Step 6: If we delete nodes i, j, and k from the extended Dynkin diagram ($i < j < k$), then the corresponding $\mathbb{Z}$-gradings are of the form

$$\mathrm{sl}(n+1) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}.$$

All the corresponding CAOs, however, are isomorphic to those of step 2 (which can again be seen from the remaining Dynkin diagram).

Step 7: If we delete four or more nodes from the extended Dynkin diagram, the corresponding $\mathbb{Z}$-grading of $\mathrm{sl}(n+1)$ has no longer the required properties (i.e., there are nonzero subspaces G_i with $|i|>2$).

IV. THE LIE ALGEBRA $B_n = \mathrm{so}(2n+1)$

$G=\mathrm{so}(2n+1)$ is the subalgebra of $\mathrm{sl}(2n+1)$ consisting of matrices of the form

$$\begin{pmatrix} a & b & c \\ d & -a^t & e \\ -e^t & -c^t & 0 \end{pmatrix}, \tag{4.1}$$

where a is any $(n\times n)$-matrix, b and d are antisymmetric $(n\times n)$-matrices, and c and e are $(n\times 1)$-matrices. The Cartan subalgebra H of G is again the subspace of diagonal matrices. The root vectors and corresponding roots of G are given by

$$e_{jk} - e_{k+n,j+n} \leftrightarrow \epsilon_j - \epsilon_k, \quad j \neq k = 1, \ldots, n,$$

$$e_{j,k+n} - e_{k,j+n} \leftrightarrow \epsilon_j + \epsilon_k, \quad j < k = 1, \ldots, n,$$

$$e_{j+n,k} - e_{k+n,j} \leftrightarrow -\epsilon_j - \epsilon_k, \quad j < k = 1, \ldots, n,$$

$$e_{j,2n+1} - e_{2n+1,j+n} \leftrightarrow \epsilon_j, \quad j = 1, \ldots, n,$$

$$e_{n+j,2n+1} - e_{2n+1,j} \leftrightarrow -\epsilon_j, \quad j = 1, \ldots, n.$$

The anti-involution is such that $\omega(e_{jk})=e_{kj}$. The simple roots, the Dynkin diagram and the extended Dynkin diagram of B_n are given in Table I. Just as for A_n, we now start the process of deleting nodes from the Dynkin diagram or from the extended Dynkin diagram.

Step 1: Delete node 1 from the Dynkin diagram. The remaining diagram is that of B_{n-1}, so $G_0=H+\mathrm{so}(2n-1)\equiv H+B_{n-1}$. There are two G_0-modules:

$$G_{-1} = \mathrm{span}\{e_{1,2n+1} - e_{2n+1,n+1},\ e_{1,k+n} - e_{k,n+1},\ e_{1k} - e_{k+n,n+1};\ k = 2, \ldots, n\}, \tag{4.2}$$

and $G_{+1}=\omega(G_{-1})$. Thus $\mathrm{so}(2n+1)$ has the following grading:

$$\mathrm{so}(2n+1) = G_{-1} \oplus G_0 \oplus G_{+1}$$

and the number of (mutually commuting) creation and annihilation operators is $N=2n-1$. Let us denote the CAOs by

$$b_{00}^- = e_{1,2n+1} - e_{2n+1,n+1}, \quad b_{00}^+ = e_{2n+1,1} - e_{n+1,2n+1},$$

$$b_{-k}^- = e_{1,n+k+1} - e_{k+1,n+1}, \quad b_{-k}^+ = e_{n+k+1,1} - e_{n+1,k+1}, \quad k = 1, \ldots, n-1, \tag{4.3}$$

$$b_{+k}^- = e_{1,k+1} - e_{n+k+1,n+1}, \quad b_{+k}^+ = e_{k+1,1} - e_{n+1,n+k+1}, \quad k = 1, \ldots, n-1.$$

The corresponding relations $\mathcal{R}$ are given by $(\xi, \eta, \epsilon=0, \pm;\ i,j,k=1,\ldots,n-1)$

$$[b_{\xi i}^+, b_{\eta j}^+] = [b_{\xi i}^-, b_{\eta j}^-] = 0,$$

$$[b^+_{-i}, b^-_{-j}] = [b^-_{+i}, b^+_{+j}], \quad i \neq j,$$

$$[b^+_{00}, b^-_{-j}] = [b^-_{00}, b^+_{+j}],$$

$$[b^+_{00}, b^-_{+j}] = [b^-_{00}, b^+_{-j}], \tag{4.4}$$

$$[[b^+_{\xi i}, b^-_{\eta j}], b^+_{\epsilon k}] = \delta_{ij}\delta_{\xi\eta}b^+_{\epsilon k} + \delta_{jk}\delta_{\eta\epsilon}b^+_{\xi i} - \delta_{ik}\delta_{\xi,-\epsilon}b^+_{-\eta j},$$

$$[[b^+_{\xi i}, b^-_{\eta j}], b^-_{\epsilon k}] = -\delta_{ij}\delta_{\xi\eta}b^-_{\epsilon k} - \delta_{ik}\delta_{\xi\epsilon}b^-_{\eta j} + \delta_{jk}\delta_{\eta,-\epsilon}b^-_{-\xi i}.$$

Step 2: Delete node i $(i=2,\ldots,n)$ from the Dynkin diagram; then the corresponding subalgebra is $G_0=H+\mathrm{sl}(i)\oplus\mathrm{so}(2(n-i)+1)$. Now there are four G_0-modules, with the following grading for G:

$$\mathrm{so}(2n+1) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$$

with

$$G_{-1} = \mathrm{span}\{e_{j,2n+1} - e_{2n+1,n+j},\ e_{j,k+n} - e_{k,n+j},\ e_{jk} - e_{k+n,n+j};\quad j=1,\ldots,i,\ k=i+1,\ldots,n\},$$

$$G_{-2} = \mathrm{span}\{e_{j,k+n} - e_{k,j+n};\ 1 \leqslant j < k \leqslant i\}. \tag{4.5}$$

The number of the annihilation operators is $N=2i(n-i)+i$. The most interesting case is that with $i=n$: this is the para-Fermi case presented in the Introduction. Indeed, let

$$f^-_j = \sqrt{2}(e_{j,2n+1} - e_{2n+1,n+j}), \quad f^+_j = \sqrt{2}(e_{2n+1,j} - e_{n+j,2n+1}), \quad j=1,\ldots,n. \tag{4.6}$$

Then there are no quadratic relations, and $\mathcal{R}$ consists of triple relations only

$$[[f^\xi_j, f^\eta_k], f^\epsilon_l] = \tfrac{1}{2}(\epsilon-\eta)^2\delta_{kl}f^\xi_j - \tfrac{1}{2}(\epsilon-\xi)^2\delta_{jl}f^\eta_k,$$

$$\xi,\eta,\epsilon = \pm \text{ or } \pm 1, \quad j,k,l = 1,\ldots,n. \tag{4.7}$$

Step 3: Delete two or more nodes from the Dynkin diagram. Then the corresponding $\mathbb{Z}$-grading of $\mathrm{so}(2n+1)$ no longer has the required properties (i.e., there are nonzero G_i with $|i|>2$).

Step 4: Now we turn to the extended Dynkin diagram. Deleting node i from this diagram, leaves the Dynkin diagram of $\mathrm{so}(2n+1)$ for $i=0,1$, of $\mathrm{so}(2n)$ for $i=n$, of $\mathrm{sl}(2)\oplus\mathrm{sl}(2)\oplus\mathrm{so}(2n-3)$ for $i=2$, of $\mathrm{sl}(4)\oplus\mathrm{so}(2n-5)$ for $i=3$, and of $\mathrm{so}(2i)\oplus\mathrm{so}(2n-2i+1)$ for $i\geqslant 4$. In all these cases there is only one G_0-module, so there are no contributions to our classification.

Step 5: Delete the adjacent nodes $(i-1)$ and i $(i=3,\ldots,n)$ from the extended Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=\mathrm{sl}(2)\oplus\mathrm{sl}(2)\oplus\mathrm{so}(2(n-i)+1)$ for $i=3$, of $\tilde{G}_0=\mathrm{sl}(4)\oplus\mathrm{so}(2(n-i)+1)$ for $i=4$, and of $\tilde{G}_0=\mathrm{so}(2(i-1))\oplus\mathrm{so}(2(n-i)+1)$ for $i>4$. In each case, there are five $\tilde{G}_0$-modules g_k, one of which is invariant under ω (say g_1). Then one must set $G_0=H+\tilde{G}_0+g_1$, and in each case one finds $G_0\equiv H+B_{n-1}$.

Now, there are only two G_0-modules and

$$\mathrm{so}(2n+1) = G_{-1} \oplus G_0 \oplus G_{+1}$$

with

$$G_{-1} = \mathrm{span}\{e_{i,2n+1} - e_{2n+1,n+i}, e_{ik} - e_{k+n,n+i}, e_{i,k+n} - e_{k,n+i};\ k \neq i = 1,\ldots,n\}. \tag{4.8}$$

The number of the anihilation operators is $N=2n-1$, and all these cases are isomorphic to those of step 1.

Step 6: Delete two nonadjacent nodes from the extended Dynkin diagram, say i and j, $i<j$, $i,j\neq 0,1$. The remaining diagram is that of $\tilde{G}_0=\mathrm{so}(2i)\oplus\mathrm{sl}(j-i)\oplus\mathrm{so}(2(n-j)+1)$ [if $i=2$ we have $\mathrm{sl}(2)\oplus\mathrm{sl}(2)$ instead of $\mathrm{so}(2i)$]. There are seven $\tilde{G}_0$-modules g_k, one of which (say g_1) with $\omega(g_1)=g_1$. Thus one must take $G_0=H+\tilde{G}_0+g_1$, and this is in fact $G_0\equiv H+\mathrm{so}(2(n-j+i)+1)\oplus\mathrm{sl}(j-i)$.

The corresponding grading is

$$\mathrm{so}(2n+1)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$$

with

$$G_{-1}=\mathrm{span}\{e_{k,2n+1}-e_{2n+1,n+k},e_{kl}-e_{l+n,n+k},e_{k,n+l}-e_{l,n+k};\ k=i+1,\ldots,j,l=1,\ldots,i,j+1,\ldots,n\},$$

$$G_{-2}=\mathrm{span}\{e_{k,n+l}-e_{l,n+k};\ i+1\leqslant k<l\leqslant j\}. \tag{4.9}$$

The number of the annihilation operators is $N=2(j-i)(n-j+i)+j-i$, and all these cases turn out to be isomorphic to those of step 2.

Step 7: If we delete three or more nodes from the extended Dynkin diagram, the corresponding $\mathbb{Z}$-grading of $\mathrm{so}(2n+1)$ has no longer the required properties (i.e., there are nonzero subspaces G_i with $|i|>2$).

V. THE LIE ALGEBRA $C_n=\mathrm{sp}(2n)$

$G=\mathrm{sp}(2n)$ is the subalgebra of $\mathrm{sl}(2n)$ consisting of matrices of the form

$$\begin{pmatrix} a & b \\ c & -a^t \end{pmatrix}, \tag{5.1}$$

where a is any $(n\times n)$-matrix, and b and c are symmetric $(n\times n)$-matrices. The Cartan subalgebra H consist of the diagonal matrices, and the root vectors and corresponding roots of G are

$$e_{jk}-e_{k+n,j+n}\leftrightarrow\epsilon_j-\epsilon_k,\quad j\neq k=1,\ldots,n,$$

$$e_{j,k+n}+e_{k,j+n}\leftrightarrow\epsilon_j+\epsilon_k,\quad j\leqslant k=1,\ldots,n,$$

$$e_{j+n,k}+e_{k+n,j}\leftrightarrow-\epsilon_j-\epsilon_k,\quad j\leqslant k=1,\ldots,n.$$

The simple roots, Dynkin diagram and extended Dynkin diagram are given in Table I. Again, the anti-involution is such that $\omega(e_{jk})=e_{kj}$. Next, we describe the process of deleting nodes and its consequences for the classification of GQS.

Step 1: Delete node i ($i=1,\ldots,n-1$) from the Dynkin diagram. The remaining diagram is that of $\mathrm{sl}(i)\oplus\mathrm{sp}(2(n-i))$, so $G_0=H+\mathrm{sl}(i)\oplus\mathrm{sp}(2(n-i))$. There are four G_0-modules, leading to the following grading:

$$\mathrm{sp}(2n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$$

with

$$\begin{aligned} G_{-1}&=\mathrm{span}\{e_{k,n+l}+e_{l,n+k},e_{kl}-e_{n+l,n+k};k=1,\ldots,i,l=i+1,\ldots,n\},\\ G_{-2}&=\mathrm{span}\{e_{k,n+l}+e_{l,n+k};1\leqslant k\leqslant l\leqslant i\}. \end{aligned} \tag{5.2}$$

The number of the annihilation operators is $N=2i(n-i)$. The most interesting cases are $i=1$ and $i=n-1$, which we shall describe in more detail.

For $i=1$, let us denote the CAOs by

$$c^{-}_{-j} = e_{1,n+j+1} + e_{j+1,n+1}, \quad c^{-}_{+j} = e_{1,j+1} - e_{n+j+1,n+1}, \quad j = 1, \ldots, n-1,$$
$$c^{+}_{-j} = e_{n+j+1,1} + e_{n+1,j+1}, \quad c^{+}_{+j} = e_{j+1,1} - e_{n+1,n+j+1}, \quad j = 1, \ldots, n-1. \tag{5.3}$$

Then the corresponding relations $\mathcal{R}$ read, with $\xi, \eta, \epsilon, \gamma = \pm$ or ± 1, and $j, k, l = 1, \ldots, n-1$,

$$[c^{\eta}_{\xi j}, c^{\eta}_{\xi k}] = 0,$$

$$[c^{+}_{-j}, c^{-}_{-k}] = [c^{-}_{+j}, c^{+}_{+k}], \quad j \neq k,$$

$$[c^{-}_{-j}, c^{-}_{+k}] = [c^{+}_{-j}, c^{+}_{+k}] = 0, \quad j \neq k,$$

$$[[c^{+}_{\xi j}, c^{-}_{\eta k}], c^{+}_{\epsilon l}] = \delta_{\xi\eta}\delta_{jk}c^{+}_{\epsilon l} + \delta_{\eta\epsilon}\delta_{kl}c^{+}_{\xi j} + (-1)^{\eta\epsilon}\delta_{\xi,-\epsilon}\delta_{jl}c^{+}_{-\eta k}, \tag{5.4}$$

$$[[c^{+}_{\xi j}, c^{-}_{\eta k}], c^{-}_{\epsilon l}] = -\delta_{\xi\eta}\delta_{jk}c^{-}_{\epsilon l} - \delta_{\xi\epsilon}\delta_{jl}c^{-}_{\eta k} + (-1)^{\xi\eta}\delta_{\eta,-\epsilon}\delta_{kl}c^{-}_{-\xi j},$$

$$[[c^{\xi}_{-j}, c^{\xi}_{+k}], c^{-\xi}_{\eta l}] = 2\eta\delta_{jk}c^{\xi}_{-\eta l},$$

$$[[c^{\gamma}_{\xi j}, c^{\gamma}_{\eta k}], c^{\gamma}_{\epsilon l}] = 0.$$

For $i = n-1$, let us also denote the CAOs by $c^{\pm}_{j}$,

$$c^{-}_{-j} = e_{j,2n} + e_{n,n+j}, \quad c^{-}_{+j} = e_{jn} - e_{2n,n+j}, \quad j = 1, \ldots, n-1,$$
$$c^{+}_{-j} = e_{2n,j} + e_{n+j,n}, \quad c^{+}_{+j} = e_{nj} - e_{n+j,2n}, \quad j = 1, \ldots, n-1. \tag{5.5}$$

Now, the corresponding relations read, with $\xi, \eta, \epsilon, \gamma = \pm$ or ± 1, $j, k, l = 1, \ldots, n-1$,

$$[c^{\eta}_{\xi j}, c^{\eta}_{\xi k}] = 0,$$

$$[c^{+}_{+j}, c^{-}_{-k}] = [c^{-}_{+j}, c^{+}_{-k}] = 0, \quad j \neq k,$$

$$[[c^{\epsilon}_{\xi j}, c^{-\epsilon}_{\xi k}], c^{\epsilon}_{\eta l}] = \xi\eta\delta_{jk}c^{\epsilon}_{\eta l} + \delta_{kl}c^{\epsilon}_{\eta j},$$

$$[[c^{\epsilon}_{+j}, c^{-\epsilon}_{-k}], c^{\xi}_{\eta l}] = (\epsilon\xi - \eta)\delta_{jk}c^{\xi}_{-\eta l}, \tag{5.6}$$

$$[[c^{\epsilon}_{+j}, c^{\epsilon}_{-k}], c^{-\epsilon}_{\xi l}] = -\xi\delta_{jl}c^{\epsilon}_{-\xi k} - \xi\delta_{kl}c^{\epsilon}_{-\xi j},$$

$$[[c^{\gamma}_{\xi j}, c^{\gamma}_{\eta k}], c^{\gamma}_{\epsilon l}] = 0.$$

This set of CAOs, together with their relations (5.6), was constructed earlier in Ref. 6. Also the CAOs (5.3) were already mentioned in Ref. 6 as a possible example, without giving the actual relations (5.4).

Step 2: When node n is deleted from the Dynkin diagram of C_n, the corresponding diagram is that of sl(n), and $G_0 = H + \mathrm{sl}(n)$. In this case, there are two G_0-modules, and sp($2n$) has the grading $\mathrm{sp}(2n) = G_{-1} \oplus G_0 \oplus G_{+1}$ with

$$G_{-1} = \{e_{j,n+k} + e_{k,n+j};\ 1 \leqslant j \leqslant k \leqslant n\}. \tag{5.7}$$

There are $N = n(n+1)/2$ commuting annihilation operators, and the relations $\mathcal{R}$ will not be given explicitly.

Step 3: Upon deleting two or more nodes from the Dynkin diagram of C_n, the corresponding

$\mathbb{Z}$-gradings have no longer the required property (there are nonzero G_i with $|i|>2$).

Step 4: Now we turn to the extended Dynkin diagram. Deleting one node from this diagram leads to a situation with only one G_0-module, irrelevant for our classification.

Step 5: Delete the adjacent nodes $(i-1)$ and i $(i=2,\ldots,n)$ from the extended Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=\mathrm{sp}(2(i-1))\oplus\mathrm{sp}(2(n-i))$. There are seven $\tilde{G}_0$-modules g_k, one of which satisfies $\omega(g_1)=g_1$. Setting $G_0=H+\tilde{G}_0+g_1$, it turns out that $G_0\equiv H+C_{n-1}$. In that case, there are only four G_0-modules and G has the grading $\mathrm{sp}(2n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{i,n+j}+e_{j,n+i},e_{ij}-e_{n+j,n+i};\ j\neq i=1,\ldots,n\}. \tag{5.8}$$

The number of the annihilation operators is $N=2(n-1)$, and all these cases are isomorphic to the $i=1$ case of step 1.

Step 6: Delete two nonadjacent nodes $i<j$ (excluding the case $i=1$ and $j=n$) from the extended Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=\mathrm{sp}(2i)\oplus\mathrm{sl}(j-i)\oplus\mathrm{sp}(2(n-j))$. There are again seven $\tilde{G}_0$-modules g_k, among which one with $\omega(g_1)=g_1$. Then $G_0=H+\tilde{G}_0+g_1$ $\equiv H+\mathrm{sl}(j-i)\oplus\mathrm{sp}(2(n-j+i))$. There are only four G_0-modules and the grading is $\mathrm{sp}(2n)=G_{-2}$ $\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{k,n+l}+e_{l,n+k},e_{kl}-e_{n+l,n+k};\ k=i+1,\ldots,j,l\neq i+1,\ldots,j\}. \tag{5.9}$$

The number of annihilation operators is $N=2(j-i)(n-j+i)$, and all these cases are isomorphic to those of step 1 with $i\neq 1$.

Step 7: Delete node 1 and n from the extended Dynkin diagram. The remaining diagram is that of $\mathrm{sl}(2)\oplus\mathrm{sl}(n-1)$. With $G_0=\mathrm{sl}(2)\oplus\mathrm{sl}(n-1)$, there are four G_0-modules and the corresponding grading is $\mathrm{sp}(2n)=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}$ with

$$G_{-1}=\mathrm{span}\{e_{1,n+k}+e_{k,n+1},e_{k1}-e_{n+1,n+k};\ k=2,\ldots,n\}. \tag{5.10}$$

This case is isomorphic to the $i=n-1$ case of step 1.

Step 8: If we delete three or more nodes from the extended Dynkin diagram, the corresponding $\mathbb{Z}$-grading of $\mathrm{sp}(2n)$ no longer has the required properties (i.e., there are nonzero subspaces G_i with $|i|>2$).

VI. THE LIE ALGEBRA $D_n=\mathrm{so}(2n)$

$G=\mathrm{so}(2n)$ is the subalgebra of $\mathrm{sl}(2n)$ consisting of matrices of the form

$$\begin{pmatrix} a & b \\ c & -a^t \end{pmatrix}, \tag{6.1}$$

where a is any $(n\times n)$-matrix, and b and c are antisymmetric $(n\times n)$-matrices. The Cartan subalgebra H consist of the diagonal matrices, and the root vectors and corresponding roots of G are

$$e_{jk}-e_{k+n,j+n}\leftrightarrow\epsilon_j-\epsilon_k,\quad j\neq k=1,\ldots,n,$$

$$e_{j,k+n}-e_{k,j+n}\leftrightarrow\epsilon_j+\epsilon_k,\quad j<k=1,\ldots,n,$$

$$e_{j+n,k}-e_{k+n,j}\leftrightarrow-\epsilon_j-\epsilon_k,\quad j<k=1,\ldots,n.$$

The simple roots, Dynkin diagram and extended Dynkin diagram are given in Table I. Again, the anti-involution is such that $\omega(e_{jk})=e_{kj}$. Next, we describe the process of deleting nodes and its consequences for the classification of GQS.

Step 1: When node 1 is deleted from the Dynkin diagram of D_n, the remaining diagram is that of D_{n-1}, so $G_0=H+D_{n-1}=H+\mathrm{so}(2(n-1))$. There are two G_0-modules,

$$G_{-1} = \mathrm{span}\{e_{1i} - e_{n+i,n+1}, e_{1,n+i} - e_{i,n+1}; i = 2, \ldots, n\}, \tag{6.2}$$

and $G_{+1} = \omega(G_{-1})$. G has the corresponding grading $\mathrm{so}(2n) = G_{-1} \oplus G_0 \oplus G_{+1}$, and there are $N = 2(n-1)$ commuting annihilation operators. Denoting the CAOs by

$$d^-_{-i} = e_{1,n+i+1} - e_{i+1,n+1}, \quad d^-_{+i} = e_{1,i+1} - e_{n+i+1,n+1}, \quad i = 1, \ldots, n-1,$$

$$d^+_{-i} = e_{n+i+1,1} - e_{n+1,i+1}, \quad d^+_{+i} = e_{i+1,1} - e_{n+1,n+i+1}, \quad i = 1, \ldots, n-1, \tag{6.3}$$

then, for $\xi, \eta, \epsilon = \pm$ and $i, j, k = 1, \ldots, n-1$, the relations $\mathcal{R}$ are given by

$$\begin{gathered}
[d^\epsilon_{\xi i}, d^\epsilon_{\eta j}] = 0, \\
[d^+_{-i}, d^-_{+i}] = [d^+_{+i}, d^-_{-i}] = 0, \\
[[d^+_{\xi i}, d^-_{\eta j}], d^-_{\epsilon k}] = -\delta_{\xi\eta}\delta_{ij} d^-_{\epsilon k} - \delta_{\xi\epsilon}\delta_{ik} d^-_{\eta j} + \delta_{\eta,-\epsilon}\delta_{jk} d^-_{-\xi,i}, \\
[[d^+_{\xi i}, d^-_{\eta j}], d^+_{\epsilon k}] = \delta_{\xi\eta}\delta_{ij} d^+_{\epsilon k} + \delta_{\eta\epsilon}\delta_{jk} d^+_{\xi i} - \delta_{\xi,-\epsilon}\delta_{ik} d^+_{-\eta,j}.
\end{gathered} \tag{6.4}$$

Although the relations (6.4) are new, the existence of the set of CAOs (6.3) was pointed out in Ref. 6.

Step 2: When node i ($i = 2, \ldots, n-2$) is deleted from the Dynkin diagram of D_n, the remaining diagram is that of $\mathrm{sl}(i) \oplus \mathrm{so}(2(n-i))$ [or $\mathrm{sl}(n-2) \oplus \mathrm{sl}(2) \oplus \mathrm{sl}(2)$ in the case $i = n-2$]. With $G_0 = \mathrm{sl}(i) \oplus \mathrm{so}(2(n-i))$, there are four G_0-modules, and $\mathrm{so}(2n)$ has the following grading $\mathrm{so}(2n) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$ with

$$G_{-1} = \mathrm{span}\{e_{kl} - e_{n+l,n+k}, e_{k,n+l} - e_{l,n+k};\ k = 1, \ldots, i, l = i+1, \ldots, n\}. \tag{6.5}$$

The number of annihilation operators is $N = 2i(n-i)$.

Step 3: Delete node $n-1$ or n from the Dynkin diagram; the remaining diagram is that of $\mathrm{sl}(n)$, and $G_0 = H + \mathrm{sl}(n)$. There are only two G_0-modules and G has the grading $\mathrm{so}(2n) = G_{-1} \oplus G_0 \oplus G_{+1}$, with

$$G_{-1} = \mathrm{span}\{e_{j,n+k} - e_{k,n+j};\ 1 \leqslant j < k \leqslant n-1\} \cup \mathrm{span}\{e_{jn} - e_{2n,n+j};\ j = 1, \ldots, n-1\}, \text{ for } i = n-1,$$

$$G_{-1} = \mathrm{span}\{e_{j,k+n} - e_{k,j+n};\ 1 \leqslant j < k \leqslant n\}, \text{ for } i = n. \tag{6.6}$$

There are $N = n(n-1)/2$ commuting annihilation operators, and these two cases are isomorphic. The relations are not given explicitly.

Step 4: Upon deleting two nodes i and j ($i < j = 1, \ldots, n-2$) or more from the Dynkin diagram of D_n, the corresponding $\mathbb{Z}$-gradings have no longer the required property (there are nonzero G_i with $|i| > 2$).

Step 5: Delete nodes $n-1$ and n from the Dynkin diagram. The remaining diagram is that of $\mathrm{sl}(n-1)$. For $G_0 = H + \mathrm{sl}(n-1)$, there are six G_0-modules. There are three different ways in which these G_0-modules can be combined, each of them yielding a $\mathbb{Z}$-grading of the form $\mathrm{so}(2n) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$, namely,

$$G_{-1} = \mathrm{span}\{e_{jn} - e_{2n,n+j},\ e_{j,2n} - e_{n,n+j};\ j = 1, \ldots, n-1\}, \tag{6.7}$$

$$G_{-1} = \mathrm{span}\{e_{jn} - e_{2n,n+j},\ j = 1, \ldots, n-1; \quad e_{n+j,k} - e_{n+k,j},\ 1 \leqslant j < k \leqslant n-1\}, \tag{6.8}$$

$$G_{-1} = \text{span}\{e_{j+n,n} - e_{2n,j},\ j = 1, \ldots, n-1; \quad e_{j,k+n} - e_{k,j+n},\ 1 \leqslant j < k \leqslant n-1\}. \tag{6.9}$$

For (6.7), we have $N=2(n-1)$; for (6.8) and (6.9), we have $N=n(n-1)/2$. It turns out that (6.8) and (6.9) are isomorphic to each other. Here, we shall give the relations only for (6.7). Denote the CAOs of (6.7) by

$$d^-_{-i} = e_{i,2n} - e_{n,n+i},\ d^-_{+i} = e_{in} - e_{2n,n+i}, \quad i = 1, \ldots, n-1,$$

$$d^+_{-i} = e_{2n,i} - e_{n+i,n}, d^+_{+i} = e_{ni} - e_{n+i,2n}, \quad i = 1, \ldots, n-1. \tag{6.10}$$

Then, with $\xi, \eta, \epsilon, \gamma = \pm$ or ± 1 and $i, j, k = 1, \ldots, n-1$, the relations are explicitly given by

$$\begin{gathered}
[d^\eta_{\xi i}, d^\eta_{\xi j}] = 0, \\
[d^+_{-i}, d^-_{+j}] = [d^+_{+i}, d^-_{-j}] = 0, \\
[d^-_{+i}, d^-_{-i}] = [d^+_{+i}, d^+_{-i}] = 0, \\
[[d^\gamma_{\xi i}, d^\gamma_{\eta j}], d^\gamma_{\epsilon k}] = 0, \\
[[d^\xi_{+i}, d^\xi_{-j}], d^{-\xi}_{\epsilon k}] = -\delta_{ik} d^\xi_{-\epsilon j} + \delta_{jk} d^\xi_{-\epsilon i}, \\
[[d^\eta_{\xi i}, d^{-\eta}_{\xi j}], d^\eta_{\epsilon k}] = \xi\epsilon\delta_{ij} d^\eta_{\epsilon k} + \delta_{jk} d^\eta_{\epsilon i}.
\end{gathered} \tag{6.11}$$

The set of CAOs (6.10) with relations (6.11) is the example that was considered earlier in Refs. 6 and 8.

Step 6: Now we move to the extended Dynkin diagram. Deleting node i leaves the Dynkin diagram of so$(2n)$ for $i=0,1,n-1,n$, of sl$(2)\oplus$sl$(2)\oplus$so$(2(n-2))$ for $i=2$, of sl$(3)\oplus$so$(2(n-3))$ for $i=3$, and of $=$so$(2i)\oplus$so$(2(n-i))$ for $i\geqslant 4$. In all these cases there is only one G_0-module, so there are no contributions to our classification.

Note that deleting nodes i and j $[1<i<j<\lfloor(n+1)/2\rfloor]$ from the extended Dynkin diagram is equivalent to delete nodes $(n-j)$ and $(n-i)$.

Step 7: Delete the adjacent nodes $(j-1)$ and j. For $j=1$ we are back to step 1, and for $j=2$ to step 2 with $i=2$. For $j\geqslant 3$ the remaining diagram is that of $\tilde{G}_0=$so$(2(j-1))\oplus$so$(2(n-j))$ [for $j=3$ this is sl$(2)\oplus$sl$(2)\oplus$so$(2(n-j))$ and for $j=4$ this is sl$(4)\oplus$so$(2(n-j))$]. There are five $\tilde{G}_0$-modules g_k, one with $\omega(g_5)=g_5$, so one must set $G_0=H+\tilde{G}_0+g_5\equiv H+so(2(n-1))$. Now, there are only two G_0-modules, G has the grading so$(2n)=G_{-1}\oplus G_0\oplus G_{+1}$, and all these cases are isomorphic to those of step 1.

Step 8: Delete the nonadjacent nodes i and j $(i<j-1)$ from the extended Dynkin diagram. The remaining diagram is that of $\tilde{G}_0=$so$(2i)\oplus$sl$(j-i)\oplus$so$(2(n-j))$ [for $i=2$ this is sl$(2)\oplus$sl$(2)\oplus$sl$(j-i)\oplus$so$(2(n-j))$; for $i=3$ this is sl$(3)\oplus$sl$(j-i)\oplus$so$(2(n-j))$]. There are nine $\tilde{G}_0$-modules g_k, one with $\omega(g_9)=g_9$. Setting $G_0=H+\tilde{G}_0+g_9\equiv H+sl(j-i)\oplus$so$(2(n-j+i))$, there are only four G_0-modules. All these cases are isomorphic to those of step 2.

Step 9: If we delete three or more nodes from the extended Dynkin diagram, the corresponding $\mathbb{Z}$-grading of so$(2n)$ no longer has the required properties (i.e., there are nonzero subspaces G_i with $|i|>2$).

VII. SUMMARY AND CONCLUSIONS

We have obtained a complete classification of all GQS associated with the classical Lie algebras. The familiar cases (para-Fermi statistics and A-statistics) appear as simple examples in our classification. It is worth observing that some other examples in this classification are also

TABLE II. Summary of the classification: all nonisomorphic GQS associated with a classical Lie algebra are given. For each GQS, we list the Dynkin diagram of G_0 (described in terms of the Dynkin diagram D of G), the subspace G_{-1} (as a reference to the main text), the number of annihilation operators (N), and the relations $\mathcal{R}$ (when given in the text).

Lie algebra	Dynkin diagram of G_0	G_{-1}	N	$\mathcal{R}$
A_n	$D-\{i\}$ $(i\leqslant\lfloor(n+1)/2\rfloor)$	(3.1)	$i(n+1-i)$	$i=1$ (3.4) $i=2$ (3.6)
	$D-\{i,j\}$ $(i\leqslant\lfloor n/2\rfloor$ $i<j<n+1-i)$	(3.7)	$(j-i)(n+1-j+i)$	$j-i=1$ (3.12)
B_n	$D-\{1\}$	(4.2)	$2n-1$	(4.4)
	$D-\{i\}$ $(2\leqslant i\leqslant n)$	(4.5)	$2i(n-i)+i$	$i=n$ (4.7)
C_n	$D-\{i\}$ $(1\leqslant i\leqslant n-1)$	(5.2)	$2i(n-i)$	$i=1$ (5.4) $i=n-1$ (5.6)
	$D-\{n\}$	(5.7)	$n/(n+1)2$	
D_n	$D-\{1\}$	(6.2)	$2(n-1)$	(6.4)
	$D-\{i\}$ $(2\leqslant i\leqslant n-2)$	(6.5)	$2i(n-i)$	
	$D-\{n\}$	(6.6)	$n/(n-1)2$	
	$D-\{n-1,n\}$	(6.7) (6.8)	$2(n-1)$ $n/(n-1)2$	(6.11)

rather simple. The GQS given in (3.6) and (3.12), e.g., seem to be closely related to *A*-statistics, except that there are two kinds of particles corresponding to the CAOs [see (3.5) and (3.11)]. The GQS of type *D* given in (6.4) has also particularly simple defining relations. For convenience, a comprehensive summary of the classification of all GQS is given in Table II.

As we have already mentioned in the main text, several cases in our classification appear as examples in Refs. 7–12 and in Palev's thesis.[6] In these papers or in the thesis, however, no classification is given, only a number of examples inspired by the para-Fermi case are considered. Furthermore, for some of these examples Fock-type representations are constructed.

In this paper, we have dealt only with a mathematical definition of generalized quantum statistics. In order to talk about a quantum statistics in the physical sense, one should take into account additional requirements for the CAOs, related to certain quantization postulates.[7] First of all, there should be a state space (possibly a Fock space) in which the CAOs act. Here, the Lie algebraic framework could be useful, since such a state space can coincide with a Lie algebra representation space (and automatically all elements in the Lie algebra G and in its universal enveloping algebra have a well-defined action in any representation). Physical observables, and in particular the Hamiltonian, should be Hermitian operators and expressible via the CAOs. The Hermiticity conditions for physical observables usually lead to conjugacy relations for the CAOs; these are often such that, for example, $(x_i^-)^\dagger = x_i^+$ (for the representatives of the CAOs in a representation). In other words, such Hermiticity conditions are often related to the anti-involution ω. The representation spaces in which the inner product is such that the Hermitian conjugate of the representative of $x \in G$ is equal to the representative of $\omega(x)$ are often called the unitary representations (with respect to the given anti-involution ω). Whether the class of finite dimensional representations of G plays a role, or whether it is a class of infinite dimensional representations, depends on the choice of ω. With the standard choice considered in this paper, the unitary representations are finite dimensional. For another choice of ω [still with $\omega(G_{-1}) = G_{+1}$, but no longer all plus signs in $\omega(x_i^-) = \pm x_i^+$], our classification of GQS remains valid, but the unitary representations will be infinite dimensional.

It is only after an investigation of such further properties, that one can talk about a quantum statistics. If one can furthermore classify the state spaces for a particular GQS, then one can study its macroscopic and microscopic properties. Such a program is feasible, and could give rise to interesting quantum statistical properties. For example, for A-statistics, the microscopic properties (i.e., the properties of the CAOs and their action on the Fock spaces) have been described in Refs. 7–11, whereas the macroscopic properties (i.e., the statistical properties of ensembles of particles satisfying this GQS) have been studied in Ref. 12. We hope that some other cases of this classification will yield similar interesting GQS.

From the mathematical point of view, a set of CAOs together with a complete set of relations $\mathcal{R}$ unambiguously describes the Lie algebra. So each case of our classification also gives the description of a classical Lie algebra in terms of a number of generators subject to certain relations. This can also be reformulated in terms of the notion of Lie triple systems.[13] According to the definition, a Lie triple system L of an associative algebra A is a subspace of A that is closed under the ternary composition $[[a,b],c]$, where $[a,b]=ab-ba$. It is easy to see that in our case the subspace $G_{-1}\oplus G_{+1}$ (i.e., the subspace spanned by all CAOs) is a Lie triple system for the universal enveloping algebra $\mathrm{U}(G)$.

This paper was devoted to classical Lie algebras only. The exceptional Lie algebras are not considered here. Although it would be possible to perform a mathematical classification of the GQS associated with G_2, F_4, E_6, E_7, and E_8, it is obvious that in such a case the number of CAOs is a fixed integer. For physical applications, it is of importance that the number of CAOs is not a fixed number but an integer parameter N. In fact, in quantum field theoretical applications, one is mainly interested in the case $N\to\infty$.

As mentioned in the Introduction, para-Bose statistics is connected with a Lie superalgebra, the orthosymplectic superalgebra $\mathrm{osp}(1|2n)$. In a future paper, we hope to classify all GQS associated with the classical Lie superalgebras.

(Received 3 August 2004; accepted 18 October 2004; published online 4 February 2005)

Dynamics of modulated waves is studied in a one-dimensional discrete nonlinear electrical transmission line. Contribution of a linear dispersive capacitance is appreciated and it is shown via a reductive perturbation method that evolution of such waves in this system is governed by a higher order nonlinear Schrödinger equation. Passing through the Stokes wave analysis, a generalized criterion for the Benjamin–Feir instability in the network is presented and exact solutions of the obtained wave equation are determined by the means of the Pathria and Morris approach. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1843272]

I. INTRODUCTION

It is well known that exactly integrable nonlinear differential equations have soliton solutions that travel stationary and collide elastically. Many wave spread phenomena can be explained by integrable equations in some ideal conditions and there is a great variety of applications of the concept of solitons in condensed matter physics.[1] It is possible to divide these applications into the following two parts: In one part continuum media are treated, e.g., in hydrodynamics,[2] and solitons arise as solutions of partial differential equations (PDE's). In the other part, intrinsically discrete models are considered, e.g., chains of magnetic ions or hydrogen-bonded chains in proteins.[1,3] Here differential-difference equations must be solved instead of the PDE's of the first part. However, apart from very few exceptions like Toda lattice,[4] the differential-difference equations cannot be solved exactly. Therefore, several soliton perturbation theories have been developed to study the effect of small perturbations on integrable equations. In these theories, the reductive perturbation method[5,6] is well known. Within this method, we have the semidiscrete approximation that consists of considering the continuum approximation to describe the envelope of the signal and treats the carrier wave with its discrete character.

The main purpose of this paper is to study the dynamics of modulated wave trains in a discrete nonlinear electrical transmission line using the semidiscrete approximation. This paper is organized as follows. In Sec. II, we present a nonlinear electrical network representing a bandpass filter with a linear dispersive capacitance C_s. In Sec. III, we use the reductive perturbation method to derive the higher order nonlinear Schrödinger equation (HONLSE) describing the propagation of modulated waves in the line. The impact of C_s on the dispersion relation is discussed. In Sec. IV, the resulting HONLSE is utilized to determine the condition for instability of slowly modulated waves. A calculation to predict the modulational instability (MI) is presented. In Sec. V, the Pathria and Morris method is exploited to check whether the HONLSE possesses solitary wave solutions which show that solitons can propagate in the network. Finally, Sec. VI is devoted to concluding remarks.

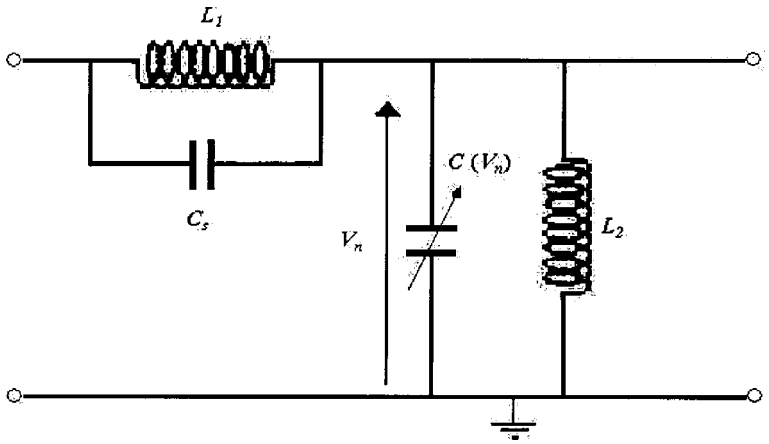

FIG. 1. Schematic representation of one unit cell of a discrete nonlinear electrical transmission line. The network is composed of N identical cells.

II. MODEL DESCRIPTION

The model under consideration is a lossless discrete nonlinear transmission line made of N identical unit cells as illustrated in Fig. 1. Each unit cell contains a linear inductance L_1 in parallel with a linear capacitance C_s in the series branch and, a linear inductance L_2 in parallel with a nonlinear capacitance $C(V)$ in the shunt branches. This nonlinear capacitance consists of a reversed-biased diode with differential capacitance function of the voltage V_n across the nth capacitor[7] and biased by a constant voltage V_0: $C(V_0+V_n)=\mathrm{d}Q_n/\mathrm{d}V_n$ in which Q_n is the corresponding nonlinear charge. For low voltages chosen around V_0 the quantity $Q_n(V_n)$ can be approximated by[8]

$$Q_n(V_n) = C_0(V_n - \alpha V_n^2 + \beta V_n^3), \tag{2.1}$$

where $C_0=C(V_0)$, α and β are positive constants, C_0 designates the characteristic capacitance, and α and β denote the nonlinear parameter. From the Kirchhoff's laws applied to the circuit of Fig. 1, we derive the following system of nonlinear equations for the voltage $V_n(t)$:

$$\frac{\mathrm{d}^2V_n}{\mathrm{d}t^2} + u_0^2(2V_n - V_{n-1} - V_{n+1}) + \lambda\frac{\mathrm{d}^2}{\mathrm{d}t^2}(2V_n - V_{n-1} - V_{n+1}) + \omega_0^2V_n = \alpha\frac{\mathrm{d}^2V_n^2}{\mathrm{d}t^2} - \beta\frac{\mathrm{d}^2V_n^3}{\mathrm{d}t^2},$$

$$n = 1,2, \ldots ,N \tag{2.2}$$

where N is the number of cells considered. In Eq. (2.2), we have set

$$u_0^2 = \frac{1}{L_1C_0}, \quad \omega_0^2 = \frac{1}{L_2C_0}, \quad \text{and } \lambda = \frac{C_s}{C_0}. \tag{2.3}$$

During computations, the following values of the network's parameters are used[8,9]

$$L_1 = 200 \pm 5\mu H, \quad L_2 = 470 \pm 10\mu H, \quad V_0 = 2V, \quad C_0 = 370 \pm 10pF,$$

$$\alpha = 0.21V^{-1}, \quad \beta = 0.0197V^{-2}, \quad \text{and } C_s = 1850 \pm 10pF. \tag{2.4}$$

III. OSCILLATORY SOLUTIONS

Now, our attention is focused on the propagation of modulated waves in the system. For this aim, the semidiscrete approximation[5,6] is employed to obtain short wavelength envelope solitons.

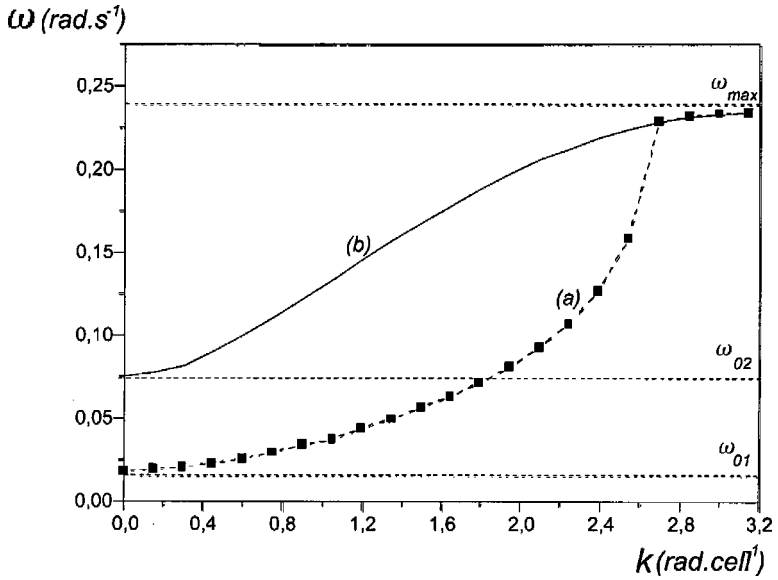

FIG. 2. Linear dispersion curve defined by relation (3.2) for the constants given by expression (2.2). (a) Case where $\lambda \neq 0$; (b) case where $\lambda = 0$. While comparing these two plots, we note that the gap zone is larger in the absence of the linear capacitance C_s (i.e., for $\lambda = 0$).

This approach allows us to treat properly the carrier with its discrete character and to describe the envelope in the continuum approximation. Therefore, slow variables (ξ, τ) are introduced as follows: $\xi = \varepsilon(n - V_g t)$, $\tau = \varepsilon^2 t$ where ε is a small parameter and V_g denotes the group velocity of the packet wave.

Leaning on the idea developed by Taniuti and Yajima,[10] the solution $V_n(t)$ of Eq. (2.2) can be taken in the following form:[11]

$$\begin{aligned} V_n(t) = {} & \varepsilon^{1/2} V_{11}(n,t) e^{i\theta} + \varepsilon [V_{20}(n,t) + V_{22}(n,t) e^{2i\theta}] + \varepsilon^{3/2} [V_{30}(n,t) + V_{33}(n,t) e^{3i\theta}] \\ & + \varepsilon^2 [V_{40}(n,t) + V_{42}(n,t) e^{2i\theta} + V_{44}(n,t) e^{4i\theta}] + \varepsilon^{5/2} [V_{50}(n,t) + V_{53}(n,t) e^{3i\theta} + V_{55}(n,t) e^{5i\theta}] \\ & + \text{c.c.} + O(\varepsilon^{7/2}), \end{aligned} \tag{3.1}$$

in which θ is the phase given by $\theta = kn - \omega t$; c.c. stands for the complex conjugation and ε is the smallness parameter that measures the size of the amplitude of the perturbation. During the computations, there are nonzero voltages $V_{lm}(n \pm 1, t)$ which are expanded in the continuum limit around $V_{lm}(x,t)$ with $n = x$. So the fast changes of the phase θ in Eq. (3.1) are correctly taken into account by considering differences in the phase for the discrete variable n. We have also scaled time and space derivatives as $\partial/\partial t \sim 0(\varepsilon)$ and $\partial/\partial x \sim 0(\varepsilon)$, respectively, and neglected consistently high order in ε terms. Then we keep up to the second order derivative terms of $V_n(t)$ to balance dispersion and nonlinearity. Introduction of $V_n(t)$ and its derivatives into Eq. (2.2) yields a series of equations distinguished by the power of ε.

From the equations of $(\varepsilon^{1/2}, e^{i\theta})$, that is the terms of $0(\varepsilon^{1/2})$ for the first harmonic, we derive the following linear dispersion law:

$$(1 + 4\lambda \cos^2(k/2))\omega^2 = \omega_0^2 + 4u_0^2 \sin^2(k/2) \tag{3.2}$$

in which the wave number k is taken in the Brillouin zone. The linear dispersion curve that deals with expression (3.2) is shown in Fig. 2(a) and represents a bandpass filter. As displayed in this figure, the corresponding linear spectrum has a gap $f_{01} = \omega_{01}/2\pi$ which is the lower cutoff frequency introduced by the parallel inductance L_2 and it is limited by the cutoff frequency

$$f_{\max} = \frac{\omega_{\max}}{2\pi} = \frac{1}{2\pi}(\omega_0^2 + 4u_0^2)^{1/2} \tag{3.3}$$

due to the lattice effects. On the other hand, Fig. 2(b) presents the plot of relation (3.2) in the case where $\lambda = 0$ that corresponds to $C_s = 0$. While comparing the graphs of Figs. 2(a) and 2(b), we note that the upper cutoff frequency $f_{\max}$ has not changed in the presence of the linear dispersion capacitance C_s in the system. But the existence of C_s reduces the value of the lower cutoff frequency since $f_{01} < f_{02}$ with $f_{02} = \omega_{02}/2\pi$. The direct physical consequence of such result is that the gap zone in the system is highly reduced. Because the width of the interval $[f_{01}, f_{\max}]$ is bigger than that of $[f_{02}, f_{\max}]$, introduction of C_s in the circuit has increased the propagation domain of the signal.

From the terms proportional to $\varepsilon^{3/2}e^{i\theta}$, we obtain the expression

$$i\left[V_g\frac{\partial V_{11}}{\partial \xi} + \frac{\partial V_{11}}{\partial \tau}\right] = -Q(k)|V_{11}|^2 V_{11} \tag{3.4}$$

in which

$$Q(k) = \frac{\omega}{2}[2\alpha(N_{20} + N_{22}) - 3\beta] = \frac{\omega}{2}\left\{4\alpha^2\left(\frac{2\omega^2}{D} + \frac{V_g^2}{V_g^2 - u_0^2}\right) - 3\beta\right\}$$

with

$$D = 4\omega^2(1 + 4\lambda\cos^2 k) - 4u_0^2\sin^2 k - \omega_0^2.$$

Here we follow the Kakutani and Michihiro idea[12] and assume that $\Delta k = k - k_c$ is of $O(\varepsilon)$ and write $Q = \varepsilon Q_1$ where Q_1 is of $O(1)$ and is given approximately by

$$Q_1(k) = \frac{\Delta k}{\varepsilon}\left(\frac{\mathrm{d}Q(k)}{\mathrm{d}k}\right)_{k=k_c} = \frac{V_g}{\omega}Q(k) - \left(\frac{\omega u_0^2}{V_g^2}\right)N_{20}^2\left[\frac{6\lambda\omega}{\chi}\sin k - \frac{V_g}{\omega} + \frac{\cos k}{\sin k}\right] + 2\alpha N_{22}V_g$$

$$- \frac{N_{22}^2}{\omega}[2\omega V_g(1 + 4\lambda\cos^2 k) - (u_0^2 + 4\lambda\omega^2)\sin 2k]. \tag{3.5}$$

In relation (3.5), the group velocity is expressed as

$$V_g = \frac{\partial \omega}{\partial k} = \frac{2}{\chi}(u_0^2 + \lambda\omega^2)\sin k, \quad \chi = \omega(1 + 4\lambda\cos^2(k/2)) \tag{3.6}$$

and real k_c designates the critical value of the wave number k of the signal. Therefore at $O(\varepsilon^{3/2})$, Eq. (3.4) becomes

$$V_g\frac{\partial V_{11}}{\partial \xi} + \frac{\partial V_{11}}{\partial \tau} = 0. \tag{3.7}$$

This result means that in the reference frame moving with the group velocity V_g, the complex amplitude V_{11} of the signal remains constant to the concerned scale.[13] Hence, the right-hand side (rhs) of Eq. (3.4) is shifted to the corresponding nonsecular condition at $O(\varepsilon^{5/2})$.

From the equations of $(\varepsilon^{5/2}, e^{i\theta})$, we establish that the resulting equation that describes dynamics of a packet wave in the discrete nonlinear transmission line (of Fig. 1) is the higher order nonlinear Schrödinger equation (HONLSE),

$$i\frac{\partial V_{11}}{\partial \tau} + P\frac{\partial^2 V_{11}}{\partial \xi^2} = Q_1|V_{11}|^2 V_{11} + Q_2|V_{11}|^4 V_{11} + iQ_3 V_{11}^2\frac{\partial V_{11}^*}{\partial \xi} + iQ_4|V_{11}|^2\frac{\partial V_{11}}{\partial \xi} \tag{3.8}$$

in which the different coefficients are defined by

$$P = \frac{1}{2\omega}[(u_0^2 + \lambda\omega_0^2)\cos k - 4\lambda V_g^2 \sin^2(k/2) - 4\omega V_g \sin k], \tag{3.9}$$

$$Q_2 = \omega\left[\alpha(N_{40} + N_{42} + N_{22}N_{33}) - \frac{3\beta}{2}(2N_{22}^2 + N_{33} + N_{20}^2 + 2N_{20}N_{22})\right], \tag{3.10}$$

$$Q_3 = 2V_g[\beta - \alpha(N_{20} + N_{22})], \tag{3.11}$$

$$Q_4 = \alpha\omega\tilde{N}_{42} + 2Q_3, \tag{3.12}$$

and Q_1 is given by relation (3.5). The diverse parameters and voltages that appear in the coefficients of Eq. (3.8) are determined in the Appendix.

The HONLSE (3.8) is known to govern modulations of weakly nonlinear ions in acoustic plasma waves,[5] ferromagnetic chain[14] and evolutions of Stokes waves.[12,15] This relation is also used as an envelope equation for describing a weakly subcritical bifurcation to counter propagating waves[16] and also accounts for the slow modulations of an oscillatory mode closed to a subcritical bifurcation[17,18] when $Q_3 = Q_4 = 0$. In Eq. (3.8), the first two terms of the rhs are the nonlinear terms while the others represent the nonlinear dispersion.

Using the line parameters (2.2) the spatial dispersion coefficient (3.9) is plotted as a function of k (Fig. 3). We could remark from these graphs that the coefficient P has both positive and negative values whether λ is null or not. When comparing Figs. 3(a)–3(c) we note that the presence of C_s (i.e., for $\lambda \neq 0$) increases the interval of the values of P. In other words, introduction of C_s adds the dispersion in the system. This result will be useful to predict the stability of modulated waves in the network.

IV. MODULATIONAL INSTABILITY

In this section, we research under which conditions a uniform wave train moving along the discrete nonlinear electrical transmission line of Fig. 1 will become unstable to a small perturbation. For this purpose, we use the HONLSE (3.8) derived from the exact equations (2.2) describing the wave propagation in the network. First, we look for solutions of Eq. (3.8) in the form

$$V_{11}(\xi, \tau) = E_0 \exp[i(k_n\xi - \omega_n\tau)], \tag{4.1}$$

where E_0 is a complex constant amplitude. Substitution of (4.1) into Eq. (3.8) yields the nonlinear dispersion law[5]

$$\omega_n = \omega_n(k_n, |E_0|^2) = Pk_n^2 + Q_1|E_0|^2 + Q_2|E_0|^4 + k_n(Q_3 - Q_4)|E_0|^2 \tag{4.2}$$

in which k_n and ω_n are, respectively, the wave number and the angular frequency of the carrier wave. From relation (4.2), the plane wave (4.1) is nonlinear and the principle of superposition is invalid. To investigate the MI[18] of the carrier wave, a small perturbation of (4.1) is taken as follows:[5,19–21]

$$V_{11}(\xi, \tau) = [1 + A(\xi, \tau)]E_0 \exp[i(k_n\xi - \omega_n\tau)], \tag{4.3}$$

where $A(\xi, \tau)$ is a complex quantity. Substituting this solution into (3.8) and linearizing the result with respect to $A(\xi, \tau)$ gives the differential equation

$$\begin{aligned} iA_\tau + P(A_{\xi\xi} + 2ik_nA_\xi) = {} & Q_1(A + A^*)|E_0|^2 + 2Q_2(A + A^*)|E_0|^4 + i(Q_3A_\xi^* + Q_4A_\xi)|E_0|^2 \\ & + k_n(Q_3 - Q_4)(A + A^*)|E_0|^2 \end{aligned} \tag{4.4}$$

in which the asterisk denotes the complex conjugation. Following the idea developed by Parkes,[5] solutions of Eq. (4.4) could be found in the form

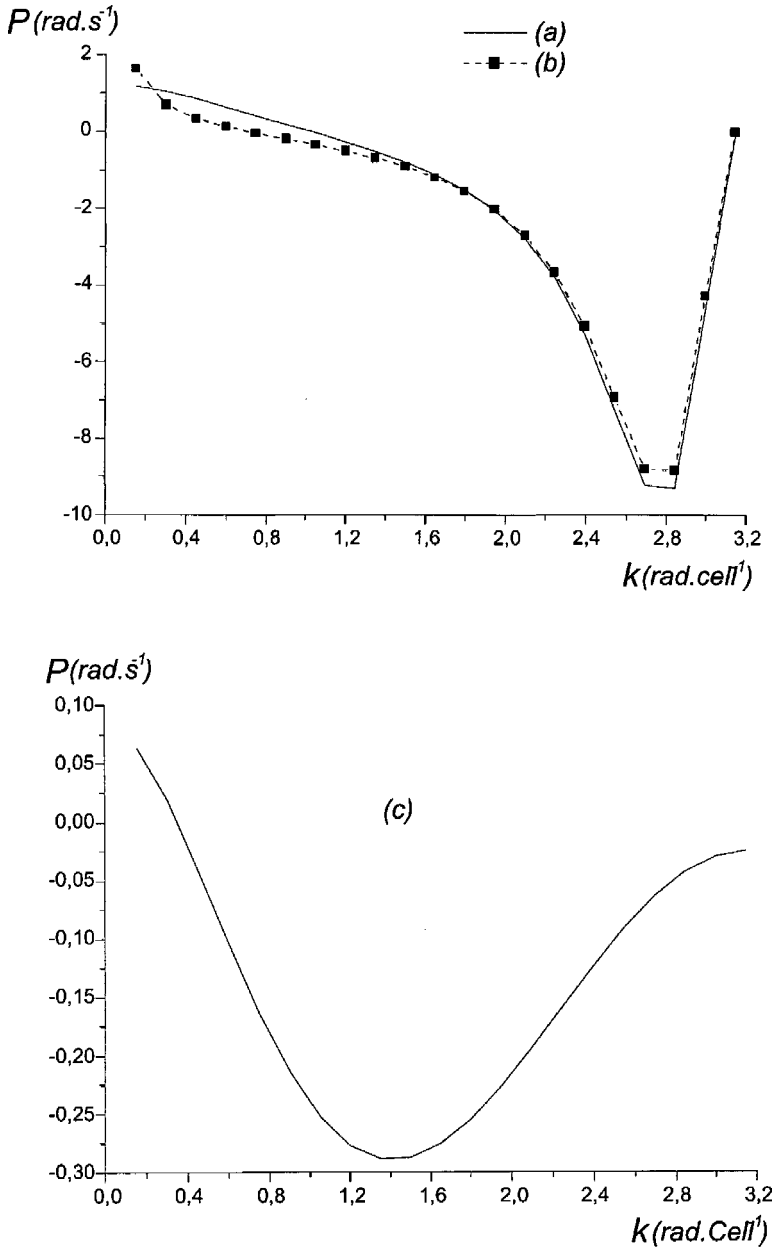

FIG. 3. Dispersive coefficient in terms of the wave number k taken in the Brillouin zone for the line parameters (2.2). (a) Case where $\lambda \neq 0$ and $\omega_0 \neq 0$; (b) case where $\lambda \neq 0$ and $\omega_0 = 0$; (c) case where $\lambda = 0$ and $\omega_0 \neq 0$. These plots show that P admits both positive and negative values and inform that the range values of the dispersion coefficient P increases with the introduction of C_s in the system.

$$A(\xi,\tau) = A_1 \exp[i(l\xi + \Omega\tau)] + A_2^* \exp[-i(l\xi + \Omega * \tau)], \tag{4.5}$$

where l and Ω indicate, respectively, the wave number and the angular frequency of the perturbation. Parameters A_1 and A_2 are complex constants. Introduction of relation (4.5) into Eq. (4.4) yields a dispersion law for the perturbation wave

$$\Omega^2 + 2b\Omega + (b^2 - P^2 l^4 - l^2 Q_3^2 |E_0|^4 - 2cPl^2) = 0, \tag{4.6}$$

which is a second order equation for Ω with real coefficients; the quantities b and c are defined by

$$b = 2k_n lP - lQ_4|E_0|^2 \quad \text{and} \quad c = Q_1|E_0|^2 + 2Q_2|E_0|^4 + k_n(Q_3 - Q_4)|E_0|^2.$$

The MI phenomenon is observed when the angular frequency Ω of the perturbation has a nonzero imaginary part leading to an exponential growth of the amplitude versus time. This situation occurs when the discriminant (Δ) of Eq. (4.6) possesses a negative value ($\Delta<0$) leading up to

$$PQ_1 - r < -\left(\frac{l^2P^2 + Q_3^2|E_0|^4}{2|E_0|^2}\right) < 0 \tag{4.7}$$

and necessarily

$$PQ_1 - r < 0 \tag{4.8}$$

with

$$r = -k_n(Q_3 - Q_4)|E_0|^2 - PQ_2|E_0|^2. \tag{4.9}$$

Relation (4.8) together with (4.9) represents the MI criterion associated to the HONLSE in the electrical transmission line of Fig. 1. We deduce from Eq. (4.7) that the wave number of the perturbation l should be taken in a finite interval namely,

$$0 < l < \frac{|E_0|}{|P|}[2(r - PQ_1) - Q_3^2|E_0|^2]^{1/2}. \tag{4.10}$$

The MI condition (4.8) is function of the nonlinear and dispersive parameters β and λ since it depends on the coefficients of Eq. (3.8) which are related to β and λ. The result (4.8) is more general than the one obtained by Ketchakeu *et al.*[11] during the study of ϕ^4 models. It also generalizes the family criterion for the standard nonlinear Schrödinger (NLS) equations.[18,22] However this criterion is similar to that established by Kakutani and Michihiro[12] when they examine the motion of water waves near the marginal state of instability.

V. EXACT SOLITARY SOLUTIONS

The main purpose of this section is to check whether the discrete nonlinear transmission line under study can support solitary waves. Hence we follow the Pathria and Morris[23] method and set $\tau = Pt$. Therefore, the amplitude wave equation (3.8) takes the form:

$$iV_{11,\tau} + V_{11,\xi\xi} + q_c|V_{11}|^2V_{11} + q_q|V_{11}|^4V_{11} + iq_mV_{11}^2V_{11,\xi}^* + iq_u|V_{11}|^2V_{11,\xi} = 0 \tag{5.1}$$

with $q_c = -Q_1/P$, $q_q = -Q_2/P$, $q_m = -Q_3/P$, and $q_u = -Q_4/P$. At this level, we introduce the following notations:

$$Q_c = q_c, \quad Q_q = q_q + \tfrac{1}{16}(q_u + q_m)(3q_m - 5q_u),$$

$$Q_m = q_m - \tfrac{1}{2}(q_u + q_m) = -\tfrac{1}{2}(q_u - q_m) \quad \text{and} \quad Q_u = q_u - q_m. \tag{5.2}$$

The solutions of Eq. (5.1) strongly depend on the sign of the coefficient[23] Q_q. Two cases can be distinguished. When $Q_q<0$, the solution of Eq. (5.1) is given by

$$V_{11}(\xi,t) = \left(\frac{r_1r_2}{r_1 + (r_1 - r_2)\sinh^2(\chi_0)}\right)^{1/2} \exp[i\phi(\xi,t)] \tag{5.3}$$

in which

$$\phi(\xi,t) = -\left(\frac{q_u+q_m}{4}\right)\sqrt{-3/Q_q}\tanh^{-1}\left(\sqrt{\frac{r_2}{r_1}}\tanh(\chi_0)\right) + \frac{\eta}{2}(\xi-\mu t) + \vartheta_0,$$

with $\chi_0=(-r_1r_2Q_q/3)^{1/2}(\xi-\eta t)+\vartheta_1$. In expressions (5.3), the quantities μ and η denote the speeds of the carrier and envelope waves of V_{11}, respectively; ϑ_0 and ϑ_1 are arbitrary constants. The values of r_1 and r_2 determine the form of this solution. Solitary waves arise in the system if r_1 and r_2 are real, with[23] $r_1>r_2>0$.

On the other hand, if $Q_q>0$, r_1 and r_2 are real with $r_1>0>r_2$, a solitary wave also exists and the corresponding solution for Eq. (5.1) is[23]

$$V_{11}(\xi,t) = \left(\frac{r_1r_2}{r_2+(r_2-r_1)\sinh^2(\chi_0)}\right)^{1/2}\exp[i\phi(\xi,t)] \tag{5.4}$$

with

$$\phi(\xi,t) = -\left(\frac{q_u+q_m}{4}\right)\sqrt{3/Q_q}\tan^{-1}\left(\sqrt{-\frac{r_1}{r_2}}\tanh(\chi_0)\right) + \frac{\eta}{2}(\xi-\mu t) + \vartheta_0,$$

and

$$\chi_0 = (-r_1r_2Q_q/3)^{1/2}(\xi-\eta t) + \vartheta_1.$$

Furthermore, if r_1 and r_2 are real with $r_1>r_2>0$, then the solution is oscillatory and has the following form:[23]

$$V_{11}(\xi,t) = \left(\frac{r_1r_2}{r_1+(r_2-r_1)\cos^2(\chi_1)}\right)^{1/2}\exp[i\phi(\xi,t)], \tag{5.5}$$

where

$$\phi(\xi,t) = -\left(\frac{q_u+q_m}{4}\right)\sqrt{3/Q_q}\tan^{-1}\left(\sqrt{\frac{r_2}{r_1}}\tanh(\chi_1)\right) + \frac{\eta}{2}(\xi-\mu t) + \vartheta_0,$$

and $\chi_1=(r_1r_2Q_q/3)^{1/2}(\xi-\eta t)+\vartheta_1$. From these investigations, we note that the HONLSE possesses solitary wave solutions for both positive and negative values of Q_q.

VI. CONCLUSION

In this paper, we have considered a discrete nonlinear electrical transmission line and examined dynamics of modulated waves. Exploiting the reductive perturbation method, it has been shown in the semidiscrete limit that propagations of modulated wave trains are governed by a modified form of the NLS equation that involves higher orders nonlinearities, i.e., the HONLSE. Through our investigations, it has been obtained that the capacitance C_s adds the linear dispersive effects in the circuit with the consequence that the gap zone is greatly reduced and the range of frequencies for the propagation of the signal has substantially increased given way to more applications of the model.

Based on the obtained amplitude wave equation, we have utilized the Stokes wave analysis to construct a criterion for the MI of a plane wave introduced in the electrical line. It has appeared that the obtained criterion generalizes the family criterion for NLS equations and depends both on the amplitude and wave number of the propagating signal.

Besides this study of the asymptotic behavior of a signal in the network, the Pathria and Morris method has been exploited to show that this discrete nonlinear transmission line can support solitary waves. This last result is of higher importance since it is known that solitons are good waves for the transport of information in some physical systems.

APPENDIX

The equations of $(\varepsilon^3, e^{0i\theta})$ lead to the potential

$$V_{20} = N_{20}|V_{11}|^2 \quad \text{with } N_{20} = \frac{2\alpha V_g^2}{V_g^2 - u_0^2}. \tag{A1}$$

From the equations of $(\varepsilon, e^{2i\theta})$, we get

$$V_{22} = N_{22}(V_{11})^2, \quad \text{where } N_{22} = \frac{4\alpha\omega^2}{D}. \tag{A2}$$

Terms proportional to $\varepsilon^{5/2}e^{2i\theta}$ and $\varepsilon^3 e^{i\theta}$ yield, respectively, the voltages

$$V_{30} = 0 \quad \text{and} \quad V_{50} = 0. \tag{A3}$$

From the equations of $(\varepsilon^{3/2}, e^{3i\theta})$, we obtain the potential

$$V_{33} = N_{33}(V_{11})^3 \quad \text{in which } N_{33} = \frac{1}{D_1}(18\alpha\omega^2 N_{22} - 9\beta\omega^2) \tag{A4}$$

with

$$D_1 = 9\omega^2(1 + 4\lambda\cos^2(3k/2)) - 4u_0^2\sin^2(3k/2) - \omega_0^2.$$

The equations of $(\varepsilon^3, e^{0i\theta})$ liberate

$$V_{40} = N_{40}|V_{11}|^4 \quad \text{with } N_{40} = \frac{1}{2}N_{20}(N_{20}^2 + 2N_{22}^2) - \frac{\beta}{\alpha}N_{20}(2N_{20} + 3N_{22}). \tag{A5}$$

From the terms proportional to $\varepsilon^2 e^{2i\theta}$, we determine the voltage

$$V_{42} = N_{42}|V_{11}|^2 V_{11}^2 + i\tilde{N}_{42}(V_{11}^2)_\xi \tag{A6}$$

in which the diverse coefficients are defined by

$$N_{42} = \frac{4\omega^2}{D}[2\alpha(N_{33} + N_{20}N_{22}) - 3\beta(N_{20} + 2N_{22})]$$

and

$$\tilde{N}_{42} = \frac{2}{D}[2\omega V_g N_{22}(1 + 4\lambda\cos^2 k) - (u_0^2 + 4\lambda\omega^2)N_{22}\sin k - 2\alpha\omega V_g].$$

Note: There exist other nonzero coefficients that do not contribute in the establishment of the amplitude wave equation (3.8) which characterizes the motion of a signal in the line. Nevertheless, their expressions are found and listed below.

From the equations of $(\varepsilon^2, e^{4i\theta})$, we deduce

$$V_{44} = N_{44}(V_{11})^4 \quad \text{wherein } N_{44} = \frac{1}{D_2}[16\alpha\omega^2(N_{22}^2 + 2N_{33}) - 48\beta\omega^2 N_{22}] \tag{A7}$$

with $D_2 = 16\omega^2(1 + 4\lambda\cos^2(2k)) - 4u_0^2\sin^2(2k) - \omega_0^2$.

The equations of $(\varepsilon^{5/2}, e^{2i\theta})$ help to determine the voltage

$$V_{53} = N_{53}|V_{11}|^2 V_{11}^3 + iN'_{53}(V_{11}^2)_\xi V_{11} + iN''_{53}(V_{11}^3)_\xi \tag{A8}$$

in which the different parameters are given by

$$N_{53} = \frac{18\omega^2}{D_1}[\alpha(N_{42} + N_{44} + N_{20}N_{33}) - \beta(2N_{33} + 2N_{20}N_{22} + 2N_{22}^2)],$$

$$N'_{53} = \frac{6\alpha\omega}{D_1}(3\omega\tilde{N}_{42} - 2V_g N_{22}),$$

and

$$N''_{53} = \frac{1}{D_1}[6\omega V_g N_{33}(1 + 4\lambda \cos^2(3k/2)) - 2(u_0^2 + 9\lambda\omega^2)N_{33}\sin 3k + 6\beta\omega V_g].$$

From the equations of $(\varepsilon^{5/2}, e^{5i\theta})$, we get

$$V_{55} = N_{44}(V_{11})^5 \quad \text{in which } N_{44} = \frac{25\omega^2}{D_3}[2\alpha(N_{44} + N_{22}N_{33}) - 3\beta(N_{22}^2 + N_{33})], \tag{A9}$$

where

$$D_3 = 25\omega^2(1 + 4\lambda \cos^2(5k/2)) - 4u_0^2 \sin^2(5k/2) - \omega_0^2.$$

(Received 4 April 2001; accepted 2 November 2004; published online 4 February 2005)

We define stochastic pants, and the stochastic parallel transport over them for the Felder–Gawedzki–Kupiainen line bundle over the loop space. It is related to the construction of stochastic integrals, where we cannot use martingale theory in order to define them. We get a stochastic fusion of the two line bundles when the two loops meet. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1847707]

I. INTRODUCTION

In conformal field theory or in string theory (see Refs. 1–3), people look at random applications ψ from a Riemann surface Σ into a Riemannian manifold M endowed with the probability measure:

$$d\mu(\psi) = Z^{-1} \exp[-I(\psi)]dD(\psi), \tag{1.1}$$

where $dD(\psi)$ is the formal Lebesgue measure over the set of maps ψ and $I(\psi)$ the energy of the map ψ. Z is the partition function of the theory such that μ is a probability measure. Z is formally infinite, but physicists regularize Z and the correlators. If Σ has boundaries, let us say exit boundaries which are circle S_i^1 and input boundaries which are circles S_i^2, the amplitude related to the measure (1.1) should realize a map from $\otimes_{\text{output}} H$ into $\otimes_{\text{input}} H$ where H is an Hilbert space associated to the loop space (see Ref. 4).

In the case where the manifold is the linear space R^n, (1.1) is a Gaussian measure, which corresponds to the free field measure. Since in two dimension, the Green kernel associated to the Laplacian has a singularity on the diagonal, the random field lives on random distributions (see Ref. 5). It is difficult to state what is a distribution with values in a curved manifold, because the notion of distribution is linear.

If $\Sigma = [0,1] \times [0,1]$, there is another process indexed by Σ with values in R, which is the Brownian sheet and which is continuous. $(\partial^2 / \partial_s \partial_t)\psi = \eta_{s,t}$ is the white noise over $[0,1] \times [0,1]$. It is a formal Gaussian random field with average 0 and covariance $\langle \eta_{s,t}, \eta_{s',t'} \rangle = \delta_{s,t}(s',t')$ where $\delta_{s,t}$ is the Dirac delta function in (s,t). On Σ, there is a natural order, and it is possible after the work of Cairoli[6] to study the stochastic differential equation in Itô meaning,

$$\delta_{s,t} x_{s,t} = A(x_{s,t}) \delta_{s,t} \psi, \tag{1.2}$$

by using martingale theory, where A is a vector field over R. This gives an example of a non-Gaussian random field parametrized by the square. In the Gaussian case, this gives the Brownian motion over the path space. Doss and Dozzi[7] have studied the formal action which is associated to (1.2), that is they have studied the large deviation theory. Léandre and Russo[8] studied the behavior of the density of the solution $x_{s,t}$ of (1.2) when $(s,t) \to (0,0)$ by using the Malliavin calculus over the Brownian sheet.[9] Norris[10] has succeeded to give a geometrical meaning to (1.2) and has constrained $x_{s,t}$ to live over a curved manifold.

[a)]Present address: Institut de Mathématiques, Faculté des Sciences, Université de Bourgogne, 21000 Dijon, France.

But it is difficult to generalize (1.2) to the case where the world sheet is not the square $[0,1]\times[0,1]$, because (1.2) uses the multiparameter martingale theory, which requests the presence of an order relation on the world sheet.

Airault–Malliavin in a series of papers (some of them are published, for instance, in Refs. 11–14) have constructed the Brownian motion over a loop group. For that, they use the Brownian motion in a Sobolev space with values in the Lie algebra of the group G. This gives a random field from the cylinder $[0,1]\times S^1$ into G. Various works were done later (see Ref. 15 for instance). Fang and Zhang[16] and Léandre[17] have studied the formal action which gives the Brownian motion over a loop group, that is they have performed the large deviation theory.

Infinite dimensional diffusion processes over infinite dimensional manifolds have a long story initiated by Kuo[18] in 1972. The Russian school has studied infinite dimensional processes over infinite dimensional manifolds (see Refs. 19 and 20). Brzezniak–Elworthy[21] have done a general theory of infinite dimensional diffusion processes over infinite dimensional manifolds over $M-2$ Banach spaces. The interest of $M-2$ Banach spaces is that there is a Doob inequality for martingales over them. They apply their theory to the case of the free loop space of a manifold. This produces random cylinders with values in a compact Riemannian manifold, or the Brownian motion with values in the loop space of a Riemannian manifold. The loops are only Hoelder.

Brzezniak–Léandre[22] have extended the construction of Ref. 21 to the case where we consider Brownian pants. The world sheet has two output boundaries and one input boundary. This gives one application from $E_c\otimes E_c$ into E_c, where E_c is the Banach space of continuous functions over the loop space. This means that the Brownian pants are Feller. This gives an approach to one of Segal's axiom of conformal field theory,[4] the Hilbert space of the loop space being replaced by the Banach space of continuous functionals over it.

Our query is to replace this Banach space by a suitable Hilbert space of sections over a suitable line bundle over the loop space.

Line bundle over C^1 loops are highly studied in the literature: they are the purpose of Kac–Moody groups[23,24] or to the works of Brylinsky[25] by starting from the transgression of a 3-form over the manifold M. In these works, the authors suppose that the free loop space is simply connected and constructed the line bundle by using its curvature. Felder–Gawedzki–Kupiainen have a more general approach by using Deligne cohomology of a line bundle over the loop space.[26] If they consider a Riemann surface with boundaries, they show that the Riemann surface realizes a map from the tensor product of the line bundles over the exit boundaries to the tensor product of the line bundles over the input boundaries.

Brzezniak–Léandre[27] have studied the diffusion over C^1-loops and the parallel transport of the Felder–Gawedzki–Kupiainen line bundle over random paths. This realizes an isometry from the Hilbert space of sections of the exit boundary to the Hilbert space of sections of the input boundary, because the parallel transport is an isometry.

We are motivated by two generalizations of this work.

(i) We work over the Hoelder loop space, that is we consider bundles with fibers almost surely defined.
(ii) We consider random pants instead of cylinders.

In the case of random cylinders, they are two possibilities to study line bundles over the loop space and the parallel transport over a path over the loop space.

Léandre[28] considers a C^1 path over the Brownian bridge and a stochastic line bundle over the Brownian bridge (with fibers almost surely defined). He shows that the parallel transport over C^1 paths of an element of the stochastic line bundle is related to multiparameter integrals: it is a classical integral in the time of propagation of the loop and a stochastic integral in the internal time of the loop[25] requested in understanding the stochastic line bundles over the loop space, and therefore in understanding the stochastic Z-valued forms over the loop space. A new stochastic differential Calculus was established in Refs. 28–31 inspired by the considerations of Iglésias,[32] Souriau,[33] and Chen[34] about diffeology. One of the main theorem of Refs. 29 and 31 is that the

stochastic cohomology of Chen–Souriau is equal of the de Rham cohomology of the Hoelder loop space. Therefore a stochastic line bundle (with fiber almost surely defined) over the Brownian bridge is isomorphic to a true line bundle over the Hoelder loop space.

Brzezniak–Léandre[27] consider a diffusion process over the set of C^1 loops in a manifold. The parallel transport of an element of a true line bundle over the C^1 loop space is related to two parameters integrals, the integral in the propagation time of the loop being stochastic and the integral in the internal time of the loop being an ordinary integral.

In this paper, we are concerned by the case where the parallel transport is related to a two-dimensional stochastic integral.

Let us consider the pant Σ. This gives a propagation time of the loop t and if $t \leqslant 1$, an internal time of the loop $s \to x_t(s)$. If $t > 1$, there are two loops, $s \to (x_t^1(s), x_t^2(s))$. The loop $s \to x_t(s)$ is only continuous as well as the two loops $s \to x_t^1(s)$ and $s \to x_t^2(s)$. Although, we can define line integrals over these loop spaces associated to a one form. We can apply the apparatus of Léandre[35] in order to define Felder–Gawedzki–Kupiainen line bundle ξ_t over the random paths $x_t(.)$ for $t \leqslant 1$, with fibers almost surely defined. For $t > 1$, we can define the tensor product of the bundles $\xi_t^1 \otimes \xi_t^2$ over the product of the two loops $x_t^1(.)$ and $x_t^2(.)$ with fibers almost surely defined with respect to the join law of $(x_t^1(.), x_t^2(.))$. Let us remark that $(x_t^1(.), x_t^2(.))$ are not independent.

In $t=1$, where the two loops $(x_1^1(.), x_1^2(.))$ meet in only one loop $x_1(.)$, there is a natural application map π, $(x_1^1(.), x_1^2(.)) \to x_1(.))$ which is the concatenation map. The beautiful properties of Felder–Gawedzki–Kupiainen line bundle imply that $\pi^*(\xi_1) = \xi_1^1 \otimes \xi_1^2$.

The parallel transport in time t is related to the existence of two-dimensional stochastic integrals. We cannot apply martingale theory to define them (we refer to Ref. 36 and references therein and Ref. 37 for analoguous considerations for one-dimensional stochastic integrals for the fractional Brownian motion where we cannot apply the martingale theory and to Ref. 38 for analoguous considerations on the sphere). We can define a stochastic parallel transport from $\xi_2^1 \otimes \xi_2^2$ into $\xi_1^1 \otimes \xi_1^2 = \xi_1$ which is almost surely an isometry and the stochastic parallel transport from ξ_1 over the fiber over the constant loop $s \to x$, because we start from the constant loop. The composite realized a map from a random section of $\xi_2^1 \otimes \xi_2^2$ over C, called $\tau_{0,2}$. We get the following theorem.

Theorem: $\tau_{0,2}$ realizes an isometry from $L^2(\xi_2^1 \otimes \xi_2^2)$ into L^2.

But since $x_2^1(.)$ and $x_2^2(.)$ are not independent, the Hilbert space of sections of $\xi_2^1 \otimes \xi_2^2$ over the product of random loops $(x_2^1(.), x_2^2(.))$ is not the tensor product of Hilbert spaces of sections of the line bundle ξ_2^1 over $x_2^1(.)$ and of L^2 sections of the Hilbert space of sections over $x_2^2(.)$ over ξ_2^2. In some sense, we have replaced the Banach space of continuous functions over the loop space by the Hilbert space of L^2 sections of the Gawedzki–Felder–Kupiainen line bundle over the loop space, but our program failed in part because $x_2^1(.)$ and $x_2^2(.)$ are not independent.

For analysis over loop space, we refer to the two surveys of Léandre.[39,40]

Let us remark that this kind of mechanism of splitting a loop in two loops is very classical in physics. We refer to the survey of Mandelstam[41] about that. Moreover, we are in this work in presence of a $1+1$ dimensional theory, we consider a diffusion process on loop space. The reader interested by a $1+2$ dimensional theory, that is a diffusion process on pants, can see Refs. 42 and 43.

II. CONSTRUCTION OF THE BROWNIAN PANTS

We recall briefly the construction of the Brownian pants of Brzezniak–Léandre.[22]

We consider a compact Riemannian manifold M of dimension d imbedded in R^n isometrically. If $x \in M$, $\Pi(x)$ is the orthogonal projection from R^n into $T_x(M)$. It can be extended to a map from R^n into the linear applications over R^n, which is smooth and have bounded derivatives of all orders. We introduce the Hilbert space $H = H^{1,2}(S^1; R^n)$ of the set of loops in R_n such that

$$\int_0^1 |\gamma(s)|^2 \, ds + \int_0^1 |d/ds\, \gamma(s)|^2 ds = \|\gamma\|^2 < \infty. \tag{2.1}$$

Let $B_t(.)$ be the Brownian motion with values in H.

We can construct it as follows. Let Ψ_s be the linear map from H into R^n defined as follows: $\Psi_s(\gamma(.)) = \gamma(s)$. Since H is an Hilbert space and since Ψ_s is continuous, we get

$$\Psi_s(\gamma(.)) = \int_0^1 \langle \gamma(u), e_s(u)\rangle du + \int_0^1 \langle d/du\ \gamma(u), d/du\ e_s(u)\rangle du, \tag{2.2}$$

$t \to B_t(s)$ is a Brownian motion with covariance $\|e_s(.)\|^2$ (we did as we were working on R in order to simplify the notation, but it is easy to reduce our study to the case of R by looking at the coordinates of Ψ_s). Moreover, if $s \neq s'$, Ψ_s is independent of $\Psi_{s'}$ as a linear map. This shows us that $e_s(.)$ and $e_{s'}(.)$ are independents and that the couple $t \to (B_t(s), B_t(s'))$ realized a nondegenerated Brownian motion over $R^n \times R^n$, although $t \to B_t(s)$ and $t \to B_t(s')$ are not independent. We have $\langle B_t(s), B_t(s')\rangle = t\langle e_s, e_s'\rangle$. Moreover the covariance matrix of $B_t(s)$ and $B_t(s')$ is not degenerated. In others words, we can write

$$B_t(s') = \alpha_1(s,s')B_t(s) + \alpha_2(s,s')B_t(s,s'), \tag{2.3}$$

where $B_t(s,s')$ is independent of $B_t(s)$ and where the two constants in the decomposition (2.3) are not equal to 0.

We can construct the Brownian motion with values in H in a more global setup. Let γ_j be an orthonormal basis of H. Let $B_t(j)$ be some independent R-valued Browian motion. We set

$$B_t(s) = \sum B_t(j)\gamma_j(s). \tag{2.4}$$

This series does not converge in H, but in a bigger space. Namely, we get, if d is the Riemannian distance on the circle $\langle B_t(s) - B_t(s'), B_t(s) - B_t(s')\rangle \leqslant Cd(s,s')$. We deduce, since $(t,s) \to B_t(s)$ is a Gaussian process, that $(t,s) \to B_t(s)$ has almost surely a version which is Hoelder, by Kolmogorov lemma. We can show that

$$\langle B_t(s), B_t(s')\rangle = t\langle e_s, e_{s'}\rangle. \tag{2.5}$$

The family of Stratonovitch equations

$$d_t x_t(s) = \Pi(x_t(s)) d_t B_t(s); \quad x_0(s) = x \tag{2.6}$$

has a meaning. It constitutes a family of Brownian motions over the manifold over M parametrized by the circle (in this work, s will denote the internal time of the loop and t the propagation time of the loop). We recall[17] that $(s,t) \to x_t(s)$ has almost surely a version which is $1/2 - \epsilon$ Hoelder for all ϵ.

Let $s_1 < s_2$ be two times. We constrain the elliptic diffusion $t \to (x_t(s_1), x_t(s_2))$ to be equal at y at time 1.

Let us recall that if we consider an elliptic diffusion $\tilde{y}_t(\tilde{x})$ over a compact manifold $\tilde{M}$, it has a heat kernel $q_t(\tilde{x}, \tilde{y})$ satisfying the estimate

$$\text{grad} \log q_t(\tilde{x}, \tilde{y}) \leqslant C \frac{\tilde{d}(\tilde{x}, \tilde{y})}{t} \tag{2.7}$$

for $\tilde{y}$ close to $\tilde{x}$ for the associated Riemannian metric and the natural Riemannian distance $\tilde{d}$ associated to the elliptic diffusion (see Refs. 44 and 45). Let us recall that if the stochastic differential equation of the elliptic diffusion is given by

$$\mathrm{d}\tilde{y}_t(\tilde{x}) = \sum \tilde{X}_i(\tilde{y}_t(\tilde{x})\mathrm{d}\tilde{w}_t^i + \tilde{X}_0(\tilde{y}_t(\tilde{x})\mathrm{d}t \tag{2.8}$$

over the compact manifold, the bridge between $\tilde{x}$ and $\tilde{y}$ satisfies to the following stochastic differential equation (in Stratonovitch sense):

$$\mathrm{d}\tilde{y}_t(\tilde{x},\tilde{y}) = \sum \tilde{X}_i(\tilde{y}_t(\tilde{x},\tilde{y})(\mathrm{d}\tilde{w}_t^i + \langle \tilde{X}_i(\tilde{y}_t(\tilde{x},\tilde{y}),\ \mathrm{grad}\log q_{1-t}(\tilde{y}_t(\tilde{x},\tilde{y}),\tilde{y})\rangle) + \tilde{X}_0(\tilde{y}_t(\tilde{x},\tilde{y})\mathrm{d}t \tag{2.9}$$

(see Refs. 44 and 45). This means that we transform $\mathrm{d}\tilde{w}_t^i$ into $\mathrm{d}\tilde{w}_t^i + \alpha_t^i\,\mathrm{d}t$ by using the equation (2.9). By the estimate (2.7), we have

$$E\left[\int_0^1 |\alpha_t^i|\mathrm{d}t\right] < \infty. \tag{2.10}$$

We write

$$B_t(s_2) = \alpha(s_1,s_2)B_t(s_1) + \beta(s_1,s_2)B_t(s_1,s_2),$$

$$B_t(s) = \alpha(s_1,s_2,s)B_t(s_1) + \beta(s_1,s_2,s)B_t(s_1,s_2) + \gamma(s_1,s_2,s)B_t(s_1,s_2,s), \tag{2.11}$$

where the Brownian motion $B_t(s_1,s_2,s)$ is independent of the Brownian motions $B_t(s_1)$ and $B_t(s_1,s_2)$. Conditionating by $x_1(s_1)=x_1(s_2)=y$ is nothing else to do the following transformation in (2.11):

$$\begin{aligned}\mathrm{d}\tilde{B}_t(s) = {}& \alpha(s_1,s_2,s)(\mathrm{d}B_t(s_1) + \alpha_t^1(s_1,s_2)\mathrm{d}t) + \beta(s_1,s_2,s)(\mathrm{d}B_t(s_1,s_2) + \alpha_t^2(s_1,s_2)\mathrm{d}t)\\ &+ \gamma(s_1,s_2,s)\mathrm{d}B_t(s_1,s_2,s).\end{aligned} \tag{2.12}$$

We set $\mathrm{d}\tilde{B}_t(s_1)=\mathrm{d}B_t(s_1)+\alpha_t^1(s_1,s_2)\mathrm{d}t$ and $\mathrm{d}\tilde{B}_t(s_2)=\mathrm{d}B_t(s_1,s_2)+\alpha_t^2(s_1,s_2)\mathrm{d}t$. Moreover,

$$\begin{aligned}\mathrm{d}\tilde{B}_t(s') = {}& \alpha(s_1,s_2,s,s')\mathrm{d}\tilde{B}_t(s_1) + \beta(s_1,s_2,s,s')\mathrm{d}\tilde{B}_t(s_2) + \gamma(s_1,s_2,s,s')\mathrm{d}B_t(s_1,s_2,s)\\ &+ \delta(s_1,s_2,s,s')\mathrm{d}B_t(s_1,s_2,s,s'),\end{aligned} \tag{2.13}$$

where $\mathrm{d}B_t(s_1,s_2,s,s')$ is independent of the others processes in (2.13).

Moreover, we have

$$\begin{aligned}|\delta(s_1,s_2,s,s')| &\leqslant C\sqrt{d(s,s')},\\ |\gamma(s_1,s_2,s,s') - \gamma(s_1,s_2,s)| &\leqslant C\sqrt{d(s,s')},\\ |\beta(s_1,s_2,s,s') - \beta(s_1,s_2,s)| &\leqslant C\sqrt{d(s,s')},\\ |\alpha(s_1,s_2,s,s') - \alpha(s_1,s_2,s,s')| &\leqslant C\sqrt{d(s,s')},\end{aligned} \tag{2.14}$$

where $d(s,s')$ is the Riemannian distance over the circle. Let us justify this fact. We have namely

$$\langle B_t(s) - B_t(s'), B_t(s) - B_t(s')\rangle \leqslant Cd(s,s'). \tag{2.15}$$

But this variance is equal to the sum of the square of the left-side hand of (2.14).

Lemma II.1: If $\int_0^1|\alpha_t^i|\mathrm{d}t<K$ (Hypothesis K), we have

$$E[|x_t(s) - x_t(s')|^p]\ |x_1(s_1) = x_1(s_2) = y\ ] \leqslant Cd(s,s')^{p/2}. \tag{2.16}$$

Proof: $x_t(s)-x_t(s')$ satisfies the equality in the Stratonovitch sense,

$$\mathrm{d}x_t(s) - \mathrm{d}x_t(s') = (\Pi(x_t(s)) - \Pi(x_t(s')))\mathrm{d}\tilde{B}_t(s) + \Pi(x_t(s'))(\mathrm{d}\tilde{B}_t(s) - \mathrm{d}\tilde{B}_t(s')). \tag{2.17}$$

By the estimates (2.14) and (Hypothesis K), the result arises by using Burkholder–Davies–Gundy inequality and Gronwall lemma. ■

By using the Kolmogorov lemma (see Ref. 46), we deduce that there exists an Hoelder version of the random field $(t,s)\to x_t(s)$ where we have conditionated by $x_1(s_1)=x_1(s_2)=y$. The loop $s\to x_1(s)$ is splitted in two loops $s\to x_i^1(s)$ and $s\to x_1^2(s)$ starting from y and satisfying the estimates if (Hypothesis K) is satisfied,

$$E[|x_1^1(s) - x_1^1(s')|^p] \leqslant Cd(s,s')^{p/2} \tag{2.18}$$

and

$$E[|x_1^2(s) - x_1^2(s')|^p] \leqslant Cd(s,s')^{p/2}. \tag{2.19}$$

Following the idea of Brzezniak–Léandre,[22] we introduce two others Brownian motion with values in the Hilbert space H $B_t^1(.)$ and $B_t^2(.)$ independent of each other and independent of the first Brownian motion $B_t(.)$. We consider the equations after time 1,

$$d_t x_{t+1}^1(s) = \Pi(x_{t+1}^1(s))\mathrm{d}B_t^1(s), \quad x_1^1(s) = x_1^1(s) \tag{2.20}$$

and

$$d_t x_{t+1}^2(s) = \Pi(x_{t+1}^2(s))\mathrm{d}B_t^2(s), \quad x_1^2(s) = x_1^2(s) \tag{2.21}$$

We have

$$x_{t+1}^1(s) - x_{t+1}^1(s') = x_1^1(s) - x_1^1(s') + \int_0^t (\Pi(x_{1+u}^1(s)) - \Pi(x_{u+1}^1(s'))\ \mathrm{d}B_u^1(s)$$

$$+ \int_0^t \Pi(x_{u+1}^1(s'))(\mathrm{d}B_u^1(s) - \mathrm{d}B_u^1(s')) \tag{2.22}$$

Lemma II.2: If (Hypothesis K) is satisfied, we have

$$E[|x_t^1(s) - x_t^1(s')|^p] \leqslant Cd(s,s')^{p/2} \tag{2.23}$$

and we have

$$E[|x_t^2(s) - x_2^2(s')|^p] \leqslant Cd(s,s')^{p/2}. \tag{2.24}$$

Proof: The result comes from (2.18), (2.19), and (2.15) and from Gronwall lemma (see Refs. 17, 43, and 47 for analoguous statements). ■

Definition II.3: The random pant is constituted for $t\leqslant 1$ by the random field $(t,s)\to x_t(s)$ with the constrain $x_1(s_1)=x_1(s_2)=y$ and for $t>1$ by the couple of diffusion processes $t\to(x_t^1(.),x_t^2(.))$

There are one input boundary at $t=0$ and two output boundaries to the pant $(x_2^1(.),x_2^2(.))$.

III. LINE INTEGRALS

The material of this part and of the following part follows closely the construction of stochastic integrals of Refs. 43, 47, and 48. So we do not give all the details, referring to these references.

We consider a 1 form ω over M conveniently extended in a 1-form over R^n with bounded derivatives of all orders. We consider $t\leqslant 1$. We consider a segment l of S^1. We would like to give a meaning to the stochastic integral $\int_l\langle\omega(x_t(s)),d_s x_t(s)\rangle$. In a second case, we consider $t>1$, and we would like to give a meaning to the two stochastics integrals $\int_l\langle\omega(x_t^1(s)),d_s x_t^1(s)\rangle$ and $\int_l\langle\omega(x_t^2(s)),d_s x_t^2(s)\rangle$. t is the time of the dynamic and s is the internal time of the loop.

We will do the exact treatment for $t=1$, the others case being similar.

Let us come back to the Brownian motion over the Sobolev space given by (2.1). Let us introduce $0 \leqslant s < t \leqslant 1$ and $\Delta s \geqslant 0$ and $\Delta t \geqslant 0$ such that $s + \Delta s \leqslant t \leqslant t + \Delta t \leqslant 1$. Let us compute the covariance of $B_\cdot(s+\Delta s) - B_\cdot(s)$ and of $B_\cdot(t+\Delta t) - B_\cdot(t)$.

For that, let us define $e(s)$ such that for all paths $\gamma(.)$ in the Sobolev space,

$$\gamma(0) = \int_0^1 \langle e(s), \gamma(s) \rangle \mathrm{d}s + \int_0^1 \langle e'(s), \gamma'(s) \rangle \mathrm{d}s, \tag{3.1}$$

$$e(s) = \lambda \exp[-s] + \mu \exp[s] \tag{3.2}$$

for some λ and some μ for $0 \leqslant s \leqslant 1$. Therefore, $e(.)$ is smooth with bounded derivatives over the closed interval $[0,1]$ with $e(0) = e(1)$ and not $e'(0) = e'(1)$. Moreover, using the natural rotational invariance of the norms given by (2.1), we get

$$\gamma(t) = \int_{S^1} \langle e(s-t), \gamma(s) \rangle \mathrm{d}s + \int_{S^1} \langle e'(s-t), \gamma'(s) \rangle \mathrm{d}s. \tag{3.3}$$

This shows us that for the Hilbert structure (2.1),

$$\langle e(.-t-\Delta t) - e(.-t), e(.-s-\Delta s) - e(.-\Delta s) \rangle = e(t+\Delta t - s - \Delta s) - e(t-s-\Delta s) - e(t+\Delta t - s) + e(t-s) = e''(t-s)\Delta t \Delta s + O(\Delta t + \Delta s)^3. \tag{3.4}$$

We can diagonalize $B_\cdot(s_1)$, $B_\cdot(s_2)$, $B_\cdot(s+\Delta s)$, $B_\cdot(t)$, $B_\cdot(t+\Delta t)$. We can find two couples of independent Brownian motion $((w_\cdot(1), w_\cdot(2))$ and $(w_\cdot(3), w_\cdot(4))$ such that

$$B_\cdot(s) = \alpha_1(s_1,s_2,s) B_t(s_1) + \beta(s_1,s_2,s) B_\cdot(s_2) + \gamma(s_1,s_2,s) w_\cdot(1),$$

$$B_\cdot(s+\Delta s) = \alpha_1(s_1,s_2,s,\Delta s) B_\cdot(s_1) + \beta(s_1,s_2,s,\Delta s) B_\cdot(s_2) + \gamma(s_1,2,s,\Delta s) w_\cdot(1) + \delta(s_1,s_2,s,\Delta s) w_\cdot(2), \tag{3.5}$$

$$B_\cdot(s') = \alpha_1(s_1,s_2,s') B_\cdot(s_1) + \beta(s_1,s_2,s') B_t(s_2) + \gamma(s_1,s_2,s') w_\cdot(3),$$

$$B_\cdot(s'+\Delta s') = \alpha_1(s_1,s_2,s',\Delta s') \tilde{B}_\cdot(s_1) + \beta(s_1,s_2,s',\Delta s') B_\cdot(s_2) + \gamma(s_1,s_2,s',\Delta s') w_\cdot(3) + \delta(s_1,s_2,s',\Delta s') w_\cdot(4),$$

$0 \leqslant s + \Delta s \leqslant s' \leqslant s' + \Delta s' \leqslant 1$. $(w_\cdot(1), w_\cdot(2))$ are independent of $(B_\cdot(s_1), B_\cdot(s_2))$. $(w_\cdot(3), w_\cdot(4))$ is independent of $(B_\cdot(s_1), B_\cdot(s_2))$. Moreover, $\alpha_1(s_1,s_2,s) - \alpha_1(s_1,s_2,s,\Delta s) = C(s_1,s_2,s)\Delta s + O(\Delta s)^{3/2}$. $\beta(s_1,s_2,s) - \beta(s_1,s_2,s,\Delta s) = C(s_1,s_2,s)\Delta s + O(\Delta s)^{3/2}$. $\gamma(s_1,s_2,s) - \gamma(s_1,s_2,s,\Delta s) = C(s_1,s_2,s)\Delta s + O(\Delta s)^{3/2}$. We have too the estimate $\delta(s_1,s_2,s,\Delta s) = C(s_1,s_2,s)\sqrt{\Delta s} + O(\Delta s)$. We deduce that $\langle w_\cdot(4), w_\cdot(1) \rangle = O(\sqrt{\Delta t})$, $\langle w_\cdot(4), w_\cdot(2) \rangle = O(\sqrt{\Delta t}\sqrt{\Delta s})$, $\langle w_\cdot(2), w_\cdot(3) \rangle = O(\sqrt{\Delta s})$.

Lemma III.1: Let H_1 be the Hilbert space spanned by $e(s_1)$ and $e(s_2)$ and P be the othogonal projection of H_1 on it. $t \to P(e(t))$ is of finite energy.

Proof: H_1 has an orthonormal basis constituted of linear combinations of $e(s_1)$ and $e(s_2)$. But $t \to \langle e(s_1), e(t) \rangle = e(s_1 - t)$ is of finite energy. The same holds for $t \to \langle e(s_2), e(t) \rangle$. Therefore the result. ■

In the sequel, we will suppose always that (Hypothesis K) is satisfied, we will remove this hypothesis only in the last part.

Since the solution of a stochastic differential equation in Stratonovitch sense is unique in law, we can replace in order to study $x_t(s)$, $x_t(s+\Delta s)$, $x_t(s')$, $x_t(s'+\Delta s')$ the leading Brownian motion by the diagonalization (3.5). If we conditionate by $x_1(s_1) = x_1(s_2) = y$, we replace $B_t(s_1)$ by $\tilde{B}_t(s_1)$, the same operation holding for $B_t(s_2)$.

If we look at the linear equation:

$$d\phi_t(s) = \frac{\partial}{\partial x}\Pi(x_t(s))\phi_t(s)d\tilde{B}_t(s) \tag{3.6}$$

it has a solution bounded in all the L^p independently of s, after doing the conditionating. Moreover $\phi_t^{-1}(s)$ is bounded in all the L^p. We deduce from (3.5) that in law

$$g_t^1(s) = \frac{\partial}{\partial\sqrt{\Delta s}}x_t(s+\Delta s)_{\Delta s=0} \tag{3.7}$$

is solution of the linear equation

$$dg_t^1(s) = \frac{\partial}{\partial x}\Pi(x_t(s))g_t^1(s)d\tilde{B}_t(s) + \Pi(x_t(s))\frac{\partial}{\partial\sqrt{\Delta s}}\delta(s_1,s_2,s,\Delta s)_{\Delta s=0}\,dw_t(2), \tag{3.8}$$

which can be solved by the method of variation of constant[46]

$$g_t^1(s) = \phi_t(s)\int_0^t \phi_u^{-1}(s)\Pi(x_t(u))\frac{\partial}{\partial\sqrt{\Delta s}}\delta(s_1,s_2,s,\Delta s)dw_u(2). \tag{3.9}$$

We deduce that in law

$$x_1(s+\Delta s) = x_1(s) + \sqrt{\Delta s}g_1^1(s) + \Delta s g_1^2(s) + O(\Delta s)^{3/2}. \tag{3.10}$$

In $g_1^2(s)$, there is a double integral in $dw_u(2)$ and a single integral in $dw_u(1)$. Lemma III.1 allows us namely to handle the finite energy terms in $d\tilde{B}_t(s_1)$ and $d\tilde{B}_t(s_2)$, there are of finite energy in s, and appear linearly in $g_1^2(s)$. $g_1^1(s)$ is a linear expression in $dw_u(2)$.

Lemma. III.2: We have the estimate

$$E[f(x_1(s))f(x_1(s'))g_1^1(s)g_1^1(s')] = C(s,s')\sqrt{\Delta s\Delta s'} + O(\sqrt{\Delta s} + \sqrt{\Delta s'})^{3/2}. \tag{3.11}$$

Proof: The proof is very similar to Lemma III.3 of Ref. 48. But before to apply Itô formula and Clark–Ocone formula,[49] we conditionate in $B_\cdot(s_1)$ and $B_\cdot(s_2)$. [The drift in $\tilde{B}_\cdot(s_1)$ and $\tilde{B}_\cdot(s_2)$ is namely $B_\cdot(s_1)$ and $B_\cdot(s_2)$ measurables]. ■

We consider N a big integer, and 2^N and the dyadic subdivision of $[0,1]$ associated to 2^N. We call its elements s_i with $s_i < s_{i+1}$ such that $s_{i+1} - s_i = 2^{-N}$. If $s \in [s_i, s_{i+1}]$, we set

$$x_t^N(s) = x_t(s_i) + \frac{(s-s_i)}{(s_{i+1}-s_i)}(x_t(s_{i+1}) - x_t(s_i)). \tag{3.12}$$

We consider

$$A^N = \int_l \langle\omega(x_1^N(s)), d_s x_1^N(s)\rangle. \tag{3.13}$$

We get the following.

Proposition III.3: When $N\to\infty$, the sequence of random variables A^N tends in L^2 to a random variable called $\int_l\langle\omega(x_1(s)), d_s x^1(s)\rangle$.

Proof: We write

$$A^N = \sum A_i^N = \sum \int_{s_i}^{s_{i+1}} \langle\omega(x_1^N(s)), d_s x_1^N(s)\rangle. \tag{3.14}$$

Let us decompose A_i^N. We write

$$A_i^N = B_i^N + C_i^N \tag{3.15}$$

with

$$B_i^N = \omega(x_1(s_i))\Delta_s x_1^N(s_i) \tag{3.16}$$

and

$$C_i^N = \int_{s_i}^{s_{i+1}} \langle \omega(x_1^N(s)) - \omega(x_1(s_i)), d_s x_t^N(s) \rangle. \tag{3.17}$$

B_i^N will converge to the Itô part of the integral in the Proposition III.3 and C_i^N to the Stratonovitch counterterm in this integral.

First step: Study of ΣB_i^N.

By (3.10), we have

$$B_i^N = \sqrt{\Delta s_i}\omega(x_1(s_i))g_1^1(s_i) + \Delta s_i \omega(x_1(s_i))g_1^2(s_i). \tag{3.18}$$

Let us show that the quantity $\Sigma \Delta s_i \omega(x_1(s_i))g_1^2(s_i)$ converges in L^2. In $g_t^2(s_i)$, there are two terms: the terms with derivatives of order two of $\delta(s_1, s_2, s, \Delta s)$ and the term where derivative of $\alpha(s_1, s_2, s, \Delta s)$, $\beta(s_1, s_2, s, \Delta s)$ and $\gamma(s_1, s_2, \Delta s)$ appear which lead to linear contributions.

The contribution of the finite variational part in $\tilde{B}_1(s_1)$ and in $\tilde{B}_1(s_2)$ is of finite energy in s by Lemma III.1 and does not cause any difficulty. We can see the contribution of the other linear tems in $g_1^2(s_1)$. As a matter of fact, these terms can be handled by the following considerations: if we do not conditionate by $x_1(s_1) = x_1(s_2) = y$, we can write

$$B_\cdot(s) = w_\cdot(1),$$

$$B_\cdot(s + \Delta s) = \alpha(s, \Delta s) w_\cdot(1) + \beta(s, \Delta s) w_\cdot(2), \tag{3.19}$$

where $\alpha(t, \Delta t) = 1 + C(t)(\Delta t) + O(\Delta t)^{3/2}$, we get

$$\alpha_1(s_1, s_2, s, \Delta s) = \alpha_1(s_1, s_2, s) C\alpha(s, \Delta s),$$

$$\beta(s_1, s_2, s, \Delta s) = \beta(s_1, s_2, s)\alpha(s, \Delta s), \tag{3.20}$$

$$\gamma(s_1, s_2, s, \Delta s) = \gamma(s_1, s_2, s)\alpha(s, \Delta s),$$

such that the linear term in g_1^2 are in fact stochastic integrals in $\mathrm{d}B_t(s)$ mutiplied by Δs. This term does not cause any difficulty.

