pi)(\alpha\,.\,x)-p'(\alpha\Pi)(\alpha\,.\,x)\|^{(\ell)}=\|\alpha(\Pi(x)-p\Pi(x))\|^{(\ell)}\leqslant\|\alpha\|^{(\ell,\ell')}\|\Pi(x)-p\Pi(x)\|^{(\ell')}\overset{\text{sp}}{\to}0; \tag{4.8}$$

due to property (2), this means that αV is sp-app for $\alpha\Pi$. Hence $N[\alpha\Pi]\subset\alpha N[\Pi]$.

To show the opposite inclusion, split $V:=N[\Pi]$ into a direct sum

$$N[\Pi]=V=V_0\oplus V_1\oplus V_2, \tag{4.9}$$

where

$$V_0=\ker\alpha\cap V,\quad \alpha V_1=N[\alpha\Pi],\quad \alpha V_2\cap N[\alpha\Pi]=\{0\}.$$

Let $p_i: V\to V_i$ $(i=0,1,2)$ denote the projection operators with respect to that direct sum, and let $p_i': \alpha V\to\alpha V_i$ $(i=1,2)$ be the projections with regard to the direct sum $\alpha V=\alpha V_1\oplus\alpha V_2$. We then have $p_i'\alpha=\alpha p_i$ for $i=1,2$. We choose projections p,p' as in Lemma 4.2; then $p_i\circ p:\mathcal{C}^\infty(\Sigma)\to V_i$ are projections onto V_i, and $p_i'\circ p':\mathcal{C}^\infty(\Sigma)\to\alpha V_i$ are projections onto αV_i. Now, since both αV and $\alpha V_1=N[\alpha\Pi]$ are sp-app for $\alpha\Pi$, we see that for sufficiently large ℓ,

$$\|(\alpha\Pi)(x)-(p_1'+p_2')p'(\alpha\Pi)(x)\|^{(\ell)}\overset{\text{sp}}{\to}0\quad\text{and}\quad\|(\alpha\Pi)(x)-p_1'p'(\alpha\Pi)(x)\|^{(\ell)}\overset{\text{sp}}{\to}0, \tag{4.10}$$

which means that

$$\|p_2'p'(\alpha\Pi)(x)\|^{(\ell)}\overset{\text{sp}}{\to}0. \tag{4.11}$$

Using the relation $p_2'p'\alpha=\alpha p_2p$ together with properties (1) and (2), and noting that α is invertible on αV_2, it follows that

$$\|p_2p\Pi(x)\|^{(\ell)}\overset{\text{sp}}{\to}0\ \Rightarrow\ \|\Pi(x)-(p_0+p_1)p\Pi(x)\|^{(\ell)}\overset{\text{sp}}{\to}0; \tag{4.12}$$

thus $V_0\oplus V_1$ is sp-app for Π. Due to the minimality of $N[\Pi]$, this is only possible if $V_2=\{0\}$; hence $\alpha N[\Pi]=\alpha V_1=N[\alpha\Pi]$. ■

The properties (1)–(3) requested for α are fulfilled by a number of relevant transformations.

Lorentz transformations: A Lorentz transformation $\alpha=\alpha(\Lambda)$ acts on $\mathcal{C}^\infty(\Sigma)^*$ "as usual" [i.e. through ad $U(\Lambda)$], on $\Phi_{\text{FH}}^{\otimes n}$ in the same way on every tensor factor, and on $\mathcal{M}$ by $\alpha\,.\,x=\Lambda x$, which is extended to $\mathcal{M}^n$ componentwise. The properties (2) and (3) are obvious. Applying ad $U(\Lambda)$ to the approximating sequences in Eq. (3.4), it is also easy to see that $\alpha(\Pi(x))=(\alpha\Pi)(\alpha\,.\,x)$. So Theorem 4.3 tells us that $N[\alpha(\Lambda)\Pi]=\alpha(\Lambda)N[\Pi]$; the normal product spaces are Lorentz covariant *as vector spaces*. Note that $N[\Pi]$ is not necessarily stable under $\alpha(\Lambda)$, since possibly $\Pi\neq\alpha(\Lambda)\Pi$; we would have to pass to a closure $\hat{N}[\Pi]=\text{span}\cup_\Lambda N[\alpha(\Lambda)\Pi]$ if we aim at a decomposition of $\Lambda\mapsto\alpha(\Lambda)$ into irreducible subrepresentations.

Other symmetries with "geometric action," such as dilations $[\alpha(\lambda)\,.\,x=\lambda x]$ and inner symmetries $(\alpha\,.\,x=x)$, show the same behavior as Lorentz transformations, as long as they are unitary implemented and fulfill certain regularity properties (cf. Lemma 5.5 of Ref. 10). Since for our construction, it suffices to use a local unitary implementation rather than a global one, it does not matter whether the symmetries are broken or unbroken.[22]

Derivatives: To treat linear differential operators in our context, it suffices to consider first order operators D_μ, which act on $\mathcal{C}^\infty(\Sigma)^*$ through $i[P_\mu,\cdot]$. Since they leave Φ_{FH} invariant,[9] they also act on $\Phi_{\text{FH}}^{\otimes n}$ by a formal product rule. As D_μ satisfies the product rule on $\mathfrak{B}(\mathcal{H})$, one may establish

$$D_\mu(\Pi(x))=(D_\mu\Pi)(x). \tag{4.13}$$

[To see this, note that the approximating sequences "$A_r\to\phi$" can be chosen to be "smeared" with some test function f_r—compare the remark after the proof of Lemma 3.5 in Ref. 9—such that

$D_\mu A_r = D_\mu(\hat{A}_r(f_r)) = \hat{A}_r(-\partial_\mu f_r)$, so D_μ preserves the localization of the operator sequence.] Again, property (3) is obvious, so the differential operators D_μ fulfill properties (1)–(3), with D_μ acting trivially on $\mathcal{M}^n$. By concatenation and linear combination, the same is then true for linear differential operators D of arbitrary order. Hence we have

$$N[D\Pi] = DN[\Pi]. \tag{4.14}$$

The perturbative analog to this relation is known as *Lowenstein's rule*.[23]

V. CONCLUSIONS AND OUTLOOK

In the course of the present paper, we have given a rigorous model-independent proof of operator product expansions, based on a physically motivated assumption that was formulated as a phase space condition. In this context, product expansions are asymptotic series in the short distance limit; their singular behavior is bounded by an inverse power. We have introduced normal products in the sense of vector spaces that consist of all fields contributing to the product expansion (up to a given level of accuracy). These vector spaces show the expected properties, such as Lorentz covariance and Lowenstein's rule.

Originally, Wilson[2] proposed operator product expansions as a substitute for the Lagrangian, as a method of defining field theoretic models. Though it would seem exaggerated to aim at constructive approaches from our results, they might indeed serve as a basis for the classification of models. For example, they could give a well-defined sense to the concept of local field equations: The famous ϕ^4 equation

$$(\Box + m^2)\phi = \lambda{:}\phi^3{:}, \quad \lambda \neq 0, \tag{5.1}$$

well known in perturbation theory,[18] can be introduced in our context as

$$(\Box + m^2)\phi \in N[\phi^{\otimes 3}] \setminus \mathbb{C}\phi. \tag{5.2}$$

At present, it is unknown whether such a relation is stringent enough to define a field theory (nor, in fact, whether it is compatible with any field theory at all). There is strong evidence[24] that in physical space–time, the standard lattice approximation approach does not lead to a theory that fulfills Eq. (5.2); however, other methods have been proposed that might result in such a solution.[25] Equation (5.2) at least allows us to pose the existence problem of ϕ_4^4 independent of specific construction schemes.

More generally, it seems interesting to what extent field equations—or other properties of product expansions—can define a field theory uniquely. One encounters some obvious obstructions here, since there exist nontrivial theories with a trivial field content[26] $\Phi_{\mathrm{FH}} = \mathbb{C}\mathbb{1}$, which might always occur as a tensor factor. We can exclude these components, however, by defining the following subnet $\mathfrak{A}_F$ of $\mathfrak{A}$ which may be regarded as the "point field part" of the theory (as remarked in Ref. 9):

$$\mathfrak{A}_F(\mathcal{O}) := \mathcal{P}(\mathcal{O})'', \tag{5.3}$$

where $\mathcal{P}(\mathcal{O})$ is the polynomial algebra generated by all $\phi(f)$ with $\phi \in \Phi_{\mathrm{FH}}$, $\operatorname{supp} f \subset \mathcal{O}$.

In models which are generated by observable point fields (such as the free-field examples in Ref. 9), we have $\mathfrak{A} = \mathfrak{A}_F$, and one would hope to find a description of $\mathfrak{A}$ in terms of field equations or similar relations. In the presence of gauge fields, on the other hand, it might happen that $\mathfrak{A}_F \subsetneq \mathfrak{A}$, since $\mathfrak{A}$ may include inherently non-point-like observables like Wilson loops or Mandelstam strings. In this case, it is possible that the dynamics of the system cannot be described in terms of Φ_{FH} alone, but that field equations need to involve the extended objects mentioned. Still, it would be worthwhile to ask what physical properties (such as cross sections) are determined by $\mathfrak{A}_F$ only. However, the details of such an analysis remain vague at the present stage.

Stability of Landau-Ginzburg branes

Johannes Walcher
School of Natural Sciences, Institute for Advanced Study, Princeton, New Jersey 08540

(Received 17 February 2005; accepted 27 June 2005; published online 22 August 2005)

We evaluate the ideas of Π-stability at the Landau-Ginzburg (LG) point in moduli space of compact Calabi-Yau manifolds, using matrix factorizations to *B*-model the topological *D*-brane category. The standard requirement of unitarity at the IR fixed point is argued to lead to a notion of "*R*-stability" for matrix factorizations of quasihomogeneous LG potentials. The *D*0-brane on the quintic at the Landau-Ginzburg point is not obviously unstable. Aiming to relate *R*-stability to a moduli space problem, we then study the action of the gauge group of similarity transformations on matrix factorizations. We define a naive moment maplike flow on the gauge orbits and use it to study boundary flows in several examples. Gauge transformations of nonzero degree play an interesting role for brane-antibrane annihilation. We also give a careful exposition of the grading of the Landau-Ginzburg category of *B*-branes, and prove an index theorem for matrix factorizations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2007590]

I. INTRODUCTION

The main purpose of this work is to develop a stability condition, to be called "*R*-stability," on the triangulated category of matrix factorizations describing *D*-branes at the Landau-Ginzburg point p_{LG} in the Kähler moduli space $\mathcal{M}_k$ of a compact Calabi-Yau manifold *X*. The proposal is motivated by physical considerations similar to the ones leading to the notion of Π-stability on the derived category of coherent sheaves $\mathbf{D}(X)$, which describes the variation of the spectrum of *B*-type BPS branes over $\mathcal{M}_k$. In fact, the notion of *R*-stability can be thought of as the specialization of Π-stability to p_{LG}. It is expected, however, that *R*-stability should be intrinsic to the Landau-Ginzburg model and does in principle not depend on knowledge of the stable spectrum elsewhere in $\mathcal{M}_k$.

In this paper, Sec. II is a brief review of the relevant aspects of Π-stability that we want to abstract to the Landau-Ginzburg model. Section III contains the basic definitions related to matrix factorizations. Section IV explains how quasihomogeneous matrix factorizations can be, first $\mathbb{Q}$-, then $\mathbb{Z}$-graded. Section V is a somewhat independent unit concerned with the (RR) Ramond-Ramond charges of matrix factorizations in string theory and an index theorem. Section VI gives a preliminary definition of *R*-stability and partial answers to the difficulties in relating it to the action of the gauge group on matrix factorizations. This general discussion is then applied in Sec. VII and the proposal shown to work well in several relevant examples. Section VIII gives a summary.

II. REVIEW OF Π-STABILITY

Π-stability was introduced in Refs. 1 and 2, and further sharpened and tested in Refs. 3 and 4. It was subsequently abstracted into a precise mathematical definition of stability condition on triangulated categories in Ref. 5. We refer to these works for the categorical aspects of Π-stability, as well as to Aspinwall's review[6] for more extensive background material. Instead, we begin with a slightly personal review of the worldsheet origin of Π-stability, following Douglas.[2]

The basic physical intuition is quite simple. Consider a fixed two-dimensional conformally invariant string worldsheet quantum field theory $\mathcal{C}$ defining a closed string background. By definition, a *D*-brane in this background is a conformally invariant boundary condition, $\mathcal{B}$, for $\mathcal{C}$. A

popular way to define $\mathcal{C}$'s and $\mathcal{B}$'s is as IR fixed points of bulk or boundary RG flows, induced by turning on a relevant operator $\mathcal{O}$ in a known bulk or boundary theory. Such a UV description is "stable" if it flows to a theory in the infrared which is "acceptable" in the sense of, e.g., having the right central charge, being unitary, etc. Finding necessary and/or sufficient stability conditions on $\mathcal{O}$ is in general a very hard question.

A situation in which more can be said is when one requires bulk and boundary theories to preserve $\mathcal{N}=2$ supersymmetry with a nonanomalous U (1) R-symmetry, so that the chiral algebra underlying $\mathcal{C}$ and $\mathcal{B}$ will contain the $\mathcal{N}=2$ superconformal algebra. A necessary condition on acceptable $\mathcal{B}$'s is that the R-charges of all open string NS chiral primary operators satisfy the unitarity constraint[7]

$$0 \leqslant q \leqslant \hat{c}, \tag{2.1}$$

where $\hat{c}$ is the central charge of the superconformal algebra. Often, $\hat{c}$ and q can be determined in the UV and the Eq. (2.1) therefore provides a stability condition in the above sense.

The ideas of Π-stability in fact go further than (2.1). Assume that $\hat{c}$ and the R-charges of $\mathcal{C}$ are all integral. The chiral algebra of $\mathcal{C}$ then contains, in addition to the $\mathcal{N}=2$ superconformal algebra, the (square of the) spectral flow operator $\mathcal{S}$. One can then contemplate imposing a boundary condition of the form

$$\mathcal{S}_L = e^{i\pi\varphi}\mathcal{S}_R, \tag{2.2}$$

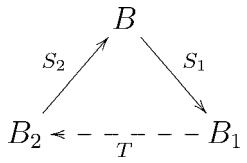
involving an arbitrary phase, φ. Standard conformal field theory arguments [using the doubling trick, one transports $\mathcal{S}^2$ around an open string vertex operator inserted at the boundary of the worldsheet, and notes that the total monodromy of $\mathcal{S}^2$, which evaluates to the difference of phases, measures the U (1) charge of the operator up to an integer] then show that the R-charges of an open string spanning between two branes $\mathcal{B}$ and $\mathcal{B}'$ (with phase φ and φ') satisfy

$$q = \varphi' - \varphi \bmod \mathbb{Z}. \tag{2.3}$$

If we bosonize the left- and right-moving U (1) currents in terms of two canonically normalized chiral bosons ϕ_L and ϕ_R, the spectral flow operators are $\mathcal{S}_{L,R}=e^{i(\sqrt{\hat{c}}/2)\phi_{L,R}}$, and we can visualize the boundary condition (2.2) as Dirichlet or Neumann boundary condition on the compact boson $\phi = \phi_L \pm \phi_R$ with radius $\sqrt{\hat{c}}$. [The sign depending on which side (A or B) of the mirror one chooses to present the conformal field theory.] Of course, the equation $e^{i(\sqrt{\hat{c}}/2)\phi_L}=e^{i\pi\varphi}e^{i(\sqrt{\hat{c}}/2)\phi_R}$ leaves a $\hat{c}$-fold ambiguity on the position/Wilson line of the boundary condition on ϕ. In such a picture,[2] the strings stretching between the different images correspond to the different values of q in (2.3).

We emphasize that, in conformal field theory, φ is defined as a real number modulo even integers. We should also like to stress that φ is, in general, independent of the phases appearing in the boundary condition on the $\mathcal{N}=2$ currents, as in, $G_L^{\pm}=e^{\pm i\alpha}G_R^{\pm}$, $G_L^{\pm}=e^{\pm i\beta}G_R^{\mp}$ for A- and B-type, respectively. (See, e.g., Ref. 8 for a BCFT discussion of this.) φ determines which $\mathcal{N}=1$ space–time supersymmetry is preserved by the brane, and can be different for different branes. On the other hand, the phases appearing in the boundary condition on the $\mathcal{N}=2$ currents determine which $\mathcal{N}=1$ worldsheet supersymmetry is preserved. This is a gauge symmetry and must be the same for all branes.

Now recall that an $\mathcal{N}=2$ field theory (conformal or not) with a conserved U (1) R-current can be twisted to a topological theory. As anticipated in Ref. 9, and by now well appreciated in the physics literature, the set of branes in the topological theory together with open strings between them carries the algebraic structure of a "triangulated category" (plus more). Two important pieces of structure are, first, the so-called "distinguished triangles," such as



(2.4)

which expresses the fact that the topological brane B can be obtained as a topological bound state of the two branes B_1 and B_2 by condensing the "topological tachyon" T on the base of the triangle. Second, a triangulated category has a so-called shift functor, which in physics terms sends a brane B to a copy of its antibrane $\bar{B}$.[1]

In relating the physical to the topological theory, one chooses a lift of the phase φ to a real number called "grade" and identifies the ghost number n of open strings as the integer appearing in (2.3), i.e.,

$$n = q + \varphi - \varphi' . \tag{2.5}$$

Consequently, for every physical brane $\mathcal{B}$ there are in fact an infinite number of topological branes $B[m]$ whose grade differs by an integers. Shifting the grade shifts the ghost number by integers, and hence modifies the topological theory. On the other hand, the topological theory is unaware of the unitarity constraint (2.1). In particular, the topological theory is independent of changes of q and φ. This decoupling of the topological theory from the variation of q with (part of) the moduli is one of the central ideas underlying Π-stability.

Π-stability, then, is designed to decide when the bound state formation described in the topological theory by triangles such as (2.4) is stable in the physical theory, and thereby provides a picture of the spectrum of BPS branes in some given closed string background. Let us, for concreteness, focus on the case of B-type D-branes on a Calabi-Yau manifold X. In that case, the topological branes are objects of the derived category of coherent sheaves, $\mathbf{D}(X)$, of the algebraic variety underlying X. $\mathbf{D}(X)$ depends only on the complex structure of X, and is independent of the Kähler moduli. Within this category of topological branes, the set of stable branes, conjectured to flow to BPS branes in the physical theory, varies over the stringy Kähler moduli space $\mathcal{M}_k$ of X. Essentially, one follows the continuous variation of the phases φ, and hence of U (1) R-charges of open strings, over $\mathcal{M}_k$. Charges leaving and/or entering the unitarity bound (2.1) signal loss and/or gain of stable branes, with decay and bound state formation described by the triangles (2.4).

For the details of this construction, consistency with monodromies in $\mathcal{M}_k$, and a lot of examples, see Ref. 6 One peculiar aspect of the story is that Π-stability really only describes the changes of the BPS spectrum as one moves around in $\mathcal{M}_k$. To determine the spectrum at any given point p of $\mathcal{M}(X)$, one must know the spectrum at some distinguished point p_0 and then follow it to p using Π-stability.

One natural choice for basepoint is large volume, p_{LV}, in the compactification of $\mathcal{M}_k$. At p_{LV}, Π-stability reduces to μ-stability for the Abelian category of coherent sheaves on X.[1] Although μ-stability does not extend over an open neighborhood of p_{LV} (and hence does not allow determining the complete BPS spectrum there), it is at present the only useful handle on the spectrum elsewhere in $\mathcal{M}_k$.

Another special point, which one expects exists when X is a noncompact Calabi-Yau manifold, is the so-called "orbifold point" p_{O} in $\mathcal{M}$. Even if X is not the resolution of an actual orbifold singularity, one may define p_{O} as a point in $\mathcal{M}_k$ at which the phases of all branes are aligned. In such a situation, determining the BPS spectrum is a problem of solving F- and D-flatness conditions in a supersymmetric quiver gauge theory, as argued in Ref. 1. More rigorously, Aspinwall shows in Ref. 10 that in an open neighborhood of such an orbifold point, Π-stability reduces to θ-stability for the Abelian category of quiver representations in the sense of King.[11]

Such a point at which all phases align is expected not to exist in the moduli space of a generic compact Calabi-Yau model. The closest one can get seems to be the Landau-Ginzburg point, which resembles ordinary orbifolds in the appearance of a discrete quantum symmetry, but with the important difference that not all phases of branes are aligned. The purpose of the present paper,

pursuing a suggestion made in Refs. 12 and 13, is to investigate the ideas underlying Π-stability at the Landau-Ginzburg orbifold point in the Kähler moduli space of compact Calabi-Yau manifolds, using the recently introduced description of the topological category using matrix factorizations. We now turn to explaining various (old and new) aspects of matrix factorizations, and pick up the stability discussion in Sec. VI.

III. MATRIX FACTORIZATIONS

Let $W \in \mathcal{R} = \mathbb{C}[x_1, \ldots, x_r]$ be a polynomial. To keep things simple, we will assume throughout that W has an isolated critical point at the origin $x_i = 0$. A matrix factorization (of dimension N) of W is a pair of square matrices $f, g \in \mathrm{Mat}(N \times N, \mathcal{R})$ with polynomial entries satisfying

$$fg = gf = W \cdot \mathrm{id}_{N \times N}. \tag{3.1}$$

A matrix factorization is called reduced if all entries of f and g have no constant term, i.e., $f(0) = g(0) = 0$.

Matrix factorizations (f, g) and (f', g') are called equivalent if they are related by a similarity transformation

$$U_1 f = f' U_2, \quad U_2 g = g' U_1, \tag{3.2}$$

where $U_1, U_2 \in \mathrm{GL}(N, \mathcal{R})$ are invertible matrices with polynomial entries.

A. Maximal Cohen-Macaulay modules

Matrix factorizations originated in Eisenbud's work[14] in the context of so-called maximal Cohen-Macaulay modules over local rings of hypersurface singularities. See Refs. 15 and 16 for some background. An example of such a ring is given by $\widetilde{\mathcal{R}}_{\mathfrak{m}} = \mathcal{R}_{\mathfrak{m}}/(W)$, where $\mathcal{R}_{\mathfrak{m}} = \mathbb{C}[[x_1, \ldots, x_r]]$ is the complete local ring of power series, with maximal ideal $\mathfrak{m} = (x_1, \ldots, x_r)$, and W is a polynomial, as above. If (f, g) is a matrix factorization of W, consider the $\mathcal{R}_{\mathfrak{m}}$-module $M = \mathrm{Coker}\, f$ with the $\mathcal{R}_{\mathfrak{m}}$-free resolution

$$0 \to G \xrightarrow{f} F \to M \to 0, \tag{3.3}$$

where $F \cong G \cong (\mathcal{R}_{\mathfrak{m}})^N$ are rank N free modules. Since multiplication by W on ((3.3)) is homotopic to zero, M descends to a $\widetilde{\mathcal{R}}_{\mathfrak{m}}$-module, with the infinite free resolution

$$\cdots \to \widetilde{G} \xrightarrow{f} \widetilde{F} \xrightarrow{g} \widetilde{G} \xrightarrow{f} \widetilde{F} \to M \to 0 \tag{3.4}$$

with $\widetilde{F} \cong \widetilde{G} \cong (\widetilde{\mathcal{R}}_{\mathfrak{m}})^N$.

The resolution (3.3) being of length one, which is the codimension of a hypersurface, makes M into a so-called maximal Cohen-Macaulay module (MCM) over $\widetilde{\mathcal{R}}_{\mathfrak{m}}$ (see Refs. 15 and 16 for the definitions). Eisenbud's theorem[14] essentially says that all MCMs over hypersurface rings come from matrix factorizations.

The category of Cohen-Macaulay modules[15] will be denoted by $\mathrm{MCM}(W)$. Objects of $\mathrm{MCM}(W)$ are matrix factorizations of W and morphism are morphisms of Cohen-Macaulay modules. In other words, a morphism from (f, g) to (f', g') in $\mathrm{MCM}(W)$ is a pair of $N' \times N$-dimensional matrices a, b, with polynomial entries, satisfying

$$bg = g'a, \quad af = f'b, \tag{3.5}$$

so that the diagram

$$\begin{array}{ccccc} F & \xrightarrow{g} & G & \xrightarrow{f} & F \\ {\scriptstyle a}\downarrow & & {\scriptstyle b}\downarrow & & {\scriptstyle a}\downarrow \\ F' & \xrightarrow{g'} & G' & \xrightarrow{f'} & F' \end{array} \tag{3.6}$$

commutes. We will make no direct use of the category MCM(W), but have included its definition here since it might play a role in a precise formulation of R-stability.

B. Triangulated category

A different category's construction based on matrix factorization was observed by Kontsevich.[17] The construction starts from triples (M,σ,Q), where M is a free $\mathcal{R}=\mathbb{C}[x_1,\ldots,x_r]$-module with a $\mathbb{Z}_2$-grading σ, and Q is an odd ($\sigma Q+Q\sigma=0$) endomorphism of M satisfying

$$Q^2 = W\cdot \mathrm{id}_M. \tag{3.7}$$

Decomposing $M=M_0\oplus M_1$ into homogeneous components, with equal rank N,Q can be represented as the matrix

$$Q=\begin{pmatrix} 0 & f \\ g & 0 \end{pmatrix}, \tag{3.8}$$

making the relation of (3.7) to (3.1) obvious. The grading is then given by the matrix

$$\sigma=\begin{pmatrix} \mathrm{id}_{N\times N} & 0 \\ 0 & -\mathrm{id}_{N\times N} \end{pmatrix}. \tag{3.9}$$

Let us denote by DG(W) the category which has such triples as objects and as morphisms the (even) morphisms of free modules (forgetting the Q's). The gauge transformations in DG(W) are the even automorphisms of M as an $\mathcal{R}$-module, $\mathrm{GL}^+(2N,\mathcal{R})$, acting as

$$\mathrm{GL}^+(2N,\mathcal{R}) \ni U=\begin{pmatrix} U_1 & 0 \\ 0 & U_2 \end{pmatrix}: Q\mapsto UQU^{-1} \tag{3.10}$$

with $U_1,U_2\in \mathrm{GL}(N,\mathcal{R})$, as in (3.2).

The point of the construction (Refs. 30 and 19) is that the category DG(W) has the structure of a differential graded category. This means that morphism spaces $\mathrm{Hom}_{\mathcal{R}}(M,M')$ are equipped with an odd differential D acting as a supercommutator

$$D\Phi = Q'\Phi-\sigma'\Phi\sigma\ \Phi Q=\begin{pmatrix} 0 & f' \\ g' & 0 \end{pmatrix}\begin{pmatrix} A & B \\ C & D \end{pmatrix}-\begin{pmatrix} A & -B \\ -C & D \end{pmatrix}\begin{pmatrix} 0 & f \\ g & 0 \end{pmatrix}, \tag{3.11}$$

on morphisms

$$\Phi=\begin{pmatrix} A & B \\ C & D \end{pmatrix} \tag{3.12}$$

in DG(W). One easily checks that $D^2=0$ by the super-Jacobi identity. By a general construction,[18,19] one can then associate a triangulated category, MF(W) to DG(W), which has the same objects as DG(W) [i.e., triples (M,σ,Q)], but in which morphisms are given by the $\mathbb{Z}_2$-graded cohomology of Q. Thus $\mathrm{Hom}_{\mathrm{MF}(W)}(M,M')=H^*(D)=\mathrm{Ker}\,D/\mathrm{Im}\,D$. We shall usually embezzle M and σ, and simply write $\mathrm{Hom}_{\mathrm{MF}(W)}(Q,Q')=H^0(Q,Q')\oplus H^1(Q,Q')$ for the morphisms in MF(W). We also write $H^0(Q),H^1(Q)$ for the morphisms from Q to itself.

For future reference, let us spell out a few triangulated constructions in the language of matrix factorizations. First, the shift functor[1] is nothing but the reversal of the $\mathbb{Z}_2$-grading $\sigma \to -\sigma$, or, equivalently, the exchange of f and g, i.e.,

$$Q[1] = \begin{pmatrix} 0 & f \\ g & 0 \end{pmatrix}[1] = \begin{pmatrix} 0 & g \\ f & 0 \end{pmatrix}, \tag{3.13}$$

with M and σ fixed. This operation obviously exchanges H^0 with H^1. Second, given two matrix factorizations Q_1 and Q_2 and an odd morphism $T \in H^1(Q_1, Q_2)$, we obtain a third factorization simply as

$$Q = \begin{pmatrix} Q_1 & 0 \\ T & Q_2 \end{pmatrix}, \tag{3.14}$$

fitting into the triangle

$$\begin{array}{ccc} & Q & \\ {\scriptstyle S_2}\nearrow & & \searrow{\scriptstyle S_1} \\ Q_2 & \xleftarrow[T]{} & Q_1 \end{array} \tag{3.15}$$

where

$$S_1 = \begin{pmatrix} 1 & 0 \end{pmatrix}, \quad S_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{3.16}$$

The construction (3.14) is referred to as the "cone" over the map $T[1] \in H^0(Q_1, Q_2[1])$.

Let us also note explicitly that the construction of MF(W) implies in particular that we identify matrix factorizations which differ by the direct addition of the trivial factorization $f=1$, $g=W$,

$$Q \equiv Q \oplus \begin{pmatrix} 0 & 1 \\ W & 0 \end{pmatrix} \equiv Q \oplus \begin{pmatrix} 0 & W \\ 1 & 0 \end{pmatrix}. \tag{3.17}$$

This identification occurs because adding the trivial factorization does not affect the cohomology of D between Q and any other factorization Q'.

C. Relation to $\mathcal{N}=2$ Landau-Ginzburg model

Orbifoldized $\mathcal{N}=2$ Landau-Ginzburg models[20] are known[21,22] to describe the small-volume continuation of Calabi-Yau sigma models, see Ref. 23 for the background. (LG also describe, in particular, the mirrors of CY sigma models, as well as the mirrors of toric Fano and noncompact Calabi-Yau manifolds, but this will not be important here. We will stay on the B side throughout.)

In the bulk, LG models are characterized by the worldsheet superpotential W, such as the polynomial we have been studying in this section. The x_i are $\mathcal{N}=2$ chiral field variables, whose interaction is described by W. The kinetic term for the x_i is described by a Kähler potential $K(x_i, \overline{x_i})$, and is usually ignored in the discussion of LG models because it does not affect topological quantities such as the chiral ring. What is more, in the quasihomogeneous case, it is actually conjectured that there is a Kähler potential, uniquely determined by the superpotential, such that the associated model is conformal. This Kähler potential can be reached by RG flow along which W is unchanged by nonrenormalization theorems.

When adding boundaries to the worldsheet of an $\mathcal{N}=2$ *LG* model, the supersymmetry variation of the superpotential exhibits a peculiar boundary term, whose nonvanishing is known as the Warner problem.[24–28] Following a proposal of Kontsevich, it was shown in Refs. 29–31 that matrix factorizations of W provide a solution of the Warner problem. More precisely, it was argued

there that the category of topological *B*-branes in a Landau-Ginzburg model is equivalent to the category MF(W) we have described in the preceding section. The extent to which MF(W) also describes "physical" branes in the untwisted Landau-Ginzburg model will be the subject of the present paper.

In the LG application, the space M is the Chan-Paton space of a (target space–time filling) DDbar-system, with equal number of branes and antibranes, and f and g describe a tachyon configuration. The shift functor[1] is nothing but the exchange of branes with antibranes. The matrix Q is part of the BRST charge, and the matrix factorization equation $Q^2=W$ is the condition that the tachyon configuration be BRST invariant (or preserve $\mathcal{N}=2$ supersymmetry in the untwisted model). Open string states between two such brane systems are given by the cohomology of D, i.e., are elements of $H^*(Q,Q')$. (H^0 being referred to as bosonic, and H^1 as fermionic.) The cone (3.14) describes the formation of a "topological bound state" between two such configurations. Finally, (3.17) simply corresponds to the addition of a brane-antibrane pair which is canceled by an identical tachyon.

For other recent work on matrix factorizations in their relation to *D*-branes in Landau-Ginzburg models, see Refs. 32–43 and 12.

IV. GRADED MATRIX FACTORIZATIONS

By construction so far, our *D*-brane category MF(W) is $\mathbb{Z}_2$-graded. In particular, the shift functor squares to the identity. On the other hand, the prime example of a triangulated category, namely the derived category of coherent sheaves on an algebraic variety $\mathbf{D}(X)$, is $\mathbb{Z}$-graded (and has shifts by arbitrary integers). As pointed out in Ref. 12, there is a simple way to improve MF(W) to a $\mathbb{Z}$-graded category in the special case that W is quasihomogeneous.

A. *R*-symmetry

W being quasihomogeneous is the condition that there exists an assignment of degrees to the variables x_i such that W has definite degree. In the physical model, this grading is worldsheet *R*-charge, and W having *R*-charge 2 is the conventional normalization. Thus, we assume that there exist *R*-charges $q_i \in \mathbb{Q}$ such that

$$W(e^{i\lambda q_i}x_i) = e^{2i\lambda}W(x_i) \quad \text{for all } \lambda \in \mathbb{R}. \tag{4.1}$$

One can think of *R*-charge as a U(1) (or $\mathbb{C}^\times$) action on the space of polynomials with respect to which W is equivariant. The U(1) action closes for $\lambda=\pi H$, where H is the smallest integer such that $Hq_i \in 2\mathbb{Z}$ for all i.

When considering matrix factorizations of W, it is natural to require that this U(1) action can be extended to (M,σ,Q). This condition that the boundary interactions preserve the U(1) *R*-symmetry is a necessary condition for the existence of a conformal IR fixed point. We will call such matrix factorizations quasihomogeneous. For compatibility with (3.7), we must require that Q has *R*-charge 1. We will, at first, assume that this U(1) acts on M as an $\mathcal{R}=\mathbb{C}[x_1,\ldots,x_r]$-module (instead of as a $\mathbb{C}$-vector space). We will, however, assume that the action is even, i.e., commutes with σ. Explicitly, we assume that there exists a map

$$\rho:\mathbb{R} \to \mathrm{GL}^+(2N,\mathcal{R}) = \mathrm{GL}(N,\mathcal{R}) \times \mathrm{GL}(N,\mathcal{R}), \tag{4.2}$$

such that

$$\rho(0,x_i) = \rho(\pi H,x_i) = \mathrm{id}_{2N\times 2N}, \tag{4.3}$$

$$\rho(\lambda,x_i)Q(e^{i\lambda q_i}x_i) = e^{i\lambda}Q(x_i)\rho(\lambda,x_i). \tag{4.4}$$

Note that this implies the slightly nonstandard group law

$$\rho(\lambda,x_i)\rho(\lambda',e^{i\lambda q_i}x_i)=\rho(\lambda+\lambda',x_i). \tag{4.5}$$

In (4.2), $\mathrm{GL}(N,\mathcal{R})$ is the group of invertible $N\times N$ matrices with polynomial entries. Under gauge transformations, $Q(x_i)\to U(x_i)Q(x_i)U(x_i)^{-1}$ with $U\in \mathrm{GL}^+(2N,\mathcal{R})$, ρ transforms as

$$\rho^U(\lambda,x_i)=U(x_i)\rho(\lambda,x_i)U(e^{i\lambda q_i}x_i)^{-1}. \tag{4.6}$$

Note that if we can find a gauge transformation such that ρ^U is diagonal, then by (4.3), ρ^U must be independent of the x_i. Hence ρ^U is an ordinary U(1) representation on M as a $\mathbb{C}$-vector space. On general grounds, one expects that one can always find such gauge transformation that makes ρ diagonal. We will assume that this is true. But, as will become clear later, we do not want to exclude altogether gauge transformations of nonzero degree which might make ρ nondiagonal (and x_i dependent).

B. Gradability is a topological condition

Consider the vector field generating the U(1) action (4.2)

$$R(\lambda,x_i)=-i\partial_\lambda\rho(\lambda,x_i)\rho(\lambda,x_i)^{-1}. \tag{4.7}$$

In general, this will depend on λ, but it is easy to see that $R(\lambda,x_i)$ is actually determined for all λ by (4.5) and $R(0,x_i)$. At $\lambda=0$, the condition (4.4) becomes

$$EQ+[R,Q]=Q, \tag{4.8}$$

where

$$E=\sum_i q_i x_i\frac{\partial}{\partial x_i} \tag{4.9}$$

is the "Euler vector field." Note that W being quasihomogeneous means $EW=2W$, and therefore, if $Q^2=W$,

$$\{Q,EQ-Q\}=0, \tag{4.10}$$

where $\{\cdot,\cdot\}$ is the anticommutator. In other words, $EQ-Q$ defines a class in $H^1(Q)$. The existence of R is the statement that this class is trivial.

The quasihomogeneity condition on matrix factorizations is therefore a topological condition that is roughly analogous, by mirror symmetry, to the vanishing of the Maslov class of Lagrangian cycles. Recall[44] that the vanishing of the Maslov class ensures that Floer cohomology can be $\mathbb{Z}$-graded. Here, requiring (4.8) will immediately only give a $\mathbb{Q}$-grading, which commutes with the $\mathbb{Z}_2$ grading. In Sec. IV F, we will combine the two gradings into a single $\mathbb{Z}$-grading.

Actually, requiring the infinitesimal version (4.8) is somewhat weaker than the integrated version (4.3) and (4.4), because it does not guarantee that R generates a compact U(1) action. Equivalently, we might not be able to diagonalize R by a gauge transformation. Deferring a discussion of this point to Sec. IV D, let us assume that R is diagonalized (and hence its entries are in $\mathbb{Q}$). We then obtain an induced (diagonalizable) U(1) action on the morphism spaces in the DG-category $\mathrm{DG}(W)$. $\mathbb{Q}$-homogeneous elements of $\mathrm{Hom}_{\mathrm{DG}(W)}(Q,Q')$ satisfy

$$E\Phi+R'\Phi-\Phi R=q_\Phi\Phi. \tag{4.11}$$

By (4.8), this descends to a $\mathbb{Q}$-grading of D-cohomology, and hence, of $\mathrm{MF}(W)$. To avoid confusion, we will use $\mathfrak{H}^*(Q,Q')=\oplus_{q\in\mathbb{Q}}\mathfrak{H}^q(Q,Q')$ to denote this $\mathbb{Q}$-graded cohomology, and also use the split

$$\mathfrak{H}^q(Q,Q')=\mathfrak{H}^{q,0}(Q,Q')\oplus\mathfrak{H}^{q,1}(Q,Q') \tag{4.12}$$

into $\mathbb{Z}_2$ even and odd pieces.

C. Serre duality

If the boundary tachyon configuration described by Q and Q' flows to a conformal theory in the IR, one expects the spectrum of Ramond ground states to be charge conjugation symmetric. As usual,[7] by spectral flow, this means for the chiral primaries, which are given by D-cohomology,

$$\begin{aligned} H^*(Q,Q') &= H^{*+r}(Q',Q), \\ \mathfrak{H}^q(Q,Q') &= \mathfrak{H}^{\hat{c}-q}(Q',Q), \end{aligned} \tag{4.13}$$

for the $\mathbb{Z}_2$- and $\mathbb{Q}$-graded cohomologies, respectively. Here $\hat{c}=\Sigma_{i=1}^{r}(1-q_i)$ is the central charge of the bulk CFT associated with W. In mathematical terms, (4.13) expresses "Serre duality" for the category MF(W), with trivial Serre functor given purely by a shift in rational degree by $\hat{c}$, and reversal of $\mathbb{Z}_2$ degree if the number of variables is odd.

Serre duality is equivalent to nondegeneracy of the boundary topological metric, which was computed in Refs. 32 and 39. If $\Phi \in \mathrm{Hom}_{\mathrm{MF}(W)}(Q,Q')$ and $\Psi \in \mathrm{Hom}_{\mathrm{MF}(W)}(Q',Q)$, this Serre pairing is given by

$$\langle \Psi\Phi \rangle = \oint \frac{\mathrm{Str}_M\left[(\partial Q)^{\wedge r}\Psi\Phi\right]}{\partial_1 W \cdots \partial_r W}, \tag{4.14}$$

where the integral is a multidimensional residue. It is easy to see that this pairing has $\mathbb{Q}$-degree $\hat{c}$, i.e., $\langle \Psi\Phi \rangle = 0$ unless $q_\Phi + q_\Psi = \hat{c}$. It also has $\mathbb{Z}_2$ grading given by r, the number of variables in the model. Thus, proving nondegeneracy of (4.14) is equivalent to (4.13). It would be interesting to show this.

D. Ambiguities of *R*

As we have mentioned, the condition (4.8) does not guarantee that R generates a compact U(1) action that closes for $\lambda = \pi H$. On the other hand, it determines R only up to an even matrix that commutes with Q, i.e., a representative of $H^0(Q)$. The author is not aware of any example in which (4.8) has a solution, but no solution which does not generate a compact U(1) action, or which is not diagonalizable.

For example, if all entries of $Q=\begin{pmatrix} 0 & f \\ g & 0 \end{pmatrix}$ are in fact homogeneous polynomials, then one expects that (4.8) generically has a solution $R=\mathrm{diag}(R_1,\ldots,R_{2N})$ which is diagonal. Indeed, denoting polynomial degree by deg, Eq. (4.8) becomes

$$\begin{aligned} R_j - R_{k+N} &= 1 - \deg(f_{jk}) \\ & \qquad \text{for } j,k = 1,\ldots,N, \\ R_{k+N} - R_j &= 1 - \deg(g_{kj}) \end{aligned} \tag{4.15}$$

which is a system of $2N^2$ equations for $2N$ unknowns. The nontrivial relations on the left-hand side of (4.15) are given by permutations $\pi \in \Sigma_N$ on N indices,

$$\sum_j \left(R_j - R_{\pi(j)+N}\right), \tag{4.16}$$

being independent of π. On the right-hand side, these relations become

$$N - \sum_j \deg(f_{j\pi(j)}). \tag{4.17}$$

On the other hand, on taking determinant of (3.1), we see that

$$\det(f)\det(g) = W^N, \tag{4.18}$$

which, assuming that W is irreducible, implies $\det(f) = W^k$ for some $0 \leqslant k \leqslant N$. Since $\Sigma \deg(f_{j\pi(j)})$ is the degree of a summand of $\det(f)$, we see that if there are no exceptional cancellations, (4.17) is independent of π. Similarly, $gf = W$ generically implies $\deg(f_{jk}) + \deg(g_{kj}) = 2$.

Thus if all entries of Q are homogeneous, we expect that there is a diagonal solution of (4.8) (this is true in all examples the author has studied). It is easy to see that the converse is also true, R is diagonal, then all entries of Q must be homogeneous. (But there are factorizations that are not quasihomogeneous, see Sec. VIII F.)

We will generally assume that there is a solution of (4.8) that is diagonalizable, keeping in mind that this assumption can conceivably fail at singular loci in the moduli space of matrix factorizations. Let us then analyze the ambiguities of R.

The proposal for fixing the ambiguity of R is motivated by the examples of Sec. VII and the general considerations of Sec. VI. (It is also reminiscent of the "a-maximization" procedure used to find the R-charge of $\mathcal{N}=1$ superconformal gauge theories in four dimensions.[45]) The essential idea is that R defines a character on the gauge group of similarity transformations. Infinitesimally, such gauge transformations are given by even endomorphisms of M as a $\mathcal{R}$-module, i.e., block-diagonal matrices $V \in \mathrm{Mat}^+(2N \times 2N, \mathcal{R})$, with $\mathrm{Tr}\, V \in \mathbb{C}$. They act on Q by $\delta Q = [V, Q]$, and the character induced by R is given by

$$\chi_R(V) = \mathrm{Tr}_M(RV). \tag{4.19}$$

The condition we would like to impose on R is that this character be trivial on the part of the gauge group acting trivially,

$$\mathrm{Tr}(RV) = 0 \quad \text{whenever} \quad [V, Q] = 0. \tag{4.20}$$

Note that under such infinitesimal gauge transformations, R transforms according to

$$\delta R = -EV - [R, V] \tag{4.21}$$

which leaves (4.8) invariant to first order. By all we have said, it might then seem natural to fix a diagonal R and restrict to gauge transformation of degree 0, i.e., those which satisfy $EV + [R, V] = 0$ leave R invariant. As we will see in Sec. VII, however, this would be too restrictive, as we would not be able to describe brane-antibrane annihilation.

To fix the ambiguity, and impose (4.20), one may proceed as follows. Start with a reference solution R_0, assumed to be diagonal. The ambiguities of (4.8), which are parametrized by even cycles of Q, can be decomposed according to the degree with respect to R_0,

$$C^0(Q) = \oplus_q \mathfrak{C}^{q,0}(Q), \tag{4.22}$$

where

$$\mathfrak{C}^{q,0} = \left\{ V \in \mathrm{Mat}(2N \times 2N, \mathcal{R}); [Q, V] = 0, [\sigma, V] = 0, EV + [R_0, V] = qV \right\}. \tag{4.23}$$

To see what can happen if we modify R_0 by an element of $C^0(Q)$, it is instructive to consider the following example. Let

$$R_0 = \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix} \tag{4.24}$$

with a and b rational. Then (we are neglecting Q and σ in this discussion—R_0 and V could be submatrices in a larger problem),

$$V = \begin{pmatrix} 0 & x \\ 0 & 0 \end{pmatrix} \tag{4.25}$$

is of (total) degree $q(V)=\deg(x)+a-b$ with respect to R_0. Clearly, R_0 generates a compact U(1) by $\rho_0(\lambda)=e^{i\lambda R_0}$, but R_0+V not necessarily so. Indeed, it is easy to see that the solution of (4.5) generated by R_0+V at $\lambda=0$ is

$$\rho(\lambda,x) = \begin{pmatrix} e^{i\lambda a} & x\dfrac{e^{i\lambda(a+\deg(x))}-e^{i\lambda b}}{a+\deg(x)-b} \\ 0 & e^{i\lambda b} \end{pmatrix}, \tag{4.26}$$

which for $b=a+\deg(x)$ goes over into

$$\rho(\lambda,x) = \begin{pmatrix} e^{i\lambda a} & ix\lambda e^{i\lambda b} \\ 0 & e^{i\lambda b} \end{pmatrix}. \tag{4.27}$$

We see that as long as $q(V)=\deg(x)+a-b\neq 0$, $R=R_0+V$ generates a compact U(1) and can be diagonalized. This fails when $q(V)=0$.

Thus, by rediagonalizing R if necessary, we can neglect the modifications of R_0 by elements of $\mathfrak{C}^{q,0}(Q)$ for $q\neq 0$. And clearly, χ_{R_0} vanishes automatically on $V\in\mathfrak{C}^{q,0}(Q)$, because such V does not have diagonal entries.

What about the ambiguities parametrized by $\mathfrak{C}^{0,0}(Q)$? As we have just seen, we cannot add V's without diagonal entries. Among those with diagonal entries, we choose a maximal commuting subalgebra, with basis $\{V_i\}_{i=1,\ldots,s}$, and impose (4.20) on the ansatz

$$R = R_0 + \sum_{i=1}^{s} a_i V_i. \tag{4.28}$$

In all examples the author has studied, this procedure leads to an unambiguously determined R which is diagonalizable and satisfies (4.20).

E. Cone construction

We next show that the grading we just introduced is compatible with the triangulated structure. In particular, we show that the cone (3.14) over a map $T[1]\in H^0(Q_1,Q_2[1])$ between two quasihomogeneous matrix factorizations is again quasihomogeneous.

Indeed,

$$\begin{aligned} EQ-Q &= \begin{pmatrix} EQ_1-Q_1 & 0 \\ ET-T & EQ_2-Q_2 \end{pmatrix} = \begin{pmatrix} [Q_1,R_1] & 0 \\ (q_T-1)T-R_2T+TR_1 & [Q_2,R_2] \end{pmatrix} \\ &= \left[Q, \begin{pmatrix} R_1+(q_T-1)\mathrm{id}_1 & 0 \\ 0 & R_2 \end{pmatrix} \right] \end{aligned} \tag{4.29}$$

is exact. More properly, we could choose

$$R = \begin{pmatrix} R_1+(q_T-1)\dfrac{N_2}{N_1+N_2}\mathrm{id}_1 & 0 \\ 0 & R_2-(q_T-1)\dfrac{N_1}{N_1+N_2}\mathrm{id}_2 \end{pmatrix} \tag{4.30}$$

so as to satisfy $\mathrm{Tr}(R)=0$ as well as $EQ-Q=[Q,R]$. But in the generic case, $C^0(Q)$ will contain more elements than just the identity so that we will not satisfy (4.20) in general.

F. Orbifolding and the phase of matrix factorizations

Recall that the Calabi-Yau/Landau-Ginzburg correspondence relates Calabi-Yau manifolds given as complete intersections in toric varieties to Landau-Ginzburg orbifold models.[22] In the simplest case, the Calabi-Yau is a hypersurface X given as the vanishing locus of a polynomial P of total degree H in weighted projective space $\mathbb{P}^{r-1}_{w_1,\ldots,w_r}$ such that $\Sigma_{i=1}^r w_i = H$. Such an X corresponds, via CY/LG correspondence, to the Landau-Ginzburg orbifold model with superpotential $W=P$ and orbifold group $\Gamma=\mathbb{Z}_H$, with central charge $\hat{c}=r-2$. The x_i have R-charge $q_i=2w_i/H$ and Γ is generated by $x_i \mapsto \omega_i x_i$ with $\omega_i = e^{i\pi q_i}$. The R-charges of the invariant part of the bulk chiral ring $\mathcal{J}=(\mathcal{R}/\partial W)^\Gamma$ are then all even integers.

Now let Q be a quasihomogeneous matrix factorization of W with R-matrix R uniquely determined as in Sec. IV D, and diagonal. Obviously, we would like to extend the Γ action to Q, and we require that it commutes with the rational and the $\mathbb{Z}_2$-grading. In other words, we are looking for a representation of Γ on (the associated $\mathbb{Z}_2$-graded $\mathcal{R}$-module of CP factors) M such that

$$\gamma Q(\omega_i x_i)\gamma^{-1} = Q(x_i). \tag{4.31}$$

It is easy to see that such a representation must be related to R in a simple manner. Indeed, we see that

$$\tilde{\gamma} = \sigma e^{-i\pi R}\gamma \tag{4.32}$$

commutes with Q. It is no restriction to assume that it is diagonal. If Q is reduced (i.e., contains not entries with a constant term), then all diagonal degree 0 elements of $C^0(Q)$ are actually nontrivial in $\mathfrak{H}^{0,0}(Q)$. We conclude that if Q is reduced and irreducible (i.e., $\mathfrak{H}^{0,0}(Q)$ is one dimensional), then $\tilde{\gamma}$ is a multiple of the identity, $\tilde{\gamma}=e^{i\pi\varphi}$. In other words, we find

$$\gamma = \sigma e^{i\pi R} e^{-i\pi\varphi}. \tag{4.33}$$

Imposing $\gamma^H=1$ fixes $\varphi \in \mathbb{R} \bmod 2/H$. Lifting to $\varphi \in \mathbb{R} \bmod 2$ gives H different equivariant factorizations for each factorization of W. (To be sure, if H is even, these correspond to $H/2$ branes together with their antibranes.)

A Γ-action on the objects induces an action on the morphism spaces $\mathfrak{H}^*(Q,Q')$, and we can project onto invariant morphisms by requiring

$$\gamma' \Phi(\omega_i x_i)\gamma^{-1} = \Phi. \tag{4.34}$$

By combining the definitions, it is easy to see that invariant morphisms satisfy the condition

$$e^{i\pi q_\Phi}(-1)^\Phi e^{\pi i(\varphi-\varphi')} = 1. \tag{4.35}$$

In other words, $q_\Phi = \varphi' - \varphi + n$, where n has the same parity as Φ. This constraint on the U(1) charges is the same as (2.3), and leads to the identification of φ as the phase of the matrix factorization.

Let us then define the category $\mathfrak{MF}(W)$, in which objects are quasihomogeneous matrix factorizations Q together with a lift of the phase φ to a real "grade," and morphism spaces are

$$\mathrm{Hom}^n((Q,\varphi),(Q',\varphi')) = \mathfrak{H}^{q=n+\varphi'-\varphi}(Q,Q'). \tag{4.36}$$

This is the promised $\mathbb{Z}$-graded category of matrix factorizations. Note in particular that the shift functor, which, because of (4.32), must be accompanied by $\varphi \to \varphi+1$, does not square to the identity in $\mathfrak{MF}(W)$.

G. Conjecture

The general decoupling statements of Ref. 2, the result that B-branes are described at large volume by the derived category of coherent sheaves, together with the assumption that all topo-

logical *B*-branes of the Landau-Ginzburg model have a description using matrix factorizations, naturally lead to the statement that—in appropriate cases—there should be an equivalence of categories

$$\mathfrak{MF}(W) \cong \mathbf{D}(X), \tag{4.37}$$

where $\mathfrak{MF}(W)$ is the category of quasihomogeneous Γ-equivariant matrix factorizations of W and $\mathbf{D}(X)$ is the derived category of coherent sheaves on the Calabi–Yau manifold X related to W/Γ by Witten's gauged linear sigma model construction.[22] Cases in which one expects such a correspondence include those GLSM's in which both large volume and Landau-Ginzburg points exist and are unique, such as the quintic in $\mathbb{P}^4$, or hypersurfaces in weighted projective spaces.

The author hopes that such a correspondence appears well-motivated from the physics point of view. It has essentially already been stated by Ashok, Dell'Aquila, and Diaconescu in Ref. 35 (for the quintic case and without the homogeneity condition). The author should, however, add that the correspondence is somewhat different from existing (and mathematically proven) equivalences between categories of matrix factorizations and other structures. Besides Eisenbud's canonical correspondence[14] with maximal Cohen-Macaulay modules, there is also an equivalence between matrix factorizations and a so-called "triangulated category of singularities" which was proven by Orlov.[19] Moreover, there is the classical correspondence of Grothendieck and Serre between graded modules over graded rings and vector bundles over the associated projective variety. This correspondence was exploited by Laza, Pfister, and Popescu in Ref. 46 for the case of the elliptic curve. If (4.37) is true, it is likely that the equivalence favored by physics is different from those just mentioned. For the elliptic curve, for instance, the methods of Ref. 46 on the one hand and Refs. 47 and 42 on the other hand yield quite different bundles corresponding to some given matrix factorization.

H. Landau-Ginzburg monodromy

We can make one further check that our conjecture makes sense. The Landau-Ginzburg point p_{LG} is an orbifold point in the Kähler moduli space $\mathcal{M}_k$. The action of the monodromy around p_{LG} acts on matrix factorizations in $\mathfrak{MF}(W)$ simply by rotating the choice of lift of φ in (4.33),

$$\varphi \to \varphi + 2/H. \tag{4.38}$$

As a consequence, the Hth power of the Landau-Ginzburg monodromy operator acts by $\varphi \to \varphi + 2$. This does nothing on the physical brane associated with Q, but is a shift by 2 in the triangulated category. This solves a problem posed in Ref. 6, in which the fifth power of the Landau-Ginzburg monodromy on the quintic Calabi-Yau was computed and found to correspond to a shift by 2 on the derived category. We can simply confirm this result using matrix factorizations, and in fact extend it to all Calabi-Yau manifolds with a Landau-Ginzburg description.

V. RR CHARGES AND INDEX THEOREM

If matrix factorizations represent *D*-branes in string theory, they must carry Ramond-Ramond (RR) charge. This charge takes value in the dual of the appropriate space $\mathcal{H}^B_{\mathrm{RR}}$ of closed string RR ground states. Because of the boundary condition on the worldsheet U(1) current, *B*-branes couple to those RR ground states with opposite left and right-moving *R*-charge, $q_L = -q_R$. The purpose of this section is to determine these RR charges of matrix factorizations. We first describe $\mathcal{H}^{\mathrm{B}}_{\mathrm{RR}}$.

The space of Ramond-Ramond ground states in Landau-Ginzburg orbifolds and their left-right *R*-charges was computed in Ref. 20. For simplicity, we will restrict here to a cyclic orbifold group $\Gamma = \mathbb{Z}_H$, as well as to integer central charge (we mostly have in mind, of course, $\hat{c}=3$). The generalization of at least some of the formulas to the more general case should be obvious. In general, those RR ground states with $q_L \neq q_R$ arise purely from the twisted sector, and if $\hat{c}$ is integer, the $\mathbb{Z}_H$ projection on twisted sectors implies that the RR ground states have $q_L \equiv q_R \equiv \hat{c}/2 \bmod \mathbb{Z}$.

Consider the lth twisted sector, and divide the field variables of the LG model into two classes, according to whether $lq_i \in 2\mathbb{Z}$ or $lq_i \notin 2\mathbb{Z}$. Those fields, $\{x_j^t\}$, with $lq_i \notin 2\mathbb{Z}$ satisfy twisted boundary condition in this sector, and must be set to zero in the semiclassical analysis used to determine the RR ground states. The contribution of those fields to the R-charges is (what we have called q_i is the sum of left- and right-moving charges of the variables x_i in the normalization of Ref. 20)

$$q_L^t = -q_R^t = \sum_{lq_i \notin \mathbb{Z}} \left(l\frac{q_i}{2} - \left[l\frac{q_i}{2} \right] - \frac{1}{2} \right). \tag{5.1}$$

On the other hand, those fields, $\{x_i^u\}_{i=1,\ldots,r_l}$, with $lq_i \in 2\mathbb{Z}$ satisfy untwisted boundary conditions in the lth twisted sector. Their quantization leads to a spectrum of RR ground states which is that corresponding to the effective potential $W_l(x_i^u) = W(x_i^u, x_i^t = 0)$. In particular, they contribute, $q_L^u = q_R^u$, equal amounts to left and right charge.

What is important for us, the ground states with $q_L = q_L^u + q_L^t = -q_R = q_R^u + q_R^t$ from the lth twisted sector correspond precisely to the neutral ground states of the effective potential $W_l(x_i^u)$ obtained by setting those fields with $lq_i \notin 2\mathbb{Z}$ to zero. These ground states have $q_L \equiv q_R \equiv \hat{c}/2 \bmod \mathbb{Z}$ if the number, r_l, of fields with $lq_i \in 2\mathbb{Z}$ is even. A basis of these ground states can be labeled as $|l;\alpha\rangle$, where l ranges between 0 and $H-1$, and α ranges over a basis $\phi_l^\alpha = (x^u)^\alpha = \prod_{i=1}^{r_l} (x_i^u)^{\alpha_i}$ of the subspace, $\mathcal{J}_l^0$, of the untwisted chiral ring $\mathcal{J}_l = \mathbb{C}[x_i^u]/\partial W_l$ with R-charge $q_L^u = q_R^u = \sum_{lq_i \in 2\mathbb{Z}} \alpha_i q_i/2 = \hat{c}^u/2$. Here, $\hat{c}^u = \sum_{lq_i \in 2\mathbb{Z}} (1-q_i)$ is the central charge corresponding to W_l. The states $|l;\alpha\rangle$ can be thought of as being obtained by acting with ϕ_α^l on the unique state $|l;0\rangle$, which has R-charge $-\hat{c}^u/2$.

Now by definition, the RR charge is the correlation function on the disk with the RR ground state inserted in the bulk. We propose that for a matrix factorization $Q \in \mathfrak{MF}(W)$, this is given by

$$\mathrm{ch}(Q): \mathcal{H}_{\mathrm{RR}}^{\mathrm{B}} \to \mathbb{C},$$

$$\mathrm{ch}(Q)(|l;\alpha\rangle) = \langle l;\alpha| Q_{\mathrm{disk}} = \frac{1}{r_l!} \mathrm{Res}_{W_l}(\phi_l^\alpha \, \mathrm{Str}[\gamma^l (\partial Q_l)^{\wedge r_l}]) = \frac{1}{r_l!} \oint \frac{\phi_l^\alpha \, \mathrm{Str}[\gamma^l (\partial Q_l)^{\wedge r_l}]}{\partial_1 W_l \cdots \partial_{r_l} W_l}, \tag{5.2}$$

where γ is the representation of the generator of $\mathbb{Z}_H$ on the matrix factorization, and $\mathrm{Str}(\cdot) = \mathrm{Tr}_M(\sigma \cdot)$ is the supertrace over the $\mathbb{Z}_2$-graded module M. The residue is the same as the one appearing in the Serre pairing (4.14). It is normalized[48] such that the determinant of the Hessian of the superpotential W_l has residue equal to the dimension of the chiral ring,

$$\mathrm{Res}_l(\det \partial_i \partial_j W_l) = \oint \frac{\det \partial_i \partial_j W_l}{\partial_1 W_l \cdots \partial_{r_l} W_l} = \dim \mathcal{J}_l = \mu_l = \prod_{lq_i \in 2\mathbb{Z}} \frac{2-q_i}{q_i}. \tag{5.3}$$

Moreover, in (5.2), $Q_l(x_i^u) = Q(x_i^u, x_i^t = 0)$ is the restriction of Q to the untwisted fields in the lth sector. It satisfies $Q_l^2 = W_l$.

Formula (5.2) makes sense since by (4.31),

$$\gamma^l Q^l(x_i^u) = Q^l(x_i^u) \gamma^l, \tag{5.4}$$

so γ^l represents a cohomology class of the matrix factorization Q_l, and (5.2) computes the disk correlation function[32,39] of $\gamma^l \phi_l^\alpha$ in this model. Moreover, since Res_l has $\mathbb{Q}$ degree $\hat{c}^u$ and $\mathbb{Z}_2$ degree r_l, we see that (5.2) would vanish if r_l were odd or if we tried to insert an element of $\mathcal{J}_l$ with charge not equal to $\hat{c}^u$.

In those twisted sectors with $r_l = 0$, i.e., $lq_i \notin 2\mathbb{Z}$ for all i, (5.2) reduces to

$$\mathrm{ch}(Q)(|l;0\rangle) = \mathrm{Str}\, \gamma^l. \tag{5.5}$$

One can check that (5.2) gives the correct value for the RR charges in those cases where an alternate computation exists, namely minimal models and their tensor products. Also, we see immediately that $\mathrm{ch}(Q[1])=-\mathrm{ch}(Q)$. The main evidence, however, that (5.2) is the correct expression for the RR charge is the index theorem for matrix factorizations, i.e., the fact that the Witten index for open strings between two matrix factorization Q and Q' can be computed via $\mathrm{ch}(Q)$ and $\mathrm{ch}(Q')$ as

$$\mathrm{Tr}(-1)^F=\sum_{n\in\mathbb{Z}}(-1)^n\dim \mathrm{Hom}^n_{\mathfrak{MF}(W)}(Q,Q')=\langle \mathrm{ch}(Q'),\mathrm{ch}(Q)\rangle, \tag{5.6}$$

where $(-1)^F$ is the $\mathbb{Z}_2$ grading (fermion number) of matrix factorizations. The Chern pairing is given by

$$\langle \mathrm{ch}(Q'),\mathrm{ch}(Q)\rangle=\frac{1}{H}\sum_{l=0}^{H-1}\sum_{\alpha,\beta}\mathrm{ch}(Q')(|l;\alpha\rangle)\frac{1}{\prod_{lq_i\notin 2\mathbb{Z}}(1-\omega_i^l)}\eta_l^{\alpha\beta}\,\mathrm{ch}(Q)(|l;\beta\rangle)^*. \tag{5.7}$$

For fixed l, $\Sigma_{\alpha,\beta}$ is a sum over the chosen basis of $\mathcal{J}_l^0$ of elements of the chiral ring $\mathcal{J}_l$ with charge $\hat{c}^u/2$, and $\eta_l^{\alpha\beta}$ is the inverse of the closed string topological metric in this sector,

$$\eta^l_{\alpha\beta}=\mathrm{Res}_l(\phi_l^\alpha\phi_l^\beta). \tag{5.8}$$

We will now prove (5.6) in the case that $r_l=0$ in all twisted sectors. The index of interest is the equivariant index of the operator D acting as in (3.11) on the complex given by the morphism space in $\mathrm{DG}(W)$, i.e.,

$$\mathrm{Tr}(-1)^F=\frac{1}{H}\sum_{l=0}^{H-1}\mathrm{Tr}(-1)^F\tilde{\gamma}^l, \tag{5.9}$$

where $\tilde{\gamma}$ is the action of the generator of $\mathbb{Z}_H$ on the cohomology spaces. We can regularize the computation of $\mathrm{Tr}(-1)^F\tilde{\gamma}=\lim_{t\to 1}Z_l(t)$ by using the $\mathbb{Q}$-grading by U(1) charge

$$Z_l(t)=\mathrm{Tr}(-1)^F t^q\tilde{\gamma}^l. \tag{5.10}$$

[More precisely, we should use an appropriate covering of this U(1) to make the charges integer.] By a standard argument, we can then replace the trace over the space of ground states by the trace over $\mathrm{Hom}_{\mathrm{DG}(W)}(Q,Q')=\mathrm{Hom}_{\mathcal{R}}(M,M')$, effectively reducing the computation to the setting $Q=Q'=0$. We decompose

$$\mathrm{Hom}_{\mathcal{R}}(M,M')=\bigoplus_{j,k=1}^{2N}\bigoplus_{\alpha}\mathcal{V}_{j,k,\alpha} \tag{5.11}$$

into one-dimensional pieces indexed by matrix entries (j,k) and monomials $x^\alpha=\Pi x_i^{\alpha_i}$ with multi-index $\alpha=(\alpha_1,\ldots,\alpha_r)$. Note that the combination of fermion number and $\mathbb{Z}_H$-action restricts on $\mathcal{V}_{j,k,\alpha}$ to

$$((-1)^F\tilde{\gamma})_{\mathcal{V}_{j,k,\alpha}}=\sigma'_j\gamma'_j\left(\prod_{i=1}^r\omega_i^{\alpha_i}\right)\sigma_k\gamma_k^{-1}, \tag{5.12}$$

where $\omega_i=e^{\pi i q_i}$, and we are using that both σ and γ are diagonal matrices. Therefore,

$$Z_l(t) = \sum_{j,k=1}^{2N} \sum_{\alpha} \sigma'_j(\gamma'_j)^l t^{R'_j} \left(\prod_{i=1}^{r} \omega_i^{l\alpha_i} t^{q_i \alpha_i} \right) \sigma_k(\gamma_k)^{-l} t^{-R_k} = \mathrm{Str}((\gamma')^l t^{R'}) \frac{1}{\prod_i (1 - t^{q_i} \omega_i^l)} \mathrm{Str}(\gamma^{-l} t^{-R}). \tag{5.13}$$

Since $\mathrm{Str}(\mathrm{id}) = 0$, and we are assuming that $lq_i \notin \mathbb{Z}$ for all other l and i, we can smoothly take $t \to 1$, and obtain

$$\mathrm{Tr}(-1)^F = \frac{1}{H} \sum_{l=1}^{H-1} \mathrm{Str}(\gamma')^l \frac{1}{\prod_i (1 - \omega_i^l)} \mathrm{Str}\ \gamma^{-l}, \tag{5.14}$$

as was to be shown.

To establish (5.6) and (5.7) in general, one should combine the proof we just gave with the formula

$$\frac{1}{(r_l!)^2} \mathrm{Res}_l(\mathrm{Str}[(\partial Q'_l)^{\wedge r_l}] \mathrm{Str}[(\partial Q_l)^{\wedge r_l}]) = \sum_{\alpha,\beta} \frac{1}{r_l!} \mathrm{Res}_l(\phi_l^\alpha \mathrm{Str}[(\partial Q'_l)^{\wedge r_l}]) \eta_l^{\alpha\beta} \frac{1}{r_l!} \mathrm{Res}_l(\phi_l^\beta \mathrm{Str}[(\partial Q_l)^{\wedge r_l}]). \tag{5.15}$$

This formula expresses the factorization rule for the topological annulus correlator[32] with no boundary insertions via two disk amplitudes and (the inverse of) the closed string topological metric $\eta^l_{\alpha,\beta}$ (5.8) given by the sphere amplitude.[48] [Note that in (5.15), the sum over α, β can be extended to the full chiral ring $\mathcal{J}_l$ because the disk correlators vanish outside of $\mathcal{J}_l^0$.] In the general axioms of open-closed topological field theory,[49,50] this factorization is known as the "Cardy condition." By the same axioms, the annulus correlator (5.15) computes the open string Witten index $\mathrm{Tr}(-1)^F$ between the matrix factorizations Q_l, Q'_l in the untwisted Landau-Ginzburg model corresponding to W_l. The author has checked the equality of the two sides of (5.15), and that they compute the open string Witten index, in all known examples, but the author does not know a proof based directly on the residue formula.

We close this section with a few comments.

First, we note that there is an obvious analogy between (5.6) and (5.7) and the well-known Hirzebruch-Riemann-Roch theorem which computes the Witten index for open strings coupled to two vector bundles E and F on the Calabi-Yau manifold X,

$$\mathrm{Tr}(-1)^F = \int \mathrm{ch}(E^*)\mathrm{ch}(F)\mathrm{Td}(X). \tag{5.16}$$

Our formula is simply the small volume version of this. In particular, the factor $\eta_l^{\alpha\beta}/\Pi(1-\omega_i^l)$ can be viewed as the analog of the Todd class of X. From this perspective, the normalization in which the square root of this factor is included in the charge might seem more natural.

Second, we return to the split of the Ramond ground states into those from twisted sectors with $r_l = 0$ and those from twisted sectors with $r_l \neq 0$ and even. In the RCFT description of LG models as Gepner models,[51] the ground states with $r_l \neq 0$ are not left-right symmetric in each individual $\mathcal{N}=2$ minimal model. (Geometrically, they correspond to nontoric blowups of X. For this reason, most models that have been studied geometrically in any depth do not have such states.) As a consequence, the BCFT constructions of boundary states in Gepner models[52] did not produce boundary states with charge under those RR ground states with $r_l \neq 0$, the only exception being related to the so-called fixed point resolution phenomenon discussed in Refs. 53 and 54 (see also Refs. 55 and 32). On the other hand, it is easy to find matrix factorizations for which charges with $r_l \neq 0$ do not vanish. (The two-variable factorizations of Sec. VII D, when embedded in the appropriate Calabi-Yau model, provide useful examples.) It seems likely that matrix factorizations span the free part of K-theory that is expected from cohomology. What the Chern classes (5.2)

miss, of course, is the torsion part of the *K*-theory. Unorbifolded minimal models, for example, have *K*-theory that is purely torsion. One might expect that some of this will survive the orbifold procedure, conceivably in the twisted sectors with r_l odd. It would be interesting to determine the full *K*-theory of these Landau-Ginzburg orbifolds and compare with their geometric computation. This would be a zeroth order check of (4.37).

VI. A STABILITY CONDITION

In mathematical models of *D*-branes similar to the one we are studying, such as Lagrangian submanifolds of symplectic manifolds, holomorphic vector bundles on complex manifolds, or representations of a quiver algebra, a stability condition is introduced with the purpose of identifying a subset of objects whose orbits under the group of appropriate automorphisms fit together into "nice" moduli spaces. Often, the stable orbits admit a distinct (unique) representative at the zero of a "moment map" associated with the stability condition (for instance, the special condition for Lagrangians or the Hermitian Yang-Mills equation for the connection on the holomorphic vector bundle). (See, e.g., Chap. 38 of Ref. 23 for a recount of these stories.)

In physics, the zeroes of the moment map are associated with the solution of the condition that the *D*-brane preserve supersymmetry in the uncompactified part of space–time. Stability is the condition that such a supersymmetric configuration can be reached by boundary renormalization group (RG) flow on the string worldsheet. In the unstable (including semistable) case, the theory is expected to split at singular points along RG flow into the direct sum of several decoupled theories. The endpoint of the flow is the decomposition into the stable pieces.

For a general Landau-Ginzburg model (orbifolded or not, with arbitrary central charge), the interpretation involving spacetime supersymmetry is not necessarily available, and we will factor it out accordingly. What remains is the unitarity constraint (2.1) and the assertion that if this condition is satisfied, worldsheet RG flow should lead to a single unitary boundary CFT in the IR (i.e., a theory with a unique open string vacuum). This is a stability condition that can be imposed on the triangulated category of any quasihomogeneous Landau-Ginzburg model.

If the model has a geometric interpretation, then in view of the expected equivalence (4.37), this is a particular stability condition on $\mathbf{D}(X)$. It is distinguished by the fact that it arises only from data involving the unorbifolded model (or equivalently, the orbifolded model divided by the quantum symmetry). In the general framework of Ref. 5, the space of (numerical) stability conditions is locally modeled on the free part of the *K*-theory. As we have seen in Sec. V, most of the *K*-theory (all of it for an odd number of variables) appears during orbifolding. Therefore, the stability condition in the Landau-Ginzburg model should be more rigid than the ones on $\mathbf{D}(X)$.

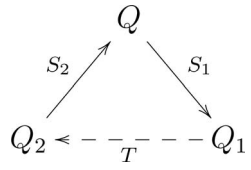
A. A notion of stability

As we have reviewed in Sec. II, the basic idea underlying Π-stability is that open strings between physical branes should satisfy the unitarity constraint $0 \leqslant q \leqslant \hat{c}$. It is hard, however, to impose such a constraint directly on individual objects to determine whether they are stable, essentially because this would involve an infinite number of checks, and moreover because a stable object does not only have strings satisfying (2.1) ending on it. Physically,[2] one should not try to impose the condition (2.1) on configurations described as (topological) bound states containing both branes and antibranes. One expects that in certain regimes,[2,4] or even at all points in the space of stability conditions,[5] integrating out all canceling brane-antibrane pairs will reduce the problem to a stability condition on an Abelian category, which involves only a finite number of checks. Still, these discussions leave open the question whether Π-stability is sufficient or just a self-consistent "bootstrap" condition. Our point of view is that the Landau-Ginzburg model should posses an intrinsic (rigid) stability condition that does not depend on what is going on in the rest of the moduli space. It is this notion of stability that we are after.

In the Landau-Ginzburg context, "integrating out brane-antibrane pairs" simply corresponds to restricting to reduced matrix factorizations, i.e., those without scalar entries. It is not unreasonable to expect, therefore, that by going to reduced matrix factorizations, one obtains the Abelian

category of interest for the discussion of Ref. 5. This Abelian category could be simply related to the category of Cohen-Macaulay module of Sec. III A. In any case, we now make the following tentative definition.

Let $W(x_1,\ldots,x_r)$ be a quasihomogeneous Landau-Ginzburg polynomial, $EW=2W$, where $E=\Sigma q_i x_i \partial_i$. Let Q be a reduced quasihomogeneous matrix factorization of W. Q is called R-semistable if in all triangles



(6.1)

in which Q participates opposite to the fermionic morphism T, we have

$$q_T \leqslant 1 \Leftrightarrow q_{S_1} \geqslant 0 \Leftrightarrow q_{S_2} \geqslant 0. \tag{6.2}$$

Q is stable if the only triangles for which $q_T=1$ are those with Q_1 or Q_2 equal to Q (and the other equivalent to 0).

Here q_T is defined by the condition

$$ET + R_2T - TR_1 = q_T T, \tag{6.3}$$

where R_1 and R_2 are the R-matrices of Q_1 and Q_2, respectively.

We can give one simple check that relates R-stability to a stability condition in the sense of Bridgeland.[5] Recall that in the orbifolded case (Sec. IV F), we have defined morphism between objects in $\mathfrak{MF}(W)$ by $\mathrm{Hom}^0(Q,Q')=\mathfrak{H}^{q=\varphi'-\varphi}(Q,Q')$. Therefore, our condition (6.2) directly implies

$$\varphi > \varphi' \Rightarrow \mathrm{Hom}^0(Q,Q') = 0, \tag{6.4}$$

which is one of the axioms of Ref. 5.

We also note that our formulation is similar to those of a stability condition for Lagrangian submanifolds proposed by Thomas[56] and further studied in Ref. 57.

B. A moment map problem?

The stability condition we have proposed is physically well motivated. It only deserves its name, however, if it can be related to the moduli space problem for matrix factorizations. In other words, one would like to show that stable matrix factorizations have nicely behaved orbits under the group of gauge equivalences. As we have mentioned before, this group is the group of similarity transformations

$$G \cong \mathrm{GL}^+(2N,\mathcal{R}) \cong \mathrm{GL}(N,\mathcal{R}) \times \mathrm{GL}(N,\mathcal{R}) \tag{6.5}$$

acting as in (3.2). Thus we have an algebraic group acting on a linear space with a constraint. This problem is quite similar to the one studied by King.[11]

In Ref. 11, the general setup of geometric invariant theory (GIT)[58] is used to define moduli spaces for representations of finite-dimensional algebras, which can be equivalently described as the representations of quiver diagrams. Quivers arise naturally as world-volume theories for D-branes at singularities, and the theory of quivers has played an important role in the development of Π-stability.[1,10] In the quiver case, the gauge group $\mathcal{G}$ is the product of general linear groups acting on the vector spaces at each node of the quiver. King uses GIT to give a geometric description of the algebraic quotient of the representation space Y with respect to a character $\chi:\mathcal{G}\to\mathbb{C}^\times$ via "Mumford's numerical criterion:" A representation $y\in Y$ is χ-semistable iff χ is

trivial on the stabilizer of y and if every one-parameter subgroup $g(\lambda)=e^{\lambda a}$ of $\mathcal{G}$, for which $\lim_{\lambda\to\infty} y$ exists, satisfies $\langle d\chi, a\rangle \geqslant 0$, where $d\chi$ is the infinitesimal version of χ evaluated on the generator a of $g(\lambda)$.

Our stability condition is precisely equivalent to such a "numerical criterion." To see this, note that all triangles in MF(W) are isomorphic to the standard cone (4.29), namely

$$Q = Q_1 \oplus Q_2 + T, \quad R = R_1 \oplus R_2 + (q_t - 1)\left[\frac{N_2}{N_1+N_2}S_1 - \frac{N_1}{N_1+N_2}S_2\right], \tag{6.6}$$

where $S_i=\mathrm{id}_i$. Under the one-parameter group of gauge transformations generated by $V=S_1$, this cone transforms as

$$Q_\lambda = e^{\lambda V} Q e^{-\lambda V} = Q_1 \otimes Q_2 + e^{-\lambda} T \underset{\lambda\to\infty}{\to} Q_1 \otimes Q_2. \tag{6.7}$$

The limit $\lambda \to \infty$ simply splits the cone back into its constituents. The condition $q_T \leqslant 1$ is equivalent to

$$-\mathrm{Tr}(RV) = -(q_t - 1)\frac{2N_2N_1}{N_2+N_1} \geqslant 0, \tag{6.8}$$

thus identifying $\mathrm{Tr}(R\cdot)$ as the character of G with respect to which we are defining stability. The condition (4.20) we are imposing to fix the ambiguities of R is precisely the condition that $\mathrm{Tr}(R\cdot)$ should vanish on the trivially acting gauge transformations. Similarly as in Ref. 11, we can then formulate a "numerical criterion" that a matrix factorization Q is R-semistable if all one-parameter subgroups $e^{\lambda V}$ of the gauge group, for which the limit $\lim_{\lambda\to\infty} e^{\lambda V} Q e^{-\lambda V}$ exists, satisfy $\mathrm{Tr}(RV) \leqslant 0$.

In Ref. 11, King then goes on to describing a symplectic quotient construction of the moduli space, which is the basis for the relation to quiver gauge theories.

We can at present see two difficulties in making such a relation in our situation more precise, both of which due to the fact that G is not as simple a gauge group as the one acting on quiver representations. First of all, as a complex Lie group, G is infinite-dimensional. This is similar to the situation with vector bundles or Lagrangian submanifolds, giving reason for hope. The second difficulty appears if, as might seem natural, we would restrict to the degree 0 gauge transformations, i.e., those generated by

$$\mathfrak{g}^0 = \{V \in \mathfrak{g}; EV + [R,V] = 0\}. \tag{6.9}$$

The problem with $\mathfrak{g}^0$ is that it is nonreductive. Indeed, since both polynomial and total degree are preserved in matrix multiplication, $\mathfrak{g}^0$ has a maximal solvable subalgebra consisting of those matrices without constant term. In other words, we can decompose $\mathfrak{g}^0$ into its maximal reductive subalgebra consisting of those elements annihilated by E, and the nilpotent part. This nonreductiveness of $\mathfrak{g}^0$ makes it more difficult to apply the general results of GIT and to find a relation with a moment map problem. In any case, however, restricting to gauge transformations of degree 0 makes the description of brane-antibrane annihilation somewhat unnatural, see Sec. VII B.

Setting aside these difficulties for the moment, we will naively follow the usual steps to write down a moment maplike flow equation on the gauge orbits. As we will see in Sec. VII, this naive flow works quite well in a number of examples. Imitating,[11] we introduce a metric on the space of matrix factorizations,

$$\langle Q, Q'\rangle = \sum_\alpha \mathrm{Tr}(Q_\alpha^\dagger Q'_\alpha), \tag{6.10}$$

where

$$Q = \sum_\alpha Q_\alpha x^\alpha, \quad Q' = \sum_\alpha Q'_\alpha x^\alpha \tag{6.11}$$

is the decomposition of Q and Q' into a sum over monomials $x^\alpha = \Pi_i x_i^{\alpha_i}$. In any given case, we restrict to a finite-dimensional subgroup of G and choose a basis of generators, $\{V_i\}$. The flow equation then is

$$\frac{dQ}{dt} = -(\langle Q, [V^i, Q]\rangle - \mathrm{Tr}\, RV^i)[V_i, Q]. \tag{6.12}$$

Note that by construction, (6.12) is indeed a moment map for the maximal reductive subgroup of the degree 0 gauge group.

Moreover, one can see that the flow (6.12) indeed reproduces the correct splitting (6.7) of the standard cone (4.29) in the case that $q_T \geqslant 1$. A simple calculation gives

$$\frac{d\lambda}{dt} = (e^{-2\lambda}\|T\|^2 + (q_T - 1)\beta) \tag{6.13}$$

where $\beta = 2N_2N_2/(N_2+N_1)$. Evidently, this has a solution at finite λ if $q_T < 1$, whereas for $q_T \geqslant 1$, the flow drives us to $\lambda \to \infty$. The form of Eq. (6.13) is of course familiar in the context of solving D-flatness conditions in four-dimensional $\mathcal{N}=1$ supersymmetric gauge theories.

VII. EXAMPLES

We conclude the paper with several concrete examples of matrix factorizations and flows on their gauge orbits defined by (6.12). As alluded to before, one can view these flows as toy models for boundary flows in Landau-Ginzburg models. (Landau-Ginzburg descriptions of boundary flows have also recently been discussed in Ref. 59.)

A. Minimal models

Matrix factorizations of A-type minimal models with type 0A GSO projection, corresponding to the LG superpotential $W = x^h$ were discussed in detail in Refs. 31, 33, 36, and 41. They are given by

$$Q_n = \begin{pmatrix} 0 & x^n \\ x^{h-n} & 0 \end{pmatrix} \quad \text{for } n = 1, \ldots, h-1. \tag{7.1}$$

The R-matrix is

$$R = \begin{pmatrix} \frac{1}{2} - \frac{n}{h} & 0 \\ 0 & -\frac{1}{2} + \frac{n}{h} \end{pmatrix}. \tag{7.2}$$

It is easy to see that there is only one nontrivial element of the degree 0 gauge algebra,

$$V = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & -\frac{1}{2} \end{pmatrix}. \tag{7.3}$$

The orbit generated by V looks like

$$Q_n(\lambda) = e^{\lambda V} Q_n e^{-\lambda V} = \begin{pmatrix} 0 & e^{\lambda} x^n \\ e^{-\lambda} x^{h-n} & \end{pmatrix}, \tag{7.4}$$

so that the flow (6.12) becomes

$$\frac{d\lambda}{dt} = -(\langle Q_n(\lambda),[V,Q_n(\lambda)]\rangle - \mathrm{Tr}\, RV) = -\left(e^{2\,\mathrm{Re}\,\lambda} - e^{-2\,\mathrm{Re}\,\lambda} - \frac{1}{2} + \frac{n}{h}\right). \tag{7.5}$$

Obviously, this flow has just one stationary point, which is stable. This is as expected. Indeed, one can check explicitly that all open strings between different minimal model factorizations satisfy $0 \leqslant q \leqslant \hat{c} = 1 - (2/h) < 1$.

B. Brane-antibrane annihilation

We have been tempted several times in this paper to restrict attention to the gauge transformations of degree 0 only. In this section, we show that in fact, the description of brane-antibrane annihilation in the context of matrix factorizations requires the inclusion of gauge transformation of nonzero degree.

Let (f,g) be a matrix factorization of W with R-matrix $R=(R_+,R_-)$, and consider the cone over the identity id, $(f,g)\to(f,g)$,

$$Q_0 = \begin{pmatrix} 0 & 0 & f & 0 \\ 0 & 0 & 1 & g \\ g & 0 & 0 & 0 \\ -1 & f & 0 & 0 \end{pmatrix}. \tag{7.6}$$

This is gauge equivalent to direct sums of the trivial factorization $W=1\cdot W$ via the gauge transformation

$$U_\lambda = \begin{pmatrix} 1 & -\lambda f & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & \lambda g \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{7.7}$$

Namely,

$$Q_\lambda = U_\lambda Q_0 U_\lambda^{-1} = \begin{pmatrix} 0 & 0 & (1-\lambda)f & (\lambda^2-2\lambda)W \\ 0 & 0 & 1 & (1-\lambda)g \\ (1-\lambda)g & (2\lambda-\lambda^2)W & 0 & 0 \\ -1 & (1-\lambda)f & 0 & 0 \end{pmatrix} \tag{7.8}$$

which for $\lambda=1$ becomes

$$Q_1 = \begin{pmatrix} 0 & 0 & 0 & -W \\ 0 & 0 & 1 & 0 \\ 0 & W & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}. \tag{7.9}$$

What is the R-matrix associated with Q_0? The cone construction of Sec. IV E gives one possible solution (4.30)

$$R^{\mathrm{cone}} = \begin{pmatrix} R_+ - \frac{1}{2} & 0 & 0 & 0 \\ 0 & R_- + \frac{1}{2} & 0 & 0 \\ 0 & 0 & R_- - \frac{1}{2} & 0 \\ 0 & 0 & 0 & R_+ + \frac{1}{2} \end{pmatrix}. \tag{7.10}$$

However, this R-matrix does not satisfy (4.20). By using the equivalence with Q_1, one finds that the generators of $C^0(Q_0)$ with nonvanishing diagonal entries and degree 0 with respect to R^{cone} are

$$V_i = \begin{pmatrix} e_i & -f_i & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -g^i \\ 0 & 0 & 0 & e_i \end{pmatrix} \quad \text{and} \quad V^i = \begin{pmatrix} 0 & f^i & 0 & 0 \\ 0 & e_i & 0 & 0 \\ 0 & 0 & e_i & g_i \\ 0 & 0 & 0 & 0 \end{pmatrix}, \tag{7.11}$$

where e_i is the $N \times N$ matrix with a 1 at the ith position on the diagonal, and zeroes elsewhere, and $f_i = e_i f$ and $f^i = f e_i$ are the ith row and column of f, respectively.

Then the combination of R^{cone}, V_i, and V^i satisfying (4.20) is

$$R_0 = \begin{pmatrix} -\frac{1}{2} & R_+ f - f R_- & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ 0 & 0 & -\frac{1}{2} & gR_+ - R_- g \\ 0 & 0 & 0 & \frac{1}{2} \end{pmatrix} = \begin{pmatrix} -\frac{1}{2} & -Ef + f & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ 0 & 0 & -\frac{1}{2} & Eg - g \\ 0 & 0 & 0 & \frac{1}{2} \end{pmatrix}. \tag{7.12}$$

Under the similarity transformation (7.8), R_0 transforms into the diagonal matrix $R_1 = \text{diag}(-1/2, 1/2, -1/2, 1/2)$. This R_1 is the R-matrix one would naturally assign to a sum of copies of the trivial branes described by Q_1.

Note that while the gauge transformation relating Q_0 and Q_1 has degree zero with respect to R^{cone}, it does not have definite degree with respect to R_0. We conclude that either we are forced to work with gauge transformations of nonzero degree or we should be using R^{cone} as R-matrix for the cone. We cannot completely exclude the second possibility since (by definition) the factorization $(1, W)$ does not have any nontrivial morphism ending on it, so there are no R-charges to check. But the symmetric end result, R_1, is good justification for the procedure we have proposed. And the moment map equation only makes sense if we use R_0. One can also check that the flow defined by (6.12) on the gauge orbit (7.8) flows to $\lambda = 1$.

C. Boundary flows in minimal models

Having argued for the general relevance of gauge transformations of nonzero degree, we now return to minimal models and study boundary flows associated with perturbations by a boundary condition changing operator. General aspects of such boundary flows in $\mathcal{N}=2$ minimal models were discussed recently in Ref. 36 and in Ref. 41. In particular, these works discuss the similarity transformations relating the different minimal model branes at the topological level, as well as the operators inducing these relations. Our flow equation (6.12) gives a handle on the complete flow in the physical theory.

We will consider as an example the starting point

$$Q_0 = \begin{pmatrix} 0 & 0 & x^2 & 0 \\ 0 & 0 & -x & x^3 \\ x^{h-2} & 0 & 0 & 0 \\ x^{h-4} & x^{h-3} & 0 & 0 \end{pmatrix}. \tag{7.13}$$

The R-matrix, obtained by the methods above is

$$\begin{pmatrix} \frac{1}{2} - \frac{4}{h} & -\frac{x}{h} & 0 & 0 \\ 0 & \frac{1}{2} - \frac{1}{h} & 0 & 0 \\ 0 & 0 & -\frac{1}{2} + \frac{1}{h} & -\frac{x^2}{h} \\ 0 & 0 & 0 & -\frac{1}{2} + \frac{4}{h} \end{pmatrix}. \tag{7.14}$$

We have studied the flow induced by (6.12) on the orbit of Q_0 under the gauge transformations generated by

$$V=\begin{pmatrix} \lambda_1 & \lambda_3 x & 0 & 0 \\ 0 & \lambda_2 & 0 & 0 \\ 0 & 0 & -\lambda_2 & \lambda_4 x^2 \\ 0 & 0 & 0 & -\lambda_1 \end{pmatrix} \tag{7.15}$$

and find that it does converge to the diagonal

$$\begin{pmatrix} 0 & 0 & 0 & \alpha x^4 \\ 0 & 0 & -\beta x & 0 \\ 0 & -\beta^{-1}x^{h-1} & 0 & 0 \\ \alpha^{-1}x^{h-4} & 0 & 0 & 0 \end{pmatrix} \cong Q_1 \oplus Q_4, \tag{7.16}$$

where α and β are the appropriate solutions of (7.5). The R-matrix becomes diag$(1/2-4/h, 1/2-1/h, -1/2+1/h, -1/2+4/h)$, which is certainly the correct result for this factorization.

We should note that the perturbation we have turned on in (7.13) is not the most relevant between the two minimal model branes Q_2 and Q_3. We have chosen this one to illustrate that there are various possible flow patterns in $\mathcal{N}=2$ minimal models. In this simple case the range of possibilities is essentially governed by the K-theory, isomorphic to $\mathbb{Z}_H$. One can create a free K-theory [and make the perturbation in (7.13) the most relevant one] by considering an appropriate orbifold.

In any case, the end result of the flow is consistent with the predictions made, for instance, in Refs. 36 and 59.

D. *D*0-brane in quintic Gepner model

In Ref. 35, matrix factorizations were constructed which describe (at the topological level) $D0$-branes at the Landau-Ginzburg orbifold point in the Kähler moduli space of the quintic Calabi-Yau. We here want to address the issue whether these factorizations can be stable by checking that the open strings stretched between this $D0$-brane and the rational tensor products of minimal model branes satisfy the unitarity bound. While this does of course not settle the question whether the $D0$-brane can become unstable far away from the large volume limit, it is certainly a nontrivial check.

The superpotential of interest is $W=\Sigma_{i=1}^5 x_i^5$. The factorizations of Ref. 35 are tensor products of minimal model factorizations in three of the five minimal factors together with a nonfactorizable factorization in the remaining two factors. Since taking tensor products simply adds U(1) charges, but does not affect the unitarity bound, it will suffice to consider this two-variable factorization. We can factorize

$$x^5-y^5=(x-y)(x^4+x^3y+x^2y^2+xy^3+y^4). \tag{7.17}$$

One can see that the R-matrix associated with this factorization is diag$(3/10,-3/10)$. We want to compute the charges of open strings between this factorization and the tensor product of minimal model branes

$$f=\begin{pmatrix} x & -y \\ -y^4 & x^4 \end{pmatrix}, \quad g=\begin{pmatrix} x^4 & y \\ y^4 & x \end{pmatrix}, \quad R=\mathrm{diag}(3/5,-3/5,0,0). \tag{7.18}$$

As computed in Ref. 35, there is one bosonic and one fermionic cohomology class between (7.17) and (7.18), represented by

$$\Phi^0=\begin{pmatrix} y^3 & 1 & 0 & 0 \\ 0 & 0 & y^3 & x^3+x^2y+xy^2+y^3 \end{pmatrix},$$

$$\Phi^1 = \begin{pmatrix} 0 & 0 & -1 & 1 \\ x^3+x^2y+xy^2+y^3 & -1 & 0 & 0 \end{pmatrix}, \tag{7.19}$$

respectively. We easily find

$$q(\Phi^0) = \tfrac{9}{10}, \quad q(\Phi^1) = \tfrac{3}{10} \tag{7.20}$$

satisfying the unitarity bound $0 \leqslant q \leqslant \hat{c} = \frac{6}{5}$. We have also checked the open strings between the $D0$-brane factorization and the other minimal model branes. They all satisfy the bound.

E. Decay of an unstable factorization

In this section, we give an example of a matrix factorization that is unstable and investigate to what extent our flow (6.12) can detect this without having to check the charges of open strings. The superpotential is $W=x^5+y^5$, and the factorization given by

$$f_{\text{unst}} = \begin{pmatrix} x & y & 0 \\ 0 & x^3 & y \\ y^3 & 0 & x \end{pmatrix}, \quad g_{\text{unst}} = \begin{pmatrix} x^4 & -xy & y^2 \\ y^4 & x^2 & -xy \\ -x^3y^3 & y^4 & x^4 \end{pmatrix},$$

$$R = \text{diag}(7/10, -1/10, -1/10, 1/10, 1/10, -7/10), \tag{7.21}$$

A morphism between this factorization and the tensor product of minimal model branes (7.18) is given by

$$T = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & x & -y & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} \tag{7.22}$$

and one can easily check that this field has R-charge $-\frac{1}{10}$, violating the unitarity bound. (Note that since T has scalar entries, it cannot be exact.) The cone over T is another copy of the tensor product of minimal branes, thus exhibiting (7.21) as an unstable bound state, obtained by "condensing" a field with $q>1$ between two such objects. Namely, $(f_{\text{unst}}, g_{\text{unst}})$ is stably equivalent to

$$F_{\text{unst}} = \begin{pmatrix} x & y & 0 & 0 \\ -y^4 & x^4 & 0 & 0 \\ 0 & -x^3 & x^4 & -y \\ y^3 & 0 & y^4 & x \end{pmatrix}, \quad \text{with corresponding } G_{\text{unst}}. \tag{7.23}$$

To be precise, we should note that $(F_{\text{unst}}, G_{\text{unst}})$ is really a cone over a brane and its own antibrane, but via a field that is not the identity. As a consequence, $(f_{\text{unst}}, g_{\text{unst}})$ has a unitarity violating field in the spectrum with itself. But since this field can easily be projected out by going to an appropriate orbifold, it should not be viewed as the cause of the instability.

In discussing the flow, it is useful to contrast the unstable factorization with a very similarly structured stable (with the same caveat as before) bound state of two minimal model tensor products, namely

$$F_{\text{stab}} = \begin{pmatrix} x & y^2 & 0 & 0 \\ -y^3 & x^4 & 0 & 0 \\ 0 & -x^3 & x^4 & -y^2 \\ y & 0 & y^3 & x \end{pmatrix}, \quad G_{\text{stab}}, \tag{7.24}$$

which can be reduced to

$$f_{\text{stab}} = \begin{pmatrix} x & y^2 & 0 \\ 0 & x^3 & y^2 \\ y & 0 & x \end{pmatrix}, \quad g_{\text{stab}} = \text{adj}(f_{\text{stab}}). \tag{7.25}$$

We have studied numerically the flow defined by (6.12) on the 12-parameter gauge orbit of $(F_{\text{unst}}, F_{\text{unst}})$ and $(F_{\text{stab}}, G_{\text{stab}})$ generated by

$$\begin{pmatrix} \lambda_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \lambda_2 & x\lambda_3 & y\lambda_4 & 0 & 0 & 0 & 0 \\ 0 & 0 & \lambda_5 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \lambda_6 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda_7 & 0 & y\lambda_8 & 0 \\ 0 & 0 & 0 & 0 & 0 & \lambda_9 & x\lambda_{10} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \lambda_{11} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_{12} \end{pmatrix} \tag{7.26}$$

and

$$\begin{pmatrix} \lambda_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \lambda_2 & x\lambda_3 & y^2\lambda_4 & 0 & 0 & 0 & 0 \\ 0 & 0 & \lambda_5 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \lambda_6 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda_7 & 0 & y^2\lambda_8 & 0 \\ 0 & 0 & 0 & 0 & 0 & \lambda_9 & x\lambda_{10} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \lambda_{11} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_{12} \end{pmatrix}, \tag{7.27}$$

respectively. We find that starting from quite general initial conditions, (6.12) indeed drives $(F_{\text{unst}}, G_{\text{unst}})$ to the split into the direct sum of two copies of the tensor product brane. On the other hand $(F_{\text{stab}}, G_{\text{stab}})$ flows to the direct sum of $(f_{\text{stab}}, g_{\text{stab}})$ and a copy of the trivial factorization $(1, W)$.

It is worthwhile emphasizing that this statement does not hold for all initial conditions. One of the consequence of nonreductiveness is that the flow defined by (6.12) is not convex. Taking a second derivative on the right-hand side does not produce something positive definite because $\langle Q, [V, Q'] \rangle \neq \langle [V^\dagger, Q], Q' \rangle$ in general. If the flow is not convex, there is no guarantee that stationary points will be unique. In the present case, there does exist a stationary point for the flow close to $f_{\text{unst}}, g_{\text{unst}} \oplus (1, W)$. But this point is a saddle point of the flow, i.e., it is unstable in the sense of dynamical systems. One must account for this possibility if one wants to make sense of (6.12) in general.

Another example of the same character as the one we have been discussing in this section arises in the series of models $W = x^h + y^3$, with factorizations given by

$$f = \begin{pmatrix} x^n & y & 0 \\ 0 & x^n & y \\ y & 0 & x^{h-2n} \end{pmatrix} \tag{7.28}$$

[and, as by now familiar, $g = \text{adj}(f)$]. By considerations similar to those we have given above, one finds that the factorizations (7.28) are stable when $n < h/6$ and (apparently) stable otherwise. (In particular, for $h < 6$, where W describes an E-type minimal model, these factorizations are all stable.)

F. A nonhomogeneous factorization

Lest we leave the impression that all matrix factorizations of quasihomogeneous polynomials are quasihomogeneous, here is a counter-example.

The superpotential $W=x^3+y^7$ is one of the simplest superpotentials that is not a simple singularity. In fact, it is unimodular. Torsion free rank one modules over local rings of unimodular singularities were classified in Ref. 60. It is a simple exercise to determine the associated matrix factorizations. On the list for $W=x^3+y^7$, one finds the following one-parameter family of factorizations:

$$f=\begin{pmatrix} x^2-\lambda y^5 & xy \\ xy+\lambda^2 y^4 & -\lambda x+y^2 \end{pmatrix},$$

$$g=\begin{pmatrix} x-\frac{y^2}{\lambda} & \frac{xy}{\lambda} \\ \frac{xy}{\lambda}+\lambda y^4 & -\frac{x^2}{\lambda}+y^5 \end{pmatrix}. \tag{7.29}$$

For $\lambda\neq 0$, this is stably equivalent to the following factorization:

$$\tilde{f}=\begin{pmatrix} -xy^5 & \lambda xy^4+y^6 & -x^2 \\ y^6 & x^2-\lambda y^5 & xy \\ -x^2-\lambda y^5 & yx+\lambda^2 y^4 & -\lambda x+y^2 \end{pmatrix},$$

$$\tilde{g}=\begin{pmatrix} \lambda & y & -x \\ y & x & 0 \\ -x & \lambda y^4 & y^5 \end{pmatrix}, \tag{7.30}$$

which is nonreduced, but has a limit as $\lambda\to 0$. While W is quasihomogeneous with $q_x=2/3$, $q_y=2/7$, we see that

$$Ef-f+R_+f-fR_-=\frac{2}{21}\lambda\begin{pmatrix} -y^5 & 0 \\ 2\lambda y^4 & -x \end{pmatrix}=\frac{2}{21}\lambda\partial_\lambda f, \tag{7.31}$$

where

$$R=\begin{pmatrix} R_+ & 0 \\ 0 & R_- \end{pmatrix}=\begin{pmatrix} -\frac{7}{42} & 0 & 0 & 0 \\ 0 & \frac{9}{42} & 0 & 0 \\ 0 & 0 & \frac{7}{42} & 0 \\ 0 & 0 & 0 & -\frac{9}{42} \end{pmatrix}. \tag{7.32}$$

Since this $\partial_\lambda f$ is the marginal deformation of the family (7.29), it is a nontrivial cohomology class (this can also be checked directly). As a consequence, the matrix factorization (f,g) is not quasihomogeneous.

It is interesting to ask for a geometric interpretation of this example. For example, one could embed $W=x^3+y^7$ into the appropriate Calabi-Yau Landau-Ginzburg model, and try to identify a mirror Lagrangian cycle. Nonhomogeneity of (f,g) should be mirror to nonvanishing of the Maslov class. Of course, it is not clear to what extent Lagrangians with nonvanishing Maslov anomaly participate in mirror symmetry. The intriguing point is that the limit of (7.29) for $\lambda\to 0$ is actually quasihomogeneous and therefore might have a good mirror. One way to avoid the paradox conclusion that the deformation of a nonanomalous Lagrangian is anomalous would be to show that the brane described by this factorization is never stable on the moduli space. (It is unstable in the Landau-Ginzburg model, as the examples in Sec. VII E.)

VIII. SUMMARY

For convenience and definiteness, we shall here give a summary of the main ingredients that are proposed to enter into a stability condition for matrix factorizations.

As explained in Sec. II, the physical origin of stability conditions in string theory is the grading by worldsheet R-charge. In the context of matrix factorizations, which originate in local commutative algebra, it is also quite natural to consider the graded situation, so it would not seem that physics has much input to give. Before repeating the claim that it does, it is worthwhile to fix the convenient normalization of the grading: Physics suggests a normalization in which W has charge 2, giving the field variables fractional charge, whereas a more standard mathematical choice is to make all degrees integer.

With this in mind, we have associated to any matrix factorization

$$Q^2 = W$$

of a Landau-Ginzburg potential W, satisfying the anomaly free condition that $EQ-Q$ is cohomologically trivial, a matrix R, defined by the conditions (4.8) and (4.20),

$$EQ - Q = [Q,R] \text{ and } \mathrm{Tr}(RV) = 0 \quad \text{whenever} \quad [V,Q] = 0,$$

where we have argued that the latter condition would fix R uniquely. Via (4.11), this induces a grading, q, of the morphism spaces.

The choice of normalization of the grading is important because we intend to compare the grading of morphisms with another natural quantity that can be associated to a Landau-Ginzburg potential, namely the central charge

$$\hat{c}.$$

A mathematical quantity that is closely related to $\hat{c}$ is the so-called "singular index" that appears in singularity theory (see Ref. 61), but it does not seem to have played a crucial role in the purely algebraic context so far.

The basic idea, motivated by Π-stability as we have explained, is to impose the unitarity constraint (2.1)

$$0 \leqslant q \leqslant \hat{c}$$

as a stability condition on the category of topological D-branes.

The problem at this point, which is inherited from Π-stability, is that it is not *a priori* clear exactly *how* to impose this condition. For example, should it be imposed on *all* morphisms, or only on all morphisms involving stable objects? Or should one rather attempt to define the stable branes as a "maximal set" of objects satisfying this (and maybe some other) condition? Although the latter option would seem to depend on too many arbitrary choices, such ambiguities might not be unnecessary. The set of stable objects is expected to be unique only up to autoequivalences of the topological category or monodromies in the moduli space.[2,6]

In the mathematical approach of Ref. 5, the problem is circumvented by postulating the existence of Abelian subcategories at each point in moduli space, on which a stability condition can be imposed in a more standard well-defined form.

We have argued here that there should be a way to identify uniquely a set of stable objects at the Landau-Ginzburg point, essentially because our definition of the grading *does not depend* on the rest of moduli space, and is hence insensitive to monodromies. *A posteriori*, this should also provide an Abelian subcategory.

To gain further confidence that such an approach is possible, we have then proposed a relation to a moduli space problem via a "moment maplike" flow equation (6.12)

$$\frac{dQ}{dt} = -(\langle Q,[V^i,Q]\rangle - \mathrm{Tr}\, RV^i)[V_i,Q],$$

which is expected to provide the split of any given object into its stable constituents. We have implemented this flow in various relevant examples, with reasonable results.

ACKNOWLEDGMENTS

It is a pleasure to thank Mike Douglas, Kentaro Hori, Calin Lazaroiu, Dmitri Orlov, Gerhard Pfister, and Piljin Yi for useful discussions, comments, and correspondence. Parts of this work were originally presented at the Fields Institute Workshop on Mirror Symmetry held at Perimeter Institute, November 19–23, 2004. The authors would like to thank the organizers for the invitation to speak and the participants, especially Andrei Caldararu, Charles Doran, and Anton Kapustin, for valuable feedback. (Received 18 February 2005; accepted 29 June 2005; published online 18 August 2005)

We show how to use the quasi-Maxwell formalism to obtain solutions of Einstein's field equations corresponding to homogeneous cosmologies—namely Einstein's universe, Gödel's universe, and the Ozsvath-Farnsworth-Kerr class I solutions—written in frames for which the associated observers are stationary. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2009587]

I. INTRODUCTION

A particularly intuitive framework for obtaining and interpreting stationary solutions of Einstein's field equations is the so-called *quasi-Maxwell formalism*.[2,5] Although such solutions have been extensively treated in the past,[1,7] this approach has been successfully used in recent times.[3,4] In this paper we apply the quasi-Maxwell formalism in the case when the space manifold is a Lie group with left-invariant metric and fields, and rediscover Einstein's universe, Gödel's universe and the Ozsvath-Farnsworth-Kerr class I solutions, sometimes written in unconventional frames.

The organization of the paper is as follows: In the first section we briefly review the quasi-Maxwell formalism for stationary spacetimes. In the second section we analyze the form taken by the quasi-Maxwell equations when the space manifold is a Lie group. In the third section we further specialize to Lie groups with class A Lie algebras. Finally, solutions of the quasi-Maxwell equations for these space manifold are obtained and identified in the last section.

We use Einstein summation convention, irrespective of the position of the indices (which will often be irrelevant as we will be leading with orthonormal frames on Riemannian manifolds). We will take Latin indices $i, j, \ldots$ to run from 1 to 3.

II. QUASI-MAXWELL FORMALISM

In this section we briefly review the quasi-Maxwell formalism for stationary spacetimes. For more details, see Ref. 5.

Recall that a *stationary spacetime* (M, g) is a Lorentzian four-manifold with a global timelike Killing vector field T. We assume that there exists a global time function $t: M \to \mathbb{R}$ such that $T = \partial/\partial t$. The quotient of M by the integral curves of T is a three-dimensional manifold Σ to which we refer as the *space manifold*. If $\{x^i\}$ are local coordinates in Σ, we can write the line element of (M, g) as

$$ds^2 = -e^{2\phi}(dt + A_i dx^i)^2 + \gamma_{ij} dx^i dx^j$$

where ϕ, A_i, and γ_{ij} do not depend on t. This allows us to interpret ϕ, $A = A_i dx^i$ and $\gamma = \gamma_{ij} dx^i \otimes dx^j$ as tensor fields on the space manifold. It turns out that γ is a Riemannian metric in Σ, independent of the choice of the global time function t. The differential forms $G = -d\phi$ and H

a)Electronic mail: jnatar@math.ist.utl.pt

$=-e^{\phi}\mathrm{d}A$ are also independent of this choice, and play a central role in the so-called *quasi-Maxwell formalism*. We define the *gravitational* and *gravitomagnetic* (vector) fields **G** and **H** through

$$G = \gamma(\mathbf{G}, \cdot\,), \tag{1}$$

$$H = \epsilon(\mathbf{H}, \cdot\,, \cdot\,) \tag{2}$$

where ϵ is a Riemannian volume form in (Σ, γ) (which we assume to be orientable).

We identify a vector $\mathbf{v} \in T_p\Sigma$ with the unique vector field v along the integral curve of T through p which is orthogonal to T and satisfies $\pi_* v = \mathbf{v}$ ($\pi: M \to \Sigma$ being the quotient map). Let $\{X_0, X_i\}$ be a local orthonormal frame on M, where $X_0 = (-g(T,T))^{-1/2}T$. If

$$u = u^0 X_0 + u^i X_i = u^0 X_0 + \mathbf{u}$$

represents the unit tangent vector to a timelike geodesic, the motion equation

$$\tilde{\nabla}_u u = 0$$

is equivalent to

$$\nabla_{\mathbf{u}}\mathbf{u} = u^0(u^0\mathbf{G} + \mathbf{u} \times \mathbf{H})$$

with $u^0 = (1+\mathbf{u}^2)^{1/2}$ (where $\tilde{\nabla}$ is the Levi-Civita connection of (M, g), ∇ is the Levi-Civita connection of (Σ, γ), and $\mathbf{u}^2 = \gamma(\mathbf{u}, \mathbf{u})$).

If we let R_{ij} and $\nabla_i G_j$ represent the components of the Ricci tensor of ∇ and of the covariant derivative of G, Einstein's equations for a perfect fluid with density ρ, pressure p and 4-velocity u reduce to the *quasi-Maxwell equations* (QM)

$$\operatorname{div} \mathbf{G} = \mathbf{G}^2 + \tfrac{1}{2}\mathbf{H}^2 - 8\pi(\rho + p)\mathbf{u}^2 - 4\pi(\rho + 3p), \tag{QM.1}$$

$$\operatorname{curl} \mathbf{H} = 2\mathbf{G} \times \mathbf{H} - 16\pi(\rho + p)u^0\mathbf{u}, \tag{QM.2}$$

$$R_{ij} + \nabla_i G_j = G_i G_j + \tfrac{1}{2}H_i H_j - \tfrac{1}{2}\mathbf{H}^2\gamma_{ij} + 8\pi\left((\rho + p)u_i u_j + \tfrac{1}{2}(\rho - p)\gamma_{ij}\right). \tag{QM.3.ij}$$

We can use QM to solve Einstein's equations by writing down a Riemannian metric for the space manifold (eventually depending on unknown functions), and solving for the fields (see Refs. 2–5). For instance, the Schwarzchild solution is the static solution (i.e., $\mathbf{H}=0$) obtained when we consider a spherically symmetric space manifold with radial **G**.

A word of caution must be issued here: the quasi-Maxwell decomposition does depend on the choice of the timelike Killing vector field T. Therefore when one solves the QM equations, one is really solving for (M, g, T). If a given space-time has a large enough isometry group, it can yield many different solutions of QM.

The goal of this paper is the classification of solutions whose space manifolds are Lie groups with left-invariant metrics, and whose vector fields **G** and **H** are left invariant.

III. QUASI-MAXWELL EQUATIONS FOR A LIE GROUP

Let the space manifold Σ be a three-dimensional Lie group. To choose a left-invariant metric we fix a frame $\{X_i\}$ of left-invariant vector fields and declare it to be orthonormal. All the information about the geometry of the space manifold will then be encoded in the structure constants, defined by

$$[X_i,X_j]=C_{ij}^kX_k=C_{kij}X_k.$$

The last equality emphasizes that there is no need to worry about the vertical position of the indices, as we're working with an orthonormal frame. The Christoffel symbols of the Levi-Civita connection are then given by

$$\Gamma_{jk}^i=\tfrac{1}{2}(C_{ijk}+C_{kij}-C_{jki}).$$

Letting $G=G_i\omega^i$, where $\{\omega^i\}$ is the dual basis of $\{X_i\}$, we have

$$\nabla_iG_j=-\Gamma_{ij}^kG_k.$$

Consequently,

$$\operatorname{div}\mathbf{G}=\nabla_iG_i=-\Gamma_{ii}^kG_k.$$

The Maurer-Cartan formula

$$d\omega^i=-\tfrac{1}{2}C_{jk}^i\omega^j\wedge\omega^k$$

assures us that the exterior derivative is a linear transformation between the spaces $\Omega_L^1(\Sigma)$ and $\Omega_L^2(\Sigma)$ of the left-invariant 1 and 2 forms, whose matrix for the bases $\{\omega^1,\omega^2,\omega^3\}$ of $\Omega_L^1(\Sigma)$ and $\{\omega^2\wedge\omega^3,\omega^3\wedge\omega^1,\omega^1\wedge\omega^2\}$ of $\Omega_L^2(\Sigma)$ is

$$D=\begin{pmatrix}C_{132} & C_{232} & C_{332}\\ C_{113} & C_{213} & C_{313}\\ C_{121} & C_{221} & C_{321}\end{pmatrix}.$$

By definition, curl $\mathbf{H}$ is the only vector field satisfying

$$\epsilon(\operatorname{curl}\mathbf{H},\cdot\,,\cdot\,)=d(\gamma(\mathbf{H},\cdot\,)).$$

Since vectors, 1 and 2 forms are related by the isomorphisms given by the metric and the volume element of Σ, we obtain

$$\operatorname{curl}\mathbf{H}=(X_1X_2X_3)\cdot D\cdot\begin{pmatrix}H_1\\ H_2\\ H_3\end{pmatrix}.$$

The fact that γ, $\mathbf{G}$, and $\mathbf{H}$ are left-invariant imposes restrictions on the fluid generating the gravitational field:

Proposition 2.1: *The density and pressure are constant and* $\mathbf{u}$ *is left invariant.*

Proof: QM.3.*ii* gives us

$$(\rho+p)u_i^2=-\tfrac{1}{2}(\rho-p)+\text{constant}.$$

Adding these three equations we obtain

$$(\rho+p)\mathbf{u}^2=-\tfrac{3}{2}(\rho-p)+\text{constant},$$

which substituted in Eq. QM.1 yields

$$-3(\rho-p)+\rho+3p=\text{constant}\Leftrightarrow 3p-\rho=\text{constant}.$$

From Eq. QM.2 we see that

$$(\rho+p)u^0u_i=\text{constant}\Rightarrow(\rho+p)^2(u^0)^2u_i^2=\text{constant}$$

$$\Leftrightarrow (\rho+p)(\mathbf{u}^2+1)(\rho+p)u_i^2 = \text{constant}$$

$$\Leftrightarrow \left[-\tfrac{3}{2}(\rho-p)+\text{constant}+(\rho+p)\right]\cdot\left[-\tfrac{1}{2}(\rho-p)+\text{constant}\right] = \text{constant}$$

$$\Leftrightarrow \tfrac{1}{4}\rho^2+\tfrac{5}{4}p^2-\tfrac{3}{2}\rho p+\text{first order terms} = \text{constant}.$$

But since $\rho=3p+\text{constant}$, we get

$$-p^2+\text{first order terms} = \text{constant}.$$

We conclude that ρ and p can take at most two distinct values in Σ, and, being so, the result follows from their continuity.

Its now clear that for $\rho+p\neq 0$ the components of $\mathbf{u}$ are constant, which suffices to insure that it is left invariant. For $\rho+p=0$, $\mathbf{u}$ becomes undefined and we can take it to be left invariant (e.g., zero) without loss of generality. □

Corollary 2.2. *The vector field u has the following proprieties*:

$$\widetilde{\operatorname{div}}\, u = 0$$

and

$$\tilde{\nabla}_u u = 0.$$

Proof: We have seen that we only have to consider the case $\rho+p\neq 0$. Euler's equation for a perfect fluid is

$$\widetilde{\operatorname{div}}\, T = 0 \Leftrightarrow \begin{cases} \widetilde{\operatorname{div}}(\rho u) + p\,\widetilde{\operatorname{div}}\, u = 0 \\ (\rho+p)\tilde{\nabla}_u u = -(\widetilde{\operatorname{grad}}\, p)^{\perp} \end{cases}$$

where $(\widetilde{\operatorname{grad}}\, p)^{\perp}$ designates the component of $\widetilde{\operatorname{grad}}\, p$ orthogonal to u. Since ρ and p are constant with $\rho+p\neq 0$, it follows that

$$\begin{cases} (\rho+p)\widetilde{\operatorname{div}}\, u = 0 \\ (\rho+p)\tilde{\nabla}_u u = 0 \end{cases} \Leftrightarrow \begin{cases} \widetilde{\operatorname{div}}\, u = 0 \\ \tilde{\nabla}_u u = 0. \end{cases}$$

□

Corollary 2.3: *The vector fields* $\mathbf{u}$ *and* $\mathbf{G}$ *are orthogonal.*

Proof: The motion equation yields

$$\tilde{\nabla}_u u = 0 \Rightarrow \nabla_{\mathbf{u}}\mathbf{u} = u^0(u^0\mathbf{G}+\mathbf{u}\times\mathbf{H}).$$

Since $\mathbf{u}$ is left invariant and u^0 is a nonzero constant,

$$0 = \frac{\mathrm{d}}{\mathrm{d}\tau}\gamma(\mathbf{u},\mathbf{u}) = 2\gamma(\nabla_{\mathbf{u}}\mathbf{u},\mathbf{u}) = 2(u^0)^2\gamma(\mathbf{G},\mathbf{u}) \Rightarrow \gamma(\mathbf{G},\mathbf{u}) = 0.$$

□

The following result relates solutions corresponding to conformally related left-invariant metrics.

Proposition 2.4. (Rescaling Lemma): *From a solution* (G_i,H_j,u_k,ρ,p) *of QM, where the left-invariant metric is associated to the frame* $\{X_i\}$, *we can construct a solution* $(\hat{G}_i,\hat{H}_j,\hat{u}_k,\hat{\rho},\hat{p})$ *for the left-invariant metric associated to the frame* $\{\hat{X}_i=\lambda X_i\}$, *by setting*

$$\hat{G}_i = \lambda G_i,$$

$$\hat{H}_j = \lambda H_j,$$

$$\hat{u}_k = u_k,$$

$$\hat{\rho} = \lambda^2 \rho,$$

$$\hat{p} = \lambda^2 p.$$

Proof: Since

$$[\hat{X}_i, \hat{X}_j] = \lambda^2 [X_i, X_j] = \lambda^2 C_{kij} X_k = \lambda C_{kij} \hat{X}_k,$$

we obtain

$$\hat{C}_{kij} = \lambda C_{kij},$$

from which follows

$$\hat{\Gamma}^i_{jk} = \lambda \Gamma^i_{jk} \quad \text{and} \quad \hat{D} = \lambda D$$

and consequently

$$\hat{R}_{ij} = \lambda^2 R_{ij}, \quad \widehat{\operatorname{div}}\, \hat{G} = \lambda^2 \operatorname{div} G, \quad \widehat{\operatorname{curl}}\, \hat{H} = \lambda^2 \operatorname{curl} H.$$

Since that, by construction, $\hat{\gamma}_{ij} = \gamma_{ij} = \delta_{ij}$, the result follows. □

It is easy to see that this rescaling corresponds to rescaling the full space-time metric by $1/\lambda^2$.

IV. CLASS A LIE ALGEBRAS

If we take Σ to be connected and simply connected, Lie's theorem[9] guarantees that the space manifold will be uniquely determined, up to isomorphism, by its Lie algebra. Therefore, the consideration of all possible space manifolds becomes the classification of three-dimensional Lie algebras—a much simpler task!

Following Ref. 8, we learn that this classification may be realized by means of a (2/0) symmetric tensor M and a covector $\nu \in \ker M$, whose components in a given basis for the Lie algebra are $\nu_i = C^k_{ki}$. It becomes natural to divide the classification in two classes: class A for Lie algebras with $\nu = 0$, and class B for Lie algebras with $\nu \neq 0$.

We shall restrict ourselves to class A algebras. These are classified by the rank and signature of the symmetric tensor M, and are six in total: the abelian algebra (corresponding to rank $M = 0$), the Heisenberg algebra (corresponding to rank $M = 1$), the semidirect products $\mathfrak{so}(1,1) \ltimes \mathbb{R}^2$ and $\mathfrak{so}(2) \ltimes \mathbb{R}^2$ (corresponding to the two possible signatures for rank $M = 2$) and the simple algebras $\mathfrak{sl}(2)$ and $\mathfrak{so}(3)$ (corresponding to the two possible signatures for rank $M = 3$). In terms of the more usual Bianchi classification, these are Bianchi types I, II, VI with parameter $h = -1$, VII with parameter $h = 0$, VIII and IX, respectively (see Refs. 6 and 7).

Since $C^k_{ki} = 0$, M can be identified, using the left-invariant metric on which the Lie algebra basis is orthonormal, with minus the linear operator yielding the exterior derivative restricted to Ω^1_L. Therefore, class A Lie algebras are classified by the rank and signature of the matrix D of the previous section. This matrix is also useful for computing the Ricci tensor:

Proposition 3.1: *In a Lie group with class A Lie algebra and left-invariant metric, the matrix of components of the Ricci tensor in the basis* $\{\omega^i \otimes \omega^j\}$, *where* $\{\omega^i\}$ *is an orthonormal left-invariant co-frame, is given by*

$$(R_{ij}) = D^2 - \tfrac{1}{2}\mathrm{tr}(D^2)I + \mathrm{cof}(D).$$

The proof of this result is straightforward but lengthy and will be omitted.

Since D is symmetric, we are guaranteed the existence of a left-invariant orthonormal coframe $\{\omega_i\}$ for which

$$D = \mathrm{diag}(C_{132}, C_{213}, C_{321}).$$

Consequently, we can eliminate two unknowns in QM:

Proposition 3.2: *There exists a left-invariant orthonormal frame* $\{\hat{X}_i\}$ *for which the exterior derivative matrix in the basis* $\{\gamma(\hat{X}_k, \cdot)\}$ *and* $\{\epsilon(\hat{X}_k, \cdot, \cdot)\}$ *is diagonal and* $\mathbf{G} = G\hat{X}_1$.

Proof: Choose $\{X_i\}$ such that $D = \mathrm{diag}(a,b,c)$ and let $\mathbf{G} = G_i X_i$. Since G is a closed 1 form, we get

$$\mathrm{d}G = \mathrm{d}(\gamma(\mathbf{G}, \cdot)) = 0 \Leftrightarrow aG_1X_1 + bG_2X_2 + cG_3X_3 = 0.$$

Rearranging the indices if necessary, the last equation tells us that:

(1) $\mathrm{rank}(D) = 3 \Rightarrow a,b,c \neq 0 \Rightarrow \mathbf{G} = \mathbf{0}$;
(2) $\mathrm{rank}(D) = 2 \Rightarrow a = 0, b, c \neq 0 \Rightarrow G_2 = G_3 = 0$;
(3) $\mathrm{rank}(D) = 1 \Rightarrow a, b = 0, c \neq 0 \Rightarrow G_3 = 0 \Rightarrow \mathbf{G} \perp X_3$. For the nontrivial case (i.e., $\mathbf{G} \neq \mathbf{0}$) it suffices to choose $\hat{X}_1 = \frac{1}{\|\mathbf{G}\|}\mathbf{G}$, $\hat{X}_3 = X_3$ and $\hat{X}_2$ in such a way as to complete the basis as an orthonormal basis;
(4) $\mathrm{rank}(D) = 0$: identical to (3).

□

We end this section with three useful results easily proved from the diagonalization of the exterior derivative matrix.

Proposition 3.3: *Left-invariant vector fields have vanishing divergence*.

Proof: If we choose a basis for which D is diagonal, we conclude that the only structure constants not necessarily zero are those with no repeated indices, and consequently

$$\Gamma^i_{jk} \neq 0 \Rightarrow (i,j,k) \text{ is a permutation of } (1,2,3).$$

The result then follows from the equation

$$\mathrm{div}\,\mathbf{G} = -\Gamma^k_{ii} G_k.$$

□

Equivalently, we have

Proposition 3.4: $d(\Omega_L^2) = 0$.

Corollary 3.5: $\mathbf{G}$ *and* $\mathbf{H}$ *are orthogonal*.

Proof: Since H is a left-invariant 2 form, the last result tells us that

$$\mathrm{d}H = 0 \Leftrightarrow d(-e^{\phi}\mathrm{d}A) = 0$$

$$\Leftrightarrow -e^{\phi} d\phi \wedge \mathrm{d}A - e^{\phi}\mathrm{d}(\mathrm{d}A) = 0$$

$$\Leftrightarrow G \wedge H = 0.$$

Using Proposition 3.2, we get

$$G_1\omega^1 \wedge (H_1\omega^2 \wedge \omega^3 + H_2\omega^3 \wedge \omega^1 + H_3\omega^1 \wedge \omega^2) = 0$$

$$\Leftrightarrow G_1H_1\omega^1 \wedge \omega^2 \wedge \omega^3 = 0 \Leftrightarrow G_1H_1 = 0 \Leftrightarrow \gamma(\mathbf{G},\mathbf{H}) = 0.$$

□

V. CLASSIFICATION

For now on we will consider only orthonormal bases $\{X_i\}$ of left-invariant vector fields for the class A Lie algebras of the space manifold such that $D=\mathrm{diag}(a,b,c)$. From Proposition 3.1 we have

$$(R_{ij})=\mathrm{diag}\left(\tfrac{1}{2}a^2-\tfrac{1}{2}b^2-\tfrac{1}{2}c^2+bc,-\tfrac{1}{2}a^2+\tfrac{1}{2}b^2-\tfrac{1}{2}c^2+ac,-\tfrac{1}{2}a^2-\tfrac{1}{2}b^2+\tfrac{1}{2}c^2+ab\right)$$

A. Vacuum solutions with cosmological constant

For convenience, we begin with the computation of QM solutions such that $\rho+p=0$. These correspond to vacuum solutions with cosmological constant.

Proposition 4.1. *The only QM vacuum solution with cosmological constant ($\rho+p=0$) is Minkowski spacetime, i.e.*, $\mathbf{G}=\mathbf{H}=0$ *and* $\rho=p=0$. *The space manifold is then Ricci-flat (Ricci* $=0$*), and hence we necessarily have* $D=\mathrm{diag}(0,b,b)$ *for some* $b\in\mathbb{R}$ *in an appropriate basis of the space manifold's Lie algebra.*

Proof: Let $\rho+p=0$. The indefiniteness of $\mathbf{u}$ allows us to assume, without loss of generality (wlg), that $\mathbf{u}=0$. From the motion equation we get

$$0=(u^0)^2\mathbf{G}=0\Leftrightarrow\mathbf{G}=0.$$

Therefore,

$$\mathrm{QM}.1\Leftrightarrow 0=\tfrac{1}{2}\mathbf{H}^2-4\pi(\rho+3p)\Leftrightarrow\mathbf{H}^2=16\pi p.$$

Since (R_{ij}) is diagonal,

$$\mathrm{QM}.3\,.\,ij(i\neq j)\Leftrightarrow 0=H_iH_j.$$

Therefore, two of the components of $\mathbf{H}$ must vanish. Taking, wlg, $\mathbf{H}=HX_1$ and writing $D=\mathrm{diag}(a,b,c)$, we get

$$QM.2\Leftrightarrow D\cdot\mathbf{H}=0\Leftrightarrow aH=0.$$

If $H=0$, we obtain $p=0\Rightarrow\rho=0$.

If $a=0$,

$$\mathrm{QM}.3\,.\,ii(i\neq 1)\Leftrightarrow R_{22}=R_{33}=-\tfrac{1}{2}\mathbf{H}^2+4\pi(\rho-p)=4\pi(\rho-3p).$$

But

$$R_{22}=R_{33}\Leftrightarrow\tfrac{1}{2}b^2-\tfrac{1}{2}c^2=-\tfrac{1}{2}b^2+\tfrac{1}{2}c^2\Leftrightarrow b^2=c^2\Rightarrow R_{22}=R_{33}=0,$$

yielding $\rho-3p=0$, and therefore $\rho=p=0$ (hence $H=0$).

Thus the only solution with $\rho+p=0$ is Minkowski spacetime, and verifies Ricci$=0$. From the diagonalization of D, it is easily seen that a space manifold is Ricci-flat if and only if there is a basis for its Lie algebra such that $D=\mathrm{diag}(0,b,b),b\in\mathbb{R}$. □

For the remaining computations we will therefore assume that $\rho+p\neq 0$.

B. Solutions with a flat space manifold

In this section we will compute all solutions of QM with flat space manifold (Σ,γ). Since this is a three-dimensional manifold, the curvature tensor is completely determined by the Ricci tensor, and therefore flatness is equivalent to Ricci-flatness.

Theorem 4.2: *The QM solutions with flat space manifold (i.e., with Ricci*$=0$*) correspond to Lie algebras with a basis for which* $D=\mathrm{diag}(0,b,b),b\in\mathbb{R}$, *and such that*:

(1) *(Gödel's universe)* $b=0$, $\mathbf{G}=\sqrt{16\pi p}X_1$, $\mathbf{H}=\sqrt{32\pi p}X_2$, $\mathbf{u}=X_3$ *and* $\rho=p\in\mathbb{R}^+$;
(2) *(Minkowski spacetime)* $\mathbf{G}=\mathbf{H}=\mathbf{0}$, $p=\rho=0$ *is a solution, for all* $b\in\mathbb{R}$ *(cf. Proposition 4.1).*

Proof: We already saw that Ricci-flatness implies that we can choose $D=\mathrm{diag}(0,b,b), b\in\mathbb{R}$. Arguing as in the demonstration of proposition 3.2, we can take $\mathbf{G}=GX_1$ and $\mathbf{H}=H_1X_1+H_2X_2$.

Suppose first that $\mathbf{G}=\mathbf{0}$. In this case,

$$\mathrm{QM.2}\Leftrightarrow\begin{cases}0=16\pi(\rho+p)u^0u_1\\ bH_2=-16\pi(\rho+p)u^0u_2\\ 0=16\pi(\rho+p)u^0u_3\end{cases}\Rightarrow u_1=u_3=0\Leftrightarrow\mathbf{u}=uX_2.$$

We then have as the only nontrivial equation Eq. QM.3.ij ($i\neq j$)

$$\mathrm{QM.3.12}\Leftrightarrow H_1H_2=0.$$

If $H_1=0$, then $\mathbf{H}=HX_2$. Therefore

$$\mathrm{QM.3}\,.\,ii\Leftrightarrow\begin{cases}0=-\frac{1}{2}H^2+4\pi(\rho-p)\\ 0=\frac{1}{2}H^2-\frac{1}{2}H^2+8\pi(\rho+p)u^2+4\pi(\rho-p)\\ 0=-\frac{1}{2}H^2+4\pi(\rho-p)\end{cases}$$

$$\Leftrightarrow\begin{cases}H^2=8\pi(\rho-p)\\ 8\pi(\rho+p)u^2=-4\pi(\rho-p)=-\frac{1}{2}H^2\end{cases}$$

and

$$\mathrm{QM.1}\Leftrightarrow 0=\tfrac{1}{2}H^2-8\pi(\rho+p)u^2-4\pi(\rho+3p)\Leftrightarrow H^2=4\pi(\rho+3p).$$

Consequently,

$$4\pi(\rho+3p)=8\pi(\rho-p)\Leftrightarrow\rho=5p,$$

and therefore

$$\mathrm{QM.3.22}\Leftrightarrow 8\pi(\rho+p)u^2=-4\pi(\rho-p)\Leftrightarrow 12pu^2=-4p\Rightarrow p=0\Rightarrow\rho=0.$$

If $H_2=0(\Rightarrow\mathbf{H}=HX_1)$, we get

$$\mathrm{QM.3}\,.\,ii\Leftrightarrow\begin{cases}0=4\pi(\rho-p)\\ 0=-\frac{1}{2}H^2+8\pi(\rho+p)u^2+4\pi(\rho-p)\\ 0=-\frac{1}{2}H^2+4\pi(\rho-p)\end{cases}$$

$$\Leftrightarrow\begin{cases}\rho=p\\ \mathbf{u}=\mathbf{H}=\mathbf{0}\end{cases}$$

and

$$\mathrm{QM.1}\Leftrightarrow 0=4\pi(\rho+3p).$$

But since $\rho=p$, we obtain $\rho=p=0$.

Let us now consider the case $\mathbf{G}\neq\mathbf{0}$. From Corollary 3.5 we have

$$\gamma(\mathbf{G},\mathbf{H}) = 0 \Leftrightarrow H_1 = 0 \Leftrightarrow \mathbf{H} = HX_2.$$

If $b=0$,

$$\text{QM.2} \Leftrightarrow \begin{cases} 0 = u_1 \\ 0 = u_2 \\ 0 = 2GH - 16\pi(\rho + p)u^0 u_3 \end{cases} \Leftrightarrow \begin{cases} \mathbf{u} = uX_3 \\ GH = 8\pi(\rho + p)u^0 u \end{cases},$$

and since

$$\begin{aligned} \nabla G &= \nabla_i G_j \omega^i \otimes \omega^j = -\Gamma^k_{ij} G_k \omega^i \otimes \omega^j = -\Gamma^1_{23} G_1 \omega^2 \otimes \omega^3 - \Gamma^1_{32} G_1 \omega^3 \otimes \omega^2 \\ &= -\tfrac{1}{2}(C_{123} + C_{312} - C_{231}) G\omega^2 \otimes \omega^3 - \tfrac{1}{2}(C_{132} + C_{213} - C_{321}) G\omega^3 \otimes \omega^2 \\ &= -\tfrac{1}{2}(0 - b + b) G\omega^2 \otimes \omega^3 - \tfrac{1}{2}(0 + b - b) G\omega^3 \otimes \omega^2 = 0, \end{aligned}$$

equations QM.3ij($i \neq j$) are trivial.

On the other hand,

$$\text{QM.3 . } ii \Leftrightarrow \begin{cases} 0 = G^2 - \dfrac{1}{2}H^2 + 4\pi(\rho - p) \\ 0 = 4\pi(\rho - p) \\ 0 = -\dfrac{1}{2}H^2 + 8\pi(\rho + p)u^2 + 4\pi(\rho - p) \end{cases}$$

$$\Leftrightarrow \begin{cases} G^2 = \dfrac{1}{2}H^2 \Rightarrow H \neq 0 \\ \rho = p \\ 16\pi p u^2 = \dfrac{1}{2}H^2 \end{cases}$$

from which

$$\text{QM.1} \Leftrightarrow 0 = G^2 + \tfrac{1}{2}H^2 - 8\pi(\rho + p)u^2 - 4\pi(\rho + 3p)$$

$$\Leftrightarrow G^2 = 4\pi(\rho + 3p) = 16\pi p \Rightarrow H^2 = 32\pi p \quad \text{and} \quad p > 0.$$

Consequently,

$$16\pi p u^2 = \tfrac{1}{2}H^2 = 16\pi p \Leftrightarrow u^2 = 1.$$

Equation QM.2.3 is immediately satisfied if we respect its only imposition: $GHu > 0$. It can be shown that this solution is in fact Gödel's universe (see Sec. V F).

We are now left with the case $\mathbf{G} \neq \mathbf{0}$, $b \neq 0$. We have

$$\text{QM.2} \Leftrightarrow \begin{cases} 0 = u_1 \\ bH = -16\pi(\rho + p)u^0 u_2 \\ 0 = 2GH - 16\pi(\rho + p)u^0 u_3 \end{cases}$$

Since $\nabla G=0$, $\mathbf{H}=HX_2$ and $u_1=0$, all of the QM.3 . ij ($i \neq j$) are trivial with the exception of

$$\text{QM.3.23} \Leftrightarrow \text{QM.3.32} \Leftrightarrow 0 = 8\pi(\rho + p)u_2 u_3 \Leftrightarrow 0 = u_2 u_3.$$

But since the components of $\mathbf{u}$ are constant,

$$\nabla_{\mathbf{u}}\mathbf{u} = u_i u_j \nabla_{X_i} X_j = u_2 u_3 (\nabla_{X_2} X_3 + \nabla_{X_3} X_2) = 0.$$

If $u_3 = 0$ we obtain $\mathbf{u}$ parallel to $\mathbf{H}$ and hence

$$\text{motion equation} \Leftrightarrow 0 = (u^0)^2 G \Leftrightarrow G = 0,$$

yielding a contradiction.

If $u_2 = 0$, $QM.2.2 \Rightarrow H = 0$ and again the motion equation will lead us to $G = 0$. Therefore we must have $b = 0$ whenever $\mathbf{G} \neq \mathbf{0}$. □

C. Solutions for Lie algebras with rank $D = 3$

It is easily seen that a change of basis from $\{X_1, X_2, X_3\}$ to $\{-X_1, X_2, X_3\}$ changes the exterior derivative matrix from $D = \text{diag}(a, b, c)$ to $D = \text{diag}(-a, -b, -c)$. Therefore we can assume wlg that $a > 0$.

Theorem 4.3: *The QM solutions with* rank $D = 3$ *correspond to Lie algebras with a basis such that* $a > 0$ *and*:

(1) *(Einstein's universe)* $D = \text{diag}(a, b, b)$, *with* $b > 0$, $a \geqslant b$, $\mathbf{G} = \mathbf{0}$, $\mathbf{H} = \sqrt{a(a-b)}X_1$, $\mathbf{u} = -\sqrt{(a-b)/b}X_1$ *and* $\rho = -3p = 3ab/32\pi$;

(2) *(Gödel's universe)* $D = \text{diag}(a, b, b)$, *with* $b < 0$, $\mathbf{G} = 0$, $\mathbf{H} = \sqrt{a(a-2b)}X_1$, $\mathbf{u} = -\sqrt{-a/2b}X_1$ *and* $\rho = p = -ab/16\pi$;

(3) *(Ozsvath-Farnsworth-Kerr class I)* $D = \text{diag}(a, b, a-b)$, *with* $16b(a-b) > 3a^2 \Leftrightarrow \frac{1}{4}a < b < \frac{3}{4}a$, $\mathbf{G} = 0$, $\mathbf{H} = \sqrt{4b(a-b) - \frac{1}{2}a^2}X_1$, $\mathbf{u} = -a/\sqrt{16b(a-b) - 3a^2}X_1$, $p = -a^2/64\pi$ *and* $\rho = 32b(a-b) - 5a^2/64\pi$.

Proof: Let $D = \text{diag}(d_1, d_2, d_3)$, with $\Pi_i d_i \neq 0$. Then $\mathbf{G} = 0$, and consequently

$$\text{QM.2} \Leftrightarrow d_i H_i = -16\pi(\rho + p)u^0 u_i \Leftrightarrow H_i = -\frac{16\pi(\rho + p)}{d_i} u^0 u_i$$

(the Einstein summation convention will not apply for the duration of this proof). Therefore,

$$QM.3\,.\,ij(i \neq j) \Leftrightarrow 0 = H_i H_j + 16\pi(\rho + p)u_i u_j$$

$$\Leftrightarrow 0 = \frac{[16\pi(\rho + p)]^2}{d_i d_j}(u^0)^2 u_i u_j + 16\pi(\rho + p)u_i u_j$$

$$\Leftrightarrow 0 = 16\pi(\rho + p)u_i u_j \left(\frac{16\pi(\rho + p)}{d_i d_j}(u^0)^2 + 1 \right)$$

$$\Leftrightarrow 0 = u_i u_j \text{ or } (u^0)^2 = -\frac{d_i d_j}{16\pi(\rho + p)}.$$

We have to consider the following cases.

(1) $u_{i_1} = 0$ and:

(a) $u_{i_2} = 0$;

(b) $(u^0)^2 = -d_{i_2} d_{i_3}/16\pi(\rho + p)$ (where (i_1, i_2, i_3) is an arbitrary permutation of (1, 2, 3));

(2) $(u^0)^2 = -d_i d_j/16\pi(\rho + p)$, for all $i, j \in \{1, 2, 3\}$ with $i \neq j$.

Let us do so:

(1) (a) Suppose, wlg, that $u_2=u_3=0\Rightarrow \mathbf{u}=uX_1$. Then $QM.2\Rightarrow \mathbf{H}=HX_1$, and therefore

$$\text{QM.3 . } ii(i\neq 1)\Leftrightarrow R_{22}=R_{33}=-\tfrac{1}{2}H^2+4\pi(\rho-p).$$

However,

$$R_{22}=R_{33}\Leftrightarrow -\tfrac{1}{2}a^2+\tfrac{1}{2}b^2-\tfrac{1}{2}c^2+ac=-\tfrac{1}{2}a^2-\tfrac{1}{2}b^2+\tfrac{1}{2}c^2+ab$$

$$\Leftrightarrow b^2-c^2+ac-ab=0$$

$$\Leftrightarrow (b-c)(b+c)-a(b-c)=0$$

$$\Leftrightarrow (b-c)(b+c-a)=0$$

$$\Leftrightarrow c=b \text{ or } c=a-b,$$

which leads us to the consideration of two subcases:

(i) $c=b$;
(ii) $c=a-b$.

Let us do so:

(i) We have $D=\mathrm{diag}(a,b,b)$. The Rescaling Lemma (Proposition 2.4) allows us to choose $a=1$. Let $\Omega=8\pi(\rho+p)\neq 0$. The QM equations are:

$$\text{QM.1}\Leftrightarrow \tfrac{1}{2}H^2=\Omega\, u^2+\tfrac{1}{2}\Omega+8\pi p;$$

$$\text{QM.2}\Leftrightarrow H=-2\Omega\, u^0 u;$$

$$\text{QM.3 . } ij\ (i\neq j) \text{ are already satisfied;}$$

$$\text{QM.3 . } ii\Leftrightarrow \begin{cases} R_{11}=\tfrac{1}{2}=\Omega\, u^2+4\pi(\rho-p) \\ R_{22}=R_{33}=b-\tfrac{1}{2}=-\tfrac{1}{2}H^2+4\pi(\rho-p) \end{cases}$$

We then have

$$\text{QM.3.11 + QM.3.22}\Leftrightarrow b=-\tfrac{1}{2}H^2+\Omega u^2+8\pi(\rho-p).$$

Inserting QM.1 in the last equation yields

$$b=-\Omega\, u^2-\tfrac{1}{2}\Omega-8\pi p+\Omega\, u^2+8\pi(\rho-p)$$

$$\Leftrightarrow b=-\tfrac{1}{2}\Omega-8\pi p+8\pi(\rho+p)-16\pi p=\tfrac{1}{2}\Omega-24\pi p$$

$$\Leftrightarrow p=\frac{1}{24\pi}\left(\tfrac{1}{2}\Omega-b\right).$$

On the other hand,

$$\text{QM.3.11}\Leftrightarrow \Omega\, u^2=\tfrac{1}{2}-4\pi(\rho-p)=\tfrac{1}{2}-4\pi(\rho+p)+8\pi p=\tfrac{1}{2}-\tfrac{1}{3}\Omega-\tfrac{1}{3}b.$$

Therefore,

$$u^2 = \frac{3-2b}{6\Omega} - \frac{1}{3}.$$

Similarly,

$$\mathrm{QM}.1 \Leftrightarrow H^2 = \frac{2}{3}(\Omega - 2b) + 1.$$

Now

$$\mathrm{QM}.2 \Leftrightarrow H = -2\,\Omega\,u^0 u$$

$$\Rightarrow H^2 = 4\,\Omega^2 (u^0)^2 u^2 \Leftrightarrow \frac{1}{4\,\Omega^2} H^2 = u^4 + u^2$$

$$\Leftrightarrow \frac{1}{4\,\Omega^2}\left(\frac{2}{3}(\Omega - 2b) + 1\right) - \left(\frac{3-2b}{6\Omega} - \frac{1}{3}\right)^2 - \left(\frac{3-2b}{6\Omega} - \frac{1}{3}\right) = 0$$

$$\Leftrightarrow \left(-\frac{b}{3} + \frac{1}{4} - \frac{(3-2b)^2}{36}\right)\frac{1}{\Omega^2} + \left(\frac{1}{6} + \frac{6-4b}{18} + \frac{2b-3}{6}\right)\frac{1}{\Omega} + \frac{2}{9} = 0$$

$$\Leftrightarrow -b^2 \frac{1}{\Omega^2} + b\frac{1}{\Omega} + 2 = 0 \Leftrightarrow \frac{1}{\Omega} = \frac{-b \pm 3b}{-2b^2}$$

$$\Leftrightarrow \Omega = \frac{b}{2} \text{ or } \Omega = -b.$$

Let $\Omega = b/2$. We easily obtain

$$H^2 = 1 - b;$$

$$u^2 = \frac{1-b}{b};$$

$$p = -\frac{b}{32\pi};$$

$$\rho = -3p.$$

To obtain the general solution, i.e., for $D = \mathrm{diag}(a,b,b)$, we have to use the Rescaling Lemma. We have

$$H^2(a,b,b) = a^2 H^2\left(1, \frac{b}{a}, \frac{b}{a}\right) = a^2\left(1 - \frac{b}{a}\right) = a(a-b)$$

yielding the condition $a \geqslant b$. Similarly,

$$u^2(a,b,b) = u^2\left(1, \frac{b}{a}, \frac{b}{a}\right) = \frac{1 - b/a}{b/a} = \frac{a-b}{b},$$

yielding the condition $b > 0$. *QM*.2 requires only that H and u satisfy $Hu \leqslant 0$. Finally,

$$p(a,b,b) = a^2\left(-\frac{b/a}{32\pi}\right) = -\frac{ab}{32\pi}.$$

It can be shown that all these solutions of QM are in fact Einstein's universe in different frames (see Sec. V F).

If $\Omega=-b$, the procedure above yields the second family of solutions, corresponding to Gödel's universe.

(ii) We have $D=\mathrm{diag}(a,b,a-b)$. Let us set $a=1$. The only changes with respect to the previous case occur in

$$\mathrm{QM.3}\,.\,ii \Leftrightarrow \begin{cases} R_{11} = 2b(1-b) = 8\pi(\rho+p)u^2 + 4\pi(\rho-p) \\ R_{22} = R_{33} = 0 = -\frac{1}{2}H^2 + 4\pi(\rho-p) \Leftrightarrow H^2 = 8\pi(\rho-p) \end{cases}.$$

From the last equation we obtain

$$\mathrm{QM.1} \Leftrightarrow 4\pi(\rho-p) = 8\pi(\rho+p)u^2 + 4\pi(\rho+3p)$$

$$\Leftrightarrow 8\pi(\rho+p)u^2 = -16\pi p$$

$$\Leftrightarrow u^2 = -\frac{2p}{\rho+p}$$

$$\Rightarrow (p \leqslant 0 \quad \text{and} \quad \rho+p>0) \text{ or } (p \geqslant 0 \quad \text{and} \quad \rho+p<0).$$

The second condition implies $\rho-p<-2p\leqslant 0$, contradicting $H^2=8\pi(\rho-p)$. Since $\rho+p>0$, H and u must have opposite signs and

$$\mathrm{QM.2} \Leftrightarrow \sqrt{8\pi(\rho-p)} = 16\pi(\rho+p)\sqrt{1-\frac{2p}{\rho+p}}\sqrt{\frac{-2p}{\rho+p}}$$

$$\Leftrightarrow \rho - p = 64\pi p(p-\rho).$$

But $\rho-p=0 \Rightarrow H=0 \overset{QM.2}{\Rightarrow} u=0 \overset{QM.3.11}{\Rightarrow} R_{11}=0 \Leftrightarrow bc=0$, which is absurd. We then have

$$p = -\frac{1}{64\pi}$$

and

$$\mathrm{QM.3.11} \Leftrightarrow \rho = \frac{32b(1-b)-5}{64\pi}.$$

From the above-mentioned equations we can then obtain the expression for H^2 and u^2, in the special case $a=1$. To obtain the general solution and the restrictions over a and b, we proceed as in the previous case. This third family of solutions can be shown to be the Ozsvath-Farnsworth-Kerr class I family of solutions.

(b) Let $u_1=0(\Rightarrow H_1=0)$ and $(u^0)^2=-bc/16\pi(\rho+p)$. We will prove that there are no solutions satisfying these hypotheses. We start by checking that

$\mathbf{u}^2+1=-bc/16\pi(\rho+p) \Leftrightarrow 8\pi(\rho+p)\mathbf{u}^2=-1/2bc-8\pi(\rho+p)$, and hence

$$\mathrm{QM.1} \Leftrightarrow \mathbf{H}^2 = -bc - 8\pi(\rho-p).$$

On the other hand,

$$\text{QM.3.11} \Leftrightarrow 8\pi(\rho - p) = R_{11} - \tfrac{1}{2}bc$$

and so

$$\text{QM.3.22} + \text{QM.3.33} \Leftrightarrow R_{22} + R_{33} = 4\pi(\rho - p) - 16\pi p$$

$$\Leftrightarrow p = \frac{2R_{11} - 4R_{22} - 4R_{33} - bc}{64\pi}.$$

It is now immediate that

$$\rho = \frac{10R_{11} - 4R_{22} - 4R_{33} - 5bc}{64\pi}.$$

On the other hand,

$$QM.2 \Leftrightarrow \begin{cases} bH_2 = -16\pi(\rho + p)u^0 u_2 \\ cH_3 = -16\pi(\rho + p)u^0 u_3 \end{cases} \Rightarrow \begin{cases} b^2(H_2)^2 = [16\pi(\rho + p)]^2 (u^0)^2 (u_2)^2 \\ c^2(H_3)^2 = [16\pi(\rho + p)]^2 (u^0)^2 (u_3)^2 \end{cases}$$

$$\Leftrightarrow \begin{cases} (H_2)^2 = -16\pi(\rho + p)\dfrac{c}{b}(u_2)^2 \\ (H_3)^2 = -16\pi(\rho + p)\dfrac{b}{c}(u_3)^2 \end{cases}.$$

Using $(\text{QM.2.2})^2$, we get

$$\text{QM.3.22} \Leftrightarrow R_{22} = \frac{1}{2}(H_2)^2 - \frac{1}{2}\mathbf{H}^2 + 8\pi(\rho + p)(u_2)^2 + 4\pi(\rho - p)$$

$$\Leftrightarrow \left(1 - \frac{c}{b}\right) 8\pi(\rho + p)(u_2)^2 = R_{22} - R_{11}.$$

It is easily checked that there are no solutions with $b = c$, and hence

$$8\pi(\rho + p)(u_2)^2 = \frac{b}{b - c}(R_{22} - R_{11}).$$

As a consequence of $(\text{QM.2.2})^2$, we have

$$(H_2)^2 = \frac{2c}{c - b}(R_{22} - R_{11}).$$

A similar procedure will give us

$$8\pi(\rho + p)(u_3)^2 = \frac{c}{c - b}(R_{33} - R_{11});$$

$$(H_3)^2 = \frac{2b}{b - c}(R_{33} - R_{11}).$$

From equation

$$(H_2)^2 + (H_3)^2 = -bc - 8\pi(\rho - p)$$

we obtain the restriction

$$-3a^2b + 3a^2c + 4ab^2 - 4ac^2 - b^3 - 4b^2c + 4bc^2 + c^3 = 0.$$

To simplify this last expression we use the Rescaling lemma to set $a=1$ and divide the resulting polynomial equation by $b-c$, thus obtaining

$$b^2 + c^2 + 5bc - 4b - 4c + 3 = 0.$$

We have

$$(u^0)^2 = -\frac{bc}{16\pi(\rho + p)} \Rightarrow bc(\rho + p) < 0.$$

The expression for $(H_3)^2$ implies that $[b/(b-c)](R_{33}-R_{11}) \geqslant 0$, and since $8\pi(\rho+p)(u_2)^2=[b/(b-c)](R_{22}-R_{11}) \Leftrightarrow 8\pi bc(\rho+p)(u_2)^2=[b^2c/(b-c)](R_{22}-R_{11})$, the restriction implied by the expression for $(u^0)^2$ gives us

$$\frac{c}{c-b}(R_{22} - R_{11}) \geqslant 0.$$

If we proceed in a similar fashion using the expressions for $(H_2)^2$ and $8\pi(\rho+p)(u_3)^2$, and then compute the components of the Ricci tensor in terms of a and b, we will obtain the following restrictions:

(i) $b^2+c^2+5bc-4b-4c+3=0$;
(ii) $c(c-b)(b-1)(b-c+1) \geqslant 0$;
(iii) $b(b-c)(c-1)(c-b+1) \geqslant 0$;
(iv) $bc(\rho+p)<0 \Rightarrow 64\pi bc(\rho+p)<0 \Rightarrow bc[3(b^2+c^2-3bc+4(b+c)-7]>0$.

From (i) we obtain $b^2+c^2=-5bc+4b+4c-3$, which when used in (iv) yields

(iv') $bc(-9bc+8b+8c-8)>0$.

It is now easy to use a geometrical argument to determine the incompatibility of restrictions (ii), (iii) and (iv'): we just have to check that the regions determined in the bc-plane by these restrictions do not intersect.

(2) It is obvious that

$$ab = bc = ac \Leftrightarrow a = b = c.$$

Symmetry allows us to consider $u_2=u_3=0$, and thus we are back to the very first case we analyzed. □

D. Solutions with G=0

The next two results complete the classification of QM class *A* solutions with zero gravitational field.

Proposition 4.4: *There are no class A QM solutions with zero gravitational field corresponding to Lie algebras with rank D*=1.

Proof: Let $D=\mathrm{diag}(0,0,1)$. Symmetry allows us to take $\mathbf{H}=H_2X_2+H_3X_3 \overset{\text{QM.2}}{\Rightarrow} \mathbf{u}=uX_3$. Therefore, QM.3.23 $\Leftrightarrow 0=H_2H_3$.

If $H_3=0 \overset{\text{QM.2}}{\Rightarrow} \mathbf{u}=0$, we have

$$\text{QM.3 . } ii \Leftrightarrow \mathbf{H}^2 = -1.$$

If $H_2=0$, we have

$$\text{QM.3 . } ii \Leftrightarrow \begin{cases} H^2 = 8\pi(\rho - p) + 1 \\ 8\pi(\rho + p)u^2 = \dfrac{1}{2} - 4\pi(\rho - p) \end{cases}$$

and

$$QM.1 \Leftrightarrow \rho = 5p \Rightarrow p \neq 0.$$

Using all this in QM.2.2 leads to $p=0$. □

Proposition 4.5: *The only class A solution of QM with zero gravitational field corresponding to a Lie algebra with* rank $D=2$ *is Minkowski spacetime*.

Proof: We can assume $a=0$. Thus $QM.2 \Rightarrow u_1=0$, and therefore

$$\begin{aligned} \nabla_{\mathbf{u}}\mathbf{u} &= u_2u_3(\Gamma^1_{23} + \Gamma^1_{32})X_1 = \tfrac{1}{2}u_2u_3(C_{123} + C_{312} - C_{231} + C_{132} + C_{213} - C_{321})X_1 \\ &= \tfrac{1}{2}u_2u_3(0 - c + b + 0 + b - c)X_1 = (b-c)u_2u_3X_1. \end{aligned}$$

We then have

$$\text{Motion equation} \Leftrightarrow \begin{cases} (b-c)u_2u_3 = u^0(u_2H_3 - u_3H_2) \\ u_3H_1 = 0 \\ u_2H_1 = 0 \end{cases} \Rightarrow H_1 = 0 \text{ or } \mathbf{u} = \mathbf{0}.$$

It can be easily seen that no solutions exist for $\mathbf{u}=\mathbf{0}$, and that solutions featuring $H_1=0$ and $u_2u_3=0$ must verify $b=c$, and hence are Minkowski spacetime (cf. Theorem 4.2).

We are left with the case $H_1=0$ and $u_2u_3 \neq 0$. Using QM.2 we obtain

$$\text{Motion equation} \Leftrightarrow \text{QM.3 . } ij(i \neq j) \Leftrightarrow (u^0)^2 = -\frac{bc}{16\pi(\rho + p)}.$$

The situation is now quite similar to the one in the demonstration of case 1b of Theorem 4.3. Using the same procedure we obtain

$$u_2 = \pm\frac{2\sqrt{3}}{3}\sqrt{\frac{b^2}{-b^2 - c^2 + bc}} \Rightarrow -b^2 - c^2 + bc > 0$$

and

$$H_2 = \pm\sqrt{-2bc} \Rightarrow bc < 0.$$

But

$$1 + (u_2)^2 + (u_3)^2 = -\frac{bc}{16\pi(\rho + p)} \Leftrightarrow b^2 + c^2 + 5bc = 0$$

and, therefore,

$$-b^2 - c^2 + bc > 0 \Leftrightarrow b^2 + c^2 + 5bc - 6bc < 0 \Leftrightarrow bc > 0,$$

yielding a contradiction. □

E. Solutions with G≠0

For solutions with $\mathbf{G} \neq 0$ we can assume $\mathbf{G}=GX_1$ with $G \neq 0$, which implies $H_1=u_1=0$ and $D=\text{diag}(0,b,c)$. It is then easy to see that QM.1+QM.3.22+QM.3.33 yields

$$G^2 + 4\pi(\rho - 5p) = 0.$$

These solutions must of course include the two-parameter family given by

$$H_2 = \sqrt{2}G\cos\theta;$$
$$H_3 = \sqrt{2}G\sin\theta;$$
$$u_2 = -\sin\theta;$$
$$u_3 = \cos\theta;$$
$$p = \rho = \frac{G^2}{16\pi};$$
$$b = c = 0,$$

corresponding to the Gödel universe. Apart from these, one can show that there exist further solutions, belonging to the category 2 of Ozsvath classification (see Sec. V F). Unfortunately, it is not possible to obtain simple expressions for these solutions.

F. Identifying the solutions

Recall that a solution of Einstein's field equations is said to be spacetime homogeneous if it admits a transitive action by isometries. This will happen if, for instance, the solution is a left-invariant metric on a (four-dimensional) Lie group.

The solutions we have been considering have in fact a Lie group structure, as $M = \mathbb{R} \times \Sigma$ and Σ is a three-dimensional Lie group.

Proposition 4.6: *A stationary spacetime* (M, g) *corresponding to a solution of QM for which the space manifold* (Σ, γ) *is a Lie group with a left-invariant Riemannian metric and whose fields* **G** *and* **H** *are left-invariant is a Lie group with a left-invariant Lorentzian metric*.

Proof: One just has to check that

$$\{X_0, X_i\}$$

is a left-invariant orthonormal frame, where $\{X_i\}$ are the vector fields in M associated to a left-invariant orthonormal frame on the space manifold. □

Since all spacetime homogeneous perfect fluid solutions which are left-invariant Lorentzian metrics on a Lie group have been classified (see Refs. 6 and 7), we can use this classification to identify the solutions we have obtained. One must be careful to use frame-independent quantities when comparing solutions; in most cases it suffices to compare the equations of state.

The recollapse problem of closed Friedmann–Robertson–Walker models in higher-order gravity theories

John Miritzis[a)]
Department of Marine Sciences, University of the Aegean, University Hill, Mytilene, 81100 Greece

(Received 2 June 2005; accepted 5 July 2005; published online 22 August 2005)

We study the closed universe recollapse conjecture for positively curved Friedmann–Robertson–Walker models with a perfect fluid matter source and a scalar field which arises in the conformal frame of the $R+\alpha R^2$ theory. By including ordinary matter, we extend the analysis of a previous work. We analyze the structure of the resulted four-dimensional dynamical system with the methods of the center manifold theory and the normal form theory. It is shown that an initially expanding closed FRW universe, starting close to the Minkowski space-time, cannot avoid recollapse. We discuss the possibility that potentials with a positive minimum may prevent the recollapse of closed universes. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2009648]

I. INTRODUCTION

A closed Friedmann–Robertson–Walker (FRW) universe is often considered almost synonymous to a recollapsing universe. This is mainly due to our experience with the dust and radiation filled FRW models usually treated in textbooks. That this picture is misleading follows clearly from an example found by Barrow *et al.*[1] according to which an expanding homogeneous and isotropic model with spatial topology S^3 satisfying the weak, the strong, the dominant energy conditions and the generic condition may not recollapse. Thus the problem of recollapse of a closed universe to a second singularity is delicate already in the FRW case.

The *closed-universe recollapse conjecture* states roughly that a closed universe cannot expand forever, provided that the matter content satisfies some energy condition and has nonnegative pressures. The conjecture was found true in certain spatially homogeneous cosmologies,[2] in certain spherically symmetric space-times[3] and in space-times admitting a constant mean-curvature foliation that possesses a maximal hypersurface.[4] In these investigations it has proved useful to demand that the dominant energy condition and the positive pressure criterion hold (see also Ref. 5 for a dynamical system approach).

In this paper we investigate the evolution of positively curved FRW models with a scalar field having the potential which arises in the conformal frame of the $R+\alpha R^2$ theory[6–8] and ordinary matter described by a perfect fluid with energy density ρ and pressure p. The motivation for this choice was presented in Ref. 9. The purpose of the present article is to generalize the results in Ref. 9 by including ordinary matter and to correct the mistake found therein. {In Ref. 9, inequality (11) has the wrong direction [compare with (12) in this paper]. This mistake and a different rescaling [compare with (8)] were the sources of the erroneous conclusion that an initially expanding universe avoids recollapse. In fact, inequality (11) must be reversed and as a consequence, the admissible trajectories of the system (16) start below the line $H=\sqrt{2}r$ in Fig. 1. This implies that an initially expanded closed universe cannot avoid recollapse. Nevertheless, the calculations and the mathematical analysis of the system (12) near the equilibrium (0,0,0) remain correct. Moreover, the above-mentioned mistake does not essentially affect the rest of the paper.}

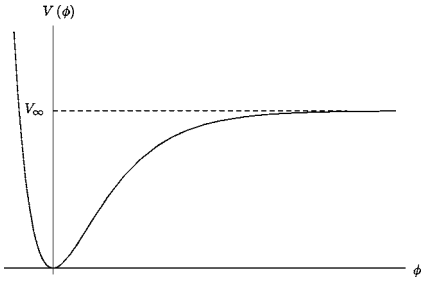

FIG. 1. The potential (5).

The plan of the paper is as follows. In the next section we write down the field equations, as a constrained five-dimensional dynamical system. We use the constraint equation to reduce the dimension of the system to four and after a suitable change of variables the system becomes quadratic. In Sec. III we analyze the structure of the equilibrium corresponding to the de Sitter solution using the methods of the center manifold theory. Further, we find the so-called normal form of the dynamical system describing a large, slowly expanding universe with low total energy density; we show that such a universe cannot avoid recollapse. In the last section, we consider potentials having a strict positive minimum and argue that this class of potentials prevent a closed universe from recollapse.

II. REDUCTION TO A FOUR-DIMENSIONAL QUADRATIC SYSTEM

In General Relativity the evolution of FRW models with a scalar field (ordinary matter is described by a perfect fluid with energy density ρ and pressure p) are governed by the Friedmann equation,

$$\left(\frac{\dot{a}}{a}\right)^2+\frac{k}{a^2}=\frac{1}{3}\left[\rho+\frac{1}{2}\dot{\phi}^2+V(\phi)\right], \tag{1}$$

the Raychaudhuri equation,

$$\frac{\ddot{\alpha}}{a}=-\frac{1}{6}(\rho+3p+2\dot{\phi}^2-2V), \tag{2}$$

the equation of motion of the scalar field,

$$\ddot{\phi}+3\frac{\dot{a}}{a}\dot{\phi}+V'(\phi)=0, \tag{3}$$

and the conservation equation,

$$\dot{\rho}+3(\rho+p)\frac{\dot{a}}{a}=0. \tag{4}$$

We adopt the metric and curvature conventions of Ref. 10. $a(t)$ is the scale factor, an overdot denotes differentiation with respect to time t, and units have been chosen so that $c=1=8\pi G$. Here $V(\phi)$ is the potential energy of the scalar field and $V'=\mathrm{d}V/\mathrm{d}\phi$. We assume an equation of state of the form $p=(\gamma-1)\rho$, with $2/3<\gamma\leqslant 2$.

In what follows we assume that the potential function of the scalar field is

$$V(\phi)=V_\infty(1-e^{-\sqrt{2/3}\phi})^2 \tag{5}$$

which arises in the conformal frame of the $R+\alpha R^2$ theory.[7] The conformal equivalence of $f(R)$ theories to general relativity raises several conceptual problems, for example, does conformal

equivalence imply physical equivalence between the two theories? For an extensive discussion of related issues see Ref. 8 and references therein. For our purposes the conformal transformation is well behaved as far as $f'(R)$ does not vanish.

The flat plateau of this potential is responsible for an early inflationary period of the universe and, for homogeneous spacetimes provides a mechanism of isotropization.[7,11] From the field equations it is easy to see that in an expanding universe the energy density of the scalar field, namely

$$E = \tfrac{1}{2}\dot{\phi}^2 + V(\phi)$$

is a decreasing function of time. Since the energy density, ρ, of ordinary matter also decreases, it may happen that in a future time, E be comparable to ρ. In particular, for closed, $k=1$, models, once the scale factor reaches its maximum value and recollapse commences i.e., $H<0$, the term $3H\dot{\phi}$ in (3) is no longer a damping factor, but acts as a driving force which forces the field ϕ to oscillate with larger and larger amplitude. If this be the case, the repulsive effect of the cosmological term may drastically change the evolution of a classical FRW model.

Setting $\dot{\phi} =: y$, $\dot{a}/a =: H$, we obtain from (1) the constraint equation

$$3H^2 + 3k/a^2 = \rho + \tfrac{1}{2}y^2 + V(\phi), \tag{6}$$

which we use to eliminate a from the evolution equations (2)–(4). As a consequence, the dimension of the dynamical system is reduced to four and we obtain

$$\begin{aligned} \dot{\phi} &= y, \\ \dot{y} &= -3Hy - V'(\phi), \\ \dot{\rho} &= -3\gamma\rho H, \\ \dot{H} &= \frac{1}{3}V(\phi) - \frac{1}{3}y^2 - \frac{3\gamma-2}{6}\rho - H^2. \end{aligned} \tag{7}$$

We remind the reader that the exponential potential which is popular in the literature of scalar-field cosmologies has the nice property that $V' \propto V$, which allows the introduction of normalized variables according to the formalism of Wainwright and Ellis.[10] For an exponential potential the dimension of the dynamical system for a closed FRW model reduces to three.[12]

We simplify the system by rescaling the variables by the equations

$$\phi \to \sqrt{3/2}\phi, \quad y \to \sqrt{2V_\infty}y, \quad \rho \to \frac{4V_\infty}{3}\rho, \quad H \to \sqrt{\frac{4V_\infty}{3}}H, \quad t \to \sqrt{\frac{3}{4V_\infty}}t. \tag{8}$$

Further, in order to take into account the equilibrium point corresponding to the point at "infinity" and to remove the transcendental functions, it is convenient to introduce the variable u defined by

$$u := e^{-\phi}, \tag{9}$$

and system (7) finally becomes

$$\begin{aligned} \dot{u} &= -uy, \\ \dot{y} &= -u + u^2 - 3Hy, \\ \dot{\rho} &= -3\gamma\rho H, \end{aligned}$$

$$\dot{H} = \frac{1}{4}(1-u)^2 - \frac{1}{2}y^2 - \frac{3\gamma - 2}{6}\rho - H^2. \tag{10}$$

Note that under the transformation (9), the resulted four-dimensional dynamical system (10) is quadratic.

Remark: The system (10) is not an arbitrary "free" four-dimensional system. In view of (6) the initial conditions have to satisfy the condition $3H_0^2 - \rho - \frac{1}{2}y_0^2 - V(\phi_0) < 0$, or, in terms of the new variables,

$$H_0^2 - \frac{1}{3}\rho - \frac{1}{4}y_0^2 - \frac{1}{4}(1-u_0)^2 < 0. \tag{11}$$

With a little manipulation of the equations (10) it can be shown that, once we start with initial conditions satisfying at time t_0 the inequality (11), the solutions of the system satisfy

$$H(t)^2 - \tfrac{1}{3}\rho(t) - \tfrac{1}{4}y(t)^2 - \tfrac{1}{4}(1-u(t))^2 < 0$$

for all $t > t_0$. This is a general property of the Einstein equations, namely that the subsequent evolution of the system is such that the solutions respect the constraint. We conclude that the phase space of the system (10) is the set

$$\Sigma := \left\{(u,y,\rho,H) \in \mathbb{R}^4 : H^2 - \tfrac{1}{3}\rho - \tfrac{1}{4}y^2 - \tfrac{1}{4}(1-u)^2 < 0\right\}. \tag{12}$$

III. STABILITY ANALYSIS

There are several equilibrium points of (10). Some of them correspond to static universes with a cosmological constant equal to $\sqrt{V_\infty}$. In the study of the equilibrium points we note that $u=1$ corresponds to $\phi=0$, i.e., to the minimum of the potential and $u=0$ corresponds to $\phi=\infty$, i.e., to the flat plateau of the potential. In the following we pay attention to the most interesting equilibrium solutions which are as follows.

EQ1: $(u=0, y=0, \rho=0, H=1/2)$. This corresponds to the de Sitter universe with a cosmological constant equal to $\sqrt{V_\infty}$. We analyze the flow of (10) near EQ1 in the next subsection.

EQ2: $(u=1, y=0, \rho=0, H=0)$. This corresponds to the limiting state of an ever-expanding universe with $H \to 0$ while the scalar field approaches the minimum of the potential and the scale factor goes to infinity. Equality in (12) which arises from the flat, $k=0$, case defines a set on the boundary of Σ. We conclude that the point EQ2 which corresponds to the Minkowski solution, is located on this boundary. The detailed structure of this equilibrium will be analyzed in Sec. III B.

As we shall see, both equilibria are non-hyperbolic, i.e., some or all of the eigenvalues of the Jacobian have zero real parts. That means that the linearization theorem does not yield any information about the stability of the equilibria and therefore, more powerful methods are needed. The study of the qualitative behaviour of a dynamical system near a nonhyperbolic equilibrium point is difficult even in two dimensions. There are two general methods for simplifying a dynamical system having a nonhyperbolic equilibrium. The first is the center manifold theory. According to the center manifold theorem, the qualitative behavior in a neighborhood of a nonhyperbolic equilibrium point $\mathbf{q}$ is determined by its behavior on the center manifold near $\mathbf{q}$. Since the dimension of the center manifold is generally smaller than the dimension of the dynamical system, this greatly simplifies the problem (cf. Refs. 13 and also 14 for cosmological applications). The second method is the normal form theory, which consists in a nonlinear coordinate transformation that allows to simplify the nonlinear part of the system (cf. Ref. 13 for a brief introduction). Both methods are used in the next two subsections.

A. Center manifold for the system at EQ1

It is easy to see that at the equilibrium point $\mathbf{q}=(u=0, y=0, \rho=0, H=1/2)$, the Jacobian matrix of (10) has one zero and three negative eigenvalues and, consequently the Hartman-Grobman

theorem does not apply. The center manifold theorem implies that there exists a local three-dimensional stable manifold through $\mathbf{q}$ (see, e.g., Ref. 13). That means that all trajectories asymptotically approaching $\mathbf{q}$ as $t\to\infty$, lie on a three-dimensional invariant manifold. Since $\mathbf{q}$ is a nonhyperbolic fixed point, the topology of the flow near $\mathbf{q}$ is nontrivial and is characterized by a one-dimensional local center manifold containing $\mathbf{q}$. We prove the following result.

Proposition: The equilibrium point $\mathbf{q}=(0,0,0,1/2)$ *of* (10) *is locally asymptotically unstable*.

In order to determine the local center manifold of (10) at $\mathbf{q}$, we have to transform the system into a form suitable for the application of the center manifold theorem. The procedure is fairly systematic and will be accomplished in the following steps.

1. The Jacobian of (10) at $\mathbf{q}=(0,0,0,1/2)$ has eigenvalues 0, -1, $-3/2$, and $-3\gamma/2$ with corresponding eigenvectors $(-2,4/3,0,1)^T$, $(0,0,0,1)^T$, $(0,1,0,0)^T$, and $(0,0,3,1)^T$. Let T be the matrix having as columns these eigenvectors. We shift the fixed point to (0, 0, 0, 0) by setting $\tilde{H}=H-1/2$ and write (10) in vector notation as

$$\dot{\mathbf{z}}=A\mathbf{z}+\mathbf{F}(\mathbf{z}), \tag{13}$$

where A is the linear part of the vector field and $\mathbf{F}(\mathbf{0})=\mathbf{0}$.

2. Using the matrix T which transforms the linear part of the vector field into Jordan canonical form, we define new variables, $(x,y_1,y_2,y_3)\equiv\mathbf{x}$, by the equations

$$u=-2x,$$

$$y=\tfrac{4}{3}x+y_2,$$

$$\rho=3y_3,$$

$$\tilde{H}=x+y_1+y_3,$$

or in vector notation $\mathbf{z}=T\mathbf{x}$, so that (13) becomes

$$\dot{\mathbf{x}}=T^{-1}AT\mathbf{x}+T^{-1}\mathbf{F}(T\mathbf{x}).$$

Denoting the canonical form of A by B we finally obtain the system

$$\dot{\mathbf{x}}=B\mathbf{x}+\mathbf{f}(\mathbf{x}), \tag{14}$$

where $\mathbf{f}(\mathbf{x}):=T^{-1}\mathbf{F}(T\mathbf{x})$. In components system (14) is

$$\begin{bmatrix}\dot{x}\\ \dot{y}_1\\ \dot{y}_2\\ \dot{y}_3\end{bmatrix}=\begin{bmatrix}0&0&0&0\\ 0&-1&0&0\\ 0&0&-3/2&0\\ 0&0&0&-3\gamma/2\end{bmatrix}\begin{bmatrix}x\\ y_1\\ y_2\\ y_3\end{bmatrix}+\begin{bmatrix}-\frac{4}{3}x^2-xy_2\\ \frac{4}{9}x^2-y_1^2-\frac{1}{2}y_2^2+(3\gamma-1)y_3^2-2xy_1-\frac{1}{3}xy_2+(3\gamma-2)xy_3+(3\gamma-2)y_1y_3\\ \frac{16}{9}x^2-\frac{3}{2}y_2^2-4xy_1-\frac{5}{3}xy_2-4xy_3-3y_1y_2-3y_2y_3\\ -3\gamma(xy_3+y_1y_3+y_3^2)\end{bmatrix}. \tag{15}$$

3. The system (15) is written in diagonal form

$$\dot{x} = Cx + f(x,\mathbf{y}),$$
$$\dot{\mathbf{y}} = P\mathbf{y} + \mathbf{g}(x,\mathbf{y}), \tag{16}$$

where $(x,\mathbf{y}) \in \mathbb{R}\times\mathbb{R}^3$, C is the zero 1×1 matrix, P is a 3×3 matrix with negative eigenvalues and $f,\mathbf{g}$ vanish at $\mathbf{0}$ and have vanishing derivatives at $\mathbf{0}$. The center manifold theorem asserts that there exists a one-dimensional invariant local center manifold $W^c(\mathbf{0})$ of (16) tangent to the center subspace (the $\mathbf{y}=\mathbf{0}$ space) at $\mathbf{0}$. Moreover, $W^c(\mathbf{0})$ can be represented as

$$W^c(\mathbf{0}) = \{(x,\mathbf{y}) \in \mathbb{R}\times\mathbb{R}^3 : \mathbf{y} = \mathbf{h}(x),\ |x| < \delta\};\quad \mathbf{h}(0) = \mathbf{0},\quad D\mathbf{h}(0) = \mathbf{0},$$

for δ sufficiently small (cf. Ref. 13, p. 155). The restriction of (16) to the center manifold is

$$\dot{x} = f(x,\mathbf{h}(x)). \tag{17}$$

According to Theorem 3.2.2 in Ref. 15, if the origin $x=0$ of (17) is stable (respectively, unstable) then the origin of (16) is also stable (respectively, unstable). Therefore, we have to find the local center manifold, i.e., the problem reduces to the computation of $\mathbf{h}(x)$.

4. Substituting $\mathbf{y}=\mathbf{h}(x)$ in the second component of (16) and using the chain rule, $\dot{\mathbf{y}} = D\mathbf{h}(x)\dot{x}$, one can show that the function $\mathbf{h}(x)$ that defines the local center manifold satisfies

$$D\mathbf{h}(x)[f(x,\mathbf{h}(x))] - P\mathbf{h}(x) - \mathbf{g}(x,\mathbf{h}(x)) = 0. \tag{18}$$

This condition allows for an approximation of $\mathbf{h}(x)$ by a Taylor series at $x=0$. Since $\mathbf{h}(0)=\mathbf{0}$ and $D\mathbf{h}(0)=\mathbf{0}$, it is obvious that $\mathbf{h}(x)$ commences with quadratic terms. We substitute

$$\mathbf{h}(x) =: \begin{bmatrix} h_1(x) \\ h_2(x) \\ h_3(x) \end{bmatrix} = \begin{bmatrix} a_1x^2 + a_2x^3 + O(x^4) \\ b_1x^2 + b_2x^3 + O(x^4) \\ c_1x^2 + c_2x^3 + O(x^4) \end{bmatrix}$$

into (18) and set the coefficients of like powers of x equal to zero to find the unknowns $a_1, b_1, c_1, \ldots$.

5. Since y_1 and y_3 are absent from the first of (15), we give only the result for $h_2(x)$. We find $b_1=32/27$, $b_2=-32/81$. Therefore, (17) yields

$$\dot{x} = -\tfrac{4}{3}x^2 - \tfrac{32}{27}x^3 + \tfrac{32}{81}x^4 + O(x^5). \tag{19}$$

It is obvious that the origin $x=0$ of (19) is asymptotically unstable (saddle point). The theorem mentioned after (17) implies that the origin $\mathbf{x}=\mathbf{0}$ of the full four-dimensional system is unstable. This completes the proof.

B. Normal form of the system near EQ2

Regarding the stability of this equilibrium, it is easy to see that the eigenvalues of the Jacobian of (10) are, $\pm i, 0, 0$, i.e., it is totally degenerate. Nevertheless, it is the most interesting case because in other equilibria the scalar field reaches the flat plateau, which is impossible if we restrict ourselves to initial values of H smaller than $\sqrt{V_\infty}$. We find the normal form of the system (10) near the equilibrium point $(u=1, y=0, \rho=0, H=0)$. The idea of the normal form theory is the following: Given a dynamical system with equilibrium point at the origin, $\dot{\mathbf{x}}=A\mathbf{x}+\mathbf{f}(\mathbf{x})$, where A is the Jordan form of the linear part and $\mathbf{f}(\mathbf{0})=\mathbf{0}$, perform a nonlinear transformation $\mathbf{x}\to\mathbf{x}+\mathbf{h}(\mathbf{x})$, where $\mathbf{h}(\mathbf{x})=O(|\mathbf{x}|^2)$ as $|\mathbf{x}|\to 0$, such that the system becomes "as simple as possible."

To write the system in a form suitable for the application of the normal form theory, we shift the fixed point to (0, 0, 0, 0) by setting $x=u-1$ and the system becomes

$$\dot{x} = -y - xy,$$

$$\dot{y} = x + x^2 - 3Hy,$$
$$\dot{\rho} = -3\gamma\rho H, \tag{20}$$
$$\dot{H} = \frac{1}{4}x^2 - \frac{1}{2}y^2 - \frac{3\gamma - 2}{6}\rho - H^2.$$

Now we make the nonlinear change of variables

$$x \to x - y^2 - \frac{3\gamma - 2}{16}\rho x + \frac{3}{4}Hy,$$

$$y \to y + xy + \frac{3\gamma - 2}{16}\rho y + \frac{3}{4}Hx,$$

$$\rho \to \rho,$$

$$H \to H + \frac{3}{8}xy,$$

and keeping only terms up to second order, we obtain the normal form of the system, viz.,

$$\dot{x} = -y - \frac{3}{2}Hx,$$

$$\dot{y} = x - \frac{3}{2}Hy,$$

$$\dot{\rho} = -3\gamma\rho H,$$

$$\dot{H} = -\frac{3\gamma - 2}{6}\rho - \frac{1}{8}(x^2 + y^2) - H^2. \tag{21}$$

Note that the results are valid only near the origin.

Passing to cylindrical coordinates ($x = r\cos\theta, y = r\sin\theta, \rho = \rho, H = H$), we have

$$\dot{r} = -\frac{3}{2}rH,$$
$$\dot{\theta} = 1,$$
$$\dot{\rho} = -3\gamma\rho H, \tag{22}$$
$$\dot{H} = -\frac{1}{8}r^2 - H^2 - \frac{3\gamma - 2}{6}\rho.$$

We note that the θ dependence of the vector field has been eliminated, so that we can study the system in the (r, ρ, H) space. The equation $\dot{\theta} = 1$ means that the trajectory in the x–y plane spirals with angular velocity 1. The constraint [cf. (12)]

$$H^2 < \tfrac{1}{3}\rho + \tfrac{1}{4}y^2 + \tfrac{1}{4}x^2$$

becomes

$$H^2 < \tfrac{1}{4}r^2 + \tfrac{1}{3}\rho. \tag{23}$$

We observe that the first and third of (22) can be written as a differential equation

$$\frac{\mathrm{d}\rho}{\mathrm{d}r} = 2\gamma\frac{\rho}{r},$$

which has the general solution

$$\rho = Cr^{2\gamma}, \quad C > 0. \tag{24}$$

Therefore, for $\gamma=1$, we obtain from (22)

$$\dot{r} = -\tfrac{3}{2}rH,$$

$$\dot{H} = -\tfrac{1}{8}r^2 - \tfrac{1}{6}Cr^2 - H^2.$$

It is convenient to rescale r by

$$r \to \sqrt{\frac{24}{4C+3}}r, \tag{25}$$

so that the projection of (22) on the r–H plane is

$$\begin{aligned} \dot{r} &= -\tfrac{3}{2}rH, \\ \dot{H} &= -r^2 - H^2. \end{aligned} \tag{26}$$

This system belongs to a family of systems studied in 1974 by Takens.[16] Note that the constraint (23) becomes in the new variables

$$H^2 < 2r^2$$

and we conclude that the phase space of (26) is given by

$$-\sqrt{2}r \leqslant H \leqslant \sqrt{2}r. \tag{27}$$

The phase portrait of (26) is shown in Fig. 2 (see Ref. 9 for a detailed analysis). The system (26) has invariant lines $H=cr$ with $c=\pm\sqrt{2}$. Since no trajectory can cross the line $H=cr$, on any trajectory starting in the first quadrant below the line $H=cr$, H becomes zero at some time and the trajectory crosses vertically the r axis. Once the trajectory enters the second quadrant, r increases and H decreases. At first sight, it seems probable that an initially expanding universe may avoid recollapse; in fact all trajectories starting above the line $H=\sqrt{2}r$, asymptotically approaches the origin and the corresponding universes would be ever-expanding. But, (27) implies that all trajectories with $H>0$ must start below the line $H=\sqrt{2}r$. In conclusion, inequality (27) leaves no room for an ever-expanding closed universe, contrary to what was claimed in Ref. 9.

We conclude that for an initially expanding universe H continuously decreases while x and y oscillate with decreasing amplitude. H becomes zero at some time and the scale factor reaches a maximum value. Subsequently the universe begins to recollapse, i.e., H continuously decreases below zero while x and y oscillate with increasing amplitude. A typical trajectory of (21) is shown in Fig. 3, where the variable ρ was suppressed. One obtains qualitatively the same picture for all $\gamma \in [2/3, 2]$.

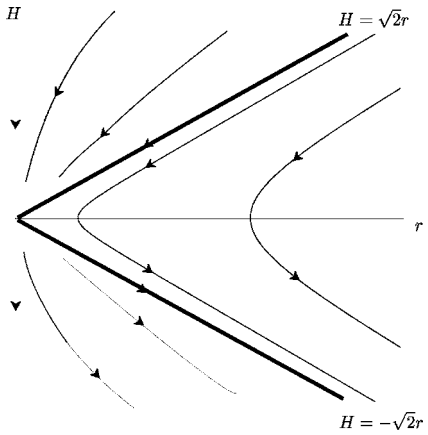

FIG. 2. The phase portrait of (26).

IV. FURTHER COMMENTS

We have analyzed the qualitative behavior of a positively curved FRW model filled with ordinary matter and containing a scalar field with the potential (5). This model is conformally equivalent to the positively curved FRW space-time in the simplest higher order gravity theory, namely the $R+\alpha R^2$ theory. We have shown that even for large initial values of H, near the flat plateau of the potential, the corresponding de Sitter equilibrium is asymptotically unstable. Further, an initially expanding closed universe in the neighborhood of EQ2 cannot avoid recollapse. This is in accordance to the well known global result concerning the closed universe recollapse conjecture, namely that a closed universe recollapses provided that the strong energy condition (SEC) is satisfied and there exists a maximal spacelike hypersurface Σ, i.e., the expansion is zero on Σ (cf. Ref. 17). In fact, it can be shown that for ϕ oscillating around the minimum of the potential, $V(0)=0$, the energy density, E, of the scalar field varies as $E\sim a^{-3}$.[18] Comparing this with the time dependence of the density $\rho\sim a^{-3\gamma}$ we arrive at the conclusion that for $\gamma\leqslant 1$, if at some time $t=t_0$

$$E<\rho, \quad 2\dot{\phi}^2-2V<\rho+3p,$$

then the SEC on the total stress-energy tensor is satisfied for all $t\geqslant t_0$. Hence the universe follows the classical Friedmannian evolution and has a time of maximum expansion. The above mentioned global theorem implies that this universe recollapses.

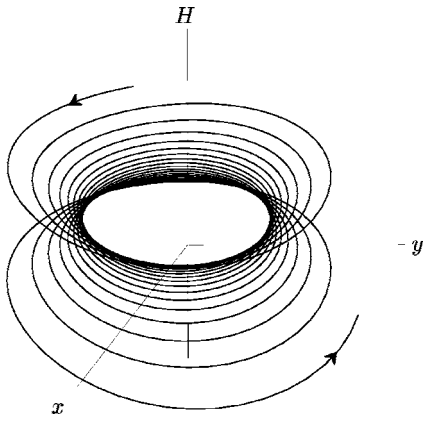

FIG. 3. A trajectory of (21).

For open and flat models having potentials with a unique minimum, $V(0)=0$, we have shown elsewhere,[18] that in an expanding universe, the energy density ρ of ordinary matter, the Hubble function H and the scalar field ϕ asymptotically approach zero. This theorem was proved without referring to the precise form of the potential. Putting all these results together, we may conjecture that potentials with a minimum equal to zero, cannot provide a mechanism of late accelerating expansion of the universe. On the other hand, in expanding universes with a potential having a positive minimum, the scalar field rolls down to the minimum of the potential and this residual cosmological term may explain the late accelerating expansion of the universe.[19]

We illustrate this idea by the example of the more general quadratic theory, derived from the Lagrangian density $R+\alpha R^2-2\Lambda$. The corresponding potential in the Einstein frame is

$$V_\Lambda(\phi) = V_\infty(1 - e^{-\sqrt{2/3}\phi})^2 + \Lambda e^{-2\sqrt{2/3}\phi}. \tag{28}$$

For every $\Lambda>0$, the functions $V_\Lambda(\phi)$ have the same qualitative behavior as (5) but, have a positive minimum, say $V_{\min}$ at some $\phi_m>0$. Both $V_{\min}$ and ϕ_m increase with increasing Λ.

We consider again expanding closed FRW models. It is easy to see that when $V_\Lambda(\phi)=V_{\min}$, the system (7) has an equilibrium $(\phi=\phi_m, y=0, \rho=0, H=\sqrt{V_{\min}/3})$ representing the de Sitter solution. It can be shown simply by the linearization theorem that this equilibrium is stable. To avoid complicating expressions for the eigenvalues we proceed as in Sec. II and obtain the following system [compare to (10)]:

$$\begin{aligned} \dot{u} &= -uy, \\ \dot{y} &= -u(1-u) + \lambda u^2 - 3Hy, \\ \dot{\rho} &= -3\gamma\rho H, \\ \dot{H} &= \frac{1}{4}(1-u)^2 + \frac{\lambda}{4}u^2 - \frac{1}{2}y^2 - \frac{3y-2}{6}\rho - H^2, \end{aligned} \tag{29}$$

with $\lambda=\Lambda/V_\infty$. The equilibrium point

$$\mathbf{p} = \left(\phi = \frac{1}{1+\lambda}, \quad y=0, \quad \rho=0, \quad H=\frac{1}{2}\sqrt{\frac{\lambda}{1+\lambda}}\right)$$

corresponds to the de Sitter solution with a cosmological term equal to $V_{\min}$. Linearization of (29) near $\mathbf{p}$ is sufficient to show that this point is a sink [all eigenvalues of the Jacobian matrix of (29) have negative real parts]. Therefore $\mathbf{p}$ attracts all nearby solutions and initially expanding closed universes enter a phase of accelerating expansion. This attracting property of the de Sitter solution for expanding models is well known from the cosmic no-hair conjecture and is not restricted only to isotropic cosmology. We conclude that $\Lambda=0$ in (28) is a bifurcation value for closed models that recollapse or not.

However, de Sitter universe is not a global attractor for (29). Numerical experiments show that for highly curved models, or models filled with an excess of ordinary matter, there are solutions of (29) which recollapse. Conditions to prevent the premature recollapse of closed models were given in Ref. 20.

Our results are based on the analysis of the behavior of the dynamical system (10) near the equilibrium solutions. A rigorous proof of the closed universe recollapse conjecture may come from the investigation of the global structure of the solutions of (2)–(4) with $k=+1$. The study of the same question for Bianchi-IX models is an interesting challenge for mathematical relativity.

Instabilities of multiphase wave trains in coupled nonlinear Schrödinger equations: A bisymplectic framework

F. E. Laine-Pearson[a)]
Department of Mathematics and Statistics, University of Surrey, Guildford, Surrey, GU2 7XH, United Kingdom

(Received 23 July 2004; accepted 15 June 2005; published online 26 July 2005)

Hamiltonian systems, with bisymplectic structure, are known to model a wide range of interesting phenomena occurring in optics, oceanography, biochemistry, geology, and materials science. Examples of such systems are nonlinear Schrödinger (NLS) equations and Klein-Gordon (KG) equations. The paper focuses on a general class of the former and presents a linear stability theory for the interaction of a basic class of periodic traveling wave solutions, which exploits the geometric structure of the system. A criterion for linear instability is derived. Additionally, for the qualitatively tractable cases, criteria for linear instability are given explicitly in terms of: the amplitudes of the modes; the parameters of the system that characterize the medium as well as the interaction between component modes; and, when the solutions of the system are both time-and space dependent, the wave numbers. An extension to the coupled NLS equations case study is introduced, namely the consideration of a related class of coupled KG equations, which has the potential to lead to further development for the underlying bisymplectic systems theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1996831]

I. INTRODUCTION

Bisymplectic systems[1] appear in many areas of the physical sciences. Formally, they are dynamical systems, describable by a Hamiltonian function, with bisymplectic structure. To put such systems into context, recall that classical symplecticity considers a system of Hamiltonian partial differential equations (PDEs) based on a single symplectic operator and a Hamiltonian function. Bisymplecticity naturally extends this concept by requiring that a distinct symplectic operator is associated with each of two coordinates (in this paper, these coordinates will be a single spatial direction and time). Consequentially, bisymplecticity will contain more geometric information than its classical (symplectic) counterpart.

There is a plethora of PDEs that can be cast into a bisymplectic framework. Examples include the semilinear wave equation,[2] the water wave equations[3,4] and classes of coupled nonlinear Schrödinger (CNLS) equations[5] as well as classes of coupled Klein-Gordon (CKG) equations.[2] Therefore, since there are numerous members of the bisymplectic systems family and bisymplecticity has more to offer than classical symplecticity, it is highly motivational to acquire the additional detail revealed by the bisymplectic structure.

The objective of this paper is to present a theory for the instability of multiphase wave-train solutions of a general class of CNLS equations by casting the system into a bisymplectic framework. The purpose is to demonstrate what can be achieved through exploiting the structure of bisymplectic systems.

The specific class of CNLS equations considered are those that can be expressed as

[a)]Electronic mail: f.laine-pearson@surrey.ac.uk

$$i\epsilon_j M_{j,T} + id_j M_{j,X} + \gamma_j M_{j,XX} + \sum_{\ell=1}^{N} \beta_{j\ell} |M_\ell|^2 M_j = 0, \quad \text{for } j = 1, \ldots, N,$$

where subscripts in T and X (after the comma) denote partial derivatives, $M_j = M_j(X,T)$ are the modes, and $\epsilon_j \neq 0$, d_j, $\gamma_j \neq 0$, $\beta_{j\ell}$, for j, $\ell = 1, \ldots, N$, are real-valued scalars with the usual hypothesis that $\beta_{j\ell} = \beta_{\ell j}$. From now on, these equations will be referred to as the "N CNLS equations." Roskes[6] remarked that similar equations can be derived from multiphase envelope equations for weakly nonlinear conservative physical systems. Moreover, these types of systems are known to appear in optics applications.[7] They are also associated with CKG equations, which have been used to model, and subsequently analyze, a wide variety of physical phenomena such as dislocations in metals, processes in DNA double helices, and wave processes in bilayers as well as crack propagation in composites (see the literature, Refs. 8–12, for further details). In particular, CNLS equations can be constructed to govern the modes of weakly nonlinear solutions of CKG equations; for recent interest see Khusnutdinova *et al.*[13,14]

It is well known that CNLS equations can be formulated as an infinite-dimensional Hamiltonian system (illustrated by Bridges and Laine-Pearson[5] for $N=2$). However, there are two disadvantages of the Hamiltonian formulation, namely

(1) the symplectic structure is on an infinite-dimensional phase space;
(2) a function space is required for the X-dependence.

In contrast, the bisymplectic formulation is advantageous as it is posed on a phase space of finite dimension. In this paper, it will be shown that N CNLS equations can be re-expressed using such a formulation.

The theory presented will indicate that in systems with N-phase wave trains and a bisymplectic structure, there are natural $2N$-parameter families of wave trains with a variational principle and a geometric instability condition. These results are presented for the N CNLS equations when accompanied by the class of solutions

$$M_j(X,T) = M_{0j} e^{i\phi_j(X,T)}, \quad \text{for } j = 1, \ldots, N,$$

with complex-valued scalars M_{0j} and where $\phi_j(X,T)$ depends linearly on X and T; that is, say, $\phi_j(X,T) = \omega_j T + k_j X$, where $(\omega_1, \ldots, \omega_N, k_1, \ldots, k_N)$ are linked with the $2N$-parameter family. Moreover, since these exact solutions are associated with a generalized toral symmetry of the N CNLS equations,[5] their linear stability equation can be analyzed explicitly. It will be shown that obtaining instability results for the N CNLS case study rests on the analysis of a $2N$th-order polynomial equation, which also can be analyzed explicitly. Inevitably, a complete investigation into such an equation will increase in difficulty as N increases.

Incidentally, the $2N$th-order stability polynomial equation can be thoroughly investigated given N small enough. Furthermore, only considering X-independent solutions will remove the odd coefficients of the polynomial equation, making the sufficient conditions for instability fully obtainable for $N \leqslant 4$ (deduced in Sec. IV). Some of these tractable cases have already been considered in the literature: the case $N=1$ is a standard result[6] and the case $N=2$ has been completely discussed.[5] In this exposition, the cases $N=3,4$ are qualitatively explored in full (motivated by the belief that these cases have previously only been partially investigated); in addition, remarks are made regarding partial results for arbitrary N. Additionally, $k_j \neq 0$ is considered for the tractable cases $N=1,2$, which are fully explored, resulting in criteria for linear instability of (X,T)-dependent solutions.

The paper is organized as follows. In Sec. II a general system of N CNLS equations is re-expressed as a bisymplectic system. A generalization of the instability theory for two-phase solutions (given in Bridges and Laine-Pearson[5]) to multiphase solutions is presented and applied in Sec. III so that the associated stability polynomial is obtained. In Sec. IV, the stability polynomial equation is analyzed in full for the tractable cases. For $k_j \neq 0$, instability criteria are determined by evaluating the polynomial equation and are found to be based on the parameters of the

governing equations, the amplitudes $|M_{0j}|$, and the wave numbers k_j. (For brevity, the instability results when $k_j=0$, for all j, are relegated to Appendix A.) A particular case for $N=2$ when $k_j \neq 0$ is presented (primarily for illustration of how the conditions for linear instability may simplify when more qualitative information is known, or can be deduced, about the modes and associated parmaeters) for the reduction of the arbitrary superposition of two traveling wave trains with quasiperiodic motion to synchronized counterpropagating waves, determining that the interaction of a pair of stable component periodic traveling waves can be stable and also that an unstable component periodic traveling wave may stabilize under the influence of a stable one. The paper concludes (Sec. V) with a short discussion on the case study as well as an introduction to a more challenging system related to the N CNLS equations that also has a bisymplectic structure (a class of CKG equations) but does not have the luxury of exact solutions associated with a symmetry of the governing equations.

II. A BISYMPLECTIC FRAMEWORK FOR CNLS EQUATIONS

Consider N CNLS equations expressed in the following form:

$$i\epsilon_j M_{j,T} + id_j M_{j,X} + \gamma_j M_{j,XX} + r_j M_j = 0, \quad \text{for } j = 1, \ldots, N, \tag{2.1}$$

where subscripts in T and X (after the comma) denote partial derivatives, and

$$\mathbf{r} = \boldsymbol{\beta}\mathbf{a}, \quad \text{where } \mathbf{r} = \begin{pmatrix} r_1 \\ r_2 \\ \vdots \\ r_N \end{pmatrix}, \quad \boldsymbol{\beta} = \begin{pmatrix} \beta_{11} & \beta_{12} & \cdots & \beta_{1N} \\ \beta_{21} & \beta_{22} & \cdots & \beta_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ \beta_{N1} & \beta_{N2} & \cdots & \beta_{NN} \end{pmatrix} \quad \text{and } \mathbf{a} = \begin{pmatrix} |M_1|^2 \\ |M_2|^2 \\ \vdots \\ |M_N|^2 \end{pmatrix},$$

with real-valued scalars $\epsilon_j \neq 0$, $\gamma_j \neq 0$, d_j, and $\beta_{j\ell}$, for $j, \ell = 1, \ldots, N$, which characterize the medium and the interaction between component modes $M_j = M_j(X,T)$. To cast system (2.1) into a bisymplectic framework, it is necessary that $\mathbf{r}$ is associated with a symmetric matrix (otherwise a suitable functional cannot be constructed, which is a necessary requirement so that system (2.1) can be rewritten as a bisymplectic system; this will be elaborated on in due course). Therefore, assume that $\beta_{j\ell} = \beta_{\ell j}$ for all j, ℓ. It is also beneficial to scale away the d_j. This is accomplished by calling on the substitution

$$M_j = e^{i(\xi_j T + \eta_j X)} \hat{M}_j, \quad \text{where } \xi_j = \frac{d_j^2}{4\gamma_j \epsilon_j} \text{ and } \eta_j = -\frac{d_j}{2\gamma_j}.$$

So, the interest now lies with the following set of N CNLS equations:

$$i\epsilon_j \hat{M}_{j,T} + \gamma_j \hat{M}_{j,XX} + \sum_{\ell=1}^{N} \beta_{j\ell} |\hat{M}_\ell|^2 \hat{M}_j = 0, \quad \text{for } j = 1, \ldots, N. \tag{2.2}$$

It is this transformed system that will be cast into a bisymplectic framework. [Incidentally, system (2.1) can also be directly manipulated into a bisymplectic framework, but the formulation is unnecessarily complicated—this matter will be readdressed in Sec. V].

To cast system (2.2) into a bisymplectic framework, introduce real variables q_{2j-1} and q_{2j} such that

$$\hat{M}_j = q_{2j-1} + iq_{2j}, \quad \text{for } j = 1, \ldots, N.$$

Furthermore, introduce the associated real variables p_{2j-1} and p_{2j}, satisfying the following expressions:

$$\gamma_j \hat{M}_{j,X} = \gamma_j \frac{\partial}{\partial X}(q_{2j-1} + iq_{2j}) = p_{2j-1} + ip_{2j}.$$

By using the q_{2j-1}, q_{2j}, p_{2j-1}, and p_{2j} coordinates to construct the vector

$$Z(X,T) = [q(X,T), p(X,T)]^{\mathrm{T}} \in \mathbb{R}^{4N},$$

where

$$q = (q_1, q_2, \ldots, q_{2N-1}, q_{2N})^{\mathrm{T}} \text{ and } p = (p_1, p_2, \ldots, p_{2N-1}, p_{2N})^{\mathrm{T}},$$

system (2.2) can be re-expressed as

$$\mathbf{M}Z_T + \mathbf{K}Z_X = \nabla S(Z), \tag{2.3}$$

where

$$\mathbf{M} = \begin{pmatrix} -\epsilon_1 \mathbf{J} & \mathbf{0}_2 & \cdots & \mathbf{0}_2 & \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 \\ \mathbf{0}_2 & -\epsilon_2 \mathbf{J} & \cdots & \mathbf{0}_2 & \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0}_2 & \mathbf{0}_2 & \cdots & -\epsilon_N \mathbf{J} & \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 \\ \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 & \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 \\ \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 & \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 & \mathbf{0}_2 & \mathbf{0}_2 & \cdots & \mathbf{0}_2 \end{pmatrix},$$

$$\mathbf{K} = \begin{pmatrix} \mathbf{0}_{2N} & -\mathbf{I}_{2N} \\ \mathbf{I}_{2N} & \mathbf{0}_{2N} \end{pmatrix}, \quad \mathbf{J} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

$\mathbf{0}_j$ and $\mathbf{I}_j$ are the $j \times j$ zero matrix and identity matrix, respectively. A fundamental underpinning of Eq. (2.3) is that both matrices $\mathbf{M}$ and $\mathbf{K}$ are skew-symmetric. The symmetry requirement $\beta_{j\ell} = \beta_{\ell j}$ permits the construction of the functional

$$S(Z) = \sum_{j=1}^{N} \frac{1}{2\gamma_j}(p_{2j-1}^2 + p_{2j}^2) + \frac{1}{4}\sum_{\ell=1}^{N}\sum_{j=1}^{N} \beta_{j\ell}(q_{2j-1}^2 + q_{2j}^2)(q_{2\ell-1}^2 + q_{2\ell}^2).$$

The gradient of this functional is taken with respect to the standard (Euclidean) inner product on $\mathbb{R}^{4N}$, resulting in the vector $\nabla S(Z) = (S_q, S_p)^T$, where

$$S_q = (\hat{r}_1 q_1, \hat{r}_1 q_2, \ldots, \hat{r}_N q_{2N-1}, \hat{r}_N q_{2N})^{\mathrm{T}},$$

$$S_p = \left(\frac{1}{\gamma_1}p_1, \frac{1}{\gamma_1}p_2, \ldots, \frac{1}{\gamma_N}p_{2N-1}, \frac{1}{\gamma_N}p_{2N}\right)^{\mathrm{T}},$$

with

$$\hat{r}_j = \sum_{\ell=1}^{N} \beta_{j\ell}(q_{2\ell-1}^2 + q_{2\ell}^2).$$

We conclude that system (2.2) has a "bisymplectic system" form, as it can be re-expressed as system (2.3), namely a system that has two distinct symplectic operators ($\mathbf{M}$ and $\mathbf{K}$) associated with each of two coordinates (T and X, respectively). Additionally, it is noted that system (2.2) cast as system (2.3) is a generalization of a result deduced by Bridges and Laine-Pearson.[5]

III. DETERMINING THE STABILITY POLYNOMIAL FOR A CLASS OF SOLUTIONS

A basic class of solutions of system (2.2) take the form

$$\hat{M}_j(X,T) = \hat{M}_{0j} e^{i\theta_j(X,T)}, \quad \text{where } \theta_j(X,T) = \omega_j T + k_j X, \tag{3.1}$$

for $j=1,\ldots,N$, with complex-valued scalars $\hat{M}_{0j}$. Assume such solutions are 2π-periodic in θ_j for each j. Substituting the coupled-wave solution (3.1) into system (2.2) results in a set of relations for the parameters ω_j, k_j, ϵ_j, γ_j, $\beta_{j\ell}$ and the amplitudes $\hat{M}_{0j}$, namely

$$\boldsymbol{\beta}\mathbf{a}_0 = \mathbf{b}, \quad \mathbf{a}_0 = \begin{pmatrix} |\hat{M}_{01}|^2 \\ |\hat{M}_{02}|^2 \\ \vdots \\ |\hat{M}_{0N}|^2 \end{pmatrix} \text{ and } \mathbf{b} = \begin{pmatrix} \epsilon_1\omega_1 + \gamma_1 k_1^2 \\ \epsilon_2\omega_2 + \gamma_2 k_2^2 \\ \vdots \\ \epsilon_N\omega_N + \gamma_N k_N^2 \end{pmatrix}. \tag{3.2}$$

The approach that follows is a generalization (from $N=2$ to arbitrary N) of results contained in a sister paper.[5] The family of solutions (3.1) can be re-expressed in bisymplectic coordinates by introducing $Z(X,T)=\hat{Z}(\boldsymbol{\theta})$, where $\boldsymbol{\theta}=(\theta_1,\theta_2,\ldots,\theta_N)$, such that

$$\hat{Z}(\boldsymbol{\theta}) = \mathbf{G}(\boldsymbol{\theta}(X,T))\mathcal{U}, \tag{3.3}$$

with a starting point

$$\mathcal{U} = (\mathcal{U}_1,\ldots,\mathcal{U}_{4N})^{\mathrm{T}} \in \mathbb{R}^{4N},$$

where

$$\hat{M}_{0j} = \mathcal{U}_{2j-1} + i\mathcal{U}_{2j} \text{ and } \gamma_j k_j \hat{M}_{0j} = \mathcal{U}_{2N+2j} - i\mathcal{U}_{2N+2j-1}, \tag{3.4}$$

and an orthogonal matrix

$$\mathbf{G}(\boldsymbol{\theta}) = \mathbf{R}(\theta_1) \oplus \cdots \oplus \mathbf{R}(\theta_N) \oplus \mathbf{R}(\theta_1) \cdots \oplus \mathbf{R}(\theta_N) \in \mathbb{R}^{4N\times 4N},$$

where

$$\mathbf{R}(\theta_j) = \begin{pmatrix} \cos\theta_j & -\sin\theta_j \\ \sin\theta_j & \cos\theta_j \end{pmatrix} \quad \text{for } j=1,\ldots,N.$$

It is emphasized that the approach embeds the family of solutions $Z(X,T)=\hat{Z}(\boldsymbol{\theta})$ in $(X,T,\omega_1,\ldots,\omega_N,k_1,\ldots,k_N)$-space, and so the introduction of $\boldsymbol{\theta}$ has reduced $2+2N$ variables to N independent variables θ_j. For then the geometry of Eq. (2.3)—reformulated from system (2.2)—and the character of solutions (3.1) suggests the association of $2N$ functionals $P_j:\mathbb{R}^{4N}\to\mathbb{R}$ and $Q_j:\mathbb{R}^{4N}\to\mathbb{R}$ such that

$$P_j(\hat{Z}) = \tfrac{1}{2}\langle \mathbf{M}\hat{Z}_{\theta_j}, \hat{Z}\rangle \quad \text{and} \quad Q_j(\hat{Z}) = \tfrac{1}{2}\langle \mathbf{K}\hat{Z}_{\theta_j}, \hat{Z}\rangle$$

(where the subscript θ_j denotes partial differentiation with respect to θ_j), which satisfy $\mathbf{M}\mathbf{G}_{\theta_j}\mathcal{U} = \nabla P_j(\hat{Z})$ and $\mathbf{K}\mathbf{G}_{\theta_j}\mathcal{U} = \nabla Q_j(\hat{Z})$. Then, Eq. (2.3), with the substitution $Z(X,T)=\hat{Z}(\boldsymbol{\theta})$, can be re-expressed as

$$\sum_{j=1}^{N} [\omega_j \nabla P_j(\hat{Z}) + k_j \nabla Q_j(\hat{Z})] = \nabla S(\hat{Z}),$$

and as such characterizes $\hat{Z}$ as a critical point of $S(\hat{Z})$ restricted to level sets of the P_j and Q_j, with the components ω_j and k_j cast as Lagrange multipliers; in other words, the expression can be

interpreted as the necessary condition for a constrained variational principle. The nondegeneracy condition for the basic state $\hat{Z}$ is given by the following expression:

$$\det\begin{pmatrix} \dfrac{\delta P}{\delta \omega} & \dfrac{\delta P}{\delta k} \\ \dfrac{\delta Q}{\delta \omega} & \dfrac{\delta Q}{\delta k} \end{pmatrix} \neq 0, \tag{3.5}$$

where

$$\frac{\delta P}{\delta \omega} = \begin{pmatrix} \dfrac{\partial P_1}{\partial \omega_1} & \cdots & \dfrac{\partial P_1}{\partial \omega_N} \\ \vdots & \ddots & \vdots \\ \dfrac{\partial P_N}{\partial \omega_1} & \cdots & \dfrac{\partial P_N}{\partial \omega_N} \end{pmatrix} \text{ and } \frac{\delta P}{\delta k} = \begin{pmatrix} \dfrac{\partial P_1}{\partial k_1} & \cdots & \dfrac{\partial P_1}{\partial k_N} \\ \vdots & \ddots & \vdots \\ \dfrac{\partial P_N}{\partial k_1} & \cdots & \dfrac{\partial P_N}{\partial k_N} \end{pmatrix};$$

similarly,

$$\frac{\delta Q}{\delta \omega} = \begin{pmatrix} \dfrac{\partial Q_1}{\partial \omega_1} & \cdots & \dfrac{\partial Q_1}{\partial \omega_N} \\ \vdots & \ddots & \vdots \\ \dfrac{\partial Q_N}{\partial \omega_1} & \cdots & \dfrac{\partial Q_N}{\partial \omega_N} \end{pmatrix} \text{ and } \frac{\delta Q}{\delta k} = \begin{pmatrix} \dfrac{\partial Q_1}{\partial k_1} & \cdots & \dfrac{\partial Q_1}{\partial k_N} \\ \vdots & \ddots & \vdots \\ \dfrac{\partial Q_N}{\partial k_1} & \cdots & \dfrac{\partial Q_N}{\partial k_N} \end{pmatrix}.$$

The entries of the matrix presented in expression (3.5) encode information regarding the linear stability problem for the basic state $\hat{Z}=\mathbf{G}\mathcal{U}$. The linear stability problem associated with basic state (3.3) and governing equation (2.3) is formulated by letting

$$Z(X,T) = \mathbf{G}(\boldsymbol{\theta}(X,T))[\mathcal{U} + \hat{V}(\boldsymbol{\theta},X,T)],$$

where $\hat{V}(\boldsymbol{\theta},X,T)$ is a perturbation considered for fixed ω_j and k_j and is assumed to be 2π-periodic in each θ_j. Substituting into system (2.3) and linearizing about $\hat{Z}$ gives

$$\mathbf{M}\hat{V}_T + \mathbf{K}\hat{V}_X = \mathbf{L}\hat{V}, \quad \text{where } \mathbf{L} = \mathrm{D}^2 S(\mathcal{U}) - \sum_{j=1}^{N} [\omega_j \mathrm{D}^2 P_j(\mathcal{U}) + k_j \mathrm{D}^2 Q_j(\mathcal{U})],$$

due to $P_j(\hat{Z})=P_j(\mathcal{U})$ and $Q_j(\hat{Z})=Q_j(\mathcal{U})$. The spectral problem associated with this equation, obtained by letting $\hat{V}(\boldsymbol{\theta},X,T)=\mathrm{Re}[e^{\lambda T+i\alpha X}V(\boldsymbol{\theta};\lambda,\alpha)]$, is

$$\mathbf{L}V = \lambda \mathbf{M}V + i\alpha \mathbf{K}V, \quad V \in \mathbb{C}^{4N}.$$

The entries of condition (3.5) will now be calculated. First, note that P_j and Q_j evaluate to the following:

$$P_j(\mathcal{U}) = \tfrac{1}{2}\epsilon_j(\mathcal{U}_{2j-1}^2 + \mathcal{U}_{2j}^2) \quad \text{and} \quad Q_j(\mathcal{U}) = \mathcal{U}_{2j-1}\mathcal{U}_{2N+2j} - \mathcal{U}_{2j}\mathcal{U}_{2N+2j-1}.$$

Therefore, under the assumption that $\boldsymbol{\beta}$ is invertible

$$[P_1(\mathcal{U}), P_2(\mathcal{U}), \ldots, P_N(\mathcal{U})]^{\mathrm{T}} = \tfrac{1}{2}\boldsymbol{\Upsilon}\,\boldsymbol{\beta}^{-1}\mathbf{b}$$

and

$$[Q_1(\mathcal{U}), Q_2(\mathcal{U}), \ldots, Q_N(\mathcal{U})]^{\mathrm{T}} = \mathbf{\Gamma}\,\boldsymbol{\beta}^{-1}\mathbf{b},$$

with

$$\mathbf{\Upsilon} = \begin{pmatrix} \epsilon_1 & 0 & \cdots & 0 \\ 0 & \epsilon_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \epsilon_N \end{pmatrix}, \quad \mathbf{\Gamma} = \begin{pmatrix} \gamma_1 k_1 & 0 & \cdots & 0 \\ 0 & \gamma_2 k_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \gamma_N k_N \end{pmatrix},$$

which is determined by noting the first set of expressions (3.4), consequently, relation (3.2) can be used. Hence

$$\frac{\delta P}{\delta \omega} = \frac{1}{2}\mathbf{\Upsilon}\,\boldsymbol{\beta}^{-1}\mathbf{\Upsilon}, \quad \frac{\delta P}{\delta k} = \mathbf{\Upsilon}\,\boldsymbol{\beta}^{-1}\mathbf{\Gamma}, \quad \frac{\delta Q}{\delta \omega} = \mathbf{\Gamma}\,\boldsymbol{\beta}^{-1}\mathbf{\Upsilon},$$

and

$$\frac{\delta Q}{\delta k} = 2\mathbf{\Gamma}\,\boldsymbol{\beta}^{-1}\mathbf{\Gamma} + \mathrm{diag}(\gamma_1|\hat{M}_{01}|^2, \ldots, \gamma_N|\hat{M}_{0N}|^2),$$

with the last evaluation simplified by noting relation (3.2). A definition for linear instability now follows.

Given

$$\hat{\Delta}(\Lambda, \alpha) := \det\left[\Lambda^2\frac{\delta P}{\delta \omega} + \alpha\Lambda\left(\frac{\delta P}{\delta k} + \frac{\delta Q}{\delta \omega}\right) + \alpha^2\frac{\delta Q}{\delta k}\right], \quad \text{where } \Lambda = -i\lambda.$$

If $\hat{\Delta}(\Lambda, \alpha) = 0$ for some $\alpha \in \mathbb{R}$ and $\Lambda \in \mathbb{C}$ with $\mathrm{Im}(\Lambda) \neq 0$ and $|\Lambda|^2 + |\alpha|^2$ sufficiently small, then the basic state $\hat{Z}(\boldsymbol{\theta}) = \mathbf{G}(\boldsymbol{\theta})\mathcal{U}$ is "linearly unstable." (The above definition is similar to the one used for two-phase solutions[5] and is consistent with the theory developed by Bridges.[3]) For the N CNLS system, the introduction of $\lambda = i\Lambda$ into the spectral problem results in $\hat{\Delta}(\Lambda, \alpha) = 0$, which is a polynomial equation with real coefficients.

Therefore, to determine sufficient conditions for linear instability, it is enough to study the qualitative aspect of the roots of the $2N$th-order polynomial equation $\hat{\Delta}(\Lambda, \alpha) = 0$. This deduction agrees with the expected outcome from implementing a classical approach to the linear stability problem, which usually consists of taking a solution of interest plus a (suitable) perturbation and then substituting the perturbed solution directly into the particular system (in this case, N CNLS equations). Such a classical approach is illustrated, for instance, by Roskes[6] when $N = 2$ and $k_j = 0$.

IV. EVALUATING THE STABILITY POLYNOMIAL

Returning to $\hat{\Delta}(\Lambda, \alpha) = 0$, determining when

$$\text{at least one } \Lambda \text{ exists such that } \mathrm{Im}(\Lambda) \neq 0, \tag{4.1}$$

will encapsulate sufficient conditions for linear instability. Fortunately, the task is less demanding when $k_j = 0$ for all $j = 1, \ldots, N$, i.e., X-independent basic solutions. In particular, determining a complete description of the parameter space where requirement (4.1) occurs is tractable for $N \leqslant 4$.

Under the assumption that $k_j = 0$ for all $j = 1, \ldots, N$, the components of the matrix given in expression (3.5) simplify to

$$\frac{\delta P}{\delta \omega} = \frac{1}{2}\mathbf{\Upsilon}\boldsymbol{\beta}^{-1}\mathbf{\Upsilon}, \quad \frac{\delta P}{\delta k} = \frac{\delta Q}{\delta \omega} = \mathbf{0}, \quad \frac{\delta Q}{\delta k} = \mathrm{diag}(\gamma_1|\hat{M}_{01}|^2, \ldots, \gamma_N|\hat{M}_{0N}|^2).$$

Therefore, obtaining stability information relies on the analysis of the roots of the even polynomial equation of order $2N$

$$a_{2N}\hat{\Lambda}^{2N} + a_{2(N-1)}\hat{\Lambda}^{2(N-1)} + \cdots + a_2\hat{\Lambda}^2 + a_0 = 0, \quad \text{with } \hat{\Lambda} = \frac{\Lambda}{\alpha}, \tag{4.2}$$

where the coefficients $a_{2\ell}$, for $\ell = 0, 1, \ldots, N$, follow a predictable pattern—this is detailed in Appendix B; additionally, the rescaling of Λ to $\hat{\Lambda}$ has removed the parameter α from the assignments of the coefficients $a_{2\ell}$. Furthermore, a complete qualitative description of the parameter space satisfying requirement (4.1), when Λ is governed by Eq. (4.2), can be given for $N \leqslant 4$. For completeness, these analyses are presented in Appendix A; some remarks are also made regarding partial descriptions of the parameter space satisfying requirement (4.1) for arbitrary N.

Now, consider $k_j \neq 0$. For $N \leqslant 2$, a full qualitative description of the parameter space satisfying requirement (4.1) can be given for the one-phase and two-phase solutions with nonzero k_j. These cases will be presented, followed by remarks regarding arbitrary N as well as an application of the case $N=2$ for a family of synchronized counterpropagating wave trains.

A. A single wave

The single wave basic state $\hat{M}_1(X,T) = \hat{M}_{01}e^{i(\omega_1 T + k_1 X)}$, where (ω_1, k_1) satisfy $\beta_{11}|\hat{M}_{01}|^2 = \epsilon_1\omega_1 + \gamma_1 k_1^2$, determined from relation (3.2), has a quadratic stability equation

$$a_2\hat{\Lambda}^2 + a_1\hat{\Lambda} + a_0 = 0,$$

where $a_2 = \epsilon_1^2$, $a_1 = 4\gamma_1\epsilon_1 k_1$ and $a_0 = 2\gamma_1(2\gamma_1 k_1^2 + \beta_{11}|\hat{M}_{01}|^2)$. For a general quadratic equation, the existence of at least one $\hat{\Lambda}$ with nonzero imaginary part [requirement (4.1)] is confirmed whenever $a_1^2 - 4a_2a_0 < 0$ holds. Since a_2, a_1, a_0 are known, the condition evaluates to $\gamma_1\beta_{11} > 0$, which is the same for when $k=0$ (confirmed in Appendix A).

B. Two coupled waves

Consider two coupled waves (3.1) with $k_j \neq 0$. Instability criteria for the arbitrary superposition of two traveling wave trains with quasiperiodic motion will now be deduced from the associated quartic stability equation

$$a_4\hat{\Lambda}^4 + a_3\hat{\Lambda}^3 + a_2\hat{\Lambda}^2 + a_1\hat{\Lambda} + a_0 = 0,$$

where

$$a_4 = \frac{1}{4}\epsilon_1^2\epsilon_2^2,$$

$$a_3 = \epsilon_1\epsilon_2(\epsilon_2\gamma_1 k_1 + \epsilon_1\gamma_2 k_2),$$

$$a_2 = (\epsilon_2\gamma_1 k_1 + \epsilon_1\gamma_2 k_2)^2 + 2\epsilon_1\epsilon_2\gamma_1\gamma_2 k_1 k_2 + \tfrac{1}{2}(\epsilon_2^2\gamma_1\beta_{11}|\hat{M}_{01}|^2 + \epsilon_1^2\gamma_2\beta_{22}|\hat{M}_{02}|^2),$$

$$a_1 = 2\gamma_1\gamma_2[\epsilon_1\beta_{22}|\hat{M}_{02}|^2 k_1 + \epsilon_2\beta_{11}|\hat{M}_{01}|^2 k_2 + 2(\epsilon_2\gamma_1 k_1 + \epsilon_1\gamma_2 k_2)k_1 k_2],$$

$$a_0 = \gamma_1\gamma_2[2(2\gamma_1\gamma_2 k_1^2 k_2^2 + \gamma_1\beta_{22}|\hat{M}_{02}|^2 k_1^2 + \gamma_2\beta_{11}|\hat{M}_{01}|^2 k_2^2) + \det(\boldsymbol{\beta})|\hat{M}_{01}|^2|\hat{M}_{02}|^2],$$

with

$$\beta_{11}|\hat{M}_{01}|^2 + \beta_{12}|\hat{M}_{02}|^2 = \epsilon_1\omega_1 + \gamma_1 k_1^2 \quad \text{and} \quad \beta_{21}|\hat{M}_{01}|^2 + \beta_{22}|\hat{M}_{02}|^2 = \epsilon_2\omega_2 + \gamma_2 k_2^2,$$

where $\beta_{12}=\beta_{21}$. Divide through by a_4 and transform the cubic term away by introducing $Y=\hat{\Lambda} + a_3/4a_4$, resulting in

$$Y^4 + \tau_1 Y^2 + \tau_2 Y + \tau_3 = 0, \tag{4.3}$$

where

$$\tau_1 = \frac{1}{a_4^2}\left(-\frac{3}{8}a_3^2 + a_4 a_2\right),$$

$$\tau_2 = \frac{1}{a_4^3}\left(\frac{1}{8}a_3^3 - \frac{1}{2}a_4 a_3 a_2 + a_4^2 a_1\right),$$

$$\tau_3 = \frac{1}{a_4^4}\left(-\frac{3}{256}a_3^4 + \frac{1}{16}a_4 a_3^2 a_2 - \frac{1}{4}a_4^2 a_3 a_1 + a_4^3 a_0\right).$$

There are three diagnostic functions associated with the general reduced quartic equation (4.3)

$$D_1 = \tau_1, \quad D_2 = \text{DISCRIMINANT}, \quad D_3 = \tau_1^2 - 4\tau_3,$$

where

$$\text{DISCRIMINANT} = 16\tau_3\tau_1^4 - 4\tau_2^2\tau_1^3 - 128\tau_3^2\tau_1^2 + 144\tau_2^2\tau_3\tau_1 - 27\tau_2^4 + 256\tau_3^3.$$

Note that, since a_4 and a_3 are real, $\text{Im}(\hat{\Lambda}) \neq 0$ if and only if $\text{Im}(Y) \neq 0$. Therefore, the conditions for instability (the existence of at least one root $\hat{\Lambda}$ with nonzero imaginary part) are

$$[D_1 > 0] \text{ or } [D_1 = 0 \text{ and } (\tau_2 \neq 0 \text{ or } \tau_3 \neq 0)]$$

$$\text{or } [D_1 < 0 \text{ and } D_2 < 0] \text{ or } [D_1 < 0, D_2 \geqslant 0 \text{ and } D_3 < 0].$$

The discriminant surface, plotted in τ-space, is illustrated in Fig. 1. If $\tau_1 > 0$, then it is immediate that there is at least one unstable eigenvalue. When $\tau_1 \leqslant 0$, then additional diagnostics require checking. A section through the discriminant surface for $\tau_1 < 0$ is shown in Fig. 2. Unless τ_2 and τ_3 are in the enclosed central region (marked with "4" in the figure) there will be a root which is unstable (having a nonzero imaginary part). Therefore, given a basic state, the problem of instability for the two-wave interaction reduces to checking the above conditions for the quartic equation. So, for a particular application, sufficient conditions for instability can be deduced by substituting the values of parameters into the diagnostic functions.

C. Remarks on *N*-coupled waves

Determining conditions for linear instability of N-interacting wave trains boils down to analyzing a $2N$th order polynomial equation. This task becomes increasingly difficult to do in full as N increases. This is clearly demonstrated by the complexity of conditions for the case of $N=2$. If further qualitative information is known about the wave type, then evaluation can become a more straightforward task. To illustrate this fact, consider the example that follows for a particular instance of the interaction of two counterpropagating waves.

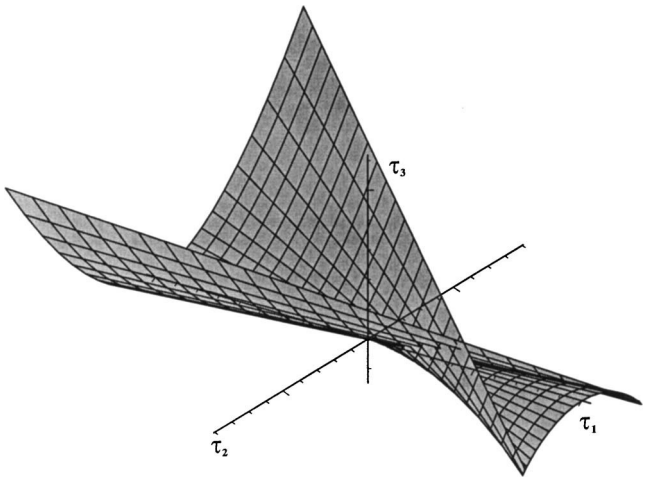

FIG. 1. The discriminant surface for the quartic equation.

D. An application: Synchronized counterpropagating waves

Consider a special case of $N=2$ where the waves are counterpropagating. Set $k_1=-k_2=k$ with $\hat{M}_{01}=\hat{M}_{02}=\hat{M}_0\neq 0$, $\epsilon_1=\epsilon_2=\epsilon$, and $\gamma_1=\gamma_2=\gamma$. Then, since $a_3=0$ (the special case $Y=\hat{\Lambda}$)

$$D_1=\frac{4\gamma}{\epsilon^2}\left[-2\gamma k^2+\frac{1}{2}(\beta_{11}+\beta_{22})|\hat{M}_0|^2\right];$$

the other diagnostic functions can be determined similarly.

For simplicity, set $\omega_1=\omega_2=\omega$. Then, $\beta_{11}=\beta_{22}$ [determined using relations (3.2)] and $a_1=0$, which means that $\tau_2=0$ too and $D_2=16\tau_3 D_3^2$. The quartic equation (4.3) simplifies to $Y^4+\tau_1 Y^2+\tau_3=0$, which is a bi-quadratic equation. Therefore, for at least one Y^2 with $\mathrm{Im}(Y^2)\neq 0$ to occur then $\tau_1^2-4\tau_3<0$ must hold—this is sufficient but not necessary for at least one Y such that $\mathrm{Im}(Y)\neq 0$. The region of (τ_1,τ_3)-space represented by the shaded region in Fig. 3 (in the diagram $y=Y$, $c_1=\tau_1$, and $c_2=\tau_3$) depicts the qualitative nature of the roots Y—for instance, the third and fourth quadrants show that two real roots and one complex pair of roots occur whenever $\tau_3<0$. For the linear instability conditions, at least one Y with $\mathrm{Im}(Y)\neq 0$ is required and so the shaded

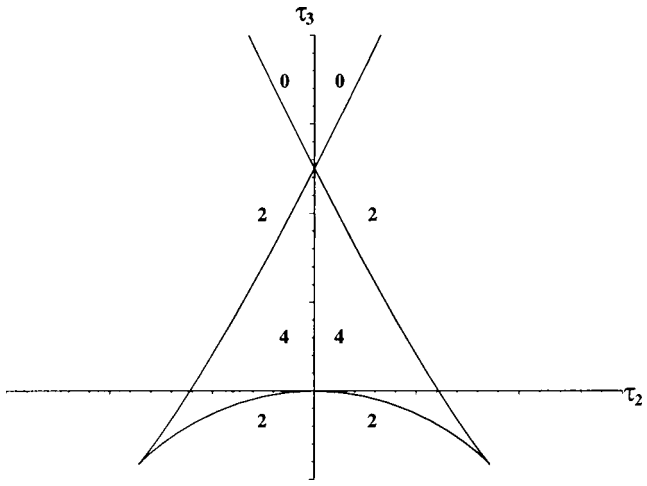

FIG. 2. A constant τ_1 section through the discriminant surface with $\tau_1<0$. The number of real roots of the quartic equation in each region of parameter space is labeled 0, 2, or 4.

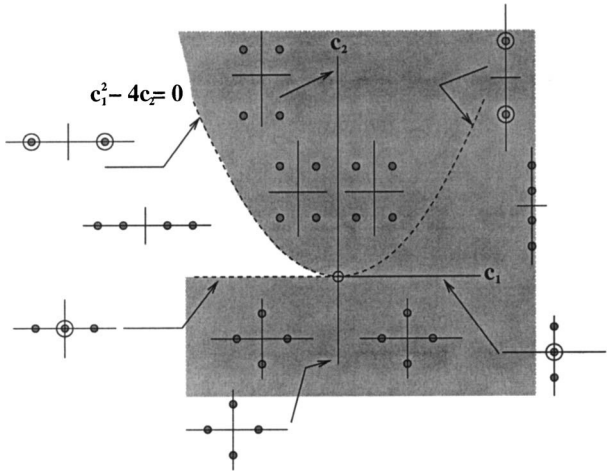

FIG. 3. The qualitative nature of the roots y satisfying $y^4+c_1y^2+c_2=0$. The shaded region indicates where at least one root y exists with $\mathrm{Im}(y)\neq 0$. Four real roots, y, occur in the unshaded region.

region includes these two quadrants. To describe this whole region in (τ_1,τ_3)-space, break it up into smaller, easily expressible, parts. (Note that this is not a unique process.) Since $Y=\hat{\Lambda}$, instability (the existence of at least one root $\hat{\Lambda}$ with nonzero imaginary part) can occur whenever any of the following conditions are satisfied:

(i) $\tau_3<0$;
(ii) $\tau_3\geqslant 0$ and $\tau_1>0$;
(iii) $\tau_1\leqslant 0$ and $\tau_1^2-4\tau_3<0$;

which evaluates to the following:

(i) $C<0$;
(ii) $C\geqslant 0$ and $\gamma(\beta_{11}|\hat{M}_0|^2-2\gamma k^2)>0$;
(iii) $\gamma(\beta_{11}|\hat{M}_0|^2-2\gamma k^2)\leqslant 0$ and $\beta_{12}^2|\hat{M}_0|^2-8\gamma\beta_{11}k^2<0$;

where $C=(\beta_{11}^2-\beta_{12}^2)|\hat{M}_0|^4+4\gamma\beta_{11}k^2|\hat{M}_0|^2+4\gamma^2k^4$ and, due to the relations (3.2), with $(\beta_{11}+\beta_{12})|\hat{M}_0|^2=\epsilon\omega+\gamma k^2$. It should be noted that these three conditions reduce to the three conditions given in Appendix A when $k=0$, $\gamma_1=\gamma_2=\gamma$, $\epsilon_1=\epsilon_2=\epsilon$, $|\hat{M}_{01}|=|\hat{M}_{02}|=|\hat{M}_0|$, $\beta_{11}=\beta_{22}$, and $\beta_{12}=\beta_{21}$, which is consistent.

In application, ϵ and γ may be given. For ease of calculation, set $\gamma=1/2$ and $\epsilon=1$. Then $(\beta_{11}+\beta_{12})|\hat{M}_0|^2=\omega+k^2/2$. Considering the interaction of both waves (see above and Sec. IV B), the criteria for linear instability simplify to the following:

(i) $C_0<0$;
(ii) $C_0\geqslant 0$ and $\beta_{11}|\hat{M}_0|^2-k^2>0$;
(iii) $\beta_{11}|\hat{M}_0|^2-k^2\leqslant 0$ and $\beta_{12}^2|\hat{M}_0|^2-4\beta_{11}k^2<0$;

where $C_0=(\beta_{11}^2-\beta_{12}^2)|\hat{M}_0|^4+2\beta_{11}k^2|\hat{M}_0|^2+k^4$. Note that the instability condition for the wave solutions $\hat{M}_1(X,T)=\hat{M}_0e^{i(\omega T+kX)}$ and $\hat{M}_2(X,T)=\hat{M}_0e^{i(\omega T-kX)}$ considered separately is $\beta_{1j}>0$ (see Sec. IV A). Therefore, the instability of the synchronized counterpropagating waves is determined by a much more complex mechanism than that for single waves.

Conversely, consider a criterion for stability, namely $\mathrm{Im}(\hat{\Lambda})=0$ for all $\hat{\Lambda}$. For the single-wave

case, the required condition is $a_1^2-4a_2a_0\geqslant 0$, which, for the example, simplifies to $\beta_{11}<0$ (noting, by construction, $\beta_{11}\neq 0$). For two coupled waves, the unshaded area in Fig. 3 (in the diagram $y=Y$, $c_1=\tau_1$, and $c_2=\tau_3$) will give the condition for stability, namely

$$\tau_3\geqslant 0, \quad \tau_1\leqslant 0, \quad \text{and } \tau_1^2-4\tau_3\geqslant 0,$$

which, for the example, simplifies to

$$C_0\geqslant 0, \quad \beta_{11}|\hat{M}_0|^2-k^2\leqslant 0, \quad \text{and} \quad \beta_{12}^2|\hat{M}_0|^2-4\beta_{11}k^2\geqslant 0.$$

Therefore the condition for stability is also more complex for the interaction of synchronized counterpropagating waves, and the region of stability is much smaller, when comparing to the component traveling waves.

A little more can be deduced. Let $D_0=\beta_{11}|\hat{M}_0|^2-k^2$. Consider two unstable component waves, for then $\beta_{11}>0$ and $\beta_{12}>0$. Assume that $\beta_{11}>\beta_{12}$. Recall that by viewing each of conditions (i) to (iii) separately, they are each a sufficient condition for instability. Instability condition

(i) is not valid, whereas
(ii) $\beta_{11}>k^2/|\hat{M}_0|^2$, is a possibility, and
(iii) $\beta_{11}\leqslant k^2/|\hat{M}_0|^2$ and $\beta_{12}^2<4k^4/|\hat{M}_0|^4$ is also a possibility.

Therefore it is possible that either condition (ii) or condition (iii) may be satisfied. The stability condition is not valid, that is, when $\beta_{11}>\beta_{12}$ the interaction of the two component waves cannot be stable. We conclude that when two component waves are unstable such that $\beta_{11}>\beta_{12}>0$, then the two-wave interaction is unstable. Now, consider when one component wave is unstable and the other is stable such that $\beta_{11}>0$ and $\beta_{12}<0$. Assume further that $|\beta_{11}|>|\beta_{12}|$. The conditions mimic those of two unstable component waves previously discussed. Consequently, when one of the component waves is unstable and the other stable such that $\beta_{11}>0$, $\beta_{12}<0$ and $|\beta_{11}|>|\beta_{12}|$, then the two-wave interaction is also unstable. Although these two situations conclude with such straightforward results, the interplay of component modes is generally a delicate issue. For instance, this may be seen when the behavior of the previous two component waves is swapped or when both component waves are stable, which could occur through $\beta_{11}<0$ (and possibly when $|\beta_{12}|>|\beta_{11}|$), then allowing the possibility of any of the three instability conditions or the stability condition to hold for a particular application (for it is the relative magnitudes of β_{11}, β_{12}, $|\hat{M}_0|$, and k that open up the possibilities further). Now there may be the potential that two stable component modes may interact in a stable manner and, perhaps, it is plausible that an unstable component mode may stabilize by interacting with a stable component mode.

These speculations can be made concrete. Note that $C_0=D_0^2+E_0$, where $E_0=(4\beta_{11}k^2-\beta_{12}^2|\hat{M}_0|^2)|\hat{M}_0|^2$. Therefore, the two-wave interaction is unstable if any of the following conditions hold:

$$(C_0<0) \text{ or } (C_0\geqslant 0 \text{ and } D_0>0) \text{ or } (D_0\leqslant 0 \text{ and } E_0>0).$$

Conversely, the interaction is stable if

$$C_0\geqslant 0, \quad D_0\leqslant 0, \quad \text{and } E_0\leqslant 0.$$

Figure 4 shows the intersection of surface C_0 in (E_0,D_0,C_0)-space. The regions of instability/stability are shown for a constant E_0 section through C_0 with $E_0<0$ in Fig. 5 and for a constant D_0 section through C_0 with $D_0<0$ in Fig. 6. The second and third quadrants of Fig. 5 and Fig. 6 show that stability can occur when $D_0\leqslant 0$ and $E_0\leqslant 0$, which automatically happens when β_{11} is negative, but must be sufficiently negative, relative to $-|\beta_{12}|$, especially as $C_0\geqslant 0$ is also required for stability; additionally, note that a component mode with $\beta_{11}<0$ is stable. Since β_{12} appears only through β_{12}^2 in the instability/stability conditions, the relevancy of whether the corresponding component mode is stable ($\beta_{12}<0$) or unstable ($\beta_{12}>0$) is of no importance for the form of the conditions derived; it is only the magnitude, $|\beta_{12}|$, that is crucial. We conclude, for this particular

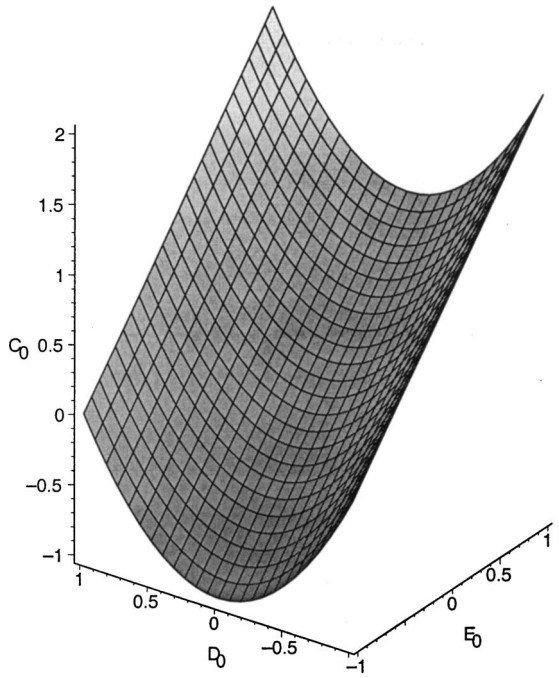

FIG. 4. The surface $C_0=D_0^2+E_0$.

application, that it is possible that two component stable modes can interact in a stable manner and an unstable component mode ($\beta_{12}>0$) can be stabilized by a stable component mode ($\beta_{11}<0$).

Last, briefly consider a specific application with the same parameters as above but with the exception that $\gamma=1$ and $\beta_{11}=\beta_{12}=\beta_{21}=\beta_{22}=\sigma/2$, where $\sigma=\pm 1$. It is noted that the $\beta_{j\ell}$ values imply that individual component modes are either both unstable ($\sigma=+1$) or both stable ($\sigma=-1$). For focusing behavior ($\sigma=+1$), the two-wave interaction is unstable. However, for defocusing behavior ($\sigma=-1$), the two-wave interaction is stable if $2k^2 \geqslant |\hat{M}_0|^2$ and unstable if $2k^2<|\hat{M}_0|^2$; in other words, at small amplitudes, the plane waves are stable to long-wave disturbances, whereas at larger amplitudes the two CNLS equations can exhibit long-wave instabilities. These deductions agree with those of Forest *et al.*[15]

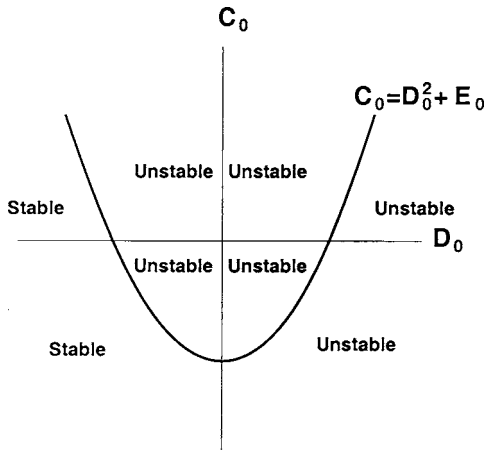

FIG. 5. A constant E_0 section through the surface $C_0=D_0^2+E_0$ with $E_0<0$. The regions of instability/stability are indicated.

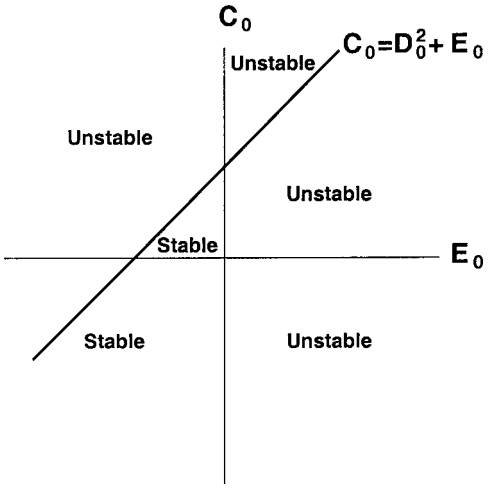

FIG. 6. A constant D_0 section through the surface $C_0=D_0^2+E_0$ with $D_0<0$. The regions of instability/stability are indicated.

V. DISCUSSION

Although it was mentioned, in Sec. II, that Eq. (2.1) can be cast into a bisymplectic framework, it is not required for directly relating the instability conditions for the modes $\hat{M}_j$ to the modes M_j. Recall that

$$M_j = e^{i(\xi_j T+\eta_j X)}\hat{M}_j = \hat{M}_{0j}e^{i[(\xi_j+\omega_j)T+(\eta_j+k_j)X]},$$

and let

$$M_j = \hat{M}_{0j}e^{i(\hat{\omega}_j T+\hat{k}_j X)},$$

where $\hat{\omega}_j=\xi_j+\omega_j$ and $\hat{k}_j=\eta_j+k_j$. Substitute $\omega_j=\hat{\omega}_j-\xi_j$ and $k_j=\hat{k}_j-\eta_j$, where

$$\xi_j = \frac{d_j^2}{4\gamma_j\epsilon_j} \quad \text{and} \quad \eta_j = -\frac{d_j}{2\gamma_j},$$

into the instability conditions: they will now be expressed in terms of the basic solution $M_j=\hat{M}_{0j}e^{i\hat{\theta}(X,T)}$, where $\hat{\theta}(X,T)=\hat{\omega}_j T+\hat{k}_j X$, of governing equations (2.1).

Returning to the transformed governing equations (2.2), in Sec. II, it was shown that this general class of N CNLS equations can be re-expressed as a bisymplectic system. The successful application of the theory to these CNLS equations is due to a very special feature of the multiphase wave trains considered, namely the basic class of N-phase wave trains can be characterized as (bisymplectic) relative equilibria.[5,16] "Relative equilibria" are solutions associated with some symmetry of the system of governing equations; for the N CNLS equations (2.2) it is a generalized toral symmetry (the symmetry group is $\mathbb{T}^N$ with action $\mathbf{G}$, a generalized rotational matrix). For the stability analysis, it is the parameter structure naturally associated with relative equilibria that is required.[16] The geometric structure is such that for the CNLS system with a basic class of multiphase wave trains with N-components, and a bisymplectic structure, there are natural $2N$-parameter families $(P_1,\ldots,P_N,Q_1,\ldots,Q_N)$ with a variational principle and a geometric instability condition. Moreover, since these parameters do not appear explicitly in the equations—although they are an intrinsic part of the structure of the system—they are not obvious. Furthermore, when treated as functions of the wave numbers and frequencies, the partial derivatives of these parameters encode stability information. Specifically, sufficient conditions for linear instability can be offered through these partial derivatives. This remarkable feature does not depend on explicit properties of N CNLS equations; it only depends on their structure.

A potentially interesting case study would be to consider the CKG equations

$$u_{tt} - u_{xx} = f_u(u,w),$$

$$w_{tt} - c^2 w_{xx} = f_w(u,w),$$

where $f(u,w)$ is a potential function of the nonlinear coupling and c is a real-valued scalar. These type of equations can also be re-expressed as a bisymplectic system.[2] Particular interest lies with weakly nonlinear solutions, which are not associated with a symmetry of the system. These weakly nonlinear solutions can be expanded in Fourier series—with the first term resembling the basic class of solution—and the linear stability problem could be investigated within a geometric framework. Although there is a potential small divisor problem,[2] the beauty of this investigation is that CNLS equations can be constructed to govern the modes of weakly nonlinear solutions of the CKG equations.[13,14] Therefore, the analysis of associated systems of CNLS equations ($N=2$,[13] and $N=4$,[14] have been proposed)—with the basic class of solution identified with the toral symmetry of the equations—may provide some insight into the stability problem for weakly nonlinear solutions of the connected CKG equations. Further details of this investigation will be presented elsewhere.

ACKNOWLEDGMENTS

The author would like to thank Professor Thomas J. Bridges for helpful discussions, Dr. Peter E. Hydon for advice, and Dr. Andrew D. Scott for proofreading earlier drafts. This investigation was partially supported by the NIH (BRP HL070542).

APPENDIX A: SUFFICIENT CONDITIONS FOR LINEAR INSTABILITY

The analyses for solutions (3.1) with $k_j=0$, for all j, governed by system (2.2), that lead to determining a complete description of the parameter space satisfying requirement (4.1) for $N \leqslant 4$ are presented. A partial description of the required region of parameter space for arbitrary N is also mentioned.

1. A single wave

The one-wave basic state

$$\hat{M}_1(X,T) = \hat{M}_{01} e^{i\omega_1 T}, \quad \text{where} \quad \omega_1 = \frac{1}{\epsilon_1}\beta_{11}|\hat{M}_{01}|^2,$$

determined from relation (3.2), has a quadratic (or bilinear) stability equation $a_2\hat{\Lambda}^2 + a_0 = 0$. Clearly, $\hat{\Lambda} = \pm\sqrt{-a_0/a_2}$. Thus, the existence of at least one root $\hat{\Lambda}$ with nonzero imaginary part is confirmed whenever $a_0 a_2 > 0$. Referring to Appendix B, this inequality evaluates to $\gamma_1\beta_{11} > 0$. According to Roskes,[6] this is exactly the necessary and sufficient condition for the single mode $\hat{M}_1$ to be unstable.

2. Two coupled waves

Consider two coupled waves (3.1) with $k_j=0$. The associated bi-quadratic stability equation is $a_4\hat{\Lambda}^4 + a_2\hat{\Lambda}^2 + a_0 = 0$. For a general bi-quadratic equation with $a_4 \neq 0$, the existence of at least one $\hat{\Lambda}$ with nonzero imaginary part is confirmed whenever any of the following criteria are satisfied:

(i) $a_0 a_4 < 0$;
(ii) $a_0 a_4 \geqslant 0$ and $a_2 a_4 > 0$;
(iii) $a_2 a_4 \leqslant 0$ and $a_2^2 - 4a_4 a_0 < 0$.

It should be noted that this description is not unique—see Fig. 3 (in the diagram $y=\hat{\Lambda}$, $c_1=\hat{a}_2$, and

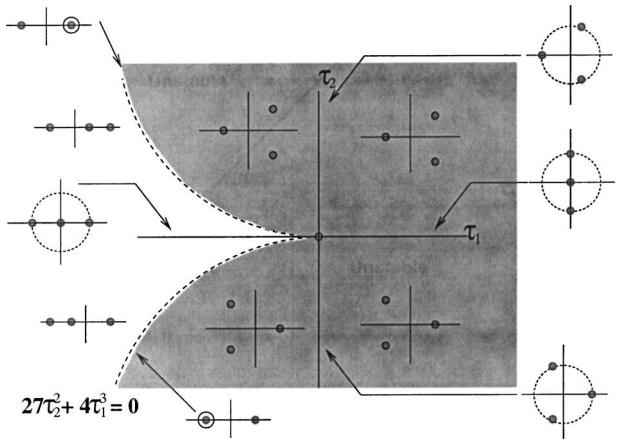

FIG. 7. The qualitative nature of the roots Y^2 satisfying $Y^6+\tau_1 Y^2+\tau_2=0$. The shaded region indicates where at least one root Y^2 exists with $\mathrm{Im}(Y^2)\neq 0$. Three real roots, Y^2, occur in the unshaded region.

$c_2=\hat{a}_0$, where $\hat{a}_{2\ell}=a_{2\ell}/a_4$). This figure highlights (shaded region) where at least one root $\hat{\Lambda}$ exists with $\mathrm{Im}(\hat{\Lambda})\neq 0$. It completely describes the region of parameter space satisfying requirement (4.1). For instance, when $a_0/a_4<0$ [exactly condition (i) given above] the root sketches show that two real roots $\hat{\Lambda}$ exist (denoted by the circles on the horizontal axes) and a pair of complex roots $\hat{\Lambda}$ exists (denoted by the circles on the vertical axes). Hence, at least one $\hat{\Lambda}$ with $\mathrm{Im}(\hat{\Lambda})\neq 0$ occurs in this part of the (a_0,a_2,a_4)-space. Referring to Appendix B, the conditions evaluate to the following:

(i) $\gamma_1\gamma_2\det(\boldsymbol{\beta})<0$;
(ii) $\gamma_1\gamma_2\det(\boldsymbol{\beta})\geqslant 0$ and $\tilde{a}_2>0$;
(iii) $\tilde{a}_2\leqslant 0$ and $\tilde{a}_2^2<4\epsilon_1^2\epsilon_2^2|\hat{M}_{01}|^2|\hat{M}_{02}|^2\gamma_1\gamma_2\det(\boldsymbol{\beta})$;

where $\tilde{a}_2=\gamma_1\epsilon_2^2\beta_{11}|\hat{M}_{01}|^2+\epsilon_1^2\gamma_2\beta_{22}|\hat{M}_{02}|^2$. The first condition was originally presented by Roskes,[6] while the other two conditions are additions presented by Bridges and Laine-Pearson.[5]

3. Three coupled waves

Consider three coupled waves (3.1) with $k_j=0$. The associated bicubic stability equation is

$$a_6\hat{\Lambda}^6+a_4\hat{\Lambda}^4+a_2\hat{\Lambda}^2+a_0=0. \tag{A1}$$

Assuming $a_6\neq 0$, the simplest way of retrieving qualitative information from this equation is to transform the fourth-order term away, obtaining

$$Y^6+\tau_1 Y^2+\tau_2=0, \quad \text{where } Y^2=\hat{\Lambda}^2+\frac{a_4}{3a_6}, \tag{A2}$$

with

$$\tau_1=\frac{1}{a_6^2}\left(-\frac{1}{3}a_4^2+a_2a_6\right) \quad \text{and} \quad \tau_2=\frac{1}{a_6^3}\left(\frac{2}{27}a_4^3-\frac{1}{3}a_2a_4a_6+a_0a_6^2\right).$$

The qualitative nature of the roots Y^2 for the reduced cubic equation (A2) is illustrated in Fig. 7. The shaded region indicates where there exists at least one Y^2 satisfying $\mathrm{Im}(Y^2)\neq 0$, which comes from one real root Y^2 (denoted by a circle on each horizontal axis of the root sketches in the shaded region) and one pair of complex roots Y^2. These roots will directly relate back to the roots $\hat{\Lambda}$—see the remarks that follow. The details for the construction of the split (τ_1,τ_2)-plane are

given, for instance, by Bruce and Giblin.[17] To describe the region where requirement (4.1) holds, note the following remarks:

(1) $\mathrm{Im}(\hat{\Lambda}^2) \neq 0$ if and only if $\mathrm{Im}(Y^2) \neq 0$;
(2) $\mathrm{Im}(\hat{\Lambda}) \neq 0$ whenever $\mathrm{Im}(\hat{\Lambda}^2) \neq 0$;
(3) all real roots Y^2 relate back to all real roots $\hat{\Lambda}^2$ but there is the possibility that at least one of these roots will be negative; hence, $\mathrm{Im}(\hat{\Lambda}) \neq 0$ for at least one $\hat{\Lambda}$.

Therefore, the existence of at least one root $\hat{\Lambda}$ with nonzero imaginary part is confirmed whenever any of the following criteria are satisfied:

(i) $27\tau_2^2+4\tau_1^3>0$;
(ii) $27\tau_2^2+4\tau_1^3\leqslant 0$, $Y^2-(a_4/3a_6)<0$, and $\tau_1\tau_2\neq 0$.

It should be noted that, for N CNLS equations, substituting the appropriate coefficient expressions from Appendix B will result in a particularly complicated pair of criteria (one of which will only be obtainable after solving the reduced cubic equation). Fortunately, condition (i) can be split into a number of smaller disjoint areas; for example, it can be represented as the union of the following:

(i)
  (a) $\tau_1>0$;
  (b) $\tau_1<0$ and $27\tau_2^2+4\tau_1^3>0$;

which is just another way of describing the shaded region in Fig. 7. Indeed, condition (i)(a) is a lot more pleasant to evaluate. Although it does not give the complete picture, it does give a relatively simpler sufficient condition for instability. On evaluating condition (i)(a), under the convenient assumption that $\epsilon_j^2=1$ for all j, the following is obtained:

$$3\textsc{Mixed} > (\gamma_1\beta_{11}|\hat{M}_{01}|^2 + \gamma_2\beta_{22}|\hat{M}_{02}|^2 + \gamma_3\beta_{33}|\hat{M}_{03}|^2)^2,$$

where

$$\begin{aligned}\textsc{Mixed} = {} & \gamma_1\gamma_2(\beta_{11}\beta_{22}-\beta_{12}\beta_{21})|\hat{M}_{01}|^2|\hat{M}_{02}|^2 + \gamma_1\gamma_3(\beta_{11}\beta_{33}-\beta_{13}\beta_{31})|\hat{M}_{01}|^2|\hat{M}_{03}|^2 \\ & + \gamma_2\gamma_3(\beta_{22}\beta_{33}-\beta_{23}\beta_{32})|\hat{M}_{02}|^2|\hat{M}_{03}|^2.\end{aligned}$$

It is noted that condition (ii) can be simplified for the nontrivial case (all roots nonzero) whenever Eq. (A1) has an odd number of negative real roots. This can be determined by considering $\mathrm{sign}(a_0/a_6)$. Therefore, a partial—but, in practice, useful—alternative to condition (ii) is the following:

$$27\tau_2^2+4\tau_1^3\leqslant 0, \quad \frac{a_0}{a_6}>0, \quad \text{and} \quad \tau_1\tau_2\neq 0.$$

It should also be noted that there is no obvious way to distinguish between two negative real roots (from three nontrivial real roots) using $\mathrm{sign}(a_0/a_6)$, as one positive and two negative real roots share the same sign as three positive real roots.

4. Four coupled waves

Consider four coupled waves (3.1) with $k_j=0$. The associated biquartic stability equation is

$$a_8\hat{\Lambda}^8 + a_6\hat{\Lambda}^6 + a_4\hat{\Lambda}^4 + a_2\hat{\Lambda}^2 + a_0 = 0. \tag{A3}$$

The retrieve qualitative information regarding the roots of Eq. (A3), first divide through by a_8 (assuming $a_8\neq 0$) and reduce Eq. (A3) to the following form:

$$Y^8 + \tau_1 Y^4 + \tau_2 Y^2 + \tau_3 = 0, \quad \text{where} \quad Y^2 = \hat{\Lambda}^2 + \frac{a_6}{4a_8}, \tag{A4}$$

with

$$\tau_1 = \frac{1}{a_8^2}\left(-\frac{3}{8}a_6^2 + a_8 a_4\right),$$

$$\tau_2 = \frac{1}{a_8^3}\left(\frac{1}{8}a_6^3 - \frac{1}{2}a_8 a_6 a_4 + a_8^2 a_2\right),$$

$$\tau_3 = \frac{1}{a_8^4}\left(-\frac{3}{256}a_6^4 + \frac{1}{16}a_8 a_6^2 a_4 - \frac{1}{4}a_8^2 a_6 a_2 + a_8^3 a_0\right).$$

Therefore, the transformation has reduced the four-parameter set $\{\hat{a}_6, \hat{a}_4, \hat{a}_2, \hat{a}_0\}$ where $\hat{a}_{2\ell} = a_{2\ell}/a_8$ to a related three-parameter set $\{\tau_1, \tau_2, \tau_3\}$, which greatly aids realizing the division of parameter space. The envelope surface for a general quartic equation, plotted in (τ_1, τ_2, τ_3)-space, is commonly known as a dovetail or swallowtail surface.[17] (See also Fig. 1.) There are three diagnostic functions associated with the general reduced quartic equation (A4), namely

$$D_1 = \tau_1, \quad D_2 = \text{DISCRIMINANT}, \quad D_3 = \tau_1^2 - 4\tau_3,$$

where

$$\text{DISCRIMINANT} = 16\tau_3\tau_1^4 - 4\tau_2^2\tau_1^3 - 128\tau_3^2\tau_1^2 + 144\tau_2^2\tau_3\tau_1 - 27\tau_2^4 + 256\tau_3^3.$$

These diagnostics will allow the region where requirement (4.1) holds to be completely described. Taking into account remarks (1)–(3), the existence of at least one $\hat{\Lambda}$ with nonzero imaginary part is confirmed whenever any of the following criteria are satisfied:

(i) $D_1 > 0$;
(ii) $D_1 = 0$ and ($\tau_2 \neq 0$ or $\tau_3 \neq 0$);
(iii) $D_1 < 0$ and $D_2 < 0$;
(iv) $D_1 < 0$, $D_2 \geqslant 0$, and $D_3 < 0$;
(v) $D_1 < 0$, $D_2 \geqslant 0$, $D_3 \geqslant 0$, and $Y^2 - (a_6/4a_8) < 0$.

Criteria (i)–(iv) result from directly analyzing the quartic equation in Y^2, while criterion (v) is an additional possibility due to investigating the roots $\hat{\Lambda}$ and can be verified for each particular application as both a_6 and a_8 will be known and Y^2 can be calculated [by solving the quartic equation (A4) for Y^2 by hand[18] or by using computer algebra software such as MAPLE[19]). Calling on Appendix B, supposing $\epsilon_j^2 = 1$ for all j, condition (i) evaluates to

$$3(\gamma_1^2\beta_{11}^2|\hat{M}_{01}|^4 + \gamma_2^2\beta_{22}^2|\hat{M}_{02}|^4 + \gamma_3^2\beta_{33}^2|\hat{M}_{03}|^4 + \gamma_4^2\beta_{44}^2|\hat{M}_{04}|^4) - 2\text{MIXED} < 0,$$

where

$$\begin{aligned}\text{MIXED} = {} & \gamma_1\gamma_2(\beta_{11}\beta_{22} - 4\beta_{12}\beta_{21})|\hat{M}_{01}|^2|\hat{M}_{02}|^2 + \gamma_1\gamma_3(\beta_{11}\beta_{33} - 4\beta_{13}\beta_{31})|\hat{M}_{01}|^2|\hat{M}_{03}|^2 + \gamma_1\gamma_4(\beta_{11}\beta_{44} \\ & - 4\beta_{14}\beta_{41})|\hat{M}_{01}|^2|\hat{M}_{04}|^2 + \gamma_2\gamma_3(\beta_{22}\beta_{33} - 4\beta_{23}\beta_{32})|\hat{M}_{02}|^2|\hat{M}_{03}|^2 + \gamma_2\gamma_4(\beta_{22}\beta_{44} - 4\beta_{24}\beta_{42}) \\ & \times|\hat{M}_{02}|^2|\hat{M}_{04}|^2 + \gamma_3\gamma_4(\beta_{33}\beta_{44} - 4\beta_{34}\beta_{43})|\hat{M}_{03}|^2|\hat{M}_{04}|^2.\end{aligned}$$

Conditions (ii)–(v) can be evaluated likewise. Similar to the analysis for the bicubic equation (A1), if Eq. (A3) has an odd number of negative real roots (for the nontrivial four real roots case), then condition (v) can be partially substituted for the simpler condition

$$D_1 < 0, \quad D_2 \geqslant 0, \quad D_3 \geqslant 0, \quad \text{and } \frac{a_0}{a_8} < 0.$$

Just as for the bicubic analysis, no simplified expression is offered for (v) with two or four negative real roots as they cannot be distinguished from an even number of positive real roots by using $\text{sign}(a_0/a_8)$.

A simpler set of criteria can be offered for the special case when $\tau_2=0$. Under this assumption, Y is governed by $Y^8+\tau_1 Y^4+\tau_3=0$. So, Y^4 satisfies a quadratic equation and, therefore, by noting remarks (1)–(3), the existence of at least one root $\hat{\Lambda}$ with nonzero imaginary part is confirmed whenever any of the following criteria are satisfied:

(I) $\tau_1 > 0$;
(II) $\tau_1 < 0$ and $\tau_3 \leqslant 0$;
(III) $\tau_1 \leqslant 0$ and $\tau_1^2 - 4\tau_3 < 0$;
(IV)

$$\tau_1 \leqslant 0, \quad \gamma_1^2 - 4\tau_3 \geqslant 0, \quad \text{and} \quad \pm\left(\frac{-\tau_1 \pm \sqrt{\tau_1^2 - 4\tau_3}}{2}\right)^{1/2} - \frac{a_6}{4a_8} < 0.$$

To emphasize the nonuniqueness for a complete description of requirement (4.1), the region encapsulated by criteria (I) and (II) could equally well be given as the following pair of criteria:

(I) $\tau_3 < 0$;
(II) $\tau_3 \geqslant 0$ and $\tau_1 > 0$.

See Fig. 3 for a graphical representation of where at least one root Y^2 exists with $\text{Im}(Y^2) \neq 0$—the shaded parts denote the relevant region (in the diagram $y=Y^2$, $c_1=\tau_1$ and $c_2=\tau_3$).

5. Remarks on *N* coupled waves

Consider N coupled waves (3.1) with $k_j=0$. It has already been illustrated that sufficient conditions for linear instability can be offered from criteria that only partially describe the parameter space satisfying requirement (4.1). These criteria must be used with care as they do not tell the whole story.

Determining sufficient conditions for instability pivots on how one attempts to analyze the stability polynomial equation (4.2). After all, other assumptions can be made, which will result in a reduced parameter space. For example, Roskes[6] noted that a generalization to N modes may be obtained by recalling there will be a suitable root of Eq. (4.2), whenever $\text{POLY}(0) < 0$, where

$$\text{POLY}(\hat{\Lambda}) = \hat{\Lambda}^{2N} + \frac{a_{2(N-1)}}{a_{2N}}\hat{\Lambda}^{2(N-1)} + \cdots + \frac{a_2}{a_{2N}}\hat{\Lambda}^2 + \frac{a_0}{a_{2N}},$$

occurring for α small, if

$$(-1)^N \det(\boldsymbol{\beta}) \prod_{j=1}^{N} \gamma_j < 0.$$

Roskes also remarked that, although this criterion conveniently generalizes the necessary and sufficient condition for instability of one mode ($\gamma_1\beta_{11}>0$), by no means is it necessary for instability of more than one mode. This was illustrated by Roskes[6] for $N=2$, which is recapped (by fixing ϵ_1 and ϵ_2) as follows. An unstable system for which $\gamma_1\gamma_2 \det(\boldsymbol{\beta}) < 0$ does not hold may be constructed by setting $\epsilon_1=\epsilon_2=1$, $\gamma_1=\gamma_2>0$, $\beta_{11}=\beta_{22}=2\beta_{12}=2\beta_{21}>0$ and, if one sets $\hat{M}_1=\hat{M}_2 \neq 0$, this returns the problem to the unstable single-mode case. Although Roskes' criterion[6] does not hold, the criterion

$$\gamma_1\gamma_2 \det(\boldsymbol{\beta}) \geqslant 0 \quad \text{and} \quad \gamma_1\epsilon_2^2\beta_{11}|\hat{M}_{01}|^2 + \epsilon_1^2\gamma_2\beta_{22}|\hat{M}_{02}|^2 > 0$$

presented by Bridges and Laine-Pearson[5]—and recalled in this paper—does.

APPENDIX B: COEFFICIENTS FOR THE *N* CNLS EQUATIONS

The coefficients that follow relate to the system of N CNLS equations (2.2) governing the solution family (3.1) with $k_j=0$, for all j.

1. One wave

For $N=1$ the stability equation is $a_2\hat{\Lambda}^2+a_0=0$, where

$$a_2 = \frac{\epsilon_1^2}{2\det(\boldsymbol{\beta})} \quad \text{and} \quad a_0 = \gamma_1|\hat{M}_{01}|^2.$$

2. Two waves

For $N=2$ the stability equation is $a_4\hat{\Lambda}^4+a_2\hat{\Lambda}^2+a_0=0$, where

$$a_4 = \frac{\epsilon_1^2\epsilon_2^2}{4\det(\boldsymbol{\beta})},$$

$$a_2 = \frac{1}{2\det(\boldsymbol{\beta})}(\gamma_1\epsilon_2^2\beta_{11}|\hat{M}_{01}|^2 + \epsilon_1^2\gamma_2\beta_{22}|\hat{M}_{02}|^2),$$

$$a_0 = \gamma_1\gamma_2|\hat{M}_{01}|^2|\hat{M}_{02}|^2.$$

3. Three waves

For $N=3$ the stability equation is $a_6\hat{\Lambda}^6+a_4\hat{\Lambda}^4+a_2\hat{\Lambda}^2+a_0=0$, where

$$a_6 = \frac{\epsilon_1^2\epsilon_2^2\epsilon_3^2}{8\det(\boldsymbol{\beta})},$$

$$a_4 = \frac{1}{4\det(\boldsymbol{\beta})}(\gamma_1\epsilon_2^2\epsilon_3^2\beta_{11}|\hat{M}_{01}|^2 + \epsilon_1^2\gamma_2\epsilon_3^2\beta_{22}|\hat{M}_{02}|^2 + \epsilon_1^2\epsilon_2^2\gamma_3\beta_{33}|\hat{M}_{03}|^2),$$

$$a_2 = \frac{1}{2\det(\boldsymbol{\beta})}\left(\gamma_1\gamma_2\epsilon_3^2\begin{vmatrix}\beta_{11} & \beta_{12}\\ \beta_{21} & \beta_{22}\end{vmatrix}|\hat{M}_{01}|^2|\hat{M}_{02}|^2 + \gamma_1\epsilon_2^2\gamma_3\begin{vmatrix}\beta_{11} & \beta_{13}\\ \beta_{31} & \beta_{33}\end{vmatrix}|\hat{M}_{01}|^2|\hat{M}_{03}|^2\epsilon_1^2\gamma_2\gamma_3\begin{vmatrix}\beta_{22} & \beta_{23}\\ \beta_{32} & \beta_{33}\end{vmatrix}\right)$$
$$\times|\hat{M}_{02}|^2|\hat{M}_{03}|^2,$$

$$a_0 = \gamma_1\gamma_2\gamma_3|\hat{M}_{01}|^2|\hat{M}_{02}|^2|\hat{M}_{03}|^2.$$

4. Four waves

For $N=4$ the stability equation is $a_8\hat{\Lambda}^8+a_6\hat{\Lambda}^6+a_4\hat{\Lambda}^4+a_2\hat{\Lambda}^2+a_0=0$, where

$$a_8 = \frac{\epsilon_1^2\epsilon_2^2\epsilon_3^3\epsilon_4^2}{16\det(\boldsymbol{\beta})},$$

$$a_6 = \frac{1}{8\,\det(\boldsymbol{\beta})}(\gamma_1\epsilon_2^2\epsilon_3^2\epsilon_4^2\beta_{11}|\hat{M}_{01}|^2 + \epsilon_1^2\gamma_2\epsilon_3^3\epsilon_4^2\beta_{22}|\hat{M}_{02}|^2 + \epsilon_1^2\epsilon_2^2\gamma_3\epsilon_4^2\beta_{33}|\hat{M}_{03}|^2 + \epsilon_1^2\epsilon_2^2\epsilon_3^3\gamma_4\beta_{44}|\hat{M}_{04}|^2),$$

$$\begin{aligned} a_4 = \frac{1}{4\,\det(\boldsymbol{\beta})}\Bigg(& \gamma_1\gamma_2\epsilon_3^2\epsilon_4^2\begin{vmatrix}\beta_{11} & \beta_{12}\\ \beta_{21} & \beta_{22}\end{vmatrix}|\hat{M}_{01}|^2|\hat{M}_{02}|^2 + \gamma_1\epsilon_2^2\gamma_3\epsilon_4^2\begin{vmatrix}\beta_{11} & \beta_{13}\\ \beta_{31} & \beta_{33}\end{vmatrix}|\hat{M}_{01}|^2|\hat{M}_{03}|^2 \\ & + \gamma_1\epsilon_2^2\epsilon_3^2\gamma_4\begin{vmatrix}\beta_{11} & \beta_{14}\\ \beta_{41} & \beta_{44}\end{vmatrix}|\hat{M}_{01}|^2|\hat{M}_{04}|^2 + \epsilon_1^2\gamma_2\gamma_3\epsilon_4^2\begin{vmatrix}\beta_{22} & \beta_{23}\\ \beta_{32} & \beta_{33}\end{vmatrix}|\hat{M}_{02}|^2|\hat{M}_{03}|^2 + \epsilon_1^2\gamma_2\epsilon_3^2\gamma_4\begin{vmatrix}\beta_{22} & \beta_{24}\\ \beta_{42} & \beta_{44}\end{vmatrix} \\ & \times|\hat{M}_{02}|^2|\hat{M}_{04}|^2 + \epsilon_1^2\epsilon_2^2\gamma_3\gamma_4\begin{vmatrix}\beta_{33} & \beta_{34}\\ \beta_{43} & \beta_{44}\end{vmatrix}|\hat{M}_{03}|^2|\hat{M}_{04}|^2\Bigg), \end{aligned}$$

$$\begin{aligned} a_2 = \frac{1}{2\,\det(\boldsymbol{\beta})}\Bigg(& \gamma_1\gamma_2\gamma_3\epsilon_4^2\begin{vmatrix}\beta_{11} & \beta_{12} & \beta_{13}\\ \beta_{21} & \beta_{22} & \beta_{23}\\ \beta_{31} & \beta_{32} & \beta_{33}\end{vmatrix}|\hat{M}_{01}|^2|\hat{M}_{02}|^2|\hat{M}_{03}|^2 + \gamma_1\gamma_2\epsilon_3^2\gamma_4\begin{vmatrix}\beta_{11} & \beta_{12} & \beta_{14}\\ \beta_{21} & \beta_{22} & \beta_{24}\\ \beta_{41} & \beta_{42} & \beta_{44}\end{vmatrix} \\ & \times|\hat{M}_{01}|^2|\hat{M}_{02}|^2|\hat{M}_{04}|^2 + \gamma_1\epsilon_2^2\gamma_3\gamma_4\begin{vmatrix}\beta_{11} & \beta_{13} & \beta_{14}\\ \beta_{31} & \beta_{33} & \beta_{34}\\ \beta_{41} & \beta_{43} & \beta_{44}\end{vmatrix}|\hat{M}_{01}|^2|\hat{M}_{03}|^2|\hat{M}_{04}|^2 \\ & + \epsilon_1^2\gamma_2\gamma_3\gamma_4\begin{vmatrix}\beta_{22} & \beta_{23} & \beta_{24}\\ \beta_{32} & \beta_{33} & \beta_{34}\\ \beta_{42} & \beta_{43} & \beta_{44}\end{vmatrix}|\hat{M}_{02}|^2|\hat{M}_{03}|^2|\hat{M}_{04}|^2\Bigg), \end{aligned}$$

$$a_0 = \gamma_1\gamma_2\gamma_3\gamma_4|\hat{M}_{01}|^2|\hat{M}_{02}|^2|\hat{M}_{03}|^2|\hat{M}_{04}|^2.$$

5. *N* waves

For arbitrary N waves the stability equation is

$$a_{2N}\hat{\Lambda}^{2N} + a_{2(N-1)}\hat{\Lambda}^{2(N-1)} + \cdots + a_2\hat{\Lambda}^2 + a_0 = 0,$$

where

$$a_{2N} = \frac{1}{2^N\,\det(\boldsymbol{\beta})}\prod_{j=1}^{N}\epsilon_j^2,$$

$$a_{2(N-1)} = \frac{1}{2^{N-1}\,\det(\boldsymbol{\beta})}\sum_{j=1}^{N}\left(\prod_{\substack{\ell=1\\ \ell\neq j}}^{N}\epsilon_\ell^2\right)\gamma_j\beta_{jj}|\hat{M}_{0j}|^2,$$

$$\vdots$$

$$a_0 = \prod_{j=1}^{N}\gamma_j|\hat{M}_{0j}|^2.$$

[1] Note that the notion of a 'bisymplectic system' is not the same as a 'bi-Hamiltonian system' (see Olver Ref. 20, for details regarding the latter).

(Received 22 April 2005; accepted 7 June 2005; published online 29 July 2005)

In this paper we study systematically the question of supersymmetrization of the nonlocal gas equation. We obtain both the $N=1$ and the $N=2$ supersymmetric generalizations of the system which are integrable. We show that both the systems are bi-Hamiltonian. While the $N=1$ supersymmetrization allows the hierarchy of equations to be extended to negative orders (local equations), we argue that this is not the case for the $N=2$ supersymmetrization. In the bosonic limit, however, the $N=2$ system of equations lead to a new coupled integrable system of equations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1993547]

I. INTRODUCTION

The classical isentropic gas equations[1]

$$u_t + uu_x + \frac{1}{v}P_x = 0,$$

$$v_t + (vu)_x = 0, \tag{1}$$

where u, v denote, respectively, the velocity and the density of the gas, are known to constitute an interesting class of dispersionless integrable systems when the pressure is a monomial function of the density. For example, $P=v^\gamma$, $\gamma \neq 0$, 1 corresponds to the polytropic gas, while $P=-1/v$ describes the Chaplygin gas.[2,3] Both these systems are of hydrodynamic type,[4] integrable, and a lot is known about the properties of these systems. Recently, it was shown that the gas equation for the case $P=-\frac{1}{2}(\partial^{-1}v)^2$ (called the nonlocal gas equation) is also integrable and has a very rich algebraic structure.[5,6] This system of equations arises in astrophysical models of dark matter.[7] In this paper, we will study the supersymmetrization of this system maintaining integrability of the model.

It is worth recalling that supersymmetrization of dispersionless systems is at best poorly understood at the present.[8,9] For example, in the case of polytropic gas, an integrable supersymmetric hierarchy has been obtained only for $N=1$ supersymmetrization besides the "trivial" susy-B supersymmetrization[10,11] and the supersymmetrization of the Chaplygin gas[12] resembles a susy-B symmetrization.[9] Even in the case of the $N=1$ supersymmetric polytropic gas (which is integrable), it is not known if it is a bi-Hamiltonian system. In contrast, we will show that integrable $N=1$ and $N=2$ supersymmetrizations are possible for the system of nonlocal gas dynamics. Furthermore, the $N=1$ supersymmetric system possesses two Hamiltonian structures which are com-

a)Electronic mail: ziemek@ift.uni.wroc.pl

patible so that it is truly a bi-Hamiltonian system and possesses all the rich algebraic structures of its bosonic counterpart. The $N=2$ supersymmetrization, on the other hand, leads to a new system of coupled integrable equations in the bosonic limit.

The paper is organized as follows. In Sec. II, we briefly recapitulate the essential features of the bosonic system and present results on the $N=1$ supersymmetric generalization that is integrable. We obtain the bi-Hamiltonian structure, the Casimir functionals as well as the conserved charges (local and nonlocal) of the system. In Sec. III, we present the essential results on the $N=2$ supersymmetrization of the system preserving integrability. We obtain the bi-Hamiltonian structure and argue that the second structure has no Casimir functional so that the system of equations cannot be extended to the negative orders. We present a brief summary of our results in Sec. IV.

II. $N=1$ SUPERSYMMETRIZATION

The nonlocal gas equation is described by the system of equations

$$u_t = -uu_x + (\partial^{-1}v),$$

$$v_t = -(uv)_x. \tag{2}$$

This system of equations is known to be integrable and alot of the algebraic properties for the system are well known. For example, it is known[5] that the system of Eqs. (2) is a bi-Hamiltonian system with the two compatible Hamiltonian structures described by

$$\mathcal{D}_1 = \begin{pmatrix} 0 & -\partial \\ -\partial & 0 \end{pmatrix}, \quad \mathcal{D}_2 = \begin{pmatrix} \partial^{-1} & -u_x \\ u_x & -(v\,\partial + \partial v) \end{pmatrix}. \tag{3}$$

The conserved charges satisfying the recursion relation can be constructed recursively and these charges are in involution by construction making the system integrable. Furthermore, the Hamiltonian structure $\mathcal{D}_1$ has three Casimir functionals (conserved charges whose gradients are annihilated by the Hamiltonian structures)

$$H_1 = \int \mathrm{d}x\, v,$$

$$H_1^{(1)} = -\int \mathrm{d}x\, u_x \to 0,$$

$$H_1^{(2)} = \int \mathrm{d}x\, u, \tag{4}$$

while the second Hamiltonian structure has a single Casimir functional

$$H_{-1} = 2\int \mathrm{d}x\left(v - \tfrac{1}{2}u_x^2\right)^{1/2}. \tag{5}$$

The existence of the Casimir functionals allows the hierarchy of flows to be extended to the negative order using the recursion relation and these are local equations unlike (2). In addition to the charges that are recursively constructed, the model also possesses two series of conserved charges whose gradients are not related by the recursion operator (and, therefore, are not in involution with the infinitely many charges which are in involution)

$$G_n = \int \mathrm{d}x\, u_x(\partial^{-1}v)^n, \quad \tilde{G}_n = \int \mathrm{d}x\left[u^2v + \frac{2}{2+n}(\partial^{-1}v)^2\right](\partial^{-1}v)^n. \tag{6}$$

However, a scalar Lax representation for the system is not known which leads to difficulties in applying the standard techniques of supersymmetrizing the system. Therefore, we construct the $N=1$ supersymmetric extension of the non-local gas equation which is integrable as follows.

Let us introduce the two fermionic superfields

$$U = \psi + \theta u, \quad V = \chi + \theta v, \tag{7}$$

where θ represents the Grassmann coordinate of the supermanifold and we assume the canonical dimensions

$$[x] = -1, \quad [t] = 2, \quad [U] = \tfrac{1}{2}, \quad [V] = \tfrac{7}{2}. \tag{8}$$

Writing out the most general equation of dimension $\left[\frac{5}{2}\right]$, the one that leads to the correct bosonic limit is given by

$$U_t = -U_x(DU) + (D^{-2}V), \tag{9}$$

$$V_t = -((DU)V)_x, \tag{10}$$

where

$$D = \frac{\partial}{\partial\theta} + \theta\frac{\partial}{\partial x}, \quad D^2 = \partial_x, \tag{11}$$

represents the supercovariant derivative on the superspace. In components, the equations take the forms

$$u_t = -uu_x + (\partial^{-1}v),$$

$$v_t = -(uv + \psi_x\chi)_x,$$

$$\psi_t = -\psi_x u + (\partial^{-1}\chi),$$

$$\chi_t = -(u\chi)_x. \tag{12}$$

Clearly, this represents a nontrivial $N=1$ supersymmetrization (and not a B-supersymmetrization) of (2). However, it is not obvious immediately if this is integrable.

We note that the system of Eqs. (10) is a Hamiltonian system of equations. In fact, the Hamiltonian

$$H_3 = \tfrac{1}{2}\int \mathrm{d}Z(V(DU)^2 + (D^{-2}V)(D^{-1}V)), \tag{13}$$

where $\mathrm{d}Z = \mathrm{d}x\mathrm{d}\theta$, together with the Hamiltonian structure

$$\mathcal{D}_1 = \begin{pmatrix} 0 & -D \\ -D & 0 \end{pmatrix}, \tag{14}$$

leads to (10) as

$$\begin{pmatrix} U_t \\ V_t \end{pmatrix} = \mathcal{D}_1 \begin{pmatrix} \dfrac{\delta H_3}{\delta U} \\ \dfrac{\delta H_3}{\delta V} \end{pmatrix}. \tag{15}$$

Similarly, it can also be checked that (10) can also be written as Hamiltonian equations with the Hamiltonian

$$H_2 = \int \mathrm{d}Z\, U(DV), \tag{16}$$

and the Hamiltonian structure

$$\mathcal{D}_2 = \begin{pmatrix} D^{-3} & -\frac{1}{2}(U_x + D^{-1}(DU_x)) \\ \frac{1}{2}(U_x + (DU_x)D^{-1}) & -\left(D(DV) + (DV)D - \frac{3}{2}DVD\right) \end{pmatrix}, \tag{17}$$

as

$$\begin{pmatrix} U_t \\ V_t \end{pmatrix} = \mathcal{D}_2 \begin{pmatrix} \dfrac{\delta H_2}{\delta U} \\ \dfrac{\delta H_2}{\delta V} \end{pmatrix}. \tag{18}$$

The Hamiltonian structures (14) and (17) have the necessary symmetry properties and it can be checked through the method of prolongation[13] that they satisfy Jacobi identity as well. Therefore, both $\mathcal{D}_1$ as well as $\mathcal{D}_2$ define genuine Hamiltonian structures. In fact, it is obvious that $\mathcal{D}_1$ satisfies Jacobi identity trivially. It can also be checked that the change of variables

$$\widetilde{U} = U_x, \quad \widetilde{V} = V - \tfrac{1}{2}(DU_x)U_x = V - \tfrac{1}{2}(D\widetilde{U})\widetilde{U}, \tag{19}$$

diagonalizes the second Hamiltonian structure which coincides with the supersymmetric $SL(2) \otimes U(1)$ algebra and thereby satisfies the Jacobi identity. More importantly, it can also be checked through the method of prolongation that an arbitrary linear combination

$$\mathcal{D} = \mathcal{D}_2 + \alpha\mathcal{D}_1, \tag{20}$$

also defines a Hamiltonian structure (satisfies Jacobi identity) so that we conclude that the system of Eqs. (10) is truly a bi-Hamiltonian system. It follows now from Magri's theorem that the supersymmetric system of equations is integrable.

From the two Hamiltonian structures in (14) and (17), we can obtain the recursion operator associated with the system defined as

$$\mathcal{R} = \mathcal{D}_2\mathcal{D}_1^{-1} \tag{21}$$

$$= \begin{pmatrix} \frac{1}{2}(U_x + D^{-1}(DU_x))D^{-1} & -D^{-4} \\ (D^2V)D^{-1} + \frac{1}{2}(DV) + \frac{3}{2}VD & -\frac{1}{2}(U_x + D^{-1}(DU_x)D^{-1} \end{pmatrix}. \tag{22}$$

This helps us determine the conserved quantities associated with the system recursively and the first few take the forms

$$H_1 = \int \mathrm{d}Z\, V,$$

$$H_2 = \int \mathrm{d}Z\, U(DV),$$

$$H_3 = \tfrac{1}{2} \int \mathrm{d}Z[(DU)^2 V + (D^{-1}V)(D^{-2}V)],$$

$$H_4 = \int \mathrm{d}Z[(DU)^3 V - 3U(D^{-1}V)^2 - 6(DU)V(D^{-3}V)],$$

$$\vdots \tag{23}$$

These charges are all conserved and are in involution with one another by construction reflecting the integrability of the system.

It is worth noting that all the charges in the series (23) are bosonic. In addition, we have found a charge that is fermionic and is conserved under the flow. It has the form

$$\widetilde{H} = \int \mathrm{d}Z\, UV(D^{-2}V). \tag{24}$$

Furthermore, much like the bosonic system, we have also found two series of bosonic conserved charges that are not related recursively

$$G_n = \int \mathrm{d}Z\, U(DV)(D^{-1}V)^n,$$

$$\widetilde{G}_n = \int \mathrm{d}Z(\partial^{-1}V)(D^{-1}V)^n[(n+2)(D^{-1}V)^2 + (n+1)(n+3)U_x V(DU) - (n+3)(D^{-1}U)(DU)(DU_x)]. \tag{25}$$

Much like the bosonic system, the $N=1$ supersymmetric system also has Casimir functionals whose gradients are annihilated by the two Hamiltonian structures of the system. It is easy to check that the three conserved quantities

$$H_1 = \int \mathrm{d}Z\, V,$$

$$H_1^{(1)} = -\int \mathrm{d}Z\, U_x \to 0,$$

$$H_1^{(2)} = \int \mathrm{d}Z\, U, \tag{26}$$

are conserved and are Casimir functionals of the first Hamiltonian structure (14), namely,

$$\mathcal{D}_1 \begin{pmatrix} \dfrac{\delta H_1}{\delta U} \\ \dfrac{\delta H_1}{\delta V} \end{pmatrix} = \mathcal{D}_1 \begin{pmatrix} \dfrac{\delta H_1^{(1)}}{\delta U} \\ \dfrac{\delta H_1^{(1)}}{\delta V} \end{pmatrix} = \mathcal{D}_1 \begin{pmatrix} \dfrac{\delta H_1^{(2)}}{\delta U} \\ \dfrac{\delta H_1^{(2)}}{\delta V} \end{pmatrix} = 0. \tag{27}$$

This is very much like in the bosonic model. Furthermore, the second Hamiltonian structure (17) also has a Casimir functional

$$H_{-1} = \int \mathrm{d}Z \frac{V - \frac{1}{2}(DU_x)U_x}{\sqrt{(DV) - \frac{1}{2}(DU_x)^2 - \frac{1}{2}U_{xx}U_x}}, \tag{28}$$

which is conserved and satisfies

$$\mathcal{D}_2 \begin{pmatrix} \dfrac{\delta H_{-1}}{\delta U} \\ \dfrac{\delta H_{-1}}{\delta V} \end{pmatrix} = 0. \tag{29}$$

The existence of Casimir functionals suggests that the hierarchy of equations generated by H_n, $n>0$ can be extended to the negative orders through the inverse of the recursion operator (22). Formally, the inverse can be defined as

$$\mathcal{R}^{-1} = \mathcal{D}_1 \mathcal{D}_2^{-1}. \tag{30}$$

However, it is worth noting here that unlike in the bosonic case where a closed form expression for the inverse exists, here we have not found such a form. However, one can easily construct the conserved charges associated with the negative order of the hierarchy using the recursion relation

$$\mathcal{D}_1 \begin{pmatrix} \dfrac{\delta H_{-n}}{\delta U} \\ \dfrac{\delta H_{-n}}{\delta V} \end{pmatrix} = \mathcal{D}_2 \begin{pmatrix} \dfrac{\delta H_{-n-1}}{\delta U} \\ \dfrac{\delta H_{-n-1}}{\delta V} \end{pmatrix}. \tag{31}$$

For example, this leads to the first few conserved local charges of the forms

$$H_{-1} = 2\int \mathrm{d}Z \frac{\tilde{V}}{\sqrt{(D\tilde{V})}},$$

$$H_{-2} = -\int \mathrm{d}Z \left[\frac{2U_{xx}}{\sqrt{(D\tilde{V})}} - \frac{(DU_{xx})\tilde{V}}{(D\tilde{V})^{3/2}} \right],$$

$$H_{-3} = \frac{1}{12}\int \mathrm{d}Z \left[\frac{\left(12U_{xx}(DU_{xx}) + 10\tilde{V}_{xx}\right)}{(D\tilde{V})^{3/2}} - \frac{9\tilde{V}\left((D\tilde{V}_{xx}) + (DU_{xx})^2\right)}{(D\tilde{V})^{5/2}} \right],$$

$$H_{-4} = \frac{1}{8}\int \mathrm{d}Z \left[\frac{10U_{xxx}(D\tilde{V}_x) - 6U_{xx}(D\tilde{V}_{xx}) - 6U_{xx}(DU_{xx})^2 - 10\tilde{V}_{xx}(DU_{xx}) - 6\tilde{V}(DU_{xxxx})}{(D\tilde{V})^{5/2}} + \frac{15\tilde{V}(D\tilde{V}_{xx})(DU_{xx}) + 5\tilde{V}(DU_{xx})^3}{(D\tilde{V})^{7/2}} \right],$$

$$\vdots \tag{32}$$

where $\tilde{V}$ is defined in (19). These charges, of course, satisfy the recursion relation (and, therefore, are in involution) and reduce to the known charges in the bosonic limit, but it is interesting to note that in the bosonic limit, the last two terms in H_{-4} vanish.