Let us compute the behavior of the quadratic term in $g_1^2(s_i)$. $\Delta s_i g_1^2(s_i)$ modulo a term in $(\Delta s_i)^{3/2}$ behaves as a double Stratonovitch integral $\alpha_\cdot(s_i)$ in $B_\cdot(s_i + \Delta s_i) - B_\cdot(s_i)$.

We refer to Ref. 47, pp. 5539, 5540, and 5541 for details. In order to do the conditionating, we conditionate in addition by $B_\cdot(s_1)$ and by $B_\cdot(s_2)$ with respect of this reference. Moreover, we replace (3.47) in Ref. 47 by the the use of the Itô–Stratonovitch formula of Ref. 50. Let X_t and Y_t be two semimartingales with values in R^n. We would like to solve the stochastic differential equation in the Stratonovitch sense,

$$\mathrm{d}x_t = \Pi(x_t)(\mathrm{d}X_t + \mathrm{d}Y_t). \tag{3.21}$$

We solve first the equation

$$\mathrm{d}y_t = \Pi(y_t)\mathrm{d}Y_t. \tag{3.22}$$

Equation (3.22) has a stochastic flow ϕ and we have $x_t = \phi(z_t)$ where z_t is the solution of the stochastic differential equation

$$\mathrm{d}z_t = \phi_t^* \Pi(z_t)\mathrm{d}X_t \tag{3.23}$$

Let N' a bigger subdivision associate to $2^{N'}$. We suppose in the sequel that $[s_j, s_{j+1}] \subseteq [s_i, s_{i+1}]$. We write

$$\sum \omega(x_t(s_i))\alpha_1(s_i) - \sum \omega(x_t(s_j))\alpha_t(s_j) = \sum \Big(\omega(x_t(s_i)) - \omega(x_t(s_j))\alpha_t(s_j) + \sum \omega(x_t(s_i))\Big) \times \Big(\sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} (\alpha_t(s_i) - \alpha_t(s_j))\Big) \tag{3.24}$$

The first term tends clearly to 0. In the double integral which compose $\alpha_t(s_i)$, we write

$$\mathrm{d}B_\cdot(s_i + \Delta s_i) - \mathrm{d}B_\cdot(s_i) = \sum \mathrm{d}B_\cdot(s_j + \Delta s_j) - \mathrm{d}B_\cdot(s_j) \tag{3.25}$$

and we distribute in the double stochastic integral. The integrand before $B_\cdot(s_i+\Delta s_i)$ is $\widetilde{B}_\cdot(s_i)$ measurable, and continuous in u. Therefore, we can replace the integrand before $B_\cdot(s_i+\Delta s_i) - B_\cdot(s_i)$ by the integrand before $B_\cdot(s_j+\Delta s_j) - B_\cdot(s_j)$. When we distribute over $[s_j, s_{j+1}] \subseteq [s_i, s_{i+1}]$, the term where we take twice the same $[s_j, s_{j+1}]$ cancel with $\alpha_t(s_j)$. Therefore, we must take the sum

$$E_t = \sum_i \sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}];[s_{j'},s_{j'+1}]\subseteq[s_i,s_{i+1}];j\neq j'} \omega(x_t(s_i)) \int_{0<u<v<t} r_u(s_j) d_u(B(s_j + \Delta s_j) - B(s_j)) r_v(s_{j'}) \mathrm{d}v(B(s_{j'} + \Delta s_{j'}) - B_\cdot(s_{j'})) \tag{3.26}$$

where $r_\cdot(s_j)$ is $B_\cdot(s_j)$ measurable and adapted. Let us show that the previous expression converges to 0.

First, we convert the Stratonovitch integral in Itô integral. Since $\langle B_\cdot(s_j+\Delta s_j) - B_\cdot(s_j), B_\cdot(s_{j'} + \Delta s_{j'}) - B_\cdot(s_{j'})\rangle = c(s_i, s_j)\Delta s_i \Delta s_j + O(\Delta s_i + \Delta s_j)^{3/2}$, this leads to a term in 2^{-N2}. This shows that the finite variational term E_t tends to 0. Let us study the martingale part of E_t and let us study the quadratic variation. This leads to a sum of quadruplets of intervalles $[s_j, s_{j+1}]$.

Let us remark, if we do not conditionate by $x_1(s_1) = x_1(s_2) = y$,

$$\langle B_\cdot(s), B_\cdot(s' + \Delta s') - B_\cdot(s')\rangle = O(\Delta s'), \tag{3.27}$$

if s is not included in the time interval $]s', s' + \Delta s'[$.

Let us suppose that all the elements of the quadruplet $[s_j, s_{j+1}]$ are different. We diagonalize $B_\cdot(s_1)$, $B_\cdot(s_2)$, $B_\cdot(s_{i'})$ and $B_\cdot(s_j)$, $B_\cdot(s_j+\Delta s_j)$ as it was done before. We start from $B_\cdot(s_1)$, $B_\cdot(s_2)$, $B_\cdot(s_i)$, $B_\cdot(s_j)$, and $B_\cdot(s_j+\Delta s_j)$ as before. By using (3.27) and (3.4) and an analoguous of (3.5), we find that the contribution where we have a quadruplet without coincidence is in $2^{-N'4}$. They are $2^{2N}2^{4(N'-N)}$ such contributions. Therefore the total contribution behaves as 2^{-2N}.

If we suppose, they are three different terms, that can come from two cases, the two last terms in the double integral are equal. Therefore we must estimate (where $k \neq j \neq j'$)

$$\int_0^t r_u(s_j)(d_u B(s_j + \Delta s_j) - d_u B(s_j)) \int_0^t r_u(s_{j'})(d_u B_u(s_{j'} + \Delta s_{j'}) - d_u B(s_j)) r_t^2(s_k)\Delta s_k. \tag{3.28}$$

By conditionating as before, this leads to a contribution in $2^{-3N'}$.

Or the two last terms are different. This leads to a contribution where $k \neq k' \neq j$

$$\int_0^t r_u(s_j)(d_u B(s_j + \Delta s_j) - d_u B(s_j))^2 r_t(s_k) r_t(s_{k'})\Delta s_k \Delta s_{k'}. \tag{3.29}$$

By diagonalizing as before, this leads to a contribution in $2^{-3N'}$. This possibility occurs $2^N 2^{3(N'-N)}$. This gives a total contribution which vanishes.

The terms where there are only two $[s_j, s_{j+1}]$ leads to a behavior in $2^{-2N'}$ because it is of the shape

$$\int_0^t r_u(s_j)(dB_u(s_j+\Delta s_j)-d_uB(s_j))^2 r_t(s_k)^2 \Delta s_k. \tag{3.30}$$

The last possibility occurs $2^N 2^{2(N'-N)}$.

This gives a total contribution which vanishes.

We write $\Sigma\sqrt{s_{i+1}-s_i}\omega(x_t(s_i))g_1^1(s_i)=\Sigma B^N(s_i)$. Let us study its convergence. We write

$$C_i = B^N(s_i) - \sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} B_{s_j}^{N'} \tag{3.31}$$

and we would like to show that ΣC_i converges in L^2 to 0.

Let us study the contribution of $E[C_iC_{i'}]$ when $i\neq i'$. We must estimate the quantity

$$E[\omega(x_1(s))g_1^1(s)\omega(x_1(s'))g_1^1(s')] \tag{3.32}$$

if $0\leqslant s\leqslant s+\Delta s\leqslant t\leqslant t+\Delta t\leqslant 1$. We have seen (Lemma III.2) that it behaves as $C(s,t)\sqrt{\Delta s\Delta t}+O(\sqrt{\Delta s}+\sqrt{\Delta t})^{3/2}$. Therefore,

$$\sum_{i\neq i'} E[C_iC_{i'}] \to 2\int_{l\times l} C_2(s,t)\mathrm{d}s\,\mathrm{d}t - 2\int_{l\times l} C(s,t)\mathrm{d}s\,\mathrm{d}t \tag{3.33}$$

which is 0.

Let us estimate $E[C_i^2]$.

We have seen that

$$B^N(s_i) = \omega(x_1(s_i))\Delta x_1(s_i) + O(s_{i+1}-s_i) \tag{3.34}$$

and the remaining term converges as before by the consideration given before. Therefore, it is enough to study the contribution of

$$C_i' = \omega(x_1(s_i))\Delta x_1(s_i) - \sum_{[s_j,s_{j+1}]} \omega(x_1(s_j))\Delta x_1(s_j) = \sum_{[s_j,s_{j+1}]} (\omega(x_1(s_i))-\omega(x_1(s_j))\Delta x_1(s_j). \tag{3.35}$$

We have to study the contribution of $E[|C_i''|^2]$ where

$$C_i'' = \sqrt{s_{j+1}-s_j}\sum_{[s_j,s_{j+1}]} (\omega(x_1(s_i))-\omega(x_1(s_j))g_1^1(s_j). \tag{3.36}$$

In $C_i''^2$, there are two contributions: the contribution where we have twice the same $[s_j,s_{j+1}]$ which leads the expression $\Sigma(s_{j+1}-s_j)O(2^{-N})=(s_{i+1}-s_i)O(2^{-N})$. This leads to a contribution where we sum over all $j\neq j'$.

So we must estimate

$$E[(\omega(x_1(s_i)))-\omega(x_1(s_j))g_1^1(s_j)(\omega(x_1(s_i)))-\omega(x_1(s_{j'}))g_1^1(s_{j'})] = \alpha_{j,j'}. \tag{3.37}$$

This leads to some improvement. Instead of diagonalizing only $B_\cdot(s_1)$, $B_\cdot(s_2)$, $B_\cdot(s_j)$, and $B_\cdot(s_j+\Delta s_j)$ as it was done before in order to get $g_1^1(s_j)$, we will diagonalize $B_\cdot(s_1)$, $B_\cdot(s_2)$, $B_\cdot(s_i)$, $B_\cdot(s_j+\Delta s_j)$, and $B_\cdot(s_j)$ in order to get $g_1^1(s_j)$. We find an expression of $\alpha_{j,j'}$ in

$$o(1/N)\sqrt{\Delta s_j}\sqrt{\Delta s_{j'}}. \tag{3.38}$$

Therefore

$$\sum \alpha_{j,j'} \sqrt{\Delta s_j} \sqrt{\Delta s_{j'}} = 2^{-2N} o(1/N) \tag{3.39}$$

is obtained exactly as in Ref. 47, p. 5542 (3.41), where we conditionate in $B_.(s_1)$ and $B_.(s_2)$ in addition, the drift namely in $\tilde{B}_t(s_1)$ and $\tilde{B}_t(s_2)$ are $B_.(s_1)$ and $B_.(s_2)$ measurables. Therefore, $\Sigma_i E[|C_i''|^2] \to 0$. It remains to see that the error term in (3.34) converges. This arises exactly from the previous considerations, because in the double integrals which appear in $g_1^2(s_j)$, we consider as leading term the double integrals in $d_u B(s_j + \Delta s_j) - d_u B(s_j)$ which are treated as before.

Second step: Let us study the convergence of ΣC_i^N in (3.17). We write

$$C_i^N = \langle \omega'(x_1(s_i)) g_1^1(s_i) g_1^1(s_i) \rangle (s_{i+1} - s_i) + O(\Delta s_i)^{3/2}. \tag{3.40}$$

We use Itô–Stratonovitch formula in order to write $g_1^1(s_i) g_1^1(s_i)$ as a double Stratonovitch integral, and we proceed as before in order to show that

$$\sum (s_{i+1} - s_i) \omega'(x_1(s_i)) g_1^1(s_i) g_1^1(s_i) \tag{3.41}$$

converges in L^2. ■

We consider a more intrinsic approximation of the stochastic integral in the Stratonovitch sense $\int_l \langle \omega(x_1(s)), d_s x_1(s) \rangle$. If $x_1(s_{i+1})$ is close of $x_1(s_i)$, we use the function

$$F_N[s, x_1(s_i), x_1(s_{i+1})] = \exp_{x_1(s_i)} \left[\frac{s - s_i}{s_{i+1} - s_i} (x_1(s_{i+1}) - x_1(s_i)) \right], \tag{3.42}$$

where exp is the Riemannian exponential and $(x_1(s_{i+1}) - x_1(s_i))$ is the unique vector in the tangent space at $x_1(s_i)$ such that $\exp_{x_1(s_i)}[x_1(s_{i+1}) - x_1(s_i)] = x_1(s_{i+1})$. We extend this map conveniently. We get another approximation $\tilde{x}_1^N(s)$.

Theorem III.4: $\int_l \langle \omega(\tilde{x}_1^N(s)), d_s \tilde{x}_1^N(s) \rangle$ converges in L^2 to $\int_l \langle \omega(x_1(s)), d_s x_1(s) \rangle$.

Proof: We have

$$\tilde{x}_1^N(s) = x_1(s_i) + \frac{s - s_i}{s_{i+1} - s_i} (x_1(s_{i+1}) - x_1(s_i)) + O\left(\left(\frac{s - s_i}{s_{i+1} - s_i} \right)^2 (x_1(s_{i+1}) - x_1(s_i))^2 \right). \tag{3.43}$$

Moreover,

$$\int_{s_i}^{s_{i+1}} \frac{(s - s_i)^2}{(s_{i+1} - s_i)^2} O(x_1(s_{i+1}) - x_1(s_i))^2 = O(s_{i+1} - s_i)^2 \tag{3.44}$$

whose sum converges to p. Therefore the result. ■

Remark: We ignore if the stochastic integral of Theorem III.2 is equal to the stochastic integral of Proposition III.1, although the Itô parts in both are equal. In the sequel we will use the stochastic integral of Theorem III.2, because it is more intrinsic.

We can repeat the argument in order to define $\int_l \langle \omega(x_{1+t}^1(s)), d_s x_{1+t}^1(s) \rangle$ and to define the line integral $\int_l \langle \omega(x_{1+t}^2(s)), d_s x_{1+t}^2(s) \rangle$ as limit in L^2 of the deterministic integral for the intrinsic polygonal approximations $\tilde{x}_{1+t}^{1,N}(s)$ or $\tilde{x}_{1+t}^{2,N}(s)$ of $s \to x_{1+t}^1(s)$ or $s \to x_{1+t}^2(s)$.

Theorem III.5: $\int_l \langle \omega(\tilde{x}_{1+t}^{1,N}(s)) d_s \tilde{x}_{1+t}^{1,N}(s) \rangle$ and $\int_l \langle \omega(\tilde{x}_{1+t}^{2,N}(s)), d_s \tilde{x}_{1+t}^{2,N}(s) \rangle$ converges in L^2 to the line integral $\int_l \langle \omega(x_{1+t}^1(s)), d_s x_{1+t}^1(s) \rangle$ and to the line integral $\int_l \langle \omega(x_{1+t}^2(s)), d_s x_{1+t}^2(s) \rangle$.

Remark: If we consider the case where $\omega = df$, Theorem III.5 leads to an Itô–Stratonovitch formula.

IV. INTEGRAL OF A TWO FORM

Let us consider a 2-form ω over M, extended in a 2-form over R^n with bounded derivatives of all orders. Consider a deterministic interval of the circle, and let $\tau \leqslant \tau'$ be two stopping times smaller than 1. We would like to define the integral $\int_\tau^{\tau'} \int_l \omega(d_t x_t(s), d_s x_t(s))$. In order to simplify the exposition, we will take $\tau = 0$ and $\tau' = 1$. Moreover, if we consider two stopping time 1

$\leqslant \tau, \tau' \leqslant 2$, we would like to define the stochastic integrals $\int_\tau^{\tau'} \int_l \omega(d_t x_t^1(s), d_s x_t^1(s))$ and $\int_\tau^{\tau'} \int_l \omega(d_t x_t^2(s), d_s x_t^2(s))$. t is the time of the dynamic, where we can apply martingale theory in order to define the stochastic integral and s is the internal time of the loop where we cannot apply martingale theory in order to define the stochastic integral but the considerations of the previous part.

We still suppose (Hypothesis K) is satisfied.

Since the second case is very similar to the first one, we will consider only the first case. After extending ω over the whole linear space R^n, we consider

$$A^N = \int_0^1 \int_{S^1} \omega(x_t^N(s))(d_t x_t^N(s), d_s x_t^N(s)), \tag{4.1}$$

where we consider the approximation $x_t^N(s)$ of $x_t(s)$ (we take the full circle S^1 instead of the interval l in order to simplify the exposition).

Proposition IV. 1: When $N \to \infty$, A^N tends in L^2 to the double stochastic Stratonovitch integral $\int_0^1 \int_{S^1} \langle \omega(x_t(s)), d_t x_t(s), d_s x_t(s) \rangle$.

Proof: Let us write

$$A^N = \sum_i \int_{[0,1]\times[s_i, s_{i+1}]} \langle \omega(x_t^N(s)), d_t x_t^N(s), d_s x_t^N(s) \rangle = \sum A_i^N. \tag{4.2}$$

Let us decompose A_i^N. We write

$$A_i^N = B_i^N + C_i^N \tag{4.3}$$

with

$$B_i^N = \int_{[0,1]\times[s_i, s_{i+1}]} \langle \omega(x_t^N(s_i)), d_t x_t^N(s_i), d_s x_t^N(s_i) \rangle = \int_{[0,1]} \langle \omega(x_t(s_i)), d_t x_t(s_i), \Delta x_t^N(s_i) \rangle \tag{4.4}$$

and

$$C_i^N = \int_{[0,1]\times[s_i, s_{i+1}]} \langle \omega(x_t^N(s)), d_t x_t^N(s), d_s x_s^N(s) \rangle - B_i^N. \tag{4.5}$$

First step: Study of B_i^N.

In the stochastic integrals which appear in B_i^N, we do the separation in a martingale part and a finite variational part. There are three problems.

The finite variational part in $\widetilde{B}_\cdot(s_1)$ and $\widetilde{B}_\cdot(s_2)$ which can be treat by Lemma III.1.

The second problem arises from a contraction betwee $d_t x_t(s_i)$ and $\Delta x_t(s_i)$, which leads to a term in Δs_i which converge.

The last one comes from the contraction between $\omega(x_t^N(s))$ and $d_t x_t^N(s)$ which leads to a double integral, which is a classical integral in t and which is in s of the type of the stochastic integral treated in Proposition III.2.

In the sequel, δ means that we take the martingale part of the processes considered and the associated Itô integral. So we must to consider only the martingale

$$(B_i^N)' = \int_{[0,1]\times[s_i, s_{i+1}]} \langle \omega(x_t(s_i),\ \delta_t x_t(s_i), \Delta x_t(s_i) \rangle. \tag{4.6}$$

We write as in (3.10) and we get

$$(B_i^N)' = \int_{[0,1]} \langle \omega(x_t(s_i)), \delta_t x_t(s_i), \sqrt{\Delta s_i} g_t^1(s_i) \rangle + \int_{[0,1]} \Delta s_i \langle \omega(x_t(s_i)), \delta x_t(s_i), g_t^2(s_i) \rangle + O(\Delta s_i^{3/2}). \tag{4.7}$$

Let us show that the sum of the second term converges in L^2. Following the notations of the previous part, we must estimate

$$\begin{aligned} &\sum_i \sum_{[s_j,s_{j+1}] \subseteq [s_i,s_{i+1}]} \Delta s_j \left(\int_0^1 \langle \omega(x_t(s_i)), \delta x_t(s_i), g_t^2(s_i) \rangle - \int_0^1 \langle \omega(x_t(s_j)), \delta_t x_t(s_j), g_t^2(s_j) \rangle \right) \\ &= \sum_i \sum_{[s_j,s_{j+1}] \subseteq [s_i,s_{i+1}]} \Delta s_j \left(\int_0^1 \langle \omega(x_t(s_i)), \delta x_t(s_i), g_t^2(s_i) \rangle - \int_0^1 \langle \omega(x_t(s_j)), \delta x_t(s_j), g_t^2(s_i) \rangle \right) \\ &\quad + \sum_i \sum_{[s_j,s_{j+1}] \subseteq [s_i,s_{i+1}]} \Delta s_j \left(\int_0^1 \langle \omega(x_t(s_j)), \delta x_t(s_j), g_t^2(s_i) - g_t^2(s_j) \rangle \right). \end{aligned} \tag{4.8}$$

The first term in (4.8) tends clearly to 0 in L^2. Namely, we can consider in $g_t^2(s_j)$ the linear term, where we consider the finite variation part of $\tilde{B}_\cdot(s_1)$ and of $\tilde{B}_\cdot(s_2)$ which can be treated by Lemma III.1. We can consider the term in $dw_u(1)$ which leads to a term in $dB_u(s_j)$ [see (3.19) and (3.20)]. Let us consider the term in $g_t^2(s)$ which leads to double stochastic integrals. We look at the right bracket of the martingale which is associated and we conclude by the same considerations as in the proof of Proposition III.1, first step [see (3.26)].

Let us study the behavior of the first term in (4.7). We write

$$C_i = \int_{[0,1]} \langle \omega(x_t(s_i)), \delta_t x_t(s_i), \sqrt{\Delta s_i} g_t^1(s_i) \rangle - \sum_{[s_j,s_{j+1}] \subseteq [s_i,s_{i+1}]} \int_0^1 \langle \omega(x_t(s_j)), \delta_t x_t(s_j), \sqrt{\Delta s_j} g_t^1(s_j) \rangle. \tag{4.9}$$

We would like to show that ΣC_i tends in 0 in L^2 when $N \to \infty$. This leads to two types of different contributions.

The contribution of $\Sigma_{i \neq i'} E[C_i C_{i'}]$. We can do as in the previous part in order to estimate the quantity

$$E\left[\int_0^1 \langle \omega(x_u(s)), \delta_u x_u(s), g_u^1(s) \rangle \int_0^1 \langle \omega(x_u(t)), \delta_u x_u(t), g_u^1(t) \rangle \right] = \alpha(s,t). \tag{4.10}$$

As in the previous part, $\alpha(s,t)$ has the asymptotic expansion $\alpha(s,t) = C_2(s,t)\sqrt{\Delta s}\sqrt{\Delta t} + O((\sqrt{\Delta s} + \sqrt{\Delta t})^3)$. In order to see that, we apply Itô formula in order to compute $\alpha(s,t)$ and we use Lemma III.2. This shows us that when $N, N' \to \infty$,

$$\sum_{i \neq i'} E[C_i C_{i'}] \to 2 \int_{S^1 \times S^1} C_2(s,t) ds\, dt - 2 \int_{S^1 \times S^1} C_2(s,t) ds\, dt. \tag{4.11}$$

The contribution of $\Sigma E[C_i^2]$. We can write if $[s_j, s_{j+1}] \subseteq [s_i, s_{i+1}]$,

$$\sqrt{\Delta s_i} \int_0^1 \langle \omega(x_t(s_i)), \delta_t x_t(s_i), g_t^1(s_i) \rangle = \int_0^1 \langle \omega(x_t(s_i)), \delta_t x_t(s_i), \Delta x_t(s_i) \rangle + O(\Delta s_i). \tag{4.12}$$

The remaining term converges in L^2 by the previous considerations. Let us write $\Delta x_t(s_i) = \Sigma \Delta x_t(s_j)$. We must estimate the L^2 norm of

$$D_i = \sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} \left(\int_0^1 \langle \omega(x_t(s_i)), \delta_t x_t(s_i), \Delta x_t(s_j)\rangle - \int_0^1 \langle \omega(x_t(s_j)), \delta_t x_t(s_j), \Delta x_t(s_j)\rangle \right) \tag{4.13}$$

or

$$D_i' = \sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} \left(\int_0^1 \langle \omega(x_t(s_i)), \delta_t x_t(s_i), g_t^1(s_j)\rangle - \int_0^1 \langle \omega(x_t(s_j)), \delta_t x_t(s_j), g_t^1(s_j)\rangle \right). \tag{4.14}$$

We compute $E[(D_i')^2]$ by using Itô formula. This leads to expressions similar to (3.37) to estimate. They can be estimated by the techniques of (3.36)–(3.39),

$$E[(C_i)^2] = (s_{i+1} - s_i) O(2^{-N}), \tag{4.15}$$

after using (3.11) for different times t and t' instead of 1 and a diagonalization of $B_\cdot(s_1), B_\cdot(s_2), B_\cdot(s_j), B_\cdot(s_j+\Delta s_j), B_\cdot(s_{j'}), B_\cdot(s_{j'}+\Delta s_{j'})$.

Second step: study of C_i^N.

We write

$$C_i^N = D_i^N + E_i^N \tag{4.16}$$

with

$$D_i^N = \int_{[0,1]\times[s_i,s_{i+1}]} \langle \omega(x_t^N(s)) - \omega(x_t^N(s_i)), d_t x_t^N(s_i), d_s x_t^N(s)\rangle \tag{4.17}$$

and

$$E_i^N = \int_{[0,1]\times[s_i,s_{i+1}]} \langle \omega(x_t(s_i)), d_t x_t^N(s) - d_t x_t(s_i), d_s x_t^N(s)\rangle. \tag{4.18}$$

We write

$$\omega(x_t^N(s)) - \omega(x_t(s_i)) = \frac{s - s_i}{\sqrt{s_{i+1} - s_i}} g_t^1(s_i) B(x_t(s_i)) + O(s - s_i). \tag{4.19}$$

We write

$$d_t x_t^N(s) = d_t x_t(s_i) + \frac{s - s_i}{\sqrt{s_{i+1} - s_i}} d_t g_t^1(s_i) + O(s - s_i) \tag{4.20}$$

and we write too

$$d_s x_t^N(s) = \frac{\mathrm{d}s}{\sqrt{s_{i+1} - s_i}} g_t^1(s_i) + \mathrm{d}s\, g_t^2(s_i) + \mathrm{d}s\, O(s - s_i). \tag{4.21}$$

The more singular term in D_i^N is

$$\int_{[0,1]\times[s_i,s_{i+1}]} \frac{s - s_i}{s_{i+1} - s_i} \langle g_t^1(s_i) B(x_t(s_i)), d_t x_t(s_i), g_t^1(s_i)\rangle = (s_{i+1} - s_i) \int_0^1 \langle B(x_t(s_i)), d_t x_t(s_i), (g_t^1(s_i))^2\rangle, \tag{4.22}$$

$(g_t^1(s_i))^2$ is a quadratic polynomial in $(g_t^1(s_i))$ and is a product of stochastic integrals. It is by the Itô formula an iterated integral of length 2 which has exactly the same behavior of $g_t^2(s_i)$, and we can apply the same procedures in order to estimate its contribution. Therefore this term converges in L^2.

The more singular term in E_i^N is

$$\int_{[0,1]\times[s_i,s_{i+1}]} \left\langle \omega(x_t(s_i)), \frac{s-s_i}{\sqrt{s_{i+1}-s_i}} d_t g_t^1(s_i), \frac{ds}{\sqrt{s_{i+1}-s_i}} g_t^1(s_i) \right\rangle$$

$$= (s_{i+1}-s_i) \int_0^1 \langle \omega(g_t(s_i)), d_t g_t^1(s_i), g_t^1(s_i) \rangle$$

$$= (s_{i+1}-s_i)(g_1(s_i))^2 \omega(x_1(s_i)) - \int_0^1 (g_t^1(s_i))^2 \omega'(x_t(s_i)) d_t x_t(s_i), \tag{4.23}$$

where $(g_t^1(s_i))^2$ is an homogeneous polynomial of order 2 in its components. We can treat this term as the contribution of $g_t^2(s_i)$. ■

We consider a more intrinsic approximation of $x_t(s)$ between $x_t(s_{i+1})$ and $x_t(s_i)$. As in the previous part, we choose

$$F_N[s, x_t(s_i), x_t(s_{i+1})] = \exp_{x_t(s_i)}\left[\frac{s-s_i}{s_{i+1}-s_i} (x_t(s_{i+1}) - x_t(s_i)) \right] = \tilde{x}_t^N(s) \tag{4.24}$$

and we can show the following theorem.

Theorem IV.2: When $N \to \infty$, the random ordinary two parameter integral $\int_0^1 \int_{S^1} \langle \omega(\tilde{x}_t^N(s)), d_t \tilde{x}_t^N(s), d_s \tilde{x}_t^N(s) \rangle$ tends in L^2 to the stochastic Stratonovitch integral $\int_0^1 \int_{S^1} \langle \omega(x_t(s)), d_t x_t(s), d_s x_t(s) \rangle$.

Remark: We ignore if the double stochastic integral of Theorem IV.2 is equal to the stochastic integral of Proposition IV.1. In the sequel, we will use the version of theorem IV.2, because it is an intrinsic version.

Remark: We have an analoguous theorem when the 2-form ω depends smoothly of a finite dimensional parameter.

V. DELIGNE COHOMOLOGY

In this part, we do not suppose that Hypothesis K is satisfied, but the stochastic integrals we consider are almost surely defined by (2.10).

Let us consider the product of loop spaces $L(M) \times L(M)$. We endow it with the probability law of $(x_2^1(.), x_2^2(.))$ We will construct a line bundle over $L(M) \times L(M)$, by using the arguments of Felder–Gawedzki–Kupiainen.[26] We will not suppose that the loop space is simply connected, because our construction is motivated by Deligne cohomology.[25]

Let O_α be a cover of M by convex contractibles open subsets of M, such that $O_{\alpha_1,\alpha_2} = O_{\alpha_1} \cap O_{\alpha_2}$, $O_{\alpha_1,\alpha_2,\alpha_3} = O_{\alpha_1} \cap O_{\alpha_2} \cap O_{\alpha_3}$ and $O_{\alpha_1,\alpha_2,\alpha_3,\alpha_4} = O_{\alpha_1} \cap O_{\alpha_2} \cap O_{\alpha_3} \cap O_{\alpha_4}$.

Let $g_{\alpha_1,\alpha_2,\alpha_3}$ be a family of smooth functions S^1-valued which are multiplicatively antisymmetric in $\alpha_1, \alpha_2, \alpha_3$ and such that

$$g_{\alpha_1,\alpha_2,\alpha_3} g_{\alpha_0,\alpha_2,\alpha_3}^{-1} g_{\alpha_0,\alpha_1,\alpha_3} g_{\alpha_0,\alpha_1,\alpha_3}^{-1} = 1 \tag{5.1}$$

over $O_{\alpha_0,\alpha_1,\alpha_2,\alpha_3}$.

Also, let $\eta_{\alpha_1,\alpha_2} = -\eta_{\alpha_2,\alpha_1}$ be a smooth real 1-form over O_{α_1,α_2} such that

$$\eta_{\alpha_1,\alpha_2} - \eta_{\alpha_0,\alpha_2} + \eta_{\alpha_0,\alpha_1} = 1/i g_{\alpha_0,\alpha_1,\alpha_2}^{-1} dg_{\alpha_0,\alpha_1,\alpha_2} \tag{5.2}$$

on $O_{\alpha_0,\alpha_1,\alpha_2}$. Finally, we suppose that ω_α is a real 2-form defined on O_α such that

$$\omega_{\alpha_1} - \omega_{\alpha_0} = \mathrm{d}\eta_{\alpha_0,\alpha_1} \tag{5.3}$$

on O_{α_0,α_1}. These data define an element of the second Deligne hypercohomology group of the manifold (see Ref. 25, pp. 250–251). If we look at the 3-form $\mathrm{d}\omega_\alpha = \omega$, they patch together by (5.3) in order to give a closed 3-form ω on M.

Consider a system (l,v) which constitutes a triangulation of the circle S^1 such that b is an edge and $v \in \partial b$ is one of its vertex. To each edge, we associate an element α_b and to each vertex v we associate a number α_v such that the following hold: we consider the set of loops γ such that for each edge $b\,\gamma(b) \subseteq O_{\alpha_b}$ and such for all vertices $\gamma(v) \in O_{\alpha_v}$. This defines an open subset

$$U_{A,\alpha} = \{\gamma : S^1 \to M | \gamma(b) \subseteq O_{\alpha_b}, \gamma(v) \in O_{\alpha_v} \quad \text{for each } (b,v) \in A\}. \tag{5.4}$$

If we consider the product of the loop space, we consider the product $U_{A,\alpha} \times U_{A',\alpha'}$ which constitutes a cover by open subsets of the product of the loop space.

We would like to define a system of transition maps of $(U_{A_1\alpha_1} \times U_{A_1',\alpha_1'}) \cap (U_{A_2,\alpha_2}) \times U_{A_2',\alpha_2'}$. Let us define the refined triangulation of both triangulation A_1 and A_2 by $(b,\overline{v})$, $\overline{v} \in \partial b$, the triangulation A_1 by (b_i,v_i), $v_i \in \partial b_i$ and the second triangulation by (b_2,v_2), $v_2 \in \partial b_2$. Let us set $\alpha_{\overline{b}}^1 = \alpha_{b_1}^1$ and $\alpha_{\overline{b}}^2 = \alpha_{b_2}^2$. If $\overline{v}$ is a vertex of the new triangulation, we set $\alpha_{\overline{v}}^1 = \alpha_{v_1}^1$ if $\overline{v} = v_1$ and $\alpha_{\overline{v}}^1 = \alpha_{b_1}^1$ if $\overline{v}$ is in the interior point of the interval b_1. We define $\alpha_{\overline{v}}^2$ analoguously. The system of transition functionals of the stochastic line bundle over $L(M) \times L(M)$ is defined by

$$\rho = \rho_{A_1,\alpha_1,A_2,\alpha_2}(x_2^1)\rho_{A_1',\alpha_1',A_2',\alpha_2'}(x_2^2), \tag{5.5}$$

where

$$\rho_{A_1,\alpha_1,A_2,\alpha_2}(x_2^1) = \exp\left[i \sum_b \int_{\overline{b}} \eta_{\alpha_{\overline{b}^1}\alpha_{\overline{b}^2}}(d_s x_2^1(s)) \right] \prod_{\overline{v},b,\overline{v} \in \partial b} \frac{g_{\alpha_{\overline{v}}^1 \alpha_{\overline{v}}^2 \alpha_{\overline{b}}^2}}{g_{\alpha_{\overline{v}}^1 \alpha_{\overline{b}}^1 \alpha_{\overline{b}}^2}}(x_2^1(v)) \tag{5.6}$$

and the analoguous formula holds for $\rho_{A_1',\alpha_1',A_2',\alpha_2'}(x_2^2)$. The transition functions are almost surely defined. So we cannot define $\xi = \xi_1 \otimes \xi_2$, but we will follow the lines of Ref. 29 in order to define the Hilbert space of L^2 sections of it.

Definition V.2: A L^2 section of the line bundle $\xi_1 \otimes \xi_2$ over $L(M) \times L(M)$ is a system of functionals over $U_{A,\alpha} \times U_{A',\alpha'}$ $f_{A,\alpha,A,\alpha'}$ submitted to the relations: almost surely, over $(U_{A_1,\alpha_1} \times U_{A_1' \times \alpha_1'}) \cap (U_{A_2,\alpha_2} \times U_{A_2',\alpha_2'})$, we get $f_{A_1,\alpha_1,A_1',\alpha_1'} = \rho f_{A_2,\alpha_2,A_2',\alpha_2'}$. We can define since ρ defined by (5.6) is of modulus 1 the norm of a section $|f|$. We suppose $E[|f|^2] < \infty$ in order to define the space of L^2 sections of $\xi_1 \otimes \xi_2$.

In order this definition has some consistency, we recall that almost surely over $(U_{A_1,\alpha_1} \times U_{A_1',\alpha_1'}) \cap (U_{A_2,\alpha_2} \times U_{A_2',\alpha_2'})$, we get

$$\begin{aligned} &\rho_{A_1,\alpha_1,A_2,\alpha_2}(x_2^1)\rho_{A_2,\alpha_2,A_1,\alpha_1}(x_2^1) = 1, \\ &\rho_{A_1',\alpha_1',A_2',\alpha_2'}(x_2^2)\rho_{A_2',\alpha_2',A_1',\alpha_1'}(x_2^2) = 1, \end{aligned} \tag{5.7}$$

and that on $U_{A_1,\alpha_1} \cap U_{A_2,\alpha_2} \cap U_{A_3,\alpha_3}$, we get almost surely

$$\rho_{A_1,\alpha_1,A_2,\alpha_2}(x_2^1)\rho_{A_2,\alpha_2,A_3,\alpha_3}(x_2^1)\rho_{A_3,\alpha_3,A_1,\alpha_1}(x_2^1) = 1. \tag{5.8}$$

This identity works still for the product of transition functions defined by $\rho_{A_1,\alpha_1,A_2,\alpha_2}(x_2^1)$ $\rho_{A_1',\alpha_1',A_2',\alpha_2'}(x_2^1)$.

In the previous definition, we have supposed that the section is almost surely defined over the product of random loops (x_2^1,x_2^2) and is (x_2^1,x_2^2) measurable. We can suppose that $f_{A,\alpha,A',\alpha'}$ depends from all the random pants, or if we choose $1 \leqslant t \leqslant 2$, $1 \leqslant t \leqslant 2$, it depends from all the paths between t and 2. $f_{A,\alpha,A',\alpha'}$ becomes an element of $L^2(\text{pant}) \otimes L^2(U_{A,\alpha}(x_2^1) \otimes U_{A',\alpha'}(x_2^1))$ and satisfies still to the consistency relations of Definition V.2. We can define the L^2 norm of the section f. This increases the degree of freedom and is done in order to define what is the parallel transport over the random path from (x_2^1,x_2^2) into the path (x_1^1,x_1^2). We will get a section of the bundle over $L_y(M) \times L_y(M)$, $\xi_1 \otimes \xi_2$ for the measure defined by (x_1^1,x_1^2), but with an extra degree of freedom,

that is the path between (x_2^1,x_2^2) to (x_1^1,x_1^2). In order to define the stochastic parallel transport from a random section over $\xi_1\otimes\xi_2$ over (x_2^1,x_2^2) to (x_1^1,x_2^1) along the path $t\to(x_t^1,x_t^2)$, we will use the double integral of the previous part.

Let us divise the time interval[1,2] into the stochastic intervals $[\tau_i,\tau_{i+1}[$ where (x_t^1,x_t^2) over $[\tau_i,\tau_{i+1}[$ the process (x_t^1,x_t^2) lives over some open subset $U_{A,\alpha}\times U_{A',\alpha'}$. We have described the time interval into a finite number of random intervals. Moreover, the times τ_i are stopping times.

Let us suppose that the parallel transport from $(x_{\tau_i}^1,x_{\tau_i}^2)$ to (x_1^1,x_1^2) is well defined. Let us call it $\tau_{1,\tau_i}=\tau_{1,\tau_i}^1\otimes\tau_{1,\tau_i}^2$ (the product formula will be explained by the next considerations). If $t\in[\tau_i,\tau_{i+1}[$, we have

$$\tau_{1,t}=\tau_{1,\tau_i}\left\{\exp\left[\sqrt{-1}\int_{\tau_i}^{t\wedge\tau_{i+1}}\sum_b\omega_{\alpha_b}(d_sx_t^1(s),d_tx_t^1(s))+\sqrt{-1}\sum_{v,b,v\in\partial b}\int_{\tau_i}^{t\wedge\tau_{i+1}}\eta_{\alpha_v,\alpha_b}(d_tx_t^1(v))\right]\right\}$$
$$\otimes\left\{\exp\left[\sqrt{-1}\int_{\tau_i}^{t\wedge\tau_{i+1}}\sum_{b'}\omega_{\alpha_{b'}}(d_sx_t^2(s),d_tx_t^2(s))+\sqrt{-1}\int_{\tau_i}^{t\wedge\tau_{i+1}}\sum_{v',b',v'\in\partial b'}\eta_{\alpha_v,\alpha_b}(d_tx_t^2(v))\right]\right\}. \tag{5.9}$$

Let us remark that by induction the parallel transport is of modulus one (5.9). The rules given in the previous parts of approximation of Stratonovitch integrals allow to state this definition.

Theorem V.3: If f is a section of $L(M)\times L(M)$ for the measure of (x_2^1,x_2^2) and measurable for (x_2^1,x_2^2), $\tau_{1,2}f$ is a section of $\xi_1\otimes\xi_2$ for the measure of (x_1^1,x_2^1) (but in an extended sense, because there are many paths joining (x_2^1,x_2^2) to (x_1^1,x_1^2). Moreover,

$$E[|\tau_{1,2}f|^2]=E[|f|^2]. \tag{5.10}$$

(We refer to Refs. 26 and 27 for analoguous results.)

Let us work in time 1. We consider the product of loop space $L_y(M)\times L_y(M)$ for the measure (x_1^1,x_1^2) and the loop $L(M)$ induced by concatenation of the two loops for the measure induced by x_1. This induces a map π,

$$L_y(M)\times L_y(M)\to L(M) \tag{5.11}$$

which preserves the measure. Over $L_y(M)\times L_y(M)$, we have the stochastic line bundle $\xi_1\otimes\xi_2$ and over $L(M)$ we have the stochastic line bundle ξ defined by the previous considerations for the random loop x_1.

For x_1, we define a triangulation by choosing vertices s_1 and s_2. We have $\gamma(s_1)=\gamma(s_2)=y\in O_{\alpha_y}$. We choose another triangulation (b^1,v^1) where we have chosen s_1 and s_2 among the vertices. For the first triangulation, we suppose $\gamma(b)\subseteq O_{\alpha_b}$ and $\gamma(v)\in O_{\alpha_v}$ where $O_{\alpha_{s_1}}=O_{\alpha_{s_2}}=\overline{O}$ is fixed, and for the second triangulation, we choose $\gamma(b')\subseteq O_{\alpha_{b'}}$ and $\gamma(v')\in O_{\alpha_{v'}}$ where $O_{\alpha_{s_1}}=O_{\alpha_{s_2}}=\overline{O}$ for the same open subset $\overline{O}$ than the first triangulation.

We deduce from the previous triangulation two triangulations of $L_y(M)$ and from the second triangulation two triangulations of $L_y(M)$. The transition map for the big loop space $L(M)$ is given by (5.6) where we replace $d_sx_2^1(s)$ by $d_sx_1(s)$ and $x_2^1(v)$ by $x_1(v)$ for the refined triangulation of the two big triangulations of the big circle. But it is almost surely equal to the product of the two transition functions where we consider the couple of loops $(x_1^1(s),x_2^1(s))$. This shows us that $\xi_1\otimes\xi_2=\pi^*\xi$. This means that a L^2 section of ξ over the random loops x_1 for $L(M)$ corresponds naturally to a L^2 section of $\xi_1\otimes\xi_2$ over $L_x(M)\times L_x(M)$ for the law (x_1^1,x_1^2) and the L^2 norms are conserved. We assimilate $\tau_{1,2}f$ to a section over x_1. Afterwards, we use the stochastic parallel transport from x_1 to x_0 $\tau_{0,1}$. We set $\tilde{f}=\tau_{0,1}\tau_{1,2}f$. Since x_0 is the constant loop $s\to x$, $\tilde{f}$ is a random variable.

Theorem V.4: $E[|\tilde{f}|^2]=E[|f|^2]$.

This comes from the fact that $\tau_{0,1}$ is a random isometry from the stochastic fiber of the bundle over the random loop x_1 to the fiber over the constant loop.

Remark: In order to define the connection form $\omega_{A,\alpha}$ over $U_{A,\alpha}$ of the stochastic bundle, we can consider the formal expression

$$\omega_{A,\alpha}=\sum_b \int_b \omega_{\alpha_b}(\mathrm{d}\gamma_s,X_s)+\sum_{v,b,v\in\partial b}\langle \eta_{\alpha_v,\alpha_b}(\gamma_v),X_v\rangle \tag{5.12}$$

(see Refs. 25–27) which can be treated by using the apparatus of the stochastic Chen–Souriau calculus. The curvature of this stochastic line bundle is the transgression of the 3-form ω, which can be treated by using the stochastic Chen–Souriau calculus, because we have line integrals in $\mathrm{d}_s x_t(s)$ (see Ref. 25), and because we can consider in the part II integral of a one-form which depends on a finite dimensional parameter.

Remark: For analoguous considerations with the measure of physicists, we refer to the work of Tsukuda.[51]

Remark: It is much more simpler to get pants by this procedure than by Dirichlet forms (see Refs. 52–55). The reader interested by various aspects and applications of infinite dimensional processes to physics can see the survey of Albeverio.[55]

(Received 21 August 2004; accepted 26 October 2004; published online 7 February 2005)

In this paper we extend the method for numerically stable calculation of the atomic integrals suggested in our previous paper for the *S*-states of two-electron atoms to the states with arbitrary total angular momenta. The extension consists in finding numerically stable forms of the solution of difference equations appearing in the calculation of the radial part of the atomic integrals. These equations become for some value of the independent variable homogenous and their solution in that region is described by one of the two linearly independent solutions. Modification of the method of the variation of constants for this special type of linear second order inhomogenous difference equations is suggested and applied. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1849811]

I. INTRODUCTION

This work grew out from the search for a numerically stable method of the solution of linear inhomogenous second order difference equations appearing in the calculation of the radial part of the atomic integrals.[1] Generally, once we know one of the two linearly independent solutions of the homogenous equation, the second solution can be obtained by the method of the reduction of order.[2] The solution of the inhomogenous equation is then obtained by the method of the variation of constants.[2] However, it turns out that for the difference equations appearing in the calculation of the atomic integrals this general well-known procedure is of little use in its standard form. The reason is that these difference equations become for certain values of the independent variable homogenous and their solution in that region is described by one of the two linearly independent solutions. This behavior results from the general formula by several cancellations of large numbers. If these cancellations are left on the computer working, for example, in double precision arithmetics, totally wrong results are obtained.

Therefore, a general method for obtaining a numerically stable solution of this type of difference equation is given in this paper. The method is applied to the special case of difference equations appearing in the calculation of the radial part of the atomic integrals. Thus, the method suggested in our previous paper for the *S*-states of the two-electron atoms is extended here to the states with arbitrary total angular momenta. Since in general there are at most two-electron interactions, these results can be extended to all atoms and more generally to all one-center integrals.

The paper is organized as follows. In Sec. II we briefly summarize the calculation of the atomic integrals via the multipole expansion of Coulomb potential. Here, we proceed along the lines of our previous paper.[1] After integrating out angular degrees of freedom, we use analog of the Wigner–Eckart theorem for the radial functions. This reduces the integration over four radial functions to the integration over two radial functions. Then we write down a generalization of the difference equations for the reduced radial integrals derived in Ref. 1 for the *S*-states to the states of arbitrary total angular momenta of the electrons. The main difference is the fact that for the states of the nonzero total angular momentum the difference equations are inhomogenous. In Sec. III we discuss solutions of these equations. We present results of numerical experiments that show

that the difference equations are in a region where they are homogenous described by just one of the two linearly independent solutions. In Sec. IV we first briefly summarize general methods of the reduction of order and the variation of constants. We modify the method of the variation of constants for the cases when the second of the two linearly independent solutions of homogenous equations is obtained by the method of the reduction of order. The form proposed by us is more suitable for computational purposes. We then turn our attention to the special type of equations appearing in the calculation of the atomic integrals and derive numerically stable forms of their solution. In Sec. V we apply the general method of Sec. IV to the difference equations for the reduced radial integrals and test it for the case of very large quantum numbers. In Sec. VI, a summary of the achieved results and perspectives of their further applications are given. In the Appendix computationally suitable forms of the hypergeometric functions needed in Secs. II and III are given.

II. CALCULATION OF THE ATOMIC INTEGRALS

In this section we derive the difference equations for the reduced radial part of the atomic integrals. The derivation of these equations was given in great detail in Ref. 1 for the *S*-states of two-electron atoms. What is difficult in the extension of the method described in Ref. 1 for the *S*-states to the general state is the *solution* of these difference equations, not their derivation. Therefore, we shall proceed very briefly.

We search for the exact two-electron wave function by the expansion into the symmetry adapted products of the one-electron wave functions

$$|i\rangle = 2^{-(1+\delta_{l_{i1},l_{i2}}\delta_{n_{i1},n_{i2}})/2}[R_{n_{i1},l_{i1}}(r_1)R_{n_{i2},l_{i2}}(r_2)|(l_{i1},l_{i2})L\rangle \pm R_{n_{i2},l_{i2}}(r_1)R_{n_{i1},l_{i1}}(r_2)|(l_{i2},l_{i1})L\rangle]. \tag{1}$$

Here, the states $|(l_1,l_2)L\rangle$ are the eigenfunctions of the square and the third component of the sum of the angular momenta of two electrons

$$|(l_1,l_2)L\rangle = \sum_{m_1=-l_1}^{l_1} (l_1,m_1,l_2,M-m_1|L,M)|l_1,m_1\rangle^{(1)}|l_2,M-m_1\rangle^{(2)}, \tag{2}$$

where $(\,|\,)$ denotes Clebsch–Gordan coefficients. Their explicit form is given, for example, in Refs. 3–5. The radial functions $R_{n,l}$ are eigenfuctions of one of the generators of the so(2,1) algebra[1] and will be described in greater detail later.

A. Multipole expansion

The matrix elements of the Coulomb interaction, i.e., repulsion integrals, are calculated by means of the multipole expansion of the operator r_{12}^{-1},

$$r_{12}^{-1} = \frac{1}{r_>}\sum_{l=0}^{\infty}\left(\frac{r_<}{r_>}\right)^l P_l(\vec{n}_1 \,.\, \vec{n}_2), \tag{3}$$

where $r_< = \min(r_1,r_2)$ and $r_> = \max(r_1,r_2)$, $P_l(x)$ denotes the Legendre polynomials. With the usual definition of the inner product (to avoid confusion we note that the inner product used in Ref. 1 differs from the usual one by the factor r^{-1}) and multipole expansion (3) the matrix elements of the operator r_{12}^{-1} between the states (1) can be written as

$$\langle i|r_{12}^{-1}|j\rangle = 2^{-(\delta_{n_{i1},n_{i2}}\delta_{l_{i1},l_{i2}}+\delta_{n_{j1},n_{j2}}\delta_{l_{j1},l_{j2}})/2}\left[\sum_{l=\max(|l_{i1}-l_{j1}|,|l_{i2}-l_{j2}|)}^{\min(l_{i1}+l_{j1},l_{i2}+l_{j2})} \theta_{l_{i1},l_{i2},l_{j1},l_{j2},l} X^{l_{i1},l_{i2},l_{j1},l_{j2},l}_{n_{i1},n_{i2},n_{j1},n_{j2}}\right.$$
$$\left. \pm \sum_{l=\max(|l_{i1}-l_{j2}|,|l_{j1}-l_{i2}|)}^{\min(l_{i1}+l_{j2},l_{j1}+l_{i2})} \theta_{l_{i1},l_{i2},l_{j2},l_{j1},l} X^{l_{i1},l_{i2},l_{j2},l_{j1},l}_{n_{i1},n_{i2},n_{j2},n_{j1}}\right], \tag{4}$$

where l in the summation increases by 2.

The angular part $\theta_{l_{i1},l_{i2},l_{j1},l_{j2},l}$ corresponds to the matrix elements of the Legendre polynomials $P_l(\vec{n}_1.\vec{n}_2)$ between the coupled states (2),

$$\begin{aligned}\theta_{l_{i1},l_{i2},l_{j1},l_{j2},l} &= \langle (l_{i1},l_{i2})L|P_l(\vec{n}_1\,.\,\vec{n}_2)|(l_{j1},l_{j2})L\rangle \\ &= (-1)^{L+l+l_{i1}-l_{j1}+l_{i2}-l_{j2}}\frac{\sqrt{(2l_{i1}+1)(2l_{i2}+1)(2l_{j1}+1)(2l_{j2}+1)}}{2l+1} \\ &\quad\times W(l_{i1},l_{j1},l_{i2},l_{j2},l,L)(l_{i1},0,l_{j1},0|l,0)(l_{i2},0,l_{j2},0|l,0),\end{aligned} \tag{5}$$

where $W(a,b,c,d;e,f)$ are the so-called Racah coefficients and their explicit form is given, for example, in Refs. 4 and 5. The Clebch–Gordan coefficients $(a,0,b,0|c,0)$ are zero unless a, b, and c satisfy the triangle inequality $|a-b|\leqslant c\leqslant a+b$ and $a+b+c$ is even. This reduces the infinite sum in Eq. (3) to the finite number of terms in Eq. (4).

The radial part of the integration reads

$$\begin{aligned}X^{l_{i1},l_{i2},l_{j1},l_{j2},l}_{n_{i1},n_{i2},n_{j1},n_{j2}} &= \int_0^\infty \mathrm{d}r_1\int_0^\infty \mathrm{d}r_2\, r_1^2 r_2^2 R_{n_{i1},l_{i1}}(r_1)R_{n_{i2},l_{i2}}(r_2)\frac{r_<^l}{r_>^{l+1}}R_{n_{j1},l_{j1}}(r_1)R_{n_{j2},l_{j2}}(r_2) \\ &= \int_0^\infty \mathrm{d}r_1\, R_{n_{i1},l_{i1}}(r_1)R_{n_{j1},l_{j1}}(r_1)r_1^{l+2}\int_{r_1}^\infty \mathrm{d}r_2\, R_{n_{i2},l_{i2}}(r_2)R_{n_{j2},l_{j2}}(r_2)r_2^{-l+1} \\ &\quad+\int_0^\infty \mathrm{d}r_1\, R_{n_{i1},l_{i1}}(r_1)R_{n_{j1},l_{j1}}(r_1)r_1^{-l+1}\int_0^{r_1} \mathrm{d}r_2\, R_{n_{i2},l_{i2}}(r_2)R_{n_{j2},l_{j2}}(r_2)r_2^{l+2}.\end{aligned} \tag{6}$$

B. Reduction of the radial integrals

Using the analog of the Wigner–Eckart theorem for so(2,1) algebra[1] we can write the integrals over four radial functions as a linear combination of the integrals over two radial functions

$$\begin{aligned}X^{l_{i1},l_{i2},l_{j1},l_{j2},l}_{n_{i1},n_{i2},n_{j1},n_{j2}} &= 2^{-2}A^{l_{i1},l_{j1}}_{n_{i1},n_{j1}}A^{l_{i2},l_{j2}}_{n_{i2},n_{j2}}\sum_{n_1=-1}^{n_{i1}+n_{j1}-l_{i1}-l_{j1}-2} c^{l_{i1},l_{j1}}_{n_{i1},n_{j1},n_1}\sum_{n_2=-1}^{n_{i2}+n_{j2}-l_{i2}-l_{j2}-2} c^{l_{i2},l_{j2}}_{n_{i2},n_{j2},n_2} \\ &\quad\times \tilde{Q}^{l_{i1}+l_{j1},l_{i2}+l_{j2},l}_{n_{i1}+n_{j1}-1-n_1,n_{i2}+n_{j2}-1-n_2},\end{aligned} \tag{7}$$

where the multiplicative factor $A^{l_i,l_j}_{n_i,n_j}$ equals

$$A^{l_i,l_j}_{n_i,n_j} = \frac{2^{1-n_i-n_j}(n_i+n_j-l_i-l_j-2)!(n_i+l_i+n_j+l_j)!}{(n_i-l_i-1)!(n_j-l_j-1)!}\sqrt{\frac{(n_i-l_i-1)!}{(n_i+l_i)!}}\sqrt{\frac{(n_j-l_j-1)!}{(n_j+l_j)!}}. \tag{8}$$

The coefficients $c^{l_i,l_j}_{n_i,n_j,n}$ of the linear combination read

$$c^{l_i,l_j}_{n_i,n_j,n} = C^{l_i,l_j}_{n_i,n_j,n} - \frac{(n_i+n_j-l_i-l_j-2-n)}{(n_i+n_j+l_i+l_j-n-1)}C^{l_i,l_j}_{n_i,n_j,n+1}, \tag{9}$$

where the coefficients $C^{l_i,l_j}_{n_i,n_j,n}$ are given as

$$C^{l_i,l_j}_{n_i,n_j,n} = \frac{F(-n_i+l_i+1,-n;-n_i-n_j+l_i+l_j+2;2)F(-n_i-l_i,-n;-n_i-n_j-l_i-l_j;2)}{(n_i+l_i+n_j+l_j-n-1)!n!} \tag{10}$$

for $n\geqslant 0$ and equal zero otherwise. Here, $F(\alpha,\beta;\gamma;z)$ denotes the hypergeometric function (see, e.g., Refs. 6–8). We note that Eq. (43) in Ref. 1 is incorrect.

$\tilde{Q}^{L_1,L_2,l}_{N_1,N_2}$ denotes the integrals over two radial functions

$$\tilde{Q}^{L_1,L_2,l}_{N_1,N_2} = \tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2} + \tilde{Q}^{-,L_1,L_2,l}_{N_1,N_2}. \tag{11}$$

Here,

$$\tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2} = \int_0^\infty \mathrm{d}r_1\, \tilde{R}_{N_1,L_1}(2r_1) r_1^{l+1} \int_{r_1}^\infty \mathrm{d}r_2\, \tilde{R}_{N_2,L_2}(2r_2) r_2^{-l} \tag{12}$$

and

$$\tilde{Q}^{-,L_1,L_2,l}_{N_1,N_2} = \int_0^\infty \mathrm{d}r_1\, \tilde{R}_{N_1,L_1}(2r_1) r_1^{-l} \int_0^{r_1} \mathrm{d}r_2\, \tilde{R}_{N_2,L_2}(2r_2) r_2^{l+1}, \tag{13}$$

where $\tilde{R}_{N,L}(r)$ differs from $R_{N,L}(r)$ by the normalization factor

$$\tilde{R}_{N,L}(r) = 2\sqrt{\frac{(N+L)!}{(N-L-1)!}} R_{N,L}(r). \tag{14}$$

We note that due to the selection rules for the Clebsch–Gordan coefficients mentioned earlier the difference $|L_1 - L_2|$ is always even. Moreover, the sum $L_1 + L_2 + l$ must be even as well.

C. Difference equations for the reduced integrals

Proceeding in complete analogy with the considerations made in Ref. 1 we obtain the following difference equations for the integrals $\tilde{Q}^{\pm,L_1,L_2,l}_{N_1,N_2}$,

$$(N_2 - L_2)\tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2+1} - (N_2 + L_2)\tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2-1} - 2l\tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2} = -p^{L_1,L_2}_{N_1,N_2} \tag{15}$$

and

$$(N_1 - L_1)\tilde{Q}^{+,L_1,L_2,l}_{N_1+1,N_2} - (N_1 + L_1)\tilde{Q}^{+,L_1,L_2,l}_{N_1-1,N_2} + 2(l+1)\tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2} = p^{L_1,L_2}_{N_1,N_2}. \tag{16}$$

The values of $\tilde{Q}^{-,L_1,L_2,l}_{N_1,N_2}$ are obtained from the relation[1]

$$\tilde{Q}^{-,L_1,L_2,l}_{N_1,N_2} = \tilde{Q}^{+,L_2,L_1,l}_{N_2,N_1}. \tag{17}$$

Here, the right-hand side of equations $p^{L_1,L_2}_{N_1,N_2}$ equals

$$p^{L_1,L_2}_{N_1,N_2} = \int_0^\infty \mathrm{d}r\, r^2 \tilde{R}_{N_1,L_1}(2r)\tilde{R}_{N_2,L_2}(2r). \tag{18}$$

Using the explicit form of the radial functions,[9]

$$\tilde{R}_{n,l}(r) = 2^2 e^{-r}(2r)^l L^{2l+1}_{n-l-1}(2r), \tag{19}$$

and the expression for the generalized Laguerre polynomials (see, e.g., Refs. 6–8)

$$L^\alpha_K(r) = \frac{1}{K!} e^r r^{-\alpha} \frac{d^K}{\mathrm{d}r^K}(e^{-r} r^{K+\alpha}), \tag{20}$$

we obtain for $L_1 > L_2 + 1$ integrating by parts (see, e.g., Ref. 5),

$$p_{N_1,N_2}^{L_1,L_2} = \frac{(L_1+L_2+2)!}{2} \sum_{q=\max(0,N_2-L_1-2)}^{\min(N_1-L_1-1,N_2-L_2-1)} (-1)^{N_2-L_2-1-q} \times \binom{N_1-L_2-q-3}{L_1-L_2-2} \binom{L_1+L_2+2+q}{L_1+L_2+2} \binom{L_1-L_2+1}{N_2-L_2-1-q} \tag{21}$$

for $N_2 \leqslant N_1+1$ and

$$p_{N_1,N_2}^{L_1,L_2} = 0 \tag{22}$$

otherwise. The values of $p_{N_1,N_2}^{L_1,L_2}$ for $L_2 > L_1+1$ are obtained from the obvious symmetry $p_{N_1,N_2}^{L_1,L_2} = p_{N_2,N_1}^{L_2,L_1}$, see Eq. (18).

Using difference equations (15) and (16) the integrals are reduced to the integrals over nodeless functions that can be calculated analytically,[1]

$$\tilde{Q}_{L_1+1,L_2+1}^{+,L_1,L_2,l} = 2^{-1}(L_1+L_2+1)!F(1,-L_2+l;-L_1-L_2-1;2). \tag{23}$$

The difference equations (15) and (16) were programmed in MAPLE in form of the recursive algorithm and solved both in rational and 16 digit arithmetics. From these numerical experiments we found that for large quantum numbers N_1, N_2, L_1, and L_2 numerical instabilities appear. Moreover, after some time the recursive algorithm took so much computer memory that further computation was not feasible.

Therefore, we search for the explicit solution of Eqs. (15) and (16). This is done in the following section.

III. SOLUTION OF DIFFERENCE EQUATIONS

In this section we discuss the explicit solution of Eqs. (15) and (16). We argue that the method of variation of constants cannot be used in its standard form and discuss the result of our numerical experiments. These experiments show that Eqs. (15) and (16) are in the region where they are homogenous described by just one of the two linearly independent solutions.

A. The extension of the method given in Ref. 1

In our previous paper[1] we solved Eqs. (15) and (16) for the *S*-states. It follows from the properties of the Clebsch–Gordan coefficients that we must consider the only case $L_1=L_2=L$. In such a case the situation is simplified by virtue of the fact that the right-hand side $p_{N_1,N_2}^{L,L}$ vanishes whenever $|N_1-N_2|>1$.[1] That means that Eqs. (15) and (16) are for most of the values N_1 and N_2 homogenous. Therefore, it was sufficient to find two linearly independent solutions (fundamental system) of homogenous equations (15) and (16) for $l<L$. The two linearly independent solutions of homogenous equation (15) are

$$a_{N_2} = (-1)^{N_2-L_2-1}F(N_2-L_2,-L_2+l;-2L_2;2) \tag{24}$$

and

$$b_{N_2} = F(N_2-L_2,-L_2-l;-2L_2;2). \tag{25}$$

The two linearly independent solutions of the homogenous equation (16) are

$$a_{N_1} = F(N_1-L_1-1,-L_1+l+1;-2L_1;2) \tag{26}$$

and

$$b_{N_1} = (-1)^{N_1-L_1-1} F(N_1 - L_1, -L_1 - l - 1; -2L_1, 2). \tag{27}$$

For $l=L$, behavior of Eqs. (15) and (16) was so simple that it was possible to guess the result directly from the numerical analysis.

The task of solving Eqs. (15) and (16) is therefore twofold.

First, to determine two linearly independent solutions of homogenous equations (15) and (16) in the cases when $l=\min(L_1,L_2)$. In these cases solutions are not hypergeometric functions. In the Appendix we give a method for finding the solution of Eqs. (15) and (16) in terms of the power series in N_1 or N_2. For $l<\min(L_1,L_2)$ we obtain in this way an alternative expression for the hypergeometric functions. For $l=\min(L_1,L_2)$ this method yields at least one of the two linearly independent solutions. The second solution is found by the method of the reduction of order described in Sec. IV A below.

Second, the fundamental system is used for the solution of inhomogenous equations by the method of the variation of constants. One possibility is to apply this method to Eq. (16) and fix constants on the values $\tilde{Q}^{+,L_1,L_2,l}_{L_1+1,N_2}$ and $\tilde{Q}^{+,L_1,L_2,l}_{L_1+2,N_2}$. Then we apply the method first to Eq. (15) for $N_1=L_1+1$ and fix constants on the values of $\tilde{Q}^{+,L_1,L_2,l}_{L_1+1,L_2+1}$ and $\tilde{Q}^{+,L_1,L_2,l}_{L_1+1,L_2+2}$. Second, we apply the method to Eq. (16) for $N_1=L_1+2$ and fix constants on the values of $\tilde{Q}^{+,L_1,L_2,l}_{L_1+2,L_2+1}$ and $\tilde{Q}^{+,L_1,L_2,l}_{L_1+2,L_2+2}$. Such solution, however, is neither fast nor numerically stable. The reason is that solution of Eqs. (15) and (16) is simplified by virtue of the fact that these equations become homogenous for $L_1<L_2$ and $N_1>N_2+1$ or $L_1>L_2$ and $N_2>N_1+1$, see Eq. (22). Further simplifications were found from numerical experiments given below. All these simplifications must be carefully examined and taken into account to get numerically stable formulas.

B. Numerical experiments

We found that Eq. (15) can be for $L_1>L_2$ and $N_2>N_1+1$ described by just one of the two linearly independent solutions,

$$Q^{+,L_1,L_2,l}_{N_1,N_2} = K(N_1,L_1,L_2,l) a_{N_2}, \tag{28}$$

where a_{N_2} is given by Eq. (24). This equation holds for $l<L_2$. For $l=L_2$ the dependence of $Q^{+,L_1,L_2,L_2}_{N_1,N_2}$ on N_2 can be described as

$$Q^{+,L_1,L_2,L_2}_{N_1,N_2} = K(N_1,L_1,L_2)(-1)^{N_2-L_2-1}. \tag{29}$$

Equation (16) behaves in the same way for $L_2>L_1$ and $N_1>N_2+1$,

$$Q^{+,L_1,L_2,l}_{N_1,N_2} = K(N_2,L_1,L_2,l) a_{N_1}, \tag{30}$$

where a_{N_1} is given by Eq. (26). This equation holds for $l<L_1$. For $l=L_1$ and $N_1>N_2$ we found

$$Q^{+,L_1,L_2,L_1}_{N_1,N_2} = 0. \tag{31}$$

These results show that Eq. (15) is for $L_1>L_2$ and $N_2>N_1+1$ described by just *one* of the two linearly independent solutions. Equation (16) behaves in this way for $L_1<L_2$ and $N_1>N_2+1$. A consequence of this is that although Eqs. (15) and (16) are three term recursion relations we need in the case of Eq. (15) for $L_1>L_2$ and in the case of Eq. (16) for $L_1<L_2$ just *one* initial condition instead of two. In the case of Eq. (16) for $L_1<L_2$ and $l=L_1$ we do not need initial conditions at all. From numerical experiments given in Sec. V below, we were able to determine these initial conditions, that means to determine behavior of $\tilde{Q}^{+,L_1,L_2,l}_{N_1,L_2+1}$ for $L_1>L_2$ and $\tilde{Q}^{+,L_1,L_2,l}_{L_1+1,N_2}$ for $L_1<L_2$ and $l<L_1$.

This simplifies the situation tremendously because it means that *instead of solving both Eqs. (16) and (15) simultaneously, we must solve only Eq. (16) for $L_1<L_2$ and Eq. (15) for $L_1>L_2$.*

As it is clear from the above discussion we need modification of the method of the variation of constants for the case when one of the solutions is obtained by the method of the reduction of order [the case $l=\min(L_1,L_2)$] and for special types of equations when for some value of independent variable equations become homogenous and their solution in that region is described by one of the two linearly independent solutions [Eq. (16) for $L_1<L_2$ and Eq. (15) for $L_1>L_2$]. A general theory of the variation of constants for these cases is given in the following section.

IV. GENERAL THEORY

In this section a general modification of the method of variation of constants is described. We consider general linear second order inhomogenous difference equations for the discrete function f_n,

$$f_{n+1} + q_n f_n + r_n f_{n-1} = s_n. \tag{32}$$

We assume that $f_n=0$ for $n<L+1$ where L is integer and that $s_n=0$ for all $n>M+1$. Equation (15) is obtained from this general equation by setting $n=N_2$, $L=L_2$, $M=N_1$, and $f_{N_2}=\tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2}$. Equation (16) is obtained from this general equation by setting $n=N_1$, $L=L_1$, $M=N_2$, and $f_{N_1}=\tilde{Q}^{+,L_1,L_2,l}_{N_1,N_2}$. With these assignments we have for both cases

$$r_n = -\frac{n+L}{n-L}. \tag{33}$$

We first show the method of the reduction of order. This is not new, but for the sake of further considerations we describe it in greater detail. Then we summarize the method of the variation of constants and modify it for the cases when one of the solutions was obtained by the reduction of order and for special types of equations appearing in the calculation of atomic integrals.

A. Reduction of order

Let a_n be a solution of the homogenous equation

$$a_{n+1} + q_n a_n + r_n a_{n-1} = 0. \tag{34}$$

The second linearly independent solution can be found by the method of the reduction of order. We search for it in the form

$$b_n = (x_n - x_L)a_n. \tag{35}$$

Inserting it into homogenous equation (32) (with $s_n=0$) and using Eq. (34) we obtain after some manipulation

$$d_{n+1} = r_n \frac{a_{n-1}}{a_{n+1}} d_n, \tag{36}$$

where

$$d_n = x_n - x_{n-1}. \tag{37}$$

Considering the last equation successively for descending n we get

$$x_j - x_n = \sum_{i=n+1}^{j} d_i. \tag{38}$$

Considering Eq. (36) successively for descending n we get

$$d_n = \prod_{k=n-m}^{n-1} r_k \frac{a_{n-m}a_{n-m-1}}{a_n a_{n-1}} d_{n-m}. \tag{39}$$

Since $a_n=0$ for $n<L+1$ we set $n-m-1=L+1$ in the last equation. Then we obtain for d_n,

$$d_n = \frac{\prod_{k=L+2}^{n-1} r_k}{a_n a_{n-1}} a_{L+2}a_{L+1}d_{L+2}. \tag{40}$$

Inserting this equation into Eq. (38) we get finally

$$x_j - x_n = a_{L+2}a_{L+1}d_{L+2} \sum_{i=n+1}^{j} \frac{\prod_{k=L+2}^{i-1} r_k}{a_i a_{i-1}}. \tag{41}$$

B. Variation of constants

Having two linearly independent solutions a_n and b_n of the homogenous equation a general solution of the inhomogenous equation (32) is obtained by the method of variation of constants[2]

$$f_n = c_1 a_n + c_2 b_n + \sum_{j=L+2}^{n-1} T_j (b_j a_n - a_j b_n). \tag{42}$$

Here, T_j denotes the ratio

$$T_j = \frac{s_j}{W_j}, \tag{43}$$

where W_j is the Wronskian of the solutions

$$W_j = a_{j+1}b_j - a_j b_{j+1}. \tag{44}$$

The constants c_1 and c_2 in Eq. (42) are fixed by the initial values f_{L+1} and f_{L+2}.

For further considerations we derive an alternative form of the Wronskian W_j, see also Ref. 2. Inserting b_j from Eq. (35) we rewrite Eq. (44) into the form

$$W_j = -a_{j+1}a_j(x_{j+1} - x_j). \tag{45}$$

Inserting the difference $x_{j+1}-x_j$ from Eq. (41) into the last equation we obtain

$$W_j = -a_{L+2}a_{L+1}d_{L+2} \prod_{k=L+2}^{j} r_k. \tag{46}$$

Since

$$W_{L+1} = -a_{L+2}a_{L+1}d_{L+2} \tag{47}$$

we can write

$$W_j = W_{L+1} \prod_{k=L+2}^{j} r_k. \tag{48}$$

By means of Eq. (47) we can rewrite also Eq. (41) into the form

$$x_j - x_n = -W_{L+1} \sum_{i=n+1}^{j} \frac{\prod_{k=L+2}^{i-1} r_k}{a_i a_{i-1}}. \tag{49}$$

We note that, quite generally, formula (42) can be set into an alternative form. Inserting b_n from Eq. (35) we get

$$f_n = a_n[c_1 + c_2(x_n - x_L) + \sum_{j=L+2}^{n-1} T_j a_j (x_j - x_n)], \tag{50}$$

where the difference $x_j - x_n$ is given by Eq. (49). This form of the solution is likely to be less numerically unstable than the form (42), especially in the cases where one of the solutions was obtained by the method of the reduction of order. The reason is that in Eq. (42) we subtract the numbers $b_j a_n$ and $a_j b_n$. Inserting b_j from Eq. (35) we see that we subtract in fact $a_j a_n (x_j - x_L)$ and $a_j a_n (x_n - x_L)$. These two numbers can be very large especially for large n and j. Therefore their subtraction can cause a loss of significant digits. The advantage of Eq. (50) is that we directly calculate the *result* of the subtraction.

C. Special type of equations

Until now, our considerations were quite general. Now we turn to the special type of Eq. (32) for which $s_n = 0$ for all $n > M+1$ where M is integer and the solution of Eq. (32) in this region is fully described by just *one* of the two linearly independent solutions of the homogenous equation

$$f_n = K a_n, \tag{51}$$

where K is independent on n. Comparing Eqs. (50) and (51) we get

$$K = c_1 + (x_n - x_L)c_2 + \sum_{j=L+2}^{M+1} T_j a_j (x_j - x_n) \tag{52}$$

for arbitrary $n > M+1$. Since this equation holds for $n > M+1$ independently on the value of n we get

$$c_1 - x_L c_2 + \sum_{j=L+2}^{M+1} T_j a_j x_j = K \tag{53}$$

and

$$c_2 - \sum_{j=L+2}^{M+1} T_j a_j = 0. \tag{54}$$

The last two equations are a source of numerical instabilities if constants c_1 and c_2 are determined from the initial values f_{L+1} and f_{L+2}. To avoid these instabilities *we use Eqs. (53) and (54) as equations determining constants* c_1 *and* c_2. If we do so and insert the result into Eq. (50) we obtain

$$f_n = a_n \left[K - \sum_{j=n}^{M+1} T_j a_j (x_j - x_n) \right]. \tag{55}$$

Considering this equation for $n = L+1$ we determine the constant K,

$$K = \frac{f_{L+1}}{a_{L+1}} + \sum_{j=L+1}^{M+1} T_j a_j (x_j - x_{L+1}). \tag{56}$$

Inserting this back into Eq. (55) we obtain finally

$$f_n = a_n \left[\frac{f_{L+1}}{a_{L+1}} + \sum_{j=L+2}^{n-1} T_j a_j (x_j - x_{L+1}) + \sum_{j=n}^{M+1} T_j a_j (x_n - x_{L+1}) \right]. \tag{57}$$

Alternatively, we can use Eq. (35) and rewrite Eq. (57) in terms of a_n and b_n,

$$f_n = \frac{a_n}{a_{L+1}} \left[f_{L+1} - \sum_{j=L+2}^{M+1} T_j a_j b_{L+1} \right] + a_n \sum_{j=L+2}^{n-1} T_j b_j + b_n \sum_{j=n}^{M+1} T_j a_j. \tag{58}$$

The last two equations are likely to be more convenient for computational purposes than Eq. (42) since there are no cancellations of large numbers in these equations. The possible exception is the subtraction in the square brackets in Eq. (58), but for the special case of interest (see Sec. V) we avoid this difficulty.

V. APPLICATION OF THE METHOD

General theory outlined in the preceding section will be applied to the difference equations (15) and (16). To do so, we need to calculate T_j from Eq. (43).

A. Calculation of T_j

First we calculate Wronskian (44) from Eq. (48). Inserting r_k from Eq. (33) into this equation we get that Wronskian behaves for both Eqs. (15) and (16) as

$$W_j = (-1)^{j-L-1} \frac{(j+L)!}{(j-L)!} \frac{W_{L+1}}{(2L+1)!}, \tag{59}$$

where we set either $L=L_2$ or $L=L_1$. We note that W_{L+1} is the only quantity in this equation that depends on the concrete form of a_j and b_j.

Second, we take the right-hand side s_j of Eq. (32) equal to

$$s_j = -\frac{p_{N_1,j}^{L_1,L_2}}{j - L_2} \tag{60}$$

in case of Eq. (15) and

$$s_j = \frac{p_{N_2,j}^{L_2,L_1}}{j - L_1} \tag{61}$$

in case of Eq. (16).

Equations (59), (60), and (61) can be used to simplify formula (43). By inserting Eq. (59) with $L=L_2$ and Eq. (60) into Eq. (43) we get in the case of Eq. (15),

$$T_j = -\frac{P_{N_1,j}^{L_1,L_2}}{W_{L_2+1}}. \tag{62}$$

Analogously, by inserting Eq. (59) with $L=L_1$ and Eq. (61) into Eq. (43) we get in the case of Eq. (16),

$$T_j = \frac{P_{N_2,j}^{L_2,L_1}}{W_{L_1+1}}. \tag{63}$$

Here, $P_{N_1,N_2}^{L_1,L_2}$ denotes

$$P_{N_1,N_2}^{L_1,L_2} = \frac{p_{N_1,N_2}^{L_1,L_2} W_{L_2+1}}{(N_2 - L_2) W_{N_2}}. \tag{64}$$

This quantity was introduced because of the symmetry

$$P_{N_1,N_2}^{L_1,L_2} = P_{N_2,N_1}^{L_2,L_1} \tag{65}$$

[see the notes after Eqs. (22) and (59)]. By combining Eqs. (21) and (59) we can write for $L_1 > L_2+1$,

$$P_{N_1,N_2}^{L_1,L_2} = \frac{(L_1 - L_2 + 1)!(2L_2 + 1)!}{2} \sum_{q=\max(0,N_2-L_1-2)}^{\min(N_1-L_1-1,N_2-L_2-1)} (-1)^q \times \binom{N_1 - L_2 - q - 3}{L_1 - L_2 - 2} \binom{N_2 - L_2 - 1}{q} \binom{L_1 + L_2 + 2 + q}{N_2 + L_2}. \tag{66}$$

The case $L_2 > L_1+1$ is calculated by means of Eq. (65).

B. Numerical experiments and final formulas

1. Case $l < \min(L_1, L_2)$

By numerical experiments we found that the initial values f_{L+1} for Eq. (15) with $L_1 > L_2$ and $l < L_2$ and for Eq. (16) with $L_1 < L_2$ and $l < L_1$ are given as

$$f_{L+1} = (a_{L+1} + b_{L+1}) \sum_{j=L+1}^{M+1} T_j a_j. \tag{67}$$

In the case of Eq. (15) this equation holds with $L = L_2$, $M = N_1$, $f_{L+1} = \tilde{Q}_{N_1,L_2+1}^{+,L_1,L_2,l}$ and with a_j, b_j, and T_j given by Eqs. (24), (25), and (62). In the case of Eq. (16) this equation holds with $L = L_1$, $M = N_2$, $f_{L+1} = \tilde{Q}_{L_1+1,N_2}^{+,L_1,L_2,l}$ and with a_j, b_j, and T_j given by Eqs. (26), (27), and (63).

Then Eq. (58) can be brought to the form

$$f_n = a_n \sum_{j=L+1}^{n-1} T_j (a_j + b_j) + (a_n + b_n) \sum_{j=n}^{M+1} T_j a_j. \tag{68}$$

2. Case $l = L_2$

It follows from Eq. (29) that in this case one of the two linearly independent solutions is

$$a_{N_2} = (-1)^{N_2 - L_2 - 1}. \tag{69}$$

The second one is determined by the reduction of order. We use Eq. (57) for $f_{N_2} = \tilde{Q}_{N_1,N_2}^{+,L_1,L_2,L_2}$ with $n = N_2$, $L = L_2$, $M = N_1$, and T_j given by Eq. (62). The value of f_{L+1} was found from numerical analysis to be

$$\tilde{Q}_{N_1,L_2+1}^{+,L_1,L_2,L_2} = \frac{(L_1 + L_2 + 1)!(N_1 - L_2 - 2)!}{2(L_1 - L_2 - 1)!(N_1 - L_1 - 1)!}. \tag{70}$$

3. Case $l=L_1$

It follows from Eq. (31) that the constant K in Eq. (51) is equal to zero, so we can use Eq. (55) for $f_{N_1}=\tilde{Q}^{+,L_1}_{N_1,N_2,L_2,L_1}$ with $n=N_1$, $L=L_1$, $M=N_2$, and T_j calculated from Eq. (63).

One of the two linearly independent solutions of homogenous equation (16) is given by Eq. (A6) of the Appendix with $J=2L_1+1$,

$$a_{N_1}=(-1)^{N_1-L_1-1}\sum_{j=0}^{2L_1+1} h_j(N_1-L_1)^j, \tag{71}$$

where h_j are given by Eq. (A11) and where $h_{2L_1+1}=1$.

Using Eqs. (33) and (49) we can write Eq. (55) for the case considered as

$$f_n=-a_n\frac{W_{L+1}}{(2L+1)!}\sum_{j=n+1}^{M+1} T_j a_j \sum_{k=n+1}^{j}\frac{(-1)^{k-L-1}(k+L-1)!}{a_k a_{k-1}(k-L-1)!}. \tag{72}$$

This expression is still not entirely satisfactory. We found that there is residual instability for n close to $L+1$. To eliminate it we rewrite the double summation in the last equation

$$f_n=-a_n\frac{W_{L+1}}{(2L+1)!}\sum_{k=n+1}^{M+1}\frac{(-1)^{k-L-1}(k+L-1)!}{a_k a_{k-1}(k-L-1)!}\sum_{j=k}^{M+1} T_j a_j. \tag{73}$$

The source of instability for n close to $L+1$ is an interesting identity,

$$\sum_{j=L+1}^{M+1} T_j a_j=0. \tag{74}$$

Therefore, we use this identity in Eq. (73) and rewrite this equation to the form

$$f_n=a_n\frac{W_{L+1}}{(2L+1)!}\sum_{k=n+1}^{M+1}\frac{(-1)^{k-L-1}(k+L-1)!}{a_k a_{k-1}(k-L-1)!}\sum_{j=L+1}^{k-1} T_j a_j. \tag{75}$$

This equation is stable for all n from $L+1$ to M. For $n>M$, it yields zero as it should.

C. Numerical tests

We tested derived formulas numerically for very large quantum numbers. First we set $L_1=16$ and $L_2=14$, second we considered $L_1=20$ and $L_2=10$. We took $N_1=50$ and varied N_2 from L_2+1 to 70 and l from 2 to L_2. Then we reversed the role of L_1 and L_2 and also N_1 and N_2. These tests are rather severe; in normal calculation one encounters much more favorable situations. The formulas were run in double precision arithmetics and compared with the exact solutions of Eqs. (15) and (16) programmed in MAPLE in the form of the recursive algorithm run in rational arithmetics. For $l<\min(L_1,L_2)$, the hypergeometric functions (24)–(27) were calculated from the MAPLE subroutine. The numerical stable way of their calculations is given in the Appendix. For $|L_1-L_2|=2$ the relative error of the derived formulas was typically of order 10^{-15}. For the case $|L_1-L_2|=10$ the relative error was typically two orders higher. This shows that numerical stability of formulas slightly deteriorates with increasing difference $|L_1-L_2|$. However, one can expect that with increasing difference of the angular momenta of the electrons the contributions of the terms with large numbers of nodes to the energy is relatively small. Therefore, the achieved numerical stability is sufficient for all practical purposes.

VI. CONCLUSIONS

In this paper we extended the method of numerically stable calculation of the atomic integrals suggested in our previous paper[1] for the S-states of two-electron atoms to the states of arbitrary

total angular momenta. Thus, in these two papers the complete solution of the numerically stable calculation of the atomic integrals is given. In the first paper[1] we succeeded in transformation of the problem of the numerical stable calculation of the atomic integrals to the problem of the numerical stable solution of the difference equations. In this paper we completed our program by solving the latter problem in required generality. To achieve this aim we suggested a computationally stable method for the solution of inhomogenous difference equations that for certain values of the discrete independent variable become homogenous and in that region are described by just one of the two linearly independent solutions. The method was applied to the difference equations appearing in the radial part of the atomic integrals and tested for very large quantum numbers. These tests show high numerical stability of the suggested method. The stability slightly decreases with increasing difference of the angular momenta of the electrons.

The method suggested in these two papers can be used for the calculation of the radial part of the Coulomb interaction between electrons whose orbitals are expanded from the same center. This covers all atoms and the simplest molecules. The results obtained in these papers can be directly used for the configuration interaction calculation of the excited states of two electron atoms. This will be reported elsewhere.

Because of the potential importance of the achieved results it would be desirable to put them on a rigorous basis. The paper is based on the observation that Eqs. (15) and (16) can be in the region where they become homogenous described by just *one* of the two linearly independent solutions. Although we are certain about this observation, one should see *why* equations behave in this way. The same applies to our guesses (67), (70), and (74), and for Eq. (A17) in the Appendix.

Therefore, we believe that the results achieved in this paper are of some interest from the point of view of atomic physics as well as pure mathematics.

APPENDIX

In this appendix we suggest a solution of the homogenous equations (15) and (16). Since this solution is given in terms of the hypergeometric function $F(a,b,c,2)$ we find a particularly useful form of these functions that can be used also in Eq. (10).

Let us rewrite homogenous equations (15) and (16) into a general form,

$$(n-L)g_{n+1}-(n+L)g_{n-1}-2(J-L)g_n=0. \tag{A1}$$

This equation is obtained from the original homogenous equation (16),

$$(n-L)f_{n+1}-(n+L)f_{n-1}+2(l+1)f_n=0, \tag{A2}$$

by setting either $f_n=g_n$ and $J=L-l-1$ or $f_n=(-1)^n g_n$ and $J=L+l+1$. Equation (A1) is obtained also from homogenous equation (15),

$$(n-L)f_{n+1}-(n+L)f_{n-1}-2lf_n=0, \tag{A3}$$

by setting either $f_n=g_n$ and $J=L+l$ or $f_n=(-1)^n g_n$ and $J=L-l$. Due to the selection rules for Clebsch–Gordan coefficients mentioned after Eq. (5), the difference $L-l$ is always even. Therefore, the parameter J is odd in the case of Eq. (16) and even in the case of Eq. (15).

For $J<L-1$ the solution of Eq. (A1) is given by the hypergeometric function

$$g_n=F(n-L,-J;-2L;2). \tag{A4}$$

Let us remind the form of the hypergeometric function $F(a,b,c,z)$ here,

$$F(a,b,c,z) = 1 + \frac{ab}{c}z + \frac{a(a+1)b(b+1)}{c(c+1)}\frac{z^2}{2!} + \cdots . \tag{A5}$$

It turns out that this form of the hypergeometric functions is useful only for a close to zero, i.e., only for n close to L. For larger n, a more suitable form is needed.

Since we want to get expression also for the hypergeometric functions appearing in Eq. (10), we allow L to be half-integral and n to be half-integral and smaller than $L+1$.

We search for the solution of Eq. (A1) in the form of the series

$$g_n = \sum_{j=0}^{J} h_j (n-L)^j . \tag{A6}$$

Later on, it will be clear why we choose the upper bound of summation J. The advantage of this expansion is that the coefficients h_j do not change the sign. Therefore, for n larger than L this way of calculating the hypergeometric functions is numerically stable and can be used for the hypergeometric functions appearing in Eqs. (24)–(27).

Since J must be a non-negative integer, for $L=l$ we obtain only one solution in the form (A6). If $l<L$, we obtain in this way two linearly independent solutions.

The remaining hypergeometric functions to be calculated are those appearing in Eq. (10). For these functions argument a in the definition (A5) is always negative. As it is clear from Eq. (A4) it corresponds to the situation when $n<L$. The use of Eq. (A6) is not advantageous in this case, because for negative value of $n-L$ we get in (A6) the sum of terms with changing signs. When n is close to L, the best way is to calculate the hypergeometric functions from the definition (A5). For n more distant from L we calculate the hypergeometric functions from the series

$$g_n = \sum_{j=0}^{J} c_j n^j . \tag{A7}$$

It appears that for even J the coefficients c_j with odd j equal zero and for odd J the coefficients c_j with even j equal zero. From this fact it immediately follows that

$$F(-n-L,-J;-2L;2) = (-1)^J F(n-L,-J;-2L,2). \tag{A8}$$

Using this equation we can always raise the value of the parameter a over $-L$.

In the following we first show how to calculate the coefficients h_j in the expansion (A6), then we calculate the coefficients c_j in the expansion (A7).

Expansion around $n=L$

We make substitution $N=n-L$ in Eq. (A1). Then Eq. (A1) reads

$$Ng_{N+1} - (N+2L)g_{N-1} - 2(J-L)g_N = 0. \tag{A9}$$

Inserting the expansion (A6) and using the binomial formula we obtain after some manipulation

$$\sum_{j=0}^{J}\left[\sum_{k=0}^{j}\binom{j}{k}N^{k+1}(1-(-1)^{j-k}) - 2L\sum_{k=0}^{j}N^k(-1)^{j-k} - 2(J-L)N^j\right]h_j = 0. \tag{A10}$$

Comparing now terms with the same powers of N we get for the highest power N^J identically zero. It means that the coefficient h_J is free for the normalization of the solution. This is the reason why we chose in Eq. (A6) the upper bound of the summation equal to J. Going then successively to the lower powers of N we obtain recurrence relations for the coefficients h_j,

$$\frac{h_{J-j}}{h_J} = \frac{1}{j(J-j)!}\sum_{p=0}^{j-1}\frac{(J-p)!}{(1+j-p)!}\left[\frac{1-(-1)^{j-p-1}}{2}(J-j) - L(1+j-p)(-1)^{j-p}\right]\frac{h_{J-p}}{h_J}. \quad \text{(A11)}$$

Normalization of the series (A6) to the hypergeometric function is done by comparing Eqs. (A4) and (A6) for some value of n. The best choice is $n=L$ since then we have

$$1 = h_J\frac{h_0}{h_J}, \quad \text{(A12)}$$

where we used the identity $F(0,-J;-2L;2)=1$. The ratio h_0/h_J is calculated from Eq. (A11).

Expansion around $n=0$

We proceed along the same lines as in the derivation of recurrence relations for the coefficients h_j. We insert the expansion (A7) into Eq. (A1), use binomial formula and compare the terms with the same powers of n. After some manipulation we obtain

$$\frac{c_{J-2p}}{c_J} = \frac{1}{2p(J-2p)!}\sum_{j=0}^{p-1}\frac{c_{J-2j}}{c_J}\frac{(J-2j)!}{(2p-2j+1)!}[J-2p-L(2p-2j+1)] \quad \text{(A13)}$$

for p running from 1 to $J/2$ for J even and to $(J-1)/2$ for J odd. The coefficients c_{J-2p-1} equal zero.

The coefficient c_J is determined by comparing series (A7) and the hypergeometric function (A4) for some n. Setting $n=L$ we obtain

$$1 = c_J\sum_{j=0}^{J}\frac{c_j}{c_J}L^j, \quad \text{(A14)}$$

where we used the identity $F(0,-J;-2L;2)=1$. For practical purposes, however, this form is not very convenient, since there is a cancellation of large numbers in the sum on the right-hand side. For this reason the use of series (A7) is not suitable for calculation of the hypergeometric functions with n comparable or greater than L. Instead we determine the constant c_J as follows.

For even values of $J=2P$ the constant c_{2P} is found by comparing Eqs. (A4) and (A7) for $n=0$,

$$F(-L,-2P;-2L;2) = c_{2P}\frac{c_0}{c_{2P}}, \quad \text{(A15)}$$

where the ratio c_0/c_{2P} is calculated from Eq. (A13). The values of $F(-L,-2P;-2L,2)$ were found from the numerical experiments to be

$$F(-L,-2P,-2L,2) = \prod_{p=0}^{P-1}\frac{2p+1}{2L-2p-1}. \quad \text{(A16)}$$

For odd values of $J=2P+1$, comparison of Eqs. (A4) and (A7) yields for $n=0$ nothing, since both sides are identically equal to zero. However, the constant c_{2P+1} can be calculated from remarkable identity

$$c_{2P+1} = \frac{c_{2P}}{L-P} \quad \text{(A17)}$$

found by numerical experiments.

(Received 16 July 2004; accepted 2 November 2004; published online 7 February 2005)

The complete tables of Clebsch–Gordan (CG) coefficients for a wide class of SO(10) SUSY grand unified theories (GUTs) are given. Explicit expressions of states of all corresponding multiplets under standard model gauge group $G_{321}=\mathrm{SU}(3)_C\times\mathrm{SU}(2)_L\times\mathrm{U}(1)_Y$, necessary for evaluation of the CG coefficients are presented. The SUSY SO(10) GUT model considered here includes most of the Higgs irreducible representations usually used in the literature, **10**, **45**, **54**, **120**, **126**, **126**, and **210**. Mass matrices of all G_{321} multiplets are found for the most general superpotential. These results are indispensable for the precision calculations of the gauge couplings unification and proton decay, etc. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1847709]

I. INTRODUCTION

A particularly attractive idea for the physics beyond the standard model (SM) is the possible appearance of grand unified theories (GUTs).[1] The idea of GUTs bears several profound features. Perhaps the most obvious one is that GUTs have the potential to unify the diverse set of particle representations and parameters found in the SM into a single, comprehensive, and hopefully predictive framework. For example, through the GUT symmetry one might hope to explain the quantum numbers of the fermion spectrum, or even the origins of fermion mass. Moreover, by unifying all U(1) generators within a non-Abelian theory, GUTs would also provide an explanation for the quantization of electric charge. By combining GUTs with supersymmetry (SUSY), we hope to unify the attractive features of GUTs simultaneously with those of SUSY into a single theory, SUSY GUTs.[2] The apparent gauge couplings unification of the minimal supersymmetric standard model (MSSM) is strong circumstantial evidence in favor of the emergence of a SUSY GUT near $M_G\simeq 2\times 10^{16}$ GeV.[3]

While there are *a priori* many choices for such possible groups, the list can be narrowed down by requiring groups of rank $\geqslant 4$ that have complex representations. The smallest groups satisfying these requirements are SU(5), SU(6), SO(10), and E_6. Amongst these choices, SO(10) is particu-

larly attractive,[4] because SO(10) is the smallest simple Lie group for which a single anomaly-free irreducible representation (irrep) (namely the spinor **16** representation) can accommodate the entire SM fermion content of each generation.

Once we fix SO(10) as the gauge group, we have also many choices of the Higgs fields though they are limited by the gauge symmetry. The Higgs fields play an essential role in the spontaneous symmetry breaking of the SO(10) gauge group and as a source of the observed fermion masses. The SO(10) gauge group must be broken down to the standard model gauge group $G_{321}=\mathrm{SU}(3)_C\times\mathrm{SU}(2)_L\times\mathrm{U}(1)_Y$ gauge group, and each SO(10) irrep must be decomposed into G_{321} multiplets. In this paper, we make an explicit construction of the states of these G_{321} multiplets. Using these states, we calculate the CG coefficients appearing in the mass matrices for the states belonging to G_{321} irreps and corresponding mass matrices in a wide class of the SO(10) models. The purpose of the present paper is to give detailed structures of the SO(10) GUTs based on a general model as far as has been possible, and to serve a wide range of unified model builders.

The paper is organized as follows. In Sec. II, we give a class of SUSY SO(10) GUTs and give an explicit form of the most general superpotential. In such a superpotential, we postulate a renormalizability in order to keep the predictability.[5–7] However, the result developed here is also applicable to the nonrenormalizable models.[8–14] The symmetry breakings are considered in Sec. III. Section IV is devoted to present explicit forms of the states in the G_{321} multiplets for all SO(10) irreps. This is the central part of the present paper. Using these tables, we give in Sec. V the mass matrices with the CG coefficients for a class of SUSY SO(10) GUTs, together with suitable tests and consistency checks for them. In Sec. VI, we consider the quark and lepton mass matrices in general SUSY SO(10) models. Section VII is devoted to conclusion. We list the decompositions of each SO(10) irreps under G_{321} subgroup in Appendix A. In Appendix B, we present the complete list of the CG coefficients for the G_{321} multiplets for all SO(10) irreps.

II. A CLASS OF SUSY SO(10) GUTs

In this section, we consider a class of renormalizable SUSY SO(10) models. They include three families of matter fields Ψ_i $(i=1,2,3)$ transforming as 16 dimensional fundamental spinor representation, **16**, gauge fields contained in the adjoint representation, and set of SO(10) multiplets of Higgs fields, enabling most general Yukawa couplings. The most general Yukawa couplings follow from decomposition of $\mathbf{16}\times\mathbf{16}=\mathbf{10}+\mathbf{120}+\mathbf{126}$, i.e., they include the Higgs fields in $H=\mathbf{10}$, $D=\mathbf{120}$, $\bar{\Delta}=\overline{\mathbf{126}}$ irreps, respectively. Furthermore, to consider as general case of the symmetry breaking of SO(10) to the standard model gauge group G_{321} as possible, we add several Higgs fields containing G_{321} singlets. They are $A=\mathbf{45}$, $\Delta=\mathbf{126}$, $\Phi=\mathbf{210}$, and $E=\mathbf{54}$ irreps. Of course, that is not the most general case. However, this set of Higgs fields is quite rich and gives rise to several realistic SUSY SO(10) models. Our aim is to give a systematic method for treatment of models with complicated Higgs sectors. This is a generalization of the method proposed in Refs. 15–17. We shall assume that the SUSY is preserved so that we consider the breaking of SUSY SO(10) to the MSSM.

Then the Yukawa couplings are

$$W_Y = Y_{10}^{ij}\Psi_i H\Psi_j + Y_{120}^{ij}\Psi_i D\Psi_j + Y_{126}^{ij}\Psi_i\bar{\Delta}\Psi_j, \tag{1}$$

where $i,j=1,2,3$ denote the generation indices. Note that H is a fundamental SO(10) irrep, and A, D, Φ, and $\Delta+\bar{\Delta}$ are antisymmetric tensors of rank 2, 3, 4, and 5, respectively. E is a symmetric traceless tensor of rank 2.

The most general Higgs superpotential is given by

$$W = \frac{1}{2}m_1\Phi^2 + m_2\overline{\Delta}\Delta + \frac{1}{2}m_3H^2 + \frac{1}{2}m_4A^2 + \frac{1}{2}m_5E^2 + \frac{1}{2}m_6D^2 + \lambda_1\Phi^3 + \lambda_2\Phi\overline{\Delta}\Delta + (\lambda_3\Delta + \lambda_4\overline{\Delta})H\Phi$$
$$+ \lambda_5A^2\Phi - i\lambda_6A\overline{\Delta}\Delta + \frac{\lambda_7}{120}\varepsilon A\Phi^2 + E(\lambda_8E^2 + \lambda_9A^2 + \lambda_{10}\Phi^2 + \lambda_{11}\Delta^2 + \lambda_{12}\overline{\Delta^2} + \lambda_{13}H^2)$$
$$+ D^2(\lambda_{14}E + \lambda_{15}\Phi) + D\{\lambda_{16}HA + \lambda_{17}H\Phi + (\lambda_{18}\Delta + \lambda_{19}\overline{\Delta})A + (\lambda_{20}\Delta + \lambda_{21}\overline{\Delta})\Phi\}, \tag{2}$$

where SO(10) invariants are defined in the fundamental SO(10) basis $1',2',\ldots,9',0'$ and in the Y diagonal basis $1,2,\ldots,9,0$ (which we will define in the next section) as follows:

$$\Phi^2 \equiv \Phi_{a'b'c'd'}\Phi_{a'b'c'd'} = \Phi_{abcd}\Phi_{\bar{a}\bar{b}\bar{c}\bar{d}},$$

$$\overline{\Delta}\Delta \equiv \overline{\Delta}_{a'b'c'd'e'}\Delta_{a'b'c'd'e'} = \overline{\Delta}_{abcde}\Delta_{\bar{a}\bar{b}\bar{c}\bar{d}\bar{e}},$$

$$H^2 \equiv H_{a'}H_{a'} = H_aH_{\bar{a}},$$

$$A^2 \equiv A_{a'b'}A_{a'b'} = A_{ab}A_{\bar{a}\bar{b}},$$

$$E^2 \equiv E_{a'b'}E_{a'b'} = E_{ab}E_{\bar{a}\bar{b}},$$

$$D^2 \equiv D_{a'b'c'}D_{a'b'c'} = D_{abc}D_{\bar{a}\bar{b}\bar{c}},$$

$$\Phi^3 \equiv \Phi_{a'b'c'd'}\Phi_{a'b'e'f'}\Phi_{c'd'e'f'} = \Phi_{\bar{a}\bar{b}\bar{c}\bar{d}}\Phi_{abef}\Phi_{cd\bar{e}\bar{f}},$$

$$\Phi\overline{\Delta}\Delta \equiv \Phi_{a'b'c'd'}\overline{\Delta}_{a'b'e'f'g'}\Delta_{c'd'e'f'g'} = \Phi_{\bar{a}\bar{b}\bar{c}\bar{d}}\overline{\Delta}_{abefg}\Delta_{cd\bar{e}\bar{f}\bar{g}},$$

$$\Delta H\Phi \equiv \Delta_{a'b'c'd'e'}H_{a'}\Phi_{b'c'd'e'} = \Delta_{\bar{a}\bar{b}\bar{c}\bar{d}\bar{e}}H_a\Phi_{bcde},$$

$$\overline{\Delta}H\Phi \equiv \overline{\Delta}_{a'b'c'd'e'}H_{a'}\Phi_{b'c'd'e'} = \overline{\Delta}_{\bar{a}\bar{b}\bar{c}\bar{d}\bar{e}}H_a\Phi_{bcde},$$

$$A^2\Phi \equiv A_{a'b'}A_{c'd'}\Phi_{a'b'c'd'} = A_{\bar{a}\bar{b}}A_{cd}\Phi_{ab\bar{c}\bar{d}},$$

$$-iA\overline{\Delta}\Delta \equiv -iA_{a'b'}\overline{\Delta}_{a'c'd'e'f'}\Delta_{b'c'd'e'f'} = -iA_{\bar{a}\bar{b}}\overline{\Delta}_{acdef}\Delta_{b\bar{c}\bar{d}\bar{e}\bar{f}},$$

$$\tfrac{1}{120}\varepsilon A\Phi^2 \equiv \tfrac{1}{120}\varepsilon_{a'_1a'_2a'_3a'_4a'_5a'_6a'_7a'_8a'_9a'_0}A_{a'_1a'_2}\Phi_{a'_3a'_4a'_5a'_6}\Phi_{a'_7a'_8a'_9a'_0}$$
$$= \tfrac{1}{120}\varepsilon_{\bar{a}_1\bar{a}_2\bar{a}_3\bar{a}_4\bar{a}_5\bar{a}_6\bar{a}_7\bar{a}_8\bar{a}_9\bar{a}_0}A_{a_1a_2}\Phi_{a_3a_4a_5a_6}\Phi_{a_7a_8a_9a_0}, \tag{3}$$

$$E^3 \equiv E_{a'b'}E_{a'c'}E_{b'c'} = E_{\bar{a}\bar{b}}E_{ac}E_{b\bar{c}},$$

$$EA^2 \equiv E_{a'b'}A_{a'c'}A_{b'c'} = E_{\bar{a}\bar{b}}A_{ac}A_{b\bar{c}},$$

$$E\Phi^2 \equiv E_{a'b'}\Phi_{a'c'd'e'}\Phi_{b'c'd'e'} = E_{\bar{a}\bar{b}}\Phi_{acde}\Phi_{b\bar{c}\bar{d}\bar{e}},$$

$$E\Delta^2 \equiv E_{a'b'}\Delta_{a'c'd'e'f'}\Delta_{b'c'd'e'f'} = E_{\bar{a}\bar{b}}\Delta_{acdef}\Delta_{b\bar{c}\bar{d}\bar{e}\bar{f}},$$

$$E\overline{\Delta}^2 \equiv E_{a'b'}\overline{\Delta}_{a'c'd'e'f'}\overline{\Delta}_{b'c'd'e'f'} = E_{\overline{ab}}\overline{\Delta}_{acdef}\overline{\Delta}_{bc\overline{de}\overline{f}},$$

$$EH^2 \equiv E_{a'b'}H_{a'}H_{b'} = E_{\overline{ab}}H_aH_b,$$

$$ED^2 \equiv E_{a'b'}D_{a'c'd'}D_{b'c'd'} = E_{\overline{ab}}D_{acd}D_{bc\overline{d}},$$

$$D^2\Phi \equiv D_{a'b'c'}D_{a'd'e'}\Phi_{b'c'd'e'} = D_{\overline{abc}}D_{ade}\Phi_{bc\overline{de}},$$

$$DHA \equiv D_{a'b'c'}H_{a'}A_{b'c'} = D_{\overline{abc}}H_aA_{bc},$$

$$DH\Phi \equiv D_{a'b'c'}H_{d'}\Phi_{a'b'c'd'} = D_{\overline{abc}}H_d\Phi_{abc\overline{d}},$$

$$D\Delta A \equiv D_{a'b'c'}\Delta_{a'b'c'd'e'}A_{d'e'} = D_{\overline{abc}}\Delta_{abcde}A_{\overline{de}},$$

$$D\overline{\Delta}A \equiv D_{a'b'c'}\overline{\Delta}_{a'b'c'd'e'}A_{d'e'} = D_{\overline{abc}}\overline{\Delta}_{abcde}A_{\overline{de}},$$

$$D\Delta\Phi \equiv D_{a'b'c'}\Delta_{a'b'd'e'f'}\Phi_{c'd'e'f'} = D_{\overline{abc}}\Delta_{abdef}\Phi_{c\overline{def}},$$

$$D\overline{\Delta}\Phi \equiv D_{a'b'c'}\overline{\Delta}_{a'b'd'e'f'}\Phi_{c'd'e'f'} = D_{\overline{abc}}\overline{\Delta}_{abdef}\Phi_{c\overline{def}}.$$

Here $a',b',c',\ldots$ $(a,b,c,\ldots)$ run over all the SO(10) vector (Y diagonal) indices and ε is a totally antisymmetric SO(10) invariant tensor with

$$\varepsilon_{1'2'3'4'5'6'7'8'9'0'} = i\varepsilon_{1234567890} = 1. \tag{4}$$

III. SYMMETRY BREAKING

Here we first introduce Y diagonal basis (see also Ref. 18): $1=1'+2'i$, $2=1'-2'i$, $3=3'+4'i$, $4=3'-4'i$, $5=5'+6'i$, $6=5'-6'i$, $7=7'+8'i$, $8=7'-8'i$, $9=9'+0'i$, $0=9'-0'i$, up to the normalization factor $1/\sqrt{2}$. It is more convenient since (1,3,5,7,9) transforms as **5**-plet and (2,4,6,8,0) transforms as $\overline{\mathbf{5}}$-plet under $\mathrm{SU}(5)\times\mathrm{U}(1)_X$ [for that reason Y diagonal basis could also be called SU(5) basis]. Consequently, (1,3) and (2,4) are $\mathrm{SU}(2)_L$ doublets with definite hypercharges $Y=\frac{1}{2}$ and $Y=-\frac{1}{2}$, respectively. Similarly, (5,7,9) and (6,8,0) transform under $\mathrm{SU}(3)_C$ as **3** and $\overline{\mathbf{3}}$ with definite hypercharges $Y=-\frac{1}{3}$ and $Y=\frac{1}{3}$, respectively. Note that under the complex conjugation (c.c.), $\overline{1}=2$, $\overline{3}=4$, $\overline{5}=6$, $\overline{7}=8$, $\overline{9}=0$, and vice versa. The SO(10) invariants are built in such a way that an index a is contracted (summed) with the corresponding c.c. index $\overline{a}$, for example, $T_{\ldots a\cdot\ldots}T_{\ldots\overline{a}\cdot\ldots}$.