Given the Hamiltonians in the negative hierarchy, we can obtain the equations through the known Hamiltonian structures. We simply note that the lowest order equation in the negative hierarchy has the form

$$U_{t_{-1}} = -D\left(\frac{1}{(D\tilde{V})^{1/2}} - D\frac{\tilde{V}}{2\tilde{V}_x^{3/2}} \right), \tag{33}$$

$$V_{t_{-1}} = -D\,\partial\left((DU_x - (\mathrm{DU}_X))\frac{1}{(D\tilde{V})^{1/2}} - (2(\mathrm{DU}_X)D - U_X\,\partial)\frac{\tilde{V}}{2(D\tilde{V})^{3/2}} \right)$$

The bosonic limit of these equations can be easily checked to be the local equations of the negative hierarchy of the nonlocal gas equation.[5]

III. *N*=2 SUPERSYMMETRIZATION

The $N=2$ supersymmetrization of the nonlocal gas equation can now be obtained in a simple manner. Let us define bosonic superfields $\bar{U}$, $\bar{V}$ in the $N=2$ extended superspace as

$$\bar{U} = U_1 + \theta_2 U, \quad \bar{V} = V_1 + \theta_2 V, \tag{34}$$

where U, V are the $N=1$ superfields defined in the last section while U_1, V_1 represent two new $N=1$ bosonic superfields. In this extended superspace, we can define two covariant derivatives as

$$D_1 = \frac{\partial}{\partial\theta_1} + \theta_1\frac{\partial}{\partial x},$$

$$D_2 = \frac{\partial}{\partial\theta_2} + \theta_2\frac{\partial}{\partial x},$$

$$D_1^2 = D_2^2 = \frac{\partial}{\partial x}, \quad D_1 D_2 + D_2 D_1 = 0. \tag{35}$$

With these, the $N=2$ supersymmetric nonlocal gas equation which reduces to the $N=1$ system (10) and is integrable takes the form

$$\bar{U}_t = -(D_1 D_2 \bar{U})\bar{U}_x + (\partial^{-1}\bar{V}),$$

$$\bar{V}_t = -(\bar{V}(D_1 D_2 \bar{U}))_x + D_1 D_2[\bar{V}\bar{U}_x + (D_2\bar{U}_x)(D_1\bar{U}_x)\bar{U}_x - (D_1 D_2 \bar{U}_x)\bar{U}_x^2]. \tag{36}$$

The system of Eqs. (36) can be written as a Hamiltonian system with

$$\mathcal{D}_1 = \begin{pmatrix} 0 & D_1 D_2 \partial^{-1} \\ D_1 D_2 \partial^{-1} & 0 \end{pmatrix},$$

$$H = \tfrac{1}{6}\int d\bar{Z}[(D_1 D_2 \bar{U}_x)\bar{U}_x^3 - 3(D_1 D_2 \partial^{-1}\bar{V})(2(D_1 D_2 \bar{U})\bar{U}_x - (\partial^{-1}\bar{V}))], \tag{37}$$

(where $d\bar{Z} = dx\, d\theta_1 d\theta_2$) so that

$$\begin{pmatrix} \bar{U}_t \\ \bar{V}_t \end{pmatrix} = \mathcal{D}_1 \begin{pmatrix} \dfrac{\delta H}{\delta \bar{U}} \\ \dfrac{\delta H}{\delta \bar{V}} \end{pmatrix}. \tag{38}$$

The Hamiltonian structure clearly has the necessary antisymmetry properties and trivially satisfies the Jacobi identity.

The system of Eqs. (36) has a second Hamiltonian description as well. It can be checked that the equations can be written in the Hamiltonian form

$$\begin{pmatrix} \bar{U}_t \\ \bar{V}_t \end{pmatrix} = \mathcal{D}_2 \begin{pmatrix} \dfrac{\delta \bar{H}}{\delta \bar{U}} \\ \dfrac{\delta \bar{H}}{\delta \bar{V}} \end{pmatrix} \tag{39}$$

with the Hamiltonian

$$\bar{H} = \int d\bar{Z}(D_1 D_2 \bar{U})\left[\bar{V} - \tfrac{1}{2}D_1(\bar{U}_x(D_2\bar{U}_x))\right], \tag{40}$$

and the second Hamiltonian structure $\mathcal{D}_2$ with the elements

$$(\mathcal{D}_2)_{11} = -\partial^{-1}D_1^{-1}D_2^{-1},$$

$$(\mathcal{D}_2)_{12} = \tfrac{1}{2}(-2\bar{U}_x + D_1^{-1}(D_1\bar{U}_x) + D_2^{-1}(D_2\bar{U}_x) + 2D_1^{-1}D_2^{-1}(D_1 D_2\bar{U}_x)),$$

$$(\mathcal{D}_2)_{21} = \tfrac{1}{2}(2\bar{U}_x + (D_1\bar{U}_x)D_1^{-1} + (D_2\bar{U}_x)D_2^{-1} - 2(D_1 D_2\bar{U}_x)D_1^{-1}D_2^{-1}),$$

$$(\mathcal{D}_2)_{22} = \tfrac{1}{2}(-2\,\partial\bar{V} - 2\bar{V}\,\partial + D_1\bar{V}D_1 + D_2\bar{V}D_2 - \partial\bar{U}_x^2 D_1D_2 + \bar{U}_x^2\,\partial D_1D_2 + D_2\bar{U}_x^2\,\partial D_1 - D_1\bar{U}_x^2\,\partial D_2)$$
$$+ (D_1D_2\bar{U}_x)\partial^{-1}D_1D_2\bar{U}_xD_1D_2. \tag{41}$$

The second Hamiltonian structure is quite complicated and one can check the Jacobi identity through the method of prolongation. However, it is much easier to check this through a change of variables

$$\tilde{\bar{U}} = \bar{U}_x, \quad \tilde{\bar{V}} = \bar{V} - (D_1D_2\tilde{\bar{U}})\tilde{\bar{U}} - \tfrac{1}{2}(D_1\tilde{\bar{U}})(D_2\tilde{\bar{U}}), \tag{42}$$

the second Hamiltonian structure coincides with the $N=2$ supersymmetric generalization of the $SL(2)\otimes U(1)$ algebra and thereby satisfies the Jacobi identity. Furthermore, the compatibility of the two structures $\mathcal{D}_1$ and $\mathcal{D}_2$ can also be checked in a straightforward manner through prolongation. Therefore, it follows that the system of $N=2$ supersymmetric Eqs. (36) are integrable. The infinite set of conserved charges in involution can be constructed using the recursion relation. However, their forms are extremely complicated and are not very enlightening. So, we do not list them here.

The bosonic limit of (36) leads to a new and interesting coupled equation that is integrable. Introducing the notation that u_0, u_1 represent the bosonic variables of the superfield $\bar{U}$ and v_0, v_1 represent the bosonic variables of the superfield $\bar{V}$, the equations can be written as

$$u_{0,t} = -u_1u_{0,x} + (\partial^{-1}v_0),$$

$$u_{1,t} = u_{0,xx}u_{0,x} - u_{1,x}u_1 + (\partial^{-1}v_1),$$

$$v_{0,t} = u_{0,xxx}u_{0,x}^2 + u_{0,xx}^2u_{0,x} - u_{1,x}^2u_{0,x} - v_{0,x}u_1 + v_1u_{0,x},$$

$$v_{1,t} = (u_{1,xx}u_{0,x}^2 + 2u_{1,x}u_{0,xx}u_{0,x} - v_{0,x}u_{0,x} - v_1u_1)_x. \tag{43}$$

This is a new integrable system of equations and has the interesting feature that the second Hamiltonian structure for this system does not have any Casimir functional. As a result, the second Hamiltonian structure for the $N=2$ supersymmetric system in (41) does not also possess any Casimir functional (although the first structure does) and the system of Eqs. (36) cannot be extended to the negative hierarchy.

IV. SUMMARY

In this paper we have systematically studied the supersymmetrization of the nonlocal gas equation preserving integrability. We obtain the $N=1$ supersymmetric system of equations and show that it has two compatible Hamiltonian structures making it a bi-Hamiltonian system. We construct the conserved charges of the system and show that the two Hamiltonian structures possess Casimir functionals. As a result, the system of supersymmetric equations can be extended to negative orders and these give rise to local equations of motion. We also construct the $N=2$ supersymmetric generalization of the nonlocal gas equation and show that it is a bi-Hamiltonian system. In the bosonic limit, this equation leads to a new coupled integrable system of equations. Furthermore, we argue that in the $N=2$ supersymmetric case, while the first Hamiltonian structure possesses Casimir functionals, the second does not. As a result, these equations cannot be extended to negative orders.

The description of a plasma as composed by two types of fluids, formed by ions and electrons, is more complete than the classical one-fluid magnetohydrodynamics (MHD) model and it has proved necessary to explain the phenomena of fast magnetic reconnection. We prove a finite-time theorem of existence and uniqueness of solutions for this system for either Dirichlet or periodic boundary conditions in dimension three. It turns out that the regularity estimates for the magnetic field are finer than the MHD ones. © *2005 American Institute of Physics.*

I. INTRODUCTION AND MATHEMATICAL SETTING

The evolution of a collection of charged particles can often be modeled as the motion of several fluid species linked by electromagnetic forces. The most important instance is probably the two-fluid case, where positive ions and electrons form a quasineutral plasma. The equations of motion of both species, under reasonable approximations[1–3] may be combined to yield

$$\rho\left(\frac{\partial \mathbf{v}}{\partial t}+\mathbf{v}\cdot\nabla\mathbf{v}\right)=\nu\Delta\mathbf{v}+\mathbf{J}\times\mathbf{B}-\nabla p+\mathbf{f}$$
$$\mathbf{E}+\mathbf{v}\times\mathbf{B}=\eta\mathbf{J}+\frac{1}{en}\mathbf{J}\times\mathbf{B}-\frac{1}{en}\nabla p_e+\frac{m}{e^2n}\frac{\partial\mathbf{J}}{\partial t}, \tag{1}$$

where the variables are explained as follows:

(1) $\mathbf{v}$ is the mass velocity

$$\mathbf{v}=\frac{M\mathbf{v}_i+m\mathbf{v}_e}{M+m},$$

where $\mathbf{v}_i$ is the ions velocity, M is its mass, $\mathbf{v}_e$ is the electrons velocity, and m is its mass. Since $M\gg m$, $\mathbf{v}\approx\mathbf{v}_i$.

(2) e is the electron charge.

(3) n is the electrons number density, approximately equal to the ions one, $\rho=n(M+m)$ the mass density. We will assume the fluid incompressible and will scale ρ to 1.

(4) ν is the kinematic viscosity and η is the resistivity. Both are taken as constant (positive) scalars, meaning that these plasma properties are homogeneous and isotropic.

(5) $p=p_i+p_e$ is the total pressure, sum of the ion and electron ones.

(6) $\mathbf{E}$ is the electric field, $\mathbf{B}$ is the magnetic one, and $\mathbf{J}=\nabla\times\mathbf{B}$ is the current density. This is also equal to $(\mathbf{v}_i-\mathbf{v}_e)en$.

(7) $\mathbf{f}$ is an arbitrary forcing on the momentum equation, given, e.g., by gravitational forces.

a)Electronic mail: mnjmhd@am.uva.es

It is apparent that the coefficient $m/(e^2n)$ is very small. Neglecting it we are left with the Hall magnetohydrodynamics (MHD) system. By neglecting also the current displacement in Maxwell's equations, an admissible procedure in low-frequency phenomena, and using Faraday's law

$$\frac{\partial \mathbf{B}}{\partial t} = -\nabla \times \mathbf{E},$$

we are left with the Hall induction equation

$$\frac{\partial \mathbf{B}}{\partial t} = -\nabla \times (\eta \mathbf{J}) + \nabla \times (\mathbf{v} \times \mathbf{B}) - \frac{1}{en} \nabla \times (\mathbf{J} \times \mathbf{B}). \tag{2}$$

The Hall current term $(1/en)\nabla \times (\mathbf{J} \times \mathbf{B})$ is small in dense plasmas, and in general at large scales its effect is less important than the one of the velocity. Omitting it and using certain vector analysis identities, we obtain the classical incompressible MHD equations

$$\frac{\partial \mathbf{v}}{\partial t} = \nu \Delta \mathbf{v} - \mathbf{v} \cdot \nabla \mathbf{v} + \mathbf{B} \cdot \nabla \mathbf{B} - \nabla \left(p + \frac{1}{2} B^2 \right) + \mathbf{f},$$

$$\frac{\partial \mathbf{B}}{\partial t} = \eta \Delta \mathbf{B} + \nabla \times (\mathbf{v} \times \mathbf{B}), \tag{3}$$

$$\nabla \cdot \mathbf{v} = \nabla \cdot \mathbf{B} = 0.$$

Its study is well known and similar in many aspects to the one of the Navier–Stokes equation.[4] However, it has become apparent that in certain important physical phenomena, in particular those involving magnetic reconnection, the one-fluid description given by (3) is not appropriate. The extremely rapid conversion rate from magnetic to kinetic energy present in such spectacular phenomena as solar flares could not be adequately explained by any MHD model, and there was no lack of effort in this sense. There exists an enormous literature on this problem: see, e.g., Refs. 5–7, and references therein. It is generally accepted now that near the current sheets where reconnection occurs, electrons and ions cease to move together: it is the high electron velocity which prevents the throttling of MHD reconnection schemes and allows fast energy conversion. It is clear that a two-fluid description is necessary and therefore it seems natural to ask for some existence theorem for the relevant equation. Although admittedly the electron inertia term $m/(e^2n)$ is small, its presence is necessary to obtain a mathematically consistent model. By taking the curl of (1) and using Faraday's law, we obtain the two-fluid MHD system

$$\frac{\partial \mathbf{v}}{\partial t} = \nu \Delta \mathbf{v} - \mathbf{v} \cdot \nabla \mathbf{v} + \mathbf{B} \cdot \nabla \mathbf{B} - \nabla \left(p + \frac{1}{2} B^2 \right) + \mathbf{f}, \tag{4}$$

$$\frac{m}{e^2 n} \frac{\partial \nabla \times \mathbf{J}}{\partial t} + \frac{\partial \mathbf{B}}{\partial t} = \eta \Delta \mathbf{B} + \nabla \times (\mathbf{v} \times \mathbf{B}) - \frac{1}{en} \nabla \times (\mathbf{J} \times \mathbf{B}), \tag{5}$$

which will be our object of study. We will abbreviate the electron inertia term $m/(e^2n)$ to α, the Hall coefficient $1/(en)$ to h. In addition to these equations, both $\mathbf{v}$ and $\mathbf{B}$ must be solenoidal. This follows automatically for $\mathbf{B}$ for all time if it happens for the initial condition at time zero, because the divergence of the induction equation yields

$$\frac{\partial(\nabla \cdot \mathbf{B})}{\partial t} = 0.$$

As for the momentum one, the task of keeping $\mathbf{v}$ solenoidal is given to the pressure: p satisfies an elliptic equation to this end. Indeed, physically the pressure compensates for the tensions created by the fluid incompressibility.

Finally, boundary conditions must be added. Although other possibilities exist, we will concentrate for simplicity on two cases:

(1) The domain Ω is smooth, and both $\mathbf{v}$ and $\mathbf{B}$ satisfy homogeneous Dirichlet conditions at its boundary $\partial\Omega$.
(2) Ω is a box $(0,L_1)\times(0,L_2)\times(0,L_3)$, and both $\mathbf{v}$ and $\mathbf{B}$ are periodic at opposite faces. Moreover, in this case the mean of both in Ω is zero.

Incidently, notice that, in contrast to the MHD and Navier–Stokes cases, there is no possibility here of studying two-dimensional problems, because even when both velocity and magnetic field are horizontal, the current density and the Hall term are not.

We first recall the definitions of the classical Lebesgue and Sobolev spaces: $L^p(\Omega)$ is the space of measurable functions f defined in Ω whose L^p-norm

$$\|f\|_p = \left(\int_\Omega |f|^p \mathrm{d}V \right)^{1/p}$$

is bounded. $L^\infty(\Omega)$ is the space of measurable functions defined in Ω such that they are bounded outside a set of zero measure E, and $\|f\|_\infty$ is the maximum of $|f(\mathbf{x})|$ when $\mathbf{x} \notin E$. $H^p(\Omega)$ is the space of functions whose differentials up to the order p are square integrable [i.e., they belong to $L^2(\Omega)$]. The norm $\|f\|_{H^p(\Omega)}$ is the sum of the L^2-norms of all the partial derivatives of f up to the order p. We will only use $H^1(\Omega)$ and $H^2(\Omega)$. $H_0^1(\Omega)$ is the subspace of $H^1(\Omega)$ formed (roughly) by the functions vanishing in the boundary $\partial\Omega$. (The correct definition is somewhat more involved, but essentially amounts to this). We will use a number of standard notations:[4,8]

In the Dirichlet case,

$$H = \{\mathbf{B} \in L^2(\Omega)^3 : \nabla \cdot \mathbf{B} = 0, \mathbf{B} \cdot \mathbf{n}|_{\partial\Omega} = 0\}. \tag{6}$$

Although this divergence and trace term must be understood in the sense of distributions, it is known that H is a closed subspace of $L^2(\Omega)^3$.

$$V = H_0^1(\Omega)^3 \cap H,$$

$$D(A) = H^2(\Omega)^3 \cap V, \tag{7}$$

$$A : D(A) \to H, \quad A = P_H \Delta,$$

where P_H is the orthogonal projection on H. In the periodic case,

$$H = \left\{ \mathbf{u} \in L^2(\Omega)^3 : \int_\Omega \mathbf{u}\, \mathrm{d}V = \mathbf{0}, \quad \nabla \cdot \mathbf{u} = 0,\ \mathbf{u} \cdot \mathbf{n} \text{ antiperiodic at opposite sides of } \Omega \right\}. \tag{8}$$

Again H is a closed subspace of $L^2(\Omega)^3$

$$V = H^1(\Omega)^3 \cap H,$$

$$D(A) = H^2(\Omega)^3 \cap V, \tag{9}$$

$$A:D(A) \to H, \quad A = \Delta.$$

In connection with these spaces, we will use the following inequality (see Ref. 8): For all $\mathbf{f} \in V, \mathbf{g} \in D(A), \mathbf{h} \in H$,

$$\left| \int_\Omega \mathbf{f} \cdot \nabla \mathbf{g} \cdot \mathbf{h} \, dV \right| \leqslant c \|\mathbf{f}\|_{H^1} \|\mathbf{g}\|_{H^1}^{1/2} \|A\mathbf{g}\|_2^{1/2} \|h\|_2. \tag{10}$$

c is a constant depending only on Ω. To avoid an unmanageable proliferation of constants, we will always denote such parameters by c: thus, e.g., $3c + c^{1/2} = c$. Constants not depending on Ω, such as the diffusivity terms or bounds depending on specific functions will be given different names.

We intend to prove local existence and uniqueness of the solution to the problem (4) and (5) with initial condition $\mathbf{v}(0) \in V, \mathbf{B}(0) \in D(A)$. We will consider first the induction equation, which in the MHD case models the so-called kinematic dynamo, where the velocity is taken as a datum. The momentum equation in a classical Navier–Stokes one with a forcing given by the Lorentz force, for which well-known estimates are available. Combining the bounds for both equations we will obtain a contractive operator whose fixed point is the unique solution. Finally we will obtain some energy inequalities emphasizing the difference with the single-fluid MHD model. All these results will hold even in infinitely conducting plasmas ($\eta = 0$), in contrast with classical MHD.

II. INDUCTION EQUATION

Definition 2.1: For $\mathbf{B} \in D(A)$ we will denote by $\mathbf{w}$ the function

$$\mathbf{w} = -\alpha \Delta \mathbf{B} + \mathbf{B}. \tag{11}$$

Notice that the properties of elliptic systems guarantee that $\mathbf{w} \in H$ and $\|\mathbf{B}\|_{H^2} \leqslant c\|\mathbf{w}\|_2$.

Lemma 2.2: *Consider the term* $\eta \Delta \mathbf{B} + \nabla \times (\mathbf{v} \times \mathbf{B}) - h \nabla \times (\mathbf{J} \times \mathbf{B})$ *as a (nonlocal) function* $F(\mathbf{w}, \mathbf{v})$. *Then, for every* $\mathbf{v} \in V, F$ *is a continuous function from* H *into* H. *Moreover, for any* $\mathbf{v} \in V, \mathbf{w} \in H$,

$$\|F(\mathbf{w}, \mathbf{v})\|_2 \leqslant c(\eta + \|\mathbf{v}\|_{H^1} + \|\mathbf{w}\|_2)\|\mathbf{w}\|_2, \tag{12}$$

and for any $\mathbf{v}_1, \mathbf{v}_2 \in V, \mathbf{w}_1, \mathbf{w}_2 \in H$,

$$\begin{aligned} &\|F(\mathbf{w}_1, \mathbf{v}_1) - F(\mathbf{w}_2, \mathbf{v}_2)\|_2 \\ &\quad \leqslant c(\eta + \|\mathbf{v}_1\|_{H^1} + \|\mathbf{v}_2\|_{H^1} + \|\mathbf{w}_1\|_2 + \|\mathbf{w}_2\|_2)\|\mathbf{w}_1 - \mathbf{w}_2\|_2 + c(\|\mathbf{w}_1\|_2 + \|\mathbf{w}_2\|)\|\mathbf{v}_1 - \mathbf{v}_2\|_{H^1}. \end{aligned} \tag{13}$$

Proof: Recall that

$$\nabla \times (\mathbf{v} \times \mathbf{B}) = -\mathbf{v} \cdot \nabla \mathbf{B} + \mathbf{B} \cdot \nabla \mathbf{v},$$

$$\nabla \times (\mathbf{J} \times \mathbf{B}) = -\mathbf{J} \cdot \nabla \mathbf{B} + \mathbf{B} \cdot \nabla \mathbf{J}.$$

By standard Sobolev inequalities:

$$\eta \|\Delta \mathbf{B}_1 - \Delta \mathbf{B}_2\|_2 \leqslant c\eta \|\mathbf{B}_1 - \mathbf{B}_2\|_{H^2} \leqslant c\eta \|\mathbf{w}_1 - \mathbf{w}_2\|_2,$$

and

$$\begin{aligned} &\|\nabla \times (\mathbf{v}_1 \times \mathbf{B}_1) - \nabla \times (\mathbf{v}_2 \times \mathbf{B}_2)\|_2 \\ &\quad = \|-\mathbf{v}_1 \cdot \nabla (\mathbf{B}_1 - \mathbf{B}_2) - (\mathbf{v}_1 - \mathbf{v}_2) \cdot \nabla \mathbf{B}_2 + \mathbf{B}_1 \cdot \nabla (\mathbf{v}_1 - \mathbf{v}_2) + (\mathbf{B}_1 - \mathbf{B}_2) \cdot \nabla \mathbf{v}_2\|_2 \\ &\quad \leqslant \|\mathbf{v}_1\|_4 \|\nabla (\mathbf{B}_1 - \mathbf{B}_2)\|_4 + \|\mathbf{v}_1 - \mathbf{v}_2\|_4 \|\nabla \mathbf{B}_2\|_4 + \|\mathbf{B}_1\|_\infty \|\nabla (\mathbf{v}_1 - \mathbf{v}_2)\|_2 + \|\mathbf{B}_1 - \mathbf{B}_2\|_\infty \|\nabla \mathbf{v}_2\|_2. \end{aligned}$$

Since for dimension 3, $V \subset L^4(\Omega)$, $D(A) \subset L^\infty(\Omega)$, this amount may be bounded by

$$c(\|\mathbf{v}_1\|_{H^1}\|\mathbf{B}_1-\mathbf{B}_2\|_{H^2}+\|\mathbf{B}_2\|_{H^2}\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}+\|\mathbf{B}_1\|_{H^2}\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}+\|\mathbf{v}_2\|_{H^1}\|\mathbf{B}_1-\mathbf{B}_2\|_{H^2}$$
$$\leqslant c(\|\mathbf{v}_1\|_{H^1}+\|\mathbf{v}_2\|_{H^1})\|\mathbf{w}_1-\mathbf{w}_2\|_2+c(\|\mathbf{w}_1\|_2+\|\mathbf{w}\|_2)\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}.$$

Finally, by changing in the previous inequalities $\mathbf{v}_i$ to $\mathbf{J}_i$ we find

$$\|\nabla\times(\mathbf{J}_1\times\mathbf{B}_1)-\nabla\times(\mathbf{J}_2\times\mathbf{B}_2)\|_2$$
$$\leqslant\|\mathbf{J}_1\|_4\|\nabla(\mathbf{B}_1-\mathbf{B}_2)\|_4+\|\mathbf{J}_1-\mathbf{J}_2\|_4\|\nabla\mathbf{B}_2\|_4+\|\mathbf{B}_1\|_\infty\|\nabla(\mathbf{J}_1-\mathbf{J}_2)\|_2+\|\mathbf{B}_1-\mathbf{B}_2\|_\infty\|\nabla\mathbf{J}_2\|_2$$
$$\leqslant c(\|\mathbf{J}_1\|_{H^1}+\|\mathbf{B}_2\|_{H^2}+\|\mathbf{B}_1\|_{H^2}+\|\mathbf{J}_2\|_{H^1})\|\mathbf{B}_1-\mathbf{B}_2\|_{H^2}\leqslant c(\|\mathbf{w}_1\|_2+\|\mathbf{w}_2\|_2)\|\mathbf{w}_1-\mathbf{w}_2\|_2.$$

The inequality (12) is a simplified version of the previous calculation, with only a single $\mathbf{v}$ and $\mathbf{w}$. This concludes the proof. ■

Theorem 2.3: *For fixed* $\mathbf{v}\in L^2((0,S),V)$, *Eq. (5), which may be written in the form*

$$\frac{d\mathbf{w}}{dt}=F(\mathbf{w},\mathbf{v}),\qquad \mathbf{w}(0)\in H, \tag{14}$$

admits a unique a.e. differentiable solution $\mathbf{w}:(0,T)\to H$, *for some* $T\leqslant S$, $T>0$. *We may take T so that this solution satisfies* $\|\mathbf{w}(t)\|_2\leqslant\|\mathbf{w}(0)\|_2+1$ *for all* $t\in(0,T)$. *Moreover, the interval* $(0,T)$ *depends only on* $\|\mathbf{w}(0)\|_2$ *and* $\|\mathbf{v}\|_{L^2((0,T),V)}$.

Proof: Let us prove that the integral operator, defined in the closed ball of $\mathcal{C}((0,T),H)$ of center $\mathbf{0}$ and radius $\|\mathbf{w}(0)\|_2+1$ given by

$$\mathbf{w}\to\mathbf{w}(0)+\int_0^t F(\mathbf{w}(s),\mathbf{v}(s))ds,$$

takes the ball to itself and is contractive for T small enough. Using (12), for any $\mathbf{w}$ bounded by $\|\mathbf{w}(0)\|_2+1$,

$$\int_0^t\|F(\mathbf{w},\mathbf{v})\|_2ds\leqslant c\int_0^t(\eta+\|\mathbf{v}\|_{H^1}+\|\mathbf{w}\|_2)\|\mathbf{w}\|_2ds$$
$$\leqslant c\left(\sqrt{T}\left(\int_0^T\|\mathbf{v}\|_{H^1}^2ds\right)^{1/2}+T(\eta+\|\mathbf{w}(0)\|_2+1)\right)(\|\mathbf{w}(0)\|_2+1).$$

Clearly we can take T so that this amount is less than 1 for all $t\in(0,T)$. Taking now (13),

$$\int_0^t\|F(\mathbf{w}_1,\mathbf{v})-F(\mathbf{w}_2,\mathbf{v})\|_2ds\leqslant c\int_0^t(\eta+2\|\mathbf{v}\|_{H^1}+\|\mathbf{w}_1\|_2+\|\mathbf{w}_2\|_2)\|\mathbf{w}_1-\mathbf{w}_2\|_2ds,$$

so that

$$\|\mathbf{w}_1-\mathbf{w}_2\|_{\mathcal{C}(0,T),H}\leqslant c\left(\int_0^T2\|v\|_{H^1}+\|\mathbf{w}_1\|_2+\|\mathbf{w}_2\|_2ds\right)\|\mathbf{w}_1-\mathbf{w}_2\|_{\mathcal{C}(0,T),H}$$
$$\leqslant c\left(2\sqrt{T}\left(\int_0^T\|\mathbf{v}\|_{H^1}^2ds\right)^{1/2}+2T(\|\mathbf{w}(0)\|_2+1)\right)\|\mathbf{w}_1-\mathbf{w}_2\|_{\mathcal{C}(0,T),H}.$$

Obviously by taking T small enough we can make this functional to take the ball of radius $\|\mathbf{w}(0)\|_2+1$ in itself in a contractive manner. The classical proof follows. ■

Let us study now the dependence of the solutions upon the velocity:

Theorem 2.4: *Let* $\mathbf{w}_1$, $\mathbf{w}_2$ *be the respective solutions of*

$$\frac{d\mathbf{w}_i}{dt} = F(\mathbf{w}_i, \mathbf{v}_i)$$
$$\mathbf{w}_i(0) = \mathbf{w}(0), \tag{15}$$

for $\mathbf{v}_i \in L^2((0,S),V)$, *and let* $(0,T)$ *be a common interval of existence of* $\mathbf{w}_1$, $\mathbf{w}_2$. *Then there exists* $T_1 \leqslant T$, *depending only on* $\|\mathbf{w}(0)\|_2$, $\|\mathbf{v}_i\|_{L^2((0,T),V)}$, *such that*

$$\|\mathbf{w}_1 - \mathbf{w}_2\|_{C((0,T_1),H)} \leqslant \tfrac{1}{2}\|\mathbf{v}_1 - \mathbf{v}_2\|_{L^2((0,T_1),V)}. \tag{16}$$

Proof: Using inequality (13), and taking an interval short enough for Therom 2.3 to hold for both $\mathbf{w}_i$,

$$\|\mathbf{w}_1(t) - \mathbf{w}_2(t)\|_2 = \left\| \int_0^t F(\mathbf{w}_1,\mathbf{v}_1) - F(\mathbf{w}_2,\mathbf{v}_2)ds \right\|_2 \leqslant c\int_0^t (\eta + \|\mathbf{v}_1\|_{H^1} + \|\mathbf{v}_2\|_{H^1} + \|\mathbf{w}_1\|_2 + \|\mathbf{w}_2\|_2)\|\mathbf{w}_1 - \mathbf{w}_2\|_2 + (\|\mathbf{w}_1\|_2 + \|\mathbf{w}_2\|_2)\|\mathbf{v}_1 - \mathbf{v}_2\|_{H^1}ds \leqslant c[\sqrt{T}(\|\mathbf{v}_1\|_{L^2((0,T),V)} + \|\mathbf{v}_2\|_{L^2((0,T),V)}) + T\eta + 2T(\|\mathbf{w}(0)\|_2 + 1)]\|\mathbf{w}_1 - \mathbf{w}_2\|_{C((0,T),H)} + 2\sqrt{T}(\|\mathbf{w}(0)\|_2 + 1)\|\mathbf{v}_1 - \mathbf{v}_2\|_{L^2((0,T),V)}.$$

Hence it is enough to take T_1 small enough for

$$c[\sqrt{T_1}(\|\mathbf{v}_1\|_{L^2((0,T_1),V)} + \|\mathbf{v}_2\|_{L^2((0,T_1),V)}) + T_1\eta + 2T_1(\|\mathbf{w}(0)\|_2 + 1)] < \tfrac{1}{2}, 2\sqrt{T_1}(\|\mathbf{w}(0)\|_2 + 1) < \tfrac{1}{4}.$$

III. MOMENTUM EQUATION

This is the Navier–Stokes one with two forcings: the independent one $\mathbf{f}$ and the Lorentz force $\mathbf{J}\times\mathbf{B}$. We will denote the last one by $G(\mathbf{w})$. Notice that

$$\|\mathbf{J}\times\mathbf{B}\|_2 \leqslant \|\mathbf{J}\|_4\|\mathbf{B}\|_4 \leqslant c\|\mathbf{w}\|_2^2. \tag{17}$$

We may apply the classical results (see, e.g., Ref. 8) and conclude the following.

(a) For every initial condition $\mathbf{v}(0) \in V$, there exists a unique solution for an interval $(0,T)$ satisfying

$$\|\mathbf{v}(t)\|_{H^1} \leqslant 2(\|\mathbf{v}(0)\|_{H^1} + 1), \tag{18}$$

where T depends only on $\|\mathbf{v}(0)\|_{H^1}$, $\|G(\mathbf{w})\|_{C((0,T),H)}$, $\sup_{(0,T)}\|\mathbf{f}\|_2$.

(b) $\mathbf{v} \in L^2((0,T),D(A))$, and the norm of $\mathbf{v}$ in this space is bounded by a constant depending only on the same quantities given in (a). We will first estimate the norm of $\mathbf{v}$ in the space $L^2((0,T),V)$. To emphasize its value, it is convenient to single out (only in this instance) the Poincaré constant in V, $\|\mathbf{v}\|_{H^1}^2 \leqslant k_p\|\nabla\mathbf{v}\|_2^2$.

Proposition 3.1.: If $\mathbf{v}$ is the solution of (4) in the interval $(0,T)$,

$$\|\mathbf{v}\|_{L^2((0,T),V)}^2 \leqslant \frac{k_p}{\nu}\|\mathbf{v}(0)\|_2^2 + c\frac{T}{\nu^2}\|\mathbf{w}\|_{C((0,T),H)}^4 + c\frac{T}{\nu^2}\sup_{(0,T)}\|\mathbf{f}\|_2^2. \tag{19}$$

Proof: By making the scalar product of (4) with $\mathbf{v}$, and using standard inequalities (Cauchy–Schwarz, Poincaré, and Young's),

$$\frac{1}{2}\frac{d\|\mathbf{v}\|_2^2}{dt} \leqslant -\nu\|\nabla\mathbf{v}\|_2^2 + \|G(\mathbf{w})\|_2\|\mathbf{v}\|_2 + \|\mathbf{f}\|_2\|\mathbf{v}\|_2 \leqslant -\nu\|\nabla\mathbf{v}\|_2^2 + c\|G(\mathbf{w})\|_2\|\nabla\mathbf{v}\|_2 + c\|\mathbf{f}\|_2\|\nabla\mathbf{v}\|_2$$

$$\leqslant -\nu\|\nabla\mathbf{v}\|_2^2 + \frac{c^2}{\nu}\|G(\mathbf{w})\|_2^2 + \frac{\nu}{4}\|\nabla\mathbf{v}\|_2^2 + \frac{c^2}{\nu}\|\mathbf{f}\|_2^2 + \frac{\nu}{4}\|\nabla\mathbf{v}\|_2^2.$$

Integrating in $(0,T)$ and omitting the term in $\|\mathbf{v}(t)\|_2$,

$$\frac{\nu}{2}\int_0^T \|\nabla\mathbf{v}\|_2^2 ds \leqslant \frac{1}{2}\|\mathbf{v}(0)\|_2^2 + \frac{c^2}{\nu}\int_0^T \|G(\mathbf{w})\|_2^2 ds + \frac{c^2}{\nu}\int_0^T \|\mathbf{f}\|_2^2 ds,$$

from which, in view of (17), the result follows. ■

Corollary 3.2.: There exists a time $T_1 \leqslant T$, depending only on $\|\mathbf{w}\|_{\mathcal{C}((0,T_1),H)}$, such that

$$\|\mathbf{v}\|_{L^2((0,T_1),V)} \leqslant \frac{k_p}{\sqrt{\nu}}\|\mathbf{v}(0)\|_2 + 1 \leqslant \frac{k_p}{\sqrt{\nu}}\|\mathbf{v}(0)\|_{H^1} + 1. \tag{20}$$

We will consider now the difference between two solutions corresponding to different $\mathbf{w}_i$ and the same initial condition:

Theorem 3.2: *Let* $\mathbf{v}_1, \mathbf{v}_2$ *be the respective solutions of Eq. (4) in* $(0,T)$ *corresponding to Lorentz forces* $\mathbf{w}_1, \mathbf{w}_2 \in \mathcal{C}((0,T),H)$ *and the same initial condition. Then there exists* $T_2 \leqslant T$, *depending only on* $\|\mathbf{w}_i\|_{\mathcal{C}((0,T),H)}$, *such that*

$$\|\mathbf{v}_1 - \mathbf{v}_2\|_{L^2((0,T_2),V)} \leqslant \frac{1}{2}\|\mathbf{w}_1 - \mathbf{w}_2\|_{\mathcal{C}((0,T_2),H)}. \tag{21}$$

Proof: The scalar product of $(\partial(\mathbf{v}_1 - \mathbf{v}_2))/(\partial t)$ with $\mathbf{v}_1 - \mathbf{v}_2$ yields

$$\frac{1}{2}\frac{\partial}{\partial t}\|\mathbf{v}_1 - \mathbf{v}_2\|_2^2 + \nu\|\nabla(\mathbf{v}_1 - \mathbf{v}_2)\|_2^2 = (-\mathbf{v}_1 \cdot \nabla\mathbf{v}_1 + \mathbf{v}_2 \cdot \nabla\mathbf{v}_2, \mathbf{v}_1 - \mathbf{v}_2) + (G(\mathbf{w}_1) - G(\mathbf{w}_2), \mathbf{v}_1 - \mathbf{v}_2)$$

$$-(\nabla(p_1 - p_2), \mathbf{v}_1 - \mathbf{v}_2).$$

The last term is zero. We have

$$(-\mathbf{v}_1 \cdot \nabla\mathbf{v}_1 + \mathbf{v}_2 \cdot \nabla\mathbf{v}_2, \mathbf{v}_1 - \mathbf{v}_2) = (-\mathbf{v}_1 \cdot \nabla(\mathbf{v}_1 - \mathbf{v}_2) + (-\mathbf{v}_1 + \mathbf{v}_2) \cdot \nabla\mathbf{v}_2, \mathbf{v}_1 - \mathbf{v}_2),$$

and $(-\mathbf{v}_1 \cdot \nabla(\mathbf{v}_1 - \mathbf{v}_2), \mathbf{v}_1 - \mathbf{v}_2) = 0$. By using inequality (10), we find

$$|(-\mathbf{v}_1 \cdot \nabla\mathbf{v}_1 + \mathbf{v}_2 \cdot \nabla\mathbf{v}_2, \mathbf{v}_1 - \mathbf{v}_2)| \leqslant \|\mathbf{v}_1 - \mathbf{v}_2\|_{H^1}\|\mathbf{v}_1 - \mathbf{v}_2\|_2\|\mathbf{v}_2\|_{H^1}^{1/2}\|A\mathbf{v}_2\|_2^{1/2}.$$

Finally

$$|(G(\mathbf{w}_1) - G(\mathbf{w}_2), \mathbf{v}_1 - \mathbf{v}_2)| \leqslant \|G(\mathbf{w}_1) - G(\mathbf{w}_2)\|_2\|\mathbf{v}_1 - \mathbf{v}_2\|_2.$$

In order to abbreviate the notation, let us denote by $\|g\|_{2,\infty}$ the supremum of $\|g\|_2$ when $t \in (0,T)$. Property (a) of the solutions of the Navier–Stokes equations guarantees that $\|\mathbf{v}_2\|_{H^1}$ is bounded in $(0,T)$ by an amount depending only on $\|\mathbf{v}_2(0)\|_{H^1}$, $\|G(\mathbf{w}_2)\|_{2,\infty}$, and $\|\mathbf{f}\|_{2,\infty}$. Let M be an upper bound of $\|\mathbf{v}_2\|_{H^1}^{1/2}$ in $(0,T)$. Integrating the resulting inequality in time,

$$\frac{1}{2}\|(\mathbf{v}_1-\mathbf{v}_2)(t)\|_2^2+\nu\int_0^t\|\nabla(\mathbf{v}_1-\mathbf{v}_2)\|_2^2\mathrm{d}s$$

$$\leqslant cM\int_0^t\|\mathbf{v}_1-\mathbf{v}_2\|_2\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}\|\mathbf{v}_2\|_{H^2}^{1/2}\mathrm{d}s+c\int_0^t\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_2\|\mathbf{v}_1-\mathbf{v}_2\|_2\mathrm{d}s$$

$$\leqslant cM\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}\left(\int_0^T\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2\mathrm{d}s\right)^{1/2}\left(\int_0^T\|\mathbf{v}_2\|_{H^2}\mathrm{d}s\right)^{1/2}$$

$$+cT\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}. \tag{22}$$

Since this is valid for any $t\in(0,T)$, by considering only the first term in the left-hand side of (22) and using Young's inequality,

$$\frac{1}{2}\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}^2\leqslant\frac{c^2M^2}{2}\left(\int_0^T\|\mathbf{v}_2\|_{H^2}\mathrm{d}s\right)\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}^2+\frac{1}{2}\int_0^T\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2\mathrm{d}s+\frac{T}{2}\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}^2$$

$$+\frac{c^2}{2}T\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}^2.$$

Since by property (b)

$$\int_0^T\|\mathbf{v}_2\|_{H^2}\mathrm{d}s\leqslant\sqrt{T}\left(\int_0^T\|\mathbf{v}_2\|_{H^2}^2\mathrm{d}s\right)^{1/2}\leqslant N\sqrt{T},$$

where N is a constant depending on the same functions stated before for $\|\mathbf{v}_2\|_{H^1}$, we find

$$(1-c^2M^2N\sqrt{T}-c^2T)\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}^2\leqslant\int_0^T\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2\mathrm{d}s+T\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}^2.$$

Taking T small enough for the constant before $\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}^2$ to be at least $1/2$, we find

$$\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}^2\leqslant 2\int_0^T\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2\mathrm{d}s+2T\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}^2,$$

which implies

$$\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}\leqslant\sqrt{2}\left(\int_0^T\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2\mathrm{d}s\right)^{1/2}+\sqrt{2}T\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}. \tag{23}$$

Let us now return to (22) omitting now the term $\|(\mathbf{v}_1-\mathbf{v}_2)(t)\|_{2,\infty}^2$, and bounding the last term in a slightly different form:

$$\int_0^T\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_2\|\mathbf{v}_1-\mathbf{v}_2\|\mathrm{d}s\leqslant\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\int_0^T\|\mathbf{v}_1-\mathbf{v}_2\|_2\mathrm{d}s$$

$$\leqslant\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\int_0^T\|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}\mathrm{d}s.$$

By using again Poincaré's inequality on $\mathbf{v}_1-\mathbf{v}_2$, we get

$$\nu\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s$$
$$\leqslant cM\|\mathbf{v}_1-\mathbf{v}_2\|_{2,\infty}\left(\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s\right)^{1/2}\left(\int_0^T \|\mathbf{v}_2\|_{H^2}\mathrm{d}s\right)^{1/2}$$
$$+ c\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}\mathrm{d}s. \tag{24}$$

This, jointly with (23), yields

$$\nu\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s \leqslant cM\left(\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s\right)\left(\int_0^T \|\mathbf{v}_2\|_{H^2}\mathrm{d}s\right)^{1/2}$$
$$+ cM\sqrt{T}\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\left(\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s\right)^{1/2}\left(\int_0^T \|\mathbf{v}_2\|_{H^2}\mathrm{d}s\right)^{1/2}$$
$$+ c\sqrt{T}\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\left(\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s\right)^{1/2}.$$

Our previous bound on the H^2 norm of $\mathbf{v}_2$ and Young's inequality yield

$$\nu\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s \leqslant cMN^{1/2}T^{1/4}\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s$$
$$+ cMN^{1/2}T^{3/4}\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\left(\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s\right)^{1/2}$$
$$+ c\sqrt{T}\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}\left(\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s\right)^{1/2}$$
$$\leqslant \left(cMN^{1/2}T^{1/4}+\frac{c^2M^2N}{2}T^{3/4}+\frac{c^2}{2}T^{1/2}\right)\int_0^T \|\mathbf{v}_1-\mathbf{v}_2\|_{H^1}^2 \mathrm{d}s$$
$$+ \frac{1}{2}(T^{3/4}+T^{1/2})\|G(\mathbf{w}_1)-G(\mathbf{w}_2)\|_{2,\infty}^2.$$

It is therefore to take $T_2 \leqslant T$ small enough for

$$cMN^{1/2}T_2^{1/4}+c^2M^2NT_2^{3/4}+c^2T_2^{1/2} \leqslant \frac{\nu}{2},\ T_2^{3/4}+T_2^{1/2} \leqslant \frac{\nu}{2},$$

for the theorem to hold. Notice that if we know an *a priori* bound on

$$\|\mathbf{w}_i\|_{2,\infty} = \|\mathbf{w}_i\|_{C((0,T),H)}$$

(say $\|\mathbf{w}(0)\|_2+1$), then M and N may also be bounded *a priori* and T_2 does not depend on any unknown quantity. ■

IV. EXISTENCE AND UNIQUENESS OF THE SOLUTIONS

We now state the main theorem of the paper. For the benefit of readers unwilling to spend time mastering all the previous mathematical notations, perhaps it is appropriate to state the result, at least approximately, in words: *When the velocity at time $t=0$ is differentiable, and the magnetic field is twice differentiable, there exists a solution of the two-fluid magnetohydrodynamics equations up to some time T. This solution is such that the velocity and its differential (with respect to*

the space variables) are continuous in time, and the magnetic field, plus its first and second differentials, are also continous in time. The rigorous form is as follows.

Theorem 4.1: *Take initial conditions* $\mathbf{v}(0)=\mathbf{v}_0 \in V$, $\mathbf{B}(0)=\mathbf{B}_0 \in D(A)$. *Then there exists an interval* $[0,T]$ *such that the two-fluid MHD Eqs. (4) and (5) have a unique solution. Moreover*

$$\mathbf{v} \in \mathcal{C}((0,T),V) \cap L^2((0,T),D(A)),$$
$$\mathbf{B} \in \mathcal{C}((0,T),D(A)). \tag{25}$$

Proof: Take $T>0$ small enough for:

(a) For $\mathbf{v}^* \in L^2((0,T),V)$, with

$$\|\mathbf{v}^*\|_{L^2((0,T),V)} \leqslant \frac{k_p}{\sqrt{\nu}}\|\mathbf{v}_0\|_{H^1} + 1, \tag{26}$$

the solution of

$$\frac{d\mathbf{w}}{dt} = F(\mathbf{w},\mathbf{v}^*), \tag{27}$$

$$\mathbf{w}(0) = \mathbf{w}_0 = -\alpha\Delta\mathbf{B}_0 + \mathbf{B}_0, \tag{28}$$

satisfies

$$\|\mathbf{w}\|_{\mathcal{C}((0,T),H)} \leqslant \|\mathbf{w}(0)\|_2 + 1, \tag{29}$$

and, for two functions $\mathbf{v}_1^*, \mathbf{v}_2^*$ satisfying (26), the solutions of

$$\frac{d\mathbf{w}_i}{dt} = F(\mathbf{w}_i,\mathbf{v}_i^*), \tag{30}$$

$$\mathbf{w}_i(0) = -\alpha\Delta\mathbf{B}_0 + \mathbf{B}_0, \tag{31}$$

satisfy

$$\|\mathbf{w}_1 - \mathbf{w}_2\|_{\mathcal{C}((0,T),H)} \leqslant \tfrac{1}{2}\|\mathbf{v}_1^* - \mathbf{v}_2^*\|_{L^2((0,T),V)}. \tag{32}$$

(b) For $\mathbf{w}^* \in \mathcal{C}((0,T),H)$, with

$$\|\mathbf{w}^*\|_{\mathcal{C}((0,T),H)} \leqslant \|\mathbf{w}(0)\|_2 + 1, \tag{33}$$

the solution of

$$\frac{\partial\mathbf{v}}{\partial t} = \nu\Delta\mathbf{v} - \mathbf{v}\cdot\nabla\mathbf{v} + G(\mathbf{w}^*) - \nabla p + \mathbf{f},$$
$$\mathbf{v}(0) = \mathbf{v}_0, \tag{34}$$

satisfies

$$\|\mathbf{v}\|_{L^2((0,T),V)} \leqslant \frac{k_p}{\sqrt{\nu}}\|\mathbf{v}_0\|_{H^1} + 1, \tag{35}$$

and, for two functions $\mathbf{w}_1^*, \mathbf{w}_2^*$ satisfying (33), the solutions of (34) with parameters $\mathbf{w}_1^*$ and $\mathbf{w}_2^*$ satisfy

$$\|\mathbf{v}_1-\mathbf{v}_2\|_{L^2((0,T),V)}\leqslant\tfrac{1}{2}\|\mathbf{w}_1^*-\mathbf{w}_2^*\|_{\mathcal{C}((0,T),H)}. \tag{36}$$

That T may be found satisfying (a) follows from Theorems 2.3 and 2.4, whereas proposition 3.1 and Theorem 3.2 guarantee that for T small enough, it also satisfies (b). Then the mapping defined in the product

$$\bar{B}_{L^2((0,T),V)}\left(\frac{k_p}{\sqrt{\nu}}\|\mathbf{v}_0\|_{H^1}+1\right)\times\bar{B}_{\mathcal{C}((0,T),H)}(\|\mathbf{w}_0\|_2+1) \tag{37}$$

and given by $(\mathbf{v}^*,\mathbf{w}^*)\to(\mathbf{v},\mathbf{w})$, takes this product of balls into itself in a contractive manner. Therefore it has a unique fixed point. This is a solution of the equation, and conversely every solution is a fixed point, which guarantees uniqueness. Although in principle we only know that $\mathbf{v}\in L^2((0,T),V)$, since $\mathbf{w}$ and therefore $G(\mathbf{w})$ are uniformly bounded in H for all $t\in(0,T)$, implies that $\mathbf{v}$, as the solution to a Navier–Stokes equation with a bounded forcing, belongs to $\mathcal{C}((0,T),V)\cap L^2((0,T),D(A))$. On the other hand, since $\|\mathbf{B}\|_{H^2}\leqslant c\|\mathbf{w}\|_2$, we find $\mathbf{B}\in\mathcal{C}((0,T),D(A))$.

V. FINAL CONSIDERATIONS

The key difference with classical MHD is that the induction equation is actually simpler in our case, since the advective and diffusive terms are actually continuous functions of the new variable $\mathbf{w}=\alpha\boldsymbol{\nabla}\times\mathbf{J}+\mathbf{B}$. However, this will not help us to prove global existence. For one thing, the induction equation remains nonlinear in $\mathbf{w}$; and second, no matter how regular the magnetic field is, the momentum equation is a Navier–Stokes one, where global existence of solutions is a celebrated unsolved question. Still, it is apparent from our proofs that the difussive term $\eta\Delta\mathbf{B}$ does not play any role and can be dispensed with. This is in sharp contrast with one-fluid MHD, and it is a welcome feature, since most of the reconnection models where two-fluid MHD becomes necessary are actually infinitely conducting, i.e., the resistivity is taken as zero. That the two-fluid MHD equations yield more regularity than the classical MHD ones is apparent from the following energy inequality: it does not involve the L^2-norm of $\mathbf{w}$, whose evolution is complex, but rather the current density norm.

Theorem 5.1: *Let k_p be the Poincaré constant $\|\mathbf{v}\|_2^2\leqslant k_p\|\nabla\mathbf{v}\|_2^2$. The solutions to systems (4) and (5) satisfy, for as long as they are defined*,

$$\begin{aligned}&\alpha\|\mathbf{J}(t)\|_2^2+\|\mathbf{B}(t)\|_2^2+\|\mathbf{v}(t)\|_2^2+2\eta\int_0^t\|\nabla\mathbf{B}\|_2^2+\nu\int_0^t\|\nabla\mathbf{v}\|_2^2\mathrm{d}s\\&\leqslant\alpha\|\mathbf{J}(0)\|_2^2+\|\mathbf{B}(0)\|_2^2+\|\mathbf{v}(0)\|_2^2+\frac{k_p}{\nu}\int_0^t\|\mathbf{f}\|_2^2\mathrm{d}s.\end{aligned} \tag{38}$$

Proof: With our boundary conditions

$$\int_\Omega J^2\mathrm{d}V=\int_\Omega\mathbf{J}\cdot(\nabla\times\mathbf{B})\mathrm{d}V=\int_\Omega(\nabla\times\mathbf{J})\cdot\mathbf{B}\,\mathrm{d}V=-\int_\Omega\Delta\mathbf{B}\cdot\mathbf{B}\,\mathrm{d}V=\int_\Omega|\nabla\mathbf{B}|^2\mathrm{d}V.$$

Therefore

$$\frac{\partial}{\partial t}\int_\Omega J^2\mathrm{d}V=2\int_\Omega\frac{\partial\nabla\mathbf{B}}{\partial t}\cdot\nabla\mathbf{B}\,\mathrm{d}V=-2\int_\Omega\frac{\partial\Delta\mathbf{B}}{\partial t}\cdot\mathbf{B}\,\mathrm{d}V=2\int_\Omega\frac{\partial(\nabla\times\mathbf{J})}{\partial t}\cdot\mathbf{B}\,\mathrm{d}V.$$

Let us multiply the momentum equation by $\mathbf{v}$, the induction one by $\mathbf{B}$, and add both. As in classical MHD, the advective terms add to zero, as well as

$$\int_\Omega \nabla\left(\frac{1}{2}B^2+p\right)\cdot\mathbf{v}\,\mathrm{d}V=\int_{\partial\Omega}\left(\frac{1}{2}B^2+p\right)\mathbf{v}\cdot\mathbf{n}\,\mathrm{d}\sigma=0.$$

As for the Hall term,

$$\int_\Omega(\nabla\times(\mathbf{J}\times\mathbf{B}))\cdot\mathbf{B}\,\mathrm{d}V=\int_\Omega(\mathbf{J}\times\mathbf{B})\cdot\mathbf{J}\,\mathrm{d}V=0.$$

Writing as usual

$$\left|\int_\Omega \mathbf{f}\cdot\mathbf{v}\,\mathrm{d}V\right|\leqslant\sqrt{k_p}\|\mathbf{f}\|_2\|\nabla\mathbf{v}\|_2\leqslant\frac{\nu}{2}\|\nabla\mathbf{v}\|_2^2+\frac{k_p}{2\nu}\|\mathbf{f}\|_2^2,$$

we obtain the stated inequality. ■

Thus, although the main existence theorem proved a finite-time bound for the maximum of $\|\mathbf{v}\|_{H^1}$ and $\|\mathbf{B}\|_{H^2}$, the present one remains valid for as long as the integrals make sense and is therefore more robust than the previous one. It plays the role of the energy inequality for MHD, but supplies more information about the smoothness of the field. Whereas in one-fluid MHD it was the total (kinetic plus magnetic) energy $\|\mathbf{v}\|_2^2+\|\mathbf{B}\|_2^2$ which remained bounded, here also the current density energy $\|\mathbf{J}\|_2^2$ does: hence the H^1-norm of the magnetic field is kept by the flow, which precludes any sharp gradients.

A relaxation method for constructing a Beltrami flow in a bounded domain

Takahiro Nishiyama[a)]
Department of Applied Science, Faculty of Engineering, Yamaguchi University, Ube 755-8611, Japan

(Received 10 March 2005; accepted 15 June 2005; published online 1 August 2005)

It is shown that a time-dependent equation generates a Beltrami flow (or a force-free field) at time $t=\infty$ from non-Beltrami initial data in an arbitrary bounded domain in three dimensions. The generated Beltrami flow has a zero normal component on the boundary and its helicity is equal to a prescribed value. The existence and uniqueness of a solution to the equation are guaranteed globally in time and no finite-time singularity occurs. © *2005 American Institute of Physics.*

I. INTRODUCTION

The three-dimensional function $\mathbf{u}$ which satisfies

$$(\nabla \times \mathbf{u}) \times \mathbf{u} = \mathbf{0}, \quad \nabla \cdot \mathbf{u} = 0 \tag{1}$$

is called a Beltrami flow or a force-free field. It is known to play an important role in fluid mechanics, magnetohydrodynamics, astrophysics, etc., and has been studied by many authors (see Refs. 4–7, 9, 13, 17, 21, and 28, and references therein). One of its properties is that its streamlines (field lines of $\mathbf{u}$) can be complex. In fact, Dombre *et al.*[10] showed that the Arnold–Beltrami–Childress (ABC) flow, which is a spatially periodic solution of $\nabla \times \mathbf{u} = \mathbf{u}$, has chaotic streamlines (see also Refs. 12 and 29). Moreover, it was shown in Refs. 23 and 30 that some Beltrami flows in a sphere have chaotic streamlines, too.

It is obvious that every Beltrami flow is a solution to the stationary Euler equations. Moffatt[19,20] pointed out that some nonstationary systems of equations for a viscous and perfectly conductive magnetofluid generate stationary Euler flows, at time $t=\infty$, whose streamline topology is complex if the topology of initial magnetic force lines is complex. Vallis *et al.*[27] obtained stationary Euler flows as equilibria of the nonstationary Euler equations with an artificial term added.

Using these ideas of Moffatt and Vallis *et al.*, the author[22] proposed the equation

$$\mathbf{w}_t = \nabla \times \{[(\nabla \times \mathbf{w}) \times \mathbf{w}] \times \mathbf{w}\} \tag{2}$$

with periodic boundary conditions. He deduced that its solution $\mathbf{w}$ converges to a Beltrami flow, as $t \to \infty$, by noting that $(\nabla \cdot \mathbf{w})_t = 0$,

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathrm{cube}} |\mathbf{w}|^2 \mathrm{d}^3\mathbf{x} = -\int_{\mathrm{cube}} |(\nabla \times \mathbf{w}) \times \mathbf{w}|^2 \mathrm{d}^3\mathbf{x},$$

[a)]Electronic mail: t-nishi@yamaguchi-u.ac.jp

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathrm{cube}} \boldsymbol{\phi}\cdot\mathbf{w}\,\mathrm{d}^3\mathbf{x}=0.$$

Here "cube" means a cube in which periodic boundary conditions are applied and $\boldsymbol{\phi}$ is a vector potential of $\mathbf{w}$. Furthermore, noting that (2) is similar to the vorticity equation of a compressible perfect fluid, we can rewrite it as

$$\left(\frac{\mathbf{w}}{\rho}\right)_t+(\mathbf{U}\cdot\boldsymbol{\nabla})\frac{\mathbf{w}}{\rho}=\left(\frac{\mathbf{w}}{\rho}\cdot\boldsymbol{\nabla}\right)\mathbf{U}\quad\text{with}\quad\rho_t+\boldsymbol{\nabla}\cdot(\rho\mathbf{U})=0,$$

where $\mathbf{U}=(\boldsymbol{\nabla}\times\mathbf{w})\times\mathbf{w}$. This implies that field lines of $\mathbf{w}/\rho$ are "frozen" in the fluid which moves with the pseudo-velocity $\mathbf{U}$. Therefore, we can obtain a Beltrami flow $\mathbf{w}|_{t=\infty}$ with complex streamline topology if topologically complex initial data $\mathbf{w}|_{t=0}$ are given. However, from a practical point of view, (2) has some problems. The integrability of $|\boldsymbol{\nabla}\times\mathbf{w}|^2$ over the cube at $t=\infty$ is not guaranteed and some singularities may occur at finite time. Besides, the applicability of (2) to a nonperiodic case has not been known.

The aim of this paper is to propose a time-dependent equation, (11) below, which generates a Beltrami flow at $t=\infty$ from non-Beltrami initial data in a bounded domain Ω in three dimensions. Here Ω is simply or multiply connected and its shape is arbitrary but its boundary $\partial\Omega$ is sufficiently smooth. The Beltrami flow obtained in this way has a zero normal component on $\partial\Omega$. Its helicity, which measures the degree of knottedness of vortex lines, is equal to a prescribed value, although (11) does not have frozen-field structure unlike (2). These facts are shown in Sec. III, after introducing some inequalities of function analysis and an operator P_X in Sec. II.

In addition to the applicability to a nonperiodic case, another advantage of (11) over (2) is that the existence and uniqueness of a solution to our initial-boundary value problem for (11) can be proved globally in time. Moreover, this solution at any $t<\infty$ is as smooth as initial data, that is, no finite-time singularity occurs. These are studied in Sec. IV. In Sec. V, our results are summarized.

We can rewrite (1) as $\boldsymbol{\nabla}\times\mathbf{u}=\lambda\mathbf{u}$ with a scalar function λ satisfying $\mathbf{u}\cdot\boldsymbol{\nabla}\lambda=0$. The existence of solutions $\mathbf{u}$ to boundary value problems for this equation was rigorously proved for constant λ in Refs. 7, 17, and 28, and for nonconstant λ in Refs. 5 and 13. Our method is completely different from the approaches in these references, although it is open whether λ is constant or nonconstant for our Beltrami flow.

The time evolution of solutions to (11) does not seem difficult to investigate numerically. This approach to numerical construction of a Beltrami flow is completely different from the algorithms in Refs. 4 and 6.

II. PRELIMINARIES

First, we define the norms $\|\cdot\|_{L^p}$, $\langle\langle\cdot\rangle\rangle_{n,L^p}$, and $\|\cdot\|_{n,L^p}$ $(n=1,2,3,\ldots;\ p\geqslant 1)$ by

$$\|\mathbf{f}\|_{L^p}=\left(\int_\Omega|\mathbf{f}|^p\mathrm{d}^3\mathbf{x}\right)^{1/p},$$

$$\langle\langle\mathbf{f}\rangle\rangle_{n,L^p}=\left(\sum_{k+l+m=n}\left\|\frac{\partial^n\mathbf{f}}{\partial x_1^k\,\partial x_2^l\,\partial x_3^m}\right\|_{L^p}^p\right)^{1/p},$$

$$\|\mathbf{f}\|_{n,L^p}=\left(\|\mathbf{f}\|_{L^p}^p+\sum_{k=1}^{n}\langle\langle\mathbf{f}\rangle\rangle_{k,L^p}^p\right)^{1/p}.$$

Particularly, in the case $p=2$, they are simply written as $\|\cdot\|$, $\langle\langle\cdot\rangle\rangle_n$, and $\|\cdot\|_n$, respectively.

The inequalities

$$\|\mathbf{f}\|_{L^q} \leqslant C\|\mathbf{f}\|_{1,L^p}, \quad 1 \leqslant p < 3, \quad 1 \leqslant q \leqslant \frac{3p}{3-p}, \tag{3}$$

$$\sup_{\mathbf{x}\in\Omega}|\mathbf{f}(\mathbf{x})| + \sup_{\mathbf{x},\mathbf{x}'\in\Omega}\frac{|\mathbf{f}(\mathbf{x})-\mathbf{f}(\mathbf{x}')|}{|\mathbf{x}-\mathbf{x}'|^{1-3/p}} \leqslant C\|\mathbf{f}\|_{1,L^p}, \quad p > 3 \tag{4}$$

are derived from the embedding theorem (see Ref. 16). Here, and from now on, we use C to denote positive constants independent of estimated functions. Its value depends on each individual equality or inequality. In the same way, C' will be also used.

It is well known that Hölder's inequality

$$\int_\Omega \prod_{k=1}^{n} |\mathbf{f}_k| \mathrm{d}^3\mathbf{x} \leqslant \|\mathbf{f}_1\|_{L^p}\|\mathbf{f}_2\|_{L^q}\cdots\|\mathbf{f}_n\|_{L^r} \tag{5}$$

is valid when $p^{-1}+q^{-1}+\cdots+r^{-1}=1$. Its combination with Young's inequality leads to

$$\int_\Omega \prod_{k=1}^{n} |\mathbf{f}_k| \mathrm{d}^3\mathbf{x} \leqslant \|\mathbf{f}_1\|_{L^p}^p + \|\mathbf{f}_2\|_{L^q}^q + \cdots + \|\mathbf{f}_n\|_{L^r}^r. \tag{6}$$

If $(\mathrm{d}/\mathrm{d}t)y(t) \leqslant c_1(t)y(t)+c_2(t)$ for non-negative functions y, c_1, and c_2, then Gronwall's inequality

$$y(t) \leqslant \left[y(0) + \int_0^t c_2(t')\mathrm{d}t' \right] \exp\left[\int_0^t c_1(t')\mathrm{d}t' \right] \tag{7}$$

is valid (an extension of Lemma 5.5 of Ref. 16).

It was shown in Refs. 11 and 24 that the space $\mathbf{L}^p(\Omega)=\{\mathbf{f}:\Omega\to\mathbf{R}^3 \,|\, \|\mathbf{f}\|_{L^p}<\infty\}$ with $p>1$ is decomposed into the two subspaces

$$L^p_\sigma = \{\mathbf{f}\in\mathbf{L}^p(\Omega) \,|\, \nabla\cdot\mathbf{f}=0,\ \mathbf{f}\cdot\hat{\mathbf{n}}|_{\partial\Omega}=0\}, \quad G_p = \{\mathbf{f}|\mathbf{f}=\nabla Q,\ \|Q\|_{1,L^p}<\infty\},$$

where $\hat{\mathbf{n}}$ is the unit outward normal vector on $\partial\Omega$. Moreover, if Ω is $(N+1)$-ply connected and the N cuts $\Sigma_1,\Sigma_2,\ldots,\Sigma_N$ ($\Sigma_j\cap\Sigma_k=\emptyset$ for $j\neq k$) make $\Omega-\cup_{j=1}^N\Sigma_j$ simply connected, then L^p_σ is decomposed into

$$X_p = \left\{ \mathbf{f}\in L^p_\sigma \,\middle|\, \int_{\Sigma_j}\mathbf{f}\cdot\hat{\mathbf{n}}_j\mathrm{d}S = 0 \text{ for } j=1,2,\cdots,N \right\}$$

and the N-dimensional irrotational subspace F_N spanned by $\{\nabla Q_1, \nabla Q_2, \ldots, \nabla Q_N\}$. Here $\hat{\mathbf{n}}_j$ is a unit normal vector on Σ_j and Q_j is a solution to

$$\Delta Q_j = 0 \quad \text{in } \Omega - \cup_{k=1}^N\Sigma_k,$$

$$\nabla Q_j\cdot\hat{\mathbf{n}}|_{\partial\Omega}=0, \quad [\nabla Q_j\cdot\hat{\mathbf{n}}_k]_k = 0 \text{ for } k=1,2,\ldots,N,$$

$$[Q_j]_k = \begin{cases} 1 \text{ for } k=j \\ 0 \text{ for } k\neq j, \end{cases}$$

$[\cdot]_k$ denotes the jump of value in passing through Σ_k in the opposite direction to $\hat{\mathbf{n}}_k$ (see Ref. 26). For example, when Ω is the interior of a torus ($N=1$) which is symmetrical with respect to the x_3-axis, $\Sigma_1=\Omega\cap\{\theta=0\}$ and $Q_1=\theta/(2\pi)$ in the cylindrical coordinate system (R,θ,x_3). Another equivalent definition of F_N was introduced in Refs. 3 and 8. If Ω is simply connected, then we set $X_p=L^p_\sigma$.

Let us introduce the projection operator P_X from $\mathbf{L}^p(\Omega)$, $p>1$, onto X_p such that

$$\nabla\cdot(P_X\mathbf{f})=0,\quad (P_X\mathbf{f})\cdot\hat{\mathbf{n}}|_{\partial\Omega}=0\quad \text{for any } \mathbf{f}\in\mathbf{L}^p(\Omega),$$

and in addition,

$$\int_{\Sigma_j}(P_X\mathbf{f})\cdot\hat{\mathbf{n}}_j\mathrm{d}S=0 \text{ for } j=1,2,\ldots,N \text{ if } \Omega \text{ is } (N+1)\text{-ply connected.}$$

When Ω is simply connected, we define P_X by $P_X\mathbf{f}=\mathbf{f}-\nabla Q_0$ with Q_0 satisfying

$$\Delta Q_0=\nabla\cdot\mathbf{f},\quad \nabla Q_0\cdot\hat{\mathbf{n}}|_{\partial\Omega}=\mathbf{f}\cdot\hat{\mathbf{n}}|_{\partial\Omega}. \tag{8}$$

In general, it is not easy to write Q_0 explicitly by using $\mathbf{f}$. For example, however, if Ω is the interior of a unit sphere, then

$$Q_0(\mathbf{x})=\int_\Omega G(\mathbf{x},\mathbf{x}')\nabla\cdot\mathbf{f}(\mathbf{x}')\mathrm{d}^3\mathbf{x}'-\int_{\partial\Omega}G(\mathbf{x},\mathbf{x}')\mathbf{f}(\mathbf{x}')\cdot\hat{\mathbf{n}}(\mathbf{x}')\mathrm{d}S'+\text{const},$$

where

$$G(\mathbf{x},\mathbf{x}')=-\frac{1}{4\pi}\left(\frac{1}{|\mathbf{x}-\mathbf{x}'|}+\frac{1}{|\mathbf{x}'||\mathbf{x}-\mathbf{x}^*|}+\ln\frac{1}{1-\mathbf{x}\cdot\mathbf{x}'+|\mathbf{x}'||\mathbf{x}-\mathbf{x}^*|}\right)$$

and $\mathbf{x}^*=\mathbf{x}'/|\mathbf{x}'|^2$ (see Eq. (2.6.62) in Ref. 14).

When Ω is $(N+1)$-ply connected, we define P_X by

$$P_X\mathbf{f}=\mathbf{f}-\nabla Q_0-\sum_{j=1}^N a_j\nabla Q_j.$$

Here Q_0 is determined by (8) with $\int_{\Sigma_j}\nabla Q_0\cdot\hat{\mathbf{n}}_j\mathrm{d}S=0$ $(j=1,2,\ldots,N)$ and a_j is given by the system of N linear equations

$$\sum_{k=1}^N\left(\int_{\Sigma_j}\nabla Q_k\cdot\hat{\mathbf{n}}_j\mathrm{d}S\right)a_k=\int_{\Sigma_j}\mathbf{f}\cdot\hat{\mathbf{n}}_j\mathrm{d}S,$$

which is uniquely solvable [Eq. (1.18) in Ref. 26].

The inequality

$$\|P_X\mathbf{f}\|_{L^p}\leqslant C\|\mathbf{f}\|_{L^p},\quad p>1 \tag{9}$$

was proved in Refs. 11 and 24. Moreover, using Lemma 2.14 of Ref. 15 in Ω (or $\Omega-\cup_{j=1}^N\Sigma_j$ if Ω is $(N+1)$-ply connected) and noting that $\nabla\times P_X\mathbf{f}=\nabla\times\mathbf{f}$, we have

$$\left.\begin{aligned}\|P_X\mathbf{f}\|_{1,L^p}&\leqslant C\|\nabla\times\mathbf{f}\|_{L^p},\quad p\geqslant 2,\\ \|P_X\mathbf{f}\|_{n+1,L^q}&\leqslant C\|\nabla\times\mathbf{f}\|_{n,L^q},\quad n=1,2,3,\ldots;q>1.\end{aligned}\right\} \tag{10}$$

III. MAIN EQUATION AND BELTRAMI FLOW

The following is our main equation:

$$\boldsymbol{\omega}_t=P_X\left[\frac{(\boldsymbol{\omega}\times\mathbf{v})\times\mathbf{v}}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\right] \tag{11}$$

with $\mathbf{v}$ defined by $\mathbf{v}=P_X\mathbf{V}$, where

$$\mathbf{V} = \nabla \times \boldsymbol{\Psi} = \nabla \times \int_\Omega \frac{\boldsymbol{\omega}(\mathbf{x}',t)}{4\pi|\mathbf{x}-\mathbf{x}'|}\mathrm{d}^3\mathbf{x}' = \int_\Omega \frac{\boldsymbol{\omega}(\mathbf{x}',t)\times(\mathbf{x}-\mathbf{x}')}{4\pi|\mathbf{x}-\mathbf{x}'|^3}\mathrm{d}^3\mathbf{x}'.$$

As an initial condition,

$$\boldsymbol{\omega}|_{t=0} = \boldsymbol{\omega}_0(\mathbf{x}) \tag{12}$$

is imposed, where $\boldsymbol{\omega}_0 \in X_2$, that is,

$$\left.\begin{array}{c} \nabla\cdot\boldsymbol{\omega}_0 = 0, \quad \boldsymbol{\omega}_0\cdot\hat{\mathbf{n}}\big|_{\partial\Omega} = 0, \quad \|\boldsymbol{\omega}_0\| < \infty \\ \left(\text{and}\int_{\Sigma_j}\boldsymbol{\omega}_0\cdot\hat{\mathbf{n}}_j\mathrm{d}S = 0 \text{ for } j = 1,2,\ldots,N \text{ if } \Omega \text{ is } (N+1)\text{-ply connected}\right). \end{array}\right\} \tag{13}$$

We denote $\mathbf{v}|_{t=0}$ by $\mathbf{v}_0$ and assume that it is non-Beltrami, that is,

$$(\nabla\times\mathbf{v}_0)\times\mathbf{v}_0 \not\equiv \mathbf{0}. \tag{14}$$

In this section, let us consider the evolution of $\boldsymbol{\omega}$ (and $\mathbf{v}$) for $t>0$ and show that $\mathbf{v}|_{t=\infty}$ is a Beltrami flow whose normal component on $\partial\Omega$ vanishes and helicity is equal to $\int_\Omega \mathbf{v}_0\cdot\boldsymbol{\omega}_0\mathrm{d}^3\mathbf{x}$.

First, it should be noted that $P_X\boldsymbol{\omega}=\boldsymbol{\omega}$, that is, $\nabla\cdot\boldsymbol{\omega}=0$ and $\boldsymbol{\omega}\cdot\hat{\mathbf{n}}|_{\partial\Omega}=0$ for every $t>0$ because of (13) and $P_X\boldsymbol{\omega}_t=\boldsymbol{\omega}_t$. This fact yields that $\nabla\cdot\boldsymbol{\Psi}=0$ (see Ref. 1) and we get

$$\nabla\times\mathbf{v} = \nabla\times\mathbf{V} = -\Delta\boldsymbol{\Psi} = \boldsymbol{\omega}.$$

It is clear that $\nabla\cdot\mathbf{v}=\nabla\cdot\mathbf{V}=0$. The difference between $\mathbf{v}$ and $\mathbf{V}$ is that $\mathbf{v}\cdot\hat{\mathbf{n}}|_{\partial\Omega}=0$ for all $t\in[0,\infty]$, while $\mathbf{V}\cdot\hat{\mathbf{n}}|_{\partial\Omega}$ does not always vanish.

Note that

$$\int_\Omega (P_X\mathbf{f})\cdot\mathbf{g}\,\mathrm{d}^3\mathbf{x} = \int_\Omega \mathbf{f}\cdot(P_X\mathbf{g})\mathrm{d}^3\mathbf{x} = \int_\Omega (P_X\mathbf{f})\cdot(P_X\mathbf{g})\mathrm{d}^3\mathbf{x}$$

is valid for any $\mathbf{f}$ and $\mathbf{g}$ if the integrals have a finite value. Particularly, if $\mathbf{f}$ is the gradient of some function, then the integrals are equal to zero. Then, from (11), $\boldsymbol{\omega}=P_X\boldsymbol{\omega}$, and

$$\begin{aligned}\int_\Omega \mathbf{v}_t\cdot\boldsymbol{\omega}\,\mathrm{d}^3\mathbf{x} &= \int_\Omega \mathbf{V}_t(\mathbf{x},t)\cdot\boldsymbol{\omega}(\mathbf{x},t)\mathrm{d}^3\mathbf{x} = \int_\Omega\int_\Omega \frac{\boldsymbol{\omega}(\mathbf{x},t)\cdot[\boldsymbol{\omega}_t(\mathbf{x}',t)\times(\mathbf{x}-\mathbf{x}')]}{4\pi|\mathbf{x}-\mathbf{x}'|^3}\mathrm{d}^3\mathbf{x}\,\mathrm{d}^3\mathbf{x}' \\ &= \int_\Omega \mathbf{V}(\mathbf{x}',t)\cdot\boldsymbol{\omega}_t(\mathbf{x}',t)\mathrm{d}^3\mathbf{x}' = \int_\Omega \mathbf{v}\cdot\boldsymbol{\omega}_t\mathrm{d}^3\mathbf{x},\end{aligned}$$

we calculate

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\boldsymbol{\omega}\|^2 = -\int_\Omega \frac{|\boldsymbol{\omega}\times\mathbf{v}|^2}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\mathrm{d}^3\mathbf{x}, \tag{15}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \mathbf{v}\cdot\boldsymbol{\omega}\,\mathrm{d}^3\mathbf{x} = 0. \tag{16}$$

It follows from (15) that $\|\boldsymbol{\omega}\|^2$ keeps decreasing with t as long as $|\boldsymbol{\omega}\times\mathbf{v}|\not\equiv 0$, and $\|\boldsymbol{\omega}\|\lneqq\|\boldsymbol{\omega}_0\|$ is valid because of (14). Moreover, (15) gives

$$\int_0^\infty\left[\int_\Omega \frac{|\boldsymbol{\omega}\times\mathbf{v}|^2}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\mathrm{d}^3\mathbf{x}\right]\mathrm{d}t \leqslant \frac{1}{2}\|\boldsymbol{\omega}_0\|^2.$$

Making use of (5) and noting that

$$\|\mathbf{v}\|_{L^4} \leqslant C\|\mathbf{v}\|_1 \leqslant C'\|\boldsymbol{\omega}\| < C'\|\boldsymbol{\omega}_0\| \tag{17}$$

follows from (3) and (10), we derive

$$\left(\int_\Omega |\boldsymbol{\omega}\times\mathbf{v}|\mathrm{d}^3\mathbf{x}\right)^2 \leqslant \int_\Omega \frac{|\boldsymbol{\omega}\times\mathbf{v}|^2}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\mathrm{d}^3\mathbf{x}\left[\int_\Omega (1+|\boldsymbol{\omega}|^2)\mathrm{d}^3\mathbf{x}\int_\Omega (1+|\mathbf{v}|^2)^2\mathrm{d}^3\mathbf{x}\right]^{1/2}$$
$$\leqslant C(\|\boldsymbol{\omega}_0\|^3+1)\int_\Omega \frac{|\boldsymbol{\omega}\times\mathbf{v}|^2}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\mathrm{d}^3\mathbf{x}.$$

Therefore,

$$\int_0^\infty \left(\int_\Omega |\boldsymbol{\omega}\times\mathbf{v}|\mathrm{d}^3\mathbf{x}\right)^2 \mathrm{d}t < \infty,$$

which means that

$$\int_\Omega |\boldsymbol{\omega}\times\mathbf{v}|\mathrm{d}^3\mathbf{x} = \int_\Omega |(\boldsymbol{\nabla}\times\mathbf{v})\times\mathbf{v}|\mathrm{d}^3\mathbf{x} = 0 \quad \text{at } t=\infty.$$

Furthermore, by (9), we obtainF

$$\|\boldsymbol{\omega}_t\|^2 \leqslant C\left\|\frac{(\boldsymbol{\omega}\times\mathbf{v})\times\mathbf{v}}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\right\|^2 \leqslant C\int_\Omega |\boldsymbol{\omega}\times\mathbf{v}|\mathrm{d}^3\mathbf{x} = 0 \quad \text{at } t=\infty.$$

These facts imply that $\boldsymbol{\omega}$ reaches a steady state at $t=\infty$ and $\mathbf{v}|_{t=\infty}$ is a Beltrami flow whose enstrophy ($\frac{1}{2}\|\boldsymbol{\omega}\|^2$ at $t=\infty$) is less than $\frac{1}{2}\|\boldsymbol{\omega}_0\|^2$ and helicity ($\int_\Omega \mathbf{v}\cdot\boldsymbol{\omega}\,\mathrm{d}^3\mathbf{x}$ at $t=\infty$) is equal to the prescribed value $\int_\Omega \mathbf{v}_0\cdot\boldsymbol{\omega}_0\mathrm{d}^3\mathbf{x}$. Particularly, if $\int_\Omega \mathbf{v}_0\cdot\boldsymbol{\omega}_0\mathrm{d}^3\mathbf{x}\neq 0$, then it is easy to see that $\|\boldsymbol{\omega}\|$ at $t=\infty$ is nonzero. Indeed, (16) with (5) and (10) yields

$$0 < \left|\int_\Omega \mathbf{v}_0\cdot\boldsymbol{\omega}_0\mathrm{d}^3\mathbf{x}\right| = \left|\int_\Omega \mathbf{v}\cdot\boldsymbol{\omega}\,\mathrm{d}^3\mathbf{x}\right| \leqslant \|\mathbf{v}\|\|\boldsymbol{\omega}\| \leqslant C\|\boldsymbol{\omega}\|^2. \tag{18}$$

The quantity $\int_\Omega \mathbf{v}\cdot\boldsymbol{\omega}\,\mathrm{d}^3\mathbf{x}$ is known to measure the degree of knottedness of $\boldsymbol{\omega}$-lines (Refs. 2 and 18). Thus we can expect that streamlines of the Beltrami flow $\mathbf{v}|_{t=\infty}$ (parallel to lines of vortex $\boldsymbol{\omega}|_{t=\infty}$) are complex if field lines of $\boldsymbol{\omega}_0$ are topologically complex, although (11) does not have frozen-field structure unlike (2).

IV. UNIQUE SOLVABILITY OF MAIN EQUATION

In this section, we discuss the existence and uniqueness of a solution $\boldsymbol{\omega}$ to our initial-boundary value problem (11) and (12), and $\boldsymbol{\omega}\cdot\hat{\mathbf{n}}|_{\partial\Omega}=0$. For this, we first calculate some estimates of $\boldsymbol{\omega}$ assuming its existence in a sufficiently smooth class.

In addition to (13), let us assume that $\|\boldsymbol{\omega}_0\|_{2,L^\alpha}<\infty$ with $\alpha>3$. Then, by (5), (9), and (11), we derive, for $\beta>2$

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\boldsymbol{\omega}\|_{L^\beta}^\beta = \beta\int_\Omega |\boldsymbol{\omega}|^{\beta-2}\boldsymbol{\omega}\cdot\boldsymbol{\omega}_t\mathrm{d}^3\mathbf{x} \leqslant \beta\|\boldsymbol{\omega}\|_{L^\beta}^{\beta-1}\|\boldsymbol{\omega}_t\|_{L^\beta},$$

$$\|\boldsymbol{\omega}_t\|_{L^\beta} \leqslant C\left\|\frac{(\boldsymbol{\omega}\times\mathbf{v})\times\mathbf{v}}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\right\|_{L^\beta} \leqslant C\left(\int_\Omega \mathrm{d}^3\mathbf{x}\right)^{1/\beta},$$

which mean $(\mathrm{d}/\mathrm{d}t)\|\boldsymbol{\omega}\|_{L^\beta}\leqslant C$. This and (10) give

$$\|\mathbf{v}\|_{1,L^\beta} \leqslant C\|\boldsymbol{\omega}\|_{L^\beta} \leqslant C\|\boldsymbol{\omega}_0\|_{L^\beta} + C't, \quad \beta > 2. \tag{19}$$

Next, verifying that

$$\left| \frac{\partial}{\partial x_j} \frac{(\boldsymbol{\omega} \times \mathbf{v}) \times \mathbf{v}}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)} \right| \leqslant C(|\boldsymbol{\omega}_{x_j}| + |\mathbf{v}_{x_j}|)$$

and making use of (6), (10), (17), and (19), we get, for $\beta \geqslant 2$

$$\frac{\mathrm{d}}{\mathrm{d}t}\langle\langle\boldsymbol{\omega}\rangle\rangle^\beta_{1,L^\beta} = \beta\sum_{j=1}^{3}\int_\Omega |\boldsymbol{\omega}_{x_j}|^{\beta-2}\boldsymbol{\omega}_{x_j}\cdot\boldsymbol{\omega}_{tx_j}\mathrm{d}^3\mathbf{x} \leqslant \beta(\langle\langle\boldsymbol{\omega}\rangle\rangle^\beta_{1,L^\beta} + \langle\langle\boldsymbol{\omega}_t\rangle\rangle^\beta_{1,L^\beta}),$$

$$\langle\langle\boldsymbol{\omega}_t\rangle\rangle^\beta_{1,L^\beta} \leqslant C\left\|\nabla\times\frac{(\boldsymbol{\omega}\times\mathbf{v})\times\mathbf{v}}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\right\|^\beta_{L^\beta} \leqslant C'(\langle\langle\boldsymbol{\omega}\rangle\rangle^\beta_{1,L^\beta} + \langle\langle\mathbf{v}\rangle\rangle^\beta_{1,L^\beta}) \leqslant C'\langle\langle\boldsymbol{\omega}\rangle\rangle^\beta_{1,L^\beta} + c(t,\|\boldsymbol{\omega}_0\|_{L^\beta}).$$

Here, and from now on, $c(t,s)$ is used without distinction in order to denote positive functions which are monotonically increasing in each of t and s, finite for any $t<\infty$ and $s<\infty$, and independent of estimated functions. From (7) and (10),

$$\|\mathbf{v}\|_{2,L^\beta} \leqslant C\|\boldsymbol{\omega}\|_{1,L^\beta} \leqslant c(t,\|\boldsymbol{\omega}_0\|_{1,L^\beta}), \quad \beta \geqslant 2 \tag{20}$$

follows. In the same way, noting that

$$\left|\frac{\partial^2}{\partial x_j\,\partial x_k}\frac{(\boldsymbol{\omega}\times\mathbf{v})\times\mathbf{v}}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\right| \leqslant C[|\boldsymbol{\omega}_{x_jx_k}| + |\mathbf{v}_{x_jx_k}| + (|\boldsymbol{\omega}_{x_j}| + |\mathbf{v}_{x_j}|)(|\boldsymbol{\omega}_{x_k}| + |\mathbf{v}_{x_k}|)],$$

we have

$$\frac{\mathrm{d}}{\mathrm{d}t}\langle\langle\boldsymbol{\omega}\rangle\rangle^{\beta/2}_{2,L^{\beta/2}} \leqslant \frac{\beta}{2}(\langle\langle\boldsymbol{\omega}\rangle\rangle^{\beta/2}_{2,L^{\beta/2}} + \langle\langle\boldsymbol{\omega}_t\rangle\rangle^{\beta/2}_{2,L^{\beta/2}}),$$

$$\langle\langle\boldsymbol{\omega}_t\rangle\rangle^{\beta/2}_{2,L^{\beta/2}} \leqslant C\left\|\nabla\times\frac{(\boldsymbol{\omega}\times\mathbf{v})\times\mathbf{v}}{\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)}\right\|^{\beta/2}_{1,L^{\beta/2}} \leqslant C'\langle\langle\boldsymbol{\omega}\rangle\rangle^{\beta/2}_{2,L^{\beta/2}} + c(t,\|\boldsymbol{\omega}_0\|_{1,L^\beta})$$

for $\beta>2$. They lead to

$$\|\mathbf{v}\|_{3,L^{\beta/2}} \leqslant C\|\boldsymbol{\omega}\|_{2,L^{\beta/2}} \leqslant c(t,\|\boldsymbol{\omega}_0\|_{2,L^{\beta/2}} + \|\boldsymbol{\omega}_0\|_{1,L^\beta}), \quad \beta > 2. \tag{21}$$

For $\beta/2=\alpha>3$,

$$\sup_{\substack{\mathbf{x}\in\Omega\\ j=1,2,3}}|\boldsymbol{\omega}_{x_j}(\mathbf{x},t)| + \sup_{\substack{\mathbf{x},\mathbf{x}'\in\Omega\\ j=1,2,3}}\frac{|\boldsymbol{\omega}_{x_j}(\mathbf{x},t)-\boldsymbol{\omega}_{x_j}(\mathbf{x}',t)|}{|\mathbf{x}-\mathbf{x}'|^{1-3/\alpha}} \leqslant C\|\boldsymbol{\omega}\|_{2,L^\alpha} \leqslant c(t,\|\boldsymbol{\omega}_0\|_{2,L^\alpha}) \tag{22}$$

follows from (4). This means that $\boldsymbol{\omega}$ at any $t<\infty$ is as smooth in $\mathbf{x}$ as $\boldsymbol{\omega}_0$, if it exists. Furthermore, since

$$\|\boldsymbol{\omega}_t\|_{2,L^\alpha} \leqslant c(t,\|\boldsymbol{\omega}_0\|_{2,L^\alpha}) \tag{23}$$

is derived from the above calculations, $\boldsymbol{\omega}$ is also smooth in t.

Using the Galerkin method in Ref. 25 and (20) for $\beta=2$ with $\|\boldsymbol{\omega}_t\|\leqslant C$, we can prove the temporally global existence of $\boldsymbol{\omega}$ such that $\boldsymbol{\omega}(\cdot,t)\in X_2$ is continuous in t. Then the differentiability of $\boldsymbol{\omega}$ is raised so that (19)–(23) hold.

This smoothness of $\boldsymbol{\omega}$ enables us to prove that the initial data $\boldsymbol{\omega}_0$ cannot generate two different solutions. Indeed, supposing that $\boldsymbol{\omega}=\boldsymbol{\omega}_1,\boldsymbol{\omega}_2$ (correspondingly, $\mathbf{v}=\mathbf{v}_1,\mathbf{v}_2$) are generated by (11) from the same initial condition and noting that $\sup_\Omega|\mathbf{v}|$ and $\sup_\Omega|\boldsymbol{\omega}|$ are bounded by $c(t,\|\boldsymbol{\omega}_0\|_{1,L^\alpha})$ with $\alpha>3$, we can obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\boldsymbol{\omega}_1-\boldsymbol{\omega}_2\|^2 \leqslant c(t,\|\boldsymbol{\omega}_0\|_{1,L^\alpha})\|\boldsymbol{\omega}_1-\boldsymbol{\omega}_2\|^2.$$

From this,

$$\|\mathbf{v}_1-\mathbf{v}_2\| \leqslant C\|\boldsymbol{\omega}_1-\boldsymbol{\omega}_2\|=0$$

is deduced by virtue of (7) and (10). By contrast we do not know whether or not two different initial data reach the same steady state $\boldsymbol{\omega}|_{t=\infty}$.

V. CONCLUSIONS

It was shown that each solution $\boldsymbol{\omega}$ to (11) with (12) reaches a steady state at $t=\infty$ and $\mathbf{u}=\mathbf{v}|_{t=\infty}$ is a solution to (1), that is, a Beltrami flow such that $\mathbf{u}\cdot\hat{\mathbf{n}}|_{\partial\Omega}=0$,

$$\|\mathbf{u}\|_1 \leqslant C\|\boldsymbol{\nabla}\times\mathbf{u}\| < C\|\boldsymbol{\omega}_0\|, \quad \int_\Omega \mathbf{u}\cdot(\boldsymbol{\nabla}\times\mathbf{u})\mathrm{d}^3\mathbf{x}=\int_\Omega \mathbf{v}_0\cdot\boldsymbol{\omega}_0\mathrm{d}^3\mathbf{x}.$$

Unlike (17) and (18), which remain valid at $t=\infty$, the estimates (19)–(23) hold only for $t<\infty$ and $\boldsymbol{\omega}$ may be nonsmooth at $t=\infty$. Nevertheless, (19)–(23) guarantee that (11) is really solvable globally in time, $\boldsymbol{\omega}$ is unique for $\boldsymbol{\omega}_0$ (not for $\boldsymbol{\omega}|_{t=\infty}$), and no finite-time singularity occurs. This fact seems convenient for numerical construction of a Beltrami flow.

It should be noted that $\mathbf{v}|_{t=\infty}$ generated by

$$\boldsymbol{\omega}_t = P_X[(\boldsymbol{\omega}\times\mathbf{v})\times\mathbf{v}] \tag{24}$$

is a Beltrami flow, too. Indeed, instead of (15)

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\boldsymbol{\omega}\|^2=-\|\boldsymbol{\omega}\times\mathbf{v}\|^2$$

is derived and (16) is also valid for (24). However, we do not know whether (19)–(23) are deduced from (24) or not. The denominator $\sqrt{1+|\boldsymbol{\omega}|^2}(1+|\mathbf{v}|^2)$ in (11) helps to obtain (19)–(23). Thus (11) seems more suitable to numerical construction of a Beltrami flow than (24).

We prove, in great generality, that in a system of bosons, whenever Bose condensation in a nonzero mode occurs then there is also spontaneous breaking of translation symmetry. In particular the proof holds for realistic Bose systems with two-body superstable interaction. This generalizes an old result proving that the occurrence of Bose-Einstein condensation in the zero mode implies spontaneous breaking of gauge invariance. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1985025]

I. INTRODUCTION

For homogenous systems of bosons, the phenomenon of Bose-Einstein condensation into the *ground state* is very well known and intensively studied. In this situation, the ground state density ρ_0 is nonzero, that is we have

$$\rho_0 = \lim_{\Lambda} \omega\left(\frac{a_0^* a_0}{V}\right) > 0, \tag{1.1}$$

where $\lim_\Lambda$ stands for $\lim_{\Lambda \nearrow \mathbb{R}^\nu}$, $\omega(\cdot)$ denotes the expectation with respect to the equilibrium state and

$$a_k^{\#} = \frac{1}{\sqrt{V}} \int_\Lambda \mathrm{d}x \, a^{\#}(x) e^{ik\cdot x}$$

are the usual creation and annihilation operators for momentum k for the system in a (cubic) domain $\Lambda \subset \mathbb{R}^\nu$ of volume V. Another manifestation of this phenomenon is breaking of gauge symmetry as expressed by the formula

$$\lim_{\Lambda} \omega\left(\frac{a_0}{\sqrt{V}}\right) \neq 0. \tag{1.2}$$

In this case we also have that

[c)]Electronic mail: zagrebnov@cpt.univ-mrs.fr

$$\rho_0 = \lim_{\Lambda} \omega\left(\frac{a_0^* a_0}{V}\right) = \lim_{\Lambda} \left|\omega\left(\frac{a_0}{\sqrt{V}}\right)\right|^2. \tag{1.3}$$

It is easy to deduce from the Cauchy-Schwarz inequality that spontaneous breaking of gauge symmetry in the sense of (1.2) implies the existence of condensation. However in the literature on Bose condensation of homogenous systems, one notices that many authors seem to take for granted or consider trivially true the converse of this statement, that is, the fact that the existence of condensation ($\rho_0 > 0$) implies spontaneous breaking of gauge symmetry. This result (1.3), which is far from trivial, indeed holds true and was first proved in a very general setting in Ref. 1, where one finds the following proposition.

Proposition 1.1: If in the state ω, *the ground state condensate density* $\rho_0 > 0$, *then there exists a family of equilibrium states* $\{\omega_\alpha | \alpha \in [0, 2\pi)\}$ *such that*

(a) $\omega = (1/2\pi)\int_0^{2\pi} \mathrm{d}\alpha\, \omega_\alpha$,
(b) $\lim_\Lambda \omega_\alpha(a_0/\sqrt{V}) \neq 0$ *for all* $\alpha \in [0, 2\pi)$.

Through the recent activity in the domain of condensation in traps (see, for example, Ref. 2), the possibility of condensation in a mode corresponding to a nonzero momentum q has arisen. This requires a generalization of above theorem to the case $q \neq 0$. In this paper we shall prove the following proposition.

Proposition 1.2: Suppose that for the equilibrium state ω, *for some* $q \neq 0$ *the condensate density* $\rho_q > 0$ *and let* $q = (2\pi/\gamma)e$ *where* e *is a unit vector in* $\mathbb{R}^\nu$ *and* $\gamma > 0$. *Then there exists a family of periodic equilibrium states* $\{\tilde{\omega}_{te} | t \in [0, \gamma)\}$, *with period* γ *such that*

(a) $\omega = (1/\gamma)\int_0^\gamma \mathrm{d}t\, \tilde{\omega}_{te}$,
(b) $\lim_\Lambda \tilde{\omega}_{te}(a_q/\sqrt{V}) \neq 0$ *for all* $t \in [0, \gamma)$.

We give the exact formulation and proof of this result in Sec. II (see Theorems 2.1 and 2.2). The statement in (b) means that now, not only the gauge symmetry is spontaneously broken, but also the space translation invariance since under translation by y, for example, the operator a_q is transformed into $e^{-iq\cdot y}a_q$. For an explicit application of this result see Ref. 3. The main practical result is that for homogenous gauge invariant systems, a thermodynamic limit Gibbs states, showing condensation in a mode $q \neq 0$, can be decomposed with respect to periodic equilibrium states also showing gauge symmetry breaking. This decomposition of the state ω in the direction of q can straightforwardly be generalized to more dimensions by constructing from ω states which are periodic in any dimension at the same time.

II. CONDENSATION AND SPONTANEOUS SYMMETRY BREAKING

The models we have in mind in this note are realistic Bose systems, with two-body interactions in dimension $\nu \geqslant 1$. The two-body potential v is supposed to be *well-behaved* and in particular *superstable*.[4]

The algebra of observables $\mathcal{A}$ (Ref. 5) is as usual generated by the Weyl operators,

$$W(h) = \exp i\{a(h) + a^*(h)\} h \in \mathcal{H} = L^2(\mathbb{R}^\nu),$$

where $a^\#(h)$ are the boson annihilation and creation operators in the symmetric Fock space $\mathcal{F}(\mathcal{H})$ satisfying the canonical commutation relations

$$[a(f), a^*(g)] = \langle f, g\rangle_{\mathcal{H}}, \tag{2.1}$$

with $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ denoting the scalar product in the Hilbert space $\mathcal{H}$.

For a cubic region Λ in $\mathbb{R}^\nu$ centered at the origin let $\mathcal{H}_\Lambda = L^2(\Lambda)$. Then the algebra $\mathcal{A}_\Lambda$ generated by $\{W(h) | h \in \mathcal{H}_\Lambda\}$ is embedded in $\mathcal{A}$ in the natural way.

On the n-particle subspaces of $\mathcal{F}(\mathcal{H}_\Lambda)$, the local Hamiltonians H_Λ are given by

$$H_\Lambda^n = T_\Lambda^n + U_\Lambda^n, \tag{2.2}$$

where $T_\Lambda^n = -\Sigma_{i=1}^n \Delta_i/2$, Δ being the self-adjoint extension of the Laplacian on $\mathcal{H}_\Lambda$ corresponding to *periodic* boundary conditions, and U_Λ^n the multiplication operator by $\Sigma_{1\leqslant i<j\leqslant n} v(|x_i - x_j|)$, $x_i, x_j \in \Lambda$. The superstability condition ensures the existence of local Gibbs states and all n-point correlation functions for any number of creation and annihilation functions, see, e.g., Refs. 4 and 5, Chap. 6.3.4. We denote the number operator for the volume Λ by N_Λ.

We are interested in the properties of the equilibrium states corresponding to the system (2.2). In what follows the most convenient way to define these states is by means of the correlation inequalities.[6] In particular a state ω on $\mathcal{A}$ is an equilibrium state at inverse temperature β and chemical potential $\mu \in \mathbb{R}$ if it satisfies the following *energy-entropy balance conditions:*

$$\beta\omega(X^*[H_\Lambda - \mu N_\Lambda, X]) \geqslant \omega(X^*X)\ln \frac{\omega(X^*X)}{\omega(XX^*)} \tag{2.3}$$

for all Λ and for any observable $X \in \mathcal{A}_\Lambda$ in the domain $\mathcal{D}([H_\Lambda - \mu N_\Lambda, \cdot])$. Our aim is to find solutions ω satisfying (2.3). The thermodynamic limit Gibbs states are solutions of (2.3) and because of the homogeneity and gauge invariance of the Hamiltonian (2.2), they are translation and gauge invariant solutions. With this in mind, we consider the class of states ω satisfying (2.3), and the following conditions which are satisfied in realistic Bose systems with superstable interaction:

(A) The state ω is translation and gauge invariant.
(B) The state ω is *analytic* in the sense of Ref. 5, Chap. 5.2.3, this means that the state can be completely described in terms of all n-point correlation functions of the creation and annihilation operators.

Denote the volume of Λ by V and let

$$\Lambda^* = \{2\pi n/V^{1/\nu} | n \in \mathbb{Z}^\nu\}$$

be the *dual momentum set* for the cubic region Λ with periodic boundary conditions. As above for any $k \in \Lambda^*$, we define the creation and annihilation operators of a particle with momentum k,

$$a_k^\# = a^\#(\phi_{\Lambda,k}) \quad \text{where } \phi_{\Lambda,k}(x) = \frac{1}{\sqrt{V}} e^{ik\cdot x}\mathbb{I}_\Lambda(x),$$

$\mathbb{I}_\Lambda$ being the characteristic function of region Λ.

We say that the state ω shows *condensation* in the mode $q \in \Lambda^*$ if

$$\rho_q = \lim_\Lambda \omega\left(\frac{a_q^* a_q}{V}\right) > 0 \tag{2.4}$$

and then ρ_q is called the *condensate density* in the q mode.

We consider the system $(\mathcal{A}, \omega)$ and its *GNS construction*[5] on the Hilbert space $\mathfrak{H}$ with cyclic and separating vector $\Omega \in \mathfrak{H}$, i.e., for all $X \in \mathcal{A}$, one has

$$\omega(X) = \langle \Omega, X\Omega \rangle, \tag{2.5}$$

where for notational convenience, we denote by the *same symbol* the element X of $\mathcal{A}$ and its image under the GNS representation, an operator on $\mathfrak{H}$. We denote by $\mathcal{A}''$ the von Neumann algebra generated by the representation of $\mathcal{A}$, and by $\mathcal{A}'$ its commutant. Take $q \in \Lambda^*$ with $q \neq 0$ and let

$$\alpha_{q,\Lambda} := a(\phi_{\Lambda,q}/\sqrt{V}) = \frac{1}{V}\int_\Lambda \mathrm{d}x\, e^{iq\cdot x} a(x). \tag{2.6}$$

This operator converges strongly to an operator α_q in the representation space $\mathfrak{H}$.[5] So, we define

$$\alpha_q = \lim_{\Lambda} \alpha_{q,\Lambda} \quad \text{and} \quad \alpha_q^* = \lim_{\Lambda} \alpha_{q,\Lambda}^*. \tag{2.7}$$

Because the operators $\alpha_{q,\Lambda}$ are local averages (2.6), α_q is a limit average operator, also called *observable at infinity*, and therefore affiliated to the *center* $\mathcal{C}=\mathcal{A}''\cap\mathcal{A}'$ of the algebra $\mathcal{A}''$, see, e.g., Ref. 5.

For $y\in\mathbb{R}^\nu$ let τ_y be the translation $*$-automorphism of $\mathcal{A}$ over the distance y, that is,

$$(\tau_y a^\#)(x) = a^\#(x+y). \tag{2.8}$$

Then from (2.6)–(2.8) we obtain

$$\tau_y \alpha_q = e^{-iq\cdot y}\alpha_q, \tag{2.9}$$

$$\tau_y(\alpha_q^*\alpha_q) = \alpha_q^*\alpha_q. \tag{2.10}$$

From (2.10) we see that the particle density operator in the mode q, $n_q := \alpha_q^*\alpha_q$, is translation invariant.

For the rest of this section we make the assumption that in the state ω there is condensation in the *nonzero* mode $q\neq 0$, i.e., we shall assume that

$$\rho_q = \omega(\alpha_q^*\alpha_q) = \omega(n_q) > 0. \tag{2.11}$$

This implies that $n_q>0$ and therefore also that

$$\omega(n_q^{1/2}) \neq 0, \tag{2.12}$$

since $\omega(n_q^{1/2})$ cannot be zero because of the *separating* character of the equilibrium state.[5] Consider the *polar decomposition* of the operator α_q,

$$\alpha_q = U_q n_q^{1/2}. \tag{2.13}$$

As α_q belongs to the center $\mathcal{C}$, it is a *normal* operator. By Ref. 7, Chap. X.9, operator U_q can be taken as the unitary extension of the partial isometry defined by the polar decomposition. Since

$$0 \neq \omega(n_q^{1/2}) = \omega(U_q^*\alpha_q) = \lim_{\Lambda} \omega(U_q^*\alpha_{q,\Lambda}),$$

we can find $h\in\mathcal{H}$ such that

$$\omega(U_q^* a(h)) \neq 0. \tag{2.14}$$

Now we define a representation of $\mathcal{A}$ on $\mathfrak{H}$. For any $h\in\mathcal{H}$, define the boson field

$$\tilde{\phi}(h) := \{U_q^* a(h) + U_q a^*(h)\}^*. \tag{2.15}$$

By definition (2.15), the operator $\tilde{\phi}(h)$ is essentially self-adjoint in $\mathfrak{H}$, and we can define Weyl operators $\tilde{W}$, $\mathcal{H}\to\mathcal{B}(\mathfrak{H})$,

$$\tilde{W}(h) := e^{i\tilde{\phi}(h)}, \quad h\in\mathcal{H}. \tag{2.16}$$

Using the fact that U_q is a unitary belonging to the center, it is trivial to check that $\tilde{W}$ is a representation of $\mathcal{A}$ on $\mathfrak{H}$. Denote by η the $*$-isomorphic map of $\mathcal{A}$ into $\mathcal{B}(\mathfrak{H})$,

$$\eta(W(h)) = \tilde{W}(h). \tag{2.17}$$

Then one can easily derive the following identities for the annihilation and creation operators:

$$\tilde{a}(h) := \eta(a(h)) = U_q^* a(h),$$

$$\tilde{a}^*(h) := \eta(a^*(h)) = U_q a^*(h).$$

For any $x \in \mathbb{R}^\nu$, we define the functional $\tilde{\omega}_x$ on $\mathcal{A}$ by

$$\tilde{\omega}_x(W(h)) := \langle \Omega, \tilde{W}(h_x)\Omega \rangle = \omega(\eta \circ \tau_x(W(h))), \tag{2.18}$$

where $h_x(y)=h(x+y)$ is the translate of h over x. It is clear from (2.18) that $\tilde{\omega}_x$ is again a state on algebra $\mathcal{A}$.

It follows immediately from (2.14) and (2.18) that the states $\tilde{\omega}_x$ are *not* gauge invariant, in particular $\tilde{\omega}_x(a(h))=\omega(U_q^*\tau_x a(h)) \neq 0$ for some $h \in \mathcal{H}$. Also directly from the definition (2.18) one sees that the states $\tilde{\omega}_x$, $x \in \mathbb{R}^\nu$, have the property that for all $y \in \mathbb{R}^\nu$,

$$\tilde{\omega}_x \circ \tau_y = \tilde{\omega}_{x+y}. \tag{2.19}$$

Now we concentrate on the direction of the translation. Let $q=(2\pi/\gamma)e$ where $e \in \mathbb{R}^\nu$ is the unit vector in the direction of q and let γ be the period or wavelength of the mode q, i.e., $\gamma = 2\pi/\|q\|$. We have the following.

Theorem 2.1 *(existence of periodic states):*

(a) *Each state $\tilde{\omega}_x$ is translation invariant in any direction orthogonal to q: for all $y \in \mathbb{R}^\nu$ such that $y \cdot q = 0$,*

$$\tilde{\omega}_{x+y} = \tilde{\omega}_x.$$

(b) *Each state $\tilde{\omega}_x$ is periodic with period γ in the direction of q:*

$$\tilde{\omega}_{x+\gamma e} = \tilde{\omega}_x.$$

Proof: From (2.15), (2.16), and (2.18) we obtain

$$\tilde{\omega}_{x+y}(W(h)) = \langle \Omega, e^{i\tilde{\phi}(h_{x+y})}\Omega \rangle. \tag{2.20}$$

Now we have

$$\tilde{\phi}(h_{x+y}) = \{U_q^* \tau_y a(h_x) + U_q \tau_y a^*(h_x)\}^* = \tau_y\{\tau_{-y}(U_q^*)a(h_x) + \tau_{-y}(U_q)a^*(h_x)\}^* \tag{2.21}$$

and from (2.9), (2.10), and (2.13) it follows that

$$\tau_y(U_q) = U_q e^{-iq\cdot y}.$$

Therefore, if $y \cdot q = 0$ or $y = \gamma e$ (since then $q \cdot y = 2\pi$), one gets $\tau_y(U_q) = U_q$. Thus for both cases we get

$$\tilde{\phi}(h_{x+y}) = \tau_y \tilde{\phi}(h_x). \tag{2.22}$$

Then inserting (2.22) into (2.20) and using the translation invariance of the state ω (2.5) one gets the proof of (a) and (b). □

Now we come to the analysis of the states and their translates in the direction of the vector q.

Theorem 2.2 *(decomposition into periodic states):*

(c) *The states $\tilde{\omega}_{te}$ are all distinct, that is, for any $t, t' \in [0, \gamma)$ such that $t \neq t'$ one has*

$$\tilde{\omega}_{te} \neq \tilde{\omega}_{t'e}.$$

(d) *The original state ω is the convex combination of the family of states $\{\tilde{\omega}_{te} | t \in [0, \gamma)\}$:*

$$\omega = \frac{1}{\gamma}\int_0^\gamma \mathrm{d}t\, \tilde{\omega}_{te}.$$

(e) *All the states $\{\tilde{\omega}_{te} | t \in [0, \gamma)\}$ are equilibrium states.*

Proof: Since the state ω is analytic [condition (B)], it follows from definition (2.18) that the

states $\tilde{\omega}_x$ are also analytic. Therefore, it is sufficient to check the statements of the theorem only for *all monomials* in the field operators (Ref. 5, Chap. 5.2.3.).

Recall that by (2.18) we have

$$\tilde{\omega}_{te}(a(h)) = \omega(U_q^* \tau_{te} a(h)).$$

Using (2.9) and the translation invariance of the state ω [condition (A)], we obtain

$$\tilde{\omega}_{te}(a(h)) = e^{-iq\cdot te}\omega(U_q^* a(h)) = e^{-i(2\pi/\gamma)t}\omega(U_q^* a(h)).$$

By (2.14), there exists an element $h \in \mathcal{H}$ such that $\omega(U_q^* a(h)) \neq 0$. Then for any $t, t' \in [0, \gamma)$, $t \neq t'$ one gets

$$(\tilde{\omega}_{te} - \tilde{\omega}_{t'e})(a(h)) = (e^{-it(2\pi/\gamma)} - e^{-it'(2\pi/\gamma)})\omega(U_q^* a(h)) \neq 0,$$

proving (c).

We now prove (d). Let $m, n \in \mathbb{N}$ and $f \in \mathcal{H}$. Then we have

$$\frac{1}{\gamma}\int_0^\gamma \mathrm{d}t\ \tilde{\omega}_{te}(a^*(f)^n a(f)^m) = \frac{1}{\gamma}\int_0^\gamma \mathrm{d}t\ \omega(\tau_{te}(a^*(f)^n)\tau_{te}(a_{te}(f)^m)U_q^n U_q^{-m}).$$

By virtue of (2.9) and by translation and gauge invariance of the state ω [condition (A)] we get

$$\begin{aligned}\frac{1}{\gamma}\int_0^\gamma \mathrm{d}t\ \tilde{\omega}_{te}(a^*(f)^n a(f)^m) &= \frac{1}{\gamma}\int_0^\gamma \mathrm{d}t\ e^{i(2\pi/\gamma)t(m-n)}\omega(a^*(f)^n a(f)^m U_q^{n-m}) \\ &= \delta_{n,m}\omega(a^*(f)^n a(f)^m) = \omega(a^*(f)^n a(f)^n),\end{aligned}$$

which proves (d).

Finally we prove that for any $t \in [0, \gamma)$ the state $\tilde{\omega}_{te}$ is an equilibrium state, by showing that these states satisfy the equilibrium conditions (2.3). Let X be an arbitrary monomial in the creation and annihilation operators. Then using condition (A) for the state ω together with the translation and gauge invariance of the local Hamiltonians (2.2), one gets

$$\begin{aligned}\lim_\Lambda \tilde{\omega}_{te}(X^*[H_\Lambda - \mu N_\Lambda, X]) &= \lim_\Lambda \omega(\eta \circ \tau_{te}(X^*[H_\Lambda - \mu N_\Lambda, X])) \\ &= \lim_\Lambda \omega((\eta \circ \tau_{te}(X))^*[H_\Lambda - \mu N_\Lambda, \eta \circ \tau_{te}(X)]) \geqslant \omega((\eta \circ \tau_{te}(X))^*(\eta \\ &\circ \tau_{te}(X))) \\ &\times \ln \frac{\omega((\eta \circ \tau_{te}(X))^* \eta \circ \tau_{te}(X))}{\omega(\eta \circ \tau_{te}(X)(\eta \circ \tau_{te}(X))^*)} = \tilde{\omega}_{te}(X^*X)\ln \frac{\tilde{\omega}_{te}(X^*X)}{\tilde{\omega}_{te}(XX^*)}.\end{aligned}$$

This yields (e) concluding the proof of the theorem. □

Theorems 2.1 and 2.2 prove that if one has an equilibrium state ω showing condensation in the *non zero q* mode (2.4) then there exists a set of periodic equilibrium states $\{\tilde{\omega}_{te} | t \in [0, \gamma)\}$ in the q direction with period γ. In directions orthogonal to q, these states remain *homogenous*. Note that these states simultaneously break the gauge symmetry and that they live in the same representation space $\mathfrak{H}$ of the CCR algebra $\mathcal{A}$ determined by the original state ω. We have proved that spontaneous translation and gauge symmetry breaking occur *simultaneously*.

The *converse* statement is clearly not true in general. For example, bosonic atoms may crystallize without undergoing Bose condensation as in the case of ^{4}He at sufficiently high pressure, see also the discussion in Sec. III. However, if we assume a *stronger* form of translation invariance symmetry breaking of the state $\tilde{\omega}_x$, namely,

$$\tilde{\omega}_x(\alpha_q) = \lim_{\Lambda} \tilde{\omega}_x(\alpha_{q,\Lambda}) \neq 0, \tag{2.23}$$

then the existence of Bose condensation in the q mode follows immediately from the Cauchy-Schwarz inequality as it does for the zero mode.

Remark 2.1: Theorems 2.1 and 2.2 are in fact valid under weaker assumptions. In particular the second condition (B) *can be dispensed with. But then one must work almost entirely with the Weyl operators as observables and not the creation/annihilation operators. Also one must replace the equilibrium conditions* (2.3) *by the KMS-state definition of equilibrium.*[5]

Remark 2.2: Above we analyzed the situation for one direction q. It is a simple exercise to generalize the analysis to an arbitrary number of dimensions. In particular, suppose that one has condensation in ν *independent directions* $q_1, \ldots, q_\nu$, *i.e., that* $\rho_{q_i} > 0$ *for* $i = 1, \ldots \nu$, *and*

$$q_i \cdot q_j = \delta_{ij} |q_i|^2.$$

Then we can perform the above constructions in each direction independently because the corresponding α*-operators commute with each other and with their adjoints. One obtains equilibrium states* $\tilde{\omega}_x$, *with* $x = t_1 e_1 + \cdots + t_\nu e_\nu$, *periodic in all directions creating a* ν*-dimensional lattice.*

III. CONCLUSION

As we mentioned in the Introduction there are situations when there is condensation in a nonzero mode. In fact in Ref. 3 we considered a model that exhibits condensation in the *zero* mode and a *nonzero* mode simultaneously. For this model Theorems 2.1 and 2.2 can be used to show the existence of *periodic* interference fringes (*condensate grating*), which is observed experimentally, see discussion in Ref. 3. Here we give a brief account of this argument.

In the limiting equilibrium state ω, which is translation invariant, clearly the average local particle density is constant. However in this model when condensation occurs in the mode $q \neq 0$ also, by Theorem 2.1 the translation invariance of equilibrium states will be broken in the direction of e simultaneously with the gauge symmetry. This implies that

$$\eta_0(t) := \lim_{\Lambda} \tilde{\omega}_{te}(\alpha_{0,\Lambda}) \neq 0 \quad \text{and} \quad \eta_q(t) := \lim_{\Lambda} \tilde{\omega}_{te}(\alpha_{q,\Lambda}) \neq 0 \tag{3.1}$$

for any of the states $\{\tilde{\omega}_{te} | t \in [0, \gamma)\}$, see Proposition 1.2 (b). Recall that the local particle density operator is given by

$$\rho_\Lambda(x) := \sum_{k \in \Lambda^*} \hat{\rho}_{k,\Lambda} e^{ik \cdot x}, \tag{3.2}$$

where

$$\hat{\rho}_{k,\Lambda} := \sum_{p \in \Lambda^*} \alpha^*_{p+k,\Lambda} \alpha_{p,\Lambda}. \tag{3.3}$$

The conservation laws for this model imply that

$$\tilde{\omega}_{te}(\alpha^*_{p+k,\Lambda} \alpha_{p,\Lambda}) = \delta_{k,q} \delta_{p,0} \tilde{\omega}_{te}(\alpha^*_{k,\Lambda} \alpha_{0,\Lambda}) + \delta_{k,0} \tilde{\omega}_{te}(\alpha^*_{p,\Lambda} \alpha_{p,\Lambda}) \tag{3.4}$$

and one also has (see Ref. 3, Sec. 4)

$$\lim_{\Lambda} \tilde{\omega}_{te}(\alpha^*_{q,\Lambda} \alpha_{0,\Lambda}) = \lim_{\Lambda} \tilde{\omega}_{te}(\alpha^*_{q,\Lambda}) \lim_{\Lambda} \tilde{\omega}_{te}(\alpha_{0,\Lambda}) = \overline{\eta_q(t)}\, \eta_0(t). \tag{3.5}$$

Then by definition (3.2) and (3.3) and by virtue of (3.1), (3.4), and (3.5) we obtain

$$\lim_{\Lambda} \tilde{\omega}_{te}(\rho_\Lambda(x)) = 2\, \mathrm{Re}\{e^{iq \cdot x} \overline{\eta_q(t)}\, \eta_0(t)\} + \lim_{\Lambda} \tilde{\omega}_{te}(\rho_\Lambda(0)). \tag{3.6}$$

This means that one gets a nonhomogeneity (*grating*) of the equilibrium total particle density, as

observed experimentally (see Refs. 2 and 3), if and only if there is simultaneous condensation in some nonzero mode and in the zero mode.

Another possible application of our general results is motivated by Remark 2. This is related to the theory of a hypothetic *coherent* boson crystals,[8,9] proposed to explain some unusual properties of ^{4}He in the solid phase. The main ingredients of this approach are the Hartree or the Gross-Pitaevskii variational calculations based on the hypothesis of the existence of the condensate in the zero mode as well as in several other *nonzero* modes to imitate an elementary cell of the solid helium. In this case the Helium atoms are *not localized* and the corresponding periodic state implies the occurrence of space variation in the particle density by virtue of (2.23) and by the arguments (3.1) and (3.6) in this section. Note that the coherent crystallization is drastically different from the standard one, where the atoms on the lattice sites are completely localized, thus do not obey many-body quantum statistics and the assumption (2.23) cannot be valid. This point of view on the crystal state, in which delocalized particles still satisfy Bose statistics, has led in turn to the hypothesis of *superfluidity* of quantum crystals, see, e.g., Ref. 10.

(Received 21 April 2005; accepted 18 May 2005; published online 28 July 2005)

We study the critical points of a nonlocal free energy functional. The functional has two minimizers (ground states) $m^{(\pm)}$ with zero energy. We prove that there is a first excited state identified as the instanton $\hat{m}_L$, and that above the energy of the instanton there is a gap. We also characterize parts of the basin of attraction of $m^{(\pm)}$ and $\hat{m}_L$ under a dynamics associated to the free energy functional. The result completes the analysis of tunneling from $m^{(-)}$ to $m^{(+)}$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1990107]

I. INTRODUCTION

In this paper we consider a nonlocal free energy functional $\mathcal{F}_L$ on $L^\infty([-L,L];[-1,1])$ defined by

$$\mathcal{F}_L(m)=\int_{-L}^{L}\phi_\beta(m)\mathrm{d}x+\frac{1}{4}\int_{-L}^{L}\int_{-L}^{L}J^{\mathrm{neum}}(x,x')[m(x)-m(x')]^2\mathrm{d}x\,\mathrm{d}x', \tag{1.1}$$

where $\beta>1$,

$$\phi_\beta(m)=\tilde{\phi}_\beta(m)-\min_{|s|\leqslant 1}\tilde{\phi}_\beta(s),\quad \tilde{\phi}_\beta(m)=-\frac{m^2}{2}-\frac{1}{\beta}\mathcal{S}(m),$$

$$\mathcal{S}(m)=-\frac{1-m}{2}\log\frac{1-m}{2}-\frac{1+m}{2}\log\frac{1+m}{2},$$

and

$$J^{\mathrm{neum}}(x,y)=J(x,y)+J(x,R_L(y))+J(x,R_{-L}(y))$$

with $R_\xi(y)=\xi-(y-\xi)$ the reflection of y around ξ and $J(x,y)$, $(x,y)\in\mathbb{R}\times\mathbb{R}$, a smooth, symmetric, translational invariant probability kernel supported in $|y-x|\leqslant 1$. We also assume that $J(0,x)$ is a nonincreasing function whenever restricted to $x\geqslant 0$. The functional (1.1) arises in statistical mechanics in the analysis of Ising systems with Kac potentials,[9] and it has been extensively studied in the recent years.

[a)]Electronic mail: belletti@mat.uniroma2.it
[b)]Electronic mail: demasi@univaq.it
[c)]Electronic mail: presutti@mat.uniroma2.it

The critical points of $\mathcal{F}_L$ are defined as the functions $m \in L^\infty([-L,L];[-1,1])$ which solve in the whole of $[-L,L]$ the "nonlocal mean field equation"

$$m = \tanh\{\beta J^{\text{neum}} * m\}. \tag{1.2}$$

(1.2) also has a dynamical interpretation as the equation for the stationary points of the evolution equation

$$u_t = g_L(u) := -u + \tanh\{\beta J^{\text{neum}} * u\} \tag{1.3}$$

which is derived from Glauber dynamics in the Ising systems with Kac potentials mentioned previously.[9]

We call "energy levels" of $\mathcal{F}_L$ its values at the critical points and borrowing from the terminology on linear operators, we call "spectrum" of $\mathcal{F}_L$ the set of all its energy levels. Many physical properties are determined by the structure of the spectrum at its bottom and its investigation is the main aim of this article. We start by observing that the spectrum of $\mathcal{F}_L$ is contained in the positive axis, as both terms on the right-hand side (r.h.s.) of (1.1) are nonnegative. The spectrum actually starts at 0. Indeed, since J^{neum} is a probability kernel, the solutions of (1.2) which are spatially homogeneous, namely $m(x)=u\in[-1,1]$ for all $x\in[-L,L]$, satisfy the "mean field equation" $u=\tanh\{\beta u\}$. As $\beta>1$, there are three solutions $u=\pm m_\beta$, $m_\beta\in(0,1)$, and $u=0$. The two critical points $m^{(\pm)}(x)=\pm m_\beta$, $x\in[-L,L]$, have zero energy, $\mathcal{F}_L(m^{(\pm)})=0$, and are called "ground states," while $\mathcal{F}_L(0)=2\phi_\beta(0)L>0$.

Thus the spectrum starts at 0 and 0 has degeneracy 2 as there is no other m besides $m^{(\pm)}$ with 0 energy. In fact the second term on the r.h.s. of (1.1) forces a minimizer to be spatially homogeneous and we have already seen that, among the spatially homogeneous functions, $m^{(\pm)}$ are the only ground states. We also know from the literature that the state $m\equiv 0$ is not the first excited state (i.e., with minimal positive energy), at least for L large enough. In fact its energy $2\phi_\beta(0)L$ becomes, as L increases, larger than the energy of the instanton $\hat{m}_L$ (a spatially nonhomogeneous critical point), which instead remains bounded as $L\to\infty$.[5–7] In this article we will prove the following.

Theorem 1.1: *For all L large enough, $\mathcal{F}_L(\hat{m}_L)$ is the first energy level above 0, it is not degenerate and above $\mathcal{F}_L(\hat{m}_L)$ there is a spectral gap, namely there is $\epsilon>0$ so that if m is a critical point and $\mathcal{F}_L(m)\leqslant\mathcal{F}_L(\hat{m}_L)+\epsilon$, then $m\in\{m^{(-)},m^{(+)},\hat{m}_L\}$.*

Such a characterization of the spectrum was the missing element in Ref. 3 in the analysis of tunnelling from $m^{(-)}$ to $m^{(+)}$, which therefore with the help of Theorem 1.1 is now complete. We can also use Theorem 1.1 to determine partially the basin of attraction of $m^{(\pm)}$ and $\hat{m}_L$.

Theorem 1.2: *For all L large enough, there is $\epsilon>0$ so that for any m such that $\mathcal{F}_L(m)\leqslant\mathcal{F}_L(\hat{m}_L)+\epsilon$*

$$\lim_{t\to\infty} S_t(m) \in \{m^{(-)},m^{(+)},\hat{m}_L\}, \tag{1.4}$$

where $S_t(m)$ is the solution of (1.3) *starting from m at time* 0.

Theorem 1.2 is a corollary of Theorem 1.1 (but the converse is also true and indeed we will prove Theorem 1.1 as a consequence of Theorem 1.2). In fact, the semigroup $S_t(m)$ decreases the energy, in the sense that $\mathcal{F}_L(S_t(m))$ is a strictly decreasing function of t, unless m is a critical point. Moreover, by compactness and continuity the limit points of an orbit $S_t(m)$ are critical points and by lower semicontinuity of $\mathcal{F}_L$ their energy is smaller than $\mathcal{F}_L(m)$, hence (1.4).

The information on the basin of attraction of $\{m^{(-)},m^{(+)},\hat{m}_L\}$ contained in Theorem 1.2 is sufficient for the analysis of tunneling, because the control parameter is the energy, but in many applications in statistical physics natural neighborhoods are in the L^∞ topology. In such neighborhoods the energy may grow proportionally to L (the domain size) and new criteria for being attracted to $\{m^{(-)},m^{(+)},\hat{m}_L\}$ are needed. To formulate the results we need some more notation and definition and we postpone the issue to the next section at the end of which we give an outline on the content of the paper. A preliminary version of the present paper is in Ref. 4.

II. DEFINITIONS AND RESULTS

For ease of notation it is sometimes convenient to work in the whole line rather than in $[-L,L]$, this is possible provided we suitably restrict the space of functions. $m \in L^\infty(\mathbb{R};[-1,1])$ is symmetric around ξ if $m(\xi+x)=m(\xi-x)$, $x \in \mathbb{R}$; it is called L-symmetric if it is symmetric around all points $(2n+1)L$, $n \in \mathbb{Z}$. The symmetric extension of $m \in L^\infty([-L,L];[-1,1])$ is then the L-symmetric function on $\mathbb{R}$ which agrees with m in $[-L,L]$ and

$$\int_{-L}^{L} \phi_\beta(m)\mathrm{d}x + \frac{1}{4}\int_{-L}^{L}\int_{\mathbb{R}} J(x,x')(m(x)-m(x'))^2\mathrm{d}x\ \mathrm{d}x' \tag{2.1}$$

is equal to $\mathcal{F}_L(m\mathbf{1}_{|x|\leqslant L})$. Moreover if m is L-symmetric and $S_t(m)$ solves

$$u_t = g(u) := -u + \tanh\{\beta J * u\}, \quad u(\cdot,0)=m, \tag{2.2}$$

then $S_t(m)$ is L-symmetric and its restriction to $[-L,L]$ solves (1.3). It is therefore equivalent to consider (2.1) and (2.2) on the space of L-symmetric functions or to work in the context of Sec. I, and we take advantage of this equivalence by setting each problem in the one of the two contexts which is more convenient for the specific purpose. To have more compact notation we sometimes use the same symbol for a function and its L-symmetric extension. Natural neighborhoods in statistical mechanics are defined in terms of "closeness in the average" and of "coarse graining" transformations. We briefly recall the main notion adapted to the present context.

Definition 2.1. (Coarse graining): Let $\mathcal{D}^{(\ell)}$, $\ell>0$, be the partition of $\mathbb{R}$ into the intervals $[n\ell, (n+1)\ell)$, $n \in \mathbb{Z}$, and $I_x^{(\ell)}$ the interval in $\mathcal{D}^{(\ell)}$ which contains the point x. Then the ℓ-coarse grained image of a L^∞ function m is

$$m^{(\ell)}(x) := \fint_{I_x^{(\ell)}} m(y)\mathrm{d}y, \quad \fint_\Lambda m(y)\mathrm{d}y := \frac{1}{|\Lambda|}\int_\Lambda m(y)\mathrm{d}y. \tag{2.3}$$

Definition 2.2. (Phase indicators): Given an "accuracy parameter" $\zeta>0$, let

$$\eta^{(\zeta,\ell)}(m;x) = \begin{cases} \pm 1 & \text{if } |m^{(\ell)}(x) \mp m_\beta| \leqslant \zeta \\ 0 & \text{otherwise.} \end{cases}$$

Denoting ℓ_- and ℓ_+ two values of the parameter ℓ, with ℓ_+ an integer multiple of ℓ_-, we then define the "phase indicator"

$$\Theta^{(\zeta,\ell_-,\ell_+)}(m;x) = \begin{cases} \pm 1 & \text{if } \eta^{(\zeta,\ell_-)}(m;\cdot) = \pm 1 \text{ in } [-L,L] \cap (I^{(\ell_+)}_{x-\ell_+} \cup I^{(\ell_+)}_x \cup I^{(\ell_+)}_{x+\ell_+}) \\ 0 & \text{otherwise.} \end{cases}$$

Definition 2.3. (Contours): The contours of a function $m \in L^\infty$ are defined as the connected components of the set $\{x:\Theta^{(\zeta,\ell_-,\ell_+)}(m;x)=0\}$. $\Gamma=[x_-,x_+)$ is a plus contour if $\eta^{(\zeta,\ell_-)}(m;x_\pm)=1$, a minus contour if $\eta^{(\zeta,\ell_-)}(m;x_\pm)=-1$, otherwise it is called mixed. The parameters (ζ,ℓ_-,ℓ_+,L) are called compatible with $(\zeta_0,c_1,\kappa) \in \mathbb{R}^3_+$ if $\zeta \in (0,\zeta_0)$, $\ell_- \leqslant \kappa\zeta$, $1/\ell_- \leqslant \ell_+$; L is a multiple integer of ℓ_+ and ℓ_+ a multiple integer of ℓ_-.

Definition 2.4. (Good choice of parameters): In the sequel we take $\zeta \leqslant \zeta_0$, $\zeta_0>0$ suitably small, $L>\zeta^{-8}$ and $\ell_\pm$ determined by L and ζ as follows. ℓ_+ is the smallest number $\geqslant \zeta^{-4}$ such that $L=n\ell_+$, $n \in \mathbb{N}$; ℓ_- is the largest number $\leqslant \zeta^2$ such that $\ell_+=p\ell_-$, $p \in \mathbb{N}$, $p>1$. To have more compact notation we will omit the dependence on (ζ,ℓ_-,ℓ_+), unless ambiguities may arise.

The regions where $\Theta^{(\zeta,\ell_-,\ell_+)}(m;x)=1$ are said to be in plus equilibrium (or in the plus phase), those where $\Theta^{(\zeta,\ell_-,\ell_+)}=-1$ are in the minus equilibrium and the mixed contours which separate plus and minus regions represent an interface. The equilibrium interface (defined by an optimization problem, see Refs. 1 and 2) is represented, when the minus phase is to the left, by the instanton $\bar{m}(x)$ which is a stationary solution of (2.2)

$$\bar{m}(x) = \tanh\{\beta(J * \bar{m})(x)\}, \quad x \in \mathbb{R}, \tag{2.4}$$

with asymptotic behavior

$$\lim_{x\to\pm\infty} \bar{m}(x) = \pm m_\beta. \tag{2.5}$$

As recalled in Sec III, $\bar{m}(x)$ is unique (modulo translations) and it is a $\mathcal{C}^\infty$, strictly increasing, antisymmetric function. We denote by $\bar{m}_\xi$ a translation of the instanton, namely

$$\bar{m}_\xi(x) = \bar{m}(x-\xi), \quad \xi \in \mathbb{R} \tag{2.6}$$

which is interpreted as the equilibrium interface located at ξ.

Definition 2.5. (Neighborhoods of pure phases and interfaces): Given $k \in \mathbb{N}$ and $(\zeta, \ell_-, \ell_+, L)$ as in Definition 2.4, setting $\Theta = \Theta^{(\zeta,\ell_-,\ell_+)}$, we define

$U_- = \{m \in L^\infty([-L,L];[-1,1]) : \Theta(m,\cdot) < 1, |\{\Theta(m,\cdot)=0\}| \le k\ell_+\}$,

$U_+ = \{m : -m \in U_-\}$,

$U_{-,+} = \{m \in L^\infty([-L,L];[-1,1]) : m$ has a unique mixed contour $\Gamma, |\Gamma| \le k\ell_+$, and there exists $\xi \in \Gamma$ such that $\mathrm{dist}(\xi, [-L,L]\setminus\Gamma) \ge \ell_+/2$, and $|m^{(\ell_-)} - \bar{m}_\xi^{(\ell_-)}| \le 2\zeta$ on $[-L,L]\}$,

$U_{+,-} = \{m : -m \in U_{-,+}\}$.

Observing that U_-, U_+, $U_{-,+}$, $U_{+,-}$ are pairwise disjoint, we finally define

$$U = U_- \cup U_{-,+} \cup U_{+,-} \cup U_+.$$

A first step in the proof of Theorem 1.2 is the following result, proved in Sec. VI.

Theorem 2.6: *If $\zeta > 0$ is small enough, there is $k \in \mathbb{N}$ such that, for L large enough*

$$\{m \in L^\infty([-L,L];[-1,1]) : \mathcal{F}_L(m) < \mathcal{F}_L(\hat{m}_L) + \zeta^{100}\} \subset U$$

(recall that U depends on k and ζ).

Of course, the number 100 in the previous statement can be replaced by any number sufficiently large. The profiles in $U_- \cup U_+$ are attracted by $m^{(\pm)}$, more precisely in Sec. VII we prove the following theorem.

Theorem 2.7: *If $\zeta > 0$ is small enough, there is $k \in \mathbb{N}$ such that, for L large enough*

$$\lim_{t\to\infty} \|S_t(m) - m^{(\pm)}\|_\infty = 0 \quad \text{for all } m \in U_\pm$$

so that if $m \in U_\pm$ is stationary then $m = m^{(\pm)}$.

If $m \in U \setminus (U_- \cup U_+)$, then m may either be attracted by $m^{(\pm)}$ as in Theorem 2.7 but it could also be attracted by $\hat{m}_L$.

Theorem 2.8: *Given any $r \in (0,1)$, for all L large enough the set $\{m \in U_{-,+} : \Gamma \cap (-L, -rL] \neq \emptyset\}$ (Γ the contour of $m \in U_{-,+}$) is attracted by $m^{(+)}$; the set $\{m \in U_{-,+} : \Gamma \cap [rL, L) \neq \emptyset\}$ by $m^{(-)}$; any other $m \in U_{-,+}$ is attracted either by $m^{(\pm)}$ or by $\hat{m}_L$.*

By symmetry under sign change, Theorem 2.8 extends to its analog in $U_{+,-}$, we do not state explicitly the result. Theorem 2.8 is proved in two steps. We show that any element in $U_{-,+}$ evolves after a finite time to a function which is in sup norm close to an instanton (restricted to $[-L,L]$); we then prove that functions close to an instanton in sup norm are attracted to $m^{(\pm)}$ if the center of the instanton is not too close to the origin, otherwise they may as well converge to $\hat{m}_L$.

Outline of the paper: In Sec. III we recall results known in the literature and which are used later in the proofs. Therefore in a first reading Sec. III may be skipped: specific references to the results stated in Sec. III will be given when needed. In Sec. IV we prove lower bounds on $\mathcal{F}_L$ analogous to the Peierls bounds in statistical mechanics. In Sec. V we prove lower bounds on the infinite volume version $\mathcal{F}$ of the free energy functional. With such a background, in Sec. VI we then prove the localization statement in Theorem 2.6. The second part of this article contains the analysis of the critical points in U: in Sec. VII we prove Theorem 2.7. In Sec. VIII we prove that

functions close to an instanton in sup norm are attracted to $m^{(\pm)}$ if the center of the instanton is not too close to the origin. This proof exploits the existence of a traveling subsolution that converges to $m^{(\pm)}$ as proved in Sec. IX and the Appendix . Finally in Sec. X we complete the proof of Theorem 2.8.

III. GENERAL BACKGROUND

In this section we collect some results in the literature which will be useful in the sequel. Some statements are not really explicit in the literature, in particular those about the finite volume instantons (see Sec. III C) which often have been proved in the presence of an external magnetic field, but they are all close enough to omit their proofs. The assumption that $J(0,x)$ is a nonincreasing function of $x \geqslant 0$ is used only in Sec. III C, all the other statements hold without such an assumption and in more generality.

In Sec. III A we state results on the spirit of the Peierls estimates for the free energy functional. To this end we need some definitions.

If Λ is a finite union of intervals contained in $[-L,L]$, we write $\Lambda^c := [-L,L] \setminus \Lambda$ for its complement in $[-L,L]$ and m_Λ for the restriction of m to Λ. We define

$$\mathcal{F}_{L;\Lambda}(m_\Lambda) = \int_\Lambda \phi_\beta(m_\Lambda)\mathrm{d}x + \frac{1}{4}\int_\Lambda \int_\Lambda J^{\mathrm{neum}}(x,x')(m_\Lambda(x) - m_\Lambda(x'))^2 \mathrm{d}x\, \mathrm{d}x',$$

$$\mathcal{F}_{L;\Lambda}(m_\Lambda | m_{\Lambda^c}) = \mathcal{F}_{L;\Lambda}(m_\Lambda) + \frac{1}{2}\int_\Lambda \int_{\Lambda^c} J^{\mathrm{neum}}(x,x')(m_\Lambda(x) - m_{\Lambda^c}(x'))^2 \mathrm{d}x\, \mathrm{d}x'. \tag{3.1}$$

We let $\mathcal{F}(m)$ be the functional on $L^\infty(\mathbb{R};[-1,1])$ with values in $[0,\infty]$ defined by (1.1) with $L = \infty$ and J in place of J^{neum}.

A. Properties of the free energy functional (Ref. 11)

We suppose that ζ_0, c_1, and $0 < \kappa < 1$ are small enough and that the parameters $(\zeta, \ell_-, \ell_+, L)$ are compatible with ζ_0, c_1, and κ.

- There is $\omega > 0$ so that for any interval $\Lambda = [x', x'') \subset [-L,L]$, union of intervals belonging to $\mathcal{D}^{(\ell_+)}$, and for any m such that $\eta^{(\zeta,\ell_-)}(m;\cdot) = 1$ on Λ, there is ψ with the following properties. $\mathcal{F}_L(m) \geqslant \mathcal{F}_L(\psi)$; $\psi = m$ on $[x'+1, x''-1]^c$; $\eta^{(\zeta,\ell_-)}(\psi;\cdot) = 1$ on Λ;

$$\psi = \tanh\{\beta J^{\mathrm{neum}} * \psi\}, \quad \text{on } [x'+1, x''-1], \tag{3.2}$$

$$|\psi(x) - m_\beta| \leqslant c_2 e^{-\omega\ \mathrm{dist}(x,\Lambda^c)}, \quad x \in [x'+1, x''-1]. \tag{3.3}$$

  Equation (3.2) supplemented by the condition $\psi = m$ outside $[x'+1, x''-1]$, has a unique solution. The analogous result holds for $\Theta^{(\zeta,\ell_-,\ell_+)}(m;\cdot) = -1$ on Λ and $-m_\beta$ replaced by m_β and when $L = \infty$ (in which case $[x', x'')$ may also be unbounded).
- Let $\Gamma = [x', x'')$ be a contour for $m \in L^\infty([-L,L];[-1,1])$. Then

$$\mathcal{F}_{L;\Gamma}(m_\Gamma | m_{\Gamma^c}) \geqslant 2c_1\zeta^2\frac{\ell_-}{\ell_+}. \tag{3.4}$$

- The functional $\mathcal{F}_L(m)$ is continuous both in L^2 and L^∞. Then (lower semicontinuity) if m_n converges to m in $L^2_{\mathrm{loc}}(\mathbb{R})$,

$$\liminf_{n\to\infty} \mathcal{F}(m_n) \geqslant \mathcal{F}(m).$$

We now state results on the dynamics (2.2) which will be used in the sequel. We start with the following theorem that summarizes general properties of the evolution whose proof can be found for instance in Ref. 11.

Theorem 3.1: *The following holds.*

(1) *Super and subsolutions.* $z(x,t)$, $x\in\mathbb{R}$, $t\geqslant 0$, *is a subsolution (respectively, a supersolution) of* (1.3) *if* $z_t - g_L(z) \leqslant 0$ *[respectively* $\geqslant 0$*]. Then* $z(\cdot,t)\leqslant S_t(m)$, *if* $z(\cdot,0)\leqslant m$ *[respectively* $z(\cdot,t)\geqslant S_t(m)$, *if* $z(\cdot,0)\geqslant m$*].*

(2) *Barrier Lemma. There is a constant* $C>0$ *so that, setting* $m_i(\cdot,t)=S_t(m_i)$, $i=1$, *2, for any* $V\geqslant e^2\beta$ *and for any* $t>0$,

$$\sup_{s\leqslant t}|m_1(0,s)-m_2(0,s)| \leqslant e^{(\beta-1)t}\sup_{|r|\leqslant Vt}|m_1(r,0)-m_2(r,0)| + Ce^{-tV\log(V/(e\beta))}. \tag{3.5}$$

(3) *Basin of attraction of* $m^{\pm}$. *The sets* $\{m\in L^\infty(\mathbb{R};[-1,1]):\lim_{t\to\infty}\|S_t(m)-m^{\pm}\|_\infty=0\}$ *are open both in* L^2 *and* L^∞ *and they contain the functions which are strictly positive, respectively negative.*

We call instantons stationary solutions of (1.3) and (2.2) which are increasing, antisymmetric, and bounded in modulus by m_β. In particular we denote by $\bar m:\mathbb{R}\to(-m_\beta,m_\beta)$ an instanton on the whole of $\mathbb{R}$ and by $\hat m_L:[-L,L]\to(-m_\beta,m_\beta)$ a finite volume instanton, thus

$$\bar m(x)=\tanh\{\beta J*\bar m(x)\},\quad x\in\mathbb{R};\qquad \hat m_L(x)=\tanh\{\beta J^{\mathrm{neum}}*\hat m_L(x)\},\quad x\in[-L,L].$$

Properties like existence, uniqueness, and stability of instantons have been widely studied and, in the next two subsections, we summarize those needed in the sequel.

B. Properties of the instanton (see Refs. 8 and 11)

There is a unique antisymmetric $\bar m(x)$ solution of (2.4) and (2.5). Further, $\bar m(x)$ is a $\mathcal{C}^\infty$, strictly increasing and antisymmetric function.

(1) *Asymptotic behavior of the instanton*. For $\beta>1$, let $\alpha>0$ be such that

$$\beta(1-m_\beta^2)\int_{\mathbb{R}} J(0,y)e^{\alpha y}\mathrm{d}y = 1. \tag{3.6}$$

Then there are $a>0$, $\alpha_0>\alpha$ and $c>0$ so that for all $x\geqslant 0$

$$|\bar m(x)-(m_\beta-ae^{-\alpha x})|+|\bar m'(x)-a\alpha e^{-\alpha x}|+|\bar m''(x)+a\alpha^2e^{-\alpha x}|\leqslant ce^{-\alpha_0 x}, \tag{3.7}$$

where $\bar m'$ and $\bar m''$ are, respectively, the first and second derivatives of $\bar m$.

(2) *Basin of attraction of the instantons manifold*. All the translations of $\bar m$ are solutions of (2.4) and, recalling (2.6), we have that the set $\{\bar m_\xi:\xi\in\mathbb{R}\}$ attracts the set

$$\mathcal{N}:=\{m\in L^\infty(\mathbb{R};[-1,1]):\limsup_{x\to-\infty}m(x)<0,\quad \liminf_{x\to\infty}m(x)>0\}. \tag{3.8}$$

Namely, if $m\in\mathcal{N}$, then there is $\xi\in\mathbb{R}$ so that

$$\lim_{t\to\infty}\|S_t(m)-\bar m_\xi\|_\infty=0. \tag{3.9}$$

(3) ξ is a center of m if

$$(m-\bar m_\xi,\bar m_\xi')_\xi=0, \tag{3.10}$$

where $(\cdot,\cdot)_\xi$ denotes the scalar product in $L^2(\mathbb{R},d\nu_\xi)$, and

$$\frac{\mathrm{d}\nu_\xi(x)}{\mathrm{d}x} = p_\xi(x)^{-1}, \quad p_\xi(x) = \beta[1 - \bar{m}_\xi(x)^2]. \tag{3.11}$$

(4) Any $m \in \mathcal{N}$ has a center. Moreover, there are positive constants c and δ so that if $v = m - \bar{m}_{\xi_0}$, $\|v\|_\infty < \delta$ then m has a unique center ξ and letting

$$N_{v,\xi} = \frac{(v, \bar{m}')_\xi}{(\bar{m}', \bar{m}')_\xi}, \quad N_{v,0} = N_v$$

we have

$$|\xi - (\xi_0 - N_{v,\xi_0})| \leq c\|v\|_\infty^2, \quad |N_{v,\xi_0}| \leq c\|v\|_\infty.$$

(5) Let Ω_ξ be the linear operator on $L^\infty(\mathbb{R})$ or $L^2(\mathbb{R}, \mathrm{d}\nu_\xi)$

$$\Omega_\xi \psi = -\psi + p_\xi J * \psi \tag{3.12}$$

obtained by linearizing (2.2) around $\bar{m}_\xi$. Ω_ξ has eigenvalue 0 with eigenvector $\bar{m}_\xi'$ and a strictly positive spectral gap both as an operator in $L^\infty(\mathbb{R})$ and in $L^2(\mathbb{R}, d\nu_\xi)$. Thus, there is $B > 0$ so that

$$(v, \Omega_\xi v)_\xi \leq -B(v,v)_\xi, \quad (v, \bar{m}_\xi')_\xi = 0. \tag{3.13}$$

C. Properties of finite volume instantons (see Refs. 5–8)

(1) The instanton $\hat{m}_L$ is an antisymmetric function, and there are $\mathfrak{s}$ and C so that

$$|\hat{m}_L(x) - m_\beta| \leq Ce^{-\mathfrak{s}(L-x)}, \quad 0 < x < L. \tag{3.14}$$

Moreover, given any $\epsilon > 0$, if L is large enough

$$\sup_{|x| \leq L} |\hat{m}_L(x) - \bar{m}(x)| \leq \epsilon.$$

(2) Let $\hat{\mathcal{L}}$ be the operator on $L^2([-L, L], \mathrm{d}\hat{\nu}_L)$, $\mathrm{d}\hat{\nu}_L/\mathrm{d}x = [\beta(1 - \hat{m}_L^2)]^{-1}$,

$$\hat{\mathcal{L}}\psi = -\psi + \beta(1 - \hat{m}_L^2) J * \psi$$

obtained by linearizing (1.3) around $\hat{m}_L$. If L is large enough, $\hat{\mathcal{L}}$ has a positive eigenvalue λ, $c_- e^{-2L} \leq \lambda \leq c_+ e^{-2L}$, $c_\pm$ positive constants, with eigenvector $e_{\hat{m}_L}(x)$, $|x| \leq L$, which is a strictly positive, regular symmetric function. Moreover, there is $B' > 0$ so that for all L large enough

$$(v, \hat{\mathcal{L}} v)_{\hat{m}_L} \leq -B'(v,v)_{\hat{m}_L}, \quad (v, e_{\hat{m}_L})_{\hat{m}_L} = 0,$$

where $(\cdot, \cdot)_{\hat{m}_L}$ is the scalar product on $L^2([-L, L], d\hat{\nu}_L)$.

(3) Given any $\epsilon > 0$ small enough and $r \in (0, 1)$, define

$$B_{\epsilon,r} := \{m \in L^\infty([-L, L]; [-1, 1]) : \exists\, \xi \in [-rL, rL] : \|m - \bar{m}_\xi \mathbf{1}_{|x| \leq L}\|_\infty \leq \epsilon\} \tag{3.15}$$

$$\Sigma_{\epsilon,r}^\pm := \{m \in L^\infty([-L, L]; [-1, 1]) : \|m - \bar{m}_\xi \mathbf{1}_{|x| \leq L}\|_\infty \leq \epsilon \quad \text{for } \xi = \pm rL\}.$$

Then, for L large enough, if m is in $B_{\epsilon,r}$ either $\lim_{t \to \infty} \|S_t(m) - \hat{m}_L\|_\infty = 0$ or else there is a time t when $S_t(m) \in \Sigma_{2\epsilon,r}^- \cup \Sigma_{2\epsilon,r}^+$ while $S_s(m) \in B_{2\epsilon,r}$ for all $s \leq t$.

(4) There exist two manifolds, $w^{(\pm)}(x, s)$, $x \in [-L, L]$, $s \in \mathbb{R}$, such that $\mathcal{F}_L(w^\pm(\cdot, s)) < \mathcal{F}_L(\hat{m}_L)$,

$$S_t(w^{(\pm)}(\cdot, s)) = w^{(\pm)}(\cdot, s + t)$$

$w^{(\pm)}(\cdot, \cdot) \in (-m_\beta, m_\beta)$ and

$$\lim_{s\to-\infty} w^{(\pm)}(\cdot,s)=\hat{m}_L,\quad \lim_{s\to\infty} w^{(\pm)}(\cdot,s)=m^{(\pm)}$$

(the limits can be taken both in L^∞ and in L^2). Moreover, for any $s\in\mathbb{R}$, $w^{(+)}(x,s)$ is a non decreasing function of $x\in[-L,L]$, $w^{(-)}(x,s)=-w^{(+)}(-x,s)$ and $w^{(+)}(x,s)>w^{(-)}(x,s)$.

IV. LOWER BOUNDS FOR $\mathcal{F}_L$

The main result of this section is Theorem 4.2 where we estimate the cost in energy of the contours. This result extends (3.4) and its proof is mainly taken from Ref. 12.

We first prove the following preliminary proposition.

Proposition 4.1: There are $c>0$ and $\omega>0$ so that for all L large enough

$$|\mathcal{F}(\bar{m})-\mathcal{F}_L(\hat{m}_L)|\leqslant ce^{-\omega L}. \tag{4.1}$$

Proof: The orbit $S_t(\bar{m}(x)\mathbf{1}_{|x|\leqslant L})$ is made of antisymmetric functions since antisymmetry is preserved by the dynamics. Thus any limit point of the orbit is antisymmetric and it is a stationary solution because $\mathcal{F}_L$ is strictly decreasing at points which are not stationary solutions. Then by item 3 of Sec. III C, $S_t(\bar{m}(x)\mathbf{1}_{|x|\leqslant L})$ converges to $\hat{m}_L$ so that

$$\mathcal{F}_L(\bar{m}\mathbf{1}_{|x|\leqslant L})\geqslant\mathcal{F}_L(\hat{m}_L). \tag{4.2}$$

On the other hand,

$$\mathcal{F}_L(\bar{m}\mathbf{1}_{|x|\leqslant L})\leqslant\mathcal{F}(\bar{m})+\frac{1}{2}\int_{[-L,L]}\int_{[-L,L]^c}J(x,y)\{(\bar{m}(x)-\bar{m}(R(y))^2-(\bar{m}(x)-\bar{m}(y))^2\}\mathrm{d}y\,\mathrm{d}x, \tag{4.3}$$

where $R(y)$ denotes the point obtained by reflecting y around $-L$ or L, respectively, when $y>L$ and $y<-L$. By (3.7), (4.2), and (4.3) we get $\mathcal{F}_L(\hat{m}_L)\leqslant\mathcal{F}(\bar{m})+ce^{-\omega L}$ for L large enough.

To prove the lower bound, we denote by $\tilde{m}(x)$ the function equal to $\hat{m}_L$ for $|x|\leqslant L$ and to $\pm m_\beta$, for $x>L$ and, respectively, $x<-L$. Then

$$\mathcal{F}_L(\hat{m}_L)=\mathcal{F}(\tilde{m})+\frac{1}{2}\int_{[-L,L]}\int_{[-L,L]^c}J(x,y)\{(\hat{m}_L(x)-\hat{m}_L(R(y))^2-(\hat{m}_L(x)\mp m_\beta)^2\}\mathrm{d}y\,\mathrm{d}x,$$

where $\mp$ is minus if $x>0$ and plus if $x<0$. By (3.9), $\lim_{t\to\infty}S_t(\tilde{m})=\bar{m}$ and since $\mathcal{F}$ is lower semicontinuous, $\mathcal{F}(\tilde{m})\geqslant\mathcal{F}(\bar{m})$. Then, by (3.14), we conclude the proof. □

Theorem 4.2: *There are positive constants ζ_0, c_1, κ, c_2, and ω so that if (ζ,ℓ_-,ℓ_+,L) is compatible with (ζ_0,c_1,κ), then*

$$\mathcal{F}_L(m)\geqslant\sum_{\Gamma\text{ contour of }m}w_{\zeta,\ell_-,\ell_+}(\Gamma)\quad\forall\, m\in L^\infty([-L,L];[-1,1]), \tag{4.4}$$

where

$$w_{\zeta,\ell_-,\ell_+}(\Gamma)=\begin{cases}2c_1\zeta^2\dfrac{\ell_-}{\ell_+}|\Gamma| & \text{if }\Gamma\text{ is a plus or a minus contour}\\ \max\left\{2c_1\zeta^2\dfrac{\ell_-}{\ell_+}|\Gamma|;\mathcal{F}(\bar{m})-c_2e^{-\omega\ell_+}\right\} & \text{if }\Gamma\text{ is a mixed contour.}\end{cases}$$

Proof: Let G_+, respectively G_-, be the collection of all plus, minus, contours for m. By (3.1) and (3.4), for any $\Gamma\in G_+\cup G_-$,

$$\mathcal{F}_L(m) = \mathcal{F}_{L;\Gamma^c}(m_{\Gamma^c}) + \mathcal{F}_{L;\Gamma}(m_\Gamma|m_{\Gamma^c}) \geqslant \mathcal{F}_{L;\Gamma^c}(m_{\Gamma^c}) + 2c_1\zeta^2\frac{\ell_-}{\ell_+}|\Gamma|.$$

Denoting by Δ the complement in $[-L,L]$ of $G_+\cup G_-$, iterating we deduce

$$\mathcal{F}_L(m) \geqslant \mathcal{F}_{L;\Delta}(m_\Delta) + 2c_1\zeta^2\frac{\ell_-}{\ell_+}\sum_{\Gamma\in G_+\cup G_-}|\Gamma|.$$

Let $\Gamma=[x',x'')$ be a mixed contour possibly still present in Δ. We could bound it using the previous procedure, but we could also use the following alternative, which will be adopted when it gives a better bound. We have $\eta^{(\zeta,\ell_-)}(m;\cdot)=-1$ on $[x'-\ell_+,x'+\ell_+)$ and $\eta^{(\zeta,\ell_-)}(m;\cdot)=1$ on $[x''-\ell_+,x''+\ell_+)$ or viceversa. Suppose for instance that the former holds. By (3.2) and (3.3), there is ψ equal to m_Δ outside $[x'-\ell_++1,x'+\ell_+-1]$ such that $\eta^{(\zeta,\ell_-)}(\psi;\cdot)=-1$ on $[x'-\ell_+,x'+\ell_+)$, $\psi=-m_\beta$ on $[x'-1,x']$ and

$$\mathcal{F}_{L;\Delta}(m_\Delta) \geqslant \mathcal{F}_{L;\Delta}(\psi) - c'e^{-\omega\ell_+}.$$

By repeating the argument relative to the interval $[x''-\ell_++1,x''+\ell_+-1]$, we conclude that there is ϕ equal to ψ outside $[x''-\ell_++1,x''+\ell_+-1]$ such that $\eta^{(\zeta,\ell_-)}(\phi;\cdot)=1$ on $[x''-\ell_+,x''+\ell_+)$, $\phi=m_\beta$ on $[x''-1,x''+1]$ and

$$\mathcal{F}_{L;\Delta}(m_\Delta) \geqslant \mathcal{F}_{L;\Delta}(\phi) - 2c'e^{-\omega\ell_+}.$$

We then have

$$\mathcal{F}_{L;\Delta}(m_\Delta) \geqslant \mathcal{F}_{L;\Delta\setminus\Gamma}(m_{\Delta\setminus\Gamma}) + \mathcal{F}_\Gamma(\phi_\Gamma|m_\beta\mathbf{1}_{x>x''} - m_\beta\mathbf{1}_{x<x'}) - 2c'e^{-\omega\ell_+}.$$

Let $u(x)$, $x\in\mathbb{R}$, be equal to ϕ on Γ and $=\pm m_\beta$ to the right and left of Γ, then

$$\mathcal{F}_\Gamma(\phi_\Gamma|m_\beta\mathbf{1}_{x>x''} - m_\beta\mathbf{1}_{x<x'}) = \mathcal{F}(u) \geqslant \mathcal{F}(\bar{m})$$

by (3.9) and because $\mathcal{F}(S_t(u))$ is decreasing and lower semicontinuous. Thus

$$\mathcal{F}_{L;\Delta}(m_\Delta) \geqslant \mathcal{F}_{L;\Delta\setminus\Gamma}(m_{\Delta\setminus\Gamma}) + \max\left\{\mathcal{F}(\bar{m}) - 2c'e^{-\omega\ell_+}; 2c_1\zeta^2\frac{\ell_-}{\ell_+}|\Gamma|\right\}.$$

By iterating the argument over all the other, possibly still present, mixed contours, we conclude the proof. □

V. LOWER BOUNDS FOR $\mathcal{F}$

In this section we prove that the free energy of a profile $m\in L^\infty(\mathbb{R};[-1,1])$ which is asymptotically strictly positive as $x\to\infty$ and negative as $x\to-\infty$ increases quadratically with the distance of m from $\bar{m}$, the precise statement is given in Proposition 5.2. We need preliminarily a regularization result.

Proposition 5.1: There is $c>0$ and for all ℓ small enough and such that $L=n\ell$, $n\in\mathbb{N}$, there is a (regularizing) map $\mathcal{R}$ from $L^\infty([-L,L];[-1,1])$ into itself, continuous in the L^∞ norm, such that $\mathcal{F}_L(m)\geqslant\mathcal{F}_L(\mathcal{R}(m))$,

$$(\mathcal{R}(m))^{(\ell)} = m^{(\ell)},$$

where $\mathcal{R}(m)$ is differentiable at all points of $[-L,L]\setminus\ell\mathbb{Z}$, and

$$\left|\frac{d\mathcal{R}(m)(x)}{dx}\right| \leqslant \beta\|J'\|_\infty, \quad x\in[-L,L]\setminus\ell\mathbb{Z}. \tag{5.1}$$

Proof: Given m we denote by

$$M_i := \fint_{I_i} m(y)\mathrm{d}y,$$

where $I_i \in \mathcal{D}^{(\ell)}$ is the ith element of the partition of $[-L,L]$.

We want to prove that there is a unique function ψ_i which verifies the following properties:

(1) $\psi_i(x)=m(x)$ for all $x \in I_i^c$,
(2) $\fint_{I_i}\psi_i(y)dy=M_i$, and
(3) if φ verifies (1) and (2), then $\mathcal{F}_L(\varphi|m_{I_i^c}) \geqslant \mathcal{F}_L(\psi_i|m_{I_i^c})$.

To prove the above-mentioned properties we introduce a Lagrange multiplier h and define

$$\mathcal{F}_{L,h}(\varphi|m_{I_i^c}) := \mathcal{F}_L(\varphi|m_{I_i^c}) - h\int_{I_i}\varphi(y)\mathrm{d}y.$$

The inf of $\mathcal{F}_{L,h}(\cdot|m_{I_i^c})$ over $L^\infty([-L,L];[-1,1])$ is reached on functions u such that $A_h(u)=u$, where

$$A_h(u) = \begin{cases} \tanh\{\beta[J*u+h]\} & \text{on } I_i \\ m_{I_i^c} & \text{on } I_i^c \end{cases}$$

(see for instance Ref. 11). For ℓ such that $\beta\|J\|_\infty\ell<1/2$, A_h is a contraction:

$$\|A_h(\phi)-A_h(\psi)\|_\infty \leqslant \beta\|J\|_\infty\ell\|\phi-\psi\|_\infty.$$

Denote by $\phi^{(h)}$ its unique fixed point: $\phi^{(h)}=A_h(\phi^{(h)})$, $\phi^{(h)}=\lim_{n\to\infty}A_h^n(u)$, where, for instance $u \equiv 0$. From such a representation we deduce that, for each x, $\phi^{(h)}(x)$ is differentiable in h. By differentiating the fixed point equation, we find for $x \in I_i$,

$$\frac{d\phi^{(h)}}{dh} = p_h\left\{J*\frac{d\phi^{(h)}}{dh}+1\right\}, \quad p_h = \frac{\beta}{\cosh^2\left\{\beta\left[J*\frac{\mathrm{d}\phi^{(h)}}{\mathrm{d}h}+h\right]\right\}}$$

with $\mathrm{d}\phi^{(h)}(x)/\mathrm{d}h=0$ when $x \notin I_i$. For the above-mentioned ℓ, this identifies uniquely $\mathrm{d}\phi^{(h)}/\mathrm{d}h$ and shows that when $x \in I_i$, the derivative is strictly positive. Then

$$a(h) := \fint_{I_i}\phi^{(h)}(x)\mathrm{d}x$$

is a strictly increasing, continuous function of h; since $a(h)\to\pm1$ as $h\to\pm\infty$, there is h^* such that, $a(h^*)=M_i$ and h^* depends continuously on M_i and since M_i is a continuous function of m, $\phi^{(h^*)}$ is a continuous function of m.

The function $\psi_i := \phi^{(h^*)}$ verifies the previous (1) and (2). Let φ be any other function which verifies (1) and (2). Then, unless $\varphi=\psi_i$ almost everywhere,

$$\mathcal{F}_L(\varphi|m_{I_i^c}) = \mathcal{F}_{L,h^*}(\varphi|m_{I_i^c}) + h^*\ell M_i > \mathcal{F}_{L,h^*}(\psi_i|m_{I_i^c}) + h^*\ell M_i = \mathcal{F}_L(\psi_i|m_{I_i^c}).$$

Finally $\phi^{(h^*)}(x)$ is differentiable with respect to (w.r.t.) x in the interior of I_i and its derivative is bounded as in (5.1), as it follows by differentiating the fixed point equation and integrating by parts using regularity of J.

By repeating the argument for the other intervals I_j's we conclude the proof of the proposition. □

Since the proof is local, Proposition 5.1 holds also when $[-L,L]$ is replaced by $\mathbb{R}$.

Proposition 5.2: There is $c>0$ so that for all ℓ small enough,

$$\mathcal{F}(m) \geqslant \mathcal{F}(\bar m) + c\,\ell\left(\inf_{\xi\in\mathbb{R}}\|m^{(\ell)}-\bar m_\xi^{(\ell)}\|_\infty\right)^2, \quad m \in \mathcal{N} \tag{5.2}$$

with $\mathcal{N}$ defined in (3.8).

Proof: Set

$$w_\ell(m) = \inf_{\xi\in\mathbb{R}} \|m^{(\ell)} - \bar{m}_\xi^{(\ell)}\|_\infty. \tag{5.3}$$

We start with an outline of the proof. By expanding $\mathcal{F}(m)$ around $\bar{m}_\xi$, and calling $v=m-\bar{m}_\xi$,

$$\mathcal{F}(m) = \mathcal{F}(\bar{m}_\xi) - (v,\Omega_\xi v)_\xi + \text{remainder terms} \tag{5.4}$$

with Ω_ξ defined in (3.12) and the scalar product right after (3.10). By (3.13), there is $B>0$ so that if $(v,\bar{m}'_\xi)_\xi=0$ then $(v,\Omega_\xi v)_\xi \leqslant -B(v,v)_\xi$. To prove (5.2) we thus have to take care of the remainder terms in (5.4), fit in the condition $(v,\bar{m}'_\xi)_\xi=0$ and finally relate the bound $(v,v)_\xi$ to the quantity $w_\ell(m)$.

We will prove that there are $\delta_0\in(0,1/2)$ and $c'>0$ so that

$$\inf_{\delta\leqslant\delta_0} \delta^{-2} \inf_{m\in\mathcal{N}:w_\ell(m)\geqslant\delta} [\mathcal{F}(m)-\mathcal{F}(\bar{m})] \geqslant c'\ell. \tag{5.5}$$

We claim that (5.2) will then hold with $c=c'\delta_0^2/4$. We first prove the claim for a function $m^*\in\mathcal{N}$ such that $\delta^* := w_\ell(m^*)\leqslant\delta_0$. Then, the inf on the left-hand side (l.h.s.) of (5.5) is not larger than the value at $\delta=\delta^*$, so that it is $\leqslant\delta^{*-2}[\mathcal{F}(m^*)-\mathcal{F}(\bar{m})]$, hence $c'\ell w_\ell(m^*)^2\leqslant[\mathcal{F}(m^*)-\mathcal{F}(\bar{m})]$, which yields (5.2) with c replaced by c'. Finally, $c'>c'\delta_0^2/4$ because $\delta_0<1/2$.

If instead $w_\ell(m^*)>\delta_0$, then (5.5) yields $\delta_0^{-2}[\mathcal{F}(m^*)-\mathcal{F}(\bar{m})]\geqslant c'\ell$ hence

$$\mathcal{F}(m^*)-\mathcal{F}(\bar{m}) \geqslant c'\ell w_\ell(m^*)^2 \frac{\delta_0^2}{w_\ell(m^*)^2}$$

which concludes the proof of the claim because $w_\ell(m^*)\leqslant 2$.

Thus (5.2) will be proved, once we show that if $\tilde{m}\in\mathcal{N}$ and $w_\ell(\tilde{m})\geqslant\delta$, then

$$\mathcal{F}(\tilde{m}) \geqslant \mathcal{F}(\bar{m}) + c'\ell\delta^2. \tag{5.6}$$

We first suppose that $w_\ell(\tilde{m})\leqslant\delta_0$. By Proposition 5.1, there is m in $\mathcal{N}$ such that

$$\mathcal{F}(\tilde{m})\geqslant\mathcal{F}(m), \quad \tilde{m}^{(\ell)}=m^{(\ell)}, \quad w_\ell(m)=w_\ell(\tilde{m})\geqslant\delta \tag{5.7}$$

with the derivative m' of m, almost everywhere well defined and such that

$$\|m'\|_\infty \leqslant \beta\|J'\|_\infty.$$

Then, given any ξ,

$$\|m^{(\ell)}-\bar{m}_\xi^{(\ell)}\|_\infty \leqslant \|m-\bar{m}_\xi\|_\infty \leqslant \|m^{(\ell)}-\bar{m}_\xi^{(\ell)}\|_\infty + \beta\|J'\|_\infty\ell.$$

Since $\|m^{(\ell)}-\bar{m}_\xi^{(\ell)}\|_\infty=\|\tilde{m}^{(\ell)}-\bar{m}_\xi^{(\ell)}\|_\infty$, if δ_0 and ℓ are small enough, by (3.12), m has a unique center ξ and

$$\delta_0+\beta\|J'\|_\infty\ell =: \epsilon \geqslant \|m-\bar{m}_\xi\|_\infty. \tag{5.8}$$

There is $a>0$ so that $\phi_\beta(m)\geqslant a(|m|-m_\beta)^2$ and, since $\phi_\beta(m)\in L^1(\mathbb{R})$ (because $\mathcal{F}(m)<\infty$), $m\mp m_\beta\in L^2(\mathbb{R}_\pm)$. Then, with ξ the center of m,

$$\mathcal{F}(m)-\mathcal{F}(\bar{m}_\xi) = -\frac{1}{\beta}\int \mathcal{S}(m(x))-\mathcal{S}(\bar{m}_\xi(x))\mathrm{d}x - \frac{1}{2}\int\int J(x,y)\{m(x)m(y)-\bar{m}_\xi(x)\bar{m}_\xi(y)\}\mathrm{d}x\,\mathrm{d}y.$$

Calling $v=m-\bar{m}_\xi$ and $\rho=\max(|m|,|\bar{m}_\xi|)$,

$$-\big(\mathcal{S}(m)-\mathcal{S}(\bar m_\xi)\big)\geqslant -\mathcal{S}'(\bar m_\xi)v+\frac{1}{1-\bar m_\xi^2}v^2-\frac{2}{1-\rho^2}|v|^3.$$

By (5.8), $\rho\leqslant m_\beta+\epsilon$ and by letting δ and ℓ small enough, $1-\rho^2\geqslant(1-m_\beta^2)/2$ so that

$$-\big(\mathcal{S}(m)-\mathcal{S}(\bar m_\xi)\big)\geqslant -\mathcal{S}'(\bar m_\xi)v+\frac{1}{1-\bar m_\xi^2}v^2-\frac{8}{1-m_\beta^2}|v|^3. \tag{5.9}$$

By (5.9) and since $-\beta^{-1}\mathcal{S}'(\bar m_\xi)-J*\bar m_\xi=0$,

$$\mathcal{F}(m)-\mathcal{F}(\bar m_\xi)\geqslant -(v,\Omega_\xi v)_\xi-\frac{8\|v\|_\infty}{1-m_\beta^2}(v,v)_\xi. \tag{5.10}$$

Since $(v,\bar m_\xi')_\xi=0$, because ξ is the center of m, by (3.13),

$$\mathcal{F}(m)-\mathcal{F}(\bar m_\xi)\geqslant (v,v)_\xi\left(B-\frac{8\|v\|_\infty}{1-m_\beta^2}\right). \tag{5.11}$$

By letting δ small enough we conclude that there is $c'>0$ so that, recalling (5.7),

$$\mathcal{F}(\tilde m)-\mathcal{F}(\bar m_\xi)\geqslant c'(v,v)_\xi\geqslant c'\ell\,\delta^2. \tag{5.12}$$

The last inequality is proved as follows. Since $w_\ell(m)=\delta$, there is an interval of $\mathcal{D}^{(\ell)}$ where $|m^{(\ell)}-\bar m_\xi^{(\ell)}|\geqslant\delta$. By using Cauchy–Schwartz in such an interval we then get (5.12).

This proves (5.6) when $w_\ell(\tilde m)\leqslant\delta_0$. This is what needed in the text and we omit, for brevity, the proof of the full statement in the theorem, which uses that if $m\in\mathcal{N}$, then $S_t(m)\to\bar m_\xi$ as $t\to\infty$, while $\mathcal{F}(S_t(m))\leqslant\mathcal{F}(m)$. The result then follows by showing that $w_\ell(S_t(m))$ is a continuous function of t, so that there is $s>0$ so that $w_\ell(S_s(m))=\delta$ with $\delta\leqslant\delta_0$. The proposition is proved.□

VI. LOCALIZATION OF THE ENERGY SUBLEVELS

In this section we prove the localization property of the free energy sublevels stated in Theorem 2.6, indeed the proof of Theorem 2.6 follows directly from Lemma 6.1 and Lemma 6.2.

Recalling Definitions 2.3 and 2.4, we choose L and $\ell_\pm$ as functions of ζ so that (ζ,ℓ_-,ℓ_+) is a good choice of the parameters. We also fix the positive constants ζ_0, c_1, κ, and c_2 of Theorem 4.2 and we write $\Theta(m;\cdot)$ for $\Theta^{(\zeta,\ell_-,\ell_+)}(m;\cdot)$. The following preliminary Lemmas are in fact corollaries of Theorem 4.2.

Lemma 6.1: There is $\zeta<\zeta_0$ so that if $m\in L^\infty([-L,L];[-1,1])$ is such that $\mathcal{F}_L(m)\leqslant\mathcal{F}_L(\hat m_L)+\zeta^{100}$, then the following holds:

$$|\{\Theta(m;\cdot)=0\}|\leqslant k\ell_+,\quad k=\text{smallest integer}\geqslant\frac{1}{c_1\zeta^2\ell_-}[\mathcal{F}_L(\hat m_L)+\zeta^{100}]. \tag{6.1}$$

Further, if there are two points $x_\pm\in[-L,L]$, $x_+>x_-$, where $\Theta(m;x_+)\Theta(m;x_-)=-1$, then there is a unique contour Γ and $|\Gamma|\leqslant k\ell_+$, k as in (6.1).

Proof: By (4.4) we have

$$c_1\zeta^2\frac{\ell_-}{\ell_+}\sum_\Gamma|\Gamma|\leqslant\mathcal{F}_L(\hat m_L)+\zeta^{100}$$

so that

$$|\{\Theta(m;\cdot)=0\}|\leqslant\frac{\ell_+}{c_1\zeta^2\ell_-}[\mathcal{F}_L(\hat m_L)+\zeta^{100}]$$

hence (6.1).

Assume now that there are $x_\pm$ as in the statement. Then there is at least one mixed contour that we denote by Γ. Suppose by contradiction that there is another contour Γ'. By using Theorem 4.2, the inequality (4.1) and the fact that $|\Gamma'|>\ell_+$ we get

$$\mathcal{F}_L(m) \geqslant \mathcal{F}(\bar{m}) - c_2 e^{-\omega\ell_+} + c_1\zeta^2\ell_- \geqslant \mathcal{F}_L(\hat{m}_L) - ce^{-\omega L} - c_2 e^{-\omega\ell_+} + c_1\zeta^2\ell_-. \tag{6.2}$$

Since $L>\zeta^{-8}$, if ζ is small enough, then the r.h.s. of (6.2) is larger than $\mathcal{F}_L(\hat{m}_L)+\zeta^{100}$, hence the desired contradiction, which shows that there is a unique contour Γ with (6.1) holding. □

Lemma 6.2: Let m, x_-, x_+ be as in Lemma 6.1 and let $\Gamma=[x_-,x_+)$ be the unique contour of m. Suppose $\Theta(m;x)=\pm 1$ for $x>x_+$, respectively $x<x_-$. Then there is $\xi\in[x_-+\ell_+/2, x_+-\ell_+/2]$, so that, for all ζ small enough,

$$\|m^{(\ell_-)} - \bar{m}_\xi^{(\ell_-)}\|_\infty \leqslant 2\zeta.$$

Proof: If $x>x_+$ then $\Theta(m;x)=1$ and for any $\xi\in\Gamma$, $\mathrm{dist}(\xi,\Gamma^c)\geqslant\ell_+/2$ from (3.7) we get

$$|m^{(\ell_-)}(x) - \bar{m}_\xi^{(\ell_-)}(x)| \leqslant |m^{(\ell_-)}(x) - m_\beta| + ce^{-\alpha\ell_+/2}.$$

Since $\eta(m;x)=1$ by taking ζ small enough we then get

$$|m^{(\ell_-)}(x) - \bar{m}_\xi^{(\ell_-)}(x)| \leqslant \zeta + ce^{-\alpha\ell_+/2} \leqslant 2\zeta \quad \text{for all } x > x_+.$$

An analogous argument applies in the case $x<x_-$ for which $\Theta(m;x)=-1$. Thus we only need to prove that there is $\xi\in[\xi_-,\xi_+]$, where $\xi_\pm=x_\pm\mp\ell_+/2$, so that,

$$\sup_{x\in\Gamma}|m^{(\ell_-)}(x) - \bar{m}_\xi^{(\ell_-)}(x)| \leqslant 2\zeta. \tag{6.3}$$

We suppose by contradiction that (6.3) is not verified by any $\xi\in[\xi_-,\xi_+]$ and want to deduce that $\mathcal{F}_L(m)>\mathcal{F}_L(\hat{m}_L)+\zeta^{100}$. The strategy for the proof is to reduce to a similar problem on the whole line where we can use Proposition 5.2.

By item 1 in Sec. III A, there is ψ which is equal to m on Γ, $\mathcal{F}_L(\psi)\leqslant\mathcal{F}_L(m)$ and

$$\sup_{x\in[-L,-L+1]}|\psi(x)+m_\beta| \leqslant c_2 e^{-\omega\ell_+}, \qquad \sup_{x\in[L-1,L]}|\psi(x)-m_\beta| \leqslant c_2 e^{-\omega\ell_+}. \tag{6.4}$$

We denote by ϕ the function on $\mathbb{R}$, equal to ψ on $[-L,L]$ and to m_β on $x>L$ and to $-m_\beta$ in $x<-L$. Then from (6.4) it follows that $\mathcal{F}_L(\phi)\geqslant\mathcal{F}(\phi)-ce^{-\omega\ell_+}$ that implies

$$\mathcal{F}_L(m) \geqslant \mathcal{F}(\phi) - c'e^{-\omega\ell_+}.$$

Since $\phi^{(\ell_-)}(x)=m^{(\ell_-)}(x)$, for all $x\in\Gamma$ and all $\xi\in[\xi_-,\xi_+]$, by the contradiction assumption

$$\sup_{x\in\Gamma}|\phi^{(\ell_-)}(x) - \bar{m}_\xi^{(\ell_-)}(x)| > 2\zeta \quad \text{for all } \xi\in[\xi_-,\xi_+].$$

Note now that if $\xi\leqslant\xi_-$ and $x=\xi_-+\ell_+/4$, then $|\phi^{(\ell_-)}(x)-\bar{m}_\xi^{(\ell_-)}(x)|\geqslant 2m_\beta-2c_2e^{-\omega\ell_+/4}-ce^{-\alpha\ell_+/8}>2\zeta$. An analogous argument applies for $\xi\geqslant\xi_+$, so that

$$\inf_{\xi\in\mathbb{R}}\|\phi^{(\ell_-)} - \bar{m}_\xi^{(\ell_-)}\|_\infty > 2\zeta.$$

Then, by Proposition 5.2, $\mathcal{F}(\phi)\geqslant\mathcal{F}(\bar{m})+c\ell_-(2\zeta)^2$. Moreover, by (4.1), $\mathcal{F}(\bar{m})\geqslant\mathcal{F}_L(\hat{m}_L)-ce^{-\omega L}$, so that $\mathcal{F}_L(m)>\mathcal{F}_L(\hat{m}_L)+2\zeta$ for ζ small enough, hence the desired contradiction. □

VII. ON THE BASIN OF ATTRACTION OF THE PURE PHASES

In this section we will prove Theorem 2.7. By symmetry it suffices to prove the statements relative to U_+. We start with the following preliminary proposition whose proof is taken from Ref. 12. Given $b>0$, $R>0$ let

$$\mathcal{M}_{b,R}=\{m\in L^\infty(\mathbb{R};[-1,1]):m(x)\geqslant b,|x|\geqslant R\}.$$

Proposition 7.1: For any ϵ, b, R *positive there is* $\tau_{\epsilon,b,R}$ *so that*

$$S_t(m)\geqslant m_\beta-\epsilon \quad \text{for all } m\in\mathcal{M}_{b,R} \quad \text{and } t\geqslant\tau_{\epsilon,b,R}. \tag{7.1}$$

Further

$$\lim_{t\to\infty}\|S_t(m)-m^{(+)}\|_\infty=0 \quad \text{for all } m\in\mathcal{M}_{b,R}. \tag{7.2}$$

Proof: By item 3 of Theorem 3.1, $\lim_{t\to\infty}S_t(-1)=-m_\beta$, where we shorthand by $S_t(a)$, $a\in\mathbb{R}$, the function $S_t(m)$ with $m\equiv a$. By item 1 of Theorem 3.1, for any $\epsilon_-<0$ there is $t_-<0$ so that for all m, $S_{t_-}(m)\geqslant S_{t_-}(-1)\geqslant -m_\beta-\epsilon_-$.

Since $\lim_{t\to\infty}S_t(b)=m_\beta$ by the Barrier Lemma (see item 2 of Theorem 3.1), for any $\epsilon'>0$, there are $t_0=t_0(b,\epsilon')$ and $a=a(b,R,\epsilon')$, $a>R$, so that, for any $m\in\mathcal{M}_{b,R}$,

$$S_{t_0}(m)\geqslant S_{t_0}(b)-\frac{\epsilon'}{2}\geqslant m_\beta-\epsilon',\quad |x|\geqslant a.$$

Thus

$$S_{t_0}(m)\geqslant\psi,\quad \psi(x)=\begin{cases}m_\beta-\epsilon' & \text{for } |x|\geqslant a\\ -m_\beta-\epsilon' & \text{otherwise.}\end{cases} \tag{7.3}$$

Let $d>0$ be such that $\bar m(x)\leqslant -m_\beta+\epsilon'$ for all $x\leqslant -d$. Then

$$\bar m_{d+a}(x)\leqslant -m_\beta+\epsilon' \quad \text{for all } x\leqslant a \tag{7.4}$$

so that, by (7.3), $\psi(x)\geqslant\bar m_{d+a}(x)-2\epsilon'$ for all $x\leqslant a$ and $\psi\geqslant\bar m_{d+a}-\epsilon'$ for all $x\geqslant a$. Hence

$$\psi\geqslant\bar m_{d+a}-2\epsilon' \quad \text{for all } x. \tag{7.5}$$

By item 2 of Sec. III B, if $\epsilon'>0$ is small enough, there is ξ so that

$$\lim_{s\to\infty}\|S_s(\bar m_{d+a}-2\epsilon')-\bar m_\xi\|_\infty=0.$$

Then any limit point ψ^* of $S_s(\psi)$ (under uniform convergence on the compacts) verifies $\psi^*\geqslant\bar m_\xi$. The set $A:=\{\xi'\in\mathbb{R}:\psi^*\geqslant\bar m_{\xi'}\}$ is thus nonempty and closed. In Sec. 5 of Ref. 11 it is proved that if m^* is stationary, $m^*\geqslant\bar m_\xi$ and $m^*\neq\bar m_\xi$ then there is $\xi'>\xi$ such that $m^*\geqslant\bar m_{\xi'}$. It then follows that either $A=\mathbb{R}$ or there is ξ'' so that $\psi^*=\bar m_{\xi''}$. The second alternative cannot be verified: denoting by $\mathcal{R}$ the reflection operator around 0, $\mathcal{R}\psi=\psi$, $S_t(\psi)=S_t(\mathcal{R}\psi)=\mathcal{R}S_t(\psi)$ and by $\{t_n\}$ the time sequence defining ψ^*,

$$\psi^*=\lim_{t_n\to\infty}S_{t_n}(\psi)=\mathcal{R}\lim_{t_n\to\infty}S_{t_n}(\psi)=\mathcal{R}\psi^*\geqslant-\bar m_{-\xi}$$

hence $\psi^*\geqslant\bar m_{\xi'}$ for all ξ'. Then ψ^* is strictly positive, and since ψ^* is stationary, $\psi^*=m_\beta$. Thus there is t_1 so that $S_{t_1}(\psi)\geqslant m_\beta-\epsilon$ and $S_{t_0+t_1}(m)\geqslant m_\beta-\epsilon$ for any $m\in\mathcal{M}_{b,R}$. From item 1 of Theorem 3.1 and from (7.1) it follows that

$$S_t(m_\beta-\epsilon)\leqslant S_{t+\tau_{\epsilon,b,R}}(m)\leqslant S_t(1). \tag{7.6}$$

Since $S_t(1)$ and $S_t(m_\beta-\epsilon)$ converge exponentially fast to m_β as $t\to\infty$, there are c and ω positive so that, for any $m\in\mathcal{M}_{b,R}$,

$$\|S_{t+\tau_{\epsilon,b,R}}(m) - m_\beta\|_\infty \leqslant ce^{-\omega t}. \tag{7.7}$$

□

By the Barrier Lemma (item 2 of Theorem 3.1) it is possible to weaken the condition $m(x) \geqslant b$ for all $|x| \geqslant R$ in Proposition 7.1. The extension is needed for applications to L-symmetric functions, which cannot be in $\mathcal{M}_{b,R}$ unless $m(x) \geqslant b$ for all x.

Let C and $V = e^2\beta$ be as in the Barrier Lemma, ζ, $\zeta' > \zeta$ and R all positive with ζ' small enough. Let

$$\tau^+_{\zeta, m_\beta - \zeta', R} = \max\{\tau_{\zeta, m_\beta - \zeta', R}, t^*\}, \quad Ce^{-t^* V} = \zeta. \tag{7.8}$$

Notice that

$$Ce^{-\tau^+ V \log\{V/(e\beta)\}} \leqslant \zeta, \quad \tau^+ = \tau^+_{\zeta, m_\beta - \zeta', R}. \tag{7.9}$$

By Proposition 7.1 we have $S_{\tau^+}(m) \geqslant m_\beta - \zeta$ for all $m \in \mathcal{M}_{m_\beta - \zeta', R}$. Moreover by items 1 and 2 of Theorem 3.1,

$$S_t(m) \geqslant m_\beta - \zeta' - \zeta \quad \text{for } |x| \geqslant R + V\tau^+ \quad \text{and } t \leqslant \tau^+. \tag{7.10}$$

Lemma 7.2: For any $\zeta' > \zeta > 0$ small enough, any $R > 0$ and ψ such that $\psi(x) > m_\beta - \zeta'$ for all $R \leqslant |x| \leqslant R + 2V\tau^+ + 1$, $\tau^+ = \tau^+_{\zeta, m_\beta - \zeta', R}$, we have

$$S_{\tau^+}(\psi) > m_\beta - 2\zeta \quad \text{for all } |x| \leqslant R + V\tau^+ + 1, \tag{7.11}$$

$$S_t(\psi) > m_\beta - \zeta' - \zeta \quad \text{for all } t \leqslant \tau^+ \text{ and all } |x| \in [R + V\tau^+, R + V\tau^+ + 1]. \tag{7.12}$$

Proof: We define

$$\psi^*(x) = \begin{cases} \psi(x) & \text{if } |x| \leqslant R + 2V\tau^+ + 1 \\ m_\beta - \zeta' & \text{otherwise.} \end{cases}$$

By (3.5) and (7.9),

$$S_t(\psi) \geqslant S_t(\psi^*) - \zeta \quad \text{for all } |x| \leqslant R + V\tau^+ + 1 \text{ and } t \leqslant \tau^+ \tag{7.13}$$

and by (7.1)

$$S_{\tau^+}(\psi^*)(x) \geqslant m_\beta - \zeta \quad \text{for all } x \in \mathbb{R}$$

and (7.11) follows. Set

$$\tilde{\psi}(x) = \begin{cases} \psi(x) & \text{for } |x| \in [R, R + 2V\tau^+ + 1] \\ m_\beta - \zeta' & \text{elsewhere} \end{cases}$$

so that $\tilde{\psi} \geqslant m_\beta - \zeta'$ everywhere. By the Barrier Lemma, $S_t(\psi) \geqslant S_t(\tilde{\psi}) - \zeta$ for all $|x| \in [R + V\tau^+, R + V\tau^+ + 1]$ and all $t \leqslant \tau^+$. Then (7.12) follows from the inequality $S_t(\tilde{\psi}) \geqslant m_\beta - \zeta'$. □

In the next lemma we will require ζ so small that

$$\beta\|J'\|_\infty \ell_- < \frac{\zeta}{2}, \quad Ce^{-\ell_+} < \zeta, \quad C \text{ as in the Barrier Lemma} \tag{7.14}$$

(recall that ℓ_- and ℓ_+ are determined by ζ, see Definition 2.4).

Lemma 7.3: Let $\zeta > 0$ be small enough and such that (7.14) *holds. Then for all $t \leqslant \ell_+/V$, $V = e^2\beta$, and all $m \in L^\infty(\mathbb{R}, [-1, 1])$,*

$$|S_t(m) - m_\beta| \leqslant 3\zeta \quad \text{for all } x \text{ such that } \Theta(m; x) = 1, \tag{7.15}$$

where $\Theta \equiv \Theta^{(\zeta,\ell_-,\ell_+)}$.

Proof: Calling $\psi(x,t)=S_t(m)-e^{-t}m$, by differentiating w.r.t. x the integral version of (1.3),

$$\left|\frac{\mathrm{d}}{\mathrm{d}x}\psi(x,t)\right| \leqslant \beta\|J'\|_\infty.$$

Let $I_x^{(\ell_-)}$ be the interval $[n\ell_-,(n+1)\ell_-)$ which contains x; we have

$$\left|\psi(x,t)-\fint_{I_x^{(\ell_-)}}\psi\right| \leqslant \beta\|J'\|_\infty\ell_- \leqslant \frac{\zeta}{2}.$$

In [Ref. 12] it is proved that for ζ small enough, $\Theta(S_t(m);\cdot)\equiv 1$ for all $t>0$ if it holds at $t=0$. Suppose $\Theta(m;\cdot)\equiv 1$, then, taking $t=\log(4\zeta)$,

$$|S_t(m)(x)-m_\beta| \leqslant 2e^{-t}+\left|\psi(x,t)-\fint_{I_x^{(\ell_-)}}\psi\right|+\left|\fint_{I_x^{(\ell_-)}}S_t(m)-m_\beta\right| \leqslant 2\zeta.$$

We will next use the Barrier Lemma to drop the assumption $\Theta(m;\cdot)\equiv 1$. Let $[a,b)$ be a maximal connected component of $\{x:\Theta(m;x)=1\}$ and $G=[a-\ell_+,b+\ell_+)$. By definition of Θ, $\eta(m;x)=1$ for all $x\in G$. Set $m^*=m$ in G and $m^*=m_\beta$ in G^c and $t^*=\ell_+/V$. Then, if $x\in[a,b)$ and $t\leqslant t^*$,

$$|S_t(m)(x)-m_\beta| \leqslant |S_t(m^*)(x)-m_\beta|+Ce^{-t^*V} \leqslant 3\zeta.$$

□

Lemma 7.4: For all $\zeta'>0$ small enough the following holds. Suppose there are m, an interval $[a,b)$ and $T>0$ such that $m\geqslant m_\beta-\zeta'$ in $[a,b)$ and $S_t(m)\geqslant m_\beta-\zeta'$ in $\{[a-1,a)\cup[b,b+1)\}\times[0,T]$. Then

$$S_t(m) \geqslant m_\beta-\zeta' \quad \text{for all } x\in[a,b) \text{ and all } t\leqslant T. \tag{7.16}$$

Proof: Denote by ψ the restriction of $S_t(m)$ to $[a,b)$, so that ψ is a function on $[a,b)\times[0,T]$. It then solves the equation

$$\frac{\mathrm{d}\psi(x,t)}{\mathrm{d}t} = -\psi(x,t)+\tanh\left\{h(x,t)+\int_{[a,b)}J(x,y)\psi(y,t)\right\}, \quad x\in[a,b), t\in[0,T]$$

with

$$h(x,t)=\int_{[a,b)^c}J(x,y)m(y,t).$$

Notice that in the previous integral $m(y,t)\geqslant m_\beta-\zeta'$ because J has range 1.

By the comparison theorem (whose validity extends to the present situation) $\psi(x,t)\geqslant\psi^*(x,t)$ for any ψ^* which solves the above equation with $h^*\leqslant h$ and $\psi(x,0)\geqslant\psi^*(x,0)$, hence (7.16). □

As a corollary of the above lemmas we have the following result.

Proposition 7.5: For ζ small enough and L large enough, there is $\tau>0$ such that if $m\in U^+$ then $S_\tau(m)(x)\geqslant m_\beta-4\zeta$ for all $x\in[-L,L]$.

Proof: We need some preliminary definitions. Recalling (7.8) we shorthand

$$\tau_R^+=\tau^+_{\zeta,m_\beta-3\zeta,R}. \tag{7.17}$$

For any interval $I=[a,b)$, denote

$$I^* = [a', b'), \quad b' = b + 2\tau^+_{(b-a)/2} + 1; \quad a' = a - 2\tau^+_{(b-a)/2} - 1. \tag{7.18}$$

Call connected two intervals I_1 and I_2 if $I_1^* \cap I_2^* \neq \emptyset$. Given a sequence $\{I_i\}$ of disjoint intervals, let $\{I_i'\}$ be the sequence of intervals obtained as follows. For any maximal connected component $\{I_{i_k}\}$ of $\{I_i\}$, let $[a,b)$ be the minimal interval which contains all I_{i_k}; the set of all such intervals defines $\{I_i'\}$.

We apply the previous to the set of contours of m. By an abuse of notation, we still denote by m its L-symmetric extension, see the notation at the beginning of Sec. II. Since $m \in U^+$, the contours $\{\Gamma_i\}$ of the L-symmetric extension of m are such that

$$\sum_{\Gamma_i} |\Gamma_i \cap [-L, L]| \leqslant \kappa \ell_+. \tag{7.19}$$

We then define iteratively $\{I_{i;n}\}$ by setting $\{I_{i;1}\} = \{\Gamma_i\}$ and, for $n > 1$, $\{I_{i;n}\} = \{I'_{i;n-1}\}$. Since m is L-symmetric, there is N so that $\{I_{i;n}\} = \{I_{i;N}\}$ for all $n \geqslant N$. Moreover by (7.19), for L large enough all $I_{i;N}$ are bounded and mutually disconnected, in particular they do not cover $\mathbb{R}$. We still need a few notations. Recalling (7.17), given an interval I we call $I^+ = \{x : \mathrm{dist}(x, I) \leqslant \tau^+_{|I|/2}\}$, and $\partial I^+ = \{x \notin I^+ : \mathrm{dist}(x, I^+) \leqslant 1\}$. Denote by $\{t_1, t_2, \dots, t_k\}$ the set $\{\tau^+_{|I_{i;N}|/2}\}$, where t_i are in increasing order, $t_1 < t_2 \cdots < t_k$. Let $\mathcal{I}_j = \{I_{i,N} : \tau^+_{|I_{i;N}|/2} = t_j\}$ and

$$\Lambda_j = \bigcup_{I \in \mathcal{I}_j} I_j^+, \quad \Lambda = \cup \Lambda_j, \tag{7.20}$$

$$\partial \Lambda_j = \bigcup_{I \in \mathcal{I}_j} \partial I_j^+. \tag{7.21}$$

By Lemma 7.3, for ζ small enough there is s_0 so that

$$|S_{s_0}(m)(x) - m_\beta| \leqslant 3\zeta \quad \text{for all } x \in G := \{x : \Theta(m; x) = 1\}. \tag{7.22}$$

Define $\zeta' := 3\zeta$ and $\psi := S_{s_0}(m)$. By (7.22) we have $\psi(x) \geqslant m_\beta - \zeta'$ for all $x \in \Lambda^c$. By Lemma 7.2 $S_{t_j}(\psi) \geqslant m_\beta - 2\zeta$ on Λ_j and $S_t(\psi) \geqslant m_\beta - \zeta - \zeta'$ on $\partial \Lambda_j$ for $t \leqslant t_j$. By Lemma 7.4, $S_{t_1}(\psi) \geqslant m_\beta - \zeta - \zeta'$ on $\Lambda^c \cup \Lambda_1$; $S_{t_2}(\psi) \geqslant m_\beta - \zeta - \zeta'$ on $\Lambda^c \cup [\Lambda_1 \cup \Lambda_2]$ and, by iteration, $S_{t_k}(\psi) \geqslant m_\beta - \zeta - \zeta'$ everywhere. □

Proof of Theorem 2.7: From Proposition 7.5 it follows that for any $m \in U_+$ and any $t \geqslant 0$,

$$S_{t+\tau}(m_\beta - 3\zeta) \leqslant S_{t+\tau}(m) \leqslant S_{t+\tau}(1).$$

Both $S_t(m_\beta - 3\zeta)$ and $S_t(1)$ converge exponentially to $m^{(+)}$ as $t \to \infty$, hence Theorem 2.7 is proved. □

VIII. INTERFACE MOTION

In this section we prove the following result. For any $\epsilon > 0$ and $r \in (0,1)$, define $\Lambda_r^+ := (-L, -rL]$, $\Lambda_r^- := [rL, L)$ and

$$\mathcal{M}^\pm_{\epsilon,r} = \{m \in L^\infty([-L,L];[-1,1]) : \exists\, \xi \in \Lambda_r^\pm : \|m - \bar{m}_\xi\|_\infty \leqslant \epsilon\}.$$

Theorem 8.1: *For any $\epsilon > 0$ and $r \in (0,1)$ there is $L(\epsilon, r)$ so that for $L > L(\epsilon, r)$,*

$$\lim_{t \to \infty} \|S_t(m) - m^{(\pm)}\|_\infty = 0 \quad \text{for all } m \in \mathcal{M}^\pm_{\epsilon,r}. \tag{8.1}$$

It is enough to prove (8.1) when $m \in \mathcal{M}^+_{\epsilon,r}$, because, by symmetry, the result extends to $m \in \mathcal{M}^-_{\epsilon,r}$. The scheme of the proof is the following.

We will prove that at the end of an initial time layer, $S_t(m)$ is above a function "much closer" than ϵ to an instanton which is "only slightly" shifted to the right of the original one (to which m is close as an element of $\mathcal{M}^+_{\epsilon,r}$). We will then complete the proof by showing that this is above a travelling subsolution of (1.3) which converges to $m^{(+)}$.

For any m close to an instanton we will construct a subsolution which starts below m and which, after a suitably long time, is much closer to a new instanton than the original m. We introduce below the parameters which will be used in the construction of the subsolution, their justification lies in the proof of Proposition 8.2 below.

Let

$$b^+_\xi = ce^{-\alpha(L-\xi)}, \quad \xi \leqslant 0; \quad c = \sup_{L\geqslant 1, \xi\leqslant 0} \max_{x\in[L-1,L], y\in[L,L+1]} |\bar m_\xi(x) - \bar m_\xi(y)| \tag{8.2}$$

with c being finite by (3.7). Let p_ξ be as in (3.11). Since $\lim_{|x|\to\infty} p_\xi(x) = \beta(1-m^2_\beta) < 1$, if L is large enough there is $N>0$ (large enough) so that, for all $|\xi - x| > N$,

$$p_\xi(x) + Cb^+_0 \leqslant p < 1, \quad C = \beta^2 \sup_{x\in\mathbb{R}} |\tanh''(x)|. \tag{8.3}$$

We finally define the positive parameters ω and T_ξ as

$$\omega = \frac{1-p}{2}, \quad \frac{1-p}{4} 2\epsilon e^{-\omega T_\xi} = b^+_\xi + Cb^{+2}_\xi \tag{8.4}$$

with T_ξ being well defined for L large enough, as the r.h.s. in the second equality vanishes as $L \to \infty$.

Proposition 8.2: With ω, N as above and $\epsilon>0$ sufficiently small, let ξ_0 be such that

$$\xi_0 \leqslant -\eta, \quad \eta = \frac{2(\omega+1)\epsilon}{\omega[\min_{|x|\leqslant N} \bar m'(x)]}. \tag{8.5}$$

Then, for all L large enough and any $t \in [0, T_{\xi_0}]$ the function

$$u(x,t) := \bar m_{\xi(t)}(x) 1_{|x|\leqslant L} - \delta(t), \quad \delta(t) = 2\epsilon e^{-\omega t}, \tag{8.6}$$

$$\xi(t) = \xi_0 + \eta[1 - e^{-\omega t}] \tag{8.7}$$

is a subsolution of (1.3)*, namely*

$$u_t - g_L(u) \leqslant 0. \tag{8.8}$$

Proof: The time derivative of $u(x,t)$ is

$$u_t = -\xi_t \mathbf{1}_{|x|\leqslant L} \bar m'_{\xi(t)} + \omega\delta(t). \tag{8.9}$$

We will see that for $x \approx \xi(t)$, $|g_L(u)| \leqslant c\delta(t)$, $c>0$ a suitable constant. Since $\bar m'$ has the order of unity and, by (8.7), ξ_t is larger than $(\omega+c)\delta(t)$, (8.8) will hold for $x \approx \xi(t)$. For $|x-\xi(t)|$ large, instead, $\omega\delta(t)$, which is dangerously positive, becomes dominant in (8.9), but, as we will see, $g_L(u)$ will contrast it.

For $|x| \leqslant L-1$, $J^{\text{neum}}(x,\cdot) = J(x,\cdot)$, so that

$$g_L(u) = \delta + \tanh\{\beta[J * \bar m_\xi - \delta(t)]\} - \tanh\{\beta J * \bar m_\xi\} \tag{8.10}$$

and, by a Taylor expansion,

$$g_L(u) \geqslant -[p_{\xi(t)} - 1]\delta(t) - \frac{C}{2}\delta(t)^2 \tag{8.11}$$

with C as in (8.3) and p_ξ as in (3.11).

Define $b_\xi(x) := J^{\text{neum}} * \bar{m}_\xi - J * \bar{m}_\xi$ and notice that $b_\xi(x) = 0$ for $|x| \leqslant L-1$. Since $\bar{m}_\xi(x)$ is an increasing function of x, for $x \in [-L, -L+1]$, $b_\xi(x) \geqslant 0$, and we get the same bound as in (8.11):

$$g_L(u) = \delta + \tanh\{\beta[J * \bar{m}_\xi + b_\xi - \delta]\} - \tanh\{\beta J * \bar{m}_\xi\} \geqslant -[p_\xi - 1]\delta - \frac{C}{2}\delta(t)^2.$$

For $x \in [L-1, L]$, instead, $b_\xi(x) \leqslant 0$ and the previous inequality fails. Recalling (8.2), for $\xi \leqslant 0$, $b_\xi^+ \geqslant \max_{x\in[L-1,L]}|b_\xi(x)|$, and, since $\xi(t) \leqslant \xi_0 + \eta \leqslant 0$,

$$g_L(u) \geqslant -[p_\xi - 1 + Cb_0^+]\delta + p_\xi b_\xi - \frac{C}{2}(\delta(t)^2 + b_\xi^{+2}).$$

For $|x - \xi(t)| \leqslant N$, we bound $g_L(u) \geqslant \delta(t)$ (see (8.10)) while, for $|x - \xi(t)| > N$, we use (8.3) and (8.4) getting

$$u_t - g_L(u) \leqslant \begin{cases} -\xi_t[\min_{|x|\leqslant N} \bar{m}'(x)] + \omega\delta(t) + \delta(t), & |x - \xi(t)| \leqslant N \\ \dfrac{p-1}{2}\delta(t) + b_\xi^+ + \dfrac{C}{2}(\delta(t)^2 + b_\xi^{+2}), & |x - \xi(t)| \geqslant N. \end{cases} \tag{8.12}$$

By (8.7) the first line in (8.12) is non positive. By the second inequality in (8.4), for $|x - \xi(t)| \geqslant N$ and $t \leqslant T_{\xi_0}$,

$$u_t - g_L(u) \leqslant -\frac{1-p}{4}\delta(t) + \frac{C}{2}\delta(t)^2 \leqslant 0$$

having supposed ϵ so small that $(1-p)/4 \geqslant (C/2)2\epsilon$. □

Let $m \in \mathcal{M}_{\epsilon,r}^+$; then there is $\xi_0 \in (-L, -rL]$ such that $\|m - \bar{m}_{\xi_0}\|_{L^\infty([-L,L])} \leqslant \epsilon$. Given any $r \in (0,1)$ for L large enough we have that $-rL < -\eta$ so that by (8.6), $m \geqslant u(\cdot, 0)$. Then, by Proposition 8.2,

$$S_{T_{\xi_0}}(m) \geqslant \bar{m}_{\xi(T_{\xi_0})} - 2\epsilon e^{-\omega T_{\xi_0}}.$$

Since $\bar{m}_\xi$ is a decreasing function of ξ, there is a positive constant c' so that

$$S_{T_{\xi_0}}(m) \geqslant \bar{m}_{\xi_0+\eta} - c' e^{-\alpha(L-\xi_0)}, \tag{8.13}$$

with η as in (8.5). We will prove (see (8.17)) that the r.h.s. of (8.13) is bounded from below by a function $z_{\xi'}$, $\xi' > \xi_0 + \eta$, where z_ξ has the following structure:

$$z_\xi(x) = \bar{m}_\xi(x) - ae^{-\alpha(2L-\xi-x)} + ae^{-\alpha(2L+\xi+x)} + \Psi_\xi(x) \tag{8.14}$$

with α and a positive constants defined in (3.7), whereas the function Ψ_ξ is small (see (8.16)) at least when ξ is away from the boundaries. The important point is that there is a decreasing function $\xi(t)$ so that $z_{\xi(t)}$ is a traveling subsolution of (1.3).

Theorem 8.3: *For any $r \in (0,1)$ and $\delta > 0$, there is $L_0(r, \delta)$ such that, for any $L > L_0(r, \delta)$, $z_{\xi(t)}$ is a subsolution of* (1.3) *for all t such that $\xi(t) \in [-(1-r)L, -rL]$ and provided*

$$\frac{d\xi(t)}{dt} = -\sqrt{\mu}K(1 - \delta)e^{-2\alpha\xi(t)} \tag{8.15}$$

with $\sqrt{\mu}$ defined in (9.13), *K in* (9.23). *Moreover $|z_\xi(x)| < m_\beta$ for all $|x| \leqslant L$ and*

$$|\Psi_\xi(x)| \leqslant \delta e^{-\alpha|\xi-x|}. \tag{8.16}$$

Theorem 8.3 will be proved in Sec. IX, where we will see that δ can be chosen exponentially small in L.

Proposition 8.4: Given any $r \in (0,\bar r)$, for all L large enough and any $\xi_0 \in (-L,-\bar r L]$ there is $\xi' \in [-(1-r)L,-rL]$ so that

$$\bar m_{\xi_0+\eta}(x) - c' e^{-\alpha(L-\xi_0)} \geqslant z_{\xi'}(x), \quad |x| \leqslant L. \tag{8.17}$$

Proof: Since $\bar m_{\xi_0+\eta}(x) - c' e^{-\alpha(L-\xi_0)}$ is a decreasing function of ξ_0, without loss of generality we may suppose $\xi_0 \in [-(1-\bar r)L,-\bar r L]$. To simplify notation, we let $\xi=\xi_0+\eta$ and will prove (8.17) with $\xi'=\xi+R$, R being a "large" constant independent of L. We will do that by deriving a lower bound for $\bar m_\xi(x)-\bar m_{\xi+R}(x)$, an upper bound for $z_{\xi+R}(x)-\bar m_{\xi+R}(x)$, with the former larger than the latter. Recalling (8.14)–(8.16),

$$z_{\xi+R}(x) - \bar m_{\xi+R}(x) \leqslant a e^{-\alpha(2L+\xi+R+x)} + \delta e^{-\alpha|\xi+R-x|}. \tag{8.18}$$

Let $N>0$ be such that $c e^{-\alpha_0 N}=(a/2)e^{-\alpha N}$, where a, α, α_0, and c are as in (3.7) (without loss of generality we may and will suppose that $c>a$). Call $m'=\bar m(N)$, choose arbitrarily $m'' \in (m', m_\beta)$, define R_0 so that $\bar m(R_0)=m''$ and require $R \geqslant 2R_0$. Then,

$$\bar m_\xi(x) - \bar m_{\xi+R}(x) \geqslant m'', \quad x \in [\xi, \xi+R]$$

as it follows by bounding $\bar m_\xi(x) \geqslant 0$, $\bar m_{\xi+R}(x) \leqslant -m''$ for $x \in [\xi, \xi+R/2]$ and using an analogous bound for $x \in [\xi+R/2, \xi+R]$. Moreover

$$\bar m_\xi(x) - \bar m_{\xi+R}(x) \geqslant m'' - m', \quad x \in [\xi - N, \xi]$$

because $\bar m_\xi(x) \geqslant -m'$ and $\bar m_{\xi+R}(x) \leqslant -m''$. For $x \leqslant \xi - N$, using that $\bar m$ is antisymmetric and (3.7), we write

$$\begin{aligned}\bar m_\xi(x) - \bar m_{\xi+R}(x) &= [\bar m(x-\xi) + m_\beta] + [\bar m(\xi+R-x) - m_\beta] \\ &\geqslant a e^{-\alpha(\xi-x)} - c e^{-\alpha_0(\xi-x)} - a e^{-\alpha(\xi+R-x)} - c e^{-\alpha_0(\xi+R-x)}.\end{aligned}$$

Using the definition of N we then get

$$\bar m_\xi(x) - \bar m_{\xi+R}(x) \geqslant \frac{a}{2} e^{-\alpha(\xi-x)} - \frac{3a}{2} e^{-\alpha(\xi+R-x)}, \quad x \leqslant \xi - N.$$

Similarly

$$\bar m_\xi(x) - \bar m_{\xi+R}(x) \geqslant m'' - m', \quad x \in [\xi+R, \xi+R+N],$$

$$\bar m_\xi(x) - \bar m_{\xi+R}(x) \geqslant -\frac{3a}{2} e^{-\alpha(x-\xi)} + \frac{a}{2} e^{-\alpha(x-[\xi+R])}, \quad x \geqslant \xi+R+N.$$

Using the above-mentioned upper bounds and by taking $\delta \leqslant a/4$ in Theorem 8.3 it is not difficult to check that for L and R sufficiently large,

$$\bar m_\xi(x) - \bar m_{\xi+R}(x) - c' e^{-\alpha(L-\xi)} \geqslant a e^{-\alpha(2L+\xi+R+x)} + \delta e^{-\alpha|\xi+R-x|}.$$

This, together with (8.18) concludes the proof of the proposition. □

By (8.13) and (8.17), pointwise,

$$S_{T_\xi}(m) \geqslant z_{\xi'}. \tag{8.19}$$

We will prove convergence of $S_t(z_{\xi+\eta+R})$ to $m^{(+)}$ in L^∞ and this will prove that any limit point ϕ of $S_t(m)$ is not smaller than $m^{(+)}$. Since any limit point is stationary, $\phi=\tanh\{\beta J^{\text{neum}} * \phi\}$; then b

$:=\max_{|x|\leq L}\phi(x)$ must be such that $b\geq\tanh\{\beta b\}$, hence $\phi(x)\leq m_\beta$ for all x, which will then conclude the proof of (8.1) of Proposition 8.1.

Proposition 8.5: For any positive $r<\bar{r}$ there is a constant $L_2(r,\epsilon)$ so that for any $L\geq L_2(r,\epsilon)$, if $m\in\mathcal{M}^+_{\epsilon,\bar{r}}$ then there is a time t^* such that

$$S_{t^*}(m)\geq z_{-(1-r)L}. \tag{8.20}$$

Proof: For L large enough, (8.19) (recalling from Proposition 8.4 that $\xi'\in[-(1-r)L,-rL]$) and Theorem 8.3 yield (8.20). □

Let $N>0$ be such that $\bar{m}(x)>m_\beta-\epsilon$ for all $x\geq N$ (ϵ as in $\mathcal{M}^+_{\epsilon,\bar{r}}$). Let

$$w(x)=\begin{cases}-m_\beta, & x<-(1-r)L-N\\ z_{-(1-r)L}, & |x+(1-r)L|\leq N\\ m_\beta-2\epsilon, & x>-(1-r)L+N.\end{cases}$$

Then, for L large enough, $z_{-(1-r)L}(x)\geq w(x)$, $|x|\leq L$ and $|w(x)-\bar{m}_{-(1-r)L}(x)|\leq 2\epsilon$ for all $|x|\leq L$.

We will prove that there is a time T such that

$$S_T(w)(x)\geq\delta>0 \quad \text{for all } |x|\leq L \tag{8.21}$$

so that also $S_T(z_{-(1-r)L})>\delta$. Since the strictly positive functions are in the basin of attraction of $m^{(+)}$ (because a strictly positive function is bounded in between two positive constants, and all constant, positive functions are attracted by $m^{(+)}$), it then follows that the limit points of $S_t(z_{-(1-r)L})$ are above $m^{(+)}$ which is what we wanted to prove.

Thus we are left with the proof of (8.21). It is now convenient to regard (1.3) as an equation on the whole line, with $J^{\text{neum}}(x,y)$ replaced by $J(x,y)$, namely we will consider Eq. (2.2). We thus need to show that there are δ and T positive such that

$$u(x,T)>\delta \quad \text{for all } |x|\leq L,\ u(\cdot,t) \text{ solving (2.2) with } u(\cdot,0)=w(\cdot),$$

where, by an abuse of notation, we have denoted by w the symmetric extension of w.

Let

$$k=-(1-r)L-N-(-L)=rL-N$$

so that $w(x)=-m_\beta$ when x is in the interval $[-L-k,-L+k]$, as well as in all its translates by $4nL$, $n\in\mathbb{Z}$. We then introduce a function w^* as follows. Let $k'=11k$ and define $w^*(x)=-m_\beta$ for all $x\in[-L-k',-L+k]$. Let then $w^*(x)=w(x+10k)$ for $x\in[-L-k'-2N,-L-k']$. We then set $w^*(x+4nL)=w^*(x)$, for all $x\in[-L-k'-2N,-L+k]$ and all $n\in\mathbb{Z}$. We complete the definition of w^* by setting $w^*(x)=w(x)$ at all other points $x\in\mathbb{R}$. It follows from this construction that $w^*(x)\leq w(x)$ for all $x\in\mathbb{R}$ and that $w^*(x)$ is invariant under reflections around the points $(-L-5k)+4nL$, $n\in\mathbb{Z}$, so that, modulo a translation, we are still in the context of (1.3).

By applying the analysis in Proposition 8.2, Theorem 8.3, and Proposition 8.4 to the evolution starting from w^*, we conclude that there is a time T so that, denoting by z_ξ the symmetric extension of the function defined in (8.14), then

$$S_T(w^*)(x)\geq z_{-(1-r)L}(x+5k)$$

which shows that for L large enough, $S_T(w^*)(x)>0$ for $x\in[-L,L]$. This concludes the proof. □

IX. A TRAVELING SUBSOLUTION

In this section we will prove Theorem 8.3. As the analysis will focus on what happens around the left end of the spatial domain, it is convenient to change coordinates, considering the interval $[0,2L]$ instead of $[-L,L]$. By an abuse of notation, we will not change symbols, thus writing

$$u_t(x,t) = g_L(u(x,t)), \quad x \in [0,2L], \quad g_L(u) = -u + \tanh\{\beta J^{\text{neum}} * u\} \tag{9.1}$$

with J^{neum} now defined with reflections at 0 and $2L$; $S_{t;L}(m)$ is here the flow solution of (9.1) with initial datum m.

As discussed in Sec. I we may regard (9.1) as an equation on the whole of $\mathbb{R}$, writing

$$u_t(x,t) = g(u(x,t)), \quad x \in \mathbb{R}, \quad g(u) = -u + \tanh\{\beta J * u\}. \tag{9.2}$$

Call "symmetric" the functions invariant under all reflections R_{n2L}, $n \in \mathbb{Z}$, then the solution of (9.2) starting from a symmetric function, is symmetric and its restriction to $x \in [0,2L]$ solves (9.1). Thus (9.2) restricted to the space of symmetric functions is equivalent to our (9.1) and we will shift back and forth in the sequel between the two representations.

The construction of a subsolution is done by adding "corrections" to the instanton like function $\bar{m}_\xi(x)$, $x \in [0,2L]$. $\bar{m}_{\xi(t)}(x)$ alone, in fact, does not do the job: indeed, $g(\bar{m}_{\xi(t)})=0$ for $x \in [1,2L-1]$ while

$$\frac{\mathrm{d}}{\mathrm{d}t}\bar{m}_{\xi(t)}(x) = -\bar{m}'_{\xi(t)}(x)\xi_t(t) > 0, \quad \xi_t(t) < 0.$$

The instanton however must have an important role, as it solves the stationary equation in the limit $L \to \infty$ and it is natural to expect that, when L is finite, the boundary effects are responsible for the motion of the "instanton." To catch the effect, we "correct" the instanton into a function $m^0_\xi(x)$, which is the symmetric extension of

$$m^0_\xi(x) = \bar{m}_\xi(x) + A_\xi(x), \quad x \in [0,2L]; \quad A_\xi(x) = -ae^{-\alpha(4L-\xi-x)} + ae^{-\alpha(\xi+x)}. \tag{9.3}$$

Recalling (3.7), we have the following nice interpretation of A_ξ, by remarking that the terms $ae^{-\alpha(x+\xi)}$ and $-ae^{-\alpha(4L-\xi-x)}$ are the corrections to the asymptotic behavior of $\bar{m}(\xi-x)$, which is the reflection of the original instanton through the origin, and, respectively, to $-\bar{m}(2L-\xi-x)$, which is the reflection through the point $2L$.

In the end, we will show that the true subsolution, denoted by $z_{\xi(t)}(x)$, differs from $m^0_{\xi(t)}$ by higher order terms, for L large. These are however necessary to have $g(z_\xi)(x)>0$ for all x, and all $\xi \in [rL,(1-r)L]$; then since $\mathrm{d}z_\xi/\mathrm{d}\xi$ is uniformly bounded, $z_t - g(z_{\xi(t)}) < 0$ if $\mathrm{d}\xi(t)/\mathrm{d}t$ is negative, but sufficiently small, hence $z_{\xi(t)}$ is a sub-solution. By a more careful analysis we will also find the right speed.

We will write

$$z_\xi = m^0_\xi + \psi_\xi + \psi^*_\xi,$$

where ψ_ξ and ψ^*_ξ are two symmetric functions to be determined. To this end, we write, for $x \in [0,2L]$,

$$g(z_\xi) = -[\bar{m}_\xi + A_\xi + \psi_\xi + \psi^*_\xi] + \tanh\{\beta J * [\bar{m}_\xi + A_\xi + B_\xi + \psi_\xi + \psi^*_\xi]\}, \tag{9.4}$$

where

$$B_\xi(x) = m^0_\xi(x) - \{\bar{m}_\xi(x) + A_\xi(x)\}, \tag{9.5}$$

namely B_ξ denotes the difference between the symmetric function $m^0_\xi(x)$ and the non symmetric one, $\bar{m}_\xi + A_\xi$. Thus $B_\xi(x)=0$ for $x \in [0,2L]$ and $\neq 0$ elsewhere and for this reason its contribution appears only in the convolution term and it is different from zero except for some $x \in [0,1]$ and $x \in [2L-1,2L]$.

Recalling that $\bar{m}_\xi = \tanh\{\beta J * \bar{m}_\xi\}$, we will next rewrite (9.4) via a Taylor expansion to second order around $\bar{m}_\xi$. Let

$$\Omega_\xi m = -m + p_\xi J * m,$$

where $p_\xi(x)$ is here the symmetric function equal to $\beta(1-\bar{m}_\xi(x)^2)$ when $x \in [0,2L]$. We regard Ω_ξ as an operator on $L^\infty(\mathbb{R})$, noticing that it maps symmetric functions into symmetric ones. We then get from (9.4) the following equality, valid for all x in $[0,2L]$:

$$g(m_\xi^0 + \psi_\xi + \psi_\xi^*) = \Omega_\xi[A_\xi + \psi_\xi + \psi_\xi^*] + p_\xi J * B_\xi + \rho_\xi[J * (A_\xi + B_\xi + \psi_\xi + \psi_\xi^*)]^2 + 0_3, \tag{9.6}$$

where

$$\rho_\xi = \frac{\beta^2}{2}\tanh''\{\beta J * \bar{m}_\xi\} \tag{9.7}$$

and 0_3 is the remainder term in the expansion: there is a constant c (proportional to β^3) so that

$$|0_3(\psi_\xi, \psi_\xi^\star, A_\xi, B_\xi)| \leqslant c \sum_{i_1+i_2+i_3=3} |J * \psi_\xi|^{i_1} |J * \psi_\xi^\star|^{i_2} |J * (A_\xi + B_\xi)|^{i_3}.$$

In the sequel we will denote by the same symbol the symmetric extension of each term on the r.h.s of (9.6), so that equality holds on the whole of $\mathbb{R}$. Thus, for instance, by $\rho_\xi(x)$ we mean the expression (9.7) if $x \in [0,2L]$, and its symmetric extension elsewhere. The same applies to all the other terms of (9.6).

By an explicit computation which uses (3.6), we get for $x \in [0,2L]$,

$$a_\xi = \Omega_\xi A_\xi = -e^{-2\alpha(2L-\xi)} k_\xi^+ + e^{-2\alpha\xi} k_\xi^-, \quad k_\xi^\pm(x) := a e^{\pm\alpha(x-\xi)} \frac{m_\beta^2 - \bar{m}_\xi(x)^2}{1-m_\beta^2} > 0 \tag{9.8}$$

which, as said previously, is then regarded as a function on the whole of $\mathbb{R}$ by symmetric extension. To specify ψ_ξ and ψ_ξ^*, we introduce the operator

$$\mathcal{T}_\xi = \sum_{n=0}^{N} (1+\Omega_\xi)^n, \quad N = \text{integer part of } L^2$$

and define

$$\psi_\xi = \mathcal{T}_\xi(a_\xi + p_\xi J * B_\xi + \rho_\xi[J * (A_\xi + B_\xi)]^2), \tag{9.9}$$

$$\psi_\xi^\star = \mathcal{T}_\xi(2\rho_\xi[J * \psi_\xi][J * (A_\xi + B_\xi)] + \rho_\xi[J * \psi_\xi]^2), \tag{9.10}$$

where, according to the previous convention, all terms on which $\mathcal{T}_\xi$ acts are symmetric functions.

Lemma 9.1: Ω_ξ *as an operator on the* L^∞ *symmetric functions is invertible and*

$$\Omega_\xi \mathcal{T}_\xi m = -m + (1+\Omega_\xi)^{N+1} m. \tag{9.11}$$

Proof: The invertibility statement is proved in Ref. 8, the remaining statements are well known algebraic identities. □

With the choice (9.9) and (9.10) and using (9.11), we get from (9.6)

$$g(m_\xi^0 + \psi_\xi + \psi_\xi^*) = (1+\Omega_\xi)^{N+1}(a_\xi + p_\xi J * B_\xi + \rho_\xi[J * (A_\xi + B_\xi)]^2) + (1+\Omega_\xi)^{N+1}(2\rho_\xi[J * \psi_\xi][J * (A_\xi + B_\xi)] + \rho_\xi[J * \psi_\xi]^2) + \rho_\xi([J * \psi_\xi^*]^2 + 2[J * \psi_\xi^*]\{[J * \psi_\xi] + [J * (A_\xi + B_\xi)]\}) + 0_3$$

so that all terms, except those that multiply ρ_ξ, which we will prove to be suitably small, are in the range of the operator $(1+\Omega_\xi)^{N+1}$ which, as we are going to see, has a nice behavior. In Ref. 8 it has been proved that there is $s^\star > 0$ so that for all $\xi \in [s^\star, 2L-s^\star]$, a Perron–Frobenius theorem holds for $1+\Omega_\xi$ (with domain the space of symmetric L^∞ functions). It is shown that Ω_ξ has a strictly positive eigenvalue λ_ξ with strictly positive eigenvector v_ξ; $\|\Omega_\xi\|_\infty = \lambda_\xi$ and the remaining part of

the spectrum is made by complex numbers whose real part is not larger than $-\omega$, $\omega>0$. Let then π_ξ be the linear functional on $L^\infty(\mathbb{R})$, defined by

$$\pi_\xi(m) := \int_0^{2L} m(x) v_\xi(x) \frac{\mathrm{d}x}{p_\xi(x)} \tag{9.12}$$

and normalize v_ξ so that

$$\pi_\xi(v_\xi) = 1$$

while we call $\mu>0$ the normalizing constant when $L=\infty$, i.e.,

$$\mu \int_{\mathbb{R}} \bar{m}'_\xi(x)^2 \frac{\mathrm{d}x}{1-\bar{m}_\xi(x)^2} \mathrm{d}x = 1. \tag{9.13}$$

We recall some results we need in the sequel, see (Ref. 8, Theorems 2.1, 2.3, 2.4), and also (Ref. 7, Theorem 3.2). There are constants $c_\pm>0$, $c'>0$ and $\delta>0$ so that for $\xi\in[s^\star, 2L-s^\star]$

$$c_-[e^{-2\alpha\xi}+e^{-2\alpha(2L-\xi)}] \leqslant \lambda_\xi \leqslant c_+[e^{-2\alpha\xi}+e^{-2\alpha(2L-\xi)}], \tag{9.14}$$

$$|v_\xi(x) - \sqrt{\mu}\bar{m}'_\xi(x)| \leqslant c_+[e^{-2\alpha\xi}+e^{-2\alpha(2L-\xi)}]e^{\alpha|\xi-x|}\xi^4 \quad \text{for } |\xi-x| \leqslant \frac{\xi}{2}, \tag{9.15}$$

$$|v_\xi(x) - \sqrt{\mu}a\alpha e^{-\alpha\xi}(e^{-\alpha x}+e^{\alpha x})| \leqslant c_+ e^{-(\alpha+\delta)(\xi-x)} \quad \text{for } x\in\left[0,\frac{\xi}{2}\right], \tag{9.16}$$

$$|v_\xi(x) - \sqrt{\mu}a\alpha e^{-\alpha(2L-\xi)}(e^{-\alpha x}+e^{\alpha x})| \leqslant c_+ e^{-(\alpha+\delta)(x-\xi)} \quad \text{for } x\in\left[\frac{3\xi}{2},2L\right]. \tag{9.17}$$

Lemma 9.2: There are c and ω positive so that for any L^∞ symmetric function m,

$$\|(1+\Omega_\xi)^{N+1}m - (1+\lambda_\xi)^{N+1}\pi_\xi(m)v_\xi\|_\infty \leqslant ce^{-\omega N}\|m\|_\infty.$$

Proof: It follows from Theorem 2.4 in Ref. 8. □

Notice that $e^{-\omega N}\leqslant e^{-\omega(L^2-1)}$, which will be a negligible error. Moreover, by (9.14), for ξ large enough, $(1+\lambda_\xi)^{N+1}\sim 1+\lambda_\xi(N+1)$ and to leading order ~ 1, so that we may think that $(1+\Omega_\xi)^{N+1}m$ is essentially given by $\pi_\xi(m)v_\xi$. We then rewrite (9.6) as

$$g(m^0_\xi+\psi_\xi+\psi^*_\xi) = d_\xi v_\xi + E_\xi + 0_3 + 0_{\exp}, \tag{9.18}$$

where

$$d_\xi = (1+\lambda_\xi)^{N+1}\pi_\xi(a_\xi + p_\xi J*B_\xi + \rho_\xi[[J*(A_\xi+B_\xi)]^2 + 2\{J*\psi_\xi\}\{J*(A_\xi+B_\xi)\} + [J*\psi_\xi]^2]), \tag{9.19}$$

$$E_\xi = \rho_\xi\{[J*\psi^\star_\xi]^2 + 2[J*\psi^\star_\xi][J*\psi_\xi + J*(A_\xi+B_\xi)]\}, \tag{9.20}$$

and $0_{\exp}$ is the error term, for replacing $(1+\Omega_\xi)^{N+1}(\cdot)$ by $(1+\lambda_\xi)^{N+1}\pi_\xi(\cdot)v_\xi$.

Lemma 9.3: There is a constant c' so that

$$|0_{\exp}| \leqslant c'N^2e^{-\omega N}. \tag{9.21}$$

Proof: Since $\|a_\xi\|_\infty\leqslant c''$, $\|A_\xi\|_\infty\leqslant c''$ and $\|B_\xi\|_\infty\leqslant c''$, $\|\mathcal{T}_\xi\|_\infty\leqslant N+1$, then $\|\psi_\xi\|_\infty\leqslant C(N+1)$ and $\|\psi^*_\xi\|_\infty\leqslant C'(N+1)^2$ and (9.21) follows. □

Lemma 9.4: There is $c_1>0$ such that $\|k^\pm_\xi\|_\infty\leqslant c_1$ and moreover

$$|\pi_\xi(a_\xi) - \sqrt{\mu}K\{e^{-2\alpha\xi} - e^{-2\alpha(2L-\xi)}\}| \leqslant c_1[e^{-5\alpha/2(2L-\xi)} + e^{-5\alpha/2\xi}], \tag{9.22}$$

where

$$K = \frac{a}{\beta(1-m_\beta^2)}\int_{\mathbb{R}} \mathrm{d}x \frac{e^{\alpha x}\bar{m}'(x)(m_\beta^2 - \bar{m}^2(x))}{1-\bar{m}^2(x)} > 0. \tag{9.23}$$

Proof: By (3.7),

$$0 \leqslant k_\xi^\pm(y) \leqslant \frac{2m_\beta}{1-m_\beta^2}[1 + e^{-(\alpha_0-\alpha)|y-\xi|}], \quad y \in [0,2L].$$

Then

$$\pi_\xi(k_\xi^\pm) = \int_{|x-\xi|\leqslant \xi/2} \frac{v_\xi(x)}{p_\xi(x)} k_\xi^\pm(x) + O(e^{-\alpha\xi/2}).$$

From (9.15) we then get that for a suitable constant $c>0$,

$$\left| \pi_\xi(k_\xi^\pm) - \int_{|y|\leqslant\xi/2} \frac{\sqrt{\mu}\bar{m}'(y)}{p(y)} k_0^\pm(y) \right| \leqslant c e^{-2\alpha\xi} e^{\alpha\xi/2}\xi^4.$$

On the other hand, using (3.7) and recalling the definition (9.23) of K we have

$$\sqrt{\mu}K = \sqrt{\mu}\int \mathrm{d}x \frac{\bar{m}'(x)}{p_{\bar{m}}(x)} k^\pm(x) = \int_{|y|\leqslant\xi/2} \frac{\sqrt{\mu}\bar{m}'(y)}{p(y)} k_0^\pm(y) + O(e^{-\alpha\xi/2})$$

so that

$$|\pi_\xi(k_\xi^\pm) - \sqrt{\mu}K| \leqslant Ce^{-\alpha\xi/2}.$$

Hence (9.22) follows. □

By using Lemma 9.4 on the r.h.s. of (9.19), we then get from (9.18)

$$g(m_\xi^0 + \psi_\xi + \psi_\xi^\star) = (1+\lambda_\xi)^{N+1}\sqrt{\mu}K\{e^{-2\alpha\xi} - e^{-2\alpha(2L-\xi)}\}v_\xi + D_\xi v_\xi + E_\xi + 0_3 + 0_{\exp}, \tag{9.24}$$

where

$$D_\xi = (1+\lambda_\xi)^{N+1}[\pi_\xi(a_\xi) - \sqrt{\mu}K\{e^{-2\alpha\xi} - e^{-2\alpha(2L-\xi)}\}] + (1+\lambda_\xi)^{N+1}\pi_\xi(p_\xi J * B_\xi + \rho_\xi[J*(A_\xi + B_\xi)]^2$$
$$+ 2\{J*\psi_\xi\}\{J*(A_\xi + B_\xi)\} + \rho_\xi[J*\psi_\xi]^2). \tag{9.25}$$

The analysis proceeds by showing that $|D_\xi|$ is negligible w.r.t. the coefficient multiplying v_ξ in the first term on the r.h.s. of (9.24). We will then show that $|E_\xi| \leqslant \epsilon e^{-2\alpha\xi - \alpha|\xi - x|}$ with $\epsilon \to 0$ as $L \to \infty$, while $\|0_3\|_\infty < ce^{-2\alpha L}$ and $0_{\exp}$ can be also bounded in the same way. The proof of such statements requires a careful bound of each one of the terms which appear in the previous expressions and uses essentially the following estimate proved by Eqs. (6.28) and (6.29) of Ref. 8: for any $\zeta \in (0,\alpha)$ there is a constant c so that, denoting by $\mathcal{T}_\xi(x,y) + \delta(x-y)$ the kernel of $\mathcal{T}_\xi$ (the δ function coming from $n=0$),

$$|\mathcal{T}_\xi(x,y)| \leqslant cN^2 e^{-\zeta|x-y|}, \quad x \neq y.$$

We will thus bound

$$|\mathcal{T}_\xi m(x)| \leqslant cN^2\left\{ |m(x)| + \int_0^{2L} e^{-\zeta|x-y|}|m(y)|\mathrm{d}y \right\}. \tag{9.26}$$

To use (9.26) we need bounds on $|m(y)|$, which, in the case of B_ξ, are proved below.

Lemma 9.5: There are positive constants c_1 and c_2 so that

$$|p_\xi J * B_\xi(x)| \leqslant c_1[(e^{-\alpha_0\xi} + e^{-\alpha(4L-\xi)})\mathbf{1}_{x\in[0,1]} + (e^{-\alpha_0(2L-\xi)} + e^{-\alpha(2L+\xi)})\mathbf{1}_{x\in[2L-1,2L]}], \quad (9.27)$$

$$|\pi_\xi(p_\xi J * B_\xi)| \leqslant c_2[e^{-(\alpha_0+\alpha)\xi} + e^{-(\alpha_0+\alpha)(2L-\xi)} + e^{-\alpha 4L}] \quad (9.28)$$

with α_0 as in (3.7).

Proof: By (9.5), $B_\xi(x)=0$ for $x\in[0,2L]$ and we just need to specify its values in the two intervals $[-1,0]$ and $[2L,2L+1]$. We write $B^0_\xi(x)=B_\xi(x)\mathbf{1}_{x\in[-1,0]}$ and $B^+_\xi(x)=B_\xi(x)\mathbf{1}_{x\in[2L,2L+1]}$. Explicitly

$$\begin{aligned} B^0_\xi(x) &= [\{\bar m(-x-\xi) - ae^{-\alpha(4L+x-\xi)} + ae^{-\alpha(-x+\xi)}\} - \{\bar m(x-\xi) - ae^{-\alpha(4L-x-\xi)} + ae^{-\alpha(x+\xi)}\}]\mathbf{1}_{x\in[-1,0]} \\ &= (ae^{-\alpha(4L-\xi)}[e^{\alpha x} - e^{-\alpha x}] + \{\bar m(-x-\xi) - [-m_\beta + ae^{-\alpha(x+\xi)}]\} \\ &\quad - \{\bar m(x-\xi) - [-m_\beta + ae^{-\alpha(\xi-x)}]\})\mathbf{1}_{x\in[-1,0]}. \end{aligned}$$

Since J has support equal to one, by using (3.7), we get

$$|p_\xi J * B^0_\xi(x)| \leqslant c(e^{-\alpha(4L-\xi)} + e^{-\alpha_0\xi})\mathbf{1}_{x\in[0,1]}.$$

Analogously we write

$$\begin{aligned} B^+_\xi(x) &= [\{\bar m(4L-x-\xi) - ae^{-\alpha(x-\xi)} + ae^{-\alpha(4L-x+\xi)}\} - \{\bar m(x-\xi) - ae^{-\alpha(4L-x-\xi)} + ae^{-\alpha(x+\xi)}\}]\mathbf{1}_{x\in[2L,2L+1]} \\ &= (ae^{-\alpha(2L+\xi)}[e^{\alpha(2L-x)} - e^{-\alpha(2L-x)}] + \{\bar m(4L-x-\xi) - m_\beta + ae^{-\alpha(4L-x-\xi)}]\} - \{\bar m(x-\xi) - m_\beta \\ &\quad + ae^{-\alpha(x-\xi)}\})\mathbf{1}_{x\in[2L,2L+1]}. \end{aligned}$$

By using again (3.7), we then get

$$|p_\xi J * B^+_\xi(x)| \leqslant c(e^{-\alpha_0(2L-\xi)} + e^{-\alpha(2L+\xi)})\mathbf{1}_{x\in[2L-1,2L]}$$

hence (9.27) follows. Applying the definition (9.12) of π_ξ, we bound $|\pi_\xi(p_\xi J * B_\xi)|$ using the l.h.s. of (9.27). We then get (9.28). □

The remaining part of the proof of Theorem 8.3 is just computational, we thus outline the way computations are performed and state the results, a few details are reported in the Appendix . The result holds for L large enough: given r we need to choose ζ (ζ as in (9.26)) sufficiently close to α, in a way which depends on r, and which then determines how large L should be. Recall that $\xi\in[(1-r)L, rL]$.

We need first to estimate $\psi_\xi(x)$, which is given by (9.9). We use (9.26), expressing a_ξ as in (9.8); bound $p_\xi J * B_\xi$ using (9.27); we are then left with integrals of functions which are piecewise pure exponentials. The result is then bounded proportionally to the value of the integrand computed at the endpoints of the intervals where it is a pure exponential. The bound is reported in (A1). The same strategy is used for $\psi^\star_\xi$, the result is (A4).

The next step is to prove that for any $\epsilon>0$, if L is large enough, then $|D_\xi|e^{2\alpha\xi}\leqslant\epsilon$, so that the first term on the r.h.s. of (9.24) dominates the second one, with D_ξ. Expression (9.25) for D_ξ involves the action of the linear functional π_ξ, namely an integral with the function v_ξ. We then take (9.15)–(9.17) and reduce them to integrals which are like those for ψ_ξ and ψ^*_ξ.

By direct inspection, given any $\epsilon>0$ and L large enough, $e^{2\alpha\xi}e^{\alpha|\xi-x|}|E_\xi(x)|\leqslant\epsilon$. Also $e^{-2\alpha(2L-\xi)}\leqslant e^{-2\alpha\xi}\epsilon$, because $2L-\xi\geqslant Lr$, it then follows from (9.24) that

$$g(m_\xi^0 + \psi_\xi + \psi_\xi^\star) \geqslant \sqrt{\mu} K e^{-2\alpha\xi}(1-\epsilon) v_\xi.$$

We then have

$$z_t(x,t) - g(z(x,t)) \leqslant -\left[\bar{m}_\xi'(x) + a\alpha e^{-\alpha(x+\xi)} - \frac{\partial \psi_\xi(x)}{\partial \xi} - \frac{\partial \psi_\xi^\star(x)}{\partial \xi}\right]\xi_t - \sqrt{\mu} K e^{-2\alpha\xi}(1-\epsilon) v_\xi(x).$$

Since the square bracket which multiplies ξ_t is bounded, the whole expression is negative with ξ_t negative but sufficiently small, hence z_ξ is a subsolution. A further analysis shows that for any $\epsilon > 0$ if L is large enough, then

$$e^{\alpha|\xi - x|}\left|\frac{\partial \psi_\xi(x)}{\partial \xi}\right| \leqslant \epsilon; \quad e^{\alpha|\xi-x|}\left|\frac{\partial \psi_\xi^\star(x)}{\partial \xi}\right| \leqslant \epsilon$$

which proves (8.15) since we can take ξ_t arbitrarily close to $-\sqrt{\mu} K e^{-2\alpha\xi}$. The proof of (8.16) is given in the Appendix , see (A6) and (A7). The proof of Theorem 8.3 is completed.

X. PROOF OF THEOREM 2.8

By Definition 2.5, for any $m \in U_{-,+}$ there exists ξ such that $L - |\xi| \geqslant \ell_+/2$ and $\sup_{|x|\leqslant L}|m^{(\ell_-)} - \bar{m}_\xi^{(\ell_-)}| \leqslant 2\zeta$.

Lemma 10.1: There is $c > 0$ so that for all L large enough, the following holds. For any $m \in U_{-,+}$ and any $t \geqslant 0$,

$$\sup_{|x|\leqslant L}|S_t(m) - \bar{m}_\xi| \leqslant e^{\beta t}(2\zeta + c\ell_-) + 2e^{-t}. \tag{10.1}$$

Proof: Let $u(\cdot,t) = S_t(m) - \bar{m}_\xi$, then, with $u^{(\ell_-)}$ as in (2.3),

$$\frac{\mathrm{d}}{\mathrm{d}t}u^{(\ell_-)} = -u^{(\ell_-)} + \tanh\{\beta J^{(\ell_-)} * m^{(\ell_-)}\} - \tanh\{\beta J^{(\ell_-)} * \bar{m}_\xi^{(\ell_-)}\} + R, \tag{10.2}$$

where, calling I_x the interval in $\mathcal{D}^{(\ell_-)}$ which contains x,

$$J^{(\ell_-)}(x,y) = \int_{I_x}\int_{I_y} J^{\mathrm{neum}}(x',y')\mathrm{d}x'\mathrm{d}y'$$

whereas the remainder R such that $\sup_{|x|\leqslant L}|R| \leqslant c'(\ell_- + e^{-\alpha\ell_+/2})$, for a suitable constant c'. The term $e^{-\alpha\ell_+/2}$ takes into account the fact that $\bar{m}_\xi \neq \tanh\{J^{\mathrm{neum}} * \bar{m}_\xi\}$ when $|x| \geqslant L-1$, but the error is exponentially small by (3.9). From (10.2) we then get

$$\sup_{|x|\leqslant L}|u^{(\ell_-)}(x,t)| \leqslant e^{(\beta-1)t}2\zeta + \frac{\|R\|_\infty}{\beta - 1}e^{(\beta-1)t}.$$

(10.1) is then a consequence of the inequality $\|\bar{m}'\|_\infty \leqslant \beta\|J'\|_\infty$ and

$$\left|\frac{\mathrm{d}}{\mathrm{d}x}\{m(x,t) - e^{-t}m(x,0)\}\right| \leqslant \beta\|J'\|_\infty$$

which follows straightly from the integral version of (2.2). Then $|u(x,t)| \leqslant |u^{(\ell_-)}(x,t)| + 2e^{-t} + c''\ell_-$ and Lemma 10.1 is proved. □

Proof of Theorem 2.8: Given $\epsilon > 0$ let t_0 be such that $2e^{-t_0} = \epsilon/2$ and ζ so small that $e^{\beta t_0}(2\zeta + c\ell_-) = \epsilon/2$. Then by (10.1)

$$\sup_{|x|\leqslant L}|S_{t_0}(m)-\bar m_\xi|\leqslant\epsilon\quad\text{for some }\xi\equiv\xi(m)\in(-L,L).$$

We fix $r\in(0,1)$ as in Proposition 8.1 and we consider the set $B_{\epsilon,r}$ defined in (3.16). It then follows that either $S_{t_0}(m)\in\mathcal{M}^+_{\epsilon,r}\cup\mathcal{M}^-_{\epsilon,r}$ or $S_{t_0}(m)\in B_{\epsilon,r}$. In the first case, from Proposition 8.1 it follows that $S_{t_0+s}(m)$ converges to $m^{(+)}$ or to $m^{(-)}$ as $s\to\infty$. In the second case, using Ref. 5, we have that either $S_{t_0+s}(m)$ converges to $\hat m_L$ as $s\to\infty$, or else, at some time s_1, $S_{t_0+s_1}(m)\in\{\Sigma^-_{2\epsilon,r}\cup\Sigma^+_{2\epsilon,r}\}$, see (3.16) for the definition of the latter. Since $\{\Sigma^-_{2\epsilon,r}\cup\Sigma^+_{2\epsilon,r}\}$ is a subset of $\mathcal{M}^+_{2\epsilon,r}\cup\mathcal{M}^-_{2\epsilon,r}$, from Proposition 8.1 it follows that $S_{t_0+s_1+s}(m)$ converges to $m^{(+)}$ or to $m^{(-)}$ as $s\to\infty$, concluding the proof of Theorem 2.8.

APPENDIX: SOME DETAILS ON THE TRAVELING SUBSOLUTION

1. Analysis of $\psi_\xi(x)$

We have

$$|\psi_\xi(x)|\leqslant n_-(x)\mathbf{1}_{x\leqslant\xi}+n_+(x)\mathbf{1}_{x\geqslant\xi},\tag{A1}$$

where

$$n_-(x)=cL^4\{e^{-2\alpha\xi}+e^{-\alpha_0\xi-\zeta x}\},$$

$$n_+(x)=cL^4\{e^{-2\alpha(2L-\xi)}+e^{-2\alpha\xi-\zeta|x-\xi|}+(e^{-\alpha_0(2L-\xi)}+e^{-\alpha(2L+\xi)})e^{-\zeta(2L-x)}\}.$$

Recalling its definition (9.9) we start by examining $\mathcal{T}_\xi a_\xi$, with a_ξ given by (9.8). We have

$$|k^+_\xi(y)|\leqslant c\{\mathbf{1}_{y\geqslant\xi}+\mathbf{1}_{y<\xi}e^{-2\alpha(\xi-y)}\},\quad |k^-_\xi(y)|\leqslant c\{e^{-2\alpha(y-\xi)}\mathbf{1}_{y\geqslant\xi}+\mathbf{1}_{y<\xi}\}.$$

We will use (9.26), so that, calling $a^\pm_\xi$ the contributions to a_ξ with $k^\pm_\xi$, and recalling that $\zeta<\alpha$,

$$|\mathcal{T}_\xi a^+_\xi|\leqslant cN^2e^{-2\alpha(2L-\xi)}\begin{cases}e^{-\zeta|\xi-x|},&x\leqslant\xi\\1,&x>\xi,\end{cases}$$

$$|\mathcal{T}_\xi a^-_\xi|\leqslant cN^2e^{-2\alpha\xi}\begin{cases}1,&x\leqslant\xi\\e^{-\zeta|x-\xi|},&x>\xi.\end{cases}$$

Since $\xi\leqslant L$,

$$|\mathcal{T}_\xi a_\xi|\leqslant cL^4\begin{cases}e^{-2\alpha\xi},&x\leqslant\xi\\e^{-2\alpha(2L-\xi)}+e^{-2\alpha\xi}e^{-\zeta|x-\xi|},&x>\xi.\end{cases}$$

Recalling (9.27), and since $\alpha_0<2\alpha$,

$$|\mathcal{T}_\xi(p_\xi J*B_\xi)|\leqslant cL^4(e^{-\alpha_0\xi}e^{-\zeta x}+(e^{-\alpha_0(2L-\xi)}+e^{-\alpha(2L+\xi)})e^{-\zeta(2L-x)})$$

and same bounds (even better) holds for $|\mathcal{T}_\xi(\rho_\xi[J*B_\xi]^2)|$.

Recalling definition (9.3) of A_ξ, we have

$$|\mathcal{T}_\xi\rho_\xi[J*A_\xi]^2|\leqslant cL^4(e^{-2\alpha(2L-\xi)}e^{-\zeta(2L-x)}+e^{-\zeta x}e^{-2\alpha\xi}).\tag{A2}$$

(A1) is thus proved. □

2. Analysis of $\psi^{\star}_{\xi}(x)$

We have

$$|\mathcal{T}_{\xi}(\rho_{\xi}[J*\psi_{\xi}]^2)| \leqslant V_1^-(x)\mathbf{1}_{x\leqslant\xi} + V_1^+(x)\mathbf{1}_{x\geqslant\xi} = V_1(x),$$

$$|\mathcal{T}_{\xi}(\rho_{\xi}[J*\psi_{\xi}][J*A_{\xi}])| \leqslant V_2^-(x)\mathbf{1}_{x\leqslant\xi} + V_2^+(x)\mathbf{1}_{x\geqslant\xi} = V_2(x),$$

$$|\mathcal{T}_{\xi}(\rho_{\xi}[J*\psi_{\xi}][J*B_{\xi}])| \leqslant V_3(x) \tag{A3}$$

so that

$$|\psi^{*}_{\xi}(x)| \leqslant V_1(x) + V_2(x) + V_3(x) \tag{A4}$$

where (bounding $e^{-(2L-\xi)(\alpha-\zeta)} \leqslant 1$)

$$V_1^- = cL^4(e^{-4\alpha\xi} + e^{-2\alpha_0\xi-\zeta x}),$$

$$V_1^+ = cL^4(e^{-\zeta(2L-x)}n_+(2L)^2 + n_+(x)^2 + e^{-\zeta(x-\xi)}[n_+(\xi)^2 + n_-(\xi)^2] + e^{-\zeta x}n_-(0)^2),$$

$$V_2^- = cL^4(e^{-\zeta x-(\alpha_0+\alpha)\xi} + e^{-\zeta(2L-x)-\alpha(2L-\xi)}),$$

$$V_2^+ = cL^4(e^{-\zeta(2L-x)}n_+(2L)A_{\xi}(2L) + n_+(x)A_{\xi}(x) + e^{-\zeta|x-\xi|}[n_+(\xi) + n_-(\xi)]A_{\xi}(\xi) + e^{-\zeta x}n_-(0)A_{\xi}(0)),$$

$$V_3 = cL^4(e^{-\zeta x}n_-(0)(e^{-\alpha_0\xi} + e^{-\alpha(4L-\xi)}) + e^{-\zeta(2L-x)}n_+(2L)(e^{-\alpha_0(2L-\xi)} + e^{-\alpha(2L+\xi)})).$$

3. Bounds on D_{ξ}

We will prove that for any $\epsilon > 0$ there is L_{ϵ} so that for any $L \geqslant L_{\epsilon}$

$$e^{2\alpha\xi}|D_{\xi}| \leqslant \epsilon.$$

Since $(1+\lambda_{\xi})^{N+1} \leqslant 2$, using (9.22), the contribution of the first term on the r.h.s. of (9.25) is bounded by

$$2c_1e^{2\alpha\xi}[e^{-(5/2)\alpha})(2L-\xi) + e^{-(5/2)\alpha\xi}$$

which, for $\xi \geqslant rL$ is exponentially small in L.

By (9.28), the contribution of the second term on the r.h.s. of (9.25) is bounded by

$$2e^{2\alpha\xi}c_2[e^{-(\alpha_0+\alpha)\xi} + e^{-(\alpha_0+\alpha)(2L-\xi)} + e^{-\alpha 4L}]$$

which is again exponentially small. Moreover

$$e^{2\alpha\xi}\pi_{\xi}(\rho_{\xi}(J*B_{\xi})^2) \leqslant ce^{2\alpha\xi}[e^{-2\alpha_0\xi}e^{-\alpha\xi} + \{e^{-2\alpha_0(2L-\xi)} + e^{-2\alpha(2L+\xi)}\}e^{-\alpha(2L-\xi)}].$$

Observe that the next bounds can be recovered from the corresponding ones with $\mathcal{T}_{\xi}(\cdot)$, provided the latter are computed at $x=\xi$ and with ζ replaced by α, the term L^4 being dropped. Thus, from (A2),

$$e^{2\alpha\xi}\pi_{\xi}(\rho_{\xi}(J*A_{\xi})^2) \leqslant ce^{2\alpha\xi}[e^{-2\alpha\xi}e^{-\alpha\xi} + e^{-2\alpha(2L-\xi)}e^{-\alpha(2L-\xi)}] \leqslant e^{-\alpha\xi} + e^{-\alpha(2L-\xi)}.$$

The same strategy applies to the terms

$$e^{2\alpha\xi}\pi_\xi(\rho_\xi(J*\psi_\xi)(J*A_\xi)),\quad e^{2\alpha\xi}|\pi_\xi(\rho_\xi[J*\psi_\xi][J*B_\xi])|,\quad e^{2\alpha\xi}|\pi_\xi(\rho_\xi[J*\psi_\xi]^2)|$$

which are estimated in terms of (A3). They also vanish as $L\to\infty$. In particular, the first one is bounded by $e^{-(\alpha+\alpha')(2L-\xi)+2\alpha\xi}$ which vanishes by the assumption that $\xi>rL$, $r>0$.

4. Bounds on E_ξ

We will prove that for any $\epsilon>0$ there is L_ϵ so that for any $L\geqslant L_\epsilon$

$$\sup_{x\in[0,2L]} e^{2\alpha\xi}e^{\alpha|\xi-x|}|E_\xi(x)|\leqslant\epsilon. \tag{A5}$$

We bound the terms in (9.20), using the bounds on ψ_ξ, ψ^*_ξ, A_ξ, and B_ξ already obtained. We distinguish the intervals $x\leqslant\xi$ and $x>\xi$. In each of them the dependence on x is of the form e^{bx}, with b depending on the term under consideration. Thus the max of the function to bound will be achieved at one of the endpoints. The bound at $x=0$ is

$$e^{3\alpha\xi}\rho_\xi[J*\psi^\star_\xi]^2|_0\leqslant cL^8e^{3\alpha\xi}\{e^{-2\alpha_0\xi}+[e^{-(\alpha_0+\alpha)\xi}+e^{-\zeta 2L-\alpha(2L-\xi)}]+[n_-(0)(e^{-\alpha_0\xi}+e^{-\alpha(4L-\xi)})+e^{-\zeta 2L}n_+(2L)(e^{-\alpha_0(2L-\xi)}+e^{-\alpha(2L+\xi)})]\}^2,$$

$$e^{3\alpha\xi}2\rho_\xi[J*\psi^\star_\xi][J*\psi_\xi]|_0\leqslant cL^8e^{3\alpha\xi}\{e^{-2\alpha_0\xi}+[e^{-(\alpha_0+\alpha)\xi}+e^{-\zeta 2L-\alpha(2L-\xi)}]+[n_-(0)(e^{-\alpha_0\xi}+e^{-\alpha(4L-\xi)})+e^{-\zeta 2L}n_+(2L)(e^{-\alpha_0(2L-\xi)}+e^{-\alpha(2L+\xi)})]\}n_-(0),$$

$$e^{3\alpha\xi}2\rho_\xi[J*\psi^\star_\xi][J*A_\xi]|_0\leqslant cL^8e^{3\alpha\xi}\{e^{-2\alpha_0\xi}+[e^{-(\alpha_0+\alpha)\xi}+e^{-\zeta 2L-\alpha(2L-\xi)}]+[n_-(0)(e^{-\alpha_0\xi}+e^{-\alpha(4L-\xi)})+e^{-\zeta 2L}n_+(2L)(e^{-\alpha_0(2L-\xi)}+e^{-\alpha(2L+\xi)})]\}[e^{-\alpha(4L-\xi)}+e^{-\alpha\xi}],$$

$$e^{3\alpha\xi}2\rho_\xi[J*\psi^\star_\xi][J*B_\xi]|_0\leqslant cL^8e^{3\alpha\xi}\{e^{-2\alpha_0\xi}+[e^{-(\alpha_0+\alpha)\xi}+e^{-\zeta 2L-\alpha(2L-\xi)}]+[n_-(0)(e^{-\alpha_0\xi}+e^{-\alpha(4L-\xi)})+e^{-\zeta 2L}n_+(2L)(e^{-\alpha_0(2L-\xi)}+e^{-\alpha(2L+\xi)})]\}e^{-\alpha_0\xi}.$$

All these terms, with $\xi<L$, are bounded by ϵ for L large enough.

When $x=\xi$, we have from (A5),

$$e^{2\alpha\xi}\rho_\xi[J*\psi^\star_\xi]|_\xi\leqslant cL^8e^{2\alpha\xi}(e^{-\alpha 4\xi}+e^{-(2\alpha_0+\zeta)\xi}+e^{-(\zeta+\alpha+\alpha_0)\xi}+e^{-(\alpha+\zeta)(2L-\xi)})$$

which vanishes as $L\to\infty$ and $(1-r)L>\xi>rL$. It then follows that the contribution in (A5) of $x=\xi$ can be made as small as desired, by taking L large. When $x=2L$,

$$e^{2\alpha\xi+\alpha(2L-\xi)}\rho_\xi[J*\psi^\star_\xi]|_{2L}\leqslant cL^8e^{2\alpha\xi+\alpha(2L-\xi)}\{e^{-(\alpha+\alpha_0)(2L-\xi)}\}.$$

This term alone does not vanish as $L\to\infty$, but once multiplied by $J*\psi_\xi$, $J*A_\xi$, $J*B_\xi$ the contribution to (A5) becomes as small as desired, for L large.

5. Asymptotic behavior of the subsolution

We will first prove that for any $\epsilon>0$ there is L_ϵ so that for $L>L_\epsilon$ and $\xi\in[rL,(1-r)L]$,

$$\sup_{x\in[0,2L]} e^{\alpha|\xi-x|}|\psi_\xi(x)|\leqslant\epsilon. \tag{A6}$$

For $x\leqslant\xi$, $e^{\alpha|\xi-x|}|\psi_\xi(x)|$ is bounded by cL^4 times

$$e^{\alpha|\xi-x|}n_-(x)\leqslant e^{\alpha(\xi-x)-2\alpha\xi}+e^{\alpha(\xi-x)-\alpha_0\xi-\zeta x}\leqslant e^{-\alpha(\xi+x)}+e^{-(\alpha+\zeta)x-(\alpha_0-\alpha)\xi}$$

which vanishes as $L\to\infty$. For $x\geqslant\xi$, $|\psi_\xi(x)|\leqslant n_+(x)$ which is the sum of three terms, thus $e^{\alpha|\xi-x|}|\psi_\xi(x)|$ is bounded by cL^4 times the sum of the following three terms.

$$e^{\alpha|x-\xi|}e^{-2\alpha(2L-\xi)} \leqslant e^{-\alpha(2L-\xi)},$$

$$e^{\alpha(x-\xi)}e^{-2\alpha\xi-\zeta(x-\xi)} \leqslant e^{(\alpha-\zeta)(2L-\xi)-2\alpha\xi},$$

$$e^{\alpha(x-\xi)}e^{-\zeta(2L-x)}\left[e^{-\alpha_0(2L-\xi)} + e^{-\alpha(2L+\xi)}\right] \leqslant e^{-(\alpha_0-\alpha)(2L-\xi)} + e^{-2\alpha\xi}.$$

We will next prove that for any $\epsilon>0$ there is L_ϵ so that for $L>L_\epsilon$ and $\xi\in[rL,(1-r)L]$,

$$\sup_{x\in[0,2L]} e^{\alpha|\xi-x|}\left|\psi^*_\xi(x)\right| \leqslant \epsilon. \tag{A7}$$

Recalling (A4), we have, with $x\leqslant\xi$,

$$e^{\alpha(\xi-x)}(V_1^- + V_2^-) \leqslant cL^4(\{e^{-2\alpha\xi} + e^{-(2\alpha_0-\alpha)\xi}\} + \{e^{-\alpha_0\xi} + e^{2\alpha\xi-(\alpha+\zeta)2L}\})$$

$$e^{\alpha(\xi-x)}V_3(x) \leqslant cL^4e^{\alpha\xi}V_3(0)$$

which vanish as $L\to\infty$.

For $x\geqslant\xi$,

$$e^{\alpha(x-\xi)}[V_1^+(x) + V_2^+(x) + V_3^+(x)] \leqslant e^{\alpha(2L-\xi)}[V_1^+(2L) + V_2^+(2L) + V_3^+(2L)]$$

which vanishes as $L\to\infty$.

(Received 14 April 2005; accepted 26 May 2005; published online 25 July 2005)

It is shown that the set of all quantum states corresponding to the motion of a free particle on the group manifold AdS_3 as the bases with two different labels, constitute a Hilbert space. The second label is bounded by the first one however, the first label is semibounded. The Casimir operator corresponding to the simultaneous and agreeable shifting generators of both labels along with the Cartan subalgebra generator describe the Hamiltonian of a free particle on AdS_3 with dynamical symmetry group U(1,1) and infinite-fold degeneracy for the energy spectrum. The Hilbert space for the Lie algebra of the dynamical symmetry group is a reducible representation space. But the Hilbert subspaces constructed by all the bases which have a given constant value for the difference of two their labels, constitute an irreducible representation for it. It is also shown that the irreducible representation subspaces of the Lie algebras u(1,1) and u(2) are separately spanned by the bases which have the same value for the second and first labels, respectively. These two bunches of Hilbert subspaces present two different types of quantum splittings on the Hilbert space. © *2005 American Institute of Physics.*

I. INTRODUCTION AND MOTIVATION

After introducing nonrelativistic supersymmetric quantum mechanics,[1–3] the study of solvable problems has attracted a considerable attention. In the beginning of the theory, a lot of fundamental results were obtained (for further review see Refs. 4–7). Based on supersymmetry, if we know the wave function of the ground state with the zero energy for a given potential then we will obtain a hierarchy of partner potentials and their wave functions as well as energy eigenvalues. During that time, Gendenshtein remarkably developed supersymmetric quantum mechanics by defining the shape invariance concept for the potentials.[8] On this basis, most of the potentials obtained by the supersymmetry and shape invariance methods had the same functional of spatial coordinates, however, they had different parameters with respect to each other. Thus, the shape invariant potentials were identified with the known potentials which had analytic solutions. At first, it was supposed that all of the solvable potentials are shape invariant. Afterwards, it was realized that the shape invariance is a sufficient and not a necessary condition for the solvability.[9] Much work has been done to investigate shape invariance in the framework of supersymmetry (for example, see Refs. 10–18).

[a)]Electronic mail: a.chenaghlou@sut.ac.ir
[b)]Electronic mail: hfakhri@ipm.ir

Simultaneous shape invariance with respect to two different parameters whose formulation was first performed for the associated hypergeometric and Jacobi functions,[19,20] and then for the associated Laguerre functions,[21] provides a rich algebraic structure for the special functions and their corresponding differential equations. However, for the special functions (polynomials) of Hermite, simultaneous shape invariance with respect to two parameters has not been propounded. Due to this fact, the harmonic oscillator as the simplest problem of quantum mechanics is derived from the Hermite differential equation and occurred as the base and foundation of much studies in physics. Since, first, the factorization and consequently the shape invariance of the Hermite differential equation take place with respect to only one parameter. Second, the corresponding raising and lowering operators are not functions from the shape invariance parameter. On the other hand, in contrast with this simple case, the complication of the hypergeometric, Jacobi (which is from the same hypergeometric type) and Laguerre (which is from the confluent hypergeometric type) differential equations supplies the simultaneous shape invariance with respect to two different parameters and also the corresponding operators are functions from the shape invariance parameters.

It seems that introducing the simultaneous shape invariance with respect to two different parameters in the equations leads to the simplification of them like the Hermite differential equation however, their applications become rich. For example, the simultaneous shape invariance with respect to two different parameters of the associated Gegenbauer differential equation has played an important role in connection with investigating dynamical symmetry groups SU(2) and SU(1,1) and realizing the representation of parasupersymmetry algebra by the quantum states corresponding to the motion of a free particle on the sphere S^2 and the two-dimensional manifold AdS_2, respectively.[22] Further, for a free particle on the sphere, Barut–Girardello coherent states have been constructed by the spherical harmonics.[23] As another two-dimensional example, applying the simultaneous shape invariance with respect to two parameters in the associated Laguerre functions, we obtained the realization of new quantum splittings for the Landau levels, and consequently construction of the corresponding coherent states.[24,25] Besides, the simultaneous shape invariance with respect to two parameters leads to a deep and extended understanding of supersymmetry for the one-dimensional solvable models like the Morse, three-dimensional harmonic oscillator, and generalized radial Hulthén potentials, and radial potential of hydrogen-like atoms.[26–28] In Ref. 29, it has been emphasized that most of the shape invariant models are classified in two different classes so that in the first and second classes, the shape invariance parameters are n (degree of polynomial) and m (the dependence index of the special functions), respectively.

In this article, by using the associated Gegenbuer functions, we construct the Hilbert space $\mathcal{H}=\mathrm{span}\{|n,m\rangle\}_{0\leqslant m\leqslant n<\infty}$ spanned by the orthonormal bases $|n,m\rangle$, with two labels and restrictions $n\geqslant 0$ and $0\leqslant m\leqslant n$ for two integers n and m, which in fact are the solutions of the eigenvalue equation associated with the Hamiltonian of a free particle on the group manifold $AdS_3 \cong \mathrm{SU}(1,1)\cong \mathrm{SL}(2,R)$. We introduce four generators of the noncompact Lie algebra u(1,1) in such a manner that their corresponding laddering generators shift both the indices n and m of quantum states $|n,m\rangle$ simultaneously and agreeably. The Casimir operator of these generators is basically the Hamiltonian that describes the dynamical symmetry group U(1,1) for the free particle moving on AdS_3. It is shown that the Hilbert space $\mathcal{H}$ as the set of all quantum states of this problem represents reducibly the Lie algebra of the dynamical symmetry group U(1,1) which has an infinite-fold degeneracy for the energy spectrum. However, the infinite dimensional Hilbert subspaces $\mathcal{H}_i=\mathrm{span}\{|m+i,m\rangle\}_{m\geqslant 0}$, $i\geqslant 0$, which divide the whole Hilbert space $\mathcal{H}$ (as $\mathcal{H}=\cup_{i=0}^{\infty}\mathcal{H}_i$ and $\mathcal{H}_i\cap\mathcal{H}_{i'}=\emptyset$ for $i\neq i'$), represent the Lie algebra irreducibly. Moreover, the Hilbert space $\mathcal{H}$ is divided by two other different ways through infinite dimensional Hilbert subspaces $\mathcal{H}_m=\mathrm{span}\{|n,m\rangle\}_{n\geqslant m}$ (as $\mathcal{H}=\cup_{m=0}^{\infty}\mathcal{H}_m$ and $\mathcal{H}_m\cap\mathcal{H}_{m'}=\emptyset$ for $m\neq m'$) and finite dimensional ones $\mathcal{H}_n=\mathrm{span}\{|n,m\rangle\}_{m\leqslant n}$ (as $\mathcal{H}=\cup_{n=0}^{\infty}\mathcal{H}_n$ and $\mathcal{H}_n\cap\mathcal{H}_{n'}=\emptyset$ for $n\neq n'$). We show that the Hilbert subspaces $\mathcal{H}_m$ as positive discrete series, and $\mathcal{H}_n$ represent the noncompact Lie algebra u(1,1), and the compact Lie algebra u(2), respectively. These representations automatically propose infinite-u(1,1)- and finite-u(2)-quantum splittings on the whole space of quantum states. Realization of the

dynamical symmetry group U(1,1) by simultaneous shift operators of both quantum states labels and also u(1,1)- and u(2)-quantum splittings is a direct consequence of the simultaneous shape invariance idea with respect to two different parameters. The discussions performed in this article may be compared with the classical and quantum mechanical investigations done in Ref. 30 for a massive particle on the group manifold AdS_3 in the framework of the Klein–Gordon equation.

II. MATHEMATICAL FOUNDATION

In Ref. 20 it has been shown that if the normalization coefficients of the associated Gegenbauer functions $P_{n,m}^{(\alpha)}(x)$ in the Rodrigues representation are chosen as

$$P_{n,m}^{(\alpha)}(x)=\frac{(-1)^m}{2^n\Gamma(\alpha+n+1)}\sqrt{\frac{\Gamma(2\alpha+n+m+1)}{\Gamma(n-m+1)}}\frac{1}{(1-x^2)^{\alpha+m/2}}\left(\frac{\mathrm{d}}{\mathrm{d}x}\right)^{n-m}(1-x^2)^{\alpha+n}, \tag{1}$$

then the following laddering relations are simultaneously realized with respect to the parameters n and m, respectively:

$$A_+(n;x)P_{n-1,m}^{(\alpha)}(x)=\sqrt{(n-m)(2\alpha+n+m)}P_{n,m}^{(\alpha)}(x), \tag{2a}$$

$$A_-(n;x)P_{n,m}^{(\alpha)}(x)=\sqrt{(n-m)(2\alpha+n+m)}P_{n-1,m}^{(\alpha)}(x), \tag{2b}$$

and

$$A_+(m;x)P_{n,m-1}^{(\alpha)}(x)=\sqrt{(n-m+1)(2\alpha+n+m)}P_{n,m}^{(\alpha)}(x), \tag{3a}$$

$$A_-(m;x)P_{n,m}^{(\alpha)}(x)=\sqrt{(n-m+1)(2\alpha+n+m)}P_{n,m-1}^{(\alpha)}(x), \tag{3b}$$

where the parameters n and m take nonnegative integer values. The explicit forms of the laddering operators $A_\pm(n;x)$ and $A_\pm(m;x)$ are calculated as

$$A_\pm(n,x)=\pm(1-x^2)\frac{d}{dx}-(n+\alpha\pm\alpha)x, \tag{4}$$

$$A_\pm(m,x)=\pm\sqrt{1-x^2}\frac{d}{dx}+\frac{\left(m+\alpha\mp\alpha-\frac{1}{2}\mp\frac{1}{2}\right)x}{\sqrt{1-x^2}}. \tag{5}$$

For a given m the number of the laddering equations with respect to n is infinite. However, for a given m, the number of the laddering equations with respect to m is finite. Combination of Eqs. (2a) and (2b) by two different ways leads to the shape invariance equations with respect to the parameter n. Similarly, combination of Eqs. (3a) and (3b) by the same procedure gives rise to the shape invariance equations with respect to the parameter n.

It is also shown that if the real parameter α is chosen as $\alpha>-1$ then, the associated Gegenbauer functions $P_{n,m}^{(\alpha)}(x)$ for a given m but with different n's are orthogonal with respect to an inner product with the weight function $(1-x^2)^\alpha$ in the interval $(-1,+1)$ so that their norms are given by the following relation:

$$\int_{-1}^{+1}P_{n,m}^{(\alpha)}(x)P_{n',m}^{(\alpha)}(x)(1-x^2)^\alpha\mathrm{d}x=\delta_{nn'}h_n^2(\alpha),\quad n,n'\geqslant m \tag{6}$$

with

$$h_n(\alpha) = \frac{2^{\alpha+1/2}}{\sqrt{2\alpha+2n+1}}.$$

Now by using the Rodrigues representation (1), let us rewrite relation (6) as

$$\int_0^1 P_{n,m}^{(\alpha)}(x) P_{n',m}^{(\alpha)}(x)(1-x^2)^{\alpha} \mathrm{d}x = \delta_{n\,n'} \frac{h_n^2(\alpha)}{2}, \quad n,n' \geqslant m. \tag{7}$$

It should be pointed out that the special case $\alpha=0$ yields the associated Legendre functions $P_{n,m}^{(0)}(x)=P_{n,m}(x)$. In this case by using just the laddering equations (3) and by replacing n with l, it is well-known that representation of Lie algebra su(2) on the space of spherical harmonics $|l,m\rangle = Y_{l\,m}(\theta,\phi)$ via shifting just m, is realized. In trigonometric harmonics $Y_{l\,m}(\theta,\phi)$, θ and ϕ are local coordinate patch on the two-dimensional sphere S^2. Realization of irreducible representation su(2) via (deformed) spherical harmonics is a problem which arises in the many many contents in mathematical physics (for example, see Refs. 31–34). In a similar approach, we shall show that simultaneous formulation of Eqs. (2) and (3) gives rise to the derivation of the hyperbolic harmonics $|n,m\rangle$ as functions of three coordinates corresponding to the parametrization of the group manifold $\mathrm{AdS}_3 \cong \mathrm{SL}(2,R)$.

III. REALIZATION OF REDUCIBLE REPRESENTATIONS OF THE LIE ALGEBRAS u(1,1) AND u(2) BY A HILBERT SPACE

In this section a Hilbert space is constructed to represent the noncompact Lie algebra u(1,1) as well as the compact Lie algebra u(2) reducibly. We also obtain the irreducible Hilbert subspaces corresponding to the representations of the Lie algebras so that each of them divides the Hilbert space separately. First of all we define the kets $|n,m\rangle$ as functions of the variables $0<r<\infty$, $0 \leqslant \phi < 2\pi$ and $-\pi \leqslant \psi < \pi$:

$$|n,m\rangle := \frac{e^{in\phi+im\psi} P_{n,m}^{(\alpha)}\left(\frac{1}{\cosh r}\right)}{\pi\sqrt{2h_n(\alpha)}}. \tag{8}$$

It is easily shown that the kets $|n,m\rangle$ form an orthonormal set with respect to both the indices, and with an inner product whose measure is $(\tanh^{2\alpha+1} r/\cosh r)\mathrm{d}r\mathrm{d}\phi\mathrm{d}\psi$:

$$\langle n,m|n',m'\rangle = \int_{r=0}^{\infty}\int_{\phi=0}^{2\pi}\int_{\psi=-\pi}^{\pi} \left(\frac{e^{in\phi+im\psi} P_{n,m}^{(\alpha)}\left(\frac{1}{\cosh r}\right)}{\pi\sqrt{2h_n(\alpha)}}\right)^* \times \left(\frac{e^{in'\phi+im'\psi} P_{n',m'}^{(\alpha)}\left(\frac{1}{\cosh r}\right)}{\pi\sqrt{2h_{n'}(\alpha)}}\right) \frac{\tanh^{2\alpha+1} r}{\cosh r} \mathrm{d}r\mathrm{d}\phi\mathrm{d}\psi = \delta_{n\,n'}\delta_{m\,m'}. \tag{9}$$

Note that by using $x=1/\cosh r$, the relation (9) converts to the relation (7). Consequently, we can introduce infinite dimensional Hilbert space $\mathcal{H}$ which is spanned by the bases $|n,m\rangle$, i.e., $\mathcal{H} := \mathrm{span}\{|n,m\rangle\}_{0\leqslant m\leqslant n<\infty}$.

Now if we define the operators L_+ and L_- as

$$L_{\pm} = e^{\pm i\phi}\left(\mp \sinh r \frac{\partial}{\partial r} + \frac{i}{\cosh r}\frac{\partial}{\partial\phi} - \frac{\alpha+\frac{1}{2} \pm \left(\alpha+\frac{1}{2}\right)}{\cosh r}\right), \tag{10}$$

then by using Eq. (2) we may show that they satisfy the raising and lowering relations of the index n for a given m as

$$L_+|n-1,m\rangle = \sqrt{\frac{(n-m)(2\alpha+n+m)(2\alpha+2n-1)}{2\alpha+2n+1}}|n,m\rangle, \tag{11a}$$

$$L_-|n,m\rangle = \sqrt{\frac{(n-m)(2\alpha+n+m)(2\alpha+2n+1)}{2\alpha+2n-1}}|n-1,m\rangle, \tag{11b}$$

respectively. Meanwhile by defining $L_3=-i\,\partial/\partial\phi$, we have

$$L_3|n,m\rangle = n|n,m\rangle. \tag{12}$$

Using the explicit forms of the operators or Eqs. (11) and (12) which represent these operators in the Hilbert space $\mathcal{H}$, it is easily seen that four generators L_+, L_-, L_3, and $I:=1$ satisfy the commutation relations of the noncompact Lie algebra u(1,1) as follows

$$[L_+,L_-] = -2L_3 - (2\alpha+1)I,$$

$$[L_3,L_\pm] = \pm L_\pm,$$

$$[\mathbf{L},I] = 0. \tag{13}$$

It is evident that for $\alpha=-\frac{1}{2}$ (the associated Chebyshev functions of the first type), the Lie algebra u(1, 1) is decomposed into $\mathrm{su}(1,1)\oplus\mathrm{u}(1)$. The representation of the noncompact Lie algebra u(1,1), i.e., (13) in the Hilbert space $\mathcal{H}$ is reducibly realized by Eqs. (11) and (12) as well as the following relation:

$$I|n,m\rangle = |n,m\rangle. \tag{14}$$

In fact for every given m, we obtain a positive discrete irreducible representation $\mathcal{D}_m^+=\{m,m+1,m+2,\ldots\}$ for the Lie algebra u(1,1). The infinite dimensional Hilbert subspaces $\mathcal{H}_m$ which are defined as $\mathcal{H}_m := \mathrm{span}\{|n,m\rangle\}_{n\geqslant m}$ represent irreducibly the Lie algebra u(1,1) again as Eqs. (11), (12), and (14). They divide the Hilbert space $\mathcal{H}$ (as $\mathcal{H}=\cup_{m=0}^{\infty}\mathcal{H}_m$ and $\mathcal{H}_m\cap\mathcal{H}_{m'}=\varnothing$ for $m\neq m'$). All bases of the irreducible subspaces $\mathcal{H}_m$ are algebraically generated by the representation relations. For this purpose by solving the differential equation $L_-|m,m\rangle=0$ which is obtained by (11b), we get the lowest base $|m,m\rangle$ as

$$|m,m\rangle = \frac{e^{im\phi+im\psi}(-1)^m}{\pi 2^{\alpha+m+1}}\frac{\sqrt{\Gamma(2\alpha+2m+2)}}{\Gamma(\alpha+m+1)}\tanh^m r, \tag{15}$$

which is consistent with (8). Equation (11a) gives all other bases of $\mathcal{H}_m$ as

$$|n,m\rangle = \sqrt{\frac{(2\alpha+2n+1)\Gamma(2\alpha+2m+1)}{(2\alpha+2m+1)\Gamma(n-m+1)\Gamma(2\alpha+n+m+1)}}L_+^{n-m}|m,m\rangle, \quad n\geqslant m. \tag{16}$$

Also, if we define operators K_+ and K_+ as

$$K_\pm := e^{\pm i\psi}\left(\mp\cosh r\frac{\partial}{\partial r} - \frac{i}{\sinh r}\frac{\partial}{\partial\psi} + \frac{\alpha\mp\alpha}{\sinh r}\right), \tag{17}$$

then by using relations (3) for a given n, we derive the raising and lowering relation of the label m, that is,

$$K_+|n,m-1\rangle = \sqrt{(n-m+1)(2\alpha+n+m)}|n,m\rangle, \tag{18a}$$

$$K_-|n,m\rangle = \sqrt{(n-m+1)(2\alpha+n+m)}|n,m-1\rangle. \tag{18b}$$

For $K_3 := -i\partial/\partial\psi$ we have

$$K_3|n,m\rangle = m|n,m\rangle. \tag{19}$$

Using the explicit forms of the operators K_+, K_-, K_3, and I or equations which are related to the operation of these operators on the Hilbert space $\mathcal{H}$, one may deduce

$$[K_+,K_-] = 2K_3 + 2\alpha I,$$

$$[K_3,K_\pm] = \pm K_\pm,$$

$$[\mathbf{K},I] = 0. \tag{20}$$

Therefore, the four generators K_+, K_-, K_3, and I satisfy the commutation relations of the compact Lie algebra u(2). The Hilbert space $\mathcal{H}$ represents this Lie algebra reducibly through Eqs. (18), (19), and (14). It is clear that for $\alpha=0$ (the associated Legendre functions), the Lie algebra u(2) i.e., (20) is decomposed into $\mathrm{su}(2)\oplus\mathrm{u}(1)$. The $(n+1)$-dimensional Hilbert subspaces $\mathcal{H}_n := \mathrm{span}\{|n,m\rangle\}_{m\leqslant n}$, which divide the Hilbert space $\mathcal{H}$ (as $\mathcal{H}=\cup_{n=0}^{\infty}\mathcal{H}_n$ and $\mathcal{H}_n\cap\mathcal{H}_{n'}=\varnothing$ for $n\neq n'$), represent the compact Lie algebra u(2) reducibly via the relations (18), (19), and (14) once again. In other words for a given n, all bases of $\mathcal{H}_n$ are calculated by an algebraic method. The highest base $|n,n\rangle$ is computed by (18a) as (15) except that m is replaced by n. Using (18b), all other bases are obtained as

$$|n,m\rangle = \sqrt{\frac{\Gamma(2\alpha+n+m+1)}{\Gamma(n-m+1)\Gamma(2\alpha+2n+1)}}K_-^{n-m}|n,n\rangle, \quad m\leqslant n. \tag{21}$$

In the next section we shall show that the bases $|n,m\rangle$ of the Hilbert space $\mathcal{H}$ are the eigensolutions of the Schrödinger operator corresponding to the motion of a free particle on the group manifold AdS_3. In addition, $\mathcal{H}$ will also represent the noncompact Lie algebra u(1,1) in a manner that is different from Eqs. (11) and (12).

IV. REALIZATION OF DYNAMICAL SYMMETRY GROUP U(1,1) FOR A FREE PARTICLE ON THE AdS_3 BY THE HILBERT SPACE $\mathcal{H}$

Simultaneous realization of representations of the noncompact Lie algebra u(1,1) and compact Lie algebra u(2) by the Hilbert space $\mathcal{H}$ via equations (11), (12), and (14), and (18), (19), and (14) respectively, gives us the possibility to define new differential generators for the Lie algebra u(1,1) (this time, they are functions from three coordinates r, ϕ, and ψ of the group manifold AdS_3) by a different method. So in addition to obtain a different representation for the Lie algebra u(1,1) by the Hilbert space $\mathcal{H}$, we can show that the Casimir operator of these new generators is basically the Schrödinger operator corresponding to the motion of a free particle on the group manifold AdS_3. First of all let us define

$$J_\pm := \pm[K_\pm,L_\pm] = e^{\pm i\phi\pm i\psi}\left[\pm\frac{\partial}{\partial r} + i\tanh r\frac{\partial}{\partial\phi} + i\coth r\frac{\partial}{\partial\psi} - \left[\left(\alpha+\frac{1}{2}\right)\pm\left(\alpha+\frac{1}{2}\right)\right]\tanh r - (\alpha\mp\alpha)\coth r\right]$$

$$J_3 := L_3 + K_3 = -i\left(\frac{\partial}{\partial\phi}+\frac{\partial}{\partial\psi}\right). \tag{22}$$

Using equations (11), (12), (18), and (19) it is easily shown that

$$J_+|n-1,m-1\rangle = \sqrt{\frac{(2\alpha+n+m)(2\alpha+n+m-1)(2\alpha+2n-1)}{2\alpha+2n+1}}|n,m\rangle, \tag{23a}$$

$$J_-|n,m\rangle = \sqrt{\frac{(2\alpha+n+m)(2\alpha+n+m-1)(2\alpha+2n+1)}{2\alpha+2n-1}}|n-1,m-1\rangle, \tag{23b}$$

$$J_3|n,m\rangle = (n+m)|n,m\rangle. \tag{23c}$$

Applying the recent result and also by using the explicit form of the generators, one can derive the commutation relations of the noncompact Lie algebra u(1,1) as

$$[J_+,J_-] = -4J_3 - 2(4\alpha+1),$$

$$[J_3,J_\pm] = \pm 2J_\pm,$$

$$[\mathbf{J},I] = 0. \tag{24}$$

Obviously, the representation of the Lie algebra u(1,1) in the Hilbert space $\mathcal{H}$ via Eqs. (23) and (14) is reducible. If we divide $\mathcal{H}$ in terms of the Hilbert subspaces $\mathcal{H}_i = \text{span}\{|m+i,m\rangle\}_{m\geqslant 0}$, $i \geqslant 0$, (as $\mathcal{H} = \cup_{i=0}^{\infty}\mathcal{H}_i$ and $\mathcal{H}_i \cap \mathcal{H}_{i'} = \varnothing$ for $i \neq i'$) then the representation of the Lie algebra u(1,1) by $\mathcal{H}_i$'s through the four generators J_+, J_-, J_3, and I will be irreducible.

The Casimir operator of the generators J_+, J_-, and J_3 has the following explicit form:

$$H = \frac{1}{2}[J_+J_- - J_3^2 - (4\alpha-1)J_3] = \frac{1}{2}\Bigg[-\frac{\partial^2}{\partial r^2} + \frac{1}{\cosh^2 r}\frac{\partial^2}{\partial\phi^2} - \frac{1}{\sinh^2 r}\frac{\partial^2}{\partial\psi^2} + [2\alpha\tanh r - (2\alpha+1)\coth r]\frac{\partial}{\partial r} + i\frac{(2\alpha+1)}{\cosh^2 r}\frac{\partial}{\partial\phi} - i\frac{2\alpha}{\sinh^2 r}\frac{\partial}{\partial\psi} + 2\alpha(2\alpha-1)\Bigg]. \tag{25}$$

The general form of the Schrödinger operator is $\mathcal{L} = -\frac{1}{2}D_i^{\mathbf{A}}D^{\mathbf{A}i} + V$ in which the index i takes the values r, ϕ, and ψ, respectively. Further, $D_i^{\mathbf{A}}$ is the covariant derivative and $\mathbf{A}$ stands for the connection associated with the presence of an external magnetic field. If we equalize the Casimir operator given in (25) with $\mathcal{L}$ then by comparing the coefficients of the second-order derivatives, the metric tensor will be calculated to yield

$$g_{ij} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -\cosh^2 r & 0 \\ 0 & 0 & \sinh^2 r \end{pmatrix}. \tag{26}$$

The nonzero components of the Christoffel symbols related to the metric (26) are computed as

$$\Gamma^r_{\phi\phi} = \tfrac{1}{2}\sinh 2r, \quad \Gamma^r_{\psi\psi} = -\tfrac{1}{2}\sinh 2r, \quad \Gamma^{\phi}_{r\phi} = \tanh r, \quad \Gamma^{\psi}_{r\psi} = \coth r. \tag{27}$$

Thus, the nonzero component of the Ricci tensor are given by

$$R_{rr} = -2, \quad R_{\phi\phi} = 2\cosh^2 r, \quad R_{\psi\psi} = -2\sinh^2 r. \tag{28}$$

Consequently, Ricci scalar curvature becomes $R = g^{ij}R_{ij} = -6$. So, the parameters r, ϕ, and ψ describe the coordinates of a three-dimensional manifold with constant negative curvature. It is well-known that[35,36] r, ϕ, and ψ can show an appropriate parametrization for the elements of the group manifold $\text{AdS}_3 \cong \text{SL}(2,R) \cong \text{SU}(1,1)$. Therefore, by using suitable matrix generators for the Lie algebra su(1,1), one can construct left and right invariant differential forms of these generators which may be compared with (22). Note that AdS_3 is not globally a hyperbolic space.

Comparing the coefficients of the first-order derivative and the terms without derivative in the Casimir and Schrödinger operators, then the components of the gauge and scalar potentials are obtained as

$$A_r = \frac{-i}{2}(2\alpha+1)\tanh r, \quad A_\phi = -\frac{1}{2}(2\alpha+1), \quad A_\psi = -\alpha, \quad V = \alpha(2\alpha-1) - \frac{3}{8}. \tag{29}$$

Hence, the two-form magnetic field and the electric field vector become zero:

$$\mathbf{B} = \frac{\partial A_j}{\partial x_i}\mathbf{dx_i} \wedge \mathbf{dx_j} = 0, \quad \mathbf{E} = -\nabla V = 0. \tag{30}$$

Thus, the Casimir operator H describes the Hamiltonian corresponding to a particle moving on the group manifold $\mathrm{SL}(2,R)$ in the absence of magnetic and electric fields. Equations (23a)–(23c) immediately give the following eigenvalue equation on the reducible representation space $\mathcal{H}$ with infinite-fold degeneracy for the energy spectrum:

$$H|n,m\rangle = \alpha(2\alpha-1)|n,m\rangle, \quad 0 \leqslant m \leqslant n < \infty. \tag{31}$$

It is clear that if we restrict the eigenvalue equation (31) on the Hilbert subspaces $\mathcal{H}_i$ which represent the Lie algebra u(1,1), i.e., (24) irreducibly, then it will have infinite-fold degeneracy for the spectrum once again. So, the bases of the Hilbert space, i.e., the kets $|n,m\rangle$ are the quantum states associated to the motion of a free particle on the group manifold AdS_3. Besides, the dynamical symmetry group U(1,1) with infinite-fold degeneracy for the spectrum is described by means of the Casimir operator H. At the same time, as has been shown in the previous section, two other symmetry are exhibited by the space $\mathcal{H}$ of quantum states. In these symmetries we introduce the generators of the non-compact Lie algebra u(1,1) and compact Lie algebra u(2) such that their irreducible representation subspaces are irrelevant with respect to the functional behavior of the variables ψ and ϕ, respectively.