The basis in $A=\mathbf{45}$, $D=\mathbf{120}$, $\Phi=\mathbf{210}$, and $\Delta+\overline{\Delta}=\mathbf{126}+\overline{\mathbf{126}}$ dimensional spaces are defined by totally antisymmetric (unit) tensors $(a'b')$, $(a'b'c')$, $(a'b'c'd')$, and $(a'b'c'd'e')$, respectively, and similarly in a, b, c, d, e indices in Y diagonal basis. The states of the Δ and $\overline{\Delta}$ have additional properties,

$$\begin{aligned} i\varepsilon_{\overline{a}_1\overline{a}_2\overline{a}_3\overline{a}_4\overline{a}_5\overline{a}_6\overline{a}_7\overline{a}_8\overline{a}_9\overline{a}_{10}}\overline{\Delta}_{a_6a_7a_8a_9a_{10}} &= \overline{\Delta}_{\overline{a}_1\overline{a}_2\overline{a}_3\overline{a}_4\overline{a}_5}, \\ i\varepsilon_{\overline{a}_1\overline{a}_2\overline{a}_3\overline{a}_4\overline{a}_5\overline{a}_6\overline{a}_7\overline{a}_8\overline{a}_9\overline{a}_{10}}\Delta_{a_6a_7a_8a_9a_{10}} &= -\Delta_{\overline{a}_1\overline{a}_2\overline{a}_3\overline{a}_4\overline{a}_5}, \end{aligned} \tag{5}$$

that allow one to project out the Δ and $\overline{\Delta}$ states, respectively, from the 256 antisymmetric states $(abcde)$. The explicit expressions for antisymmetric tensors are, for example,

$$(ab) = ab - ba,$$

$$(abc) = abc + cab + bca - bac - acb - cba, \tag{6}$$

etc. Important relations are

$$(12) = -i(1'2'),$$

$$(34) = -i(3'4'),$$

$$(56) = -i(5'6'), \tag{7}$$

$$(78) = -i(7'8'),$$

$$(90) = -i(9'0').$$

Symmetric $E=\mathbf{54}$ dimensional space is spanned by traceless symmetric states $\{a'b'\} \equiv a'b' + b'a'(a', b' = 1', 2', \ldots, 9', 0')$ and $\Sigma_{a'} c_{a'} \{a'a'\}$ with $\Sigma_{a'} c_{a'} \equiv 0$. Also, important relations are

$$\{12\} = 1'1' + 2'2',$$

$$\{34\} = 3'3' + 4'4',$$

$$\{56\} = 5'5' + 6'6', \tag{8}$$

$$\{78\} = 7'7' + 8'8',$$

$$\{90\} = 9'9' + 0'0'.$$

Now, the Higgs fields A, E, Δ, $\overline{\Delta}$, and Φ contain eight directions of singlets under the G_{321} subgroup (see Appendix A). The corresponding vacuum expectation values (VEVs) are defined by

$$\langle A \rangle = \sum_{i=1}^{2} A_i \hat{A}_i, \tag{9}$$

$$\langle E \rangle = E\hat{E}, \tag{10}$$

$$\langle \Delta \rangle = v_R \hat{v_R}, \tag{11}$$

$$\langle \overline{\Delta} \rangle = \overline{v_R}\,\widehat{\overline{v_R}}, \tag{12}$$

$$\langle \Phi \rangle = \sum_{i=1}^{3} \Phi_i \hat{\Phi}_i, \tag{13}$$

where unit directions $\hat{A}_i$ $(i=1,2)$, $\hat{E}$, $\hat{v_R}$, $\widehat{\overline{v_R}}$ and $\hat{\Phi}_i$ $(i=1,2,3)$ in the Y diagonal basis are

$$\hat{A}_1 = \hat{A}^{(1,1,0)}_{(1,1,3)} = \frac{i}{2}(12 + 34), \tag{14}$$

$$\hat{A}_2 = \hat{A}^{(1,1,0)}_{(15,1,1)} = \frac{i}{\sqrt{6}}(56 + 78 + 90), \tag{15}$$

$$\hat{E} = \hat{E}^{(1,1,0)}_{(1,1,1)} = \frac{1}{\sqrt{60}}\{3 \times [12 + 34] - 2 \times [56 + 78 + 90]\}, \tag{16}$$

$$\widehat{v_R} = \hat{\Delta}^{(1,1,0)}_{(10,1,3)} = \frac{1}{\sqrt{120}}(24\,680), \tag{17}$$

$$\widehat{\overline{v_R}} = \hat{\overline{\Delta}}^{(1,1,0)}_{(10,1,3)} = \frac{1}{\sqrt{120}}(13\,579), \tag{18}$$

$$\hat{\Phi}_1 = \hat{\Phi}^{(1,1,0)}_{(1,1,1)} = -\frac{1}{\sqrt{24}}(1234), \tag{19}$$

$$\hat{\Phi}_2 = \hat{\Phi}^{(1,1,0)}_{(15,1,1)} = -\frac{1}{\sqrt{72}}(5678 + 5690 + 7890), \tag{20}$$

$$\hat{\Phi}_3 = \hat{\Phi}^{(1,1,0)}_{(15,1,3)} = -\frac{1}{12}([12 + 34][56 + 78 + 90]). \tag{21}$$

Here and hereafter, the upper and the lower indices indicate the $SU(3)_C \times SU(2)_L \times U(1)_Y$, $SU(4) \times SU(2)_L \times SU(2)_R$ quantum numbers, respectively in the case of double indices. A word about notation: the square brackets are used for grouping of indices. This grouping of indices is used to emphasize the $SU(2)_L$ and $SU(3)_C$ structures within the state vectors. The square brackets satisfy usual distributive law with respect to summation of indices and tensor product of indices, e.g.,

$$\begin{aligned}([12 + 34][56 + 78 + 90]) &= (1256 + 1278 + 1290 + 3456 + 3478 + 3490)\\ &= (1256) + (1278) + (1290) + (3456) + (3478) + (3490),\end{aligned}$$

$$\begin{aligned}([1,3][5[78 + 90], 7[56 + 90], 9[56 + 78]]) &= (1578 + 1590, 1756 + 1790, 1956 + 1978, 3578\\ &\quad + 3590, 3756 + 3790, 3956 + 3978)\\ &= (1578, 1756, 1956, 3578, 3756, 3956)\\ &\quad + (1590, 1790, 1978, 3590, 3790, 3978).\end{aligned} \tag{22}$$

Further, the numerical factors which could be misinterpreted as additional SO(10) indices are written in italics.

The unit directions appearing in VEVs satisfy the following orthonormality relations:

$$\hat{A}_i \cdot \hat{A}_j = \delta_{ij} \quad (i,j = 1,2),$$

$$\hat{E}^2 = 1,$$

$$\widehat{v_R} \cdot \widehat{v_R} = \widehat{\overline{v_R}} \cdot \widehat{\overline{v_R}} = 0, \tag{23}$$

$$\widehat{v_R}\cdot\widehat{\overline{v_R}}=1,$$

$$\widehat{\Phi_i}\cdot\widehat{\Phi_j}=\delta_{ij}\quad(i,j=1,2,3).$$

Due to the D-flatness condition the absolute values of the VEVs, v_R and $\overline{v_R}$ are equal,

$$|v_R|=|\overline{v_R}|. \tag{24}$$

The superpotential of Eq. (2) calculated at the VEVs in Eqs. (14)–(21) is

$$\langle W\rangle=\frac{1}{2}m_1\langle\Phi\rangle^2+m_2\langle\overline{\Delta}\rangle\langle\Delta\rangle+\frac{1}{2}m_4\langle A\rangle^2+\frac{1}{2}m_5\langle E\rangle^2+\lambda_1\langle\Phi\rangle^3+\lambda_2\langle\Phi\rangle\langle\overline{\Delta}\rangle\langle\Delta\rangle+\lambda_5\langle A\rangle^2\langle\Phi\rangle$$
$$-i\lambda_6\langle A\rangle\langle\overline{\Delta}\rangle\langle\Delta\rangle+\frac{\lambda_7}{120}\varepsilon\langle A\rangle\langle\Phi\rangle^2+\langle E\rangle[\lambda_8\langle E\rangle^2+\lambda_9\langle A\rangle^2+\lambda_{10}\langle\Phi\rangle^2]. \tag{25}$$

Inserting the VEVs from Eqs. (14)–(21), one obtains

$$\langle W\rangle=\frac{1}{2}m_1[\Phi_1^2+\Phi_2^2+\Phi_3^2]+m_2v_R\overline{v_R}+\frac{1}{2}m_4(A_1^2+A_2^2)+\frac{1}{2}m_5E^2$$
$$+\lambda_1\left[\Phi_2^3\frac{1}{9\sqrt{2}}+3\Phi_1\Phi_3^2\frac{1}{6\sqrt{6}}+3\Phi_2\Phi_3^2\frac{1}{9\sqrt{2}}\right]+\lambda_2\left[\Phi_1\frac{1}{10\sqrt{6}}+\Phi_2\frac{1}{10\sqrt{2}}+\Phi_3\frac{1}{10}\right]v_R\overline{v_R}$$
$$+\lambda_5\left[A_1^2\Phi_1\frac{1}{\sqrt{6}}+A_2^2\Phi_2\frac{\sqrt{2}}{3}+A_1A_2\Phi_3\frac{2}{\sqrt{6}}\right]+\lambda_6\left[A_1\left(-\frac{1}{5}\right)+A_2\left(-\frac{3}{5\sqrt{6}}\right)\right]v_R\overline{v_R}$$
$$+\lambda_7\left[2A_2\Phi_1\Phi_2\frac{\sqrt{2}}{5}+A_2\Phi_3^2\frac{2\sqrt{2}}{5\sqrt{3}}+2A_1\Phi_2\Phi_3\frac{\sqrt{2}}{5}\right]+\lambda_8E^3\frac{1}{2\sqrt{15}}+\lambda_9E\left[A_1^2\frac{\sqrt{3}}{2\sqrt{5}}+A_2^2\left(-\frac{1}{\sqrt{15}}\right)\right]$$
$$+\lambda_{10}E\left[\Phi_1^2\frac{\sqrt{3}}{2\sqrt{5}}+\Phi_2^2\left(-\frac{1}{\sqrt{15}}\right)+\Phi_3^2\frac{1}{4\sqrt{15}}\right]. \tag{26}$$

The VEVs are determined by the following equation:

$$\left\{\frac{\partial}{\partial\Phi_1},\frac{\partial}{\partial\Phi_2},\frac{\partial}{\partial\Phi_3},\frac{\partial}{\partial v_R},\frac{\partial}{\partial\overline{v_R}},\frac{\partial}{\partial A_1},\frac{\partial}{\partial A_2},\frac{\partial}{\partial E}\right\}\langle W\rangle=0. \tag{27}$$

From Eq. (27), we obtain seven equations for Φ_1, Φ_2, Φ_3, A_1, A_1, E, and $v_R\overline{v_R}$. They are the following:

$$0=m_1\Phi_1+\frac{\lambda_1\Phi_3^2}{2\sqrt{6}}+\frac{\lambda_2v_R\overline{v_R}}{10\sqrt{6}}+\frac{\lambda_5A_1^2}{\sqrt{6}}+\frac{2\sqrt{2}\lambda_7A_2\Phi_2}{5}+\frac{\sqrt{3}\lambda_{10}\Phi_1E}{\sqrt{5}},$$

$$0=m_1\Phi_2+\frac{\lambda_1\Phi_2^2}{3\sqrt{2}}+\frac{\lambda_1\Phi_3^2}{3\sqrt{2}}+\frac{\lambda_2v_R\overline{v_R}}{10\sqrt{2}}+\frac{\sqrt{2}}{3}\lambda_5A_2^2+\frac{2\sqrt{2}\lambda_7\Phi_1A_2}{5}+\frac{2\sqrt{2}\lambda_7A_1\Phi_3}{5}-\frac{2\lambda_{10}\Phi_2E}{\sqrt{15}},$$

$$0=m_1\Phi_3+\frac{\lambda_1\Phi_1\Phi_3}{\sqrt{6}}+\frac{\sqrt{2}\lambda_1\Phi_2\Phi_3}{3}+\frac{\lambda_2v_R\overline{v_R}}{10}+\frac{\sqrt{2}\lambda_5A_1A_2}{\sqrt{3}}+\frac{2\sqrt{2}\lambda_7A_1\Phi_2}{5}+\frac{4\sqrt{2}\lambda_7A_2\Phi_3}{5\sqrt{3}}+\frac{\lambda_{10}\Phi_3E}{2\sqrt{15}},$$

$$0=v_R\overline{v_R}\left[m_2+\frac{\lambda_2\Phi_1}{10\sqrt{6}}+\frac{\lambda_2\Phi_2}{10\sqrt{2}}+\frac{\lambda_2\Phi_3}{10}-\frac{\lambda_6A_1}{5}-\frac{\sqrt{3}\lambda_6A_2}{5\sqrt{2}}\right], \tag{28}$$

$$0 = m_4 A_1 + \frac{\sqrt{2}\lambda_5 A_1 \Phi_1}{\sqrt{3}} + \frac{\sqrt{2}\lambda_5 A_2 \Phi_3}{\sqrt{3}} - \frac{\lambda_6 v_R \overline{v_R}}{5} + \frac{2\sqrt{2}\lambda_7 \Phi_2 \Phi_3}{5} + \frac{\sqrt{3}\lambda_9 A_1 E}{\sqrt{5}},$$

$$0 = m_4 A_2 + \frac{\sqrt{2}\lambda_5 A_1 \Phi_3}{\sqrt{3}} + \frac{2\sqrt{2}\lambda_5 A_2 \Phi_2}{3} - \frac{\sqrt{3}\lambda_6 v_R \overline{v_R}}{5\sqrt{2}} + \frac{2\sqrt{2}\lambda_7 \Phi_3^2}{5\sqrt{3}} + \frac{2\sqrt{2}\lambda_7 \Phi_1 \Phi_2}{5} - \frac{2\lambda_9 A_2 E}{\sqrt{15}},$$

$$0 = m_5 E + \frac{\sqrt{3}\lambda_8 E^2}{2\sqrt{5}} + \frac{\sqrt{3}\lambda_9 A_1^2}{2\sqrt{5}} - \frac{\lambda_9 A_2^2}{\sqrt{15}} + \frac{\sqrt{3}\lambda_{10} \Phi_1^2}{2\sqrt{5}} - \frac{\lambda_{10} \Phi_2^2}{\sqrt{15}} + \frac{\lambda_{10} \Phi_3^2}{4\sqrt{15}}.$$

If we assume $v_R \overline{v_R} \neq 0$, we obtain five quadratic equations and one linear equation for Φ_i, A_i, and E. For that case there are 32 solutions. Two of them correspond to SU(5) symmetry and remaining 30 solutions to G_{321} standard gauge group symmetry solutions. If we set $v_R = 0$, we find six quadratic equations for Φ_1, Φ_2, Φ_3, A_1, A_2, and E with 64 solutions with symmetry groups having rank 5. They are isomorphic to $G_{3211} \equiv \mathrm{SU}(3)_C \times \mathrm{SU}(2)_L \times \mathrm{U}(1)_R \times \mathrm{U}(1)_{B-L}$. However, there are solutions with higher symmetries. They are G_{3221}, G_{421}, G_{422}, and G_{51} (for the reader's convenience, we list the decompositions of each representation in Appendix A). For general coupling constants $\lambda_1, \ldots, \lambda_{21}$, $m_1, \ldots, m_8$, the solutions with higher symmetries are specified by the following relations. Solutions with higher symmetries are characterized by the following:

(1) $\mathrm{SU}(5) \times \mathrm{U}(1)_X$ and $(\mathrm{SU}(5) \times \mathrm{U}(1))^{\mathrm{flipped}}$ symmetry solutions,

$$E = v_R = 0,$$
$$\Phi_1 = \frac{\varepsilon}{\sqrt{6}} \Phi_3, \quad \Phi_2 = \frac{\varepsilon}{\sqrt{2}} \Phi_3, \quad A_1 = \frac{2\varepsilon}{\sqrt{6}} A_2, \tag{29}$$

where $\varepsilon = 1$ and $\varepsilon = -1$ correspond to the $\mathrm{SU}(5) \times \mathrm{U}(1)_X$ symmetric vacua and $(\mathrm{SU}(5) \times \mathrm{U}(1))^{\mathrm{flipped}}$ symmetric vacua, respectively.

(2) SU(5) symmetry solutions,

$$E = 0,$$
$$\Phi_1 = \frac{1}{\sqrt{6}} \Phi_3, \quad \Phi_2 = \frac{1}{\sqrt{2}} \Phi_3, \quad A_1 = \frac{2}{\sqrt{6}} A_2, \quad v_R \neq 0. \tag{30}$$

(3) $G_{422} \equiv \mathrm{SU}(4) \times \mathrm{SU}(2)_L \times \mathrm{SU}(2)_R$ symmetry solutions,

$$\Phi_2 = \Phi_3 = A_1 = A_2 = v_R = 0,$$
$$\Phi_1 \neq 0, \quad E \neq 0. \tag{31}$$

(4) $G_{3221} \equiv \mathrm{SU}(3)_C \times \mathrm{SU}(2)_L \times \mathrm{SU}(2)_R \times \mathrm{U}(1)_{B-L}$ symmetry solutions,

$$\Phi_3 = A_1 = v_R = 0,$$
$$\Phi_1 \neq 0, \quad \Phi_2 \neq 0, \quad A_2 \neq 0, \quad E \neq 0. \tag{32}$$

(5) $G_{421} \equiv \mathrm{SU}(4) \times \mathrm{SU}(2)_L \times \mathrm{U}(1)$ symmetry solutions,

$$\Phi_2 = \Phi_3 = A_2 = v_R = 0,$$
$$\Phi_1 \neq 0, \quad A_1 \neq 0, \quad E \neq 0. \tag{33}$$

(6) $G_{3211} \equiv \mathrm{SU}(3)_C \times \mathrm{SU}(2)_L \times \mathrm{U}(1)_R \times \mathrm{U}(1)_{B-L}$ symmetry solutions,

$$v_R = 0,$$
$$\Phi_i \neq 0 \quad (i=1,2,3), \quad A_i \neq (i=1,2), \quad E \neq 0. \tag{34}$$

The higher symmetry solutions given in Eqs. (29)–(34) lead to the crucial consistency checks for all results in this paper.

IV. THE STATES AND CLEBSCH–GORDAN COEFFICIENTS

A. The states in the G_{321} multiplets

In order to obtain and study the mass matrices, it is convenient to decompose the Higgs representations under the G_{321} gauge group. The explicit decompositions of **10**, **45**, **54**, **120**, **126**, $\overline{\mathbf{126}}$, and **210** representations in Y diagonal basis are presented according to the G_{321} multiplets with the same quantum numbers which generally mix among themselves. The eight singlets $(\mathbf{1},\mathbf{1},0)$ are already given in Eqs. (14)–(21). There are $45-12=33$ would-be NG modes. They are in the following multiplets: $(\mathbf{1},\mathbf{1},0)$, $[(\mathbf{3},\mathbf{2},-\frac{5}{6})+\text{c.c.}]$, $[(\mathbf{1},\mathbf{1},1)+\text{c.c.}]$, $[(\mathbf{3},\mathbf{1},\frac{2}{3})+\text{c.c.}]$, and $[(\mathbf{3},\mathbf{2},\frac{1}{6})+\text{c.c.}]$. The corresponding orthonormal states are listed in Table 1 (Ref. 19) in Y-diagonal basis. The physically important modes, so-called, Higgs doublets $[(\mathbf{1},\mathbf{2},\frac{1}{2})+\text{c.c.}]$ and color triplets $[(\mathbf{3},\mathbf{1},-\frac{1}{3})+\text{c.c.}]$ states are listed in Tables 2 (Ref. 19) and 3 (Ref. 19), respectively. The remaining G_{321} multiplets are listed in Tables 4 (Ref. 19) and 5 (Ref. 19). There are altogether 691 states accommodated in G_{321} multiplets [see Table 6 (Ref. 19)]. There are 26 mass matrices, five containing NG modes, one containing doublets, one containing color triplets, 19 containing the other modes. There are five multiplets (33 states) with zero mass and 69 G_{321} multiplets with masses different from zero (containing $691-33=658$ states). Hence the mass spectrum contains 70 different mass eigenvalues. For the SU (5) solutions, there are only 21 different masses and G_{321} multiplets are grouped into multiplets transforming under the SU (5) group. For the G_{422} solutions, there are 27 different mass eigenvalues and G_{321} multiplets are grouped into multiplets transforming under the G_{422} group (see Appendix A). The higher symmetries serve as a strong consistency check of our mass matrices and CG coefficients.

We point out that the main basic blocks in all 691 states are $\mathrm{SU}(2)_L$ irreps **1**, **2**, and **3**, and SU (3) irreps **1**, **3**, $\overline{\mathbf{3}}$, **6**, $\overline{\mathbf{6}}$, and **8**:

$$\mathrm{SU}(2)_L,$$

$$\mathbf{1} \quad [12+34],\ (13),(24),\ (1234),$$

$$\mathbf{2} \quad [1,3],\ [-3,1],\ [2,4],[-4,2],$$

$$\mathbf{3} \quad \left[14,32,\frac{12-34}{\sqrt{2}}\right],\ \left\{\frac{11}{2},-\frac{33}{2},-\frac{13}{\sqrt{2}}\right\},\ \left\{\frac{22}{2},-\frac{44}{2},-\frac{24}{\sqrt{2}}\right\} \tag{35}$$

$$\mathrm{SU}(3)_C,$$

$$\mathbf{1} \quad [56+78+90],\ (579),\ (680),\ (5678+5690+7890),$$

$$\mathbf{3} \quad [5,7,9],\ (80,06,68),\ (5680,7806,9068),$$

$$\overline{\mathbf{3}} \quad [6,8,0],\ (79,95,57),\ (5697,7859,9075),$$

$$\mathbf{6} \quad \left(580,670,689,\frac{6[90-78]}{\sqrt{2}},\frac{8[56-90]}{\sqrt{2}},\frac{0[78-56]}{\sqrt{2}}\right),$$
$$\left\{\frac{55}{2},\frac{77}{2},\frac{99}{2},\frac{79}{\sqrt{2}},\frac{95}{\sqrt{2}},\frac{57}{\sqrt{2}}\right\}, \tag{36}$$

$$\overline{\mathbf{6}} \quad \left(679,589,570,\frac{5[09-78]}{\sqrt{2}},\frac{7[65-09]}{\sqrt{2}},\frac{9[87-65]}{\sqrt{2}}\right),$$
$$\left\{\frac{66}{2},\frac{88}{2},\frac{00}{2},\frac{\{80\}}{\sqrt{2}},\frac{\{06\}}{\sqrt{2}},\frac{\{68\}}{\sqrt{2}}\right\},$$

$$\mathbf{8} \quad \left[58,50,70,76,96,98,\frac{56-78}{\sqrt{2}},\frac{56+78-2\times 90}{\sqrt{6}}\right],$$
$$\left(5890,5078,7056,7690,9678,9856,\frac{5690-7890}{\sqrt{2}},\frac{2\times 5678-5690-7890}{\sqrt{6}}\right).$$

All states can be constructed combining and antisymmetrizing or symmetrizing the basic blocks. The basic blocks (35) and (36) which appear only in antisymmetric tensors are embraced by parentheses, the basic blocks which appear only in the symmetric tensors are embraced by curly brackets ($\{aa\}/2=aa$), while the basic blocks that appear both in symmetric and antisymmetric tensors are embraced by square brackets.

B. $\mathcal{H}$ operators and Clebsch–Gordan coefficients

Let us denote by R the sum of all representations **10**, **45**, **54**, **120**, **126**, $\overline{\mathbf{126}}$, and **210**,

$$R=\sum_I R^I, \quad \dim R=691. \tag{37}$$

There are 21 cubic invariants [see Eq. (3)],

$$\mathcal{I}(R^I,R^J,R^{\bar{K}})\equiv \mathcal{I}^{IJ\bar{K}}, \quad \overline{R^K}\equiv R^{\bar{K}}, \tag{38}$$

where $R^I\times R^J=\Sigma_K R^K$.

Let us denote $\mathcal{H}$-operators (see Refs. 15 and 16),

$$\mathcal{H}_K(R^I,R^J)=\mathcal{H}_K(R^J,R^I)\sim R^K \tag{39}$$

transforming as R^K and

$$\mathcal{H}_K(R^I,R^J)=\frac{1}{N}\frac{\partial \mathcal{I}^{IJ\bar{K}}}{\partial R^{\bar{K}}}. \tag{40}$$

The normalization factor N is chosen so that

$$\mathcal{H}_K(R^I,R^J)R^{\bar{K}}=\mathcal{I}^{IJ\bar{K}}. \tag{41}$$

For example, in the Y-diagonal basis

$$[\mathcal{H}_\Phi(\Phi_1,\Phi_2)]_{abcd} = \tfrac{1}{6}[(\Phi_1)_{abef}(\Phi_2)_{cd\overline{ef}} - (\Phi_1)_{acef}(\Phi_2)_{bd\overline{ef}} + (\Phi_1)_{adef}(\Phi_2)_{bc\overline{ef}} + (\Phi_1)_{cdef}(\Phi_2)_{ab\overline{ef}} - (\Phi_1)_{bdef}(\Phi_2)_{ac\overline{ef}} + (\Phi_1)_{bcef}(\Phi_2)_{ad\overline{ef}}]. \tag{42}$$

For invariants of the type $\mathcal{I}^{III}$, there is only one $\mathcal{H}$ operator, $\mathcal{H}_I$, for invariants of the type $\mathcal{I}^{II\overline{K}}$ there are two $\mathcal{H}$ operators, $\mathcal{H}_{\overline{I}}$ and $\mathcal{H}_K$, and for invariants of the type $\mathcal{I}^{IJ\overline{K}}$ there are three $\mathcal{H}$ operators, $\mathcal{H}_{\overline{I}}$, $\mathcal{H}_{\overline{J}}$, and $\mathcal{H}_K$. The $\mathcal{H}$ operators are symmetric in R^I and R^J, $\mathcal{H}(R^I,R^J)=\mathcal{H}(R^J,R^I)$. More generally,

$$\mathcal{I}^{IJ\overline{K}} = \mathcal{I}^{JI\overline{K}} = \mathcal{I}^{I\overline{K}J} = \mathcal{I}^{J\overline{K}I} = \mathcal{I}^{\overline{K}IJ} = \mathcal{I}^{\overline{K}JI}. \tag{43}$$

We are especially interested in CG coefficients when at least one of the states transforms as a singlet under the G_{321} group. That requires the decomposition of each SO(10) irrep R^I into G_{321} irreps,

$$R^I = \sum_i R_i^I, \tag{44}$$

where indices "i" just enumerate the G_{321} irreps with fixed Y contained in a specific R^I irrep. There are eight singlets, denoted here shortly by S_i^I, defined in Eqs. (14)–(21). For this choice of G_{321}-singlet states, the action of $\mathcal{H}$ operators are reduced to the invariant subspaces of states with fixed G_{321} quantum numbers, which are listed in Tables 1–5 (Ref. 19),

$$\mathcal{H}_K(\hat{S}_i^I,R_j^J) = \sum_k C_{ijk}^{IJK} R_k^K, \tag{45}$$

where R_j^J and R_k^K transform as identical G_{321} irreps (have the same G_{321} quantum numbers). For example, for the evaluation of the first column in the $(\mathbf{1},\mathbf{3},1)$ mass matrix [see Eq. (74)], the following $\mathcal{H}$ operators must be evaluated:

$$\mathcal{H}_E(\hat{E},\hat{E}_{(1,3,3)}^{(1,3,1)}) = \frac{\sqrt{3}}{2\sqrt{5}}\hat{E}_{(1,3,3)}^{(1,3,1)},$$
$$\mathcal{H}_{\overline{\Delta}}(\widehat{v_R},\hat{E}_{(1,3,3)}^{(1,3,1)}) = \frac{1}{5}\hat{\overline{\Delta}}_{(10,3,1)}^{(1,3,1)}. \tag{46}$$

Note that

$$C_{ijk}^{IJK} = \mathcal{I}(\hat{S}_i^I,\hat{R}_j^J,\hat{R}_k^{\overline{K}}) \equiv \hat{S}_i^I\hat{R}_j^J\hat{R}_k^{\overline{K}} \tag{47}$$

[the second part of Eq. (47) defines shortand notation] where

$$\hat{R}_i^{\overline{I}} \equiv \overline{\hat{R}_i^I} \tag{48}$$

is the complex conjugated irrep of $\hat{R}_i^I$. The CG coefficients are listed in 25 tables in Appendix B. Note that the CG coefficients depend only on the indices $i,j,\ldots$, that represent G_{321} multiplets and not on the specific states within the G_{321} multiplets. That can be used as a consistency check of the states belonging to the specific G_{321} multiplets.

We choose all SO(10) invariants in Eq. (3) to be real, except for invariants containing the Δ or the $\overline{\Delta}$ field separately (for example, $\Delta H\Phi$ or $E\overline{\Delta}^2$). In this last case, the sum of the two invariants, one containing Δ field and the other having $\overline{\Delta}$ field in place of Δ, are real. Generally, CG coefficients are complex (in our case they are either real or pure imaginary). Starting with cubic invariants in Eq. (3), our choice of phases of states in Tables 1–5 (Ref. 19) is such that it leads to the minimal number of imaginary terms in the mass matrices.

Symmetry relations imply

$$C_{ijk}^{IJK} = C_{jik}^{JIK}. \tag{49}$$

CG coefficients also satisfy Hermiticity relations,

$$\overline{C_{ijk}^{IJK}} = C_{\bar{i}kj}^{\bar{I}KJ}. \tag{50}$$

Here the $\bar{i}$ represents the label assigned to the irrep complex conjugated to the irrep designated by i.

Furthermore, following relations are valid:

$$\sum_j C_{ijj}^{IJ\bar{J}} \dim R_j^J = 0, \quad \sum_j \dim R_j^J = \dim R^J, \tag{51}$$

$$\sum_i \sum_j C_{ijk}^{IJK} C_{\bar{i}\bar{j}\bar{l}}^{\bar{I}\bar{J}\bar{K}} \dim R_i^I \dim R_j^J = C(I,J,K)\delta_{kl}^{-},$$

$$\sum_i \dim R_i^I = \dim R^I, \quad \sum_j \dim R_j^J = \dim R^J, \tag{52}$$

where $C(I,J,K)$ are constants depending on irreps R^I, R^J, and R^K.

V. MASS MATRICES

A. Mass matrices

For the sum of all representations R [see Eq. (37)], we define fluctuations of the Higgs field around the VEVs as

$$R = \langle R \rangle + \sum_{I,i} r_i^I. \tag{53}$$

Then the matrix element of the mass matrix corresponding to G_{321} multiplets i,j (R_i^I and R_j^J transform identically under G_{321}) is

$$\mathcal{M}_{ij}^{IJ} = \left(\frac{\partial^2 W}{\partial r_i^I \partial \overline{r_j^J}} \right)_{R=\langle R \rangle}, \tag{54}$$

$$\mathcal{M}_{ij}^{IJ} = m_I \delta_{IJ} \delta_{ij} + \sum_{K,k} \lambda^{IJK} S_i^I C_{ijk}^{IJK}, \tag{55}$$

where $\lambda^{III}=6\lambda_p$, $\lambda^{IIK}=2\lambda_p$, and $\lambda^{IJK}=\lambda_p$ for invariants containing three identical representations, two identical representations (different from the third one), and three different representations, respectively. Specifically, $\{\lambda^{IJK}\}=\{6\lambda_1, 6\lambda_8, 2\lambda_5, 2\lambda_7, 2\lambda_9, 2\lambda_{10}, 2\lambda_{11}, 2\lambda_{12}, 2\lambda_{13}, 2\lambda_{14}, 2\lambda_{15}, \lambda_2, \lambda_3, \lambda_4, \lambda_6, \lambda_{16}, \lambda_{17}, \lambda_{18}, \lambda_{19}, \lambda_{20}, \lambda_{21}\}$.

According to Eq. (51) the trace of the total mass matrix over all $\dim R$ states in R is

$$\mathrm{Tr}\, \mathcal{M} = \sum_I m_I \dim R^I. \tag{56}$$

The mass matrices are generally non-Hermitian. So the squares of physical masses are equal to the eigenvalues of matrices $\mathcal{M}^\dagger \mathcal{M}$ and $\mathcal{M}\mathcal{M}^\dagger$. (One can obtain Hermitian matrices $\mathcal{M}^\dagger \mathcal{M}$, i.e., $\mathcal{M}\mathcal{M}^\dagger$ with the same spectra.) For a real superpotential, that is for $\lambda_3=\lambda_4$, $\lambda_{11}=\lambda_{12}$, $\lambda_{18}=\lambda_{19}$, and $\lambda_{20}=\lambda_{21}$ and all coupling constants and VEVs real, the matrices are Hermitian due to the Hermiticity relation (50).

Now we are ready to present the explicit forms of the mass matrices calculated from the superpotential of Eq. (2). Every matrix is designated with the corresponding G_{321} multiplet and appears dim R_i^I times in the total mass matrix $\mathcal{M}$. A mass matrix associated with a G_{321} multiplet and the mass matrix associated with the corresponding complex conjugated G_{321} multiplet are equal up to transposition, and therefore for multiplets with $Y \neq 0$ we list only one of the two mass matrices. Of course, when enumerating the total degrees of freedom, one must include all mass eigenvalues (691 in total). The basis designating the columns ($\mathbf{c}$:) of the mass matrices listed below is given in the same way as shown in Tables 1, 2, 3, 4, and 5 (Ref. 19), while the rows are designated by the corresponding complex conjugated G_{321} multiplets ($\mathbf{r}$:),

$(\mathbf{1},\mathbf{1},0)$

$\mathbf{c}$: $\hat{A}^{(1,1,0)}_{(1,1,3)}, \hat{A}^{(1,1,0)}_{(15,1,1)}, \hat{E}^{(1,1,0)}_{(1,1,1)}, \hat{\Delta}^{(1,1,0)}_{(\overline{10},1,3)}, \hat{\bar{\Delta}}^{(1,1,0)}_{(10,1,3)}, \hat{\Phi}^{(1,1,0)}_{(1,1,1)}, \hat{\Phi}^{(1,1,0)}_{(15,1,1)}, \hat{\Phi}^{(1,1,0)}_{(15,1,3)}$

$\mathbf{r}$: $\hat{A}^{(1,1,0)}_{(1,1,3)}, \hat{A}^{(1,1,0)}_{(15,1,1)}, \hat{E}^{(1,1,0)}_{(1,1,1)}, \hat{\bar{\Delta}}^{(1,1,0)}_{(10,1,3)}, \hat{\Delta}^{(1,1,0)}_{(\overline{10},1,3)}, \hat{\Phi}^{(1,1,0)}_{(1,1,1)}, \hat{\Phi}^{(1,1,0)}_{(15,1,1)}, \hat{\Phi}^{(1,1,0)}_{(15,1,3)}$

$$\begin{pmatrix}
m_{11}^{(1,1,0)} & \sqrt{\frac{2}{3}}\lambda_5\Phi_3 & \sqrt{\frac{3}{5}}\lambda_9 A_1 & -\frac{\lambda_6 \overline{v_R}}{5} & -\frac{\lambda_6 v_R}{5} & \sqrt{\frac{2}{3}}\lambda_5 A_1 & \frac{2\sqrt{2}\lambda_7\Phi_3}{5} & m_{81}^{(1,1,0)} \\

B. Tests and consistency checks of the total mass matrix

The following consistency checks of the total mass matrix have been performed (see also Ref. 17):

(1) The CG coefficients appearing in the total mass matrix have been found to satisfy the Hermiticity relation (50).

(2) The trace of the total mass matrix has been evaluated and it has been found that it satisfies Eq. (56).

(3) For the G_{321} symmetric vacuum, the number of the would-be NG modes have been found to be equal to the number of the broken generators, i.e., massive gauge bosons, $45-12=33$. Here, 45 represents the number of gauge bosons in the adjoint irrep of the SO(10) group, and 12 represents the number of the gauge bosons in the standard model (G_{321} group). The check has been performed numerically for several tens of randomly chosen sets of the parameters of the superpotential $\lambda_1,\ldots,\lambda_{21}$ and $m_1,\ldots,m_6$, constrained by VEV Eqs. (28).

(4) For the SU(5) symmetric vacuum, it has been found that the number of the different mass eigenvalues is 21. The number of independent SU(5) irreps contained in the total representation of the model R is 22 (see Appendix A), and the would-be NG bosons are in two multiplets $[(\mathbf{1})+(\mathbf{10}+\overline{\mathbf{10}})]$. Therefore, there are in total 21 mass eigenvalues: 20 different from zero and one equal to zero. All other states must be accommodated in the SU(5) irreps. Further, for the SU(5) symmetric vacuum, all eigenvalues of the doublet Higgs matrix $(\mathbf{1},\mathbf{2},\frac{1}{2})$ are contained in the spectrum of the triplet Higgs matrix $(\mathbf{3},\mathbf{1},-\frac{1}{3})$. The only mass eigenvalue of the triplet Higgs matrix spectrum not contained in the doublet mass spectrum belongs to the SU(5) multiplet **50**, leading to the following relation between determinants of these two matrices:

$$\det(M^{(3,1,-1/3)} - \lambda \times \mathbf{1}) = (m_{50}^{(3,1,-1/3)} - \lambda)\det(M^{(1,2,1/2)} - \lambda \times \mathbf{1}). \tag{93}$$

The above relation gives a very strong test for these two matrices. All above checks have been performed numerically, in the same way as explained in the previous item. Our mass matrices passed all checks. For the SU(5) symmetric vacuum, all VEVs, except E, are different from zero, and they are nontrivially correlated through the VEV Eqs. (28) and SU(5) symmetry conditions (30). Therefore, these tests serve as a strong check of the total mass matrix up to terms which depend on E.

(5) For the G_{422} symmetric vacuum, it has been found that the number of different mass eigenvalues is 27, what is just the number of the independent G_{422} irreps (see Appendix A). The number of NG states, contained in G_{422} irrep $(\mathbf{6},\mathbf{2},\mathbf{2})$ is $45-21=24$. These checks have been performed numerically as explained above. All other states have been found to be accommodated in G_{422} irreps. For the G_{422} symmetric vacuum, VEVs different from zero are Φ_1 and E, and therefore this serves as a check of the E-dependent parts of the total mass matrix.

(6) Similar tests are satisfied for other higher symmetries G_{51}, G_{421}, G_{3221}, and G_{3211}.

We stress that all mass matrices in Ref. 17, derived for minimal SO(10) model ($R=\mathbf{10}+\mathbf{126}+\overline{\mathbf{126}}+\mathbf{210}$), satisfy all of the above consistency checks, and are just a special case of the mass matrices in this paper. Further, all results including CG coefficients and mass matrices were obtained analytically including checks.

In the recent calculations in Refs. 20 and 21, that appeared after Ref. 17, the necessary condition (93) between doublets and triplets is not satisfied. The Hermiticity condition (50) and the total trace relation (56) are also not satisfied in these references. Further, none of the higher symmetry tests is satisfied. That is a consequence of different phase conventions in Ref. 17 and phase conventions in Refs. 20 and 21.

In this paper, all results for the CG coefficients and mass matrices have been also obtained analytically. Checks have been performed numerically and it has been found that the mass matrices satisfy ALL consistency checks.

VI. MASS MATRICES OF QUARKS AND LEPTONS

After the symmetry breaking down to the G_{321} subgroup, the electroweak symmetry breaking $\mathrm{SU}(2)_L\times\mathrm{U}(1)_Y\to\mathrm{U}(1)_{\mathrm{em}}$ can be achieved by the VEVs of doublets included in the fields H, D, Δ, $\overline{\Delta}$, and Φ. These fields are given by [see Table 2 (Ref. 19)] $\tilde{H}_{u/d}=H^{(1,2,\pm1/2)}_{(1,2,2)}$, $D_{u/d}=D^{(1,2,\pm1/2)}_{(1,2,2)}$, $\tilde{D}_{u/d}=D^{(1,2,\pm1/2)}_{(15,2,2)}$, $\overline{\Delta}_{u/d}=\overline{\Delta}^{(1,2,\pm1/2)}_{(15,2,2)}$, $\Delta_{u/d}=\Delta^{(1,2,\pm1/2)}_{(15,2,2)}$, $\Phi_{u/d}=\Phi^{(1,2,\pm1/2)}_{(\overline{10},2,2)}$. The Yukawa couplings of Eq. (1) including these doublets can be written as follows:

$$\begin{aligned}W_Y &= U^c_i(Y^{ij}_{10}\tilde{H}_u + Y^{ij}_{120}D_u + Y^{ij}_{120}\tilde{D}_u + Y^{ij}_{126}\overline{\Delta}_u)Q_j + D^c_i(Y^{ij}_{10}\tilde{H}_d + Y^{ij}_{120}D_d + Y^{ij}_{120}\tilde{D}_d + Y^{ij}_{126}\overline{\Delta}_d)Q_j\\ &\quad + N^c_i(Y^{ij}_{10}\tilde{H}_u + Y^{ij}_{120}D_u - 3Y^{ij}_{120}\tilde{D}_u - 3Y^{ij}_{126}\overline{\Delta}_u)L_j + E^c_i(Y^{ij}_{10}\tilde{H}_d + Y^{ij}_{120}D_d - 3Y^{ij}_{120}\tilde{D}_d - 3Y^{ij}_{126}\overline{\Delta}_d)L_j,\end{aligned} \tag{94}$$

where U^c, D^c, N^c, and E^c are the right-handed $\mathrm{SU}(2)_L$ singlet quark and lepton superfields, Q and L are the left-handed $\mathrm{SU}(2)_L$ doublet quark and lepton superfields, respectively. This is a generalization of the renormalizable minimal SO(10) model,[6,7] including **120**. Note that the successful gauge-couplings unification is realized with only the MSSM particle contents. This means that only one pair of Higgs doublets remains light and others should be heavy ($\geqslant M_G$). Here we accept the simple picture that the low-energy superpotential is described by only one pair of light Higgs doublets (H_u and H_d) in the MSSM. But, in general, these Higgs fields are admixtures of all Higgs doublets having the same quantum numbers in the original model such as

$$\begin{aligned}H_u &= \tilde{\alpha}^1_u\tilde{H}_u + \tilde{\alpha}^2_u D_u + \tilde{\alpha}^3_u\tilde{D}_u + \tilde{\alpha}^4_u\overline{\Delta}_u + \tilde{\alpha}^5_u\Delta_u + \tilde{\alpha}^6_u\Phi_u,\\ H_d &= \tilde{\alpha}^1_d\tilde{H}_d + \tilde{\alpha}^2_d D_d + \tilde{\alpha}^3_d\tilde{D}_d + \tilde{\alpha}^4_d\overline{\Delta}_d + \tilde{\alpha}^5_d\Delta_d + \tilde{\alpha}^6_d\Phi_d,\end{aligned} \tag{95}$$

where $\tilde{\alpha}^i_{u,d}$ ($i=1,2,\ldots,5,6$) denote elements of the unitary matrix which rotate the flavor basis in the original model into the (SUSY) mass eigenstates. As mentioned above, the low-energy superpotential is described only by the light Higgs doublets H_u and H_d,

$$\begin{aligned}W_Y &= U^c_i(\alpha^1_u Y^{ij}_{10} + \alpha^2_u Y^{ij}_{120} + \alpha^3_u Y^{ij}_{120} + \alpha^4_u Y^{ij}_{126})H_u Q_j + D^c_i(\alpha^1_d Y^{ij}_{10} + \alpha^2_d Y^{ij}_{120} + \alpha^3_d Y^{ij}_{120} + \alpha^4_d Y^{ij}_{126})H_d Q_j\\ &\quad + N^c_i(\alpha^1_u Y^{ij}_{10} + \alpha^2_u Y^{ij}_{120} - 3\alpha^3_u Y^{ij}_{120} - 3\alpha^4_u Y^{ij}_{126})H_u L_j + E^c_i(\alpha^1_d Y^{ij}_{10} + \alpha^2_d Y^{ij}_{120} - 3\alpha^3_d Y^{ij}_{120}\\ &\quad - 3\alpha^4_d Y^{ij}_{126})H_d L_j,\end{aligned} \tag{96}$$

where the formulas of the inverse unitary transformation of Eq. (95),

$$\tilde{H}_u = \alpha^1_u H_u, \quad D_u = \alpha^2_u H_u,$$

$$\begin{aligned} \tilde{D}_u &= \alpha_u^3 H_u, \quad \overline{\Delta}_u = \alpha_u^4 H_u, \\ \tilde{H}_d &= \alpha_d^1 H_d, \quad D_d = \alpha_d^2 H_d, \\ \tilde{D}_d &= \alpha_d^3 H_d, \quad \overline{\Delta}_d = \alpha_d^4 H_d, \end{aligned} \tag{97}$$

have been used.

Providing the Higgs VEVs, $H_u = v \sin\beta$ and $H_d = v \cos\beta$ with $v \simeq 174.1(\mathrm{GeV})$, the quark and lepton mass matrices can be read off as

$$\begin{aligned} M_u &= c_{10} M_{10} + c_{120} M_{120} + \tilde{c}_{120} \tilde{M}_{120} + c_{126} M_{126}, \\ M_d &= M_{10} + M_{120} + \tilde{M}_{120} + M_{126}, \\ M_D &= c_{10} M_{10} + c_{120} M_{120} - 3\tilde{c}_{120} \tilde{M}_{120} - 3 c_{126} M_{126}, \\ M_e &= M_{10} + M_{120} - 3\tilde{M}_{120} - 3 M_{126}, \\ M_R &= c_R M_{126}, \end{aligned} \tag{98}$$

where M_u, M_d, M_D, M_e, and M_R denote the up-type quark, down-type quark, neutrino Dirac, charged-lepton, and right-handed neutrino Majorana mass matrices, respectively. Note that the mass matrices at the right-hand side of Eq. (98) are defined as $M_{10} = Y_{10}\alpha_d^1 v \cos\beta$, $M_{120} = Y_{120}\alpha_d^2 v \cos\beta$, $\tilde{M}_{120} = Y_{120}\alpha_d^3 v \cos\beta$, and $M_{126} = Y_{126}\alpha_d^4 v \cos\beta$, respectively, and the coefficients are defined as $c_{10} = (\alpha_u^1/\alpha_d^1)\tan\beta$, $c_{120} = (\alpha_u^2/\alpha_d^2)\tan\beta$, $\tilde{c}_{120} = (\alpha_u^3/\alpha_d^3)\tan\beta$, $c_{126} = (\alpha_u^4/\alpha_d^4)\tan\beta$, and $c_R = v_R/(\alpha_d^4 v \cos\beta)$. These mass matrices are directly connected with low-energy observations and are crucial to model judgement.

VII. CONCLUSION

We have presented a simple method for the calculation of CG coefficients. We have constructed all states for all antisymmetric and symmetric SO(10) tensor irreps. We list all tables for the CG coefficients for the SO(10) irreps **10**, **45**, **54**, **120**, **126**, $\overline{\mathbf{126}}$, and **210**, for all possible cubic invariants. We have constructed all mass matrices for the corresponding Higgs-Higgsino sector is SUSY GUT SO(10) models. We have found a set of consistency checks for the CG coefficients and mass matrices which proved the correctness of all our results. The results obtained here are useful for a wide class of GUT models based on the SO (10) group.

APPENDIX A: DECOMPOSITION OF REPRESENTATIONS UNDER G_{321}

Here we list the decompositions of **10, 16, 45, 54, 120**, $\overline{\mathbf{126}}$, and **210** representations under the chain of subgroups $G_{422} \supset G_{3122} \supset G_{3121} \supset G_{321}$ in Tables 7, 8, 9, 10, 11, 12, and 13 (Ref. 19), where U(1) groups are related to $\mathrm{SU}(4) \to \mathrm{SU}(3)_C \times \mathrm{U}(1)_{B-L}$, $\mathrm{SU}(2)_L \times \mathrm{SU}(2)_R \to \mathrm{SU}(2)_L$

$\times U(1)_R$. [We use the same notation as Slansky[22] but with the proper U(1) normalizations.] Note also that we may consider another chain of subgroups $SO(10) \rightarrow SU(5) \times U(1)_X$ and $SU(5) \rightarrow G_{321}$. The relations between the generators of $U(1)_{X,Y}$ and $U(1)_{B-L,R}$ are

$$\begin{aligned} \tfrac{1}{10}(-X+4Y) &= B-L, \\ Y &= B-L+T_R^3, \end{aligned} \tag{A1}$$

where T_R^3 denotes the $U(1)_R$ generator.

APPENDIX B: CG COEFFICIENTS

The CG coefficients for HH, AA, EE, DD, $\Delta\Delta$, $\overline{\Delta\Delta}$, $\overline{\Delta}\Delta$, $\Phi\Phi$, EA, $A\Phi$, $E\Delta$, $E\overline{\Delta}$, $E\Phi$, ΔH, $\overline{\Delta}H$, $H\Phi$, $\Phi\Delta$, $\Phi\overline{\Delta}$, $A\Delta$, $A\overline{\Delta}$, DH, DA, $D\Delta$, $D\overline{\Delta}$, and $D\Phi$ combinations are listed in Tables 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, and 39, respectively.[19]

Quantum integrability of the deformed elliptic Calogero–Moser problem

L. A. Khodarinova[a)]
Magnetic Resonance Centre, School of Physics and Astronomy, University of Nottingham, Nottingham, England NG7 2RD

(Received 7 July 2004; accepted 30 September 2004; published online 10 February 2005)

The integrability of the deformed quantum elliptic Calogero–Moser problem introduced by Chalykh, Feigin, and Veselov is proven. Explicit recursive formulas for the integrals are found. For integer values of the parameter this implies the algebraic integrability of the systems. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1829375]

I. INTRODUCTION

Deformed quantum Calogero–Moser (CM) systems were introduced by Chalykh, Feigin, and Veselov,[1,2] who proved their integrability in rational and trigonometric cases and conjectured that the same is true in the elliptic case. The aim of this paper is to prove this conjecture.

Elliptic deformed CM system corresponds to the following Schrödinger operator:

$$L_m^{(n)} = \sum_{j=1}^{n} \frac{\hat{p}_j^2}{m_j} + 2m(m+1) \sum_{1\leqslant j<k\leqslant n}^{n} m_j m_k \wp(x_j - x_k), \tag{1}$$

where all but one "masses" are equal, $m_1 = m^{-1}$, $m_2 = \cdots = m_n = 1$, m is a real parameter, $\hat{p}_j = i(\partial/\partial x_j)$, $j = 1, \ldots, n$, and $\wp$ is the classical Weierstrass elliptic function. The case when m is integer is a special one: in that case a stronger version of integrability (the so-called algebraic integrability) was conjectured.[2] The first results in this direction were found by Prikhodsky and the author,[3] who proved the conjecture in the simplest nontrivial case $n=3$, $m=2$.

The main result of the present paper is an explicit recursive formula for the quantum integrals of the elliptic deformed CM system. This proves integrability of the system for all n and m and due to a general recent result by Chalykh, Etingof, and Oblomkov[4] this also implies the algebraic integrability for integer values of the parameter m.

As a by-product we have also new formulas for the integrals of the usual quantum elliptic CM problem, which was the subject of many investigations since the 1970s.[5–11] We will be using some technical tricks from these important papers. In trigonometric and rational limits we have the formulas for the quantum integrals of the corresponding deformed CM systems which also seem to be new.

II. PRELIMINARIES AND MAIN FORMULAS

Quantum Hamiltonian of the deformed elliptic CM problem has the following form:

$$H = -(m\partial_1^2 + \partial_2^2 + \cdots + \partial_{n-1}^2 + \partial_n^2) + 2(m+1)\sum_{k=2}^{n} \wp_{1k} + 2m(m+1) \sum_{2\leqslant j<k\leqslant n} \wp_{jk}, \tag{2}$$

where $\partial_i = \partial/\partial x_i$, $\wp_{jk} = \wp(x_j - x_k)$. Here $\wp$ is the classical Weierstrass elliptic function,[12] which can be determined by the differential equation

[a)]Electronic mail: larisakhodarinova@hotmail.com

$$(\mathfrak{p}'(z))^2 = 4(\mathfrak{p}(z) - e_1)(\mathfrak{p}(z) - e_2)(\mathfrak{p}(z) - e_3) = 4\mathfrak{p}^3(z) - g_2\mathfrak{p}(z) - g_3. \tag{3}$$

The Laurent expansion of $\mathfrak{p}$ at the origin is of the following form:[12]

$$\mathfrak{p}(z) = z^{-2} + \sum_{k=1}^{\infty} \gamma_{2k} z^{2k}, \tag{4}$$

where

$$\gamma_2 = \tfrac{1}{20} g_2, \quad \gamma_4 = \tfrac{1}{28} g_3.$$

The coefficients γ_{2k} are related to the so-called *Bernoulli–Hurwitz numbers*[13] BH (k),

$$\gamma_{2k} = \frac{1}{(2k)!} \frac{\mathrm{BH}(2k+2)}{(2k+2)}.$$

There is a recursive formula which allows one to obtain the coefficients γ_{2k+2} from the coefficients of the lower order,

$$\gamma_{2k+2} = \frac{3}{(k-1)(2k+5)} \sum_{j=1}^{k-1} \gamma_{2j}\gamma_{2k-2j}, \quad k = 2,3, \ldots . \tag{5}$$

The relationship (5) is easy to verify. One needs to differentiate (3) to obtain

$$\mathfrak{p}''(z) = 6\mathfrak{p}^2(z) - \tfrac{1}{2} g_2,$$

use the expansion (4) and collect terms at the appropriate degrees of z.

To construct the integrals of the operator (2) we will follow the idea going back to the papers by Sawada and Kotera[6] and Olshanetsky and Perelomov.[7] Namely, the integrals are constructed from the highest one by successive commutators with some function which in our case is $m^{-1}x_1 + x_2 + \cdots + x_n$. This highest integral is of order n and will be denoted below as I. The rest of this section is to explain the main ingredients of the formula for I.

Let us introduce the following differential operators $\mathfrak{D}^k$ in ∂_1 with constant coefficients,

$$\mathfrak{D}^1 = \partial_1, \quad \mathfrak{D}^2 = \frac{(1-m)}{2!}\partial_1^2, \quad \mathfrak{D}^3 = \frac{(1-m)(1-2m)}{3!}\partial_1^3, \quad \mathfrak{D}^4 = \frac{(1-m)(1-2m)(1-3m)}{4!}\partial_1^4,$$

$$\mathfrak{D}^k = p_{0,k}\partial_1^k + \sum_{i=2}^{[k/2]} p_{2i,k}\partial_1^{k-2i}. \tag{6}$$

The constants $p_{0,k}$, $k=2,3,\ldots$, are given by

$$p_{0,k} = \frac{1}{k!} \prod_{l=1}^{k-1} (1 - lm), \quad k = 2,3, \ldots , \tag{7}$$

and constants $p_{2i,k}$, $i=2,3,\ldots$, $k=2i, 2i+1, \ldots$, are determined by the following recursive relations:

$$p_{2i,2i} = 0, \quad i = 2,3, \ldots , \tag{8}$$

$$p_{2i,k} = \frac{(1 - m(k-2i-1))}{k-2i} p_{2i,k-1} - (1+m) \sum_{\substack{j=1 \\ j\neq 2}}^{i-1} (2i-2j)! C_{k-2j+1}^{k-2i} \gamma_{2i-2j} p_{2j-2,k-1},$$

$$i = 2,3, \ldots, \quad k = 2i+1, 2i+2, \ldots, \tag{9}$$

where $C_n^k = n!/(k!(n-k)!)$ is a binomial coefficient. To illustrate the formula (9) let us write explicitly the formulas for the first few values of i,

$$p_{4,k} = \frac{(1-m(k-5))}{k-4} p_{4,k-1} - (1+m)\frac{\prod_{l=1}^{3}(k-l)}{3}\gamma_2 p_{0,k-1}, \quad k = 5,6, \ldots,$$

$$p_{6,k} = \frac{(1-m(k-7))}{k-6} p_{6,k-1} - (1+m)\frac{\prod_{l=1}^{5}(k-l)}{5}\gamma_4 p_{0,k-1}, \quad k = 7,8, \ldots,$$

$$p_{8,k} = \frac{(1-m(k-9))}{k-8} p_{8,k-1} - (1+m)\left(\frac{\prod_{l=1}^{7}(k-l)}{7}\gamma_6 p_{0,k-1} + \frac{\prod_{l=5}^{7}(k-l)}{3}\gamma_2 p_{4,k-1}\right), \quad k = 9,10, \ldots.$$

It is interesting to note that for the special values of parameter $m = 1/l$, where l is a positive integer number, most of the constants (7) and (9) are zero. For example, if $m = \frac{1}{2}$ only $p_{0,2}$ is nonzero, if $m = \frac{1}{3}$ then only $p_{0,2}$ and $p_{0,3}$ are nonzero, if $m = \frac{1}{4}$ then only $p_{0,2}$, $p_{0,3}$, $p_{0,4}$ and $p_{4,5}$, $p_{4,6} = p_{0,2}p_{4,5}$, $p_{4,7} = p_{0,3}p_{4,5}$, $p_{4,8} = p_{0,4}p_{4,5}$ are nonzero and so on.

Let us introduce the following notations:

$$\mathfrak{s}_j = (m+1)\mathfrak{s}(x_1 - x_j), \quad 2 \leqslant j \leqslant n,$$

$$u_{1j} = (m+1)\mathfrak{p}(x_1 - x_j), \quad 2 \leqslant j \leqslant n,$$

$$u_{kl} = m(m+1)\mathfrak{p}(x_k - x_l), \quad 2 \leqslant k < l \leqslant n,$$

where $\mathfrak{s}$ is the standard elliptic $\mathfrak{s}$-function $d\mathfrak{s}(z)/dz = -\mathfrak{p}(z)$.

We will need also to consider all the subsystems of the deformed CM system. Let S be a subset of k indices of the set $\{1,2,\ldots,n\}$ and $\sigma = \{j_1, j_2, \ldots, j_t\}$, $j_1 < j_2 < \cdots < j_t$, be a subset of t indices chosen from S. The set of all different subsets σ of size t of the set S will be denoted by

$$\mathfrak{S}(S;t) = \{\sigma = \{j_1, j_2, \ldots, j_t\} : j_1 < j_2 < \ldots < j_t, j_l \in S\}.$$

If $\sigma \in \mathfrak{S}(S;t)$ define the set $S \setminus \sigma = \{j : j \in S \text{ and } j \notin \sigma\}$. If $S = \{1,2,\ldots,n\}$ we will use short notations $\mathfrak{S}(t) = \mathfrak{S}(\{1,2,\ldots,n\};t)$ and $\hat{\sigma} = \{1,2,\ldots,n\} \setminus \sigma$. If σ contains only one element $\sigma = \{l\}$ the brackets will be omitted: l will denote a set which contains one element $\{l\}$, $S \setminus l = S \setminus \{l\}$ and $\hat{l} = \{1,2,\ldots,n\} \setminus \{l\}$ We will also use notation $\hat{\sigma}_1\hat{\sigma}_2$ to denote the intersection of the subsets $\hat{\sigma}_1$ and $\hat{\sigma}_2$, $\hat{\sigma}_1\hat{\sigma}_2 = \hat{\sigma}_1 \cap \hat{\sigma}_2$.

We will distinguish two cases, $1 \in S$ and $1 \notin S$. In the second case we will use the notation $\mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^r)$ for the repeated commutator

$$\mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^r) = [\mathfrak{s}_{i_t}, \ldots [\mathfrak{s}_{i_2}, [\mathfrak{s}_{i_1}, \mathfrak{D}^r]]], \quad \sigma = \{i_1, i_2, \ldots, i_t\}. \tag{10}$$

Note that the order in which $\mathfrak{s}_{i_k}$ are used is not important because of the form of the operator $\mathfrak{D}^r$ We will use also the notation e_S^j for the elementary symmetric polynomials of degree j of the symbols ∂_l, $l \in S$, $e_S^0 = 1$, $e_S^1 = \sum_{l \in S}\partial_l$, $e_S^2 = \sum_{l,r \in S}^{l<r} \partial_l\partial_r$, etc.

Now, define

$$\Theta = \mathfrak{D}^n + \sum_{t=1}^{[n/2]} \sum_{\sigma \in \mathfrak{S}(\hat{1};t)} \mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-t}) = \sum_{t=0}^{[n/2]} \sum_{\sigma \in \mathfrak{S}(\hat{1};t)} \mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-t})$$

and

$$\Theta_S = \mathfrak{D}^k + \sum_{t=1}^{[k/2]} \sum_{\sigma \in \mathfrak{S}(S\setminus 1;t)} \mathrm{ad}^t_{\mathfrak{s}_\sigma}(\mathfrak{D}^{k-t}) = \sum_{t=0}^{[k/2]} \sum_{\sigma \in \mathfrak{S}(S\setminus 1;t)} \mathrm{ad}^t_{\mathfrak{s}_\sigma}(\mathfrak{D}^{k-t}), \tag{11}$$

when the set S consists of k elements and contains 1. Here and below by $[x]$ we mean the integer part of the number x.

Consider now the quantum system with the Hamiltonian,

$$H_S = -\Delta_S + 2 \sum_{\substack{j<k \\ j,k\in S}} u_{jk},$$

where $\Delta_S = m\partial_1^2 + \Sigma_{j\in S\setminus 1}\partial_j^2$ if $1 \in S$ and $\Delta_S = \Sigma_{j\in S}\partial_j^2$ otherwise. If $1 \notin S$ then this is the standard CM system which is well known to have complete set of quantum integrals.[6–10] In particular, it has the integral with the highest term $\partial_S = \Pi_{j\in S}\partial_j$. We will denote this integral I_S.

If the set S consists of k elements and contains 1 then H_S is the Hamiltonian of the deformed CM system (2) with k particles. We claim that this system has the integral (which we also denote as I_S) with the constant highest term of the form

$$E_S = \partial_1 e^{k-1}_{S\setminus 1} + p_{0,2}\partial_1^2 e^{k-2}_{S\setminus 1} + p_{0,3}\partial_1^3 e^{k-3}_{S\setminus 1} + \cdots + p_{0,k}\partial_1^k e^0_{S\setminus 1},$$

where the constants $p_{0,s}$ are given by the formula (7) above. Note that when $m=1$ they all are zero and E_S reduces to $\partial_S = \Pi_{j\in S}\partial_j$, so the integral I_S can be considered as a deformation of the corresponding integral of the usual CM system.

We define I_S inductively. Namely, assuming that we know these integrals for the subsystems consisting of less than n particles define

$$I = \sum_{t=1}^{n-2} (-1)^{t+1} \sum_{\sigma\in\mathfrak{S}(t)} I_{\hat\sigma}\partial_\sigma + (-1)^n (n-1)\partial_1\cdots\partial_n + X. \tag{12}$$

Here

$$X = \Theta + \sum_{t=1}^{[(n-2)/2]} \sum_{\sigma\in\mathfrak{S}(\hat 1;2t)} X_\sigma \Theta_{\hat\sigma} \tag{13}$$

with the coefficients

$$X_S = \sum u_{i_1 j_1} u_{i_2 j_2}\cdots u_{i_p j_p}, \tag{14}$$

where the sum is taken over all partitions of S into two-element subsets $S = \{i_1,j_1\}\cup\{i_2,j_2\}\cup\cdots\cup\{i_p,j_p\}$, in the case when the size of S is even and $X_S=0$ otherwise. These coefficients can also be determined by the recurrent formulas

$$X_{\hat 1} = \sum_{j=2}^{n-1} X_{\{j,n\}} X_{\hat 1\setminus\{j,n\}} \quad \text{if } n = 2p+1 \text{ and } X_{\hat 1} = 0 \text{ if } n = 2p \tag{15}$$

with $X_{\{2,3\}} = u_{23}$.

Theorem 1: *The operator I defined by (12) and (13) commutes with the deformed elliptic CM operator (2).*

Remark: The formula (12) is valid in the nondeformed case also, the operator

$$I_{\hat 1} = \sum_{t=1}^{n-3} (-1)^{t+1} \sum_{\sigma\in\mathfrak{S}(\hat 1,t)} I_{\hat\sigma}\partial_\sigma + (-1)^n (n-2)\partial_2\cdots\partial_n + X_{\hat 1}$$

commutes with the operator

$$H_{\hat{1}} = -(\partial_2^2 + \cdots + \partial_{n-1}^2 + \partial_n^2) + 2m(m+1)\sum_{2\leqslant j<k\leqslant n} \mathfrak{p}_{jk},$$

which is the usual $n-1$ particle elliptic CM operator.

Idea of the proof of Theorem 1: The proof will be done by induction. The main idea behind the formula (12) consists in the observation that one can use the commutativity of $I_{\hat{\sigma}}\partial_\sigma$ with $H_{\hat{\sigma}}$ to simplify the commutator $[I,H]$ to the expression

$$[I,H] = [X,H] + \sum_{j=1}^{n}\left[X_{\hat{j}}\partial_j, 2\sum_{\substack{l=1\\ l\neq j}}^{n} u_{jl}\right] + \sum_{1\leqslant k<l\leqslant n}[X_{\hat{k}\hat{l}}\partial_k\partial_l, 2u_{kl}],$$

where terms X, $X_{\hat{j}}$, and $X_{\hat{k}\hat{l}}$ depend only on ∂_1 and u_{sr}, $1\leqslant s<r\leqslant n$. This is shown in Lemma 1 in Sec. VI. At the next step we notice that if X is given by (13) the commutator $[I,H]$ can be simplified further to the following expression:

$$[I,H] = [\Theta,H] + \sum_{j=2}^{n}\left[\Theta_{\hat{j}}\partial_j, 2\sum_{\substack{l=1\\ l\neq j}}^{n} u_{jl}\right] + \sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}}, 2(u_{1k}+u_{1l})]X_{\{k,l\}},$$

where Θ, $\Theta_{\hat{j}}$, and $\Theta_{\hat{k}\hat{l}}$ depend only on ∂_1 and u_{1s}, $2\leqslant s\leqslant n$. From this we can deduce that

$$\frac{\partial\Theta}{\partial x_k} = [u_{1k}, \Theta_{\hat{k}}]$$

and, therefore, it seems natural to use the operators $\mathrm{ad}_{\mathfrak{s}_\sigma}^t$ to construct Θ. At this stage the only freedom left is in choosing operators $\mathfrak{D}^k$ which must be the operators in ∂_1 with constant coefficients. To ensure that $[I,H]=0$ these operators must satisfy the relation

$$[\mathfrak{D}^n, \mathfrak{p}(x_1-x_i)] + (1+m)[[\mathfrak{s}(x_1-x_i), \mathfrak{D}^{n-1}], \mathfrak{p}(x_1-x_i)] + m[\mathfrak{D}^{n-1}, \mathfrak{p}(x_1-x_i)]\partial_1 - \frac{(1+m)}{2}\mathfrak{p}'(x_1-x_i)\mathfrak{D}^{n-1} - \frac{(1-m)}{2}\mathfrak{D}^{n-1}\mathfrak{p}'(x_1-x_i) = 0,$$

which is equivalent to a large set of identities. It is remarkable that the constants in $\mathfrak{D}^k$ can be chosen in such a way that all these identities are satisfied (Lemma 3 of Sec. VI). The choice of the constants is related to the Bernoulli–Hurwitz numbers and is described above. The complete proof of the theorem is quite technical and is given in a separate section.

III. EXAMPLES: FORMULAS FOR TWO, THREE, AND FOUR PARTICLES

To illuminate our formulas let us consider more explicitly the case of small n.

Two-particle case: In this case we have the operator

$$H = -m\partial_1^2 - \partial_2^2 + 2(m+1)\mathfrak{p}_{12} = -m\partial_1^2 - \partial_2^2 + 2u_{12}$$

which is trivially integrable since the operator $\partial_1+\partial_2$ obviously commutes with it. This system gives the formula for operator $I_{\{1,2\}}$ which starts the recursive construction of the integral I (12). We have

$$I = I_{\{1,2\}} = \frac{1}{2}(H + (\partial_1+\partial_2)^2) = \partial_1\partial_2 + \frac{(1-m)}{2}\partial_1^2 + (m+1)\mathfrak{p}_{12} = \partial_1\partial_2 + \mathfrak{D}^2 + u_{12},$$

$$X = X_{\{1,2\}} = \Theta_{\{1,2\}} = \mathfrak{D}^2 + u_{12} = \mathfrak{D}^2 + [\mathfrak{s}_2, \mathfrak{D}].$$

Three-particle case: The integrals for the problem in this case have been found by the author.[14] The operator of the third order has the form

$$I = \partial_1\partial_2\partial_3 + \frac{(1-m)}{2}(\partial_2+\partial_3)\partial_1^2 + \frac{(1-m)(1-2m)}{3!}\partial_1^3 + (m+1)(m\mathfrak{p}_{23}\partial_1 + \mathfrak{p}_{13}\partial_2 + \mathfrak{p}_{12}\partial_3)$$
$$+ \frac{(1-m)}{2}(m+1)((\mathfrak{p}_{12}+\mathfrak{p}_{13})\partial_1 + \partial_1(\mathfrak{p}_{12}+\mathfrak{p}_{13}))$$
$$= \partial_1\partial_2\partial_3 + p_{0,2}(\partial_2+\partial_3)\partial_1^2 + u_{23}\partial_1 + u_{13}\partial_2 + u_{12}\partial_3 + \mathfrak{D}^3 + [\mathfrak{s}_2,\mathfrak{D}^2] + [\mathfrak{s}_3,\mathfrak{D}^2].$$

Operator I can be rewritten as

$$I = I_{\{2,3\}}\partial_1 + I_{\{1,3\}}\partial_2 + I_{\{1,2\}}\partial_3 - 2\partial_1\partial_2\partial_3 + X,$$

where

$$X = \Theta = \mathfrak{D}^3 + [\mathfrak{s}_2,\mathfrak{D}^2] + [\mathfrak{s}_3,\mathfrak{D}^2] \quad \text{and } I_{\{2,3\}} = \partial_2\partial_3 + u_{23}.$$

Four-particle case: One can check by direct calculation that the operator

$$I = \partial_1\partial_2\partial_3\partial_4 + \frac{(1-m)}{2}(\partial_2\partial_3+\partial_2\partial_4+\partial_3\partial_4)\partial_1^2 + \frac{(1-m)(1-2m)}{3!}(\partial_2+\partial_3+\partial_4)\partial_1^3$$
$$+ \frac{(1-m)(1-2m)(1-3m)}{4!}\partial_1^4 + m(m+1)(\mathfrak{p}_{34}\partial_1\partial_2 + \mathfrak{p}_{24}\partial_1\partial_3 + \mathfrak{p}_{23}\partial_1\partial_4) + (m+1)(\mathfrak{p}_{14}\partial_2\partial_3$$
$$+ \mathfrak{p}_{13}\partial_2\partial_4 + \mathfrak{p}_{12}\partial_3\partial_4) + \frac{(1-m)(m+1)}{2}\partial_1((\mathfrak{p}_{13}+\mathfrak{p}_{14})\partial_2 + (\mathfrak{p}_{12}+\mathfrak{p}_{14})\partial_3 + (\mathfrak{p}_{12}+\mathfrak{p}_{13})\partial_4)$$
$$+ \frac{(1-m)(m+1)}{2}((\mathfrak{p}_{13}+\mathfrak{p}_{14})\partial_2 + (\mathfrak{p}_{12}+\mathfrak{p}_{14})\partial_3 + (\mathfrak{p}_{12}+\mathfrak{p}_{13})\partial_4)\partial_1 + \frac{(1-m)(1-2m)(m+1)}{3!}((\mathfrak{p}_{12}$$
$$+ \mathfrak{p}_{13}+\mathfrak{p}_{14})\partial_1^2 + \partial_1(\mathfrak{p}_{12}+\mathfrak{p}_{13}+\mathfrak{p}_{14})\partial_1 + \partial_1^2(\mathfrak{p}_{12}+\mathfrak{p}_{13}+\mathfrak{p}_{14})) + \frac{(1-m)m(m+1)}{2}(\mathfrak{p}_{34}+\mathfrak{p}_{24}+\mathfrak{p}_{23})\partial_1^2$$
$$+ (m+1)^2((1-m)(\mathfrak{p}_{14}\mathfrak{p}_{24}+\mathfrak{p}_{14}\mathfrak{p}_{34}+\mathfrak{p}_{24}\mathfrak{p}_{34}) + m(\mathfrak{p}_{12}\mathfrak{p}_{34}+\mathfrak{p}_{13}\mathfrak{p}_{24}+\mathfrak{p}_{14}\mathfrak{p}_{23}))$$

commutes with H. The operator I can be rewritten in the following recursive form:

$$I = 3\partial_1\partial_2\partial_3\partial_4 + X + I_{\{2,3,4\}}\partial_1 + I_{\{1,3,4\}}\partial_2 + I_{\{1,2,4\}}\partial_3 + I_{\{1,2,3\}}\partial_4 - I_{\{3,4\}}\partial_1\partial_2 - I_{\{2,4\}}\partial_1\partial_3 - I_{\{2,3\}}\partial_1\partial_4$$
$$- I_{\{1,4\}}\partial_2\partial_3 - I_{\{1,3\}}\partial_2\partial_4 - I_{\{1,2\}}\partial_3\partial_4, \tag{16}$$

where

$$X = \Theta + X_{\{2,3\}}\Theta_{\{1,4\}} + X_{\{2,4\}}\Theta_{\{1,3\}} + X_{\{3,4\}}\Theta_{\{1,2\}}$$
$$= \mathfrak{D}^4 + [\mathfrak{s}_2,\mathfrak{D}^3] + [\mathfrak{s}_3,\mathfrak{D}^3] + [\mathfrak{s}_4,\mathfrak{D}^3] + [\mathfrak{s}_2,[\mathfrak{s}_3,\mathfrak{D}^2]]$$
$$+ [\mathfrak{s}_2,[\mathfrak{s}_4,\mathfrak{D}^2]] + [\mathfrak{s}_3,[\mathfrak{s}_4,\mathfrak{D}^2]] + u_{23}(\mathfrak{D}^2 + [\mathfrak{s}_4,\mathfrak{D}]) + u_{24}(\mathfrak{D}^2 + [\mathfrak{s}_3,\mathfrak{D}]) + u_{34}(\mathfrak{D}^2 + [\mathfrak{s}_2,\mathfrak{D}]).$$

and

$$I_{\{2,3,4\}} = \partial_1\partial_2\partial_3 + u_{23}\partial_1 + u_{13}\partial_2 + u_{12}\partial_3.$$

IV. INTEGRABILITY OF THE DEFORMED ELLIPTIC QUANTUM CM PROBLEM

Let us introduce the function $\theta=m^{-1}x_1+x_2+\cdots+x_n$ and consider the corresponding "ad"-operation: $\mathrm{ad}_\theta(L)=[\theta,L]$. Following to the procedure known for the usual CM system (see, for example, Olshanetsky and Perelomov[8] consider the operators $L_k=\mathrm{ad}_\theta^k(I)$, $k=0,1,\ldots,n-1$.

Theorem 2: *Operators* $L_k=\mathrm{ad}_\theta^k(I)$, $k=0,1,\ldots,n-1$, *where I is given by (12), commute with each other and with operator H*.

Proof: The proof is similar to the nondeformed case.[8,11]

Let us first prove that L_k commute with H and with $\Sigma_{j=1}^n\partial_j$. Proof is by induction in k. For $k=0$ it follows from Theorem 1. Let us assume that this is true for $k=i$, then for $k=i+1$ we have by the Jacobi identity

$$[H,L_{i+1}]=[H,[\theta,L_i]]=[[H,\theta],L_i]+[[L_i,H],\theta]=2\left[\sum_{j=1}^n\partial_j,L_i\right]+[0,\theta]=0$$

and

$$\left[\sum_{j=1}^n\partial_j,L_{i+1}\right]=\left[\sum_{j=1}^n\partial_j,[\theta,L_i]\right]=\left[\left[\sum_{j=1}^n\partial_j,\theta\right],L_i\right]+\left[\left[L_i,\sum_{j=1}^n\partial_j\right],\theta\right]$$
$$=[(m^{-1}+n-1)Id,L_i^m]+[0,\theta]=0.$$

To prove that operators L_k and L_l, $k\neq l$, commute one can use the arguments of Oshima's paper.[11] Consider an involution δ on the space of all differential operators on R^n corresponding to the change $x\to -x$ and the anti-involution $*$ such that the operator L^* is a formal adjoint to L. Our operators L_k have the following properties with respect to these involutions: $L_k^*=L_k^\delta=(-1)^kL_k$. Now, consider the commutator $C=[L_k,L_l]$. By the Jacobi identity $[C,H]=0$, therefore we can use Berezin's lemma[15] which states that in such a case the highest symbol of C is polynomial in x. In this case it is also periodic, hence the highest symbol must be constant. We have

$$C^\delta=[L_k,L_l]^\delta=[L_k^\delta,L_l^\delta]=[L_k^*,L_l^*]=-[L_k,L_l]^*=-C^*. \tag{17}$$

Since the highest symbol of C is constant the highest symbols of C^* and C^δ are the same, which contradicts to (17) unless the highest symbol of C is zero and hence $[L_k,L_l]=0$.

Theorem 3: *Deformed quantum CM problem (1) is integrable for all n and m and algebraically integrable for integer m*.

Proof: The complete family of the commuting quantum integrals for arbitrary m is given by the previous theorems. The algebraic integrability in the case when m is integer follows from the general result due to Chalykh, Etingof, and Oblomkov[4] (see Theorem 3.8).

V. TRIGONOMETRIC AND RATIONAL DEGENERATIONS

Trigonometric degenerations of the Weierstrass $\mathfrak{p}$-function corresponds to the case when one of the half-periods ω_1 or ω_2 is infinite, which happens when two of the roots of the polynomial (3) collide. For example, the case of $e_1=e_2=a$ and $e_3=-2a$ corresponds to $\omega=\infty$, $\tilde{\omega}=i(\pi/\sqrt{12a})$, and $\mathfrak{p}(z)=a+(3a/\sinh^2\sqrt{3a}z)$. Choosing $a=\frac{1}{3}$ we have

$$\mathfrak{p}(z)=\frac{1}{3}+\frac{1}{\sinh^2 z}=z^{-2}-\sum_{k=1}^{\infty}\frac{2^{2k+2}}{(2k+2)}\frac{B_{2k+2}}{(2k)!}z^{2k},\quad \mathfrak{s}(z)=-\frac{1}{3}z+\coth z,$$

$$\gamma_{2k}=-\frac{2^{2k+2}}{(2k+2)}\frac{B_{2k+2}}{(2k)!},$$

where B_{2k+2} are the classical Bernoulli numbers defined by the expansion

$$\frac{z}{e^z-1}=1-\frac{1}{2}z+\sum_{k=1}^{\infty}\frac{B_{2k}}{(2k)!}z^{2k}.$$

In this case the Hamiltonian H takes the form

$$H=-(m\partial_1^2+\partial_2^2+\cdots+\partial_{n-1}^2+\partial_n^2)+\frac{(m+1)(n-1)}{3}\left(1-m+\frac{mn}{2}\right)+\sum_{k=2}^{n}\frac{2(m+1)}{\sinh^2(x_1-x_k)}$$
$$+\sum_{2\leqslant j<k\leqslant n}\frac{2m(m+1)}{\sinh^2(x_j-x_k)}.$$

Therefore, the formulas for the integrals in this case can be obtained using the following recursive formulas for constants $p_{2i,k}$:

$$p_{2i,k}=\frac{(1-m(k-2i-1))}{k-2i}p_{2i,k-1}+(1+m)\sum_{\substack{j=1\\ j\neq 2}}^{i-1}C_{k-2j+1}^{k-2i}\frac{2^{2i-2j+2}}{(2i-2j+2)}B_{2i-2j+2}p_{2j-2,k-1}.$$

The integrability of this problem was shown by Chalykh, Feigin, and Veselov.[2] Sergeev and Veselov[16] found a recurrent formula for the quantum integrals with the highest symbols given by the deformed Newton sums. Our formulas correspond to the deformed elementary symmetric polynomials and seem to be new even in that degenerate case.

The rational degeneration corresponds to both periods being equal to infinity. In this case $\mathfrak{P}(z)=z^{-2}$ and all $\gamma_{2k}=0$. Therefore, in this case only constants $p_{0,k}$ $k=1,2,\ldots$, are nonzero.

VI. PROOF OF THEOREM 1

We prove Theorem 1 by induction in n. For small n we showed this in Sec. III. Now assume that the statement of the theorem is true for all $k<n$ and show that it is true for $k=n$.

Under this assumption, let us first show that commutator $[I,H]$ can be reduced to an expression on the additional terms X, $X_{\hat{j}}$, and $X_{\hat{k}\hat{l}}$.

Lemma 1:

$$[I,H]=[X,H]+\sum_{j=1}^{n}\left[X_{\hat{j}}\partial_j,2\sum_{\substack{l=1\\ l\neq j}}^{n}u_{jl}\right]+\sum_{1\leqslant k<l\leqslant n}[X_{\hat{k}\hat{l}}\partial_k\partial_l,2u_{kl}]. \tag{18}$$

Proof: Using (12) we obtain

$$[I,H]=\sum_{t=1}^{n-2}(-1)^{t+1}\sum_{\sigma\in\mathfrak{S}(t)}[I_{\hat{\sigma}}\partial_\sigma,H]+(-1)^n(n-1)[\partial_1\cdots\partial_n,H]+[X,H],$$

which is equal to

$$(-1)^n(n-1)\left[\partial_1\cdots\partial_n,2\sum_{1\leqslant j<k\leqslant n}u_{jk}\right]+[X,H]+\sum_{j=1}^{n}\left[I_{\hat{j}}\partial_j,H_{\hat{j}}-\Delta_j+2\sum_{\substack{k=1\\ k\neq j}}^{n}u_{jk}\right]$$
$$+\sum_{t=2}^{n-2}(-1)^{t+1}\sum_{\sigma\in\mathfrak{S}(t)}\left[I_{\hat{\sigma}}\partial_\sigma,H_{\hat{\sigma}}-\Delta_\sigma+2\sum_{j\in\sigma}\sum_{\substack{k=1\\ k\neq j}}^{n}u_{jk}-2\sum_{\substack{j<k\\ j,k\in\sigma}}u_{jk}\right].$$

Since $I_{\hat{\sigma}}$ commutes with $H_{\hat{\sigma}}$ (by the induction assumption) and $I_{\hat{\sigma}}$ with $-\Delta_\sigma$ (since it does not depend on x_i, $i\in\sigma$) we have

$$[I,H]=\sum_{j=1}^{n}\left[I_{\hat{j}}\partial_j,2\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}\right]+\sum_{t=2}^{n-2}(-1)^{t+1}\sum_{\sigma\in\mathfrak{S}(t)}\left[I_{\hat{\sigma}}\partial_\sigma,2\sum_{j\in\sigma}\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}-2\sum_{\substack{j<k\\j,k\in\sigma}}u_{jk}\right]+(-1)^n(n-1)$$
$$\times\left[\partial_1\cdots\partial_n,2\sum_{1\leqslant j<k\leqslant n}u_{jk}\right]+[X,H].$$

Now we use (12) again and obtain

$$[I,H]=\sum_{j=1}^{n}\sum_{t=1}^{n-3}(-1)^{t+1}\sum_{\sigma\in\mathfrak{S}(\hat{j};t)}\left[I_{\hat{j}\hat{\sigma}}\partial_\sigma\partial_j,2\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}\right]+(-1)^n(n-1)\left[\partial_1\cdots\partial_n,2\sum_{1\leqslant j<k\leqslant n}u_{jk}\right]$$
$$+\sum_{j=1}^{n}\left[(-1)^{n-1}(n-2)\partial_1\cdots\partial_n+X_{\hat{j}}\partial_j,2\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}\right]+[X,H]+\sum_{t=2}^{n-2}(-1)^{t+1}$$
$$\times\sum_{\sigma\in\mathfrak{S}(t)}\left[I_{\hat{\sigma}}\partial_\sigma,2\sum_{j\in\sigma}\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}-2\sum_{\substack{j<k\\j,k\in\sigma}}u_{jk}\right].$$

If we cancel the repeated terms we obtain

$$[I,H]=\sum_{j=1}^{n}\left[(-1)^{n-1}(n-2)\partial_1\cdots\partial_n+X_{\hat{j}}\partial_j,2\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}\right]+\sum_{t=2}^{n-2}(-1)^t\sum_{\sigma\in\mathfrak{S}(t)}\left[I_{\hat{\sigma}}\partial_\sigma,2\sum_{\substack{j<k\\j,k\in\sigma}}u_{jk}\right]$$
$$+(-1)^n(n-1)\left[\partial_1\cdots\partial_n,2\sum_{1\leqslant j<k\leqslant n}u_{jk}\right]+[X,H].$$

We use (12) again,

$$[I,H]=\sum_{j=1}^{n}\left[(-1)^{n-1}(n-2)\partial_1\cdots\partial_n+X_{\hat{j}}\partial_j,2\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}\right]+\sum_{t=3}^{n-2}(-1)^t\sum_{\sigma\in\mathfrak{S}(t)}\left[I_{\hat{\sigma}}\partial_\sigma,2\sum_{\substack{j<k\\j,k\in\sigma}}u_{jk}\right]$$
$$+\sum_{1\leqslant j<k\leqslant n}\left[\sum_{t=1}^{n-4}(-1)^{t+1}\sum_{\sigma\in\mathfrak{S}(\hat{j}\hat{k};t)}I_{\hat{\sigma}\hat{j}\hat{k}}\partial_\sigma\partial_j\partial_k,2u_{jk}\right]+\sum_{1\leqslant j<k\leqslant n}[(-1)^{n-2}(n-3)\partial_1\cdots\partial_n$$
$$+X_{\hat{j}\hat{k}}\partial_j\partial_k,2u_{jk}]+(-1)^n(n-1)\left[\partial_1\cdots\partial_n,2\sum_{1\leqslant j<k\leqslant n}u_{jk}\right]+[X,H].$$

Finally, canceling the repeated terms, we get

$$[I,H]=(-1)^n2\left[\partial_1\cdots\partial_n,-(n-2)\sum_{j=1}^{n}\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}+(n-3)\sum_{1\leqslant j<k\leqslant n}u_{jk}+(n-1)\sum_{1\leqslant j<k\leqslant n}u_{jk}\right]+[X,H]$$
$$+\sum_{j=2}^{n}\left[X_{\hat{j}}\partial_j,2\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}\right]+\sum_{1\leqslant j<k\leqslant n}[X_{\hat{j}\hat{k}}\partial_j\partial_k,2u_{jk}],$$

which simplifies to

$$[I,H]=[X,H]+\sum_{j=1}^{n}\left[X_{\hat{j}}\partial_j,2\sum_{\substack{k=1\\k\neq j}}^{n}u_{jk}\right]+\sum_{1\leqslant j<k\leqslant n}[X_{\hat{j}\hat{k}}\partial_j\partial_k,2u_{jk}].$$

Lemma 1 is proven.

Lemma 2: In the nondeformed case

$$[I_{\hat{1}},H_{\hat{1}}]=[X_{\hat{1}},H_{\hat{1}}]+\sum_{j=2}^{n}\left[X_{\hat{1}\hat{j}}\partial_j,2\sum_{\substack{l=2\\l\neq j}}^{n}u_{jl}\right]+\sum_{2\leqslant k<l\leqslant n}[X_{\hat{1}\hat{k}\hat{l}}\partial_k\partial_l,2u_{kl}]=0. \tag{19}$$

Proof: To prove that

$$[I_{\hat{1}},H_{\hat{1}}]=[X_{\hat{1}},H_{\hat{1}}]+\sum_{j=2}^{n}\left[X_{\hat{1}\hat{j}}\partial_j,2\sum_{\substack{l=2\\l\neq j}}^{n}u_{jl}\right]+\sum_{2\leqslant k<l\leqslant n}[X_{\hat{1}\hat{k}\hat{l}}\partial_k\partial_l,2u_{kl}]$$

one must repeat the arguments of Lemma 1. We will need the addition theorem for the Weierstrass elliptic function,[12]

$$T_{ijk}\equiv\det\begin{pmatrix}\mathfrak{p}_{ij} & \mathfrak{p}_{jk} & \mathfrak{p}_{ki}\\ \mathfrak{p}'_{ij} & \mathfrak{p}'_{jk} & \mathfrak{p}'_{ki}\\ 1 & 1 & 1\end{pmatrix}\equiv 0.$$

Two cases must be considered to prove the lemma: n is odd and n is even. If n is even (19) is reduced to $2\Sigma_{j=2}^{n}\Sigma_{\substack{l=2\\l\neq j}}^{n}[X_{\hat{1}\hat{j}}\partial_j,u_{jl}]=0$, as $X_{\hat{1}}=0$ and $X_{\hat{1}\hat{k}\hat{l}}=0$, $2\leqslant k<l\leqslant n$. In this case we have

$$\begin{aligned}\sum_{j=2}^{n}\sum_{\substack{l=2\\l\neq j}}^{n}[X_{\hat{1}\hat{j}}\partial_j,u_{jl}]&=\sum_{j=2}^{n}\sum_{\substack{l=2\\l\neq j}}^{n}X_{\hat{1}\hat{j}}[\partial_j,u_{jl}]=m(m+1)\sum_{j=2}^{n}\sum_{\substack{l=2\\l\neq j}}^{n}X_{\hat{1}\hat{j}}\mathfrak{p}'_{jl}\\&=m(m+1)\sum_{2\leqslant j<l\leqslant n}\mathfrak{p}'_{jl}(X_{\hat{1}\hat{j}}-X_{\hat{1}\hat{l}})\\&=m(m+1)\sum_{2\leqslant i<j<k\leqslant n}T_{ijk}X_{\hat{1}\hat{i}\hat{j}\hat{k}}=0.\end{aligned}$$

If n is odd (19) becomes $[X_{\hat{1}},-\Delta_{\hat{1}}]+\Sigma_{2\leqslant k<l\leqslant n}[X_{\hat{1}\hat{k}\hat{l}}\partial_k\partial_l,2u_{kl}]=0$, since in this case $X_{\hat{1}\hat{j}}=0$, $j=2,\ldots,n$. We have

$$\begin{aligned}[X_{\hat{1}},-\Delta_{\hat{1}}]+\sum_{2\leqslant k<l\leqslant n}[X_{\hat{1}\hat{k}\hat{l}}\partial_k\partial_l,2u_{kl}]&=\sum_{k=2}^{n}\frac{\partial^2X_{\hat{1}}}{\partial x_k^2}+2\sum_{k=2}^{n}\frac{\partial X_{\hat{1}}}{\partial x_k}\partial_k+2\sum_{2\leqslant k<l\leqslant n}X_{\hat{1}\hat{k}\hat{l}}(u'_{kl}\partial_l-u'_{kl}\partial_k-u''_{kl})\\&=\sum_{k=2}^{n}\frac{\partial^2X_{\hat{1}}}{\partial x_k^2}-2\sum_{2\leqslant k<l\leqslant n}X_{\hat{1}\hat{k}\hat{l}}u''_{kl}+2\sum_{k=2}^{n}\left(\frac{\partial X_{\hat{1}}}{\partial x_k}-\sum_{\substack{l=2\\l\neq k}}^{n}X_{\hat{1}\hat{k}\hat{l}}u'_{kl}\right)\partial_k=0.\end{aligned}$$

Lemma 2 is proven.

Lemma 3: The operators $\mathfrak{D}^n$ satisfy the relation

$$[\mathfrak{D}^n,\mathfrak{p}(x_1-x_i)]+(1+m)[[\mathfrak{s}(x_1-x_i),\mathfrak{D}^{n-1}],\mathfrak{p}(x_1-x_i)]+m[\mathfrak{D}^{n-1},\mathfrak{p}(x_1-x_i)]\partial-\frac{(1+m)}{2}$$

$$\times\mathfrak{p}'(x_1-x_i)\mathfrak{D}^{n-1}-\frac{(1-m)}{2}\mathfrak{D}^{n-1}\mathfrak{p}'(x_1-x_i)=0 \tag{20}$$

for any $i=2,\ldots,n$, where $\partial=\partial/\partial x_1$.

Proof: Let us denote the left-hand side of the relation (20) by $\mathcal{Y}_n$.