V. CONCLUSION

In this article, in addition to obtaining a dynamical symmetry group U(1,1) via simultaneous shift operators of two parameters n and m, we obtained two different quantum splittings for all the quantum states of a free particle on AdS_3. These two types of quantum splittings are realized by the raising and lowering generators of the noncompact Lie algebra u(1,1) and compact Lie algebra u(2) corresponding to the shift of just the index n for a given m, and the shift of just the index m for a given n, respectively. In other words, there exist two different types of quantum splitting with u(1,1)- and u(2)-irreducible representations on the space of all quantum states. They are infinite- and finite-dimensional Hilbert subspaces with the same functionalities of variables ψ and ϕ for the bases, respectively. Further, the functionalities of both variables ψ and ϕ are changed in the irreducible representations of dynamical symmetry group U(1,1).

(Received 24 December 2004; accepted 31 May 2005; published online 25 July 2005)

We consider wavelets in $L^2(\mathbb{R}^d)$ which have generalized multiresolutions. This means that the initial resolution subspace V_0 in $L^2(\mathbb{R}^d)$ is not singly generated. As a result, the representation of the integer lattice $\mathbb{Z}^d$ restricted to V_0 has a nontrivial multiplicity function. We show how the corresponding analysis and synthesis for these wavelets can be understood in terms of unitary-matrix-valued functions on a torus acting on a certain vector bundle. Specifically, we show how the wavelet functions on $\mathbb{R}^d$ can be constructed directly from the generalized wavelet filters. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1982768]

I. INTRODUCTION

The theory of wavelets is concerned with the Hilbert space $L^2(\mathbb{R}^d)$. The problem is to find "good" orthonormal bases (ONB), where "good" makes reference to several conflicting requirements:

(1) These bases must be constructed from a small number of model functions, called wavelets, and two discrete operations, translation, and scaling. In this article, we are concerned with translation by the standard integer lattice $\mathbb{Z}^d$, and scaling by some prescribed integral matrix A which is assumed expansive.
(2) In passing from function to expansion coefficients, referring to a wavelet basis, and back again (this is called analysis/synthesis), the steps must be algorithmic, ideally avoiding direct reference to integration over $\mathbb{R}^d$.
(3) The wavelet functions should have compact support, and should have some prescribed number of derivatives.

The algorithms that have been popular since the mid-1980s are based on what is called multiresolution analysis (MRA). This was pioneered by Daubechies,[1] Mallat,[2] and Meyer,[3,4] and the idea, although simple, has been extremely powerful. The idea itself is much like that of the

Gram–Schmidt algorithm from Hilbert space, in that it is based on a scale of closed subspaces, resolutions V_n, and relative orthogonal complements, detail subspaces W_n. The scale of subspaces V_n play the role of martingales from probability theory.

Daubechies's book[1] stresses how Requirements (1)–(3) can be met with the MRA approach, and all starting with a fixed cleverly chosen function φ in the subspace V_0 from the resolution. The function φ, the father function, is the solution in L^2 to a scaling, or refinement, equation; a solution which results from a cascade approximation. The wavelet functions, mother functions, can then be constructed from the subspace W_0 which is the relative orthocomplement of V_0 in V_1. One drawback of this approach is that if $N=|\det A|$, then $N-1$ wavelet generators from W_0 are needed. In the dyadic case, $d=1$, $N=2$, that makes one function, but in general, N can be large. Now the spaces V_0 and W_0 are invariant under translation by $\mathbb{Z}^d$, and there is a corresponding pair of multiplicity functions which dictate a minimal choice of generators for V_0 and W_0.

In fact, for the general case of $L^2(\mathbb{R}^d)$ and a fixed scaling matrix A, it is possible to get W_0 singly generated, i.e., to find a single generator ψ. In some cases ψ may be taken to be the inverse Fourier transform of a subset E of $\mathbb{R}^d$. Such subsets E are called wavelet sets, see Refs. 5–10. But there are other choices of sets of generating functions ψ, with the number of generators between 1 and $N-1$. What emerges is that these constructions force frequency localization, and the compact support in the x variable is typically lost, i.e., we must relax Requirement (3). As it turns out, the kind of frequency localization we obtain is well suited for effective sampling algorithms. A second issue enters: The wavelet algorithm may lead to bases which only satisfy a certain Parseval property (also called "normalized tight frames"). Although we still have the resolution structure V_n, the number of generators in V_0 may increase, but they are not directly part of the wavelet basis. This setup is referred to as a generalized multiresolution analysis (GMRA); see Refs. 8–10.

The GMRA theory was in fact introduced (in an operator-theoretic/operator-algebraic framework) in a pioneering paper by Baggett, *et al.*[11] By now there is a rich journal literature which reflects wavelet constructions with some degree of multiplicity; see, e.g., Refs. 12–24. In addition our multiplicity analysis has recently been used in papers by Dutkay and Jorgensen[25–28] in the study of nonlinear dynamical models.

A recent and interesting paper of Papadakis[29] offers a global and natural approach to generalized multiresolution analyses (GMRAs) based on a geometric frame construction which has the advantage of including all GMRA constructions in $L^2(\mathbb{R})$. Some of the differences between the approach in Ref. 29 and the present one lie in our use here of operator algebraic tools deriving from the Cuntz algebras[30] in operator theory. Further, our use of vector bundles in Sec. IV offers a rather explicit and concrete representation of the matrix functions which in turn describe the filters for GMRA normalized tight frame wavelets, alias, for Parseval wavelet frames.

Our article and other recent articles on wavelet frames may be said to generalize a celebrated theorem first proved by Lawton in this journal.[31] Lawton's pioneering result states that a trigonometric low-pass filter which satisfies a certain conjugate-mirror filter condition must give rise to a wavelet frame. However, the resulting wavelet frame may not be associated with a classical MRA. We generalize Lawton's theorem in several directions to a much broader class of subband wavelet filters. Our matrix-valued low-pass filters are still associated with GMRA wavelets. These in turn are the most general types of multiresolution structures.

Finally, we emphasize that the use of wavelet filters derives historically from signal processing in communications engineering, see e.g., Ref. 32.

In the standard case of MRAs, it is well known how the subband filters from signal processing allow us to construct the wavelet functions by an elegant algorithm. The function φ is a solution to a certain refinement equation. The subband filters may be thought of as functions on a torus $\mathbb{T}$, frequency response functions. But in the case of multiplicity and multiple generators, the corresponding functions on $\mathbb{T}$ are matrix valued, and the refinement equation is a matrix equation.

In this article we show that the generalized setup admits solutions in $L^2(\mathbb{R}^d)$ starting with this matrix/vector version of the refinement equation. Starting with a matrix system of subband filter functions on a torus, we show that our corresponding wavelet solutions are in $L^2(\mathbb{R}^d)$, and that they will be Parseval frames for the Hilbert space $L^2(\mathbb{R}^d)$.

Although this is a weakening of the stricter ONB in Requirement (2), the Parseval frame property still allows the same recursive analysis/synthesis algorithms popular in the MRA case. The now classical method of Mallat and Meyer for constructing an orthonormal wavelet in $L^2(\mathbb{R})$ [relative to translation by integers and dilation by 2 (Refs. 2 and 3)] proceeds as follows: Let h be a periodic function on $\mathbb{R}$ that satisfies the "conjugate mirror filter condition" (the so-called Smith–Barnwell condition)

$$|h(x)|^2 + \left|h\left(x+\tfrac{1}{2}\right)\right|^2 = 2. \tag{1.1}$$

The function h is the conjugate mirror filter, referred to previously, and in our context is called a *low-pass filter*. Consider the infinite product

$$P(x) = \prod_{j=1}^{\infty} \frac{1}{\sqrt{2}} h\left(\frac{x}{2^j}\right),$$

and suppose that there exists a nonzero L^2 function ϕ whose Fourier transform $\hat{\phi}$ coincides with P. Under not too strenuous assumptions on h, this does in fact hold. For instance, if we take h to be smooth, and satisfying Cohen's orthogonality conditions and the *low-pass condition* $|h(0)| = \sqrt{2}$, the set of integer translates of ϕ turn out to be orthonormal functions in L^2, and in fact ϕ is a scaling function for a multiresolution analysis $\{V_j\}$.

Given such a low-pass filter function h, there exists an associated periodic function g, which also satisfies the filter equation (1.1), and such that h and g satisfy the following orthogonality condition:

$$h(x)\overline{g(x)} + h\left(x+\tfrac{1}{2}\right)\overline{g\left(x+\tfrac{1}{2}\right)} = 0. \tag{1.2}$$

Any such function g, called a *high-pass filter*, can be obtained from the low-pass filter function via the standard technique of constructing a unitary matrix whose first row is given by $((h(x)/\sqrt{2}), (h(x+1/2)/\sqrt{2})$ Finally, the function ψ, defined by

$$\hat{\psi}(x) = \frac{1}{\sqrt{2}} g\left(\frac{x}{2}\right)\hat{\phi}\left(\frac{x}{2}\right)$$

is an orthonormal wavelet. That is, the collection $\{\psi_{j,n}\} \equiv \{\sqrt{2}^j \psi(2^j x - n)\}$, for j and n in $\mathbb{Z}$, forms an orthonormal basis for $L^2(\mathbb{R})$.

A famous example of Cohen[33] shows that eliminating the nonvanishing condition can cause the Mallat–Meyer method to go wrong in an interesting but not disastrous way. Cohen exhibited a low-pass filter function h, for which the infinite product P exists, is the Fourier transform of a nonzero L^2 function ϕ, but for which the integer translates of ϕ are not orthonormal. Further, the translates and dilates $\{\psi_{j,n}\}$ of the corresponding function ψ, defined just as in the classical method, is not an orthonormal basis. So, for this choice of filter h, the Mallat–Meyer procedure fails to produce a scaling function, and the resulting function ψ is not an orthonormal wavelet. Nevertheless, its translates and dilates do form what is called a *Parseval frame*. By definition, this means that for each $f \in L^2(\mathbb{R})$ we have

$$\|f\|^2 = \sum_j \sum_n |\langle f|\psi_{j,n}\rangle|^2.$$

In Refs. 31 and 34, the Mallat–Meyer phenomenon was generalized to incorporate the Cohen example in the following way. Suppose h is a low-pass filter for dilation by a positive integer N, i.e., satisfies the filter equation

$$\sum_{l=0}^{N-1} \left| h\left(x+\frac{l}{N}\right)\right|^2 = N$$

and the low-pass condition $|h(0)| = \sqrt{N}$, and suppose $g_1, \ldots, g_{N-1}$ are corresponding high-pass filters, i.e., are periodic functions for which the N functions $h, g_1, \ldots, g_{N-1}$ satisfy the following orthogonality conditions:

$$\sum_{l=0}^{N-1} h\left(x+\frac{l}{N}\right)\overline{g_i}\left(x+\frac{l}{N}\right) = 0$$

for all $1 \leqslant i \leqslant N-1$, and

$$\sum_{l=0}^{N-1} g_i\left(x+\frac{l}{N}\right)\overline{g_j\left(x+\frac{l}{N}\right)} = \begin{cases} N, & i=j \\ 0, & i \neq j, \end{cases}$$

for all i, j between 1 and $N-1$. Again, these $N-1$ high-pass filters can be constructed from the low-pass filter h by the matrix completion technique.

Let P be the infinite product

$$P = \prod_{j=1}^{\infty} \frac{1}{\sqrt{N}} h\left(\frac{x}{N^j}\right).$$

Then, if the functions $h, g_1, \ldots, g_{N-1}$ are Lipschitz continuous, it is shown in Ref. 34 that there exists a nonzero L^2 function ϕ whose Fourier transform coincides with P, and the $N-1$ functions $\{\psi_k\}$, defined by

$$\widehat{\psi_k}(x) = \frac{1}{\sqrt{N}} g_k\left(\frac{x}{N}\right)\hat{\phi}\left(\frac{x}{N}\right),$$

form a Parseval frame multiwavelet. That is, the collection

$$\{\psi_{j,n,k} \equiv \sqrt{N}^j \psi_k(N^j x - n)\},$$

$j, n \in \mathbb{Z}$ and $1 \leqslant k \leqslant N-1$, forms a Parseval frame for $L^2(\mathbb{R})$.

Just as in the Cohen phenomenon in the Mallat–Meyer constructions, the integer translates of the function ϕ may or may not be orthonormal, even though their closed linear span V_0 does form the core subspace of a (generalized) multiresolution analysis. Also, the wavelets ψ_k may or may not have orthonormal translates and dilates, and may or may not belong to the subspace $V_1 \ominus V_0$ of this associated GMRA.

The arguments in the proof of this result introduce some ideas from operator theory, specifically in the form of the Ruelle operator and partial isometries that satisfy relations similar to the Cuntz relations.[30] In the case of dilation by 2, Lawton[31] used a cascade algorithm in the time domain to independently derive the same result (in the special case of trigonometric polynomials, i.e., the case corresponding to a single compactly supported scaling function).

Although the constructions of Refs. 31 and 34 start with filters associated with a classical multiresolution analysis, they build a frame wavelet that may be obtained from only a generalized multiresolution analysis. The purpose of the present article is to extend and clarify this kind of result to filters defined in higher dimensional and non MRA contexts. That is, we suppose that A is an expansive, integral, $d \times d$ matrix, and we investigate frame wavelets constructed from filter systems associated to generalized multiresolution analyses in $L^2(\mathbb{R}^d)$ relative to dilation by A and translation by lattice points in $\mathbb{Z}^d$.

The theory of generalized conjugate mirror filters relative to a generalized multiresolution analysis was first developed in Refs. 35 and 36. In Sec. II we briefly review that subject, and in particular we recall the analogs to Eqs. (1.1) and (1.2), i.e., generalized filter and orthogonality

equations. These generalized equations are considerably different from the original ones, because the right-hand side now involves an integer-valued multiplicity function on the d-dimensional torus $\mathbb{T}^d \equiv [-\frac{1}{2}, \frac{1}{2})^d$. In general, the low-pass filter becomes a square matrix $H=[h_{i,j}]$ of periodic functions, and the high-pass filter becomes a not necessarily square matrix $G=[g_{k,j}]$ of periodic functions. Because the filters in this generalized context are matrices of periodic functions, we refer to them as redundant systems of filters.

By generalizing the arguments in Ref. 34, we are able here to build wavelets from generalized filters more simply and with fewer restrictions than in Ref. 36. In Sec. III, under smoothness and low-pass conditions analogous to those in Ref. 34, we prove that the infinite matrix product

$$P = \prod_{j=1}^{\infty} \frac{1}{\sqrt{|\det(A)|}} H(A^{t^{-j}}(x))$$

converges pointwise, and the first column Φ of P is the Fourier transform of a set $\phi_1, \phi_2, \ldots$ of L^2 functions that together generate a generalized multiresolution analysis. We then prove that the functions $\{\psi_k\}$ given by

$$\widehat{\psi_k}(x) = \frac{1}{\sqrt{|\det(A)|}} \sum_j g_{k,j}(A^{t^{-1}}(x)) \widehat{\phi_j}(A^{t^{-1}}(x))$$

form a Parseval wavelet frame for $L^2(\mathbb{R}^d)$.

In engineering, the various classes of multiresolution analyses are motivated by filters from signal and image processing. Although these are practical concerns, our present aim is theoretical. In most of the engineering MRA constructions, the multiplicity function is equal to 1 on the entire fundamental domain $[-1/2, 1/2)$, so this only produces classical MRA quadrature-mirror filters. One must choose the multiplicity function to be mixed, i.e., equal to the characteristic function of delicately selected configurations of subsets of $[-1/2, 1/2)$, to get genuinely generalized filters, i.e., GMRA filters. If the multiplicity function is not constant, the filters can never all be continuous in the frequency domain, which can be a problem for engineers. The reason that all the filters for a GMRA cannot be continuous is that they must satisfy the filter equations (2.4) and (2.5), both of which involve noncontinuous characteristic functions for nonconstant multiplicity functions. This particular feature of our theory becomes evident in our example in Sec. III, Example 3.6. Yet, this example is surprising in two ways. First, it is related to a nonclassical MRA wavelet, the Journé wavelet. Second, we construct two low-pass filters which have discontinuities in the frequency domain, but the resulting scaling functions are C^∞ in the frequency domain! This prompts the following question: can the scaling functions and wavelets associated to GMRAs be constructed to have nice properties in both the time and the frequency domains? From the viewpoint of engineering, this is an important question, and it is addressed in a sequel paper[37] in much more detail. We have established this in the affirmative in Ref. 37, where we construct a frame wavelet that is C^r in the time domain and C^∞ in the frequency domain. More importantly, it would be interesting to know whether or not scaling functions and frame wavelets that have nice properties in both the time and frequency domains can be constructed for every choice of a multiplicity function.

In Ref. 34 the set of functions $h, g_1, \ldots, g_{N-1}$ is called an *M system*. It is shown in Ref. 34 that there is a group that acts freely and transitively on the set of M systems, thus suggesting a natural structure on these systems and therefore on the corresponding frame wavelet systems. In Sec. IV of this article, we describe an analogous action on the generalized filter systems we have introduced. This time, it is a group bundle that acts freely and transitively.

II. GENERALIZED FILTERS

We collect here the relevant definitions concerning wavelets and multiresolution analyses in $L^2(\mathbb{R}^d)$, relative to translation by lattice points and dilation by an expansive integer matrix A; i.e., a matrix each of whose eigenvalues has modulus greater than 1.

Recall that a *frame* in $L^2(\mathbb{R}^d)$ is a sequence $\{f_n\}$ for which there exist positive numbers a and b such that

$$a\|f\|_2^2 \leqslant \sum_n |\langle f|f_n\rangle|^2 \leqslant b\|f\|_2^2$$

for every $f \in L^2(\mathbb{R}^d)$. It is called a *Parseval frame* or a *normalized tight frame* if $a=b=1$ in the inequalities above. That is, $\{f_n\}$ is a Parseval frame if $\|f\|_2^2=\Sigma_n|\langle f|f_n\rangle|^2$ for every $f \in L^2(\mathbb{R}^d)$.

For each $z \in \mathbb{Z}^d$, we write τ_z for the unitary *translation operator* on $L^2(\mathbb{R}^d)$ given by $[\tau_z(f)](t)=f(t+z)$. Fix an expansive, $d\times d$, integer matrix A and let $B=A^t$ and $N=|\det(A)|$. We write δ for the unitary *dilation operator* given by $[\delta(f)](t)=\sqrt{N}f(A(t))$. For each element $\omega \in \mathbb{T}^d$, there exist exactly N distinct points $\zeta \in \mathbb{T}^d$ such that $\alpha(\zeta)=\omega$, where α denotes the endomorphism on $\mathbb{T}^d$ induced by the action of B on $\mathbb{R}^d$. We denote these points ζ in a Borel manner as $\omega_0, \omega_1, \ldots, \omega_{N-1}$. Note also that, because A is an expansive matrix, the endomorphism α is ergodic.

Definition 2.1: A MRA in $L^2(\mathbb{R}^d)$, relative to the group $\{\tau_z\}$ of translation operators and the dilation operator δ, is a sequence $\{V_j\}_{-\infty}^{\infty}$ of closed subspaces of $L^2(\mathbb{R}^d)$ for which:

(1) $V_j \subseteq V_{j+1}$;
(2) $V_{j+1}=\delta(V_j)$;
(3) $\cup V_j$ is dense in $L^2(\mathbb{R}^d)$, and $\cap V_j=\{0\}$; and
(4) There exists an element $\phi \in V_0$ whose translates $\{\tau_z(\phi)\}$ form an orthonormal basis for V_0. Such an element ϕ is called a *scaling function* for the multiresolution analysis.

A GMRA is a sequence $\{V_j\}$ of closed subspaces of $L^2(\mathbb{R}^d)$ that satisfies Conditions (1), (2), and (3) mentioned above, but satisfies the weaker fourth condition

(4′) V_0 is invariant under all the translation operators τ_z.

In both cases, the subspace V_0 is called the *core subspace* of the GMRA.

The theory of GMRAs is developed in Refs. 9–11 (see also Ref. 20). In particular, it is shown there that by Stone's theorem for unitary representations of the group $\mathbb{Z}^d$, or more generally by spectral multiplicity theory for a set of commuting unitary operators, the invariance under translation of the core subspace V_0 implies the existence of a *multiplicity function* $m:\mathbb{T}^d \mapsto \{0,1,2,\ldots,\infty\}$. The multiplicity function m counts the number of times each exponential function is represented as a subrepresentation of translation by $\mathbb{Z}^d$ on V_0. We will assume in this paper that m is bounded, with maximum value c. We let $S_i=\{\omega \in \mathbb{T}^d: m(\omega) \geqslant i\}$, and recall from Ref. 10 that there exist *generalized scaling functions* $\{\phi_i\}_{1\leqslant i\leqslant c}$ such that the collection $\{\tau_z(\phi_i)\}$ for $z \in \mathbb{Z}^d$ and $1 \leqslant i \leqslant c$ forms a Parseval frame for V_0, and such that $\Sigma_{z\in\mathbb{Z}^d}|\hat{\phi}_i(\omega+z)|^2=\chi_{S_i}(\omega)$. Note that these results translate to the classical conditions in an MRA, which is the special case of a GMRA in which the multiplicity function is identically 1.

If V_0 is the core subspace of a generalized multiresolution analysis $\{V_j\}$, then the subspace $W_0=V_1 \cap V_0^{\perp}$ of a GMRA $\{V_j\}$ also is invariant under all the translation operators τ_z. Hence, again by Stone's theorem, there exists a *complementary multiplicity function* $\tilde{m}:\mathbb{T}^d \mapsto \{0,1,2,\ldots,\infty\}$ that characterizes the representation of $\mathbb{Z}^d$ on W_0. As a direct result of the fact that $V_1=V_0 \oplus W_0$, the multiplicity functions m and $\tilde{m}$ must satisfy the following *consistency equation* (see Ref. 9):

$$m(\omega)+\tilde{m}(\omega)=\sum_{l=0}^{N-1} m(\omega_l). \tag{2.1}$$

By the consistency equation, the assumption that m is bounded implies that $\tilde{m}$ is bounded as well. We write $\tilde{c}$ for the maximum value of $\tilde{m}$, and $\tilde{S}_k$ for $\{\omega \in \mathbb{T}^d: \tilde{m}(\omega) \geqslant k\}$.

Generalized multiresolution analyses are useful because of their relationship to wavelets. In particular, in Ref. 9 it is shown that every orthonormal multiwavelet is associated to a GMRA with $\tilde{m}$=the number of wavelets. We recall the relevant definitions here:

Definition 2.2: An *orthonormal wavelet*, or more generally an *orthonormal multiwavelet*, in

$L^2(\mathbb{R}^d)$, relative to the group $\{\tau_z\}$ of translation operators and the dilation operator δ, is a finite set $\psi_1,\ldots,\psi_m$ of functions in $L^2(\mathbb{R}^d)$ for which the collection $\{\psi_{j,z,k}\}\equiv\{\delta^j(\tau_z(\psi_k))\}$ forms an orthonormal basis for $L^2(\mathbb{R}^d)$. A set of functions $\psi_1,\ldots,\psi_m$ forms a *frame multiwavelet* if the collection $\{\psi_{j,z,k}\}$ forms a frame for $L^2(\mathbb{R}^d)$, and the set is called a *Parseval frame multiwavelet* if the collection $\{\psi_{j,z,k}\}$ forms a Parseval frame for $L^2(\mathbb{R}^d)$.

We now are ready to develop the definition of generalized filters. The classical filter equation [Eq. (1.1)], which is the basis for the Mallat–Meyer construction of scaling functions and wavelets, emerges naturally from the study of classical multiresolution analyses. For, if ϕ is a function, for which the closure of the linear span of the translates of ϕ is invariant under the dilation $f(x)\to f(x/2)$, e.g., if ϕ is a scaling function for a MRA, then it follows from elementary Fourier analysis that $\hat{\phi}$ satisfies the following classical *refinement equation*:

$$\sqrt{2}\hat{\phi}(2x)=h(x)\hat{\phi}(x), \tag{2.2}$$

where h is a periodic function that satisfies the filter equation (1.1). As described in Sec. I, the Mallat–Meyer construction[2,3] reverses this procedure, by beginning with a sufficiently well behaved function h that satisfies filter equation (1.1), and producing a corresponding scaling function and multiresolution analysis by iterating Eq. (2.2) to get an infinite product expression for $\hat{\phi}$.

In an analogous way, the theory of generalized filters emerges naturally from the study of generalized multiresolution analyses (see Refs. 35 and 36). Because $V_{-1}=\delta^{-1}(V_0)$ is contained in V_0, it follows that, for each i, there exists a sequence $\{h_{i,j}\}$ of functions on the torus $\mathbb{T}^d$ such that

$$\sqrt{N}\hat{\phi}_i(B(x))=\sum_j h_{i,j}(x)\widehat{\phi_j}(x). \tag{2.3}$$

As is shown in Ref. 36, these generalized filters satisfy the *generalized filter equation*:

$$\sum_j\sum_{l=0}^{N-1} h_{i,j}(\omega_l)\overline{h_{i',j}(\omega_l)}=\delta_{i,i'}N\chi_{S_i}(\omega), \tag{2.4}$$

and also have $h_{i,j}$ supported on S_j. In analogy with the classical case, we make the following definition.

Definition 2.3: A *generalized low-pass filter* relative to a GMRA with multiplicity functions m and $\tilde{m}$ is a matrix of functions $H=[h_{i,j}]$ on $\mathbb{T}^d$ (or equivalently $\mathbb{Z}^d$ periodic functions on $\mathbb{R}^d$), with $h_{i,j}$ supported on S_j (or the periodization of S_j), that satisfy both the generalized filter equation (2.4) and the generalized low-pass condition $h_{i,j}(0)=\delta_{i,1}\delta_{j,1}\sqrt{N}$.

Just as in the classical case, we can sometimes reverse the procedure of producing filters from wavelets. In particular, generalized low-pass filters give rise to generalized high-pass filters. The relevant result is contained in the following theorem, again from Ref. 36.

Theorem 2.4: *Let $H=[h_{i,j}]$ be a generalized low-pass filter relative to a GMRA with multiplicity functions m and $\tilde{m}$. Then there exists a matrix $G=[g_{k,j}]$ of functions on $\mathbb{T}^d$ satisfying*

$$\sum_j\sum_{l=0}^{N-1} g_{k,j}(\omega_l)\overline{g_{k',j}(\omega_l)}=\delta_{k,k'}N\chi_{\tilde{S}_k}(\omega), \tag{2.5}$$

and

$$\sum_j\sum_{l=0}^{N-1} h_{i,j}(\omega_l)\overline{g_{k,j}(\omega_l)}=0 \tag{2.6}$$

for all i and k. The matrix of functions $G=[g_{k,j}]$ is called a generalized high-pass filter.

Under conditions which allow the production of generalized scaling functions from generalized low-pass filters, these high-pass filters can be used to build frame multiwavelets. Some narrow conditions that allow this are described in Ref. 36. In Sec. III, we show that more general conditions allow the same construction.

There is one final property of a generalized low-pass and high-pass filter that we will need in Sec. III, which was not presented in Ref. 36.

Theorem 2.5: *Let H and G be a generalized low-pass and high-pass filter relative to multiplicity and complementary multiplicity functions m and $\tilde{m}$. Assume that the maximum value of m is c and the maximum value of $\tilde{m}$ is $\tilde{c}$. Then*

$$\sum_{i=1}^{c} h_{i,j}(\omega_l)\overline{h_{i,j'}(\omega_{l'})} + \sum_{k=1}^{\tilde{c}} g_{k,j}(\omega_l)\overline{g_{k,j'}(\omega_{l'})} = \delta_{j,j'}\delta_{l,l'}N\chi_{S_j}(\omega_l). \tag{2.7}$$

Proof: For each $\omega \in \mathbb{T}^d$, we define a matrix $K(\omega)$ having $c+\tilde{c}$ rows and $c\times N$ columns as follows: We index the $c\times N$ columns of $K(\omega)$ by pairs (j,l), where $1\leqslant j\leqslant c$ and $0\leqslant l\leqslant N-1$. Then the entry $k_{i,(j,l)}(\omega)$ is defined to be $(1/\sqrt{N})h_{i,j}(\omega_l)$ if $1\leqslant i\leqslant c$, and $k_{i,(j,l)}(\omega) = (1/\sqrt{N})g_{i-c,j}(\omega_l)$ if $c<i\leqslant\tilde{c}$. We see directly from Eq. (2.4) that, for $1\leqslant i\leqslant c$, the ith row of the matrix $K(\omega)$ contains a nonzero entry if and only if $\omega\in S_i$, i.e., if and only if $i\leqslant m(\omega)$. And, from Eq. (2.5), for $c<i\leqslant c+\tilde{c}$, the ith row of $K(\omega)$ contains a nonzero entry if and only if $\omega\in\tilde{S}_{(i-c)}$, i.e., if and only if $i-c\leqslant\tilde{m}(\omega)$. Therefore, there are exactly $m(\omega)+\tilde{m}(\omega)$ nonzero rows in $K(\omega)$.

Next, we note that the column indexed by the pair (j,l) has a nonzero entry only when some $h_{i,j}(\omega_l)$ or $g_{i,j}(\omega_l)$ is nonzero. That is, the (j,l)th column has a nonzero entry only when $\omega_l\in S_j$, i.e., only when $j\leqslant m(\omega_l)$. So, the maximum number of columns having a nonzero entry in them is equal to $\Sigma_{l=0}^{N-1}m(\omega_l)$, which, by the consistency equation (2.1), equals $m(\omega)+\tilde{m}(\omega)$, and this is exactly the number of rows of $K(\omega)$ that have a nonzero entry.

Therefore, the set of nonzero entries in the matrix $K(\omega)$ are contained in a square submatrix $L(\omega)$ of size $(m(\omega)+\tilde{m}(\omega))\times(m(\omega)+\tilde{m}(\omega))$.

Finally, from Eqs. (2.4)–(2.6), we see that the rows of this square matrix $L(\omega)$ are orthonormal. Hence, the columns of $L(\omega)$ are also orthonormal, and this implies the orthogonality equations of the theorem. □

III. CONSTRUCTION OF FRAME WAVELETS FROM GENERALIZED FILTERS

We are now ready to use the generalized filters from Sec. II to extend the construction procedure for frame wavelets described in Ref. 34. Just as in the classical case, the first step of the construction is to take an infinite product of dilations of the low-pass filters.

Proposition 3.1: Let $H=[h_{i,j}]$ be a generalized low-pass filter as in Definition 2.3 Assume that the components of H are Lipschitz continuous functions in a neighborhood of 0.

(1) *The infinite product*

$$P = \prod_{q=1}^{\infty} \frac{1}{\sqrt{N}} H(B^{-q}(x))$$

converges almost everywhere on $\mathbb{R}^d$, and the entries $P_{i,j}$ of P are square-integrable functions on $\mathbb{R}^d$, with $P_{i,j}=0$ for $j>1$.

(2) *For $1\leqslant i\leqslant c$, let ϕ_i be the inverse Fourier transform of the function $P_{i,1}$. Then the $\hat{\phi}_i$'s are continuous at 0, satisfy $\hat{\phi}_{i,1}(0)=\delta_{i,1}$, and also satisfy the following generalized refinement equation.*

$$\hat{\phi}_i(B(x)) = \frac{1}{\sqrt{N}}\sum_{j=1}^{c} h_{i,j}(x)\hat{\phi}_j(x).$$

Proof: Throughout the proof, we will use the following result from linear algebra. If C is a

$c \times c$ matrix all of whose eigenvalues have modulus less than 1, then $\Sigma_{k=0}^{\infty}\|C^k(x)\|$ converges, for every $x \in \mathbb{R}^c$. This result follows by using the Jordan canonical form for the matrix C to show that $\Sigma\|C^k(x)\|$ is dominated by a convergent geometric series.

We prove the convergence of the infinite product first. If β is the Lipschitz constant, note that by the low-pass condition we have $\|h_{i,j}(x)\| \leq \beta\|x\|$ for $\{i,j\} \neq \{1,1\}$, and $\|h_{1,1}(x) - \sqrt{N}\| \leq \beta\|x\|$, both for $\|x\|$ sufficiently small. Write P^k for the partial product $\Pi_{q=1}^{k}\left(1/\sqrt{N}\right)H(B^{-q}(x))$, where as before $N=|\det(A)|$. We first show by induction that for each fixed x, there is a bound K such that $|P_{i,j}^k(x)| \leq K$ for all $1 \leq i,j \leq c$, and $k \geq 1$. To see this, write

$$|P_{i,j}^k(x)| = \sum_{l=1}^{c} P_{i,l}^{k-1}(x)\frac{1}{\sqrt{N}}h_{l,j}(B^{-k}(x)) \leq |P_{i,1}^{k-1}(x)| + \left|\sum_{l=2}^{c} P_{i,l}^{k-1}(x)\right|\frac{\beta}{\sqrt{N}}\|B^{-k}(x)\|,$$

for k sufficiently large (where in the first term we use the fact that the orthogonality conditions give $|h_{i,1}| \leq \sqrt{N}$). Using induction on k, and the linear algebra result mentioned above, we get the bound we seek.

Now, using this bound, we see that for fixed x and for $j \geq 2$, $|P_{i,j}^k(x)| \leq |\Sigma_{l=1}^{c} P_{i,l}^{k-1}(x)|\left(\beta/\sqrt{N}\right)\|B^{-k}(x)\| \to 0$ as $k \to \infty$. For the remaining case of $j=1$, we have

$$\begin{aligned}
|P_{i,1}^k(x) - P_{i,1}^{k-1}(x)| &= \left|\sum_{l=1}^{c} P_{i,l}^{k-1}(x)\frac{1}{\sqrt{N}}h_{l,1}(B^{-k}x) - P_{i,1}^{k-1}(x)\right| \\
&= \left|P_{i,1}^{k-1}(x)\left(\frac{1}{\sqrt{N}}h_{1,1}(B^{-k}x) - 1\right) + \sum_{l=2}^{c} P_{i,l}^{k-1}(x)\left(\frac{1}{\sqrt{N}}h_{l,1}(B^{-k}x)\right)\right| \\
&\leq \sum_{l=1}^{c} |P_{i,l}^{k-1}(x)|\frac{\beta}{\sqrt{N}}\|B^{-k}x\| < \frac{\beta}{\sqrt{N}}cK\|B^{-k}x\|.
\end{aligned}$$

We then see that $\{P_{i,1}^k(x)\}$ is Cauchy and thus convergent, again by using the linear algebra result mentioned at the beginning of the proof.

To complete the proof of (1), it remains to show that the limiting functions $P_{i,1}$ are in $L^2(\mathbb{R}^d)$. To do this, we will first use induction to prove that

$$\sum_{j=1}^{c}\int_{B^k(Q)} |P_{i,j}^k(x)|^2 \mathrm{d}x \leq 1.$$

We note that because the $h_{k,j}$ are periodic modulo $\mathbb{Z}^d$, the $P_{i,j}^k$ are periodic modulo $B^k(\mathbb{Z}^d)$, and thus the domain of integration can be replaced by any set that is congruent to $B^k(Q)$ modulo $B^k(\mathbb{Z}^d)$. To select the replacement set, we first choose coset representatives $\omega_1=0, \omega_2, \cdots, \omega_N$ of $\mathbb{Z}^d/B(\mathbb{Z}^d)$. Since

$$\sqcup_{n=1}^{N}(Q+\omega_n) \equiv B(Q) \quad \text{modulo } B(\mathbb{Z}^d),$$

we can take as our domain of integration the set $B^{k-1}(\sqcup_{n=1}^{N}(Q+\omega_n))$ Using this, we have

$$\begin{aligned}
\sum_{j=1}^{c}\int_{B^k(Q)} |P_{i,j}^k(x)|^2 \mathrm{d}x &= \sum_{j=1}^{c}\int_{B^{k-1}\sqcup_{n=1}^{N}(Q+\omega_n)} \left(\sum_{l=1}^{c} P_{i,l}^{k-1}(x)\frac{1}{\sqrt{N}}h_{l,j}(B^{-k}x)\right)\overline{\left(\sum_{m=1}^{c} P_{i,m}^{k-1}(x)\frac{1}{\sqrt{N}}h_{m,j}(B^{-l}x)\right)}\mathrm{d}x \\
&= N^{k-1}\int_{\sqcup_{n=1}^{N}(Q+\omega_n)} \sum_{j,l,m} P_{i,l}^{k-1}(B^{k-1}x)\overline{P_{i,m}^{k-1}(B^{k-1}x)}\frac{1}{\sqrt{N}}h_{l,j}(B^{-1}x)\overline{\frac{1}{\sqrt{N}}h_{m,j}(B^{-1}x)}\mathrm{d}x \\
&= N^{k-1}\int_{Q} \sum_{l,m} P_{i,l}^{k-1}(B^{k-1}x)\overline{P_{i,m}^{k-1}(B^{k-1}x)}\sum_{j=1}^{c}\sum_{n=1}^{N}\frac{1}{\sqrt{N}}h_{l,j}(B^{-1}x - B^{-1}\omega_n)\overline{\frac{1}{\sqrt{N}}h_{m,j}(B^{-1}x - B^{-1}\omega_n)}\mathrm{d}x.
\end{aligned}$$

We note now that modulo $\mathbb{Z}^d$, the set $\{B^{-1}\omega_1, B^{-1}\omega_2, \ldots, B^{-1}\omega_N\}$ parameterize the distinct N elements of $Q=\left[-\frac{1}{2},\frac{1}{2}\right)^d$ that map to (0, 0, …, 0) under the endomorphism $\alpha:\mathbb{T}^d\to\mathbb{T}^d$, where here we are identifying $\mathbb{T}^d$ and $\left[-\frac{1}{2},\frac{1}{2}\right)^d$. Using the orthogonality relations satisfied by the $h_{l,j}$, the last equation simplifies to

$$N^{k-1}\int_Q \sum_{l=1}^{c} P_{i,l}^{k-1}(B^{k-1}x)\overline{P_{i,l}^{k-1}(B^{k-1}x)}\chi_{S_l}(x)\mathrm{d}x \leqslant \sum_{l=1}^{c}\int_{B^{k-1}(Q)} |P_{i,l}^{k-1}(x)|^2\mathrm{d}x \leqslant 1.$$

It follows that

$$\sum_{j=1}^{c}\int_{B^k(Q)} |P_{i,j}^{k}(x)|^2\mathrm{d}x \leqslant 1$$

for all $k\in\mathbb{N}$, and since $\cup_{k=0}^{\infty}B^k(Q)=\mathbb{R}^d$, by Fatou's Lemma we have

$$\sum_{j=1}^{c}\int_{\mathbb{R}^d} |P_{i,j}(x)|^2\mathrm{d}x \leqslant 1.$$

In particular we get $P_{i,j}\in L^2(\mathbb{R}^d)$, which completes the proof of Part (1).

The refinement equation in Part (2) is immediate. It also follows from the proof above that the infinite product P converges uniformly on neighborhoods of 0, and thus that the $\hat{\phi}_i$'s are continuous at 0. Finally, $\hat{\phi}_i(0)=\delta_{i,1}$ is a consequence of the low-pass condition. □

We will now use the results of Proposition 3.1 to build a frame wavelet. We begin by generalizing the computational ideas in Ref. 34. Define two Hilbert spaces $\mathcal{H}$ and $\widetilde{\mathcal{H}}$ by $\mathcal{H}=\oplus_{j=1}^{c}L^2(S_i)$ and $\widetilde{\mathcal{H}}=\oplus_{k=1}^{\tilde{c}}L^2(\widetilde{S}_k)$; and two operators $S_H:\mathcal{H}\to\mathcal{H}$ and $S_G:\widetilde{\mathcal{H}}\to\mathcal{H}$ by

$$[S_H(f)](\omega)=H^t(\omega)f(\alpha(\omega))$$

and

$$[S_G(\widetilde{f})](\omega)=G^t(\omega)\widetilde{f}(\alpha(\omega)),$$

where $f\equiv\oplus f_j\in\mathcal{H}$, H^t and G^t denote the transposes of the matrix functions H and G, respectively, and as α denotes the map on the torus $\mathbb{T}^d$ induced by the action of the transpose B of A acting on $\mathbb{R}^d$. Note that $f_j(\alpha(\omega))$ and $\widetilde{f}_k(\alpha(\omega))$ are necessarily only defined when $\alpha(\omega)$ belongs to S_j for the first case and $\widetilde{S}_k$ for the second. We define these functions to be 0 outside of these domains. We record here the formulas for the adjoints of the two operators:

$$[S_H^*(f)](\omega)=\frac{1}{N}\sum_{l=0}^{N-1}\bar{H}(\omega_l)f(\omega_l),$$

$$[S_G^*(f)](\omega)=\frac{1}{N}\sum_{l=0}^{N-1}\bar{G}(\omega_l)f(\omega_l). \tag{3.1}$$

It will also be convenient to have explicit formulas for the powers of both S_H and S_H^*:

$$[S_H^n(f)](\omega)=\prod_{k=0}^{n-1}H^t(\alpha^k(\omega))f(\alpha^n(\omega)), \tag{3.2}$$

$$[S_H^{*n}(f)](\omega) = \frac{1}{N^n} \sum_{l=0}^{N^n-1} \prod_{k=n-1}^{0} \bar{H}(\alpha^k(\omega_{l,n}))f(\omega_{l,n}),$$

where the $\omega_{l,n}$'s are the N^n points $\zeta \in \mathbb{T}^d$ for which $\omega = \alpha^n(\zeta)$.

We also include here an estimate involving these operators that we will need later,

$$\sum_{i=1}^{c}\sum_{j=1}^{c}\sum_{l=0}^{N^n-1} \left| \left[\prod_{k=0}^{n-1} H^t(\alpha^k(\omega_{l,n})) \right]_{i,j} \right|^2 \leqslant cN^n, \tag{3.3}$$

which we prove using induction. The case $n=1$,

$$\sum_{i=1}^{c}\sum_{j=1}^{c}\sum_{l=0}^{N-1} |h_{j,i}(\omega_l)|^2 \leqslant cN,$$

follows from Eq. (2.4) together with the fact that $\Sigma_{j=1}^{c}\chi_{S_j}(\omega) = m(\omega) \leqslant c$. For the induction step, note that the $\omega_{l,n+1}$ can be labeled in such a way that $\alpha^n(\omega_{sN+q,n+1}) = \omega_q$, so that $\omega_{sN+q,n+1} = (\omega_q)_{s,N}$. Thus, writing $l = sN+q$ and using the Cauchy–Schwarz inequality, we obtain:

$$\begin{aligned}
\sum_{i=1}^{c}\sum_{j=1}^{c}\sum_{l=0}^{N^{n+1}-1} \left| \left[\prod_{k=0}^{n} H^t(\alpha^k(\omega_{l,n+1})) \right]_{i,j} \right|^2 &= \sum_{i=1}^{c}\sum_{j=1}^{c}\sum_{l=0}^{N^{n+1}-1} \left| \sum_{r=1}^{c} \left[\prod_{k=0}^{n-1} H^t(\alpha^k(\omega_{l,n+1})) \right]_{i,r} \left[H^t(\omega_q) \right]_{r,j} \right|^2 \\
&\leqslant \sum_{i=1}^{c}\sum_{j=1}^{c}\sum_{s=0}^{N^n-1}\sum_{q=0}^{N-1} \left(\sum_{r=1}^{c} \left| \prod_{k=0}^{n-1} h_{r,i}(\alpha^k(\omega_{sN+q,n+1})) \right|^2 \right) \\
&\quad \times \left(\sum_{r'=1}^{c} |h_{j,r'}(\omega_q)|^2 \right) \leqslant cN^nN
\end{aligned}$$

Lemma 3.2: The operators S_H and S_G satisfy the following relations:

(1) $S_H^* S_H = I$, *the identity operator on* $\mathcal{H}$;
(2) $S_G^* S_G = \tilde{I}$, *the identity operator on* $\tilde{\mathcal{H}}$;
(3) $S_H^* S_G = 0$ *and* $S_G^* S_H = \tilde{0}$, *the* 0 *operators on the appropriate Hilbert spaces*; and
(4) $S_H S_H^* + S_G S_G^* = I$, *the identity operator on* $\mathcal{H}$.

Proof: These are direct consequences of the orthogonality relations satisfied by generalized filter systems relative to m and $\tilde{m}$. For example, to prove relation (1), in Lemma 3.2 for $f \in \mathcal{H}$, we write

$$S_H^* S_H f(\omega) = \frac{1}{N}\sum_{l=0}^{N-1} \overline{H(\omega_l} S_H f(\omega_l) = \frac{1}{N}\sum_{l=0}^{N-1} \overline{H(\omega_l)} H^t(\omega_l) f(\omega) = f(\omega),$$

where the last equality follows from (2.4). The other parts of the lemma follow similarly from (2.5), (2.6), and (2.7), respectively. □

We note that both S_H and S_G are partial isometries, and that the relations in the lemma are similar to the famous relations defining the Cuntz algebra $\mathcal{O}_2$. We now use these operators to decompose the Hilbert space $\mathcal{H}$ in a convenient way.

Lemma 3.3: Let R_0 denote the range of S_G, and let $R_n = S_H^n(R_0)$. Then $\mathcal{H} = \oplus_{n=0}^{\infty} R_n$. Moreover, if z is any element in $\mathbb{Z}^d$, and $\tilde{f}_{k,z}$ is the element of $\tilde{\mathcal{H}}$ whose kth component is the exponential function $e^{2\pi i\langle\omega|z\rangle}$ and whose other components are 0, then the collection $\{S_H^n(S_G(\tilde{f}_{k,z}))\}$, for k running from 1 to $\tilde{c}$ and each z running through $\mathbb{Z}^d$, forms a Parseval frame for the subspace R_n. Consequently, the collection $\{S_H^n(S_G(\tilde{f}_{k,z}))\}$, $1 \leqslant k \leqslant \tilde{c}$, $z \in \mathbb{Z}^d$, and $0 \leqslant n < \infty$, forms a Parseval frame for $\mathcal{H}$.

Proof: That the subspaces $\{R_n\}$ are orthogonal follows directly from the relations in Lemma 3.2. That the elements $\{S_H^n(S_g(\tilde{f}_{k,z}))\}$ form a Parseval frame for R_n follows from the fact that S_H and S_G are partial isometries, together with the fact that the elements $\{\tilde{f}_{k,z}\}$, as k runs from 1 to $\tilde{c}$ and z runs over $\mathbb{Z}^d$, form a Parseval frame for $\tilde{\mathcal{H}}$.

Write R_∞ for the orthogonal complement in $\mathcal{H}$ of the direct sum $\oplus R_n$. We must show that $R_\infty=\{0\}$. Note that R_∞ is invariant under both S_H and S_H^*, and therefore that the restriction of both these operators to R_∞ are unitary operators.

By way of contradiction, suppose that f_0 is a unit vector in R_∞. For each natural number n, write $f_n=S_H^{*n}(f_0)$. Note that $f_{n+m}=S_H^{*m}(f_n)$. We make two observations about f_n. First of all, for almost all $\omega\in\mathbb{T}^d$, we have

$$\begin{aligned}\|f_n(\omega)\|^2=\|S_H^{*n}(f_0(\omega))\|^2&=\frac{1}{N^{2n}}\sum_{i=1}^{c}\left|\sum_{p=1}^{c}\sum_{l=0}^{N^n-1}\left[\prod_{k=n-1}^{0}\bar{H}(\alpha^k(\omega_{l,n}))\right]_{i,p}[f_0]_p(\omega_{l,n})\right|^2\\&\leqslant\frac{1}{N^n}\sum_{i=1}^{c}\sum_{p=1}^{c}\sum_{l=0}^{N^n-1}\left|\left[\prod_{k=n-1}^{0}\bar{H}(\alpha^k(\omega_{l,n}))\right]_{i,p}\right|^2\times\frac{1}{N^m}\sum_{p'=1}^{c}\sum_{l'=0}^{N^n-1}|[f_0]_{p'}(\omega_{l',n})|^2\\&\leqslant c\times\frac{1}{N^m}\sum_{p'=1}^{c}\sum_{l'=0}^{N^n-1}|[f_0]_{p'}(\omega_{l',n})|^2,\end{aligned}$$

where the last inequality follows from the transpose of Eq. (3.3). By the pointwise ergodic theorem this then implies that

$$\limsup\|f_n(\omega)\|^2\leqslant c\int_0^1\|f_0(\omega)\|^2\mathrm{d}\omega=c.$$

Second, since S_H is unitary on R_∞, we have

$$\begin{aligned}\frac{1}{N^n}\sum_{l=0}^{N^n-1}\|f_0(\omega_{l,n})\|^2&=\frac{1}{N^n}\sum_{l=0}^{N^n-1}\|S_H^nS_H^{*n}(f_0)(\omega_{l,n})\|^2\\&=\frac{1}{N^n}\sum_{l=0}^{N^n-1}\sum_{i=1}^{c}\left|\sum_{p=1}^{c}\left[\prod_{k=0}^{n-1}H^t(\alpha^k(\omega_{l,n}))\right]_{i,p}[S_H^{*n}(f_0)]_p(\omega)\right|^2\\&\leqslant\frac{1}{N^n}\sum_{i=1}^{c}\sum_{l=0}^{N^n-1}\sum_{p=1}^{c}\left|\left[\prod_{k=0}^{n-1}H^t(\alpha^k(\omega_{l,n}))\right]_{i,p}\right|^2\times\sum_{p'=1}^{c}|[f_n]_{p'}(\omega)|^2\leqslant c\|f_n(\omega)\|^2,\end{aligned}$$

implying (again by the pointwise ergodic theorem) that

$$\liminf\|f_n(\omega)\|^2\geqslant\frac{1}{c}.$$

Consequently, by Egorov's Theorem, for any $\epsilon>0$, there exists an M_0 and a set $E\subseteq\mathbb{T}^d$ such that the measure of the complement of E is less than ϵ, and $1/c-\epsilon<\|f_n(\omega)\|^2<c+\epsilon$ for all $\omega\in E$ and all $n\geqslant M_0$. Before we apply this theorem, we will establish some other estimates needed in our choice of ϵ.

First, we pick an integer $K_0\geqslant 3\log_2 c+9$, so that we then have

$$\sqrt{N}^{K_0+1}>32c^{3/2}. \tag{3.4}$$

(This follows since $N=|\det A|\geqslant 2$.)

Next, we choose a $\delta>0$ so that

$$\delta < \frac{1}{4c^{K_0+3}\sqrt{N}^{K_0}} \tag{3.5}$$

and

$$\sqrt{N}(1-\delta)^{K_0+1} - \delta c^{K_0} > \frac{\sqrt{N}}{2}. \tag{3.6}$$

Note the second condition is possible since the function on the left-hand side approaches $\sqrt{N}$ as δ goes to 0.

From the low-pass condition and the requirement of Lipschitz near 0, we know that for any $\delta>0$ there exists a neighborhood U of $0\in\mathbb{T}^d$ such that $|h_{i,j}(\omega)|<\delta$ for all $\omega\in U$ and all pairs $(i,j)\neq(1,1)$, and $|h_{1,1}(\omega)|>\sqrt{N}(1-\delta)$ for all $\omega\in U$. Let U be the neighborhood corresponding to our choice of δ satisfying (1) and (2). By continuity of α, there further exists a neighborhood $V\subseteq U$ such that for every $\omega\in V$ we have $\alpha^k(\omega)\in U$ for all $0\leqslant k\leqslant 2(K_0+1)$. Hence, if $\widetilde{P}(\omega)$ is the matrix given by $\widetilde{P}(\omega)=\Pi_{k=0}^{5}H^t(\alpha^k(\omega))$, then for $(i,j)\neq(1,1)$, $0\leqslant l\leqslant K_0+1$ and $\omega\in V$,

$$|\widetilde{P}_{i,j}(\alpha^l(\omega))| \leqslant \delta(c\sqrt{N})^{K_0}.$$

(There are c^{K_0} summands, each having K_0 factors, and in each, one factor is bounded by δ, and the other factors [by (2.4)] are bounded by $\sqrt{N}$.) For $(i,j)=(1,1)$, we have

$$(\sqrt{N}(1-\delta))^{K_0+1} - \delta(c\sqrt{N})^{K_0} \leqslant |\widetilde{P}_{1,1}(\alpha^l(\omega))| \leqslant \sqrt{N}^{K_0+1} + \delta(c\sqrt{N})^{K_0}.$$

(Again, there are c^{K_0} summands, each having K_0+1 factors. One of these summands is bounded below by $(\sqrt{N}(1-\delta))^{K_0+1}$ and above by $\sqrt{N}^{K_0+1}$, and the other $(c^{K_0}-1)$ summands are bounded by $\delta\sqrt{N}^{K_0}$.)

Now choose an ϵ smaller than the measure of V, and also smaller than $1/(4c)$, so that we are assured that the corresponding set E will satisfy $\lambda(E\cap V)>0$. In fact, we may even assume that the set of $\omega\in V$ for which $\alpha^k(\omega)\in E\cap U$ for all $0\leqslant k\leqslant 2(K_0+1)$ has positive measure.

Fix an $\omega\in E\cap V$ for which $\alpha^k(\omega)\in E\cap U$ for $0\leqslant k\leqslant 2(K_0+1)$. If M_0 is the natural number corresponding to this choice of ϵ as mentioned above, and $n\geqslant M_0$, we have the following estimates on the components of $f_n(\omega)$. First, for $i\neq 1$ and $0\leqslant l\leqslant K_0+1$,

$$|f_{n_i}(\alpha^l(\omega))| = |[S_H^{K_0+1}(f_{n+K_0+1})]_i(\alpha^l(\omega))| = \left|\sum_{j=1}^{c}\widetilde{P}_{i,j}(\alpha^l(\omega))[f_{n+K_0+1}]_j(\alpha^{l+K_0+1}(\omega))\right| \leqslant \sum_{j=1}^{c}|\widetilde{P}_{i,j}(\alpha^l(\omega))|$$
$$\times |[f_{n+K_0+1}]_j(\alpha^{l+K_0+1}(\omega))| \leqslant c\,\delta(c\sqrt{N})^{K_0}\sqrt{c+\epsilon} \leqslant 2\,\delta c^{K_0+2}\sqrt{N}^{K_0},$$

so that by condition (3.5) on δ,

$$\sum_{i=2}^{c}|[f_n]_i(\alpha^l(\omega))|^2 \leqslant 4c\,\delta^2 c^{2(K_0+2)}N^{K_0} < \frac{1}{2c}.$$

Therefore, because $\omega\in E$, for all $n\geqslant N_0$ we must have, for $0\leqslant l\leqslant K_0+1$,

$$|[f_n]_1(\alpha^l(\omega))|^2 > \frac{1}{2c} - \epsilon > \frac{1}{4c}.$$

On the other hand,

$$[f_n]_1(\omega) = \sum_{j=1}^{c} \widetilde{P}_{1,j}(\omega)[f_{n+K_0+1}]_j(\alpha^{K_0+1}(\omega)) = \widetilde{P}_{1,1}(\omega)[f_{n+K_0+1}]_1(\alpha^{K_0+1}(\omega)) + \sum_{j=2}^{c} \widetilde{P}_{1,j}(\omega) \times [f_{n+K_0+1}]_j(\alpha^{K_0+1}(\omega)),$$

implying that

$$|[f_{n+K_0+1}]_1(\alpha^{K_0+1}(\omega))| \leqslant \frac{|[f_n]_1(\omega)| + \sum_{j=2}^{c} |\widetilde{P}_{1,j}(\omega)| \times |[f_{n+K_0+1}]_j(\alpha^{K_0+1}(\omega))|}{|\widetilde{P}_{1,1}(\omega)|}$$
$$\leqslant \frac{\sqrt{c+\epsilon} + c\delta(c\sqrt{N})^{K_0}\sqrt{c+\epsilon}}{(\sqrt{N}(1-\delta))^{K_0+1} - \delta(c\sqrt{N})^{K_0}} \leqslant \frac{4\sqrt{c+\epsilon}}{\sqrt{N}^{K_0+1}} \leqslant \frac{8\sqrt{c}}{\sqrt{N}^{K_0+1}} \leqslant \frac{1}{4c},$$

where in the third step we use conditions (3.5) and (3.6) to simplify the numerator and denominator, respectively, and in the final step, we use condition (3.4). Hence, the point $\alpha^{K_0+1}(\omega)$ satisfies

$$\frac{1}{4c} \leqslant |[f_{n+K_0+1}]_1(\alpha^{K_0+1}(\omega))|^2 < \frac{1}{4c},$$

which is a contradiction. □

We now state our main result.

Theorem 3.4: *Let ϕ_i be defined from the infinite product of the low-pass filter system H as in Proposition 3.1, and let $G=[g_{k,j}]$ be the corresponding high-pass filter system. Then, if we define a function $\psi_k \in L^2(\mathbb{R}^d)$, for $1 \leqslant k \leqslant \widetilde{c}$, by*

$$\widehat{\psi_k}(x) = \frac{1}{\sqrt{N}} \sum_{j=1}^{c} g_{k,j}(B^{-1}(x))\widehat{\phi_j}(B^{-1}(x)),$$

the collection $\{\psi_k\}$ is a Parseval frame wavelet for $L^2(\mathbb{R}^d)$ relative to dilation by A and translation by lattice points $z \in \mathbb{Z}^d$. Further, if V_0 is the closed linear span of the translates of the ϕ_i's by lattice elements $z \in \mathbb{Z}^d$, then $\{V_j\} \equiv \{\delta^j(V_0)\}_{j\in\mathbb{Z}}$ is a generalized multiresolution analysis for $L^2(\mathbb{R}^d)$.

Proof: We prove first that the $\{\psi_k\}$ form a frame wavelet. For convenience in what follows, we introduce the following notation. For each $1 \leqslant k \leqslant \widetilde{c}$ and each $z \in \mathbb{Z}^d$, write $\gamma^{k,z}$ for the element $S_G(\widetilde{f}_{k,z})$ of $R_0 \subseteq \mathcal{H}$, where as in the previous lemma, $\widetilde{f}_{k,z}$ is the element of $\widetilde{\mathcal{H}}$ whose kth component is the exponential function $e^{2\pi i\langle\omega|z\rangle}$ and whose other components are 0. Note that $\gamma^{k,z} = \oplus_{j=1}^{c} \gamma_j^{k,z}$, where

$$\gamma_j^{k,z}(\omega) = g_{k,j}(\omega)e^{2\pi i\langle\alpha(\omega)|z\rangle}.$$

It then follows from Lemma 3.3 that for each $F \in \mathcal{H}$ we have

$$\|F\|^2 = \sum_{n=0}^{\infty} \sum_{k=1}^{\widetilde{c}} \sum_{z\in\mathbb{Z}^d} |\langle F|S_H^n(\gamma^{k,z})\rangle|^2.$$

For each integer n, each $1 \leqslant k \leqslant \widetilde{c}$, and each $z \in \mathbb{Z}^d$, define the function $\psi_{n,k,z}$ by

$$\psi_{n,k,z}(t) = \sqrt{N^n}\psi_k(A^n(t) + z),$$

and note that the Fourier transform of $\psi_{n,k,z}$ is given by

$$\widehat{\psi_{n,k,z}}(x) = N^{(-n-1)/2} e^{2\pi i \langle B^{-n}(x)|z\rangle} \sum_{j=1}^{c} g_{k,j}(B^{-n-1}(x))\, \widehat{\phi_j}(B^{-n-1}(x)).$$

We wish to prove that the collection $\{\psi_{n,k,z}\}$ is a Parseval frame for $L^2(\mathbb{R}^d)$.

Now, let f be an element of $L^2(\mathbb{R}^d)$ whose Fourier transform $\hat{f}$ has compact support. For a fixed integer $J \geqslant 0$, we have

$$\begin{aligned}
&\sum_{n=-\infty}^{J} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} |\langle f|\psi_{n,k,z}\rangle|^2 \\
&\quad = \sum_{n=-\infty}^{J} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} |\langle \hat{f}|\widehat{\psi_{n,k,z}}\rangle|^2 \\
&\quad = \sum_{n=-\infty}^{J} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} \left| \int_{\mathbb{R}^d} \hat{f}(x) N^{\frac{-n-1}{2}} \overline{\sum_{j=1}^{c} e^{2\pi i \langle B^{-n}(x)|z\rangle} g_{k,j}(B^{-n-1}(x))\, \widehat{\phi_j}(B^{-n-1}(x))}\, \mathrm{d}x \right|^2 \\
&\quad = \sum_{n=-\infty}^{J} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} N^{-n+2J+1} \left| \int_{\mathbb{R}^d} \hat{f}(B^{J+1}(x)) \overline{e^{2\pi i \langle B^{-n+J+1}(x)|z\rangle}} \times \overline{\sum_{j=1}^{c} g_{k,j}(B^{-n+J}(x))\, \widehat{\phi_j}(B^{-n+J}(x))}\, \mathrm{d}x \right|^2 \\
&\quad = \sum_{n=0}^{\infty} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} N^{n+1+J} \left| \int_{\mathbb{R}^d} \hat{f}(B^{J+1}(x)) \overline{e^{2\pi i \langle B^{n+1}(x)|z\rangle} \sum_{j=1}^{c} g_{k,j}(B^{n}(x))\, \widehat{\phi_j}(B^{n}(x))}\, dx \right|^2 \\
&\quad = \sum_{n=0}^{\infty} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} N^{1+J} \left| \int_{\mathbb{R}^d} \hat{f}(B^{J+1}(x) e^{2\pi i \langle B^{n+1}(x)|z\rangle} \overline{\sum_{j=1}^{c} g_{k,j}(B^{n}(x))} \times \overline{\left[\prod_{p=n-1}^{0} H(B^p(x))\Phi(x)\right]_j} dx \right|^2 \\
&\quad = \sum_{n=0}^{\infty} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} N^{1+J} \left| \int_{\mathbb{T}^d} \sum_{j=1}^{c} \sum_{\zeta\in\mathbb{Z}^d} \hat{f}(B^{J+1}(x+\zeta))\, \overline{\widehat{\phi_j}(x+\zeta)} \overline{\prod_{p=0}^{n-1} H^t(B^p(x))}\, \overline{\gamma^{k,z}}(B^n(x)) dx \right|^2 \\
&\quad = \sum_{n=0}^{\infty} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} |\langle F^J|S_H^n(\gamma^{k,z})\rangle_{\mathcal{H}}|^2 = \|F^J\|_{\mathcal{H}}^2,
\end{aligned}$$

where $F^J = \oplus F^J_j$ is the element of $\mathcal{H}$ given by

$$F^J_j(\omega) = \sqrt{N}^{1+J} \sum_{\zeta\in\mathbb{Z}^d} \hat{f}(B^{1+J}(x+\zeta))\, \overline{\widehat{\phi_j}}(x+\zeta).$$

Hence,

$$\begin{aligned}
\sum_{n=-\infty}^{J} \sum_{k=1}^{\tilde{c}} \sum_{z\in\mathbb{Z}^d} |\langle f|\psi_{n,k,z}\rangle|^2 &= \sum_{j=1}^{c} \int_{\mathbb{T}^d} |F^J_j(\omega)|^2 \mathrm{d}\omega \\
&= \sum_{j=1}^{c} \int_{B^{1+J}(\mathbb{T}^d)} \left| \sum_{\zeta\in\mathbb{Z}^d} \hat{f}(x + B^{1+J}(\zeta))\, \overline{\widehat{\phi_j}}(B^{-1-J}(x)+\zeta) \right|^2 \mathrm{d}x \\
&= \sum_{j=1}^{c} \int_{\mathbb{R}^d} \chi_{B^{1+J}(\mathbb{T}^d)}(x) \left| \sum_{\zeta\in\mathbb{Z}^d} \hat{f}(x + B^{1+J}(\zeta))\, \overline{\phi_j}(B^{-1-J}(x)+\zeta) \right|^2 \mathrm{d}x.
\end{aligned}$$

Now, because $\hat{f}$ has compact support, and the matrix B is expansive, there exists a J' such that the support of $\hat{f}$ is contained in $B^{1+J'}(Q)$. There must also exist, by the compactness of $B^{1+J'}(\overline{Q})$, a J_0

such that $B^{1+J}(Q)$ contains $B^{1+J'}(Q)$ for all $J \geqslant J_0$. Now, for $J \geqslant J_0$, the product $\chi_{B^{1+J}(Q)}(x)\hat{f}(x+B^{1+J}(\zeta))$ is nonzero only if $x=B^{1+J}(y)$ for some $y \in Q$, and also $x+B^{1+J}(\zeta) = B^{1+J}(y+\zeta) \in B^{1+J}(Q)$. Consequently, for any $J>J_0$, and any $\zeta \neq 0$, we must have $\chi_{B^{1+J}(Q)}(x)\hat{f}(x+B^{1+J}(\zeta))=0$ for all $x \neq 0$. Hence, for $J>J_0$ we have

$$\sum_{n=-\infty}^{J} \sum_{k=1}^{\tilde{c}} \sum_{z \in \mathbb{Z}^d} |\langle f|\psi_{n,k,z}\rangle|^2 = \sum_{j=1}^{c} \int_{\mathbb{R}^d} |\hat{f}(x)|^2 |\widehat{\phi_j}(B^{-1-J}(x))|^2 \mathrm{d}x,$$

so that, by the Dominated Convergence Theorem, we obtain

$$\sum_{n=-\infty}^{\infty} \sum_{k=1}^{\tilde{c}} \sum_{z \in \mathbb{Z}^d} |\langle f|\psi_{n,k,z}\rangle|^2 = \int_{\mathbb{R}^d} |\hat{f}(x)|^2 \sum_{j=1}^{c} |\widehat{\phi_j}(0)|^2 \mathrm{d}x = \|f\|^2.$$

This demonstrates the Parseval frame property for elements f whose Fourier transforms have compact support. For general $f \in L^2(\mathbb{R}^d)$, the Parseval equality follows from the density of these functions.

It remains to show that $\{V_j\}$ form a GMRA. Properties (2) and (4′) of Definition 2.1 are direct consequences of the definition of the V_j, and property (1) follows immediately from Proposition 3.1 (2). The density required in Property (3) is a consequence of the fact that the $\{\psi_{n,k,z}\}$ form a Parseval frame for $L^2(\mathbb{R}^d)$.

To finish the proof, we now show that $\cap V_j=\{0\}$. Write $\{\phi_i'\}$ for a sequence of elements whose translates form a Parseval frame for V_0 (such a sequence must exist since V_0 is closed under translation), and P_j for the orthogonal projection operator onto the subspace V_j. To prove that $\cap V_j=\{0\}$, it will suffice to show that $\lim_{j\to\infty}\|P_{-j}(f)\|=0$ for each $f \in L^2(\mathbb{R}^d)$. By a standard approximation argument, it will suffice to show this holds on a dense subset of $L^2(\mathbb{R}^d)$. Thus, let f be a Schwartz function for which $\hat{f}$ vanishes in some neighborhood N_f of 0, and write C_f for the (finite) number $\Sigma_k|f*f^*(k)|$. Such f's are dense in $L^2(\mathbb{R}^d)$. The Poisson summation formula holds for such an f, and we will use it in the following form:

$$\frac{1}{N^j}\sum_l |\hat{f}(B^{-j}(\xi+l))|^2 = \sum_k f*f^*(A^j(k))e^{-2\pi i\langle k|\xi\rangle}.$$

Now, for each $\xi \in \mathbb{T}^d$, let $l_j(\xi)$ be the largest number for which $B^{-j}(\xi+l) \in N_f$ for all $\|l\|<l_j(\xi)$. Because A (and thus $B=A^t$) is expansive, we must have that $l_j(\xi)$ tends to infinity for almost every ξ. Finally, we use the fact that the function

$$m(\omega) = \sum_i \chi_{S_i}(\omega) = \sum_i \sum_l |\widehat{\phi_i'}(\omega+l)|^2$$

is integrable on the cube. Hence, we have

$$\begin{aligned}
\|P_{-j}(f)\|^2 &= N^j \sum_i \sum_z \left| \int_{\mathbb{R}^d} \widehat{\phi_i'}(B^j(\xi))\bar{\hat{f}}(\xi)e^{-2\pi i\langle B^j(\xi)|z\rangle}\mathrm{d}\xi \right|^2 \\
&= \frac{1}{N^j}\sum_i \sum_z \left| \int_{\mathbb{R}^d} \widehat{\phi_i'}(\xi)\bar{\hat{f}}(B^{-j}(\xi))e^{-2\pi i\langle z|\xi\rangle}\mathrm{d}\xi \right|^2 = \frac{1}{N^j}\sum_i \int_{\mathbb{T}^d} \left| \sum_l \widehat{\phi_i'}(\xi+l)\bar{\hat{f}}(B^{-j}(\xi+l)) \right|^2 \mathrm{d}\xi \\
&= \frac{1}{N^j}\sum_i \int_{\mathbb{T}^d} \left| \sum_{\|l\|\geqslant l_j(\xi)} \widehat{\phi_i'}(\xi+l)\bar{\hat{f}}(B^{-j}(\xi+l)) \right|^2 \mathrm{d}\xi \leqslant \frac{1}{N^j}\sum_i \int_{\mathbb{T}^d} \sum_{|l|\geqslant l_j(\xi)} |\widehat{\phi_i'}(\xi+l)|^2 \\
&\quad \times \sum_{|l|\geqslant l_j(\xi)} |\hat{f}(B^{-j}(\xi+l))|^2 \mathrm{d}\xi = \int_{\mathbb{T}^d} \left[\sum_i \sum_{|l|\geqslant l_j(\xi)} |\widehat{\phi_i'}(\xi+l)|^2 \right] \left[\frac{1}{N^j}\sum_l |\hat{f}(B^{-j}(\xi+l))|^2 \right] \mathrm{d}\xi
\end{aligned}$$

$$= \int_{\mathbb{T}^d} \left[\sum_i \sum_{|l| \geqslant l_j(\xi)} |\widehat{\phi_i'}(\xi + l)|^2 \right] \left[\sum_k f * f^*(A^j(k)) e^{-2\pi i \langle k|\xi \rangle} \right] \mathrm{d}\xi \leqslant \int_{\mathbb{T}^d} \left[\sum_i \sum_{|l| \geqslant l_j(\xi)} |\widehat{\phi_i'}(\xi + l)|^2 \right]$$

$$\times \left[\times \sum_k |f * f^*(A^j(k))| \right] \mathrm{d}\xi \leqslant C_f \int_{\mathbb{T}^d} \sum_i \sum_{|l| \geqslant l_j(\xi)} |\widehat{\phi_i'}(\xi + l)|^2 \mathrm{d}\xi,$$

which approaches 0 as j goes to infinity by the dominated convergence theorem, the integrand here being bounded by m. □

Theorem 3.4 shows that the functions ψ_k are in the set V_1, so that the Parseval frame wavelet $\{\psi_k\}$ that we have constructed is *obtained from* the GMRA $\{V_j\}$, in the sense defined by Zalik.[38] It is an open question whether the wavelet is *associated with* the GMRA $\{V_j\}$ in the sense that V_j is the closure of the span of $\{\delta'(\tau_z(\psi_k))\}_{l<j}$ (see e.g., Ref. 39). Moreover, the multiplicity function of the GMRA produced by the theorem may not coincide with the multiplicity function used in the construction of the filters, as the first of the examples shows.

Example 3.5: Let $d=1$, $A=2$, and the multiplicity functions m and $\tilde{m}$ both be identically 1, so that we start in the classical setting. For our filters, we take

$$h = \sqrt{2}[\chi_{-1/8,1/8)} + \chi_{\pm[1/4,3/8)}],$$

and

$$g = \sqrt{2}[\chi_{\pm 1/8,1/4)} + \chi_{\pm[3/8,1/2)}].$$

Note that h and g satisfy the definitions of generalized low- and high-pass filters, and are Lipschitz in a neighborhood of 0. The infinite product $P = \prod_{j=1}^{\infty} \frac{1}{\sqrt{2}} h(x/2^j)$ equals $\chi_{[-1/4,1/4)}$. The integer translates of the function ϕ whose Fourier transform is this infinite product P, are not orthonormal, and do not determine the core subspace of any classical multiresolution analysis. On the other hand, as predicted by Theorem 3.4, the standard construction in this case does produce a generalized multiresolution analysis $\{V_j\}$, with multiplicity function $m = \chi_{[-1/4,1/4)}$. As guaranteed by Theorem 3.4, the construction also produces a Parseval frame wavelet ψ, here given by

$$\hat{\psi}(x) = \chi_{[-1/2,-1/4)} + \chi_{[1/4,1/2)}.$$

In this case the function ϕ is easily constructed out of negative dilates of ψ, so the wavelet is necessarily associated with as well as obtained by the GMRA.

We end this section with an another example for dilation by 2 in $L^2(\mathbb{R})$. This one begins with filters for the multiplicity function of the well-known Journé wavelet, whose Fourier transform is the characteristic function of the set

$$\left[-\frac{16}{7}, -2 \right) \cup \left[-\frac{1}{2}, -\frac{2}{7} \right) \cup \left[\frac{2}{7}, \frac{1}{2} \right] \cup \left[2, \frac{16}{7} \right).$$

We use Theorem 3.4 to build a Parseval wavelet with a C^∞ Fourier transform that is associated with the Journé multiplicity function.

Example 3.6: The Journé multiplicity function m takes on the values 0, 1, and 2, with $S_1 = [-\frac{1}{2}, -\frac{3}{7}) \cup [-\frac{2}{7}, \frac{2}{7}) \cup [\frac{3}{7}, \frac{1}{2})$ and $S_2 = [-\frac{1}{7}, \frac{1}{7})$. The complementary multiplicity function $\tilde{m}(x) \equiv 1$, since the Journé wavelet is a single orthonormal wavelet.

To build the filters, we let p_0 be a C^∞ classical (MRA) low-pass filter for dilation by 2 [i.e., that satisfies the classical filter equation (1.1)], that in addition satisfies $p_0(x) = 0$ for $x \in \pm(\frac{1}{7} - \epsilon, \frac{3}{14} + \epsilon) \cup (\frac{3}{7} - \epsilon, \frac{4}{7} + \epsilon)$. Note that by (1.1), we then have $p_0(x) = \sqrt{2}$ for $x \in \pm(\frac{2}{7} - \epsilon, \frac{5}{14} + \epsilon) \cup (-\frac{1}{14} - \epsilon, \frac{1}{14} + \epsilon)$. Let p_1 be the standard choice of C^∞ high-pass filter associated to p_0, given by $p_1(x) = e^{2\pi i x} \overline{p_0(x + \frac{1}{2})}$. Then it is easily checked that the following functions satisfy (2.4)–(2.6), and thus are generalized low- and high-pass filters by our definitions in Sec. II.

$$h_{1,1}(x)=\begin{cases}p_0(x), & x\in\left[-\frac{2}{7},\frac{2}{7}\right)\\ 0 & \text{otherwise},\end{cases}$$

$$h_{1,2}(x)=\begin{cases}p_0\left(x+\frac{1}{2}\right), & x\in\left[-\frac{1}{7},\frac{1}{7}\right)\\ 0 & \text{otherwise},\end{cases}$$

$$h_{2,1}(x)=\begin{cases}\sqrt{2}, & x\in\pm\left[\frac{3}{7},\frac{1}{2}\right)\\ 0 & \text{otherwise},\end{cases}$$

$$h_{2,2}(x)=0,$$

$$g_1(x)=\begin{cases}p_1(x), & x\in\left[-\frac{2}{7},\frac{2}{7}\right)\\ 0 & \text{otherwise},\end{cases}$$

$$g_2(x)=\begin{cases}p_1\left(x+\frac{1}{2}\right), & x\in\left[\frac{-1}{7},\frac{1}{7}\right)\\ 0 & \text{otherwise}.\end{cases}$$

Now we check that the resulting wavelet does in fact have a C^∞ transform. We first fix an x and show that $\hat{\phi}_1$ and $\hat{\phi}_2$ are C^∞ in a neighborhood of x. Recall that these functions form the first column of the infinite product matrix

$$\prod_{j=1}^{\infty}\frac{1}{\sqrt{2}}\begin{pmatrix}h_{1,1}\left(\frac{x}{2^j}\right) & h_{1,2}\left(\frac{x}{2^j}\right)\\ h_{2,1}\left(\frac{x}{2^j}\right) & 0\end{pmatrix}.$$

Because $h_{2,1}$ is 0 on $\left(-\frac{3}{7},\frac{3}{7}\right)$, all but a finite number of the matrix factors are upper triangular. Thus, each of the entries in the first column of the infinite product contains only a finite number of terms. Since $h_{1,1}=\sqrt{2}$ in a neighborhood of 0, each of the terms has only a finite number of factors not equal to 1. Thus, it will suffice to show that each of the factors in each of the terms is C^∞.

By construction, we have that the $h_{i,j}$ are all C^∞ everywhere except for $h_{1,1}$ at $n\pm\frac{2}{7}$, $h_{1,2}$ at $n\pm\frac{1}{7}$, and $h_{2,1}$ at $n\pm\frac{3}{7}$ for $n\in\mathbb{Z}$. We will show that whenever one of these discontinuities occurs as a factor in the infinite product, it is cancelled by a following factor that is 0 in a neighborhood of the point of discontinuity. Note that the product of two adjacent factors in the infinite matrix product has the form

$$\begin{pmatrix}h_{1,1}(y)h_{1,1}\left(\frac{y}{2}\right)+h_{1,2}(y)h_{2,1}\left(\frac{y}{2}\right) & h_{1,1}(y)h_{1,2}\left(\frac{y}{2}\right)\\ h_{2,1}(y)h_{1,1}\left(\frac{y}{2}\right) & h_{2,1}(y)h_{1,2}\left(\frac{y}{2}\right)\end{pmatrix}.$$

Thus any term in the infinite product that contains a factor of $h_{2,1}\left(n\pm\frac{3}{7}\right)$ must also contain a factor of one of the forms $h_{1,1}\left(n\pm\frac{2}{7}\right)$, $h_{1,1}\left(n\pm\frac{3}{14}\right)$, $h_{1,2}\left(n\pm\frac{3}{14}\right)$, and $h_{1,2}\left(n\pm\frac{2}{7}\right)$. The first three possibilities are 0 in a neighborhood of the point in question, so if we have a discontinuous factor of $h_{2,1}$, it is

either cancelled out by a 0 factor, or we also have a factor of $h_{1,1}\left(n\pm\frac{2}{7}\right)$ with a smaller n. Similarly, any term in the infinite product that contains a factor of $h_{1,1}\left(n\pm\frac{2}{7}\right)$ must also contain a factor of one of the forms $h_{1,1}\left(n\pm\frac{5}{14}\right)$, $h_{1,1}\left(n\pm\frac{1}{7}\right)$, $h_{1,2}\left(n\pm\frac{5}{14}\right)$, or $h_{1,2}\left(n\pm\frac{1}{7}\right)$. The first three of these possibilities are 0 in a neighborhood of the points in question, so any discontinuous factor of $h_{1,1}$ is either cancelled out by a 0 factor, or is followed by a factor of $h_{1,2}\left(n\pm\frac{1}{7}\right)$ with an equal or smaller n. Finally, any term in the infinite product that contains a factor of $h_{1,2}\left(n\pm\frac{1}{7}\right)$ must also contain a factor of either the form $h_{2,1}\left(n\pm\frac{1}{14}\right)$ or the form $h_{2,1}\left(n\pm\frac{3}{7}\right)$. The first of these possibilities is 0 in again 0 in a neighborhood of the point in question; the second possibility throws us back into the first type of discontinuity we considered above, but with a smaller n. We can repeat the above sequence of arguments if necessary, noting that each succeeding factor is evaluated at a point half the distance from the origin as its predecessor, so that the chain above must eventually end with a factor of 0.

This argument shows that $\hat{\phi}_1$ and $\hat{\phi}_2$ are C^∞. To see that $\hat{\psi}$ is C^∞ as well, it suffices to note that g_1 and g_2 are.

Remark 3.7: With some more work it is possible to slightly improve the previous arguments and to show that in fact the Fourier transform vanishes rapidly at infinity.

IV. A GENERALIZED LOOP GROUPOID ACTION ON THE BUNDLE OF GENERALIZED FILTER SYSTEMS

Let $\{h_{i,j}\}_{1\leqslant i,j\leqslant c}$ and $\{g_{k,j}\}_{1\leqslant k\leqslant\tilde{c},1\leqslant j\leqslant c}$ be generalized low-pass and high-pass filter functions defined as in Sec. II. Since $\oplus_{i=1}^{c}L^2(S_i)\cong L^2(\sqcup_{i=1}^{c}S_i)$, we can suppress the second index of the filter functions and view generalized filter functions as a vector ($c+\tilde{c}$-tuple) of functions:

$$(h_1,h_2,\ldots,h_c,g_1,g_2,\ldots,g_{\tilde{c}})\in\left[L^2\left(\bigsqcup_{i=1}^{c}S_i\right)\right]^{c+\tilde{c}}.$$

Further, we note that for any fixed $\omega\in\mathbb{T}^d$, all the information in the output of the vector of functions $(h_1,h_2,\ldots,h_c,g_1,g_2,\ldots,g_{\tilde{c}})$ is actually in $\mathbb{C}^{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))}$, where as in Sec. II, α is the endomorphism of $\mathbb{T}^d$ defined by the matrix $B=A^t$, since by the orthogonality relations, $h_i(\omega)=0$ if $i>m(\alpha(\omega))$ and $g_k(x)=0$ if $k>\tilde{m}(\alpha(\omega))$.

We want to generalize the discussion given by Bratteli and Jorgensen in Ref. 40, and construct a loop groupoid which acts on the class of filter systems with bounded multiplicity functions corresponding to a fixed dilation matrix A acting on $\mathbb{R}^n$. We will also impose the condition the filter systems satisfy some "initial conditions" that are in some sense canonical.

We first remind readers of the notion of a vector bundle over a topological space X; more details can be found in Ref. 41.

Definition 4.1: Let X be a topological space. A (finite dimensional) vector bundle over the space X, denoted by (E,p,X), is a topological space E, together with a continuous open surjection $p:E\to X$, and operations and norms making each fiber $E_x=p^{-1}(X)$ into a (finite dimensional) vector space, which in addition satisfies the following conditions:

(i) $y\mapsto\|y\|$ is continuous from E to $\mathbb{R}$.
(ii) The operation + is continuous as a function from $\{(y,z)\in E\times E:p(y)=p(z)\}$ to E.
(iii) For each $\lambda\in\mathbb{C}$, the map $y\mapsto\lambda\cdot y$ is continuous from E to E.
(iv) If $x\in X$ and $\{y_i\}$ is any net of elements of E such that $\|y_i\|\to 0$ and $p(y_i)\to x$ in X, then $y_i\to\vec{0}\in E_x$ in E.

A Borel map $s:X\to E$ is called a Borel cross section if $p\circ s(x)=x,\ \forall x\in X$.

We review the notion of essentially bounded multiplicity functions m associated to a dilation matrix A that can give rise to GMRAs, as described in Refs. 10 and 36. We first recall that m must satisfy the consistency inequality

$$m(\omega) \leqslant \sum_{l=0}^{N-1} m(\omega_l), \tag{4.1}$$

where we recall from Sec. II that $\{\omega_l: 0 \leqslant l \leqslant N-1\}$ is the set of N distinct preimages of $\omega \in \mathbb{T}^d$ under the endomorphism α given by $\alpha(\omega)=B(\omega)$, for $\omega \in \mathbb{T}^d=\mathbb{R}^d/\mathbb{Z}^d$ and $B=A^t$. This inequality leads to the consistency equality Equation (2.1) discussed in Sec. II. Moreover, we can enumerate the ω_l as follows. Enumerate a set of coset representatives $\{\xi_0=\vec{0}, \xi_1, \ldots, \xi_{N-1}\}$ for $B^{-1}(\mathbb{Z}^d)/\mathbb{Z}^d$ including $\vec{0} \in B^{-1}(\mathbb{Z}^d)$. For each $l, 0 \leqslant l \leqslant N-1\}$ let ζ_l be the image of ξ_l under the natural projection from $\mathbb{R}^d$ onto $\mathbb{T}^d=\mathbb{R}^d/\mathbb{Z}^d$. Note that the ζ_l are distinct elements of $\mathbb{T}^d$ and that $\alpha(\zeta_l)=\vec{0}$, $0 \leqslant l \leqslant N-1$. Find a Borel cross section $\sigma: \mathbb{T}^n=\mathbb{R}^d/\mathbb{Z}^d \to \mathbb{T}^n=\mathbb{R}^d/B^{-1}(\mathbb{Z}^d) \cong [\mathbb{R}^d/\mathbb{Z}^d]/[B^{-1}(\mathbb{Z}^d)/\mathbb{Z}^d]$, with $\sigma(\vec{0})=\vec{0}$. This Borel map satisfies $\alpha \circ \sigma(\omega)=\omega$ for all $\omega \in \mathbb{T}^d$. Then define

$$\omega_l = \sigma(\omega)\zeta_l, \quad 0 \leqslant l \leqslant N-1;$$

one easily verifies that the $\{\omega_l: 0 \leqslant l \leqslant N-1\}$ are the N distinct preimages of $\omega \in \mathbb{T}^d$ under α.

Let $\Delta=\cup_{k=0}^{\infty} B^k(S_1+\mathbb{Z}^d)$. Recall from Refs. 10 and 42 that in order for m to be the multiplicity function for a GMRA, Δ must satisfy

$$\sum_{n \in \mathbb{Z}^d} \chi_\Delta(\omega+n) \geqslant m(\omega). \tag{4.2}$$

Finally, Δ should satisfy

$$\cup_{p \in \mathbb{Z}} B^p(\Delta) = \mathbb{R}^n. \tag{4.3}$$

If conditions (4.1)–(4.3) are satisfied we say that m is an (essentially) bounded multiplicity function with respect to the dilation matrix A. Given such an m, we construct the conjugate multiplicity function $\tilde{m}$ by defining

$$\tilde{m}(\omega) = \sum_{l=0}^{N-1} m(\omega_l) - m(\omega), \omega \in \mathbb{T}^d; \tag{4.4}$$

by definition, m and $\tilde{m}$ will satisfy Eq. (2.1).

Given an (essentially) bounded multiplicity function m on $\mathbb{T}^d$, let $c=\operatorname{ess\,sup} m$, and $\tilde{c}=\operatorname{ess\,sup} \tilde{m}$. We recall from Baggett *et al.* that to such an m we can explicitly construct a canonical system of low-pass filters, or "generalized conjugate mirror filters" $\{h_{i,j}^{\mathcal{C}}: 1 \leqslant i,j \leqslant c\}$, by using the method of Theorem 3.6 of Ref. 36. Given this system $\{h_{i,j}^{\mathcal{C}}: 1 \leqslant i,j \leqslant c\}$, Theorem 2.5 item (1) of Ref. 36 gives us a way of explicitly constructing an associated system of high-pass filters, or "complementary conjugate mirror filters," $\{g_{k,j}^{\mathcal{C}}: 1 \leqslant k \leqslant \tilde{c}, 1 \leqslant j \leqslant c\}$. We call this family of filters $\{h_{i,j}^{\mathcal{C}}: 1 \leqslant i,j \leqslant c\} \cup \{g_{k,j}^{\mathcal{C}}: 1 \leqslant k \leqslant \tilde{c}, 1 \leqslant j \leqslant c\}$ the **canonical filter system** associated to the multiplicity function m.

Now let $T_j=\{\omega \in \mathbb{T}^d: m(\alpha(\omega))+\tilde{m}(\alpha(\omega))=j\}$, $0 \leqslant j \leqslant c+\tilde{c}$. Set $T_{i,j}=S_i \cap T_j$, $0 \leqslant j \leqslant c+\tilde{c}$; then each $T_{i,j}$ is Borel and $S_i=\sqcup_{j=0}^{c+\tilde{c}} T_{i,j}$.

Definition 4.2: Fix a bounded multiplicity function m associated to the dilation matrix A. Let E_m be the Borel space given by

$$E_m = \bigsqcup_{i=1}^{c} \bigsqcup_{j=0}^{c+\tilde{c}} [T_{i,j} \times \mathbb{C}^j].$$

Let $(E_m, p, \sqcup_{i=1}^c S_i)$ be the Borel vector bundle where the map $p: E_m \to \sqcup_{i=1}^c S_i$ is defined by $p(x,\vec{v})=x$, $(x,\vec{v}) \in T_{i,j} \times \mathbb{C}^j$. By definition, $(E_m, p, \sqcup_{i=1}^c S_i)$ is a vector bundle over $\sqcup_{i=1}^c S_i$ whose fiber over $\omega \in S_i$ is a complex vector space of dimension $m(\alpha(\omega))+\tilde{m}(\alpha(\omega))$. An M **system associated to the multiplicity function** m is a Borel cross section $M: \sqcup_{j=1}^c S_j \to E_m$ of this bundle whose values, $(M_1(\omega), M_2(\omega), \ldots, M_{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))})$, are the output of a vector of generalized low-

and high-pass filters. That is, for fixed $\omega \in \sqcup_{j=1}^{c} S_j$, the first $m(\alpha(\omega))$ components of the vector $M(\omega)$ correspond exactly to the generalized low-pass filter function values $h_1(\omega)$, $h_2(\omega)$, …, $h_{m((\alpha(\omega))}(\omega)$, and the last $\tilde{m}(\alpha(\omega))$ components of $M(\omega)$ correspond to the generalized high-pass filter function values $g_1(\omega)$, $g_2(\omega)$, …, $g_{\tilde{m}(\alpha(\omega))}(\omega)$, where the filters involved satisfy the low-pass and Lipschitz conditions defined in Sec. II, and where in addition the filters $\{h_i\} \cup \{g_k\}$ satisfy the initial conditions $h_i(\zeta_l) = h_i^C(\zeta_l)$, $1 \leqslant i \leqslant c$, $0 \leqslant l \leqslant N-1$, and $g_k(\zeta_l) = g_k^C(\zeta_l)$, $1 \leqslant k \leqslant \tilde{c}$, $0 \leqslant l \leqslant N-1$, where the h_i^C and the g_k^C are the canonical filters associated to m in the previous paragraph. Denote by $\mathcal{M}_m$ the set of M systems associated to the bounded multiplicity function m. We remark that $\mathcal{M}_m$ can be given the structure of a topological space if its elements are viewed as elements of the Hilbert space $\oplus_{i=0}^{c} \oplus_{j=0}^{c+\tilde{c}} L^2(T_{i,j}) \otimes \mathbb{C}^j$.

Remark 4.3: The above-mentioned definition is essentially the same as Definition 4.2 of Ref. 8 except for the additional assumption that the M system have the appropriate canonical values at the preimages of $\vec{0}$ under the endomorphism α, which was missing from Ref. 8. Note all the information about the generalized filters $\{h_{i,j}\}$ and $\{g_{k,j}\}$ is encoded in the M system. In particular, for any fixed multiplicity function m, such that both m and $\tilde{m}$ are constant in a neighborhood of the origin, we have a one-to-one correspondence between M systems and collections of generalized filter functions as defined in Section II which satisfy the canonical initial conditions. These generalized filters will in turn give rise to an orthonormal frame wavelet family and its associated GMRA $\{V_j\}$ by Theorem 3.4 from Sec. III. However, as shown by one of the examples given in Sec. III, the multiplicity function m' for the GMRA $\{V_j\}$ **need not** be equal to m. So, there is no correspondence in general, between the class of M-systems associated to a given multiplicity function m and the class of GMRAs associated to m.

To develop the loop group action on these M systems, we first define an endomorphism $\Pi_\alpha : \sqcup_{i=1}^{c} S_i \to \mathbb{T}^d$ by $\Pi_\alpha(\omega) = \alpha(\omega)$. Each $\omega \in \mathbb{T}^d$ has $\Sigma_{l=0}^{N-1} m(\omega_l) = m(\omega) + \tilde{m}(\omega)$ preimages in $\sqcup_{i=1}^{c} S_i$, where the $\{\omega_l : 0 \leqslant l \leqslant N-1\}$ are the N distinct preimages of ω in $\mathbb{T}^d$ under the endomorphism α, parametrized as discussed earlier. For convenience of notation, we label these preimage maps $r_{(l,j)}$, where $r_{(l,j)}(\omega) = \omega_l \in S_j \subseteq \sqcup_{i=1}^{c} S_i$ for $1 \leqslant j \leqslant m(\omega_l)$. (Note that this range on j, as l varies from 0 to $N-1$, gives all the preimages, since if $j > m(\omega_l)$, by definition ω_l is not an element of S_j.) For each fixed ω, we give the pairs (l,j) the lexicographical order, so that $(l_1, j_1) \leqslant (l_2, j_2)$ if $l_1 < l_2$ or if $l_1 = l_2$ and $j_1 \leqslant j_2$. We thus implicitly define a 1-1 map λ_ω taking the pairs (l,j) onto the integers from 1 to $m(\omega) + \tilde{m}(\omega)$.

We now construct a unitary group bundle $(F, q, \mathbb{T}^d)$ as follows. For each $j \in \{1, \ldots, c+\tilde{c}, \}$, let $Z_j = \{\omega \in \mathbb{T}^d : m(\omega) + m(\tilde{\omega}) = j\}$. Let

$$F_m = \sqcup_{j=0}^{c+\tilde{c}} [Z_j \times U(j, \mathbb{C})],$$

where $U(j, \mathbb{C})$ is viewed as a the topological group of unitary $j \times j$ matrices: it inherits its topology from being a subset of C^*-algebra of complex $j \times j$ matrices given the operator norm. Define $q : F_m \to \mathbb{T}^d$ by $q(\omega, T) = \omega$, for $(\omega, T) \in F_m$, and note that $q : F_m \to \mathbb{T}^d$ is a continuous open surjection, and the fiber $q^{-1}(\omega)$ of the bundle consists of the group of complex unitary matrices $U(m(\omega) + \tilde{m}(\omega), \mathbb{C})$. Borel cross sections to this group bundle consist of Borel maps $L : \mathbb{T}^d \to F_m$ such that $q \circ L(\omega) = \omega$. Note also that $(F_m, q, \mathbb{T}^d)$ is a subset of a Borel vector bundle over $\mathbb{T}^d$ in the sense of Definition 4.1, whose fibers over particular values of $\omega \in \mathbb{T}^d$ are made up of algebras of finite-dimensional matrices of varying dimension. We denote the set of sections of this bundle by $\Gamma_m(F_m, q)$. Note $\Gamma_m(F_m, q)$ is a group under pointwise operations on $\mathbb{T}^d$, where the identity element of the group is given by that section whose value at ω is equal to $Id_{m(\omega)+\tilde{m}(\omega)}$.

Also, it is possible to define a groupoid corresponding to a dilation matrix A as follows. Let Ω_A consist of the set of all bounded multiplicity functions corresponding to the dilation matrix A, that is, $\Omega_A = \{m : \mathbb{T}^d \to \mathbb{N} \cup \{0\} : m$ is essentially bounded and satisties (4.1)–(4.3)$\}$, where two multiplicity functions for A are identified if they are equal almost everywhere on $\mathbb{T}^d$. There are a variety of topologies we can put on Ω_A; for the moment the Hilbert space topology of L^2 functions on $\mathbb{T}^d$ will do. We call Ω_A **the multiplicity function space associated to** A. Now set

$$\mathcal{L}_A = \bigsqcup_{m \in \Omega_A} \Gamma_m(F_m, q).$$

Then $\mathcal{L}_A$ is a groupoid, with range map r equal to the source map s defined from $\mathcal{L}_A$ to Ω_A by $r(\gamma)=s(\gamma)=m$ for $\gamma \in \Gamma_m(F_m,q)$. Hence two elements γ_1 and γ_2 of $\mathcal{L}_A$ can be multiplied together if and only if $\gamma_1, \gamma_2 \in \Gamma_m(F_m,q)$ for a fixed bounded multiplicity function m.

We are now state a theorem about M-systems that can be derived in a fairly straightforward fashion from the orthogonality relations. This theorem is a generalization of Theorem 4.3 of Ref. 8, and thus we merely sketch the proof and refer the reader to Ref. 8 for details.

Theorem 4.4: *Let $\Gamma_m(F_m,q)$ be the group of cross sections of the group bundle associated to a fixed bounded multiplicity function m defined above. Let $M: \sqcup_{j=1}^{c} S_j \to E$ be an M-system associated to m. Then $\omega \mapsto (L_{i,\lambda_\omega(l,j)}(\omega))$, where*

$$L_{i,\lambda_\omega(l,j)}(\omega) = \sqrt{\frac{1}{N}} M_i(r_{(l,j)}(\omega))$$

is an element of $\Gamma_m(F_m,q)$.

Proof: As noted previously, $1 \leq \lambda_\omega(l,j) \leq m(\omega)+\tilde{m}(\omega)$, so for each $\omega \in \mathbb{T}$, the matrix $(L_{i,\lambda_\omega(l,j)}(\omega))$ is a square matrix of the correct dimension.

We shall show that for all $\omega \in \mathbb{T}^d$, the rows of $(L_{i,\lambda_\omega(l,j)}(\omega))$ are orthonormal, by means of the orthogonality relations for generalized filter functions given in Eq. (2.7) in the statement of Theorem 2.5.

Write L_i for the ith row of $(L_{i,\lambda_\omega(l,j)}(\omega))$. If $1 \leq i \leq i' \leq m(\omega)$,

$$\langle L_i, L_{i'} \rangle = \sum_{\lambda_\omega(l,j)=1}^{m(\omega)+\tilde{m}(\omega)} L_{i,\lambda_\omega(l,j)}(\omega)\overline{L_{i,\lambda_\omega(l,j)}(\omega)} = \sum_{l=0}^{N-1} \sum_{j=1}^{m(\omega_l)} \sqrt{\frac{1}{N}} M_i(r_{(l,j)}(\omega)) \overline{\sqrt{\frac{1}{N}} M_{i'}(r_{(l,j)}(x))}$$

$$= \sum_{l=0}^{N-1} \sum_{j=1}^{m(\omega_l)} \frac{1}{N} h_{i,j}(\omega_l)\overline{h_{i',j}(\omega_l)} = \frac{1}{N} \sum_{j=1}^{c} \sum_{l=0}^{N-1} h_{i,j}(\omega_l)\overline{h_{i',j}(\omega_l)}$$

(as $h_{i,j}(\omega_l)=0$ for $j > \mu(\omega_l)$, since $\omega_l \notin S_j$ in that case)

$$= [\text{by Eq. 2.2}] N \tfrac{1}{N} \delta_{i,i'} \chi_{S_i}(\omega) = \delta_{i,i'}$$

[we note that $\chi_{S_i}(\omega)=1$ since we have $i \leq m(\omega)$ and for those values of i, $\omega \in S_i$ by definition of $m(\omega)$].

The cases $m(\omega) < i \leq i' \leq m(\omega)+\tilde{m}(\omega)$ and $1 \leq i \leq m(\omega) < i' \leq m(\omega)+\tilde{m}(\omega)$ follow from similar arguments using Eqs. (2.4) and (2.5). Thus we have that in all cases, the rows of $(L_{i,\lambda_\omega(l,j)} \times(\omega))$ are orthonormal, and we have the desired unitary matrix. □

Remark 4.5: We note that for $\omega \in \mathbb{T}^d$, the $(m(\omega)+\tilde{m}(\omega)) \times (m(\omega)+\tilde{m}(\omega))$ matrix $L(\omega)$ is exactly the submatrix $L(\omega)$ of the matrix $K(\omega)$ defined in Theorem 2.5. Thus in some sense the proof given above is redundant. We have added in the extra detail because we want to exercise care in enumerating the rows and columns of $L(\omega)$ for future use. We also note that the "initial condition" on M systems given in Definition 4.2 can be rephrased as follows. Let $L^{\mathcal{C}}_{i,\lambda_\omega(l,j)}(\omega))$ be the element of $\Gamma_m(F_m,q)$ corresponding to the "canonical" filter system associated to the multiplicity function m, and let $L_{\mathcal{C}}$ be the $[m(\vec{0})+\tilde{m}(\vec{0})] \times [m(\vec{0})+\tilde{m}(\vec{0})]$ unitary matrix $L^{\mathcal{C}}_{i,\lambda_\omega(l,j)}(\vec{0})$. Then for any M system M associated to m, we have $\sqrt{1/N} M_i(r_{(l,j)}(\vec{0})) = L_{\mathcal{C}}$. This follows from the initial conditions satisfied by any M system outlined in Definition 4.2.

The results of Theorem 4.4 imply that the columns of $(L_{i,\lambda_\omega(l,j)}(\omega))$ are orthonormal as well, and allow us to obtain the following corollary, which is a generalization of Corollary 4.4 of Ref. 8.

Corollary 4.6: Let m and $\tilde{m}$ be bounded multiplicity and conjugate multiplicity functions associated to a dilation matrix A that are constant in a neighborhood of the origin, with related

sequences of sets $\{S_i | 1 \leqslant i \leqslant c\}$ *and* $\{\widetilde{S}_k | 1 \leqslant k \leqslant \tilde{c}\}$. *Suppose* $\{h_{i,j}\}_{1 \leqslant i,j \leqslant c}$ *and* $\{g_{k,j}\}_{1 \leqslant k \leqslant \tilde{c}, 1 \leqslant j \leqslant c}$ *are generalized low-pass and high-pass filter functions associated to the multiplicity function m. Then for all* $\omega \in \mathbb{T}^d$, *and for all* l, $l' \in \{0,1,\ldots,N-1\}$ *and* j, $j' \in \{1,\ldots,c)\}$, *we have*

$$\sum_{i=1}^{c+\tilde{c}} \frac{1}{N} M_i(r_{(l,j)}(\omega))\overline{M_i(r_{(l',j')}(\omega))} = \sum_{i=1}^{c} \frac{1}{N} h_{i,j}(\omega_l)\overline{h_{i,j'}(\omega_l)} + \sum_{k=1}^{\tilde{c}} \frac{1}{N} g_{k,j}(\omega_l)\overline{g_{k,j'}(\omega_l)} = \delta_{j,j'}\delta_{l,l'},$$

where here the M_i *correspond to the generalized filter functions* $h_{i,j}$ *and* $g_{k,j}$ *as given in Definition 4.2.*

Proof: This result follows fairly directly from Theorems 2.5 and 4.4, and we omit the details of the proof. □

We are ready to define the generalized loop group and its associated action on the set of M systems associated to a multiplicity function m.

Definition 4.7: The **loop group** associated to the multiplicity function m is defined to be the subgroup $\mathrm{Loop}_m(F_m,q)$ of the group of Borel sections $\Gamma_m(F_m,q)$ whose elements K satisfy $L(\vec{0}) = Id_{m(\vec{0})+\tilde{m}(\vec{0})}$, and $L_{i,\lambda_\omega(j,l)}$ are Lip_1 in a neighborhood of the origin.

We now prove that the generalized loop group $\mathrm{Loop}_m(F,q)$ acts freely and transitively on the set of M-systems associated to the multiplicity function m. The following theorem generalizes Theorem 4.7 of Ref. 8.

Theorem 4.8: *There is a free and transitive action of* $\mathrm{Loop}_m(F,q)$ *on the set of M-systems associated to an essentially bounded multiplicity function m such that m is constant in neighborhoods of* 0_l, $0 \leqslant l \leqslant N-1$, *where the set* $\{0_l : 0 \leqslant l \leqslant N-1\}$ *consists of the preimages of* 0 *under the endomorphism* $\alpha : \mathbb{T}^d \to \mathbb{T}^d$. *This action is given by*

$$L \cdot M(\omega) = L(\Pi_\alpha(\omega))[(M_1(\omega), M_2(\omega), \ldots, M_{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))}(\omega))]^t.$$

Proof: We first prove the transitivity. Suppose we are given two different M-systems, labeled $M=(M_i)$ and $\widetilde{M}=(\widetilde{M}_i)$. Define an element L of the group bundle associated to m, that is, an element of $\Gamma_m(F,q)$, where $L(\omega)$ has dimension $m(\omega)+\tilde{m}(\omega)$, as follows:

$$L_{i,i'}(\omega) = \frac{1}{N} \sum_{\lambda_\omega(l,j)=1}^{m(\omega)+\tilde{m}(\omega)} \overline{M_{i'}(r_{(l,j)}(\omega))}\widetilde{M}_i(r_{(l,j)}(\omega)). \tag{4.5}$$

Since the M systems M and $\widetilde{M}$ have the same values at $\vec{0}$ and at the preimages ζ_l of $\vec{0}$ under the automorphism α, one easily verifies that $L(\vec{0}) = Id_{m(\vec{0})+\tilde{m}(\vec{0})}$. Also, one sees by inspection that if L_M and $L_{\widetilde{M}}$ are the elements of $\Gamma_m(F_m,q)$ corresponding to the M-systems M and $\widetilde{M}$ as in Theorem 4.4, then the proposed element L of $\mathrm{Loop}_m(F,q)$ given in Eq. (4.5) is exactly $L(\omega) = L_{\widetilde{M}}(\omega) \times [L_M(\omega)]^*$.

In addition, as shown by Bratteli and Jorgensen in the classical case, we have

$$\begin{aligned}
[L \cdot M]_i(\omega) &= \sum_{i'=1}^{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))} L_{i,i'}(\Pi_\alpha(\omega))M_{i'}(\omega) \\
&= \sum_{i'=1}^{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))} \left(\frac{1}{N} \sum_{\lambda_{\alpha(\omega)}(l,j)=1}^{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))} \overline{M_{i'}(r_{(l,j)}(\alpha(\omega)))}\widetilde{M}_i(r_{(l,j)}(\alpha(\omega))) \right) M_{i'}(\omega) \\
&= \sum_{\lambda_{\alpha(\omega)}(l,j)=1}^{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))} \widetilde{M}_i(r_{(l,j)}(\alpha(\omega))) \left(\sum_{i'=1}^{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))} \overline{M_{i'}(r_{(l,j)}(\alpha(\omega)))}M_{i'}(\omega) \right) = \widetilde{M}_i(\omega),
\end{aligned}$$

where the last equality follows from the orthogonality of the columns of M as established in Corollary 2.7, so that the inside sum is 0 except for the single values of l and j where $r_{l,j}(\alpha(\omega)) = \omega$.

To prove that the action is free, suppose $M=(M_i)$ is a M system associated to m and $L \in \mathrm{Loop}_m(F,q)$ satisfies

$$L(\Pi_\alpha(\omega))[(M_1(\omega),M_2(\omega),\ldots,M_{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))}(\omega))]^t=[(M_1(\omega),M_2(\omega),\ldots,M_{m(\alpha(\omega))+\tilde{m}(\alpha(\omega))}(\omega))]^t.$$

Using Theorem 4.4, for each $\omega \in \mathbb{T}^d$ we define a $(m(\alpha(\omega))+\tilde{m}(\alpha(\omega)))\times(m(\alpha(\omega))+\tilde{m}(\alpha(\omega)))$ unitary matrix $\mathcal{M}$ by

$$\mathcal{M}_{i,\lambda_{\alpha(\omega)}(l,j)}(\omega)=\sqrt{\frac{1}{N}}M_i(r_{(l,j)}(\alpha(\omega))),$$

$$1 \leqslant i \leqslant m(\alpha(\omega))+\tilde{m}(\alpha(\omega)),\ 0 \leqslant l \leqslant N-1,\ 1 \leqslant j \leqslant m(\alpha(\omega)_l).$$

We then see that $L(\alpha(\omega))\mathcal{M}(\omega)=\mathcal{M}(\omega)$ for all $\omega \in \mathbb{T}^d$. By unitarity of $\mathcal{M}(\omega)$, this shows that $L(\alpha(\omega))$ is the $(m(\alpha(\omega))+\tilde{m}(\alpha(\omega)))\times(m(\alpha(\omega))+\tilde{m}(\alpha(\omega)))$ identity matrix for all $\omega \in \mathbb{T}^d$, which implies that L is the identity element of $\mathrm{Loop}_m(F,q)$, as desired. □

Similarly, we can define the generalized loop groupoid assigned to a dilation matrix A.

Definition 4.9: Let A be a $d\times d$ integer dilation matrix. Let Ω_A be the multiplicity function space associated to A. The **loop groupoid** associated to A consists of the set

$$\mathcal{LOOP}_A=\bigsqcup_{m\in\Omega_A}\mathrm{Loop}_m(F_m,q),$$

where $r=s:\mathcal{LOOP}_A\to\Omega_A$ is defined by $r(L)=s(L)=m$ for $L \in \mathrm{Loop}_m(F_m,q)$.

We can also define a fiber bundle of M systems over Ω_A as follows.

Definition 4.10: Let Ω_A be the multiplicity function space associated to A. Define $\mathbb{M}_A=\cup_{m\in\Omega_A}\{m\}\times\mathbb{M}_m$, where $\mathbb{M}_m$ consists of the set of M systems associated to a fixed multiplicity function m, where two M systems are identified if they are equal almost everywhere. Give elements of $\mathbb{M}_m$ the Hilbert space topology mentioned in Definition 4.2. The topology on $\mathbb{M}_A$ is obtained from viewing an element $(m,\mathcal{M}) \in \mathbb{M}_A$ as a tuple $(m,\mathcal{M})$ of functions defined on the Cartesian product space $\mathbb{T}^d\times\sqcup_{i=1}^{\infty}[\mathbb{T}^d]_i$, taking on values in $[\mathbb{N}\cup\{0\}]\oplus l_2(\mathbb{N})$, where

$$(m,\mathcal{M})(\omega,z)=(m(\omega),\mathcal{M}_1(z),\mathcal{M}_2(z),\ldots,\mathcal{M}_{m(\alpha(z))+\tilde{m}(\alpha(z))}(z),0,0,0,\cdots),$$

and where $\mathcal{M}_j(z)=M_j(z)$ if $z \in \sqcup_{i=1}^{c}S_i$ and $1\leqslant j\leqslant m(\alpha(z))+\tilde{m}(\alpha(z))$, and $\mathcal{M}_j(z)=0$ if $z \notin \sqcup_{i=1}^{c}S_i$, for $\{S_i\}$ the standard subsets of $\mathbb{T}^d$ associated to the multiplicity function m. Then $\mathbb{M}_A$ is a topological space, if we view elements of $\mathbb{M}_A$ as elements in the Hilbert space $L^2(\mathbb{T}^d)\oplus L^2(\sqcup_{i=1}^{\infty}[\mathbb{T}^d]_i)\otimes[l_2(\mathbb{N})]$. Define a map $\Pi:\mathbb{M}_A\to\Omega_A$ by $\Pi((m,\mathcal{M}))=m$. Then Π is a continuous surjection, since it is a restriction of the Hilbert space projection from $L^2(\mathbb{T}^d)\oplus L^2(\sqcup_{i=1}^{\infty}[\mathbb{T}^d]_i)\otimes[l_2(\mathbb{N})]$ onto $L^2(\mathbb{T}^d)\oplus[\{\vec{0}\}]\cong L^2(\mathbb{T}^d)$, and $\Pi^{-1}(m)=\mathbb{M}_m$, so that $\mathbb{M}_A$ is a fiber bundle over Ω_A, called the **fiber bundle of M systems associated to A**.

Using these definitions, we obtain the following corollary to Theorem 4.8.

Corollary 4.11: Let A be a $d\times d$ integer dilation matrix, and let $\mathcal{LOOP}_A$ and $\mathbb{M}_A$ the loop groupoid and fiber bundle of M systems associated to A, respectively. Then there is a groupoid action of $\mathcal{LOOP}_A$ on $\mathbb{M}_A$, where $L \in \mathcal{LOOP}_A$ is allowed to act on $\mathcal{M} \in \mathbb{M}_A$ if and only if $r(L)=\Pi(\mathcal{M})=m$. This action is fiber-wise transitive.

Proof: This is just a restatement of part of Theorem 4.8. □

We now modify Example 4.5 of Ref. 8, in order to show how we can use the loop group action to transform the canonical filter functions for the Journé wavelet into the filter functions discussed in Example 3.6. The construction of the canonical filter functions for the Journé wavelet was first done in the thesis of Courter.[35]

Example 4.12: The Journé wavelet in the frequency domain is the characteristic function of the set

$$\left[-\frac{16}{7},-2\right)\cup\left[-\frac{1}{2},-\frac{2}{7}\right)\cup\left[\frac{2}{7},\frac{1}{2}\right]\cup\left[2,\frac{16}{7}\right).$$

Here the multiplicity function m takes on the values 0, 1, and 2, and $\tilde{m}(x)\equiv 1$, since the Journé wavelet is a single orthonormal wavelet. If we identify $\mathbb{T}$ with $\left[-\frac{1}{2},\frac{1}{2}\right)$, we can write $S_1=\left[-\frac{1}{2},-\frac{3}{7}\right)\cup\left[-\frac{2}{7},\frac{2}{7}\right)\cup\left[\frac{3}{7},\frac{1}{2}\right)$, $S_2=\left[-\frac{1}{7},\frac{1}{7}\right)$, and $\widetilde{S_1}=\left[-\frac{1}{2},\frac{1}{2}\right]$. The canonical generalized filter functions then are:

$$h_{1,1}^{\mathcal{C}}(x)=\sqrt{2}\chi_{\left[-\frac{2}{7},-\frac{1}{4}\right)\cup\left[-\frac{1}{7},\frac{1}{7}\right)\cup\left[\frac{1}{4},\frac{2}{7}\right)}(x),$$

$$h_{2,1}^{\mathcal{C}}=\sqrt{2}\chi_{\left[-\frac{1}{2},-\frac{3}{7}\right)\cup\left[\frac{3}{7},\frac{1}{2}\right)}(x),$$

$$g_1^{\mathcal{C}}(x)=\sqrt{2}\chi_{\left[-\frac{1}{4},-\frac{1}{7}\right)\cup\left[\frac{1}{7},\frac{1}{4}\right)}(x);$$

$$h_{1,2}^{\mathcal{C}}(x)=0,$$

$$h_{2,2}^{\mathcal{C}}(x)=0,$$

$$g_2^{\mathcal{C}}(x)=\sqrt{2}\chi_{\left[-\frac{1}{7},\frac{1}{7}\right)}(x).$$

One calculates that the "initial condition" matrix $L_{\mathcal{C}}$ discussed in Remark 4.5 corresponding to this canonical filter system is the 3×3 matrix

$$L_{\mathcal{C}}=\begin{pmatrix}1&0&0\\0&0&1\\0&1&0\end{pmatrix}.$$

We now construct an element of the loop group L_p such that if M_J is the M-system corresponding to the above output of generalized low- and high-pass filters, the M-system $L_p\cdot M_J$ has as its output the filter functions corresponding to those given in the example in Section III. Consider the decomposition of the disjoint union $S_1\sqcup S_2$ (identified with a subset of $\left[-\frac{1}{2},\frac{1}{2}\right)\sqcup\left[-\frac{1}{2},\frac{1}{2}\right)$) given by

$$T_{1,1}=\pm\left[\frac{1}{7},\frac{3}{14}\right)(\text{here } m(x)\geqslant 1, m(2x)+\tilde{m}(2x)=1),$$

$$T_{1,2}=\pm\left[\frac{1}{14},\frac{1}{7}\right)\cup\pm\left[\frac{3}{14},\frac{2}{7}\right)(\text{here } m(x)\geqslant 1, m(2x)+\tilde{m}(2x)=2),$$

$$T_{1,3}=\left[-\frac{1}{14},\frac{1}{14}\right)\cup\pm\left[\frac{3}{7},\frac{1}{2}\right)(\text{here } m(x)\geqslant 1, m(2x)+\tilde{m}(2x)=3),$$

$$T_{2,2}=\pm\left[\frac{1}{14},\frac{1}{7}\right)(\text{here } m(x)=2, m(2x)+\tilde{m}(2x)=2),$$

$$T_{2,3}=\left[-\frac{1}{14},\frac{1}{14}\right)(\text{here } m(x)=2, m(2x)+\tilde{m}(2x)=3).$$

Then as in the general case, $S_j=\sqcup_{k=0}^{3}T_{j,k}$, $j=1,2$.

We now describe the M system $M_J: \sqcup_{i=1}^{2} S_i \to E_m$ associated to the filter functions above. We describe M_J as a cross section separately on both of the (disjoint) sets S_1 and S_2.

On S_1, M_J is given by

$$[M_J(x)] = \begin{cases} [\sqrt{2}] & \text{if } x \in T_{1,1} \\ [\sqrt{2},0] & \text{if } x \in \pm\left[\frac{1}{14},\frac{1}{7}\right) \cup \pm\left[\frac{1}{4},\frac{2}{7}\right) \subseteq T_{1,2} \\ [0,\sqrt{2}] & \text{if } x \in \pm\left[\frac{3}{14},\frac{1}{4}\right) \subseteq T_{1,2} \\ [0,\sqrt{2},0] & \text{if } x \in T_{1,3} \setminus T_{2,3} \\ [\sqrt{2},0,0] & \text{if } x \in [T_{1,3} \cap T_{2,3}]. \end{cases}$$

On S_2, M_J is given by

$$[M_J(x)] = \begin{cases} [0,\sqrt{2}] & \text{if } x \in T_{2,2} \\ [0,0,\sqrt{2}] & \text{if } x \in T_{2,3}. \end{cases}$$

Consider the decomposition of the circle $\mathbb{T}$ (identified with $[-\frac{1}{2}, \frac{1}{2})$) given by

$$P_1 = \left[-\frac{1}{7},\frac{1}{7}\right)\left(\text{here } m(x)=2, m\left(\frac{x}{2}\right)=2, m\left(\frac{x+1}{2}\right)=1\right),$$

$$P_2 = \pm\left[\frac{1}{7},\frac{2}{7}\right)\left(\text{here } m(x)=1, m\left(\frac{x}{2}\right)=2, m\left(\frac{x+1}{2}\right)=0\right),$$

$$P_3 = \pm\left[\frac{2}{7},\frac{3}{7}\right), \left(\text{here } m(x)=0, m\left(\frac{x}{2}\right)=1, m\left(\frac{x+1}{2}\right)=0\right),$$

$$P_4 = \pm\left[\frac{3}{7},\frac{1}{2}\right)\left(\text{here } m(x)=1, m\left(\frac{x}{2}\right)=1, m\left(\frac{x+1}{2}\right)=1\right).$$

We note the following, which will be useful in our calculations: $2T_{1,1}=P_3$, $2\left(\pm\left[\frac{3}{14},\frac{1}{4}\right)\right) = 2\left(\pm\left[\frac{1}{4},\frac{2}{7}\right)\right)=P_4$, $2T_{1,3}=P_1$, $2\left(\pm\left[\frac{1}{14},\frac{1}{7}\right)\right)=2T_{2,2}=P_2$, and $2T_{2,3}=P_1$.

Now as in Example 3.5, let p_0 be any classical (MRA) low-pass filter for dilation by 2, [i.e., one that satisfies the classical filter equation (1.1)], that also satisfies $p_0(x)=0$ for $x \in \pm\left(\frac{1}{7}-\epsilon, \frac{3}{14}+\epsilon\right) \cup \left(\frac{3}{7}-\epsilon, \frac{4}{7}+\epsilon\right)$. Note that by Eq. (1.1), we then have $p_0(x)=\sqrt{2}$ for $x \in \pm\left(\frac{2}{7}-\epsilon, \frac{5}{14}+\epsilon\right) \cup \left(-\frac{1}{14}-\epsilon, \frac{1}{14}+\epsilon\right)$. Let $\widetilde{p_0}=p_0/\sqrt{2}$ be the normalization of p_0, so that $\widetilde{p_0}(0)=1$. Let p_1 be the standard choice of associated high-pass filter, so that $p_1(x)=e^{2\pi i x}\overline{p_0\left(x+\frac{1}{2}\right)}$, and let $\widetilde{p_1}=p_1/\sqrt{2}$ be the normalization of p_1. Again, by Eq. (1.1), $\widetilde{p_1}$ must have modulus 1 for $x \in \pm\left(\frac{1}{7}-\epsilon, \frac{3}{14}+\epsilon\right) \cup \left(\frac{3}{7}-\epsilon, \frac{4}{7}+\epsilon\right)$.

The associated element of the loop group L_p that we want to choose is:

$$L_p(x)=\begin{cases}\begin{pmatrix}\widetilde{p_0}\left(\frac{x}{2}\right) & 0 & \widetilde{p_0}\left(\frac{x+1}{2}\right)\\ 0 & 1 & 0\\ \widetilde{p_1}\left(\frac{x}{2}\right) & 0 & \widetilde{p_1}\left(\frac{x+1}{2}\right)\end{pmatrix} & \text{if } x\in P_1\\ \begin{pmatrix}\widetilde{p_0}\left(\frac{x}{2}\right) & \widetilde{p_0}\left(\frac{x+1}{2}\right)\\ \widetilde{p_1}\left(\frac{x}{2}\right) & \widetilde{p_1}\left(\frac{x+1}{2}\right)\end{pmatrix} & \text{if } x\in P_2\\ \widetilde{p_1}\left(\frac{x}{2}\right) & \text{if } x\in P_3\\ \begin{pmatrix}\widetilde{p_0}\left(\frac{x+1}{2}\right) & \widetilde{p_0}\left(\frac{x}{2}\right)\\ \widetilde{p_1}\left(\frac{x+1}{2}\right) & \widetilde{p_1}\left(\frac{x}{2}\right)\end{pmatrix} & \text{if } x\in P_4.\end{cases}$$

On S_1, our new M system $[M_{p,J}(x)]=[L_p(2x)[M_J(x)]^t]^t$ is the M system $M_{p,J}$ defined by

$$[M_{p,J}](x)=\begin{cases}[p_1(x)] & \text{if } x\in T_{1,1}\\ [p_0(x),p_1(x)] & \text{if } x\in \pm\left[\frac{1}{14},\frac{1}{7}\right)\cup\pm\left[\frac{3}{14},\frac{1}{4}\right)\subseteq T_{1,2}\\ [p_0(x),p_1(x)] & \text{if } x\in \pm\left[\frac{1}{4},\frac{2}{7}\right)\subseteq T_{1,2}\\ [0,\sqrt{2},0] & \text{if } x\in \pm\left[\frac{3}{7},\frac{1}{2}\right)=T_{1,3}\setminus T_{2,3}\\ [p_0(x),0,p_1(x)] & \text{if } x\in \left[-\frac{1}{14},\frac{1}{14}\right)=T_{1,3}\cap T_{2,3}\\ \left[p_0\left(x+\frac{1}{2}\right),p_1\left(x+\frac{1}{2}\right)\right] & \text{if } x\in T_{2,2}\\ \left[p_0\left(x+\frac{1}{2}\right),0,p_1\left(x+\frac{1}{2}\right)\right] & \text{if } x\in T_{2,3}.\end{cases}$$

We thus obtain the generalized filter functions coming from $M_{p,J}$:

$$h^p_{1,1}(x)=p_0(x)\chi_{[-2/7,2/7)}(x),$$

$$h^p_{2,1}(x)=\sqrt{2}\chi_{[-1/2,-3/7)\cup[3/7,1/2)}(x),$$

$$g^p_1(x)=p_1(x)\chi_{[-2/7,1/7)\cup[1/7,2/7)}(x),$$

$$h^p_{1,2}(x)=p_0\left(x+\tfrac{1}{2}\right)\chi_{[-1/7,1/7)}(x),$$

$$h^p_{2,2}(x)=0,$$

$$g^p_2(x)=p_1\left(x+\tfrac{1}{2}\right)\chi_{[-1/7,1/7)}(x).$$

Note that these are exactly the filter functions obtained in Example 3.6.

One could no doubt adapt the previous example to obtain generalized filters similar to those given in Examples 4.2 and 4.3 of Ref. 36.

(Received 3 January 2005; accepted 31 May 2005; published online 26 July 2005)

We propose an alternative axiomatic description for noncommutative field theories (NCFT) based on some ideas by Soloviev to nonlocal quantum fields. The local commutativity axiom is replaced by the weaker condition that the fields commute at sufficiently large spatial separations, called asymptotic commutativity, formulated in terms of the theory of analytic functionals. The question of a possible violation of the CPT and spin-statistics theorems caused by nonlocality of the commutation relations $[\hat{x}_\mu,\hat{x}_\nu]=i\theta_{\mu\nu}$ is investigated. In spite of this inherent nonlocality, we show that the modification aforementioned is sufficient to ensure the validity of these theorems for NCFT. We restrict ourselves to the simplest model of a scalar field in the case of only space–space noncommutativity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1982769]

I. INTRODUCTION

In recent years a considerable effort has been made to clarify the structural aspects of noncommutative field theories (NCFT). The first paper on quantum field theory by exploring the noncommutativity of a space–time manifold was published by Snyder, in 1947,[1] who used this idea to give a solution for the problem of ultraviolet divergences which had plagued quantum field theories from the very beginning. Since then, due to the success of the renormalization theory, this subject was abandoned. Only recently the plan of investigating field theories on noncommutative space–times has been revived. In a fundamental paper Doplicher–Fredenhagen–Roberts[2] have shown that a model quantum space–time can be described by a noncommutative algebra whose commutation relations do imply uncertainty relations motivated by Heisenberg's uncertainty principle and by Einstein's theory. Later, in a different context, NCFT appear directly related with the string theory:[3] the noncommutative Yang–Mills theory can be seen as a vestige, in the low-energy limit, of open strings in the presence of a constant magnetic field, $B_{\mu\nu}$ (for a review see Refs. 4 and 5).

From an axiomatic standpoint, a language has been developed which, in principle, ought to enable one to extend the Wightman axioms to this context. Álvarez-Gaumé and Vásquez-Mozo[6] have recently taken the first step to examine general properties of NCFT within the axiomatic framework by modifying the standard Wightman axioms. By using as guiding principles the breaking of Lorentz symmetry down to the subgroup $\mathrm{O}(1,1)\times\mathrm{SO}(2)$, which leaves invariant the commutation relations for the coordinate operators $[\hat{x}_\mu,\hat{x}_\nu]=i\theta_{\mu\nu}$, and the relaxation of local commutativity to make it compatible with the causal structure of the theory, described by the light wedge associated with the O(1, 1) factor of the kinematical symmetry group, they have demonstrated the validity of the CPT theorem for NCFT. As it was stressed in Ref. 6, a source of

[a)]On leave from the Centro de Estudos de Física Teórica, Belo Horizonte, MG, Brasil. Electronic mail: dhtf@terra.com.br

difficulty in formulating NCFT which satisfy the adapted axioms has been the very harmful UV/IR mixing, which is probably the most surprising feature of these theories. The existence of hard infrared singularities in the nonplanar sector of the theory, induced by uncancelled quadratic ultraviolet divergences, can result in two kinds of problems: they can destroy the *tempered* nature of the Wightman functions and/or they can introduce tachyonic states in the spectrum, so the modified postulate of local commutativity is not preserved. This can be a signal that the NCFT must be analyzed from another set of principles, whose mathematical basis may shed new light on the existence (or not) of many of the desirable properties of fields, in particular the CPT operator and the connection between spin-statistics.

Clearly, in order to formulate a NCFT, a different type of generalized function space has to be used. First, we must to keep in mind that NCFT are *nonlocal* due to the commutation relations $[\hat{x}_\mu,\hat{x}_\nu]=i\theta_{\mu\nu}$. Second, this nonlocality can have implications on highly physical properties. For example, in the formulation of general properties of a field theory the localization plays a fundamental role in the concrete realization of the locality of field operators in coordinate space and the spectral condition in energy–momentum space, which are achieved through the *localization of test functions*—the fields are considered tempered functionals on the test function space $\mathcal{S}(\mathbb{R}^n)$, the Schwartz space of rapidly decreasing functions. However, the nonlocal character of the interactions in NCFT seems to suggest that there are good reasons to expect that fields are not tempered. Therefore, from a mathematical point of view, we must to have serious attention with the decision about the choice of the test function space to be used. This means that the extension of Wightman axioms to the context of NCFT has deeper roots in the mathematical structure and must first start with the replacement of the standard space $\mathcal{S}(\mathbb{R}^n)$ by another suitable space. As a matter of fact, since Wightman and Gårding formulated the quantum field theory in an axiomatic way, by regarding fields as operator-valued tempered distributions, many authors have attempted to generalize the theory to take in more fields represented by more singular generalized functions by restricting the class of test functions. We would like to mention the work by Jaffe,[7] on the strictly localizable field theory, and the work by Nagamachi–Mugibayashi[8] and Brüning–Nagamachi[9] on the field theory in terms of Fourier hyperfunctions. Wightman himself suggested that physically relevant interacting fields do not seem to be tempered.[10]

The class of distributions on which a NCFT should be built has been explored some time by Lücke[11–13] and Soloviev.[14–17] These authors have shown that one adequate solution to treat field theories with nonlocal interactions, it is to take the fields to be averaged with test functions belonging to the space $\mathcal{S}^0(\mathbb{R}^n)$ consisting of the restrictions to $\mathbb{R}^n$ of entire analytic functions on $\mathbb{C}^n$, whose Fourier transform is just the Schwartz space $\mathcal{D}(\mathbb{R}^n)$ of C^∞ functions of compact support. The space $\mathcal{S}^0(\mathbb{R}^n)$ is the smallest space among the Gelfand–Shilov spaces,[18] $\mathcal{S}^\beta(\mathbb{R}^n)$, where $0 \leqslant \beta < 1$, which naturally allows us to treat a theory of *nonlocalizable fields*. Elements in the dual space $\mathcal{S}'^0$ of the space of entire functions are called analytic functionals. Because the elements in $\mathcal{S}^0$ are entire functions, the locality axiom cannot be formulated in the usual way, i.e., there is no sensible notion of support for distributions in $\mathcal{S}'^0$. For this reason, in principle, expressing physical requirements such as the causality in clear way become problematic. Consequently, structural results of quantum field theories (QFT) usually seen to be firmly dependent on the locality, and that are supposed to be universally valid, do not *a priori* hold to the NCFT case. These structural results of QFT we have in mind here are (i) the existence of the fundamental symmetry CPT, and (ii) the spin-statistics connection.

The main purpose of this work is to show that, from a distributional-theoretical framework, the analysis of Álvarez-Gaumé and Vásquez-Mozo[6] on the extension of the Wightman axioms to the context of NCFT can be reformulated by adoption immediate of some ideas introduced by Soloviev,[14–17] which are applicable to noncommutative quantum field models. Then, we examine how essential are the locality of interactions and the microcausality axiom in order to reach a conclusion about the validity of the CPT and spin-statistics theorems in NCFT, in the case of only spatial noncommutativity—this choice preserves the unitarity[19] and the causality.[20] We show that both theorems hold within this environment if the postulate of microcausality suggested by

Álvarez-Gaumé and Vásquez-Mozo[6] is replaced with a condition implying the macrocausality as suggested by Soloviev.[14–17] This makes our proofs stronger than ones given byÁlvarez-Gaumé and Vásquez-Mozo,[6] in the sense that our hypotheses are weaker.

The article is organized as follows. Section II contains a brief sketch of some results by Soloviev about modern functional analysis that make it possible to extend the basic results of axiomatic approach[21,22] to nonlocal interactions. In Sec. III, the necessary modifications of the Wightman axioms to include the case of NCFT are explained. In Sec. IV, we outline the arguments that guarantee the validity of the CPT theorem and the spin-statistics relation for NCFT. Section V contains concluding remarks. We conclude with the Appendix which contains the sketch of proof of Proposition 4.1.

II. ANALYTIC FUNCTIONALS AND ANGULAR LOCALIZABILITY

In this section, we are going to introduce the basic facts which allow handling the analytic functionals of class $\mathcal{S}'^0$, in most cases, as easily as tempered distributions. As mentioned previously, the elements of $\mathcal{S}'^0$ are analytic functionals in the coordinate representation for which the notion of support is inapplicable. Nevertheless, Soloviev has shown that the functionals of this class retain a kind of *angular localizability*, which ensures the existence of minimal carrier cones of the distributions in $\mathcal{S}'^0$. This replaces the notion of support for nonlocalizable distributions and leads to a natural generalization of the local commutativity in NCFT with singular short distance behavior, since the latter theories are nonlocal. For sake of completeness, we recall this property here *mutatis mutandis*—the reader is referred to Refs. 14–17, and references therein for details.

We start recalling that the space of test functions composed by entire analytic functions is such that the following estimate holds:

$$|f(z)| \leqslant C_N(1+|x|)^{-N}e^{b|y|} \quad (z=x+iy), \quad N=0,1,\ldots,$$

where b and C_N are positive constants depending on f. The space of functions satisfying the previous estimate, with fixed b, is denoted as $\mathcal{S}^{0,b}$, whereas in nonlocal field theory the union $\cup_{b>0}\mathcal{S}^{0,b}$ is denoted as $\mathcal{S}^0$. Together with space $\mathcal{S}^0(\mathbb{R}^n)$, we introduce a space associated with closed cones $K\subset\mathbb{R}^n$. One recalls that K is called a cone if $x\in K$ implies $\lambda x\in K$ for all $\lambda>0$. Let U be an open cone in $\mathbb{R}^n$. For each U, one assigns a space $\mathcal{S}^0(U)$ consisting of those entire analytic functions on $\mathbb{C}^n$, that satisfy the inequalities

$$|f(z)| \leqslant C_N(1+|x|)^{-N}e^{b|y|+bd(x,U)}, \quad N=0,1,\ldots, \tag{2.1}$$

with $d(x,U)$ being the distance from the point x to the cone U (the norm in $\mathbb{R}^n$ is assumed to be Euclidean). This space can naturally be given a topology by regarding it as the inductive limit of the family of countably normed spaces $\mathcal{S}^{0,b}(U)$ whose norms are defined in accordance with inequalities (2.1), i.e.,

$$\|f\|_{U,b,N}=\sup_z|f(z)|(1+|x|)^N e^{-b|y|-bd(x,U)}.$$

For each closed cone $K\subset\mathbb{R}^n$, one also defines a space $\mathcal{S}^0(K)$ by taking another inductive limit through those open cones U that contain the set $K\backslash\{0\}$ and shrink to it. Clearly, $\mathcal{S}^0(\mathbb{R}^n)=\mathcal{S}^0$. As usual, we use a prime to denote the continuous dual of a space under consideration. A closed cone $K\subset\mathbb{R}^n$ is said to be a *carrier* of a functional $v\in\mathcal{S}'^0$ if v has a continuous extension to the space $\mathcal{S}^0(K)$, i.e., belongs to $\mathcal{S}'^0(K)$. As is seen from estimate (2.1), this property may be thought of as a fast decrease—no worse than an exponential decrease of order 1 and maximum type—of v in the complement of K. It should also be emphasized that if v is a tempered distribution with support in K, then the restriction $v|_{\mathcal{S}^0}$ is carried by K.

We now list some results proved by Soloviev, which formalize the property of angular localizability:

R.1: The spaces $\mathcal{S}^0(U)$ are Hausdorff and complete. A set $B\subset\mathcal{S}^0(U)$ is bounded if, and only if, it is contained in some space $\mathcal{S}^{0,b}(U)$ and is bounded in each of its norms.

R.2: The space $\mathcal{S}^0$ *is dense in every* $\mathcal{S}^0(U)$ *and in every* $\mathcal{S}^0(K)$.

R.3: If a functional $v \in \mathcal{S}'^0$ *is carried by each of closed cones* K_1 *and* K_2, *then it is carried by their intersection*.

R.4: If $v \in \mathcal{S}'^0(K_1 \cup K_2)$, *then* $v = v_1 + v_2$, *where* $v_j \in \mathcal{S}'^0(U_j)$ *and* U_j *are any open cones such that* $U_j \supset K_j \backslash \{0\}$, $j = 1, 2$.

III. ALTERNATIVE AXIOMATIC DESCRIPTION FOR NCFT

The axiomatic approach proposed by Gårding and Wightman for QFT consists of studying the consequences of a set of a few fundamental postulates on the theory such as the relativistic invariance, the locality, the existence and stability of the vacuum, in order to verify whether are logically consistent the basic principles suggested by the two pillars of the modern physics: the relativity theory and the quantum mechanics. The Wightman axioms can be summarized as follows: (i) States are described by vectors of a Hilbert space with positive definite metric. (ii) There is a *vacuum state* $|\Omega_0\rangle$ with the properties of being the state of lowest energy and invariant by all the unitary operators $\mathcal{U}(\Lambda, a)$ of the Poincaré group, where a is a space–time translation and Λ is a Lorentz transformation. (iii) The local fields are tempered distribution valued field operators. (iv) The spectrum of the energy–momentum operator is contained in the closed forward light cone. This condition is equivalent to the condition that the operators p_0 and p^2 are both positive. (v) Cyclicity of the vacuum. This means that one can construct a dense set of states in Hilbert space by application of products of field operators on this state. This condition ensures that the Hilbert space is not too large.

It turns out that these properties can be fully re-expressed in terms of an equivalent set of properties of the vacuum expectation values of their ordinary field products, called *Wightman functions* (or correlation functions of the theory):

$$\mathcal{W}_n(x_1, \ldots, x_n) \overset{\text{def}}{=} \langle \Omega_0 | \Phi(x_1) \cdots \Phi(x_n) | \Omega_0 \rangle. \tag{3.1}$$

For most purposes, the basis of the formulation of a QFT starts from a given set of Wightman functions which are assumed to satisfy the following properties:

P.1: Wightman functions are tempered distributions.

P.2: Wightman functions are invariant under the inhomogeneous Lorentz group.

P.3: Spectral condition: the Fourier transforms of the Wightman functions have support in the region

$$\left\{ (p_1, \ldots, p_n) \in \mathbb{R}^{4n} \Big| \sum_{j=1}^{n} p_j = 0, \sum_{j=1}^{k} p_j \in \bar{V}_+, k = 1, \ldots, n-1 \right\}, \tag{SC}$$

where $\bar{V}_+ = \{(p^0, \mathbf{p}) \in \mathbb{R}^4 | p^2 \geqslant 0, p^0 \geqslant 0\}$ is the closed forward light cone.

P.4: Local commutativity

$$\mathcal{W}_n(x_1, \ldots, x_i, x_{i+1}, \ldots, x_n) = \mathcal{W}_n(x_1, \ldots, x_{i+1}, x_i, \ldots, x_n) \quad \text{if } (x_i - x_{i+1})^2 < 0.$$

P.5: Condition of positive definiteness.

It can be shown on general grounds that a quantum field theory which satisfies all these conditions respect the CPT and spin-statistics theorems.[21,22]

As indicated in Sec. I, in NCFT the contact with the axiomatic formalism is made by modifying some of the Wightman axioms. In effect, most of the properties can be taken over in parallel with Wightman approach for tempered fields, except by following modifications:

Modification 1: We replace the test function space $\mathcal{S}(\mathbb{R}^n)$ by $\mathcal{S}^0(\mathbb{R}^n)$.

Modification 2: We replace the axiom of local commutativity, which cannot be formulated in terms of the analytic test functions, by asymptotic commutativity in the sense of Soloviev.

The main purpose of the present article is to show that NCFT subject to these modifications respect the CPT and spin-statistics theorems, within the same framework along the lines sketched in Refs. 14–17.

A. Fields are operator-valued distributions

As already mentioned, for NCFT we will assume that all fields are operator-valued generalized functions (throughout this paper, the term generalized functions is used synonymously with distributions) living in an appropriate space of functions $f(x) \in \mathcal{S}^0(\mathbb{R}^{4n})$, the space of entire analytic test functions. In particular, we will consider only one scalar field $\Phi(x)$. We shall denote by D_0 the minimal common invariant domain, which is assumed to be dense, of the field operators in the Hilbert space $\mathcal{H}$ of states, i.e., the vector subspace of $\mathcal{H}$ that is spanned by the vacuum state $|\Omega_0\rangle$ and by various vectors of the form $\Phi(f_1)\ldots\Phi(f_n)|\Omega_0\rangle$—with $(n=1,2,\ldots)$–where $f_i(x) \in \mathcal{S}^0(\mathbb{R}^4)$. It should be noted that, the space $\mathcal{S}^0$, being Fourier isomorphic to $\mathfrak{D}$, is *nuclear*. The property of nuclearity enables us to define in addition the expressions

$$\Phi^n(f) = \int \mathrm{d}x_1 \cdots \mathrm{d}x_n \Phi(x_1) \cdots \Phi(x_n) f(x_1,\ldots,x_n)|\Omega_0\rangle \quad (n=1,2,\ldots), \tag{3.2}$$

and to verify that every operator $\Phi(f)$ can be extended to the subspace $D_1 \supset D_0$ spanned by vectors (3.2).

Vacuum Expectation Values of Fields: The Wightman generalized functions $\mathcal{W}_n \in \mathcal{S}'^0(\mathbb{R}^{4n})$, i.e., the vacuum expectation values of fields (3.1) define analytic distributions on space $\mathcal{S}^0(\mathbb{R}^{4n})$. In Ref. 23, Chaichian *et al.* propose new Wightman functions as vacuum expectation values of field operators which involve the ★ products

$$\mathcal{W}_\star(x_1,\ldots,x_n) \overset{\text{def}}{=} \langle\Omega_0|\Phi(x_1) \star \Phi(x_2) \star \cdots \star \Phi(x_n)|\Omega_0\rangle, \tag{3.3}$$

where

$$\Phi(x_1) \star \Phi(x_2) = \exp\left(\frac{i}{2}\theta^{\mu\nu}\frac{\partial}{\partial x_1^\mu}\frac{\partial}{\partial x_2^\nu}\right)\Phi(x_1)\Phi(x_2),$$

represents a generalization of the ★ product for noncoinciding points, with the relation between the ordinary Wightman functions $\mathcal{W}_n(x_1,\ldots,x_n)$ and the new functions $\mathcal{W}_\star(x_1,\ldots,x_n)$ being defined by

$$\mathcal{W}_\star(x_1,\ldots,x_n) = \exp\left(\frac{i}{2}\theta^{\mu\nu}\sum_{i<j}\frac{\partial}{\partial x_i^\mu}\frac{\partial}{\partial x_j^\nu}\right)\mathcal{W}_n(x_1,\ldots,x_n),$$

which is a consequence of

$$\Phi(x_1) \star \cdots \star \Phi(x_n) = \exp\left(\frac{i}{2}\theta^{\mu\nu}\sum_{i<j}\frac{\partial}{\partial x_i^\mu}\frac{\partial}{\partial x_j^\nu}\right)\Phi(x_1)\cdots\Phi(x_n).$$

The new formulation of the Wightman functions has the advantage of including explicitly noncommutativity effects. In Ref. 6 the deformation parameter θ appears only to indicate that the Lorentz invariance is "broken" to a lower symmetry. However, in Ref. 23 the fields are still assumed to be *tempered* fields. In our opinion, same within the framework proposed in Ref. 23 the fields must be considered as generalized functions on space $\mathcal{S}^0(\mathbb{R}^{4n})$.

In what follows, by Wightman distributions we shall understand the vacuum expectation values of fields given by (3.1). It is very clear that the proofs of the CPT and spin-statistics theorems in Sec. V hold without modifications for the distributions (3.3), since the ★-products

introduced in the new Wightman functions no affect the analytic continuation of these functions to the complex plane with respect the "electrical" coordinates $x_e=(x^0,x^1)$. (The coordinates $\vec{x}_m=(x^2,x^3)$ are called "magnetic" coordinates in Ref. 6.)

B. Asymptotic commutativity

In extending the usual Wightman framework of the axiomatic quantum field theory our greatest concern is how to formulate the locality axiom for NCFT. The strict localizability of fields is connected, mathematically, with the fact that the test function space contains C^∞ functions of compact support. This requirement is satisfied by Wightman fields, because these fields were originally constructed on the basis of the space $\mathcal{S}$. But, this is not the case for fields constructed on the basis of the space $\mathcal{S}^0$.

In order to adapt the postulate of microcausality for NCFT, Álvarez-Gaumé and Vázquez-Mozo[6] (see also Ref. 24) have relaxed the condition that field (anti)commutators vanish outside the light cone, by replacing the light cone by the light *wedge* $V_{lw}=\{(x_e,\vec{x}_m)\in\mathbb{R}^4 \,|\, x_e^2=0\}$ so that

$$[\Phi(x_e,\vec{x}_m),\Phi(x'_e,\vec{x}'_m)]_\pm=0 \quad \text{if } (x_e-x'_e)^2=(x^0-x'^0)^2-(x^1-x'^1)^2<0. \tag{3.4}$$

Here, following Soloviev,[14–17] we relax the condition (3.4) and introduce, as a substitute for the axiom of locality, the following axiom:

Definition 3.1 (axiom of asymptotic (anti)commutativity): (It should be mentioned that the term "asymptotic commutativity" was introduced within the context which we have followed in Ref. 25 and with some other meaning in Ref. 11.) *The field components* $\Phi(x_e,\vec{x}_m)$ *and* $\Phi(x'_e,\vec{x}'_m)$ *are said to (anti)commute asymptotically for sufficiently large space-like separation of their arguments, if the functional*

$$f=\langle\Theta,[\Phi(x_e,\vec{x}_m),\Phi(x'_e,\vec{x}'_m)]_\pm\Psi\rangle, \tag{3.5}$$

is carried by the closed light wedge $\bar{V}_e^{(2)}\times\mathbb{R}^4=\{(x_e,\vec{x}_m);(x'_e,\vec{x}'_m)\in\mathbb{R}^{4\cdot2} \,|\, (x_e-x'_e)^2\geqslant 0\}$ *for any vectors* Θ, $\Psi\in D_0$.

A few comments about our requirement that the functional (3.5) is carried by the closed wedge $\bar{V}_e^{(2)}\times\mathbb{R}^4$ are now in order. In Ref. 6 this condition has been supported by the $\mathrm{SO}(1,1)\times\mathrm{SO}(2)$ symmetry, which is the feature arising when one has only spatial noncommutativity.[26] This fact leads the authors of Ref. 6 to argue that the notion of a light cone is generally modified to that of a light wedge. More recently, Chu *et al.*[29] have shown that the reduction from light cone to light wedge is a generic effect for noncommutative geometry and it is independent of the type of Lorentz symmetry breaking interaction.

A key point of the our argument is the equality $\mathcal{S}^0(\mathbb{R}^4\times\mathbb{R}^4)=\mathcal{S}^0(\mathbb{R}^4)\hat{\otimes}_i\mathcal{S}^0(\mathbb{R}^4)$, where the index i indicates that the tensor product is endowed with the inductive topology and the hat means the corresponding completion. By definition of the inductive topology, the dual space of $\mathcal{S}^0(\mathbb{R}^4)\hat{\otimes}_i\mathcal{S}^0(\mathbb{R}^4)$ is isomorphic to the space of separately continuous functionals on $\mathcal{S}^0(\mathbb{R}^4)\times\mathcal{S}^0(\mathbb{R}^4)$ (see Refs. 16 and 17). By result *R.2* in Sec. II, the space $\mathcal{S}^0(\mathbb{R}^4)$ is dense in $\mathcal{S}^0(U)$, where U is any open cone in $\mathbb{R}^4$ such that $\bar{V}_e^{(2)}\backslash\{0\}\subset U$. Hence, the functional f is carried by the closed cone $\bar{V}_e^{(2)}\times\mathbb{R}^4$. Moreover, a consideration analogous to that of Lemma 3 in Ref. 16 shows that if we introduce, for $0\leqslant j\leqslant n$ and $n=0,1,2,\ldots$, Wightman functions $\mathcal{W}_{n,j}\in\mathcal{S}'^0(\mathbb{R}^{4(n+2)})$ defined by

$$\mathcal{W}_{n,j}(x_1,\ldots,x_j,x,y,x_{j+1},\ldots,x_n)=\mathcal{W}_{n+2}(x_1,\ldots,x_j,x,y,x_{j+1},\ldots,x_n)\pm\mathcal{W}_{n+2}(x_1,\ldots,x_j,y,x,x_{j+1},\ldots,x_n),$$

it follows from the asymptotic commutativity condition that $\mathcal{W}_{n,j}$ defined on $\mathcal{S}^0(\mathbb{R}^{4(n+2)})$ has a continuous extension to the space $\mathcal{S}^0(\mathbb{R}^{4j}\times(U\times\mathbb{R}^4)\times\mathbb{R}^{4(n-j)})$. Then, $\mathcal{W}_{n,j}$ is carried by the closed cone $\mathbb{R}^{4j}\times(\bar{V}_e^{(2)}\times\mathbb{R}^4)\times\mathbb{R}^{4(n-j)}$.

IV. PROOF OF THE CPT AND SPIN-STATISTICS THEOREMS

In this section, we want to show that the above-mentioned arguments allow us to deduce some structural results of NCFT. We have in mind here the existence of the CPT symmetry[6,30] and the connection between spin and statistics.[30] The proof of these results as given in the literature[21,22] usually seem to rely on the tempered character of the distributions in an essential way. In the approach which we follow the main sources of difficulties in proving these results are: the absence of test functions of compact support and the fact that for functionals belonging to $\mathcal{S}'^0$ the notion of support breaks down. In Refs. 12 and 13, Lücke overcame this problem using the analyticity properties of vacuum expectation values in the momentum space and analyzed the relevant envelopes of holomorphy. More recently, an alternative and elegant solution has been given by Soloviev[14–16] using the notion of the analytic wavefront set and a type of uniqueness theorem for distributions. For simplicity, we are going to discuss the CPT and spin-statistics theorems only for the scalar field $\Phi(x)$. Ours results are corollaries of the Soloviev's theorems generalizing the CPT invariance and spin-statistics connection for nonlocal field theories, and our proofs follow directly from the chain of reasoning of Refs. 14–17.

A. CPT invariance

Let $\Phi(x)$ be a Hermitian scalar field. For this field, it is well known that in terms of the Wightman functions, a necessary and sufficient condition for the existence of CPT theorem is given by

$$\mathcal{W}_n(x_1,\ldots,x_n)=\mathcal{W}_n(-x_n,\ldots,-x_1). \tag{4.1}$$

Under the usual temperedness assumption, the proof of the equality (4.1) as given by Jost[31] starts from the weak local commutativity (WLC) condition, namely under the condition that the vacuum expectation value of the commutator of n scalar fields vanishes outside the light cone, which in terms of Wightman functions takes the form

$$\mathcal{W}_n(x_1,\ldots,x_n)-\mathcal{W}_n(x_n,\ldots,x_1)=0 \quad \text{for } (x_1,\ldots,x_n)\in\mathcal{J}_n, \tag{4.2}$$

where $\mathcal{J}_n$ represents the set of Jost points, which are real points lying outside the light cone. This implies that $(x_k-x_{k+1})^2<0$ for $k=1,\ldots,n-1$. Jost's proof that the WLC condition (4.2) is equivalent to the CPT symmetry (4.1) one relies on the fact that the proper complex Lorentz group contains the total space–time inversion. Therefore, by the Bargmann-Hall-Wightman (BHW) theorem, the equality $\mathcal{W}_n(x_n,\ldots,x_1)=\mathcal{W}_n(-x_n,\ldots,-x_1)$ holds taking into account the symmetry property $\mathcal{J}_n=-\mathcal{J}_n$ in whole extended analyticity domain.

In order to prove that equality (4.1) holds in NCFT, the following auxiliary proposition (proved in the Appendix) will be fundamental.

Proposition 4.1: The functional $F(x)=\mathcal{W}_n(x_1,\ldots,x_n)-\mathcal{W}_n(-x_1,\ldots,-x_n)$, *is carried by the complement of the Jost points*

$$\mathcal{J}_n=\left\{(x_1,\ldots,x_n)\in\mathbb{R}^{4n}\Big|\left(\sum_{i=1}^{n-1}\lambda_i(x_{e_i}-x_{e_{i+1}})\right)^2<0,\lambda_i\geqslant 0,\sum_{i=1}^{n-1}\lambda_i>0\right\}. \tag{JP}$$

Remark 1: It is worthwhile to emphasize that, according to Ref. 6, for $n>2$ the Jost points are formed by $(x_{e_i}-x_{e_{i+1}})^2<0$ with the condition that $x_i^1-x_{i+1}^1>0$.

We also formulate an analogous of the WLC condition:

Definition 4.2: The noncommutative quantum field $\Phi(x)$ *defined on the test function space* $\mathcal{S}^0(\mathbb{R}^{4n})$ *is said to satisfy the weak asymptotic commutativity (WAC) condition if the functional on left-hand side of Eq. (4.2) is carried by the set* $\complement\mathcal{J}_n$ *complementary to the Jost points (JP).*

Theorem 4.3 (Modified CPT Theorem): *In a noncommutative scalar field theory in which the modified Wightman axioms hold, the weak asymptotic commutativity condition is equivalent to the CPT invariance.*

Proof: We start assuming that the CPT invariance is fulfilled. This implies the equality

$$\mathcal{W}_n(x_1,\ldots,x_n) = \mathcal{W}_n(-x_n,\ldots,-x_1). \tag{4.3}$$

Then, one subtracts the functional $\mathcal{W}_n(-x_1,\ldots,-x_n)$ from the left-hand and right-hand sides of (4.3) in order to obtain the expression:

$$[\mathcal{W}_n(x_1,\ldots,x_n) - \mathcal{W}_n(-x_1,\ldots,-x_n)] = [\mathcal{W}_n(-x_n,\ldots,-x_1) - \mathcal{W}_n(-x_1,\ldots,-x_n)].$$

By Proposition 4.1, the difference functional on the left-hand side, denoted by $F(x)$, is carried by set $\complement\mathcal{J}_n$. Hence, from the previous functional equality, we conclude that the weak asymptotic commutativity condition is fulfilled. The reverse is also easily proved. If the WAC is satisfied, then the difference $\mathcal{W}_n(x_1,\ldots,x_n)-\mathcal{W}_n(-x_n,\ldots,-x_1)$ is carried by the set $\complement\mathcal{J}_n \neq \mathbb{R}^{4n}$. On the other hand, by virtue of the spectral condition,[32] the Fourier transform of this difference has support in the properly convex cone (SC), defined by Property P.3, in Sec. III. Therefore, the CPT invariance holds identically by Theorem 4 in Ref. 15, which asserts that $\mathcal{W}_n(x_1,\ldots,x_n)-\mathcal{W}_n(-x_n,\ldots,-x_1) \equiv 0$, since the property of this functional of having its Fourier transform supported by the aforementioned properly convex cone requires that each carrier of $\mathcal{W}_n(x_1,\ldots,x_n)-\mathcal{W}_n(-x_n,\ldots,-x_1)$ cannot be different from the whole space $\mathbb{R}^{4n}$. ■

B. Spin-statistics connection

Here, let us state the theorem for a scalar field only. The general case, mainly when gauge fields are present, deserves careful study once we have to admit an indefinite metric, which invalidates the connection of spin with statistics due the existence of "scalar fermions" as the Faddeev–Popov ghosts.[33]

Theorem 4.4 (Spin-Statistics Theorem): *Suppose that* Φ *and its Hermitian conjugate* Φ^* *satisfy the weak asymptotic condition with the "wrong" connection of spin and statistics. Then* $\Phi(x)\Omega_0=\Phi^*(x)\Omega_0=0$.

Proof: Under the hypothesis of the anomalous connection between spin and statistics, the weak asymptotic condition implies that

$$W_2(\xi) + W_2^{\mathrm{tr}}(-\xi) \in \mathcal{S}'^0(\bar{V}_e \times \mathbb{R}^2), \quad \xi = x_1 - x_2, \tag{4.4}$$

with $W_2(x_1-x_2)=\langle\Omega_0,\Phi(x_1)\Phi^*(x_2)\Omega_0\rangle$ and $W_2^{\mathrm{tr}}(x_2-x_1)=\langle\Omega_0,\Phi^*(x_2)\Phi(x_1)\Omega_0\rangle$. Using the same arguments as in the proof of the Proposition 4.1, we conclude that for the regularized function $W_2^{(\Lambda)}(\xi)$, the equality $W_2^{(\Lambda)}(\xi)=W_2^{(\Lambda)}(-\xi)$ takes place for the complement of the closed light wedge $\bar{V}_e\times\mathbb{R}^2$, according to BHW theorem. This implies that the difference $W_2^{(\Lambda)}(\xi)-W_2^{(\Lambda)}(-\xi)$ is carried by $\bar{V}_e\times\mathbb{R}^2$. Since the unregularized difference $W_2(\xi)-W_2(-\xi)$ admits a continuous extension to the space $\mathcal{S}^0(\bar{V}_e\times\mathbb{R}^2)$ as $\Lambda\to\infty$, it is possible to rewrite the condition (4.4) as $W_2(\xi)+W_2^{\mathrm{tr}}(\xi) \in \mathcal{S}'^0(\bar{V}_e\times\mathbb{R}^2)$. On the other hand, because of the spectral condition, in momentum space, $\tilde{W}_2 + \tilde{W}_2^{\mathrm{tr}}$ has support in the convex cone $\{(p_1,p_2)\in\mathbb{R}^8 \,|\, p_1+p_2=0, p_1\in\bar{V}_+\}$. Hence, again by Theorem 4 in Ref. 15 we get $W_2(\xi)+W_2^{\mathrm{tr}}(\xi)\equiv 0$. Finally, after averaging the fields with a test function, we obtain $\|\Phi^*(f)\Omega_0\|^2+\|\Phi(\bar{f})\Omega_0\|^2=0$, which yields $\Phi(x)\Omega_0=\Phi^*(x)\Omega_0=0$. ■

V. CONCLUDING REMARKS

In the present paper, we reexamine the recent work byÁlvarez-Gaumé and Vásquez-Mozo[6] on the extension of the Wightman axioms to the context of NCFT under another outlook. Our results are similar to those published in Ref. 6, but are obtained under mildly more general assumptions. We assume a weaker version of Wightman's axioms, where (a) fields are operator-valued generalized functions living in an appropriate space of functions $f(x)\in\mathcal{S}^0(\mathbb{R}^{4n})$, the space of entire analytic test functions, (b) the local (anti)commutativity is replaced by the asymptotic variant in the sense of Soloviev. Two profound results of the ordinary QFT, the existence of the symmetry

CPT and the spin-statistics connection were proved to hold for the case of a theory with space–space noncommutativity. Here, we restrict ourselves to the simplest case, that of a single, scalar, Hermitian field $\Phi(x)$ associated with spinless particles of mass $m>0$.

We would like to conclude mentioning a number of questions for future research based on the ideas of this paper:

(1) The arguments that we have used evidently may provide new insights which will allow us to study others structural results of QFT within the axiomatic description of NCFT, such as the existence of the Borchers class of quantum fields, a representation of the Jost–Lehmann–Dyson type, the Haag's theorem and so on.

(2) As it was pointed out in Ref. 6, for gauge theories, in particular the noncommutative QED (NCQED), the questions associated to the Wightman axioms and their consequences are more involved due to the UV/IR mixing. As already mentioned, the existence of hard infrared singularities in the nonplanar sector of the theory, induced by uncanceled quadratic ultraviolet divergences, can result in two kinds of problems: they can destroy the *tempered* nature of the Wightman functions and/or they can introduce tachyonic states in the spectrum, so the modified postulate of local commutativity *is not preserved*. Nevertheless, it is worthwhile to call attention to the fact that the nontemperedness arising from hard infrared singularities in NCFT is not a newness. Actually, in the case of the local and covariant formulation of standard gauge quantum field theories the necessary lack of positivity allows the occurrence of hard infrared singularities which recall those related to the UV/IR mixing in NCFT. These results appear to reinforce the hypothesis that the infrared issue in NCFT must be dealt with another approach which enables the simultaneous control of infrared singularities. This problem could be attacked with the Gelfand–Shilov spaces $\mathcal{S}^0_\alpha(\mathbb{R}^n)$, with $\alpha>1$—in order to obtain the nontriviality of $\mathcal{S}^0_\alpha$—being a multi-index which control the infrared behavior of the Wightman functions.[16,34] In this case the fields under consideration are ultradistributions, not distributions, in variables of the momentum space. This may be an interesting step in the proof of absence of the UV/IR mixing in NCFT and of the spin-statistics theorem for NCQED.

These topics are under investigation. We intend to report our conclusions on these issues in forthcoming papers.

ACKNOWLEDGMENTS

One of the authors (D.H.T.F.) would like to express his heartfelt gratitude to Professor O. Piguet for his kind invitations at the Departamento de Física, Universidade Federal do Espírito Santo (UFES). The other author (C.M.M.P.) was supported by the Brazilian agency CAPES. The authors are specially indebted to the referee for valuable comments and suggestions, which in fact lead to the clarification of various points. They are very grateful for his constructive criticisms.

APPENDIX: SKETCH OF PROOF OF THE PROPOSITION 4.1

Due to the nuclearity property for $\mathcal{S}^0(\mathbb{R}^{4n})$,[36] $\mathcal{W}_n$ is a multilinear functional which can be uniquely identified with a functional $\mathcal{W}_n(f,g)$ in $\mathcal{S}'^0(\mathbb{R}^{2n}\times\mathbb{R}^{2n})$, continuous separately over $f \in \mathcal{S}^0(\mathbb{R}^{2n})$ and $g \in \mathcal{S}^0(\mathbb{R}^{2n})$, defined by

$$\int \prod_{i=1}^{n} \mathrm{d}^2x_{e_i}\mathrm{d}^2\vec{x}_{m_i}\mathcal{W}_n((x_{e_1},\vec{x}_{m_1}),\ldots,(x_{e_n},\vec{x}_{m_n}))f(x_{e_1},\ldots,x_{e_n})g(\vec{x}_{m_1},\ldots,\vec{x}_{m_n}).$$

Taking into account the invariance under translations, we pass to the difference variables ξ_k, in order to obtain a generalized function

$$\mathcal{W}_n((x_{e_1},\vec{x}_{m_1}),\ldots,(x_{e_n},\vec{x}_{m_n})) = W_n((\xi_{e_1},\vec{\xi}_{m_1}),\ldots,(\xi_{e_{n-1}},\vec{\xi}_{m_{n-1}})),$$

in $\mathcal{S}'^0(\mathbb{R}^{2(n-1)}\times\mathbb{R}^{2(n-1)})$, which depends on the variables $\xi_{e_i}\in\mathbb{R}^{2(n-1)}$ and $\vec{\xi}_{m_i}\in\mathbb{R}^{2(n-1)}$. Following Soloviev,[16] we regularize the ultraviolet behavior of W_n by multiplying its Fourier transform $\widetilde{W}_n$ with a cutoff function. Then, with the "magnetic" coordinates being held fixed, we regularize the Fourier transform of $W_n((\xi_{e_1},\vec{\xi}_{m_1}),\ldots,(\xi_{e_{n-1}},\vec{\xi}_{m_{n-1}}))$ with an invariant cutoff function of form $\omega_\Lambda(p_e)=\omega((p_e\cdot p_e)/\Lambda^2)\in C_0^\infty(\mathbb{R})$, where $p_e\cdot p_e=p_0^2-p_1^2$ and such that $\omega_\Lambda(p_e)=1$ for $|(p_e\cdot p_e)/\Lambda^2|\leqslant 1$. The regularized distribution $W_n^{(\Lambda)}$ turns into a tempered distribution, in the "electrical" coordinates. Thus, $\widetilde{W}_n^{(\Lambda)}$ has an inverse Fourier–Laplace transform $\mathbf{W}_n^{(\Lambda)}$. The generalized function $\mathbf{W}_n^{(\Lambda)}((\zeta_{e_1},\vec{\xi}_{m_1}),\ldots,(\zeta_{e_{n-1}},\vec{\xi}_{m_{n-1}}))$, with $\zeta_{e_j}=\xi_{e_j}-i\eta_{e_j}$, is an analytic function of $2(n-1)$ complex variables on the "subtube" $T_{n-1}=\mathbb{R}^{2(n-1)}-iV_{e_+}^{(n-1)}$, where V_{e_+} is a subcone of the forward light cone V_+:

$$V_{e_+}=\{(\eta_e,\vec{\eta}_m)\in V_+|\,\eta_e^2>0,\eta^0>0,\vec{\eta}_m=0\}.$$

Under temperedness assumption, the function $\mathbf{W}_n^{(\Lambda)}$ can be analytically continued into the extended subtube $T_{n-1}^{\text{ext.}}$ by the BHW theorem, with the continued function being covariant under the Lorentz group $\mathcal{L}_+(\mathbb{C})$—the complexification of O(1,1) is made of similar way with that of the Lorentz group O(1,3). In particular, the transformations of $\mathcal{L}_+(\mathbb{C})$ leave the magnetic coordinates invariant (see Ref. 6 for details). Moreover, $\mathbf{W}_n^{(\Lambda)}$ has $W_n^{(\Lambda)}((\xi_{e_1},\vec{\xi}_{m_1}),\ldots,(\xi_{e_{n-1}},\vec{\xi}_{m_{n-1}}))=\mathcal{W}_n^{(\Lambda)}((x_{e_1},\vec{x}_{m_1}),\ldots,(x_{e_n},\vec{x}_{m_n}))$ as boundary value as $\eta_{e_j}\to 0$. Hence, the equality $\mathcal{W}_n^{(\Lambda)}(x_1,\ldots,x_n)=\mathcal{W}_n^{(\Lambda)}(-x_1,\ldots,-x_n)$ takes place in the corresponding analyticity domain, keeping in mind that the inversion of the four space-time coordinates is the product of the transformations $I_{\text{st}}\in\mathcal{L}_+(\mathbb{C})$ [see Eq. (3.5) in Ref. 6] and a SO(2) rotation of 180°. Since $T_{n-1}^{\text{ext.}}$ contains the Jost points, the tempered distribution $F^\Lambda(x)=\mathcal{W}_n^{(\Lambda)}(x_1,\ldots,x_n)-\mathcal{W}_n^{(\Lambda)}(-x_1,\ldots,-x_n)$ vanishes for the Jost points and its restriction to $\mathcal{S}^0$ is carried by $\complement\mathcal{J}_n$. By construction, $\widetilde{F}^\Lambda(p)$ coincides with $\widetilde{F}(p)$ in a neighborhood of the origin, which enlarges indefinitely as $\Lambda\to\infty$, and given that the space $\mathcal{S}^0(\mathbb{R}^{4n})$ is dense in $\mathcal{S}^0(\complement\mathcal{J}_n)$, the unregularized generalized function $F(x)\in\mathcal{S}'^0(\mathbb{R}^{4n})$ admits a continuous extension to the space $\mathcal{S}^0(\complement\mathcal{J}_n)$. This completes the outline of the proof.

[26] Undoubtedly, the analysis based in the *residual* symmetry $SO(1,1)\times SO(2)$ shows an inconvenience: both SO(1,1) and SO(2) being abelian groups, they have only one-dimensional unitary irreducible representations so that the particles cannot be classified according to the four-dimensional Wigner particle concept (Ref. 27). Hence, it would be interesting and instructive to reconsider the results obtained here on the light of the work of Doplicher–Fredenhagen–Roberts (Ref. 2), since the full Poincaré group is preserved, and/or on the light of the recent work of Chaichian *et al.* (Ref. 28), which invokes the concept of twisted Poincaré symmetry in order to show that the commutation relations $[\hat{x}_\mu,\hat{x}_\nu]=i\theta_{\mu\nu}$ can be interpreted in a Lorentz invariant way. In both approaches particles can be classified *à la* Wigner.

[32] Since there is no noncommutativity in momentum space, by assumption all Wightman function $\mathcal{W}_n$ satisfy the usual spectral condition so that for every n the support of the Fourier transform of $\mathcal{W}_n$ is contained in the set (SC)—defined by Property P.3, in Sec. III. Moreover, for a NCFT with $\theta_{\mu\nu}$ a constant matrix, the spectral condition (SC) is strongly supported by twisted Poincaré symmetry (Ref. 28). It has been shown that the commutation relations $[\hat{x}_\mu,\hat{x}_\nu]=i\theta_{\mu\nu}$ can be interpreted in a Lorentz invariant way and particles can be classified as in the usual commutative QFT case. As a result of this, the SC is given in terms of the invariants of the theory.

[33] N. Ohta, Phys. Rev. D **31**, 442 (1985).

[34] Particularly, this idea brings us back to a paper of Moschella-Strocchi (Ref. 35) in which it was suggested that, because of the nontemperedness, local and covariant formulations of gauge quantum field theories may require the use of test functions space of the type $\mathcal{S}^{\beta}_{\alpha}(\mathbb{R}^n)$.

[35] U. Moschella and F. Strocchi, Lett. Math. Phys. **24**, 103 (1992).

[36] Let us recall Lemma 2 of Ref. 13 in a form using the notion of carrier. Let $(f_1,\ldots,f_n)\to F_o(f_1,\ldots,f_n)$ be a multilinear functional on $\mathcal{S}^0(\mathbb{R})\times\cdots\times\mathcal{S}^0(\mathbb{R})$ that is continuous in each variable separately. Then there is a unique generalized function $F\in\mathcal{S}'^0(\mathbb{R}^n)$ fulfilling $F_o(f_1,\ldots,f_n)=\int \mathrm{d}x_1\cdots\mathrm{d}x_n F(x_1,\ldots,x_n)f(x_1)\cdots f(x_n)$, for $f(x_i)\in\mathcal{S}^0(\mathbb{R})$, with $i=1,\ldots,n$. Moreover, let $n'<n$ and let $M=\bar{M}\subset\mathbb{R}^{n'}$. If, for arbitrary $g(x_i)\in\mathcal{S}^0(\mathbb{R})$, with $i=n'+1,\ldots,n$, M is a carrier of $\mathcal{S}'^0(\mathbb{R}^{n'})$ element $f\to\int \mathrm{d}x_1\cdots\mathrm{d}x_n F(x_1,\ldots,x_n)f(x_1,\ldots,x_{n'})g(x_{n'+1})\cdots g(x_n)$, then $M\times\mathbb{R}^{n-n'}$ is a carrier of $F\in\mathcal{S}'^0(\mathbb{R}^n)$.

(Received 10 February 2005; accepted 15 March 2005; published online 27 July 2005)

In this article we study the following nonlinear Schrödinger equation $iu_t=\Delta u - g|u|^{p-1}u$ in a domain $\Omega\subset\mathbb{R}^n$ with initial condition $u(x,0)=\phi(x)$ and the Dirichlet boundary condition $u(x,t)=Q(x,t)$ on $\partial\Omega$, where ϕ, Q are given smooth functions. The nonlinear term contributes a negative term to the energy (i.e., $g<0$). We present the existence theorem for a global solution of finite energy when $p\leqslant 1+2/n$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1914730]

I. PRELIMINARIES

In this paper we are concerned with a Dirichlet inhomogeneous boundary value problem for a nonlinear Schrödinger equation in n space dimensions:

$$\begin{aligned} &i\,\partial_t u = \Delta u - g|u|^{p-1}u, \quad \text{for } x\in\Omega\subset\mathbb{R}^n,\\ &u(x,0)=\phi(x), \quad u(x,t)=Q(x,t), \quad \text{for } x\in\partial\Omega, \end{aligned} \tag{1.1}$$

where $g\in\mathrm{R}$ is a constant.

Inhomogeneous boundary value problems for nonlinear PDEs such as the NLS have physical implications. For example, in one space dimension, such problems are often called forced problems when an external force is applied to the time evolution of systems governed by nonlinear partial differential equations. Frequently the forcing is put in as a boundary condition. For instance, in ionospheric modification experiments of one space dimension, one directs a radio frequency wave at the ionosphere. At the reflection point of the wave, a sufficient level of electron plasma waves is excited to make the nonlinear behavior important. This may be described by the NLS equation with the cubic nonlinear term and a Dirichlet type of boundary condition.

It is well known that there is a very large literature on nonlinear Schrödinger equations in $\mathbb{R}^n$. However, for boundary value problems in a domain Ω, results are rare. Tsutsumi[1] and Tsutsumi[2] obtained well-posedness for the homogeneous problem in an exterior domain with sufficiently small and smooth initial data. Brezis and Gallouet[3] and Tsutsumi[4] studied the case of large initial data in two dimensions.

For inhomogeneous boundary conditions there were certain results in one space dimension. Bu[5] proved the well-posedness of smooth solutions with arbitrarily large data for $n=1$ and a nonlinear term of positive energy. Carroll and Bu[6] proved the same for $n=1$ and a nonlinear cubic term of either sign. There are also some results in one dimension using inverse scattering techniques.

[a)]Corresponding author. Electronic mail: cbu@wellesley.edu; fax (781) 283-3642.

When space dimension $n>1$, Strauss and Bu[7] obtained the global existence of an H^1 solution if the nonlinear term contributes a positive term to the energy, i.e., $g>0$.

Our main objective is to prove a similar theorem when $g<0$.

II. *A PRIORI* ESTIMATES

Write $P=\nabla u|_{\partial\Omega}$, $\eta=\Sigma_j \partial_j \xi_j=\nabla\cdot\xi$, and $\mathbf{n}=(n_1,n_2,\ldots,n_n)$ standard unit outer normal vector for $\partial\Omega$. Since $\partial\Omega$ is smooth, there exists a smooth function $\xi=(\xi_1,\xi_2,\ldots,\xi_n)$ independent of t from $\mathbb{R}^n$ to $\mathbb{R}^n$, such that $\xi|_{\partial\Omega}=(n_1,n_2,\ldots,n_n)=\mathbf{n}$. In case $\partial\Omega$ is unbounded, we assume that (a) the derivatives up to third order of ξ are bounded and (b) there exists $R>0$ such that $Q(x,t)=0$ for $|x|>R$. We sometimes denote $\partial_j u=\partial u/\partial x_j$ for $j=1,2,\ldots,n$.

The following lemma was proved in Ref. 7.

Lemma 2.1: For the nonlinear Schrödinger equation in n space dimensions with Dirichlet inhomogeneous boundary condition (1.1), four a priori identities are available: First,

$$\partial_t \int_\Omega |u|^2\,\mathrm{d}x = 2\,\mathrm{Im}\int_{\partial\Omega}(\mathbf{n}\cdot P)\bar{Q}\,\mathrm{d}S. \tag{2.1}$$

Second,

$$\partial_t \int_\Omega \left(|\nabla u|^2+\frac{2g}{p+1}|u|^{p+1}\right)\mathrm{d}x = 2\,\mathrm{Re}\int_{\partial\Omega}(\mathbf{n}\cdot P)\bar{Q}_t\,\mathrm{d}S. \tag{2.2}$$

Third,

$$\begin{aligned}\partial_t \int_\Omega u(\xi\cdot\nabla u)\mathrm{d}x - \int_{\partial\Omega} Q\bar{Q}_t\,\mathrm{d}S + \int_\Omega \eta u\bar{u}_t\,\mathrm{d}x = &-2i\int_{\partial\Omega}|\mathbf{n}\cdot P|^2\,\mathrm{d}S - \sum_{m,j}\int_\Omega \partial_m\xi_j\,\partial_m u\,\partial_j\bar{u}\,\mathrm{d}x\\ &+ i\int_{\partial\Omega}|P|^2\,\mathrm{d}S - i\int_\Omega \eta|\nabla u|^2\,\mathrm{d}x\\ &+ i\frac{2g}{p+1}\int_{\partial\Omega}|Q|^{p+1}\,\mathrm{d}S - i\frac{2g}{p+1}\int_\Omega \eta|u|^{p+1}\,\mathrm{d}x.\end{aligned} \tag{2.3}$$

Fourth,

$$\begin{aligned}i\int_{\partial\Omega}[2|\mathbf{n}\cdot P|^2-|P|^2+(\mathbf{n}\cdot\bar{P})Q\eta]\mathrm{d}S = &\int_{\partial\Omega}\left[Q\bar{Q}_t+i\frac{2g}{p+1}|Q|^{p+1}\right]\mathrm{d}S - \partial_t\int_\Omega u(\xi\cdot\nabla u)\mathrm{d}x\\ &- i\int_\Omega\left\{\eta\left[+\frac{2g}{p+1}|u|^{p+1}\right]-(\nabla\eta\cdot\nabla\bar{u})u\right\}\mathrm{d}x\\ &-\int_\Omega\left\{\sum_{j,m}\partial_m\xi_j\,\partial_m u\,\partial_j\bar{u}-\mathrm{i}\,\eta|u|^{p+1}\right\}\mathrm{d}x.\end{aligned} \tag{2.4}$$

To prove global existence, consider $[0,T]$ for any $T>0$. We define

$$|P|^2=|\mathbf{n}\cdot P|^2+|A\cdot P|^2=|\mathbf{n}\cdot P|^2+|A\cdot\nabla\tilde{Q}|^2 \tag{2.5}$$

and

$$J^2 = \int_0^t \int_{\partial\Omega} |\mathbf{n} \cdot P|^2 \, \mathrm{d}S \, \mathrm{d}\tau, \tag{2.6}$$

where $A \cdot P$ denotes the tangential component of P. Integrating (2.1) and (2.2) over $[0,t]$, we obtain

$$\|u\|_2^2 \leqslant c + cJ \quad \text{and} \quad \|\nabla u\|_2^2 + \frac{2g}{p+1}\|u\|_{p+1}^{p+1} \leqslant c + cJ, \tag{2.7}$$

where c is treated as a generic constant (see Ref. 7, for example).

From Gagliardo-Nirenburg estimate:[10]

$$\|u\|_{p+1} \leqslant m(\|\nabla u\|_2^a \|u\|_2^{1-a} + \|u\|_2), \tag{2.8}$$

where

$$\frac{1}{p+1} = a\left(\frac{1}{2} - \frac{1}{n}\right) + \frac{1-a}{2}. \tag{2.9}$$

We find

$$a = \frac{n}{2} - \frac{n}{p+1}, \tag{2.10}$$

$$a(p+1) = \frac{n}{2}(p-1), \tag{2.11}$$

and

$$(1-a)(p+1) = \left(1 - \frac{n}{2}\right)(p+1) + n. \tag{2.12}$$

Case (i): $p < 1 + 2/n$. From (2.11) and (2.12) one has

$$a(p+1) = \beta < \frac{n}{2}\left(1 + \frac{2}{n} - 1\right) = 1 \tag{2.13}$$

and

$$(1-a)(p+1) \leqslant \left(1 - \frac{n}{2}\right)\left(2 + \frac{2}{n}\right) + n = 1 + \frac{2}{n} \leqslant 2; \tag{2.14}$$

here we assume that $n \geqslant 2$.

Therefore (2.8), (2.13), and (2.14) imply that (noting that $p+1 \leqslant 2 + \frac{2}{h} \leqslant 3$)

$$\|u\|_{p+1}^{p+1} \leqslant (\|\nabla u\|_2^\beta (\|u\|_2^2 + 1) + \|u\|_2^3 + 1) \leqslant \epsilon \|\nabla u\|_2^2 + \epsilon \|u\|_2^4 + c \leqslant c + cJ + c\epsilon J^2, \tag{2.15}$$

for any $\epsilon > 0$ and some c depending on m, ϵ and initial data.

Combining (2.6), (2.7), and (2.15) one has (again we treat c as a generic constant)

$$\|u\|_2^2 + \|\nabla u\|_2^2 \leqslant c + cJ + c\epsilon J^2. \tag{2.16}$$

Substituting (2.5) into (2.4), integrating over $[0,t]$, where $t < T$ and using the assumption that up to three derivatives of ξ are bounded, we obtain

$$J^2 \leqslant \left| \int_\Omega u(\xi \cdot \nabla u)\mathrm{d}x \right| + \left| \int_\Omega \phi(\xi \cdot \nabla \phi)\mathrm{d}x \right| + \int_0^t \int_{\partial\Omega} |A \cdot \nabla \tilde{Q}|^2 \,\mathrm{d}S\,\mathrm{d}\tau + \int_0^t \int_{\partial\Omega} |Q\bar{Q}_t|\mathrm{d}S\,\mathrm{d}\tau$$
$$+ c\int_0^t \int_{\partial\Omega} |(\mathbf{n}\cdot\bar{P})Q|\mathrm{d}S\,\mathrm{d}\tau + c\int_0^t \int_\Omega |\nabla u||u|\mathrm{d}x\,\mathrm{d}\tau + c\int_0^t \int_\Omega |\nabla u|^2\,\mathrm{d}x\,\mathrm{d}\tau$$
$$- \frac{2g}{p+1}\int_0^t \int_{\partial\Omega} |Q|^{p+1}\,\mathrm{d}S\,\mathrm{d}\tau - \frac{2g}{p+1}\int_0^t \int_\Omega |u|^{p+1}\,\mathrm{d}x\,\mathrm{d}\tau. \tag{2.17}$$

Since $\phi \in H^1(\Omega)$, Q is C^3 with compact support in x, each term in (2.17) involving ϕ and Q is bounded. Therefore (2.17) is estimated as

$$J^2 \leqslant c' + c'J + c'\int_\Omega (|u|^2 + |\nabla u|^2)\mathrm{d}x + c'\int_0^t \int_\Omega (|u|^2 + |\nabla u|^2)\mathrm{d}x\,\mathrm{d}\tau + c'\int_0^t \int_\Omega |u|^{p+1}\,\mathrm{d}x\,\mathrm{d}\tau. \tag{2.18}$$

It is important to note that all the constants denoted by c and c' only depend on n, p, Q, T, ϕ, and $\partial\Omega$, but not on u. Let ϵ be sufficiently small such that $\epsilon c c' = \frac{1}{4}$. Substituting (2.15) and (2.16) into (2.18) we obtain

$$\begin{aligned} J^2 &\leqslant c' + c'J + c'(c + cJ + c\epsilon J^2) + 2c'\int_0^t (c + cJ + c\epsilon J^2)\mathrm{d}\tau \\ &\leqslant c' + \frac{1}{2}\left((2c')^2 + \left(\frac{J}{2}\right)^2\right) + c'c + \frac{1}{2}\left((2c'c)^2 + \left(\frac{J}{2}\right)^2\right) + \frac{J^2}{4} + 2c'\int_0^t \left(c + \frac{1}{2}(c^2 + J^2) + c\epsilon J^2\right)\mathrm{d}\tau \\ &\leqslant c' + 2(c')^2 + \frac{J^2}{8} + c'c + 2(c'c)^2 + \frac{J^2}{8} + \frac{J^2}{4} + 2c'cT + c'c^2T + \left(c' + \frac{1}{2}\right)\int_0^t J^2\,\mathrm{d}\tau \\ &\leqslant c_0 + \frac{J^2}{2} + c_0\int_0^t J^2\,\mathrm{d}\tau. \end{aligned} \tag{2.19}$$

Then (2.19) implies that

$$J^2 \leqslant 2c_0 + 2c_0\int_0^t J^2\,\mathrm{d}\tau. \tag{2.20}$$

By Gronwall's lemma there exists $M > 0$ depending on n, p, Q, T, ϕ, and $\partial\Omega$, such that

$$J^2 \leqslant M, \tag{2.21}$$

for any $t \in [0, T]$.

By (2.16) we deduce that $\|u\|_{H^1}$ is bounded for bounded T.

Case (ii) $p = 1 + 2/n$. For any $\epsilon > 0$, let t_1 be sufficiently small, such that

$$\int_0^{t_1} \int_{\partial\Omega} (|Q|^2 + |Q_t|^2)\mathrm{d}S\,\mathrm{d}\tau < \epsilon. \tag{2.22}$$

Thus (2.6) and (2.7) are modified as

$$\|u\|_2^2 \leqslant c + \epsilon J \tag{2.23}$$

and

$$\|\nabla u\|_2^2 + \frac{2g}{p+1}\|u\|_{p+1}^{p+1} \leqslant c + \epsilon J, \tag{2.24}$$

for $t \in [0,t_1]$. Since

$$a(p+1) = \frac{n}{2}\left(1 + \frac{2}{n} - 1\right) = 1 \tag{2.25}$$

and

$$(1-a)(p+1) = \left(1 - \frac{n}{2}\right)\left(2 + \frac{2}{n}\right) + n = 1 + \frac{2}{n} \leqslant 2, \tag{2.26}$$

(2.15) becomes (for any $t \in [0,t_1]$)

$$\|u\|_{p+1}^{p+1} \leqslant (\|\nabla u\|_2(\|u\|_2^2 + 1) + \|u\|_2^3 + 1) \leqslant \delta\|\nabla u\|_2^2 + c'\|u\|_2^4 + c', \tag{2.27}$$

for any sufficiently small δ.

Substituting (2.23) and (2.27) into (2.24) we obtain

$$\|\nabla u\|_2^2 \leqslant \tilde{c}(c + \epsilon J + \|u\|_2^4) \leqslant \tilde{c}(c + \epsilon J + (c + \epsilon J)^2) \leqslant \hat{c} + \hat{c}\epsilon J^2. \tag{2.28}$$

By combining (2.23), (2.27), and (2.28), and choosing ϵ, δ sufficiently small, we estimate (2.17) as

$$J^2 \leqslant c + c\epsilon J^2 + \int_0^t (c + c\epsilon J^2)\mathrm{d}\tau, \tag{2.29}$$

where c only depends on ϵ, δ, n, p, Q, t_1, ϕ, and $\partial\Omega$. This proves that u is bounded in H^1 space on $[0,t_1]$.

Since $Q \in C^3$ has compact support, for any $\epsilon > 0$, $T > 0$ there exists a finite partition $0 \leqslant t_1 \leqslant t_2, \cdots \leqslant t_N = T$, such that

$$\int_{t_i}^{t_{i+1}} (|Q|^2 + |Q_t|^2)\mathrm{d}\tau \leqslant \epsilon, \tag{2.30}$$

for $i = 1,2,\ldots,N-1$. By mathematical induction we conclude that u is bounded in H^1 space on $[0,T]$. Since T is arbitrary, this solution is a global solution in H^1.

The existence and uniqueness theorem can be obtained in the similar manner as in Refs. 7–9 by truncating the nonlinear term, converting the original problem into a problem with a homogeneous boundary condition, and applying Aubin's compactness theorem and Cantor diagonalization. For uniqueness, we notice that $p < 1 + 4/(n-2)$ is required in case of $g > 0$ for a Dirichlet inhomogeneous boundary value problem for the NLS.[7] However, $p \leqslant 1 + 2/n$ would ensure that. Therefore, we have the following result.

Global existence-uniqueness theorem: *For $n > 1$, $g < 0$, assume that $p \leqslant 1 + 2/n$. Let $\phi \in H^1(\Omega)$ and Ω be a (bounded or unbounded) open subset of $\mathbb{R}^n$ with a C^∞ boundary. Suppose that $Q \in C^3(\partial\Omega \times (-\infty,\infty))$ has compact support and satisfies the compatibility condition $\phi(x) \equiv Q(x,0)$ on $\partial\Omega$ in the sense of traces. Then there exists a solution $u \in L^\infty_{\mathrm{loc}}((-\infty,\infty); H^1(\Omega) \cap L^{p+1}(\Omega))$ to the problem (1.1) for $-\infty < t < \infty$. The PDE is understood in the sense of distributions while the boundary condition is understood as $u(\cdot,t) - Q(\cdot,t) \in H_0^1(\Omega)$ for a.e. t. Further, if $\|e^{i\Delta t}\|_{\mathcal{L}(L^1(\Omega),L^\infty(\Omega))} \leqslant c/t^{n/2}$, where $e^{i\,\Delta t}$ denotes the evolution operator for the free Schrödinger equation with a homogeneous boundary condition on $\partial\Omega$, then this solution is unique.*

We state the following remark as the conclusion of this paper.

Remark: In the case of $n = 1$, we note that global existence was found if $p < 3$ (see Ref. 6), which is consistent with our criteria for global existence in general n space dimensions $p < 1 + 2/n$. We also did some numerical calculations using the FLEXPDE *program when $n = 2,3$. We are*

particularly interested in the situation $p>1+2/n$ *when* $n=2$ *and* $1+2/n<p<1+4/(n-2)$ *when* $n=3$ *with assorted initial and boundary data. However, the results do not seem to be conclusive and therefore further study is needed.*

(Received 8 February 2005; accepted 6 June 2005; published online 27 July 2005)

We consider the variational problem of maximizing the weighted equilibrium Green's energy of a distribution of charges free to move in a subset of the upper half-plane, under a particular external field. We show that this problem admits a solution and that, under some conditions, this solution is an S-curve (in the sense of Gonchar-Rakhmanov). The above problem appears in the theory of the semiclassical limit of the integrable focusing nonlinear Schrödinger equation. In particular, its solution provides a justification of a crucial step in the asymptotic theory of nonlinear steepest descent for the inverse scattering problem of the associated linear non-self-adjoint Zakharov-Shabat operator and the equivalent Riemann-Hilbert factorization problem. © *2005 American Institute of Physics.*

I. INTRODUCTION

Let $\mathbb{H}=\{z:\operatorname{Im} z>0\}$ be the complex upper-half plane and $\overline{\mathbb{H}}=\{z:\operatorname{Im} z\geqslant 0\}\cup\{\infty\}$ be the closure of $\mathbb{H}$. Let also $\mathbb{K}=\{z:\operatorname{Im} z>0\}\backslash\{z:\operatorname{Re} z=0, 0<\operatorname{Im} z\leqslant A\}$, where A is a positive constant. In the closure of this space, $\overline{\mathbb{K}}$, we consider the points ix_+ and ix_-, where $0\leqslant x<A$ as distinct. In other words, we cut a slit in the upper half-plane along the segment $(0,iA)$ and distinguish between the two sides of the slit. The point infinity belongs to $\overline{\mathbb{K}}$, but not $\mathbb{K}$. We define $\mathbb{F}$ to be the set of all "continua" F in $\overline{\mathbb{K}}$ (i.e., connected compact sets) containing the distinguished points $0_+,0_-$.

Next, let $\rho^0(z)$ be a given complex-valued function on $\overline{\mathbb{H}}$ satisfying

$$\begin{gathered}\rho^0(z)\ \textit{is holomorphic in}\ \mathbb{H},\\ \rho^0(z)\ \textit{is continuous in}\ \overline{\mathbb{H}},\\ \operatorname{Re}[\rho^0(z)]=0,\quad \textit{for}\ z\in[0,iA],\\ \operatorname{Im}[\rho^0(z)]>0,\quad \textit{for}\ z\in(0,iA]\cup\mathbb{R}.\end{gathered}\tag{1}$$

Define $G(z;\eta)$ to be the Green's function for the upper half-plane

$$G(z;\eta)=\log\frac{|z-\eta^*|}{|z-\eta|}\tag{2}$$

and let $\mathrm{d}\mu^0(\eta)$ be the non-negative measure $-\rho^0(\eta)\mathrm{d}\eta$ on the segment $[0,iA]$ oriented from 0 to iA. The star denotes complex conjugation. Let the "external field" ϕ be defined by

$$\phi(z) = -\int G(z;\eta)\mathrm{d}\mu^0(\eta) - \mathrm{Re}\left(i\pi J \int_z^{iA} \rho^0(\eta)\mathrm{d}\eta + 2iJ(zx+z^2t)\right), \tag{3}$$

where x,t are real parameters with $t\geqslant 0$ and $J=1$, *for* $x\geqslant 0$, while $J=-1$, *for* $x<0$. Re denotes the real part.

The particular form of this field is dictated by the particular application to the dynamical system we are interested in. The conditions (1) are natural in view of this application. But many of our results in this paper are valid if the term $zx+z^2t$ is replaced by any polynomial in z. Here x,t are in fact the space and time variables for the associated partial differential equation (PDE) problem [see (9) and (10) below].

Let $\mathbb{M}$ be the set of all positive Borel measures on $\overline{\mathbb{K}}$, such that both the free energy

$$E(\mu) = \int\int G(x,y)\mathrm{d}\mu(x)\mathrm{d}\mu(y), \quad \mu \in \mathbb{M} \tag{4}$$

and $\int \phi\, \mathrm{d}\mu$ are finite. Also, let

$$V^{\mu}(z) = \int G(z,x)\mathrm{d}\mu(x), \quad \mu \in \mathbb{M} \tag{5}$$

be the Green's potential of the measure μ.

The weighted energy of the field ϕ is

$$E_{\phi}(\mu) = E(\mu) + 2\int \phi\, \mathrm{d}\mu, \quad \mu \in \mathbb{M}. \tag{6}$$

Now, given any continuum $F \in \mathbb{F}$, the equilibrium measure λ^F supported in F is defined by

$$E_{\phi}(\lambda^F) = \min_{\mu \in M(F)} E_{\phi}(\mu), \tag{7}$$

where $M(F)$ is the set of measures in $\mathbb{M}$ which are supported in F, provided such a measure exists. $E_{\phi}(\lambda^F)$ is the equilibrium energy of F.

The aim of this paper is to prove the existence of a so-called S-curve (Ref. 1) joining the points 0_+ and 0_- and lying entirely in $\overline{\mathbb{K}}$, at least under some extra assumptions. By S-curve we mean an oriented curve F such that the equilibrium measure λ^F exists, its support consists of a finite union of analytic arcs and at any interior point of supp μ,

$$\frac{d}{\mathrm{d}n_+}(\phi + V^{\lambda^F}) = \frac{d}{\mathrm{d}n_-}(\phi + V^{\lambda^F}), \tag{8}$$

where the two derivatives above denote the normal (to supp μ) derivatives.

To prove the existence of the S-curve we will first need to prove the existence of a continuum F maximizing the equilibrium energy over $\mathbb{F}$. Then we will show that the maximizer is in fact an S-curve.

It is not always true that an equilibrium measure exists for a given continuum. The Gauss-Frostman theorem (Ref. 2, p.135) guarantees the existence of the equilibrium measure when F does not touch the boundary of the domain $\mathbb{H}$. This is not the case here. Still, as we show in the next section, in the particular case of our special external field, for any given x,t and for a large class of continua F not containing infinity, the weighted energy is bounded below and λ^F exists. So, in particular, we do know that the supremum of the equilibrium weighted energies over all continua is greater than $-\infty$.

S-curves were first defined in Ref. 1, where the concept first arose in connection with the problem of rational approximation of analytic functions. Our own motivation comes from a seem-

ingly completely different problem, which is the analysis of the so-called semiclassical asymptotics for the focusing nonlinear Schrödinger equation. More precisely, we are interested in studying the behavior of solutions of

$$i\hbar\partial_t\psi + \frac{\hbar^2}{2}\partial_x^2\psi + |\psi|^2\psi = 0,$$
$$\text{under } \psi(x,0) = \psi_0(x), \tag{9}$$

in the so-called semiclassical limit, i.e., as $\hbar \to 0$. For a concrete discussion, let us here assume that $\psi_0(x)$ is a positive "bell-shaped" function; in other words assume that

$$\psi_0(x) > 0, \quad x \in \mathbb{R},$$
$$\psi_0(-x) = \psi_0(x),$$
$$\psi_0 \text{ has one single local maximum at } 0, \quad \psi_0(0) = A, \tag{10}$$
$$\psi_0''(0) < 0,$$
$$\psi_0 \text{ is Schwartz}.$$

This is a completely integrable PDE and can be solved via the method of inverse scattering. The semiclassical limit is analyzed in the recent research monograph.[3] In Chap. 8 of Ref. 3 it is noted that the semiclassical problem is related and can be reduced to a particular "electrostatic" variational problem of maximizing the equilibrium energy of a distribution of charges that are free to move under a given external electrostatic field (assuming that the WKB-approximated density of the eigenvalues admits a holomorphic extension in the upper half-plane). In fact, it is pointed out that the existence and regularity of an S-curve implies the existence of the so-called "g-function" necessary to justify the otherwise rigorous methods employed in Ref. 3.

We would like to point out that the problem of the existence of the "g function" for the semiclassical nonlinear Schrödinger problem is not a mere technicality of isolated interest. Rather, it is an instance of a crucial element in the asymptotic theory of Riemann-Hilbert problem factorizations associated to integrable systems. This asymptotic method has been made rigorous and systematic in Ref. 4 where in fact the term "nonlinear steepest descent method" was first employed to stress the relation with the classical "steepest descent method" initiated by Riemann in the study of exponential integrals with a large phase parameter. Such exponential integrals appear in the solution of Cauchy problems for linear evolution equations, when one employs the method of Fourier transforms. In the case of nonlinear integrable equations, on the other hand, the nonlinear analog of the Fourier transform is the scattering transform and the inverse problem is now a Riemann-Hilbert factorization problem. While in the "linear steepest descent method" the contour of integration must be deformed to a union of contours of "steepest descent" which will make the explicit integration of the integral possible, in the case of the "nonlinear steepest descent method" one deforms the original Riemann-Hilbert factorization contour to appropriate steepest descent contours where the resulting Riemann-Hilbert problems are explicitly solvable.

In the linear case, if the phase and the critical points of the phase are real it may not be necessary to deform the integration contour. One has rather a Laplace integral problem on the contour given. For Riemann-Hilbert problems the analog is the self-adjointness of the underlying Lax operator. In this case the spectrum of the associated linear Lax operator is real and the original Riemann-Hilbert contour is real. The "deformation contour" must then stay near the real line. One novelty of the semiclassical problem for (9) and (10) studied in Ref. 3 however is that, due to the non-self-adjointness of the underlying Lax operator, the "target contour" is very specific (if not

unique) and by no means obvious. It is best characterized via the solution of a maximin energy problem, in fact it is an S-curve. The term "nonlinear steepest descent method" thus acquires full meaning in the non-self-adjoint case.

Given the importance and the recent popularity of the "steepest descent method" and the various different applications to such topics as soliton theory, orthogonal polynomials, solvable models in statistical mechanics, random matrices, combinatorics and representation theory, we believe that the present work offers an important contribution. In particular we expect that the results of this paper may be useful in the treatment of Riemann-Hilbert problems arising in the analysis of general complex or normal random matrices.

On the other hand, we believe that the main results of this paper, Theorems 3, 4, 5, 7, 8 are interesting on their own. This paper can be read without the applications to dynamical systems in mind. It concerns existence and regularity of a solution to an energy variational maximin problem in the complex plane.

The method used to prove the existence of the S-curves arising in the solution of the "max-min" energy problem was first outlined in Ref. 1 and further developed in Ref. 5, at least for logarithmic potentials. But, the concrete particular problem addressed in this paper involves additional technical issues.

The main points of the proof of our results are as follows:

(i) Appropriate definition of the underlying space of continua (connected compact sets) and its topology. This ensures the compactness of our space of continua which is crucial in proving the existence of an energy maximizing element.
(ii) Proof of the semicontinuity of the energy functional that takes a continuum to the energy of its associated equilibrium measure (Theorem 3).
(iii) Proof of existence of an energy maximizing continuum (Theorem 4).
(iv) A discussion of how some assumptions ensure that the maximizing continuum does not touch the boundary of the underlying space except at a finite number of points. This ensures that variations of continua can be taken.
(v) Proof of formula (22) involving the support of the equilibrium measure on the maximizing continuum and the external field (Theorem 5).
(vi) Proof that the support of the equilibrium measure on the maximizing continuum consists of a union of finitely many analytic arcs.
(vii) Proof that the maximizing continuum is an S-curve (Theorems 7 and 8).

The paper is organized as follows. In the rest of Sec. I, we introduce the appropriate topology for our set of continua that will provide the necessary compactness. In Sec. II, we prove a "Gauss-Frostman" type theorem which shows that the variational problem that we wish to solve is not vacuous. In Sec. III, we present the proof of upper semicontinuity of a particularly defined "energy functional." In Sec. IV, we present a proof of existence of a solution of the variational problem. Existence is thus derived from the semicontinuity and the compactness results acquired earlier. In Sec. V, we show that, at least under a simplifying assumption, the "max-min" solution of the variational problem does not touch the boundary of the underlying domain, except possibly at some special points. This enables us to eventually take variations and show that the max-min property implies regularity of the support of the solution and the S-property in Secs. VI and VII. By regularity, we mean that the support of the maximizing measure is a finite union of analytic arcs. In Sec. VIII, we conclude by stating the consequence of the above results in regard to the semiclassical limit of the nonlinear Schödinger equation.

We also include three appendixes. The first one discusses in detail some topological facts regarding the set of closed subsets of a compact space, equipped with the so-called Hausdorff distance. The fact that such a space is compact is vital for proving existence of a solution for the variational problem. The second appendix presents the semiclassical asymptotics for the initial value problem (9) and (10) in terms of theta functions, under the S-curve assumption (as in Ref. 3). It is included so that the connection with the original motivating problem of semiclassical NLS is made more explicit. The third appendix sketches an argument on how to get rid of the simpli-

fying assumption introduced in Sec. V. We feel that the argument leading to Theorem 9 is quite transparent, although an absolutely rigorous proof would require a thorough revisiting of the discussion and results in Ref. 3.

Following Ref. 6 (see Appendix A) we introduce an appropriate topology on $\mathbb{F}$. We think of the closed upper half-plane $\overline{\mathbb{H}}$ as a compact space in the Riemann sphere. We thus choose to equip $\overline{\mathbb{H}}$ with the "chordal" distance, denoted by d_0, that is the distance between the images of z and ζ under the stereographic projection. This induces naturally a distance in $\overline{\mathbb{K}}$ [so $d_0(0_+,0_-)\neq 0$]. We also denote by d_0 the induced distance between compact sets E,F in $\overline{\mathbb{K}}$, $d_0(E,F)=\max_{z\in E}\min_{\zeta\in F} d_0(z,\zeta)$. Then, we define the so-called Hausdorff metric on the set $I(\overline{\mathbb{K}})$ of closed nonempty subsets of $\overline{\mathbb{K}}$ as follows:

$$d_{\mathbb{K}}(A,B)=\sup(d_0(A,B),d_0(B,A)). \tag{11}$$

In Appendix A, we prove the following.

Lemma A.1: The Hausdorff metric defined by (11) is indeed a metric. The set $I(\overline{\mathbb{K}})$ is compact and complete.

Now, it is easy to see that $\mathbb{F}$ is a closed subset of $I(\overline{\mathbb{K}})$. Hence $\mathbb{F}$ is also compact and complete.

Remarks: (1) Because of the particular symmetry $\psi(x)=\psi(-x)$ of the solution to the Cauchy problem (9) and (10) we will restrict ourselves to the case $x\geqslant 0$ from now on. We then set $J=1$ and the external field is

$$\phi(z)=-\int G(z;\eta)\mathrm{d}\mu^0(\eta)-\mathrm{Re}\left(i\pi\int_z^{iA}\rho^0(\eta)\mathrm{d}\eta+2i(zx+z^2t)\right). \tag{3'}$$

(2) The function ρ^0 expresses the density of eigenvalues of the Lax operator associated to (9), in the limit as $h\to 0$. WKB theory can be used to derive an expression for ρ^0 in terms of the initial data $\psi^0(x)$ via an Abel transform (see Ref. 3), from which it follows that

$$\mathrm{Re}[\rho^0(z)]=0 \quad \text{for } z\in[0,iA],$$

$$\mathrm{Im}[\rho^0(z)]>0 \quad \text{for } z\in(0,iA].$$

The rest of the conditions (1) are not a necessary consequence of WKB theory. In particular, it is not *a priori* clear what the analyticity properties of ρ^0 are. In this paper, we *assume*, for simplicity, that ρ^0 admits a continuous extension in the closed upper complex plane which is holomorphic in the open upper complex plane. We also assume that $\mathrm{Im}\,\rho^0$ is positive in the real axis. This will be used later to show that the maximizing continuum does not touch the real line, except at $0_+,0_-,\infty$. It is a simplifying but not essential assumption. All conditions (1) are satisfied in the simple case where the initial data are given by $\psi(x,0)=A\,\mathrm{sech}\,x$, where A is a positive constant.

(3) It follows that ϕ is a subharmonic function in $\mathbb{H}$ which is actually harmonic in $\mathbb{K}$; it also follows that it is upper semicontinuous in $\mathbb{H}$. It is then subharmonic and upper semicontinuous in $\overline{\mathbb{H}}$ except at infinity.

(4) Even though in the end we wish that the maximum of $E_\phi(\lambda^F)$ over "continua" F is a regular curve, we will begin by studying the variational problem over the set of continua $\mathbb{F}$ and only later (in Sec. VI) we will show that the maximizing continuum is in fact a nice curve. The reason is that the set $\mathbb{F}$ is compact, so once we prove in Sec. III the upper semicontinuity of the energy functional, existence of a maximizing continuum will follow immediately.

II. A GAUSS-FROSTMAN THEOREM

We claim that for any continuum $F \in \mathbb{F}$, not containing the point ∞ and approaching 0_+, 0_- nontangentially to the real line, the weighted energy is bounded below and the equilibrium measure λ^F exists. This is not true for any external field, but it is true for the field given by (3′) because of the particular behavior of the function ρ^0 near zero.

We begin by considering the equilibrium measure on the particular contour F_0 that wraps itself around the straight line segment $[0, iA]$, say λ_0^F. We have

Proposition 1: Consider the contour $F_0 \in \mathbb{F}$ consisting of the straight line segments joining 0_+ to $iA_+ = iA$ and $iA = iA_-$ to 0_-. The equilibrium measure λ_0^F exists. Its support is the imaginary segment $[0, ib_0(x)]$, for some $0 < b_0(x) \leqslant A$, lying on the right-hand side of the slit $[0, iA]$. It can be written as $\rho(z)\mathrm{d}z$ where $\rho(z)$ is a differentiable function in $[0, ib(x)]$, such that $\rho - \rho^0$ belongs in the Hölder class with exponent $1/2$.

Proof: See section 6.2.1 of Ref. 3; $\rho(z)$ can be expressed explicitly. The Hölder condition follows from 5.14 of Ref. 3. Note that the field ϕ is independent of time on F_0, so λ_0^F is also independent of time.

From Proposition 1, it follows that the maximum equilibrium energy over continua is bounded below,

$$\max_{F \in \mathbb{F}} E_\phi(\lambda^F) = \max_{F \in \mathbb{F}} \min_{\mu \in M(F)} E_\phi(\mu) > -\infty. \tag{12}$$

The following formula is easy to verify:

$$E_\phi(\mu) - E_\phi(\lambda^F) = E(\mu - \lambda^F) + 2 \int (V^{\lambda^F} + \phi) d(\mu - \lambda^F), \tag{13}$$

for any μ which is a positive measure on the continuum F. Here

$$V^{\lambda^F}(u) = \int G(u,v)\mathrm{d}\lambda^F(v),$$

where again $G(u,v)$ is the Green function for the upper half-plane.

To show that $E_\phi(\mu)$ is bounded below, all we need to show is that the difference $E_\phi(\mu) - E_\phi(\lambda^F)$ is bounded below.

Note that since $V^{\lambda^F} + \phi = 0$, *on* $\mathrm{supp}(\lambda^F)$, the integral in (13) can be written as $\int (V^{\lambda^F} + \phi)\mathrm{d}\mu$.

We have

$$\begin{aligned} V^{\lambda^F}(z) + \phi(z) &= \int_0^{b_0(x)} \log \frac{|z+iu|}{|z-iu|} (-\rho)_{t=0}\, \mathrm{d}u + \phi \\ &= -\mathrm{Re}\left(\int_0^{b_0(x)} \log \frac{|z+iu|}{|z-iu|} u^{1/2}\, \mathrm{d}u \right) + O(|z|) = O(|z|) \ \textit{near}\ z = 0. \end{aligned}$$

So we can write $V^{\lambda^F} + \phi \geqslant c(A,x)|z|$ in a neighborhood of $z=0$, where $c(A,x)$ will be some negative constant independent of z. Note that the dependence on t is not suppressed, but it is of order $O(|z^2|)$.

It is now not hard to see that the $O(|z|)$ decay implies our result.

Write $\mu = M\sigma$, where $M > 0$ is the total mass of μ and σ is a probability measure (on F). Choose ϵ such that for $|u| < \epsilon$ we have $V^{\lambda^F} + \phi \geqslant c(A,x)|u|$. Then

$$\begin{aligned} E_\phi(\mu) - E_\phi(\lambda^F) \geqslant & \int G(u,v) d(\mu - \lambda^F)(u) d(\mu - \lambda^F)(v) + 2 \int_{|v| \geqslant \epsilon} (V^{\lambda^F} + \phi)(v) \mathrm{d}\mu(v) \\ & + \int_{|v| < \epsilon} 2c(A,x)|v| d(\mu - \lambda^F)(v). \end{aligned} \tag{14}$$

The first integral of the right-hand side (RHS) can be written as $\int_{|u|\geqslant\epsilon,|v|\geqslant\epsilon}+2\int_{|u|<\epsilon,|v|\geqslant\epsilon}+\int_{|u|,|v|<\epsilon}$. The sum of the first integral plus the second term on the RHS of (14) is bounded below, by the standard Gauss-Frostman theorem (Ref. 6, p. 135). It remains to consider

$$\left(\int_F+\int_{|v|\geqslant\epsilon}\right)\left(\int_{|u|<\epsilon}G(u,v)d(\mu-\lambda^F)(u)\right)d(\mu-\lambda^F)(v)+\int_{|v|<\epsilon}2c(A,x)|v|d(\mu-\lambda^F)(v)$$
$$\geqslant\left(\int_F+\int_{|v|\geqslant\epsilon}\right)\left(\int_{|u|<\epsilon}G(u,v)d(M\sigma-\lambda^F)(u)+2c(A,x)|v|\right)d(M\sigma-\lambda^F)(v). \tag{15}$$

Now, it is easy to see that for M large, and since F is nontangential to the real line,

$$\int_{|u|<\epsilon}G(u,v)d(M\sigma-\lambda^F)(u)+2c(A,x)|v|\geqslant|v\log v|+2c(A,x)|v|. \tag{16}$$

By adjusting ϵ if necessary, we have $|v\log v|>2|c(A,x)||v|$, and hence the integral in (16) is positive. Integrating again with respect to $M\,\mathrm{d}\sigma-\mathrm{d}\lambda^F$, again for M large, we see that the integral of (15) is positive.

Since when M is bounded above we have our estimates trivially, we get boundedness below over all positive M.

We have thus proved one part of our (generalized) Gauss-Frostman theorem.

Theorem 1: Let ϕ be given by (3′). Let F be a continuum in $\overline{\mathbb{K}}\backslash\infty$ and suppose that F is contained in some sector $\pi<\alpha<\arg(\lambda)<\beta<0$ as $\lambda\to0$. Let $M(F)$ be the set of measures $\in\mathbb{M}$ which are supported in F. [So, in particular their free energy is finite and $\phi\in L_1(\mu)$.] We have

$$\inf_{\mu\in M(F)}E_\phi(\mu)>-\infty. \tag{17}$$

Furthermore the equilibrium measure on F exists, that is there is a measure $\lambda^F\in M(F)$ such that $E_\phi[F]=E_\phi(\lambda^F)=\inf_{\mu\in M(F)}E_\phi(\mu)$.

Proof: The proof that (17) implies the existence of an equilibrium measure is a well-known theorem. For our particular field ϕ given by (3) it is easy to prove. Indeed, the identity

$$E(\mu-\nu)=2E_\phi(\mu)+2E_\phi(\nu)-4E_\phi\left(\frac{\mu+\nu}{2}\right)$$

implies that any sequence μ_n minimizing $E_\phi(\mu)$ is a Cauchy sequence in (unweighted) energy. Since the space of positive measures is complete (see, for example, Ref. 7, Theorem 1.18, p. 90), there is a measure μ_0 such that $E(\mu_n-\mu_0)\to0$. We then have $E(\mu_n)\to E(\mu_0)<+\infty$ and hence $\mu_n\to\mu_0$ weakly (see, e.g., Ref. 7, pp. 82–88; this is a standard result).

The fact that $\phi\in L_1(\mu_0)$ is trivial for our particular field.

III. SEMICONTINUITY OF THE ENERGY FUNCTIONAL

We consider the functional that takes a given continuum F to the equilibrium energy on this continuum,

$$\mathbb{E}:F\to E_\psi[F]=E_\psi(\lambda^F)=\inf_{\mu\in M(F)}\left(E(\mu)+2\int\psi\,\mathrm{d}\mu\right) \tag{18}$$

and we want to show that it is continuous, if ψ is continuous in $\overline{\mathbb{H}}$. Note that this is not the case for the field ϕ given by (3′), since it has a singularity at ∞; that field is only upper semicontinuous. We will see how to circumvent this difficulty later. For the moment, ψ is simply assumed to be a continuous function in $\overline{\mathbb{H}}$.

Theorem 2: If ψ is a continuous function in $\overline{\mathbb{H}}\backslash\infty$ then the energy functional defined by (18) is continuous at any given continuum F not containing the point ∞.

Proof: Suppose $G \in \mathbb{F}$, also not containing ∞, with $d_{\mathbb{K}}(F,G) < d$, a small positive constant. Let $\lambda = \lambda_\psi^F$ be the equilibrium measure on F and $\mu = \lambda_\psi^G$ be the equilibrium measure on G.

We consider the Green's balayage of μ on F, say $\hat{\mu}$. Then supp $\hat{\mu} \in F$ and

$$V^{\hat{\mu}} = V^{\mu} \quad \text{on } F,$$

$$\int u \, \mathrm{d}\hat{\mu} = \int u \, \mathrm{d}\mu,$$

for any function u that is harmonic in $\mathbb{H}\backslash F$ and continuous in $\overline{\mathbb{H}}$.

Similarly consider $\hat{\lambda}$, the balayage of λ to G. We trivially have

$$E_\psi[G] \leqslant E_\psi(\hat{\lambda}),$$

$$E_\psi[F] \leqslant E_\psi(\hat{\mu}).$$

Lemma 1: Suppose $Q \in \mathbb{F}$, μ some positive measure supported in $\mathbb{K}$ and $\hat{\mu}$ is the Green's balayage to Q. Then

$$V^{\hat{\mu}} = V^{\mu} - V^{\mu}_{Q^c},$$

$$E(\hat{\mu}) = E(\mu) - E_{Q^c}(\mu),$$

where $E_{Q^c}(\mu)$ is the unweighted Green energy with respect to $Q^c = \mathbb{K}\backslash Q$. In particular, since unweighted energies are non-negative,

$$E(\hat{\mu}) \leqslant E(\mu).$$

Proof: The first identity follows from the fact that $V^{\hat{\mu}} - V^{\mu}$ vanishes on Q and the real line, and is harmonic in Q^c and superharmonic in $\mathbb{K}$.

Integrating $E(\hat{\mu}) = \int V^{\hat{\mu}} \, \mathrm{d}\hat{\mu} = \int V^{\mu} \, \mathrm{d}\hat{\mu} - \int V^{\mu}_{Q^c} \, \mathrm{d}\hat{\mu} = \int (V^{\mu} - V^{\mu}_{Q^c}) \mathrm{d}\mu = E(\mu) - E_{Q^c}(\mu)$. The proof of the Lemma follows.

So, let u_ψ be a function harmonic in $\mathbb{H}\backslash F$ such that $u_\psi = \psi$ on F and $u_\psi = 0$ on $\partial\mathbb{H}\backslash F$. By the definition of balayage one has $\int \psi \, \mathrm{d}\hat{\mu} = \int u_\psi \, \mathrm{d}\mu$.

We have $E_\psi[F] \leqslant E_\psi(\hat{\mu}) = E(\hat{\mu}) + 2\int \psi \, \mathrm{d}\hat{\mu} \leqslant E(\mu) + 2\int \psi \, \mathrm{d}\mu + 2\int (u_\psi - \psi) \mathrm{d}\mu = E_\psi(\mu) + 2\int (u_\psi - \psi) \mathrm{d}\mu = E_\psi[G] + 2\int (u_\psi - \psi) \mathrm{d}\mu$.

In a small neighborhood of F, $\overline{F_d} = \{z : d(z,F) \leqslant d\}$, we have

$$\left| 2 \int (u_\psi - \psi)(y) \mathrm{d}\mu(y) \right| \leqslant C \max_{y \in \overline{F_d}} |u_\psi(y) - \psi(y)|. \tag{19}$$

We assumed here that the equilibrium measures on continua near F are bounded above. This is easy to see. Suppose, first, that the point ∞ is not in F. Indeed, on the support of the equilibrium measure λ, we have

$$V^{\lambda} + \psi = 0.$$

If the equilibrium measures on continua near F were unbounded, then so would be the potentials V^{λ}. But ψ is definitely bounded near F. This contradicts the above equality.

Now given $y \in \overline{F_d}$, choose $z \in F$ such that $|z - y| = d$. The above expression (19) is less or equal than

$$C \max_{y \in \overline{F_d}} |u_\psi(y) - \psi(y) - u_\psi(z) + \psi(z)| \leqslant o(1) + C \max_{y \in \overline{F_d}} |u_\psi(y) - u_\psi(z)|.$$

It remains to bound $|u_\psi(y) - u_\psi(z)|$ by an $o(1)$ quantity.

The next Lemma is due to Milloux and can be found in Ref. 8.

Lemma 2: Suppose D is an open disc of radius R, with center z_0; let y be a point in D, F a continuum in $\mathbb{C}$, containing z_0, and Ω be the connected component of $D\backslash F$ containing y. Let $w(z)$ be a function harmonic in Ω such that

$$w(z)=0, \quad z \in F \cap \partial\Omega,$$

$$w(z)=1, \quad z \in \partial\Omega \setminus F.$$

Then $w(y) \leqslant C(|y-z_0|/R)^{1/2}$.

Proof: See Ref. 8, p. 347.

Now, select a disc of radius $d^{1/2}$, centered on z. We have $|u_\psi(y)-u_\psi(z)|=o(1)$ on the part of F lying in the disc, while $|u_\psi(y)-u_\psi(z)|$ is bounded by some positive constant M on the disc boundary.

Lemma 3: Let Ω be a domain, $\partial\Omega=F_1\cup F_2$ and

$$w_1=0, \quad z \in F_1=1, \quad z \in F_2,$$

$$w_2=1, \quad z \in F_1=0, \quad z \in F_2.$$

Suppose u is harmonic in Ω and

$$u(z) \leqslant \epsilon, \quad z \in F_1,$$

$$u(z) \leqslant M, \quad z \in F_2.$$

Then $u(z) \leqslant \epsilon w_2(z)+Mw_1(z)$.

Proof: Maximum principle.

Now, using Milloux's lemma, we get $|u_\psi(y)-u_\psi(z)| \leqslant o(1)w_2(z)+Mw_1(z) \leqslant o(1)+MC(|y-z|/d)^{1/2} \leqslant o(1)+MCd^{1/2}$. This concludes the proof of Theorem 2.

We now recall that the energy continuity proof was based on the continuity of ψ. In our case, ϕ is upper semicontinuous and discontinuous at ∞. Still we can prove that the energy is upper semicontinuous and that will be enough.

Theorem 3: For the external field given by (3′), the energy functional defined in (18) is upper semicontinuous.

Proof: We first note that if the external field ϕ' is upper semicontinuous away from infinity then so is the energy functional that takes a given continuum F to the equilibrium energy of F. Indeed, if ϕ' is upper semicontinuous away from infinity, then there exists a sequence of continuous functions (away from infinity) such that $\phi_n \downarrow \phi'$. Each functional $E_{\phi_n}[F]$ is continuous, away from infinity, and $E_{\phi_n}[F] \downarrow E_{\phi'}[F]$. So, $E_{\phi'}[F]$ is upper semicontinuous, away from infinity.

Now consider the field ϕ given by (3′). Let F be a continuum. If ∞ is not in F, then we are done. If $\infty \in F$, let $\lambda=\lambda^F$ be the equilibrium measure. We can assume that on the equilibrium measure ϕ is bounded by 0. Indeed, on the support of the equilibrium measure λ, we have

$$V^\lambda + \phi = 0.$$

But $V^\lambda \geqslant 0$, so $\phi \leqslant 0$.

This means that we can change ϕ to $\phi'=\min(\phi,0)$, which *is* an upper semicontinuous function. Theorem 3 is proved.

Remark: If we naively consider the functional taking a measure to its weighted energy we will see that it is not continuous even if the external field is continuous. It is essential that the energy functional is defined on equilibrium measures.

IV. PROOF OF EXISTENCE OF A MAXIMIZING CONTINUUM

Theorem 4: For the external field given by $(3')$, there exists a continuum $F \in \mathbb{F}$ such that the equilibrium measure λ^F exists and

$$E_\phi[F](=E_\phi(\lambda^F)) = \max_{F\in\mathbb{F}} \min_{\mu\in M(F)} E_\phi(\mu).$$

Proof: We know (see, for example, Sec. II) that there is at least one continuum F for which the equilibrium measure exists and $E_\phi(\lambda^F) > -\infty$, for all time. On the other hand, clearly $E_\phi(\lambda^F) \leqslant 0$ for any F. Hence the supremum over continua in $\mathbb{F}$ is finite (and trivially nonpositive), since $\mathbb{F}$ is compact. Call it L.

We can now take a sequence F_n such that $E_\phi[F_n] \to L$. Choose a convergent subsequence of continua $F_n \to F$, say. By upper semicontinuity of the weighted energy functional,

$$\limsup E_\phi[F_n] \leqslant E_\phi[F] \leqslant L = \lim E_\phi[F_n].$$

So $L = E_\phi[F]$. The theorem is proved.

V. ACCEPTABILITY OF THE CONTINUUM

We have thus shown that a solution of the maximum-minimum problem exists. We do not know yet that the maximizing continuum is a contour. Clearly the pieces of the continuum lying in the region where the external field is positive do not support the equilibrium measure and by the continuity of the external field they can be perturbed to a finite union of analytic arcs. The real problem is to show that the support of the equilibrium measure is a finite union of analytic arcs. This will follow from the analyticity properties of the external field.

Note that the maximizing continuum cannot be unique, since the subset where the equilibrium measure is zero can be perturbed without changing the energy. A more interesting question is whether the support of the equilibrium measure of the maximizing contour is unique. We do not know the answer to this question but it is not important as far as the application to the semiclassical limit of NLS is concerned. (See Appendix B.)

It is important however, that the maximizing continuum does not touch the boundary of the space $\mathbb{K}$ except of course at the points 0^-, 0^+, and perhaps at ∞. This is to guarantee that variations with respect to the maximizing contour can be properly taken.

The proof of the acceptability of the continuum requires two things.

(i) The continuum does not touch the real negative axis.
(ii) The continuum does not touch the real positive axis.

We will also make the following assumption.

Assumption (A): The continuum maximizing the equilibrium energy does not touch the linear segment $(0, iA]$.

Remark: Assumption (A) is not satisfied at $t=0$, where in fact the continuum is a contour F_0 wrapping around the linear segment $[0, iA]$. However, the case $t=0$ is well understood. The equilibrium measure for F_0 exists and its support is connected. On the other hand, assumption (A) *is* satisfied for small $t>0$. (See Chap. 6 of Ref. 3.)

Remark: It is conceivable that at some positive t_0 there is an x for which assumption (A) is not satisfied. It can in fact be dropped but the analysis of the semiclassical limit of the nonlinear Schrödinger equation will get more tedious; see Appendix C.

Proposition 2: The continuum maximizing the equilibrium energy does not touch the real axis except at the points zero and possibly infinity.

Proof: (i) If $z<0$, then $\phi(z) = \pi \int_z^0 |\rho^0(\eta)| \mathrm{d}\eta > 0$.

This follows from an easy calculation, using the conditions defining ρ^0. But we can always delete the strictly positive measure lying in a region where the field is positive and make the energy smaller. So even the solution of the "inner" minimizing problem must lie away from the real negative axis.

(ii) If $z>0$, then again a short calculation shows that $\mathrm{d}\phi/d\,\mathrm{Im}\,z>0$, *for* $t>0$.

It is crucial here that if $u\in\mathbb{R}$ then $G(u,v)=0$, while if both u, v are off the real line $G(u,v)>0$. Hence, for any configuration that involves a continuum including points on the real line, we can find a configuration with no points on the real line, by pushing measures up away from the real axis, which has greater (unweighted *and* weighted) energy. So, suppose the maximizing continuum touches the axis. We can always push the measures up away from the real axis and end up with a continuum that has greater minimal energy, thus arriving at a contradiction.

The proposition is now proved.

Remark: It is also important to consider the point at infinity. We cannot prove that the continuum does not hit this point. [In fact, our numerics (Ref. 3, Chap. 6) show that it may well do so.] In connection with the semiclassical problem (9) and (10) as analyzed in Ref. 3, it might seem at first that the maximizing continuum should not pass through infinity. Indeed, the transformations (2.17) and (4.1) of Ref. 3 implicitly assume that the continuum C lies in $\mathbb{C}$. Otherwise, one would lose the appropriate normalization for M at infinity. However, one must simply notice that infinity is just an arbitrary choice of normalizing point, once we view our Riemann-Hilbert problems in the compact Riemann sphere. The important observation is that the composition of transformations (2.17) and (4.1) (which are purely formal, i.e., no estimates are required and no approximation is needed) does not introduce any bad (essential) singularities. In the end, the asymptotic behavior of $\widetilde{N}^{\sigma}$ is still the identity as $z\to\infty$ in the lower half-plane and nonsingular as $z\to\infty$ in the upper half-plane. So, in the end it *is* acceptable for a continuum to go through the point infinity.

VI. TAKING SMALL VARIATIONS

We now complexify the external field and extend it to a function in the whole complex plane, by turning a Green's potential to a logarithmic potential. We will thus be able to make direct use of the results of Ref. 5.

We let, for any complex z,

$$V(z)=-\int_{-iA}^{iA}\log(z-\eta)\rho^{0}(\eta)\mathrm{d}\eta-\left(2ixz+2itz^{2}+i\pi\int_{z}^{iA}\rho^{0}(\eta)\mathrm{d}\eta\right) \tag{20}$$

and $V_R=\mathrm{Re}\,V$ be the real part of V. In the lower half-plane the function ρ^0 is extended simply by

$$\rho^{0}(\eta^{*})=(\rho^{0}(\eta))^{*}. \tag{20'}$$

Note right away that the field ϕ defined in (3′) is the restriction of $V_R=\mathrm{Re}\,V$ to the closed upper half-plane.

The actual contour of the logarithmic integral is chosen to be the linear segment χ joining the points $-iA,0,iA$. The branch of the logarithm function $\log(z-\eta)$ is then defined to agree with the principal branch as $z\to\infty$, and with jump across the very contour χ.

The unweighted Green's energy (4) can be written as

$$E_{V_R}(\mu)=\int_{\mathrm{supp}\,\mu}\int_{\mathrm{supp}\,\mu}\log\frac{1}{|u-v|}\mathrm{d}\mu(u)\mathrm{d}\mu(v)+2\int_{\mathrm{supp}\,\mu}V_{R}(u)\mathrm{d}\mu(u), \tag{21}$$

where the measures μ are extended to the lower half complex plane by

$$\mu(z^{*})=-\mu(z). \tag{21'}$$

(So they are "signed" measures.)

Having established in Sec. V that the contour solving the variational problem does not touch the real line we can take small variations of measures and contours, never intersecting the real line, and keeping the points 0_-, 0_+ fixed. In view of (21′) we can think of them as variations of measures symmetric under (21′) in the full complex plane, never intersecting the real line, and

keeping the points 0_-, 0_+ fixed. The perturbed measures do not change sign. The fact that ∞ can belong to the contour is not a problem. Our variations will keep it automatically fixed.

The first step is to show that the solution of the variational problem satisfies a crucial relation.

Remark: It is not hard to see that the variational problem of Theorem 4 is actually *equivalent* to the variational problem of maximizing equilibrium measures on continua in the whole complex plane, under the symmetry (21′) and the condition that measures are to positive in the upper half-plane and negative in the lower half-plane.

Theorem 5: Let F be the maximizing continuum of Theorem 4 and λ^F be the equilibrium measure minimizing the weighted logarithmic energy (6) under the external field $V_R=\mathrm{Re}\, V$ where V is given by (20). Let μ be the extension of λ^F to the lower complex plane via $\mu(z^*)=-\mu(z)$. Then

$$\mathrm{Re}\left(\int \frac{\mathrm{d}\mu(u)}{u-z}+V'(z)\right)^2=\mathrm{Re}(V'(z))^2-2\,\mathrm{Re}\int\frac{V'(z)-V'(u)}{z-u}\mathrm{d}\mu(u)+\mathrm{Re}\left(\frac{1}{z^2}\int 2(u+z)V'(u)\mathrm{d}\mu(u)\right). \tag{22}$$

Proof: We first need to prove the following.

Theorem 6: Let Γ be a critical point of the functional taking a continuum $\Gamma\in\mathbb{F}$ to $E_{V_R}(\lambda^\Gamma)$, and assume that Γ is not tangent to $\mathbb{R}$. Also assume that Γ does not touch the segment $[0,iA]$ except at zero. Let μ be the extension of λ^Γ via $\mu(z^*)=-\mu(z)$, O_Γ be an open set containing the interior of $\Gamma\cup\Gamma^*$ and $h\in C^1(O_\Gamma)$ such that $h(0)=0$. We have

$$\mathrm{Re}\left(\int\int\frac{h(u)-h(v)}{u-v}\mathrm{d}\mu(u)\mathrm{d}\mu(v)\right)=2\,\mathrm{Re}\left(\int V'(u)h(u)\mathrm{d}\mu(u)\right). \tag{23}$$

Proof: Consider the family of (signed) measures $\{\mu^\tau,\tau\in\mathbb{C},|\tau|<\tau_0\}$ defined by $\mathrm{d}\mu^\tau(z^\tau)=\mathrm{d}\mu(z)$ where $z^\tau=z+\tau h(z)$, or equivalently, $\int f(z)\mathrm{d}\mu^\tau(z)=\int f(z^\tau)\mathrm{d}\mu(z)$, $f\in L_1(O_\Gamma)$. Assume that τ is small enough so that the support of the deformed continuum does not hit the linear segment $(0,iA]$ or a nonzero point in the real line.

With $\hat{h}=\hat{h}(u,v)=[h(u)-h(v)]/(u-v)$, we have $(u^\tau-v^\tau)/(u-v)=1+\tau\hat{h}$, so that $\log(1/|u^\tau-v^\tau|)-\log(1/|u-v|)=-\log|1+\tau\hat{h}|=-\mathrm{Re}(\tau\hat{h})+O(\tau^2)$.

Integrating with respect to $\mathrm{d}\mu(u)\mathrm{d}\mu(v)$ we arrive at

$$E(\mu^\tau)-E(\mu)=-\mathrm{Re}\left(\tau\int\hat{h}\,\mathrm{d}\mu(u)\mathrm{d}\mu(v)\right)+O(\tau^2), \tag{24}$$

where $E(\mu)$ denotes the free logarithmic energy of the measure μ. Also,

$$\int V_R\,\mathrm{d}\mu^\tau-\int V_R\,\mathrm{d}\mu=2\int(V_R(u^\tau)-V_R(u))\mathrm{d}\mu(u)=2\,\mathrm{Re}\left(\tau\int V'(u)h(u)\mathrm{d}\mu(u)\right)+O(\tau^2).$$

Combining with the above,

$$E_{V_R}(\mu^\tau)-E_{V_R}(\mu)=\mathrm{Re}\left(-\tau\int\hat{h}\,\mathrm{d}\mu(u)\mathrm{d}\mu(v)+2\tau\int V'h\,\mathrm{d}\mu\right)+O(\tau^2). \tag{25}$$

So, if μ is (the symmetric extension of) a critical point of the map $\mu\to E_{V_R}(\mu)$ the linear part of the increment is zero. In other words given a C^1 function h and a measure μ the function $E_{V_R}(\mu^\tau)$ of τ is differentiable at $\tau=0$ and the derivative is

$$\mathrm{Re}(-H(\mu)),\quad \textit{where } H(\mu)=\int\int\hat{h}\,\mathrm{d}\mu^2-2\int V'h\,\mathrm{d}\mu. \tag{26}$$

But what we really want is the derivative of the energy as a function of the equilibrium measure. This function can be shown to be differentiable and its derivative can be set to zero at a critical continuum.

Indeed, we need to show the following.

Lemma 4:

$$\frac{d}{d\tau}E_{V_R}((\lambda^\Gamma)^\tau)\big|_{\tau=0} = \frac{d}{d\tau}E_{V_R}(\lambda^{\Gamma_\tau})\big|_{\tau=0} = 0.$$

In the relation above $\Gamma_\tau = \mathrm{supp}(\lambda^\Gamma)^\tau$. The first derivative is of a function of general measures. The second derivative is of a function of equilibrium measures.

Proof: Define the measure σ_τ with support Γ and such that $(\sigma_\tau)^\tau = \lambda^{\Gamma_\tau}$.

LEMMA 5: With H defined by (26), we have

$$\mathrm{Re}\, H(\sigma_\tau) \to \mathrm{Re}\, H(\lambda^\Gamma),$$

as $\tau \to 0$.

Proof: By (25) and (26), we have

$$E_{V_R}((\lambda^\Gamma)^\tau) - E_{V_R}(\lambda^\Gamma) = -\mathrm{Re}(\tau H(\lambda^\Gamma) + O(\tau^2)),$$

$$E_{V_R}(\lambda^{\Gamma_\tau}) - E_{V_R}(\sigma_\tau) = -\mathrm{Re}(\tau H(\sigma_\tau) + O(\tau^2)).$$

On the other hand, $E_{V_R}(\sigma_\tau) \geqslant E_{V_R}(\lambda^\Gamma)$, and $E_{V_R}((\lambda^\Gamma)^\tau) \geqslant E_{V_R}(\lambda^{\Gamma_\tau})$. It follows that

$$E_{V_R}(\sigma_\tau) - \mathrm{Re}(\tau H(\sigma_\tau)) + O(\tau^2) = E_{V_R}(\lambda^{\Gamma_\tau}) \leqslant E_{V_R}((\lambda^\Gamma)^\tau) = E_{V_R}(\lambda^\Gamma) - \mathrm{Re}(\tau H(\lambda^\Gamma)) + O(\tau^2).$$

Hence $E_{V_R}(\sigma_\tau) \to E_{V_R}(\lambda^\Gamma)$.

As in the proof of Theorem 1, it follows that $\sigma_\tau \to \lambda^\Gamma$ weakly; see Ref. 7, pp. 82–88. It then follows immediately that $H(\sigma_\tau) \to H(\lambda^\Gamma)$. This proves Lemma 5.

To complete the proof of Lemma 4, we note that $0 \geqslant E_{V_R}((\lambda^\Gamma)^\tau) - E_{V_R}(\lambda^\Gamma) \geqslant E_{V_R}(\lambda^{\Gamma_\tau}) - E_{V_R}(\sigma_\tau) = -\mathrm{Re}(\tau H(\sigma_\tau)) + O(\tau^2)$. Hence the derivative of $E_{V_R}((\lambda^\Gamma)^\tau)$ at $\tau = 0$ is equal to the derivative of $E_{V_R}(\lambda^{\Gamma_\tau})$ at $\tau = 0$ which is equal to $\mathrm{Re}\, H(\lambda^\Gamma)$. This proves Lemma 4 and Theorem 6.

Proof of Theorem 5: Consider the Schiffer variation, i.e., take $h(u) = u^2/(u-z)$ where z is some fixed point not in Γ. Note that $h(0) = 0$ so that the deformation $z^\tau = z + \tau h(z)$ keeps the points $0_+, 0_-$ fixed. Also assume that τ is small enough so that the support of the deformed continuum does not hit the linear segment $(0, iA]$ or a nonzero point in the real line. We have

$$\hat{h} = \hat{h}(u,v) = \frac{h(u) - h(v)}{u - v} = 1 - \frac{z^2}{(u-z)(v-z)},$$

and therefore

$$\mathrm{Re}\left(\int \int \hat{h}(u,v)\, d\mu(u)\, d\mu(v) \right) = \mathrm{Re}\left[\int \int du(u)\, d\mu(v) - z^2 \left(\int_{\mathrm{supp}\ \mu} \frac{d\mu(u)}{u - z} \right)^2 \right].$$

Next

$$\mathrm{Re}\left(\int 2V'(u)h(u)\mathrm{d}\mu(u)\right) = 2\,\mathrm{Re}\left(\int (u+z)V'(u)\mathrm{d}\mu(u) + z^2\int \frac{V'(u)\mathrm{d}\mu(u)}{u-z}\right)$$
$$= \mathrm{Re}\left(\int 2V'(u)(u+z)\mathrm{d}\mu(u) + 2z^2\int \frac{V'(u)-V'(z)}{u-z}\mathrm{d}\mu(u)\right.$$
$$\left. + 2z^2V'(z)\int \frac{\mathrm{d}\mu(u)}{u-z}\right).$$

Theorem 5 now follows from Theorem 6.

Remark: If our continuum is allowed to touch the point iA [so we slightly weaken assumption (A)] then we may need to keep points $\pm iA$ fixed under a small variation. We can then choose the Schiffer variation $h(u)=u^2(u^2+A^2)/(u-z)$. We will arrive at a similar and equally useful formula.

In general if one wants to keep points $a_1,\ldots,a_s$ fixed, the appropriate Schiffer variation is $h(u)=\Pi_{i=1}^{i=s}(u-a_i)/(u-z)$.

Proposition 3: The support of the equilibrium measure consists of a finite number of analytic arcs.

Proof: Theorem 5 above implies that the support of μ is the level set of the real part of a function that is analytic except at countably many branch points. In fact, supp μ is characterized by $\int\log(1/|u-z|)\mathrm{d}\mu(u)+V_R(z)=0$. From Theorem 5 we get

$$\mathrm{Re}\left(\int \frac{\mathrm{d}\mu(u)}{u-z} + V'(z)\right) = \mathrm{Re}[(R_\mu(z))^{1/2}], \tag{27}$$

where

$$R_\mu(z) = (V'(z))^2 - 2\int_{\mathrm{supp}\ \mu} \frac{V'(z)-V'(u)}{z-u}\mathrm{d}\mu(u) + \frac{1}{z^2}\left(\int_{\mathrm{supp}\ \mu} 2(u+z)V'(u)\mathrm{d}\mu(u)\right). \tag{28}$$

This is a function analytic in K, with possibly a pole at zero. By integrating, we have that supp(μ) is characterized by

$$\mathrm{Re}\int^z (R_\mu)^{1/2}\,\mathrm{d}z = 0. \tag{29}$$

The locus defined by (29) is a union of arcs with endpoints at zeros of R_μ. To see this, consider (29) as an equation of two real variables $f(u,v)=0$ and try to solve for u as an analytic expression of v. One can only do this if the derivative of f is nonzero, which means (via the Cauchy-Riemann equations) that $R_\mu\neq 0$. The points where $R_\mu=0$ are exactly the points where the analytic arcs cannot be continued.

Note that

$$R_\mu(z) \sim -[16t^2z^2 + \pi^2(\rho^0(z))^2], \quad \text{as } z\to\infty,$$
$$R_\mu(z) \sim \frac{1}{z^2}\int 2uV'(u)\mathrm{d}\mu(u), \quad \text{as } z\to 0. \tag{30}$$

By conditions (1) for ρ^0, R_μ is blowing up at the point ∞ (at least for $t>0$; but the case $t=0$ is well understood: the equilibrium measure consists of a single analytic arc; see Sec. V). Hence it can only have finitely many zeros near infinity, otherwise they would have to accumulate near ∞ and then R_μ would be 0 there. On the other hand, R_μ cannot have an accumulation point of zeros at $z=0$, because even if the pole at 0 were removed (the coefficients of $1/z^2$, $1/z$ being zero), R_μ would be holomorphically extended across $z=0$. So, R_μ can only have a finite number of zeros in $\mathbb{K}$. It follows that the support of the maximizing equilibrium measure consists of only finitely many arcs.

REMARK: Of course, conditions (1) can be weakened. We could allow ρ^0 to have a pole at infinity of order other than two. But our aim here is not to prove the most general theorem possible, but instead illustrate a method that can be applied in the most general settings under appropriate amendments.

Remark: The assumption that ρ^0 is continuous and hence bounded at infinity is only needed to prove the finiteness of the components of the support of the equilibrium measure of the maximizing continuum. If it is dropped then we may have an infinite number of components for isolated values of x,t. This will result in infinite genus representations of the semiclassical asymptotics. Of course infinite genus solutions of the focusing NLS equation are known and well understood. So the analysis of Ref. 3 is expected to also apply in that case, although it will be more tedious.

For a justification of the "finite gap ansatz," concerning the semiclassical limit of focusing NLS, it only remains to verify the "S-property."

VII. THE S-PROPERTY

Theorem 7: (The S-property.)

Let C be the contour maximizing the equilibrium energy, for the field given by (3′) with conditions (1). Let μ be the extension of its equilibrium measure to the full complex plane via (21′). Assume for simplicity that assumption (A) holds. Let $X(z)=\int_{\mathrm{supp}\,\mu}\log[1/(u-z)]\mathrm{d}\mu(u)$, $X_R(z)=\mathrm{Re}\,X(z)=\int_{\mathrm{supp}\,\mu}\log(1/|u-z|)\mathrm{d}\mu(u)$, $W_\mu=X'$. Then, at any interior point of supp μ other than zero,

$$\frac{d}{\mathrm{d}n_+}(V_R+X_R)=\frac{d}{\mathrm{d}n_-}(V_R+X_R), \tag{8′}$$

where the two derivatives above denote the normal derivatives, on the + and − sides, respectively.

Proof: From Theorem 5, we have

$$|\mathrm{Re}(W_\mu(z)+V'(z))|=|\mathrm{Re}(R_\mu)|^{1/2}.$$

Using the definition for X, the above relation becomes

$$\left|\frac{d}{\mathrm{d}z}\,\mathrm{Re}(X+V)\right|=|\mathrm{Re}(R_\mu)|^{1/2}.$$

Now, $\mathrm{Re}(X+V)=0$ on the support of the equilibrium measure. So, in particular $\mathrm{Re}(X+V)$ is constant along the equilibrium measure. Hence $|(d/\mathrm{d}z)\mathrm{Re}(X+V)|$ must be equal to the modulus of *each* normal derivative across the equilibrium measure. So,

$$\left|\frac{d}{\mathrm{d}n_\pm}(V_R+\mathrm{Re}\,X)\right|=\left|\frac{d}{\mathrm{d}z}\,\mathrm{Re}(X+V)\right|=|\mathrm{Re}(R_\mu)|^{1/2}.$$

Hence,

$$\left|\frac{d}{\mathrm{d}n_+}(V_R+\mathrm{Re}\,X)\right|=\left|\frac{d}{\mathrm{d}n_-}(V_R+\mathrm{Re}\,X)\right|.$$

But it is easy to see that both LHS and RHS quantities inside the modulus sign are negative. This is because $V_R+\mathrm{Re}\,X=0$ on supp μ and negative on each side of supp μ. Hence result.

Remark: Once Theorem 7 is proved it follows by the Cauchy-Riemann equations that $(V_I+\mathrm{Im}\,X)_+-(V_I+\mathrm{Im}\,X)_-$ is constant on each connected component of supp μ, which means that $\mathrm{Im}\,\tilde{\phi}$ is constant on connected components of the contour, where $\tilde{\phi}$ is as defined in formula (4.13) of Ref. 3. This proves the existence of the appropriate "g functions" in Ref. 3.

We recapitulate our results in the following theorem, set in the upper complex half-plane. Note that (8′) is the "doubled up" version of (8).

Theorem 8: Let ϕ be given by (3′), where ρ^0 satisfies conditions (1). Under assumption (A), there is a piecewise smooth contour $C \in \mathbb{F}$, containing points $0_+, 0_-$ and otherwise lying in the cut upper half-plane $\mathbb{K}$, with equilibrium measure λ^C, such that $\mathrm{supp}(\lambda^C)$ consists of a union of finitely many analytic arcs and

$$E_\phi(\lambda^C) = \max_{C' \in \mathbb{F}} E_\phi(\lambda^{C'}) = \max_{C' \in \mathbb{F}} [\inf_{\mu \in M(F)} E_\phi(\mu)].$$

On each interior point of $\mathrm{supp}(\lambda^C)$ we have

$$\frac{d}{dn_+}(\phi + V^{\lambda^C}) = \frac{d}{dn_-}(\phi + V^{\lambda^C}), \tag{8''}$$

where V^{λ^C} is the Green's potential of the equilibrium measure λ^C [see (5)] and the two derivatives above are the normal derivatives.

A curve satisfying (8) such that the support of its equilibrium measure consists of a union of finitely many analytic arcs is called an S-curve.

Proof: The fact that the maximizing continuum C is actually a contour is proved as follows. If this were not the case, then we could choose a subset of C, say F, which *is* a contour, starting at 0_+ and ending at 0_-, and going around the point iA. Clearly, by definition, the equilibrium energy of C is less than the equilibrium energy of F, i.e., $E_\phi(\lambda^C) \leqslant E_\phi(\lambda^F)$. On the other hand, since C maximizes the equilibrium energy, we have $E_\phi(\lambda^F) \leqslant E_\phi(\lambda^C)$. So $E_\phi(\lambda^F) = E_\phi(\lambda^C)$.

VIII. CONCLUSION

In view of the interpretation of the variational problem in terms of the semiclassical NLS problem, we have the following result.

Consider the semiclassical limit ($\hbar \to 0$) of the solution of (9) and (10) with bell-shaped initial data. Replace the initial data by the so-called soliton ensembles data (as introduced in Ref. 3) defined by replacing the scattering data for $\psi(x,0) = \psi_0(x)$ by their WKB approximation, so that the spectral density of eigenvalues is

$$d\mu_0^{\mathrm{WKB}}(\eta) := \rho^0(\eta)\chi_{[0,iA]}(\eta)d\eta + \rho^0(\eta^*)\chi_{[-iA,0]}(\eta)d\eta,$$

$$\text{with } \rho^0(\eta) := \frac{\eta}{\pi}\int_{x_-(\eta)}^{x_+(\eta)} \frac{dx}{\sqrt{A(x)^2 + \eta^2}} = \frac{1}{\pi}\frac{d}{d\eta}\int_{x_-(\eta)}^{x_+(\eta)} \sqrt{A(x)^2 + \eta^2}\, d\mu,$$

for $\eta \in (0, iA)$, where $x_-(\eta) < x_+(\eta)$ are the two real turning points, i.e., $(A(x_\pm))^2 + \eta^2 = 0$, the square root is positive and the imaginary segments $(-iA, 0)$ and $(0, iA)$ are both considered to be oriented from bottom to top to define the differential $d\eta$.

Assume that ρ^0 satisfies conditions (1). Then, under assumption (A), asymptotically as $\hbar \to 0$, the solution $\psi(x,t)$ admits a "finite genus description." (For a more precise explanation, see Appendix B.)

The proof of this is the main result of Ref. 3, *assuming* that the variational problem of Sec. I has an S-curve as a solution. But this is now guaranteed by Theorem 8.

Remark: For conditions weaker than the above, the particular spectral density ρ^0 arising in the semiclassical NLS problem can conceivably admit branch singularities in the upper complex plane and condition (1) will not be satisfied. We claim that even in such a case the finite gap genus can be justified, at least generically. The proof of this fact will require setting the variational problem on a Riemann surface with moduli at the branch singularities of ρ^0.

Remark: Consider the semiclassical problem (9) and (10) in the case of initial data $\psi_0(x) = A \operatorname{sech} x$, where $A > 0$. Then the WKB density is given by $\rho^0 = i$ [see (3.1) and (3.2) of Ref. 3; note that condition (1) is satisfied]. So the finite genus ansatz holds for any x, t, as long as the assumption (A) of Sec. V holds. But then assumption (A) can be eventually dropped; see Appendix C.

Remark: The behavior of a solution of (9) in general depends not only on the eigenvalues of the Lax operator, but also on the associated norming constants and the reflection coefficient. In the special case of the soliton ensembles data the norming constants alternate between -1 and 1 while the reflection coefficient is by definition zero. More generally, for real analytic data decaying at infinity the reflection coefficient is exponentially small everywhere except at zero and can be neglected (although the rigorous proof of this is not trivial).

APPENDIX A: COMPACTNESS OF THE SET OF CONTINUA

In this section we prove that the sets $I(\overline{\mathbb{K}})$ and hence $\mathbb{F}$ defined in Sec. I are compact and complete.

As stated in Sec. I, the space we must work with is the upper half-plane: $\mathbb{H}=\{z:\mathrm{Im}\, z>0\}$. The closure of this space is $\overline{\mathbb{H}}=\{z:\mathrm{Im}\ z\geqslant 0\}\cup\{\infty\}$. Also $\mathbb{K}=\{z:\mathrm{Im}\, z>0\}\backslash\{z:\mathrm{Re}\, z=0, 0<\mathrm{Im}\, z\leqslant A\}$. In the closure of this space, $\overline{\mathbb{K}}$, we consider the points ix_+ and ix_-, where $0\leqslant x<A$ as distinct.

Even though we eventually wish to consider only smooth contours, we are forced to *a priori* work with general closed sets. The reason is that the set of contours is not compact in any reasonable way, so it seems impossible to prove any existence theorem for a variational problem defined only on contours. Instead, we define $\mathbb{F}$ to be the set of all "continua" F in $\overline{\mathbb{K}}$ (i.e., connected compact sets, containing the points $0_+, 0_-$).

Furthermore, we need to introduce an appropriate topology on $\mathbb{F}$, that will make it a compact set. In this we follow the discussion of Dieudonné (Ref. 6, Chap. III.16).

We think of the closed upper half-plane $\overline{\mathbb{H}}$ as a compact space in the Riemann sphere. We thus choose to equip $\overline{\mathbb{H}}$ with the "chordal" distance, denoted by $d_0(z,\zeta)$, that is the distance between the images of z and ζ under the stereographic projection. This induces naturally a distance in $\overline{\mathbb{K}}$ [so, for example, $d_0(0_+,0_-)\neq 0$]. We also denote by d_0 the induced distance between compact sets E,F in $\overline{\mathbb{K}}$: $d_0(E,F)=\max_{z\in E}\min_{\zeta\in F} d_0(z,\zeta)$. Then, we define the so-called Hausdorff metric on the set $I(\overline{\mathbb{K}})$ of closed nonempty subsets of $\overline{\mathbb{K}}$ as follows:

$$d_{\mathbb{K}}(A,B)=\sup(d_0(A,B),d_0(B,A)). \tag{A1}$$

Lemma A.1: The Hausdorff metric defined by (A1) is indeed a metric. The set $I(\overline{\mathbb{K}})$ is compact and complete.

Proof: It is clear that $d_{\mathbb{K}}(A,B)$ is non-negative and symmetric by definition. Also if $d_{\mathbb{K}}(A,B)=0$, then $d_0(A,B)=0$, hence $\max_{z\in A}\min_{\zeta\in B} d_0(z,\zeta)=0$ and thus for all $z\in A$, we have $\min_{\zeta\in B} d_0(z,\zeta)=0$. In other words, $z\in B$. By symmetry, $A=B$.

The triangle inequality follows from the triangle inequality for d_0. Indeed, suppose $A,B,C\in I(\overline{\mathbb{K}})$. Then $d_{\mathbb{K}}(A,B)=\sup(d_0(A,B),d_0(B,A))=d_0(A,B)$, without loss of generality. Now,

$$d_0(A,B)=\max_{z\in A}\min_{\zeta\in B} d_0(z,\zeta)\leqslant \max_{z\in A}\min_{\zeta\in B}\min_{\zeta_0\in C}(d_0(z,\zeta_0)+d_0(\zeta_0,\zeta)),$$

by the triangle inequality for d_0. Let $z=z_0\in A$ be the value of z that maximizes $\min_{\zeta\in B}\min_{\zeta_0\in C}(d_0(z,\zeta_0)+d_0(\zeta_0,\zeta))$. This is then

$$\min_{\zeta\in B}\min_{\zeta_0\in C}(d_0(z_0,\zeta_0)+d_0(\zeta_0,\zeta)) \leqslant \min_{\zeta_0\in C} d_0(z_0,\zeta_0)+\min_{\zeta\in B}\min_{\zeta_0\in C} d_0(\zeta_0,\zeta)$$
$$\leqslant \max_{z\in A}\min_{\zeta_0\in C} d_0(z,\zeta_0)+\max_{\zeta\in B}\min_{\zeta_0\in C} d_0(\zeta_0,\zeta)$$
$$\leqslant d_0(A,C)+d_0(B,C)\leqslant d_{\mathbb{K}}(A,C)+d_{\mathbb{K}}(B,C).$$

The result follows from symmetry.

We will next show that $I(\overline{\mathbb{K}})$ is complete and precompact. Since a precompact, complete metric space is compact [Ref. 6, proposition (3.16.1)] the proof of Lemma A.1 follows.

Lemma A.2: If the metric space $\mathbb{E}$ equipped with a distance d_0 is complete, then so is $I(\mathbb{E})$, the set of closed nonempty subsets of $\mathbb{E}$, equipped with the Hausdorff distance

$$d_{\mathbb{E}}(A,B)=\sup(d_0(A,B),d_0(B,A)),$$

for any closed nonempty subsets A,B, where $d_0(A,B)=\max_{a\in A}\min_{b\in B} d_0(a,b)$.

Furthermore, if $\mathbb{E}$ is precompact, then so is $I(\mathbb{E})$.

Proof: Suppose $\mathbb{E}$ is complete. Let X_n be a Cauchy sequence in $I(\mathbb{E})$. We will show that X_n converges to $X=\cap_{n\geqslant 0}\overline{\cup}_{p\geqslant 0}X_{n+p}$. (Overbar denotes closure.)

Indeed, given any $\epsilon>0$,

$$d_0(X_n,X)=\max_{x\in X_n}\min_{y\in X} d_0(x,y)\leqslant \max_{x\in X_n}\max_{y\in \bar{\cup}_{p\geqslant 0}X_{n+p}} d_0(x,y)<\varepsilon,$$

for large n, by the completeness of $\mathbb{E}$. Similarly,

$$d_0(X,X_n)=\max_{x\in X}\min_{y\in X_n} d_0(x,y)\leqslant \max_{x\in \bar{\cup}_{p\geqslant 0}X_{n+p}}\min_{y\in X_n} d_0(x,y)<\varepsilon.$$

Next, suppose $\mathbb{E}$ is precompact. Then, by definition, given any $\epsilon>0$, there is a finite set, say $S=\{s_1,s_2,\ldots,s_n\}$, where n is a finite integer, such that any point x of $\mathbb{E}$ is at a distance d_0 less than ϵ to the set S. Now, consider the set of subsets of S, which is of course finite. Clearly every closed set is at a distance less than ϵ to a member of that set,

$$d_0(A,S)=\max_{a\in A}\min_{s\in S} d_0(a,s)<\varepsilon,$$

$$d_0(S,A)=\max_{s\in S}\min_{a\in A} d_0(a,s)<\varepsilon,$$

for any closed nonempty set A. Hence $d_{\mathbb{E}}(A,S)<\epsilon$.

So, any closed nonempty set A is at a distance less than ϵ to the finite power set of S. So $I(\mathbb{E})$ is precompact.

APPENDIX B: THE DESCRIPTION OF THE SEMICLASSICAL LIMIT OF THE FOCUSING NLS EQUATION UNDER THE FINITE GENUS ANSATZ

We present one of the main results of Ref. 3 on the semiclassical asymptotics for problem (9) and (10), in view of the fact that the finite genus ansatz holds. In particular, we fix x,t and use the result that the support of the maximizing measure of Theorems 4 and 8 consists of a finite union of analytic arcs.

First, we define the so-called g function. Let C be the maximizing contour of Theorem 4. *A priori* we seek a function satisfying

$$g(\lambda) \textit{ is independent of } \hbar,$$

$$g(\lambda) \textit{ is analytic for } \lambda\in\mathbb{C}\setminus(C\cup C^*),$$

$$g(\lambda)\to 0 \textit{ as } \lambda\to\infty,$$

$$g(\lambda) \textit{ assumes continuous boundary values from both sides of } C\cup C^*,$$

denoted by $g_+(g_-)$ on the left (right) of $C \cup C^*$,

$$g(\lambda^*) + g(\lambda)^* = 0 \quad \textit{for all } \lambda \in \mathbb{C} \setminus (C \cup C^*).$$

The assumptions above are satisfied if we write g in terms of the maximizing equilibrium measure of Theorem 8, $\mathrm{d}\mu = \mathrm{d}\lambda^C = \rho(\eta)\mathrm{d}\eta$, doubled up according to (21′). Indeed,

$$g(\lambda) = \int_{C \cup C^*} \log(\lambda - \eta)\rho(\eta)\mathrm{d}\eta,$$

for an appropriate definition of the logarithm branch (see Ref. 3).

For $\lambda \in C$, define the functions

$$\theta(\lambda) := i(g_+(\lambda) - g_-(\lambda)),$$

$$\Phi(\lambda) := \int_0^{iA} \log(\lambda - \eta)\rho^0(\eta)\mathrm{d}\eta + \int_{-iA}^0 \log(\lambda - \eta)\rho^0(\eta^*)^*\mathrm{d}\eta$$

$$+ 2i\lambda x + 2i\lambda^2 t + i\pi \int_\lambda^{iA} \rho^0(\eta)\mathrm{d}\eta - g_+(\lambda) - g_-(\lambda),$$

where $\rho^0(\eta)$ is the holomorphic function (WKB density of eigenvalues) introduced in Sec. I [see conditions (1)].

The finite genus ansatz implies that for each x,t there is a finite positive integer G such that the contour C can be divided into "bands" [the support of $\rho(\eta)\mathrm{d}\eta$] and "gaps" (where $\rho=0$). We denote these bands by I_j. More precisely, we define the analytic arcs $I_j, I_j^*, j=1,\ldots,G/2$ as follows (they come in conjugate pairs). Let the points λ_j, $j=0,\ldots,G$, in the open upper half-plane be the branch points of the function g. All such points lie on the contour C and we order them as $\lambda_0,\lambda_1,\ldots,\lambda_G$, according to the direction given to C. The points $\lambda_0^*,\lambda_1^*,\ldots,\lambda_G^*$ are their complex conjugates. Then let $I_0=[0,\lambda_0]$ be the subarc of C joining points 0 and λ_0. Similarly, $I_j = [\lambda_{2j-1},\lambda_{2j}]$, $j=1,\ldots,G/2$. The connected components of the set $\mathbb{C}\setminus\cup_j(I_j \cup I_j^*)$ are the so-called "gaps," for example, the gap Γ_1 joins λ_0 to λ_1, etc.

It actually follows from the properties of g, ρ that the function $\theta(\lambda)$ defined on C is constant on each of the gaps Γ_j, taking a value which we will denote by θ_j, while the function Φ is constant on each of the bands, taking the value denoted by α_j on the band I_j.

The finite genus ansatz for the given fixed x,t implies that the asymptotics of the solution of (9) and (10) as $\hbar \to 0$ can be given by the next theorem.

Theorem A.1: Let x_0, t_0 be given. The solution $\psi(x,t)$ of (9) and (10) is asymptotically described (locally) as a slowly modulated $G+1$ phase wavetrain. Setting $x=x_0+\hbar\hat{x}$ and $t=t_0+\hbar\hat{t}$, so that x_0,t_0 are "slow" variables while $\hat{x},\hat{t}$ are "fast" variables, there exist parameters

$a, U=(U_0,U_1,\ldots,U_G)^T$, $k=(k_0,k_1,\ldots,k_G)^T$, $w=(w_0,w_1,\ldots,w_G)^T$, $Y=(Y_0,Y_1,\ldots,Y_G)^T$, $Z=(Z_0,Z_1,\ldots,Z_G)^T$ [depending on the slow variables x_0 and t_0 (but not $\hat{x}\hat{t}$) such that

$$\psi(x,t) = \psi(x_0+\hbar\hat{x}, t_0+\hbar t) \sim a(x_0,t_0)e^{iU_0(x_0,t_0)/\hbar}e^{i(k_0(x_0,t_0)\hat{x} - w_0(x_0,t_0)t)} \times \frac{\Theta(Y(x_0,t_0) + iU(x_0,t_0)/\hbar + i(k(x_0,t_0)\hat{x} - w(x_0,t_0)t))}{\Theta(Z(x_0,t_0) + iU(x_0,t_0)/\hbar + i(k(x_0,t_0)\hat{x} - w(x_0,t_0)t))}. \tag{B1}$$

All parameters can be defined in terms of an underlying Riemann surface X. The moduli of X are given by λ_j, $j=0,\ldots,G$ and their complex conjugates λ_j^*, $j=0,\ldots,G$. The genus of X is G. The moduli of X vary slowly with x,t, i.e., they depend on x_0,t_0 but not $\hat{x},\hat{t}$. For the exact formulas for the parameters as well as the definition of the theta functions we present the following construction.

The Riemann surface X is constructed by cutting two copies of the complex sphere along the slits $I_0 \cup I_0^*, I_j, I_j^*, j=1,\dots,G$, and pasting the "top" copy to the "bottom" copy along these very slits.

We define the homology cycles a_j, b_j, $j=1,\dots,G$ as follows. Cycle a_1 goes around the slit $I_0 \cup I_0^*$ joining λ_0 to λ_0^*, remaining on the top sheet, oriented counterclockwise, a_2 goes through the slits I_{-1} and I_1 starting from the top sheet, also oriented counterclockwise, a_3 goes around the slits $I_{-1}, I_0 \cup I_0^*, I_1$ remaining on the top sheet, oriented counterclockwise, etc. Cycle b_1 goes through I_0 and I_1 oriented counterclockwise, cycle b_2 goes through I_{-1} and I_1, also oriented counterclockwise, cycle b_3 goes through I_{-1} and I_2, and around the slits $I_{-1}, I_0 \cup I_0^*, I_1$, oriented counterclockwise, etc.

On X there is a complex G-dimensional linear space of holomorphic differentials, with basis elements $\nu_k(P)$ for $k=1,\dots,G$ that can be written in the form

$$\nu_k(P) = \frac{\sum_{j=0}^{G-1} c_{kj} \lambda(P)^j}{R_X(P)} \mathrm{d}\lambda(P),$$

where $R_X(P)$ is a "lifting" of the function $R(\lambda)$ from the cut plane to X, if P is on the first sheet of X then $R_X(P)=R(\lambda(P))$ and if P is on the second sheet of X then $R_X(P)=-R(\lambda(P))$. The coefficients c_{kj} are uniquely determined by the constraint that the differentials satisfy the normalization conditions

$$\oint_{a_j} \nu_k(P) = 2\pi i \delta_{jk}.$$

From the normalized differentials, one defines a $G \times G$ matrix H (the period matrix) by the formula

$$H_{jk} = \oint_{b_j} \nu_k(P).$$

It is a consequence of the standard theory of Riemann surfaces that H is a symmetric matrix whose real part is negative definite.

In particular, we can define the theta function

$$\Theta(w) := \sum_{n \in \mathbb{Z}^G} \exp\left(\frac{1}{2} n^T H n + n^T w\right),$$

where H is the period matrix associated to X. Since the real part of H is negative definite, the series converges.

We arbitrarily fix a base point P_0 on X. The Abel map $A: X \to \mathrm{Jac}(X)$ is then defined componentwise as follows:

$$A_k(P; P_0) := \int_{P_0}^{P} \nu_k(P'), \quad k = 1, \dots, G,$$

where P' is an integration variable.

A particularly important element of the Jacobian is the Riemann constant vector K which is defined, modulo the lattice Λ, componentwise by

$$K_k := \pi i + \frac{H_{kk}}{2} - \frac{1}{2\pi i} \sum_{\substack{j=1 \\ j \neq k}}^{G} \oint_{a_j} \left(\nu_j(P) \int_{P_0}^{P} \nu_k(P') \right),$$

where the index k varies between 1 and G.

Next, we will need to define a certain meromorphic differential on X. Let $\Omega(P)$ be holomorphic away from the points ∞_1 and ∞_2, where it has the behavior

$$\Omega(P) = \mathrm{d}p(\lambda(P)) + \left(\frac{\mathrm{d}\lambda(P)}{\lambda(P)^2}\right), \quad P \to \infty_1,$$

$$\Omega(P) = -\mathrm{d}p(\lambda(P)) + O\left(\frac{\mathrm{d}\lambda(P)}{\lambda(P)^2}\right), \quad P \to \infty_2,$$

and made unique by the normalization conditions

$$\oint_{a_j} \Omega(P) = 0, \quad j = 1, \ldots, G.$$

Here p is a polynomial, defined as follows.

First, let us introduce the function $R(\lambda)$ defined by

$$R(\lambda)^2 = \prod_{k=0}^{G} (\lambda - \lambda_k)(\lambda - \lambda_k^*),$$

choosing the particular branch that is cut along the bands I_k^+ and I_k^- and satisfies

$$\lim_{x\to\infty} \frac{R(\lambda)}{\lambda^{G+1}} = -1.$$

This defines a real function, i.e., one that satisfies $R(\lambda^*) = R(\lambda)^*$. At the bands, we have $R_+(\lambda) = -R_-(\lambda)$, while $R(\lambda)$ is analytic in the gaps. Next, let us introduce the function $k(\lambda)$ defined by

$$k(\lambda) = \frac{1}{2\pi i}\sum_{n=1}^{G/2} \theta_n \int_{\Gamma_n^+\cup\Gamma_n^-} \frac{\mathrm{d}\eta}{(\lambda - \eta)R(\eta)} + \frac{1}{2\pi i}\sum_{n=0}^{G/2} \int_{I_n^+\cup I_n^-} \frac{\alpha_n \,\mathrm{d}\eta}{(\lambda - \eta)R_+(\eta)}.$$

Next let

$$H(\lambda) = k(\lambda)R(\lambda).$$

The function k satisfies the jump relations

$$k_+(\lambda) - k_-(\lambda) = -\frac{\theta_n}{R(\lambda)}, \quad \lambda \in \Gamma_n^+ \cup \Gamma_n^-,$$

$$k_+(\lambda) - k_-(\lambda) = -\frac{\alpha_n}{R_+(\lambda)}, \quad \lambda \in I_n^+ \cup I_n^-,$$

and is otherwise analytic. It blows up like $(\lambda - \lambda_n)^{-1/2}$ near each endpoint, has continuous boundary values in between the endpoints, and vanishes like $1/\lambda$ for large λ. It is the only such solution of the jump relations. The factor of $R(\lambda)$ renormalizes the singularities at the endpoints, so that, as desired, the boundary values of $H(\lambda)$ are bounded continuous functions. Near infinity, there is the asymptotic expansion

$$H(\lambda) = H_G\lambda^G + H_{G-1}\lambda^{G-1} + \cdots + H_1\lambda + H_0 + O(\lambda^{-1}) = p(\lambda) + O(\lambda^{-1}), \tag{B2}$$

where all coefficients H_j of the polynomial $p(\lambda)$ can be found explicitly by expanding $R(\lambda)$ and the Cauchy integral $k(\lambda)$ for large λ. It is easy to see from the reality of θ_j and α_j that $p(\lambda)$ is a polynomial with real coefficients.

Thus the polynomial $p(\lambda)$ is defined and hence the meromorphic differential $\Omega(P)$ is defined.

Let the vector $U \in \mathbb{C}^G$ be defined componentwise by

$$U_j := \oint_{b_j} \Omega(P).$$

Note that $\Omega(P)$ has no residues.

Let the vectors V_1, V_2 be defined componentwise by

$$V_{1,k} = (A_k(\lambda_{1+}^*) + A_k(\lambda_{2+}) + A_k(\lambda_{3+}^*) + \cdots + A_k(\lambda_{G+})) + A_k(\infty) + \pi i + \frac{H_{kk}}{2},$$

$$V_{2,k} = (A_k(\lambda_{1+}^*) + A_k(\lambda_{2+}) + A_k(\lambda_{3+}^*) + \cdots + A_k(\lambda_{G+})) - A_k(\infty) + \pi i + \frac{H_{kk}}{2},$$

where $k=1,\ldots,G$, and the $+$ index means that the integral for A is to be taken on the first sheet of X, with base point λ_+^0.

Finally, let

$$a = \frac{\Theta(Z)}{\Theta(Y)} \sum_{k=0}^{G} (-1)^k \mathfrak{J}(\lambda_k),$$

$$k_n = \partial_x U_n, \quad w_n = -\partial_t U_n, \quad n = 0, \ldots, G,$$

where

$$Y = -A(\infty) - V_1, \quad Z = A(\infty) - V_1,$$

and $U_0 = -(\theta_1 + \alpha_0)$ where θ_1 is the (constant in λ) value of the function θ in the gap Γ_1 and α_0 is the (constant) value of the function ϕ in the band I_0.

Now, the parameters appearing in formula (B1) are completely described.

We simply note here that the U_i and hence the k_i and w_i are real. We also note that the denominator in (B1) never vanishes (for any $x_0, t_0, \hat{x}, \hat{t}$).

Remark: Theorem A.1 presents pointwise asymptotics in x,t. In Ref. 3, these are extended to uniform asymptotics in certain compact sets covering the x,t plane. Error estimates are also given in Ref. 3.

Remark: As mentioned above, we do not know if the support of the equilibrium measure of the maximizing continuum is unique. But the asymptotic formula (B1) depends only on the endpoints λ_j of the analytic subarcs of the support. Since the asymptotic expression (B1) must be unique, it is easy to see that the endpoints also must be unique. Different Riemann surfaces give different formulas (except of course in degenerate cases, a degenerate genus 2 surface can be a pinched genus 0 surface and so on).

APPENDIX C: DROPPING ASSUMPTION (A) OF SEC. V

In Sec. V, we have assumed that the solution of the problem of the maximization of the equilibrium energy is a continuum, say F, which does not intersect the linear segment $[0, iA]$ except of course at $0_+, 0_-$. We also prove that F does not touch the real line, except of course at 0 and possibly ∞. This enables us to take variations in Sec. VI, keeping fixed a finite number of points, and thus arrive at the identity of Theorem 5, from which we derive the regularity of F and the fact that F is, after all, an S-curve.

In general, it is conceivable that F intersects the linear segment $[0, iA]$ at points other than $0_+, 0_-$. If the set of such points is finite, there is no problem, since we can always consider variations keeping fixed a finite number of points, and arrive at the same result (see the remark after the proof of Theorem 5).

If, on the other hand, this is not the case, we have a different kind of problem, because the function V introduced in Sec. VI (the complexification of the field) is not analytic across the segment $[-iA, iA]$.

What is true, however, is that V is analytic in a Riemann surface consisting of infinitely many sheets, cut along the line segment $[-iA, iA]$. So, the appropriate, underlying space for the (doubled up) variational problem should now be a noncompact Riemann surface, say $\mathbb{L}$.

Compactness is crucial in the proof of a maximizing continuum. But we can compactify the Riemann surface $\mathbb{L}$ by compactifying the complex plane. Let the map $\mathbb{C} \to \mathbb{L}$ be defined by

$$y = \log(z - iA) - \log(z + iA).$$

The point $z = iA$ corresponds to infinitely many y points, i.e., $y = -\infty + i\theta$, $\theta \in \mathbb{R}$, which will be identified. Similarly, the point $z = -iA$ corresponds to infinitely many points $y = +\infty + i\theta$, $\theta \in \mathbb{R}$, which will also be identified. The point $0 \in \mathbb{C}$ corresponds to the points $k\pi i$, k odd.

By compactifying the plane we then compactify the Riemann surface $\mathbb{L}$. The distance between two points in the Riemann surface $\mathbb{L}$ is defined to be the corresponding stereographic distance between the images of these points in the compactified $\mathbb{C}$.

With these changes, the proof of the existence of the maximizing continuum in Secs. I, III, and IV goes through virtually unaltered. In Sec. VI, we would have to consider the complex field V as a function defined in the Riemann surface $\mathbb{L}$ and all proofs go through. The corresponding result of Sec. VII will give us an S-curve C in the Riemann surface $\mathbb{L}$. We then have the following facts.

Consider the image $\mathbb{D}$ of the closed upper half-plane under

$$y = \log(z - iA) - \log(z + iA).$$

Consider continua in $\mathbb{D}$ containing the points $y = \pi i$ and $y = -\pi i$. Define the Green's potential and Green's energy of a Borel measure by (4)–(6) and the equilibrium measure by (7). Then there exists a continuum C maximizing the equilibrium energy, for the field given by (3) with conditions (1). C does not touch $\partial\mathbb{D}$ except at a finite number of points. By taking variations as in Sec. VI, one sees that C is a S-curve. In particular, the support of the equilibrium measure on C is a union of analytic arcs and at any interior point of supp μ,

$$\frac{d}{dn_+}(\phi + V^{\lambda^C}) = \frac{d}{dn_-}(\phi + V^{\lambda^C}), \tag{8'''}$$

where the two derivatives above denote the normal derivatives.

As far as the consequences of the above facts regarding the semiclassical limit of NLS, some more work on the details is necessary. Indeed, the analysis of the dynamics of the semiclassical problem (9) and (10) presented in Ref. 3 assumes that the S-curve C lies entirely in $\mathbb{K} \cup \{0_+, 0_-\}$. However, the explicit computation of the equilibrium measure on the S-curve and the derivation of the equations implicitly defining the endpoints of the components of the support of the equilibrium measure also make sense when extended to the Riemann surface $\mathbb{L}$. As a result the statement of Theorem A.1 is correct, when interpreted correctly, i.e., allowing for all contours involved in the definition of the line integrals appearing in formula (B1) as well as the bands $I_0 \cup I_0^*, I_j, I_j^*, j = 1, \ldots, G$ and the gaps Γ_j to lie in $\mathbb{L}$.

We plan to describe the details of the evolution of the S-curve in the Riemann surface $\mathbb{L}$ in a later publication. In particular, one must check that all the deformations described in Ref. 3 are valid; this is indeed true, as one can see by the analysis of Ref. 3 transferred to the Riemann surface $\mathbb{L}$.

Remark: The "discrete-to-continuous" passage.

The following caveat has to be addressed here. One of the problems dealt with in Ref. 3 was to transform the so-called "discrete" Riemann-Hilbert problem (problem 4.1.1 of Ref. 3) to a "continuous" Riemann-Hilbert problem (problem 4.2.1 of Ref. 3). The initial (discrete) problem posed is to construct a (matrix) meromorphic function from the information on its poles. These poles indeed accumulate (as $\hbar$ goes to 0) along the segment $(-iA, iA)$. Then one transforms the

problem to a properly speaking (continuous) holomorphic Riemann-Hilbert problem with jumps, by constructing two contours, one encircling the poles with positive imaginary part and the other encircling the poles with negative imaginary part, and redefining the matrix functions inside the contours so that the singularities are removed. Naturally the information concerning the poles appears in the arising jump along the two loops.

One then (formally at first) approximates the jump on the loops in an obvious way (it is a Riemann sum approximated by an integral). This jump involves a logarithmic function with a cut along the linear segment $[-iA, iA]$.

Now, to rigorously show that the approximation is valid one needs a very careful analysis of what happens near 0, because the "Riemann sum" approximation breaks down there. Indeed this is done in Sec. 4.4.3 of Ref. 3, where, however, it is assumed that the loop (the jump contour) is located exactly at the S-curve (which solves the variational problem), and that this S-curve emanates from 0+ at an acute, nonright, angle to the horizontal axis.

Even though in Ref. 3 the S-curve is assumed not to touch the linear segment $[-iA, iA]$, this condition is actually only necessary *locally* near 0. There is no problem in allowing the S-curve to intersect the spike, as long as it emanates from 0_+ at an acute, nonright, angle to the horizontal axis. Now it is *proved* in Ref. 3 that the S-curve solving the variational problem must emanate from 0+ at an acute, nonright, angle to the horizontal axis. [This in fact follows immediately from the measure reality condition (4.18) applied at the origin.] So the proof of Theorem A.1 will go through even if the S-curve intersects the linear segment $[-iA, iA]$.

We then have the following.

Theorem 9: Consider the semiclassical limit ($\hbar \to 0$) of the solution of (9) and (10) with bell-shaped initial data. Replace the initial data by the so-called soliton ensembles data (as introduced in Ref. 3) defined by replacing the scattering data for $\psi(x,0)=\psi_0(x)$ by their WKB approximation. Assume, for simplicity, that the spectral density of eigenvalues satisfies conditions (1).

Then, asymptotically as $\hbar \to 0$, the solution $\psi(x,t)$ admits a "finite genus description," in the sense of Theorem A.1.

(Received 4 April 2005; accepted 6 June 2005; published online 28 July 2005)

The nonlinear fractional diffusion equation $\partial_t\rho=r^{1-d}\partial_r^{\mu'}\{r^{d-1}\mathcal{D}(r,t;\rho)\partial_r^{\mu}\rho^{\nu}\}-r^{1-d}\partial_r\{r^{d-1}F(r,t)\rho\}+\overline{\alpha}(t)\rho$ is studied by considering the diffusion coefficient $\mathcal{D}(r,t;\rho)=\mathcal{D}(t)r^{-\theta}\rho^{\gamma}$ and the external force $F(r,t)=-k_1(t)r+k_\alpha r^{\alpha}$. In addition, a rich class of diffusive processes, including normal and anomalous ones, is obtained from the study present in this work. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1993527]

I. INTRODUCTION

Due to the broadness of physical applications covering almost every field, the diffusion equations have been widely investigated. In this direction, we have, for instance, the nonlinear diffusion equations, the fractional diffusion equations, and the diffusion equations that contain a mix of nonlinear terms and fractional derivatives. These equations extend the usual diffusion equation by considering the presence of nonlinear terms and fractional derivatives. They have been applied to several scenarios such as percolation of gases through porous media,[1] thin saturated regions in porous media,[2] a standard solid-on-solid model for surface growth, thin liquid films spreading under gravity,[3] modeling of non-Markovian dynamical processes in protein folding,[4] relaxation to equilibrium in system (such as polymer chains and membranes) with long temporal memory,[5] and in anomalous transport in disordered systems.[6] A representative nonlinear diffusion equation usually employed in the above context is the *porous medium equation*.[7,8] We may also have the high order diffusion-like equation such as the thin film equation,[9] which contains a fourth order derivative. This kind of diffusion equation can be applied to describe the lubrication models for thin viscous films, spreading droplets, and Hele–Shaw cells.[10] In addition to the above context, the fractional equations[11] have also been employed to investigate the situations related to the anomalous diffusion and, in particular, the diffusion equations that accomplish nonlinear terms and fractional derivatives.[12,13]

From the previous discussion, we note the importance of these equations not only due to the various types of scenarios which can be described, but also due to the growing interest on the feasibility of covering new situations. In this direction, we have, for example, the displacement of a viscous fluid by a less viscous one in a petroleum reservoir requires a more general approach in order to take the nonlinear behavior of the interface into account, and also the fractal or multifractal characteristics of porous rocks in which the oil is immersed. In particular, the geostatistics of these reservoirs are well described by a fractional Brownian motion and fractional Levy motion.[14] Thus, the present work intends to establish some classes of solutions of a general nonlinear fractional diffusion equation with absorption and investigate the classes of diffusive processes described by this equation. More precisely, we focus our attention on the following generalized equation:

$$\frac{\partial}{\partial t}\rho(r,t)=\frac{1}{r^{d-1}}\frac{\partial^{\mu'}}{\partial r^{\mu'}}\left\{r^{d-1}\mathcal{D}(r,t;\rho)\frac{\partial^{\mu}}{\partial r^{\mu}}[\rho(r,t)]^{\nu}\right\}-\frac{1}{r^{d-1}}\frac{\partial}{\partial r}\{r^{d-1}F(r,t)\rho(r,t)\}+\overline{\alpha}(t)\rho(r,t), \tag{1}$$

where ρ is a density function, d is a spatial dimension of the system under consideration, r is nonnegative, the parameters $\nu,\mu',\mu\in\mathcal{R}$, $\mathcal{D}(r,t;\rho)=\mathcal{D}(t)r^{-\theta}[\rho(r,t)]^{\gamma}$ is the diffusion coefficient, $F(r,t)$ is an external force (*drift*), and $\overline{\alpha}(t)$ plays the role of an absorbent (or source) rate related to a reaction-diffusion process. The presence of the reaction term like the one given in the above equation has been studied in several situations. Here, for example, we may recall the catalytic processes in regular, heterogeneous, or disordered systems.[15] Another example is an irreversible first-order reaction of transported substance so that the rate of removal is $\overline{\alpha}\rho$.[16] This extra term may also appear when a tracer undergoing radioactive decay is transported through a porous medium,[17] in heat flow involving heat production.[18] Equation (1) applies in these situations and in solute transport through adsorbent samples that are usually proportional to the concentration in the solution. It is also interesting to note that Eq. (1) may be related to several physical situations such as the axisymmetric flow of a very viscous fluid,[19] turbulent diffusion,[20] adsorption-desorption equilibrium locally maintained through a permeable solid,[21] and nonlinear diffusion in hard and soft superconductors.[22]

For $\overline{\alpha}(t)=0$, one can verify that $\int_0^{\infty}drr^{d-1}\rho(r,t)$ is time independent (hence, if ρ is normalized at $t=0$, it will remain so forever). Indeed, if Eq. (1) is written as $\partial_t\rho=-r^{1-d}\partial_r\mathcal{J}$ and the boundary condition $\mathcal{J}(r\to\infty,t)\to 0$ is assumed, it can be shown that $\int_0^{\infty}drr^{d-1}\rho(r,t)$ is a constant of motion. According to Refs. 12 and 13, we use the Riemann–Liouville operator[11,23] for the spatial fractional derivatives. Also, we employ the boundary condition $\rho(r\to\infty,t)\to 0$. Note that Eq. (1) recovers, for $(\mu',\mu,\gamma,\nu)=(1,1,0,1)$, the standard Fokker–Planck equation[24] in the presence of a drift with an adsorbent (source) term for a d-dimensional case within radial symmetry. The particular case $F(r,t)=0$ (no drift), $\mathcal{D}(r,t)=$*constant*, and $(\mu',\mu,\gamma,d)=(1,1,0,1)$ has been considered by Spohn.[8] Other features of Eq. (1) with $(\mu',\mu,\theta,\gamma,d)=(1,1,0,0,1)$ have also been considered in Refs. 25 and 26. The case $(\mu',\theta,\gamma,d)=(0,0,0,1)$ with $\mathcal{D}(t)=$*constant* without external force has been investigated in Ref. 12. In Ref. 13 the presence of external forces and a spatial time dependence on the diffusion coefficient has been considered for $(d,\mu')=(1,1)$. Therefore, our present discussion involves extensions of these cases by taking a wide variety of situations into account; employing the nonlinear, fractional, and the mixing of these cases. Moreover, we develop, in a unified approach, extending the results presented in Refs. 8, 12, 25, and 26 for a d-dimensional case by considering the presence of fractional derivatives, external forces and a spatial time dependent diffusion coefficient. The remainder of this paper goes as follows. In Sec. II, we consider several situations for Eq. (1) as well as the connection of the solutions with the ones obtained within the maximum entropy principle. In Sec. III, we present our conclusions.

II. DIFFUSION EQUATION: SOLUTIONS

This section considers the solutions for Eq. (1) expressed as a scaled function of the type

$$\overline{\rho}(r,t)=\frac{1}{\Phi(t)}\tilde{\rho}\left[\frac{r}{\Phi(t)}\right], \tag{2}$$

where $\Phi(t)$ is a positive time dependent function. These solutions may satisfy the initial and the boundary condition. Before substituting Eq. (2) in Eq. (1), some changes in Eq. (1) are carried out in order to simplify the analysis. Supposing the solution of Eq. (1) can be given by $\rho(r,t)=\exp[\int_0^t d\tilde{t}\overline{\alpha}(\tilde{t})]\overline{\rho}(r,t)/r^{d-1}$, where $\overline{\rho}(r,t)$ is a function to be determined, yields

$$\frac{\partial}{\partial t}\overline{\rho}(r,t)=\overline{\mathcal{D}}(t)\frac{\partial^{\mu'}}{\partial r^{\mu'}}\left\{r^{(1-\gamma)(d-1)-\theta}[\overline{\rho}(r,t)]^{\gamma}\frac{\partial^{\mu}}{\partial r^{\mu}}\{r^{-\nu(d-1)}[\overline{\rho}(r,t)]^{\nu}\}\right\}-\frac{\partial}{\partial r}\{F(r,t)\overline{\rho}(r,t)\}, \tag{3}$$

with $\overline{\mathcal{D}}(t)=\mathcal{D}(t)\exp[(\nu+\gamma-1)\int_0^t d\tilde{t}\overline{\alpha}(\tilde{t})]$.

Applying Eq. (2) in Eq. (3) by taking the drift term, specifically, $F(r,t)=-k_1(t)r$ into account and following the procedure employed in Refs. 12 and 13, Eq. (3) can be reduced to

$$\frac{d^{\mu'}}{dz^{\mu'}}\left\{z^{(1-\gamma)(d-1)-\theta}[\tilde{\rho}(z)]^{\gamma}\frac{d^{\mu}}{dz^{\mu}}\{z^{-\nu(d-1)}[\tilde{\rho}(z)]^{\nu}\}\right\}=\overline{k}\frac{d}{dz}[z\tilde{\rho}(z)] \tag{4}$$

and

$$[\Phi(t)]^{\xi-2}\frac{d}{dt}\Phi(t)+k_1(t)[\Phi(t)]^{\xi-1}=-\overline{kD}(t), \tag{5}$$

where $\xi=d(\gamma+\nu)-(d-1)+\mu+\mu'+\theta$, $z=r/\Phi(t)$ and $\overline{k}$ is an arbitrary constant. Note that we have used the generic property

$$\frac{d^{\delta}}{dx^{\delta}}\mathcal{G}(ax)=a^{\delta}\frac{d^{\delta}}{d\overline{z}^{\delta}}\mathcal{G}(\overline{z})\quad(\delta\in\mathcal{R}), \tag{6}$$

where $\overline{z}=ax$. This basic property holds not only for the ordinary derivative but also for all fractional operators which are considered in this analysis. By solving Eq. (5), results

$$\Phi(t)=\left[(\Phi(0))^{\xi-1}+k'\int_0^t d\tilde{t}\mathcal{D}(\tilde{t})e^{(\nu+\gamma-1)\int_0^{\tilde{t}}dt'\overline{\alpha}(t')+(\xi-1)\int_0^{\tilde{t}}dt'k_1(t')}\right]^{1/(\xi-1)}e^{-\int_0^t dt'k_1(t')}, \tag{7}$$

with $k'=(1-\xi)\overline{k}$. Performing an integration in Eq. (4), we have that

$$\frac{d^{\mu'-1}}{dz^{\mu'-1}}\left\{z^{(1-\gamma)(d-1)-\theta}[\tilde{\rho}(z)]^{\gamma}\frac{d^{\mu}}{dz^{\mu}}\{z^{-\nu(d-1)}[\tilde{\rho}(z)]^{\nu}\}\right\}=\overline{k}z\tilde{\rho}(z)+\mathcal{C}, \tag{8}$$

where $\mathcal{C}$ is an integration constant (see Refs. 12 and 13 for details).

The next step is the analysis of the solutions of Eq. (8) by considering several situations of the parameters μ', μ, θ, γ, and d. Starting our study by the solutions of Eq. (8) with the following case, $\mu'=1$, $\mathcal{C}=0$ and (μ,θ,γ,d) being arbitraries, it is feasible to propose the following *ansatz*: $\tilde{\rho}(z)=\mathcal{N}z^{\alpha/\nu}(a+bz)^{\beta/\nu}$, as a solution for Eq. (8). To verify the last statement, the following result is considered:

$$\frac{d^{\delta}}{dz^{\delta}}\left[z^{\alpha}(a+bz)^{\beta}\right]=a^{\delta}\frac{\Gamma[\alpha+1]}{\Gamma[\alpha+1-\delta]}z^{\alpha-\delta}(a+bz)^{\beta-\delta}, \tag{9}$$

when $\delta=\alpha+\beta+1$ ($\Gamma[\ldots]$ is the Gamma function). By applying the ansatz and the above equation in Eq. (8), we find

$$\frac{\alpha}{\nu}=\frac{(1+\mu+\theta)(2+\mu+\theta)}{(1+2\mu+\theta)(\gamma-1)}+d-1,$$

$$\frac{\beta}{\nu}=\frac{\mu(2+\mu+\theta)}{(1+2\mu+\theta)(\gamma-1)},$$

$$\nu=\frac{(\mu-1)(\gamma-1)}{2+\mu+\theta}. \tag{10}$$

Note that the above results recover those obtained in Ref. 12 for $(\theta,\gamma,d)=(0,0,1)$ and contain the results obtained in Ref. 13 for $d=1$ by replacing μ with $\mu-1$ as a consequence. These results allow us to write the solution in the form

$$\tilde{\rho}(z) = \mathcal{N} z^{d-1}\left[z^{1+\mu+\theta}(1+bz)^{\mu}\right]^{(2+\mu+\theta)/[(1+2\mu+\theta)(\gamma-1)]}, \tag{11}$$

with

$$\mathcal{N} = \left[\frac{\overline{k\Gamma}(-\beta)}{\Gamma(1+\alpha-\nu(d-1))}\right]^{1/(\nu+\gamma-1)}, \tag{12}$$

where b is an arbitrary constant to be taken as ± 1 according to the specific solutions to be studied in order that the solution satisfies the boundary condition (consequently normalization condition) and $\mathcal{N}$ can be determined be the normalization condition. For $b=-1$, we have a cutoff distribution and for $b=1$ we have classical solutions which are nonvanishing on the whole positive axis. In addition, the requirement of normalization for $\mathcal{N}$ implies that $\rho(r,t)$ is normalized to unity at least for the initial time $t=0$. Note that the explicit form of $\mathcal{N}$ and b depend on the behavior of the density function which is defined by the parameters μ, θ, γ, and d, see the cases worked below.

In order to analyze the behavior of the solution $\rho(r,t)$ several range values for the parameters μ, d, θ, and γ may be considered. For simplicity, taking $\alpha(t)=0$ we illustrate three of them: (i) $\mu>0$ with $\mu+\theta \geqslant 0$ and $\gamma>1$, (ii) $-1<\mu+\theta<0$ with $\mu>1$ and $\gamma=1-1/d$, and (iii) $d(1-\gamma)-(2+\theta)<\mu<-(1+\theta)/2$, $d>2$, $1/d<\gamma<1-1/d$, $\mu<0$ and $\theta>2d(1-\gamma)-3$. Starting by case (i), without loss of generality, $b=-1$ can be chosen. The normalization condition

$$\mathcal{N}\int_0^1 z^{d-1}\left[z^{1+\mu+\theta}(1-z)^{\mu}\right]^{(2+\mu+\theta)/[(1+2\mu+\theta)(\gamma-1)]}dz = 1 \tag{13}$$

implies that

$$\mathcal{N} = \frac{\Gamma\left(1+d+\dfrac{2+\mu+\theta}{\gamma-1}\right)}{\Gamma\left(1+\dfrac{\mu(2+\mu+\theta)}{(1+2\mu+\theta)(\gamma-1)}\right)\Gamma\left(d+\dfrac{(1+\mu+\theta)(2+\mu+\theta)}{(1+2\mu+\theta)(\gamma-1)}\right)}, \tag{14}$$

(see Fig. 1). The second moment obtained from the above equation is $\langle r^2\rangle \propto [\Phi(t)]^2$. For cases (ii) and (iii), $b=1$ is taken. The normalization factor yields

$$\mathcal{N} = \frac{\Gamma\left(\dfrac{\mu(2+\mu+\theta)}{(1+2\mu+\theta)(1-\gamma)}\right)}{\Gamma\left(d-\dfrac{(1+\mu+\theta)(2+\mu+\theta)}{(1+2\mu+\theta)(1-\gamma)}\right)\Gamma\left(\dfrac{2+\mu+\theta}{1-\gamma}-d\right)} \tag{15}$$

(see Fig. 2). It is interesting to note that this case has a divergent behavior at the origin for the normalized density probability. Case (iii), in contrast to case (ii), presents a defined behavior at the origin as shown in Fig. 3 and it has a long tail behavior.

Following the previous procedure, the above result can be extended by considering $\mu' \neq 1$, leading to the solution for this case given by

$$\tilde{\rho}(z) = \overline{\mathcal{N}} z^{d-1}\left[z^{\mu+\theta+\mu'}(1+bz)^{\mu+\mu'-1}\right]^{(\mu+2\mu'+\theta)/[(1-2(\mu+\mu')-\theta)(1-\gamma)]}, \tag{16}$$

where

$$\overline{\mathcal{N}} = \left[\frac{\Gamma(1+\alpha-\nu(d-1))}{\overline{k\Gamma}(1+\alpha-\nu(d-1)-\mu)}\frac{\Gamma\left(\alpha\left(1+\dfrac{\gamma}{\nu}\right)+(1-\gamma-\nu)(d-1)-\theta-\mu+1\right)}{\Gamma\left(\alpha\left(1+\dfrac{\gamma}{\nu}\right)+(1-\gamma-\nu)(d-1)-\theta-\mu-\mu'+2\right)}\right]^{1/(1-\nu-\gamma)}$$

and

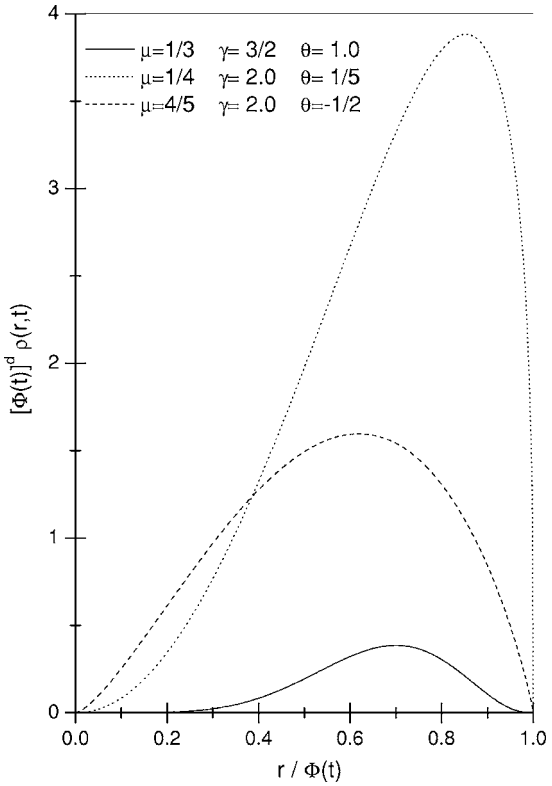

FIG. 1. Behavior of $[\Phi(t)]^d\rho(r,t)$ vs $r/\Phi(t)$ which illustrates the solution with typical values for $\mu>0$ with $\mu+\theta \geqslant 0$, $d=3$, $\gamma>1$ and $\overline{\alpha}(t)=0$. We notice that the distribution vanishes at the abcissa equal to 1, and remains zero outside this interval.

$$\frac{\beta}{\nu}=\frac{(\mu+\mu'-1)(\mu+2\mu'+\theta)}{(1-2(\mu+\mu')-\theta)(1-\gamma)},$$

$$\frac{\alpha}{\nu}=\frac{(\mu+\mu'+\theta)(\mu+2\mu'+\theta)}{(1-2(\mu+\mu')-\theta)(1-\gamma)}+d-1,$$

$$\nu=\frac{(1-\mu)(1-\gamma)}{\mu+2\mu'+\theta},$$

$$\gamma=-\frac{\mu+\theta-d}{\mu'+d}. \tag{17}$$

Note that Eq. (16) presents a similar structure of Eq. (11), however, the conditions on the parameters γ, β, μ, μ', ν, and θ are different.

Now, particular cases of Eq. (8) are discussed by considering special values of μ and μ', with $\mathcal{C}=0$ and (θ,γ,d) arbitraries. Considering $\mu=0$, $\mu'=2$, and $\overline{k}=-k''$, Eq. (8) turns out to be

$$\frac{d}{dz}\left\{z^{(1-\gamma-\nu)(d-1)-\theta}[\tilde{\rho}(z)]^{\gamma+\nu}\right\}=-k''z\tilde{\rho}(z). \tag{18}$$

Solving Eq. (18), we obtain

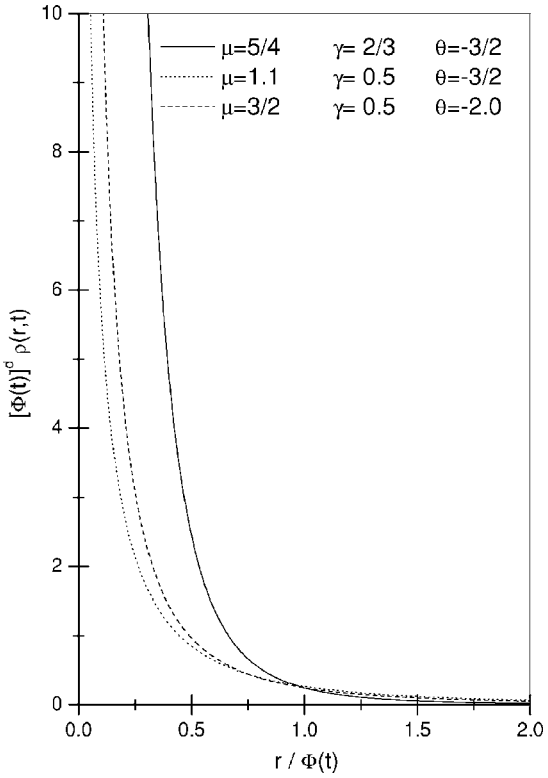

FIG. 2. Behavior of $[\Phi(t)]^d\rho(r,t)$ vs $r/\Phi(t)$ which illustrates the solution with typical values for $-1<\mu+\theta<0$ with $\mu>1$, $\gamma=1-1/d$, and $\overline{\alpha}(t)=0$.

$$\tilde{\rho}(z) = z^{d-1+(1+\theta-d)/(\nu+\gamma)}\exp_q\left[-\mathcal{K}z^{1+d+1+\theta-d/\gamma+\nu}\right] \tag{19}$$

with $\mathcal{K}=k''/[1-d+\theta+(\gamma+\nu)(d+1)]$, $q=2-\nu-\gamma$, where $\exp_q(r)\equiv[1+(1-q)r]^{1/1-q}$ is the q-exponential function that arises within the nonextensive thermostatistical formalism by optimizing, under appropriate constraints, the entropic form[27]

$$S_q = \frac{1-\int dr' r'^{d-1}[p(r')]^q}{q-1}. \tag{20}$$

The constant k'' can be obtained from the normalization condition. By using Eq. (19), $\rho(r,t)$ is illustrated in Fig. 4 by considering the absence of source (absorbent) term. Note that $d(\nu+\gamma)-d+\theta>0$, $d(\nu+\gamma)-d+\theta=0$, and $d(\nu+\gamma)-d+\theta<0$, respectively, correspond to the subdiffusive, normal, and superdiffusive regimes for $(k_1(t),\overline{\alpha}(t))=(0,0)$, since $\langle r^2\rangle\propto t^{2/(2+d(\nu+\gamma)-d+\theta)}$. Note that the above equation leads to an explicit dependence on the dimension d in $\rho(r,t)$, differently from Eqs. (11) and (16).

The solution (19) can also be extended by assuming the external force as $F(r,t)=-k_1(t)r+k_\alpha r^\alpha$ and $\overline{\mathcal{D}}(t)=constant$. It is still not known what happens in the general case for $(\alpha,\theta,\nu,\gamma)$, but there is a special case for which the scaled solution of the type indicated in Eq. (2) can be used. This special case corresponds to $\alpha=d(1-\gamma-\nu)-1-\theta$, i.e., $\alpha+\theta+(2-q)d=d-1$. If this condition is satisfied, we obtain

$$\tilde{\rho}(z') = z'^{d-1}z'^{(1+\theta-d)/(\nu+\gamma)}\exp_q\left[-\frac{\mathcal{K}}{\overline{\mathcal{D}}}z'^{1+d+(1+\theta-d)/(\gamma+\nu)}+\frac{k_\alpha}{(\nu+\gamma)\overline{\mathcal{D}}}\ln_{\bar{q}}(z')\right],$$

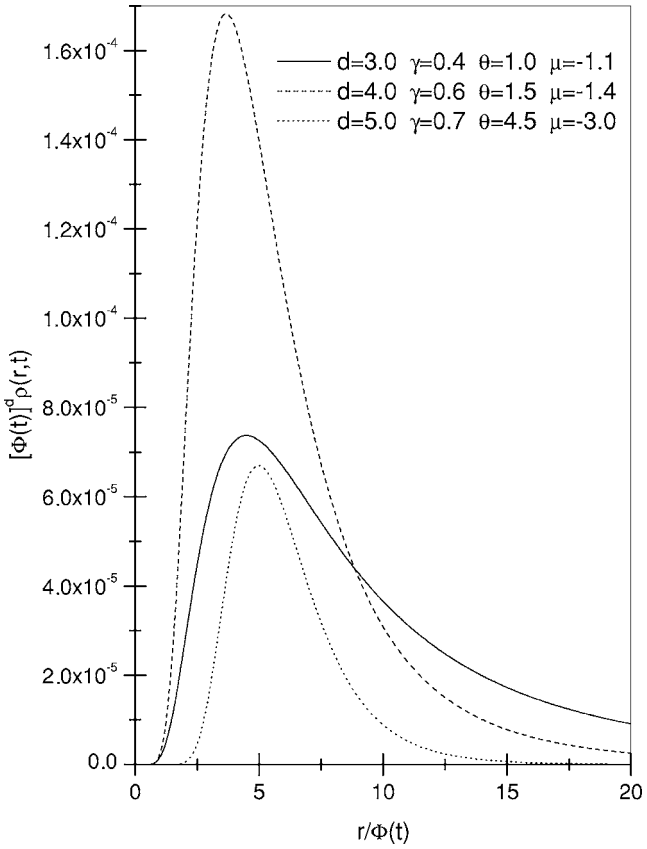

FIG. 3. Behavior of $[\Phi(t)]^d\rho(r,t)$ vs $r/\Phi(t)$, which illustrates the solution with typical values for $d(1-\gamma)-(2+\theta)<\mu<-(1+\theta)/2$, $d>2$, $1/d<\gamma<1-1/d$, $\mu<0$, $\theta>2d(1-\gamma)-3$, and $\overline{\alpha}(t)=0$.

$$\overline{\Phi}(t)=\left[(\overline{\Phi}(0))^{\overline{\xi}+1}+\mathcal{C}_1\int_0^t d\tilde{t}e^{(\overline{\xi}+1)\int_0^{\tilde{t}}dt'k_1(t')}\right]^{1/\overline{\xi}+1}e^{-\int_0^t dt'k_1(t')} \text{ and } z'=\frac{r}{\overline{\Phi}(t)}, \tag{21}$$

where $\overline{q}=1+\overline{\xi}-d-(1+\theta-d)/(\nu+\gamma)$, $\overline{\xi}=1-d+\theta+d(\nu+\gamma)$, $\mathcal{C}_1=(\overline{\xi}+1)k''$, and $\ln_q x\equiv(x^{1-q}-1)/(1-q)$ is the q-logarithm function (that is, the inverse function of the q-exponential). Eq. (21) exhibits an explicit dependence on the dimension d in $\rho(r,t)$ as well as Eq. (19).

Now we focus our attention on the case $\mu=1$, $\mu'=1$ and $\overline{k}=-\tilde{k}$. By substituting these values in Eq. (8), we obtain

$$z^{(1-\gamma)(d-1)-\theta}[\tilde{\rho}(z)]^{\gamma}\frac{d}{dz}\{z^{-\nu(d-1)}[\tilde{\rho}(z)]^{\nu}\}=\tilde{k}z\tilde{\rho}(z). \tag{22}$$

The solution for the above equation is also given in terms of the q-exponential functions as well as the solutions found for Eq. (18). In particular, the solution for Eq. (22) is given by

$$\tilde{\rho}(z)=z^{d-1}\exp_q\left[-\frac{\tilde{k}}{\nu(2+\theta)}z^{2+\theta}\right], \tag{23}$$

with $q=2-(\nu+\gamma)$.

Another interesting case is given by $\mu'=1$ and $\mu=-1$. For this case Eq. (8) reads

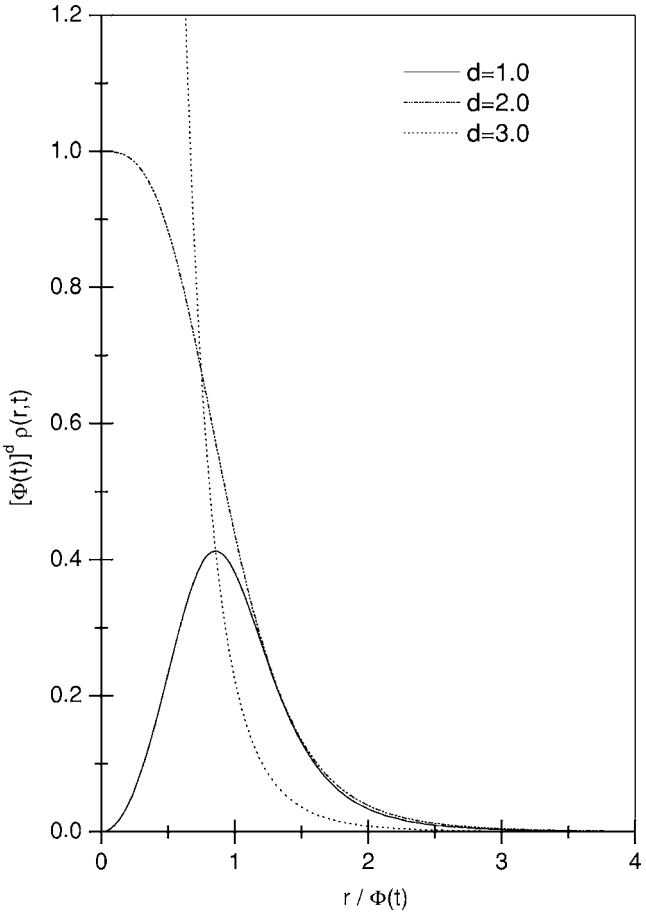

FIG. 4. We show the behavior of $[\Phi(t)]^d\rho(r,t)$ vs $r/\Phi(t)$ for a typical value of d with $\theta=1$, $\nu+\gamma=1/2$ and $\overline{\alpha}(t)=0$. It is interesting to note that depending on the value of d we can have a divergent behavior for $\rho(r,t)$, since in these cases $\rho(r,t)$ is normalized.

$$z^{(1-\gamma)(d-1)-\theta}[\tilde{\rho}(\overline{z})]^{\gamma}\int_0^z d\overline{z}\,\overline{z}^{\nu(d-1)}[\tilde{\rho}(\overline{z})]^{\nu}=\overline{k}z\tilde{\rho}(z). \tag{24}$$

After some calculations, it is possible to show that a solution for Eq. (24) is

$$\tilde{\rho}(z)=z^{d-1-(1+\theta)/(1-\gamma)}\left[1+\overline{\mathcal{C}}z^{1-\nu(1+\theta)/1-\gamma}\right]^{1/(1-\nu-\gamma)}, \tag{25}$$

where $\overline{\mathcal{C}}$ is a constant.

The case $\mu'=0$ and $\mu=0$ leads to

$$\int_0^z d\overline{z}\,\overline{z}^{(d-1)(1-\gamma-\nu)-\theta}[\tilde{\rho}(\overline{z})]^{\gamma+\nu}=\overline{k}z\tilde{\rho}(z). \tag{26}$$

The corresponding solution is given by

$$\tilde{\rho}(z)=\frac{1}{z}\left[1+\mathcal{K}'z^{\alpha'}\right]^{1/(1-\gamma-\nu)}, \tag{27}$$

where $\mathcal{K}'=(1-\gamma-\nu)/[1-\theta+(d-1)(1-2(\nu+\gamma))\overline{k}]$ and $\alpha'=1-\theta+(d-1)[1-2(\nu+\gamma)]$.

To analyze the case $\mu=0$, $\mu'=1$, and $\mathcal{C}\neq 0$ it is convenient to go back to Eq. (4) in order to obtain its solution. Thus, it follows that:

$$\overline{kz}\tilde{\rho}(z) = z^{(1-\nu-\gamma)(d-1)-\theta}[\tilde{\rho}(z)]^{\gamma+\nu} + \overline{\mathcal{C}}, \tag{28}$$

which implicitly determines $\tilde{\rho}(z)$. The solution corresponding to $\mathcal{C}=0$ is $\tilde{\rho}(z)\propto z^{d-1+(1+\theta)/(\gamma+\nu-1)}$.

Considering $\mu'=1$, $\mu=2$, and $\overline{k}=-\tilde{k}'$ Eq. (1) can be reduced to a thin-film-like equation. By applying these assumptions into Eq. (1) and using the above procedure the equation for $\tilde{\rho}(z)$ obtained from Eq. (8) is given by

$$z^{(1-\gamma)(d-1)-\theta}[\tilde{\rho}(z)]^{\gamma}\frac{d^2}{dz^2}\{z^{-\nu(d-1)}[\tilde{\rho}(z)]^{\nu}\} = -\tilde{k}'z\tilde{\rho}(z), \tag{29}$$

and for the time function, by using Eq. (7), we obtain

$$\Phi(t) = \left[(\Phi(0))^{\varepsilon-1} + k'\int_0^t d\tilde{t}\mathcal{D}(\tilde{t})e^{(\nu+\gamma-1)\int_0^{\tilde{t}}dt'\overline{\alpha}(t')+(\varepsilon-1)\int_0^{\tilde{t}}dt'k_1(t')}\right]^{1/(\varepsilon-1)} e^{-\int_0^t dt'k_1(t')}, \tag{30}$$

with $k'=(\varepsilon-1)\tilde{k}'$ where $\varepsilon=4+d(\gamma+\nu)-d+\theta$. The solution for Eq. (29) may be obtained by considering the *ansatz*: $\tilde{\rho}(z)=\mathcal{N}'z^{d-1}(1+\alpha'z^{\lambda})^{\eta/\nu}$. Applying the proposed *ansatz* in Eq. (29) we obtain the following conditions on the parameters η, λ, and ν:

$$\lambda = 3+\theta; \quad \eta = \frac{1}{3+\theta}; \quad \nu = \frac{\gamma-1}{5+2\theta}, \tag{31}$$

with $\alpha'=-\tilde{k}'/(2+\theta)$ where $\gamma>1$ and $\theta>-2$. By substituting the above parameters in Eq. (19), $\tilde{\rho}(z)$ is given by

$$\tilde{\rho}(z) = \mathcal{N}'z^{d-1}(1+\alpha'z^{3+\theta})^{(5+2\theta)/[(\gamma-1)(3+\theta)]}. \tag{32}$$

III. CONCLUSIONS

In summary, a generalized diffusion equation (Eq. (1)) has been worked out for several situations by incorporating some space and time dependent classes of drifts and diffusion coefficients. We have shown that it admits exact solutions where the space scales with a function of time. For Eqs. (19) and (21), we have discussed the explicit dependence on the dimension d in the solution $\rho(r,t)$. This result is very interesting since it shows that, depending on the parameters θ, γ, and ν, we may have an anomalous diffusion (i.e., $\langle r^2\rangle\propto t^{\alpha}$) for a given dimension and a usual diffusion (i.e., $\langle r^2\rangle\propto t$) for other dimensions. Another interesting point is the presence of the q-exponential and the q-logarithm functions of the nonextensive formalism in some solutions, suggesting that these solutions may also be obtained by using the maximum principle of entropy and the nonextensive entropy with adequate constraints. The results obtained in Refs. 12, 13, 25, and 26 have been extended. Finally, we hope that the results obtained here may be useful to discuss the physical situations where the anomalous diffusion is present.

Threshold properties of matrix-valued Schrödinger operators

Michael Melgaard[a)]
Department of Mathematics, Uppsala University, Box 480, S-751 06 Uppsala, Sweden

(Received 2 May 2005; accepted 6 June 2005; published online 29 July 2005)

We present some results on the perturbation of eigenvalues embedded at a threshold for a two-channel Hamiltonian with three-dimensional Schrödinger operators as entries and with a small off-diagonal perturbation. In particular, we show how the threshold eigenvalue gives rise to discrete eigenvalues below the threshold and, moreover, we establish a criterion on existence of half-bound states associated with embedded pseudo eigenvalues. © *2005 American Institute of Physics.*

I. INTRODUCTION

Consider matrix-valued Schrödinger operators of the form

$$H=\widetilde{H}_0+V=\begin{pmatrix}-\Delta & 0\\ 0 & -\Delta+\lambda_0\end{pmatrix}+V(x),\quad x\in\mathbb{R}^3, \tag{1.1}$$

in $\mathcal{H}=L^2(\mathbb{R}^3)\oplus L^2(\mathbb{R}^3)$, where $0<\lambda_0\in\mathbb{R}$ and $V(x)$ is a 2×2 operator-valued matrix

$$V(x)=\begin{pmatrix}V_a & V_{ab}\\ V_{ba} & V_b\end{pmatrix},\quad V(x)^*=V(x), \tag{1.2}$$

which is $\widetilde{H}_0$ compact. We may introduce

$$H_0=\begin{pmatrix}H_a & 0\\ 0 & H_b\end{pmatrix}=\begin{pmatrix}-\Delta+V_a & 0\\ 0 & -\Delta+\lambda_0+V_b\end{pmatrix} \tag{1.3}$$

and write, with g being a real off-diagonal coupling constant

$$H(g):=H_0+g\begin{pmatrix}0 & V_{ab}\\ V_{ba} & 0\end{pmatrix}. \tag{1.4}$$

In particular, $H=H(1)$. The direct sum structure of H_0 means that one can easily give examples of eigenvalues embedded at the threshold λ_0.

A particular case of interest is the following. Under appropriate conditions on V_a we have $\sigma_{\mathrm{ac}}(H_a)=[0,\infty)$ and H_a has discrete spectrum in $(-\infty,0)$. Similarly, $\sigma_{\mathrm{ac}}(H_b)=[\lambda_0,\infty)$ and H_b has discrete spectrum in $(-\infty,\lambda_0)$. Furthermore, we assume that 0 is an (isolated) eigenvalue of H_b (well-defined under suitable decay conditions on V_b) with, say, multiplicity $\varkappa$. Thus $H(0)=H_0$ has an eigenvalue embedded at the threshold 0. To obtain information on what happens when the off-diagonal interaction is switched on, we assume that 0 is a regular point of H_a (see Sec. IV for the terminology). It turns out that the spectral properties of $H(g)$ in the vicinity of 0 are determined by a matrix

a)Electronic mail: melgaard@math.uu.se

$$M_{ab} = (\langle R_a(0) V_{ab} \psi_j, V_{ab} \psi_k \rangle)_{1 \leqslant j,k \leqslant \varkappa}, \tag{1.5}$$

where $R_a(\zeta) = (H_a - \zeta)^{-1}$ is the resolvent of H_a and ψ_k, $k = 1, \ldots, \varkappa$, are the normalized eigenfunctions corresponding to the zero eigenvalue of H_b. Assuming that M_{ab} has strictly positive (real) eigenvalues, the following result holds (see Theorem 4.2). There exist $\eta_0 > 0$ and $\delta_0 > 0$ such that

$$(-\delta_0, 0) \cap \sigma_{\mathrm{pp}}(H(g)) \text{ is discrete and nonempty} \tag{1.6}$$

for all g with $g \in (0, \eta_0]$. This result should be compared with the one in Ref. 7, where the same situation (and several other cases) is considered. Under the hypothesis that a certain (effective interaction of off-diagonal part) operator is strictly positive and invertible, it is shown in Ref. 7 that there are no eigenvalues of $H(g)$ contained in an interval of the form $(-cg^2, \delta_0)$, some $c > 0$. It is worth it to mention that the methods used in the present work are quite different from the ones used in Ref. 7.

In some cases one would expect that embedded eigenvalues become resonances under perturbation. In this paper we are not imposing assumptions on the Hamiltonians, which makes it possible to give a reasonable definition of a resonance, hence, we have no results in this direction here; for two-channel Hamiltonians with one-dimensional Schrödinger operators as components, some results were established in Ref. 11 by a different method.

The proof of Theorem 4.2 can easily be seen to give a necessary and sufficient criterion (see Theorem 5.2) on the existence of half-bound states associated with embedded pseudo eigenvalues of $H(g)$; see Definition 5.1 for this notion. Within this context Theorem 5.4 asserts that if $\lambda \in (0, \lambda_0)$ is an eigenvalue of H_b and $M_{ab}(\lambda + i0)$ (see (1.5)) has no real eigenvalues, then there exist $\eta_0 > 0$ and $\delta_0 > 0$ such that

$$[\lambda - \delta_0, \lambda + \delta_0] \cap \sigma_{\mathrm{pp}}(H(g)) = \emptyset. \tag{1.7}$$

The results obtained herein give rise to two open problems: under suitable hypotheses on V, can one prove that

- negative eigenvalues of M_{ab} (cf. Theorem 4.2) give rise to resonances?
- Theorem 5.2 holds if, in its formulation, pseudo eigenvalues are replaced by eigenvalues in the usual sense?

These problems will be pursued elsewhere.

Except for the work in Ref. 7, there seems to be few results on this problem. A general result on absorption of eigenvalues in the continuum is given in Ref. 16. In Ref. 1 a result is obtained concerning the survival of the ground state of a Pauli–Fierz Hamiltonian. In Ref. 2 the possibility of having a modified Fermi Golden Rule at a threshold is considered. In a time-dependent framework the perturbation of threshold eigenvalues has been discussed in Ref. 17. Another closely related issue is the derivation of asymptotic expansions of the resolvent as the spectral parameter tends to a threshold. Results on two-channel Hamiltonians are given in Ref. 9, based on resolvent expansions for three-dimensional and one-dimensional Schrödinger operators found in Refs. 6 and 12. The latter results are applied to scattering theory for pairs of two-channel Hamiltonians in Ref. 10 and also to scattering theory near the lowest Landau threshold for the three-dimensional Schrödinger operator with a constant magnetic field.[13,14] There is a vast literature on 2×2 operator-valued matrices, e.g., in system theory (see, e.g., Ref. 3) and in semigroup theory (see, e.g., Ref. 5). Most notably in this context is the substantial number of questions of a general nature which have been answered on spectral theory in recent years, see, e.g., Ref. 18. However, the methods therein are not related to ours although some of the questions addressed clearly are, e.g. the appearance of resonances discussed in Ref. 15.

II. PRELIMINARIES

Let us fix some basic notation. Let $\mathcal{H}$ be a separable complex Hilbert space. We denote its scalar product and norm by $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ and $\| \cdot \|_{\mathcal{H}}$, respectively. If $\mathcal{K}$ is another Hilbert space, then we

write $\mathcal{K}\subset\mathcal{H}$ if $\mathcal{K}$ is embedded in $\mathcal{H}$. Let T be a self-adjoint operator on a Hilbert space $\mathcal{H}$ with domain $\mathfrak{D}(T)$. The spectrum and resolvent set are denoted by $\sigma(T)$ and $\rho(T)$, respectively. We use standard terminology for the various parts of the spectrum, see for example, Ref. 8. The resolvent is $R(\zeta)=(T-\zeta)^{-1}$. The spaces of bounded and compact operators from a Hilbert space $\mathcal{H}_1$ into a Hilbert space $\mathcal{H}_2$ are denoted by $\mathcal{B}(\mathcal{H}_1,\mathcal{H}_2)$ and $\mathcal{K}(\mathcal{H}_1,\mathcal{H}_2)$, respectively. If $\mathcal{H}:=\mathcal{H}_1=\mathcal{H}_2$ we use the notation $\mathcal{B}(\mathcal{H})$ and $\mathcal{K}(\mathcal{H})$, respectively.

We adopt the usual notation for function spaces: C_0^∞, L^2, etc. The Schwartz space of rapidly decreasing functions and its adjoint space of tempered distributions are denoted by $\mathcal{L}$ and $\mathcal{L}'$, respectively. The Fourier transformation is denoted by $\mathcal{F}$. The weighted Sobolev spaces on $\mathbb{R}^3$ are defined by

$$H^{t,s}(\mathbb{R}^3)=\{\psi\in\mathcal{L}'(\mathbb{R}^3):\langle p\rangle^s\langle x\rangle^t\psi\in L^2(\mathbb{R}^3)\}.$$

Here $\langle x\rangle$ denotes the operator of multiplication by the function $(1+|x|^2)^{1/2}$ and $\langle p\rangle=\mathcal{F}^*\langle x\rangle\mathcal{F}$. In particular, the weighted L^2 spaces are defined by $L^{2,s}(\mathbb{R}^3):=H^{0,s}(\mathbb{R}^3)$ and the standard Sobolev spaces are defined by $H^t(\mathbb{R}^3)=H^{t,0}(\mathbb{R}^3)$.

It is convenient to introduce the following short-hand notation: $\mathcal{L}^{2,s}(\mathbb{R}^3):=L^{2,s}(\mathbb{R}^3)\oplus L^{2,s}(\mathbb{R}^3)$, $\mathcal{L}^2(\mathbb{R}^3):=\mathcal{L}^{2,0}(\mathbb{R}^3)$, $\mathcal{H}^t(\mathbb{R}^3):=H^t(\mathbb{R}^3)\oplus H^t(\mathbb{R}^3)$ and also $\mathcal{H}^{t,s}(\mathbb{R}^3):=H^{t,s}(\mathbb{R}^3)\oplus H^{t,s}(\mathbb{R}^3)$.

The Feshbach formula gives a convenient explicit representation of the resolvent $R(g;\zeta)$ of $H(g)$. There are two variants. We give only one of them. The other version is just an interchange of indices. Define

$$R_a(\zeta):=(H_a-\zeta)^{-1},\quad R_b(\zeta):=(H_b-\zeta)^{-1},\tag{2.1}$$

$$W_b(\zeta):=V_{ab}R_b(\zeta)V_{ba},\tag{2.2}$$

and

$$T_a(g;\zeta):=R_a(\zeta)(1-g^2W_b(\zeta)R_a(\zeta))^{-1}.\tag{2.3}$$

Then, for $\operatorname{Im}\zeta\neq 0$, we have

$$R(g;\zeta)=\begin{pmatrix} T_a(g;\zeta) & -gT_a(g;\zeta)V_{ab}R_b(\zeta)\\ -gR_b(\zeta)V_{ba}T_a(g;\zeta) & R_b(\zeta)(1+g^2V_{ba}T_a(g;\zeta)V_{ab}R_b(\zeta))\end{pmatrix}.\tag{2.4}$$

In this way we have solved the (Feshbach) problem $(H(g)-\zeta)\Psi=\Phi$, $\operatorname{Im}\zeta\neq 0$.

We impose the following hypotheses on V_a, V_b, and V_{ab}:

Assumption 2.1:

(i) $V_\#\in\mathcal{K}(H^2(\mathbb{R}^3),L^2(\mathbb{R}^3))$ for $\#=a,b$.

(ii) $x\nabla V\in\mathcal{K}(H^2(\mathbb{R}^3),H^{-2}(\mathbb{R}^3))$ for $\#=a,b$.

(iii) For $\#=a,b$ and some $\beta_\#>0$,

$$|V_\#(x)|\leq C\langle x\rangle^{-\beta_\#}$$

for $|x|$ large.

(iv) $V_{ab}\in\mathcal{K}(H^2(\mathbb{R}^3),L^2(\mathbb{R}^3))$, $x\nabla V_{ab}\in\mathcal{K}(H^2(\mathbb{R}^3),H^{-2}(\mathbb{R}^3))$ and, for some $\beta>0$,

$$|V_{ab}(x)|\leq C\langle x\rangle^{-\beta},$$

for large $|x|$.

Assumption 2.1, in conjunction with the Kato–Rellich theorem, ensures that H_a and H_b are well-defined as self-adjoint operators in $L^2(\mathbb{R}^3)$, with domain $\mathfrak{D}(H_a)=\mathfrak{D}(H_b)=H^2(\mathbb{R}^3)$, and the basic spectral properties are as described in the Introduction. Moreover, V is $\widetilde{H}_0$ compact, which implies that H is a well-defined self-adjoint operator in $\mathcal{L}^2(\mathbb{R}^3)$, with domain $\mathcal{H}^2(\mathbb{R}^3)$.

We begin by considering the resolvent of $H(g)$. For this purpose we define the following set. Let $0<l<r<\lambda_0$ and set $\Lambda=[l,r]$. For some $\delta_0>0$ define

$$\Omega=\{\zeta=\mu+i\epsilon\in\mathbb{C}:\mu\in\Lambda,\operatorname{dist}(\mu,\sigma(H_b))\geqslant\delta_0 \text{ and } \epsilon\in(0,1]\}. \tag{2.5}$$

Lemma 2.2: *Let Assumption 2.1 hold with $\beta>1/2$. Then there exists $\eta_0>0$ such that, for $g\in(0,\eta_0]$, $\zeta\mapsto R(g;\zeta)$ has a norm-continuous extension to $\bar{\Omega}$, uniformly bounded in g, with values in $\mathcal{B}(L^{2,s}(\mathbb{R}^3)\oplus L^2(\mathbb{R}^3),H^{2,-s}(\mathbb{R}^3)\oplus H^2(\mathbb{R}^3))$, $s>1/2$.*

Proof: Under the hypotheses, the limiting absorption principle is valid for H_a (see, e.g., Ref. 4). It asserts that $R_a(\zeta)$, defined initially on $\operatorname{Im}\zeta>0$, extends continuously to $\zeta\in\bar{\Omega}$ as an operator in $\mathcal{B}(L^{2,s}(\mathbb{R}^3),L^{2,-s}(\mathbb{R}^3))$, $s>1/2$. Taking $\beta>1/2$ and $1/2<s<\beta$ ensure that $g^2W_b(\zeta)R_a(\zeta)$ maps $L^{2,s}(\mathbb{R}^3)$ into $L^{2,2\beta-s}(\mathbb{R}^3)\subset L^{2,s}(\mathbb{R}^3)$ and it is uniformly bounded by g^2 (up to a multiplicative constant). Hence, choosing η_0 sufficiently small,

$$1-g^2W_b(\zeta)R_a(\zeta):L^{2,s}(\mathbb{R}^3)\to L^{2,s}(\mathbb{R}^3)$$

is invertible and it has a uniformly bounded inverse. It follows that:

$$T_a(g;\zeta)=R_a(\zeta)(1-g^2W_b(\zeta)R_a(\zeta))^{-1}:L^{2,s}(\mathbb{R}^3)\to H^{2,-s}(\mathbb{R}^3)$$

is uniformly bounded and it extends continuously to $\bar{\Omega}$. □

III. A FACTORIZATION OF THE RESOLVENT

Throughout this section we consider the following situation.

Assumption 3.1: Let $\lambda\in\sigma(H_b)$

(i) Assume $\lambda\in(0,\lambda_0)$ is an eigenvalue of H_b having multiplicity $\varkappa$, with normalized eigenfunctions ψ_k, $k=1,\ldots,\varkappa$.
(ii) Assume that $\delta_0>0$ is chosen such that $\operatorname{dist}(\lambda,\sigma(H_b)\backslash\{\lambda\})\geqslant 2\delta_0$.

Corresponding to the eigenvalue λ of H_b we use the notation P_b for the eigenprojection and, moreover, we set $Q_b:=1-P_b$.

Define $\tilde{H}_b:=Q_bH_bQ_b$, $\tilde{R}_b(\zeta):=(\tilde{H}_b-\zeta)^{-1}Q_b$,

$$\tilde{W}_b(\zeta):=V_{ab}\tilde{R}_b(\zeta)V_{ba}, \tag{3.1}$$

$$\tilde{T}_a(g;\zeta):=R_a(\zeta)(1-g^2\tilde{W}_b(\zeta)R_a(\zeta))^{-1}, \tag{3.2}$$

and

$$\tilde{R}(g;\zeta):=\begin{pmatrix}\tilde{T}_a(g;\zeta) & -g\tilde{T}_a(g;\zeta)V_{ab}\tilde{R}_b(\zeta)\\ -g\tilde{R}_b(\zeta)V_{ba}\tilde{T}_a(g;\zeta) & \tilde{R}_b(\zeta)(1+g^2V_{ba}\tilde{T}_a(g;\zeta)V_{ab}\tilde{R}_b(\zeta))\end{pmatrix}. \tag{3.3}$$

Define

$$\Omega_+(\delta_0;\lambda):=\{\zeta=\mu+i\epsilon\in\mathbb{C}:\mu\in(\lambda-\delta_0,\lambda+\delta_0)\text{and }\epsilon\in(0,1]\}.$$

Then, for $\zeta\in\Omega_+(\delta_0;\lambda)$, we have that

$$(H(g)-\zeta)\tilde{R}(g;\zeta)=\begin{pmatrix}1 & 0\\ gP_bV_{ba}\tilde{T}_a(g;\zeta) & Q_b-g^2P_bV_{ba}\tilde{T}_a(g;\zeta)V_{ab}\tilde{R}_b(\zeta)\end{pmatrix}. \tag{3.4}$$

Consider the equation $(H(g)-\zeta)\Psi=\Phi$ on $\Omega_+(\delta_0;\lambda)$. We wish to derive a formula for the resolvent which solves this problem. For this purpose we define

$$\tilde{X}_r:\mathbb{C}^\varkappa \ni (z_1,\ldots,z_\varkappa) \mapsto \left(0,\sum_{k=1}^{\varkappa} z_k\psi_k\right) \in \mathcal{H}^2(\mathbb{R}^3), \tag{3.5}$$

$$\tilde{X}_l:\mathcal{L}^2(\mathbb{R}^3) \ni (\phi,\psi) \mapsto (\langle\psi_1,\psi\rangle,\ldots,\langle\psi_\varkappa,\psi\rangle) \in \mathbb{C}^\varkappa, \tag{3.6}$$

and consider an analogous equation related to the operator

$$\mathbf{H}(g;\zeta) = \begin{pmatrix} H(g)-\zeta & \tilde{X}_r \\ \tilde{X}_l & 0 \end{pmatrix}:\mathcal{H}^2(\mathbb{R}^3)\oplus\mathbb{C}^\varkappa \to \mathcal{L}^2(\mathbb{R}^3)\oplus\mathbb{C}^\varkappa. \tag{3.7}$$

The structure of (3.4) motivates the introduction of

$$Y(g;\zeta) := \begin{pmatrix} 0 & 0 \\ gP_bV_{ba}\tilde{T}_a(g;\zeta) & -g^2P_bV_{ba}\tilde{T}_a(g;\zeta)V_{ab}\tilde{R}_b(\zeta) \end{pmatrix}, \tag{3.8}$$

$$Z(g;\zeta) := (H(g)-\zeta)\tilde{X}_r. \tag{3.9}$$

Then the inverse of $\mathbf{H}(g;\zeta)$, denoted by $\mathbf{R}(g;\zeta)$, is given by

$$\mathbf{R}(g;\zeta) = \begin{pmatrix} \tilde{R}(g;\zeta)(1-Y(g;\zeta)) & \tilde{X}_r-\tilde{R}(g;\zeta)(1-Y(g;\zeta))Z(g;\zeta) \\ \tilde{X}_l(1-Y(g;\zeta)) & -\tilde{X}_l(1-Y(g;\zeta))Z(g;\zeta) \end{pmatrix} =: \begin{pmatrix} X(g;\zeta) & X_r(g;\zeta) \\ X_l(g;\zeta) & X_{rl}(g;\zeta) \end{pmatrix}. \tag{3.10}$$

By introducing

$$\tilde{X}_r':\mathbb{C}^\varkappa \ni (z_1,\ldots,z_\varkappa) \mapsto \psi = \sum_{k=1}^{\varkappa} z_k\psi_k$$

and its adjoint, denoted by $\tilde{X}_l'$, we may write

$$X_{rl}(g;\zeta) = \tilde{X}_l'(\zeta-\lambda+g^2V_{ba}\tilde{T}_a(g;\zeta)V_{ab})\tilde{X}_r'. \tag{3.11}$$

Then it follows from the latter that, for $\zeta\in\mathbb{C}_+$,

$$R(g;\zeta) = X(g;\zeta) - X_r(g;\zeta)X_{rl}(g;\zeta)^{-1}X_l(g;\zeta). \tag{3.12}$$

To determine the mapping properties of the operator-valued functions X, X_r, etc., we begin by taking a closer look at $\tilde{T}_a(g;\mu+i0)$.

Lemma 3.2: *Let Assumption 2.1 hold with $\beta>1/2$. Moreover, let Assumption 3.1 be satisfied. Then there exists $\eta_0>0$ such that, for $g\in(0,\eta_0]$, $\tilde{T}_a(g;\mu+i0)$ exists in $\mathcal{B}(L^{2,s}(\mathbb{R}^3),L^{2,-s}(\mathbb{R}^3))$, $s>1/2$, and it is Hölder continuous in μ provided $|\mu-\lambda|\leqslant\delta_0$; uniformly in $g\in(0,\eta_0]$.*

Proof: As an operator from $L^2(\mathbb{R}^3)$ into $L^{2,2\beta}(\mathbb{R}^3)$, $\tilde{W}_b(\zeta)=V_{ab}\tilde{R}_b(\zeta)V_{ba}$ is continuous in $\zeta\in\overline{\Omega_+(\delta_0;\lambda)}$. Since $R_a(\mu+i0):L^{2,s}\to L^{2,-s}$ exists (due, once again, to the limiting absorption principle) and is Hölder continuous in $\mu>0$ (provided $s>1/2$), we infer that

$$\zeta\mapsto\tilde{W}_b(\zeta)R_a(\zeta)\in\mathcal{B}(L^{2,s}(\mathbb{R}^3),L^{2,s}(\mathbb{R}^3))$$

is uniformly bounded and the limiting value $\tilde{W}_b(\mu)R_a(\mu+i0)$ exists in $\mathcal{B}(L^{2,s}(\mathbb{R}^3),L^{2,-s}(\mathbb{R}^3))$ provided $1/2<s<\beta$ and $|\mu-\lambda|\leqslant\delta_0$. In particular, for $g\in(0,\eta_0]$ with η_0 sufficiently small, the operator $1-g^2\tilde{W}_b(\mu)R_a(\mu+i0):L^{2,s}(\mathbb{R}^3)\to L^{2,s}(\mathbb{R}^3)$ is invertible and

$$\widetilde{T}_a(g;\mu+i0) = R_a(\mu+i0)(1-g^2\widetilde{W}_b(\mu)R_a(\mu+i0))^{-1}: L^{2,s}(\mathbb{R}^3) \to L^{2,-s}(\mathbb{R}^3)$$

exists and it is Hölder continuous in μ on $|\mu-\lambda| \leqslant \delta_0$; uniformly in g. □

We immediately obtain the next result.

Proposition 3.3: *Let Assumption 2.1 hold with $\beta > 1/2$. Moreover, let Assumption 3.1 be satisfied. Then there exists $\eta_0 > 0$ such that, for $g \in (0, \eta_0]$ and $s > 1/2$, the operator-valued functions*

$$\zeta \mapsto X(g;\zeta) \in \mathcal{B}(L^{2,s}(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3), H^{2,-s}(\mathbb{R}^3) \oplus H^2(\mathbb{R}^3)),$$

$$\zeta \mapsto X_r(g;\zeta) \in \mathcal{B}(\mathbb{C}^\varkappa, H^{2,-s}(\mathbb{R}^3) \oplus H^2(\mathbb{R}^3)),$$

$$\zeta \mapsto X_l(g;\zeta) \in \mathcal{B}(L^{2,s}(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3), \mathbb{C}^\varkappa),$$

$$\zeta \mapsto X_{rl}(g;\zeta) \in \mathcal{B}(\mathbb{C}^\varkappa)$$

are analytic in ζ on $\zeta \in \mathbb{C}_+$ and they extend continuously to $\zeta \in \overline{\Omega_+(\delta_0,\lambda)}$; uniformly in $g \in (0, \eta_0]$.

IV. PERTURBATION OF AN EIGENVALUE AT A THRESHOLD

A priori zero can be an eigenvalue of H_a or a zero resonance for H_a, or both. We have a zero resonance (or half-bound state) if $H_a\psi = 0$ has a solution ψ in a space slightly larger than $L^2(\mathbb{R}^3)$. It turns out that essentially three cases may occur: H_a has no eigenvalue zero and no zero resonance (*zero is a regular point*), H_a has no eigenvalue zero but has a zero resonance (*zero is an exceptional point of first kind*), H_a has eigenvalue zero but has no zero resonance (*zero is an exceptional point of second kind*), or H_a has both eigenvalue zero and a zero resonance (*zero is an exceptional point of the third kind*).

When zero is a regular point, say, of H_a, then $\zeta \mapsto R_a(\zeta) \in \mathcal{B}(L^{2,s}(\mathbb{R}^3), L^{2,-s}(\mathbb{R}^3))$, $s > 1/2$, defined on $\zeta \in \mathbb{C}_+$, extends continuously up to the real axis in a neighborhood of zero.

We first consider the case, which we discussed in the Introduction.

Assumption 4.1:

(i) Assume that zero is a regular point of H_a.

(ii) Assume that zero is an eigenvalue of H_b having multiplicity $\varkappa$, with normalized eigenfunctions ψ_k, $k = 1, \ldots, \varkappa$.

To ensure that a zero eigenvalue of H_b is well-defined, we require that Assumption 2.1(iii) holds with $\beta_b > 2$; see Ref. 6, Sec. 2 for an explanation.

Theorem 4.2: *Let Assumption 2.1 hold with $\beta_b > 2$ and $\beta > 1/2$. Moreover, let Assumption 4.1 hold. If*

$$M_{ab} = (\langle R_a(0)V_{ab}\psi_j, V_{ab}\psi_k\rangle)_{1 \leqslant j,k \leqslant \varkappa}$$

has ϑ strictly positive eigenvalues ν_l, $1 \leqslant l \leqslant \vartheta$ (taking into account multiplicity), then there exist $\eta_0 > 0$ and $\delta_0 > 0$ such that, for $g \in (0, \eta_0]$, the operator $H(g)$ has at least ϑ eigenvalues (again counting multiplicity) $\nu_l(g)$ in $(-\delta_0, 0)$ obeying

$$\nu_l(g) = -\nu_l g^2 + o(g^2), \quad 1 \leqslant l \leqslant \vartheta. \tag{4.1}$$

If, in particular, M_{ab} is positive definite, then $H(g)$ has exactly $\varkappa$ eigenvalues in $(-\delta_0, 0)$ given by (4.1) *with $\varkappa = \vartheta$.*

Proof: We divide the proof into two steps.

Step 1. In this step we prove that, for $\mu \in (-\delta_0, \delta_0)$, the equation $H(g)\Phi = \mu\Phi$ has a solution $\Phi \in \mathcal{H}^{2,-s}(\mathbb{R}^3)$ for any $s > 1/2$ if and only if $\det X_{rl}(g;\mu+i0) = 0$; see (3.10) for the definition of $X_{rl}(g;\zeta)$.

We first observe that Proposition 3.3 asserts that the identities $\mathbf{H}(g;\zeta)\mathbf{R}(g;\zeta)=1$ on $\mathcal{L}^2(\mathbb{R}^3)$ and $\mathbf{R}(g;\zeta)\mathbf{H}(g;\zeta)=1$ on $\mathcal{H}^2(\mathbb{R}^3)$ extend continuously to $[-\delta_0,\delta_0]$ in the setting of weighted spaces. In particular

$$(H(g)-\zeta)X_r(g;\zeta)+\widetilde{X}_rX_{rl}(g;\zeta)=0, \tag{4.2}$$

$$X_l(g;\zeta)(H(g)-\zeta)+X_{rl}(g;\zeta)\widetilde{X}_l=0 \tag{4.3}$$

are valid for $\zeta\in\overline{\Omega_+(\delta_0;0)}$.

Now if $\mu\in[-\delta_0,\delta_0]$ fulfills $H(g)\Phi=\mu\Phi$ with $\Phi=(\varphi_a,\varphi_b)\neq 0$ as above, then (4.3) implies that

$$X_{rl}(g;\mu+i0)\widetilde{X}_l\Phi=0.$$

Since, as an operator from $H^{2,-s}(\mathbb{R}^3)\oplus H^2(\mathbb{R}^3)$ into itself

$$X(g;\mu+i0)(H(g)-\mu)+X_r(g;\mu+i0)\widetilde{X}_l=1,$$

we deduce that

$$X_r(g;\mu+i0)\widetilde{X}_l\Phi=\Phi,$$

and $\widetilde{X}_l\Phi=(\langle\varphi_b,\psi_1\rangle,\ldots,\langle\varphi_b,\psi_\varkappa\rangle)\neq 0$. Hence, $\det X_{rl}(g;\mu+i0)=0$. On the other hand, if $\det X_{rl}(g;\mu+i0)=0$ and $z\in\mathbb{C}^\varkappa\backslash\{0\}$ belongs to $\operatorname{Ker}X_{rl}(g;\mu+i0)$, then, by setting $\Phi=X_r(g;\mu+i0)z\in H^{2,-s}(\mathbb{R}^3)\oplus H^2(\mathbb{R}^3)$ for any $s>1/2$, (4.2) implies that $(H(g)-\mu)\Phi=0$ and $\Phi\neq 0$ because $\widetilde{X}_r\Phi=\widetilde{X}_lX_r(g;\mu+i0)z=z\neq 0$. This proves the assertion.

Step 2. For $\delta_0>0$ we bear in mind that $(-\delta_0,0)\cap\sigma(H_a)=\varnothing$ and that $R_a(\mu+i0)=R_a(\mu)$ is symmetric for $\mu\in(-\delta_0,0]$. In view of (3.11) with $\lambda=0$, we have that, for $\mu\in(-\delta_0,0]$,

$$X_{rl}(g;\mu+i0)=\mu+g^2M(\mu)+g^4N(g;\mu),$$

where the matrices $M(\mu)$ and $N(g;\mu)$ are given by

$$M(\mu)=(R_a(\mu)V_{ab}\psi_j,V_{ab}\psi_k\rangle_{1\leqslant j,k\leqslant\varkappa},$$

$$N(g;\mu)=(\langle R_a(\mu)\widetilde{W}_b(\mu)\widetilde{T}_a(g;\mu)V_{ab}\psi_j,V_{ab}\psi_k\rangle)_{1\leqslant j,k\leqslant\varkappa}.$$

Let $\nu_0>0$ be an eigenvalue of M_{ab} having multiplicity $\varkappa_0$. The continuity of $N(g;\mu)$ in μ and its analyticity with respect to g^2 in a neighborhood of 0 in conjunction with standard (finite-dimensional) perturbation theory imply that, for every $\mu\in(-\delta_0,0]$, there exist $\varkappa_0$ eigenvalues $\xi_k(g;\mu)$ of $M(\mu)+g^2N(g;\mu)$ (taking into counting multiplicity). The eigenvalues are analytic in g^2 in a neighborhood of 0 and they satisfy

$$\xi_k(g;\mu)=\xi_k(\mu)+\sum_{l=1}^{\infty}g^{2l}\xi_{kl}(\mu),\quad k=1,\ldots,\varkappa_0, \tag{4.4}$$

where $\xi_k(\mu)$ are eigenvalues of $M(\mu)$ which converge to ν_0 as $\mu\to 0$. Provided η_0 is sufficiently small, the function $h_k(g;\mu)=\mu+g^2\xi_k(g;\mu)$ obeys $h_k(g;-\delta_0)<0$ and $h_k(g;0)=\nu_0+O(g^2)>0$. The continuity and real valuedness of h_k imply that h_k has at least one zero in $(-\delta_0,0)$, $\mu=\nu_k(g)$, which fulfills

$$\nu_k(g)=-g^2\xi_k(g;\nu_k(g)).$$

Then (4.4) yields that

$$\nu_k(g) = -g^2(\nu_0 + o(1)) \text{ as } g \downarrow 0.$$

Now let $w_k(g;\mu)$ be normalized eigenfunctions of $M(\mu)+g^2N(g;\mu)$ corresponding to the eigenvalues $\xi_k(g;\mu)$, $k=1,\ldots,\varkappa_0$. Evidently $v_k(g)=w_k(g;\nu_k(g)) \in \operatorname{Ker} X_{rl}(g;\nu_k(g)+i0)$, $k=1,\ldots,\varkappa_0$. If $\nu_j(g)=\nu_k(g)$, then $v_j(g)$ and $v_k(g)$ are orthogonal. Following the reasoning in Step 1, we deduce that $v_k(g)$ generates $\varkappa_0$ linearly independent functions, namely $\Phi_k(g)=X(g;\nu_k(g)+i0)v_k(g) \in H^{2,-s}(\mathbb{R}^3)\oplus H^2(\mathbb{R}^3)$, which satisfy $H(g)\Phi_k(g)=\nu_k(g)\Phi_k(g)$. We note that, in fact, $\nu_k(g)<0$ implies that $\Phi_k(g) \in \mathcal{H}^2(\mathbb{R}^3)$ is an eigenfunction of $H(g)$ in the usual sense. Consequently, from a positive eigenvalue of multiplicity $\varkappa_0$ of M_{ab}, we can construct $\varkappa_0$ independent eigenfunctions of $H(g)$. This proves the first assertion. Invoking (3.12) we infer that $H(g)$ has at most $\varkappa$ eigenvalues in $(-\delta_0,\delta_0)$ (counting multiplicity). Therefore, if M_{ab} is positive definite, then each of these eigenvalues is given by (4.1) with $\varkappa=\vartheta$. □

Next we investigate another situation.

Assumption 4.3:

(i) Assume that 0 is an eigenvalue of H_a, but not a zero resonance, having multiplicity $\varkappa$, with normalized eigenfunctions ψ_k, $k=1,\ldots,\varkappa$.
(ii) Assume that $0 \notin \sigma_d(H_b)$.

Bear in mind that $G_0=\lim_{\zeta\to 0,\operatorname{Im}\zeta>0}(-\Delta-\zeta)^{-1}$ exists as an operator from $H^{-1,s}(\mathbb{R}^3)$ to $H^{1,-s}(\mathbb{R}^3)$ provided $s>1$, and $\operatorname{Ker}(1+G_0V_a)$ in $H^{1,-s}(\mathbb{R}^3)$ coincides with the eigenspace of H_a corresponding to the zero eigenvalue provided and $s>1/2$ and $\beta_a>2\beta_a>2$.[9] As usual we use the notation P_a for the eigenprojection corresponding to the zero eigenvalue of H_a. Its complement is denoted by Q_a. The operator

$$\widetilde{R}_a(\zeta) := (Q_aH_aQ_a-\zeta)^{-1}Q_a,$$

defined initially on $\operatorname{Im}\zeta>0$ is bounded as a map from $L^{2,s}(\mathbb{R}^3)$ to $L^{2,-s}(\mathbb{R}^3)$ and it extends continuously up to the real axis in a neighborhood of 0. Define

$$\widetilde{R}(g;\zeta) := \begin{pmatrix} \widetilde{R}_a(\zeta)+g^2\widetilde{R}_a(\zeta)V_{ab}\widetilde{T}_b(g;\zeta)V_{ba}\widetilde{R}_a(\zeta) & -g\widetilde{R}_a(\zeta)V_{ab}\widetilde{T}_b(g;\zeta) \\ -g\widetilde{T}_b(g;\zeta)V_{ba}\widetilde{R}_a(\zeta) & \widetilde{T}_b(g;\zeta) \end{pmatrix}$$

with

$$\widetilde{W}_a(\zeta) := V_{ba}\widetilde{R}_a(\zeta)V_{ab} \tag{4.5}$$

and

$$\widetilde{T}_b(g;\zeta) := (H_b-\zeta-g^2\widetilde{W}_a(\zeta))^{-1}. \tag{4.6}$$

Introduce

$$\widetilde{Y}_r:\mathbb{C}^\varkappa \ni (z_1,\ldots,z_\varkappa) \mapsto \left(\sum_{k=1}^{\varkappa} z_k\psi_k,0\right) \in \mathcal{H}^2(\mathbb{R}^3), \tag{4.7}$$

$$\widetilde{Y}_l:\mathcal{L}^2(\mathbb{R}^3) \ni (\phi,\psi) \mapsto (\langle\psi_1,\phi\rangle,\ldots,\langle\psi_\varkappa,\phi\rangle) \in \mathbb{C}^\varkappa. \tag{4.8}$$

We shall investigate the Feshbach problem related to the operator

$$\mathbf{H}(g;\zeta) = \begin{pmatrix} H(g)-\zeta & \widetilde{Y}_r \\ \widetilde{Y}_l & 0 \end{pmatrix}:\mathcal{H}^2(\mathbb{R}^3)\oplus\mathbb{C}^\varkappa \to \mathcal{L}^2(\mathbb{R}^3)\oplus\mathbb{C}^\varkappa. \tag{4.9}$$

Similar to (3.10), the inverse

$$\mathbf{R}(g;\zeta)=\begin{pmatrix} Y(g;\zeta) & Y_r(g;\zeta) \\ Y_l(g;\zeta) & Y_{rl}(g;\zeta) \end{pmatrix} \tag{4.10}$$

is computed explicitly for $\zeta\in\mathbb{C}_+$ and, in suitable function spaces, it extends continuously up to a small interval containing 0. In analogy with (3.11), we find that

$$Y_{rl}(g;\zeta)=\widetilde{Y}_l'(\zeta-\lambda+g^2V_{ba}\widetilde{T}_b(g;\zeta)V_{ab})\widetilde{Y}_r',$$

where

$$\widetilde{Y}_{r,2}:\mathbb{C}^\varkappa\ni(z_1,\ldots,z_\varkappa)\to\phi=\sum_{k=1}^{\varkappa}z_k\psi_k$$

and its adjoint is denoted by $\widetilde{Y}_{l,2}$.

In analogy with Theorem 4.2 we obtain the following result.

Theorem 4.4: *Let Assumption 2.1 hold with $\beta_a>2$ and $\beta>1/2$. Moreover, let Assumption 4.3 hold. If*

$$M_{ba}=(\langle R_b(0)V_{ba}\psi_j,V_{ba}\psi_k\rangle)_{1\leqslant j,k\leqslant\varkappa}$$

has ϑ strictly positive eigenvalues ν_l, $1\leqslant l\leqslant\vartheta$ (taking into account multiplicity). Then there exist $\eta_0>0$ and $\delta_0>0$ such that, for $g\in(0,\eta_0]$, the operator $H(g)$ has at least ϑ eigenvalues (again counting multiplicity) $\nu_l(g)$ in $(-\delta_0,0)$ obeying

$$\nu_l(g)=-\nu_lg^2+o(g^2),\quad 1\leqslant l\leqslant\vartheta. \tag{4.11}$$

If, in particular, M_{ab} is positive definite, then $H(g)$ has exactly $\varkappa$ eigenvalues in $(-\delta_0,\delta_0)$ given by (4.11) with $\vartheta=\varkappa$.

Proof: Follows the same reasoning as in the proof of Theorem 4.2. □

The results in Theorems 4.2 and 4.4 should be compared with the results in Ref. 7. We have already discussed this issue in the Introduction.

Our approach allows us to treat also the case where zero is an eigenvalue of both H_a and H_b, provided H_a does not have a zero resonance. The situation where H_a has a zero resonance seems to be more difficult to handle.

V. EXISTENCE OF HALF-BOUND STATES

Now we return to the situation characterized in Assumption 3.1. We begin with a definition.

Definition 5.1: A real number μ is said to be a pseudo eigenvalue of $H(g)$ if there exists a nonzero function $\Phi\in\mathcal{L}^{2,-s}(\mathbb{R}^3)$ satisfying

$$H(g)\Phi=\mu\Phi$$

with $s>1$ if $\mu=0$ or $\mu=\lambda_0$, and with $s>1/2$ if $\mu\neq0,\lambda_0$.
The function Φ is called a half-bound state.

From Step 1 in the proof of Theorem 4.2 we immediately obtain the following result.

Theorem 5.2: *Let Assumption 2.1 hold with $\beta>1/2$. Moreover, let Assumption 3.1 be satisfied and let $\mu\in[\lambda-\delta_0,\lambda+\delta_0]$. Then there exists η_0 such that, for $g\in(0,\eta_0]$, μ is a pseudo eigenvalue of $H(g)$ if and only if*

$$\det X_{rl}(g;\mu+i0)=0.$$

Remark 5.3: Theorem 5.2 also holds when Assumption 3.1 is replaced by Assumption 4.1; see the proof of Theorem 4.2, Step 1.

To formulate the next result, we define

$$M(\zeta)=(\langle R_a(\zeta)V_{ab}\psi_j,V_{ab}\psi_k\rangle)_{1\leqslant j,k\leqslant\varkappa},\quad \zeta\in\overline{\Omega_+(\delta_0;\lambda)}.$$

Theorem 5.4: *Let Assumption 2.1 hold with* $\beta > 1/2$. *Moreover, let Assumption 3.1 be satisfied. If* $M(\lambda + i0)$ *has no real eigenvalues, then there exists* η_0 *such that* $[\lambda - \delta_0, \lambda + \delta_0] \cap \sigma_{\mathrm{pp}}(H(g)) = \emptyset$ *for any* $g \in (0, \eta_0]$.

Proof: As $g \to 0$, the definition of $\widetilde{T}_a(g;\zeta)$ and Lemma 3.2 imply that

$$\widetilde{T}_a(g;\zeta) = R_a(\zeta) + O(g^2)$$

holds in $\mathcal{B}(L^{2,s}(\mathbb{R}^3), L^{2,-s}(\mathbb{R}^3))$, $1/2 < s < \beta$, uniformly in $\zeta = \mu + i\epsilon \in \Omega_+(\delta_0;\lambda)$. In addition, we have that

$$X_{rl}(g;\mu + i0) = \mu - \lambda + g^2(M(\mu + i0) + O(g^2)) \tag{5.1}$$

$$= \mu - \lambda + g^2(M(\lambda + i0) + o(1) + O(g^2)), \tag{5.2}$$

which holds uniformly in μ in the vicinity of λ. By hypothesis, $M(\lambda + i0)$ has no real eigenvalues, i.e., there exists C_0 such that, for all $\nu \in \mathbb{R}$,

$$\|(\nu + M(\lambda + i0))^{-1}\|_{\mathcal{B}(\mathbb{C}^\varkappa)} \leq C_0.$$

We next let $\mu = \lambda + g^2\tilde{\mu}(g)$ for a real $\tilde{\mu}(g)$. Choosing $|\mu - \lambda| \geq \delta_0$ and $\eta_0 > 0$ sufficiently small ensures invertibility of the matrix

$$X_{rl}(\mu + i0) = g^2(\tilde{\mu}(g) + M(\lambda + i0)) \times \{1 + (\tilde{\mu}(g) + M(\lambda + i0))^{-1}(o(1) + O(g^2)\}. \tag{5.3}$$

This verifies that $\det X_{rl}(g;\mu + i0) \neq 0$. In view of Theorem 5.2, $H(g)$ has no pseudo eigenvalues and thus no usual eigenvalues in $(-\lambda - \delta_0, \lambda + \delta_0)$. □

Remark 5.5: Theorem 5.4 also holds when Assumption 3.1 is replaced by Assumption 4.1.

(Received 15 February 2005; accepted 15 June 2005; published online 29 July 2005)

We construct and investigate smooth orientable surfaces in $\mathfrak{su}(N)$ algebras. The structural equations of surfaces associated with Grassmannian sigma models on Minkowski space are studied using moving frames adapted to the surfaces. The first and second fundamental forms of these surfaces as well as the relations between them as expressed in the Gauss–Weingarten and Gauss–Codazzi–Ricci equations are found. The scalar curvature and the mean curvature vector expressed in terms of a solution of Grassmanian sigma model are obtained. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1996369]

I. INTRODUCTION

Sigma models are of great interest in mathematical physics because a significant number of physical systems can be reduced to these relatively simple models, either on Euclidean or Minkowski space. One such example is the string theory in which sigma models on spacetime and their supersymmetric extensions play a crucial role. Other relevant applications of recent interest are in the areas of statistical physics (for example, reduction of self-dual Yang–Mills equations to the Ernst model[1,2]), phase transitions,[3,4] and the theory of fluid membranes.[5,6]

The objective of this paper is to study geometric properties of surfaces in Lie algebras associated with sigma models on Minkowski space. Recently, we investigated surfaces in $\mathfrak{su}(N)$ associated with $\mathbb{C}P^{N-1}$ sigma models[7] and found a few examples.[8] In this paper we extend this approach to more general models based on Grassmannian manifolds, i.e., the homogeneous spaces

$$G(m,n)=\frac{SU(N)}{S(U(m)\times U(n))},\quad N=m+n.$$

Grassmannian sigma models are a generalization of $\mathbb{C}P^{N-1}$ sigma models. Their important common feature is that the Euler–Lagrange equations can be written in terms of projectors only.[9] They share a lot of properties like an infinite number of local and/or nonlocal conserved quantities, Hamiltonian structure, complete integrability, infinite-dimensional symmetry algebra, existence of multisoliton solutions, etc. The $N\times N$ projector matrix P for the complex Grassmannian sigma models has, in general, rank lower than the corresponding one for the $\mathbb{C}P^{N-1}$ sigma model and consequently some new phenomena can arise.

The generalization of our previous results[7,8] to Grassmannian sigma models seemed to be rather natural—in fact, it was in a sense more straightforward than the generalization from $\mathbb{C}P^1$ to

[a)]Electronic mail: grundlan@crm.umontreal.ca
[b)]Electronic mail: libor.snobl@fjfi.cvut.cz

$\mathbb{C}P^{N-1}$, provided one expressed the corresponding formulas in terms of the projector (2.8). On the other hand, a different perspective obtained in more general case allowed us to write some of the results in a more compact and presumably more natural way.

The results can be of interest in the area of relativistic classical and quantum field theory[10,11] and in string theory in which sigma models on space-time and their supersymmetric extensions play a crucial role.[12] Other relevant applications of recent interest are in the areas of nonlinear interactions in particle physics.[13] The explicit forms of the surfaces can serve to illuminate the role of the Kac–Moody algebras in integrable models associated with the Grassmannian sigma models.[14,15]

The paper is organized as follows. In Sec. II we recall some basic notions and definitions dealing with the complex Grassmannian sigma models and their Euler–Lagrange equations. In Sec. III we perform the analysis of two-dimensional surfaces immersed in the $\mathfrak{su}(N)$ algebra, associated with these models. The geometric properties of surfaces and the construction of moving frames are discussed in detail in Sec. IV and V. Finally, we summarize our results.

II. GRASSMANNIAN SIGMA MODELS AND THEIR EULER–LAGRANGE EQUATIONS

As a starting point let us present some basic formulas and notation for complex Grassmannian sigma models defined on Minkowski space. We adapt to our signature the notation introduced in Ref. 9 for Euclidean Grassmannian sigma models.

The Grassmannian manifold is defined as a homogeneous space

$$G(m,n)=\frac{SU(N)}{S(U(m)\times U(n))},\quad N=m+n. \tag{2.1}$$

We express the elements of $G(m,n)$ using the equivalence classes of elements $g\in SU(N)$ as

$$[g]=\{g\,.\,\psi|\psi=\begin{pmatrix}U_m & 0\\ 0 & U_n\end{pmatrix},\quad U_m\in U(m),\quad U_n\in U(n),\quad \det\psi=1\}\,. \tag{2.2}$$

We decompose $g\in SU(N)$ into the submatrices X,Y,

$$g=(\phi_1,\ldots,\phi_N)=(X,Y),\quad X=(\phi_1,\ldots,\phi_m),\quad Y=(\phi_{m+1},\ldots,\phi_N), \tag{2.3}$$

and from $g^\dagger g=\mathbf{1}$, i.e., $\phi_j^\dagger\phi_k=\delta_{jk}$, we find

$$X^\dagger X=\mathbf{1}_{m\times m},\quad X^\dagger Y=0,\quad Y^\dagger X=0,\quad Y^\dagger Y=\mathbf{1}_{n\times n}.$$

From these orthogonality relations and (2.2) we realize that on the subset of $G(m,n)$ such that the lower square $n\times n$ submatrix of Y is nonsingular, X itself is sufficient to determine $[g]$ (since U_n can be used to bring the lower square part of Y to $\mathbf{1}_{n\times n}$ and the remaining entries in Y are fully determined by the orthogonality properties). In the following we shall assume that we are working in such a chart. Evidently it covers the whole $G(m,n)$ up to lower dimensional submanifolds. We shall denote the equivalence classes either $[X]$ or $[g]$ depending on circumstances. Note that there is still some freedom in the choice of X, namely X and $X.h, h\in\begin{pmatrix}SU(m) & 0\\ 0 & \mathbf{1}\end{pmatrix}$ give rise to the same equivalence class $[X]=[Xh]$. Therefore, one cannot identify $X=[X]$.

Let ξ^0, ξ^1 be the standard Minkowski coordinates in $\mathbb{R}^2$, with the metric

$$(\mathrm{d}s)^2=(\mathrm{d}\xi^0)^2-(\mathrm{d}\xi^1)^2.$$

In what follows we suppose that $\xi_L=\xi^0+\xi^1$, $\xi_R=\xi^0-\xi^1$ are the light-cone coordinates in $\mathbb{R}^2$, i.e.,

$$(\mathrm{d}s)^2=\mathrm{d}\xi_L\mathrm{d}\xi_R. \tag{2.4}$$

We shall denote by ∂_L and ∂_R the derivatives with respect to ξ_L and ξ_R, respectively.

Let us assume that Ω is an open, connected, and simply connected subset in $\mathbb{R}^2$ with Minkowski metric (2.4). We define covariant derivatives D_μ acting on maps $X:\Omega\to G(m,n)$ by

$$D_\mu X = \partial_\mu X - XX^\dagger \partial_\mu X, \quad \partial_\mu \equiv \partial_{\xi^\mu}, \quad \mu = 0,1. \tag{2.5}$$

In the study of Grassmannian sigma models we are interested in maps $X:\Omega\to G(m,n)$ which are stationary points of the action functional

$$\mathcal{S} = \int_\Omega \mathrm{tr}\{(D_\mu X)^\dagger (D^\mu X)\} \mathrm{d}\xi^0 \mathrm{d}\xi^1. \tag{2.6}$$

The Lagrangian density can be further developed to get

$$\mathcal{L} = \mathrm{tr}\{(D_\mu X)^\dagger (D^\mu X)\} = \mathrm{tr}\{\partial^\mu X (\partial_\mu X)^\dagger P\}, \tag{2.7}$$

where

$$P = \mathbf{1} - XX^\dagger \tag{2.8}$$

is an orthogonal projector, i.e., $P^2=P$, $P^\dagger=P$ satisfying $PX=0$, $X^\dagger P=0$.

The action (2.6) has the local (gauge) $SU(m)$ symmetry

$$X(\xi_L,\xi_R) \to X(\xi_L,\xi_R)\,.\,h(\xi_L,\xi_R), \quad h(\xi_L,\xi_R) \in \begin{pmatrix} SU(m) & 0 \\ 0 & \mathbf{1} \end{pmatrix} \tag{2.9}$$

proving that the model does not depend on the choice of representatives X of elements $[X]$ of $G(m,n)$; and the $SU(N)$ global symmetry

$$X(\xi_L,\xi_R) \to g\,.\,X(\xi_L,\xi_R), \quad g \in SU(N). \tag{2.10}$$

It is also invariant under the conformal transformations

$$\xi_L \to \alpha(\xi_L), \quad \xi_R \to \beta(\xi_R), \tag{2.11}$$

where $\alpha,\beta:\mathbb{R}\to\mathbb{R}$ are arbitrary 1-to-1 maps such that $\partial_L\alpha(\xi_L)\neq 0$, $\partial_R\beta(\xi_R)\neq 0$, as well as under the parity transformation

$$\xi_L \to \xi_R, \quad \xi_R \to \xi_L. \tag{2.12}$$

Let us note that the invariance properties (2.9)–(2.12) are naturally reproduced on the level of the Euler–Lagrange equations.

By variation of the action (2.6) respecting the constraint

$$X^\dagger X = \mathbf{1},$$

i.e.,

$$\delta X^\dagger X + X^\dagger \delta X = 0, \quad \partial_\mu X^\dagger X + X\partial_\mu \delta X = 0, \tag{2.13}$$

and assuming that due to suitable boundary conditions the boundary terms vanish we find the Euler–Lagrange equations

$$P(\partial_L\partial_R X - \partial_L XX^\dagger \partial_R X - \partial_R XX^\dagger \partial_L X) = 0. \tag{2.14}$$

They can be also expressed in the matrix form

$$[\partial_L\partial_R P, P] = 0 \tag{2.15}$$

or in the form of a conservation law

$$\partial_L[\partial_R P, P] + \partial_R[\partial_L P, P] = 0. \tag{2.16}$$

Methods for finding special solutions of (2.14), e.g., soliton solutions, are known.[16,17]

By explicit calculation one can check that the real-valued functions

$$J_L = \mathrm{tr}(\partial_L X \partial_L X^\dagger P), \quad J_R = \mathrm{tr}(\partial_R X \partial_R X^\dagger P) \tag{2.17}$$

satisfy

$$\partial_L J_R = \partial_R J_L = 0 \tag{2.18}$$

for any solution X of the Euler–Lagrange equations (2.14). The functions J_L, J_R are invariant under local $SU(m)$ and global $SU(N)$ transformations (2.9) and (2.10).

III. SURFACES OBTAINED FROM THE GRASSMANNIAN SIGMA MODEL

Let us now discuss the analytical description of a two-dimensional smooth orientable surface $\mathcal{F}$ immersed in the $\mathfrak{su}(N)$ algebra, associated with the Grassmannian sigma model (2.14). We shall construct an exact $\mathfrak{su}(N)$-valued one-form whose "potential" zero-form defines the surface $\mathcal{F}$. Next, we shall investigate the geometric characteristics of the surface $\mathcal{F}$.

Let us introduce a scalar product

$$(A,B) = -\tfrac{1}{2}\mathrm{tr}\, AB$$

on $\mathfrak{su}(N)$ and identify the (N^2-1)-dimensional Euclidean space with the $\mathfrak{su}(N)$ algebra

$$\mathbb{R}^{N^2-1} \simeq \mathfrak{su}(N).$$

We denote

$$M_L = [\partial_L P, P], \quad M_R = [\partial_R P, P]. \tag{3.1}$$

It follows from (2.16) that if X is a solution of the Euler–Lagrange equations (2.14) then

$$\partial_L M_R + \partial_R M_L = 0. \tag{3.2}$$

We identify tangent vectors to the surface $\mathcal{F}$ with the matrices M_L and M_R, as follows:

$$\mathcal{Z}_L = M_L, \quad \mathcal{Z}_R = -M_R. \tag{3.3}$$

Equation (3.2) implies there exists a closed $\mathfrak{su}(N)$-valued one-form on Ω,

$$\mathcal{Z} = \mathcal{Z}_L \mathrm{d}\xi_L + \mathcal{Z}_R \mathrm{d}\xi_R, \quad \mathrm{d}\mathcal{Z} = 0.$$

Because $\mathcal{Z}$ is closed and Ω is connected and simply connected, $\mathcal{Z}$ is also exact. In other words, there exists a well-defined $\mathfrak{su}(N)$-valued function Z on Ω such that $\mathcal{Z}=\mathrm{d}Z$. The matrix function Z is unique up to addition of any constant element of $\mathfrak{su}(N)$ and we identify the components of Z with the coordinates of the sought-after surface $\mathcal{F}$ in $\mathbb{R}^{N^2-1}$. Consequently, we get

$$\partial_L Z = \mathcal{Z}_L, \quad \partial_R Z = \mathcal{Z}_R. \tag{3.4}$$

The map Z is called the Weierstrass formula for immersion. In practice, the surface $\mathcal{F}$ is found by integration

$$\mathcal{F}{:}Z\,(\xi_L,\xi_R) = \int_{\gamma(\xi_L,\xi_R)} \mathcal{Z} \tag{3.5}$$

along any curve $\gamma(\xi_L,\xi_R)$ in Ω connecting the point $(\xi_L,\xi_R) \in \Omega$ with an arbitrary chosen point $(\xi_L^0,\xi_R^0) \in \Omega$.

By computation of the traces of $\mathcal{Z}_B.\mathcal{Z}_D$, $B,D=L,R$ we find the components of the induced metric on the surface $\mathcal{F}$,

$$G=\begin{pmatrix} G_{LL}, & G_{LR} \\ G_{LR}, & G_{RR} \end{pmatrix}=\begin{pmatrix} J_L & -\mathrm{tr}\left(\frac{\partial_L X\partial_R X^\dagger+\partial_R X\partial_L X^\dagger}{2}P\right) \\ -\mathrm{tr}\left(\frac{\partial_L X\partial_R X^\dagger+\partial_R X\partial_L X^\dagger}{2}P\right) & J_R \end{pmatrix}. \tag{3.6}$$

The first fundamental form of the surface $\mathcal{F}$ takes surprisingly compact form

$$I=J_L(\mathrm{d}\xi_L)^2-2G_{LR}\mathrm{d}\xi_L\mathrm{d}\xi_R+J_R(\mathrm{d}\xi_R)^2$$

$$=(2\delta_{B,D}-1)\mathrm{tr}(\partial_B X\partial_D X^\dagger P)\mathrm{d}\xi_B\mathrm{d}\xi_D, \tag{3.7}$$

where summation over repeated indices $B,D=L,R$ applies and $\delta_{B,D}=1$ if $B=D$ and 0 otherwise.

In order to establish conditions on a solution X of the Euler–Lagrange equations (2.14) under which the surface exists, we check explicitly whether the induced first fundamental form (3.7) is positive (as it must be by construction even when the surface degenerates to a curve) and when it is positively definite, i.e., we really have a surface.

We introduce a scalar product on the space of $N\times m$ matrices X,

$$\langle a,b\rangle=\mathrm{tr}(a^\dagger\cdot b), a,b\in\mathbb{C}^{N\times m}.$$

Due to the positivity of the projector P we may write

$$J_D=\langle P\partial_D X,\partial_D X\rangle\geqslant 0,\quad D=L,R. \tag{3.8}$$

Further, using the Schwarz inequality

$$|\langle Ab,a\rangle|^2\leqslant\langle Aa,a\rangle\langle Ab,b\rangle \tag{3.9}$$

valid for any positive Hermitian operator A, namely for $P:P(a)=P\cdot a$ we find

$$\langle P\partial_L X,\partial_L X\rangle\langle P\partial_R X,\partial_R X\rangle\geqslant|\langle P\partial_L X,\partial_R X\rangle|^2\geqslant(\Re\langle P\partial_L X,\partial_R X\rangle)^2,$$

i.e.,

$$\det G=\langle P\partial_L X,\partial_L X\rangle\langle P\partial_R X,\partial_R X\rangle-(\Re\langle P\partial_L X,\partial_R X\rangle)^2\geqslant 0. \tag{3.10}$$

Therefore, the 2×2 Hermitian matrix of the metric (3.6) has non-negative diagonal elements and determinant, and consequently, as one may easily show, its eigenvalues are non-negative. This means that the first fundamental form I defined by (3.7) is positive for any solution X of the Euler–Lagrange equations (2.14).

Investigating when sharp inequalities hold we find that I is positive definite in the point (ξ_L^0,ξ_R^0) either if the inequality

$$\Im\,\mathrm{tr}(\partial_L X\partial_R X^\dagger P)\neq 0 \tag{3.11}$$

holds in (ξ_L^0,ξ_R^0) or if the matrices

$$\partial_L X(\xi_L^0,\xi_R^0),\quad \partial_R X(\xi_L^0,\xi_R^0),\quad X(\xi_L^0,\xi_R^0) \tag{3.12}$$

are linearly independent. Therefore any of the conditions (3.11) and (3.12) is a sufficient condition for the existence of the surface $\mathcal{F}$ associated with the solution X of the Euler–Lagrange equations (2.14) in the vicinity of the point (ξ_L^0,ξ_R^0).

Using (3.6) we can write the formula for scalar curvature[18] as

$$K=\frac{1}{\sqrt{J_L J_R-G_{LR}^2}}\partial_R\left(\frac{\partial_L G_{LR}-\frac{1}{2}G_{LR}\partial_L(\ln J_L)}{\sqrt{J_L J_R-G_{LR}^2}}\right). \tag{3.13}$$

IV. THE GAUSS–WEINGARTEN EQUATIONS

Now we may formally determine a moving frame on the surface $\mathcal{F}$ and write the Gauss–Weingarten equations. Let X be a solution of the Euler–Lagrange equations (2.14) such that $\det(G)$ is not zero in a neighborhood of a regular point (ξ_L^0, ξ_R^0) in Ω. Assume also that the surface $\mathcal{F}$ (3.5), associated with these equations is described by the moving frame

$$\vec{\tau} = (\partial_L Z, \partial_R Z, n_3, \ldots, n_{N^2-1})^T,$$

where the vectors $\partial_L Z, \partial_R Z, n_3, \ldots, n_{N^2-1}$ satisfy the normalization conditions

$$(\partial_L Z, n_k) = (\partial_R Z, n_k) = 0, \quad (n_j, n_k) = \delta_{jk}. \tag{4.1}$$

We now show that the moving frame satisfies the Gauss–Weingarten equations

$$\begin{aligned}
\partial_L \partial_L Z &= A_L^L \partial_L Z + A_R^L \partial_R Z + Q_j^L n_j, \\
\partial_L \partial_R Z &= H_j n_j, \\
\partial_L n_j &= \alpha_j^L \partial_L Z + \beta_j^L \partial_R Z + s_{jk}^L n_k, \\
\partial_R \partial_L Z &= H_j n_j, \\
\partial_R \partial_R Z &= A_L^R \partial_L Z + A_R^R \partial_R Z + Q_j^R n_j, \\
\partial_R n_j &= \alpha_j^R \partial_L Z + \beta_j^R \partial_R Z + s_{jk}^R n_k,
\end{aligned} \tag{4.2}$$

where $s_{jk}^L + s_{kj}^L = 0$, $s_{jk}^R + s_{kj}^R = 0$, $j,k = 3, \ldots, N^2 - 1$,

$$\alpha_j^L = \frac{H_j G_{LR} - Q_j^L J_R}{\det G}, \quad \beta_j^L = \frac{Q_j^L G_{LR} - H_j J_L}{\det G},$$

$$\alpha_j^R = \frac{Q_j^R G_{LR} - H_j J_R}{\det G}, \quad \beta_j^R = \frac{H_j G_{LR} - Q_j^R J_L}{\det G},$$

and A_L^L, A_R^L (A_L^R, A_R^R have similar form which can be obtained by exchanging $L \leftrightarrow R$) are written as

$$\begin{aligned}
A_L^L &= \frac{1}{\det G}(J_R(\partial_L \partial_L Z, \partial_L Z) - G_{LR}(\partial_L \partial_L Z, \partial_R Z)), \\
A_R^L &= \frac{1}{\det G}(J_L(\partial_L \partial_L Z, \partial_R Z) - G_{LR}(\partial_L \partial_L Z, \partial_L Z)),
\end{aligned} \tag{4.3}$$

where

$$\begin{aligned}
(\partial_L \partial_L Z, \partial_L Z) &= \tfrac{1}{2}\mathrm{tr}((\partial_L \partial_L X \partial_L X^\dagger + \partial_L X \partial_L \partial_L X^\dagger) P), \\
(\partial_L \partial_L Z, \partial_R Z) &= -\tfrac{1}{2}\mathrm{tr}((\partial_L \partial_L X \partial_R X^\dagger + \partial_R X \partial_L \partial_L X^\dagger) P + 2 \partial_L X \partial_L X^\dagger (X \partial_R X^\dagger + \partial_R X X^\dagger)).
\end{aligned} \tag{4.4}$$

Note that in fact we can write it in a compact way

$$(\partial_B \partial_B Z, \partial_D Z) = \left(\delta_{B,D} - \tfrac{1}{2}\right)\mathrm{tr}((\partial_B \partial_B X \partial_D X^\dagger + \partial_D X \partial_B \partial_B X^\dagger) P + 2 \partial_B X \partial_B X^\dagger (X \partial_D X^\dagger + \partial_D X X^\dagger)). \tag{4.5}$$

The explicit form of the coefficients H_j, Q_j^D (where $D=L,R$; $j=3,\ldots,N^2-1$) depends on the chosen orthonormal basis $\{n_3,\ldots,n_{N^2-1}\}$ of the normal space to the surface $\mathcal{F}$ at the point $X(\xi_L^0,\xi_R^0)$. Partial information about them will be obtained in (5.6).

Indeed, if $\partial_L Z, \partial_R Z$ are defined by (3.4) for an arbitrary solution X of the Euler–Lagrange equations (2.14), then by straightforward calculation using (2.15) one finds that

$$\partial_L\partial_R Z = \partial_R\partial_L Z = [\partial_L P, \partial_R P] = \lambda - \lambda XX^\dagger - XX^\dagger\lambda + X(\partial_L X^\dagger \partial_R X - \partial_R X^\dagger \partial_L X)X^\dagger,$$

where

$$\lambda = \partial_L X \partial_R X^\dagger - \partial_R X \partial_L X^\dagger.$$

By computing

$$\mathrm{tr}(\partial_L\partial_R Z \,.\, \partial_D Z) = \pm\,\mathrm{tr}([\partial_L P, \partial_R P] \,.\, [\partial_D P, P]) = 0, \quad D = L,R \tag{4.6}$$

we conclude that $\partial_L\partial_R Z$ is perpendicular to the surface $\mathcal{F}$ and consequently it has the form given in (4.2).

The remaining relations in (4.2) and (4.3) follow as differential consequences from the assumed normalizations of the normals (4.1), e.g.,

$$(n_j, n_k) = 0, \quad j \neq k,$$

which gives

$$0 = (\partial_L n_j, n_k) + (\partial_L n_k, n_j) = s_{jk}^L + s_{kj}^L.$$

Similarly

$$(n_j, \partial_L Z) = 0, \quad (n_j, \partial_R Z) = 0$$

by differentiation leads to

$$(\partial_R n_j, \partial_L Z) + (n_j, \partial_L\partial_R Z) = 0, \quad (\partial_R n_j, \partial_R Z) + (n_j, \partial_R\partial_R Z) = 0$$

implying

$$J_L \alpha_j^R + G_{LR}\beta_j^R + H_j = 0, \quad G_{LR}\alpha_j^R + J_R\beta_j^R + Q_j^R = 0.$$

Consequently, α_j^R, β_j^R can be determined in terms of H_j, Q_j^R and of the components of the induced metric G. The remaining coefficients α_j^L, β_j^L are derived in an analogous way by exchanging indices $L \leftrightarrow R$ in the successive differentiations.

The coefficients $A_L^L,\ldots,A_R^R$ are obtained by the requirement that $(\partial_D\partial_D Z - A_L^D\partial_L Z - A_R^D\partial_R Z)$ is normal to the surface, i.e.,

$$\mathrm{tr}(\partial_B Z \,.\, (\partial_D\partial_D Z - A_L^D\partial_L Z - A_R^D\partial_R Z)) = 0, \quad B,D = L,R. \tag{4.7}$$

From (3.1) and (3.4) we find

$$\begin{aligned}\partial_L\partial_L Z = [\partial_L\partial_L P, P] &= \partial_L\partial_L XX^\dagger - XX^\dagger\partial_L\partial_L XX^\dagger + X\partial_L\partial_L X^\dagger XX^\dagger - X\partial_L\partial_L X^\dagger + 2X\partial_L X^\dagger X\partial_L X^\dagger \\ &\quad - 2\partial_L XX^\dagger\partial_L XX^\dagger.\end{aligned} \tag{4.8}$$

The expression for $\partial_R\partial_R Z$ is obtained by the change of the overall sign and $L \leftrightarrow R$. After substituting the above expressions into (4.7) we solve the resulting linear equations for A_B^D.

Let us note that the Gauss–Weingarten equations (4.2) can be written equivalently in the $N \times N$ matrix form

$$\partial_L\vec{\tau} = U\vec{\tau}, \quad \partial_R\vec{\tau} = V\vec{\tau}, \tag{4.9}$$

where

$$U=\begin{pmatrix} A_L^L & A_R^L & Q_3^L & \cdots & Q_{N^2-1}^L \\ 0 & 0 & H_3 & \cdots & H_{N^2-1} \\ \alpha_3^L & \beta_3^L & s_{33}^L & \cdots & s_{3(N^2-1)}^L \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ \alpha_{(N^2-1)}^L & \beta_{(N^2-1)}^L & s_{(N^2-1)3}^L & \cdots & s_{(N^2-1)(N^2-1)}^L \end{pmatrix},$$

$$V=\begin{pmatrix} 0 & 0 & H_3 & \cdots & H_{N^2-1} \\ A_L^R & A_R^R & Q_3^R & \cdots & Q_{N^2-1}^R \\ \alpha_3^R & \beta_3^R & s_{33}^R & \cdots & s_{3(N^2-1)}^R \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ \alpha_{(N^2-1)}^R & \beta_{(N^2-1)}^R & s_{(N^2-1)3}^R & \cdots & s_{(N^2-1)(N^2-1)}^R \end{pmatrix}. \tag{4.10}$$

The Gauss–Codazzi–Ricci equations

$$\partial_R U-\partial_L V+[U,V]=0 \tag{4.11}$$

are the compatibility conditions for the Gauss–Weingarten equations (4.2). They are the necessary and sufficient conditions for the local existence of the corresponding surface $\mathcal{F}$. They are satisfied for any solution X of the Euler–Lagrange equations (2.14), provided that explicit forms of Q_j^D, H_j are inserted (they can be found, for example, by the method developed in Sec V.). On the other hand, the Gauss–Codazzi–Ricci equations (4.11) can be used to derive differential constraints that Q_j^D, H_j must satisfy for any possible choice of normals n_j.

The second fundamental form and the mean curvature vector of the surface $\mathcal{F}$ at the regular point p can be expressed, according to Refs. 19 and 20, as

$$\begin{aligned} \mathbf{II}&=(\partial_L\partial_L Z)^{\perp}\mathrm{d}\xi_L\mathrm{d}\xi_L+2(\partial_L\partial_R Z)^{\perp}\mathrm{d}\xi_L\mathrm{d}\xi_R+(\partial_R\partial_R Z)^{\perp}\mathrm{d}\xi_R\mathrm{d}\xi_R,\\ \mathbf{H}&=\frac{1}{\det G}(J_R(\partial_L\partial_L Z)^{\perp}-2G_{LR}(\partial_L\partial_R Z)^{\perp}+J_L(\partial_R\partial_R Z)^{\perp}), \end{aligned} \tag{4.12}$$

where $(\ )^{\perp}$ denotes the normal part of the vector. In our case the expressions (4.12) take the form

$$\begin{aligned} \mathbf{II}&=\left(Q_j^L\mathrm{d}\xi_L\mathrm{d}\xi_L+2H_j\mathrm{d}\xi_L\mathrm{d}\xi_R+Q_j^R\mathrm{d}\xi_R\mathrm{d}\xi_R\right)n_j=(\partial_L\partial_L Z-A_L^L\partial_L Z-A_R^L\partial_R Z)\mathrm{d}\xi_L\mathrm{d}\xi_L+2(\partial_L\partial_R Z)\mathrm{d}\xi_L\mathrm{d}\xi_R\\ &\quad+(\partial_R\partial_R Z-A_L^R\partial_L Z-A_R^R\partial_R Z)\mathrm{d}\xi_R\mathrm{d}\xi_R,\\ \mathbf{H}&=\frac{1}{\det G}(J_RQ_j^L-2G_{LR}H_j+J_LQ_j^R)n_j=\frac{1}{\det G}(J_R(\partial_L\partial_L Z-A_L^L\partial_L Z-A_R^L\partial_R Z)-2G_{LR}(\partial_L\partial_R Z)\\ &\quad+J_L(\partial_R\partial_R Z-A_L^R\partial_L Z-A_R^R\partial_R Z)). \end{aligned} \tag{4.13}$$

The derivatives $\partial_D\partial_B Z$ are expressed explicitly in terms of X in Eqs. (4.6) and (4.8) but after substitution of them into (4.13) the expressions get rather complicated, therefore we do not present them here.

V. THE MOVING FRAME OF A SURFACE IN THE ALGEBRA (N)

Now we proceed to construct the moving frame of the surface $\mathcal{F}$ immersed in the $\mathfrak{su}(N)$ algebra, i.e., matrices $\partial_L Z, \partial_R Z, n_a$, $a=3,\ldots,N^2-1$ satisfying (4.1).

Let X be a solution of the Euler–Lagrange equations (2.14) and let (ξ_L^0,ξ_R^0) be a regular point in Ω, i.e., such that $\det G(X(\xi_L^0,\xi_R^0))\neq 0$. Let us denote $X^0=X(\xi_L^0,\xi_R^0)$, $Z^0=Z(\xi_L^0,\xi_R^0)$. Taking into account that

$$\mathrm{tr}(A) = \mathrm{tr}(\Phi A \Phi^{\dagger}), \quad A \in \mathfrak{su}(N), \quad \Phi \in SU(N),$$

we employ the adjoint representation of the group $SU(N)$ in order to bring $\partial_L Z, \partial_R Z, n_a$ to the simplest form possible. We shall request in the neighborhood of (ξ_L^0, ξ_R^0) that

$$X(\xi_L, \xi_R) = \Phi(\xi_L, \xi_R) \begin{pmatrix} \mathbf{1}_{m\times m} \\ \mathbf{0}_{n\times m} \end{pmatrix}. \tag{5.1}$$

The existence of such a matrix function $\Phi(\xi_L, \xi_R)$ follows from the fact that $G(m,n)$ is a homogeneous space (2.1). In fact $\Phi(\xi_L, \xi_R)$ is just any representative in $SU(N)$ of the equivalence class $[X(\xi_L, \xi_R)]$ such that

$$X(\xi_L, \xi_R) = \begin{pmatrix} \Phi_{11}(\xi_L, \xi_R) & \cdots & \Phi_{1m}(\xi_L, \xi_R) \\ & \cdots & \\ \Phi_{N1}(\xi_L, \xi_R) & \cdots & \Phi_{Nm}(\xi_L, \xi_R) \end{pmatrix},$$

$$[X(\xi_L, \xi_R)] = [\Phi(\xi_L, \xi_R)]$$

and consequently $\Phi(\xi_L, \xi_R)$ is not unique. An explicit (local) construction of $\Phi(\xi_L, \xi_R)$ can be performed algorithmically in such a way that Φ depends smoothly on ξ_L, ξ_R (for a detailed explanation in the case $G(m,1) = \mathbb{C}P^m$ see Ref. 7).

Let us choose an orthonormal basis in $\mathfrak{su}(N)$ of the following form:

$$\begin{aligned} (A_{jk})_{ab} &= i(\delta_{ja}\delta_{kb} + \delta_{jb}\delta_{ka}), \quad 1 \leqslant j < k \leqslant N, \\ (B_{jk})_{ab} &= (\delta_{ja}\delta_{kb} - \delta_{jb}\delta_{ka}), \quad 1 \leqslant j < k \leqslant N, \end{aligned} \tag{5.2}$$

$$(C_p)_{ab} = i\sqrt{\frac{2}{p(p+1)}} \left(\sum_{d=1}^{p} \delta_{da}\delta_{db} - p\,\delta_{p+1,a}\delta_{p+1,b} \right), \quad 1 \leqslant p \leqslant N-1.$$

Using the definition of $\partial_D Z$ (3.1)–(3.4) in terms of the projector P and its derivatives, we find that $\partial_D^{\Phi} Z \equiv \Phi^{\dagger} \partial_D Z(\xi_L, \xi_R) \Phi$ has a simple block off-diagonal structure

$$\partial_D^{\Phi} Z = \Phi^{\dagger} \partial_D Z(\xi_L, \xi_R) \Phi = \begin{pmatrix} \mathbf{0}_{m\times m} & -(Z_D^{\Phi})^{\dagger} \\ Z_D^{\Phi} & \mathbf{0}_{n\times n} \end{pmatrix}, \tag{5.3}$$

where the nontrivial blocks Z_D^{Φ} are defined by the relation (5.3).

When the matrix function Φ satisfying (5.1) is found, the construction of the moving frame can proceed as follows. Assume that one finds, using a variant of Gramm–Schmidt orthogonalization procedure, for each ξ_L, ξ_R, the orthonormal vectors

$$\widetilde{A}_{aj}, \widetilde{B}_{aj}, \quad a = 1, \ldots, m, \quad j = m+1, \ldots, N, \quad a + j > m + 2$$

satisfying

$$(\partial_D^{\Phi} Z, \widetilde{A}_{aj}) = 0, \quad (\partial_D^{\Phi} Z, \widetilde{B}_{bj}) = 0$$

and

$$\mathrm{span}(\partial_D^{\Phi} Z, \widetilde{A}_{aj}, \widetilde{B}_{aj})_{D=L,R,a=1,\ldots,m,j=m+2,\ldots,N,a+j>m+2} = \mathrm{span}(A_{aj}, B_{aj})_{a=1,\ldots,m,j=m+1,\ldots,N}. \tag{5.4}$$

[The vectors $\widetilde{A}_{aj}, \widetilde{B}_{aj}$ as well as $\partial_D^{\Phi} Z$ are functions of ξ_L, ξ_R, the arguments are not written out in order to save space. The relations hold for each pair of values of ξ_L, ξ_R in the considered neighborhood of (ξ_L^0, ξ_R^0)]. We identify the remaining tilded and untilded matrices

$$\tilde{A}_{jk} = A_{jk}, \quad \tilde{B}_{jk} = B_{jk}, \quad \tilde{C}_p = C_p,$$

where $a,j=1,\ldots,m$ or $a,j=m+1,\ldots,N$, $1 \leqslant p \leqslant N-1$. As a result, from Gramm–Schmidt orthogonalization and (5.3) we get

$$(\partial_D^\Phi Z, \tilde{A}_{ak}) = (\partial_D^\Phi Z, \tilde{B}_{ak}) = (\partial_D^\Phi Z, \tilde{C}_p) = 0$$

and

$$(\tilde{A}_{ai}, \tilde{A}_{bk}) = (\tilde{B}_{ai}, \tilde{A}_{bk}) = \delta_{ab}\delta_{ik}, \quad (\tilde{C}_p, \tilde{C}_q) = \delta_{pq},$$

$$(\tilde{A}_{1i}, \tilde{B}_{jk}) = (\tilde{A}_{1i}, \tilde{C}_p) = (\tilde{B}_{1i}, \tilde{C}_p) = 0,$$

where indices run through all the values for which the respective tilded matrices are defined.

Therefore, under the above-given assumptions and notation, we can state the following

Proposition 1: Let the moving frame of the surface $\mathcal{F}$ in the neighborhood Υ of point $Z^0 = Z(\xi_L^0, \xi_R^0)$ be

$$\partial_L Z = \Phi \partial_L^\Phi Z \Phi^\dagger,$$

$$\partial_R Z = \Phi \partial_R^\Phi Z \Phi^\dagger,$$

$$n_{jk}^A = \Phi \tilde{A}_{jk} \Phi^\dagger, \tag{5.5}$$

$$n_{jk}^B = \Phi \tilde{B}_{jk} \Phi^\dagger,$$

$$n_p^C = \Phi \tilde{C}_p \Phi^\dagger,$$

where indices run through the values for which $\tilde{A}, \tilde{B}, \tilde{C}$ are defined and $\Phi(\xi_L, \xi_R)$ on Υ satisfies

$$X(\xi_L, \xi_R) = \Phi(\xi_L, \xi_R) \begin{pmatrix} \mathbf{1}_{m\times m} \\ \mathbf{0}_{n\times m} \end{pmatrix}.$$

Then (5.5) satisfies the normalization conditions (4.1) and consequently the Gauss–Weingarten equations (4.2).

Note that the first two lines of (5.5) are equivalent to (5.3). The remaining lines of (5.5) give a rather explicit description of the normals to the surface $\mathcal{F}$. Since the construction is local, we do not have an *a priori* control of the orientation of the normals. Of course, in the neighborhood where the procedure is applied the normals have the same orientation.

The explicit form of the moving frame (5.5) might be quite complicated because of the orthogonalization process involved in the construction of

$$n_{aj}^A, n_{aj}^B, \quad a = 1,\ldots,m, \quad j = m+1,\ldots,N, \quad a + j > m + 2$$

(i.e., in the construction of $\tilde{A}_{1j}, \tilde{B}_{1j}$). On the other hand, the remaining normals

$$n_{ak}^A, n_{ak}^B, n_p^C$$

where $a,j=1,\ldots,m$ or $a,j=m+1,\ldots,N$, $1 \leqslant p \leqslant N-1$ can be constructed immediately after finding Φ. In fact, one particular combination of normals n_p^C of the form

$$n_P = i\sqrt{2}\left(\sqrt{\frac{N-m}{mN}}\mathbf{1} - \sqrt{\frac{N-m}{m(N-m)}}P\right)$$

can be constructed from X, i.e., P, alone, without the knowledge of corresponding Φ.

If we choose another matrix Φ satisfying (5.1), the constructed normals would have been rotated by a local (gauge) transformation from the subgroup of $SU(N)$ leaving $\partial_L Z, \partial_R Z$ invariant.

It is worth noting that from Eqs. (4.6) and (4.8) it immediately follows that

$$\begin{aligned}(\partial_L\partial_L Z)^\perp, (\partial_R\partial_R Z)^\perp &\in \operatorname{span}(n^A_{1j}, n^B_{1j})_{a=1,\ldots,m, j=m+1,\ldots,N},\\ (\partial_L\partial_R Z)^\perp = \partial_L\partial_R Z &\in \operatorname{span}(n^A_{jk}, n^B_{jk}, n^C_p)_{a,j=1,\ldots,m, \text{ or } a,j=m+1,\ldots,N, p<N},\end{aligned} \tag{5.6}$$

i.e., $\partial_L\partial_R Z$ is orthogonal to $\partial_L\partial_L Z, \partial_R\partial_R Z$ [and also to the surface, see (4.2)].

VI. FINAL REMARKS

The above presented technique for finding surfaces associated with complex Grassmannian sigma models defined on Minkowski space can be seen to give a rather detailed analytical description of the surfaces in question. This description provides effective tools for constructing surfaces without reference to additional considerations, proceeding directly from the given complex Grassmannian sigma model equations (2.14). Through the use of Cartan's language of moving frames we derived via this sigma model, the structural equations of two-dimensional smooth surfaces immersed in $\mathfrak{su}(N)$ algebra. It allows one to find the first and second fundamental forms of the surfaces as well as the relations between them as expressed in the Gauss–Weingarten and Gauss–Codazzi–Ricci equations. An extension of the classical Enneper–Weierstrass representation of surfaces in multidimensional spaces, expressed in terms of any nonsingular solution of (2.14), was presented in an explicit form.

Explicit examples of surfaces constructed by the presented method were given in Ref. 8 in the $\mathbb{C}P^1$ case. In the more complicated $\mathbb{C}P^N$ and truly Grassmannian cases the construction of examples relies on the knowledge of explicit solutions in closed form of the corresponding sigma models on Minkowski space (numerical solutions are not good enough, since the numerical computation of derivatives in the construction of the tangent vectors $\mathcal{Z}$ would lead to unreliable results). Finding such solutions is by itself a nontrivial task which we plan to investigate in the future. (For example, the solutions obtained by the method presented in Ref. 21 are becoming computationally too complicated to allow even numerical computation of the surface in feasible time.)

We consider sums over the square lattice which depend only on radial distance, and provide formulas which enable sums of functions with Neumann series to be reexpressed as combinations of hypergeometric series. We illustrate the procedure using trigonometric sums previously studied by Borwein and Borwein, sums combining logarithms, Bessel functions J_λ, and powers of distance, and sums of Neumann functions. We also exhibit sums which may be evaluated analytically and recurrence formulas linking sums. © *2005 American Institute of Physics.*

I. INTRODUCTION

Many problems involving wave propagation through periodic structures can be dealt with through the construction of Green's functions built up from lattice sums which incorporate the periodicity required of the solution. The long history of lattice sums was reviewed by Glasser and Zucker[1] in 1980, but there have been a number of recent papers dealing with new methods to evaluate efficiently and accurately these slowly converging or conditionally converging series.[2–8] Many of these papers deal with techniques well adapted to particular sums, but difficult to adapt to variants on the form of the summand. Here we will deal with more general methods and will concentrate on sums over the square lattice which depend only on the radial distance to the lattice point. While similar methods may be applied to sums depending on the angle of the lattice point as well as its distance,[9] there are considerable advantages of simplicity to be gained by considering sums over distance alone.

We commence by studying a Schlömilch series of general form over the square lattice and treat this using the Poisson summation formula, expressing it as a series of hypergeometric type in which the sums over the square lattice have been evaluated analytically. We illustrate particular cases where the Schlömilch series can be summed analytically, as well as integral and differential recurrence relations for them.

We next apply these results to Neumann series involving Bessel functions of even order, for which simple results can be obtained. We illustrate this by considering a cosine double sum previously evaluated by Borwein and Borwein.[10] For sums over Bessel functions of odd order, the results are more complicated, but once again we show the results agree with those previously established for a sine double sum.

We show next that, by taking an appropriate partial derivative of the Schlömilch series, we can generate a general formula for a sum involving the logarithm of distance, as well as Bessel functions and powers of it. We then consider double sums over Neumann functions, Y_n, where another partial derivative of the Schlömilch series is required. We obtain highly accurate and efficient expressions for the sums of Y_0 and Y_2 over the square lattice, and show for the former how the range of convergence of these expressions may be increased if required.

II. ANALYTIC EXPRESSIONS FOR NONANGULAR ARRAY SUMS

Many interesting results have been derived for lattice sums using Schlömilch series.[1,11,12] We wish to consider here a general sum $\mathcal{S}$ which depends on distance from the origin to a general point $K_h=2\pi\sqrt{h_1^2+h_2^2}$ in the reciprocal lattice of a square lattice with unit period:

$$\mathcal{S}_{\lambda,0,\nu}(\xi)=\sum_{h\neq 0}\frac{J_\lambda(K_h\xi)}{K_h^\nu}, \tag{1}$$

where the indices λ and μ are integral, real, or complex, and h is a pair of subscripts (h_1,h_2). The parameter ξ is taken to be real and positive. We generalize the argument in Ref. 3 to allow for these (possibly) complex indices. We use the Poisson summation formula

$$\sum_h f(\mathbf{K}_h)=\frac{1}{(2\pi)^2}\sum_p F(\mathbf{R}_p), \tag{2}$$

where

$$F(\mathbf{R}_p)=\int\int_{\mathbb{R}^2} f(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{R}_p}\,d\mathbf{k}, \quad f(\mathbf{K}_h)=\frac{1}{(2\pi)^2}\int\int_{\mathbb{R}^2} F(\mathbf{r})e^{i\mathbf{K}_h\cdot\mathbf{r}}\,d\mathbf{r}, \tag{3}$$

R_p are direct lattice vectors, and $p=(p_1,p_2)$. We assume $\mathrm{Re}(\lambda)>\mathrm{Re}(\nu)$, so the term $h=(0,0)$ can be included in $\mathcal{S}$ without changing its value. From (3), with

$$f(\mathbf{k})=\frac{J_\lambda(k\xi)}{k^\nu}, \tag{4}$$

we arrive at an integral of the Weber-Schafheitlin form:[13,14]

$$F(\mathbf{R}_p)=2\pi\int_0^\infty \frac{J_\lambda(k\xi)J_0(kR_p)}{k^{\nu-1}}\,dk. \tag{5}$$

If $\xi<R_p$ and $\mathrm{Re}(\nu)>0$, or $\xi\leqslant R_p$ and $\mathrm{Re}(\nu)>1$, the integral converges for $\mathrm{Re}(\lambda-\nu+2)>0$ and may be expressed as a hypergeometric function:

$$F(\mathbf{R}_p)=\frac{\xi^\lambda\pi\Gamma((\lambda-\nu+2)2)}{2^{\nu-2}R_p^{\lambda-\nu+2}\Gamma(\lambda+1)\Gamma((\nu-\lambda)/2)}\,{}_2F_1\left(\frac{\lambda-\nu+2}{2},\frac{\lambda-\nu+2}{2};\lambda+1;\left(\frac{\xi}{R_p}\right)^2\right). \tag{6}$$

For $p=0$, we have $R_0=0$, and the integral in (5) is

$$F(\mathbf{0})=2\pi\int_0^\infty \frac{J_\lambda(k\xi)}{k^{\nu-1}}\,dk=2\pi\xi^{\nu-2}\frac{2^{-\nu+1}\Gamma((\lambda-\nu+2)/2)}{\Gamma((\lambda+\nu)/2)}, \tag{7}$$

provided that $\mathrm{Re}(\lambda-\nu)>-2$, $\mathrm{Re}(\nu)>\frac{1}{2}$.[13,14] Consequently,

$$\mathcal{S}_{\lambda,0,\nu}(\xi)=\xi^{\nu-2}\frac{\Gamma((\lambda-\nu+2)/2)}{2^\nu\pi\Gamma((\lambda+\nu)/2)}+\sum_{p\neq 0}\frac{\xi^\lambda\Gamma((\lambda-\nu+2)/2)}{2^\nu\pi R_p^{\lambda-\nu+2}\Gamma(\lambda+1)\Gamma((\nu-\lambda)/2)}$$
$$\times\,{}_2F_1\left(\frac{\lambda-\nu+2}{2},\frac{\lambda-\nu+2}{2};\lambda+1;\left(\frac{\xi}{R_p}\right)^2\right). \tag{8}$$

We complete this derivation using the series expansion for the hypergeometric function:

$$ {}_2F_1(a,b;c;z) = \frac{\Gamma(c)}{\Gamma(a)\Gamma(b)} \sum_{k=0}^{\infty} \frac{\Gamma(a+k)\Gamma(b+k)}{\Gamma(c+k)} \frac{z^k}{k!}, \tag{9} $$

which converges absolutely in $|z|<1$, and absolutely on $|z|=1$ provided that $\mathrm{Re}(c-a-b)>0$.[14] In our case, this translates to $\mathrm{Re}(\nu)>1$, and (9) gives

$$ \mathcal{S}_{\lambda,0,\nu}(\xi) = \xi^{\nu-2} \frac{\Gamma((\lambda-\nu+2)/2)}{2^\nu \pi \Gamma((\lambda+\nu)/2)} + \frac{\xi^\lambda \sin(\pi(\nu-\lambda)/2)}{2^\nu \pi^2} \sum_{k=0}^{\infty} \frac{[\Gamma((\lambda-\nu)/2+1+k)]^2}{\Gamma(\lambda+k+1)k!} \xi^{2k} \sigma^0_{2k+2+\lambda-\nu}. \tag{10} $$

Here[1]

$$ \sigma^0_{2s} = \sum_{p_1,p_2}{}' \frac{1}{(p_1^2+p_2^2)^s} = 4\zeta(s)\beta(s), \tag{11} $$

where the sum over $(p_1,p_2)\in\mathbb{Z}^2$ excludes $p_1=p_2=0$, as denoted by the prime, with $\beta(s)$ denoting the Catalan β function

$$ \beta(s) = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)^s}. \tag{12} $$

A useful summary of the properties of $\beta(s)$ has been given by Glasser.[15] The quantities σ^0_{2s} satisfy the reflection formula

$$ \sigma^0_{2s} = \sigma^0_{2-2s} \left[\frac{\pi^{2s-1}\Gamma(1-s)}{\Gamma(s)} \right], \tag{13} $$

which follows from the reflection formulae for the β function[15]

$$ 2^s \Gamma(s) \sin(s\pi/2)\beta(s) = \pi^s \beta(1-s), $$

and for the ζ function[14]

$$ \zeta(s) = 2^s \pi^{s-1} \sin(s\pi/2)\Gamma(1-s)\zeta(1-s). $$

The expression (10) was derived under the conditions $\mathrm{Re}(\lambda)>\mathrm{Re}(\nu)$, $\mathrm{Re}(\nu)>\frac{1}{2}$ and $|\xi|<1$. However, wherever the right-hand side is convergent, it provides, by analytic continuation, the definition of the left-hand side. The sum in (10) is cancelled out by its prefactor when $\lambda-\nu=2p$, for p a positive integer, in which case

$$ \mathcal{S}_{\nu+2p,0,\nu}(\xi) = \xi^{\nu-2} \frac{\Gamma(p+1)}{2^\nu \pi \Gamma(\nu+p)}. \tag{14} $$

This expression may be verified by direct numerical summation when $\mathrm{Re}(\nu)>2$. Regarded as a function of ν, $\mathcal{S}_{\nu+2p,0,\nu}(\xi)$ is analytic, with simple zeros at $\nu=-p-n$, for $n=0,1,2,\ldots$, for fixed $\xi\neq 0$.

We can derive the result for $\lambda=\nu$ from (10) letting $\lambda\to\nu$, and noting that the pole of σ^0_s at $s=1$ cancels the zero of $\sin\pi(\nu-\lambda)/2$. Alternatively, we can use (13) in (10), to give

$$ \mathcal{S}_{\lambda,0,\nu}(\xi) = \xi^{\nu-2} \frac{\Gamma((\lambda-\nu+2)/2)}{2^\nu \pi \Gamma((\lambda+\nu)/2)} + \frac{\xi^\lambda \pi^{\lambda-\nu}}{2^{\nu-2}} \sum_{k=0}^{\infty} \frac{\pi^{2k}(-1)^k \xi^{2k}}{\Gamma(\lambda+k+1)k!} \beta(-k+(\nu-\lambda)/2)\zeta(-k+(\nu-\lambda)/2), \tag{15} $$

where we note that the product $\zeta(s)\beta(s)$ is zero whenever s is a negative integer. The result is

$$\mathcal{S}_{\nu,0,\nu}(\xi) = \frac{\xi^{\nu-2}}{2^\nu \pi \Gamma(\nu)} - \frac{\xi^\nu}{2^\nu \Gamma(\nu+1)} = \frac{\xi^{\nu-2}}{2^\nu \Gamma(\nu+1)}\left(\frac{\nu}{\pi} - \xi^2\right), \tag{16}$$

which is a generalization of the result

$$\mathcal{S}_{n,0,n}(\xi) = \frac{1}{(2n)!!}\left(\frac{n}{\pi}\xi^{n-2} - \xi^n\right), \quad n \in \mathbb{N},$$

derived in Ref. 5 in a different fashion. It is interesting to take $\nu=0$ in (16), with the result $\mathcal{S}_{0,0,0}(\xi)=-1$. The result from Ref. 5 is

$$\mathcal{S}_{0,0,0}(\xi) = \frac{\delta(\xi)}{2\pi\xi} - 1, \tag{17}$$

which agrees with (16) apart from the distributive term, which one would not expect to exist in an analytic continuation. Indeed, in the definition of sums (1) we have assumed that ξ is real and positive so that the two results are equivalent. For fixed $\xi \neq 0$, the expression (16) is an analytic function of ν, with zeros at $\nu=-1,-2,\ldots$, and also at $\nu=\pi\xi^2$. Once again, the expression (16) may be exemplified numerically by choosing $\mathrm{Re}(\nu)>2$.

Another special case of (10) is the formula (43) from Ref. 3, valid for $\lambda-\nu=2p+1$, where λ and ν are non-negative integers, and p is a positive integer. We repeat it here, with an error in a sign factor corrected:

$$\mathcal{S}_{\lambda,0,\nu}(\xi) = \xi^{\nu-2}\frac{\Gamma((\lambda-\nu+2)/2)}{2^\nu \pi \Gamma((\lambda+\nu)/2)} + \frac{(-1)^{(\lambda-\nu+1)/2}\xi^\lambda}{2^\nu \pi^2}\sum_{k=0}^{\infty}\frac{[\Gamma((\lambda-\nu)/2+1+k)]^2}{k!(k+\lambda)!}\xi^{2k}\sigma^0_{2k+2+\lambda-\nu}.$$

The lattice sums $\mathcal{S}$ obey four recurrence relations based on certain integral and differential relations, satisfied by the Bessel functions[3] (see also the Appendix). The forms

$$\mathcal{S}_{\lambda+1,0,\nu+1}(\xi) = \frac{1}{\xi^{\lambda+1}}\int_0^\xi \eta^{\lambda+1}\mathcal{S}_{\lambda,0,\nu}(\eta)\,d\eta, \quad \text{for } \mathrm{Re}(\lambda) > -1, \tag{18}$$

and

$$\mathcal{S}_{\lambda-1,0,\nu+1}(\xi) = \frac{\xi^{\lambda-1}}{2^{\lambda-1}(2\pi)^{\nu-\lambda+2}\Gamma(\lambda)}\sigma^0_{\nu-\lambda+2} - \frac{1}{\xi^{-\lambda+1}}\int_0^\xi \eta^{-\lambda+1}\mathcal{S}_{\lambda,0,\nu}(\eta)\,d\eta \tag{19}$$

act by integration to increment the third subscript. The two differential relations are

$$\mathcal{S}_{\lambda-1,0,\nu-1}(\xi) = \xi^{-\lambda}[\xi^\lambda \mathcal{S}_{\lambda,0,\nu}(\xi)]', \tag{20}$$

and

$$\mathcal{S}_{\lambda+1,0,\nu-1}(\xi) = -\xi^\lambda[\xi^{-\lambda}\mathcal{S}_{\lambda,0,\nu}(\xi)]', \tag{21}$$

which both decrement the third subscript. Appropriate pairwise combinations of these act on either the first or the third subscript alone:

$$\mathcal{S}_{\lambda+2,0,\nu}(\xi) = \frac{2(\lambda+1)}{\xi^{\lambda+2}}\int_0^\xi \eta^{\lambda+1}\mathcal{S}_{\lambda,0,\nu}(\eta)\,d\eta - \mathcal{S}_{\lambda,0,\nu}(\xi), \tag{22}$$

$$\mathcal{S}_{\lambda,0,\nu}(\xi) = \frac{\xi^{\lambda}}{2^{\lambda}(2\pi)^{\nu-\lambda}\Gamma(\lambda+1)}\sigma^{0}_{\nu-\lambda} - \frac{2(\lambda+1)}{\xi^{-\lambda}}\int_{0}^{\xi}\eta^{-\lambda-1}\mathcal{S}_{\lambda+2,0,\nu}(\eta)d\eta - \mathcal{S}_{\lambda+2,0,\nu}(\xi) \tag{23}$$

are inverse operations on the first subscript. The lowering and raising relations for the third subscript are

$$\mathcal{S}_{\lambda,0,\nu-2}(\xi) = \frac{\lambda^2}{\xi^2}\mathcal{S}_{\lambda,0,\nu}(\xi) - \frac{1}{\xi}\mathcal{S}'_{\lambda,0,\nu}(\xi) - \mathcal{S}''_{\lambda-0,\nu}(\xi) \tag{24}$$

and

$$\mathcal{S}_{\lambda,0,\nu+2}(\xi) = \frac{\xi^{\lambda}}{2^{\lambda}(2\pi)^{\nu-\lambda+2}\Gamma(\lambda+1)}\sigma^{0}_{\nu-\lambda+2} - \frac{1}{\xi^{-\lambda}}\int_{0}^{\xi}\left[\frac{1}{\eta^{2\lambda+1}}\int_{0}^{\eta}\tau^{\lambda+1}\mathcal{S}_{\lambda,0,\nu}(\tau)d\tau\right]d\eta. \tag{25}$$

We can verify that the expression (10) satisfies each of the recurrence relations (18)–(21). The algebra is elementary, with the exception of (19), where (13) needs to be used to transform $\sigma^{0}_{\nu-\lambda+2}$ into $\sigma^{0}_{\lambda-\nu}$, before this term is combined with the hypergeometric series. We can thus use either the recurrence relations or the hypergeometric expression (10) in order to extend the calculation of the $\mathcal{S}_{\lambda,0,\nu}(\xi)$ from the region of derivation $\mathrm{Re}(\lambda-\nu)>-2$, $\mathrm{Re}(\nu)>1$ over the whole range of the two complex variables λ and ν. Note the structure of (10); the first term will have simple poles at $\lambda-\nu=-2m$, where m is a positive integer, whereas in the hypergeometric sum the poles of $[\Gamma((\lambda-\nu)/2+1+k)]^2$ are exactly compensated for by the zeros of $\sin(\pi(\nu-\lambda)/2)$ and $\sigma^{0}_{2k+2+\lambda-\nu}$ at the same locations. This is also evident from (15). The hypergeometric sum gives a simple pole at $\nu-\lambda=2k+2$, due to the pole of σ^{0}.

III. NEUMANN SERIES WITH BESSEL FUNCTIONS OF EVEN ORDER

Neumann series express general functions as a combination of Bessel functions J_l of constant argument and varying integer order l.[13,14] The expansion coefficients are given by contour integral of the product of the function and the Neumann polynomials, or can be deduced from the Maclaurin series coefficients of the function.

We start with sums over the square array of Bessel functions of even order:[5]

$$\sum_{h} J_0(K_h\xi) = \sum_{h_1,h_2=-\infty}^{\infty} J_0(2\pi\xi\sqrt{h_1^2+h_2^2}) = \frac{\delta(\xi)}{2\pi\xi} \tag{26}$$

and

$$\sum_{h} J_{2l}(K_h\xi) = \sum_{h_1,h_2=-\infty}^{\infty} J_{2l}(2\pi\xi\sqrt{h_1^2+h_2^2}) = \frac{1}{\pi\xi^2}, \tag{27}$$

for $l\neq 0$. These results can be used to evaluate sums over the square array of functions of distance whose Neumann expansions only involve Bessel functions of even order. As an example, we consider one of the sums evaluated using Abel summation by Borwein and Borwein:[10]

$$\sum_{h_1,h_2}{}' \frac{\sin(\theta\sqrt{h_1^2+h_2^2})}{\sqrt{h_1^2+h_2^2}} = \frac{2\pi}{\theta} - \theta, \quad 0<|\theta|<2\pi. \tag{28}$$

Firstly, we use a Neumann series from Prudnikov *et al.*:[16]

$$\frac{\sin z}{z} = J_0(z) - 2\sum_{l=1}^{\infty}\frac{(-1)^l J_{2l}(z)}{(4l^2-1)}. \tag{29}$$

Then, substituting (26) and (27) into (29) we have

$$\sum_{h_1,h_2}{}' \frac{\sin(2\pi\xi\sqrt{h_1^2+h_2^2})}{\sqrt{h_1^2+h_2^2}} = \delta(\xi) - 2\pi\xi - \frac{4}{\xi}\sum_{l=1}^{\infty}\frac{(-1)^l}{4l^2-1}, \tag{30}$$

where the sum over h_1 and h_2 excludes $h_1=h_2=0$, as denoted by the prime. The sum on the right-hand side of (30) has the value $\left(-\frac{1}{4}\right)$, so that we obtain

$$\sum_{h_1,h_2}{}' \frac{\sin(2\pi\xi\sqrt{h_1^2+h_2^2})}{\sqrt{h_1^2+h_2^2}} = \delta(\xi) - 2\pi\xi + \frac{1}{\xi}. \tag{31}$$

This can be compared with the result of Borwein and Borwein (28). Evidently the two results agree, except that (31), having been obtained using the theory of distributions, includes a delta function term missing from (28).

We next consider the Neumann series:

$$\cos z = J_0(z) + 2\sum_{l=1}^{\infty}(-1)^l J_{2l}(z). \tag{32}$$

Hence,

$$\sum_{h_1,h_2}{}' \cos(2\pi\xi\sqrt{h_1^2+h_2^2}) = \frac{\delta(\xi)}{2\pi\xi} - 1 + \frac{2}{\pi\xi^2}\sum_{l=1}^{\infty}(-1)^l l. \tag{33}$$

The sum is evaluated using the binomial series for $-1/(1+z)^2$ at $z=1$, with the result

$$\mathcal{C}(\xi) = \sum_{h_1,h_2}{}' \cos(2\pi\xi\sqrt{h_1^2+h_2^2}) = \frac{\delta(\xi)}{2\pi\xi} - 1 - \frac{1}{2\pi\xi^2}. \tag{34}$$

Note that, if we differentiate (31) with respect to ξ, we obtain the nondistributive terms in (34).

IV. NEUMANN SERIES WITH BESSEL FUNCTIONS OF ODD ORDER

Results for odd orders corresponding to (26) and (27) were not given in Ref. 5. They may be derived from (10). Hence, we have

$$\sum_h J_{2l+1}(K_h\xi) = \sum_{h_1,h_2=-\infty}^{\infty} J_{2l+1}(2\pi\xi\sqrt{h_1^2+h_2^2}) = \frac{1}{\pi\xi^2}\left(l+\frac{1}{2}\right) - \frac{4}{\pi^2}(-1)^l\sum_{k=0}^{\infty}\frac{[\Gamma(k+l+3/2)]^2}{k!(k+2l+1)!}\zeta(k+l+3/2)\beta(k+l+3/2)\xi^{2k+2l+1}. \tag{35}$$

We apply (35) to the evaluation of

$$\mathcal{S}(\xi) = \sum_{h_1,h_2}{}' \sin(2\pi\xi\sqrt{h_1^2+h_2^2}) = 2\sum_{h_1,h_2}{}'\sum_{l=0}^{\infty}(-1)^l J_{2l+1}\left(2\pi\xi\sqrt{h_1^2+h_2^2}\right). \tag{36}$$

We note that there is no contribution from the $1/\xi^2$ term which arises from using (35) in (36). The evaluation of this contribution is somewhat delicate, since conditionally convergent sums arise. It may be approached using binomial series of the functions $1/(1+z)$ and $-1/(1+z)^2$, and analytic continuation for $z=1$. More rapidly, we may note[15] that

$$\sum_{l=0}^{\infty}(-1)^l\left(l+\frac{1}{2}\right) = \frac{1}{2}\sum_{l=0}^{\infty}\frac{(-1)^l}{(2l+1)^{-1}} = \frac{1}{2}\beta(-1) = 0. \tag{37}$$

Hence,

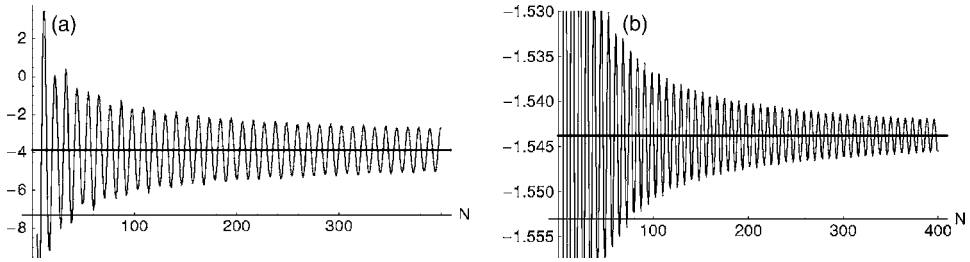

FIG. 1. Partial sums for the left-hand sides of (42) (left) and (43) (right) obtained by summation over a square region, centered on the origin and having side length of $2N+1$, for N up to 400. These are compared with the right-hand sides (solid line) of these equations for $\theta=0.583$.

$$\mathcal{S}(\xi) = -\frac{8}{\pi^2}\sum_{k=0}^{\infty}\sum_{l=0}^{\infty}\frac{[\Gamma(k+l+3/2)]^2}{k!(k+2l+1)!}\zeta(k+l+3/2)\beta(k+l+3/2)\xi^{2k+2l+1}. \tag{38}$$

We can transform the double sum to a single sum, by replacing $k+l$ by n, and using the result

$$\sum_{k,l\geqslant 0,k+l=n}\frac{(2n+1)!}{k!(k+2l+1)!} = \frac{1}{2}\sum_{k=0}^{2n+1}\binom{2n+1}{k} = 2^{2n}. \tag{39}$$

We find

$$\mathcal{S}(\xi) = -\frac{8}{\pi^2}\sum_{n=0}^{\infty}\frac{[\Gamma(n+3/2)]^2}{(2n+1)!}2^{2n}\zeta(n+3/2)\beta(n+3/2)\xi^{2n+1}. \tag{40}$$

After some manipulation of the Γ function term, this becomes

$$\mathcal{S}(\xi) = {\sum_{h_1,h_2}}'\sin(2\pi\xi\sqrt{h_1^2+h_2^2}) = -\frac{4}{\pi}\sum_{n=0}^{\infty}\frac{(2n+1)!}{(n!)^2}\zeta(n+3/2)\beta(n+3/2)\left(\frac{\xi}{2}\right)^{2n+1}. \tag{41}$$

This will be recognized as being identical to the derivative of the result from Borwein and Borwein,[10]

$${\sum_{h_1,h_2}}'\frac{\cos(\theta\sqrt{h_1^2+h_2^2})}{\sqrt{h_1^2+h_2^2}} = 4\sum_{n=0}^{\infty}\frac{(2n)!}{(n!)^2}\zeta(n+1/2)\beta(n+1/2)\left(\frac{\theta}{4\pi}\right)^{2n}, \quad 0<|\theta|<2\pi. \tag{42}$$

Borwein and Borwein[10] also consider the series on the left of (42) with an alternating sign included:

$${\sum_{h_1,h_2}}'(-1)^{h_1+h_2}\frac{\cos(\theta\sqrt{h_1^2+h_2^2})}{\sqrt{h_1^2+h_2^2}} = 4\sum_{n=0}^{\infty}\frac{(2n)!}{(n!)^2}\zeta(n+1/2)\beta(n+1/2)(2^{n+1/2}-1)\left(\frac{\theta}{4\pi}\right)^{2n},$$
$$0<|\theta|<\sqrt{2}\pi. \tag{43}$$

Numerical examples of the convergence of (42) (left) and (43) (right) by direct summation are presented in Fig. 1, together with the results of the rapidly convergent series on their right-hand sides.

V. SERIES COMBINING BESSEL FUNCTIONS AND LOGARITHMS

From the definition (1) we can construct a general formula for sums combining a logarithm with a Bessel function and a power of the distance:

$$\mathcal{L}_{\lambda,0,\nu}(\xi) = -\frac{\partial}{\partial\nu}\mathcal{S}_{\lambda,0,\nu}(\xi) = \sum_{h\neq 0} \log(K_h)\frac{J_\lambda(K_h\xi)}{K_h^\nu}. \tag{44}$$

Using the sum (11) and the expansion (15), we find

$$\mathcal{L}_{\lambda,0,\nu}(\xi) = \left[-\log\left(\frac{\xi}{2}\right) + \frac{1}{2}\psi\left(\frac{\lambda-\nu+2}{2}\right) + \frac{1}{2}\psi\left(\frac{\lambda+\nu}{2}\right)\right]\xi^{\nu-2}\frac{\Gamma((\lambda-\nu+2)/2)}{2^\nu\pi\Gamma((\lambda+\nu)/2)}$$
$$+ \frac{\xi^\lambda\pi^{\lambda-\nu}\log(2\pi)}{2^\nu}\sum_{k=0}^{\infty}\frac{\pi^{2k}(-1)^k\xi^{2k}}{\Gamma(\lambda+k+1)k!}\sigma^0_{\nu-\lambda-2k} - \frac{\xi^\lambda\pi^{\lambda-\nu}}{2^\nu}\sum_{k=0}^{\infty}\frac{\pi^{2k}(-1)^k\xi^{2k}}{\Gamma(\lambda+k+1)k!}\sigma^{0\prime}_{\nu-\lambda-2k}. \tag{45}$$

We now evaluate $\mathcal{L}_{0,0,0}(\xi)$:

$$\mathcal{L}_{0,0,0}(\xi) = \left[-\log\left(\frac{\xi}{2}\right) + \frac{1}{2}\psi(1) + \frac{1}{2}\psi(0)\right]\xi^{-2}\frac{1}{\pi\Gamma(0)} + \log(2\pi)\sum_{k=0}^{\infty}\frac{(-1)^k(\pi\xi)^{2k}}{(k!)^2}\sigma^0_{-2k}$$
$$- \sum_{k=0}^{\infty}\frac{(-1)^k(\pi\xi)^{2k}}{(k!)^2}\sigma^{0\prime}_{-2k}. \tag{46}$$

The factor $1/\Gamma(0)$ makes zero the first term on the right-hand side of (46), apart from the term involving $\psi(0)$. Taking the appropriate limit from (45), we find that we should make the identification $\psi(0)/\Gamma(0)=-1$. The first infinite series reduces just to the term $k=0$, since $\sigma^0_{-2k}=0$ for $k \geqslant 1$, while $\sigma^0_0=-1$. The second series involves the derivative

$$\sigma^{0\prime}_{-2k} = \left.\frac{\partial\sigma^0_{\nu-\lambda-2k}}{\partial\nu}\right|_{\nu=\lambda=0}$$

for negative even order subscripts. Separating out $k=0$ first of all, we use the expansion

$$\sigma^0_{2+\delta\lambda} = \frac{2\pi}{\delta\lambda} + D, \tag{47}$$

where $D=\pi(2\gamma+\log(\pi/2)-C)$, and $C=\log[\Gamma(1/4)^4/(8\pi^2)]\approx 0.783\,188\,785\,414$.[17] We may also write $D=\pi\mathsf{S}\approx 2.584\,981\,759\,5$, where S is the Sierpinski constant.[18] We then obtain

$$\sigma^{0\prime}_0 = \frac{D}{2\pi} - \gamma - \log(\pi). \tag{48}$$

For general $\sigma^{0\prime}_{-2k}$, we take the derivative of the reflection equation (13), and obtain for positive integral k

$$\sigma^{0\prime}_{-2k} = \frac{(-1)^k(k!)^2}{2\pi^{2k+1}}\sigma^0_{2+2k}. \tag{49}$$

Using (48) and (49) in (46), we find

$$\mathcal{L}_{0,0,0}(\xi) = -\frac{1}{2\pi\xi^2} - \frac{D}{2\pi} + \gamma - \log(2) - \frac{1}{2\pi}\sum_{k=1}^{\infty}\xi^{2k}\sigma^0_{2+2k}. \tag{50}$$

A numerical example of this is given in Fig. 2. Note how the envelopes of the results of direct summation separate slowly, due to the extra logarithmic factor in the definition of $\mathcal{L}$. However, the mean of the numerical results (−1.800 32) is in reasonable accord with the analytic result (−1.837 134).

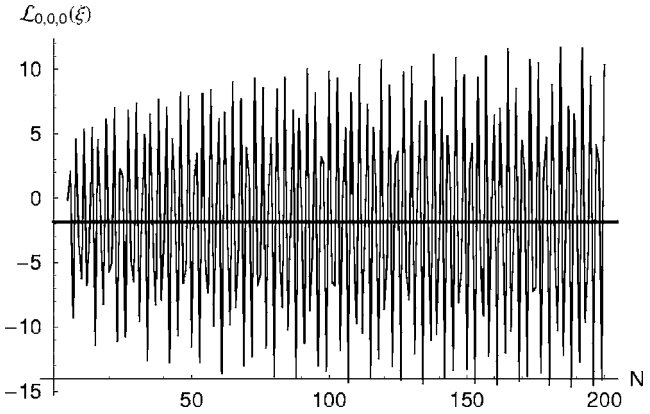

FIG. 2. Partial sums for $\mathcal{L}_{0,0,0}(\xi)$, with $\xi=0.37$, obtained by summation over a square region, centered on the origin and having side length of $2N+1$, for N up to 200. The analytical result (50) is indicated by the horizontal line.

Consider next the form of $\mathcal{L}_{2,0,0}(\xi)$. This is more straightforward than $\mathcal{L}_{0,0,0}(\xi)$, in that the first series in (45) vanishes, and only (49) is needed in the second series. We obtain

$$\mathcal{L}_{2,0,0}(\xi) = -\frac{1}{\pi\xi^2}\log\left(\frac{\xi}{2}\right) + \frac{1-2\gamma}{2\pi\xi^2} + \frac{\xi^2}{2\pi}\sum_{k=0}^{\infty}\frac{k+1}{k+2}\xi^{2k}\sigma^0_{4+2k}. \tag{51}$$

A numerical example of this is given in Fig. 3. The mean of the numerical results is 3.781 26, while the result of (51) is 3.820 33.

VI. SERIES OF NEUMANN FUNCTIONS

These series are of particular interest in the construction of Green's functions for the Helmholtz equation.[2,3,5–8] We start with a particular case of (10):

$$\mathcal{S}_{\lambda,0,0}(\xi) = \frac{\lambda}{2\pi\xi^2} - \frac{\sin(\pi\lambda/2)[\Gamma(1+\lambda/2)]^2}{\pi^2\Gamma(1+\lambda)}\xi^{\lambda}\sigma^0_{2+\lambda} - \frac{\sin(\pi\lambda/2)}{\pi^2}\sum_{k=1}^{\infty}\frac{[\Gamma(\lambda/2+1+k)]^2}{\Gamma(\lambda+k+1)k!}\xi^{2k+\lambda}\sigma^0_{2k+2+\lambda}. \tag{52}$$

We will replace λ by $\delta\lambda$, and expand this to first order in $\delta\lambda$. We use (47) to give

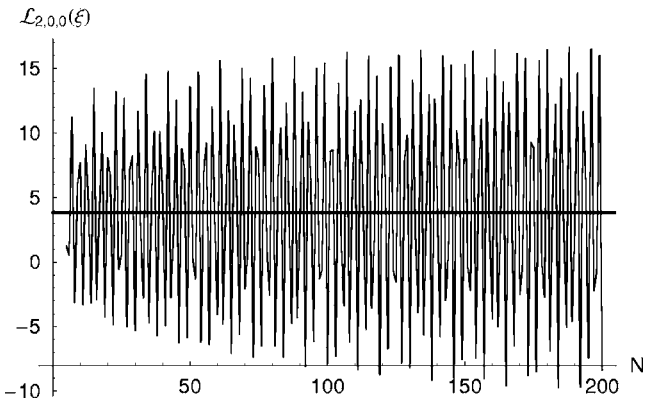

FIG. 3. Partial sums for $\mathcal{L}_{2,0,0}(\xi)$, with $\xi=0.37$, obtained by summation over a square region, centered on the origin and having side length of $2N+1$, for N up to 200. The analytical result (51) is indicated by the horizontal line.

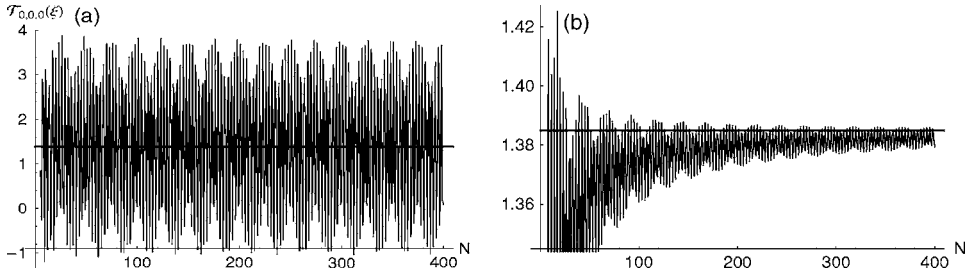

FIG. 4. On the left: partial sums for $\mathcal{T}_{0,0,0}(\xi)$ obtained by summation over a square region, centered on the origin and having side length of $2N+1$, for N up to 400. On the right: the growing mean of the data in the graph on the left. We used $\xi=0.32$, with the analytic result (56) being given by the horizontal line.

$$\mathcal{S}_{\delta\lambda,0,0}(\xi) = \frac{\delta\lambda}{2\pi\xi^2} - 1 - \delta\lambda\left[\log\xi + \frac{D}{2\pi} + \frac{2}{\pi}\sum_{k=1}^{\infty}\xi^{2k}\zeta(k+1)\beta(k+1)\right]. \tag{53}$$

Now, the Neumann functions of zeroth order are defined[13,14] as

$$Y_0(z) = \lim_{\lambda\to 0}\frac{J_\lambda(z)\cos(\lambda\pi) - J_{-\lambda}(z)}{\sin(\lambda\pi)} = \lim_{\lambda\to 0}\frac{J_\lambda(z) - J_{-\lambda}(z)}{\lambda\pi}$$

and, if we denote by

$$\mathcal{T}_{0,0,0}(\xi) = \sum_{h\neq 0} Y_0(K_h\xi), \tag{54}$$

then

$$\mathcal{T}_{0,0,0}(\xi) = \lim_{\delta\lambda\to 0}\frac{\mathcal{S}_{\delta\lambda,0,0}(\xi) - \mathcal{S}_{-\delta\lambda,0,0}(\xi)}{\pi\delta\lambda}. \tag{55}$$

Using (53) in (55), we obtain

$$\mathcal{T}_{0,0,0}(\xi) = \frac{1}{\pi^2\xi^2} - \frac{2}{\pi}\log\xi - \frac{D}{\pi^2} - \frac{4}{\pi^2}\sum_{k=1}^{\infty}\xi^{2k}\zeta(k+1)\beta(k+1). \tag{56}$$

In Fig. 4 we show a comparison of direct summation of (54), and running averages, with the result of (56). Such comparisons are useful in detecting possible algebraic errors in formulas such as (56), but do not provide precise validation because of the slowness of convergence of direct summation. However, rapidly convergent representations of Bessel function series have been found which give $\mathcal{T}_{0,0,0}(\xi)$.[2,4] In the example of Fig. 4, both (56) and accelerated summation[4] give the value 1.384 941 001 791 97. Of course, the computational burden in using Bessel function summation as in Ref. 4 is much larger than that involved in using (56) (for which 15 terms in a Mathematica[19] evaluation of the series gave the 14 decimal places quoted).

An alternative derivation of (56) uses the result (50) and the Neumann expansion:[13,14]

$$Y_0(z) = \frac{2}{\pi}\left[\log\left(\frac{z}{2}\right) + \gamma\right]J_0(z) - \frac{4}{\pi}\sum_{k=1}^{\infty}\frac{(-1)^k J_{2k}(z)}{k}. \tag{57}$$

This procedure also uses (27) to arrive at (56).

The radius of convergence of the series on the right-hand side of (56) is unity. This may be increased by subtracting terms from the product $\zeta\beta$ and adding them analytically. The product

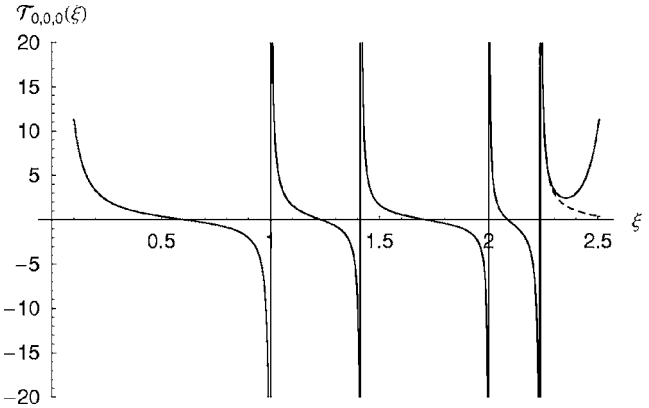

FIG. 5. $\mathcal{T}_{0,0,0}(\xi)$ from Eq. (60) with $N=5$ is compared for summation over k with 10 and 20 terms.

$$\zeta(s)\beta(s) = 1 + \frac{1}{2^s} + \frac{1}{4^s} + \frac{2}{5^s} + \frac{1}{8^s} + \frac{1}{9^s} + \frac{2}{10^s} + \frac{2}{13^s} + \frac{1}{16^s} + \frac{2}{17^s} + \cdots \tag{58}$$

may be written as

$$\zeta(s)\beta(s) = \frac{1}{4}\sum_{n=1}^{\infty} \frac{r_2(n)}{n^s}, \tag{59}$$

where the multiplicities $r_2(n)$ are equal to the number of representations of n by a sum of two squares of integers, allowing zeros and distinguishing signs and order.[20] We substitute (59) into (56), change the order of summation in the double sum, and split the sum over n at $n=N$ to obtain

$$\mathcal{T}_{0,0,0}(\xi) = \frac{1}{\pi^2\xi^2} - \frac{2}{\pi}\log\xi - \frac{D}{\pi^2} - \frac{1}{\pi^2}\sum_{k=1}^{\infty} \xi^{2k}\sigma_N^{\infty}(2k+2) - \frac{1}{\pi^2}\sum_{n=1}^{N} r_2(n)\left[\frac{1}{n-\xi^2} - \frac{1}{n}\right], \tag{60}$$

where the symbol $\sigma_N^{\infty}(2k+2)$ denotes the lattice sum obtained by including only n values in excess of N:

$$\sigma_N^{\infty}(2k+2) = \sum_{n=N+1}^{\infty} \frac{r_2(n)}{n^{k+1}}.$$

This procedure extends the ξ range over which the expression (56) is valid, and the expansion (60) works up until $\xi=\sqrt{N}$.

As an example of the use of (60), we show in Fig. 5 a comparison of the results for summation over k with 10 and 20 terms for $N=5$. The two curves lie on top of each other for ξ up to the last singularity taken into account at an abscissa of $\sqrt{5}$, but then start to separate.

Note that in (60), the only transcendental quantities which require evaluation are the $\sigma_N^{\infty}(2k+2)$. N may be chosen taking into account the upper limit desired for the frequency (say), given by the limit on ξ, and then the $\sigma_N^{\infty}(2k+2)$ may be evaluated once and for all and stored, since they do not depend on ξ. This makes the numerical evaluation of $\mathcal{T}_{0,0,0}(\xi)$ from (60) particularly rapid.

The differential recurrence relations (20) and (21) apply equally to the Neumann sums

$$\mathcal{T}_{\lambda,0,\nu}(\xi) = \sum_{h\neq 0} \frac{Y_\lambda(K_h\xi)}{K_h^\nu}. \tag{61}$$

However, due to the different behaviors between J_λ and Y_λ at the origin, the integral relations (18) and (19) must be altered and become (see the Appendix)

$$\mathcal{T}_{\lambda+1,0,\nu+1}(\xi) = -\frac{\Gamma(1+\lambda)}{2^{\nu+1}\pi^{\lambda+\nu+3}\xi^{\lambda+1}}\sigma^0_{\nu+\lambda+2} + \frac{1}{\xi^{\lambda+1}}\int_0^\xi \eta^{\lambda+1}\mathcal{T}_{\lambda,0,\nu}(\eta)d\eta, \tag{62}$$

and

$$\mathcal{T}_{\lambda-1,0,\nu+1}(\xi) = \frac{\Gamma(1-\lambda)\cos(\lambda\pi)}{2^{\nu+1}\pi^{\nu-\lambda+3}\xi^{-\lambda+1}}\sigma^0_{\nu-\lambda+2} - \frac{1}{\xi^{-\lambda+1}}\int_0^\xi \eta^{-\lambda+1}\mathcal{T}_{\lambda,0,\nu}(\eta)d\eta, \quad \text{for } \mathrm{Re}(\lambda) < 1. \tag{63}$$

The recurrence relation which increments the first subscript alone follows from (62) and the recurrence relations satisfied by Bessel functions

$$\frac{2(\lambda+1)}{z}Y_{\lambda+1}(z) = Y_\lambda(z) + Y_{\lambda+2}(z),$$

and has the form

$$\mathcal{T}_{\lambda+2,0,\nu}(\xi) = -\frac{\Gamma(2+\lambda)}{2^{\nu}\pi^{\nu+\lambda+3}\xi^{\lambda+2}}\sigma^0_{\nu+\lambda+2} + \frac{2(\lambda+1)}{\xi^{\lambda+2}}\int_0^\xi \eta^{\lambda+1}\mathcal{T}_{\lambda,0,\nu}(\eta)d\eta - \mathcal{T}_{\lambda,0,\nu}(\xi). \tag{64}$$

That which decrements the first subscript alone is

$$\mathcal{T}_{\lambda-2,0,\nu}(\xi) = -\frac{\Gamma(2-\lambda)\cos(\lambda\pi)}{2^{\nu}\pi^{\nu-\lambda+3}\xi^{-\lambda+2}}\sigma^0_{\nu-\lambda+2} - \frac{2(\lambda-1)}{\xi^{-\lambda+2}}\int_0^\xi \eta^{-\lambda+1}\mathcal{T}_{\lambda,0,\nu}(\eta)d\eta - \mathcal{T}_{\lambda,0,\nu}(\xi), \tag{65}$$

and holds for $\mathrm{Re}(\lambda) < 1$.

Note that we cannot apply (64) directly to (56), since we would encounter the divergent quantity σ^0_2. Instead, to find $\mathcal{T}_{2,0,0}(\xi)$, we use the same limiting argument as we used to derive (56). We use

$$\mathcal{S}_{2+\delta\lambda,0,0}(\xi) = \frac{1}{\pi\xi^2} + \frac{\delta\lambda}{2\pi\xi^2} + \frac{\delta\lambda}{2\pi}\sum_{k=0}^{\infty}\frac{k+1}{k+2}\xi^{2k+2}\sigma^0_{2k+4}. \tag{66}$$

The calculation for $\mathcal{S}_{-2-\delta\lambda,0,0}(\xi)$ is more involved, since in the sum over k the first two terms are best treated using the form of summand found in (15) rather than (10). The result is

$$\mathcal{S}_{-2-\delta\lambda,0,0}(\xi) = \frac{1}{\pi\xi^2} - \frac{\delta\lambda}{2\pi\xi^2} - \frac{\delta\lambda}{2\pi}\sum_{k=0}^{\infty}\frac{k+1}{k+2}\xi^{2k+2}\sigma^0_{2k+4} - \delta\lambda + \frac{\delta\lambda}{\pi^2\xi^2}[D - 2\pi\log(\pi\xi) + 2\pi(1-\gamma)]. \tag{67}$$

Combining (66) and (67), we obtain

$$\mathcal{T}_{2,0,0}(\xi) = \lim_{\delta\lambda\to 0}\frac{\mathcal{S}_{2+\delta\lambda,0,0}(\xi) - \mathcal{S}_{-2-\delta\lambda,0,0}(\xi)}{\pi\delta\lambda} = \frac{1}{\pi^2\xi^2}\left[-1 + 2\gamma - \frac{D}{\pi} + 2\log(\pi\xi)\right] + \frac{1}{\pi} + \frac{1}{\pi^2}\sum_{k=0}^{\infty}\frac{k+1}{k+2}\xi^{2k+2}\sigma^0_{2k+4}. \tag{68}$$

In the numerical example shown in Fig. 6 the mean of the results from direct summation is −0.285 082, while the result of (68) is −0.297 607.

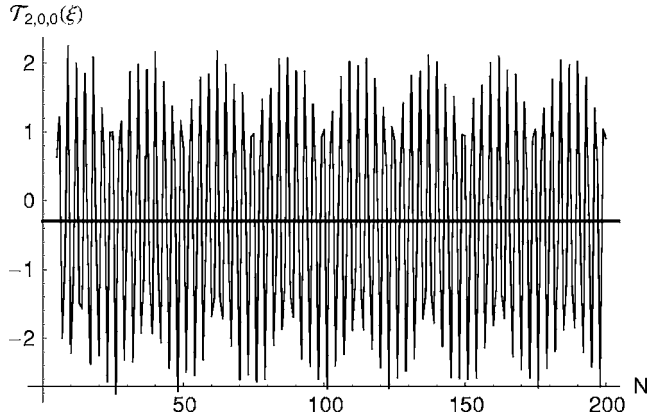

FIG. 6. Partial sums for $\mathcal{T}_{2,0,0}(\xi)$, with $\xi=0.32$, obtained by summation over a square region, centered on the origin and having side length of $2N+1$, for N up to 200. The analytical result (68) is indicated by the horizontal line.

VII. CONCLUSIONS

The results we have given here by no means exhaust those which may be derived using the basic sums (26) and (27) in the Neumann series, or the Schlömilch series (10) and (15). We have also obtained similar results for sums over positive integers rather than the square lattice, which we will submit for publication.

APPENDIX: RAISING AND LOWERING OPERATORS FOR BESSEL FUNCTIONS

The derivation of recurrence relations for the sums (1) and (61) are based on two differential and two integral relations, satisfied by the Bessel functions. The differential relations are the same for both kinds of Bessel functions,[13,14]

$$\left[\frac{1}{b}x^{\lambda+1}Z_{\lambda+1}(bx)\right]' = x^{\lambda+1}Z_{\lambda}(bx),$$

$$\left[\frac{1}{b}x^{-\lambda+1}Z_{\lambda-1}(bx)\right]' = -x^{-\lambda+1}Z_{\lambda}(bx), \tag{A1}$$

where Z represents one of the Bessel functions J or Y, and the prime denotes a differentiation with respect to x. Due to the different behaviors between J_λ and Y_λ at the origin, the corresponding integral relations are[13,14]

$$\int_0^a x^{\lambda+1}J_{\lambda}(bx)dx = a^{\lambda+1}\frac{J_{\lambda+1}(ba)}{b}, \quad \text{for } \mathrm{Re}(\lambda) > -1 \text{ and } a,b \geqslant 0,$$

$$\int_0^a x^{-\lambda+1}J_{\lambda}(bx)dx = \frac{b^{\lambda-2}}{2^{\lambda-1}\Gamma(\lambda)} - a^{-\lambda+1}\frac{J_{\lambda-1}(ba)}{b}, \quad \text{for } a,b \geqslant 0, \tag{A2}$$

for Bessel functions of the first kind, and

$$\int_0^a x^{\lambda+1} Y_\lambda(bx)dx = \frac{2^{\lambda+1}\Gamma(1+\lambda)}{\pi b^{\lambda+2}} + a^{\lambda+1}\frac{Y_{\lambda+1}(ba)}{b}, \quad \text{for } a,b \geqslant 0,$$

$$\int_0^a x^{-\lambda+1} Y_\lambda(bx)dx = \frac{b^{\lambda-2}\Gamma(1-\lambda)\cos(\lambda\pi)}{2^{\lambda-1}\pi} - a^{-\lambda+1}\frac{Y_{\lambda-1}(ba)}{b}, \quad \text{for } \mathrm{Re}(\lambda) < 1 \text{ and } a,b \geqslant 0, \tag{A3}$$

for Bessel functions of the second kind.

The relationship between the Wigner-Weyl kinetic formalism and the complex geometrical optics method

Omar Maj[a)]

(Received 4 October 2004; accepted 15 June 2005; published online 4 August 2005; publisher error corrected 19 August 2005)

The relationship between two different asymptotic techniques, namely, the Wigner-Weyl kinetic formalism and the complex geometrical optics method, is addressed within the framework of semiclassical theory of wave propagation. More specifically, in correspondence to appropriate boundary conditions, the solution of the wave kinetic equation, relevant to the Wigner-Weyl formalism, is obtained in terms of the corresponding solution of the complex geometrical optics equations. In particular, this implies that the two considered techniques yield the same wavefield intensity. Such a result is also discussed on the basis of the analytical solution of the wave kinetic equation specific to Gaussian beams of electromagnetic waves propagating in a "lens-like" medium for which the complex geometrical optics solution is already available. © *2005 American Institute of Physics.*

I. INTRODUCTION

In the framework of the semiclassical theory of waves,[1–5] i.e., short wavelength asymptotics, the uniform (global) description of the wavefield is complicated by the formation of caustic singularities.[1,2,6–8] Although a complete and deep understanding of the wavefield structure near caustic regions is obtained on the basis of catastrophe theory[2,6,8] and the unfolding of the corresponding singularities can be treated by means of symplectic techniques,[1,2,9] the application of such methods to realistic cases, e.g., to waves in magnetically confined plasmas,[10] appears rather difficult. Therefore, with specific regard to physical applications, several asymptotic methods have been developed which yield numerically tractable equations, though being limited concerning the global properties of the asymptotic solutions.

Such asymptotic techniques can be classified into two different families, depending on whether the relevant wave equation is described in the phase space, *microlocal techniques*, or directly in the configuration space where the wavefield is defined, *quasi-optical methods*.

This work aims to give a detailed comparative analysis of two such techniques, namely, the Wigner-Weyl kinetic formalism[11–13] and the complex geometrical optics (CGO) method,[14–17] which can be considered as benchmarks for microlocal and quasi-optical methods, respectively.

Specifically, in Sec. II, the Wigner-Weyl formalism and the complex geometrical optics method are reviewed and compared. In particular, it is pointed out that, within the Wigner-Weyl formalism, physically meaningful solutions should have a specific form, referred to as momentum distribution, which is characterized in Sec. III.

On the basis of the mathematical properties of momentum distributions, our main result is obtained in Sec. IV. In particular, it is shown that, in correspondence to appropriate boundary conditions, there exists a specific asymptotic solution of the wave kinetic equation relevant to the Wigner-Weyl formalism that can be written in terms of the corresponding solution of the complex geometrical optics equations. This allows us to relate the two considered methods as well as to

[a)]Electronic mail: maj@fisicavolta.unipv.it

determine the specific class of boundary conditions for which they are equivalent. In Sec. V, this general result is illustrated by means of an analytically tractable example, i.e., the propagation of a Gaussian beam of electromagnetic waves in an isotropic "lens-like" medium. In conclusion, a summary of the main results is given in Sec. VI.

II. THE WIGNER-WEYL FORMALISM VERSUS THE CGO METHOD

In order to set up the framework, let us discuss the relevant boundary value problem for a generic *scalar* pseudodifferential wave equation, together with the required mathematical definitions.

Specifically, we will consider the case of a scalar (real or complex) wavefield $\psi(x)$ propagating in the N-dimensional linear space $\mathbb{R}^N$ with $x=(x^1,\ldots,x^N)$ a generic set of Cartesian coordinates and denote by $k=(k_1,\ldots,k_N)$ the corresponding coordinates in the dual space $(\mathbb{R}^N)' \cong \mathbb{R}^N$. Time-dependent wavefields are included as one of the coordinates can play the role of time, e.g., $x^N=ct$, c being a reference speed, and the corresponding dual coordinate is related to frequency, e.g., $k_N=-\omega/c$. To some extent, the results for a scalar wave equation are valid also for a multicomponent wave equation as the latter can be reduced to a set of *independent* scalar equations far from mode conversion regions.[5]

Thereafter, the Wigner-Weyl formalism will be formulated entirely in the space $\mathbb{R}^N \times (\mathbb{R}^N)' \cong \mathbb{R}^{2N}$, with coordinates (x,k), which is viewed as the trivial cotangent bundle[21] over the configuration space $\mathbb{R}^N$ where the wavefield is defined. No explicit reference to the propagation direction is made, differently from the classical derivations.[13] As for the CGO method, it has been originally developed for solving the second-order partial differential equation relevant to the propagation of electromagnetic wave beams in stationary spatially nondispersive media. Hence, we will need to discuss its application to generic pseudodifferential equations. In particular, it is shown that the CGO method yields an approximation of the wavefield directly in the configuration space, provided that the wave equation satisfies an appropriate condition.

First, let us define the class of wave equations undergone to solution. A pseudodifferential wave equation is an equation of the form

$$(\hat{D}\psi)(x) = \frac{1}{(2\pi)^N} \int e^{ik\cdot(x-x')} d(x,x',k)\psi(x')\, d^N x'\, d^N k = 0, \tag{1}$$

which admits propagating wave solutions. The operator $\hat{D}$ is a pseudodifferential operator[3,18–20] acting on the wavefield as a Fourier integral operator[20] characterized by the bilinear phase function $k\cdot(x-x')$. Here, $d(x,x',k)$ belongs to a particular class of smooth functions, referred to as *symbols*, which, roughly speaking, behave like a polynomial in k for $|k|$ large enough. Specifically, a smooth function $a(z,k)$ with $z \in \mathbb{R}^M$ and $k \in (\mathbb{R}^N)'$ is a symbol of order $m \in \mathbb{R}$ if for every multiindices α, β there is a constant $C_{\alpha,\beta} > 0$ such that

$$|\partial_z^\alpha \partial_k^\beta a(z,k)| \leqslant \frac{C_{\alpha,\beta}}{L^{|\alpha|-|\beta|}} (1+|kL|)^{m-|\beta|}, \quad \text{uniformly in } (z,k) \in \mathbb{R}^M \times (\mathbb{R}^N)', \tag{2}$$

and one writes $a \in S^m(\mathbb{R}^M \times (\mathbb{R}^N)')$. In virtue of the symbol estimate (2) the integral in (1) makes sense for $\psi \in \mathcal{S}'(\mathbb{R}^N)$, the space of tempered distribution.[18,21] Moreover, the scale length L characterizes the variations of symbols with respect to the spatial coordinate z and it can be eliminated by the rescaling $z \to z/L$ and $k \to kL$. It is worth noting that any linear differential operator with smooth and bounded coefficients is a pseudodifferential operator.[19]

Boundary conditions of Cauchy type are given on an $(N-1)$-dimensional hypersurface Σ: for simplicity, one can assume Σ to be the hyperplane $\{x: x^N=0\}$ where the wavefield $\psi_0(\mathbf{x})$, $\mathbf{x}=(x^1,\ldots,x^{N-1})$, is assigned together with as many derivatives $\psi_n(\mathbf{x}) = \partial^n \psi / \partial (x^N)^n$ as appropriate. We are interested in semiclassical solutions for which only the covectors k with

$$\kappa = |kL| \gg 1$$

are significant, in the integral in (1). As a consequence, the wavefield should be a highly oscillating function on the (large) scale length L and it should correspond to a specific set of highly oscillating boundary conditions of the form

$$\psi_0(\mathbf{x}) = A_0(\mathbf{x}) e^{iS_0(\mathbf{x})}, \quad \partial_{\mathbf{x}} S_0(\mathbf{x}) L \sim \kappa \gg 1, \tag{3}$$

the amplitude A being slowly varying, that is, $|\partial_x A| \sim |A|/L$.

A. The Wigner-Weyl formalism

In the Wigner-Weyl formalism, the Weyl-symbol map σ^W is applied in order to represent the wave equation (1) in $\mathbb{R}^N \times (\mathbb{R}^N)'$ which is naturally endowed with a phase-space structure. The Weyl-symbol map transforms an operator $\hat{A}: \mathcal{S}(\mathbb{R}^N) \to \mathcal{S}'(\mathbb{R}^N)$, $\mathcal{S}(\mathbb{R}^N)$ being the space of Schwartz's functions,[21] into a tempered distribution by acting on the Schwartz kernel $\mathcal{A}(x_1, x_2) \in \mathcal{S}'(\mathbb{R}^{2N})$ of the operator $\hat{A}$ according to[13]

$$\mathcal{A}(x_1, x_2) \mapsto \sigma^W(\hat{A})(x,k) = \int \mathcal{A}\left(x + \frac{1}{2}s, x - \frac{1}{2}s\right) e^{-ik\cdot s} d^N s. \tag{4}$$

It is worth noting that for the pseudodifferential operator in (1) the Schwartz kernel is

$$\mathcal{D}(x_1, x_2) = \frac{1}{(2\pi)^N} \int e^{ik\cdot(x_1 - x_2)} d(x_1, x_2, k)\, d^N k,$$

thus, the image of $\hat{D}$ under the Weyl-symbol map amounts to the formal series of decreasing order symbols

$$\sigma^W(\hat{D})(x,k) = \sum_\alpha \frac{i^{|\alpha|}}{\alpha!} \partial_s^\alpha \partial_k^\alpha d \left(x + \frac{1}{2}s, x - \frac{1}{2}s, k\right)\Big|_{s=0},$$

where Taylor expansion has been used and $\partial_s^\alpha \partial_k^\alpha d \in S^{m-|\alpha|}$. Series of that kind admit always an asymptotic resummation[3,19] to a symbol of order m,

$$D(x,k) \sim \sigma^W(\hat{D})(x,k) \in S^m, \tag{5}$$

which is referred to as *Weyl symbol* of $\hat{D}$. In (5) the $\sim$ denotes the asymptotic equivalence of symbols.[3,19] On the other hand, one can consider the correlation operator[13] $\hat{S}$ whose Schwartz kernel is given by the tensor product $\psi(x_1)\psi^*(x_2)$. Then the Weyl-symbol map yields the *Wigner function*

$$W(x,k) = \sigma^W(\hat{S})(x,k) = \int \psi\left(x + \frac{1}{2}s\right) \psi^*\left(x - \frac{1}{2}s\right) e^{-ik\cdot s}\, d^N s. \tag{6}$$

The wave equation (1) can be written in the equivalent form $\hat{D}\hat{S}=0$ and, on applying the Weyl-symbol map, one gets[3,13]

$$\sigma^W(\hat{D}\hat{S})(x,k) \sim \sum_{\alpha,\beta} \frac{(-1)^{|\alpha|}}{(2i)^{|\alpha+\beta|}\alpha!\beta!} (\partial_x^\alpha \partial_k^\beta D(x,k))(\partial_x^\beta \partial_k^\alpha W(x,k)) = 0. \tag{7}$$

In the semiclassical limit one has $\partial_x^\alpha \partial_k^\beta D = O(\kappa^{m-|\beta|})$ so that, on assuming the same ordering for the Wigner function,[13] the foregoing equation separates into

$$D'(x,k) W(x,k) = 0, \tag{8a}$$

$$\{W(x,k),D'(x,k)\} = 2D''(x,k)W(x,k), \tag{8b}$$

where $D' \in S^m$ and $D'' \in S^{m-1}$ are the real and imaginary parts of the Weyl symbol; in particular, one has $D''/D' = O(\kappa^{-1})$ which is the condition for weak absorption and/or instabilities.[13] Equation (8a) is a constraint to Eq. (8b) which, on the other hand, has the form of a kinetic equation in the x-k phase space, $\{\cdot,\cdot\}$ being the corresponding Poisson brackets. We will refer to the whole system (8) as the *wave kinetic equation*.

In general, a solution of the wave kinetic equation is a tempered distribution, however, one usually restricts the class of solutions to semiclassical measures. This allows us to make sense of the integrals of the form[3,13]

$$\langle \hat{A} \rangle_\psi = \frac{1}{(2\pi)^N} \int A(x,k)W(x,k)\, d^N x\, d^N k,$$

which expresses the expectation value of a physical quantity represented by the pseudodifferential operator $\hat{A}$ with Weyl symbol $A(x,k)$. In the following we will assume further regularity with respect to x so that the expectation values of physical quantities can be defined *locally*, that is,

$$A(x) = \int \frac{d^N k}{(2\pi)^N} A(x,k)W(x,k) \tag{9a}$$

makes sense as a smooth function in $x \in \mathbb{R}^N$. In particular, the wavefield intensity amounts to

$$|\psi(x)|^2 = \int \frac{d^N k}{(2\pi)^N} W(x,k). \tag{9b}$$

Such a restriction of the class of solutions is justified as, in general wave propagation problems, one needs a description of the space and time profiles of physical quantities.

Let us now discuss the appropriate boundary conditions for (8). On the hyperplane $\Sigma = \{x : x^N = 0\}$ the wavefield $\psi_0(\mathbf{x})$ has been assigned and one can compute the corresponding Wigner function $W_0(\mathbf{x},\mathbf{k}) = \sigma^W(\hat{S}_0)(\mathbf{x},\mathbf{k})$, $\hat{S}_0$ being the correlation operator associated to ψ_0 and $\mathbf{k} = (k_1, \ldots, k_{N-1})$ the coordinates dual to $\mathbf{x}$; then a solution $W(x,k)$ should match $W_0(\mathbf{x},\mathbf{k})$ in some appropriate sense. Specifically, one should impose that the local value $A(x)$ of any physical quantity evaluated on Σ is the same whether it is evaluated by $W(x,k)$ or by $W_0(\mathbf{x},\mathbf{k})$. Within this formulation, the Weyl symbol $A(x,k)$ should be restricted to $\mathbb{R}^{2N-2}$ where W_0 is defined. One can note that the suitable embeddings Γ of $\mathbb{R}^{2N-2}$ into $\mathbb{R}^{2N}$ such that Γ lies over Σ, i.e., $\pi\Gamma = \Sigma$ with $\pi : (x,k) \mapsto x$ the canonical projection,[21] are of the form $\Gamma = \{(x,k) : x^N = 0, k_N = H(\mathbf{x},\mathbf{k})\}$ with $H(\mathbf{x},\mathbf{k})$ a generic smooth function; correspondingly, the restriction of a symbol is readily defined as $A|_\Gamma(\mathbf{x},\mathbf{k}) = A(\mathbf{x},0,\mathbf{k},H(\mathbf{x},\mathbf{k}))$. Then the boundary value conditions read

$$\int \frac{d^N k}{(2\pi)^N} W(x,k)A(x,k)\bigg|_\Sigma = \int \frac{d^{N-1}\mathbf{k}}{(2\pi)^{N-1}} W_0(\mathbf{x},\mathbf{k})A|_\Gamma(\mathbf{x},\mathbf{k}), \tag{10a}$$

which is equivalent to

$$W|_\Sigma(\mathbf{x},\mathbf{k},k_N) = 2\pi W_0(\mathbf{x},\mathbf{k})\,\delta(k_N - H(\mathbf{x},\mathbf{k})). \tag{10b}$$

The function H cannot be arbitrary as (10b) should satisfy the constraint (8a) which reads

$$D'(\mathbf{x},0,\mathbf{k},H(\mathbf{x},\mathbf{k})) = 0, \tag{11}$$

hence, the appropriate functions H are obtained on solving the so-called *local dispersion relation* evaluated on Σ. Since Σ has been assumed to be noncharacteristic, i.e., $\partial D'/\partial k_N \neq 0$ on Γ, the function H is well defined and smooth at least locally, in view of the implicit function theorem. On the other hand, it is not unique since (11) may have multiple solutions, each one corresponding to a specific branch of the dispersion relation. In virtue of the superposition principle for linear wave

equations, the total wavefield is a linear superposition of the contributions from each branch of the dispersion relation, the coefficients being determined by the Cauchy boundary values of the normal derivatives $\partial^n\psi/\partial(x^N)^n|_\Sigma$. Therefore, one has a specific Cauchy boundary value problem for the Wigner function of each branch and the sum over all branches yields the total Wigner function. Since one has

$$|\psi|^2 = \sum_{b,b'} \psi_{b'}^* \psi_b = \sum_b |\psi_b|^2 + \sum_{b\neq b'} \psi_{b'}^* \psi_b,$$

where the indices b and b' run over all branches, and, on noting that the average $\langle\cdot\rangle$ over short-scale oscillations cancels out the mixed terms, $\langle\psi_{b'}^*\psi_b\rangle=0$ for $b'\neq b$, whereas $\langle|\psi_b|^2\rangle=|\psi_b|^2$, one gets

$$\langle|\psi(x)|^2\rangle = \sum_b \int \frac{d^N k}{(2\pi)^N} W_b(x,k) = \int \frac{d^N k}{(2\pi)^N} W(x,k), \tag{12}$$

that is, the projection of the total Wigner function yields the *averaged wavefield intensity* and, thus, it does not account for, e.g., the formation of short-scale diffraction patterns.

B. The complex geometrical optics method

Let us now turn to the complex geometrical optics (CGO) method and, in particular, let us discuss its application to pseudodifferential wave equations. This is based on approximating the solution of (1) by a smooth wave function of the form

$$\psi(x) = u(x)e^{i\bar{S}(x)} = u(x)e^{-\phi(x)}e^{iS(x)}, \tag{13}$$

where, according to the semiclassical limit, $|\partial_x S(x)L|\sim\kappa$ and $\partial_x u(x)|\sim|u(x)|/L$. In addition to the standard oscillating exponential $e^{iS(x)}$, the wave object (13) exhibits a novel scale length $w\sim|\partial_x\phi(x)|^{-1}$ which accounts for intermediate-scales variations of the amplitude profile $A(x)=u(x)e^{-\phi(x)}$ with $\kappa\gg|kw|\gg 1$. In general, such an intermediate scale length w can be determined by both (strong) absorption[16] and diffraction;[17] however, in this paper, it is assumed that the medium is weakly nondissipative [cf. comments after Eqs. (8)] so that only diffraction effects are significant. The total short- and intermediate-scale variations of the wavefield are accounted for by the *complex eikonal function* $\bar{S}(x)=S(x)+i\phi(x)$.

The relevant equations for the three unknown functions u, ϕ, and S are determined on substituting the ansatz (13) into the wave equation (1). For the specific case for which $\hat{D}$ is a differential operator this is straightforward. On the other hand, for the general case, one should deal with the nonlocal response of the operator.[22] With this aim it is convenient writing (1) in the configuration space in terms of the Schwartz kernel, namely,

$$\int \mathcal{D}(x,x')\psi(x')d^N x' \sim \int \mathcal{D}^{(s)}\left(\frac{x+x'}{2}, x-x'\right)\psi(x')\,d^N x' = 0,$$

where the exact kernel has been replaced by the $\mathcal{D}^{(s)}=\sigma^{W-1}(D)$ where D is the Weyl symbol. Actually, one could make use of other symbol maps,[3] yielding asymptotically equivalent results; here the Weyl-symbol maps has been chosen for direct comparison with the Wigner-Weyl approach.

Let us further assume that the kernel $\mathcal{D}^{(s)}(x_1,x_2)$ amounts to a distribution smoothly dependent on x_1 and with compact support in x_2. In virtue of the Paley-Wiener-Schwartz theorem,[21] this is equivalent to assume that the corresponding Weyl symbol $D(x,k)$ extends to an *entire* function of the complex-valued dual vector $\bar{k}=k+ik''$, smoothly dependent on $x\in\mathbb{R}^N$. From a physical standpoint, the foregoing assumption implies that nonlocal effects have a finite range: the response $(\hat{D}\psi)(x)$ of the operator $\hat{D}$ depends only on the value of the wavefield ψ in a compact set.

Within this condition, one can substitute the complex eikonal ansatz (13) into (1) and expand in Taylor series with respect to $s=x-x'$. As a result one has[22]

$$D(x,\bar{k}(x))u(x) - i\frac{\partial D(x,\bar{k}(x))}{\partial k_i}\frac{\partial u(x)}{\partial x^i} - \frac{i}{2}\frac{\partial^2 D(x,\bar{k}(x))}{\partial x^i \partial k_i}u(x) - \frac{i}{2}\frac{\partial^2 \bar{S}(x)}{\partial x^i \partial x^j}\frac{\partial^2 D(x,\bar{k}(x))}{\partial k_i \partial k_j}u(x) = O(\kappa^{-2}),$$

where $\bar{k}(x)=\partial_x S(x)+i\partial_x \phi(x)$ and, for the Paley-Wiener-Schwartz theorem, the estimate $|\partial_x^\alpha \partial_k^\beta D| = O(\kappa^{m-|\beta|})$ is still valid for complex-extended symbols. To leading orders in κ, and for a weakly dissipative media, i.e., $D''/D' = O(\kappa^{-1})$, one gets

$$D'(x,\partial_x \bar{S}(x)) = 0, \tag{14a}$$

$$\frac{\partial D'(x,\partial_x \bar{S}(x))}{\partial k_i}\frac{\partial u(x)}{\partial x^i} = \left[D''(x,\partial_x \bar{S}(x)) - \frac{1}{2}\frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,\partial_x \bar{S}(x))}{\partial k_i} \right] \right] u(x), \tag{14b}$$

$D'(x,\bar{k})$ and $D''(x,\bar{k})$ being the real and imaginary parts of D extended in the complex $\bar{k}$ space and, in general, are complex valued. It is worth noting that the foregoing equations can be formally obtained from the standard geometrical optics equations, e.g., in the form given by Littlejohn and Flynn,[5] by replacing $k(x)$ with $\bar{k}(x)$.

The CGO equations (14) have been dealt with both by means of the characteristics method in the complex domain[15] and on expanding the equations with respect to $\epsilon \equiv |k''(x)|/|k(x)| \sim |k(x)w|^{-1} \ll 1$.[17] In particular, on referring to the latter approach, in the weak-diffraction regime $\epsilon \sim \kappa^{-1/2}$, terms up to order $\epsilon^2 \sim \kappa^{-1}$ should be considered in the CGO equation for the complex eikonal $\bar{S}(x)$, which, after separating the real and imaginary parts, amounts to

$$D'(x,k(x)) - \frac{1}{2}k_i''(x)k_j''(x)\frac{\partial^2 D'(x,k(x))}{\partial k_i \partial k_j} = 0, \tag{15a}$$

$$k_i''(x)\frac{\partial D'(x,k(x))}{\partial k_i} = 0. \tag{15b}$$

Equations (15a) and (15b) constitute a set of coupled first-order partial differential equations for $S(x)$ and $\phi(x)$ with $k(x)=\partial_x S(x)$ and $k''(x)=\partial_x \phi(x)$. As for the complex amplitude $u(x)$, only the lowest order approximation with respect to ϵ is significant, so that the real amplitude $|u(x)|$ is decoupled from the phase $\arg[u(x)]$ (not considered hereafter) and determined by means of the transport equation

$$\frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,k(x))}{\partial k_i}|u(x)|^2 \right] = 2D''(x,k(x))|u(x)|^2. \tag{15c}$$

This is formally the same equation as the geometrical optics transport equation,[5] but diffraction effects are accounted for through the wavevector-field $k(x)$ which differs from that obtained in the geometrical optics. The approximated form (15) of the CGO equations is the one used in physical applications. Moreover, in the zero-diffraction regime ($w \gtrsim L$), one has $\epsilon \sim \kappa^{-1}$, thus terms up to first order only should be considered, with the result that equations (15a) and (15b) are decoupled and the whole set of CGO equations (15) reduces to the standard geometrical optics equations, ϕ being effectively zero.

Equations (15a) and (15b) are usually solved by computing the characteristic curves[18,21] of (15a) with (15b) regarded as a constraint with the result that the characteristics curves thus obtained resemble the geometrical optics rays.[4,5] Therefore, the appropriate boundary conditions should be enough to determine the initial values of the complex vector $\bar{k}|_\Sigma(\mathbf{x})$ evaluated on the boundary surface Σ.

Such conditions are obtained from the Cauchy data (3) on writing

$$\psi_0(\mathbf{x}) = A_0(\mathbf{x})e^{iS_0(\mathbf{x})} = u_0(\mathbf{x})e^{-\phi_0(\mathbf{x})}e^{iS_0(\mathbf{x})} + O(\epsilon), \tag{16}$$

for some functions u_0 and ϕ_0 such that $|\partial_{\mathbf{x}}u_0| \sim |u_0|/L$ and $|\partial_{\mathbf{x}}\phi_0| \sim \phi_0/w$. From (16) one readily gets the value of the component of the complex vector $\bar{k}=k+ik''$ tangent to Σ, namely, $\mathbf{k}(\mathbf{x}) = \partial_{\mathbf{x}}S_0(\mathbf{x})$ and $\mathbf{k}''(\mathbf{x})=\partial_{\mathbf{x}}\phi_0(\mathbf{x})$. The remaining normal component is obtained on imposing that the CGO equations (15) are satisfied on Σ; this yields two equations for k_N and k_N'', viz.,

$$D'(\mathbf{x},0,\mathbf{k}(\mathbf{x}),k_N) - \frac{1}{2}\sum_{i,j<N} A_{ij}(\mathbf{x},0,\mathbf{k}(\mathbf{x}),k_N)k_i''(\mathbf{x})k_j''(\mathbf{x}) = 0, \tag{17a}$$

$$k_N''(\mathbf{x}) = -\sum_{i<N} k_i''(\mathbf{x})X_i(\mathbf{x},0,\mathbf{k}(\mathbf{x}),k_N), \tag{17b}$$

where $A_{ij}(x,k) \in S^{m-2}$ and $X_i(x,k) \in S^0$ are obtained in terms of the first- and second-order k derivatives of D' and evaluated at $x^N=0$. Equation (17a) is an $O(\epsilon^2)$ perturbation of the local dispersion relation (11), hence, it can be solved by

$$k_N(\mathbf{x}) = H(\mathbf{x},\mathbf{k}(\mathbf{x})) + O(\epsilon^2), \tag{18}$$

and, in correspondence of (18), Eq. (17b) yields $k_N''(\mathbf{x})$. As in the Wigner-Weyl formalism, if multiple solutions are found, one should write the wavefield as a sum of contributions from each branch of the local dispersion relation.

From the foregoing discussion, one should note that the CGO method yields the solution directly in the configuration space, but one should deal with the set of partial differential equations (15), the numerical solution of which can be rather cumbersome. Although the characteristics technique can be used for Eq. (15a), the constraint (15b) should be solved in parallel, thus increasing the computational complexity of the problem. As for the global properties of the CGO solution, to our knowledge no general result is still available, though numerical solutions[17] show that the CGO solution is regular even near focal points where the standard geometrical optics solution exhibits a caustic singularity.

In contrast, the Wigner-Weyl formalism appears better suited for numerical solutions. In particular, the wave kinetic equation can be solved along the corresponding Hamiltonian orbits in the phase space so that it is reduced to a set of ordinary differential equations that require limited computational efforts and the solution thus obtained has a global validity in the phase space since the Hamiltonian orbits do not cross each other. In this respect, the constraint (8a) does not constitute a limitation as D' is a constant of motion. Moreover, there is no limitation on the nonlocal response of pseudodifferential operators to which the Wigner-Weyl formalism applies. On the other hand, the solution in the phase space should be projected into the configuration space and, thus, an integral with respect to the momentum k should be carried out numerically.

Notwithstanding these differences, the Wigner-Weyl kinetic formalism and the complex geometrical optics method share a number of features, e.g., the solution of the local dispersion relation (18) relevant to the CGO method is obtained, to the lowest significant order in ϵ, on evaluating the corresponding solution (11) for $\mathbf{k}=\mathbf{k}(\mathbf{x})$. In the following sections, it will be proved that one can project the wave kinetic equation from the phase space into the configuration space in such a way that the CGO equations (15) are recovered.

III. A NOVEL CLASS OF SOLUTIONS TO THE WAVE KINETIC EQUATION

As discussed in Sec. II, the solutions of the wave kinetic equation are usually sought in the space $\mathcal{S}'(\mathbb{R}^N)$ of tempered distributions,[24] or in the space of semiclassical measures.[3] The first formulation is the more general, whereas the second follows from the physical requirement that expectation values (9a) are well defined. Moreover, we have pointed out that, for general wave propagation problems, physics requires a stronger condition on the Wigner function, namely, the

expectation values of physical quantities should be locally defined according to (9b). For instance, if one deals with a time-dependent wavefield for which $x^N=ct$ and $k_N=-\omega/c$, the integral

$$J(\mathbf{x},t)=\int \frac{d^{N-1}\mathbf{k}}{(2\pi)^{N-1}}\int \frac{d\omega}{2\pi}\frac{\partial D'}{\partial \omega}W$$

yields the wave action density $J(\mathbf{x},t)$ in the space-time.[13]

In this section, a mathematical characterization of such novel solutions is given and the corresponding differential calculus is put forward.

First, let us note that for any Schwartz function $\varphi(k)\in\mathcal{S}(\mathbb{R}^N)$ and for any tempered distribution $f\in\mathcal{S}'(\mathbb{R}^{2N})$ one can define a tempered distribution $f_\varphi\in\mathcal{S}'(\mathbb{R}^N)$ over the configuration space only, given by

$$\langle f_\varphi,\chi\rangle=\langle f,\chi\varphi\rangle=\int f(x,k)\chi(x)\varphi(k)\,d^Nx\,d^Nk,\quad \chi\in\mathcal{S}(\mathbb{R}^N),\tag{19}$$

where, in general, angle brackets and the integral are alternative ways to denote the action of a distribution on the corresponding test function. The distribution f is smooth with respect to $x\in\mathbb{R}^N$ if and only if f_φ amounts to a smooth function $f_\varphi(x)$. In this case the map $\varphi\mapsto f_\varphi(x)$ for $\varphi\in\mathcal{S}(\mathbb{R}^N)$ defines at every point location $x\in\mathbb{R}^N$ a tempered distribution $f_x\in\mathcal{S}'(\mathbb{R}^N)$ with

$$\langle f_x,\varphi\rangle=f_\varphi(x)\quad \text{for } \varphi\in\mathcal{S}(\mathbb{R}^N).\tag{20}$$

This is a consequence of the completeness of $\mathcal{S}'(\mathbb{R}^N)$ along with the identity $f_\varphi(x)=\lim_{\delta\to 0}\langle f,\chi_\delta(\cdot-x)\varphi\rangle$ where χ_δ is a compact-supported function that approximates the Dirac's δ function for $\delta\to 0$.

Let us now consider a symbol $A\in S^{-\infty}=\cap_m S^m$, that is, A fulfills the symbol estimate (2) for every order m. It follows that $A_x=A(x,\cdot)\in\mathcal{S}(\mathbb{R}^N)$ and for any $f\in\mathcal{S}'(\mathbb{R}^{2N})$ which is smooth with respect to x one can define

$$\int f(x,k)A(x,k)\,d^Nk=\langle f_x,A_x\rangle,\tag{21}$$

and this is a smooth function on $\mathbb{R}^N$ as required in (9b). The definition (21) should be extended for any symbol $A\in S^m$ with arbitrary order. With this aim, the class of physically admissible solutions [in the sense of (9b)] is restricted. In particular, it is appropriate considering the tempered distributions $f\in\mathcal{S}'(\mathbb{R}^{2N})$ that satisfy the following conditions:

(1) f is smooth with respect to x and
(2) the restriction f_x amounts to a distribution with compact support, i.e., $f_x\in\mathcal{E}'(\mathbb{R}^N)$, where $\mathcal{E}'(\mathbb{R}^N)$ is continuously embedded in $\mathcal{S}'(\mathbb{R}^N)$ in the weak topology.

Such a distribution f will be called *momentum distribution* since for every x its restriction f_x represents the distribution of momentum k over x. For short let us write $f\in\mathcal{M}$ for the space of momentum distributions.

Within this formulation for every $f\in\mathcal{M}$ and for every $A\in S^m$ Eq. (21) is well posed and defines a smooth function on $\mathbb{R}^N$. Let us note that the foregoing definition of the space $\mathcal{M}$ is not the optimal one as functions rapidly decreasing in k are also admissible momentum distributions. However, in the semiclassical limit these functions can be ignored and only compact-supported distributions are significant.

Let us now address the derivatives of a momentum distribution $f\in\mathcal{M}$. First, the derivatives with respect to the momentum k are defined throughout every order. Specifically, since

$$\langle(\partial_k^\alpha f)_\varphi,\chi\rangle=\langle\partial_k^\alpha f,\chi\varphi\rangle=(-1)^{|\alpha|}\langle f,\chi\partial_k^\alpha\phi\rangle=(-1)^{|\alpha|}\langle f_{\partial_k^\alpha\varphi},\chi\rangle,$$

$\partial_k^\alpha f$ is smooth with respect to x; moreover, for every $\varphi\in\mathcal{S}(\mathbb{R}^N)$,

$$\langle(\partial_k^\alpha f)_x,\varphi\rangle=(-1)^{|\alpha|}f_{\partial_k^\alpha\varphi}(x)=(-1)^{|\alpha|}\langle f_x,\partial_k^\alpha\varphi\rangle=\langle\partial_k^\alpha f_x,\varphi\rangle,$$

hence, $(\partial_k^\alpha f)_x$ is compactly supported, and, thus, $\partial_k^\alpha f\in\mathcal{M}$. In terms of the integral notation the latter result evaluated for symbols reads

$$\int\partial_k^\alpha f(x,k)A(x,k)\,d^Nk=(-1)^{|\alpha|}\int f(x,k)\partial_k^\alpha A(x,k)\,d^Nk, \tag{22}$$

which is the "integration-by-parts" formula. On the other hand, the derivatives with respect to x should be dealt with more carefully. For simplicity, let us consider first-order derivative $\partial f/\partial x^i$ for $f\in\mathcal{M}$. One has that

$$(\partial f/\partial x^i)_\varphi=\partial f_\varphi/\partial x^i,$$

in virtue of (19), so that $\partial f/\partial x^i$ is smooth with respect to x. Furthermore,

$$\langle(\partial f/\partial x^i)_x,\varphi\rangle=\frac{\partial}{\partial x^i}\langle f_x,\varphi\rangle,$$

hence $(\partial f/\partial x^i)_x$ is compactly supported and $\partial f/\partial x^i\in\mathcal{M}$. The explicit formula for the derivative is obtained on noting that for every symbol $A\in S^m$, $Af\in\mathcal{M}$ and

$$\langle(\partial Af/\partial x^i)_x,1\rangle=\langle(f\partial A/\partial x^i+A\partial f/\partial x^i)_x,1\rangle=\langle f_x,(\partial A/\partial x^i)_x\rangle+\langle(\partial f/\partial x^i)_x,A_x\rangle,$$

which in the integral notation takes the form

$$\int\frac{\partial f(x,k)}{\partial x^i}A(x,k)\,d^Nk=\frac{\partial}{\partial x^i}\int f(x,k)A(x,k)\,d^Nk-\int f(x,k)\frac{\partial A(x,k)}{\partial x^i}\,d^Nk. \tag{23}$$

The same result would be obtained from the definition $\lim_{\delta\to0}\langle\partial f/\partial x^i,\chi_\delta(\cdot-x)A_x\rangle$ through straightforward but longer calculations. Higher-order derivatives can be defined by recurrence, but they are not explicitly needed in the following.

Searching for solutions of the wave kinetic equations (8) in the space of momentum distributions leads to the weak formulation

$$\int D'(x,k)W(x,k)A(x,k)d^Nk=0, \tag{24a}$$

$$\frac{1}{(2\pi)^N}\int[\{W(x,k),D'(x,k)\}-2D''(x,k)W(x,k)]A(x,k)d^Nk=0, \tag{24b}$$

with $W\in\mathcal{M}$. Furthermore, we are interested in semiclassical solutions for which only large-enough momenta are significant. On recalling that $\langle W_x,1\rangle=(2\pi)^N|\psi(x)|^2$, we will search for solution of (24) in the form

$$W(x,k)=(2\pi)^Nf(x,k-\partial_xS(x))|\psi(x)|^2 \tag{25}$$

where $S(x)$ and $|\psi(x)|^2$ are smooth functions to be determined; in particular, $S(x)$ defines a Lagrangian manifold $k=\partial_xS(x)$ in the x-k phase space. Moreover, $f\in\mathcal{M}$ is normalized, i.e., $\int f\,d^Nk=\langle f_x,1\rangle=1$, and such that

$$K_\alpha(x)\equiv\int f(x,\tilde{k})\tilde{k}^\alpha\,d^N\tilde{k}=O(\tilde{w}^{-|\alpha|}), \tag{26}$$

for any multi-index α. The integrals in (26) are well posed since $\tilde{k}^\alpha=(k-\partial_xS(x))^\alpha$ are symbols of order $|\alpha|$, and the corresponding quantities $K_\alpha(x)$ express the statistical moments of the distribu-

tion f, i.e., they express how important are the *deviations* $\tilde{k}$ of the momentum from the Lagrangian manifold $k=\partial_x S(x)$. In particular, $K_0(x)=1$ in view of the normalization condition. In the semiclassical limit it is assumed that the scale length $\tilde{w}$ characterizing the range of the momentum deviations is large enough as compared to $|\partial_x S(x)|^{-1}=|k(x)|^{-1}$, namely, $|k(x)\tilde{w}| \gg 1$.

In the Appendix, it is proved that, within the weak formulation (24), the momentum distribution f, satisfying the foregoing conditions, can be represented by the asymptotic series, cf. Eq. (A4),

$$f(x,k-\partial_x S(x)) \sim \sum_{\beta} \frac{(-1)^{|\beta|}}{\beta!} K_\beta(x) \partial_k^\beta \delta(k-\partial_x S(x)), \tag{27}$$

controlled by the small parameter $\tilde{\epsilon} \equiv |k(x)\tilde{w}|^{-1} \ll 1$. It is worth noting that $f(x,k-\partial_x S(x))$ is thus represented by a distribution which is point supported on the Lagrangian manifold $k=\partial_x S(x)$ and completely determined by its statistical moments $K_\beta(x)$.

In correspondence of the asymptotic expansion (27), Eq. (24a) reduces to

$$\sum_{\alpha} \frac{1}{\alpha!} \partial_k^\alpha D'(x,\partial_x S(x)) K_{\alpha+\beta}(x) = 0, \tag{28}$$

as shown in details in the Appendix, cf., in particular, Eq. (A5). Formally, Eq. (28) constitutes an infinite set of algebraic equations for the statistical moments $K_\alpha(x)$ characterizing the momentum distribution, where each equation, labelled by β, is expressed as an asymptotic series in $\tilde{\epsilon}$; the function $S(x)$ is determined by imposing that the system (28) admits nontrivial solutions. Equations (28) are valid for a general momentum distribution f which satisfies (24a). In particular, on setting $K_\alpha(x)=0$ for $\alpha \neq 0$, Eq. (27) reduces to

$$f(x,k-\partial_x S(x)) = (2\pi)^N \delta(k-\partial_x S(x)),$$

which is the geometrical-optics-like solution obtained by Bornatici and Kravtsov[23] and by Sparber, Markowich and Mauser,[24] whereas in (28) the only nontrivial equation reduces to the geometrical optics eikonal equation[5] for $S(x)$, namely, $D'(x,\partial_x S(x))=0$.

IV. THE CGO-LIKE SOLUTION OF THE WAVE KINETIC EQUATION

On the basis of the asymptotic expansion (27) for a momentum distribution, one can prove the main result of this paper, that is, relating the wave kinetic equation to the CGO equations for suitable boundary conditions.

First let us consider the specific momentum distribution for which

$$K_\alpha(x) = \begin{cases} 0, & \text{for } |\alpha| = 2n+1 (\text{odd}), \\ (-1)^n (k''(x))^\alpha, & \text{for } |\alpha| = 2n \text{ (even)}, \end{cases} \tag{29}$$

that is, odd-order moments have been set to zero, whereas even-order moments have been related to a single vector field $k''(x)=\partial_x \phi(x)$, with ϕ an unknown smooth function. Correspondingly, the momentum distribution (27) takes the form

$$f(x,k-\partial_x S(x)) \sim \sum_{|\beta|=\text{even}} \frac{(-1)^{|\beta|/2}}{\beta!} (k''(x))^\beta \partial_k^\beta \delta(k-\partial_x S(x)) = \sum_{n=0}^{+\infty} \frac{(-1)^n}{(2n)!} \left[k_i''(x) \frac{\partial}{\partial k_i} \right]^{2n} \delta(k-\partial_x S(x)), \tag{30}$$

the second identity being obtained by means of the multinomial formula

$$\sum_{|\beta|=n} \frac{1}{\beta!} a_1^{\beta_1} \cdots a_N^{\beta_N} = \frac{1}{n!}(a_1 + \cdots + a_N)^n, \tag{31}$$

with $a_i = k_i'' \partial / \partial k_i$ (no sum over i). Let us note that the momentum distribution (30) is symmetric with respect to the Lagrangian manifold $k = \partial_x S(x)$, as even-order moments only appear; in particular, the second order moment $-k_i''(x)k_j''(x)$ for $i=j$ is negative, so that such a distribution cannot be interpreted as a probability measure.

The momentum distribution (30) should be multiplied by $|\psi(x)|^2$ to get the whole Wigner function (25). Let us consider the case for which

$$|\psi(x)|^2 = |u(x)|^2 e^{-2\phi(x)}, \tag{32}$$

$\phi(x)$ being defined in (29) and $|u(x)|^2$ is ordered according to $|\partial_x u| \sim |u|/L$ with $L \gg \tilde{w} \sim |\partial_x \phi|^{-1}$. As a consequence, $\tilde{w}$ is the shortest scale length characterizing the wavefield intensity $|\psi(x)|^2$, hence it can be identified with the scale length w defined after Eq. (13), namely, $\tilde{w} \sim w$ and $\tilde{\epsilon} \sim \epsilon$.

Then one has the following:

The Wigner function $W(x,k) = (2\pi)^N f(x, k - \partial_x S(x))|\psi(x)|^2$, *with* f *given by (30) and* $|\psi(x)|^2$ *expressed in the form (32), satisfies asymptotically the wave kinetic equation in the weak formulation (24) with an* $O(\epsilon)$ *remainder if and only if*

(i) *the smooth functions* $S(x)$ *and* $\phi(x)$ *satisfy the complex geometrical optics equations (15a) and (15b), and*

(ii) the smooth slowly varying function $|u(x)|^2$ *satisfies the transport equation (15c).*

First, let us prove the statement (*i*). In view of the ansatz (29), all the equations obtained from (28) with β such that $|\beta|$ is an even integer reduce to the same equation which reads

$$\sum_{|\alpha|=\text{even}} \frac{(-1)^{|\alpha|/2}}{\alpha!} \partial_k^\alpha D'(x,k(x))(k''(x))^\alpha = \sum_{n=0}^{+\infty} \frac{(-1)^n}{(2n)!} \left[k_i''(x) \frac{\partial}{\partial k_i} \right]^{2n} D'(x,k(x)) = 0, \tag{33a}$$

and, analogously, all the equations obtained from (28) with β such that $|\beta|$ is an odd integer reduce to

$$\sum_{|\alpha|=\text{odd}} \frac{(-1)^{(|\alpha|+1)/2}}{\alpha!} \partial_k^\alpha D'(x,k(x))(k''(x))^\alpha = \sum_{n=0}^{+\infty} \frac{(-1)^{n+1}}{(2n+1)!} \left[k_i''(x) \frac{\partial}{\partial k_i} \right]^{2n+1} D'(x,k(x)) = 0, \tag{33b}$$

where the second identity in both equations (33) follows on using the multinomial formula (31). Equations (33) constitute a set of two coupled equations for the real functions $S(x)$ and $\phi(x)$, and, to lowest significant orders in ϵ, they are the same as the CGO equations (15a) and (15b); this completes the proof of (*i*).

As for (*ii*), on account of the differential calculus for momentum distributions put forward in Sec. III, the term connected with the Poisson brackets in Eq. (24b) should be written in the form, cf. Eq. (23),

$$\int \frac{d^N k}{(2\pi)^N} \{W, D'\} A = \frac{\partial}{\partial x^i} \int \frac{d^N k}{(2\pi)^N} W \frac{\partial D'}{\partial k_i} A - \int \frac{d^N k}{(2\pi)^N} W \frac{\partial}{\partial x^i} \left(\frac{\partial D'}{\partial k_i} A \right) - \int \frac{d^N k}{(2\pi)^N} \frac{\partial W}{\partial k_i} \frac{\partial D'}{\partial x^i} A. \tag{34}$$

Using the specific momentum distribution (30) for which

$$W(x,k) = (2\pi)^N \delta(k - \partial_x S(x))|\psi(x)|^2 + O(\epsilon^2) \tag{35}$$

yields

$$\int \frac{d^N k}{(2\pi)^N}\{W,D'\}A = \frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,k(x))}{\partial k_i}|\psi(x)|^2 A(x,k(x))\right] - \left[\frac{\partial D'(x,k(x))}{\partial k_i}\frac{\partial A(x,k(x))}{\partial x^i} - \frac{\partial D'(x,k(x))}{\partial x^i}\frac{\partial A(x,k(x))}{\partial k_i}\right]|\psi(x)|^2 + O(\epsilon^2)$$
$$= \frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,k(x))}{\partial k_i}|\psi(x)|^2\right]A(x,k(x)) + O(\epsilon). \tag{36}$$

The last identity follows on noting that taking the derivative of (33a) with respect to x^j yields

$$\frac{\partial D'(x,\,k(x))}{\partial k_i}\frac{\partial k_j(x)}{\partial x^i} = \frac{\partial D'(x,\,k(x))}{\partial k_i}\frac{\partial k_i(x)}{\partial x^j} = -\frac{\partial D'(x,\,k(x))}{\partial x^j} + O(\epsilon)$$

with $k_j(x) = \partial S(x)/\partial x^j$. Equation (36) implies that

$$\{W,D'\} = (2\pi)^N \frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,k(x))}{\partial k_i}|\psi(x)|^2\right]\delta(k - \partial_x S(x)) + O(\epsilon)$$

in the weak sense. Hence, from the wave kinetic equation, to lowest order in ϵ, one gets the transport equation

$$\frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,k(x))}{\partial k_i}|\psi(x)|^2\right] = 2D''(x,k(x))|\psi(x)|^2,$$

which reduces to the CGO transport equation (15c) for $|u(x)|^2$, cf. Eq. (32), on noting that, to lowest significant order,

$$\frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,k(x))}{\partial k_i}|u(x)|^2 e^{-2\phi(x)}\right] = e^{-2\phi(x)}\frac{\partial}{\partial x^i}\left[\frac{\partial D'(x,k(x))}{\partial k_i}|u(x)|^2\right],$$

in view of Eq. (33b). This concludes the proof.

The foregoing result shows that there exists a specific form of the Wigner function for which the wave kinetic equation is reduced to the CGO equations.

In order to compare the wavefield intensities predicted by the wave kinetic description with that obtained on solving the CGO equations, one should complete the foregoing argument by discussing Cauchy boundary conditions. With reference to (10) and (11) one has the following:

Let $W(x,k)$ be the weak solution of the wave kinetic equation (8) corresponding to the Cauchy boundary conditions

$$W|_\Sigma(\mathbf{x},\mathbf{k},k_N) = (2\pi)^N \delta(\mathbf{k} - \mathbf{k}(\mathbf{x}))\,\delta(k_N - H(\mathbf{x},\mathbf{k}(\mathbf{x})))|u_0(\mathbf{x})|^2 e^{-2\phi_0(\mathbf{x})} + O(\epsilon), \tag{37}$$

for some smooth functions $S_0(\mathbf{x})$, $\phi_0(\mathbf{x}) \geqslant 0$, and $|u_0(\mathbf{x})|^2$ with $\mathbf{k}(\mathbf{x}) = \partial_{\mathbf{x}} S_0(\mathbf{x})$ satisfying the CGO ordering defined after (16), and let $S(x)$, $\phi(x)$, and $|u(x)|^2$ be solution of the CGO equations (15) with Cauchy boundary conditions given by the same function S_0, ϕ_0, and $|u_0|^2$. Then $W(x,k)$ can be approximated according to

$$W(x,k) = (2\pi)^N \delta(k - \partial_x S(x))|u(x)|^2 e^{-2\phi(x)} + O(\epsilon) \tag{38}$$

in the weak sense of Sec. III.

First, let us note that the Cauchy data (37) is a particular case of (10b) which corresponds to

$$W_0(\mathbf{x},\mathbf{k}) = (2\pi)^{N-1}\delta(\mathbf{k} - \partial_{\mathbf{x}}S_0(\mathbf{x}))|u_0(\mathbf{x})|^2 e^{-2\phi_0(\mathbf{x})} + O(\epsilon); \tag{39}$$

in particular, the Wigner function corresponding to the complex-eikonal wave object (16) can be written in the form (39).

In order to prove the foregoing statement, we will make use of the previous result of this section. Specifically, we have proved that the Wigner function

$$\tilde{W}(x,k) = (2\pi)^N f(x,k - \partial_x S(x))|u(x)|^2 e^{-2\phi(x)},$$

f being the momentum distribution (30), solves asymptotically the wave kinetic equation in the weak sense within an $O(\epsilon)$ accuracy. Moreover,

$$\tilde{W}(x,k) = (2\pi)^N \delta(k - \partial_x S(x))|u(x)|^2 e^{-2\phi(x)} + O(\epsilon^2),$$

in view of (35). As for the boundary condition (37) one gets

$$\begin{aligned}\tilde{W}|_{\Sigma}(\mathbf{x},\mathbf{k},k_N) &= (2\pi)^N \delta(\mathbf{k} - \partial_{\mathbf{x}}S(\mathbf{x},0))\,\delta(k_N - \partial_{x^N}S(\mathbf{x},0))|u(\mathbf{x},0)|^2 e^{-2\phi(\mathbf{x},0)} + O(\epsilon^2)\\ &= (2\pi)^N \delta(\mathbf{k} - \partial_{\mathbf{x}}S_0(\mathbf{x}))\,\delta(k_N - k_N(\mathbf{x}))|u_0(\mathbf{x})|^2 e^{-2\phi_0(\mathbf{x})} + O(\epsilon^2),\end{aligned}$$

where $k_N(\mathbf{x}) = \partial_{\mathbf{x}}S(\mathbf{x},0)$. According to (18), $k_N(\mathbf{x}) = H(\mathbf{x},\mathbf{k}(\mathbf{x})) + O(\epsilon^2)$, and, thus, $\delta(k_N - k_N(\mathbf{x})) = \delta(k_N - H(\mathbf{x},\mathbf{k}(\mathbf{x}))) + O(\epsilon^2)$ in the weak sense, so that $\tilde{W}(x,k)$ matches the boundary conditions (37). Since the solution of the wave kinetic equation along with the Cauchy boundary condition (37) is unique and since $\tilde{W}$ is an $O(\epsilon)$ solution, it follows that

$$W(x,k) = \tilde{W}(x,k) + O(\epsilon),$$

which concludes the proof of (38).

This implies that, whenever the solutions of both the wave kinetic equation and the CGO equations exist, thus, in particular, the Cauchy boundary conditions are of the form (39), the Wigner-Weyl formalism and the complex geometrical optics method are equivalent within an $O(\epsilon)$ accuracy. In particular, the wavefield intensity predicted by the Wigner-Weyl kinetic formalism is the same as that predicted by the CGO method, namely,

$$|\psi(x)|^2 = \int \frac{d^N k}{(2\pi)^N} W(x,k) = |u(x)|^2 e^{-2\phi(x)} + O(\epsilon), \tag{40}$$

the second identity following from (38). In the next section, an analytically tractable case is considered as an example. Specifically, the solution of the wave kinetic equation relevant to the paraxial propagation of a Gaussian wave beam in a "lens-like" medium is obtained and shown to be the same as the corresponding CGO solution.

V. THE KINETIC DESCRIPTION OF DIFFRACTION EFFECTS FOR A "LENS-LIKE" MEDIUM AND ITS ANALOGY WITH THE QUANTUM HARMONIC OSCILLATOR

Let us address the case of a monochromatic ($e^{-i\omega t}$) beam of electromagnetic waves propagating in a *lossless* "lens-like" medium[25] with *real* refractive index $n(\mathbf{r},\omega) \equiv n(x) = n_0[1 - (x/L)]^{1/2}$. It is assumed that the wavefield is localized near the axis $x=0$ of the medium, that is, $(x/L) \ll 1$; moreover, the wave electric field is written in the form $\mathbf{E}(\mathbf{r},\omega) = \hat{\mathbf{y}}E(x,z;\omega)$, i.e., it is polarized along the y axis and propagates in the x-z plane. The relevant wave equation for the wavefield real amplitude $E(x,z;\omega)$ is thus the Helmholtz equation. The corresponding Weyl symbol is real valued and given by

$$D(x,k_x,k_z) = -(k_x^2+k_z^2) + \frac{\omega^2}{c^2}n^2(x) = -(k_x^2+k_z^2) + \frac{\omega^2}{c^2}n_0^2[1-(x/L)^2], \tag{41}$$

thus, the dispersion relation $D=0$ yields two branches, to be referred to as the progressive and the regressive waves. As for the Cauchy boundary conditions, let us assume that the wavefield is purely Gaussian at $z=0$, i.e., $E(x,0;\omega)=u_0\exp[-(x-x_0)^2/w_0^2]$, w_0 being the initial width, and the propagation occurs along the z axis, so that one should solve the dispersion relation $D=0$ for k_z. On assuming that each branch of the dispersion relation carries half of the wavefield intensity, one can consider the progressive wave only which reads

$$\frac{k_z}{k_0} = \sqrt{1-\left(\frac{x}{L}\right)^2 - \left(\frac{k_x}{k_0}\right)^2} \simeq 1 - \frac{1}{2}\left(\frac{x}{L}\right)^2 - \frac{1}{2}\left(\frac{k_x}{k_0}\right)^2 \tag{42}$$

where $k_0=\omega n_0/c$ is the wavevector at $x=0$ and the paraxial approximation $(k_x/k_0)^2 \sim (x/L)^2 \sim (w/L)^2 \sim \lambda/L \ll 1$ has been exploited as relevant to the weak-diffraction regime.[25] It is convenient noting that the dispersion relation corresponding to the second form of (42) can be written as

$$\frac{1}{k_0}(k_0-k_z) - \frac{1}{2}\left(\frac{k_x}{k_0}\right)^2 - \frac{1}{2}\left(\frac{x}{L}\right)^2 = 0, \tag{43}$$

which is formally analogous to the dispersion relation relevant to a quantum harmonic oscillator[13] with unit mass and $1/k_0 \to \hbar$, $1/L \to \omega_0$, ω_0 being the characteristic frequency of the oscillator, $z \to t$, and $k_0-k_z(>0) \to \omega$. In particular, the frequency ω corresponds to the shifted wavevector k_0-k_z along the propagation direction z. The shift occurs because of the oscillations of the wavefield along the propagation direction z.

This analogy allows to make use of the well-known solution of the wave kinetic equation for the quantum harmonic oscillator[13] to describe the paraxial propagation of a Gaussian beam in the "lens-like" medium. More specifically, the solution of the wave kinetic equation for the harmonic oscillator corresponding to an initially Gaussian wave packet $\psi(x,0)=(w_0\sqrt{\pi/2})^{-1/2}\exp[-(x-x_0)^2/w_0^2]$ is[13]

$$|\psi(x,t)|^2 = \sqrt{\frac{2}{\pi w(t)^2}}\exp\left(-2\frac{(x-x_0\cos(\omega_0 t))^2}{w(t)^2}\right), \tag{44a}$$

$$w^2(t) = [\cos^2(\omega_0 t) + \varepsilon^2\sin^2(\omega_0 t)]w_0^2, \tag{44b}$$

where $w(t)$ is the width of the wave packet as a function of time and $\varepsilon=2\hbar/m\omega_0 w_0^2$, m being the mass of the oscillator and x_0 the initial displacement of the Gaussian from the center of the elastic force acting on the oscillator.

Correspondingly, the solution for the wave electric field intensity in the "lens-like" medium, with the considered launching conditions, is

$$\langle|\mathbf{E}(x,z;\omega)|^2\rangle = u_0^2\frac{w_0}{w(z)}\exp\left(-2\frac{(x-x_0\cos(z/L))^2}{w(z)^2}\right), \tag{45a}$$

$$w^2(z) = \left[\cos^2(z/L) + \left(\frac{2L}{k_0 w_0^2}\right)^2\sin^2(z/L)\right]w_0^2 = \left[1+\left(\left(\frac{L}{z_R}\right)^2-1\right)\sin^2(z/L)\right]w_0^2, \tag{45b}$$

with $z_R=k_0w_0^2/2$ the Rayleigh range in the medium. In Eq. (45b), it has been explicitly indicated that the solution obtained from the wave kinetic equation amounts to the averaged intensity $\langle|\mathbf{E}(x,z;\omega)^2\rangle$, rather than to the exact value $|\mathbf{E}(x,z;\omega)|^2$ since two branches of the dispersion relation exist, each one carrying half of the wavefield intensity, cf. comments after Eqs. (12). The intensity (45a) and the beam width (45b) are the same as the corresponding quantities obtained

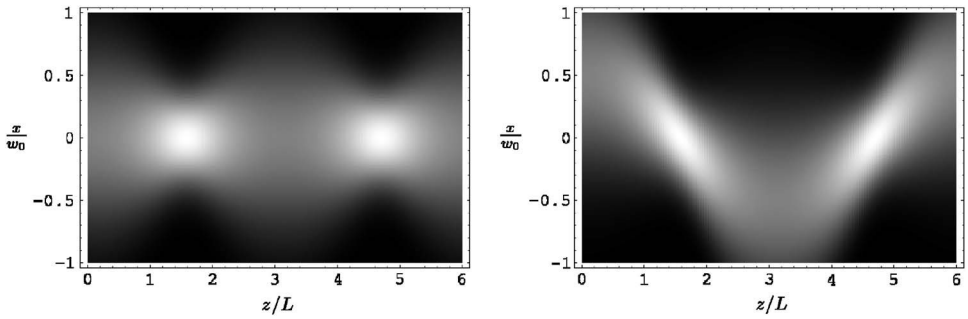

FIG. 1. The wavefield intensity (45) in the (x,z)-plane as obtained from the wave kinetic equations (8) (bright regions correspond to high intensity), for the case $L/z_R=0.5$ [cf. Eq. (45b)] with $x_0=0$ and $x_0=\frac{1}{2}w_0$, respectively. One should note that the wave beam exhibits a finite width even near focal points (characterized by bright spots) where the geometrical optics solution exhibits caustic singularities.

from the CGO solution.[25] As a consequence the intensity profile (45) accounts for diffraction effects as shown in Fig. 1.

One can conclude that, according to results of Sec. IV, the *kinetic formalism can be used to describe the effects of diffraction on the propagation of wave beams*, and, for the case under consideration, it yields the same result as the CGO method. Nevertheless, the detailed structure of the wavefield, i.e., the oscillations along the propagation direction z, the effects of the curvature of phase fronts and the Gouy shift, which are available from the CGO solution,[25] *cannot be resolved by means of the wave kinetic equation*, which instead gives the averaged intensity distribution.

VI. CONCLUSIONS

Within the framework of semiclassical wave propagation, two specific asymptotic techniques have been considered, namely, the Wigner-Weyl kinetic formalism and the complex geometrical optics (CGO) method. A detailed comparative analysis of these techniques has been given in Sec. II, for the case of scalar pseudodifferential wave equations, with Cauchy boundary conditions.

In particular, in the Wigner-Weyl formalism, the wavefield is represented in the phase space by the Wigner function which is a solution to the wave kinetic equation. In the most general case the Wigner function amounts to a tempered distribution. However, physical considerations lead to the definition of a novel class of weak solutions which have been characterized in Sec. III. Such specific weak solutions are referred to as *momentum distributions* since, for every point location x in the configuration space, they give the distribution of momentum k over x, in the x-k phase space.

On the other hand, the CGO method yields an asymptotics solution of a pseudodifferential wave equation directly in the configuration space, in terms of three smoothly varying functions representing, the phase, the wavefield envelope, and the amplitude, respectively.

In Sec. IV, on the basis of the mathematical framework developed in Sec. III, we have proved that, whenever both the solutions of the wave kinetic equation and of the CGO equations exist, thus, in particular, the Cauchy data are of the form (39), the former can be approximated by a momentum distribution, cf. Eq. (38), written in terms of the three smoothly varying functions that solve the CGO equations (15). As a consequence, the two considered techniques are asymptotically equivalent and, in particular, to lowest significant order, the wavefield intensity predicted by the Wigner-Weyl formalism is the same as that predicted by the CGO method, cf. Eq. (40).

In addition, one can conclude that the Wigner-Weyl kinetic formalism properly describes the wavefield near focal points. This is also shown by comparing the solution of the kinetic equation to that of the CGO equations for a specific case, namely, the propagation of electromagnetic Gaussian wave beams in an isotropic "lens-like" medium, cf. Sec. V. In particular, the relevant solution of the wave kinetic equation has been obtained on the basis of the analogy between the "lens-like" medium and the quantum harmonic oscillator.

APPENDIX: THE ASYMPTOTIC SERIES EXPANSION OF THE MOMENTUM DISTRIBUTION

In this appendix the asymptotic series expansion (27) of the momentum distribution is proved and the corresponding equations (28) are derived from the weak form (24a) of the dispersion relationship (8a).

Since both $D'(x,k)$ and $A(x,k)$ are symbols, they are, in particular, smooth functions, and one can apply the Taylor's formula

$$\begin{bmatrix} D' \\ A \end{bmatrix}(x,k(x)+\tilde{k}) = \sum_{|\alpha|\leqslant n-1} \frac{1}{\alpha!}\begin{bmatrix} \partial_k^\alpha D' \\ \partial_k^\alpha A \end{bmatrix}(x,k(x))\tilde{k}^\alpha + \sum_{|\alpha|=n}\begin{bmatrix} d_\alpha(x,\tilde{k}) \\ a_\alpha(x,\tilde{k}) \end{bmatrix}\tilde{k}^\alpha, \tag{A1}$$

$\alpha=(\alpha_1,\ldots,\alpha_N)$ being an N-dimensional multi-index and

$$\begin{bmatrix} d_\alpha(x,\tilde{k}) \\ a_\alpha(x,\tilde{k}) \end{bmatrix} = \frac{|\alpha|}{\alpha!}\int_0^1 dt(1-t)^{n-1}\begin{bmatrix} \partial_k^\alpha D' \\ \partial_k^\alpha A \end{bmatrix}(x,(1-t)k(x)+t\tilde{k})$$

the remainder of order n relevant to the expansions of D' and A, respectively. More specifically, on making use of (A1) to evaluate the left-hand side of (24a), one gets

$$\int f(x,\tilde{k})D'(x,k(x)+\tilde{k})A(x,k(x)+\tilde{k})d^N\tilde{k} \sim \sum_{\alpha,\beta}\frac{1}{\alpha!\beta!}\partial_k^\alpha D'(x,k(x))\partial_k^\beta A(x,k(x))K_{\alpha+\beta}(x), \tag{A2}$$

where $K_\alpha(x)=O(\tilde{w}^{-|\alpha|})$ are the statistical moments of the momentum distribution $f(x,\tilde{k})$, cf. Eq. (26). By virtue of the symbol estimate (2), symbols are such that, e.g., $|\partial_k^\alpha A(x,k)|=O(|k|^{m-|\alpha|})$ in the semiclassical limit $|k|\to+\infty$ uniformly in x, hence, the asymptotic series expansion (A2) is controlled by the (small) parameter $\tilde{\epsilon}\equiv|k(x)\tilde{w}|^{-1}$. Moreover, on noting that

$$\partial_k^\beta A(x,k(x)) = (-1)^{|\beta|}\int \partial_k^\beta\delta(k-k(x))A(x,k)d^Nk,$$

Eq. (A2) takes the form

$$\int D'(x,k)f(x,k-k(x))A(x,k)d^Nk \sim \int\left[\sum_{\alpha,\beta}\frac{(-1)^{|\beta|}}{\alpha!\beta!}\partial_k^\alpha D'(x,k(x))K_{\alpha+\beta}(x)\partial_k^\beta\delta(k-k(x))\right]A(x,k)d^Nk$$

and, in view of the arbitrariness of $A(x,k)$, one gets

$$D'(x,k)f(x,k-k(x)) \sim \sum_{\alpha,\beta}\frac{(-1)^{|\beta|}}{\alpha!\beta!}\partial_k^\alpha D'(x,k(x))K_{\alpha+\beta}(x)\partial_k^\beta\delta(k-k(x)), \tag{A3}$$

in the weak sense. It is worth noting that the derivation of (A3) does not depend on the explicit form of the symbol $D'(x,k)$, thus, on setting $D'(x,k)=1$, Eq. (A3) reduces to

$$f(x,k-k(x)) \sim \sum_{\beta} \frac{(-1)^{|\beta|}}{\beta!} K_{\beta}(x) \partial_k^{\beta} \delta(k-k(x)), \tag{A4}$$

which is just the general asymptotic expansion (27) of the momentum distribution.

Going back to Eq. (24a), its solution is obtained on setting the expansion (A3) to zero and exploiting the linear independence of the derivatives of the Dirac's δ function, thus yielding a set of equations for the statistical moments, namely,

$$\sum_{\alpha} \frac{1}{\alpha!} \partial_k^{\alpha} D'(x,k(x)) K_{\alpha+\beta}(x) = 0, \tag{A5}$$

which is just Eq. (28). It is worth noting that Eq. (A5) can be also obtained on substituting (A4) into (24a) and exploiting the Leibniz's formula

$$\partial_k^{\beta}(D'A) = \sum_{\alpha+\gamma=\beta} \frac{\beta!}{\alpha!\gamma!} \partial_k^{\alpha} D' \partial_k^{\gamma} A,$$

which expresses the derivative of a product to any orders.

(Received 14 April 2005; accepted 6 June 2005; published online 5 August 2005)

We consider the numbers arising in the problem of normal ordering of expressions in boson creation $a^\dagger$ and annihilation a operators ($[a,a^\dagger]=1$). We treat a general form of a boson string $(a^\dagger)^{r_n}a^{s_n}\ldots(a^\dagger)^{r_2}a^{s_2}(a^\dagger)^{r_1}a^{s_1}$ which is shown to be associated with generalizations of Stirling and Bell numbers. The recurrence relations and closed-form expressions (Dobiński-type formulas) are obtained for these quantities by both algebraic and combinatorial methods. By extensive use of methods of combinatorial analysis we prove the equivalence of the aforementioned problem to the enumeration of special families of graphs. This link provides a combinatorial interpretation of the numbers arising in this normal ordering problem. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1990120]

I. INTRODUCTION

In this article we consider a pair of boson creation $a^\dagger$ and annihilation a operators satisfying the commutation relation

$$[a,a^\dagger]=1. \tag{1}$$

These operators play a fundamental role in the formalism of second quantization in quantum mechanics and quantum field theory (QFT).[1–3] Because the creation and annihilation operators do not commute there are certain problems with their ordering. A very convenient and well defined form of the operators depending on a and $a^\dagger$ is the so-called normally ordered form.[4] An operator is said to be in a normally ordered form if all creation operators stand to the left of the annihilation operators. The most important application field of the normal order is the QFT.[3] For a recent study of the interplay of the QFT, normal order, and combinatorics see Ref. 5. Procedure of normal ordering of the operator, i.e., moving all the creation operators to the left with the use of relation (1), is in general a nontrivial task. A first example is ordering of the power of the number operator:[6,7]

[a)]Electronic mail: mmendez@cauchy.ivic.ve
[b)]Electronic mail: Pawel.Blasiak@ifj.edu.pl
[c)]Electronic mail: penson@lptl.jussieu.fr

$$(a^\dagger a)^n = \sum_{k=1}^{n} S(n,k)(a^\dagger)^k a^k, \tag{2}$$

where $S(n,k)$ are the Stirling numbers of the second kind[8] enumerating partitions of the set of n elements into k nonempty subsets, and satisfying the following recurrence relation: $S(n+1,k) = S(n,k-1)+kS(n,k)$ with initial values $S(n,n)=S(n,1)=1$.

As the extension of this result we have considered operators in the form $(a^\dagger)^r a^s$ (r, s positive integers, $r \geqslant s$), for which a normally ordered form is given by

$$[(a^\dagger)^r a^s]^n = (a^\dagger)^{n(r-s)} \sum_{k=s}^{ns} S_{r,s}(n,k)(a^\dagger)^k a^k, \tag{3}$$

where $S_{r,s}(n,k)$ are generalized Stirling numbers.[9–14] These kinds of formulas allow one to write the exponentials $e^{\lambda(a^\dagger)^r a^s}$ in the normally ordered form and then easily calculate the coherent state expectation values which are of importance, e.g., in quantum optics.[4] The clue to these calculations is the knowledge of the properties of the numbers $S_{r,s}(n,k)$. As they are of a combinatorial origin, the recurrence relations, Dobiński-type formulas, closed-form expresions and generating functions were extensively studied.[10] In the following we further extend these results to normal ordering of a general *boson string* in the form $(a^\dagger)^{r_n} a^{s_n} \ldots (a^\dagger)^{r_2} a^{s_2} (a^\dagger)^{r_1} a^{s_1}$, by establishing a link to special structures in enumerative combinatorics. This in turn gives us the rigorous demonstration of the properties of the generalized Stirling and Bell numbers arising in this problem. The construction of the graphs (the so called "bugs") associated with these numbers provides a graphical interpretation of the normal ordering procedure.

II. GENERALIZED BELL AND STIRLING NUMBERS

In this section we define the generalization of ordinary Bell and Stirling numbers which arise in the solution of the normal ordering problem for a boson string. Given two sequences of positive integers $\mathbf{r}=(r_1, r_2, \ldots, r_n)$ and $\mathbf{s}=(s_1, s_2, \ldots, s_n)$ we let $S_{\mathbf{r},\mathbf{s}}(k)$ be the positive integers appearing in

$$(a^\dagger)^{r_n} a^{s_n} \ldots (a^\dagger)^{r_2} a^{s_2} (a^\dagger)^{r_1} a^{s_1} = (a^\dagger)^{d_n} \sum_{k=s_1}^{s_1+s_2+\ldots+s_n} S_{\mathbf{r},\mathbf{s}}(k)(a^\dagger)^k a^k, \tag{4}$$

where $d_n = \sum_{i=1}^{n}(r_i - s_i)$, which we assume here to be nonnegative. We observe that the whole theory can be carried through for d_n negative, at the cost of minor adaptations, which however do not change the numbers involved. Note that the r.h.s. of Eq. (4) is already normally ordered.

We call $S_{\mathbf{r},\mathbf{s}}(k)$ the generalized Stirling numbers of the second kind. The generalized Bell number is defined as the sum

$$B_{\mathbf{r},\mathbf{s}} = \sum_{k=s_1}^{s_1+s_2+\ldots+s_n} S_{\mathbf{r},\mathbf{s}}(k). \tag{5}$$

In this notation the generalized Stirling numbers defined in Eq. (3) correspond to a *uniform* case

$$\mathbf{r} = \overbrace{(r, r, \ldots, r)}^{n} \text{ and } \mathbf{s} = \overbrace{(s, s, \ldots, s)}^{n}.$$

We introduce the notation $\mathbf{r} \uplus r_{n+1} = (r_1, r_2, \ldots, r_n, r_{n+1})$ and $\mathbf{s} \uplus s_{n+1} = (s_1, s_2, \ldots, s_n, s_{n+1})$ and state the recurrence relation satisfied by generalized Stirling numbers $S_{\mathbf{r},\mathbf{s}}(k)$

$$S_{\mathbf{r}\uplus r_{n+1},\mathbf{s}\uplus s_{n+1}}(k) = \sum_{j=0}^{s_{n+1}} \binom{s_{n+1}}{j} (d_n + k - j)_{s_{n+1}-j} S_{\mathbf{r},\mathbf{s}}(k-j), \tag{6}$$

where $(l)_p = l\cdot(l-1)\cdot \ldots \cdot(l-p+1)$ is the falling factorial.

One can give the derivation of Eq. (6) by induction using the following consequence of Eq. (1) (see the proof in Ref. 2):

$$a^k(a^\dagger)^l = \sum_{p=0}^{k} \binom{k}{p} (l)_p (a^\dagger)^{l-p} a^{k-p}. \tag{7}$$

The full details of this approach can be consulted in Ref. 14.

Observe that the problem stated previously can also be formulated in terms of the multiplication X and derivative D operators as they satisfy $[D,X]=1$. The representation of boson commutation relation with the D and X operators resembles the Bargmann representation,[4] used in connection with coherent states. (Here we do not enter into that framework, with all the intricacies of the scalar product, hermiticity, etc., as in our context only the algebraic properties matter.) Then Eq. (4) can be rewritten as

$$X^{r_n} D^{s_n} \ldots X^{r_2} D^{s_2} X^{r_1} D^{s_1} = X^{d_n} \sum_{k=s_1}^{s_1+s_2+\ldots+s_n} S_{\mathbf{r},\mathbf{s}}(k) X^k D^k. \tag{8}$$

Acting with both sides of Eq. (8) on the exponential function e^x we get the identity

$$X^{r_n} D^{s_n} \ldots X^{r_2} D^{s_2} X^{r_1} D^{s_1} e^x = x^{d_n} e^x B_{\mathbf{r},\mathbf{s}}(x), \tag{9}$$

where

$$B_{\mathbf{r},\mathbf{s}}(x) = \sum_{k=s_1}^{s_1+s_2+\ldots+s_n} S_{\mathbf{r},\mathbf{s}}(k) x^k \tag{10}$$

is the so-called generalized Bell polynomial. Observe that the order of the so-defined generalized Bell polynomial does not depend on $\mathbf{r}$. Equation (9) gives the formula

$$X^{d_{n+1}} e^x B_{\mathbf{r} \uplus r_{n+1}, \mathbf{s} \uplus s_{n+1}}(x) = X^{r_{n+1}} D^{s_{n+1}} e^x x^{d_n} B_{\mathbf{r},\mathbf{s}}(x). \tag{11}$$

Using the well known commutation rule (equivalent to the Leibniz rule) $D^n e^x f(x) = e^x (D+I)^n f(x)$ we get the recursive formula

$$B_{\mathbf{r} \uplus r_{n+1}, \mathbf{s} \uplus s_{n+1}}(x) = X^{s_{n+1}-d_n} (D+I)^{s_{n+1}} X^{d_n} B_{\mathbf{r},\mathbf{s}}(x). \tag{12}$$

By taking coefficients of x^k on both sides of Eq. (12) we obtain the recurrence relation for the generalized Stirling numbers of Eq. (6).

Observe that the action of the left-hand-side (l.h.s.) of Eq. (8) on e^x may be calculated explicitly. To this end one first evaluates it on the monomial x^n yielding $[\Pi_{j=1}^{n} (d_{j-1}+n)_{s_j}] x^{n+d_n}$ which in turn easily gives the result of the action on the exponential function e^x.

With this observation, together with Eq. (9) we arrive at the extended Dobiński-type relation for generalized Bell polynomials

$$B_{\mathbf{r},\mathbf{s}}(x) = e^{-x} \sum_{m=s_1}^{\infty} \left[\prod_{j=1}^{n} (m + d_{j-1})_{s_j} \right] \frac{x^m}{m!}, \tag{13}$$

which by Cauchy's multiplication of series yields the expression for $S_{\mathbf{r},\mathbf{s}}(k)$:

$$S_{\mathbf{r},\mathbf{s}}(k) = \frac{1}{k!} \sum_{m=0}^{k} \binom{k}{m} (-1)^{k-m} \cdot \prod_{j=1}^{n} (m + d_{j-1})_{s_j}. \tag{14}$$

An alternative, very similar demonstration of the previous results can be carried through with the use of coherent states. These are defined for complex z, as $|z\rangle = e^{-|z|^2/2} \Sigma_{n=0}^{\infty} (z^n / \sqrt{n!}) |n\rangle$, where

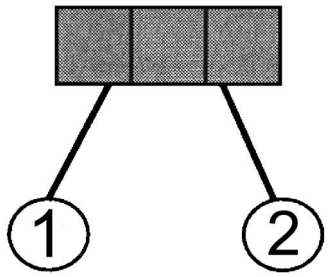

FIG. 1. A (3, 2)-bug.

$a^\dagger a|n\rangle = n|n\rangle$, $a|z\rangle = z|z\rangle$, and $\langle n|n'\rangle = \delta_{n,n'}$.[4] The $|n\rangle$'s are called the number states. The coherent state matrix element of Eq. (4) establishes a link to generalized Bell polynomials of Eq. (10):

$$\langle z|(a^\dagger)^{r_n}a^{s_n}\ldots(a^\dagger)^{r_2}a^{s_2}(a^\dagger)^{r_1}a^{s_1}|z\rangle = (z^*)^{d_n}B_{\mathbf{r},\mathbf{s}}(|z|^2), \tag{15}$$

which after some algebra, provides an equivalent derivation of Eqs. (13) and (14). The first instance where the relation between the coherent state matrix elements and the Bell polynomials appears is Ref. 7, again for the generic case of Eq. (2), for which conventional Bell polynomials are obtained.

We shall proceed now to give a combinatorial interpretation of the previous results. The essence of subsequent paragraphs will be a graph-theoretical description of the problem. We define the structures (graphs) that are counted by the generalized Bell and Stirling numbers and then give a thorough combinatorial derivation of the recurrence relations, Dobiński-type formulas and other closed-form expressions. The Eqs. (6), (13), and (14) will emerge from purely combinatorial considerations and this will permit the bijective identification of algebraic and combinatorial structures.

III. BUGS, COLONIES, SETTLEMENTS, AND RECURRENCE RELATIONS

We introduce now a number of tools needed to describe the problem in the graph-theoretical language.

Definition 3.1: A *bug* of *type* (r,s) consists of a body and s legs. The body is formed by r linearly ordered empty cells. Each foot of the s legs is labeled with one number from an integer segment $(m,m+s] := \{m+1,m+2,\ldots,m+s\}$, see Fig. 1.

Definition 3.2: Consider a set of n bugs, the first one of type (r_1,s_1) and feet labeled with labels in $(0,s_1]$, the second of type (r_2,s_2) with labels in $(s_1,s_1+s_2]$ and so on. A *colony* is one of the possible ways of organizing the bugs using the following procedure. The first bug has to stand over the ground. Once the $(j-1)$th bug is placed, the jth is placed by putting some (or none) of its s_j feet in the ground and each one of the rest in one of the empty cells of the bodies of the preceding bugs, see Fig. 2. The pair of sequences $(\mathbf{r},\mathbf{s})$, $\mathbf{r}=(r_1,r_2,\ldots,r_n)$, $\mathbf{s}=(s_1,s_2,\ldots,s_n)$, carrying the information about the types of the bugs is called the *type* of the colony. The legs of the colony standing on the ground are called *free*.

Assume now that there is a set of m empty cells in the ground. An *m-settlement* is a colony

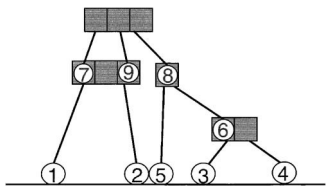

FIG. 2. A colony of type (3,2,1,3;2,2,2,3) and 5 free legs.

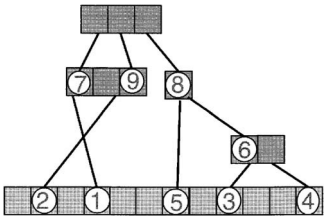

FIG. 3. A 12-settlement of the colony in Fig. 2.

where each one of the feet corresponding to the free legs is placed in one of the ground cells. A *surjective settlement* is one where all the ground cells are occupied. The type of a settlement is defined to be the type of the subjacent colony.

The main theorem of interest for us is as follows.

Theorem 3.1: *The Stirling number* $S_{\mathbf{r},\mathbf{s}}(k)$, $s_1 \leqslant k \leqslant s_1+s_2+\ldots+s_n$, *counts the number of colonies of type* $(\mathbf{r},\mathbf{s})$ *having exactly k free legs. The Bell number* $B_{\mathbf{r},\mathbf{s}}$ *counts the number of colonies of type* $(\mathbf{r},\mathbf{s})$.

Before proving it, we state the following.

Lemma 3.1: A colony of type $(\mathbf{r},\mathbf{s})$ and with k free legs has exactly d_n+k empty cells.

Proof: The total number of cells of the colony is equal to $\Sigma_{i=1}^{n} r_i$. The number of occupied cells is equal to the total number of legs minus the number of free legs $(\Sigma_{i=1}^{n} s_i - k)$. □

Now we are ready to prove the Theorem 3.1.

Proof: Denote by $C_{\mathbf{r},\mathbf{s}}(k)$ the number of colonies of type $(\mathbf{r},\mathbf{s})$ with exactly k free legs. Since $C_{(r_1;s_1)}(k)=S_{(r_1;s_1)}(k)=\delta(s_1,k)$ it is enough to prove that the numbers $C_{\mathbf{r},\mathbf{s}}(k)$ satisfy the same recursion as the generalized Stirling numbers of Eq. (6)

$$C_{\mathbf{r}\uplus r_{n+1},\mathbf{s}\uplus s_{n+1}}(k) = \sum_{j=0}^{s_{n+1}} \binom{s_{n+1}}{j} (d_n + k - j)_{s_{n+1-j}} C_{\mathbf{r},\mathbf{s}}(k-j). \tag{16}$$

The l.h.s. is the number of colonies of type $(\mathbf{r}\uplus r_{n+1},\mathbf{s}\uplus s_{n+1})$ having exactly k free legs. We claim that on the right-hand side (r.h.s.), the expression

$$\binom{s_{n+1}}{j} (d_n + k - j)_{s_{n+1-j}} C_{\mathbf{r},\mathbf{s}}(k-j)$$

gives the number of such colonies where the $(n+1)$th bug has exactly j free legs. Obviously, this would prove the identity. We now prove our claim. In order to get a colony with k free legs the $(n+1)$th bug has to be placed in a colony of type $(\mathbf{r},\mathbf{s})$ and $k-j$ free legs. $C_{\mathbf{r},\mathbf{s}}(k-j)$ is the number of such colonies. We choose the free legs of the $(n+1)$th bug in $\binom{s_{n+1}}{j}$ ways. Since by Lemma (3.1) there are d_n+k-j empty cells in the n bugs colony, $(d_n+k-j)_{s_{n+1-j}}$ gives the number of ways of distributing the rest of the feet of the $(n+1)$th bug into the empty cells. □

In the next section will follow a number of propositions clarifying the properties of structures in question.

IV. COUNTING SETTLEMENTS AND DOBIŃSKI-TYPE RELATIONS

We shall count now the number of m-settlements which will provide the link with Eqs. (13) and (14) viewed from the combinatorial perspective (see Fig. 3).

Theorem 4.1: *Let* $p(m,\mathbf{r},\mathbf{s})$ *be the number of m-settlements of type* $(\mathbf{r},\mathbf{s})$. *We have*

$$p(m,\mathbf{r},\mathbf{s}) = \prod_{j=1}^{n} (m + d_{j-1})_{s_j}. \tag{17}$$

Proof: There are $(m)_{s_1}$ ways of placing the feet of the first bug into the m ground cells. After placing the $(j-1)$th bug there are $m+d_{j-1}$ empty cells available (the previously placed bugs have provided $\Sigma_{i=1}^{j-1} r_i$ empty cells and occupied $\Sigma_{i=1}^{j-1} s_i$ cells). Then, there are $(m+d_{j-1})_{s_j}$ ways of placing the s_j feet of the jth bug. □

Corollary 4.1: We have the polynomial identity

$$\prod_{j=1}^{n} (x+d_{j-1})_{s_j} = \sum_{k=s_1}^{s_1+s_2+\ldots+s_n} S_{\mathbf{r},\mathbf{s}}(k)(x)_k. \tag{18}$$

Proof: By the previous theorem, for an integer value of x the l.h.s. counts the number of x settlements of type $(\mathbf{r},\mathbf{s})$. $S_{\mathbf{r},\mathbf{s}}(k)(x)_k$ counts the number of ways of settling a colony of type $(\mathbf{r},\mathbf{s})$ with k free legs in x ground cells. Then, the r.h.s. is another way of counting x-settlements. □
The exponential generating function of the surjective settlements is equal to the polynomials

$$B_{\mathbf{r},\mathbf{s}}(x) = \sum_{k=s_1}^{s_1+s_2+\ldots+s_n} S_{\mathbf{r},\mathbf{s}}(k) k! \frac{x^k}{k!} = \sum_{k=s_1}^{s_1+s_2+\ldots+s_n} S_{\mathbf{r},\mathbf{s}}(k) x^k.$$

Corollary 4.2 (Extended Dobiński-type relations):
We have the identity

$$B_{\mathbf{r},\mathbf{s}}(x) e^x = \sum_{m=s_1}^{\infty} \prod_{j=1}^{n} (m+d_{j-1})_{s_j} \frac{x^m}{m!}. \tag{19}$$

Proof: Taking the coefficient of $x^m/m!$ on the l.h.s. we obtain

$$\sum_{k=0}^{m} \binom{m}{k} S_{\mathbf{r},\mathbf{s}}(k) k! = \sum_{k=0}^{m} S_{\mathbf{r},\mathbf{s}}(k)(m)_k.$$

By the previous corollary it is equal to the coefficient of $x^m/m!$ on the r.h.s. □
From Eq. (19) we obtain

$$B_{\mathbf{r},\mathbf{s}}(x) = e^{-x} \sum_{m=s_1}^{\infty} \prod_{j=1}^{n} (m+d_{j-1})_{s_j} \frac{x^m}{m!} \tag{20}$$

and

$$B_{\mathbf{r},\mathbf{s}} \equiv B_{\mathbf{r},\mathbf{s}}(1) = e^{-1} \sum_{m=s_1}^{\infty} \frac{1}{m!} \prod_{j=1}^{n} (m+d_{j-1})_{s_j}. \tag{21}$$

Taking the coefficient of $x^k/k!$ on both sides of Eq. (20) we obtain the formula for the generalized Stirling numbers

$$S_{\mathbf{r},\mathbf{s}}(k) = \frac{1}{k!} \sum_{m=0}^{k} \binom{k}{m} (-1)^{k-m} \prod_{j=1}^{n} (m+d_{j-1})_{s_j}. \tag{22}$$

Evidently Eq. (20) is identical to Eq. (13) and so are Eqs. (22) and (14). This emphasizes again the already stated bijective correspondence between algebraic and combinatorial structures.

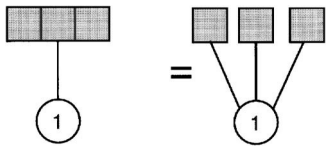

FIG. 4. A (3, 1)-bug and corresponding small planar tree.

V. UNIFORM COLONIES AND SETTLEMENTS

A colony or a settlement with all the bugs of the same type is called *uniform*. A uniform colony with n bugs of type (r,s) is called a colony of type $(r,s)^n$. Following the notation of Ref. 10 the corresponding Stirling and Bell numbers, enumerating uniform colonies of type $(r,s)^n$, are denoted respectively by $S_{r,s}(n,k)$ and $B_{r,s}(n)$. Clearly, for $\mathbf{r}=(\overbrace{r,r,\ldots,r}^{n})$ and $\mathbf{s}=(\overbrace{s,s,\ldots,s}^{k})$, $S_{r,s}(n,k)=S_{\mathbf{r},\mathbf{s}}(k)$ and $B_{r,s}(n)=B_{\mathbf{r},\mathbf{s}}$. The recursive formula, Dobiński-type relations and its consequences appearing here are natural extensions of those investigated in Ref. 10.

The case $s=1$ can be mapped into trees and forests. An $(r,1)$ bug can be identified with a planar tree, i.e., a tree where the leaves are all connected to the root and linearly ordered (see Fig. 4). An increasing tree is one where the internal vertices are labeled with labels in a totally ordered set and the labels increase on any path from the root to any internal vertex. The uniform colonies with $s=1$ corresponds to forests of increasing r-ary planar trees. The free legs are the roots of the trees (see Fig. 5). For $r=1$, there is only one 1-ary increasing tree for each n. Then $B_{1,1}(n)=B(n)$ is the ordinary Bell number.

The exponential generating function of the r-ary planar increasing trees $T_r(x)$ satisfy the differential equation (see Ref. 15, Chap. 5) $y'=(y)^r$. From this we obtain $T_r(x)=\sqrt[1-r]{1-(r-1)x}$, for $r>1$. The generalized Bell number $B_{r,1}(n)$ counts the number of r-forests with n internal vertices. By the exponential formula we obtain

$$\sum_{n=0}^{\infty} B_{r,1}(n)\frac{x^n}{n!}=\exp\{\sqrt[1-r]{1-(r-1)x}-1\}. \tag{23}$$

We quote the explicit expression:[10]

$$B_{r,1}(n)=\frac{(r-1)^{n-1}}{e}\sum_{k=1}^{\infty}\frac{\Gamma\left(n+\frac{k}{r-1}\right)}{\Gamma\left(1+\frac{k}{r-1}\right)(k-1)!}. \tag{24}$$

In a subsequent publication we shall demonstrate that the summation formulas of the type Eq. (24) can be also obtained for many other strings describing the uniform case.

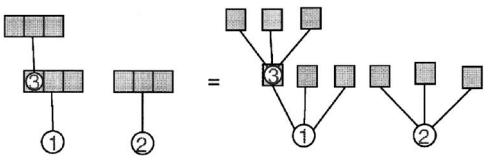

FIG. 5. A uniform colony of type $(3,1)^3$ and the corresponding forest of increasing trees.

VI. CONCLUSIONS

We have obtained analytic expressions and combinatorial interpretation of the integers generalizing conventional Bell and Stirling numbers, arising in the normal ordering of a boson string. All of their properties can be interpreted in terms of graph-theoretical language. The proof of the main result may also be obtained with the use of combinatorial theory of species.[15–17] The results constitute an application of combinatorial analysis which produces the solution of quantum mechanical problem of normal ordering. For alternative interpretations of the numbers investigated in this work see Refs. 18 and 19. It is an outstanding problem how to extend the key results of this work to the boson q-analogs. In this respect the Refs. 20–22 will be of essential help.

(Received 6 May 2005; accepted 13 June 2005; published online 8 August 2005)

We provide a simple coordinatization for the group G_2, which is analogous to the Euler coordinatization for SU(2). We show how to obtain the general element of the group in a form emphasizing the structure of the fibration of G_2 with fiber SO(4) and base $\mathcal{H}$, the variety of quaternionic subalgebras of octonions. In particular this allows us to obtain a simple expression for the Haar measure on G_2. Moreover, as a by-product it yields a concrete realization and an Einstein metric for $\mathcal{H}$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1993549]

I. INTRODUCTION

The relevance of Lie groups in physics is a well established fact: They appear both in classical and in quantum problems. In this context an important role is played by the Haar measure, needed, e.g., for the construction of a consistent path integral in lattice gauge theories.[1] The canonical 1-form θ of the compact Lie group G is the fundamental structure customarily used to find this measure. In fact the components of θ with respect to a basis of Lie(G) are everywhere linear independent, smooth, left-invariant 1-form on G.[2] So their wedge product gives us a left-invariant volume form. In order to perform explicit calculations we have to choose a suitable local chart and the related local expression for the Haar measure. The logarithmic coordinates[3] are the most obvious choice for a coordinatization of G. In this case the canonical 1-form becomes

$$\theta(X) = \int_0^1 e^{s\ \mathrm{ad}X} ds.$$

The related volume form is

$$\omega = \prod_{\lambda \in \sigma(\mathrm{ad}X)} \frac{1-e^{-\lambda}}{\lambda} d\alpha_1 \wedge \cdots \wedge d\alpha_n,$$

where $\sigma(\mathrm{ad}X)$ denotes the spectrum of ad$X$ and α_i are a basis of Lie$(G)^*$. However, these coordinates do not display generally the subgroup structure of G which usually is relevant in the physical applications. The difficulties of such a kind of coordinatization arise when one needs to explicitly determine the global range of the coordinates. A coordinatization which yields a simple form for the Haar measure and at the same time allows a simple determination of the range for the angles can become crucial for numerical computations, e.g., in lattice gauge theories or in random matrix models. For unitary groups such a coordinatization has been constructed in Ref. 4, generalizing the "Euler angle parameterization" for SU(2).

In this paper we provide an analogous simple coordinatization for the exceptional Lie group G_2. We start by showing how a simple matrix realization of the algebra can be obtained starting from the octonions. Then a proposal for a representation of the group elements, based on the previous construction and emphasizing the $SO(4)$ subgroup embedded in G_2, is given and it is proven to cover the whole group.

After computing the left-invariant currents in a way that respects the structure of the fibration, the infinitesimal invariant measure is determined with a suitable normalization. We then use topological tools and symmetry arguments to determine the correct range of the coordinates. As a by-product we obtain a coordinatization and an Einstein metric for the eight-dimensional variety of quaternionic subalgebras of octonions.

Motivations for considering models with G_2 symmetries are provided by different physical systems, for example they arise in the study of deconfinement phase transitions,[5] in random matrix models,[6] or in the new matrix models related to D-brane physics.[7]

II. THE G_2 ALGEBRA

The octonions $\mathbb{O}$ are an eight-dimensional real algebra whose generic element a is a pair of quaternions (α_1, α_2) with the following multiplication rules:

$$(\alpha_1, \alpha_2) \cdot (\beta_1, \beta_2) = (\alpha_1\beta_1 - \overline{\beta_2}\alpha_2, \beta_2\alpha_1 + \alpha_2\overline{\beta_1}). \tag{2.1}$$

Here (α_1, α_2), (β_1, β_2) are generic octonions. This algebra comes naturally equipped with an involution called conjugation

$$\overline{(\alpha_1, \alpha_2)} = (\overline{\alpha_1}, -\alpha_2).$$

Denoting by 1, i, j, k the usual basis of the quaternions yields the following canonical basis for the algebra $\mathbb{O}$

$$e_0 = (1,0), \quad e_1 = (i,0), \quad e_2 = (j,0), \quad e_3 = (k,0), \quad e_4 = (0,1), \quad e_5 = (0,i), \quad e_6 = (0,j),$$
$$e_7 = (0,k).$$

Using this basis it follows easily that the subspace $\mathbb{H}$ spanned by $\{1, e_1, e_2, e_3\}$ is in fact a quaternionic subalgebra that we call the canonical quaternionic subalgebra. Moreover we can consider $\mathbb{O}$ as a two-dimensional module over $\mathbb{H}$, i.e., every octonion z can be decomposed as $z=x+ye_4$, where x, y are suitable quaternions.

The octonions, together with $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$, are the only normed division algebras. The norm is induced by the standard Euclidean structure of the underlying real vector space. They are neither commutative nor associative, but they are alternative, i.e., any subalgebra generated by two octonions is associative. This weak form of associativity implies the Moufang identities,[8] which are multiplication laws among octonions and will prove very useful in the following:

$$(ax)(ya) = a(xy)a,$$

$$a(x(ay)) = (axa)y,$$

$$y(a(xa)) = y(axa). \tag{2.2}$$

The relevance of the octonions in mathematics is due to their deep connection with the exceptional Lie groups (Ref. 9, and references therein). We are interested in the group G_2. In this case the link is easy to understand: G_2 is the automorphism group of the octonions. For every octonion a we denote by l_a the left multiplication $l_a(x)=ax$. Under suitable hypothesis the composition of left multiplications generates elements of G_2. In fact it holds

Proposition 1: *Let* $g=l_{a_1}\ldots l_{a_n}$, *where* $a_1,\ldots,a_n$ *are unitary purely imaginary octonions. If* $g(1)=1$, *then* $g\in G_2$.

Proof: We have to show that $g(x)g(y)=g(xy)$ for all $x,y\in\mathbb{O}$. To this end we prove by induction on n that

$$g(x)g(y) = g((xb)y), \tag{2.3}$$

where $b=(\ldots(a_1a_2)\ldots)a_n$.

For the moment we avoid the hypothesis $g(1)=1$.

If $n=1$ we have

$$(ax)(ay) = -a^2((ax)(ay)) = -a((a(ax)a)y) = a((xa)y),$$

where the first equality holds because a is purely imaginary and the others by the Moufang identities.

Now we suppose the statement is true for n. So we have

$$g(ax)g(ay) = g(((ax)b)(ay)) = -g(a^2(((ax)b)(ay))) = g(a((x(ba))y)),$$

which is Eq. (2.3), if we replace g by gl_a and b by ba.

Finally, to complete the proof we have to show that $b=(\ldots(a_1a_2)\ldots)a_n=1$. So, applying the operator $l_{a_n}\ldots l_{a_1}$ to both members of the equation $1=g(1)=a_1(\ldots(a_{n-1}a_n)\ldots)$ gives us $a_n(a_{n-1}(\ldots(a_2a_1)\ldots))=(-1)^n$, and then by conjugation we obtain $(-1)^n(\ldots(a_1a_2)\ldots)a_n=(-1)^n$ which implies $b=1$. □

We can get some interesting subgroups of G_2 by imposing additional conditions on g. If we add the hypothesis $g(e_1)=e_1$ we obtain a SU(3) subgroup denoted in the following by P. Moreover, imposing also $g(e_2)=e_2$, the resulting subgroup is a copy of SU(2), which we call S.

In order to write down generalized Eulerian coordinates we need to describe the embedding of SO(4) in G_2.[10]

To this end we identify as usual SU(2) with the 3–sphere of unitary quaternions and we consider the following homomorphism:

$$\gamma:\mathrm{SU}(2)\times\mathrm{SU}(2)\to G_2,$$

$$(a,b)\mapsto\gamma_{ab}, \tag{2.4}$$

where $\gamma_{ab}(x+ye_4)=ax\overline{a}+(by\overline{a})e_4$. Using the Moufang identities it is not hard to check that γ_{ab} is truly an octonion automorphism. Fixing $a=1$ provides us with the embedding γ_{1b} of SU(2) in G_2, whose image is the subgroup S. On the other hand the image of the embedding γ_{a1} is a SU(2), which we denote by Σ and which is not conjugate to S.

The map γ is not injective and its kernel is the subgroup $\mathbb{Z}_2=\{(1,1),(-1,-1)\}$. By the homomorphism theorem the image of the map γ in G_2 is isomorphic to $(\mathrm{SU}(2)\times\mathrm{SU}(2))/\mathbb{Z}_2$, which is SO(4) as well known. In the following sections we will refer to the image of γ simply as SO(4).

The homogeneous space $\mathcal{H}=G_2/\mathrm{SO}(4)$ is the eight-dimensional variety of the quaternionic subalgebras of $\mathbb{O}$. So $\mathbb{H}$ can be thought as a point of $\mathcal{H}$. G_2 acts transitively on $\mathcal{H}$ and the stabilizer of $\mathbb{H}$ is the image of γ.[10]
Then we have the fibration

$$\begin{array}{c} \mathrm{SO}(4) \hookrightarrow G_2 \\ \downarrow \\ \mathcal{H}. \end{array}$$

The G_2 generators provided in proposition 1 are useful in particular to find a basis of the Lie algebra $\mathrm{Lie}(G_2)$. Actually, let us take an element of G_2 of the form $g_{abc}=-l_{(cb)a}l_a l_b l_c$, where $(cb)a$, a, b, c are unitary and purely imaginary (i.e., $a+\bar{a}=0$). Notice that the choice of $-(cb)a$ guarantees $g_{abc}1=1$. The condition that $(cb)a$ be purely imaginary amounts to $(cb)\perp a$.

Consider now a path $g_{a_t bc}=-l_{(cb)a_t}l_{a_t}l_b l_c$ where $a_t=c\cos(t)+a\sin(t)$ and with the additional requirements $b\perp c$, $b\perp a$, and $a\perp c$.

By definition $C_{abc}=d/dt|_{t=0}g_{abc}(t)$ is an element of $\mathrm{Lie}(G_2)$. With suitable choices of the elements a, b, and c among the elements of the canonical basis of $\mathbb{O}$ we can find a basis of this algebra. The representative matrices, written below with respect to the canonical basis, are normalized with the condition $\mathrm{Tr}(C_I C_J)=-4\delta_{IJ}$. We remark that they are seven-dimensional because of the trivial action on the real unity.

$$C_1=\begin{pmatrix} 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&-1\\ 0&0&0&0&0&-1&0\\ 0&0&0&0&1&0&0\\ 0&0&0&1&0&0&0 \end{pmatrix} \quad C_2=\begin{pmatrix} 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&1&0\\ 0&0&0&0&0&0&-1\\ 0&0&0&-1&0&0&0\\ 0&0&0&0&1&0&0 \end{pmatrix}$$

$$C_3=\begin{pmatrix} 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&-1&0&0\\ 0&0&0&1&0&0&0\\ 0&0&0&0&0&0&-1\\ 0&0&0&0&0&1&0 \end{pmatrix} \quad C_4=\begin{pmatrix} 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&1\\ 0&0&0&0&0&1&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&-1&0&0&0&0\\ 0&-1&0&0&0&0&0 \end{pmatrix}$$

$$C_5=\begin{pmatrix} 0&0&0&0&0&0&0\\ 0&0&0&0&0&-1&0\\ 0&0&0&0&0&0&1\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&1&0&0&0&0&0\\ 0&0&-1&0&0&0&0 \end{pmatrix} \quad C_6=\begin{pmatrix} 0&0&0&0&0&0&0\\ 0&0&0&0&1&0&0\\ 0&0&0&-1&0&0&0\\ 0&0&1&0&0&0&0\\ 0&-1&0&0&0&0&0\\ 0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0 \end{pmatrix}$$

$$C_7=\begin{pmatrix}0&0&0&0&0&0&0\\0&0&0&-1&0&0&0\\0&0&0&0&-1&0&0\\0&1&0&0&0&0&0\\0&0&1&0&0&0&0\\0&0&0&0&0&0&0\\0&0&0&0&0&0&0\end{pmatrix}\quad C_8=\frac{1}{\sqrt{3}}\begin{pmatrix}0&0&0&0&0&0&0\\0&0&-2&0&0&0&0\\0&2&0&0&0&0&0\\0&0&0&0&1&0&0\\0&0&0&-1&0&0&0\\0&0&0&0&0&0&-1\\0&0&0&0&0&1&0\end{pmatrix}$$

$$C_9=\frac{1}{\sqrt{3}}\begin{pmatrix}0&-2&0&0&0&0&0\\2&0&0&0&0&0&0\\0&0&0&0&0&0&0\\0&0&0&0&0&0&1\\0&0&0&0&0&-1&0\\0&0&0&0&1&0&0\\0&0&0&-1&0&0&0\end{pmatrix}\quad C_{10}=\frac{1}{\sqrt{3}}\begin{pmatrix}0&0&-2&0&0&0&0\\0&0&0&0&0&0&0\\2&0&0&0&0&0&0\\0&0&0&0&0&-1&0\\0&0&0&0&0&0&-1\\0&0&0&1&0&0&0\\0&0&0&0&1&0&0\end{pmatrix}$$

$$C_{11}=\frac{1}{\sqrt{3}}\begin{pmatrix}0&0&0&-2&0&0&0\\0&0&0&0&0&0&-1\\0&0&0&0&0&1&0\\2&0&0&0&0&0&0\\0&0&0&0&0&0&0\\0&0&-1&0&0&0&0\\0&1&0&0&0&0&0\end{pmatrix}\quad C_{12}=\frac{1}{\sqrt{3}}\begin{pmatrix}0&0&0&0&-2&0&0\\0&0&0&0&0&1&0\\0&0&0&0&0&0&1\\0&0&0&0&0&0&0\\2&0&0&0&0&0&0\\0&-1&0&0&0&0&0\\0&0&-1&0&0&0&0\end{pmatrix}$$

$$C_{13}=\frac{1}{\sqrt{3}}\begin{pmatrix}0&0&0&0&0&-2&0\\0&0&0&0&-1&0&0\\0&0&0&-1&0&0&0\\0&0&1&0&0&0&0\\0&1&0&0&0&0&0\\2&0&0&0&0&0&0\\0&0&0&0&0&0&0\end{pmatrix}\quad C_{14}=\frac{1}{\sqrt{3}}\begin{pmatrix}0&0&0&0&0&0&-2\\0&0&0&1&0&0&0\\0&0&0&0&-1&0&0\\0&-1&0&0&0&0&0\\0&0&1&0&0&0&0\\0&0&0&0&0&0&0\\2&0&0&0&0&0&0\end{pmatrix}$$

This basis satisfies the commutation rules summarized in the antisymmetric matrix $B_{IJ}=[C_I,C_J]$ given in Appendix A.

Among that matrices we can recognize the Lie algebras corresponding to the subgroups of G_2 mentioned above. The first eight matrices generate Lie(P) and they are reminiscent of the Gell–Mann matrices. Moreover, the matrices $\{C_1,C_2,C_3\}$ generate Lie(S) and finally $\{C_8,C_9,C_{10}\}$ generate Lie(Σ).

Since the elements C_5 and C_{11} commute, they generate a Cartan subalgebra of Lie(G_2) which is the Lie algebra of the maximal torus T of G_2. Notice that the commutators among the basis of Lie(S), Lie(Σ), and Lie(T) generate the whole basis of Lie(G_2). Our previous observations lead us to the conjecture that a good coordinatization for the generic element $g\in G_2$ can be defined by

$$g=\sigma(a_1,a_2,a_3)s(a_4,a_5,a_6)e^{\sqrt{3}a_7C_{11}}e^{a_8C_5}u(a_9,a_{10},a_{11};a_{12},a_{13},a_{14}),\tag{2.5}$$

where

$$s(x,y,z)=e^{xC_3}e^{yC_2}e^{zC_3},\tag{2.6}$$

$$\sigma(x',y',z') = e^{\sqrt{3}x'C_8} e^{\sqrt{3}y'C_9} e^{\sqrt{3}z'C_8}, \tag{2.7}$$

$$u(x,y,z;x',y',z') = s(x,y,z)\sigma(x',y',z') \tag{2.8}$$

are elements, respectively, of S, Σ, and SO(4).

In this paper we prove that this is in fact a good coordinatization for G_2, which could be used to determine a simple form for the Haar measure on the group. In order to achieve this we will first determine the corresponding invariant metric and then compute the range of the coordinates $a_1, a_2, \ldots, a_{14}$.

III. THE INVARIANT METRIC FOR G_2

In order to compute the invariant metric over the Lie group G_2 we will first show how our coordinatization (2.5) is related to the fibration described in the previous section.

It is well known that for a simple group, and therefore in particular for G_2, the invariant metric is uniquely defined (up to a normalization constant) by the Killing form over the algebra. More precisely, the Killing form defines a metric (and a Lebesgue measure) over the tangent space to the identity, which can be pulled back via the left (or right) multiplication. If $f_{IJ}{}^K$ are the structure constants of the algebra, then the Killing metric has components

$$K_{IJ} = (C_I, C_J) = -k f_{IL}{}^M f_{JM}{}^L, \tag{3.1}$$

where k is a normalization constant. In our case we find $K_{IJ} = 16k\delta_{IJ}$, which suggests to choose $k = 1/16$ conveniently in such a way that the generators $\{C_I\}_{I=1}^{14}$ are orthonormal: $(C_I, C_J) = \delta_{IJ}$. By right multiplication we can associate to every matrix C_I a vector field in the tangent bundle. Its dual (defined using the pullback of the Killing form) is a left-invariant 1-form and the collection of those 1-forms provides a trivialization of the cotangent bundle. In a coordinate patch $\{w^I\}$ the canonical 1-form J becomes

$$J = J^I C_I = g^{-1} \frac{\partial g}{\partial w^J} dw^J, \tag{3.2}$$

so that the invariant metric is

$$ds^2 = g_{IJ} dw^I \otimes dw^J = J^L \otimes J^M (C_L, C_M). \tag{3.3}$$

Therefore, if we define the matrix $\underline{J} = \{J^I{}_K\}$ with components $J^I = J^I{}_K dw^K$ and remember our normalization, we find for the components of the metric

$$g_{IJ} = \delta_{LM} J^L{}_I J^M{}_J. \tag{3.4}$$

This means that the right currents define a 14–bein over the Lie group G_2. In particular the invariant volume form is

$$\omega = J^1 \wedge \ldots \wedge J^{14} = \det(\underline{J}) dx^1 \wedge \ldots \wedge dx^{14} \tag{3.5}$$

and the associated Haar measure is

$$d\mu = \det(\underline{J}) \prod_{I=1}^{14} dw^I. \tag{3.6}$$

Now we use our coordinatization (2.5), which we rewrite in the form

$$g = h(a_1,a_2,a_3,a_4,a_5,a_6,a_7,a_8)u(a_9,a_{10},a_{11};a_{12},a_{13},a_{14}). \tag{3.7}$$

Note that u is the generic element of the subgroup SO(4), while h is an element of $S\Sigma T$ which is not a subgroup of G_2. We can express the currents associated to the elements u and h, respectively, as

$$J_u = duu^{-1} = \sum_{i\in A} J_u^i C_i, \quad J_h = h^{-1}dh = \sum_{i=1}^{14} J_h^i C_i, \tag{3.8}$$

where $A=\{1,2,3,8,9,10\}$. Note that for J_u we have chosen the left currents. This is because from the orthonormality condition it follows that:

$$ds^2 = \sum_{i\in A} (J_u^i + J_h^i)^2 + \sum_{i\notin A} (J_h^i)^2. \tag{3.9}$$

This particular form of the metric stresses the relation with the fibration of G_2 over the variety $\mathcal{H}$. In fact it shows explicitly the separation between the base and the fiber and if we fix the coordinates $(a_1,a_2,a_3,a_4,a_5,a_6,a_7,a_8)$, it reduces to the metric on the fiber SO(4). On the other hand the term $\Sigma_{i\notin A}(J_h^i)^2$ corresponds to the acht-bein $\tilde{J}_h$ obtained after projecting the currents J_h orthogonally to the fiber, and therefore it has to coincide with the metric on the base.

This decomposition greatly simplifies the explicit computation of the metric, the main task being the computation of J_h.

In order to determine J_u remember that $u(x,y,z;x',y',z')=s(x,y,z)\sigma(x',y',z')$ and that s and σ commute, so that in terms of $J_s=dss^{-1}$ and $J_\sigma=d\sigma\sigma^{-1}$, we get $J_u=J_s+J_\sigma$ with

$$\begin{aligned} J_S(x,y,z) &= [-\sin(2x)dy + \cos(2x)\sin(2y)dz]C_1 + [\cos(2x)dy + \sin(2x)\sin(2y)dz]C_2 \\ &\quad + [dx + \cos(2y)dz]C_3, \end{aligned}$$

$$\begin{aligned} J_\Sigma(x,y,z) &= \sqrt{3}[dx + \cos(2y)dz]C_8 + \sqrt{3}[\cos(2x)dy + \sin(2x)\sin(2y)dz]C_9 \\ &\quad + \sqrt{3}[\sin(2x)dy - \cos(2x)\sin(2y)dz]C_{10}. \end{aligned} \tag{3.10}$$

Using Mathematica we have found for the currents J_h the expressions written in Appendix B.

We are now able to compute the Haar measure in our coordinates. In fact, if $\underline{\tilde{J}_h}$ is the 8×8 matrix given by the acht-bein $\tilde{J}_h$ and $\underline{J_s}$, $\underline{J_\sigma}$ are the 3×3 matrices associated to the drei-bein J_s and J_σ, respectively, then $\det(\underline{J})=\det(\underline{\tilde{J}_h})\det(\underline{J_s})\det(\underline{J_\sigma})$ so that

$$d\mu = 27\sqrt{3}f(2a_7,2a_8)\sin(2a_2)\sin(2a_5)\sin(2a_{10})\sin(2a_{13})\prod_{i=1}^{14} da_i, \tag{3.11}$$

where

$$\begin{aligned} f(\alpha,\beta) &= \sin\left(\frac{\beta-\alpha}{2}\right)\sin\left(\frac{\beta+\alpha}{2}\right)\sin\left(\frac{\beta-3\alpha}{2}\right)\sin\left(\frac{\beta+3\alpha}{2}\right)\sin(\alpha)\sin(\beta) \\ &= \tfrac{1}{4}(\cos(\alpha)+\cos(\beta))(\cos(3\alpha)+\cos(\beta))\sin(\alpha)\sin(\beta). \end{aligned} \tag{3.12}$$

This, however, is not the end of the story. We need in fact to determine the range of the coordinates which covers the whole group G_2, apart from a subset of zero measure. To this end we will use a topological argument.

IV. THE RANGE OF THE COORDINATES

Before entering into more details, let us explain our strategy.

Looking at the measure (3.11) one immediately sees that for some values of the coordinates it vanishes. This happens for certain values of the angles a_2, a_5 , a_7 , a_8 , a_{10} , a_{13}. Let us suppose we choose the range for these coordinates in such a way that it delimits a region where $d\mu$ is vanishing only on the boundary. For the other coordinates the range is fixed in such a way that each of them goes around a closed orbit exactly once.

This describes a 14-dimensional closed cycle V which represents an element of the homology group $[V] \in H_{14}(G_2, \mathbb{Z})$. (However, for our purposes it would be enough to consider the homology with rational or real coefficients.) Using the pairing $B: H^k \times H_k \to \mathbb{R}$ given by

$$B([\xi],[W]) = \int_W \xi, \tag{4.1}$$

we define the normalized form

$$\tau = B([\omega],[G_2])^{-1}\omega. \tag{4.2}$$

It is clear that the function $B([\tau], \cdot)$ takes only integer values. In particular $B([\tau],[W])$ counts the number of times the cycle W wraps G_2. Once this is known all we need to do is to find how to restrict the range of coordinates until we obtain a cycle V which wraps G_2 once. We are now going to enter into more details and compute τ in three steps.

A. The evaluation of $B([\omega],[G_2])$

There is a simple way to compute the total volume of a connected simple Lie group, described by Macdonald in Ref. 11. It works as follows.

If G is the group, $t \subset \mathrm{Lie}(G)$ a Cartan subalgebra, and $t_{\mathbb{Z}}$ the integer lattice generated in t by the simple roots, then $T = t/t_{\mathbb{Z}}$ is a torus with the same dimension as t. Let $\alpha > 0$ denote the positive roots and $|\alpha|$ their length.

Then from Hopf theorem, the rational homology of G is equal to the rational homology of a product of odd-dimensional spheres: $H_*(G, \mathbb{Q}) \sim H_*(\Pi_{i=1}^k (S^{2i+1})^{n_i}, \mathbb{Q})$, where n_i is the number of times the given sphere appears. Let $Vol(S^{2i+1}) = 2\pi^{i+1}/i!$ be the volume of the $(2i+1)$-dimensional unit sphere and $Vol(T)$ be the volume of the torus computed using the measure induced by the Lebesgue measure on the algebra. Then the whole volume determined via the pullback of the Lebesgue measure on the algebra is

$$Vol(G) = Vol(T) \cdot \prod_{i=1}^{k} Vol(S^{2i+1})^{n_i} \cdot \prod_{\alpha>0} \frac{4}{|\alpha|^2}. \tag{4.3}$$

The roots of G_2 computed with our choice for the algebra and the normalization, are shown in Appendix C. From the figure we see that there are three positive roots of length 2 and three of length $2/\sqrt{3}$. The torus associated to the simple roots α_1 and α_2 is generated by the coroots H_1 and H_2. Remembering the relations $|H| = 2/|\alpha|$, we find $Vol(T) = \sqrt{3}/2$. Since S^3 and S^{11} are the odd spheres which generate the rational homology of G_2, we obtain the desired result

$$B(\mu, G_2) = Vol(G_2) = 9\sqrt{3}\frac{\pi^8}{20}. \tag{4.4}$$

We are now ready for the next step.

B. The construction of the cycle V

Let us look at (2.5): to determine a closed cycle we first observe that for each one of the two SU(2) subgroups S and Σ it is possible to choose the range of the coordinates in such a way as to cover the whole 3-sphere. The method to do this is well-known (Euler angles) and here we give only the final result

$$0 \leqslant a_1 \leqslant 2\pi, \quad 0 \leqslant a_2 \leqslant \frac{\pi}{2}, \quad 0 \leqslant a_3 \leqslant \pi,$$

$$0 \leqslant a_4 \leqslant 2\pi, \quad 0 \leqslant a_5 \leqslant \frac{\pi}{2}, \quad 0 \leqslant a_6 \leqslant \pi,$$

$$0 \leqslant a_9 \leqslant 2\pi, \quad 0 \leqslant a_{10} \leqslant \frac{\pi}{2}, \quad 0 \leqslant a_{11} \leqslant \pi,$$

$$0 \leqslant a_{12} \leqslant 2\pi, \quad 0 \leqslant a_{13} \leqslant \frac{\pi}{2}, \quad 0 \leqslant a_{14} \leqslant \pi. \tag{4.5}$$

To complete the cycle we need to determine the range for a_7 and a_8 in such a way that $d\mu$ does not vanish. To this end we solve the inequality $f(x,y)>0$ and obtain a tiling of the fundamental region

$$(2a_7, 2a_8) \in [0,2\pi] \times [0,2\pi], \tag{4.6}$$

as we show in Appendix D. There, we also prove that every region of the tiling gives the same (absolute value) contribution to the measure.

The cycle V is then obtained by choosing any one of these regions, for example the one denoted by B in the figure.

C. The evaluation of τ and the range of the Euler angles for G_2

We can now evaluate the degree of the map $V \to G_2$. Using (4.5) for the range of the coordinates, (3.11) for $d\mu$ and (4.4) for $Vol(G_2)$, we easily find $B(\tau,V)=16$. Therefore, our next task is to understand the origin of this factor.

A factor of 4 can be easily accounted for in the following way. We have built the cycle V starting from the closed submanifolds S and Σ corresponding to the two SU(2) embeddings. Thus, naively, we would expect to find a $\mathrm{SU}(2)\times\mathrm{SU}(2)$ submanifold embedded in G_2. But a direct inspection shows that this is not exactly true. In fact, varying for example $a_1 \in [0,2\pi]$ provides a double covering of the six-dimensional submanifold obtained by taking $a_1 \in [0,\pi]$ and $a_2,\ldots,a_6$ as in (4.5). This is because the image of $\mathrm{SU}(2)\times\mathrm{SU}(2)$ in G_2 is $\mathrm{SO}(4)=(\mathrm{SU}(2)\times\mathrm{SU}(2))/\mathbb{Z}_2$, as previously remarked in Sec. II.

Similarly, we must reduce the range of a_{12} to $a_{12} \in [0,\pi]$. The new cycle we obtain in this way wraps G_2 four times.

Now, let us consider the torus $T(a_7,a_8) := e^{\sqrt{3}a_7 C_{11}} e^{a_8 C_5}$. We need to determine the subgroup of 7×7 orthogonal matrices A of SO(4), which leaves each element $T(a_7,a_8)$ invariant under the adjoint action

$$AT(a_7,a_8)A^t = T(a_7,a_8). \tag{4.7}$$

It turns out that it is a finite group generated by the idempotent matrices $\sigma(\sigma=\sigma^{-1})$ and $\eta\ (\eta=\eta^{-1})$

$$\sigma=\begin{pmatrix}1&0&0&0&0&0&0\\0&-1&0&0&0&0&0\\0&0&-1&0&0&0&0\\0&0&0&1&0&0&0\\0&0&0&0&1&0&0\\0&0&0&0&0&-1&0\\0&0&0&0&0&0&-1\end{pmatrix}\quad \eta=\begin{pmatrix}-1&0&0&0&0&0&0\\0&0&1&0&0&0&0\\0&1&0&0&0&0&0\\0&0&0&-1&0&0&0\\0&0&0&0&1&0&0\\0&0&0&0&0&0&-1\\0&0&0&0&0&-1&0\end{pmatrix}. \tag{4.8}$$

Considering the action of σ one finds

$$\begin{aligned}g&=U(a_4,a_5,a_6;a_1,a_2,a_3)T(a_7,a_8)U(a_9,a_{10},a_{11};a_{12},a_{13},a_{14})\\&=U(a_4,a_5,a_6;a_1,a_2,a_3)\sigma T(a_7,a_8)\sigma U(a_9,a_{10},a_{11};a_{12},a_{13},a_{14})\\&=U\left(a_4,a_5,a_6+\frac{\pi}{2};a_1,a_2,a_3+\frac{\pi}{2}\right)T(a_7,a_8)U\left(a_9+\frac{\pi}{2},a_{10},a_{11};a_{12}+\frac{\pi}{2},a_{13},a_{14}\right).\end{aligned} \tag{4.9}$$

Therefore, we can restrict $0\leqslant a_3<\pi/2$.

Analogously, let us now look at the symmetry generated by η:

$$\begin{aligned}g&=U(a_4,a_5,a_6;a_1,a_2,a_3)T(a_7,a_8)U(a_9,a_{10},a_{11};a_{12},a_{13},a_{14})\\&=U(a_4,a_5,a_6;a_1,a_2,a_3)\,\eta T(a_7,a_8)\,\eta U(a_9,a_{10},a_{11};a_{12},a_{13},a_{14}),\end{aligned} \tag{4.10}$$

and restrict our attention to the factor ηU on the right. (Similar relations are true for the factor on the left.) A direct computation using the explicit expression of the matrices shows that the left action of η on U is equivalent to the shift

$$a_9\mapsto\frac{\pi}{4}-a_9,\quad a_{10}\mapsto a_{10}+\frac{\pi}{2},\quad a_{11}\mapsto a_{11},$$

$$a_{12}\mapsto-\frac{\pi}{4}-a_{12},\quad a_{13}\mapsto a_{13}+\frac{\pi}{2},\quad a_{14}\mapsto a_{14}. \tag{4.11}$$

The analysis is more complicated than for the action of σ, because now some of the angles are mapped to values which are outside of the range (4.5) we have fixed. For example, $a_{10}+\pi/2\in[\pi/2,\pi]$, when $a_{10}\in[0,\pi/2]$. Therefore, we need to use other equivalence relations to map the angles back to the original region (4.5).

In fact, the following symmetries hold for S and Σ:

$$S[a_9,a_{10},a_{11}]\sim S\left[a_9+\frac{\pi}{2},\pi-a_{10},a_{11}+\frac{\pi}{2}\right]$$

$$\Sigma[a_{12},a_{13},a_{14}]\sim\Sigma\left[a_{12}+\frac{\pi}{2},\pi-a_{13},a_{14}+\frac{\pi}{2}\right]. \tag{4.12}$$

These are the known symmetries which have been used to determine (4.5) in the first place. Thus the action (4.11) of η is equivalent to

$$a_9\mapsto\frac{3}{4}\pi-a_9,\quad a_{10}\mapsto\frac{\pi}{2}-a_{10},\quad a_{11}\mapsto a_{11}+\frac{\pi}{2},$$

$$a_{12} \mapsto \frac{\pi}{4} - a_{12}, \quad a_{13} \mapsto \frac{\pi}{2} - a_{13}, \quad a_{14} \mapsto a_{14} + \frac{\pi}{2}, \tag{4.13}$$

where now a_{10} and a_{13} stay inside the allowed intervals. The next point to notice is that for the remaining coordinates it is possible to use similarity relations which does not involve a_{10} and a_{13}, e.g.,

$$S[a_9,a_{10},a_{11}]\Sigma[a_{12},a_{13},a_{14}] \sim S[a_9+\pi,a_{10},a_{11}]\Sigma[a_{12}+\pi,a_{13},a_{14}] \tag{4.14}$$

and similar symmetries. Moreover, η is a linear transformation, so that it is enough to restrict the range of one of the angles. Therefore, luckily, we actually do not need to know the action of η on the whole set of coordinates. The solution of our problem simply consists in restricting the range of either a_{10} or a_{13} in the SO(4) factor $U(a_9,a_{10},a_{11};a_{12},a_{13},a_{14})$ on the right. Alternatively, the same result can be achieved by restricting the range of either a_2 or a_5 in the factor $U(a_4,a_5,a_6;a_1,a_2,a_3)$ on the left. Since we prefer a coordinatization which respects the fibration described in Sec. II and we want the angles $a_9,\ldots,a_{14}$ to span the whole fiber $U(a_9,\ldots,a_{14})$, we choose the second option and restrict the range of a_5.

Finally, we can summarize our results for the range of the angles describing G_2:

$$0 \leqslant a_1 \leqslant \pi, \quad 0 \leqslant a_2 \leqslant \frac{\pi}{2}, \quad 0 \leqslant a_3 \leqslant \frac{\pi}{2},$$

$$0 \leqslant a_4 \leqslant 2\pi, \quad 0 \leqslant a_5 \leqslant \frac{\pi}{4}, \quad 0 \leqslant a_6 \leqslant \pi,$$

$$0 \leqslant a_9 \leqslant 2\pi, \quad 0 \leqslant a_{10} \leqslant \frac{\pi}{2}, \quad 0 \leqslant a_{11} \leqslant \pi,$$

$$0 \leqslant a_{12} \leqslant \pi, \quad 0 \leqslant a_{13} \leqslant \frac{\pi}{2}, \quad 0 \leqslant a_{14} \leqslant \pi,$$

$$0 \leqslant a_7 \leqslant \frac{\pi}{6}, \quad 3a_7 \leqslant a_8 \leqslant \frac{\pi}{2}. \tag{4.15}$$

V. CONCLUSIONS

We have found a coordinatization of the G_2 group with a one to one correspondence between the range of coordinates and a full measure subset of the group. In particular, this has allowed us to obtain a quite simple expression for the Haar measure, which should make numerical computations involving the geometry of G_2 much easier, for example in lattice gauge theories or in random matrix models.

However, note that to find an Haar measure on the group we would not have actually needed the last step of the work, i.e., the determination of the correct range of the coordinates which yields an injective map.

In fact, if $d\mu$ indicates the measure over the cycle V, it is possible to simply get an Haar measure $d\tilde{\mu}$ over the Lie group G_2 by just taking

$$d\tilde{\mu} := \frac{1}{16} d\mu, \tag{5.1}$$

16 being the degree of the map $V \to G_2$.

On the other hand the determination of the correct range of coordinates, which covers the whole G_2 wrapping it exactly once except for a subset of vanishing measure, provides a new result, since it determines also a coordinatization of the homogeneous space $\mathcal{H}=G_2/\mathrm{SO}(4)$ of quaternionic subalgebras of octonions.

Moreover, we have also computed the induced metric of $\mathcal{H}$

$$ds^2_{\mathcal{H}} = \delta_{ab} \tilde{J}^a_h \otimes \tilde{J}^b_h, \tag{5.2}$$

and shown that it is an Einstein metric. This result is proven in Appendix E.

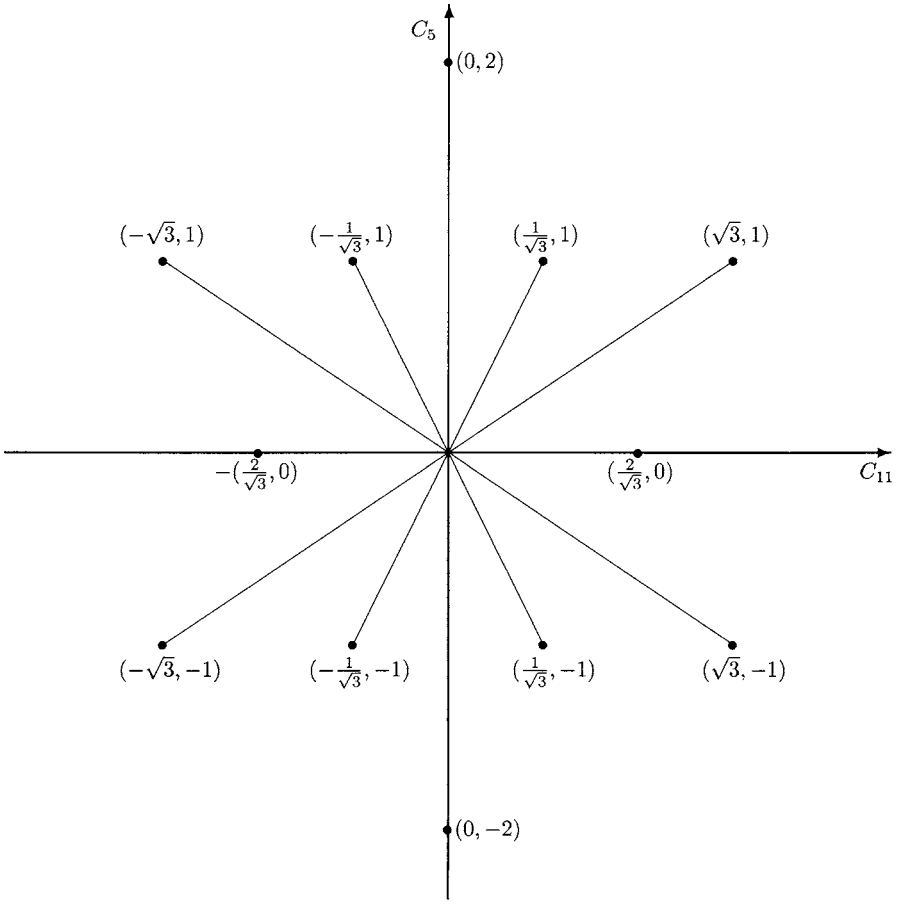
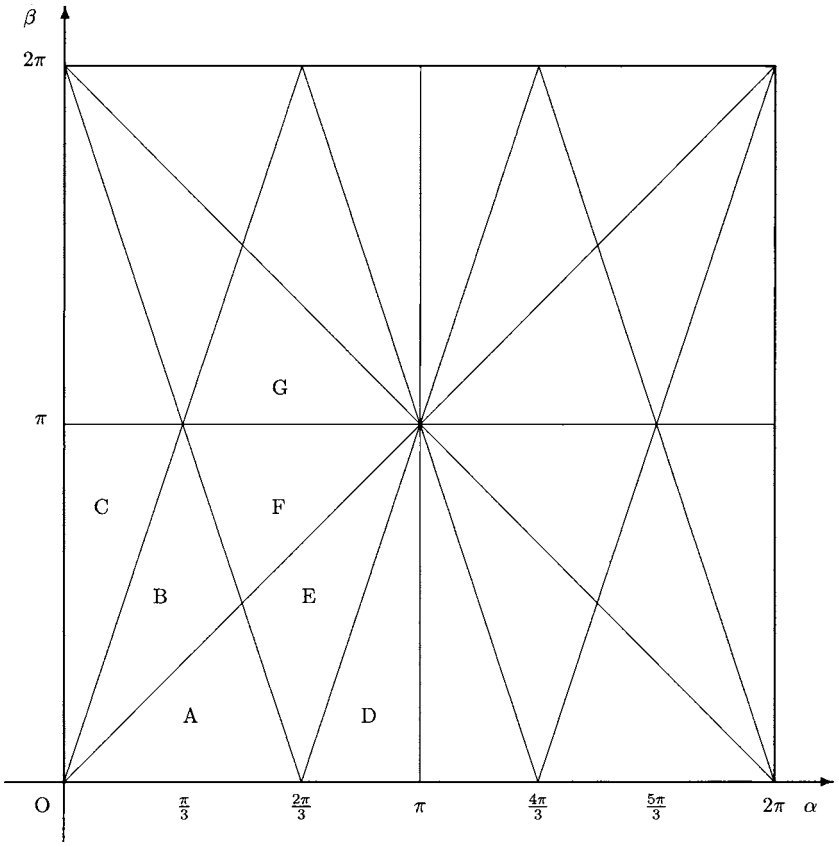
APPENDIX C: THE ROOT SYSTEM

Here we show the roots computed using C_5 and C_{11} normalized to 1. The long roots have length 2 and the short ones have length $2/\sqrt{3}$.