It can be shown by a simple direct calculation that (20) is true if $n=1,2,3,4$. The equations in these cases are

$$n=1:\mathcal{Y}_1=[\partial,\mathfrak{p}]+m[1,\mathfrak{p}]\partial-\frac{(1+m)}{2}\mathfrak{p}'-\frac{(1-m)}{2}\mathfrak{p}'=0,$$

$$n=2:\mathcal{Y}_2=\left[\frac{1-m}{2}\partial^2,\mathfrak{p}\right]+(1+m)[[\mathfrak{s},\partial],\mathfrak{p}]+m[\partial,\mathfrak{p}]\partial-\frac{(1+m)}{2}\mathfrak{p}'\partial-\frac{(1-m)}{2}\partial\mathfrak{p}'=0,$$

$$n=3:\mathcal{Y}_3=\left[\frac{1-2m}{3}\partial^3,\mathfrak{p}\right]+(1+m)[[\mathfrak{s},\partial^2],\mathfrak{p}]+m[\partial^2,\mathfrak{p}]\partial-\frac{(1+m)}{2}\mathfrak{p}'\partial^2-\frac{(1-m)}{2}\partial^2\mathfrak{p}'=0,$$

$$n=4:\mathcal{Y}_4=\left[\frac{1-3m}{4}\partial^4,\mathfrak{p}\right]+(1+m)[[\mathfrak{s},\partial^3],\mathfrak{p}]+m[\partial^3,\mathfrak{p}]\partial-\frac{(1+m)}{2}\mathfrak{p}'\partial^3-\frac{(1-m)}{2}\partial^3\mathfrak{p}'=0.$$

For $n\geqslant 5$ we use (6) to obtain

$$\begin{aligned}\mathcal{Y}_n=&[p_{0,n}\partial^n,\mathfrak{p}]+(1+m)[[\mathfrak{s},p_{0,n-1}\partial^{n-1}],\mathfrak{p}]+m[p_{0,n-1}\partial^{n-1},\mathfrak{p}]\partial-\frac{(1+m)}{2}\mathfrak{p}'p_{0,n-1}\partial^{n-1}\\&-\frac{(1-m)}{2}p_{0,n-1}\partial^{n-1}\mathfrak{p}'+\left[\sum_{i=2}^{[n/2]}p_{2i,n}\partial^{n-2i},\mathfrak{p}\right]+(1+m)\left[\left[\mathfrak{s},\sum_{i=2}^{[(n-1)/2]}p_{2i,n-1}\partial^{n-1-2i}\right],\mathfrak{p}\right]\\&+m\left[\sum_{i=2}^{[(n-1)/2]}p_{2i,n-1}\partial^{n-1-2i},\mathfrak{p}\right]\partial-\frac{(1+m)}{2}\mathfrak{p}'\sum_{i=2}^{[(n-1)/2]}p_{2i,n-1}\partial^{n-1-2i}\\&-\frac{(1-m)}{2}\sum_{i=2}^{[(n-1)/2]}p_{2i,n-1}\partial^{n-1-2i}\mathfrak{p}'.\end{aligned}$$

We can express $p_{0,n}$ through $p_{0,n-1}$ and $p_{2i,n}$ through $p_{2l,n-1}$, $l=0,\ldots,2i$, as described by (9) and obtain

$$\begin{aligned}\mathcal{Y}_n=&\left[\frac{1-m(n-1)}{n}p_{0,n-1}\partial^n,\mathfrak{p}\right]+(1+m)[[\mathfrak{s},p_{0,n-1}\partial^{n-1}],\mathfrak{p}]+m[p_{0,n-1}\partial^{n-1},\mathfrak{p}]\partial\\&-\frac{(1+m)}{2}\mathfrak{p}'p_{0,n-1}\partial^{n-1}-\frac{(1-m)}{2}p_{0,n-1}\partial^{n-1}\mathfrak{p}'+m\left[\sum_{i=2}^{[(n-1)/2]}p_{2i,n-1}\partial^{n-1-2i},\mathfrak{p}\right]\partial-(1+m)\\&\times\left[\sum_{i=2}^{[(n-1)/2]}(2i-2)!C_{n-1}^{n-2i}\gamma_{2i-2}p_{0,n-1}\partial^{n-2i},\mathfrak{p}\right]+\left[\sum_{i=2}^{[(n-1)/2]}\frac{(1-m(n-2i-1))}{n-2i}p_{2i,n-1}\partial^{n-2i},\mathfrak{p}\right]\\&+(1+m)\left[\left[\mathfrak{s},\sum_{i=2}^{[(n-1)/2]}p_{2i,n-1}\partial^{n-1-2i}\right],\mathfrak{p}\right]-\frac{(1+m)}{2}\mathfrak{p}'\sum_{i=2}^{[(n-1)/2]}p_{2i,n-1}\partial^{n-1-2i}\end{aligned}$$

$$-\frac{(1-m)}{2}\sum_{i=2}^{[(n-1)/2]} p_{2i,n-1}\partial^{n-1-2i}\mathfrak{p}'$$
$$-(1+m)\sum_{i=2}^{[(n-1)/2]-2}\left[\sum_{j=i+2}^{[(n-1)/2]}(2j-2i-2)!C_{n-2i-1}^{n-2j}\gamma_{2j-2i-2}p_{2i,n-1}\partial^{n-2j},\mathfrak{p}\right].$$

Denote

$$\mathcal{W}_k=\left[\frac{1-m(k-1)}{k}\partial^k,\mathfrak{p}\right]+(1+m)[[\mathfrak{s},\partial^{k-1}],\mathfrak{p}]+m[\partial^{k-1},\mathfrak{p}]\partial-\frac{(1+m)}{2}\mathfrak{p}'\partial^{k-1}-\frac{(1-m)}{2}\partial^{k-1}\mathfrak{p}'$$
$$-(1+m)\sum_{i=2}^{[(k-1)/2]}[(2i-2)!C_{k-1}^{k-2i}\gamma_{2i-2}\partial^{k-2i},\mathfrak{p}],$$

then

$$\mathcal{Y}_5=p_{0,4}\mathcal{W}_5+p_{4,4}\mathcal{Y}_1,\quad \mathcal{Y}_6=p_{0,5}\mathcal{W}_6+p_{4,5}\mathcal{Y}_2,$$

$$\mathcal{Y}_7=p_{0,6}\mathcal{W}_7+p_{4,6}\mathcal{Y}_3+p_{6,6}\mathcal{Y}_1,\quad \mathcal{Y}_8=p_{0,7}\mathcal{W}_8+p_{4,7}\mathcal{Y}_4+p_{6,7}\mathcal{Y}_2$$

and for $k\geqslant 5$,

$$\mathcal{Y}_{2k-1}=p_{0,2k-2}\mathcal{W}_{2k-1}+\sum_{i=2}^{k-3}p_{2i,2k-2}\mathcal{W}_{2k-1-2i}+p_{2k-4,2k-2}\mathcal{Y}_3+p_{2k-2,2k-2}\mathcal{Y}_1,$$

$$\mathcal{Y}_{2k}=p_{0,2k-1}\mathcal{W}_{2k}+\sum_{i=2}^{k-3}p_{2i,2k-1}\mathcal{W}_{2k-2i}+p_{2k-4,2k-1}\mathcal{Y}_4+p_{2k-2,2k-1}\mathcal{Y}_2.$$

Below we show that $\mathcal{W}_n=0$ for $n\geqslant 5$. First,

$$\frac{10}{1+m}\mathcal{W}_5=2[\partial^4,\mathfrak{p}]\partial-3\partial^4\mathfrak{p}'+10[[\mathfrak{s},\partial^4],\mathfrak{p}]-5\mathfrak{p}'\partial^4-80[\gamma_2\partial^1,\mathfrak{p}]+2\partial[\partial^3,\mathfrak{p}]\partial-3\mathfrak{p}'\partial^4-3\partial^4\mathfrak{p}'$$
$$+10\partial[[\mathfrak{s},\partial^3],\mathfrak{p}]+10[\partial,\mathfrak{p}][\mathfrak{s},\partial^3]+10[\mathfrak{s},\partial][\partial^3,\mathfrak{p}]-80[\gamma_2\partial^1,\mathfrak{p}].$$

We calculate that $\partial[[\mathfrak{s},\partial^3],\mathfrak{p}]=-\frac{1}{4}\partial[\partial^3,\mathfrak{p}]\partial+\frac{1}{2}\partial\mathfrak{p}'\partial^3+\frac{1}{4}\partial^4\mathfrak{p}'$, therefore

$$\frac{10}{1+m}\mathcal{W}_5=-\frac{1}{2}\partial[\partial^3,\mathfrak{p}]\partial-3\mathfrak{p}'\partial^4-\frac{1}{2}\partial^4\mathfrak{p}'+5\partial\mathfrak{p}'\partial^3+10\mathfrak{p}'[\mathfrak{s},\partial^3]+10\mathfrak{p}[\partial^3,\mathfrak{p}]-80\gamma_2\mathfrak{p}'-5\mathfrak{p}'''\partial^2$$
$$-\frac{5}{2}\mathfrak{p}^{(4)}\partial-\frac{1}{2}\mathfrak{p}^{(5)}-80\gamma_2\mathfrak{p}'+10\mathfrak{p}'(3\mathfrak{p}\partial^2+3\mathfrak{p}'\partial+\mathfrak{p}'')+10\mathfrak{p}(3\mathfrak{p}'\partial^2+3\mathfrak{p}''\partial+\mathfrak{p}''')=0.$$

In this calculation the identities which are the derivatives of the differential equation of the Weierstrass elliptic function (3) have been used. At the next step we use the induction assumption that for any $s<k$, $\mathcal{W}_s=0$. Then $\mathcal{W}_k$ can be simplified into

$$\mathcal{W}_k=\frac{1+m}{k}[\partial^{k-1},\mathfrak{p}]\partial-\frac{(1+m)}{2}\frac{k-2}{k}\partial^{k-1}\mathfrak{p}'+(1+m)[[\mathfrak{s},\partial^{k-1}],\mathfrak{p}]-\frac{(1+m)}{2}\mathfrak{p}'\partial^{k-1}$$
$$-(1+m)\sum_{j=2}^{[k-1/2]}[(2j-2)!C_{k-1}^{k-2j}\gamma_{2j-2}\partial^{k-2j},\mathfrak{p}].$$

We consider

$$\frac{1}{1+m}\mathcal{W}_k = \frac{1}{k}[\partial^{k-1},\mathfrak{p}]\partial - \frac{k-2}{2k}\partial^{k-1}\mathfrak{p}' + [[\mathfrak{s},\partial^{k-1}],\mathfrak{p}] - \frac{1}{2}\mathfrak{p}'\partial^{k-1} - \sum_{j=2}^{[k-1/2]}[(2j-2)!C_{k-1}^{k-2j}\gamma_{2j-2}\partial^{k-2j},\mathfrak{p}].$$

If $k=2l$,

$$\frac{1}{1+m}\mathcal{W}_{2l} = \frac{1}{2l}[\partial^{2l-1},\mathfrak{p}]\partial - \frac{l-1}{2l}\partial^{2l-1}\mathfrak{p}' + [[\mathfrak{s},\partial^{2l-1}],\mathfrak{p}] - \frac{1}{2}\mathfrak{p}'\partial^{2l-1} - \sum_{j=2}^{l-1}[(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\partial^{2l-2j},\mathfrak{p}]$$

and if $k=2l+1$,

$$\frac{1}{1+m}\mathcal{W}_{2l+1} = \frac{1}{(2l+1)}[\partial^{2l},\mathfrak{p}]\partial - \frac{2l-1}{2(2l+1)}\partial^{2l}\mathfrak{p}' + [[\mathfrak{s},\partial^{2l}],\mathfrak{p}] - \frac{1}{2}\mathfrak{p}'\partial^{2l} - \sum_{j=2}^{l}[(2j-2)!C_{2l}^{2l+1-2j}\gamma_{2j-2}\partial^{2l+1-2j},\mathfrak{p}].$$

We show below that $\mathcal{W}_{2l}=0$. The case of $\mathcal{W}_{2l+1}$ can be dealt with in the same way,

$$\begin{aligned}\frac{1}{1+m}\mathcal{W}_{2l} &= \frac{1}{2l}[\partial^{2l-1},\mathfrak{p}]\partial - \frac{1}{2l}(l-1)\partial^{2l-1}\mathfrak{p}' + [[\mathfrak{s},\partial^{2l-1}],\mathfrak{p}] - \frac{1}{2}\mathfrak{p}'\partial^{2l-1} \\ &\quad - \sum_{j=2}^{l-1}[(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\partial^{2l-2j},\mathfrak{p}] \\ &= \frac{1}{2l}[\partial\partial^{2l-2},\mathfrak{p}]\partial - \frac{l-1}{2l}\partial\partial^{2l-2}\mathfrak{p}' + [[\mathfrak{s},\partial\partial^{2l-2}],\mathfrak{p}] - \frac{1}{2}\mathfrak{p}'\partial\partial^{2l-2} \\ &\quad - \sum_{j=2}^{l-1}[(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\partial\partial^{2l-2j-1},\mathfrak{p}] \\ &= \frac{1}{2l}\partial[\partial^{2l-2},\mathfrak{p}]\partial - \frac{l-1}{2l}\partial\partial^{2l-2}\mathfrak{p}' - \frac{l-1}{2l}\mathfrak{p}'\partial\partial^{2l-2} \\ &\quad + \partial[[\mathfrak{s},\partial^{2l-2}],\mathfrak{p}] + [\partial,\mathfrak{p}][\mathfrak{s},\partial^{2l-2}] + [\mathfrak{s},\partial][\partial^{2l-2},\mathfrak{p}] - \partial\sum_{j=2}^{l-1}[(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\partial^{2l-2j-1},\mathfrak{p}] \\ &\quad - \sum_{j=2}^{l-1}(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\mathfrak{p}'\partial^{2l-2j-1}.\end{aligned}$$

From the inductive assumption we have that $\mathcal{W}_{2l-1}=0$, then

$$[[\mathfrak{s},\partial^{2l-2}],\mathfrak{p}] = -\frac{1}{2l-1}[\partial^{2l-2},\mathfrak{p}]\partial + \frac{2l-3}{2(2l-1)}\partial^{2l-2}\mathfrak{p}' + \frac{1}{2}\mathfrak{p}'\partial^{2l-2} + \sum_{j=2}^{l-1}[(2j-2)!C_{2l-2}^{2l-1-2j}\gamma_{2j-2}\partial^{2l-1-2j},\mathfrak{p}]$$

and therefore,

$$
\begin{aligned}
-\frac{1}{1+m}\mathcal{W}_{2l} &= \frac{1}{2l(2l-1)}\partial[\partial^{2l-2},\mathfrak{p}]\partial + \frac{1}{2l(2l-1)}\partial\partial^{2l-2}\mathfrak{p}' - \frac{1}{2}\mathfrak{p}''\partial^{2l-2} - \frac{1}{2l}\mathfrak{p}'\partial\partial^{2l-2} \\
&\quad + \partial\sum_{j=2}^{l-1}\left[\frac{(2l-2)!}{(2l-2j)!}\gamma_{2j-2}\partial^{2l-1-2j},\mathfrak{p}\right] - \mathfrak{p}'[\mathfrak{s},\partial^{2l-2}] - \mathfrak{p}[\partial^{2l-2},\mathfrak{p}] \\
&\quad + \sum_{j=2}^{l-1}(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\mathfrak{p}'\partial^{2l-2j-1} \\
&= \frac{1}{2l(2l-1)}\partial[\partial^{2l-1},\mathfrak{p}] - \frac{1}{2}\mathfrak{p}''\partial^{2l-2} - \frac{1}{2l}\mathfrak{p}'\partial^{2l-1} - \mathfrak{p}'[\mathfrak{s},\partial^{2l-2}] \\
&\quad - \mathfrak{p}[\partial^{2l-2},\mathfrak{p}] + \partial\sum_{j=2}^{l-1}\frac{(2l-2)!}{(2l-2j)!}\gamma_{2j-2}[\partial^{2l-1-2j},\mathfrak{p}] + \sum_{j=2}^{l-1}(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\mathfrak{p}'\partial^{2l-2j-1}.
\end{aligned}
$$

The commutators can be rewritten as

$$
[\partial^{2l-1},\mathfrak{p}] = \sum_{k=0}^{2l-2} C_{2l-1}^{2l-1-k}\mathfrak{p}^{(2l-1-k)}\partial^k, \quad [\partial^{2l-2},\mathfrak{p}] = \sum_{k=0}^{2l-3} C_{2l-2}^{2l-2-k}\mathfrak{p}^{(2l-2-k)}\partial^k,
$$

$$
[\mathfrak{s},\partial^{2l-2}] = \sum_{k=0}^{2l-3} C_{2l-2}^{2l-2-k}\mathfrak{p}^{(2l-3-k)}\partial^k, \quad [\partial^{2l-1-2j},\mathfrak{p}] = \sum_{k=0}^{2l-2-2j} C_{2l-1-2j}^{2l-1-2j-k}\mathfrak{p}^{(2l-1-2j-k)}\partial^k,
$$

and, hence,

$$
\begin{aligned}
-\frac{1}{1+m}\mathcal{W}_{2l} &= \frac{1}{2l(2l-1)}\sum_{k=1}^{2l-1} C_{2l-1}^{2l-k}\mathfrak{p}^{(2l-k)}\partial^k + \frac{1}{2l(2l-1)}\sum_{k=0}^{2l-2} C_{2l-1}^{2l-1-k}\mathfrak{p}^{(2l-k)}\partial^k - \sum_{k=0}^{2l-3} C_{2l-2}^{2l-2-k}\mathfrak{p}'\mathfrak{p}^{(2l-3-k)}\partial^k \\
&\quad - \sum_{k=0}^{2l-3} C_{2l-2}^{2l-2-k}\mathfrak{p}\mathfrak{p}^{(2l-2-k)}\partial^k + \sum_{j=2}^{l-1}\frac{(2l-2)!}{(2l-2j)!}\gamma_{2j-2}\sum_{k=1}^{2l-1-2j} C_{2l-1-2j}^{2l-2j-k}\mathfrak{p}^{(2l-2j-k)}\partial^k \\
&\quad + \sum_{j=2}^{l-1}\frac{(2l-2)!}{(2l-2j)!}\gamma_{2j-2}\sum_{k=0}^{2l-2-2j} C_{2l-1-2j}^{2l-1-2j-k}\mathfrak{p}^{(2l-2j-k)}\partial^k + \sum_{j=2}^{l-1}(2j-2)!C_{2l-1}^{2l-2j}\gamma_{2j-2}\mathfrak{p}'\partial^{2l-2j-1} \\
&\quad - \frac{1}{2}\mathfrak{p}''\partial^{2l-2} - \frac{1}{2l}\mathfrak{p}'\partial^{2l-1}
\end{aligned}
$$

which can be rewritten as

$$
\begin{aligned}
-\frac{1}{1+m}\mathcal{W}_{2l} &= \frac{1}{2l(2l-1)}\sum_{k=1}^{2l-1} C_{2l-1}^{2l-k}\mathfrak{p}^{(2l-k)}\partial^k + \frac{1}{2l(2l-1)}\sum_{k=0}^{2l-2} C_{2l-1}^{2l-1-k}\mathfrak{p}^{(2l-k)}\partial^k - \frac{1}{2}\mathfrak{p}''\partial^{2l-2} - \frac{1}{2l}\mathfrak{p}'\partial^{2l-1} \\
&\quad - \sum_{k=0}^{2l-3} C_{2l-2}^{2l-2-k}(\mathfrak{p}'\mathfrak{p}^{(2l-3-k)} + \mathfrak{p}\mathfrak{p}^{(2l-2-k)})\partial^k \\
&\quad + \sum_{k=1}^{2l-5}\sum_{j=2}^{l-1-[k/2]}\frac{(2l-2)!}{(2l-2j)!}\gamma_{2j-2}C_{2l-1-2j}^{2l-2j-k}\mathfrak{p}^{(2l-2j-k)}\partial^k \\
&\quad + \sum_{k=0}^{2l-6}\sum_{j=2}^{l-1-[(k+1)/2]}\frac{(2l-2)!}{(2l-2j)!}\gamma_{2j-2}C_{2l-1-2j}^{2l-1-2j-k}\mathfrak{p}^{(2l-2j-k)}\partial^k
\end{aligned}
$$

$$+\sum_{k=1}^{l-2}(2l-2k-2)!C_{2l-1}^{2k}\gamma_{2l-2k-2}\mathfrak{p}'\partial^{2k-1}.$$

It is shown below that the coefficients by all ∂^k, $k=0,1,\ldots,2l-1$, are zero. We have

$$\partial^{2l-1}:\quad \frac{1}{2l(2l-1)}C_{2l-1}^{1}\mathfrak{p}'-\frac{1}{2l}\mathfrak{p}'=0,$$

$$\partial^{2l-2}:\quad \frac{1}{2l(2l-1)}C_{2l-1}^{2}\mathfrak{p}''+\frac{1}{2l(2l-1)}C_{2l-1}^{1}\mathfrak{p}''-\frac{1}{2}\mathfrak{p}''=0,$$

$$\partial^{2l-3}:\quad \frac{1}{2l(2l-1)}C_{2l-1}^{3}\mathfrak{p}^{(3)}+\frac{1}{2l(2l-1)}C_{2l-1}^{2}\mathfrak{p}^{(3)}-2C_{2l-2}^{1}\mathfrak{p}'\mathfrak{p}$$
$$=\left(\frac{12}{2l(2l-1)}C_{2l-1}^{3}+\frac{12}{2l(2l-1)}C_{2l-1}^{2}-2C_{2l-2}^{1}\right)\mathfrak{p}'\mathfrak{p}=0,$$

$$\partial^{2l-4}:\quad \frac{1}{2l(2l-1)}C_{2l-1}^{4}\mathfrak{p}^{(4)}+\frac{1}{2l(2l-1)}C_{2l-1}^{3}\mathfrak{p}^{(4)}-C_{2l-2}^{2}(\mathfrak{p}'\mathfrak{p}'+\mathfrak{p}\mathfrak{p}^{(2)})$$
$$=\left(\frac{12}{2l(2l-1)}C_{2l-1}^{4}+\frac{12}{2l(2l-1)}C_{2l-1}^{3}-C_{2l-2}^{2}\right)(\mathfrak{p}'\mathfrak{p}'+\mathfrak{p}\mathfrak{p}^{(2)})=0.$$

When $k=2l-2q-1$, $q=2,\ldots,l-1$, coefficient by $\partial^{2l-2q-1}$ is

$$K_{2l-2q-1}=\frac{(2l-2)!}{(2l-2q-1)!}\left(\frac{\mathfrak{p}^{(2q+1)}}{(2q+1)!}-\frac{\mathfrak{p}'\mathfrak{p}^{(2q-2)}+\mathfrak{p}\mathfrak{p}^{(2q-1)}}{(2q-1)!}+\sum_{j=2}^{q-1}\frac{\gamma_{2j-2}}{(2q+1-2j)!}\mathfrak{p}^{(2q+1-2j)}\right.$$
$$\left.+\frac{2q}{2q-1}\gamma_{2q-2}\mathfrak{p}'\right).$$

To show that this coefficient is zero let us calculate its Laurent expansion and show that it consists of the terms by the positive degrees of z only. Since it is also a doubly periodic function it can only be zero. The Laurent expansion for the derivatives of the Weierstrass function are given by

$$\mathfrak{p}'=-2z^{-3}+O(z),$$

$$\mathfrak{p}^{(2q+1)}=-(2q+2)!z^{-(2q+3)}+O(z),$$

$$\mathfrak{p}^{(2q+1-2j)}=-(2q+2-2j)!z^{-(2q-2j+3)}+O(z).$$

Therefore, we can find that

$$\mathfrak{p}\mathfrak{p}^{(2q-1)}=-(2q)!z^{-(2q+3)}-(2q)!\sum_{i=1}^{q-1}\gamma_{2i}z^{-(2q+1-2i)}+O(z),$$

$$\mathfrak{p}'\mathfrak{p}^{(2q-2)}=-2(2q-1)!z^{-(2q+3)}-2(2q-2)!\gamma_{2q-2}z^{-3}+(2q-1)!\sum_{i=1}^{q-1}2i\gamma_{2i}z^{-(2q+1-2i)}+O(z),$$

and

$$-\frac{(\wp'\wp^{(2q-2)}+\wp\wp^{(2q-1)})}{(2q-1)!}=(2q+2)z^{-(2q+3)}+\sum_{i=1}^{q-2}(2q-2i)\gamma_{2i}z^{-(2q+1-2i)}+\frac{4q}{2q-1}\gamma_{2q-2}z^{-3}+O(z).$$

Therefore

$$\begin{aligned}K_{2l-2q-1}=&\frac{(2l-2)!}{(2l-2q-1)!}\Bigg(-(2q+2)z^{-(2q+3)}+(2q+2)z^{-(2q+3)}+\sum_{i=1}^{q-2}(2q-2i)\gamma_{2i}z^{-(2q+1-2i)}\\&+\frac{4q}{2q-1}\gamma_{2q-2}z^{-3}-\sum_{i=2}^{q-1}\gamma_{2j-2}(2q+2-2j)z^{-(2q-2j+3)}-\gamma_{2q-2}\frac{4q}{2q-1}z^{-3}+O(z)\Bigg)\\=&\frac{(2l-2)!}{(2l-2q-1)!}(O(z))=0.\end{aligned}$$

When $k=2l-2q$; $q=3,\ldots,l-1$, coefficient by ∂^{2l-2q} is

$$K_{2l-2q}=\frac{(2l-2)!}{(2l-2q)!}\left(\frac{1}{(2q)!}\wp^{(2q)}-\frac{(\wp'\wp^{(2q-3)}+\wp\wp^{(2q-2)})}{(2q-2)!}+\sum_{j=2}^{q-1}\frac{1}{(2q-2j)!}\gamma_{2j-2}\wp^{(2q-2j)}\right).$$

The Laurent expansion for the derivatives of the Weierstrass function are given by

$$\wp^{(2q)}=(2q+1)!z^{-(2q+2)}+(2q)!\gamma_{2q}+O(z^2),$$

$$\wp^{(2q-2j)}=(2q-2j+1)!z^{-(2q-2j+2)}+(2q-2j)!\gamma_{2q-2j}+O(z^2),$$

and we calculate that

$$\begin{aligned}\wp\wp^{(2q-2)}=&(2q-1)!z^{-(2q+2)}+(2q-2)!(2q)\gamma_{2q-2}z^{-2}+(2q-1)!(q+1)\gamma_{2q}\\&+(2q-1)!\left(\sum_{i=1}^{q-2}\gamma_{2i}z^{-(2q-2i)}\right)+O(z^2),\end{aligned}$$

$$\begin{aligned}\wp'\wp^{(2q-3)}=&2(2q-2)!z^{-(2q+2)}-(2q-2)!(2q)\gamma_{2q-2}z^{-2}-(2q-2)!(2q)\left(\frac{2q+2}{3}\right)\gamma_{2q}\\&-(2q-2)!\sum_{i=1}^{q-2}2i\gamma_{2i}z^{-(2q-2i)}+O(z^2),\end{aligned}$$

and

$$\begin{aligned}-\frac{(\wp\wp^{(2q-2)}+\wp'\wp^{(2q-3)})}{(2q-2)!}=&-(2q+1)z^{-(2q+2)}-\sum_{i=1}^{q-2}(2q-1-2i)\gamma_{2i}z^{-(2q-2i)}\\&-\left(\frac{(1+q)(2q-3)}{3}\right)\gamma_{2q}+O(z^2).\end{aligned}$$

Therefore

$$K_{2l-2q} = \frac{(2l-2)!}{(2l-2q)!}\Bigg((2q+1)z^{-(2q+2)} + \gamma_{2q} - (2q+1)z^{-(2q+2)} - \sum_{i=1}^{q-2} (2q-1-2i)\gamma_{2i} z^{-(2q-2i)}$$
$$- \frac{(1+q)(2q-3)}{3}\gamma_{2q} + \sum_{j=2}^{q-1} \gamma_{2j-2}(2q-2j+1)z^{-(2q-2j+2)} + \sum_{j=2}^{q-1} \gamma_{2j-2}\gamma_{2q-2j} + O(z^2)\Bigg)$$
$$= \frac{(2l-2)!}{(2l-2q)!}\Bigg(- \frac{(2q+3)(q-2)}{3}\gamma_{2q} + \sum_{j=2}^{q-1} \gamma_{2j-2}\gamma_{2q-2j} + O(z^2)\Bigg) = 0.$$

Here we have used the identity (5).

The last case to consider is when $k=0$. In this case we need to show that

$$K_0 = \frac{1}{2l(2l-1)}\mathfrak{p}^{(2l)} - (\mathfrak{p}'\mathfrak{p}^{(2l-3)} + \mathfrak{p}\mathfrak{p}^{(2l-2)}) + \sum_{j=2}^{l-1} \frac{(2l-2)!}{(2l-2j)!}\gamma_{2j-2}\mathfrak{p}^{(2l-2j)}$$

is zero. We have

$$K_0 = (2l-2)!\Bigg((2l+1)z^{-(2l+2)} + \gamma_{2l} - (2l+1)z^{-(2l+2)} - \sum_{i=1}^{l-2} (2l-1-2i)\gamma_{2i} z^{-(2l-2i)}$$
$$- \frac{(1+l)(2l-3)}{3}\gamma_{2l} + \sum_{j=2}^{l-1} \gamma_{2j-2}(2l-2j+1)z^{-(2l-2j+2)} + \sum_{j=2}^{l-1} \gamma_{2j-2}\gamma_{2l-2j} + O(z^2)\Bigg)$$
$$= (2l-2)!\Bigg(- \frac{(2l+3)(l-2)}{3}\gamma_{2l} + \sum_{j=2}^{l-1} \gamma_{2j-2}\gamma_{2l-2j} + O(z^2)\Bigg) = 0.$$

The proof of Lemma 3 is now finished.

Lemma 4: The following identity holds:

$$\Bigg[\Theta, \sum_{j=2}^{n} u_{1j}\Bigg] + m\sum_{j=2}^{n} [\Theta_{\hat{j}}, u_{1j}]\partial - \frac{(1+m)}{2}\sum_{j=2}^{n} u'_{1j}\Theta_{\hat{j}} - \frac{(1-m)}{2}\sum_{j=2}^{n} \Theta_{\hat{j}} u'_{1j} + m\sum_{k=2}^{n}\sum_{\substack{l=2 \\ l\neq k}}^{n} [\Theta_{\hat{k}\hat{l}}, u_{1k}]u_{1l} = 0.$$

Here again $\partial = \partial/\partial x_1$.

Proof: From Lemma 3,

$$[\mathfrak{D}^n, u_{1j}] + [[\mathfrak{s}_j, \mathfrak{D}^{n-1}], u_{1j}] + m[\mathfrak{D}^{n-1}, u_{1j}]\partial - \frac{(1+m)}{2}u'_{1j}\mathfrak{D}^{n-1} - \frac{(1-m)}{2}\mathfrak{D}^{n-1}u'_{1j} = 0. \qquad (21)$$

Note also that

$$\sum_{j=2}^{n}\sum_{\sigma\in\mathfrak{S}(1\hat{j};t)} \mathrm{ad}^t_{\mathfrak{s}_\sigma}([\mathfrak{D}^{n-t-1}, u_{1j}]\partial) = \sum_{j=2}^{n}\sum_{\sigma\in\mathfrak{S}(1\hat{j};t)} \mathrm{ad}^t_{\mathfrak{s}_\sigma}([\mathfrak{D}^{n-t-1}, u_{1j}])\partial$$
$$+ \sum_{k=2}^{n}\sum_{\substack{l=2 \\ l\neq k}}^{n}\sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{k}\hat{l};t)} [\mathrm{ad}^t_{\mathfrak{s}_\sigma}(\mathfrak{D}^{n-2-t}), u_{1k}]u_{1l}.$$

We sum (21) and then use (11) to obtain Θ and $\Theta^n_{\hat{k}}$. We have

$$
\begin{aligned}
0 &= \sum_{t=0}^{[n/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} \mathrm{ad}_{\mathfrak{s}_\sigma}^t \Big([\mathfrak{D}^{n-t}, u_{1j}] + [[\mathfrak{s}_j, \mathfrak{D}^{n-t-1}], u_{1j}] + m[\mathfrak{D}^{n-t-1}, u_{1j}]\partial - \frac{(1+m)}{2} u'_{1j}\mathfrak{D}^{n-t-1} \\
&\quad - \frac{(1-m)}{2}\mathfrak{D}^{n-t-1}u'_{1j} \Big) \\
&= \sum_{t=0}^{[n/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} [\mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-t}), u_{1j}] + m \sum_{t=0}^{[(n-2)/2]} \sum_{k=2}^{n} \sum_{\substack{l=2 \\ l\neq k}}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{k}\hat{l};t)} [\mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-2-t}), u_{1k}]u_{1l} \\
&\quad + m \sum_{t=0}^{[(n-1)/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} \mathrm{ad}_{\mathfrak{s}_\sigma}^t([\mathfrak{D}^{n-t-1}, u_{1j}])\partial + \sum_{t=0}^{[(n-1)/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} [\mathrm{ad}_{\mathfrak{s}_{\{j,\sigma\}}}^t(\mathfrak{D}^{n-t-1}), u_{1j}] \\
&\quad - \frac{(1+m)}{2} \sum_{t=0}^{[(n-1)/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} u'_{1j}\,\mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-t-1}) - \frac{(1-m)}{2} \sum_{t=0}^{[(n-1)/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} \mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-t-1})u'_{1j} \\
&= \sum_{t=0}^{[n/2]} \sum_{\sigma\in\mathfrak{S}(\hat{1};t)} \left[\mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-t}), \sum_{j=2}^{n} u_{1j} \right] + m \sum_{t=0}^{[(n-1)/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} \mathrm{ad}_{\mathfrak{s}_\sigma}^t([\mathfrak{D}^{n-t-1}, u_{1j}])\partial \\
&\quad + m \sum_{t=0}^{[(n-2)/2]} \sum_{k=2}^{n} \sum_{\substack{l=2 \\ l\neq k}}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{k}\hat{l};t)} [\mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-2-t}), u_{1k}]u_{1l} - \frac{(1+m)}{2} \sum_{t=0}^{[(n-1)/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} u'_{1j}\,\mathrm{ad}_{\mathfrak{s}_\sigma^\mu}^t(\mathfrak{D}^{n-t-1}) \\
&\quad - \frac{(1-m)}{2} \sum_{t=0}^{[(n-1)/2]} \sum_{j=2}^{n} \sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};t)} \mathrm{ad}_{\mathfrak{s}_\sigma}^t(\mathfrak{D}^{n-t-1})u'_{1j} = \left[\Theta, \sum_{j=2}^{n} u_{1j} \right] + m\sum_{j=2}^{n} [\Theta_{\hat{j}}, u_{1j}]\partial \\
&\quad - \frac{(1+m)}{2}\sum_{j=2}^{n} u'_{1j}\Theta_{\hat{j}} - \frac{(1-m)}{2}\sum_{j=2}^{n} \Theta_{\hat{j}}u'_{1j} + m\sum_{k=2}^{n}\sum_{\substack{l=2 \\ l\neq k}}^{n} [\Theta_{\hat{k}\hat{l}}, u_{1k}]u_{1l}.
\end{aligned}
$$

Lemma 4 is proven.

Lemma 5: The following identity holds:

$$
[\Delta, \Theta] = 2\sum_{k=2}^{n} [u_{1k}, \Theta_{\hat{k}}]\partial_k - 2m\sum_{k=2}^{n} [u_{1k}, \Theta_{\hat{k}}]\partial_1 - (1+m)\sum_{k=2}^{n} [u'_{1k}, \Theta_{\hat{k}}] + m\sum_{k=2}^{n}\sum_{\substack{l=2 \\ l\neq k}}^{n} [u_{1k}, [u_{1l}, \Theta_{\hat{k}\hat{l}}]]. \tag{22}
$$

Proof:

$$
[\Delta, \Theta] = 2m\frac{\partial\Theta}{\partial x_1}\partial_1 + 2\sum_{k=2}^{n}\frac{\partial\Theta}{\partial x_k}\partial_k + m\frac{\partial^2\Theta}{\partial x_1^2} + \sum_{k=2}^{n}\frac{\partial^2\Theta}{\partial x_k^2}.
$$

From (11) it follows that $\partial\Theta/\partial x_k = [u_{1k}, \Theta_{\hat{k}}]$ and $\partial\Theta/\partial x_1 = -\Sigma_{k=2}^n [u_{1k}, \Theta_{\hat{k}}]$, therefore $\partial^2\Theta/\partial x_k^2 = -[u'_{1k}, \Theta_{\hat{k}}]$ and $\partial^2\Theta/\partial x_1^2 = -\Sigma_{k=2}^n [u'_{1k}, \Theta_{\hat{k}}] + \Sigma_{k=2}^n \Sigma_{\substack{l=2 \\ l\neq k}}^n [u_{1k}, [u_{1l}, \Theta_{\hat{k}\hat{l}}]]$, and we arrive at (22).

Lemma 6:

$$
R = [\Theta, H] + \sum_{j=2}^{n} \left[\Theta_{\hat{j}}\partial_j, 2\sum_{\substack{l=1 \\ l\neq j}}^{n} u_{jl} \right] + \sum_{2\leqslant k<l\leqslant n} [\Theta_{\hat{k}\hat{l}}, 2(u_{1k} + u_{1l})]X_{\{k,l\}} = 0.
$$

Proof: We have

$$R=[\Delta,\Theta]+2\sum_{k=2}^{n}[\Theta,u_{1k}]+2\sum_{j=2}^{n}\sum_{\substack{l=1\\ l\neq j}}^{n}[\Theta_{\hat{j}},u_{jl}]\partial_j+2\sum_{j=2}^{n}\sum_{\substack{l=1\\ l\neq j}}^{n}\Theta_{\hat{j}}[\partial_j,u_{jl}]+2\sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}},u_{1k}+u_{1l}]u_{kl}.$$

Using Lemma 5, R is rewritten as

$$R=2\sum_{k=2}^{n}[u_{1k},\Theta_{\hat{k}}]\partial_k-2m\sum_{k=2}^{n}[u_{1k},\Theta_{\hat{k}}]\partial_1-(1+m)\sum_{k=2}^{n}[u'_{1k},\Theta_{\hat{k}}]+m\sum_{k=2}^{n}\sum_{\substack{l=2\\ l\neq k}}^{n}[u_{1k},[u_{1l},\Theta_{\hat{k}\hat{l}}]]$$

$$+2\sum_{k=2}^{n}[\Theta,u_{1k}]+2\sum_{j=2}^{n}[\Theta_{\hat{j}},u_{1j}]\partial_j+2\sum_{j=2}^{n}\sum_{\substack{l=1\\ l\neq j}}^{n}\Theta_{\hat{j}}u'_{jl}+2\sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}},u_{1k}+u_{1l}]u_{kl}$$

and, hence,

$$R=-2m\sum_{k=2}^{n}[u_{1k},\Theta_{\hat{k}}]\partial-(1+m)\sum_{k=2}^{n}[u'_{1k},\Theta_{\hat{k}}]+m\sum_{k=2}^{n}\sum_{\substack{l=2\\ l\neq k}}^{n}[u_{1k},[u_{1l},\Theta_{\hat{k}\hat{l}}]]+2\sum_{k=2}^{n}[\Theta,u_{1k}]-2\sum_{j=2}^{n}\Theta_{\hat{j}}u'_{1j}$$

$$+2\sum_{2\leqslant k<l\leqslant n}(\Theta_{\hat{k}}-\Theta_{\hat{l}})u'_{kl}+2\sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}},u_{1k}+u_{1l}]u_{kl}.$$

Now, let us apply Lemma 4 which simplifies the above expression into the following:

$$R=(1+m)\sum_{k=2}^{n}u'_{1k}\Theta_{\hat{k}}+(1-m)\sum_{k=2}^{n}\Theta_{\hat{k}}u'_{1k}-2m\sum_{k=2}^{n}\sum_{\substack{l=2\\ l\neq k}}^{n}[\Theta_{\hat{k}\hat{l}},u_{1k}]u_{1l}-(1+m)\sum_{k=2}^{n}u'_{1k}\Theta_{\hat{k}}$$

$$+(1+m)\sum_{k=2}^{n}\Theta_{\hat{k}}u'_{1k}+m\sum_{k=2}^{n}\sum_{\substack{l=2\\ l\neq k}}^{n}[u_{1k},[u_{1l},\Theta_{\hat{k}\hat{l}}]]+\sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}},2(u_{1k}+u_{1l})]u_{kl}$$

$$-2\sum_{j=2}^{n}\Theta_{\hat{j}}u'_{1j}+2\sum_{2\leqslant k<l\leqslant n}(\Theta_{\hat{k}}-\Theta_{\hat{l}})u'_{kl}$$

$$=-2m\sum_{k=2}^{n}\sum_{\substack{l=2\\ l\neq k}}^{n}[\Theta_{\hat{k}\hat{l}},u_{1k}]u_{1l}+m\sum_{k=2}^{n}\sum_{\substack{l=2\\ l\neq k}}^{n}[u_{1k},[u_{1l},\Theta_{\hat{k}\hat{l}}]]$$

$$+2\sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}},(u_{1k}+u_{1l})]u_{kl}+2\sum_{2\leqslant k<l\leqslant n}(\Theta_{\hat{k}}-\Theta_{\hat{l}})u'_{kl}.$$

From (11) $\Theta_{\hat{k}}-\Theta_{\hat{l}}=[\varsigma_l-\varsigma_k,\Theta_{\hat{k}\hat{l}}]$ and, therefore, R is simplified to

$$R=m\sum_{k=2}^{n}\sum_{\substack{l=2\\ l\neq k}}^{n}[u_{1k}u_{1l},\Theta_{\hat{k}\hat{l}}]+2\sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}},(u_{1k}+u_{1l})u_{kl}]+2\sum_{2\leqslant k<l\leqslant n}[\varsigma_{1l}-\varsigma_{1k},\Theta_{\hat{k}\hat{l}}]u'_{kl}$$

$$=2\sum_{2\leqslant k<l\leqslant n}[(\varsigma_l-\varsigma_k)u'_{kl}-(u_{1k}+u_{1l})u_{kl}+mu_{1k}u_{1l},\Theta_{\hat{k}\hat{l}}].$$

All derivatives with respect to x_1 of the term

$$(\varsigma_l-\varsigma_k)u'_{kl}-(u_{1k}+u_{1l})u_{kl}+mu_{1k}u_{1l}=m(m+1)^2((\varsigma(x_1-x_l)-\varsigma(x_1-x_k))\wp'_{kl}-(\wp_{1k}+\wp_{1l})\wp_{kl}+\wp_{1k}\wp_{1l})$$

are zero. Indeed, this follows from the fact that the first derivative is the addition theorem for the Weierstrass $\wp$-function,

$$\frac{\partial}{\partial x_1}((\varsigma(x_1-x_l)-\varsigma(x_1-x_k))\wp'_{kl}-(\wp_{1k}+\wp_{1l})\wp_{kl}+\wp_{1k}\wp_{1l})$$
$$=(\wp_{1k}-\wp_{1l})\wp'_{kl}-(\wp'_{1k}+\wp'_{1l})\wp_{kl}+\wp'_{1k}\wp_{1l}+\wp_{1k}\wp'_{1l}=0.$$

Therefore $R=2\Sigma_{2\leqslant k<l\leqslant n}[(\varsigma_{1l}-\varsigma_{1k})u'_{kl}-(u_{1k}+u_{1l})u_{kl}+mu_{1k}u_{1l},\Theta_{\hat{k}\hat{l}}]=0$ and Lemma 6 is proven.

Proof of Theorem 1: We use Lemma 3 to reduce the commutator $[I,H]$ to the expression (18) and we show below that (18) is zero. From (13),

$$X=\Theta+\sum_{t=1}^{[(n-2)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1};2t)}X_\sigma\Theta_{\hat{\sigma}},$$

therefore we can rewrite (18) as the following:

$$\begin{aligned}
[I,H]&=\left[X_{\hat{1}}\partial_1,2\sum_{l=2}^{n}u_{1l}\right]+\left[\sum_{k=2}^{n}X_{\hat{1}\hat{k}}\partial_1\partial_k,2u_{1k}\right]+\left[\Theta+\sum_{t=1}^{[(n-2)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1};2t)}X_\sigma\Theta_{\hat{\sigma}},H\right]\\
&+\left[\sum_{j=2}^{n}\left(\Theta_{\hat{j}}+\sum_{t=1}^{[(n-3)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};2t)}X_\sigma\Theta_{\hat{j}\hat{\sigma}}\right)\partial_j,2\sum_{\substack{l=1\\l\neq j}}^{n}u_{jl}\right]\\
&+\left[\sum_{2\leqslant i<j\leqslant n}\left(\Theta_{\hat{i}\hat{j}}+\sum_{t=1}^{[(n-4)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{i}\hat{j};2t)}X_\sigma\Theta_{\hat{i}\hat{j}\hat{\sigma}}\right)\partial_i\partial_j,2u_{ij}\right]\\
&=[\Theta,H]+\sum_{t=1}^{[(n-2)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1};2t)}[X_\sigma,-\Delta_\sigma]\Theta_{\hat{\sigma}}\\
&+\sum_{t=1}^{[(n-2)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1};2t)}\left[\Theta_{\hat{\sigma}},-\Delta_{\hat{\sigma}}+2\sum_{j=2}^{n}u_{1j}\right]X_\sigma+\sum_{j=2}^{n}\left[\Theta_{\hat{j}}\partial_j,2\sum_{\substack{l=1\\l\neq j}}^{n}u_{jl}\right]\\
&+\sum_{j=2}^{n}\sum_{t=1}^{[(n-3)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};2t)}\left[X_\sigma\partial_j,2\sum_{l\in\sigma}u_{jl}\right]\Theta_{\hat{j}\hat{\sigma}}+\sum_{j=2}^{n}\sum_{t=1}^{[(n-3)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};2t)}\left[\Theta_{\hat{j}\hat{\sigma}}\partial_j,2\sum_{\substack{l=1\\l\notin j\cup\sigma}}^{n}u_{jl}\right]X_\sigma\\
&+\left[\sum_{2\leqslant i<j\leqslant n}\partial_i\partial_j,2u_{ij}\right]\Theta_{\hat{i}\hat{j}}+\sum_{2\leqslant i<j\leqslant n}\sum_{t=1}^{[(n-4)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{i}\hat{j};2t)}[X_\sigma\partial_i\partial_j,2u_{ij}]\Theta_{\hat{i}\hat{j}\hat{\sigma}}\\
&+\left[X_{\hat{1}}\partial_1,2\sum_{l=2}^{n}u_{1l}\right]+\left[\sum_{k=2}^{n}X_{\hat{1}\hat{k}}\partial_1\partial_k,2u_{1k}\right]
\end{aligned}$$

From the formulas for the system with $n=2$ we have

$$[X_{\{k,l\}},-\Delta_{\{k,l\}}]=-[\partial_k\partial_l,2u_{kl}]\quad\text{and}\quad[\partial_1\partial_k,2u_{1k}]=-[\Theta_{\{1,k\}},H_{\{1,k\}}],$$

and from Lemma 2 we have that for any $\sigma'\in\mathfrak{S}(\hat{1};2t)$, $t\geqslant 2$,

$$[X_{\sigma'},-\Delta_{\sigma'}]=-2\sum_{\substack{k<l\\ k,l\in\sigma'}}[X_{\sigma'\setminus\{k,l\}}\partial_k\partial_l,u_{kl}]$$

and

$$\sum_{t=1}^{[(n-3)/2]}\sum_{j=2}^{n}\sum_{\sigma\in\mathfrak{S}(\sigma'\setminus\{j\};2t)}\left[X_\sigma\partial_j,2\sum_{l\in\sigma}u_{jl}\right]\Theta_{\hat{j}\hat{\sigma}}=0.$$

Hence, $[I,H]$ can be simplified to

$$\begin{aligned}[I,H]=[\Theta,H]&+\sum_{t=1}^{[(n-2)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1};2t)}[\Theta_{\hat{\sigma}},H_{\hat{\sigma}}]X_\sigma+\sum_{t=1}^{[(n-2)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1};2t)}\left[\Theta_{\hat{\sigma}},2\sum_{j\in\sigma}u_{1j}\right]X_\sigma\\&+\sum_{j=2}^{n}\left[\Theta_{\hat{j}}\partial_j,2\sum_{\substack{l=1\\ l\neq j}}^{n}u_{jl}\right]+\sum_{j=2}^{n}\sum_{t=1}^{[(n-3)/2]}\sum_{\sigma\in\mathfrak{S}(\hat{1}\hat{j};2t)}\left[\Theta_{\hat{j}\hat{\sigma}}\partial_j,2\sum_{\substack{l=1\\ l\notin j\cup\sigma}}^{n}u_{jl}\right]X_\sigma+\left[X_{\hat{1}}\partial_1,2\sum_{l=2}^{n}u_{1l}\right]\\&-\sum_{k=2}^{n}[\Theta_{\{1,k\}},H_{\{1,k\}}]X_{\hat{1}\hat{k}}.\end{aligned}$$

This expression is equal to zero. To verify this we should use relation (15), apply Lemma 6, which gives us

$$[\Theta,H]=-\sum_{j=2}^{n}\left[\Theta_{\hat{j}}\partial_j,2\sum_{\substack{l=1\\ l\neq j}}^{n}u_{jl}\right]-\sum_{2\leqslant k<l\leqslant n}[\Theta_{\hat{k}\hat{l}},2(u_{1k}+u_{1l})]X_{\{k,l\}}$$

and

$$[\Theta_{\hat{\sigma}},H_{\hat{\sigma}}]=-\sum_{\substack{j=2\\ j\notin\sigma}}^{n}\left[\Theta_{\hat{\sigma}\hat{j}}\partial_j,2\sum_{\substack{l=1\\ l\neq j,\sigma}}^{n}u_{jl}\right]-\sum_{\substack{2\leqslant k<l\leqslant n\\ k,l\notin\sigma}}[\Theta_{\hat{\sigma}\hat{k}\hat{l}},2(u_{1k}+u_{1l})]X_{\{k,l\}},$$

and equality

$$[\Theta_{\{1,k,l\}},H_{\{1,k,l\}}]=-[\partial_1,2(u_{1k}+u_{1l})]X_{\{k,l\}}-[\Theta_{\{1,l\}}\partial_k,2(u_{1k}+u_{kl})]-[\Theta_{\{1,k\}}\partial_l,2(u_{1l}+u_{kl})].$$

The last equality can be obtained by direct calculation or using formulas for the three-particle case. Once all these substitutions are made it can be easily seen that all terms in (18) are canceled. This completes the proof of Theorem 1.

VII. CONCLUDING REMARKS

A more general class of the deformed CM operators related to any Lie superalgebra has been recently introduced by Sergeev and Veselov,[16] who found also recurrent formulas for the quantum integrals in the trigonometric case for the classical series. In the elliptic case the integrability of these systems is an open problem. Within this approach the operator (1) considered in our paper corresponds to the Lie superalgebra $\mathrm{sl}(n-1,1)$. The author hopes that the technique developed in this paper can be applied to more general deformed elliptic CM operators related to the Lie superalgebra $\mathrm{sl}(n,p)$.

In this relation it is worth mentioning that as one can see from our formulas (6) the parameters $m=1/l$, $l=1,2,3,\ldots$ play a special role in the theory of the deformed CM operators. These values

of the parameters have also an interesting geometric interpretation,[16,17] they correspond to the strata in the discriminant variety of the polynomials having a root of multiplicity l.

Integrable couplings of vector AKNS soliton equations

Wen-Xiu Ma[a)]
Department of Mathematics, University of South Florida, Tampa, Florida 33620-5700

(Received 15 October 2004; accepted 12 November 2004;
published online 10 February 2005)

By enlarging the associated matrix spectral problems, two specific classes of multicomponent integrable couplings of the physically important vector AKNS soliton equations are constructed, which can be linked to each other by a Bäcklund transformation. The resulting two hierarchies of integrable couplings possess the enlarged zero curvature representations and recursion structures, and thus each system in the two hierarchies has infinitely many commuting symmetries. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1845971]

I. INTRODUCTION

It is in the direction of solving the integrability problem of nonlinear differential equations to search for completely integrable differential equations and to accumulate characteristics of integrability. Integrability of ordinary differential equations and $1+1$ dimensional partial differential equations, especially scalar ones, was extensively studied and various criteria such as the Liouville–Arnold theorem, the inverse scattering transform and the Painlevé test were proposed for testing integrability.[1,2] But the higher dimensions of differential equations and the multiplicity of systems of differential equations cause much difficulty in determining their integrability. Both the dimension and the multiplicity bring a diversity of mathematical structures of integrable systems, and indeed, nonlinear differential equations in higher dimensions and systems of nonlinear differential equations often need specific consideration due to complex characteristics of integrability that they may have.

Integrable couplings show one of diverse integrable structures that the multiplicity of integrable systems bring. The problem of integrable couplings was presented and studied extensively by various perturbations in Ref. 3. The interest in studying integrable couplings comes from the study of the symmetry problem and its related Virasoro algebra.

To present the definition of integrable couplings concretely, let us first look at a triangular system of differential equations

$$X(x,u) \equiv X(x,u,D_x u, \dots) = 0, \tag{1a}$$

$$Y(\bar{x},u,v) \equiv Y(\bar{x},u,v,D_{\bar{x}}u, D_{\bar{x}}v, \dots) = 0, \tag{1b}$$

where x, $\bar{x}$, u, v, X, and Y all can be multicomponent vectors, and $D_y w$ means the derivative of w with respect to y. The vector $\bar{x}$ can contain one or more variables in x, or be the same as x, or contain the whole vector x. Such a triangular system is called nontrivial with respect to the system $X(x,u)=0$, if the second subsystem $Y(\bar{x},u,v)=0$ involves the dependent variable u of the first subsystem $X(x,u)=0$. This nontriviality property implies that diagonal systems with $Y(\bar{x},u,v) = Y(\bar{x},v)$, especially $Y(\bar{x},u,v)=X(x,v)$, are trivial, and so they are not interesting and will be excluded from our discussion.

Definition: A non-trivial triangular system of differential equations (1) with respect to a given

a)Electronic mail: mawx@math.usf.edu

system $X(x,u,D_x u,\ldots)=0$ *is called an integrable coupling of the system* $X(x,u,D_x u,\ldots)=0$, *if (1) is integrable*.

Among the primary problems of integrable couplings are how one can construct integrable couplings for a given system and what mathematical structures integrable couplings should possess. The study of integrable couplings will also help classify integrable systems in whatever dimensions, along a direction of transforming them into triangular forms. What is more, all possible methods for constructing integrable couplings will tell us how to extend integrable systems, from small to large and from simple to complicated. The resulting integrable couplings themselves provide us with new models of integrable systems, which are probably difficult to find in other ways.

For evolution equations, the perturbation method to construct integrable couplings was systematically developed and various mathematical properties associated with the resulting integrable couplings were discussed in Ref. 3, motivated by the work on perturbations around solutions of evolution equations by Lakshmanan and Tamizhmani[4] and the perturbation bundle by Fuchssteiner.[5] As by-products, local $2+1$ dimensional integrable bi-Hamiltonian systems were presented among the resulting integrable couplings of the Korteweg–de Vries (KdV) equation,[6] which also provide counter examples for the conjecture on nonexistence of local integrable bi-Hamiltonian systems in higher dimensions, made by Zakharov and Konopelchenko.[7] One of such $2+1$ dimensional integrable bi-Hamiltonian systems is

$$u_t = u_{xxx} + 6uu_x, \tag{2a}$$

$$v_t = v_{xxx} + 3u_{xxy} + 6(uv)_x + 6uu_y, \tag{2b}$$

which was presented in Ref. 8 and whose Painlevé property was studied in Ref. 9. This $2+1$ dimensional system has a local bi-Hamiltonian structure[6]

$$\begin{pmatrix} u \\ v \end{pmatrix}_t = J\begin{pmatrix} \dfrac{\delta \tilde{H}_1}{\delta u} \\ \dfrac{\delta \tilde{H}_1}{\delta v} \end{pmatrix} = M\begin{pmatrix} \dfrac{\delta \tilde{H}_0}{\delta u} \\ \dfrac{\delta \tilde{H}_0}{\delta v} \end{pmatrix}, \tag{3}$$

where $\delta/\delta u$ and $\delta/\delta v$ are variational derivatives with respect to u and v, respectively; the Hamiltonian pair, J and M, is defined by

$$J = \begin{pmatrix} 0 & \partial_x \\ \partial_x & \partial_y \end{pmatrix}, \quad M = \begin{pmatrix} 0 & \partial_x^3 + 2u_x + 4u\partial_x \\ \partial_x^3 + 2u_x + 4u\partial_x & Q \end{pmatrix}, \tag{4}$$

with Q being given by

$$Q = 3\partial_x^2\partial_y + 2v_x + 2u_y + 4v\partial_x + 4u\partial_y; \tag{5}$$

and the Hamiltonian functionals, $\tilde{H}_0$ and $\tilde{H}_1$, are defined by

$$\tilde{H}_0 = \int\int uv\, \mathrm{d}x\, \mathrm{d}y, \quad \tilde{H}_1 = \int\int \left(\frac{1}{2}uv_{xx}uu_{xy} + \frac{1}{2}u_{xx}v + 3u^3v\right)\mathrm{d}x\, \mathrm{d}y. \tag{6}$$

This bi-Hamiltonian structure gives rise to a hereditary recursion operator (see Refs. 10 and 11 for definition) of the system (2),

$$\Phi = \begin{pmatrix} \partial_x^2 + 2u_x\partial_x^{-1} + 4u & 0 \\ 2\partial_x\partial_y - 2u_x\partial_x^{-2}\partial_y + 2(v_x + u_y)\partial_x^{-1} + 4v & \partial_x^2 + 2u_x\partial_x^{-1} + 4u \end{pmatrix}. \tag{7}$$

On the other hand, a basic integrable coupling of an evolution equation $u_t = K(u)$:

$$u_t = K(u), \quad v_t = K'(u)[v] \tag{8}$$

can also be generated by a perturbation around a solution of the equation $u_t=K(u)$. In the above system and elsewhere throughout this paper, $P'(u)[v]$ denotes the Gateaux derivative of $P(u) \equiv P(u, D_x u, \ldots)$ with respect to u in a direction v, i.e.,

$$P'(u)[v] = \left.\frac{\partial}{\partial \varepsilon} P(u+\varepsilon v)\right|_{\varepsilon=0} = \left.\frac{\partial}{\partial \varepsilon} P(u+\varepsilon v, D_x u + \varepsilon D_x v, \ldots)\right|_{\varepsilon=0}.$$

A symmetry $S(u)$ of the equation $u_t=K(u)$ leads to a solution $(u, S(u))$ to the above integrable coupling (8). However, the second component v of a solution (u,v) to the integrable coupling (8) is generally not a symmetry of the equation $u_t=K(u)$. This is because v satisfies the linearized equation $v_t=K'(u)[v]$ only for one solution, not for all solutions of the equation $u_t=K(u)$. Therefore, the integrable coupling (8) is a generalization of the symmetry problem, which also provides a stimulus for us to study the problem of integrable couplings. Moreover, the function $u+\varepsilon v$ presents an approximate solution to the equation $u_t=K(u)$ up to a precision $o(\varepsilon)$, if (u,v) solves the integrable coupling (8). Another basic integrable coupling of an evolution equation $u_t=K(u)$, generated by perturbation, is given by

$$u_t = K(u), \quad v_t = K'(u)[v] + K(u). \tag{9}$$

Interestingly, it has a set of hereditary recursion operators[3]

$$\Phi(\beta_1, \beta_2) = \begin{pmatrix} \beta_1 \Phi(u) & 0 \\ \beta_1 \Phi'(u)[v] + \beta_2 \Phi(u) & \beta_1 \Phi(u) \end{pmatrix} \tag{10}$$

with two arbitrary constants β_1 and β_2, if the original equation $u_t=K(u)$ has a hereditary recursion operator $\Phi(u)$. This also shows that the multiplicity of integrable systems bring the diversity of integrable structures.

A natural and interesting question for us now is whether there are other kinds of integrable couplings and what mathematical structures the resulting integrable couplings can have. In this paper, we aim at presenting two classes of multicomponent integrable couplings for the physically important vector AKNS soliton equations by enlarging the associated spectral problems. All resulting integrable couplings of the vector AKNS soliton equations possess the enlarged zero curvature representations and infinitely many commuting symmetries with recursion structures, but they are different from the integrable couplings obtained through perturbations. Unlike the case of perturbations,[3,6] it is unclear to us whether the resulting integrable couplings have infinitely many commuting conservation laws and Hamiltonian structures. A few concluding remarks will be given in the last section.

II. VECTOR AKNS SOLITON HIERARCHY

A. Soliton hierarchy

Let m be an arbitrary natural number. To display the vector AKNS soliton hierarchy, we start from the following $(m+1)\times(m+1)$ matrix spectral problem:

$$\phi_x = U(u,\lambda)\phi, \quad U(u,\lambda) = \begin{pmatrix} \alpha\lambda & q \\ r & \beta\lambda I_m \end{pmatrix} = U_0\lambda + U_1, \quad \frac{\partial U_0}{\partial \lambda} = \frac{\partial U_1}{\partial \lambda} = 0, \tag{11}$$

where λ is a spectral parameter, α and β are two distinct constants, I_m is the $m\times m$ unit matrix, and

$$q = (q_1, q_2, \ldots, q_m), \quad r = (r_1, r_2, \ldots, r_m)^T, \quad u = (q, r^T)^T. \tag{12}$$

If $m=1$ and $\alpha=-\beta=i$, where i is the square root of -1, the above spectral problem becomes the AKNS spectral problem.[12] Therefore, we say that (11) is the vector AKNS spectral problem. A

special traceless vector AKNS spectral problem, i.e., the case of (11) under $\alpha=-m$ and $\beta=1$, was discussed in Ref. 13.

As usual, to derive an associated soliton hierarchy, we first solve the stationary zero curvature equation

$$V_x = [U,V] \tag{13}$$

of the spectral problem (11). We assume that a solution V can be given by

$$V = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \tag{14}$$

where a is a scalar, b^T and c are m-dimensional columns, and d is an $m\times m$ matrix. Then we have

$$[U,V] = \begin{pmatrix} qc-br & (\alpha-\beta)\lambda b + qd - aq \\ (\beta-\alpha)\lambda c + ra - dr & rb - cq \end{pmatrix}.$$

Therefore, the stationary zero curvature equation (13) becomes

$$a_x = qc - br, \quad b_x = (\alpha-\beta)\lambda b + qd - aq, \tag{15a}$$

$$c_x = (\beta-\alpha)\lambda c + ra - dr, \quad d_x = rb - cq. \tag{15b}$$

Let us seek a formal solution of the type

$$V = \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \sum_{k=0}^{\infty} V_k \lambda^{-k}, \quad V_k = \begin{pmatrix} a^{(k)} & b^{(k)} \\ c^{(k)} & d^{(k)} \end{pmatrix}, \quad k \geqslant 0, \tag{16}$$

where $b^{(k)}$, $c^{(k)}$, and $d^{(k)}$ are assumed to be

$$b^{(k)} = (b_1^{(k)}, b_2^{(k)}, \ldots, b_m^{(k)}), \quad c^{(k)} = (c_1^{(k)}, c_2^{(k)}, \ldots, c_m^{(k)})^T, \quad d^{(k)} = (d_{ij}^{(k)})_{m\times m}. \tag{17}$$

Then, the equations (15) equivalently yield the following recursion relation:

$$b^{(0)} = 0, \quad c^{(0)} = 0, \quad a_x^{(0)} = 0, \quad d_x^{(0)} = 0, \tag{18a}$$

$$b^{(k+1)} = \frac{1}{\beta-\alpha}(-b_x^{(k)} + qd^{(k)} - a^{(k)}q), \quad k \geqslant 0, \tag{18b}$$

$$c^{(k+1)} = \frac{1}{\beta-\alpha}(c_x^{(k)} - ra^{(k)} + d^{(k)}r), \quad k \geqslant 0, \tag{18c}$$

$$a_x^{(k+1)} = qc^{(k+1)} - b^{(k+1)}r, \quad d_x^{(k+1)} = rb^{(k+1)} - c^{(k+1)}q, \quad k \geqslant 0. \tag{18d}$$

To uniquely determine $a^{(k)}$, $b^{(k)}$, $c^{(k)}$, and $d^{(k)}$, we fix the following initial data:

$$a^{(0)} = \alpha, \quad d^{(0)} = \beta I_m, \tag{19}$$

which leads to $V_0 = U_0$, and require that

$$V_k|_{u=0} = 0, \quad k \geqslant 1. \tag{20}$$

The requirement (20) implies to identify all constants of integration as zero while using (18) to determine V. One can also release (19) and (20), and choose arbitrary constants of integration. But the results of V_k are just linear combinations of the expressions of V_k under (19) and (20). Now it is direct to generate from (18) under the selections (19) and (20) that

$$b_i^{(1)} = q_i, \quad c_i^{(1)} = r_i, \quad a^{(1)} = 0, \quad d_{ij}^{(1)} = 0,$$

$$b_i^{(2)} = \frac{1}{\alpha-\beta} q_{i,x}, \quad c_i^{(2)} = \frac{1}{\beta-\alpha} r_{i,x}, \quad a^{(2)} = \frac{1}{\beta-\alpha} \sum_{i=1}^{m} q_i r_i, \quad d_{ij}^{(2)} = \frac{1}{\alpha-\beta} r_i q_j,$$

$$b_i^{(3)} = \frac{1}{(\beta-\alpha)^2} \left(q_{i,xx} - 2q_i \sum_{j=1}^{m} q_j r_j \right), \quad c_i^{(3)} = \frac{1}{(\beta-\alpha)^2} \left(r_{i,xx} - 2r_i \sum_{j=1}^{m} q_j r_j \right),$$

$$a^{(3)} = \frac{1}{(\beta-\alpha)^2} \sum_{i=1}^{m} (q_i r_{i,x} - q_{i,x} r_i), \quad d_{ij}^{(3)} = \frac{1}{(\beta-\alpha)^2} (r_i q_{j,x} - r_{i,x} q_j),$$

$$b_i^{(4)} = \frac{1}{(\beta-\alpha)^3} \left[-q_{i,xxx} + 3 \sum_{j=1}^{m} (q_i q_j)_x r_j \right], \quad c_i^{(4)} = \frac{1}{(\beta-\alpha)^3} \left[r_{i,xxx} - 3 \sum_{j=1}^{m} (r_i r_j)_x q_j \right],$$

$$a^{(4)} = \frac{1}{(\beta-\alpha)^3} \left[\sum_{i=1}^{m} (q_i r_{i,xx} - q_{i,x} r_{i,x} + q_{i,xx} r_i) - 3 \sum_{i,j=1}^{m} q_i q_j r_i r_j \right],$$

$$d_{ij}^{(4)} = \frac{1}{(\beta-\alpha)^3} \left(-r_i q_{j,xx} r_{i,x} q_{j,x} - r_{i,xx} q_j + 3 r_i q_j \sum_{k=1}^{m} r_k q_k \right),$$

where $1 \leqslant i, j \leqslant m$. From (18d), we have

$$a^{(k)} = \partial^{-1}(qc^{(k)} - b^{(k)}r), \quad d^{(k)} = \partial^{-1}(rb^{(k)} - c^{(k)}q), \quad k \geqslant 1, \tag{21}$$

where the operator ∂^{-1} is the inverse of the operator ∂,

$$\partial\partial^{-1} = \partial^{-1}\partial = 1, \quad \partial = \partial_x = \frac{\partial}{\partial x}. \tag{22}$$

Then we can obtain the following recursion relation for $b^{(k)}$ and $c^{(k)}$:

$$\begin{pmatrix} c^{(k+1)} \\ b^{(k+1)T} \end{pmatrix} = \Psi \begin{pmatrix} c^{(k)} \\ b^{(k)T} \end{pmatrix}, \quad k \geqslant 1, \tag{23}$$

where the $2m \times 2m$ matrix operator Ψ is given by

$$\Psi = \frac{1}{\beta-\alpha} \begin{pmatrix} \left(\partial - \sum_{k=1}^{m} r_k \partial^{-1} q_k \right) I_m - r\partial^{-1} q & r\partial^{-1} r^T + (r\partial^{-1} r^T)^T \\ -q^T \partial^{-1} q - (q^T \partial^{-1} q)^T & \left(-\partial + \sum_{k=1}^{m} q_k \partial^{-1} r_k \right) I_m + q^T \partial^{-1} r^T \end{pmatrix}. \tag{24}$$

As in the cases of the AKNS spectral problem[12] and the traceless vector AKNS spectral problem,[13] we take the temporal spectral matrices as

$$V^{(n)} = (\lambda^n V)_+ \equiv \sum_{j=0}^{n} V_j \lambda^{n-j} = \sum_{j=0}^{n} \begin{pmatrix} a^{(j)} & b^{(j)} \\ c^{(j)} & d^{(j)} \end{pmatrix} \lambda^{n-j}, \quad n \geqslant 0, \tag{25}$$

and then introduce the temporal spectral problems,

$$\phi_{t_n} = V^{(n)}\phi = V^{(n)}\left(u, u_x, \ldots, \frac{\partial^{n-1}u}{\partial x^{n-1}}; \lambda\right)\phi, \quad n \geqslant 0. \tag{26}$$

The compatibility condition of the spectral spectral problem (11) and the temporal spectral problems (26), i.e., the zero curvature equations

$$U_{t_n} - V_x^{(n)} + [U, V^{(n)}] = 0, \quad n \geqslant 0, \tag{27}$$

lead to a hierarchy of systems of evolution equations

$$u_{t_n} = \begin{pmatrix} q^T \\ r \end{pmatrix}_{t_n} = K_n = \begin{pmatrix} (\alpha-\beta)b^{(n+1)T} \\ (\beta-\alpha)c^{(n+1)} \end{pmatrix} = \Phi^n \begin{pmatrix} (\alpha-\beta)q^T \\ (\beta-\alpha)r \end{pmatrix}, \quad n \geqslant 0, \tag{28}$$

where Φ is the conjugate operator of the operator Ψ, i.e., $\Phi = \Psi^\dagger$. The soliton hierarchy (28) is called the vector AKNS soliton hierarchy with multiplicity m.

The first nonlinear system in (28) reads as

$$(q_i)_{t_2} = \frac{1}{\alpha-\beta}\left[(q_i)_{xx} - 2q_i\sum_{j=1}^{m} q_j r_j\right], \quad 1 \leqslant i \leqslant m, \tag{29a}$$

$$(r_i)_{t_2} = \frac{1}{\beta-\alpha}\left[(r_i)_{xx} - 2r_i\sum_{j=1}^{m} q_j r_j\right], \quad 1 \leqslant i \leqslant m. \tag{29b}$$

In particular, the case of $\alpha-\beta=2i$, where i is the square root of -1, will give us two important reductions of (29).[14] The first is the vector nonlinear Schrödinger equation

$$iq_{t_2} = \tfrac{1}{2}q_{xx} + |q|^2 q,$$

which corresponds to the reduction $r=-q^H=-\overline{q}^T$. The second is the vector defocusing nonlinear Schrödinger equation

$$iq_{t_2} = \tfrac{1}{2}q_{xx} - |q|^2 q,$$

which corresponds to the reduction $r=q^H=\overline{q}^T$.

B. Bi-Hamiltonian structure

To exhibit a bi-Hamiltonian structure of the vector AKNS soliton hierarchy (28), we apply the trace identity proposed by Tu (see Ref. 15 for more applications):

$$\frac{\delta}{\delta u}\int \operatorname{tr}\left(V\frac{\partial U}{\partial \lambda}\right)\mathrm{d}x = \lambda^{-\gamma}\frac{\partial}{\partial\lambda}\left[\lambda^{\gamma}\operatorname{tr}\left(V\frac{\partial U}{\partial u}\right)\right], \tag{30}$$

where γ is a constant to be determined and $\delta/\delta u$ is the variational derivative with respect to u as before. It is direct to compute that

$$\operatorname{tr}\left(V\frac{\partial U}{\partial\lambda}\right) = \alpha a + \beta\operatorname{tr}(d) = \sum_{k\geqslant 0}\left(\alpha a^{(k)} + \beta\sum_{i=1}^{m} d_{ii}^{(k)}\right)\lambda^{-k}, \tag{31}$$

and

$$\operatorname{tr}\left(V\frac{\partial U}{\partial u}\right) = \begin{pmatrix} c \\ b^T \end{pmatrix} = \sum_{k\geqslant 0} G_{k-1}\lambda^{-k}, \quad G_{k-1} = \begin{pmatrix} c^{(k)} \\ b^{(k)T} \end{pmatrix}, \quad k \geqslant 0. \tag{32}$$

Upon inserting these two expressions into the trace identity (30), we obtain

$$\frac{\delta}{\delta u}\int\left(\alpha a^{(k+1)}+\beta\sum_{i=1}^{m}d_{ii}^{(k+1)}\right)\mathrm{d}x=(\gamma-k)G_{k-1},\quad k\geqslant 0.$$

Then considering the case of $k=1$, we know $\gamma=0$, and thus we have

$$\frac{\delta\tilde{H}_n}{\delta u}=G_{n-1},\quad \tilde{H}_n=-\frac{1}{n}\int\left(\alpha a^{(n+1)}+\beta\sum_{i=1}^{m}d_{ii}^{(n+1)}\right)\mathrm{d}x,\quad n\geqslant 1. \tag{33}$$

Now it follows from (33) that the vector AKNS soliton equations (28) have the following bi-Hamiltonian structure

$$u_{t_n}=K_n=JG_n=J\frac{\delta\tilde{H}_{n+1}}{\delta u}=M\frac{\delta\tilde{H}_n}{\delta u}, \tag{34}$$

where the Hamiltonian pair, J and $M=J\Psi$, is defined by

$$J=\begin{pmatrix}0 & (\alpha-\beta)I_m\\ (\beta-\alpha)I_m & 0\end{pmatrix}, \tag{35a}$$

$$M=\begin{pmatrix}q^T\partial^{-1}q+(q^T\partial^{-1}q)^T & \left(\partial-\sum_{k=1}^{M}q_k\partial^{-1}r_k\right)I_m-q^T\partial^{-1}r^T\\ \left(\partial-\sum_{k=1}^{M}r_k\partial^{-1}q_k\right)I_m-r\partial^{-1}q & r\partial^{-1}r^T+(r\partial^{-1}r^T)^T\end{pmatrix}. \tag{35b}$$

Of course, the nth system in (28) has an n-Hamiltonian structure. This bi-Hamiltonian structure leads to infinitely many symmetries $\{K_i\}_{i=0}^{\infty}$ and infinitely many conserved functionals $\{\tilde{H}_i\}_{i=0}^{\infty}$, and the hereditary recursion operator $\Phi=MJ^{-1}$,

$$\Phi=\frac{1}{\beta-\alpha}\begin{pmatrix}\left(-\partial+\sum_{k=1}^{M}q_k\partial^{-1}r_k\right)I_m+q^T\partial^{-1}r^T & q^T\partial^{-1}q+(q^T\partial^{-1}q)^T\\ -r\partial^{-1}r^T-(r\partial^{-1}r^T)^T & \left(\partial-\sum_{k=1}^{M}r_k\partial^{-1}q_k\right)I_m-r\partial^{-1}q\end{pmatrix} \tag{36}$$

for the vector AKNS soliton hierarchy (28). The recursion operator Φ can also be used to generate master symmetries[16] and a τ-algebra[17] of symmetries including time-dependent symmetries for the vector AKNS soliton hierarchy (28) (see Ref. 18 for the discussion in the case of the vector nonlinear Schrödinger equation).

III. INTEGRABLE COUPLINGS

A. Enlarged zero curvature equations

To construct integrable couplings of the vector AKNS soliton equations in the hierarchy (28), we use an idea of enlarging spectral problems[19] to make an enlarged spectral problem of (11) as follows:

$$\bar{\phi}_x=\bar{U}\bar{\phi}=\bar{U}(\bar{u},\lambda)\bar{\phi},\quad \bar{\phi}=(\phi^T,\phi_e^T)^T, \tag{37}$$

with the enlarged spectral square matrix

$$\overline{U} = \overline{U}(\overline{u}) = \begin{pmatrix} U & U_a \\ U_b & 0 \end{pmatrix} = \begin{pmatrix} U(u) & U_a \\ U_b & 0 \end{pmatrix}, \tag{38}$$

where the additional matrices U_a and U_b give additional dependent variables and the new potential $\overline{u}$ consists of both the original dependent variables and additional dependent variables. This enlarged spectral matrix $\overline{U}$ is associated with a larger loop Lie algebra than U. The spectral problem (37) is equivalent to

$$\phi_x = U\phi + U_a\phi_e, \quad (\phi_e)_x = U_b\phi.$$

As usual, solve the stationary zero curvature equation $\overline{V}_x = [\overline{U}, \overline{V}]$ by choosing

$$\overline{V} = \overline{V}(\overline{u}) = \begin{pmatrix} V & V_a \\ V_b & 0 \end{pmatrix} = \begin{pmatrix} V(u) & V_a(\overline{u}) \\ V_b(\overline{u}) & 0 \end{pmatrix}, \tag{39}$$

where V_a and V_b are assumed to have the same sizes as U_a and U_b, respectively. We are then led to a set of differential equations

$$V_x = [U,V] + U_aV_b - V_aU_b, \tag{40a}$$

$$(V_a)_x = UV_a - VU_a, \tag{40b}$$

$$(V_b)_x = U_bV - V_bU, \tag{40c}$$

besides a closed condition for the matrix Lie algebra:

$$U_bV_a - V_bU_a = 0. \tag{41}$$

The system (40) is a linear system of differential equations for V_a and V_b, and thus there always exist solutions, but (41) is a restricted condition for U_a, U_b, V_a, and V_b.

Now we enlarge the associated temporal spectral matrices as follows:

$$\overline{V}^{(n)} = \begin{pmatrix} V^{(n)} & V_a^{(n)} \\ V_b^{(n)} & 0 \end{pmatrix} = \begin{pmatrix} V^{(n)}(u) & V_a^{(n)}(\overline{u}) \\ V_b^{(n)}(\overline{u}) & 0 \end{pmatrix}, \quad n \geqslant 0, \tag{42}$$

where $V_a^{(n)}$ and $V_b^{(n)}$ are assumed to have the same sizes as U_a and U_b, respectively, and usually generated from V_a and V_b. Then, the enlarged zero curvature equations

$$\overline{U}_{t_n} - \overline{V}_x^{(n)} + [\overline{U}, \overline{V}^{(n)}] = 0, \quad n \geqslant 0, \tag{43}$$

equivalently yield the following systems:

$$U_{t_n} - V_x^{(n)} + [U,V^{(n)}] + U_aV_b^{(n)} - V_a^{(n)}U_b = 0, \quad n \geqslant 0, \tag{44a}$$

$$(U_a)_{t_n} - (V_a^{(n)})_x + UV_a^{(n)} - V^{(n)}U_a = 0, \quad n \geqslant 0, \tag{44b}$$

$$(U_b)_{t_n} - (V_b^{(n)})_x + U_bV^{(n)} - V_b^{(n)}U = 0, \quad n \geqslant 0, \tag{44c}$$

together with the closed condition $U_bV_a^{(n)} - V_b^{(n)}U_a = 0$, $n \geqslant 0$. If we assume that

$$U_aV_b^{(n)} - V_a^{(n)}U_b = 0, \quad U_bV_a^{(n)} - V_b^{(n)}U_a = 0, \quad n \geqslant 0, \tag{45}$$

then the hierarchy (44) of systems determined by the enlarged zero curvature equations becomes the following hierarchy of triangular systems:

$$U_{t_n} - V_x^{(n)} + [U, V^{(n)}] = 0, \quad n \geqslant 0, \tag{46}$$

$$(U_a)_{t_n} - (V_a^{(n)})_x + UV_a^{(n)} - V^{(n)}U_a = 0, \quad n \geqslant 0, \tag{47}$$

$$(U_b)_{t_n} - (V_b^{(n)})_x + U_bV^{(n)} - V_b^{(n)}U = 0, \quad n \geqslant 0. \tag{48}$$

The first equation engenders exactly the vector AKNS soliton equations in the hierarchy (28), but the second and third equations present a coupled system involving u, U_a, and U_b. Therefore, they provide a class of candidates of integrable couplings for the vector AKNS soliton equations in (28).

In what follows, we shall assume that

$$\frac{\partial U_a}{\partial \lambda} = 0, \quad \frac{\partial U_b}{\partial \lambda} = 0. \tag{49}$$

Moreover, to satisfy the basic condition in (41), we choose

$$U_b = V_b = 0 \quad \text{or } U_a = V_a = 0,$$

and then the system (40) becomes

$$(V_a)_x = UV_a - VU_a \quad \text{or } (V_b)_x = U_bV - V_bU, \tag{50}$$

together with the original stationary zero curvature equation $V_x = [U, V]$. To satisfy the basic conditions in (45), we shall similarly choose

$$U_b = V_b^{(n)} = 0 \quad \text{or } U_a = V_a^{(n)} = 0,$$

and then (48) or (47) disappears. Those two classes will be discussed in details and two classes of integrable couplings will then be generated for the vector AKNS soliton equations in (28).

B. First class of integrable couplings

1. First enlarged soliton hierarchy

Let us consider the first specific case of the enlarged spectral problem (37),

$$\overline{\phi}_x = \overline{U}\overline{\phi} = \overline{U}(\overline{u}, \lambda)\overline{\phi}, \quad \overline{\phi} = (\phi^T, \phi_a^T)^T, \tag{51}$$

with the enlarged spectral square matrix

$$\overline{U} = \overline{U}(\overline{u}) = \begin{pmatrix} U & U_a \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} U(u) & U_a \\ 0 & 0 \end{pmatrix}, \quad \frac{\partial U_a}{\partial \lambda} = 0. \tag{52}$$

This enlarged spectral problem is equivalent to

$$\phi_x = U\phi + U_a\phi_a, \quad (\phi_a)_x = 0.$$

Choose a solution for $\overline{V} = [\overline{U}, \overline{V}]$ as

$$\overline{V} = \overline{V}(\overline{u}) = \begin{pmatrix} V & V_a \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} V(u) & V_a(\overline{u}) \\ 0 & 0 \end{pmatrix}, \tag{53}$$

and then we are led to the additional equations

$$(V_a)_x = UV_a - VU_a, \tag{54}$$

besides $V_x = [U, V]$. The enlarged temporal spectral matrices read as

$$\overline{V}^{(n)} = \begin{pmatrix} V^{(n)} & V_a^{(n)} \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} V^{(n)}(u) & V_a^{(n)}(\overline{u}) \\ 0 & 0 \end{pmatrix}, \quad n \geqslant 0, \tag{55}$$

and thus the enlarged associated temporal spectral problem

$$\overline{\phi}_{t_n} = \overline{V}^{(n)}\overline{\phi}, \quad \overline{\phi} = (\phi^T, \phi_a^T)^T, \quad n \geqslant 0, \tag{56}$$

are equivalent to

$$\phi_{t_n} = V^{(n)}\phi + V_a^{(n)}\phi_a, \quad (\phi_a)_{t_n} = 0, \quad n \geqslant 0.$$

Therefore, the enlarged zero curvature equations

$$\overline{U}_{t_n} - \overline{V}_x^{(n)} + [\overline{U}, \overline{V}^{(n)}] = 0, \quad n \geqslant 0,$$

equivalently yield the following triangular systems:

$$U_{t_n} - V_x^{(n)} + [U, V^{(n)}] = 0, \quad n \geqslant 0, \tag{57}$$

$$(U_a)_{t_n} - (V_a^{(n)})_x + UV_a^{(n)} - V^{(n)}U_a = 0, \quad n \geqslant 0. \tag{58}$$

To present a realization of the above structure, let us introduce

$$V_a = \sum_{i \geqslant 0} V_{a,i}\lambda^{-i-1}, \quad \frac{\partial V_{a,i}}{\partial \lambda} = 0, \tag{59}$$

and then (54) implies that

$$U_0 V_{a,0} - V_0 U_a = 0, \tag{60}$$

$$(V_{a,i})_x = U_0 V_{a,i+1} + U_1 V_{a,i} - V_{i+1}U_a, \quad i \geqslant 0, \tag{61}$$

where U_0 and U_1 are defined by (11), and V_i, by (16).

We assume that

$$\alpha\beta \neq 0, \quad \text{i.e., } \alpha \neq 0 \quad \text{and } \beta \neq 0, \tag{62}$$

in order to determine V_a. Then, U_0 is invertible, and so the matrix V_a in (59) is uniquely determined by (60) and (61). Define the additional Lax matrices as

$$V_a^{(n)} = (\lambda^n V_a)_+, \quad n \geqslant 0, \tag{63}$$

where the subscript $+$ denotes to take the polynomial part in λ. Then by (54), we have

$$(V_a^{(n)})_x = (\lambda^n U V_a)_+ - (\lambda^n V)_+ U_a = (\lambda^n U V_a)_+ - V^{(n)}U_a,$$

and further, we can compute that

$$\begin{aligned} -(V_a^{(n)})_x + UV_a^{(n)} - V^{(n)}U_a &= -(\lambda^n U V_a)_+ + UV_a^{(n)} = -U_0 V_a^{(n+1)} - U_1 V_a^{(n)} + (\lambda U_0 + U_1)V_a^{(n)} \\ &= -U_0 V_a^{(n+1)} + \lambda U_0 V_a^{(n)} \\ &= -U_0(V_{a,n} + \lambda V_a^{(n)}) + \lambda U_0 V_a^{(n)} = -U_0 V_{a,n}. \end{aligned}$$

It follows that the additional equations determined by (58) become

$$(U_a)_{t_n} = U_0 V_{a,n}, \quad n \geqslant 0, \tag{64}$$

and so the candidates of integrable couplings are given by

$$u_{t_n} = K_n(u), \quad (U_a)_{t_n} = U_0 V_{a,n}, \quad n \geqslant 0, \tag{65}$$

To get the concrete expression of (65), we now specify U_a and $V_{a,i}$ as follows:

$$U_a = \begin{pmatrix} v_1 & \cdots & v_l \\ w_1 & \cdots & w_l \end{pmatrix}, \quad V_{a,i} = \begin{pmatrix} e_1^{(i)} & \cdots & e_l^{(i)} \\ f_1^{(i)} & \cdots & f_l^{(i)} \end{pmatrix}, \quad i \geqslant 0, \tag{66}$$

where l is an arbitrary natural number, v_j and $e_j^{(i)}$ are scalars but w_j and $f_j^{(i)}$ are m-dimensional columns. Then, the recursion relation defined by (60) and (61) yields

$$\begin{pmatrix} e_j^{(0)} \\ f_j^{(0)} \end{pmatrix} = U_0^{-1} V_0 \begin{pmatrix} v_j \\ w_j \end{pmatrix} = \begin{pmatrix} v_j \\ w_j \end{pmatrix}, \quad 1 \leqslant j \leqslant l, \tag{67}$$

$$\begin{pmatrix} e_j^{(i+1)} \\ f_j^{(i+1)} \end{pmatrix} = U_0^{-1} \begin{pmatrix} e_j^{(i)} \\ f_j^{(i)} \end{pmatrix} + U_0^{-1} V_{i+1} \begin{pmatrix} v_j \\ w_j \end{pmatrix} - U_0^{-1} U_1 \begin{pmatrix} e_j^{(i)} \\ f_j^{(i)} \end{pmatrix}, \quad 1 \leqslant j \leqslant l, \quad i \geqslant 0, \tag{68}$$

and the additional equations determined by (64) become

$$\begin{pmatrix} v_1 & \cdots & v_l \\ w_1 & \cdots & w_l \end{pmatrix}_{t_n}, \quad U_0 V_{a,n} = \begin{pmatrix} \alpha e_1^{(n)} & \cdots & \alpha e_l^{(n)} \\ \beta f_1^{(n)} & \cdots & \beta f_l^{(n)} \end{pmatrix}, \quad n \geqslant 0. \tag{69}$$

Therefore, the enlarged hierarchy (65) of the vector AKNS soliton equations reads as

$$\overline{u_{t_n}} \equiv \begin{pmatrix} q^T \\ r \\ v_1 \\ w_1 \\ \vdots \\ v_l \\ w_l \end{pmatrix}_{t_n} = \overline{K_n} \equiv \begin{pmatrix} (\alpha - \beta) b^{(n+1)T} \\ (\beta - \alpha) c^{(n+1)} \\ \alpha e_1^{(n)} \\ \beta f_1^{(n)} \\ \vdots \\ \alpha e_l^{(n)} \\ \beta f_l^{(n)} \end{pmatrix}, \quad n \geqslant 0. \tag{70}$$

2. Recursion structure for the first enlarged hierarchy

Let us now derive a recursion structure for the first enlarged soliton hierarchy (70). From the above recursion relation (68) for $e_j^{(i)}$ and $f_j^{(i)}$, we have

$$\alpha e_j^{(i+1)} = (e_j^{(i)})_x - q f_j^{(i)} + (a^{(i+1)} v_j + b^{(i+1)} w_j), \quad 1 \leqslant j \leqslant l, \; i \geqslant 0, \tag{71a}$$

$$\beta f_j^{(i+1)} = (f_j^{(i)})_x - r e_j^{(i)} + (c^{(i+1)} v_j + d^{(i+1)} w_j), \quad 1 \leqslant j \leqslant l, \; i \geqslant 0. \tag{71b}$$

In particular, this gives rise to

$$e_j^{(1)} = \frac{1}{\alpha}(v_j)_x, \quad f_j^{(1)} = \frac{1}{\beta}(w_j)_x, \quad 1 \leqslant j \leqslant l,$$

$$e_j^{(2)} = \frac{1}{\alpha}\left[\frac{1}{\alpha}(v_j)_{xx} - \frac{1}{\beta} q (w_j)_x + \frac{1}{\beta - \alpha} q r v_j + \frac{1}{\alpha - \beta} q_x w_j\right], \quad 1 \leqslant j \leqslant l,$$

$$f_j^{(2)} = \frac{1}{\beta}\left[\frac{1}{\beta}(w_j)_{xx} - \frac{1}{\alpha} r (v_j)_x + \frac{1}{\beta - \alpha} r_x v_j + \frac{1}{\alpha - \beta} q r w_j\right], \quad 1 \leqslant j \leqslant l.$$

In order to get a recursion structure, we rewrite the equations (69) as

$$\begin{pmatrix} v_j \\ w_j \end{pmatrix}_{t_n} = \begin{pmatrix} \alpha e_j^{(n)} \\ \beta f_j^{(n)} \end{pmatrix} = \overline{\Phi}_j \begin{pmatrix} (\alpha-\beta)b^{(n)T} \\ (\beta-\alpha)c^{(n)} \end{pmatrix} + \overline{\Phi}_0 \begin{pmatrix} \alpha e_j^{(n-1)} \\ \beta f_j^{(n-1)} \end{pmatrix}, \quad 1 \leqslant j \leqslant l,\ n \geqslant 0. \tag{72}$$

Then based on (71) and (21), we find that the $(m+1)\times(m+1)$ matrix $\overline{\Phi}_0$ can be chosen as

$$\overline{\Phi}_0 = \overline{\Phi}_0(q,r) = \begin{pmatrix} \frac{1}{\alpha}\partial & -\frac{1}{\beta}q \\ -\frac{1}{\alpha}r & \frac{1}{\beta}\partial I_m \end{pmatrix}, \tag{73}$$

and further, the $(m+1)\times 2m$ matrix operators $\overline{\Phi}_j$ can be chosen as

$$\overline{\Phi}_j = \overline{\Phi}_j(q,r,v_j,w_j) = \frac{1}{\beta-\alpha}\begin{pmatrix} v_j\partial^{-1}L_{r^T} - L_{w_j^T} & v_j\partial^{-1}L_q \\ -R_{w_j}\partial^{-1}L_T T & v_j I_m - R_{w_j}\partial^{-1}R_q \end{pmatrix}, \quad 1 \leqslant j \leqslant l, \tag{74}$$

where $(R_A)B=BA$, $(L_A)B=AB$, and $TB=B^T$ for two matrices A and B [note that $L_{r^T}A=r^TA$ but $(L_rT)A=rA^T$]. Therefore, the enlarged vector AKNS hierarchy (70) possesses the following recursion structure:

$$\begin{pmatrix} q^T \\ r \\ v_1 \\ w_1 \\ \vdots \\ v_l \\ w_l \end{pmatrix}_{t_n} = \overline{\Phi}\begin{pmatrix} (\alpha-\beta)b^{(n)T} \\ (\beta-\alpha)c^{(n)} \\ \alpha e_1^{(n-1)} \\ \beta f_1^{(n-1)} \\ \vdots \\ \alpha e_l^{(n-1)} \\ \beta f_l^{(n-1)} \end{pmatrix} = \overline{\Phi}^n \begin{pmatrix} (\alpha-\beta)b^{(1)T} \\ (\beta-\alpha)c^{(1)} \\ \alpha e_1^{(0)} \\ \beta f_1^{(0)} \\ \vdots \\ \alpha e_l^{(0)} \\ \beta f_l^{(0)} \end{pmatrix} = \overline{\Phi}^n \begin{pmatrix} (\alpha-\beta)q^T \\ (\beta-\alpha)r \\ \alpha v_1 \\ \beta w_1 \\ \vdots \\ \alpha v_l \\ \beta w_l \end{pmatrix}, \quad n \geqslant 0, \tag{75}$$

if we define the recursion operator $\overline{\Phi}$ as

$$\overline{\Phi} = \begin{pmatrix} \Phi & & & & 0 \\ \overline{\Phi}_1 & \overline{\Phi}_0 & & & \\ \overline{\Phi}_2 & 0 & \overline{\Phi}_0 & & \\ \vdots & \ddots & \ddots & \ddots & \\ \overline{\Phi}_l & 0 & \cdots & 0 & \overline{\Phi}_0 \end{pmatrix}, \tag{76}$$

where $\Phi=\Psi^\dagger$ is the hereditary recursion operator of (28) defined by (36). We point out that there may exist other choices for $\overline{\Phi}_j$ and $\overline{\Phi}_0$ in the recursion structure (72).

The triangular systems in (70) are commutative. This can be shown, for example, by using the uniqueness property of the spectral problem $\phi_x=U\phi$, that is, if a Lax matrix V has zero initial value $V|_{u=0}=0$, i.e., if $U'[K]-V_x+[U,V]=0$ and $V|_{u=0}=0$, then the Lax matrix $V=0$.[17] Keeping the equation (58) in mind, it is easy to verify that if the original spectral problem $\phi_x=U\phi$ possesses the uniqueness property, then so does the enlarged spectral problem (51). In this way, we can prove that the spectral problem (51) has the uniqueness property. On the other hand, the Lax matrices

$$\overline{V}^{k,l}(\overline{u}) \equiv (\overline{V}^{(k)})'(\overline{u})[\overline{K}_l] - (\overline{V}^{(l)})'(\overline{u})[\overline{K}_k] + [\overline{V}^{(k)}(\overline{u}), \overline{V}^{(l)}(\overline{u})], \quad k,l \geqslant 0, \tag{77}$$

have zero initial value $\overline{V}^{k,l}(\overline{u})|_{\overline{u}=0}=0$ (see Refs. 17 and 20 for more discussion). Therefore, the new enlarged soliton hierarchy defined by (70) or (75) is commutative, and so it is a common hierarchy of commuting integrable couplings for all the vector AKNS soliton equations in the

hierarchy (28). The integrability here denotes the existence of infinitely many symmetries.[21] Its first nonlinear system reads as

$$q_{t_2} = \frac{1}{\alpha - \beta}(q_{xx} - 2qrq), \tag{78a}$$

$$r_{t_2} = \frac{1}{\beta - \alpha}(r_{xx} - 2rqr), \tag{78b}$$

$$(v_j)_{t_2} = \frac{1}{\alpha}(v_j)_{xx} - \frac{1}{\beta}q(w_j)_x + \frac{1}{\beta - \alpha}qrv_j + \frac{1}{\alpha - \beta}q_x w_j, \quad 1 \leqslant j \leqslant l, \tag{78c}$$

$$(w_j)_{t_2} = \frac{1}{\beta}(w_j)_{xx} - \frac{1}{\alpha}r(v_j)_x + \frac{1}{\beta - \alpha}r_x v_j + \frac{1}{\alpha - \beta}qrw_j, \quad 1 \leqslant j \leqslant l, \tag{78d}$$

where q^T, r, w_j are m-dimensional columns and v_j are scalar variables.

C. Second class of integrable couplings

1. Second enlarged soliton hierarchy

Let us consider the second specific case of the enlarged spectral problem (37):

$$\tilde{\phi}_x = \tilde{U}\tilde{\phi} = \tilde{U}(\tilde{u}, \lambda)\tilde{\phi}, \quad \tilde{\phi} = (\phi^T, \phi_b^T)^T, \tag{79}$$

with the enlarged spectral square matrix

$$\tilde{U} = \tilde{U}(\tilde{u}) = \begin{pmatrix} U & 0 \\ U_b & 0 \end{pmatrix} = \begin{pmatrix} U(u) & 0 \\ U_b & 0 \end{pmatrix}, \quad \frac{\partial U_b}{\partial \lambda} = 0. \tag{80}$$

It is equivalent to

$$\phi_x = U\phi, \quad (\phi_b)_x = U_b\phi.$$

Choose a solution for $\tilde{V}=[\tilde{U}, \tilde{V}]$ as

$$\tilde{V} = \tilde{V}(\tilde{u}) = \begin{pmatrix} V & 0 \\ V_b & 0 \end{pmatrix} = \begin{pmatrix} V(u) & 0 \\ V_b(\tilde{u}) & 0 \end{pmatrix}, \tag{81}$$

and we are then led to

$$(V_b)_x = U_b V - V_b U, \tag{82}$$

besides $V_x=[U, V]$. The enlarged temporal spectral matrices read as

$$\tilde{V}^{(n)} = \begin{pmatrix} V^{(n)} & 0 \\ V_b^{(n)} & 0 \end{pmatrix} = \begin{pmatrix} V^{(n)}(u) & 0 \\ V_b^{(n)}(\tilde{u}) & 0 \end{pmatrix}, \quad n \geqslant 0, \tag{83}$$

and so the enlarged temporal spectral problems

$$\tilde{\phi}_{t_n} = \tilde{V}^{(n)}\tilde{\phi}, \quad \tilde{\phi} = (\phi^T, \phi_b^T)^T, \quad n \geqslant 0, \tag{84}$$

are equivalent to

$$\phi_{t_n} = V^{(n)}\phi, \quad (\phi_b)_{t_n} = V_b^{(n)}\phi, \quad n \geqslant 0.$$

Now the enlarged zero curvature equations

$$\tilde{U}_{t_n} - \tilde{V}_x^{(n)} + [\tilde{U}, \tilde{V}^{(n)}] = 0, \quad n \geqslant 0,$$

equivalently engender the triangular systems

$$U_{t_n} - V_x^{(n)} + [U, V^{(n)}] = 0, \quad n \geqslant 0, \tag{85}$$

$$(U_b)_{t_n} - (V_b^{(n)})_x + U_b V^{(n)} - V_b^{(n)} U = 0, \quad n \geqslant 0. \tag{86}$$

To present the second enlarged soliton hierarchy, let us similarly introduce

$$V_b = \sum_{i \geqslant 0} V_{b,i} \lambda^{-i-1}, \quad \frac{\partial V_{b,i}}{\partial \lambda} = 0, \tag{87}$$

and then (82) leads to

$$V_{b,0} U_0 - U_b V_0 = 0, \tag{88}$$

$$(V_{b,i})_x = U_b V_{i+1} - V_{b,i+1} U_0 - V_{b,i} U_1, \quad i \geqslant 0, \tag{89}$$

where U_0 and U_1 are defined by (11), and V_i, by (16).

We also assume that the conditions in (62) are satisfied, to determine V_b uniquely. Then, U_0 is invertible, and so the matrix V_b in (87) is uniquely determined by (88) and (89), indeed. Define the additional Lax matrices as

$$V_b^{(n)} = (\lambda^n V_b)_+, \quad n \geqslant 0, \tag{90}$$

where the subscript + denotes to take the polynomial part in λ. Then, using (82), we have

$$(V_b^{(n)})_x = (\lambda^n U_b V)_+ - (\lambda^n V_b U)_+ = U_b V^{(n)} - (\lambda^n V_b U)_+,$$

and we can further compute that

$$\begin{aligned} -(V_b^{(n)})_x + U_b V^{(n)} - V_b^{(n)} U &= (\lambda^n V_b U)_+ - V_b^{(n)} U \\ &= V_b^{(n+1)} U_0 + V_b^{(n)} U_1 - V_b^{(n)} (\lambda U_0 + U_1) \\ &= V_b^{(n+1)} U_0 - \lambda V_b^{(n)} U_0 \\ &= (V_{b,n} + \lambda V_b^{(n)}) U_0 - \lambda V_b^{(n)} U_0 \\ &= V_{b,n} U_0. \end{aligned}$$

It now follows that the additional equations determined by (86) become

$$(U_b)_{t_n} = -V_{b,n} U_0, \quad n \geqslant 0, \tag{91}$$

and thus, the candidates of integrable couplings are determined by

$$u_{t_n} = K_n(u), \quad (U_b)_{t_n} = -V_{b,n} U_0, \quad n \geqslant 0, \tag{92}$$

Let us now proceed to present the concrete expression of (92). Similarly, we specify U_b and $V_{b,i}$ as follows:

$$U_b = \begin{pmatrix} y_1 & z_1 \\ \vdots & \vdots \\ y_l & z_l \end{pmatrix}, \quad V_{b,i} = \begin{pmatrix} g_1^{(i)} & h_1^{(i)} \\ \vdots & \vdots \\ g_l^{(i)} & h_l^{(i)} \end{pmatrix}, \quad i \geqslant 0, \tag{93}$$

where l is an arbitrary natural number, y_j and $g_j^{(i)}$, $1 \leqslant j \leqslant l$, are scalars but z_j and $h_j^{(i)}$, $1 \leqslant j \leqslant l$, are m-dimensional rows. Then, the recursion relation defined by (88) and (89) gives rise to

$$(g_j^{(0)} h_j^{(0)}) = (y_j z_j) V_0 U_0^{-1} = (y_j z_j), \quad 1 \leqslant j \leqslant l, \tag{94}$$

$$(g_j^{(i+1)} h_j^{(i+1)}) = -(g_j^{(i)} h_j^{(i)})_x U_0^{-1} + (y_j z_j) V_{i+1} U_0^{-1} - (g_j^{(i)} h_j^{(i)}) U_1 U_0^{-1}, \quad 1 \leqslant j \leqslant l, \quad i \geqslant 0, \tag{95}$$

and the additional equations determined by (91) become

$$\begin{pmatrix} y_1 & z_1 \\ \vdots & \vdots \\ y_l & z_l \end{pmatrix}_{t_n} = -V_{b,n} U_0 = -\begin{pmatrix} \alpha g_1^{(n)} & \beta h_1^{(n)} \\ \vdots & \vdots \\ \alpha g_l^{(n)} & \beta h_l^{(n)} \end{pmatrix}, \quad n \geqslant 0. \tag{96}$$

Therefore, the enlarged hierarchy (92) of the vector AKNS soliton equations reads as

$$\tilde{u}_{t_n} \equiv \begin{pmatrix} q^T \\ r \\ y_1 \\ z_1^T \\ \vdots \\ y_l \\ z_l^T \end{pmatrix}_{t_n} = \tilde{K}_n \equiv \begin{pmatrix} (\alpha - \beta) b^{(n+1)T} \\ (\beta - \alpha) c^{(n+1)} \\ -\alpha g_1^{(n)} \\ -\beta h_1^{(n)T} \\ \vdots \\ -\alpha g_l^{(n)} \\ -\beta h_l^{(n)T} \end{pmatrix}, \quad n \geqslant 0. \tag{97}$$

2. Recursion structure for the second enlarged hierarchy

Let us now derive a recursion structure for the second enlarged soliton hierarchy (97). From the above recursion relation (95) for $g_j^{(i)}$ and $h_j^{(i)}$, we have

$$\alpha g_j^{(i+1)} = -(g_j^{(i)})_x - h_j^{(i)} r + (y_j a^{(i+1)} + z_j b^{(i+1)}), \quad i \geqslant 0, \tag{98a}$$

$$\beta h_j^{(i+1)} = -(h_j^{(i)})_x - g_j^{(i)} q + (y_j b^{(i+1)} + z_j d^{(i+1)}), \quad i \geqslant 0. \tag{98b}$$

In particular, this generates

$$g_j^{(1)} = -\frac{1}{\alpha}(y_j)_x, \quad h_j^{(1)} = -\frac{1}{\beta}(z_j)_x, \quad 1 \leqslant j \leqslant l,$$

$$g_j^{(2)} = \frac{1}{\alpha}\left[\frac{1}{\alpha}(y_j)_{xx} + \frac{1}{\beta}(z_j)_x r + \frac{1}{\beta - \alpha} y_j q r + \frac{1}{\beta - \alpha} z_j r_x\right], \quad 1 \leqslant j \leqslant l,$$

$$h_j^{(2)} = \frac{1}{\beta}\left[\frac{1}{\beta}(z_j)_{xx} + \frac{1}{\alpha}(y_j)_x q + \frac{1}{\alpha - \beta} y_j q_x + \frac{1}{\alpha - \beta} z_j r q\right], \quad 1 \leqslant j \leqslant l.$$

To obtain a recursion structure, we rewrite the equations (96) as

$$\begin{pmatrix} y_j \\ z_j^T \end{pmatrix}_{t_n} = \begin{pmatrix} -\alpha g_j^{(n)} \\ -\beta h_j^{(n)T} \end{pmatrix} = \tilde{\Phi}_j \begin{pmatrix} (\alpha-\beta) b^{(n)T} \\ (\beta-\alpha) c^{(n)} \end{pmatrix} + \tilde{\Phi}_0 \begin{pmatrix} -\alpha g_j^{(n-1)} \\ -\beta h_j^{(n-1)T} \end{pmatrix}, \quad 1 \leqslant j \leqslant l, \quad n \geqslant 0. \tag{99}$$

Then it follows from (98) and (21) that the $(m+1)\times(m+1)$ matrix $\tilde{\Phi}_0$ can be taken as

$$\tilde{\Phi}_0 = \tilde{\Phi}_0(q,r) = \begin{pmatrix} -\frac{1}{\alpha}\partial & -\frac{1}{\beta} r^T \\ -\frac{1}{\alpha} q^T & -\frac{1}{\beta}\partial I_m \end{pmatrix}, \tag{100}$$

and further, the $(m+1)\times 2m$ matrix operators $\tilde{\Phi}_j$ can be taken as

$$\tilde{\Phi}_j = \tilde{\Phi}_j(q,r,y_j,z_j) = \frac{1}{\beta-\alpha} \begin{pmatrix} -y_j \partial^{-1} L_{r^T} & -y_j \partial^{-1} L_q - L_{z_j} \\ y_j I_m + R_{z_j^T} \partial^{-1} R_{r^T} & R_{z_j^T} \partial^{-1} L_{q^T} T \end{pmatrix}, \quad 1 \leqslant j \leqslant l, \tag{101}$$

where $(R_A)B = BA$, $(L_A)B = AB$, and $TB = B^T$ for two matrices A and B. Therefore, the enlarged vector AKNS hierarchy (97) possesses the following recursion structure:

$$\begin{pmatrix} q^T \\ r \\ y_1 \\ z_1^T \\ \vdots \\ y_l \\ z_l^T \end{pmatrix}_{t_n} = \tilde{\Phi} \begin{pmatrix} (\alpha-\beta) b^{(n)T} \\ (\beta-\alpha) c^{(n)} \\ -\alpha g_1^{(n-1)} \\ -\beta h_1^{(n-1)} \\ \vdots \\ -\alpha g_l^{(n-1)} \\ -\beta h_l^{(n-1)} \end{pmatrix} = \tilde{\Phi}^n \begin{pmatrix} (\alpha-\beta) b^{(1)T} \\ (\beta-\alpha) c^{(1)} \\ -\alpha g_1^{(0)} \\ -\beta h_1^{(0)} \\ \vdots \\ -\alpha g_1^{(0)} \\ -\beta h_1^{(0)} \end{pmatrix} = \tilde{\Phi}^n \begin{pmatrix} (\alpha-\beta) q^T \\ (\beta-\alpha) r \\ -\alpha y_1 \\ -\beta z_1 \\ \vdots \\ -\alpha y_l \\ -\beta z_l^T \end{pmatrix}, \quad n \geqslant 0, \tag{102}$$

once we define the recursion operator $\tilde{\Phi}$ as

$$\tilde{\Phi} = \begin{pmatrix} \Phi & & & & & 0 \\ \tilde{\Phi}_1 & \tilde{\Phi}_0 & & & & \\ \tilde{\Phi}_2 & 0 & \tilde{\Phi}_0 & & & \\ \vdots & \ddots & \ddots & \ddots & & \\ \tilde{\Phi}_l & 0 & \cdots & \cdots & 0 & \tilde{\Phi}_0 \end{pmatrix}, \tag{103}$$

where $\Phi = \Psi^{\dagger}$ is the hereditary recursion operator defined by (36). Note that there may also exist other choices for $\tilde{\Phi}_j$ and $\tilde{\Phi}_0$ in the recursion structure (99).

The triangular systems in (97) are commutative, which can be shown in a similar manner to the proof for the first class. The enlarged spectral problem (79) has the uniqueness property, indeed, which can also be directly verified. Moreover, the Lax matrices

$$\tilde{V}^{k,l}(\tilde{u}) \equiv (\tilde{V}^{(k)})'(\tilde{u})[\tilde{K}_l] - (\tilde{V}^{(l)})'(\tilde{u})[\tilde{K}_k] + [\tilde{V}^{(k)}(\tilde{u}), \tilde{V}^{(l)}(\tilde{u})], \quad k,l \geqslant 0, \tag{104}$$

have zero initial value $\tilde{V}^{k,l}(\tilde{u})|_{\tilde{u}=0} = 0$. Therefore, by the so-called uniqueness property,[17] the new enlarged soliton hierarchy defined by (97) or (102) is commutative, and so it is a common hierarchy of commuting integrable couplings for all the vector AKNS soliton equations in (28). The first nonlinear system in the hierarchy reads as

$$q_{t_2} = \frac{1}{\alpha-\beta}(q_{xx} - 2qrq), \tag{105a}$$

$$r_{t_2} = \frac{1}{\beta - \alpha}(r_{xx} - 2rqr), \tag{105b}$$

$$(y_j)_{t_2} = -\left[\frac{1}{\alpha}(y_j)_{xx} + \frac{1}{\beta}(z_j)_x r + \frac{1}{\beta - \alpha} y_j qr + \frac{1}{\beta - \alpha} y_j r_x\right], \quad 1 \leqslant j \leqslant l, \tag{105c}$$

$$(z_j)_{t_2} = -\left[\frac{1}{\beta}(z_j)_{xx} + \frac{1}{\alpha}(y_j)_x q + \frac{1}{\alpha - \beta} y_j q_x + \frac{1}{\alpha - \beta} z_j rq\right], \quad 1 \leqslant j \leqslant l, \tag{105d}$$

where q, r^T, z_j are m-dimensional rows and y_j are scalar variables.

D. Bäcklund transformation and special solutions

It is known that the adjoint zero curvature equation

$$(-U^T)_t - (-V^T)_x + [-U^T, -V^T] = 0$$

is equivalent to the zero curvature equation

$$U_t - V_x + [U, V] = 0.$$

Therefore, they lead to the same soliton equation. Using this fact, our two classes of enlarged specific spectral problems of the equal sizes can be linked to each other. More specifically, we can take

$$\overline{U} = -(\widetilde{U})^T, \quad \overline{V} = -(\widetilde{V})^T, \quad \overline{V}^{(n)} = -(\widetilde{V}^{(n)})^T, \quad n \geqslant 0,$$

to transform one to another of the equal sizes, and thus the two classes of integrable couplings can be transformed into each other. The resulting Bäcklund transformation from $\overline{U} = -(\widetilde{U})^T$ reads as

$$q \to -r^T, \quad r \to -q^T, \quad v_j \to -y_j, \quad w_j \to -z_j^T, \quad \alpha \to -\alpha, \quad \beta \to -\beta.$$

Under this transformation, the first hierarchy of integrable couplings (70) becomes the second hierarchy (97) of integrable couplings. In particular, the first nonlinear integrable coupling (78) in the first enlarged soliton hierarchy becomes the first nonlinear integrable coupling (105) in the second enlarged soliton hierarchy. Therefore, the above Bäcklund transformation links the two classes of integrable couplings together, and also provides another way to generate the second class of integrable couplings.

On the other hand, we point out that some special classes of exact solutions can be explicitly presented for the resulting integrable coupling (78). First, let us choose

$$q = 0, \quad r_{t_2} = \frac{1}{\beta - \alpha} r_{xx}, \quad (v_j)_{t_2} = \frac{1}{\alpha}(v_j)_{xx}, \quad 1 \leqslant j \leqslant l,$$

and then solving the nonhomogeneous heat equations for w_j,

$$(w_j)_{t_2} = \frac{1}{\beta}(w_j)_{xx} - \frac{1}{\alpha} r (v_j)_x + \frac{1}{\beta - \alpha} r_x v_j, \quad 1 \leqslant j \leqslant l,$$

gives a class of solutions to the integrable coupling (78). Second, let us choose

$$q_{t_2} = \frac{1}{\alpha - \beta} q_{xx}, \quad r = 0, \quad (w_j)_{t_2} = \frac{1}{\beta}(w_j)_{xx}, \quad 1 \leqslant j \leqslant l,$$

and then solving the nonhomogeneous heat equations for v_j,

$$(v_j)_{t_2} = \frac{1}{\alpha}(v_j)_{xx} - \frac{1}{\beta}q(w_j)_x + \frac{1}{\alpha-\beta}q_x w_j, \quad 1 \leqslant j \leqslant l,$$

gives another class of solutions to the integrable coupling (78). In particular, when $m=l=1$, we can have the following two concrete solutions:

$$q = 0, \quad r = \frac{c_1}{\sqrt{t_2-\eta_1}} \exp\left(\frac{(\alpha-\beta)(x-\xi_1)^2}{4(t_2-\eta_1)}\right),$$

$$v_1 = \frac{c_2}{\sqrt{t_2-\eta_1}} \exp\left(-\frac{\alpha(x-\xi_1)^2}{4(t_2-\eta_1)}\right), \quad w_1 = \sum_{i=1}^{k} \frac{d_i}{\sqrt{t_2-\eta_i}} \exp\left(-\frac{\beta(x-\xi_i)^2}{4(t_2-\eta_i)}\right) + d_{k+1},$$

and

$$q = \frac{c_1}{\sqrt{t_2-\eta_1}} \exp\left(\frac{(\beta-\alpha)(x-\xi_1)^2}{4(t_2-\eta_1)}\right), \quad r = 0,$$

$$v_1 = \sum_{i=1}^{k} \frac{d_2}{\sqrt{t_2-\eta_i}} \exp\left(-\frac{\alpha(x-\xi_i)^2}{4(t_2-\eta_i)}\right) + d_{k+1}, \quad w_1 = \frac{c_i}{\sqrt{t_2-\eta_1}} \exp\left(-\frac{\beta(x-\xi_1)^2}{4(t_2-\eta_1)}\right),$$

where k is an arbitrary natural number, and η_i, ξ_i, c_i, and d_i are arbitrary constants. The solution analysis made here also implies that coupled systems of differential equations can possess diverse solutions,[22] like integrable equations in higher dimensions.[23] Actually, even in the case of 1+1 dimensions, a new kind of exact solutions, so-called complexitons, were recently shown to exist for the Korteweg–de Vries equation[24] and the Toda lattice equation.[25]

IV. CONCLUDING REMARKS

Two specific classes of multicomponent integrable couplings have been presented for the physically important vector AKNS soliton hierarchy. The basic idea in our construction is to apply an idea of enlarging the associated spectral problems or the associated loop Lie algebras underlying the spectral problems. The enlarged vector AKNS soliton hierarchies also possess zero curvature representations and recursion structures, which guarantee the existence of infinitely many symmetries of the enlarged soliton hierarchies. Under the reduction of $\alpha=-1$, $\beta=1$, and $m=l=1$, the first class of integrable couplings boil down to the integrable couplings of the scalar AKNS soliton equations presented in Ref. 19.

We point out that there is another successful choice of enlarged spectral matrices

$$\overline{U} = \hat{U}(u,v) \equiv \begin{pmatrix} U(u) & 0 \\ U'(u)[v] & U(u) \end{pmatrix} \quad \text{or} \begin{pmatrix} U(u) & U'(u)[v] \\ 0 & U(u) \end{pmatrix},$$

which correspond to the spectral matrices generated by perturbation.[3] The additional potential v in the above enlarged spectral matrix $\hat{U}(u,v)$ must have the same number of dependent variables as u. But the enlarged spectral matrix $\hat{U}(u,v)$ has a symmetric structure, which ensures that there exist Hamiltonian structures for the enlarged soliton equations.[3] On the other hand, we can relax the conditions in (49), i.e., let the additional matrices U_a and U_b in (38) depend on the spectral parameter λ. For example, we can choose

$$U_a = \sum_{i=1}^{k} U_{a,i}\lambda^{i-1} = \sum_{i=1}^{k} \begin{pmatrix} v_{1,i} & \cdots & v_{l,i} \\ w_{1,i} & \cdots & w_{l,i} \end{pmatrix} \lambda^{i-1}, \quad k,l \geqslant 1,$$

$$U_b = \sum_{i=1}^{k} U_{b,i}\lambda^{i-1} = \sum_{i=1}^{k} \begin{pmatrix} y_{1,i} & z_{1,i} \\ \vdots & \vdots \\ y_{l,i} & z_{l,i} \end{pmatrix} \lambda^{i-1}, \quad k,l \geqslant 1.$$

Then, much more diverse integrable couplings can be expected to obtain.

We would also like to emphasize that the resulting integrable couplings by enlarging spectral problems are different from the ones obtained by the method of perturbations. Actually, the integrable couplings (78) and (105), for example, cannot be obtained through using perturbations at all. On the other hand, it should be very important to investigate the Painlevé property and bilinear forms of the enlarged soliton hierarchies (70) and (97), especially the integrable couplings (78) and (105), from the solution perspective. The systems (78) and (105) reduce to two systems of variable coefficient partial differential equations, if q and r are given.

We finally remark that the integrability property usually requires the existence of infinitely many conservation laws.[26] The perturbation procedure of enlarging spectral problems guarantees Hamiltonian structures and thus infinitely many conservation laws.[3,6] It is an interesting question whether the enlarged vector AKNS soliton hierarchies (70) and (97) possess infinitely many conservation laws of the enlarged type, i.e., involving the additional variables [v_j and w_j in the case of (70), and y_j and z_j in the case of (97)] and their derivatives with respect to x.

Validity and failure of some entropy inequalities for CAR systems

Hajime Moriya[a)]

(Received 17 May 2004; accepted 9 November 2004; published online 11 February 2005)

Basic properties of von Neumann entropy such as the triangle inequality and what we call MONO–SSA are studied for CAR systems. We show that both inequalities hold for every even state by using symmetric purification which is applicable to such a state. We construct a certain class of noneven states giving examples of the nonvalidity of those inequalities. © *2005 American Institute of Physics.*

I. INTRODUCTION

Let $\mathcal{H}$ be a Hilbert space and D be a density matrix on $\mathcal{H}$, i.e., a positive trace class operator on $\mathcal{H}$ whose trace is unity. The von Neumann entropy is given by

$$-\mathbf{Tr}(D\log D), \tag{1}$$

where **Tr** denotes the trace which takes the value 1 on each minimal projection. Let ϱ be a normal state of $\mathcal{B}(\mathcal{H})$, the set of all bounded linear operators on $\mathcal{H}$. Then ϱ has its density matrix D_ϱ, and its von Neumann entropy $S(\varrho)$ is given by (1) with $D=D_\varrho$.

It has been known that von Neumann entropy is useful for description and characterization of state correlation for composite systems. Among others, the following inequality called strong subadditivity (SSA) is remarkable:

$$S(\varphi_{I\cup J})-S(\varphi_I)-S(\varphi_J)+S(\varphi_{I\cap J})\leqslant 0, \tag{2}$$

where I, J, $I\cap J$, and $I\cup J$ denote the indexes of subsystems and φ_I denotes the restriction of a state φ to the subsystem indexed by I, and so on. Such entropy inequalities have been studied for quantum systems, see e.g., Refs. 4,5,9,11,13,15, and also their references. However, the composite systems considered there were mostly tensor product of matrix algebras to which we refer as the tensor product systems.