APPENDIX D: THE RANGE FOR a_7 AND a_8

Here we show a plot of the fundamental region for the variables a_7 and a_8, which is determined by the condition $f(\alpha,\beta)>0$ where f is given in (3.12). We obtain a tiling of the torus in 24 triangles, over which the sign of the measure alternates, starting with a positive sign in the region B. In the edges the measure vanishes.



We now show that any sector of this tiling gives exactly the same contribution (obviously up to a sign) to the volume of G_2. To this end we describe some symmetry property of the function $f(\alpha,\beta)$. The translation symmetries $f(\alpha,\beta)=f(\alpha+\pi,\beta+\pi)=f(\alpha-\pi,\beta+\pi)$ and the reflection symmetries $-f(\alpha,\beta)=f(-\alpha,\beta)=f(\alpha,-\beta)$ allows to restrict us to the square $[0,\pi]\times[0,\pi]$. Moreover, the translations gives the equivalence of the triangles A, B, and D with F, E, and C, respectively.

At this point we are left with only three different kinds of triangles: A, B, and D. The symmetry $f(\alpha,\beta)=f((\alpha+\beta)/2,(3\alpha-\beta)/2)$ maps A to B, B to A, and D to G. This proves that we can choose whatever triangle, for example A, as the fundamental region.

APPENDIX E: A METRIC FOR $\mathcal{H}$

Here we give the expression for the metric on $\mathcal{H}$ induced by the metric on G_2, and show that it is an Einstein metric. Let us introduce the 1-forms

$$I_1(x,y,z) := \sin(2y)\cos(2z)dx - \sin(2z)dy,$$

$$I_2(x,y,z) := \sin(2y)\sin(2z)dx + \cos(2z)dy,$$

$$I_3(x,y,z) := dz + \cos(2y)dx. \tag{E1}$$

Thus we can write

$$
\begin{aligned}
ds^2_{\mathcal{H}} = {} & da_8^2 + da_7^2 + [\sin^2 a_8 \cos^2 a_7 + \cos^2 a_8 \sin^2 a_7] \\
& \times (da_5^2 + \sin^2(2a_5) da_4^2 + 3da_2^2 + 3 \sin^2 2a_2 da_1^2) \tfrac{1}{2} \cos(2a_8) \cos 2a_7 \sin^2 2a_7 \\
& \times \{[I_1(a_4,a_5,a_6) + 3I_2(a_1,a_2,a_3)]^2 + [I_2(a_4,a_5,a_6) - 3I_1(a_1,a_2,a_3)]^2\} \\
& + \tfrac{3}{4} \sin^2 2a_7 [I_3(a_4,a_5,a_6) - I_3(a_1,a_2,a_3)]^2 + \tfrac{1}{4} \sin^2(2a_8) [I_3(a_4,a_5,a_6) + 3I_3(a_1,a_2,a_3)]^2 .
\end{aligned}
\tag{E2}
$$

We will now compute the curvature of such a metric. Let us use capital indices for the full algebra, $I=1, \ldots, 14$, Latin indices for the SO(4) subalgebra, $i \in \{1,2,3,8,9,10\}$, and Greek indices for the complementary elements, $\alpha \in \{4,5,6,7,11,12,13,14\}$. Let f_{IJK} be the structure constants with one index lowered through the identity matrix. It is then clear that the nonvanishing structure constants are those with either none or two Greek indices: f_{ijk}, $f_{\alpha\beta k}$ and permutations. Using this fact and the Maurer-Cartan equations (we use the following notations: The spin connection is uniquely defined by $d\tilde{J}_h^\alpha = -\omega^\alpha{}_\beta \tilde{J}_h^\beta$ and $\omega_{\alpha\beta} = -\omega_{\beta\alpha}$; the Riemann tensor field is then $\mathrm{R}^\alpha{}_\beta = d\omega^\alpha{}_\beta + \omega^\alpha{}_\gamma \wedge \omega^\gamma{}_\beta$ with components $R_{\alpha\beta}{}^\gamma{}_\delta$ such that $\mathrm{R}^\gamma{}_\delta = (1/2) R_{\alpha\beta}{}^\gamma{}_\delta J_h^\alpha \wedge J_h^\beta$), the components of the Riemann tensor with respect to the acht-bein are found using only the algebra.

In fact by construction we have that (E2) takes the form $ds^2_{\mathcal{H}} = g_{\alpha\beta} da^\alpha \otimes da^\beta$, with

$$
g_{\alpha\beta} = \tilde{J}^\gamma_\alpha \tilde{J}^\delta_\beta \delta_{\gamma\delta}. \tag{E3}
$$

Let us note that, using notations as in Sec. III, we have

$$
J_h = \tilde{J}_h + J_h^i C_i. \tag{E4}
$$

On the other hand, using $J_h = h^{-1} dh$ one finds

$$
dJ_h = -J_h \wedge J_h = -\tfrac{1}{2} J^I \wedge J^J f_{IJ}{}^K C_K. \tag{E5}
$$

The spin connection can be determined computing $d\tilde{J}_h$ from (E4). Being $\tilde{J}_h^\alpha = J_h^\alpha$ we can omit the tilde in what follows and write:

$$
dJ_h^\alpha = -\tfrac{1}{2} J^I J^J f_{IJ}{}^\alpha = -\tfrac{1}{2} J^\beta J^\gamma f_{\beta\gamma}{}^\alpha - J^i J^\beta f_{i\beta}{}^\alpha, \tag{E6}
$$

where we used the properties of the structure constants. From this we can read the expression for the spin connection one-form, which can be written in the form

$$
\omega^\alpha{}_\beta = J_h^I f_{I\beta}{}^\alpha - \tfrac{1}{2} J_h^\gamma f_{\gamma\beta}{}^\alpha. \tag{E7}
$$

The curvature tensor can then be computed directly

$$
\mathrm{R}^\alpha{}_\beta = J_h^\lambda J_h^\mu \Big[-f_{\lambda i}{}^\alpha f_{\mu\beta}{}^i + \tfrac{1}{4} f_{\lambda\mu}{}^\nu f_{\nu\beta}{}^\alpha - \tfrac{1}{4} f_{\mu\nu}{}^\alpha f_{\lambda\beta}{}^\nu - f_{\lambda\nu}{}^\alpha f_{\mu\beta}{}^\nu \Big], \tag{E8}
$$

or in components

$$
R_{\alpha\beta}{}^\gamma{}_\delta = -f_{\alpha I}{}^\gamma f_{\beta\delta}{}^I + f_{\beta I}{}^\gamma f_{\alpha\delta}{}^I + \tfrac{1}{2} f_{\alpha\beta}{}^I f_{I\delta}{}^\gamma - \tfrac{1}{4} f_{\beta\delta}{}^I f_{I\alpha}{}^\gamma + \tfrac{1}{4} f_{\alpha\delta}{}^I f_{I\beta}{}^\gamma. \tag{E9}
$$

The Ricci tensor $\rho_{\alpha\beta} := R_{\gamma\alpha}{}^\gamma{}_\beta$ is then

$$
\rho_{\alpha\beta} = \tfrac{1}{4} f_\alpha{}^{IJ} f_{\beta IJ} + \tfrac{1}{2} f_\alpha{}^{\gamma i} f_{\beta\gamma i} + \tfrac{1}{2} f_\beta{}^{\gamma i} f_{\alpha\gamma i}. \tag{E10}
$$

The explicit form of the structure constants in our base then yields

$$
\rho_{\alpha\beta} = 8 \delta_{\alpha\beta}, \tag{E11}
$$

or in curvilinear coordinates $\rho_{\mu\nu} dx^\mu \otimes dx^\nu = 8 ds^2_{\mathcal{H}}$.

(Received 14 October 2004; accepted 17 June 2005; published online 10 August 2005)

In this paper we consider the diffusion process X determined by the one-variable time-dependent Fokker-Planck equation, $(\partial/\partial t)P(y,t)=-g(t)(\partial/\partial y)yP(y,t)+\frac{1}{2}f(t)^2(\partial^2/\partial y^2)P(y,t)$, where $f,g:\mathbb{R}_+\to\mathbb{R}_+$ are two continuous functions, i.e., X satisfies Itô stochastic differential equation, $\mathrm{d}X_t=f(t)\mathrm{d}B_t-g(t)X_t\,\mathrm{d}t$, where B is a standard Brownian motion starting at zero. We obtain L^p estimates on the process, and we show that $\|\sqrt{\log(1+J_\tau)}\|_p$ and $\|\sup_{0\leqslant t\leqslant\tau}|a(t)X_t|\|_p$ are equivalent for all stopping times τ of B, where $J_t=\int_0^t a^2(s)f^2(s)\mathrm{d}s$ and $a:\mathbb{R}_+\to\mathbb{R}_+$ the solution to the equation $(\mathrm{d}a/\mathrm{d}t)-g(t)a=-a^3f^2(t)$, $a(0)=1$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2000208]

I. INTRODUCTION

The Fokker-Planck equation (see, for example, Refs. 4, 19, and 22) is one of the most celebrated equations in Physics, since it has been very useful for studying dynamic behavior of stochastic differential equations driven by Gaussian noises. It is a special type of master equation, which is often used as an approximation to the actual equation or as a model for more general Markov processes. We have known that the linear Fokker-Planck equation

$$\frac{\partial}{\partial t}P(y,t)=-\lambda\frac{\partial}{\partial y}yP(y,t)+\frac{1}{2}\nu\frac{\partial^2}{\partial y^2}P(y,t), \tag{1.1}$$

arises in many fields of applied sciences such that statistical mechanics, chemistry, mathematical finance (see Refs. 4, 19, and 22). Such that a drift-diffusion equation can be derived from the Langevin equation

$$\mathrm{d}V_t=-\lambda V_t\,\mathrm{d}t+\nu^{1/2}\,\mathrm{d}B_t,\quad V_0=x, \tag{1.2}$$

where B is a standard Brownian motion starting at 0, to model the Brownian motion of particles in thermodynamical equilibrium. In this case, the parameters λ and ν are two positive constants which represent, respectively, the friction term and the temperature of the system. The stationary Markov process determined by the linear Fokker-Planck equation (1.1) with $\lambda,\nu>0$ is the Ornstein-Uhlenbeck process. The Ornstein-Uhlenbeck process has a notable history in physics, and it is a better model to make the velocity of the particle diffusion process, and it is the solution of the Langevin equation (1.2). Clearly, we have

[a)]Electronic mail: litanyan@dhu.edu.cn

$$V_t = e^{-\lambda t}\left(x + \nu \int_0^t e^{\lambda s}\, \mathrm{d}B_s\right),$$

and furthermore, one can also write

$$V_t = xe^{-\lambda t} + \frac{\nu}{\sqrt{2\lambda}} B_{1-e^{-2\lambda t}}$$

in the sense of the same finite dimensional distributions. For more information on the Ornstein-Uhlenbeck process, see Refs. 4, 16, 18, 20, and 22.

Recently, for the Ornstein-Uhlenbeck process V with $V_0=0$, Graversen and Peskir[9] showed that there exist two universal constants $b_1, b_2 > 0$ such that the inequalities

$$\frac{b_1}{\sqrt{\beta}} E[\sqrt{\log(1+\beta\tau)}] \leqslant E \sup_{0\leqslant t\leqslant \tau} |V_t| \leqslant \frac{b_1}{\sqrt{\beta}} E[\sqrt{\log(1+\beta\tau)}] \tag{1.3}$$

hold for all stopping times τ of B, where $\beta=\lambda/\nu$. This result shows that the maximal velocity of the Brownian particle, taken up to a stopping time τ, in average behaves as $\sqrt{\log(1+\tau)}$. The main objective of this paper is to generalize this result allowing the friction term λ and the temperature ν to fluctuate with time. In this case, the Fokker-Planck equation (1.1) reads

$$\frac{\partial}{\partial t} P(y,t) = -\, g(t) \frac{\partial}{\partial y} y P(y,t) + \frac{1}{2} f(t)^2 \frac{\partial^2}{\partial y^2} P(y,t), \tag{1.4}$$

where $f, g : \mathbb{R}_+ \to \mathbb{R}_+$ are two continuous functions. Nonautonomous Fokker-Planck equations arise for instance in the study of a periodically driven Brownian rotor[1] and in this case $g(t)$ and $f(t)$ are periodic functions of time. In statistical mechanics, Eq. (1.4) arises as a natural generalization of Eq. (1.1) in the context of nonequilibrium thermodynamics.[15] Among other models, Eq. (1.4) appears in the study of the tagged particle dynamics of a heavy particle in a gas of much lighter inelastic particles. As observed by Brey, Dufty, and Santos,[3] the large particles exhibit Brownian motion and the Boltzmann-Lorentz kinetic equation satisfied by the distribution function of large particles can be reduced to a Fokker-Planck equation whose coefficients depend on the temperature of the surrounding gas. Granular gases being nonequilibrium systems, this temperature turns out to be time dependent and the Fokker-Planck equation derived in Ref. 3 is of the shape (1.4). Furthermore, in Ref. 14, Lods and Toscani analyzed the asymptotic behavior of the time-dependent Fokker-Planck equation (1.1).

Clearly, the time-inhomogeneous diffusion processes X determined by Eq. (1.4) is the unique strong solution to the stochastic differential equation

$$\mathrm{d}X_t = f(t)\mathrm{d}B_t - g(t)X_t\, \mathrm{d}t, \quad X_0 = y. \tag{1.5}$$

According to Ref. 12, the process X is called the *Ornstein-Uhlenbeck type process*. Our starting point is Theorem 2.1, where, we show that for all stopping times τ and all $0<p<\infty$, the inequalities

$$\frac{1}{b_p} \left\| \sqrt{\log(1+J_\tau)} \right\|_p \leqslant \left\| \sup_{0\leqslant t\leqslant \tau} |a(t)X_t| \right\|_p \leqslant \sqrt{2} b_p \left\| \sqrt{\log(1+J_\tau)} \right\|_p \tag{1.6}$$

hold with $b_p = 3(e+ep)^{(1+p)/p}$, where $J_t = \int_0^t a^2(s) f^2(s) \mathrm{d}s$ and $a : \mathbb{R}_+ \to \mathbb{R}_+$ the solution to the equation

$$\frac{\mathrm{d}a}{\mathrm{d}t} - g(t)a = -\, a^3 f^2(t), \quad a(0) = 1.$$

As an interesting related problem, we consider the process X given by the equation

$$dX_t = 2f(t)\sqrt{X_t}\,dB_t + \delta g(t)dt, \quad X_0 = 0 \tag{1.7}$$

with $\delta > 0$. Clearly, If $f \equiv 1$ and $g \equiv 1$, then the squares of the solution is a Bessel process of dimension $\delta > 0$ starting at $\sqrt{x_0}$ (see Refs. 6, 7, and 18 for Bessel processes). For the process X given by (1.7) we show that the inequalities

$$\frac{\delta}{C_p}\left\|\int_0^\tau g(t)dt\right\|_p \leqslant \left\|\sup_{0\leqslant t\leqslant\tau} X_t\right\|_p \leqslant \delta C_p\left\|\int_0^\tau g(t)dt\right\|_p$$

hold for all stopping times τ and all $0 < p < \infty$, where $C_p = 9(e+2ep)^{(1+2p)/p}$. This extends the inequalities with $\delta \geqslant 1$ obtained by Graversen and Peskir[8] (see also DeBlassie,[5] Dubins *et al.*,[6] Rosenkrantz and Sawyer[21]). (Also see Ref. 10.)

II. RESULTS AND PROOFS

In this section we give L^p estimates on the time-inhomogeneous diffusion process determined by Eq. (1.4) and some related results. In order to obtain these inequalities we need some preliminaries.

Let $a: \mathbb{R}_+ \to \mathbb{R}_+$ be the solution to the equation

$$\frac{da}{dt} - g(t)a = -a^3 f^2(t), \quad a(0) = 1 \tag{2.1}$$

and let for $x \in \mathbb{R}$,

$$h(x) = 2\int_0^x e^{z^2}\,dz \int_0^z e^{-s^2}\,ds. \tag{2.2}$$

For $x \in \mathbb{R}, t \geqslant 0$ we set $F(t,x) = h(a(t)x)$. Then F satisfies

$$\frac{\partial F}{\partial t} - g(t)x\frac{\partial F}{\partial x} + \frac{1}{2}f^2(t)\frac{\partial^2 F}{\partial x^2} = a^2(t)f^2(t) \tag{2.3}$$

and $F(t,0) = (\partial F/\partial x)(t,0) = 0$ for all $t \geqslant 0$.

On the other hand, it is not difficult to show that

$$e^{x^2/2} - 1 \leqslant h(x) \leqslant e^{x^2} - 1 \quad (x \geqslant 0) \tag{2.4}$$

hold. For $x \geqslant 0$ we define the function $H_p: \mathbb{R}_+ \to \mathbb{R}_+$ by

$$H_p(h(x)) = x^p \quad (p > 0).$$

Then H_p is an increasing continuous function on $\mathbb{R}_+$ with $H_p(0) = 0$. For $x \geqslant 0$ we set

$$\tilde{H}_p(x) = x\int_x^\infty \frac{1}{s}dH_p(s) + 2H_p(x).$$

Lemma 2.1: Let H_p and $\tilde{H}_p$ be defined as above. Then for all $p > 0$ we have

$$\log^{p/2}(1+x) \leqslant H_p(x) \leqslant 2^{p/2}\log^{p/2}(1+x) \quad (x \geqslant 0), \tag{2.5}$$

and for $0 < p < 2$ we have

$$\tilde{H}_p(x) \leqslant \frac{4-p}{2-p}H_p(x) \quad (x \geqslant 0). \tag{2.6}$$

Proof: The inequalities (2.5) follows from (2.4). To prove (2.6), it now is enough to assume that

$$H_p(x) = A_p \log^{p/2}(1+x) \quad (p > 0)$$

for some constant $A_p > 0$ depending only on p. For $x \geqslant 0$ we set $G_p(x) \equiv [x/H_p(x)] \int_x^\infty (1/s) \mathrm{d}H_p(s)$. An elementary calculation can show that for all $x \geqslant 0$ and all $0 < p < 2$,

$$\lim_{x \downarrow 0} G_p(x) = \frac{p}{2-p}, \quad \lim_{x \to +\infty} G(x) = 0$$

and

$$0 \leqslant G_p(x) \leqslant \frac{p}{2-p}.$$

It follows that

$$\widetilde{H}_p(x) = x \int_x^\infty \frac{1}{s} \mathrm{d}H_p(s) + 2H_p(x) \leqslant \frac{4-p}{2-p} H_p(x)$$

for all $x \geqslant 0$ and all $0 < p < 2$. This completes the proof. □

Lemma 2.2: Let $D = (D_t)_{t \geqslant 0}$ be a non-negative right-continuous process, and let $A = (A_t)_{t \geqslant 0}$ be an increasing continuous process with $A_0 = 0$. Assume that $H : \mathbb{R}_+ \to \mathbb{R}_+$ is an increasing continuous function with $H(0) = 0$. If for all bounded stopping times τ

$$E[D_\tau] \leqslant E[A_\tau],$$

then

$$E(\sup_{0 \leqslant t \leqslant \tau} H(D_t)) \leqslant E[\widetilde{H}(A_\tau)]$$

holds for all stopping times τ, where $\widetilde{H} : \mathbb{R}_+ \to \mathbb{R}_+$ is defined by

$$\widetilde{H}(x) = x \int_x^\infty \frac{1}{s} \mathrm{d}H(s) + 2H(x), \quad x \geqslant 0.$$

The proof of the lemma above can be found in (Ref. 18, pp. 162–163) (also see Lemma 2.1 in Ref. 17), and the following lemma is a modification of Lemma 1.1 in Ref. 13, and it is a useful technique to obtain L^p estimates of random variables, which is proved in Ref. 11 (see also Ref. 2).

Lemma 2.3 (Ref. 11): Let A and B be two continuous, $(\mathcal{F}_t)$-adapted, increasing processes, with $A_0 = 0$ and $B_0 = 0$. If there exist some constants $\alpha, \beta > 0$ such that

$$E[(A_T^\beta - A_S^\beta)^\alpha] \leqslant \|B_T\|_\infty^{\alpha\beta} P(S < T)$$

holds for all couples (S, T) of stopping times S, T with $S \leqslant T$. Then, for any $0 < p < \infty$, we have

$$E[A_\infty^p] \leqslant (e + ep/\alpha\beta)^{1+p/\beta} E[B_\infty^p].$$

Theorem 2.1: *Let the diffusion process X be given by the equation*

$$\mathrm{d}X_t = f(t)\mathrm{d}B_t - g(t)X_t \, \mathrm{d}t \tag{2.7}$$

with $X_0 = 0$, where $f, g : \mathbb{R}_+ \to \mathbb{R}_+$ are two continuous functions, and let $a : \mathbb{R}_+ \to \mathbb{R}_+$ be the solution to Eq. (2.1). *For $t \geqslant 0$ we define*

$$J_t = \int_0^t a^2(s) f^2(s) \mathrm{d}s.$$

Then for all $0<p<\infty$ *and all stopping times* τ, *we have*

$$b_p^{-1}\|\sqrt{\log(1+J_\tau)}\|_p \leqslant \|\sup_{0\leqslant t\leqslant\tau}|a(t)X_t|\|_p \leqslant \sqrt{2}b_p\|\sqrt{\log(1+J_\tau)}\|_p, \tag{2.8}$$

where $b_p=3(e+ep)^{(1+p)/p}$, *in particular, for* $0<p<2$ *we have*

$$\frac{2-p}{4-p}E[\log^{p/2}(1+J_\tau)] \leqslant E[\sup_{0\leqslant t\leqslant\tau}|a(t)X_t|^p] \leqslant 2^{p/2}\frac{4-p}{2-p}E[\log^{p/2}(1+J_\tau)].$$

Proof: Let a and h be given by (2.1) and (2.2), respectively, and let $F(t,x)=h(a(t)x)$ for $t\geqslant 0$, $x\in\mathbb{R}$. Noting that h is even, we get by the Itô formula and Eq. (2.3),

$$h(|a(t)X_t|)=h(a(t)X_t)=F(t,X_t)=\int_0^t\frac{\partial}{\partial s}F(s,X_s)\mathrm{d}s+\int_0^t f(s)\frac{\partial}{\partial x}F(s,X_s)\mathrm{d}B_s-\int_0^t g(s)X_s\frac{\partial}{\partial x}F(s,X_s)\mathrm{d}s$$
$$+\frac{1}{2}\int_0^t f^2(s)\frac{\partial^2}{\partial x^2}F(s,X_s)\mathrm{d}s=\int_0^t f(s)\frac{\partial}{\partial x}F(s,X_s)\mathrm{d}B_s+\int_0^t a^2(s)f^2(s)\mathrm{d}s.$$

It follows that for all bounded stopping times τ

$$E[F(\tau,X_\tau)]=E[J_\tau]. \tag{2.9}$$

Now, for these processes $D=(F(t,X_t);t\geqslant 0)$ and $A=(J_t;t\geqslant 0)$, by using Lemma 2.1 and Lemma 2.2, we get

$$E[\sup_{0\leqslant t\leqslant\tau}|a(t)X_t|]=E[\sup_{0\leqslant t\leqslant\tau}H_p(F(t,X_t))]\leqslant E[\tilde{H}_p(J_\tau)]\leqslant\frac{4-p}{2-p}E[H_p(J_\tau)]$$
$$\leqslant 2^{p/2}\frac{4-p}{2-p}E[\log^{p/2}(1+J_\tau)]$$

for all stopping times τ and $0<p<2$. On the other hand, we see that (2.9) implies

$$E[J_\tau]\leqslant E[\sup_{0\leqslant t\leqslant\tau}F(t,X_t)]$$

for all bounded stopping times τ. Consequently, by using Lemma 2.1 and Lemma 2.2 to these processes $D=(J_t;t\geqslant 0)$ and $A=(\sup_{0\leqslant s\leqslant t}F(s,X_s);t\geqslant 0)$, we get

$$E[H_p(J_\tau)]\leqslant E[\tilde{H}_p(\sup_{0\leqslant t\leqslant\tau}F(t,X_t))]\leqslant\frac{4-p}{2-p}E[H_p(\sup_{0\leqslant t\leqslant\tau}F(t,X_t))]=\frac{4-p}{2-p}E[\sup_{0\leqslant t\leqslant\tau}|a(t)X_t|^p]$$

for all stopping times τ and all $0<p<2$. Thus, we obtain the following inequalities:

$$\frac{2-p}{4-p}E[\log^{p/2}(1+J_\tau)]\leqslant E[\sup_{0\leqslant t\leqslant\tau}|a(t)X_t|^p]\leqslant 2^{p/2}\frac{4-p}{2-p}E[\log^{p/2}(1+J_\tau)] \tag{2.10}$$

for all stopping times τ and all $0<p<2$.

Next, we extend (2.10) to all $0<p<\infty$ by using Lemma 2.3. Consider any couple (S,T) of stopping times S, T with $S\leqslant T$. Then, from the left inequality in (2.10) with $p=1$ and the inequality

$$\log(1+x)-\log(1+y)\leqslant\log(1+x-y)\quad(x\geqslant y\geqslant 0),$$

we find

$$E[\sqrt{\log(1+J_T)}-\sqrt{\log(1+J_S)}] \leqslant E[\sqrt{\log(1+J_T-J_S)}] \leqslant E[\sqrt{\log(1+J_{T1_{\{T>S\}}})}]$$
$$\leqslant 3E[\sup_{0\leqslant t\leqslant T1_{\{T>S\}}}|a(t)X_t|] \leqslant \|3\sup_{0\leqslant t\leqslant T}|a(t)X_t|\|_\infty P(T>S),$$

where 1_A stands for the indicate function of set A, which shows for all stopping times T and all $0<p<\infty$,

$$\|\sqrt{\log(1+J_T)}\|_p \leqslant 3(e+ep)^{(1+p)/p}\|\sup_{0\leqslant t\leqslant T}|a(t)X_t|\|_p$$

by Lemma 2.3 with $\alpha=\beta=1$.

To prove the right inequality in (2.8), for any couple (S,T) of stopping times S, T with $S \leqslant T$, we have by the right inequality in (2.10) with $p=1$,

$$E[\sup_{0\leqslant t\leqslant T}|a(t)X_t|-\sup_{0\leqslant t\leqslant S}|a(t)X_t|] \leqslant E[\sup_{S\leqslant t\leqslant T}\|a(t)X_t|-|a(S)X_S\|1_{\{S<T\}}]$$
$$\leqslant E[\sup_{0\leqslant t\leqslant (T-S)1_{\{T>S\}}}|a(t+S)X_{t+S}|]$$
$$\leqslant 3\sqrt{2}E[\sqrt{\log(1+J_T)}1_{\{T>S\}}] \leqslant \|3\sqrt{2}\sqrt{\log(1+J_T)}\|_\infty P(S<T),$$

which shows for all stopping times T and all $0<p<\infty$,

$$\|\sup_{0\leqslant t\leqslant T}|a(t)X_t|\|_p \leqslant 3\sqrt{2}(e+ep)^{(1+p)/p}\|\sqrt{\log(1+J_T)}\|_p$$

by Lemma 2.3 with $\alpha=\beta=1$. This completes the proof. □

We now consider some very interesting examples. Let $t\mapsto K(t)$ be a differentiable function on $\mathbb{R}_+$ with $K(t)>0$ for all $t\geqslant 0$ and let $X_t=B_t/K(t)$, $t\geqslant 0$, where B is a standard Brownian motion starting at zero. Then we have by Itô's formula

$$\mathrm{d}X_t=\frac{1}{K(t)}\mathrm{d}B_t-\frac{K'(t)}{K(t)}X_t\,\mathrm{d}t$$

with $X_0=0$. On the other hand, from (2.1) we have for all $t\geqslant 0$,

$$a(t)^{-2}=e^{-2\int_0^t g(s)\mathrm{d}s}\left(2\int_0^t f^2(s)e^{2\int_0^s g(z)\mathrm{d}z}\,\mathrm{d}s+1\right)=\frac{1}{K(t)^2}(2t+K(0)),$$

since $f(t)=1/K(t)$ and $g(t)=K'(t)/K(t)$.

Without loss of generality, one may assume $K(0)=2$. It follows that

$$J_t=\int_0^t a^2(s)f^2(s)\mathrm{d}s=\frac{1}{2}\log(1+t)$$

for all $t\geqslant 0$. Thus, the following corollary follows from Theorem 2.1.

Corollary 2.1 *(Ref. 9): Let B be a standard Brownian motion starting at zero. Then we have*

$$c_p\|\log^{1/2}(1+\log(1+\tau))\|_p \leqslant \left\|\sup_{0\leqslant t\leqslant \tau}\frac{|B_t|}{\sqrt{1+t}}\right\|_p \leqslant C_p\|\log^{1/2}(1+\log(1+\tau))\|_p$$

for all $0<p<\infty$ and all stopping times τ of B, where c_p and C_p are some positive constants depending only on p.

From the above we can conjecture that the following inequalities hold:

$$c_p\|\sqrt{\log(1+L_{m+1}(\tau))}\|_p \leqslant \left\| \sup_{0\leqslant t\leqslant \tau} \frac{|B_t|}{\prod_{i=0}^{m}(1+L_i(t))^{1/2}} \right\|_p \leqslant C_p\|\sqrt{\log(1+L_{m+1}(\tau))}\|_p$$

for all stopping times τ of B, where c_p and C_p are some positive constants depending only on p, and the function $t\mapsto L_{m+1}(t)$ inductively by

$$L_{m+1}(t)=\log(1+L_m(t)) \quad (m=0,1,2,\ldots)$$

with $L_0(t)=t$.

At the end of this paper, we consider the equation

$$\mathrm{d}X_t = 2f(t)\sqrt{X_t}\,\mathrm{d}B_t + \delta g(t)\mathrm{d}t, \quad X_0 = x_0 \geqslant 0, \tag{2.11}$$

where $\delta>0$ and f, g two positive, bounded continuous functions defined on $\mathbb{R}_+$. Then we have the following.

Theorem 2.2: *Let X be a process given by* (2.16) *with $x_0=0$. Then the inequalities*

$$\frac{\delta}{C_p}\left\|\int_0^\tau g(t)\mathrm{d}t\right\|_p \leqslant \|\sup_{0\leqslant t\leqslant\tau} X_t\|_p \leqslant \delta C_p\left\|\int_0^\tau g(t)\mathrm{d}t\right\|_p \tag{2.12}$$

hold with $0<p<\infty$ for all stopping times τ, where $C_p=9(e+2ep)^{(1+2p)/p}$.

It is easy to see that Eq. (2.11) admits a unique solution and the solution is strong, and furthermore the solution $X_t\geqslant 0$ for all $x_0\geqslant 0$. If $f\equiv 1$ and $g\equiv 1$, then the solution is called the squares of a Bessel process of dimension $\delta>0$ starting at $\sqrt{x_0}$ (see Refs. 6, 7, and 18 for Bessel processes). Thus, the theorem above extends the inequalities with $\delta\geqslant 1$ obtained by Graversen and Peskir[8] (see also DeBlassie,[5] Dubins *et al.*,[6] Rosenkrantz and Sawyer[21]).

Proof of Theorem 2.2: Let X be a process given by (2.16) with $x_0=0$. It follows that for all bounded stopping times τ,

$$E[X_\tau] = \delta E\left[\int_0^\tau g(t)\mathrm{d}t\right]. \tag{2.13}$$

Consequently, from Lemma 2.2 we get for all stopping times τ,

$$E[(\sup_{0\leqslant t\leqslant\tau} X_t)^p] \leqslant \delta^p \frac{2-p}{1-p} E\left[\left(\int_0^\tau g(t)\mathrm{d}t\right)^p\right] \tag{2.14}$$

by assuming $H_p(x)=x^p$ for $x\geqslant 0$ and $0<p<1$. On the other hand, we see that (2.13) implies

$$\delta E\left[\int_0^\tau g(t)\mathrm{d}t\right] \leqslant E[\sup_{0\leqslant t\leqslant\tau} X_t]$$

for all bounded stopping times τ. From Lemma 2.2 with $H_p(x)=x^p(0<p<1)$ it follows that

$$\delta^p E\left[\left(\int_0^\tau g(t)\mathrm{d}t\right)^p\right] \leqslant \frac{2-p}{1-p} E[(\sup_{0\leqslant t\leqslant\tau} X_t)^p] \tag{2.15}$$

for all stopping times τ. Thus, we obtain the following inequalities:

$$\delta^p \frac{1-p}{2-p} E\left[\left(\int_0^t g(t)\mathrm{d}t\right)^p\right] \leqslant E[(\sup_{0\leqslant t\leqslant T} X_t)^p] \leqslant \delta^p \frac{2-p}{1-p} E\left[\left(\int_0^\tau g(t)\mathrm{d}t\right)^p\right] \tag{2.16}$$

for all stopping times τ and all $0<p<1$.

Now, it is not difficult to extend (2.16) to all $0<p<\infty$ by using Lemma 2.3. Indeed, for any couple (S,T) of stopping times S, T with $S\leqslant T$ we have from (2.16) with $p=\frac{1}{2}$,

$$E\left[\sqrt{\int_0^T g(t)\mathrm{d}t}-\sqrt{\int_0^S g(t)\mathrm{d}t}\right]\leqslant E\left[\sqrt{\int_0^{T1_{\{T>S\}}} g(t)\mathrm{d}t}\right]\leqslant \frac{3}{\sqrt{\delta}}E\left[\sqrt{\sup_{0\leqslant t\leqslant T1_{\{T>S\}}} X_t}\right]$$
$$\leqslant \frac{3}{\sqrt{\delta}}E\left[\sqrt{\sup_{0\leqslant t\leqslant T} X_t}1_{\{T>S\}}\right]\leqslant \left\|\frac{9}{\delta}X_T^*\right\|_\infty^{1/2} P(T>S)$$

and

$$E\left[\sqrt{\sup_{0\leqslant t\leqslant T} X_t}-\sqrt{\sup_{0\leqslant t\leqslant T} X_s}\right]\leqslant E\left[\sqrt{\sup_{S\leqslant t\leqslant T}|X_t-X_S|1_{\{S<T\}}}\right]=E\left[\sqrt{\sup_{0\leqslant t\leqslant (T-S)1_{\{S<T\}}}|X_{t+S}-X_S|}\right]$$
$$\leqslant 3\sqrt{\delta}E\left[\sqrt{\int_0^{T1_{\{T>S\}}} g(t)\mathrm{d}t}\right]\leqslant \left\|9\delta\int_0^T g(t)\mathrm{d}t\right\|_\infty^{1/2} P(S<T).$$

Combining these with Lemma 2.3, we obtain the inequalities (2.12).

The Perron-Frobenius operators, invariant measures and representations of the Cuntz-Krieger algebras

Katsunori Kawamura[a)]
Research Institute for Mathematical Sciences, Kyoto University, Kyoto 606-8502, Japan

(Received 6 May 2005; accepted 17 June 2005; published online 11 August 2005)

For a transformation F on a measure space (X,μ), we show that the Perron-Frobenius operator of F can be written by a representation $(L_2(X,\mu),\pi)$ of the Cuntz-Krieger algebra $\mathcal{O}_A$ associated with F when F satisfies some assumption. Especially, when $\mathcal{O}_A$ is the Cuntz algebra $\mathcal{O}_N$ and $(L_2(X,\mu),\pi)$ in the above is some irreducible representation of $\mathcal{O}_N$, then there is an F-invariant measure on X which is absolutely continuous with respect to μ. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2000209]

I. INTRODUCTION

The representation theory of groups is an important tool for modern physics. For a family of invertible transformations, such method is useful. On the other hand, transformations in dynamical systems are not always invertible. We show a relation between the theory of dynamical systems and the representation theory of operator algebras by the Perron-Frobenius operator. Invariant measures (especially, Haar measures) play an important role in the representation theory of Lie groups and harmonic analysis. On the other hand, invariant measures of noninvertible transformations are studied in Refs. 7–9 by the Perron-Frobenius operators of dynamical systems. By using the Perron-Frobenius operators, the characterization of a given dynamical system and the construction of invariant measure are obtained. We show their roles in representation theory of operator algebras in this paper.

Let $L_p(X,\mu)$ be the set of all complex-valued measurable functions ϕ on a measure space (X,μ) satisfying $\|\phi\|_{L_p}<\infty$ and let $L_p(X,\mu;\mathbf{R})$ be the subset of all real-valued functions in $L_p(X,\mu)$ for $p=1,2,\infty$. For a nonsingular transformation F on X, that is, $\mu(F^{-1}(A))=0$ if $\mu(A)=0$ for $A\subset X$, P_F is the *Perron-Frobenius operator* of F if P_F is the operator on $L_1(X,\mu)$ which satisfies

$$\int_A (P_F\psi)(x)\mathrm{d}\mu(x)=\int_{F^{-1}(A)}\psi(x)\mathrm{d}\mu(x)\quad(\forall\,\psi\in L_1(X,\mu)) \tag{1.1}$$

for each measurable subset A of X.[7] By (1.1), $P_F\psi$ is uniquely determined as an element in $L_1(X,\mu)$ for each $\psi\in L_1(X,\mu)$. For $\psi\in L_1(X,\mu)$ and $\theta\in L_\infty(X,\mu)$, we obtain $\int_X\theta(F(x))\psi(x)\mathrm{d}\mu(x)=\int_X\theta(x)(P_F\psi)(x)\mathrm{d}\mu(x)$. From this, P_F is a bounded linear operator on $L_1(X,\mu)$ and $\|P_F\psi\|_{L_1}\leqslant\|\psi\|_{L_1}$ for each $\psi\in L_1(X,\mu;\mathbf{R})$. Further, a positive function $\rho\in L_1(X,\mu)$ satisfies $P_F\rho=\rho$ if and only if ρ is the density of an *F-invariant measure*, that is, the following holds for any $\psi\in L_1(X,\mu)$:

$$\int_X\psi(F(x))\rho(x)\mathrm{d}\mu(x)=\int_X\psi(x)\rho(x)\mathrm{d}\mu(x). \tag{1.2}$$

In order to describe both the Perron-Frobenius operators and representations of the Cuntz-Krieger algebras simultaneously, we introduce branching function systems on a measure space (X,μ). A family $f=\{f_i\}_{i=1}^N$ of maps on X is a *semibranching function system* if there is a finite family $\{D_i\}_{i=1}^N$ of measurable subsets of X such that f_i is a measurable map from D_i to $R_i \equiv f_i(D_i)$, $\mu(X\backslash R_1\cup\cdots\cup R_N)=0$, $\mu(R_i\cap R_j)=0$ when $i\neq j$ and there is the Radon-Nikodým derivative Φ_{f_i} of $\mu\circ f_i$ with respect to μ and $\Phi_{f_i}>0$ almost everywhere in D_i for $i=1,\ldots,N$. A map F on X is called the *coding map* of a semibranching function system $f=\{f_i\}_{i=1}^N$ if $F\circ f_i=id_{D_i}$ for $i=1,\ldots,N$.

For a semibranching function system $f=\{f_i\}_{i=1}^N$ with the coding map F, define a family $\{S(f_i)\}_{i=1}^N$ of operators on $L_2(X,\mu)$ by

$$(S(f_i)\phi)(x)\equiv\chi_{R_i}(x)\cdot\{\Phi_F(x)\}^{1/2}\cdot\phi(F(x))\quad(\phi\in L_2(X,\mu)),\tag{1.3}$$

where χ_{R_i} is the characteristic function of R_i. Then $S(f_i)$ is a partial isometry and $S(f_i)S(f_j)=S(f_i\circ f_j)$ when $D_j\subset R_i$. For $N\geqslant 2$, let A be an $N\times N$ matrix which consists of elements 0 or 1 and any column and row are not 0. A semibranching function system $f=\{f_i\}_{i=1}^N$ is an *A-branching function system* if $\mu(D_i\backslash\cup_{j;a_{ij}=1}R_j)=0$ for each $i=1,\ldots,N$. For an A-branching function system $f=\{f_i\}_{i=1}^N$,

$$\pi_f(s_i)\equiv S(f_i)\quad(i=1,\ldots,N),\tag{1.4}$$

defines a representation $(L_2(X,\mu),\pi_f)$ of the Cuntz-Krieger algebra $\mathcal{O}_A$.[5]

Mori computed eigenvalues of the Perron-Frobenius operator by algebraic method for a concrete example in Ref. 10. On the other hand, we were interested in construction of representations of the Cuntz algebra by using interval dynamical systems in order to find new examples.[4,5] He pointed out the similarity among his study and ours. Hence we obtain Theorem 1.1 and Theorem 1.2.

Theorem 1.1: *For an A-branching function system $f=\{f_i\}_{i=1}^N$ with the coding map F, the following holds:*

$$(P_F\psi)(x)=\{(\pi_f(s_1^*)\sqrt{\psi})(x)\}^2+\cdots+\{(\pi_f(s_N^*)\sqrt{\psi})(x)\}^2$$

for any positive function $\psi\in L_1(X,\mu)$ where $\sqrt{\psi}(x)\equiv\sqrt{\psi(x)}$.

Theorem 1.2: *Assume that F is the coding map of an A-branching function system $f=\{f_i\}_{i=1}^N$ on a measure space (X,μ) and $b_i\equiv\Phi_{f_i}$ is constant for $i=1,\ldots,N$ and $\mu(X)<\infty$. Then the following holds:*

(i) *Define a subspace $V\equiv\mathrm{Lin}\langle\{\chi_{R_1},\ldots,\chi_{R_N}\}\rangle$ of $L_2(X,\mu)$. Then $P_FV\subset V$ where R_i is the image of f_i.*

(ii) *For a diagonal matrix $B\equiv\mathrm{diag}(b_1,\ldots,b_N)\in M_N(\mathbf{R})$, the following identity of matrices holds:*

$$P_{F|V}=BA,$$

where $P_{F|V}$ is the matrix representation over the basis $\chi_{R_1},\ldots,\chi_{R_N}$ of V and the rhs is the product of matrices.

In Theorem 1.2 (ii), the eigenvalues of the Perron-Frobenius operator associated with F depend on not only A but also B. In this sense, eigenvalues of the Perron-Frobenius operator have the information of a representation of the Cuntz-Krieger algebra.

It is an important problem to construct the invariant measure for a given dynamical system. For example, Lasota-York theorem shows a construction of invariant measure by using the Perron-Frobenius operator of a dynamical system.[8] We show the condition of existence of invariant measure from the viewpoint of representation theory of the Cuntz algebra.

$f=\{f_i\}_{i=1}^N$ is a *branching function system* if $f=\{f_i\}_{i=1}^N$ is an A-branching function system for a matrix $A=(a_{ij})$, $a_{ij}=1$ for each $i,j=1,\ldots,N$. In this case, $(L_2(X,\mu),\pi_f)$ is a representation of the

Cuntz algebra $\mathcal{O}_N$. For $z=(z_i)_{i=1}^N \in S^{N-1} \equiv \{y \in \mathbf{R}^N : \|y\|=1\}$, $(\mathcal{H}, \pi)$ is $GP(z)$ of $\mathcal{O}_N$ (Ref. 6) if there is a unit cyclic vector $\Omega \in \mathcal{H}$ such that

$$\pi(z_1 s_1 + \cdots + z_N s_N)\Omega = \Omega. \tag{1.5}$$

We call Ω by the *GP vector* of $(\mathcal{H}, \pi)$. In this case, there is $g \in O(N) \subset U(N)$ such that $(\pi \circ \alpha_g)(s_1)\Omega = \Omega$ where α is the canonical action of $U(N)$ on $\mathcal{O}_N$. This implies that $(\mathcal{H}, \pi \circ \alpha_g)$ is an irreducible permutative representation of $\mathcal{O}_N$.[1] Hence $GP(z)$ of $\mathcal{O}_N$ exists uniquely up to unitary equivalence and it is irreducible. Further we see that $GP(z) \sim GP(y)$ if and only if $z=y$ where $\sim$ means the unitary equivalence.

Theorem 1.3: *Let F be the coding map of a branching function system f on a measure space (X, μ). If there is $z \in S^{N-1}$ such that $(L_2(X, \mu), \pi_f)$ is $GP(z)$ with the GP vector $\Omega \in L_2(X, \mu; \mathbf{R})$, then there is a probabilistic F-invariant measure ν on X which is absolutely continuous with respect to μ and it is given as follows:*

$$\mathrm{d}\nu(x) \equiv \{\Omega(x)\}^2 \mathrm{d}\mu(x) \quad (x \in X).$$

In Sec. II, we show the main theorems. It is explained that (1.5) implies the eigenequation of the Perron-Frobenius operator. In Sec. III, we show concrete examples.

II. PROOFS OF THE MAIN THEOREMS

For $N \geqslant 2$, let $M_N(\{0,1\})$ be the set of all $N \times N$ matrices such that each element is 0 or 1 and any row and column is not 0. For $A=(a_{ij}) \in M_N(\{0,1\})$, $\mathcal{O}_A$ is the *Cuntz-Krieger algebra by A* if $\mathcal{O}_A$ is a C*-algebra which is universally generated by partial isometries $s_1, \ldots, s_N$ and they satisfy $s_i^* s_i = \Sigma_{j=1}^N a_{ij} s_j s_j^*$ for $i=1, \ldots, N$ and $\Sigma_{i=1}^N s_i s_i^* = I$.[3] Especially, when $a_{ij}=1$ for each $i, j=1, \ldots, N$, $\mathcal{O}_A$ is the *Cuntz algebra* $\mathcal{O}_N$.[2] In this paper, any representation is unital and $*$-preserving.

Proof of Theorem 1.1: By (1.3), the adjoint operator $S(f_i)^*$ of $S(f_i)$ on $L_2(X, \mu)$ is as follows:

$$(S(f_i)^* \phi)(x) = \chi_{D_i}(x) \cdot \{\Phi_{f_i}(x)\}^{1/2} \cdot \phi(f_i(x)) \quad (\phi \in L_2(X, \mu)). \tag{2.1}$$

For the coding map F of a semibranching function system $f=\{f_i\}_{i=1}^N$, we have

$$(P_F \psi)(x) = \sum_{i=1}^N \chi_{D_i}(x) \cdot \Phi_{f_i}(x) \cdot \psi(f_i(x)) \quad (\psi \in L_1(X, \mu)). \tag{2.2}$$

(2.2) is obtained by (1.1).[7] By (2.1), (2.2), and (1.4), the statement holds. ■

Proof of Theorem 1.2: Define $v_i \equiv \chi_{R_i}$ for $i=1, \ldots, N$. By (2.1), $S(f_i)^* v_j = \Sigma_{k=1}^N b_i^{-1/2} c_{ik}^{(j)} v_k$ for $i=1, \ldots, N$ where $c_{ik}^{(j)} = \delta_{ij} b_i a_{ik}$. This implies that $S(f_i)^*|_V = (b_i^{-1/2} c_{jk}^{(i)})$ as a matrix with respect to $v_1, \ldots, v_N$ and $S(f_i)^* V \subset V$. By (2.2), $P_F = b_1^{1/2} S(f_1)^* + \cdots + b_N^{1/2} S(f_N)^*$. Hence the statements hold. ■

Corollary 2.1: Let X be a bounded closed interval of $\mathbf{R}$ and $A \in M_N(\{0,1\})$. Assume that $f=\{f_i\}_{i=1}^N$ is an A-branching function system on X and $b_i \equiv \Phi_{f_i}$ is constant for each $i=1, \ldots, N$. Then the eigenvalue of BA becomes that of P_F for the coding map F of f where $B \equiv \mathrm{diag}(b_1, \ldots, b_N)$.

Proof of Theorem 1.3: Assume that $\Omega \in L_2(X, \mu; \mathbf{R})$ satisfies $\pi_f(z_1 s_1 + \cdots + z_N s_N)\Omega = \Omega$. Define $\rho(x) \equiv \{\Omega(x)\}^2$ for $x \in X$. By Theorem 1.1 and $\pi_f(s_i)^* \Omega = z_i \Omega$, we have $P_F \rho = \rho$. Hence the statement holds. ■

Corollary 2.2: Let X be a measurable subset of $\mathbf{R}$. Assume that a piecewise C^1-class map F on X is the coding map of a branching function system $\{f_i\}_{i=1}^N$ on the measure space $(X, \mathrm{d}x)$ where $\mathrm{d}x$ is the Lebesgue measure. If $\phi_0 \in L_2(X, \mathrm{d}x; \mathbf{R})$ satisfies that

$$\sqrt{|F'(x)|}\,\phi_0(F(x)) = \sqrt{N}\phi_0(x) \quad (a.e.\ x \in X), \tag{2.3}$$

then $\mathrm{d}\mu(x) \equiv \{\phi_0(x)\}^2 \mathrm{d}x$ is an invariant measure on X with respect to F.

Proof: By (1.3) and (1.4), we see that $(\pi_f(s_1 + \cdots + s_N)\phi)(x) = \sqrt{|F'(x)|}\,\phi(F(x))$ for each $\phi \in L_2(X, \mathrm{d}x)$. From this and (2.3), $N^{-1/2} \pi_f(s_1 + \cdots + s_N)\phi_0 = \phi_0$. By Theorem 1.3 for $z=(N^{-1/2}, \ldots, N^{-1/2}) \in S^{N-1}$, the statement holds. ■

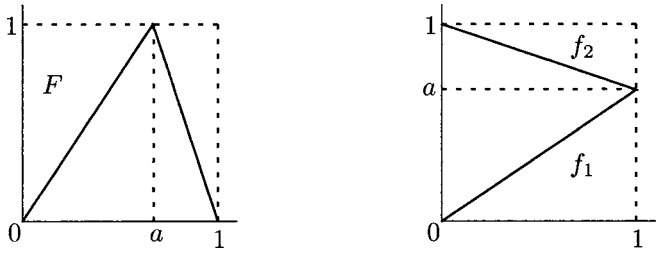
In Sec. 6.5 of Ref. 7, it is explained that intertwiners among dynamical systems bring new invariant measures from known ones. We show its unitary version as follows:

Proposition 2.3: Let F be the coding map of a branching function system $f=\{f_i\}_{i=1}^N$ on a measure space (X,μ). Assume that $(L_2(X,\mu),\pi_f)$ is $GP(z)$ for $z\in S^{N-1}$ with the GP vector $\Omega\in L_2(X,\mu;\mathbf{R})$. If ζ is a measure space isomorphism from (X,μ) to other (Y,ν) and $G\equiv\zeta\circ F\circ\zeta^{-1}$, then $\rho\equiv\{S(\zeta)\Omega\}^2$ is the density of a probabilistic G-invariant measure on Y which is absolutely continuous with respect to ν where $S(\zeta)$ is a unitary operator from $L_2(X,\mu)$ to $L_2(Y,\nu)$ defined by $(S(\zeta)\phi)(y)\equiv\{\Phi_{\zeta^{-1}}(y)\}^{1/2}\phi(\zeta^{-1}(y))$.

Proof: Define $g=\{g_i\}_{i=1}^N$ by $g_i\equiv\zeta\circ f_i\circ\zeta^{-1}$. Then G is the coding map of g. We see that $S(\zeta)\pi_f(\cdot)S(\zeta)^*=\pi_g(\cdot)$ and $\pi_g(z_1s_1+\cdots+z_Ns_N)\Omega'=\Omega'$ for $\Omega'\equiv S(\zeta)\Omega\in L_2(Y,\nu;\mathbf{R})$. Hence $(L_2(Y,\nu),\pi_g)$ is $GP(z)$ with the GP vector Ω'. By Theorem 1.3, we have the statement. ■

III. EXAMPLES

Example 3.1: Let $0<a<1$ and $X\equiv[0,1]$. Define a map F on X by $F(x)\equiv x/a$ on $R_1\equiv[0,a]$ and $F(x)\equiv-(x-1)/(1-a)$ on $R_2\equiv[a,1]$.



Then F is the coding map of a branching function system $f\equiv\{f_1,f_2\}$ defined by $f_i\equiv(F|_{R_i})^{-1}$ for $i=1,2$. Then $(\pi_f(s_1)\phi)(x)=a^{-1/2}\chi_{R_1}(x)\phi(x/a)$, $(\pi_f(s_2)\phi)(x)=(1-a)^{-1/2}\chi_{R_2}(x)\phi(-(x-1)/(1-a))$ for $\phi\in L_2(X,\mathrm{d}x)$.

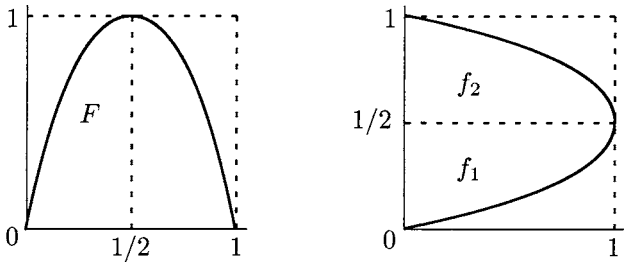
$$(P_F\psi)(x)=a\psi(ax)+(1-a)\psi(-(1-a)x+1)\quad(\psi\in L_1(X,\mathrm{d}x)).$$

We see that Theorem 1.1 holds. The Lebesgue measure $\mathrm{d}x$ is the probabilistic invariant measure of X with respect to F. $(L_2(X,\mathrm{d}x),\pi_f)$ is $GP(\sqrt{a},\sqrt{1-a})$ of $\mathcal{O}_2$ with the GP vector 1. The invariant measure is independent in the parameter a.

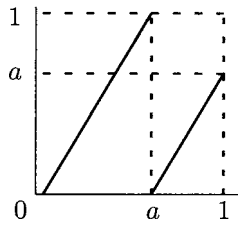
Example 3.2: For $a,b\in\mathbf{R}$, $a\neq0$, define $F(x)\equiv(x-b)^2/a+b-2a$ on $X\equiv[-2|a|+b,2|a|+b]$. Define a branching function system $f=\{f_1,f_2\}$ on X by $f_i\equiv(F|_{R_i})^{-1}$, $i=1,2$ for $R_1\equiv[-2|a|+b,b]$ and $R_2\equiv[b,2|a|+b]$. Then $\pi_f(s_1+s_2)\Omega=\sqrt{2}\Omega$ for $\Omega(x)\equiv\pi^{-1/2}\{4a^2-(x-b)^2\}^{-1/4}$. We see that $(L_2(X),\pi_f)$ is $GP(2^{-1/2},2^{-1/2})$ of $\mathcal{O}_2$ with the GP vector Ω.[4] By Theorem 1.3,

$$p(x)\equiv\frac{1}{\pi}\frac{1}{\sqrt{4a^2-(x-b)^2}}$$

is the density of a probabilistic invariant measure on X with respect to F. When $a=-1/4$ and $b=1/2$, we have $F(x)=4x(1-x)$ and $\rho(x)=1/(\pi\sqrt{x(1-x)})$. This was first obtained by Ulam and von Neumann.[11]



Example 3.3: For $0<a<1$, define a map $F:[0,1]\to[0,1]$ as follows:



Define $R_1\equiv[0,a]$, $R_2\equiv[a,1]$, $D_1\equiv[0,1]$, $D_2\equiv[0,a]$. Then F is the coding map of the following $A=\left(\begin{smallmatrix}1&1\\1&0\end{smallmatrix}\right)$-branching function system on $X=[0,1]$: $f_i:D_i\to R_i$, $f_1(x)=ax$ for $x\in[0,1]$ and $f_2(x)=(1-a)x/a+a$ for $x\in[0,a]$. Define $v_1\equiv\chi_{[0,a]}$, $v_2\equiv\chi_{[a,1]}$, $V\equiv\mathrm{Lin}\langle\{v_1,v_2\}\rangle$. By Theorem 1.2, the matrix representation of P_F with respect to v_1, v_2 is given as follows:

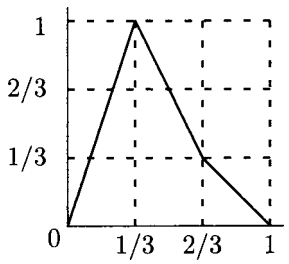
$$P_{F|V}=\begin{pmatrix}a & (1-a)/a\\ a & 0\end{pmatrix}.$$

Hence its eigenvalues are $a-1$ and 1. Their normalized eigenvectors are given as follows:

$$w_1=\sqrt{\frac{1-a}{a}}\chi_{[0,a]}-\sqrt{\frac{a}{1-a}}\chi_{[a,1]},\quad w_2=\frac{1}{\sqrt{a(1+a-a^2)}}(\chi_{[0,a]}+a\chi_{[a,1]}).$$

Especially $(w_2)^2$ is the density of the invariant measure on [0,1] with respect to F.

Example 3.4: Let F be a map defined by the following graph:



Define

$$A\equiv\begin{pmatrix}1&1&1\\0&1&1\\1&0&0\end{pmatrix},$$

$B\equiv\mathrm{diag}(1/3,1/2,1)$, $R_1\equiv[0,1/3]$, $R_2\equiv[1/3,2/3]$, $R_3\equiv[2/3,1]$, $D_1\equiv[0,1]$, $D_2\equiv[1/3,1]$, $D_3\equiv[0,1/3]$. The A-branching function system $f=\{f_1,f_2,f_3\}$, $f_i:D_i\to R_i$, $i=1,2,3$, with the coding map F is given by $f_1(x)=x/3$, $f_2(x)=-(x-1)/2+1/3$, $f_3(x)=-x+1$. From this and Theorem 1.2 (ii), $P_F|_W=BA$ where $W\equiv\mathrm{Lin}\langle\{\chi_{R_1},\chi_{R_2},\chi_{R_3}\}\rangle$. We see that 0, $-1/6$, 1 are eigenvalues of $P_F|_W$. Hence they are eigenvalues of P_F.

Example 3.5: For $A\in M_N(\{0,1\})$ and an A-branching function system $f=\{f_i\}_{i=1}^N$ on a measure

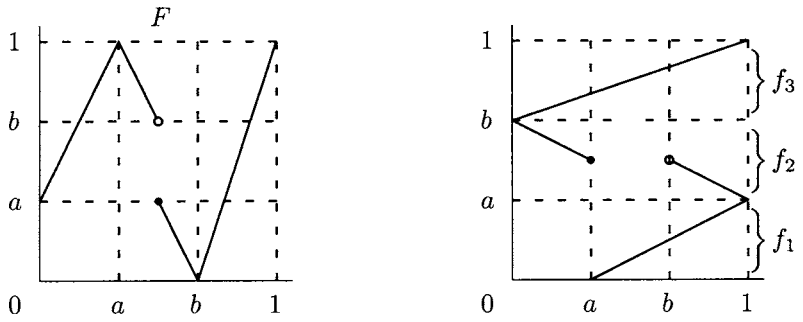
space (X,μ), $\mu(X)<\infty$, assume that $b_i \equiv \Phi_{f_i}$ is constant for each $i=1,\ldots,N$. Then $b_i = r_i/(\Sigma_{j=1}^{N} a_{ij} r_j)$ where $r_i \equiv \mu(R_i)$. When

$$A \equiv \begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 1 \end{pmatrix},$$

we have

$$B = (b_1, b_2, b_3) = \mathrm{diag}\left(\frac{r_1}{r_2 + r_3}, \frac{r_2}{r_1 + r_3}, \frac{r_3}{r_1 + r_2 + r_3} \right).$$

For $0<a<b<1$, consider the case F on $X=[0,1]$ which graph is given as follows:



F is the coding map of an A-branching function system given as follows: $f_i : D_i \to R_i$, $i=1,2,3$,

$$\begin{cases} f_1(x) = \dfrac{a}{1-a}(x-a) \quad (x \in D_1), \\ f_2(x) = \begin{cases} -\dfrac{b-a}{1-b+a}x + b, & (x \in R_1), \\ -\dfrac{b-a}{1-b+a}(x-1) + a & (x \in R_3), \end{cases} \\ f_3(x) = (1-b)x + b \quad (x \in [0,1]), \end{cases}$$

where $R_1 \equiv [0,a]$, $R_2 \equiv [a,b]$, $R_3 \equiv [b,1]$, $D_1 \equiv [a,1]$, $D_2 \equiv [0,a] \cup (b,1]$, $D_3 \equiv [0,1]$. From these, we have $B = \mathrm{diag}(a/(1-a), (b-a)/(1-b+a), 1-b)$.

Darboux transformations for Schrödinger equations in two variables

Mayer Humi
Department of Mathematical Sciences, Worcester Polytechnic Institute, Worcester, Massachusetts 01609

(Received 7 June 2005; accepted 17 June 2005; published online 11 August 2005)

Darboux transformations in one variable form the basis for the factorization methods and have numerous applications to geometry, nonlinear equations and SUSY quantum mechanics. In spite of this wide range of applications the theory of Darboux transformations in two variables and its elegant relationship to analytic complex functions has not been recognized in the literature. To close this gap we develop in this paper the theory of Darboux transformation in the context of Schrödinger equations in two variables. This yields a constructive algorithm to determine the relationship between potential functions which are related by Darboux transformations. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2000727]

I. INTRODUCTION

For over half a century Darboux transformations in one independent variable have found numerous application in various field of mathematics and physics.[1–4] (References 1 and 2 contain an extensive list of references.) In particular the factorization method[5,6] and its generalizations[7–11] which have been instrumental in many physical applications [including SUSY quantum mechanics (QM)[12]] has its roots based on these transformations. Recently however these transformations were generalized and applied to systems of nonlinear equations such as the KdV hierarchy and others.[13] In addition various applications of this method in geometry were worked out and form an important ongoing research area.[2] Extensions of the method to multidimensional oriented Riemann manifolds,[14] time dependent potentials[15] and shape invariant potentials[16] have appeared in the literature.

It is surprising that in spite of this extensive research effort the theory of these transformations in two variables and its elegant relationship to complex analytic function theory has not been worked out (as far as we could ascertain). An exception is the recent paper by Demircioglu *et al.*[17] which considered these transformations under some additional constraints using real variables and polar coordinates. However under these additional constraints only partial results were obtained and the relationship between these transformations and analytic complex functions was lost.

We now give a short overview of Darboux transformations for Schrödinger equation in one variable.

We say that the solutions of two Schrödinger equations with different potentials $u(x)$, $v(x)$, i.e.,

$$\phi'' = (u(x) + \lambda)\phi, \tag{1.1}$$

$$\psi'' = (v(x) + \lambda)\psi, \tag{1.2}$$

are related by a Darboux transformation if there exist $A(x)$, $B(x)$ so that

$$\psi = \left[A(x) + B(x)\frac{\partial}{\partial x} \right] \phi(x). \tag{1.3}$$

Letting $B(x)=1$ one can easily show that in order for Eqs (1.1) and (1.2) to be related by the transformation (1.3) $A(x)$, $u(x)$, $v(x)$ must satisfy

$$A'' + u' + A(u - v) = 0, \tag{1.4}$$

$$2A' + u - v = 0. \tag{1.5}$$

Eliminating $(u-v)$ between these equations and integration yields

$$A' - A^2 + u = -\nu, \tag{1.6}$$

where ν is an integration constant. Equation (1.6) is a Riccati equation which can be linearized by the transformation $A=-\zeta'/\zeta$ which leads to

$$\zeta'' = (u(x) + \nu)\zeta. \tag{1.7}$$

Thus ζ is an eigenfunction of the original Eq. (1.2) with $\lambda=\nu$. From (1.5) we now infer that

$$v = u - 2(\ln \zeta)'', \tag{1.8}$$

i.e., a Darboux transformation changes the potential function $u(x)$ by $\Delta u=-2(\ln \zeta)''$ where ζ is an arbitrary eigenfunction of (1.1).

Our objective in this paper is to generalize these transformations to Schrödinger equations in two independent variables and determine the relationship between their potentials. From a broader point of view the goal of this project is to derive for two dimensional nonseparable potentials results similar to those that followed from the application of Darboux transformations and the factorization method in one dimension. That is an enumeration of physically important potentials which can be treated and solved by these transformations. This program includes the exploration of the Lie algebraic structure underlying these potentials and may lead to the definition of generic families of "special functions" in two variables. (That is, functions which cannot be expressed as a finite sum of products of functions in one variable.) The present paper represents the first step towards achieving these objectives.

The plan of the paper is as follows: In Sec. II we derive the basic equations that constrain Darboux transformations in two variables and their solutions. In Secs. III and IV we construct explicitly some Darboux transformations and their related potentials. In Sec. V we consider potential cascades whose functional form is preserved under these transformations. We end up in Sec VI with summary and conclusions.

II. DARBOUX TRANSFORMATIONS IN TWO VARIABLES

We shall say that two Schrödinger equations in two independent variables

$$\nabla^2 \phi = u(x,y,\lambda)\phi, \tag{2.1}$$

$$\nabla^2 \psi = v(x,y,\lambda)\psi, \tag{2.2}$$

are related by a Darboux transformation if there exist (smooth functions) $A(x,y)$, $B(x,y)$, $C(x,y)$ so that their solutions satisfy

$$\psi(x,y) = \left[A(x,y) + B(x,y)\frac{\partial}{\partial x} + C(x,y)\frac{\partial}{\partial y} \right] \phi(x,y). \tag{2.3}$$

For brevity we drop in the following the dependence of the various functions on the independent variables.

Using Eq. (2.3) to substitute for ψ in Eq. (2.2) and eliminating the higher order derivatives of ϕ and $\partial^2\phi/\partial y^2$ using Eq. (2.1) we obtain

$$\left[-2\frac{\partial C}{\partial y}+2\frac{\partial B}{\partial x}\right]\frac{\partial^2\phi}{\partial x^2}+\left[2\frac{\partial B}{\partial y}+2\frac{\partial C}{\partial x}\right]\frac{\partial^2\phi}{\partial x\,\partial y}+\left\{\nabla^2 C+2\frac{\partial A}{\partial y}+C[u-v]\right\}\frac{\partial\phi}{\partial y}$$
$$+\left\{\nabla^2 B+2\frac{\partial A}{\partial x}+B[u-v]\right\}\frac{\partial\phi}{\partial x}+\left\{\nabla^2 A+2\frac{\partial C}{\partial y}u+A[u-v]+B\frac{\partial u}{\partial x}+C\frac{\partial u}{\partial y}\right\}\phi=0. \tag{2.4}$$

To satisfy this equation we treat ϕ and its derivatives as independent variables and let their coefficients be zero. This leads then to the following system of equations:

$$\frac{\partial B}{\partial x}-\frac{\partial C}{\partial y}=0, \tag{2.5}$$

$$\frac{\partial B}{\partial y}+\frac{\partial C}{\partial x}=0, \tag{2.6}$$

$$\nabla^2 B+2\frac{\partial A}{\partial x}+B[u-v]=0, \tag{2.7}$$

$$\nabla^2 C+2\frac{\partial A}{\partial y}+C[u-v]=0, \tag{2.8}$$

$$\nabla^2 A+A[u-v]+2\frac{\partial C}{\partial y}u+B\frac{\partial u}{\partial x}+C\frac{\partial u}{\partial y}=0. \tag{2.9}$$

We observe that Eq. (2.9) can be rewritten in a symmetric form in B, C in view of Eq. (2.5).

Equations (2.5) and (2.6) are Cauchy-Riemann equations for B, C. Hence these functions must be harmonic conjugates and

$$\Phi=B+iC \tag{2.10}$$

is analytic. In view of this fact $\nabla^2 C=\nabla^2 B=0$ and Eqs. (2.7) and (2.8) simplify to

$$2\frac{\partial A}{\partial x}+B[u-v]=0,\quad 2\frac{\partial A}{\partial y}+C[u-v]=0. \tag{2.11}$$

By eliminating $u-v$ we then get the following equation for A:

$$C\frac{\partial A}{\partial x}-B\frac{\partial A}{\partial y}=0. \tag{2.12}$$

This leads us to consider the following equation:

$$B\,\mathrm{d}x+C\,\mathrm{d}y=0. \tag{2.13}$$

Although this equation is not exact an integrating factor is given by $1/(B^2+C^2)$. (This fact follows from Cauchy-Riemann equations for B, C.) The general solution of this equation can be expressed therefore by the standard formula

$$w(x,y)=\int_{x_0}^{x}\frac{B(x,y)}{B(x,y)^2+C(x,y)^2}\mathrm{d}x+\int_{y_0}^{y}\frac{C(x_0,y)}{B(x_0,y)^2+C(x_0,y)^2}\mathrm{d}y. \tag{2.14}$$

It follows then that the general solution for A is of the form $A=f(w)$ where f is any smooth function of w.

To treat Eq. (2.9) we use Eq. (2.7) to eliminate $u-v$. This leads to

$$B\frac{\partial u}{\partial x}+C\frac{\partial u}{\partial y}+2\frac{\partial C}{\partial y}u=-\nabla^2 A+\frac{2A\dfrac{\partial A}{\partial x}}{B}. \tag{2.15}$$

This equation can be used now to determine u for a proper choice of the function $f(w)$. To proceed we now note that [using Eq. (2.14)]

$$-\nabla^2 A+\frac{2A\dfrac{\partial A}{\partial x}}{B}=\frac{1}{B^2+C^2}[-f'+f^2]'. \tag{2.16}$$

Hence we set

$$[-f'+f^2]'=g'(w), \tag{2.17}$$

where $g(w)$ is some smooth function. As a result we are led to the following equation for $f(w)$:

$$f'-f^2+g(w)=0. \tag{2.18}$$

[We are not adding a constant of integration since $g(w)$ is arbitrary.] This is a Riccati equation which can be linearized by the transformation $f=-q'/q$ and this leads to

$$q''-g(w)q=0. \tag{2.19}$$

Since we want to consider only analytic solutions to this equation which can be expressed in terms of known functions the function $g(w)$ must be chosen appropriately. In particular $g(w)$ can be chosen so that Eq. (2.19) is factorizable.[5] Here we consider only three possible choices for $g(w)$,

(1) $g(w)=\text{constant}=c$. If c is negative $c=-\alpha^2$ then $q=D\cos(\alpha w+\eta)$ where D, η are constants. Hence $f=\alpha\tan(\alpha w+\eta)$. If on the other hand $c=0$ then $q=Dw+E$ (E is a constant) and hence $f=-D/(Dw+E)$. Finally if c is positive $c=\alpha^2$ then $q=D\cosh(\alpha w+\eta)$ and $f=-\alpha\tanh(\alpha w+\eta)$.

(2) $g(w)=w^2-(2n+1)$, $n=0, 1,\ldots$. (This is the kernel of the differential equation for the harmonic oscillator.) For $n=0$ this leads to $f=w$ while for $n>0$ we obtain $f=w-[2nH_{n-1(w)}/H_n(w)]$, where $H_n(w)$ are Hermite functions.

(3) $g(w)=n(n-1)/w^2$, $n=2, 3,\ldots$. In this case Eq. (2.19) is a Euler equation and $q=w^n$ or $q=w^{-(n-1)}$. In either case this leads to $f\sim 1/w$.

We observe that different choices of $g(w)$ can lead to the same $f(w)$.

Having made a choice for $g(w)$ Eq. (2.15) becomes

$$B\frac{\partial u}{\partial x}+C\frac{\partial u}{\partial y}+2\frac{\partial C}{\partial y}u=\frac{g'}{B^2+C^2}. \tag{2.20}$$

To find the general solution to this equation we must find two independent solutions to the system,

$$\frac{dx}{B} = \frac{dy}{C} = \frac{-du}{2u\dfrac{\partial C}{\partial y} - \dfrac{g'}{B^2 + C^2}}. \tag{2.21}$$

The first equality in this equation leads to

$$C\,dx - B\,dy = 0. \tag{2.22}$$

Once again this equation is not exact but an integrating factor is given by $1/(B^2+C^2)$ and the solution of the equation $w_1(x,y)$ can be expressed then by a standard formula similar to Eq. (2.14). Using w_1 we can eliminate x or y from the second equation in (2.21) and find a solution $w_2(u,y)$. The function u is given then implicitly by any smooth function $F(w_1,w_2)=0$. Once u has been determined v can be computed from Eq. (2.7) or (2.8).

To summarize the procedure, one starts by choosing an analytic function $\Phi=B+iC$ then computes w using Eq. (2.14). For a proper choice of $g(w)$ one computes $A=f(w)$ from Eq. (2.19). The determination of u (and hence v) requires then the solution of Eqs. (2.20) and (2.21). We note however that instead of choosing the function g one can choose u so that the left-hand side of Eq. (2.20) multiplied by B^2+C^2 is a function of w only. This will determine g' and hence A from Eq. (2.18).

In the following section we work out this procedure for the (complex) functions $\Phi=z^n$ and $\Phi=iz^n$.

III. DARBOUX TRANSFORMATIONS WITH $\Phi=z^n$

A. $n\neq 1$

In this case $B=r^n\cos(n\theta)$ and $C=r^n\sin(n\theta)$ hence it is expedient to work in polar coordinates. Equation (2.12) becomes

$$(C\cos\theta - B\sin\theta)\frac{\partial A}{\partial r} - \frac{1}{r}(C\sin\theta + B\cos\theta)\frac{\partial A}{\partial \theta} = 0. \tag{3.1}$$

For the present choice of B, C this yields

$$\sin[(n-1)\theta]\frac{\partial A}{\partial r} - \frac{1}{r}\cos[(n-1)\theta]\frac{\partial A}{\partial \theta} = 0. \tag{3.2}$$

From Eq. (2.14) we then find that

$$w = -\frac{\cos[(n-1)\theta]}{(n-1)r^{(n-1)}}. \tag{3.3}$$

Choosing $g(w)=0$ in Eq. (2.17) we find that $A=f(w)=-D/(Dw+E)$. (In the following we let $D=1$, $E=0$.) Equation (2.20) for u becomes

$$r\frac{\partial u}{\partial r} + \tan[(n-1)\theta]\frac{\partial u}{\partial \theta} + 2nu = 0. \tag{3.4}$$

The general solution of this equation is given implicitly by

$$F\left(r^{2n}u, \frac{r^{(n-1)}}{\sin[(n-1)\theta]}\right) = 0$$

where F is a smooth function. For example, if $F(w_1,w_2)=w_1-w_2$ then

$$u = \frac{1}{r^{(n+1)} \sin[(n-1)\theta]}. \tag{3.5}$$

Using Eq. (2.7) to compute $u-v=-2f'(w)/(B^2+C^2)$ we find for the present choice of f,

$$u - v = -\frac{2(n-1)^2}{r^2 \cos^2[(n-1)\theta]}. \tag{3.6}$$

B. $n=1$

In this case $B=x$ and $C=y$. Hence from Eq. (2.14) we deduce that $w=\ln r$ and $A=f(w)$. [Since f is arbitrary we could have written this relation as $A=f(r)$ but this will change the expression for $\nabla^2 A$ in Eq. (2.15)]. Equation (2.15) with the left-hand side reexpressed in polar coordinates becomes

$$r\frac{\partial u}{\partial r} + 2u = \frac{g'(w)}{r^2}. \tag{3.7}$$

We conclude then that in this case u is given by

$$u = \frac{G(\theta)}{r^2} + \frac{1}{r^2}\int \frac{g'(w)}{r} \mathrm{d}r, \tag{3.8}$$

where $G(\theta)$ is a smooth function and $u-v=-2[f'(w)/r^2]$.

IV. DARBOUX TRANSFORMATIONS WITH $\Phi=iz^n$

A. $n\neq 1$

For this choice of Φ we have $B=-r^n \sin(n\theta)$, $C=r^n \cos(n\theta)$ and the roles of B, C have been (essentially) exchanged. In this case w is given by

$$w = \frac{\sin[(n-1)\theta]}{(n-1)r^{(n-1)}} \tag{4.1}$$

and $A=f(w)$. The equation for u with $g'(w)=0$ becomes

$$r\frac{\partial u}{\partial r} - \cot[(n-1)\theta]\frac{\partial u}{\partial \theta} + 2nu = 0 \tag{4.2}$$

whose general solution is of the form

$$F\left(r^{2n}u, \frac{r^{(n-1)}}{\cos[(n-1)\theta]}\right) = 0, \tag{4.3}$$

where $F(w_1, w_2)$ is a smooth function. If we let $f(w)=-1/w$ then

$$u - v = -\frac{2(n-1)^2}{r^2 \sin^2[(n-1)\theta]}. \tag{4.4}$$

B. $n=1$

In this case $B=-y$ and $C=x$. Hence $w=\theta$, $A=f(\theta)$ and the equation for u in polar coordinate is

$$\frac{\partial u}{\partial \theta} = \frac{g'(w)}{r^2}. \tag{4.5}$$

Hence

$$u = \frac{g(\theta)}{r^2} + G(r) \tag{4.6}$$

and $u-v=-2f'(\theta)/r^2$.

V. CASCADES

One of the important (and interesting) features of the factorization method in one independent variable is that the application of the ladder operator (or equivalently a Darboux transformation) on a potential $u(x)$ leads to potentials with the same dependence on x but with different parameters. As a result one can apply these operators on "essentially the same potential" a finite or infinite number of times creating a cascade of potentials whose solutions are interrelated by Darboux transformations.

To explore the existence of such cascades in two independent variables we shall assume that $\beta(u-v)=u$. Using this relation to substitute in Eq. (2.7) we obtain

$$u = -\frac{2\beta\dfrac{\partial A}{\partial x}}{B}. \tag{5.1}$$

Substituting this expression for u in Eq. (2.9) and using Eqs. (2.5) and (2.12) to simplify we infer that A must satisfy

$$(2\beta-1)\nabla^2 A + \frac{2A\dfrac{\partial A}{\partial x}}{B} = 0 \tag{5.2}$$

and therefore [since $A=f(w)$]

$$[(2\beta-1)f'(w) + f^2(w)]' = 0. \tag{5.3}$$

Hence

$$(2\beta-1)f'(w) + f^2(w) = c, \tag{5.4}$$

where c is a constant. We deduce then (following the discussion in Sec. II of a similar equation) that $f(w)$ can take any of the following forms:

(1) $c=0$ then $f(w)=(2\beta-1)/(w+c_1)$,
(2) $c=\gamma^2$ then $f(w)=\gamma\tanh[(\gamma w+c_2)/(2\beta-1)]$,
(3) $c=-\gamma^2$ then $f(w)=-\gamma\tan[(\gamma w+c_3)/(2\beta-1)]$.

[We assumed that $2\beta\neq 1$ since otherwise $f(w)=$constant.] Here c_1, c_2, c_3 are arbitrary constants and the corresponding potential u can be computed from Eq. (5.1).

For $c=c_1=0$ and $\Phi=z^n(n\neq 1)$ this leads to

$$u = \frac{2\beta(2\beta-1)(n-1)^2}{r^2\cos^2[(n-1)\theta]}. \tag{5.5}$$

Similarly for $\Phi=iz^n$ it follows that

$$u = \frac{2\beta(2\beta-1)(n-1)^2}{r^2 \sin^2[(n-1)\theta]}. \tag{5.6}$$

Similar but more complicated expressions can be obtained for the other choices of c.

For $n=1$ we infer from Eqs. (3.8) and (4.6) that cascades exist but the corresponding potentials are essentially in one variable. In particular for $\Phi=iz$ Eq. (4.6) implies that a cascade exists when $G(r)=0$ and

$$g(\theta) = -2\beta f'(\theta). \tag{5.7}$$

Substituting this relation in eq. (2.18) it follows that

$$(1-2\beta)f'(\theta) - f^2(\theta) = 0 \tag{5.8}$$

and therefore $f(\theta)=-[(1-2\beta)/(\theta+c_4)]$ where c_4 is a constant.

VI. SUMMARY AND CONCLUSIONS

In this paper we showed that Darboux transformations in two independent variables have strong affinity to the theory of analytic complex functions. This relationship enabled us to analyze these transformations in full. It allowed us also to give a constructive algorithm for the application of these transformations. This algorithm was used to make a partial classification of Darboux transformations for two classes of analytic functions and their related potentials. Further (exhaustive) enumeration of other potential functions especially those that related to the factorization method through Eq. (2.19) [by the choice of the function $g(w)$] is needed. Moreover it will be important to identify classes of physically interesting nonseparable potentials in two variables and find out if they are amenable to treatment by Darboux transformations through the application of Eq. (2.20). We discussed also the existence of potential cascades whose form is preserved under these transformations. However there are other possible definitions of this property, e.g., $u-v$ =constant. The differential equations that correspond to these cascades are the exact analogs of factorizable equations in one dimension and their algebraic structure from group theoretical point of view remains an important open question.

Consistent tensor products on auxiliary spaces, hereafter denoted "fusion procedures," and commuting transfer matrices are defined for general quadratic algebras, nondynamical and dynamical, inspired by results on reflection algebras. Applications of these procedures then yield integer-indexed families of commuting Hamiltonians. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2007587]

I. INTRODUCTION

A procedure to construct commuting quantum traces for a particular form of quadratic exchange algebras, known as reflection algebra,[1] was recently developed in Ref. 2, building on the pioneering work in Ref. 3. We recall that it entails three different steps, construction of the quadratic exchange algebra itself, and its so-called "dual" (this notion will be clarified soon); construction of realizations of the exchange algebra and its dual on consistent tensor products of the initial auxiliary space (which we will denote here as "fusion" procedure) while keeping a single "quantum" Hilbert space on which all operators are assumed to act; combination of these realizations into traces over the tensorized auxiliary spaces, yielding commuting operators acting on the original quantum space, labeled by the integer set of tensorial powers of the auxiliary space.

We immediately insist that this procedure is distinct of, and in a sense complements, the familiar construction of transfer matrices by tensoring over distinct quantum spaces (using an appropriate comodule structure of the quantum algebra) while keeping a single common auxiliary space; the trace is then taken over the auxiliary space to yield a generating functional of commuting operators.[4] In the case when there exists a universal formulation of the algebra as a bialgebra with a coproduct structure, both constructions stem from two separate applications of this coproduct. However, the resulting operators are quite distinct, the trace of the monodromy matrix yields commuting operators acting on a tensor product of Hilbert spaces (as in, e.g., the case of spin chains); the trace of the fused auxiliary matrix yields operators acting on one single Hilbert space. These can be shown in some particular cases to realize the quantum analog of the classical Poisson-commuting traces of powers of the classical Lax-matrix $\mathrm{Tr}(L^n)$ (see Refs. 2, 5, and 6). This is the reason for our phrasing of "quantum traces" actually borrowed from Ref. 7. In addition it must be emphasized that the procedure itself, combining a construction of a "dual" algebra and

[d]Electronic mail: rollet@ptm.u-cergy.fr

the establishing of exact fusion formulas, yields very interesting results on the quadratic exchange algebra itself, and its possible identification as a coalgebra (e.g., Hopf or quasi-Hopf). As we will later comment, it also plays a central role in the (similarly named) Mezincescu-Nepomechie fusion constructions for spin chains.[8,9]

A word of caution is in order. Throughout the paper, we use the term "fusion" in a restrictive sense, insofar as we only consider the possibility of acting on auxiliary spaces. The general fusion procedure itself has been applied also to the quantum spaces, yielding, e.g., higher spin interactions[10] or multiparticle bound states S matrices.

Our purpose here is to fully describe the quantum trace procedure for three types of general quadratic algebras. The first one is the quantum nondynamical quadratic exchange algebra introduced in Ref. 3. The second one was formulated in Ref. 11 as a dynamical version of the quadratic exchange algebras in Ref. 3 with particular zero-weight conditions. It will be denoted "semidynamical" here, for reasons to be explained later. The third one (similarly denoted here as "fully dynamical") was first built in Ref. 12 for the $\mathfrak{sl}(2)$ case, and extended to the $\mathfrak{sl}_n$ case in Ref. 13, albeit with particular restrictions on the coefficient matrices. The zero-weight conditions are different; the algebra structure itself mimicks the reflection algebra introduced by Cherednik and Sklyanin in Ref. 1; a comodule structure was identified and a universal structure was proposed in Ref. 14. We will here briefly comment on the differences between the quantum traces built in both dynamical cases.

II. NONDYNAMICAL QUADRATIC ALGEBRAS

These algebras were recognized[1,7] as generalizations of the usual R-matrix and quantum group structure, leading to non skewsymmetrical r-matrices in the quasiclassical limit.

They are characterized by the following exchange relations:

$$A_{12}T_1B_{12}T_2 = T_2C_{12}T_1D_{12}, \tag{1}$$

where, as usual, the quantum generators sit in the matrix entries of T. Let us recall some examples of this structure.

(i) The Yangian and quantum group structures where $A=D$, $B=C=\mathbf{1}$.
(ii) Donin-Kulish-Mudrov (DKM) reflection algebra without spectral parameters.[15] $A=C$, $B=D=A^{\pi}$, where $(\,)^{\pi}$ denotes the permutation of auxiliary spaces, $(A^{\pi})_{12}=A_{21}$.
(iii) Kulish-Sklyanin-type reflection algebra containing spectral parameters,[2,16] $A=R^{-}_{12}$, $B=R^{+}_{21}$, $C=R^{+}_{12}$, $D=R^{-}_{21}$ ($\pm$ signs refer to the relative signs of spectral parameters in the R-matrix).

In Refs. 3 and 17 consistency relations involving the structure matrices were derived and it was found that they had the form of cubic relations on the matrices A,B,C,D,

$$A_{12}A_{13}A_{23} = A_{23}A_{13}A_{12}, \tag{2}$$

$$A_{12}C_{13}C_{23} = C_{23}C_{13}A_{12}, \tag{3}$$

$$D_{12}D_{13}D_{23} = D_{23}D_{13}D_{12}, \tag{4}$$

$$D_{12}B_{13}B_{23} = B_{23}B_{13}D_{12}. \tag{5}$$

We can see that A and D obey the usual YB equations whereas C and B are their respective representations.

Furthermore, generalized unitarity conditions can be derived from self-consistency of (1) under exchange of spaces 1 and 2 which imposes

$$A_{12} = \alpha A_{21}^{-1}, \quad D_{12} = \beta D_{21}^{-1}, \quad B_{12} = \gamma C_{21} \quad (\alpha, \beta, \gamma \in \mathbb{C}). \tag{6}$$

The constants of proportionality must obey an additional constraint, $\alpha\gamma = \beta\gamma^{-1}$. In the sequel, we will restrict ourselves to the simplest choice of $\alpha = \beta = \gamma = 1$.

Let us also note that although $B_{12} = C_{21}$, for aesthetical and mnemotechnical reasons we continue to use C whenever it allows for the more familiar and significant (12, 13, 23) display of indices.

In Ref. 3 the authors had already introduced an algebra which they called "dual" to (1). This "dual" structure is characterized by the following exchange relation,

$$(A_{12}^{-1})^{t_1 t_2} K_1 ((B_{12}^{t_1})^{-1})^{t_2} K_2 = K_2 ((C_{12}^{t_2})^{-1})^{t_1} K_1 (D_{12}^{t_1 t_2})^{-1}. \tag{7}$$

Two respective representations of (1) and (7) (assumed to act on different quantum spaces) can be combined by means of a trace[3,8,16] on the common auxiliary space to generate commuting quantum operators. It is with respect to this trace that Eq. (7) can be characterized as the dual of Eq. (1). We formulate the conjecture that this is the trace of a $*$-algebra structure on some underlying universal algebra. Some freedom remains as to the actual form of the trace and in the sequel we will stick to the choice of H as $\mathrm{Tr}_V(K^t T)$. Here the superscript t stands for any antimorphism on the auxiliary space V, which satisfies also the trace invariance property $\mathrm{Tr}(KT) = \mathrm{Tr}(K^t T^t)$, for all matrices K and T. The actual antimorphism may differ from the usual transposition (e.g., by additional conjugation, crossing operation) since the proof of commutation uses only (see theorems 5, 6, and 14) the antimorphism and trace invariance properties (see, e.g., the supertransposition in superalgebras, or the crossing operation in R-matrices). Let us also remark here that it is possible to choose a trace formula where the antimorphism acts on the quantum space, as it is the case in Ref. 2, but we prefer not to do so here. Our particular choice is motivated by the fact that transposition on the auxiliary space is always defined whereas on the quantum space it is not necessarily straightforward and could require a supplementary hypothesis on this quantum representation which may not be easily implemented.

The quantum trace formulation for such a nondynamical algebra stems from the results in Refs. 2 and 3; it is however interesting to give a rather detailed derivation of it in the general case, since both dynamical algebras will present similar features, albeit with crucial modifications in the fusion and trace formulas induced by the dynamical dependence.

We will describe two fusions (consistent tensor product of auxiliary spaces) of Eq. (1), respectively, inspired by Refs. 2 (itself relying on Ref. 1) and 15. While the fusion of the structure matrices is uniquely defined in each case, the solutions of the fused exchange relations are not. In particular, they can be dressed, i.e., multiplied by suitable "coupling" factors. This dressing procedure turns out to be crucial, indeed, when the simplest solutions of the fused exchange relation are combined in a quantum trace, they decouple, giving rise to products of lower order Hamiltonians. To obtain nontrivial commuting quantities these fused T-matrices must be dressed.

We will finally show that the two fusion procedures identified in Refs. 2 and 15 are related by a coupling matrix L_M and that they generate the same commuting quantities.

A. First fusion procedure

Let us first start by introducing some convenient notations (see Ref. 2) for fused matrices,

$$A_{MN'} = \prod_{i \in M}^{\rightarrow} \prod_{j \in N'}^{\rightarrow} A_{ij} = A_{11'} A_{12'} \cdots A_{1n'} \times A_{21'} A_{22'} \cdots A_{2n'} \cdots \times A_{m1'} \cdots A_{mn'}, \tag{8}$$

where $M = \langle 1, 2, \ldots, m \rangle$ and $N' = \langle 1', 2', \ldots, n' \rangle$ are ordered sets of labels. The same sets with reversed ordering are denoted by $\bar{M}$ and $\bar{N}'$. A set M deprived of its lowest (highest) element is denoted by $M_0 (M^0)$.

Remark: In many explicit examples we would have to deal only with one single exchange formula (1) with two isomorphic auxiliary spaces. However our derivation also applies to a

situation where more general coupled sets of exchange relations would occur as $A_{ij}T_iB_{ij}T_j = T_jC_{ij}T_iD_{ij}$ with $\{i,j\}\subset\{1,\ldots,m_0<\infty\}$ and generically $V_i\neq V_j$. Such situations will occur whenever a universal structure is identifiable and the auxiliary spaces V_i carry different representations of the algebra, as in, e.g., Ref. 15. It is therefore crucial that the order in the index set be stipulated.

Similar notations are used for the fusion of the other structure matrices. The next lemma states that the structure matrices in (1) can be fused in a way that respects the YB equations (2)–(5).

Lemma 1: Let A,B,C,D be solutions of the Yang-Baxter equations (2)–(5).

Then the following fused Yang-Baxter equations hold:

$$A_{M\bar{N}'}A_{M\bar{L}''}A_{N'\bar{L}''} = A_{N'\bar{L}''}A_{M\bar{L}''}A_{M\bar{N}'}, \tag{9}$$

$$A_{M\bar{N}'}C_{ML''}C_{N'L''} = C_{N'L''}C_{ML''}A_{M\bar{N}'}, \tag{10}$$

$$D_{M\bar{N}'}D_{M\bar{L}''}D_{N'\bar{L}''} = D_{N'\bar{L}''}D_{M\bar{L}''}D_{M\bar{N}'}, \tag{11}$$

$$D_{M\bar{N}'}B_{ML''}B_{N'L''} = B_{N'L''}B_{ML''}D_{M\bar{N}'}. \tag{12}$$

Proof: Simple induction on $\#M+\#N'$. ■

We now describe a fusion procedure for the algebra characterized by (1), generalizing the one introduced in Ref. 2.

Theorem 1: *If T is a solution of*

$$A_{12}T_1B_{12}T_2 = T_2C_{12}T_1D_{12} \tag{13}$$

then

$$T_M = \prod_{i\in M}^{\rightarrow}\left(T_i\left(\prod_{\substack{i<j\\ j\in M}}^{\rightarrow}B_{ij}\right)\right) \tag{14}$$

verifies the following fused equation:

$$A_{M\bar{N}'}T_MB_{MN'}T_{N'} = T_{N'}C_{MN'}T_MD_{M\bar{N}'}. \tag{15}$$

Proof: Induction on the cardinality n of the index sets, $n=\#M+\#N'$ which repeats and generalizes the steps in Ref. 2. ■

The solution T_M obtained above can be dressed, i.e., can be multiplied from the left and the right by suitable factors.

Proposition 1: Let T_M be a solution of the fused exchange relation. Then $Q_MT_MS_M$ is also a solution of the fused exchange relation provided Q_M and S_M verify

$$\begin{aligned}&[Q_M,A_{M\bar{N}'}] = [Q_{N'},A_{M\bar{N}'}] = [Q_{N'},B_{MN'}] = [Q_M,C_{MN'}] = 0,\\ &[S_M,D_{M\bar{N}'}] = [S_{N'},D_{M\bar{N}'}] = [S_{N'},C_{MN'}] = [S_M,B_{MN'}] = 0.\end{aligned} \tag{16}$$

A particular solution of these constraints is provided by

$$\begin{aligned}Q_M &= \check{A}_{12}\check{A}_{23}\ldots\check{A}_{m-1,m},\\ S_M &= \check{D}_{12}\check{D}_{23}\ldots\check{D}_{m-1,m},\end{aligned} \tag{17}$$

where $\check{A}_{12}=P_{12}A_{12},\ldots P_{12}$ being the permutation exchanging two auxiliary spaces.

Proof: Again by induction on the cardinality of the index sets. In the induction step we use the decomposition $Q_{N'}B_{MN'}=\check{A}_{12}\cdots\check{A}_{n'-1,n'}B_{M,N'00}B_{M,n'-1}B_{M,n'}$, for example. ■

The fusion procedure can be repeated for the dual exchange relation as follows.

Theorem 2: *If K is a solution of the dual exchange relation,*

$$(A_{12}^{-1})^{t_1t_2}K_1((B_{12}^{t_1})^{-1})^{t_2}K_2 = K_2((C_{12}^{t_2})^{-1})^{t_1}K_1(D_{12}^{t_1t_2})^{-1} \tag{18}$$

then

$$K_M = \prod_{i\in M}^{\rightarrow}\left(K_i\left(\prod_{\substack{i<j\\ j\in M}}^{\rightarrow}((B_{ij}^{t_1})^{-1})^{t_2}\right)\right) \tag{19}$$

is a solution of the dual fused equation

$$(A_{M\bar{N}'}^{-1})^{t_Mt_{N'}}K_M((B_{MN'}^{t_M})^{-1})^{t_{N'}}K_{N'} = K_{N'}((C_{MN'}^{t_{N'}})^{-1})^{t_M}K_M(D_{M\bar{N}'}^{t_Mt_{N'}})^{-1}. \tag{20}$$

Proof: Similar to that of Theorem 1. Note that the dual structure matrices obey a set of appropriate YB equations, isomorphic to (9)–(12), for instance,

$$(A_{M\bar{N}'}^{-1})^{t_Mt_{N'}}(A_{M\bar{L}''}^{-1})^{t_Mt_{L''}}(A_{N\bar{L}''}^{-1})^{t_Nt_{L''}} = (A_{N\bar{L}''}^{-1})^{t_Nt_{L''}}(A_{M\bar{L}''}^{-1})^{t_Mt_{L''}}(A_{M\bar{N}'}^{-1})^{t_Mt_{N'}}. \tag{21}$$

■

A similar dual dressing procedure exists: Any dressing of a solution of (18) should obey the commutativity constraints

$$\begin{aligned}[Q'_M,(A_{M\bar{N}'}^{-1})^{t_Mt_{N'}}] = [Q'_{N'},(A_{M\bar{N}'}^{-1})^{t_Mt_{N'}}] = [Q'_{N'},((B_{MN'}^{t_M})^{-1}\ ] = [Q'_M,((C_{MN'}^{t_{N'}})^{-1}\ ] = [S'_M,(D_{M\bar{N}'}^{t_Mt_{N'}})^{-1}]\\ = [S'_{N'},(D_{M\bar{N}'}^{t_Mt_{N'}})^{-1}] = [S'_{N'},((C_{MN'}^{t_{N'}})^{-1}\ ] = [S'_M,((B_{MN'}^{t_M})^{-1}\ ] = 0\end{aligned} \tag{22}$$

involving fused dual structure matrices. It is easy to check that if Q_M and S_M dress solutions of (15) then $Q'_M=Q_M^{t_M}$ and $S'_M=S_M^{t_M}$ dress solutions of (18).

B. Second fusion procedure

Results in Ref. 15 hint that relation (1) admits another fusion procedure. We will explicitely link the fusion described in the preceding section to the one inspired by Ref. 15.

The DKM type fusion is characterized by the following fused exchange relation for fused matrices $\tilde{T}$ to be described in the following:

$$A_{\bar{M}N'}\tilde{T}_MB_{M\bar{N}'}\tilde{T}_{N'} = \tilde{T}_{N'}C_{\bar{M}N'}\tilde{T}_MD_{M\bar{N}'}. \tag{23}$$

This equation can actually be obtained from a multiplication of the KS exchange relation (15) by suitable factors reversing the ordering of indices where it is needed. The next lemma specifies this statement.

Lemma 2: Let T_M be a solution of the fused exchange relation (15). If L_M verifies the following commutation rules:

$$\begin{aligned}L_MA_{M\bar{N}'} = A_{\bar{M}\bar{N}'}L_M,\quad L_{N'}A_{M\bar{N}'} = A_{MN'}L_{N'},\\ L_{N'}B_{MN'} = B_{M\bar{N}'}L_{N'},\quad L_MC_{MN'} = C_{\bar{M}N'}L_M\end{aligned} \tag{24}$$

then $\tilde{T}_M=L_MT_M$ is a solution of the exchange relation

$$A_{\bar{M}N'}\tilde{T}_MB_{M\bar{N}'}\tilde{T}_{N'} = \tilde{T}_{N'}C_{\bar{M}N'}\tilde{T}_MD_{M\bar{N}'}. \tag{25}$$

An example of such an L_M is given by

$$L_M = A_{12}\cdots A_{1m}A_{23}\cdots A_{2m}\cdots A_{m-1,m} = \overrightarrow{\prod_{1\leqslant i<j\leqslant m}} A_{ij}. \tag{26}$$

Proof: The first part is straightforward. Example (26) is verified by induction using $L_M = A_{1M_0}L_{M_0}$. For instance, the first relation of (24) is proved as

$$L_M A_{M\bar{N}'} = A_{1M_0}L_{M_0}A_{1\bar{N}'}A_{M_0\bar{N}'} = A_{1M_0}A_{1\bar{N}'}L_{M_0}A_{M_0\bar{N}'} = A_{1M_0}A_{1\bar{N}'}A_{\bar{M}_0\bar{N}'}L_{M_0} = A_{\bar{M}_0\bar{N}'}A_{1\bar{N}'}A_{1M_0}$$
$$= A_{\bar{M}\bar{N}'}L_M,$$

where fused YB equations are used. ■

Combined with Theorem 1, this lemma leads to the following.

Theorem 3: *If $\tilde{T}$ is a solution of*

$$A_{12}\tilde{T}_1B_{12}\tilde{T}_2 = \tilde{T}_2C_{12}\tilde{T}_1D_{12} \tag{27}$$

then

$$\tilde{T}_M = \overrightarrow{\prod_{i\in M}}\left(\overrightarrow{\prod_{\substack{j>i\\ j\in M}}} A_{ij}\tilde{T}_i \overleftarrow{\prod_{\substack{j>i\\ j\in M}}} B_{ij}\right) \tag{28}$$

is a solution of

$$A_{\bar{M}N'}\tilde{T}_MB_{M\bar{N}'}\tilde{T}_{N'} = \tilde{T}_{N'}C_{\bar{M}N'}\tilde{T}_MD_{M\bar{N}'}. \tag{29}$$

Proof: The only property left to check is that the solution $\tilde{T}_M$ in (28) is obtained from T_M in (14) by a multiplication by L_M in (26). It is enough to show that $\tilde{T}_M = A_{1M_0}\tilde{T}_1B_{1\bar{M}_0}\tilde{T}_{M_0}$. We only develop the induction step,

$$L_MT_M = A_{1M_0}L_{M_0}T_1B_{1M_0}T_{M_0} = A_{1M_0}T_1L_{M_0}B_{1M_0}T_{M_0} = A_{1M_0}T_1B_{1\bar{M}_0}L_{M_0}T_{M_0} = A_{1M_0}\tilde{T}_1B_{1\bar{M}_0}\tilde{T}_{M_0}. \tag{30}$$

■

The next proposition describes the dressing of the solutions.

Proposition 2: Let $\tilde{T}_M$ be a solution of the DKM-type fused exchange relations. Then $\tilde{Q}_M\tilde{T}_M\tilde{S}_M$ is also a solution provided $\tilde{Q}_M$ and $\tilde{S}_M$ verify

$$[\tilde{Q}_M, A_{\bar{M}N'}] = [\tilde{Q}_{N'}, A_{\bar{M}N'}] = [\tilde{Q}_{N'}, B_{M\bar{N}'}] = [\tilde{Q}_M, C_{\bar{M}N'}] = 0,$$
$$[\tilde{S}_M, D_{M\bar{N}'}] = [\tilde{S}_{N'}, D_{M\bar{N}'}] = [\tilde{S}_{N'}, C_{\bar{M}N'}] = [\tilde{S}_M, B_{M\bar{N}'}] = 0. \tag{31}$$

These equations are solved by

$$\tilde{Q}_M = L_MQ_ML_M^{-1}, \quad \tilde{S}_M = S_M,$$

where Q_M and *S_M dress the solutions of the fused exchange relation (15) and L_M is a solution of (24).*

Proof: Straightforward. ■

We saw that T_M and $\tilde{T}_M$ were linked by a factor L_M. The question arises whether there is a similar relation between the corresponding dual exchange algebras and their solutions. The relation is established in the following.

Theorem 4: *Let K_M be a solution of the first fused exchange relation (15) and L_M be a solution of (24). Then $\tilde{K}_M = (L_M^{t_M})^{-1}K_M$ is a solution of the KDM-type dual fused exchange relation:*

$$(A^{-1}_{\bar{M}N'})^{t_M t_{N'}}\widetilde{K}_M((B^{t_M}_{M\bar{N}'})^{-1})^{t_{N'}}\widetilde{K}_{N'} = \widetilde{K}_{N'}((C^{t_{N'}}_{\bar{M}N'})^{-1})^{t_M}\widetilde{K}_M(D^{t_M t_{N'}}_{M\bar{N}'})^{-1}. \tag{32}$$

Proof: We first see that (32) is indeed the dual exchange relation associated with (25). The next step is to check that $(L^{t_M}_M)^{-1}$ obeys the appropriate commutation relations that enable it to transform the fused dual AD type algebra (18) into the fused dual DKM-type one (32). It is obvious since these equations are the inverse transpose of (24). ■

Dressings of these dual fused solutions are obtained from dressings of (25) by the same operation as for the AD type fusion, i.e., by transposing.

C. Commuting traces

In the preceding sections we have derived two distinct fusion procedures both of which allow for building commuting quantities. In this section we will describe this construction, and show the two different quantum traces are identified once the dressing is used.

We first establish the following.

Theorem 5: *Let $\mathcal{T}_M$ be a solution of the fused AD-type exchange relation (15). $\mathcal{T}_M$ acts on the tensor product of the auxiliary spaces labeled by M and on the quantum space V_q.*

Let $\mathcal{K}_M$ be a solution of the dual fused AD-type exchange relation (18). $\mathcal{K}_M$ acts on the tensor product of the auxiliary spaces labeled by M and on the quantum space $V_{q'}$.

The following operators,

$$H_M = \mathrm{Tr}_M(\mathcal{K}^{t_M}_M \mathcal{T}_M), \tag{33}$$

constitute a family of mutually commuting quantum operators acting on $V_q \otimes V_{q'}$:

$$[H_M, H_{N'}] = 0. \tag{34}$$

Proof: It repeats the steps of Refs. 2 and 16. ■

The proof is independent of the particular fusion procedure so it remains valid for the DKM case too. Thus we have the following.

Theorem 6: *Let $\widetilde{\mathcal{T}}_M$ be a solution of the fused DKM-type exchange relation (25). $\widetilde{\mathcal{T}}_M$ acts on the tensor product of the auxiliary spaces labeled by M and on the quantum space V_q.*

Let $\widetilde{\mathcal{K}}_M$ be a solution of the dual fused DKM-type exchange relation (32). $\widetilde{\mathcal{K}}_M$ acts on the tensor product of the auxiliary spaces labeled by M and on the quantum space $V_{q'}$.

The following operators:

$$\widetilde{H}_M = \mathrm{Tr}_M(\widetilde{\mathcal{K}}^{t_M}_M \widetilde{\mathcal{T}}_M) \tag{35}$$

constitute a family of mutually commuting quantum operators acting on $V_q \otimes V_{q'}$:

$$[\widetilde{H}_M, \widetilde{H}_{N'}] = 0. \tag{36}$$

So far we have two seemingly different sets of commuting quantities obtained from the same defining relations (1) via two distinct fusion procedures. However we will show that the operation consisting in dressing and taking the trace smears out this difference and one is left with only one set of commuting Hamiltonians. This is summarized in.

Proposition 3: The quantum commuting Hamiltonians obtained from any set of solutions T_M, K_M of (15) and (20) are identified with the quantum commuting Hamiltonians obtained from a suitable set of solutions $\widetilde{T}_M, \widetilde{K}_M$ of (25) and (32). This identification is implemented by a coupling matrix L_M.

Proof: Let $\mathcal{T}_M$ be the solution (14) and $\mathcal{K}_M$ the corresponding dual solution (19). The results of the multiplication by L_M and $(L^{t_M}_M)^{-1}$ are denoted by $\widetilde{\mathcal{T}}M$ and $\widetilde{\mathcal{K}}M$. We calculate the tilded Hamiltonians after dressing and we find that they are equal to the dressed untilded ones,

$$\mathrm{Tr}_M(\widetilde{\mathcal{K}}_M^{t_M}\widetilde{Q}_M\widetilde{\mathcal{T}}_M\widetilde{S}_M)=\mathrm{Tr}_M(\mathcal{K}_M^{t_M}L_M^{-1}L_MQ_ML_M^{-1}L_M\mathcal{T}_MS_M)=\mathrm{Tr}_M(\mathcal{K}_M^{t_M}Q_M\mathcal{T}_MS_M). \tag{37}$$

■

The following proposition justifies the technical relevance of dressings.

Proposition 4: Operators built from the solution (14) decouple as $H_N=\mathrm{Tr}_N(K_N^{t_N}T_N)=\mathrm{Tr}(K^tT)^{\#N}$.

Proof: By induction using the property $T_N=T_1B_{1N_0}T_{N_0}$. Let us detail the induction step,

$$H_N=\mathrm{Tr}_N(K_N^{t_N}T_N)=\mathrm{Tr}((K_1(B_{1N_0}^{t_1})^{-1t_{N_0}}K_{N_0})^{t_N}T_1B_{1N_0}T_{N_0})=\mathrm{Tr}((K_1(B_{1N_0}^{t_1})^{-1t_{N_0}}K_{N_0})^{t_{N_0}}(T_1B_{1N_0}T_{N_0})^{t_1})$$
$$=\mathrm{Tr}(K_1K_{N_0}^{t_{N_0}}(B_{1N_0}^{t_1})^{-1}B_{1N_0}^{t_1}T_1^{t_1}T_{N_0})=\mathrm{Tr}(K_1T_1^{t_1})\mathrm{Tr}(K_{N_0}^{t_{N_0}}T_{N_0}).$$

■

Note that the result in Proposition 3 implies that the same goes for the operators built using the second fusion. Three important remarks are in order here.

The use of dressed quantum traces: Dressed quantum traces yield *a priori* independent operators. Indeed, the classical limit of a quantum trace computed with the particular dressing (17) in Proposition 1 will yield $\mathrm{Tr}\,T^n$ instead of $(\mathrm{Tr}\,T)^n$ (since $A,B,C,D\to\mathbf{1}\otimes\mathbf{1}$ but $P_{12}\to P_{12}$!). Quantum traces are directly, in this particular case, (as was already known in the context of quantum group structures[6]) quantum analogs of the classical Poisson-commuting power traces $\mathrm{Tr}\,T^n$.

The use of undressed quantum traces: It must on the other hand, be emphasized that the decoupling of the undressed fused quantities plays an essential role in the formulation of the analytical Bethe ansatz solution of $\mathfrak{sl}(n)$ spin chains (as is seen in Ref. 9) and more generally in the formulation of a generalized Mezincescu-Nepomechie procedure for fusion of transfer matrices,[8] in that it gives a natural construction of products of monodromy matrices such as are required by this formulation.

Explicit computation of the dressings: From a more theoretical point of view, it must be noticed that Eq. (24), as already discussed for the particular example treated in Ref. 2, would appear as a condition obeyed by coproducts of the central elements of a (hypothetical) universal algebra, thereby promoting the dressing matrices Q and S from "technical auxiliaries" to get nontrivial traces, to representations of Casimir elements of the algebra itself (this was pointed out to us by Arnaudon).

A second more technical remark is required here regarding the actual computation of the quantum traces with the particular explicit dressing determined in Proposition 1. Difficulties in applying (35) with the explicit dressings (17) may occur when the auxiliary space V is a loop space $V^{(n)}\otimes\mathbb{C}(z)$ (n=finite dimension of the vector space). Indeed, the permutation of spectral parameters required in formula (17) is only achieved at a formal level by the singular distribution $\delta(z_i/z_j)$ (see Ref. 2 for discussions). Hence the actual explicit computations of such quantum traces may entail delicate regularization procedures. However, if one only focuses on the practical purpose of the quantum trace procedure, which is to build a set of commuting operators, use of higher-power fused objects as in (14) and (19) is mostly required when no spectral parameter is present in the represented exchange algebra (1). Otherwise one needs to consider only the first order trace $\mathrm{Tr}_1\,\widetilde{K}_1(z_1)T_1(z_1)$ and expand it in formal series in z_1. If no spectral parameter is available, one can then use (14), (19), (17), and (35) to build explicitly without difficulties *a priori* independent commuting quantum operators. (For an application to a different algebraic structure see Ref. 5.)

D. Further example, "soliton nonpreserving" boundary conditions: Twisted Yangians

We have mentioned in the Introduction several examples of nondynamical quadratic exchange algebras. Another interesting example to which we plan to apply this scheme is related to the so-called "soliton nonpreserving" boundary conditions in integrable lattice models (see Ref. 18). To characterize it we will focus on the $\mathfrak{su}(n)$ invariant R-matrix given by

$$R_{12}(\lambda) = \lambda I + i\mathcal{P}_{12}, \tag{38}$$

where $\mathcal{P}$ is the permutation operator on the tensor product $V_1 \otimes V_2$. The R matrix is a solution of the Yang-Baxter equation[19–22] and also satisfies the following.

(i) *Unitarity*,

$$R_{12}(\lambda)R_{21}(-\lambda) = \zeta(\lambda), \tag{39}$$

where $R_{21}(\lambda)=\mathcal{P}_{12}R_{12}(\lambda)\mathcal{P}_{12}=R^{t12}_{12}(\lambda)$ and $\mathcal{P}$ is the permutation operator.

(ii) *Crossing unitarity*,

$$R^{t_1}_{12}(\lambda)M_1R^{t_2}_{12}(-\lambda - 2i\rho)M_1^{-1} = \zeta'(\lambda + i\rho), \tag{40}$$

$M=V^tV$ [$M=1$ for the $\mathfrak{su}(n)$ case], $\rho=n/2$ and also

$$[M_1M_2, R_{12}(\lambda)] = 0, \tag{41}$$

$$\zeta(\lambda) = (\lambda + i)(-\lambda + i), \quad \zeta'(\lambda) = (-\lambda + i\rho)(\lambda + i\rho). \tag{42}$$

It is interpreted as the scattering matrix[23,22,24] describing the interaction between two solitons—objects that correspond to the fundamental representation of $\mathfrak{su}(n)$.

One may also derive the scattering matrix that describes the interaction between a soliton and an antisoliton, which corresponds to the conjugate representation of $\mathfrak{su}(n)$. It reads

$$R_{\bar{1}\bar{2}}(\lambda) = R_{1\bar{2}}(\lambda) = \bar{R}_{12}(\lambda) = U_1R^{t_2}_{12}(-\lambda - i\rho)U_1, \tag{43}$$

and it can also be written as

$$\bar{R}_{12}(\lambda) = (-\lambda - i\rho)I + iQ, \tag{44}$$

where Q is a projector onto a one-dimensional space, and where U is a matrix of square 1. Note that for the su(2) case

$$\bar{R}_{12}(\lambda) = R_{12}(\lambda), \tag{45}$$

which is expected because su(2) is self-conjugate. The $\bar{R}$-matrix also satisfies the Yang-Baxter equation and

(i) *Unitarity*,

$$\bar{R}_{12}(\lambda)\bar{R}_{21}(-\lambda) = \zeta'(\lambda). \tag{46}$$

(ii) *Crossing unitarity*

$$\bar{R}^{t_1}_{12}(\lambda)M_1\bar{R}^{t_2}_{12}(-\lambda - 2i\rho)M_1^{-1} = \zeta(\lambda). \tag{47}$$

The reflection equation: The usual reflection equation[1] describes physically the reflection of a soliton [fundamental representation of $\mathfrak{su}(n)$] as a soliton. The associated quadratic algebra was considered, e.g., in Ref. 2,

$$R_{12}(\lambda_1 - \lambda_2)T_1(\lambda_1)R_{21}(\lambda_1 + \lambda_2)T_2(\lambda_2) = T_2(\lambda_2)R_{12}(\lambda_1 + \lambda_2)T_1(\lambda_1)R_{21}(\lambda_1 - \lambda_2). \tag{48}$$

Considering now the reflection of a soliton as antisoliton one is similarly lead to the formulation of another quadratic algebra,

$$R_{12}(\lambda_1-\lambda_2)T_1(\lambda_1)\bar{R}_{21}(\lambda_1+\lambda_2)T_2(\lambda_2)=T_2(\lambda_2)\bar{R}_{12}(\lambda_1+\lambda_2)T_1(\lambda_1)R_{21}(\lambda_1-\lambda_2). \tag{49}$$

More specifically Eq. (49) is the definition of the so-called twisted Yangian. Its dual reflection equation is obtained essentially by taking its formal transposition

$$\begin{aligned}&R_{12}(-\lambda_1+\lambda_2)K_1^{t_1}(\lambda_1)M_1^{-1}\bar{R}_{21}(-\lambda_1-\lambda_2-2i\rho)M_1K_2^{t_2}(\lambda_2)\\&\quad=K_2^{t_2}(\lambda_2)M_1\bar{R}_{12}(-\lambda_1-\lambda_2-2i\rho)M_1^{-1}K_1^{t_1}(\lambda_1)R_{21}(-\lambda_1+\lambda_2).\end{aligned} \tag{50}$$

This indeed realizes the general quadratic exchange relation (1) and (7), with the following identifications (using unitarity and crossing symmetries of the R-matrix):

$$A_{12}=R_{12}(\lambda_1-\lambda_2),\quad B_{12}=\bar{R}_{21}(\lambda_1+\lambda_2),\quad C_{12}=\bar{R}_{12}(\lambda_1+\lambda_2),\quad D_{12}=R_{21}(\lambda_1-\lambda_2),$$

$$(A_{12}^{-1})^{t_1t_2}=R_{12}(-\lambda_1+\lambda_2),\quad ((B_{12}^{t_1})^{-1})^{t_2}=M_1\bar{R}_{12}(-\lambda_1-\lambda_2-2i\rho)M_1^{-1},$$

$$((C_{12}^{t_2})^{-1})^{t_1}=M_1^{-1}\bar{R}_{21}(-\lambda_1-\lambda_2-2i\rho)M_1,\quad (D_{12}^{-1})^{t_1t_2}=R_{21}(-\lambda_1+\lambda_2).$$

Explicit application of the quantum trace procedure to this particular algebra will be left for further studies.

III. QUANTUM TRACES FOR SEMIDYNAMICAL QUADRATIC ALGEBRAS

The second type of quadratic exchange relations considered here consists of the dynamical quadratic algebras generically described and studied in Ref. 11 which were first exemplified in the context of scalar Ruijsenaars-Schneider models in Ref. 26. Fusion procedures and commuting traces can be built up for these dynamical quadratic algebras following the same overall procedure as in the nondynamical case, albeit with crucial, nontrivial differences.

A. The semidynamical quadratic algebra

Let us recall here the basic definitions. Our starting point is the dynamical quadratic exchange relation

$$A_{12}(\lambda)T_1(\lambda)B_{12}(\lambda)T_2(\lambda+\gamma h_1)=T_2(\lambda)C_{12}(\lambda)T_1(\lambda+\gamma h_2)D_{12}. \tag{51}$$

This describes an algebra generated by the matrix entries of T. A,B,C,D are matrices in End($V\otimes V$) depending on $\lambda\in\mathfrak{h}^*$ where $\mathfrak{h}$ is a commutative Lie algebra, of dimension n, making V a diagonalizable $\mathfrak{h}$-module. Introducing coordinates λ_i on $\mathfrak{h}^*$ and the dual base h_i on $\mathfrak{h}$ the shift $\lambda+\gamma h$ can be defined in the following way. For any differentiable function $f(\lambda)=f(\{\lambda_i\})$,

$$f(\lambda+\gamma h)=e^{\gamma\mathcal{D}}f(\lambda)e^{-\gamma\mathcal{D}}, \tag{52}$$

where

$$\mathcal{D}=\sum_i h_i\partial_{\lambda_i}. \tag{53}$$

In the forthcoming calculations γ is set to 1 for simplification. Zero weight conditions are imposed on the first space of B and the second one of C; D is of total weight zero,

$$[B_{12},h\otimes\mathbf{1}]=[C_{12},\mathbf{1}\otimes h]=[D_{12},h\otimes\mathbf{1}+\mathbf{1}\otimes h]=0\quad(h\in\mathfrak{h}). \tag{54}$$

These particular conditions, together with the absence of dynamical shift in two out of four T matrices in (51), lead us to denote this structure as "semidynamical." We will restrict ourselves from now on to the case where V is of dimension n, the basis of V and the generators of $\mathfrak{h}$, can then be chosen so that one identifies $h_i=E_{ii}$ [diagonal basis elements of $\mathfrak{gl}(n)$, see, e.g., Ref. 25 for

introduction of this condition]. These conditions mean in particular that B and C are diagonal on the corresponding spaces, respectively, V_1 and V_2. In addition, D has components on basis elements $E_{ij}\otimes E_{kl}$ of $\mathfrak{gl}(n)\otimes\mathfrak{gl}(n)$ only when the sets $\{i,k\}$ and $\{j,l\}$ are equal (property ZW). In other words nonzero elements have identical unordered multiplets of line and column indices.

For the consistency of the exchange relations the following set of coupled "dynamical" YB equations is imposed,

$$A_{12}A_{13}A_{23} = A_{23}A_{13}A_{12}, \tag{55}$$

$$D_{12}(\lambda + \gamma h_3)D_{13}D_{23}(\lambda + \gamma h_1) = D_{23}D_{13}(\lambda + \gamma h_2)D_{12}, \tag{56}$$

$$D_{12}B_{13}B_{23}(\lambda + \gamma h_1) = B_{23}B_{13}(\lambda + \gamma h_2)D_{12}, \tag{57}$$

$$A_{12}C_{13}C_{23} = C_{23}C_{13}A_{12}(\lambda + \gamma h_3). \tag{58}$$

The simplest example of this algebra is related to the elliptic scalar $\mathfrak{gl}(n)$ Ruijsenaars-Schneider model and was first written in Ref. 26. We only write down its rational limit here,

$$A(\lambda) = 1 + \sum_{i\neq j}\frac{\gamma}{\lambda_{ij}}(E_{ii} - E_{ij})\otimes(E_{jj} - E_{ji}), \tag{59}$$

$$B(\lambda) = C(\lambda)^{\pi} = 1 + \sum_{i\neq j}\frac{\gamma}{\lambda_{ij} - \gamma}E_{jj}\otimes(E_{ii} - E_{ij}), \tag{60}$$

$$D(\lambda) = 1 - \sum_{i\neq j}\frac{\gamma}{\lambda_{ij}}E_{ii}\otimes E_{jj} + \sum_{i\neq j}\frac{\gamma}{\lambda_{ij}}E_{ij}\otimes E_{ji}, \tag{61}$$

where E_{ij} is the elementary matrix whose entries are $(E_{ij})_{kl}=\delta_{ik}\delta_{jl}$ and $\lambda_{ij}=\lambda_i-\lambda_j$. These matrices verify the consistency conditions (55)–(58). A scalar representation of the exchange algebra defined with these structure matrices is then provided by

$$T(\lambda) = \sum_{ij}\frac{\prod_{a\neq i}(\lambda_{aj} + \tilde{\gamma})}{\prod_{a\neq j}\lambda_{aj}}E_{ij}\otimes\mathbf{1}. \tag{62}$$

The word "scalar" is used here in the sense that $T(\lambda)$ acts on a one-dimensional (trivial) quantum space. The exchange relation (51) is just a c-number equality. Representation of (51) on nontrivial quantum spaces is provided in this context by the comodule structure in Ref. 11.

Let us note here that the condition $AB=CD$ found in Ref. 26 means in this context that the identity matrix is also a solution of (51). This is not a trivial statement; in fact it does not hold in general, and is not preserved by fusion procedures.

B. Fusion procedures and the "dual" algebra

Let A,B,C,D be solutions of the dynamical exchange relation. We will define their fusion by induction as follows. We omit the dependence on λ and simplify the notations of the shifts as $(h_{(\ldots)})$; otherwise we use the notations introduced in Sec. II A, defining the multiple-index matrices by induction as

$$A_{M\bar{N}'} = A_{1\bar{N}'}A_{M_0\bar{N}'} = A_{Mn'}A_{M\bar{N}'_0},$$

$$B_{MN'} = B_{M1'}B_{MN'_0} = B_{1N'}[B_{M_0N'}(h_1)],$$

$$C_{MN'} = C_{1N'} C_{M_0 N'} = C_{M1'}[C_{MN'_0}(h_{1'})],$$

$$D_{M\bar{N}'} = D_{1\bar{N}'}[D_{M_0\bar{N}'}(h_1)] = [D_{Mn'}(h_{(1',n'-1)})] D_{M\bar{N}'_0}.$$

It is clear that there is no change in the fusion of A, cf. Eq. (8). As for the three other matrices, their fusion is written in a more explicit form as

$$B_{MN'} = B_{11'} B_{12'} \cdots B_{1n'} \times B_{21'}(h_1) B_{22'}(h_1) \cdots B_{2n'}(h_1) \cdots \times B_{m1'}(h_1 + \cdots + h_{m-1}) \cdots \times B_{mn'}(h_1 + \cdots + h_{m-1}), \tag{63}$$

$$C_{MN'} = C_{11'} C_{12'}(h_{1'}) \cdots C_{1n'}(h_{(1',n'-1)}) \times C_{21'} C_{22'}(h_{1'}) \cdots C_{2n'}(h_{(1',n'-1)}) \cdots \times C_{m1'} C_{m2'}(h_{1'}) \cdots C_{mn'}(h_{(1',n'-1)}), \tag{64}$$

$$D_{M\bar{N}'} = D_{1n'}(h_{(1',n'-1)}) D_{1,n'-1}(h_{(1',n'-2)}) \cdots D_{11'} \times D_{2n'}(h_1 + h_{(1',n'-1)}) D_{2,n'-1}(h_1 + h_{(1',n'-2)}) \cdots \times D_{21'}(h_1) \cdots \times D_{mn'}(h_{(1,m-1)} + h_{(1',n'-1)}) D_{m,n'-1}(h_{(1,m-1)} + h_{(1',n'-2)}) \cdots D_{m1'}(h_{(1,m-1)}), \tag{65}$$

where $h_{(i,j)} := \sum_{k=i}^{j} h_k$. These fused structure matrices verify the fused dynamical YB equations which are gathered together in the next proposition.

Proposition 5. Let A, B, C, D be solutions of the dynamical Yang-Baxter equations (55)–(58). Then the following fused dynamical Yang-Baxter equations hold

$$A_{M\bar{N}'} A_{M\bar{L}''} A_{N'\bar{L}''} = A_{N'\bar{L}''} A_{M\bar{L}''} A_{M\bar{N}'},$$

$$A_{M\bar{N}'} C_{ML''} C_{N'L''} = C_{N'L''} C_{ML''} A_{M\bar{N}'}(h_{L''}),$$

$$D_{M\bar{N}'}(h_{L''}) D_{M\bar{L}''} D_{N'\bar{L}''}(h_M) = D_{N'\bar{L}''} D_{M\bar{L}'}(h_{N'}) D_{M\bar{N}'},$$

$$D_{M\bar{N}'} B_{ML''} B_{N'L''}(h_M) = B_{N'L''} B_{ML''}(h_{N'}) D_{M\bar{N}'}.$$

Proof: By induction, using at crucial stages the zero weight properties. The fusion procedure respects the property ZW for D and the diagonality of B. It is also clear from the fusion procedure that the fused shift matrix h_M is identified with $h_{(1,m)}$. ■

Theorem 7: *Let T be a solution of the dynamical quadratic exchange relation*,

$$A_{12} T_1 B_{12} T_2(h_1) = T_2 C_{12} T_1(h_2) D_{12}, \tag{66}$$

then

$$T_M = \prod_{i \in M}^{\rightarrow} \left(T_i \left(\sum_{\substack{k<i \\ k \in M}} h_k \right) \left(\prod_{\substack{j>i \\ j \in M}}^{\rightarrow} B_{ij} \right) \right) \tag{67}$$

verifies the fused dynamical exchange relation

$$A_{M\bar{N}'} T_M B_{MN'} T_{N'}(h_M) = T_{N'} C_{MN'} T_M(h_{N'}) D_{M\bar{N}'}. \tag{68}$$

Proof: Similar to that of Theorem 1 but the induction step uses the fact that $T_M = T_1 B_{1M_0} T_{M_0}(h_1)$ and uses the fused dynamical YB equations. ■

The dual exchange relation and an associated fusion procedure are described in the next theorem.

Theorem 8: *Let K be a solution of the dynamical quadratic exchange relation*,

$$(A_{12}^{-1})^{t_1t_2}K_1(B_{12}^{t_2})^{-1}K_2(h_1) = K_2(C_{12}^{t_1})^{-1}K_1(h_2)(D_{12}^{-1})^{t_1t_2} \tag{69}$$

then

$$K_M = \overrightarrow{\prod_{i\in M}} \left(K_i\left(\sum_{\substack{k<i \\ k\in M}} h_k \right) \left(\overrightarrow{\prod_{\substack{j>i \\ j\in M}}} (B_{ij}^{t_j})^{-1} \right) \right) \tag{70}$$

verifies the fused dynamical exchange relation

$$(A_{M\bar{N}'}^{-1})^{t_Mt_N}K_M(B_{MN'}^{t_{N'}})^{-1}K_{N'}(h_M) = K_{N'}(C_{MN'}^{t_M})^{-1}K_M(h_{N'})(D_{M\bar{N}'}^{-1})^{t_Mt_{N'}}. \tag{71}$$

Proof: Similar to the nondynamical case. ■

Note that the structure matrices of this dual relation are related to original ones in the same way as in the nondynamical case once we take into account the partial zero weight property of B and C which implies diagonality on the corresponding spaces, respectively, V_1 and V_2.

C. Second fusion

As in the nondynamical case, one can define another KDM-type fusion with the appropriate shifts. This fusion is characterized by the following exchange relation:

$$A_{\bar{M}N'}T_MB_{M\bar{N}'}T_{N'}(h_M) = T_{N'}C_{\bar{M}N'}T_M(h_{N'})D_{M\bar{N}'}. \tag{72}$$

The analogy with the nondynamical case can be pushed further, i.e., there exists an object L_M linking the fusions in Theorems 7 and 9. This allows us to use directly the proofs of Theorems 3 and 4.

Lemma 3: Let T_M be a solution of the fused equation (68). If L_M verifies the following commutation rules:

$$\begin{gathered} L_MA_{M\bar{N}'} = A_{\bar{M}\bar{N}'}L_M, \\ L_{N'}A_{M\bar{N}'} = A_{MN'}L_{N'}, \\ L_{N'}B_{MN'} = B_{M\bar{N}'}L_{N'}(h_M), \\ L_MC_{MN'} = C_{\bar{M}N'}L_M(h_{N'}) \end{gathered} \tag{73}$$

then L_MT_M is a solution of the exchange relation

$$A_{\bar{M}N'}T_MB_{\bar{M}N'}T_{N'}(h_M) = T_{N'}C_{M\bar{N}'}T_M(h_{N'})D_{M\bar{N}'}. \tag{74}$$

An example of such an L_M is given by

$$L_M = A_{12}\cdots A_{1m}A_{23}\cdots A_{2m}\cdots A_{m-1,m} = \overrightarrow{\prod_{1\leqslant i<j\leqslant m}} A_{ij}. \tag{75}$$

Proof: Straightforward, using the dynamical YB equations (55)–(57). ■

Now we state the dynamical versions of Theorems 3 and 4.

Theorem 9: *Let T be a solution of the dynamical quadratic exchange relation*

$$A_{12}T_1B_{12}T_2(h_1) = T_2C_{12}T_1(h_2)D_{12} \tag{76}$$

then

$$T_M = \prod_{i\in M}^{\rightarrow} \left(\prod_{\substack{j>i \\ j\in M}}^{\rightarrow} A_{ij} T_i \left(\sum_{\substack{k<i \\ k\in M}} h_k \right) \prod_{\substack{j>i \\ j\in M}}^{\leftarrow} B_{ij} \right) \tag{77}$$

verifies the fused dynamical exchange relation

$$A_{\bar{M}N'} T_M B_{M\bar{N}'} T_{N'}(h_M) = T_{N'} C_{\bar{M}N'} T_M(h_{N'}) D_{M\bar{N}'}. \tag{78}$$

Proof: Reproduces the proof of Theorem 3, with suitable dynamical shifts. ■

The dual exchange relation and an associated fusion procedure are described in the next theorem.

Theorem 10: *Let K_M be a solution of the first fused exchange relation (69) and L_M be a solution of (73). Then $\tilde{K}_M = (L_M^{t_M})^{-1} K_M$ is a solution of the KDM-type dual fused exchange relation*

$$(A^{-1}_{\bar{M}N'})^{t_M t_{N'}} \tilde{K}_M ((B^{t_M}_{M\bar{N}'})^{-1})^{t_{N'}} \tilde{K}_{N'}(h_M) = \tilde{K}_{N'}((C^{t_{N'}}_{\bar{M}N'})^{-1})^{t_M} \tilde{K}_M(h_{N'}) (D^{t_M t_{N'}}_{M\bar{N}'})^{-1}. \tag{79}$$

Proof: Reproduces the proof of Theorem 4, with suitable dynamical shifts. ■

D. Dressing

Solutions T_M of the fused dynamical exchange relations also admit dressing procedures. However, because of the dynamical nature of the exchange relations some of the equations that the dressings Q_M and S_M obey exhibit shifts, too. Specifically we have the following.

Proposition 6: Let T_M be a solution of the fused dynamical exchange relation. Then $Q_M T_M S_M$ is also a solution of the fused exchange relation provided Q_M and S_M verify

$$[Q_M, A_{M\bar{N}'}] = [Q_{N'}, A_{M\bar{N}'}] = 0, \tag{80}$$

$$Q_{N'} B_{MN'} = B_{MN'} Q_{N'}(h_M), \quad Q_M C_{MN'} = C_{MN'} Q_M(h_{N'}),$$

$$[S_{N'}, C_{MN'}] = [S_M, B_{MN'}] = 0, \tag{81}$$

$$S_M(h_{N'}) D_{M\bar{N}'} = D_{M\bar{N}'} S_M, \quad S_{N'} D_{M\bar{N}'} = D_{M\bar{N}'} S_{N'}(h_M).$$

A particular solution of these constraints is given by

$$Q_M = \check{A}_{12} \check{A}_{23} \cdots \check{A}_{m-1,m},$$

$$S_M = \check{D}_{12} \check{D}_{23}(h_1) \cdots \check{D}_{m-1,m}(h_{(1,m-2)}).$$

Proof: By induction, similar to the nondynamical dressings. ■

An interesting comparison can be drawn between this formula for S_M and the formula used in Ref. 5 to dress the quantum traces for dynamical quantum groups. The formula for S_M is exactly the "mirror image" of the formula $S_M^{ABB} = \check{R}_{12}(h_{(3,m)}) \cdots \check{R}_{m,m-1}$.

E. Three lemmas: dynamical and cyclic properties of *D*

Three easy technical lemmas are required to proceed with the construction.

Lemma 4 (dynamical transposition): Let $R(q)$ and $S(q)$ be two matrices with mutually commuting entries depending on a set of commuting coordinates $\{q_k\}_{k=1}^n$. We then have

$$(R(q) e^{\mathcal{D}} S(q))^t = [S^{SL}(q)]^t e^{\mathcal{D}} [R^{SC}(q)]^t, \tag{82}$$

where $S^{SL}(q)_{ij}=e^{\partial_i}S(q)_{ij}e^{-\partial_i}=S_{ij}((q_1,\ldots,q_{\{i\}}+1,\ldots,q_n))$ *(shift on line index) and* $R^{SC}(q)_{ij}=e^{-\partial_j}R(q)_{ij}e^{\partial_j}$ *(shift on column index).*

Proof: We compare the ijth entry on both sides using the fact that entries of S^{SL} and R^{SC} do not contain explicit shift quantities e^{∂} and therefore commute with each other. If (in the case of k-tensor products) "i" denotes a k-uple of indices $(i_1,\ldots,i_k)$, the notation $q_{\{i\}}+1$ must be interpreted as $q_{i_1}+1,\ldots,q_{i_k}+1$. ■

Remark: Later we will use this lemma in the special case when $R(q)$ is diagonal. This implies $R^{SC}(q)=e^{-\mathcal{D}}R(q)e^{\mathcal{D}}$.

Lemma 5 (matrix dynamical shift): Let $D(q)$ be a matrix obeying the zero weight condition

$$[D_{12},h\otimes\mathbf{1}+\mathbf{1}\otimes h]=0\quad(h\in\mathfrak{h}). \tag{83}$$

Then the exponentials can be "pushed through" D, that is we have

$$e^{-\mathcal{D}_1-\mathcal{D}_2}D_{12}=\bar{D}_{12}e^{-\mathcal{D}_1-\mathcal{D}_2}, \tag{84}$$

where $\bar{D}_{12}=D_{12}^{-SL_{12}}$.

Proof: What this lemma means is that one can write $e^{-\mathcal{D}_1-\mathcal{D}_2}D_{12}e^{\mathcal{D}_1+\mathcal{D}_2}$ in a *matrix form* where the exponentials of derivatives cancel out. The proof is straightforward because the zero weight condition implies the identification of incoming and outgoing indices of D. One then verifies easily the equality of the two sides. ■

Lemma 6: Let $D(q)$ be a matrix obeying the zero weight condition:

$$[D_{12},h\otimes\mathbf{1}+\mathbf{1}\otimes h]=0\quad(h\in\mathfrak{h}). \tag{85}$$

Then D is cyclic with respect to the trace operation over $V_1\otimes V_2$ as follows:

$$\mathrm{Tr}_{12}(D_{12}X_{12}D_{12}^{-1}e^{\mathcal{D}_1}e^{\mathcal{D}_2})=\mathrm{Tr}_{12}(X_{12}e^{\mathcal{D}_1}e^{\mathcal{D}_2}), \tag{86}$$

where X is an arbitrary matrix the entries of which commute with the entries of D.

Proof: Consequence of the ZW property of D, which allows to reinterpret the matrix indices of $e^{\mathcal{D}_1+\mathcal{D}_2}$ as line instead of column indices of D_{12}^{-1}, allowing then to independently sum over the now decoupled column indices of D_{12}^{-1} with line indices of D_{12} to altogether eliminate the matrix D from the trace. Labels 1 and 2 formally denote here tensored auxiliary spaces. ■

F. Commuting Hamiltonians

We can now state the fundamental result of this section.

Theorem 11: *Let $\mathcal{T}_M$ be a solution of the fused dynamical exchange relations (68). $\mathcal{T}_M$ acts on the tensor product of the auxiliary spaces labeled by M and on the quantum space V_q.*

Let $\mathcal{K}_M$ be a solution of the dual fused dynamical exchange relation (71). $\mathcal{K}_M$ acts on the tensor product of the auxiliary spaces labeled by M and on the quantum space $V_{q'}$.

The following operators,

$$H_M=\mathrm{Tr}_M(T_Me^{\mathcal{D}_M}(K_M^{SC})^{t_M}), \tag{87}$$

constitute a family of mutually commuting quantum operators acting on $V_q\otimes V_{q'}$,

$$[H_M,H_{N'}]=0. \tag{88}$$

Proof: Similar to the preceding one, but extra care must be taken because of the shift operators that enter the expression. Using the dynamical transposition lemma for $K_{N'}$ one has

$$H_MH_{N'}=\mathrm{Tr}(T_Me^{\mathcal{D}_M}(K_M^{SC})^{t_M}T_{N'}e^{\mathcal{D}_{N'}}(K_{N'}^{SC})^{t_{N'}})=\mathrm{Tr}(T_Me^{\mathcal{D}_M}(K_M^{SC})^{t_M}T_{N'}^{t_{N'}}K_{N'}e^{\mathcal{D}_{N'}}), \tag{89}$$

since the invariance of the trace with respect to transposition is preserved in the dynamical case. One then writes

$$\mathrm{Tr}(T_M T_{N'}^{t_{N'}}(h_M) e^{\mathcal{D}_M} (K_M^{SC})^{t_M} K_{N'} e^{\mathcal{D}_{N'}}) = \mathrm{Tr}(T_M T_{N'}^{t_{N'}}(h_M) B_{MN'}^{t_{N'}} (B_{MN'}^{t_{N'}})^{-1} e^{\mathcal{D}_M} (K_M^{SC})^{t_M} K_{N'} e^{\mathcal{D}_{N'}})$$
$$= \mathrm{Tr}((T_M B_{MN'} T_{N'}(h_M))^{t_M t_{N'}} ((B_{MN'}^{t_{N'}})^{-1} e^{\mathcal{D}_M} (K_M^{SC})^{t_M})^{t_M} K_{N'} e^{\mathcal{D}_{N'}}).$$

In the last equality the identification $T_{N'}^{t_{N'}}(h_M) B_{MN'}^{t_{N'}} = (B_{MN'} T_{N'}(h_M))^{t_{N'}}$ uses the zero-weight condition $[B_{MN'}, h_M] = 0$. Using once again the dynamical transposition lemma and the zero-weight condition on B which guarantees $e^{\mathcal{D}_M}((B_{MN'}^{t_{N'}})^{-1})^{SCt_M} = (B_{MN'}^{t_{N'}})^{-1} e^{\mathcal{D}_M}$ as commented above, one gets

$$\mathrm{Tr}((T_M B_{MN'} T_{N'}(h_M))^{t_M t_{N'}} A_{MN'}^{t_M t_{N'}} (A_{MN'}^{t_M t_{N'}})^{-1} K_M (B_{MN'}^{t_{N'}})^{-1} e^{\mathcal{D}_M} K_{N'} e^{\mathcal{D}_{N'}})$$
$$= \mathrm{Tr}((A_{MN'} T_M B_{MN'} T_{N'}(h_M))^{t_M t_{N'}} (A_{MN'}^{t_M t_{N'}})^{-1} K_M (B_{MN'}^{t_{N'}})^{-1} K_{N'}(h_M) e^{\mathcal{D}_M} e^{\mathcal{D}_{N'}}).$$

One here identifies the direct and dual exchange relation, to yield

$$\mathrm{Tr}((T_{N'} C_{MN'} T_M(h_{N'}) D_{MN'})^{t_M t_{N'}} K_{N'} (C_{MN'}^{t_M})^{-1} K_M(h_{N'}) (D_{MN'}^{t_M t_{N'}})^{-1} e^{\mathcal{D}_M} e^{\mathcal{D}_{N'}})$$
$$= \mathrm{Tr}(D_{MN'}^{t_M t_{N'}} (T_{N'} C_{MN'} T_M(h_{N'}))^{t_M t_{N'}} K_{N'} (C_{MN'}^{t_M})^{-1} K_M(h_{N'}) (D_{MN'}^{t_M t_{N'}})^{-1} e^{\mathcal{D}_M} e^{\mathcal{D}_{N'}}).$$

Here Lemma 6 is at work,

$$\mathrm{Tr}((T_{N'} C_{MN'} T_M(h_{N'}))^{t_M t_{N'}} K_{N'} (C_{MN'}^{t_M})^{-1} K_M(h_{N'}) e^{\mathcal{D}_M} e^{\mathcal{D}_{N'}})$$
$$= \mathrm{Tr}(T_{N'} (C_{MN'} T_M(h_{N'}))^{t_M} (K_{N'} (C_{MN'}^{t_M})^{-1} e^{\mathcal{D}_{N'}})^{t_{N'}} K_M e^{\mathcal{D}_M})$$
$$= \mathrm{Tr}(T_{N'} T_M^{t_M}(h_{N'}) C_{MN'}^{t_M} (C_{MN'}^{t_M})^{-1} e^{\mathcal{D}_{N'}} K_{N'}^{SCt_{N'}} K_M e^{\mathcal{D}_M}).$$

Once again we have used the dynamical transposition lemma and the partial weight zero property of $C_{MN'}$,

$$\mathrm{Tr}(T_{N'} T_M^{t_M}(h_{N'}) e^{\mathcal{D}_{N'}} (K_{N'}^{SC})^{t_{N'}} K_M e^{\mathcal{D}_M}) = \mathrm{Tr}(T_{N'} e^{\mathcal{D}_{N'}} (K_{N'}^{SC})^{t_{N'}} T_M^{t_M} K_M e^{\mathcal{D}_M})$$
$$= \mathrm{Tr}(T_{N'} e^{\mathcal{D}_{N'}} K_{N'} T_M e^{\mathcal{D}_M} (K_M^{SC})^{t_M}).$$

■

Without the dressing described by Proposition 6 the traces constructed in (67) decouple just as in the nondynamical case. Indeed we have the following.

Proposition 7: Operators built from the solution (67) decouple as

$$\mathrm{Tr}_M(T_M e^{\mathcal{D}_M} (K_M^{SC}(\ {}^{t_M}) \quad = \mathrm{Tr}(T e^{\mathcal{D}} (K^{SC})^t)^{\#M}.$$

Proof: We will prove the proposition for M with two elements. The statement remains valid for higher powers by induction. We also need to set the trace under a more amenable form. In fact, $\mathrm{Tr}(T_M e^{\mathcal{D}_M} (K_M^{SC})^{t_M}) = \mathrm{Tr}(T_M^{t_M} K_M e^{\mathcal{D}_M})$. By virtue of Lemma 4,

$$\mathrm{Tr}([T_1 B_{12} T_2(h_1)]^{t_1 t_2} K_1 (B_{12}^{t_2})^{-1} K_2(h_1) e^{\mathcal{D}_1 + \mathcal{D}_2}) = \mathrm{Tr}(T_1 [B_{12} T_2(h_1)]^{t_2} [K_1 e^{\mathcal{D}_1} ((B_{12}^{t_2})^{-1})^{SC_1}]^{t_1} K_2 e^{\mathcal{D}_2}),$$

where $(\ )^{SC_1}$ means $(\ )^{SC}$ operation applied on the first space,

$$\mathrm{Tr}(T_1 T_2^{t_2}(h_1) B_{12}^{t_2} (B_{12}^{t_2})^{-1} e^{\mathcal{D}_1} K_1^{SCt_1} K_2 e^{\mathcal{D}_2}) = \mathrm{Tr}(T_1 e^{\mathcal{D}_1} T_2^{t_2} K_1^{SCt_1} K_2 e^{\mathcal{D}_2}) = \mathrm{Tr}(T_1 e^{\mathcal{D}_1} K_1^{SCt_1} T_2^{t_2} K_2 e^{\mathcal{D}_2})$$
$$= \mathrm{Tr}(T e^{\mathcal{D}} K^{SCt})^2.$$

■

Of course, the three comments made after Proposition 4 in the nondynamical case remain valid, although we do not know yet of explicit examples for Mezincescu-Nepomechie procedure in a dynamical context.

IV. THE FULLY DYNAMICAL ALGEBRA

The third type of quadratic algebra considered here is the extension to general structure matrices A,B,C,D of the "boundary dynamical algebra" (BDA) considered in Refs. 13 and 27. Fusion and trace formulas were defined in Ref. 13 for the particular case of BDA where $A=D=R(u_1-u_2)$, $B=C=R(u_1+u_2)$, R being the IRF $\mathbb{Z}_n$ R-matrix. The most general "fully dynamical" (denomination to be justified presently) exchange algebra reads

$$A_{12}(\lambda)T_1(\lambda+\gamma h_2)B_{12}(\lambda)T_2(\lambda+\gamma h_1)=T_2(\lambda+\gamma h_1)C_{12}(\lambda)T_1(\lambda+\gamma h_2)D_{12}(\lambda). \tag{90}$$

Once again we assume $\dim \mathfrak{h}=\dim V$.[25] The following conditions are imposed on the structure matrices ($R=A$, B, C or D) unitarity;

$$R_{12}(u_1,u_2;\lambda)R_{21}(u_2,u_1;\lambda)=\mathbf{1}. \tag{91}$$

Zero weight property,

$$[h\otimes\mathbf{1}+\mathbf{1}\otimes h,R_{12}(u_1,u_2;\lambda)]=0 \quad (h\in\mathfrak{h}). \tag{92}$$

R then verifies the same ZW property as in the semidynamical case. By contrast with the previous case all four matrices in (90) exhibit a dynamical shift and all four structure matrices have (1+2) zero weight, hence the denomination "fully dynamical." In some specific examples[27,28] the structure matrices also obey the dynamical zero weight property,

$$[\mathcal{D}\otimes\mathbf{1}+\mathbf{1}\otimes\mathcal{D},R_{12}(u_1,u_2;\lambda)]=0. \tag{93}$$

Structure matrices all obey Gervais-Neveu-Felder-type equations,

$$\begin{aligned}
&A_{12}(\lambda)A_{13}(\lambda+\gamma h_2)A_{23}(\lambda)=A_{23}(\lambda+\gamma h_1)A_{13}(\lambda)A_{12}(\lambda+\gamma h_3),\\
&A_{12}(\lambda)C_{13}(\lambda+\gamma h_2)C_{23}(\lambda)=C_{23}(\lambda+\gamma h_1)C_{13}(\lambda)A_{12}(\lambda+\gamma h_3),\\
&D_{12}(\lambda+\gamma h_3)D_{13}(\lambda)D_{23}(\lambda+\gamma h_1)=D_{23}(\lambda)D_{13}(\lambda+\gamma h_2)D_{12}(\lambda),\\
&D_{12}(\lambda+\gamma h_3)B_{13}(\lambda)B_{23}(\lambda+\gamma h_1)=B_{23}(\lambda)B_{13}(\lambda+\gamma h_2)D_{12}(\lambda).
\end{aligned} \tag{94}$$

If the dynamical zero weight property is verified then all equations can be rewritten under the more familiar alternating shift form,

$$R_{12}(\lambda-\gamma h_3)R_{13}(\lambda+\gamma h_2)R_{23}(\lambda-\gamma h_1)=R_{23}(\lambda+\gamma h_1)R_{13}(\lambda-\gamma h_2)R_{12}(\lambda+\gamma h_3).$$

As in the previous situation, these equations ensure the compatibility of the algebra in the following sense. Let us take the left-hand side of exchange relation (90), embed it in a triple tensor product and shift it on the third space. Then let us multiply it with $B_{13}(u_1,u_3;\lambda)B_{23}(u_2,u_3;\lambda+\gamma h_1)T_3(u_3;\lambda+\gamma h_1+\gamma h_2)$. One can reverse the order of the T's in two different ways which yield the same result if Eqs. (94) are obeyed.

A. Fusion procedure and the "dual" algebra

The fusion of the structure matrices is again defined by induction as follows:

$$A_{M\bar{N}'}=A_{1\bar{N}'}(h_{(2,m)})A_{M_0\bar{N}'}=A_{Mn'}A_{M\bar{N}'_0}(h_{n'}),$$

$$B_{MN'}=B_{1N'}B_{M_0N'}(h_1)=B_{M1'}(h_{(2',n')})B_{MN'_0},$$

$$C_{MN'}=C_{1N'}(h_{(2,m)})C_{M_0N'}=C_{M1'}C_{MN'_0}(h_1),$$

$$D_{M\bar{N}'} = D_{1\bar{N}'} D_{M_0\bar{N}'}(h_1) = D_{Mn'}(h_{(1',n'-1)}) D_{M\bar{N}'_0}.$$

A and C are fused in the same way which is written more explicitly as

$$A_{M\bar{N}'} = A_{1n'}(h_{(2,m)}) A_{1,n'-1}(h_{n'} + h_{(2,m)}) \cdots A_{11'}(h_{(2',n')} + h_{(2,m)}) A_{2n'}(h_{(3,m)}) A_{2,n'-1}(h_{n'} + h_{(3,m)}) \cdots$$
$$\times A_{21'}(h_{(2',n')} + h_{(3,m)}) \cdots \times A_{mn'} A_{m,n'-1}(h_{n'}) \cdots A_{m1'}(h_{(2',n')}). \tag{95}$$

B and D are otherwise fused in the same way as in Eq. (65).

These fused matrices verify the corresponding fused YB equations and the ZW property.

Proposition 8: Let A,B,C,D be solutions of the dynamical Yang-Baxter equations (94). Then the following fused dynamical Yang-Baxter equations hold:

$$A_{M\bar{N}'} A_{M\bar{L}''}(h_{N'}) A_{N'\bar{L}''} = A_{N'\bar{L}''}(h_M) A_{M\bar{L}''} A_{M\bar{N}'}(h_{L''}),$$

$$A_{M\bar{N}'} C_{ML''}(h_{N'}) C_{N'L''} = C_{N'L''}(h_M) C_{ML''} A_{M\bar{N}'}(h_{L''}),$$

$$D_{M\bar{N}'}(h_{L''}) D_{M\bar{L}''} D_{N'\bar{L}''}(h_M) = D_{N'\bar{L}''} D_{M\bar{L}''}(h_{N'}) D_{M\bar{N}'},$$

$$D_{M\bar{N}'}(h_{L''}) B_{ML''} B_{N'L''}(h_M) = B_{N'L''} B_{ML''}(h_{N'}) D_{M\bar{N}'}.$$

Proof. Straightforward by induction. ∎

Note that the dynamical zero weight property does not survive fusion, but algebraic zero weight does. In this sense this dynamical zero weight property is not relevant for the construction of commuting traces, and is not (generically) a feature of the universal algebra. We will from now on disregard it. In addition, we will concentrate here on the most relevant features of quantum trace building, ignoring for instance the possibility of a "second fusion."

Theorem 12: *Let T be a solution of the dynamical quadratic exchange relation*

$$A_{12} T_1(h_2) B_{12} T_2(h_1) = T_2 C_{12} T_1(h_2) D_{12}, \tag{96}$$

then

$$T_M = \overrightarrow{\prod_{i \in M}} \left(T_i \left(\sum_{\substack{k \neq i \\ k \in M}} h_k \right) \left(\overrightarrow{\prod_{\substack{j > i \\ j \in M}}} B_{ij} \left(\sum_{\substack{k < i \\ k \in M}} h_k + \sum_{\substack{k > j \\ k \in M}} h_k \right) \right) \right) \tag{97}$$

verifies the fused dynamical exchange relation

$$A_{M\bar{N}'} T_M(h_{N'}) B_{MN'} T_{N'}(h_M) = T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{M\bar{N}'}. \tag{98}$$

Proof: Similar to that of Theorem 1 but the induction step uses the fact that $T_M = T_1(h_{M_0}) B_{1M_0} T_{M_0}(h_1)$ and uses the fused dynamical YB equations. ∎

The dual exchange relation and the associated fusion procedure are described in the next theorem.

Theorem 13: *Let K be a solution of the dynamical quadratic exchange relation*

$$A^d_{12}(\lambda) K_1\ (\lambda + \gamma h_2) B^d_{12}(\lambda)) K_2(\lambda + \gamma h_1) = K_2(\lambda + \gamma h_1) C^d_{12}(\lambda) K_1(\lambda + \gamma h_2) D^d_{12}(\lambda),$$

where

$$A^d_{12} = ((A_{12}^{-SL_{12}})^{-1})^{-SC_{12}t_{12}}\ B^d_{12} = (((B_{12}^{-SL_{12}})^{-SC_2 t_2})^{-1})^{SL_1 t_1},$$

$$C^d_{12} = (((C_{12}^{-SL_{12}})^{-SC_1 t_1})^{-1})^{SL_2 t_2}\ D^d_{12} = ((D_{12}^{-SL_{12}})^{-1})^{SL_{12} t_{12}},$$

then

$$K_M = \overrightarrow{\prod_{i\in M}} \left(K_i\left(\sum_{\substack{k\neq i\\ k\in M}} h_k \right) \left(\overrightarrow{\prod_{\substack{j>i\\ j\in M}}} B^d_{ij}\left(\sum_{\substack{k<i\\ k\in M}} h_k + \sum_{\substack{k>j\\ k\in M}} h_k \right) \right) \right) \tag{99}$$

verifies the fused dynamical exchange relation

$$A^d_{M\bar{N}'} K_M(h_{N'}) B^d_{MN'} K_{N'}(h_M) = K_{N'}(h_M) C^d_{MN'} K_M(h_{N'}) D^d_{M\bar{N}'}. \tag{100}$$

Proof: Straightforward once one has established that the fused dual structure matrix is equal to the dual of the fused structure matrix and that the YB equations obeyed by the dual structure matrices derive from the equations (94). ■

B. Dressing

Proposition 9: Let T_M be a solution of the fused fully dynamical exchange relation. Then $Q_M T_M S_M$ is also a solution of the fused exchange relation provided Q_M and S_M verify

$$\begin{aligned} &Q_M A_{M\bar{N}'} = A_{M\bar{N}'} Q_M(h_{N'}), \quad Q_{N'}(h_M) A_{M\bar{N}'} = A_{M\bar{N}'} Q_{N'}, \\ &Q_{N'} B_{MN'} = B_{MN'} Q_{N'}(h_M), \quad Q_M C_{MN'} = C_{MN'} Q_M(h_{N'}), \end{aligned} \tag{101}$$

$$\begin{aligned} &S_{N'}(h_M) C_{MN'} = C_{MN'} S_{N'}, \quad S_M(h_{N'}) B_{MN'} = B_{MN'} S_M, \\ &S_M(h_{N'}) D_{M\bar{N}'} = D_{M\bar{N}'} S_M, \quad S_{N'} D_{M\bar{N}'} = D_{M\bar{N}'} S_{N'}(h_M). \end{aligned} \tag{102}$$

A particular solution of these constraints is given by

$$Q_M = \check{A}_{12}(h_{(3,m)}) \check{A}_{23}(h_{(4,m)}) \cdots \check{A}_{m-1,m},$$

$$S_M = \check{D}_{12} \check{D}_{23}(h_1) \cdots \check{D}_{m-1,m}(h_{(1,m-2)}).$$

Proof: By induction. ■

C. Commuting traces

We use the following properties inferred from Lemma 5:

$$e^{-\mathcal{D}_1-\mathcal{D}_2} A_{12} = A_{12}^{-SL_{12}} e^{-\mathcal{D}_1-\mathcal{D}_2} = \bar{A}_{12} e^{-\mathcal{D}_1-\mathcal{D}_2},$$

$$e^{-\mathcal{D}_2} A_{12} e^{\mathcal{D}_1} = e^{\mathcal{D}_1} \bar{A}_{12} e^{-\mathcal{D}_2},$$

and their transposed variants

$$e^{\mathcal{D}_1} (\bar{A}_{12}^{-SC_2 t_2})^{-1} e^{\mathcal{D}_2} = e^{\mathcal{D}_2} (A_{12}^{-SL_2 t_2})^{-1} e^{\mathcal{D}_1} \tag{103}$$

and so on. Since these relations are immediately derived from the ZW property on the structure matrices, they remain valid for fused structure matrices, too, since the fusion respects the zero weight property as opposed to the dynamical zero weight property (cf. remark above). In this case labels 1 and 2 formally denote tensored auxiliary spaces.

Theorem 14: *Let $\mathcal{T}_M$ be a solution of the fused dynamical exchange relations (68). $\mathcal{T}_M$ acts on the tensor product of the auxiliary spaces labeled by M and on the quantum space V_q.*

Let $\mathcal{K}_M$ be a solution of the dual fused dynamical exchange relation (72). $\mathcal{K}_M$ acts on the

tensor product of the auxiliary spaces labeled by M and on the quantum space $V_{q'}$.

The following operators:

$$H_M = \mathrm{Tr}_M e^{-\mathcal{D}_M} T_M e^{\mathcal{D}_M} K_M^{SCt_M} \tag{104}$$

constitute a family of commuting operators acting on $V_q \otimes V_{q'}$

$$[H_M, H_{N'}] = 0. \tag{105}$$

Proof: It is worth to give a detailed description of the proof as in Theorem 11 since the occurence of derivative objects $\sim e^{\mathcal{D}_M}$ considerably modifies it in comparison to the standard Sklyanin-type proof for nondynamical algebras. Once again the dynamical transposition lemma plays an essential role,

$$\begin{aligned}
H_M H_{N'} &= \mathrm{Tr}\, e^{-\mathcal{D}_M} T_M e^{\mathcal{D}_M} K_M^{SC_M t_M} e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} K_{N'}^{SC_{N'} t_{N'}} \\
&= \mathrm{Tr}\, e^{-\mathcal{D}_M} T_M e^{\mathcal{D}_M} K_M^{SC_M t_M} (e^{-\mathcal{D}_{N'}} T_{N'})^{t_{N'}} (e^{\mathcal{D}_{N'}} K_{N'}^{SC_{N'} t_{N'}})^{t_{N'}} \\
&= \mathrm{Tr}\, e^{-\mathcal{D}_M} T_M e^{\mathcal{D}_M} K_M^{SC_M t_M} T_{N'}^{-SL_{N'} t_{N'}} e^{-\mathcal{D}_{N'}} K_{N'} e^{\mathcal{D}_{N'}} \\
&= \mathrm{Tr}\, e^{-\mathcal{D}_M} T_M e^{\mathcal{D}_M} T_{N'}^{-SL_{N'} t_{N'}} K_M^{SC_M t_M} e^{-\mathcal{D}_{N'}} K_{N'} e^{\mathcal{D}_{N'}} \\
&= \mathrm{Tr}\, e^{-\mathcal{D}_M} [e^{-\mathcal{D}_{N'}} A_{MN'}^{-1} T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'} e^{\mathcal{D}_M}]^{t_{N'}} \\
&\quad \times (\bar{B}_{MN'}^{-SC_{N'} t_{N'}})^{-1} e^{\mathcal{D}_{N'}} K_M^{SC_M t_M} e^{-\mathcal{D}_{N'}} K_{N'} e^{\mathcal{D}_{N'}} \\
&= \mathrm{Tr} [e^{-\mathcal{D}_M - \mathcal{D}_{N'}} A_{MN'}^{-1} T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'}]^{t_{MN'}} \\
&\quad \times [e^{\mathcal{D}_M} (\bar{B}_{MN'}^{-SC_{N'} t_{N'}})^{-1} e^{\mathcal{D}_{N'}} K_M^{SC_M t_M}]^{t_M} e^{-\mathcal{D}_{N'}} K_{N'} e^{\mathcal{D}_{N'}}.
\end{aligned}$$

Pushing exponentials through B,

$$\begin{aligned}
&\mathrm{Tr}[e^{-\mathcal{D}_M - \mathcal{D}_{N'}} A_{MN'}^{-1} T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'}]^{t_{MN'}} e^{\mathcal{D}_{N'}} [(B_{MN'}^{-SL_{N'} t_{N'}})^{-1} e^{\mathcal{D}_M} K_M^{SC_M t_M}]^{t_M} e^{-\mathcal{D}_{N'}} K_{N'} e^{\mathcal{D}_{N'}} \\
&= \mathrm{Tr}[\bar{A}_{MN'}^{-1} e^{-\mathcal{D}_M - \mathcal{D}_{N'}} T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'}]^{t_{MN'}} e^{\mathcal{D}_{N'}} K_M e^{\mathcal{D}_M} ((B_{MN'}^{-SL_{N'} t_{N'}})^{-1})^{SC_M t_M} e^{-\mathcal{D}_{N'}} K_{N'} e^{\mathcal{D}_{N'}}.
\end{aligned}$$

Using zero weight of A and B transposed,

$$\begin{aligned}
&\mathrm{Tr}[T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'}]^{-SL_{MN'} t_{MN'}} \\
&\quad \times e^{-\mathcal{D}_M - \mathcal{D}_{N'}} (\bar{A}_{MN'}^{-1})^{-SC_{MN'} t_{MN'}} e^{\mathcal{D}_{N'}} K_M e^{-\mathcal{D}_{N'}} ((\bar{B}_{MN'}^{-SC_{N'} t_{N'}})^{-1})^{SL_1 t_M} e^{\mathcal{D}_M} K_{N'} e^{-\mathcal{D}_M} e^{\mathcal{D}_M + \mathcal{D}_{N'}} \\
&= \mathrm{Tr}[T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'}]^{-SL_{MN'} t_{MN'}} \\
&\quad \times e^{-\mathcal{D}_M - \mathcal{D}_{N'}} \{(\bar{A}_{MN'}^{-1})^{-SC_{MN'} t_{MN'}} K_M(h_{N'}) ((B_{MN'}^{-SC_{N'} t_{N'}})^{-1})^{SL_1 t_M} K_{N'}(h_M)\} e^{\mathcal{D}_M + \mathcal{D}_{N'}} \\
&= \mathrm{Tr}[T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'}]^{-SL_{MN'} t_{MN'}} e^{-\mathcal{D}_M - \mathcal{D}_{N'}} K_{N'}(h_M) ((\bar{C}_{MN'}^{-SC_M t_M})^{-1})^{SL_{N'} t_{N'}} \\
&\quad \times K_M(h_{N'}) (\bar{D}_{MN'}^{-1})^{SL_{MN'} t_{MN'}} e^{\mathcal{D}_M + \mathcal{D}_{N'}} \\
&= \mathrm{Tr}[e^{-\mathcal{D}_M - \mathcal{D}_{N'}} T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'}][K_{N'}(h_M) ((\bar{C}_{MN'}^{-SC_M t_M})^{-1})^{SL_{N'} t_{N'}} \\
&\quad \times K_M(h_{N'}) e^{\mathcal{D}_M + \mathcal{D}_{N'}} (D_{MN'}^{-1})^{SC_{MN'} t_{MN'}}]^{t_{MN'}} \\
&= \mathrm{Tr}\, e^{-\mathcal{D}_M - \mathcal{D}_{N'}} T_{N'}(h_M) C_{MN'} T_M(h_{N'}) D_{MN'} D_{MN'}^{-1} e^{\mathcal{D}_M + \mathcal{D}_{N'}} \\
&\quad \times [K_{N'}(h_M) ((\bar{C}_{MN'}^{-SC_M t_M})^{-1})^{SL_{N'} t_{N'}} K_M(h_{N'})]^{SL_{MN'} t_{MN'}}
\end{aligned}$$

$$= \mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} [e^{-\mathcal{D}_M} C_{MN'} e^{\mathcal{D}_{N'}} T_M]^{t_M} e^{\mathcal{D}_M - \mathcal{D}_{N'}}$$

$$\times [K_{N'} e^{-\mathcal{D}_M} ((\bar{C}_{MN'}^{-SC_M t_M})^{-1})^{SL_{N't_{N'}}} e^{\mathcal{D}_{N'}}]^{t_{N'}} K_M e^{\mathcal{D}_M}$$

$$= \mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} [\bar{C}_{MN'} e^{-\mathcal{D}_M} T_M]^{t_M} e^{\mathcal{D}_M - \mathcal{D}_{N'}} [K_{N'} e^{\mathcal{D}_{N'}} \ (C_{MN'}^{-SL_1 t_M})^{-1})^{SC_{N't_{N'}}}]^{t_{N'}} e^{-\mathcal{D}_M} K_M e^{\mathcal{D}_M}$$

$$= \mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} T_M^{-SL_1 t_M} e^{-\mathcal{D}_M} \bar{C}_{MN'}^{-SC_M t_M} e^{\mathcal{D}_M - \mathcal{D}_{N'}} (C_{MN'}^{-SL_1 t_M})^{-1} e^{\mathcal{D}_{N'}} K_{N'}^{SC_{N't_{N'}}} e^{-\mathcal{D}_M} K_M e^{\mathcal{D}_M}.$$

Using zero weight of C,

$$\mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} T_M^{-SL_1 t_M} e^{-\mathcal{D}_{N'}} C_{MN'}^{-SL_1 t_M} (C_{MN'}^{-SL_1 t_M})^{-1} e^{\mathcal{D}_{N'}} K_{N'}^{SC_{N't_{N'}}} e^{-\mathcal{D}_M} K_M e^{\mathcal{D}_M}$$

$$= \mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} T_M^{-SL_1 t_M} K_{N'}^{SC_{N't_{N'}}} e^{-\mathcal{D}_M} K_M e^{\mathcal{D}_M}$$

$$= \mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} K_{N'}^{SC_{N't_{N'}}} T_M^{-SL_1 t_M} e^{-\mathcal{D}_M} K_M e^{\mathcal{D}_M}$$

$$= \mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} K_{N'}^{SC_{N't_{N'}}} [T_M^{-SL_1 t_M} e^{-\mathcal{D}_M}]^{t_M} [K_M e^{\mathcal{D}_M}]^{t_M}$$

$$= \mathrm{Tr}\, e^{-\mathcal{D}_{N'}} T_{N'} e^{\mathcal{D}_{N'}} y K_{N'}^{SC_{N't_{N'}}} e^{-\mathcal{D}_M} T_M e^{\mathcal{D}_M} K_M^{SC_M t_M} = H_{N'} H_M.$$

■

V. CONCLUSION

We have now defined fusion and trace procedures in view of obtaining commuting Hamiltonians of "quantum trace type," for the nondynamical general quadratic algebra (1), for the semidynamical quadratic algebra (51) and for the fully dynamical quadratic algebra (90). Our immediate interest is now to apply this procedure to some particularly interesting examples of such quadratic algebras, the most relevant being at this time the scalar Ruijsenaars-Schneider quantum Lax formulation (semidynamical type).[29]

Note in this respect that previous application of an order-one trace formulation (i.e., without auxiliary space tensor products) to the specific case of "boundary dynamical $\mathfrak{sl}(2)$ algebras" considered in Ref. 12 yielded models described in Ref. 27 as generalizations of the Gaudin models. Positions of the sites were associated with values of the spectral parameters (in a spin-chain-type construction), not with the dynamical variable itself whose interpretation is unclear.

As already emphasized, our elucidation of tensor product structure for quadratic algebras is also very important in formulating generalizations of the Mezincescu-Nepomechie fusion procedure in general open spin chains.[9]

Our constructions moreover also shed light on some characteristic properties of the quadratic algebra. The building of commuting traces requires first of all the introduction of a dual exchange relation. It seems possible that this notion reflects the existence of antiautomorphisms of the underlying hypothetical algebra structure, of which the transposition and crossing relations used in the nondynamical cases (see Ref. 2) would be realizations.

The explicit formulation of consistent fusion relations should also help in understanding the meaning of quantum algebra (QA) structures and characterizing in particular their coalgebra properties. As pointed out, the DKM-type fusions do stem in at least one case from a universal structure,[15] and so does the fusion for boundary dynamical algebra (case when A,B,C,D stem from one single dynamical R-matrix[14]). Regarding the semidynamical QA it was already known[11] that one could extend the quantum space on which entries of T act, by auxiliary spaces of A and B or C and D matrices, thereby obtaining spin-chain-type construction of a monodromy matrix (comodule structure). We have now defined the complementary procedure, extending the auxiliary space by a "fusion" procedure. This yields the full "coproduct" or rather comodule structure of the DQA (51).

The global strong solutions of Hasegawa-Mima-Charney-Obukhov equation

Hongjun Gao[a] and Anyou Zhu
School of Mathematics and Computer Sciences, Nanjing Normal University, Nanjing, 210097, People's Republic of China

(Received 30 April 2005; accepted 27 June 2005; published online 12 August 2005)

The quasigeostrophic model is a simplified geophysical fluid model at asymptotically high rotation rate or at small Rossby number. We consider the quasigeostrophic equation with no dissipation term which was obtained as an asymptotic model from the Euler equations with free surface under a quasigeostrophic velocity field assumption. It is called the Hasegawa-Mima-Charney-Obukhov equation, which also arises from plasmas theory. We use *a priori* estimates to get the global existence of strong solutions for an Hasegawa-Mima-Charney-Obukhov equation. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2008208]

I. INTRODUCTION

This paper is devoted to study of the Cauchy problem on R^2 and to the existence of strong solutions for a general class of equations arising in plasma theory and geophysics. The quasigeostrophic equations describe large scale motion in the atmosphere and oceans at middle latitudes. Being considerably simper than the primitive equations, they have been widely used for modeling atmospheric and oceanic circulation, and for studies of stability, frontogenesis, and turbulence. A number of assertions have been made about these equations. Charney[4] and Obukhov[16] have derived a shallow water model from the Euler equation with free surface under a quasigeostrophic velocity field assumption. The reader could find some additional details on the formal derivation in Ref. 18. As in Ref. 17, by an asymptotic multiscale development with respect to δ (Aspect ratio) and ϵ (Rossby number) and using the β-plane approximation, the following quasigeostrophic equation was obtained:

$$(\Delta\eta_0 - F\eta_0)_t + J(\eta_0, \Delta\eta_0) + J(\eta_0, \eta_B + \beta y) = 0,$$

where η_0 is the amplitude of the surface perturbation at the lowest order in ϵ, $\eta_B(x,y)$ is the equation of the bottom and J is the Poisson bracket $J(u,v)=u_x v_y - u_y v_x$, F is Froude number. In this context, η_0 is a wave function of the velocity field. Moreover, for sake of simplicity we consider a flat bottom that is η_B is taken to be zero:

$$(\Delta\eta_0 - F\eta_0)_t + J(\eta_0, \Delta\eta_0) + \beta\eta_{0_x} = 0. \tag{1.1}$$

In plasma theory, these models describe drift waves in a nonuniform, β-low plasma in magnetic field and Eq. (1.1) was first derived in this setting by Hasegawa and Mima (see Refs. 8 and 9).

In Ref. 1, based on the results of Refs. 10 and 11, the authors obtained an existence and uniqueness theorem for a simplified quasigeostrophic equation in a bounded open annular cylinder. In Ref. 2, a coupled system of a second-order elliptic equation for a stream function, first-order hyperbolic equations for relative potential vorticity, and surface potential temperatures on a three-dimensional domain which is periodic in both horizontal spatial coordinates had been stud-

[a]Electronic mail: gaohj@njnu.edu.cn

ied. The authors of Ref. 2 used Schauder estimates and a Schauder fixed-point theorem to prove the existence and uniqueness of strong solution of the model in a finite interval of time, which is inversely proportional to the sum of the norms for the initial vorticity and surface temperatures.

In Refs. 5, 6, 15, and 19, the authors considered the initial value problem for two-dimensional critical dissipative quasigeostrophic equation:

$$\partial_t\theta + u\cdot\nabla\theta + \kappa(-\Delta)^\alpha\theta = f, \quad x\in\Omega, \quad t>0, \tag{1.2}$$

where $\kappa>0$, $\alpha\in[0,1]$, θ is a scalar function of x and t, and $u=(u_1,u_2)$ is the velocity field determined from θ by a stream function ψ via the auxiliary relations:

$$u=(u_1,u_2)=\left(-\frac{\partial\psi}{\partial x_2},\frac{\partial\psi}{\partial x_1}\right) \text{ and } (-\Delta)^{1/2}\psi=-\theta.$$

The authors have obtained many results for (1.2).

Let us remark that, (1.1) with $F=\beta=0$ could be treated as the two-dimensional Euler equation by setting $u=(-\eta_{0_y},\eta_{0_x})$. About the Euler equations for incompressible fluid motion in R^n for $n\geqslant 2$, it is proved by Kato and Lai,[12] Kato and Ponce[13] that there exists a $W^{s,p}(s>n/p+1)$ solution on the interval $[0,T)$. The time interval T of existence of the solution depends only on initial value in $W^{s,p}$-norm. It is an interesting question whether the solution is global one.

In this paper, for the simplicity, letting $F=1$, then we could rewrite the Cauchy problem for (1.1) as

$$(\Delta-I)u_t+u_x+J(u,\Delta u)=0, \quad u(0,x,y)=u_0(x,y)\in H^2(R^2). \tag{1.3}$$

The existence and uniqueness of local strong solution for (1.3) was obtained in Ref. 17. In this paper, our major goal is to get a global strong solution with H^4 initial data for (1.3). So, our result gives a partial answer in R^2. First, let us recall the results from Ref. 17.

Theorem 1.1: Let u_0 in $H^s(R^2)$ for an integer $s\geqslant 4$, then there exist $T^*=T^*(\|u_0\|_s)$ and a unique $u=u(t,x,y)$ satisfying

$$u\in L^\infty([0,T^*],H^s(R^2))\cap C^0([0,T^*],H^1(R^2)),$$

$$u_t\in L^\infty([0,T^*],H^{s-1}(R^2))\cap C^0([0,T^*],L^2(R^2))$$

and

$$(\Delta-I)u_t+u_x+J(u,\Delta u)=0, \quad u(0,x,y)=u_0(x,y)$$

with

$$J(u,\Delta u)\in L^\infty([0,T^*],H^{s-3}(R^2)).$$

The proof of this theorem can be found in Ref. 17. In Sec. II, we will use *a priori* estimates to prove the existence and uniqueness of global strong solution of (1.3).

II. GLOBAL THEORY IN $H^4(R^2)$

Hereafter C will denote possibly different constants. Let $\|\cdot\|_{H^s}$ and $|\cdot|_{L^2}$ denote the norm in the standard Sobolev space H^s (s is an integer) and L^2, respectively. And $\int_{R^2}u$ denote $\int_{R^2}u\mathrm{d}x\mathrm{d}y$.

Lemma 2.1: For any solution u from Theorem 1.1, we have

$$\frac{\mathrm{d}}{\mathrm{d}t}(|\nabla u|_{L^2}^2+|u|_{L^2}^2)=0, \tag{2.1}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}(|\Delta u|_{L^2}^2+|\nabla u|_{L^2}^2)=0. \tag{2.2}$$

Proof: Multiplying (1.3) by u and Δu, respectively, and integrating over R^2, we will obtain (2.1) and (2.2) immediately.

Lemma 2.2: For any solution u from Theorem 1.1, we have

$$\frac{\mathrm{d}}{\mathrm{d}t}(|\nabla^3 u|_{L^2}^2 + |\Delta u|_{L^2}^2) \leqslant C(1+\log(1+\|u\|_{H^4}))\|u\|_{H^4}^2. \tag{2.3}$$

Proof: Multiplying (1.3) by $\Delta^2 u$ and integrating over R^2, we obtain

$$-\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(|\nabla^3 u|_{L^2}^2 + |\Delta u|_{L^2}^2) + \int_{R^2} u_x \Delta^2 u + \int_{R^2} J(u,\Delta u)\Delta^2 u = 0.$$

Since $\int_{R^2} u_x \Delta^2 u = 0$, we get

$$-\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(|\nabla^3 u|_{L^2}^2 + |\Delta u|_{L^2}^2) + \int_{R^2} J(u,\Delta u)\Delta^2 u = 0. \tag{2.4}$$

Furthermore, we have

$$\begin{aligned}
\left|\int_{R^2} J(u,\Delta u)\Delta^2 u\right| &= \left|\int_{R^2} (u_x \Delta u_y \Delta^2 u - u_y \Delta u_x \Delta^2 u)\right| \leqslant \left|\int_{R^2} u_x \Delta u_y \Delta^2 u\right| + \left|\int_{R^2} u_y \Delta u_x \Delta^2 u\right| \\
&\leqslant |u_x|_{L^\infty}\int_{R^2} |\Delta u_y||\Delta^2 u| + |u_y|_{L^\infty}\int_{R^2} |\Delta u_x||\Delta^2 u| \leqslant |u_x|_{L^\infty}|\Delta u_y|_{L^2}|\Delta^2 u|_{L^2} \\
&\quad + |u_y|_{L^\infty}|\Delta u_x|_{L^2}|\Delta^2 u|_{L^2} \leqslant C(1+\log(1+\|u\|_{H^3}))(\|u\|_{H^3}\|u\|_{H^4} + \|u\|_{H^3}\|u\|_{H^4}) \\
&\leqslant C(1+\log(1+\|u\|_{H^3}))\|u\|_{H^4}^2 \leqslant C(1+\log(1+\|u\|_{H^4}))\|u\|_{H^4}^2,
\end{aligned} \tag{2.5}$$

where the Brezis-Gallouet's inequality[3] has been used. Combining (2.4) and (2.5), the proof of Lemma 2.2 is completed.

Lemma 2.3: For any solution u from Theorem 1.1, we have

$$\frac{\mathrm{d}}{\mathrm{d}t}(|\Delta^2 u|_{L^2}^2 + |\nabla^3 u|_{L^2}^2) \leqslant C(1+\log(1+\|u\|_{H^4}))\|u\|_{H^4}^2. \tag{2.6}$$

Proof: Multiplying Eq. (1.3) by $\Delta^3 u$, and integrating over R^2, we get

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(|\Delta^2 u|_{L^2}^2 + |\nabla^3 u|_{L^2}^2) + \int_{R^2} u_x \Delta^3 u + \int_{R^2} J(u,\Delta u)\Delta^3 u = 0.$$

Since $\int_{R^2} u_x \Delta^3 u = 0$, we obtain,

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(|\Delta^2 u|_{L^2}^2 + |\nabla^3 u|_{L^2}^2) + \int_{R^2} J(u,\Delta u)\Delta^3 u = 0. \tag{2.7}$$

Since,

$$\begin{aligned}
\left|\int_{R^2} J(u,\Delta u)\Delta^3 u\right| &= \left|\int_{R^2} u_x \Delta u_y \Delta^3 u - \int_{R^2} u_y \Delta u_x \Delta^3 u\right| = \left|\int_{R^2} \Delta(u_x \Delta u_y)\Delta^2 u - \int_{R^2} \Delta(u_y \Delta u_x)\Delta^2 u\right| \\
&= \left|\int_{R^2} \mathrm{div}(\nabla u_x \Delta u_y + u_x \nabla \Delta u_y)\Delta^2 u - \int_{R^2} \mathrm{div}(\nabla u_y \Delta u_x + u_y \nabla \Delta u_x)\Delta^2 u\right| \\
&= \left|\int_{R^2} (\Delta u_x \Delta u_y + \nabla u_x \nabla \Delta u_y + \nabla u_x \nabla \Delta u_y + u_x \Delta^2 u_y)\Delta^2 u - \int_{R^2} (\Delta u_y \Delta u_x\right.
\end{aligned}$$

$$+ \nabla u_y \nabla \Delta u_x + \nabla u_y \nabla \Delta u_x + u_y \Delta^2 u_x) \Delta^2 u \Big| = \Big| 2 \int_{R^2} (\nabla u_x \nabla \Delta u_y \Delta^2 u$$

$$- \nabla u_y \nabla \Delta u_x \Delta^2 u) + \int_{R^2} (u_x \Delta^2 u_y \Delta^2 u - u_y \Delta^2 u_x) \Delta^2 u) \Big|$$

$$= \Big| 2 \int_{R^2} (\nabla u_x \nabla \Delta u_y \Delta^2 u - \nabla u_y \nabla \Delta u_x \Delta^2 u) + \int_{R^2} J(u, \Delta^2 u) \Delta^2 u \Big|$$

$$= \Big| 2 \int_{R^2} (\nabla u_x \nabla \Delta u_y \Delta^2 u - \nabla u_y \nabla \Delta u_x \Delta^2 u) \Big| \leqslant 2 |\nabla u_x|_{L^\infty} |\nabla \Delta u_y|_{L^2} |\Delta^2 u|_{L^2}$$

$$+ 2 |\nabla u_y|_{L^\infty} |\nabla \Delta u_x|_{L^2} |\Delta^2 u|_{L^2} \leqslant C(1 + \log(1 + \|u\|_{H^4}))(\|u\|_{H^4} \|u\|_{H^4} + \|u\|_{H^4} \|u\|_{H^4})$$

$$= C(1 + \log(1 + \|u\|_{H^4})) \|u\|_{H^4}^2, \tag{2.8}$$

where we have used the property $\int_{R^2} J(u, \Delta^2 u) \Delta^2 u = 0$ (which we obtain by integrating by parts) and Brezis-Gallouet's inequality. Combining (2.7) and (2.8), the proof of Lemma 2.3 is completed.

Lemma 2.4: There exist constant C, C' and constant $C''(\|u_0\|_{H^4})$ such that, for every $T > 0$:

$$\|u\|_{H^4} \leqslant C' e^{1/2 e^{CT + C''(\|u_0\|_{H^4})}}.$$

Proof: From (2.1), (2.3), and (2.6), we deduce

$$\frac{\mathrm{d}}{\mathrm{d}t} (|\Delta^2 u|_{L^2}^2 + |\nabla^3 u|_{L^2}^2 + |\nabla^3 u|_{L^2}^2 + |\Delta u|_{L^2}^2 + |\nabla u|_{L^2}^2 + |u|_{L^2}^2) \leqslant C(1 + \log(1 + \|u\|_{H^4}))\|u\|_{H^4}^2.$$

Let

$$|\Delta^2 u|_{L^2}^2 + 2|\nabla^3 u|_{L^2}^2 + |\Delta u|_{L^2}^2 + |\nabla u|_{L^2}^2 + |u|_{L^2}^2 = [u]_{H^4}^2.$$

It is well known that the norm $\|\cdot\|_{H^s}$ is equivalent to

$$\sqrt{\sum_{|\alpha| \leqslant s} |\partial^\alpha|_{L^2}}$$

(s is an integer), so $\|\cdot\|_{H^4}$ and $[\cdot]_{H^4}$ are equivalent norms,[14] and there exists one constant C_1, such that, $\|u\|_{H^4} \leqslant C_1 [u]_{H^4}$, and

$$\frac{\mathrm{d}}{\mathrm{d}t} [u]_{H^4}^2 \leqslant C(1 + \log(1 + C_1 [u]_{H^4}))[u]_{H^4}^2 \leqslant C(1 + \log(1 + [u]_{H^4}^2))[u]_{H^4}^2,$$

where the Cauchy's inequality has been used. Then, we can choose one suitable constant $N(C, C_1)$, if $[u]_{H^4} \leqslant N(C, C_1)$, for every $T > 0$, the conclusion will be obtained. Otherwise, for suitable C, we have

$$\frac{\mathrm{d}}{\mathrm{d}t} [u]_{H^4}^2 \leqslant C[u]_{H^4}^2 \log [u]_{H^4}^2.$$

So, for every $T > 0$, we have

$$\log \log [u]_{H^4}^2 \leqslant CT + \log \log [u]_{H^4}^2(0) \leqslant CT + C''(\|u_0\|_{H^4}),$$

$$[u]_{H^4}^2 \leqslant e^{e^{CT + C''(\|u_0\|_{H^4})}},$$

$$[u]_{H^4} \leqslant e^{(1/2)e^{CT+C''(\|u_0\|_{H^4})}},$$

so, by the equivalence of $\|\cdot\|_{H^4}$ and $[\cdot]_{H^4}$, we have

$$\|u\|_{H^4} \leqslant C' e^{(1/2)e^{CT+C''(\|u_0\|_{H^4})}}.$$

Theorem 2.1: Let $u_0 \in H^4$, then problem (1.3) has a global unique solution in H^4.

Proof: From Theorem 1.1, we know problem (1.3) has a unique local strong solution $u(t,x,y) \in L^\infty([0,T^*],H^4(R^2)) \cap C^0([0,T^*],H^1(R^2))$, where T^* depends on $\|u_0\|_{H^4}$. By Lemma 2.4, for any given $T>0$, $\|u\|_{H^4}$ is bounded. We have global existence for (1.3) using the standard discussion (for example, Ref. 7).

Remark 2.1: Results of Theorem 2.1 remain true in $H^s(s \geqslant 4)$ for any $u_0 \in H^s$. To prove this, we multiply (1.3) by $\Delta^s u$ and integrate by parts over R^2, and then we use the property[1]

$$\begin{aligned}\left| \int_{R^2} \Delta^{s/2-1}(u_x \Delta u_y - u_y \Delta u_x)\Delta^{s/2} u \right| &= \left| \int_{R^2} \sum_{|\alpha| \leqslant s-2, |\beta| \leqslant s} C_{\alpha,\beta} \partial_\alpha u \partial_\beta u \Delta^{s/2} u \right| \\ &\leqslant C \sum_{|\alpha| \leqslant s-2, |\beta| \leqslant s} |\partial_\alpha u|_{L^\infty} |\partial_\beta u|_{L^2} |\Delta^{s/2} u|_{L^2} \\ &\leqslant C(1 + \log(1 + \|u\|_{H^s}))\|u\|_{H^s}^2\end{aligned}$$

and the equivalence of the norms (similar to lemma 2.4).

Analytical solution of the time evolution of an entangled electron spin pair in a double quantum dot nanostructure

M. Blaauboer
Kavli Institute of Nanoscience, Delft University of Technology, Lorentzweg 1, 2628 CJ Delft, The Netherlands

(Received 10 May 2005; accepted 27 June 2005; published online 16 August 2005)

Using master equations, we present an analytical solution of the time evolution of an entangled electron spin pair which can occupy 36 different quantum states in a double quantum dot nanostructure. This solution is exact, given a few realistic assumptions, and takes into account relaxation and decoherence rates of the electron spins as phenomenological parameters. Our systematic method of solving a large set of coupled differential equations is straightforward and can be used to obtain analytical predictions of the quantum evolution of a large class of complex quantum systems, for which until now commonly numerical solutions have been sought. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2007629]

I. INTRODUCTION

Master equations are used to describe the quantum evolution of a physical system interacting with some "reservoir,"[1] and have been applied to a wide variety of physical systems, ranging from two-level atoms in the presence of light fields[2] to solid-state nanostructures such as quantum dots and Josephson junction devices.[3] For simple systems, such as a two-level atom damped by a reservoir consisting of simple harmonic oscillators[4] or an electron in a single or double quantum dot coupled to external leads,[5] the set of master equations that describes the quantum dynamics of the system is small and its solution can be obtained analytically in a straightforward way. If the system is more involved, however, due to the presence of quite a few atomic levels or because the nanostructure is composed of various coherent parts, its quantum state space consists of a large number of quantum states with various coherent and incoherent couplings between them, and the analytical solution of the corresponding large set of coupled master equations does not spring to the eye. Hence, often a numerical solution is sought.[6] Understanding the quantum evolution of such "complex" quantum systems—where complex refers to a system which is described by a large number of coupled quantum states—has recently become increasingly important, in particular in fundamental research aimed at investigating the dynamic behavior of qubits, the basic building blocks for quantum computation.[7] A large theoretical and experimental effort in various fields, e.g., quantum optics, atomic physics, and condensed-matter physics, is presently directed toward investigating possibilities to use two-level systems such as polarized photons, cold atoms, electron spins, and superconducting circuits as qubits, and finding ways to couple these qubits together. In the latter three systems, one of the major questions involved is how the desired coherent evolution of the system will be affected by coupling to the environment, which is necessary to manipulate and measure the states of the qubits but invariably introduces undesired decoherence of their quantum states. A master equation model of the quantum evolution of one or more qubits interacting with their environment allows one to construct transparent general formulas and is therefore very suitable to give both qualitative and quantitative insight into the dynamics of these complex quantum systems.

In this paper we present an analytical solution of a large set of coupled master equations that describes the quantum evolution of a particular condensed-matter system, namely the time evolution of an entangled electron spin pair in a double quantum dot nanostructure. Even though our

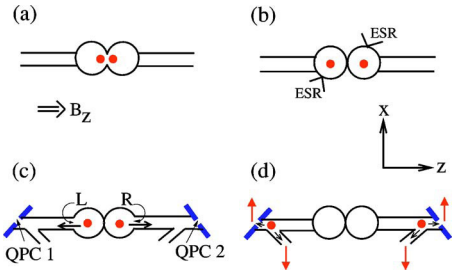

FIG. 1. Schematic top view of the double quantum dot nanostructure as discussed in Sec. II.

model applies to this specific quantum system, the presented method of solving the master equations is general and can be applied to study the dynamics of many other complex quantum systems. The time evolution of the electron spins is governed by several coherent and incoherent processes, each of which depends on time in a simple way as either oscillatory (cosine) or exponential functions. The solution we obtain shows how these simple ingredients combine to describe the evolution of the entangled spins in a complex nanostructure which consists of several coherent parts. It can be used to predict the occupation probability of all quantum states at any given time and to provide analytical estimates of the important time scales in the problem, such as the time at which decoherence of the entangled pair becomes substantial.[8]

The paper is organized as follows. In Sec. II the quantum nanostructure and the assumptions made are described. Section III contains the master equations and their solution, with technical details given in Appendixes A and B. A summary of the results and their range of applicability is presented in Sec. IV.

II. THE DOUBLE QUANTUM DOT NANOSTRUCTURE

The system we consider consists of a double quantum dot nanostructure, which is occupied by two entangled electron spins and operated as a turnstile. We studied this system in an earlier paper as a suitable setup for the detection of entanglement between electron spins.[9] Here, we focus on the dynamic evolution of the electron pair in the system, which is depicted in Fig. 1.

In detail, the structure consists of two adjacent quantum dots in a parallel magnetic field $B_z\hat{z}$, which are connected to two quantum point contacts (QPCs) via empty quantum channels. A quantum dot is a small metallic or semiconducting island, confined by gates and connected to electron reservoirs (leads) through quantum point contacts. If the gates are nearly closed and form tunnel barriers, the dot is occupied by a finite and controllable number of electrons which occupy discrete quantum levels, similar to atomic orbitals in atoms.[10] In our system, the gate between the two dots is assumed to be initially open and the dots are occupied by two electrons[11] [Fig. 1(a)] in their lowest energy state, the singlet state.[12] The gate between the two dots is then adiabatically closed, so that the electrons become separated and one dot is occupied by an electron with spin-up and the other by one with spin-down. The two spins do not interact anymore and are independently rotated by electron spin resonance (ESR) fields [Fig. 1(b)]. The latter are oscillating magnetic fields which, if the frequency of oscillation matches the energy difference between the two spin-split single-electron energy levels, cause coherent rotations of a spin between these levels, analogous to Rabi oscillations in a two-level atom. After spin rotation, the electrons are emitted into empty quantum channels by opening gates L and R [Fig. 1(c)] and scattered at quantum point contacts QPC 1 and QPC 2. In a parallel magnetic field and for conductances $G_{\mathrm{QPC1(QPC2)}} \leqslant e^2/h$ these QPCs are spin selective,[13] transmitting electrons with spin-up and reflecting those with spin-down [Fig. 1(d)]. The transmitted and reflected electrons are separately detected in the four exits.

In the next section we analyze the dynamics of the two spins from the moment they are separated and each occupies one of the two dots, until both have been detected in one of the four

exits. We use a master equation approach in which the effects of relaxation and decoherence are included as phenomenological decay rates.[1] The solution presented is exact under three assumptions:

(i) The time evolution during ESR in the dots is decoupled from the time evolution in the channels and exits. Physically, this means that the gates between the dots and channels are closed during the ESR rotations, so no tunneling occurs out of the dots during that time.
(ii) Once the electrons are in a channel they cannot tunnel back into the dots, i.e., backreflection of the electrons to the dots during their journey to the detectors is neglected. This corresponds to ballistic transport through the channels.
(iii) Once the electrons are in one of the exits they cannot return to the channels, i.e., the electrons are immediately detected and absorbed into the detectors.

III. THE MASTER EQUATIONS AND THEIR SOLUTION

In the setup as depicted in Fig. 1, each electron is assumed to be either in a dot, in a channel, or detected. This leads to a set of 36 possible quantum states represented by a 36×36 density matrix $\rho(t)$. This set consists of all possible combinations $A\sigma B\sigma'$, with $A\in\{D,C,X\}$ and $\sigma\in\{\uparrow,\downarrow\}$ indicating, respectively, the position (D=dot, C=channel, and X=exit) and the spin direction along $\hat{z}$ of the electron which started out in the left dot, and $B\in\{D,C,X\}$ and $\sigma'\in\{\uparrow,\downarrow\}$ representing the position and spin direction of the electron which started out in the right dot. The set is given by

$$\begin{aligned}\{&D\uparrow D\uparrow, D\uparrow D\downarrow, D\downarrow D\uparrow, D\downarrow D\downarrow, C\uparrow D\uparrow, C\uparrow D\downarrow, C\downarrow D\uparrow, C\downarrow D\downarrow, D\uparrow C\uparrow, D\uparrow C\downarrow, D\downarrow C\uparrow, D\downarrow C\downarrow, C\uparrow C\uparrow,\\ &C\uparrow C\downarrow, C\downarrow C\uparrow, C\downarrow C\downarrow, X\uparrow D\uparrow, X\uparrow D\downarrow, X\downarrow D\uparrow, X\downarrow D\downarrow, D\uparrow X\uparrow, D\uparrow X\downarrow, D\downarrow X\uparrow, D\downarrow X\downarrow, X\uparrow C\uparrow, X\uparrow C\downarrow,\\ &X\downarrow C\uparrow, X\downarrow C\downarrow, C\uparrow X\uparrow, C\uparrow X\downarrow, C\downarrow X\uparrow, C\downarrow X\downarrow, X\uparrow X\uparrow, X\uparrow X\downarrow, X\downarrow X\uparrow, X\downarrow X\downarrow\}.\end{aligned} \tag{1}$$

We number the states in set (1) by the numbers 1 to 36, so $1=D\uparrow D\uparrow$, $2=D\uparrow D\downarrow$, etc. The states labeled by C and X do not refer to *individual* quantum states in the channels and detectors, since in a channel many longitudinal modes exist and the detectors consist of many quantum states which together form a macroscopic state. What is meant by the states C and X is the *set* of all channel modes, respectively, all quantum states in the detectors. These states thus describe the probability of an electron to occupy any one of these channel modes or detector states. We come back to why this definition is useful and appropriate in the paragraph below Eq. (9). For long times, the only states that are occupied are 33–36, in which both electrons have entered into an exit and the channels and dots are empty.

The time evolution of the density matrix elements $\rho_{nm}(t)$ is given by the master equations[1]

$$\dot{\rho}_n(t) = -\frac{i}{\hbar}[\mathcal{H}(t),\rho(t)]_{nn} + \sum_{m\neq n}[W_{nm}\rho_m(t) - W_{mn}\rho_n(t)], \tag{2a}$$

$$\dot{\rho}_{n,m}(t) = -\frac{i}{\hbar}[\mathcal{H}(t),\rho(t)]_{nm} - V_{nm}\rho_{n,m}(t) \quad n\neq m, \tag{2b}$$

for $n,m\in\{1,\ldots,36\}$. The Hamiltonian $\mathcal{H}(t)$ describes the coherent evolution of the spins in the quantum dots due to the ESR fields and is given by, for two oscillating magnetic fields $B_{xL}\cos(\omega t)\hat{x}$ and $B_{xR}\cos(\omega t)\hat{x}$ applied to the left and right dots, respectively,

$$\mathcal{H}(t) = \mathcal{H}_0 - \tfrac{1}{2}g^*\mu_B\cos(\omega t)\sum_{\substack{M,N\in\{L,R\}\\ M\neq N}}(B_{xM}+\epsilon B_{xN})\bar{\sigma}_{xM}. \tag{3}$$

Here, $\mathcal{H}_0$ is a diagonal matrix containing the energies $E_n(n=1,\ldots,36)$ of each state, g^* the electron g factor, μ_B the Bohr magneton, and $\bar{\sigma}_{xL(R)}$ a 36×36 matrix with elements $(\bar{\sigma}_{xL(R)})_{ij}=1$

for each pair of states (i,j) that is coupled by the oscillating field $B_{xL(R)}$ and zero otherwise. For $g^*<0$ the 4×4 upper-left corner $\mathcal{H}_{\text{dots}}(t)$ of $\mathcal{H}(t)$ is then given explicitly as

$$\mathcal{H}_{\text{dots}}(t)=\begin{pmatrix} E_1 & \hbar\Delta_{RL}\cos(\omega t) & \hbar\Delta_{LR}\cos(\omega t) & 0 \\ \hbar\Delta_{RL}\cos(\omega t) & E_2 & 0 & \hbar\Delta_{LR}\cos(\omega t) \\ \hbar\Delta_{LR}\cos(\omega t) & 0 & E_3 & \hbar\Delta_{RL}\cos(\omega t) \\ 0 & \hbar\Delta_{LR}\cos(\omega t) & \hbar\Delta_{RL}\cos(\omega t) & E_4 \end{pmatrix},$$

with $E_1=2E_\uparrow+E_C$, $E_2=E_3=E_\uparrow+E_\downarrow+E_C$, and $E_4=2E_\downarrow+E_C$ in terms of the single-particle energies $E_\uparrow$ and $E_\downarrow$ and the charging energy $E_C=e^2/C$, where C is the total capacitance of the quantum dot (assumed to be equal for both dots), $\Delta_{RL}\equiv\Delta_R+\delta_L$ and $\Delta_{LR}\equiv\Delta_L+\delta_R$, with $\Delta_{R(L)}\equiv[|g^*|\mu_B B_{xR(L)}]/2\hbar$ and $\delta_{R(L)}\equiv[\epsilon|g^*|\mu_B B_{xR(L)}]/2\hbar$. The parameter ϵ, with $0\leqslant\epsilon<1$, represents the relative reduction of the field which is applied to one dot at the position of the spin in the other dot.[9] The remaining 32×32 part of the matrix $\mathcal{H}(t)$ is diagonal and equal to $\mathcal{H}_0$, since the ESR fields are applied when both electrons are located in a dot and the quantum channels do not contain any electrons whose spin might otherwise also be rotated by these fields.

Turning to the transition rates W_{nm} (from state m to n) in Eq. (2a), we distinguish between two kinds of transitions: (1) spin-flip transitions between two quantum states that differ by the direction of one spin only and (2) tunneling (without spin-flip) between quantum states that involve adjacent parts of the system, i.e., from dot to channel and from channel to exit. The latter are externally controlled by opening and closing the gates between the dots and channels. The former are modeled by the phenomenological rate $1/T_{1,\alpha}\equiv W_{\alpha\uparrow\downarrow}+W_{\alpha\downarrow\uparrow}$, with $\alpha\in\{D,C\}$ for spin flips in a dot or channel. Here, the W's depend on the Zeeman energy $\Delta E_Z\equiv|g^*|\mu_B B_z$ and temperature T via detailed balance $W_{\alpha\uparrow\downarrow}/W_{\alpha\downarrow\uparrow}=e^{\Delta E_Z/k_BT}$, so that

$$W_{\alpha\uparrow\downarrow(\downarrow\uparrow)}=\frac{1}{T_{1,\alpha}}\frac{1}{1+e^{-(+)\Delta E_Z/k_BT}},\quad \alpha\in\{D,C\}. \tag{4}$$

The spin decoherence rates V_{nm} in Eqs. (2b) for states n and m with $n,m\in\{1,\ldots,4\}$, i.e., the decoherence rate between states in which both electrons are located in a quantum dot, is given by

$$V_{nm}=\frac{1}{T_{2,D}}+\frac{1}{2}\sum_{j\neq n,m}(W_{jn}+W_{jm})\quad n,m\in\{1,\ldots,4\}, \tag{5}$$

where the W's refer to tunnel rates out of a dot. The coherence between state n and m thus not only depends on the intrinsic spin decoherence time $T_{2,D}$ which is caused by, e.g., spin-orbit or hyperfine interactions in the dots,[14] but is also reduced by the (incoherent) tunneling processes from dot to channel.[15] Similarly, V_{nm} for all other states n and m is given by

$$V_{nm}=\begin{cases}\dfrac{1}{T_{2,C}}+\dfrac{1}{2}\displaystyle\sum_{j\neq n,m}(W_{jn}+W_{jm}) & n,m\in\{1,\ldots,16\},\ \text{but not both } n,m\in\{1,\ldots,4\} \\ \infty & n\in\{17,\ldots,36\}\ \text{and/or}\ m\in\{17,\ldots,36\},\end{cases} \tag{6}$$

with the W's tunnel rates from a channel to an exit. Note that energy relaxation processes between different modes in the channels, i.e., between modes that contribute to the same set of channel states C, do not affect the transition rates W_{nm} and decoherence rates V_{nm} for the states where either n or m or both refer to a channel state. The reason for this is that these rates refer to, respectively, *spin* flip and *spin* decoherence processes, which are not affected by *orbital* (energy) relaxation and decoherence.[16] Hence, our definition of the channel states as sets of all modes with the same spin does not interfere with the definition of spin relaxation and decoherence of the quantum states.

With the above ingredients, the coupled equations (2) can be solved analytically. We proceed in three steps: ESR applied to the left dot, ESR applied to the right dot, and the time evolution

after the gates to the quantum channels have been opened. During each step only part of the quantum states are evolving in time, while the others remain unchanged. This simplifies the procedure to obtain an analytical solution.

A. Step 1: ESR applied to the left dot

Initially, at time $t=0$, both spins are assumed to be in the singlet state in the quantum dots, so

$$\rho_2(0)=\rho_3(0)=1/2;\quad \rho_j(0)=0\quad \forall\, j\in\{1,4,5,\ldots,36\}, \tag{7a}$$

$$\rho_{2,3}(0)=\rho_{3,2}(0)=-1/2;\quad \rho_{i,j}(0)=0 \text{ otherwise}. \tag{7b}$$

During ESR applied to the left dot, quantum states $\rho_5(t)-\rho_{36}(t)$ remain unchanged, since the gates between the dots and channels are closed. The coherent evolution of $\rho_1(t)-\rho_4(t)$ is then governed by the Hamiltonian

$$\mathcal{H}_{\mathrm{ESR}}(t)=\begin{pmatrix} E_1 & \hbar\delta_L\cos(\omega t) & \hbar\Delta_L\cos(\omega t) & 0\\ \hbar\delta_L\cos(\omega t) & E_2 & 0 & \hbar\Delta_L\cos(\omega t)\\ \hbar\Delta_L\cos(\omega t) & 0 & E_2 & \hbar\delta_L\cos(\omega t)\\ 0 & \hbar\Delta_L\cos(\omega t) & \hbar\delta_L\cos(\omega t) & E_4 \end{pmatrix}.$$

Including spin-flip rates $W_{D\uparrow\downarrow}$ and $W_{D\downarrow\uparrow}$ and the decoherence rate $\Gamma\equiv 1/T_{2,D}$ for both dots,[17] we then obtain from Eqs. (2) the master equations

$$\dot\rho_1=-\delta_L\,\mathrm{Im}\,\tilde\rho_{1,2}-\Delta_L\,\mathrm{Im}\,\tilde\rho_{1,3}-2W_{D\downarrow\uparrow}\rho_1+W_{D\uparrow\downarrow}(\rho_2+\rho_3), \tag{8a}$$

$$\dot\rho_2=\delta_L\,\mathrm{Im}\,\tilde\rho_{1,2}-\Delta_L\,\mathrm{Im}\,\tilde\rho_{2,4}+W_{D\uparrow\downarrow}+(W_{D\downarrow\uparrow}-W_{D\uparrow\downarrow})\rho_1-(2W_{D\uparrow\downarrow}+W_{D\downarrow\uparrow})\rho_2-W_{D\uparrow\downarrow}\rho_3, \tag{8b}$$

$$\dot\rho_3=-\delta_L\,\mathrm{Im}\,\tilde\rho_{3,4}+\Delta_L\,\mathrm{Im}\,\tilde\rho_{1,3}+W_{D\uparrow\downarrow}+(W_{D\downarrow\uparrow}-W_{D\uparrow\downarrow})\rho_1-W_{D\uparrow\downarrow}\rho_2-(2W_{D\uparrow\downarrow}+W_{D\downarrow\uparrow})\rho_3, \tag{8c}$$

$$\mathrm{Im}\,\dot{\tilde\rho}_{1,2}=-\frac{\delta_L}{2}(\rho_2-\rho_1)+\frac{\Delta_L}{2}(\mathrm{Re}\,\tilde\rho_{1,4}-\mathrm{Re}\,\tilde\rho_{2,3})-\Gamma\,\mathrm{Im}\,\tilde\rho_{1,2}, \tag{8d}$$

$$\mathrm{Im}\,\dot{\tilde\rho}_{1,3}=-\frac{\Delta_L}{2}(\rho_3-\rho_1)+\frac{\delta_L}{2}(\mathrm{Re}\,\tilde\rho_{1,4}-\mathrm{Re}\,\tilde\rho_{2,3})-\Gamma\,\mathrm{Im}\,\tilde\rho_{1,3}, \tag{8e}$$

$$\mathrm{Im}\,\dot{\tilde\rho}_{2,4}=-\frac{\Delta_L}{2}(\rho_4-\rho_2)-\frac{\delta_L}{2}(\mathrm{Re}\,\tilde\rho_{1,4}-\mathrm{Re}\,\tilde\rho_{2,3})-\Gamma\,\mathrm{Im}\,\tilde\rho_{2,4}, \tag{8f}$$

$$\mathrm{Im}\,\dot{\tilde\rho}_{3,4}=-\frac{\delta_L}{2}(\rho_4-\rho_3)-\frac{\Delta_L}{2}(\mathrm{Re}\,\tilde\rho_{1,4}-\mathrm{Re}\,\tilde\rho_{2,3})-\Gamma\,\mathrm{Im}\,\tilde\rho_{3,4}, \tag{8g}$$

$$\mathrm{Re}\,\dot{\tilde\rho}_{1,4}=-\frac{\delta_L}{2}(\mathrm{Im}\,\tilde\rho_{1,3}-\mathrm{Im}\,\tilde\rho_{2,4})-\frac{\Delta_L}{2}(\mathrm{Im}\,\tilde\rho_{1,2}-\mathrm{Im}\,\tilde\rho_{3,4})-\Gamma\,\mathrm{Re}\,\tilde\rho_{1,4}, \tag{8h}$$

$$\mathrm{Re}\,\dot{\tilde\rho}_{2,3}=\frac{\delta_L}{2}(\mathrm{Im}\,\tilde\rho_{1,3}-\mathrm{Im}\,\tilde\rho_{2,4})+\frac{\Delta_L}{2}(\mathrm{Im}\,\tilde\rho_{1,2}-\mathrm{Im}\,\tilde\rho_{3,4})-\Gamma\,\mathrm{Re}\,\tilde\rho_{2,3}, \tag{8i}$$

$$\mathrm{Re}\,\dot{\tilde{\rho}}_{1,2} = -\frac{\Delta_L}{2}(\mathrm{Im}\,\tilde{\rho}_{1,4} + \mathrm{Im}\,\tilde{\rho}_{2,3}) - \Gamma\,\mathrm{Re}\,\tilde{\rho}_{1,2}, \tag{8j}$$

$$\mathrm{Re}\,\dot{\tilde{\rho}}_{1,3} = -\frac{\delta_L}{2}(\mathrm{Im}\,\tilde{\rho}_{1,4} - \mathrm{Im}\,\tilde{\rho}_{2,3}) - \Gamma\,\mathrm{Re}\,\tilde{\rho}_{1,3} \tag{8k}$$

$$\mathrm{Re}\,\dot{\tilde{\rho}}_{2,4} = \frac{\delta_L}{2}(\mathrm{Im}\,\tilde{\rho}_{1,4} - \mathrm{Im}\,\tilde{\rho}_{2,3}) - \Gamma\,\mathrm{Re}\,\tilde{\rho}_{2,4}, \tag{8l}$$

$$\mathrm{Re}\,\dot{\tilde{\rho}}_{3,4} = \frac{\Delta_L}{2}(\mathrm{Im}\,\tilde{\rho}_{1,4} + \mathrm{Im}\,\tilde{\rho}_{2,3}) - \Gamma\,\mathrm{Re}\,\tilde{\rho}_{3,4}, \tag{8m}$$

$$\mathrm{Im}\,\dot{\tilde{\rho}}_{1,4} = \frac{\delta_L}{2}(\mathrm{Re}\,\tilde{\rho}_{1,3} - \mathrm{Re}\,\tilde{\rho}_{2,4}) + \frac{\Delta_L}{2}(\mathrm{Re}\,\tilde{\rho}_{1,2} - \mathrm{Re}\,\tilde{\rho}_{3,4}) - \Gamma\,\mathrm{Im}\,\tilde{\rho}_{1,4}, \tag{8n}$$

$$\mathrm{Im}\,\dot{\tilde{\rho}}_{2,3} = -\frac{\delta_L}{2}(\mathrm{Re}\,\tilde{\rho}_{1,3} - \mathrm{Re}\,\tilde{\rho}_{2,4}) + \frac{\Delta_L}{2}(\mathrm{Re}\,\tilde{\rho}_{1,2} - \mathrm{Re}\,\dot{\tilde{\rho}}_{3,4}) - \Gamma\,\mathrm{Im}\,\tilde{\rho}_{2,3}, \tag{8o}$$

with $\tilde{\rho}_{i,j}(t) \equiv \rho_{i,j}(t)e^{-i\omega t}$ for $(ij) \in \{(12), (13), (24), (34)\}$, $\tilde{\rho}_{1,4}(t) \equiv \rho_{1,4}(t)e^{-2i\omega t}$ and $\tilde{\rho}_{2,3}(t) \equiv \rho_{2,3}(t)$. Equations (8) are valid on resonance, so $\hbar\omega \equiv E_2 - E_1 = E_4 - E_2 = \Delta E_Z$ and within the rotating wave approximation (RWA).[18] Here, $\rho_4(t)$ is given by $\rho_4(t) = 1 - \rho_1(t) - \rho_2(t) - \rho_3(t)$.

Equations (8) can be split into two sets of coupled equations: Eqs. (8a)–(8i) and Eqs. (8j)–(8o). The solution of the second set is straightforwardly obtained and given by

$$\begin{aligned}\mathrm{Re}\,\tilde{\rho}_{1,2}(t) = \tfrac{1}{2}(&\mathrm{Re}[\tilde{\rho}_{1,2}(0) - \tilde{\rho}_{3,4}(0)]\cos(\Delta_L t) - \mathrm{Im}[\tilde{\rho}_{1,4}(0) + \tilde{\rho}_{2,3}(0)]\sin(\Delta_L t)\\ &+ \mathrm{Re}[\tilde{\rho}_{1,2}(0) + \tilde{\rho}_{3,4}(0)])e^{-\Gamma t},\end{aligned} \tag{9a}$$

$$\begin{aligned}\mathrm{Re}\,\tilde{\rho}_{1,3}(t) = \tfrac{1}{2}(&\mathrm{Re}[\tilde{\rho}_{1,3}(0) - \tilde{\rho}_{2,4}(0)]\cos(\delta_L t) - \mathrm{Im}[\tilde{\rho}_{1,4}(0) - \tilde{\rho}_{2,3}(0)]\sin(\delta_L t)\\ &+ \mathrm{Re}[\tilde{\rho}_{1,3}(0) + \tilde{\rho}_{2,4}(0)])e^{-\Gamma t},\end{aligned} \tag{9b}$$

$$\begin{aligned}\mathrm{Re}\,\tilde{\rho}_{2,4}(t) = \tfrac{1}{2}(&-\mathrm{Re}[\tilde{\rho}_{1,3}(0) - \tilde{\rho}_{2,4}(0)]\cos(\delta_L t) + \mathrm{Im}[\tilde{\rho}_{1,4}(0) - \tilde{\rho}_{2,3}(0)]\sin(\delta_L t)\\ &+ \mathrm{Re}[\tilde{\rho}_{1,3}(0) + \tilde{\rho}_{2,4}(0)])e^{-\Gamma t},\end{aligned} \tag{9c}$$

$$\begin{aligned}\mathrm{Re}\,\tilde{\rho}_{3,4}(t) = \tfrac{1}{2}(&-\mathrm{Re}[\tilde{\rho}_{1,2}(0) - \tilde{\rho}_{3,4}(0)]\cos(\Delta_L t) + \mathrm{Im}[\tilde{\rho}_{1,4}(0) + \tilde{\rho}_{2,3}(0)]\sin(\Delta_L t)\\ &+ \mathrm{Re}[\tilde{\rho}_{1,2}(0) + \tilde{\rho}_{3,4}(0)])e^{-\Gamma t},\end{aligned} \tag{9d}$$

$$\begin{aligned}\mathrm{Im}\,\tilde{\rho}_{1,4}(t) = \tfrac{1}{2}(&\mathrm{Im}[\tilde{\rho}_{1,4}(0) + \tilde{\rho}_{2,3}(0)]\cos(\Delta_L t) + \mathrm{Im}[\tilde{\rho}_{1,4}(0) - \tilde{\rho}_{2,3}(0)]\cos(\delta_L t)\\ &+ \mathrm{Re}[\tilde{\rho}_{1,2}(0) - \tilde{\rho}_{3,4}(0)]\sin(\Delta_L t) + \mathrm{Re}[\tilde{\rho}_{1,3}(0) - \tilde{\rho}_{2,4}(0)]\sin(\delta_L t))e^{-\Gamma t},\end{aligned} \tag{9e}$$

$$\begin{aligned}\mathrm{Im}\,\tilde{\rho}_{2,3}(t) = \tfrac{1}{2}(&\mathrm{Im}[\tilde{\rho}_{1,4}(0) + \tilde{\rho}_{2,3}(0)]\cos(\Delta_L t) - \mathrm{Im}[\tilde{\rho}_{1,4}(0) - \tilde{\rho}_{2,3}(0)]\cos(\delta_L t)\\ &+ \mathrm{Re}[\tilde{\rho}_{1,2}(0) - \tilde{\rho}_{3,4}(0)]\sin(\Delta_L t) - \mathrm{Re}[\tilde{\rho}_{1,3}(0) - \tilde{\rho}_{2,4}(0)]\sin(\delta_L t))e^{-\Gamma t}.\end{aligned} \tag{9f}$$

In order to solve the set of equations (8a)–(8i) we express $\rho_1 - \rho_3$, $\mathrm{Im}\,\tilde{\rho}_{1,2}$, $\mathrm{Im}\,\tilde{\rho}_{1,3}$, $\mathrm{Im}\,\tilde{\rho}_{2,4}$, $\mathrm{Im}\,\tilde{\rho}_{3,4}$, $\mathrm{Re}\,\tilde{\rho}_{1,4}$, and $\mathrm{Re}\,\tilde{\rho}_{2,3}$ in terms of new variables $x_1 - x_8$ as follows:

$$\rho_1(t) = \tfrac{1}{2}(x_1(t) + x_2(t) - x_3(t))e^{-\Gamma t},$$

$$\rho_2(t) = \tfrac{1}{2}(x_1(t) - x_2(t) + x_3(t))e^{-\Gamma t},$$

$$\rho_3(t) = \tfrac{1}{2}(-x_1(t) + x_2(t) + x_3(t))e^{-\Gamma t},$$

$$\mathrm{Im}\ \tilde{\rho}_{1,2}(t) = \tfrac{1}{2}(x_4(t) + x_6(t))e^{-\Gamma t},$$

$$\mathrm{Im}\ \tilde{\rho}_{1,3}(t) = \tfrac{1}{2}(x_5(t) + x_7(t))e^{-\Gamma t},$$

$$\mathrm{Im}\ \tilde{\rho}_{2,4}(t) = \tfrac{1}{2}(x_5(t) - x_7(t))e^{-\Gamma t},$$

$$\mathrm{Im}\ \tilde{\rho}_{3,4}(t) = \tfrac{1}{2}(x_4(t) - x_6(t))e^{-\Gamma t},$$

$$\mathrm{Re}\ \tilde{\rho}_{1,4}(t) = x_8(t)e^{-\Gamma t},$$

$$\mathrm{Re}\ \tilde{\rho}_{2,3}(t) = (-x_8(t) + Z)e^{-\Gamma t}, \tag{10}$$

with $Z \equiv \mathrm{Re}[\tilde{\rho}_{1,4}(0) + \tilde{\rho}_{2,3}(0)]$. The transformation (10) originates from pairwise adding and subtracting those equations among (8d)–(8i) which share a common term on the right-hand side, e.g., the equations for $\mathrm{Im}\ \dot{\tilde{\rho}}_{1,2}$ and $\mathrm{Im}\ \dot{\tilde{\rho}}_{3,4}$. The definition of $x_1 - x_8$ then naturally arises. Physically, the new variables x_1, x_2, and x_3 can be interpreted as $x_{1(2)}$ = the probability for the spin in the left (right) dot to be up, and x_3 = the probability for the two spins to be antiparallel, each modulated by the exponential dependence on the decoherence rate Γ. Using (10), Eqs. (8a)–(8i) are rewritten in terms of $x_1(t) - x_8(t)$, which leads to three sets of coupled equations. These equations and their solution are given in Appendix A. Equations (10) at time $t = t_1$, where t_1 is the time during which the ESR field is switched on, thus represent the density matrix elements for the double-dot states after the ESR rotation applied to the left dot.

B. Step 2: ESR applied to the right dot

Equations (10) can also be used directly to obtain the solution after the second ESR rotation applied to the right dot, by substituting $\Delta_L \to \delta_R$ and $\delta_L \to \Delta_R$ in Eqs. (9) and (A2), and by exchanging $x_6 \leftrightarrow x_7$ in Eqs. (A4), using $\rho_1(t_1)$ instead of $\rho_1(0)$, etc., as initial conditions. In order to illustrate this solution, let us consider the initial condition of a singlet in the double dot [Eq. (7)], and let t_2 be the duration of the second ESR rotation. In the case of no dissipation (all W's = 0) and no influence of ESR applied to one dot on the spin in the other dot, we then obtain from Eqs. (10), (A2), and (A4), e.g., the occupation probability $\rho_2(t_1 + t_2)$ the expression

$$\rho_2(t_1 + t_2) = \frac{1}{4}\left[1 + \left\{\left[\cos(\tilde{\Omega}_\Delta t_1) + \frac{\Gamma}{2\tilde{\Omega}_\Delta}\sin(\tilde{\Omega}_\Delta t_1)\right]\left[\cos(\tilde{\Omega}_\Delta t_2) + \frac{\Gamma}{2\tilde{\Omega}_\Delta}\sin(\tilde{\Omega}_\Delta t_2)\right] + \frac{\Delta}{\tilde{\Omega}_\Delta}\sin(\Delta\, t_1)\sin(\tilde{\Omega}_\Delta t_2)e^{-(\Gamma/2)t_1}\right\}e^{-(\Gamma/2)(t_1+t_2)}\right], \tag{11}$$

with $\tilde{\Omega}_\Delta \equiv \frac{1}{2}\sqrt{4\Delta^2 - \Gamma^2}$ and $\Delta \equiv \Delta_L = \Delta_R$. In the absence of decoherence ($\Gamma = 0$) the expressions for $\rho_2(t_1 + t_2)$ and the other density matrix elements simplify to

$$\rho_1(t_1 + t_2) = \rho_4(t_1 + t_2) = \tfrac{1}{4}(1 - \cos\,\theta_1 \cos\,\theta_2 - \sin\,\theta_1 \sin\,\theta_2), \tag{12a}$$

$$\rho_2(t_1 + t_2) = \rho_3(t_1 + t_2) = \tfrac{1}{4}(1 + \cos\,\theta_1 \cos\,\theta_2 + \sin\,\theta_1 \sin\,\theta_2), \tag{12b}$$

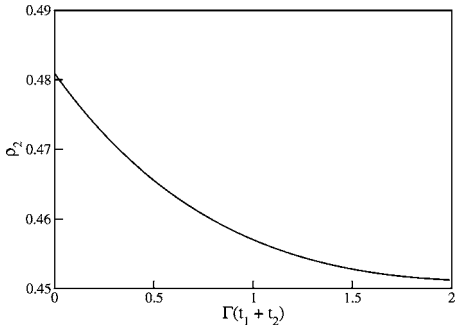

FIG. 2. The occupation probability $\rho_2(t_1+t_2)$ [Eq. (11)] of the quantum state $D\uparrow D\downarrow$ as a function of the amount of decoherence [in units of $1/(t_1+t_2)$]. For $\Gamma=0$ ρ_2 is given by Eq. (12b). Parameters used are $\Delta t_1=\pi/4$, $\Delta t_2=\pi/8$, and all W's=0.

$$\rho_{1,2}(t_1+t_2)=\rho_{2,4}(t_1+t_2)=-\frac{i}{4}(\cos\theta_1\sin\theta_2-\sin\theta_1\cos\theta_2), \tag{12c}$$

$$\rho_{1,3}(t_1+t_2)=\rho_{3,4}(t_1+t_2)=\frac{i}{4}(\cos\theta_1\sin\theta_2-\sin\theta_1\cos\theta_2), \tag{12d}$$

$$\rho_{1,4}(t_1+t_2)=-\tfrac{1}{4}(1-\cos\theta_1\cos\theta_2-\sin\theta_1\sin\theta_2), \tag{12e}$$

$$\rho_{2,3}(t_1+t_2)=-\tfrac{1}{4}(1+\cos\theta_1\cos\theta_2+\sin\theta_1\sin\theta_2), \tag{12f}$$

with $\theta_1\equiv\tilde{\Omega}_\Delta t_1$ and $\theta_2\equiv\tilde{\Omega}_\Delta t_2$. Equation (11) is plotted in Fig. 2 as a function of the amount of decoherence Γ.

Already for moderate amounts of decoherence $\Gamma(t_1+t_2)=0.001$, the occupation probability has become 0.01% less than its value in the absence of decoherence $\rho_2^{\Gamma=0}(t_1+t_2)=0.481$, for the set of parameters chosen in Fig. 2. This increases to 0.1% for $\Gamma(t_1+t_2)=0.01$.

C. Step 3: Time evolution after the gates to the channels have been opened

We now turn to the next step in the evolution of the entangled pair in Fig. 1, namely the time evolution of the density matrix elements after the ESR rotations are completed and the gates to the quantum channels are opened; see Fig. 1(c). From this moment onward the coherent evolution due to the first term on the right-hand side of Eqs. (2) stops and the time evolution of the matrix elements is solely determined by decay and decoherence rates represented by the second terms on the right-hand side of Eqs. (2). The off-diagonal elements $\rho_{i,j}(t)$ then rotate with $(E_i-E_j)/\hbar$ and decay with rate V_{ij}

$$\rho_{i,j}(t)=\rho_{i,j}(t_{\mathrm{ESR}})e^{i(E_i-E_j)(t-t_{\mathrm{ESR}})/\hbar}e^{-V_{ij}(t-t_{\mathrm{ESR}})}\quad\text{for } t\geqslant t_{\mathrm{ESR}}, \tag{13}$$

where $t_{\mathrm{ESR}}\equiv t_1+t_2$ and V_{ij} is given by Eq. (5) for $i,j\in\{1,\ldots,4\}$ and Eq. (6) otherwise. The initial values $\rho_{i,j}(t_{\mathrm{ESR}})$ for $i,j\in\{1,\ldots,16\}$ are given by $\rho_{m,n}(t_{\mathrm{ESR}})$ for $m,n\in\{1,\ldots,4\}$ [Eqs. (10)] with the correspondence in indices

$$i(j)\in\{1,5,9,13\}\leftrightarrow m(n)=1,$$

$$i(j)\in\{2,6,10,14\}\leftrightarrow m(n)=2,$$

$$i(j)\in\{3,7,11,15\}\leftrightarrow m(n)=3,$$

$$i(j) \in \{4,8,12,16\} \leftrightarrow m(n) = 4.$$

In this way the coherence at time t_{ESR} between any pair of states $i,j \in \{1,\ldots,16\}$ is given by the coherence at t_{ESR} between those dot states $m,n \in \{1,\ldots,4\}$ which can (eventually) coherently evolve into i and j, i.e., the dot states m and n which have the same spin states as i and j, respectively. So, for example, $\rho_{C\uparrow C\uparrow,D\downarrow C\downarrow}(t_{\mathrm{ESR}}) = \rho_{D\uparrow D\uparrow,D\downarrow D\downarrow}(t_{\mathrm{ESR}}) \equiv \rho_{1,4}(t_{\mathrm{ESR}})$. Note that $\rho_{i,j}(t)=0$ for those states in which at least one electron has reached a detector ($i \in \{17,\ldots,36\}$ and/or $j \in \{17,\ldots,36\}$), since for those states $V_{ij}=\infty$. This corresponds to the assumption of immediate detection.

In the remaining part of this paper we focus on the evolution of the populations $\rho_1(t)-\rho_{36}(t)$ for times $t \geqslant t_{\mathrm{ESR}}$ under the following conditions:

(i) We neglect the possibility of spin flips in the dots, i.e., we set $W_{D\uparrow\downarrow}=W_{D\downarrow\uparrow}=0$. This is based on the fact that $T_{1,D}$ is known to be much longer (0.85 ms at magnetic fields $B_z=8T$) (Ref. 19) than the time required to travel through the channels to the exits. This assumption is not essential to obtain an analytical solution; it only simplifies the resulting equations.

(ii) We assume that the tunnel rate W_T out of the dots into the channels is equal for spin-up and spin-down electrons, i.e., the two electrons tunnel out of the singlet state with a negligible time delay t_{delay} in between, and that spin is conserved during this tunneling process. Typically[20] $t_{\mathrm{delay}} \approx 10^{-13}$ s, which is much less than the travel time through a channel, $\sim 10^{-10}$ s.

(iii) The tunnel rate W_E through the QPCs is taken to be constant and equal for spin-up and spin-down electrons, i.e., the setup is assumed to be constructed in such a way that the detection time for spin-up and spin-down electrons once they have reached the QPCs is the same.

(iv) Spin flips in the exits are neglected, i.e., detection is assumed to be faster (with typical times $\sim 10^{-11}$ s) (Ref. 21) than the spin-flip rate ($\geqslant 10^{-11}$ s) (Ref. 9) in the detectors.

The evolution equations for $\rho_1(t)-\rho_{36}(t)$ for times $t \geqslant t_{\mathrm{ESR}}$ are then given by the master equations

$$\dot{\rho}_i = -2W_T\rho_i \text{ for } i \in \{1,\ldots,4\}. \tag{14}$$

$$\dot{\rho}_i = W_T\rho_{i-4} + W_{C\uparrow\downarrow}\rho_{i+2} - (W_E + W_T + W_{C\downarrow\uparrow})\rho_i, \quad i \in \{5,6\}, \tag{15a}$$

$$\dot{\rho}_i = W_T\rho_{i-4} + W_{C\downarrow\uparrow}\rho_{i-2} - (W_E + W_T + W_{C\uparrow\downarrow})\rho_i, \quad i \in \{7,8\}, \tag{15b}$$

$$\dot{\rho}_i = W_T\rho_{i-8} + W_{C\uparrow\downarrow}\rho_{i+1} - (W_E + W_T + W_{C\downarrow\uparrow})\rho_i, \quad i \in \{9,11\}, \tag{15c}$$

$$\dot{\rho}_i = W_T\rho_{i-8} + W_{C\downarrow\uparrow}\rho_{i-1} - (W_E + W_T + W_{C\uparrow\downarrow})\rho_i, \quad i \in \{10,12\}. \tag{15d}$$

$$\dot{\rho}_{13} = W_T(\rho_5 + \rho_9) + W_{C\uparrow\downarrow}(\rho_{14} + \rho_{15}) - 2(W_E + W_{C\downarrow\uparrow})\rho_{13}, \tag{16a}$$

$$\dot{\rho}_{14} = W_T(\rho_6 + \rho_{10}) + W_{C\downarrow\uparrow}\rho_{13} + W_{C\uparrow\downarrow}\rho_{16} - (2W_E + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow})\rho_{14}, \tag{16b}$$

$$\dot{\rho}_{15} = W_T(\rho_7 + \rho_{11}) + W_{C\downarrow\uparrow}\rho_{13} + W_{C\uparrow\downarrow}\rho_{16} - (2W_E + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow})\rho_{15}, \tag{16c}$$

$$\dot{\rho}_{16} = W_T(\rho_8 + \rho_{12}) + W_{C\downarrow\uparrow}(\rho_{14} + \rho_{15}) - 2(W_E + W_{C\uparrow\downarrow})\rho_{16}. \tag{16d}$$

$$\dot{\rho}_i(t) = W_E\rho_{i-12}(t - t_{\mathrm{travel}} + t_{\mathrm{ESR}}) - W_T\rho_i(t), \quad i \in \{17,\ldots,24\}. \tag{17}$$

$$\dot{\rho}_i(t) = W_T\rho_{i-8}(t) + W_E\rho_{i-12}(t - t_{\text{travel}} + t_{\text{ESR}}) + W_{C\uparrow\downarrow}\rho_{i+1}(t) - (W_E + W_{C\downarrow\uparrow})\rho_i(t) \quad \text{for } i \in \{25,27\}, \tag{18a}$$

$$\dot{\rho}_i(t) = W_T\rho_{i-8}(t) + W_E\rho_{i-12}(t - t_{\text{travel}} + t_{\text{ESR}}) + W_{C\downarrow\uparrow}\rho_{i-1}(t) - (W_E + W_{C\uparrow\downarrow})\rho_i(t) \quad \text{for } i \in \{26,28\}, \tag{18b}$$

$$\dot{\rho}_i(t) = W_T\rho_{i-8}(t) + W_E\rho_{i-16}(t - t_{\text{travel}} + t_{\text{ESR}}) + W_{C\uparrow\downarrow}\rho_{i+2}(t) - (W_E + W_{C\downarrow\uparrow})\rho_i(t) \quad \text{for } i \in \{29,30\}, \tag{18c}$$

$$\dot{\rho}_i(t) = W_T\rho_{i-8}(t) + W_E\rho_{i-16}(t - t_{\text{travel}} + t_{\text{ESR}}) + W_{C\downarrow\uparrow}\rho_{i-2}(t) - (W_E + W_{C\uparrow\downarrow})\rho_i(t) \quad \text{for } i \in \{31,32\}. \tag{18d}$$

$$\dot{\rho}_i = W_E(\rho_{i-8} + \rho_{i-4}) \quad i \in \{33, \ldots, 36\}. \tag{19}$$

Here, $t_{\text{travel}} > t_{\text{ESR}}$ denotes the earliest time at which an electron has traveled through the channels and reached an exit. For times $t \leqslant t_{\text{travel}}$, $\rho_1(t) - \rho_{36}(t)$ is thus given by Eqs. (14)–(19) for $W_E = 0$, since at those times no electron can have arrived at a detector yet. The above sets of coupled equations can be solved one by one: first those for $\rho_1(t) - \rho_4(t)$, then once the latter are known those for $\rho_5(t) - \rho_{12}(t)$ [in the pairs (5,7), (6,8), (9,10), and (11,12)], then $\rho_{13}(t) - \rho_{16}(t)$ and $\rho_{17}(t) - \rho_{24}(t)$, subsequently $\rho_{25}(t) - \rho_{32}(t)$ [in the pairs (25,26), (27,28), (29,31), and (30,32)] and finally $\rho_{33}(t) - \rho_{36}(t)$. Proceeding in this order and using initial conditions

$$\rho_i(t_{\text{ESR}}) = \begin{cases} \text{Eqs. (10)} & \text{for } i = 1, \ldots, 4, \\ 0 & \text{for } i = 5, \ldots, 36, \end{cases} \tag{20}$$

we obtain for $\rho_1(t) - \rho_4(t)$, the states in which both electrons are located in a dot,

$$\rho_i(t) = \rho_i(t_{\text{ESR}})e^{-2W_T(t - t_{\text{ESR}})} \quad i \in \{1, \ldots, 4\},\ t \geqslant t_{\text{ESR}}. \tag{21}$$

Next, we find for $\rho_5(t) - \rho_{12}(t)$, which correspond to the quantum states in which one electron is located in a dot and the other in a channel, from Eqs. (15)

$$\rho_5(t) = A_{5,7,1,3}e^{-W_{ETC}(t - t_{\text{ESR}})} + B_{5,7,1,3}e^{-(W_E + W_T)(t - t_{\text{ESR}})} + C_{1,3}e^{-2W_T(t - t_{\text{ESR}})}, \tag{22a}$$

$$\rho_6(t) = A_{6,8,2,4}e^{-W_{ETC}(t - t_{\text{ESR}})} + B_{6,8,2,4}e^{-(W_E + W_T)(t - t_{\text{ESR}})} + C_{2,4}e^{-2W_T(t - t_{\text{ESR}})}, \tag{22b}$$

$$\rho_7(t) = -A_{5,7,1,3}e^{-W_{ETC}(t - t_{\text{ESR}})} + \frac{W_{C\downarrow\uparrow}}{W_{C\uparrow\downarrow}}B_{5,7,1,3}e^{-(W_E + W_T)(t - t_{\text{ESR}})} + D_{1,3}e^{-2W_T(t - t_{\text{ESR}})}, \tag{22c}$$

$$\rho_8(t) = -A_{6,8,2,4}e^{-W_{ETC}(t - t_{\text{ESR}})} + \frac{W_{C\downarrow\uparrow}}{W_{C\uparrow\downarrow}}B_{6,8,2,4}e^{-(W_E + W_T)(t - t_{\text{ESR}})} + D_{2,4}e^{-2W_T(t - t_{\text{ESR}})}, \tag{22d}$$

$$\rho_9(t) = A_{9,10,1,2}e^{-W_{ETC}(t - t_{\text{ESR}})} + B_{9,10,1,2}e^{-(W_E + W_T)(t - t_{\text{ESR}})} + C_{1,2}e^{-2W_T(t - t_{\text{ESR}})}, \tag{22e}$$

$$\rho_{10}(t) = -A_{9,10,1,2}e^{-W_{ETC}(t - t_{\text{ESR}})} + \frac{W_{C\downarrow\uparrow}}{W_{C\uparrow\downarrow}}B_{9,10,1,2}e^{-(W_E + W_T)(t - t_{\text{ESR}})} + D_{1,2}e^{-2W_T(t - t_{\text{ESR}})}, \tag{22f}$$

$$\rho_{11}(t) = A_{11,12,3,4}e^{-W_{ETC}(t - t_{\text{ESR}})} + B_{11,12,3,4}e^{-(W_E + W_T)(t - t_{\text{ESR}})} + C_{3,4}e^{-2W_T(t - t_{\text{ESR}})}, \tag{22g}$$

$$\rho_{12}(t) = -A_{11,12,3,4}e^{-W_{ETC}(t-t_{\mathrm{ESR}})} + \frac{W_{C\downarrow\uparrow}}{W_{C\uparrow\downarrow}}B_{11,12,3,4}e^{-(W_E+W_T)(t-t_{\mathrm{ESR}})} + D_{3,4}e^{-2W_T(t-t_{\mathrm{ESR}})}, \quad (22h)$$

where

$$W_{ETC} \equiv W_E + W_T + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow}, \quad (23a)$$

$$A_{i,j,k,l} \equiv \frac{W_{C\downarrow\uparrow}\rho_i(t_{\mathrm{ESR}}) - W_{C\uparrow\downarrow}\rho_j(t_{\mathrm{ESR}})}{W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow}} + \frac{W_T(-W_{C\downarrow\uparrow}\rho_k(t_{\mathrm{ESR}}) + W_{C\uparrow\downarrow}\rho_l(t_{\mathrm{ESR}}))}{(W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow})(W_E - W_T + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow})}, \quad (23b)$$

$$B_{i,j,k,l} \equiv \frac{W_{C\uparrow\downarrow}}{W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow}}\left[\rho_i(t_{\mathrm{ESR}}) + \rho_j(t_{\mathrm{ESR}}) - \frac{W_T}{W_E - W_T}(\rho_k(t_{\mathrm{ESR}}) + \rho_l(t_{\mathrm{ESR}}))\right], \quad (23c)$$

$$C_{i,j} = \frac{W_T}{W_E - W_T}\frac{(W_E - W_T + W_{C\uparrow\downarrow})\rho_i(t_{\mathrm{ESR}}) + W_{C\uparrow\downarrow}\rho_j(t_{\mathrm{ESR}})}{W_E - W_T + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow}}, \quad (23d)$$

$$D_{i,j} = \frac{W_T}{W_E - W_T}\frac{W_{C\downarrow\uparrow}\rho_i(t_{\mathrm{ESR}}) + (W_E - W_T + W_{C\downarrow\uparrow})\rho_j(t_{\mathrm{ESR}})}{W_E - W_T + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow}}. \quad (23e)$$

For times $t \leqslant t_{\mathrm{travel}}$, the evolution of $\rho_5(t)-\rho_{12}(t)$ is given by Eqs. (22) with $W_E=0$. For times $t \geqslant t_{\mathrm{travel}}$, these populations are given by Eqs. (22) with $t_{\mathrm{ESR}} \to t_{\mathrm{travel}}$.

In order to obtain the solution for $\rho_{13}(t)-\rho_{16}(t)$, which corrresponds to the situation in which both electrons are located in a channel, we rewrite the equations for $\rho_{13}-\rho_{16}$ as

$$\dot{\rho}_{13} = W_T(\rho_5 + \rho_9) + W_{C\uparrow\downarrow}(\rho_{14} + \rho_{15}) - 2(W_E + W_{C\downarrow\uparrow})\rho_{13}, \quad (24a)$$

$$\dot{\rho}_{14} + \dot{\rho}_{15} = W_T(\rho_6 + \rho_7 + \rho_{10} + \rho_{11}) + 2W_{C\downarrow\uparrow}\rho_{13} - (2W_E + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow})(\rho_{14} + \rho_{15}) + 2W_{C\uparrow\downarrow}\rho_{16}, \quad (24b)$$

$$\dot{\rho}_{16} = W_T(\rho_8 + \rho_{12}) + W_{C\downarrow\uparrow}(\rho_{14} + \rho_{15}) - 2(W_E + W_{C\uparrow\downarrow})\rho_{16}, \quad (24c)$$

$$\dot{\rho}_{14} - \dot{\rho}_{15} = W_T(\rho_6 - \rho_7 + \rho_{10} - \rho_{11}) - (2W_E + W_{C\uparrow\downarrow} + W_{C\downarrow\uparrow})(\rho_{14} - \rho_{15}). \quad (24d)$$

Equations (24) consist of three coupled equations (24a)–(24c) and a separate one, Eq. (24d). We first solve the latter and then the first three. In each case the solution is a combination of a homogeneous and a particular solution. Taking from now on $W_{C\uparrow\downarrow}=W_{C\downarrow\uparrow}\equiv W_C$,[22] we obtain

$$\rho_{13}(t) = -Ee^{-2(W_E+W_C)(t-t_{\mathrm{ESR}})} + \tfrac{1}{2}Fe^{-2W_E(t-t_{\mathrm{ESR}})} - \tfrac{1}{2}\widetilde{F}e^{-2(W_E+2W_C)(t-t_{\mathrm{ESR}})} + H_{13}e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{ESR}})} + K_{13}e^{-(W_E+W_T)(t-t_{\mathrm{ESR}})} + L_{13}e^{-2W_T(t-t_{\mathrm{ESR}})}, \quad (25a)$$

$$\rho_{14}(t) = \widetilde{E}e^{-2(W_E+W_C)(t-t_{\mathrm{ESR}})} + \tfrac{1}{2}Fe^{-2W_E(t-t_{\mathrm{ESR}})} + \tfrac{1}{2}\widetilde{F}e^{-2(W_E+2W_C)(t-t_{\mathrm{ESR}})} + H_{14}e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{ESR}})} + K_{14}e^{-(W_E+W_T)(t-t_{\mathrm{ESR}})} + L_{14}e^{-2W_T(t-t_{\mathrm{ESR}})}, \quad (25b)$$

$$\rho_{15}(t) = -\widetilde{E}e^{-2(W_E+W_C)(t-t_{\mathrm{ESR}})} + \tfrac{1}{2}Fe^{-2W_E(t-t_{\mathrm{ESR}})} + \tfrac{1}{2}\widetilde{F}e^{-2(W_E+2W_C)(t-t_{\mathrm{ESR}})} + H_{15}e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{ESR}})} + K_{15}e^{-(W_E+W_T)(t-t_{\mathrm{ESR}})} + L_{15}e^{-2W_T(t-t_{\mathrm{ESR}})}, \quad (25c)$$

TABLE I. Coefficients A_i, B_i, and C_i in Eqs. (26).

i	A_i	B_i	C_i
17	$-W_E A_{5,7,1,3}/(W_E+2W_C)$	$B_{5,7,1,3}$	$W_E/W_T C_{1,3}$
18	$-W_E A_{6,8,2,4}/(W_E+2W_C)$	$B_{6,8,2,4}$	$W_E/W_T C_{2,4}$
19	$W_E A_{5,7,1,3}/(W_E+2W_C)$	$B_{5,7,1,3}$	$W_E/W_T D_{1,3}$
20	$W_E A_{6,8,2,4}/(W_E+2W_C)$	$B_{6,8,2,4}$	$W_E/W_T D_{2,4}$
21	$-W_E A_{9,10,1,2}/(W_E+2W_C)$	$B_{9,10,1,2}$	$W_E/W_T C_{1,2}$
22	$W_E A_{9,10,1,2}/(W_E+2W_C)$	$B_{9,10,1,2}$	$W_E/W_T D_{1,2}$
23	$-W_E A_{11,12,3,4}/(W_E+2W_C)$	$B_{11,12,3,4}$	$W_E/W_T C_{3,4}$
24	$W_E A_{11,12,3,4}/(W_E+2W_C)$	$B_{11,12,3,4}$	$W_E/W_T D_{3,4}$

$$\rho_{16}(t) = Ee^{-2(W_E+W_C)(t-t_{\mathrm{ESR}})} + \tfrac{1}{2}Fe^{-2W_E(t-t_{\mathrm{ESR}})} - \tfrac{1}{2}\tilde{F}e^{-2(W_E+2W_C)(t-t_{\mathrm{ESR}})} + H_{16}e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{ESR}})} + K_{16}e^{-(W_E+W_T)(t-t_{\mathrm{ESR}})} + L_{16}e^{-2W_T(t-t_{\mathrm{ESR}})}. \tag{25d}$$

The coefficients in Eqs. (25) are given in Appendix B. Also here, $\rho_{13}(t)-\rho_{16}(t)$ for times $t \leqslant t_{\mathrm{travel}}$ are given by Eqs. (25) with $W_E=0$, and for times $t \geqslant t_{\mathrm{travel}}$ these populations are given by Eqs. (25) with $t_{\mathrm{ESR}} \to t_{\mathrm{travel}}$.

The solution of the next set, $\rho_{17}(t)-\rho_{24}(t)$, corresponding to the states in which one electron is located in a dot while the other has reached a detector, is given by

$$\rho_i(t) = A_i e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{travel}})} - B_i e^{-(W_E+W_T)(t-t_{\mathrm{travel}})} - C_i e^{-2W_T(t-t_{\mathrm{travel}})} + [\rho_i(t_{\mathrm{travel}}) - A_i + B_i + C_i]e^{-W_T(t-t_{\mathrm{travel}})} \quad \text{for } i \in \{17, \ldots, 24\},\ t \geqslant t_{\mathrm{travel}}, \tag{26}$$

and $\rho_i(t)=0$ for $t \leqslant t_{\mathrm{travel}}$. The coefficients A_i, B_i, and C_i in Eqs. (26) are given in Table I. Next, we solve for $\rho_{25}(t)-\rho_{32}(t)$, the states in which one spin has reached a detector, while the other is still in a channel, in the pairs $\rho_i(t)\&\rho_j(t) \in \{\rho_{25}(t)\&\rho_{26}(t), \rho_{27}(t)\&\rho_{28}(t), \rho_{29}(t)\&\rho_{31}(t),$ and $\rho_{30}(t)\&\rho_{32}(t)\}$; see Eqs. (18). For each pair the solution is given by, for times $t \geqslant t_{\mathrm{travel}}$

$$\rho_i(t) = P_{i,j}e^{-W_E(t-t_{\mathrm{travel}})} + Q_{i,j}e^{-(W_E+2W_C)(t-t_{\mathrm{travel}})} + M_{i,1}e^{-2(W_E+W_C)(t-t_{\mathrm{travel}})} + M_{i,2}e^{-2W_E(t-t_{\mathrm{travel}})} + M_{i,3}e^{-2(W_E+2W_C)(t-t_{\mathrm{travel}})} + M_{i,4}e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{travel}})} + M_{i,5}e^{-(W_E+W_T)(t-t_{\mathrm{travel}})} + M_{i,6}e^{-2W_T(t-t_{\mathrm{travel}})} + M_{i,7}e^{-W_T(t-t_{\mathrm{travel}})}, \tag{27a}$$

$$\rho_j(t) = P_{j,i}e^{-W_E(t-t_{\mathrm{travel}})} + Q_{j,i}e^{-(W_E+2W_C)(t-t_{\mathrm{travel}})} + M_{j,1}e^{-2(W_E+W_C)(t-t_{\mathrm{travel}})} + M_{j,2}e^{-2W_E(t-t_{\mathrm{travel}})} + M_{j,3}e^{-2(W_E+2W_C)(t-t_{\mathrm{travel}})} + M_{j,4}e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{travel}})} + M_{j,5}e^{-(W_E+W_T)(t-t_{\mathrm{travel}})} + M_{j,6}e^{-2W_T(t-t_{\mathrm{travel}})} + M_{j,7}e^{-W_T(t-t_{\mathrm{travel}})}, \tag{27b}$$

and $\rho_i(t)=\rho_j(t)=0$ for $t \leqslant t_{\mathrm{travel}}$. The coefficients $P_{i,j}$, $Q_{i,j}$, and $M_{i,1}, \ldots, M_{i,7}$ for $i,j \in \{25, \ldots, 32\}$ are given in Appendix B.

Finally, we obtain the time evolution of the states $\rho_{33}(t)-\rho_{36}(t)$ in which both electrons have reached an exit. This is given by, for times $t \geqslant t_{\mathrm{travel}}$

$$\rho_j(t) = -W_E\left\{\frac{P_{m,p}+P_{n,q}}{W_E}e^{-W_E(t-t_{\mathrm{travel}})} + \frac{Q_{m,p}+Q_{n,q}}{W_E+2W_C}e^{-(W_E+2W_C)(t-t_{\mathrm{travel}})} + \frac{M_{m,1}+M_{n,1}}{2(W_E+W_C)}e^{-2(W_E+W_C)(t-t_{\mathrm{travel}})} + \frac{M_{m,2}+M_{n,2}}{2W_E}e^{-2W_E(t-t_{\mathrm{travel}})} + \frac{M_{m,3}+M_{n,3}}{2(W_E+2W_C)}e^{-2(W_E+2W_C)(t-t_{\mathrm{travel}})} + \frac{M_{m,4}+M_{n,4}}{W_E+W_T+2W_C}e^{-(W_E+W_T+2W_C)(t-t_{\mathrm{travel}})}\right.$$

$$+\frac{M_{m,5}+M_{n,5}}{W_E+W_T}e^{-(W_E+W_T)(t-t_{\text{travel}})}+\frac{M_{m,6}+M_{n,6}}{2W_T}e^{-2W_T(t-t_{\text{travel}})}+\frac{M_{m,7}+M_{n,7}}{W_T}e^{-W_T(t-t_{\text{travel}})}\Bigg\}$$
$$+W_E\left(\text{sum of all previous coefficients, so }\frac{P_{m,p}+P_{n,q}}{W_E}+\frac{Q_{m,p}+Q_{n,q}}{W_E+2W_C}+\cdots\right), \tag{28}$$

for

$$(j,m,n,p,q)\in\{(33,25,29,26,31),(34,26,30,25,32),(35,27,31,28,29),(36,28,32,27,30)\}.$$

Special case. In order to illustrate the solution (28), we now derive explicit expressions for $\rho_{33}(t)$ and $\rho_{34}(t)$, the probabilities that a spin-up is detected in the left detector and, respectively, a spin-up or a spin-down in the right detector, for the special case of $\Gamma=0$ (no decoherence in the dots) and $W_{C\uparrow\downarrow}=W_{C\downarrow\uparrow}=0$ (no relaxation in the channel). This corresponds to the situation in which the time evolution occurs in the absence of any decoherence and dissipation mechanisms in the dots and channels and only depends on W_T, the tunnel rate from dot to channel, and W_E, the tunnel rate from channel to exit.

We are interested in finding $\rho_{33}(t)$ and $\rho_{34}(t)$ for times $t\geqslant t_{\text{travel}}$ [since $\rho_{33}(t)=\rho_{34}(t)=0\ \forall t\leqslant t_{\text{travel}}$]. To that end, we first calculate $\rho_j(t_{\text{travel}})$ for $j\leqslant 16$ from Eqs. (21), (22), and (25) and then all coefficients entering the expressions for $\rho_{33}(t)$ and $\rho_{34}(t)$ in Eqs. (28). For $\rho_1(t_{\text{travel}})$ -$\rho_{16}(t_{\text{travel}})$ we then obtain

$$\rho_1(t_{\text{travel}})=\rho_4(t_{\text{travel}})=\rho_1(t_{\text{ESR}})e^{-2W_T(t_{\text{travel}}-t_{\text{ESR}})}, \tag{29a}$$

$$\rho_2(t_{\text{travel}})=\rho_3(t_{\text{travel}})=\rho_2(t_{\text{ESR}})e^{-2W_T(t_{\text{travel}}-t_{\text{ESR}})}, \tag{29b}$$

$$\rho_i(t_{\text{travel}})=\rho_1(t_{\text{ESR}})e^{-W_T(t_{\text{travel}}-t_{\text{ESR}})}(1-e^{-W_T(t_{\text{travel}}-t_{\text{ESR}})}),\quad i\in\{5,8,9,12\}, \tag{29c}$$

$$\rho_i(t_{\text{travel}})=\rho_2(t_{\text{ESR}})e^{-W_T(t_{\text{travel}}-t_{\text{ESR}})}(1-e^{-W_T(t_{\text{travel}}-t_{\text{ESR}})}),\quad i\in\{6,7,10,11\}, \tag{29d}$$

$$\rho_{13}(t_{\text{travel}})=\rho_{16}(t_{\text{travel}})=\rho_1(t_{\text{ESR}})(1-e^{-W_T(t_{\text{travel}}-t_{\text{ESR}})})^2, \tag{29e}$$

$$\rho_{14}(t_{\text{travel}})=\rho_{15}(t_{\text{travel}})=\rho_2(t_{\text{ESR}})(1-e^{-W_T(t_{\text{travel}}-t_{\text{ESR}})})^2. \tag{29f}$$

Equation (29) form the initial conditions that appear in the expressions for $\rho_{33}(t)-\rho_{36}(t)$ [Eqs. (28)]. We then find $\forall t\geqslant t_{\text{travel}}$

$$\rho_{33}(t)=\left(\rho_{13}(t_{\text{travel}})-\frac{2W_T}{W_E-W_T}\rho_5(t_{\text{travel}})+\frac{W_T^2}{(W_E-W_T)^2}\rho_1(t_{\text{travel}})\right)e^{-2W_E(t-t_{\text{travel}})}+\Bigg(-2\rho_{13}(t_{\text{travel}})$$
$$-\frac{2(W_E-2W_T)}{W_E-W_T}\rho_5(t_{\text{travel}})+\frac{2W_T}{W_E-W_T}\rho_1(t_{\text{travel}})\Bigg)e^{-W_E(t-t_{\text{travel}})}+\frac{2W_E}{W_E-W_T}\Bigg(\rho_5(t_{\text{travel}})$$
$$-\frac{W_T}{W_E-W_T}\rho_1(t_{\text{travel}})\Bigg)e^{-(W_E+W_T)(t-t_{\text{travel}})}-\frac{2W_E}{W_E-W_T}(\rho_5(t_{\text{travel}})+\rho_1(t_{\text{travel}}))e^{-W_T(t-t_{\text{travel}})}$$
$$+\frac{W_E^2}{(W_E-W_T)^2}\rho_1(t_{\text{travel}})e^{-2W_T(t-t_{\text{travel}})}+\rho_{13}(t_{\text{travel}})+2\rho_5(t_{\text{travel}})+\rho_1(t_{\text{travel}}), \tag{30a}$$

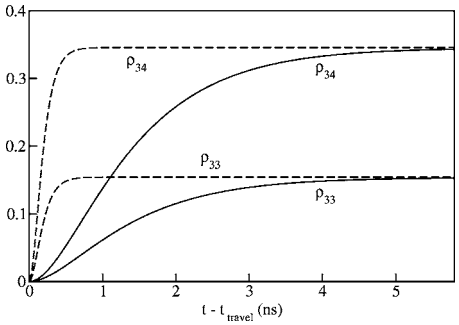

FIG. 3. The probabilities ρ_{33} to measure two spin-up electrons and ρ_{34} to measure a spin-up and a spin-down electron in the left and right exits, respectively, for times $t \geqslant t_{\text{travel}}$. Parameters used are $\theta_1 = \pi/2$, $\theta_2 = \pi/8$ [so that $\rho_1(t_{\text{ESR}}) = 0.154$ and $\rho_2(t_{\text{ESR}}) = 0.346$], $t_{\text{travel}} - t_{\text{ESR}} = 0.1$ ns, $W_E = 10^{10}$ s^{-1} and $W_T = 10^9$ s^{-1} (9.9×10^9 s^{-1}) for the solid (dashed) curves.

$$\rho_{34}(t) = \left(\rho_{14}(t_{\text{travel}}) - \frac{2W_T}{W_E - W_T}\rho_6(t_{\text{travel}}) + \frac{W_T^2}{(W_E - W_T)^2}\rho_2(t_{\text{travel}})\right)e^{-2W_E(t-t_{\text{travel}})} + \left(-2\rho_{14}(t_{\text{travel}})\right.$$
$$\left. - \frac{2(W_E - 2W_T)}{W_E - W_T}\rho_6(t_{\text{travel}}) + \frac{2W_T}{W_E - W_T}\rho_2(t_{\text{travel}})\right)e^{-W_E(t-t_{\text{travel}})} + \frac{2W_E}{W_E - W_T}\left(\rho_6(t_{\text{travel}})\right.$$
$$\left. - \frac{W_T}{W_E - W_T}\rho_2(t_{\text{travel}})\right)e^{-(W_E+W_T)(t-t_{\text{travel}})} - \frac{2W_E}{W_E - W_T}(\rho_6(t_{\text{travel}}) + \rho_2(t_{\text{travel}}))e^{-W_T(t-t_{\text{travel}})}$$
$$+ \frac{W_E^2}{(W_E - W_T)^2}\rho_2(t_{\text{travel}})e^{-2W_T(t-t_{\text{travel}})} + \rho_{14}(t_{\text{travel}}) + 2\rho_6(t_{\text{travel}}) + \rho_2(t_{\text{travel}}). \tag{30b}$$

One can see directly from Eqs. (30) that the time dependence of ρ_{33} and ρ_{34} is determined by five exponential functions, whose relative magnitude depends on the ratio between W_E and W_T. This is illustrated in Fig. 3, which shows Eqs. (30) as a function of $t - t_{\text{travel}}$ for various rates W_E and W_T. For $W_T \ll W_E$ the time needed to reach the stationary state (the average detection time) is dominated by the term $\sim e^{-W_T(t-t_{\text{travel}})}$, whereas for $W_T \approx W_E$ the terms $\sim e^{-2W_E(t-t_{\text{travel}})}$, $e^{-(W_E+W_T)(t-t_{\text{travel}})}$, and $e^{-2W_T(t-t_{\text{travel}})}$ dominate.

IV. CONCLUSION

In summary, we have presented an analytical solution of a set of coupled master equations that describes the time evolution of an entangled electron spin pair which can occupy 36 different quantum states in a double quantum dot nanostructure. Our method of solving these equations is based on separating the time evolution in three parts, namely two coherent rotations of the electron spins in the isolated quantum dots and the subsequent travel of the electrons through two quantum channels. As a result of this separation, the total number of master equations is split into various closed subsets of coupled equations. Our analytical solution is the first of its kind for a large set of coupled master equations, and the same method can be used to study and predict the quantum evolution of other quantum systems which are described by a large set of quantum states. This type of analysis complements numerical approaches to study the dynamic evolution of complex quantum systems and allows one to obtain qualitative insight in the competition between time scales in these systems.

APPENDIX A: SOLUTION OF EQS. (8a)–(8i)

Using the substitution Eqs. (10), Eqs. (8a)–(8i) transform into

$$\dot{x}_1 = -(W_{D\downarrow\uparrow} + W_{D\uparrow\downarrow} - \Gamma)x_1 - \Delta_L x_5 + W_{D\uparrow\downarrow}e^{\Gamma t}, \tag{A1a}$$

$$\dot{x}_5 = \Delta_L x_1 - \frac{\Delta_L}{2}e^{\Gamma t}, \tag{A1b}$$

$$\dot{x}_2 = -(W_{D\downarrow\uparrow} + W_{D\uparrow\downarrow} - \Gamma)x_2 - \delta_L x_4 + W_{D\uparrow\downarrow}e^{\Gamma t}, \tag{A1c}$$

$$\dot{x}_4 = \delta_L x_2 - \frac{\delta_L}{2}e^{\Gamma t}, \tag{A1d}$$

$$\dot{x}_3 = -(2W_{D\downarrow\uparrow} + 2W_{D\uparrow\downarrow} - \Gamma)x_3 + \delta_L x_6 + \Delta_L x_7 + 2W_{D\uparrow\downarrow}e^{\Gamma t} + (W_{D\downarrow\uparrow} - W_{D\uparrow\downarrow})(x_1 + x_2), \tag{A1e}$$

$$\dot{x}_6 = -\delta_L x_3 + 2\Delta_L x_8 + \frac{\delta_L}{2}e^{\Gamma t} - \Delta_L Z, \tag{A1f}$$

$$\dot{x}_7 = -\Delta_L x_3 + 2\delta_L x_8 + \frac{\Delta_L}{2}e^{\Gamma t} - \delta_L Z, \tag{A1g}$$

$$\dot{x}_8 = -\frac{\Delta_L}{2}x_6 - \frac{\delta_L}{2}x_7, \tag{A1h}$$

with $Z \equiv \mathrm{Re}[\tilde{\rho}_{1,4}(0) + \tilde{\rho}_{2,3}(0)]$. In deriving Eqs. (A1), we have used that

$$\rho_4 = 1 - \rho_1 - \rho_2 - \rho_3,$$

$$\mathrm{Re}\,\tilde{\rho}_{2,3} = -\mathrm{Re}\,\tilde{\rho}_{1,4} + Ze^{-\Gamma t}.$$

Equations (A1) consist of three sets of coupled equations: (A1a)–(A1b), (A1c)–(A1d), and (A1e)–(A1h). The solution of the first two sets is given by

$$x_1(t) = \left[-\left(\frac{(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)(x_1(0) - A_1) + 2\Delta_L(x_5(0) - A_2)}{2\Omega_\Delta} \right) \sin \Omega_\Delta t + (x_1(0) - A_1)\cos \Omega_\Delta t \right] e^{-(1/2)(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)t} + A_1 e^{\Gamma t}, \tag{A2a}$$

$$x_5(t) = \left[\left(\frac{2\Delta_L(x_1(0) - A_1) + (W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)(x_5(0) - A_2)}{2\Omega_\Delta} \right) \sin \Omega_\Delta t + (x_5(0) - A_2)\cos \Omega_\Delta t \right] e^{-(1/2)(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)t} + A_2 e^{\Gamma t}, \tag{A2b}$$

$$x_2(t) = \left[-\left(\frac{(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)(x_2(0) - A_3) + 2\delta_L(x_4(0) - A_4)}{2\Omega_\delta} \right) \sin \Omega_\delta t \right.$$
$$\left. + (x_2(0) - A_3)\cos \Omega_\delta t \right] e^{-(1/2)(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)t} + A_3 e^{\Gamma t}, \tag{A2c}$$

$$x_4(t) = \left[\left(\frac{2\delta_L(x_2(0) - A_3) + (W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)(x_4(0) - A_4)}{2\Omega_\delta} \right) \sin \Omega_\delta t \right.$$
$$\left. + (x_4(0) - A_4)\cos \Omega_\delta t \right] e^{-(1/2)(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)t} + A_4 e^{\Gamma t}, \tag{A2d}$$

with

$$\Omega_\Delta = \frac{1}{2}\sqrt{4\Delta_L^2 - (W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)^2}, \tag{A3a}$$

$$\Omega_\delta = \frac{1}{2}\sqrt{4\delta_L^2 - (W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow} - \Gamma)^2}, \tag{A3b}$$

$$A_1 = \frac{\Delta_L^2 + 2\Gamma W_{D\uparrow\downarrow}}{2(\Delta_L^2 + \Gamma(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow}))}, \tag{A3c}$$

$$A_2 = \frac{\Delta_L(W_{D\uparrow\downarrow} - W_{D\downarrow\uparrow})}{2(\Delta_L^2 + \Gamma(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow}))}, \tag{A3d}$$

$$A_3 = \frac{\delta_L^2 + 2\Gamma W_{D\uparrow\downarrow}}{2(\delta_L^2 + \Gamma(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow}))}, \tag{A3e}$$

$$A_4 = \frac{\delta_L(W_{D\uparrow\downarrow} - W_{D\downarrow\uparrow})}{2(\delta_L^2 + \Gamma(W_{D\uparrow\downarrow} + W_{D\downarrow\uparrow}))}. \tag{A3f}$$

So far no approximations have been made, apart from assuming the decoherence rate Γ to be equal for all off-diagonal terms of the density matrix ρ [Eqs. (8)]. In order to obtain the solution of the remaining equations (A1e)–(A1h), we assume $\delta_L = 0$ (no influence of the ESR field on the spin in the right dot) and $W_{D\uparrow\downarrow} = W_{D\downarrow\uparrow} = 0$,[23] and find[24]

$$x_3(t) = \left[\frac{\Gamma\left(x_3(0) - \frac{1}{2}\right) + 2\Delta_L x_7(0)}{2\tilde{\Omega}_\Delta} \sin \tilde{\Omega}_\Delta t + \left(x_3(0) - \frac{1}{2}\right)\cos \tilde{\Omega}_\Delta t \right] e^{(\Gamma/2)t} + \frac{1}{2}e^{\Gamma t}, \tag{A4a}$$

$$x_6(t) = x_6(0)\cos \Delta_L t + (2x_8(0) - Z)\sin \Delta_L t, \tag{A4b}$$

$$x_7(t) = \left[\frac{-2\Delta_L\left(x_3(0) - \frac{1}{2}\right) - \Gamma x_7(0)}{2\tilde{\Omega}_\Delta} \sin \tilde{\Omega}_\Delta t + x_7(0)\cos \tilde{\Omega}_\Delta t \right] e^{(\Gamma/2)t}, \tag{A4c}$$

$$x_8(t) = \tfrac{1}{2}[-x_6(0)\sin\Delta_L t + (2x_8(0) - Z)\cos\Delta_L t + Z], \tag{A4d}$$

with $\tilde{\Omega}_\Delta = \frac{1}{2}\sqrt{4\Delta_L^2 - \Gamma^2}$.

APPENDIX B: COEFFICIENTS OF EQS. (25) and (27)

The coefficients in Eqs. (25) are given by

$$E = \frac{-\rho_{13}(t_{\mathrm{ESR}}) + \rho_{16}(t_{\mathrm{ESR}}) + H_{13} - H_{16} + K_{13} - K_{16} + L_{13} - L_{16}}{2},$$

$$\tilde{E} = \frac{\rho_{14}(t_{\mathrm{ESR}}) - \rho_{15}(t_{\mathrm{ESR}}) - H_{14} + H_{15} - K_{14} + K_{15} - L_{14} + L_{15}}{2},$$

$$F = \frac{\rho_{13}(t_{\mathrm{ESR}}) + \rho_{14}(t_{\mathrm{ESR}}) + \rho_{15}(t_{\mathrm{ESR}}) + \rho_{16}(t_{\mathrm{ESR}}) - 2(K_{14} + K_{15}) - L_{13} - L_{14} - L_{15} - L_{16}}{2},$$

$$\tilde{F} = \frac{-\rho_{13}(t_{\mathrm{ESR}}) + \rho_{14}(t_{\mathrm{ESR}}) + \rho_{15}(t_{\mathrm{ESR}}) - \rho_{16}(t_{\mathrm{ESR}}) - 2(H_{14} + H_{15}) + L_{13} - L_{14} - L_{15} + L_{16}}{2},$$

$$H_{13} = \frac{W_T[(W_E - W_T + W_C)(A_{5,7,1,3} + A_{9,10,1,2}) + W_C(A_{6,8,2,4} + A_{11,12,3,4})]}{(W_E - W_T)(W_E - W_T + 2W_C)},$$

$$H_{14} = \frac{W_T[W_C(A_{5,7,1,3} - A_{11,12,3,4}) + (W_E - W_T + W_C)(A_{6,8,2,4} - A_{9,10,1,2})]}{(W_E - W_T)(W_E - W_T + 2W_C)},$$

$$H_{15} = -H_{14}[(5,7,1,3) \leftrightarrow (6,8,2,4), (9,10,1,2) \leftrightarrow (11,12,3,4)],$$

$$H_{16} = -H_{13}[(5,7,1,3) \leftrightarrow (6,8,2,4), (9,10,1,2) \leftrightarrow (11,12,3,4)],$$

$$K_{13} = H_{13}(A \to B),$$

$$K_{14} = \frac{W_T[W_C(B_{5,7,1,3} + B_{11,12,3,4}) + (W_E - W_T + W_C)(B_{6,8,2,4} + B_{9,10,1,2})]}{(W_E - W_T)(W_E - W_T + 2W_C)},$$

$$K_{15} = K_{14}[(5,7,1,3) \leftrightarrow (6,8,2,4), (9,10,1,2) \leftrightarrow (11,12,3,4)],$$

$$K_{16} = H_{16}(A \to -B),$$

$$\begin{aligned} L_{13} = W_T[&(2(W_E - W_T + W_C)^2 - W_C^2)(C_{1,2} + C_{1,3}) + W_C^2(D_{2,4} + D_{3,4}) + W_C(W_E - W_T + W_C) \\ &\times (C_{2,4} + C_{3,4} + D_{1,2} + D_{1,3})]/[4(W_E - W_T)(W_E - W_T + 2W_C)(W_E - W_T + W_C)], \end{aligned}$$

$$\begin{aligned} L_{14} = W_T[&W_C(W_E - W_T + W_C)(C_{1,2} + C_{1,3} + D_{2,4} + D_{3,4}) + 2(W_E - W_T + W_C)^2(C_{2,4} + D_{1,2}) \\ &+ W_C^2(C_{3,4} - C_{2,4} - D_{1,2} + D_{1,3})]/[4(W_E - W_T)(W_E - W_T + 2W_C)(W_E - W_T + W_C)], \end{aligned}$$

$$L_{15} = L_{14}(C_{2,4} \leftrightarrow C_{3,4}, D_{1,2} \leftrightarrow D_{1,3}),$$

$$L_{16} = L_{13}(C_{1,2} \leftrightarrow D_{2,4}, C_{1,3} \leftrightarrow D_{3,4}). \tag{B1}$$

For $(i,j)=(25,26)$ the coefficients in Eqs. (27) are given by

$$P_{25,26} = P_{26,25} = -\frac{1}{2}\sum_{k=1}^{7}(M_{25,k} + M_{26,k}),$$

$$Q_{25,26} = -Q_{26,25} = -\frac{1}{2}\sum_{k=1}^{7}(M_{25,k} - M_{26,k}),$$

$$M_{25,1} = \frac{(W_E + W_C)E + W_C\tilde{E}}{W_E + 2W_C},$$

$$M_{26,1} = M_{25,1}(E \leftrightarrow -\tilde{E}),$$

$$M_{25,2} = M_{26,2} = -\frac{1}{2}F,$$

$$M_{25,3} = -M_{26,3} = \frac{W_E}{2(W_E + 2W_C)}\tilde{F},$$

$$M_{25,4} = \frac{W_E[-(W_T + W_C)((W_E + 2W_C)H_{13} - W_T A_{5,7,1,3}) + W_C((W_E + 2W_C)H_{14} - W_T A_{6,8,2,4})]}{W_T(W_E + 2W_C)(W_T + 2W_C)},$$

$$M_{26,4} = M_{25,4}(H_{13} \leftrightarrow H_{14}, A_{5,7,1,3} \leftrightarrow A_{6,8,2,4}),$$

$$M_{25,5} = \frac{(W_C - W_T)(W_E K_{13} - W_T B_{5,7,1,3}) + W_C(W_E K_{14} - W_T B_{6,8,2,4})}{W_T(W_T - 2W_C)},$$

$$M_{26,5} = M_{25,5}(K_{13} \leftrightarrow K_{14}, B_{5,7,1,3} \leftrightarrow B_{6,8,2,4}),$$

$$M_{25,6} = \frac{W_E[(W_E - 2W_T + W_C)(L_{13} - C_{1,3}) + W_C(L_{14} - C_{2,4})]}{(W_E - 2W_T + 2W_C)(W_E - 2W_T)},$$

$$M_{26,6} = M_{25,6}(L_{13} \leftrightarrow L_{14}, C_{1,3} \leftrightarrow C_{2,4}),$$

$$M_{25,7} = W_T[(W_E - W_T + W_C)[-A_{17} + B_{17} + C_{17}] + W_C[-A_{18} + B_{18} + C_{18}]]/[(W_E - W_T + 2W_C) \times (W_E - W_T)],$$

$$M_{26,7} = M_{25,7}(17 \leftrightarrow 18). \tag{B2}$$

TABLE II. Required substitution of indices and coefficients in Eqs. (27) in order to obtain the corresponding coefficients for $\rho_i(t)\&\rho_j(t)$ with $(i,j) \in \{(27,28),(29,31),(30,32)\}$.

[15] See Sec. II C in H. A. Engel and D. Loss, Phys. Rev. B **65**, 195321 (2002).
[16] For the same reason tunneling of an electron from dot to channel—which is an incoherent process and may involve inelastic scattering from one orbital to another—does not affect the *spin* coherence of the entangled pair.
[17] Assuming the same decoherence rate Γ for both dots is not a crucial assumption and Eqs. (8) can straightforwardly be solved for different decoherence rates in the left and right dot. The resulting solution is qualitatively of the same form as Eqs. (9) and (10), only with more lengthy expressions.
[18] The RWA approximation (Ref. 2) is not essential and one can solve Eqs. (8) without it, which results in a solution that is qualitatively similar. Since $\omega t_1 \ll 1$ in our system (Ref. 9), where t_1 is the time required to rotate one spin, the RWA is an excellent approximation in practice.

[22] See the calculation of $W_{C\uparrow\downarrow}$ and $W_{C\downarrow\uparrow}$ in Ref. 9.
[23] For the general case the expressions are rather lengthy, but not qualitatively different.
[24] The solutions for $x_6(t)$ and $x_8(t)$ given here are valid for $\delta_L=0$, i.e., assuming the W's to be zero is not necessary.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 083519 (2005)

Semilattice graded weak Hopf algebra and its related quantum G-double

Fang Li[a] and Haijun Cao[b]
Department of Mathematics, Zhejiang University, Hangzhou, Zhejiang 310028, China

(Received 12 January 2005; accepted 15 June 2005; published online 18 August 2005)

The major purpose of this paper is to construct a weak Hopf algebra with grading from a family of Hopf algebras, and then to gain a related quantum G-double with regular R-matrix. First, over a field k, we introduce a so-called semilattice graded weak Hopf algebra $H=\oplus_{\alpha\in Y}H_\alpha$. Then the quantum G-double $D'(H)$ of H is obtained in case that H is commutative. Moreover, it is shown that $D'(H)$ is semisimple (respectively, von Neumann regular) if and only if H is a semisimple (respectively, von Neumann regular) Hopf algebra. At last, a nontrivial example of semilattice graded weak Hopf algebras is obtained. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2000687]

I. INTRODUCTION

Because of the important role of Hopf algebra in the theory of quantum group and related mathematical physics, along with the deepening of researches, the meaning of some weaker concepts of Hopf algebra is understood and is paid close attention more and more. A well-known example is weak Hopf algebra, which is introduced in Ref. 6 for studying the noninvertible solution of the Yang-Baxter equation based on this class of bialgebras (in Refs. 6 and 12). Due to the importance of the Yang-Baxter equation in theoretical physics, its solution is the keystone in research. The theory of singular solutions extends largely the scope of the research field. On the other aspect, there is a tight relation between weak Hopf algebra and regular monoid, for example, a semigroup algebra is a weak Hopf algebra if and only if the semigroup is a regular monoid. Obviously, it is necessary to find more nontrivial weak Hopf algebras in order to study these two aspects deeply. In this paper, we construct a so-called semilattice graded weak Hopf algebra from a family of Hopf algebras. An example of semilattice graded weak Hopf algebra is just Clifford moniod algebra. And, based on Ref. 13, a regular solution of the Yang-Baxter equation and its decomposition can be obtained. Moreover, similar to the corresponding results in Ref. 10, we will finish the decomposition and semisimplicity of G-quantum doubles of semilattice graded weak Hopf algebras under the condition of commutativity.

First, we introduce some useful concepts.

H is called an *almost bialgebra* if H is an algebra and also a coalgebra and the comultiplication of H is an algebra morphism.

A bialgebra H over k is called a *weak Hopf algebra*[6] if there exists $T\in \mathrm{Hom}_k(H,H)$ (the convolution algebra) satisfying $\mathrm{id}*T*\mathrm{id}=\mathrm{id}$ and $T*\mathrm{id}*T=T$, where T is called a *weak antipode* of H. A weak Hopf algebra H is called (1) a *perfect weak Hopf algebra*[7] if its weak antipode T is an antibialgebra morphism satisfying $(\mathrm{id}*T)(H)\subseteq C(H)$ (the center of H); (2) a *coperfect weak Hopf algebra*[9] if its weak antipode is an antibialgebra morphism satisfying $\Sigma_{(x)}x'T(x'')\otimes x'''=\Sigma_{(x)}x''T(x''')\otimes x'$ for any $x\in H$; (3) a *biperfect weak Hopf algebra* if it is perfect and also coperfect.

[a]Electronic mail: fangli@zju.edu.cn
[b]Electronic mail: hjcao99@163.com

Since the concept of weak Hopf algebra was introduced in Ref. 6, and more early, in an unpublished report,[11] one has only two ways to give examples, that is, through semigroup algebras of regular monoids (in particular, Clifford monoids) and the weak quantum algebras $wsl_q(2)$ and $vsl_q(2)$ (see Ref. 12).

The same name "weak Hopf algebra" was also used as another kind of generalization of Hopf algebra in Refs. 2, 20, and 16 which comultiplication is no longer required to preserve the unit (equivalently, the counit is not required to be an algebra homomorphism). We must point out that these two kinds of weak Hopf algebra are completely different generalizations of each other in various directions, since the only common subclass just consists of Hopf algebras (see Ref. 8). The initial motivation of the latter was its connection with the theory of algebra extension.

In this paper, we always assume H denotes a weak Hopf algebra under Li's meaning over a field k and $G(H)$ the monoid of all grouplike elements in H. A semigroup with identity is called a *monoid*.

A semigroup S is called a *Clifford semigroup*[17] if it is a regular semigroup and all of its idempotents lie in its center $C(S)$. An equivalent definition is that a Clifford semigroup S is a semilattice of groups, which means the set of maximal subgroups $\{G_\alpha : \alpha \in Y\}$ of S can be indexed by elements of a semilattice (i.e., a commutative semigroup of idempotents) Y such that $S = \cup_{\alpha \in Y} G_\alpha$ and $G_\alpha G_\beta \subseteq G_{\alpha\beta}$ for each $\alpha, \beta \in Y$. For each $\alpha, \beta \in Y$ with $\alpha\beta = \beta$ there exists a homomorphism $\varphi_{\alpha,\beta} : G_\alpha \to G_\beta$. The homomorphisms are such that $\varphi_{\alpha,\alpha}$ is the identity map on G_α, and if $\alpha\beta = \beta$, $\beta\gamma = \gamma$, then $\varphi_{\beta,\gamma}\varphi_{\alpha,\beta} = \varphi_{\alpha,\gamma}$. For any $\alpha, \beta \in Y$ and $a \in G_\alpha$, $b \in G_\beta$, the multiplication in S is given by $ab = \varphi_{\alpha,\alpha\beta}(a)\varphi_{\beta,\alpha\beta}(b)$. In a semilattice Y, a partial order $\leqslant$ is defined satisfying $\alpha \leqslant \beta$ if $\alpha\beta = \alpha$ for $\alpha, \beta \in Y$, which is called the *natural partial order* in Y.

It is easy to see for every Clifford monoid S, the semigroup algebra kS is a weak Hopf algebra and $kS = \oplus_{\alpha \in Y} kG_\alpha$ is a semilattice grading sum. As its natural generalization, we will define the following concept, which provides a way to obtain a class of weak Hopf algebras through some given Hopf algebras.

Definition I.1: A weak Hopf algebra H with weak antipode T is called a semilattice graded weak Hopf algebra *if $H = \oplus_{\alpha \in Y} H_\alpha$ is a semilattice grading sum where H_α is a weak sub-Hopf algebras of H which is a Hopf algebra with antipodes $T|_{H_\alpha}$ for each $\alpha \in Y$ and there homomorphisms of Hopf algebras $\varphi_{\alpha,\beta}$ from H_α to H_β if $\alpha\beta = \beta$, such that for $a \in H_\alpha$ and $b \in H_\beta$, the multiplication $a * b$ in H can be given by $a * b = \varphi_{\alpha,\alpha\beta}(a)\varphi_{\beta,\alpha\beta}(b)$.*

Thus the set of grouplike elements of H is the Clifford monoid $G(H) = [Y; G(H_\alpha), \varphi_{\alpha,\beta}]$.

In Sec. II, for a semilattice graded weak Hopf algebra $H = \oplus_{\alpha \in Y} H_\alpha$, we define a kind of product, the quantum G-double $D'(H) = H^{op^*} \infty' H$ which give a nontrivial solution for the Yang-Baxter equation in case H is commutative. In Sec. III, we discuss the structure of $D'(H)$ depending upon $D'(H_\alpha)(\alpha \in Y)$ and then obtain the structure theorem Theorem III.4. Moreover, in Sec. IV, by using this structure theorem, we will verify that the quantum G-double $D'(H)$ of H cannot be semisimple unless H is a Hopf algebra. In the special case for a commutative Clifford monoid, our result in Sec. IV is similar to that in Ref. 10. At last, we will construct an example of this kind of weak Hopf algebras through Ore extension as the construction producing pointed Hopf algebras from a group algebra in Ref. 1.

II. QUANTUM G-DOUBLE OF A COMMUTATIVE WEAK HOPF ALGEBRA

In this section, we suppose a semilattice graded weak Hopf algebra $H = \oplus_{\alpha \in Y} H_\alpha$ is commutative with finite dimension.

Let B_α be a basis of H_α for every $\alpha \in Y$, then $B = \cup_{\alpha \in Y} B_\alpha$ is a basis of H. For any $a \in B_\alpha$, let ϕ_a be the dual morphism of a in H_α^*, that is,

$$\phi_a(x) = \begin{cases} 1 & \text{if } a = x \in H_\alpha, \\ 0 & \text{if } a \neq x \in H_\alpha. \end{cases}$$

Then, $\{\phi_a | a \in B_\alpha\}$ is a basis of H_α^* for any $\alpha \in Y$.

At k-linear spaces, we have $H^*\otimes H=H^*\otimes(\oplus_{\alpha\in Y}H_\alpha)$. Moreover, $H^*=(\oplus_{\alpha\in Y}H_\alpha)^*=\Pi_{\alpha\in Y}(H_\alpha)^*$. Y is finite since H is finite dimensional. As is known, the direct product and the direct sum are equivalent for a finite number of linear spaces. So, $\Pi_{\alpha\in Y}(H_\alpha)^*=\oplus_{\alpha\in Y}(H_\alpha)^*$.

Since for any $f\in H^*=\oplus_{\alpha\in Y}H_\alpha^*$, it can be decomposed to $f=\Sigma_{\alpha\in Y}f_\alpha$ with $f_\alpha\in H_\alpha^*$. So we can introduce a kind of product as follows.

Definition II.1: For a semilattice graded weak Hopf algebra $H=\oplus_{\alpha\in Y}H_\alpha$, we define a product $D'(H)=H^{op^*}\infty' H$ *from H which can be constructed by*

$$(f\infty' a)(g\infty' b)=fg(1_{H_\alpha}?)\infty' ab$$

for $f\in H_{\alpha_1}^{op^*}$, $g\in H_{\alpha_2}^{op^*}$, $a\in H_{\beta_1}$, $b\in H_{\beta_2}$, *where* $fg(1_{H_\alpha}?)$ *means the morphism,* $x\mapsto\Sigma_{(x)}f(x')g(1_{H_\alpha}x'')$ *for* $x\in H_{\alpha_1}$. *We call* $D'(H)$ *the* quantum G-double *of H. (Note that all "?" in this paper are under the same meaning.)*

Thus, we get $D'(H)=\oplus_{\alpha,\beta\in Y}(H_\alpha^*\otimes H_\beta)$ as linear spaces. Denote $D'(H_\alpha,H_\beta)=H_\alpha^{op^*}\otimes H_\beta$ and $Q_H(H_\alpha)=H_\alpha^{op^*}\otimes H=\oplus_{\beta\in Y}D'(H_\alpha,H_\beta)$. Then, as linear spaces,

$$D'(H)=\bigoplus_{\alpha\in Y}Q_H(H_\alpha)=\bigoplus_{\alpha,\beta\in Y}D'(H_\alpha,H_\beta). \tag{2.1}$$

Theorem II.2: *For a commutative semilattice graded weak Hopf algebra $H=\oplus_{\alpha\in Y}H_\alpha$, the quantum G-double $D'(H)$ defined above is a noncommutative and noncocommutative almost bialgebra with regular R-matrix $R=\Sigma_{\alpha\in Y}\Sigma_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})$, but it is usually not quasitriangular although $(\Delta\otimes\mathrm{id}_H)(R)=R_{13}R_{23}$ and $(\mathrm{id}_H\otimes\Delta)(R)=R_{13}R_{12}$ hold.*

Proof: (1) First we can prove that $D'(H)$ is an almost bialgebra.

For any $\alpha_1,\alpha_2,\beta_1,\beta_2\in Y$, $x\in B_{\beta_1}$, $y\in B_{\beta_2}$, $a\in B_{\alpha_1}$ and its duality ϕ_a in $H_{\alpha_1}^{op^*}$, $b\in B_{\alpha_2}$ and its duality ϕ_b in $H_{\alpha_2}^{op^*}$, we have

$$(\phi_a\infty' x)(\phi_b\infty' y)=(\phi_a\infty' x)(\phi_b\infty' y)=\phi_a\phi_b(1_{H_{\beta_1}}?)\infty' xy,$$

where

$$\phi_a\phi_b(1_{H_{\beta_1}}?)=\begin{cases}0 & \text{if } \alpha_1\beta_1\neq\alpha_2,\\ \phi_a\phi_b(1_{H_\beta}?) & \text{if } \alpha_1\beta_1=\alpha_2.\end{cases}$$

Then, for any $x\in B_{\alpha_1}$, $y\in B_{\alpha_2}$, $z\in B_{\alpha_3}$, $a\in B_{\beta_1}$ and its duality ϕ_a in $H_{\beta_1}^{op^*}$, $b\in B_{\beta_2}$ and its duality ϕ_b in $H_{\beta_2}^{op^*}$, $c\in B_{\beta_3}$ and its duality ϕ_c in $H_{\beta_3}^{op^*}$, we have

$$\begin{aligned}((\phi_a\infty' x)(\phi_b\infty' y))(\phi_c\infty' z)&=(\phi_a\phi_b(1_{H_{\alpha_1}}?)\infty' xy)(\phi_c\infty' z)\\&=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\beta_2\\ (\phi_a\phi_b(1_{H_{\alpha_1}}?)\infty' xy)(\phi_c\infty' z) & \text{if } \alpha_1\beta_1=\alpha_2\end{cases}\\&=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\beta_2 \quad\text{or } \beta_1\alpha_1\alpha_2\neq\beta_3\\ \phi_a\phi_b(1_{H_{\alpha_1}}?)\phi_c(1_{H_{\alpha_1\alpha_2}})\infty' xyz & \text{if } \beta_1\alpha_1=\beta_2 \quad\text{and } \beta_1\alpha_1\alpha_2=\beta_3,\end{cases}\end{aligned}$$

$$\begin{aligned}(\phi_a\infty' x)((\phi_b\infty' y)(\phi_c\infty' z))&=(\phi_a\infty' x)(\phi_b\phi_c(1_{H_{\alpha_2}}?)\infty' yz)\\&=\begin{cases}0 & \text{if } \alpha_2\beta_2\neq\beta_3\\ ((\phi_a\infty' x)(\phi_b\phi_c(1_{H_{\alpha_2}}?)\infty' yz) & \text{if } \alpha_2\beta_2=\beta_3\end{cases}\\&=\begin{cases}0 & \text{if } \alpha_2\beta_2\neq\beta_3 \quad\text{or } \alpha_1\beta_1\neq\beta_2\\ \phi_a(\phi_b\phi_c(1_{H_{\alpha_2}}?)(1_{H_{\alpha_1}}?))\infty' xyz & \text{if } \alpha_2\beta_2=\beta_3 \quad\text{and } \alpha_1\beta_1=\beta_2.\end{cases}\end{aligned}$$

If $\beta_1\alpha_1=\beta_2$ and $\beta_1\alpha_1\alpha_2=\beta_3$, then $\alpha_2\beta_2=\alpha_2\beta_1\alpha_1=\beta_1\alpha_1\alpha_2=\beta_3$; conversely, if $\alpha_1\beta_1=\beta_2$ and $\alpha_2\beta_2=\beta_3$, then $\beta_1\alpha_1\alpha_2=\beta_2\alpha_2=\beta_3$. Hence, $\beta_1\alpha_1=\beta_2$ and $\beta_1\alpha_1\alpha_2=\beta_3\Leftrightarrow\alpha_1\beta_1=\beta_2$ and $\alpha_2\beta_2=\beta_3$. So, for some $d\in H_{\beta_1}$ and $u\in H^*$, then

$$(\phi_a\phi_b(1_{H_{\alpha_1}}?)\phi_c(1_{H_{\alpha_1\alpha_2}}?)\infty' xyz)(d\otimes u)=\sum_{(d)}\phi_a(d')\phi_b(1_{H_{\alpha_1}}d'')\phi_c(1_{H_{\alpha_1\alpha_2}}d''')u(xyz),$$

$$\begin{aligned}(\phi_a(\phi_b\phi_c(1_{H_{\alpha_2}}?))(1_{H_{\alpha_1}}?)\infty' xyz)(d\otimes u)&=\sum_{(d)}\phi_a(d')\phi_b\phi_c(1_{H_{\alpha_2}}?)(1_{H_{\alpha_1}}d'')u(xyz)\\&=\sum_{(d)}\phi_a(d')\phi_b((1_{H_{\alpha_1}}d'')')\phi_c(1_{H_{\alpha_2}}(1_{H_{\alpha_1}}d'')'')u(xyz)\\&=\sum_{(d)}\phi_a(d')\phi_b(1_{H_{\alpha_1}}d'')\phi_c(1_{H_{\alpha_2}}1_{H_{\alpha_1}}d''')u(xyz)\\&=\sum_{(d)}\phi_a(d')\phi_b(1_{H_{\alpha_1}}d'')\phi_c(1_{H_{\alpha_1\alpha_2}}d''')u(xyz).\end{aligned}$$

That is $((\phi_a\infty' x)(\phi_b\infty' y))(\phi_c\infty' z)=(\phi_a\infty' x)((\phi_b\infty' y)(\phi_c\infty' z))$.