We investigate some well-known entropy inequalities, the triangle inequality and MONO–SSA (which will be specified soon later), for CAR systems. This study is relevant to our previous works on state correlations such as quantum-entanglement[7] and separability[8] for CAR systems. In a certain sense, the conditions of validity and failure of such entropy inequalities which we are going to establish will explain the similarities and differences in the possible forms of state correlations between CAR and tensor product systems.

Let $\mathcal{L}$ be an arbitrary discrete set. The canonical anticommutation relations (CAR) are

$$\{a_i^*,a_j\}=\delta_{i,j}\mathbf{1},$$

a)Electronic mail: moriya@ihes.fr

$$\{a_i^*, a_j^*\} = \{a_i, a_j\} = 0,$$

where $i, j \in \mathcal{L}$, and $\{A,B\}=AB+BA$ (anticommutator). For each subset I of $\mathcal{L}$, $\mathcal{A}(I)$ denotes the subsystem on I given as the $\mathbf{C}^*$-algebra generated by all a_i^* and a_i with $i \in I$. For $I \subset J$, $\mathcal{A}(I)$ is naturally imbedded in $\mathcal{A}(J)$ as its subalgebra.

We have already shown that SSA (2) holds for the CAR systems. For the convenience, we sketch its proof given in Ref. 6 and Theorem 10.1 of Ref. 2 First we check the commuting square property for a CAR system as follows:

$$\begin{array}{ccc} \mathcal{A}(I \cup J) & \xrightarrow{E_1} & \mathcal{A}(I) \\ E_J \downarrow & & \downarrow E_{I\cap J} \\ \mathcal{A}(J) & \xrightarrow[E_{I\cap J}]{} & \mathcal{A}(I \cap J) \end{array},$$

where E denotes the conditional expectation with respect to the tracial state onto the subsystem with a specified index. From this property SSA follows for every state (without any assumption on the state, like its evenness) by a well-known proof method using the monotonicity of relative entropy under the action of conditional expectations.

We move to entropy inequalities for which CAR makes a difference. The following is usually referred to as the triangle inequality:

$$|S(\varphi_I) - S(\varphi_J)| \leqslant S(\varphi_{I\cup J}), \tag{3}$$

where I and J are disjoint. While this is satisfied for the tensor product systems,[1] it is not valid in general for the CAR systems; there is a counter example.[7]

We next introduce our main target,

$$S(\varphi_I) + S(\varphi_J) \leqslant S(\varphi_{K\cup I}) + S(\varphi_{K\cup J}), \tag{4}$$

where I, J, and K are disjoint. We may call (4) "MONO–SSA," because it is equivalent to SSA (2) for the tensor product systems at least, and it obviously implies the monotonicity of the following function:

$$K \mapsto S(\varphi_{K\cup I}) + S(\varphi_{K\cup J}),$$

with respect to the inclusion of the index K. Our question is whether MONO–SSA holds for the CAR systems, if not, under what condition it is satisfied.

The MONO–SSA for the tensor product systems is shown by what is called purification implying the equivalence of MONO–SSA and SSA for those systems (see 3.3 of Ref. 11). We note that the purification is a sort of state extension, and is not automatic for the CAR systems. We shall review the basic concept of state extension.

In the description of a quantum composite system, the total system is given by a $\mathbf{C}^*$-algebra $\mathcal{A}$, and its subsystems are described by $\mathbf{C}^*$-subalgebras $\mathcal{A}_i$ of $\mathcal{A}$ indexed by $i=1,2,\ldots$. Let φ be a state of $\mathcal{A}$. We denote its restrictions to $\mathcal{A}_i$ by φ_i. Surely φ_i is a state of $\mathcal{A}_i$. Conversely, suppose that a set of states φ_i of $\mathcal{A}_i$, $i=1,2,\ldots$, are given. Then a state φ of $\mathcal{A}$ is called an extension of $\{\varphi_i\}$ if its restriction to each $\mathcal{A}_i$ coincides with φ_i.

For tensor product systems, there always exists a state extension for any given prepared states $\{\varphi_i\}$ on disjoint regions, at least their product state extension $\varphi=\varphi_1 \otimes \cdots \otimes \varphi_i \otimes \cdots$, and generically other extensions. On the contrary, it is not always the case for CAR systems. When two (or more than two) prepared states on disjoint regions are not even, there may be no state extension. We have shown that if all of them are noneven pure states, then there exists no state extension.[7,3]

We explain the above-mentioned purification in terms of state extension. We are given a state ϱ_1 of $\mathcal{A}(I)$. We then prepare some state ϱ_2 on some $\mathcal{A}(J)$ with $J \cap I = \varnothing$ such that it has the same nonzero eigenvalues and their multiplicities as ϱ_1 for their density matrices. We want to construct their pure state extension to $\mathcal{A}(I \cup J)$. We use the term "symmetric purification" to refer to this

TABLE I. Truth and the falsity of von Neumann entropy inequalities.

Property	Tensor-product systems	CAR systems
SSA	○	○
Triangle	○	× in general, but ○ for every even state
MONO–SSA	○	× in general, but ○ for every even state

procedure where the "symmetric" may indicate the above specified property of ϱ_2. For the tensor product systems, symmetric purification exists for every ϱ_1. On the contrary for the CAR systems, though we can easily make a pure state extension of ϱ_1, its pair ϱ_2 cannot always be chosen among those states which have the same nonzero eigenvalues and their multiplicities as ϱ_1. In the above and what follows, we shall identify states with their density matrices when there is no fear of confusion.

We will show that MONO–SSA is not satisfied in general in Sec. III. However it is shown to hold for every even state in Sec. II. Table I above shows the truth (○) and the falsity (×) of the entropy inequalities.

We fix our notation. The even–odd grading Θ is determined by

$$\Theta(a_i^*) = -a_i^*, \quad \Theta(a_i) = -a_i. \tag{5}$$

The even and odd parts of $\mathcal{A}(I)$ are given by

$$\mathcal{A}(I)_\pm \equiv \{A \in \mathcal{A}(I) | \Theta(A) = \pm A\}.$$

For an element $A \in \mathcal{A}(I)$ we have the decomposition

$$A = A_+ + A_-, \quad A_\pm \equiv \tfrac{1}{2}(A \pm \Theta(A)) \in \mathcal{A}(I)_\pm.$$

For a finite subset I, define

$$v_I \equiv \prod_{i \in I} v_i, \quad v_i \equiv a_i^* a_i - a_i a_i^*. \tag{6}$$

By a simple computation, v_I is a self-adjoint unitary operator in $\mathcal{A}(I)_+$ implementing Θ, namely

$$\mathrm{Ad}(v_I)(A) = \Theta(A), \quad A \in \mathcal{A}(I). \tag{7}$$

For a finite subset I, every even pure state of $\mathcal{A}(I)$ is given by an eigenvector of v_I as its vector state.

The following is a simple consequence of the CAR given, e.g., in Sec. 4.5 of Ref. 2.

Lemma 1: *Let I be a finite subset and J be a (finite or infinite) subset disjoint with J. Let $\mathcal{A}(I'|I \cup J) \equiv \mathcal{A}(I)' \cap \mathcal{A}(I \cup J)$ and $\mathcal{A}(I'|J) \equiv \mathcal{A}(I)' \cap \mathcal{A}(J)$, the commutant of $\mathcal{A}(I)$ in $\mathcal{A}(I \cup J)$ and that in $\mathcal{A}(J)$, respectively. Then*

$$\mathcal{A}(I'|I \cup J) = \mathcal{A}(J)_+ + v_I \mathcal{A}(J)_-, \tag{8}$$

$$\mathcal{A}(I'|J) = \mathcal{A}(J)_+. \tag{9}$$

In this note we restrict our discussion to finite-dimensional systems so as to exclude from the outset the cases where our statements themselves on von Neumann entropy do not make sense; for infinite-dimensional systems a density matrix does not exist in general for a given state. (However in the proof of Proposition 8 we shall mention possible infinite-dimensional extensions of some results.)

II. SYMMETRIC PURIFICATION FOR EVEN STATES

Symmetric purification is a useful mathematical technique having a lot of applications. For example, we can derive MONO–SSA from SSA for the tensor product systems by using it.

We now discuss symmetric purification for the CAR systems. We shall show its existence for even states.

Lemma 2: *Let I and J be mutually disjoint finite subsets. Let ϱ be an even pure state of $\mathcal{A}(I\cup J)$, and let ϱ_1 and ϱ_2 be its restrictions to $\mathcal{A}(I)$ and $\mathcal{A}(J)$. Then the density matrix of ϱ_1 has the same nonzero eigenvalues and their multiplicities as those of ϱ_2. In particular, $S(\varrho_1)=S(\varrho_2)$.*

Proof: We have $\mathcal{A}(I\cup J)=\mathcal{A}(I)\otimes\mathcal{A}(I'|I\cup J)$ by (8). By some finite-dimensional Hilbert spaces $\mathcal{H}_1$, $\mathcal{H}_2$, and $\mathcal{H}_{1,2}\equiv\mathcal{H}_1\otimes\mathcal{H}_2$, we can write $\mathcal{A}(I\cup J)=\mathcal{B}(\mathcal{H}_{1,2})$, $\mathcal{A}(I)=\mathcal{B}(\mathcal{H}_1)$, and $\mathcal{A}(I'|I\cup J)=\mathcal{B}(\mathcal{H}_2)$.

Since ϱ is a pure state of $\mathcal{A}(I\cup J)$, its density matrix [with respect to the non-normalized trace **Tr** of $\mathcal{B}(\mathcal{H}_{1,2})$] is a one-dimensional projection operator of $\mathcal{B}(\mathcal{H}_{1,2})$, and hence there exists a unit vector $\xi\in\mathcal{H}_{1,2}$ such that $D_\varrho\eta=(\xi,\eta)\xi$ for any $\eta\in\mathcal{H}_{1,2}$. By using the Schmidt decomposition,[12] we have the following decomposed form:

$$\xi=\sum_i \lambda_i\xi_{1i}\otimes\xi_{2i},\quad \lambda_i>0, \tag{10}$$

where $\{\xi_{1i}\}$ and $\{\xi_{2i}\}$ are some orthonormal sets of vectors of $\mathcal{H}_1$ and $\mathcal{H}_2$. For $\nu=1,2$, let $P(\xi_{\nu i})$ denote the projection operator on the one-dimensional subspace of $\mathcal{H}_\nu$ containing $\xi_{\nu i}$. We denote the restricted states of ϱ onto $\mathcal{B}(\mathcal{H}_2)$ by $\tilde{\varrho}_2$. By (10), the density matrices of ϱ_1 and $\tilde{\varrho}_2$ have the following symmetric forms:

$$D_{\varrho_1}=\sum_i \lambda_i^2 P(\xi_{1i}),\quad D_{\tilde{\varrho}_2}=\sum_i \lambda_i^2 P(\xi_{2i}). \tag{11}$$

Since ϱ is an even state, its restriction ϱ_2 is even and hence its density matrix D_{ϱ_2} belongs to $\mathcal{A}(J)_+$.

On the other hand, the even state ϱ is invariant under the action of $\mathrm{Ad}(v_{I\cup J})=\mathrm{Ad}(v_I v_J)$:

$$v_{I\cup J}D_\varrho v_{I\cup J}=v_I v_J D_\varrho v_I v_J=D_\varrho.$$

Acting the conditional expectation onto $\mathcal{B}(\mathcal{H}_2)$ with respect to the tracial state of $\mathrm{B}(\mathcal{H}_{1,2})$ on the above equality, we obtain

$$v_J D_{\tilde{\varrho}_2} v_J=D_{\tilde{\varrho}_2}$$

noting that v_I belongs to $\mathcal{B}(\mathcal{H}_1)=\mathcal{B}(\mathcal{H}_2)'\cap\mathcal{B}(\mathcal{H}_{1,2})$.

We denote $\mathcal{B}(\mathcal{H}_2)_+\equiv\mathcal{B}(\mathcal{H}_2)\cap\mathcal{A}(I\cup J)_+$, the set of all invariant elements under $\mathrm{Ad}(v_I v_J)$ in $\mathcal{B}(\mathcal{H}_2)$. By (8), $\mathcal{B}(\mathcal{H}_2)_+$ is equal to $\mathcal{A}(J)_+$, and also to the set of all invariant elements under $\mathrm{Ad}(v_J)$ in $\mathcal{B}(\mathcal{H}_2)$. Therefore both $D_{\tilde{\varrho}_2}$ and D_{ϱ_2} belong to $\mathcal{B}(\mathcal{H}_2)_+$. Accordingly, $D_{\tilde{\varrho}_2}$ is equal to D_{ϱ_2} as the density of the state ϱ restricted to $\mathcal{B}(\mathcal{H}_2)_+$, and hence

$$D_{\varrho_2}=D_{\tilde{\varrho}_2}=\sum_i \lambda_i^2 P(\xi_{2i}). \tag{12}$$

From (11) and (12), it follows that ϱ_1 and ϱ_2 have the same nonzero eigenvalues and their multiplicities equal to $\{\lambda_i^2\}$. Thus

$$S(\varrho_1)=S(\varrho_2).$$

■

For a subset I of $\mathcal{L}$, $|I|$ denotes the number of sites in I.

Lemma 3. Let I be a finite subset and ϱ_1 be a state of $\mathcal{A}(I)$. Let J be a finite subset such that $J\cap I=\emptyset$ and $|J|\geqslant|I|$. Then there exists a pure state ϱ on $\mathcal{A}(I\cup J)$ satisfying

$$\varrho|_{\mathcal{A}(I)} = \varrho_1. \tag{13}$$

Moreover, if ϱ_1 is even, then the above ϱ can be taken to be even.

Proof: We use the same notation as in the proof of the preceding lemma and write $\mathcal{A}(I\cup J) = \mathcal{B}(\mathcal{H}_{1,2})$, $\mathcal{A}(I)=\mathcal{B}(\mathcal{H}_1)$, and $\mathcal{A}(I'|I\cup J)=\mathcal{B}(\mathcal{H}_2)$. Let $\varrho_1=\Sigma_i\lambda_i^2 P(\xi_{1i})$, where $\lambda_i>0$, $\{\xi_{1i}\}$ is an orthonormal set of $\mathcal{H}_1$, and $P(\xi_{1i})$ is the projection operator on the one-dimensional subspace of $\mathcal{H}_1$ containing ξ_{1i}. Since $|J|\geqslant|I|$ and hence $\dim\mathcal{H}_2\geqslant\dim\mathcal{H}_1$, we can take an orthonormal set of vectors $\{\xi_{2i}\}$ of $\mathcal{H}_2$ having the same cardinality as $\{\xi_{1i}\}$. Define a unit vector $\xi\in\mathcal{H}_{1,2}$ by the same formula as (10) and let ϱ be its vector state, namely the state whose density matrix is the projection operator on the one-dimensional subspace of $\mathcal{H}_{1,2}$ containing ξ. This ϱ is a pure state extension of ϱ_1 to $\mathcal{A}(I\cup J)$ by its definition.

Assume now that ϱ_1 is even, and hence its density matrix is in $\mathcal{A}(I)_+$. For each eigenvalue, the associated spectral projection is also even and commutes with v_I, and its range is invariant under v_I. Therefore we can choose an orthonormal basis of the range of the projection which consists of eigenvectors of v_I. We take $\{\xi_{1i}\}$ to be a set of eigenvectors of v_I.

Since v_J belongs to $\mathcal{B}(\mathcal{H}_2)_+(=\mathcal{A}(J)_+)$, there exists an orthonormal basis of $\mathcal{H}_2$ consisting of eigenvectors of v_J. Due to the assumption $|J|\geqslant|I|$, we can take a set of different eigenvectors $\{\xi_{2i}\}$ of v_J such that for each i its eigenvalue, $+1$ or -1, is equal to that of ξ_{1i} for v_I. Define a unit vector ξ by (10) using these $\{\xi_{1i}\}$ and $\{\xi_{2i}\}$. Since this ξ is an eigenvector of $v_{I\cup J}$ by its definition, its vector state ϱ is even. ■

Combining the above two lemmas we obtain the following.

Proposition 4: Let I be a finite subset and ϱ_1 be an even state of $\mathcal{A}(I)$. Let J be a finite subset such that $J\cap I=\emptyset$ and $|J|\geqslant|I|$. Then there exists an even pure state ϱ on $\mathcal{A}(I\cup J)$ such that its restriction to $\mathcal{A}(I)$ is equal to ϱ_1 and the density matrix of its restricted state $\varrho_2\equiv\varrho|_{\mathcal{A}(J)}$ has the same nonzero eigenvalues and their multiplicities as those of ϱ_1.

We may call the above state extension from ϱ_1 to ϱ the symmetric purification. Thanks to this, we obtain the following two theorems.

Theorem 5: *Let I, J, and K be mutually disjoint finite subsets. For every even state φ, MONO–SSA,*

$$S(\varphi_I)+S(\varphi_J)\leqslant S(\varphi_{K\cup I})+S(\varphi_{K\cup J}) \tag{14}$$

is satisfied.

Proof: The equivalence of MONO–SSA and SSA for even states follows from Proposition 4 in the same way as (3), p. 164 of Ref. 1. Since SSA holds for every state, MONO–SSA is valid for every even state. ■

Similarly, by using Proposition 4 we immediately obtain the triangle inequality for even states in much the same way as (3.1) of Ref. 1. We omit its proof.

Theorem 6: *Let I and J be mutually disjoint finite subsets. For every even state φ, the triangle inequality*

$$|S(\varphi_I)-S(\varphi_J)|\leqslant S(\varphi_{I\cup J}) \tag{15}$$

holds.

III. VIOLATION OF MONO–SSA

In this section we give a certain class of noneven states. We shall give a sketch of our model indicated by Fig. 1 (below). We can take a pure state $\varrho_{I\cup K}$ on $I\cup K$ whose restriction ϱ_K is a pure state, but ϱ_I is nonpure, say the tracial state. Such $\varrho_{I\cup K}$ does not satisfy the triangle inequality, because the entropies on I and on K are different, whereas the entropy on $I\cup K$ is zero. It can be said that the pure state $\varrho_{I\cup K}$ has the asymmetric restrictions in our terminology. This asymmetry is due to the large amount of the oddness of ϱ_K, whose precise meaning will be given soon. [Note however that for the infinite-dimensional case, the GNS representations π_{ϱ_K} and $\pi_{\varrho_K\Theta}$ should be

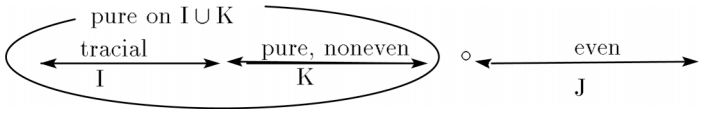

FIG. 1. A state not satisfying MONO–SSA.

unitarily equivalent, see Proposition 8(i).] We take an arbitrary even state ϱ_J on J. The desired state on $\varrho_{I\cup K\cup J}$ on $I\cup K\cup J$ is given by the product state extension of $\varrho_{I\cup K}$ and ϱ_J, which will be denoted by $\varrho_{I\cup K}\circ\varrho_J$.

We recall the definition of the transition probability.[14] For two states φ and ψ of $\mathcal{A}(I)$ (where $|I|$ is finite or infinite), take any representation π of $\mathcal{A}(I)$ on a Hilbert space $\mathcal{H}$ containing vectors Φ and Ψ such that

$$\varphi(A)=(\Phi,\pi(A)\Phi),\quad \psi(A)=(\Psi,\pi(A)\Psi), \tag{16}$$

for all $A\in\mathcal{A}(I)$. The transition probability between φ and ψ is given by

$$P(\varphi,\psi)\equiv\sup|(\Phi,\Psi)|^2, \tag{17}$$

where the supremum is taken over all $\mathcal{H}$, π, Φ, and Ψ as described above. For a state φ of $\mathcal{A}(I)$, we define

$$p_\Theta(\varphi)\equiv P(\varphi,\varphi\Theta)^{1/2}, \tag{18}$$

where $\varphi\Theta$ denotes the state $\varphi\Theta(A)=\varphi(\Theta(A))$, $A\in\mathcal{A}(I)$. Intuitively, $p_\Theta(\varphi)$ quantifies the amount of *oddness* of the state φ. If $p_\Theta(\varphi)=0$ or nearby, then we may say that the difference between φ and $\varphi\Theta$ is large. If φ is even, $p_\Theta(\varphi)$ obviously takes the maximum value 1.

The following is Lemma 3.1 of Ref. 2.

Lemma 7: If ϱ_1 is a pure state of $\mathcal{A}(K)$ and π_{ϱ_1} and $\pi_{\varrho_1\Theta}$ are unitarily equivalent, then there exists a self-adjoint unitary $u_1\in\pi_{\varrho_1}(\mathcal{A}(K)_+)''$ satisfying

$$u_1\pi_{\varrho_1}(A)u_1=\pi_{\varrho_1}(\Theta(A)),\quad A\in\mathcal{A}(K). \tag{19}$$

The next proposition is a basis of our construction. It is a generalization of Ref. 7. The first paragraph is in principle excerpted from Theorem 4 (4) and (5) of Ref. 2. The second paragraph is necessary for the argument of entropy.

Proposition 8. Let K and I be mutually disjoint subsets. Assume that ϱ_1 is a (noneven) pure state of $\mathcal{A}(K)$ satisfying $p_\Theta(\varrho_1)=0$. Assume that ϱ_2 is an even state of $\mathcal{A}(I)$. There exists a joint extension of ϱ_1 and ϱ_2 other than their product state extension if and only if ϱ_1 and ϱ_2 satisfy the following pair of conditions:

(i) *π_{ϱ_1} and $\pi_{\varrho_1\Theta}$ are unitarily equivalent.*

(ii) *There exists a state $\tilde{\varrho}_2$ of $\mathcal{A}(I)$ such that $\tilde{\varrho}_2\neq\tilde{\varrho}_2\Theta$ and*

$$\varrho_2=\tfrac{1}{2}(\tilde{\varrho}_2+\tilde{\varrho}_2\Theta). \tag{20}$$

For each $\tilde{\varrho}_2$ above, there exists the joint extension of ϱ_1 and ϱ_2 to $\mathcal{A}(K\cup I)$ denoted by $\psi_{\tilde{\varrho}_2}$ which satisfies

$$\psi_{\tilde{\varrho}_2}(A_1A_2)=\varrho_1(A_1)\varrho_2(A_{2+})+\overline{\varrho_1}(\pi_{\varrho_1}(A_1)u_1)\tilde{\varrho}_2(A_{2-}), \tag{21}$$

where $\overline{\varrho_1}$ is the GNS-extension of ϱ_1 to $\pi_{\varrho_1}(\mathcal{A}(K))''$.

If K and I are finite subsets, then the entropy of $\tilde{\varrho}_2$ is equal to that of $\psi_{\tilde{\varrho}_2}$.

Proof: We shall show only the sufficiency of the pair of conditions (i) and (ii). For the necessity of (i) see 5.2 in Ref. 2, and for that of (ii) see (d) in the proof of its Theorem 4(4).

Let $(\mathcal{H}_{\varrho_1}, \pi_{\varrho_1}, \Omega_{\varrho_1})$ be a GNS triplet for ϱ_1 and $(\mathcal{H}_{\tilde{\varrho}_2}, \pi_{\tilde{\varrho}_2}, \Omega_{\tilde{\varrho}_2})$ be that for $\tilde{\varrho}_2$. Define

$$\mathcal{H} \equiv \mathcal{H}_{\varrho_1} \otimes \mathcal{H}_{\tilde{\varrho}_2}, \quad \Omega \equiv \Omega_{\varrho_1} \otimes \Omega_{\tilde{\varrho}_2}, \tag{22}$$

$$\pi(A_1A_2) \equiv \pi_{\varrho_1}(A_1) \otimes \pi_{\tilde{\varrho}_2}(A_{2+}) + \pi_{\varrho_1}(A_1)u_1 \otimes \pi_{\tilde{\varrho}_2}(A_{2-}), \tag{23}$$

for $A_1 \in \mathcal{A}(K)$, $A_2 = A_{2+} + A_{2-}$, $A_{2\pm} \in \mathcal{A}(I)_{\pm}$. Let $\mathbf{1}_1$ be the identity operator of $\mathcal{H}_{\varrho_1}$ and $\mathbf{1}_2$ be that of $\mathcal{H}_{\tilde{\varrho}_2}$.

We can check that the operators $\pi(\mathcal{A}(K \cup I))$ satisfy the CAR by using (19), and hence π extends to a representation of $\mathcal{A}(K \cup I)$. We define the state $\psi_{\tilde{\varrho}_2}$ on $\mathcal{A}(K \cup I)$ as

$$\psi_{\tilde{\varrho}_2}(A) \equiv (\Omega, \pi(A)\Omega) \tag{24}$$

for $A \in \mathcal{A}(K \cup I)$. The von Neumann algebra $\pi(\mathcal{A}(K \cup I))''$ is generated by $\pi_{\varrho_1}(\mathcal{A}(K))'' \otimes \mathbf{1}_2$, $\mathbf{1}_1 \otimes \pi_{\tilde{\varrho}_2}(\mathcal{A}(\mathbf{I})_+)''$, and the weak closure of $\mathbf{1}_1 \otimes \pi_{\tilde{\varrho}_2}(\mathcal{A}(I)_-)$, where we have noted $u_1 \in \pi_{\varrho_1}(\mathcal{A}(K)_+)'' = \mathcal{B}(\mathcal{H}_{\varrho_1})$. Therefore

$$\pi(\mathcal{A}(K \cup I))'' = \mathcal{B}(\mathcal{H}_{\varrho_1}) \otimes \pi_{\tilde{\varrho}_2}(\mathcal{A}(I))''. \tag{25}$$

From this it follows that the vector Ω is cyclic for the representation π of $\mathcal{A}(K \cup I)$ in $\mathcal{H}$. Hence $(\mathcal{H}, \pi, \Omega)$ gives a GNS triplet for the state $\psi_{\tilde{\varrho}_2}$ on $\mathcal{A}(K \cup I)$.

We have

$$\psi_{\tilde{\varrho}_2}(A_1A_2) = (\Omega, \pi(A_1A_2)\Omega) = \varrho_1(A_1)\tilde{\varrho}_2(A_{2+}) + \overline{\varrho_1}(\pi_{\varrho_1}(A_1)u_1)\tilde{\varrho}_2(A_{2-}), \tag{26}$$

for $A_1 \in \mathcal{A}(K)$, $A_2 = A_{2+} + A_{2-}$, $A_{2\pm} \in \mathcal{A}(I)_{\pm}$. Taking $A_2 = \mathbf{1}$ in (26), we obtain

$$\psi_{\tilde{\varrho}_2}(A_1) = \varrho_1(A_1). \tag{27}$$

We will then show

$$\psi_{\tilde{\varrho}_2}(A_2) = \varrho_2(A_2). \tag{28}$$

Under the condition of Lemma 7 (which is our case), we have

$$p_\Theta(\varrho_1) = |\overline{\varrho_1}(u_1)|, \tag{29}$$

because the transition probability between the vector states of the algebra $\mathcal{B}(\mathcal{H}_{\varrho_1}) = \pi_{\varrho_1}(\mathcal{A}(K))''$ is equal to the (usual) transition probability of their vectors and hence $p_\Theta(\varrho_1) = |(\Omega_{\varrho_1}, u_1\Omega_{\varrho_1})|$. By the assumption $p_\Theta(\varrho_1) = 0$, (29) implies

$$\overline{\varrho_1}(u_1) = 0. \tag{30}$$

Setting $A_1 = \mathbf{1}$ in (26), we obtain

$$\psi_{\tilde{\varrho}_2}(A_2) = \tilde{\varrho}_2(A_{2+}) + \overline{\varrho_1}(u_1)\tilde{\varrho}_2(A_{2-}) = \tilde{\varrho}_2(A_{2+}). \tag{31}$$

By (20),

$$\varrho_2(A_2) = \varrho_2(A_{2+}) = \tilde{\varrho}_2(A_{2+}). \tag{32}$$

From (31) and (32), (28) follows. We have now shown that $\psi_{\tilde{\varrho}_2}$ is an extension of ϱ_1 and ϱ_2.

We will show the second paragraph. By (25) and the commutant theorem, $\pi(\mathcal{A}(K \cup I))' = \mathbf{1}_1 \otimes \pi_{\tilde{\varrho}_2}(\mathcal{A}(I))'$, where the commutant is taken in each GNS space. Thus we have the following isomorphism:

$$b \mapsto \mathbf{1}_1 \otimes b, \quad b \in \pi_{\tilde{\varrho}_2}(\mathcal{A}(I))' \tag{33}$$

from $\pi_{\tilde{\varrho}_2}(\mathcal{A}(I))'$ onto $\pi(\mathcal{A}(K\cup I))'$. Furthermore by (22) we obtain

$$(\Omega,(\mathbf{1}_1 \otimes b)\Omega) = (\Omega_{\varrho_1} \otimes \Omega_{\tilde{\varrho}_2}, \Omega_{\varrho_1} \otimes b\Omega_{\tilde{\varrho}_2}) = (\Omega_{\tilde{\varrho}_2}, b\Omega_{\tilde{\varrho}_2}). \tag{34}$$

From the assumption that K and I are finite subsets (which we have not used so far), $\pi_{\tilde{\varrho}_2}(\mathcal{A}(I))'$ and $\pi(\mathcal{A}(K\cup I))'$ are both finite-dimensional type I factors.

Now we note the following basic fact about GNS representations for states of finite-dimensional type I factors which can be considered as the counterpart of Lemma 2 for the usual case, namely for a pair of isomorphic systems coupled by tensor product. Let ω be a state of a finite-dimensional type I factor $\mathfrak{U}$ and $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$ denote a GNS triplet of ω. The GNS vector Ω_ω of ω induces a state on the commutant $\pi_\omega(\mathfrak{U})'$ whose expectation value for $a \in \pi_\omega(\mathfrak{U})'$ is given by $(\Omega_\omega, a\Omega_\omega)$. We call this state on $\pi_\omega(\mathfrak{U})'$ "ω on the commutant." [In our terminology, the pure state with respect to Ω_ω on $\mathcal{B}(\mathcal{H}_\omega) = \pi_\omega(\mathfrak{U}) \otimes \pi_\omega(\mathfrak{U})'$ gives a symmetric purification of ω. Also ω on the commutant is symmetric to ω.] Then the entropy of ω on $\mathfrak{U}$ [equivalently that on $\pi_\omega(\mathfrak{U})$] is equal to the entropy of ω on the commutant by the same reason described in Lemma 2. We note that this holds for a general $\mathbf{C}^*$-algebra if the GNS representation of a given state generates a type I von Neumann algebra with a discrete center. Similarly the extension of Lemma 2 is possible under the above condition on the state.

From the above fact with (33) and (34), we deduce the equality of the entropies of $\tilde{\varrho}_2$ and of $\psi_{\tilde{\varrho}_2}$. ■

Remark 1: Note that this $\psi_{\tilde{\varrho}_2}$ is a state extension of ϱ_1 and ϱ_2, not that of ϱ_1 and $\tilde{\varrho}_2$. The possibility of the state extension of ϱ_1 and $\tilde{\varrho}_2$ is negated by Theorem 4(3) of Ref. 3.

Remark 2: We can easily make examples of states in this proposition. Take a finite subset K and an odd self-adjoint element A in the algebra $\mathcal{A}(K)$ which we will identify with $\mathcal{B}(\mathcal{H})$ on a finite-dimensional Hilbert space $\mathcal{H}$. Let $\eta \in \mathcal{H}$ be a normalized eigenvector of this A and ω_η denote the associated vector state. Then $\eta \perp v_K\eta$, and $\omega_\eta\Theta$ becomes the vector state with respect to $v_K\eta$. Hence $p_\Theta(\omega_\eta)=0$. This ω_η obviously satisfies (i). For the existence of ϱ_2 satisfying (ii), take, for example, the above ω_η for $\tilde{\varrho}_2$ (with $i \in I$), $\omega_\eta\Theta$ for $\tilde{\varrho}_2\Theta$, and their affine sum (20) for ϱ_2.

Proposition 8 yields the following construction giving counter examples of MONO–SSA and those of the triangle inequality.

Theorem 9: *Let K, I, and J be mutually disjoint subsets. Let $\varrho_K = \varrho_1$ and $\varrho_I = \varrho_2$ where ϱ_1 and ϱ_2 are those states on $\mathcal{A}(K)$ and on $\mathcal{A}(I)$ given in Proposition 8. Let $\varrho_{K\cup I}$ be the state extension of ϱ_K and ϱ_I to $\mathcal{A}(K\cup J)$ given by $\psi_{\tilde{\varrho}_2}$ in the form of (21). Let ϱ_J be an arbitrary even state of $\mathcal{A}(J)$. Then for such $\varrho_{K\cup I}$ and ϱ_J, there exists a (unique) product state extension $\varrho_{K\cup I}\circ\varrho_J$ on $\mathcal{A}(K\cup I\cup J)$. If all K, I, and J are finite subsets, then*

$$S(\varrho_{K\cup I}) + S(\varrho_{K\cup J}) < S(\varrho_I) + S(\varrho_J), \tag{35}$$

and

$$|S(\varrho_I) - S(\varrho_K)| = S(\varrho_I) > S(\varrho_{K\cup I}). \tag{36}$$

Proof: By Ref. 10 or Theorem 1(1) of Ref. 2, there exists a unique product state extension of a pair of states on disjoint regions if (and only if) at least one of them is even, and hence the (unique) existence of $\varrho_{K\cup I}\circ\varrho_J$ follows.

By the second paragraph of Proposition 8, we obtain

$$S(\varrho_{K\cup I}) = S(\psi_{\tilde{\varrho}_2}) = S(\tilde{\varrho}_2). \tag{37}$$

Since $\varrho_2 = \frac{1}{2}(\tilde{\varrho}_2 + \tilde{\varrho}_2\Theta)$ and $\tilde{\varrho}_2 \neq \tilde{\varrho}_2\Theta$, we have

$$S(\varrho_I) = S(\varrho_2) = S(1/2(\tilde{\varrho}_2 + \tilde{\varrho}_2\Theta)) > 1/2S(\tilde{\varrho}_2) + 1/2S(\tilde{\varrho}_2\Theta) \tag{38}$$

by the strict concavity of von Neumann entropy with respect to the affine sum of states (see

Remark 3 below). Due to the unitary invariance of von Neumann entropy,

$$S(\tilde{\varrho}_2) = S(\tilde{\varrho}_2\Theta). \tag{39}$$

By (37), (38), and (39), we have

$$S(\varrho_I) > S(\varrho_{K\cup I}). \tag{40}$$

By the product property of $\varrho_{K\cup J}=\varrho_K\circ\varrho_J$ the density matrix of $\varrho_{K\cup J}$ is a product of the density matrices of ϱ_K and ϱ_J which mutually commute because $\varrho_J\in\mathcal{A}(J)_+$. Hence by a direct computation we have

$$S(\varrho_{K\cup J}) = S(\varrho_K) + S(\varrho_J).$$

Since ϱ_K is assumed to be pure and hence $S(\varrho_K)=0$, we have

$$S(\varrho_{K\cup J}) = S(\varrho_J). \tag{41}$$

From (40) and (41), we obtain (35). From (40) and $S(\varrho_K)=0$, we obtain (36). ■

Remark 3: Let $\mathcal{H}$ be a finite-dimensional Hilbert space. For states φ and ψ on the algebra $\mathcal{B}(\mathcal{H})$ and for $0\leqslant\lambda\leqslant 1$, the following von Neumann entropy inequalities are well known:

$$S(\lambda\varphi + (1-\lambda)\psi) \geqslant \lambda S(\varphi) + (1-\lambda)S(\psi), \tag{42}$$

$$S(\lambda\varphi + (1-\lambda)\psi) \leqslant \lambda S(\varphi) + (1-\lambda)S(\psi) - \lambda\log\lambda - (1-\lambda)\log(1-\lambda). \tag{43}$$

We refer to Proposition 6.2.25 of Ref. 4 for their proofs. We now see the strict concavity of von Neumann entropy which was used in the proof of Theorem 9, namely for $0<\lambda<1$ the equality of (42) holds if and only if $\varphi=\psi$. We employ the proof method given in the above-mentioned reference. Let $\mathcal{K}$ be a two-dimensional Hilbert space and P denote a one-dimensional projection of $\mathcal{B}(\mathcal{K})$. We denote $\mathcal{A}_1\equiv\mathcal{B}(\mathcal{H})$, $\mathcal{A}_2\equiv\mathcal{B}(\mathcal{K})$, and $\mathcal{A}_{1,2}\equiv\mathcal{B}(\mathcal{H}\otimes\mathcal{K})$. Let ω denote a state on $\mathcal{A}_{1,2}$ whose density matrix D_ω is given by

$$\lambda D_\varphi\otimes P + (1-\lambda)D_\psi\otimes(1-P).$$

We denote ω restricted to $\mathcal{A}_1$ (to $\mathcal{A}_2$, respectively) by ω_1 (and ω_2). We see that ω_1 is equal to $\lambda\varphi+(1-\lambda)\psi$, hence

$$S(\omega_1) = S(\lambda\varphi + (1-\lambda)\psi).$$

Also we have

$$S(\omega) - S(\omega_2) = \lambda S(\varphi) + (1-\lambda)S(\psi).$$

Since

$$S(\omega_1) + S(\omega_2) - S(\omega) = \omega(\log D_\omega - \log(D_{\omega_1}\otimes D_{\omega_2})) \equiv S(\omega|\omega_1\otimes\omega_2) \geqslant 0,$$

which is equivalent to the subadditivity of entropy, we obtain (42). This $S(\omega|\omega_1\otimes\omega_2)$ is relative entropy of the two states in its argument and is known to have strict positivity, i.e., $S(\omega|\omega_1\otimes\omega_2)=0$ if and only if $\omega=\omega_1\otimes\omega_2$, which is equivalent to $\varphi=\psi$ for $0<\lambda<1$. Hence our desired strictness of (42) is shown.

Remark 4: We shall give a rough estimation of the amount of violation of the triangle inequality, i.e., $|S(\varphi_I)-S(\varphi_K)|-S(\varphi_{K\cup I})$ of (36) for a general state φ. Let $\hat{\varphi}\equiv 1/2(\varphi+\varphi\Theta)$. Then it obviously satisfies the triangle inequality. By (42) and (43), we have $|S(\hat{\varphi}_{K\cup I})-S(\varphi_{K\cup I})|\leqslant -1/2\log 1/2-1/2\log 1/2=\log 2$, and similarly $|S(\hat{\varphi}_I)-S(\varphi_I)|\leqslant\log 2$ and $|S(\hat{\varphi}_K)-S(\varphi_K)|\leqslant\log 2$. Hence $|S(\varphi_I)-S(\varphi_K)|-S(\varphi_{K\cup I})$ is at most $3\log 2$. However, we do not know its possible maximal value. (The violation of the triangle inequality for our concrete model considered in Ref. 7 ranges from 0 up to $\log 2$.)

(Received 11 March 2004; accepted 9 November 2004; published online 11 February 2005)

Generalizing the Lie derivative of smooth tensor fields to distribution-valued tensors, we examine the Killing symmetries and the collineations of the curvature tensors of some distributional domain wall geometries. The chosen geometries are rigorously the distributional thin wall limit of self-gravitating scalar field configurations representing thick domain walls and the permanence and/or the rising of symmetries in the limit process is studied. We show that, for all the thin wall space–times considered, the symmetries of the distributional curvature tensors turns out to be the Killing symmetries of the pullback of the metric tensor to the surface where the singular part of these tensors is supported. Remarkably enough, for the nonreflection symmetric domain wall studied, these Killing symmetries are not necessarily symmetries of the ambient space–time on both sides of the wall. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1851603]

I. INTRODUCTION

Consider a family of space–times $(\mathcal{M}, {}^{\gamma}\mathbf{g})$, where ${}^{\gamma}\mathbf{g}$ is C^{∞} metric tensor which depends on a parameter γ. An isometry ψ on $(\mathcal{M}, {}^{\gamma}\mathbf{g})$ is defined to be a diffeomorphism $\psi: \mathcal{M} \to \mathcal{M}$ for which $\psi^{*}{}^{\gamma}\mathbf{g} = {}^{\gamma}\mathbf{g}$. The infinitesimal generator of a one-parameter group ψ_{λ} of local isometries is the C^{∞} vector field $\mathbf{V}$ on $\mathcal{M}$ that satisfies

$$\mathcal{L}_{\mathbf{V}}{}^{\gamma}\mathbf{g} = 0, \tag{1}$$

and $\mathbf{V}$ is called a Killing vector field on $(\mathcal{M}, {}^{\gamma}\mathbf{g})$ relative to this group. To every one-parameter family of Killing symmetries there is an associated conserved quantity along the geodesics of the space–time and these conserved quantities are useful for integrating the geodesic equation.[1]

Although isometries are the most important transformations on $(\mathcal{M}, {}^{\gamma}\mathbf{g})$, geometric symmetries other than Killing symmetries may also be considered. Let ${}^{\gamma}\mathbf{Ric}$ be the Ricci curvature tensor of ${}^{\gamma}\mathbf{g}$. A vector field $\mathbf{V}$ on $\mathcal{M}$ that satisfies

$$\mathcal{L}_{\mathbf{V}}{}^{\gamma}\mathbf{Ric} = 0, \tag{2}$$

is called a Ricci collineation. It is well known that for every vector field $\mathbf{V}$ such that (1) is satisfied, i.e., for every Killing vector field, (2) is also satisfied and the Ricci tensor inherits the symmetries of the metric. However, other vector fields that are not Killing vectors may exist for which (2) is satisfied and these are called proper Ricci collineations. Since **Ric** is obtained by contracting the Riemann curvature tensor, Ricci collineations have a natural geometrical significance and it is believed that they can be useful to understand the interplay between geometry and physics in general relativity (for more details on these and other geometric symmetries, see Refs. 2–5).

Now, consider a space–time $(\mathcal{M}, \mathbf{g})$ of low differentiability, revealing itself through a lack of smoothness of the metric $\mathbf{g}$ and its curvature tensors. Up to what extent can the classical concept of a geometric symmetry (in the smooth case) be carried over to this situation? Let us assume that the metric tensors $\mathbf{g}$ and ${}^{\gamma}\mathbf{g}$ are distribution-valued tensors that satisfy

$$\mathbf{g} \equiv \lim_{\gamma \to 0} {}^{\gamma}\mathbf{g} \tag{3}$$

(in the sense of distributions) and that their corresponding curvature tensors have a well-defined distributional meaning. Further, assume that the following diagram holds;

$$\begin{array}{ccccccc} {}^{\gamma}\mathbf{g} & \longrightarrow & {}^{\gamma}\mathbf{Riem} & \longrightarrow & {}^{\gamma}\mathbf{Ric} & \longrightarrow & {}^{\gamma}\mathbf{G} \\ \downarrow_{\gamma \to 0} & & \downarrow_{\gamma \to 0} & & \downarrow_{\gamma \to 0} & & \downarrow_{\gamma \to 0} \\ \mathbf{g} & \longrightarrow & \mathbf{Riem} & \longrightarrow & \mathbf{Ric} & \longrightarrow & \mathbf{G} \end{array} \tag{4}$$

where ${}^{\gamma}\mathbf{g}$, ${}^{\gamma}\mathbf{Riem}$, ${}^{\gamma}\mathbf{Ric}$, ${}^{\gamma}\mathbf{G}$ and $\mathbf{g}$, **Riem**, **Ric**, **G** are the distribution valued metric, Riemann, Ricci and Einstein tensors of the smooth and the distributional geometries, respectively. Although distributional curvatures are in general ill-defined due to the nonlinearities of general relativity, there is a class of distributional metrics for which the Riemann curvature tensor and its contractions can be interpreted as distributions.[6] Metrics for thin shells[7] are included into this class.[6,8] Furthermore, for such a class an appropriate notion of convergence of metrics has been stated which ensures the convergence of the respective curvatures,[6] in the sense that the diagram (4) holds.

Since the derivative of a distribution is a distribution, for a distributional metric whose curvature tensors make sense as distributions, it makes sense to consider their geometric symmetries. Obviously, this situation should be considered also from the distributional point of view. For example, Eq. (2) contains products of the Ricci tensor and the vector field which generates the symmetry, so that for a distribution-valued Ricci tensor such equation restricts the vector field to be C^{∞}. With this proviso, we can consider geometric symmetries in cases in which the curvature tensors are zero almost everywhere (when obtained within standard differential geometry). Furthermore, for distributional geometries such that the above diagram holds, we can study the permanence and/or the rising of symmetries in the limit process. Thus, from the study of these geometries we expect to get further insight about the nature of distributional curvatures in general relativity.

Killing symmetries of distributional metrics have been considered previously in Ref. 9, where it is shown that the Killing fields of the Schwarzschild metric are also Killing of its ultrarelativistic limit, the last one being a *pp*-wave with a distributional δ profile.[10] In addition, based on the analysis of the adjoint orbits of normal-form-preserving diffeomorphisms, Killing symmetries of impulsive *pp*-waves with distributional profiles have been analyzed[11] and the existence of nonsmooth Killing vectors put forward.[12]

In this paper, adopting a different approach for a rigorous definition of symmetries of distributional geometries, we are concerned with symmetries of domain wall space–times. Such space–times have been the subject of intense investigation, after it was realized in Ref. 13 that our four-dimensional universe might be a thin (codimension one) distributional domain wall embedded in a five-dimensional space–time. Thin wall geometries have distribution-valued curvature tensor fields whose singular parts are proportional to a Dirac distribution supported on the surface where the wall is localized. All the metrics representing the possible backgrounds of an infinitely thin domain wall[14] have been found and classified,[15,16] these being joined at a common boundary, the surface where the wall is localized, following the Darmois–Israel formalism.[7] On the other hand, smooth domain wall geometries can be obtained as solutions to the coupled Einstein-scalar field system with a suitable symmetry breaking potential $V(\phi)$.[14,17–20] The behavior of gravity in some of these models has been also investigated.[21–23] Recently, following the convergence criteria of Ref. 6, the distributional thin wall limit of some classes of domain wall space–times has been rigourously analyzed[24,25] showing that the diagram (4), in which ${}^{\gamma}\mathbf{g}$ and $\mathbf{g}$ are the distribution valued metric tensors of the thick and thin domain wall space–times, respectively, holds. Specifically, we will study the symmetries of the metric and its curvature tensors of these distributional domain wall geometries. Domain walls have drastic gravitational effects in the ambient space and, due to its role in brane-world models, we are interested in their geometric symmetries besides those defining the plane-parallel symmetry since a larger group may exists for various particular models.

In Sec. II, after an overview on the subject of distribution-valued tensors, we give the definition of the Lie derivative of a tensor distribution along a C^∞ vector field. In the next three sections, we examine the Killing symmetries and the collineations of the singular Ricci and Einstein curvature tensors associated to the distributional thin wall limit of some thick domain wall space–times for which the diagram (4) holds.[24] The last section is devoted to summarize and discuss the results.

II. MATHEMATICAL FRAMEWORK

We first recall some fundamental results about distribution-valued tensors on a C^∞ paracompact n-dimensional manifold $\mathcal{M}$.[26–28]

Let $\mathcal{D}_p(\mathcal{M})$ be the space of C^∞ p-tensor fields on $\mathcal{M}$ with compact support endowed with its Schwartz topology, i.e., the space of test p-tensor fields. The space of p-cotensor distributions on $\mathcal{M}$, $\mathcal{D}_p^{*'}(\mathcal{M})$, is defined as the dual of $\mathcal{D}_p(\mathcal{M})$. Now, in order to keep things simple, we endow the C^∞ paracompact manifold $\mathcal{M}$ with a C^∞ metric $\boldsymbol{\eta}$. However, it should be noted that tensor distributions and their derivatives can be described without assuming the presence of a metric[29] and that, by using de Rham currents[30] and replacing test tensors by test n-forms, the introduction of a volume form can also be avoided. Here we shall follow the approach of Ref. 26.

Let $\mathbf{U}$ be a test p-tensor field on $\mathcal{M}$. The identification of a locally integrable p-cotensor field $\mathbf{T}$ with a distribution-valued tensor is defined by

$$\mathbf{T}[\mathbf{U}] \equiv \int_{\mathcal{M}} \mathbf{T}\cdot\mathbf{U}\boldsymbol{\omega}_\eta, \tag{5}$$

where $\mathbf{T}\cdot\mathbf{U}$ denotes the scalar product of $\mathbf{T}$ and $\mathbf{U}$, and $\boldsymbol{\omega}_\eta$ is the volume element of $\boldsymbol{\eta}$. Since (5) is the integral of an n-form with compact support, we have

$$\mathbf{T}[\mathbf{U}] \equiv \int_{\varphi(\mathcal{M})} T_{i_1\cdots i_p} U^{i_1\cdots i_p} |\det\,\eta|^{1/2}\, \mathrm{d}x^1\cdots\,\mathrm{d}x^n \tag{6}$$

in the domain $\varphi(\mathcal{M})$ of the chart $(x^1,\ldots,x^n)$. Obviously, (6) is independent of the choice of coordinate system covering the corresponding domain. Further, although (5) depends on the choice of $\boldsymbol{\eta}$, the space of locally integrable tensor fields does not.[26]

Next, let us define the Lie derivative of a tensor field in the sense of distributions. Let $\mathbf{V}$ be a C^∞ vector field and $\mathbf{T}$ be a C^1 p-cotensor field on $\mathcal{M}$. The Lie derivative of $\mathbf{T}$ is the p-cotensor field $\mathcal{L}_\mathbf{v}\mathbf{T}$ such that, for every test p-tensor field $\mathbf{U}$,

$$\mathcal{L}_\mathbf{v}\mathbf{T}[\mathbf{U}] \equiv \int_{\mathcal{M}} \mathcal{L}_\mathbf{v}\mathbf{T}\cdot\mathbf{U}\boldsymbol{\omega}_\eta = \int_{\mathcal{M}} \mathcal{L}_\mathbf{v}(\mathbf{T}\cdot\mathbf{U}\boldsymbol{\omega}_\eta) - \int_{\mathcal{M}} ((\mathbf{T}\cdot\mathcal{L}_\mathbf{v}\mathbf{U})\boldsymbol{\omega}_\eta + (\mathbf{T}\cdot\mathbf{U})\mathcal{L}_\mathbf{v}\boldsymbol{\omega}_\eta). \tag{7}$$

Now, since $\mathbf{T}\cdot\mathbf{U}\boldsymbol{\omega}_\eta$ is an n-form with compact support, we have

$$\int_{\mathcal{M}} \mathcal{L}_\mathbf{v}(\mathbf{T}\cdot\mathbf{U}\boldsymbol{\omega}_\eta) = \int_{\mathcal{M}} \mathbf{d}\mathbf{i}_\mathbf{v}(\mathbf{T}\cdot\mathbf{U}\boldsymbol{\omega}_\eta) = \int_{\partial\mathcal{M}} \mathbf{i}_\mathbf{v}(\mathbf{T}\cdot\mathbf{U}\boldsymbol{\omega}_\eta) = 0, \tag{8}$$

where $\mathbf{i}_\mathbf{v}$ denotes interior product, in the last step we have used Stokes' theorem and the surface term vanishes because $\mathbf{U}$ has compact support. Therefore

$$\mathcal{L}_\mathbf{v}\mathbf{T}[\mathbf{U}] = -\int_{\mathcal{M}} ((\mathbf{T}\cdot\mathcal{L}_\mathbf{v}\mathbf{U})\boldsymbol{\omega}_\eta + (\mathbf{T}\cdot\mathbf{U})\mathcal{L}_\mathbf{v}\boldsymbol{\omega}_\eta). \tag{9}$$

On the other hand, we have

$$\mathcal{L}_{\mathbf{v}}\boldsymbol{\omega}_{\eta} = (\nabla \cdot \mathbf{V})\boldsymbol{\omega}_{\eta} \tag{10}$$

where ∇ is the torsion free metric compatible Levi–Civita covariant derivative associated with $\boldsymbol{\eta}$ and

$$\nabla \cdot \mathbf{V} \equiv \nabla_j V^j. \tag{11}$$

It follows that

$$\mathcal{L}_{\mathbf{v}}\mathbf{T}[\mathbf{U}] = -\int_{\mathcal{M}} \mathbf{T} \cdot (\mathcal{L}_{\mathbf{v}}\mathbf{U} + \mathbf{U}(\nabla \cdot \mathbf{V}))\boldsymbol{\omega}_{\eta}. \tag{12}$$

Therefore, to have a definition which coincides with the usual one when $\mathbf{T}$ is C^1, we define for $\mathbf{T}$ an arbitrary p-cotensor distribution and $\mathbf{V}$ a C^{∞} vector field on $\mathcal{M}$ the Lie derivative of $\mathbf{T}$ as the p-cotensor distribution given by

$$\mathcal{L}_{\mathbf{v}}\mathbf{T}[\mathbf{U}] \equiv -\mathbf{T}[\mathcal{L}_{\mathbf{v}}\mathbf{U} + (\nabla \cdot \mathbf{V})\mathbf{U}]. \tag{13}$$

Note that (13) makes sense since both $\mathcal{L}_{\mathbf{v}}\mathbf{U}$ and $(\nabla \cdot \mathbf{V})\mathbf{U}$ are test p-tensor fields if $\mathbf{V}$ is a C^{∞} vector field. Further, it should be stressed that the distributional Lie derivative of a tensor distribution, (13), reduce to the classical Lie derivative of an ordinary smooth tensor for a tensor distribution associated to a smooth tensor. This claim follows directly from the derivation of (12).

In the next sections, (13) will be used to define and compute the Lie derivative of a distribution-valued metric tensor $\mathbf{g}$ with $\mathbf{V}$ a C^{∞} vector field that generates a one parameter group of isometries of the space–time $(\mathcal{M}, \mathbf{g})$. We also make use of (13) to define and compute the Ricci and Einstein collineations of the distributional geometry associated to these space–times. Since all the distribution-valued metric tensors that we shall consider are regular metrics in the sense of Ref. 6, let us recall their definition. Suppose that $(\mathcal{M}, \mathbf{g})$ are given such that

(1) $\mathbf{g}$ and $(\mathbf{g}^{-1})$ exist everywhere and are locally bounded,
(2) the first derivative $\nabla\mathbf{g}$ (in the sense of distributions) of $\mathbf{g}$ in some smooth derivative operator ∇ exists and is locally square-integrable, i.e., the outer product of the derivative with itself is locally integrable.

Following Ref. 6, these are the minimal conditions for the Riemann curvature tensor to be definable as a distribution by the usual coordinate formula and we shall say that $\mathbf{g}$ is a regular metric. Since for this class of metrics the outer product of any number of metrics and inverse metrics with the Riemann curvature tensor can be interpreted as distributions, the Ricci and Einstein curvature tensors of a regular metric make sense as distributions. Finally, it should be stressed that for such class an appropriate notion of convergence of metrics exists which ensures the convergence of the respective curvatures,[6] in the sense that the diagram (4) holds (for details, see Ref. 6).

III. A DOMAIN WALL WITH A DE SITTER EXPANSION

Consider the space–time $(\mathbb{R}^4, {}^{\gamma}\mathbf{g})$ where the metric tensor ${}^{\gamma}\mathbf{g}$, in a particular coordinate basis, is given by

$${}^{\gamma}\mathbf{g} = \cosh^{-2\gamma}\frac{\beta x}{\gamma}(-\mathbf{d}t \otimes \mathbf{d}t + \mathbf{d}x \otimes \mathbf{d}x + e^{2\beta t}(\mathbf{d}y \otimes \mathbf{d}y + \mathbf{d}z \otimes \mathbf{d}z)), \tag{14}$$

where β and γ are constants, with $0 < \gamma < 1$. This space–time is generated by a thick domain wall, i.e., a solution to the coupled Einstein-scalar field equations

$${}^{\gamma}\mathbf{G} + {}^{\gamma}\mathbf{g}\Lambda \equiv {}^{\gamma}\mathbf{Ric} - \tfrac{1}{2}{}^{\gamma}\mathbf{g}{}^{\gamma}R + {}^{\gamma}\mathbf{g}\Lambda = 8\pi\left[\mathbf{d}\phi \otimes \mathbf{d}\phi - \mathbf{g}\left(\tfrac{1}{2}\mathbf{d}\phi \cdot \tilde{\mathbf{d}}\phi + V(\phi)\right)\right], \tag{15}$$

where the vector field $\tilde{\mathbf{d}}\phi$ is the metric dual to $\mathbf{d}\phi$ and

$$\Box\phi - \frac{d}{d\phi}V(\phi) = 0, \tag{16}$$

where $-\Box \equiv \boldsymbol{\delta}\mathbf{d} + \mathbf{d}\boldsymbol{\delta}$, with $\mathbf{d}$ and $\boldsymbol{\delta}$ the exterior derivative and the codifferential, respectively. In this case we have

$$\phi = \phi_0 \tan^{-1}(\sinh(\beta x/\gamma)\ , \quad \phi_0 \equiv \sqrt{\gamma(1-\gamma)/4\pi}, \tag{17}$$

$$V(\phi) = \frac{1}{8\pi}\beta^2\left(2 + \frac{1}{\gamma}\right)\cos^{2(1-\gamma)}(\phi/\phi_0), \quad \Lambda = 0. \tag{18}$$

The scalar field takes values $\pm\pi\phi_0/2$ at $x = \pm\infty$ corresponding to two consecutive minima of the potential and interpolates smoothly between these values,[17,18,20] with γ playing the role of the wall's thickness.[24] The five-dimensional analogue of this geometry, considered as a thick brane-world model, has been studied in Ref. 23.

Note that (14) is C^∞ as are also all its curvature tensor fields. In particular, for the Ricci and Einstein tensor fields we obtain

$${}^\gamma\mathbf{Ric} = -\left(2 + \frac{1}{\gamma}\right)\beta^2 \cosh^{-2}\frac{\beta x}{\gamma}\left(-\mathbf{d}t\,\mathbf{d}t + \frac{3}{1+2\gamma}\mathbf{d}x\,\mathbf{d}x + e^{2\beta t}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)\right) \tag{19}$$

and

$${}^\gamma\mathbf{G} = -\left(1 + \frac{2}{\gamma}\right)\beta^2 \cosh^{-2}\frac{\beta x}{\gamma}\left(-\mathbf{d}t\,\mathbf{d}t + \frac{3\gamma}{2+\gamma}\mathbf{d}x\,\mathbf{d}x + e^{2\beta t}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)\right), \tag{20}$$

where, following standard practice, we have omitted writing the outer product sign.

Now, from (1) and (14), we obtain six linearly independent Killing vector fields on $(\mathbb{R}^4, {}^\gamma\mathbf{g})$ given by

$$\mathbf{V}_1 = \boldsymbol{\partial}_y, \quad \mathbf{V}_2 = \boldsymbol{\partial}_z, \quad \mathbf{V}_3 = z\boldsymbol{\partial}_y - y\boldsymbol{\partial}_z, \tag{21}$$

$$\mathbf{V}_4 = \boldsymbol{\partial}_t - \beta(y\boldsymbol{\partial}_y + z\boldsymbol{\partial}_z), \tag{22}$$

$$\mathbf{V}_5 = 2\beta y\mathbf{V}_4 + (\beta^2(y^2+z^2) - e^{-2\beta t})\boldsymbol{\partial}_y, \tag{23}$$

$$\mathbf{V}_6 = 2\beta z\mathbf{V}_4 + (\beta^2(y^2+z^2) - e^{-2\beta t})\boldsymbol{\partial}_z. \tag{24}$$

The Killing vectors (21) are generic to the plane parallel symmetry, two spatial translations $\mathbf{V}_1$, $\mathbf{V}_2$ and one spatial rotation $\mathbf{V}_3$. The six vector fields (21)–(24) are also Killing vectors on the (2+1)-dimensional de Sitter space–time $(\mathbb{R}^3, \overline{\mathbf{g}})$ with

$$\overline{\mathbf{g}} = -\mathbf{d}t\,\mathbf{d}t + e^{2\beta t}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z), \tag{25}$$

where $\mathbf{V}_4$ is a quasitime translation and $\mathbf{V}_5$, $\mathbf{V}_6$ are quasi-Lorentz rotations. Note that (21)–(24) are all independent of the thickness γ of the wall. It is straightforward to show that for (21)–(24) we have in the classical (i.e., nondistributional) sense

$$\mathcal{L}_\mathbf{v}\,{}^\gamma\mathbf{Ric} = 0, \quad \mathcal{L}_\mathbf{v}{}^\gamma\mathbf{G} = 0. \tag{26}$$

One can also show that there are no other vector fields for which (26) is satisfied. Hence, the Ricci (19) and Einstein (20) curvature tensors only admit improper collineations.

Next, consider the Lie derivative of (14) in the sense of distributions as given by (13). Let $\boldsymbol{\eta}$ be the ordinary four-dimensional Minkowski metric tensor in Cartesian coordinates

$$\boldsymbol{\eta} = -\,\mathbf{d}t\,\mathbf{d}t + \mathbf{d}x\,\mathbf{d}x + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z, \tag{27}$$

and let ∇ be the Levi–Civita covariant derivative associated with $\boldsymbol{\eta}$. Let $\mathbf{U}$ be a test tensor on $\mathbb{R}^4$. From (13), it is straightforward to verify that for all Killing vectors (21)–(24), we have

$$\mathcal{L}_{\mathbf{v}}{}^{\gamma}\mathbf{g}[\mathbf{U}] = 0, \tag{28}$$

as expected. Indeed, it is to make such things true that the Lie derivative is defined as in (13). For the sake of completeness, let us show explicitly the computation of this derivative for the Killing vector given by (22). We have

$$\mathcal{L}_{\mathbf{v}_4}{}^{\gamma}\mathbf{g}[\mathbf{U}] \equiv -\,{}^{\gamma}\mathbf{g}[\mathcal{L}_{\mathbf{v}_4}\mathbf{U} + (\nabla\cdot\mathbf{V}_4)\mathbf{U}] = -\int_{\mathbb{R}^4} {}^{\gamma}\mathbf{g}\cdot(\mathcal{L}_{\mathbf{v}_4}\mathbf{U} + \mathbf{U}(\nabla\cdot\mathbf{V}_4))\boldsymbol{\omega}_{\eta} = -\int_{\mathbb{R}^4} \cosh^{-2\gamma}\frac{\beta x}{\gamma}((\partial_t - \beta y\partial_y - \beta z\partial_z - 2\beta)(-U^{tt} + U^{xx}) + e^{2\beta t}(\partial_t - \beta y\partial_y - \beta z\partial_z)(U^{yy} + U^{zz}))\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z = 0, \tag{29}$$

where in the last step we have integrated by parts and used the fact that $\mathbf{U}$ is of compact support. For all the Killing vector fields (21)–(24), analogous computations show that

$$\mathcal{L}_{\mathbf{v}}{}^{\gamma}\mathbf{Ric}[\mathbf{U}] = 0, \quad \mathcal{L}_{\mathbf{v}}{}^{\gamma}\mathbf{G}[\mathbf{U}] = 0, \tag{30}$$

as expected.

We turn now to consider the $\gamma\to 0$ limit of this geometry. In Ref. 24, it has been proved that (14) provides a sequence of metrics that satisfies the convergence conditions of Ref. 6 such that the limit of the Riemann curvature tensor exists and is the Riemann tensor of the limit metric. The same holds for the other curvature tensors. We have

$$\mathbf{g} \equiv \lim_{\gamma\to 0} {}^{\gamma}\mathbf{g} = (\Theta_x^- e^{2\beta x} + \Theta_x^+ e^{-2\beta x})(-\,\mathbf{d}t\,\mathbf{d}t + \mathbf{d}x\,\mathbf{d}x + e^{2\beta t}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)), \tag{31}$$

$$\mathbf{Ric} \equiv \lim_{\gamma\to 0} {}^{\gamma}\mathbf{Ric} = 2\beta\delta_0(\mathbf{d}t\,\mathbf{d}t - 3\,\mathbf{d}x\,\mathbf{d}x - e^{2\beta t}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)), \tag{32}$$

$$\mathbf{G} \equiv \lim_{\gamma\to 0} {}^{\gamma}\mathbf{G} = 4\beta\delta_0(\mathbf{d}t\,\mathbf{d}t - e^{2\beta t}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)), \tag{33}$$

where Θ_x^- and Θ_x^+ are the Heaviside distributions with support on $x<0$ and $x>0$, respectively, and δ_0 is the Dirac measure with support on the surface $x=0$. Note that $\mathbf{g}$ is piecewise smooth and that the pullback of $\mathbf{g}$ to the surface $x=0$ is the same from both sides. Note also that this pullback is given by (25). Indeed, the above expressions should be understood in the sense of distributions. Thus, $\mathbf{g}\equiv\lim_{\gamma\to 0}{}^{\gamma}\mathbf{g}$ means

$$\mathbf{g}[\mathbf{U}] \equiv \lim_{\gamma\to 0} {}^{\gamma}\mathbf{g}[\mathbf{U}]. \tag{34}$$

In fact, ${}^{\gamma}\mathbf{g}$, $({}^{\gamma}\mathbf{g})^{-1}$ and $\nabla{}^{\gamma}\mathbf{g}$, with ∇ the covariant derivative associated with (27), converge locally (in square integral) to $\mathbf{g}$, $(\mathbf{g})^{-1}$, and $\nabla\mathbf{g}$, respectively.[24] (Remarkably enough, with ${}^{\mathbf{g}}\nabla$ the covariant derivative associated to any regular metric tensor $\mathbf{g}$ we have ${}^{\mathbf{g}}\nabla\mathbf{g}=0$ in the sense of distributions.[6]) Hence, **Ric** and **G** are the distribution-valued Ricci and Einstein curvatures of $\mathbf{g}$.[24] It follows that the diagram (4), in which ${}^{\gamma}\mathbf{g}$ and $\mathbf{g}$ are the distribution valued metric tensors of the thick and thin domain wall space–times, respectively, holds in the sense of distributions.

Now, as follows from the distributional convergence (4) proved in Ref. 24 and the fact that the vectors (21)–(24) are all smooth vector fields independent of the wall's thickness, these are also Killing vectors of $(\mathbb{R}^4,\mathbf{g})$ in the sense that $\mathcal{L}_{\mathbf{v}}\mathbf{g}$ is the zero distribution on $\mathbb{R}^4$. As an example, consider the Killing vector given by (22). For (31) we have

$$\mathcal{L}_{\mathbf{v}_4}\mathbf{g}[\mathbf{U}] \equiv -\mathbf{g}[\mathcal{L}_{\mathbf{v}_4}\mathbf{U} + (\nabla\cdot\mathbf{V}_4)\mathbf{U}] = -\int_{\mathbb{R}^4}\mathbf{g}\cdot(\mathcal{L}_{\mathbf{v}_4}\mathbf{U} + \mathbf{U}(\nabla\cdot\mathbf{V}_4))\boldsymbol{\omega}_\eta = -\int_{x<0} e^{2\beta x}((\partial_t - \beta y\partial_y - \beta z\partial_z - 2\beta)(-U^{tt} + U^{xx}) + e^{2\beta t}(\partial_t - \beta y\partial_y - \beta z\partial_z)(U^{yy} + U^{zz}))\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z - \int_{x>0} e^{-2\beta x}((\partial_t - \beta y\partial_y - \beta z\partial_z - 2\beta)(-U^{tt} + U^{xx}) + e^{2\beta t}(\partial_t - \beta y\partial_y - \beta z\partial_z)(U^{yy} + U^{zz}))\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z = 0, \tag{35}$$

where we have integrated by parts and used the fact that **U** is of compact support.

Indeed, (21)–(24) are also improper Ricci collineations. For (32) and (22) we have

$$\mathcal{L}_{\mathbf{v}_4}\mathbf{Ric}[\mathbf{U}] \equiv -\mathbf{Ric}[\mathcal{L}_{\mathbf{v}_4}\mathbf{U} + (\nabla\cdot\mathbf{V}_4)\mathbf{U}] = -\beta\int_{x=0}((\partial_t - \beta y\partial_y - \beta z\partial_z - 2\beta)(2U^{tt} - 3U^{xx}) - 2e^{2\beta t}(\partial_t - \beta y\partial_y - \beta z\partial_z)(U^{yy} + U^{zz}))\mathrm{d}t\,\mathrm{d}y\,\mathrm{d}z = 0, \tag{36}$$

where in the last step we have integrated by parts and used again the fact that **U** is of compact support. Analogous computations show that

$$\mathcal{L}_{\mathbf{v}}\mathbf{Ric}[\mathbf{U}] = 0, \quad \mathcal{L}_{\mathbf{v}}\mathbf{G}[\mathbf{U}] = 0, \tag{37}$$

for all the Killing symmetries of (14), a result that obviously cannot be proved outside the distributional setting. It follows that for this space–time the diagram

$$\begin{array}{ccccc} \mathcal{L}_{\mathbf{v}}{}^{\gamma}\mathbf{g} = 0 & \longrightarrow & \mathcal{L}_{\mathbf{v}}{}^{\gamma}\mathbf{Ric} = 0 & \longrightarrow & \mathcal{L}_{\mathbf{v}}{}^{\gamma}\mathbf{G} = 0 \\ \downarrow_{\gamma\to 0} & & \downarrow_{\gamma\to 0} & & \downarrow_{\gamma\to 0} \\ \mathcal{L}_{\mathbf{v}}\mathbf{g} = 0 & \longrightarrow & \mathcal{L}_{\mathbf{v}}\mathbf{Ric} = 0 & \longrightarrow & \mathcal{L}_{\mathbf{v}}\mathbf{G} = 0 \end{array} \tag{38}$$

holds in the sense of distributions. Besides (21)–(24), there is no other C^∞ vector field for which (37) are satisfied. It should be noted that both diagrams, (4) and (38), hold under γ-dependent smooth diffeomorphisms, whenever in the limit $\gamma\to 0$ these remain bounded in order to avoid different identifications of points in the manifold under these diffeomorphisms.

Finally, it should be stressed that any smooth metric can be chosen as an auxiliary metric in (13). We have made the choice (27) for simplicity. In this sense, any C^∞ metric tensor field $\boldsymbol{\eta}$ whose Killing vectors are given by (21)–(24) is also a convenient choice for explicit calculations since in this case $\nabla\cdot\mathbf{V}=0$. Now, with ${}^{\mathbf{g}}\nabla$ the covariant derivative associated to **g**, we have ${}^{\mathbf{g}}\nabla\cdot\mathbf{V}=0$ for **g** given by (31) and **V** any of its Killing vector fields (21)–(24). However, (31) cannot be chosen as an auxiliary metric, since for **V** an arbitrary C^∞ vector field, $({}^{\mathbf{g}}\nabla\cdot\mathbf{V})$ turns out to be discontinuous at the surface $x=0$ and $({}^{\mathbf{g}}\nabla\cdot\mathbf{V})\mathbf{U}$ is not a test tensor field.

IV. A DOMAIN WALL EMBEDDED IN AN ANTI-DE SITTER SPACE–TIME

Consider the space–time $(\mathbb{R}^4, {}^{\gamma}\mathbf{g})$ where the metric tensor is given by

$${}^{\gamma}\mathbf{g} = \cosh^{-2\gamma}\frac{\beta x}{\gamma}(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z) + \mathbf{d}x\,\mathbf{d}x, \tag{39}$$

with β and γ constants and $\gamma>0$. This is a thick domain wall space–time, solution to the coupled Einstein-scalar field equations (15) and (16) with $\Lambda=-3\beta^2$ and

$$\phi = \phi_0\tan^{-1}(\sinh(\beta x/\gamma)), \quad \phi_0 \equiv \sqrt{\gamma/4\pi} \tag{40}$$

and

$$V(\phi) = \frac{1}{8\pi}\beta^2\left(3 + \frac{1}{\gamma}\right)\cos^2(\phi/\phi_0). \tag{41}$$

This space–time behaves asymptotically (i.e., far away of the wall) as an anti-de Sitter space–time[24] and its five-dimensional analogue provides a thick domain wall version[22] of the original Randall–Sundrum scenario.[13] Here, γ plays the role of the wall's thickness and the distributional $\gamma \to 0$ limit of this geometry has been analyzed in Ref. 24.

There are six Killing vector fields on $(\mathbb{R}^4, {}^{\gamma}\mathbf{g})$, given by

$$\mathbf{V}_1 = \boldsymbol{\partial}_y, \quad \mathbf{V}_2 = \boldsymbol{\partial}_z, \quad \mathbf{V}_3 = z\boldsymbol{\partial}_y - y\boldsymbol{\partial}_z, \tag{42}$$

$$\mathbf{V}_4 = \boldsymbol{\partial}_t, \quad \mathbf{V}_5 = t\boldsymbol{\partial}_y + y\boldsymbol{\partial}_t, \quad \mathbf{V}_6 = z\boldsymbol{\partial}_t + t\boldsymbol{\partial}_z, \tag{43}$$

where $\mathbf{V}_4$ is a time translation and $\mathbf{V}_5$, $\mathbf{V}_6$ are Lorentz rotations.

The Ricci and Einstein tensor fields of (39) are given by

$${}^{\gamma}\mathbf{Ric} = \Lambda \tanh^2\frac{\beta x}{\gamma}\,{}^{\gamma}\mathbf{g} + \frac{\beta^2}{\gamma}\cosh^{-2}\frac{\beta x}{\gamma}\left(\cosh^{-2\gamma}\frac{\beta x}{\gamma}(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z) + 3\,\mathbf{d}x\,\mathbf{d}x\right), \tag{44}$$

$${}^{\gamma}\mathbf{G} = -\Lambda \tanh^2\frac{\beta x}{\gamma}\,{}^{\gamma}\mathbf{g} - \frac{2\beta^2}{\gamma}\cosh^{-2(\gamma+1)}\frac{\beta x}{\gamma}(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z). \tag{45}$$

The distributional thin wall limits of (39), (44), and (45) are given by

$$\mathbf{g} \equiv \lim_{\gamma\to 0}\,{}^{\gamma}\mathbf{g} = (\Theta_x^- e^{2\beta x} + \Theta_x^+ e^{-2\beta x})(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z) + \mathbf{d}x\,\mathbf{d}x, \tag{46}$$

$$\mathbf{Ric} \equiv \lim_{\gamma\to 0}\,{}^{\gamma}\mathbf{Ric} = \Lambda\mathbf{g} + 2\beta\delta_0(-\mathbf{d}t\,\mathbf{d}t + 3\,\mathbf{d}x\,\mathbf{d}x + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z), \tag{47}$$

$$\mathbf{G} + \mathbf{g}\Lambda \equiv \lim_{\gamma\to 0}\left({}^{\gamma}\mathbf{G} + {}^{\gamma}\mathbf{g}\Lambda\right) = 4\beta\delta_0(\mathbf{d}t\,\mathbf{d}t - \mathbf{d}y\,\mathbf{d}y - \mathbf{d}z\,\mathbf{d}z), \tag{48}$$

where **Ric** and **G** are the distribution-valued Ricci and Einstein curvatures of **g**.[24] The diagram (4), in which ${}^{\gamma}\mathbf{g}$ and **g** are given by (39) and (46), respectively, holds in the sense of distributions.

Note that **g** is piecewise smooth and that the pullback of **g** to the surface $x=0$ is the same from both sides of this surface. Note also that the six vector fields (42) and (43) are also Killing vectors on the $(2+1)$-dimensional Minkowski space–time $(\mathbb{R}^3, \overline{\mathbf{g}})$ with $\overline{\mathbf{g}}$ the Minkowski metric which appears as this pullback.

Next, let $\boldsymbol{\eta}$ be the Minkowski metric tensor (27) and let ∇ be the Levi–Civita covariant derivative associated with $\boldsymbol{\eta}$. Let **U** be a test 2-tensor field on $\mathbb{R}^4$. From (13), it is straightforward to verify that for the vector fields given by (42) and (43), we have

$$\mathcal{L}_{\mathbf{v}}\,{}^{\gamma}\mathbf{g}[\mathbf{U}] = 0, \quad \mathcal{L}_{\mathbf{v}}\mathbf{g}[\mathbf{U}] = 0, \tag{49}$$

as expected. Hence, (42) and (43) are Killing vectors of $(\mathbb{R}^4, \mathbf{g})$ in the sense that $\mathcal{L}_{\mathbf{v}}\mathbf{g}$ along these vectors is the zero distribution on $\mathbb{R}^4$. Analogous computations show that

$$\mathcal{L}_{\mathbf{v}}\,{}^{\gamma}\mathbf{Ric}[\mathbf{U}] = 0, \quad \mathcal{L}_{\mathbf{v}}\,{}^{\gamma}\mathbf{G}[\mathbf{U}] = 0 \tag{50}$$

and

$$\mathcal{L}_{\mathbf{v}}\,\mathbf{Ric}[\mathbf{U}] = 0, \quad \mathcal{L}_{\mathbf{v}}\mathbf{G}[\mathbf{U}] = 0. \tag{51}$$

It follows that for this space–time the diagram (38) holds in the sense of distributions. Besides (42) and (43), there is no other C^∞ vector field for which (50) and (51) are satisfied on $\mathbb{R}^4$.

Next, let $\mathcal{M}^+ \equiv \{(t,x,y,z) \in \mathbb{R}^4, x>0\}$ and let $\mathbf{U}^+$ be a test tensor of compact support $\mathcal{K} \subset \mathcal{M}^+$. From (12) we find that

$$\mathcal{L}_{\mathbf{v}}\mathbf{g}[\mathbf{U}^+] = 0 \tag{52}$$

is satisfied along the C^∞ vector fields on $\mathbb{R}^4$ given by

$$\mathbf{V}_7 = \boldsymbol{\partial}_x + \beta(t\boldsymbol{\partial}_t + y\boldsymbol{\partial}_y + z\boldsymbol{\partial}_z), \tag{53}$$

$$\mathbf{V}_8 = \beta t\mathbf{V}_7 + \left(\tfrac{1}{2}\beta^2(-t^2+y^2+z^2) + \tfrac{1}{8}e^{2\beta x}\right)\boldsymbol{\partial}_t, \tag{54}$$

$$\mathbf{V}_9 = \beta y\mathbf{V}_7 - \left(\tfrac{1}{2}\beta^2(-t^2+y^2+z^2) + \tfrac{1}{8}e^{2\beta x}\right)\boldsymbol{\partial}_y, \tag{55}$$

$$\mathbf{V}_{10} = \beta z\mathbf{V}_7 - \left(\tfrac{1}{2}\beta^2(-t^2+y^2+z^2) + \tfrac{1}{8}e^{2\beta x}\right)\boldsymbol{\partial}_z. \tag{56}$$

It follows that $\mathcal{L}_{\mathbf{v}}\mathbf{g}$ is the zero distribution on $\mathcal{M}^+$, along these vector fields.

Now, let $\mathbf{U}$ be a test tensor on $\mathbb{R}^4$ and let us consider the Lie derivatives (in the sense of distributions) of (39) and (46) along the vector fields (53)–(56). Since ${}^\gamma\mathbf{g}$ and $\nabla{}^\gamma\mathbf{g}$ converge locally to $\mathbf{g}$ and $\nabla\mathbf{g}$ for $\gamma\to 0$,[24] it follows directly that $\mathcal{L}_{\mathbf{v}}{}^\gamma\mathbf{g}$ also converge locally to $\mathcal{L}_{\mathbf{v}}\mathbf{g}$ along the smooth vector fields (53)–(56). Thus, for $\mathbf{V}_7$ we have

$$\mathcal{L}_{\mathbf{V}_7}{}^\gamma\mathbf{g} = 2\beta\cosh^{-2\gamma}\frac{\beta x}{\gamma}\left(1-\tanh\frac{\beta x}{\gamma}\right)(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z), \tag{57}$$

$$\mathcal{L}_{\mathbf{V}_7}\mathbf{g} = \Theta_x^-\, 4\beta e^{2\beta x}(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z), \tag{58}$$

that satisfy

$$\lim_{\gamma\to 0}\mathcal{L}_{\mathbf{V}_7}{}^\gamma\mathbf{g}[\mathbf{U}] = \mathcal{L}_{\mathbf{V}_7}\mathbf{g}[\mathbf{U}]. \tag{59}$$

The fact that $\mathcal{L}_{\mathbf{v}_7}\mathbf{g}$ is the zero distribution on $\mathcal{M}^+$ may be interpreted naturally as a Killing symmetry of $\mathbf{g}$ on $\mathcal{M}^+$ generated by $\mathbf{V}_7$. Since this symmetry arises in the limit $\gamma\to 0$ of ${}^\gamma\mathbf{g}$, $\mathbf{V}_7$ is an *asymptotic* Killing vector field on $(\mathbb{R}^4, {}^\gamma\mathbf{g})$. The same considerations holds for the other C^∞ vector fields (54)–(56). Further, since $(\mathbb{R}^4, \mathbf{g})$ is reflection symmetric along the direction perpendicular to the wall, a symmetry inherited from $(\mathbb{R}^4, {}^\gamma\mathbf{g})$, the above considerations can be extended to $\mathcal{M}^- \equiv \{(t,x,y,z) \in \mathbb{R}^4, x<0\}$ under the replacement $x\to -x$. Indeed, these results are by no means unexpected, they simply put in a rigorous setting the emergence of additional symmetries in the $\gamma\to 0$ limit of the space–time $(\mathbb{R}^4, {}^\gamma\mathbf{g})$, where we have an absolute control over what is going on.

For the sake of completeness, let us analyze the action of $\mathcal{L}_{\mathbf{v}}$ on the distribution-valued curvature tensors of the metric (46) along the vector fields (53)–(56). Let us consider again the vector field $\mathbf{V}_7$. We find

$$\mathcal{L}_{\mathbf{V}_7}\mathbf{Ric} = 2\beta(\delta_0' - 2\beta\delta_0)(-\mathbf{d}t\,\mathbf{d}t + 3\,\mathbf{d}x\,\mathbf{d}x + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z) - \Theta_x^-\, 12\beta^3 e^{2\beta x}(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z) \tag{60}$$

and

$$\mathcal{L}_{\mathbf{V}_7}(8\pi\mathbf{T}) \equiv \mathcal{L}_{\mathbf{V}_7}(\mathbf{G}+\Lambda\mathbf{g}) = 4\beta(\delta_0' + 2\beta\delta_0)(-\,\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z). \tag{61}$$

Indeed, $\mathbf{V}_7$ is neither a Ricci collineation nor a matter collineation and the same conclusion extends to the vector fields (54)–(56). In particular, this shows explicitly that the distributional energy momentum tensor of the brane does not inherit all the symmetries of the bulk.

V. AN ASYMMETRIC DOMAIN WALL SPACE–TIME

Let us now to consider the space–time $(\mathbb{R}^4, {}^{\gamma}\mathbf{g})$ where the C^∞ metric tensor ${}^{\gamma}\mathbf{g}$ is given by

$${}^{\gamma}\mathbf{g} = \cosh^{-2\gamma/3}\frac{\beta x}{\gamma}e^{-4\beta x/3}(-\,\mathbf{d}t\,\mathbf{d}t + e^{2\beta x}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)) + \cosh^{-2\gamma}\frac{\beta x}{\gamma}\mathbf{d}x\,\mathbf{d}x, \tag{62}$$

with β and γ constants and $0<\gamma<1$. This represents a two-parameter family of plane symmetric static domain wall space–times in which the reflection symmetry along the direction perpendicular to the wall has been relaxed, being asymptotically (i.e., far away of the wall) flat for $x>0$ and behaving asymptotically as the Taub space–time for $x<0$.[20] The metric (62) is solution to the coupled Einstein-scalar field equations (15) and (16) with $\Lambda=0$ and

$$\phi = \phi_0 \tan^{-1}(\sinh(\beta x/\gamma), \quad \phi_0 \equiv \tfrac{1}{6}\sqrt{3\gamma(1-\gamma)/\pi} \tag{63}$$

and

$$V(\phi) = \frac{1}{24\pi}\beta^2\frac{1}{\gamma}\cos^{2(1-\gamma)}(\phi/\phi_0), \tag{64}$$

where γ plays the role of the wall's thickness. The distributional $\gamma\to 0$ limit of this geometry has been analyzed in Ref. 25. It should be noted that (62) does not inherit the Z_2 symmetry of $V(\phi)$, a fact that makes very interesting the analysis of the symmetries of this space–time.

The Ricci and Einstein tensor fields of (62) are given by

$${}^{\gamma}\mathbf{Ric} = \frac{\beta^2}{3\gamma}\left(\cosh\frac{\beta x}{\gamma}\right)^{-2(1-2\gamma/3)}(-\,e^{-4\beta x/3}\,\mathbf{d}t\,\mathbf{d}t + e^{2\beta x/3}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)) + \frac{\beta^2}{3\gamma}(3 - 2\gamma)\cosh^{-2}\frac{\beta x}{\gamma}\mathbf{d}x\,\mathbf{d}x, \tag{65}$$

$${}^{\gamma}\mathbf{G} = \frac{\beta^2}{3\gamma}\left(\cosh\frac{\beta x}{\gamma}\right)^{-2(1-2\gamma/3)}(2-\gamma)(e^{-4\beta x/3}\,\mathbf{d}t\,\mathbf{d}t - e^{2\beta x/3}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)) - \frac{\beta^2}{3}\cosh^{-2}\frac{\beta x}{\gamma}\mathbf{d}x\,\mathbf{d}x, \tag{66}$$

and the distributional thin wall limits of (62), (65), and (66) are given by[25]

$$\mathbf{g} \equiv \lim_{\gamma\to 0}{}^{\gamma}\mathbf{g} = \Theta_x^-(-\,e^{-2\beta x/3}\,\mathbf{d}t\,\mathbf{d}t + e^{2\beta x}\,\mathbf{d}x\,\mathbf{d}x + e^{4\beta x/3}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)) + \Theta_x^+(-\,e^{-2\beta x}\,\mathbf{d}t\,\mathbf{d}t + e^{-2\beta x}\,\mathbf{d}x\,\mathbf{d}x + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z), \tag{67}$$

$$\mathbf{Ric} \equiv \lim_{\gamma\to 0}{}^{\gamma}\mathbf{Ric} = \tfrac{1}{3}\beta\delta_0(-\,\mathbf{d}t\,\mathbf{d}t + 3\,\mathbf{d}x\,\mathbf{d}x + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z), \tag{68}$$

$$\mathbf{G} \equiv \lim_{\gamma\to 0}{}^{\gamma}\mathbf{G} = \tfrac{2}{3}\beta\delta_0(\mathbf{d}t\,\mathbf{d}t - \mathbf{d}y\,\mathbf{d}y - \mathbf{d}z\,\mathbf{d}z). \tag{69}$$

Note that $\mathbf{g}$ is piecewise smooth and that the pullback of $\mathbf{g}$ to the surface $x=0$ is the same from both sides and coincides with the ordinary $(2+1)$-dimensional Minkowski metric. Like its smoothed version (62), $\mathbf{g}$ is not reflection symmetric along the coordinate perpendicular to the

wall. The space–time $(\mathbb{R}^4, \mathbf{g})$ for $x>0$ is isometric to the ordinary $(3+1)$-dimensional Minkowski space–time, while for $x<0$ it is the Taub space–time.[20,25]

There are only four independent Killing vector fields on $(\mathbb{R}^4, {}^{\gamma}\mathbf{g})$ and these are given by

$$\mathbf{V}_1 = \boldsymbol{\partial}_y, \quad \mathbf{V}_2 = \boldsymbol{\partial}_z, \quad \mathbf{V}_3 = z\boldsymbol{\partial}_y - y\boldsymbol{\partial}_z, \quad \mathbf{V}_4 = \boldsymbol{\partial}_t. \tag{70}$$

Let ∇ be the derivative operator in the ordinary Minkowski metric tensor (27). Let $\mathbf{U}$ be a test 2-tensor field on $\mathbb{R}^4$. From (13) it is straightforward to show that the four vectors given in (70) generate also isometries of (67) and are improper collineations for the distributional Ricci and Einstein curvature tensors. It follows that for this space–time the diagram (38) holds in the sense of distributions.

Next, consider the C^∞ vector fields given by

$$\mathbf{V}_5 = t\boldsymbol{\partial}_y + y\boldsymbol{\partial}_t, \quad \mathbf{V}_6 = z\boldsymbol{\partial}_t + t\boldsymbol{\partial}_z. \tag{71}$$

We have

$$\mathcal{L}_{\mathbf{V}_5}\mathbf{g}[\mathbf{U}] \equiv -\mathbf{g}[\mathcal{L}_{\mathbf{V}_5}\mathbf{U} + (\nabla\cdot\mathbf{V}_5)\mathbf{U}] = -\int_{\mathbb{R}^4} \mathbf{g}\cdot(\mathcal{L}_{\mathbf{V}_5}\mathbf{U} + \mathbf{U}(\nabla\cdot\mathbf{V}_5))\boldsymbol{\omega}_\eta = -\int_{x<0} (e^{-2\beta x/3} - e^{4\beta x/3})$$
$$\times (U^{ty} + U^{yt})\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z - \int_{x>0} (e^{-2\beta x} - 1)(U^{ty} + U^{yt})\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}y\,\mathrm{d}z, \tag{72}$$

where we have integrated by parts and used the fact that $\mathbf{U}$ is of compact support. It follows

$$\mathcal{L}_{\mathbf{V}_5}\mathbf{g} = 2(\Theta_x^- e^{\beta x/3} + \Theta_x^+ e^{-\beta x})\sinh\beta x(\mathbf{d}t\,\mathbf{d}y + \mathbf{d}y\,\mathbf{d}t). \tag{73}$$

On the other hand, as can be guessed from the explicit form of **Ric**, we have

$$\mathcal{L}_{\mathbf{V}_5}\mathbf{Ric}[\mathbf{U}] \equiv -\mathbf{Ric}[\mathcal{L}_{\mathbf{V}_5}\mathbf{U} + (\nabla\cdot\mathbf{V}_5)\mathbf{U}]$$
$$= -\frac{1}{3}\beta\int_{x=0} (y\partial_t + t\partial_y)(U^{tt} + 3U^{xx} + U^{yy} + U^{zz})\mathrm{d}t\,\mathrm{d}y\,\mathrm{d}z = 0, \tag{74}$$

where in the last step we have integrated by parts and used again the fact that $\mathbf{U}$ is of compact support. Analogous computations show that

$$\mathcal{L}_{\mathbf{V}_6}\mathbf{g} = 2(\Theta_x^- e^{\beta x/3} + \Theta_x^+ e^{-\beta x})\sinh\beta x(\mathbf{d}t\,\mathbf{d}z + \mathbf{d}z\,\mathbf{d}t), \tag{75}$$

$$\mathcal{L}_{\mathbf{V}_6}\mathbf{Ric} = 0. \tag{76}$$

Hence, although V_5 and V_6 are not Killing vectors of $(\mathbb{R}^4, \mathbf{g})$, they are Ricci collineations. Further,

$$\mathcal{L}_{\mathbf{V}_5}\mathbf{G} = 0, \quad \mathcal{L}_{\mathbf{V}_6}\mathbf{G} = 0, \tag{77}$$

and V_5 and V_6 are also Einstein collineations. Indeed, the above expressions should be understood in the sense of distributions. Besides (70) and (71), there is no other C^∞ vector field that generates symmetries of **Ric** and **G**.

It should be noted that $\mathcal{L}_{\mathbf{v}_5}\mathbf{g}$ and $\mathcal{L}_{\mathbf{v}_6}\mathbf{g}$ are piecewise smooth and that the pullbacks of $\mathcal{L}_{\mathbf{v}_5}\mathbf{g}$ and $\mathcal{L}_{\mathbf{v}_6}\mathbf{g}$ to the surface $x=0$ are the same from both sides of the wall and vanish. It follows that the symmetries of the distribution-valued curvature tensors **Ric** and **G** (which are supported on the surface $x=0$) coincide with the Killing symmetries of the pullback of $\mathbf{g}$ to this surface. For the sake of completeness, let us show that the same result is also reached within the standard thin shell formalism.[7,31] For $(\mathbb{R}^4, \mathbf{g})$ with $\mathbf{g}$ given by (67), the pullback $\overline{\mathbf{g}}$ of $\mathbf{g}$ to the surface $x=0$ is the same from both sides and is given by

$$\overline{\mathbf{g}} = (-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z). \tag{78}$$

The extrinsic curvature tensor $\mathbf{K}$ of the surfaces $x=x_0$ as submanifolds of $(\mathbb{R}^4,\mathbf{g})$, is the C^∞ regularly discontinuous tensor across the surface $x=0$ given by

$$\mathbf{K} = -\tfrac{1}{3}\beta\Theta_x^-(e^{-2\beta x_0/3}\,\mathbf{d}t\,\mathbf{d}t + 2e^{-4\beta x_0/3}(\mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z)) - \beta\Theta_x^+ e^{-2\beta x_0}\,\mathbf{d}t\,\mathbf{d}t. \tag{79}$$

Thus, the discontinuity $[[\mathbf{K}]] \equiv \mathbf{K}|_{x_0=0^+} - \mathbf{K}|_{x_0=0^-}$ of $\mathbf{K}$ across the surface $x=0$, which is declared as a purely intrinsic property of this surface, is the ordinary C^∞ tensor field defined on the surface $x=0$ given by

$$[[\mathbf{K}]] = \tfrac{2}{3}\beta(-\mathbf{d}t\,\mathbf{d}t + \mathbf{d}y\,\mathbf{d}y + \mathbf{d}z\,\mathbf{d}z). \tag{80}$$

Therefore, the symmetries of $[[\mathbf{K}]]$ are the symmetries of the pullback $\overline{\mathbf{g}}$ of $\mathbf{g}$ to the surface $x=0$. Now, we have

$$\mathbf{Ric} = \tfrac{1}{2}\delta_0([[\mathbf{K}]] + (\overline{\mathbf{g}}^{-1}\cdot[[\mathbf{K}]])\mathbf{d}x\,\mathbf{d}x), \tag{81}$$

from which it follows that the symmetries of the distributional Ricci tensor of $\mathbf{g}$ turns out to be the Killing symmetries of the induced metric $\overline{\mathbf{g}}$ on the surface $x=0$ where the 2-brane is localized. It should be noted that this is not an example of the well known (trivial) symmetry inheritance. Although, the pullback $\overline{\mathbf{g}}$ of $\mathbf{g}$ to the surface $x=0$ acts a metric on this surface (as follows from the fact that the surface $x=0$ has a well-defined intrinsic geometry) and therefore the Killing vectors of this pullback are naturally collineations of the curvature tensors of this pullback, **Ric** given by (68) or (81) is not the Ricci tensor of $\overline{\mathbf{g}}$. The same conclusions can be extended also to all the thin domain wall geometries considered in the preceding sections.

Remarkably enough, the asymmetric geometry considered here, explicitly shows that the Killing symmetries of the pullback of the metric tensor to the surface where the thin wall is localized may form a larger group than the group of Killing symmetries which are common to the ambient space–time on both sides of the wall.

VI. SUMMARY AND DISCUSSION

In this work, by generalizing the Lie derivative of smooth tensor fields to distribution-valued tensors, we defined and computed the Killing symmetries and the Ricci and Einstein collineations of some distributional domain wall geometries for which the diagram (4), with ${}^\gamma\mathbf{g}$ and $\mathbf{g}$ the distribution valued metric tensors of the thick and thin domain wall space–times, respectively, holds rigourously in the sense of distributions. For all the geometries considered, the distribution-valued curvature tensors of the thin wall limit have singular parts proportional to a Dirac distribution supported on the surface Σ where the thin wall is localized. We found that the Killing symmetries of the distributional geometry of the thin wall space–time $(\mathbb{R}^4,\mathbf{g})$ are the Killing symmetries of the smooth thick domain wall space–time $(\mathbb{R}^4,{}^\gamma\mathbf{g})$ and that, besides these, there are no other isometries. However, as expected, the thin wall geometry may show additional symmetries on the open disjoint sets $\mathcal{M}^+$ and $\mathcal{M}^-$, that admit Σ as a boundary, which are not isometries inherited from the corresponding smooth geometry. These symmetries are the asymptotic (i.e., far away of the wall) Killing symmetries of $(\mathbb{R}^4,{}^\gamma\mathbf{g})$.

For the thin domain walls with reflection symmetry of Secs. III and IV, the Killing vectors of $(\mathbb{R}^4,\mathbf{g})$ are the only symmetries of the corresponding distribution-valued Ricci and Einstein tensors. Therefore the Ricci and Einstein collineations of these thin wall geometries are improper. For the asymmetric thin domain wall of Sec. V, we found that the collineations of the distributional Ricci and Einstein tensors form a larger group than the one formed by the Killing symmetries of the corresponding space–time $(\mathbb{R}^4,\mathbf{g})$. The additional symmetries are then proper Ricci and Einstein collineations. Finally, for all the thin wall space–times $(\mathbb{R}^4,\mathbf{g})$ considered, the symmetries of the distributional curvature tensors turns out to be the Killing symmetries of $(\Sigma,\overline{\mathbf{g}})$, where $\overline{\mathbf{g}}$ is the pullback of $\mathbf{g}$ to Σ.

Although we have restricted ourselves to consider four-dimensional domain wall space–times, these models are straightforwardly generalized to D-dimensional domain wall space–times.[25] On the other hand, the analysis presented here can be carried out, in principle, for all the distribution-valued curvature tensors of a space–time $(\mathcal{M},\mathbf{g})$, whenever the distribution-valued metric tensor $\mathbf{g}$ is a regular metric in the sense of Ref. 6. This generalization and its implications will be discussed in a forthcoming paper.

(Received 3 August 2004; accepted 15 October 2004; published online 11 February 2005)

Among the many families of nonperiodic tilings known so far, SCD tilings are still a bit mysterious. Here, we determine the diffraction spectra of point sets derived from SCD tilings and show that they have no absolutely continuous part, that they have a uniformly discrete pure point part on the axis $\mathbb{R}\boldsymbol{e}_3$, and that they are otherwise supported on a set of concentric cylinder surfaces around this axis. For SCD tilings with additional properties, more detailed results are given. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1842355]

I. THE TILINGS

After the discovery of families of tiles that permit only aperiodic tilings, the question arose whether there exists a single tile that permits *only* aperiodic tilings by copies of itself (an *aperiodic prototile*). A first example, which gives tilings in Euclidean 3-space, was found by Schmitt in 1988. It was elaborated later by Conway and Danzer (cf. Ref. 7). In particular, they modified Schmitt's prototile to a convex one. We refer to these tilings—which will be described in this section—as SCD tilings.

A *tiling* in $\mathbb{R}^d$ is a collection of tiles $\{T_n\}_{n\geqslant 0}$ which covers $\mathbb{R}^d$ and contains no overlapping tiles, i.e., $\mathrm{int}(T_k)\cap\mathrm{int}(T_n)=\varnothing$ for $k\neq n$. A *tile* is a nonempty compact set $T\subset\mathbb{R}^d$ with the property that $\mathrm{cl}(\mathrm{int}(T))=T$. A tiling $\mathcal{T}$ is called *aperiodic*, if $\mathcal{T}+\boldsymbol{x}=\mathcal{T}$ implies $\boldsymbol{x}=\boldsymbol{0}$.

The SCD tilings are built from a single kind of tile—a single *prototile*—which we refer to as *SCD tile*. Essentially, the main idea is that the only possible tilings are of the following form: The tiles can be put together to form layers, which extend in two dimensions; these layers can be stacked, but only in such a way that two consecutive layers are rotated against each other by a fixed angle, which may be incommensurate to π. Then, the symmetry groups of the resulting tilings may still be nontrivial, even infinite, but they contain no translation. To achieve this, we allow only directly congruent copies of the tiles, but no mirror images (cf. Sec. III).

The SCD tile: Choose $0<\lambda<1$, and positive real numbers b_1, b_2, c. Let $\varphi=\arctan(b_1/b_2)$, set $a=\sqrt{b_1^2+b_2^2}$, and

$$\boldsymbol{a}=(a,0,0),\quad \boldsymbol{b}=(b_1,b_2,0),\quad \boldsymbol{c}=\lambda\boldsymbol{b}+(0,0,c),\quad \boldsymbol{d}=\lambda\boldsymbol{a}-(0,0,c),$$

(cf. Fig. 1). Now, we define the SCD tile as

$$T=\mathrm{conv}(\boldsymbol{0},\boldsymbol{a},\boldsymbol{b},\boldsymbol{a}+\boldsymbol{b},\boldsymbol{c},\boldsymbol{a}+\boldsymbol{c},\boldsymbol{d},\boldsymbol{b}+\boldsymbol{d}), \tag{1}$$

where $\mathrm{conv}(M)$ denotes the convex hull of M. The result is the union of the two triangular prisms $\mathrm{conv}(\boldsymbol{0},\boldsymbol{a},\boldsymbol{b},\boldsymbol{a}+\boldsymbol{b},\boldsymbol{c},\boldsymbol{a}+\boldsymbol{c})$ and $\mathrm{conv}(\boldsymbol{0},\boldsymbol{a},\boldsymbol{b},\boldsymbol{a}+\boldsymbol{b},\boldsymbol{d},\boldsymbol{b}+\boldsymbol{d})$, glued together at the rhomb-shaped

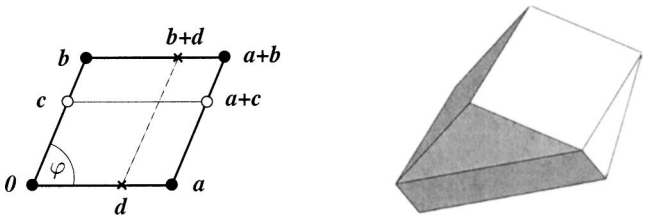

FIG. 1. The construction of an SCD tile (left) and a view of an SCD tile (right).

facet conv($\mathbf{0},\boldsymbol{a},\boldsymbol{b},\boldsymbol{a}+\boldsymbol{b}$). This is the reason that it is sometimes called Conway's biprism. If $\varphi \notin \pi\mathbb{Q}$, we will call the SCD tile *incommensurate* (which is the classical case), otherwise *commensurate*.

We should mention that this is only one possible construction. Several generalizations or variations are possible (cf. Sec. III or Ref. 7). But all these tiles give rise to tilings with basically the same structure.

The SCD tilings: Using translations of the SCD tile, one can put them together (i) by joining triangular facets conv($\mathbf{0},\boldsymbol{b},\boldsymbol{c}$) with conv($\boldsymbol{a},\boldsymbol{a}+\boldsymbol{b},\boldsymbol{a}+\boldsymbol{c}$), and (ii) by joining triangular facets conv($\mathbf{0},\boldsymbol{a},\boldsymbol{d}$) with conv($\boldsymbol{b},\boldsymbol{b}+\boldsymbol{a},\boldsymbol{b}+\boldsymbol{d}$). If we do so inductively until no triangular facet remains uncovered, we end up with a planar layer covering a two-dimensional plane.

This layer is congruent to $L=\{\boldsymbol{x}+T \,|\, \boldsymbol{x}\in\Gamma\}$, where Γ is the two-dimensional point lattice spanned by $\boldsymbol{a}$ and $\boldsymbol{b}$, i.e., $\Gamma=\mathbb{Z}\boldsymbol{a}+\mathbb{Z}\boldsymbol{b}$. The top of L shows ridges and valleys, all parallel to each other, and all parallel to $\boldsymbol{b}$. The bottom of L also shows "down under" (or upside down) valleys and ridges, all of them parallel to $\boldsymbol{a}$. In order to stack the layers, consider a layer $L'=L-\boldsymbol{c}$. Take a second layer $L''=(0,0,c)+RL'$, where R is a rotation through $-\varphi$ around the axis $\mathbb{R}\boldsymbol{e}_3=\langle(0,0,1)\rangle_{\mathbb{R}}$. L'' fits exactly on top of L'. In the same fashion, we proceed stacking layers and obtain

$$\mathcal{T}=\bigcup_{m\in\mathbb{Z}} m(0,0,c)+R^m L', \tag{2}$$

which is a tiling of $\mathbb{R}^3$. There are many other possibilities to build SCD tilings. For example, two consecutive layers can be shifted against each other by an arbitrary translation in the direction of $R^m\boldsymbol{b}$, which is the direction of the matching valleys and ridges of the two layers. Let us mention that Danzer's version restricts these translations to a discrete set $\mathbb{Z}R^m\boldsymbol{b}$ in order to allow crystallographic applications. Therefore, "SC tilings" might be a better notation for the more general tilings we consider here. Nevertheless, we will stick to the well-known notation of SCD tilings throughout this paper, holding in mind that the SCD tilings in Ref. 7 are a proper subset of the SCD tilings here. In this sense, all possible SCD tilings are congruent to

$$\mathcal{T}=\bigcup_{m\in\mathbb{Z}} m(0,0,c)+\boldsymbol{v}_m+R^m L', \tag{3}$$

for some $\boldsymbol{v}_m=(v_1^{(m)},v_2^{(m)},0)$, where $\boldsymbol{v}_{m+1}-\boldsymbol{v}_m$ is a (real) multiple of $R^m\boldsymbol{b}$. For a more thorough discussion of all possible SCD tilings, see Sec. III or Ref. 7.

As with tiles, we will distinguish between *incommensurate* SCD tilings, if they are built from incommensurate SCD tiles, and *commensurate* SCD tilings otherwise. Now, it is easy to see that incommensurate SCD tilings are aperiodic: Since $\varphi\notin\pi\mathbb{Q}$, all layers $m(0,0,c)+\boldsymbol{v}_m+R^mL$ have pairwise different orientations. Consequently, a possible translation $\boldsymbol{x}$ with $\mathcal{T}+\boldsymbol{x}=\mathcal{T}$ must map every layer onto itself. The translation vectors that fix the mth layer $m(0,0,c)+\boldsymbol{v}_m+R^mL$ are those in $R^m\Gamma$. So, the translation vectors which fix the whole tiling are elements of

$$\bigcap_{m\in\mathbb{Z}} R^m\Gamma=\{0\},$$

wherefore all incommensurate SCD tilings are aperiodic.

Note that even in the incommensurate case *finitely* many layers could still possess nontrivial translation symmetries, as two layers might still share a so-called coincidence site lattice Γ' of finite index in Γ. Then, any finite number of layers still may admit one, where the index grows with the number of layers. In the limit of infinitely many layers, only the trivial translation survives, hence the final incommensurate SCD tiling is aperiodic, compare Ref. 7 for details.

II. THE DIFFRACTION SPECTRUM

Since the discovery of quasicrystals, a central point in the study of tilings is the diffraction behavior of tilings or point sets (cf. Ref. 16). With point sets, one can model the structure of quasicrystals quite well, e.g., by representing every atom by a point. But many interesting structures were originally described in terms of tilings. The usual way to examine the diffraction behavior of such structures is to replace every tile by one (or more) reference points, in a way that the tiling and the point set determine each other uniquely by local rules (i.e., they are "mutually locally derivable," cf. Refs. 1 and 3), and then to determine the diffraction behavior of the resulting point set. In this sense, *crystallographic* tilings in $\mathbb{R}^d$—i.e., tilings which permit d linearly independent translations—correspond to crystallographic point sets, which again model ideal crystals. These show a sharp diffraction spectrum consisting of bright spots only, the "Bragg peaks," located on a uniformly discrete point set, compare Refs. 6 and 9.

The Fourier transform of structures like tilings or point sets (this will be made precise below) gives a desription of their diffraction behavior. For example, the diffraction spectrum of quasiperiodic point sets, corresponding to physical quasicrystals (cf. Ref. 9), consists of Bragg peaks only, but their positions need not be discrete. In general, any diffraction spectrum, described in terms of a positive measure μ, consists of three (unique) parts,

$$\mu = \mu_{pp} + \mu_{sc} + \mu_{ac},$$

compare Ref. 2 for examples and further references. The *pure point* part $\mu_{pp} = \Sigma_{\boldsymbol{x} \in \Lambda} I(\boldsymbol{x}) \delta_{\boldsymbol{x}}$ is the sum of weighted Dirac measures (the so-called Bragg peaks) over a countable set Λ, where $\delta_{\boldsymbol{x}}$ is the normalized point measure at $\boldsymbol{x}$ [i.e., $\delta_{\boldsymbol{x}}(M) = 1$, if $\boldsymbol{x} \in M$, and $\delta_{\boldsymbol{x}}(M) = 0$ otherwise] and $I(\boldsymbol{x})$ denotes the intensity. The *singular continuous* part μ_{sc} satisfies $\mu_{sc}(\{\boldsymbol{x}\}) = 0$ for all $\boldsymbol{x}$, but is supported (or concentrated) on a set of Lebesgue measure zero. The *absolutely continuous* part μ_{ac} corresponds to a measure with a locally integrable density function and is supported on a set of positive Lebesgue measure. The diffraction spectrum μ of a structure is called *singular*, if μ_{ac} vanishes. It is called *pure point*, if μ_{ac} and μ_{sc} vanish; i.e., if it consists of Bragg peaks only. For example, the latter case occurs if the considered structure is a *model set* (cf. Ref. 10). In this case, there is a rich theory one may use to examine the diffraction spectrum. In this paper, however, we leave the realm of pure point diffractive structures and have to use different methods.

This section makes use of the calculus of tempered distributions, also known as generalized functions (compare Refs. 4, 13, and 15). In particular, this allows for a unified treatment of functions and measures. The following common notations are used: $\mathcal{S}(\mathbb{R}^d)$ denotes the Schwartz space of rapidly decreasing functions on $\mathbb{R}^d$. The function $\widetilde{f}$ is given by $\widetilde{f}(x) = \overline{f(-x)}$. The Fourier transform of f is denoted by $\hat{f}$. The tempered distributions, $\mathcal{S}'$, are the continuous linear functionals on $\mathcal{S}(\mathbb{R}^d)$. For $T \in \mathcal{S}'$ and $\varphi \in \mathcal{S}(\mathbb{R}^d)$, we will often write $\langle T, \varphi \rangle$ instead of $T(\varphi)$. As described above, one now constructs an *SCD set* Λ_{SCD} from an SCD tiling and determines the diffraction spectrum of Λ_{SCD}, taking up and extending previous work in this direction.[7,12] To do so, choose a point $\boldsymbol{z}$ in the interior of the SCD tile T in (1), choose an SCD tiling $\mathcal{T}$ and set

$$\Lambda := \Lambda_{\mathrm{SCD}} := \{\boldsymbol{v} + R^m \boldsymbol{z} | (\boldsymbol{v} + R^m T) \in \mathcal{T}\},$$

i.e., replace every tile $\boldsymbol{v} + R^m T$ by the corresponding reference point $\boldsymbol{v} + R^m \boldsymbol{z}$. Obviously, Λ consists of layers which are congruent to the lattice Γ. Now, define the measure

$$\omega := \omega_{\mathrm{SCD}} := \sum_{x\in\Lambda} \delta_x .$$

Let $C_r=[-r/2,r/2]^3$ be the closed cube of side length r centered at the origin. The diffraction spectrum of Λ is described by the Fourier transform $\hat{\gamma}$ of the autocorrelation

$$\gamma = \lim_{r\to\infty} r^{-3} \sum_{x,y\in\Lambda\cap C_r} \delta_{x-y},$$

where the limit of these measures is taken in the vague topology. *A priori*, it is not clear whether this limit exists. But since the considered measures are translation bounded, there is at least one convergent subsequence [Ref. 9, Proposition 2.2]. In this case, we restrict to this convergent subsequence. If there is more than one convergent subsequence, we consider each one separately. This way, we can now always assume that γ exists as a tempered measure.

Let $\omega_r=\Sigma_{x\in\Lambda\cap C_r}\delta_x$. Then,

$$\gamma = \lim_{r\to\infty} r^{-3}\omega_r * \tilde{\omega}_r,$$

where $\tilde{\omega}_r := (\omega_r)^{\sim}$. By definition, this means that $\lim_{r\to\infty} r^{-3}\langle \omega_r * \tilde{\omega}_r, \varphi\rangle$ exists for all test functions $\varphi\in\mathcal{S}(\mathbb{R}^3)$. So,

$$\begin{aligned}
\lim_{r\to\infty} r^{-3}\langle \omega_r * \tilde{\omega}_r, \varphi\rangle &= \lim_{r\to\infty} r^{-3} \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \varphi(x+y)\,\mathrm{d}\tilde{\omega}_r(y)\,\mathrm{d}\omega_r(x) \\
&= \lim_{r\to\infty} r^{-3} \int_{C_r}\int_{\mathbb{R}^3} \varphi(x+y)\,\mathrm{d}\tilde{\omega}_r(y)\,\mathrm{d}\omega(x) \\
&= \lim_{r\to\infty} r^{-3} \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \varphi(x+y)\,\mathrm{d}\tilde{\omega}_r(y)\,\mathrm{d}\omega(x) \\
&= \lim_{r\to\infty} r^{-3}\langle \omega * \tilde{\omega}_r, \varphi\rangle
\end{aligned}$$

and therefore

$$\gamma = \lim_{r\to\infty} r^{-3}\omega * \tilde{\omega}_r. \tag{4}$$

This can also be deduced from Lemma 1.2 in Ref. 14.

In order to determine $\hat{\gamma}$, we compute the Fourier transform of $\lim_{r\to\infty} r^{-3}\omega * \tilde{\omega}_r$. Since the Fourier transform is continuous on the set $\mathcal{S}'$ of tempered distributions, we have

$$\Big(\lim_{r\to\infty} r^{-3}\omega * \tilde{\omega}_r\Big)\hat{} = \lim_{r\to\infty} r^{-3}(\omega * \tilde{\omega}_r)\hat{}.$$

So, we proceed to compute $(\omega * \tilde{\omega}_r)\hat{}$. Since $\tilde{\omega}_r$ has compact support, we have $\hat{\tilde{\omega}}_r\in\mathcal{C}^\infty$ and $\tilde{\omega}_r * \omega = \omega * \tilde{\omega}_r$. The convolution theorem for distributions yields

$$\langle (\omega * \tilde{\omega}_r)\hat{}, \varphi\rangle = \langle \hat{\omega}, \hat{\tilde{\omega}}_r \cdot \varphi\rangle \tag{5}$$

for all $\varphi\in\mathcal{S}(\mathbb{R}^3)$. Let us take a closer look at ω. It can be written as

$$\omega = \sum_{m\in\mathbb{Z}} \delta^{(2)}_{v_m+R^m\Gamma} \otimes \delta^{(1)}_{mc},$$

where $v_m=(v_1^{(m)},v_2^{(m)})$, compare (3). Here and in what follows, $\delta_M := \Sigma_{x\in M}\delta_x$. Note that $\delta^{(2)}_{v_m+R^m\Gamma}$ is a measure on $\mathbb{R}^2$ and $\delta^{(1)}_{mc}$ is one on $\mathbb{R}^1$. Let $\varphi\in\mathcal{S}(\mathbb{R}^3)$ be of the form $\varphi(x_1,x_2,x_3) = f(x_1,x_2)g(x_3)$, i.e., $f\in\mathcal{S}(\mathbb{R}^2)$, $g\in\mathcal{S}(\mathbb{R})$, and $\varphi=f\cdot g$. Since linear combinations of such functions

φ are dense in $\mathcal{S}(\mathbb{R}^3)$, see Ref. 4, the following calculation for tempered distributions holds:

$$\hat{\omega} = \sum_{m\in\mathbb{Z}} \widehat{\delta^{(2)}_{\boldsymbol{v}_m+R^m\Gamma}} \otimes \widehat{\delta^{(1)}_{mc}}.$$

It remains to examine $\widehat{\delta^{(1)}_{mc}}$, which equals $e^{-2\pi imcx_3}$, and

$$\widehat{\delta^{(2)}_{\boldsymbol{v}_m+R^m\Gamma}} = (\delta^{(2)}_{\boldsymbol{v}_m} * \delta^{(2)}_{R^m\Gamma})\hat{} = \widehat{\delta^{(2)}_{\boldsymbol{v}_m}} \cdot \widehat{\delta^{(2)}_{R^m\Gamma}} = e^{-2\pi i(x_1 v_1^{(m)} + x_2 v_2^{(m)})} \mathrm{dens}^{(2)}(\Gamma)\, \delta^{(2)}_{R^m\Gamma^*},$$

where $\mathrm{dens}^{(2)}$ denotes the two-dimensional density of Γ. The last equality uses the Poisson summation formula in distribution form (Ref. 15, p. 254)

$$\widehat{\delta_\Gamma} = \mathrm{dens}(\Gamma)\, \delta_{\Gamma^*}, \tag{6}$$

where $\Gamma^* = \{\boldsymbol{y} \,|\, \boldsymbol{y}\boldsymbol{x} \in \mathbb{Z} \text{ for all } \boldsymbol{x} \in \Gamma\}$ denotes the dual (or reciprocal) lattice. The dual lattice of $R^m\Gamma$ is indeed $R^m\Gamma^*$, since

$$\boldsymbol{y} \in (R^m\Gamma)^* \Leftrightarrow \forall\, \boldsymbol{x}' \in R^m\Gamma : \boldsymbol{y}\boldsymbol{x}' \in \mathbb{Z} \Leftrightarrow \forall\, \boldsymbol{x} \in \Gamma : \boldsymbol{y}R^m\boldsymbol{x} \in \mathbb{Z}$$

$$\Leftrightarrow \forall\, \boldsymbol{x} \in \Gamma : R^{-m}\boldsymbol{y}\boldsymbol{x} \in \mathbb{Z} \;\Leftrightarrow R^{-m}\boldsymbol{y} \in \Gamma^* \Leftrightarrow \boldsymbol{y} \in R^m\Gamma^*.$$

Altogether, we get the following result. Let $\varphi(\boldsymbol{x}) = 0$ for all $\boldsymbol{x} \in M' = (\cup_{m\in\mathbb{Z}} R^m\Gamma^*) \times \mathbb{R}$ [and thus $\varphi(\boldsymbol{x}) = 0$ for all $\boldsymbol{x} \in M := \mathrm{cl}(M')$, since φ is continuous]; in other words, let the interior of the support of φ be contained in the complement of M. Then,

$$\langle \hat{\omega}, \varphi \rangle = \left\langle \sum_{m\in\mathbb{Z}} e^{-2\pi i(x_1 v_1^{(m)} + x_2 v_2^{(m)} + mcx_3)} \mathrm{dens}^{(2)}(\Gamma)\, \delta^{(2)}_{R^m\Gamma^*}, \varphi \right\rangle = 0, \tag{7}$$

where $\hat{\omega}$ is already known to be a tempered distribution. Since the term $\delta^{(2)}_{R^m\Gamma^*}$ refers only to the two coordinates x_1, x_2, we conclude that the support of $\hat{\omega}$ is a subset of M, as is the support of $(\tilde{\omega}_r * \omega)\hat{}$, by (5). So, the support of $\hat{\gamma}$ is a subset of M. So far, we have established the following.

Theorem 2.1: *The diffraction spectrum of any SCD set* Λ_{SCD} *is a singular measure, and it is supported on the set*

$$M = \mathrm{cl}\left(\bigcup_{m\in\mathbb{Z}} R^m\Gamma^* \right) \times \mathbb{R}.$$

■

In the case of incommensurate SCD tilings, M is the union of all concentric cylinder surfaces S with central axis $\mathbb{R}\boldsymbol{e}_3$, where the radius of each S is $\|\boldsymbol{v}\|$ for some $\boldsymbol{v} \in \Gamma^*$. In the case of commensurate SCD tilings, M is a union of lines parallel to $\mathbb{R}\boldsymbol{e}_3$. In this case, as we will see later on in an example, the support of $\hat{\gamma}$ is a true subset of M.

Now, take a closer look at the diffraction spectrum along $\mathbb{R}\boldsymbol{e}_3$. From (7), we conclude

$$\hat{\omega} = \mathrm{dens}^{(2)}(\Gamma) \sum_{m\in\mathbb{Z}} e^{-2\pi i(x_1 v_1^{(m)} + x_2 v_2^{(m)} + mcx_3)}\, \delta^{(2)}_{R^m\Gamma^*}, \tag{8}$$

which might not be a measure in $\mathbb{R}^3$, but has a clear meaning as a tempered distribution. The coefficient of $\delta^{(2)}_0$ can be calculated by means of (6) as follows:

$$\sum_{m\in\mathbb{Z}} e^{-2\pi imcx_3} = \sum_{n\in c\mathbb{Z}} \widehat{\delta^{(1)}_n} = (\delta^{(1)}_{c\mathbb{Z}})\hat{} = \mathrm{dens}^{(1)}(c\mathbb{Z})\, \delta^{(1)}_{(c\mathbb{Z})^*} = c^{-1}\delta^{(1)}_{c^{-1}\mathbb{Z}}, \tag{9}$$

to be read as an equation for tempered distributions in $\mathcal{S}' = \mathcal{S}'(\mathbb{R})$.

On the other hand, since $\widetilde{\omega}_r$ is a finite measure with compact support, its Fourier transform is an analytic function and can be written as

$$\widehat{\widetilde{\omega}_r}(\boldsymbol{x}) = \sum_{\boldsymbol{y}\in\Lambda\cap C_r} e^{2\pi i(x_1y_1+x_2y_2+x_3y_3)}. \tag{10}$$

For $\boldsymbol{x}=(0,0,x_3)$, we thus get

$$\begin{aligned}\lim_{r\to\infty} r^{-3}\widehat{\widetilde{\omega}}_r\hat{\omega} &= \mathrm{dens}^{(2)}(\Gamma)\lim_{r\to\infty} r^{-3}\left(\sum_{\boldsymbol{y}\in\Lambda\cap C_r} e^{2\pi i x_3y_3}\right)\left(\sum_{n\in\mathbb{Z}} e^{-2\pi i n c x_3}\delta^{(2)}_{R^n\Gamma^*}\right)\\ &= \mathrm{dens}^{(2)}(\Gamma)\lim_{r\to\infty} r^{-3}\left(\sum_{m=-\lceil r/2\rceil}^{\lfloor r/2\rfloor} d_r^{(m)} r^2 e^{2\pi i m c y_3}\right)\left(\sum_{n\in\mathbb{Z}} e^{-2\pi i n c x_3}\delta^{(2)}_{R^n\Gamma^*}\right).\end{aligned}$$

Here, $d_r^{(m)}$ is chosen such that $d_r^{(m)}r^2$ counts the number of elements of $\Lambda\cap C_r$ in layer m. So, $d_r^{(m)}$ depends on $\mathrm{dens}^{(2)}(\Gamma)$, and $\lim_{r\to\infty} d_r^{(m)} = \mathrm{dens}^{(2)}(\Gamma)$ for all $m\in\mathbb{Z}$, uniformly in m.

Putting the pieces together, and restricting to the central axis, we obtain

$$\lim_{r\to\infty} r^{-3}\,\widehat{\widetilde{\omega}}_r\hat{\omega}|_{\mathbb{R}\boldsymbol{e}_3} = c^{-1}(\mathrm{dens}^{(2)}(\Gamma))^2\lim_{r\to\infty} r^{-1}\left(\sum_{m=-\lceil r/2\rceil}^{\lfloor r/2\rfloor} e^{-2\pi i m c x_3}\right)\delta^{(1)}_{c^{-1}\mathbb{Z}}.$$

This expression vanishes for $x_3\notin c^{-1}\mathbb{Z}$, while for $x_3\in c^{-1}\mathbb{Z}$ we get

$$c^{-1}(\mathrm{dens}^{(2)}(\Gamma))^2\lim_{r\to\infty} r^{-1}\sum_{m=-\lceil r/2\rceil}^{\lfloor r/2\rfloor} 1 = c^{-1}(\mathrm{dens}^{(2)}(\Gamma))^2 = \mathrm{dens}^{(2)}(\Gamma)\mathrm{dens}^{(3)}(\Lambda_{\mathrm{SCD}}).$$

In analogy to $\mathrm{dens}^{(2)}$, $\mathrm{dens}^{(3)}$ denotes three-dimensional density. It follows:

Theorem 2.2: *The diffraction spectrum $\hat{\gamma}$ of any SCD set Λ_{SCD}, restricted to $\mathbb{R}\boldsymbol{e}_3$, is pure point. In particular,*

$$\hat{\gamma}\big|_{\mathbb{R}\boldsymbol{e}_3} = \mathrm{dens}^{(2)}(\Gamma)\mathrm{dens}^{(3)}(\Lambda_{\mathrm{SCD}})\sum_{\boldsymbol{x}\in c^{-1}\mathbb{Z}\boldsymbol{e}_3}\delta_{\boldsymbol{x}}.$$

■

For special cases, this result already appears in Ref. 12. In the general case, it seems difficult to achieve results about the explicit behavior on the cylinder surfaces. If the SCD tiling has additionial properties, it is possible to show that all existing Bragg peaks are located on $\mathbb{R}\boldsymbol{e}_3$.

Definition 2.3: *A point set Λ in $\mathbb{R}^d$ is called* repetitive, *if for every $r>0$ some $R>0$ exists such that for all $\boldsymbol{x},\boldsymbol{y}\in\mathbb{R}^d$ a congruent copy of $(\boldsymbol{x}+C_r)\cap\Lambda$ occurs in every set $(\boldsymbol{y}+C_R)\cap\Lambda$.*

This definition has a natural extension to the repetitivity of tilings. For our purposes, it suffices to call an SCD tiling repetitive, if the corresponding SCD sets are repetitive. In particular, if $\mathcal{T}$ is repetitive, there are only finitely many ways how two tiles can touch each other. (Otherwise, there would be infinitely many different pairs of tiles, each fitting into a box C_r with $r=2\|\boldsymbol{a}+\boldsymbol{b}\|$. This infinitely many pairs, having all the same positive volume, must be contained in a finite ball of radius R, which is impossible.)

Proposition 2.4: If an SCD tiling $\mathcal{T}$ is repetitive, then $\varphi=\arccos(p/q)$, with $p,q\in\mathbb{Z}$.

Proof: Let $\mathcal{T}$ be repetitive. Then, the tiles of two consecutive layers L_i, L_{i-1} can touch each other in only finitely many ways. Let $L_i=T+\Gamma$, $L_{i-1}=R^{-1}(T+\Gamma)-R^{-1}\boldsymbol{c}$, and $\Gamma=\langle(1,0),(b_1,b_2)\rangle_{\mathbb{Z}}$. By the definition of T and $\mathcal{T}$, it follows that $b_1=\cos(\varphi)$, $b_2=\sin(\varphi)$ and that R^{-1} (recall that R is a rotation through the angle $-\varphi$) is given by

$$\begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix}.$$

So, $R^{-1}\Gamma = \langle (b_1,b_2), (b_1^2-b_2^2, 2b_1b_2)\rangle_{\mathbb{Z}}$. Obviously, $\langle (b_1,b_2)\rangle_{\mathbb{Z}} \subseteq \Gamma \cap R^{-1}\Gamma$. Since the tiles of L_i and L_{i-1} touch each other in finitely many ways, there are only finitely many possibilities how a point of Γ is positioned relative to its nearest point in $R^{-1}\Gamma$. Consequently, one has $(\Gamma \cap R^{-1}\Gamma)\backslash\langle (b_1,b_2)\rangle_{\mathbb{Z}} \neq \emptyset$. Therefore, the equation

$$\kappa(1,0) + \lambda(b_1,b_2) = \mu(b_1,b_2) + \nu(b_1^2 - b_2^2, 2b_1b_2) \tag{11}$$

has a solution, where $\kappa \neq 0 \neq \nu$. We must show that this is only possible if b_1 is a rational number p/q. Let b_1 be an irrational number. From $\lambda b_2 = \mu b_2 - \nu 2b_1b_2$ ($\lambda, \mu, \nu \in \mathbb{Z}$), one concludes $\nu = 0$ and $\lambda = \mu$. Therefore,

$$\kappa + \lambda b_1 = \mu b_1 + \nu(b_1^2 - b_2^2)$$

gives $\kappa = 0$, so there is no solution of (11) with $\kappa \neq 0 \neq \nu$. ■

Theorem 2.5: *Let Λ be an incommensurate SCD set. If $R^m\Lambda + m\boldsymbol{c} = \Lambda$ for some $m \geqslant 1$, or if Λ is repetitive and $\varphi = \arccos(p/q)$, where q is odd, then the diffraction spectrum of Λ is singular continuous on $M\backslash\mathbb{R}\boldsymbol{e}_3$.*

Lemma 2.6: Let R be an orthogonal map, μ a measure, and let the measure $R.\mu$ be given by $R.\mu(A) = \mu(R^{-1}A)$. Then

$$R.\widehat{\mu} = \widehat{R.\mu}.$$

Proof: Let $\varphi \in \mathcal{S}(\mathbb{R}^3)$. It is clear that $\langle R.\mu, \varphi\rangle = \langle \mu, \varphi \circ R\rangle$. Since

$$\widehat{\varphi \circ R}(\boldsymbol{x}) = \int \varphi(R\boldsymbol{y}) e^{-2\pi i \boldsymbol{x}\boldsymbol{y}}\, \mathrm{d}\boldsymbol{y} = \int \varphi(\tilde{\boldsymbol{y}}) e^{-2\pi i \boldsymbol{x}(R^{-1}\tilde{\boldsymbol{y}})} \mathrm{d}\tilde{\boldsymbol{y}} = \int \varphi(\tilde{\boldsymbol{y}}) e^{-2\pi i (R\boldsymbol{x})\tilde{\boldsymbol{y}}} \mathrm{d}\tilde{\boldsymbol{y}} = \hat{\varphi}(R\boldsymbol{x}),$$

where $\tilde{\boldsymbol{y}} = R\boldsymbol{y}$, it follows that $\widehat{\varphi \circ R} = \hat{\varphi} \circ R$. Thus

$$\langle \widehat{R.\mu}, \varphi\rangle = \langle R.\mu, \hat{\varphi}\rangle = \langle \mu, \hat{\varphi} \circ R\rangle = \langle \mu, \widehat{\varphi \circ R}\rangle = \langle \hat{\mu}, \varphi \circ R\rangle = \langle R.\hat{\mu}, \varphi\rangle$$

which proves the claim. ■

Proof of Theorem 2.5: Let $R^m\Lambda + m\boldsymbol{c} = \Lambda$. The support of the autocorrelation γ is the closure of the set $\Lambda - \Lambda = \{\boldsymbol{x} - \boldsymbol{y} \,|\, \boldsymbol{x}, \boldsymbol{y} \in \Lambda\}$. Since

$$R^m(\Lambda - \Lambda) = R^m\Lambda + m\boldsymbol{c} - (R^m\Lambda + m\boldsymbol{c}) = \Lambda - \Lambda,$$

we get $\gamma = R^m.\gamma$. Lemma 2.6 implies $\hat{\gamma} = \widehat{R^m.\gamma} = R^m.\hat{\gamma}$, and therefore $\hat{\gamma} = R^{km}.\hat{\gamma}$ for all $k \in \mathbb{Z}$.

Now, let Λ be repetitive and $\varphi = \arccos(p/q)$, where q is odd. Like Λ itself, the set $\Lambda - \Lambda$ consists of equidistant layers. If $\Lambda = \cup_{k\in\mathbb{Z}} R^k\Gamma + \boldsymbol{v}_k + k\boldsymbol{c}_0$ [where $\boldsymbol{c}_0 = (0,0,c)$], then

$$\Lambda - \Lambda = \bigcup_{i\in\mathbb{Z}} \bigcup_{k\in\mathbb{Z}} R^{k+i}\Gamma + \boldsymbol{v}_{k+i} + (k+i)\boldsymbol{c}_0 - (R^k\Gamma + \boldsymbol{v}_k + k\boldsymbol{c}_0).$$

Now, we use a fact from Ref. 7: If $\mathcal{T}$ is a repetitive SCD tiling, and if $\varphi = \arccos(p/q)$ with q odd, then the union of i consecutive layers in $\mathcal{T}$ is congruent to any other such union of i consecutive layers in $\mathcal{T}$. Therefore, all difference sets $R^{k+i}\Gamma + \boldsymbol{v}_{k+i} + (k+i)\boldsymbol{c}_0 - (R^k\Gamma + \boldsymbol{v}_k + k\boldsymbol{c}_0)$ are congruent. This means $\boldsymbol{v}_{k+i} - \boldsymbol{v}_k = R^k(\boldsymbol{v}_i - \boldsymbol{v}_0)$. Since $R\boldsymbol{c}_0 = \boldsymbol{c}_0$, it follows:

$$R(\Lambda-\Lambda)=R\Bigg(\bigcup_{i\in\mathbb{Z}}\bigcup_{k\in\mathbb{Z}}R^k(R^i\Gamma-\Gamma+\boldsymbol{v}_i-\boldsymbol{v}_0)+i\boldsymbol{c}_0\Bigg)$$
$$=R\Bigg(\bigcup_{k\in\mathbb{Z}}R^k\Bigg(\bigcup_{i\in\mathbb{Z}}R^i\Gamma-\Gamma+\boldsymbol{v}_i-\boldsymbol{v}_0+i\boldsymbol{c}_0\Bigg)\Bigg)=\Lambda-\Lambda.$$

Therefore, one has $\hat{\gamma}=R^k.\hat{\gamma}$ for all $k\in\mathbb{Z}$.

In both cases, the following argument applies: If there is a Bragg peak $I(\boldsymbol{x})\delta_{\boldsymbol{x}}$ at $\boldsymbol{x}\in M\backslash\mathbb{R}\boldsymbol{e}_3$ with intensity $I(\boldsymbol{x})>0$, then there are infinitely many Bragg peaks $I(\boldsymbol{x})\delta_{R^{km}\boldsymbol{x}}$, with $k\in\mathbb{Z}$, on a circle of diameter $\|\boldsymbol{x}\|$. But since $\hat{\gamma}$ is a tempered distribution, it is bounded on every compact set $K\subset\mathbb{R}^3$. This is a contradiction. Therefore, no Bragg peaks occur in $M\backslash\mathbb{R}\boldsymbol{e}_3$. The claim now follows from Theorem 2.1. ■

In contrast to this situation, let us ask what happens for a fully periodic SCD tiling. This is only possible if it is a commensurate SCD tiling (which means that R is of finite order), and if the sequence $(v_1^{(m)},v_2^{(m)})$ is periodic (to be precise, periodic mod $R^m\boldsymbol{a}$). Equivalently, there is a $k\geqslant 1$, such that $R^k=\mathrm{id}$ and $v_1^{(m+k)}\equiv v_1^{(m)}, v_2^{(m+k)}\equiv v_2^{(m)} \bmod R^m\boldsymbol{a}$ for all $m\in\mathbb{Z}$. In this case, (8) gives

$$\hat{\omega}=\mathrm{dens}^{(2)}(\Gamma)\sum_{n\in k\mathbb{Z}}\sum_{j=0}^{k-1}e^{-2\pi i(x_1v_1^{(j)}+x_2v_2^{(j)}+(n+j)cx_3)}\delta^{(2)}_{R^{n+j}\Gamma^*}$$
$$=\mathrm{dens}^{(2)}(\Gamma)\sum_{j=0}^{k-1}e^{-2\pi i(x_1v_1^{(j)}+x_2v_2^{(j)}+jcx_3)}\Bigg(\sum_{n\in ck\mathbb{Z}}e^{-2\pi inx_3}\Bigg)\delta^{(2)}_{R^j\Gamma^*}$$
$$=\mathrm{dens}^{(2)}(\Gamma)\sum_{j=0}^{k-1}e^{-2\pi i(x_1v_1^{(j)}+x_2v_2^{(j)}+jcx_3)}(ck)^{-1}(\delta^{(2)}_{R^j\Gamma^*}\otimes\delta^{(1)}_{(ck)^{-1}\mathbb{Z}}).$$

This term vanishes everywhere except on $(\cup_{j=1}^{k}R^j\Gamma^*)\times(ck)^{-1}\mathbb{Z}$. So, the diffraction spectrum of a fully periodic SCD tiling is, as expected, supported on a uniformly discrete point set. It is, in fact, a pure point diffraction spectrum, consisting of isolated Bragg peaks. The support is indeed *uniformly* discrete, since from the periodicity of the tiling the repetitivity follows, wherefore Proposition 2.4 yields $\varphi=\arccos(p/q)$ $(p,q\in\mathbb{Z})$. Since the tiling is commensurate, (p,q) can take the values (0,1) or (1,2) only.

III. FURTHER REMARKS

(1) One special case which occurs is the body-centered-cubic lattice (bcc) as the underlying point set of an SCD tiling. It is the dual of the root lattice D_3, compare Ref. 5,

$$\mathrm{bcc}=D_3^*=\langle(1,0,0),(0,1,0),(\tfrac{1}{2},\tfrac{1}{2},\tfrac{1}{2})\rangle_{\mathbb{Z}}.$$

This is achieved by placing the reference point $\boldsymbol{z}$ in the center $\frac{1}{2}(\boldsymbol{a}+\boldsymbol{b})$ of the SCD tile, and choosing (cf. Sec. I),

$$\boldsymbol{a}=(1,0,0),\quad \boldsymbol{b}=(0,1,0),\quad \boldsymbol{c}=(0,\tfrac{1}{2},\tfrac{1}{2}),\quad \boldsymbol{d}=(\tfrac{1}{2},0,-\tfrac{1}{2}),\quad v_1^{(m)}=v_2^{(m)}=\begin{cases}0, & m\text{ even},\\ \frac{1}{2}, & m\text{ odd}.\end{cases}$$

Using (8) and (10), one finds for this case

$$\widehat{\gamma_{\mathrm{bcc}}}=\lim_{r\to\infty}r^{-3}\Bigg(\sum_{\boldsymbol{y}\in\mathrm{bcc}\cap C_r}e^{2\pi i\boldsymbol{x}\boldsymbol{y}}\Bigg)\Bigg(\sum_{m\in\mathbb{Z}}e^{-2\pi i(x_1v_1^{(m)}+x_2v_2^{(m)}+x_3m/2)}\Bigg)\mathrm{dens}^{(2)}(\mathbb{Z}^2)\delta^{(2)}_{\mathbb{Z}^2}.$$

This measure vanishes on $\{\boldsymbol{x}\,|\,(x_1,x_2)\notin\mathbb{Z}^2\}$. For $(x_1,x_2)\in\mathbb{Z}^2$, one finds

$$\lim_{r\to\infty} r^{-3}\left(\sum_{n=-\lfloor r\rfloor}^{\lfloor r\rfloor} r^2 e^{2\pi i x_3 n/2}\right)\left(\sum_{m\in 2\mathbb{Z}+1} e^{-\pi i(x_1+x_2+x_3 m)} + \sum_{m\in 2\mathbb{Z}} e^{-2\pi i x_3 m/2}\right)$$
$$= \lim_{r\to\infty} r^{-1}\left(\sum_{n=-\lfloor r\rfloor}^{\lfloor r\rfloor} e^{2\pi i x_3 n/2}\right)(1+e^{-\pi i(x_1+x_2+x_3)})\sum_{m\in\mathbb{Z}} e^{-2\pi i x_3 m}.$$

From (9), one gets $\Sigma_{m\in\mathbb{Z}} e^{-2\pi i x_3 m} = \delta^{(1)}_{\mathbb{Z}}$. So, this term vanishes for $x_3 \notin \mathbb{Z}$, and for $x_3 \in \mathbb{Z}$ we have to examine the factor $1+e^{-\pi i(x_1+x_2+x_3)}$. It equals 2 (respectively, 0) if $x_1+x_2+x_3$ is even (respectively, odd). In the even case, the first sum does not converge, so the limit is not zero. Altogether, the diffraction spectrum of bcc consists of Bragg peaks on points in

$$D_3 = \{\, \boldsymbol{x} \mid x_1 + x_2 + x_3 \equiv 0 \bmod 2\}.$$

In this way, we retrieve the well-known result that the diffraction image of the bcc is pure point, with Bragg peaks on the points of the dual lattice $(D_3^*)^* = D_3 = 2$ fcc.

In a similar way, one finds further structures that are well known from crystallography or discrete geometry, such as the root lattices $\mathbb{Z}^3$ and D_3 [which is a scaled version of the face-centered-cubic lattice (fcc)], or the hexagonal close packing (compare Ref. 5).

(2) The description of the SCD tile in Sec. I follows the idea of Conway, see Ref. 7. The prototile found by Schmitt is not convex, but showed itself the valleys and ridges, which occur on the layers of our tilings (and his tilings have essentially the same structure as ours). Anyway, both tiles lead to the same SCD sets, and both tiles are examples of aperiodic prototiles. But the latter is only true if we forbid tilings which contain both our SCD tile and its mirror image. For example, let T be as in (1) and T' the mirror image of T under reflection in the plane spanned by $\boldsymbol{a}$ and $\boldsymbol{b}$. The layer $L = T + \Gamma$ contains only translations of T, the layer $L' = T' + \boldsymbol{c} + \Gamma$ contains only translations of T'. The tiling

$$\mathcal{T} = \bigcup_{m\in 2\mathbb{Z}} (0,0,mc) + (L \cup L')$$

is invariant under the translations $t(\boldsymbol{x}) = \boldsymbol{x} + (0,0,2c)$ and $u(\boldsymbol{x}) = \boldsymbol{x} + \boldsymbol{b}$, hence not aperiodic.

In our description, the angle φ can take any value in $]0, \pi/2[$. The SCD tile described by Danzer (Ref. 7) uses $\varphi = \arccos(p/q)$, where p, q are positive integers, $p < q, q \geqslant 3$ (leading to incommensurate SCD tilings). In this case, it is possible to *enforce* SCD tilings which are repetitive. Then, in particular, two tiles can touch each other only in finitely many different ways. (This is clearly not true for all SCD tilings considered in this paper.) Using this, one can modify the shape of the prototile in such a way that the occurrence of mirror images of the prototile is ruled out. This can be done, e.g., by adding protrusions and indentations to the tiles, fitting together like key and keyhole, but only if the tiles are directly congruent. So, in this case, one has indeed a single prototile—no longer convex—permitting only aperiodic tilings, just by its shape.

Anyway, even in the last setting, there may occur other symmetries, namely screw motions. Obviously, the tiling $\mathcal{T}$ in (2) is invariant under the map $s(\boldsymbol{x}) = R\boldsymbol{x} + (0,0,c)$. More generally, if we choose an arbitrary SCD tile as discussed here, then in the set of all tilings built from this tile we will always find tilings invariant under the maps s^k $(k \in \mathbb{Z})$. Thus the symmetry group of such tilings is infinite. In less than three dimensions, aperiodicity is equivalent to finiteness of the symmetry group. The SCD tilings show that this is not true in general. Therefore, it makes sense to rephrase the question "Is there an aperiodic prototile?" as "Is there a prototile that permits only tilings with finite symmetry group?," shortly, "Is there a *strongly aperiodic* prototile?" (cf. Ref. 11). To our knowledge, no answer to this question is known so far.

(3) To some extent, the underlying mechanism of SCD tilings does occur in nature. The structure of smectic C^* liquid crystals resembles the layer structure: planar, two-periodic "sheets" of tilted molecules (called directors) are stacked with a screw order on top of each other.[8] This happens in such a way that the (effective) period in direction $\mathbb{R}\boldsymbol{e}_3$ is on a much greater length scale than the elementary periods within the layers.

A geometric approach to scalar field theories on the supersphere

A. F. Schunck[a] and Chris Wainwright[b]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Wilberforce Road, Cambridge CB3 0WA, United Kingdom

(Received 4 October 2004; accepted 17 November 2004; published online 11 February 2005)

Following a strictly geometric approach we construct globally supersymmetric scalar field theories on the supersphere, defined as the quotient space $S^{2|2}=\mathrm{UOSp}(1|2)/\mathcal{U}(1)$. We analyze the superspace geometry of the supersphere, in particular deriving the invariant vielbein and spin connection from a generalization of the left-invariant Maurer–Cartan form for Lie groups. Using this information we proceed to construct a superscalar field action on $S^{2|2}$, which can be decomposed in terms of the component fields, yielding a supersymmetric action on the ordinary two-sphere. We are able to derive Lagrange equations and Noether's theorem for the superscalar field itself. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1850363]

I. INTRODUCTION

While superspheres have been extensively studied as target spaces for supersymmetric sigma models, see, e.g., Refs. 1 and 2, little attention has been paid to considering the supersphere as the base space for supersymmetric field theories. However, treating the supersphere as such provides us with an interesting model for studying globally supersymmetric field theories in curved space.

In this paper we present a strictly geometric approach to constructing globally supersymmetric scalar field theories on the supersphere, defined here as the coset space $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$,[3,4] the body of which is given by the ordinary two-sphere. We should emphasize here that there is an ambiguity in defining a supersphere, i.e., a supersymmetric generalization of the ordinary two-sphere, the only criterion being that the body of the respective supermanifold coincides with S^2. Another example of a supersymmetric generalization of S^2 would be the quotient space $\mathrm{SU}(2|1)/\mathrm{U}(1|1)$, as considered in, e.g., Ref. 5. If one insists, however, on the additional condition that the resultant coset space is not just a supermanifold but rather a *superspace*, this excludes, for example, the latter possibility and leaves as one obvious choice precisely the coset space $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$.

While it is not important to insist on this additional condition for the purpose of using the supermanifold as the target space for some supersymmetric sigma model, it is crucial to enforce it if one wants to construct a field theory on the supermanifold as the background. This is because the superspace condition ensures first that the tangent space group of the supermanifold under consideration corresponds to the even Grassmann extension of the tangent space group of the body of the respective coset space and second that the fermionic field content of the theory will transform as *spinor* fields under the action of the tangent space group (see Secs. III E and V B).

Note, however, that taking the coset space $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$ as the supersymmetric generalization of the ordinary sphere involves inevitably the usage of a rather unfamiliar extension of complex conjugation to supernumbers, referred to as pseudoconjugation,[6] see Sec. II A, together with the definition of a graded adjoint, see Sec. II B.

[a]Electronic mail: a.f.schunck@damtp.cam.ac.uk
[b]Electronic mail: c.j.wainwright@damtp.cam.ac.uk

We shall emphasize one other important point about our approach to constructing scalar field theories on $S^{2|2}$. While it is possible to construct supersymmetric theories on certain curved backgrounds using component fields from the outset, as in, e.g., Ref. 7 for the case of AdS_2, we instead rigorously pursue a superspace approach; analyzing the superspace geometry of the supersphere we construct in particular the invariant vielbein and spin connection, using a supergeneralization of the left-invariant Maurer–Cartan form for ordinary Lie groups (see Sec. V). Having this information at hand we proceed to construct a *superscalar* field theory on $S^{2|2}$, which only when written in terms of the component fields of the superscalar field under consideration, and after integrating out the odd coordinates, becomes a field theory on the ordinary sphere. Having derived the component field version of the superfield action in Sec. VII, we will be able to briefly discuss supersymmetry breaking in Sec. VIII. Notably, the superspace approach also makes it possible to derive Lagrange equations as well as Noether's theorem for the superscalar field itself, see Sec. IX.

II. THE UNITARY ORTHOSYMPLECTIC GROUP

A. Pseudoconjugation

We expand an arbitrary (complex) supernumber z in terms of the generators of a Grassmann algebra ζ_i, $i=1,\ldots,N$, as

$$z = z_0 + z_i\zeta_i + z_{ij}\zeta_i\zeta_j + z_{ijk}\zeta_i\zeta_j\zeta_k + \cdots . \tag{1}$$

We use a subscript 0 to denote the *body* of the supernumber, the remaining terms are called the *soul*. A supernumber is said to be *even* if the above expansion does not contain terms with an odd number of generators. The set of even supernumbers will be denoted by $\mathbb{C}_c$. A supernumber is said to be *odd* if it contains only terms with an odd number of generators. The odd supernumbers will be denoted by $\mathbb{C}_a$. The set of all supernumbers will be denoted by $\mathbb{C}_N$. We will normally, however, consider the formal limit $N\to\infty$ and denote the supernumbers by $\mathbb{C}_\infty$. Note also that $\mathbb{C}_0\cong\mathbb{C}$ is precisely the set of ordinary complex numbers.

The standard extension of ordinary complex conjugation to supernumbers is given in Ref. 8. It is defined as a map

$$*: \begin{cases} \mathbb{C}_c \to \mathbb{C}_c, \\ \mathbb{C}_a \to \mathbb{C}_a, \end{cases}$$

which agrees with complex conjugation on ordinary numbers and satisfies the following properties:

$$(a+b)^* = a^* + b^*,$$

$$(ab)^* = b^*a^*,$$

$$a^{**} = a,$$

for arbitrary supernumbers a and b. Note that when taking the conjugate of a product the order is reversed. The Grassmann generators can be taken to be real with respect to this conjugation, i.e., $\zeta_i^* = \zeta_i$, and the expansion of z^* is given by

$$z^* = z_0^* + z_i^*\zeta_i - z_{ij}^*\zeta_i\zeta_j - z_{ijk}^*\zeta_i\zeta_j\zeta_k + \cdots .$$

Note that the minus signs are due to the reordering of the Grassmann generators.

It is possible to define another extension of complex conjugation to supernumbers, called *pseudoconjugation*.[6] Pseudoconjugation is defined as a map

$$\diamondsuit: \begin{cases} \mathbb{C}_c \to \mathbb{C}_c, \\ \mathbb{C}_a \to \mathbb{C}_a, \end{cases} \tag{2}$$

which agrees with complex conjugation on ordinary numbers and satisfies the following properties:

$$(a+b)^{\diamond} = a^{\diamond} + b^{\diamond}, \tag{3a}$$

$$(ab)^{\diamond} = a^{\diamond} b^{\diamond}, \tag{3b}$$

$$a^{\diamond\diamond} = (-1)^{\epsilon_a} a, \tag{3c}$$

for arbitrary supernumbers a and b, where $\epsilon_a = 0$ if $a \in \mathbb{C}_c$ and $\epsilon_a = 1$ if $a \in \mathbb{C}_a$. Note that the pseudoconjugate does *not* switch the order when applied to a product. A consequence of this definition is that the generators of the Grassmann algebra can no longer be described as real with respect to pseudoconjugation in the same way as for standard conjugation. To see this note that if we had $\zeta_i^{\diamond} = \zeta_i$ this would imply that $\zeta_i^{\diamond\diamond} = \zeta_i$ which contradicts Eq. (3c). In fact, a definition of how the pseudoconjugate acts on the Grassmann generators which is consistent with Eqs. (2), (3a)–(3c) is not always possible. If however N is even, or indeed infinite, we can proceed as follows. Let W be the N-dimensional vector space of Grassmann generators. Pick a semilinear map[9] $f: W \to W$ such that $f^2 = -1$, for example, the matrix

$$J = \begin{pmatrix} 0 & \mathbb{1}_{N/2} \\ -\mathbb{1}_{N/2} & 0 \end{pmatrix},$$

and then define $\zeta_i^{\diamond} = f(\zeta_i)$. Using this definition of the pseudoconjugate on the Grassmann generators it is possible to write down the expansion for an arbitrary supernumber as

$$z^{\diamond} = z_0^* + z_i^* \zeta_i^{\diamond} + z_{ij}^* \zeta_i^{\diamond} \zeta_j^{\diamond} + z_{ijk}^* \zeta_i^{\diamond} \zeta_j^{\diamond} \zeta_k^{\diamond} + \cdots .$$

B. Graded adjoint

Using ordinary complex conjugation of supernumbers it is possible to define an adjoint operation on *pure supermatrices*. A pure, i.e., *even* or *odd*, $(p|q)$-dimensional supermatrix is written in block form as

$$X = \begin{pmatrix} A & B \\ C & D \end{pmatrix}. \tag{4}$$

The matrix is said to be even if $A \in \mathrm{Mat}_{p\times p}(\mathbb{C}_c)$, $B \in \mathrm{Mat}_{p\times q}(\mathbb{C}_a)$, $C \in \mathrm{Mat}_{q\times p}(\mathbb{C}_a)$, and $D \in \mathrm{Mat}_{q\times q}(\mathbb{C}_c)$. The matrix is called odd if $A \in \mathrm{Mat}_{p\times p}(\mathbb{C}_a)$, $B \in \mathrm{Mat}_{p\times q}(\mathbb{C}_c)$, $C \in \mathrm{Mat}_{q\times p}(\mathbb{C}_c)$, and $D \in \mathrm{Mat}_{q\times q}(\mathbb{C}_a)$. Here $\mathrm{Mat}_{m\times n}(\mathbb{F})$ are $m \times n$ matrices over $\mathbb{F}$.

The standard adjoint operation is defined, as usual, by the conjugate transpose

$$X^{\dagger} = X^{*t}, \tag{5}$$

or in block form

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{\dagger} = \begin{pmatrix} A^{*t} & C^{*t} \\ B^{*t} & D^{*t} \end{pmatrix}.$$

This satisfies the usual properties of an adjoint

$$(XY)^{\dagger} = Y^{\dagger} X^{\dagger},$$

$$X^{\dagger\dagger} = X.$$

It is also possible to use the pseudoconjugate to construct a *graded adjoint*.[6] Note, however, that one cannot construct an adjoint operation which has sensible properties using the pseudoconjugate combined with the ordinary transpose, but rather one must use the *supertranspose*. The supertranspose of a pure $(p|q)$-dimensional supermatrix is defined by

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{st} = \begin{pmatrix} A^t & (-1)^{\epsilon_X} C^t \\ -(-1)^{\epsilon_X} B^t & D^t \end{pmatrix}, \tag{6}$$

where $\epsilon_X = 0$ for even supermatrices, and $\epsilon_X = 1$ for odd supermatrices. Note that with this definition of the supertranspose we have that in general $(X^{st})^{st} \neq X$, see Ref. 6. The graded adjoint is then defined as

$$X^{\ddagger} = X^{\diamond\, st}, \tag{7}$$

and this satisfies a graded version of the properties of the standard adjoint

$$(XY)^{\ddagger} = (-1)^{\epsilon_X \epsilon_Y} Y^{\ddagger} X^{\ddagger},$$

$$X^{\ddagger\ddagger} = (-1)^{\epsilon_X} X.$$

We may also extend the definition of the graded adjoint to *supervectors* in a manner consistent with the definition for supermatrices. We write a pure, i.e., even or odd, $(p|q)$-dimensional supervector as

$$V = \begin{pmatrix} u \\ w \end{pmatrix}.$$

The supervector is said to be even, i.e., $\epsilon_V = 0$, if $u \in \mathrm{Mat}_{p\times 1}(\mathbb{C}_c)$ and $w \in \mathrm{Mat}_{q\times 1}(\mathbb{C}_a)$. It is called odd, i.e., $\epsilon_V = 1$, if $u \in \mathrm{Mat}_{p\times 1}(\mathbb{C}_a)$ and $w \in \mathrm{Mat}_{q\times 1}(\mathbb{C}_c)$. We define the supertranspose of V to be

$$V^{st} = (u^t,\ (-1)^{\epsilon_V} w^t)$$

and the graded adjoint is then defined by

$$V^{\ddagger} = V^{\diamond\, st}.$$

C. Compact form of OSp($n|2m$)

Using the graded adjoint one can define a compact (i.e., unitary) form of the orthosymplectic supergroup $\mathrm{OSp}(n|2m)$ which is not possible with the ordinary adjoint.

The orthosymplectic supergroup is defined by[6]

$$\mathrm{OSp}(n|2m) = \{s \in \mathrm{PL}(n|2m) : s^{st} g s = g\}, \tag{8}$$

where $\mathrm{PL}(n|2m)$ are the invertible even supermatrices of dimension $(n|2m)$ and

$$g = \begin{pmatrix} \mathbb{1}_n & 0 \\ 0 & J_{2m} \end{pmatrix}, \quad J_{2m} = \begin{pmatrix} 0 & \mathbb{1}_m \\ -\mathbb{1}_m & 0 \end{pmatrix}.$$

The algebra is given by

$$\mathrm{osp}(n|2m) = \{X \in \mathrm{pl}(n|2m) : X^{st} g + g X = 0\}, \tag{9}$$

where $\mathrm{pl}(n|2m)$ is the algebra of $\mathrm{PL}(n|2m)$. If we write X in block form, as in Eq. (4), then for X to be in the algebra it must satisfy

$$A^t + A = 0, \tag{10a}$$

$$B + C^t J = 0, \tag{10b}$$

$$D^t J + JD = 0. \tag{10c}$$

From Eqs. (10a) and (10c) we see that the body of the algebra is

$$\mathrm{osp}(n|2m)_0 = o(n) \times \mathrm{sp}(2m).$$

To find a compact form of an algebra we must first complexify it and then impose a consistent anti-Hermitian condition, which yields a unitary group. For the orthosymplectic algebra the standard adjoint of Eq. (5) does not give a consistent anti-Hermitian condition. To see this, note that imposing $X^\dagger = -X$, we find $B^{*t} = -C$ and $C^{*t} = -B$. From Eq. (10b) we have

$$0 = (B + C^t J)^* J = -C^t J + B$$

which together with Eq. (10b) would imply $B = C = 0$. This problem is avoided by using the graded adjoint. Imposing $X^\ddagger = -X$ we have $B^{\diamond t} = C$ and $C^{\diamond t} = -B$. The previous argument now gives

$$0 = (B + C^t J)^{\diamond} J = C^t J + B$$

and hence no inconsistency.

The *unitary* orthosymplectic algebra can now be defined as

$$\mathrm{uosp}(n|2m) = \{X \in \mathrm{osp}(n|2m) \otimes \mathbb{C}_c : X^\ddagger = -X\}, \tag{11}$$

and the group as

$$\mathrm{UOSp}(n|2m) = \{s \in \mathrm{OSp}(n|2m) \otimes \mathbb{C}_c : s^\ddagger = s^{-1}, \mathrm{sdet}(s) = 1\}, \tag{12}$$

where the *superdeterminant* is defined by

$$\mathrm{sdet}\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \det(A - BD^{-1}C)\det(D)^{-1}. \tag{13}$$

Note that in the definition of $\mathrm{UOSp}(n|2m)$ we have imposed the condition $\mathrm{sdet}(s) = 1$, hence strictly speaking we are dealing with the *special* unitary orthosymplectic group, we shall not however refer to it as such.

D. UOSp(1|2)

We will be interested in the particular case of UOSp(1|2). The algebra has three even generators J_i, $i = 0, 1, 2$ and two odd generators Q_α, $\alpha = -, +$, which can be represented as supermatrices

$$J_i = \frac{i}{2}\left(\begin{array}{c|cc} 0 & 0 & 0 \\ \hline 0 & & \\ & & \sigma_i \\ 0 & & \end{array}\right), \quad Q_- = \frac{1}{2}\left(\begin{array}{c|cc} 0 & 0 & 1 \\ \hline 1 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right), \quad Q_+ = \frac{1}{2}\left(\begin{array}{c|cc} 0 & -1 & 0 \\ \hline 0 & 0 & 0 \\ 1 & 0 & 0 \end{array}\right), \tag{14}$$

where $(\sigma_i)^\alpha{}_\beta$ are the standard Pauli matrices. The generators of the algebra satisfy the following commutation and anticommutation relations,

$$[J_i, J_j] = -\epsilon_{ij}{}^k J_k, \tag{15a}$$

$$[J_i, Q_\alpha] = \frac{i}{2}(\sigma_i)_\alpha{}^\beta Q_\beta, \tag{15b}$$

$$[Q_\alpha, Q_\beta] = \frac{i}{2}(\sigma^i)_{\alpha\beta} J_i, \tag{15c}$$

where ϵ_{ijk} is completely antisymmetric with $\epsilon_{012}=1$. The indices $i,j,\ldots$ have been raised and lowered using $\delta^{ij}=\delta_{ij}=\delta^i_j$, whereas $\alpha,\beta,\ldots$ have been raised and lowered using the antisymmetric symbols $\epsilon^{\alpha\beta}$ and $\epsilon_{\alpha\beta}$, with $\epsilon^{-+}=\epsilon_{-+}=1$. The raising and lowering conventions, along with their application to the Pauli matrices, are discussed more in Appendix A. The bracket [,] shall denote the anticommutator whenever both entries are odd, as, e.g., in Eq. (15c). In any other case [,] is to be understood as the commutator.

The Casimir operator C of uosp(1|2) is given by

$$C = J^i J_i - \epsilon^{\alpha\beta} Q_\alpha Q_\beta.$$

A general element of the algebra can be expanded as $X=\theta^i J_i + \eta^\alpha Q_\alpha$, where $\theta^i \in \mathbb{R}_c$ and $\eta^- = \eta^\diamond$, $\eta^+ = \eta$, with $\eta \in \mathbb{C}_a$. We find that X is anti-Hermitian as the generators satisfy the following Hermiticity properties:

$$J_i^\ddagger = -J_i,$$

$$(Q_\alpha)^\ddagger = \epsilon^{\alpha\beta} Q_\beta.$$

Note that if we naively multiplied the generators by a supernumber we would not obtain an anti-Hermitian element X. The correct definition of left and right multiplication is[10]

$$z\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \begin{pmatrix} zA & zB \\ (-1)^{\epsilon_z} zC & (-1)^{\epsilon_z} zD \end{pmatrix},$$

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} z = \begin{pmatrix} Az & (-1)^{\epsilon_z} Bz \\ Cz & (-1)^{\epsilon_z} Dz \end{pmatrix}.$$

The general element of the group UOSp(1|2) can be represented by a supermatrix

$$s(a,b,\eta) = \begin{pmatrix} 1+\frac{1}{4}\eta\eta^\diamond & -\frac{1}{2}\eta & \frac{1}{2}\eta^\diamond \\ -\frac{1}{2}\eta^\diamond & 1-\frac{1}{8}\eta\eta^\diamond & 0 \\ -\frac{1}{2}\eta & 0 & 1-\frac{1}{8}\eta\eta^\diamond \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & a & -b^\diamond \\ 0 & b & a^\diamond \end{pmatrix} \tag{16a}$$

$$= \begin{pmatrix} 1+\frac{1}{4}\eta\eta^\diamond & -\frac{1}{2}(\eta a - \eta^\diamond b) & \frac{1}{2}(\eta b^\diamond + \eta^\diamond a^\diamond) \\ -\frac{1}{2}\eta^\diamond & \left(1-\frac{1}{8}\eta\eta^\diamond\right)a & -\left(1-\frac{1}{8}\eta\eta^\diamond\right)b^\diamond \\ -\frac{1}{2}\eta & \left(1-\frac{1}{8}\eta\eta^\diamond\right)b & \left(1-\frac{1}{8}\eta\eta^\diamond\right)a^\diamond \end{pmatrix}, \tag{16b}$$

where the parameters $a,b \in \mathbb{C}_c$ are constrained by $\mathrm{sdet}(s) = aa^\diamond + bb^\diamond = 1$, and $\eta \in \mathbb{C}_a$ is unconstrained. Note that the first matrix on the right-hand side of Eq. (16a) is just $\exp(\eta^\alpha Q_\alpha)$. The second matrix is of the form $\exp(\theta^i J_i)$, for some $\theta^i \in \mathbb{R}_c$ determining the constrained parameters a and b. From this we see that the body of uosp(1|2) is simply $\mathrm{uosp}(1|2)_0 = \mathrm{su}(2)$ which will be important in the next section.

III. CONSTRUCTING THE SUPERSPHERE

A. General coset spaces

We shall briefly review the general formalism for constructing spaces as coset spaces, covered in, for example, Ref. 11.

Consider a group G with a subgroup H. We define an equivalence relation on G by

$$g_1 \sim g_2 \Leftrightarrow g_2^{-1} g_1 \in H.$$

Each element $g \in G$ lies in an equivalence class

$$gH \equiv \{gh\colon\ h \in H\}.$$

The set of all equivalence classes is the (right-)coset space G/H, written as

$$G/H \equiv \{gH\colon\ g \in G\}.$$

We can define a projection map $\pi\colon\ G \to G/H$ by sending an element $g \in G$ to its equivalence class $gH \in G/H$. Also, for each point in the coset space we may choose a particular element of G which projects down to this point under π, this group element is called a *coset representative*.

The left action of G on itself descends to an action of G on the coset space

$$g'\colon\ G/H \to G/H$$

$$:gH \mapsto g'gH.$$

This is well defined as it is clearly independent of the coset representative chosen.

In Sec. V we will introduce a vielbein and spin connection on G/H which are invariant under this left action, and as such we will think of G as the isometry group of the coset space.

B. The sphere as a coset space

We first review how the ordinary sphere can be constructed as the coset space $S^2 = \mathrm{SU}(2)/\mathrm{U}(1)$. This construction is then straightforward to generalize to the case of the supersphere.

The group SU(2) has the 2×2 matrix representation

$$s(a,b) = \begin{pmatrix} a & -b^* \\ b & a^* \end{pmatrix},$$

where the parameters $a, b \in \mathbb{C}_0$ are just ordinary complex numbers which are constrained by $aa^* + bb^* = 1$. The matrices $s(w,0)$, with $ww^* = 1$, form a U(1) subgroup. We define an equivalence relation on SU(2) by multiplication on the right with an element of this U(1) subgroup,

$$s(a,b) \sim s(a',b') = s(a,b)s(w,0).$$

This equivalence relation defines the coset space SU(2)/U(1). The projection map for this coset space is the standard *Hopf map*, it can be written as

$$\pi\colon\ \mathrm{SU}(2) \to \mathrm{SU}(2)/\mathrm{U}(1)$$

$$:s(a,b) \mapsto s(a,b)\hat{J}_0 s(a,b)^\dagger,$$

where $\hat{J}_0 = (i/2)\sigma_0$ is the element of the algebra su(2) which generates the U(1) subgroup. Note we consider the image of π as a subset of the algebra su(2), which is just $\mathbb{R}^3$ as a vector space. Expanding the image in coordinates we have

$$s(a,b)\hat{J}_0 s(a,b)^\dagger = \sum_{i=0}^{2} x^i \hat{J}_i,$$

where $x^i \in \mathbb{R}$. This equation leads to the constraint

$$(x^0)^2 + (x^1)^2 + (x^2)^2 = 1,$$

hence the coset space SU(2)/U(1) is just an ordinary sphere, $S^2 \subseteq \mathbb{R}^3$.

C. The supersphere as a coset space

The construction of the preceding section naturally generalizes to the case of the supersphere,[3,4] which we will see can be defined as the coset space $S^{2|2}=\mathrm{UOSp}(1|2)/\mathcal{U}(1)$. Here $\mathcal{U}(1)\equiv\{w\in\mathbb{C}_c: ww^{\diamond}=1\}$ is the even Grassmann extension of the group U(1).

We use the matrix representation of UOSp(1|2) defined in Eqs. (16a) and (16b). The equivalence relation on UOSp(1|2) is given by multiplication on the right with an element of a $\mathcal{U}(1)$ subgroup,

$$s(a,b,\eta)\sim s(a',b',\eta')=s(a,b,\eta)s(w,0,0). \tag{17}$$

In terms of the group parameters we have

$$a'=aw,\quad b'=bw,\quad \eta'=\eta.$$

This equivalence relation defines the coset space $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$. Note that the body of this coset space is just SU(2)/U(1), which as we showed in the preceding section is just an S^2. The projection map for this coset is a supersymmetric generalization of the ordinary Hopf map, it can be written as

$$\begin{aligned}\pi:\ &\mathrm{UOSp}(1|2)\to\mathrm{UOSp}(1|2)/\mathcal{U}(1)\\ &:s(a,b,\eta)\mapsto s(a,b,\eta)J_0s(a,b,\eta)^{\ddagger}.\end{aligned} \tag{18}$$

Note that the image of this map is considered as a subset of the algebra uosp(1|2). Expanding the image in coordinates we have

$$s(a,b,\eta)J_0s(a,b,\eta)^{\ddagger}=\sum_{i=0}^{2}x^iJ_i+\sum_{\alpha=\pm}\xi^{\alpha}Q_{\alpha}, \tag{19}$$

where $x^i\in\mathbb{R}_c$ and $\xi^{\pm}\in\mathbb{C}_a$. It is then possible to solve for the coordinates in terms of the group parameters, which yields

$$x^0=(1-\tfrac{1}{4}\eta\eta^{\diamond})(aa^{\diamond}-bb^{\diamond}), \tag{20a}$$

$$x^1=(1-\tfrac{1}{4}\eta\eta^{\diamond})(ab^{\diamond}+a^{\diamond}b), \tag{20b}$$

$$x^2=i(1-\tfrac{1}{4}\eta\eta^{\diamond})(ab^{\diamond}-a^{\diamond}b), \tag{20c}$$

$$\xi^{-}=-\frac{i}{2}(2\eta ab^{\diamond}+\eta^{\diamond}(aa^{\diamond}-bb^{\diamond})), \tag{20d}$$

$$\xi^{+}=-\frac{i}{2}(2\eta^{\diamond}a^{\diamond}b-\eta(aa^{\diamond}-bb^{\diamond})). \tag{20e}$$

These coordinates satisfy the constraint

$$(x^0)^2+(x^1)^2+(x^2)^2-2\xi^{-}\xi^{+}=1, \tag{21}$$

which is the equation for the unit supersphere $S^{2|2}\subseteq\mathbb{R}^{3|2}$. Another way to think about this equation is as a two-sphere in the even coordinates, with a radius dependent on the odd coordinates, given by $1+\xi^{-}\xi^{+}=1-\frac{1}{4}\eta\eta^{\diamond}$. It is also clear from Eq. (21) that the body of the supersphere is just an ordinary sphere, as expected.

The reality of the coordinates x^i and ξ^{α} is defined with respect to the pseudoconjugate; we have $(x^i)^{\diamond}=x^i$ and $(\xi^{-})^{\diamond}=-\xi^{+}$, $((\xi^{+})^{\diamond}=\xi^{-})$. Note that if we expand out the coordinates in terms of

the Grassmann generators as in Eq. (1) then these reality conditions give the same number of constraints, as would be obtained with standard complex conjugation, which reduces the dimensionality down from that of $\mathbb{C}^{3|2}$ to that of $\mathbb{R}^{3|2}$. Obviously for the purposes of counting these constraints we must take the number of Grassmann generators, N, to be finite.

D. Unconstrained coordinates

In this section we will construct unconstrained coordinates on the supersphere. On S^2 we can define, for example, polar and stereographic coordinates and we will generalize these to $S^{2|2}$ in the following.

We first note that the general element of UOSp(1|2) can be written as

$$s = e^{\eta^\alpha Q_\alpha} e^{-\varphi J_0} e^{-\theta J_2} e^{-\psi J_0}.$$

Here $\theta, \varphi, \psi \in \mathbb{R}_c$, and their bodies are chosen to be in the range $0 \leqslant \theta_0 \leqslant \pi$, $-\pi < \varphi_0 \leqslant \pi$ and $-\pi < \psi_0 \leqslant \pi$. Here θ_0, the body of θ, should not be confused with the coordinate θ^0. A convenient choice of coset representative is given by taking $\psi = 0$, i.e.,

$$L_1(\theta, \varphi, \eta, \eta^\diamond) = e^{\eta^\alpha Q_\alpha} e^{-\varphi J_0} e^{-\theta J_2}. \tag{22}$$

Thus we have $(\theta, \varphi, \eta, \eta^\diamond)$ as coordinates on $S^{2|2}$. The constrained coordinates $(x^0, x^1, x^2, \xi^-, \xi^+)$ of Eqs. (20a)–(20e) can be written in terms of these generalized polar coordinates as

$$x^0 = (1 - \tfrac{1}{4}\eta\eta^\diamond)\cos\theta, \tag{23a}$$

$$x^1 = (1 - \tfrac{1}{4}\eta\eta^\diamond)\sin\theta\cos\varphi, \tag{23b}$$

$$x^2 = (1 - \tfrac{1}{4}\eta\eta^\diamond)\sin\theta\sin\varphi, \tag{23c}$$

$$\xi^- = -\frac{i}{2}(\eta e^{-i\varphi}\sin\theta + \eta^\diamond\cos\theta), \tag{23d}$$

$$\xi^+ = -\frac{i}{2}(\eta^\diamond e^{i\varphi}\sin\theta - \eta\cos\theta). \tag{23e}$$

Note that the trigonometric functions for supernumbers are defined in terms of the usual power series; the usual trigonometric identities are satisfied if the angles are even supernumbers. Also note the appearance of the radius factor, $1 - \frac{1}{4}\eta\eta^\diamond$, in Eqs. (23a)–(23c).

To define a generalization of stereographic coordinates we take a different coset representative $L_2(z, z^\diamond, \eta, \eta^\diamond)$, which can be written in the matrix representation of Eq. (16a) as

$$L_2 = \begin{pmatrix} 1 + \frac{1}{4}\eta\eta^\diamond & -\frac{1}{2}\eta & \frac{1}{2}\eta^\diamond \\ -\frac{1}{2}\eta^\diamond & 1 - \frac{1}{8}\eta\eta^\diamond & 0 \\ -\frac{1}{2}\eta & 0 & 1 - \frac{1}{8}\eta\eta^\diamond \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{z^\diamond}{(1+zz^\diamond)^{1/2}} & \frac{-1}{(1+zz^\diamond)^{1/2}} \\ 0 & \frac{1}{(1+zz^\diamond)^{1/2}} & \frac{z}{(1+zz^\diamond)^{1/2}} \end{pmatrix}. \tag{24}$$

The complex coordinate z is related to the previous coordinates by

$$z = \frac{x^1 + ix^2}{1 + \xi^- \xi^+ - x^0} = \frac{e^{i\varphi} \sin\theta}{1 - \cos\theta}, \tag{25}$$

where again the radius factor, $1+\xi^-\xi^+$, appears. We will find later that the coordinate η is not the most convenient for our purposes, with hindsight we thus define a new odd coordinate χ, and its pseudoconjugate $\chi^\diamond$, by

$$\chi = -\frac{i}{2}(\eta^\diamond z + \eta), \quad \chi^\diamond = \frac{i}{2}(\eta^\diamond - \eta z^\diamond). \tag{26}$$

These relations can be inverted, giving

$$\eta = \frac{2i(\chi^\diamond z + \chi)}{(1 + zz^\diamond)}, \quad \eta^\diamond = \frac{2i(\chi z^\diamond - \chi^\diamond)}{(1 + zz^\diamond)}.$$

Rewriting η in terms of χ gives us the coset representative for the point (z,χ), which we write as

$$L_3(z,z^\diamond,\chi,\chi^\diamond) = L_2(z,z^\diamond,\eta(\chi,\chi^\diamond),\eta^\diamond(\chi,\chi^\diamond)). \tag{27}$$

Note that the coordinates (z,χ) cover a single $\mathbb{C}^{1|1}$ chart on $S^{2|2}$. From Eq. (25) we see that as $\theta_0 \to 0$ we have $z \to \infty$, thus these coordinates can be viewed as generalizations of stereographic coordinates projected from the north pole (i.e., $\theta=0$). To cover the entire supersphere we need a second coordinate patch, which we will think of as projection from the south pole. Away from both the north and south pole we define a new (even) complex coordinate by $w=z^{-1}$. A coset representative for the point (w,η) is given by

$$L_2' = \begin{pmatrix} 1 + \frac{1}{4}\eta\eta^\diamond & -\frac{1}{2}\eta & \frac{1}{2}\eta^\diamond \\ -\frac{1}{2}\eta^\diamond & 1 - \frac{1}{8}\eta\eta^\diamond & 0 \\ -\frac{1}{2}\eta & 0 & 1 - \frac{1}{8}\eta\eta^\diamond \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{(1+ww^\diamond)^{1/2}} & \frac{-w}{(1+ww^\diamond)^{1/2}} \\ 0 & \frac{w^\diamond}{(1+ww^\diamond)^{1/2}} & \frac{1}{(1+ww^\diamond)^{1/2}} \end{pmatrix}.$$

This can be obtained from the coset representative L_2 by multiplication on the right with

$$s\left(\frac{z}{(zz^\diamond)^{1/2}},0,0\right) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{z}{(zz^\diamond)^{1/2}} & 0 \\ 0 & 0 & \frac{z^\diamond}{(zz^\diamond)^{1/2}} \end{pmatrix},$$

which, as it should be, is an element of the $\mathcal{U}(1)$ subgroup of UOSp(1|2). We will also need the analogue of the coordinate χ for this patch, which we take to be

$$\zeta = \frac{i}{2}(\eta^\diamond w + \eta). \tag{28}$$

Away from the poles, the two coordinate patches are related by the holomorphic transformations

$$w = \frac{1}{z}, \quad \zeta = -\frac{\chi}{z}. \tag{29}$$

The two patches (z,χ) and (w,ζ) taken together cover the whole supersphere.

E. Other superspheres

At this stage we should mention that the coset space $S^{2|2}=\mathrm{UOSp}(1|2)/\mathcal{U}(1)$ is not the only way in which a supersphere can be defined. There are at least two other possible coset constructions.

(i) $\mathrm{OSp}(3|2)/\mathrm{OSp}(2|2)$—The ordinary two-sphere can be constructed as the coset space O(3)/O(2); since the body of $\mathrm{OSp}(n|2m)$ is just $\mathrm{O}(n)\times\mathrm{Sp}(2m)$ it is natural to consider the coset space $\mathrm{OSp}(3|2)/\mathrm{OSp}(2|2)$ as a supersymmetric generalization of this.[2] The body of this space is clearly just the ordinary two-sphere. Just as $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$ is, as a subset of $\mathbb{R}^{3|2}$, given by Eq. (21), so is $\mathrm{OSp}(3|2)/\mathrm{OSp}(2|2)$. Now, however, the coordinates x^i and ξ^α are just real supernumbers, i.e., when expanded in the Grassmann generators, as in Eq. (1), all the coefficients are real numbers.

(ii) $\mathrm{SU}(2|1)/\mathrm{U}(1|1)$—This construction is a generalization of that of the complex projective plane. The body of this coset space is given by $\mathrm{U}(2)/(\mathrm{U}(1)\times\mathrm{U}(1))=\mathbb{C}P^1$. As the orthosymplectic groups are not used in this construction the use of the pseudoconjugate and graded adjoint is not required. This space, called $\mathbb{C}P^{1|1}$, and its generalizations $\mathbb{C}P^{n|m}$ are considered further in Ref. 5.

However, neither of these two coset spaces can naturally be considered what one calls a *superspace*. A coset space G/H will be a superspace if it satisfies two conditions. First, the subgroup H should be (the even Grassmann extension of) the tangent space group of the body of the coset space. This will correspond to a restriction of the tangent space group of a general supermanifold. Second, we require that under the (co)-adjoint action of H the odd generators of the algebra of G transform as spinors. The coset space $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$ satisfies both of these conditions, U(1) is the tangent space group of the ordinary sphere, and we see from Eq. (15b) that $Q_\pm$ transform as spinors. Most other treatments use the supersphere as a target space for some sigma model[1,2] and thus do not require a superspace structure. Here we shall be treating the supersphere as the base space for our field theories and as such require it to be a superspace. This will be discussed more in Sec. V.

IV. ACTION OF UOSp(1|2) ON $S^{2|2}$

A. Transformation of the coordinates under UOSp(1|2)

Using the general result of Sec. III A we see that the left action of UOSp(1|2) is well defined on the coset space $S^{2|2}$. First we wish to show how such a transformation acts on the unconstrained coordinates (z,χ) which were defined in Sec. III D. The left action of the arbitrary element $s(c,d,\beta)\in\mathrm{UOSp}(1|2)$ transforms the coset representative $L_3(z,z^\diamond,\chi,\chi^\diamond)$ as

$$L_3(z,z^\diamond,\chi,\chi^\diamond)\to L_3(z',z'^\diamond,\chi',\chi'^\diamond)=s(c,d,\beta)L_3(z,z^\diamond,\chi,\chi^\diamond).$$

We can split the transformation as $s(c,d,\beta)=s(1,0,\beta)s(c,d,0)$ and analyze the two parts separately. Using Eqs. (16a) and (27) we find, that under the action of $s(c,d,0)$ the coordinates transform as

$$z'=\frac{c^\diamond z-d}{d^\diamond z+c}, \tag{30a}$$

$$\chi'=\frac{\chi}{d^\diamond z+c}, \tag{30b}$$

whereas under $s(1,0,\beta)$ we have

$$z'=\left(1-\frac{i}{2}\beta^\diamond\chi\right)z-\frac{i}{2}\beta\chi, \tag{31a}$$

$$\chi' = \left(1 + \frac{1}{8}\beta\beta^{\diamond}\right)\chi - \frac{i}{2}(\beta + \beta^{\diamond} z). \tag{31b}$$

Obviously we can take the pseudoconjugate of these equations to find how $z^{\diamond}$ and $\chi^{\diamond}$ transform.

Note that the group element $s(c,d,0)$ is obtained by exponentiating just the J_i generators of the uosp(1|2) algebra. We also see that the form of Eq. (30a) is that of a Möbius transformation corresponding to the rotation of a sphere. We thus refer to the transformations of Eqs. (30a) and (30b) as the rotations of the supersphere. The group element $s(1,0,\beta)$ is obtained by exponentiating only the Q_α algebra generators. We will therefore refer to Eqs. (31a) and (31b) as the supersymmetry transformations.

For completeness we must also consider how the (w,ζ) coordinates of the other patch transform. We find that under rotations given by $s(c,d,0)$ we have

$$w' = \frac{d^{\diamond} + cw}{c^{\diamond} - dw},$$

$$\zeta' = \frac{\zeta}{c^{\diamond} - dw}.$$

Under supersymmetry transformations given by $s(1,0,\beta)$ we have

$$w' = \left(1 - \frac{i}{2}\beta\zeta\right)w - \frac{i}{2}\beta^{\diamond}\zeta,$$

$$\zeta' = \left(1 + \frac{1}{8}\beta\beta^{\diamond}\right)\zeta + \frac{i}{2}(\beta^{\diamond} + \beta w).$$

Again we may take the pseudoconjugate of these equations to find the transformation properties of $w^{\diamond}$ and $\zeta^{\diamond}$.

B. Differential operator representation of uosp(1|2)

We may use the transformation properties of the coordinates under UOSp(1|2) to construct a differential operator representation of the algebra uosp(1|2).

The coordinates $(z,z^{\diamond},\chi,\chi^{\diamond})$ can be represented by a single superspace coordinate X^M, where the index $M=(m,\mu)$ runs over $m=z,z^{\diamond}$, $\mu=\chi,\chi^{\diamond}$. We may then define a superscalar field Φ on the supersphere, which is just a supernumber valued function on $S^{2|2}$. In this coordinate patch it takes the value $\Phi(X)$.

Now consider an infinitesimal active coordinate transformation $X \to X + \delta X$. As discussed more in Appendix F, we may alternatively think of this as a transformation of the field, $\Phi(X)$, given by

$$\Phi(X) \to \Phi'(X) = \Phi(X - \delta X). \tag{32}$$

Expanding to first order we have

$$\delta\Phi(X) = -\delta X^M \partial_M \Phi(X). \tag{33}$$

For the case of an isometry we can write $\delta X^M = \delta u K^M$, where δu is some small parameter, and K^M is a Killing supervector. The quantity $-K^M\partial_M$ will then be the differential operator corresponding to the isometry.

First we shall consider the rotations of Eqs. (30a) and (30b). For a rotation generated by the element J_0 we have $s(c,d,0)=e^{\theta^0 J_0}$, hence

$$c = e^{i\theta^0/2}, \quad d = 0.$$

Expanding Eqs. (30a) and (30b) to first order in θ^0 we find

$$\delta z = -i\theta^0 z, \quad \delta\chi = -\frac{i}{2}\theta^0\chi,$$

$\delta z^\diamond$ and $\delta\chi^\diamond$ are obtained by taking the pseudoconjugate of these equations. Substituting into Eq. (33) gives us the differential operator corresponding to J_0, namely,

$$\tilde{J}_0 = i\left[z\frac{\partial}{\partial z} - z^\diamond\frac{\partial}{\partial z^\diamond} + \frac{1}{2}\chi\frac{\partial}{\partial\chi} - \frac{1}{2}\chi^\diamond\frac{\partial}{\partial\chi^\diamond}\right]. \tag{34a}$$

A similar argument leads to the differential operators for J_1 and J_2,

$$\tilde{J}_1 = \frac{i}{2}\left[(1-z^2)\frac{\partial}{\partial z} - (1-z^{\diamond 2})\frac{\partial}{\partial z^\diamond} - z\chi\frac{\partial}{\partial\chi} + z^\diamond\chi^\diamond\frac{\partial}{\partial\chi^\diamond}\right], \tag{34b}$$

$$\tilde{J}_2 = -\frac{1}{2}\left[(1+z^2)\frac{\partial}{\partial z} + (1+z^{\diamond 2})\frac{\partial}{\partial z^\diamond} + z\chi\frac{\partial}{\partial\chi} + z^\diamond\chi^\diamond\frac{\partial}{\partial\chi^\diamond}\right]. \tag{34c}$$

Now consider the supersymmetry transformations of Eqs. (31a) and (31b). Expanding these to first order in β and $\beta^\diamond$, and substituting into Eq. (33) we find the differential operators corresponding to Q_- and Q_+,

$$\tilde{Q}_- = \frac{i}{2}\left[\chi z\frac{\partial}{\partial z} - \chi^\diamond\frac{\partial}{\partial z^\diamond} + z\frac{\partial}{\partial\chi} - \frac{\partial}{\partial\chi^\diamond}\right], \tag{34d}$$

$$\tilde{Q}_+ = \frac{i}{2}\left[\chi\frac{\partial}{\partial z} + \chi^\diamond z^\diamond\frac{\partial}{\partial z^\diamond} + \frac{\partial}{\partial\chi} + z^\diamond\frac{\partial}{\partial\chi^\diamond}\right]. \tag{34e}$$

It is straightforward to verify that the generators of Eqs. (34a)–(34e) satisfy the uosp$(1|2)$ algebra. As stated earlier they are of the form $-K_p^M\partial_M$, where $p=0,1,2,-,+$ labels the generators. This allows us to read off the Killing supervectors K_p^M of the supersphere.

In order to construct a superfield theory on $S^{2|2}$ we first have to introduce the invariant vielbein and spin connection, which we do next.

V. COSET SPACE GEOMETRY

A. Vielbein and spin connection for reductive coset spaces

Consider some Lie group G, a subgroup H of G and the space of right cosets $G/H = \{gH: g \in G\}$. The Lie algebra $\mathfrak{h}$ of H is spanned by the generators $H_I \in \mathfrak{h}$, $I=1,\ldots,\dim H$. Let the remaining generators of the Lie algebra $\mathfrak{g}$ of G span $\mathfrak{k} \subseteq \mathfrak{g}$. We shall denote these remaining generators by $K_A \in \mathfrak{k}$, $A=1,\ldots,\dim G - \dim H$. As a vector space we then have

$$\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{k}.$$

The structure constants of G are defined by

$$[H_I, H_J] = f_{IJ}{}^K H_K,$$

$$[H_I, K_A] = f_{IA}{}^J H_J + f_{IA}{}^B K_B,$$

$$[K_A,K_B] = f_{AB}{}^J H_J + f_{AB}{}^C K_C.$$

If $\mathfrak{k}$ can be chosen such that the structure constants $f_{IA}{}^J$ vanish, the coset space G/H is said to be *reductive*.

Suppose now that the coset manifold G/H is parametrized by coordinates Y^M, $M=1,\ldots,\dim G-\dim H$, and so the coset representative may be written $L(Y^M)$. For reductive coset spaces we can then define an invariant vielbein E^A and spin connection ω^I by

$$L^{-1}(Y)dL(Y) = E^A K_A + \omega^I H_I, \tag{35}$$

which is a generalization of the left-invariant Maurer–Cartan form for Lie groups. Here $L(Y)$ is assumed to be in a matrix representation.

Note that these are indeed *invariant* one-forms since under a left action of $g \in G$ on the coset space we have

$$L \mapsto gL, \tag{36a}$$

$$L^{-1}dL \mapsto (L^{-1}g^{-1})d(gL) = L^{-1}dL, \tag{36b}$$

where g is constant on the coset space. Hence we can think of this action as an isometry.

In contrast, under a right action of $h^{-1} \in H$ on the coset space we find

$$L \mapsto Lh^{-1}, \tag{37a}$$

$$L^{-1}dL \mapsto hL^{-1}d(Lh^{-1}) = h(L^{-1}dL)h^{-1} + hdh^{-1}, \tag{37b}$$

and hence

$$E^A K_A + \omega^I H_I \mapsto \underbrace{h(E^A K_A)h^{-1}}_{\in \mathfrak{k}} + \underbrace{h(\omega^I H_I)h^{-1} + hdh^{-1}}_{\in \mathfrak{h}}.$$

Here $h=h(Y)$, i.e., h is not necessarily constant on the coset space, but is rather a local transformation. Note that $h(E^A K_A)h^{-1} \in \mathfrak{k}$ is only true for reductive coset spaces. Thus we have

$$E^A K_A \mapsto E'^A K_A = E^A(hK_A h^{-1}), \tag{38a}$$

$$\omega^I H_I \mapsto \omega'^I H_I = \omega^I(hH_I h^{-1}) + hdh^{-1}. \tag{38b}$$

We can rewrite this using the co-adjoint representation[12] of G, i.e., $g \mapsto R_p{}^q(g)$, which is defined as

$$g^{-1}T_p g = R_p{}^q(g)T_q, \tag{39}$$

where T_p, $p=1,\ldots,\dim G$, are the generators of $\mathfrak{g}$. Thus we have

$$hK_A h^{-1} = R_A{}^B(h^{-1})K_B$$

and so we can alternatively write

$$E^A \mapsto E'^A = E^B R_B{}^A(h^{-1}). \tag{40}$$

Rewriting Eq. (38b) in the co-adjoint representation we find

$$\omega'^I(\tilde{H}_I)_A{}^B = \omega^I R_A{}^C(h)(\tilde{H}_I)_C{}^D R_D{}^B(h^{-1}) + R_A{}^C(h)dR_C{}^B(h^{-1}),$$

where $\tilde{H}_I$ denotes the generator H_I in the co-adjoint representation. Defining $\Omega_A{}^B = \omega^I(\tilde{H}_I)_A{}^B$ we can finally write Eq. (38b) as

$$\Omega_A{}^B \mapsto \Omega'^B_A = R_A{}^C(h)\Omega_C{}^D R_D{}^B(h^{-1}) + R_A{}^C(h)dR_C{}^B(h^{-1}).$$

In this sense the right action of h^{-1} on the coset space, defined in Eq. (37a), can be regarded as a local gauge transformation acting on the tangent space.

B. Vielbein and spin connection for $S^{2|2}$

We will now derive the superzweibein and spin connection for $S^{2|2}$ following the construction given in the preceding section.

As mentioned in Sec. III C the supersphere $S^{2|2}$ is, as a coset space, given by $S^{2|2} = \mathrm{UOSp}(1|2)/\mathcal{U}(1)$. As before we will split up the generators of $G=\mathrm{UOSp}(1|2)$ into the generator of the subgroup $H=\mathcal{U}(1)$, which we take to be J_0, and the remaining generators K_A, $A=(a,\alpha)$, which are given by J_a, Q_α, with $a=1,2$, $\alpha=-,+$, see Eqs. (15a)–(15c). In this case we have—apart from $S^{2|2}$ being a reductive coset space—the additional structure that

$$[H,Q] \subseteq Q,$$

$$[H,J] \subseteq J,$$

hence

$$h^{-1}Q_\alpha h = R_\alpha{}^A(h)K_A = R_\alpha{}^\beta(h)Q_\beta,$$

$$h^{-1}J_a h = R_a{}^A(h)K_A = R_a{}^b(h)J_b,$$

Thus $R_A{}^B(h)$ takes block diagonal form

$$R_A{}^B(h) = \begin{pmatrix} R_a{}^b(h) & 0 \\ 0 & R_\alpha{}^\beta(h) \end{pmatrix}. \tag{41}$$

Using the matrix representation of the UOSp(1|2) algebra, see Eq. (14), we find for $R_a{}^b(h)$ and $R_\alpha{}^\beta(h)$, respectively,

$$R_a{}^b(h) = \begin{pmatrix} \cos\varphi & \sin\varphi \\ -\sin\varphi & \cos\varphi \end{pmatrix}, \tag{42a}$$

$$R_\alpha{}^\beta(h) = \begin{pmatrix} e^{-i\varphi/2} & 0 \\ 0 & e^{i\varphi/2} \end{pmatrix}. \tag{42b}$$

We see that tangent supervectors V^A belong to a (completely) reducible representation of the tangent space group; the components V^a transform in the vector representation, whereas the components V^α transform in the corresponding spinor representation of $\mathcal{U}(1)$. In this sense we are dealing with a superspace rather than just a supermanifold (see Sec. III E).

To construct the superzweibein and spin connection in the particular case of $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$ we must choose an appropriate coset representative. This is given by

$$L_1(\theta,\phi,\eta,\eta^\diamond) = e^{\eta^\alpha Q_\alpha} e^{-\phi J_0} e^{-\theta J_2},$$

as defined in Eq. (22). In matrix form [see Eq. (16a)] we have

$$L_1(\theta,\phi,\eta,\eta^\diamond)=\begin{pmatrix} 1+\frac{1}{4}\eta\eta^\diamond & -\frac{1}{2}\eta & \frac{1}{2}\eta^\diamond \\ -\frac{1}{2}\eta^\diamond & 1-\frac{1}{8}\eta\eta^\diamond & 0 \\ -\frac{1}{2}\eta & 0 & 1-\frac{1}{8}\eta\eta^\diamond \end{pmatrix}\begin{pmatrix} 1 & 0 & 0 \\ 0 & a & -b^\diamond \\ 0 & b & a^\diamond \end{pmatrix},$$

where here $a(\theta,\varphi)=e^{-i\varphi/2}\cos(\theta/2)$ and $b(\theta,\varphi)=e^{i\varphi/2}\sin(\theta/2)$. According to the general formalism derived in the preceding section, the superzweibein and spin connection for $S^{2|2}$ as the coset space can be derived from the generalized Maurer–Cartan one-form, Eq. (35),

$$L_1{}^{-1}(\theta,\phi,\eta,\eta^\diamond)dL_1(\theta,\phi,\eta,\eta^\diamond)=E^AK_A+\omega^IH_I,$$

with $H_I=J_0$ and $K_A=(J_a,Q_\alpha)$, $a=1,2$, $\alpha=-,+$. This way we obtain the superzweibein and spin connection in (super)-polar coordinates. Their explicit form is given in Appendix B.

Using instead the coset representative defined in Eq. (27) we find for the superzweibein in complex (stereographic) coordinates

$$(E_M{}^A)=\begin{pmatrix} \frac{-i}{1+zz^\diamond+\chi\chi^\diamond} & \frac{1}{1+zz^\diamond+\chi\chi^\diamond} & \frac{-2i(\chi z^\diamond-\chi^\diamond)}{(1+zz^\diamond)^{3/2}} & 0 \\ \frac{i}{1+zz^\diamond+\chi\chi^\diamond} & \frac{1}{1+zz^\diamond+\chi\chi^\diamond} & 0 & \frac{-2i(\chi^\diamond z+\chi)}{(1+zz^\diamond)^{3/2}} \\ \frac{-i\chi}{1+zz^\diamond} & \frac{\chi}{1+zz^\diamond} & \frac{2i}{(1+zz^\diamond-\chi\chi^\diamond)^{1/2}} & 0 \\ \frac{i\chi^\diamond}{1+zz^\diamond} & \frac{\chi^\diamond}{1+zz^\diamond} & 0 & \frac{2i}{(1+zz^\diamond-\chi\chi^\diamond)^{1/2}} \end{pmatrix},$$

where the index M, as before, runs over z, $z^\diamond$, χ, $\chi^\diamond$. For the inverse superzweibein, which we will make extensive use of later, we have

$$(E_A{}^M)=\begin{pmatrix} \frac{i}{2}(1+zz^\diamond) & -\frac{i}{2}(1+zz^\diamond) & \frac{i}{2}(\chi z^\diamond-\chi^\diamond) & -\frac{i}{2}(\chi^\diamond z+\chi) \\ \frac{1}{2}(1+zz^\diamond) & \frac{1}{2}(1+zz^\diamond) & \frac{1}{2}(\chi z^\diamond-\chi^\diamond) & \frac{1}{2}(\chi^\diamond z+\chi) \\ \frac{i}{2}(1+zz^\diamond)^{1/2}\chi & 0 & -\frac{i}{2}(1+zz^\diamond+\chi\chi^\diamond)^{1/2} & 0 \\ 0 & \frac{i}{2}(1+zz^\diamond)^{1/2}\chi^\diamond & 0 & -\frac{i}{2}(1+zz^\diamond+\chi\chi^\diamond)^{1/2} \end{pmatrix}.$$

Note that the two coset representatives, Eqs. (22) and (27), differ by a gauge transformation only. Thus, the superzweibein in complex coordinates can be derived from the one in polar coordinates by means of a gauge transformation, see Eq. (40).

In order to construct a superfield Lagrangian later on we will make special use of E_- and E_+, which we can read off from $(E_A{}^M)$ above. We have

$$E_-=\frac{i}{2}(1+zz^\diamond+\chi\chi^\diamond)^{1/2}(\chi\partial_z-\partial_\chi), \tag{43a}$$

$$E_+=\frac{i}{2}(1+zz^\diamond+\chi\chi^\diamond)^{1/2}(\chi^\diamond\partial_{z^\diamond}-\partial_{\chi^\diamond}). \tag{43b}$$

The superdeterminant [cf. Eq. (13)] of $(E_M{}^A)$ is given by

$$E \equiv \mathrm{sdet}(E_M{}^A) = \frac{i}{2}\frac{1}{1+zz^\diamond+\chi\chi^\diamond} = \frac{i}{2}\frac{1+zz^\diamond-\chi\chi^\diamond}{(1+zz^\diamond)^2}. \tag{44}$$

Finally, we have for the spin connection in complex coordinates

$$\begin{aligned}\omega^0 &= \frac{i}{1+zz^\diamond+\chi\chi^\diamond}(z^\diamond dz - zdz^\diamond + d\chi\chi^\diamond + d\chi^\diamond\chi)\\ &= -\frac{1}{2}(z^\diamond+z)E^1 + \frac{i}{2}(z^\diamond - z)E^2 + \frac{1}{2}\frac{\chi z^\diamond - \chi^\diamond}{(1+zz^\diamond)^{1/2}}E^- - \frac{1}{2}\frac{\chi^\diamond z+\chi}{(1+zz^\diamond)^{1/2}}E^+,\end{aligned} \tag{45}$$

hence in the co-adjoint representation

$$\Omega_B{}^C = \omega^0 (J_0)_B{}^C,$$

where

$$(J_0)_B{}^C = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & -\frac{i}{2} & 0 \\ 0 & 0 & 0 & \frac{i}{2} \end{pmatrix}.$$

Note that the body of $\Omega_\alpha{}^\beta$ is given by

$$\Omega_\alpha{}^\beta|_0 = \frac{i}{1+z_0 z_0^*}(z_0^* dz_0 - z_0 dz_0^*)(J_0)_\alpha{}^\beta,$$

which matches the result expected for the ordinary sphere. Similar expressions for the super-zweibein, its dual and the spin connection can be obtained for the (w,ζ) coordinate patch (see Sec. III D). They are given in Appendix C.

The results developed in this section can be used to define a covariant derivative on the supersphere. This will be given by

$$\mathcal{D}_A = E_A{}^M(\partial_M + \omega_M^0 J_0) = E_A + \Omega_A, \tag{46}$$

with $\Omega_A = E_A{}^M \omega_M^0 J_0$ and where J_0 is taken to be in the representation appropriate to the field being acted on.

C. Torsion and curvature of $S^{2|2}$

We are now in the position to calculate the torsion components for the supersphere and hence—by Dragon's theorem[13]—the curvature components. This can be done using the fact that the (anti-)commutator of two covariant derivatives is determined in terms of the supertorsion $T_{AB}{}^C$ and the supercurvature R_{AB} as follows:

$$[\mathcal{D}_A, \mathcal{D}_B] = T_{AB}{}^C \mathcal{D}_C + R_{AB}. \tag{47}$$

Here, both the torsion and the curvature are two-forms which have the following symmetry properties:

$$T_{AB}{}^C = -(-1)^{\epsilon_A\epsilon_B} T_{BA}{}^C,$$

$$R_{AB} = -(-1)^{\epsilon_A\epsilon_B} R_{BA},$$

with

$$\epsilon_A = \begin{cases} 0 & \text{if } A = a, \\ 1 & \text{if } A = \alpha. \end{cases}$$

It is convenient to directly express the torsion and curvature components in terms of the superzweibein and spin connection. Defining the so-called *anholonomy* coefficients $\mathcal{C}_{AB}{}^{C}$ by

$$[E_A, E_B] = \mathcal{C}_{AB}{}^{C} E_C,$$

we have

$$T_{AB}{}^{C} = \mathcal{C}_{AB}{}^{C} + \Omega_{AB}{}^{C} - (-1)^{\epsilon_A \epsilon_B} \Omega_{BA}{}^{C},$$

$$R_{ABC}{}^{D} = E_A \Omega_{BC}{}^{D} + \Omega_{AC}{}^{E} \Omega_{BE}{}^{D} - (-1)^{\epsilon_A \epsilon_B} (A \leftrightarrow B) - \mathcal{C}_{AB}{}^{E} \Omega_{EC}{}^{D}.$$

Note that as a result of the Bianchi identities and of the restricted choice of tangent space group the curvature is completely determined in terms of the torsion. This is known as *Dragon's theorem*.

The only nonvanishing torsion components are given by

$$T_{\alpha\beta}{}^{a} = \frac{i}{2} (\sigma^a)_{\alpha\beta}, \tag{48a}$$

$$T_{\alpha a}{}^{\beta} = -\frac{i}{2} (\sigma_a)_{\alpha}{}^{\beta}, \tag{48b}$$

where the invariant tensor $(\sigma^a)^{\alpha}{}_{\beta}$ is given in Appendix A. Note that even for flat superspace one finds nonzero torsion components $T_{\alpha\beta}{}^{a}$. Since the curvature is completely determined in terms of the torsion we must therefore expect some other nonvanishing torsion components in the case of $S^{2|2}$, which is a curved superspace. Thus it is not surprising that we encounter the additional torsion components $T_{\alpha a}{}^{\beta}$.

For the only nonvanishing curvature components we find

$$R_{12B}{}^{C} = -R_{21B}{}^{C} = (J_0)_B{}^{C}, \tag{49a}$$

$$R_{-+B}{}^{C} = R_{+-B}{}^{C} = -\frac{i}{2} (J_0)_B{}^{C}. \tag{49b}$$

Note that the only nonzero components of the body of the curvature tensor, $R_{abc}{}^{d}$, are given by $R_{12a}{}^{b} = -R_{21a}{}^{b} = (J_0)_a{}^{b}$, which matches the result for the ordinary sphere.

In the following we will use the geometric structure developed in this section to formulate scalar field theories on $S^{2|2}$. Before we do so, however, we will discuss superscalar fields on the supersphere and their transformation properties under isometries.

VI. SUPERFIELDS ON THE SUPERSPHERE

A. Component fields

In Sec. IV B we defined a superscalar field, Φ, on the supersphere. Working in the (z, χ) coordinate patch we can perform an expansion in the χ and $\chi^{\diamond}$ variables, giving

$$\Phi = A(z, z^{\diamond}) + \chi \psi_{\chi}(z, z^{\diamond}) + \chi^{\diamond} \psi_{\chi^{\diamond}}(z, z^{\diamond}) + \chi \chi^{\diamond} F(z, z^{\diamond}). \tag{50}$$

The fields A, ψ_{χ}, $\psi_{\chi^{\diamond}}$, and F are called the component fields of Φ, and are functions of z and $z^{\diamond}$ only. F is often referred to as the *auxiliary* field.

Since we know how the superfield Φ transforms under isometries [see Eq. (33)], it is possible to derive how the component fields transform. For example, under the action of J_0 we have $\delta\Phi = \theta^0 \tilde{J}_0 \Phi$, which gives

$$\delta A = i\theta^0 (z\partial_z - z^\diamond \partial_{z^\diamond}) A, \tag{51a}$$

$$\delta \psi_\chi = i\theta^0 (z\partial_z - z^\diamond \partial_{z^\diamond} + \tfrac{1}{2}) \psi_\chi, \tag{51b}$$

$$\delta \psi_{\chi^\diamond} = i\theta^0 (z\partial_z - z^\diamond \partial_{z^\diamond} - \tfrac{1}{2}) \psi_{\chi^\diamond}, \tag{51c}$$

$$\delta F = i\theta^0 (z\partial_z - z^\diamond \partial_{z^\diamond}) F. \tag{51d}$$

Similar expressions for the transformation properties under J_1 and J_2 can also be found. An identical argument gives the transformation of the component fields under the supersymmetry transformation $\delta\Phi = \beta^\alpha \tilde{Q}_\alpha \Phi$. We find

$$\delta A = \frac{i}{2}((\beta^\diamond z + \beta)\psi_\chi + (\beta z^\diamond - \beta^\diamond)\psi_{\chi^\diamond}), \tag{52a}$$

$$\delta \psi_\chi = \frac{i}{2}((\beta z^\diamond - \beta^\diamond)F - (\beta^\diamond z + \beta)\partial_z A), \tag{52b}$$

$$\delta \psi_{\chi^\diamond} = -\frac{i}{2}((\beta^\diamond z + \beta)F + (\beta z^\diamond - \beta^\diamond)\partial_{z^\diamond} A), \tag{52c}$$

$$\delta F = \frac{i}{2}((\beta^\diamond z + \beta)\partial_z \psi_{\chi^\diamond} - (\beta z^\diamond - \beta^\diamond)\partial_{z^\diamond} \psi_\chi). \tag{52d}$$

It is possible to put these equations in a more familiar form by rewriting them using *Killing spinors*, which we do next.

B. Killing spinors

In order to define Killing spinors we must first introduce some more notation concerning the geometry of $S^{2|0}$, the even Grassmann extension of the ordinary two-sphere. The gamma matrices, γ^m, $m = z, z^\diamond$, for $S^{2|0}$, can be taken to be

$$\gamma^z = -i(1 + zz^\diamond)\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},$$

$$\gamma^{z^\diamond} = i(1 + zz^\diamond)\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

These satisfy $\{\gamma^m, \gamma^n\} = 2g^{mn}$ where the metric g_{mn} has the following nonzero components:

$$g_{zz^\diamond} = g_{z^\diamond z} = \frac{2}{(1 + zz^\diamond)^2}.$$

As we can see from Eq. (45), the restriction of the spin connection ω^0 from the supersphere to $S^{2|0}$ is given by

$$\omega \equiv \omega^0|_{\chi,\chi^\diamond=0} = \omega_z dz + \omega_{z^\diamond} dz^\diamond = \frac{i}{(1+zz^\diamond)}(z^\diamond dz - z dz^\diamond)\begin{pmatrix} -\frac{i}{2} & 0 \\ 0 & \frac{i}{2} \end{pmatrix}.$$

This allows us to define the covariant derivative $D_m = \partial_m + \omega_m$.

Killing spinors on $S^{2|0}$ are defined by (see Ref. 14)

$$D_m \boldsymbol{\epsilon} = \frac{i}{2}\kappa\gamma_m\boldsymbol{\epsilon}, \tag{53}$$

where $\kappa = \pm 1$. A solution to this equation with $\kappa = -1$ reads

$$\boldsymbol{\epsilon} = \frac{1}{2(1+zz^\diamond)^{1/2}}\begin{pmatrix} \beta^\diamond - \beta z^\diamond \\ \beta^\diamond z + \beta \end{pmatrix}, \tag{54}$$

where $\beta \in \mathbb{C}_a$ is some arbitrary constant.

In order to rewrite Eqs. (52a)–(52d) using Killing spinors we also need to introduce a new set of component fields, which are obtained from the superfield Φ. In the case of the spinor and auxiliary fields this will require the use of the covariant derivative. We define

$$\widetilde{A} = \Phi|_{\chi,\chi^\diamond=0}, \tag{55a}$$

$$\psi_\alpha = 2(\mathcal{D}_\alpha\Phi)|_{\chi,\chi^\diamond=0}, \tag{55b}$$

$$F_{\alpha\beta} = -((\mathcal{D}_\alpha\mathcal{D}_\beta - \mathcal{D}_\beta\mathcal{D}_\alpha)\Phi)|_{\chi,\chi^\diamond=0}. \tag{55c}$$

We can use $F_{\alpha\beta}$ to alternatively define

$$\widetilde{F} = \epsilon^{\alpha\beta}F_{\alpha\beta}, \tag{55d}$$

where $\epsilon^{-+} = 1$.

The set of fields given by $\widetilde{A}$, ψ_-, ψ_+, and $\widetilde{F}$ turns out to be a conformal rescaling of the original component fields defined in the preceding section. We find

$$\widetilde{A} = A, \tag{56a}$$

$$\psi_- = -i(1+zz^\diamond)^{1/2}\psi_\chi, \tag{56b}$$

$$\psi_+ = -i(1+zz^\diamond)^{1/2}\psi_{\chi^\diamond}, \tag{56c}$$

$$\widetilde{F} = -(1+zz^\diamond)F. \tag{56d}$$

Note that from Eq. (55b) we see immediately that the fields ψ_- and ψ_+, carrying the tangent space index α, indeed transform as spinors under the action of the tangent space group $\mathcal{U}(1)$. The components ψ_- and ψ_+ can be grouped into a two-component spinor, $\boldsymbol{\psi}$, as

$$\boldsymbol{\psi} = \begin{pmatrix} \psi_- \\ \psi_+ \end{pmatrix}.$$

Using these results we can rewrite the transformation of the component fields under the supersymmetry transformations, given in Eqs. (52a)–(52d), in the more compact form

$$\delta\tilde{A} = \boldsymbol{\epsilon}^{\ddagger}\boldsymbol{\psi}, \tag{57a}$$

$$\delta\boldsymbol{\psi} = (-i\partial\!\!\!/\tilde{A} + \tilde{F})\boldsymbol{\epsilon}, \tag{57b}$$

$$\delta\tilde{F} = -i\boldsymbol{\epsilon}^{\ddagger}\not{D}\boldsymbol{\psi}, \tag{57c}$$

where the spinors $\boldsymbol{\epsilon}$ and $\boldsymbol{\psi}$ are considered as $(0|2)$-dimensional even supervectors in order to define their graded adjoints (see Sec. II B). These equations should be compared with standard results, for instance in Ref. 7. Note that here the graded adjoint plays the role of the Dirac conjugate.

VII. SCALAR FIELD ACTIONS ON $S^{2|2}$

A. Kinetic part of superfield action

We are now in the position to write down a Lagrangian in terms of some superscalar field Φ. Remember that we can expand $\Phi(z,\chi)$ in terms of the χ variables as

$$\Phi = A(z,z^{\diamond}) + \chi\psi_{\chi}(z,z^{\diamond}) + \chi^{\diamond}\psi_{\chi^{\diamond}}(z,z^{\diamond}) + \chi\chi^{\diamond}F(z,z^{\diamond}).$$

Here we want to restrict our attention to (pseudo)real superfields only. We therefore impose the reality condition

$$\Phi^{\diamond} = \Phi,$$

which reads in terms of the component fields

$$A^{\diamond} = A,$$

$$(\psi_{\chi^{\diamond}})^{\diamond} = -\psi_{\chi},$$

$$(\psi_{\chi})^{\diamond} = \psi_{\chi^{\diamond}},$$

$$F^{\diamond} = F.$$

Let us consider the following kinetic Lagrangian[15] for the superscalar field Φ,

$$L_{\text{kin}} = \mathcal{D}_{-}\Phi\mathcal{D}_{+}\Phi = E_{-}\Phi E_{+}\Phi. \tag{58}$$

In order to write down an action on the supersphere we will need the invariant volume form $dzdz^{\diamond}d\chi d\chi^{\diamond}E$, with $E=\text{sdet}(E_M{}^A)$ as in Eq. (44). We thus have for the action

$$I_{\text{kin}} = \int dzdz^{\diamond}d\chi d\chi^{\diamond}EE_{-}\Phi E_{+}\Phi. \tag{59}$$

This will be invariant under supersymmetry transformations, as long as the Lagrangian L_{kin} transforms as a scalar, e.g., as Φ. This is the case, provided that under a supersymmetry transformation with parameter β, we have

$$L_{\text{kin}} \to e^{\beta^{\alpha}\tilde{Q}_{\alpha}}L_{\text{kin}}.$$

To check this, note that under a supersymmetry transformation with small β we have

$$\delta L_{\text{kin}} = E_{-}\Phi E_{+}(\beta^{\alpha}\tilde{Q}_{\alpha}\Phi) + E_{-}(\beta^{\alpha}\tilde{Q}_{\alpha}\Phi)E_{+}\Phi.$$

Now using the fact that

$$[E_-,\tilde{Q}_-] = -\frac{i}{4}\chi E_-, \quad [E_+,\tilde{Q}_-] = \frac{i}{4}\chi E_+,$$

$$[E_-,\tilde{Q}_+] = \frac{i}{4}\chi^\diamond E_-, \quad [E_+,\tilde{Q}_+] = -\frac{i}{4}\chi^\diamond E_+,$$

we find that L_{kin} indeed transforms as a scalar under supersymmetry transformations

$$\delta L_{\text{kin}} = \beta^\alpha \tilde{Q}_\alpha L_{\text{kin}}.$$

Similarly the action will be invariant under rotations if the Lagrangian transforms as

$$L_{\text{kin}} \to e^{\theta^i \tilde{J}_i} L_{\text{kin}}.$$

Under rotations, for small θ^i, we have

$$\delta L_{\text{kin}} = E_-\Phi E_+(\theta^i \tilde{J}_i \Phi) + E_-(\theta^i \tilde{J}_i \Phi) E_+ \Phi,$$

which we can rewrite using

$$[E_-,\tilde{J}_0] = \frac{i}{2}E_-, \quad [E_+,\tilde{J}_0] = -\frac{i}{2}E_+,$$

$$[E_-,\tilde{J}_1] = -\frac{i}{4}(z + z^\diamond)E_-, \quad [E_+,\tilde{J}_1] = \frac{i}{4}(z + z^\diamond)E_+,$$

$$[E_-,\tilde{J}_2] = -\frac{1}{4}(z - z^\diamond)E_-, \quad [E_+,\tilde{J}_2] = \frac{1}{4}(z - z^\diamond)E_+.$$

Doing so we find

$$\delta L_{\text{kin}} = \theta^i \tilde{J}_i L_{\text{kin}}.$$

Thus the action is invariant not only under supersymmetry transformations but also under rotations.