Moreover, $1_{D(H)}=\varepsilon_H\infty' 1_H=\Sigma_{\alpha\in Y}\varepsilon_{H_\alpha}\infty' 1_H$ is the identity of $D'(H)$. Since for any $\phi_a\in H_\alpha^*$, $x\in H_\beta$,

$$(\varepsilon_H\infty' 1_H)(\phi_a\infty' x)=\varepsilon_H\phi_a(1_H?)\infty' 1_H x=\varepsilon_{H_\alpha}\phi_a\infty' x,$$

$$(\phi_a\infty' x)(\varepsilon_H\infty' 1_H)=\phi_a\varepsilon_H(1_{H_\beta}?)\infty' x1_H=\phi_a\varepsilon_H(1_{H_\beta})\varepsilon_H(?)\infty' x=\phi_a\varepsilon_H\infty' x,$$

and for any $z\in H_\alpha$, $\phi_a\varepsilon_H(z)=\Sigma_{(z)}\phi_a(z')\varepsilon_H(z'')=\Sigma_{(z)}\phi_a(z')\varepsilon_{H_\alpha}(z'')=\phi_a(x)$, that is $(\varepsilon_H\infty' 1_H)\times(\phi_a\infty' x)=(\phi_a\infty' x)(\varepsilon_H\infty' 1_H)=\phi_a\infty x'$.

Therefore $D'(H)$ is an algebra.

The comultiplication Δ in $D'(H)$ is trivial, that is, for $f\in H^{op*}$ and $x\in B$,

$$\Delta(f\infty' x)=\sum_{(f)(x)}(f'\infty' x')\otimes(f''\infty' x''),$$

where $\Delta(f)=\Sigma_{(f)}f'\otimes f''$ according to the comultiplication in H^{op*}.

The counit ε of $D'(H)$ is given as $\varepsilon(\phi_a\infty' x)=\varepsilon_{H_\alpha^{op*}}(\phi_a)\varepsilon_{H_\beta}(x)$ for $a\in B_\alpha$, $x\in B_\beta$. But, $\varepsilon_{H_\alpha^{op*}}(\phi_a)=\eta_{H_\alpha^*}(\phi_a)(1_k)=\phi_a\eta_{H_\alpha}(1_k)=\phi_a(1_{H_\alpha})=\delta_{a,1_{H_\alpha}}$. Therefore, we get

$$\varepsilon(\phi_a\infty' x)=\delta_{a,1H\alpha}\varepsilon_{H_\beta}(x).$$

Obviously, $(\Delta\otimes 1)\Delta=(1\otimes\Delta)\Delta$.

For any $f\in H_\alpha^*$, $x\in H_\beta$, $(\varepsilon\otimes 1)\Delta(f\infty' x)=(\varepsilon\otimes 1)\Sigma_{(f),(x)}(f'\infty' x')\otimes(f''\infty' x'')=\Sigma_{(f),(x)}\varepsilon(f'\infty' x')\times(f''\infty' x'')=\Sigma_{(f),(x)}\varepsilon_{H_\alpha^{op*}}(f')\varepsilon_{H_\beta}(x')f''\infty' x''=\Sigma_{(f),(x)}\varepsilon_{H_\alpha^{op*}}(f')f''\infty'\varepsilon_{H_\beta}(x')x''=f\infty' x$. Similarly, $(1\otimes\varepsilon)\Delta(f\infty' x)=f\infty' x$. Hence, $(\varepsilon\otimes 1)\Delta=(1\otimes\varepsilon)\Delta=\mathrm{id}$. Therefore, $D'(H)$ becomes a coalgebra on Δ and ε.

For any $a\in B_{\alpha_1}$, $b\in B_{\alpha_2}$, $x\in B_{\beta_1}$, $y\in B_{\beta_2}$,

(a) Δ is an algebra homomorphism,

$$\Delta((\phi_a\infty' x)(\phi_b\infty' y))=\Delta(\phi_a\phi_b(1_{H_{\beta_1}}?)\infty' xy)=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \Delta(\phi_a\phi_b(1_{H_{\beta_1}}?)\infty' xy) & \text{if } \beta_1\alpha_1=\alpha_2\end{cases}$$

$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \sum((\phi_a\phi_b(1_{H_{\beta_1}}?))'\infty' x'y')\otimes((\phi_a\phi_b(1_{H_{\beta_1}}?))''\infty' x''y'') & \text{if } \beta_1\alpha_1=\alpha_2,\end{cases}$$

$$\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y)=\Big(\sum_{(\phi_a),(x)}(\phi_a'\infty' x')\otimes(\phi_a''\infty' x'')\Big)\Big(\sum_{(\phi_b),(y)}(\phi_b'\infty' y')\otimes(\phi_b''\infty' y'')\Big)$$
$$=\sum_{(\phi_a),(\phi_b),(x),(y)}(\phi_a'\infty' x')(\phi_b'\infty' y')\otimes(\phi_a''\infty' x'')(\phi_b''\infty' y'')$$
$$=\sum_{(\phi_a),(\phi_b),(x),(y)}(\phi_a'\phi_b'(1_{H_{\beta_1}}?)\infty' x'y')\otimes(\phi_a''\phi_b''(1_{H_{\beta_1}}?)\infty' x''y'')$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \displaystyle\sum_{(\phi_a),(\phi_b),(x),(y)}(\phi_a'\phi_b'(1_{H_{\beta_1}}?)\infty' x'y')\otimes(\phi_a''\phi_b''(1_{H_{\beta_1}}?)\infty' x''y'') & \text{if } \beta_1\alpha_1=\alpha_2.\end{cases}$$

For any $u, v\in H^*$, $s, t\in B_{\alpha_1}$,

$$\Delta((\phi_a\infty' x)(\phi_b\infty' y))(s\otimes u\otimes t\otimes v)$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \sum(\phi_a\phi_b(1_{H_{\beta_1}}?))'(s)u(x'y')(\phi_a\phi_b(1_{H_{\beta_1}}?))''(t)v(x''y'') & \text{if } \beta_1\alpha_1=\alpha_2\end{cases}$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \sum(\phi_a\phi_b(1_{H_{\beta_1}}?))(st)u(x'y')v(x''y'') & \text{if } \beta_1\alpha_1=\alpha_2\end{cases}$$

$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \displaystyle\sum_{(st)}\phi_a(s't')\phi_b(1_{H_{\beta_1}}s''t'')u(x'y')v(x''y'') & \text{if } \beta_1\alpha_1=\alpha_2,\end{cases}$$

$$\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y)(s\otimes u\otimes t\otimes v)$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \displaystyle\sum_{(s),(t)}\phi_a'(s')\phi_b'(1_{H_{\beta_1}}s'')u(x'y')\phi_a''(t')\phi_b''(1_{H_{\beta_1}}t'')v(x''y'') & \text{if } \beta_1\alpha_1=\alpha_2\end{cases}$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \displaystyle\sum_{(s),(t)}\phi_a(s't')\phi_b(1_{H_{\beta_1}}s''1_{H_{\beta_1}}t'')u(x'y')v(x''y'') & \text{if } \beta_1\alpha_1=\alpha_2\end{cases}$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \displaystyle\sum_{(s),(t)}\phi_a(s't')\phi_b(1_{H_{\beta_1}}s''t'')u(x'y')v(x''y'') & \text{if } \beta_1\alpha_1=\alpha_2.\end{cases}$$

Thus, we have $\Delta((\phi_a\infty' x)(\phi_b\infty' y))(s\otimes u\otimes t\otimes v)=\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y)(s\otimes u\otimes t\otimes v)$ for any $u, v\in H^*$, $s, t\in B_{\alpha_1}$. It implies

$$\Delta((\phi_a\infty' x)(\phi_b\infty' y))=\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y).$$

(b) ε is not an algebra homomorphism,

$$\varepsilon((\phi_a\infty' x)(\phi_b\infty' y))=\varepsilon(\phi_a\phi_b(1_{H_{\beta_1}}?)\infty' xy)$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \varepsilon_{H^*_{\alpha_1}}(\phi_a)\varepsilon_{H^*_{\alpha_1}}(\phi_b(1_{H_{\beta_1}}?))\varepsilon_{H_{\beta_1\beta_2}}(xy) & \text{if } \beta_1\alpha_1=\alpha_2\end{cases}$$
$$=\begin{cases}0 & \text{if } \beta_1\alpha_1\neq\alpha_2\\ \phi_a(1_{H_{\alpha_1}})\phi_b(1_{H_{\beta_1}}1_{H_{\alpha_1}})\varepsilon_{H_{\beta_1\beta_2}}(xy) & \text{if } \beta_1\alpha_1=\alpha_2\end{cases}$$

$$= \begin{cases} 0 & \text{if } \beta_1\alpha_1 \neq \alpha_2 \\ \delta_{a,1_{H_{\alpha_1}}}\delta_{b,1_{H_{\alpha_2}}}\varepsilon_{H_{\beta_1\beta_2}}(xy) & \text{if } \beta_1\alpha_1 = \alpha_2, \end{cases}$$

$$\varepsilon(\phi_a \infty' x)\varepsilon(\phi_b \infty' y) = \varepsilon_{H^*_{\alpha_1}}(\phi_a)\varepsilon_{H_{\beta_1}}(x)\varepsilon_{H^*_{\alpha_2}}(\phi_b)\varepsilon_{H_{\beta_2}}(y) = \delta_{a,1_{H_{\alpha_1}}}\delta_{b,1_{H_{\alpha_2}}}\varepsilon_{H_{\beta_1}}(x)\varepsilon_{H_{\beta_2}}(y).$$

So, in the usual, $\varepsilon((\phi_a \infty' x)(\phi_b \infty' y)) \neq \varepsilon(\phi_a \infty' x)\varepsilon(\phi_b \infty' y)$, hence the counit ε is not an algebra homomorphism.

It implies, in general, $D'(H)$ is only an almost bialgebra but not a bialgebra.

(2) Next, we can find a regular R-matrix $R=\Sigma_{\alpha\in Y}\Sigma_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})$ (i.e., there exists a $\bar{R}$ such that $\bar{R}R\bar{R}=\bar{R}$ and $R\bar{R}R=R$) which is a nontrival solution of the Yang-Baxter equation [i.e., not the identity of $(H^{op^*}\infty' H)\otimes(H^{op^*}\infty' H)$]. This is the reason we say $D'(H)$ directly as the so-called quantum G-double.

Since

$$R_{12} = \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\otimes(\varepsilon_H\infty' 1_H),$$

$$R_{13} = \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\varepsilon_H\infty' 1_H)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha}),$$

$$R_{23} = \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_H\infty' 1_H)\otimes(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha}),$$

and

$$\begin{aligned} R_{12}R_{13} &= \Big(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\otimes(\varepsilon_H\infty' 1_H)\Big)\Big(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha) \\ &\quad \otimes(\varepsilon_H\infty' 1_H)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\Big) \\ &= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha\in B_\alpha, b_\beta\in B_\beta}(\varepsilon_{H_\alpha}\infty' a_\alpha)(\varepsilon_{H_\beta}\infty' b\beta)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})(\varepsilon_H\infty' 1_H)\otimes(\varepsilon_H\infty' 1_H)(\phi_{b_\beta}\infty' 1_{H_\beta}) \\ &= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha\in B_\alpha, b_\beta\in B_\beta}(\varepsilon_{H_\alpha}\varepsilon_{H_\beta}(1_{H_\alpha}?)\infty' a_\alpha b_\beta) \\ &\quad \otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\otimes(\phi_{b_\beta}\infty' 1_{H_\beta}). \end{aligned}$$

From the definition we know that $\varepsilon_{H_\alpha}\varepsilon_{H_\beta}(1_{H_\alpha}?)=0$ if $\alpha\neq\beta$, hence

$$\varepsilon_{H_\alpha}\varepsilon_{H_\beta}(1_{H_\alpha}?)\infty' a_\alpha b_\beta = \begin{cases} 0 & \text{if } \alpha\neq\beta, \\ \varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha & \text{if } \alpha=\beta. \end{cases}$$

Then

$$R_{12}R_{13} = \sum_{\alpha\in Y}\sum_{a_\alpha, b_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\otimes(\phi_{b_\alpha}\infty' 1_{H_\alpha}),$$

$$
\begin{aligned}
R_{12}R_{13}R_{23} &= \Bigg(\sum_{\alpha\in Y}\sum_{a_\alpha,b_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\otimes(\phi_{b_\alpha}\infty' 1_{H_\alpha})\Bigg)\Bigg(\sum_{\alpha\in Y}\sum_{c_\alpha\in B_\alpha}(\varepsilon_H\infty' 1_H)\\
&\quad\otimes(\varepsilon_{H_\alpha}\infty' c_\alpha)\otimes(\phi_{c_\alpha}\infty' 1_{H_\alpha})\Bigg)\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha,b_\alpha\in B_\alpha,c_\beta\in B_\beta}(\varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha)(\varepsilon_H\infty' 1_H)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})(\varepsilon_{H_\beta}\infty' c_\beta)\\
&\quad\otimes(\phi_{b_\alpha}\infty' 1_{H_\alpha})(\phi_{c_\beta}\infty' 1_{H_\beta})\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha,b_\alpha\in B_\alpha,c_\beta\in B_\beta}(\varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha)\otimes(\phi_{a_\alpha}\varepsilon_{H_\beta}(1_{H_\alpha}?)\infty' c_\beta)\\
&\quad\otimes(\phi_{b_\alpha}\phi_{c_\beta}(1_{H_\alpha}?)\infty' 1_{H_\alpha}1_{H_\beta})\\
&= \sum_{\alpha\in Y}\sum_{a_\alpha,b_\alpha,c_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha)\otimes(\phi_{a_\alpha}\infty' c_\alpha)\otimes(\phi_{b_\alpha}\phi_{c_\alpha}\infty' 1_{H_\alpha}).
\end{aligned}
$$

Similarly, we can get

$$
R_{23}R_{13}R_{12} = \sum_{\alpha\in Y}\sum_{c_\alpha,b_\alpha,a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' b_\alpha a_\alpha)\otimes(\phi_{a_\alpha}\infty' c_\alpha)\otimes(\phi_{c_\alpha}\phi_{b_\alpha}\infty' 1_{H_\alpha}).
$$

Since H is commutative and the random choosing of a_α, b_α, c_α, we can conclude that $R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12}$. This shows that R is a nontrivial solution of Yang-Baxter equation.

It can be proved that R is regular with the regular inverse $\bar{R}=\Sigma_{\alpha\in Y}\Sigma_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes((\phi_{a_\alpha}\circ T)\otimes 1_{H_\alpha})$. In fact, since

$$
\begin{aligned}
R\bar{R} &= \Bigg(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\Bigg)\Bigg(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes((\phi_{a_\alpha}\circ T)\infty' 1_{H_\alpha})\Bigg)\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha\in B_\alpha,b_\beta\in B_\beta}(\varepsilon_{H_\alpha}\infty' a_\alpha)(\varepsilon_{H_\beta}\infty' b_\beta)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})((\phi_{b_\beta}\circ T)\infty' 1_{H_\beta})\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha\in B_\alpha,b_\beta\in B_\beta}(\varepsilon_{H_\alpha}\varepsilon_{H_\beta}(1_{H_\alpha}?)\infty' a_\alpha b_\beta)\otimes(\phi_{a_\alpha}(\phi_{b_\beta}\circ T)(1_{H_\alpha}?)\infty' 1_{H_\alpha}1_{H_\beta})\\
&= \sum_{\alpha\in Y}\sum_{a_\alpha,b_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha)\otimes(\phi_{a_\alpha}(\phi_{b_\alpha}\circ T)\infty' 1_{H_\alpha}).
\end{aligned}
$$

Consider an element $\xi=b\otimes u\otimes c\otimes v$ with b, $c\in H$ and u, $v\in H^*$. Since $\varepsilon_{H_\alpha}(H_\beta)=0$ if $\alpha\neq\beta$, we can suppose that b, $c\in H_\alpha$ for some $\alpha\in Y$. So,

$$
\begin{aligned}
\langle R\bar{R},\xi\rangle &= \sum_{\alpha\in Y}\sum_{a_\alpha,b_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha b_\alpha)\otimes(\phi_{a_\alpha}(\phi_{b_\alpha}\circ T)\infty' 1_{H_\alpha})(b\otimes u\otimes c\otimes v)\\
&= \sum_{\alpha\in Y}\sum_{a_\alpha,b_\alpha\in B_\alpha}\varepsilon_{H_\alpha}(b)u(a_\alpha b_\alpha)\sum_{(c)}\phi_{a_\alpha}(c')(\phi_{b_\alpha}\circ T)(c'')v(1_{H_\alpha})\\
&= \varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\sum_{\alpha\in Y}\sum_{a_\alpha,b_\alpha\in B_\alpha}\sum_{(c)}u(a_\alpha b_\alpha)\phi_{a_\alpha}(c')\phi_{b_\alpha}(T(c''))\\
&= \varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\sum_{(c)}u\Bigg(\sum_{a_\alpha\in B_\alpha}\phi_{a_\alpha}(c')a_\alpha\Bigg)u\Bigg(\sum_{b_\alpha\in B_\alpha}\phi_{b_\alpha}(T(c''))b_\alpha\Bigg)\Bigg(\sum_{a_\alpha\in B_\alpha}\phi_{a_\alpha}(x)a_\alpha = x\Bigg)\\
&= \varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\sum_{(c)}u(c')u(T(c'')) = \varepsilon_{H_\alpha}(b)v(1_{H_\alpha})u(c'T(c'')) = \varepsilon_{H_\alpha}(b)v(1_{H_\alpha})u(\varepsilon_{H_\alpha}(c)1_{H_\alpha})\\
&= \varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\varepsilon_{H_\alpha}(c)u(1_{H_\alpha}) = ((\varepsilon_{H_\alpha}\infty' 1_{H_\alpha})\otimes(\varepsilon_{H_\alpha}\infty' 1_{H_\alpha}))(b\otimes u\otimes c\otimes v).
\end{aligned}
$$

From random of choice of α, we can get $R\bar{R}=\Sigma_{\alpha\in Y}(\varepsilon_{H_\alpha}\infty' 1_{H_\alpha})\otimes(\varepsilon_{H_\alpha}\infty' 1_{H_\alpha})$. Hence,

$$
\begin{aligned}
R\bar{R}R &= \left(\sum_{\alpha\in Y}(\varepsilon_{H_\alpha}\infty' 1_{H_\alpha})\otimes(\varepsilon_{H_\alpha}\infty' 1_{H_\alpha})\right)\left(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\right)\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\beta\in B_\beta}(\varepsilon_{H_\alpha}\infty' 1_{H_\alpha})(\varepsilon_{H_\beta}\otimes a_\beta)\otimes(\varepsilon_{H_\alpha}\infty' 1_{H_\alpha})(\phi_{a_\beta}\infty' 1_{H_\beta})\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\beta\in B_\beta}(\varepsilon_{H_\alpha}\varepsilon_{H_\beta}(1_{H_\alpha}?)\infty' 1_{H_\alpha}a_\beta)\otimes(\varepsilon_{H_\alpha}\phi_{a_\beta}(1_{H_\alpha}?)\infty' 1_{H_\alpha}1_{H_\beta})\\
&= \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\infty'(\varepsilon_{H_\alpha}\phi_{a_\alpha}\infty' 1_{H_\alpha}) = \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha}) = R.
\end{aligned}
$$

Similarly, we can prove that $\bar{R}R\bar{R}=\bar{R}$. So $\bar{R}$ is a regular inverse of R.

It can be proved that R satisfies $(\Delta\otimes \mathrm{id}_H)(R)=R_{13}R_{23}$ and $(\mathrm{id}_H\otimes\Delta)(R)=R_{13}R_{12}$ as follows:

$$
\begin{aligned}
(\Delta\otimes \mathrm{id}_H)(R) &= (\Delta\otimes \mathrm{id}_H)\left(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\right)\\
&= \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}\sum_{(a_\alpha)}(\varepsilon_{H_\alpha}\infty' a'_\alpha)\otimes(\varepsilon_{H_\alpha}\infty' a''_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha}),
\end{aligned}
$$

$$
\begin{aligned}
R_{13}R_{23} &= \left(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\varepsilon_H\infty' 1_H)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\right)\\
&\quad\times\left(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_H\infty' 1_H)\otimes(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\right)\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha\in B_\alpha, b_\beta\in B_\beta}(\varepsilon_{H_\alpha}\infty' a_\alpha)(\varepsilon_H\infty' 1_H)\otimes(\varepsilon_H\infty' 1_H)(\varepsilon_{H_\beta}\infty' b_\beta)\otimes(\phi_{a_\alpha}\infty 1_{H_\alpha})(\phi_{b_\beta}\infty' 1_{H_\beta})\\
&= \sum_{\alpha,\beta\in Y}\sum_{a_\alpha\in B_\alpha, b_\beta\in B_\beta}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\varepsilon_{H_\beta}\infty' b_\beta)\otimes(\phi_{a_\alpha}\phi_{b_\beta}(1_{H_\alpha}?)\infty' 1_{H_\alpha}1_{H_\beta})\\
&= \sum_{\alpha\in Y}\sum_{a_\alpha, b_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\varepsilon_{H_\alpha}\infty' b_\alpha)\otimes(\phi_{a_\alpha}\phi_{b_\alpha}\infty' 1_{H_\alpha})
\end{aligned}
$$

since $\phi_{a_\alpha}\phi_{b_\beta}(1_{H_\alpha}?)=0$ if $\alpha\neq\beta$.

For some $a\otimes t\otimes b\otimes u\otimes c\otimes v=\theta$, if $a\notin H_\alpha$, then $\varepsilon_{H_\alpha}(a)=0$, similarly discussed we can suppose that there exists a $a\in Y$ such that a, b, $c\in H_\alpha$, and t, u, $v\in H^*$. Then

$$
\begin{aligned}
\langle(\Delta\otimes \mathrm{id}_H)(R),\theta\rangle &= \sum_{a_\alpha\in B_\alpha}\sum_{(a_\alpha)}\varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)\phi_{a_\alpha}(c)t(a'_\alpha)u(a''_\alpha)v(1_{H_\alpha})\\
&= \varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\sum_{a_\alpha\in B_\alpha}\sum_{(a_\alpha)}\phi_{a_\alpha}(c)t(a'_\alpha)u(a''_\alpha)\\
&\quad\left(\text{since } a=\sum_{a_\alpha\in B_\alpha}\phi_{a_\alpha}(a)a_\alpha,\ \Delta(a)=\sum_{(a)}a'\otimes a''=\sum_{a_\alpha\in B_\alpha}\phi_{a_\alpha}(a)a'_\alpha\otimes a''_\alpha\right)\\
&= \varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\sum_{(c)}t(c')u(c'') = \varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)v(1_{H_\alpha})uv(c),
\end{aligned}
$$

$$
\begin{aligned}
\langle R_{13}R_{23},\theta\rangle &= \sum_{a_\alpha, b_\alpha\in B_\alpha}\varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)v(1_{H_\alpha})t(a_\alpha)u_{b_\alpha}\phi_{a_\alpha}\phi_{b_\alpha}(c)\\
&= \varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\sum_{(c)}t\left(\sum_{a_\alpha\in B_\alpha}\phi_{a_\alpha}(c')a_\alpha\right)u\left(\sum_{b_\alpha\in B_\alpha}\phi_{b_\alpha}(c'')b_\alpha\right)\\
&= \varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)v(1_{H_\alpha})\sum_{(c)}t(c')u(c'') = \varepsilon_{H_\alpha}(a)\varepsilon_{H_\alpha}(b)v(1_{H_\alpha})uv(c).
\end{aligned}
$$

From the random choice of α, we can conclude that $(\Delta\otimes \mathrm{id}_H)(R)=R_{13}R_{23}$. Similarly, we can prove that $(\mathrm{id}_H\otimes\Delta(R))=R_{13}R_{12}$.

Now, we explain that R usually does not satisfy $\Delta^{op}(h)R=R\Delta(h)$ for any $h\in D'(H)$, that is, $D'(H)$ is not almost cocommutative in general.

For any $a\in B_\beta$, $x\in B_\gamma$, we have

$$\begin{aligned}\Delta^{op}(\phi_a\infty' x)R &= \left(\sum_{(\phi_a),(x)}(\phi_a''\infty' x'')\otimes(\phi_a'\infty x')\right)\left(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\right)\\ &= \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}(\phi_a''\infty' x'')(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_a'\infty' x')(\phi_{a_\alpha}\infty' 1_{H_\alpha})\\ &= \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}(\phi_a''\varepsilon_{H_\alpha}(1_{H_\gamma}?)\infty' x''a_\alpha)\otimes(\phi_a'\phi_{a_\alpha}(1_{H_\gamma}?)\infty' x'1_{H_\alpha})\\ &= \sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}(\phi_a''\varepsilon_{H_\alpha}(1_{H_\gamma}?)\infty' x''a_\alpha)\otimes(\phi_a'\phi_{a_\alpha}(1_{H_\gamma}?)\infty' x'1_{H_\alpha})\quad(\text{when }\alpha=\beta\gamma),\end{aligned}$$

$$\begin{aligned}R\Delta(\phi_a\infty' x) &= \left(\sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})\right)\left(\sum_{(\phi_a),(x)}(\phi_a'\infty' x')\otimes(\phi_a''\infty x'')\right)\\ &= \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}(\varepsilon_{H_\alpha}\infty' a_\alpha)(\phi_a'\infty' x')\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})(\phi_a''\infty' x'')\\ &= \sum_{\alpha\in Y}\sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}(\varepsilon_{H_\alpha}\phi_a'(1_{H_\alpha}?)\infty' a_\alpha x')\otimes(\phi_{a_\alpha}\phi_a''(1_{H_\alpha}?)\infty' 1_{H_\alpha}x'')\\ &= \sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}(\phi_a'\infty' a_\alpha x')\otimes(\phi_{a_\alpha}\phi_a''\infty' 1_{H_\alpha}x'')\quad(\text{when }\alpha=\beta).\end{aligned}$$

Then, for some $\xi=b\otimes u\otimes c\otimes v$, with b, $c\in H_\beta$ and u, $v\in H^*$, we can get

$$\begin{aligned}\langle\Delta^{op}(\phi_a\infty' x)R,\xi\rangle &= \sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}\sum_{(b),(c)}\phi_a''(b')\varepsilon_{H_\alpha}(1_{H_\gamma}b'')u(x''a_\alpha)\phi_a'(c')\phi_{a_\alpha}(c'')v(x'1_{H_\alpha})\\ &= \sum_{a_\alpha\in B_\alpha}\sum_{(x)}\sum_{(b),(c)}\phi_a(b'c')\varepsilon_{H_\alpha}(b''\varphi_{\beta,\alpha}1_{H_\gamma}\varphi_{\gamma,\alpha})u(x''a_\alpha)\phi_{a_\alpha}(1_{H_\gamma}c'')v(x'1_{H_\alpha})\\ &= \sum_{a_\alpha\in B_\alpha}\sum_{(x)}\sum_{(b),(c)}\phi_a(b'c')\varepsilon_{H_\beta}(b'')\varepsilon_{H_\gamma}(1_{H_\gamma})u(x''a_\alpha)\phi_{a_\alpha}(1_{H_\gamma}c'')v(x'1_{H_\alpha})\\ &= \sum_{(x)}\sum_{(b),(c)}\phi_a(b'\varepsilon_{H_\beta}(b'')c')u\left(x''\sum_{a_\alpha\in B_\alpha}\phi_{a_\alpha}(1_{H_\gamma}c'')a_\alpha\right)v(x'1_{H_\alpha})\\ &= \sum_{(x)}\sum_{(c)}\phi_a(bc')u(x''1_{H_\gamma}c'')v(x'1_{H_\alpha})=\sum_{(x)}\sum_{(c)}\phi_a(bc')u(x''c'')v(x'1_{H_\alpha}),\end{aligned}$$

$$\begin{aligned}\langle R\Delta(\phi_a\infty' x),\xi\rangle &= \sum_{a_\alpha\in B_\alpha}\sum_{(\phi_a),(x)}\sum_{(c)}\phi_a'(b)u(a_\alpha x')\phi_{a_\alpha}(c')\phi_a''(c'')v(x''1_{H_\alpha})\\ &= \sum_{(x)}\sum_{(c)}\phi_a(bc')u\left(\sum_{a_\alpha\in B_\alpha}\phi_{a_\alpha}(c')a_\alpha x'\right)v(x''1_{H_\alpha})=\sum_{(x)}\sum_{(c)}\phi_a(bc')u(c'x')v(x''1_{H_\alpha}).\end{aligned}$$

From the above equation, we can see that in general $\Delta^{op}(\phi_a\infty' x)R\neq R\Delta(\phi_a\infty' x)$ unless H is cocommutative.

Remark: The R-matrix can be decomposed as $R=\Sigma_{\alpha\in Y}\Sigma_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})=\Sigma_{\alpha\in Y}R_\alpha$, where $R_\alpha=\Sigma_{a_\alpha\in B_\alpha}(\varepsilon_{H_\alpha}\infty' a_\alpha)\otimes(\phi_{a_\alpha}\infty' 1_{H_\alpha})$ is the R-matrix for the classical quantum double $D(H_\alpha)$ for every $\alpha\in Y$. Moreover, for any α, $\beta\in Y$,

$$
\begin{aligned}
R_\alpha R_\beta &= \left(\sum_{a_\alpha \in B_\alpha} (\varepsilon_{H_\alpha} \infty' a_\alpha) \otimes (\phi_{a_\alpha} \infty' 1_{H_\alpha})\right)\left(\sum_{a_\beta \in B_\beta} (\varepsilon_{H_\beta} \infty' a_\beta) \otimes (\phi_{a_\beta} \infty' 1_{H_\beta})\right) \\
&= \sum_{a_\alpha \in B_\alpha, b_\beta \in B_\beta} ((\varepsilon_{H_\alpha} \infty' a_\alpha)(\varepsilon_{H_\beta} \infty' b_\beta)) \otimes ((\phi_{a_\alpha} \infty' 1_{H_\alpha})(\phi_{b_\beta} \infty' 1_{H_\beta})) \\
&= \sum_{a_\alpha \in B_\alpha, b_\beta \in B_\beta} (\varepsilon_{H_\alpha} \varepsilon_{H_\beta} (1_{H_\alpha} ?) \infty' a_\alpha b_\beta) \otimes (\phi_{a_\alpha} \phi_{b_\beta} (1_{H_\alpha} ?) \infty' 1_{H_\alpha} 1_{H_\beta}) \\
&= \begin{cases} 0 & \text{if } \alpha \neq \beta, \\ \displaystyle\sum_{a_\alpha, b_\alpha \in B_\alpha} (\varepsilon_{H_\alpha} \infty' a_\alpha b_\alpha) \otimes (\phi_{a_\alpha} \phi_{b_\alpha} \infty' 1_{H_\alpha}) & \text{if } \alpha = \beta, \end{cases}
\end{aligned}
$$

which usually is not equal to $R_{\alpha\beta}$.

This implies that $R = \Sigma_{\alpha \in Y} R_\alpha$ does not have the graded structure.

III. STRUCTURE OF QUANTUM G-DOUBLE

In this section, we discuss the structure of $D'(H)$ depending upon $D'(H_\alpha)(\alpha \in Y)$ and then obtain the structure theorem.

First, for α_1, α_2, β_1, $\beta_2 \in Y$, we consider the multiplication between $D'(H_{\alpha_1}, H_{\beta_1})$ and $D'(H_{\alpha_2}, H_{\beta_2})$. For $x \in B_{\beta_1}$, $y \in B_{\beta_2}$, $a \in B_{\alpha_1}$ and its duality ϕ_a in $H_{\alpha_1}^{op^*}$, $b \in B_{\alpha_2}$ and its duality ϕ_b in $H_{\alpha_2}^{op^*}$, from definition we have

$$
(\phi_a \infty x)(\phi_b \infty y) = \phi_a \phi_b (1_{H_{\beta_1}} ?) \infty xy = \begin{cases} 0 & \text{if } \beta_1 \alpha_1 \neq \alpha_2, \\ \phi_a \phi_b (1_{H_{\beta_1}} ?) & \text{if } \beta_1 \alpha_1 = \alpha_2, \end{cases}
$$

hence, $\phi_a \phi_b (1_{H_{B_1}} ?)$ is always in $H_{\alpha_1}^{op^*}$. And, $xy \in H_{\beta_1 \beta_2}$. Therefore, $(\phi_a \infty' x) \times (\phi_b \infty' y) \in H_{\alpha_1}^{op^*} \infty' H_{\beta_1 \beta_2}$. Since $\{\phi_a : a \in B_{\alpha_1}\}$ and $\{\phi_b : b \in B_{\alpha_2}\}$ are, respectively, a basis of $H_{\alpha_1}^{op^*}$ and $H_{\alpha_2}^{op^*}$, we get that

$$
(H_{\alpha_1}^{op^*} \infty' H_{\beta_1})(H_{\alpha_2}^{op^*} \infty' H_{\beta_2}) \subseteq H_{\alpha_1}^{op^*} \infty' H_{\beta_1 \beta_2},
$$

that is,

$$
D'(H_{\alpha_1}, H_{\beta_1}) D'(H_{\alpha_2}, H_{\beta_2}) \subseteq D'(H_{\alpha_1}, H_{\beta_1 \beta_2}); \tag{3.1}
$$

and, if and only if $\alpha_2 \not\leq \alpha_1$ or $\alpha_2 \not\leq \beta_1$, the following holds:

$$
D'(H_{\alpha_1}, H_{\beta_1}) D'(H_{\alpha_2}, H_{\beta_2}) = 0, \tag{3.2}
$$

since in this case, $1_{H_{\beta_1}} a \notin H_{\alpha_2}$; then always $1_{H_{\beta_1}} a \neq b$.

In (3.1), let $\alpha_1 = \alpha_2 = \alpha$, then

$$
D'(H_\alpha, H_{\beta_1}) D'(H_\alpha, H_{\beta_2}) \subseteq D'(H_\alpha, H_{\beta_1 \beta_2}). \tag{3.3}
$$

We call $D'(H_\alpha, H_\beta)$ the *bicrossed G-product* of two subweak Hopf algebras H_α and H_β which are included in $H = \oplus_{\alpha \in Y} H_\alpha$; $Q_H(H_\alpha)$ the *bicrossed G-product* of H and its subweak Hopf algebra H_α. Denote $D'(H_\alpha, H_\beta) = H_\alpha^{op^*} \infty' H_\beta$; $Q_H(H_\alpha) = H_\alpha^{op^*} \infty' H$.

First, we need the following lemmas on $D'(H_\alpha, H_\beta)$ and $Q_H(H_\alpha)$.

Lemma III.1: For all α, $\beta \in Y$, $D'(H_\alpha, H_\beta)$ are coalgebras and subrings of $D'(H)$. For any $\alpha \not\leq \beta$, $D'(H_\alpha, H_\beta)$ is a null subring. For any $\alpha \leqslant \beta$, $D'(H_\alpha, H_\beta)$ is a bialgebra under the same multiplication.

Proof: For $f \in H_\alpha^{op^*}$ and $x \in H_\beta$,

(i) define Δ, $D'(H_\alpha, H_\beta) \to D'(H_\alpha, H_\beta) \otimes D'(H_\alpha, H_\beta)$ satisfying $\Delta(f \infty' x) = \Sigma_{(f)(x)} (f' \infty' x') \otimes (f'' \infty' x'')$, where $\Delta(f) = \Sigma_{(f)} f' \otimes f''$ according to the comultiplication of $H_\alpha^{op^*}$.

(ii) Define ε, $D'(H_\alpha,H_\beta)\to k$ satisfying $\varepsilon(f\infty' x)=\varepsilon_{H_\alpha^{op*}}(f)\varepsilon_{H_\beta}(x)$.

From the discussion of Theorem II.2 we know $D'(H_\alpha,H_\beta)$ becomes a coalgebra on Δ and ε.

The multiplication of $D'(H_\alpha,H_\beta)$ is given as that of $D'(H)$, that is, for $\alpha,\beta\in Y$, $a,b\in B_\alpha$, and $x,y\in B_\beta$,

$$(\phi_a\infty' x)(\phi_b\infty' y)=\phi_a\phi_b(1_{H_\beta}{}^?)\infty' xy=\begin{cases}0 & \text{if } \beta\alpha\neq\alpha,\\ \phi_a\phi_b(1_{H_\beta}{}^?)\infty' xy & \text{if } \beta\alpha=\alpha.\end{cases}$$

In (3.3), let $\beta_1=\beta_2=\beta$, then $D'(H_\alpha,H_\beta)D'(H_\alpha,H_\beta)\subseteq D'(H_\alpha,H_\beta)$ since $\beta\beta=\beta$. Then, every $D'(H_\alpha,H_\beta)$ is a subring of $D'(H)$.

By (3.2), when and only when $\alpha\not\leqslant\beta$, $D'(H_\alpha,H_\beta)D'(H_\alpha,H_\beta)=0$. Hence, in this case, $D'(H_\alpha,H_\beta)$ is a null subring.

Now, suppose that $\alpha\leqslant\beta$. $D'(H_\alpha,H_\beta)$ possesses the identity $\varepsilon_{H_\alpha}\infty' 1_{H_\beta}$ since for any $a\in B_\alpha$, $x\in B_\beta$, $(\phi_a\infty' x)(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})=\phi_a\varepsilon_{H_\alpha}(1_{H_\beta}{}^?)\infty' x1_{H_\beta}=\phi_a\varepsilon_{H_\alpha}(1_{H_\beta}{}^?)\infty' x$, and $(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})(\phi_a\infty' x)=\varepsilon_{H_\alpha}\phi_a(1_{H_\beta}{}^?)\infty' x$ since $\alpha\leqslant\beta$, that is $\beta\alpha=\alpha$, hence, for any $b\in H_\alpha$, $u\in H^*$, we have

$$\begin{aligned}((\phi_a\infty' x)(\varepsilon_{H_\alpha}\infty' 1_{H_\beta}))(b\otimes u)&=\sum_{(b)}\phi_a(b')\varepsilon_{H_\alpha}(1_{H_\beta}b'')u(x)=\sum_{(b)}\phi_a(b')\varepsilon_{H_\alpha}(\varphi_{\beta,\alpha}(1_{H_\beta})\varphi_{\alpha,\alpha}(b''))u(x)\\&=\sum_{(b)}\phi_a(b')\varepsilon_{H_\alpha}\varphi_{\beta,\alpha}(1_{H_\beta})\varepsilon_{H_\alpha}(b'')u(x)\\&=\sum_{(b)}\phi_a(b'\varepsilon_{H_\alpha}(b''))\varepsilon_{H_\beta}(1_{H_\beta})u(x)=\phi_a(b)u(x)=(\phi_a\infty' x)(b\otimes u)\end{aligned}$$

and

$$\begin{aligned}((\varepsilon_{H_\alpha}\infty' 1_{H_\beta})(\phi_a\infty' x))(b\otimes u)&=\sum_{(b)}\varepsilon_{H_\alpha}(b')\phi_a(1_{H_\beta}b'')u(x)=\sum_{(b)}\phi_a(1_{H_\beta}\varepsilon_{H_\alpha}(b')b'')u(x)\\&=\phi_a(1_{H_\beta}b)u(x)=\phi_a(\varphi_{\beta,\alpha}(1_{H_\beta})\varphi_{\alpha,\alpha}(b))u(x)=\phi_a(1_{H_\alpha}b)u(x)\\&=\phi_a(b)u(x)=(\phi_a\infty' x)(b\otimes u).\end{aligned}$$

That is $(\phi_a\infty' x)(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})=(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})(\phi_a\infty' x)=\phi_a\infty' x$.

Therefore $D'(H_\alpha,H_\beta)$ itself is an algebra.

For any $a,b\in B_\alpha$, $x,y\in B_\beta$, as discussed in Theorem II.2, in the case of $\alpha_1=\alpha_2$, $\beta_1=\beta_2$, we can have

$$\Delta((\phi_a\infty' x)(\phi_b\infty' y))=\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y).$$

Obviously,

$$\Delta(1_{D'(H_\alpha,H_\beta)})=\Delta(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})=(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})\otimes(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})=1_{D'(H_\alpha,H_\beta)}\otimes 1_{D'(H_\alpha,H_\beta)}.$$

Since $\alpha\leqslant\beta$, then from Theorem II.2, in the case of $\beta_1=\beta_2$, $\alpha_1=\alpha_2$ we have $\varepsilon((\phi_a\infty' x)\times(\phi_b\infty' y))=\varepsilon(\phi_a\infty' x)\varepsilon(\phi_b\infty' y)$. And, $\varepsilon(1_{D'(H_\alpha,H_\beta)})=\varepsilon(\varepsilon_{H_\alpha}\infty' 1_{H_\beta})=\varepsilon_{H_\alpha^{op*}}(\varepsilon_{H_\alpha})\varepsilon_{H_\beta}(1_{H_\beta})=\varepsilon_{H_\alpha}(1_{H_\alpha})1=1$. Therefore, ε is an algebra morphism.

From the discussion above, we know that $D'(H_\alpha,H_\beta)$ becomes a bialgebra.

Lemma III.2: *For any $\alpha\in Y$, $Q_H(H_\alpha)$ is a right ideal of $D'(H)$ and itself is a coalgebra with comultiplication Δ satisfying $\Delta((\phi_a\infty' x)(\phi_b\infty' y))=\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y)$ for any $x,y\in B$ and $a,b\in B_\alpha$. Moreover, $Q_H(H_\alpha)=N_H(H_\alpha)\oplus B_H(H_\alpha)$ where $N_H(H_\alpha)=\Sigma_{\beta\in Y,\beta\not\geqslant\alpha}D'(H_\alpha,H_\beta)$ is a null right ideal of $D'(H)$ and is a subcoalgebra and ideal of $Q_H(H_\alpha)$, $B_H(H_\alpha)=\Sigma_{\beta\in Y,\beta\geqslant\alpha}D'(H_\alpha,H_\beta)$ is a sub-bialgebra of $Q_H(H_\alpha)$ with $N_H(H_\alpha)B_H(H_\alpha)=0$ and $B_H(H_\alpha)N_H(H_\alpha)\subseteq N_H(H_\alpha)$.*

Proof: From (3.1) and (3.3), we get $Q_H(H_\alpha)D'(H)\subseteq Q_H(H_\alpha)$ for any $\alpha\in Y$, which means that $Q_H(H_\alpha)$ is a right ideal of $D'(H)$, and thus $D'(H)$ can be decomposed into a direct sum of these ideals.

For $f\in H_\alpha^{op^*}$ and $x\in B$,

(1) Define $Q_H(H_\alpha)\to Q_H(H_\alpha)\otimes Q_H(H_\alpha)$ satisfying $\Delta(f\infty' x)=\Sigma_{(f),(x)}(f'\infty' x')\otimes(f''\infty' x'')$, where $\Delta(f)=\Sigma_{(f)}f'\otimes f''$ according to the comultiplication of $H_\alpha^{op^*}$.
(2) Define ε, $Q_H(H_\alpha)\to k$ satisfying $\varepsilon(f\infty' x)=\varepsilon_{H_\alpha^{op^*}}(f)\varepsilon_H(x)$.

As for $D'(H_\alpha,H_\beta)$ in Lemma III.1, $Q_H(H_\alpha)$ is a coalgebra on Δ and ε. And as discussed in Theorem II.2, in the case of $\alpha_1=\alpha_2$. That is, for any a, $b\in B_\alpha$, $x\in B_{\beta_1}\subset B$, $y\in B_{\beta_2}\subset B$, we have

$$\Delta((\phi_a\infty' x)(\phi_b\infty' y))=\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y).$$

By the definition of Δ, $N_H(H_\alpha)$ and $B_H(H_\alpha)$ are both subcoalgebras of $Q_H(H_\alpha)$.

Let $\beta\not\geqslant\alpha$ and $\gamma\in Y$. From (3.3), $D'(H_\alpha,H_\beta)D'(H_\alpha,H_\gamma)=0$. It means that $N_H(H_\alpha)Q_H(H_\alpha)=0$. Specially for $N_H(H_\alpha)N_H(H_\alpha)=0$ [i.e., $N_H(H_\alpha)$ is null] and $N_H(H_\alpha)B_H(H_\alpha)=0$.

For any $D'(H_\gamma,H_\xi)$ in $D'(H)$, $D'(H_\alpha,H_\beta)D'(H_\gamma,H_\xi)\subseteq D'(H_\alpha,H_{\beta\xi})$. But, $\alpha\not\leqslant\beta$. So, $\alpha\not\leqslant\beta\xi$. Then, $D'(H_\alpha,H_{\beta\xi})\subseteq N_H(H_\alpha)$. Thus, $N_H(H_\alpha)$ is a right ideal of $D'(H)$.

If $\alpha\leqslant\gamma$, then $\alpha\not\leqslant\gamma\beta$ since $\alpha\not\leqslant\beta$, thus $D'(H_\alpha,H_\gamma)D'(H_\alpha,H_\beta)\subseteq D'(H_\alpha,H_{\gamma\beta})\subseteq N_H(H_\alpha)$. It follows that $B_H(H_\alpha)N_H(H_\alpha)\subseteq N_H(H_\alpha)$ and $N_H(H_\alpha)$ is an ideal of $Q_H(H_\alpha)$.

It is easy to see that $B_H(H_\alpha)$ possesses the identity $1_{B_H(H_\alpha)}=\varepsilon_{H_\alpha}\infty' 1_H$ and $B_H(H_\alpha)B_H(H_\alpha)\subseteq B_H(H_\alpha)$. So, $B_H(H_\alpha)$ is an algebra and a subring of $Q_H(H_\alpha)$. Since $B_H(H_\alpha)$ is a subcoalgebra of $Q_H(H_\alpha)$, $\Delta((\phi_a\infty' x)(\phi_b\infty' y))=\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y)$ for any a, $b\in B_\alpha$, x, $y\in B_\beta$, where $\alpha\leqslant\beta$. As like in Lemma III.1, we also have $\varepsilon((\phi_a\infty' x)(\phi_b\infty' y))=\varepsilon(\phi_a\infty' x)\varepsilon(\phi_b\infty' y)$, $\varepsilon(1_{B_H(H_\alpha)})=1$. Therefore, we know that $B_H(H_\alpha)$ is a bialgebra.

Note that the comultiplication, the unit and the counit of $D'(H)$ are not correspondent with those of $D'(H_\alpha,H_\beta)$ and $B_H(H_\alpha)$. And, let $\alpha=\beta$ in $D'(H_\alpha,H_\beta)$, then $D'(H_\alpha,H_\alpha)=H_\alpha^{op^*}\infty' H_\alpha$. Since the multiplication is given by $(\phi_a\infty' x)(\phi_b\infty' y)=\phi_a\phi_b(1_{H_\alpha}?)\infty' xy$, which is the same as the quantum double $D'(H_\alpha)$ of H_α the condition commutative and H satisfies $\Sigma_{(a)}T(a''')a'\otimes a''=\Sigma_{(a)}T(a'')a'''\otimes a'$ for any $a\in H$. Since for $x\in B_{\beta_1}$, $y\in B_{\beta_2}$, $a\in B_{\alpha_1}$ and its duality ϕ_a in $H_{\alpha_1}^{op^*}$, $b\in B_{\alpha_2}$ and its duality ϕ_b in $H_{\alpha_2}^{op^*}$, we have

$$\begin{aligned}(\phi_a\infty x)(\phi_b\infty y)&=\sum_{(x)}\phi_a\phi_b(T^{-1}(x''')?x')\infty x''y=\sum_{(x)}\phi_a\phi_b(T^{-1}(x''')x'?)\infty x''y\\&=\sum_{(x)}\phi_a\phi_b(T^{-1}(x'')x'''?)\infty x'y=\sum_{(x)}\phi_a\phi_b(\varepsilon_{\beta_1}(x'')1_{H_{\beta_1}}?)\infty x'y\\&=\sum_{(x)}\phi_a\phi_b(1_{H_{\beta_1}}?)\infty\varepsilon_{\beta_1}(x'')x'y=\phi_a\phi_b(1_{H_{\beta_1}}?)\infty xy.\end{aligned}$$

Hence $D'(H_\alpha,H_\beta)$ is iust $D'(H_\alpha)$, as a sub-bialgebra of $D'(H)$.

Definition III.3 (Ref. 21):

(1) *A ring R is a* semilattice sum of subrings R_α, $\alpha\in\Omega$, *if* Ω *is a semilattice*, $R=\Sigma_{\alpha\in\Omega}R_\alpha$ *and* $R_\alpha R_\beta\subseteq R_{\alpha\beta}$.
(2) *A ring R is a* supplementary semilattice sum of subrings R_α, $\alpha\in\Omega$, *if R is a semilattice sum of subrings* R_a, $\alpha\in\Omega$, *and if for every* $\alpha\in\Omega$, $R_\alpha\cap\Sigma_{\beta\neq\alpha}R_\beta=\{0\}$; *i.e., if the sum is direct*.

By (3.3) and Definition III.3, every $Q_H(H_\alpha)$ is a supplementary semilattice sum of $D'(H_\alpha,H_\beta)$ for $\beta\in Y$.

From the discussion above, we get the following main result.

Theorem III.4 ***(structure theorem)***: *For a finite dimensional commutative semilattice graded weak Hopf algebra* $H=\oplus_{\alpha\in Y}H_\alpha$ *with weak antipode T, where Y is a semilattice and* H_α *a subweak Hopf algebra of H which is a Hopf algebra with antipode* $T|_{H_\alpha}$ *for each* $\alpha\in Y$, *suppose there exists a basis* B_α *of* H_α *for every* $\alpha\in Y$, *such that* $B=\cup_{\alpha\in Y}B_\alpha$ *a basis of H. Then the quantum G-double* $D'(H)$ *is a direct sum of right ideals* $Q_H(H_\alpha)$, $\alpha\in Y$, *where*

(1) *every* $Q_H(H_\alpha)$ *is a supplementary semilattice sum of subrings* $D'(H_\alpha,H_\beta)$ *for* $\beta\in Y$ *and is a coalgebra with comultiplication* Δ *satisfying* $\Delta((\phi_a\infty' x)(\phi_b\infty' y))=\Delta(\phi_a\infty' x)\Delta(\phi_b\infty' y)$ *for any* $x, y\in B$ *and* $a, b\in B_\alpha$;

(2) $Q_H(H_\alpha)=N_H(H_\alpha)\oplus B_H(H_\alpha)$ *where* $N_H(H_\alpha)=\Sigma_{\beta\in Y,\beta\not\geqslant\alpha}D'(H_\alpha,H_\beta)$ *is a null right ideal of* $D'(H)$ *and is a subcoalgebra and ideal of* $Q_H(H_\alpha)$, $B_H(H_\alpha)=\Sigma_{\beta\in Y,\beta\geqslant\alpha}D'(H_\alpha,H_\beta)$ *is a subbialgebra of* $Q_H(H_\alpha)$ *with* $N_H(H_\alpha)B_H(H_\alpha)=0$ *and* $B_H(H_\alpha)N_H(H_\alpha)\subseteq N_H(H_\alpha)$;

(3) $D'(H_\alpha,H_\beta)$ *are subcoalgebras of* $Q_H(H_\alpha)$. *If* $\alpha\not\leqslant\beta$, $D'(H_\alpha,H_\beta)$ *is a null subring. If* $\alpha\leqslant\beta$, $D'(H_\alpha,H_\beta)$ *is a bialgebra. If* $\alpha=\beta$, *then* $D'(H_\alpha,H_\alpha)=D'(H_\alpha)$, *which means that every quantum G-double* $D'(H_\alpha)$ *is a direct sum component of* $D'(H)$.

In fact, Theorem III.4 is similar to the main conclusion in Ref. 10 for noncommutative Clifford monoid algebras.

IV. SEMISIMPLICITY OF QUANTUM G-DOUBLE

In this section, as an application to Theorem III.4, we discuss the semisimplicity of quantum G-doubles.

In Ref. 22, it is shown that for a finite group G, the quantum double $D(G)$ is semisimple as an algebra if and only if the characteristic p of k does not divide the order $|G|$ of G. Here, we will consider the similar question for a semilattice grading weak Hopf algebra as above, i.e., under what conditions, the quantum G-double $D'(H)$ is semisimple as an algebra.

On the other hand, we know[3] that an algebra is semisimple if and only if it is regular and Noetherian. But, for a finite-dimensional weak Hopf algebra H, $D'(H)$ is finite dimensional, then it is Noetherian. Hence, in fact, $D'(H)$ is regular if and only if it is semisimple. So, in the sequel, we will only study the regularity of $D'(H)$.

Suppose $D'(H)$ is a semisimple algebra for H is commutative. A k-algebra is semisimple if it is a semisimple right module over itself, and any submodule of a semisimple module is semisimple. Then, $D'(H)$ is semisimple as a right $D'(H)$ module. From Theorem III.4, every $Q_H(H_\alpha)$ is a right ideal of $D'(H)$, then is a right $D'(H)$ submodule of the right $D'(H)$ module $D'(H)$. Hence $Q_H(H_\alpha)$ must be semisimple as a right $D'(H)$ module.

Suppose $N_H(H_\alpha)\neq 0$ for an arbitrary fixed $\alpha\in Y$. Then there exists $\beta\in Y$ such that $\alpha\not\leqslant\beta$. From the semisimplicity of $Q_H(H_\alpha)$, we know that $N_S(H_\alpha)$ is also semisimple as right $D'(H)$ module since it is a right submodule of $Q_H(H_\alpha)$. Then, $N_H(H_\alpha)$ can be decomposed as a direct sum of some simple right $D'(H)$ submodules.

Let $\theta=\Pi_{\lambda\in Y}\lambda$. Then $\theta\leqslant\lambda$ for all $\lambda\in Y$ and $\alpha\not\leqslant\theta$ [otherwise, $N_H(H_\alpha)=0$]. Thus, $D'(H_\alpha,H_\theta)\subseteq N_H(H_\alpha)$. It is easy to see that $D'(H_\alpha,H_\theta)$ is a right $D'(H)$ submodule of $N_H(H_\alpha)$.

We will make our discussion through two steps.

Lemma IV.1: $N_H(H_\alpha)=D'(H_\alpha,H_\theta)$.

Proof: Assume M is a simple right $D'(H)$ submodule of $N_H(H_\alpha)$. Let $0\neq z\in M$. Then $zD'(H)=M$. Write $z=\Sigma_{i=1}^m k_i(\phi_{a_i}\infty' x_i)$ where $0\neq k_i\in k$, $a_i\in B_\alpha$, $x_i\in B_{\gamma_i}(\alpha\not\leqslant\gamma_i)$ and $\phi_{a_i}\infty' x_i\neq\phi_{a_j}\infty' x_j$ for $i\neq j$, i.e., $x_i\neq x_j$ or $a_i\neq a_j$.

Set $b\in B_{\gamma_1\alpha}$ ($\notin H_\alpha$ since $\alpha\not\leqslant\gamma_1$) and $x\in B_\theta$. Consider

$$z(\phi_b\infty' x)=\sum_{i=1}^m k_i(\phi_{a_i}\phi_b(1H_{\gamma_i}?)\infty' x_i x). \tag{4.1}$$

Since $b\in B_{\gamma_1\alpha}$ we get $\phi_{a_1}\phi_b(1_{H_{\gamma_1}}?)\neq 0$ and $\phi_{a_1}\phi_b(1_{H_{\gamma_1}}?)\in H_\alpha^*$. In other terms for $i=1$, if $x_i=x_1$ then $a_i\neq a_1$ thus $\phi_{a_i}\phi_b(1_{H_{\gamma_i}}?)\infty' x_i x=\phi_{a_i}\phi_b(1_{H_{\gamma_1}}?)\neq 0$ since $\gamma_1=\gamma_i$; if $x_i\neq x_1$, then $\phi_{a_i}\phi_b(1_{H_{\gamma_i}}?)\infty' x_i x=0$ since $\alpha\not\leqslant\gamma_i$.

Hence on the right-hand side of (4.1), every term is 0 or $\phi_{a_i}\phi_b(1_{H_{\gamma_1}}?)\infty' x_i x$. Note the these nonzero terms are all in $Q_H(H_\alpha)$ and at least one of them [i.e., $\phi_{a_1}\phi_b(1_{H_{\gamma_1}}?)\infty' x_1 x$] is not equal to 0. It implies this sum is not equal to 0. Then $z(\phi_b\infty' x)\neq 0$.

And, $x_i x \in H_{\gamma_i \theta} = H_\theta$. So, every nonzero term $\phi_{a_1}\phi_b(1_{H_{\gamma_1}}?)\infty' x_i x \in D'(H_\alpha, H_\theta)$. Thus, $z(\phi_b \infty' x) \in D'(H_\alpha, H_\theta)$. It follows that $0 \neq z(\phi_b \infty' x) \in M \cap D'(H_\alpha, H_\theta)$. Then, we get a nonzero right $D'(H)$ submodule $M \cap D'(H_\alpha, H_\theta)$ of M. But M is simple, it means $M \cap D'(H_\alpha, H_\theta) = M$. Thus, $M \subseteq D'(H_\alpha, H_\theta)$. Since M is an arbitrary simple submodule in the semisimple module $N_H(H_\alpha)$. Therefore, it must get $N_H(H_\alpha) \subseteq D'(H_\alpha, H_\theta)$. Finally, we have $N_H(H_\alpha) = D'(H_\alpha, H_\theta)$.

Lemma IV.2: $Q_H(H_\alpha) = N_H(H_\alpha)$.

Proof: Assume W is a simple right $D'(H)$ submodule of $Q_H(H_\alpha)$. Let $0 \neq w \in W$. Then $wD'(H) = W$. Write $w = u + v$ where $u \in N_H(H_\alpha)$ and $v \in B_H(H_\alpha)$. $N_H(H_\alpha)$ is null, so $uN_H(H_\alpha) = 0$. By Theorem III.4, $vN_H(H_\alpha) \subseteq N_H(H_\alpha)$.

Write $v = \Sigma_{i=1}^m k_i(\phi_{\alpha_i} \infty' x_i)$ where $0 \neq k_i \in k$, $a_i \in B_\alpha$, $x_i \in B_{\beta_i}(\beta_i \geqslant \alpha)$, and $\phi_{a_i} \infty' x_i \neq \phi_{a_j} \infty' x_j$ for $i \neq j$, i.e., $x_i \neq x_j$ or $a_i \neq a_j$.

Set $b \in B_{\beta_1 \alpha}$ ($\in B_\alpha$ since $\alpha \leqslant \beta_1$) and $x \in B_\theta$. Consider $z(\phi_b \infty' x) = \Sigma_{i=1}^m k_i(\phi_{a_i}\phi_b(1_{H_{\gamma_i}}?)\infty' x_i x)$. By the similar method in (i), we can get $v(\phi_b \infty' x) \neq 0$.

And, $x_i x \in H_{\beta_i \theta} = H_\theta$. So, every nonzero term $\phi_{a_i}\phi_b(1_{H_{\beta_i}}?)\infty' x_i x \in D'(H_\alpha, H_\theta)$. Thus, $v(\phi_b \infty' x) \in D'(H_\alpha, H_\theta) = N_H(H_\alpha)$. It follows that $0 \neq v(\phi_b \infty' x) \in W \cap N_H(H_\alpha)$. Then, we get a nonzero right $D'(H)$ submodule $W \cap N_H(H_\alpha)$ of M. But W is simple, it means $W \cap N_H(H_\alpha) = W$. Thus, $W \subseteq N_H(H_\alpha)$ where W is an arbitrary simple submodule in the semisimple module $Q_H(H_\alpha)$.

From this, we get $Q_H(H_\alpha) \subseteq N_H(H_\alpha)$. Thus, $Q_H(H_\alpha) = N_H(H_\alpha)$.

From Lemma IV.2, we get $B_H(H_\alpha) = 0$. But it is impossible in fact, since $0 \neq D'(H_\alpha) \subseteq B_H(H_\alpha)$ by Theorem III.4. From this contradiction, we know that the supposition $N_H(H_\alpha) \neq 0$ is not true. Therefore $N_H(H_\alpha) = 0$. It means $\alpha \leqslant \beta$ for any $\beta \in Y$, i.e., $\alpha = \theta$. Note that α is arbitrary in Y. Hence, we know θ is the unique element of Y, i.e., $H = H_\theta$ is a Hopf algebra, whose quantum G-double is semisimple if and only if H_θ is semisimple by Ref. 15.

So, we get the following.

Theorem IV.3: *For a finite-dimensional commutative weak Hopf algebra H satisfying the same conditions in Theorem III.4, its quantum G-double $D'(H)$ over a field k is semisimple (respectively, regular) if and only if H is a semisimple Hopf algebra (respectively, regular).*

The similar result of this theorem for classical quantum groups holds in the case of $H = kS$ with S a noncommutative Clifford monoid (see Ref. 10).

V. EXAMPLES

The concept of semilattice graded weak Hopf algebra, introduced in this paper, is important for our research. Of course, Clifford monoid algebras are examples for this concept. However, we hope to give more nontrivial examples.

In Ref. 1, there is a general construction producing pointed Hopf algebras through Ore extension from a group algebra. This gives an idea to construct semilattice graded weak Hopf algebras through the Ore extension.

First, we need some preparation works.

Recall, that for a k-algebra A, an algebra endomorphism φ of A, and a φ derivation δ of A [i.e., a linear map $\delta : A \to A$ such that $\delta(ab) = \delta(a)b + \varphi(a)\delta(b)$ for all $a, b \in A$], the Ore extension $A[X, \varphi, \delta]$ is $A[X]$ as an Abelian group, with multiplication induced by $Xa = \delta(a) + \varphi(a)X$ for all $a \in A$.

The following is an obvious extension of the universal property for polynomial rings.

Lemma V.1 (Ref. 1): *Let $A[X, \varphi, \delta]$ be an Ore extension of A and $i : A \to A[X, \varphi, \delta]$ the inclusion morphism. Then for any algebra B, any algebra morphism $f : A \to B$ and every element $b \in B$ such that $bf(a) = f(\delta(a)) + f(\varphi(a))b$ for all $a \in A$, there exists a unique algebra morphism $\overline{f} : A[X, \varphi, \delta] \to B$ such that $\overline{f}(X) = b$ and $\overline{f}i = f$.*

Let S be a finite semigroup, an element a of a semigroup is called *regular* if there exists $x \in S$ such that $axa = a$. The semigroup S is called *regular* if all its elements are regular. We write $a \mathcal{J} b$ if there exist x, y, u, v in $S^1 = S \cup \{1\}$ for which $xay = b$ and $ubv = a$. Obviously, $\mathcal{J}$ is an equivalent relation on S. This equivalent relation is one of the important five kinds of equivalent relations on a semigroup S. A $\mathcal{J}$ class of some element $x \in S$ is the set $\{y \in S | x \mathcal{J} y\}$, i.e., the equivalent class

including x under the relation $\mathcal{J}$. A $\mathcal{J}$ class is called regular $\mathcal{J}$ class if all its elements are regular (see Ref. 17).

If $\Gamma: S \to \mathrm{Hom}(A,A)$ is a representation of S, by linear transformations of a finite-dimensional vector space A over the complex field $\mathbf{C}$, then the *character* χ_Γ of Γ is the function $S \to \mathbf{C}$ defined by

$$\chi_\Gamma(x) = \mathrm{Tr}\,\Gamma(x) \quad \textit{for each } x \in S,$$

where $\mathrm{Tr}\,\Gamma(x)$ denotes the sum of the diagonal entries in any matrix expression of $\Gamma(x)$. Let $a \in S$ and let $\bar{a}=ae$, where e is the unique idempotent in the cyclic subsemigroup $\langle a\rangle$ generated by a, we shall say that two elements $a, b \in S$, are *conjugate* if and only if $\bar{b}=x'\bar{a}x$, $\bar{a}=x\bar{b}x'$ for some regular element x with inverse x', i.e., $xx'x=x$, $x'xx'=x'$. Then a function $S \to \mathbf{C}$ is called a *class function* if it is constant on each conjugacy class of S, and all the class functions form an algebra over $\mathbf{C}$ under pointwise addition and multiplication, we denote this algebra by *cfS*. The *character ring* of S, which is denoted by *chS*, is a subring of the class function algebra which is spanned by the irreducible characters of S (see Ref. 14).

Lemma V.2 (Ref. 14): Let S be a finite semigroup, let $J_1,\ldots,J_r$, be the regular $\mathcal{J}$ classes of S, and let $H_1,\ldots,H_r$ be the maximal subgroups of $J_1,\ldots,J_r$, respectively. Then, $chS \cong chH_1 \times \cdots \times chH_r$.

For a Clifford semigroup S, we can see that J_i, $i=1,2,\ldots,r$ are the maximal subgroups G_α, $\alpha \in Y$ of S. Hence, $chS \cong \Pi_{\alpha\in Y} chG_\alpha$.

Second, we will construct a pointed weak Hopf algebra by starting with the coradical, forming Ore extensions.

Let $A=kS=\oplus_{\alpha\in Y} kG_\alpha$ be the algebra of a finite commutative Clifford monoid $S=[Y;G_\alpha,\varphi_{\alpha,\beta}]$ (the method for constructing some concrete Clifford monoids can be seen in Ref. 13.) Let G_α^* be the character group of G_α for each $\alpha \in Y$, then the character semigroup of S is $\Pi_{\alpha\in Y} G_\alpha^*$. Since S is a monoid, we can assume that the maximal subgroup which contains 1 is G_i, where i is the identity element in Y.

Let $c \in G_i$ and $c^* \in G_i^*$. According to Lemma V.2, for each $\alpha \in Y$, chG_α is embeded into *chS* such that for any $c^* \in chG_i$ is mapped to $\chi=(c^*,1,\ldots,1) \in chS \cong \Pi_{\alpha\in Y} chG_\alpha$.

Let φ be an algebra automorphism of A defined by $\varphi(x)=\langle \chi,x\rangle x$ for all $x \in S$, then it is clear that if $x \in G_i$, then $\langle \chi,x\rangle=\langle c^*,x\rangle$; if $x \in G_\alpha$ with $\alpha \neq i$, then $\langle \chi,x\rangle=\langle 1,x\rangle=1$. Consider the Ore extension $A_1=A[X,\varphi,\delta]=A[X,\varphi,0]$, where $\delta=0$. Apply Lemma V.I first with $B=A_1\otimes A_1$, $f=(i\otimes i)\cdot\Delta_A$, $b=c\otimes X+X\otimes 1$ and then with $B=k$, $f=\epsilon_A$, $b=0$, to define algebra homomorphism $\Delta: A_1 \to A_1\otimes A_1$ and $\epsilon: A_1 \to k$ by

$$\Delta(X) = c\otimes X + X\otimes 1 \quad \textit{and } \epsilon(X)=0.$$

It is easily checked that Δ and ϵ defined a bialgebra structure on A_1. The weak antipode T of A extends to a weak antipode on A_1 by $T(X)=-c^{-1}X$ and $T(Xe_\alpha)=-(ce_\alpha)^{-1}X=-c^{-1}e_\alpha X$.

If we let $A_1^\alpha=kG_\alpha[Xe_\alpha,\varphi^\alpha,\delta^\alpha]=kG_\alpha[Xe_\alpha,\varphi^\alpha,0]$, where $\delta^\alpha=0$ and $\varphi^\alpha(g_\alpha)=\langle \chi|_{chG_\alpha}, g_\alpha\rangle g_\alpha$. Then A_1^α is a subweak Hopf algebra of A_1 which is a Hopf algebra for each $\alpha \in Y$ under the defined Δ, ϵ and antipode T. We have

$$Xe_\alpha g_\alpha = Xg_\alpha = \langle \chi, g_\alpha\rangle g_\alpha = g_\alpha X,$$

$$\Delta(Xe_\alpha) = (c\otimes X + X\otimes 1)(e_\alpha\otimes e_\alpha) = ce_\alpha\otimes Xe_\alpha + Xe_\alpha\otimes 1e_\alpha = ce_\alpha\otimes Xe_\alpha + Xe_\alpha\otimes e_\alpha$$

[i.e., Xe_α is (e_α, ce_α)-primitive], and

$$\epsilon(Xe_\alpha) = \epsilon(X)\epsilon(e_\alpha) = 0.$$

At the same time, $m(\mathrm{id}*T)\Delta(Xe_\alpha)=ce_\alpha S(Xe_\alpha)+Xe_\alpha S(e_\alpha)=ce_\alpha(-c^{-1})e_\alpha X+Xe_\alpha e_\alpha=-1e_\alpha X+Xe_\alpha=-Xe_\alpha+Xe_\alpha=0=\epsilon(Xe_\alpha)$.

Thus, we can get the following proposition.

Proposition V.3: The Ore extension $A_1=A[X,\varphi,0]=\oplus_{\alpha\in Y}A_1^\alpha$ *and* $A_1^\alpha=kG_\alpha[Xe_\alpha,\varphi^\alpha,0]$ *as defined above is a subweak Hopf algebra of* A_1 *which is a Hopf algebra for each* $\alpha\in Y$. *Define a Hopf algebra homomorphism* $\phi_{\alpha,\beta}$ *from* A_1^α *to* A_1^β *if* $\alpha\beta=\beta$ *satisfying* $\phi_{\alpha,\beta}(a_\alpha)=\varphi_{\alpha,\beta}(a_\alpha)$ *for any* $a_\alpha\in G_\alpha$ *and* $\phi_{\alpha,\beta}(Xe_\alpha)=Xe_\beta$. *Then* A_1 *is a semilattice graded weak Hopf algebra.*

Proof: The above construction shows that A_1 has a basis $\{gX^n|g\in S,n\in N\}$ and A_1^α has a basis $B_\alpha=\{g_\alpha(Xe_\alpha)^n|g_\alpha\in G_\alpha,n\in N\}$ for each $\alpha\in Y$.

We have known that $Xe_\alpha=e_\alpha X$ for any $\alpha\in Y$ and $Xg_\alpha=g_\alpha X$ for any $g_\alpha\in G_\alpha$ with $\alpha\neq i$, therefore for any $g_\alpha(Xe_\alpha)^{n_1}\in B_\alpha$, $g_\beta(Xe_\beta)^{n_2}\in B_\beta$, it follows that

$$\begin{aligned}
g_\alpha(Xe_\alpha)^{n_1}g_\beta(Xe_\beta)^{n_2} &= g_\alpha X^{n_1}e_\alpha g_\beta X^{n_2}e_\beta\\
&= g_\alpha X^{n_1}\varphi_{\alpha,\alpha\beta}(e_\alpha)\varphi_{\beta,\alpha\beta}(g_\beta)X^{n_2}e_\beta\\
&= g_\alpha X^{n_1}e_{\alpha\beta}\varphi_{\beta,\alpha\beta}(g_\beta)X^{n_2}e_\beta = g_\alpha X^{n_1}\varphi_{\beta,\alpha\beta}(g_\beta)e_\beta X^{n_2}\\
&= \langle\chi,\varphi_{\beta,\alpha\beta}(g_\beta)\rangle^{n_1}g_\alpha\varphi_{\beta,\alpha\beta}(g_\beta)e_\beta X^{n_1}X^{n_2}\\
&= \langle\chi,\varphi_{\beta,\alpha\beta}(g_\beta)\rangle^{n_1}\varphi_{\alpha,\alpha\beta}(g_\alpha)\varphi_{\beta,\alpha\beta}(g_\beta)\varphi_{\beta,\alpha\beta}(e_\beta)X^{n_1+n_2}\\
&= \langle\chi,\varphi_{\beta,\alpha\beta}(g_\beta)\rangle^{n_1}(g_\alpha g_\beta)(e_{\alpha\beta}X^{n_1+n_2}\\
&= \langle\chi,\varphi_{\beta,\alpha\beta}(g_\beta)\rangle^{n_1}(g_\alpha g_\beta)(Xe_{\alpha\beta})^{n_1+n_2}\in A_1^{\alpha\beta}.
\end{aligned}$$

It means $A_1^\alpha A_1^\beta\subseteq A_1^{\alpha\beta}$ for any α, $\beta\in Y$. And,

$$\begin{aligned}
\phi_{\alpha,\alpha\beta}(g_\alpha(Xe_\alpha)^{n_1})\phi_{\beta,\alpha\beta}(g_\beta(Xe_\beta)^{n_2}) &= \varphi_{\alpha,\alpha\beta}(g_\alpha)(\phi_{\alpha,\alpha\beta}(Xe_\alpha)^{n_1})\varphi_{\beta,\alpha\beta}(g_\beta)(\phi_{\beta,\alpha\beta}(Xe_\beta)^{n_2})\\
&= \varphi_{\alpha,\alpha\beta}(g_\alpha)(\phi_{\alpha,\alpha\beta}(Xe_\alpha))^{n_1}\varphi_{\beta,\alpha\beta}(g_\beta)(\phi_{\beta,\alpha\beta}(Xe_\beta))^{n_2}\\
&= \varphi_{\alpha,\alpha\beta}(g_\alpha)(Xe_{\alpha\beta})^{n_1}\varphi_{\beta,\alpha\beta}(g_\beta)(Xe_{\alpha\beta})^{n_2}\\
&= \varphi_{\alpha,\alpha\beta}(g_\alpha)(X^{n_1}e_{\alpha\beta})\varphi_{\beta,\alpha\beta}(g_\beta)(X^{n_2}e_{\alpha\beta})\\
&= \langle\chi,\varphi_{\beta,\alpha\beta}(g_\beta)\rangle^{n_1}\varphi_{\alpha,\alpha\beta}(g_\alpha)\varphi_{\beta,\alpha\beta}(g_\beta)X^{n_1}X^{n_2}e_{\alpha\beta}\\
&= \langle\chi,\varphi_{\beta,\alpha\beta}(g_\beta)\rangle^{n_1}(g_\alpha g_\beta)(Xe_{\alpha\beta})^{n_1+n_2}.
\end{aligned}$$

So, $g_\alpha(Xe_\alpha)^{n_1}g_\beta(Xe_\beta)^{n_2}=(g_\alpha(Xe_\alpha)^{n_1})\phi_{\alpha,\alpha\beta}(g_\beta(Xe_\beta)^{n_2})\phi_{\beta,\alpha\beta}$. Hence, A_1 is a semilattice graded weak Hopf algebra. (See also Refs. 4, 5, 18, and 19.)

If we choose $c^*\neq 1\in G_i^*$, $Xg_\alpha=\langle\chi,g_\alpha\rangle g_\alpha X\neq g_\alpha X$ for $\alpha=i$, hence A_1 is noncommutative and noncocommutative. Otherwise, let $c^*=1\in G_i^*$, $\chi=(1,\ldots,1)$, $Xg_\alpha=\langle\chi,g_\alpha\rangle g_\alpha X=g_\alpha X$ for any $\alpha\in Y$, hence A_1 is commutative. In this case, by Proposition V.3, one can see that A_1 is a nontrivial example satisfying the condition in Theorem III.4.

A simple parametrization for G_2

Sergio L. Cacciatori[a)]

(Received 25 May 2005; accepted 5 July 2005; published online 19 August 2005)

We give a simple parametrization of the G_2 group, which is consistent with the structure of G_2 as a SU(3) fibration. We also explicitly compute the (bi)invariant measure, which turns out to have a simple expression. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2009627]

I. INTRODUCTION

Group theory plays an important role in physics. When a group describes a symmetry of the system, invariant quantities are often obtained by integrating over the group. For example, to have an unbroken symmetry in a path-integral formulation of gauge field theory, the integration measure must be invariant under the group action.

Every semisimple group has a unique invariant measure (up to normalization constants), obtained by pulling back the Killing form on its Lie algebra via the group left action. However, it is generally difficult to find an explicit parametrization of the group elements by which the invariant measure acquires a reasonably simple expression while also allowing for a full specification of the range of parameters. This is indeed what is needed in performing practical computations.

In Ref. 1, a solution of this problem was found for the group G_2. The group parametrization given there, emphasizes the structure of G_2 as a fibration over the base space $\mathcal{H}$ of quaternionic linear subalgebras of octonions and fiber SO(4). Here we give another parametrization of the same group based on the well-known fact that G_2 can be seen as an SU(3) fibration over the six sphere S^6. (See, for example, Ref. 2.) The resulting measure turns out to have a very simple expression, with all the parameters varying in a 14-dimensional hypercube.

The motivation for G_2 comes from nonperturbative gauge theory used to test confinement in lattice chromodynamics. It is believed that confinement should be due to excitation modes belonging to the center of the gauge group so that a group with no center, preventing the existence of these modes, should not produce confinement. So if one observes no confinement in a toy model gauge theory with group G_2 which is center free, this belief is proved to be consistent. Having a global explicit parametrization of the group renders nonperturbative computations easier to work out and implement.

II. THE REPRESENTATION ALGEBRA AND THE GROUP ANSATZ

For the algebra, we choose the fundamental representation (**7**) as done in Ref. 1. All the notations employed here will agree with those used in that reference. Since from that paper, we will only use the commutators matrix $B_{IJ}:=[C_I,C_J]$ we have transcribed it and set it in Appendix C. Now note that the $\{C_i\}_{i=1}^8$ generates an su(3) algebra. Thus we want to use this fact to produce a parametrization for the G_2 elements capable of highlighting the SU(3) subgroup.

With this purpose, let us note that the C_9 commutator with su(3) suffices to reproduce all the remaining generators of the g_2 algebra. Then we can hope to find a parametrization of the group resembling the Euler parametrization for SU(n). Let us write the generic element of G_2 as

a)Electronic mail: sergio.cacciatori@mi.infn.it

$$g = \mathrm{SU}(3)[\alpha_1,\ldots,\alpha_8]e^{\beta C_9}\,\mathrm{SU}(3)[\gamma_1,\ldots,\gamma_8], \tag{2.1}$$

where $\mathrm{SU}(3)[\alpha_1,\ldots,\alpha_8]$ is the general Euler parametrization of SU(3) shown in Appendix A. Note that here we have three redundant parameters, the dimension of G_2 being 14. We can easily cancel them out as follows. In (2.1) the left-hand side SU(3) term has the expansion

$$\mathrm{SU}(3)[\alpha_1,\ldots,\alpha_8] = h[\alpha_1,\ldots,\alpha_5]e^{\alpha_6 C_3}e^{\alpha_7 C_2}e^{\alpha_8 C_3}. \tag{2.2}$$

But C_1, C_2, C_3 commute with C_9 so that $\alpha_1, \alpha_2, \alpha_3$ can be reabsorbed in the right-hand side SU(3) in (2.1). Thus, it seems clear we should make the ansatz

$$g[\alpha_1,\ldots,\alpha_6;\gamma_1,\ldots,\gamma_8] = \Sigma[\alpha_1,\ldots,\alpha_6]\mathrm{SU}(3)[\gamma_1,\ldots,\gamma_8] \tag{2.3}$$

with

$$\Sigma[\alpha_1,\ldots,\alpha_6] = e^{\alpha_1 C_3}e^{\alpha_2 C_2}e^{\alpha_3 C_3}e^{(\sqrt{3}/2)\alpha_4 C_8}e^{\alpha_5 C_5}e^{(\sqrt{3}/2)\alpha_6 C_9}. \tag{2.4}$$

To prove that this ansatz is the right one, we show that it allows to fix the range of parameters so as to cover (up to a a subset of vanishing measure) all of G_2 only once.

A. Fibration and computation of the metric

We have said that the quotient of G_2 by its SU(3) subgroup is a sphere S^6. We will use this information to compute the range of parameters. For brevity we will call $S := \mathrm{SU}(3)[\gamma_1,\ldots,\gamma_8]$. The group metric can be deduced from the left-hand side invariant currents

$$Jg = g^{-1}\,\mathrm{d}g = \sum_{I=1}^{14} Jg^I C_I \tag{2.5}$$

via

$$\mathrm{d}s^2_{G_2} = -\tfrac{1}{4}\mathrm{Trace}\{Jg \otimes Jg\}. \tag{2.6}$$

[The factor $-\frac{1}{4}$ is due to the normalization $\mathrm{Trace}\{C_I C_J\} = -4\delta_{IJ}$. Choosing a metric $(C_I|C_J) = \delta_{IJ}$ on the algebra is equivalent to fixing normalizations such that long and short roots of g_2 have length 2 and $2/\sqrt{3}$, respectively.[1]]

If we now write

$$J_\Sigma = \Sigma^{-1}\,\mathrm{d}\Sigma = \sum_{I=1}^{14} J^I_\Sigma C_I, \tag{2.7}$$

$$J_S = \mathrm{d}S\,S = \sum_{I=1}^{8} J^I_S C_I, \tag{2.8}$$

it is straightforward to show that

$$\mathrm{d}s^2_{G_2} = \sum_{I=1}^{8}(J^I_S + J^I_\Sigma)^2 + \sum_{I=9}^{14}(J^I_\Sigma)^2. \tag{2.9}$$

Now Σ parametrizes the quotient space between G_2 and the SU(3) orbits generated by S. Fixing the base point Σ we recover the SU(3) invariant metric as

$$ds^2_{SU(3)} = \sum_{I=1}^{8} (J^I_S)^2. \tag{2.10}$$

To find the induced metric on the base one should compute the current $\Sigma^{-1}\,d\Sigma$ and project out the components that are tangent to the su(3) directions. Doing so we find

$$ds^2_{BASE} = \sum_{I=9}^{14} (J^I_\Sigma)^2. \tag{2.11}$$

This term should represent the metric of a six sphere. We now show that this is exactly the case. Using the results obtained in Appendix B for the currents, one finds

$$\frac{4}{3} ds^2_{BASE} = d\alpha_6^2 + \sin^2\alpha_6 \left\{ d\alpha_5^2 + \cos^2\alpha_5\, d\alpha_4^2 + \sin^2\alpha_5 \left[s_1^2 + s_2^2 + \left(s_3 + \tfrac{1}{2} d\alpha_4 \right)^2 \right] \right\}, \tag{2.12}$$

where

$$\begin{aligned} s_1 &= -\sin(2\alpha_2)\cos(2\alpha_3) d\alpha_1 + \sin(2\alpha_3) d\alpha_2, \\ s_2 &= \sin(2\alpha_2)\sin(2\alpha_3) d\alpha_1 + \cos(2\alpha_3) d\alpha_2, \\ s_3 &= \cos(2\alpha_2) d\alpha_1 + d\alpha_3. \end{aligned} \tag{2.13}$$

We can now recognize the metric of a six sphere S^6 with coordinates $(\alpha_6, \vec{X})$, where α_6 is the azimuthal coordinate, $\alpha_6 \in [0, \pi]$, and $\vec{X}$ covers a five sphere. We can look at this sphere as immersed in $\mathbb{C}^3$ via

$$\vec{X} = (z_1, z_2, z_3) = (\cos\alpha_5 e^{i\alpha_4}, \sin\alpha_5 \cos\alpha_2 e^{i[\alpha_1+\alpha_3+(\alpha_4/2)]}, \sin\alpha_5 \sin\alpha_2 e^{i[\alpha_1-\alpha_3-(\alpha_4/2)]}),$$

$$\alpha_1 \in [0,\pi], \quad \alpha_2 \in \left[0, \frac{\pi}{2}\right], \quad \alpha_3 \in [0, 2\pi], \quad \alpha_4 \in [0, 2\pi], \quad \alpha_5 \in \left[0, \frac{\pi}{2}\right].$$

Computing the metric $ds^2_{S^5} = |dz_1|^2 + |dz_2|^2 + |dz_3|^2$ in these coordinates we find

$$\tfrac{4}{3} ds^2_{BASE} = d\alpha_6^2 + \sin^2\alpha_6 \{ ds^2_{S^5} \}. \tag{2.14}$$

which completes our identification.

III. CONCLUSIONS

We have shown that the elements of the group G_2 can be parametrized as

$$g = e^{\alpha_1 C_3} e^{\alpha_2 C_2} e^{\alpha_3 C_3} e^{(\sqrt{3}/2)\alpha_4 C_8} e^{\alpha_5 C_5} e^{(\sqrt{3}/2)\alpha_6 C_9} \mathrm{SU}(3)[\gamma_1, \ldots, \gamma_8] \tag{3.1}$$

with

$$\alpha_1 \in [0,\pi], \quad \alpha_2 \in \left[0, \frac{\pi}{2}\right], \quad \alpha_3 \in [0, 2\pi], \quad \alpha_4 \in [0, 2\pi], \quad \alpha_5 \in \left[0, \frac{\pi}{2}\right], \quad \alpha_6 \in [0, \pi], \tag{3.2}$$

$$\gamma_1 \in [0, 2\pi], \quad \gamma_2 \in \left[0, \frac{\pi}{2}\right], \quad \gamma_3 \in [0, \pi], \quad \gamma_4 \in \left[0, \frac{\pi}{2}\right], \quad \gamma_5 \in [0, 2\pi], \quad \gamma_6 \in [0, \pi],$$

$$\gamma_7 \in \left[0, \frac{\pi}{2}\right], \quad \gamma_8 \in [0, \pi].$$

From (2.9) one could easily find the (bi)invariant metric. The corresponding invariant measure is

$$d\mu_{G_2} = \tfrac{27}{32}\sin^5\alpha_6 \cos\alpha_5 \sin^3\alpha_5 \sin(2\alpha_2) d\mu_{SU(3)} d\alpha_6\, d\alpha_5\, d\alpha_4\, d\alpha_3\, d\alpha_2\, d\alpha_1. \tag{3.3}$$

$d\mu_{SU(3)}$ being the invariant measure over SU(3) as given in Appendix A.

This is a quite simple parametrization for G_2, which evidences the SU(3) subgroup, as a fiber over S^6. It should be useful for implementing analytical or numerical computations in lattice gauge theory and in random matrix models.

The approach employed here to determine the range of parameters, is mainly a geometrical one. The same results could also be obtained by means of topological arguments of the type developed in Ref. 1.

APPENDIX A: EULER PARAMETRIZATION FOR SU(3)

The Euler parametrization for SU(3) can be easily obtained as (again the ranges could be found using the topological method, however we simply rearranged the results shown in Appendix B of Ref. 3 to our case)

$$SU(3)[\gamma_1,\ldots,\gamma_8] = e^{\gamma_1 C_3} e^{\gamma_2 C_2} e^{\gamma_3 C_3} e^{\gamma_4 C_5} e^{\sqrt{3}\gamma_5 C_8} e^{\gamma_6 C_3} e^{\gamma_7 C_2} e^{\gamma_8 C_3}, \tag{A1}$$

with range

$$\gamma_1 \in [0,2\pi], \quad \gamma_2 \in \left[0,\frac{\pi}{2}\right], \quad \gamma_3 \in [0,\pi], \quad \gamma_4 \in \left[0,\frac{\pi}{2}\right], \tag{A2}$$

$$\gamma_5 \in [0,2\pi], \quad \gamma_6 \in [0,\pi], \quad \gamma_7 \in \left[0,\frac{\pi}{2}\right], \quad \gamma_8 \in [0,\pi].$$

In this way $\gamma_1, \gamma_2, \gamma_3$ cover an SU(2) subgroup, the γ_5 covers an U (1) and $\gamma_6, \gamma_7, \gamma_8$ cover SO (3). The resulting invariant measure is

$$d\mu_{SU(3)} = \sqrt{3}\sin(2\gamma_2)\sin^3\gamma_4 \cos\gamma_4 \sin(2\gamma_7) \prod_{i=1}^{8} d\gamma_i. \tag{A3}$$

APPENDIX B: J_h CURRENTS

Here we give the currents J_h used to generate the metric on the base manifold. The required relations follow from the commutators matrix given in Appendix C and are given by

$$e^{-xC_3} C_2 e^{xC_3} = \cos(2x) C_2 + \sin(2x) C_1,$$

$$e^{-xC_3} C_1 e^{xC_3} = \cos(2x) C_1 - \sin(2x) C_2,$$

$$e^{-xC_2} C_3 e^{xC_2} = \cos(2x) C_3 + \sin(2x) C_1,$$

$$e^{-xC_5} C_1 e^{xC_5} = \cos x C_1 + \sin x C_6,$$

$$e^{-xC_5}C_2e^{xC_5} = \cos xC_2 + \sin xC_7,$$

$$e^{-xC_5}C_3e^{xC_5} = \frac{1}{4}(3+\cos(2x))C_3 - \frac{1}{2}\sin(2x)C_4 - \frac{\sqrt{3}}{2}\sin^2 xC_8,$$

$$e^{-xC_5}C_8e^{xC_5} = \frac{1}{4}(1+3\cos(2x))C_3 - \frac{\sqrt{3}}{2}\sin(2x)C_4 - \frac{\sqrt{3}}{2}\sin^2 xC_3,$$

$$e^{-\sqrt{3}xC_9}C_4e^{\sqrt{3}xC_9} = \cos^3 xC_4 - \sin^3 xC_7 + \sqrt{3}\cos x\sin^2 xC_{11} - \sqrt{3}\sin x\cos^2 xC_{14},$$

$$e^{-\sqrt{3}xC_9}C_5e^{\sqrt{3}xC_9} = \cos^3 xC_5 + \sin^3 xC_6 + \sqrt{3}\cos x\sin^2 xC_{12} + \sqrt{3}\sin x\cos^2 xC_{13},$$

$$e^{-\sqrt{3}xC_9}C_6e^{\sqrt{3}xC_9} = \cos^3 xC_6 - \sin^3 xC_5 + \sqrt{3}\cos x\sin^2 xC_{13} - \sqrt{3}\sin x\cos^2 xC_{12},$$

$$e^{-\sqrt{3}xC_9}C_7e^{\sqrt{3}xC_9} = \cos^3 xC_7 + \sin^3 xC_4 + \sqrt{3}\cos x\sin^2 xC_{14} + \sqrt{3}\sin x\cos^2 xC_{11},$$

$$e^{-\sqrt{3}xC_9}C_8e^{\sqrt{3}xC_9} = \cos(2x)C_8 + \sin(2x)C_{10}, \tag{B1}$$

along with the fact that C_9 commutes with C_1, C_2, and C_3.

If we set

$$s_1 = -\sin(2\alpha_2)\cos(2\alpha_3)\mathrm{d}\alpha_1 + \sin(2\alpha_3)\mathrm{d}\alpha_2,$$

$$s_2 = \sin(2\alpha_2)\sin(2\alpha_3)\mathrm{d}\alpha_1 + \cos(2\alpha_3)\mathrm{d}\alpha_2,$$

$$s_3 = \cos(2\alpha_2)\mathrm{d}\alpha_1 + \mathrm{d}\alpha_3, \tag{B2}$$

the resulting currents are shown to be

$$J_h^1 = \cos\alpha_5 s_1,$$

$$J_h^2 = \cos\alpha_5 s_2,$$

$$J_h^3 = \tfrac{1}{4}(3+\cos(2\alpha_5))s_3 - \tfrac{3}{4}\sin^2\alpha_5\,\mathrm{d}\alpha_4,$$

$$J_h^4 = -\frac{1}{2}\sin(2\alpha_5)\cos^3\frac{\alpha_6}{2}\left[s_3 + \frac{3}{2}d\alpha_4\right] + \sin a_5\sin^3\frac{\alpha_6}{2}s_2,$$

$$J_h^5 = -\sin\alpha_5\sin^3\frac{\alpha_6}{2}s_1 + \cos^3\frac{\alpha_6}{2}\mathrm{d}\alpha_5,$$

$$J_h^6 = \cos\alpha_5\sin^3\frac{\alpha_6}{2}s_1 + \sin^3\frac{\alpha_6}{2}\mathrm{d}\alpha_5,$$

$$J_h^7 = \frac{1}{2}\sin(2\alpha_5)\sin^3\frac{\alpha_6}{2}\left[s_3 + \frac{3}{2}\mathrm{d}\alpha_4\right] + \sin\alpha_5\cos^3\frac{\alpha_6}{2}s_2,$$

$$J_h^8 = \cos\alpha_6\left[\frac{1}{4}(1+3\cos(2\alpha_5)) - \frac{\sqrt{3}}{2}\sin^2\alpha_5 s_3\right],$$

$$J_h^9 = \frac{\sqrt{3}}{2} \mathrm{d}\alpha_6,$$

$$J_h^{10} = \frac{\sqrt{3}}{2} \sin\alpha_6 \left[\frac{1}{4}(1 + 3\cos(2\alpha_5))\mathrm{d}\alpha_4 - \sin^2\alpha_5 s_3 \right],$$

$$J_h^{11} = -\frac{\sqrt{3}}{2} \sin(2\alpha_5)\cos\frac{\alpha_6}{2}\sin^2\frac{\alpha_6}{2}\left[s_3 + \frac{3}{2}\mathrm{d}\alpha_4 \right] + \sqrt{3}\sin\alpha_5 \sin\frac{\alpha_6}{2}\cos^2\frac{\alpha_6}{2} s_2,$$

$$J_h^{12} = -\sqrt{3}\sin\alpha_5 \sin\frac{\alpha_6}{2}\cos^2\frac{\alpha_6}{2} s_1 + \sqrt{3}\cos\frac{\alpha_6}{2}\sin^2\frac{\alpha_6}{2}\mathrm{d}\alpha_5,$$

$$J_h^{13} = \sqrt{3}\sin\alpha_5 \cos\frac{\alpha_6}{2}\sin^2\frac{\alpha_6}{2} s_1 + \sqrt{3}\sin\frac{\alpha_6}{2}\cos^2\frac{\alpha_6}{2}\mathrm{d}\alpha_5,$$

$$J_h^{14} = \frac{\sqrt{3}}{2}\sin(2\alpha_5)\sin\frac{\alpha_6}{2}\cos^2\frac{\alpha_6}{2}\left[s_3 + \frac{3}{2} d\alpha_4 \right] + \sqrt{3}\sin\alpha_5 \cos\frac{\alpha_6}{2}\sin^2\frac{\alpha_6}{2} s_2. \tag{B3}$$

These currents, together with the SU(3) currents (as given in Ref. 3 can be used in (2.9) to compute the full (bi-)invariant metric of G_2.

Discrete vakonomic mechanics

Roberto Benito[a] and David Martín de Diego[b]
Instituto de Matemáticas y Física Fundamental, CSIC, Serrano 123, 28006 Madrid, Spain

(Received 15 March 2005; accepted 1 July 2005; published online 22 August 2005)

Discretizations of vakonomic mechanics are developed by using the methodology of variational integrators. The resulting algorithms are symplectic (in some sense that we will explain) and preserve the momentum map associated with a Lie group of symmetries. A specific example illustrating the theory is tested numerically. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2008214]

I. INTRODUCTION

This paper is devoted to the so-called vakonomic mechanics, a terminology coined by Arnold and Kozlov (see Ref. 1). Vakonomic mechanics are obtained from a Lagrangian function subject to nonholonomic constraints, but instead of using Lagrange-d'Alembert principle as in nonholonomic mechanical systems, one uses a variational principle, that is, one looks for extremals of the integral functional determined by the Lagrangian among all the curves satisfying the constraints (see Refs. 3, 7, and 19). As we will briefly discuss, vakonomic mechanics describe interesting and applied problems such as optimal control theory, mathematical economics (for instance, economic growth theory), sub-Riemannian geometry, motion of microorganisms, etc.

In this paper, we will develop variational integrators for this kind of problem. Variational integrators are symplectic integrators,[26] preserving momentum and they are known to have near-energy preservation behavior. These integrators have their roots in the optimal control literature in the 1960s and 1970s (see Ref. 4) and recently, they were studied by many authors from a more geometrical point of view (Refs. 13, 20, 8, 9, and 29, and references therein).

Throughtout the paper, Einstein convention will be used without explicit mention.

A. Vakonomic mechanics

Vakonomic mechanics were introduced by V. V. Kozlov in Ref. 16, see also Ref. 1. Such systems are defined by a regular Lagrangian $\mathbb{L}:TQ\to\mathbb{R}$ on the tangent bundle TQ of the configuration space Q subject to nonholonomic constraints $\phi^\alpha(q,\dot{q})=0$, $1\leqslant\alpha\leqslant m$, determining a $2n-m$ dimensional submanifold M of TQ. We will take fibered coordinates $(q^A,\dot{q}^A)$ in TQ.

These systems are usually described by the extended Lagrangian $\mathcal{L}=\mathbb{L}+\lambda_\alpha\phi^\alpha$, which includes the Lagrange multipliers λ_α as new extra variables. The equations of motion for the vakonomic problem are the Euler-Lagrange equations for $\mathcal{L}$; that is

$$\begin{cases}\dfrac{\mathrm{d}}{\mathrm{d}t}\left(\dfrac{\partial\mathbb{L}}{\partial\dot{q}}\right)-\dfrac{\partial\mathbb{L}}{\partial q}=-\dot{\lambda}_\alpha\dfrac{\partial\phi^\alpha}{\partial\dot{q}}-\lambda_\alpha\left[\dfrac{\mathrm{d}}{\mathrm{d}t}\left(\dfrac{\partial\phi^\alpha}{\partial\dot{q}}\right)-\dfrac{\partial\phi^\alpha}{\partial q}\right],\\ \phi^\alpha(q,\dot{q})=0,1\leqslant\alpha\leqslant m,\end{cases}\tag{1}$$

Observe that the Lagrangian $\mathcal{L}:T(Q\times\mathbb{R}^m)\to\mathbb{R}$ is degenerate, since the extra velocities $\dot{\lambda}^\alpha$ do not appear. Therefore, it is necessary to apply the Dirac-Bergmann-Gotay-Nester constraint procedure developed in Ref. 12 in order to find, if it exists, a final constraint submanifold where the

[a]Electronic mail: rbenito@imaff.cfmac.csic.es
[b]Electronic mail: d.martin@imaff.cfmac.csic.es

dynamics of the vakonomic problem are well defined (see Refs. 21 and 5). Thus, Eq. (1) has solution on the final constraint submanifold (see Ref. 21 for more details).

Moreover, solutions to Eq. (1) are exactly the same as the solutions obtained extremizing the functional $\mathcal{J}=\int_0^1 \mathbb{L}(\dot{c}(t))\mathrm{d}t$, among the curves satisfying the constraints. Precisely, for this type of system it was coined the name *vakonomic* (mechanics of variational axiomatic kind) in Ref. 1.

An interesting remark is that Eq. (1) is expressed in terms of the ambient Lagrangian $\mathbb{L}:TQ \to \mathbb{R}$, but, from the above description, these equations only depend on $\widetilde{\mathbb{L}}=\mathbb{L}_{|M}:M\to\mathbb{R}$, the restriction of $\mathbb{L}$ to M (see Ref. 6, and references therein).

Recently, the second author and collaborators[6] proposed an intrinsic version of vakonomic mechanics. First, they consider the Whitney sum of T^*Q and TQ: $T^*Q\oplus TQ$ and its submanifold $W_0=T^*Q\times_Q M$. Let $\pi_1:T^*Q\times_Q M\to T^*Q$ and $\pi_2:T^*Q\times_Q M\to M$ be the canonical projections. Define in $T^*Q\times_Q M$ the presymplectic two-form $\omega=\pi_1^*\omega_Q$, where ω_Q is the canonical symplectic form in T^*Q, and the Hamiltonian function $H=\langle\pi_1,\pi_2\rangle-\pi_2^*\widetilde{\mathbb{L}}$ where $\widetilde{\mathbb{L}}:M\to\mathbb{R}$ is the restriction of $\mathbb{L}$ to M. Therefore, vakonomic dynamics are intrinsically described by the equation $i_X\omega=dH$ of the presymplectic system $(T^*Q\times_Q M,\omega,H)$.

B. Vakonomic mechanics: Applications

The main goal of the following is to illustrate from different points of view the importance of developing geometric integrators, showing different applications of vakonomic mechanics.

1. Optimal control theory

It is well known that the dynamics of a large class of engineering and economic systems can be expressed as a set of differential equations

$$\dot{q}^A=\Gamma^A(q(t),u(t)),\quad 1\leqslant A\leqslant n, \tag{2}$$

where t is the time, q^A, $1\leqslant A\leqslant n$, denote the state variables, and u^a, $1\leqslant a\leqslant m$, the control inputs to the system that must be specified. Given an initial condition of the state variables and given control inputs, we completely know the trajectory of the state variables $q(t)$ (all the functions are assumed to be at least C^2).

With a fixed initial condition, usually $q_0=q(t_0)$, our aim is to find a C^2-piecewise smooth curve $\gamma(t)=(q(t),u(t))$, satisfying the control equations (2) and minimizing the functional

$$\mathcal{J}(\gamma)=\int_{t_0}^{T} L(q(t),u(t))\mathrm{d}t, \tag{3}$$

for some fixed and given final time $T\in\mathbb{R}^+$. The integral $\int_{t_0}^{T}L(q(t),u(t))\mathrm{d}t$ depends on the time history (from t_0 to T) of the state variables and the control inputs.

A necessary condition for the solutions of such problem is provided by Pontryaguin's maximum principle. If we construct the pseudo-Hamiltonian function:

$$H(q,p,u)=p_A\Gamma^A(q,u)-L(q,u) \tag{4}$$

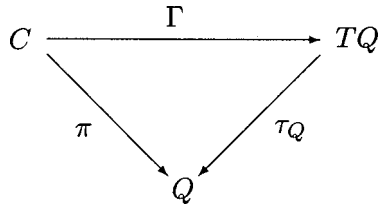
where p_A, $1\leqslant A\leqslant n$, are now considered as Lagrange's multipliers, then a curve $\gamma:[t_0,T]\to C$, $\gamma(t)=(q(t),u(t))$, is an optimal trajectory if there exist functions $p_A(t)$, $1\leqslant A\leqslant n$, such that

$$\begin{cases} \dot{q}^A(t) = \dfrac{\partial H}{\partial p_A}(q(t),p(t),u(t)), \\ \dot{p}_A(t) = -\dfrac{\partial H}{\partial q^A}(q(t),p(t),u(t)), \\ 0 = \dfrac{\partial H}{\partial u^a} \end{cases} \tag{5}$$

jointly with transversality conditions: $q(t_0)=q_0$ and $p(T)=0$.

In a global description, one assumes a fiber bundle structure $\pi: C \to Q$, where Q is the configuration manifold with local coordinates (q^A) and C is the bundle of controls, with coordinates (q^A, u^a), $1 \leqslant A \leqslant n$, $1 \leqslant a \leqslant m$.

The ordinary differential equations (2) on Q depending on the parameters u can be seen as a vector field Γ along the projection map π, that is, Γ is a smooth map $\Gamma: C \to TQ$ such that the diagram



is commutative, where $\tau_Q: TQ \to \mathbb{R}$ is the canonical projection. This vector field is locally written as $\Gamma = \Gamma^A(q,u)(\partial/\partial q^A)$.

Next, we will show that optimal control problems, under adequate regularity assumptions, can be reformulated in terms of vakonomic dynamics (see Ref. 21 for an alternative approach).

Proposition 1.1: Suppose that $\Gamma: C \to TQ$ is an embedding, then if we denote by $G: \Gamma(C) \to C$ the diffeomorphism such that $\Gamma \circ G = \mathrm{id}_C$, we have that the solutions of the optimal control problem

$$extremize \int_{t_0}^{T} L(q(t),u(t))\mathrm{d}t$$

subject to $\dot{q} = \Gamma(q,u)$ are solutions of the vakonomic problem determined by the function $\bar{L}: \Gamma(C) \to \mathbb{R}$, where $\bar{L} = L \circ G$, and the constraint submanifold $\Gamma(C)$.

Conversely, if we have a vakonomic problem given by (i) a submanifold M of TQ, verifying that $\tau_Q: M \to Q$ is a surjective submersion, (ii) the Lagrangian $\mathbb{L}: TQ \to \mathbb{R}$; then the solutions of the vakonomic problem are the solutions of the optimal control problem determined by $C = M$ and $L = \mathbb{L}_{|M}$.

Proof: Using Pontryaguin's maximum principle, an optimal trajectory $(q(t),u(t))$ of the optimal control problem satisfies

$$\begin{cases} \dot{q}^A = \Gamma^A(q,u), \\ \dot{p}_A = \dfrac{\partial L}{\partial q^A} - p_B \dfrac{\partial \Gamma^B}{\partial q^A}, \\ 0 = -\dfrac{\partial L}{\partial u^a} + p_B \dfrac{\partial \Gamma^B}{\partial u^a}. \end{cases} \tag{6}$$

Since Γ is an embedding we can consider local coordinates $(\tilde{q}^A, \tilde{u}^a)$ such that

$$\Gamma: (\tilde{q}^A, \tilde{u}^a) \to (\tilde{q}^A, \tilde{u}^a, \Psi^\alpha(\tilde{q},\tilde{u})), \quad 1 \leqslant A \leqslant N, \quad 1 \leqslant a \leqslant m, \quad 1 \leqslant \alpha \leqslant n-m.$$

Observe that $\dot{\tilde{q}}^a = \tilde{u}^a$ and $\dot{\tilde{q}}^\alpha = \Psi^\alpha(\tilde{q}^A, \tilde{u}^a)$.

Rewriting Eq. (6) in terms of these coordinates:

$$\begin{cases} \dot{\tilde{q}}^{\alpha} = \Psi^{\alpha}(\tilde{q},\tilde{u}), \\ \dot{\tilde{q}}^{a} = \tilde{u}^{a}, \\ \dot{p}_A = \dfrac{\partial \bar{L}}{\partial \tilde{q}^A} - p_{\alpha}\dfrac{\partial \Psi^{\alpha}}{\partial \tilde{q}^A}, \\ 0 = -\dfrac{\partial \bar{L}}{\partial \tilde{q}^a} + p_a + p_{\alpha}\dfrac{\partial \Psi^{\alpha}}{\partial \tilde{q}^a}, \end{cases} \tag{7}$$

which are the vakonomic equations obtained in Ref. 6 (see also Ref. 14). The converse is trivial.■

Example 1.2 Optimal control and a particle in a magnetic field: (See Ref. 2, p. 353 for a detailed exposition)

Consider the optimal control problem

$$\min \int (u^2 + v^2)\mathrm{d}t$$

subject to equations $\dot{x}=u$, $\dot{y}=v$, $\dot{z}=A_1(x,y)u+A_2(x,y)v$. Obviously it is equivalent to the vakonomic problem given by $\mathbb{L}=\frac{1}{2}(\dot{x}^2+\dot{y}^2)$ and the nonholonomic constraint $\dot{z}=A_1(x,y)\dot{x}+A_2(x,y)\dot{y}$.

2. SubRiemannian geometry

A subRiemannian structure on a manifold is a generalization of a Riemannian structure where the metric is only defined on a vector subbundle of the tangent bundle to the manifold. In such case, the notion of length is only assigned to a subclass of curves, namely curves with tangent vectors belonging to the vector subbundle for each point.[18,23,28] More precisely, consider an n-dimensional manifold equipped with a smooth distribution D of constant rank $n-m$. A *subRiemannian metric* on D consists of giving a positive definite quadratic form g_q on $\mathcal{D}_q$ smoothly varying in q. We will say that a piecewise smooth curve γ in Q is *admissible* if $\dot{\gamma}(t) \in D_{\gamma(t)}$ for all t. Using g, it is possible to define the length

$$\mathrm{length}(\gamma) = \int_0^h \sqrt{g(\dot{\gamma}(t),\dot{\gamma}(t))}\mathrm{d}t$$

for admissible curves $\gamma:[0,h]\to Q$. From this definition, we define the distance between two points $x,y \in Q$ as

$$\mathrm{d}(x,y) = \inf_{\gamma}(\mathrm{length}(\gamma)),$$

if there exists admissible curves γ connecting x and y; in other case, the distance is considered infinite. A curve which realizes the distance between two points is called a *minimizing subRiemannian geodesic*. Let $\mu_1,\ldots,\mu_m$ be a basis of one-forms for the annihilator D^o. Then, an admissible path must verify the nonholonomic constraints

$$\mu_i(\dot{\gamma}) = 0, \quad 1 \leqslant i \leqslant m. \tag{8}$$

Therefore, it is clear that the problem of finding minimizing subRiemannian geodesics is exactly the same as the vakonomic problem determined by the restricted Lagrangian $\widetilde{L}=\frac{1}{2}g$ and the nonholonomic constraints (8).

3. Economic growth theory

Optimization is a crucial topic in dynamic economic analysis. Therefore, variational calculus (free or constrained) and optimal control theory play an important role as fundamental tools.[15,27] A typical optimization problem in modern economics deals with extremizing the functional

$$\int_0^T \rho(t)U[f(t,k,\dot{k})]\mathrm{d}t$$

subject or not to constraints. Here, $\rho(t)$ is a discount rate factor, U an utility function, f a consumption function, and k the capital-labor ratio.

For instance, a classical example is the closed von Neumann system,[25] given by a transformation function $F(K_1,\ldots,K_n,\dot{K}_1,\ldots,\dot{K}_n)$ which relates n capital goods $K_1,K_2,\ldots,K_n$ and the net capital formations $\dot{K}_1,\dot{K}_2,\ldots,\dot{K}_n$. The von Neumann problem consists of maximizing the functional $\int_0^T \dot{K}_n \mathrm{d}t$ subject to $F(K_1,\ldots,K_n,\dot{K}_1,\ldots,\dot{K}_n)=0$.

C. Discrete variational calculus

Now, we will briefly describe discrete variational calculus, following the approach in Refs. 29 and 20. A discrete Lagrangian is a map $\mathbb{L}_d: Q\times Q\to\mathbb{R}$ (this discrete Lagrangian may be considered as an approximation of the continuous Lagrangian $\mathbb{L}: TQ\to\mathbb{R}$). Define the action sum $S_d: Q^{N+1}\to\mathbb{R}$ corresponding to the Lagrangian $\mathbb{L}_d$ by

$$S_d=\sum_{k=1}^{N}\mathbb{L}_d(q_{k-1},q_k),$$

where $q_k\in Q$ for $0\leqslant k\leqslant N$.

Observe that for any covector $\alpha\in T^*_{(x_1,x_2)}(Q\times Q)$, we have the decomposition $\alpha=\alpha_1+\alpha_2$ where $\alpha_i\in T^*_{x_i}Q$, thus,

$$\mathrm{d}\mathbb{L}_d(q_0,q_1)=D_1\mathbb{L}_d(q_0,q_1)+D_2\mathbb{L}_d(q_0,q_1).$$

The discrete variational principle states that the solutions of the discrete system determined by $\mathbb{L}_d$ must extremize the action sum given fixed points q_0 and q_N. Extremizing S_d over q_k, we obtain the following system of difference equations:

$$D_1\mathbb{L}_d(q_k,q_{k+1})+D_2\mathbb{L}_d(q_{k-1},q_k)=0,\quad 1\leqslant k\leqslant N-1. \tag{9}$$

These equations are usually called the *Discrete Euler-Lagrange equations*. Under some regularity hypothesis (the matrix $(D_{12}\mathbb{L}_d(q_k,q_{k+1}))$ is regular), it is possible to define a discrete flow $\Upsilon: Q\times Q\to Q\times Q$, by $\Upsilon(q_{k-1},q_k)=(q_k,q_{k+1})$ from Eq. (9).

Define the discrete Legendre transformation associated with $\mathbb{L}_d$ by

$$\mathbb{FL}_d: Q\times Q\to T^*Q$$

$$(q_0,q_1)\mapsto(q_0,-D_1\mathbb{L}_d(q_0,q_1)),$$

and the two-form $\omega_d=F\mathbb{L}_d^*\omega_Q$, where ω_Q is the canonical symplectic form on T^*Q. The discrete algorithm determined by Υ preserves the symplectic form ω_d, i.e., $\Upsilon^*\omega_d=\omega_d$. Moreover, if the discrete Lagrangian is invariant under the diagonal action of a Lie group G, then the discrete momentum map $J_d: Q\times Q\to\ ^*$ defined by $\langle J_d(q_k,q_{k+1}),\xi\rangle=\langle D_2\mathbb{L}_d(q_k,q_{k+1}),\xi_Q(q_{k+1})\rangle$ is preserved by the discrete flow. Therefore, these integrators are symplectic-momentum preserving. Here, ξ_Q is the fundamental vector field determined by $\xi\in\ $, the Lie algebra of G.

II. A GEOMETRIC APPROACH TO VAKONOMIC MECHANICS

In this section we obtain the equations of motion for vakonomic mechanics from a different point of view which, in Sec. III, will be useful in the construction of variational integrators.

Let Q be the configuration manifold of dimension n and TQ its tangent bundle with $\mathbb{L}$ the Lagrangian function $\mathbb{L}:TQ\to\mathbb{R}$. Consider the constraints $\phi^\alpha:TQ\to\mathbb{R}$, $1\leqslant\alpha\leqslant m$, and the augmented Lagrangian

$$\widetilde{\mathbb{L}}:TQ\times\mathbb{R}^m\to\mathbb{R}$$

$$(v_q,\lambda)\mapsto(\mathbb{L}+\lambda_\alpha\phi^\alpha)(v_q)$$

where summation over the repeated indexes α is understood.

Consider also the fiber derivative:

$$\mathbb{F}\widetilde{\mathbb{L}}:TQ\times\mathbb{R}^m\to T^*Q$$

$$(v_q,\lambda)\mapsto \mathrm{d}(\widetilde{\mathbb{L}}|_{T_qQ\times\{\lambda\}})(v_q)$$

which in local coordinates is

$$\mathbb{F}\widetilde{\mathbb{L}}(q^A,\dot{q}^A,\lambda_\alpha)=\left(q^A,\frac{\partial\widetilde{\mathbb{L}}}{\partial\dot{q}^A}(q^A,\dot{q}^A,\lambda_\alpha)\right). \tag{10}$$

Now, we can define a two-form ω in $TQ\times\mathbb{R}^m$ by pulling back by $\mathbb{F}\widetilde{\mathbb{L}}$ the canonical symplectic two-form ω_Q on T^*Q; that is, $\omega=\mathbb{F}\widetilde{\mathbb{L}}^*(\omega_Q)$. In local coordinates we have

$$\omega=\mathbb{F}\widetilde{\mathbb{L}}^*(\mathrm{d}q^A\wedge\mathrm{d}p_A)=\mathrm{d}q^A\wedge d\left(\frac{\partial\widetilde{\mathbb{L}}}{\partial\dot{q}^A}\right)=\frac{\partial^2\widetilde{\mathbb{L}}}{\partial\dot{q}^A\partial q^B}\mathrm{d}q^A\wedge\mathrm{d}q^B+\frac{\partial^2\widetilde{\mathbb{L}}}{\partial\dot{q}^A\partial\dot{q}^B}\mathrm{d}q^A\wedge\mathrm{d}\dot{q}^B+\frac{\partial^2\widetilde{\mathbb{L}}}{\partial\lambda_\alpha\partial\dot{q}^A}\mathrm{d}q^A\wedge\mathrm{d}\lambda_\alpha.$$

The energy function associated with the augmented Lagrangian $\widetilde{\mathbb{L}}$ is: $E_{\widetilde{\mathbb{L}}}=\Delta\widetilde{\mathbb{L}}-\widetilde{\mathbb{L}}$ where Δ stands for the Liouville vector field on TQ. Locally, $\Delta=\dot{q}^A(\partial/\partial\dot{q}^A)$ and $E_{\widetilde{\mathbb{L}}}=\dot{q}^A(\partial\widetilde{\mathbb{L}}/\partial\dot{q}^A)-\widetilde{\mathbb{L}}$.

Next, we will see how the dynamics of the vakonomic system determined by $(\mathbb{L},\phi^\alpha)$ is determined by the solutions of

$$i_X\omega=dE_{\widetilde{\mathbb{L}}}. \tag{11}$$

Observe that the system $(TQ\times\mathbb{R}^m,\omega,E_{\widetilde{\mathbb{L}}})$ is a presymplectic system (see Ref. 12).

In what follows, we will assume that

$$\widetilde{\mathcal{W}}=\left(\frac{\partial^2\widetilde{\mathbb{L}}}{\partial\dot{q}^A\partial\dot{q}^B}\right)=\left(\frac{\partial^2\mathbb{L}}{\partial\dot{q}^A\partial\dot{q}^B}+\lambda_\alpha\frac{\partial^2\phi_\alpha}{\partial\dot{q}^A\partial\dot{q}^B}\right)$$

is regular (see Ref. 1).

First, note that

$$\mathrm{d}E_{\widetilde{\mathbb{L}}}=\dot{q}^A\frac{\partial^2\widetilde{\mathbb{L}}}{\partial\dot{q}^A\partial q^B}\mathrm{d}q^B+\dot{q}^A\frac{\partial^2\widetilde{\mathbb{L}}}{\partial\dot{q}^A\partial\dot{q}^B}\mathrm{d}\dot{q}^B+\dot{q}^A\frac{\partial\phi^\alpha}{\partial\dot{q}^A}\mathrm{d}\lambda_\alpha-\frac{\partial\widetilde{\mathbb{L}}}{\partial q^A}\mathrm{d}q^A-\frac{\partial\widetilde{\mathbb{L}}}{\partial\lambda_\alpha}\mathrm{d}\lambda_\alpha.$$

Now let

$$\xi = X^A \frac{\partial}{\partial q^A} + Y^A \frac{\partial}{\partial \dot{q}^A} + Z_\alpha \frac{\partial}{\partial \lambda_\alpha}$$

be a generic vector field on $TQ \times \mathbb{R}^m$, a direct computation shows that $i_\xi \omega = \mathrm{d}E_{\tilde{\mathbb{L}}}$ if and only if X^A, Y^A, and Z_α satisfy the following conditions:

$$\begin{cases} X^A = \dot{q}^A, \\ \dfrac{\partial \tilde{\mathbb{L}}}{\partial \lambda_\alpha} = 0, \\ \dfrac{\partial \tilde{\mathbb{L}}}{\partial q^A} = X^B \dfrac{\partial^2 \tilde{\mathbb{L}}}{\partial \dot{q}^A \partial q^B} + Y^B \dfrac{\partial^2 \tilde{\mathbb{L}}}{\partial \dot{q}^A \partial \dot{q}^B} + Z_\alpha \dfrac{\partial^2 \tilde{\mathbb{L}}}{\partial \lambda_\alpha \partial \dot{q}^A}. \end{cases}$$

The first of these conditions implies the SODE character of the equations on q's, the second one is just the statement $\phi^\alpha = 0$ (the constraint conditions). Therefore, $M_1 = \{(v_q, \lambda) \in TQ \times \mathbb{R}^m / \phi^\alpha(v_q) = 0\}$ is the first constraint submanifold after applying the Dirac-Bergmann-Gotay-Nester algorithm[11,12] to the presymplectic system $(TQ \times \mathbb{R}^m, \omega, E_{\tilde{\mathbb{L}}})$.

If we suppose that $\gamma(t) = (q(t), \dot{q}(t), \lambda(t))$ is an integral curve for ξ, the following equations must hold along γ:

$$\begin{cases} \dfrac{\partial \tilde{\mathbb{L}}}{\partial q^A} = \dot{q}^B \dfrac{\partial^2 \tilde{\mathbb{L}}}{\partial \dot{q}^A \partial q^B} + \ddot{q}^B \dfrac{\partial^2 \tilde{\mathbb{L}}}{\partial \dot{q}^A \partial \dot{q}^B} + \dot{\lambda}_\alpha \dfrac{\partial^2 \tilde{\mathbb{L}}}{\partial \lambda_\alpha \partial \dot{q}^A}, \\ \phi^\alpha = 0. \end{cases}$$

Since

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial \tilde{\mathbb{L}}}{\partial \dot{q}^A} \right) = \dot{q}^B \frac{\partial^2 \tilde{\mathbb{L}}}{\partial \dot{q}^A \partial q^B} + \ddot{q}^B \frac{\partial^2 \tilde{\mathbb{L}}}{\partial \dot{q}^A \partial \dot{q}^B} + \dot{\lambda}_\alpha \frac{\partial^2 \tilde{\mathbb{L}}}{\partial \lambda_\alpha \partial \dot{q}^A},$$

if we expand $\tilde{\mathbb{L}} = \mathbb{L} + \lambda_\alpha \phi^\alpha$ then we obtain (1), which are exactly the vakonomic equations of motion for the constrained system given by $(\mathbb{L}, \phi^\alpha)$, $\alpha = 1, \ldots, m$.

The solutions on M_1 may not be tangent to M_1. In such case, we have to restrict M_1 to the submanifold M_2 where there exists a solution tangent to M_1. Proceeding further, we obtain a sequence of submanifolds (assuming that all the subsets generated by the algorithm are submanifolds, in other case see Ref. 17)

$$\cdots \hookrightarrow M_k \hookrightarrow \cdots \hookrightarrow M_2 \hookrightarrow M_1 \hookrightarrow M_0 = TQ \times \mathbb{R}^m.$$

If this constraint algorithm stabilizes, i.e., if there exists a positive integer $k \in \mathbb{N}$ such that $M_{k+1} = M_k$ and $\dim M_k \neq 0$, then we would have a final constraint submanifold $M_f = M_k$ on which a vector field X exists such that

$$(i_X \omega = dE_{\tilde{\mathbb{L}}})_{|M_f}.$$

An interesting case is when the final constraint submanifold is just M_1, say $M_f = M_1$. Additionally, observe that $\dim M_1 = 2n$. Denote by ω_{M_1} the restriction of the presymplectic two-form ω to W_1 and by $\tilde{\mathcal{C}}_2 = (\tilde{C}_{A\alpha})$ the $n \times m$ matrix with entries $\tilde{C}_{A\alpha} = \partial \phi^\alpha / \partial \dot{q}^A$.

Proposition 2.1: (M_1, ω_{M_1}) *is a symplectic manifold if and only if, for any choice of coordinates* $(q^A, \dot{q}^A, \lambda_\alpha)$ *on* $TQ \times \mathbb{R}^m$ *and every point in* M_1,

$$\begin{pmatrix} \tilde{\mathcal{W}} & \tilde{\mathcal{C}}_2 \\ \tilde{\mathcal{C}}_2^T & \mathbf{0}_{m \times m} \end{pmatrix}$$

is invertible.

Proof: It is proved following the same arguments as in Theorem 4.2. ■

Observe that if (M_1,ω_{M_1}) is a symplectic manifold then $(\mathbb{F}\widetilde{\mathbb{L}})_1=\mathbb{F}\widetilde{\mathbb{L}}\circ i_{M_1}:M_1\to T^*Q$ is a symplectomorphism (see Ref. 1, p. 34, for more details), where $i_{M_1}:M_1\hookrightarrow TQ\times\mathbb{R}^m$ is the canonical inclusion.

III. A DISCRETE ALGORITHM FOR VARIATIONAL CONSTRAINED OPTIMIZATION

In this section, inspired by our last geometric approach to vakonomic mechanics, we develop a numerical integrator that preserves, as we shall discuss later, certain structures naturally associated with this system.

Given an n-dimensional configuration space Q, a Lagrangian function $\mathbb{L}:TQ\to\mathbb{R}$, and constraints $\phi^\alpha:TQ\to\mathbb{R}$, $1\leqslant\alpha\leqslant m$, let $\mathbb{L}_d:Q\times Q\to\mathbb{R}$ and $\phi_d^\alpha:Q\times Q\to\mathbb{R}$ be discrete versions of these Lagrangian and constraints, respectively.[29]

Thus we can consider the following problem of static constrained optimization which will be called the discrete version of constrained variational calculus (or discrete vakonomic mechanics):

$$\begin{cases}\min \mathbb{S}(q_0,q_1,\ldots,q_N) & \text{with fixed } q_0 \text{ and } q_N\\ \text{subject to } \phi_d^\alpha(q_k,q_{k+1})=0, & 1\leqslant\alpha\leqslant m,\ 0\leqslant k\leqslant N-1,\end{cases}\tag{12}$$

where $\mathbb{S}(q_0,q_1,\ldots,q_N)=\Sigma_{k=0}^{N-1}\mathbb{L}_d(q_k,q_{k+1})$ stands for the discrete action. Observe that the system is subjected to $N\cdot m$ constraint functions.

Considering (12) as a typical constrained optimization problem, we define a discrete augmented Lagrangian $\widetilde{\mathbb{L}}_d(x,y,\lambda)=\mathbb{L}_d(x,y)+\lambda_\alpha\phi_d^\alpha(x,y)$ on $Q\times Q\times\mathbb{R}^m$ and the associated unconstrained discrete variational problem:

$$\begin{cases}\min \widetilde{\mathbb{S}}(q_0,q_1,\ldots,q_N,\lambda^0,\lambda^1,\ldots,\lambda^{N-1}) & \text{with fixed } q_0 \text{ and } q_N\\ q_k\in Q, \quad \lambda_k\in\mathbb{R}^m \quad k=0,\ldots,N-1, & q_N\in Q,\end{cases}\tag{13}$$

where $\widetilde{\mathbb{S}}(q_0,q_1,\ldots,q_N,\lambda^0,\lambda^1,\ldots,\lambda^{N-1})=\Sigma_{k=0}^{N-1}\widetilde{\mathbb{L}}_d(q_k,q_{k+1},\lambda^k)=\Sigma_{k=0}^{N-1}[\mathbb{L}_d(q_k,q_{k+1})+\lambda_\alpha^k\phi_d^\alpha(q_k,q_{k+1})]$ where λ^k is an m-vector with components $\lambda_\alpha^k, 1\leqslant\alpha\leqslant m$.

The critical points of problem (13), will be those annihilating $\partial\widetilde{\mathbb{S}}/\partial q_k$, $k=1,\ldots,N-1$ (q_0 and q_N are fixed) and the constraints equations ($\partial\widetilde{\mathbb{S}}/\partial\lambda^k=0, k=0,\ldots,N-1$). Thus, the *discrete vakonomic equations* are:

$$\begin{cases}D_1\mathbb{L}_d(q_k,q_{k+1})+D_2\mathbb{L}_d(q_{k-1},q_k)+\lambda_\alpha^k D_1\phi_d^\alpha(q_k,q_{k+1})+\lambda_\alpha^{k-1}D_2\phi_d^\alpha(q_{k-1},q_k)=0, \quad 1\leqslant k\leqslant N-1,\\ \phi_d^\alpha(q_k,q_{k+1})=0, \quad 1\leqslant\alpha\leqslant m, \quad 0\leqslant k\leqslant N-1\end{cases}.\tag{14}$$

In the sequel, we will use the notation $D_{12}F$ to denote the $n\times n$ matrix $(\partial^2F/\partial x^A\partial y^B)$ for any C^2-function $F:Q\times Q\to\mathbb{R}$. Now, if the matrix

$$\begin{pmatrix} D_{12}\mathbb{L}_d+\lambda_\alpha D_{12}\phi_d^\alpha & \dfrac{\partial\phi_d^\alpha}{\partial x}\\ \left(\dfrac{\partial\phi_d^\alpha}{\partial y}\right)^T & \mathbf{0}_{m\times m}\end{pmatrix}\in\mathcal{M}_{(n+m)\times(n+m)}(\mathbb{R})$$

is invertible, then there exists a local discrete map:

$$\Phi:Q\times Q\times\mathbb{R}^m\to Q\times Q\times\mathbb{R}^m$$

$$(x,y,\lambda)\mapsto(y,v,\Lambda)$$

such that along solutions $(q_0,q_1,\ldots,q_N,\lambda^0,\lambda^1,\ldots,\lambda^{N-1})$ of Eq. (14) we have that

$$\Phi(q_{k-1},q_k,\lambda^{k-1}) = (q_k,q_{k+1},\lambda^k),$$

which is our integrator for the vakonomic problem.

Remark 3.1: In the case where the constraints are holonomic (i.e., $\phi^\alpha: Q \to \mathbb{R}$), we can choose (between many others) the discretization:

$$\phi_d^\alpha: Q \times Q \to \mathbb{R}$$

$$(q_0,q_1) \mapsto \phi^\alpha(q_0)$$

and then our procedure leads to the same equations as those proposed in Ref. 20 just for the holonomic case.

IV. SYMPLECTIC-MOMENTUM INTEGRATOR

In Sec. III, we have constructed a variational integrator for vakonomic mechanics. In what follows, we want to study the symplectic and momentum preserving character of this algorithm. First, it is necessary to make precise the sense in which Φ is symplectic and also to define a suitable discrete momentum map related obviously to the original continuous case.

A. Symplectic behavior

Consider the discrete fiber derivative

$$\mathbb{F}_d: Q \times Q \times \mathbb{R}^m \to T^*Q$$

$$(x,y,\lambda) \mapsto -D_1\tilde{\mathbb{L}}_d(x,y,\lambda) = -D_1\mathbb{L}_d(x,y) - \lambda_\alpha D_1\phi_d^\alpha(x,y) \in T_x^*Q.$$

Following the lines developed in Sec. II, we now define the two-form ω_d on $Q\times Q\times\mathbb{R}^m$ by pulling back the canonical symplectic two-form $\omega_Q = \mathrm{d}q^A \wedge \mathrm{d}p_A = -\mathrm{d}(p_A \mathrm{d}q^A)$ on T^*Q via $\mathbb{F}_d$; that is

$$\omega_d = \mathbb{F}_d^*(\omega_Q) = \mathrm{d}[D_1\mathbb{L}_d + \lambda_\alpha D_1\phi_d^\alpha]. \tag{15}$$

Thus, the coordinate expression for ω_d is

$$\omega_d(x,y,\lambda) = -\left[\frac{\partial^2\mathbb{L}_d}{\partial x^A \partial y^B}(x,y) + \lambda_\alpha \frac{\partial^2\phi_d^\alpha}{\partial x^A \partial y^B}(x,y)\right]\mathrm{d}x^A \wedge \mathrm{d}y^B + \frac{\partial\phi_d^\alpha}{\partial x^A}(x,y)\mathrm{d}\lambda_\alpha \wedge \mathrm{d}x^A. \tag{16}$$

Next, consider the constraint submanifold $\tilde{M}_d \subset Q\times Q$ determined by the vanishing of the constraints $\phi_d^\alpha = 0$, $1 \leqslant \alpha \leqslant m$, with canonical inclusion $j: \tilde{M}_d \times \mathbb{R}^m \hookrightarrow Q\times Q\times\mathbb{R}^m$, and the two-form $\omega_{\tilde{M}_d} = j^*\omega_d$. From the definition of Φ it is obvious that it applies $\tilde{M}_d \times \mathbb{R}^m$ onto itself. Our aim now is to prove that $(\Phi_{|\tilde{M}_d\times\mathbb{R}^m})^*\omega_{\tilde{M}_d} = \omega_{\tilde{M}_d}$.

Lemma 4.1:

$$\omega_d = \mathrm{d}(D_1\mathbb{L}_d + \lambda_\alpha D_1\phi_d^\alpha) = -\mathrm{d}(D_2\mathbb{L}_d + \lambda_\alpha D_2\phi_d^\alpha) - \mathrm{d}\phi_d^\alpha \wedge \mathrm{d}\lambda_\alpha$$

Proof:

$$\begin{aligned} 0 &= \mathrm{d}(d\mathbb{L}_d + \mathrm{d}(\lambda_\alpha\phi_d^\alpha)) = \mathrm{d}(D_1\mathbb{L}_d + D_2\mathbb{L}_d + \lambda_\alpha D_1\phi_d^\alpha + \lambda_\alpha D_2\phi_d^\alpha + \phi_d^\alpha d\lambda_\alpha) \\ &= \mathrm{d}(D_1\mathbb{L}_d + \lambda_\alpha D_1\phi_d^\alpha) + \mathrm{d}(D_2\mathbb{L}_d + \lambda_\alpha D_2\phi_d^\alpha) + d\phi_d^\alpha \wedge d\lambda_\alpha \end{aligned}$$

■

Now, properties of the pull-back, Eq. (14), and the above lemma imply that

$$\Phi^*\omega_d = \Phi^*[\mathrm{d}(D_1\mathbb{L}_d + \lambda_\alpha D_1\phi_d^\alpha)] = \mathrm{d}[\Phi^*(D_1\mathbb{L}_d + \lambda_\alpha D_1\phi_d^\alpha)] = \mathrm{d}[-(D_2\mathbb{L}_d + \lambda_\alpha D_2\phi_d^\alpha)]$$
$$= \mathrm{d}\,(D_1\mathbb{L}_d + \lambda_\alpha D_1\phi_d^\alpha)] + \mathrm{d}\phi_d^\alpha \wedge \mathrm{d}\lambda_\alpha = \omega_d + d\phi_d^\alpha \wedge d\lambda_\alpha$$

and then $(\Phi|_{\tilde{M}_d\times\mathbb{R}^m})^*\omega_{\tilde{M}_d} = \omega_{\tilde{M}_d}$ since $d\phi_d^\alpha$ vanishes on tangent vectors to $\tilde{M}_d$.

Observe now that $\tilde{M}_d \times \mathbb{R}^m$ is a $2n$-dimensional manifold. Therefore, it is a natural question to ask about conditions that ensure the symplectic character of the two-form $\omega_{\tilde{M}_d}$.

Theorem 4.2: *Suppose that the $n\times n$ matrix $\mathcal{A}=(D_{12}\mathbb{L}_d+\lambda_\alpha D_{12}\phi_d^\alpha)$ is invertible. Then $\omega_{\tilde{M}_d}$ is symplectic if and only if the matrix*

$$\begin{pmatrix} (D_{12}\mathbb{L}_d + \lambda_\alpha D_{12}\phi_d^\alpha) & \mathcal{C}_1 \\ \mathcal{C}_2^T & \mathbf{0}_{m\times m} \end{pmatrix}$$

is invertible. Here, $\mathcal{C}_1$ and $\mathcal{C}_2$ denote the $n\times m$ matrices:

$$\mathcal{C}_1 = ((\mathcal{C}_1)_{A\alpha}) = \left(\frac{\partial\phi_d^\alpha}{\partial x^A}\right) \text{ and } \mathcal{C}_2 = ((\mathcal{C}_2)_{A\alpha}) = \left(\frac{\partial\phi_d^\alpha}{\partial y^A}\right).$$

Proof: Let $\mathcal{C}$ be the $(2n+m)\times m$ matrix defined by

$$\mathcal{C} = \begin{pmatrix} \mathcal{C}_1 \\ \mathcal{C}_2 \\ \mathbf{0}_{m\times m} \end{pmatrix}.$$

Moreover, $\mathcal{B}$ is the $(2n+m)\times(2n+m)$ matrix defined by

$$\mathcal{B} = \begin{pmatrix} 0 & -\mathcal{A} & -\mathcal{C}_1 \\ \mathcal{A}^T & \mathbf{0}_{n\times n} & \mathbf{0}_{n\times m} \\ \mathcal{C}_1^T & \mathbf{0}_{m\times n} & \mathbf{0}_{m\times m} \end{pmatrix}.$$

The matrix $\mathcal{B}$ represents the two-form ω_d [see Eq. (16)] and then, the two-form $\omega_{\tilde{M}_d}$ is symplectic if and only if the following system of equations admits as unique solution $(X^A, Y^A, C^\alpha) = \mathbf{0}_{1\times(2n+m)}$:

$$\left.\begin{aligned} &(\tilde{X}^A, \tilde{Y}^A, \tilde{C}^\alpha)\cdot\mathcal{B}\cdot(X^A, Y^A, C^\alpha)^T = 0 \\ &(X^A, Y^A, C^\alpha)\cdot\mathcal{C} = \mathbf{0}_{1\times m} \end{aligned}\right\} \text{ for all } (\tilde{X}^A, \tilde{Y}^A, \tilde{C}^\alpha) \text{ verifying } (\tilde{X}^A, \tilde{Y}^A, \tilde{C}^\alpha)\cdot\mathcal{C} = \mathbf{0}_{1\times m}.$$

This problem is equivalent to the regularity of the $(2n+2m)\times(2n+2m)$ matrix:

$$\mathcal{D} = \begin{pmatrix} 0 & -\mathcal{A} & -\mathcal{C}_1 & -\mathcal{C}_1 \\ \mathcal{A}^T & \mathbf{0}_{n\times n} & \mathbf{0}_{n\times m} & -\mathcal{C}_2 \\ \mathcal{C}_1^T & \mathbf{0}_{m\times n} & \mathbf{0}_{m\times m} & \mathbf{0}_{m\times m} \\ \mathcal{C}_1^T & \mathcal{C}_2^T & \mathbf{0}_{m\times m} & \mathbf{0}_{m\times m} \end{pmatrix}.$$

Since the $n\times n$ matrix $\mathcal{A}$ is invertible, then so is the matrix in the upper left quarter part of $\mathcal{D}$ and, taking its Schur complement in $\mathcal{D}$ (see Ref. 24), the regularity of $\mathcal{D}$ is equivalent to

$$0 \neq \left| \begin{pmatrix} \mathcal{C}_1^T & \mathbf{0}_{m\times n} \\ \mathcal{C}_1^T & \mathcal{C}_2^T \end{pmatrix} \cdot \begin{pmatrix} \mathbf{0}_{n\times n} & (\mathcal{A}^T)^{-1} \\ (-\mathcal{A})^{-1} & \mathbf{0}_{n\times n} \end{pmatrix} \cdot \begin{pmatrix} -\mathcal{C}_1 & -\mathcal{C}_1 \\ \mathbf{0}_{n\times m} & -\mathcal{C}_2 \end{pmatrix} \right| = \begin{vmatrix} \mathbf{0}_{m\times m} & -\mathcal{C}_1^T(\mathcal{A}^T)^{-1}\mathcal{C}_2 \\ \mathcal{C}_2^T\mathcal{A}^{-1}\mathcal{C}_1 & \mathcal{C}_2^T\mathcal{A}^{-1}\mathcal{C}_1 - \mathcal{C}_1^T(\mathcal{A}^T)^{-1}\mathcal{C}_2 \end{vmatrix}$$

$$= \begin{vmatrix} \mathbf{0}_{m\times m} & -(\mathcal{C}_2^T\mathcal{A}^{-1}\mathcal{C}_1)^T \\ \mathcal{C}_2^T\mathcal{A}^{-1}\mathcal{C}_1 & \mathbf{0}_{m\times m} \end{vmatrix},$$

which is equivalent to the regularity of the matrix $\mathcal{C}_2^T\mathcal{A}^{-1}\mathcal{C}_1$, the Schur complement of $\mathcal{A}$ in the matrix:

$$\begin{pmatrix} \mathcal{A} & \mathcal{C}_1 \\ \mathcal{C}_2^T & \mathbf{0}_{m\times m} \end{pmatrix}$$

Therefore, this last matrix is invertible if and only $\omega_{\tilde{M}_d}$ is symplectic. ■

In the conditions of Theorem 4.2, the variational algorithm is symplectic.

Remark 4.3: The classical approach to constrained variational calculus is developed by using the extended Lagrangian $\mathcal{L}: T(Q\times\mathbb{R}^m)\to\mathbb{R}$ defined by $\mathcal{L}=L+\lambda_\alpha\phi_d^\alpha$. A natural discretization of this extended Lagrangian is

$$\mathcal{L}_d = \mathbb{L}_d + \lambda_\alpha\phi_d^\alpha,$$

where $\mathcal{L}_d: Q\times\mathbb{R}^m\times Q\times\mathbb{R}^m\to\mathbb{R}$. The action sum is

$$\widetilde{\mathbb{S}} = \sum_{k=0}^{N-1} \mathcal{L}_d(q_k,\lambda^k,q_{k+1},\lambda^{k+1}) = \sum_{k=0}^{N-1} (\mathbb{L}_d(q_k,q_{k+1}) + \lambda_\alpha^k\phi_d^\alpha(q_k,q_{k+1})),$$

where $q_k\in Q$ and $\lambda^k=(\lambda_\alpha^k)\in\mathbb{R}^m$.

The discrete Euler-Lagrange equations (DEL) are

$$D_1\mathcal{L}_d(q_k,\lambda^k,q_{k+1},\lambda^{k+1}) + D_2\mathcal{L}_d(q_{k-1},\lambda^{k-1},q_k,\lambda^k) = 0, \quad 1\leqslant k\leqslant N-1, \tag{17}$$

which are equivalent to

$$\begin{cases} D_1\mathbb{L}_d(q_k,q_{k+1}) + \lambda_\alpha^k D_1\phi_d^\alpha(q_k,q_{k+1}) + D_2\mathbb{L}_d(q_{k-1},q_k) + \lambda_\alpha^{k-1}D_2\phi_d^\alpha(q_{k-1},q_k) = 0, \\ \phi_d^\alpha(q_k,q_{k+1}) = 0. \end{cases}$$

Now, (17) are exactly (14). Observe that our procedure is more direct and, moreover, the analysis of the geometric properties is easier with the approach that we follow. For instance, observe that using the extended approach the final constraint submanifold,

$$\bar{M}_d = \{\phi_d^\alpha = 0\} \subset Q\times\mathbb{R}^m\times Q\times\mathbb{R}^m,$$

is *presymplectic* instead of symplectic.

B. Momentum preservation

Let $\mathbb{L}_d$ be the discrete Lagrangian and ϕ_d^α, $1\leqslant\alpha\leqslant m$ the discrete constraints. Suppose that $\mathbb{L}_d$ and ϕ_d^α are invariant under the diagonal action of a Lie group G on Q. Therefore, for any $\xi\in$ (where is the Lie algebra of G) we have:

$$\mathbb{L}_d(\exp(s\xi)q_k,\exp(s\xi)q_{k+1}) = \mathbb{L}_d(q_k,q_{k+1}), \tag{18}$$

$$\phi_d^\alpha(\exp(s\xi)q_k,\exp(s\xi)q_{k+1}) = \phi_d^\alpha(q_k,q_{k+1}),\ 1\leqslant\alpha\leqslant m \tag{19}$$

Consider the discrete momentum map

$$J_d: Q\times Q\times\mathbb{R}^m\to\ ^*$$

$$(x,y,\lambda) \mapsto J_d(x,y,\lambda): \quad \to \mathbb{R}$$

$$\xi \mapsto \langle D_2\mathbb{L}_d(x,y) + \lambda_\alpha D_2\phi_d^\alpha(x,y), \xi_Q(y)\rangle,$$

where ξ_Q is the infinitesimal generator of ξ.

Proposition 4.4: The flow $\Phi: Q\times Q\times\mathbb{R}^m \to Q\times Q\times\mathbb{R}^m$ *preserves the momentum map.*

Proof: Differentiating Eqs. (18) and (19) and taking $s=0$ we obtain the following two equations:

$$D_1\mathbb{L}_d(q_k,q_{k+1})\xi_Q(q_k) + D_2\mathbb{L}_d(q_k,q_{k+1})\xi_Q(q_{k+1}) = 0,$$

$$D_1\phi_d^\alpha(q_k,q_{k+1})\xi_Q(q_k) + D_2\phi_d^\alpha(q_k,q_{k+1})\xi_Q(q_{k+1}) = 0.$$

Multiplying the latter equation by λ_α^k, adding then the former equation, and using Eq. (14) then we have

$$\begin{aligned} &D_2\mathbb{L}_d(q_k,q_{k+1})\xi_Q(q_{k+1}) + \lambda_\alpha^k D_2\phi_d^\alpha(q_k,q_{k+1})\xi_Q(q_{k+1}) \\ &\quad = D_2\mathbb{L}_d(q_{k-1},q_k)\xi_Q(q_k) + \lambda_\alpha^{k-1} D_2\phi_d^\alpha(q_{k-1},q_k)\xi_Q(q_k) \end{aligned}$$

or

$$J_d[\Phi(q_{k-1},q_k,\lambda^{k-1})] = J_d(q_{k-1},q_k,\lambda^{k-1}).$$

■

Remark 4.5: Observe that, more generally, we may impose the condition of invariance of $\widetilde{\mathbb{L}}_d=\mathbb{L}_d+\lambda_\alpha\phi_d^\alpha$ instead of the stronger condition of invariance of $\mathbb{L}_d$ and ϕ_d^α, independently.

V. EXAMPLE: THE HEISENBERG SYSTEM

Define the differential one-form Θ in $Q=\mathbb{R}^3$ by

$$\Theta = \mathrm{d}z - y\mathrm{d}x + x\mathrm{d}y$$

and its associated distribution:

$$\mathcal{H}_{(x,y,z)} = \{\Theta(x,y,z)\}^0 = \{(v_1,v_2,v_3) \in \mathbb{R}^3 : v_3 - yv_1 + xv_2 = 0\},$$

which can be alternatively expressed as

$$\mathcal{H}_{(x,y,z)} = \mathrm{Span}\{(1,0,y),(0,-1,x)\}.$$

We can then compute the Lie bracket of both generators: $[(1,0,y),(0,-1,x)]=(0,0,2)$, which is not in $\mathcal{H}_{\{(x,y,z)\}}$, therefore the distribution is not integrable. In fact,

$$\mathbb{R}^3 = \mathrm{Span}\{(1,0,y),(0,-1,x),(0,0,2)\}$$

and, considered as a Lie algebra, it is just the Heisenberg algebra that one meets in quantum mechanics: $(1,0,y)$ and $(0,-1,x)$ corresponding to position and momentum operators and (0,0,2) to a multiple of the identity. Anyway, we have chosen the Heisenberg system just as an example of vakonomic dynamics[2,23] when we take the kinematic Lagrangian: $\mathbb{L}=\frac{1}{2}(\dot{x}^2+\dot{y}^2+\dot{z}^2)$ and force the velocity vectors of admissible curves to lie in the distribution $\mathcal{H}$; that is, we require that the solutions satisfy the nonholonomic constraint: $\phi=\dot{z}-y\dot{x}+x\dot{y}=0$. The equations for this vakonomic problem turn out to be

$$\begin{cases} \ddot{x} = 2\lambda\dot{y} + \dot{\lambda}y, \\ \ddot{y} = -2\lambda\dot{x} - \dot{\lambda}x, \\ \ddot{z} = \dot{\lambda}, \\ \dot{z} = y\dot{x} - x\dot{y}(\text{the constraint}), \end{cases} \tag{20}$$

supplied with initial conditions in positions and velocities or, alternatively, initial and final conditions in positions.

Let us now consider the action of the group

$$G = S^1 = \{e^{i\alpha}, \alpha \in [0,2\pi]\} = \left\{ \begin{pmatrix} \cos\alpha & -\sin\alpha & 0 & 0 \\ \sin\alpha & \cos\alpha & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} : \alpha \in [0,2\pi] \right\}$$

over $\mathbb{R}^3 \times \mathbb{R}$:

$$\Phi^Q : G \times \mathbb{R}^3 \times \mathbb{R} \to \mathbb{R}^3 \times \mathbb{R}$$

$$(e^{i\alpha}, (x,y,z,\lambda)) \mapsto (x\cos\alpha - y\sin\alpha, x\sin\alpha + y\cos\alpha, z, \lambda),$$

which induces an action of G over $T(\mathbb{R}^3 \times \mathbb{R}) \simeq \mathbb{R}^3 \times \mathbb{R} \times \mathbb{R}^3 \times \mathbb{R}$:

$$\Phi^{TQ}(e^{i\alpha}, (x,y,z,\lambda), (v_1,v_2,v_3,v_4)) = (\Phi^Q(e^{i\alpha}, (x,y,z,\lambda)), (v_1\cos\alpha - v_2\sin\alpha, v_1\sin\alpha + v_2\cos\alpha, v_3, v_4))$$

and, due to the fact that G leaves invariant the augmented Lagrangian $\tilde{L}$, the momentum map $J_{\tilde{L}}$ provide us a *conserved quantity:*

$$J_{\tilde{L}}((x,y,z,\lambda),(v_1,v_2,v_3,v_4)): \quad \to \mathbb{R}$$

$$\xi \mapsto (xv_2 - v_1 y + \lambda(x^2 + y^2))\xi$$

Therefore, along solution curves, the function:

$$f : T(\mathbb{R}^3 \times \mathbb{R}) \to \mathbb{R}$$

$$(x,y,z,\lambda,\dot{x},\dot{y},\dot{z},\dot{\lambda}) \mapsto x\dot{y} - \dot{x}y + \lambda(x^2 + y^2)$$

remains constant.

Vakonomic integrator. We turn now to our discrete scheme. First, we select the usual discretization of variables when we are on vector spaces (as is the case): $x = (x_0 + x_1)/2$; $\dot{x} = (x_1 - x_0)/h$; and the analogue for $y, \dot{y}, z, \dot{z}$. Then the discretization of the Lagrangian and constraint function results on

$$\mathbb{L} = \frac{1}{2}(\dot{x}^2 + \dot{y}^2 + \dot{z}^2), \quad \mathbb{L}_d = \frac{1}{2h^2}[(x_1 - x_0)^2 + (y_1 - y_0)^2 + (z_1 - z_0)^2],$$

$$\phi = \dot{z} - y\dot{x} + x\dot{y}, \quad \phi_d = \frac{1}{h}(z_1 - z_0 + x_0 y_1 - x_1 y_0).$$

After some computing, we find that

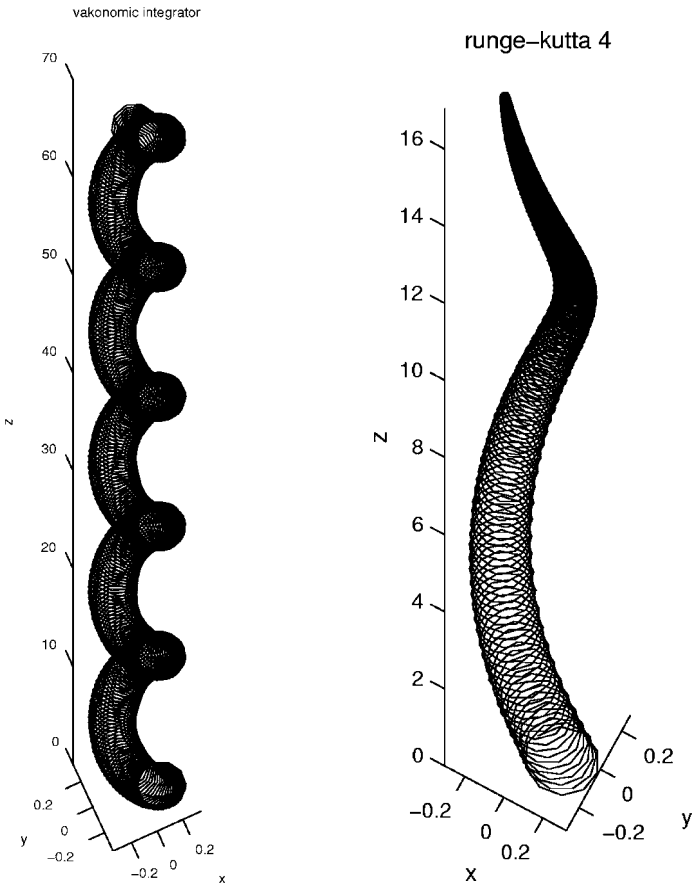


FIG. 1. Vakonomic integrator and Runge-Kutta.

$$\begin{pmatrix} (D_{12}\mathbb{L}_d + \lambda_\alpha D_{12}\phi_d^\alpha) & D_1\phi_d^\alpha \\ (D_2\phi_d^\alpha)^T & 0 \end{pmatrix}_{|(x_0,y_0,z_0,x_1,y_1,z_1,\lambda^0)} = \frac{1}{h^2}\begin{pmatrix} -1 & -\lambda^0 h & 0 & hy_1 \\ \lambda^0 h & -1 & 0 & -hx_1 \\ 0 & 0 & -1 & -h \\ -hy_0 & hx_0 & h & 0 \end{pmatrix}$$

whose determinant is equal to $(1+(\lambda^0)^2h^2)(1+y_1y_0+x_1x_0)=1+O(h^2)$. We can run our method for h enough small such that the discrete vakonomic equations become

$$\begin{cases} 0 = -x_2 + 2x_1 - x_0 + h(\lambda^1 y_2 - \lambda^0 y_0), \\ 0 = -y_2 + 2y_1 - y_0 + h(\lambda^0 x_0 - \lambda^1 x_2), \\ 0 = -z_2 + 2z_1 - z_0 + h(\lambda^0 - \lambda^1), \\ 0 = z_2 - z_1 + x_1 y_2 - x_2 y_1, \end{cases}$$

which are a discrete version of the continuous equations at the end of the last paragraph and can be solved with initial conditions (x_0,y_0,z_0,λ^0) and (x_1,y_1,z_1) or initial and final conditions (x_0,y_0,z_0,λ^0) and (x_N,y_N,z_N), all them satisfying the constraint $\phi_d=0$. In the first case, resolution of the vakonomic equations gives us (x_2,y_2,z_2,λ^1), and from it and (x_1,y_1,z_1) we obtain (x_3,y_3,z_3,λ^2) and so on. To compare our method with the classical four-order Runge-Kutta method (RK4), we write Eq. (20) as follows:

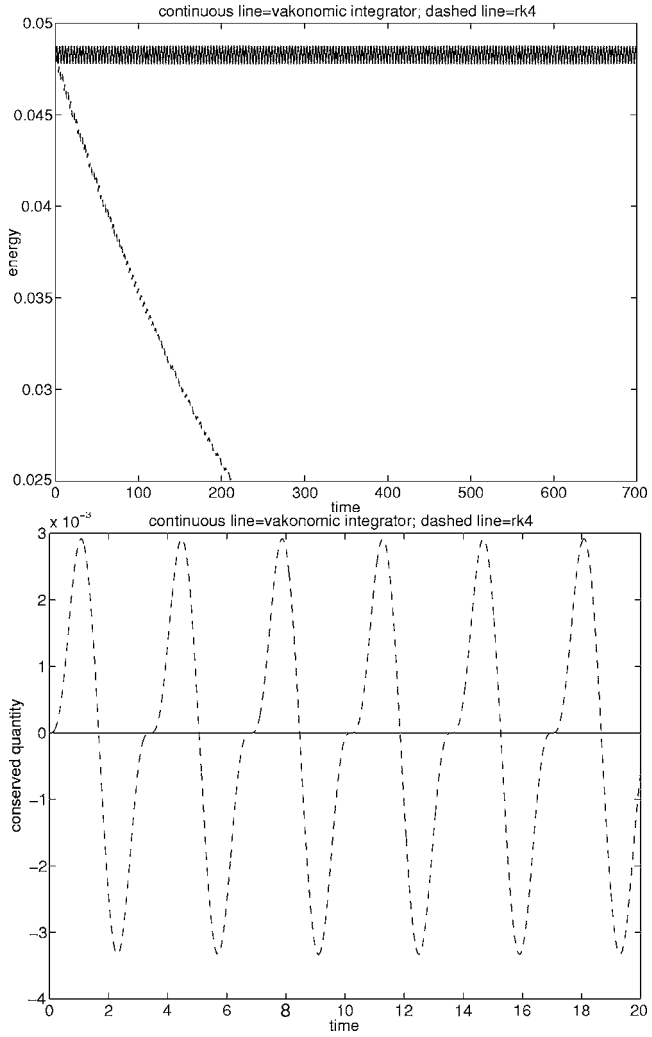

FIG. 2. Energy behavior and preservation of the discrete momentum map.

$$\begin{cases} \dot{x} = u, \\ \dot{y} = v, \\ \dot{z} = yu - xv, \\ \dot{\lambda} = \dfrac{-2\lambda(xu+yv)}{1+x^2+y^2}, \\ \dot{u} = 2\lambda v + y\left(\dfrac{-2\lambda(xu+yv)}{1+x^2+y^2}\right), \\ \dot{v} = -2\lambda u - x\left(\dfrac{-2\lambda(xu+yv)}{1+x^2+y^2}\right). \end{cases} \tag{21}$$

Then, we apply RK4 to Eq. (21) with $h=0.35$, $N=4000$ and initial conditions: $x_0=y_0=z_0=0$; $u_0=0.1$; $v_0=0.3$; $\lambda^0=1$. We also use these initial conditions, together with the (x_1,y_1,z_1) calculated by RK4, to start the vakonomic integrator (Fig. 1). Results and comparison of energies are shown in Fig. 2 (left). They show that the variational integrator behavior is much better in the long time running.

Observe that Φ^Q induces an action on $\mathbb{R}^3\times\mathbb{R}^3$:

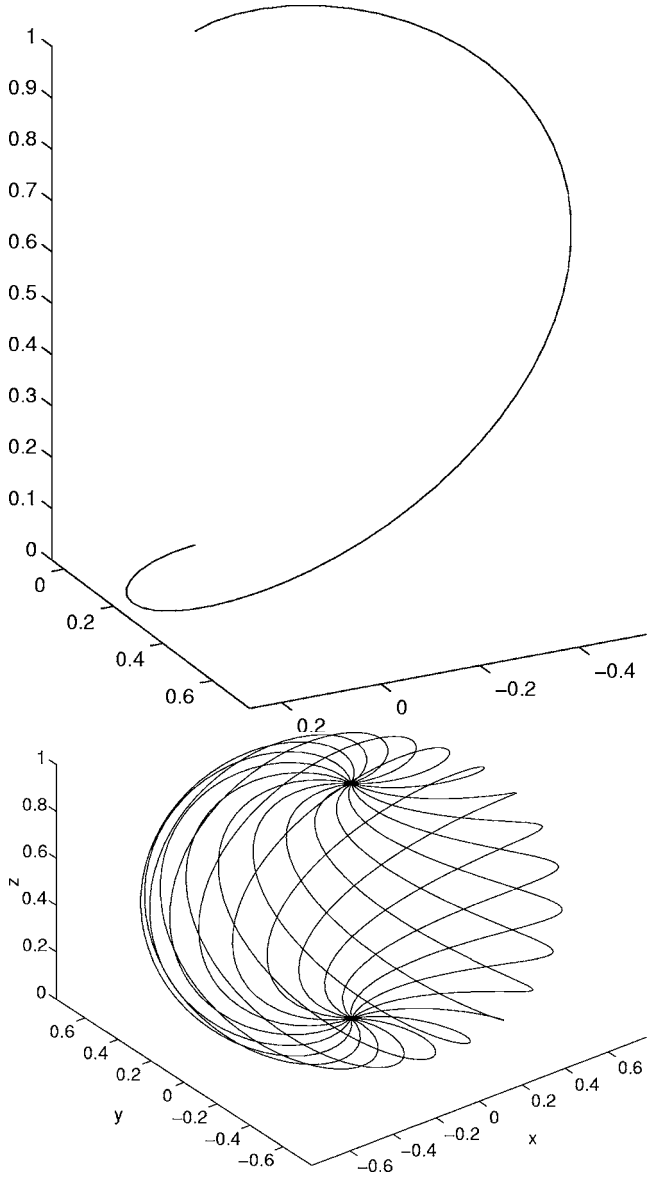

FIG. 3. Initial and final conditions.

$$\Phi_d : G \times \mathbb{R}^3 \times \mathbb{R}^3 \to \mathbb{R}^3 \times \mathbb{R}^3$$

and, being ϕ_d and L_d invariants under the action of G, the discrete momentum map J_d:

$$J_d(x_0, y_0, z_0, x_1, y_1, z_1, \lambda): \quad \to \mathbb{R}$$

$$\xi \mapsto (y_1 x_0 - x_1 y_0 + \lambda h(x_0 x_1 + y_0 y_1))\xi$$

gives us the following conserved quantity:

$$f_d = y_1 x_0 - x_1 y_0 + \lambda^0 h(x_0 x_1 + y_0 y_1).$$

Figure 2 (on the right) shows the behavior of f_d for the variational integrator and RK4, respectively. Initial conditions are the same as those for Fig. 1 while the step has been reduced to $h=0.01$ and the number of steps has been reduced to $N=2000$. It is shown that RK4 does not preserve f_d even in better conditions for its implementation.

In the case, where initial and final conditions (x_0,y_0,z_0) and (x_N,y_N,z_N) are given, we set a system of $4(N-1)$ equations taking $h=T/N$ where T is the time in which the final position is reached. Then, we solve that system by using Newton's method. Figure 3 (on the left) shows the result for the problem of connecting the origin with the point (0,0,1) with $N=50$, $T=10$. In Fig. 3 (on the right) we show some solutions after rotation using the symmetry of the problem (Refs. 10 and 22).

The Ginzburg–Landau model has met with phenomenal success in capturing the behavior of superconductors in a wide variety of settings. In particular, it has been used for many years to interpret experiments and to predict new results related to phase transitions, vortex creation and dynamics, Josephson junctions, etc. The papers in this volume cover a wide spectrum of topics of current interest in research on the Ginzburg–Landau model.

- The volume contains one review paper by Du on the numerical approximation of the Ginzburg–Landau model. In addition to finding special explicit solutions and asymptotic limits for the equations, it is useful to have solutions in general domains with general parameters. Additionally, efficient and accurate computations on the model allow one to conduct extensive numerical experimentation. Du reviews several numerical methods including finite elements, finite differences, and finite volumes.
  The rest of the volume consists of ten research papers covering a wide range of current topics in Ginzburg–Landau research.
- Alama and Bronsard study the effect of impurities on vortex formation and location for samples with large Ginzburg–Landau parameters. The impurities are modeled through a pinning term in the quartic potential appearing in the energy.
- It is well known that vortices exhibit a lattice structure in bulk samples. On the other hand, in finite samples, superconductivity concentrates near the boundary for magnetic fields just below the critical value H_{c3}. Almog's paper bridges the gap between these two regimes.
- Two of the papers in the volume deal with the time-dependent Ginzburg–Landau system. Baumann *et al.* close an important gap in the existence, uniqueness, and regularity theory for the three-dimensional time-dependent Ginzburg–Landau system by considering the interior problem coupled to the Maxwell equations on the exterior. Another intriguing problem in modeling the time-dependent problem is the nature of the boundary condition on the sample's surface. Most authors assume the supercurrent has only a tangential component at the boundary. However, a more appropriate condition seems to be that the total current (super plus normal) would have no normal component at the boundary. Berger examines this issue and derives conditions under which the supercurrent itself is indeed tangential to the boundary.
- There is considerable recent activity, both theoretical and experimental on mesoscopic superconducting samples. Because the domain size is of the same scale as the coherence length, the shape of the boundary plays a major role in the observed patterns and dynamics. One important topic is the formation and motion of vortices in such samples. Berdiyorov *et al.* study this problem in the London limit. Chibotaru *et al.* consider the phase transition curve $T(H)$ in small samples. It is known that singularites on the boundary, such as vertices in polygons, affect this curve. The authors numerically compute these phase transition curves in triangles, rectangles, and discs, and compare their results to their experimental observations.
- The Ginzburg–Landau model serves as a prototypical energy functional in several physical disciplines, in particular in liquid crystals. Berlyand and Khruslov study a variant of the Ginzburg–Landau model that incorporates small inclusions with very strong anchoring conditions. They find a canonical scaling for the model and homogenize it. Kim *et al.* exploit the

analogy between nematic liquid crystals and superconductors to predict the existence of topologically driven patterns in nematic liquid crystals. These patterns are reminiscent of persistent currents in superconductivity.

- The richness of the Ginzburg–Landau model is evidenced by an elaborate bifurcation picture controlled by several parameters in the problem. Kosugi *et al.* consider bifurcation diagrams for a one-dimensional Ginzburg–Landau model on a circle. This model serves as a paradigm for Little-Parks oscillations. The existence of a stable bifurcating branch from the normal state means that the phase transition is second order, i.e., smooth. Physically, a strong Meissner effect destabilizes the bifurcation branch and favors first-order phase transitions. Ma and Wang study the stability question and derive a general formula to determine whether or not the bifurcating branch is stable.

Pinning effects and their breakdown for a Ginzburg–Landau model with normal inclusions

Stan Alama[a] and Lia Bronsard[b]
Department of Mathematics and Statistics, McMaster University, Hamilton, Ontario, Canada L8S 4K1

(Received 22 April 2005; accepted 22 April 2005; published online 29 September 2005)

We study a Ginzburg–Landau model for an inhomogeneous superconductor in the singular limit as the Ginzburg–Landau parameter $\kappa=1/\epsilon\to\infty$. The inhomogeneity is represented by a potential term $V(\psi)=\frac{1}{4}(a(x)-|\psi|^2)^2$, with a given smooth function $a(x)$ which is assumed to become negative in finitely many smooth subdomains, the "normally included" regions. For bounded applied fields (independent of the Ginzburg–Landau parameter $\kappa=1/\epsilon\to\infty$) we show that the normal regions act as "giant vortices," acquiring large vorticity for large (fixed) applied field h_{ex}. For $h_{ex}=O(|\ln\epsilon|)$ we show that this pinning effect eventually breaks down, and free vortices begin to appear in the superconducting region where $a(x)>0$, at a point set which is determined by solving an elliptic boundary-value problem. The associated operators are strictly but not uniformly elliptic, leading to some regularity questions to be resolved near the boundaries of the normal regions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2010354]

I. INTRODUCTION

In this article we study a two-dimensional Ginzburg–Landau model for an inhomogeneous superconductor with finitely many "normal" regions in the interior. Inhomogeneous Ginzburg–Landau models have been introduced in order to understand vortex pinning (see, e.g., Ref. 8). Typically, the inhomogeneity is introduced via a potential term

$$V(\psi)=\tfrac{1}{4}(a(x)-|\psi|^2)^2,$$

with real-valued function $a(x)$. Since $a(x)\sim(T_c-T)$, its spatial variation indicates that the critical temperature may vary within the sample. One expects that vortices will be drawn to the least strongly superconducting regions, at local minima of $a(x)$, and this phenomenon is called pinning. In most studies of pinning the coefficient $a(x)$ is assumed to be strictly positive in the sample (see, e.g., Refs. 5, 2, and 11), but a recent article by André *et al.*[4] considers the interesting case where $a(x)=0$ at finitely many isolated points. These pinning points represent defects where the material assumes normal conductivity. In this paper we consider the case where $a(x)<0$ in the pinning sites, and thus model "normal inclusions," open regions of normally conducting material in the interior of the superconducting sample.

Let $\mathcal{D}\subset\mathbf{R}^2$ be a smooth simply connected domain, $\psi\in H^1(\mathcal{D};\mathbf{C})$ the complex-valued order parameter, $A\in H^1(\mathcal{D};\mathbf{R}^2)$ the vector potential, $h=\operatorname{curl}A=\partial_x A_y-\partial_y A_x$, and h_{ex} a constant applied field. We define the energy:

[a]Electronic mail: alama@mcmaster.ca
[b]Electronic mail: bronsard@mcmaster.ca

$$E_\epsilon(\psi,A) := \int_{\mathcal{D}} \left\{ \frac{1}{2}|(\nabla - iA)\psi|^2 + \frac{1}{4\epsilon^2}[(|\psi|^2 - a(x))^2 - (a^-)^2] + \frac{1}{2}(h - h_{ex})^2 \right\} \mathrm{d}x. \tag{1.1}$$

Note that subtracting $(a^-)^2$ alters the usual inhomogeneous Ginzburg–Landau energy by a constant, which would give the highest order term $O(\epsilon^{-2})$ as $\epsilon \to 0$. Note that the energy density is still nonnegative everywhere in the sample $\mathcal{D}$. We assume the following conditions on $a(x)$;

(H1) $a(x) \in C^2(\bar{\mathcal{D}})$.

(H2) $\{x \in \bar{\mathcal{D}} : a(x) \leqslant 0\} = \overline{\cup_{j=1}^n \omega_j}$, with finitely many smooth, simply connected domains $\omega_j \subset\subset \mathcal{D}$.

(H3) $\nabla a(x) \neq 0$ for all $x \in \partial\omega_j$, $j = 1, \ldots, n$.

We define

$$\Omega = \mathcal{D} \setminus \{x : a(x) \leqslant 0\} = \mathcal{D} \setminus \left(\cup_{j=1}^n \overline{\omega_j} \right).$$

Note that it follows from the above-mentioned hypotheses that $a(x)$ is bounded away from zero on the exterior boundary $\partial\mathcal{D}$. In addition, we do not allow any isolated pinning points $a(x_0) = 0$: unlike the case studied in Ref. 4, we admit only normal inclusions with nonempty interior.

It is intuitively clear that (as long as the energy of minimizers remains small compared with $1/\epsilon^2$,) in the limit the order parameter's modulus $|\psi|$ will tend to $\sqrt{a^+(x)}$ in the bulk of the sample. In other words, the sets on which $a(x) < 0$ strongly penalize superconducting order and essentially act as holes punched in the domain. Thus the situation closely resembles the problem studied in our previous article,[3] in which a uniform superconductor (i.e., $a(x) \equiv 1$) occupied a multiply connected domain $\Omega = \mathcal{D} \setminus \cup_{j=1}^n \omega_j$, with finitely many holes ω_j. In Ref. 3 we present two results for different regimes of the applied field h_{ex}. First, we show that when the applied field is fixed (independent of ϵ) there are no interior vortices in Ω but the holes ω_j act as "giant vortices," with nonzero winding of the phase of ψ for large enough h_{ex}. There is an associated limiting problem which governs the distribution of vorticity among the holes, and these degrees are directly calculable from h_{ex}.

Next we pose the question: for which h_{ex} do vortices first appear in the bulk Ω, and at which locations? We show that interior vortices appear at $h_{ex} = O(|\ln \epsilon|)$. The appearance of interior vortices for the Ginzburg–Landau model in simply connected domains for fields of order $|\ln \epsilon|$ is well-known to physicists, and the mathematics of this phenomenon has been thoroughly and elegantly studied in works by Serfaty,[18,19] Sandier and Serfaty.[15,17] In our setting (as in the multiply connected case[3]) these "free" vortices coexist with giant vortices of high degree in each hole, and the location of the free vortices is precisely determined by maximizing an auxilliary function depending only on the geometry of the multiply connected domain Ω. We show that the vortices do not cluster near the holes ω_j, but choose to accumulate on one of a finite number of points or closed curves strictly contained within the bulk Ω.

Another related problem, arising in the context of Bose–Einstein condensates (BEC) is presented in Ref. 1. In the BEC problem, the condensate is assumed to be subjected to a uniform rotation ω which plays the role of the applied field in (1.1), but the vector potential $A = \omega(-x_2, x_1)$ is predetermined. In Ref. 1 the domain $\mathcal{D}$ is a disk, and $a(x)$ is chosen to be radial with a positive in a symmetric circular annulus Ω and negative in the hole. The negativity of a forces the order parameter to zero in the hole, and the situation is qualitatively very similar to having a doubly connected domain. The results of Ref. 1 are parallel to those in Ref. 3: one concerning pinning for bounded rotations, and one concerning the breakdown of pinning when the rotation $\omega = O(|\ln \epsilon|)$. In the second result, the vortices again appear far from the hole, and accumulate along a finite number of concentric circles with radii explicitly determined by the function

$a(x)$. Some care must be taken due to the vanishing of $a(x)$ near the boundary of the hole, and in Ref. 1 the radial symmetry of the domain was used to circumvent some technical points and focus on the qualitative nature of the results.

Our results in this article combine many aspects of both papers. The general scheme to find interior vortices will be along the same lines as in the multiply connected case,[3] and the vanishing (and negativity) of $a(x)$ will play a role much as in the BEC setting.[1] However, in Ref. 1 radial symmetry was used in an essential way to deal with many difficult technical problems arising due to the vanishing of $a(x)$ near the hole. In the general nonsymmetric setting many of these arguments rely on sharp estimates for solutions to boundary-value problems for elliptic operators which are strictly elliptic, but lose uniform ellipticity at each $\partial\omega_j$. (See, e.g., (1.4) in Sec. I A). In the radial case of [Ref. 1] these are obtained explicitly by integration; here we provide some regularity results near the boundary of the holes (see Sec. III). Even with these estimates the nonsymmetric setting requires substantial refinement of the analysis of vortices near the holes from Refs. 1 and 3, and so we provide full details of this analysis in Sec. V.

Our results can also be applied to the BEC context, and we make some remarks on this connection at the end of the Introduction.

We now give some more detailed description of the content of the paper. As mentioned above, the presence of the inhomogeneity $a(x)$ creates problems near the boundaries of the pinning sites. For starters, under our hypotheses, $\sqrt{a^+(x)} \notin H^1(\Omega)$, and this results in a singular boundary layer as $\epsilon \to 0$. Fortunately, a remarkable identity (see Lassoued and Mironescu[12]) allows us to split this singular part from the rest of the energy. Define a functional,

$$J_\epsilon(\eta) := \int_{\mathcal{D}} \left\{ \frac{1}{2}|\nabla \eta|^2 + \frac{1}{4\epsilon^2}[(\eta^2 - a(x))^2 - (a^-)^2] \right\} dx,$$

and let $\eta_\epsilon \in H^1(\mathcal{D};\mathbf{R})$ be the (unique) minimizer. With $u = \psi/\eta_\epsilon$ we have

$$E_\epsilon(\psi,A) = J_\epsilon(\eta_\epsilon) + \int_{\mathcal{D}} \left\{ \frac{\eta_\epsilon^2}{2}|\nabla_A u|^2 + \frac{\eta_\epsilon^4}{4\epsilon^2}(|u|^2 - 1)^2 + \frac{1}{2}(h - h_{ex})^2 \right\} dx =: J_\epsilon(\eta_\epsilon) + F_\epsilon(u,A),$$

and the object of interest becomes the reduced energy F_ϵ. We now consider various aspects of the problem separately.

A. A limiting energy

The most important consequence of the presence of holes is that there is a rich class of "vortexless" configurations. These are obtained as critical points of the limiting energy:

$$F_\infty(u,A) := \frac{1}{2}\int_\Omega a(x)|\nabla_A u|^2 dx + \frac{1}{2}\int_{\mathcal{D}} (h - h_{ex})^2,$$

for

$$u \in H^1_a(\Omega;S^1) := \left\{ u \in W^1(\Omega;S^1) : \|u\|^2_{H^1_a} := \int_\Omega a(x)|\nabla u|^2 dx < \infty \right\}, \tag{1.2}$$

and $A \in H^1(\mathcal{D};\mathbf{R}^2)$. Although these configurations cannot have any vortices in the sense of zeros of u in Ω, nevertheless they do exhibit vorticity around the holes ω_j due to the nontrivial topology of Ω. In Sec. III we study this minimization problem as a function of the applied field h_{ex}. We show that minimizers of the limit problem are completely characterized by the magnetic field $h = \operatorname{curl} A$, much in the same way that the harmonic conjugate function is used by Bethuel *et al.*[6] to solve the S^1-harmonic map problem. We have:

Theorem 1.1: *There exists a constant E_0 (independent of h_{ex}) such that*

$$\min_{(u,A)\in\mathcal{H}_\infty} F_\infty(u,A) = h_{ex}^2 E_0 + g(D_*;h_{ex}), \tag{1.3}$$

where $D_*=[D_1,\ldots,D_n]\in\mathbf{Z}^n$ minimizes

$$g(D;h_{ex}) := \pi(\vec{D}\cdot C\vec{D} - 2h_{ex}\vec{X}\cdot\vec{D}) = \pi\sum_{i,k=1}^{n} c_{i,k}D_iD_k - 2\pi h_{ex}\sum_{i=1}^{n} c_{0,i}D_i,$$

for a uniquely determined constant matrix $C=(C_{i,k})$ and constant vector $\vec{X}=(c_{0,1},\ldots,c_{0,n})$. The minimizers (u_*,A_*) of F_∞ satisfy $|u_*|=1$ almost everywhere in Ω, and $\deg(u_*;\partial\omega_j)=D_j$ for each $j=1,\ldots,n$.

The constants $C=(c_{i,j})$ and $\vec{X}$ are explicitly calculated from solutions to elliptic boundary-value problems in $\mathcal{D}$ (see Eq. (3.14)).

The optimal magnetic field $h_*=\operatorname{curl} A_*$ is given approximately by $h_*(x)\simeq h_{ex}(1-\zeta(x))$, where $\zeta(x)$ solves

$$-\nabla\left(\frac{1}{a(x)}\nabla\zeta\right)+\zeta=1 \text{ in } \Omega,$$

$$\zeta=0 \text{ on } \partial\Omega. \tag{1.4}$$

(Lemma 3.4 gives precise statement of this fact.) An analogous function was used in Ref. 3, and has been instrumental in the study, by Serfaty,[18] of vortices in simply connected domains, where it describes the vortexless Meissner phase. In a multiply connected domain there are many such phases, and ζ chooses the one which minimizes the energy of the limit problem. In particular, we will show in Sec. III that the degrees of the holes ω_j will be determined by h_{ex} and the boundary value of $\partial\zeta/\partial\nu$ on each ω_j, giving an explicit formula for each degree.

B. Vortex pinning in bounded fields

When h_{ex} is independent of ϵ we prove the convergence result below for minimizers of E_ϵ. Since our functionals E_ϵ, F_∞ are gauge invariant we must choose spaces $\mathcal{H}$, $\mathcal{H}_\infty$ (respectively) which fix a gauge. These are defined in Sec. II.

Theorem 1.2: *Let h_{ex} be fixed, $\vec{D}_*$ as in Theorem 1.1, and let $(\psi_\epsilon,A_\epsilon)$ be minimizers of E_ϵ in $\mathcal{H}$.*

(i) $E_\epsilon(\psi_\epsilon,A_\epsilon)-J_\epsilon(\eta_\epsilon)\to\min_{\mathcal{H}_\infty}F_\infty=h_{ex}^2E_0+g(D_*;h_{ex})$ *as* $\epsilon\to 0$.

(ii) $(\psi_\epsilon/\eta_\epsilon,A_\epsilon)\to(u_*,A_*)$ *strongly in* $H^1_{loc}(\Omega)\times H^1(\mathcal{D};\mathbf{R}^2)$, *with* (u_*,A_*) *minimizers of* F_∞.

According to Theorem 1.2 we can expect minimizers to have nontrivial winding for sufficiently large but bounded (in ϵ) fields h_{ex}. This is in contrast to the simply connected case where the solution exhibits no winding until the appearance of the first vortex, at applied fields of order $|\ln\epsilon|$. In our model, the minimizers undergo a sequence of transitions to higher and higher winding number as h_{ex} increases, although the ratios of the degrees among the holes ω_j remains fixed, modulo the discontinuous constraint that the degrees must be integers. The limit functional F_∞ completely describes the system for ϵ small, and minimization of F_∞ itself is completely characterized by the finite dimensional function g.

We note that Ginzburg–Landau solutions with nontrivial winding numbers in nonsimply connected domains have been studied by several authors; see for instance Refs. 10 and 13. In these cases there was no applied field, and the solutions obtained were local minimizers of the energy within a fixed homotopy class, representing the phenomenon of "permanent currents." Here our solutions will be the *global* minimizers, and the applied field and the topology of the domain work together to choose the homotopy class of the minimizers.

C. The breakdown of pinning in stronger fields

When the applied field attains $O(|\ln \epsilon|)$ the pinning effect breaks down, and vortices are nucleated in Ω, at a field strength and location determined by ζ. For this part of the paper, we impose an additional condition on $a(x)$:

(H4) $a(x)$ is real analytic in $\mathcal{D}$.

Under (H4), the function ζ is real-analytic in Ω, and hence also ζ/a, and consequently ζ/a attains its maximum on a set Γ with finitely many connected components. Those components could consist of *isolated points* inside Ω together with *closed curves* which may wind around one or more of the pinning sites ω_j. We will show that the vortices of any minimizer must be localized to the set Γ as $\epsilon \to 0$. We distinguish two possibilities:

Case A: Γ is a finite point set.

Case B: Γ contains at least one closed curve γ.

The nature of minimizers will be different in the two cases. In Case A, the situation is analogous to that of Ref. 17, in which it is shown that if vortices can only accumulate at a finite number of points in Ω then the total degree of all vortices is uniformly bounded in ϵ. In Case B, we have shown for a similar problem in the circular annulus[1] that the number of vortices accumulating on a circle diverges as $\ln|\ln \epsilon|$. In both cases, there is coexistence of large vorticity in the pinning sites with point vortices along Γ inside Ω. We expect to see similar phenomena in our setting.

As in Refs. 1 and 3, we express our minimizers $(\psi_\epsilon, A_\epsilon)$ as perturbations of the minimizers (u_*, A_*) of the limit energy F_∞ (with the given, ϵ-dependent applied field h_{ex}.) There is a technical problem to overcome, as minimization of the limit energy defines u_* in Ω, while ψ_ϵ is defined in the entire bulk $\mathcal{D}$. This difficulty affects mostly the upper bound on the energy; for the lower bound we merely neglect the condensation energy in each pinning site, which is expected to be very small. The ansatz $\psi_\epsilon = \eta_\epsilon u_* v_\epsilon$ in Ω, $A_\epsilon = A_* + A_v$ then leads to a further splitting of the energy, giving a new functional for (v_ϵ, A_v) which measures the internal energy of vortices in Ω and their interaction with the pinning sites (see Lemma 5.1).

Let us explain here what we mean by "vortices" in this paper. We locate the vortices by means of energy concentration, using the method of "vortex balls" of Sandier and Serfaty[16] to derive sharp lower bounds on the energy. Using the result of Ref. 16 we show (see Proposition 5.2) that minimizers have $|u| \simeq 1$ except in a finite number of balls $B_i = B_{s_i}(p_i)$ with vanishingly small total radii, $\Sigma s_i \leqslant |\ln \epsilon|^{-12}$. We associate a degree $d_i = \deg(u/|u|; \partial B_i) = \deg(\psi/|\psi|; \partial B_i)$ to each ball. We say that ψ has an *essential vortex* at $p_i \in \mathcal{A}_\rho$ if there is a vortex ball B_i centered at p_i with degree $d_i \neq 0$.

As in Ref. 1, the vanishing of a near $\partial\omega_j$ blurs the distinction between vortices close to the pinning sites and the pinning sites themselves. The energy cost and benefit of having vortices very close to a pinning site ω_j is very small, and may be too small to capture with our methods. Therefore, we excise a vanishingly small neighborhood of each ω_j, and speak only of vortices which lie outside that slightly enlarged hole. Let ρ_ϵ be chosen with $(\ln|\ln \epsilon|)^2/|\ln \epsilon|^{1/2} \ll \rho_\epsilon \ll 1$, and

$$\Omega_{\rho_\epsilon} := \{x \in \Omega : \mathrm{dist}(x, \cup_{j=1}^n \partial\omega_j) > \rho_\epsilon\}.$$

We then prove the following results for global minimizers:

Theorem 1.3: *Assume hypotheses (H1)–(H4), and* $h_{ex} = \lambda|\ln \epsilon| + \mu \ln|\ln \epsilon|$. *Let* $(\psi_\epsilon, A_\epsilon)$ *be minimizers of* E_ϵ. *Then*:

(i) *if either* $\lambda < \lambda_*$ *or both* $\lambda = \lambda_*$ *and* $\mu < \mu_*$, *then for all* ϵ *sufficiently small* ψ_ϵ *has no essential vortices in* Ω_{ρ_ϵ}: $\mathbf{D}_\epsilon := \Sigma_{p_i \in \Omega_{\rho_\epsilon}} |d_i| = 0$.

(ii) *if* $\lambda = \lambda_*$ *and* $\mu > \mu_*$ *then for all* ϵ *sufficiently small, any essential vortex in* Ω_{ρ_ϵ} *has positive degree and is localized on the set* Γ *in the following sense: there exists an* $M \in \mathbf{N}$ *such that if* p_i *are the centers of the vortex balls* B_i,

$$\sum_{\substack{d_i<0\\ p_i\in\Omega_{\rho_\epsilon}}} |d_i| + \sum_{\substack{\mathrm{dist}(p_i,\mathcal{C})>\\ [\ln\epsilon]^{-1/4M}\\ p_i\in\Omega_{\rho_\epsilon}}} |d_i| = 0$$

for all ϵ sufficiently small. Moreover, the total degree in Ω,

$$\mathbf{D}_\epsilon = \sum_{p_i\in\Omega_{\rho_\epsilon}} |d_i| = \sum_{\substack{\mathrm{dist}(p_i,\mathcal{C})<\\ [\ln\epsilon]^{-1/4M}\\ p_i\in\Omega_{\rho_\epsilon}}} d_i \leqslant \begin{cases} C & \text{in Case A,} \\ C\ln|\ln\epsilon| & \text{in Case B.} \end{cases}$$

for $C=C(\mu)$ independent of ϵ.

(iii) *in Case B, there exists $\mu_\#>0$ so that whenever $\mu\geqslant\mu_\#$ and $\lambda=\lambda_*$, then $\mathbf{D}_\epsilon\geqslant c\ln|\ln\epsilon|$ for c independent of ϵ.*

(iv) *if γ is any simple closed curve in Ω, homotopic to $\partial\omega_j$ for some $j\in\{1,\ldots,n\}$, which does not wind around any subset of Γ, then for all ϵ sufficiently small* $\deg(\psi/|\psi|;\gamma)=D_j+O(\ln|\ln\epsilon|)$, *where D_j is as in Theorem 1.1.*

We emphasize that, as in Ref. 1, these vortices will *not* cluster around the holes, but rather choose fixed optimal locations strictly inside the superconducting bulk Ω. This is why we call this phenomenon the "breakdown of pinning." The key to proving this property is a boundary estimate on the function ζ at each pinning site: in a neighborhood of each ω_j, we prove $0<\zeta(x)\leqslant C\rho^2(x)\ln|\ln\rho(x)|$ where $\rho(x):=\min_j\mathrm{dist}(x,\partial\omega_j)$. Since (by (H3)) $a(x)$ is linear near each $\partial\omega_j$, the maximum of $2\zeta/a$ must therefore occur away from ω_j.

D. Bose–Einstein condensates

As was mentioned previously, we may also apply our analysis to study Bose–Einstein condensates with anharmonic traps which favor multiply connected regions. The variational problem takes the form

$$H_\epsilon(u)=\int_{\mathcal{D}}\left\{\frac{1}{2}|\nabla u|^2-\tau x^\perp\cdot\mathrm{Im}\,(\bar{u}\,\nabla\,u)+\frac{1}{4\epsilon^2}[(|u|^2-a(x))^2-(a^-(x))^2]\right\}\mathrm{d}x, \tag{1.5}$$

for a complex-valued wave function $u\in H_0^1(\mathcal{D})$, where $\epsilon>0$ and τ represents an imposed angular speed of rotation. A discussion of the origins of this model is presented in Ref. 1. The function $a(x)$ now represents the trapping potential, modeling the laser confinement of BEC in laboratory conditions. In early experiments on BEC the trapping was assumed to be harmonic, giving an ellipsoidal form to the condensate domain, $\{x:a(x)>0\}$. In more recent experiments other confinement geometries have been considered, including the annular shape studied in Ref. 1. If we impose hypotheses on $a(x)$,

(H1′) $a(x)\in C^\infty(\mathcal{D})$, and $a(x)=0$ on $\partial\mathcal{D}$;

(H2′) $\{x\in\mathcal{D}:a(x)\leqslant 0\}$
$=\overline{\cup_{j=1}^n\omega_j}$, with finitely many smooth, simply connected domains $\omega_j\subset\subset\mathcal{D}$;

(H3′) $\nabla a(x) \neq 0$ for all $x \in \partial\omega_j, j = 1,\ldots,n$ and for all $x \in \partial\mathcal{D}$;

(H4′) $\int_{\mathcal{D}} a^+(x)dx = 1$;

we may obtain results for H_ϵ which are analogous to those above, but with the imposed rotation τ playing the role of the applied field h_{ex}. Aside from the difference in boundary condition on $\partial\mathcal{D}$, the major difference is that the magnetic field is replaced by the fixed vector field, $\tau x^\perp$ which models the rotation. The consequence of this is that the limiting problem is slightly different, although it is still of a similar type and susceptible to the same solution method. (See the end of Sec. III.) The results for BEC will be the same as those of superconductivity, but with the presence of an additional boundary layer near the exterior boundary $\partial\mathcal{D}$, where we also lose control of the number and location of individual vortices due to the vanishing of $a(x)$.

II. PRELIMINARIES

In this section, we present some preliminary results which we will require throughout the paper.

A. Spaces, gauges, and equations

We define here the appropriate spaces and write down the Euler–Lagrange equations for minimizers.

The energy functional E_ϵ is gauge-invariant: if $\varphi \in H^2(\mathcal{D};\mathbf{R})$ is any scalar potential, then $E_\epsilon(\psi\exp[i\varphi], A+\nabla\varphi) = E_\epsilon(\psi, A)$. As usual we restrict our spaces to eliminate this degeneracy by fixing the Coulomb gauge. We say $(\psi, A) \in \mathcal{H}$ if $\psi \in H^1(\mathcal{D};\mathbf{C})$ and $A \in H^1(\mathcal{D};\mathbf{R}^2)$ with

$$\operatorname{div} A = 0 \text{ in } \mathcal{D}, \quad A \cdot \nu = 0 \text{ on } \partial\mathcal{D}. \tag{2.1}$$

This choice is made with no loss of generality, as to any arbitrary configuration $(\psi, A) \in H^1(\Omega;\mathbf{C}) \times H^1(\mathcal{D};\mathbf{R}^2)$ we may find a function φ so that the gauge-equivalent configuration $(\psi\exp[i\varphi], A+\nabla\varphi) \in \mathcal{H}$ with the same energy. Indeed, we can choose φ to be a solution (unique up to an additive constant) of

$$\Delta\varphi = -\operatorname{div} A \text{ in } \mathcal{D}, \qquad \left.\frac{\partial\varphi}{\partial\nu}\right|_{\partial\mathcal{D}} = A \cdot \nu|_{\partial\mathcal{D}}.$$

We also recall that the magnetic field $h(x) \in L^2(\mathcal{D})$ uniquely determines its vector potential A in the Coulomb gauge. To see this, we solve the Dirichlet problem,

$$\Delta b = h \text{ in } \mathcal{D}, \quad b|_{\partial\mathcal{D}} = 0, \tag{2.2}$$

and then $A = \nabla^\perp b = (-\partial_y b, \partial_x b)$ gives the desired potential. We obtain from this the main analytical advantage of the Coulomb gauge, control of the potential by the L^2 norm of its field: there exists a constant $C_\mathcal{D}$ (depending only on $\mathcal{D}$) such that

$$\|A\|_{H^1(\mathcal{D})} \leqslant C_\mathcal{D}\|h\|_{L^2(\mathcal{D})}. \tag{2.3}$$

The estimate (2.3) follows from the regularity theory for the Dirichlet problem mentioned previously.

Minimizers of E_ϵ satisfy the Ginzburg–Landau system in Ω,

$$-\nabla_A^2\psi + \frac{1}{\epsilon^2}(|\psi|^2 - a(x))\psi = 0 \text{ in } \mathcal{D}, \tag{2.4}$$

$$-\nabla^\perp h = \vec{j} := \operatorname{Im}\{\bar{\psi}(\nabla - iA)\psi\} \text{ in } \mathcal{D}, \tag{2.5}$$

$$h = h_{ex} \text{ on } \partial\mathcal{D}. \tag{2.6}$$

Here we denote $\nabla_A\psi := \nabla\psi - iA\psi$. There is also a boundary condition $\nabla_A\psi\cdot\nu = 0$ on $\partial\mathcal{D}$. From Lemma 1.1 of [4] we have the basic estimate

$$|\psi(x)| \leqslant \sup_{\mathcal{D}}\sqrt{a^+(x)}, \quad \forall\ x \in \Omega, \tag{2.7}$$

where $a^+(x) = \max\{a(x), 0\}$. This is a consequence of the maximum principle applied to the equation for $|\psi|^2$.

B. Decoupling the density profile

As $\epsilon \to 0$ we expect that the potential term in the energy E_ϵ will force $|\psi|^2 \to a^+(x)$. The hypotheses on $a(x)$ do not allow $\sqrt{a^+} \in H^1(\mathcal{D})$, and so this creates a singular boundary layer near the zero set of a. Here we study this boundary layer, so that it can be effectively removed from our energy calculations in the following sections.

Define a functional,

$$J_\epsilon(\eta) := \int_{\mathcal{D}} \left\{ \frac{1}{2}|\nabla\eta|^2 + \frac{1}{4\epsilon^2}[(\eta^2 - a(x))^2 - (a^-)^2] \right\} dx, \tag{2.8}$$

for real-valued functions $\eta \in H^1(\mathcal{D}; \mathbf{R})$. Critical points of J_ϵ solve the boundary-value problem

$$-\Delta\eta + \frac{1}{\epsilon^2}(\eta^2 - a(x))\eta = 0, \text{ in } \mathcal{D}, \quad \frac{\partial\eta}{\partial\nu} = 0, \text{ on } \partial\mathcal{D}. \tag{2.9}$$

Proposition 2.1: Problem (2.9) *admits a unique positive solution* η_ϵ*, which is the unique minimizer of* J_ϵ *in* $H_0^1(\mathcal{D})$ *up to a complex multiplier of modulus one. In addition,*

(i) $0 < \eta_\epsilon(x) \leqslant \max_{\mathcal{D}} a$, *and* $|\nabla\eta_\epsilon| \leqslant C/\epsilon$;

(ii) $J_\epsilon(\eta_\epsilon) \leqslant C|\ln\epsilon|$ *and* η_ϵ *is bounded in* $L^\infty(\Omega)$;

(iii) *There exists a constant* C *independent of* ϵ *so that*

$$|\eta_\epsilon(x) - \sqrt{a^+(x)}| \leqslant C\epsilon^{1/3}\sqrt{a^+(x)} \text{ for every } x \in \Omega \text{ with } \operatorname{dist}(x, \partial\Omega) \geqslant \epsilon^{1/3}; \tag{2.10}$$

(iv) *For every* $j = 1, \ldots, n$ *and* $x \in \omega_j$ *with* $\operatorname{dist}(x, \partial\omega_j) \geqslant \epsilon^{1/3}$,

$$0 < \eta_\epsilon(x) \leqslant C\epsilon^{1/6}\exp[-\operatorname{dist}(x, \partial\omega_j)/\epsilon^{2/3}], \tag{2.11}$$

where $C > 0$ *is a constant independent of* ϵ.

In particular, (iv) implies that $\eta_\epsilon \to 0$ locally uniformly in the holes ω_j. The assertion (iv) implies that $|\eta_\epsilon^2(x) - a^+(x)|$ is small with respect to $a^+(x)$ itself provided we remain at a small distance ($\epsilon^{1/3}$) from the boundary of each $\partial\omega_j$.

The proof of Proposition 2.1 is identical to that of Proposition 2.1 of Ref. 1. In addition we have the result of Proposition 2.3 of Ref. 1 which implies that the negativity of $a(x)$ in the normal regions ω_j acts more or less like an imposed Dirichlet condition:

Proposition 2.2: Assume $h_{ex} \leqslant C_0|\ln\epsilon|$ *for some constant* $C_0 > 0$. *Then, for any minimizer* (ψ, A) *of* E_ϵ *in* $\mathbf{H}$,

$$\int_\Omega (|\psi|^2 - a)^2 + \int_{\cup\omega_j} |\psi|^4 \leqslant C_1\epsilon^2|\ln\epsilon|^2, \tag{2.12}$$

with constant C_1 *depending on* C_0. *Moreover,* $|\psi(x)| \to 0$ *locally uniformly in* $\cup_j \omega_j$ *and*

$$|\psi(x)| \leqslant C\epsilon^{1/6}\exp[-\operatorname{dist}(x,\partial\omega_j)/\epsilon^{2/3}] \tag{2.13}$$

for all $x \in \omega_j$ *with* $\operatorname{dist}(x,\partial\omega_j) \geqslant \epsilon^{1/3}$ *and* $j=1,\ldots,n$.

Again the proof is identical to that in Ref. 1 and is omitted.

We now apply the remarkable observation (see Ref. 12) that the energy of the profile η_ϵ and the remaining complex order parameter $v=u/\eta_\epsilon$ decouple exactly into two independent pieces.

Lemma 2.3: Let $(\psi,A) \in \mathbf{H}$. *Then,* $u=\psi/\eta_\epsilon$ *is well defined, belongs to* $H^1_{\eta_\epsilon^2}$ *(defined in (1.2),) and*

$$E_\epsilon(\psi,A) = J_\epsilon(\eta_\epsilon) + F_\epsilon(u,A) \tag{2.14}$$

where

$$F_\epsilon(u,A) = \int_{\mathcal{D}} \left\{ \frac{\eta_\epsilon^2}{2}|\nabla_A u|^2 + \frac{\eta_\epsilon^4}{4\epsilon^2}(|u|^2-1)^2 + \frac{1}{2}(h-h_{ex})^2 \right\} \mathrm{d}x. \tag{2.15}$$

Proof: Note that v is well defined in $\mathcal{D}$, since $\eta_\epsilon > 0$. The decomposition and the fact that $v \in H^1_{\eta_\epsilon}(\mathcal{D})$ follow exactly as in Serfaty.[20] □

III. THE LIMIT PROBLEM

In this section we consider a limiting energy F_∞, which represents in a formal sense the limit of F_ϵ as $\epsilon \to 0$. Indeed, heuristically we expect that in this limit, $|u| \to 1$ in Ω, but $\eta_\epsilon \to 0$ exponentially fast in each ω_j (by Lemma 2.2), and thus the contribution of the order parameter to the energy from the pinning sites is negligible. Thus, we define:

$$F_\infty(u,A) := \frac{1}{2}\int_\Omega a(x)|\nabla_A u|^2 dx + \frac{1}{2}\int_{\mathcal{D}} (h-h_{ex})^2, \tag{3.1}$$

for

$$u \in H^1_a(\Omega;S^1) := \left\{ u \in W^1(\Omega;S^1) : \|u\|^2_{H^1_a} := \int_\Omega a(x)|\nabla u|^2 dx < \infty \right\},$$

and $A \in H^1(\mathcal{D};\mathbf{R}^2)$. As in the previous part, we refine our space to fix a gauge, and denote by $\mathcal{H}_\infty$ the subspace of $H^1_a(\Omega;S^1)\times H^1(\mathcal{D};\mathbf{R}^2)$ such that A satisfies (2.1). The same remarks concerning the gauges and spaces as above then apply, since the gauge changes affect only the complex phase of u and not its magnitude.

Note the essential differences with the original problem: now the order parameter is only defined in the region $\Omega=\mathcal{D}\backslash\{x : a(x) \leqslant 0\}$, although the magnetic field is calculated everywhere in $\mathcal{D}$. Thus the limit problem strongly resembles the problem in multiply connected domains studied in Ref. 3, although we must now deal with some delicate regularity issues near $\partial\omega_j$, where $a(x)$ vanishes.

The Euler–Langrange equations for the limit problem are

$$-\nabla_A \cdot (a(x)\nabla_A u) = |\nabla_A u|^2 u, \text{ in } \Omega; \tag{3.2}$$

$$-\nabla^\perp h = \vec{j} := a(x)\operatorname{Im}\{\bar{u}\nabla_A u\} \text{ in } \Omega; \tag{3.3}$$

$$h = H_j \text{ (constant) in each } \omega_j, \quad j = 1, \ldots, n; \tag{3.4}$$

$$h = h_{ex} \text{ on } \partial\mathcal{D}. \tag{3.5}$$

There is also a boundary condition, $a(x)\nabla_A u \cdot \nu = 0$, on the exterior boundary $\partial\mathcal{D}$. Note that the constants $H_j = h|_{\omega_j}$ are not prescribed, but are determined by the solution h itself.

Since $|u| = 1$ we may then write locally $u = e^{i\phi}$ for real phase ϕ, and it is then easy to derive from (3.3) the following London equation for $h = \operatorname{curl} A$,

$$-\operatorname{div}\left(\frac{1}{a(x)}\nabla h\right) + h = 0 \text{ in } \Omega. \tag{3.6}$$

This equation is then supplemented by the boundary conditions (3.4) and (3.5). There is an important additional condition on each $\partial\omega_j$, obtained from integrating equation (3.3) around each $\partial\omega_j$ separately:

$$\begin{aligned}\int_{\partial\omega_j} \frac{1}{a}\frac{\partial h}{\partial \nu}\mathrm{d}s &= \int_{\partial\omega_j} \frac{1}{a}\nabla^{\perp} h \cdot \tau \,\mathrm{d}s = -\int_{\partial\omega_j} \mathrm{Im}\{\bar{u}\,\nabla u\} \cdot \tau \, ds + \int_{\partial\omega_j} A \cdot \tau \,\mathrm{d}s \\ &= -2\pi \deg(u, \partial\omega_j) + \int_{\omega_j} h \,\mathrm{d}x = -2\pi \deg(u, \partial\omega_j) + H_j|\omega_j|. \end{aligned} \tag{3.7}$$

Because $|u| = 1$ we may express $|\nabla_A u|^2 = |\nabla\phi - A|^2 = |\vec{j}|^2$ and thus the limiting energy of a minimizer (u, A) may be expressed entirely in terms of the field $h = \operatorname{curl} A$,

$$\min F_\infty(u, A) = \frac{1}{2}\int_\Omega \frac{1}{a(x)}|\nabla h|^2 \mathrm{d}x + \frac{1}{2}\int_{\mathcal{D}} (h - h_{ex})^2 \mathrm{d}x =: E_*(h). \tag{3.8}$$

This characterization of the minimum energy will be especially useful, as it will allow us later on to evaluate the energy explicitly in terms of the degrees around each pinning site.

Our analysis of the limit problem follows[3] in the large. The main difference is that the equations here involve the operator,

$$\mathcal{L}h = -\operatorname{div}\left(\frac{1}{a(x)}\nabla h\right) + h,$$

which is strictly, but not uniformly, elliptic, due to the vanishing of $a(x)$ at the boundary of each pinning site ω_j. As in Ref. 3, we may decompose the magnetic field in order to calculate the contribution from each giant vortex in each pinning site, as well as the contribution to h from the external field. Let $\xi_i(x)$, $i = 0, \ldots, n$ solve

$$\mathcal{L}\xi_i = \delta_{i,0} \text{ in } \Omega,$$

$$\xi_i = 0 \text{ on } \partial\mathcal{D},$$

$$\xi_i = c_{i,j} \text{ on } \omega_j, \quad j = 1, \ldots, n,$$

$$\int_{\partial\omega_j} \frac{1}{a}\frac{\partial \xi_i}{\partial \nu} = -2\pi\delta_{i,j} + c_{i,j}|\omega_j|, \quad j = 1, \ldots, n. \tag{3.9}$$

Here, $c_{i,j}$, $i = 0, \ldots, n$, $j = 1, \ldots, n$ are *constants* determined by the solutions $\xi_i(x)$, and we emphasize that $\delta_{i,j}$ denotes the Kronecker (and not the Dirac) delta. Then the desired field h is given in terms of these via:

$$h = h_{ex}(1 - \xi_0) + \sum_{i=1}^{n} D_i \xi_i, \tag{3.10}$$

where $D_i = \deg(u, \partial\omega_i)$ for the order parameter u associated to h via (3.3). The existence and uniqueness of the components ξ_i follows from a variational problem as in Ref. 6. The regularity is complicated by the fact that uniform ellipticity is lost at the inner boundaries $\partial\omega_j$, but the necessary estimates follow by constructing barriers, blowing up near the boundary, and a modification of the method of Trudinger.[21]

Lemma 3.1: There exist unique constants $\{c_{i,j}\}_{j=1,\ldots,n}^{i=0,\ldots,n}$, *and unique weak solutions* $\xi_0, \ldots, \xi_n$ *to* (3.9). *Moreover*,

(i) *each* $\xi_i \in C^\infty(\mathcal{D}\backslash\overline{\cup_j \omega_j}) \cap C^1(\overline{\mathcal{D}\backslash\cup_j \omega_j})$, $i = 1, \ldots, n$;
(ii) *each* $\xi_i(x) > 0$ *for all* $x \in \Omega$, $i = 0, \ldots, n$;
(iii) *for all* $i = 0, \ldots, n$ *there exists constants* $C > 0$, $\delta_0 > 0$ *so that for every* $j = 1, \ldots, n$ *and for all* x *with* $\rho(x) := \operatorname{dist}(x, \cup_j \partial\omega_j) < \delta_0$,

$$|\xi_i(x) - c_{i,j}| \leqslant C(\rho(x))^2 \ln|\ln \rho(x)| \tag{3.11}$$

$$|\nabla \xi_i(x)| \leqslant C\rho(x) \ln|\ln \rho(x)|. \tag{3.12}$$

Note in particular that (ii) implies that the constant values $c_{i,j} = \xi_i|_{\omega_j} \geqslant 0$. To maintain continuity of presentation we defer the proof of Lemma 3.1 to the end of this section.

As in Lemma 2.2 of Ref. 3, the minimum energy is then expressed in terms of the degrees D_j at each pinning site ω_j and the external field (see also Theorem 3.4 of Ref. 4):

Lemma 3.2: *Let* (u_*, A_*) *minimize* F_∞ *in* $\mathcal{H}$ *and* $h_* = \operatorname{curl} A_*$. *Then*,

$$\min F_\infty = E_*(h_*) = h_{ex}^2 \epsilon_0 + \pi \sum_{i,k=1}^{n} c_{i,k} D_i D_k - 2\pi h_{ex} \sum_{i=1}^{n} c_{0,i} D_i, \tag{3.13}$$

where

$$\epsilon_0 := \frac{1}{2} \int_\Omega \frac{1}{a} |\nabla \xi_0|^2 + \frac{1}{2} \int_{\mathcal{D}} \xi_0^2.$$

Proof: The proof is identical to that of Ref. 3, but we sketch it for completeness. We write $h_* - h_{ex} = -h_{ex}\xi_0 + \Sigma_{i=1}^n D_i \xi_i$ and expand the squares. The constants are obtained by integration by parts, together with (3.9):

$$\int_\Omega \frac{1}{a} \nabla \xi_i \cdot \nabla \xi_k + \int_{\mathcal{D}} \xi_i \xi_k = -\sum_{j=1}^{n} \int_{\partial\omega_j} \frac{1}{a} \frac{\partial \xi_i}{\partial \nu} \xi_k ds + \int_{\cup_j \omega_j} \xi_i \xi_k = 2\pi c_{i,k}. \tag{3.14}$$

□

As in Lemma 2.4 of Ref. 3 (see also Lemma 3.3 of Ref. 4), we have the following.

Lemma 3.3: The matrix $C = (c_{i,k})_{i,k=1,\ldots,n}$ *is positive definite. In particular, it is invertible and its inverse* C^{-1} *is a symmetric positive definite matrix.*

The proof is identical to that of Lemma 2.4 of Ref. 3 and is omitted.

The importance of the preceding analysis is that it enables us to write down *explicitly* the map from the applied field h_{ex} to the degrees $\vec{D}$ of minimizers, just by solving a finite dimensional minimization problem for the quadratic expression given in Lemma 3.2. Indeed, the critical point equation for $\vec{D}$ is easily calculated,

$$\vec{D} = h_{ex} C^{-1} X,$$

$$\text{where } X = (c_{0,1}, \ldots, c_{0,n}). \tag{3.15}$$

Here (as in Ref. 3) we raise a subtle point: in order to represent the magnetic field of actual minimizers of F_∞ it is necessary that the degrees D_j be *integers*. Therefore we must restrict our minimization of the quadratic expression in Lemma 3.2 to $\vec{D} \in \mathbf{Z}^n$, and then the minimizer is given by

$$D_i = \left[\!\!\left[h_{ex} \sum_{k=1}^{n} c_{i,k}^{-1} c_{0,k} \right]\!\!\right], \tag{3.16}$$

the nearest integer to what would normally be the minimizing vector. Here we denote $C^{-1} = (c_{i,k}^{-1})$.

We now present the *proof of Theorem 1.1*. Let $\vec{D}$ be chosen as in (3.16), to minimize (3.13). By the representation (3.10) we then recover a magnetic field h_*, which satisfies (3.7) at each boundary component. We then obtain A_* from h_* with the usual Coulomb gauge by solving the Dirichlet problem (2.2) described in Sec. II. To recover the order parameter u_*, we use the Maxwell equation, (3.3). Since the vector field $A_* - (1/a)\nabla^\perp h_*$ is irrotational in Ω by (3.6), we may define locally a real phase ϕ_* via

$$\nabla \phi_* = A_* - \frac{1}{a} \nabla^\perp h_*. \tag{3.17}$$

In fact, $u_* = \exp(i\phi_*)$ is a well-defined, single-valued function in Ω, since (3.7) implies:

$$\int_{\partial \omega_j} \nabla \phi_* \cdot \tau \, ds = \int_{\partial \omega_j} \left(A_* \cdot \tau - \frac{1}{a} \nabla h_* \cdot \nu \right) ds = 2\pi D_j \in \mathbf{Z}.$$

We thus obtain a configuration $(u_*, A_*) \in \mathcal{H}_\infty$ with $F_\infty(u_*, A_*) = E_*(h_*) = \min_{\vec{D} \in \mathbf{Z}^n} g(\vec{D}; h_{ex})$. By Lemma 3.2, this identifies the minimizer of F_∞, and Theorem 1.1 is proven. □

Despite the above-mentioned remarks concerning the degrees, it will nevertheless be convenient in the following analysis to permit the optimal degrees to be real valued, that is to use (3.15) to define a real vector $\vec{T} \in \mathbf{R}^n$, and to replace $\vec{D} \to \vec{T}$ in (3.10). In this case, the minimizer scales exactly linearly with h_{ex}, and so we define $\vec{T} = (t_1, \ldots, t_n)$ with

$$t_i = \sum_{k=1}^{n} c_{i,k}^{-1} c_{0,k} = (C^{-1} X)_i,$$

which exactly solves the minimization problem of Lemma 3.2 for $\vec{T} \in \mathbf{R}^n$, when $h_{ex} = 1$. The associated applied field $h_1(x) = 1 - \zeta(x)$, with ζ defined by

$$\zeta(x) = \xi_0(x) - \sum_{i=1}^{n} t_i \xi_i(x).$$

Using the equations for ξ_i and for $\vec{T}$ mentioned previously, we observe that $\zeta(x)$ solves:

$$\mathcal{L}\zeta = 1 \text{ in } \Omega,$$

$$\zeta = 0 \text{ on } \partial\mathcal{D} \cup (\overline{\cup_j \omega_j}),$$

$$\int_{\partial\omega_j} \frac{1}{a}\frac{\partial\zeta}{\partial\nu} = 2\pi t_j - |\omega_j|. \tag{3.18}$$

Of course, the first two conditions of (3.18) suffice to determine ζ exactly, and so the third line can be seen as an equivalent definition of the coefficients t_j.

In the case that the solution of the vector equation $C\vec{D}=X$ happens to be a vector of integers (an unlikely coincidence), then the energy minimizing field $h_*=h_{ex}h_1=h_{ex}(1-\zeta)$ exactly. Generically, the two do not differ by much:

Lemma 3.4: There exists a constant C_1 independent of h_{ex} such that if h_* is the magnetic field associated to the minimizers (u_*,A_*) of F_∞ with $h=h_{ex}$, then

$$\max_{\bar{\mathcal{D}}} |h_* - h_{ex}(1-\zeta)| \leqslant C_1.$$

Proof:

$$|h_* - h_{ex}(1-\zeta)| = \left| \sum_{i=1}^{n} (D_i - h_{ex}t_i)\xi_i \right| \leqslant \sum_{i=1}^{N} |D_i - h_{ex}t_i|\xi_i,$$

which is uniformly bounded (independent of h_{ex}) since $D_i=[\![h_{ex}t_i]\!]$ implies $|D_i-h_{ex}t_i|\leqslant 1$, and the ξ_i are uniformly bounded. □

Remark 3.5: Notice that the result of Lemma 3.4 could have been stated in any "reasonable" norm, that is in any norm for which each ξ_i is bounded.

Proof of Lemma 3.1: First we define an appropriate space of functions which take constant values on each ω_j. Adapting the definition in Ref. 21 to our setting, we define $\mathbf{H}$ to be the closure in the norm

$$\|f\|_{\mathbf{H}}^2 := \int_\Omega \frac{1}{a(x)}|\nabla f|^2,$$

of the linear subspace of $C_0^\infty(\mathcal{D})$ consisting of all functions which are constant in a neighborhood of ω_j for each $j=1,\ldots,n$. Since $1/a(x)$ is locally integrable in Ω, this definition is well-defined and $\mathbf{H}$ defines a Hilbert Space. As $a(x)$ is bounded above in Ω, the $\mathbf{H}$-norm dominates the usual H_0^1-norm on $\mathcal{D}$, and so the Poincaré, trace, and Sobolev inequalities hold for functions in $\mathbf{H}$.

To obtain the desired solutions we minimize the energy

$$F_i(\varphi) = \frac{1}{2}\int_\Omega \left[\frac{1}{a}|\nabla\varphi|^2 - \delta_{i0}\varphi\right] + \frac{1}{2}\int_{\mathcal{D}} \varphi^2 - 2\pi(1-\delta_{i0})\varphi\big|_{\omega_i},$$

$i=0,\ldots,n$, for $\varphi\in\mathbf{H}$. By the Poincaré inequality and the trace inequalities, F_i is bounded below on $\mathbf{H}$, and by convexity it attains a unique minimizer ξ_i. A simple computation shows that minimizers give weak solutions to the boundary-value problem (3.9). Indeed, the first variation yields,

$$0 = DF_i(\xi_i)u = \int_\Omega \left[\frac{1}{a} \nabla \xi_i \cdot \nabla u - \delta_{i0} u \right] + \int_{\mathcal{D}} \xi_i u - 2\pi(1-\delta_{i0})u\big|_{\omega_i}$$

$$= \int_\Omega \left[\frac{1}{a} \nabla \xi_i \cdot \nabla u + \xi_i u - \delta_{i0} u \right] + \sum_{j=1}^{n} \left(|\omega_j| \xi_i\big|_{\omega_j} - 2\pi\delta_{ij} \right) u\big|_{\omega_j}, \tag{3.19}$$

for all $u \in \mathbf{H}$. The equation and boundary conditions then follow from choosing u with values either zero or one in the appropriate domains ω_j. Since the coeffient $1/a$ is smooth away from $\cup_j \omega_j$ we have each ξ_i smooth in the interior by standard regularity theory.

As in Ref. 21, the weak maximum principle holds for this equation, since it is nevertheless strictly elliptic in Ω. Taking $u(x) = \xi_i^-(x) = \min\{0, \xi_i(x)\} \leqslant 0$, we have $u \in \mathbf{H}$ and inserting in (3.19) we obtain $\|\xi_i^-\|_{\mathbf{H}} = 0$, that is $\xi_i \geqslant 0$.

Finally, for the global and boundary regularity we require some results from Ref. 21. By Case I of Theorem 4.1 of Ref. 21 the solutions are uniformly bounded. To obtain the boundary behavior (3.11) and (3.12) near $\partial\omega_j$, we construct barriers. Let $\xi(x) = a(x)^2 \ln|\ln a(x)|$. We calculate:

$$\mathcal{L}\xi = \left(\frac{2}{|\ln a(x)|} + \frac{1}{(\ln a(x))^2} \right) \frac{|\nabla a|^2}{a} - \left(2\ln|\ln a| + \frac{1}{\ln a} \right) \Delta a + a(x)^2 \ln|\ln a(x)|.$$

By hypothesis (H3), $a(x) \simeq \alpha_0 \rho(x)$ for x in a neighborhood of $\partial\omega_j$, for each $j = 1, \ldots, n$. In particular, $|\nabla a|$ is bounded away from zero in a neighborhood of each $\partial\omega_j$, and hence the first term on the right-hand side is dominant and tends to $+\infty$ as $\delta(x) \to 0$. Therefore, there exists $\delta_0 > 0$ such that $\mathcal{L}\xi > 1$ for all x with $\rho(x) < \delta_0$.

Now let $\bar{\xi}_{i,j}(x) := c_{i,j} + b_{i,j} a(x)^2 \ln|\ln a(x)|$, with positive constants $b_{i,j} \geqslant 1$. Then $\mathcal{L}\bar{\xi}_{i,j}(x) > c_{i,j} + b_{i,j} \geqslant \delta_{i,j}$ for $\rho(x) < \delta_0$, and so $\bar{\xi}_{i,j}$ is a supersolution in each connected component of $\mathcal{N}_{\delta_0} := \{x \in \Omega : \rho(x) < \delta_0\}$. Note that $\bar{\xi}_{i,j}|_{\partial\omega_j} = c_{i,j} = \xi_i|_{\partial\omega_j}$. Since each $\xi_i(x)$ is uniformly bounded in Ω, we can choose the constants $b_{i,j}$ large enough such that $\bar{\xi}_{i,j} \geqslant \xi_i$ on $\partial\mathcal{N}_{\delta_0} \cap \Omega$. Applying the weak maximum principle in each component of $\mathcal{N}_{\delta_0}$ we conclude that $\xi_i(x) \leqslant \bar{\xi}_{i,j}(x)$ in each component of $\mathcal{N}_{\delta_0}$. The complementary lower bound may be obtained using the subsolution $\underline{\xi}_{i,j} = c_{i,j} - \tilde{b}_{i,j} a(x)^2 \ln|\ln a(x)|$ for constants $\tilde{b}_{i,j}$ appropriately large. This proves (3.11).

To prove (3.12), we use a blow-up argument. Let $x_0 \in \Omega$, and $\delta > 0$ with dist $(x_0, \partial\omega_j) = 2\delta$ for some $j = 1, \ldots, n$. We then blow up the disk $B_\delta(x_0)$: let $x = x_0 + \delta y$ with $y \in B_1(0)$, and define

$$v(y) = \xi_i(x) - c_{i,j} = \xi_i(x_0 + \delta y) - c_{i,j}, \quad y \in B_1(0).$$

By rotating the y plane if necessary, we may assume that the shortest segment joining x_0 to $\partial\omega_j$ is mapped to the y_1 axis, and hence the image $\tilde{\omega}_j = (1/\delta)(\omega_j - \{x_0\})$ of the hole ω_j lies in the half plane $y_1 < -2$ and the distance $\tilde{\rho}(y) := \text{dist}(y, \partial\tilde{\omega}_j) \geqslant y_1 + 2 \geqslant 1$ for $y \in B_1(0)$.

Since $\rho(x)/a(x)$ is smooth and nonzero in a neighborhood of $\partial\omega_j$ in Ω, there exists $b(x)$, smooth and $b(x) > 0$ in a neighborhood of $\partial\omega_j$ with

$$\frac{1}{a(x)} = \frac{b(x)}{\rho(x)}.$$

By homogeneity, $\rho(x) = \delta\tilde{\rho}(y)$, and hence

$$\frac{1}{a(x)} = \frac{1}{\delta} \left(\frac{b(x_0 + \delta y)}{\tilde{\rho}(y)} \right) =: \frac{1}{\delta} \beta_{\delta, x_0}(y).$$

Therefore, the equation for ξ_i implies,

$$-\nabla_y \cdot (\beta_{\delta,x_0}(y)\nabla_y v) = \delta^3(v + \delta_{i,0} + c_{i,j}) =: F_{\delta,x_0}(y).$$

By the above-mentioned remarks, the coefficient β_{δ,x_0} is smooth in $B_1(0)$, and there exist constants $0<\lambda_1<\lambda_2$, $C>0$ (independent of δ,x_0) so that

$$\lambda_1 \leqslant \beta_{\delta,x_0}(y) \leqslant \lambda_2, \quad |\nabla\beta_{\delta,x_0}(y)| \leqslant C,$$

for all $y \in B_1(0)$. Hence Theorem 9.11 of Ref. 9 holds, uniformly in δ,x_0, and for every $p \geqslant 2$ there exists a constant (independent of δ,x_0) $K>0$ with

$$\|v\|_{W^{2,p}(B_{1/2}(0))} \leqslant K(\|v\|_{L^p(B_1(0))} + \|\tilde{F}_{\delta,x_0}\|_{L^p(B_1(0))}) \leqslant K'(\|v\|_{L^\infty(B_1(0))} + \delta^3\|\tilde{f}\|_{L^\infty(B_1(0))}) \leqslant K''\delta^2|\ln|\ln\delta||,$$

using the estimate (3.11) in the last line. By the Sobolev embedding, taking $p>2$ we conclude that v is uniformly bounded in $C^{1,\alpha}(B_{1/2}(0))$, and in particular $|\nabla v(0)| \leqslant C\delta^2|\ln|\ln\delta||$ with constant C independent of x_0, δ. Rescaling, we obtain $|\nabla\xi_i(x_0)| \leqslant C\delta|\ln|\ln\delta|| \leqslant C'\rho(x_0)|\ln|\ln\rho(x_0)||$, which is the desired conclusion (3.12). □

Remark 3.6: We note that in case $\Delta a(x)>0$ on $\partial\omega_j$ we would be able to use $\xi(x)=a(x)^2$ as a supersolution in the above calculation and obtain a slightly better estimate $|\xi_i(x)-c_{i,j}| \leqslant C(\rho(x))^2$ (and similarly for $|\nabla\xi_i|$), on the boundary behavior of solutions. We also remark that in case $\mathcal{D}$ is a disk and $a(x)$ radially symmetric, then the functions ξ_i are radial and the sharper estimate $\xi_i - c_{i,j} = O(\rho(x)^2)$ holds in this case as well.

Finally, the following estimates follow easily from Lemma 3.1, but are stated in a form which will be useful in studying the breakdown of pinning:

Lemma 3.7: For any $\delta>0$, *let* $\Omega_\delta := \{x \in \Omega : \mathrm{dist}(x,\omega_j) > \delta$, *for some* $j \in \{1,\ldots,n\}\}$. *Then, there exists a constant* $C>0$ *so that*

$$\sup_{x\in\Omega_\delta}\left|\frac{\nabla h_*}{a}\right| \leqslant Ch_{ex}|\ln|\ln\delta||, \tag{3.20}$$

$$\int_{\Omega\setminus\Omega_\delta}\frac{1}{a}|\nabla h_*|^2 dx \leqslant Ch_{ex}^2\delta^2[|\ln|\ln\delta||]^2. \tag{3.21}$$

Bose–Einstein Condensates: For the problem of a Bose–Einstein condensate described by the functional H_ϵ of Sec. I, after the reduction via Ref. 12 and formal passage to the $\epsilon\to 0$ limit, we arrive at a similar limit problem,

$$I_\infty(v) = \int_\Omega \left\{\frac{a}{2}|\nabla v|^2 - a(x)\pi x^\perp \cdot \mathrm{Im}[\bar{v}\nabla v]\right\} dx,$$

for $v \in H^1_a(\Omega;S^1)$ with $|v|=1$. There is no associated magnetic field, but minimizers satisfy the conservation of momentum, $\mathrm{div}\,\vec{j} = \mathrm{div}(a(x)[\mathrm{Im}\{\bar{v}\nabla v\} - \pi x^\perp]) = 0$, and hence there is a conjugate function (in the sense of harmonic maps[6]), $h \in H^1_{1/a}(\Omega)$ with

$$\nabla^\perp h = -\vec{j}.$$

It is easy to verify that h satisfies

$$-\mathrm{div}\left(\frac{1}{a(x)}\nabla h\right) = 2\pi \quad \text{in } \Omega,$$

with $h=H_j$ constant on each ω_j, and we may choose $h=0$ on $\partial\mathcal{D}$. By following the same calculations as (3.7) we obtain the flux conditions,

$$\int_{\partial\omega_j} \frac{1}{a}\frac{\partial h}{\partial \nu} ds = -2\pi \deg(v, \partial\omega_j) + 2|\omega_j|, \quad j = 1, \ldots, n.$$

Decomposing $h = \tau\xi_0 - \Sigma d_j \xi_j$ as before, we must solve for

$$-\operatorname{div}\left(\frac{1}{a(x)} \nabla \xi_i\right) = 2\delta_{i,0} \text{ in } \Omega,$$

$$\xi_i = 0 \text{ on } \partial\mathcal{D},$$

$$\xi_i = c_{i,j} \text{ on } \omega_j, \quad j = 1, \ldots, n,$$

$$\int_{\partial\omega_j} \frac{1}{a}\partial_\nu \xi_i = -2\pi\delta_{i,j} + 2|\omega_j|\delta_{i,0}, \quad j = 1, \ldots, n.$$

These may be found by minimizing the functionals

$$I_i(\varphi) = \frac{1}{2}\int_\Omega |\nabla\varphi|^2 dx - \delta_{i,0}\int_{\mathcal{D}} 2\varphi \, dx - \pi(1-\delta_{i,0})\varphi\big|_{\omega_i},$$

over the space **H** defined previously, with φ=constant on each ω_j. The existence and boundary regularity (including now the exterior boundary $\partial\mathcal{D}$) of these solutions follow exactly as in Lemma 3.1, and the expression of the limiting energy in terms of the degrees D_j at each of the holes ω_j is also the same. We leave the details to the interested reader.

IV. PINNING IN BOUNDED FIELDS

In this section we prove Theorem 1.2, with h_{ex} fixed, independent of $\epsilon \to 0$. We begin with an upper bound on the energy, stated in a form which will be useful also in our analysis of the breakdown of pinning for larger h_{ex}. For each given value of h_{ex}, we first take the minimizer (u_*, A_*) of the limiting energy F_∞, as described in the previous section. The degrees $\vec{D}_* = (D_1, \ldots, D_n) = [\![h_{ex} C^{-1} X]\!]$ determined by minimizing (3.13), and the limit energy is given as in Lemma 3.2,

$$F_\infty(u_*, A_*) = h_{ex}^2 \epsilon_0 + g(D; h_{ex}), \tag{4.1}$$

where we denote

$$g(D; h_{ex}) := \pi(\vec{D} \cdot C\vec{D} - 2h_{ex}\vec{X} \cdot \vec{D}) = \pi \sum_{i,k=1}^{n} c_{i,k} D_i D_k - 2\pi h_{ex} \sum_{i=1}^{n} c_{0,i} D_i.$$

Note that this energy is of the order h_{ex}^2. We would like to use (u_*, A_*) as a test function in the energy, but u_* is only defined in Ω and hence we must extend it to the entire domain $\mathcal{D}$. We obtain the following:

Proposition 4.1: Assume $h_{ex} \leqslant C|\ln \epsilon|$. *Then*,

$$\inf E_\epsilon(u, A) \leqslant J_\epsilon(\eta_\epsilon) + F_\infty(u_*, A_*) + o(1) = J_\epsilon(\eta_\epsilon) + h_{ex}^2 \epsilon_0 + g(D_*; h_{ex}) + o(1), \tag{4.2}$$

where (u_*, A_*), $g(D_*; h_{ex})$ *and* D_* *are as mentioned above.*

Proof: Let $\rho(x) := \operatorname{dist}(x, \cup_j \partial\omega_j)$ denote signed distance, with positive values in Ω and negative values in each ω_j. Define a one-sided neighborhood of the holes, $\Delta'_\epsilon := \{x \in \Omega : 0 < \rho(x) < 2\epsilon^{1/6}\}$. By the estimate (3.21) we have

$$\int_{\Delta'_\epsilon} a|\nabla_{A_*} u_*|^2 = \int_{\Delta'_\epsilon} \frac{1}{a}|\nabla h_*|^2 \leqslant C\epsilon^{1/3}(\ln|\ln \epsilon^{1/6}|)^2|\ln \epsilon|^2 = o(1). \tag{4.3}$$

We may therefore excise a portion of the neighborhood Δ'_ϵ with negligible energy cost.

By the energy estimate and Hölder's inequality,

$$\int_{\Delta'_\epsilon} a(x)A_*^2 \leqslant \|A_*\|_{L^4}^2 \left(\int_{\Delta'_\epsilon} a(x)^2 \right)^{1/2} \leqslant \epsilon^{1/4}|\ln \epsilon|^2 = o(1), \tag{4.4}$$

and hence (4.3) implies that

$$\int_{\Delta'_\epsilon} a|\nabla u_*|^2 \leqslant C\epsilon^{1/6}(\ln|\ln \epsilon^{1/6}|)^2|\ln \epsilon|^2.$$

From the previous estimate and Fubini's theorem, there exists a constant C' and $\delta_\epsilon \in (\epsilon^{1/6}, 2\epsilon^{1/6})$ such that

$$\int_{\{\rho(x)=\delta_\epsilon\}} a(x)|\nabla u_*|^2 \leqslant C'(\ln|\ln \epsilon^{1/6}|)^2|\ln \epsilon|^2.$$

Using hypothesis (H3) we then have

$$\int_{\{\rho(x)=\delta_\epsilon\}} |\nabla u_*|^2 \leqslant C''\epsilon^{-1/6}(\ln|\ln \epsilon^{1/6}|)^2|\ln \epsilon|^2, \tag{4.5}$$

for appropriate constant C''.

Define the two-sided neighborhood,

$$\mathcal{N}_\epsilon := \{x \in \mathcal{D} : -\delta_\epsilon < \rho(x) < \delta_\epsilon\}.$$

We claim the following:

Lemma 4.2: There exists a constant $C>0$, independent of ϵ, so that

$$\eta_\epsilon^2(x) \leqslant C\delta_\epsilon \quad \textit{for } x \in \mathcal{N}_\epsilon. \tag{4.6}$$

We defer the proof of Lemma 4.2 until the end.

We now extend the order parameter u_* as $\hat{u}_* = \exp(i\hat{\phi}_*)$ to $\mathcal{N}_\epsilon$ by extending the real phase function $\hat{\phi}_*$ from $\{x : \rho(x) = \delta_\epsilon\}$ to $\mathcal{N}_\epsilon$ as a constant along the normal lines to each $\partial\omega_j$. Note that in $\mathcal{N}_\epsilon$, $|\hat{u}_*| = 1$ and

$$|\nabla \hat{u}_*(x)| = |\nabla \hat{\phi}_*(x)| = |\partial_\tau \hat{\phi}_*(x)| \leqslant C[|\nabla \phi_*|]_{\rho(x)=\delta_\epsilon}. \tag{4.7}$$

In particular, integrating along curves equidistant to $\partial\omega_j$, we then have

$$\begin{aligned} \int_{\mathcal{N}_\epsilon} \eta_\epsilon^2|\nabla_{A_*}\hat{u}_*|^2 &\leqslant 2\int_{\mathcal{N}_\epsilon} \eta_\epsilon^2|\nabla \hat{\phi}_*|^2 + 2\int_{\mathcal{N}_\epsilon} \eta_\epsilon^2 A_*^2 \leqslant C\int_{-\delta_\epsilon}^{\delta_\epsilon} \int_{\rho(x)=t} \eta_\epsilon^2|\nabla \hat{\phi}_*|^2 \mathrm{d}s_t \mathrm{d}t + o(1) \\ &\leqslant C\delta_\epsilon^2\epsilon^{-1/6}(\ln|\ln \epsilon^{1/6}|)^2|\ln \epsilon|^2 = o(1), \end{aligned} \tag{4.8}$$

where we have used (4.4), (4.5), and (4.7), and the estimate (4.6). In summary, we have shown that there exists an extension $\hat{u}_*$ of u_* to $\mathcal{N}_\epsilon$, a small distance into the pinning sites ω_j, with small energy in this neighborhood.

To conclude, we introduce a smooth cut-off, $\chi_\epsilon(x)$ with $0 \leqslant \chi_\epsilon(x) \leqslant 1$,

$$\chi_\epsilon(x) = \begin{cases} 1 & \text{if } \rho(x) > -\dfrac{\delta_\epsilon}{2}, \\ 0 & \text{if } \rho(x) < -\delta_\epsilon, \end{cases}$$

and $|\nabla\chi_\epsilon(x)| \leq C/\delta_\epsilon$. Our test function for the energy F_ϵ is then $u = \chi_\epsilon \hat{u}_*$, $A = A_*$, and we have

$$\begin{aligned} \int_{\mathcal{D}} \eta_\epsilon^2 |\nabla_{A_*} u|^2 &\leq \int_{\Omega \setminus \mathcal{N}_\epsilon} \eta_\epsilon^2 |\nabla_{A_*} u_*|^2 + 2\int_{\mathcal{N}_\epsilon} \eta_\epsilon^2 |\nabla\chi_\epsilon|^2 + 2\int_{\mathcal{N}_\epsilon} \eta_\epsilon^2 |\nabla_{A_*}\hat{u}_*|^2 \\ &= \int_\Omega a(x)|\nabla_{A_*} u_*|^2 + \frac{C}{\delta_\epsilon^2}\int_{\{-\delta_\epsilon < \rho < -\delta_\epsilon/2\}} \eta_\epsilon^2 + o(1) = \int_\Omega a(x)|\nabla_{A_*} u_*|^2 + o(1), \end{aligned}$$

where we have used (2.10), (2.11), (4.3), and (4.8) in the second line. Finally, by (iv) of Proposition 2.1 we have

$$\int_{\mathcal{D}} \frac{\eta_\epsilon^4}{4\epsilon^2}(|\chi_\epsilon \hat{u}_*|^2 - 1)^2 \leq \int_{\left\{-\delta_\epsilon < \rho(x) < -\frac{\delta_\epsilon}{2}\right\}} \frac{\eta_\epsilon^4}{4\epsilon^2} \leq C\frac{\exp[-4\epsilon^{-1/2}]}{\epsilon^{4/3}} = o(1).$$

In conclusion, we have the upper bound:

$$\inf E_\epsilon \leq J_\epsilon(\eta_\epsilon) + F_\epsilon(\chi_\epsilon \hat{u}_*, A_*) \leq J_\epsilon(\eta_\epsilon) + F_\infty(u_*, A_*) + o(1),$$

which concludes the proof of Proposition 4.1. □

Proof of Lemma 4.2: By the choice of δ_ϵ and (2.10) we have $\eta_\epsilon^2(x) \leq 2a(x)$ on $\Gamma = \{x \in \Omega : \rho(x) = \delta_\epsilon\}$. Let $D_\epsilon := \{x \in \mathcal{D} : \rho(x) < \delta_\epsilon\}$, with boundary Γ (including the pinning sites, since we define ρ as the signed distance). Set

$$\bar{u} = \sqrt{2\max_{x\in\Gamma} a(x)} \leq C\sqrt{\delta_\epsilon},$$

with constant $C > 0$ independent of ϵ. Then $\bar{u}$ is a supersolution for the Dirichlet problem,

$$-\Delta u + \frac{1}{\epsilon^2}(u^2 - a(x))u = 0, \quad x \in D_\epsilon,$$

$$u(x) = \eta_\epsilon(x), \quad x \in \Gamma. \tag{4.9}$$

Since $\underline{u} = 0$ is a subsolution, we obtain a solution $0 \leq u(x) \leq \bar{u}$ in D_ϵ. By the result of Brezis and Oswald,[7] the Dirichlet problem (4.9) admits a unique solution for any given boundary condition. Since η_ϵ also solves (4.9) we conclude that the estimate holds for η_ϵ. □

The proof of Theorem 1.2 then follows the same lines as that of Theorem 1.1 of Ref. 1. We sketch the steps here.

Let h_{ex} be fixed, and $(\psi_\epsilon, A_\epsilon)$ minimizers of E_ϵ. From Lemma 2.3 we then have

$$F_\epsilon(u_\epsilon, A_\epsilon) \leq F_\infty(u_*, A_*) + o(1),$$

with $u_\epsilon = \psi_\epsilon/\eta_\epsilon$. It immediately follows that $\|h_\epsilon\|_{L^2(\mathcal{D})}$ and $\|\eta_\epsilon \nabla_{A_\epsilon} u_\epsilon\|_{L^2(\mathcal{D})}$ are uniformly bounded, and

$$\eta_\epsilon^2(|u_\epsilon|^2 - 1) \to 0 \quad \text{strongly in } L^2(\mathcal{D}). \tag{4.10}$$

Extracting a subsequence, $h_\epsilon \rightharpoonup h_0$ in $L^2(\mathcal{D})$ and $A_\epsilon \rightharpoonup A_0$ in $H^1(\mathcal{D})$, with

$$\liminf_{\epsilon\to 0}\int_{\mathcal{D}}(h_\epsilon - h_{ex})^2 \geqslant \int_{\mathcal{D}}(h_0 - h_{ex})^2.$$

Then $\eta_\epsilon \nabla u_\epsilon$ is also bounded in $L^2(\mathcal{D})$, and hence there exists w_0 with $\eta_\epsilon \nabla u_\epsilon \rightharpoonup w_0$ in $L^2(\mathcal{D})$.

Fix $\delta > 0$ and consider $\Omega_\delta = \{x \in \Omega : \rho(x) > \delta\}$. Then

$$\int_{\Omega_\delta} |\nabla u_\epsilon|^2 \leqslant \frac{C}{\delta}\int_{\Omega_\delta} a|\nabla u_\epsilon|^2 \leqslant \frac{2C}{\delta}\int_{\Omega_\delta} \eta_\epsilon |\nabla u_\epsilon|^2 \leqslant C.$$

By a diagonal argument we may extract a further subsequence and $u_0 \in H^1_{loc}(\Omega)$ such that $u_\epsilon \rightharpoonup u_0$ in $H^1(\Omega_\delta)$ for each $\delta > 0$. By lower semicontinuity,

$$\liminf_{\epsilon\to 0}\int_{\Omega} \eta_\epsilon^2 |\nabla u_\epsilon|^2 \geqslant \liminf_{\epsilon\to 0}\int_{\Omega_\delta} \eta_\epsilon^2 |\nabla u_\epsilon|^2 \geqslant \int_{\Omega_\delta} a|\nabla u_0|^2.$$

Again, this is true for all $\delta > 0$, and hence we have $\int_\Omega a|\nabla u_0|^2 \leqslant C$, so $u_0 \in H^1_a(\Omega)$. By (4.10) we conclude that $|u_0| = 1$ almost everywhere in Ω. In addition, we identify the limit $w_0 = \sqrt{a}\nabla u_0$, that is $\eta_\epsilon \nabla u_\epsilon \rightharpoonup \sqrt{a}\nabla u_0$ in $L^2(\Omega)$. By the weak H^1 convergence and uniform convergence $\eta_\epsilon^2 \to a$ in Ω_δ, we also have $\eta_\epsilon A_\epsilon u_\epsilon \to \sqrt{a}A_0 u_0$ in $L^2(\Omega_\delta)$, and hence $\eta_\epsilon \nabla_{A_\epsilon} u_\epsilon \rightharpoonup \sqrt{a}\nabla_{A_0} u_0$ in $L^2(\Omega_\delta)$. Then, by semicontinuity,

$$\liminf_{\epsilon\to 0}\int_{\Omega_\delta} \eta_\epsilon^2 |\nabla_{A_\epsilon} u_\epsilon|^2 \geqslant \int_{\Omega_\delta} a|\nabla_{A_0} u_0|^2.$$

The left-hand side is bounded, independent of δ and so we have

$$F_\infty(u_0, A_0) = \int_\Omega \frac{a}{2}|\nabla_{A_0} u_0|^2 + \frac{1}{2}\int_{\mathcal{D}} (h_0 - h_{ex})^2 \leqslant F_\infty(u_*, A_*).$$

In other words, (u_0, A_0) is a minimizer of E_ϵ, and hence the inequalities above are actually equalities. In particular, we conclude $\eta_\epsilon \nabla u_\epsilon \to \sqrt{a}\nabla u_0$ strongly in $L^2(\Omega)$, and hence $u_\epsilon \to u_0$ strongly in $H^1_{loc}(\Omega)$. Note that in the (generic) case that $\vec{D}$ is the unique minimizer in Lemma 3.2, the limit exists without subsequences.

This concludes the proof of Theorem 1.2.

V. THE BREAKDOWN OF PINNING

In this section we consider external fields of the order $|\ln \epsilon|$, where we expect vortices to nucleate in the superconducting bulk. We assume throughout that the dependence of h_{ex} on ϵ is given by

$$h_{ex} = \lambda|\ln \epsilon| + \mu \ln|\ln \epsilon|, \tag{5.1}$$

for λ, μ constants independent of ϵ.

A. Decoupling the pinning sites

We refine our decomposition of Lemma 2.3 to incorporate the effect of the pinning sites ω_j. It will be necessary to excise not only the pinning sites ω_j, but also a very small neighborhood of each, since the accounting of the energy of vortices near these "holes" is too delicate for our methods. To this end, we define

$$\delta_\epsilon := \frac{1}{|\ln \epsilon|^2},$$

and

$$\Omega_{\delta_\epsilon} := \{x \in \Omega : \mathrm{dist}(x, \partial\omega_j) > \delta_\epsilon, \quad \forall\, j = 1, \ldots, n\}.$$

We then define (v, A_v) via:

$$\psi = \eta_\epsilon u_* v, \text{ for } x \in \Omega, \quad A = A_* + A_v, \text{ for } x \in \mathcal{D}, \tag{5.2}$$

where as usual (u_*, A_*) denote the minimizers of F_∞ with h_{ex} as given, described in the previous section. The energy then decomposes as follows:

Lemma 5.1: Let (ψ, A) *be minimizers of* E_ϵ, *and* (v, A_v) *be defined as in* (5.2). *Then*, $v \in H^1_a(\Omega_{\delta_\epsilon}; \mathbf{C})$, $A_v \in H^1(\mathcal{D}; \mathbf{R}^2)$, *and*

$$E_\epsilon(\psi, A) \geqslant J_\epsilon(\eta_\epsilon) + E_*(h_*) + G_\epsilon(v, A_v) - \int_{\Omega_{\delta_\epsilon}} \nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v} \nabla v\} \mathrm{d}x - o(1), \tag{5.3}$$

where $E_*(h_*) = \min F_\infty$ *(as in Lemma 3.2) and*

$$G_\epsilon(v, A_v) := \int_{\Omega_{\delta_\epsilon}} \left\{ \frac{a}{2} |(\nabla - iA_v)v|^2 + \frac{a^2}{4\epsilon^2}(|v|^2 - 1)^2 \right\} \mathrm{d}x + \frac{1}{2} \int_{\mathcal{D}} |\mathrm{curl}\, A_v|^2 \mathrm{d}x.$$

Proof: As in Lemma 2.3 we write $\psi = \eta_\epsilon u$. Since $|u_*| = 1$ we have $|v| = |u|$. From the upper bound (4.2) and the expansion of Lemma 2.3 we have:

$$C|\ln \epsilon|^2 \geqslant F_\epsilon(u_* v, A_* + A_v) \geqslant \int_{\Omega_{\delta_\epsilon}} \left\{ \frac{\eta_\epsilon^2}{2} |\nabla_A u|^2 + \frac{\eta_\epsilon^4}{4\epsilon^2}(|v|^2 - 1)^2 \right\} \mathrm{d}x + \frac{1}{2} \int_{\mathcal{D}} (h_* - h_{ex} + \mathrm{curl}\, A_v)^2. \tag{5.4}$$

Since $|u_*| = 1$ we have $(|u|^2 - 1)^2 = (|v|^2 - 1)^2$. We immediately conclude that

$$\int_{\Omega_{\delta_\epsilon}} [a(x)]^2 (|v|^2 - 1)^2 \leqslant C\epsilon^2 |\ln \epsilon|^2, \tag{5.5}$$

and that

$$\|A_v\|^2_{H^1(\mathcal{D}; \mathbf{R}^2)} \leqslant C \int_{\mathcal{D}} (\mathrm{curl}\, A_v)^2 \mathrm{d}x \leqslant C |\ln \epsilon|^2. \tag{5.6}$$

We also require a basic estimate on v. Using $v = \bar{u}_* u$,

$$\begin{aligned} \int_{\Omega_{\delta_\epsilon}} a|\nabla v|^2 &\leqslant 2 \int_{\Omega_{\delta_\epsilon}} a(|\nabla u|^2 + |v|^2 |\nabla u_*|^2) \\ &= 2 \int_{\Omega_{\delta_\epsilon}} (\eta_\epsilon^2 |\nabla u|^2 + (a - \eta_\epsilon^2)|\nabla u|^2 + a|\nabla u_*|^2 + (|v|^2 - 1)a|\nabla u_*|^2). \end{aligned} \tag{5.7}$$

We now estimate each term separately. From the energy estimate we estimate the first term by:

$$\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^2 |\nabla u|^2 \leqslant 2\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^2 |v|^2 |A_v|^2 dx + C|\ln \epsilon|^2 = 2\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^2 [(|v|^2-1)|A_v|^2 + |A_v|^2] + C|\ln \epsilon|^2$$
$$\leqslant C\left[\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^4 (|v|^2-1)^2 \int_{\Omega_{\delta_\epsilon}} |A_v|^4\right]^{1/2} + \|A_v\|_{H^1}^2 + C|\ln \epsilon|^2 \leqslant C|\ln \epsilon|^2.$$

Using (2.10), the second term of (5.7) is small compared to the first. The third term of (5.7) is of order $|\ln \epsilon|^2$ by the choice of degrees in the previous section. For the last term, we again use (2.10) to replace $a(x)$ by $\eta_\epsilon^2(x)$, making an error small compared to the integral itself. Thus,

$$\left|\int_{\Omega_{\delta_\epsilon}} (|v|^2-1)a|\nabla u_*|^2\right| \leqslant \left|\int_{\Omega_{\delta_\epsilon}} 2\eta_\epsilon^2 (|v|^2-1) 2\left(\frac{1}{a^2}|\nabla h_*|^2 + |A_*|^2\right)\right|$$
$$\leqslant C\left\{\sup_{x\in\Omega_{\delta_\epsilon}}\left[\frac{|\nabla h_*|}{a}\right]^2 + \|A_*\|_{H^1}^2\right\}\left[\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^4 (|v|^2-1)^2\right]^{1/2}$$
$$\leqslant C\epsilon(\ln|\ln \delta_\epsilon|)^2 |\ln \epsilon|^3 = o(1),$$

using (3.21) and the same argument as in the previous calculation. Substituting into (5.7), we obtain

$$\int_{\Omega_{\delta_\epsilon}} a(x)|\nabla v|^2 \leqslant C|\ln \epsilon|^2. \tag{5.8}$$

We now expand the gradient term in (5.4):

$$\eta_\epsilon^2 |(\nabla - iA)u|^2 = \eta_\epsilon^2 [|v|^2 |(\nabla - iA_*)u_*|^2 + |(\nabla - iA_v)v|^2 + 2\,\mathrm{Re}\{(u_*\overline{\nabla u_*} + iA_*)(\bar v\,\nabla\, v - iA_v|v|^2)\}] \tag{5.9}$$

$$= \eta_\epsilon^2 \left[|v|^2 \frac{1}{a^2}|\nabla h_*|^2 + |(\nabla - iA_v)v|^2 - 2\frac{1}{a}\nabla^\perp h_* \cdot \mathrm{Im}\{\bar v\,\nabla\, v\} + 2A_v|v|^2 \cdot \frac{1}{a}\nabla^\perp h_*\right], \tag{5.10}$$

using the definition (3.17) of $u_* = e^{i\phi_*}$ in terms of the field h_*. We simplify each term in turn. First,

$$\left|\int_{\Omega_{\delta_\epsilon}} \frac{\eta_\epsilon^2}{a^2}|v|^2|\nabla h_*|^2 - \int_{\Omega_{\delta_\epsilon}} \frac{1}{a}|\nabla h_*|^2\right| \leqslant \left|\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^2 (|v|^2-1)\frac{1}{a^2}|\nabla h_*|^2\right| + \left|\int_{\Omega_{\delta_\epsilon}} (\eta_\epsilon^2 - a)\frac{1}{a^2}|\nabla h_*|^2\right|$$
$$\leqslant C\sup_{\Omega_{\delta_\epsilon}}\left|\frac{\nabla h_*}{a}\right|^2 \{\|\eta_\epsilon^2(|v|^2-1)\|_{L^2(\Omega_{\delta_\epsilon})} + \|\eta_\epsilon^2 - a\|_{L^2(\Omega_{\delta_\epsilon})}\}$$
$$\leqslant C(\ln|\ln \delta_\epsilon|)^2 |\ln \epsilon|^3 \epsilon = o(1). \tag{5.11}$$

By (3.21) we have

$$\int_{\Omega\setminus\Omega_{\delta_\epsilon}} \frac{1}{a}|\nabla h_*|^2 \leqslant C{\delta_\epsilon}^2 (\ln|\ln \delta_\epsilon|)^2 |\ln \epsilon|^2 = o(1).$$

Therefore, the first term of (5.10) may be expressed as

$$\int_{\Omega_{\delta_\epsilon}} \frac{\eta_\epsilon^2}{a^2}|v|^2|\nabla h_*|^2 = \int_\Omega \frac{1}{a}|\nabla h_*|^2 + o(1). \tag{5.12}$$

For the second term, we use (2.10), (5.6), and (5.8) to obtain,

$$\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^2 |(\nabla - iA_v)v|^2 = \int_{\Omega_{\delta_\epsilon}} a|(\nabla - iA_v)v|^2 + \int_{\Omega_{\delta_\epsilon}} (\eta_\epsilon^2 - a)|(\nabla - iA_v)v|^2$$
$$= \int_{\Omega_{\delta_\epsilon}} a|(\nabla - iA_v)v|^2(1 + O(\epsilon^{1/3})) = \int_{\Omega_{\delta_\epsilon}} a|(\nabla - iA_v)v|^2 + o(1). \tag{5.13}$$

The third term may be treated as follows:

$$\left| \int_{\Omega_{\delta_\epsilon}} 2\frac{\eta_\epsilon^2}{a} \nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v}\,\nabla\, v\} - \int_{\Omega_{\delta_\epsilon}} 2\nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v}\,\nabla\, v\} \right| \tag{5.14}$$

$$\leqslant \sup_{\Omega_{\delta_\epsilon}} \left| \frac{\eta_\epsilon^2}{a} - 1 \right| \left| \int_{\Omega_{\delta_\epsilon}} 2\nabla^\perp h_* \cdot \mathrm{Im}\,\{\bar{v}\,\nabla\, v\} \right|$$
$$\leqslant C\epsilon^{1/3} \sup_{\Omega_{\delta_\epsilon}} \left| \frac{\nabla h_*}{a} \right| \int_{\Omega_{\delta_\epsilon}} a(x)((|v|^2 - 1) + 1 + |\nabla v|^2)$$
$$\leqslant C\epsilon^{1/3} \ln|\ln\, \delta_\epsilon| |\ln\, \epsilon|^3 = o(1), \tag{5.15}$$

using (5.5) and (5.8).

For the last term in (5.10), we proceed in two steps. First, using (2.10), (3.21), and (5.6),

$$\left| \int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^2 A_v |v|^2 \cdot \frac{1}{a} \nabla^\perp h_* - \int_{\Omega_{\delta_\epsilon}} A_v \cdot \nabla^\perp h_* \right|$$
$$\leqslant \int_{\Omega_{\delta_\epsilon}} |A_v| \eta_\epsilon^2 ||v|^2 - 1| \frac{1}{a} |\nabla h_*| + \int_{\Omega_{\delta_\epsilon}} |A_v| |\nabla h_*| \left| \frac{\eta_\epsilon^2}{a} - 1 \right|$$
$$\leqslant \sup_{\Omega_{\delta_\epsilon}} \left| \frac{\nabla h_*}{a} \right| \| \eta_\epsilon^2 (|v|^2 - 1)\|_{L^2} \|A_v\|_{L^2(\Omega_{\delta_\epsilon})} + C\|A_v\|_{L^2} \|\nabla h_*\|_{L^\infty(\Omega_{\delta_\epsilon})} \sup_{\Omega_{\delta_\epsilon}} \left| \frac{\eta_\epsilon^2}{a} - 1 \right|$$
$$\leqslant C\epsilon \ln|\ln\, \delta_\epsilon| |\ln\, \epsilon|^2 + C\epsilon^{1/3} |\ln\, \epsilon|^2 = o(1).$$

Next, we compare with the value in all of Ω:

$$\left| \int_{\Omega \setminus \Omega_{\delta_\epsilon}} A_v \cdot \nabla^\perp h_* \right| \leqslant \|A_v\|_{L^2} \left(\int_{\Omega \setminus \Omega_{\delta_\epsilon}} |\nabla h_*|^2 \right)^{1/2} \leqslant C|\ln\, \epsilon|^2 \delta_\epsilon^{3/2} \ln|\ln\, \delta_\epsilon| = o(1). \tag{5.16}$$

Putting these estimates together and using (3.21), we obtain:

$$\int_{\Omega_{\delta_\epsilon}} \eta_\epsilon^2 |(\nabla - iA)u|^2 = \int_{\Omega_{\delta_\epsilon}} \{a(x)|(\nabla - iA_v)v|^2 - 2\nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v}\,\nabla\, v\}\} + \int_\Omega \left\{ \frac{1}{a} |\nabla h_*|^2 + 2A_v \cdot \nabla^\perp h_* \right\}$$
$$+ o(1). \tag{5.17}$$

What's more, we may integrate the last term in (5.17) by parts, recalling that h_* is constant in each pinning site ω_j,

$$\int_\Omega 2A_v \cdot \nabla^\perp h_* = 2\int_\Omega A_v \cdot \nabla^\perp (h_* - h_{ex}) = 2\int_{\partial\Omega} (h_* - h_{ex}) A_v \cdot \tau - 2\int_\Omega (h_* - h_{ex}) \nabla^\perp \cdot A_v$$

$$= -2\left(\sum_{j=1}^{n} (h_* - h_{ex}) \,\Big|_{\omega_j} \int_{\omega_j} \operatorname{curl} A_v + \int_\Omega (h_* - h_{ex}) \operatorname{curl} A_v \right)$$

$$= -2\int_{\mathcal{D}} (h_* - h_{ex}) \operatorname{curl} A_v .$$

On the other hand, we have

$$\int_{\mathcal{D}} (h - h_{ex})^2 = \int_{\mathcal{D}} (h_* - h_{ex})^2 + \int_{\mathcal{D}} (\operatorname{curl} A_v)^2 + \int_{\mathcal{D}} 2(h_* - h_{ex}) \operatorname{curl} A_v ,$$

and so the last term from (5.17) in fact cancels leaving us with the desired conclusion. □

We now define

$$\mathcal{E}_\epsilon(v, A_v) = G_\epsilon(v, A_v) - \int_{\Omega_{\delta_\epsilon}} \nabla^\perp h_* \cdot \operatorname{Im}\{\bar{v} \nabla v\} dx$$

$$= \int_{\Omega_{\delta_\epsilon}} \left\{ \frac{a}{2} |(\nabla - iA_v)v|^2 + \frac{a^2}{4\epsilon^2} (|v|^2 - 1)^2 - \nabla^\perp h_* \cdot \operatorname{Im}\{\bar{v} \nabla v\} \right\} dx + \frac{1}{2}\int_{\mathcal{D}} |\operatorname{curl} A_v|^2 dx .$$

The upper bound (4.2) then implies that for global minimizers, the associated (v, A_v) satisfy the upper bound,

$$\mathcal{E}_\epsilon(v, A_v) \leq o(1). \tag{5.18}$$

B. Vortex balls

Now in Ω_{δ_ϵ}, we may isolate the vortices using the method of Sandier[14] and Sandier and Serfaty.[16] We have the following result.

Proposition 5.2: Assume $h_{ex} \leq C|\ln \epsilon|$. *For any* $C > 0$ *there exist positive constants* ϵ_0, C_0 *so that for any* (v, A_v) *satisfying* (5.18) *there exists a finite collection* $\{B_i = B(p_i, s_i)\}_{i=1,\ldots,m}$ *of disjoint balls such that:*

$$\{x \in \Omega_{\delta_\epsilon} : |v| < 1 - |\ln \epsilon|^{-4}\} \subset \cup_{i=1}^m B_i ; \tag{5.19}$$

$$\sum_{i=1}^{m} s_i < |\ln \epsilon|^{-12} ; \tag{5.20}$$

$$\deg_{\partial B_i}\left(\frac{v}{|v|} \right) := d_i \quad \textit{for all } i ; \tag{5.21}$$

$$\int_{B_i} \left[\frac{a}{2} |(\nabla - iA_v)v|^2 + (\operatorname{curl} A_v)^2 \right] \geq \pi a(p_i) |d_i| (|\ln \epsilon| - C_0 \ln|\ln \epsilon|) \quad \textit{for all } i. \tag{5.22}$$

Sketch of Proof: We sketch the proof, as the details are minor modifications of the analogous results in Refs. 15 and 16. First, from (5.5), (5.6), and (5.8) we have $G_\epsilon(v, A_v) \leq C|\ln \epsilon|^2$. Since $a(x) \geq C\delta_\epsilon$ for $x \in \Omega_{\delta_\epsilon}$, setting $f := |v|$ we have

$$\delta_\epsilon{}^2 \int_{\Omega_{\delta_\epsilon}} \left(\frac{1}{2}|\nabla f|^2 + \frac{1}{4\epsilon^2}(f^2-1)^2 \right) \leqslant C|\ln \epsilon|^2,$$

and hence

$$\int_{\Omega_{\delta_\epsilon}} \left(\frac{1}{2}|\nabla f|^2 + \frac{1}{4\epsilon^2}(f^2-1)^2 \right) \leqslant C|\ln \epsilon|^6.$$

Let $U_{\delta_\epsilon,t} := \{x \in \Omega_{\delta_\epsilon} : f(x) < 1-t\}$, and $\gamma_t = \partial U_{\delta_\epsilon,t}$. Using the co-area formula as in Ref. 16, there exists $t_0 \in (0, |\ln \epsilon|^{-4})$ and a finite set of balls $B_1, \ldots, B_k$ with radii $s_1, \ldots, s_k$ which cover γ_{t_0}, satisfying $\Sigma_i s_i \leqslant C\epsilon|\ln \epsilon|^8$. In $\Omega_{\delta_\epsilon} \setminus U_{\delta_\epsilon,t_0}$ we have $f = |v| \geqslant 1-t$, and we may write $v = fe^{i\phi}$ for a (possibly multivalued) H^1_{loc} function $\phi(x)$.

We then let the balls grow continuously, using the process described in Refs. 14 and 16, to obtain a lower bound in the expanding balls,

$$\int_{B_i \setminus U_{\delta_\epsilon,t_0}} \left[\frac{a}{2}|\nabla \phi - A_v|^2 + (\operatorname{curl} A_v)^2 \right] \geqslant \pi(\min_{B_i} a)|d_i|(\ln \epsilon - \bar{C}_0 \ln|\ln \epsilon|),$$

with constant $\bar{C}_0$ independent of ϵ. Note that the minimum of $a(x)$ over B_i is nonincreasing as the radii increase and as balls are merged (when they touch in the expansion process). We terminate the process when the sum of the radii of the balls equals $|\ln \epsilon|^{-12}$. By continuity of $a(x)$ we may then replace the minimum of a on each ball by the value at its center p_i, making an error which is small compared to $a(p_i)$ itself. This error can then be absorbed into the coefficient of $\ln|\ln \epsilon|$.

Finally,

$$\begin{aligned}
\int_{B_i} \left[\frac{a}{2}|(\nabla - iA_v)v|^2 + (\operatorname{curl} A_v)^2 \right] &\geqslant \int_{B_j \setminus U_{\delta'_\epsilon,t_0}} \left[\frac{a}{2}(1+f^2-1)|\nabla \phi - A_v|^2 + (\operatorname{curl} A_v)^2 \right] \\
&\geqslant (1 - C|\ln \epsilon|^{-4}) \int_{B_j \setminus U_{\delta_\epsilon,t_0}} \frac{a}{2}[|\nabla \phi - A_v|^2 + (\operatorname{curl} A_v)^2] \\
&\geqslant (1 - C|\ln \epsilon|^{-4})(\pi a(p_i)|d_i|(|\ln \epsilon| - \bar{C}_0 \ln|\ln \epsilon|)) \\
&\geqslant \pi a(p_i)|d_i|(|\ln \epsilon| - C_0 \ln|\ln \epsilon|),
\end{aligned}$$

for constant C_0 independent of ϵ, which completes the sketch of the proof of the proposition. □

We recall from Sec. I the following definition: We say ψ has an *essential vortex* at $p_i \in \Omega_{\delta_\epsilon}$ if there is a vortex ball B_i centered at p_i with degree $d_i \neq 0$. Note that $\psi/|\psi| = u/|u| = v/|v|$ in Ω_{δ_ϵ}, and so each has the same essential vortices.

C. A lower bound

To prove Theorem 1.3 we match the upper bound (5.18) with a sharp lower bound for the energy in terms of the vortex balls. We define $\rho_j(x) := \operatorname{dist}(x, \partial\omega_j)$, $j = 1, \ldots, n$, and sets

$$\gamma_{t,j} := \{x \in \Omega : \rho_j(x) = t\}, \quad \gamma_t = \cup_{j=1}^n \gamma_{t,j}.$$

We now choose

$$\sigma_\epsilon \in \left[\frac{[\ln|\ln \epsilon|]^{1/4}}{|\ln \epsilon|}, 2\frac{[\ln|\ln \epsilon|]^{1/4}}{|\ln \epsilon|} \right], \tag{5.23}$$

with the property that $\gamma_{\sigma_\epsilon} \cap (\cup_i B_i) = \emptyset$. This is possible by (5.20). We may then define degrees,

$$\Delta_j := \deg\left(\frac{v}{|v|}; \gamma_{\sigma_\epsilon, j}\right), \quad j = 1, \ldots, n,$$

associated to each interior boundary curve of the domain

$$\Omega_{\sigma_\epsilon} := \{x \in \Omega : \rho(x) > \sigma_\epsilon\}.$$

Then, we prove the following lower bound in Ω_{σ_ϵ}:

Lemma 5.3: There exist bounded constants, $\beta_{\epsilon,j}$, $j=1,\ldots,n$, such that:

$$\mathcal{E}_\epsilon(v, A_v) \geqslant \pi \sum_{\rho(p_i)>\sigma_\epsilon} a(p_i)|d_i|(|\ln \epsilon| - C_0 \ln|\ln \epsilon|) + 2\pi \sum_{\rho(p_i)>\sigma_\epsilon} (h_*(p_i) - h_{ex})d_i + 2\pi \sum_{j=1}^{n} \beta_{\epsilon,j}\Delta_j + \int_{\Omega_{\sigma_\epsilon} \setminus \cup B_i} \left\{ \frac{a}{2}|(\nabla - iA_v)v|^2 + (\operatorname{curl} A_v)^2 \right\} + O([\ln|\ln \epsilon|]^{1/2}).$$

Proof:

Step 1: The first step is to modify δ_ϵ. We claim that there exists $\delta_\epsilon' \in [\delta_\epsilon, 2\delta_\epsilon]$ and a constant $C>0$ (independent of ϵ) so that

$$|v| \geqslant 1 - |\ln \epsilon|^{-5} \quad \text{for all } x \in \gamma_{\delta_\epsilon'}, \tag{5.24}$$

$$\int_{\gamma_{\delta_\epsilon'}} |\nabla v|^2 \mathrm{d}s \leqslant C\frac{|\ln \epsilon|^2}{\delta_\epsilon^2}. \tag{5.25}$$

Indeed, let

$$I_\epsilon = \{t \in [\delta_\epsilon, 2\delta_\epsilon] : \gamma_t \cap (\cup_i B_i) = \emptyset\}.$$

By (5.20), the measure $|I_\epsilon| \geqslant \frac{1}{2}\delta_\epsilon$, and for all $t \in I_\epsilon$ and $x \in \gamma_t$, $|u(x)| \geqslant 1 - |\ln \epsilon|^{-5}$. Define

$$\mathcal{N}_{2\delta_\epsilon} := \{x \in \Omega : \rho(x) \leqslant 2\delta_\epsilon\}.$$

Since

$$\int_{\mathcal{N}_{2\delta_\epsilon}} |\nabla v|^2 \leqslant \delta_\epsilon^{-1} \int_{\mathcal{N}_{2\delta_\epsilon}} a|\nabla v|^2 \leqslant \delta_\epsilon^{-1}|\ln \epsilon|^2,$$

we have

$$\delta_\epsilon^{-1}|\ln \epsilon|^2 \geqslant C\int_{\delta_\epsilon}^{2\delta_\epsilon} \int_{\gamma_t} |\nabla v|^2 \mathrm{d}s_t \mathrm{d}t \geqslant C\int_{I_\epsilon} \int_{\gamma_t} |\nabla v|^2 \mathrm{d}s_t \mathrm{d}t,$$

where ds_t denotes arclength measure on γ_t. Therefore, there exists $C>0$ and $\delta_\epsilon' \in I_\epsilon$ such that

$$\int_{\gamma_{\delta_\epsilon'}} |\nabla v|^2 \mathrm{d}s \leqslant \frac{C|\ln \epsilon|^2}{|I_\epsilon|\delta_\epsilon} \leqslant \frac{2C|\ln \epsilon|^2}{\delta_\epsilon^2}.$$

This proves (5.24) and (5.25).

Step 2: Next, we claim that replacing Ω_{δ_ϵ} with $\Omega_{\delta_\epsilon'}$ in the definition of $\mathcal{E}_\epsilon$ results in an error which is very small.

Indeed, we estimate as in the proof of Lemma 5.1:

$$\left| \int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} \nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v}\,\nabla\, v\} \right| \leqslant \int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} |\nabla h_*||v||\nabla_{A_v} v| + |\nabla h_*||A_v||v|^2$$
$$\leqslant \int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} \left[\frac{1}{2}|\nabla_{A_v} v|^2 + \frac{1}{2}|v|^2|\nabla h_*|^2 + (|v|^2-1)|\nabla h_*||A_v| + |\nabla h_*||A_v| \right]. \tag{5.26}$$

The first term on the right-hand side appears in the integrand in $\mathcal{E}_\epsilon$. The second term estimates as:

$$\int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} |v|^2|\nabla h_*|^2 = \int_{\Omega_{\delta_\epsilon{}'}\setminus\Omega_{\delta_\epsilon}} |\nabla h_*|^2[(|v|^2-1)+1]$$
$$\leqslant C \max_{x\in\Omega_{\delta'_\epsilon}} \frac{|\nabla h_*|^2}{a^2} |\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}|^{1/2} \left(\int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} a^2(|v|^2-1)^2 \right)^{1/2} + \int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} |\nabla h_*|^2$$
$$\leqslant \frac{C \ln\ln|\ln\epsilon|}{|\ln\epsilon|^4},$$

using (3.21). The third term is done in a similar way,

$$\int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} (|v|^2-1)|\nabla h_*|^2|A_v| \leqslant \max_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} \frac{|\nabla h_*|}{a(x)} \left(\int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} a^2(|v|^2-1)^2 \right)^{1/2} \left(\int_{\Omega_{\delta'_\epsilon}\setminus\Omega_{\delta_\epsilon}} A_v^2 \right)^{1/2}$$
$$\leqslant C\,\epsilon\delta_\epsilon |\ln\ln\delta_\epsilon| |\ln\epsilon|^3.$$

Finally, the last term in (5.26) is estimated already in (5.16), so we conclude that the difference in energies in (5.26) is vanishingly small, which completes the claim.

Step 3: Integration by parts:

$$\int_{\Omega_{\delta'_\epsilon}} \nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v}\,\nabla\, v\} = -2\pi \sum_{i=1}^m (h_*(p_i) - h_{ex}) d_i - \int_{\gamma_{\delta'_\epsilon}} (h_* - h_{ex}) \mathrm{Im}\{\bar{w}\,\nabla\, w\} \cdot \tau \,\mathrm{d}s$$
$$+ o(1) \left[1 + \sum_{i=1}^m a(p_i)|d_i| \right], \tag{5.27}$$

where $w = v/|v|$ and τ is the unit tangent vector to each $\gamma_{\delta'_\epsilon,j}$. This step follows exactly as in Lemma II.3 of Ref. 15, with some attention payed to relating the error to the weighted sum of the degrees. We leave the details to the interested reader.

Step 4: We claim

$$\int_{\gamma_{\delta'_\epsilon}} (h_* - h_{ex}) \mathrm{Im}\{\bar{w}\,\nabla\, w\} \cdot \tau \,\mathrm{d}s = 2\pi \sum_{j=1}^n \beta_{\epsilon,j} \deg(w; \gamma_{\delta'_\epsilon,j}) + O(\ln(\ln|\ln\epsilon|)), \tag{5.28}$$

with constants

$$\beta_{\epsilon,j} := (h_*(x) - h_{ex})\big|_{x\in\omega_j}. \tag{5.29}$$

Recall from the previous section that $h_*(x)$ is constant in each ω_j, and $\beta_{\epsilon,j}$ are uniformly bounded, independent of ϵ by Lemma 3.4 and (3.18).

To prove Step 4 we recall the boundary estimate (3.11): when applied to h_* we have

$$|h_*(x) - h_{ex} - \beta_{\epsilon,j}| \leq C(\delta'_\epsilon)^2 \ln|\ln \delta_\epsilon'||\ln \epsilon|, \quad x \in \gamma_{\delta'_\epsilon,j}, \quad j = 1,\ldots,n, \tag{5.30}$$

with constant C independent of ϵ. Hence,

$$\begin{aligned}\left| \int_{\gamma_{\delta'_\epsilon}} (h_* - h_{ex} - \beta_{\epsilon,j}) \mathrm{Im}\{\bar{w} \nabla w\} \cdot \tau \, ds \right| &\leq C(\delta'_\epsilon)^2 \ln|\ln \delta_\epsilon'||\ln \epsilon| \left[\int_{\gamma_{\delta'_\epsilon,j}} |\nabla w|^2 \mathrm{d}s \right]^{1/2} \\ &\leq 2C(\delta'_\epsilon)^2 \ln|\ln \delta_\epsilon'||\ln \epsilon| \left[\int_{\gamma_{\delta'_\epsilon,j}} |\nabla v|^2 \mathrm{d}s \right]^{1/2} \\ &\leq C' \delta'_\epsilon \ln|\ln \delta_\epsilon'||\ln \epsilon|^2 \leq C'' \ln(\ln|\ln \epsilon|),\end{aligned}$$

using (5.24) to replace $|\nabla w|^2 = |\nabla v|^2/|v|^2 \leq 2|\nabla v|^2$, and (5.25) for the next-to-last line above. Then, we calculate,

$$\begin{aligned}\int_{\gamma_{\delta'_\epsilon}} (h_* - h_{ex}) \mathrm{Im}\{\bar{w} \nabla w\} \cdot \tau \, \mathrm{d}s &= \int_{\gamma_{\delta'_\epsilon}} \beta_{\epsilon,j} \mathrm{Im}\{\bar{w} \nabla w\} \cdot \tau \, \mathrm{d}s + \int_{\gamma_{\delta'_\epsilon}} (h_* - h_{ex} - \beta_{\epsilon,j}) \mathrm{Im}\{\bar{w} \nabla w\} \cdot \tau \, \mathrm{d}s \\ &= 2\pi \beta_{\epsilon,j} \deg(w; \gamma_{\delta'_\epsilon,j}) + O(\ln(\ln|\ln \epsilon|)),\end{aligned}$$

which establishes Step 4.

Step 5: Conclusion. By (5.30) and the linear growth of a (hypothesis (H3)) if $\rho_j(p_i) = \mathrm{dist}(p_i, \partial\omega_j) \in [\delta'_\epsilon, \sigma_\epsilon]$, (with σ_ϵ as in (5.23)),

$$|h_*(p_i) - h_{ex} - \beta_{\epsilon,j}| \leq C[\rho_j(p_i)]^2 \ln|\ln \rho(p_i)||\ln \epsilon| \leq C\rho_j(p_i)\sigma_\epsilon \ln|\ln \sigma_\epsilon||\ln \epsilon| \leq Ca(p_i)(\ln|\ln \epsilon|)^{1/2}.$$

Combining Steps 2, 3, and 4, we have,

$$\begin{aligned}\int_{\Omega_{\delta'_\epsilon}} \nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v} \nabla v\} = &-2\pi \sum_{\rho(p_i) > \sigma_\epsilon} (h_*(p_i) - h_{ex}) d_i - 2\pi \sum_{j=1}^n \beta_{\epsilon,j} \deg(w; \gamma_{\delta'_\epsilon,j}) \\ &- 2\pi \sum_{j=1}^n \left[\sum_{\delta'_\epsilon < \rho_j(p_i) \leq \sigma_\epsilon} \beta_{\epsilon,j} d_i \right] + O((\ln|\ln \epsilon|)^{1/2}) \left[1 + \sum_{\rho_j(p_i) > \delta'_\epsilon} a(p_i)|d_i| \right].\end{aligned}$$

Since

$$\deg(w; \gamma_{\sigma_\epsilon,j}) = \deg(w; \gamma_{\delta'_\epsilon,j}) + \sum_{\delta'_\epsilon < \rho_j(p_i) \leq \sigma_\epsilon} d_i,$$

we obtain

$$\begin{aligned}\int_{\Omega_{\delta'_\epsilon}} \nabla^\perp h_* \cdot \mathrm{Im}\{\bar{v} \nabla v\} = &-2\pi \sum_{\rho(p_i) > \sigma_\epsilon} (h_*(p_i) - h_{ex}) d_i - 2\pi \sum_{j=1}^n \beta_{\epsilon,j} \deg(w; \gamma_{\sigma_\epsilon,j}) \\ &+ O((\ln|\ln \epsilon|)^{1/2}) \left[1 + \sum_{\rho(p_i) > \delta'_\epsilon} a(p_i)|d_i| \right].\end{aligned}$$

This last error term may be absorbed into the first term in the lower bound expansion in the balls, (5.22), by adjusting the constant C_0. The conclusion of the Lemma then follows by combining the above with (5.22) in the definition of $\mathcal{E}_\epsilon$. □

D. Analysis of vortices

We now proceed to the proof of Theorem 1.3 using the lower bound established in Lemma 5.3. From the upper bound (5.18) and Lemma 5.3 we have the estimate,

$$O([\ln|\ln \epsilon|]^{1/2}) \geq \pi \sum_{\rho(p_i)>\sigma_\epsilon} a(p_i)|d_i|(|\ln \epsilon| - C_0 \ln|\ln \epsilon|) + 2\pi \sum_{\rho(p_i)>\sigma_\epsilon} (h_*(p_i) - h_{ex})d_i + 2\pi \sum_{j=1}^{n} \beta_{\epsilon,j}\Delta_j + \int_{\Omega_{\sigma_\epsilon}\setminus \cup B_i} \left\{ \frac{a}{2}|(\nabla - iA_v)v|^2 + \frac{a^2}{4\epsilon^2}(|v|^2-1)^2 + (\operatorname{curl} A_v)^2 \right\}, \tag{5.31}$$

in terms of the vortex balls defined in Proposition 5.2. If we consider only the net contribution of interior vortices to (5.31), we see that adding vortex at location p_i becomes economical when $2(h_{ex} - h_*(p_i)) \simeq 2h_{ex}\zeta(p_i)$ exceeds $a(p_i)|\ln \epsilon|$. This rough observation leads us to choose a candidate for a critical value λ_*, defined by

$$\frac{1}{\lambda_*} := \max_{x\in\Omega} \frac{2\zeta(x)}{a(x)}. \tag{5.32}$$

We note that the boundary estimate (3.11), when applied to ζ, shows that

$$0 < \zeta(x)/a(x) \leq C\rho(x)\ln|\ln \rho(x)|$$

for x near each $\partial\omega_j$, and hence the maximum is attained on a set

$$\Gamma := \{x \in \Omega : 2\lambda_*\zeta(x) = a(x)\}$$

which lies strictly *inside* Ω. We note as in the Introduction, the optimal set Γ can be of two different forms:

Case A: Γ is a finite point set.

Case B: Γ contains at least one closed curve γ. In either case we have the following.

Lemma 5.4: There exist constants $K_1 > 0$ and $M \geq 1$ such that

$$\frac{2\zeta(x)}{a(x)} \leq \frac{1}{\lambda_*} - \frac{K_1}{\sqrt{|\ln \epsilon|}} \tag{5.33}$$

whenever $\operatorname{dist}(x,\Gamma) \geq |\ln \epsilon|^{-1/4M}$.

The proof, based on the real analyticity of ζ and a, is exactly as in Ref. 3, and is omitted.

We now proceed as in Refs. 1 and 3 and treat the vortices in different cases, depending on whether they lie close to the optimal set Γ or the boundaries of ω_j. Let $\gamma > 0$ to be chosen so that

$$\frac{\zeta(x)}{a(x)} < \frac{1}{8\lambda_*} \quad \text{for all } x \in \Omega \text{ with } \rho(x) < \gamma. \tag{5.34}$$

Then we define index sets,

$$Z_\gamma := \{i : \sigma_\epsilon < \operatorname{dist}(p_i, \cup_{j=1}^n \partial\omega_j) \leq \gamma\},$$

$$Z_* := \{i : \operatorname{dist}(p_i,\Gamma) < |\ln \epsilon|^{-1/2M} \quad \text{and} \quad d_i \geq 0\},$$

$$Z_- := \{i : \operatorname{dist}(p_i,\Gamma) < |\ln \epsilon|^{-1/2M} \quad \text{and} \quad d_i < 0\},$$

$$Z_0 := (Z_* \cup Z_- \cup Z_\gamma)^C,$$

and set

$$N_x := \sum_{Z_x} a(p_i)|d_i|, \quad x = \gamma, *, -, 0; \quad \mathbf{N}_\epsilon = \sum a(p_i)|d_i| = N_* + N_\gamma + N_- + N_0.$$

The estimate of the interaction term in (5.31) is then different depending on which category the vortex ball belongs to.

Consider first vortex balls with $i \in Z_\gamma$. For such vortex balls, $a(p_i)|\ln \epsilon| \geqslant C\sigma_\epsilon|\ln \epsilon| \geqslant C[\ln|\ln \epsilon|]^{1/4}$. Therefore, using Lemma 3.4 we have:

$$\begin{aligned}|h_{ex} - h_*(p_i)| &\leqslant h_{ex}\zeta(p_i) + |h_{ex}(1-\zeta(p_i)) - h_*(p_i)| \leqslant \frac{1}{8\lambda_*}a(p_i)h_{ex} + C \\ &\leqslant \frac{1}{8\lambda_*}a(p_i)h_{ex} + \frac{C'}{[\ln|\ln \epsilon|]^{1/4}}a(p_i)|\ln \epsilon| \leqslant \frac{1}{6\lambda_*}a(p_i)h_{ex}.\end{aligned}$$

Therefore, recalling that $h_{ex} = \lambda|\ln \epsilon| + \mu \ln|\ln \epsilon|$, we estimate the first two terms in (5.31) corresponding to vortex balls counted by Z_γ by

$$\begin{aligned}&\pi\sum_{Z_\gamma} a(p_i)|d_i|(|\ln \epsilon| - C_0\ln|\ln \epsilon|) + 2\pi\sum_{Z_\gamma}(h_*(p_i) - h_{ex})d_i \\ &\quad \geqslant \pi N_\gamma\left[\left(1 - \frac{\lambda}{3\lambda_*}\right)|\ln \epsilon| - \left(C_0 + \frac{\mu}{3\lambda_*}\right)\ln|\ln \epsilon|\right] \geqslant \pi N_\gamma\left(1 - \frac{\lambda}{2\lambda_*}\right)|\ln \epsilon|. \qquad (5.35)\end{aligned}$$

When $\mathrm{dist}(p_i, \partial\omega_j) \geqslant \gamma$, we use Lemma 3.4 to obtain:

$$|h_*(p_i) - h_{ex} + h_{ex}\zeta(p_i)| \leqslant C \leqslant \frac{C}{a_0}a(p_i),$$

where $a_0 = \min\{a(x) : \mathrm{dist}(x, \cup_j \partial\omega_j) \geqslant \gamma\}$. Hence,

$$\begin{aligned}&\pi\sum_{i \in Z_* \cup Z_- \cup Z_0} \{a(p_i)|d_i|(|\ln \epsilon| - C_0\ln|\ln \epsilon|) + 2(h_*(p_i) - h_{ex})d_i\} \\ &\quad \geqslant \pi\sum_{i \in Z_* \cup Z_- \cup Z_0} \{a(p_i)|d_i|(|\ln \epsilon| - C_0'\ln|\ln \epsilon|) - 2h_{ex}\zeta(p_i)d_i\},\end{aligned}$$

with constant $C_0' \geqslant C_0$, absorbing the $O(1)$ term above. For vortices counted by Z_* and by Z_- we are content to estimate $0 < \zeta(p_i)/a(p_i) \leqslant 1/2\lambda_*$. For Z_*, this results in a lower bound,

$$\pi\sum_{Z_*} a(p_i)|d_i|(|\ln \epsilon| - C_0'\ln|\ln \epsilon|) - 2\pi h_{ex}\sum_{Z_*}\zeta(p_i)d_i \geqslant \pi N_*\left[\left(1 - \frac{\lambda}{\lambda_*}\right)|\ln \epsilon| - \left(C_0' + \frac{\mu}{\lambda_*}\right)\ln|\ln \epsilon|\right]. \qquad (5.36)$$

For vortices counted by Z_- we note in addition that the contribution to the energy is positive. Hence, the first two terms in (5.31) coming from these vortex balls may be estimated by

$$\pi\sum_{Z_-} a(p_i)|d_i|(|\ln \epsilon| - C_0'\ln|\ln \epsilon|) - 2\pi h_{ex}\sum_{Z_-}\zeta(p_i)d_i \geqslant \frac{\pi}{2}N_-|\ln \epsilon|. \qquad (5.37)$$

Finally, when the vortices are counted by Z_0 we use (5.33). This leads to the lower bound,

$$\begin{aligned}
&\pi\sum_{Z_0} a(p_i)|d_i|(|\ln\epsilon| - C_0'\ln|\ln\epsilon|) - 2\pi h_{ex}\sum_{Z_0}\zeta(p_i)d_i \\
&\quad\geqslant \pi N_0\left[\left(1-\frac{\lambda}{\lambda_*}+\frac{K_1}{\sqrt{|\ln\epsilon|}}\right)|\ln\epsilon| - \left(C_0'+\frac{\mu}{\lambda_*}\right)\ln|\ln\epsilon| + o(1)\right] \\
&\quad\geqslant \pi N_0\left(1-\frac{\lambda}{\lambda_*}+\frac{K_2}{\sqrt{|\ln\epsilon|}}\right)|\ln\epsilon|. \qquad (5.38)
\end{aligned}$$

Substituting (5.35)–(5.38) into (5.31) we obtain:

$$\begin{aligned}
O([\ln|\ln\epsilon|]^{1/2}) &\geqslant \pi N_\gamma\left(1-\frac{\lambda}{2\lambda_*}\right)|\ln\epsilon| + \frac{1}{2}\pi N_-|\ln\epsilon| + \pi N_*\left[\left(1-\frac{\lambda}{\lambda_*}\right)|\ln\epsilon| - \left(C_0'+\frac{\mu}{\lambda_*}\right)\ln|\ln\epsilon|\right] \\
&\quad + \pi N_0\left(1-\frac{\lambda}{\lambda_*}+\frac{K_2}{\sqrt{|\ln\epsilon|}}\right)|\ln\epsilon| + 2\pi\sum_{j=1}^{n}\beta_{\epsilon,j}\Delta_j \\
&\quad + \int_{\Omega_{\sigma_\epsilon}\setminus\cup B_i}\left\{\frac{a}{2}|(\nabla - iA_v)v|^2 + (\operatorname{curl} A_v)^2\right\}. \qquad (5.39)
\end{aligned}$$

One difficulty in dealing with this lower bound expansion is the presence of the boundary terms coming from each $\partial\omega_j$, since we have no *a priori* bound on the degrees Δ_j around each curve $\gamma_{j,\sigma_\epsilon}$ surrounding the pinning sites. As in Refs. 1 and 3 we must consider two cases separately.

Case I: $\max_{j=1,\ldots,n}|\Delta_j| \leqslant 2\Sigma_{i=1}^{m}|d_i|$.

Since each $\beta_{\epsilon,j}$ is uniformly bounded (independent of ϵ),

$$\begin{aligned}
|\beta_{\epsilon,j}\Delta_j| &\leqslant C\sum_{i=1}^{m}|d_i| \leqslant \left[\frac{C}{[\ln|\ln\epsilon|]^{1/4}}\sum_{Z_\gamma}a(p_i)|d_i||\ln\epsilon| + \frac{C}{a_\gamma}\sum_{Z_*\cup Z_0\cup Z_-}a(p_i)|d_i|\right] \\
&\leqslant \frac{\pi}{8}N_\gamma|\ln\epsilon| + C'(N_* + N_0 + N_-),
\end{aligned}$$

with $a_\gamma = \min\{a(x):\rho(x)\geqslant\gamma\}$. In particular, we may absorb these terms into (5.39) without affecting the sign of each term for $\lambda\leqslant\lambda_*$:

$$\begin{aligned}
O([\ln|\ln\epsilon|]^{1/2}) &\geqslant \pi N_\gamma\left(\frac{3}{4}-\frac{\lambda}{2\lambda_*}\right)|\ln\epsilon| + \pi N_-\left(\frac{1}{4}+\frac{\lambda}{\lambda_*}\right)|\ln\epsilon| + \pi N_*\left[\left(1-\frac{\lambda}{\lambda_*}\right)|\ln\epsilon|\right. \\
&\quad \left. - \left(C_0''+\frac{\mu}{\lambda_*}\right)\ln|\ln\epsilon|\right] + \pi N_0\left(1-\frac{\lambda}{\lambda_*}+\frac{K_3}{\sqrt{|\ln\epsilon|}}\right)|\ln\epsilon| \\
&\quad + \int_{\Omega_{\sigma_\epsilon}\setminus\cup B_i}\left\{\frac{a}{2}|(\nabla - iA_v)v|^2 + (\operatorname{curl} A_v)^2\right\}, \qquad (5.40)
\end{aligned}$$

with C_0'', K_3 constant.