Let us rewrite the kinetic part of the superfield action in terms of component fields. To do so first note that we can write the Lagrangian as

$$L_{\text{kin}} = E_-\Phi E_+\Phi = -\tfrac{1}{4}(1 + zz^\diamond + \chi\chi^\diamond)[(\chi\partial_z - \partial_\chi)\Phi][(\chi^\diamond \partial_{z^\diamond} - \partial_{\chi^\diamond})\Phi],$$

and thus we have for the Lagrangian density $\mathcal{L}_{\text{kin}}$,

$$\mathcal{L}_{\text{kin}} = E L_{\text{kin}} = -\frac{i}{8}[(\chi\partial_z - \partial_\chi)\Phi][(\chi^\diamond \partial_{z^\diamond} - \partial_{\chi^\diamond})\Phi]. \tag{60}$$

Expanding $\mathcal{L}_{\text{kin}}$ in terms of the χ variables we need to keep track only of terms proportional to $\chi\chi^\diamond$, as these are the only ones which will survive the Grassmann integration over χ and $\chi^\diamond$ in the action. We have

$$\mathcal{L}_{\text{kin}}|_{\chi\chi^\diamond} = -\frac{i}{8}(\partial_z A \partial_{z^\diamond} A + \psi_\chi \partial_{z^\diamond}\psi_\chi + \psi_{\chi^\diamond}\partial_z \psi_{\chi^\diamond} + F^2).$$

Hence we find for the action in terms of the component fields after integrating out the $\chi,\chi^\diamond$ dependence

$$I_{\mathrm{kin}} = \frac{i}{8}\int dz dz^{\diamond}(\partial_z A \partial_z{}^{\diamond} A + \psi_\chi \partial_z{}^{\diamond}\psi_\chi + \psi_\chi{}^{\diamond}\partial_z \psi_\chi{}^{\diamond} + F^2). \tag{61}$$

Note that had we used the η coordinates instead of the χ coordinates the action would not have taken this simple form. Note further that the kinetic part of the component field action is conformally invariant, see Appendix E.

For the Euler–Lagrange equations we find

$$\partial_z \partial_z{}^{\diamond} A = 0, \tag{62a}$$

$$\partial_z{}^{\diamond}\psi_\chi = 0, \tag{62b}$$

$$\partial_z \psi_\chi{}^{\diamond} = 0, \tag{62c}$$

$$F = 0. \tag{62d}$$

These imply that A is a harmonic function of z and $z^{\diamond}$, ψ_χ is a holomorphic function and $\psi_\chi{}^{\diamond}$ is an antiholomorphic function of z. Thus if we insist on boundedness of the solutions, A as well as ψ_χ and $\psi_\chi{}^{\diamond}$ are constant in this coordinate patch. Remember, however, that only the two coordinate patches (z,χ) and (w,ζ) taken together cover the whole sphere, see Sec. III D. Thus, in order to make a global statement, we also have to consider the field equations following from the action written in the (w,ζ) patch. To do so, first note that we can rewrite the superfield Φ in terms of the w and ζ coordinates as

$$\Phi(z,\chi) = A(z) + \chi\psi_\chi(z) + \chi^{\diamond}\psi_\chi{}^{\diamond}(z) + \chi\chi^{\diamond}F(z) = A(z) - \frac{\zeta}{w}\psi_\chi(z) - \frac{\zeta^{\diamond}}{w^{\diamond}}\psi_\chi{}^{\diamond}(z) + \frac{\zeta\zeta^{\diamond}}{ww^{\diamond}}F(z).$$

Then defining the fields

$$\hat{A}(w) = A(z), \tag{63a}$$

$$\psi_\zeta(w) = -z\psi_\chi(z), \tag{63b}$$

$$\psi_\zeta{}^{\diamond}(w) = -z^{\diamond}\psi_\chi{}^{\diamond}(z), \tag{63c}$$

$$\hat{F}(w) = zz^{\diamond}F(z), \tag{63d}$$

we have

$$\Phi(w,\zeta) \equiv \hat{A}(w) + \zeta\psi_\zeta(w) + \zeta^{\diamond}\psi_\zeta{}^{\diamond}(w) + \zeta\zeta^{\diamond}\hat{F}(w).$$

Using the inverse superzweibein in the (w,ζ) coordinate patch, see Appendix C, we find for the Lagrangian [Eq. (58)]

$$E_-\Phi E_+\Phi = E'_-\Phi E'_+\Phi$$

and hence for the action in terms of the component fields defined in Eqs. (63a)–(63d)

$$I_{\mathrm{kin}} = \frac{i}{8}\int dw dw^{\diamond}(\partial_w \hat{A}\partial_w{}^{\diamond}\hat{A} + \psi_\zeta \partial_w{}^{\diamond}\psi_\zeta + \psi_\zeta{}^{\diamond}\partial_w \psi_\zeta{}^{\diamond} + \hat{F}^2).$$

The Euler–Lagrange equations following from this action are

$$\partial_w \partial_{w^\diamond} \hat{A} = 0, \tag{64a}$$

$$\partial_w \psi_{\zeta^\diamond} = 0, \tag{64b}$$

$$\partial_{w^\diamond} \psi_\zeta = 0, \tag{64c}$$

$$\hat{F} = 0. \tag{64d}$$

Now Eq. (64c), for example, implies that ψ_ζ is a holomorphic function of w. If, however, we insist also on boundedness of the solution we have—since $\psi_\zeta = -z\psi_\chi(z)$ and since Eq. (62b) implies that ψ_χ is constant—that both $\psi_\chi(z)$ and $\psi_\zeta(w)$ must be zero. An analogous argument shows that also $\psi_{\chi^\diamond}(z)$ and $\psi_{\zeta^\diamond}(w)$ must be taken to be zero.

B. Full superfield action

Now let us add a potential term to the kinetic part of the superfield action given in Eq. (59). This will allow us later to study supersymmetry breaking in this theory. Note that adding a potential term breaks the conformal invariance of the action.

The potential part of the superfield action will be taken to be

$$I_{\text{pot}} = \frac{1}{4} \int dz dz^\diamond d\chi d\chi^\diamond E U(\Phi), \tag{65}$$

with $U(\Phi)$ some superpotential. When expanding $U(\Phi)$ in terms of the odd variables one should note that, since

$$E = \frac{i}{2} \frac{1 + zz^\diamond - \chi\chi^\diamond}{(1 + zz^\diamond)^2},$$

the only terms contributing to the action after integrating out the $\chi, \chi^\diamond$ dependence will be the ones proportional to 1 and $\chi\chi^\diamond$. Keeping this in mind we write

$$U(\Phi) = U(A + \chi\psi_\chi + \chi^\diamond \psi_{\chi^\diamond} + \chi\chi^\diamond F) = U(A) + \chi\chi^\diamond (FU'(A) - \psi_\chi \psi_{\chi^\diamond} U''(A)) + \cdots,$$

where the dots stand for the terms proportional to χ and $\chi^\diamond$, respectively. Thus we can rewrite I_{pot} in terms of the component fields as

$$I_{\text{pot}} = \frac{i}{8} \int dz dz^\diamond \left(\frac{U(A)}{(1 + zz^\diamond)^2} - \frac{FU'(A) - \psi_\chi \psi_{\chi^\diamond} U''(A)}{1 + zz^\diamond} \right). \tag{66}$$

The full action $I = I_{\text{kin}} + I_{\text{pot}}$ in terms of the component fields is then given by

$$I = \frac{i}{8} \int dz dz^\diamond \left(\partial_z A \partial_{z^\diamond} A + \psi_\chi \partial_{z^\diamond} \psi_\chi + \psi_{\chi^\diamond} \partial_z \psi_{\chi^\diamond} + F^2 + \frac{U(A)}{(1 + zz^\diamond)^2} - \frac{FU'(A) - \psi_\chi \psi_{\chi^\diamond} U''(A)}{1 + zz^\diamond} \right). \tag{67}$$

The Euler–Lagrange equations corresponding to the full action can be found in Appendix D. Note that we can check the invariance of the action under rotations and supersymmetry transformations explicitly using the transformation laws given in Eqs. (51a)–(51d) and (52a)–(52d).

Seeing as F is just an auxiliary field we may eliminate it from the action. The field equation for F is purely algebraic, we have

$$F = \frac{1}{2}\frac{U'(A)}{1+zz^{\diamond}},$$

and thus eliminating it from the action we find

$$I = \frac{i}{8}\int dzdz^{\diamond}\left(\partial_z A\partial_{z^{\diamond}}A + \psi_\chi\partial_{z^{\diamond}}\psi_\chi + \psi_{\chi^{\diamond}}\partial_z\psi_{\chi^{\diamond}} + \frac{U(A)-\frac{1}{4}(U'(A))^2}{(1+zz^{\diamond})^2} + \frac{U''(A)}{1+zz^{\diamond}}\psi_\chi\psi_{\chi^{\diamond}}\right).$$

For later convenience we define the effective potential V by

$$V(A) = U(A) - \tfrac{1}{4}(U'(A))^2. \tag{68}$$

Note that the factor $(1+zz^{\diamond})^{-2}$ contributes to the invariant volume element of $S^{2|0}$ and as such is not part of the effective potential. Also note that the effective potential will be unbounded from below whenever $U(A)$ is given by a polynomial of degree greater than 2. However, there exist nonpolynomial choices of the potential $U(A)$, for example, a Gaussian, which lead to effective potentials that are bounded from below.

The truncated supersymmetry transformations are

$$\delta A = \frac{i}{2}((\beta^{\diamond}z+\beta)\psi_\chi + (\beta z^{\diamond}-\beta^{\diamond})\psi_{\chi^{\diamond}}),$$

$$\delta\psi_\chi = \frac{i}{2}\left((\beta z^{\diamond}-\beta^{\diamond})\frac{1}{2}\frac{U'(A)}{1+zz^{\diamond}} - (\beta^{\diamond}z+\beta)\partial_z A\right),$$

$$\delta\psi_{\chi^{\diamond}} = -\frac{i}{2}\left((\beta^{\diamond}z+\beta)\frac{1}{2}\frac{U'(A)}{1+zz^{\diamond}} + (\beta z^{\diamond}-\beta^{\diamond})\partial_{z^{\diamond}}A\right).$$

Note that the truncated action will be invariant under these supersymmetry transformations. However, the truncated transformations will not close unless we impose the field equations, i.e., the commutator of two supersymmetry transformations will give a rotation only on-shell.

VIII. SUPERSYMMETRY BREAKING

In this section we will investigate supersymmetry breaking in this model for different choices of the potential $U(\Phi)$. In order to do so let us consider an SO(3) invariant classical vacuum solution given by $A=$constant and $\psi_\chi=\psi_{\chi^{\diamond}}=0$. Under supersymmetry this solution transforms as

$$\delta A = 0,$$

$$\delta\psi_\chi = \frac{i}{4}(\beta z^{\diamond}-\beta^{\diamond})\frac{U'(A)}{1+zz^{\diamond}},$$

$$\delta\psi_{\chi^{\diamond}} = -\frac{i}{4}(\beta^{\diamond}z+\beta)\frac{U'(A)}{1+zz^{\diamond}}.$$

Thus this solution will be supersymmetry preserving if $U'(A)=0$, i.e., if $F=0$. On the other hand, $F\neq 0$ indicates states of broken supersymmetry.

Note that vacuum solutions correspond to critical points of the effective potential V, given in Eq. (68). Since

$$V'(A) = U'(A)(1 - \tfrac{1}{2}U''(A))$$

we have two types of stationary points, namely $U'(A)=0$ and $U''(A)=2$, the former corresponding to states with unbroken supersymmetry, the latter corresponding to states for which supersymmetry is possibly broken.

As a first example consider the potential $U(A)=mA^2$, where $m \in \mathbb{R}_0$ is some constant parameter. Here $\mathbb{R}_0 \cong \mathbb{R}$ denotes the body of $\mathbb{R}_c$. We shall look for critical points of the effective potential, which is

$$V(A) = (m - m^2)A^2. \tag{69}$$

Note that if $m=0$ or 1 the effective potential is identically zero. In the case of $m>1$ or $m<0$ there exists neither a global nor a local minimum. If, however, $0<m<1$ the potential possesses a global minimum at $A=0$. As this implies that $U'(A)=2mA=0$, supersymmetry will be preserved for this solution.

As a second example we will consider the potential

$$U(A) = \tfrac{1}{3}gA^3 + \lambda A,$$

with $g, \lambda \in \mathbb{R}_0$ constant. The extrema of the effective potential

$$V(A) = \lambda A + \tfrac{1}{3}gA^3 - \tfrac{1}{4}(gA^2 + \lambda)^2 \tag{70}$$

are given by

$$U'(A) = gA^2 + \lambda = 0 \Rightarrow A = \pm \sqrt{\frac{-\lambda}{g}},$$

$$U''(A) = 2gA = 2 \Rightarrow A = \frac{1}{g}.$$

In order to decide whether we can have stable supersymmetry preserving vacuum solutions, we need to know for which parameter values $A=\pm\sqrt{-\lambda/g}$ correspond to local minima. Thus we need to investigate $V''(A)$ at these points. We have

$$V''(A) = U''(A)(1 - \tfrac{1}{2}U''(A)) - \tfrac{1}{2}U'(A)U'''(A) = -2\sqrt{-\lambda g}(\sqrt{-\lambda g} \mp 1).$$

One must distinguish between four different cases.

(i) Suppose $\sqrt{-\lambda g}>1$. In this case $V''(A)<0$ for both the roots $A=\pm\sqrt{-\lambda/g}$, hence $U''(A)=2$ must correspond to the local minimum. Thus for this vacuum solution supersymmetry will be broken [see Fig. 1(a)].

(ii) Suppose $0<\sqrt{-\lambda g}<1$. In this case one of the roots $A=\pm\sqrt{-\lambda/g}$ will correspond to a local maximum the other to a local minimum. Thus there exists a supersymmetry preserving vacuum solution [see Fig. 1(b)].

(iii) Suppose $-\lambda g=1$. Then $A=\pm\sqrt{-\lambda/g}=\pm 1/g$ implies that one of the two roots corresponds to $V''(A)=0$, the other to a maximum. Thus there exists no stable supersymmetry preserving vacuum state [see Fig. 1(c)].

(iv) Suppose $\lambda g>0$. There is no solution to $U'(A)=0$, hence supersymmetry will be broken. However, in this case $V(A)$ has a single maximum at $A=1/g$ and thus any vacuum solution will be unstable anyway [see Fig. 1(d)].

Note, however, that the effective potential of Eq. (70) is unbounded from below and as such exhibits only local minima. Therefore there do not exist true vacuum solutions.

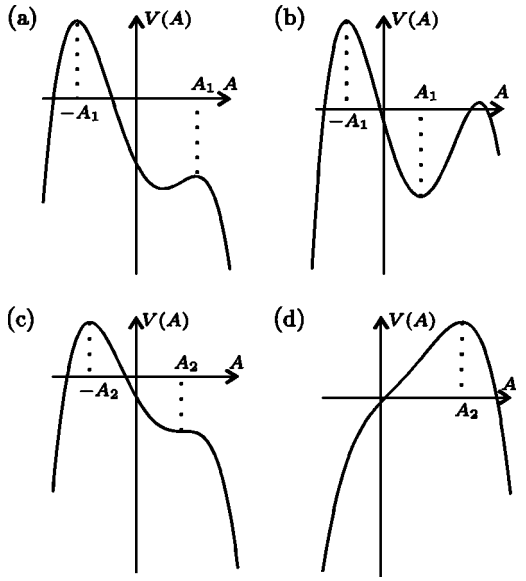

FIG. 1. A sketch of the effective potential $V(A)=\lambda A+\frac{1}{3}gA^3-\frac{1}{4}(gA^2+\lambda)^2$ for the four different cases discussed in the text. Here $A_1=\sqrt{-\lambda/g}$ and $A_2=1/g$.

IX. CONSERVED CURRENTS FROM SUPERFIELD FORMALISM

Using the superfield formalism we will derive in this section a supersymmetric generalization of the energy-momentum tensor.

In order to do so consider some superfield Lagrangian density $\mathcal{L}=\mathcal{L}(\Phi,\partial\Phi)$. Remember that a coordinate transformation $X^M\to X^M+\delta X^M$ is realized on superscalar fields as [see Eq. (33)] $\Phi\to\Phi(X-\delta X)=\Phi(X)+\delta\Phi(X)$ where $\delta\Phi=-\delta X^M\partial_M\Phi$. Note that in the case of an isometry, as we shall assume here, we have $\delta X^M=\delta u K^M$, with K^M a Killing supervector.

Similarly we find that the Lagrangian density transforms under an isometry as

$$\delta\mathcal{L}=-(-1)^M\partial_M(\delta X^M\mathcal{L}). \tag{71}$$

For a derivation of this result see Appendix F. On the other hand, we find that the change in the Lagrangian density obtained by varying the fields is

$$\delta\mathcal{L}=\delta\Phi\frac{\partial\mathcal{L}}{\partial\Phi}+(\partial_M\delta\Phi)\frac{\partial\mathcal{L}}{\partial(\partial_M\Phi)}=\delta\Phi\left(\frac{\partial\mathcal{L}}{\partial\Phi}-\partial_M\left(\frac{\partial\mathcal{L}}{\partial(\partial_M\Phi)}\right)\right)+\partial_M\left(\delta\Phi\frac{\partial\mathcal{L}}{\partial(\partial_M\Phi)}\right). \tag{72}$$

Note that the superzweibein is invariant under an isometry, thus the variation of $\mathcal{L}$ with respect to the superzweibein is zero. From Eq. (72) we see that the Euler–Lagrange equations are

$$\frac{\partial\mathcal{L}}{\partial\Phi}-\partial_M\left(\frac{\partial L}{\partial(\partial_M\Phi)}\right)=0. \tag{73}$$

Thus if we impose the field equations the first term in Eq. (72) vanishes and we can set the remaining term equal to $-(-1)^M\partial_M(\delta X^M\mathcal{L})$. Then using $\delta\Phi=-\delta X^M\partial_M\Phi$ we find

$$\partial_M\left(\delta X^N\left((-1)^M\delta_N{}^M\mathcal{L}-\partial_N\Phi\frac{\partial\mathcal{L}}{\partial(\partial_M\Phi)}\right)\right)=0. \tag{74}$$

We are now in the position to define the superenergy-momentum tensor $\mathcal{T}_N{}^M$,

$$\mathcal{T}_N{}^M = (-1)^M \delta_N{}^M \mathcal{L} - \partial_N \Phi \frac{\partial \mathcal{L}}{\partial(\partial_M \Phi)}. \tag{75}$$

The corresponding super-Noether current $\mathcal{J}^M$ is then defined by

$$\mathcal{J}^M = K^N \mathcal{T}_N{}^M. \tag{76}$$

By means of Eq. (74) $\mathcal{J}^M$ will satisfy the superconservation law

$$\partial_M \mathcal{J}^M = 0. \tag{77}$$

Let us now consider the specific Lagrangian density for $S^{2|2}$ given by [see Eqs. (59) and (65)]

$$\mathcal{L} = E(E_- \Phi E_+ \Phi + \tfrac{1}{4} U(\Phi)). \tag{78}$$

One can check that the field equations given by Eq. (73) indeed coincide—when written in terms of the component fields—with the field equations given in Appendix D, which were directly derived from the action in terms of the component fields.

For the superenergy-momentum tensor we find in this case

$$\mathcal{T}_N{}^M = (-1)^M \delta_N{}^M E(E_- \Phi E_+ \Phi + \tfrac{1}{4} U(\Phi)) - \partial_N \Phi E(E_-{}^M E_+ \Phi + (-1)^M E_- \Phi E_+{}^M).$$

The supercurrents are given by

$$\mathcal{J}_p{}^M = K_p{}^N \mathcal{T}_N{}^M,$$

with $p = 0, 1, 2, -, +$, as before. The Killing supervectors $K_p{}^N$ can be read off from Eqs. (34a)–(34c) and (34e). Note that by taking the $\chi\chi^\diamond$ component of the conservation equation, Eq. (77), we find a conservation equation purely in z

$$(\partial_M \mathcal{J}_p{}^M)|_{\chi\chi^\diamond} = (\partial_z \mathcal{J}_p{}^z + \partial_{z^\diamond} J_p{}^{z^\diamond})|_{\chi\chi^\diamond} = (\partial_m \mathcal{J}_p{}^m)|_{\chi\chi^\diamond} = 0, \tag{79}$$

as both $\partial_\chi \mathcal{J}_p{}^\chi$ and $\partial_{\chi^\diamond} \mathcal{J}_p{}^{\chi^\diamond}$ do not contribute a $\chi\chi^\diamond$ term. It will turn out that it is this $\chi\chi^\diamond$ contribution to the conservation equation that gives rise to the familiar energy-momentum tensor and fermionic currents, which can alternatively be derived directly from the action in terms of the component fields. Considering other components of the conservation equation, say the χ component, we find

$$(\partial_z \mathcal{J}_p{}^z + \partial_{z^\diamond} \mathcal{J}_p{}^{z^\diamond})|_\chi = -(\partial_{\chi^\diamond} \mathcal{J}_p{}^{\chi^\diamond})|_\chi.$$

Note that this also is a conservation equation purely in z. However, the term on the right-hand side of the equation, $-(\partial_{\chi^\diamond} \mathcal{J}_p{}^{\chi^\diamond})|_\chi$, which does not involve any derivatives with respect to z, must be understood as some kind of source term. Yet, the interpretation of these additional conservation equations remains unclear.

Now let us consider the currents $\mathcal{J}_i{}^m$, $i = 0, 1, 2$, in more detail. We have

$$\mathcal{J}_i{}^m = K_i{}^N \mathcal{T}_N{}^m = K_i{}^n \mathcal{T}_n{}^m + K_i{}^\mu \mathcal{T}_\mu{}^m.$$

By direct calculation one finds that the components $\mathcal{T}_\chi{}^m$ are proportional to χ and similarly the components $\mathcal{T}_{\chi^\diamond}{}^m$ are proportional to $\chi^\diamond$. Now, as also $K_i{}^\chi$ is proportional to χ and similarly $K_i{}^{\chi^\diamond}$ is proportional to $\chi^\diamond$ the above equation simplifies to

$$\mathcal{J}_i{}^m = K_i{}^n \mathcal{T}_n{}^m.$$

Note that $K_i{}^n = K_i{}^n|_{\chi\chi^\diamond} \equiv k_i{}^n$ correspond to the usual Killing vectors on the sphere $S^{2|0}$,

$$(k_0^m) = i(z, -z^\diamond),$$

$$(k_1^m) = \frac{i}{2}((1-z^2), -(1-z^{\diamond 2})),$$

$$(k_2^m) = -\tfrac{1}{2}((1+z^2), (1+z^{\diamond 2})).$$

Defining $j_i{}^m$ and $t_m{}^n$ as the $\chi\chi^\diamond$ components of $\mathcal{J}_i^n$ and $\mathcal{T}_m{}^n$, respectively,

$$j_i{}^m \equiv \mathcal{J}_i^m|_{\chi\chi^\diamond}, \quad t_m{}^n \equiv \mathcal{T}_m{}^n|_{\chi\chi^\diamond}$$

we can rewrite the conservation equation, Eq. (79), for the bosonic currents $\mathcal{J}_i^m$ as

$$\partial_m j_i{}^m = \partial_m(k_i{}^n t_n{}^m) = 0.$$

For $t_m{}^n$ we find in terms of the conformally rescaled fields $\tilde{A}, \psi_-, \psi_+$, as given in Eqs. (56a)–(56c),

$$t_{mn} = \frac{i}{8}\sqrt{|g|}\left(\partial_m\tilde{A}\partial_n\tilde{A} + \frac{i}{2}\boldsymbol{\psi}^\ddagger\gamma_m\partial_n\boldsymbol{\psi} - g_{mn}\left[\frac{1}{2}(\partial\tilde{A})^2 - \frac{1}{8}U'(\tilde{A})^2 + \frac{1}{2}U(\tilde{A})\right]\right), \tag{80}$$

where the index has been lowered using the metric g_{mn}. Note that the auxiliary field $\tilde{F}$ has been eliminated.

We shall now consider the $\chi\chi^\diamond$ contribution to the currents $\mathcal{J}_\alpha{}^m$, $\alpha = -, +$. Let us define

$$j_\alpha{}^m \equiv \mathcal{J}_\alpha{}^m|_{\chi\chi^\diamond}$$

and also

$$j^m \equiv \beta^\diamond j_-{}^m + \beta j_+{}^m.$$

From Eq. (79) we see that j^m satisfies the conservation equation

$$\partial_m j^m = 0.$$

Rewriting this fermionic current in terms of the rescaled fields $\tilde{A}, \psi_-, \psi_+$, as we did before in the case of t_{mn}, we find

$$j^m = \frac{i}{8}\sqrt{|g|}\boldsymbol{\epsilon}^\ddagger\left(\not{\partial}\tilde{A} + \frac{i}{2}U'(\tilde{A})\right)\gamma^m\boldsymbol{\psi}, \tag{81}$$

where $\boldsymbol{\epsilon}$ is the Killing spinor defined in Eq. (54).

X. CONCLUSIONS AND OUTLOOK

We have shown how to construct the supersphere $S^{2|2}$ as the coset space $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$, analogous to the construction of flat superspace as the super Poincaré group quotiented by the Lorentz group. The definition of UOSp(1|2), which is the isometry group of the supersphere, required the notions of pseudoconjugation and graded adjoint.

The coset space $\mathrm{UOSp}(1|2)/\mathcal{U}(1)$ has the structure of a superspace, rather than just being a supermanifold as is the case for other coset space definitions of the supersphere. This allowed us to consider the supersphere as a base space for a superscalar field theory. As $S^{2|2}$ is an example of a curved superspace on which we have *rigid* supersymmetry transformations, i.e., the supersymmetry parameter is not position dependent, the theory we constructed exhibits global supersymmetry. Upon integrating out the odd coordinate dependence, this superscalar field theory becomes a supersymmetric theory on the ordinary sphere with a scalar, spinor, and auxiliary field. Choosing a polynomial potential we saw that solutions at local minima may break supersymmetry, provided certain conditions are met. Also recall that, contrary to what is expected, the effective potential for this model is not typically bounded from below. This appears to be due to the Euclidean nature of

the theory. However, as we pointed out, nonpolynomial potentials can be found which will exhibit global minima and thus true vacuum solutions.

Using the superfield formalism we were able to derive Euler–Lagrange equations and Noether's theorem for the superscalar field Φ itself, starting from some general superfield Lagrangian density $\mathcal{L}(\Phi,\partial\Phi)$. When applying Euler–Lagrange equations to the specific Lagrangian density constructed for $S^{2|2}$ we found that the field equations for Φ reduce, when written in terms of the component fields, to the ones derived directly from the action on the ordinary sphere. The superconservation equations derived from Noether's theorem—when applied to the Lagrangian density for the supersphere—give rise to the familiar energy-momentum tensor and fermionic currents expected from the component field action. Notably, though, the super conservation equations also give rise to additional conservation laws, that appear to be independent of the familiar ones and which thus call for some interpretation.

In this work we have concentrated on superscalar field theories on the supersphere. Using the methods we have presented it would be possible to further this study by investigating more general field theories, for example, gauge theories or sigma models with the supersphere as the base space. Another possible extension of this work would be to quantize the scalar field theory, which due to its Euclidean nature would correspond to a statistical field theory.

ACKNOWLEDGMENTS

The authors would like to thank Professor N. S. Manton for suggesting this project and for many helpful conversations. APPENDIX A: RAISING AND LOWERING CONVENTIONS FOR SPINOR INDICES

Raising and lowering of spinor indices $\alpha,\beta,\ldots$ is achieved with the use of the antisymmetric epsilon symbols $\epsilon^{\alpha\beta}$ and $\epsilon_{\alpha\beta}$; the convention we will follow is that of Ref. 16. When raising an index we always contract on the second index of $\epsilon^{\alpha\beta}$, e.g.,

$$\psi^{\alpha}=\epsilon^{\alpha\beta}\psi_{\beta}.$$

However, when lowering an index we always contract on the first index of $\epsilon_{\alpha\beta}$, e.g.,

$$\psi_{\beta}=\epsilon_{\gamma\beta}\psi^{\gamma}.$$

Combining the preceding two equations we see that

$$\epsilon^{\alpha\beta}\epsilon_{\gamma\beta}=\delta^{\alpha}{}_{\gamma}.$$

Hence we see that if we choose $\epsilon_{-+}=1$, then we must also have $\epsilon^{-+}=1$. Note that we can think of $\epsilon^{\alpha\beta}$ as $\epsilon_{\alpha\beta}$ with both indices raised.

The (components of the) standard Pauli matrices are taken to be $(\sigma^{i})^{\alpha}{}_{\beta}$. Lowering the first index allows us to construct the quantity

$$(\sigma^{i})_{\alpha\beta}=\epsilon_{\gamma\alpha}(\sigma^{i})^{\gamma}{}_{\beta}=-\epsilon_{\alpha\gamma}(\sigma^{i})^{\gamma}{}_{\beta},$$

which is symmetric in α,β. We can then raise the second index to give

$$(\sigma^{i})_{\alpha}{}^{\beta}=\epsilon_{\gamma\alpha}(\sigma^{i})^{\gamma}{}_{\delta}\epsilon^{\beta\delta}=\epsilon_{\alpha\gamma}(\sigma^{i})^{\gamma}{}_{\delta}\epsilon^{\delta\beta}.$$

Notice that the third terms in the above two equations have been written in a way more suggestive of standard matrix multiplication. In fact, if we define the antisymmetric matrix $\epsilon=(\epsilon_{\alpha\beta})$, we may think of these quantities as the components of the matrices $-\epsilon\sigma^{i}$ and $\epsilon\sigma^{i}\epsilon=(\sigma^{i})^{t}$, respectively.

The quantity $(\sigma^{i})_{\alpha}{}^{\beta}$ [as well as $(\sigma^{a})_{\alpha}{}^{\beta}$] is a $\mathcal{U}(1)$ invariant tensor, i.e.,

$$(\sigma^j)_\alpha{}^\beta = R_\alpha{}^\gamma(h)(\sigma^j)_\gamma{}^\delta R_\delta{}^\beta(h^{-1})R_j{}^i(h^{-1}),$$

where $R_p{}^q(h)$ is as given in Eq. (39).

APPENDIX B: SUPERZWEIBEIN AND SPIN CONNECTION IN POLAR COORDINATES

We obtain for the superzweibein in (super)-polar coordinates

$$(\tilde{E}_M{}^A)$$

$$= \begin{pmatrix} \sin\theta & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ \frac{i}{4}(\eta^\diamond \sin\theta - \eta\cos\theta e^{-i\varphi}) & -\frac{1}{4}\eta e^{-i\varphi} & \left(1+\frac{1}{8}\eta\eta^\diamond\right)\sin\frac{\theta}{2}e^{-i\varphi/2} & \left(1+\frac{1}{8}\eta\eta^\diamond\right)\cos\frac{\theta}{2}e^{-i\varphi/2} \\ \frac{i}{4}(\eta\sin\theta + \eta^\diamond\cos\theta e^{i\varphi}) & -\frac{1}{4}\eta^\diamond e^{i\varphi} & \left(1+\frac{1}{8}\eta\eta^\diamond\right)\cos\frac{\theta}{2}e^{i\varphi/2} & -\left(1+\frac{1}{8}\eta\eta^\diamond\right)\sin\frac{\theta}{2}e^{i\varphi/2} \end{pmatrix},$$

where the index M here runs over $\varphi, \theta, \eta, \eta^\diamond$. The spin connection is in polar coordinates given by

$$\begin{aligned}\omega^0 &= -d\varphi\cos\theta - \frac{i}{4}d\eta^\diamond(\eta\cos\theta - \eta^\diamond e^{i\varphi}\sin\theta) - \frac{i}{4}d\eta(\eta^\diamond\cos\theta + \eta e^{-i\varphi}\sin\theta) \\ &= -\cot\theta\,\tilde{E}^1 + \frac{i}{4}\frac{1}{\sin\theta}\left(\eta e^{-i\varphi/2}\sin\frac{\theta}{2} - \eta^\diamond e^{i\varphi/2}\cos\frac{\theta}{2}\right)\tilde{E}^- + \frac{i}{4}\frac{1}{\sin\theta}\left(\eta e^{-i\varphi/2}\cos\frac{\theta}{2}\right. \\ &\quad \left. + \eta^\diamond e^{i\varphi/2}\sin\frac{\theta}{2}\right)\tilde{E}^+.\end{aligned}$$

APPENDIX C: SUPERZWEIBEIN AND SPIN CONNECTION IN THE (w,ζ) PATCH

We find for the superzweibein in the (w,ζ) coordinate patch

$$(E'_M{}^A) = \begin{pmatrix} \frac{i}{1+ww^\diamond+\zeta\zeta^\diamond} & \frac{-1}{1+ww^\diamond+\zeta\zeta^\diamond} & \frac{2i(\zeta w^\diamond+\zeta^\diamond)}{(1+ww^\diamond)^{3/2}} & 0 \\ \frac{-i}{1+ww^\diamond+\zeta\zeta^\diamond} & \frac{-1}{1+ww^\diamond+\zeta\zeta^\diamond} & 0 & \frac{2i(\zeta^\diamond w-\zeta)}{(1+ww^\diamond)^{3/2}} \\ \frac{-i\zeta}{1+ww^\diamond} & \frac{\zeta}{1+ww^\diamond} & \frac{-2i}{(1+ww^\diamond-\zeta\zeta^\diamond)^{1/2}} & 0 \\ \frac{i\zeta^\diamond}{1+ww^\diamond} & \frac{\zeta^\diamond}{1+ww^\diamond} & 0 & \frac{-2i}{(1+ww^\diamond-\zeta\zeta^\diamond)^{1/2}} \end{pmatrix},$$

where the index M now runs over $w, w^\diamond, \zeta, \zeta^\diamond$. The inverse superzweibein is given by

$$(E'^{M}_{A}) = \begin{pmatrix} -\frac{i}{2}(1+ww^{\diamond}) & \frac{i}{2}(1+ww^{\diamond}) & -\frac{i}{2}(\zeta w^{\diamond}+\zeta^{\diamond}) & \frac{i}{2}(\zeta^{\diamond}w-\zeta) \\ -\frac{1}{2}(1+ww^{\diamond}) & -\frac{1}{2}(1+ww^{\diamond}) & -\frac{1}{2}(\zeta w^{\diamond}+\zeta^{\diamond}) & -\frac{1}{2}(\zeta^{\diamond}w-\zeta) \\ \frac{i}{2}(1+ww^{\diamond})^{1/2}\zeta & 0 & \frac{i}{2}(1+ww^{\diamond}+\zeta\zeta^{\diamond})^{1/2} & 0 \\ 0 & \frac{i}{2}(1+ww^{\diamond})^{1/2}\zeta^{\diamond} & 0 & \frac{i}{2}(1+ww^{\diamond}+\zeta\zeta^{\diamond})^{1/2} \end{pmatrix}.$$

The superdeterminant of (E'^{A}_{M}) is given by

$$E' \equiv \mathrm{sdet}(E'^{A}_{M}) = \frac{i}{2}\frac{1}{1+ww^{\diamond}+\zeta\zeta^{\diamond}}.$$

Finally, we find for the spin connection in the (w,ζ) coordinate patch

$$\begin{aligned}\omega'^{0} &= \frac{i}{1+ww^{\diamond}+\zeta\zeta^{\diamond}}(w^{\diamond}dw - wdw^{\diamond} + d\zeta\zeta^{\diamond} + d\zeta^{\diamond}\zeta) \\ &= \frac{1}{2}(w^{\diamond}+w)E'^{1} - \frac{i}{2}(w^{\diamond}-w)E'^{2} + \frac{1}{2}\frac{\zeta w^{\diamond}+\zeta^{\diamond}}{(1+ww^{\diamond})^{1/2}}E'^{-} - \frac{1}{2}\frac{\zeta^{\diamond}w-\zeta}{(1+ww^{\diamond})^{1/2}}E'^{+}.\end{aligned}$$

APPENDIX D: EULER–LAGRANGE EQUATIONS FOR THE FULL ACTION

The field equations following from the full action given in Eq. (67) are

$$\partial_z\partial_z{}^{\diamond}A = \frac{1}{2}\frac{U'(A)}{(1+zz^{\diamond})^2} - \frac{1}{2}\frac{FU''(A)}{1+zz^{\diamond}} + \frac{1}{2}\frac{\psi_\chi\psi_\chi{}^{\diamond}U'''(A)}{1+zz^{\diamond}},$$

$$\partial_z{}^{\diamond}\psi_\chi = -\frac{1}{2}\frac{\psi_\chi{}^{\diamond}U''(A)}{1+zz^{\diamond}},$$

$$\partial_z\psi_\chi{}^{\diamond} = \frac{1}{2}\frac{\psi_\chi U''(A)}{1+zz^{\diamond}},$$

$$F = \frac{1}{2}\frac{U'(A)}{1+zz^{\diamond}}.$$

APPENDIX E: CONFORMAL INVARIANCE OF THE KINETIC PART OF THE ACTION

The superscalar field action, Eq. (67), can be rewritten using the notation of Sec. VI B. We find it to be

$$I = \frac{i}{16}\int d^2z\sqrt{|g|}\left(g^{mn}\partial_m\tilde{A}\partial_n\tilde{A} + i\boldsymbol{\psi}^{\ddagger}\partial\!\!\!/\boldsymbol{\psi} + \tilde{F}^2 - \frac{1}{2}\boldsymbol{\psi}^{\ddagger}\boldsymbol{\psi}U''(\tilde{A}) + U(\tilde{A}) + \tilde{F}U'(\tilde{A})\right),$$

where g is the determinant of the metric. The kinetic part of the action is obtained by setting $U(\tilde{A})=0$. Note that we could replace the second term, $i\boldsymbol{\psi}^{\ddagger}\partial\!\!\!/\boldsymbol{\psi}$, with $i\boldsymbol{\psi}^{\ddagger}\mathbb{D}\boldsymbol{\psi}$. This is because the term involving the spin connection will vanish due to the anticommuting nature of $\boldsymbol{\psi}$ and the form of the gamma matrices.

Under a conformal transformation, the metric and gamma matrices transform as

$$g_{mn} \to \lambda^2 g_{mn},$$

$$\gamma^m \to \lambda^{-1}\gamma^m,$$

where λ is some positive function on the sphere. It is then possible to define the transformation properties of the component fields in such a way that the kinetic part of the action will remain invariant. We find

$$\tilde{A} \to \tilde{A},$$

$$\boldsymbol{\psi} \to \lambda^{-1/2}\boldsymbol{\psi},$$

$$\tilde{F} \to \lambda^{-1}\tilde{F}.$$

The presence of a nonzero potential will break this conformal invariance.

APPENDIX F: TRANSFORMATION PROPERTIES OF SUPERSCALAR DENSITIES

Using the infinitesimal point transformation $X'^M = X^M + \delta u \Xi^M(X)$ we can define the Lie derivative of any supertensor field $T(X)$ by

$$\mathcal{L}_\Xi T(X) = \lim_{\delta u \to 0} \frac{T(X') - T'(X')}{\delta u}.$$

For instance, a superscalar transforms as $\Phi'(X') = \Phi(X)$, hence the Lie derivative can be calculated by using a Taylor expansion. We find

$$\mathcal{L}_\Xi \Phi(X) = \Xi^M \partial_M \Phi(X).$$

Now, let $\mathfrak{T}(X)$ be a superscalar density of weight +1. It is defined to transform as

$$\mathfrak{T}'(X') = J(X)\mathfrak{T}(X),$$

where $J(X)$ is given by the superdeterminant

$$J(X) = \mathrm{sdet}\left(\frac{\partial X^M}{\partial X'^N}\right) = 1 - \delta u(-1)^M \partial_M \Xi^M + \cdots .$$

Note that in the last line we have expanded the superdeterminant to first order, resulting in the appearance of a supertrace, this explains the factor $(-1)^M$ in the summation over M. Also we can expand

$$\mathfrak{T}(X') = \mathfrak{T}(X) + \delta u \Xi^M \partial_M \mathfrak{T}(X) + \cdots .$$

Combining these gives us the Lie derivative of a superscalar density

$$\mathcal{L}_\Xi \mathfrak{T}(X) = (-1)^M \partial_M (\Xi^M \mathfrak{T}(X)).$$

The same procedure can be used to calculate the Lie derivative of any supertensor field.

Using the Lie derivative we can describe the infinitesimal active coordinate transformation, $X \to X + \delta u \Xi$, alternatively as a transformation of the fields. We need to find the difference between the tensor which has been dragged along $\delta u \Xi$ to the point X, and the tensor which was already at X. For the supertensor field $T(X)$ this difference is given by

$$\delta T(X) = -\delta u \mathcal{L}_\Xi T(X).$$

Level shift operator and second order perturbation theory

Jan Dereziński[a] and Rafal Früboes[b]
Department of Mathematical Methods in Physics, Warsaw University, Hoża 74, 00-682, Warsaw, Poland

(Received 6 October 2004; accepted 30 November 2004; published online 11 February 2005)

We give approximate formulas for spectrum and the corresponding spectral projections of perturbed linear operators. The main tool is the so-called *level shift operator*, which expresses the effects of second order perturbation theory on the point spectrum. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1850833]

I. INTRODUCTION

One of the main tools of quantum mechanics is perturbation theory for eigenvalues of family of linear operators of the form $L_\lambda := L_0 + \lambda Q$. This theory is particularly simple if one considers an isolated eigenvalue of L_0 of finite degeneracy and one assumes that L_0 and Q are self-adjoint. In this case, both the eigenvalues and the eigenvectors can be described by functions analytic in the coupling constant $e(\lambda)$. This is described in almost every textbook on quantum mechanics.

In quantum mechanics self-adjoint operators play a prominent role. However, non-self-adjoint operators are also physically relevant. For instance, they are used to describe resonances. In fact, resonances are often defined as complex eigenvalues of analytically deformed Hamiltonians, which are usually non-self-adjoint. The perturbation theory of non-self-adjoint operators is more complicated than that of self-adjoint operators. In the case of non-self-adjoint operators, eigenvalues and eigenvectors are typically described by a multivalued analytic function with a branch point at $\lambda = 0$. This is described, e.g., in Refs. 11 and 16.

The method of analytic functions may be inapplicable if the isolated eigenvalue has infinite degeneracy, because it may then happen that the perturbed operator has continuous spectrum close to the unperturbed eigenvalue. Thus one cannot follow individual eigenvalues.

In practice one is not interested in the full perturbation expansion of eigenvalues or eigenvectors. One usually uses the lowest order approximation. The first order approximation to the eigenvalue is very simple—it is just the appropriate matrix element of the perturbation. More interesting is the second order approximation. Its importance has been noted since the early days of quantum mechanics. Not without a reason the computations based on the second order perturbation theory have been called by Fermi the golden rule of quantum mechanics.

In our paper we describe a method of constructing approximate eigenvalues and approximate eigenprojections that summarizes the usual second order perturbation theory. We do not restrict ourselves to self-adjoint operators. We prove that our construction can be applied without any problem in the case when the eigenvalue has infinite multiplicity. Thus, the formulas that we give are quite robust—they do not need the assumptions typical of the usual approach to perturbation theory through expansion in a power series.

Let us now describe our results a little more closely. Suppose that L_0 is a closed operator having a cluster of isolated eigenvalues Ξ. The spectral projection of L_0 onto Ξ, denoted $\mathbf{1}_\Xi(L_0)$, gives a natural decomposition of the Banach space into a direct sum $\mathcal{H} = \mathcal{H}^v \oplus \mathcal{H}^{\bar{v}}$.

Let Q be a perturbation. Our main object is the perturbed operator

[a]Electronic mail: jan.derezinski@fuw.edu.pl
[b]Electronic mail: rafal.fruboes@fuw.edu.pl

$$L_{\lambda,\beta} := L_0 + \lambda(Q^{v\bar{v}} + Q^{\bar{v}v}) + \beta Q^{\bar{v}\bar{v}}.$$

Note that we assume that inside $\mathcal{H}^v$ the perturbation is zero. This guarantees that there is no first order shift of the spectrum. $Q^{v\bar{v}} + Q^{\bar{v}v}$ is the "off-diagonal" part of the perturbation—it connects $\mathcal{H}^v$ and $\mathcal{H}^{\bar{v}}$. $Q^{\bar{v}\bar{v}}$ is the "external" part of the perturbation—it acts inside $\mathcal{H}^{\bar{v}}$. We use two perturbation parameters, λ for the off-diagonal and β for the diagonal part. We are interested in what happens for small complex λ and β. We will try to estimate carefully the deviations from our predictions in terms of these two coupling constants.

It is easy to see that for small λ and β, the spectrum of $L_{\lambda,\beta}$ does not differ much from the spectrum L_0. Thus, for small λ and β, for any isolated point e of Ξ, there exists a patch of spectrum of $L_{\lambda,\beta}$ located around e, which we will denote by Θ_e. (We say "a patch," not "a cluster," because the spectrum does not have to be discrete.) We will give the formula for a projection p_e that approximates the spectral projection of $L_{\lambda,\beta}$ onto Θ_e. We will show that this projection approximately diagonalizes $L_{\lambda,\beta}$. By this we mean that $L - p_e L_{\lambda,\beta} p_e - (\mathbf{1} - p_e) L_{\lambda,\beta} (\mathbf{1} - p_e)$ is small.

The above results are contained in Theorem 2.1. They are quite easy. What is more interesting is the study of the splitting of the patch Θ_e, which is the subject of Theorem 2.3—the main result of our paper.

We show that if the eigenvalue e is semisimple then the patch of the spectrum around e naturally splits into subpatches separated by a distance of order $O(|\lambda|^2)$. The subpatches will be parametrized by eigenvalues of the so-called *level shift operator* (LSO). The level shift operator is a certain operator that describes the shift of spectrum under the influence of second order perturbation theory. The subpatch of the spectrum of $L_{\lambda,\beta}$ around $e + \lambda^2 m$, where m is an eigenvalue of the LSO, will be denoted by $\Theta_{e,m}$. We will also give a formula for the projection $p_{e,m}$ that approximates the spectral projection of $L_{\lambda,\beta}$ onto $\Theta_{e,m}$. Finally, we will show that $p_{e,m}$ approximately diagonalizes $L_{\lambda,\beta}$.

Clearly, the results that we present are quite general and applicable in many situations. The main motivation for our paper comes, however, from the class of problems first considered by Jaksic and Pillet in Refs. 12, 13, and 15. Using the terminology of Ref. 7 we can say that the results of our paper can be used to describe approximately resonances of Pauli–Fierz Liouvillean. The last section is devoted to a short description of this application.

Let us briefly explain what we mean by resonances of Pauli–Fierz Liouvilleans. We use the name "Pauli–Fierz system" to describe a quantum system consisting of a small system (e.g., an atom) interacting with a bosonic field (e.g., photons or phonons). We are especially interested in the case when the field has a positive density, for instance it is at a positive temperature. The dynamics of this system is generated by a certain self-adjoint operator, which, following Ref. 7, we call the "Pauli–Fierz Liouvillean." Next we apply the so-called Jaksic–Pillet method and we obtain an analytically deformed Pauli–Fierz Liouvillean. Analytically deformed Liouvilleans are non-self-adjoint and have spectrum in the lower half-plane. Moreover, they often have isolated eigenvalues. These eigenvalues are called resonances. They do not depend on the parameter of deformation. They are physically relevant, they are responsible for the decay of certain correlation functions. They can be naturally written as the sum of an explicit operator with discrete eigenvalues and a perturbation. The method of our paper allows us to give approximate predictions about the resonances.

Another class of operators (not discussed in our paper) where our results could be applied are the generators of a Pauli–Fierz dynamics on an operator algebra (called *C*-Liouvilleans in Ref. 14).

Level shift operators appear in the mathematics and physics literature in various disguises whenever the second order perturbation theory is considered. They are often introduced in the case of embedded eigenvalues. For instance, they appeared implicitly in the work of Ref. 6 devoted to the perturbation theory for embedded eigenvalues of Pauli–Fierz operators. The analysis of the point spectrum given in Ref. 6 is very closely related to the analysis given in our paper. Nevertheless, there are some differences. Reference 6 was devoted to the study of *embedded* eigenvalues, and therefore additional tools were required: the limiting absorption principle and Mourre's

positive commutator method. Another difference is the self-adjointness of the operator studied in Ref. 6, whereas in our paper we do not restrict ourselves to self-adjoint operators.

Constructions similar to ours can be found in the papers of Bach–Fröhlich–Sigal.[1,2] The authors study the spectrum of certain operators (similar to the Pauli–Fierz operators considered in Refs. 6 and 7) by an iterative procedure ("renormalization group"). The basic step of this procedure resembles our prescription for locating the spectrum and constructing the approximate spectral projection.

The LSO appears naturally in the so-called weak coupling (van Hove) limit.[4,5,8] In this context it is sometimes called the Davies generator.

II. MAIN RESULTS

A. Notation

If $\Xi \subset \Theta \subset \mathbb{C}$, then we say that Ξ is an isolated subset of Θ if it is closed and open in the relative topology of Θ.

Θ^{cl} denotes the closure of Θ in $\mathbb{C}$.

If L is a linear operator, $\mathrm{sp}\, L$ denotes its spectrum and $\mathrm{Dom}\, L$ its domain. If Ξ is an isolated and bounded subset of $\mathrm{sp}\, L$, then we can define the spectral projection of L onto Ξ by the formula

$$\mathbf{1}_{\Xi}(L) = \frac{1}{2\pi i}\oint_{\gamma} (z-L)^{-1}\, \mathrm{d}z,$$

where γ is a closed path that encircles Ξ counterclockwise.

If e is an isolated point of $\mathrm{sp}\, L$, then we will write $\mathbf{1}_e(L)$ for $\mathbf{1}_{\{e\}}(L)$. For such e set $N_e := (L-e)\mathbf{1}_e(L)$. We say that the degree of nilpotence of e is equal to n iff $N_e^{n-1} \neq 0$ but $N_e^n = 0$. We say that e is semisimple iff $n=1$ (i.e., $N_e = 0$).

If $\Theta \subset \mathbb{C}$ and $\epsilon > 0$, then we set

$$\mathrm{D}(\Theta, \epsilon) := \{z \in \mathbb{C} : \mathrm{dist}(z, \Theta) < \epsilon\}.$$

For $e \in \mathbb{C}$, $\mathrm{D}(e, \epsilon)$ will denote the open disc centered at e with radius ϵ. Moreover, we set $\mathrm{D}(\emptyset, \epsilon) := \emptyset$.

If $A(\lambda, \beta)$ are bounded operators, and $f(\lambda, \beta)$ a positive function, then

$$A(\lambda, \beta) = O(f(\lambda, \beta))$$

means that there exists c such that

$$\|A(\lambda, \beta)\| \leqslant c f(\lambda, \beta).$$

Moreover,

$$A_1(\lambda, \beta) = A_2(\lambda, \beta) + O(f(\lambda, \beta))$$

or

$$A_1(\lambda, \beta) \overset{O(f(\lambda,\beta))}{=} A_2(\lambda, \beta)$$

means that

$$A_1(\lambda, \beta) - A_2(\lambda, \beta) = O(f(\lambda, \beta)).$$

B. Assumptions

Let L_0 be a closed operator on a Banach space $\mathcal{H}$. Suppose that Ξ is an isolated bounded subset of $\mathrm{sp}\, L_0$.

It will be convenient to denote $\mathbf{1}_{\Xi}(L_0)$ by $\mathbf{1}^{vv}$ and set $\mathbf{1}^{\overline{vv}} := \mathbf{1} - \mathbf{1}^{vv}$. We can also introduce the subspaces

$$\mathcal{H}^v := \mathbf{1}^{vv}\mathcal{H}, \quad \mathcal{H}^{\overline{v}} := \mathbf{1}^{\overline{vv}}\mathcal{H},$$

so that $\mathcal{H}$ is decomposed into a direct sum

$$\mathcal{H} = \mathcal{H}^v \oplus \mathcal{H}^{\overline{v}}. \tag{2.1}$$

With respect to the decomposition (2.1) any operator B on $\mathcal{H}$ satisfying

$$\mathrm{Dom}(B) = (\mathrm{Dom}(B) \cap \mathcal{H}^v) \oplus (\mathrm{Dom}(B) \cap \mathcal{H}^{\overline{v}})$$

can be written as

$$B = \begin{bmatrix} B^{vv} & B^{v\overline{v}} \\ B^{\overline{v}v} & B^{\overline{vv}} \end{bmatrix}. \tag{2.2}$$

In particular, we have

$$L_0 = \begin{bmatrix} L_0^{vv} & 0 \\ 0 & L_0^{\overline{vv}} \end{bmatrix}. \tag{2.3}$$

It will be convenient to write E for L_0^{vv}. Note that E is a bounded operator on $\mathcal{H}^v$ and $\mathrm{sp}(E) = \overline{\Xi}$.

Let Q be another operator, that we will treat as a perturbation of L_0. More precisely, we make the following assumptions.

Assumption 2.A: $Q^{vv} = 0$.

Assumption 2.B: Off-diagonal elements of Q, i.e., $Q^{v\overline{v}}$ and $Q^{\overline{v}v}$, are bounded.

We will also use either one of the following two assumptions.

Assumption 2.C: $Q^{\overline{vv}}$ is an operator bounded perturbation of $L_0^{\overline{vv}}$ (Ref. 11).

Assumption 2.D: $\mathcal{H}^{\overline{vv}}$ is a Hilbert space, $L_0^{\overline{vv}}$ is self-adjoint, bounded from below and $Q^{\overline{vv}}$ is a form bounded perturbation of $L_0^{\overline{vv}}$ (Ref. 11).

Let $\lambda, \beta \in \mathbb{C}$. Note that under Assumption 2.C or 2.D the operator $L_0^{\overline{vv}} + \beta Q^{\overline{vv}}$ is well defined for small enough β (Ref. 11). Likewise,

$$L_{\lambda,\beta} := L_0 + \lambda Q^{v\overline{v}} + \lambda Q^{\overline{v}v} + \beta Q^{\overline{vv}} = \begin{bmatrix} E & \lambda Q^{v\overline{v}} \\ \lambda Q^{\overline{v}v} & L_0^{\overline{vv}} + \beta Q^{\overline{vv}} \end{bmatrix}$$

is well defined for small enough β. For simplicity we will write L instead of $L_{\lambda,\beta}$.

Fix an open subset $\Omega \subset \mathbb{C}$ such that $\Omega^{\mathrm{cl}} \cap \mathrm{sp}\, L_0 = \overline{\Xi}$ and $\Xi \subset \Omega$. Note that there exists β_0 such that, for $|\beta| \leqslant \beta_0$, $\mathrm{sp}(L_0^{\overline{vv}} + \beta Q^{\overline{vv}}) \cap \Omega^{\mathrm{cl}} = \varnothing$. We fix β_0 satisfying these conditions.

C. Results

The main results of our paper are stated in the following two theorems. Note that Theorem 2.1 is quite easy and basically describes the well-known stability of spectrum under a perturbation. Theorem 2.3 is more difficult—it describes the splitting of the spectrum according to second order perturbation theory. In that theorem, an important role is played by the level shift operator. Note that we tried to make the two theorems as parallel as possible.

Theorem 2.1: *Suppose that Assumptions 2.A and 2.B hold. We also suppose that either Assumption 2.C or 2.D is satisfied. Then the following is true:*

(1) *There exists a continuous and increasing function*

$$[0, \infty[\ni x \mapsto \delta(x) \in [0, \infty],$$

such that $\lim_{x \to 0} \delta(x) = 0$, *and for* $|\beta| < \beta_0$ *and* $|\lambda| < \lambda_0$, *for some* $\lambda_0 > 0$, *we have*

$$\mathrm{sp}(L) \cap \Omega \subset \mathrm{D}(\mathrm{sp}\, E, \delta(|\lambda|))^{\mathrm{cl}}. \tag{2.4}$$

(2) *In what follows we assume that* $\mathcal{E}$ *is an isolated subset of* sp E. *Clearly,* (1) *implies that there exists* $0<\lambda_{\mathcal{E}}$ *such that, for* $|\lambda|<\lambda_{\mathcal{E}}$,

$$\Theta_{\mathcal{E}} := \mathrm{D}(\mathcal{E}, \delta(|\lambda|))^{\mathrm{cl}} \cap \mathrm{sp}\, L \tag{2.5}$$

is an isolated subset of sp L *and* $\Theta_{\mathcal{E}} \subset \Omega$.

(3) *For* $|\lambda|<\lambda_{\mathcal{E}}$ *we have*

$$\mathbf{1}_{\Theta_{\mathcal{E}}}(L) - \mathbf{1}_{\mathcal{E}}(L_0) = O(|\lambda|). \tag{2.6}$$

(4) *For* $|\lambda|<\lambda_{\mathcal{E}}$ *we have*

$$\dim \mathbf{1}_{\Theta_{\mathcal{E}}}(L) = \dim \mathbf{1}_{\mathcal{E}}(L_0). \tag{2.7}$$

(5) *In what follows we assume that* e *is an isolated point of* sp E. *We will write* Θ_e *for* $\Theta_{\{e\}}$. *If the degree of nilpotence of* e *as an eigenvalue of* E *is equal to* n, *then there exists* C_e *such that*

$$\Theta_e \subset \mathrm{D}(e, C_e|\lambda|^{2/n})^{\mathrm{cl}}.$$

(6) *For*

$$|\lambda| < \|\mathbf{1}_e(L_0) Q^{v\overline{v}} (e\mathbf{1}^{\overline{v}\overline{v}} - L_0^{\overline{v}\overline{v}})^{-2} Q^{\overline{v}v} \mathbf{1}_e(L_0)\|^{-1/2} =: \widehat{\lambda_e}, \tag{2.8}$$

we set

$$\begin{aligned} p_e := {} & (\mathbf{1}_e(L_0) + \lambda (e\mathbf{1}^{\overline{v}\overline{v}} - L_0^{\overline{v}\overline{v}})^{-1} Q^{\overline{v}v} \mathbf{1}_e(L_0))(\mathbf{1}_e(L_0) + \lambda^2 \mathbf{1}_e(L_0) Q^{v\overline{v}} (e\mathbf{1}^{\overline{v}\overline{v}} - L_0^{\overline{v}\overline{v}})^{-2} Q^{\overline{v}v} \mathbf{1}_e(L_0))^{-1} \\ & \times (\mathbf{1}_e(L_0) + \lambda \mathbf{1}_e(L_0) Q^{v\overline{v}} (e\mathbf{1}^{\overline{v}\overline{v}} - L_0^{\overline{v}\overline{v}})^{-1}). \end{aligned} \tag{2.9}$$

Then p_e *is a projection. Moreover,*

(a)

$$\mathbf{1}_{\Theta_e}(L) - p_e = O(|\lambda|); \tag{2.10}$$

(b) *if* e *is a semisimple eigenvalue of* E *then*

$$\mathbf{1}_{\Theta_e}(L) - p_e = O(|\lambda|^2 + |\lambda\beta|); \tag{2.11}$$

(c) *if, in addition,* sp$(E)=\{e\}$, *then*

$$\mathbf{1}_{\Theta_e}(L) - p_e = O(|\lambda|^3 + |\lambda\beta|). \tag{2.12}$$

(7) *For* $|\lambda|<\widehat{\lambda_e}$ *we have*

(a)

$$L - p_e L p_e - (\mathbf{1} - p_e) L (\mathbf{1} - p_e) = O(|\lambda|); \tag{2.13}$$

(b) *if* e *is a semisimple eigenvalue of* E *then*

$$L - p_e L p_e - (\mathbf{1} - p_e) L (\mathbf{1} - p_e) = O(|\lambda|^2 + |\lambda\beta|); \tag{2.14}$$

(c) *if, moreover,* sp$(E)=\{e\}$ *then*

$$L - p_e L p_e - (\mathbf{1} - p_e) L (\mathbf{1} - p_e) = O(|\lambda|^3 + |\lambda\beta|). \tag{2.15}$$

Note that in Eq. (2.9) we use the notation $(e\mathbf{1}^{\overline{v}\overline{v}} - L^{\overline{v}\overline{v}})^{-1}$ for the inverse of the operator $e\mathbf{1}^{\overline{v}\overline{v}} - L^{\overline{v}\overline{v}}$ *restricted to* $\mathcal{H}^{\overline{v}}$. In what follows we will often use similar notation without a comment.

Let us now assume that sp E is a finite set.

Definition 2.2: We define the level shift operator (LSO) as

$$\Gamma := \sum_{e\in \mathrm{sp}(E)} \mathbf{1}_e(E) Q^{\nu\overline{\nu}} (e\mathbf{1}^{\overline{\nu}\overline{\nu}} - L_0^{\overline{\nu}\overline{\nu}})^{-1} Q^{\overline{\nu}\nu} \mathbf{1}_e(E).$$

From now on we will write for shortness $\Gamma^{ee} := \mathbf{1}_e(E)\Gamma\mathbf{1}_e(E)$.

Now we are ready to state our main theorem.

Theorem 2.3: Suppose that Assumptions 2.A and 2.B hold. We also assume either Assumption 2.C or 2.D. Assume also that sp E *is a finite set consisting of semisimple eigenvalues. Then the following is true:*

(1) *There exists a continuous and increasing function*

$$[0,\infty[\ni x \mapsto \delta(x) \in [0,\infty],$$

such that $\lim_{x\to 0}\delta(x)=0$, *and, for* $|\beta|<\beta_0$, $|\lambda|<\lambda_0$, *for some* $\lambda_0>0$, *we have*

$$\mathrm{sp}(L)\cap\Omega \subset \mathrm{D}(\mathrm{sp}(E+\lambda^2\Gamma), |\lambda|^2\delta(|\lambda|^2+|\beta|))^{\mathrm{cl}} = \bigcup_{e\in\mathrm{sp}(E)} \mathrm{D}(e+\lambda^2\,\mathrm{sp}(\Gamma^{ee}), |\lambda|^2\delta(|\lambda|^2+|\beta|))^{\mathrm{cl}}. \tag{2.16}$$

(2) *In what follows we fix* $e\in$ sp E, *and* $\mathcal{M}$ *is an isolated subset of* sp Γ^{ee}. *Clearly, (1) implies that there exists* $0<\lambda_{e,\mathcal{M}}$ *and* $0<\beta_{e,\mathcal{M}}$ *such that for* $|\lambda|<\lambda_{e,\mathcal{M}}$ *and* $|\beta|<\beta_{e,\mathcal{M}}$,

$$\Theta_{e,\mathcal{M}} := \mathrm{D}(e+\lambda^2\mathcal{M}, |\lambda|^2\delta(|\lambda|^2+|\beta|))^{\mathrm{cl}} \cap \mathrm{sp}\, L$$

is an isolated subset of sp L *and* $\Theta_{e,\mathcal{M}}\subset\Omega$.

(3) *For* $|\lambda|<\lambda_{e,\mathcal{M}}$ *and* $|\beta|<\beta_{e,\mathcal{M}}$ *we have*

$$\mathbf{1}_{\Theta_{e,\mathcal{M}}}(L) - \mathbf{1}_{\mathcal{M}}(\Gamma^{ee}) = O(|\lambda|+|\beta|). \tag{2.17}$$

(4) *For* $|\lambda|<\lambda_{e,\mathcal{M}}$ *and* $|\beta|<\beta_{e,\mathcal{M}}$ *we have*

$$\dim \mathbf{1}_{\Theta_{e,\mathcal{M}}}(L) = \dim \mathbf{1}_{\mathcal{M}}(\Gamma^{ee}). \tag{2.18}$$

(5) *Assume now that* m *is an isolated point of* sp Γ^{ee}. *We will write* $\Theta_{e,m}$ *for* $\Theta_{e,\{m\}}$. *Suppose that the degree of nilpotence of* m *as an eigenvalue of* Γ^{ee} *is equal to* n. *Then*

$$\Theta_{e,m} \subset \mathrm{D}(e+\lambda^2 m, C_{e,m}|\lambda|^2(|\lambda|^2+|\beta|)^{1/n})^{\mathrm{cl}},$$

for some $C_{e,m}>0$.

(6) *For*

$$|\lambda| < \|\mathbf{1}_m(\Gamma^{ee})Q^{\nu\overline{\nu}}(e\mathbf{1}^{\overline{\nu}\overline{\nu}} - L_0^{\overline{\nu}\overline{\nu}})^{-2}Q^{\overline{\nu}\nu}\mathbf{1}_m(\Gamma^{ee})\|^{-1/2} =: \widehat{\lambda_{e,m}}, \tag{2.19}$$

we set

$$\begin{aligned} p_{e,m} := {} & (\mathbf{1}_m(\Gamma^{ee}) + \lambda(e\mathbf{1}^{\overline{\nu}\overline{\nu}} - L_0^{\overline{\nu}\overline{\nu}})^{-1}Q^{\overline{\nu}\nu}\mathbf{1}_m(\Gamma^{ee}))(\mathbf{1}_m(\Gamma^{ee}) + \lambda^2\mathbf{1}_m(\Gamma^{ee})Q^{\nu\overline{\nu}}(e\mathbf{1}^{\overline{\nu}\overline{\nu}} - L_0^{\overline{\nu}\overline{\nu}})^{-2} \\ & \times Q^{\overline{\nu}\nu}\mathbf{1}_m(\Gamma^{ee}))^{-1}(\mathbf{1}_m(\Gamma^{ee}) + \lambda\mathbf{1}_m(\Gamma^{ee})Q^{\nu\overline{\nu}}(e\mathbf{1}^{\overline{\nu}\overline{\nu}} - L_0^{\overline{\nu}\overline{\nu}})^{-1}). \end{aligned} \tag{2.20}$$

Then $p_{e,m}$ *is a projection. Moreover*,

(a)

$$\mathbf{1}_{\Theta_{e,m}}(L) - p_{e,m} = O(|\lambda|+|\beta|); \tag{2.21}$$

(b) *if* m *is a semisimple eigenvalue of* Γ^{ee} *then*

$$\mathbf{1}_{\Theta_{e,m}}(L) - p_{e,m} = O(|\lambda|^2+|\beta|). \tag{2.22}$$

(7) *For* $|\lambda| < \widehat{\lambda_{e,m}}$ *we have*

(a)

$$L - p_{e,m}Lp_{e,m} - (\mathbf{1} - p_{e,m})L(\mathbf{1} - p_{e,m}) = O(|\lambda|^2 + |\lambda\beta|);$$

(b) *if* $\mathbf{1}^{vv} = \mathbf{1}_m(\Gamma^{ee})$ *then*

$$L - p_{e,m}Lp_{e,m} - (\mathbf{1} - p_{e,m})L(\mathbf{1} - p_{e,m}) = O(|\lambda|^3 + |\lambda\beta|).$$

Remark 2.4: Note that in both theorems (6) describes how close the projections p_e *and* $p_{e,m}$ *are to the corresponding spectral projections of* L *and (7) describes how well they diagonalize* L.

In Theorem 2.1, we have the same order of smallness in (6) and (7). We will see from the proof, that (7) essentially follows from (6).

On the other hand, in Theorem 2.3, the order of smallness of (7) is much better than that of (6). Thus (7) requires a separate proof.

III. PROOFS

Let us begin with a general fact about the stability of the spectrum of bounded operators (Ref. 11).

Theorem 3.1: *Let* $A \in B(\mathcal{H})$. *Then there exists an increasing and continuous function,*

$$[0,\infty\,[\ni x \mapsto \mu_A(x) \ \in [0,\infty],$$

such that $\lim_{x\to 0} \mu_A(x) = 0$ *and for any* $B \in B(\mathcal{H})$ *we have* $\mathrm{sp}(A+B) \subset \mathrm{D}(\mathrm{sp}(A), \mu_A(\|B\|))^{\mathrm{cl}}$.

If $a \in \mathrm{sp}(A)$ *is an isolated eigenvalue with the degree of nilpotence equal to* n, *then there exists* $\epsilon > 0$ *such that for* $z \in \mathrm{D}(a,\epsilon)\backslash\{a\}$ *we have*

$$\|(z - A)^{-1}\| \leqslant C|z - a|^{-n}, \tag{3.1}$$

for some $C > 0$. *Moreover, for* $|\lambda| < \Lambda_a$ *for some* $\Lambda_a > 0$ *we have*

$$\mathrm{sp}(A + \lambda B) \cap \mathrm{D}(a,\epsilon) \subset \mathrm{D}(a, c|\lambda|^{1/n})^{\mathrm{cl}}, \tag{3.2}$$

where $c = (C\|B\|)^{1/n}$.

Proof: We prove only the last statement. Let $|\lambda| < \epsilon^n(C\|B\|)^{-1}$. If $z \in \mathrm{D}(a,\epsilon)\backslash\mathrm{D}(a,(C\|\lambda B\|)^{1/n})^{\mathrm{cl}}$ then

$$|z - a| > (C\|\lambda B\|)^{1/n},$$

so by the inequality (3.1),

$$1 > C\|\lambda B\|\,|z - a|^{-n} \geqslant \|\lambda B\|\,\|(z - A)^{-1}\| \geqslant \|\lambda B(z - A)^{-1}\|.$$

This shows that $z - A - \lambda B$ is invertible and hence $z \notin \mathrm{sp}(A + \lambda B)$, so we get (3.2). ■

Let us comment on some additional notation that we will use. For $\mathcal{E}$ an isolated subset of $\mathrm{sp}(E)$ we will write

$$\mathbf{1}^{\mathcal{E}\mathcal{E}} := \mathbf{1}_{\mathcal{E}}(E) = \mathbf{1}_{\mathcal{E}}(L_0), \quad \mathbf{1}^{\overline{\mathcal{E}}\overline{\mathcal{E}}} := \mathbf{1} - \mathbf{1}^{\mathcal{E}\mathcal{E}}, \quad \mathbf{1}^{\underline{\mathcal{E}}\underline{\mathcal{E}}} := \mathbf{1}^{vv} - \mathbf{1}^{\mathcal{E}\mathcal{E}},$$

$$\mathcal{H}^{\mathcal{E}} := \mathrm{Ran}\,\mathbf{1}_{\mathcal{E}}(E), \quad \mathcal{H}^{\overline{\mathcal{E}}} := \mathrm{Ran}\,\mathbf{1}^{\overline{\mathcal{E}}\overline{\mathcal{E}}}, \quad \mathcal{H}^{\underline{\mathcal{E}}} := \mathrm{Ran}\,\mathbf{1}^{\underline{\mathcal{E}}\underline{\mathcal{E}}}.$$

Now the Banach space $\mathcal{H}$ can be decomposed in the following way:

$$\mathcal{H} = \mathcal{H}^{\mathcal{E}} \oplus \mathcal{H}^{\overline{\mathcal{E}}} = \mathcal{H}^{\mathcal{E}} \oplus \mathcal{H}^{\underline{\mathcal{E}}} \oplus \mathcal{H}^{\overline{v}},$$

and operator L can be written as

$$L = \begin{bmatrix} E^{\mathcal{E}\mathcal{E}} & \lambda Q^{\mathcal{E}\overline{\mathcal{E}}} \\ \lambda Q^{\overline{\mathcal{E}}\mathcal{E}} & L^{\overline{\mathcal{E}}\overline{\mathcal{E}}} \end{bmatrix} = \begin{bmatrix} E^{\mathcal{E}\mathcal{E}} & 0 & \lambda Q^{\mathcal{E}\overline{v}} \\ 0 & E^{\underline{\mathcal{E}}\underline{\mathcal{E}}} & \lambda Q^{\underline{\mathcal{E}}\overline{v}} \\ \lambda Q^{\overline{v}\mathcal{E}} & \lambda Q^{\overline{v}\underline{\mathcal{E}}} & L_0^{\overline{v}\overline{v}} + \beta Q^{\overline{v}\overline{v}} \end{bmatrix}. \tag{3.3}$$

If e is an isolated point of $\mathrm{sp}(E)$ then we write $\mathbf{1}^{ee}$ for $\mathbf{1}^{\{e\}\{e\}}$, $\mathcal{H}^e$ for $\mathcal{H}^{\{e\}}$, etc. Note that $E^{\overline{\mathcal{E}}\overline{\mathcal{E}}} = E^{\underline{\mathcal{E}}\underline{\mathcal{E}}}$.

We will use the following theorem for several operators and for various decompositions of the space $\mathcal{H}$.

Theorem 3.2: *Let H be a closed operator on a Banach space $\mathcal{H} = \mathcal{H}^{\underline{v}} \oplus \mathcal{H}^{\overline{v}}$. Assume that off-diagonal elements of H,* i.e., *$H^{\underline{v}\overline{v}}$* and *$H^{\overline{v}\underline{v}}$ are bounded. For $z \in \mathbb{C}\backslash \mathrm{sp}(H^{\underline{v}\underline{v}})$ define*

$$G_v(z) := z\mathbf{1}^{\underline{v}\underline{v}} - H^{\underline{v}\underline{v}} - H^{\underline{v}\overline{v}}(z\mathbf{1}^{\overline{v}\overline{v}} - H^{\overline{v}\overline{v}})^{-1}H^{\overline{v}\underline{v}}.$$

Then for $z \notin \mathrm{sp}(H^{\overline{v}\overline{v}})$ we have

(1) $z \in \mathrm{sp}(H)$ *iff* $0 \in \mathrm{sp}(G_v(z))$,
(2) *if* $0 \notin \mathrm{sp}(G_v(z))$ *then*

$$(z - H)^{-1} = (z\mathbf{1}^{\overline{v}\overline{v}} - H^{\overline{v}\overline{v}})^{-1} + (\mathbf{1}^{\underline{v}\underline{v}} + (z\mathbf{1}^{\overline{v}\overline{v}} - H^{\overline{v}\overline{v}})^{-1}H^{\overline{v}\underline{v}})G_v^{-1}(z)(\mathbf{1}^{\underline{v}\underline{v}} + H^{\underline{v}\overline{v}}(z\mathbf{1}^{\overline{v}\overline{v}} - H^{\overline{v}\overline{v}})^{-1}).$$

The last equation is often called the Feshbach formula. We will keep this name. For more information about the above theorem the reader is referred to Refs. 6 and 10.

Lemma 3.3: Suppose that Assumptions 2.A and 2.B hold. We also assume either Assumption 2.C or 2.D. Let $\mathcal{E}$ be an isolated subset of $\mathrm{sp}(E)$ *and fix $r > 0$. Then there exists $0 < \Lambda_{\mathcal{E}}$ such that for $|\lambda| < \Lambda_{\mathcal{E}}$, $|\beta| < \beta_0$ we have $(\Omega\backslash \mathrm{D}(\mathrm{sp}(E^{\overline{\mathcal{E}}\overline{\mathcal{E}}}), r)) \cap \mathrm{sp}(L^{\overline{\mathcal{E}}\overline{\mathcal{E}}}) = \emptyset$ and*

$$\sup_{\substack{z \in \Omega\backslash \mathrm{D}(\mathrm{sp}(E^{\overline{\mathcal{E}}\overline{\mathcal{E}}}), r) \\ |\lambda| < \Lambda_{\mathcal{E}},\ |\beta| < \beta_0}} \|(z\mathbf{1}^{\overline{\mathcal{E}}\overline{\mathcal{E}}} - L^{\overline{\mathcal{E}}\overline{\mathcal{E}}})^{-1}\| < \infty. \tag{3.4}$$

Proof: If $z \in \Omega$ and $|\beta| < \beta_0$ then $z \notin \mathrm{sp}(L^{\overline{v}\overline{v}})$ and hence we can use the Theorem 3.2 for the operator $L^{\overline{\mathcal{E}}\overline{\mathcal{E}}}$ and for decomposition $\mathcal{H}^{\overline{\mathcal{E}}} := \mathcal{H}^{\underline{\mathcal{E}}} \oplus \mathcal{H}^{\overline{v}}$. We obtain that, for some $\Lambda_{\mathcal{E}} > 0$, and $|\lambda| < \Lambda_{\mathcal{E}}$ and for $z \in \Omega\backslash \mathrm{D}(\mathrm{sp}(E^{\underline{\mathcal{E}}\underline{\mathcal{E}}}), r)$,

$$G_{\underline{\mathcal{E}}}(z) = z\mathbf{1}^{\underline{\mathcal{E}}\underline{\mathcal{E}}} - E^{\underline{\mathcal{E}}\underline{\mathcal{E}}} - \lambda^2 Q^{\underline{\mathcal{E}}\overline{v}}(z\mathbf{1}^{\overline{v}\overline{v}} - L^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}\underline{\mathcal{E}}},$$

is invertible and hence $z \notin \mathrm{sp}(L^{\overline{\mathcal{E}}\overline{\mathcal{E}}})$. Moreover, for such z, $G_{\underline{\mathcal{E}}}(z)$ has a uniformly bounded inverse. Therefore, the Feshbach formula implies (3.4). ∎

Proof of the Theorem 2.1: (1) By Theorem 3.2, $z \in \mathrm{sp}(L) \cap \Omega$ iff $z \in \mathrm{sp}(E + \lambda^2 Q^{\underline{v}\overline{v}}(z1^{\overline{v}\overline{v}} - L^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}\underline{v}}) \cap \Omega$. By Theorem 3.1,

$$\mathrm{sp}(E + \lambda^2 Q^{\underline{v}\overline{v}}(z\mathbf{1}^{\overline{v}\overline{v}} - L^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}\underline{v}}) \subset \mathrm{D}(\mathrm{sp}(E), \mu_E(|\lambda|^2 c))^{\mathrm{cl}},$$

where

$$c = \sup_{z \in \Omega, |\beta| < \beta_0} \|Q^{\underline{v}\overline{v}}(z\mathbf{1}^{\overline{v}\overline{v}} - L^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}\underline{v}}\|,$$

(which as we know is finite), and $\mu_E : [0, \infty[\to [0, \infty[$ is a continuous increasing function with $\lim_{x \to 0} \mu_E(x) = 0$. Thus $\mathrm{sp}(L) \cap \Omega \subset \mathrm{D}(\mathrm{sp}(E), \delta(|\lambda|))^{\mathrm{cl}}$, where $\delta(x) = \mu_E(x^2 c)$.

(2) A simple consequence of (1).

(3) For some $0 < \lambda_{\mathcal{E}}$, $|\lambda| < \lambda_{\mathcal{E}}$, and $|\beta| < \beta_0$, there exists a closed path $\gamma \subset \Omega$ that encircles $\Theta_{\mathcal{E}}$ counterclockwise, but no other parts of $\mathrm{sp}(L)$. We have

$$\sup_{\substack{z\in\gamma,\ |\beta|<\beta_0\\ |\lambda|<\lambda_{\mathcal{E}}}} \|(z-L)^{-1}\|<\infty.$$

Besides,

$$(2\pi i)^{-1}\oint_\gamma (z\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}\,\mathrm{d}z=(2\pi i)^{-1}\oint_\gamma (z\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}\,\mathrm{d}z=0.$$

Therefore,

$$\begin{aligned}\mathbf{1}_{\Theta_{\mathcal{E}}}(L)-\mathbf{1}_{\mathcal{E}}(L_0)&=(2\pi i)^{-1}\oint_\gamma ((z\mathbf{1}-L)^{-1}-(z\mathbf{1}^{vv}-E)^{-1}-(z\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1})\mathrm{d}z\\ &=\lambda(2\pi i)^{-1}\oint_\gamma (z\mathbf{1}-L)^{-1}(Q^{v\overline{v}}+Q^{\overline{v}v})((z\mathbf{1}^{vv}-E)^{-1}+(z\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1})\mathrm{d}z=O(|\lambda|).\end{aligned}$$

(4) Equation (2.6) implies that for $|\lambda|$ sufficiently small we have $\|\mathbf{1}_{\Theta_{\mathcal{E}}}(L)-\mathbf{1}_{\mathcal{E}}(L_0)\|<1$ so by a well-known theorem (Ref. 11) Eq. (2.7) holds for $|\lambda|$ small. But $\lambda\mapsto\dim\mathbf{1}_{\Theta_{\mathcal{E}}}(L)\in\mathbb{N}$ is a continuous function so (2.7) holds for all $|\lambda|<\lambda_{\mathcal{E}}$.

(5) Let $\mathcal{E}$, r, and $\Lambda_{\mathcal{E}}$ be the same as in the Lemma 3.3. For $|\lambda|<\Lambda_{\mathcal{E}}$, $|\beta|<\beta_0$, we can use Theorem 3.2, which implies that for $z\in\Omega\backslash\mathrm{D}(\mathrm{sp}(E^{\overline{\mathcal{E}}\overline{\mathcal{E}}}),r)$ we have $z\in\mathrm{sp}(L)$ iff

$$z\in\mathrm{sp}(E^{\mathcal{E}\mathcal{E}}+\lambda^2Q^{\mathcal{E}\overline{\mathcal{E}}}(z\mathbf{1}^{\overline{\mathcal{E}}\overline{\mathcal{E}}}-L^{\overline{\mathcal{E}}\overline{\mathcal{E}}})^{-1}Q^{\overline{\mathcal{E}}\mathcal{E}}).$$

By Theorem 3.1 we get

$$\mathrm{sp}(E^{\mathcal{E}\mathcal{E}}+\lambda^2Q^{\mathcal{E}\overline{\mathcal{E}}}(z\mathbf{1}^{\overline{\mathcal{E}}\overline{\mathcal{E}}}-L^{\overline{\mathcal{E}}\overline{\mathcal{E}}})^{-1}Q^{\overline{\mathcal{E}}\mathcal{E}})\subset\mathrm{D}(\mathcal{E},\mu_{E^{\mathcal{E}\mathcal{E}}}(|\lambda|^2c))^{\mathrm{cl}},\tag{3.5}$$

where

$$c:=\sup_{\substack{z\in\Omega\backslash\mathrm{D}(\mathrm{sp}(E^{\overline{\mathcal{E}}\overline{\mathcal{E}}}),r)\\ |\beta|<\beta_0,\ |\lambda|<\Lambda_{\mathcal{E}}}}\|Q^{\mathcal{E}\overline{\mathcal{E}}}(z\mathbf{1}^{\overline{\mathcal{E}}\overline{\mathcal{E}}}-L^{\overline{\mathcal{E}}\overline{\mathcal{E}}})^{-1}Q^{\overline{\mathcal{E}}\mathcal{E}}\|$$

is finite by Lemma 3.3.

Now set $\mathcal{E}=\{e\}$ and assume that e has a degree of nilpotence equal to n. Then by Theorem 3.1 we can take $\mu_{E^{ee}}(x):=c_1x^{1/n}$.

(6) For $|\lambda|<\widehat{\lambda_e}$,

$$\mathbf{1}^{ee}+\lambda^2Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}e},$$

is an invertible operator so the expression for p_e makes sense. Direct computations show that $p_e^2=p_e$. Note that

$$(\mathbf{1}^{ee}+\lambda^2Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}e})^{-1}=\mathbf{1}^{ee}-\lambda^2Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}e}+O(\lambda^4)$$

so

$$\begin{aligned}p_e=\mathbf{1}^{ee}&+\lambda(Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}+(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}Q^{\overline{v}e})+\lambda^2((e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}Q^{\overline{v}e}Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}\\ &-Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}e})+O(|\lambda|^3).\end{aligned}\tag{3.6}$$

We have

$$\mathbf{1}_{\Theta_e}(L) = \mathbf{1}_e(L_0) + \lambda(2\pi i)^{-1}\oint_\gamma ((z\mathbf{1}^{vv} - E)^{-1}Q^{v\overline{v}}(z\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1} + (z\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}Q^{\overline{v}v}(z\mathbf{1}^{vv} - E)^{-1})\mathrm{d}z$$
$$+ \lambda^2(2\pi i)^{-1}\oint_\gamma ((z\mathbf{1}^{vv} - E)^{-1}Q^{v\overline{v}}(z\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}Q^{\overline{v}v}(z\mathbf{1}^{vv} - E)^{-1}$$
$$+ (z\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}Q^{\overline{v}v}(z\mathbf{1}^{vv} - E)^{-1}Q^{v\overline{v}}(z\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1})\mathrm{d}z + O(|\lambda|^3 + |\lambda\beta|).$$

e is the only one eigenvalue of E inside γ so $(z\mathbf{1}^{vv}-E)^{-1}$ has only one pole inside γ. All points on and inside γ are not in $\mathrm{sp}(L_0^{\overline{ee}})$ so $(z\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}$ is analytic inside and continuous on γ. If e is semisimple then $(z\mathbf{1}^{vv}-E)^{-1}=(z-e)^{-1}\mathbf{1}^{ee}+$*analytic part* and hence

$$\mathbf{1}_{\Theta_e}(L) = \mathbf{1}_e(L_0) + \lambda(Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1} + (e\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}Q^{\overline{v}e}) + \lambda^2\Bigg((2\pi i)^{-1}\oint_\gamma (z\mathbf{1}^{vv} - E)^{-1}Q^{v\overline{v}}$$
$$\times(z\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}Q^{\overline{v}v}(z\mathbf{1}^{vv} - E)^{-1}\,\mathrm{d}z + (e\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}Q^{\overline{v}e}Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}\Bigg) + O(|\lambda|^3$$
$$+ |\lambda\beta|). \tag{3.7}$$

Now part (b) [Eq. (2.11)] is a simple consequence of (3.7) and (3.6). In general, when e is not semisimple, terms of order $O(|\lambda|)$ will not cancel so part (a) [Eq. (2.10)] cannot be improved.

If $\mathrm{sp}(E)=\{e\}$ and e is semisimple then $(z\mathbf{1}^{vv}-E)^{-1}=(z-e)^{-1}\mathbf{1}^{ee}=(z-e)^{-1}\mathbf{1}^{vv}$. Now

$$(2\pi i)^{-1}\oint_\gamma (z\mathbf{1}^{vv} - E)^{-1}Q^{v\overline{v}}(z\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-1}Q^{\overline{v}v}(z\mathbf{1}^{vv} - E)^{-1}\,\mathrm{d}z = -\,Q^{e\overline{v}}(e\mathbf{1}^{\overline{vv}} - L_0^{\overline{vv}})^{-2}Q^{\overline{v}e}.$$

Now part (c) [Eq. (2.12)] is a simple consequence of (3.7) and (3.6).

(7) The proof of (6) in the cases (a), (b), and (c) shows actually slightly improved results,

$$(\mathbf{1}_{\Theta_e}(L) - p_e)L = O(|\lambda|), \quad O(|\lambda|^2 + |\lambda\beta|), \quad \text{and } O(|\lambda|^3 + |\lambda\beta|),$$

$$L(\mathbf{1}_{\Theta_e}(L) - p_e) = O(|\lambda|), \quad O(|\lambda|^2 + |\lambda\beta|), \quad \text{and } O(|\lambda|^3 + |\lambda\beta|).$$

To obtain (7) we use

$$L - p_eLp_e - (\mathbf{1} - p_e)L(\mathbf{1} - p_e) = -\,[p_e,[p_e,L]] = -\,[p_e,[p_e - \mathbf{1}_e(L),L]].$$

■

Proof of the Theorem 2.3: (1) Let $e\in\mathrm{sp}(E)$. Let $\mathcal{E}=\{e\}$, $\Lambda_e=\Lambda_{\mathcal{E}}$ and r be the same as in the Lemma 3.3 and in the proof of (5) of the previous theorem. For $|\lambda|<\Lambda_e$, $|\beta|<\beta_0$ and for $z\in\Omega\backslash\mathrm{D}(\mathrm{sp}(E^{\overline{ee}}),r)$ we can use Theorem 3.2 for the operator L and for decomposition $\mathcal{H}:=\mathcal{H}^e\oplus\mathcal{H}^{\overline{e}}$. If $z\in\mathrm{sp}(L)\cap\Omega\backslash\mathrm{D}(\mathrm{sp}(E^{\overline{ee}}),r)$ then

$$0\in\mathrm{sp}(z\mathbf{1}^{ee} - E^{ee} - \lambda^2Q^{e\overline{e}}(z\mathbf{1}^{\overline{ee}} - L^{\overline{ee}})^{-1}Q^{\overline{e}e}). \tag{3.8}$$

Note that $e\in\mathrm{sp}(E)$ is semisimple so $E^{ee}=e\mathbf{1}^{ee}$ and moreover, we have $Q^{\overline{e}e}=Q^{\overline{v}e}$ and $Q^{e\overline{e}}=Q^{e\overline{v}}$. Now (3.8) can be written as

$$\frac{z-e}{\lambda^2}\in\mathrm{sp}(Q^{e\overline{v}}(z\mathbf{1}^{\overline{ee}} - L^{\overline{ee}})^{-1}Q^{\overline{v}e}). \tag{3.9}$$

Note that

$$(z\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1} = (e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1} + (e-z)(z\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}(e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}$$
$$= (e\mathbf{1}^{\underline{e}\underline{e}} - L_0^{\underline{e}\underline{e}})^{-1} + (e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}(\lambda(Q^{\underline{e}\overline{v}} + Q^{\overline{v}\underline{e}}) + \beta Q^{\overline{v}\overline{v}})(e\mathbf{1}^{\underline{e}\underline{e}} - L_0^{\underline{e}\underline{e}})^{-1}$$
$$+ (e-z)(z\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}(e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}, \tag{3.10}$$

and $(e\mathbf{1}^{\underline{e}\underline{e}} - L_0^{\underline{e}\underline{e}})^{-1} = (e\mathbf{1}^{\underline{e}\underline{e}} - E^{\underline{e}\underline{e}})^{-1} + (e\mathbf{1}^{\overline{v}\overline{v}} - L_0^{\overline{v}\overline{v}})^{-1}$. Now we can write

$$Q^{e\overline{v}}(z\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}Q^{\overline{v}e} = \Gamma^{ee} + \mathbf{I} + \mathbf{II} + \mathbf{III}, \tag{3.11}$$

where

$$\mathbf{I} = \beta Q^{e\overline{v}}(e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}Q^{\overline{v}\overline{v}}(e\mathbf{1}^{\underline{e}\underline{e}} - L_0^{\underline{e}\underline{e}})^{-1}Q^{\overline{v}e},$$

$$\mathbf{II} = \lambda Q^{e\overline{v}}(e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}(Q^{\overline{v}\underline{e}} + Q^{\underline{e}\overline{v}})(e\mathbf{1}^{\underline{e}\underline{e}} - L_0^{\underline{e}\underline{e}})^{-1}Q^{\overline{v}e}, \tag{3.12}$$

$$\mathbf{III} = (e-z)Q^{e\overline{v}}(z\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}(e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}Q^{\overline{v}e}.$$

Clearly, $\|\mathbf{I}\| \leqslant C_{\mathrm{I}}|\beta|$. If we note that

$$\mathbf{1}^{\overline{v}\overline{v}}(e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}\mathbf{1}^{\underline{e}\underline{e}} = \lambda(e\mathbf{1}^{\overline{v}\overline{v}} - L^{\overline{v}\overline{v}})^{-1}Q^{\overline{v}\underline{e}}G_{\underline{e}}^{-1}(e) = O(\lambda)$$

and similarly $\mathbf{1}^{\underline{e}\underline{e}}(e\mathbf{1}^{\underline{e}\underline{e}} - L^{\underline{e}\underline{e}})^{-1}\mathbf{1}^{\overline{v}\overline{v}} = O(\lambda)$ then we get $\|\mathbf{II}\| \leqslant C_{\mathrm{II}}|\lambda|^2$. Moreover, Theorem 2.1 implies that $|z-e| < C\lambda^2$ and hence by the Lemma 3.3 [Eq. (3.4)] we get $\|\mathbf{III}\| \leqslant C_{\mathrm{III}}\lambda^2$. So for $|\lambda| < \Lambda_e$ and $|\beta| < \beta_0$ we have

$$\|\mathbf{I} + \mathbf{II} + \mathbf{III}\| < C_e(|\lambda|^2 + |\beta|)$$

for some $C_e > 0$. Now we can apply the Theorem 3.1 to the expression (3.9) and get for $|\lambda| < \Lambda_e$ and $|\beta| < \beta_0$,

$$\frac{z-e}{\lambda^2} \in \mathrm{D}(\mathrm{sp}(\Gamma^{ee}), \mu_{\Gamma^{ee}}(C_e(|\lambda|^2 + |\beta|)))^{\mathrm{cl}}, \tag{3.13}$$

where functions $\mu_{\Gamma^{ee}}: [0,\infty[\to [0,\infty]$ are continuous, increasing and $\lim_{x\to 0}\mu_{\Gamma^{ee}}(x) = 0$. This implies

$$\mathrm{sp}(L) \cap \Omega \setminus \mathrm{D}(\mathrm{sp}(E^{\underline{e}\underline{e}}), r) \subset \mathrm{D}(e + \lambda^2\,\mathrm{sp}(\Gamma^{ee}), |\lambda|^2\mu_{\Gamma^{ee}}(C_e(|\lambda|^2 + |\beta|)))^{\mathrm{cl}},$$

and hence for $|\lambda| < \lambda_0 := \min_{e\in\mathrm{sp}(E)}\Lambda_e$ and $|\beta| < \beta_0$ we have

$$\mathrm{sp}(L) \cap \Omega \subset \bigcup_{e\in\mathrm{sp}(E)} \mathrm{D}(e + \lambda^2\,\mathrm{sp}(\Gamma^{ee}), |\lambda|^2\delta(|\lambda|^2 + |\beta|))^{\mathrm{cl}},$$

where we denoted $\delta(x) := \max_{e\in\mathrm{sp}(E)}(\mu_{\Gamma^{ee}}(C_e x))$.

(2) A simple consequence of (1).

(3) Let γ be a closed path such that γ encircles $\mathcal{M}$ but no other parts of $\mathrm{sp}(\Gamma^{ee})$. By (1) and (2), for small enough λ and β, the translated and rescaled path $e+\lambda^2\gamma$ encircles only $\Theta_{e,\mathcal{M}}$ but no other parts of $\mathrm{sp}(L)$. Now

$$\mathbf{1}_{\Theta_{e,\mathcal{M}}}(L) = (2\pi i)^{-1}\oint_{e+\lambda^2\gamma} \frac{1}{\eta\mathbf{1} - L}\mathrm{d}\eta.$$

For all $\eta \in e+\lambda^2\gamma$ we can use Feshbach formula for the operator L and for the decomposition $\mathcal{H} = \mathcal{H}^e \oplus \mathcal{H}^{\overline{e}}$. We get

$$\oint_{e+\lambda^2\gamma}(\eta\mathbf{1}-L)^{-1}\,\mathrm{d}\eta=\oint_{e+\lambda^2\gamma}(\mathbf{1}^{ee}+(\eta\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}\lambda Q^{\overline{ee}})G_e^{-1}(\eta)(\mathbf{1}^{ee}+\lambda Q^{e\overline{e}}(\eta\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1})\mathrm{d}\eta,$$

where

$$G_e(\eta)=\eta\mathbf{1}^{ee}-e\mathbf{1}^{ee}-\lambda^2Q^{e\overline{e}}(\eta\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}Q^{\overline{e}e}.$$

Note that

$$\begin{aligned}((\eta-e)\mathbf{1}^{ee}-\lambda^2\Gamma^{ee})^{-1}-G_e^{-1}(\eta)=\lambda^2((\eta-e)\mathbf{1}^{ee}-\lambda^2\Gamma^{ee})^{-1}Q^{e\overline{v}}((e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}\\ -\mathbf{1}^{\overline{vv}}(\eta\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}\mathbf{1}^{\overline{vv}})Q^{\overline{v}e}G_e^{-1}(\eta),\end{aligned}\tag{3.14}$$

where we used $Q^{\overline{v}e}=Q^{\overline{e}\overline{e}}$ and $Q^{e\overline{v}}=Q^{e\overline{e}}$. Moreover,

$$\begin{aligned}&(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}-\mathbf{1}^{\overline{vv}}(\eta\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}\mathbf{1}^{\overline{vv}}\\ &\quad=(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}-(\eta\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}}-\beta Q^{\overline{vv}})^{-1}-\lambda^2(\eta\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}}-\beta Q^{\overline{vv}})^{-1}Q^{\overline{v}\underline{e}}G_{\underline{e}}^{-1}(\eta)\\ &\qquad\times Q^{\underline{e}\overline{v}}(\eta\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}}-\beta Q^{\overline{vv}})^{-1}\\ &\quad=(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}((\eta-e)\mathbf{1}^{\overline{vv}}+\beta Q^{\overline{vv}})(\eta\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}}-\beta Q^{\overline{vv}})^{-1}-\lambda^2(\eta\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}}-\beta Q^{\overline{vv}})^{-1}\\ &\qquad\times Q^{\overline{v}\underline{e}}G_{\underline{e}}^{-1}(\eta)Q^{\underline{e}\overline{v}}(\eta\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}}-\beta Q^{\overline{vv}})^{-1},\end{aligned}\tag{3.15}$$

where

$$G_{\underline{e}}(\eta)=\eta\mathbf{1}^{\underline{ee}}-E^{\underline{ee}}-\lambda^2Q^{\underline{e}\overline{v}}(\eta\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{v}\underline{e}}.$$

If we change the variable $\eta=e+\lambda^2z$ and use the equations (3.14) and (3.15) we get

$$\begin{aligned}\oint_{e+\lambda^2\gamma}(\eta\mathbf{1}-L)^{-1}\,\mathrm{d}\eta=\oint_{\gamma}(\mathbf{1}^{ee}+((e+\lambda^2z)\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}\lambda Q^{\overline{ee}})(z\mathbf{1}^{ee}-\Gamma^{ee})^{-1}\\ \times(\mathbf{1}^{ee}+\lambda Q^{e\overline{e}}((e+\lambda^2z)\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1})\mathrm{d}z+O(|\lambda|^2+|\beta|).\end{aligned}\tag{3.16}$$

Since

$$(2\pi i)^{-1}\oint_{\gamma}(z\mathbf{1}^{ee}-\Gamma^{ee})^{-1}\,\mathrm{d}z=\mathbf{1}_{\mathcal{M}}(\Gamma^{ee}),$$

we get $\mathbf{1}_{\Theta_{e,\mathcal{M}}}(L)-\mathbf{1}_{\mathcal{M}}(\Gamma^{ee})=O(|\lambda|+|\beta|)$.

(4) Equation (2.17) implies that for $|\lambda|$ and $|\beta|$ sufficiently small we have $\|\mathbf{1}_{\Theta_{e,\mathcal{M}}}(L)-\mathbf{1}_{\mathcal{M}}(\Gamma^{ee})\|<1$ so by a well-known theorem (Ref. 11) equality (2.18) holds. But $\dim\mathbf{1}_{\Theta_{\mathcal{E}}}(L)\in\mathbb{N}$ is a continuous function of λ and β so (2.18) holds for all $|\lambda|<\lambda_{e,\mathcal{M}}$ and $|\beta|<\beta_{e,\mathcal{M}}$.

(5) If the degree of nilpotence of m as an eigenvalue of Γ^{ee} is n then due to the Theorem 3.1, Eq. (3.13) can be written as

$$\frac{z-e}{\lambda^2}\in\mathrm{D}(m,C_{e,m}(|\lambda|^2+|\beta|)^{1/n})^{\mathrm{cl}}\cup\mathrm{D}(\mathrm{sp}(\Gamma^{ee})\setminus\{m\},\mu_{\Gamma^{ee}}(C_e(|\lambda|^2+|\beta|)))^{\mathrm{cl}}.$$

(6) For $|\lambda|<\widehat{\lambda_{e,m}}$,

$$\mathbf{1}_m(\Gamma^{ee})+\lambda^2\mathbf{1}_m(\Gamma^{ee})Q^{v\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{vv}}\mathbf{1}_m(\Gamma^{ee})$$

is an invertible operator so the expression for $p_{e,m}$ makes sense. Direct computations show that $p_{e,m}^2=p_{e,m}$.

In the proof of the part (3) we showed that $\mathbf{1}_{\Theta_{e,m}}(L)=\mathbf{1}_m(\Gamma^{ee})+O(|\lambda|+|\beta|)$ so (a) is already done. To show (b), we use the approximation for $\mathbf{1}_{\Theta_{e,m}}(L)$ given by (3.16);

$$\begin{aligned}\mathbf{1}_{\Theta_{e,m}}(L) &\overset{O(|\lambda^2|+|\beta|)}{=} \frac{1}{2\pi i}\oint_\gamma (\lambda((e+\lambda^2 z)\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}Q^{\overline{ee}}+\mathbf{1}^{ee})(z\mathbf{1}^{ee}-\Gamma^{ee})^{-1}\\ &\times(\lambda Q^{\overline{ee}}((e+\lambda^2 z)\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}+\mathbf{1}^{ee})\mathrm{d}z \overset{O(|\lambda^2|+|\lambda\beta|)}{=} \frac{1}{2\pi i}\oint_\gamma (\lambda(e+\lambda^2 z)\ \mathbf{1}^{\overline{ee}}-L_0^{\overline{ee}})^{-1}\\ &\times Q^{\overline{ee}}+\mathbf{1}^{ee})(z\mathbf{1}^{ee}-\Gamma^{ee})^{-1}(\lambda Q^{e\overline{e}}((e+\lambda^2 z)\mathbf{1}^{\overline{ee}}-L_0^{\overline{ee}})^{-1}+\mathbf{1}^{ee})\mathrm{d}z\\ &=(\lambda((e+\lambda^2 m)\mathbf{1}^{\overline{ee}}-L_0^{\overline{ee}})^{-1}Q^{\overline{ee}}+\mathbf{1}^{ee})\mathbf{1}_m(\Gamma^{ee})(\lambda Q^{e\overline{e}}((e+\lambda^2 m)\mathbf{1}^{\overline{ee}}-L_0^{\overline{ee}})^{-1}+\mathbf{1}^{ee}) \overset{O(|\lambda|^3)}{=} p_{e,m},\end{aligned}$$

where we used

$$((e+\lambda^2 z)\mathbf{1}^{\overline{ee}}-L_0^{\overline{ee}})^{-1}-((e+\lambda^2 z)\mathbf{1}^{\overline{ee}}-L^{\overline{ee}})^{-1}=O(|\lambda|+|\beta|).$$

(7) Let us denote $\mathbf{1}^{mm}:=\mathbf{1}_m(\Gamma^{ee})$, $Q^{m\overline{v}}:=\mathbf{1}^{mm}Q^{v\overline{v}}$ and $Q^{\overline{v}m}:=Q^{\overline{v}\overline{v}}\mathbf{1}^{mm}$, so that

$$\begin{aligned}p_{e,m}=&(\mathbf{1}^{mm}+\lambda(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}Q^{\overline{v}m})(\mathbf{1}^{mm}+\lambda^2 Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}m})^{-1}\\ &\times(\mathbf{1}^{mm}+\lambda Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}).\end{aligned}$$

We compute

$$\begin{aligned}p_{e,m}(L-e)=&(\mathbf{1}^{mm}+\lambda(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}Q^{\overline{v}m})(\mathbf{1}^{mm}+\lambda^2 Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}m})^{-1}\\ &\times(\lambda^2 Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{vv}}+\lambda\beta Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{vv}})=O(|\lambda|^2+|\lambda\beta|),\end{aligned}$$

$$\begin{aligned}p_{e,m}Lp_{e,m}-ep_{e,m}=&(\mathbf{1}^{mm}+\lambda(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1}Q^{\overline{v}m})(\mathbf{1}^{mm}+\lambda^2 Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}m})^{-1}\\ &\times(\lambda^2 Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{v}m}+\lambda^2\beta Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{vv}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{v}m})\\ &\times(\mathbf{1}^{mm}+\lambda^2 Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-2}Q^{\overline{v}m})^{-1}(\mathbf{1}^{mm}+\lambda Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L_0^{\overline{vv}})^{-1})\\ =&O(|\lambda|^2+|\lambda\beta|).\end{aligned}$$

Thus

$$p_{e,m}(L-e)(\mathbf{1}-p_{e,m})=O(|\lambda|^2+|\lambda\beta|).$$

Similarly,

$$(\mathbf{1}-p_{e,m})(L-e)p_{e,m}=O(|\lambda|^2+|\lambda\beta|).$$

Finally, we use

$$L-p_{e,m}Lp_{e,m}-(\mathbf{1}-p_{e,m})L(\mathbf{1}-p_{e,m})=p_{e,m}(L-e)(\mathbf{1}-p_{e,m})+(\mathbf{1}-p_{e,m})(L-e)p_{e,m}.$$

This proves (a).

Assume now that $\mathrm{sp}(E)=\{e\}$. Then

$$Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{vv}}=Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{ve}}=Q^{m\overline{v}}(e\mathbf{1}^{\overline{vv}}-L^{\overline{vv}})^{-1}Q^{\overline{v}m}.$$

[The first identity follows from $\mathrm{sp}(E)=\{e\}$, the second is a consequence of the definition of $\mathbf{1}^{mm}$.] Using this we get

$$p_{e,m}(L-e) = (\mathbf{1}^{mm} + \lambda(e\mathbf{1}^{\overline{\upsilon\upsilon}} - L_0^{\overline{\upsilon\upsilon}})^{-1}Q^{\overline{\upsilon}m})(\mathbf{1}^{mm} + \lambda^2 Q^{m\overline{\upsilon}}(e\mathbf{1}^{\overline{\upsilon\upsilon}} - L_0^{\overline{\upsilon\upsilon}})^{-2}Q^{\overline{\upsilon}m})^{-1}\lambda^2 Q^{m\overline{\upsilon}}(e\mathbf{1}^{\overline{\upsilon\upsilon}} - L^{\overline{\upsilon\upsilon}})^{-1}$$
$$\times Q^{\overline{\upsilon}m}(\mathbf{1}^{mm} + \lambda^2 Q^{m\overline{\upsilon}}(e\mathbf{1}^{\overline{\upsilon\upsilon}} - L_0^{\overline{\upsilon\upsilon}})^{-2}Q^{\overline{\upsilon}m})^{-1}(\mathbf{1}^{mm} + \lambda Q^{m\overline{\upsilon}}(e\mathbf{1}^{\overline{\upsilon\upsilon}} - L_0^{\overline{\upsilon\upsilon}})^{-1}) + O(|\lambda|^3).$$

This proves (b). ■

IV. APPLICATION: ANALYTICALLY DEFORMED PAULI–FIERZ LIOUVILLEANS

In this section we describe a class of operators to which the results of our paper can be applied. These operators arise naturally as models used in quantum physics. They provided for us a part of motivation to write this paper.