Consider first the subcritical case $\lambda<\lambda_*$ in (5.1). Then all coefficients of $|\ln\epsilon|$ are positive, and we have

$$\mathbf{N}_\epsilon = N_* + N_- + N_0 + N_\gamma \leqslant O\left(\frac{[\ln|\ln\epsilon|]^{1/2}}{|\ln\epsilon|}\right).$$

Because of the vanishing of $a(x)$ near each $\partial\omega_j$, we cannot directly conclude that there are no vortex balls in Ω_{σ_ϵ}; however, we can restrict our attention to a smaller set to obtain the desired conclusion. Let σ'_ϵ be chosen with

$$\frac{[\ln|\ln\epsilon|]^{1/2}}{|\ln\epsilon|} \ll \sigma'_\epsilon \ll 1.$$

Then for any such choice, by the linearity of $a(x)$ near $\partial\omega_j$, we have

$$\sum_{\Omega_{\sigma'_\epsilon}} |d_i| \leqslant \frac{1}{\sigma'_\epsilon}\sum_{\Omega_{\sigma'_\epsilon}} a(p_i)|d_i| = o(1),$$

and hence there are no essential vortices in $\Omega_{\sigma'_\epsilon}$ for $\lambda < \lambda_*$.

Now consider the critical case, $\lambda = \lambda_*$. Now there is cancellation of the terms multiplying $|\ln\epsilon|$, and (5.40) implies:

$$O([\ln|\ln\epsilon|]^{1/2}) \geqslant \frac{\pi}{4}N_\gamma|\ln\epsilon| + \pi N_-|\ln\epsilon| + CN_0\sqrt{|\ln\epsilon|} - \pi N_*\left(C_0'' + \frac{\mu}{\lambda_*}\right)\ln|\ln\epsilon| + G_\epsilon(v,A_v;\Omega_\epsilon \setminus \cup B_i), \tag{5.41}$$

where we define for $U \subset \Omega$,

$$G_\epsilon(v,A_v;U) := \int_U \left\{\frac{a}{2}|\nabla_{A_v}v|^2 + \frac{a^2}{4\epsilon^2}(|v|^2-1)^2 + \frac{1}{2}(\operatorname{curl} A_v)^2\right\}. \tag{5.42}$$

When $\mu < -C_0''\lambda_*$ all terms on the right-hand side have positive coefficients, and so we conclude that:

$$\sum_{\sigma_\epsilon < \operatorname{dist}(p_i,\cup\omega_j) < \sigma'_\epsilon} |d_i| < o(|\ln\epsilon|[\ln|\ln\epsilon|]^{-1/2})\sum_{Z_\gamma} a(p_i)|d_i| = o(1),$$

$$\sum_{Z_*} |d_i| \leqslant CN_* = O([\ln|\ln\epsilon|]^{-1/2}) = o(1),$$

$$\sum_{Z_-} |d_i| \leqslant CN_- = O([\ln|\ln\epsilon|]^{1/2}|\ln\epsilon|^{-1}) = o(1),$$

$$\sum_{Z_0} |d_i| \leqslant CN_0 = O([\ln|\ln\epsilon|]^{1/2}|\ln\epsilon|^{-1/2}) = o(1).$$

Each of these being integer valued, we conclude that there are no essential vortices in $\Omega_{\sigma'_\epsilon}$ for small ϵ when $\lambda = \lambda_*$ but $\mu < \mu_*$. This proves part (i) of Theorem 1.3, in Case I.

If the applied field is larger at the scale $\ln|\ln\epsilon|$, $\mu > \mu_* = -C_0''\lambda_*$, we may rearrange the terms of (5.41) and divide by $\sqrt{|\ln\epsilon|}$ to arrive at an inequality,

$$N_\gamma + N_0 + N_- \leqslant CN_*\frac{\ln|\ln\epsilon|}{\sqrt{|\ln\epsilon|}} + O\left(\frac{[\ln|\ln\epsilon|]^{1/2}}{\sqrt{|\ln\epsilon|}}\right), \tag{5.43}$$

with C independent of ϵ. Already this implies that a negligable fraction of the essential vortices are outside of a vanishingly small neighborhood of Γ or have negative degrees. We will use the

remaining term (the energy of (v,A_v) outside the balls) to bound N_* and eliminate these undesirable vortices (counted by N_γ, N_-, N_0) completely. We follow the argument of Ref. 3.

By hypothesis, each of the $(n+1)$ boundary curves (one for each $\partial\omega_j$, and the exterior boundary $\partial\mathcal{D}$) is smooth, and hence the distance functions

$$\rho_j(x) = \begin{cases} \operatorname{dist}(x,\partial\omega_j) & \text{for } j=1,\dots,n; \\ \operatorname{dist}(x,\partial\mathcal{D}) & \text{for } j=0, \end{cases}$$

are smooth in some neighborhood of each boundary curve. Let $z_0>0$ be chosen small enough that each ρ_j is smooth in the set $\widetilde{\Omega}_{z_0}=\{x\in\Omega:\operatorname{dist}(x,\partial\Omega)<z_0\}$. Then for all $0<z<z_0$, $|\nabla\rho_j|=1$ and $\partial\widetilde{\Omega}_z$ consists of exactly $(n+1)$ smooth curves $\gamma_{j,z}$, $j=0,\dots,n$, each homotopic to a component of $\partial\Omega$. Denote also $\widetilde{\Omega}_{j,z}$ the component of $\widetilde{\Omega}_z$ bounded by $\gamma_{j,z}$ and $\widetilde{\Omega}_{j,z_1,z_2}=\widetilde{\Omega}_{j,z_2}\setminus\widetilde{\Omega}_{j,z_1}$, an annular domain for each $j=0,\dots,n$.

Define $I_0:=(0,z_0)$ and

$$J_{j,\epsilon} := \left\{ z\in(0,z_0): \gamma_{j,z}\cap \cup B_{s_i}(p_i)=\emptyset \right\}.$$

In other words, $z\in J_{j,\epsilon}$ if the curve $\gamma_{j,z}$ intersects none of the vortex balls. By Proposition 5.2 the set $J_{j,\epsilon}$ is a finite union of intervals whose complement $|(0,z_0)\setminus J_{j,\epsilon}|<|\ln\epsilon|^{-12}$ has very small measure. For each $z\in J_\epsilon$, it follows that $|v|\geqslant 1-|\ln\epsilon|^{-4}$ and hence we may define

$$\Delta_j(z) := \deg\left(\frac{v}{|v|},\gamma_{j,z}\right), \quad j=0,\dots,n.$$

For $j\in\{0,\dots,n\}$ fixed, choose $0<z_1<z_2<z_0$ so that both $z_1,z_2\in J_{j,\epsilon}$. Let

$$a_0 := \min\left\{a(x): x\in \cup_{j=0}^n \widetilde{\Omega}_{j,z_1,z_2}\right\} > 0.$$

Using (5.43), we have

$$|\Delta_j(z_1)-\Delta_j(z_2)| = \left|\sum_{p_i\in\Omega_{j,z_1,z_2}} d_i\right| \leqslant \frac{1}{a_0}\sum_{p_i\in\Omega_{j,z_1,z_2}} a(p_i)|d_i| \leqslant N_0 \leqslant o(1)N_*. \tag{5.44}$$

Now, γ_{0,z_2} encloses all the inner curves γ_{j,z_2}, $j=1,\dots,n$, as well as the optimal set Γ, and therefore

$$\left|\Delta_0(z_2)-\sum_{j=1}^n \Delta_j(z_2)\right| = \left|\sum_{\operatorname{dist}(p_i,\partial\Omega)\geqslant z_2} d_i\right| \geqslant \sum_{\substack{\operatorname{dist}(p_i,\partial\Omega)\geqslant z_2 \\ d_i\geqslant 0}} d_i - \sum_{\substack{\operatorname{dist}(p_i\partial\Omega)\geqslant z_2 \\ d_i<0}} d_i$$

$$\geqslant \frac{1}{a_0}(N_*-(N_-+N_0+N_\gamma)) \geqslant \frac{1}{a_0}N_*(1-o(1)).$$

In particular, it follows that there exists at least one $j_0\in\{0,\dots,n\}$ such that

$$|\Delta_{j_0}(z_2)| \geqslant \frac{1}{a_0(n+1)}N_*.$$

By (5.44) we have

$$|\Delta_{j_0}(z)| \geqslant \frac{1}{2a_0(n+1)}N_* \quad \text{for every } z\in[z_1,z_2]. \tag{5.45}$$

Writing $v=|v|e^{i\phi}$ we estimate the remaining term in the energy using the coarea formula,

$$\int_{\widetilde{\Omega}_{j_0,z_1,z_2}\setminus\cup B_i} a|(\nabla - iA_v)v|^2 dx \geqslant a_0 \int_{\widetilde{\Omega}_{j_0,z_1,z_2}\setminus\cup B_i} \frac{|(\nabla - iA_v)v|^2}{|\nabla \rho_{j_0}|} |\nabla \rho_{j_0}| \mathrm{d}x$$

$$\geqslant a_0 \int_{J_{j_0,\epsilon}} \int_{\gamma_{j_0,z}} |(\nabla - iA_v)v|^2 \mathrm{d}\mathcal{H}^1 \mathrm{d}z$$

$$= a_0 \int_{J_{j_0,\epsilon}} \int_{\gamma_{j_0,z}} |v|^2 |\nabla\phi - A_v|^2 \mathrm{d}\mathcal{H}^1 \mathrm{d}z$$

$$\geqslant \frac{a_0}{2} \int_{J_{j_0,\epsilon}} \int_{\gamma_{j_0,z}} |\nabla\phi - A_v|^2 \mathrm{d}\mathcal{H}^1 \mathrm{d}z, \tag{5.46}$$

since $|v(x)| \geqslant 1 - |\ln \epsilon|^{-4}$ for $z \in J_{j_0,\epsilon}$.

To estimate the last term in (5.46) we use the definition of the degrees and Stokes' Theorem: for $z \in J_{j_0,\epsilon}$,

$$2\pi\Delta_{j_0}(z) - \int_{\widetilde{\Omega}_{j_0,z}} \operatorname{curl} A_v \mathrm{d}x = \int_{\gamma_{j_0,z}} (\nabla\phi - A_v)\cdot\tau \,\mathrm{d}\mathcal{H}^1 \leqslant \left[\mathcal{H}^1(\gamma_{j_0,z}) \int_{\gamma_{j_0,z}} |\nabla\phi - A_v|^2\right]^{1/2},$$

by Cauchy–Schwartz. Rearranging and squaring,

$$4\pi^2[\Delta_{j_0}(z)]^2 \leqslant 2\mathcal{H}^1(\gamma_{j_0,z}) \int_{\gamma_{j_0,z}} |\nabla\phi - A_v|^2 + 2\left[\int_{\widetilde{\Omega}_{j_0,z}\setminus\cup B_i} \operatorname{curl} A_v \mathrm{d}x + \int_{\widetilde{\Omega}_{j_0,z}\cap(\cup B_i)} \operatorname{curl} A_v \mathrm{d}x\right]^2$$

$$\leqslant C\left[\int_{\gamma_{j_0,z}} |\nabla\phi - A_v|^2 + \int_{\widetilde{\Omega}_{j_0,z}\setminus\cup B_i} (\operatorname{curl} A_v)^2 \mathrm{d}x\right] + o(1). \tag{5.47}$$

We now integrate for $z \in (z_1, z_2)$, use (5.45) and (5.46), and substitute into $G_\epsilon(v, A_v; \widetilde{\Omega}_{j_0,z_1,z_2}\setminus\cup B_i)$:

$$G_\epsilon(v, A_v; \widetilde{\Omega}_{j_0,z_1,z_2}\setminus\cup B_i) \geqslant C\int_{J_{j_0,\epsilon}} [\Delta_{j_0}(z)]^2 \mathrm{d}z \geqslant C\mathcal{L}(J_{j_0,\epsilon})N_*^2(1 - o(1)) \geqslant C_1 N_*^2. \tag{5.48}$$

Returning to the estimate (5.41) we see

$$O([\ln|\ln\epsilon|]^{1/2}) \geqslant C_1 N_*^2 - C_2 N_* \ln|\ln\epsilon|,$$

with constants C_1, C_2 independent of ϵ. We conclude that

$$N_* \leqslant C \ln|\ln\epsilon|. \tag{5.49}$$

Since $a(x)$ is bounded below in a neighborhood of the optimal set Γ, we also conclude that the total degree of interior vortices,

$$\sum_{\operatorname{dist}(p_i,\Gamma)<[|\ln\epsilon|]^{-1/4M}} |d_i| \leqslant C \ln|\ln\epsilon|.$$

With (5.43) and (5.49) we have

$$\max\{N_\gamma, N_-, N_0\} \leqslant C\frac{(\ln|\ln\epsilon|)^2}{|\ln\epsilon|^{1/2}} - o(1).$$

Again we are faced with the problem that $a(x)$ vanishes at each pinning site, and so we again need to further restrict the domain to reach a conclusion concerning the nonexistence of interior vortices. Choose any ρ_ϵ with

$$\frac{(\ln|\ln\epsilon|)^2}{|\ln\epsilon|^{1/2}} \ll \rho_\epsilon \ll 1.$$

Then, hypothesis (H3) again implies that

$$\sum_{\substack{i\in Z_\gamma\cup Z_0\cup Z_- \\ \mathrm{dist}(p_i,\cup\omega_j)>\rho_\epsilon}} |d_i| = o(1).$$

Since the degrees are integers, this implies that they are all zero for ϵ sufficiently small, and hence all vortices which lie at least a distance ρ_ϵ from the pinning sites must have nonnegative degree and lie nearby Γ. This, together with (5.49), proves the first part of (ii) of Theorem 1.3 in Case I. To verify (iv) in Case I, we return to the estimate (5.48): choose z_1, z_2 so that each $\widetilde{\Omega}_{j,z_1,z_2}$ lies strictly between the set Γ and the boundary components ω_j, $j=1,\ldots,n$. Recall that we have already shown that there are no essential vortex balls (that is, balls with $d_i\neq 0$) inside $\widetilde{\Omega}_{j,z_1,z_2}$, so $\Delta_j(z)=\Delta_j(z_1)$ is constant in each of these regions. We then re-do estimate (5.48) to obtain a lower bound in terms of $\Delta_j(z_1)$, for each $j=1,\ldots,n$:

$$G_\epsilon(v,A_v;\widetilde{\Omega}_{j_0,z_1,z_2}\setminus\cup B_i) \geqslant C\int_{J_{j,\epsilon}} [\Delta_j(z)]^2 dz \geqslant C\mathcal{L}(J_{j,\epsilon})[\Delta_j(z_1)^2] \geqslant C[\Delta_j(z_1)]^2.$$

Substituting all we know into (5.41) we then have

$$C\sum_{j=1}^{n}[\Delta_j(z_1)]^2 \leqslant G_\epsilon(v,A_v;\widetilde{\Omega}_{j,z_1,z_2}) \leqslant N_*\ln|\ln\epsilon| + O([\ln|\ln\epsilon|]^{1/2}) \leqslant C[\ln|\ln\epsilon|]^2.$$

Hence we conclude $|\Delta_j(z_1)|=|\deg(v/|v|\gamma_{z_1,j})|\leqslant C\ln|\ln\epsilon|$. Since there are no essential vortices between a neighborhood of Γ and a neighborhood of $\cup_j\omega_j$, for any fixed simple closed curve γ homotopic to $\partial\omega_j$ (for some j) which does not wind around any subset of Γ we obtain $|\deg(v/|v|;\gamma)|\leqslant C\ln|\ln\epsilon|$, proving (iv) in Case I.

It remains to prove the upper bound on the total degree stated in parts (ii) and (iii). First we consider Case A, when Γ is a set of isolated points. We return to (5.41) and estimate from below the term $G_\epsilon(v,A_v;\widetilde{\Omega}_\epsilon)$ as in Step 3 of Ref. 17. For any isolated point $P\in\Gamma$ there exists $R>0$ so that $B_R(P)$ remains disjoint from all other points of Γ and from $\partial\Omega$. Let $a_P=\min_{x\in B_R(P)}a(x)>0$. Define $\tau_\epsilon:=|\ln\epsilon|^{-1/4M}$, and

$$D_P = \sum_{\mathrm{dist}(p_i,P)<\tau_\epsilon} d_i.$$

By the analysis above, $\deg(v/|v|;\partial B_r(P))=D_P$ is constant for all $r\in(\rho,R)$, since we have shown already that there are no vortex balls with nonzero degree in the annular region surrounding P. Step 3 of Ref. 17 then applies without modification to obtain the lower bound,

$$\begin{aligned}
&\frac{1}{2}\int_{B_R(P)\setminus B_{\tau_\epsilon}(P)}\left(a(x)|(\nabla-iA_v)v|^2+\frac{a^2(x)}{2\epsilon^2}(|v|^2-1)^2\right)+\frac{1}{2}\int_{B_R(P)}(\mathrm{curl}\,A)^2\\
&\quad\geqslant \min\{a_P,1\}\frac{1}{2}\int_{B_R(P)\setminus B_{\tau_\epsilon}(P)}\left(|(\nabla-iA_v)v|^2+\frac{1}{2\epsilon^2}(|v|^2-1)^2\right)+\frac{1}{2}\int_{B_R(P)}(\mathrm{curl}\,A)^2\\
&\quad\geqslant CD_P^2\ln|\ln\epsilon|+o(1),
\end{aligned}$$

with constant C independent of ϵ. Since the facts $N_0=N_-=0$ imply $N_*=\Sigma_{P\in\Gamma}a(P)D_P$ we have the lower bound

$$G_\epsilon(v,A_v;\cup_{P\in\Gamma}(B_R(P)\setminus B_{\tau_\epsilon}(P))) \geq C' N_*^2 \ln|\ln\epsilon| + o(1),$$

with constant C' independent of ϵ. Replacing this estimate in (5.41) we have

$$O(\sqrt{\ln|\ln\epsilon|}) \geq C' N_*^2 \ln|\ln\epsilon| - \pi N_* \left(C_0'' + \frac{\mu}{\lambda_*}\right)\ln|\ln\epsilon|,$$

and hence N_* is uniformly bounded.

The upper bound on N_* for Case B requires a sharper energy estimate; we will present this proof in the final section. This concludes the analysis for Case I.

Case II: $|\Delta_j| > 2\Sigma_{\rho(p_i)\geq\sigma_\epsilon}|d_i|$ **for at least one** $j\in\{1,\ldots,n\}$.

Let $|\Delta_{j_0}| = \max|\Delta_j|$. Let z_0, $\widetilde{\Omega}_{j,z}$, $\widetilde{\Omega}_{j,z_1,z_2}$, $\Delta_j(r)$, J_ϵ be as in the previous case. By hypothesis,

$$|\Delta_{j_0}(z)| = \left|\Delta_{j_0} + \sum_{p_i\in\Omega_{j_0,z}} d_i\right| \geq \frac{1}{2}|\Delta_{j_0}| \quad \text{for all } z\in J_{j_0,\epsilon}.$$

We then estimate as in (5.46) and (5.47) to obtain:

$$G_\epsilon(v,A_v;\widetilde{\Omega}_{j_0,z_2}\setminus\cup B_i) \geq C\int_{J_{j_0,\epsilon}} (\Delta_{j_0}(z))^2 dz \geq C\frac{1}{4}\mathcal{L}(J_{j_0,\epsilon})\Delta_{j_0}^2 \geq C_1\Delta_{j_0}^2. \tag{5.50}$$

The boundary terms are estimated simply, as $|\beta_j|$ are uniformly bounded,

$$\left|2\pi\sum_{j=1}^{n}\Delta_j\beta_j\right| \leq C_2|\Delta_{j_0}|.$$

The lower bound (5.31) then gives,

$$\begin{aligned} O(\sqrt{\ln|\ln\epsilon|}) \geq{}& C_1\Delta_{j_0}^2 - C_2|\Delta_{j_0}| + \pi\sum_{\rho(p_i)\geq\sigma_\epsilon} a(p_i)|d_i|(|\ln\epsilon| - C_0\ln|\ln\epsilon|) + 2\pi\sum_{\rho(p_i)\geq\sigma_\epsilon} d_i(h_*(p_i)-h_{ex}) \\ &+ G_\epsilon(v,A_v;\Omega\setminus[\widetilde{\Omega}_{j_0,z_2}\cup(\cup B_i)]). \end{aligned}$$

We may now repeat the same steps as in Case I to derive (as in (5.40)),

$$\begin{aligned} O(\sqrt{\ln|\ln\epsilon|}) \geq{}& C_1\Delta_{j_0}^2 - C_2|\Delta_{j_0}| + \pi N_\gamma\left(\frac{3}{4}-\frac{\lambda}{2\lambda_*}\right)|\ln\epsilon| + \pi(N_*+N_0)|\ln\epsilon|\left(1-\frac{\lambda}{\lambda_*}\right) \\ &+ \pi N_-|\ln\epsilon|\left(\frac{1}{4}+\frac{\lambda}{\lambda_*}\right)(1+o(1)) - \pi N_*\left(C_0''+\frac{\mu}{\lambda_*}\right)\ln|\ln\epsilon| + CN_0\sqrt{|\ln\epsilon|}. \end{aligned} \tag{5.51}$$

Since $C_1\Delta_{j_0}^2 - C_2|\Delta_{j_0}| \geq -C_2/2C_1$ is uniformly bounded below, we may repeat the arguments from Case I to conclude that $\mathbf{N}_\epsilon = 0$ for $\lambda<\lambda_*$ or for $\lambda=\lambda_*$ and $\mu<-C_0\lambda_*$. In case $\lambda=\lambda_*$ and $\mu > -C_0\lambda_*$ we obtain (5.43) exactly as in Case I. Using the hypothesis of Case II we obtain from (5.51) that,

$$O(\sqrt{\ln|\ln\epsilon|}) \geq C_1\Delta_{j_0}^2 - C_2|\Delta_{j_0}| - C_3N_*\ln|\ln\epsilon| \geq C_1\Delta_{j_0}^2 - C_4(1+\ln|\ln\epsilon|)|\Delta_{j_0}|.$$

From this we obtain $|\Delta_{j_0}| \leq C\ln|\ln\epsilon|$ for constant C independent of ϵ, and by the Case II hypothesis then $N_* \leq \frac{1}{2}|\Delta_{j_0}| \leq C\ln|\ln\epsilon|$, and the remaining conclusions follow as in Case I.

This completes the proof of parts (i) and (ii) of Theorem 1.3.

E. Case B: Γ contains a closed curve

Now we consider the case that the optimal set Γ contains one or more closed curves γ, in which case Theorem 1.3 asserts that the total degree inside Ω is at least of the order $O(\ln|\ln \epsilon|)$. This part is very similar to the analogous parts of Refs. 1 and 3, and we only provide a sketch here for completeness. The main idea is to derive a stronger upper bound on the energy, with n_ϵ simple vortices regularly placed along γ. The construction uses a modified Green's function to construct a trial configuraton, which we expect well approximates the actual minimizer.

To avoid some technical difficulties associated with the vanishing of a at $\partial\Omega$ we fix t with $0<t<\max_{x\in\Gamma} a(x)$, and consider the truncation

$$a_t(x) := \max\{a(x),t\}.$$

Following Refs. 16, 20, and 2 we use a Green's function to construct our trial function.

Lemma 5.5: *For every fixed $y\in\Omega$ there exist $G(x,y)$ and constants $g_j=g_j(y)$, $j=1,\ldots,n$, such that*

$$-\operatorname{div}_x\left(\frac{1}{a_t}\nabla_x G(x,y)\right)+G(x,y)=\delta_y(x) \quad \text{in } \mathcal{D}'(\mathcal{D}), \tag{5.52}$$

$$G(x,y)\big|_{x\in\partial\mathcal{D}}=0, \tag{5.53}$$

$$G(x,y)\big|_{x\in\partial\omega_j}=g_j, \tag{5.54}$$

$$\int_{\partial\omega_j}\frac{1}{a_t}\frac{\partial G}{\partial \nu_x}=g_j|\omega|. \tag{5.55}$$

Moreover:

(i) $G(x,y)\geqslant 0$ *in* $x\in\bar{\Omega}\backslash\{y\}$ *for each* $y\in\Omega$.

(ii) *For any compact set* $K\subset\subset\Omega$ *there exists a constant* C_K *such that*

$$\left|G(x,y)+\frac{a_t(x)}{2\pi}\ln|x-y|\right|\leqslant C(K) \tag{5.56}$$

for all $y\in K$ *and* $x\in\bar{\Omega}$.

The proof is a combination of the analogous results in Refs. 1 and 3, and is omitted.

To construct the upper bound, we adapt a construction from Ref. 16. (See also Refs. 20 and 2.) Choose n_ϵ points $\{p_i\}_{i=1,\ldots,n_\epsilon}$ which are equidistributed on γ. In particular, we have $|p_i-p_j|\geqslant C/n_\epsilon$ for some $C>0$. Define

$$f_\epsilon^i(x)=\frac{2}{\epsilon^2}\chi_{B_\epsilon(p_i)},$$

the characteristic function of the ball $B_\epsilon(p_i)$, normalized to have total integral 2π. Let

$$f_\epsilon(x)=\frac{1}{n_\epsilon}\sum_{i=1}^{n_\epsilon} f_\epsilon^i(x).$$

The f_ϵ converge weak-$*$ in the sense of measures, $f_\epsilon\rightharpoonup\mu_*=[2\pi/\mathrm{per}_\Omega(\gamma)]\delta_\gamma$, the arclength measure on γ normalized to have mass 2π.

We define the trial function via its magnetic field,

$$h_\epsilon(x) = n_\epsilon \int_\Omega G(x,y) f_\epsilon(y) \mathrm{d}y, \quad x \in \Omega.$$

Then h_ϵ solves the boundary-value problem,

$$-\nabla \cdot \left(\frac{1}{a_t} \nabla h_\epsilon \right) + h_\epsilon = n_\epsilon f_\epsilon \quad \text{in } \Omega,$$

$$h|_{\partial \mathcal{D}} = 0,$$

$$h|_{\partial \omega_j} = n_\epsilon \int_\Omega g_j(y) f_\epsilon(y) \mathrm{d}y := H_{\epsilon,j}(\text{constant}),$$

$$\int_{\partial \omega_j} \frac{1}{a_t} \frac{\partial h_\epsilon}{\partial \nu} = H_{\epsilon,j} |\omega_j|, \quad j = 1, \ldots, n.$$

We then extend $h_\epsilon(x)$ to all of $\mathcal{D}$ by defining h_ϵ to be constant $h_\epsilon(x) = H_{\epsilon,j}$ in each ω_j. Finally, we define A_ϵ to be the associated vector potential in the Coulomb gauge, defined as in (2.3).

Next, we define an order parameter V associated to h_ϵ. Since

$$\operatorname{curl}\left(\frac{1}{a_t} \nabla^\perp h_\epsilon - A_\epsilon \right) = \nabla \cdot \left(\frac{1}{a_t} \nabla h_\epsilon \right) - h_\epsilon = n_\epsilon f_\epsilon$$

has support in $\cup B_\epsilon(p_i)$, we may define a phase ϕ locally in $\Omega \setminus \cup_i B_\epsilon(p_i)$ by

$$\nabla \phi(x) = -\frac{1}{a_t} \nabla^\perp h_\epsilon(x) + A_\epsilon(x), \quad x \in \Omega \setminus \cup B_\epsilon(p_i).$$

We now show that ϕ is single-valued modulo 2π. Let σ be any Jordan curve in $\Omega \setminus \cup B_\epsilon(p_i)$ which encloses a region $\Sigma \subset \mathcal{D}$. The region Σ could enclose some collection $\{\omega_j\}_{j \in J}$ of the holes. Then,

$$\begin{aligned}
\int_\sigma \nabla \phi \cdot \tau \, ds &= -\int_\sigma \frac{1}{a_t} \nabla h_\epsilon \cdot \nu \, \mathrm{d}s + \int_\sigma A_\epsilon \cdot \tau \, \mathrm{d}s \\
&= -\int_{\Sigma \setminus \cup_{j \in J} \omega_j} \nabla \cdot \frac{1}{a_t} \nabla h_\epsilon \mathrm{d}x - \sum_{j \in J} \int_{\partial \omega_j} \frac{1}{a_t} \frac{\partial h_\epsilon}{\partial \nu} + \int_\Sigma h_\epsilon \mathrm{d}x \\
&= \int_{\Sigma \setminus \cup_{j \in J} \omega_j} \left(-\nabla \cdot \frac{1}{a_t} \nabla h_\epsilon + h_\epsilon \right) \mathrm{d}x + \sum_{j \in J} \left[-H_{\epsilon,j} |\omega_j| + \int_{\omega_j} h_\epsilon \right] \\
&= \int_{\Sigma \setminus \cup_{j \in J} \omega_j} n_\epsilon f_\epsilon \mathrm{d}x = 2\pi z_\epsilon,
\end{aligned}$$

for some integer $z_\epsilon \in \mathbf{Z}$, by the quantization of f_ϵ. Therefore $\exp(i\phi(x))$ is well-defined in $\Omega \setminus \cup B_\epsilon(p_i)$.

To complete the definition of V for $x \in \Omega$, take a smooth function $\rho_0(x)$ such that $0 \leqslant \rho_0(x) \leqslant 1$, $\rho_0(x) \equiv 1$ in $|x| \geqslant 2$, and $\rho_0(x) \equiv 0$ when $|x| \leqslant 1$. Define

$$\rho(x) = \rho_\epsilon(x) = \begin{cases} \rho_0\left(\dfrac{x - p_i}{\epsilon} \right) & \text{when } x \in B_{2\epsilon}(p_i), \quad i = 1, \ldots, n_\epsilon, \\ 1 & \text{when } x \in \Omega \setminus \cup B_{2\epsilon}(p_i). \end{cases}$$

Then define

$$V(x) := \rho(x)e^{i\phi(x)},$$

where we interpret this to mean that $V(x) \equiv 0$ in $\cup B_\epsilon(p_i)$. Finally, we extend V to the pinning sites ω_j by the same procedure as in Proposition 4.1.

Following the calculations of Refs. 1 and 3, we then expand the energy: after some computation we obtain the upper bound,

$$\mathcal{E}_\epsilon(V,A_\epsilon) \leqslant \frac{1}{2}n_\epsilon^2 A_* - \pi\frac{\mu}{\lambda_*}n_\epsilon \ln|\ln \epsilon| + O(n_\epsilon \ln n_\epsilon),$$

with constant

$$A_* = \int\int_{\Omega\times\Omega} G(x,y)\mathrm{d}\mu_*(x)\mathrm{d}\mu_*(y).$$

We now choose $n_\epsilon = [\ln|\ln \epsilon|]$, and hence

$$\mathcal{E}_\epsilon(V) \leqslant [\bar{A}(\mu) + o(1)](\ln|\ln \epsilon|)^2,$$

with $\bar{A}(\mu) = \frac{1}{2}A_* - \pi\mu/\lambda_*$. Returning to (5.41), and inserting $N_\gamma, N_0, N_- = 0$ (which we know from our previous analysis), we have

$$\inf \mathcal{E}_\epsilon \geqslant N_*(\underline{A}(\mu) - o(1))\ln|\ln \epsilon|,$$

with $\underline{A}(\mu) = \pi C_0 - \pi\mu/\lambda_*$. When ω_1 is large enough both $\underline{A}, \bar{A} < 0$, and so we have

$$(-\underline{A} + o(1))N_* \geqslant (-\bar{A} - o(1))\ln|\ln \epsilon|,$$

and hence we have $N_* \geqslant C \ln|\ln \epsilon|$. Since a is bounded above we obtain the lower bound for Σd_i claimed in (iii) of Theorem 1.3. This completes the proof of Theorem 1.3 □

Emergence of the triangular lattice near a flat wall

Y. Almog[a)]

(Received 19 May 2005; accepted 19 May 2005; published online 29 September 2005)

The bifurcation of periodic solutions near a flat wall for applied magnetic fields which are slightly weaker than H_{C_2} is considered for a reduced Ginzburg–Landau model obtained in the large κ limit. We formally demonstrate that following the bifurcation of the first mode, when the applied magnetic field is further decreased, there is a second bifurcation, after which the solution develops continuously into the well-known triangular lattice. © *2005 American Institute of Physics.*

I. INTRODUCTION

Consider a planar superconducting body at a sufficiently low temperature (below the critical one) under the action of an applied magnetic field. Its energy is given by the Ginzburg–Landau energy functional which can be represented in the dimensionless form[1]

$$E=\int_{\Omega}\left(-|\Psi|^2+\frac{|\Psi|^4}{2}+|h-h_{\mathrm{ex}}|^2+\left|\frac{i}{\kappa}\nabla\Psi+A\Psi\right|^2\right)\mathrm{d}x_1\mathrm{d}x_2, \tag{1.1}$$

in which Ψ is the (complex) superconducting order parameter, such that $|\Psi|$ varies from $|\Psi|=0$ (when the material is at a normal state) to $|\Psi|=1$ (for the purely superconducting state). The magnetic vector potential is denoted by A (the magnetic field is thus $h=\nabla\times A$), h_{ex} is the constant applied magnetic field, and κ denotes the Ginzburg–Landau parameter which is a material property. The superconductor lies in Ω, which is a connected domain. Its Gibbs free energy is given by E, which is invariant under the gauge transformation

$$\Psi\to e^{i\kappa\eta}\Psi;\quad A\to A+\nabla\eta. \tag{1.2}$$

wherein η is any smooth function.

For sufficiently large magnetic fields it is well known, from both experimental observations[2] and theoretical predictions,[3] that superconductivity is destroyed and the material must be at the normal state. If the applied magnetic field is then decreased there exists a critical field where the material enters the superconducting phase. This field is called "the onset field" and is denoted by H_{C_3}.

It is well-known that at the bifurcation from the normal state, superconductivity is concentrated near the boundary. Alternatively we can say that Ψ decays exponentially fast away from the boundaries as either κ or the size of Ω tend to infinity, which is why the phenomenon has been termed surface superconductivity. This result has first been established for a half-plane,[4] then for disks,[5] and for general smooth bounded domains in $\mathbb{R}^2$.[6–9] It has later been extended to weakly nonlinear cases in the large κ limit.[10]

In the absence of boundaries the critical field at which superconductivity nucleates is denoted by H_{C_2} and is smaller than H_{C_3} ($H_{C_3}\approx 1.7\kappa$ whereas $H_{C_2}=\kappa$). Further, the bifurcating modes are periodic Abrikosov lattices[11–13] which have been observed experimentally.[14] Rubinstein[15] has

[a)]Present address: Department of Mathematics, Louisiana State University, Baton Rouge, LA 70803, USA

therefore conjectured that superconductivity remains concentrated near the boundary for $H_{C_2}<h_{\mathrm{ex}}<H_{C_3}$; when $h_{\mathrm{ex}}\approx H_{C_2}$ (either for κ large or for large domains) Abrikosov's lattices bifurcate away from the wall.

Recently, it has been proved both in the large κ limit,[16,17] and in the large domain limit[18] that as long as $H_{C_2}<h_{\mathrm{ex}}<H_{C_3}$ superconductivity remains concentrated near the boundaries. Further, Pan[16] proved that when $\kappa\gg 1$, the solution near the boundary is close to the solution of the problem

$$(i\nabla + x_1\hat{i}_2)^2\psi=\lambda\psi(1-|\psi|^2) \quad \text{in } \mathbb{R}^2_+, \tag{1.3a}$$

$$\left.\frac{\partial\psi}{\partial x_1}\right|_{x_1=0}=0, \tag{1.3b}$$

where $\lambda=\kappa/h_{\mathrm{ex}}$. In addition, it is conjectured in Ref. 16, that the unique bounded solution when $\lambda<1$ is essentially one-dimensional, i.e.,

$$\psi=f(x_1,\lambda)e^{i\omega_0 x_2}, \tag{1.4}$$

for some $\omega_0\in\mathbb{R}$ and $f(x_1,\lambda)$ which satisfies

$$-f''+(x-\omega_0)^2 f=\lambda f(1-f^2); \quad f'(0)=0.$$

Nontrivial positive solutions exist for all $\lambda>\beta(\omega_0)$, where

$$\beta(z)=\inf_{\phi\in H^1(z,\infty)}\frac{\displaystyle\int_z^\infty |\phi'|^2+x^2|\phi|^2}{\displaystyle\int_z^\infty |\phi|^2}. \tag{1.5}$$

Further, $f<1$, and[16]

$$f(x)\sim x^{-(1-\lambda)/2}e^{-(1/2)x^2} \quad \text{as } x\to\infty, \tag{1.6}$$

(cf. Ref. 19 for the definition of $\sim$). In a previous contribution,[20] we studied (1.3), after applying the transformation

$$x_1\to x_1-\omega_0,$$

in the space

$$\mathcal{P}_L^{\omega_0}=\{\phi\in H^1_{\mathrm{mag}}([-\omega_0,\infty)\times\mathbb{R})\,|\,\phi(x_1,x_2+L)=\phi(x_1,x_2)\}. \tag{1.7}$$

In this setting the solutions of (1.3a) a may be treated as critical points of the functional

$$\mathcal{E}(\psi)=\int_0^\infty\int_0^{2\pi/\omega}|(i\nabla+x_1\hat{i}_2)\psi|^2+\lambda\left(\frac{1}{2}|\psi|^4-|\psi|^2\right)\mathrm{d}x_2\mathrm{d}x_1. \tag{1.8}$$

We proved in Ref. 20 that (1.4) must undergo a bifurcation for λ slightly greater than unity, i.e., we proved the existence of a sequence of critical values $\{\lambda_n\}_{n=1}^\infty$ such that $\lambda_n\to 1$ as $n\to\infty$ where a bifurcation from (1.4) can take place. Further, we proved that near the bifurcation, the bifurcating branch is given in the form

$$\lambda\cong\lambda_n+\epsilon^2\left(\frac{\omega}{2\pi}\right)^{3/2}+O(\epsilon^3) \tag{1.9a}$$

$$\psi \cong e^{i\omega_0 x_2}\{f(x_1,\lambda) + \epsilon[\phi_n(x_1)e^{in\omega x_2} + \phi_{-n}(x_1)e^{-in\omega x_2}]\} + O(\epsilon^2), \tag{1.9b}$$

where $\epsilon \ll 1$, $\omega = 2\pi/L$, and $\phi_{\pm n}$ satisfy a system of ordinary differential equations which is described in the next section. Finally, we proved that near the bifurcation, the energy of the bifurcating branch is lower than the energy of (1.4). Hence, for $\lambda > 1$ (1.4) must lose its stability.

While the results in Ref. 20 prove the bifurcation of a single Fourier mode, they do not address the behavior of the bifurcating branch with increasing λ. It was expected in Ref. 20 that with growing λ the solution tends to become periodic in the x_1 direction as well. In other words, the solution should approach an Abrikosov lattice.[12,13] The manner by which (1.9) develops into a periodic solution is not clear: it may either result from a sequence of bifurcations, or it may evolve continuously, or else undergo some combination of the above.

The present contribution focuses on the evolution of (1.9) with increasing λ. We assume that the first bifurcation takes place at $\lambda = \lambda_N$, where $N \gg 1$ (we discuss this choice in Sec. V). Then, by using a combination of formal and rigorous arguments, we find

(1) The value of λ at which the next bifurcation (hereafter referred to as the "second" bifurcation) should take place.
(2) The bifurcating mode.
(3) The behavior of the solution with increasing λ following the second bifurcation. We find that if no other bifurcation occurs after the second bifurcation, then, as $N \to \infty$, for $\lambda > \lambda_{N-l}$ where $1 \ll l \ll N$, the solution tends pointwise to the triangular lattice[21] for

$$\left(N - \frac{5}{8}l\right)\omega < x_1 < \left(N - \frac{3}{8}l\right)\omega.$$

We note that there are many indications, both theoretical[12,13,21] and experimental,[14] that the minimizer of (1.1) is indeed the triangular lattice. It is thus plausible that the transition from (1.9) to a periodic solution in the x_1 direction is indeed described by the results in this work, despite a number of gaps that must be addressed in order to prove these results rigorously.

The rest of this contribution is arranged as follows: In the next section we prove the exact asymptotic behavior of λ_n and $\phi_{\pm n}$ as $n \to \infty$ and conjecture that $\lambda_n > 1$ for all n. In Sec. III we make use of the asymptotic formulas and the above-mentioned conjecture to analyze the second bifurcation. In Sec. IV we formally analyze the behaviour of the solution with increasing λ after the second bifurcation. Finally, in Sec. V, we briefly summarize the main results of this work, emphasize some additional key points, and list the gaps that must be bridged in order to rigorously prove the main results.

II. PRELIMINARIES

Consider the problem

$$(i\nabla + x_1\hat{i}_2)^2\psi = \lambda\psi(1 - |\psi|^2) \text{ in } \mathbb{R}^2_+, \tag{2.1a}$$

$$\left.\frac{\partial\psi}{\partial x_1}\right|_{x_1=0} = 0 \quad \psi(x_1, x_2 + L) = e^{i\theta}\psi(x_1, x_2), \tag{2.1b}$$

where θ is constant. Pan[16] conjectured that for $\lambda < 1$ the unique solution of (2.1) is given by (1.4). In Ref. 20 we prove that there exists a sequence of critical values $\{\lambda_n\}_{n=n_0}^{\infty}$ where solutions of (2.1) can bifurcate from (1.4) such that $\lambda_n \downarrow 1$. Further, near the bifurcation,

$$\psi \approx f(x_1)e^{i\omega_0 x_2} + C(\lambda)[\phi_n(x_1)e^{in\omega x_2} + \phi_{-n}(x_1)e^{-in\omega x_2}],$$

where upon applying the transformation $x \to x - \omega_0$, ϕ_n, ϕ_{-n} satisfy

$$-\phi_n'' + [(x_1 - n\omega)^2 - \lambda]\phi_n + \lambda f^2(2\phi_n + \overline{\phi_{-n}}) = 0 \quad x_1 > -\omega_0, \tag{2.2a}$$

$$-\phi''_{-n}+[(x_1+n\omega)^2-\lambda]\phi_{-n}+\lambda f^2(2\phi_{-n}+\overline{\phi_n})=0 \quad x_1>-\omega_0, \tag{2.2b}$$

$$\phi'_n(-\omega_0)=\phi'_{-n}(-\omega_0)=0, \tag{2.2c}$$

and $C(\lambda)\sim O(|\lambda-\lambda_n|^{1/2})$. The asymptotic behavior of λ_n has been studied as well. In particular, it is proved in Ref. 20, that

$$1+C_1e^{-(1/2)(n\omega+\omega_0)^2}<\lambda_n<1+C_2e^{-(1/2)(n\omega+\omega_0)^2}. \tag{2.3}$$

We now prove the exact asymptotic behavior of λ_n.

Lemma 2.1: Let λ_n be the lowest critical value of (2.2). *Then*

$$\lambda_n\sim 1+2a^2e^{-(n\omega+\omega_0)^2/2}+O(e^{-2(n\omega+\omega_0)^2/3}) \quad \text{as } n\to\infty, \tag{2.4a}$$

where

$$a=\lim_{x\to\infty}e^{x^2/2}f(x,1). \tag{2.4b}$$

Further, let ϕ_n,ϕ_{-n} be the corresponding eigenmodes. Then, for sufficiently large n we have

$$\|\phi_n-e^{-(x-n\omega)^2/2}\|_2^2+\|\phi_{-n}\|_2^2\leqslant e^{-2(n\omega+\omega_0)^2/3}, \tag{2.5}$$

where $\|\cdot\|_2$ denotes the L^2 norm on $(-\omega_0,\infty)$.

Proof: Let

$$\mathcal{H}=\{\phi\in H^2(-\omega_0,\infty)|x\phi\in L^2(-\omega_0,\infty);\phi'(-\omega_0)=0\},$$

and $\mathcal{P}_n:\mathcal{H}\times\mathcal{H}\to L^2\times L^2$ denote the operator

$$\mathcal{P}_n=\begin{bmatrix}-\dfrac{d^2}{dx_1^2}+(x_1-n\omega)^2 & 0\\ 0 & -\dfrac{d^2}{dx_1^2}+(x_1+n\omega)^2\end{bmatrix}+\lambda_n f^2(x_1,\lambda_n)\begin{bmatrix}2&1\\1&2\end{bmatrix}.$$

Clearly,

$$(\mathcal{P}_n-\lambda_n)\begin{bmatrix}\phi_n\\ \bar{\phi}_{-n}\end{bmatrix}=0.$$

We now choose the quasimode

$$v_n=C_n\begin{bmatrix}\chi(x+\omega_0)e^{(-x-n\omega)^2/2}\\ 0\end{bmatrix},$$

where C_n is chosen such that $||v_n||^2=1$ and χ is a smooth cutoff function satisfying

$$\chi(x)=\begin{cases}0 & x\leqslant\dfrac{1}{2},\\ 1 & x\geqslant 1.\end{cases}$$

Let

$$\alpha_n=1+2\lambda_n\int f^2(x,\lambda_n)|v_n|^2.$$

Then

$$|\langle v_n,(\mathcal{P}_n-\alpha_n)v_n\rangle| \leqslant \int |-\chi''+2(x-n\omega)\chi'|e^{-(x-n\omega)^2} \leqslant Ce^{-(n\omega+\omega_0)^2}. \tag{2.6}$$

We now represent the quasimode v_n as

$$v_n = a_n\Phi_n + \tilde{v}_n,$$

where

$$\Phi_n = \begin{bmatrix} \phi_n \\ \phi_{-n} \end{bmatrix},$$

and

$$a_n = \langle v_n, \Phi_n\rangle.$$

From (2.6) we have

$$a_n^2|\lambda_n-\alpha_n| \leqslant |\langle v_n,(\mathcal{P}_n-\alpha_n)v_n\rangle| + |\langle \tilde{v}_n,(\mathcal{P}_n-\alpha_n)\tilde{v}_n\rangle| \leqslant \|\tilde{v}_n\|_2\|(\mathcal{P}_n-\alpha_n)v_n\|_2 + Ce^{-(n\omega+\omega_0)^2}. \tag{2.7}$$

Let

$$\mu_n = \inf_{\substack{u\in\tilde{\mathcal{H}}_n \\ \|u\|_2=1}} \langle \mathcal{P}_n u,u\rangle,$$

where $\tilde{\mathcal{H}}_n$ is the orthogonal complement of span $\{\Phi_n\}$ in $\mathcal{H}\times\mathcal{H}$.

Then,

$$\|\tilde{v}_n\|_2^2 \leqslant \frac{\|(\mathcal{P}_n-\alpha_n)\tilde{v}_n\|_2^2}{|\mu_n-\alpha_n|^2} \leqslant \frac{\|(\mathcal{P}_n-\alpha_n)v_n\|_2^2}{|\mu_n-\alpha_n|^2}. \tag{2.8}$$

We claim that

$$\liminf_{n\to\infty} \mu_n-\alpha_n = 2. \tag{2.9}$$

To prove (2.9) we define the operator

$$Q_n = \begin{bmatrix} -\dfrac{\mathrm{d}^2}{\mathrm{d}x_1^2}+(x_1-n\omega)^2 & 0 \\ 0 & -\dfrac{\mathrm{d}^2}{\mathrm{d}x_1^2}+(x_1+n\omega)^2 \end{bmatrix}. \tag{2.10}$$

Clearly,

$$\nu_n = \inf_{\substack{u\in\tilde{\mathcal{H}}_n \\ \|u\|_2=1}} \langle \mathcal{Q}_n u,u\rangle \leqslant \mu_n. \tag{2.11}$$

We now prove that

$$\liminf_{n\to\infty} \nu_n \geqslant 3. \tag{2.12}$$

Denote by U_n the minimizer of $\langle Q_n u,u\rangle$ in $\mathcal{H}\times\mathcal{H}$. For sufficiently large n we have

$$U_n = \begin{bmatrix} u_n \\ 0 \end{bmatrix},$$

where u_n satisfies

$$-u_n'' + (x - n\omega)^2 u_n = \beta_n u_n, \quad u_n'(-\omega_0) = 0,$$

in which $\beta_n = \beta(-n\omega - \omega_0)$ is given by (1.5) and $\|u_n\|_2 = 1$. Let w denote a unit vector in $\widetilde{\mathcal{H}}_n$. Then,

$$\langle w, U_n \rangle = \langle w, -\Phi_n + \langle \Phi_n, U_n \rangle U_n \rangle + (1 - \langle \Phi_n, U_n \rangle)\langle w, U_n \rangle.$$

We seek to estimate the norm of $\Phi_n - \langle \Phi_n, U_n \rangle U_n$. To this end we apply to it first $Q_n - \beta_n$ and then estimate the norm of the outcome. We have

$$\int |(\mathcal{Q}_n - \beta_n)(\Phi_n - \langle \Phi_n, U_n \rangle U_n)|^2 \leqslant (\lambda_n - \beta_n)^2 + 4\lambda_n^2 \int f^2(|\phi_n|^2 + |\phi_{-n}|^2).$$

To estimate the second term on the right-hand-side, we recall from[20] that

$$\lambda_n \int f^2(|\phi_n|^2 + |\phi_{-n}|^2 + |\phi_n + \overline{\phi}_{-n}|^2) = -\int [|\phi_n'|^2 + |\phi_{-n}'|^2 + (x - n\omega)^2|\phi_n|^2 + (x + n\omega)^2|\phi_{-n}|^2] + \lambda_n$$
$$\leqslant (\lambda_n - \beta_n).$$

From Refs. 7 and 22 we know that

$$\beta_n \sim 1 - O(e^{-(n\omega + \omega_0)^2}).$$

Hence, in view of (2.3) we obtain

$$\int |(\mathcal{Q}_n - \beta_n)(\Phi_n - \langle \Phi_n, U_n \rangle U_n)|^2 \leqslant Ce^{-(n\omega + \omega_0)^2/2}. \tag{2.13}$$

Since $\Phi_n - \langle \Phi_n, U_n \rangle U_n$ is orthogonal to U_n we have

$$\int |(\mathcal{Q}_n - \beta_n)(\Phi_n - \langle \Phi_n, U_n \rangle U_n)|^2 \geqslant (\sigma_n - \beta_n)^2 \|\Phi_n - \langle \Phi_n, U_n \rangle U_n\|_2^2,$$

where

$$\sigma_n = \inf_{\substack{u \in span\{U_n\}^\perp \\ \|u\|_2 = 1}} \langle \mathcal{Q}_n u, u \rangle.$$

Semi-classical analysis[22,23] shows that

$$\sigma_n \xrightarrow[n \to \infty]{} 3. \tag{2.14}$$

Combining the above with (2.13) yields

$$\|\Phi_n - \langle \Phi_n, U_n \rangle U_n\|_2^2 \leqslant Ce^{-(n\omega + \omega_0)^2/2},$$

and consequently

$$|\langle w, U_n \rangle| \leqslant Ce^{-(n\omega + \omega_0)^2/4}, \tag{2.15}$$

where C is independent of w and n.

We now present w in the form

$$w = \langle w, U_n\rangle U_n + w_n.$$

Clearly, $w_n \perp U_n$, and hence

$$\langle \mathcal{Q}_n w, w\rangle = \beta_n \langle w, U_n\rangle^2 + \langle \mathcal{Q}_n w_n, w_n\rangle \geqslant \sigma_n \|w_n\|_2^2 \geqslant \sigma_n (1 - e^{-(n\omega + \omega_0)^2/2}),$$

which proves (2.12). In view of (2.11), we have proved (2.9) too.

We now substitute (2.9) into (2.8) and then into (2.7) to obtain

$$a_n^2 |\lambda_n - \alpha_n| \leqslant \|(\mathcal{P}_n - \alpha_n) v_n\|_2^2 + C e^{-(n\omega + \omega_0)^2},$$

or, equivalently

$$a_n^2 |\lambda_n - \alpha_n| \leqslant 2(\alpha_n - 1)^2 + 5 \int f^4 |v_n|^2 + C e^{-(n\omega + \omega_0)^2} \leqslant C e^{-2(n\omega + \omega_0)^2/3}.$$

Further,

$$a_n^2 = 1 - \|v_n\|_2^2 \geqslant 1 - \|(\mathcal{P}_n - \alpha_n) v_n\|_2^2 \geqslant 1 - C e^{-2(n\omega + \omega_0)^2/3}.$$

Hence,

$$\lambda_n \sim 1 + 2\lambda_n \int f^2(x, \lambda_n) |v_n|^2 + O(e^{-2(n\omega + \omega_0)^2/3}) \quad \text{as } n \to \infty. \tag{2.16}$$

In Ref. 20 we proved that $|\partial f / \partial \lambda| \leqslant C$ for all x in some neighborhood of $\lambda = 1$. Utilizing this result together with (2.3) we obtain

$$\lambda_n \sim 1 + 2 \int f^2(x, 1) e^{-(x - n\omega)^2} + O(e^{-2(n\omega + \omega_0)^2/3}) \quad \text{as } n \to \infty,$$

from which (2.4) readily follows. Similarly, from (2.8) we obtain (2.5). □

We conclude this section by stating the following conjecture, and by making a simple observation.

Conjecture 1: Let

$$\gamma_n(\lambda) = \inf_{\substack{(\chi_n, \chi_{-n}) \in \mathcal{H} \times \mathcal{H} \\ \|\chi_n\|_2^2 + \|\chi_{-n}\|_2^2 = 1}} \mathcal{J}_n(\chi_n, \chi_{-n}), \tag{2.17a}$$

where

$$\begin{aligned} \mathcal{J}_n(\chi_n, \chi_{-n}) := \int_{-\omega_0}^{\infty} & |\chi_n'|^2 + (x - n\omega)^2 |\chi_n|^2 + |\chi_{-n}'|^2 + (x + n\omega)^2 |\chi_{-n}|^2 \\ & - \lambda [|\chi_n|^2 + |\chi_{-n}|^2 - f^2(|\chi_n|^2 + |\chi_n + \bar{\chi}_{-n}|^2 + |\chi_{-n}|^2)]. \end{aligned} \tag{2.17b}$$

Then,

$$\forall n \in \mathbb{N}, \exists\, \delta_n > 0 \colon \lambda < 1 + \delta_n \Rightarrow \gamma_n(\lambda) > 0. \tag{2.18}$$

Note that by (2.4) the above-mentioned conjecture is correct for sufficiently large n, since $\gamma_n(\lambda) > 0$ for all $\lambda < \lambda_n$. For n which is not necessarily large, it is still expected that (2.18) remains valid since otherwise the surface superconductivity solution (1.4) would lose its stability for $\lambda \leqslant 1$ for some $n \in \mathbb{N}$. This would contradict the physical intuition suggesting that (1.4) must be stable for $\lambda \leqslant 1$.

Finally, we prove the leading asymptotic behavior for $\gamma_n(\lambda)$ as $n \to \infty$.

Lemma 2.2: Let $\lambda < 2$. *Then*,

$$\gamma_n(\lambda) \sim (\lambda_n - \lambda)(1 + Ce^{-(1/3)(n\omega + \omega_0)^2}). \tag{2.19}$$

Proof: It is easy to show that

$$-\phi_n'' + [(x_1 - n\omega)^2 - \lambda - \gamma_n]\phi_n + \lambda f^2(2\phi_n + \overline{\phi_{-n}}) = 0, \quad x_1 > -\omega_0$$

$$-\phi_{-n}'' + [(x_1 + n\omega)^2 - \lambda - \gamma_n]\phi_{-n} + \lambda f^2(2\phi_{-n} + \overline{\phi_n}) = 0, \quad x_1 > -\omega_0$$

$$\phi_n'(-\omega_0) = \phi_{-n}'(-\omega_0) = 0.$$

Consequently, in the same manner used to derive (2.16) we can obtain that

$$\gamma_n(\lambda) \sim 1 + 2\lambda \int f^2(x,\lambda)|v_n|^2 + O(e^{-2(n\omega + \omega_0)^2/3}) - \lambda \quad \text{as } n \to \infty.$$

Utilizing (2.16) we have

$$\gamma_n(\lambda) \sim (\lambda_n - \lambda)\left(1 + 2\int f^2(x,\lambda_n)|v_n|^2\right) + 2\lambda \int [f^2(x,\lambda) - f^2(x,\lambda_n)]|v_n|^2$$

and since $|\partial f/\partial\lambda| \leqslant C$ (cf. Ref. 20) we readily obtain (2.19).

III. THE SECOND BIFURCATION

In the preceding section we have considered the bifurcation from the one-dimensional solution (1.4). In this section we study the linear bifurcation from the bifurcating branch, i.e., the second bifurcation. Let then

$$\psi = \psi_0 + u \tag{3.1}$$

where $\psi_0(\lambda)$ denotes the solution which bifurcates from (1.4) at $\lambda = \lambda_N$ for $N \gg 1$. It is convenient to present ψ_0 using the parametric form

$$\psi_0 \cong f_0 + \epsilon V_0 + O(\epsilon^2, e^{-(N\omega + \omega_0)^2/2}), \tag{3.2a}$$

$$\lambda \cong \lambda_N + \epsilon^2\lambda_N^{(2)} + O(\epsilon^2), \tag{3.2b}$$

in which

$$V_n = \phi_{n+N}(x_1)e^{i(n+N)\omega x_2} + \phi_{-n-N}(x_1)e^{-i(n+N)\omega x_2}, \tag{3.2c}$$

$$f_0(x_1) = f(x_1, 1), \tag{3.2d}$$

$$\lambda_N^{(2)} \cong \left(\frac{\omega}{2\pi}\right)^{3/2} + O(e^{-(\omega N + \omega_0)^2/2}). \tag{3.2e}$$

We shall consider in the sequel positive ϵ values which are of $O(e^{-[(N-N_0)\omega + \omega_0]^2/4})$ for $N_0 \ll N$. In view of (3.2c) we have

$$(i\nabla + x_1\hat{i}_2)^2 v_n - \lambda_{N+n}[v_n - f^2|_{\lambda=\lambda_{N+n}}(2v_n + \bar{v}_n)] = 0. \tag{3.3}$$

Consider now the bifurcation from the branch which bifurcated at $\lambda=\lambda_{\tilde{N}}$ from the surface superconductivity solution (1.4) for $\tilde{N}\neq N$ which is still much greater than 1. In this case we obtain from (2.5) that apart from an exponentially small error

$$\tilde{\psi}_0 - f_0|_{(x_1,x_2)} \cong \tilde{\psi}_0 - f_0|_{(x_1+\omega(\tilde{N}-N),x_2}\,,$$

where $\tilde{\psi}_0$ is the mode bifurcating from f at $\lambda=\lambda_{\tilde{N}}$. Thus, the choice of N has little impact on the results obtained in this section. We shall return to this problem in the last section.

Substituting (3.1) into (2.1) while keeping in mind that ψ_0 is a solution of (2.1), we obtain

$$(i\nabla + x_1\hat{i}_2)^2 u - \lambda[u - (2|\psi_0|^2 u + \psi_0^2\bar{u} + 2|u|^2\psi_0 + u^2\bar{\psi}_0 + |u|^2 u)] = 0 \quad x \in \mathbb{R}^2_{\omega_0}, \tag{3.4a}$$

$$u_{x_1}(-\omega_0, x_2) = 0; \tag{3.4b}$$

$$u(x_1, x_2 + L) = u(x_1, x_2), \tag{3.4c}$$

where $L=2\pi/\omega$, and $\mathbb{R}^2_{\omega_0}=\{(x_1,x_2)\,|-\omega_0<x_1,x_2\in\mathbb{R}\}$. We look for solutions in $\mathcal{P}^{\omega_0}_L$ which bifurcate from $u\equiv 0$. We thus assume that such a bifurcation takes place at $\lambda=\mu$ and linearize (3.4) by introducing the expansion

$$\lambda \cong \mu + \delta\mu^{(1)} + \delta^2\mu^{(2)} + O(\delta^3), \tag{3.5a}$$

$$u \cong \delta u^{(0)} + \delta^2 u^{(1)} + \delta^3 u^{(2)} + O(\delta^4), \tag{3.5b}$$

to obtain

$$(i\nabla + x_1\hat{i}_2)^2 u^{(0)} - \mu[u^{(0)} - (2|\psi_0|^2 u^{(0)} + \psi_0^2\bar{u}^{(0)})] = 0, \tag{3.6}$$

together with (3.4b) and (3.4c).

We shall now obtain a necessary condition for the existence of nontrivial solutions of (3.6) involving V_n with $N+n\gg 1$.

Lemma 3.1: Let

$$\mu = \lambda_N + \epsilon^2\lambda_N^{(2)},$$

where $\lambda_N^{(2)}$ *is given by (3.2e). Let further* ψ_0 *be given by (3.2) and* $u^{(0)}$ *satisfy (3.6). Denote by* $\hat{u}_n$ *the Fourier coefficient*

$$\hat{u}_n = \int_0^{2\pi/\omega} e^{-i\omega n x_2}\mathrm{d}x_2.$$

Then, if there exist $\epsilon\leqslant\exp\{-\frac{1}{4}[(N-l)\omega+\omega_0]^2\}$ *(where* $l\ll N$*) such that a nontrivial* $u^{(0)}$ *satisfying*

$$\int_{-\omega_0}^{\infty} |\hat{u}_{N+n}|^2 + |\hat{u}_{N-n}|^2 dx_1 \geqslant \frac{1}{2} \tag{3.7}$$

exists for some $0\leqslant n\leqslant l$*, we must have*

$$\epsilon^2 \cong \eta_{-n}^2 \frac{1-2q^{n^2}}{(1-2q^{n^2})^2 - q^{4n^2}} \tag{3.8a}$$

and

$$\frac{2}{\omega}\pi^{3/2}u^{(0)} \cong \frac{1-2q^{n^2}}{\sqrt{(1-2q^{n^2})^2+q^{4n^2}}}\exp\left\{-\frac{1}{2}[x_1-(N-n)\omega]^2+i\omega(N-n)x_2\right\}$$
$$+\frac{q^{2n^2}}{\sqrt{(1-2q^{n^2})^2+q^{4n^2}}}\exp\left\{-\frac{1}{2}[x_1-(N+n)\omega]^2+i\omega(N+n)x_2\right\}, \tag{3.8b}$$

where

$$\eta_n^2=\left(\frac{2\pi}{\omega}\right)^{3/2}(\lambda_N-\lambda_{N+n}); \quad \eta_{-n}^2=\left(\frac{2\pi}{\omega}\right)^{3/2}(\lambda_N-\lambda_{N+n}), \tag{3.8c}$$

and

$$q=e^{-w^2/2}. \tag{3.8d}$$

Proof: Multiplying (3.6) by $\bar{V}_n$ and integrating by parts over $D=(-\omega_0,\infty)\times(0,L)$ we obtain

$$(\mu-\lambda_{N+n})\int u^{(0)}\bar{V}_n=(\mu-\lambda_{N+n})\int \bar{V}_n[2|\psi_0|^2u^{(0)}+\psi_0^2\bar{u}^{(0)}]+\lambda_{N+n}\int f^2(u^{(0)}\bar{V}_n-\bar{u}^{(0)}V_n)$$
$$+\lambda_{N+n}\int \bar{V}_n[2(|\psi_0|^2-f^2)u^{(0)}+(\psi_0^2-f^2)\bar{u}^{(0)}]. \tag{3.9}$$

We need first an estimate for the first two integrals on the right-hand side of (3.9). Without loss of generality we assume that $\|u^{(0)}\|_{L^2(D)}=1$ (which may always be achieved through appropriately adjusting δ). By (3.6) we also have

$$\int |(i\nabla+x_1\hat{i}_2)u^{(0)}|^2 \leqslant C\int |u^{(0)}|^2 \leqslant C. \tag{3.10}$$

For the first integral on the right-hand side of (3.9) we obtain by using (3.2)

$$\int \bar{V}_n|\psi_0|^2u^{(0)} \cong \int \bar{V}_nf_0^2u^{(0)}+2\epsilon\int \bar{V}_nf_0\Re(V_0)u^{(0)}+O(\epsilon^2).$$

Then, utilizing (2.5) we have

$$\left|\int \bar{V}_nf_0^2u^{(0)}\right|^2 \leqslant \int f_0^4|V_n|^2 \leqslant Ce^{-2[(N+n)\omega+\omega_0]^2/3},$$

$$\left|\int \bar{V}_nf_0V_0u^{(0)}\right|^2 \leqslant \int f_0^2|V_n|^2|V_0|^2 \leqslant Ce^{-2[(N+n/2)\omega+\omega_0]^2/3}.$$

To estimate the second integral on the right-hand side of (3.9) we multiply (3.6) once by $e^{-i(N+n)x_2}$ and once by $e^{i(N+n)x_2}$ and integrate by parts to obtain the system

$$-\hat{u}''_{N+n}+[(x-n\omega)^2-\mu]\hat{u}_{N+n}+\mu f^2(2\hat{u}_{N+n}+\overline{\hat{u}_{-N-n}})$$
$$=-\int_0^{2\pi/\omega}[(|\psi_0|^2-f^2)2u^{(0)}+(\psi_0^2-f^2)\bar{u}^{(0)}]e^{-i\omega(N+n)x_2}\mathrm{d}x_2 \tag{3.11a}$$

$$-\hat{u}''_{-N-n}+[(x+n\omega)^2-\mu]\hat{u}_{-N-n}+\mu f^2(2\hat{u}_{-N-n}+\overline{\hat{u}_{N+n}})$$
$$=-\int_0^{2\pi/\omega}[(|\psi_0|^2-f^2)2u^{(0)}+(\psi_0^2-f^2)\bar{u}^{(0)}]e^{i\omega(N+n)x_2}\mathrm{d}x_2 \tag{3.11b}$$

$$\hat{u}'_{N+n}(-\omega_0) = \hat{u}'_{-N-n}(-\omega_0) = 0. \tag{3.11c}$$

Multiplying (3.11a) by $\bar{\hat{u}}_{N+n}$ and (3.11b) by $\bar{\hat{u}}_{-N-n}$, summing the resulting equations, and integrating with respect to x_1 we obtain

$$\mathcal{J}_{N+n}(\hat{u}_{N+n}, \hat{u}_{-N-n}, \mu) = \int [\overline{e^{-i\omega(N+n)x_2}\hat{u}_{N+n} + e^{i\omega(N+n)x_2}\hat{u}_{-N-n}}] \cdot [(|\psi_0|^2 - f^2)2u^{(0)} + (\psi_0^2 - f^2)\bar{u}^{(0)}],$$

where $\mathcal{J}$ is defined in (2.17). Since $\hat{u}_n e^{i\omega n x_2}$ is the projection of $u^{(0)}$ on the subspace of the n'th Fourier harmonic, it is easy to show that its H^1_{mag} norm is uniformly bounded for all N and n. Consequently,

$$\|u^{(0)}\|_{L^4} \leqslant C; \quad \|\hat{u}_n e^{i\omega n x_2}\|_{L^4} \leqslant C.$$

Therefore, it is not difficult to show that for sufficiently large $N+n$

$$\int |\hat{u}_{-N-n}|^2 + f^2|\hat{u}_{N+n}|^2 - (\mu - \beta|_{z=\omega(N+n)+\omega_0}) \leqslant \mathcal{J}_{N+n}(\hat{u}_{N+n}, \hat{u}_{-N-n}, \mu) \leqslant C(\epsilon + e^{-(N\omega+\omega_0)^2/4})^2. \tag{3.12}$$

where $\beta(z)$ is defined in (1.5). It is thus easy to show from (3.12) that

$$\int |\hat{u}_{-N-n}|^2 + f^2|\hat{u}_{N+n}|^2 \leqslant C(\epsilon + e^{-(N\omega+\omega_0)^2/4})^2.$$

Let U_n be the minimizer of $\langle \mathcal{Q}_n u, u\rangle$ in $\mathcal{H}\times\mathcal{H}$ where $\mathcal{Q}_n$ is defined in (2.10). Let further

$$\hat{u}_{N+n} = \langle \hat{u}_{N+n}, U_{N+n}\rangle U_{N+n} + \tilde{u}_{N+n}. \tag{3.13}$$

Then, by (3.12) and (2.14) we also have

$$\int |\tilde{u}_{N+n}|^2 \leqslant C(\epsilon + e^{-(N\omega+\omega_0)^2/4})^2. \tag{3.14}$$

We now return to the second integral on the right-hand side of (3.9). Obviously,

$$\int f^2 \bar{u}^{(0)} \bar{V}_n = \int_{-\omega_0}^{\infty} f^2[\bar{\phi}_{N+n}\bar{\hat{u}}_{-N-n} + \bar{\phi}_{-N-n}\bar{\hat{u}}_{N+n}]\mathrm{d}x_1. \tag{3.15}$$

From (3.12) and (2.5) and (2.4a) and (2.4b) we obtain

$$\left|\int_{-\omega_0}^{\infty} f^2\bar{\phi}_{N+n}\bar{\hat{u}}_{-N-n}\right|^2 \leqslant \int_{-\omega_0}^{\infty} f^4|\phi_{N+n}|^2 \int_{-\omega_0}^{\infty} |\hat{u}_{-N-n}|^2 \leqslant C(\epsilon + e^{-[\omega(N+n)+\omega_0]^2/4})^2 e^{-2[\omega(N+n)+\omega_0]^2/3}, \tag{3.16}$$

and

$$\left|\int_{-\omega_0}^{\infty} f^2\bar{\phi}_{-N-n}\bar{\hat{u}}_{N+n}\right|^2 \leqslant \int_{-\omega_0}^{\infty} f^4|\hat{u}_{N+n}|^2 \int_{-\omega_0}^{\infty} |\phi_{-N-n}|^2 \leqslant C(\epsilon + e^{-[\omega(N+n)+\omega_0]^2/4})^2 e^{-2[\omega(N+n)+\omega_0]^2/3}. \tag{3.17}$$

Consequently,

$$(\mu-\lambda_{N+n})\int u^{(0)}\bar{V}_n=\lambda_{N+n}\int \bar{V}_n[2(|\psi_0|^2-f^2)u^{(0)}+(\psi_0^2-f^2)\bar{u}^{(0)}]+\tilde{\epsilon}, \tag{3.18a}$$

where

$$|\tilde{\epsilon}|\leqslant C\{\epsilon^2(\epsilon+e^{-[\omega(N+n)+\omega_0]^2/3})^2+(\epsilon+e^{-[\omega(N+n)+\omega_0]^2/4})^2e^{-[\omega(N+n)+\omega_0]^2/3}\}. \tag{3.18b}$$

We now estimate the remaining terms on the right-hand side of (3.9). Evidently,

$$\int \bar{V}_n(|\psi_0|^2-f^2)u^{(0)}\cong\int \bar{V}_n(f_0^2-f^2)u^{(0)}+2\epsilon\int f_0\Re\{V_0u^{(0)}\bar{V}_n\}+\epsilon^2\int |V_0|^2u^{(0)}\bar{V}_n+O(\epsilon^3). \tag{3.19}$$

For the first term on the right-hand side we have

$$\left|\int \bar{V}_n(f_0^2-f^2)u^{(0)}\right|^2\leqslant\left\|\frac{\partial f}{\partial\lambda}\right\|^2_{L^\infty(-\omega_0,\infty)}|\lambda_n-1|^2\int (f_0+f)^2|V_n|^2.$$

In view of (2.4) and since $\partial f/\partial\lambda$ is uniformly bounded,[20] we have

$$\left|\int \bar{V}_n(f_0^2-f^2)u^{(0)}\right|^2\leqslant Ce^{-3[\omega(N+n)+\omega_0]^2/2}. \tag{3.20}$$

For the second term on the right-hand side of (3.19) we have

$$\left|\int f_0\Re\{V_0u^{(0)}\bar{V}_n\}\right|^2\leqslant\int f_0^2|V_0V_n|^2\leqslant Ce^{-2[\omega(N+n)+\omega_0]^2/3}. \tag{3.21}$$

Combining (3.19)–(3.21) we obtain

$$\int \bar{V}_n(|\psi_0|^2-f^2)u^{(0)}\cong\epsilon^2\int |V_0|^2u^{(0)}\bar{V}_n+O(\epsilon^2e^{-[\omega(N+n)+\omega_0]^2/12}).$$

In a similar manner we can obtain a similar estimate for the second term on the right-hand side of (3.18a). Thus,

$$(\mu-\lambda_{N+n})\int u^{(0)}\bar{V}_n=\epsilon^2\int \bar{V}_n[2|V_0|^2u^{(0)}+V_0^2\bar{u}^{(0)}]+\epsilon^2\tilde{\epsilon}_n, \tag{3.22a}$$

where

$$|\tilde{\epsilon}_n|\leqslant e^{-[\omega(N+n)+\omega_0]^2/12}. \tag{3.22b}$$

Let

$$\tilde{d}_n=\int u^{(0)}\bar{V}_n.$$

Then, we can write (3.22) in the form

$$(\epsilon^2+\eta_n^2)\tilde{d}_n=\epsilon^2q^{n^2}[2\tilde{d}_n+\bar{\tilde{d}}_{-n}q^{n^2}]+C\epsilon^2\tilde{\epsilon}_n, \tag{3.23a}$$

$$(\epsilon^2-\eta_{-n}^2)\tilde{d}_{-n}=\epsilon^2q^{n^2}[2\tilde{d}_{-n}+\bar{\tilde{d}}_nq^{n^2}]+C\epsilon^2\tilde{\epsilon}_{-n}. \tag{3.23b}$$

Let $[d_n,d_{-n}]^T$ denote a nontrivial solution and $\epsilon_n^{(0)}$ be a critical value of

$$(\epsilon^2 - \eta_{-n}^2)d_{-n} = \epsilon^2 q^{n^2}[2d_{-n} + \bar{d}_n q^{n^2}] \tag{3.24a}$$

$$(\epsilon^2 - \eta_{-n}^2)d_{-n} = \epsilon^2 q^{n^2}[2d_{-n} + \bar{d}_n q^{n^2}]. \tag{3.24b}$$

Let further μ_{N-n} denote a critical value of μ for which a nontrivial solution of (3.6) satisfying (3.7) exists. Let ϵ_n be given by

$$\epsilon_n^2 = \frac{\mu_{N-n} - \lambda_N}{\lambda_N^{(2)}}.$$

By (3.7) we have to look for a solution of (3.23) which satisfies

$$|\tilde{d}_n|^2 + |\tilde{d}_{-n}|^2 \geqslant \frac{1}{2}.$$

It is not difficult to show that

$$|\epsilon_n - \epsilon_n^{(0)}| + |\tilde{d}_n - d_n| + |\tilde{d}_{-n} - d_{-n}| \leqslant C\tilde{\epsilon}_n, \tag{3.25}$$

where C is independent of n and N. Further, one can easily show that whenever $1 \leqslant k \leqslant 2l$ and $k \neq n$, the solutions of (3.23) with $\epsilon = \epsilon_k$ must satisfy

$$|\tilde{d}_n| + |\tilde{d}_{-n}| \leqslant C\tilde{\epsilon}_n. \tag{3.26}$$

To solve (3.24) we multiply (3.24a) by $\bar{d}_{-n}$ and (3.24b) by $\bar{d}_n$ to obtain

$$[\epsilon^2(1 - 2q^{n^2}) - \eta_{-n}^2]|d_{-n}|^2 = \epsilon^2 q^{2n^2}\bar{d}_n\bar{d}_{-n}, \tag{3.27a}$$

$$[\epsilon^2(1 - 2q^{n^2}) + \eta_n^2]|d_n|^2 = \epsilon^2 q^{2n^2}\bar{d}_n\bar{d}_{-n}. \tag{3.27b}$$

We confine the subsequent discussion to the case $q < 1/2$, (and later also to $q < \sqrt{2} - 1$). This is done because most of the analysis in the next section will be devoted to the limit $q \to 0$. Further, the periodic solution with the minimal energy in $\mathbb{R}^2$ is the triangular lattice[11–13] for which q is either $e^{-\pi\sqrt{3}}$ or $e^{-\pi/\sqrt{3}}$ which are both smaller than $1/2$.

For $q < 1/2$ we must have by (3.27b)

$$\bar{d}_n\bar{d}_{-n} = |d_n||d_{-n}|.$$

Hence,

$$\det\begin{bmatrix} (\epsilon_n^{(0)})^2(1 - 2q^{n^2}) - \eta_{-n}^2 & -(\epsilon_n^{(0)})^2 q^{2n^2} \\ -(\epsilon_n^{(0)})^2 q^{2n^2} & (\epsilon_n^{(0)})^2(1 - 2q^{n^2}) + \eta_n^2 \end{bmatrix} = 0.$$

We now observe that by (2.4)

$$\frac{\eta_n^2}{\eta_{-n}^2} \leqslant Ce^{-\omega nN}.$$

Hence, we can approximate $\epsilon_n^{(0)}$ by

$$(\epsilon_n^{(0)})^2 \cong \eta_{-n}^2 \frac{1 - 2q^{n^2}}{(1 - 2q^{n^2})^2 - q^{4n^2}}.$$

Using (3.2b) the critical values of λ are accordingly

$$\mu_{N-n} = \lambda_N + \frac{1-2q^{n^2}}{(1-2q^{n^2})^2 - q^{4n^2}}(\lambda_{N-n} - \lambda_N).$$

As long as $q < \sqrt{2}-1$ we have

$$\lambda_{N-n} < \mu_{N-n} < \lambda_{N-n-1},$$

and

$$\frac{\mu_{N-n} - \lambda_{N-n}}{\lambda_{N-n-1} - \lambda_{N-n}} \leqslant Ce^{-\omega N}.$$

Consequently, we can assert that the next bifurcation takes place at $\lambda = \mu_{N-1}$ where

$$\mu_{N-1} \cong \lambda_N + \frac{1-2q}{(1-2q)^2 - q^4}(\lambda_{N-1} - \lambda_N). \tag{3.28}$$

The corresponding eigenmode is

$$\frac{2}{\omega}\pi^{3/2}\begin{bmatrix} d_{-1} \\ d_1 \end{bmatrix} = \frac{1}{\sqrt{(1-2q)^2 + q^4}}\begin{bmatrix} 1-2q \\ q^2 \end{bmatrix}. \tag{3.29}$$

Combining (3.13), (3.14), (3.25), and (3.26) we obtain

$$\begin{aligned}\frac{2}{\omega}\pi^{3/2}u^{(0)} \cong{}& \frac{1-2q}{\sqrt{(1-2q)^2+q^4}} \exp\left\{-\frac{1}{2}[x_1 - (N-1)\omega]^2 + i\omega(N-1)x_2\right\} \\ &+ \frac{q^2}{\sqrt{(1-2q)^2+q^4}} \exp\left\{-\frac{1}{2}[x_1 - (N+1)\omega]^2 + i\omega(N+1)x_2\right\} + \tilde{v}_l,\end{aligned} \tag{3.30}$$

where $\tilde{v}_l$ satisfies

$$\int_0^{2\pi/\omega} e^{-i\omega n x_2}\tilde{v}_l dx_2 = 0, \quad \forall\, x_1 \in (-\omega_0, \infty), \quad N - 2l \leqslant |n| \leqslant N + 2l.$$

We first consider the case $|n| \leqslant N-l-1$. By (3.12) and (2.17) we have

$$\gamma_n(\mu)[\|\hat{u}_n\|_2^2 + \|\hat{u}_{-n}\|_2^2] \leqslant C(\epsilon + e^{-(N\omega + \omega_0)^2/4})^2.$$

By (2.19) and (2.18) there exists n_0 such that

$$n > n_0 \Rightarrow \gamma_n(\mu) \geqslant \tfrac{1}{2}(\lambda_n - \mu).$$

Let first $n_0 < n \leqslant N-l-1$. Then

$$\|\hat{u}_n\|_2^2 + \|\hat{u}_{-n}\|_2^2 \leqslant C\frac{\epsilon^2}{\lambda_n - \mu} \leqslant C\frac{\mu - \lambda_N}{\lambda_n - \mu} \leqslant C\frac{\mu - \lambda_N}{\lambda_n - \mu} \leqslant C\frac{\lambda_{N-l} - \lambda_N}{\lambda_{N-2l} - \lambda_{N-l}} \leqslant Ce^{-(1/2)lN\omega}.$$

Consider now the case $n \leqslant n_0$. Let

$$\tilde{\gamma} = \min_{\substack{1 \leqslant n \leqslant n_0 \\ 1 \leqslant \mu \leqslant \lambda_{N-l}}} \gamma_n(\mu).$$

By (2.18) $\tilde{\gamma}$ must be positive for sufficiently large N. Consequently,

$$\|\hat{u}_n\|_2^2 + \|\hat{u}_{-n}\|_2^2 \leqslant C\frac{\epsilon^2}{\tilde{\gamma}}.$$

Finally, we consider the case $n \geqslant N+2l+1$. In this case we can write instead of (3.23a)

$$(\epsilon^2 + \eta_n^2)\tilde{d}_n = 2\epsilon^2 q^{n^2}\tilde{d}_n + C\epsilon^2\tilde{\epsilon}_n,$$

wherein

$$\tilde{\epsilon}_n \leqslant e^{-(1/4)lN\omega}.$$

Hence, $\tilde{d}_n \leqslant C\tilde{\epsilon}_n$. Since (3.14) is still valid we have

$$\|\tilde{v}_l\| \leqslant Ce^{-(1/4)lN\omega},$$

which completes the proof of (3.8). □

Note that as $q \to 0$

$$\mu \to \lambda_{N-1}; \quad \begin{bmatrix} d_{-1} \\ d_1 \end{bmatrix} \to \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$

This is the limit of weak interaction between the modes: As $q \to 0$, ω tends to ∞ and hence, since $\phi_n \sim \exp\{-(x-n\omega)^2/2\}$, we obtain exponentially small interaction between the V_0 and its adjacent modes V_1 and V_{-1}. Consequently, as $q \to 0$, the next bifurcation is almost identical in nature with the first bifurcation: It takes place at, $\mu = \lambda_{N-1}$ and the bifurcating mode is V_{N-1}.

The fact that by (3.30) $u^{(0)}$ depends only on a finite number of modes is surprising: One expects that the bifurcating branch would include infinitely many modes since the term $|\psi|^2\psi$ on the right-hand side of (2.1) does not allow us to separate a finite number of modes from the others. It is thus expected that if we consider additional terms in the expansion (3.5), we shall obtain additional modes, so that u, the solution of (3.4) would consist of an infinite number of modes.

Upon multiplying (3.4) by $\bar{V}_n$ and integrating by parts we obtain

$$(\lambda - \lambda_{N+n}) \int u\bar{V}_n = (\lambda - \lambda_{N+n}) \int \bar{V}_n[2|\psi_0|^2 u + \psi_0^2\bar{u}] + \lambda_{N+n} \int f^2(u\bar{V}_n - \bar{u}V_n) + \lambda_{N+n}$$
$$\times \int \bar{V}_n[2(|\psi_0|^2 - f^2)u + (\psi_0^2 - f^2)\bar{u}] + \lambda \int \bar{V}_n[2|u|^2\psi_0 + u^2\bar{\psi}_0] + \lambda \int \bar{V}_n|u|^2 u.$$

We now substitute (3.5) into the above and obtain for the $O(\delta^2)$ balance for $n = \pm 1$, making the same approximations as before

$$\left(\frac{\omega}{2\pi}\right)^{3/2}[\epsilon_1^2 \pm \eta_{\pm 1}^2) \int u^{(0)}\bar{V}_n + \mu_{N-1}^{(1)} \int u^{(0)}\bar{V}_n = \epsilon_1^2 \int \bar{V}_n[2|V_0|^2 u^{(1)} + V_0^2\bar{u}^{(1)}] + \epsilon_1 \int \bar{V}_n[2|u^{(0)}|^2 V_0$$
$$+ V_0(u^{(0)})^2] + \mu_{N-1}^{(1)}\left(\frac{2\pi}{\omega}\right)^{3/2} \int \bar{V}_n[2|V_0|^2 u^{(0)}$$
$$+ V_0^2\bar{u}^{(0)}] + \epsilon_1^2\hat{\epsilon}_n. \tag{3.31}$$

It is possible to show that $\hat{\epsilon}_n$ is exponentially small as $N \to \infty$, since it results from interactions between "distant" modes, e.g., f_0 and V_n. We skip the details here and proceed by formally obtaining the next-order term.

To find $\mu_{N-1}^{(1)}$ we write the equations for $n = \pm 1$ neglecting the exponentially small terms

$$(\epsilon_1^2 - \eta_{-1}^2)d_{-1}^{(1)} = \epsilon_1^2 q[2d_{-1}^{(1)} + \overline{d^{(1)}}_1 q] + \mu_{N-1}^{(1)}[(1-2q)^2 - q^4], \tag{3.32}$$

$$(\epsilon_1^2 + \eta_1^2)d_1^{(1)} = \epsilon_1^2 q[2d_1^{(1)} + \overline{d^{(1)}}_{-1} q], \tag{3.33}$$

where

$$d_n^{(1)} = \int u^{(1)} \bar{V}_n. \tag{3.34}$$

It is easy to show that (3.32) can have solutions only if

$$\mu_{N-1}^{(1)} = 0. \tag{3.35}$$

In this case the solutions are proportional to (3.29) and are therefore of no interest. For $n=0$ we have

$$d_0^{(1)} = 2d_0^{(1)} + \bar{d}_0^{(1)} + \frac{2q}{\epsilon_1}[(1-2q)^2 + q^3 - q^4].$$

Hence,

$$d_0^{(1)} = -\frac{q}{\epsilon_1}[(1-2q)^2 + q^3 - q^4] + iC, \tag{3.36}$$

where the last term can be eliminated using the gauge transformation (1.2). For $n=\pm 2$ we obtain

$$(\epsilon_1^2 - \eta_{-2}^2) d_{-2}^{(1)} = \epsilon_1^2 q^4 [2d_{-2}^{(1)} + \overline{d^{(1)}}_2 q^4] + \epsilon_1 q^2 (1-2q)[2q^5 + 1 - 2q],$$

$$(\epsilon_1^2 + \eta_2^2) d_2^{(1)} = \epsilon_1^2 q^4 [2d_2^{(1)} + \overline{d^{(1)}}_{-2} q^4] + \epsilon_1 q^6 [2q(1-2q) + 1].$$

Since $\epsilon_1^2 / \eta_{-2}^2 \sim O(e^{-\omega N})$, we obtain

$$|d_{-2}^{(1)}| \sim O(e^{-\omega N}).$$

One can then obtain

$$d_2^{(1)} \cong \frac{q^6}{\epsilon_1}[2q(1-2q) + 1] + (e^{-\omega N}).$$

For $n \geqslant 3$ it is easy to show that $d_{\pm n}^{(1)} = 0$.

We can proceed in the same manner to obtain the next order term in the expansion (3.5). However, this solution will not provide any significant information except for the fact that

$$\mu^{(2)} \cong \left(\frac{\omega}{2\pi}\right)^{3/2} [\epsilon_1 (4d_{-1}^{(0)} d_0^{(1)} q + 2d_1^{(0)} d_0^{(1)} q^2 + 2d_1^{(0)} d_2^{(1)} q^5) + (|d_{-1}^{(0)}|^2 + 2q^4 |d_1^{(0)}|^2) d_{-1}^{(0)}] \frac{1 + O(e^{-\omega N})}{(1-2q)^2 - q^4}$$
$$\cong 1 - 2q + O(q^2, e^{-\omega N}) \quad \text{as } q \to 0. \tag{3.37}$$

We see that while $u^{(0)}$ contains the modes V_1 and V_{-1}, $u^{(1)}$ contains V_2 and V_{-2} as well. It can be shown that $u^{(n-1)}$ contains V_n and V_{-n} and hence by (3.5) u contains infinitely many modes. However, the coefficients of V_{-n} for $n \geqslant 2$ are exponentially small.

If we increase δ in (3.5) such that $\delta \gg \epsilon_1$, then the series (3.5) does not seem to converge: It is possible to show from (3.31) that $u^{(n)} \sim O(q^n / \epsilon_1^n)$. Therefore, convergence of (3.5) can be guaranteed only when $\delta \ll \epsilon_1 / q$. We are interested, however, in the behavior of the bifurcating branch when $\delta \gg \epsilon_1$ as well and therefore need to apply a different approach to obtain this behavior, which is what we do in the next section.

To this end we discuss here the behavior of u near the bifurcation in the limit $q \to 0$. Let then,

$$a_n = \lim_{q \to 0} \int u \bar{V}_n.$$

Formally, we have

$$a_n = \sum_{k=1}^{\infty} a_n^{(k)} \delta^k,$$

where

$$a_n^{(k)} = \lim_{q \to 0} \int u^{(k-1)} \bar{V}_n.$$

By (3.8b) we have

$$a_n^{(1)} = \begin{cases} 1 & n = -1, \\ 0 & n \neq -1. \end{cases}$$

Further, since

$$u^{(n)} \sim O(q^n) \quad \text{as } q \to 0,$$

we must have $a_n^{(k)} = 0$ for all n and $k \geqslant 2$. Consequently,

$$\psi \sim f_0 + \epsilon V_0 + \delta V_{-1} + O(q) \quad \text{as } q \to 0. \tag{3.38}$$

IV. POSTBIFURCATION BEHAVIOR

Consider again (2.1). We multiply the equation by $\bar{V}_n$ and integrate by parts to obtain

$$\lambda \int \psi(1 - |\psi|^2)\bar{V}_n = \lambda_{N+n} \int \psi[\bar{V}_n - f^2(2\bar{V}_n + V_n)],$$

or

$$(\lambda - \lambda_{N+n}) \int \psi \bar{V}_n = (\lambda - \lambda_{N+n}) \int \psi|\psi|^2 \bar{V}_n + \lambda_{N+n} \int \psi|\psi - f|^2 \bar{V}_n - \lambda_{N+n} \int f^2[(\bar{\psi} - f)\bar{V}_n - (\psi - f)V_n]. \tag{4.1}$$

We look for solutions of (2.1) for

$$0 < \lambda - \mu_{N-1} \ll 1,$$

which are close to (1.4), i.e.,

$$\lambda = \lambda_N + \left(\frac{\omega}{2\pi}\right)^{3/2} \epsilon^2 \tag{4.2a}$$

and

$$\psi \cong f_0 + \epsilon \psi^{(1)} + \epsilon^2 \psi^{(2)}, \tag{4.2b}$$

where

$$\psi^{(1)} = \sum_{n=-N+1} C_n V_n, \tag{4.2c}$$

$\epsilon_1 < \epsilon \ll 1$, and $\|\psi^{(2)}\|$ is bounded as $\epsilon \to \epsilon_1$ and $N \to \infty$. [Note that (4.2) is an extrapolation of the results in the preceding section.]

We now estimate the various terms on the right-hand side of (4.1). For the first term we have

$$\int \psi|\psi|^2\bar{V}_n = \epsilon \int f^2[2\psi^{(1)} + \bar{\psi}^{(1)}]\bar{V}_n + \epsilon^2 \int f^2[2\psi^{(2)} + \bar{\psi}^{(2)}]\bar{V}_n + \epsilon^2 \int f[2|\psi^{(1)}|^2 + (\psi^{(1)})^2]\bar{V}_n,$$

in which we have the estimates

$$\left| \int f^2[2\psi^{(1)} + \bar{\psi}^{(1)}]\bar{V}_n \right|^2 \leqslant C \int f^4|V_n|^2 \int |\psi^{(1)}|^2 \leqslant Ce^{-2[(N+n)\omega + \omega_0]^2/3},$$

$$\left| \int f[2|\psi^{(1)}|^2 + (\psi^{(1)})^2]\bar{V}_n \right|^2 \leqslant e^{-[(N+n)\omega + \omega_0]^2/2}.$$

Hence,

$$\left| (\lambda - \lambda_{N+n}) \int \psi|\psi|^2\bar{V}_n \right| \leqslant C|\lambda - \lambda_{N+n}|[\epsilon e^{-[(N+n)\omega + \omega_0]^2/3} + \epsilon^2 e^{-[(N+n)\omega + \omega_0]^2/4} + \epsilon^3]. \quad (4.3)$$

For the last term on the right-hand side of (4.1) we have

$$\int f^2[(\bar{\psi} - f)\bar{V}_n - (\psi - f)V_n] = \epsilon \int f^2[\bar{\psi}^{(1)}\bar{V}_n - \psi^{(1)}V_n] + \epsilon^2 \int f^2[\overline{\psi^{(2)}}\bar{V}_n - \psi^{(2)}V_n],$$

in which we have the estimates

$$\left| \int f^2[\bar{\psi}^{(1)}\bar{V}_n - \psi^{(1)}V_n] \right| \leqslant C \left| \int_{-\omega_0}^{\infty} f^2\phi_n\phi_{-n}dx_1 \right| \leqslant Ce^{-2[(N+n)\omega + \omega_0]^2/3},$$

$$\left| \int f^2\psi^{(2)}V_n \right| \leqslant Ce^{-[(N+n)\omega + \omega_0]^2/3}.$$

For the second term on the right-hand side of (4.1) we have

$$\int \psi|\psi - f|^2\bar{V}_n = \epsilon^2 \int f|\psi^{(1)}|^2\bar{V}_n + 2\epsilon^3 \int f\Re\{\bar{\psi}^{(1)}\psi^{(2)}\}\bar{V}_n + \epsilon^3 \int \psi^{(1)}|\psi^{(1)}|^2\bar{V}_n + O(\epsilon^4),$$

in which

$$\left| \int f|\psi^{(1)}|^2\bar{V}_n \right| \leqslant C \sup_{k<n} \left| \int fV_kV_{n-k-N}\bar{V}_n \right| \leqslant Ce^{-[(N+n)\omega + \omega_0]^2/2},$$

and

$$\left| \int f\Re\{\bar{\psi}^{(1)}\psi^{(2)}\}\bar{V}_n \right| \leqslant Ce^{-[(N+n)\omega + \omega_0]^2/4}.$$

Combining the above estimates and (4.1) we obtain

$$(\lambda - \lambda_{N+n}) \int \psi^{(1)}\bar{V}_n = \epsilon^2 \int \psi^{(1)}|\psi^{(1)}|^2\bar{V}_n + \epsilon^2\tilde{\epsilon}_n, \quad (4.4)$$

where $\tilde{\epsilon}_n$ satisfies (3.22b).

Substituting (4.2) into (4.4) and neglecting the exponentially small terms yields

$$\sum_{r,m=n-N+1}^{\infty} C_{n+r}\bar{C}_{n+r+m}C_{n+m}q^{m^2+r^2} - \nu_n C_n = 0, \tag{4.5a}$$

where

$$\nu_n^2 = \frac{\lambda - \lambda_{N+n}}{\lambda - \lambda_N} \tag{4.5b}$$

which is formally valid only when $(N+n) \gg 1$. Let $l \in \mathbb{N}$ and

$$\tfrac{1}{2}(\lambda_{N-l+1} + \lambda_{N-l}) < \lambda \leqslant \tfrac{1}{2}(\lambda_{N-l} + \lambda_{N-l-1}).$$

Then, by (2.4), we have

$$\nu_n \sim \begin{cases} 1 + O(e^{-\omega N}), & n \geqslant -l+1, \\ -O(e^{\omega N}), & n \leqslant -l-1. \end{cases} \tag{4.6}$$

For $n=-l$ the above ratio varies from a negative $O(e^{\omega N})$ value for $\lambda=(\lambda_{N-l+1}+\lambda_{N-l})/2$ to a value close to unity for $\lambda=\frac{1}{2}(\lambda_{N-l}+\lambda_{N-l-1})$. An immediate consequence of (4.6) is that

$$C_n \sim O(e^{-\omega N}), \quad \forall\, n \leqslant -l-1. \tag{4.7}$$

Equation (4.5) possesses infinitely many solutions. We first consider solutions which are analytic functions of q, i.e.,

$$C_n = \sum_{k=0}^{\infty} a_{nk} q^k. \tag{4.8}$$

We first look at $\lambda(q)$ such that ν_{-l} is independent of q. Note that by (4.6) ν_n remains too independent of q except for an $O(e^{-\omega N})$ term, which is negligible for $\omega \ll N$. For $q=0$ (4.5) has the form

$$a_{n0} = |a_{n0}|^2 a_{n0}, \quad -l+1 \leqslant n, \tag{4.9a}$$

$$\nu_{-l} a_{-l,0} = |a_{-l,0}|^2 a_{-l,0}. \tag{4.9b}$$

Note that the real roots of (4.9) are all simple provided that $\lambda \neq \lambda_{N-l}$. Consequently, all real solutions of (4.5) are holomorphic in q in some neighborhood of $q=0$ for $\lambda \neq \lambda_{N-l}$. We later show that the converse statement is also true, i.e., every solution of the form (4.8) is essentially real.

Consider first the case $l=-1$. We shall assume that (3.5) and (4.2) should match $\delta \sim o(\epsilon_1)$. If we continue (3.5) into the region where $\delta \gg \epsilon_1$ [where (3.5) does not necessarily converge], we obtain via the superposition $\psi=\psi_0+u$ a solution in the form (4.2). Near the bifurcation we have by (3.38)

$$a_{n0} = 0, \quad \forall\, n \neq 0, -1. \tag{4.10}$$

By (3.38) we have

$$a_{00} = 1; \quad a_{-1,0} = \lim_{\substack{q \to 0 \\ \nu_{-1}=\text{const.}}} \frac{\delta}{\epsilon}, \tag{4.11}$$

or, equivalently, that near the bifurcation

$$|a_{-1,0}|^2 = \nu_{-1},$$

which is in accordance with (4.9).

We now make the following claim

Lemma 4.1: Let $\{C_n\}_{n=-N+1}^{\infty}$ *satisfy (4.5) and (4.8). Then*,

$$C_n = e^{i[\theta_0(q)+n\theta_1(q)]}C_n', \tag{4.12}$$

where $C_n' \in \mathbb{R}$ *for all* $n \geqslant -N+1$, *and* $\theta_0(q)$ *and* $\theta_1(q)$ *are holomorphic in* q *in some neighborhood of* $q=0$. *Further, let* $\{a_{n0}\}_{n=-N+1}^{\infty}$ *be real solutions of* (4.9). *Then, there exists a unique solution of* (4.5) *which satisfies* (4.8) *in some neighborhood of* $q=0$.

We bring the proof in the Appendix.

In view of (4.12) we can replace $\{C_n\}_{n=-N+1}^{\infty}$ by $\{C_n'\}_{n=-N+1}^{\infty}$ by applying the transformation

$$\psi \to e^{i\theta_0(q)}\psi(x_1, x_2 + \theta_1(q)/\omega).$$

We may thus assume that the C_n's are all real [all other solutions will be gauge equivalent by (4.12)].

Consequently, using (4.12), we can set

$$a_{-1,0} = (\nu_{-1})^{1/2}.$$

When $\lambda - \lambda_{N-1} \gg \lambda_{N-1} - 1$ we obtain $a_{-1,0}=1$.

We now set $l=-2$ to examine the behavior of C_{-2} with increasing λ. As stated earlier C_{-2} is exponentially small when $\lambda - 1 \ll \lambda_{N-2} - 1$. However, we expect C_{-2} to become $O(1)$ for $\lambda > \lambda_{N-2}$.

Substituting (4.8) into (4.5) we obtain for the $O(q)$ balance

$$\nu_n a_{n1} = 3a_{n0}^2 a_{n1} + 2[a_{n+1,0}^2 + a_{n-1,0}^2]a_{n0}. \tag{4.13}$$

For $n \neq 0, -1$ we have $a_{n1}=0$. For $n=0, -1$ we have

$$a_{01} = -\nu_{-1}; \quad a_{-1,1} = -\frac{1}{\nu_{-1}^{1/2}}.$$

The $O(q^2)$ balance is

$$\begin{aligned}\nu_n a_{n2} = {} & 3a_{n0}^2 a_{n2} + 3a_{n1}^2 a_{n0} + 4(a_{n+1,0}a_{n+1,1} + a_{n-1,0}a_{n-1,1})a_{n0} + 2[a_{n+1,0}^2 + a_{n-1,0}^2]a_{n1} \\ & + [a_{n+1,0}^2 a_{n+2,0} + 2a_{n+1,0}a_{n0}a_{n-1,0} + a_{n-1,0}^2 a_{n-2,0}].\end{aligned} \tag{4.14}$$

Since we are interested in the behavior of C_{-2} with increasing λ we solve (4.14) for $n=-2$

$$\nu_{-2}a_{-2,2} = a_{-1,0}^2 a_{00}.$$

Consequently,

$$C_{-2} \sim \frac{\nu_{-1}}{\nu_{-2}}q^2. \tag{4.15}$$

As was expected in (4.7), C_{-2} is exponentially small provided that $\lambda - 1 \ll \lambda_{N-2} - 1$. If, however, $\lambda \uparrow \lambda_{N+2}$, then $a_{-2,2} \to -\infty$ and (4.15) ceases to be valid. To obtain the leading behaviour of C_{-2} in the limit $q \to 0$ when $\nu_{-2} \ll 1$ we consider first the case where $\nu_{-2} \sim O(q)$. Let then

$$\nu_{-2} = \rho q.$$

Substituting into (4.9), (4.13), and (4.14) (recalling that $\nu_{-1} \cong 1$ up to an exponentially small error) we obtain

$$a_{-2,0} = 0,$$

$$\rho a_{-2,1} = 2.$$

Consequently,

$$C_{-2} \cong \frac{1}{\rho - 2} q. \tag{4.16}$$

It is not difficult to show that in the overlap range where $\nu_{-2} \sim O(q^{\alpha})$ for $0 < \alpha < 1$ (4.15) and (4.16) match. We thus formally conclude that (4.15) develops into (4.16), which is valid as long as $\rho < 2$.

When $\rho \uparrow 2$, $a_{-2,1} \to -\infty$ and hence we must consider separately the case $|\rho - 2| \ll 1$. We thus consider ν_{-2} values satisfying

$$\nu_{-2} = 2q + \tau q^{4/3}.$$

In this case (4.8) is no longer valid. We therefore use the more general ansatz

$$C_n = \sum_{k=0}^{\infty} b_{nk} q^{k/3}.$$

Substituting in (4.5) and applying an appropriate gauge transformation we obtain

$$b_{00} = 1; \quad b_{-1,0} = 1; \quad b_{-2,0} = 0,$$

$$b_{-2,1} = 0,$$

and

$$(|b_{-2,2}|^2 - \tau) b_{-2,2} = - b_{-1,0}^2 b_{00} = -1. \tag{4.17}$$

Since our goal is to follow C_{-2} with increasing λ we look for the solution of (4.17) which matches (4.16) as $\tau \to -\infty$. Consequently, we must have

$$b_{-2,2} \sim \frac{1}{\tau} \quad \text{as } \tau \to -\infty.$$

Using the theory of cubic equations, it is easy to show that (4.17) has only one solution for

$$\tau < \tau_c = \frac{3}{2\sqrt[3]{2}},$$

since (4.17) admits only real solutions. We now follow this solution with increasing value of τ in order to find its behaviour as $\tau \to \infty$.

When $\tau = \tau_c$, (4.17) possesses two distinct solutions

$$b_{-2,2} = \frac{1}{\sqrt[3]{2}} \quad \text{with double multiplicity} \tag{4.18a}$$

and

$$b_{-2,2} = \sqrt[3]{4} \quad \text{with single multiplicity}. \tag{4.18b}$$

The former solution does not exist for $\tau < \tau_c$, and therefore, the latter solution is the one we follow. Since $|b_{-2,2}(\tau_c)|^2 > \tau_c$, we must have $|b_{-2,2}(\tau)|^2 > \tau$ for all $\tau \geqslant \tau_c$. Consequently, as $\tau \to \infty$,

$$C_{-2} \sim - \tau^{1/2} q^{2/3} C_{-1}^2 C_0 \sim - \tau^{1/2} q^{2/3}. \tag{4.19}$$

Consider now the case $\nu_{-2} = \rho q$ when $\rho > 2$. In this case we use the ansatz

$$C_n = \sum_{k=0}^{\infty} B_{nk} q^{k/2}.$$

Substituting into (4.5) yields, upon applying an appropriate gauge transformation,

$$B_{00} = 1; \quad B_{-1,0} = 1; \quad B_{-2,0} = 0,$$

$$|B_{-2,1}| = \sqrt{\rho - 2}. \tag{4.20a}$$

To find the phase of $B_{-2,1}$ we match (4.20) with (4.19) to obtain

$$C_{-2} \sim -\sqrt{\rho - 2} q^{1/2} C_{-1}^2 C_0 \sim -\sqrt{\rho - 2} q^{1/2}. \tag{4.21}$$

Finally, we consider positive $\nu_{-2} \sim O(1)$. Here we assume (4.8) once again. By (4.9) we have

$$|a_{-2,0}| = \sqrt{\nu_{-2}}.$$

The sign of $a_{-2,0}$ is determined from matching with (4.21). We obtain

$$C_{-2} \sim -\nu_{-2}^{1/2} C_{-1}^2 C_0 \sim -\nu_{-2}^{1/2}. \tag{4.22}$$

If λ further increases so that $\lambda_{N-2} - 1 \ll \lambda - 1 \ll \lambda_{N-3} - 1$, then $\nu_{-2} \sim 1$ and $C_{-2} \sim -1$.

To summarize: we have followed the $C_{-2}(\lambda)$ and found that it varies from a small negative value when $\lambda - 1 \ll \lambda_{N-2} - 1$ to approximately -1 for $\lambda - 1 \gg \lambda_{N-2} - 1$. This procedure can be applied recursively to obtain

$$C_{-l} \sim -C_{-l+1}^2 C_{l+2}, \tag{4.23}$$

from which we obtain

$$C_n \sim \begin{cases} (-1)^{[(n+1)/2]}, & -l \leqslant n \leqslant 0 \\ 0 & \text{otherwise} \end{cases} + O(q), \tag{4.24}$$

wherein $[\cdot]$ denotes the integer value.

We have thus formally obtained the behavior of the C_n's in the limit $q \to 0$. We now claim that for $l \gg 1$ and $N - l \gg 1$, when substituting (4.24) into (4.2c), ψ becomes close to the well-known triangular lattice.[11–13,21] The following lemma proves a stronger result: If a_{n0} satisfy (4.24), then any solution of the form (4.8) is close to the triangular lattice, for all q where (4.8) converges and not only when $q \to 0$. We should, however, emphasize that the foregoing discussion demonstrates (4.24) only formally and in the limit $q \to 0$. No such result has been proved for a_{n0}.

Lemma 4.2: Let

$$\phi = \epsilon D(q) \sum_{n=-\infty}^{\infty} (-1)^{[(n+1)/2]} \exp\left\{ -\frac{1}{2}(x_1 - n\omega)^2 + in\omega x_2 \right\}, \tag{4.25a}$$

where

$$\frac{1}{D^2} = \sum_{(m,r) \in \mathbb{Z}^2} (-1)^{mr} q^{m^2 + r^2}. \tag{4.25b}$$

Let ψ be given by (4.2) *and* $\{C_n\}_{n=-N+1}^{\infty}$ *satisfy* (4.5). *Then*,

$$\|\phi - \psi\|_{\infty} \leqslant C\epsilon \left[q^{l^2/64} + \epsilon^{1/2} + e^{Cl^2 - \omega N l/4} \right], \tag{4.26a}$$

where

$$\|\cdot\|_{\infty} = \|\cdot\|_{L^{\infty}\{[(N-5l/8)\omega, (N-3l/8)\omega] \times [0, 2\pi/\omega]\}}. \tag{4.26b}$$

Proof: Let

$$\tilde{\psi} = \epsilon \sum_{n=-\infty}^{\infty} e_n \exp\left\{ -\frac{1}{2}(x_1 - n\omega)^2 + in\omega x_2 \right\}, \tag{4.27}$$

where $\{e_n\}_{n=-\infty}^{\infty}$ denotes the solution of

$$\sum_{(r,m)\in\mathbb{Z}^2} e_r \bar{e}_{m-n+r} e_m q^{(r-n)^2+(m-n)^2} - e_n = 0, \tag{4.28}$$

which is holomorphic in q, or

$$e_n = \sum_{k=0}^{\infty} e_{nk} q^k,$$

such that

$$e_{n0} = \begin{cases} (-1)^{[(n+1)/2]}, & -l \leqslant n \leqslant 0 \\ 0 & \text{otherwise} \end{cases}. \tag{4.29}$$

We first prove that there exists $A>0$ which is independent of k, l, ω, q, and N such that

$$|e_{nk} - a_{nk}| \leqslant A^k e^{-\omega Nl/4}, \tag{4.30}$$

for all $0\leqslant k\leqslant l^2/16$ and $-3l/4\leqslant n\leqslant -l/4$. This can be done by using the recurrence relation obtained by substituting (4.8) into (4.5):

$$\nu_n a_{nk} = \sum_{r^2+s^2\leqslant k} \sum_{\substack{m,j\geqslant 0 \\ m+j\leqslant M}} a_{(n+r)j} a_{(n+r+s)(M-m-j)} a_{(n+s)m}, \tag{4.31}$$

where $M(r,s)=k-r^2-s^2$. Note that the C_n's were assumed all real in view of (4.12). By (4.28), e_{nk} satisfy the same recurrence relation with $\nu_n=1$. We can thus proceed by induction: We assume (4.30) for $0\leqslant k\leqslant K-1$. Substituting in (4.31) we obtain

$$\nu_n a_{nK} = \sum_{r^2+s^2\leqslant K} \sum_{\substack{m,j\geqslant 0 \\ m+j\leqslant M(K)}} e_{(n+r)j} e_{(n+r+s)(M-m-j)} e_{(n+s)m} + \Delta_{nK},$$

where

$$\Delta_{nK} \leqslant \sum_{j=1}^{K} 3A^{K-j} j^2 e^{-\omega Nl/4}.$$

Any $A>0$ satisfying

$$\sum_{n=1}^{\infty} A^{-n} n^2 \leqslant \frac{1}{3}$$

would then satisfy (4.30).

Using (4.27) and (4.2) we now have

$$\|\psi - \tilde{\psi}\|_\infty \leqslant \|f_0\|_\infty + \epsilon \sum_{n=-\infty}^{\infty} |C_n - e_n| \| e^{-(1/2)(x_1 - n\omega)^2} \|_\infty.$$

For the first term we have, since $l \ll N$,

$$\|f_0\|_\infty \leqslant C \exp\left\{-\frac{1}{2}\left(N-\frac{5}{8}l\right)^2\omega^2\right\} \leqslant C \exp\left\{-\frac{3}{8}N^2\omega^2\right\} \leqslant C\epsilon^{3/2}.$$

For the second term we have the bound

$$\epsilon \sum_{n=-\infty}^{\infty} |C_n - e_n| \left\| e^{-1/2(x_1 - n\omega)^2} \right\|_\infty \leqslant \epsilon \sum_{n=-3l/4}^{-l/4} |C_n - e_n| + Ce^{-l^2\omega^2/128} \leqslant \epsilon \frac{l}{2} \sum_{k=0}^{l^2/64} (Aq)^k e^{-\omega Nl/4} + Cq^{l^2/64},$$

from which we obtain

$$\|\psi - \tilde{\psi}\|_\infty \leqslant C\epsilon(q^{l^2/64} + \epsilon^{1/2} + e^{Cl^2 - \omega Nl/4}). \tag{4.32}$$

To complete the proof we need to obtain a similar estimate for $\|\phi - \tilde{\psi}\|_\infty$. By (4.25) we can write

$$\phi = \epsilon \sum_{n=-\infty}^{\infty} g_n \exp\left\{-\frac{1}{2}(x_1 - n\omega)^2 + in\omega x_2\right\},$$

where $\{g_n\}_{n=-\infty}^{\infty}$ satisfies (4.28) and

$$g_n = \sum_{k=0}^{\infty} g_{nk} q^k,$$

but in contrast with $\{e_n\}_{n=-\infty}^{\infty}$

$$g_{n0} = (-1)^{[(n+1)/2]}.$$

Substituting the above into (4.28) yields

$$g_{nk} = e_{nk}$$

for all $0 \leqslant k \leqslant l^2/16$ and $-3l/4 \leqslant n \leqslant -l/4$. The proof of the lemma then easily follows. □

V. CONCLUDING REMARKS

In Sec. II we prove the exact asymptotic behaviour of the critical values $\{\lambda_n\}_{n=1}^{\infty}$ of (2.2) and their corresponding modes. We proved that

$$\lambda_n \sim 1 + 2a^2 e^{-(n\omega + \omega_0)^2/2} + O(e^{-2(n\omega + \omega_0)^2/3}) \quad \text{as } n \to \infty,$$

where

$$a = \lim_{x \to \infty} e^{x^2/2} f(x, 1),$$

and that

$$\|\phi_n - e^{-(x_1 - n\omega)^2/2}\|_2^2 + \|\phi_{-n}\|_2^2 \leqslant e^{-2(n\omega + \omega_0)^2/3}.$$

Consequently, immediately after the first bifurcation we have

$$\lambda \cong \lambda_n + \epsilon^2 \left(\frac{\omega}{2\pi}\right)^{3/2},$$

$$\psi \cong e^{i\omega_0 x_2}\{f(x_1,\lambda) + \epsilon e^{-(x_1 - n\omega)^2/2} e^{in\omega x_2}\} + O(e^{-(n\omega + \omega_0)^2/3}),$$

Where f is given in (1.4).

At the conclusion of Sec. II we conjecture that $\lambda_n > 1$ for all $n \in \mathbb{N}$. This appears plausible since we expect that (1.4) would serve as the global minimizer of (1.8) in $\mathcal{P}_L^{\omega_0}$ when $\lambda \leqslant 1$. In Ref. 20 it was shown that any bifurcating branch has lower energy than (1.4) independently of n and λ. Thus, no bifurcation should take place for $\lambda \leqslant 1$ if (1.4) is indeed the global minimizer.

In Sec. III we consider the second bifurcation, while assuming that the first bifurcation takes place at $\lambda = \lambda_N$. We can explain this choice by considering (1.3a) not in $\mathbb{R}_2^+$ but in $[0,d] \times \mathbb{R}$ in the limit $d \to \infty$. In this case we have to add to (2.2) the boundary conditions

$$\phi_n'(d - \omega_0) = \phi_{-n}'(d - \omega_0) = 0.$$

As a result of the introduction of the additional boundary we have

$$\lambda_n(d) \sim n^2\omega^2 \quad \text{when } n\omega \gg d. \tag{5.1}$$

However, because of continuity,[24] one expects that

$$\lambda_n(d) \xrightarrow[d\to\infty]{} \lambda_n(\infty).$$

Although the above convergence is clearly not uniform in n, it still implies that for sufficiently large d there is a large number of critical values $\lambda_n(d)$ which can be approximated by (2.4). Let then,

$$\lambda_N = \min_{n\in\mathbb{N}} \lambda_n(d).$$

In view of (5.1) such a minimum must exist. Further, if (2.18) is correct then λ_N must be very close to 1. Since with increasing λ the first bifurcation from (1.4) must take place at $\lambda = \lambda_N$ we see that the assumption that the bifurcation takes place at $\lambda = \lambda_N$ is in accordance in principle with the situation in finite domains.

We show in Sec. III that, if the second bifurcation exists and if (2.18) is correct, then the second bifurcation must take place at

$$\mu_{N-1} \cong \lambda_N + \frac{1-2q}{(1-2q)^2 - q^4}(\lambda_{N-1} - \lambda_N),$$

where $q = e^{-\omega^2/2}$, and the bifurcating mode must have the form

$$\frac{2}{\omega}\pi^{3/2}u^{(0)} \cong \frac{1-2q}{\sqrt{(1-2q)^2+q^4}} \exp\left\{-\frac{1}{2}[x_1 - (N-n)\omega]^2 + i\omega(N-n)x_2\right\} + \frac{q^2}{\sqrt{(1-2q)^2+q^4}} \exp\left\{-\frac{1}{2}[x_1 - (N+n)\omega]^2 + i\omega(N+n)x_2\right\}.$$

By formally evaluating the next order terms in (3.5) we obtain that each term provides two additional Fourier modes to ψ. Thus, $u^{(1)}$ adds the modes V_{-2} and V_2, etc. However, the coefficients of V_{-k} have been shown to be exponentially small for all $k \geqslant 2$.

In Sec. IV we extrapolate the behaviour of ψ near the bifurcation into the region where

$$\lambda - \mu_{N-1} \sim O(\lambda - \lambda_N).$$

To this end we assume that

$$\psi \cong f + \epsilon \sum_{n=-N+1}^{\infty} C_n V_n, \tag{5.2}$$

and

$$\lambda \cong \lambda_N + \epsilon^2 \left(\frac{\omega}{2\pi} \right)^{3/2}.$$

Based upon this assumption we find that as $N \to \infty$ the C_n's must satisfy the system

$$\sum_{r,m=n-N+1}^{\infty} C_{n+r} \bar{C}_{n+r+m} C_{n+m} q^{m^2+r^2} - \nu_n^2 C_n = 0,$$

where

$$\nu_n^2 = \frac{\lambda - \lambda_{N+n}}{\lambda - \lambda_N}.$$

This system of polynomial equations is very similar to the one obtained by Abrikosov[1] in the absence of boundaries where

$$\sum_{r,m=-\infty}^{\infty} C_{n+r} \bar{C}_{n+r+m} C_{n+m} q^{m^2+r^2} - \nu C_n = 0,$$

in which ν is proportional to $\lambda - 1$.

To investigate the solution of the above-mentioned system with increasing λ we first match (5.2) with the solution obtained in Sec. III. We obtain that near $\lambda = \mu_{N-1}$ as $q \to 0$ with fixed ν_{-1} we have

$$C_0 \sim 1 \quad C_{-1} \sim \sqrt{\nu_{-1}}.$$

By following the leading order of C_{-2} as $q \to 0$ (with fixed ν_{-2}) with increasing λ, we obtain that when $\nu_{-2} \sim 1$

$$C_{-2} \sim -C_0^2 C_{-1} = -1.$$

Since the same procedure can be applied again to derive the behavior of C_{-n} when $\nu_{-n} \sim 1$, we obtain that

$$C_n \sim \begin{cases} (-1)^{[(n+1)/2]}, & -l \leqslant n \leqslant 0 \\ 0 & \text{otherwise.} \end{cases} + O(q)$$

Finally, we show that if C_n is holomorphic in q for all n, then the above-mentioned asymptotic relation implies that (5.2) is closed to the triangular lattice, which is given by

$$\phi = \epsilon D(q) \sum_{n=-\infty}^{\infty} (-1)^{[(n+1)/2]} \exp\left\{ -\frac{1}{2}(x_1 - n\omega)^2 + in\omega x_2 \right\},$$

where

$$\frac{1}{D^2} = \sum_{(m,r) \in \mathbb{Z}^2} (-1)^{mr} q^{m^2+r^2}.$$

We prove that

$$\|\phi - \psi\|_\infty \leqslant C\epsilon[q^{l^2/64} + \epsilon^{1/2} + e^{Cl^2-\omega Nl/4}],$$

where $1 \ll l \ll N$ and

$$\|\cdot\|_\infty = \|\cdot\|_{L^\infty\{[(N-5l/8)\omega,(N-3l/8)\omega]\times[0,2\pi/\omega]\}}.$$

We conclude this section by listing the main gaps which need to be addressed in order to establish a rigorous proof of the main result of this work

(1) Proof of (2.18).
(2) Existence proof of the second bifurcation.
(3) Proving that (5.2) is indeed a continuation of (3.1).
(4) Proving that C_n must be holomorphic in q when $\nu_n \sim 1$ for $n \geqslant -l$ and $\nu_n \sim -O(e^{\omega N})$ for $n \leqslant -l-1$ (here l is any integer smaller than $N/2$).
(5) Proof that either no other bifurcation exists after the second one or, if another bifurcation does exist, then (5.2) has lower energy than the supposed bifurcating branch.

APPENDIX: PROOF OF LEMMA 4.1

We prove here an equivalent statement to (4.12), i.e., that

$$C_{n-1}\bar{C}_n^2 C_{n+1} \in \mathbb{R}. \tag{A1}$$

We prove (A1) by invoking inductive arguments. We first prove that

$$\mathfrak{I}(C_{n-1}\bar{C}_n^2 C_{n+1}) \sim O(q), \quad \forall\, n, \tag{A2}$$

and then that

$$\mathfrak{I}(C_{n-1}\bar{C}_n^2 C_{n+1}) \sim O(q^k) \Rightarrow \mathfrak{I}(C_{n-1}\bar{C}_n^2 C_{n+1}) \sim O(q^{k+1}), \quad \forall\, n. \tag{A3}$$

Substituting (4.8) into (4.5) we obtain from the $O(q^2)$ balance that[13]

$$\mathfrak{I}\{\bar{a}_{(n+2)0}a_{(n+1)0}^2\bar{a}_{n0} + 2a_{(n+1)0}(\bar{a}_{n0})^2 a_{(n-1)0} + \bar{a}_{(n-2)0}a_{(n-1)0}^2\bar{a}_{n0}\} = 0, \quad \forall\, n.$$

From this we easily conclude that

$$\mathfrak{I}\{a_{(n+1)0}(\bar{a}_{n0})^2 a_{(n-1)0}\} = 0, \quad \forall\, n,$$

which is exactly (A2).

To prove (A3) we assume by induction that

$$\mathfrak{I}(C_{n-1}\bar{C}_n^2 C_{n+1}) \sim O(q^k).$$

Equivalently we may assume the existence of θ_0, θ_1, holomorphic in q, such that

$$\mathfrak{I}\{C_n e^{i[\theta_0(q)+n\theta_1(q)]}\} \sim O(q^k).$$

Let

$$C_n' = e^{i[\theta_0(q)+n\theta_1(q)]}C_n.$$

Then,

$$c_n' = \sum_{j=0}^{\infty} a_{nj}' q^j,$$

where

$$a'_{nj} \in \mathbb{R}, \quad \forall\, 0 \leqslant j \leqslant k-1.$$

Let further

$$a'_{nk} = [a'_n + b_n^k]a'_{n0}, \quad -l \leqslant n \leqslant 0.$$

It is easy to show that when $a'_{n0}=0$, then $a'_{nk} \in \mathbb{R}$. Thus, it remains necessary to show that $b_n^k=0$ for all $-l \leqslant n \leqslant 0$. The recurrence relation (4.31) for complex a_{nj} becomes

$$\nu_n a'_{nj} = \sum_{r^2+s^2 \leqslant j} \sum_{\substack{m,j \geqslant 0 \\ m+j \leqslant M}} a'_{(n+r)j} \bar{a}'_{(n+r+s)(M-m-j)} a'_{(n+s)m}, \tag{A4}$$

where $M(r,s)=j-r^2-s^2$. It is easy to show that (A4) is satisfied for $j=k$ and $j=k+1$ independently of the values of the b_n^k's. For $j=k+2$ we obtain after a tedious calculation that (A4) is solvable if and only if

$$Pb = 0 \tag{A5a}$$

where b is the vector

$$b = \begin{bmatrix} b_{0k} \\ \vdots \\ b_{-l,k} \end{bmatrix}, \tag{A5b}$$

and p is the matrix

$$P = \begin{bmatrix} -p_{-l+1} & 2p_{-l+1} & -p_{-l+1} & 0 & \cdots & 0 \\ 2p_{-l+1} & -4p_{-l+1}-p_{-l+2} & 2(p_{-l+1}+p_{-l+2}) & -p_{-l+2} & 0 & \cdots \\ -p_{-l+1} & 2(p_{-l+1}+p_{-l+2}) & -p_{-l+1}-4p_{-l+2}-p_{-l+3} & 2(p_{-l+2}+p_{-l+3}) & -p_{-l+3} & \cdots \\ \vdots & \vdots & \cdots & \cdots & \cdots & \vdots \\ 0 & \cdots & 0 & -p_{-1} & 2p_{-1} & -p_{-1} \end{bmatrix}, \tag{A5c}$$

in which,

$$p_n = a'_{n-1,0}(a'_{n0})^2 a'_{n+1,0}. \tag{A5d}$$

The matrix P can conveniently be decomposed into the product

$$P = P^{(1)}P^{(2)}, \tag{A6a}$$

where

$$P^{(1)} = \begin{bmatrix} 0 & -p_{-l+1} & 0 & 0 & \cdots & 0 & 0 \\ 0 & 2p_{-l+1} & -p_{-l+2} & 0 & \cdots & 0 & 0 \\ 0 & -p_{-l+1} & 2p_{-l+2} & -p_{-l+3} & \cdots & 0 & 0 \\ \vdots & & & & & & \vdots \\ 0 & 0 & 0 & 0 & \cdots & -p_{-1} & 0 \end{bmatrix}, \tag{A6b}$$

and

$$P^{(2)} = \begin{bmatrix} -2 & 1 & 0 & \cdots & & 0 & 1 \\ 1 & -2 & 1 & 0 & \cdots & & 0 \\ \vdots & & & & & & \vdots \\ 0 & \cdots & & & 0 & 1 & -2 & 1 \end{bmatrix}. \tag{A6c}$$

The matrix $P^{(2)}$ is circulant. Its kernel is spanned by $[1,\ldots,1]^T$. For $P^{(1)}$ we have

$$\ker P^{(1)} = \operatorname{span}\left\{\begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}; \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}\right\}.$$

Obviously $[1,\ldots,1]^T \in \ker P$. Further, any vector $b \in \mathbb{R}^{l+1}$ for which $P^{(2)}b \in \ker P^{(1)}$ belongs to $\ker P$ as well. Consequently, $r(P)=2$ and

$$\ker P = \operatorname{span}\left\{\begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}; \begin{bmatrix} 0 \\ 1 \\ \vdots \\ l \end{bmatrix}\right\}.$$

and hence

$$b_n^k = b^k + n\tilde{b}^k,$$

which proves (A3). □

The initial value problem for the time dependent Ginzburg–Landau equations used to model the electrodynamics of a superconducting body surrounded by a vacuum in $\mathbb{R}^3$ is studied. We prove existence, uniqueness, and regularity results for solutions in the Coulomb, Lorentz, and temporal gauges. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2012107]

I. INTRODUCTION

In this article we study an initial value problem for the time dependent Ginzburg–Landau (TDGL) equations used to model the electrodynamics of a nonmagnetic superconducting body $\Omega \subset \mathbb{R}^3$ placed in a vacuum.[11] We prove existence, uniqueness, and regularity results for solutions $(\psi, \mathbf{A}, \phi)$ where $\psi(\cdot,t):\Omega \to \mathbb{C}$ is the Ginzburg–Landau order parameter, $\mathbf{A}(\cdot,t):\mathbb{R}^3 \to \mathbb{R}^3$ is the magnetic vector potential, and $\phi(\cdot,t):\mathbb{R}^3 \to \mathbb{R}$ is the scalar electric potential. We use the notation $(a,b)=\mathcal{R}_e(a^*b)=(a^*b+ab^*)/2$ for $a,b \in \mathbb{C}$ to denote the real inner product on $\mathbb{C}\times\mathbb{C}$, $\nabla_{\mathbf{A}}=\nabla-i\mathbf{A}$ for the covariant derivative, $D_T=\Omega\times(0,T)$, and $E_T=\mathbb{R}^3\times(0,T)$. The TDGL equations, also known as the Gorkov-Eliashberg equations[5] are

$$\partial_t\psi + i\phi\psi - \nabla_{\mathbf{A}}^2\psi + \kappa^2(|\psi|^2-1)\psi = 0 \quad \text{in } D_T, \tag{1.1}$$

$$\sigma\chi_\Omega(\partial_t\mathbf{A}+\nabla\phi) + \operatorname{curl}^2\mathbf{A} = \chi_\Omega(i\psi,\nabla_{\mathbf{A}}\psi) \quad \text{in } E_T. \tag{1.2}$$

The term $|\psi|^2$ represents the density of superconducting electron pairs in Ω, and $\mathbf{j}_s=(i\psi,\nabla_{\mathbf{A}}\psi)$ denotes the supercurrent density in the body. The quantity $\mathbf{E}=-\partial_t\mathbf{A}-\nabla\phi$ is the electric field. The normal current density is characterized by Ohm's law, $\mathbf{j}_n=\sigma\mathbf{E}$ in Ω. The constants κ and σ are positive and fixed determined by the material, κ is the Ginzburg–Landau constant and σ is the normal conductivity. Writing the total current density as $\mathbf{j}=\mathbf{j}_s+\mathbf{j}_n$ we see that (1.2) can be written as

$$\operatorname{curl}^2\mathbf{A} = \chi_\Omega(\mathbf{j}_s+\mathbf{j}_n) = \chi_\Omega\mathbf{j}. \tag{1.3}$$

This is the quasistatic approximation to Ampere's law for a nonmagnetic, conducting body surrounded by a vacuum.

The domain Ω is an open bounded connected set in $\mathbb{R}^3$ where $\partial\Omega$ will be as smooth as needed (at least $C^{3+\alpha}$). We assume that

$$\nabla_{\mathbf{A}}\psi\cdot\boldsymbol{\nu}=0 \quad \text{on } \partial\Omega, \tag{1.4}$$

where $\boldsymbol{\nu}$ is the exterior normal to the boundary. Since $\mathbb{R}^3\backslash\bar{\Omega}$ is a vacuum neither super or normal current crosses $\partial\Omega$. To see that this property is implied by the system note from (1.4) that

$$0=(i\psi,\nabla_{\mathbf{A}}\psi)\cdot\boldsymbol{\nu}=\mathbf{j}_s\cdot\boldsymbol{\nu} \quad \text{on } \partial\Omega.$$

Further, from (1.3), assuming that $\mathbf{j}$ is sufficiently regular, we have

$$0=\operatorname{div}(\chi_\Omega\mathbf{j})=\chi_\Omega \operatorname{div}\mathbf{j}+\mathbf{j}\cdot\boldsymbol{\nu}dH^2_{\llcorner\partial\Omega} \quad \text{in } \mathcal{D}'(\mathbb{R}^3).$$

Thus $0=\mathbf{j}\cdot\boldsymbol{\nu}$ on $\partial\Omega$, and it follows that $\mathbf{j}_n\cdot\boldsymbol{\nu}=-\mathbf{j}_s\cdot\boldsymbol{\nu}=0$ on $\partial\Omega$ as well.

The electrodynamics are driven by a constant applied magnetic field $\mathbf{H}=h\mathbf{e}_3$ and initial values. These are reflected in the conditions

$$(\operatorname{curl}\mathbf{A}-h\mathbf{e}_3)\in\mathbf{L}_2(\mathbb{R}^3) \quad \text{for } 0\leqslant t<T,$$

$$\psi(x,0)=\psi_0(x) \quad \text{in } \Omega$$

with $|\psi_0|\leqslant 1$,

$$\mathbf{A}(x,0)=\mathbf{A}_0(x) \quad \text{in } \mathbb{R}^3,$$

where $\operatorname{curl}^2\mathbf{A}_0=0$ in $\mathcal{D}'(\mathbb{R}^3\backslash\bar{\Omega})$. The last condition is to be expected since by (1.3) we have $\operatorname{curl}^2\mathbf{A}=0$ in $\mathbb{R}^3\backslash\bar{\Omega}$ for $t>0$.

A specific magnetic potential for the applied field is $h\mathbf{a}(x)=(0,hx_1,0)$, and in this article we view $\mathbf{A}$ as a perturbation of this field, $\mathbf{A}=\tilde{\mathbf{A}}+h\mathbf{a}$. We consider $\tilde{\mathbf{A}}\in\check{\mathbf{H}}(\mathbb{R}^3)$ where $\check{\mathbf{H}}$ is the Hilbert space defined on the closure of $\mathbf{C}_c^\infty(\mathbb{R}^3;\mathbb{R}^3)$ in the norm $\|\tilde{\mathbf{A}}\|_{\check{\mathbf{H}}}=(\int_{\mathbb{R}^3}|\nabla\tilde{\mathbf{A}}|^2\mathrm{d}x)^{1/2}$. Thus $(\psi,\tilde{\mathbf{A}},\phi)$ is a solution to the system,

$$\partial_t\psi+i\phi\psi-\nabla^2_{(\tilde{\mathbf{A}}+h\mathbf{a})}\psi+\kappa^2(|\psi|^2-1)\psi=0 \quad \text{in } D_T, \tag{1.5}$$

$$\sigma\chi_\Omega(\partial_t\tilde{\mathbf{A}}+\nabla\phi)+\operatorname{curl}^2\tilde{\mathbf{A}}=\chi_\Omega\cdot(i\psi,\nabla_{(\tilde{\mathbf{A}}+h\mathbf{a})}\psi) \quad \text{in } E_T, \tag{1.6}$$

$$\nabla_{(\tilde{\mathbf{A}}+h\mathbf{a})}\psi\cdot\boldsymbol{\nu}=0 \quad \text{on } \partial\bar{\Omega}\times(0,T), \tag{1.7}$$

$$\tilde{\mathbf{A}}\in\check{\mathbf{H}}(\mathbb{R}^3) \quad \text{for } 0\leqslant t<T, \tag{1.8}$$

$$\int_\Omega\phi\mathrm{d}x=0 \quad \text{for } 0\leqslant t<T, \tag{1.9}$$

$$\psi=\psi_0, \quad \tilde{\mathbf{A}}=\mathbf{A}_0-h\mathbf{a} \quad \text{at } t=0. \tag{1.10}$$

For $p\in[1,\infty]$ and integer $m\geqslant 1$, $W_p^m(\Omega)$ is the space of functions having all weak derivatives of order up to m in $L_p(\Omega)$, for $p\in[1,\infty)$, $\mathring{W}_p^m(\Omega)$ denotes the closure of $C_c^\infty(\Omega)$ in the $W_p^m(\Omega)$ norm, and $W_p^{2,1}(D_T)$ is the space of functions where weak derivatives $u_{x_i}=\partial_{x_i}u$, $u_{x_ix_j}=\partial_{x_i}\partial_{x_j}u$, $\partial_t u$ belong to $L_p(\Omega)$. Furthermore if W denotes a space of real valued functions then we use $\mathbf{W}$ for the corresponding space of vector valued functions, and $\mathcal{W}$ if the functions are complex valued.

A. The spaces $\check{\mathbf{H}}(\mathbb{R}^3)$ and $\check{\mathbf{G}}(\mathbb{R}^3)$

Elements $\mathbf{B} \in \check{\mathbf{H}}(\mathbb{R}^3)$ satisfy

$$\|\mathbf{B}\|_{\mathbf{L}_6(\mathbb{R}^3)} \leqslant C\|\nabla \mathbf{B}\|_{\mathbf{L}_2(\mathbb{R}^3)}, \tag{1.11}$$

$$\int_{\mathbb{R}^3} |\nabla \mathbf{B}|^2 \mathrm{d}x = \int_{\mathbb{R}^3} [(\operatorname{div} \mathbf{B})^2 + |\operatorname{curl} \mathbf{B}|^2] \mathrm{d}x. \tag{1.12}$$

These are proved first for $\mathbf{B} \in \mathbf{C}_c^\infty(\mathbb{R}^3;\mathbb{R}^3)$ and then follow by density. Inequality (1.11) is a Sobolev inequality where C is a universal constant. Equation (1.12) follows from the identity, $-\Delta \mathbf{B} = -\nabla(\operatorname{div} \mathbf{B}) + \operatorname{curl}^2 \mathbf{B}$ and integration by parts. The space $\check{\mathbf{H}}(\mathbb{R}^3)$ can be written as the direct sum of orthogonal subspaces, $\check{\mathbf{H}}(\mathbb{R}^3) = \mathbb{V}_1 \oplus \mathbb{V}_2$, where

$$\mathbb{V}_1 = \{\mathbf{B} \in \check{\mathbf{H}}(\mathbb{R}^3) : \operatorname{curl} \mathbf{B} = 0\} = \{\mathbf{B} \in \check{\mathbf{H}}(\mathbb{R}^3) : \mathbf{B} = \nabla f \text{ for some } f \in W^2_{2,loc}(\mathbb{R}^3)\},$$

$$\mathbb{V}_2 = \{\mathbf{B} \in \check{\mathbf{H}}(\mathbb{R}^3) : \operatorname{div} \mathbf{B} = 0\}.$$

See the appendix.

Let $(\psi, \widetilde{\mathbf{A}}, \phi)$ be a solution to (1.5)–(1.10). For each t we decompose $\widetilde{\mathbf{A}}(\cdot, t)$ uniquely as $\widetilde{\mathbf{A}} = \nabla f + \mathbf{g}$ where $\nabla f \in \mathbb{V}_1$ and $\mathbf{g} \in \mathbb{V}_2$. The equations (1.5) and (1.6) only require that ∇f and ϕ be specified on Ω. As such we adopt the convention of giving particular extensions of these functions to $\mathbb{R}^3 \backslash \Omega$. Recall $\partial\Omega \in C^{3+\alpha}$, fix $R > 0$ such that $\bar{\Omega} \subset B_R(0)$. Let $\mathcal{E}: W_2^3(\Omega) \to \mathring{W}_2^3(B_R)$ be the bounded extension operator given in Ref. 6 (p. 170). For $0 \leqslant k \leqslant 2, \mathcal{E}(\cdot)$ has a unique continuous extension

$$\mathcal{E}: W_2^k(\Omega) \to \mathring{W}_2^k(B_R),$$

so that for $0 \leqslant k \leqslant 3$ there is a constant C for which

$$\|\mathcal{E}(u)\|_{\mathring{W}_2^k(B_R)} \leqslant C\|u\|_{W_2^k(\Omega)}$$

for all $u \in W_2^k(\Omega)$.

The space $\check{\mathbf{G}}(\mathbb{R}^3)$ is defined as the subspace of $\check{\mathbf{H}}(\mathbb{R}^3)$ given by

$$\check{\mathbf{G}}(\mathbb{R}^3) = \{\mathbf{B} \in \check{\mathbf{H}}(\mathbb{R}^3) : \mathbf{B} = \nabla \mathcal{E}(f) + \mathbf{g}$$

for some $f \in W_2^2(\Omega)$ with $\int_\Omega f \mathrm{d}x = 0$ and $\mathbf{g} \in \mathbb{V}_2\}$.

In this article $\widetilde{\mathbf{A}}(\cdot, t)$ will be constructed so that $\widetilde{\mathbf{A}} \in \check{\mathbf{G}}(\mathbb{R}^3)$ and ϕ will be understood equaling $\mathcal{E}(\phi) = \mathcal{E}(\phi_{\llcorner \Omega})$.

B. Gauge invariance

The evolution problem (1.5)–(1.10) has multiple solutions, even with the extension convention given above. Indeed, the TDGL equations are *gauge invariant* with respect to the transformation $T_q(\psi, \mathbf{A}, \phi) = (\upsilon, \mathbf{B}, \zeta)$ defined by:

$$\upsilon = \psi e^{iq}, \quad \mathbf{B} = \mathbf{A} + \nabla q, \quad \zeta = \phi - \partial_t q \tag{1.13}$$

for some function q. By this, it is meant that $(\upsilon, \mathbf{B}, \zeta)$ is a solution to (1.5)–(1.7) if $(\psi, \mathbf{A}, \phi)$ is one as well, provided q is sufficiently regular. The two solutions are called *gauge equivalent*. Some quantities that are invariant under a change of gauge are the density $|\psi|^2$, the currents $\mathbf{j}_s = (i\psi, \nabla_{\mathbf{A}}\psi)$ and $\mathbf{j}_n = \sigma(\partial_t \mathbf{A} + \nabla\phi)$, and the magnetic intensity curl $\mathbf{A}$. The function q can be chosen so that $(\upsilon, \mathbb{B}, \zeta)$ satisfies prescribed conditions for the equations, boundary, or initial values. The gauge choices used here are listed below:

(i) The Coulomb gauge,

$$\operatorname{div} \mathbf{B} = 0 \quad \text{in } E_T,$$

here q is chosen to satisfy $\Delta q = -\operatorname{div} \mathbf{A}$ in E_T, and $\int_\Omega q \, dx = 0$ for each t.

(ii) The temporal gauge,

$$\zeta = 0 \quad \text{in } E_T,$$

where q is chosen so that $\partial_t q = \phi$ in E_T, and $q(x,0)$ is such that $\operatorname{div}(\chi_\Omega(\nabla q(x,0) + \mathbf{A}_0(x)) = 0$ in $\mathbb{R}^3$. In this case it will follow that we also have

$$\mathbf{B} \cdot \boldsymbol{\nu} = 0 \quad \text{on } \partial\Omega \times (0,T), \tag{1.14}$$

and

$$\operatorname{div}(\chi_\Omega \mathbf{B}(x,0)) = 0 \quad \text{in } \mathbb{R}^3. \tag{1.15}$$

(iii) The Lorentz gauge,

$$\operatorname{div} \mathbf{B} + \sigma\xi = 0 \quad \text{in } D_T,$$

here q is defined on E_T so that

$$\sigma \partial_t q - \Delta q = \operatorname{div} \mathbf{A} + \sigma\phi \quad \text{in } D_T,$$

$$\partial_\nu q = -\mathbf{A} \cdot \boldsymbol{\nu} \quad \text{on } \partial\Omega \times [0,T),$$

$$-\Delta q(x,0) = \operatorname{div} \mathbf{A}(x,0) \quad \text{on } \Omega,$$

and $q = \mathcal{E}(q)$. Moreover $\mathbf{B}$ satisfies (1.14) and (1.15) as well.

C. Results

The TDGL equations are a gradient flow in the $\phi = 0$ gauge, (ii). Using this feature, in Sec. II we prove that the initial value problem has a unique solution. The hypotheses for initial values, $(\psi_0, \mathbf{A}_0)$ in this gauge are as follows:

$\mathfrak{H}$: $\psi_0 \in \mathcal{W}_2^1(\Omega)$ such that $|\psi_0| \leqslant 1$, $(\mathbf{A}_0 - h\mathbf{a}) \in \check{\mathbf{G}}(\mathbb{R}^3)$ such that $\operatorname{curl}^2 \mathbf{A}_0 = 0$ in $\mathbb{R}^3 \backslash \bar{\Omega}$, and $\operatorname{div}(\chi_\Omega \mathbf{A}_0) = 0$ in $\mathbb{R}^3$.

Define the admissible class,

$$\mathfrak{A} = \{(\psi, \mathbf{A}) : |\partial_t \psi|, \quad |\partial_t \mathbf{A}| \in L_2(D_T), \quad \psi \in L_\infty((0,T); \mathcal{W}_2^1(\Omega)),$$

$$(\mathbf{A} - h\mathbf{a}) \in L_\infty((0,T); \dot{\check{\mathbf{G}}}(\mathbb{R}^3)), \quad \psi(0) = \psi_0, \quad \mathbf{A}(0) = \mathbf{A}_0 \quad \text{in } \Omega\}.$$

Using (ii) the problem becomes

$$\partial_t \psi - \nabla_{\mathbf{A}}^2 \psi + \kappa^2(|\psi|^2 - 1)\psi = 0 \quad \text{in } D_T, \tag{1.16}$$

$$\sigma \chi_\Omega \partial_t \mathbf{A} + \operatorname{curl}^2 \mathbf{A} = \chi_\Omega (i\psi, \nabla_{\mathbf{A}} \psi) \quad \text{in } E_T, \tag{1.17}$$

$$(\mathbf{A} - h\mathbf{a}) \in \check{\mathbf{G}}(\mathbb{R}^3) \quad \text{for } 0 \leqslant t < T, \tag{1.18}$$

$$\partial_{\boldsymbol{\nu}} \psi = 0, \ \mathbf{A} \cdot \boldsymbol{\nu} = 0 \quad \text{on } \partial\Omega \times (0,T), \tag{1.19}$$

$$\psi(x,0) = \psi_0(x) \quad \text{in } \Omega, \quad \mathbf{A}(x,0) = \mathbf{A}_0(x) \quad \text{in } \mathbb{R}^3. \tag{1.20}$$

We say that $(\psi,\mathbf{A})\in\mathfrak{A}$ is a *weak solution* to (1.16)–(1.20) if $(\psi,\mathbf{A}-\mathbf{ha})$ satisfies (2.12) and (2.13).

Theorem 1: *Let* $(\psi_0,\mathbf{A}_0)$ *satisfy* $\mathfrak{H}$. *Then there exists a unique weak solution to (1.16)–(1.20) in* $\mathfrak{A}$. *Moreover* $(\psi,\mathbf{A})$ *satisfies*

$$(\psi(t),\mathbf{A}(t)-h\mathbf{a})\to(\psi_0,\mathbf{A}_0-h\mathbf{a})\quad \text{as } t\downarrow 0\quad \text{in } \mathcal{W}_2^1(\Omega)\times\check{\mathbf{G}}(\mathbb{R}^3). \tag{1.21}$$

In Sec. III, this solution is transformed to the $\operatorname{div}\mathbf{A}=-\sigma\phi$ gauge, (iii) where the equations have a parabolic structure in D_T,

$$\partial_t\psi-\frac{i}{\sigma}(\operatorname{div}\mathbf{A})\psi-\nabla_{\mathbf{A}}^2\psi+\kappa^2(|\psi|^2-1)\psi=0\quad \text{in } D_T \tag{1.22}$$

$$\sigma\chi_\Omega\left(\partial_t\mathbf{A}-\frac{1}{\sigma}\nabla(\operatorname{div}\mathbf{A})\right)+\operatorname{curl}^2\mathbf{A}=\chi_\Omega(i\psi,\nabla_{\mathbf{A}}\psi)\quad \text{in } E_T, \tag{1.23}$$

$$(\mathbf{A}(t)-h\mathbf{a})\in\check{\mathbf{G}}(\mathbb{R}^3)\quad \text{for } 0\leqslant t<T, \tag{1.24}$$

$$\partial_{\boldsymbol{\nu}}\psi=0,\quad \mathbf{A}\cdot\boldsymbol{\nu}=0\quad \text{on } \partial\Omega\times(0,T), \tag{1.25}$$

$$\psi(x,0)=\psi_0(x)\quad \text{in } \Omega,\quad \mathbf{A}(x,0)=\mathbf{A}_0(x)\quad \text{in } \mathbb{R}^3. \tag{1.26}$$

Theorem 2: *Assume* $\partial\Omega\in C^{k+\alpha}$ *where k is an integer,* $k\geqslant 3$. *If* $(\psi_0,\mathbf{A}_0)$ *satisfies* $\mathfrak{H}$ *then there exists a unique solution to (1.22)–(1.26) among functions satisfying* $(\psi,\mathbf{A})\in\mathfrak{A}$ *and* $\nabla(\operatorname{div}\mathbf{A})\in\mathbf{L}_2(D_T)$. *The solution is such that*

$$\psi\in C^\infty((0,T);\mathcal{C}^{k+\alpha}(\bar{\Omega})), \tag{1.27}$$

for any $r>0$ *and* $0<\gamma<1$

$$(\mathbf{A}-h\mathbf{a})\in C^\infty((0,T);\mathbf{C}^{1+\gamma}(\bar{B}_r)),$$

and writing $\mathbf{A}=\nabla f+\mathbf{g}$ *where* $\int_\Omega f\,dx=0$, *with* $\nabla f\in\mathbb{V}_1$ *and* $\mathbf{g}=(g_1,g_2,g_3)\in\mathbb{V}_2$, *it holds that*

$$f,g_j\in C^\infty((0,T);C^{k+\alpha}(\bar{\Omega}))\cap C^\infty((0,T);C^{k+\alpha}(\bar{B}_r\setminus\Omega)). \tag{1.28}$$

In addition $(\psi,\mathbf{A})$ *satisfies (1.21).*

Note, it follows that

$$\mathbf{A}\in C^\infty((0,T);\mathbf{C}^{k-1+\alpha}(\bar{\Omega}))\cap C^\infty((0,T);\mathbf{C}^{k-1+\alpha}(\bar{B}_r\setminus\Omega)).$$

Solutions that are regular up to the boundary in the sense of (1.27) and (1.28) are called *classical*. Thus the solution found in Theorem 2 is classical for $t>0$ and the transmission condition at the material-vacuum boundary, $\mathbf{j}_n\cdot\boldsymbol{\nu}=\mathbf{j}_s\cdot\boldsymbol{\nu}=0$ holds pointwise. Further, the gauge invariant terms $|\psi|^2$, $\mathbf{j}_s$, $\mathbf{j}_n$, and $\operatorname{curl}\mathbf{A}$ are regular up to $\partial\Omega$ as well.

In Sec. IV, we describe the solution in the $\phi=0$ gauge in more detail and discuss the case of the $\operatorname{div}\mathbf{A}=0$ gauge. We prove

Theorem 3: *Let* $(\psi,\mathbf{A})$ *be the solution from Theorem 1. Then there is a classical solution to (1.16)–(1.19),* $(v,\mathbf{B})$ *and a function* $q\in\mathring{W}_2^2(B_R)$ *so that* $(\psi,\mathbf{A})=(ve^{iq},\mathbf{B}+\nabla q)$.

Thus solutions in the $\phi=0$ gauge are classical for $t>0$ up to a steady state gauge transformation. For the $\operatorname{div}\mathbf{A}=0$ gauge, we have

Theorem 4: *Let* $\psi_0\in\mathcal{W}_2^1(\Omega)$, $|\psi_0|\leqslant 1$, *and* $(\mathbf{A}_0-h\mathbf{a})\in\mathbb{V}_2$ *such that*

$$\operatorname{curl}^2 \mathbf{A}_0 = 0 \quad \text{in } \mathbb{R}^3 \setminus \bar{\Omega}.$$

Assume $\partial\Omega \in C^{k+\alpha}$ *for some integer* $k \geqslant 3$. *Then there is a unique solution* $(\psi, \mathbf{A}, \phi)$ *to (1.5)–(1.10) among functions that are classical for* $t > 0$, *for which* $\operatorname{div} \mathbf{A} = 0$ *in* E_T, $\phi = \mathcal{E}(\phi)$ *in* $\mathbb{R}^3 \setminus \Omega$, *and such that*

$$(\psi(t), \mathbf{A}(t) - h\mathbf{a}) \to (\psi_0, \mathbf{A}_0 - h\mathbf{a}) \quad \text{in } \mathcal{W}_2^1(\Omega) \times \mathbb{V}_2 \quad \text{as } t \downarrow 0.$$

D. Earlier work

Prior work proving existence, uniqueness, and regularity results for the TDGL equations, modeling a superconducting body in a vacuum, has been done in two dimensions. In this case Ω represents the cross section of an infinitely long cylinder with its generator parallel to the applied magnetic field $h\mathbf{e}_3$. The equations reduce to an evolution problem on the domain Ω with prescribed boundary conditions. See Refs. 1–4 and 9. The main difference between dimensions $d = 2$ and 3 is that for $d = 2$ the magnetic field is constant in the vacuum. Indeed, the interface condition at $\partial\Omega$ implied by Maxwell's equation (1.3) is the transmission condition

$$[\operatorname{curl} \mathbf{A}] \wedge \boldsymbol{\nu} = 0, \tag{1.29}$$

here $[f] := f_{\text{vac}} - f_\Omega$. For $d = 2$ one has $\operatorname{curl} \mathbf{A} = h\mathbf{e}_3$ in $\mathbb{R}^2 \setminus \Omega$ and furthermore (1.29) reduces to $[\operatorname{curl} \mathbf{A}] = 0$. Thus for two dimensions (1.29) is equivalent to the prescribed boundary condition

$$\operatorname{curl} \mathbf{A} = h\mathbf{e}_3 \quad \text{on } \partial\Omega. \tag{1.30}$$

In Refs. 1, 4, and 9 the same methods are applied to a problem for $d = 3$ where (1.29) is formally replaced with the boundary condition

$$\operatorname{curl} \mathbf{A} \wedge \boldsymbol{\nu} = h\mathbf{e}_3 \wedge \boldsymbol{\nu} \quad \text{on } \partial\Omega. \tag{1.31}$$

This can be viewed as a combined approximation to (1.29) and (1.30), and leads to a well posed evolution problem for the TDGL equations on Ω with prescribed boundary conditions. We treat the full problem here and this is the main contribution of the article.

II. THE TEMPORAL GAUGE

We begin by constructing a discrete (in t) version of (1.1) and (1.2) for the $\phi = 0$ gauge, (i). This is known as Rothe's method (see Ref. 8) and is used in Ref. 3 to prove existence of solutions to discrete TDGL equations in two dimensions. Here however the problem is defined on all space and requires a different proof. Fix $\tau > 0$, $\hat{\upsilon} \in \mathcal{W}_2^1(\Omega)$ such that $|\hat{\upsilon}| \leqslant 1$, $\hat{\mathcal{S}} \in \check{\mathbf{H}}(\mathbb{R}^2)$ and consider the energy

$$I(\upsilon, \mathbf{S}) := I(\upsilon, \mathbf{S}; \hat{\upsilon}, \hat{\mathbf{S}}) = \frac{1}{\tau}\int_\Omega (|\upsilon - \hat{\upsilon}|^2 + \sigma|\mathbf{S} - \hat{\mathbf{S}}|^2)\mathrm{d}x + \int_\Omega \left(|\nabla_{(\mathbf{S}+h\mathbf{a})}\upsilon|^2 + \frac{\kappa^2}{2}(|\upsilon|^2 - 1)^2 \right)\mathrm{d}x$$
$$+ \int_{\mathbb{R}^3} |\operatorname{curl} \mathbf{S}|^2 \mathrm{d}x.$$

Set $\mathbb{B} = \mathcal{W}_2^1(\Omega) \times \check{\mathbf{H}}(\mathbb{R}^3)$.

Proposition 1: The energy I has a minimizer $(\upsilon, \mathbf{S}) \in \mathbb{B}$ *such that* $|\upsilon| \leqslant 1$ *and* $\mathbf{S} \in \check{\mathbf{G}}(\mathbb{R}^3)$.

Proof: Let $\{(\upsilon_n, \mathbf{S}_n)\} \subset \mathbb{B}$ be a minimizing sequence for I. Set

$$\bar{v}_n = \begin{cases} v_n & \text{if } |v_n| \leqslant 1 \\ v_n/|v_n| & \text{if } |v_n| > 1 \end{cases}.$$

Then $I(\bar{v}_n, \mathbf{S}_n) \leqslant I(v_n, \mathbf{S}_n)$ with a strict inequality if $|\{x \in \Omega : |v_n(x)| > 1\}| > 0$. Indeed, fix $x_0 \in \Omega$ and assume without loss of generality that $v_n(x_0) \in \mathbb{R}$. Writing $\hat{v}(x_0) = \hat{v}_1 + i\hat{v}_2$ then

$$|v_n(x_0) - \hat{v}(x_0)|^2 = (v_n(x_0) - \hat{v}_1)^2 + (\hat{v}_2)^2.$$

Using $|\hat{v}| \leqslant 1$ it follows directly that

$$(\bar{v}_n(x_0) - \hat{v}_1)^2 \leqslant (v_n(x_0) - \hat{v}_1)^2$$

with equality if and only if $|v_n(x_0)| \leqslant 1$. The other terms in the integrand for I are nonincreasing when v is replaced by $\bar{v}_n$ as well. To see this for the first term we write $v_n = |v_n| v_n'$ then

$$|\nabla_{(\mathbf{S}_n + h\mathbf{a})} v_n|^2 = |\nabla |v_n||^2 + |v_n|^2 |\nabla v_n' - A|^2$$

and it follows that $|\nabla_{(\mathbf{S}_n + h\mathbf{a}_n)} \bar{v}_n|^2 \leqslant |\nabla_{(\mathbf{S}_n + h\mathbf{a})} v_n|^2$. Thus we may assume that $|v_n| \leqslant 1$ in Ω.

We next write $\mathbf{S}_n = \nabla f_n + \mathbf{g}_n$ where $\mathbf{g}_n \in \mathbb{V}_2$ and $\nabla f_n \in \mathbb{V}_1$ with $\int_\Omega f_n \mathrm{d}x = 0$. Passing to a subsequence, we can assume that $v_n \rightharpoonup v_0$ in $\mathcal{W}_2^1(\Omega)$, $f_n \rightharpoonup f_0$ in $\mathcal{W}_2^1(\Omega)$, and $\mathbf{g}_n \rightharpoonup \mathbf{g}_0 \in \check{\mathbf{H}}(\mathbb{R}^3)$. Since $|v_n| \leqslant 1$ it follows that $\nabla_{(\mathbf{S}_n + h\mathbf{a})} v_n \rightharpoonup \nabla_{(\mathbf{S}_0 + h\mathbf{a})} v_0$ in $\mathcal{L}_2(\Omega)$. Note that the energy $I(v, \nabla f + \mathbf{g})$ is well defined for $v \in \mathcal{W}_2^1(\Omega) \cap \mathcal{L}_\infty(\Omega)$, $f \in W_2^1(\Omega)$, and $\mathbf{g} \in \mathbb{V}_2$. We have by weak lower semi-continuity that

$$I(v_0, \nabla f_0 + \mathbf{g}_0) \leqslant \lim_{n \to \infty} I(v_n, \mathbf{S}_n) = \inf_{(v, \mathbf{S}) \in \mathbb{B}} I(v, \mathbf{S}).$$

We in fact have

$$I(v_0, \nabla f_0 + \mathbf{g}_0) \leqslant I(v_0, \nabla (f_0 + k) + \mathbf{g}_0) \tag{2.1}$$

and

$$I(v_0, \nabla f_0 + \mathbf{g}_0) \leqslant I(v_0 e^{ik}, \nabla f_0 + \mathbf{g}_0) \tag{2.2}$$

for any $k(x) \in C^2(\bar{\Omega})$. To prove (2.1), we assume that it is false for some k. Then since the integrand is a polynomial, we expand it to write

$$I(v, \nabla (f + k) + \mathbf{g}) = I(v, \nabla f + \mathbf{g}) + \mathcal{I}(v, \nabla f, \mathbf{g}, k),$$

where $\lim_{n \to \infty} \mathcal{I}(v_n, \nabla f_n, \mathbf{g}_n, k) = \mathcal{I}(v_0, \nabla f_0, \mathbf{g}_0, k)$. Our assumption is that $\mathcal{I}(v_0, \nabla f_0, \mathbf{g}_0, k) = \beta < 0$, so for n sufficiently large we have $\mathcal{I}(v_n, \nabla f_n, \mathbf{g}_n, k) \leqslant \beta/2$. This implies that

$$I(v_n, \nabla \mathcal{E}(f_n + k) + \mathbf{g}_n) \leqslant I(v_n, \nabla f_n + \mathbf{g}_n) + \frac{\beta}{2},$$

and contradicts the assumption that $\{(v_n, \mathbf{S}_n)\}$ is a minimizing sequence. The inequality (2.2) is proved in the same way.

We will show that $f_0 \in W_2^2(\Omega)$. The proof will then be complete since this implies that

$$I(v_0, \nabla \mathcal{E}(f_0) + \mathbf{g}_0) = I(v_0, \nabla f_0 + \mathbf{g}_0) \leqslant \inf_{(v, \mathbf{S}) \in \mathbb{B}} I(v, \mathbf{S})$$

with $\nabla \mathcal{E}(f_0) + \mathbf{g}_0 \in \check{\mathbf{G}}(\mathbb{R}^3)$.

From (2.1) and (2.2) we have

$$0 = \partial_\varepsilon I(v_0, \nabla f_0 + \varepsilon \nabla k + \mathbf{g}_0)|_{\varepsilon = 0},$$

and

$$0 = \partial_\varepsilon I(v_0 e^{i\epsilon k}, \nabla f_0 + \mathbf{g}_0)|_{\varepsilon=0}.$$

These lead to

$$\frac{\sigma}{\tau}(\Delta f_0 - \operatorname{div} \hat{\mathbf{S}}) = \operatorname{div}(iv_0, \nabla v_0 - i(\nabla f_0 + \mathbf{g}_0)v_0) = \frac{1}{\tau}(iv_0, v_0 - \hat{v}) \quad \text{in } \Omega,$$

$$\partial_{\boldsymbol{\nu}} f_0 - (\hat{\mathbf{S}} - \mathbf{g}_0) \cdot \boldsymbol{\nu} = (iv_0, \nabla v_0 - i(\nabla f_0 + \mathbf{g}_0)v_0) \cdot \boldsymbol{\nu} = 0 \quad \text{on } \partial\Omega.$$

Since $(iv_0, v_0 - \hat{v}) \in L_2(\Omega)$ and $\hat{\mathbf{S}}, \mathbf{g}_0 \in \mathbf{W}_2^1(\Omega)$ it follows from elliptic estimates that $f_0 \in W_2^2(\Omega)$.□

Let $(v_0, \mathbf{S}_0 + h\mathbf{a})$ satisfy $\mathfrak{H}$. Fix an integer M and set $\tau = T/M$. For $1 \leqslant m \leqslant M$ we let $\{(v_m, \mathbf{S}_m)\} \subset \mathcal{W}_2^1(\Omega) \times \check{\mathbf{G}}(\mathbb{R}^3)$ be a family of minimizers for

$$I_m(v, \mathbf{S}) = I(v, \mathbf{S}; v_{m-1}, \mathbf{S}_{m-1}).$$

We write

$$\delta_\tau v_m(x) = \frac{v_m - v_{m-1}}{\tau}$$

and a similar definition for $\delta_\tau \mathbf{S}_m$. Next we derive

$$0 = \frac{1}{2}\partial_\varepsilon I_m\,(v_m + \varepsilon\zeta, \mathbf{S}_m)|_{\varepsilon=0} = \int_\Omega (\delta_\tau v_m + \kappa^2 v_m(|v_m|^2 - 1), \zeta)\mathrm{d}x + \int_\Omega (\nabla_{(\mathbf{S}_m + h\mathbf{a})} v_m, \nabla_{(\mathbf{S}_m + h\mathbf{a})}\zeta)\mathrm{d}x \tag{2.3}$$

$$0 = \frac{1}{2}\partial_\varepsilon I_m\,(v_m, \mathbf{S}_m + \varepsilon\mathbf{B})|_{\varepsilon=0} = \int_\Omega \sigma\delta_\tau \mathbf{S}_m \cdot \mathbf{B}\mathrm{d}x + \int_{\mathbb{R}^3} \operatorname{curl} \mathbf{S}_m \cdot \operatorname{curl} \mathbf{B}\mathrm{d}x - \int_\Omega (iv_m, \nabla_{(\mathbf{S}_m + h\mathbf{a})} v_m) \cdot \mathbf{B}\mathrm{d}x \tag{2.4}$$

for $\zeta \in \mathcal{W}_2^1(\Omega)$, $\mathbf{B} \in \check{\mathbf{H}}(\mathbb{R}^3)$, and $1 \leqslant m \leqslant M$.

Thus we have weak solutions to the iterative system:

$$\delta_\tau v_m - \nabla^2_{(\mathbf{S}_m + h\mathbf{a})} v_m + \kappa^2 v_m(|v_m|^2 - 1) = 0 \quad \text{in } \Omega \tag{2.5}$$

$$\sigma\chi_\Omega \delta_\tau \mathbf{S}_m + \operatorname{curl}^2 \mathbf{S}_m = \chi_\Omega \mathbf{J}_m \quad \text{in } \mathbb{R}^3, \tag{2.6}$$

$$\nabla_{(\mathbf{S}_m + h\mathbf{a})} v_m \cdot \boldsymbol{\nu} = 0 \quad \text{on } \partial\Omega, \tag{2.7}$$

$$\mathbf{S}_m \in \check{\mathbf{G}}(\mathbb{R}^3), \tag{2.8}$$

where $\mathbf{J}_m = (iv_m, \nabla_{(\mathbf{S}_m + h\mathbf{a})} v_m)$.

We set

$$G(v, \mathbf{S}) = \int_\Omega \left[|\nabla_{(\mathbf{S} + h\mathbf{a})} v|^2 + \frac{\kappa^2}{2}(|v|^2 - 1)^2 \right] \mathrm{d}x + \int_{\mathbb{R}^3} |\operatorname{curl} \mathbf{S}|^2 \mathrm{d}x \tag{2.9}$$

where G is the Ginzburg–Landau free energy. Thus

$$I_m(\upsilon,\mathbf{S}) = \frac{1}{\tau}\int_\Omega [|\upsilon-\upsilon_{m-1}|^2 + \sigma|\mathbf{S}-\mathbf{S}_{m-1}|^2]\mathrm{d}x + G(\upsilon,\mathbf{S}).$$

The next lemma characterizes energy dissipation along the sequence of minimizers.

Lemma 1: For $1\leqslant m\leqslant M$

$$\sum_{n=1}^{m} \tau\{\|\delta_\tau\upsilon_n\|^2_{\mathcal{L}^2(\Omega)} + \sigma\|\delta_\tau\mathbf{S}_n\|^2_{\mathbf{L}_2(\Omega)}\} + G(\upsilon_m,\mathbf{S}_m) \leqslant G(\upsilon_0,\mathbf{S}_0). \tag{2.10}$$

Proof: Since $(\upsilon_m,\mathbf{S}_m)$ is a minimizer for I_m we find

$$G(\upsilon_m,\mathbf{S}_m) \leqslant I_m(\upsilon_m,\mathbf{S}_m) \leqslant I_m(\upsilon_{m-1},\mathbf{S}_{m-1}) = G(\upsilon_{m-1}\mathbf{S}_{m-1}).$$

Next we add the $(m-1)$st difference quotient to the second and fourth terms mentioned above. We have

$$\sum_{n=m-1}^{m} \tau\{\|\delta_\tau\upsilon_n\|^2_{\mathcal{L}_2(\Omega)} + \sigma\|\delta_\tau\mathbf{S}_n\|^2_{\mathbf{L}_2(\Omega)}\} + G(\upsilon_m,\mathbf{S}_m) \leqslant \tau\{\|\delta_\tau\upsilon_{m-1}\|^2_{\mathcal{L}_2(\Omega)} + \sigma\|\delta_\tau\mathbf{S}_{m-1}\|^2_{\mathbf{L}_2(\Omega)}\} + G(\upsilon_{m-1},\mathbf{S}_{m-1})$$

$$= I_{m-1}(\upsilon_{m-1},\mathbf{S}_{m-1}).$$

Our assertion follows after repeating this argument $m-2$ times. □

Corollary 1:

$$\max_{1\leqslant m\leqslant M} \{\|\mathbf{S}_m\|^2_{\mathbf{L}_2(\Omega)} + \|\nabla\upsilon_m\|^2_{\mathcal{L}_2(\Omega)} + \|\mathrm{curl}\ \mathbf{S}_m\|^2_{\mathbf{L}_2(\mathbb{R}^3)}\} \leqslant C \tag{2.11}$$

where C *depends on* $\|\mathbf{S}_0\|^2_{\check{\mathbf{H}}(\mathbb{R}^3)}$, $\|\nabla\upsilon_0\|^2_{\mathcal{L}_2(\Omega)}$, h, and T.

Proof: For $1\leqslant m\leqslant M$

$$\|\mathbf{S}_m\|^2_{\mathbf{L}_2(\Omega)} - \|\mathbf{S}_0\|^2_{\mathbf{L}_2(\Omega)} = \sum_{n=1}^{m}\tau\int_\Omega \delta_\tau|\mathbf{S}_n|^2\mathrm{d}x \leqslant \sum_{n=1}^{m}\tau\|(\mathbf{S}_n+\mathbf{S}_{n-1})\cdot\delta_\tau\mathbf{S}_n\|_{\mathbf{L}_1(\Omega)}$$

$$\leqslant \frac{1}{2}\max_{1\leqslant n\leqslant m}\|\mathbf{S}_n\|^2_{\mathbf{L}_2(\Omega)} + 4T\sum_{n=1}^{m}\tau\|\delta_\tau\mathbf{S}_n\|^2_{\mathbf{L}_2(\Omega)}.$$

We take the maximum of the left side over $1\leqslant m\leqslant M$ and use (2.10).

Next note that

$$\frac{1}{2}\|\nabla\upsilon_m\|^2_{\mathcal{L}_2(\Omega)} + \|\mathrm{curl}\ \mathbf{S}_m\|^2_{\mathbf{L}_2(\mathbb{R}^3)} \leqslant G(\upsilon_m,\mathbf{S}_m) + 2\|\mathbf{S}_m\|^2_{\mathbf{L}_2(\Omega)} + h^2C$$

for some constant $C(\Omega)$. The assertion follows from these estimates and Lemma 1. □

Lemma 2:

$$\max_{1\leqslant m\leqslant M}\|\mathbf{S}_m\|^2_{\check{\mathbf{H}}(\mathbb{R}^3)} \leqslant C$$

where C *depends on* $\|\mathbf{S}_0\|^2_{\check{\mathbf{H}}(\mathbb{R}^3)}$, $\|\nabla\upsilon_0\|^2_{\mathcal{L}_2(\Omega)}$, h, *and* T.

Proof: From (1.12) we have

$$\|\mathbf{S}_m\|^2_{\check{\mathbf{H}}(\mathbb{R}^3)} = \|\mathrm{div}\ \mathbf{S}_m\|^2_{L_2(\mathbb{R}^3)} + \|\mathrm{curl}\ \mathbf{S}_m\|^2_{\mathbf{L}_2(\mathbb{R}^3)}$$

and from (2.11) we see that it suffices to bound $\|\mathrm{div}\ \mathbf{S}_m\|^2_{L_2(\mathbb{R}^3)}$. Since $\mathbf{S}_m\in\check{\mathbf{G}}(\mathbb{R}^3)$, we have $\mathbf{S}_m = \nabla f_m + \mathbf{g}_m$ where $\mathbf{g}_m\in\mathbb{V}_2$ and $f_m = \mathcal{E}(f_{m\llcorner\Omega})\in\mathring{W}^2_2(B_R)$. Thus

$$\|\operatorname{div} \mathbf{S}_m\|^2_{L_2(\mathbb{R}^3)} = \|\Delta f_m\|^2_{L_2(\mathbb{R}^3)} \leqslant C\|f_m\|^2_{W_2^2(\Omega)}.$$

To estimate the right-hand side we use $\zeta = i\upsilon_m k$, with $k \in C^2(\bar{\Omega})$, as a test function in (2.3). We get

$$\chi_\Omega(i\upsilon_m, \delta_\tau \upsilon_m) = \operatorname{div}(\chi_\Omega \mathbf{J}_m) \quad \text{in } \mathcal{D}'(\mathbb{R}^3).$$

Taking the divergence of (2.6) then gives

$$\sigma \operatorname{div}(\chi_\Omega \delta_\tau \mathbf{S}_m) = \operatorname{div}(\chi_\Omega \mathbf{J}_m) \quad \text{in } \mathcal{D}'(\mathbb{R}^3).$$

Comparing these equalities we see

$$\|\operatorname{div}(\delta_\tau \mathbf{S}_m)\|^2_{L_2(\Omega)} \leqslant \sigma^{-2}\|\delta_\tau \upsilon_m\|^2_{\mathcal{L}_2(\Omega)}$$

and

$$\delta_\tau \mathbf{S}_m \cdot \boldsymbol{\nu} = 0 \quad \text{on } \partial\Omega.$$

Now $\mathbf{S}_m = \Sigma_{n=1}^m \tau \delta_\tau \mathbf{S}_n + \mathbf{S}_0$. Since $\mathbf{S}_0 + h\mathbf{a}$ satisfies $\mathfrak{H}$ we find

$$\|\Delta f_m\|^2_{L_2(\Omega)} = \|\operatorname{div} \mathbf{S}_m\|^2_{L_2(\Omega)} \leqslant \frac{T}{\sigma^2}\sum_{n=1}^m \tau\|\delta_\tau \upsilon_n\|^2_{\mathcal{L}_2(\Omega)},$$

and

$$\partial_\nu f_m = -\mathbf{g}_m \cdot \boldsymbol{\nu} + \mathbf{S}_0 \cdot \boldsymbol{\nu} \quad \text{on } \partial\Omega.$$

Since f_m has mean zero it follows from elliptic estimates that

$$\|f_m\|^2_{W_2^2(\Omega)} \leqslant \Lambda(\|\Delta f_m\|^2_{L_2(\Omega)} + \|\mathbf{g}_m\|^2_{\mathbf{W}_2^1(\Omega)} + \|\mathbf{S}_0\|^2_{\mathbf{W}_2^1(\Omega)}).$$

Using (2.10) and the fact that $\|\mathbf{g}_m\|^2_{\mathbf{W}_2^1(\Omega)} \leqslant C\|\mathbf{g}_m\|^2_{\check{\mathbf{H}}(\mathbb{R}^3)}$ we see that $\|f_m\|^2_{W_2^2(\Omega)} \leqslant C$ where C depends on $\|\mathbf{S}_0\|_{\check{\mathbf{H}}(\mathbb{R}^3)}$, $\|\nabla \upsilon_0\|_{\mathcal{L}_2(\Omega)}$, h and T. □

We now consider a limit as $\tau \to 0$ and pass to the continuous problem. Set

$$\upsilon_\tau(x,t) = \frac{(t-(m-1)\tau)}{\tau}\upsilon_m(x) + \frac{(m\tau - t)}{\tau}\upsilon_{m-1}(x)$$

for $t \in [(m-1)\tau, m\tau]$, and a corresponding interpolate $\mathbf{S}_\tau$. We have $|\upsilon_m| \leqslant 1$, uniform bounds on $\{\upsilon_\tau\}$ in $\mathcal{L}_\infty((0,T);\mathcal{W}_2^1(\Omega)) \cap \mathcal{W}_2^{0,1}(D_T)$. Thus a subsequence $\{\upsilon_{\tau_j}\}$ converges weakly to $\upsilon \in \mathcal{W}_2^{1,1}(D_T)$. Similarly $\{\mathbf{S}_\tau\}$ is uniformly bounded in

$$L_\infty((0,T);\check{\mathbf{G}}(\mathbb{R}^3)) \cap \mathbf{W}_2^{0,1}(D_T) \text{ and for a}$$

further a subsequence $\mathbf{S}_{\tau_j} \rightharpoonup \mathbf{S} \in L^2((0,T);\check{\mathbf{G}}(\mathbb{R}^3)) \cap \mathbf{W}_2^{1,1}(D_T)$.

We now pass to the limit as $\tau_j \to 0$ in the variational forms (2.3) and (2.4), assuming initially that the test functions are smooth, multiplying each equation by τ_j, summing over m, and estimating the difference between the functions that are piecewise constant in t and the interpolates.

We find in weak form, $(\upsilon, \mathbf{S})$ is a solution to

$$\int_{D_T} [(\partial_t \upsilon, \zeta) + (\nabla_{(\mathbf{S}+h\mathbf{a})}\upsilon, \nabla_{(\mathbf{S}+h\mathbf{a})}\zeta) + \kappa^2(\upsilon(|\upsilon|^2 - 1), \zeta)]\mathrm{d}x\mathrm{d}t = 0, \tag{2.12}$$

$$\int_{D_T} [\sigma \partial_t \mathbf{S} \cdot \mathbf{B} - \mathbf{j}_s \cdot \mathbf{B}] \mathrm{d}x\mathrm{d}t + \int_{E_T} \operatorname{curl} \mathbf{S} \cdot \operatorname{curl} \mathbf{B}\, \mathrm{d}x\mathrm{d}t = 0 \tag{2.13}$$

for every $\zeta \in L^2((0,T);\mathcal{W}_2^1(\Omega))$ and $\mathbf{B} \in L^2((0,T);\check{\mathbf{H}}(\mathbb{R}^3))$, such that $\mathbf{S}(x,0)=\mathbf{S}_0(x)$ and $\upsilon(x,0)=\upsilon_0(x)$ in Ω. The estimates from Lemmas 1 and 2 extend to the limit $(\upsilon,\mathbf{S})$. We have

$$|\upsilon| \leqslant 1 \quad \text{in } D_T,$$

$$\sup_{0\leqslant t\leqslant T} \{\|\nabla \upsilon\|_{\mathcal{L}_2(\Omega)} + \|\mathbf{S}\|_{\check{\mathbf{H}}(\mathbb{R}^3)}\} \leqslant C, \tag{2.14}$$

and

$$(\|\partial_t \upsilon\|^2_{\mathcal{L}_2(D_T)} + \sigma \|\partial_t \mathbf{S}\|^2_{\mathbf{L}_2(D_T)}) + \sup_{0\leqslant t\leqslant T} G(\upsilon(t),\mathbf{S}(t)) \leqslant G(\upsilon_0,\mathbf{S}_0), \tag{2.15}$$

where C depends on $\|\nabla \upsilon_0\|_{\mathcal{L}_2(\Omega)}$, $\|\mathbf{S}_0\|_{\check{\mathbf{H}}(\mathbb{R}^3)}$, h, and T.

We next analyze div $\mathbf{S}$.

Lemma 3: div $\mathbf{S} \in W_2^{0,1}(D_T)$ *with*

$$\|\operatorname{div}(\partial_t \mathbf{S})\|_{L_2(D_T)} \leqslant C$$

where C *depends on* $\|\nabla \upsilon_0\|_{\mathcal{L}_2(\Omega)}\|$, $\|\mathbf{S}_0\|_{\check{\mathbf{H}}(\mathbb{R}^3)}$, T, *and* h. *Moreover* $(\mathbf{S}+h\mathbf{a})\cdot\boldsymbol{\nu}=0$ *on* $\partial\Omega$ *for* $0\leqslant t<T$.

Proof: Let $k \in C_c^2(\bar{E}_T)$. Take $\zeta = i\upsilon k$ and $\mathbf{B}=\nabla k$ in (2.12) and (2.13), respectively. We obtain

$$\chi_\Omega(\partial_t \upsilon, i\upsilon) = \operatorname{div}(\chi_\Omega \mathbf{j}_s) = \sigma \operatorname{div}(\chi_\Omega \partial_t \mathbf{S}) \quad \text{in } \mathcal{D}'(\bar{E}_T).$$

Using (2.15) we see

$$\|(\partial_t \upsilon, i\upsilon)\|_{L_2(D_T)} \leqslant C$$

and it follows that div $\partial_t \mathbf{S} \in L_2(D_T)$ with $\|\operatorname{div} \partial_t \mathbf{S}\|_{L_2(D_T)} \leqslant C$ depending on the initial data, T and h. Finally letting $k=k(x)$ and integrating over E_t for $0<t<T$ we find

$$\operatorname{div}(\chi_\Omega(\mathbf{S}(t)-\mathbf{S}(0))) \in L_2(\mathbb{R}^3).$$

This implies that $(\mathbf{S}(t)-\mathbf{S}(0))\cdot\boldsymbol{\nu}=0$ on $\partial\Omega$. Thus $(\mathbf{S}(t)+h\mathbf{a})\cdot\boldsymbol{\nu}=(\mathbf{S}(0)+h\mathbf{a})\cdot\boldsymbol{\nu}=0$ on $\partial\Omega$. □

From (2.12) we obtain the boundary condition (1.4). Combining these results gives

$$\partial_{\boldsymbol{\nu}} \upsilon = 0 \quad \text{on } \partial\Omega \text{ for } 0<t<T.$$

We next examine $\mathbf{S}(\cdot,t)$ in $\mathbb{R}^3\backslash\bar{\Omega}$. We have that $\operatorname{curl}^2 \mathbf{S}(\cdot,t)=0$ in $\mathbb{R}^3\backslash\bar{\Omega}$ for almost every t. We next show that this extension from Ω is done in a unique way.

Lemma 4: Let $\mathbf{B} \in \mathbf{W}_2^1(\Omega;\mathbb{R}^3)$. *Then there is a unique* $\bar{\mathbf{B}} \in \check{\mathbf{G}}(\mathbb{R}^3)$ *so that* $\bar{\mathbf{B}}=\mathbf{B}$ *in* Ω and $\operatorname{curl}^2 \bar{\mathbf{B}}=0$ *in* $\mathbb{R}^3\backslash\Omega$.

Proof: Set $C(\mathbf{K})=\int_{\mathbb{R}^3}|\operatorname{curl} \mathbf{K}|^2 \mathrm{d}x$ for $\mathbf{K} \in \{\mathbf{F} \in \check{\mathbf{H}}(\mathbb{R}^3) : \mathbf{F}=\mathbf{B} \text{ in } \Omega\}$ and let $\{\mathbf{K}_n\}$ be a minimizing sequence. We write $\mathbf{K}_n=\nabla f_n+\mathbf{g}_n$ with $\nabla f_n \in \mathbb{V}_1$ such that $\int_\Omega f_n \mathrm{d}x=0$, and $\mathbf{g}_n \in \mathbb{V}_2$. We can replace f_n by $\mathcal{E}(f_{n\llcorner\Omega}) \in W_2^2(B_R)$ and not change the value of $C(\mathbf{K}_n)$. Thus it is without loss of generality to assume that $\{\mathbf{K}_n\} \subset \check{\mathbf{G}}(\mathbb{R}^3)$. Using Mazur's theorem we can assume that $\mathbf{g}_n \to \mathbf{g}$ in $\mathbb{V}_2$ as $n\to\infty$. Since $\mathbf{K}_n=\mathbf{B}$ in Ω we see that $\{\nabla f_n\}$ is a Cauchy sequence in $W_2^1(\Omega)$ and by the construction of $\check{\mathbf{G}}(\mathbb{R}^3)$ it follows that there is an f so that $f_n \to f$ in $\mathring{W}_2^2(B_R)$ as $n\to\infty$. Thus $\mathbf{K}_0 \equiv \nabla f+g \in \check{\mathbf{G}}(\mathbb{R}^3)$ and minimizes $C(\cdot)$.

Clearly $\operatorname{curl}^2 \mathbf{K}_0=0$ in $\mathbb{R}^3\backslash\bar{\Omega}$, so we can set $\bar{\mathbf{B}}=\mathbf{K}_0$.

If there is another extension of $\mathbf{B}$, $\mathbf{K}_1 \in \check{\mathbf{G}}(\mathbb{R}^3)$ such that $\operatorname{curl}^2 \mathbf{K}_1=0$ in $\mathbb{R}^3\backslash\bar{\Omega}$ then

$$\int_{\mathbb{R}^3} |\mathrm{curl}(\mathbf{K}_1 - \mathbf{K}_0)|^2 \mathrm{d}x = \int_{\mathbb{R}^3\setminus\bar{\Omega}} \mathrm{curl}\,\mathbf{K}_1 \cdot \mathrm{curl}(\mathbf{K}_1 - \mathbf{K}_0)\mathrm{d}x - \int_{\mathbb{R}^3\setminus\bar{\Omega}} \mathrm{curl}\,\mathbf{K}_0 \cdot \mathrm{curl}(\mathbf{K}_1 - \mathbf{K}_0)\mathrm{d}x.$$

Since $\mathbf{K}_0 = \mathbf{K}_1$ in Ω and $\mathrm{curl}^2\,\mathbf{K}_1 = \mathrm{curl}^2\,\mathbf{K}_0 = 0$ in $\mathbb{R}^3\setminus\bar{\Omega}$ we see that both integrals on the right-hand side vanish. Thus $\mathrm{curl}\,\mathbf{K}_1 = \mathrm{curl}\,\mathbf{K}_0$. Writing $\mathbf{K}_0 = \nabla f + \mathbf{g}$ and $\mathbf{K}_1 = \nabla f_1 + \mathbf{g}_1$ we have $\mathbf{g}_1 = \mathbf{g}$. This implies that $\nabla f_1 = \nabla f$ in Ω. By the construction of $\check{\mathbf{G}}$ this implies that $f_1 = f$ in $\mathbb{R}^3$ and thus $\mathbf{K}_1 = \mathbf{K}_0$. □

We have $\mathbf{S}(t) \in C([0,T];\mathbf{L}_2(\Omega)) \cap L_\infty((0,T);\check{\mathbf{G}}(\mathbb{R}^3))$. The lemma above implies that the condition $\mathrm{curl}^2\,\mathbf{S}(t) = 0$ in $\mathbb{R}^3\setminus\bar{\Omega}$ uniquely determines $\mathbf{S}(t)$ in $\mathbb{R}^3\setminus\bar{\Omega}$. With this we can give a more specific description of the trace of $(\upsilon, \mathbf{S})$ as $t \downarrow 0$.

Lemma 5:

$$(\upsilon(t), \mathbf{S}(t)) \to (\upsilon_0, \mathbf{S}_0) \quad \textit{in } \mathcal{W}_2^1(\Omega) \times \check{\mathbf{G}}(\mathbb{R}^3) \quad \textit{as } t \downarrow 0. \tag{2.16}$$

Proof: From our construction of $(\upsilon, \mathbf{S})$ and the previous lemma we have $(\upsilon(t), \mathbf{S}(t)) \rightharpoonup (\upsilon_0, \mathbf{S}_0)$ as $t \downarrow 0$ in $\mathcal{W}_2^1(\Omega) \times \check{\mathbf{G}}(\mathbb{R}^3)$. Expanding the integrand of the Ginzburg–Landau energy (2.9) we have

$$G(\upsilon(t), \mathbf{S}(t)) = \int_\Omega |\nabla \upsilon(t)|^2 \mathrm{d}x + \int_{\mathbb{R}^3} |\mathrm{curl}\,\mathbf{S}(t)|^2 \mathrm{d}x + \mathcal{G}(\upsilon(t), \mathbf{S}(t))$$

where $\lim_{t\to 0} \mathcal{G}(\upsilon(t), \mathbf{S}(t)) = \mathcal{G}(\upsilon_0, \mathbf{S}_0)$. From (2.15) we have $\limsup_{t\to 0} G(\upsilon(t), \mathbf{S}(t)) \leqslant G(\upsilon_0, \mathbf{S}_0)$, and from weak lower semicontinuity we have

$$G(\upsilon_0, \mathbf{S}_0) \leqslant \liminf_{t\to 0} G(\upsilon(t), \mathbf{S}(t)).$$

Thus

$$\lim_{t\to 0} \left\{ \int_\Omega |\nabla \upsilon(t)|^2 \mathrm{d}x + \int_{\mathbb{R}^3} |\mathrm{curl}\,\mathbf{S}(t)|^2 \mathrm{d}x \right\} = \int_\Omega |\nabla \upsilon_0|^2 \mathrm{d}x + \int_{\mathbb{R}^3} |\mathrm{curl}\,\mathbf{S}_0|^2 \mathrm{d}x.$$

Writing $\mathbf{S}(t) = \nabla \tilde{f}(t) + \mathbf{g}(t)$ with $\tilde{f}(t) \in \mathring{W}_2^2(B_R)$ and $\mathbf{g}(t) \in \mathbb{V}_2$ we have

$$(\upsilon(t), \mathbf{g}(t)) \to (\upsilon_0, \mathbf{g}_0) \quad \text{in } \mathcal{W}_2^1(\Omega) \times \mathbb{V}_2 \quad \text{as } t \downarrow 0.$$

We write

$$\Delta f(t) = \mathrm{div}\,\mathbf{S}(t) \quad \text{in } \Omega,$$

$$\partial_\nu f(t) = -\mathbf{g}(t) \cdot \boldsymbol{\nu} - h\mathbf{a} \cdot \boldsymbol{\nu} \quad \text{on } \partial\Omega.$$

From Lemma 3 we have $\mathrm{div}\,\mathbf{S}(t) \to \mathrm{div}\,\mathbf{S}_0 = 0$ in $L^2(\Omega)$ and from the preceding argument $\mathbf{g}(t) \to \mathbf{g}_0$ in $\mathbf{W}_2^1(\Omega)$ as $t \to 0$. Thus from elliptic estimates we have $f(t) \to f_0$ in $\mathcal{W}_2^2(\Omega)$ as $t \to 0$. From the definition of $\check{\mathbf{G}}(\mathbb{R}^3)$ we then have $f(t) \to f_0$ in $\mathring{W}_2^2(B_R)$.

Thus

$$(\upsilon(t), \mathbf{S}(t)) \to (\upsilon_0, \mathbf{S}_0) \quad \text{in } \mathcal{W}_2^1(\Omega) \times \check{\mathbf{G}}(\mathbb{R}^3) \quad \text{as } t \downarrow 0.$$

□

We have $(\upsilon, \mathbf{S} + h\mathbf{a}) \in \mathfrak{A}$ with $|\upsilon| \leqslant 1$, satisfying (2.12) and (2.13), and such that (2.16) holds at $t = 0$. It follows that $(\upsilon, \mathbf{S})$ is a weak solution to

$$\partial_t \upsilon - \Delta \upsilon = -2i\nabla \upsilon \cdot (\mathbf{S} + h\mathbf{a}) - i\upsilon\,\mathrm{div}\,\mathbf{S} - |\mathbf{S} + h\mathbf{a}|^2 \upsilon - \kappa^2 \upsilon(|\upsilon|^2 - 1) \quad \text{in } D_T, \tag{2.17}$$

$$\sigma\chi_\Omega\partial_t\mathbf{S}+\operatorname{curl}^2\mathbf{S}=\chi_\Omega\mathbf{j}_s \quad \text{in } E_T, \tag{2.18}$$

$$(\mathbf{S}+h\mathbf{a})\cdot\boldsymbol{\nu}=0 \text{ and } \partial_{\boldsymbol{\nu}}\upsilon=0 \quad \text{on } \partial\Omega\times(0,T), \tag{2.19}$$

$$\upsilon(x,0)=\upsilon_0(x) \quad \text{in } \Omega, \quad \mathbf{S}(x,0)=\mathbf{S}_0(x) \quad \text{in } \mathbb{R}^3. \tag{2.20}$$

Lemma 6: Let $(\upsilon,\mathbf{S}+h\mathbf{a})\in\mathfrak{A}$ *be a weak solution to (2.12) and (2.13), then* $\upsilon\in\mathcal{W}_2^{2,1}(D_T)$.

Proof: Weak solutions to (1.16) with $|\upsilon_0|\leqslant 1$ satisfy $|\upsilon|\leqslant 1$. See Ref. 2. Furthermore we have $\upsilon\in\mathcal{W}_2^{1,1}(D_T)$, and thus (2.17) can be written as

$$\int_{D_T}(\nabla\upsilon,\nabla\zeta)\mathrm{d}x\mathrm{d}t=-\int_{\delta_\tau}(2i\nabla\upsilon\cdot\mathbf{S},\zeta)\mathrm{d}x\mathrm{d}t+\int_{\delta_\tau}(f,\zeta)\mathrm{d}x\mathrm{d}t$$

for $\zeta\in L_2((0,T);\mathcal{W}_2^1(\Omega))$ where $f\in\mathcal{L}_2(D_T)$. We have using (2.14) and (1.11) that

$$\int_{D_T}|\nabla\upsilon\cdot\mathbf{S}|^{3/2}\mathrm{d}x\mathrm{d}t\leqslant\int_{D_T}(|\nabla\upsilon|^2+|\mathbf{S}|^6)\mathrm{d}x\mathrm{d}t<\infty.$$

Setting $f'=-2i\nabla\upsilon\cdot\mathbf{S}+f$ we have $f'\in\mathcal{L}_{3/2}(D_T)$. It follows from elliptic estimates then that $\upsilon(t)\in\mathcal{W}_{3/2}^2(\Omega)$ for almost every $0<t<T$, and satisfies

$$-\Delta\upsilon=f' \quad \text{in } \Omega,$$

$$\partial_{\boldsymbol{\nu}}\upsilon=0 \quad \text{on } \partial\Omega. \tag{2.21}$$

From elliptic estimates then we have

$$\|\upsilon(t)\|_{\mathcal{W}_{3/2}^2(\Omega)}\leqslant C(\|f'(t)\|_{\mathcal{L}_{3/2}(\Omega)}+1).$$

It follows that

$$\|\upsilon\|_{\mathcal{W}_{3/2}^{2,0}(D_T)}\leqslant C(\|f'\|_{\mathcal{L}_{3/2}(D_T)}+1).$$

For almost every $0<t<T$ we apply the Gagliardo-Nirenberg inequality,[10]

$$\|\nabla\upsilon\|_{\mathcal{L}_3(\Omega)}^3\leqslant C\|\upsilon\|_{\mathcal{W}_{3/2}^2(\Omega)}^{3/2}\cdot\|\upsilon\|_{\mathcal{L}_\infty(\Omega)}^{3/2}.$$

Since $|\upsilon|\leqslant 1$ this implies that $\nabla\upsilon\in\mathcal{L}_3(D_T)$. From (1.11) we have $\mathbf{S}\in\mathbf{L}_6(D_T)$ and it follows that $|\nabla\upsilon\cdot\mathbf{S}|\in L_2(D_T)$. Returning to (2.21) then we see $\upsilon\in\mathcal{W}_2^{2,1}(D_T)$. □

We next prove that weak solutions are unique.

Lemma 7: Let $(\upsilon_0,\mathbf{S}_0+h\mathbf{a})$ *satisfy* $\mathfrak{H}$. *Then there is at most one* $(\upsilon,\mathbf{S}+h\mathbf{a})\in\mathfrak{A}$ *that is a weak solution to* (2.12) and (2.13) *with* $(\upsilon(0),\mathbf{S}(0))=(\upsilon_0,\mathbf{S}_0)$.

Proof: Let $(\upsilon_1,\mathbf{S}_1)$ and $(\upsilon_2,\mathbf{S}_2)$ be two solutions to (2.12) and (2.13) and set $(\upsilon_d,\mathbf{S}_d)$ to be their difference. Equations (2.12) and (2.13) imply the existence of weak equations for almost every $0<t<T$. For each such t we take the differences evaluated at the two solutions and use $\upsilon_d(t)$ and $\mathbf{S}_d(t)$ as test functions. We can then estimate

$$\int_\Omega(\partial_t|\upsilon_d|^2+\partial_t|\mathbf{S}_d|^2+|\nabla\upsilon_d|^2)\mathrm{d}x+\int_{\mathbb{R}^3}|\operatorname{curl}\mathbf{S}_d|^2\mathrm{d}x.$$

This is bounded above by the following sum, where we have integrated by parts in the terms containing div $\mathbf{S}_d$, div$(\mathbf{S}_1+h\mathbf{a})$, or div$(\mathbf{S}_2+h\mathbf{a})$ and used (2.19),

$$C_1\Bigg\{\sum_{m=1}^{2}\Bigg(\int_\Omega|\nabla v_d||\mathbf{S}_m||v_d|\mathrm{d}x+\int_\Omega|\nabla v_m||\mathbf{S}_d||v_d|\mathrm{d}x+\int_\Omega|\mathbf{S}_d||\nabla v_d|\mathrm{d}x+\int_\Omega|\mathbf{S}_m||\mathbf{S}_d||v_d|\mathrm{d}x$$
$$+\int_\Omega|\mathbf{S}_m|^2|v_d|^2\mathrm{d}x+\int_\Omega|\nabla v_d||v_d|\mathrm{d}x+\int_\Omega|\nabla v_m||v_d|^2\mathrm{d}x\Bigg)+\int_\Omega|\mathbf{S}_d|^2\mathrm{d}x+\int_\Omega|v_d|^2\mathrm{d}x\Bigg\}.$$

We label the first integrals $I,\ldots,VII$ and estimate each. We repeatedly use that $\|\mathbf{S}_m(t)\|_{\mathbf{L}_6(\Omega)}\leqslant C$ uniformly in t, the Gagliardo-Nirenberg inequality,

$$\|v\|_{\mathcal{L}_3(\Omega)}\leqslant C\|v\|^{1/2}_{\mathcal{W}^1_2(\Omega)}\|v\|^{1/2}_{\mathcal{L}_2(\Omega)},\tag{2.22}$$

and from Lemma 6 that both $v_1,\ v_2\in\mathcal{W}_2^{2,1}(D_T)$. We have

$$I\leqslant\|\mathbf{S}_m\|_{\mathbf{L}_6(\Omega)}\|\nabla v_d\|_{\mathcal{L}_2(\Omega)}\|v_d\|_{\mathcal{L}_3(\Omega)}\leqslant C\|v_d\|^{3/2}_{\mathcal{W}^1_2(\Omega)}\|v_d\|^{1/2}_{\mathcal{L}_2(\Omega)}\leqslant\epsilon\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}+C\|v_d\|^2_{\mathcal{L}_2(\Omega)}.$$

$$II\leqslant\|\mathbf{S}_d\|_{\mathbf{L}_2(\Omega)}\|\nabla v_m\|_{\mathcal{L}_6(\Omega)}\|v_d\|_{\mathcal{L}_3(\Omega)}\leqslant\|\mathbf{S}_d\|_{\mathbf{L}_2(\Omega)}\|v_m\|_{\mathcal{W}^2_2(\Omega)}\|v_d\|_{\mathcal{L}_3(\Omega)}\leqslant\|\mathbf{S}_d\|^2_{\mathbf{L}_2(\Omega)}\|v_m\|^2_{\mathcal{W}^2_2(\Omega)}+\varepsilon\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}$$
$$+C\|v_d\|^2_{\mathcal{L}_2(\Omega)}.$$

$$III\leqslant\varepsilon\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}+C\|\mathbf{S}_d\|^2_{\mathbf{L}_2(\Omega)}.$$

$$IV\leqslant\|\mathbf{S}_m\|_{\mathbf{L}_6(\Omega)}\|\mathbf{S}_d\|_{\mathbf{L}_2(\Omega)}\|v_d\|_{\mathcal{L}_3(\Omega)}\leqslant\|\mathbf{S}_d\|^2_{\mathbf{L}_2(\Omega)}+\varepsilon\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}+C\|v_d\|^2_{\mathcal{L}_2(\Omega)}.$$

$$V\leqslant\|\mathbf{S}_m\|^2_{\mathbf{L}_6(\Omega)}\|v_d\|^2_{\mathcal{L}_3(\Omega)}\leqslant\varepsilon\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}+C\|v_d\|^2_{\mathcal{L}_2(\Omega)}.$$

$$VI\leqslant\varepsilon\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}+C\|v_d\|^2_{\mathcal{L}_2(\Omega)}.$$

$$VII\leqslant\|\nabla v_m\|_{\mathcal{L}_3(\Omega)}\|v_d\|^2_{\mathcal{L}_3(\Omega)}\leqslant C(1+\|v_m\|^2_{\mathcal{W}^2_2(\Omega)})\|v_d\|^2_{\mathcal{L}_2(a)}+\varepsilon\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}.$$

Set $r(t)=Mt+\int_0^t(\|v_1(\tau)\|^2_{\mathcal{W}^2_2(\Omega)}+\|v_2(\tau)\|^2_{\mathcal{W}^2_2(\Omega)})\mathrm{d}\tau$. From Lemma 6 we see that $r(t)$ is bounded. Then for ε small and M large, depending on C and C_1 we have

$$C_1(I+\cdots+IX)\leqslant\frac{\mathrm{d}r}{\mathrm{d}t}(\|v_d\|^2_{\mathcal{L}_2(\Omega)}+\|\mathbf{S}_d\|^2_{\mathbf{L}_2(\Omega)})+\frac{1}{2}\|\nabla v_d\|^2_{\mathcal{L}_2(\Omega)}.$$

Thus

$$\frac{\mathrm{d}}{\mathrm{d}t}(e^{-r(t)}(\|v_d\|^2_{\mathcal{L}_2(\Omega)}+\|\mathbf{S}_d\|^2_{\mathbf{L}_2(\Omega)}))+e^{-r(t)}\|\mathrm{curl}\,\mathbf{S}_d\|^2_{\mathbf{L}_2(\mathbb{R}^3)}\leqslant 0.$$

This leads to

$$e^{-r(t)}(\|v_d(t)\|^2_{\mathcal{L}_2(\Omega)}+\|\mathbf{S}_d(t)\|^2_{\mathbf{L}_2(\Omega)})+\int_0^t e^{-r(\tau)}\|\mathrm{curl}\,\mathbf{S}_d(\tau)\|^2_{\mathbf{L}_2(\mathbb{R}^3)}\mathrm{d}\tau\leqslant\|v_d(0)\|^2_{\mathcal{L}_2(\Omega)}+\|\mathbf{S}_d(0)\|^2_{\mathbf{L}_2(\Omega)}=0.$$

Thus $v_1=v_2$, $\mathbf{S}_1=\mathbf{S}_2$ in D_T, and curl $\mathbf{S}_1=$curl $\mathbf{S}_2$ in E_T. From Lemma 4 we see that this implies $\mathbf{S}_1=\mathbf{S}_2$ in E_T as well. □

Proof of Theorem 1: Since $(\psi_0,\mathbf{A}_0)$ satisfies $\mathfrak{H}$ we see that $(v,\mathbf{S}+h\mathbf{a})=(\psi,\mathbf{A})$ is a solution to

(2.17)–(2.20). Using Lemmas 5 and 7 we see that $(\psi,\mathbf{A})$ is the unique weak solution and that it converges strongly to the initial trace as $t\downarrow 0$. □

Weak solutions in the $\phi=0$ gauge are not classical for $t>0$ in general. The gauge invariant quantities such as $\mathbf{j}_s$, $\mathbf{j}_n$, curl $\mathbf{A}$, and $|\psi|$ are classical however. We prove this by transforming $(v,\mathbf{S}+h\mathbf{a},0)$ to the div $\mathbf{A}+\sigma\phi=0$ gauge where we show that weak solutions are regular for $t>0$.

III. THE LORENTZ GAUGE

We begin by preforming a gauge transformation to $(v,\mathbf{S}+h\mathbf{a},0)$. Let q solve

$$\sigma\partial_t q-\Delta q=\operatorname{div}\mathbf{S}\quad \text{in } D_T,$$

$$\partial_\nu q=0\quad \text{on } \partial\Omega\times[0,T),$$

$$q(x,0)=0\quad \text{in } \Omega. \tag{3.1}$$

Since $\operatorname{div}\mathbf{S}\in W_2^1((0,T);L_2(\Omega))$ and $\operatorname{div}\mathbf{S}(x,0)=0$ in Ω we have that q, $\partial_t q\in W_2^{2,1}(D_T)$, $q\in L_\infty(D_T)$, and $\partial_t q(x,0)=0$. Furthermore since $\int_\Omega \operatorname{div}\mathbf{S}(t)\mathrm{d}x=0$ we have $\int_\Omega q(t)\mathrm{d}x=\int_{\partial\Omega}\partial_t q(t)\mathrm{d}x=0$. As such we can extend q and $\partial_t q$ to $\mathbb{R}^3\backslash\Omega\times[0,T]$ by $\mathcal{E}(q)$ and $\mathcal{E}(\partial_t q)=\partial_t\mathcal{E}(q)$ where these are in $W_2^{2,1}(E_T)$ with support in $\bar{B}_R\times[0,T]$. We use the gauge transformation $T_q(v,\mathbf{S}+h\mathbf{a},0)=(\omega,\mathbf{Q}+h\mathbf{a},p)$. Where $\mathbf{Q}=\mathbf{S}+\nabla q$ and $p=-\partial_t q$ satisfy

$$\operatorname{div}\mathbf{Q}=-\sigma p\quad \text{in } \Omega.$$

The regularity of q and $(v,\mathbf{S})$ imply that

$$\omega\in L_\infty((0,T);\mathcal{W}_2^1(\Omega))\cap\mathcal{W}_2^{1,2}(D_T)\cap\mathcal{L}_\infty(D_T),$$

$$\mathbf{Q}\in L_\infty((0,T);\check{\mathbf{G}}(\mathbb{R}^3))\cap\mathbf{W}_2^{1,1}(D_T),$$

and $p\in W_2^{2,1}(E_T)$.

The system (2.17)–(2.20) becomes

$$\partial_t\omega-\Delta\omega=-2i(\mathbf{Q}+h\mathbf{a})\cdot\nabla\omega+i\left(\frac{1}{\sigma}-1\right)\omega\operatorname{div}\mathbf{Q}-|\mathbf{Q}+h\mathbf{a}|^2\omega-\kappa^2(|\omega|^2-1)\omega\quad \text{in } D_T, \tag{3.2}$$

$$\sigma\chi_\Omega\left(\partial_t\mathbf{Q}-\frac{1}{\sigma}\nabla\ \operatorname{div}\mathbf{Q}\right)+\operatorname{curl}^2\mathbf{Q}=\chi_\Omega\mathbf{j}_s\ \text{in } E_T \tag{3.3}$$

$$\partial_\nu\omega=0\quad \text{on } \partial\Omega\times(0,T), \tag{3.4}$$

$$(\mathbf{Q}+h\mathbf{a})\cdot\boldsymbol{\nu}=0\quad \text{on } \partial\Omega\times[0,T), \tag{3.5}$$

$$\omega(x,0)=\omega_0(x)\quad \text{in } \Omega, \tag{3.6}$$

$$\mathbf{Q}(x,0)=\mathbf{Q}_0(x)\quad \text{in } \mathbb{R}^3, \tag{3.7}$$

where since $q(x,0)=0$ we have $(\omega_0,\mathbf{Q}_0)=(v_0,\mathbf{S}_0)$. The estimates and uniqueness results in the $\phi=0$ gauge carry over to corresponding statements in the present gauge.

Lemma 8: The function $(\omega,\mathbf{Q}+h\mathbf{a})$ *is the unique solution to* (3.2)–(3.7) *among functions*

satisfying $(\omega, \mathbf{Q}+h\mathbf{a}) \in \mathfrak{A}$ *and* $\nabla(\operatorname{div} \mathbf{Q}) \in \mathbf{L}_2(D_T)$. *Moreover it is such that*

$$|\omega| \leqslant 1,$$

$$\|\partial_t \omega\|_{\mathcal{L}_2(D_T)} + \|\partial_t \mathbf{Q}\|_{\mathbf{L}_2(D_T)} + \sup_{0\leqslant t\leqslant T}\{\|\nabla \omega(t)\|_{\mathcal{L}^2(\Omega)} + \|\mathbf{Q}(t)\|_{\check{\mathbf{H}}(\mathbb{R}^3)}\} \leqslant C \tag{3.8}$$

where C *depends on* h, T, $\|\nabla \omega_0\|_{\mathcal{L}_2(\Omega)}$, *and* $\|\mathbf{Q}_0\|_{\check{\mathbf{H}}(\mathbb{R}^3)}$,

$$G(\omega(t), \mathbf{Q}(t)) \leqslant G(\omega_0, \mathbf{Q}_0) \tag{3.9}$$

for $0 \leqslant t \leqslant T$.

Lemma 9: The function $\operatorname{div} \mathbf{Q} \in W_2^{2,1}(D_T)$ *and satisfies*

$$\sigma \partial_t \operatorname{div} \mathbf{Q} - \Delta \operatorname{div} \mathbf{Q} = \operatorname{div} \mathbf{j}_s \quad \text{in } D_T,$$

$$\partial_\nu \operatorname{div} \mathbf{Q} = 0 \quad \text{on } \partial\Omega \times (0,T),$$

$$\operatorname{div} \mathbf{Q}(x,0) = 0 \quad \text{in } \Omega. \tag{3.10}$$

Furthermore

$$\sup_{0\leqslant t\leqslant T} \|\operatorname{div} \mathbf{Q}(t)\|_{W_2^1(\Omega)} \leqslant C, \tag{3.11}$$

where C *depends on* ω_0, $\mathbf{Q}_0$, σ *and* h.

Proof: Since $\operatorname{div} \mathbf{Q} = \sigma \partial_t q$ in Ω we see that (3.10) follows from (3.3). From (3.10) we have $\int_\Omega \operatorname{div} \mathbf{Q}(t) \mathbf{d}s = 0$ and

$$\sup_{0<t<T} \|\nabla \operatorname{div} \mathbf{Q}(t)\|_{\mathbf{L}_2(\Omega)} \leqslant C_1 \|\operatorname{div} \mathbf{j}_s\|_{L_2(D_T)}.$$

Thus

$$\sup_{0<t<T} \|\operatorname{div} \mathbf{Q}(t)\|_{W_2^1(\Omega)} \leqslant C_2 \sup_{0\leqslant t\leqslant T} \|\operatorname{div} \mathbf{j}_s\|_{L_2(D_T)} \leqslant C_3 \|\partial_t \upsilon\|_{\mathcal{L}_2(D_T)} \leqslant C_4,$$

where C_4 depends on $(\upsilon_0, \mathbf{S}_0) = (\omega_0, \mathbf{Q}_0)$, h, and T. □

We now develop higher regularity properties of solutions for $0 < t_0 < t < T$.

Define

$$D_{t_0,T} = \Omega \times (t_0, T) \text{ and } E_{t_0,T} = \mathbb{R}^3 \times (t_0, T).$$

Let $k(t) \in C^\infty(\mathbb{R})$ be a cut off function such that $k(t) = 0$ for $t \leqslant t_0/2$ and $k(t) = 1$ for $t_0 \leqslant t$.

Lemma 10: $\nabla \partial_t \omega \in \mathcal{L}_2(D_{t_0,T})$ *for each* $t_0 > 0$ *and*

$$\sup_{t_0<t<T} \|\partial_t \omega(t)\|_{\mathcal{L}_2(D_{t_0,T})} + \|\nabla \partial_t \omega\|_{\mathcal{L}_2(D_{t_0,T})} \leqslant C,$$

where C *depends on* $\|\omega_0\|_{\mathcal{W}_2^1(\Omega)}$, $\|\mathbf{Q}_0\|_{\check{\mathbf{H}}(\mathbb{R}^3)}$, h, t_0, and T.

Proof: Set

$$D_\tau \omega(x,t) = \frac{\omega(x, t+\tau) - \omega(x,t)}{\tau} \quad \text{for } \tau > 0,$$

and $\eta = k D_\tau \omega$. Using (3.2) we write

$$\partial_t \eta - \Delta \eta = -2i(\mathbf{Q}(t) + ha) \cdot \nabla \eta + i\left(\frac{1}{\sigma} - 1\right) \operatorname{div} \mathbf{Q}(t)\, \eta - |\mathbf{Q}(t) + ha|^2 \eta - 2i \nabla\, \omega(t+\tau) k D_\tau \mathbf{Q}$$

$$+ i\left(\frac{1}{\sigma} - 1\right) \omega(t+\tau) k D_\tau (\operatorname{div} \mathbf{Q}) + \omega(t+\tau) k(t) D_\tau |\mathbf{Q} + \mathbf{a}h|^2 + f_1 \eta + f_2 \quad \text{in } D_T,$$

$$\partial_\nu \eta = 0 \quad \text{on } \partial\Omega \times (0,T),$$

$$\eta(x,0) = 0 \quad \text{in } \Omega, \tag{3.12}$$

where $\|f_1\|_{\mathcal{L}_\infty(D_T)} + \|f_2\|_{\mathcal{L}2}(D_T) \leqslant C(t_0)$ uniformly in τ, $0 < \tau < 1$. We take the inner product of (3.12) with η and integrate over Ω. We further integrate by parts in the fourth term on the right side, using (3.5). The left-hand side becomes

$$\frac{1}{2} \frac{\mathrm{d}}{\mathrm{d}t} \left(\int_\Omega |\eta|^2 \mathrm{d}x + \int_\Omega |\nabla \eta|^2 \mathrm{d}x \right). \tag{3.13}$$

This is bounded by

$$C\left(\int_\Omega |\operatorname{div} \mathbf{Q}(t)||\eta|^2 \mathrm{d}x + \int_\Omega |\mathbf{Q}(t)|^2 |\eta|^2 \mathrm{d}x + \int_\Omega |D_\tau \operatorname{div} \mathbf{Q}||\eta| \mathrm{d}x + \int_\Omega |D_\tau \mathbf{Q}||\nabla \eta| \mathrm{d}x + \int_\Omega (|\mathbf{Q}(t)| \right.$$

$$\left. + |\mathbf{Q}(t+\tau)|) |D_\tau \mathbf{Q}||\eta| \mathrm{d}x \int_\Omega |\eta|^2 \mathrm{d}x + 1 \right) + \frac{1}{2} \int_\Omega (\nabla \eta)^2 \mathrm{d}x. \tag{3.14}$$

We label the first five integrals $I, \ldots, V$ and estimate each.

$$I \leqslant \|\operatorname{div} \mathbf{Q}(t)\|_{L_3(\Omega)} \|\eta\|^2_{\mathcal{L}_3(\Omega)} \leqslant \varepsilon \|\nabla \eta\|^2_{\mathcal{L}_2(\Omega)} + C \|\eta\|^2_{\mathcal{L}_2(\Omega)}$$

for any $\varepsilon > 0$ and $C(\varepsilon)$ independent of t. Here we used (2.22) and (3.11).

$$II \leqslant \|\mathbf{Q}(t)\|^2_{\mathbf{L}_6(\Omega)} \|\eta\|^2_{\mathcal{L}_3(\Omega)} \leqslant \varepsilon \|\nabla \eta\|^2_{\mathcal{L}_2(\Omega)} + C \|\eta\|^2_{\mathcal{L}_2(\Omega)},$$

where we use (1.11). Next we estimate

$$III \leqslant \|\operatorname{div} D_\tau \mathbf{Q}(t)\|^2_{L_2(\Omega)} + \|\eta\|^2_{\mathcal{L}_2(\Omega)},$$

$$IV \leqslant \varepsilon \|\nabla \eta\|^2_{\mathcal{L}_2(\Omega)} + C \|D_\tau \mathbf{Q}(t)\|^2_{\mathbf{L}_2(\Omega)}$$

and

$$V \leqslant \Big(\sup_{0 \leqslant t \leqslant T+1} \|\mathbf{Q}(t)\|_{\mathbf{L}_6(\Omega)} \Big) \|\eta\|_{\mathcal{L}_3(\Omega)} \|D_\tau \mathbf{Q}(t)\|_{\mathbf{L}_2(\Omega)} \leqslant \varepsilon \|\nabla \eta\|^2_{\mathcal{L}_2(\Omega)} + C_1 \|\eta\|^2_{\mathcal{L}_2(\Omega)} + C_2 \|D_\tau \mathbf{Q}(t)\|^2_{\mathbf{L}_2(\Omega)}.$$

Combining these estimates with (3.13) and (3.14) we find

$$\sup_{t_0 \leqslant t \leqslant T} \|D_\tau \omega(t)\|^2_{\mathcal{L}_2(\Omega)} + \|\nabla D_\tau \omega\|^2_{\mathcal{L}_2(D_{t_0,T})} \leqslant C,$$

where C depends on the initial data, h, t_0, and T but independent of $\tau, 0 < \tau < 1$. Letting $\tau \downarrow 0$ we have our assertion. □

Lemma 11: $\omega \in \mathcal{W}^{2,1}_3(D_{t_0,T})$.

Proof: Set $\rho = k\omega$. Then $\rho \in \mathcal{W}^{1,2}_2(D_T)$, $|\rho| \leqslant 1$, and from (3.2)

$$\partial_t \rho - \Delta \rho = \mathbf{F} \cdot \nabla \rho + f \quad \text{in } D_T,$$

$$\partial_\nu \rho = 0 \quad \text{on } \partial\Omega \times (0,T),$$

$$\rho(x,0) = 0 \quad \text{in } \Omega,$$

where $\mathbf{F} = -2i(\mathbf{Q} + h\mathbf{a}) \in L_\infty((0,T);\mathcal{L}_6(\Omega))$ and $f \in \mathcal{L}_3(D_T)$. Set $s = \sup\{m \leqslant 3 : \rho \in \mathcal{W}_m^{2,1}(D_T)\}$. We have the Gagliardo–Nirenberg inequality

$$\|\nabla\rho\|_{\mathcal{L}_{2m}(\Omega)} \leqslant C\|\rho\|^{1/2}_{\mathcal{W}^2_m(\Omega)}\|\rho\|^{1/2}_{\mathcal{L}_\infty(\Omega)}, \tag{3.15}$$

where C is uniformly bounded for $2 \leqslant m \leqslant 3$. From parabolic estimates we have

$$\|\rho\|_{\mathcal{W}_m^{2,1}(D_T)} \leqslant \Lambda(\|\mathbf{F}\|^2_{\mathcal{L}_{2m}(D_T)} + \|f\|_{\mathcal{L}_3(D_T)} + 1)$$

where Λ is independent of m for $2 \leqslant m \leqslant 3$. It follows that

$$\|\rho\|_{\mathcal{W}_m^{2,1}(D_T)} \leqslant \Lambda(\|\mathbf{F}\|^2_{\mathcal{L}_6(D_T)} + \|f\|_{\mathcal{L}_3(D_T)} + 1)$$

for all $m < s$. This implies $\|\rho\|_{\mathcal{W}_s^{2,1}(D_T)}$ is finite and satisfies the same bound.

We claim that $s = 3$. If this is not the case let $s < s' \leqslant 3$. Then

$$\|\mathbf{F}\cdot\nabla\rho\|_{\mathcal{L}_{s'}(D_T)} \leqslant \|\mathbf{F}\|_{\mathcal{L}_6(D_T)}\|\nabla\rho\|_{\mathcal{L}_{6s'/(6-s')}(D_T)} \leqslant C\|\rho\|^{1/2}_{\mathcal{W}^{2,0}_{3s'/(6-s')}(D_T)}. \tag{3.16}$$

Note $3s/(6-s) < s$ if $s < 3$. Thus if $s < s'$, with $s' - s$ sufficiently small we have $3s'/(6-s') < s$ and it follows from (3.16), and parabolic estimates that $\|\rho\|_{\mathcal{W}^{2,1}_{s'}(D_T)} < \infty$. This contradicts the definition of s. □

We can now estimate $\partial_t \mathbf{j}_s$.

Lemma 12: $\partial_t \mathbf{j}_s \in L^2(D_{t_0,T})$.

Proof: We can estimate

$$\|D_\tau \mathbf{j}_s\|^2_{\mathbf{L}_2(D_{t_0,T})} \leqslant \|\nabla D_\tau\omega\|^2_{\mathcal{L}_2(D_{t_0,T})} + \|(\nabla\omega)D_\tau\omega\|^2_{\mathcal{L}_2(D_{t_0,T})} + \|(D_\tau\omega)\mathbf{Q}\|^2_{\mathcal{L}_2(D_{t,T})} + \|D_\tau\mathbf{Q}\|^2_{\mathbf{L}^2(D_{t,T})}.$$

Each term on the right-hand side is bounded by a constant depending only on the data, t_0, and T. Indeed this holds for the first term by Lemma 10. The second term is estimated by

$$\|(\nabla\omega)D_\tau\omega\|^2_{\mathcal{L}_2(D_{t_0,T})} \leqslant \|\nabla\omega\|^2_{\mathcal{L}_6(D_{t_0,T})}\|D_\tau\omega\|^2_{\mathcal{L}_3(D_{t_0,T})} \leqslant C\|\omega\|^3_{\mathcal{W}^{2,1}_3(D_{t_0,T+1})},$$

and this is bounded using Lemma 11. The third term is bounded using Lemma 11 and (3.8), and the fourth term is estimated using (3.8). □

We can now differentiate (3.3) to get further estimates on $\mathbf{Q}$. We use the notation $(\partial_t)^\ell f = f^{(\ell)}$.

Lemma 13: $\mathbf{Q}(t) \in W_2^2(\Omega)$ *for* $t > 0$ *and* $\|\mathbf{Q}\|_{\mathbf{W}_2^2(\Omega)} \leqslant C$ *for* $t_0 \leqslant t < T$ *where* C *depends on the data*, t_0, *and* T.

Proof: Set $\mathbf{V} = k(t)D_\tau\mathbf{Q}$. Then we have

$$\sigma\chi_\Omega\partial_t\mathbf{V} - \chi_\Omega\nabla\ \mathrm{div}\,\mathbf{V} + \mathrm{curl}^2\,\mathbf{V} = \chi_\Omega(kD_\tau\mathbf{j}_s + \sigma\partial_t\mathbf{k}D_\tau Q)$$

Dotting this equation with $\mathbf{V}$, integrating over E_T, and letting $\tau \to 0$ we get $\mathbf{Q}^{(1)} \in L_2(t_0, T; \check{\mathbf{G}}(\mathbb{R}^3))$ for any $t_0 > 0$. Next dotting the equation with $\partial_t\mathbf{V}$, integrating on E_T, and letting $\tau \to 0$ we find that $\mathbf{Q}^{(1)} \in \mathbf{W}_2^{1,1}(D_{t_0,T}) \cap L_\infty((t_0,T);\check{\mathbf{G}}(\mathbb{R}^3))$ and satisfies the estimate

$$\|\mathbf{Q}^{(2)}\|^2_{\mathbf{L}^2(D_{t_0,T})} + \sup_{t_0 \leqslant t \leqslant T}\|\mathbf{Q}^{(1)}(t)\|^2_{\check{\mathbf{G}}(\mathbb{R}^3)} \leqslant C \tag{3.17}$$

where C depends on the data, t_0, and T. The only step in the preceding argument that needs comment is the inequality

$$\|\mathbf{V}\|^2_{\check{\mathbf{H}}(\mathbb{R}^3)} \leqslant C(\|\text{div } \mathbf{V}\|^2_{L_2(\Omega)} + \|\text{curl } \mathbf{V}\|^2_{\mathbf{L}_2(\mathbb{R}^3)}).$$

To see this recall that $\mathbf{V}\cdot\boldsymbol{\nu}=0$ on $\partial\Omega$,

$$\|\mathbf{V}\|^2_{\check{\mathbf{H}}(\mathbb{R})} = \|\text{div } \mathbf{V}\|^2_{L_2(\mathbb{R}^3)} + \|\text{curl } \mathbf{V}\|^2_{\mathbf{L}_2(\mathbb{R}^3)},$$

and by the construction of $\check{\mathbf{G}}(\mathbb{R}^3)$ that

$$\|\text{div } \mathbf{V}\|^2_{L_2(\mathbb{R}^3)} \leqslant C(\|\text{div } \mathbf{V}\|^2_{L_2(\Omega)} + \|\text{curl } \mathbf{V}\|^2_{\mathbf{L}_2(\mathbb{R}^3)} + \|\mathbf{V}\cdot\boldsymbol{\nu}\|^2_{W_2^{1/2}(\partial\Omega)}).$$

From (3.11) and (3.17), and Lemma 12, we have,

$$\|\mathbf{Q}^{(1)}(t)\|_{\mathbf{L}_2(\Omega)} + \|\nabla \text{ div } \mathbf{Q}(t)\|_{\mathbf{L}_2(\Omega)} + \|\mathbf{j}_s(t)\|_{\mathbf{L}_2(\Omega)} \leqslant C \tag{3.18}$$

for $t_0 \leqslant t \leqslant T$. It follows from (3.3) that curl $\mathbf{Q}(t) \in \check{\mathbf{H}}(\mathbb{R}^3)$ and

$$\|\text{curl } \mathbf{Q}(t)\|_{\check{\mathbf{H}}(\mathbb{R}^3)} = \|\text{curl}^2 \mathbf{Q}(t)\|_{\mathbf{L}_2(\mathbb{R}^3)} \leqslant C \tag{3.19}$$

for $t_0 \leqslant t \leqslant T$. We now apply Theorem 3.4 from Ref. 1, which is valid since $(\mathbf{Q}+h\mathbf{a})\cdot\boldsymbol{\nu}=0$ on $\partial\Omega$, to obtain the estimate

$$\|\mathbf{Q}(t)\|_{\mathbf{W}_2^2(\Omega)} \leqslant C(\|\text{curl } \mathbf{Q}(t)\|_{\mathbf{W}_2^1(\Omega)} + \|\mathbf{Q}(t)\|_{\mathbf{L}_2(\Omega)} + \|\Delta\mathbf{Q}(t)\|_{\mathbf{L}_2(\Omega)} + h).$$

Using (3.18) and (3.19) we see

$$\sup_{t_0\leqslant t\leqslant T} \|\mathbf{Q}(t)\|_{\mathbf{W}_2^2(\Omega)} \leqslant C.$$

□

Note, it follows that

$$\|\mathbf{Q}(t)\|_{\mathbf{L}_\infty(\Omega)} \leqslant C \tag{3.20}$$

uniformly for $t_0 \leqslant t \leqslant T$.

We return to (3.2) and (3.4) which we write as

$$\partial_t\omega - \Delta\omega = f \quad \text{in } D_T,$$

$$\partial_\nu\omega = 0 \quad \text{on } \partial\Omega\times(0,T).$$

Using Lemma 11, (3.11), (3.15), and (3.20) we obtain $f \in \mathcal{L}_6(D_{t_0,T})$ for any $0<t_0<T$. As such $\omega \in \mathcal{W}_6^{2,1}(D_{t_0,T})$. It then follows that

$$\text{div } \mathbf{j}_s = \left(i\omega, \partial_t\omega - \frac{i}{\sigma}\omega \text{ div } \mathbf{Q}\right) \in L_6(D_{t_0,T}),$$

and then from (3.10) that div $\mathbf{Q} \in W_6^{2,1}(D_{t_0,T})$ where the $W_6^{2,1}$ estimates depend only on the initial data, h, t_0, and T. These estimates establish the initial step to the induction argument for the next lemma where higher regularity properties for $\omega^{(j)}$ and $\mathbf{Q}^{(j)}$ are proved. The idea behind their proof is to carry enough information forward from the jth step so that $\omega^{(j+1)}$ and $\mathbf{Q}^{(j+1)}$ will be weak solutions to equations with bounded coefficients and thereby easy to analyze.

Lemma 14: $\omega \in C^\infty((0,T);\mathcal{W}_6^2(\Omega))$ *and* $\mathbf{Q} \in C^\infty((0,T);\mathbf{W}_2^2(\Omega)) \cap C^\infty((0,T);\check{\mathbf{G}}(\mathbb{R}^3))$.

Proof: It suffices to prove that $\omega^{(j)} \in \mathcal{W}_6^{2,1}(D_{t_0,T})$ and

$$\mathbf{Q}^{(j)} \in L_\infty((t_0,T); \quad \mathbf{W}_2^2(\Omega)) \cap L_\infty((t_0,T); \quad \check{\mathbf{G}}(\mathbb{R}^3))$$

for each integer $j \geqslant 0$ and $T>t_0>0$.

We will prove:

If $\omega^{(k)} \in \mathcal{W}_6^{2,1}(D_{t_0,T})$, $\operatorname{div} \mathbf{Q}^{(k)} \in W_6^{2,1}(D_{t_0,T})$, $\mathbf{Q}^{(k)} \in \mathbf{L}_2(D_{t_0,T})$, and $\mathbf{Q}^{(m)} \in L_\infty((t_0,T);\mathbf{W}_2^2(\Omega)) \cap L_\infty((t_0,T);\check{\mathbf{G}}(\mathbb{R}^3))$ where $0 \leqslant k \leqslant j$ and $m \leqslant \max(0,j-1)$ for each $0 < t_0 < T$ then $\omega^{(j+1)} \in \mathcal{W}_6^{2,1}(D_{t_0,T})$, $\operatorname{div} \mathbf{Q}^{(j+1)} \in W_6^{2,1}(D_{t_0,T})$, $\mathbf{Q}^{(j+1)} \in \mathbf{L}_2(D_{t_0,T})$, and $\mathbf{Q}^{(j)} \in L_\infty((t_0,T);\mathbf{W}_2^2(\Omega)) \cap L_\infty((t_0,T);\check{\mathbf{G}}(\mathbb{R}^3))$ for each $0 < t_0 < T$.

The induction hypotheses for $j=0$ have been established previously. Assuming these for j, we then have from standard embedding theorems that $\omega^{(k)}$, $\operatorname{div} \mathbf{Q}^{(k)} \in C^{1+1/6,7/12}(\bar{D}_{t_0,T})$, $\mathbf{Q}^{(k)} \in \mathbf{L}_2(D_{t_0,T})$, and $\mathbf{Q}^{(m)} \in \mathbf{L}_\infty(D_{t_0,T})$ for $k \leqslant j$ and $m \leqslant \max(0,j-1)$. It follows that $\mathbf{j}_s^{(j)} \in \mathbf{L}_2(D_{t_0,T})$. Then as in the proof of Lemma 13 we have $\mathbf{Q}^{(j+1)} \in \mathbf{L}_2(D_{t_0,T})$ and $\mathbf{Q}^{(j)} \in L_\infty((t_0,T);\check{\mathbf{G}}(\mathbb{R}^3))$.

We next prove that $\omega^{(j+1)} \in \mathcal{W}_2^{2,1}(D_{t_0,T})$. From the hypotheses we can differentiate (3.2) with respect to t,j times. We then form an equation for $\eta = k(t) D_\tau \omega^{(j)}$ for $\tau > 0$, in D_T. For $j=0$ this is (3.12); we see that η satisfies

$$\partial_t \eta - \Delta \eta = a_1 \cdot \nabla \eta + a_2 \eta + a_3 \quad \text{in } D_T,$$

$$\partial_\nu \eta = 0 \quad \text{on } \partial\Omega \times (0,T),$$

$$\eta(x,0) = 0 \quad \text{in } \Omega,$$

where from the hypotheses and (3.17) we have a_1, $a_2 \in \mathcal{L}_\infty(D_T)$ and $a_3 \in \mathcal{L}_6(D_T)$. Thus $\omega^{(1)} \in \mathcal{W}_2^{2,1}(D)$.

For $j \geqslant 1$ the equation for η is more complex. We write

$$\begin{aligned} L(\eta) :&= \partial_t \eta - \Delta \eta + 2i(\mathbf{Q} + h\mathbf{a}) \cdot \nabla \eta + i\left(\frac{1}{\sigma} - 1\right) \eta \operatorname{div} \mathbf{Q} + |\mathbf{Q} + h\mathbf{a}|^2 \eta + \kappa^2 (|\omega|^2 - 1)\eta + \kappa^2 \omega(\omega \eta^* \\ &\quad + \omega^* \eta) = a_1 \mathbf{Q}^{(j)} + a_2 D_\tau \mathbf{Q}^{(j-1)} + a_3 D_\tau \mathbf{Q}^{(j)} + a_4 D_\tau (\operatorname{div} \mathbf{Q}^{(j)}) + a_5 \mathbf{Q}^{(1)} D_\tau \mathbf{Q} + a_6 \mathbf{Q}^{(1)}(t+\tau) D_\tau \mathbf{Q} \\ &\quad + a_7 \end{aligned}$$

where the a_i are bounded for $1 \leqslant i \leqslant 6$ and $a_7 \in \mathcal{L}_6(D_T)$. Note that the coefficients of $L(\cdot)$ are bounded in $D_{t',T}$ for each $0 < t'$. The first four terms on the right are in $\mathcal{L}_2(D_T)$ and the fifth and sixth terms are the product of functions in $\mathcal{L}_6(D_T)$. It follows that $\eta \in \mathcal{W}_2^{2,1}(D_T)$ uniformly in $\tau, 0 < \tau < 1$. Thus

$$\omega^{(j+1)} \in \mathcal{W}_2^{2,1}(D_{t_0,T}). \tag{3.21}$$

It follows that $\mathbf{j}_s^{(j+1)} \in \mathbf{L}_2(D_{t_0,T})$, and using (3.3) as before

$$\mathbf{Q}^{(j+1)} \in L_\infty((t_0,T); \quad \check{\mathbf{G}}(\mathbb{R}^3)) \cap \mathbf{W}_2^{0,1}(D_{t_0,T}). \tag{3.22}$$

Whence $\mathbf{j}_s^{(j)}, \mathbf{Q}^{(j+1)} \in L_\infty((t_0,T);\mathbf{L}_2(\Omega))$. Using the identity

$$\operatorname{div} \mathbf{j}_s = \left(i\omega, \partial_t \omega - \frac{i}{\sigma} \omega \operatorname{div} \mathbf{Q} \right), \tag{3.23}$$

together with (3.10) and the hypotheses it follows that $\nabla \operatorname{div} \mathbf{Q}^{(j)} \in L_\infty(t_0,T;\mathbf{L}_2(\Omega))$ as well.

From (3.3) then we have $\operatorname{curl}^2 \mathbf{Q}^{(j)} \in L_\infty((t_0,T);\mathbf{L}_2(\mathbb{R}^3))$. Since $\operatorname{curl} \mathbf{Q}^{(j)}(t) \in \mathbf{L}_2(\mathbb{R}^3)$ we have $\operatorname{curl} \mathbf{Q}^{(j)}(t) \in \check{\mathbf{H}}(\mathbb{R}^3)$ and as such

$$\operatorname{curl} \mathbf{Q}^{(j)} \in L_\infty((t_0,T);\mathbf{W}_2^1(\Omega)).$$

Arguing as in Lemma 13, we apply Ref. 1, Theorem 3.4 to obtain

$$\mathbf{Q}^{(j)} \in L_\infty((t_0,T);\mathbf{W}_2^2(\Omega)).$$

It remains to prove $\omega^{(j+1)} \in \mathcal{W}_6^{2,1}(D_{t_0,T})$ and $\operatorname{div} \mathbf{Q}^{(j+1)} \in W_6^{2,1}(D_{t_0,T})$. From (3.21)–(3.23) we have that $\operatorname{div} \mathbf{j}_s^{(j+1)} \in L_2(D_{t_0,T})$. Thus from (3.10) we obtain

$$\operatorname{div} \mathbf{Q}^{(j+1)} \in W_2^{2,1}(D_{t_0,T}) \cap L_\infty((t_0,T);L_6(\Omega)). \tag{3.24}$$

It follows from this and (3.22) that $L(\omega^{(j+1)}) \in \mathcal{L}_6(D_{t',T})$ for any $0<t'<T$, implying that $\omega^{(j+1)} \in \mathcal{W}_6^{2,1}(D_{t_0,T})$. Using this, (3.23) and (3.24) we have $\operatorname{div} \mathbf{j}_s^{(j+1)} \in L_6(D_{t',T})$ for $0<t'<T$. It follows from (3.10) that $\operatorname{div} \mathbf{Q}^{(j+1)} \in W_6^{2,1}(D_{t_0,T})$. □

Lemma 15: $\omega \in C^\infty((0,T);\mathcal{C}^{3+\alpha}(\bar{\Omega}))$, $\operatorname{div} \mathbf{Q} \in C^\infty((0,T);C^{3+\alpha}(\bar{\Omega}))$ *and* $\mathbf{Q} \in C^\infty((0,T);\mathbf{C}^{1+\gamma}(K))$ *for any compact* $K \subset \mathbb{R}^3$ *and* $0<\gamma<1$.

Proof: We have $\mathbf{Q}^{(j)} = \nabla f^{(j)} + \mathbf{g}^{(j)}$ where $\mathbf{g}^{(j)} \in \mathbb{V}_2$ and $f^{(j)} \in \mathring{W}_2^2(B_R)$. Furthermore, from Lemma 14 we have

$$\mathbf{j}_s^{(j)} + \nabla \operatorname{div} \mathbf{Q}^{(j)} - \mathbf{Q}^{(j+1)} \in L_\infty((t_0,T);\mathbf{L}_6(\Omega)).$$

Thus $\Delta \mathbf{g}^{(j)} = -\operatorname{curl}^2 \mathbf{g}^{(j)} \in L_\infty((t_0,T);\mathbf{L}_6(\mathbb{R}^3))$. Since $\mathbf{g}^{(j)} \in L_\infty((t_0,T);\mathbf{L}_6(\mathbb{R}^3))$ and $\operatorname{supp} \Delta \mathbf{g}^{(j)} \subset \bar{\Omega}$ it follows that $\mathbf{g}^{(j)} \in L_\infty((t_0,T);\mathbf{W}_6^2(\mathbb{R}^3))$ for any $t_0>0$, implying that

$$\mathbf{g} \in C^\infty((0,T);\mathbf{W}_6^2(\mathbb{R}^3)). \tag{3.25}$$

We now analyze $\nabla f^{(j)}$. We have

$$\Delta f^{(j)} = \operatorname{div} \mathbf{Q}^{(j)} \quad \text{in } \Omega,$$

$$\partial_{\boldsymbol{\nu}} f^{(j)} = -\mathbf{g}^{(j)} \cdot \boldsymbol{\nu} - h\mathbf{a}^{(j)} \cdot \boldsymbol{\nu} \quad \text{on } \partial\Omega. \tag{3.26}$$

Since $\partial\Omega \in C^{3+\alpha}$ and $\int_\Omega f^{(j)} dx = 0$ we have from elliptic estimates that

$$\|f^{(j)}\|_{W_6^3(\Omega)} \leqslant C(\|\operatorname{div} \mathbf{Q}^{(j)}\|_{W_6^1(\Omega)} + \|\mathbf{g}^{(j)}\|_{\mathbf{W}_6^2(\Omega)} + 1).$$

It follows that $f \in C^\infty((0,T);W_6^3(\Omega))$. From the definition of $\mathcal{E}(f)$ we have $f = \mathcal{E}(f) \in C^\infty((0,T);\mathring{W}_6^3(B_R))$. With this and (3.25) we see that

$$\mathbf{Q} \in C^\infty((0,T);\mathbf{C}^{1+1/2}(K)) \tag{3.27}$$

for any compact set $K \subset \mathbb{R}^3$. We next write

$$\Delta \omega(t) = F(t) \quad \text{in } \Omega,$$

$$\partial_{\boldsymbol{\nu}} \omega(t) = 0 \quad \text{on } \partial\Omega \tag{3.28}$$

where F is a polynomial in the components of ω, $\nabla\omega$, $\partial_t\omega$, $\mathbf{Q}$, and $\operatorname{div} \mathbf{Q}$. Using (3.27) and the estimates from Lemma 14, together with elliptic estimates applied to (3.28) we find that $\omega \in C^\infty((0,T);\mathcal{C}^{3+\beta}(\bar{\Omega}))$ where $\beta = \min(\alpha, \frac{1}{2})$. We get the corresponding result for $\operatorname{div} \mathbf{Q}$ using (3.10).

Our next step is to write $\mathbf{Q} = \nabla f + \mathbf{g}$ with $\mathbf{g} \in \mathbb{V}_2$ for each t where $\mathbf{g}$ satisfies

$$\Delta \mathbf{g} = \chi_\Omega(\sigma \partial_t \mathbf{Q} - \nabla(\operatorname{div} \mathbf{Q}) - \mathbf{j}_s) \equiv \chi_\Omega \ell. \tag{3.29}$$

We have $\ell \in C^\infty((0,T);\mathbf{C}^{1+\beta}(\bar{\Omega}))$ and it follows that $\mathbf{g} \in C^\infty((0,T);\mathbf{W}_p^2(\mathbb{R}^3))$ for any $3<p<\infty$. We can now argue as above, using (3.26), to get $f \in C^\infty((0,T);\mathring{W}_p^3(B_R))$. As a result we get

$$\mathbf{Q} \in C^\infty((0,T);\mathbf{C}^{1+\gamma}(K))$$

for any $0<\gamma<1$ and compact $K \subset \mathbb{R}^3$.

We return to (3.28) and are now able to assert that $F \in C^\infty((0,T);\mathcal{C}^{1+\alpha}(\bar{\Omega}))$. It follows that $\omega \in C^\infty((0,T);\mathcal{C}^{3+\alpha}(\bar{\Omega}))$ and a similar argument proves that $\operatorname{div} \mathbf{Q} \in C^\infty((0,T);C^{3+\alpha}(\bar{\Omega}))$ as well. □

We view equation (3.29) as a diffraction problem. Let k be an integer $k \geqslant 2$. The classical regularity result for a solution $\mathbf{g} \in \mathbf{W}^2_{2,loc}(\mathbb{R}^3)$, provided $\ell \in \mathbf{C}^{k+\alpha-2}(\bar{\Omega})$ and $\partial\Omega \in C^{k+\alpha}$ is that $\mathbf{g} \in \mathbf{C}^1(\mathbb{R}^3) \cap \mathbf{C}^{k+\alpha}(\bar{\Omega}) \cap \mathbf{C}^{k+\alpha}(\mathbb{R}^3 \setminus \Omega)$, satisfying

$$\|\mathbf{g}\|_{\mathbf{C}^{k+\alpha}(\bar{\Omega})} + \|\mathbf{g}\|_{\mathbf{C}^{k+\alpha}(\overline{B_R}\setminus\Omega)} \leqslant \Lambda(\|\ell\|_{\mathbf{C}^{k+\alpha-2}(\bar{\Omega})} + \|\mathbf{g}\|_{\mathbf{C}^0(\bar{B}_{2R})}) \tag{3.30}$$

for any B_R such that $\bar{\Omega} \subset B_R$. This is given in Ref. 7 (p. 198), for the case $k=2$. To prove it for integers $k>2$ one can locally flatten $\partial\Omega$ and establish an estimate analogous to (3.30) with $k=2$, and $\mathbf{g}$ and ℓ replaced by derivatives tangent to the flattened interface. Estimates for the remaining derivatives of $\mathbf{g}$, on either side of the interface, are found in terms of the tangential derivatives using the equation's ellipticity.

We use (3.30) to prove higher regularity properties for ω and $\mathbf{Q}$.

Lemma 16: Assume that $\partial\Omega \in C^{k+\alpha}$ where k is an integer with $k \geqslant 3$, and $\bar{\Omega} \subset B_R$. Then writing $\mathbf{Q} = \nabla f + \mathbf{g}$ we have

$$g_j,\ f \in C^\infty((0,T); C^{k+\alpha}(\bar{\Omega})) \cap C^\infty((0,T); C^{k+\alpha}(\bar{B}_R \setminus \Omega)), \tag{3.31}$$

$$\operatorname{div} \mathbf{Q} \in C^\infty((0,T); C^{k+\alpha}(\bar{\Omega})), \tag{3.32}$$

and

$$\omega \in C^\infty((0,T); \mathcal{C}^{k+\alpha}(\bar{\Omega})). \tag{3.33}$$

Proof: We begin with the case $k=3$. From the proof of Lemma 15, we find that $\ell \in C^\infty(t_0, T; \mathbf{C}^{1+\alpha}(\bar{\Omega}))$. Then using (3.30) for the equations $\Delta \mathbf{g}^{(j)} = \chi_\Omega \ell^{(j)}$ we see that (3.31) holds for $\mathbf{g}$. It remains to establish (3.31) for f. Using (3.26) and Lemma 15 we have $\Delta f \in C^\infty((0,T); C^{3+\alpha}(\bar{\Omega}))$. Using (3.31) for $\mathbf{g}$ with $k=3$, we have $\partial_\nu f \in C^\infty((0,T); C^{2+\alpha}(\partial\Omega))$. It follows from elliptic estimates applied to (3.26) that $f \in C^\infty((0,T); C^{3+\alpha}(\bar{\Omega}))$.

We next assume that $3 < k$ and that (3.31)–(3.33) hold for $3 \leqslant m < k$. These imply that $\Delta\omega$, $\mathbf{Q}$, $\ell \in C^\infty((0,T); C^{m-1+\alpha}(\bar{\Omega}))$. Then using (3.10), (3.23), and (3.28) we get ω, $\operatorname{div} \mathbf{Q} \in C^\infty((0,T); C^{m+1+\alpha}(\bar{\Omega}))$ and using (3.30) we get

$$\mathbf{g} \in C^\infty((0,T); \mathbf{C}^{m+1+\alpha}(\bar{\Omega})) \cap C^\infty((0,T); \mathbf{C}^{m+1+\alpha}(\bar{B}_R \setminus \Omega)).$$

We have $\Delta f \in C^\infty((0,T); C^{m+1+\alpha}(\bar{\Omega}))$, $\partial_\nu f \in C^\infty((0,T); C^{m+\alpha}(\partial\Omega))$, and $\partial\Omega \in C^{m+1+\alpha}$ (since $m+1 \leqslant k$). It follows that $f \in C^\infty((0,T); C^{m+1+\alpha}(\bar{\Omega}))$. By the construction of the extension $\mathcal{E}(f)$, if $f \in C^{m+1+\alpha}(\bar{\Omega})$ then

$$\mathcal{E}(f)_{\llcorner B_R \setminus \Omega} \in C_c^{m+1+\alpha}(B_R \setminus \Omega)$$

and there is a constant C so that

$$\|\mathcal{E}(f)\|_{C^{m+1+\alpha}(\bar{B}_R \setminus \Omega)} \leqslant C \|f\|_{C^{m+1+\alpha}(\bar{\Omega})}.$$

Thus we see that $f \in C^\infty((0,T); C^{m+1+\gamma}(\bar{B}_R \setminus \Omega))$ as well. This proves (3.31)–(3.33). □

Proof of Theorem 2: Let $(\psi_0, \mathbf{A}_0)$ satisfy $\mathfrak{H}$. Then $(\psi, \mathbf{A}) = (\omega, \mathbf{Q} + h\mathbf{a})$ is a solution to (3.2)–(3.7), with the required regularity for $t>0$, and such that $(\psi(t), \mathbf{A}(t)) \rightharpoonup (\psi_0, \mathbf{A}_0)$ in $\mathcal{W}^1_2(\Omega) \times \mathbf{W}^1_2(\Omega)$ as $t \downarrow 0$. Furthermore, since (3.9) holds it follows that the proof of Lemma 5 carries over in this gauge. Thus $(\psi(t), \mathbf{A}(t))$ converges strongly to (ψ_0, A_0) in $\mathbf{W}^1_2(\Omega) \times \check{\mathbf{G}}(\mathbb{R}^3)$ as $t \downarrow 0$. Finally the proof of uniqueness from Lemma 7 carries over as well. □

IV. THE COULOMB GAUGE

We next transform $(\omega,\mathbf{Q})$ to other gauges and examine solutions there. We first consider the $\phi=0$ gauge.

Proof of Theorem 3: Let $q(x,t)$ satisfy

$$\partial_t q = \frac{1}{\sigma}\,\mathrm{div}\,\mathbf{Q} \quad \text{in } D_T,$$

$$q\left(x,\frac{T}{2}\right)=0 \quad \text{for } x\in\Omega,$$

$$q=\mathcal{E}(q) \quad \text{in } E_T.$$

From Sec. III that we have

$$\mathcal{E}(\mathrm{div}\,\mathbf{Q})\in C^\infty((0,T);C_c^{2+\alpha}(B_R))\cap W_2^{2,1}(E_T)$$

and $\partial_{\boldsymbol{\nu}}\,\mathrm{div}\,\mathbf{Q}=0$ on $\partial\Omega\times(0,T)$. Moreover if $\partial\Omega\in C^{k+\alpha}$ for $k\geqslant 3$ then

$$\mathcal{E}(\mathrm{div}\,\mathbf{Q})\in C^\infty((0,T);C^{k+\alpha}(\bar{\Omega}))\cap C^\infty((0,T);C_c^{k+\alpha}(B_R\setminus\Omega)).$$

It follows that

$$(\upsilon,\mathbf{B})\equiv(\upsilon,\mathbf{S}+h\mathbf{a})\equiv(\omega e^{-iq},\mathbf{Q}-\nabla q+h\mathbf{a})$$

is a solution to (2.17)–(2.19) in $\mathfrak{A}$, that is classical for $t>0$ with $(\upsilon(x,0),\mathbf{B}(x,0))=(\psi_0 e^{-iq(x,0)},\mathbf{A}_0-\nabla q(x,0))$. Thus the weak solution $(\psi,\mathbf{A})$ to (2.17)–(2.20) is represented as

$$(\psi,\mathbf{A})=(\upsilon e^{iq(x,0)},\mathbf{B}+\nabla q(x,0)). \tag{4.1}$$

□

We next solve the initial value problem in the $\mathrm{div}\,\mathbf{A}=0$ gauge.

Proof of Theorem 4: Given $(\psi_0,\mathbf{A}_0)$ we write $\mathbf{A}_0=\tilde{\mathbf{A}}_0+h\mathbf{a}$ with $\tilde{\mathbf{A}}_0\in\mathbb{V}_2$. Let f_0 satisfy

$$\Delta f_0=0 \quad \text{in } \Omega,$$

$$\partial_{\boldsymbol{\nu}} f_0=-\mathbf{A}_0\cdot\boldsymbol{\nu} \quad \text{on } \partial\Omega, \tag{4.2}$$

such that $\int_\Omega f_0\,dx=0$ and $f_0=\mathcal{E}(f_0)$ in $\mathbb{R}^3$. Then $f_0\in\mathring{W}_2^2(B_R)$ and $(\psi_0(x)e^{if_0(x)},\nabla f_0(x)+\mathbf{A}_0)\in\mathfrak{H}$. Let $(\omega,\mathbf{Q}+h\mathbf{a})$ be the solution from Theorem 2 with $(\omega(x,0),\mathbf{Q}(x,0))=(\psi_0 e^{if_0},\nabla f_0+\tilde{\mathbf{A}}_0)$. We decompose $\mathbf{Q}=\nabla f+\mathbf{g}$ with $\nabla f\in\mathbb{V}_1$, and $\mathbf{g}\in\mathbb{V}_2$. Set $q=-f$, $(\psi,\tilde{\mathbf{A}})=(\omega e^{-if},\mathbf{Q}-\nabla f)$, and $\phi=\mathcal{E}((-(1/\sigma)\mathrm{div}\,\mathbf{Q})_{\llcorner\Omega})+\partial_t f$. From the properties for f established in the proof of Theorem 2 we have that $(\psi_1,\mathbf{A}_1,\phi_1)\equiv(\psi,\tilde{\mathbf{A}}+h\mathbf{a},\phi)$ is a classical solution to (1.1) and (1.2) for $t>0$ such that $(\psi_1(t),\mathbf{A}_1(t)-h\mathbf{a})\to(\psi_0,\tilde{\mathbf{A}}_0)$ in $\mathbf{W}_2^1(\Omega)\times\mathbb{V}_2$ as $t\downarrow 0$.

Suppose that there is a second solution $(\psi_2,\mathbf{A}_2,\phi_2)$. Since it is classical as well for $t>0$ we can take the inner product of (1.1) with $\partial_t\psi_m+i\phi_m\psi_m$, the dot product of (1.2) with $\partial_t\mathbf{A}_m+\nabla\phi_m$ for $m=1,2$, and integrate over $\mathbb{R}^3\times(t_0,T)$ for $0<t_0<T$. To get

$$2\int_{t_0}^{T}[\|\partial_t\psi_m+i\phi_m\psi_m\|_{\mathcal{L}_2(\Omega)}^2+\sigma\|\partial_t\mathbf{A}_m+\nabla\phi_m\|_{\mathbf{L}_2(\Omega)}^2]\,dt+G(\psi_m,\mathbf{A}_m)(T)=G(\psi_m,\mathbf{A}_0)(t_0). \tag{4.3}$$

Since $(\psi_m(t),\mathbf{A}_m(t))\to(\psi_0,\mathbf{A}_0)$ as $t\downarrow 0$ for $m=1,2$ we can let $t_0\downarrow 0$ and conclude that (4.3) is valid with $t_0=0$ such that all terms are finite.

Next we set $u_{m,n}(x,t)=\int_{1/n}^{t}\phi_m(x,\tau)\mathrm{d}\tau$ for $m=1,2$ and $n\in\mathbb{N}$. Then we have

$$\sigma\Delta u_{m,n}=\int_{1/n}^{t}\operatorname{div}\mathbf{j}_{s,m}\mathrm{d}\tau \quad \text{in } \Omega,$$

$$\partial_{\boldsymbol{\nu}}u_{m,n}=(\mathbf{A}_m(x,1/n)-\mathbf{A}_m(x,t))\cdot\boldsymbol{\nu} \quad \text{on } \partial\Omega$$

for each $t>0$. It follows from this, that $\lim_{n\to\infty}u_{m,n}=\int_0^t\phi_m\mathrm{d}\tau$ exists in $C([0,T);W_2^2(\Omega))$. We set $q_m=\int_0^t\phi_m\mathrm{d}\tau+f_0$ where f_0 satisfies (4.2). Using this and (4.3) it follows that

$$(\upsilon_m,\mathbf{S}_m)\equiv(\psi_m e^{iq_m},\mathbf{A}_m+\nabla q_m)\in\mathfrak{A}$$

for each m with the same initial data at $t=0$ on Ω. Moreover both are solutions to (2.12) and (2.13). It follows from Lemma 7 that $(\upsilon_1,\mathbf{S}_1)=(\upsilon_2,\mathbf{S}_2)$. This implies, by gauge invariance that curl $\mathbf{A}_1=$curl $\mathbf{A}_2$. Since div $\mathbf{A}_1=$div $\mathbf{A}_2=0$ we have $\mathbf{A}_1=\mathbf{A}_2$. Furthermore $\mathbf{j}_{1,s}=\mathbf{j}_{2,s}$. Since ϕ_m satisfy

$$\Delta\phi_m=\sigma\operatorname{div}\mathbf{j}_{m,s} \quad \text{in } \Omega,$$

$$\partial_{\boldsymbol{\nu}}\phi_m=-\partial_t\mathbf{A}_m\cdot\boldsymbol{\nu} \quad \text{on } \partial\Omega,$$

and $\int_\Omega\phi_m\mathrm{d}x=0$ for each $t>0$ we have $\phi_1=\phi_2$. This implies that

$$\psi_1=\upsilon_1e^{-iq_1}=\upsilon_2e^{-iq_2}=\psi_2.$$

Thus the solution is unique. □

APPENDIX

Lemma A.1: Let $k\in L_2(\mathbb{R}^3)$. *Then there exists a function* $f\in W^2_{2,loc}(\mathbb{R}^3)$ *such that* $\nabla f\in\check{\mathbf{H}}(\mathbb{R}^3)$, $\int_\Omega f\mathrm{d}x=0$, *and* $\Delta f=k$ *in* $\mathbb{R}^3$.

Proof: Let $\{k_\varepsilon\}\subset C_c^\infty(\mathbb{R}^3)$ such that $k_\varepsilon\to k$ in $L_2(\mathbb{R}^3)$ as $\varepsilon\to0$. Set $w_\varepsilon=\Gamma*k_\varepsilon\in C^\infty(\mathbb{R}^3)$ where Γ is the fundamental solution for Δ, $\Gamma(x)=C/|x|$. Then $\nabla w_\varepsilon=0(|x|^{-2})$ and $\nabla^2w_\varepsilon=O(|x|^{-3})$ as $|x|\to\infty$. For r large we have

$$\int_{B_r}|\nabla^2w_\varepsilon|^2\mathrm{d}x=\int_{B_r}|\Delta w_\varepsilon|^2\mathrm{d}x-\int_{\partial B_r}\Delta w_\varepsilon\partial_{\boldsymbol{\nu}}w_\varepsilon\mathrm{d}H^2+\int_{\partial B_r}\partial_{x_i}w_\varepsilon\partial_{\boldsymbol{\nu}}(\partial_{x_i}w_\varepsilon)\mathrm{d}H^2$$

Thus

$$\int_{B_r}|\nabla^2w_\varepsilon|^2\mathrm{d}x=\int_{B_r}|\Delta w_\varepsilon|^2\mathrm{d}x+O(r^{-3}),$$

implying

$$\int_{\mathbb{R}^3}|\nabla^2w_\varepsilon|\mathrm{d}x=\int_{\mathbb{R}^3}|k_\varepsilon|^2\mathrm{d}x.$$

Next we let φ_m be a C^∞ cut off function such that $\varphi_m=1$ on B_m and $\varphi_m=0$ on B_{m+1}^c. Set $\mathbf{Z}_m=\varphi_m\nabla w_\varepsilon\in\mathbf{C}_c^\infty(\mathbb{R}^3;\mathbb{R}^3)$. We see for $n,m\geqslant n_0$ and $\varepsilon>0$ fixed that

$$\|\mathbf{Z}_n - \mathbf{Z}_m\|_{\check{\mathbf{H}}(\mathbb{R}^3)} = O(n_0^{-2}).$$

This implies that $\{\mathbf{Z}_m\}$ is a Cauchy sequence in $\check{\mathbf{H}}(\mathbb{R}^3)$ such that $\mathbf{Z}_m \to \nabla w_\varepsilon$ pointwise.

It follows that $\nabla w_\varepsilon \check{\mathbf{H}}(\mathbb{R}^3)$ for each $\varepsilon > 0$.

Let d_ε be a constant so that $\int_\Omega (d_\varepsilon + w_\varepsilon) dx = 0$ and set $f_\varepsilon = d_\varepsilon + w_\varepsilon$. Let R be such that $\Omega \subset\subset B_R$. Then there exists constants $m_j(R)$, $j = 1, 2$ so that

$$\|f_\varepsilon\|_{L_2(B_R)} \leq m_1 \|\nabla f_\varepsilon\|_{\mathbf{L}_2(B_R)} \leq m_2 \|\nabla f_\varepsilon\|_{\mathbf{L}_6(\mathbb{R}^3)} \leq C m_2 \|\nabla f_\varepsilon\|_{\check{\mathbf{H}}(\mathbb{R}^3)} = C m_2 \|k_\varepsilon\|_{L_2(\mathbb{R}^3)}$$

where C is from (1.11).

Since $k_\varepsilon \to k$ in $L_2(\mathbb{R}^3)$ as $\varepsilon \to 0$ we see there exists $f \in W^2_{2,loc}(\mathbb{R}^3)$ with $\int_\Omega f dx = 0$ so that $f_\varepsilon \to f$ in $W_2^2(B_R)$ for each $R < \infty$, $\nabla f_\varepsilon \to \nabla f$ in $\check{\mathbf{H}}(\mathbb{R}^3)$, and $\Delta f = k$. □

Proposition A.1. $\check{\mathbf{V}}(\mathbb{R}^3) = \mathbb{V}_1 \oplus \mathbb{V}_2$ where

$$\mathbb{V}_1 = \{\mathbf{V} \in \check{\mathbf{H}}(\mathbb{R}^3) : \operatorname{curl} \mathbf{V} = 0\},$$

$$\mathbb{V}_2 = \{\mathbf{W} \in \check{\mathbf{H}}(\mathbb{R}^3) : \operatorname{div} \mathbf{W} = 0\},$$

and $\mathbb{V}_1 \perp \mathbb{V}_2$.

Proof: Let $\mathbf{Z} \in \check{\mathbf{H}}(\mathbb{R}^3)$ and take f as in Lemma A.1 so that $\Delta f = \operatorname{div} \mathbf{Z}$ and $\nabla f \in \check{\mathbf{H}}(\mathbb{R}^3)$. Then $\nabla f \in \mathbb{V}_1$. Set $\mathbf{W} = \mathbf{Z} - \nabla f \in \check{\mathbf{H}}(\mathbb{R}^3)$, then $\operatorname{div} \mathbf{W} = 0$ so that $\mathbf{W} \in \mathbb{V}_2$. The decomposition is unique, since if not there would exist $\mathbb{U} \neq 0$ such that $\mathbf{U} \in \mathbb{V}_1 \cap \mathbb{V}_2$. We see from (1.12) that this is impossible.

Finally since we have

$$\|\mathbf{Z}\|^2_{\check{\mathbf{H}}(\mathbb{R}^3)} = \int_{\mathbb{R}^3} [(\operatorname{div} \mathbf{Z})^2 + |\operatorname{curl} \mathbf{Z}|^2] dx$$

we see the inner product on $\check{\mathbf{H}}(\mathbb{R}^3)$ can be represented as

$$\langle \mathbf{Z}, \mathbf{U} \rangle = \int_{\mathbb{R}^3} [\operatorname{div} \mathbf{Z} \operatorname{div} \mathbf{U} + \operatorname{curl} \mathbf{Z} \cdot \operatorname{curl} \mathbf{U}] dx.$$

From this it is clear that $\mathbb{V}_1 \perp \mathbb{V}_2$. □

Surface barrier for flux entry and exit in mesoscopic superconducting systems

G. R. Berdiyorov, L. R. E. Cabral,[a] and F. M. Peeters[b]
Departement Fysica, Universiteit Antwerpen (Campus Groenenborger), Groenenborgerlaan 171, B-2020 Antwerpen, Belgium

(Received 18 April 2005; accepted 20 April 2005; published online 29 September 2005)

The energy barrier which has to be overcome for a single vortex to enter or exit the sample is studied for thin superconducting disks, rings, and squares using the nonlinear Ginzburg–Landau theory. The shape and the height of the nucleation barrier is investigated for different sample radii and thicknesses and for different values of the Ginzburg–Landau parameter κ. It is shown that the London theory considerably overestimates (underestimates) the energy barrier for vortex expulsion (penetration). © *2005 American Institute of Physics.* [DOI: 10.1063/1.2010351]

I. INTRODUCTION

Vortex matter in superconducting samples with sizes on the scale of the coherence and penetration lengths has attracted much attention in recent years.[1,2] In such small confined systems the interaction between the vortices and the sample surface, which tries to impose the symmetry of the sample boundary on the vortex configurations, becomes important. This interaction of vortices with the surface manifests itself through the existence of hysteresis behavior and different phase transitions.[1,3–8] The hysteresis effect is a consequence of the presence of an energy barrier between the states with vorticity L and $L+1$, known as the Bean-Livingston energy barrier,[9] (see also Ref. 10) which increases the first-vortex entry field H_s beyond the first critical field H_{c1}. According to this model the surface barrier appears due to a competition between the vortex attraction to the sample walls by its mirror image and its repulsion by screening currents. This model was further developed for cylindrical samples,[11–13] thin disks,[14–16] rings,[17–20] and strips.[21–25] Most of these barrier models are based on the London theory and do not account for the process of vortex formation (vortices are treated as point particles) and describe only the vortex motion far from the sample boundary. In this limit it is possible to find an analytical expression for the energy and forces for an arbitrary arrangement of vortices inside the superconductor.

The origin of barriers for flux penetration and expulsion has been considered recently through a numerical study of the Ginzburg–Landau (GL) equations.[26–30] Within the GL theory vortices are extended objects where the superconducting condensate vanishes over a length scale ξ, which is very different from the London theory where vortices are point particles, i.e., $\xi \to 0$. The allowed vortex configurations correspond to different minima of the free energy in configurational space and the lowest barrier between those two minima is a saddle point which corresponds to the flux penetration and expulsion state. Schweigert and Peeters[27,28] presented an approach for finding the saddle point states in thin disks and calculated numerically the heights of the free energy barriers separating the stable states with a different number of vortices. Their approach was later extended to the case of superconducting rings.[29]

In this article we study the surface barrier in mesoscopic disks, rings, and squares for different values of the GL parameter κ though a numerical solution of the GL equations using analytical expressions for the phase of the order parameter as obtained from the London approach. Previous

[a]Present address: Departamento de Fisica, Universidade Federal de Pernambuco, 50670-901, Recife-PE, Brazil.
[b]Electronic mail: francois.peeters@ua.ac.be

studies were limited to the London theory or assumed the limit of very thin disks such that only the first GL equation had to be solved. In our approach, both GL equations are solved self-consistently and by fixing the phase of the order parameter locally we are able to move the vortex through the sample. We compare our results with those obtained from the London theory.

The article is organized as follows. The theoretical formulation of the problem is given in Sec. II. The Bean-Livingston barrier for a single vortex entry/exit in a small radius disk is studied in Sec. III for different thickness of the disk and for different values of the GL parameter. In Sec. IV we compare our calculations with the results obtained from the London theory. The $L=2$ giant vortex state in a superconducting disk is considered in Sec. V, and the break up into a multivortex state is investigated. The surface barrier for vortices in a superconducting ring and in a square sample is investigated in Secs. VI and VII, respectively. The results of the present paper are summarized in Sec. VIII.

II. THEORETICAL FORMALISM

A. Ginzburg–Landau theory

We consider a thin superconducting disk or ring with thickness $d<\xi,\lambda$ immersed in an insulating medium in the presence of a perpendicular uniform magnetic field H_0. Measuring the distance in units of the coherence length ξ, the vector potential $\vec{A}$ in $c\hbar/2e\xi$, the magnetic field in $H_{c2}=c\hbar/2e\xi^2=\kappa\sqrt{2}H_c$, and the order parameter Ψ in $\sqrt{-\alpha/\beta}$ with α,β being the GL coefficients, the system of GL equations can be written in the following form:[5]

$$(-i\vec{\nabla}_{2\mathrm{D}}-\vec{A})^2\Psi=\Psi(1-|\Psi|^2), \tag{1a}$$

$$-\Delta_{3\mathrm{D}}\vec{A}=\frac{d}{\kappa^2}\delta(z)\vec{j}_{2\mathrm{D}}, \tag{1b}$$

$$\vec{j}_{2\mathrm{D}}=\frac{1}{2i}(\Psi^*\vec{\nabla}_{2\mathrm{D}}\Psi-\Psi\vec{\nabla}_{2\mathrm{D}}\Psi^*)-|\Psi|^2\vec{A}, \tag{1c}$$

where the indices 2D, 3D refer to two- and three-dimensional operators, respectively, and $\vec{j}_{2D}$ is the density of the superconducting current. The boundary conditions to Eqs. (1a) and (1b) correspond to zero superconducting current at the sample boundaries and an uniform external magnetic field far from the sample $\vec{A}_{|\vec{r}|\to\infty}=\frac{1}{2}[\vec{r}\times\vec{H}_0]$, respectively. To solve the coupled set of nonlinear Eqs. (1a) and (1b) we follow the numerical approach of Schweigert and Peeters.[4,5]

The Gibbs free energy, in units of $F_0=H_c^2V/8\pi$, for the given vortex states is calculated from

$$F=V^{-1}\int_V[2(\vec{A}-\vec{A}_0)\cdot\vec{j}_{2D}-|\Psi|^4]\mathrm{d}\vec{r}, \tag{2}$$

where integration is performed over the sample volume V, and $\vec{A}_0$ is the vector potential of the uniform magnetic field. For Al disks with 1.3 μm (0.2 μm) radius and 0.13 μm (0.01 μm) thickness the unit F_0 is of the order $\sim 10^3$ eV (2 eV) (see, e.g., Ref. 1). The dimensionless magnetization is defined as

$$M=\frac{\langle H\rangle-H_0}{4\pi}, \tag{3}$$

where $\langle H\rangle$ is the magnetic field averaged over the sample.

B. London approach and phase of the order parameter

In thin films, within the limits $S\gg\xi$ (where S are the transverse dimensions of the film) and $H\ll H_{c2}$, $|\Psi|^2$ is practically constant throughout the specimen, except at distances $\sim\xi$ from the vortex cores or the interface. These conditions are satisfied in the London limit, and one may

consider $|\Psi|^2=$const. with singularities in the phase of Ψ at the vortex core positions. Considering the magnetic field pointing in the z direction, the second G-L equation reduces to the London equation,

$$H_z + \frac{4\pi\Lambda}{c}(\nabla \times \vec{J})_z = \Phi_0 \sum_{k=1}^{L} \delta(\vec{r} - \vec{r}_k), \tag{4}$$

where $\vec{J}=\int_0^d \vec{j}\mathrm{d}z \approx \vec{j}d$, $\Lambda=\lambda^2/d$, and $\vec{r}_k$ is the position of vortex k, d is the film thickness.

In order to solve the London equation one may consider taking $\vec{J}=\nabla\times\hat{z}g$, where $g(\vec{r})$ is the streamline function.[31] This function has the property that $g_\Gamma=$constant, where g_Γ represents the value of $g(\vec{r})$ at the specimen edges. For samples without holes, one may consider $g_\Gamma=0$. Otherwise, $g(\vec{r})$ may take different constant values at each hole and at the edges.[20,32] In addition, in thin films where $\Lambda \gg S$, demagnetization effects can be disregarded, and $H_z \approx H_0$ in Eq. (4). This makes the London equation of the Poisson type

$$-\frac{4\pi\Lambda}{c}\nabla^2 g = \Phi_0 \sum_{k=1}^{L} \delta(\vec{r} - \vec{r}_k) - H_0, \tag{5}$$

which can be solved by standard techniques. Analytical solutions, for example, of the problem of a vortex in a thin disk[14,15] or in a ring,[20] have been found. Such analytical expressions—from which the energy of the system can be calculated—are suitable for simulations of systems containing a large number of vortices.[16]

As pointed out by Fetter[14] g_v, which is the streamline function for a vortex inside the mesoscopic superconductor with zero external magnetic field, and θ (in two-dimensional systems) are related by the real and imaginary parts of a complex function, $\Omega(z)$, since both g_v and θ satisfy Laplace equation (except at the vortex core positions). This allows one to obtain analytic expressions for the phase of the order parameter, θ. For a disk, the phase of the order parameter is given by the imaginary part of[14,16] (see also Ref. 33)

$$\Omega = \sum_{j=1}^{L} \ln\left[\left(\frac{z-(R/z_j)^2 z_j}{z-z_j}\right)\frac{r_j}{R}\right], \tag{6}$$

where $z=r\exp(i\phi)=x+iy$, $z_j=r_j\exp(i\phi_j)$ is the position of vortex j, and R is the disk radius. For the case of rings with inner (outer) radius $a(b)$, θ–for one vortex at $(x,0)$–is the imaginary part of

$$\Omega = \ln\left[\frac{A(z,x))}{B(x)}\right] - \left[N + \frac{\ln(b/x)}{\ln(b/a)}\right]\ln(z/a),$$

$$A(z,x) = \frac{\mathrm{cn}[2\gamma\ln(x/a),m]}{\mathrm{sn}[2\gamma\ln(x/a),m]} - \frac{\mathrm{cn}[\gamma\ln(x/z),m]}{\mathrm{sn}[\gamma\ln(x/z),m]},$$

$$B(x) = \frac{\mathrm{cn}[2\gamma\ln(x/a),m]}{\mathrm{sn}[2\gamma\ln(x/a),m]} - \frac{\mathrm{cn}[\gamma\ln(x/a),m]}{\mathrm{sn}[\gamma\ln(x/a),m]}, \tag{7}$$

where N is the number of vortices inside the hole, $(a\leqslant x\leqslant b,0)$ is the vortex position, cn and sn are the Jacobi elliptic functions, $\gamma=K(m)/\ln(b/a)$, $K(m)$ is the complete elliptic integral and the parameter m is determined by the relation $K(1-m)\ln(b/a)=\pi K(m)$ according to Ref. 20.

For a rectangle with dimensions $0\leqslant x\leqslant a$ and $0\leqslant y\leqslant b$, the complex function which is a solution of Eq. (5) (for $H_0=0$) is given by

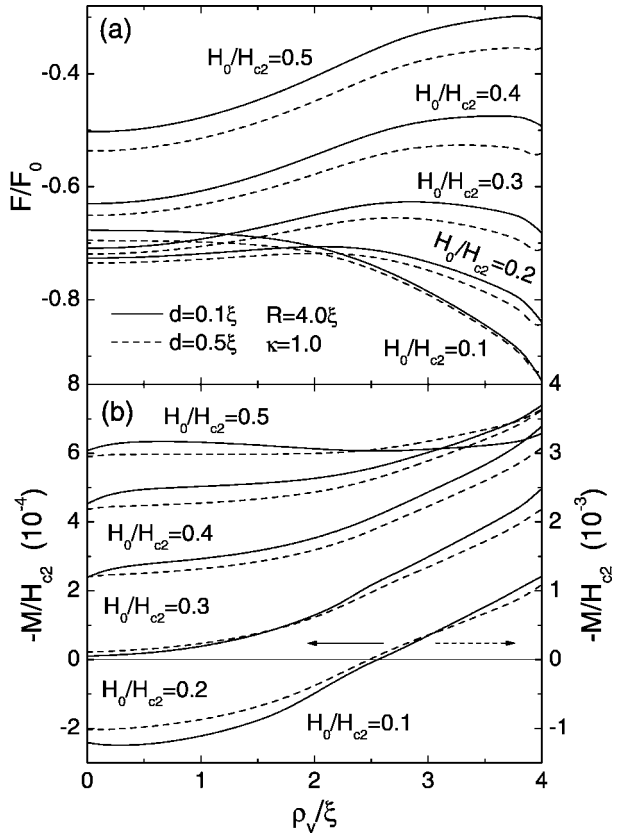

FIG. 1. (a) The free energy and (b) the magnetization of the $L=1$ state as a function of the radial position of the vortex for different values of the applied magnetic field. The radius of the disk is $R=4.0\xi$, the thickness is $d=0.1\xi$ (solid curves) and $d=0.5\xi$ (dashed curves referred to the right axis). The Ginzburg–Landau parameter is $\kappa=1.0$.

$$\Omega=\sum_{j=1}^{L}\ln\left[\frac{\mathrm{sn}^2(K(m)z/a,m)-\mathrm{sn}^2(K(m)z_j^*/a,m)}{\mathrm{sn}^2(K(m)z/a,m)-\mathrm{sn}^2(K(m)z_j/a,m)}\right], \tag{8}$$

which is the same as for the problem of an electric charge inside a rectangle held at zero potential (see Ref. 34). The value of m is now chosen to satisfy $K(1-m)=(b/a)K(m)$ and $z_j^*=r_j\exp(-i\phi_j)$ is the conjugate of the position of vortex j.

III. A SUPERCONDUCTING DISK WITH A SINGLE VORTEX

In earlier works (see, e.g., Refs. 3–5) which were devoted to the study of the properties of superconducting disks, vortex configurations were obtained through a minimization of the energy. In this work we investigate the energy and magnetization of a superconducting disk, by fixing vortices in an arbitrary position for different applied magnetic field. In general, such vortex configurations are not stable. In experiments this can be realized, e.g., by pinning vortices through a pinning potential. First, we consider in Fig. 1 a superconducting disk with radius $R=4.0\xi$ and different thickness d and GL parameter $\kappa=1.0$. For the given parameters of the disk, the $L=1$ state is stable in the magnetic field range $H_0/H_{c2}=0.125-0.71$.[35] As for the bulk case,[9] an energy barrier to flux penetration and expulsion in the disk exists in some magnetic field range. Below this magnetic field range the function $F(\rho_v)$, where ρ_v is the radial position of the vortex, has only one extremum which is a maximum at $\rho_v=0$, i.e., the vortex will leave the sample. At low fields vortices are unstable inside the sample and there is an energy cost associated with vortex entrance. For higher fields it is energetically favorable for the vortex to sit inside the sample and $F(\rho_v)$ is a

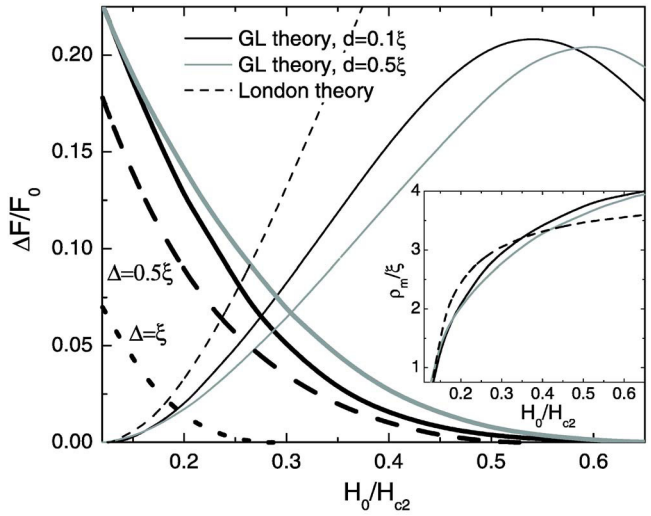

FIG. 2. Energy barrier for the vortex penetration (thick curves) and escape (thin curves) as a function of the applied field for a disk with $R=4.0\xi$, $d=0.1\xi$ (solid black curves), and $d=0.5\xi$ (solid gray curves) and for $\kappa=1.0$. The inset shows the position of the barrier maximum ρ_m as a function of the applied field. The results of the London theory are given by the dashed curves for two different values of the cutoff parameter Δ.

function with a single minimum at $\rho_v=0$. The increase of the disk thickness does not change the qualitative behavior of the free energy but shifts the free energy to lower energy. For small fields the magnetization curves show paramagnetic response (i.e., $M>0$) when the vortex is located close to the center and $-M$ increases with shifting the vortex from the center of the sample. This paramagnetic behavior for the total magnetization results from the existence of the energy barrier. Increasing the disk thickness leads to more flux expulsion from the sample.

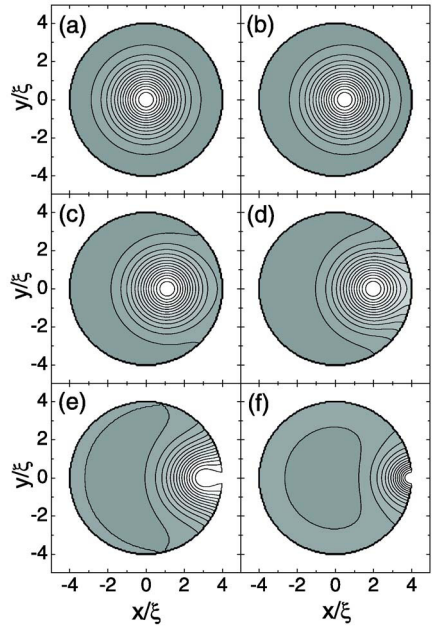

FIG. 3. Contour plots of the Cooper pair density distribution in the disk with radius $R=4.0\xi$, thickness $d=0.1\xi$, $\kappa=1.0$ at $H_0/H_{c2}=0.2$ for different values of the vortex position: (a) $\rho=0\xi$, (b) $\rho=0.5\xi$, (c) $\rho=1.0\xi$, (d) $\rho=2.0\xi$, (e) $\rho=3.0\xi$, and (f) $\rho=3.85\xi$.

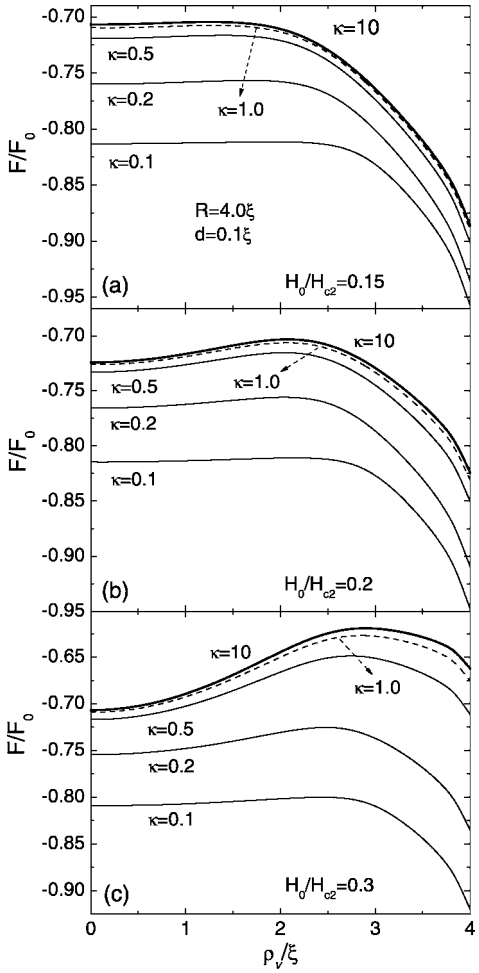

FIG. 4. The free energy as a function of the radial position of the vortex ρ_v for different values of the GL parameter κ and for the applied fields (a) $H_0/H_{c2}=0.15$, (b) $H_0/H_{c2}=0.2$, and (c) $H_0/H_{c2}=0.3$. The radius of the disk is $R=4.0\xi$ and the thickness is $d=0.1\xi$.

Figure 2 presents the energy barrier for vortex penetration (thick curves), $\Delta F_{\text{penetration}}=F_{\max}-F_{\rho_v=R}$, and expulsion (thin curves), $\Delta F_{\text{expulsion}}=F_{\max}-F_{\rho_v=0}$, as a function of the applied field for $d=0.1\xi$ (solid black curves) and $d=0.5\xi$ (solid gray curves). As seen from this figure, the barrier for flux escape disappears at low fields, whereas the barrier for vortex entry increases. Increasing the external field leads to an increase of the barrier for vortex expulsion and to a decrease of the barrier for vortex penetration. The first critical field H_{c1} is the field at which the energy for a vortex inside the superconductor is the same as the energy of the vortex at the sample edge, i.e., $\Delta F_{\text{penetration}}=\Delta F_{\text{expulsion}}$. Therefore, the crossing point of the two barriers determines the first critical field H_{c1}. This barrier is influenced by the sample thickness: the expulsion barrier decreases and the penetration barrier and critical field H_{c1} increases by increasing the thickness. The latter indicates the larger repulsion of the vortex from the surface of the sample with larger thickness. The London theory (dashed curves in Fig. 2) predicts a much larger energy barrier for vortex expulsion (near H_{c1} it is almost a factor of 2 larger). Because the London theory fails close to the sample boundary (i.e., $F\to-\infty$ when $r\to R$), we need to introduce a cutoff distance Δ in order to find finite value for $\Delta F_{\text{penetration}}$. Therefore, within the London theory, we defined $\Delta F_{\text{penetration}}=F_{\max}-F_{\rho_v=R-\Delta}$. The results for two different choices, i.e., $\Delta=\xi$ (dotted curve) and $\Delta=0.5\xi$ (dashed curve), are shown in Fig. 2. For both choices we find that the penetration barrier and the magnetic field range over which this barrier exists, is much smaller within the London approach as

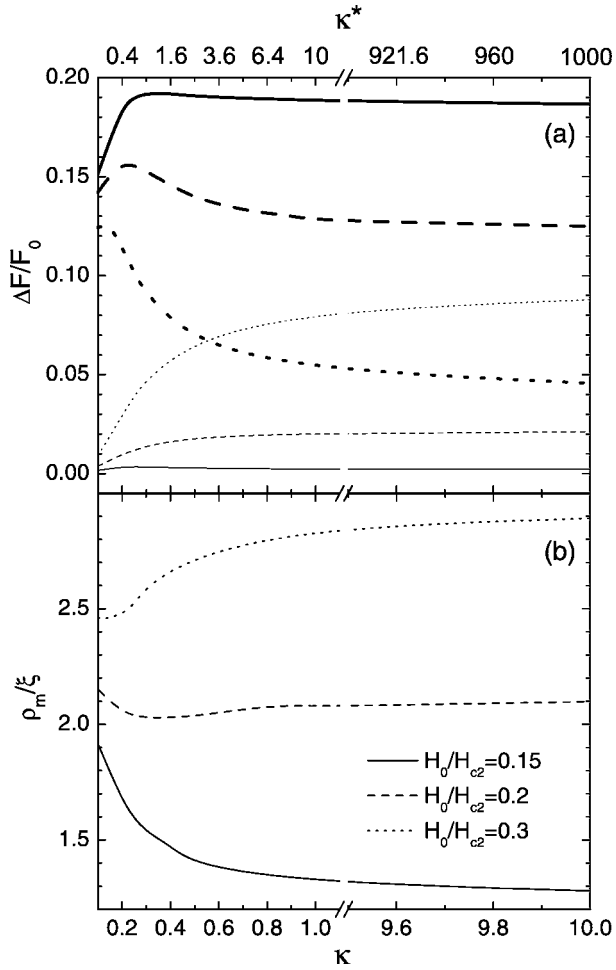

FIG. 5. (a) Energy barrier for flux penetration (thick curves) and escape (thin curves) and (b) the position of the barrier maximum ρ_m as a function of the GL parameter κ for the applied fields $H_0/H_{c2}=0.15$ (solid lines), $H_0/H_{c2}=0.2$ (dashed lines), and $H_0/H_{c2}=0.3$ (dotted lines), with a break at $\kappa=1.1$.

compared to the one in the GL theory. These results show clearly the limited applicability of the surface barrier when obtained from the London theory in case of finite values of the GL-parameter. When calculating the saddle point states, Schweigert and Peeters[27] found a better agreement with the London theory, and a small difference was found only beyond H_{c1}. The position of the barrier maximum ρ_m (see the inset of Fig. 2) is shifted from the center of the sample to the sample boundary with increasing applied field. For small fields ρ_m calculated from the London theory is larger compared to the one obtained from the GL theory and for larger fields the reverse is found.

We found that there is no energy barrier when we place an antivortex inside the disk for any radius of the sample and any positive applied field. The energy minimum is at the edge of the disk and consequently the antivortex will leave the sample.

The spatial distribution of the Cooper-pair density $|\Psi|^2$ calculated for different vortex positions ρ_v is plotted in Fig. 3 for $H_0/H_{c2}=0.2$ and for disk thickness $d=0.1\xi$. Notice the noncircular shape of the contour lines, when the vortex is close to the sample boundary.

The dependence of the surface barrier on the GL parameter κ is shown in Fig. 4. This figure gives the free energy of the disk with radius $R=4.0\xi$ and thickness $d=0.1\xi$, as a function of the vortex position ρ_v for different values of κ, at (a) $H_0/H_{c2}=0.15$, (b) $H_0/H_{c2}=0.2$, and (c) $H_0/H_{c2}=0.3$. Note that the free energy strongly depends on κ: with increasing GL parameter from $\kappa=0.1$ (corresponding to an effective GL parameter $\kappa^*=\kappa^2\xi/d=0.1$) to $\kappa=1.0$ ($\kappa^*=10.0$) (dashed

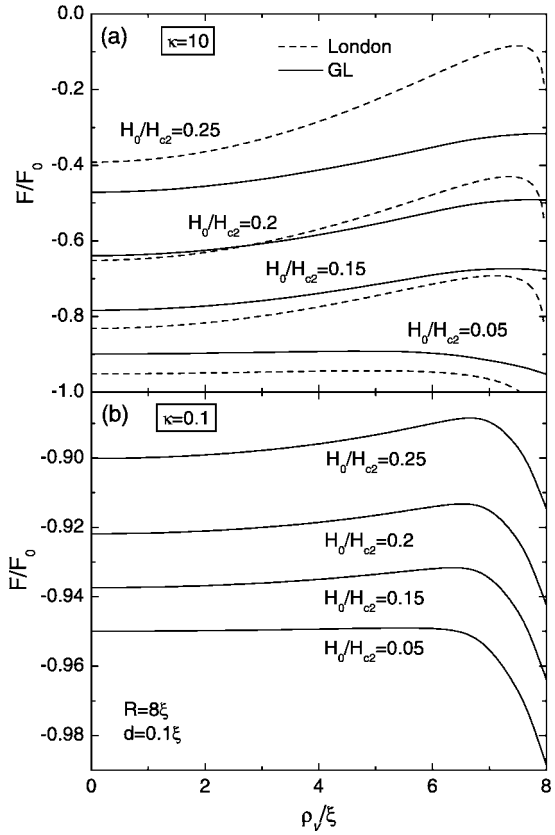

FIG. 6. The free energy of the disk with radius $R=8.0\xi$ and thickness $d=0.1\xi$ as a function of the radial position of the vortex ρ_v for different values of the applied magnetic field. The results from the London theory are given by dashed curves and the results of the GL theory are given by solid curves for (a) $\kappa=10$ and (b) $\kappa=0.1$.

line) the free energy increases considerably, which is due to the larger penetration of the field inside the sample; further increase of κ (thick solid line) leads only to a minor increase of the free energy. We found that the results for $\kappa=10$ ($\kappa^*=1000$) is identical to the results for $\kappa\geqslant 100$.

Figures 5(a) and 5(b) show the height of the barrier for vortex penetration (thick curves) and expulsion (thin curves) and the position of the barrier maximum as a function of κ. At low fields (solid line) the maximum in the expulsion barrier (thin curves) is found for small values of κ and the barrier decreases with further increase of κ. For higher fields (dashed and dotted curves) the expulsion barrier increases with increasing κ and we see the crossing of the curves for penetration and expulsion barrier. At small fields the position of the barrier maximum [Fig. 5(b)] decreases with increasing κ and for higher fields a minimum appears in the plot of the barrier position.

IV. COMPARISON WITH LONDON THEORY FOR LARGE DISKS

The London theory fails close to the sample boundaries at distances of order ξ and for small inter-vortex distances. As a consequence the applicability of the London theory for very small mesoscopic samples is questionable. Therefore, we will consider larger disks and compare the results of the London theory with our GL calculations. In this case the London approach, in which the superconducting density is assumed to be a constant, gives rather accurate results. This model was extended to arbitrary radius of the disk by taking into account the spatial nonuniformity of the modulus of the order parameter in Refs. 16 and 27. This improved version of the London theory was shown to be in good agreement with the GL theory below the nucleation field $H=H_n$ and breaks down for higher fields.

Figure 6 shows the free energy of the superconducting disk with radius $R=8.0\xi$ as a function

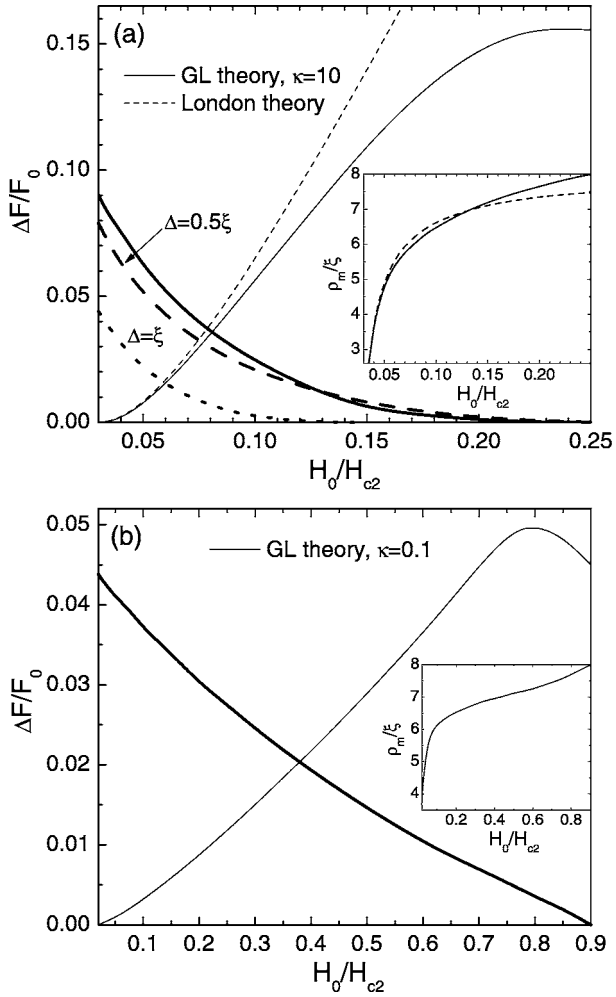

FIG. 7. Energy barrier for vortex penetration (thick curves) and escape (thin curves) as a function of the applied magnetic field for the disk of Fig. 6. Dashed curves are the results of the London theory and solid curves are the one of the GL theory for (a) $\kappa=10$ and (b) $\kappa=0.1$. The insets show the position of the barrier maximum ρ_m as a function of the applied field.

of the vortex position ρ_v, calculated from the London theory (dashed curves) and the GL theory (solid curves) for (a) $\kappa=10$ and (b) $\kappa=0.1$ at different applied fields. The disk thickness is $d=0.1\xi$ whose value is less important in the GL theory [see Eq. (1b)] for larger κ. The free energy shows a similar qualitative behavior in both cases: the appearance of the energy barrier at high fields and its disappearance at lower fields. But the value of the free energy is not the same: at low fields the free energy from the London theory is lower than the free energy of the GL theory which is opposite at higher fields. For small κ the free energy calculated within the GL theory is lower than in the corresponding case of $\kappa=10$, which is the reason why the results of the London theory are not shown in Fig. 6(b).

The height of the energy barrier for the vortex penetration (thick curves) and expulsion (thin curves) is given in Fig. 7 as a function of the applied field. It is seen from this figure that for larger value of κ (a) and at small fields ($H_0<H_{c1}$) our results for the expulsion barrier show good agreement with the one from the London approach. At higher fields the London theory gives a larger expulsion barrier. The penetration barrier within the London limit is calculated for two different values of the cutoff parameter $\Delta=0.5\xi$ (tick dotted curve) and $\Delta=\xi$ (thick dashed curve). For $\Delta=\xi$ a reasonable good agreement with the GL-approach is found for $H_0>H_{c1}$. For small κ [Fig. 7(b)] a surface barrier is found over a larger range of magnetic field, whereas the barrier itself

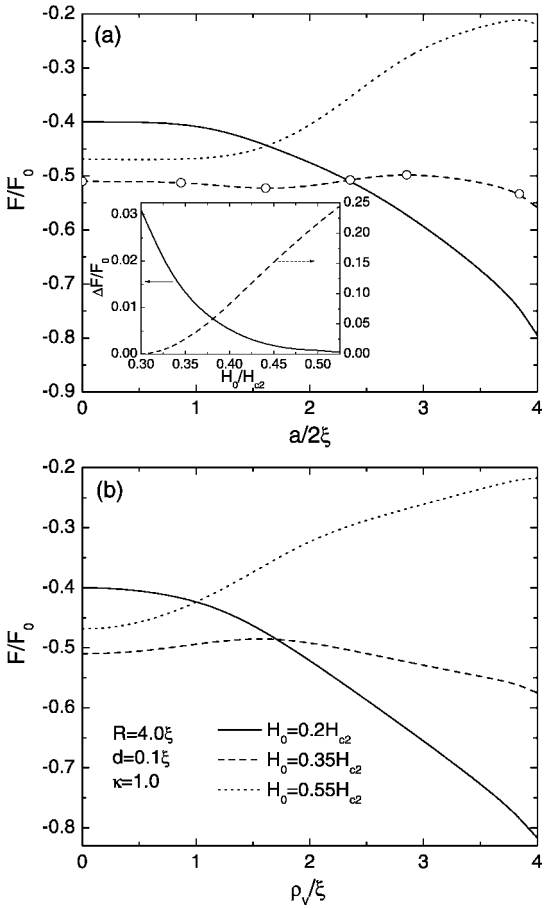

FIG. 8. (a) The free energy of the multivortex ($L=2$) state as a function of the inter-vortex distance a, and (b) the free energy of the giant vortex ($L=2$) state as a function of the radial position of the giant vortex ρ_v for different magnetic fields. The inset shows the height of the energy barrier for the transition from the multivortex $L=2$ state to the giant vortex $L=2$ state (solid curve) and for the transition from multivortex $L=2$ state to the $L=0$ state (dashed curve, referred to the right axis) as a function of the applied field. The radius of the disk is $R=4.0\xi$, the thickness is $d=0.1\xi$, and $\kappa=1.0$.

is smaller than for the larger κ case. If we compare these results with the one for a smaller disk radius (Fig. 2) we see that the barrier height and the magnetic field range, where this barrier exists, decreases with increasing R for fixed κ.

V. THE $L=2$ STATE IN A DISK

A. Giant vortex versus multivortex state

For larger disk radius (i.e., $R \geqslant 3.0\xi$), several vortices can enter the sample at once (see for example Ref. 28), indicating that at the entrance field the energy barriers separating the different vortex states become very small. In such samples many different superconducting states can exist at a given magnetic field. Our approach allows us to study the transitions between these states and calculate the energy barrier as a function of the vortex position for any number of vortices L.

We start with the most simple case—the $L=2$ state, which was studied in Ref. 28 within the modified London approach. Figure 8(a) shows the free energy for a disk with $R=4.0\xi$ and $d=0.1\xi$ as a function of the inter-vortex distance a for different applied fields. It is seen that, at larger magnetic fields (dotted curve, $H_0=0.55H_{c2}$), the free energy has a minimum when both vortices are located in the center implying that the giant vortex state is preferred. With decreasing magnetic field (dashed curve, $H_0=0.35H_{c2}$) the free energy has a minimum when the vortices are separated at a distance $a=3.22\xi$ and has a maximum for $a=5.7\xi$, which shows that at this mag-

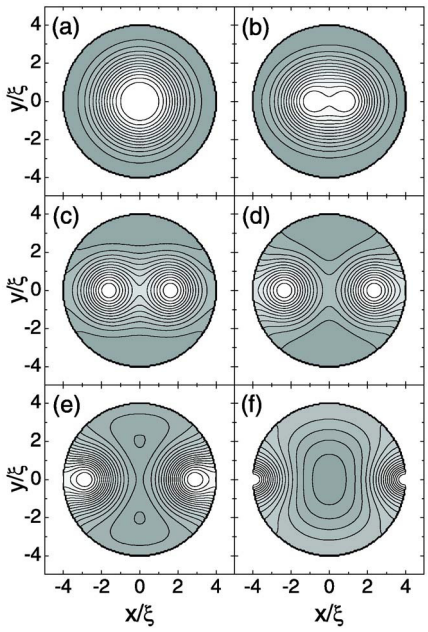

FIG. 9. Contour-plot of the Cooper pair density for a disk with $R=4.0\xi$, $d=0.1\xi$, $\kappa=1.0\xi$ at $H_0/H_{c2}=0.35$ and the distance between vortices is: (a) $a/2=0\xi$, (b) $a/2=0.87\xi$, (c) $a/2=1.61\xi$, (d) $a/2=2.36\xi$, (e) $a/2=2.85\xi$, and (f) $a/2=3.85\xi$.

netic field the multivortex state is energetically favorable. The inset of Fig. 8 shows the height of the energy barrier for the transition from this multivortex state to the giant vortex state (solid curve) and for the transition from the multivortex state to the $L=0$ state (dashed curve, referred to the right axis). Further decreasing the field (solid line, $H_0=0.2H_{c2}$) there is no energy barrier for vortex expulsion and vortices leave the sample. To compare with the multi-vortex state, we plotted in Fig. 8(b) the free energy of the giant vortex state with $L=2$ as a function of the radial position of the giant vortex. It is seen from this figure that the giant vortex behaves similar to what we found for a single vortex: at small fields there is a barrier for the giant vortex to enter the sample which disappears with increasing applied field. The distribution of the Cooper-pair density for different values of a, which are indicated by open circles in Fig. 8, is shown in Fig. 9.

B. Entrance and exit of the second vortex

Contrary to macroscopic samples, where vortices can be located far from the edge of the sample, in mesoscopic samples vortices are confined by the potential well generated by the sample surface, and even a vortex fixed in the center of the sample is still influenced by the edge, generating a contribution to the barrier for the next vortex entry and exit. Now, we fix the first vortex at a given point and change the position of the second vortex. Although the presence of a second vortex influences the first vortex position, a pinning center can fix the first vortex position, i.e., one can study the energy landscape for the second vortex when the first is pinned at ρ_0.

Figures 10(a)–10(c) show the free energy of the superconducting disk for $R=4.0\xi$ and $d=0.1\xi$ as a function of the second vortex position ρ_v, when the first vortex is fixed in the same radial line with the second one (see Fig. 11) at $\rho_0=0$ (solid curve), $\rho_0=R/2$ (dashed curve), and $\rho_0=R$ (dotted curve). At $H_0/H_{c2}=0.2$ (a) and $\rho_0=0$ the second vortex prefers to leave the sample, because there is no barrier for the exit of this vortex (solid line). The barrier for the second vortex exit appears when we shift the first vortex to the sample boundary (dotted line). Notice that for this value of the applied field a single vortex feels a largest energy barrier (compare with Fig. 2). For higher fields [Figs. 10(b) and 10(c)] a giant vortex state in the center of the sample becomes energetically favorable. Figure 11 shows the contour plot for the Cooper pair density for different positions of the first and second vortex at $H_0/H_{c2}=0.35$.

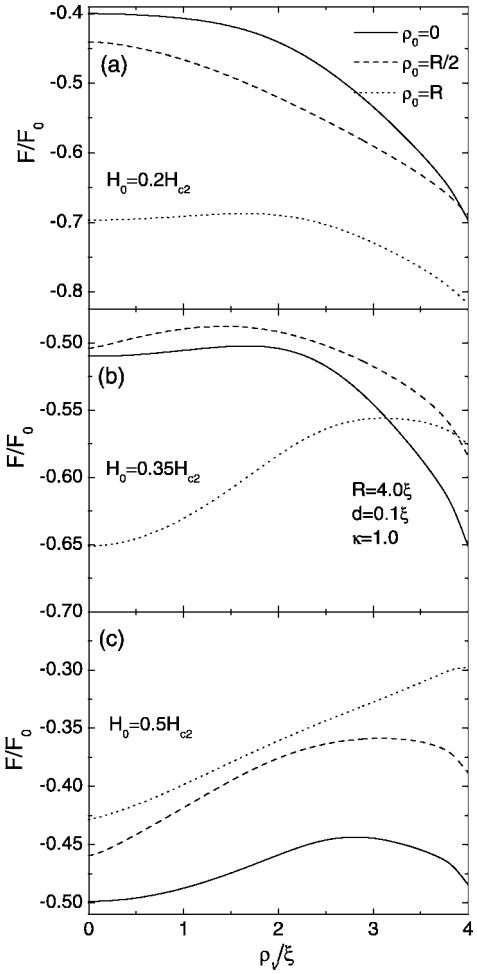

FIG. 10. The free energy of the $L=2$ state as a function of the second vortex position ρ_v, when the first vortex is fixed at $\rho_0=0$ (solid curve), $\rho_0=R/2$ (dashed curve), and $\rho_0=R$ (dotted curve), at different magnetic fields (a) $H_0=0.2H_{c2}$, (b) $H_0=0.35H_{c2}$, and (c) $H_0=0.5H_{c2}$. The radius is $R=4.0\xi$, thickness is $d=0.1\xi$ and $\kappa=1.0$.

VI. SUPERCONDUCTING RING

Although the problem of flux quantization in large superconducting rings was shown experimentally a long time ago,[36] recently there was renewed interest for fluxoid dynamics in such a geometry (see, e.g., Ref. 19), where jumps in the magnetization curve corresponding to changes of the vorticity larger than unity[17] were observed. These jumps appear due to the presence of several metastable states with different vorticity L at a given field and strongly depends on the stability condition for those metastable states.[18] Transitions between these states were investigated within the GL theory in Ref. 29 through the saddle point, i.e., the lowest barrier between two different energy minima. The time for flux penetration and expulsion is determined by the height of the energy barrier. In this section we consider superconducting rings with different inner and outer radii and calculate the energy barrier for flux penetration/exit. This problem was recently considered in Ref. 20 in the London limit.

As an example, we consider a superconducting ring with outer radius $R=15\xi$, inner radius $R_i=5\xi$, thickness $d=0.1\xi$, and $\kappa=1.0$. Figures 12(a)–12(c) show the free energy of the ring as a function of the radial position of the vortex ρ_v for different values of the applied field. At low fields (a) and when there is no vortex trapped inside the ring ($L_0=0$) the maximum of the barrier is in the center of the superconducting region of the ring and the free energy is lowest at the outer

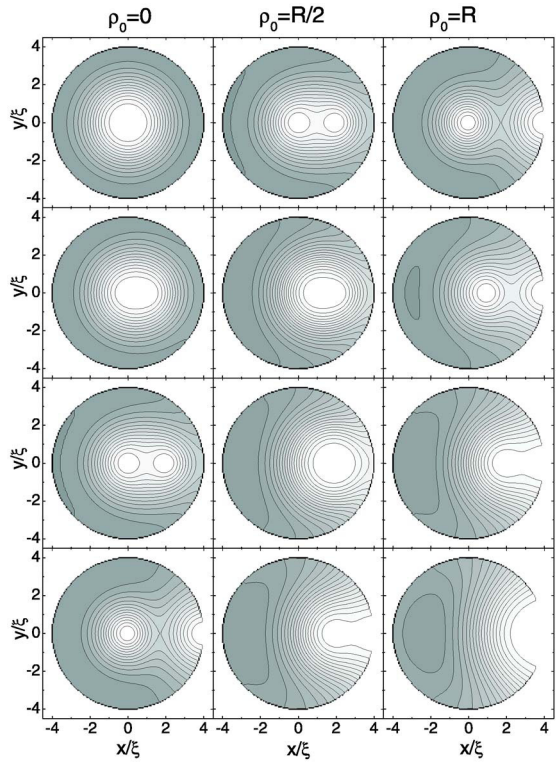

FIG. 11. The Cooper pair density of the $L=2$ state in the disk with $R=4.0\xi$ and $d=0.1\xi$ at $H_0/H_{c2}=0.35$. The first vortex is fixed at $\rho_0=0$ (first column), $\rho_0=R/2$ (second column), and $\rho_0=R$ (third column). From top to bottom figures we positioned the second vortex at $\rho_1=0$ (first row), $\rho_1=1.0\xi$ (second row), $\rho_1=2.0\xi$ (third row), and $\rho_1=4.0\xi$ (fourth row).

ring edge indicating that it costs energy to add an additional vortex inside the ring. When increasing the field the barrier maximum shifts to the outer boundary of the sample [Figs. 12(b) and 12(c)]. The inset of Fig. 12 shows the height of the energy barrier for flux penetration (thick curve) and escape (thin curve) as a function of the applied field. It is seen from this figure that even for zero applied field there is a barrier for vortex expulsion and we have to apply negative field to transit to the $L=0$ state. If there are one or more vortices inside the ring the energy barrier shifts to the inner boundary of the sample and the vortex prefers to leave the sample. For some critical value of the applied field and for a given number of vortices inside the ring the energy has a local minimum in the superconducting region of the ring [dotted and thick solid curves in Fig. 12(c)] indicating that a vortex can be trapped in a metastable state in the superconducting region of the ring. This is more pronounced when there are more vortices inside the ring and the field is higher [thick solid curve in Fig. 12(c)]. For $H_0/H_{c2}=0.05$ it is clear from Fig. 12(c) that energetically it is more favorable to add one extra vortex inside the sample when $L_0 \leqslant 3$. Figure 13 shows contour plots of the phase of the order parameter (left column) and Cooper pair density (right column) for $L_0=1$ and different position of the vortex. Notice that a closed path within $\rho < rho_v$, we correctly have a change in the phase of 2π (i.e., one flux is trapped inside the ring). If, otherwise, we choose a closed path including the vortex position, ρ_v, the phase changes by 4π. The contour lines of the Cooper pair density are nearly circular close to the vortex core, but are distorted farther away due to the geometry of the sample.

VII. SQUARE SAMPLE

The energy barrier for flux penetration and exit in mesoscopic superconductors is partly due to a geometric barrier, which depends on the shape of the sample, and is even more pronounced for superconductors with rectangular cross section. In such samples the edge barrier is caused by a

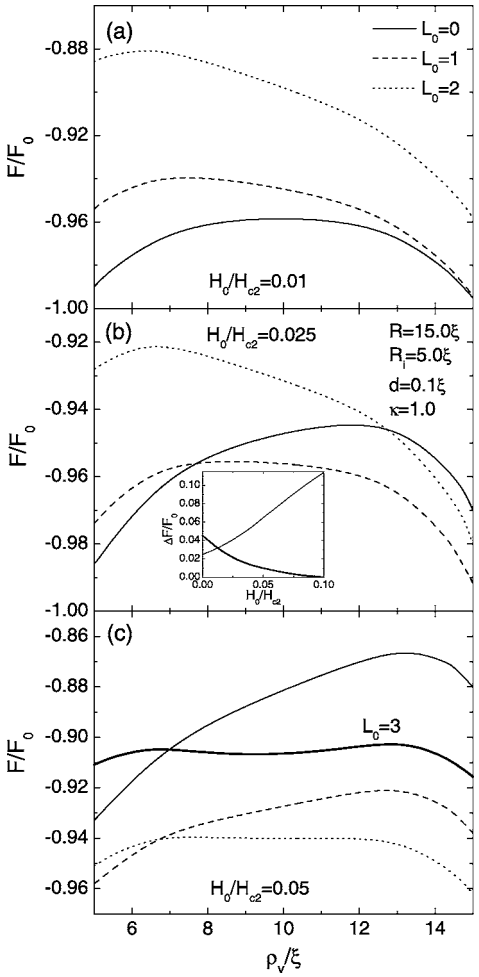

FIG. 12. The free energy of the superconducting ring with outer radius $R=15\xi$, inner radius $R_i=5\xi$, thickness $d=0.1\xi$, and $\kappa=1.0$ as a function of the radial position of the vortex ρ_v for three values of the applied field (a) $H_0=0.01H_{c2}$, (b) $H_0=0.025H_{c2}$, and (c) $H_0=0.05H_{c2}$. The number of vortices inside the hole is $L_0=0$ (solid curves), $L_0=1$ (dashed curves), and $L_0=2$ (dotted curves). Thick solid curve (c) corresponds to $L_0=3$ and $H_0=0.075H_{c2}$. The inset in (b) shows the height of the energy barrier for flux penetration (thick curve) and expulsion (thin curve) for $L_0=0$ as a function of the applied field.

delayed penetration of flux lines at the four corners and exhibits hysteretic behavior even if the sample is free of pinning centers.[22–24] Therefore, in this section we consider a square superconducting sample to study the influence of its edges to the surface barrier. Superconducting cylinders with rectangular cross section were recently considered in Ref. 37 within the London theory in the presence of an axial magnetic field. Calculations show that the energy barrier is higher in the corners and the first vortex tends to enter the sample through the middle of the edges.[38]

Figure 14 shows the contour plot of the free energy of the square superconductor with size $a=8.0\xi$, thickness $d=0.1\xi$, and $\kappa=1.0$ for four different values of the applied field, where dark gray regions correspond to higher energy. At small fields (a) the energy is maximum when the vortex is at the center of the sample and decreases when the vortex approaches to the boundary. The plot of the cross sections (right column) shows that the energy is lower in the corners. An increase of the magnetic field leads to the appearance of an energy barrier (b,c) which is higher near the corners of the sample. By further increasing the applied field (d) the position of the barrier shifts to the sample boundary. It is seen from the plot of the cross sections of the barrier energy that the barrier disappears first near the edges of the sample, which means that the vortex penetrates the sample through the center of the edges and not through the corners of the sample.

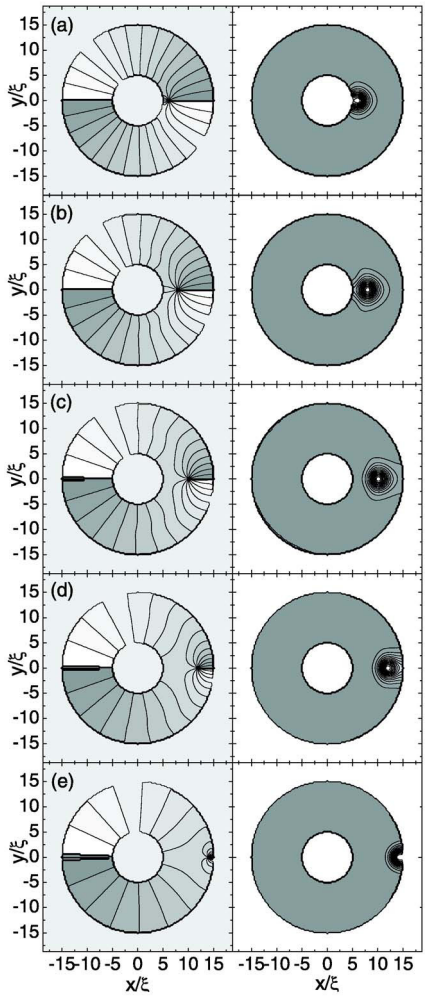

FIG. 13. Contour plots of the phase of the order parameter (left column) and Cooper pair density (right column) at $H_0/H_{c2}=0.01$ for $L_0=1$ for the ring of Fig. 12. Phases near zero are given by white regions and phases near 2π by gray regions. The position of the vortex is (a) $\rho_v=6.0\xi$, (b) $\rho_v=8.0\xi$, (c) $\rho_v=10.0\xi$, (d) $\rho_v=12.0\xi$, and (e) $\rho_v=14.0\xi$.

Figure 15 shows the energy barrier for vortex penetration (thick curves) and expulsion (thin curves) along the diagonal (dashed curves) and side (solid curves) of the square. It is seen from this figure that the vortex feels the largest barrier along the diagonal of the sample. This also means that a vortex placed in the square center has more freedom to wander laterally towards the edges than along the diagonals of the square.

VIII. CONCLUSIONS

We have presented an approach to calculate the energy barrier when a single vortex enters or exits superconducting mesoscopic finite size sample. Our approach is based on a numerical solution of the coupled nonlinear GL equations using analytical expressions for the phase of the order parameter obtained from the London theory.

First we calculated the energy barrier in superconducting disks with small radius and for different values of the disk thickness and GL parameter κ. These results for the energy barrier show clearly the limitations of the London theory which considerably overestimates (underestimates) the barrier for vortex expulsion (penetration). The discrepancy between the results from the GL approach and the one from the London theory decreases with increasing size of the disk. The

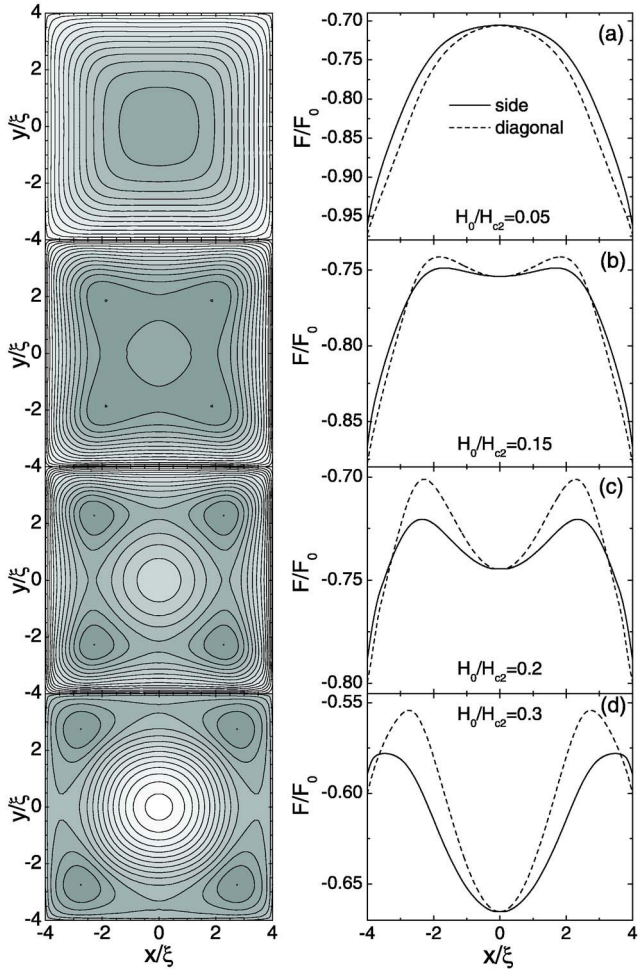

FIG. 14. Contour plots of the dependence of the free energy (left column) on the position of the vortex and cross sections (right column) for $y=0$ (solid curves) and for $x=y$ (dashed curves) in a square sample with side $a=8.0\xi$ and thickness $d=0.1\xi$ and $\kappa=1.0$ for four values of the applied field: (a) $H_0/H_{c2}=0.05$, (b) $H_0/H_{c2}=0.15$, (c) $H_0/H_{c2}=0.2$, and (d) $H_0/H_{c2}=0.3$.

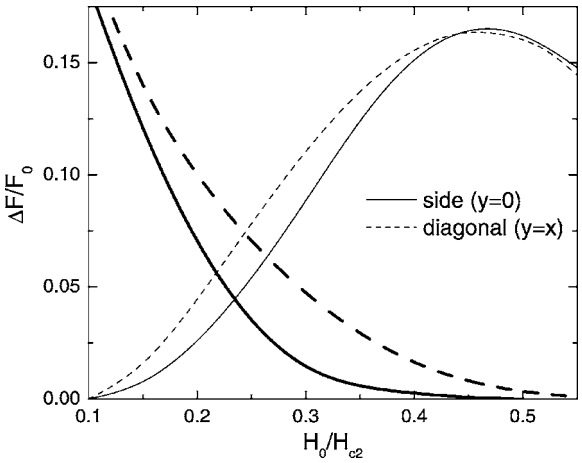

FIG. 15. The energy barrier for vortex penetration (thick curves) and expulsion (thin curves) along the side (solid curves) and diagonal (dashed curves) of the sample as a function of the external field for the sample of Fig. 14.

energy barrier strongly depends on the GL parameter κ: the magnetic field range over which the barrier exists is larger (consequently, the first critical field H_{c1}) for small values of κ, for which the sample behaves like a type-I superconductor.

We also studied the $L=2$ state in the disk and found for some values of the field an energy barrier between the multivortex and the giant vortex state. We also considered a superconducting ring and a square disk. For a superconducting ring we found a minimum in the free energy in the superconducting region of the sample for some range of magnetic field values when there are a number of vortices inside the hole, indicating that a vortex can be trapped in a metastable state in this region. For a superconducting square the vortex feels a larger barrier along the diagonal of the sample, while the lowest barrier is found along the middle of the sides of the square. The results for the square confirm the vortex entry laterally, through the sample edge.

(Received 22 April 2005; accepted 22 April 2005; published online 29 September 2005)

We build a discrete form for the Ginzburg–Landau thermodynamic potential for an infinite film and find how the TDGL equations are related to it. We discuss why the usual superconductor-insulator boundary condition, which prohibits the passage of superconducting current, should be questioned in dynamic problems; nevertheless, we conclude that this condition remains valid. The formalism we develop enables us to deal with situations in which surface charge is present at the boundaries. These situations include the Hall configuration when the influence of the normal electrons is not negligible and the case of an electromagnetic wave parallel to the film. In the case of the electromagnetic wave, we evaluate the electromagnetic field inside the superconductor and follow the motion of the vortices. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2010352]

I. INTRODUCTION

A widely used system of equations for the evolution of physical quantities in a superconductor is a simplified version of the time-dependent Ginzburg–Landau equations:[1]

$$\partial_t \psi = -\frac{1}{\eta}[(-i\nabla - \mathbf{A})^2\psi + (1-T)(|\psi|^2 - 1)\psi] + \tilde{f}, \tag{1}$$

$$\partial_t \mathbf{A} = (1-T)\mathrm{Re}[\overline{\psi}(-i\nabla - \mathbf{A})\psi] - \kappa^2 \nabla \times \nabla \times \mathbf{A}. \tag{2}$$

Here ψ is the order parameter, t is time, $\mathbf{A}$ is the electromagnetic vector potential, η is the ratio between the relaxation times of ψ and $\mathbf{A}$, κ is the Ginzburg-Landau parameter, T is the temperature and $\tilde{f}$ a random "force" that simulates thermal fluctuations. ψ has been normalized so that in the absence of electromagnetic field its absolute value would be 1, the unit of time is $4\pi\kappa^2\xi^2(0)\sigma/c^2$, where $\xi(0)$ is the coherence length at zero temperature and σ is the conductivity, the unit of length is $\xi(0)$, the unit of temperature is the critical temperature, and the the unit of $\mathbf{A}$ is $\Phi_0/2\pi\xi(0)$, where $\Phi_0 = hc/2e$ is the quantum of flux. We have chosen a gauge such that the scalar potential is zero.

We will regard η as a material-dependent parameter, although for given microscopic models its value is prescribed by the model. As a general policy for this article, the parameter values that we will consider are not necessarily those of typical materials, but rather those that easily exhibit the effects that I would like to present.

When the exterior of the sample is insulating, these equations are usually supplemented by the boundary conditions

a)Electronic mail: phr76jb@tx.technion.ac.il

$$\hat{\nu} \cdot (-i\nabla - \mathbf{A})\psi = 0, \tag{3}$$

where $\hat{\nu}$ is a vector perpendicular to the interface, and

$$\nabla \times \mathbf{A} = \nabla \times \mathbf{A}_e, \tag{4}$$

where $\mathbf{A}_e$ is the vector potential at the external part of the interface and in general is obtained by solving Maxwell's equations in the exterior. The main purpose of this article is the revision of these boundary conditions.

This set of equations is usually integrated by a finite-differences method. As a few examples, see Refs. 2–5.

In this study we will limit ourselves to a very simple geometry: an infinite superconducting film with boundaries at the planes $y=0$ and $y=d$, with magnetic field in the z direction. We will assume that the quantities in the problem do not depend on z. In this situation, $\mathbf{A}$ can be taken perpendicular to the z axis.

II. USEFUL EQUALITIES

A. Gauge factor

We define the unitary fields

$$\mathcal{U}^x(x,y,t) = \exp\left(-i\int_0^x A_x(x',y,t)\mathrm{d}x'\right), \tag{5}$$

and similarly we define $\mathcal{U}^y$. We follow a notation in which A_x denotes the component of $\mathbf{A}$ in the x direction. An inherent problem when using A_x is that it grows indefinitely with time if the average electric field in the x direction does not vanish; use of $\mathcal{U}^x$ avoids this problem.

By direct derivation and using the notation $\mathcal{J}^x = \partial_x(\mathcal{U}^x\psi)$ we obtain

$$\overline{\mathcal{U}^x}\mathcal{J}^x = \overline{\mathcal{U}^x}\partial_x(\mathcal{U}^x\psi) = (\partial_x - iA_x)\psi \tag{6}$$

and

$$\overline{\mathcal{U}^x}\partial_x\mathcal{J}^x = \overline{\mathcal{U}^x}\partial_{xx}^2(\mathcal{U}^x\psi) = (\partial_x - iA_x)^2\psi, \tag{7}$$

where the bar denotes complex conjugation.

B. Discretization

Having in view a numeric treatment of the problem by means of a finite difference technique, we introduce a rectangular grid for the coordinates of the position in the sample. Figure 1 shows a miscellaneous portion of the grid. It contains N_y rectangular cells in the y direction. Since we consider an infinite sample, we shall take a reasonably large number N_x of cells in the x direction, that cover a length L, and assume periodic boundary conditions in that direction, with periodicity L. Our discretization scheme will take $\psi(x,y)$ as constant in rectangles centered at the vertices of the grid, as the rectangle "I." The value of $\psi(x,y)$ in the rectangle will be denoted by $\psi_{i,j}$, where (i,j) are the integer coordinates of the vertex at which the rectangle is centered. The sides of the rectangle are $a_x = L/N_x$ and $a_y = d/N_y$. On the other hand, $\partial_x\psi(x,y)$ and $A_x(x,y)$ will be taken as constant in rectangles such as II, which have their vertical sides centered at neighboring vertices. The size of these rectangles is also $a_x \times a_y$.

Special care is required when dealing with quantities at the boundaries $y=0$ and $y=d$, which are marked as thick lines in Fig. 1. $\psi_{5,0}$ is the value of ψ in rectangle III, and the subscript $(3,N_y)$ will be used for $\partial_x\psi$ and A_x in rectangle IV. Both these rectangles have size $a_x \times a_y/2$. On the other hand $\partial_y\psi$ and A_y will have a constant value in rectangles like V, which have size $a_x \times a_y$, even if they touch the boundary.

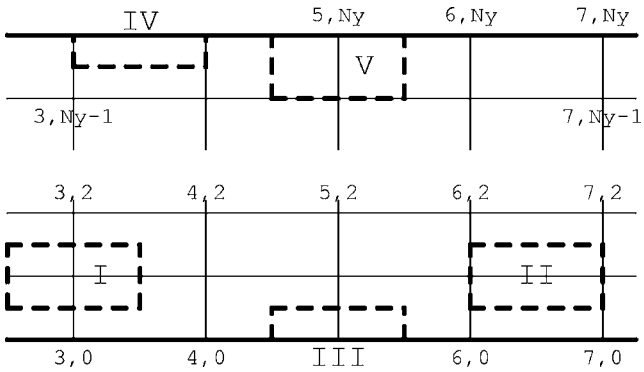

FIG. 1. The dashed rectangles enclose areas over which the fields of the model are approximated by constants. The thick lines are the boundaries of the superconductor.

We define now the link variable $U^x_{i,j}=\exp(-iA_x a_x)$ [respectively, $U^y_{i,j}=\exp(-iA_y a_y)$] where A_x is taken at the rectangle between the vertices (i,j) and $(i+1,j)$ [respectively, between (i,j) and $(i,j+1)$]. In the discrete approximation we have

$$\mathcal{U}^x(x_i,y_j)=\prod_{k=0}^{i-1} U^x_{k,j}, \tag{8}$$

where $x_i=ia_x$ and $y_j=ja_y$, and similarly for $\mathcal{U}^y$. Using Eqs. (7) and (8) and discretizing the second derivative we obtain

$$(\partial_x - iA_x)^2\psi\big|_{x_i,y_j}=(U^x_{i,j}\psi_{i+1,j}-2\psi_{i,j}+\overline{U}^x_{i-1,j}\psi_{i-1,j})/a_x^2 \tag{9}$$

so that the discrete approximation for Eq. (1), excluding the noise, can be written as

$$\eta\partial_t\psi_{i,j}=\frac{U^x_{i,j}\psi_{i+1,j}-2\psi_{i,j}+\overline{U}^x_{i-1,j}\psi_{i-1,j}}{a_x^2}+\frac{U^y_{i,j}\psi_{i,j+1}-2\psi_{i,j}+\overline{U}^y_{i,j-1}\psi_{i,j-1}}{a_y^2}-(1-T)(|\psi_{i,j}|^2-1)\psi_{i,j}. \tag{10}$$

We build now a discrete free energy. The Ginzburg–Landau free energy can be written as

$$G=G^v+G^x+G^y+G^A \tag{11}$$

where G^v is the contribution of the vertices, G^x is the contribution of the links in the x direction and G^y in the y direction, and G^A does not depend on ψ. Explicitly,

$$G^v=(1-T)\int(|\psi|^4/2-|\psi|^2)\mathrm{d}x\,\mathrm{d}y, \tag{12}$$

$$G^x=\int|(-i\partial_x-A_x)\psi|^2\mathrm{d}x\,\mathrm{d}y=\int|\partial_x(\mathcal{U}^x\psi)|^2\mathrm{d}x\,\mathrm{d}y \tag{13}$$

and similarly for G^y. The integrals are over the volume of a period.

We now replace the integrals over volume by sums over rectangles. For G^v we obtain

$$G^v = (1-T)\sum ((\overline{\psi}_{i,j}\psi_{i,j})^2/2 - \overline{\psi}_{i,j}\psi_{i,j})V^v_{i,j}, \tag{14}$$

where $V^v_{i,j}$ is the volume of a rectangle of the type I or III in Fig. 1, which is appropriate for the vertex at (i,j). The sum is over a set of rectangles that cover a period. For G^x we discretize the derivative, make use of Eq. (8) and obtain

$$G^x = \frac{1}{a_x^2}\sum (\overline{U^x_{i,j}\psi}_{i+1,j} - \overline{\psi}_{i,j})(U^x_{i,j}\psi_{i+1,j} - \psi_{i,j})V^x_{i,j}, \tag{15}$$

where $V^x_{i,j}$ is the volume of the appropriate rectangle between the vertices at (i,j) and at $(i+1,j)$. For G^y we have a similar expression, but this time the rectangles are between the vertices at (i,j) and at $(i,j+1)$.

For a vertex (i,j) in the interior of the sample, all the four neighbors $(i\pm1,j)$ and $(i,j\pm1)$ are present in the sums and $V^v_{i,j}=V^x_{i,j}=V^y_{i,j}=a_xa_y$, so that

$$-\frac{1}{V^v_{i,j}}\frac{\partial G}{\partial\overline{\psi}_{i,j}} = -(1-T)(|\psi_{i,j}|^2-1)\psi_{i,j} + \frac{U^x_{i,j}\psi_{i+1,j} - 2\psi_{i,j} + \overline{U^x_{i-1,j}\psi}_{i-1,j}}{a_x^2} + \frac{U^y_{i,j}\psi_{i,j+1} - 2\psi_{i,j} + \overline{U^y_{i,j-1}\psi}_{i,j-1}}{a_y^2} \tag{16}$$

and comparison with Eq. (10) gives

$$\eta\partial_t\psi_{i,j} = -\frac{1}{V^v_{i,j}}\frac{\partial G}{\partial\overline{\psi}_{i,j}} \tag{17}$$

for every vertex in the interior of the sample.

III. BOUNDARY CONDITION FOR THE MAGNETIC FIELD

Assuming that the superconductor and the insulator are not magnetic (i.e., have the same permeability as in vacuum), which is the usual situation in superconductivity, there is no need to distinguish between the magnetic field and the magnetic induction (except for a possible universal factor that depends on the units) and this field is given by $\nabla\times\mathbf{A}$. Since the divergence of $\nabla\times\mathbf{A}$ vanishes identically and since its rotor is proportional to the current density, that is finite, $\nabla\times\mathbf{A}$ is continuous everywhere and Eq. (4) follows.

In some articles it is claimed that only some of the components of $\nabla\times\mathbf{A}$ are continuous at the interface. This would be the case if the permeability were discontinuous, but in practically any situation this is an unnecessary complication.

In most articles that deal with numeric solutions, the implementation of Eq. (4) is not shown explicitly. Perhaps the only exception is Ref. 4. In Ref. 4 Eq. (4) is not enforced at the boundary itself, but rather at the cells that touch the boundary. Although both requirements become equivalent in the limit of a dense grid, Eq. (4) can be substituted by a condition at the boundary itself by requiring an adapted form of Eq. (2):

$$\partial_t(A_x)_{i,0} = \frac{1-T}{a_x}\mathrm{Im}(\overline{\psi}_{i,0}U^x_{i,0}\psi_{i+1,0}) + \frac{2\kappa^2}{a_xa_y^2}\mathrm{Im}(\exp(ia_xa_yH_e)U^x_{i,0}U^y_{i+1,0}\overline{U^x_{i,1}}\,\overline{U^y_{i,0}}), \tag{18}$$

where $H_e=\nabla\times\mathbf{A}_e\cdot\hat{z}$, and similarly for $\partial_t(A_x)_{i,N_y}$. The left-hand side of this equality stands for minus the normal current density, the first term at the right-hand side for the supercurrent density and the last term for minus the total current density. The terms at the right are worked out in Ref. 4. The first term is based on Eq. (6) and the last term approximates the argument of the product of unitary numbers by its imaginary part. The factor 2 in the last term comes from the fact that the magnetic field changes from its value at the rectangle $[(i,0),(i+1,0),(i+1,1),(i,1)]$ to H_e over a

length $a_y/2$. Since the usual computational variable is U^x rather than A_x, one can replace $\partial_t(A_x)_{i,0}=i\overline{U}^x_{i,0}\partial_t U^x_{i,0}/a_x$.

Although Eq. (18) is equivalent to Eq. (4) in the appropriate limit, one might say that it has a different "numerical philosophy," in the sense that Eq. (4) has the form of a constraint, whereas Eq. (18) has the form of an evolution equation.

IV. BOUNDARY CONDITION FOR THE ORDER PARAMETER

A. A "natural" condition

The mathematical inclination toward condition (3) in static problems is that it is a "natural" boundary condition, i.e., when we solve the variational problem $\delta G/\delta\overline{\psi}=0$ without requirements at the boundary, Eq. (3) is automatically obtained. In other words, Eq. (3) causes $\delta G/\delta\overline{\psi}=0$ to have the same form at the boundary as in the interior of the superconductor.

The physical justification for Eq. (3) in static problems is that charge cannot leak into the insulating material. Therefore, the component of the current in the ν direction has to vanish and this is proportional to the real part of the product of expression (3) times $\overline{\psi}$. In order to eliminate the imaginary part too, the De Gennes criterion[6] has to be invoked.

In a dynamic situation, none of these arguments is valid. $\delta G/\delta\overline{\psi}\neq 0$, the De Gennes criterion is not intended to be valid, and it is only the total current that has to be tangential to the interface. *A priori*, there is no physical restriction to the possibility of a supercurrent bringing electrons from the interior to the boundary, and a normal current bringing the electrons back to the interior. Moreover, if the supercurrent is indeed tangential, then the normal current and thus the electric field have to be tangential too. Since there are several problems in which the electric field does have a component perpendicular to the interface, the requirement that this component vanish at the boundary seems quite artificial. Examples in which a perpendicular component of the electric field is expected to exist include the Hall effect,[7,8] anisotropic superconductors[9] and cases in which an electric field is externally applied.[10] We should therefore refrain from accepting condition (3) for time-dependent situations, unless we can extend the justification for it.

We suggest that the natural boundary condition for a time-dependent problem be such that it results in an evolution equation of the same form at the boundary and in the interior. In our case, we will require Eq. (1) to remain valid at the boundaries. But Eq. (1) (without noise) can be written as $\eta\partial_t\psi=-\delta G/\delta\overline{\psi}$. Therefore, since it is Eq. (3) that renders $\delta G/\delta\overline{\psi}$ insensitive to the presence of the boundary, Eq. (3) should remain the natural boundary condition for the time-dependent problem. As a matter of taste, I find it more convincing to show this feature for the discretized problem: we will require that the same evolution equation (17) be obeyed at the vertices located at the boundary. Explicitly, let us consider the vertex $(i,0)$. In this case $\overline{V}^v_{i,0}=a_xa_y/2$ and there are four rectangles that contribute a term to the free energy that includes $\overline{\psi}_{i,0}$. The sum of these terms is

$$G_{i,0}=\frac{a_xa_y}{2}\left((1-T)\left(\frac{(\overline{\psi}_{i,0}\psi_{i,0})^2}{2}-\overline{\psi}_{i,0}\psi_{i,0}\right)+\frac{(\overline{U}^x_{i,0}\overline{\psi}_{i+1,0}-\overline{\psi}_{i,0})(U^x_{i,0}\psi_{i+1,0}-\psi_{i,0})}{a_x^2}\right.$$
$$\left.+\frac{(\overline{U}^x_{i-1,0}\overline{\psi}_{i,0}-\overline{\psi}_{i-1,0})(U^x_{i-1,0}\psi_{i,0}-\psi_{i-1,0})}{a_x^2}\right)+a_xa_y\frac{(\overline{U}^y_{i,0}\overline{\psi}_{i,1}-\overline{\psi}_{i,0})(U^y_{i,0}\psi_{i,1}-\psi_{i,0})}{a_y^2} \quad (19)$$

and Eq. (17) gives

$$\eta\partial_t\psi_{i,0} = -(1-T)(|\psi_{i,0}|^2-1)\psi_{i,0} + \frac{2(U^y_{i,0}\psi_{i,1}-\psi_{i,0})}{a_y^2} + \frac{U^x_{i,0}\psi_{i+1,0} - 2\psi_{i,0} + \overline{U}^x_{i-1,0}\psi_{i-1,0}}{a_x^2} \quad (20)$$

and a similar expression is obtained for the evolution of ψ_{i,N_y}. This equation was also suggested in Ref. 4, using a different line of argument. As in the case of Eq. (18), Eq. (20) replaces a constraint by an evolution equation.

We will now see that in the limit of a dense grid Eq. (20) is equivalent to Eq. (3). We define

$$\mathcal{F}_{i,j} = \mathcal{U}^y_{i,j}\left(\eta\partial_t\psi_{i,j} + (1-T)(|\psi_{i,j}|^2-1)\psi_{i,j} - \frac{U^x_{i,j}\psi_{i+1,j} - 2\psi_{i,j} + \overline{U}^x_{i-1,j}\psi_{i-1,j}}{a_x^2}\right) \quad (21)$$

and note that $\mathcal{F}_{i,j}$ remains finite in the limit of a dense grid. From Eq. (20) and discretization of $\mathcal{J}^y = \partial_y(\mathcal{U}^y\psi)$ we have

$$\mathcal{J}^y\big|_{x_i,a_y/2} = a_y\mathcal{F}_{i,0}/2 + O(a_y^2); \quad (22)$$

likewise, from Eq. (10),

$$\partial_y\mathcal{J}^y\big|_{x_i,a_y} = \mathcal{F}_{i,1} + O(a_y) \quad (23)$$

so that

$$\mathcal{J}^y\big|_{x_i,0} = a_y(\mathcal{F}_{i,0} - \mathcal{F}_{i,1})/2 + O(a_y^2) = 0 + O(a_y^2). \quad (24)$$

But due to Eq. (6), this is the same as condition (3).

The outcome of this subsection is thus that, instead of finding an alternative to Eq. (3), we have found a justification for it.

B. An alternative implementation

If we accept that the boundary condition is Eq. (3), it follows from identity (6) that $\mathcal{J}^y|_{x,0} = 0$ and therefore $\mathcal{U}^y(x,2a_y)\psi(x,2a_y) - \mathcal{U}^y(x,0)\psi(x,0) \approx 4(\mathcal{U}^y(x,a_y)\psi(x,a_y) - \mathcal{U}^y(x,0)\psi(x,0))$. From here we can isolate the order parameter at the boundary and obtain

$$\psi_{i,0} = \tfrac{1}{3}U^y_{i,0}(4\psi_{i,1} - U^y_{i,1}\psi_{i,2}) + O(a_y^3). \quad (25)$$

Since that $U^y_{i,1}\psi_{i,2} - \psi_{i,1}$ is of order $O(a_y^2)$, we can also write $\psi_{i,0} = U^y_{i,0}\psi_{i,1} + O(a_y^2)$. Similarly, at the other boundary, $\psi_{i,N_y} = (1/3)\overline{U}^y_{i,N_y-1}(4\psi_{i,N_y-1} - \overline{U}^y_{i,N_y-2}\psi_{i,N_y-2}) + O(a_y^3)$.

C. Example

We consider a situation in which external sources create a constant magnetic field $0.5\hat{z}$ [in units $\Phi_0/2\pi\xi^2(0)$], while a current I along the film induces an additional field. In appropriate units, the magnetic field will be $(0.5-I)\hat{z}$ for $y<0$ and $(0.5+I)\hat{z}$ for $y>d$. The reason for studying this situation is that we know[8] that for appropriate parameters the transverse electric field does not vanish.

Figure 2 shows the volume average of the component of the electric field in the y-direction, as a function of the current. The same quantity was once evaluated using Eq. (20) for the order parameter at the boundaries, and also using Eq. (25) without the $O(a_y^2)$-correction term. There is practically full agreement between these two methods. When the entire Eq. (25) is used, the evaluation algorithm seems to be unstable for the chosen parameters.

As reported in Ref. 8, this example exhibits chaotic behavior: minute changes in the initial values of ψ and $\mathbf{A}$ can reverse the sign of E_y. For the purpose of comparison, all the results in Fig. 2 are presented with the same sign.

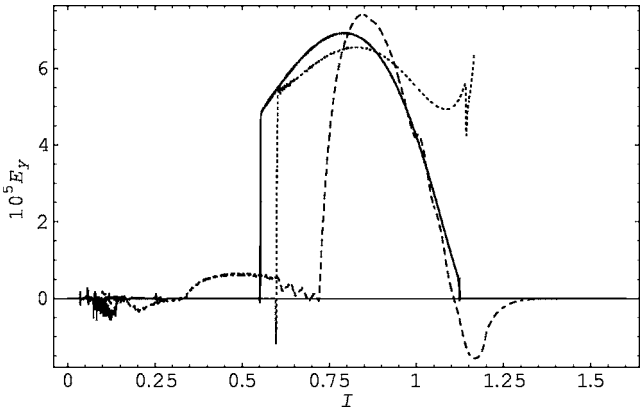

FIG. 2. Volume average of the transverse electric field as a function of the current. There are two solid lines that coalesce within the scale of this graph; these were obtained using Eq. (20) and the $O(a_y^2)$ approximation for Eq. (25). The dotted line was obtained using the entire Eq. (25) and the dashed line was obtained using the method developed in Sec. V, which permits accumulation of volume and surface charge. The unit of current is $c\Phi_0/[2\pi\xi(0)]^2$ per cm of length in the z direction; the electric field unit is $c\Phi_0/[8\pi^2\kappa^2\sigma\xi^3(0)]$. Parameters used: $\eta=0.03$, $\kappa=2$, $d=8$, $dI/dt=3.3\times10^{-4}$ (see Ref. 8 for further details).

V. INTRODUCTION OF A SURFACE CHARGE

The robustness of Eq. (3) when dealing with the Hall effect is somehow surprising, since in the case of a classical normal conductor the Hall field is generated by charges that accumulate at the surface of the conductor, and this field is uniform. However, a model based on Eq. (2) is unable to create a surface charge. Equation (2) can be written as

$$\boldsymbol{\nabla}\times\boldsymbol{\nabla}\times\mathbf{A}\propto\mathbf{j}_T, \tag{26}$$

where $\mathbf{j}_T$ is the total (superconducting plus normal) current density. From here it follows that $\boldsymbol{\nabla}\cdot\mathbf{j}_T=0$ and therefore there cannot be any charge redistribution.

In order to enable the creation of volume and surface charges, we introduce the displacement current and replace Eq. (2) by the entire Maxwell equation:

$$\kappa^2\boldsymbol{\nabla}\times\boldsymbol{\nabla}\times\mathbf{A}+\gamma\partial_{tt}^2\mathbf{A}+\partial_t\mathbf{A}=(1-T)\mathrm{Re}[\overline{\psi}(-i\boldsymbol{\nabla}-\mathbf{A})\psi], \tag{27}$$

where $\gamma=(\kappa/c)^2$ or, dividing the denominator by the unit of velocity, $\gamma=(c/4\pi\kappa\sigma\xi(0))^2$. This reduces to Eq. (2) if we set $\gamma=0$. As in the case of η, we will assume that γ depends on the material and can take a wide range of values.

Since Eq. (27) contains a second derivative with respect to t, Euler integration requires two steps. We define

$$\mathcal{E}_{i,j}^y=-a_y\partial_t A_y\big|_{x_i,(j+1/2)a_y}=-i\overline{U}_{i,j}^y\partial_t U_{i,j}^y, \tag{28}$$

and similarly for the x direction. The y-component of the electric field is $\mathcal{E}_{i,j}^y/ca_y$. From Eq. (27), $\mathcal{E}_{i,j}^y$ obeys

$$\frac{\mathcal{E}_{i,j}^y(t+\Delta t)-\mathcal{E}_{i,j}^y(t)}{\Delta t}=\frac{\mathcal{C}-\mathcal{E}_{i,j}^y(t)}{\gamma}, \tag{29}$$

where Δt is the time step and we have used as shorthand

$$\mathcal{C} = a_y(\kappa^2(\nabla \times \nabla \times \mathbf{A})_y - (1-T)\mathrm{Re}[\overline{\psi}(-i\partial_y - A_y)\psi])|_{x_i,(j+1/2)a_y} =$$

$$-\frac{\kappa^2}{a_x^2}\mathrm{Im}(\overline{U}^x_{i,j}\overline{U}^y_{i+1,j}U^x_{i,j+1}(U^y_{i,j})^2U^x_{i-1,j}\overline{U}^x_{i-1,j+1}\overline{U}^y_{i-1,j}) - (1-T)\mathrm{Im}(\overline{\psi}_{i,j}U^y_{i,j}\psi_{i,j+1}). \tag{30}$$

The algorithm (29) may lead to numerical difficulties for small γ. Therefore, keeping the same order in Δt, we substitute $\mathcal{E}^y_{i,j}(t)$ by $\mathcal{E}^y_{i,j}(t+\Delta t)$ at the right-hand side of Eq. (29) and isolate $\mathcal{E}^y_{i,j}(t+\Delta t)$. This gives

$$\mathcal{E}^y_{i,j}(t+\Delta t) = \frac{\gamma\mathcal{E}^y_{i,j}(t) + \Delta t\mathcal{C}}{\gamma + \Delta t}. \tag{31}$$

After $\mathcal{E}^y_{i,j}(t+\Delta t)$ is evaluated, $U^y_{i,j}(t+\Delta t)$ is evaluated using Eq. (28), i.e.,

$$U^y_{i,j}(t+\Delta t) = U^y_{i,j}(t)(1 + i\Delta t\mathcal{E}^y_{i,j}(t+\Delta t)). \tag{32}$$

The same procedure is followed for $U^x_{i,j}(t+\Delta t)$.

The volume density of charge (per unit length in the z-direction) at an internal vertex (i,j) is given by Gauss law:

$$\rho_{i,j} = \frac{1}{4\pi c}\left(\frac{\mathcal{E}^x_{i,j} - \mathcal{E}^x_{i-1,j}}{a_x^2} + \frac{\mathcal{E}^y_{i,j} - \mathcal{E}^y_{i,j-1}}{a_y^2}\right); \tag{33}$$

for a vertex at the boundary $y=0$

$$\rho_{i,0} = \frac{1}{4\pi c}\left(\frac{\mathcal{E}^x_{i,0} - \mathcal{E}^x_{i-1,0}}{a_x^2} + \frac{2\left(\mathcal{E}^y_{i,0} + a_y\partial_t A_y\big|_{x_i,0}\right)}{a_y^2}\right), \tag{34}$$

and similarly for $y=d$.

A. The Hall field

The same problem treated in Sec. IV C was considered again, using Eq. (27) with $\gamma \neq 0$. The magnetic field is independent of time outside the superconducting film (assuming that the current varies slowly), implying that the electric field has to be uniform in the exterior regions. The easiest way to achieve this condition is by requiring that the electric field vanish outside the film. The result for the average value of the transverse field for $\gamma=100$ is shown in Fig. 2. The curve is rounded, suggesting a sort of capacitive behavior, but the average transverse field is not always smaller than in the case $\gamma=0$.

Figure 3 shows the profile of the transverse field (averaged over t and x only) across the film, for a current close to the maximum in Fig. 2. From the slope of the curve we see that (on the average) there is volume charge in the region between $y=0$ and $y\approx 5.5$; the sign of the charge changes roughly in the middle of this range. At the boundaries, we obtain $E_y(0^+)=E_y(d^-)=0$. In Fig. 4 we investigate whether $E_y(0^+)$ vanishes for the entire range of currents. For this purpose we plot E_y in the closest and next to closest links to the boundary, which correspond to the positions $y=1/2$ and $y=3/2$. If $E_y(0^+)=0$, then in the linear approximation we should have $E_y(1/2)=E_y(3/2)/3$ and Fig. 4 indicates that this is indeed the case.

As a conclusion of this subsection we might state that the behavior of the Hall effect for a superconductor is opposite to that for a classical normal conductor: volume charges are present and surface charges are absent. The absence of surface charge is not surprising if we note that we have entirely neglected the influence of the normal electrons; this influence will be added in the following subsection.

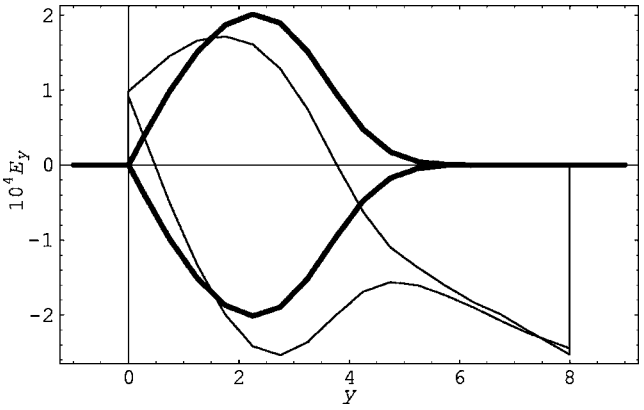

FIG. 3. Transverse component of the electric field as a function of position for $I=0.85$ and $\gamma=100$. The superconducting film occupies the region $0\leqslant y\leqslant 8$. Minute changes in the initial fields may reverse the sign of the contribution of the superconducting electrons to E_y;[8] both cases are presented. Thick lines: $\chi=0$ (Sec. V A); thin lines: $\chi=-5\times10^{-4}$ and $n=2$ (Sec. V B).

B. Influence of the magnetic force

The last term in the left-hand side of Eq. (27) stands for the normal current density. On doing this identification, we are assuming that the normal current density is proportional to the electric field **E**. This assumption is inaccurate; the normal current density is actually proportional to the force exerted on every charge carrier, which equals the charge times $\mathbf{E}+\mathbf{v}\times\mathbf{B}/c$, where **v** is the velocity of the carrier and $\mathbf{B}=\boldsymbol{\nabla}\times\mathbf{A}$ is the magnetic field. This means that Eq. (27) becomes

$$\kappa^2\boldsymbol{\nabla}\times\boldsymbol{\nabla}\times\mathbf{A}+\gamma\partial_{tt}^2\mathbf{A}+\partial_t\mathbf{A}-\mathbf{v}\times(\boldsymbol{\nabla}\times\mathbf{A})=(1-T)\mathrm{Re}[\overline{\psi}(-i\boldsymbol{\nabla}-\mathbf{A})\psi], \tag{35}$$

where **v** is the drift velocity of the normal electrons.

Translated into the variables we are using, substitution of **E** by $\mathbf{E}+\mathbf{v}\times\mathbf{B}/c$ amounts to the replacement of $\mathcal{E}_{i,j}$ at the right-hand side of Eq. (29):

$$\mathcal{E}^x_{i,j}\to\mathcal{E}^x_{i,j}+\frac{v_y}{2a_y}\mathrm{Im}(\overline{U}^x_{i,j-1}\overline{U}^y_{i+1,j-1}\overline{U}^y_{i+1,j}U^y_{i,j-1}U^y_{i,j}U^x_{i,j+1}), \tag{36}$$

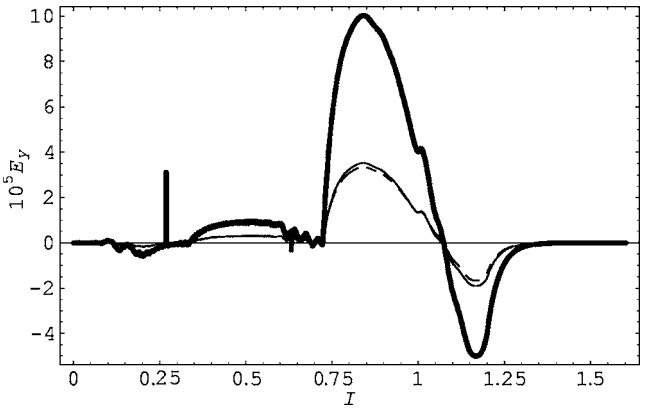

FIG. 4. Transverse component of the electric field at the links close to the boundary at $y=0$. The thick line stands for links centered at $y=3a_y/2$, the thin line for $y=a_y/2$, and the dashed line was obtained by dividing $E_y(3a_y/2)$ by 3. The feature at $I\sim0.25$ corresponds to a short range of currents where E_y is chaotic.

$$\mathcal{E}^y_{i,j} \to \mathcal{E}^y_{i,j} + \frac{v_x}{2a_x}\mathrm{Im}(\overline{U^y_{i-1,j}}\,\overline{U^x_{i-1,j+1}}\,\overline{U^x_{i,j+1}}U^x_{i-1,j}U^x_{i,j}U^y_{i+1,j}). \tag{37}$$

If $j=0$ or $j=N_y$, the term added to $\mathcal{E}^x_{i,j}$ in Eq. (36) should be substituted by $a_x v_y H_e$, where H_e is the magnetic field at the appropriate boundary (and in the present example is affected by the current along the film).

Let us now adopt a model for the drift velocity. Denoting by $-e$ the charge of an electron and by n the total density of electrons relative to the maximal density of condensed electrons, then, in appropriate units, the normal current density is $-e(n-|\psi|^2)\mathbf{v}$. By Ohm's law, this current density equals $\sigma(\mathbf{E}+\mathbf{v}\times\mathbf{B}/c)$, but assuming that the magnetic force is much smaller than the electric force it can be approximated by $\sigma\mathbf{E}$. The conductivity σ might depend on $|\psi|$, but since it is conventionally absorbed within the time unit, we will stick to the assumption that σ is constant. These assumptions lead to the form

$$\mathbf{v} = \frac{\chi\mathbf{E}}{n-|\psi|^2}, \tag{38}$$

where χ and n are "material constants." Operationally, $|\psi|^2$ is conveniently approximated by taking the geometric average of $|\psi_{i,j}|^2$ at both extremes of the appropriate link.

A comparison between this model and the case in which the magnetic force is disregarded is presented in Fig. 3. For the present model E_y is discontinuous at the boundaries, showing that there is indeed a surface charge. E_y has opposite signs at both boundaries; this is due to the fact that in the considered situation the total magnetic field has opposite signs at both boundaries. Also, the size of the magnetic field at $y=8$ is almost four times larger than that at $y=0$, and this has an influence on the respective sizes of E_y. The curves for $\chi=-5\times10^{-4}$ are above the curves for $\chi=0$ for y below ~1.5 and then the situation is reversed; we have verified that this is where the average magnetic field changes sign.

C. Effect of a parallel electromagnetic wave

Let us finally consider a situation in which a time dependent transverse electric field is applied. We consider the case in which outside the superconducting film there is a plane monochromatic electromagnetic wave moving in the x direction, with electric field in the y direction. In order to fit the periodicity that was imposed in the previous sections, we take a wavelength $L'=39.5$. (L' is a bit shorter than L, since a row of links has to overlap in order to implement periodicity.) Let us take $\kappa=2$ and $\gamma=1$, implying that $c=2$. In order to have a concrete problem let us take, outside the film, an electromagnetic potential in the y-direction with

$$A_y = 0.5x - 0.1\frac{L'}{2\pi}\cos\left(\frac{2\pi}{L'}[x-2t]\right) + C, \tag{39}$$

where C is a constant that might be different for $y>d$ and $y<0$. This potential satisfies the Maxwell equation outside the film [Eq. (27) without the right hand side and without the term $\partial_t\mathbf{A}$] and is therefore an acceptable external condition. Equation (39) describes the total external electromagnetic potential; we will not analyze what its sources are. On the average, this potential describes an external magnetic field $0.5\hat{z}$, as in the previous problem. Superimposed to this static field, there is an electromagnetic wave that produces an electric field

$$-\frac{1}{c}\partial_t\mathbf{A} = 0.1\,\sin\left(\frac{2\pi}{L'}[x-2t]\right)\hat{y} \tag{40}$$

outside the film. This time we assume that no net current flows along the film. We will also neglect the magnetic force considered in Sec. V B.

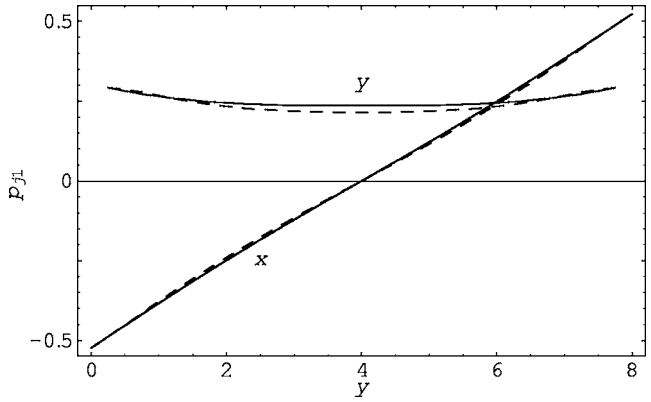

FIG. 5. Size of the first harmonic of the components of the electric field, $p^x_{j,1}$ and $p^y_{j,1}$. The line that refers to $p^x_{j,1}$ (respectively, $p^y_{j,1}$) is marked with the letter "x" (respectively, "y"). The abscissa y is related to the discrete index j through $y=ja_y$ (resp. $y=(j+1/2)a_y$). The dashed lines were evaluated using surface charge only.

Introducing the appropriate expression for the external field H_e into the program, we can find the fields inside the sample. After a transient stage, the electric field, the charge distribution, and the magnetic field take the form of a wave that moves together with the external wave and may be approximated by

$$E_x(x,ja_y,t) \approx 0.1\sum_{m=1}^{\infty} p^x_{j,m}\sin\left(\frac{2m\pi}{L'}[x-2t]+\varphi^x_{j,m}\right),$$

$$E_y(x,(j+1/2)a_y,t) \approx 0.1\sum_{m=1}^{\infty} p^y_{j,m}\sin\left(\frac{2m\pi}{L'}[x-2t]+\varphi^y_{j,m}\right),$$

$$\rho(x,ja_y,t) \approx 0.1\sum_{m=1}^{\infty} p^\rho_{j,m}\sin\left(\frac{2m\pi}{L'}[x-2t]+\varphi^\rho_{j,m}\right),$$

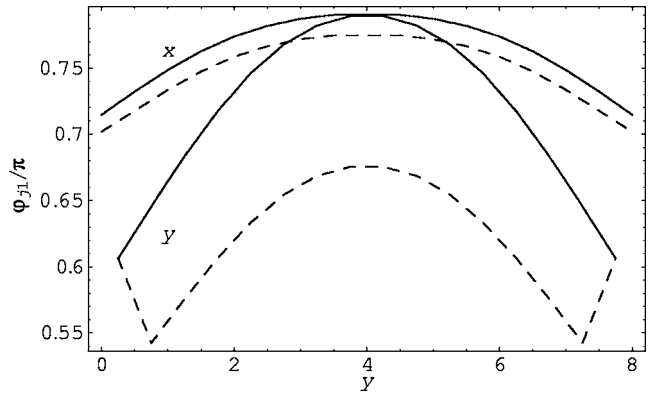

FIG. 6. Phase lag of the first harmonic of the components of the electric field inside the superconducting film. The conventions are the same as in Fig. 5.

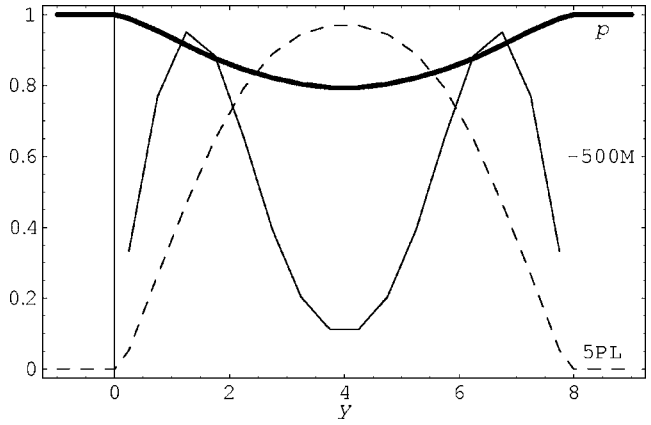

FIG. 7. y dependence of the main contributions to the magnetic field. The thick line ("p") stands for the size of the first harmonic, $p^B_{j,1}$; the dashed line ("5PL") stands for the phase lag and equals $5\varphi^B_{j,1}/\pi$; the thin line ("$-500M$") is the contribution that can be related to the vortex pattern and equals $-500M$, where the magnetization $M\hat{z}$ is the time average of $\nabla\times(\mathbf{A}-\mathbf{A}_e)/4\pi$. The abscissa y is related to the discrete index j through $y=(j+1/2)a_y$.

$$B_z(x,(j+1/2)a_y,t)-0.5\approx 0.1\sum_{m=1}^{\infty} p^B_{j,m}\sin\left(\frac{2m\pi}{L'}[x-2t]+\varphi^B_{j,m}\right), \tag{41}$$

where the $p_{j,m}$ and $\varphi_{j,m}$ sets are constants that can be found by performing a Fourier analysis. The factor 0.1 has been kept for the purpose of comparison with the external field. The main results of this analysis are shown in Figs. 5–7. The coefficients $p_{j,m}$ decrease by an order of magnitude for every unit added to m, and we present the first harmonic only.

We see from Figs. 5 and 6 that the electric field is not continuous at the boundaries, i.e., $p^y_{j,1}$ does not tend to 1 and $p^x_{j,1}$ and $\varphi^y_{j,1}$ do not tend to 0. This discontinuity requires a surface charge. Indeed, evaluation of $p^\rho_{j,1}$ shows that the values of $p^\rho_{0,1}$ and $p^\rho_{N_y,1}$ are more than 600 times larger than the average value of $p^\rho_{j,1}$ in the interior, so that these may be regarded as surface charges. We also checked what happens if only these surface charges are considered and the volume charges are neglected, i.e., we used Eq. (27) only for the links that touch the boundaries and Eq. (2) for the interior links. The results are shown by dashed lines in Figs. 5 and 6 and differ just slightly from those obtained when Eq. (27) is used everywhere.

Figure 7 shows [in agreement with Eq. (4)] that the magnetic field is continuous at the boundaries, implying that there is no surface current. This result may seem surprising, since there

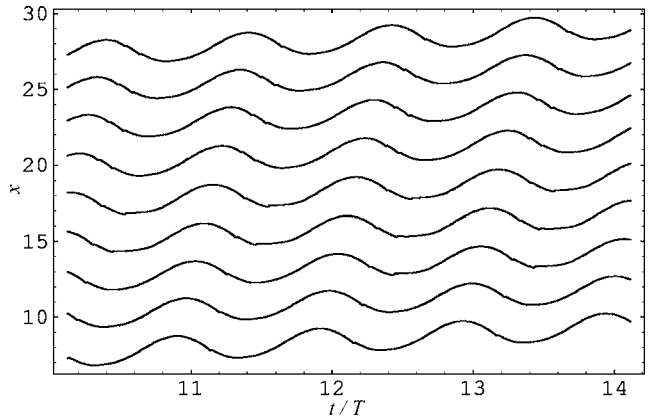

FIG. 8. Positions of several vortices as functions of the number of elapsed periods. $T=L'/2$.

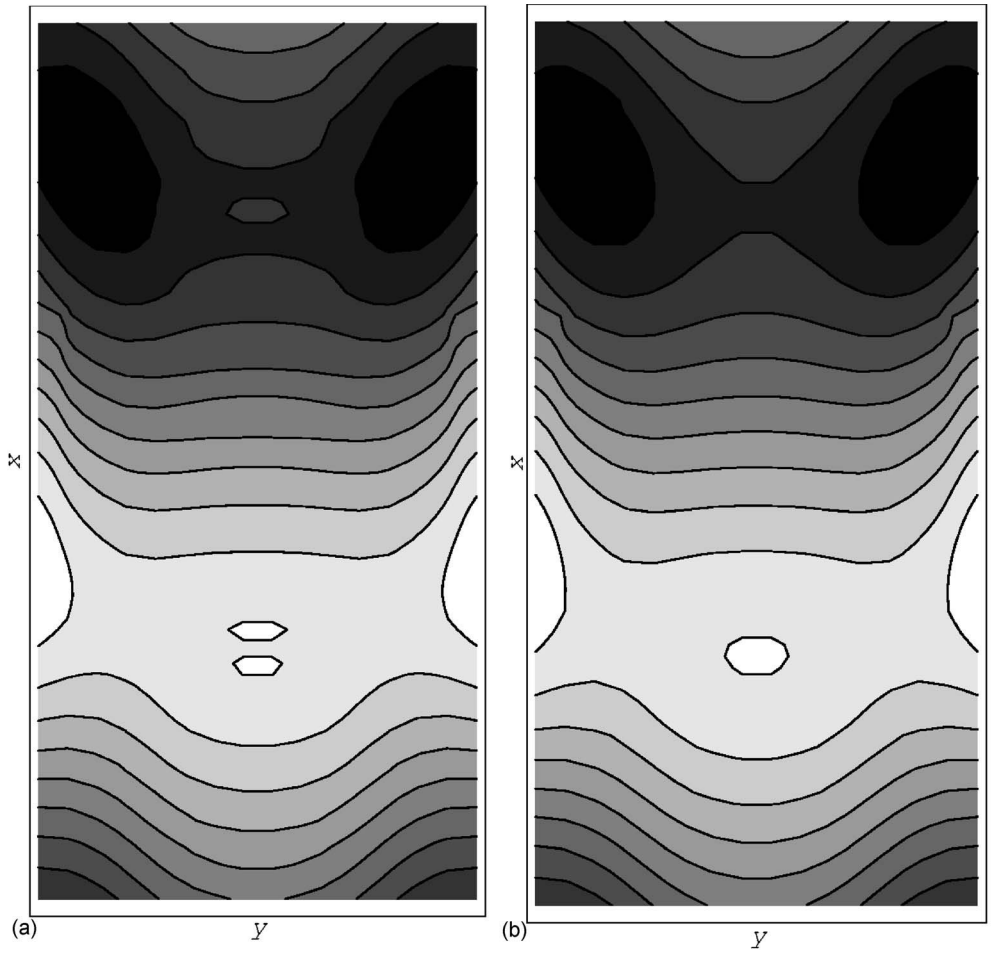

FIG. 9. Contour plots of the magnetic field at time $t=230$. (a) Direct evaluation and (b) approximaton that takes the first harmonic in Eq. (41) and the time average of the magnetization. The plots cover the region $0.25 \leqslant x \leqslant 39.25$, $0.25 \leqslant y \leqslant 7.75$.

are surface charges and the charge distribution advances together with the wave; in order to preserve the continuity of the magnetic field, the motion of these charges has to be compensated by Maxwell's displacement current.

Besides the electromagnetic field, the position of the vortices is usually of interest. We evaluate these positions as follows. We first locate a vertex (i_0, j_0) where the absolute value of the order parameter $\psi_{i,j}$ has a discrete local minimum; we then obtain a fit of ψ as a linear function of x and y in the region that contains nine vertices with corners at $(i_0 \pm 1, j_0 \pm 1)$, and finally solve for the position at which $\psi(x,y)=0$. For the particular example we are considering, when only the static magnetic field is applied and the wave is absent, there is a line of vortices along $y=d/2$. When the wave is applied, we find that the vortices scarcely move in the y direction; the x values for the vortices along a region of half a wavelength are shown in Fig. 8.

We see that the positions of the vortices oscillate in response to the wave, but they are also dragged with a velocity $1.24 \times 10^{-2} c$. Due to this drag, the period of the oscillatory part of a vortex motion is not the same as that of the wave, but is slightly Doppler-shifted.

Since the vortices are arranged in a nearly periodic pattern, with a periodicity and drag velocity that differ from those of the wave, we might also expect contributions to the electromagnetic field that exhibit this periodicity. However, for the parameters chosen in this example, this contribution is smaller by three orders of magnitude than that of the first harmonic that follows the

wave. What happens is that the distance between consecutive vortices is of the order of the magnetic penetration depth and the line of vortices behaves approximately as a continuum. As a consequence, their contribution is approximately independent of x and may be fairly described by the average magnetization $M(y)$. Figure 9 describes the magnetic field for a given instant and compares it to the approximation $B_z(x,(j+1/2)a_y)=0.5+0.1p^B_{j,1}\sin\left(\frac{2\pi}{L'}[x-2t]+\varphi^B_{j,1}\right)+4\pi M(y)$.

VI. DISCUSSION

For a time-independent situation there are good reasons to assume that the supercurrent has to be tangential to the superconductor-insulator boundaries. For time-dependent situations these reasons are no longer valid, but we find new reasons to preserve this assumption. Since the total current cannot cross the boundary, it follows that the normal current has to be tangential too.

Taking into account the displacement current enables the accumulation of charge at the boundary and the total current is not necessarily tangential. However, for a stationary situation, the amount of charge at the boundary achieves a final value and from then on the total and the normal currents become tangential. In the case of a superconducting film in the Hall configuration, when the magnetic force on the normal electrons is not neglected, the electric field is not tangential. This does not imply that the normal current is not tangential, since in this case the normal current is not proportional to the electric force on the electrons.

In the presence of an oscillating electric field perpendicular to the boundary, as may be encountered when a polarized grazing electromagnetic wave propagates parallel to a film, the surface charge also oscillates and does not attain a final value. Accordingly, the total and the normal currents are not tangential.

This work has been supported in part by the Israel Science Foundation. I would like to acknowledge the IMA at the University of Minnesota for the hospitality during part of the time devoted to this study. I wish to thank Gustavo Buscaglia for sending me the program used in Ref. 3.

(Received 13 June 2005; accepted 24 June 2005; published online 29 September 2005)

We consider a Ginzburg–Landau three-dimensional functional with a surface energy term to model a nematic liquid crystal with inclusions. The locations and radii of the inclusions are randomly distributed and described by a set of finite dimensional distribution functions. We show that the presence of inclusions can be accounted for by an effective potential. Our main objectives are (a) to derive the sufficient conditions on the distribution functions such that the solutions converge in probability to a solution of a homogenized deterministic problem and (b) to compute the effective potential. © *2005 American Institute of Physics.*

I. INTRODUCTION

Intermediate between ordered solids and amorphous liquids, liquid crystals possess both special structure and unique optical properties. The simplest kind of a liquid crystal, known as a nematic, is composed of rodlike molecules exhibiting *local orientational order*. That is, the molecules locally orient themselves along some preferred direction, while maintaining the ability to move around freely. The preferred direction can vary from point to point and coincides locally with the direction of the optic axis. As for any heterogeneous, optically uniaxial medium, the overall optical properties of a nematic material are determined by the spatial distribution of the direction of the optic axis.

Because positions of their molecules are not constrained, nematic liquid crystals can flow like liquids. At the same time, spatially nonuniform orientational order can produce elastic interactions that lead to complex nematic structures with elaborate patterns and topological defects. These structures can be subsequently manipulated by influencing molecular orientations with external electromagnetic forces. The corresponding changes in optical characteristics drive most of the current practical uses of liquid crystal materials.

Although in their "pure" form liquid crystals have been widely used in a variety of important applications, most notably liquid crystal displays, a significant research effort has been concentrated recently on liquid crystal-based composites. These materials are of considerable interest for display technologies based upon changing the light scattering properties of composite systems via external fields. Such systems can have distorted or multiply connected random geometries,[14] such as those produced by the polymer-dispersed liquid crystals (PDLC),[13] or dispersions of agglomerations of silica spheres in a nematic host.[17]

A structure of a liquid crystal-based composite depends strongly on whether or not a liquid crystal is used as its host material. For example, in a *direct nematic emulsion*[14] a nematic dispersed

[a)]Electronic mail: berlyand@math.psu.edu
[b)]Electronic mail: khruslov@ilt.kharkov.ua

in water separates into distinct, nearly spherical drops. The drops have simple structures dependent on the boundary conditions at the nematic-water interface. For this reason, direct liquid crystal emulsions have been used as a model medium to study topological defects.[14]

An inverse nematic emulsion[19] differs from a direct emulsion in that isotropic water droplets are dispersed in a nematic host. Structures of inverse emulsions are significantly more complex than direct emulsions. In inverse nematic emulsions and, more generally, in *colloid suspensions* in nematic liquid crystals, the interactions between foreign inclusions in a nematic host lead to formation of a variety of ordered and disordered structures. A defining impact on formation of structures is made by both anchoring conditions on the surfaces of inclusions and the global geometry of a liquid crystalline matrix.

The rheological effects in liquid crystals with inclusions depend crucially on the volume fraction of inclusions (see, e.g., Ref. 26). For example, a soft *solid* with a significant storage modulus was obtained in Ref. 20 by mixing model colloidal particles with a thermotropic nematic liquid crystal. The suspended particles with very small radii, behaving as nearly perfect hard spheres, constituted up to 20% of the mixture. The colloid-liquid-crystal composite described in Ref. 20 is a switchable electro-optical solid material, giving it significant advantages in handling and processing over the conventional, free-flowing liquid crystals.

In this paper we consider a mathematical model for a class of nematic liquid crystal composites with low volume fraction of small *randomly* distributed inclusions. Within this model, a nematic liquid crystal is described by the Ginzburg–Landau functional (2.2) with a (positive or negative) surface energy term. We assume that both the surface energy density and sizes of inclusions are controlled by the same small parameter ϵ. Randomness in the particle's sizes and locations is the main issue of our consideration and the main two objectives of this work are (a) to derive the conditions on the distribution functions such that the solutions converge in probability measure to a solution of a homogenized deterministic problem and (b) to compute the effective potential.

A similar problem for a *deterministic* geometry characterized by a small volume fraction of inclusions was considered in Refs. 4 and 6 (see also Refs. 16 and 25 for physical problems). It was shown that the presence of inclusions can be accounted for by an effective potential that was computed explicitly as a function of material parameters and geometric characteristics of inclusions. Two main control parameters were introduced—the average size of inclusions and the inverse intensity of the surface energy. The asymptotic limits when both parameters tend to zero were considered and all possible relationships between these two parameters that lead to nontrivial homogenization limits were identified and studied. We emphasize that these relationships were not deduced from a specific physical problem—on the contrary, they arose in the course of the homogenization analysis of the model. The relevance of these relationships to liquid crystal composites is an interesting open question suggested by our analysis. In the present paper we show that in the random setting the same scaling relationships lead to a nontrivial deterministic limit.

In Ref. 6, the effective potential was represented as a sum of two terms responsible for the surface and the bulk energy of a thin boundary layer around inclusions, respectively. The analytic formulas for the effective potential that were obtained in Ref. 6 do not require the solution of a cell problem. (Cell problems for linear elliptic problems are defined in Ref. 3.) An additional geometric condition under which the homogenization procedure was carried out in Refs. 4 and 6 was that the inclusions cannot form clusters.

The presence of the surface energy term in a variational formulation of our problem implies that the minimizer (which solves the nonlinear Ginzburg–Landau equation) is subject to Robin boundary conditions on surfaces of inclusions. For linear scalar problems (Laplace operator) a homogenization problem for perforated domains with Robin boundary condition on boundaries of holes has been studied by several authors. In Refs. 8 and 9 the case of large holes, where the homogenized operator becomes anisotropic, has been considered by using the method of mesocharacteristics. In Refs. 11 and 12 several possible relations between a parameter in Robin boundary condition and sizes of periodically arranged holes have been thoroughly studied and classified.

In the same work, a version of the two-scale approach (Refs. 1, 3, 15, and 21) suitable for the analysis of the Robin boundary condition on surfaces of holes, has been developed.

The case of deterministic inclusion that remains sufficiently far apart (the ratio of the size of an inclusion to the distance between it and other inclusions is bounded) was treated in Ref. 5. The domains were not required to have periodic geometry, and the surface energy term in (2.2) was not assumed to be negative. The main consequence of the lack of non-negativity is that there is no *a priori* lower bound on the energy, and this bound must be established independently.

Under these assumptions on the functional and the geometry of the domain, it was shown in Ref. 5 that one can account for inclusions by an anisotropy of the homogenized differential operator and an effective potential. The potential can be viewed as an effective external field. Furthermore, it was established that a "cross-term" of the form $c_{ikj}(\partial u_k/\partial x_j)u_i$ is not present in the homogenized energy. However, such a cross term may appear for more general domains, where distances between inclusions can be much smaller than their sizes. At present this is an interesting open question.

Finally we note that in recent works[22,2] homogenization problems for liquid crystals with a periodic array of polymeric inclusions in the presence of an applied magnetic field were considered.

II. FORMULATION OF THE PROBLEM AND THE MAIN RESULT

An idealized mathematical model for a liquid crystal with spherical inclusions can be formulated as follows.

Let G be a bounded domain in $\mathbf{R}^3$ with a piecewise smooth boundary ∂G and $B^i_\epsilon = B(x^i_\epsilon, a_{i\epsilon})$ be the balls of small radii $a_{i\epsilon}$ centered at the points x^i_ϵ $(i=1,\ldots,N_\epsilon)$.

The small parameter ϵ is of order of the average distance between the nearest balls and also characterizes the sizes of the balls B^i_ϵ. We assume that $N_\epsilon \sim \epsilon^{-3}$ and $a_{i\epsilon} = O(\epsilon^\alpha)$. Here $\alpha > 2$, that is the balls are small with respect to the average distance to the nearest neighbor.

Let

$$G_\epsilon = G \setminus \bigcup_{i=1}^{N_\epsilon} B^i_\epsilon$$

be the perforated domain occupied by a liquid crystal. We introduce the class $H^1_U(G_\epsilon) \subset H^1(G_\epsilon)$ of vector functions $u: G_\epsilon \to \mathbf{R}^3$ with the trace $u = U$ on ∂G, where $U: G \to \mathbf{R}^3$. For simplicity we assume that $U \in C^1(\bar{G})$.

Consider the variational problem

$$E_\epsilon[u] \to \min, \quad u \in H^1_U(G_\epsilon) \tag{2.1}$$

for the Ginzburg–Landau functional with a surface energy contribution on S^i_ϵ,

$$E_\epsilon[u] \equiv k \int_{G_\epsilon} |\nabla u|^2 + \int_{G_\epsilon} (|u|^2 - 1)^2 + q \sum_i \int_{S^i_\epsilon} (1 + \kappa_\epsilon(\nu, u)^2). \tag{2.2}$$

Here $S^i_\epsilon = \partial B^i_\epsilon$ and ν is the unit normal vector to S^i_ϵ (for the sake of definiteness we assume that ν is directed into the domain G_ϵ). The quantity $(\nu, u) = \Sigma_{i=1}^3 \nu_i u_i$ is the scalar product in $\mathbf{R}^3$ and k, q, and κ_ϵ are given parameters.

It follows from standard analysis[18] that there exists at least one global minimizer $u_\epsilon \in H^1_U(G_\epsilon)$ of the problem (2.1) and (2.2). One can show that under certain conditions on the parameters k, q, κ_ϵ, the sizes of the domain G, and the balls B^i_ϵ, the minimizer is unique. However, generally, there could be more than one minimizer. Further, the minimizers of problem (2.1) and (2.2) exist even if the balls intersect, i.e., when the surface term in (2.2) is not defined at the points of intersection of the spheres S^i_ϵ (the surface measure of the set of such points is zero).

The minimizers of the problem (2.1) and (2.2) describe the equilibrium state of a liquid crystalline medium occupying the domain G_ϵ.

The direction of the vector-valued minimizer u_ϵ determines the average direction of the liquid crystal molecules in the neighborhood of the point x and its magnitude determines, roughly speaking, the fraction of the molecules in a neighborhood of a point x oriented along the preferred direction of u (the orientational rate). The parameters k, q, κ_ϵ characterize the materials properties of the liquid crystal and interfacial effects between the liquid crystal and the inclusions. These parameters satisfy the following conditions: $0<k<\infty$, $0\leqslant q<\infty$, and $-1\leqslant\kappa_\epsilon<\infty$.

In this paper we study the asymptotic behavior of the minimizers of problem (2.1) and (2.2) as $\epsilon\to 0$, when the number of the balls N_ϵ tends to infinity, their radii tend to zero, and the locations of the balls in G and their radii are random.

More precisely we assume that the centers x^i_ϵ of the balls B^i_ϵ and their radii $a_{i\epsilon}$ are defined by the set of s-partial distribution functions

$$f^\epsilon_s(x^1,\ldots,x^s;a_1,\ldots,a_s):\quad (G)^s\times[0,\infty)^s\to[0,\infty)\quad (s=1,2,\ldots,N_\epsilon).$$

The probability of finding the location of the centers and the radii of a group of s balls in $(x^i,x^i+\mathrm{d}x^i)$, $(a_i,a_i+\mathrm{d}a_i)$, where $i=1,\ldots,s$ is

$$f^\epsilon_s(x^1,\ldots,x^s;a_1,\ldots,a_s)\mathrm{d}x^1\cdots\mathrm{d}x^s\,\mathrm{d}a_1\cdots\mathrm{d}a_s.$$

These functions satisfy the conditions of symmetry, normalization, and concordance which follow from their probabilistic interpertation (see, e.g., Ref. 10)

$$f^\epsilon_s(x^1,\ldots,x^k,\ldots,x^l,\ldots,x^s;a_1,\ldots,a_k,\ldots,a_l,\ldots,a_s)=f^\epsilon_s(x^1,\ldots,x^l,\ldots,x^k,\ldots,x^s;a_1,\ldots,a_l,\ldots,a_k,\ldots,a_s),$$

$$\int_G\int_0^\infty\cdots\int_G\int_0^\infty f^\epsilon_s(x^1,\cdots,x^s;a_1,\cdots,a_s)\mathrm{d}a_1\,\mathrm{d}x^1\cdots\mathrm{d}a_s\,\mathrm{d}x^s=1,\quad s=1,\ldots,N_\epsilon,$$

$$\int_G\int_0^\infty f^\epsilon_s(x^1,\ldots,x^s;a_1,\ldots,a_s)\mathrm{d}a_s\,\mathrm{d}x^s=f^\epsilon_{s-1}(x^1,\ldots,x^{s-1};a_1,\ldots,a_{s-1}),\quad s=2,\ldots,N_\epsilon.$$

The distribution functions generate the probability measure P_ϵ in the probability space Ω_ϵ. The points ω_ϵ of this space are in one-to-one correspondence with the random sets $B(\omega_\epsilon)=\cup_i B^i_\epsilon$ in G.[23] For any realization of the set $B(\omega_\epsilon)$ there exists at least one minimizer $u_\epsilon(x,\omega_\epsilon)$ of problem (2.1) and (2.2) in the domain $G(\omega_\epsilon)=G\backslash B(\omega_\epsilon)$. Let us denote by $M(\omega_\epsilon)$ the set of the minimizers which correspond to $\omega_\epsilon\in\Omega_\epsilon$ and consider in the space Ω_ϵ the random variable

$$\rho(\omega_\epsilon)=\max_{M(\omega_\epsilon)}\int_{G(\omega_\epsilon)}|u_\epsilon(x,\omega_\epsilon)-u(x)\chi(x,\omega_\epsilon)|^2\,\mathrm{d}x,\tag{2.3}$$

where u is a vector-valued function $u\in H^1(G)$ and $\chi(x,\omega_\epsilon)$ is the characterisic function of the subdomain $G(\omega_\epsilon)\subset G$.

We will show that under some conditions on the distribution functions $f^\epsilon_1(x;a)$ and $f^\epsilon_2(x^1,x^2;a_1,a_2)$ and with the appropriate choice of the vector function u the random variable (2.3) converges to zero in probability P_ϵ as $\epsilon\to 0$, i.e.,

$$\lim_{\epsilon\to 0}P_\epsilon\{\omega_\epsilon\in\Omega_\epsilon:\rho(\omega_\epsilon)<\delta\}=1\tag{2.4}$$

for any $\delta>0$.

We now introduce the limiting (homogenized) vector function u and the conditions on the one-point and two-point distribution functions f^ϵ_1 and f^ϵ_2 for which the convergence takes place.

First, we assume that these functions have the form

(1) $f^\epsilon_1(x;a)=\epsilon^{-\alpha}f(x;\epsilon^{-\alpha}a)$,

(2) $f_2^\epsilon(x^1,x^2;a_1,a_2)=f_1^\epsilon(x^1;a_1)f_1^\epsilon(x^2;a_2)$,
where $f(x;r)\in L^\infty(G\times[0,\infty))$ is some non-negative function normalized by 1 in $L^\infty(G\times[0,\infty))$ with a compact support $G'\times[a_0,A_0]$ in $G\times[0,\infty)$ $(G'\subset G, 0<a_0<A_0<\infty)$.
We also assume that the parameter κ_ϵ which characterizes the properties of the surfaces S_ϵ^i of the balls B_ϵ^i has the form

(3) $\kappa_\epsilon=\kappa_0\epsilon^\beta$, where $\kappa_0\in[-\epsilon^\beta,\infty)$, $\beta\in(-\infty,\infty)$. We set $g_\epsilon=q\kappa_\epsilon\equiv g\epsilon^\beta$, then $g\in(-\infty,\infty)$. Moreover, if $g<0$ we assume that

$$A_0<k|g|^{-1}, \tag{2.5}$$

where A_0 is a number which defines the diameter of the support of the function $f(x;r)$ [see condition (1)], k and $g=q\kappa_0$ are the parameters of the functional (2.2).

This choice of scaling (3) and the condition (2.5) were introduced in Ref. 6 for a deterministic model (see the introduction).

Next we define the limiting vector function u, which appears in the definition (2.3).

We set

$$p(x)=\int_0^\infty p_{\alpha\beta}(a)f(x;a)\mathrm{d}a, \tag{2.6}$$

where $f(x;a)$ is the function from the condition (1) and the functions $p_{\alpha\beta}(a)$ are defined as follows:

$$p_{\alpha\beta}(a)=\begin{cases}\dfrac{4\pi}{3}ga^2 & \text{for } 2<\alpha<3,\ \beta=3-2\alpha,\\ \dfrac{12\pi(22g^2a^3+45k^2ga^2)}{5(9k+5ga)^2} & \text{for } \alpha=3,\ \beta=-3,\\ \dfrac{264}{125}\pi ka & \text{for } \alpha=3,\ \beta<-3,\\ 0 & \text{for } \alpha,\ \beta\in\Lambda_g.\end{cases} \tag{2.7}$$

The sets Λ_g in (2.7) are defined as follows:

$$\Lambda_g=\{2<\alpha\leqslant 3,\beta>3-2\alpha\}\cup\{\alpha>3,-\infty<\beta<\infty\}$$

if $g\geqslant 0$,

$$\Lambda_g=\{2<\alpha\leqslant 3,\beta>3-2\alpha\}\cup\{\alpha>3,\beta\geqslant-\alpha\}$$

if $g<0$.

Also the potential $p(x)$ satisfies the following condition:

$$p(x)\geqslant\min\left\{1,\frac{1}{\lambda_0}-k\right\}, \tag{2.8}$$

where $\lambda_0=\lambda_0(G)$ is the minimal eigenvalue of the operator $-\Delta$ in G with the homogeneous boundary condition on ∂G. Both conditions (2.7) and (2.8) were introduced in an analogous deterministic problem in Ref. 7 and we refer the reader to Ref. 7 for further details.

Consider a variational problem

$$E_p[u]\to\min,\quad u\in H_U^1(G) \tag{2.9}$$

for the functional

$$E_p[u] \equiv k\int_G |\nabla u|^2\,\mathrm{d}x + \int_G (|u|^2-1)^2 + \int_G p(x)|u|^2\,\mathrm{d}x, \tag{2.10}$$

where the function $p(x)$ is defined by (2.6) and (2.7) and satisfies the inequality (2.8).

As it had been pointed out previously, there exists the unique global minimizer u of the problem (2.9) and (2.10). The function u enters into the definition of the random variable (2.3).

The main result of the paper is the following.

Theorem 2.1: *Let the conditions (1)–(3), and the inequalities (2.5) (for $g<0$) and (2.8) hold. Then the random variable $\rho(\omega_\epsilon)$ defined in (2.3) using the minimizers $u_\epsilon(x,\omega_\epsilon)$ and $u(x)$ of problems (2.1), (2.2), (2.9), and (2.10), respectively, converges to zero in probability [i.e., in the sense of (2.4)] as $\epsilon\to 0$.*

Remark 2.1: Theorem 2.1 states the conditions under which all random minimizers of a stochastic problem (2.1) and (2.2) converge in probability in the space $L^2(G_\epsilon)$ to a nonrandom vector function $u(x)$ and this function is the unique minimizer of a deterministic problem (2.9) and (2.10).

Remark 2.2: Condition (1) (scaling) defines the characteristic dimensions of the balls (inclusions) $B^i_\epsilon(\omega_\epsilon)$ in the probabilistic sense. The assumption that the function $f(x;r)$ has a compact support $G'\times[a_0,A_0]$ in $G\times[0,\infty]$ is made for the sake of simplicity only. It can be dropped, but then the proof of Theorem 2.1 becomes much more technical.

Condition (2) means that the balls $B^i_\epsilon(\omega_\epsilon)$ are "pairwise independent." While this condition admits a possibility of their intersection, i.e., $B^i_\epsilon(\omega_\epsilon)\cap B^j_\epsilon(\omega_\epsilon)\neq\emptyset$ (which is not physical), it follows from Lemma 4.1 that the probability of realizations with intersections tends to zero as $\epsilon\to 0$. This condition can be relaxed to a weaker condition of "pairwise almost independence."

Condition (3) defines the character and the strength of the orientation of liquid crystal molecules on the surfaces of the inclusions. They "prefer" to be orientated along the normal vector when $g<0$ and along the tangent vector when $g>0$.

Finally, the inequality (2.8) guarantees the uniqueness of the solution of the problem (2.9) and (2.10) (see Ref. 6).

The proof of Theorem 2.1 is based on the main theorem from Ref. 6, where an analogous deterministic problem was considered. The theorem from Ref. 6 is proved under deterministic conditions on the distribution of the balls B^i_ϵ and their radii. These conditions are presented below (see Theorem 3.1 in Sec. II). In Sec. III we show that if the distribution functions satisfy the conditions stated above, then the conditions of Theorem 3.1 hold "in probabilistic sense" (and for $\alpha>2$). In Sec. IV we use this fact and Theorem 3.1 to prove Theorem 2.1.

III. DETERMINISTIC DISTRIBUTION OF THE BALLS

For convenience of the reader we now present an outline of the results of the paper[6] which will be used below. Let us consider problem (2.1) and (2.2) in a deterministic domain $G_\epsilon = G\setminus\cup_{i=1}^{N_\epsilon} B^i_\epsilon$, where $B^i_\epsilon\,(i=1,\ldots,N_\epsilon)$ are the balls centered at given points $x^i_\epsilon (i=1,\ldots,N_\epsilon)$ of radii $a_{i\epsilon}$. We assume that the following dependences of the parameters of the problem on ϵ hold:

$$(a_1)\quad g_\epsilon = q\kappa_\epsilon \equiv g\epsilon^\beta, \quad \text{where } \beta, g\in(-\infty,\infty).$$

$$(a_2)\quad a_0\epsilon^\alpha \leqslant a_{i\epsilon} \leqslant A_0\epsilon^\alpha, \quad \alpha>1, 0<a_0<A_0<\infty, \text{ also, if } g<0 \text{ then } A_0<k|g|^{-1}.$$

Next, we introduce the following notations:

$$R_{i\epsilon} = \operatorname{dist}\Big(x^i_\epsilon, \cup_{j\neq i} x^j_\epsilon \cup \partial G\Big) = \min\{\min_{j\neq i}|x^j_\epsilon - x^i_\epsilon|, \operatorname{dist}(x^i_\epsilon, \partial G)\} \tag{3.1}$$

and

$$b_{i\epsilon} = b_{i\epsilon}(\alpha,\beta) = \begin{cases} |g_\epsilon| a^2_{i\epsilon} & \text{for } 1<\alpha\leqslant 3,\ \beta\geqslant 3-2\alpha \text{ and } \alpha\geqslant 3,\ \beta\geqslant -\alpha, \\ a_{i\epsilon} & \text{for } \alpha\geqslant 3,\ \beta<-\alpha. \end{cases} \tag{3.2}$$

We assume that the balls B_ϵ^i are located in the domain G and cannot form clusters so that the following conditions hold:

$$(a_3) \quad R_{i\epsilon} \geqslant a_{i\epsilon}^{\kappa} \text{ for some } \kappa\,(2/\alpha < \kappa < 1),$$

$$(a_4) \quad \text{for some } \sigma\,(3/2 < \sigma \leqslant 2), \text{ we have}$$

$$\sum_{i=1}^{N_\epsilon} \frac{b_{i\epsilon}^{\sigma}}{R_{i\epsilon}^{3(\sigma-1)}} < C_\sigma,$$

where C_σ is a constant independent of ϵ.

Introduce a generalized function

$$p_\epsilon(x) = \sum_{i=1}^{N_\epsilon} (p_{si}^{\epsilon} + p_{vi}^{\epsilon})\,\delta(x - x_\epsilon^i), \tag{3.3}$$

where p_{si}^{ϵ} and p_{vi}^{ϵ} are the specific surface and boundary layer energies, respectively, for the ith ball, defined as follows:

$$p_{si}^{\epsilon} = \begin{cases} \dfrac{4\pi}{3} g_\epsilon a_{i\epsilon}^2 & \text{for } 1 < \alpha < 3,\ \beta = 3 - 2\alpha, \\ \dfrac{4\pi}{3} g_\epsilon a_{i\epsilon}^2 \dfrac{(9k)^2}{(9k + 5g_\epsilon a_{i\epsilon})^2} & \text{for } \alpha = 3,\ \beta = -3, \\ 0 & \text{for } (\alpha,\beta) \in \Lambda^+ \setminus (1 < \alpha \leqslant 3, \beta = 3 - 2\alpha), \end{cases} \tag{3.4}$$

and

$$p_{vi}^{\epsilon} = \begin{cases} \dfrac{264\pi}{5(9k + 5g_\epsilon a_{i\epsilon})^2} k (g_\epsilon a_{i\epsilon})^2 a_{i\epsilon} & \text{for } \alpha = 3,\ \beta = -3, \\ \dfrac{264}{125} \pi k a_{i\epsilon} & \text{for } \alpha = 3,\ \beta < -3, \\ 0 & \text{for } (\alpha,\beta) \in \Lambda^+ \setminus (\alpha = 3, \beta \leqslant -3), \end{cases} \tag{3.5}$$

where

$$\Lambda^+ = \{1 < \alpha \leqslant 3, \beta \geqslant 3 - 2\alpha\} \cup \{\alpha \geqslant 3, -\infty < \beta < \infty\}.$$

Suppose that there exists a limit in a weak topology $\mathcal{D}'(G)$,

$$(b) \quad w - \lim_{\epsilon \to 0} p_\epsilon(x) = p(x), \quad \text{where } p \in L^\infty(G) \text{ satisfies inequality (2.8).}$$

The following theorem is proved in Ref. 6.

Theorem 3.1: *If the conditions* (a_1)–(a_4), (b) *and (2.8) hold, then all minimizers of the problem (2.1) and (2.2)* $(u_\epsilon(x) \in M_\epsilon)$ *converge to the unique minimizer* $u(x)$ *of the problem (2.9) and (2.10) in the following sense;*

$$\max_{u_\epsilon(x) \in M_\epsilon} \int_{G_\epsilon} |u_\epsilon(x) - u(x)\chi_\epsilon(x)|^2\, dx \to 0,$$

as $\epsilon \to 0$, *where the function* $p(x)$ *is defined in the condition* (b). *This convergence takes place in the following range of parameters* α, *and* β *:*

$$\Lambda^+ = \{1 < \alpha \leqslant 3,\ \beta \geqslant 3 - 2\alpha\} \cup \{\alpha \geqslant 3,\ -\infty < \beta < \infty\}$$

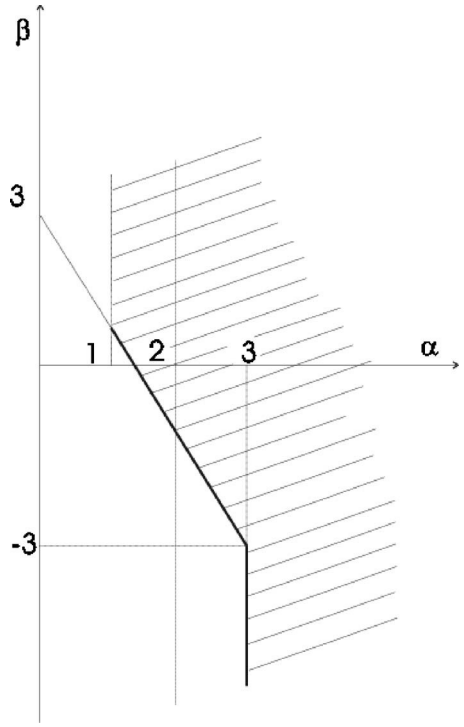

FIG. 1. $g>0$.

when $g_\epsilon>0$ *and*

$$\Lambda^- = \{1 < \alpha \leqslant 3,\ \beta \geqslant 3 - 2\alpha\} \cup \{\alpha \geqslant 3,\ \beta \geqslant -\alpha\}$$

when $g_\epsilon<0$.

The domains Λ^+ and Λ^- are presented (shaded) in Figs. 1 and 2. Notice that the function $p(x)\neq 0$ only on the bold lines. Also, note that we are able to prove a probabilistic analog of this theorem only for the subdomains located in $\Lambda^\pm$ to the right of the vertical line passing through the point $\alpha=2$.

IV. PROBABILISTIC ANALOG OF THE CONDITIONS OF THEOREM 3.1

First, note that the conditions (a_1) and (a_2) are satisfied with probability (1) [this follows from conditions (1) and (3) of Sec. II].

We now show that condition (a_3) holds "in probability." Let μ be a number such that $2/\alpha < \mu < 1$ and let $T^i_{r_\epsilon}$ be the balls centered at the points x^i_ϵ and of radii $r_\epsilon=\epsilon^{\alpha\mu}$. It is clear that $B^i_\epsilon \subset T^i_{r_\epsilon}$. Since the support G' of the function $f(x;a)$ with respect to x is a compact set in G, then (for a sufficiently small ϵ), the balls $T^i_{r_\epsilon}$ do not intersect the boundary ∂G. Consider the event A^μ_ϵ from Ω_ϵ such that the balls $T^i_{r_\epsilon}$ do not have pairwise intersection, i.e.,

$$A^\mu_\epsilon = \{\omega_\epsilon \in \Omega_\epsilon : T^i_{r_\epsilon} \cap T^j_{r_\epsilon} = \emptyset, i,j = 1,\ldots,N_\epsilon, i \neq j\}.$$

Lemma 4.1: If the conditions (1) and (2) of Theorem 2.1 hold, then

$$\lim_{\epsilon\to 0} P_\epsilon\{A^\mu_\epsilon\} = 1.$$

.

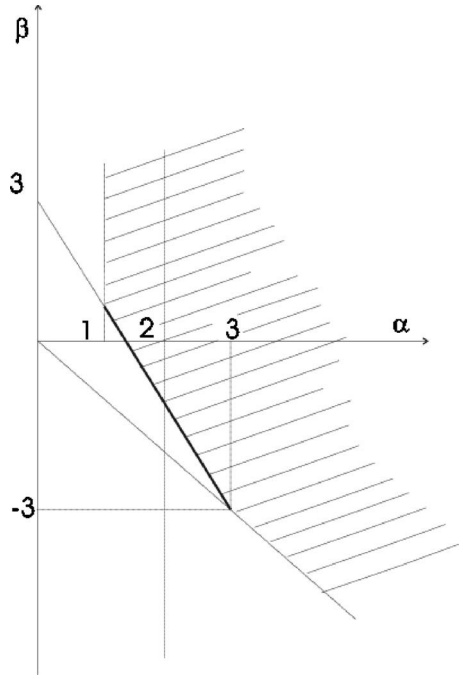

FIG. 2. $g<0$.

Proof: Let $\bar{A}_\epsilon^\mu=\Omega_\epsilon\backslash A_\epsilon^\mu$ be the event that at least one pair of balls $T_{r_\epsilon}^i$ and $T_{r_\epsilon}^j$ intersect, i.e., $\bar{A}_\epsilon^\mu$ is a complement to A_ϵ^μ. Then

$$P_\epsilon\{A_\epsilon^\mu\}=1-P_\epsilon\{\bar{A}_\epsilon^\mu\} \tag{4.1}$$

and

$$\begin{aligned}P_\epsilon\{\bar{A}_\epsilon^\mu\}&=\sum_{\substack{j,i=1\\ j>i}}^{N_\epsilon}\int_G\int_0^\infty\int_{T_{2r_\epsilon}^i}\int_0^\infty f_2^\epsilon(x^i,x^j;a_i,a_j)\mathrm{d}a_j\,\mathrm{d}x^j\,\mathrm{d}a_i\,\mathrm{d}x^i\\&=\frac{N_\epsilon(N_\epsilon-1)}{2}\int_G\int_0^\infty\int_{T_{2r_\epsilon}^1}\int_0^\infty f_2^\epsilon(x^1,x^2;a_1,a_2)\mathrm{d}a_2\,\mathrm{d}x^2\,\mathrm{d}a_1\,\mathrm{d}x^1.\end{aligned}$$

Since $N_\epsilon=\epsilon^{-3}$ and meas $(T_{2r_\epsilon}^1)=(32\pi/3)\epsilon^{3\mu\alpha}$, from conditions (2), (1) and this equality we get

$$\begin{aligned}P_\epsilon\{\bar{A}_\epsilon^\mu\}&\leqslant\frac{\epsilon^{-6}}{2}\int_G\int_0^\infty\int_{T_{2r_\epsilon}^1}\int_0^\infty f_1^\epsilon(x^1;a_1)f_1^\epsilon(x^2;a_2)\mathrm{d}a_2\,\mathrm{d}x^2\,\mathrm{d}a_1\,\mathrm{d}x^1\\&\leqslant\frac{\epsilon^{-6}}{2}\int_G\int_0^\infty f^\epsilon(x^1;a_1)\left(\int_{T_{2r_\epsilon}^1}\int_0^\infty f^\epsilon(x^2;a_2)\mathrm{d}a_2\,\mathrm{d}x^2\right)\mathrm{d}a_1\,\mathrm{d}x^1\leqslant C\epsilon^{3\mu\alpha-6}.\end{aligned}$$

Since $\mu\alpha>2$, the statement of the lemma follows from (4.1). □

Corollary 4.2: It follows from Lemma 4.1 that, if we choose κ *in condition* (a_3) *such that* $2/\alpha<\mu<\kappa<1$, *then for any i* $(i=1,\ldots,N_\epsilon)$ *the inequalities* $R_{i\epsilon}\geqslant a_{i\epsilon}^\kappa$ *hold in probability, i.e.,*

$$\lim_{\epsilon\to0}P_\epsilon\{\omega_\epsilon\in\Omega_\epsilon:R_{i\epsilon}\geqslant a_{i\epsilon}^\kappa,i=1,\ldots,N_\epsilon\}=1.$$

Let us consider now the condition (a_4). To this end we introduce a random variable

$$\zeta_\sigma^\epsilon(\omega_\epsilon)=\sum_{i=1}^{N_\epsilon}\frac{b_{i\epsilon}^\sigma}{R_{i\epsilon}^{3(\sigma-1)}},$$

where $b_{i\epsilon}=b_{i\epsilon}(\omega_\epsilon)$ and $R_{i\epsilon}=R_{i\epsilon}(\omega_\epsilon)$ are random variables defined by (3.2) and (3.1).

Lemma 4.3: If $3/2<\sigma<2$, *then*

$$\overline{\lim_{\epsilon\to 0}}\,P_\epsilon\{\omega_\epsilon\in\Omega_\epsilon:\zeta_\sigma^\epsilon(\omega_\epsilon)\leqslant N\}\geqslant 1-\frac{C(\sigma)}{N}$$

for any $N>0$, *where* $C(\sigma)$ *is independent of* N.

Proof: It follows from the definition of $R_{i\epsilon}$ that

$$\zeta_\sigma^\epsilon(\omega_\epsilon)\leqslant\zeta_{1\sigma}^\epsilon(\omega_\epsilon)+\zeta_{2\sigma}^\epsilon(\omega_\epsilon),$$

where $\zeta_{1\sigma}^\epsilon(\omega_\epsilon)$ and $\zeta_{2\sigma}^\epsilon(\omega_\epsilon)$ are random variables, which are defined as follows:

$$\zeta_{1\sigma}^\epsilon(\omega_\epsilon)=\sum_{i=1}^{N_\epsilon}b_{i\epsilon}^\sigma\max_{j\neq i}\frac{1}{|x_\epsilon^j-x_\epsilon^i|^{3(\sigma-1)}},$$

$$\zeta_{2\sigma}^\epsilon(\omega_\epsilon)=\sum_{i=1}^{N_\epsilon}\frac{b_{i\epsilon}^\sigma}{[\rho(x_\epsilon^i,\partial G)]^{3(\sigma-1)}}.$$

Therefore, it follows from the Chebyshev's inequality that

$$P_\epsilon\{\omega_\epsilon\in\Omega_\epsilon:\zeta_\sigma^\epsilon(\omega_\epsilon)\leqslant N\}\geqslant P_\epsilon\left\{\omega_\epsilon\in\Omega_\epsilon:\sum_{i=1}^{2}\zeta_{i\sigma}^\epsilon(\omega_\epsilon)\leqslant N\right\}\geqslant 1-\frac{\mathbf{M}\left(\sum_{i=1}^{2}\zeta_{i\sigma}^\epsilon\right)}{N}$$
$$=1-\frac{\mathbf{M}(\zeta_{1\sigma}^\epsilon)}{N}-\frac{\mathbf{M}(\zeta_{2\sigma}^\epsilon)}{N}\tag{4.2}$$

for any $N>0$. Here $\mathbf{M}(\cdot)$ is the expectation and in the second inequality it is taken into account that the random variable $\Sigma_{i=1}^2\zeta_{i\sigma}^\epsilon(\omega_\epsilon)$ is positive.

It follows from the properties of the distribution functions (see conditions of Theorem 2.1) that

$$\mathbf{M}(\zeta_{2\sigma}^\epsilon(\omega_\epsilon))=N_\epsilon\int_G\int_0^\infty\frac{b_\epsilon^\sigma(a)f_1^\epsilon(x;a)}{[\rho(x,\partial G)]^{3(\sigma-1)}}\mathrm{d}a\,\mathrm{d}x\leqslant Cb_\epsilon^\sigma(\epsilon^\alpha)N_\epsilon\int_{G'}\frac{\mathrm{d}x}{[\rho(x,\partial G)]^{3(\sigma-1)}},\tag{4.3}$$

where G' is the support of the function $f(x;a)$ with respect to the variable $x\in G$ and the functions $b_\epsilon(a)$ are defined as follows:

$$b_\epsilon(a)=\begin{cases}|g_\epsilon|a^2\equiv|g|\epsilon^\beta a^2 & \text{for } 2<\alpha\leqslant 3,\beta\geqslant 3-2\alpha \text{ and } \alpha\geqslant 3,\beta\geqslant-\alpha,\\ a & \text{for } \alpha\geqslant 3,\beta<-\alpha.\end{cases}$$

Notice that $b_\epsilon(\epsilon^\alpha)\leqslant C\epsilon^\alpha$ for any α, $\beta\in\Lambda^+$. Since $G'\subset G$, then $\rho(x,\partial G)\geqslant\rho_0>0$ for $x\in G'$. Therefore, it follows from (4.3) that

$$\mathbf{M}(\zeta_{2\sigma}^\epsilon)\leqslant C\epsilon^{\sigma\alpha-3},$$

where C is a constant independent of ϵ.

Since $\sigma>3/2$ and $\alpha>2$, from this inequality we have

$$\lim_{\epsilon\to 0}\mathbf{M}(\zeta_{2\sigma}^\epsilon)=0.\tag{4.4}$$

Next we estimate the expectation of the random variable $\zeta^{\epsilon}_{1\sigma}(\omega_\epsilon)$. It is clear that

$$\max_{j\neq i}\frac{1}{|x^j-x^i|^{3(\sigma-1)}}\leqslant L_\epsilon^{3(\sigma-1)}+\sum_{j\neq i}\frac{\chi_{L_\epsilon}(|x^j-x^i|)}{|x^j-x^i|^{3(\sigma-1)}}$$

for any $L_\epsilon>0$. Here $\chi_{L_\epsilon}(t)$ is the indicator of the segment $[0,L_\epsilon^{-1}]$. Therefore, it follows from the properties of the distribution functions (see the conditions of Theorem 2.1) that

$$\begin{aligned}\mathbf{M}(\zeta^{\epsilon}_{1\sigma})&=\int_0^\infty\int_G\cdots\int_0^\infty\int_G\sum_{i=1}^{N_\epsilon}b^{\sigma}_{\epsilon}(a_i)\max_{j\neq i}\frac{1}{|x^j-x^i|^{3(\sigma-1)}}\\&\times f^{\epsilon}_{N_\epsilon}(x^1,\ldots,x^{N_\epsilon};a_1,\ldots,a_{N_\epsilon})\mathrm{d}x^1\,\mathrm{d}a_1\cdots\mathrm{d}x^{N_\epsilon}\,\mathrm{d}a_{N_\epsilon}\leqslant C_1L_\epsilon^{3(\sigma-1)}N_\epsilon b^{\sigma}_{\epsilon}(\epsilon^{\alpha})\\&+\sum_{i=1}^{N_\epsilon}\sum_{j\neq i}\int_0^\infty\int_G\cdots\int_0^\infty\int_G\frac{b^{\sigma}_{\epsilon}(a_i)\chi_{L_\epsilon}(|x^j-x^i|)}{|x^j-x^i|^{3(\sigma-1)}}\\&\times f^{\epsilon}_{N_\epsilon}(x^1,\ldots,x^{N_\epsilon};a_1,\ldots,a_{N_\epsilon})\mathrm{d}x^1\,\mathrm{d}a_1\cdots\mathrm{d}x^{N_\epsilon}\,\mathrm{d}a_{N_\epsilon}\leqslant C_1L_\epsilon^{3(\sigma-1)}\epsilon^{-3}b^{\sigma}_{\epsilon}(\epsilon^{\alpha})+N_\epsilon(N_\epsilon\\&-1)\int_G\int_0^\infty\int_G\int_0^\infty\frac{b^{\sigma}_{\epsilon}(a_1)\chi_{L_\epsilon}(|x^2-x^1|)}{|x^2-x^1|^{3(\sigma-1)}}f^{\epsilon}_1(x^1;a_1)f^{\epsilon}_1(x^2;a_2)\mathrm{d}a_1\,\mathrm{d}x^1\,\mathrm{d}a_2\,\mathrm{d}x^2\\&\leqslant C_1L_\epsilon^{3(\sigma-1)}\epsilon^{\sigma\eta-3}+C_2\epsilon^{\sigma\eta-6}\int_0^{L^{-1}}\frac{r^2\,\mathrm{d}r}{r^{3(\sigma-1)}}\leqslant C_1(\sigma)[L_\epsilon^{3(\sigma-1)}\epsilon^{\sigma\eta-3}+L_\epsilon^{3\sigma-6}\epsilon^{\sigma\eta-6}],\end{aligned}\tag{4.5}$$

where $C_1(\sigma)$ is a constant independent of ϵ and $\eta=\eta(\alpha,\beta)$ is defined as follows:

$$\eta(\alpha,\beta)=\begin{cases}\beta+2\alpha & \text{for } 2<\alpha\leqslant 3,\beta\geqslant 3-2\alpha \text{ and } \alpha\geqslant 3,\beta\geqslant-\alpha,\\ \alpha & \text{for } \alpha\geqslant 3,\beta<-\alpha.\end{cases}$$

Notice, that when we calculated the integral with respect to r from 0 to L_ϵ^{-1} we used the condition $\sigma<2$ for the first time.

Now we choose L_ϵ as follows :

$$L_\epsilon=\begin{cases}\epsilon^{-1} & \text{for } 2<\alpha\leqslant 3,\\ \epsilon^{-\alpha/3} & \text{for } 3\leqslant\alpha\leqslant\infty.\end{cases}$$

Since $\eta(\alpha,\beta)\geqslant 3$ for $2<\alpha\leqslant 3$ and $\eta(\alpha,\beta)\geqslant\alpha$ for $3\leqslant\alpha\leqslant\infty$, it follows from (4.5) that

$$\overline{\lim_{\epsilon\to 0}}\,\mathbf{M}(\zeta^{\epsilon}_{1\sigma})\leqslant 2C_1(\sigma).\tag{4.6}$$

The statement of the lemma follows now from (4.2), (4.4), and (4.6). □

We next show that condition (b) also holds in probability.

Let $\varphi(x)$ be an arbitrary function from $C(\bar{G})$. Consider a random variable

$$\zeta^{\epsilon}_{\varphi}(\omega_\epsilon)=\int_G p_{\alpha\beta}(x,\omega_\epsilon)\varphi(x)\mathrm{d}x,$$

where $p_{\alpha\beta}(x,\omega_\epsilon)$ is defined by (3.3)–(3.5).

Lemma 4.4: Suppose that the conditions (1)–(3) of Theorem 2.1 hold, then

$$\lim_{\epsilon\to 0}P_\epsilon\left\{\omega_\epsilon\in\Omega_\epsilon:\left|\zeta^{\epsilon}_{\varphi}(\omega_\epsilon)-\int_G p(x)\varphi(x)\mathrm{d}x\right|<\delta\right\}=1,$$

where $p(x)$ is the function defined by (2.6) and (2.7).

Proof: It follows from the Chebyshev's inquality[23] that

$$P_\epsilon\{\omega_\epsilon \in \Omega_\epsilon : |\zeta_\varphi^\epsilon(\omega_\epsilon) - \mathbf{M}(\zeta_\varphi^\epsilon)| < \delta\} \geqslant 1 - \frac{\mathbf{D}(\zeta_\varphi^\epsilon)}{\delta^2}, \tag{4.7}$$

where $\mathbf{M}(\zeta_\varphi^\epsilon)$ and $\mathbf{D}(\zeta_\varphi^\epsilon)$ are the expectation and the variance of the random variable ζ_φ^ϵ, respectively.

Using (3.3) we can represent ζ_φ^ϵ as follows :

$$\zeta_\varphi^\epsilon(\omega_\epsilon) = \sum_{i=1}^{N_\epsilon} p_i^\epsilon \varphi(x_\epsilon^i),$$

where $x_\epsilon^i = x_\epsilon^i(\omega_\epsilon)$ are the random centers of the balls B_ϵ^i and $p_i^\epsilon = p_{si}^\epsilon(\omega_\epsilon) + p_{vi}^\epsilon(\omega_\epsilon)$ are the random variables which are defined by (3.4) and (3.5). Using this representation, the properties of the distribution functions, and condition (1) we have

$$\begin{aligned}\mathbf{M}(\zeta_\varphi^\epsilon) &= \int_0^\infty \int_G \cdots \int_0^\infty \int_G \sum_{i=1}^{N_\epsilon} p^\epsilon(a_i)\varphi(x^i) f_{N_\epsilon}^\epsilon(x^1,\ldots,x^{N_\epsilon};a_1,\ldots,a_{N_\epsilon})\mathrm{d}x^1\,\mathrm{d}a_1\cdots\mathrm{d}x^{N_\epsilon}\,\mathrm{d}a_{N_\epsilon} \\ &= N_\epsilon \int_G \int_0^\infty p^\epsilon(a)\varphi(x) f_1^\epsilon(x;a)\mathrm{d}x\,\mathrm{d}a = N_\epsilon \int_G \int_0^\infty p^\epsilon(a)\varphi(x)\epsilon^{-\alpha} f(x;\epsilon^{-\alpha}a)\mathrm{d}x\,\mathrm{d}a,\end{aligned}$$

where $p^\epsilon(a) = p_s^\epsilon(a) + p_v^\epsilon(a)$ and $p_s^\epsilon(a)$, $p_v^\epsilon(a)$ are defined by (3.4) and (3.5) with a instead of $a_{i\epsilon}$.

Since $N_\epsilon = \epsilon^{-3}$, from this equality, condition (3) and (3.4) and (3.5), we get

$$\mathbf{M}(\zeta_\varphi^\epsilon) = \int_G \varphi(x) \int_0^\infty p_{\alpha\beta}(a) f(x;a)\mathrm{d}a\,\mathrm{d}x = \int_G p(x)\varphi(x)\mathrm{d}x \equiv p_\varphi, \tag{4.8}$$

where $p_{\alpha\beta}(x)$ is defined by (2.7) and $p(x)$ is defined by (2.6).

Similarly, taking into account (4.8) and condition (2), we estimate the variance

$$\begin{aligned}\mathbf{D}(\zeta_\varphi^\epsilon) = \mathbf{M}[(\zeta_\varphi^\epsilon - \mathbf{M}(\zeta_\varphi^\epsilon))^2] &= \int_0^\infty \int_G \cdots \int_0^\infty \int_G \left(\sum_{i=1}^{N_\epsilon} p^\epsilon(a_i)\varphi(x^i) - p_\varphi \right)^2 \\ &\times f_{N_\epsilon}^\epsilon(x^1,\ldots,x^{N_\epsilon};a_1,\ldots,a_{N_\epsilon})\mathrm{d}x^1\,\mathrm{d}a_1\cdots\mathrm{d}x^{N_\epsilon}\,\mathrm{d}a_{N_\epsilon} = \epsilon^6 \int_0^\infty \int_G \cdots \int_0^\infty \int_G \sum_{i=1}^{N_\epsilon} (\epsilon^{-3}p^\epsilon(a_i)\varphi(x^i) \\ &- p_\varphi)^2 f_{N_\epsilon}^\epsilon(x^1,\ldots,x^{N_\epsilon};a_1,\ldots,a_{N_\epsilon})\mathrm{d}x^1\,\mathrm{d}a_1\cdots\mathrm{d}x^{N_\epsilon}\,\mathrm{d}a_{N_\epsilon} \\ &+ \epsilon^6 \int_0^\infty \int_G \cdots \int_0^\infty \int_G \sum_{\substack{i,j=1 \\ i\neq j}}^{N_\epsilon} (\epsilon^{-3}p^\epsilon(a_i)\varphi(x^i) - p_\varphi)(\epsilon^{-3}p^\epsilon(a_j)\varphi(x^j) - p_\varphi) \\ &\times f_{N_\epsilon}^\epsilon(x^1,\ldots,x^{N_\epsilon};a_1,\ldots,a_{N_\epsilon})\mathrm{d}x^1\,\mathrm{d}a_1\cdots\mathrm{d}x^{N_\epsilon}\,\mathrm{d}a_{N_\epsilon} = N_\epsilon\epsilon^6 \int_0^\infty \int_G (\epsilon^{-3}p^\epsilon(a)\varphi(x) \\ &- p_\varphi)^2 f_1^\epsilon(x;a)\mathrm{d}x\,\mathrm{d}a + N_\epsilon(N_\epsilon - 1)\epsilon^6 \int_0^\infty \int_G \int_0^\infty \int_G (\epsilon^{-3}p^\epsilon(a_1)\varphi(x^1) - p_\varphi)(\epsilon^{-3}p^\epsilon(a_2)\varphi(x^2) \\ &- p_\varphi) f_1^\epsilon(x^1;a_1) f_1^\epsilon(x^2;a_2)\mathrm{d}x^1\,\mathrm{d}a_1\,\mathrm{d}x^2\,\mathrm{d}a_2 = \epsilon^3 \int_0^\infty \int_G (p_{\alpha\beta}(a)\varphi(x) - p_\varphi)^2 f(x;a)\mathrm{d}x\,\mathrm{d}a \\ &+ (1-\epsilon^3) \int_0^\infty \int_G \int_0^\infty \int_G (p_{\alpha\beta}(a_1)\varphi(x^1) - p_\varphi)(p_{\alpha\beta}(a_2)\varphi(x^2) \\ &- p_\varphi) f(x^1;a_1) f(x^2;a_2)\mathrm{d}x^1\,\mathrm{d}a_1\,\mathrm{d}x^2\,\mathrm{d}a_2.\end{aligned}$$

It follows from (4.8) that the second term on the right-hand side of the last equality is equal to zero. Therefore, we get

$$\mathbf{D}(\zeta_{\varphi}^{\epsilon}) \leqslant C\epsilon^{3}. \tag{4.9}$$

The statement of the lemma follows now from (4.7)–(4.9). □

V. END OF THE PROOF OF THEOREM 2.1

Consider the following events in probability space Ω_ϵ:

$$A_{1\epsilon} = \{\omega_\epsilon \in \Omega_\epsilon : a_0\epsilon^\alpha \leqslant a_{i\epsilon}(\omega_\epsilon) \leqslant A_0\epsilon^\alpha; (\alpha > 2), i = 1,\ldots,N_\epsilon\},$$

$$A_{2\epsilon} = \{\omega_\epsilon \in \Omega_\epsilon : R_{i\epsilon} \geqslant a_{i\epsilon}^{\kappa}, (2/\alpha < \kappa < 1), i = 1,\ldots,N_\epsilon\},$$

$$A_{3\epsilon}(N) = \left\{ \omega_\epsilon \in \Omega_\epsilon : \sum_{i=1}^{N_\epsilon} \frac{b_{i\epsilon}^{\sigma}}{R_{i\epsilon}^{3(\sigma-1)}} < N, (3/2 < \sigma < 2) \right\},$$

$$A_{4\epsilon}(j,m) = \left\{ \omega_\epsilon \in \Omega_\epsilon : \left| \int_G p_\epsilon(x,\omega_\epsilon)\varphi_j(x)\mathrm{d}x - \int_G p(x)\varphi_j(x)\mathrm{d}x \right| < \frac{1}{m} \right\},$$

$$A_{5\epsilon}(\nu) = \{\omega_\epsilon \in \Omega_\epsilon : \rho(\omega_\epsilon) > \nu\},$$

where $\varphi_j(x)$ $(j=1,2,\ldots)$ is a sequence of functions which is dense $C(\bar{G})$, $\rho(\omega_\epsilon)$ is a random value defined by (2.3), $\nu > 0$, and $m \in \mathbf{N}$.

It follows from condition (1) of Theorem 2.1 that

$$P_\epsilon\{A_{1\epsilon}\} = 1 \tag{5.1}$$

for any $\epsilon > 0$.

Assume that the conclusion of Theorem 2.1 does not hold. Then there exist $\delta > 0$, $\nu > 0$, and a sequence $\{\epsilon_k \to 0, k = 1,2,\ldots\}$ such that

$$\lim_{\epsilon = \epsilon_k \to 0} P_\epsilon\{A_{5\epsilon}(\nu)\} > \delta. \tag{5.2}$$

On the other hand, it follows from the Corollary 4.2 and Lemma 4.3 and 4.4 that for any j, $m \in \mathbf{N}$ and $N > 0$ there exist $C(\sigma)$ and $\hat{\epsilon} = \hat{\epsilon}(\delta, N, j, m)$ such that

$$P_\epsilon\{A_{2\epsilon}\} \geqslant 1 - \frac{\delta}{4},$$

$$P_\epsilon\{A_{3\epsilon}(N)\} \geqslant 1 - \frac{C(\delta)}{N},$$

$$P_\epsilon\{A_{4\epsilon}(j,m)\} \geqslant 1 - \frac{\delta}{2^{j+m+2}}, \tag{5.3}$$

for any $\epsilon < \hat{\epsilon}$.

Set $N = 4C(\delta)/\delta$ and consider the event

$$A_{\epsilon_k} = A_{1\epsilon_k} \cap A_{2\epsilon_k} \cap A_{3\epsilon_k}(N) \cap \left[\bigcap_{m=1}^{m_k} \bigcap_{j=1}^{j_k} A_{4\epsilon_k}(j,m) \right] \cap A_{5\epsilon_k}(\nu), \tag{5.4}$$

where we choose the numbers m_k and j_k to be such that the inequalities (5.3) hold for $\epsilon=\epsilon_k$ and $m \leqslant m_k$, $j \leqslant j_k$, $N=4C(\delta)/\delta$. Since $\epsilon_k \to 0$ as $k \to \infty$, the numbers m_k and j_k tend to infinity as $k \to \infty$.

Now we show that there is no k for which the event $A_{\epsilon_k} \subset \Omega_{\epsilon_k}$ is not empty. It follows from our choice of N and inequalities (5.3) that

$$P_{\epsilon_k}\left\{ \bar{A}_{2\epsilon_k} \cup \bar{A}_{3\epsilon_k}(N) \cup \left[\bigcup_{m=1}^{m_k} \bigcup_{j=1}^{j_k} \bar{A}_{4\epsilon_k}(j,m) \right] \right\} \leqslant \frac{\delta}{4} + \frac{\delta}{4} + \delta \sum_{j,m=1}^{\infty} \frac{1}{2^{j+m+2}} = \frac{3}{4}\delta.$$

Therefore,

$$P_{\epsilon_k}\left\{ A_{2\epsilon_k} \cap A_{3\epsilon_k}(N) \cap \left[\bigcap_{m=1}^{m_k} \bigcap_{j=1}^{j_k} A_{4\epsilon_k}(j,m) \right] \right\} \geqslant 1 - \frac{3}{4}\delta. \tag{5.5}$$

Here the bar denotes the complementary event.

It follows from (5.4), (5.1), (5.2), and (5.5) that the events A_{ϵ_k} $(k=1,2,\ldots)$ are not empty. For any A_{ϵ_k} we choose a point $\omega(\epsilon_k)=\omega_k$ from this set and consider the corresponding realization of the balls $B^i_{\epsilon_k}(\omega_k)$ $(i=1,\ldots,N_{\epsilon_k})$ in G and the values $\rho(\omega_k)$ constructed by using the minimizers $u_{\epsilon_k}(x,\omega_k) \in M(\omega_k)$ of problem (2.1) and (2.2) in the domain $G_{\epsilon_k}(\omega_k)=G \setminus \cup_i B^i_{\epsilon_k}(\omega_k)$.

It follows from the definition of A_{ϵ_k} that all the conditions of Theorem 3.1 are satisfied as $\epsilon \to 0$ but $\rho(\omega_k)$ does not tend to zero. This contradiction proves Theorem 2.1. (Also see Ref. 24.)

(Received 22 June 2005; accepted 22 June 2005; published online 29 September 2005)

An approach to the Ginzburg–Landau problem for superconducting regular polygons is developed making use of an analytical gauge transformation for the vector potential $\mathbf{A}$ which gives $A_n=0$ for the normal component along the boundary line of different symmetric polygons. As a result the corresponding linearized Ginzburg–Landau equation reduces to an eigenvalue problem in the basis set of functions obeying Neumann boundary condition. Such basis sets are found analytically for several symmetric structures. The proposed approach allows for accurate calculations of the order parameter distributions at low calculational cost (small basis sets) for moderate applied magnetic fields. This is illustrated by considering the nucleation of superconductivity in squares, equilateral triangles and rectangles, where vortex patterns containing antivortices are obtained on the T_c–H phase boundary. The calculated phase boundaries are compared with the experimental $T_c(H)$ curves measured for squares, triangles, disks, rectangles, and loops. The stability of the symmetry consistent solutions against small deviations from the phase boundary line deep into the superconducting state is investigated by considering the full Ginzburg–Landau functional. It is shown that below the nucleation temperature symmetry-switching or symmetry-breaking phase transitions can take place. The symmetry-breaking phase transition has the same structure as the pseudo-Jahn-Teller instability of high symmetry nuclear configurations in molecules. The existence of these transitions is predicted to be strongly dependent on the size of the samples. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2013107]

I. INTRODUCTION

"Confinement" and "quantization" are two closely related definitions: if a particle is "confined" then its energy is "quantized," and vice versa. According to the dictionary, to "confine" means to "restrict within limits," to "enclose," and even to "imprison." A typical example, illustrating the relation between confinement and quantization, is the restriction of the motion of a particle by enclosing it within an infinite potential well of size L_A.

Recent impressive progress in nanofabrication has made it possible to realize the whole range of confinement lengths L_A, from 1 μm (photo- and e-beam lithography), via 1 nm to 1 Å (single atom manipulation) and, through that, to control the confinement energy (temperature) from a few mK higher up to far above room temperature.

This progress has stimulated dramatically the experimental and theoretical studies of different

[a]On leave from Laboratorio de Baixas Temperaturas e Superconductividade, Departamento de Física da Materia Condensada, Universidade de Santiago de Compostela, E-15782 Santiago de Compostela, Spain.

nanostructured materials and individual nanostructures. The interest towards such structures arises from the remarkable principle of "quantum design," when quantum mechanics can be efficiently used to tailor the physical properties of nanostructured materials.

Modifying the sample topology in nanostructured materials creates a unique possibility to impose the desired boundary conditions, and through that to change the properties of the sample. A Fermi liquid or a superconducting condensate confined within such materials will be subjected to severe constraints and, as a result, the properties of these materials will be strongly affected by the boundary conditions.[1]

While a normal metallic system should be considered quantum mechanically by solving the Schrödinger equation:

$$\frac{1}{2m}(-\imath\hbar\vec{\nabla}-e\vec{A})^2\Psi+U\Psi=E\Psi, \tag{1}$$

a superconducting system is described by the two coupled Ginzburg–Landau (GL) equations,[2]

$$\frac{1}{2m^\star}(-i\hbar\vec{\nabla}-e^\star\vec{A})^2\Psi_s+\beta|\Psi_s|^2\Psi_s=-\alpha\Psi_s, \tag{2}$$

$$\vec{j}=\vec{\nabla}\times\vec{h}=\frac{e^\star}{2m^\star}[\Psi_s^\star(-\imath\hbar\vec{\nabla}-e^\star\vec{A})\Psi_s+\Psi_s(\imath\hbar\vec{\nabla}-e^\star\vec{A})\Psi_s^\star], \tag{3}$$

with $\vec{A}$ the vector potential which corresponds to the microscopic field $\vec{h}=\mathrm{rot}\,\vec{A}/\mu_0$, U the potential energy, E the total energy, α a temperature dependent parameter changing sign from $\alpha>0$ to $\alpha<0$ as T is decreased through T_c, β a positive temperature independent constant, $m^\star$ the effective mass which can be chosen arbitrarily and is generally taken as twice the free electron mass m.

Note that the first GL equation [Eq. (2)], with the nonlinear term $\beta|\Psi_s|^2\Psi_s$ neglected, is the analogue of the Schrödinger equation [Eq. (1)] with $U=0$, when making a few substitutions, $\Psi_s\leftrightarrow\Psi$, $e^\star\leftrightarrow e$, $-\alpha\leftrightarrow E$, and $m^\star\leftrightarrow m$. The superconducting order parameter Ψ_s corresponds to the wave function Ψ in Eq. (1). The effective charge $e^\star$ in the GL equations is $2e$, i.e., the charge of a Cooper pair, while the temperature dependent GL parameter α,

$$-\alpha=\frac{\hbar^2}{2m^\star\xi^2(T)}, \tag{4}$$

plays the role of E in the Schrödinger equation. Here $\xi(T)$ is the temperature dependent coherence length,

$$\xi(T)=\frac{\xi(0)}{\sqrt{1-\dfrac{T}{T_{c0}}}}. \tag{5}$$

The boundary conditions for interfaces normal metal vacuum and superconductor vacuum are, however, different,[3]

$$\Psi\Psi^\star|_b=0, \tag{6}$$

$$(-\imath\hbar\vec{\nabla}-e^\star\vec{A})\Psi_s|_{\perp,b}=0, \tag{7}$$

i.e., for normal metallic systems *the density* is zero at the boundary (Dirichlet boundary condition), while for superconducting systems, *the current density* has no component perpendicular to the boundary. As a consequence, the supercurrent cannot flow through the boundary. The nucleation of the superconducting condensate is favored at the superconductor/vacuum interfaces, thus leading

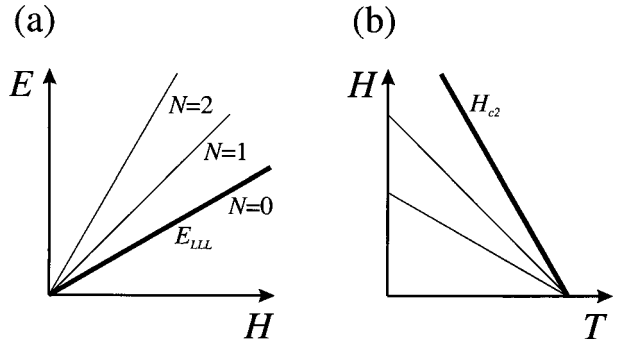

FIG. 1. Landau level scheme in the bulk. From the lowest Landau level $E_{\mathrm{LLL}}(H)=\hbar\omega/2$ [panel (a)] the second critical field $H_{c2}(T)$ [panel (b)] is derived.

to the appearance of superconductivity, at the third critical field $H_{c3}(T)$, in a surface sheet with a thickness $\xi(T)$.

For bulk superconductors the surface-to-volume ratio is negligible and therefore superconductivity in the bulk is not affected by a thin superconducting surface layer. For nanostructured superconductors with antidot arrays, however, the boundary conditions [Eq. (7)] and the surface superconductivity introduced through them become very important if $L_A \leqslant \xi(T)$. The advantage of superconducting materials in this case is that it is not even necessary to go to nm scale (like for normal metals), since for L_A of the order of 0.1–1.0 μm the temperature range where $L_A \leqslant \xi(T)$, spreads over 0.01–0.1 K below T_c due to the divergence of $\xi(T)$ at $T \to T_{c0}$ [Eq. (5)].

In principle, the mesoscopic regime $L_A \leqslant \xi(T)$ [and $L_A \leqslant \lambda(T)$, with λ the magnetic penetration depth] can eventually be reached even in bulk superconducting samples with $L_A \sim 1$ cm^{-1} m, since $\xi(T)$ [and $\lambda(T)$ as well] diverges at $T \to T_{c0}$. However, the temperature window where $L_A \leqslant \xi(T)$ is so narrow, not more than ~ 1 nK below T_{c0}, that one needs ideal sample homogeneity and perfect temperature stability.

In the mesoscopic regime $L_A \leqslant \xi(T)$, which is quite easily realized in nanostructured materials, the surface superconductivity can cover the whole available space occupied by the material, thus spreading superconductivity all over the sample. It is then evident that in this case the surface effects play the role of bulk effects.

Using the similarity between the linearized GL equation [Eq. (2)] and the Schrödinger equation [Eq. (1)], the approach to determine $T_c(H)$ can be formalized as follows: since the parameter $-\alpha$ [Eqs. (2) and (4)] plays the role of energy E [Eq. (1)], then *the highest possible temperature $T_c(H)$ for the nucleation of the superconducting state in presence of the magnetic field H always corresponds to the lowest Landau level $E_{\mathrm{LLL}}(H)$* found by solving the Schrödinger equation [Eq. (1)] with "superconducting" boundary conditions [Eq. (7)].

Figure 1 illustrates the application of this basic rule to the calculation of the upper critical field $H_{c2}(T)$, indeed, if the well-known classical Landau solution for the lowest level in a bulk sample $E_{\mathrm{LLL}}(H)=\hbar\omega/2$, where $\omega=e^{\star}\mu_0 H/m^{\star}$ is the cyclotron frequency, is taken, then, from $-\alpha = E_{\mathrm{LLL}}(H)$, we have

$$\frac{\hbar^2}{2m^{\star}\xi^2(T)} = \left.\frac{\hbar\omega}{2}\right|_{H=H_{c2}} \tag{8}$$

with the help of Eq. (4). We obtain

$$\mu_0 H_{c2}(T) = \frac{\Phi_0}{2\pi\xi^2(T)}, \tag{9}$$

with $\Phi_0 = h/e^{\star} = h/2e$ the superconducting flux quantum.

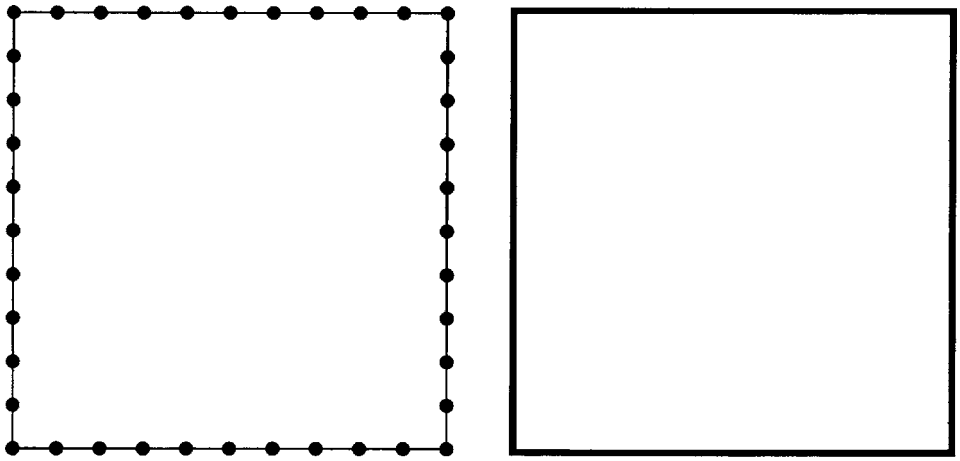

FIG. 2. Domains (bold dots and lines) of the boundary line where the condition in Eq. (7) is satisfied exactly for the case of finite grid (a) and appropriate vector potential gauge (b) methods.

In nanostructured superconductors, where the boundary conditions [Eq. (7)] strongly influence the Landau level scheme, $E_{\mathrm{LLL}}(H)$ must be calculated for each specific confinement geometry. By measuring the shift of the critical temperature $T_c(H)$ in a magnetic field, one can compare the experimental phase boundary $T_c(H)$ with the calculated level $E_{\mathrm{LLL}}(H)$ and thus check the effect of the confinement topology on the superconducting phase boundary for a series of nanostructured superconducting samples. The transition between normal and superconducting states is usually very sharp and therefore the lowest Landau level can be easily traced as a function of applied magnetic field. The midpoint of the resistive transition from the superconducting to the normal state is usually taken as the criterion to determine $T_c(H)$.

This defines the main strategy of our paper to use systematically the GL approach to calculate the condensate density and the energy levels [including $E_{\mathrm{LLL}}(H)$ for superconducting samples of different geometries and topologies and to compare the calculated lowest level $E_{\mathrm{LLL}}(H)$] with the measured $T_c(H)$ phase boundary.

The presence of the vector potential in the boundary condition, Eq. (4), seriously complicates the solution of the Ginzburg–Landau equations for samples of arbitrary geometry. Existing treatments use numerical methods like the method of finite differences. This way proved to be successful for the description of superconductivity in mesoscopic structures[4,5] although it is usually achieved at the expense of high computational costs. The problem, however, simplifies very much if one can find a gauge for the vector potential ($\tilde{\mathbf{A}}$) giving zero normal component on the boundary line

$$\tilde{\mathbf{A}}|_n = 0. \tag{10}$$

In these cases the superconducting boundary condition in Eq. (7) reduces to the Neumann boundary condition,

$$\nabla\Psi|_n = 0, \tag{11}$$

which is much easier to satisfy. Such gauges have been found in the past for infinite slabs,[6] semiplanes with a wedge,[7,8] and disks.[9–12]

The major difference between the above approaches is the extent to which they fulfill the superconducting boundary condition. As Fig. 2 shows, the method of finite differences satisfies Eq. (7) only on a finite set of points along the boundary line, while by using an appropriate gauge for the vector potential (10) we are able *to satisfy the boundary condition everywhere on the*

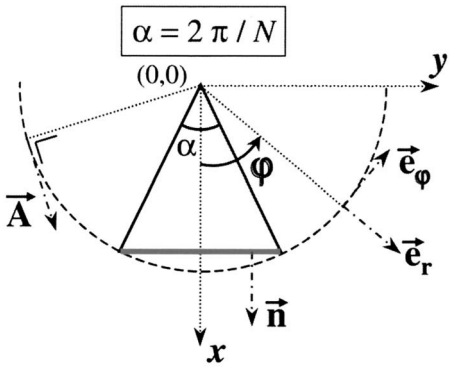

FIG. 3. Piece of a regular polygon containing one edge (thick line). The origin of the coordinate system is chosen in the center of the polygon. $\mathbf{n}$ is the unit vector normal to the edge. $\mathbf{e}_r$ and $\mathbf{e}_\varphi$ are unit vectors of the cylindrical coordinate system. The z axis coincides with the N fold rotational axis of the polygon.

boundary. Since Eq. (7) is nothing but a sort of quantization condition for our problem, we can conclude that finite grid methods always imply an *approximate* solution of Eq. (7), while the methods using the appropriate gauge for the vector potential treat it *exactly*. This is crucial for the proper description of the order parameter in the cases when the boundary becomes important, i.e., for low values of the applied flux.

In this paper we review the development of this second type of approach to the Ginzburg–Landau problem for symmetric superconducting polygons in external magnetic field. In Secs. II and III we present the derivation of vector potential gauge and the basis set for several symmetric structures. The application of this approach to the description of the nucleation of superconductivity in different polygons is given in Sec. IV. Here the evolution of the vortex patterns as a function of applied magnetic field is investigated in detail. We also compare the calculated superconducting/normal phase boundary lines with the experimental ones. The evolution from a disk to thin loops is discussed in Sec. V. In Sec. VI we study the stability of the LGL solutions corresponding to nucleated phases and the conditions for the arising of different phase transitions when the temperature is lowered from the nucleation point. Finally Sec. VII gives some conclusions and the perspective for the future work.

II. VECTOR POTENTIAL GAUGE FOR SYMMETRIC POLYGONS

Consider a regular polygon with N edges. It has a symmetry axis of order N, corresponding to rotations by angles which are multiples of $2\pi/N$. An external homogeneous magnetic field applied along this axis can be described by a vector potential

$$\mathbf{A} = \tfrac{1}{2}\mathbf{H} \times \mathbf{r}, \tag{12}$$

where the radius vector lies in the xy plane (Fig. 3) and $\mathbf{H} \| \mathbf{z}$. Equation (12) defines the cylindrical gauge for $\mathbf{A}$. It is often preferred over many other possible choices[13] due to the high symmetry which allows to preserve the rotational symmetry of the system without field. The direction of $\mathbf{A}$ is tangential to concentric circumferences, $\mathbf{A} \| \mathbf{e}_\varphi$, which are also equipotential lines for the vector potential.

As one can see from Fig. 3, the vector potential in Eq. (12) is not tangential to the boundary line (i.e., the edges) of a polygon. On the edge shown in Fig. 3 it contains a normal component

$$A_n(\varphi) = -C \tan \varphi,$$

$$C = \tfrac{1}{4} H a, \tag{13}$$

where φ is the polar angle and a is the diameter of the circumference inscribed in the regular polygon. Our purpose is to find a new vector potential which would be tangential to the edges. This can be done by the following gauge transformation:[13]

$$\tilde{\mathbf{A}} = \mathbf{A} + \nabla S, \tag{14}$$

where $\mathbf{A}$ is the old and $\tilde{\mathbf{A}}$ is the new vector potential and S is an arbitrary scalar function. This function is found from the condition $\tilde{A}_n = 0$ on the boundary line. This is equivalent to the equation

$$A_n = -\nabla_n S, \tag{15}$$

which must be obeyed on each edge. In order to keep the rotational symmetry of the regular polygon $\tilde{\mathbf{A}}$ and S should be periodic functions of φ with the period α (Fig. 3). Because $\tilde{\mathbf{A}}$ is real, this suggests the following general form for S (in polar coordinates):

$$S(r,\varphi) = \sum_m [R_m^s(r)\sin(Nm\varphi) + R_m^c(r)\cos(Nm\varphi)], \tag{16}$$

where m are non-negative integers. Due to the rotational periodicity of the function S it is enough to satisfy Eq. (15) on one single edge. The form in Eq. (16) is further simplified due to the symmetry requirement that $\tilde{\mathbf{A}}$ is purely tangential on the radial lines defined by $\varphi = \pm\alpha/2$ and $\varphi = 0$ (Fig. 3). The latter requirement means that ∇S is purely tangential on the radial line $\varphi = 0$ which can only be the case if one takes $R_m^c(r) = 0$ in Eq. (16).

Next we simplify the remaining part of the form (16) by confining ourselves to one single term in the summation. Obviously this cannot be the term $m = 0$ because ∇S should be dependent on φ as it is easily seen from Eqs. (13) and (15). Therefore the simplest possible term is $m = 1$ which leads to the ansatz,

$$S_N(r,\varphi) = R_N(r)\sin(N\varphi). \tag{17}$$

Substituting Eqs. (13) and (17) into (15), after eliminating the r variable on the edge line,

$$r = \frac{a}{2\cos\varphi},$$

$$\frac{\partial}{\partial r} = \frac{2}{a}\frac{\cos^2\varphi}{\sin\varphi}\frac{\partial}{\partial\varphi}, \tag{18}$$

one obtains the following equation in φ:

$$\tilde{R}_N' \sin(N\varphi)\cos^2\varphi - \tilde{R}_N \sin(N\varphi)'\sin^2\varphi = \tan^2\varphi, \tag{19}$$

where the prime in the superscript means the first derivative after φ and the following notation was introduced:

$$\tilde{R}_N(\varphi) = \frac{2}{aC} R_N\left(\frac{a}{2\cos\varphi}\right). \tag{20}$$

Bringing Eq. (19) to the form

$$\tilde{R}_N' + \xi(\varphi)\tilde{R}_N = \eta(\varphi), \tag{21}$$

where

$$\xi(\varphi) = -N\cot(N\varphi)\tan^2\varphi,$$

$$\eta(\varphi) = \csc(N\varphi)\tan^2\varphi/\cos^2\varphi, \tag{22}$$

allows us to write down the general solution[14]

$$\tilde{R}_N(\varphi) = \frac{1}{\mu(\varphi)}\left(\int \eta(\varphi)\mu(\varphi)\mathrm{d}\varphi + C_1\right),$$

$$\mu(\varphi) = \exp\left(\int \xi(\varphi)\mathrm{d}\varphi\right). \tag{23}$$

The solution (23) describes the radial function in Eq. (17) only for values of r which are radius vectors of the points on the edge's line. One can extend this solution over the whole range of r by the inverse transformation to (18), $a/2\cos\varphi \to r$. Then using again Eqs. (14), (17), and (20) we can express the polar components of the gauge transformed vector potential $\tilde{\mathbf{A}}$,

$$\tilde{A}_r = \frac{\partial R_N(r)}{\partial r}\sin(N\varphi),$$

$$\tilde{A}_\varphi = \frac{1}{2}Hr + \frac{N}{r}R_N(r)\cos(N\varphi), \tag{24}$$

through the solution (23). The constant C_1 contained in that solution should be chosen in such a way as to provide nondivergent components of the vector potential (24). In contrast to $\mathbf{A}$ in Eq. (12), the vector potential defined by Eqs. (24) does not obey the Coulomb gauge, $\nabla\cdot\mathbf{A}=0$. Hence the term $\nabla\cdot\mathbf{A}$ plays the role of a scalar potential in a Hamiltonian and should be nondivergent either. Fortunately both requirements are met within the area of the polygon under the simple condition $C_1=0$.

Analytical expressions of Eqs. (23) for some regular polygons are given in Ref. 15.

In the case of equilateral triangle the solutions (24) have the form

$$\tilde{A}_r = \tfrac{27}{2}Ha\left(9r'^8 - 7r'^6 + \tfrac{5}{3}r'^4\right)\sin 3\varphi,$$

$$\tilde{A}_\varphi = \tfrac{1}{2}Hr + \tfrac{81}{2}Ha\left(r'^8 - r'^6 + \tfrac{1}{3}r'^4\right)\cos 3\varphi,$$

$$r' = r/\sqrt{3}a, \tag{25}$$

where a is the side length of the triangle. Figure 4 shows how the gauge transformed vector potential looks for the equilateral triangle. We can see that it gradually changes from the cylindrical gauge in the central region to a triangular pattern close to the edges. According to this gauge transformation one should add to Eq. (4) the following divergency term:

$$\nabla\cdot\tilde{\mathbf{A}} = H\frac{9\sqrt{3}}{2}\left(72r'^7 - 40r'^5 + \frac{16}{3}r'^3\right)\sin 3\varphi. \tag{26}$$

In the case of a square the solutions of Eqs. (23) and (24) yield the following gauge transformed vector potential (Fig. 5):

$$\tilde{A}_r = -\frac{1}{4\sqrt{2}}Ha(1+u)^{3/2}[-1+u+(1+2u-u^2)e^{-u}Ei(u)]\sin 4\varphi,$$

$$\tilde{A}_\varphi = \frac{1}{2}Hr + \frac{1}{2\sqrt{2}}Ha(1+u)^{3/2}[1-ue^{-u}Ei(u)]\cos 4\varphi,$$

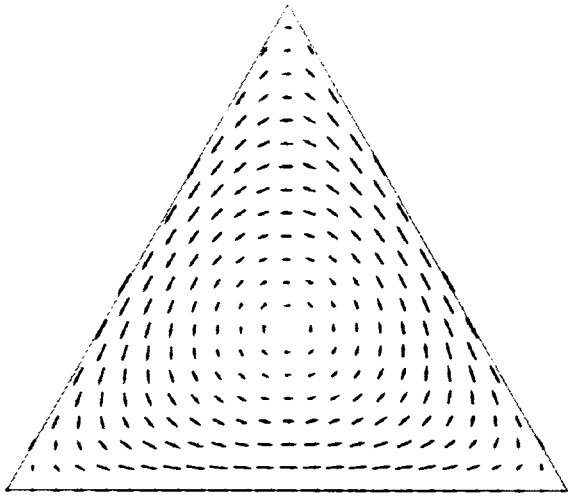

FIG. 4. Vector potential for the equilateral triangle (arbitrary units) after the gauge transformation, described by Eqs. (25).

$$u = 2(r/a)^2 - 1, \tag{27}$$

where $Ei(u)$ is the exponential integral function[16] and a is the side length of the square. In full analogy with the previous case (Fig. 4), this vector potential coincides with the cylindrical gauge in the central region and smoothly changes into a square symmetry pattern when approaching the boundaries. The corresponding divergency term is obtained as follows:

$$\boldsymbol{\nabla} \cdot \tilde{\mathbf{A}} = H\frac{(1+u)^2}{2u}[-1-5u+u^2-u(3-6u+u^2)e^{-u}Ei(u)]\sin 4\varphi. \tag{28}$$

The results for the square are easily extended over arbitrary rectangles, described by the aspect

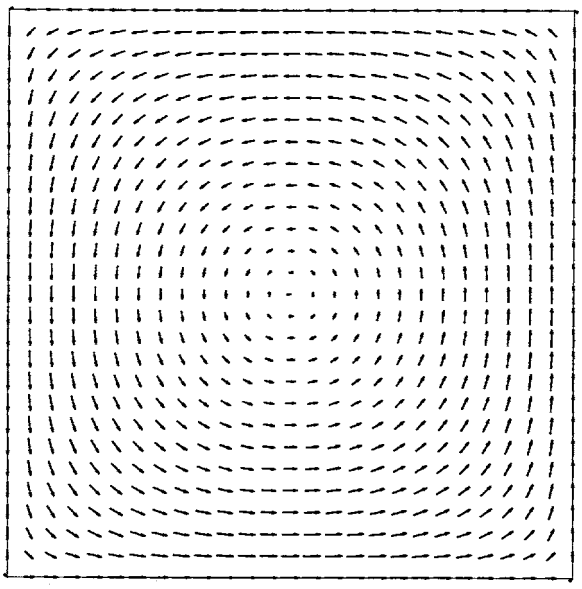

FIG. 5. Vector potential for the square (arbitrary units) after the gauge transformation, described by Eqs. (27).

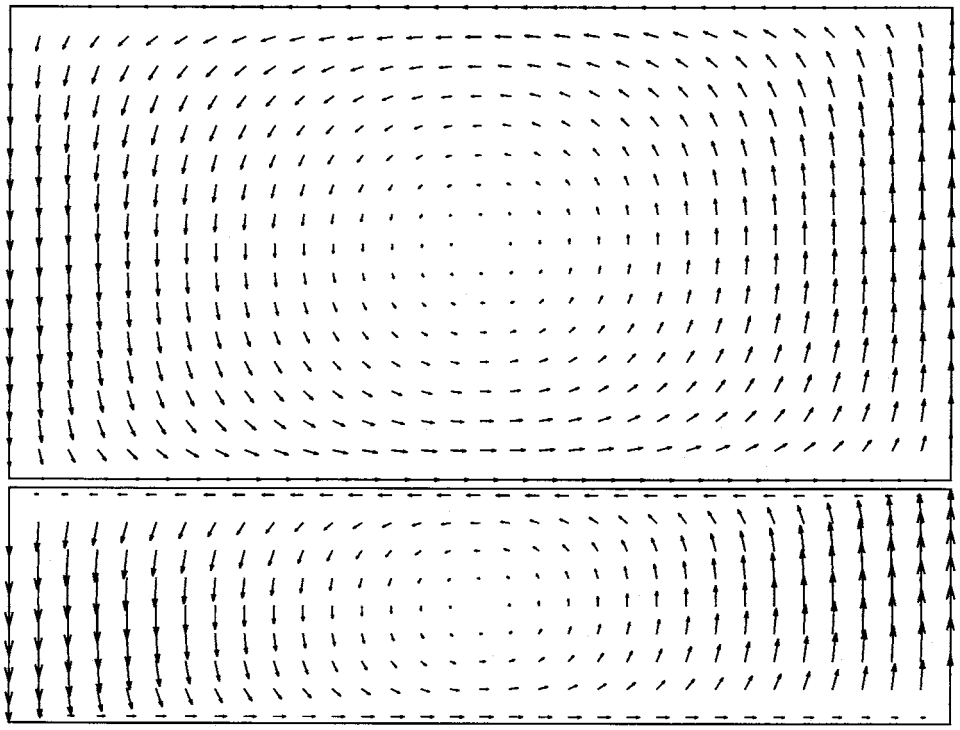

FIG. 6. Vector potential for the rectangle (arbitrary units) with aspect ratio two (top) and four (bottom) after the gauge transformation, described by Eqs. (14), (27), and (29).

ratios $\zeta=a/b$, where a and b are the lengths of the two sides. Directing the Cartesian axes x and y along the sides a and b, respectively, we find the following relation for the scalar function S entering the gauge transformed vector potential (14) for the rectangle:

$$S_{\mathrm{rect}}(x,y) = S_{\mathrm{sq}}\left(\frac{1}{\sqrt{\zeta}}x, \sqrt{\zeta}y\right), \tag{29}$$

where S_{sq} is the scalar function for the square with the side length $a/\sqrt{\zeta}=\sqrt{\zeta}b$. After substitution of Eq. (29) into (14), written in polar coordinates, we can make direct use of Eqs. (27). The resulting gauge transformed vector potential is shown in Fig. 6. The divergency term to be inserted into Eq. (4) is just ΔS_{rect}.

Another extension of the above approach concerns symmetric nonhomogeneous applied magnetic fields. These can be induced, for instance, by setting a cylindrical quantum dot uniformly magnetized along its axis on the top of a superconducting sample.[17,18] This magnetic field together with an independent homogeneous component corresponds to a vector potential of cylindrical symmetry[19]

$$A_{\varphi}(r) = \frac{1}{2}Hr + 4M\sqrt{\frac{R}{r}}\int_0^l \frac{\left[\left(1-\frac{k^2}{2}\right)K(k) - E(k)\right]}{k}\mathrm{d}z,$$

$$k^2 = \frac{4rR}{(r+R)^2+z^2}, \tag{30}$$

where R, l, and M are the radius, the height, and the density of magnetization of the cylindrical dot, respectively; K and E are elliptic integrals of first and second kind, respectively, and H is the

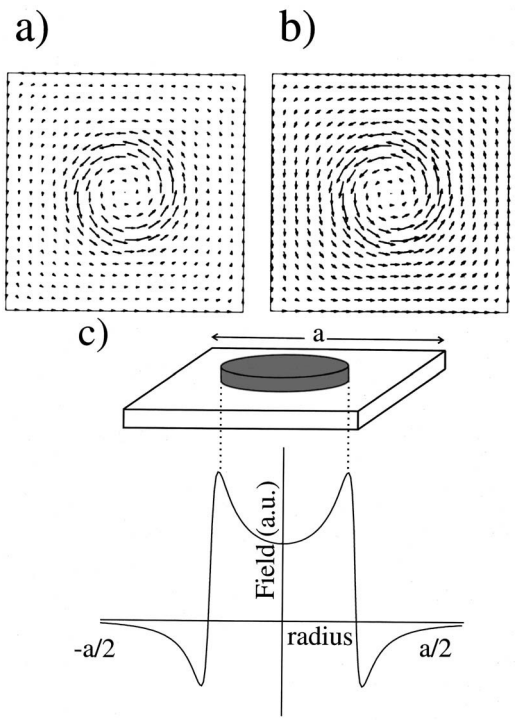

FIG. 7. Vector potential for a square with cylindrical uniformly magnetized quantum dot (a) in an external homogeneous magnetic field producing one flux quantum in the sample, (b) in zero external field. The dot has a radius 0.2 times and a height 0.032 times the sample size a and the magnetization produces one flux quantum in the sample. (c) Schematic drawing of the superconducting square with the magnetic dot (gray) and the corresponding field profile.

intensity of the homogeneous magnetic field as before. Repeating all derivations with the new applied vector potential (30) instead of the cylindrical one (12) we obtain similar results as in Eqs. (22), (23), and (24), where the second equation from (22) should be replaced by

$$\eta(\varphi) = \csc(N\varphi)\frac{\tan^2\varphi}{\cos\varphi}A_\varphi\left(\frac{a}{2\cos\varphi}\right), \tag{31}$$

and A_φ should replace $Hr/2$ in the second equation of (24). However now we can no longer find the primitive in the first equation of (23) in analytical form. This complication can be avoided if we approximate the function $A_\varphi(r)$ by polynomials. This can be done for arbitrary parameters of the dot, which allows to obtain the explicit expressions for the components of the gauge transformed vector potential.[20] Figure 7 shows the gauge transformed vector potential for a square with a cylindrical magnetic dot on top of it. We can see that the behavior of $\tilde{\mathbf{A}}$ as function of r is similar to the previous cases.

III. BASIS SET FOR THE GL PROBLEM OF SYMMETRIC POLYGONS

Having found a gauge for the vector potential ($\tilde{\mathbf{A}}$) satisfying the condition (10) on the boundary line, it follows immediately from Eq. (7) that the order parameter can be expanded into a set of functions, $\{\psi_m\}$,

$$\Psi = \sum_m c_m\psi_m, \tag{32}$$

obeying the Neumann boundary condition,

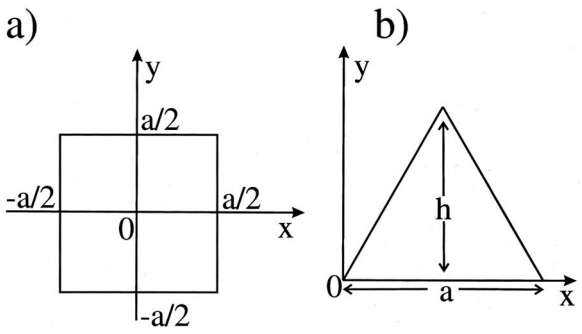

FIG. 8. Coordinate systems used in the derivation of the basis set for a square (a) and an equilateral triangle (b).

$$\nabla \psi_m|_n = 0. \tag{33}$$

For calculational convenience the functions ψ_m are supposed to form an orthonormal set. Furthermore, in order to reduce the dimension of the basis set these functions should be as close as possible to the expected solutions of Eq. (4). Since we are interested in solutions for moderate values of applied magnetic fluxes both requirements are met for sets of low-lying eigenfunctions of the zero-field (i.e., particle in the polygonal box) eigenvalue problem,

$$-\frac{\hbar^2}{2m^*}\Delta\psi_m = \epsilon_m \psi_m, \tag{34}$$

obeying the boundary condition (33).

Consider a regular polygon shaped sample of a constant width in a homogeneous magnetic field applied along the direction perpendicular to the polygonal surface ($\mathbf{H}\|\mathbf{z}$). Then the associated vector potential $\mathbf{A}$ is directed in the xy plane (see Fig. 3). Since $A_z=0$ and the other two components depend on x and y only, the solution of Eq. (34) factorizes as $\Psi(x,y)\Phi(z)$. The z-dependent component of the solution satisfying the boundary condition $d\Phi/dz=0$, $z=\pm d/2$, and corresponding to the lowest value of $-\alpha$ in Eq. (4) has the form $\Phi=$const. This means that the superconductivity nucleates homogeneously across the width of the sample and the solution of the LGL equation reduces to a two-dimensional (2D) problem.

The transformation (14) and (17) keeps the symmetry of the vector potential [and of Eqs. (4)] equal to the rotational symmetry of the sample, described by the point group C_N. Since the LGL equation is a linear eigenvalue problem its solutions, according to Wigner's theorem,[21] are characterized by irreducible representations (irreps) of the corresponding symmetry group. The point group C_N is Abelian and therefore contains N different one-dimensional irreps which transform as

$$\psi_n(\varphi) \sim \exp(in\varphi),$$

$$n = 0,1,\ldots,N-1, \tag{35}$$

under rotations around the z axis by symmetry angles, the smallest of which coincides with the angle α in Fig. 3. The symmetry analysis provides a set of N labels to assign eigenfunctions and splits the matrix eigenvalue equation into diagonal blocks corresponding to different irreps[21] which simplifies the calculations.

A. Square and rectangle

In these geometries the boundary conditions allow the separation of variables in the eigenvalue problem (34) if one chooses the coordinate axes parallel to corresponding edges [Fig. 8(a)].

Along each coordinate the problem reduces to a particle in the box with infinite potential walls.[21] The corresponding solution for the boundary conditions (33) has the form (l is the dimension of the box)

$$\psi_k^1(x) = \sqrt{\frac{2}{l}}\cos kx, \quad k = \frac{2n\pi}{l},$$

$$\psi_k^2(x) = \sqrt{\frac{2}{l}}\sin kx, \quad k = \frac{(2n+1)\pi}{l},$$

$$n = 0,1,2,\ldots . \tag{36}$$

The full solutions in a rectangular box are just the products $\psi_{k_x}(x)\psi_{k_y}(y)$ and correspond to the energy,

$$E_{k_x k_y} = \frac{\hbar^2(k_x^2 + k_y^2)}{2m^*}. \tag{37}$$

These solutions however do not correspond to any definite symmetry. Therefore they should be symmetrized if we want to take advantage of the symmetry of the samples as discussed above.

A *square* in homogeneous magnetic field has the symmetry described by the rotational point group C_4, which contains the irreps A, B, E_+, and E_- with the corresponding numbers $n=0$, 2, 1, and -1 (or 3) in Eq. (35). Using the conventional symmetry projection technique[21] the symmetrized basis set is easily constructed from the solutions in Eq. (37). Thus we obtain the following types of solutions, for the irrep A:

$$\psi_A^1 = \frac{\sqrt{2}}{a}[\cos k_1 x \cos k_2 y + \cos k_2 x \cos k_1 y],$$

$$k_1 > k_2 \geqslant 0, \quad k_i = \frac{2n_i\pi}{a},$$

$$\psi_A^2 = \frac{2}{a}\cos kx \cos ky, \quad k = \frac{2n\pi}{a} \geqslant 0,$$

$$\psi_A^3 = \frac{\sqrt{2}}{a}[\sin k_1 x \sin k_2 y - \sin k_2 x \sin k_1 y],$$

$$k_1 > k_2 > 0, \quad k_i = \frac{(2n_i+1)\pi}{a}, \tag{38}$$

for the irrep B,

$$\psi_B^1 = \frac{\sqrt{2}}{a}[\cos k_1 x \cos k_2 y - \cos k_2 x \cos k_1 y],$$

$$k_1 > k_2 \geqslant 0, \quad k_i = \frac{2n_i\pi}{a},$$

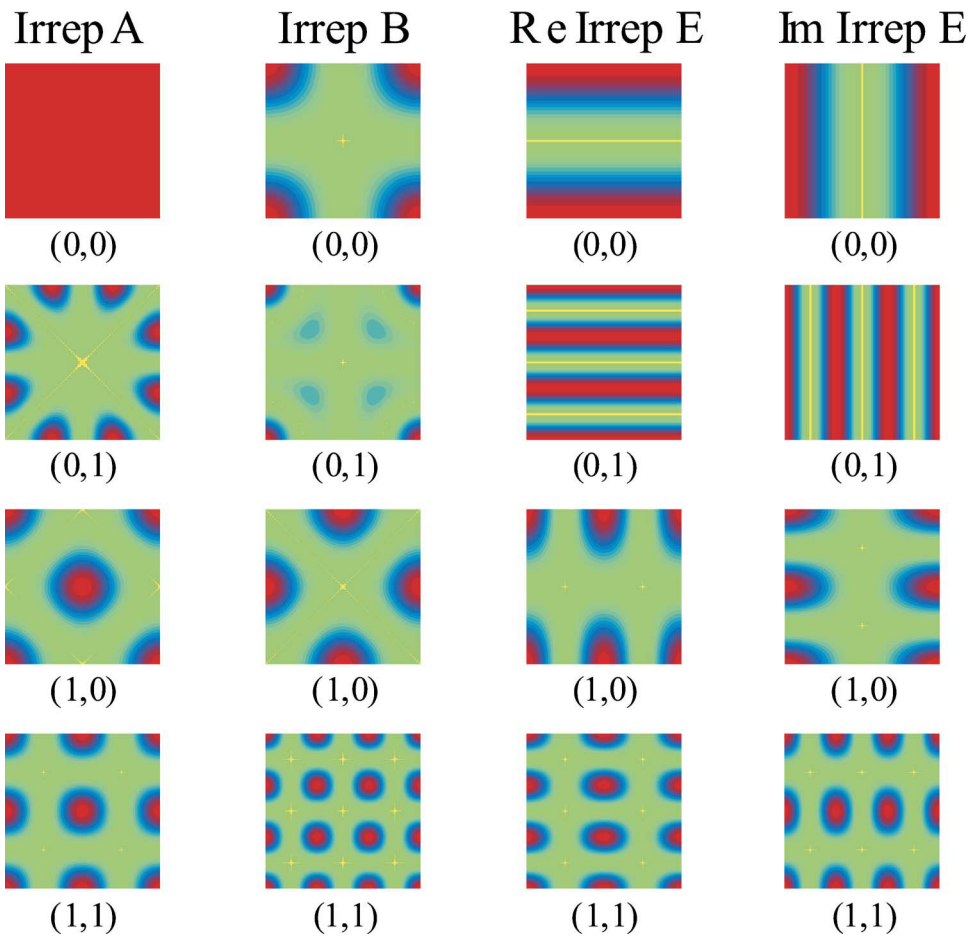

FIG. 9. (Color online) Symmetrized basis functions for a square. The highest density is shown in darker shades and the lowest $|\psi|^2$ values are lighter shades. The numbers in parentheses stand for n_1 and n_2, respectively.

$$\psi_B^2 = \frac{2}{a}\sin kx \sin ky, \quad k = \frac{(2n+1)\pi}{a} > 0,$$

$$\psi_B^3 = \frac{\sqrt{2}}{a}[\sin k_1 x \sin k_2 y + \sin k_2 x \sin k_1 y],$$

$$k_1 > k_2 > 0, \quad k_i = \frac{(2n_i+1)\pi}{a} \tag{39}$$

and for the irrep E,

$$\psi_{E_{+,-}} = \frac{\sqrt{2}}{a}[\cos k_1 x \sin k_2 y \pm i \cos k_1 y \sin k_2 x],$$

$$k_1 = \frac{2n_1\pi}{a} \geqslant 0, \quad k_2 = \frac{(2n_2+1)\pi}{a} \geqslant 0, \tag{40}$$

where n_i are integers. Figure 9 shows graphically some of these symmetrized functions.

In a *rectangle* the symmetry in homogeneous magnetic field is described by the point group

C_2 containing only two irreps, A and B. The reduction of symmetry with respect to the square induces the following reduction of the irreps of C_4: $A,B\rightarrow A$, $E_+,E_-\rightarrow B$. The basis function resulting from this reduction have the following form, for irrep A:

$$\psi_A^1=\frac{2}{\sqrt{ab}}\cos k_1x\cos k_2y,$$

$$k_1=\frac{2n_1\pi}{a},\quad k_2=\frac{2n_2\pi}{b},$$

$$\psi_A^2=\frac{2}{\sqrt{ab}}\sin k_1x\sin k_2y,$$

$$k_1=\frac{(2n_1+1)\pi}{a},\quad k_2=\frac{(2n_2+1)\pi}{b}, \tag{41}$$

and for the irrep B,

$$\psi_B^1=\frac{2}{\sqrt{ab}}\cos k_1x\sin k_2y,$$

$$k_1=\frac{2n_1\pi}{a},\quad k_2=\frac{2(n_2+1)\pi}{b},$$

$$\psi_B^2=\frac{2}{\sqrt{ab}}\sin k_1x\cos k_2y,$$

$$k_1=\frac{(2n_1+1)\pi}{a},\quad k_2=\frac{2n_2\pi}{b} \tag{42}$$

where n_i are integers.

B. Equilateral triangle

This case is more involved since the geometry of the boundary does not allow the separation of variables in the eigenvalue problem (34). Nevertheless it is still possible to express the solutions as a linear combination of a small number ($\leqslant 6$) of plane waves as shown below.

The equilateral triangle in a homogeneous magnetic field has a symmetry corresponding to the rotational point group C_3, which contains the irreps A, E_+, and E_- matching the numbers $n=0$, 1, and -1 (or 2) in Eq. (35), respectively. We make use of this symmetry in the next section when we analyze the solutions of the corresponding LGL equation. The particle in the box problem, however, is characterized by a higher symmetry group C_{3v}, containing in addition three vertical reflection planes, which are absent when the magnetic field is applied. It is convenient to use this higher symmetry group in further derivation. The method used here follows closely the one employed by Li and Blinder for a triangular box with Dirichlet boundary conditions.[22] For an equilateral triangle located with respect to Cartesian axes as shown in Fig. 8(b) we introduce three variables (h is the height of the triangle),

$$u=\frac{2\pi}{h}y,$$

$$v = \frac{2\pi}{h}\left(-\frac{1}{2}y + \frac{\sqrt{3}}{2}x\right),$$

$$w = \frac{2\pi}{h}\left(-\frac{1}{2}y - \frac{\sqrt{3}}{2}x\right) + 2\pi, \tag{43}$$

which are obviously linearly dependent. These variables are transformed into each other under symmetry operations of the C_{3v} group and obey simple relations on the boundaries of the triangle. For instance, on the edge $y=0$ [Fig. 8(b)] we have

$$u = 0, \quad v = 2\pi - w. \tag{44}$$

Equation (34) is satisfied for a harmonic function with arbitrary linear combination of x and y in the argument. It is convenient to take this function in the form $f(pu-qv)$,[22] where u and v are variables introduced in Eq. (43), corresponding to the energy (in units of $\hbar^2/2m^*$),

$$E_{pq} = 4\frac{\pi^2}{h^2}(p^2 + pq + q^2). \tag{45}$$

Starting from the function f, we construct wave functions of definite symmetry by using the method of symmetry projection.[21] The projected functions are linear combinations of functions f of different arguments, all of which obviously correspond to the same energy (45). Due to this symmetrization it is enough to satisfy the boundary condition (33) on a single edge, e.g., $y=0$ [Fig. 8(b)]. Equation (44) shows that on that boundary the wave function depends on a single variable v. The boundary condition is then satisfied by choosing appropriate values of the constants p and q which, at their turn, define the allowed values of the energy (45).

Irrep A_1: The boundary condition at the edge $y=0$ is obtained in the form

$$\left.\frac{\partial \psi_{A_1}}{\partial u}\right|_{u=0} = (2p+q)(f'_u[-qv] + f'_u[qv - 2\pi q]) + (-p+q)(f'_u[-(p+q)v + 2\pi p] + f'_u[(p+q)v - 2\pi q]) - (p+2q)(f'_u[-pv + 2\pi p] + f'_u[pv]) = 0. \tag{46}$$

Since f is a harmonic function with the period 2π, the above equation is only satisfied for integer values of p and q and $f=\cos$. Furthermore, the function ψ_{A_1} is invariant under the following replacements of the two constants: $p,q \to q,p$, $p,q \to -p,-q$ and $p+q,-p \to p,q$. This restricts p and q to positive values. Rewriting this function in x and y variables we obtain (without normalization)

$$\psi^{A_1}_{pq}(x,y) = \cos\frac{\pi}{h}(2p+q)y \cos\frac{\pi}{h}\sqrt{3}qx + \cos\frac{\pi}{h}(-p+q)y \cos\frac{\pi}{h}\sqrt{3}(p+q)x + \cos\frac{\pi}{h}(p+2q)y \cos\frac{\pi}{h}\sqrt{3}px,$$

$$p \geqslant q = 0,1,2,\ldots. \tag{47}$$

Irrep A_2: The boundary conditions for ψ_{A_2} lead to an equation similar to (46) with the only difference that now differences of derivatives f'_u enter in each of the square brackets instead of their sum. This means that the only choice for the harmonic function is $f=\sin$. The constants p and q are again integers and obey the same symmetry relations as in the previous case. Therefore, we obtain for the irrep A_2 the following unnormalized eigenfunctions:

$$\psi_{pq}^{A_2}(x,y) = -\sin\frac{\pi}{h}\sqrt{3}qx\cos\frac{\pi}{h}(2p+q)y + \sin\frac{\pi}{h}\sqrt{3}(p+q)x\cos\frac{\pi}{h}(-p+q)y$$
$$-\sin\frac{\pi}{h}\sqrt{3}px\cos\frac{\pi}{h}(p+2q)y,$$

$$p \geqslant q = 1,2,\ldots . \tag{48}$$

Note that in the presence of homogeneous magnetic field both ψ_{A_1} and ψ_{A_2} reduce to the same irrep A of the group C_3.

Irrep E: Because this irrep is twofold degenerate the corresponding two eigenfunctions are defined up to an arbitrary linear combination. It is convenient to choose these functions as complex conjugate to each other because then they belong automatically to the irreps E_+ and E_- of the group C_3, respectively. This requirement leaves us the only choice for the harmonic function, $\exp[i(pu-qv)]$. After similar derivations as in previous cases we obtain for the unnormalized eigenfunctions $[\psi^{E_-}=(\psi^{E_+})^*]$

$$\psi_{pq}^{E_-}(x,y) = \exp\left\{\frac{\pi i}{h}[(2p+q)y-\sqrt{3}qx]\right\} + \exp\left\{\frac{\pi i}{h}[(p+2q)y-\sqrt{3}px]\right\}$$
$$+\exp\left\{\frac{\pi i}{h}[(-p+q)y+\sqrt{3}(p+q)x]-2\pi qi \pm \frac{2\pi}{3}i\right\}$$
$$+\exp\left\{\frac{\pi i}{h}[-(p+2q)y-\sqrt{3}px]+2\pi pi \mp \frac{2\pi}{3}i\right\}$$
$$+\exp\left\{\frac{\pi i}{h}[(p-q)y+\sqrt{3}(p+q)x]-2\pi pi \pm \frac{2\pi}{3}i\right\}$$
$$+\exp\left\{\frac{\pi i}{h}[-(2p+q)y-\sqrt{3}qx]+2\pi qi \mp \frac{2\pi}{3}i\right\}, \tag{49}$$

where the two signs correspond to the following quantum numbers:

$$q = n + 1/3, \quad p = q, q+1, q+2, \ldots, \quad \text{upper sign},$$

$$q = n + 2/3, \quad p = q, q+1, q+2, \ldots, \quad \text{lower sign},$$

$$n = 0,1,2,\ldots . \tag{50}$$

Note that these eigenfunctions are characterized by fractional quantum numbers p and q.

Figure 10 shows the graphics of some of the solutions (47), (48), and (49) for low values of (p,q). Note that these solutions are very similar for the solutions or the Schrödinger equation for a particle in an equilateral triangle.[22]

The above approach cannot be extended straightforwardly to other geometries. The reason for this is a theorem stating that only in the cases of square and triangular boxes the eigenfunctions can be expanded in a finite set of plane waves.[23] On the other hand, if the boundary line does not deviate strongly from a circumference (as, e.g., in higher polygons), we can again construct a finite basis set by making a radial rescaling of the eigenfunctions for a disk with equal area.[24]

IV. NUCLEATION OF SUPERCONDUCTIVITY IN BASIC POLYGONS

Using the developments of the preceding sections we can solve now the LGL equation (34) with the boundary condition (7) for several symmetric structures. An important feature of vector potential gauge approach is its ability to provide accurate description of the order parameter

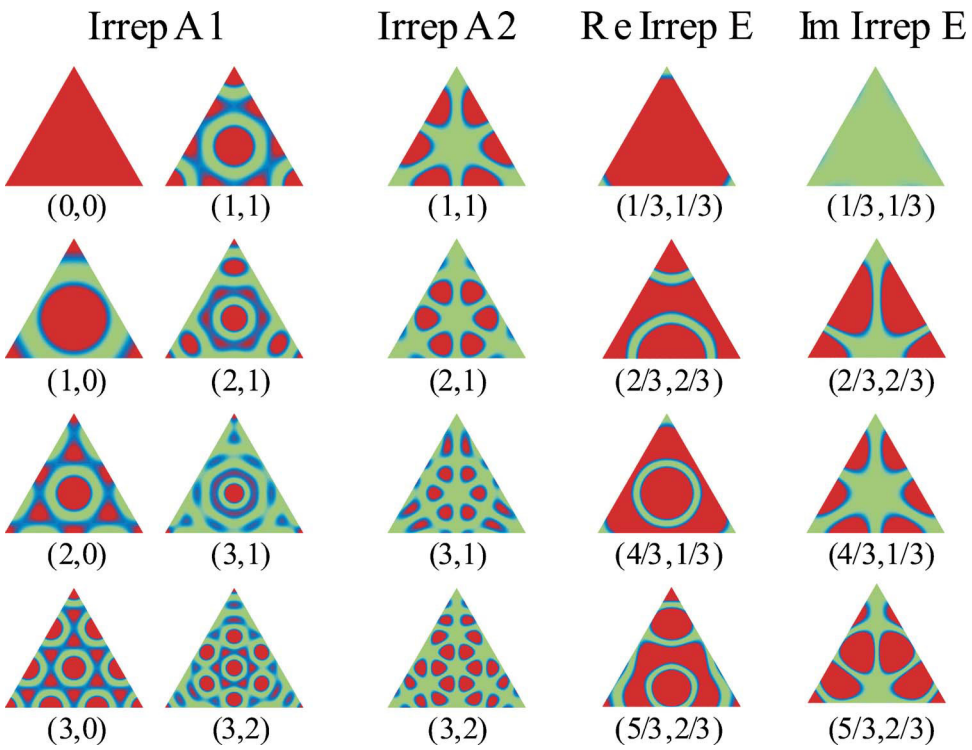

FIG. 10. (Color online) Symmetrized basis functions for an equilateral triangle. The highest density is shown in darker shades and the lowest $|\psi|^2$ values are lighter shades. The numbers in parentheses stand for p and q, respectively.

already for quite limited sizes of the basis sets at moderate applied fields. An accurate calculation of Ψ is often crucial for a correct description of vortex patterns in mesoscopic samples. In this connection we mention that reflections in vertical planes, if they are contained in the symmetry group of the sample, act as time inversion operators, $\sigma_v\Psi=\Psi^*$. Therefore $\Psi^*\Psi$ is invariant under these reflections and the density distribution of the order parameter is described by the full symmetry of the sample.

A. The triangle and square

As shown above it is possible to classify the solutions for a square and a triangle according to the irreducible representations (irreps) of the symmetry groups C_3 and C_4. This classification will include different order parameter patterns, since the solutions are contained in different subclasses characterized by a certain irrep. As can be seen in Figs. 11 and 12 the eigenvalues of the LGL equation belonging to the different irreps will form the complete spectrum of eigenvalues.[25,26] However, *eigenvalues belonging to the same irrep will never cross*. Moreover the lowest eigenvalues form separated bands existing out of an eigenvalue for each irrep, which are crossing in a regular pattern. In this way the H–T phase boundary $T_c(H)$, which is the lowest eigenvalue $E_{\mathrm{LLL}}(H)$, shows an oscillatory cusplike behavior as a function of flux and with every cusp the solution corresponds to a different irrep. The sequence of the $T_c(H)$ oscillations is always A, E_+, B, and E_- in the case of a square, and A, E_+, and E_- in the case of a triangle. The vorticity increases by one when passing a cusp along the H–T phase boundary with increasing field (cf. the Little-Parks experiment) and consequently to the next irrep.

Even as the symmetry of the structure gives rise to a cusplike H–T phase boundary, it still shows a predominantly linear dependence between the magnetic field and the temperature. This is not surprising since a linear H–T phase boundary is the solution for the bulk problem. However, the slope has changed compared to the bulk case, as can be seen in Fig. 13. When comparing the

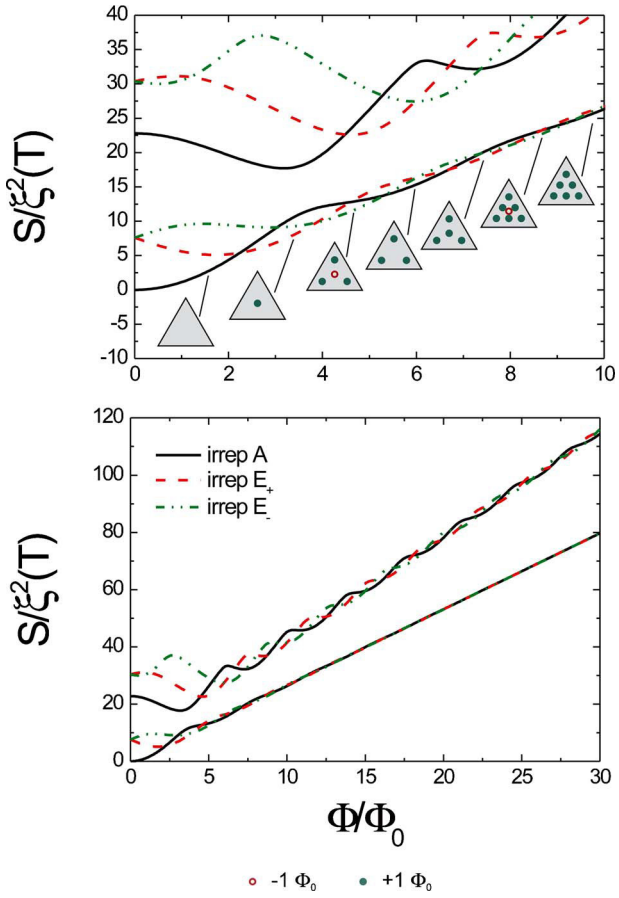

FIG. 11. (Color online) Lower eigenvalues of the LGL equation for the mesoscopic triangle, as a function of the magnetic flux Φ/Φ_0, with superconductor-vacuum boundary conditions. The different lines correspond to the three irreducible representations (irreps) A (full black line), E_+ (dashed red line) and E_- (dashed-dotted-dotted green line). Since the problem has a discrete C_3 symmetry there is a 'repulsion' of the levels, giving a regular pattern of avoided crossing between levels belonging to the same irrep. The flux is defined as $\Phi=\mu_0 HS$, with S the surface of the triangle, $\mu_0 H$ the applied magnetic field and $\Phi_0=h/2e$ the superconducting flux quantum. The lowest sequence of the cusp-like pieces from different irreps forms the lowest eigenvalue $E_{\mathrm{LLL}}(H)$, directly corresponding to the $T_c(H)$ line. For detailed comparison with the experiment see Fig. 19. Along the vertical axis, the critical temperature T_c is linearly decreasing with increasing $S/\xi^2(T)$.

considered shapes with equal surface, it is evident that superconductivity nucleates with decreasing magnetic field H and temperature T, first in the triangle, then the square, the disk[12,28–35] and finally in the bulk material. This can be understood from the results obtained on the nucleation of superconductivity in an infinite wedge[7,8,36–39] where the nucleation field $H_{c3}^{\star}$ increases with reducing angle Γ of the infinite wedge. Consequently we should observe the largest $H_{c3}^{\star}$ for the triangle, since the triangle has the smallest angles in the corners. That is precisely what we observe.

Furthermore, the phase boundary for the square has been calculated by other groups, like Jadallah *et al.*[27] and Schweigert *et al.*[37,40,41] When comparing for instance the positions of the cusps at the phase boundary we see a good agreement between the different calculations at lower fields. However, at higher fields we see a slight deviation between our results and the results of Jadallah *et al.*[27] (see Table I).

Additionally, there is a good agreement between the amplitudes of the oscillations found in our work[26] and Schweigert *et al.*[41] and for certain values of magnetic field and temperature we also find the same vortex patterns. However we also find some large differences in the vortex patterns, specifically vortex-antivortex patterns compared to a giant vortex.

Since the rotational axis in the triangle is of finite order we do not expect the giant vortex state

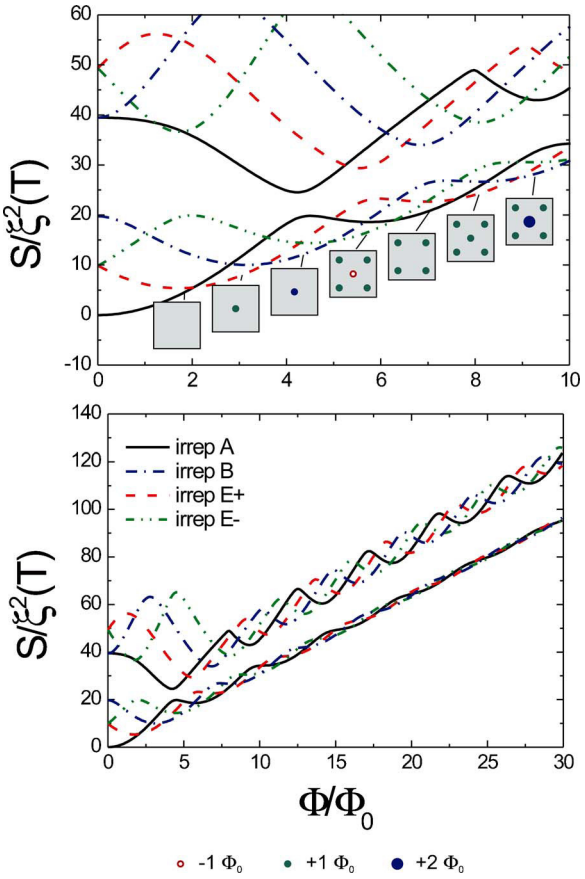

FIG. 12. Lower eigenvalues of the LGL equation for the mesoscopic square, as a function of the magnetic flux Φ/Φ_0, with superconductor-vacuum boundary conditions. The different lines correspond to the four irreducible representations (irreps) A (full black line), B (dashed-dotted line), E_+ (dashed line), and E_- (dashed-dotted-dotted line). Since the problem has a discrete C_4 symmetry there is a 'repulsion' of the levels, giving a regular pattern of avoided crossing between levels belonging to the same irrep. The flux is defined as $\Phi=\mu_0 HS$, with S the surface of the square, $\mu_0 H$ the applied magnetic field and $\Phi_0=h/2e$ the superconducting flux quantum. The lowest sequence of the cusp-like pieces from different irreps forms the lowest eigenvalue $E_{\mathrm{LLL}}(H)$, directly corresponding to the $T_c(H)$ line. For detailed comparison with the experiment see Fig. 20. Along the vertical axis, the critical temperature T_c is linearly decreasing with increasing $S/\xi^2(T)$.

to be always a ground state solution. Actually there are no vortices in the first state ($L=0$), there is one Φ_0 vortex in the cental position in the second state ($L=1$), and there is one $-\Phi_0$ antivortex in the center and three Φ_0 vortices at the diagonal positions in the third state ($L=-1+3=2$). This sequence is periodically repeated when going to higher applied fluxes. For instance, the fourth state ($L=3$) will contain three Φ_0 vortices dispatched along the diagonals of the triangle. Figure 14 shows the distribution of the order parameter in the above states. The total winding number is a sum of the vorticity numbers of the central and diagonal vortices as follows:

$$L = n + 3m,$$

$$n = 0, 1, -1, \tag{51}$$

where $m=0, 1, \ldots$ is the number of vortex triades. The number n in this equation matches the corresponding irrep via Eq. (35).

The seven insets in Fig. 12 show schematically the distribution of vortices in the square, which are clearly different from the giant vortex states.

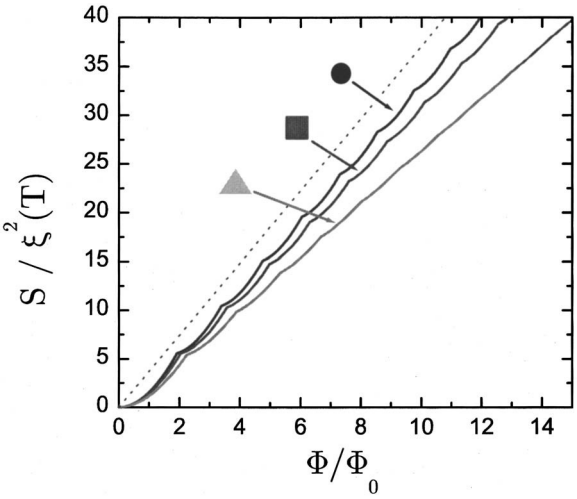

FIG. 13. The calculated *H–T* phase boundary for a disk, square, and triangle. The dotted straight line is the surface critical field for a semi-infinite slab with a straight superconductor/vacuum border $H_{c3}=1.69\,H_{c2}$.

In the case of small L's, vortices can occupy one central and four diagonal positions. In contrast to the diagonal vortices which always enclose a single quantum Φ_0, the central vortex can have different winding numbers in order to conserve the total vorticity of a given state. The contribution of the two kinds of vortices (central+four diagonal) to the total winding number of the states shown in Fig. 12 is given by

$$L = n + 4m,$$

$$n = 0,1,2,-1, \tag{52}$$

where $m=0$, 1. Note that the four numbers in the second equation match the n numbers in the expressions for the basis functions of the corresponding irreps, Eq. (35). This is not surprising since these resemble the eigenfunctions of a 2D rotator with momentum n.

As a result the nature of the central vortex changes, whenever vorticity is changed by one. Thus the central vortex is absent in the first state, it is a Φ_0 vortex in the second state, it is a giant vortex in the third state and it is an *antivortex* (the winding number is negative!) in the fourth state

TABLE I. Calculated cusps positions in $T_c(\Phi)$ for the triangle, the square, and the disk at particular values of the normalized flux Φ/Φ_0. The different calculated values for the square deviate slightly at high winding number L.

$L\rightarrow L+1$ After Ref.	Triangle 25	Square 26	Square 27	Disk 28

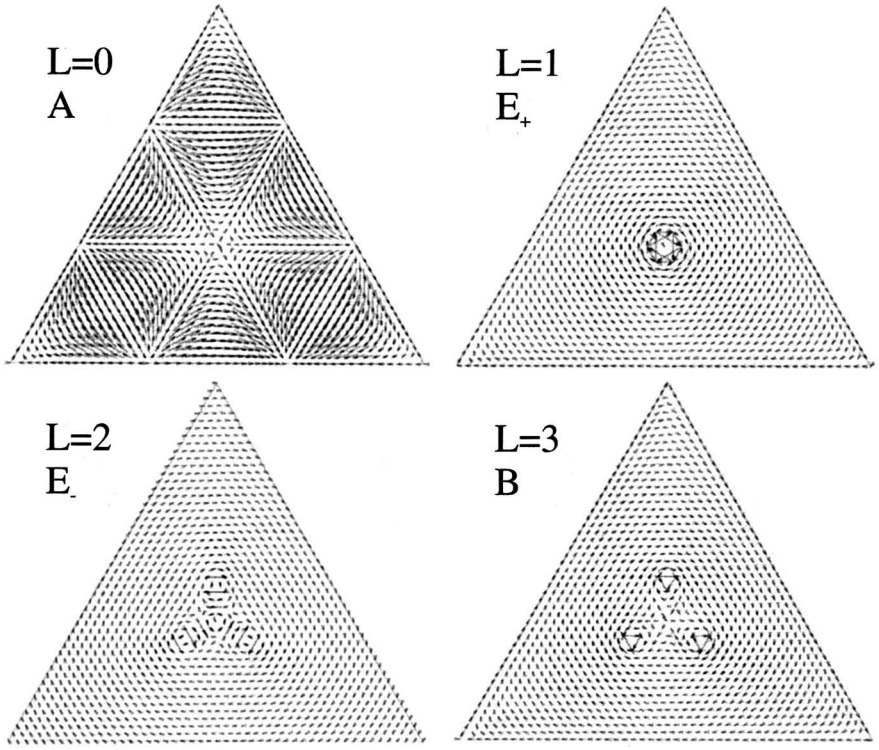

FIG. 14. Gradients of phase of the order parameter at the middle of the lowest four cusps in the $T_c(H)$ phase diagram in Fig. 11. Large arrows rotating clockwise encircle the vortices and those rotating in the anticlockwise direction display the antivortex. The panel for the E_- state, zoomed 16 times, shows the presence of an Φ_0 antivortex in the center.

(see Fig. 12). The sequence of winding numbers of the central vortex $(-1, 0, 1, 2)$ is periodically repeated when going to the right of the phase diagram.

Because the kinetic energy of a vortex is proportional to L^2, the system prefers to split the giant vortex into a sum of smaller vortices[42] if there are no special symmetry restrictions. Another energy based reason is that vortices get attracted to the corners as it was shown for the case of a semi-infinite plane with a wedge.[39] This explains why the four dispatched vortices prefer to stay on the diagonal positions in the ground states. The combination of these two arguments explains why only four numbers mentioned above appear as winding numbers for the central vortex. On the other hand, the formation of antivortices is dictated completely by the discrete symmetry. Indeed, in the state with $L=3$, one cannot distribute three Φ_0 vortices on the square keeping the symmetry. The dilemma is solved by having four diagonal Φ_0 vortices and adding one antivortex in the center.

Figure 15(a) shows the distribution of the order parameter corresponding to the antivortex solution. The central antivortex is separated from vortices on the square diagonals by about 2% of the edge length. The maximal value of the order parameter on the line connecting the antivortex with one vortex does not exceed one-thousandth of its value in the corners of the square. Note that this solution is obtained within the present approach by using a moderate basis set. To reproduce these features by finite grid methods a very large basis set corresponding to at least a 400×400 grid should be involved in the calculations.[43]

At higher values of applied field the additional vortices will continue to occupy the diagonal positions as shown in Fig. 16 for states of symmetry A.

On the whole, the nucleation of superconductivity in squares has similar features with the equilateral triangles. We expect most of these features to be general for higher order regular polygons too since they are based on symmetry grounds. For instance, the avoided crossing

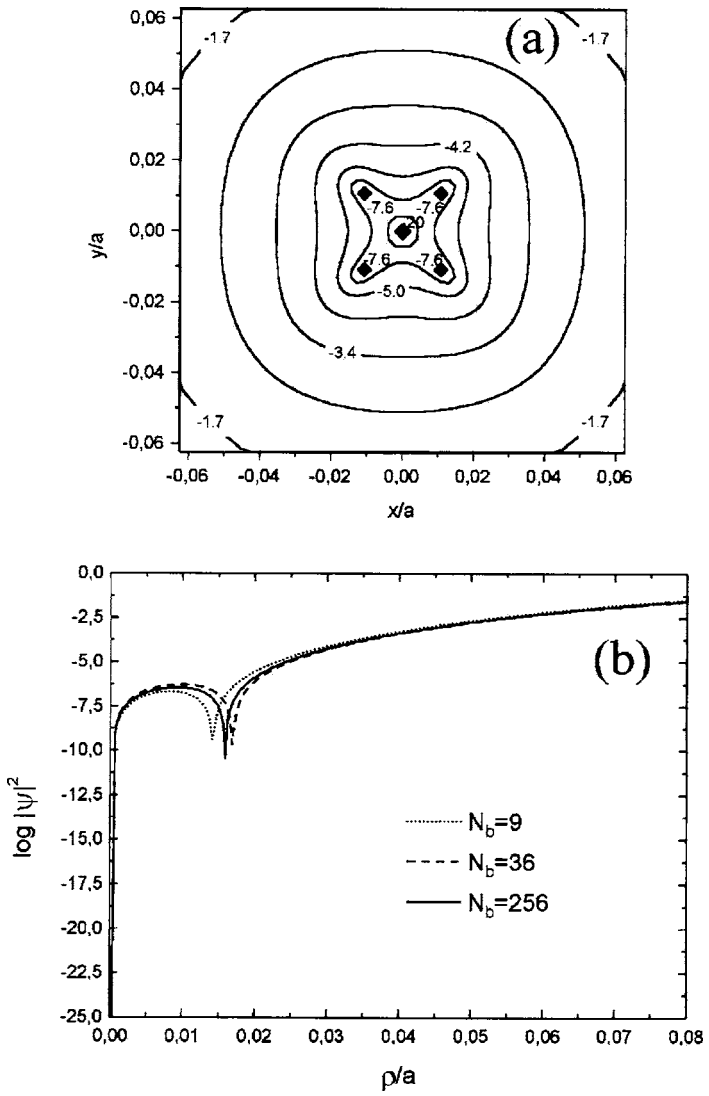

FIG. 15. Order parameter plots corresponding to the ground state of the square in an applied magnetic flux $\Phi=5.5\Phi_0$. The contour plot (a) shows (in logarithmic scale) the vortex pattern in the central region of the square zoomed in eight times after convergence with respect to the basis set size was achieved. The panel (b) displays the cross section in the diagonal direction $\rho=0$ is the center of the square) for different sizes of basis sets used in the calculations.

patterns of levels belonging to the same irrep is a common feature. One can see that it is more pronounced in the triangle (Fig. 11) than in the square (Fig. 12) and will generally diminish with increasing order of the polygon, disappearing completely in the case of disk ($N\rightarrow\infty$). The same for the vortex patterns; they are expected to shrink with increasing N and merge into giant vortex states in the limit of the disk. The asymptotic behavior of the ground state solutions in the limit of high applied field corresponds to the N-fold degenerate ground Landau level, the components of which belong to N different irreps of the corresponding polygon. This becomes infinitely degenerate in the case of disk, containing all different rotational (vorticity) states as components.[11]

B. Experimental phase boundary

To check the theoretical prediction for the lowest Landau level $E_{\mathrm{LLL}}(H)$ for different geometries (triangle, square, disk), superconducting Al samples have been made to measure the $T_c(H)$ line.

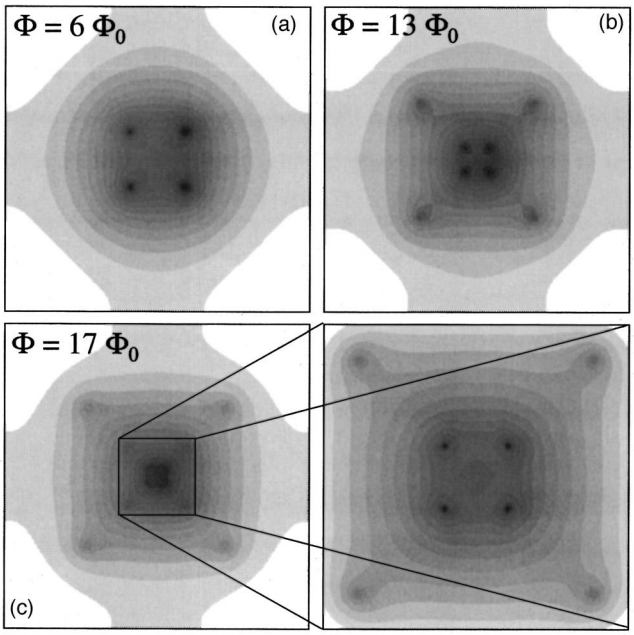

FIG. 16. Three vortex patterns corresponding to the symmetry A of the order parameter and the total vorticity $L=4$ (a), $L=8$ (b), and $L=12$ (c). In all cases the vortices are arranged symmetrically along the diagonals of the square. The panel in the left bottom corner shows the zoomed in central region of the plot c.

1. Sample characteristics

Figure 17 shows AFM and SEM micrographs of the triangle, the square and the disk. Wedge shaped current and voltage leads with an opening angle of $\Gamma=15°$ and with a narrow width of the interface between the structure and the current leads were used in order to minimize their influence on the superconducting properties of the structure.[44,45] The square and the disk were evaporated in the same run. A thickness $\tau=39$ nm was obtained from x-ray and AFM measurements. The radius of the disk, measured with AFM and SEM, was 1 μm. For the square, lateral dimensions of 2×2 μm^2 were obtained. The samples have a coherence length, determined from a coevaporated reference sample, of $\xi(0)=156$ nm and a critical temperature of $T_c=1.32$ and 1.33 K for the square and the disk, respectively. The equilateral triangle has a thickness $\tau=43$ nm, a basis of 2.33 μm. A coherence length of $\xi(0)=130$ nm and critical temperature of $T_c=1.34$ K were found for this sample.

The $T_c(H)$ phase boundary is measured by four-point resistance measurements using a lock-in amplifier. An ac transport current of 0.1 μA is sent through the two current leads (horizontal

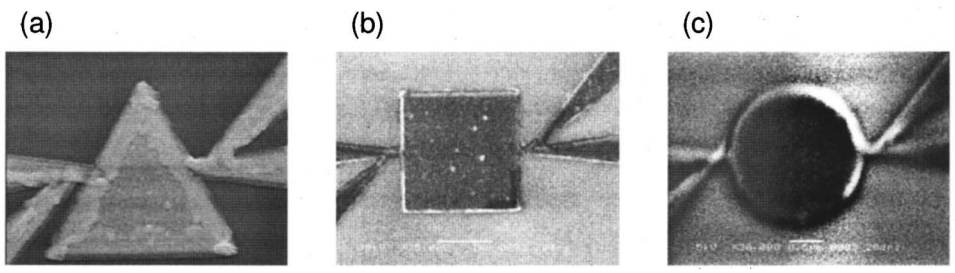

FIG. 17. AFM and SEM micrograph of an Al triangle (a) with basis of 2.33 μm, of a square (b) with a lateral dimension of 2 μm and of a disk (c) with a radius of 1 μm.

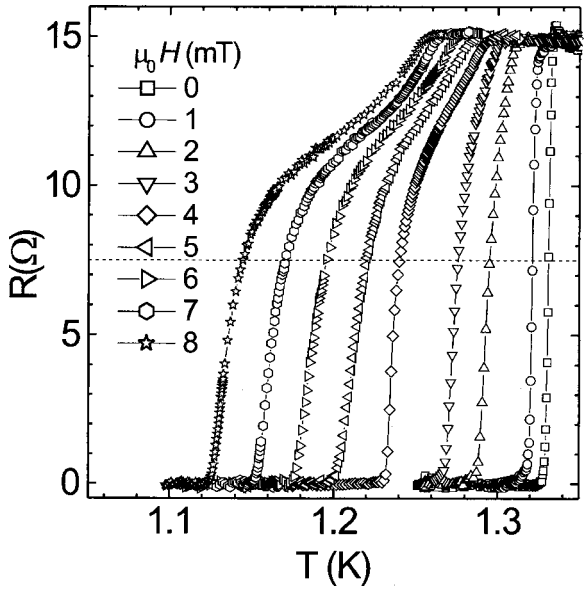

FIG. 18. Resistive transitions $R(T)$ for the triangle in different magnetic fields. From $\mu_0 H=0$ mT (open squares) to 8 mT (open stars). The dashed line shows the resistance criterion used to determine the $T_c(H)$ phase boundary.

contacts in Fig. 28). In order to construct the H–T phase diagram a set of $R(H)$ magnetoresistance curves are measured at various temperatures. The phase line is in a next step extracted from the data using a certain resistance criterion R_c.

2. Triangle

Figure 18 shows the resistive transitions of a mesoscopic triangle with wedge shaped contacts. The $R(T)$ curves are composed of two parts with different slopes. The upper part of this double transition shows a slowly decaying resistance while a steeper drop is seen in the lower part. This effect becomes more pronounced with increasing magnetic field. The appearance of the two distinct parts in the transition curves arises from the different field dependence of the nucleation temperature in the triangle and in the wedge shaped contacts.[45] The upper part of the $R(T)$ curves corresponds to the nucleation in the contacts followed by the nucleation in the triangle for lower temperatures at the lower part. The square and the disk show very similar resistive transitions.

The result of a continuous $T_c(H)$ measurement of a mesoscopic triangle is given in Fig. 19. The $T_c(H)$ phase boundary, measured for the triangle, is shown as open circles in Fig. 19 with the coherence length $\xi(0)=130$ nm determined from a coevaporated reference film and the surface $S=2.36\ \mu\text{m}^2$ found from AFM and SEM investigations. The open squares represent the measured phase boundary with the best fitting parameters, the best value for the coherence length is $\xi(0)=118$ nm and the effective area of the sample $S=2.25\ \mu\text{m}^2$. This leads to a difference of 10% between the measured and the fitted coherence length and a difference of 5% between the measured and the fitted sample areas S. After this small correction an excellent agreement between the experiment and the theory is observed. The amplitude of the oscillations and the position of the cusps are in perfect accordance.

From the AFM and SEM measurements, features that could be attributed to resist at the boundaries of the structures were observed. Since the area written by e-beam lithography was $S=2.25\ \mu\text{m}^2$, we believe that the exact surface of the Al triangle is slightly lower than the measured one ($S=2.36\ \mu\text{m}^2$). Another explanation for the different obtained values of the fitting parameter for the area of the triangle and the measured area could be the error margin on the measured value. A possible reason for the deviation between measured and the fitted coherence length might be the presence of the wedge contacts. The wedge-shaped contacts will probably not change the value of

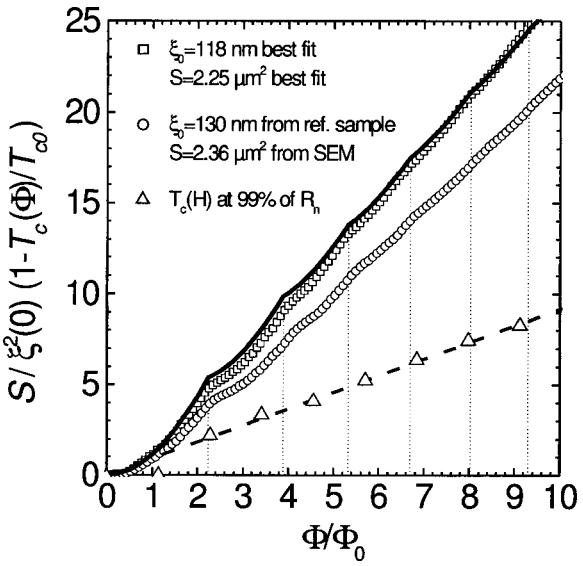

FIG. 19. Experimental $T_c(H)$ phase boundary of an equilateral triangle with wedge-shaped contacts. The open circles represent the data obtained using the measured sample size $S=2.36\ \mu\text{m}^2$ and the coherence length $\xi(0)=130$ nm. The best agreement between the measured and the theoretical phase boundary was found using the parameters $S=2.25\ \mu\text{m}^2$ $\xi(0)=110$ nm, see the open squares in the figure. The full line represents the theoretical curve (Ref. 32). The open triangles are taken from the resistance transition $R(T)$ for a resistance criterion of 99% R_n. The dashed line is the theoretical phase boundary of the wedge-shaped contacts with opening angle $\Gamma=15°$.

the coherence length, but shift the phase boundary of the triangle in the direction of the phase boundary for a wedge with opening angle $\Gamma=15°$. Another possibility for this small discrepancy could be a difference between the coherence length of the coevaporated reference film and the coherence length of the mesoscopic triangle that cannot be measured directly. A potential origin of the discrepancy between the two coherence lengths could be a slight contamination of Al by the resist used in the preparation of the mesoscopic structures, that would decrease the elastic mean free path ℓ_{el} and consequently also ξ. A lower resistance criterion (smaller than the 50% of R_n criterion used) for the determination of the phase boundary, will give a small reduction of the divergence, but cannot remove completely the difference between the two coherence length values. Another reason for this small discrepancy could arise from the not perfectly shaped triangles. Since the opening angle of the corners plays the major role in the determination of the slope of the $T_c(H)$ curve, we could expect that not perfectly sharp corners would decrease the critical field. In our experiment, the measured phase boundaries are shifted to the opposite direction, so that it cannot be attributed to the rounded corners of the triangles.

The open triangles in Fig. 19 show the critical temperature of the triangle for a chosen resistive criterion equal to 99% of the normal state resistance from the $R(T)$ curves. A perfect agreement between the theoretical phase boundary of the contacts and the point on the $R(T)$ curve where the resistance starts to drop is observed. The double resistance transition observed in the measurements (see Fig. 18) is therefore due to two different superconducting/normal transitions. From this observation, it is clear that the resistance criterion for the determination of the phase boundary of the structure must be chosen in the low resistance region of the $R(T)$ transition. If the resistance chosen for this criterion is too high, the nonlocal effect of the contacts on the triangle will be probed.

3. Square

The experimental phase boundary of a square is displayed in Fig. 20 and is compared with the theoretical calculations. While previous measurements[2,46] showed a strongly oscillating $T_c(H)$ dependence superimposed with a pronounced quadratic background, our results are in very good

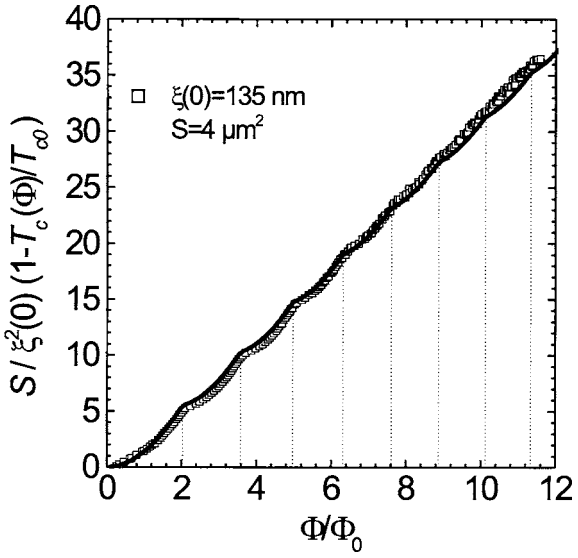

FIG. 20. Experimental $T_c(H)$ phase boundary of a square. The open squares represent the measured value using the measured sample size $S=4\ \mu\text{m}^2$ and the coherence length $\xi(0)=135$ nm. The full line is the theoretical curve $E_{\text{LLL}}(H)$.[26]

agreement with the theoretical predictions. Only a smaller coherence length $\xi(0)=135$ nm was used. The second parameter S used to compare the experimental and the theoretical data was found to be in the error margin of the determined area from SEM and AFM measurements. The main difference between the presented experimental phase boundary and previous reports is the shape and the size of the current and voltage contacts that can be extremely invasive in mesoscopic superconductors.

4. Disk

The $T_c(H)$ phase boundary of the disk is shown in Fig. 21 using a resistance criterion of

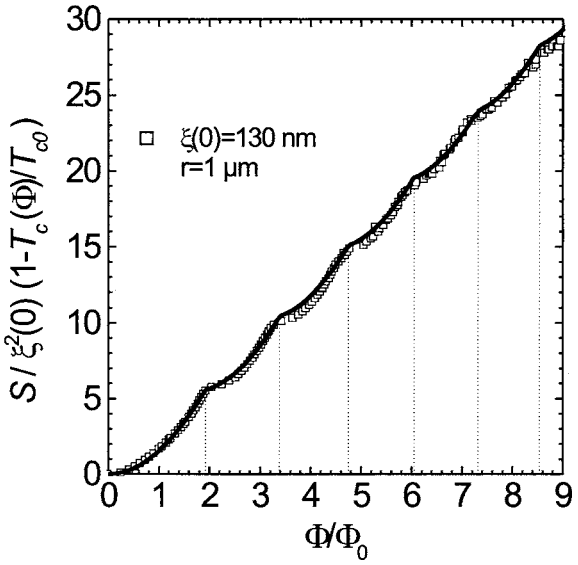

FIG. 21. Experimental $T_c(H)$ phase boundary of a disk determined for a resistance criterion of $2/3\ R_n$. The open squares represent the measured value using the radius $r=1\ \mu$m and the coherence length $\xi(0)=130$ nm. The full line is the theoretical curve $E_{\text{LLL}}(H)$.

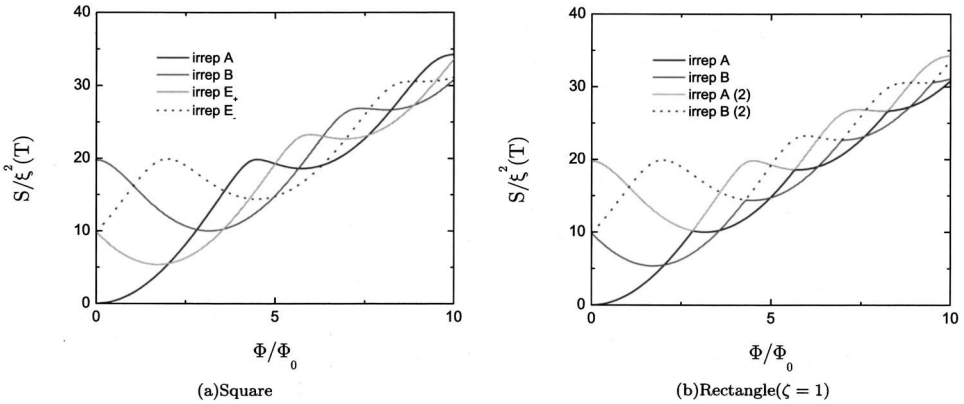

FIG. 22. In the case of the square [panel (a)] the lowest Landau level is constructed by the four lowest eigenvalues, corresponding to different irreps. However, the lowest Landau level $E_{\mathrm{LLL}}(H)$ in the rectangle with aspect ratio one [panel (b)] is obtained from just the lowest two eigenvalues, and the same spectrum of eigenvalues is formed with the two lowest pairs of eigenvalues. Deviations from aspect ratio one for the rectangle will lead to a gap between these two pairs of eigenvalues.

$2/3\,R_n$. Already in 1965, Saint-James calculated the phase boundary of a singly connected cylinder[9] with the gauge chosen as $\vec{A}=(\mu_0 Hr/2)\vec{e}_\phi$. With this particular choice, the superconducting boundary condition is imposed only on the gradient of the order parameter $|\Psi|$ along the radial axis. Since under these conditions $|\Psi|$ has no z-dependence, the phase boundary of a disk or an infinitely long cylinder will be the same. The solution of the linearized GL equation for a disk is a Kummer function of the first kind.[28,29] The nucleation temperature at a fixed magnetic field value can be found by taking the vorticity L that minimizes the eigenvalue giving rise to a cusplike phase boundary as shown by the full line in Fig. 21.

In order to fit the theoretical curve, the measured value of the radius $r=1$ μm and a slightly different coherence length of 130 nm, instead of the value of 154 nm determined from the reference sample, were used. After this small correction a good agreement is found between the theoretical and the experimental phase boundary for the position of the cusps. However, as in the measurements of Buisson *et al.*,[47] where a substantially larger disk was measured, the amplitude of the oscillation in the experimental curve is stronger than for the theoretical predictions. In our experiment, an excellent agreement between the theory and the experiment was found (see Fig. 21) by using a resistance criterion of $2/3\,R_n$. The positions of the cusps as well as the amplitude of the oscillations in the experimental curve match the theoretical phase boundary.

C. From square to rectangle

When crossing over from a square ($\zeta=1$) to a rectangle, we should go from a fourfold to a twofold rotational symmetry. The lowest Landau level in a superconducting square follows a cusplike profile corresponding to successive crossings of the solutions corresponding to four different representations. This is reproduced in the rectangle with aspect ratio one by a pair of crossing irreducible representations (irreps). However to obtain the full spectrum of eigenvalues formed by the four lowest crossing solutions in a square, two pairs of crossing irreps are needed, not only the lowest solutions but also the first excited ones of the A and B symmetry (see Fig. 22).[48] Departure from aspect ratio one leads to a splitting between the lowest and first excited solutions. Small deviations from the square have no noticeable effect on the lowest Landau level. All aspect ratios close to one have a lowest Landau level showing an oscillatory behavior with a predominantly linear background dependence on the field.

At a field of 5 up to 6.3 Φ/Φ_0 we find that the lowest Landau level corresponds to a solution with vorticity three. Although the energy levels and vorticity of all rectangles with an aspect ratio very close to one are the same, the vortex pattern can nevertheless be very different (Fig. 23). In

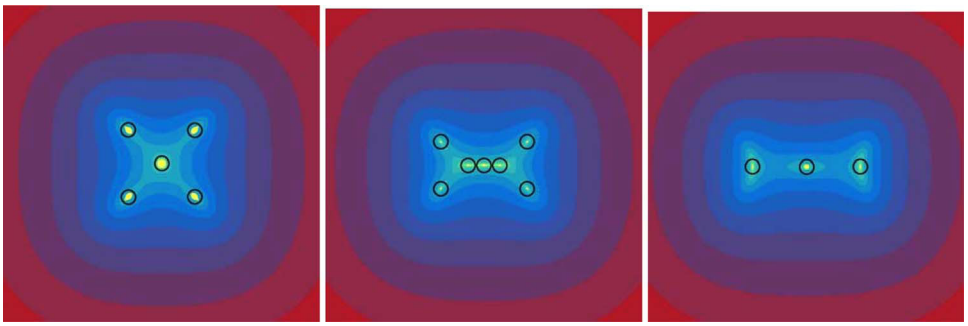

FIG. 23. (Color online) The figures show the density of the order parameter $|\psi|^2$ of the central $(a/10)\times(b/10)$ region in the rectangle in a log scale, where a is the long side and b is the short side. The highest density is shown in darker shades and the lowest $|\psi|^2$ values are in lighter shades, indicating the position of vortices and antivortices. Every shade corresponds to roughly half an order of magnitude. At a field of 5.5 Φ/Φ_0 the rectangles with, respectively, aspect ratio 1, 1.01, and 1.02 have very different vortex patterns. For aspect ratio one we observe the known configuration with one antivortex in the center and four vortices on the diagonals. However, at aspect ratio 1.01 we see four vortices on the diagonals, one in the center and two antivortices next to the central vortex. Finally at aspect ratio 1.02 we find that there are three vortices positioned on the long axis of the rectangle.

a *square* vorticity three is formed by *four vortices on the diagonals and one antivortex in the center*. At an aspect ratio 1.02 vorticity three already corresponds to *three vortices on a row* along the longest axis. However when we consider an aspect ratio 1.01, which lies between these two values, the pattern is more complex. The vortex pattern is now built up from four vortices on the diagonals, one vortex in the center and two antivortices located on the left and right from the central vortex along the long axis. This suggests the following evolution from aspect ratio 1 to aspect ratio 1.02. By varying the aspect ratio from one the antivortex in the center splits into two antivortices plus one vortex in the center. These antivortices move away from the center along the long axis, where each antivortex merges with the pair of vortices, respectively, at the left and right of the antivortex, leaving as a result three vortices on the longest axis. We must point out that the vortex pattern observed at aspect ratio 1.01 with a central vortex and two neighboring antivortices is in itself embedded into a region where the order parameter is already suppressed by orders of magnitude, which implies that we can also consider this structure as one elongated antivortex with a nontrivial $(-1+1-1)$ core structure.

1. Larger aspect ratios

It is surprising to see that the H–T phase boundary [Fig. 24(a)] remains almost the same for the aspect ratio between 1 and 1.333. However, the amplitude of the oscillations within the same irrep is reduced without substantial change in the lowest Landau level. Only when the aspect ratio becomes two or larger, a noticeable shift in the lowest Landau level is seen. Except for the first cusp the lowest Landau level still shows an oscillatory behavior on top of a linear dependence on the field, though with a reduced slope. At an aspect ratio of four we can hardly observe the crossing of the different irreps as they almost completely merge together, only the first cusp remains clearly visible. For fields higher than the first crossing of solutions, the field dependence becomes again linear. The same pattern persists for even higher aspect ratios. However, the field, at which the solutions for the first time cross, increases with the aspect ratio (Fig. 25). This crossing of the two irreps corresponds to the appearance of the first vortex in the rectangle, because the irrep B describes solutions that have a vortex in the center, while the irrep A solutions are without a vortex in the center. As a consequence every crossing of the solutions corresponding to the two irreps, will change the vorticity by one. The H–T phase boundaries for the different aspect ratios not only show the same behavior, they additionally can be scaled on one *universal* curve, apart from the oscillations [Fig. 24(b)]. The scaling is performed by dividing $S/\xi^2(T)$ and Φ/Φ_0 by the aspect ratio ζ,

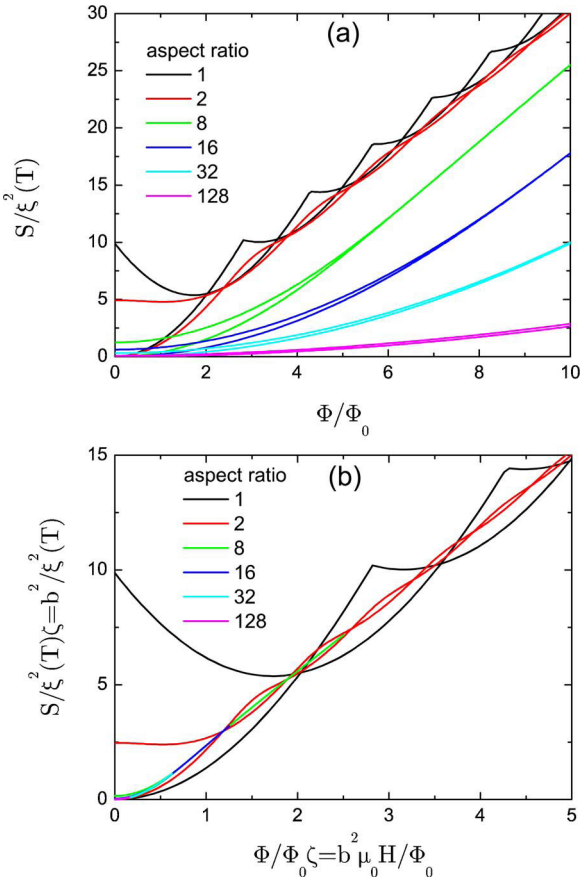

FIG. 24. (Color online) (a) Calculated superconducting H–T phase boundary for rectangles with different aspect ratios. The superconducting phase is located above (lower T) and the normal phase below the H–T phase boundary. For every aspect ratio the lowest two eigenvalues of the LGL equation for the mesoscopic rectangles with superconductor-vacuum boundary conditions as a function of magnetic flux Φ/Φ_0 are shown, with the lowest eigenvalue $E_{\mathrm{LLL}}(H)$ corresponding to the phase boundary. The different shades correspond to different aspect ratios, as indicated in the figure, however with the same surface S. The lowest graph at zero field for the same shade is the solution for irrep A and the highest graph is the solution for irrep B. The flux is defined as $\Phi=\mu_0 HS$ with S the surface of the rectangle, $\mu_0 H$ the applied magnetic field. (b) Different H–T phase boundaries show fundamentally the same behavior in a different field and temperature range, by scaling the different curves with the aspect ratio ζ onto the same universal curve, apart from the oscillations.

$$\frac{ab}{\xi^2(T)\zeta}=\frac{b^2}{\xi^2(T)},\quad \frac{\Phi}{\Phi_0\zeta}=\frac{ab\mu_0 H}{\Phi_0\zeta}=\frac{b^2\mu_0 H}{\Phi_0}. \tag{53}$$

Therefore we can conclude that the length b of the shortest side of the rectangle controls to a large part the behavior of the superconducting mesoscopic rectangle, such as the entry of the first vortex and the slope of the phase boundaries.

Since the curves can be scaled on a universal curve neglecting the cusps, it is also possible to describe the H–T phase boundary with a single function with the same dependence on the aspect ratio as the scaling,

$$\frac{S}{\xi^2(T)}=\frac{3}{\zeta}\left(\frac{\Phi}{\Phi_0}\right)^2\quad\left(\frac{\Phi}{\Phi_0}<0.535\zeta\right), \tag{54}$$

$$\frac{S}{\xi^2(T)}=6\left(\frac{\Phi}{\Phi_0}\right)-3(0.535)^2\zeta\quad\left(\frac{\Phi}{\Phi_0}\geqslant 0.535\zeta\right). \tag{55}$$

However, this fit only works well at aspect ratio $\zeta\geqslant 4$ where the cusps are negligible.

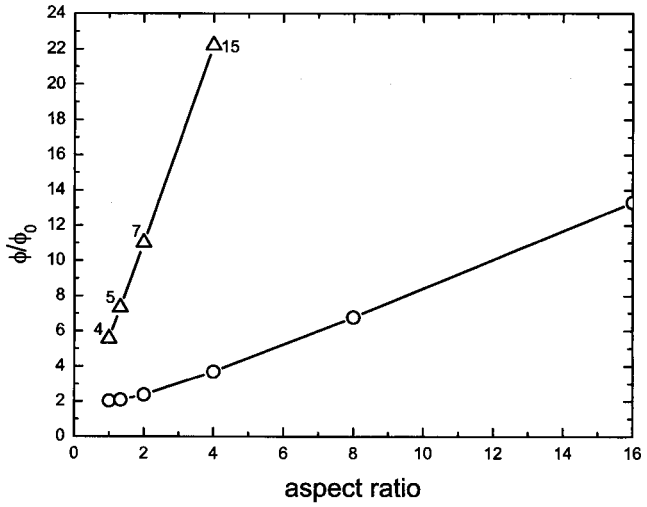

FIG. 25. The circles show the flux at which the first vortex enters the rectangle. The open triangles are the first points on the T_c–H phase boundary where vortices are located on the bisectors for the different aspect ratios. The numbers next to the squares indicate the corresponding number of vortices present in the rectangle at these fields.

In the case of aspect ratio 1.333 the vortices are situated in the central region on the longest axis of the rectangle. However, when the vorticity equals four, the vortices are sitting very close together. As a consequence the vortices move away from the axis and instead are placed on the *bisectors*, which go from the corners to the long axis of the rectangle (see also Fig. 27). The subsequent vortices appear again on the longest axis until the vorticity becomes 12. At this point another four vortices move away from the axis towards the corners along the bisectors. This of course is in contrast to the square where all the vortices are always on the diagonals at the H–T phase boundary in the considered field range.

The preference for positioning the vortices on the bisectors originates from the observed Meissner currents (Fig. 26) which make a hard bend there up to the longest axis (very weak screening), therefore the kinetic energy of the supercurrents is lower when a vortex is present on these bisectors compared to when a vortex is positioned away from the bisectors and from the

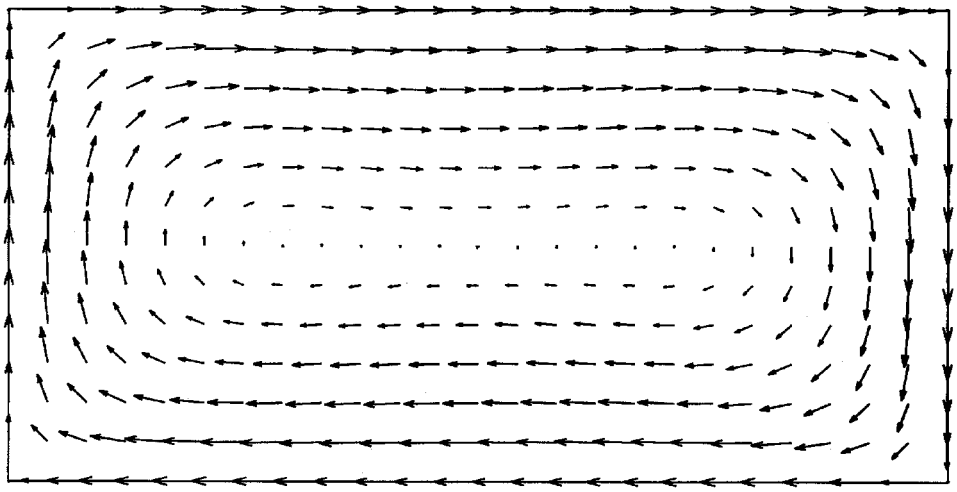

FIG. 26. The graph shows the supercurrents in arbitrary units in a rectangle with aspect ratio two just before the entrance of the first vortex at a magnetic field giving rise to magnetic flux of $\Phi=2.2\Phi_0$.

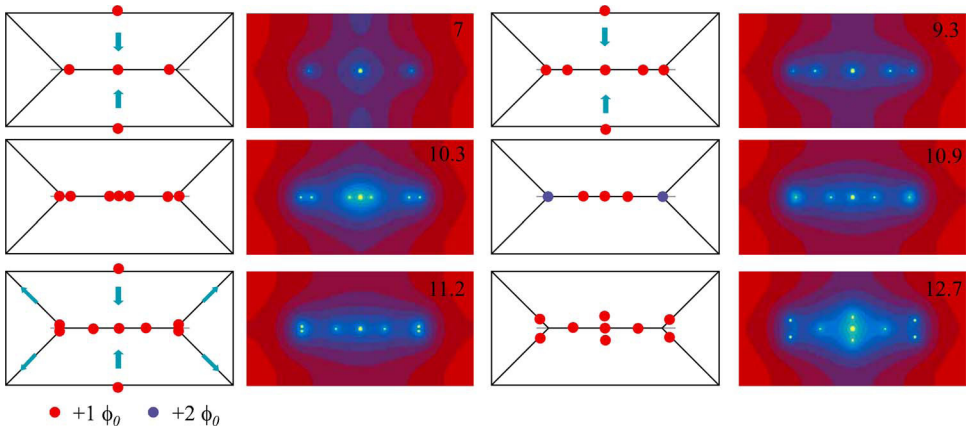

FIG. 27. (Color online) The figures show the evolution of the vortex pattern in the rectangle with aspect ratio two while following a single solution corresponding to irrep B with increasing field. The same shade conventions as in Fig. 23 were used. The numbers indicate the flux in the rectangle in units of the flux quantum Φ_0. The black lines are constructed by dividing the long axis with length a in three regions. Both outer regions have a length of $b/2$. If we would remove the central region, a square would remain with the black lines forming its diagonals.

central region of the longest axis. A similar pattern of Meissner currents leads to a discontinuity along the bisectors in the problem of the entry of flux lines in a rectangle away from the H–T phase boundary observed by magneto-optical techniques.[49–51]

The same scheme repeats itself for aspect ratio two. However we must wait until there are seven vortices in the rectangle before four vortices start to be located on the bisectors. For the aspect ratio four it takes 15 vortices to initiate the vortex redistribution from the axis to the bisectors. So it is clear that with growing aspect ratio the field at which the vortices start to take positions on the bisectors increases. From Fig. 25 we can see that the lowest field at which vortices appear first at the bisectors increases linearly with the aspect ratio for at least the lowest aspect ratios. For aspect ratios beyond four we cannot go high enough in field with a basis set of 1764 basis functions to see vortices on the bisectors. For the largest aspect ratios even the entrance of the first vortex in the rectangle is beyond the field range accessible for a limited number of basis functions in the set.

In summary it has been shown that the vortex pattern in a rectangle is composed of a central row of vortices along the longest axis and the vortices that are situated on the bisectors. These bisectors span the left and right $b/2$ region, where b is the short side of the rectangle. The vortices forming a row parallel to the longest axis only move into these two outer regions when they are ready to reposition themselves onto the bisectors, as shown in Fig. 27. When following the same irrep with increasing field (Fig. 27), we can observe the vortices enter in pairs through the centers of the long edges. When more vortices accumulate on the central line, migration starts to the outer $b/2$ regions. In this region on the longest axis two pairs of vortices will merge at the two points where the bisectors cross and form two giant vortices with vorticity two. These giant vortices split again into separate vortices which move along the bisectors now.

2. Lines

When increasing the aspect ratio to large values, the rectangle eventually resembles a line. The H–T phase boundary for a line with a width smaller than the coherence length $\xi(T)$ in a perpendicular magnetic field is well known for the London limit since it coincides with the problem of a thin (thickness $\ll\xi(T)$) superconducting plane in a parallel magnetic field.[1,52] We have

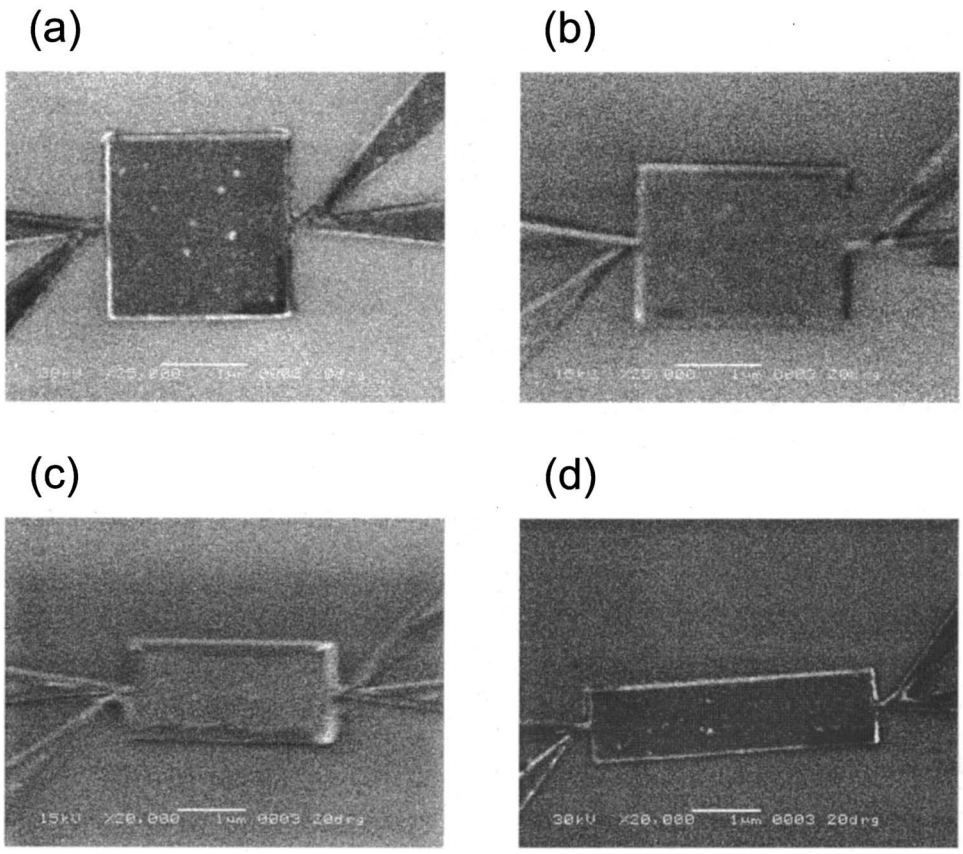

FIG. 28. SEM micrograph (a) of an Al square with lateral dimensions 2×2 μm^2 ($\zeta=1$) and of a rectangle with lateral dimensions of (b) 1.73×2.31 μm^2 ($\zeta=4/3$), (c) 1.41×2.83 μm^2 ($\zeta=2$), and (d) 1×4 μm^2 ($\zeta=4$).

$$\frac{1}{\xi^2(T)}=\frac{\pi^2w^2\mu_0^2H^2}{3\Phi_0^2}. \tag{56}$$

We can get an approximation for the rectangle with large aspect ratio when we substitute the width w^2 with $b^2=ab/\zeta$ where ζ is the aspect ratio, a is the long side, and b is the short side of the rectangle,

$$\frac{ab}{\xi^2(T)}=\frac{\mu_0^2\pi^2}{3\zeta}\left(\frac{\Phi}{\Phi_0}\right)^2. \tag{57}$$

This solution, which is obtained by minimizing the GL free energy in the London limit, is only valid when $|\Psi|$ is approximately spatially constant. Consequently the valid field region will increase with aspect ratio, since the field of the first entrance of a vortex increases with increasing aspect ratio. For instance, we determined that within the shown field region this approximation already coincides perfectly with our calculations for a rectangle with aspect ratio 64.

D. Experimental phase boundary

To investigate experimentally the crossover square-rectangle, four rectangles with different aspect ratio ($\zeta=1$, $4/3$, 2, and 4) were studied. They were all evaporated in the same run. The four structures have the same area of $S=4$ μm^2. A SEM micrograph of the studied samples is shown in Fig. 28. The rectangles with aspect ratio $\zeta=1$, $4/3$, 2, and 4 have dimensions of 2×2 μm^2,

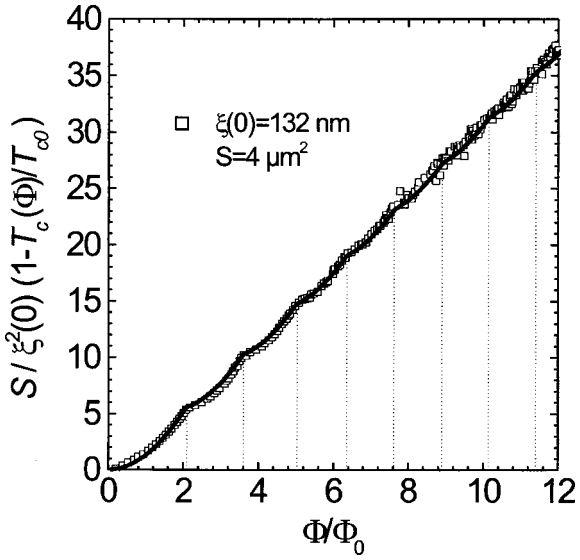

FIG. 29. Experimental $T_c(H)$ phase boundary of a rectangle with $\zeta=4/3$. The open squares represent the measured value using the measured sample size $S=4\ \mu\text{m}^2$ and the coherence length $\xi(0)=132$ nm. The full line is the theoretical curve $E_{\text{LLL}}(H)$.

$1.73\times2.31\ \mu\text{m}^2$, $1.41\times2.83\ \mu\text{m}^2$, and $1\times4\ \mu\text{m}^2$. The thickness τ is 39 nm and the coherence length of the coevaporated reference sample is 156 nm.

The experimental $T_c(H)$ curve of the different rectangles is presented in Figs. 29, 30, and 31. The critical temperature of the rectangles with $\zeta=4/3$ (Fig. 29) and 2 (Fig. 30) shows small oscillations superimposed with a linear dependence of the magnetic field. They have an almost identical phase boundary as the square (see Fig. 20). Only very small changes in the position of the cusps are observed. The magnetic field value where the vorticity changes from L to $L+1$ is slightly delayed when changing the value of ζ from one. No significant change in the slope and the amplitude of the oscillations could be observed.

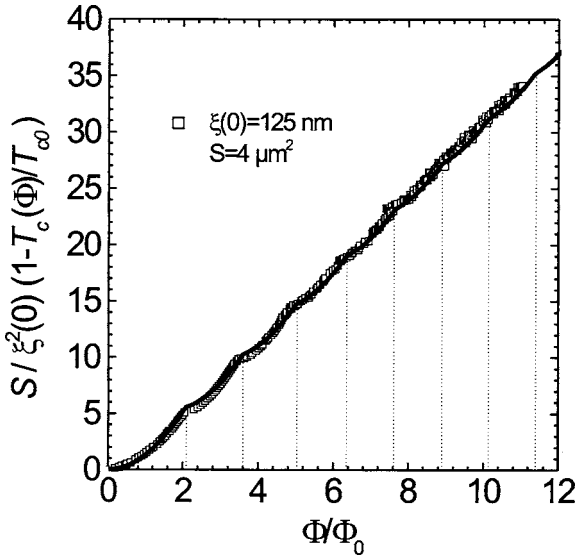

FIG. 30. Experimental $T_c(H)$ phase boundary of a rectangle with $\zeta=2$. The open squares represent the measured value using the measured sample size $S=4\ \mu\text{m}^2$ and the coherence length $\xi(0)=125$ nm. The full line is the theoretical curve $E_{\text{LLL}}(H)$.

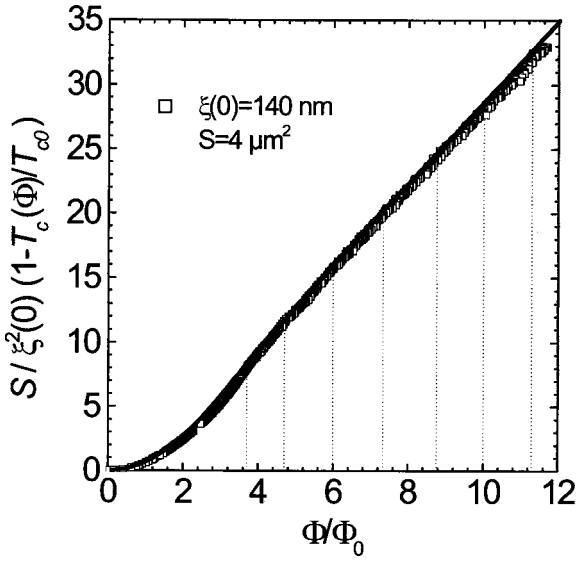

FIG. 31. Experimental $T_c(H)$ phase boundary of a rectangle with $\zeta=4$. The open squares represent the measured value using the measured sample size $S=4$ μm^2 and the coherence length $\xi(0)=140$ nm for a resistance criterion of 40% of R_n. The full line is the theoretical curve $E_{\mathrm{LLL}}(H)$.

A very good agreement between the experimental and the theoretical curves, as well as for the position of the cusp as for the amplitude of the oscillations, is obtained for these two rectangles. Even a large deformation of the square ($\zeta=2$) gives only minor changes in the phase boundary.

For a rectangle with aspect ratio $\zeta=4$, the phase boundary (Fig. 31) is strongly transformed compared to the case of the square. The oscillations are hardly seen and the position of the first vortex entry is delayed to $\Phi/\Phi_0\cong 3.7$ (left dotted line in Fig. 31) instead of the value of $\Phi/\Phi_0 \cong 2$ found for a square. A good agreement between the experimental and the theoretical curves is obtained for a resistance criterion of 40% of R_n.

V. SUPERCONDUCTING RINGS

A. Theoretical formalism

Bruyndoncx *et al.*[53] solved the linear GL equation for a loop of finite width by neglecting the induced magnetic fields. These two assumptions are valid near the phase boundary where $\Psi \rightarrow 0$. Using polar coordinates, with the gauge chosen as $\vec{A}=(\mu_0 Hr/2)\vec{e}_\phi$ so that the vector potential has no radial component, the boundary conditions reduce to the simple case of the Neumann boundary conditions,

$$\left.\frac{\partial|\Psi(r)|}{\partial r}\right|_{r=r_o,r=r_i}=0. \tag{58}$$

The solution for Ψ in cylindrical coordinates takes the following form:[11,28,29,54,55]

$$\Psi(\Phi,\varphi)=e^{-iL\varphi}\left(\frac{\Phi}{\Phi_0}\right)^{L/2}\exp\left(-\frac{\Phi}{2\Phi_0}\right)\times\left(c_1 M\left(-n,L+1,\frac{\Phi}{\Phi_0}\right)+c_2 U\left(-n,L+1,\frac{\Phi}{\Phi_0}\right)\right), \tag{59}$$

where the number n determines the energy eigenvalue and M and U are Kummer functions of the first and second kind, respectively.

The eigenenergies of Eq. (4) are

$$|-\alpha| = \hbar \frac{2e\mu_0 H}{m^\star}\left(n+\frac{1}{2}\right) = \hbar\omega\left(n+\frac{1}{2}\right). \tag{60}$$

It is worth emphasizing that the parameter n depends on L but is not necessarily an integer number. This can be rewritten as

$$\frac{r_o^2}{\xi^2(T_c)} = \frac{r_o^2}{\xi^2(0)}\left(1-\frac{T_c(H)}{T_{c0}}\right) = 4\left(n+\frac{1}{2}\right)\frac{\Phi}{\Phi_0} = \epsilon(H_{c3}^*)\frac{\Phi}{\Phi_0}. \tag{61}$$

The Landau levels in a bulk superconductor are recovered by substituting $n=0,1,2,\ldots$ in Eqs. (60) and (61), meaning that the lowest level $n=0$ corresponds to the upper critical field. It is important to note that the lowest Landau level ($n=0$) for a bulk superconductor is degenerate in the phase winding number L, and therefore the eigenfunction can be expanded as $\Psi=\Sigma c_L \Psi_L$.

Using $\mathrm{d}M(a,c,y)/\mathrm{d}y=(a/c)M(a+1,c+1,y)$ and $\mathrm{d}U(a,c,y)/\mathrm{d}y=-aU(a+1,c+1,y)$ for the derivatives of the first and second type of Kummer functions, respectively,[16] and inserting Eq. (59) into Eq. (58) gives

$$\begin{aligned} c_1\left[\left(L-\frac{\Phi}{\Phi_0}\right)M(-n,L+1,\Phi/\Phi_0) - \frac{2n}{L+1}\frac{\Phi}{\Phi_0}M(-n+1,L+2,\Phi/\Phi_0)\right] \\ + c_2\left[\left(L-\frac{\Phi}{\Phi_0}\right)U(-n,L+1,\Phi/\Phi_0) + 2n\frac{\Phi}{\Phi_0}U(-n+1,L+2,\Phi/\Phi_0)\right]\Bigg|_b = 0, \end{aligned} \tag{62}$$

which must be solved numerically for each integer value of L, resulting in a set of values $n(L,\Phi)$, with $\Phi=\mu_0 H\pi r_o^2$.

For a disk geometry,[9,11,47] we must take $c_2=0$ in Eqs. (59) and (62) in order to avoid the divergency of $U(a,c,y\to 0)=\infty$ at the origin. Following the lowest Landau level at each value Φ, one ends up with a cusplike $T_c(H)$ phase boundary,[9] which is composed of values $n<0$ in Eq. (60), thus leading to $H_{c3}^*(T)>H_{c2}(T)$. A similar calculation was performed for a single circular microhole in a plane film by Bezryadin *et al.*,[54,55] where $c_1=0$ in Eqs. (59) and (62), since $M(a,c,y\to\infty)=\infty$. Here as well, the lowest Landau level consists of solutions with $n<0$. At each cusp in $T_c(\Phi)$, the system makes a transition $L\leftrightarrow L+1$, i.e., a vortex penetrates or is expelled from the sample.

The loops of finite width discussed in this section have two superconducting/vacuum interfaces, one at the outer radius r_o, and one at the inner radius r_i. Consequently, the boundary condition [Eq. (62)] must be fulfilled at both r_o and r_i. As a result, we have a system of two equations and two variables n and c_2 ($c_1=1$ is chosen), which were solved for different values of $x=r_i/r_o$. Note that in this case n is a positive or a negative number, just found from these two equations, it is not necessarily a positive integer number.

B. Sample properties

A SEM micrograph of the different studied samples prepared with *e*-beam lithography is given in Fig. 32. All the structures consist of disks with external radii of $r_o=1$ μm. The radii of the holes, determined from SEM micrograph, were $r_i=0$ μm (a), $r_i=0.1$ μm (b), $r_i=0.3$ μm (c), $r_i=0.5$ μm (d), and $r_i=0.7$ μm (e). All the samples were evaporated in the same run, except for the thinnest loop. A different evaporation will only slightly alter the superconducting properties like the coherence length and the critical temperature. Wedge shaped contacts with opening angle $\Gamma=15°$ are used in order to minimize the influence of the contacts on the superconducting properties of the structures.[44,45] The coherence length determined from a macroscopic coevaporated sample was found to be $\xi(0)=156$ nm for the disk and the three loops with a small opening. The thickness was $\tau=39$ nm. For the sample presented in Fig. 32(e), a coherence length of $\xi(0)=120$ nm was determined in the same way as for the other structures. A thickness of $\tau=54$ nm was found from low angle x-ray diffraction on a coevaporated film and from AFM for the loop with $r_i=0.7$ μm.

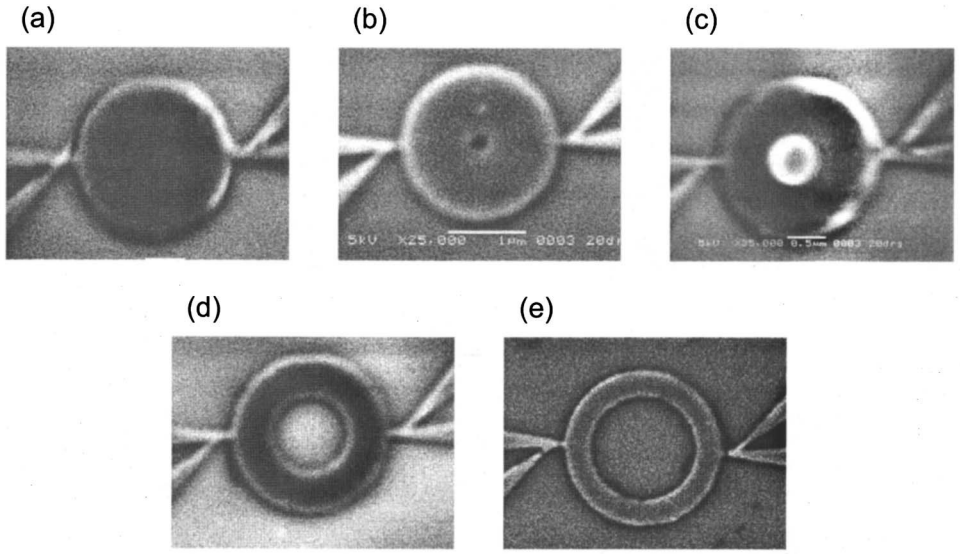

FIG. 32. SEM micrograph of (a) an Al disk with outer radius $r_o=1$ μm and of a loop with outer radius $r_o=1$ μm and inner radius (b) $r_i=0.1$ μm, (c) $r_i=0.3$ μm, (d) $r_i=0.5$ μm, and (e) $r_i=0.7$ μm.

C. Resistance transitions

The superconducting/normal resistance transitions for the disk and the rings with an inner to outer radius ratio $x=r_i/r_o=0.7$ are shown in Fig. 33. The five different samples have a very similar temperature dependence of the resistance at different magnetic field as the samples with wedge shaped contacts with opening angle $\Gamma=15°$ presented above. They are characterized by a slowly decreasing resistance at high temperatures arising from the nucleation of superconductivity in the wedge contacts, followed by a sharp drop of the resistance once superconductivity nucleates in the ring.[56] The samples with $x=0.3$, $x=0.5$, and $x=0.7$ show a different behavior at low magnetic

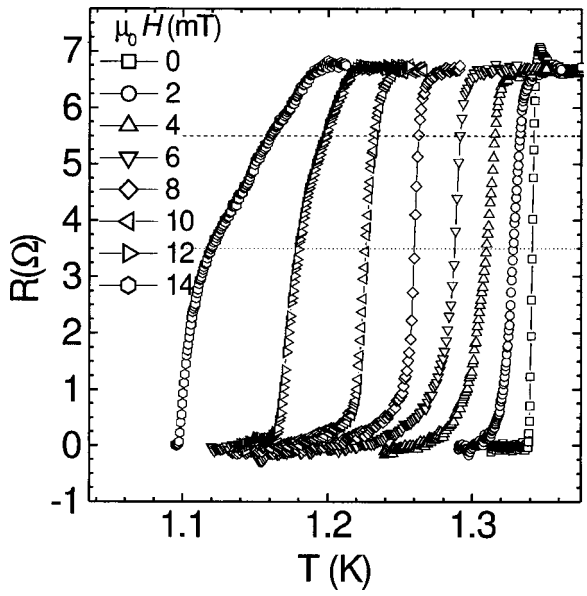

FIG. 33. Resistive transitions $R(T)$ for a loop with inner to outer radius ratio $x=0.7$ in different magnetic fields. The dashed and dotted lines show the resistance criteria used to determine the $T_c(H)$ phase boundary.

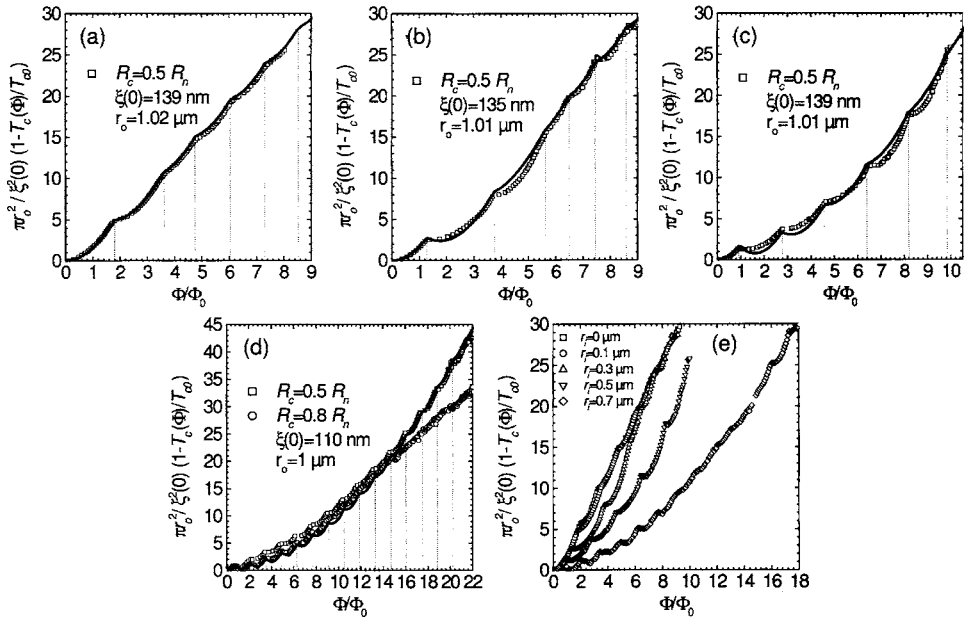

FIG. 34. The $T_c(H)$ phase boundary of a loop with inner to outer radius ratio (a) $x=0.1$, (b) $x=0.3$, (c) $x=0.5$, and (d) $x=0.7$. The open squares [and the open circles in (d)] represent the measured data. The solid lines are the calculated $E_{\mathrm{LLL}}(H)$. The experimental $T_c(H)$ phase boundaries of the different structures are compared in (e).

fields. There, the situation is reversed. A sharp transition is first observed, followed by a broad transition at low resistance. We will show below that the broad transition also corresponds to the nucleation in the wedges. This effect is observed in a broader magnetic field range when the ratio x increases.

D. $T_c(H)$ phase boundaries

The experimental phase boundary of the disk has already been presented in Fig. 21. The data for the ring with $x=0.1$ are shown in Fig. 34(a). The flux Φ on the field axis denotes the flux $\Phi=\mu_0 H\pi r_o^2$ through the ring and the hole. The H–T diagram of the ring with the smallest hole resembles strongly the $T_c(H)$ line of the disk displayed in Fig. 21. The phase boundary has a linear background superimposed with oscillations. A very good agreement between the measured and the calculated curves is found.

Figure 34(b) shows the H–T diagram of the ring with $x=0.3$. Here, the linear dependence is only seen for vorticity $L>4$. At lower magnetic field, a parabolic background suppression of T_c is observed. The crossover from the linear to the parabolic regime occurs at $\pi r_o^2/\xi^2(T)\approx 20$. This corresponds to a value $r_o-r_i\approx 1.8\ \xi(T)$, which is in a good agreement with the thickness $\tau=1.84\ \xi(T)$ for a crossover from a one-dimensional (1D) to a 2D regime for a thin film in a parallel magnetic field.[57,58]

A good agreement with the position of the cusps in the theoretical curve has been found. The amplitude of the oscillations in the experimental curve deviates slightly from the calculated one. At $L=1$, between the first and the second $T_c(H)$ cusps, the experimental oscillation is less pronounced. For higher vorticity, the opposite situation is seen where the amplitude of the experimental oscillations is larger than in the theoretical curve.

The penetration of the first vortex in the ring occurs at a lower magnetic field value than for the ring with the smallest hole [see Fig. 34(a)], while the transitions $L=1\leftrightarrow 2$ to $L=5\leftrightarrow 6$ occur at a higher magnetic field. That the transitions take place at lower magnetic field value for a ring with thinner lines is expected since the transition between L and $L+1$ occurs at $\Phi/\Phi_0=L+1/2$ for an infinitely thin loop or cylinder. At higher magnetic fields, a giant vortex state is formed[53] and the

disk with a small hole in the center behaves like the disk without hole. This, however, cannot fully explain why the change in vorticity is delayed at high magnetic fields by introducing a small hole in a disk.

The measured $T_c(H)$ phase boundary of the ring with ratio $x=0.5$ is shown in Fig. 34(c). In the temperature range accessible with our experimental setup, only a parabolic background dependence of the critical temperature on the magnetic field has been measured. By comparing the experimental results with the calculations, a similar behavior as for the ring with $x=0.3$ is seen. The position of the cusps in the experimental curve matches with the calculated transitions. However, no good agreement is found for the amplitude of the oscillations. For the vorticities $L=1$ and 2, the amplitude is lower in the experimental curve, while for $L>3$, the amplitude is larger. At low L, the transition between states with different vorticities occurs at a lower magnetic field than for the disk, while the transitions $L=3\leftrightarrow 4$, $L=4\leftrightarrow 5$ and $L=5\leftrightarrow 6$ take place at a higher magnetic field, similar to what was observed for the ring with $x=0.3$.

The H–T diagram of the ring with the thinnest line ($x=0.7$) is shown in Fig. 34(d). Two experimental curves are presented, one for $R_c=0.5R_n$ (open squares) and the second for $R_c=0.8R_n$ (open circles). It can be seen that at a higher resistance criterion the parabolic dependence switches to a linear regime at high magnetic field. For the curve calculated with the low resistance criterion, a quasiparabolic background suppression of $T_c(H)$ is observed over the whole measured range. The amplitude of the $T_c(H)$ oscillations is larger than in the samples with smaller x and the transition between states with different vorticities is almost periodic in field. A good agreement between the theoretical curve and the experimental curve with $R_c=0.5R_n$ is seen at high magnetic fields. At lower magnetic fields, a good agreement is found when using a higher resistance criterion.

The phase boundaries of the four different loops are compared with the critical temperature of the disk in Fig. 34(e). All the curves overlap with each other for $L=0$. *It is interesting to note that an opening in the disk does not affect the phase boundary as long as no vortex is trapped inside the superconductor*. Only the magnetic field range over which the state with $L=0$ exists at the phase boundary is lowered by introducing a hole in the disk. The $T_c(H)$ line of the disk with the smallest hole in the middle does not deviate substantially from the phase boundary of the disk without any opening. Only small changes in the position of the cusps is observed at low vorticity. For larger holes, the crossover from 2D to 1D regime is clearly seen. The samples with the thinnest lines do not show the 2D regime in the studied temperature interval and only the parabolic dependence is seen.

In order to reveal the origin of this different behavior at low and high magnetic field, a contour plot of the resistance $R(H,T)$ is presented in Fig. 35. Two different parts are clearly distinguished. Below 10 mT, the low resistance is linear, while the high resistance exhibits a parabolic background superimposed with oscillations. Above 10 mT, the opposite situation occurs, where the low resistance has a parabolic decay with small oscillations while the high resistance decreases monotonously. The parabolic part coincides with the nucleation of superconductivity in the loop shown as a full line. The linear part arises from the nucleation in the wedge contacts.

By fitting the theoretical critical temperature of a wedge with opening angle $\Gamma=15°$ to the linear part of the contour plot (dashed line), a coherence length $\xi(0)=140$ nm is obtained. This differs from the coherence length $\xi(0)=110$ nm that was used to find a good agreement between the experiment and the theoretical curve of a loop. A possible origin of this discrepancy could be a width of the loop that has been evaluated to be smaller than the real size. An estimate of the thickness that would satisfy the coherence length used for the calculation of the wedge contacts can be obtained from the analysis of the nucleation field of a thin wire of a film in a parallel magnetic field. From the calculation of the nucleation field of a thin film in a parallel field,[52] a value for the width of the loop of 0.38 μm is obtained instead of 0.3 μm found from SEM measurements. This difference is too large to be explained only by an error in the characterization of the sample. The opening angle of the contacts can be determined with a high accuracy so that a divergence arising from a wrong determination of Γ could be excluded. It means that either the nucleation of superconductivity is delayed in the wedges due to the presence of the loop or that the

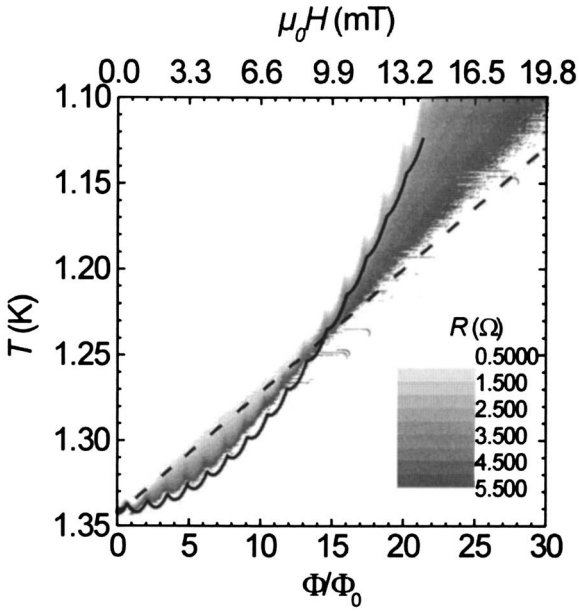

FIG. 35. Contour plot of the resistance $R(H,T)$ of a loop with $x=0.7$. The full line represents the calculated phase boundary of a loop with $r_i=0.7$ μm and $r_o=1$ μm, using a coherence length of 110 nm. The dashed line is the theoretical critical temperature of a wedge with opening angle $\Gamma=15°$ with $\xi=140$ nm.

nucleation in the loop is enhanced by the contacts. It is also possible that the coherence length in the loop is slightly different from that in the wedge. The sample geometry can indeed affect the superconducting parameters λ and ξ in a structure of mesoscopic size similar to the case of a thin film where the effective penetration depth increases as $\lambda'=\lambda^2/\tau$, taking into account the demagnetization effects. The renormalization of λ and ξ should therefore be calculated in a self-consistent way from the sample geometry.

The shape of the resistive curves in Fig. 33 can be easily understood from Fig. 35. It was clearly seen that in low magnetic fields the nucleation first occurs in the ring and is then followed by the nucleation in the contacts. Due to the different field dependence of the $T_c(H)$ of the ring and the contacts, the opposite occurs in higher magnetic fields. Two different shapes are therefore distinguished in the resistive curves depending on the part where superconductivity starts to nucleate. The same happens in the rings with $x=0.3$ and $x=0.5$ since T_c also has a parabolic field dependence for low fields. The normal parts of the sample can however partially become superconducting by the proximity effect with the neighboring superconducting part.

VI. STABILITY OF THE LGL SOLUTIONS AND THE PHASE TRANSITIONS BELOW THE NUCLEATION TEMPERATURE

The lowest level E_{LLL} of the LGL equation, describing the nucleation of superconductivity in applied magnetic field, $T_c(H)$, is always nondegenerate for finite size samples.[59] Therefore the corresponding solution is fully consistent with the symmetry of the sample in applied field as we have seen in the preceding section. This is opposite to the case of bulk type-II superconductors without boundaries, where $E_{\mathrm{LLL}}(H)$ is an infinitely degenerate Landau level while the nucleating order parameter is a combination of its degenerate components,[42] always of broken symmetry (BS) type. Besides the symmetry, the discreteness of the spectrum of the LGL equation in mesoscopic superconductors implies the stability of the shape of the nucleated order parameter in a range of temperatures close to the $T_c(H)$ line. Such stability of a symmetric order parameter has been found for mesoscopic cylinders,[30,34,40,60,61] squares and triangles.[62–66] Remarkably, a similar phenomenon is encountered in molecular physics where it is known as the pseudo-Jahn-Teller effect.[67]

In this section we investigate the mechanisms of phase transitions from a nucleated order parameter of a mesoscopic superconductor to another symmetry or broken symmetry phase when temperature is lowered.[68] We find that in the case of BS phase transitions most often only one single LGL solution of different symmetry effectively admixes to the nucleated phase. In this case the description of the phase transition is equivalent to the description of vibronic instability in a simple (two-level) pseudo-Jahn-Teller problem. Such analogy is specific to mesoscopic superconductors, which have discrete LGL spectrum, and gives a "molecular" view on the mechanism of BS phase transitions in mesoscopic samples. We also investigate the existence of different phases as a function of the samples size and find that the region on the phase diagram corresponding to the nucleated order parameter of S solution increases with reducing the size. The critical sizes, corresponding to the disappearence of BS phase transitions (when the nucleated S phases persist down to $T=0$) are predicted to be in the range of micrometers for conventional superconductors, i.e., within the reach of current experimental techniques. This opens possibilities for the experimental verification of different transitions predicted here on the basis of the similarities with pseudo-Jahn-Teller mechanism.

As before we consider a superconducting polygon of size a (a^2 is the surface of the sample) and thickness d in a perpendicular uniform magnetic field H. For small ($a \sim \xi$, the coherence length) and thin ($d \ll \xi$) samples one can neglect the variation of the order parameter across thickness[30,40] and the distortion of the magnetic field induced by screening and vortex currents. The order parameter Ψ is found from the minimization of the two-dimensional GL functional,

$$\Delta F = \int \left[\alpha |\Psi|^2 + \frac{1}{2}\beta |\Psi|^4 + \frac{1}{2m^*} \left| \left(-i\hbar \nabla - \frac{2e}{c}\mathbf{A} \right) \Psi \right|^2 \right] \mathrm{d}S, \tag{63}$$

with the boundary condition (7). Minimizing (63) without the term $\sim|\Psi|^4$ results in the linear eigenvalue equation (4) with the solutions which we further denote by ϕ_i, ϵ_i. The lowest solution ϕ_1 describes the nucleation phase boundary via the equation $\epsilon_1 = -\alpha$. The eigenvalues ϵ_i, measured in units of $\hbar^2/2m^* a^2 (\epsilon_i')$, depend only on the applied magnetic flux $\Phi = Ha^2$, presented in units of the superconducting flux quantum Φ_0. The eigenstates of (34), normalized to unity within the surface of the sample, are used further as the basis set for the order parameter,

$$\Psi = \sum_{i=1}^{N} c_i \phi_i, \tag{64}$$

where N is the dimension of the basis set. Substitution of (64) into (63) yields ΔF as a function of the expansion coefficients

$$\Delta F = \sum_i \alpha_i |c_i|^2 + \frac{\beta}{2a^2} \sum_{ijkl} A_{ij}^{kl} c_i^* c_j^* c_k c_l,$$

$$\alpha_i \equiv \alpha + \epsilon_i, \tag{65}$$

where the parameters

$$A_{ij}^{kl} = a^2 \int \phi_i^* \phi_j^* \phi_k \phi_l \, \mathrm{d}S \tag{66}$$

depend only on the geometry but not on the size of the sample. A_{ii}^{ii} is precisely the Abrikosov parameter β_A[69] for the state ϕ_i, which is a measure of its "flatness."

The actual parameters defining the relative free energy in Eq. (65) can be found as follows. If we use coefficients $c_i \to a\sqrt{-\alpha_1/\beta} c_i$ and measure the free energy in units of $a^2\alpha_1^2/\beta$ (α_1 corresponds to the lowest LGL eigenvalue ϵ_1) then the right-hand side of Eq. (65) will depend (besides

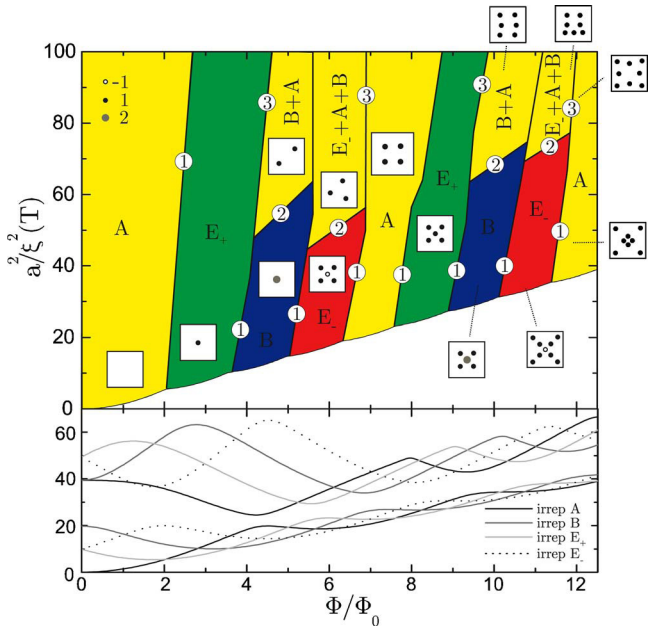

FIG. 36. (Color online) Lower panel, LGL solutions ϵ_i' for a square with superconductor-vacuum boundary condition, characterized by irreps A ($m=0$), B ($m=2$), E_+ ($m=1$), and E_- ($m=-1$). Upper panel, the corresponding phase diagram obtained by Monte Carlo calculations. For each phase, the vortex structure is shown schematically and the involved irreps are indicated. The number at each boundary line denotes the type of transition (Table II). In the color online version: the colors stand for the winding number of the central vortex: 0 (yellow), 1 (green), 2 (blue), and −1 (red).

A_{ij}^{kl}) only on the ratios $\alpha_i/\alpha_1=(a^2/\xi^2+\epsilon_i')/(a^2/\xi^2+\epsilon_1')$. Hence the GL functional for a given sample (measured in units of $a^2\alpha_1^2/\beta$) and the emerging phase diagram are only dependent on $(a/\xi(T))^2$ and Φ/Φ_0.

As we have already seen (Figs. 11 and 12), the spectrum of eigenvalues of the LGL equation is strongly influenced by the symmetry of the problem. If the sample has a rotational symmetry axis C_n, the Landau levels are split in groups of n levels belonging to different irreps, because only these can intersect each other. In addition, the C_n symmetry imposes the selection rules on integrals in Eq. (66), $m_k+m_l-m_i-m_j=0$, similar to the case of cylindrical symmetry.[34,60]

Because the fourth order terms in (65) are overall positive, it is generally expected that only the states ϕ_i with $\alpha_i<0$ will effectively contribute to the order parameter. In the close vicinity to the nucleation phase boundary only α_1 is negative, therefore $\Psi\approx c_1\phi_1$, with $c_1=a\sqrt{-\alpha_1/\beta A_{11}^{11}}$ $\sim\sqrt{(a/\xi)^2-\epsilon_1'}$ and the free energy $\Delta F_1=-(\alpha_1^2/2\beta A_{11}^{11})a^2$. The only allowed admixtures in this phase are from the excited LGL states of the same irrep, $\phi_{1'}$, described by the coefficients $c_{1'}$,

$$\frac{c_{1'}}{c_1}\approx-\frac{A_{11'}^{11}c_1^2}{\alpha_{1'}/\beta+[2A_{11'}^{11'}+|A_{11'}^{11}|\cos(\chi_{1'1'}^{11}-2\chi_{11'}^{11})]c_1^2}, \tag{67}$$

where $\chi_{ij}^{kl}=\arg A_{ij}^{kl}$. In the temperature region where $\alpha_{1'}>0$ the coefficients $c_{1'}$ in (67) show smooth behavior, with continuous derivatives with respect to temperature. The symmetry-preserving phase transitions can therefore occur only when some of $\alpha_{1'}$ become negative. However in symmetric samples the ϕ_i states which are close to ϵ_1 are always of different symmetry (lower panel in Fig. 36) so that many of the corresponding parameters α_i will become negative before $\alpha_{1'}$. We can conclude that the nucleated order parameter will undergo a phase transition *modifying its symmetry* when temperature is lowered.

Even if there are many LGL states with $\alpha_i<0$ at a given temperature, only a few of them actually contribute to the order parameter. This is due to the fact that while the terms $\sim A_{ii}^{ii}$ and $\sim A_{ii}^{jj}$ give net contributions to "repulsion," the other terms, which could become negative, partially

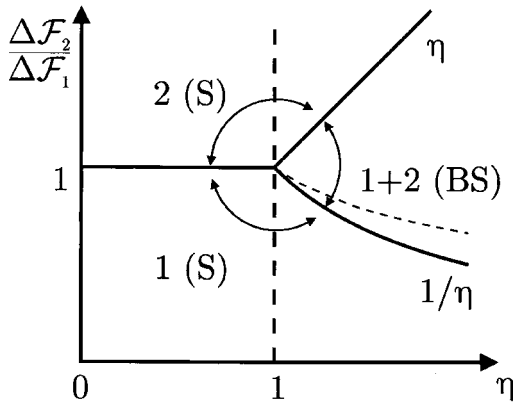

FIG. 37. Diagram of thermodynamically stable phases (solid lines) for the effective two-state model (68) as a function of the parameters from Eqs. (69) and (70). 1, 2 are pure phases and 1+2 is the mixed one.

cancel out when N is increased. One can check indeed that already for $N>3$ there are less available phases of complex c_i coefficients than A_{ij}^{kl} terms to be optimized. The mutual reduction of these terms increases with the number of mixed LGL states which means that at a certain value of N further admixture will become unfavorable. It is expected therefore that only a few different irreps will effectively admix at the transition point.

Next we adopt a general description of the phase transitions from a nucleated order parameter, which is achieved by the following consideration. Given the small number of different irreps among the states ϕ_i which admix at the transition point, we can always divide the corresponding $\{c_i\}$ in two groups so as to bring the functional (65) to the following basic form:

$$\Delta F = \tilde{\alpha}_1 c_1'^2 + \tilde{\alpha}_2 c_2'^2 + \frac{\beta}{2a^2}(A_{11}c_1'^4 + A_{22}c_2'^4 + 2A_{12}c_1'^2 c_2'^2), \tag{68}$$

where c_1' and c_2' are the norms of the coefficients in the first and the second group, respectively, while the parameters $\tilde{\alpha}_1$, $\tilde{\alpha}_2(<0)$ and A_{11}, A_{22}, $A_{12}(>0)$ are functions of associated angular variables to be specified below. The two groups contain different irreps, in numbers n_1 and n_2, correspondingly (ϕ_1 belongs to the first group). Minimization with respect to c_1' and c_2' for fixed values of the five parameters in (68) results in three (meta)stable phases,

$$\Delta F_1 = -\frac{\tilde{\alpha}_1^2}{2\beta A_{11}}a^2, \quad \Delta F_2 = -\frac{\tilde{\alpha}_2^2}{2\beta A_{22}}a^2,$$

$$\frac{\Delta F_{12}}{\Delta F_1} = \frac{(\sqrt{\eta \Delta F_2/\Delta F_1} - 1)^2}{\eta - 1} + 1, \tag{69}$$

where

$$\eta = \frac{A_{11}A_{22}}{A_{12}^2}. \tag{70}$$

The first two are pure phases, with $c_2'=0$ and $c_1'=0$, respectively, while ΔF_{12} is the mixed one $(c_1', c_2' \neq 0)$. Figure 37 shows the diagram of the thermodynamically stable phases. The vertical line $\eta=1$ divides the diagram in two regions. On the left-hand side we have a switch between pure phases (first-order transition). On the right-hand side the two phase boundary lines correspond to the second order transitions. At temperatures close to the lower phase boundary, $T=T_{\mathrm{BS}}-\Delta T$, $\xi=\xi_{\mathrm{BS}}-\Delta\xi$, the BS phase will grow as $c_2' \sim \sqrt{\Delta T}$, $\sqrt{\Delta\xi}$.

Now the free energy expressions (69) are minimized with respect to the remaining variables from $\tilde{\alpha}_i$ and A_{ij} resulting in the lowest energy phase for a given temperature. Since we are looking for phase transitions from the nucleated S-order parameter, the pure phase 1 in Fig. 37 always corresponds to ϕ_1 with possible small admixtures of the same symmetry, Eq. (67). Depending on the symmetries of other LGL states which admix through the transition we can have several types of phase transitions which are investigated below. As in the case of ϕ_1, the contributions from states of other symmetries are mainly represented by one LGL state. Therefore to simplify further analysis we will consider that only one state per irrep contributes.

In the case of a single admixed state (ϕ_2) one should substitute $c_1=c_1'$ and $c_2=c_2'$ in Eq. (68) and $\tilde{\alpha}_i=\alpha_i$, $A_{ii}=A_{ii}^{ii}$ and $A_{12}=2A_{12}^{12}-|A_{11}^{22}|$ into (69) and (70). When the interaction between these states, A_{12}, is larger than $\sqrt{A_{11}^{11}A_{22}^{22}}$, the order parameter corresponds either to ϕ_1 or ϕ_2 (left-hand side of the diagram in Fig. 37). The transition from ϕ_1 to ϕ_2 takes place when

$$\frac{\alpha_2}{\alpha_1} > \sqrt{\frac{A_{22}^{22}}{A_{11}^{11}}}. \tag{71}$$

The left-hand side of this equation increases with lowering the temperature, being always <1. Therefore the transition between symmetric states can only occur if $A_{22}^{22}<A_{11}^{11}$. When the interaction is weaker, $\eta>1$, the transition from ϕ_1 to a BS order parameter (right-hand side of the phase diagram) can arise under the condition

$$\frac{\alpha_2}{\alpha_1} > \frac{A_{12}}{A_{11}^{11}}. \tag{72}$$

When two states of different symmetry mix with ϕ_1, two situations can occur.

(1) If the involved irreps obey the inequalities $m_1+m_3-2m_2\neq 0,\pm n$, $m_1+m_2-2m_3\neq 0,\pm n$, then one has $c_1=c_1'$, $c_2=c_2'\cos\varphi$, $c_3=c_2'\sin\varphi$, and

$$\tilde{\alpha}_1=\alpha_1,$$

$$\tilde{\alpha}_2=\alpha_2\cos^2\varphi+\alpha_3\sin^2\varphi,$$

$$A_{11}=A_{11}^{11},$$

$$A_{22}=A_{22}^{22}\cos^4\varphi+A_{33}^{33}\sin^4\varphi+(A_{23}^{23}-|A_{22}^{33}|/2)\sin^2 2\varphi,$$

$$A_{12}=2A_{12}^{12}\cos^2\varphi+2A_{13}^{13}\sin^2\varphi-|A_{11}^{23}|\sin 2\varphi, \tag{73}$$