In order to introduce these operators we have to introduce a number of concepts taken from operator algebra and mathematical physics. Our presentation is based on Refs. 6, 7, 12, 13, and 9.

A. W^*-dynamical systems and Liouvilleans

Let us start with a brief description of some elements of theory of operator algebras, that we will use.[3,9]

A pair $(\mathfrak{M}, \tau^t)$, where $\mathfrak{M}$ is a W^*-algebra and τ^t is a σ-weakly continuous group of automorphisms of $\mathfrak{M}$, is called a W^*-dynamical system. In many circumstances it is convenient to describe a quantum system by a W^*-dynamical system. One of important results of theory of W^*-algebras says that there exists a distinguished representation, unique up to the unitary equivalence, called the standard representation.[3,9] It is a quadruple $(\pi, \mathcal{W}, J, \mathcal{W}_+)$, where $\mathcal{W}$ is a Hilbert space, $\pi := \mathfrak{M} \to B(\mathcal{W})$ is a *-representation, J an antiunitary involution, called the modular conjugation, and $\mathcal{W}_+$ is a self-dual cone, called the positive cone, in $\mathcal{W}$ satisfying certain axioms. In this representation there exists a unique self-adjoint operator L, called the Liouvillean, that implements the dynamics

$$\pi(\tau^t(A)) := e^{itL}\pi(A)e^{-itL}$$

and leaves invariant the positive cone, $e^{itL}\mathcal{W}_+ = \mathcal{W}_+$.

The properties of the W^*-dynamics τ^t are encoded in a simple way in the Liouvillean. For instance, the dynamics τ^t has no stationary states iff L has no point spectrum; it has a single stationary state iff L has a simple eigenvalue at zero.

One can argue that the resonances of L correspond to metastable states of the system $(\mathfrak{M}, \tau)$.

B. Massless bosons at zero density interacting with a small quantum system

Our main object of interest will be Pauli–Fierz systems at a positive density. They will be introduced in the next section. In order, however, to understand their physical content it is appropriate to describe first Pauli–Fierz systems at a zero density (in other words, at zero temperature), which we will do in this section.

Let $\mathcal{K}$ be a Hilbert space associated with quantum mechanical system and let K be a self-adjoint Hamiltonian for this system.

Let $L^2(\mathbb{R}^d)$ be the one particle bosonic space and let h be the one particle energy operator given by the multiplication by $|\xi|$ where $\xi \in \mathbb{R}^d$. The Hamiltonian $\mathrm{d}\Gamma(h)$ of the Bose gas acts on the symmetric (bosonic) Fock space $\Gamma_s(L^2(\mathbb{R}^d))$.

Let the interaction between systems be given by a measurable operator valued function $\mathbb{R}^d \ni \xi \mapsto v(\xi) \in B(\mathcal{K})$. The following sections are based on Ref. 7 (see also Ref. 6).

The Hilbert space of the system at zero density (zero temperature) is $\mathcal{H} = \mathcal{K} \otimes \Gamma_s(L^2(\mathbb{R}^d))$ and the free Hamiltonian is

$$H_{\mathrm{fr}} := K \otimes \mathbf{1}_{\Gamma_s(L^2(\mathbb{R}^d))} + \mathbf{1}_{\mathcal{K}} \otimes \int |\xi| a^*(\xi) a(\xi) \mathrm{d}\xi,$$

where $a^*(\xi)/a(\xi)$ are the usual creation/annihilation operators of the boson of momentum ξ. The interaction is given by the operator

$$V := \int (v(\xi) \otimes a^*(\xi) + v^*(\xi) \otimes a(\xi)) \mathrm{d}\xi.$$

The full Pauli–Fierz Hamiltonian equals

$$H := H_{\mathrm{fr}} + \lambda V,$$

where $\lambda \in \mathbb{R}$. To guarantee the self-adjointness of H we can assume that $\int (1+|\xi|^{-1}) \|v(\xi)\|^2 \, \mathrm{d}\xi < \infty$.

C. Massless bosons at density ρ interacting with a small quantum system

In this section we explain the notion of a Pauli–Fierz system at density ρ.

Suppose that we are given a measurable function

$$\mathbb{R}^d \ni \xi \mapsto \rho(\xi) \in [0, \infty[.$$

Let us consider the "doubled" Fock space $\Gamma_s(L^2(\mathbb{R}^d) \oplus L^2(\mathbb{R}))$. The creation/annihilation operators corresponding to the left/right $L^2(\mathbb{R}^d)$ will be denoted by $a_{\mathrm{l}}^*(\xi)/a_{\mathrm{l}}(\xi)$ and $a_r^*(\xi)/a_r(\xi)$, respectively. Let us introduce the left and right Araki–Woods creation and annihilation operators

$$a_{\rho,\mathrm{l}}^*(\xi) := \sqrt{1+\rho(\xi)}\, a_{\mathrm{l}}^*(\xi) + \sqrt{\rho(\xi)}\, a_r(\xi),$$

$$a_{\rho,\mathrm{l}}(\xi) := \sqrt{1+\rho(\xi)}\, a_{\mathrm{l}}(\xi) + \sqrt{\rho(\xi)}\, a_r^*(\xi),$$

$$a_{\rho,r}^*(\xi) := \sqrt{\rho(\xi)}\, a_{\mathrm{l}}(\xi) + \sqrt{1+\rho(\xi)}\, a_r^*(\xi),$$

$$a_{\rho,r}(\xi) := \sqrt{\rho(\xi)}\, a_{\mathrm{l}}^*(\xi) + \sqrt{1+\rho(\xi)}\, a_r(\xi).$$

The sub-W^*-algebra of $\mathcal{B}(\mathcal{K} \otimes \overline{\mathcal{K}} \otimes \Gamma_s(L^2(\mathbb{R}^d) \oplus L^2(\mathbb{R}^d)))$ generated by operators of the form

$$A \otimes \mathbf{1}_{\overline{\mathcal{K}}} \otimes \exp\left(i \int f(\xi) a_{\rho,\mathrm{l}}^*(\xi) \mathrm{d}\xi + i \int \overline{f}(\xi) a_{\rho,\mathrm{l}}(\xi) \mathrm{d}\xi \right),$$

where $A \in \mathcal{B}(\mathcal{K})$ and $\int |f(\xi)|^2 \delta(\xi) d\xi < \infty$, will be called the Pauli–Fierz W^*-algebra. It is in a standard representation.

Note that the Pauli–Fierz algebra is isomorphic to the tensor product of the algebra of the small system $\mathcal{B}(\mathcal{K})$ and the algebra of Araki–Woods canonical commutation relations at density ρ.

The free Liouvillean is given by

$$L_{\mathrm{fr}} := K \otimes \mathbf{1} \otimes \mathbf{1} - \mathbf{1} \otimes \overline{K} \otimes \mathbf{1} + \mathbf{1} \otimes \mathbf{1} \otimes \int (|\xi| a_{\mathrm{l}}^*(\xi) a_{\mathrm{l}}(\xi) - |\xi| a_r^*(\xi) a_r(\xi)) \mathrm{d}\xi;$$

the perturbation is

$$Q_\rho := \int v(\xi) \otimes 1 \otimes a_{\rho,\mathrm{l}}^*(\xi) \mathrm{d}\xi + hc - \int (\mathbf{1} \otimes \overline{v}(\xi)) \otimes a_{\rho,r}^*(\xi) \mathrm{d}\xi + hc.$$

Assumption 4.A: If $\int (1+|\xi|^2)(1+\rho(\xi)) \|v(\xi)\|^2 \, \mathrm{d}\xi < \infty$ *holds then*

$$L_\rho := L_{\mathrm{fr}} + \lambda Q_\rho$$

essentially self-adjoint on the intersection of the domains of L_{fr} *and* Q_ρ.

The most important class of densities is that given by the Planck law at the inverse temperature β,

$$\rho_\beta{}^{(\xi)} := (e^{\beta|\xi|} - 1)^{-1}.$$

In particular, $\beta=\infty$ corresponds to the temperature zero (and density zero), and the corresponding Liouvillean is unitarily equivalent to

$$H \otimes \mathbf{1} - \mathbf{1} \otimes \overline{H}. \tag{4.1}$$

Thus in this case all the information is encoded in the Pauli–Fierz Hamiltonian described in the preceding section. One can argue that for a general ρ, L_ρ is a kind of a thermodynamical limit (4.1).

D. Analytically deformed Pauli–Fierz Liouvilleans

Pauli–Fierz Liouvilleans have continuous spectrum that covers the whole real line. They may also have some embedded eigenvalues. In particular, a thermal Pauli–Fierz Liouvillean (i.e., whose density is given by the Planck law) always has a zero eigenvalue corresponding to a KMS state. In general, eigenvalues of a Liouvillean are related to stationary states, therefore their study is very important from the physical point of view.

Another physically relevant question about Pauli–Fierz Liouvilleans is whether they have resonances and if so what is their location. They may manifest themselves as poles of an S-matrix or decay rates of certain correlation functions.

In order to define resonances we use the approach of Jaksic–Pillet. The first step of this approach consists of "gluing" the "left" and "right" one-particle subspaces. This is done as follows. We use the spherical coordinates in $\mathbb{R}^d$ and we introduce the Jaksic–Pillet gluing map defined as

$$L^2(\mathbb{R}^d) \oplus \overline{L^2(\mathbb{R}^d)} \ni (f_+, \overline{f_-}) \mapsto f \in L^2(\mathbb{R}) \otimes L^2(S^{d-1}), \tag{4.2}$$

$$f(p,\omega) := \begin{cases} p^{(d-1)/2} f_+(p\omega), & p > 0, \\ (-p)^{(d-1)/2} \overline{f_-}(-p\omega), & p \leqslant 0. \end{cases}$$

Here, $(p,\omega) \in \mathbb{R} \times S^{d-1}$ and S^{d-1} denotes $(d-1)$ dimensional sphere. The canonical conjugation in $L^2(\mathbb{R}) \otimes L^2(S^{d-1})$ is given by the complex conjugation.

If we assume that

$$v^*(\xi) = v(-\xi), \quad \rho(\xi) = \rho(-\xi)$$

and introduce

$$v_\rho(p,\omega) := \begin{cases} p^{(d-1)/2}(1+\rho(p\omega))^{1/2} v(p\omega), & p > 0, \\ (-p)^{(d-1)/2} \rho(p\omega)^{1/2} v(p\omega), & p \leqslant 0. \end{cases}$$

In the new representation, the free Liouvillean and its perturbation can be written as

$$L_{\mathrm{fr}} := K \otimes \mathbf{1} \otimes \mathbf{1} - \mathbf{1} \otimes \overline{K} \otimes \mathbf{1} + \mathbf{1} \otimes \mathbf{1} \otimes \int p a^*(p,\omega) a(p,\omega) \mathrm{d}p \, \mathrm{d}\omega,$$

$$Q_\rho = \int (v_\rho(p,\omega)\otimes \mathbf{1}\otimes a^*(p,\omega) + v_\rho^*(p,\omega)\otimes \mathbf{1}\otimes a(p,\omega))\mathrm{d}p\,\mathrm{d}\omega$$

$$+ \int (\mathbf{1}\otimes \overline{v_\rho}(p,\omega)\otimes a^*(-p,\omega) + \mathbf{1}\otimes \overline{v_\rho^*}(p,\omega)\otimes a(-p,\omega))\mathrm{d}p\,\mathrm{d}\omega$$

as an operator on $\mathcal{K}\otimes\overline{\mathcal{K}}\otimes\Gamma_s(L^2(\mathbb{R})\otimes L^2(S^{d-1}))$.

Let us make the following assumption.

Assumption 4.B: The function

$$\mathbb{R}\ni p\mapsto v_\rho(p,\cdot)\in\mathcal{B}(\mathcal{K},\mathcal{K}\otimes L^2(S^{d-1}))$$

extends to an analytic function in a strip $|\mathrm{Im}\,p|<\eta_0$ *and*

$$\sup_{|\mathrm{Im}p|<\eta_0}\int \|v_\rho(p,\cdot)\|^2\mathrm{d}(\mathrm{Re}\,p)<\infty.$$

Let $i^{-1}\nabla_p$ be the generator of translations on $L^2(\mathbb{R})$ in the spectral parameter p. Let $S := \mathrm{d}\Gamma(i^{-1}\nabla_p)$ be its second quantization. Note that for any complex η,

$$L_{\mathrm{fr}}(\eta) := e^{i\eta S}L_{\mathrm{fr}}e^{-i\eta S} = L_{\mathrm{fr}} + \eta\mathbf{1}^{\otimes 1}\otimes N,$$

where $N=\mathrm{d}\Gamma(1)$ is the number operator. Moreover, for $|\mathrm{Im}\,\eta|<\eta_0$,

$$Q_\rho(\eta) := e^{i\eta S}Q_\rho e^{-i\eta S}$$

$$= \int v_\rho((p+\eta),\omega)\otimes\mathbf{1}\otimes a^*(p,\omega)\mathrm{d}p\,\mathrm{d}\omega + \int v_\rho^*((p+\overline{\eta}),\omega)\otimes\mathbf{1}\otimes a(p,\omega)\mathrm{d}p\,\mathrm{d}\omega$$

$$+ \int \mathbf{1}\otimes\overline{v_\rho}((p+\overline{\eta}),\omega)\otimes a^*(-p,\omega)\mathrm{d}p\,\mathrm{d}\omega + \int \mathbf{1}\otimes\overline{v_\rho^*}((p+\eta),\omega)\otimes a(-p,\omega)\mathrm{d}p\,\mathrm{d}\omega.$$

Theorem 4.1: *Assume that 4.A, and 4.B hold. Then we have the following.*

(1) *There exists a unique operator-valued function* $\eta\mapsto L_\rho(\eta)$ *defined for* $0\leqslant -\mathrm{Im}\,\eta<\eta_0$ *such that*

- (a) $L_\rho(\eta)=e^{i\eta S}L_\rho e^{-i\eta S}$ *for* $\eta\in\mathbb{R}$.
- (b) *For* $0<\mathrm{Im}\,\eta<\eta_0$, $\eta\mapsto L_\rho(\eta)$ *is an analytic family.*
- (c) *For* $\mathrm{Im}z>0$, $(z-L_\rho(\eta))^{-1}$ *is strongly continuous up to* $\mathrm{Im}\,\eta=0$.

(2) *For and open* $U\subset\mathbb{C}$, $U\cap\mathrm{sp}_{\mathrm{disc}}(L_\rho(\eta))$ *is locally independent of* η, *as long as* $U\cap\mathrm{sp}_{\mathrm{ess}}(L_\rho(\eta))=\emptyset$.

If we assume that $\dim K<\infty$, *then for* $0\leqslant -\mathrm{Im}\,\eta<\eta_0$ *there exists* $\lambda_0>0$ *such that for* $|\lambda|<\lambda_0$ *the following statements hold:*

(3) $\mathrm{sp}L_\rho(\eta)\subset\{z\in\mathbb{C}:\mathrm{Im}z\leqslant 0\}$,

(4) *There exists* $c>0$ *such that*

$$\mathrm{sp}_{\mathrm{ess}}L_\rho(\eta)\subset\{z\in\mathbb{C}:\mathrm{Im}z<-|\mathrm{Im}\,\eta|(1-c|\lambda|)\}.$$

(5) *Real eigenvalues of* $L_\rho(\eta)$ *are semisimple and*

$$\mathrm{sp}_{\mathrm{pp}}L_\rho=\mathrm{sp}\,L_\rho(\eta)\cap\mathbb{R}.$$

So real discrete eigenvalues of $L_\rho(\eta)$ are semisimple, independent of η and coincide with the embedded eigenvalues of L_ρ. The nonreal discrete eigenvalues of $L_\rho(\eta)$, which are called resonances or metastable states, are also independent of η but they do not have to be semisimple.

E. LSO for Pauli–Fierz Liouvilleans

In this section we indicate how one can apply the method described in our paper to an analytically deformed Pauli–Fierz Liouvillean. We will see that many objects, including the LSO, do not depend on the parameter of deformation η, or depend rather mildly.

It is easy to see that $\mathbb{R}\cap \mathrm{sp}\, L_{\mathrm{fr}}(\eta)$ is an isolated subset of $\mathrm{sp}\, L_{\mathrm{fr}}(\eta)$ equal to

$$\mathrm{sp}(K\otimes \mathbf{1}-\mathbf{1}\otimes \overline{K})=\{k_1-k_2: k_1,k_2\in\ \mathrm{sp}\, K\}.$$

The corresponding spectral projection equals the orthogonal projection onto $\mathcal{K}\otimes\overline{\mathcal{K}}\otimes\Omega$, where Ω is the Fock vacuum. Note that it does not depend on η. Denote this projection by $\mathbf{1}^{vv}$. Clearly, $E=\mathbf{1}^{vv}L_{\mathrm{fr}}(\eta)$ does not depend on η either and can be identified with $K\otimes\mathbf{1}-\mathbf{1}\otimes\overline{K}$.

We can apply the method developed in this paper to the operator $L_\rho(\eta)=L_{\mathrm{fr}}(\eta)+\lambda Q_\rho(\eta)$ obtaining the LSO, which again does not depend on η,

$$\Gamma_\rho := \sum_{e\in \mathrm{sp}(E)} \mathbf{1}_e(E)Q_\rho^{v\overline{v}}(\eta)(e\mathbf{1}^{\overline{vv}}-L_{\mathrm{fr}}^{\overline{vv}}(\eta))^{-1}Q_\rho^{\overline{vv}}(\eta)\mathbf{1}_e(E).$$

One can compute Γ_ρ from the undeformed Liouvillean as well,

$$\Gamma_\rho=\lim_{\epsilon\searrow 0}\sum_{e\in \mathrm{sp}(E)} \mathbf{1}_e(E)Q_\rho^{v\overline{v}}((e+i\in)\mathbf{1}^{\overline{vv}}-\ L_{\mathrm{fr}}^{\overline{vv}}))^{-1}Q_\rho^{\overline{vv}}\mathbf{1}_e(E). \tag{4.3}$$

Note that (4.3) coincides with the definition of LSO contained in Ref. 7.

One can also compute the projectors $p_e(\eta)$ and $p_{e,m}(\eta)$. They depend on η, but in a rather controlled way, they are analytic functions of η for satisfying $s\in\mathbb{R}$,

$$p_e(\eta)=e^{isS}p_e(\eta+s)e^{-isS},\quad p_{e,m}(\eta)=e^{isS}p_{e,m}(\eta+s)e^{-isS}.$$

(Received 24 March 2004; accepted 3 November 2004; published online 14 February 2005)

In this paper we study different models of the Teichmüller space of compact hyperbolic surfaces with special emphasis on their construction by geodesic octagons. Such surfaces have become increasingly interesting due to their applications to the physical behavior of chaotic quantum systems. They are, on the one hand, complex enough to show the relevant features, and on the other hand, they possess a simple mathematical structure allowing practical implementations. We give a new description of Teichmüller space and the mapping class group in terms of geometric data of the octagons. This provides modellings based on the vertices and also on the generators of the associated isometry group. In addition, we explicitly connect our approach with other models currently used in the literature (Helling matrices, Fenchel–Nielsen parameters). The result of the paper may be considered as a computational tool kit to work with a specific model and to relate it with the others. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1850177]

I. INTRODUCTION

The purpose of this paper is to provide tools for computation and experimentation on compact Riemann surfaces of genus 2, starting from their description via the pasting of a fundamental octagon. A Riemann surface here is understood as a compact two-dimensional orientable manifold with a Riemannian metric of constant curvature −1. The universal covering of such surfaces is the hyperbolic plane for which we shall use the Poincaré disc model.

Over the years, many authors have studied the particular case of genus 2: this case gives access to quite explicit calculations but is still complex enough for the study of relevant phenomena in a model situation.

In Ref. 10, 12, 19, and 32 , for instance, explicit presentations of the mapping class group are given; in Refs. 7, 15, 20–24, 29, 34, 35, and 39, suitable parameters are introduced for the construction of algebraic and geometric models of Teichmüller space and in order to approach the moduli problem. Computations of explicit examples and numerical experiments are carried out for the Koebe–Poincaré uniformization theorem in Refs. 2, 14, 16, 28, 30, 31, 38, 41, and 42. Bounds and numerical computations for small eigenvalues of the Laplace–Beltrami operator are given in Ref. 25 and 27.

In Refs. 4, 6–9, and 36, the Hadamard–Gutzwiller model is studied from a physical point of view. Eigenvalues and eigenfunctions of a quantum mechanical system which describes the motion of a particle on a surface of constant negative curvature (hyperbolic octagon) are analyzed

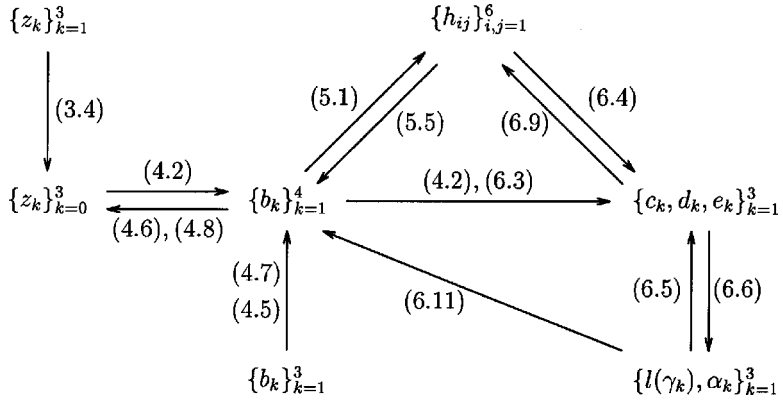
TABLE I. Changes of parameters.



with respect to its strongly chaotic behavior. Numerical experiments are performed in order to investigate the statistical properties of highly excited states[8] and the lengths of periodic orbits are related with an arithmetical structure of chaos.[3,5]

The use of a fundamental polygon as the "input device" for such computations has a number of advantages. First of all, to designate any example, it is sufficient to give the sequence of vertices.[7] Second, a function on the surface (such as an eigenfunction of the Laplacian) is represented simply as a function on a compact plane domain. Finally, by letting the mapping class group operate on these polygons (see Sec. VIII), we obtain geometrically different domains representing the same surface, hence a possibility of checking numerical accuracy experimentally.

The paper is organized as follows. In Sec. II we briefly review the connection between the hyperbolic octagons and the corresponding Riemann surfaces and Fuchsian groups of genus 2. In Sec. III, we show how the octagon is computed if three of its vertices are given. Not all triples lead to a result and so we solve the problem of how to overview the admissible triples in Sec. VII. This yields a new description of the Teichmüller space in genus 2 (Theorem 7.3). In Sec. IV and Theorem 7.2, the same is carried out in terms of Fuchsian groups.

In Secs. V and VI, we relate the parameters used in this paper to other parameters known in the literature. Here we have made an effort to provide simple formulas that are easily programmable. Table I shows the global structure of the formulas for the parameter changes settled in this paper. In this table, z_0, z_1, z_2, z_3 are vertices of the octagon, b_1, b_2, b_3, b_4 are generators of the Fuchsian group related to the octagon, $\{h_{ij}\}$ is Helling's matrix from Ref. 24, c_k, d_k, e_k for $k=1$, 2, 3, are trace parameters (the Fenchel–Nielsen triples) and $l(\gamma_k), \alpha_k$ the corresponding Fenchel–Nielsen length and twist parameters. The arrows point out the different possible ways of expressing one set of parameters in terms of the others. The numbers refer to the corresponding transformation formulas in the text.

Finally, in Sec. VIII, we introduce elementary operations on the octagon and prove that they generate the mapping class group. The proof uses a new technique introduced in the thesis[1] and is different from the usual approach by Dehn twists.

II. OCTAGONS AND TEICHMÜLLER SPACE

In this section we describe the relation between the symmetric hyperbolic octagons and the compact Riemann surfaces of genus 2. The construction is standard, for details see, e.g., Refs. 11 and 40.

We work in the unit disc model

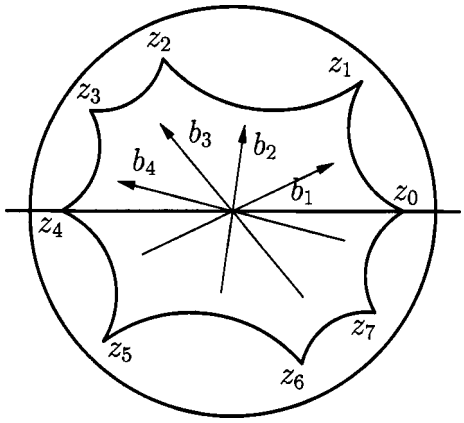


FIG. 1. Symmetric hyperbolic octagon in the unit disk and generators of the Fuchsian group.

$$\mathbb{D} = \{z = x + iy \in \mathbb{C} \,|\, |z| < 1\}$$

of hyperbolic geometry with the Riemannian metric

$$\mathrm{d}s^2 = \frac{4(\mathrm{d}x^2 + \mathrm{d}y^2)}{(1 - x^2 - y^2)^2}$$

of constant curvature -1. The hyperbolic distance of $z, w \in \mathbb{D}$ is denoted by $\mathrm{dist}_{\mathbb{D}}(z, w)$ and the Euclidean distance by $|z - w|$.

The orientation-preserving isometries of $(\mathbb{D}, \mathrm{d}s^2)$ are the Möbius transformations

$$z \mapsto g(z) = \frac{az + b}{\overline{b}z + \overline{a}}, \quad z \in \mathbb{D},$$

where $a, b \in \mathbb{C}$ are complex numbers satisfying $|a|^2 - |b|^2 = 1$, and $\overline{a}, \overline{b}$ are the complex conjugates. The group of all orientation-preserving isometries of $(\mathbb{D}, \mathrm{d}s^2)$ is denoted by $\mathrm{Isom}^+(\mathbb{D})$.

The geodesics in this model are the intersections with $\mathbb{D}$ of the Euclidean circles and the Euclidean straight lines that intersect the boundary $\partial\mathbb{D}$ orthogonally.

A hyperbolic n-gon is a simply connected compact domain $\Omega \subset \mathbb{D}$, whose boundary consists of n geodesic arcs, the *sides* of Ω, whose endpoints are the *vertices*. Denoting the interior angles at these vertices by $\delta_1, \ldots, \delta_n$, we have the *area formula*

$$\mathrm{area}(\Omega) = (n - 2)\pi - (\delta_1 + \cdots + \delta_n). \tag{2.1}$$

Now let $z_1, z_2, z_3 \in \mathbb{D}^+ = \{x + iy \in \mathbb{D} \,|\, y > 0\}$ be points with arguments

$$0 < \arg(z_1) < \arg(z_2) < \arg(z_3) < \pi$$

and let $z_0 \in]0, 1[\subset \mathbb{D}$ be on the positive real axis. Setting

$$z_4 = -z_0, \quad z_5 = -z_1, \quad z_6 = -z_2, \quad z_7 = -z_3$$

we obtain a geodesic octagon $P = P[z_0, z_1, z_2, z_3]$ with vertices $z_0, \ldots, z_7$ and sides $s_k = z_{k-1}z_k$, $k = 1, \ldots, 8$, where we write $z_8 = z_0$. By construction, P is invariant under the rotation $z \mapsto -z$ so that opposite sides have the same lengths. For $k = 1, \ldots, 4$, we therefore have a uniquely defined isometry $b_k \in \mathrm{Isom}^+(\mathbb{D})$ sending side s_{k+4} to s_k in such a way that

$$b_k(z_{k+3}) = z_k, \quad b_k(z_{k+4}) = z_{k-1}.$$

(See Fig. 1.)

For these isometries we have $b_k(P)\cap P=s_k$. Pasting sides s_{k+4} and s_k together, for $k=1, 2, 3, 4$ [by identifying any $z\in s_{k+4}$ with $b_k(z)\in s_k$], we therefore obtain a closed surface S of genus 2, which carries the hyperbolic metric inherited from P. This metric is smooth, except possibly at the point $w_0\in S$ which corresponds to the vertices of P. It follows that the metric is smooth at w_0 if and only if the sum of the interior angles of P equals 2π.

We call P *admissible* if this angle sum equals 2π. By the area formula (2.1), this is the same as requiring that $\text{area}(P)=4\pi$.

A classical result, which can be traced back to Fricke–Klein,[18] says that *any compact Riemann surface of genus 2 can be obtained by the above construction out of some admissible octagon.*

The proof uses the fact that on any such surface S there exists a curve system Σ consisting of simple closed geodesics $\sigma_1,\sigma_2,\sigma_3,\sigma_4$ which intersect each other pairwise at one and the same point w_0. Cutting S open along Σ gives a symmetric octagon.

This brings us as follows to the concept of Teichmüller space (see Ref. 26 for a general account).

If $\phi:S\to S$ is a homeomorphism, then the closed geodesics in the homotopy classes of the image curves $\phi\circ\sigma_k$ also decompose S into an admissible octagon. Hence, different octagons may lead to the same surface. For this reason it has become useful to *mark* a surface by selecting a curve system Σ on it. Two marked surfaces (S,Σ) and (S',Σ') are then called *marking equivalent* if there exists an isometry $h:S\to S'$ sending Σ to Σ'. The *Teichmüller space* $\mathcal{T}_2$ (for genus 2) is the set of all marking equivalence classes.

If, in the above construction, S is marked with the geodesics σ_k that result from the couples of sides s_{k+4}, s_k of the octagon, then it is not difficult to show that there is a one-to-one correspondence between the set $\mathcal{P}_2$ of all admissible octagons and the Teichmüller space $\mathcal{T}_2$. *We may therefore identify $\mathcal{P}_2$ with the Teichmüller space in genus 2.*

The surface obtained from P may also be described in terms of Fuchsian groups. If P is admissible, then by a theorem of Poincaré,[17,33,37] the isometries b_1,b_2,b_3,b_4 generate a Fuchsian group $\Gamma\subset\text{Isom}^+(\mathbb{D})$ with fundamental domain P, and S is the quotient surface $S=\mathbb{D}/\Gamma$. We may *mark* Γ by the selection of the generators $b_1,\ldots,b_4$ and call Γ with these generators and Γ' with generators $b_1',\ldots,b_4'$ marking equivalent if there exist $g\in\text{Isom}^+(\mathbb{D})$ satisfying $b_k'=gb_kg^{-1}$, $k=1,\ldots,4$. It can be shown that this establishes a one-to-one correspondence between the set $\mathcal{P}_2$ of all admissible polygons and the set $\mathcal{F}_2$ of all marking equivalence classes of Fuchsian groups (for genus 2), see, e.g., Refs. 12, 23, and 24.

III. COMPUTATION OF z_0

Definition 3.1: A triple of complex numbers $z_1,z_2,z_3\in\mathbb{D}$ satisfying

$$0<\arg(z_1)<\arg(z_2)<\arg(z_3)<\pi$$

is called admissible *if there exists $z_0\in\,]0,1[$ such that the symmetric octagon $P[z_0,z_1,z_2,z_3]$ is admissible.*

Instead of using the octagon we shall work most of the time with the pentagon $G=G[z_0,z_1,z_2,z_3]$ given by the vertices $z_0,z_1,z_2,z_3,z_4=-z_0$.

The triple z_1,z_2,z_3, and likewise the pentagon G is admissible if and only if $\text{area}(G)=2\pi$. As we shall see in Lemma 3.3, z_0 is uniquely determined by z_1,z_2,z_3.

Lemma 3.2: $G[z_0,z_1,z_2,z_3]$ is an admissible pentagon if and only if

$$\text{Im}\prod_{k=0}^{3}(1-z_k\overline{z_{k+1}})=0. \tag{3.1}$$

Proof: We use the area formula for triangles $D(z_k,z_{k+1})$ with vertices 0, z_k, z_{k+1} given in (A7):

$$\text{area } D(z_k, z_{k+1}) = 2 \arg(1 - z_k \overline{z_{k+1}}) \quad (k = 0,1,2,3). \tag{3.2}$$

The area of this triangle (as for any geodesic triangle in $\mathbb{D}$) is a number between 0 and π. Therefore we have $0 < \arg(1 - z_k \overline{z_{k+1}}) < \pi/2$. The sum of these areas is equal to the area of $G[z_0, z_1, z_2, z_3]$ and, since the latter is less than 3π, we have

$$0 < \sum_{k=0}^{3} \arg(1 - z_k \overline{z_{k+1}}) < \frac{3\pi}{2}.$$

Since all four arguments lie between 0 and $\pi/2$, we have

$$\sum_{k=0}^{3} \arg(1 - z_k \overline{z_{k+1}}) = \arg \prod_{k=0}^{3} (1 - z_k \overline{z_{k+1}})$$

(an equality between real numbers and not an equality modulo 2π). This gives us the formula

$$\text{area } G[z_0, z_1, z_2, z_3] = 2 \arg \prod_{k=0}^{3} (1 - z_k \overline{z_{k+1}}). \tag{3.3}$$

Now the argument of the product equals π if and only if the imaginary part equals zero, and the lemma follows. ■

In the next lemma we show how to compute z_0 out of an admissible triple z_1, z_2, z_3 such that $G[z_0, z_1, z_2, z_3]$ becomes an admissible pentagon. The lemma is formulated in such a way that the formula for z_0 is easily programmable and is valid for all cases.

Lemma 3.3: Let $z_1, z_2, z_3 \in \mathbb{D}$ *be complex numbers satisfying* $0 < \arg(z_1) < \arg(z_2) < \arg(z_3) < \pi$. *Abbreviate*

$$u = (1 - z_1 \overline{z_2})(1 - z_2 \overline{z_3}),$$

$$a = \text{Im}\{-u \overline{z_1} z_3\},$$

$$b = \text{Im}\{u(z_3 - \overline{z_1})\},$$

$$c = \text{Im}\{u\}. \tag{3.4a}$$

The triple z_1, z_2, z_3 *is admissible if and only if* $a + b + c < 0$. *If the triple is admissible, then there exists exactly one* $z_0 \in (0,1)$ *such that* $G[z_0, z_1, z_2, z_3]$ *is admissible. This* z_0 *is given by the formula*

$$z_0 = \frac{2c}{-b + \sqrt{b^2 - 4ac}}. \tag{3.4b}$$

Remark: In the future (but not yet during the proof of the lemma), if an admissible triple is given, then z_0 always means the real number given by this formula. As we shall see, for admissible triples, parameter c is always positive, and therefore if a becomes zero, formula (3.4b) is never singular.

Proof of the lemma: Let us first consider the value of c. By equation (3.3), we have

$$0 < 2 \arg(u) = \text{area } D(z_1, z_2) + \text{area } D(z_2, z_3) < 2\pi.$$

Hence $c = \text{Im}\{u\} > 0$.

Next let us consider the area of $G[z_0, z_1, z_2, z_3]$ where we keep z_1, z_2, z_3 fixed (admissible or not) and vary z_0 from 0 to 1, including the limiting cases $z_0 = 0$ and $z_0 = 1$. For $z_0 = 0$ the pentagon is singular and consists just of two triangles, $G[z_0, z_1, z_2, z_3] = D(z_1, z_2) \cup D(z_2, z_3)$, and its area is

$<2\pi$. As we continuously increase z_0, the area of the pentagon increases strictly to a maximum at $z_0=1$, where area $G[1,z_1,z_2,z_3]=2\arg[(1-\overline{z_1})u(1+z_3)]$. Consequently, the triple z_1,z_2,z_3 is admissible if and only if $\arg[(1-\overline{z_1})u(1+z_3)]>\pi$. Since $\mathrm{Im}((1-\overline{z_1})u(1+z_3))=a+b+c$, this is equivalent to saying that $a+b+c<0$.

Now let us assume that the triple is admissible, and hence $a+b+c<0$. From what we have just seen, there exists exactly one value of z_0 in the interval (0, 1) for which $G[z_0,z_1,z_2,z_3]$ is admissible. By virtue of Lemma 3.2, this value is the unique solution in the interval (0, 1) of the equation $\mathrm{Im}\,\Pi_{k=0}^{3}(1-z_k\overline{z_{k+1}})=0$. This equation is the same as

$$az_0^2+bz_0+c=0 \tag{3.5}$$

(with the above-defined values of a,b,c). In the case $a=0$, we have $b+c=a+b+c<0$. Using that $c>0$, we obtain $b<-c<0$ and the solution of equation (3.5) is $z_0=c/(-b)$. This indeed lies in the interval (0, 1) and is also given by the formula of the lemma.

If $a\neq 0$, (3.5) has the two distinct solutions

$$z_0=\frac{2c}{-b\pm\sqrt{b^2-4ac}},$$

where we already know that exactly one of them lies in the interval (0, 1). In particular, this means that $\sqrt{b^2-4ac}$ is a real number. It remains to be shown that the solution in (0, 1) is the one with the plus sign.

If $a<0$, then $b^2-4ac>b^2$ and therefore $-b-\sqrt{b^2-4ac}<0$. In this case the solution with the minus sign lies in the interval $(-\infty,0)$.

If $a>0$, we first conclude from $a+b+c<0$ that $b<0$. Furthermore, $b^2-4ac<b^2$, so that in this case $-b-\sqrt{b^2-4ac}>0$. Again from $a+b+c<0$, we have $-a>b+c$ and so $b^2-4ac>b^2+4bc+4c^2=(-b-2c)^2$. From this we find $\sqrt{b^2-4ac}>-b-2c$ and thence $-b-\sqrt{b^2-4ac}<2c$.

Altogether $2c/(-b-\sqrt{b^2-4ac})>1$, so that the solution with the minus sign now lies in the interval $(1,\infty)$. This concludes the proof of the lemma. ∎

Remark: The expression $(1/2a)(-b\pm\sqrt{b^2-4ac})$ for the solution of (3.5) is less useful than that given in Lemma 3.3 because a becomes 0 in certain cases.

IV. GENERATORS OF THE FUCHSIAN GROUP

In this section we compute the generators of the Fuchsian group which arise naturally from the octagon and vice versa.

The generators are $b_1,b_2,b_3,b_4\in\mathrm{Isom}^+(\mathbb{D})$, where, for $k=1$, 2, 3, 4, b_k is the (uniquely determined) orientation-preserving isometry mapping side $z_{k+3}z_{k+4}$ onto side z_kz_{k-1} in such a way that $b_k(z_{k+3})=z_k$ and $b_k(z_{k+4})=z_{k-1}$ (with the notation $z_8\doteq z_0$). It is well known that b_1,b_2,b_3,b_4 generate the Fuchsian group Γ of the octagon and that the following relation [which also follows from (4.3) below] holds:

$$b_1b_2^{-1}b_3b_4^{-1}b_1^{-1}b_2b_3^{-1}b_4=\mathrm{id}. \tag{4.1}$$

We express the generators by half turns. Let p_k be the midpoint of side $z_{k-1}z_k$ for $k=1$, 2, 3, 4; set $p_5=0$, $p_6=z_0$ and let m_k be the half turn around p_k ($k=1$, …, 6), i.e., the rotation with angle π and center p_k (so that p_k is the unique fixed point of m_k and $m_k^2=\mathrm{id}$).

In the next lemma, we use the notation

$$B[z]=\frac{az+b}{cz+d}\quad\text{for } B=\begin{bmatrix}a & b\\ c & d\end{bmatrix}\in \mathrm{GL}(2,\mathbb{C}).$$

Lemma 4.1: Let z_1,z_2,z_3 be an admissible triple and assume that z_0 has been computed so that $G[z_0,z_1,z_2,z_3]$ is admissible. Set

$$\omega_k = \frac{z_{k-1}(1-|z_k|^2) + z_k(1-|z_{k-1}|^2)}{1-|z_{k-1}z_k|^2}, \quad k=1,\ldots,4, \tag{4.2a}$$

then $|\omega_k|<1$. *Furthermore, the matrix*

$$B_k = \frac{-1}{\sqrt{1-|\omega_k|^2}}\begin{bmatrix} 1 & \omega_k \\ \overline{\omega_k} & 1 \end{bmatrix}, \quad k=1,\ldots,4 \tag{4.2b}$$

is well defined and satisfies

$$B_k[z] = b_k(z), \quad z \in \mathbb{D}, \quad k=1,\ldots,4,$$

i.e., the B_k *are matrices representing the generators of the Fuchsian group for the octagon* $P[z_0,z_1,z_2,z_3]$.

Proof: From (A1) and (A2) it follows that $|\omega_k|<1$ for $k=1, \ldots, 4$.

Let m_k denote the half turn around the midpoint p_k of side $z_{k-1}z_k$, $k=1, \ldots, 4$, and let m_5 denote the half turn around the point $p_5 \doteq 0$. From (A3), m_k is given by the matrix

$$M_k = \frac{i}{\sqrt{1-|\omega_k|^2}}\begin{bmatrix} 1 & -\omega_k \\ \overline{\omega_k} & -1 \end{bmatrix}, \quad k=1,\ldots,5, \tag{4.2c}$$

where we set $\omega_5 \doteq 0$. From (A4), the midpoints and centers of rotation are

$$p_k = \frac{\omega_k}{1+\sqrt{1-|\omega_k|^2}}, \quad k=1,\ldots,5. \tag{4.2d}$$

Note that $M_kM_5=B_k$, $k=1, \ldots, 4$.

It remains to be shown that

$$b_k = m_km_5. \tag{4.2e}$$

Now $m_5(z)=-z$ for $z \in \mathbb{D}$ and therefore, in particular,

$$m_km_5(z_{k+3}) = m_k(z_{k-1}) = z_k,$$

$$m_km_5(z_{k+4}) = m_k(z_k) = z_{k-1}.$$

Since any isometry from $\mathrm{Isom}^+(\mathbb{D})$ is uniquely determined by the images of two distinct points, this proves that indeed $m_km_5=b_k$ and the proof of Lemma 4.1 is complete. ■

The remainder of this section concerns the converse problem of finding the vertices of the octagon from a given set of generators.

By virtue of the relation (4.1), any one of the generators is determined by the other three. We shall assume that b_1,b_2,b_3 are given and compute b_4 as well as z_0,z_1,z_2,z_3.

For this we first consider some mapping properties of the half turns m_k.

Let α_k be the interior angle of $G=G[z_0,z_1,z_2,z_3]$ at vertex z_k, $k=0, 1, 2, 3, 4$. As may be seen from Fig. 2, the images G, $m_1(G)$, $m_1m_2(G)$, $m_1m_2m_3(G)$, and $m_1m_2m_3m_4(G)$ cover an angular sector of angle $\alpha_0+\alpha_1+\alpha_2+\alpha_3+\alpha_4$ at z_0. Since the angle sum of G is π, it follows that $m_1m_2m_3m_4(G)$ is the same as $\tau(G)$, where τ denotes the isometry with axis through z_4 and z_0 which maps z_4 onto z_0. Denoting by m_6 the half turn around $z_0=p_6$, we can write

$$\tau = m_6m_5.$$

Since $m_1m_2m_3m_4(G)=\tau(G)$, we conclude that $m_1m_2m_3m_4=m_6m_5$, or

$$m_1m_2m_3m_4m_5m_6 = \mathrm{id}. \tag{4.3}$$

Note that (4.3) implies (4.1).

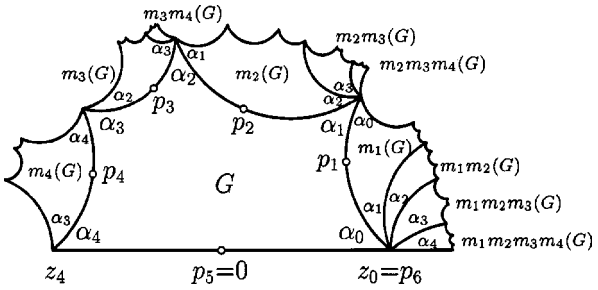

FIG. 2. A succession of half turns.

We also need this relation in terms of the matrices (4.2c). *A priori*, we can only say that $M_1\cdots M_6=\pm\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}$. However, the set of all admissible triples z_1,z_2,z_3 is a *connected* open subset of $\mathbb{D}\times\mathbb{D}\times\mathbb{D}$ (Theorem 7.3). Hence, by continuity, the sign is always the same. Taking any example, we see that it is the plus sign. Thus the matrices M_k in (4.2c), representing the half turns m_k satisfy

$$M_1M_2M_3M_4M_5M_6=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}. \tag{4.4}$$

A convenient way to "input" the generators is to define them by means of the points p_1,p_2,p_3, in much the same way as the octagon is defined by giving z_1,z_2,z_3. For the triple p_1,p_2,p_3, we assume

$$0<\arg(p_1)<\arg(p_2)<\arg(p_3)<\pi$$

and call it *admissible* if there exists an admissible $G[z_0,z_1,z_2,z_3]$ such that p_k is the midpoint of side $z_{k-1}z_k$, $k=1,2,3$ (a more convenient criterion for this admissibility is given in Theorem 7.1).

From (A3) and (A5), the half turn m_k around p_k is given by the matrix

$$M_k=\frac{i}{\sqrt{1-|\omega_k|^2}}\begin{bmatrix}1-\omega_k\\ \overline{\omega_k}-1\end{bmatrix},\quad k=1,2,3, \tag{4.5a}$$

where the invariant ω_k and point p_k are related by

$$\omega_k=\frac{2p_k}{1+|p_k|^2},\quad p_k=\frac{\omega_k}{1+\sqrt{1-|\omega_k|^2}},\quad k=1,2,3. \tag{4.5b}$$

The corresponding generator is given by the matrix

$$B_k\doteq\begin{bmatrix}\beta_k & \delta_k\\ \overline{\delta_k} & \overline{\beta_k}\end{bmatrix}=\frac{-1}{\sqrt{1-|\omega_k|^2}}\begin{bmatrix}1 & \omega_k\\ \overline{\omega_k} & 1\end{bmatrix},\quad k=1,2,3, \tag{4.5c}$$

where

$$\beta_k=\frac{-1}{\sqrt{1-|\omega_k|^2}},\quad \delta_k=\frac{-\omega_k}{\sqrt{1-|\omega_k|^2}},\quad \omega_k=\frac{\delta_k}{\beta_k}. \tag{4.5d}$$

These relations show that it is equivalent to give either B_k, p_k, or ω_k. We call the generators b_1,b_2,b_3, given by B_1,B_2,B_3 *admissible* if the corresponding points p_1,p_2,p_3 form an admissible triple.

In Theorem 7.1 we give a geometric criterion for the admissibility of the triple p_1,p_2,p_3 and we now prove the following

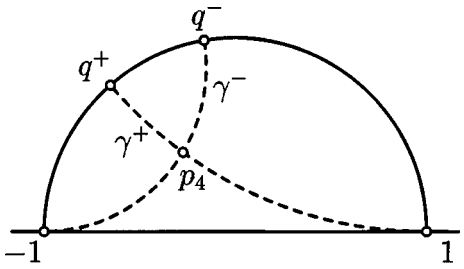

FIG. 3. Construction of p_4 and b_4.

Lemma 4.2: Let b_1, b_2, b_3 be an admissible triple of generators and let

$$A = \begin{bmatrix} \alpha & \beta \\ \overline{\beta} & \overline{\alpha} \end{bmatrix} \doteq B_3 B_2^{-1} B_1$$

be the matrix representing the product $b_3 b_2^{-1} b_1$. Then the octagon has the vertex

$$z_0 = \frac{\omega_6}{1 + \sqrt{1 - \omega_6^2}} \quad \text{with } \omega_6 = \frac{\alpha - \overline{\alpha}}{\beta - \overline{\beta}}, \tag{4.6}$$

The generator b_4 is given by the matrix

$$B_4 = AW \quad \text{where } W \doteq \frac{-1}{\sqrt{1 - \omega_6^2}} \begin{bmatrix} 1 & -\omega_6 \\ -\omega_6 & 1 \end{bmatrix}. \tag{4.7}$$

The remaining vertices are obtained from z_0 via the generators

$$z_4 = -z_0, \quad z_1 = b_1(z_4), \quad z_5 = -z_1, \quad z_2 = b_2(z_5), \quad etc. \tag{4.8}$$

Proof: From (4.3),

$$m_4 = m_3 m_2 m_1 m_6 m_5 = m_3 m_5 m_5 m_2 m_1 m_5 m_5 m_6 m_5 = b_3 b_2^{-1} b_1 m_5 m_6 m_5.$$

The half turn m_4 is represented by the matrix

$$M_4 = \frac{i}{\sqrt{1 - \omega_6^2}} A \begin{bmatrix} 1 & \omega_6 \\ -\omega_6 & -1 \end{bmatrix}.$$

We determine ω_6 such that M_4 is a half turn. This is the case if and only if the trace of the matrix is zero. Evaluating the trace, we find that it is zero if and only if

$$\alpha - \overline{\alpha} + \omega_6(\overline{\beta} - \beta) = 0.$$

The solution to this is $\omega_6 = (\alpha - \overline{\alpha})/(\beta - \overline{\beta})$. The formula for B_4 is now clear and the expression for z_0 (which is the fixed point of m_6 where m_6 is determined by ω_0) is given by (A4). ■

Remark 4.3: There is a simple geometric construction of b_4 out of b_3, b_2, b_1.

We recall that $b_k = m_k m_5$. The construction is described in terms of m_1, m_2, m_3 and yields the center p_4 of the half turn m_4.

Let $q^+ = m_3 m_2 m_1(1)$ and $q^- = m_3 m_2 m_1(-1)$ and draw the geodesics γ^+ from 1 to q^+ and γ^- from -1 to q^- (the points 1, q^+ and $-1, q^-$ are "points at infinity," respectively, of these geodesics). We claim that p_4 is the intersection of γ^- and γ^+. (See Fig. 3.)

To see this, we again use the relation (4.3). The product m_6m_5 is a hyperbolic transformation with axis from -1 to 1, i.e., $m_6m_5(-1)=-1$ and $m_6m_5(1)=1$. Therefore, $m_3m_2m_1(-1)=m_4(-1)$ and $m_3m_2m_1(1)=m_4(1)$. In other words, m_4 exchanges -1 and q^- so that $m_4(\gamma^-)=\gamma^-$ and the fixed point of m_4 lies on γ^-. For the same reason, it also lies on γ^+.

V. THE HELLING MATRIX

It may be desirable to describe the octagon in a way which does not involve its position in the unit disc $\mathbb{D}$. In Ref. 24, Helling introduces the invariants h_{ij} which are defined in the following way. Let again $m_1,\ldots,m_6$ be the half turns around $p_1,\ldots,p_6$, respectively. We use the matrices M_i corresponding to the half turns m_i as in (4.2c), and set

$$h_{ij} = -\tfrac{1}{2}\operatorname{tr} M_iM_j, \quad i,j=1,\ldots,6, \tag{5.1}$$

where tr denotes the trace. We call $H=\{h_{ij}\}$ the *Helling matrix*.

From the sign property (A6) we have $\operatorname{tr} M_iM_j<0$ so that the h_{ij} are positive. The geometric meaning of the h_{ij} is given by

$$h_{ij} = \cosh \operatorname{dist}_{\mathbb{D}}(p_i,\, p_j). \tag{5.2}$$

In order to compute the half turns (and hence the octagon) out of the Helling matrix, we use the following formula which we state in an independent form.

Lemma 5.1: Let M_1,M_2,M_3 be the matrices for the half turns with centers $q_1,q_2,q_3\in\mathbb{D}$, set $a_{ij}=-\frac{1}{2}\operatorname{tr}M_iM_j$ and define

$$a_{123} = \det\begin{bmatrix} 1 & a_{12} & a_{13} \\ a_{21} & 1 & a_{23} \\ a_{31} & a_{23} & 1 \end{bmatrix} = 1 + 2a_{12}a_{23}a_{31} - a_{12}^2 - a_{23}^2 - a_{31}^2. \tag{5.3}$$

It then follows that

$$M_3 = \frac{(a_{12}a_{23}-a_{13})}{a_{12}^2-1}M_1 + \frac{(a_{12}a_{13}-a_{23})}{a_{12}^2-1}M_2 + \frac{1}{2(a_{12}^2-1)}\ \operatorname{or}(q_1,q_2,q_3)\sqrt{a_{123}}(M_1M_2-M_2M_1), \tag{5.4}$$

where or *denotes the orientation of the triple*.

Proof: Since the formula remains invariant if all the half turns are conjugated by the same matrix $\begin{bmatrix} \alpha & \beta \\ \bar\beta & \bar\alpha \end{bmatrix}$ for suitable α,β, we may assume that points q_1,q_2,q_3 are given by

$$q_1=0, \quad q_2=t\in[0,1), \quad q_3=u+iv.$$

The determinant then becomes

$$a_{123} = 16t^2v^2(1-t)^{-2}(1-u^2-v^2)^{-2},$$

and the stated formula reads

$$\frac{t(1+u^2+v^2)-u(1+t^2)}{t(1-u^2-v^2)}\begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix} + \frac{u(1-t^2)}{t(1-u^2-v^2)}\frac{i}{1-t^2}\begin{bmatrix} 1+t^2 & -2t \\ 2t & -(1+t^2) \end{bmatrix} \pm \frac{2v}{1-u^2-v^2}\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$
$$= \frac{i}{1-u^2-v^2}\begin{bmatrix} 1+u^2+v^2 & -2(u+iv) \\ 2(u-iv) & -(1+u^2+v^2) \end{bmatrix}.$$

The equality is now easily verified. ∎

To obtain the half turns we first recall that

$$p_5 = 0, \quad M_5 = \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix}. \tag{5.5a}$$

Furthermore,

$$M_5 M_6 = \frac{-1}{1-p_6^2}\begin{bmatrix} 1+p_6^2 & -2p_6 \\ -2p_6 & 1+p_6^2 \end{bmatrix}, \quad h_{56} = \frac{1+p_6^2}{1-p_6^2},$$

which yields

$$p_6 = \sqrt{\frac{h_{56}-1}{h_{56}+1}}, \quad M_6 = i\begin{bmatrix} h_{56} & -\sqrt{h_{56}^2-1} \\ \sqrt{h_{56}^2-1} & -h_{56} \end{bmatrix}. \tag{5.5b}$$

With Lemma 5.1, and knowing that all triples p_5, p_6, p_k are positively orientated, we obtain

$$M_k = \frac{(h_{56}h_{6k}-h_{5k})}{h_{56}^2-1}M_5 + \frac{(h_{56}h_{5k}-h_{6k})}{h_{56}^2-1}M_6 + \frac{\sqrt{\delta_k}}{\sqrt{h_{56}^2-1}}\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \tag{5.5c}$$

for $k=1, 2, 3, 4$, where

$$\delta_k = \det\begin{bmatrix} 1 & h_{56} & h_{5k} \\ h_{56} & 1 & h_{6k} \\ h_{5k} & h_{6k} & 1 \end{bmatrix}. \tag{5.5d}$$

VI. FENCHEL–NIELSEN PARAMETERS

The Fenchel–Nielsen parameters, frequently used in the literature, are another type of parameter arising from certain sets of closed geodesics[14,26,40] and are defined as follows.

Let $p_k' = -p_k$, $k=1,\ldots, 6$, and consider the geodesic arcs c_1 from p_1 to p_2 and c_1' from p_2' to p_1'. On the surface S (obtained by pasting the sides of the octagon), the two arcs together form a smooth closed geodesic γ_1. Similarly, a closed geodesic γ_2 is obtained from the arcs c_2 and c_2', which run, respectively, from p_3 to p_4 and from p_4' to p_3'. The diagonal p_6p_6' yields a closed geodesic γ_3.

The triple $\gamma_1, \gamma_2, \gamma_3$ dissects S into two parts ("pairs of pants") which have the topological type of a sphere from which three pairwise disjoint discs have been removed. The pairs of pants are determined, up to isometry, by the lengths $l(\gamma_1), l(\gamma_2), l(\gamma_3)$. When the pairs of pants are pasted together again to yield S, there arises an additional degree of freedom at each γ_k, the so-called *twist parameter* (see α_k below). This parameter is determined by the lengths of two additional closed geodesics μ_k, η_k. We define them in terms of generators of the fundamental group of S.

For $k=0,\ldots, 4$, we denote the geodesic arc from p_5 to $m_k(p_5)$ by $\tilde{\beta}_k$, and the corresponding curve on S by β_k. Note that $\tilde{\beta}_k$ lies on the axis of the generator b_k of the group Γ which corresponds to the octagon. The geodesics are defined in Table II.

In Table II the expression "$\gamma_1 \sim \beta_2\beta_1^{-1}$" means that γ_1 is the closed geodesic in the free homotopy class of $\beta_2\beta_1^{-1}$, etc., and the symbol $\leftrightarrow$ means that the corresponding $b_2b_1^{-1}$ in Γ is $b_2b_1^{-1} = m_2m_1$, etc. Points $w_1, \ldots, w_6$ on the surface correspond to $p_1, \ldots, p_6$ in the octagon. For $k=1, 2, 3, 4$, the closed geodesic β_k corresponds to the straight line on the octagon joining p_k' to p_k.

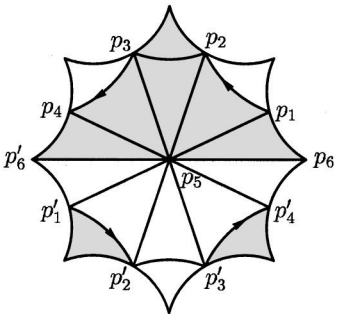
For $k=1, 2, 3$, the geodesics μ_k, η_k intersect γ_k—each in two points—and are disjoint from the other γ_i. We call the numbers

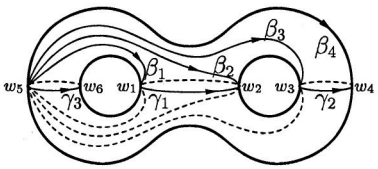
$$c_k = \cosh\tfrac{1}{2}l(\gamma_k), \quad d_k = \cosh\tfrac{1}{2}l(\mu_k), \quad e_k = \cosh\tfrac{1}{2}l(\eta_k), \tag{6.1}$$

the *Fenchel–Nielsen triples*. In (6.5) and (6.6) we shall derive the twist parameters from these, but before that we relate them to the half turns and the Helling matrix.

Using the relation for $X \in \mathrm{SL}(2, \mathbb{C})$,

TABLE II. The Fenchel–Nielsen parameter geodesics.





$$\gamma_1 \sim \beta_2\beta_1^{-1} \leftrightarrow m_2m_1$$

$$\mu_1 \sim \beta_1\beta_0^{-1}\beta_1^{-1}\beta_0 \leftrightarrow (m_1m_6m_5)^2$$

$$\eta_1 \sim \beta_2\beta_0^{-1}\beta_2^{-1}\beta_0 \leftrightarrow (m_2m_6m_5)^2$$

$$\gamma_2 \sim \beta_4\beta_3^{-1} \leftrightarrow m_4m_3$$

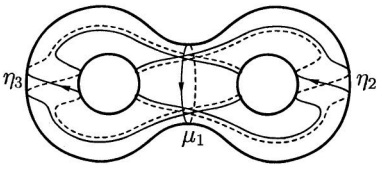
$$\mu_2 \sim \beta_3\beta_2^{-1}\beta_1\beta_3^{-1}\beta_2\beta_1^{-1} \leftrightarrow (m_3m_2m_1)^2$$

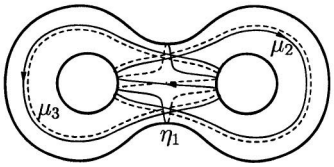
$$\eta_2 \sim \beta_4\beta_2^{-1}\beta_1\beta_4^{-1}\beta_2\beta_1^{-1} \leftrightarrow (m_4m_2m_1)^2$$

$$\gamma_3 \sim \beta_0 \leftrightarrow m_6m_5$$

$$\mu_3 \sim \beta_4^{-1}\beta_3\beta_4\beta_3^{-1} \leftrightarrow (m_5m_4m_3)^2$$

$$\eta_3 \sim \beta_0\beta_4^{-1}\beta_3\beta_0^{-1}\beta_4\beta_3^{-1} \leftrightarrow (m_6m_4m_3)^2$$





$$\operatorname{tr} X^2 = \operatorname{tr}^2 X - 2, \tag{6.2}$$

for $k=1, 2, 3$ and indices mod 6, the above list gives

$$c_k = -\tfrac{1}{2}\operatorname{tr}(M_{2k-1}M_{2k}),$$

$$d_k = \tfrac{1}{2}\operatorname{tr}^2(M_{2k-1}M_{2k-2}M_{2k-3}) - 1,$$

$$e_k = \tfrac{1}{2}\operatorname{tr}^2(M_{2k}M_{2k-2}M_{2k-3}) - 1. \tag{6.3}$$

Note that c_k is positive by (A6).

In Ref. 24, it is shown that, for $A, B, C \in \mathrm{SL}(2,\mathbb{C})$ with $\operatorname{tr} A = \operatorname{tr} B = \operatorname{tr} C = 0$,

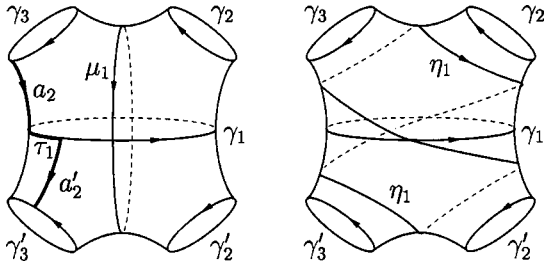


FIG. 4. Defining the twist parameter α_1.

$$\mathrm{tr}^2(ABC) + \mathrm{tr}(AB)\mathrm{tr}(BC)\mathrm{tr}(CA) + \mathrm{tr}^2(AB) + \mathrm{tr}^2(BC) + \mathrm{tr}^2(CA) - 4 = 0.$$

For $k=1, 2, 3$, this yields

$$c_k = h_{2k-1,2k},$$

$$d_k = 2\delta(h_{2k-1,2k-2}, h_{2k-1,2k-3}, h_{2k-2,2k-3}) - 1,$$

$$e_k = 2\delta(h_{2k,2k-2}, h_{2k,2k-3}, h_{2k-2,2k-3}) - 1, \tag{6.4}$$

where δ denotes the polynomial

$$\delta(a,b,c) = \det\begin{bmatrix} 1 & a & b \\ a & 1 & c \\ b & c & 1 \end{bmatrix}.$$

In order to obtain the other parameters from the Fenchel–Nielsen triples, we use twists.

We give the description for γ_1, since the twists along γ_2, γ_3 are defined in the same way and the formulas are obtained by cyclic permutation. (See Fig. 4.)

For convenient viewing we cut S open along γ_2 and γ_3 into a four-holed sphere X. The cuts appear as closed boundary geodesics γ_2, γ_2' and γ_3, γ_3'. The geodesic γ_1 further separates X into two isometric three-holed spheres Y, with boundary geodesics $\gamma_1, \gamma_2, \gamma_3$, and Y' with boundary geodesics $\gamma_1', \gamma_2', \gamma_3'$.

The shortest geodesic arc a_2 on Y from γ_3 to γ_1 and the shortest geodesic arc a_2' on Y' from γ_1 to γ_3' both have the same length given by

$$\cosh^2 l(a_2) = \cosh^2 l(a_2') = \frac{(c_2 + c_1c_3)^2}{(c_1^2 - 1)(c_3^2 - 1)}$$

[see Ref. 13, Theorem 2.4.1(i)]. On γ_1, let τ_1 be the geodesic arc going from the end point of a_2 to the initial point of a_2'. There are infinitely many such arcs (winding around γ_1). We render the selection of τ_1 unique by requiring that the closed curve $a_2\tau_1 a_2'(\gamma_3')^{-1}(a_2')^{-1}\tau_1^{-1}a_2^{-1}\gamma_3$ lies in the free homotopy class of μ_1. The *twist parameter* α_1 is defined as

$$\alpha_1 = \pm\frac{l(\tau_1)}{l(\gamma_1)},$$

where we take the plus sign if τ_1 goes in the same direction as γ_1 and the minus sign if τ_1 goes in the opposite direction.

In Ref. 13 [Proposition 3.3.11 in connection with the above expression for $\cosh^2 l(a_2)$] it is shown that

$$d_1 = \cosh\tfrac{1}{2} l(\mu_1) = F_1(\alpha_1),$$

where F_1 is the function

$$F_1(\alpha) \doteq \frac{1}{c_1^2 - 1}(c_1^2 + c_2^2 + c_3^2 + 2c_1c_2c_3 - 1)(1 + \cosh \alpha l(\gamma_1)) - 1.$$

Replacing τ_1 by the arc τ_1' which winds an additional time around γ_1 gives the curve $a_2\tau_1' a_2'(\gamma_3')^{-1}(a_2')^{-1}(\tau_1')^{-1}a_2^{-1}\gamma_3$ in the free homotopy class of η_1. Accordingly,

$$e_1 = \cosh\tfrac{1}{2} l(\eta_1) = F_1(\alpha_1 + 1).$$

The twist parameters α_2, α_3 are defined in the same way and the relation with the Fenchel–Nielsen triples is as follows.

Lemma 6.1: For $k=1, 2, 3$, *if*

$$p = c_1^2 + c_2^2 + c_3^2 + 2c_1c_2c_3 - 1, \quad \Gamma_k = e_k + 1 - (2c_k^2 - 1)(d_k + 1) + 2p,$$

then

$$c_k = \cosh\tfrac{1}{2} l(\gamma_k),$$

$$d_k = \frac{p}{c_k^2 - 1}(1 + \cosh \alpha_k l(\gamma_k)) - 1,$$

$$e_k = \frac{p}{c_k^2 - 1}(1 + \cosh(\alpha_k + 1) l(\gamma_k)) - 1, \tag{6.5}$$

and

$$\sinh \alpha_k l(\gamma_k) = \frac{\Gamma_k \sqrt{c_k^2 - 1}}{2c_k p}. \tag{6.6}$$

Proof: The first two formulas have already been proved. For the third, we apply the rule

$$\cosh(x + y) = \cosh x \cosh y + \sinh x \sinh y$$

to $x = \alpha_k l(\gamma_k)$ and $y = l(\gamma_k)$. ■

The twists now allow us to solve for the h_{ij} in the system of equations (6.4), using the fact that

$$\cosh\frac{\alpha_k}{2} l(\gamma_k) = \sqrt{\frac{1 + \cosh \alpha_k l(\gamma_k)}{2}} = \frac{1}{\sqrt{2p}}\sqrt{(d_k + 1)(c_k^2 - 1)},$$

$$\sinh\frac{\alpha_k}{2} l(\gamma_k) = \frac{\sinh \alpha_k l(\gamma_k)}{2 \cosh\frac{\alpha_k}{2} l(\gamma_k)} = \frac{\Gamma_k}{2c_k\sqrt{2p}\sqrt{d_k + 1}}. \tag{6.7}$$

The geometric interpretation of the h_{ij} on Y is shown in Fig. 5 for the case where $\alpha_1, \alpha_2, \alpha_3$ have small positive values.

Arcs p_5p_6, p_1p_2, p_3p_4 on the pentagon P correspond, respectively, to one-half of the boundary geodesics $\gamma_1, \gamma_2, \gamma_3$ of Y. Arcs p_6p_1, p_2p_3, p_4p_5 correspond to arcs on Y which decompose Y into two hexagons (which are not isometric and do not generally even have the same area). Since points w_5, w_6 on γ_3, corresponding to p_5, p_6, are opposite, we have

$$h_{56} = c_3. \tag{6.8}$$

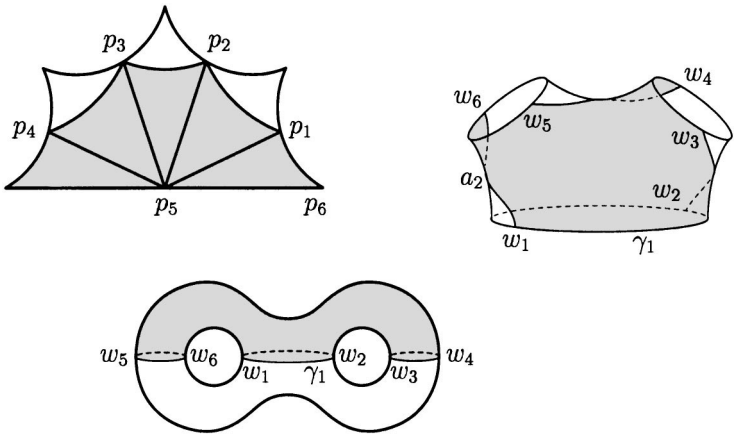

FIG. 5. Geodesic arcs for the Helling matrix.

Arc a_2 and the arc w_1w_6 which corresponds to p_1p_6, form a quadrilateral on Y with right angles at the end points of a_2. Using the trigonometry for such quadrilateral gives

$$h_{61} = G(\alpha_3 l(\gamma_3), \alpha_1 l(\gamma_1)),$$

where G is the function

$$G(x,y) = \cosh a_2 \cosh\frac{x}{2}\cosh\frac{y}{2} + \sinh\frac{x}{2}\sinh\frac{y}{2}.$$

From the arcs connecting p_6 with p_2, etc., we obtain similar quadrilaterals which differ from the first by plus or minus one-half of the boundary geodesics γ_1, γ_2. Thus,

$$h_{62} = G(\alpha_3 l(\gamma_3), (\alpha_1 + 1) l(\gamma_1)),$$

$$h_{51} = G((\alpha_3 - 1) l(\gamma_3), \alpha_1 l(\gamma_1)),$$

$$h_{52} = G((\alpha_3 - 1) l(\gamma_3), (\alpha_1 + 1) l(\gamma_1)).$$

Using the abbreviations, for $k=1, 2, 3$,

$$x_{k,1} = \sqrt{d_k + 1}, \quad y_{k,1} = \frac{\Gamma_k}{2c_k\sqrt{d_k + 1}},$$

$$x_{k,2} = c_k x_{k,1} + y_{k,1}, \quad y_{k,2} = c_k y_{k,1} + (c_k^2 - 1) x_{k,1},$$

$$x_{k,3} = c_k x_{k,1} - y_{k,1}, \quad y_{k,3} = c_k y_{k,1} - (c_k^2 - 1) x_{k,1}, \tag{6.9a}$$

and recalling that

$$\Gamma_k = e_k + 1 - (2c_k^2 - 1)(d_k + 1) + 2p, \quad p = c_1^2 + c_2^2 + c_3^2 + 2c_1c_2c_3 - 1, \tag{6.9b}$$

then, applying cyclic permutations to $\gamma_1, \gamma_2, \gamma_3$ in (6.5)–(6.8), we obtain

$$h_{2k-1,2k} = h_{2k,2k-1} = c_k,$$

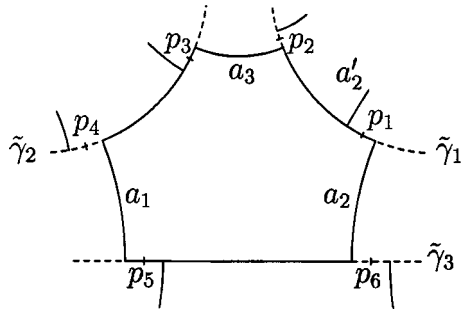

FIG. 6. Twist parameters as seen in the universal covering.

$$h_{2k-2-i,2k-1+j} = h_{2k-1+j,2k-2-i} = \frac{1}{2p}((c_{k+1} + c_k c_{k+2})x_{k,1+j}x_{k-1,1-i} + y_{k,1+j}y_{k-1,1-i}), \tag{6.9c}$$

for $k=1, 2, 3$, $i=0, 1$, $j=0, 1$, where the indices of h are mod 6 and the remaining indices are mod 3.

In order to see how the octagon can follow directly from the twist and length parameters, we use the fact that the shortest connections a_1, a_2, a_3, which, respectively, link γ_2 to γ_3, γ_3 to γ_1, and γ_1 to γ_2, separate the three-holed sphere Y into two right angled geodesic hexagons. Figure 6 shows one of these hexagons drawn in $\mathbb{D}$, the universal covering of $S=\mathbb{D}/\Gamma$.

The selected covering curves of $\gamma_1, \gamma_2, \gamma_3$ are the geodesics $\tilde{\gamma}_1$ through p_1, p_2, $\tilde{\gamma}_2$ through p_3, p_4 and $\tilde{\gamma}_3$ through p_5, p_6. Now a_k appears as the common perpendicular of $\tilde{\gamma}_{k-1}$ and $\tilde{\gamma}_{k+1}$, $k=1, 2, 3$ (indices mod 3). The arc a_2' (see Figs. 4 and 6), which was used to define the twist parameter α_1, now appears as a perpendicular arc of $\tilde{\gamma}_1$ that is opposite to a_2 and shifted along $\tilde{\gamma}_1$ by $|\alpha_1| l(\gamma_1)$. The shift is to the left if α_1 is positive and to the right if α_1 is negative. It is well known that the surface S has a rotational symmetry (the so-called hyperelliptic involution) with fixed points $w_1, \ldots, w_6$, and it therefore follows that p_1 lies at a point on $\tilde{\gamma}_1$ that is equidistant from the end points of a_2 and a_2'. The points $p_2, \ldots, p_6$ have analogous properties. The positions of these points in $\mathbb{D}$ may thus be found by applying the isometries given by the matrices

$$R_t \doteq \begin{bmatrix} 1+\cosh t & \sinh t \\ \sinh t & 1+\cosh t \end{bmatrix}, \quad U_t \doteq \begin{bmatrix} 1+\cosh t & i\sinh t \\ -i\sinh t & 1+\cosh t \end{bmatrix}, \quad t \in \mathbb{R}. \tag{6.10}$$

Geometrically, R_t is a hyperbolic isometry with axis from -1 to 1, shifting 0 to the point $\sinh t/(1+\cosh t)=\tanh(t/2)$, whose hyperbolic distance to 0 is t. Similarly, U_t is a hyperbolic isometry with axis from $-i$ to i, shifting 0 to $i\tanh t/2$ with the same distance. Hence to obtain the points $p_1, \ldots, p_6$ from the lengths $l(\gamma_k)$ and twists α_k, we set

$$\lambda_k = \tfrac{1}{2} l(\gamma_k), \quad c_k = \cosh \lambda_k,$$

$$\vartheta_k = \tfrac{1}{2}\alpha_k l(\gamma_k), \quad a_k = \operatorname{arccosh} \frac{c_k + c_{k-1}c_{k+1}}{\sqrt{(c_{k-1}^2-1)(c_{k+1}^2-1)}}, \tag{6.11a}$$

and apply products of R_t and U_t given by the following list:

$$p_5 = 0, \quad p_6 = R_{\lambda_3}[0],$$

$$p_1 = R_{\lambda_3 - \vartheta_3} U_{a_2} R_{-\vartheta_1}[0],$$

$$p_2 = R_{\lambda_3 - \vartheta_3} U_{a_2} R_{-\lambda_1 - \vartheta_1}[0],$$

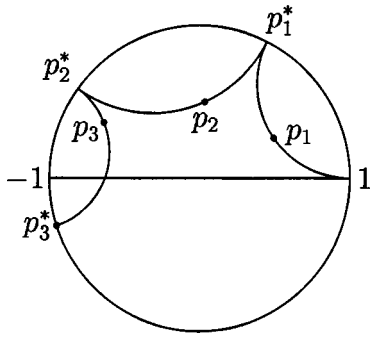

FIG. 7. A non-admissible triple of midpoints.

$$p_3 = R_{-\vartheta_3} U_{a_1} R_{\lambda_2 - \vartheta_2}[0],$$

$$p_4 = R_{-\vartheta_3} U_{a_1} R_{-\vartheta_2}[0]. \tag{6.11b}$$

VII. A PICTURE OF TEICHMÜLLER SPACE

In the first part of this section we give a simple criterion for the admissibility of the triple of generators b_1, b_2, b_3 and thus a geometric picture of Teichmüller space in terms of octagons. In the second part, a similar description is given in terms of the vertices z_1, z_2, z_3. The main results are summarized in Theorems 7.2 and 7.3.

Any b_k is the product of half turns $b_k = m_k m_5$ [cf. (4.2e)], where m_5 is the half turn with center 0. Describing the admissible triples b_1, b_2, b_3 is therefore equivalent to describing the centers of rotation p_1, p_2, p_3 of the corresponding half turns m_1, m_2, m_3.

For any triple of points $p_1, p_2, p_3 \in \mathbb{D}^+$ with

$$0 < \arg(p_1) < \arg(p_2) < \arg(p_3) < \pi,$$

we construct a triple $p_1^*, p_2^*, p_3^* \in \partial\mathbb{D}$ as follows: p_1^* is the second end point at infinity of the geodesic through p_1 whose first end point at infinity is 1; p_2^* is the second end point at infinity of the geodesic through p_1^* and p_2; p_3^* is the end point at infinity of the geodesic through p_2^* and p_3. (See Fig. 7.)

Theorem 7.1: *The triple p_1, p_2, p_3 is admissible if and only if the points p_k^* satisfy*

$$0 < \arg(p_1^*) < \arg(p_2^*) < \arg(p_3^*) < \pi.$$

Proof: We use a continuity argument. Assuming first that p_1, p_2, p_3 is admissible, there is an admissible pentagon $z_0 z_1 z_2 z_3 z_4$ such that p_k is the midpoint of side $z_{k-1} z_k$, $k = 1, 2, 3$, and we label p_4 the midpoint of side $z_3 z_4$.

Shifting z_0 towards 1 by a small amount $t > 0$, i.e., replacing it by the point z_0^t on the geodesic γ from -1 to 1, whose hyperbolic distance from z_0 is t and which lies nearer 1, gives a new pentagon with vertices z_0^t, $z_1^t \doteq m_1(z_0^t)$, $z_2^t \doteq m_2(z_1^t)$, $z_3^t \doteq m_3(z_2^t)$, $z_4^t \doteq m_4(z_3^t)$. Thus, the new pentagon has the same midpoints p_1, p_2, p_3, p_4, but it is no longer centered at 0. (See Fig. 8.)

Now, from (4.3), $z_4^t = m_4 m_3 m_2 m_1(z_0^t) = m_6 m_5(z_0^t)$, where in this case $m_6 m_5$ is the hyperbolic isometry with axis γ. Hence, $z_4^t \in \gamma$ and $\mathrm{dist}_{\mathbb{D}}(z_0^t, z_4^t) = \mathrm{dist}_{\mathbb{D}}(z_0, z_4)$ so that the point z_4 is also shifted towards 1 by t. Since for $k = 1, 2, 3, 4$ the triangles $z_{k-1} z_{k-1}^t p_k$ and $z_k z_k^t p_k$ (being exchanged by m_k) have the same area, *the area of the new pentagon is still* 2π.

Similarly, as t is increased by small amounts, the pentagon retains the area 2π and therefore remains convex. As $t \to \infty$, z_k^t converges to p_k^* for $k = 1, 2, 3$ and z_4^t converges to 1, so the quadrilateral $1 p_1^* p_2^* p_3^*$ is convex. Moreover, p_3^* is the end point at infinity of the geodesic through 1 and p_4 (as observed in a different way at the end of the section precedent). It follows that

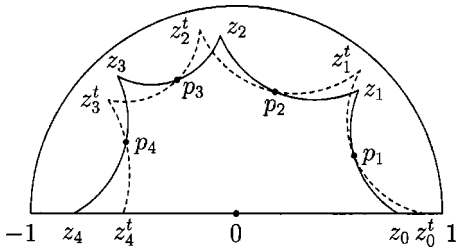

FIG. 8. Deforming the pentagon.

$$0 < \arg(p_1^*) < \arg(p_2^*) < \arg(p_3^*) < \pi.$$

Conversely, if this relation holds, we let $z_0^t \in \gamma$ be a moving point between 0 and 1 and consider the pentagon P^t with vertices z_0^t, $z_1^t = m_1(z_0^t)$, $z_2^t = m_2(z_1^t)$, $z_3^t = m_3(z_2^t)$, $z_4^{tt} = -z_0^t$ [in contrast to $z_4^t = m_4(z_3^t)$ used before]. For $z_0^t = 1$, P^t is an ideal pentagon with area 3π. As z_0^t moves towards 0, P^t remains convex and the area changes continuously. For $z_0^t = 0$, P^t becomes a quadrilateral with area $< 2\pi$. Hence there exists $z_0^t \in (0,1)$ for which the area of the pentagon is exactly 2π, which means that p_1, p_2, p_3 is admissible. ■

Theorem 7.1 provides a convenient way to overview the domain $\mathcal{P} \subset \mathbb{D}^+ \times \mathbb{D}^+ \times \mathbb{D}^+$ of all admissible triples, starting from a random choice of $p_1 \in \mathbb{D}^+$,

For any $p_1 \in \mathbb{D}^+$, the geodesic from -1 to p_1^* separates $\mathbb{D}^+$ into two open convex subsets. If $\mathbb{D}[p_1]$ is the one which does not contain p_1, then, by Theorem 7.1, a triple p_1, p_2, p_3 can only be admissible if $p_2 \in \mathbb{D}[p_1]$. (See Fig. 9.)

Similarly, for $p_2 \in \mathbb{D}[p_1]$ with p_2^* the second end point at infinity of the geodesic through p_1^* and p_2, the geodesic from -1 to p_2^* separates $\mathbb{D}[p_1]$ into two open convex subsets and we let $\mathbb{D}[p_1, p_2]$ be the one which does not contain p_2.

Again by Theorem 7.1, a triple p_1, p_2, p_3 is admissible if and only if $p_3 \in \mathbb{D}[p_1, p_2]$. This yields the following geometric picture of Teichmüller space in genus 2.

Theorem 7.2: *The set $\mathcal{P}$ of all admissible triples p_1, p_2, p_3 is given as*

$$\mathcal{P} = \{(p_1, p_2, p_3) \in \mathbb{D}^+ \times \mathbb{D}^+ \times \mathbb{D}^+ | p_2 \in \mathbb{D}[p_1], p_3 \in \mathbb{D}[p_1, p_2]\}.$$

Clearly, Theorem 7.2 shows that $\mathcal{P}$ is homeomorphic to $\mathbb{D}^+ \times \mathbb{D}^+ \times \mathbb{D}^+$ or, equivalently, to $\mathbb{R}^6$.

Remark: The description may be varied. For instance, if $p_2 \in \mathbb{D}^+$ is chosen freely, then let $\tilde{p}_2$ be the second end point at infinity of the geodesic through -1 and p_2, with $\tilde{\mathbb{D}}[p_2]$ the domain cut away by the geodesic from 1 to $\tilde{p}_2$ which does not contain p_2. A triple $p_1 p_2 p_3$ is then admissible if and only if $p_1 \in \tilde{\mathbb{D}}[p_2]$ and $p_3 \in \tilde{\mathbb{D}}[p_1, p_2]$, etc.

In the second part of this section we outline a similar picture in terms of the set $\mathcal{Z}$ of all admissible triples z_1, z_2, z_3.

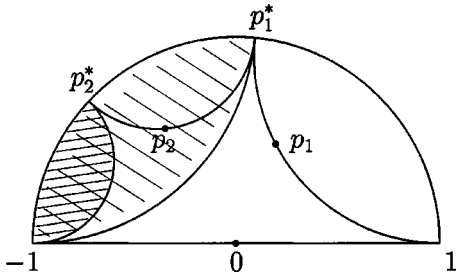

FIG. 9. Domains of admissible midpoints.

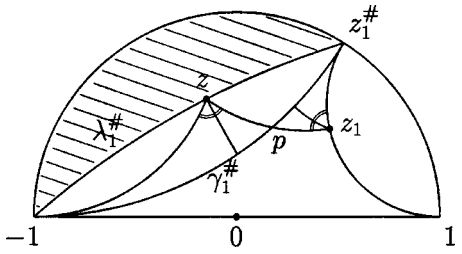

FIG. 10. The connected open component $\mathbb{D}^\#[z_1]$ of $\mathbb{D}^+$ (shaded area).

As before, $z_1 \in \mathbb{D}^+$ is selected arbitrarily and $z_1^\# \in \partial\mathbb{D}$ is the end point of the geodesic through 1 and z_1. If $\gamma_1^\#$ is the geodesic from -1 to $z_1^\#$, then, in the disc model $\mathbb{D}$ of the hyperbolic plane, it is well known that the line $\lambda_1^\#$, consisting of all points $z \in \mathbb{D}^+$ whose distance from $\gamma_1^\#$ is the same as the distance of z_1 to $\gamma_1^\#$ and which lie on the opposite side of $\gamma_1^\#$ to z_1, is a circular arc.

For $z \in \lambda_1^\#$, the geodesic arc from z to z_1 intersects $\gamma_1^\#$ at its midpoint p (there are two right-angled triangles with the same angle at p and the same length of opposite side). Hence, the half turn with center p sends the triangle $pz(-1)$ to $pz_1z_1^\#$. In particular, the angles at z and z_1 are the same. It follows that the quadrilaterals $(-1)(1)z_1z$ and $(-1)(1)z_1z_1^\#$ have the same angle sum π.

Line $\lambda_1^\#$ separates $\mathbb{D}^+$ into two connected open components and we denote the one which does not contain z_1 by $\mathbb{D}^\#[z_1]$ (the shaded area in Fig. 10). For $z_2 \in \mathbb{D}^+$, the quadrilateral $(-1)(1)z_1z_2$ has angle sum $<\pi$ if and only if $z_2 \in \mathbb{D}^\#[z_1]$.

Now taking $z_2 \in \mathbb{D}^\#[z_1]$, but instead of choosing the end point of the geodesic through z_1, z_2 as in the previous step, let $z_2^\# \in \partial\mathbb{D}$ be such that the pentagon $(-1)(1)z_1z_2z_2^\#$ has angle sum π. The remainder of the construction is as before: $\gamma_2^\#$ is the geodesic from -1 to $z_2^\#$; $\lambda_2^\#$ is the line of all points, on the opposite side of $\gamma_2^\#$ from z_2, which are equidistant with z_2 from $\gamma_2^\#$. This line separates $\mathbb{D}^+$ into two connected open components and we denote the one which does not contain z_2 by $\mathbb{D}^\#[z_1, z_2]$.

For a triple z_1, z_2, z_3, the angle sum of the pentagon $(-1)(1)z_1z_2z_3$ is equal to π for $z_3 \in \lambda_2^\#$, it is smaller than π if $z_3 \in \mathbb{D}^\#[z_1, z_2]$ and greater than π otherwise. If the angle sum is smaller than π then there exists $z_0 \in (0,1)$ such that the angle sum of the pentagon $-z_0z_0z_1z_2z_3$ is exactly π.

We summarize the result in the next theorem.

Theorem 7.3: *The set $\mathcal{Z}$ of all admissible triples of vertices z_1, z_2, z_3 is given as*

$$\mathcal{Z} = \{(z_1, z_2, z_3) \in \mathbb{D}^+ \times \mathbb{D}^+ \times \mathbb{D}^+ | z_2 \in \mathbb{D}^\#[z_1], z_3 \in \mathbb{D}^\#[z_1, z_2]\}.$$

VIII. GENERATORS OF THE MODULAR GROUP

A compact Riemann surface of genus 2 may be decomposed into symmetric octagons in infinitely many different ways. We call two octagons *equivalent* if the two surfaces obtained by pasting together the pairs of opposite sides are isometric. From the theory of Teichmüller spaces, it is well known that there exists a group $\mathcal{M}$ operating on the parameter space such that two octagons are equivalent if and only if there exists $\mu \in \mathcal{M}$ sending the first octagon to the second. This group is known as the *modular group*. Generators of $\mathcal{M}$ are described in this section.

The idea is borrowed from the thesis of Aigon[1] who studied group actions on surfaces of signature (0; 2, 2, 2, 2, 2). The generators are similar to those used in Ref. 12.

In the parameter space of the set Z of all admissible triples (z_1, z_2, z_3), each $\mu \in \mathcal{M}$ applied to one such triple yields a new admissible triple,

$$(z_1', z_2', z_3') = \mu[z_1, z_2, z_3],$$

with the property that the corresponding octagon $z_0'z_1' \cdots z_7'$ is equivalent to $z_0z_1 \cdots z_7$. Applying the given generators successively to (z_1, z_2, z_3) and its images yields all equivalent octagons [it re-

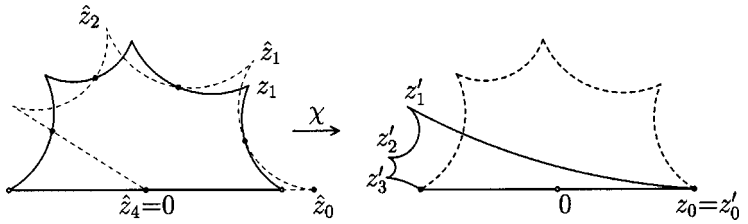

FIG. 11. Shear transformation.

mains however a difficult problem to determine whether or not two given triples (z_1,z_2,z_3) and $(\zeta_1,\zeta_2,\zeta_3)$ lie in the same orbit of $\mathcal{M}$].

Since the octagons are determined by the pentagons, we describe the action of $\mathcal{M}$ in terms of operations on pentagons. When points z_0,p_1,p_2, etc., occur in the formulas, it is always assumed that these are the corresponding points of the octagon determined by the triple z_1,z_2,z_3.

The first operation shears the pentagon and shifts the result into normal position. (See Fig. 11.)

The sheared points are

$$\hat{z}_0 = m_6(0), \quad \hat{z}_k = m_k(\hat{z}_{k-1}), \quad k = 1,2,3,4.$$

By (4.3) we have $\hat{z}_4=0$. The points p_1,p_2,p_3,p_4,p_5 are the midpoints of the sides of the pentagon $\hat{P}$ with vertices $\hat{z}_0,\ldots,\hat{z}_4$ and moreover, P and $\hat{P}$ have the same area (as already observed in the proof of Theorem 7.1). From this it is easily seen that $\hat{P}$ is a fundamental domain for the action of the group Γ^1 generated by $m_1,\ldots,m_5$. If $\hat{P}$ is now shifted using the isometry

$$z \mapsto h(z) = \frac{z - z_0}{1 - z_0 z}, \tag{8.1}$$

then $h(\hat{P})$ is an admissible pentagon equivalent to P. Altogether, this gives the operation $\chi \in \mathcal{M}$ defined as

$$\chi[z_1,z_2,z_3] = (h(\hat{z}_1),h(\hat{z}_2),h(\hat{z}_3)), \tag{8.2}$$

with

$$\hat{z}_0 = m_6(0), \quad \hat{z}_1 = m_1(\hat{z}_0), \quad \hat{z}_2 = m_2(\hat{z}_1), \quad \hat{z}_3 = m_3(\hat{z}_2).$$

The next operation is

$$\tau[z_1,z_2,z_3] = (z_1,z_2,m_3(z_4)). \tag{8.3}$$

The pentagon P' with vertices $z_0,z_1,z_2,m_3(z_4),z_4$ has normal position, area $P'=$area P and the points p_1,p_2,p_3,p_5 are also the midpoints of P'. Hence P' is a fundamental domain for the action of Γ^1 and therefore P and P' are equivalent. (See Fig. 12.)

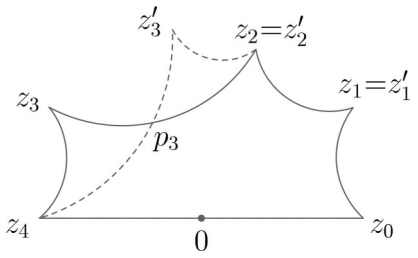

FIG. 12. Transformation of type τ.

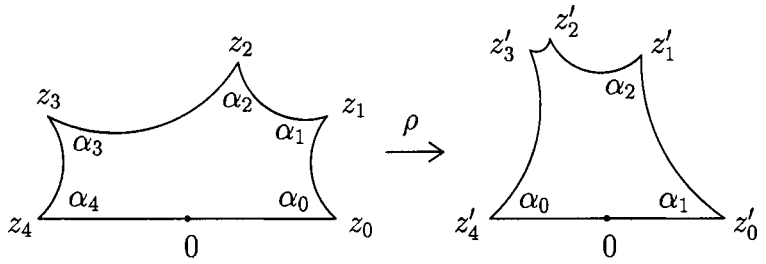

FIG. 13. Rotating the pentagon.

The remaining two operations merely change the position of the pentagon. The first one rotates it

$$\rho[z_1,z_2,z_3] = (r(z_2),r(z_3),r(z_4)), \tag{8.4}$$

with

$$r(z) = \frac{r^1(z)}{r^1(z_1)}|r^1(z_1)|, \quad r^1(z) = \frac{z-p_1}{1-\overline{p_1}z}.$$

The mapping $r^1:\mathbb{D}\to\mathbb{D}$ is the hyperbolic isometry with axis through 0, p_1 which moves p_1 to 0. The multiplication by $|r^1(z_1)|/r^1(z_1)$ is a rotation around 0 bringing $r^1(z_1)$ to the positive part of the real axis. (See Fig. 13.)

The second operation is the symmetry about the imaginary axis

$$\sigma[z_1,z_2,z_3] = (-\overline{z_3},-\overline{z_2},-\overline{z_1}), \tag{8.5}$$

where the bar indicates the complex conjugate.

Theorem 8.1: *The operations χ,ρ,σ,τ generate the modular group $\mathcal{M}$.*

Proof: We have to show that if z_1,z_2,z_3 and z_1',z_2',z_3' are equivalent admissible triples then we can obtain one from the other by a succession of applications of χ,ρ,σ,τ.

Let P,P' be the corresponding pentagons, R,R' the Riemann surfaces obtained by pasting the sides of the corresponding octagons and S,S' the surfaces obtained by pasting the sides of P,P', respectively, in the following way: for $k=1,\ldots,5$, m_k maps side $z_{k-1}z_k$ (i.e., z_4z_0 for $k=5$) onto itself and any point z on this side is pasted to point $m_k(z)$. The resulting surface is topologically a sphere: points $p_1,\ldots,p_5$ turn into points $w_1,\ldots,w_5$ on S and the vertices $z_0,\ldots,z_4$ of P turn into a single point w_6 on S. The surface S carries a hyperbolic metric inherited from P, which is, however, singular at $w_1,\ldots,w_6$. The sides of P become five geodesic arcs at w_6 connecting w_6 with $w_1,\ldots,w_5$. The same holds for S', with singular points $w_1',\ldots,w_6'$.

From the geometry of compact Riemann surfaces of genus 2, it is known that R' is isometric to R if and only if S' is isometric to S with an isometry $g:S'\to S$ sending $w_1',\ldots,w_6'$ to $w_1,\ldots,w_6$. In our case, such an isometry is indeed given, and it carries the arcs from w_6' to $w_1',\ldots,w_5'$ to geodesic arcs on S connecting some w_k to the remaining w_i. These arcs are simple and intersect each other only at w_k. We call them the "*w-curves*."

On P again, these curves are split into a number of geodesic arcs—the *w*-arcs—each of which is either a side of P or else runs through the interior connecting two boundary points of P with each other. Some of the latter have an end point at one of the vertices of P. If the number of these is r and the number of *w*-sides of P is s, then $r+s=5$.

The strategy is to apply χ,ρ,σ,τ successively to P (still calling the successive images P) so that the number of interior *w*-arcs is reduced at each step until eventually they all disappear.

The initial step depends on the above isometry $g:S'\to S$. If $g(w_6')=w_6$ then nothing is carried out in this step. If $g(w_6')=w_k$ with $k\neq 6$, then the position of P is changed using ρ^{5-k}. Corresponding to our notation, this results in a cyclic permutation of the labelling of the points $w_1,\ldots,w_5$ on

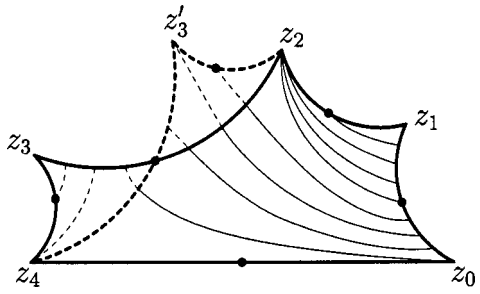

FIG. 14. Reduction of *w*-arcs.

S so that we can now say that g sends w_6' to w_5. We then apply the shear transformation χ. After this initial step we have $g(w_6')=w_6$. The shear χ is not used again in the later steps.

There are now two possible situations. In the first, it is found that, after a suitable change of the position of P via ρ and σ, there exists a *w*-arc from a vertex z_4 to a point on side z_2z_3 which is not z_3 (see Fig. 14 which shows two such arcs). In this case, we apply τ to P so that the vertices are now z_0, z_1, z_2, z_3', z_4. Since *w*-arcs do not intersect each other in the interior of P, no *w*-arc can connect an interior point of side z_3z_4 ("interior" here means different from z_3, z_4) with a boundary point of P which does not lie on side z_2z_3. Any end point of a *w*-arc on p_3z_3 is pasted onto an end point of a *w*-arc on p_3z_2. From this it is easily seen that the number of interior *w*-arcs is reduced at least by one in this step. It is possible that side $z_3'z_4$ is now of *w*-type.

In the remaining case, any *w*-arc in the interior of P and emanating from a vertex of P has its end point on the opposite side. If we change the position of P (via applications of ρ and σ) so that the vertex is z_4 then this arc goes from z_4 to side z_1z_2 and so *any* *w*-arc emanating from a vertex into the interior of P goes from z_4 to side z_1z_2. (See Fig. 15.)

Here we apply $\tau\rho\tau\rho^{-1}$ to P. Under $\rho\tau\rho^{-1}$, P becomes $z_0z_1z_2'z_3z_4$ and under τ it then becomes $z_0z_1z_2'z_3'z_4$. From the same argument as before, the number of *w*-arcs in the interior of P has become smaller and after some steps all interior *w*-arcs have disappeared. This means that the above isometry $g: S' \to S$ maps P' to P, i.e., P and P' are isometric. Hence we may change the position of P using ρ and σ so that finally $P=P'$. ■

Remark: The generators in Theorem 8.1 are for practical use and are not kept to a minimum number. Lu,[32] for the case of genus 2, and later Wajnryb[43] for the general case, showed that the mapping class group of a surface of genus $\geqslant 1$ can be generated by two elements.

APPENDIX

For convenience we review some facts from hyperbolic geometry in the unit disc model.

For given points $z_1, z_2 \in \mathbb{D}$, let $p = p_{z_1 z_2}$ be the midpoint of the geodesic segment $z_1 z_2$ and $m = m_{z_1 z_2}$ the half turn with center p. Thus,

$$m(p) = p, \quad m(z_1) = z_2, \quad m(z_2) = z_1, \quad m^2 = \mathrm{id}.$$

In order to obtain manageable formulas, we introduce the constant

$$\omega = \omega_{z_1 z_2} \doteq \frac{z_1(1 - |z_2|^2) + z_2(1 - |z_1|^2)}{1 - |z_1 z_2|^2}. \tag{A1}$$

Abbreviating $x = |z_1|$, $y = |z_2|$,

$$x + y = 1 + xy - (1 - x)(1 - y) \text{ and } xy < 1,$$

so that

$$|\omega| < \frac{x(1 - y^2) + y(1 - x^2)}{1 - x^2 y^2} = \frac{(1 - xy)(x + y)}{(1 - xy)(1 + xy)} < 1,$$

i.e.,

$$|\omega_{z_1 z_2}| < 1. \tag{A2}$$

For the half turn we define

$$M = M_{z_1 z_2} \doteq \frac{i}{\sqrt{1 - |\omega_{z_1 z_2}|^2}} \begin{bmatrix} 1 & -\omega_{z_1 z_2} \\ \overline{\omega_{z_1 z_2}} & -1 \end{bmatrix}, \tag{A3}$$

and let $m = m_{z_1 z_2}$ be the isometry $m \in \mathrm{Isom}^+(\mathbb{D})$ defined by this matrix. It follows immediately that $m(z_1) = z_2$, $m(z_2) = z_1$, and $m^2 = \mathrm{id}$. It can also be verified directly that the midpoint of $z_1 z_2$ is

$$p = p_{z_1 z_2} = \frac{\omega_{z_1 z_2}}{1 + \sqrt{1 - |\omega_{z_1 z_2}|^2}}. \tag{A4}$$

Conversely,

$$\omega = \frac{2p}{1 + |p|^2}, \quad M = \frac{i}{1 - |p|^2} \begin{bmatrix} 1 + |p|^2 & -2p \\ 2\overline{p} & -(1 + |p|^2) \end{bmatrix}. \tag{A5}$$

If M and M' are two matrices for half turns as in (A5), then it is easily seen that

$$\mathrm{tr}\, MM' < 0. \tag{A6}$$

In the remaining part we prove the area formula for a geodesic triangle $D(z_1, z_2)$ with vertices $0, z_1, z_2$ used in Sec. III

$$\mathrm{area}\, D(z_1, z_2) = 2 \arg(1 - z_1 \overline{z_2}), \tag{A7}$$

assuming that $0 \leqslant \arg z_1 \leqslant \arg z_2 \leqslant \pi$. [This assumption is unnecessary if we wish to interpret (A7) as a formula for the oriented area.]

The proof is seen from the construction shown in Fig. 16.

If $\mathcal{C} \subset \mathbb{C}$ is the circle through z_1, z_2 which intersects $\partial\mathbb{D}$ orthogonally, then $\mathcal{C} \cap \mathbb{D}$ is the geodesic through z_1, z_2. Since circles orthogonal to $\partial\mathbb{D}$ are invariant under the antiholomorphic involution

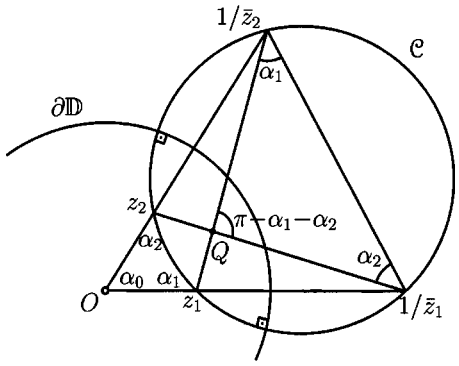

FIG. 16. Angles and area formula.

$z\mapsto 1/\overline{z}$, it follows that $1/\overline{z_1}$ and $1/\overline{z_2}$ lie on $\mathcal{C}$. Denoting the interior angles of $D(z_1,z_2)$ at $0, z_1, z_2$, respectively, by $\alpha_0,\alpha_1,\alpha_2$, then applying the peripheric angle theorem to the Euclidean triangle $(z_2,1/\overline{z_1},1/\overline{z_2})$ inscribed in $\mathcal{C}$ gives the angle at vertex $1/\overline{z_1}$ as

$$\measuredangle(z_2 1/\overline{z_1},1/\overline{z_2})=\alpha_2$$

as marked in the figure. Similarly, triangle $(z_1,1/\overline{z_2},1/\overline{z_1})$ has angle $\measuredangle(z_1,1/\overline{z_2},1/\overline{z_1})=\alpha_1$ at vertex $1/\overline{z_2}$.

The triangle $(1/\overline{z_2},Q,1/\overline{z_1})$ has angle $\pi-\alpha_1-\alpha_2$ at Q, the intersection point of the line segments $(z_1,1/\overline{z_2})$ and $(z_2,1/\overline{z_1})$.

The formula which gives the area of $D(z_1,z_2)$ in terms of z_1 and z_2 is based on the simple fact that if $b_1=r_1e^{i\beta_1}$ and $b_2=r_2e^{i\beta_2}$ are two complex numbers with $0\leqslant\beta_1\leqslant\beta_2\leqslant\pi$, then $\measuredangle(b_2,0,b_1)=\beta_2-\beta_1=\arg(b_2\overline{b_1})$.

Setting

$$b_1=\frac{1}{\overline{z_1}}-z_2 \text{ and } b_2=\frac{1}{\overline{z_2}}-z_1,$$

we have

$$\pi-\alpha_1-\alpha_2=\arg\left(\left(\frac{1}{\overline{z_2}}-z_1\right)\left(\frac{1}{z_1}-\overline{z_2}\right)\right)=\arg\left(\frac{1}{z_1\overline{z_2}}(1-z_1\overline{z_2})^2\right)$$
$$=-\arg(z_1\overline{z_2})+2\arg(1-z_1\overline{z_2})=-(-\alpha_0)+2\arg(1-z_1\overline{z_2}).$$

As area $D(z_1,z_2)=\pi-(\alpha_0+\alpha_1+\alpha_2)$, it follows that

$$\text{area } D(z_1,z_2)=2\arg(1-z_1\overline{z_2}).$$

SU(*N*) Wigner–Racah algebra for the matrix of second moments of embedded Gaussian unitary ensemble of random matrices

V. K. B. Kota
Physical Research Laboratory, Ahmedabad 380 009, India

(Received 20 July 2004; accepted 3 November 2004; published online 16 February 2005)

Recently Pluhar and Weidenmüller [Ann. Phys. (N.Y.) **297**, 344 (2002)] showed that the eigenvectors of the matrix of second moments of embedded Gaussian unitary ensemble of random matrices generated by k-body interactions [EGUE(k)] for m fermions in N single particle states are SU(N) Wigner coefficients and derived also an expression for the eigenvalues. Going beyond this work, we will show that the eigenvalues of this matrix are square of a SU(N) Racah coefficient and thus the matrix of second moments of EGUE(k) is solved completely by SU(N) Wigner–Racah algebra. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1850179]

I. INTRODUCTION

Interacting finite quantum systems such as nuclei, atoms, quantum dots, nanometer-scale metallic grains, etc., are governed by Hamiltonians of low (compared to the number of particles in the system) particle rank. Therefore, for many purposes, the random matrix models appropriate for these systems are embedded random matrix ensembles of k-body interactions originally introduced, via nuclear shell model calculations, by French and Wong and Bohigas and Flores.[1] For a system of m spinless fermions in N single particle states (we will use fermions throughout this paper and turn briefly to bosons at the end) the embedded Gaussian unitary ensemble of random matrices of k-body interactions [EGUE(k)] is generated by defining the Hamiltonian H, which is given to be k-body, to be GUE in the k-particle spaces and then propagating it to the m particle spaces by using the geometry (direct product structure) of the m-particle spaces. Just as EGUE(k), the EGOE(k) and other embedded ensembles are defined.[2] With m particle space dimension given by $N_m=\binom{N}{m}$, one has the unitary groups SU(N), U(N_k), and U(N_m) with EGUE(k) invariant under U(N_k) and the embedding in m-particle spaces is defined by SU(N); note that a GUE in m particle spaces is invariant under U(N_m) but not the EGUE(k), $k<m$. Very early, using the so-called binary correlation approximation, Mon and French[3] and later French *et al.*[4] derived some analytical properties of embedded ensembles valid in the dilute limit [defined by $(N,m,k)\rightarrow\infty$, $m/N\rightarrow 0$ and $k/m\rightarrow 0$]. However only recently rigorous analytical results, valid for any (N,m,k) are derived for these ensembles by Benet *et al.*[5] and very soon Pluhar and Weidenmüller (hereafter called PW) demonstrated[6] that these results indeed follow from considerations based on the SU(N) embedding algebra. With all the m-particle matrix elements being linear combinations of the k-particle matrix elements [see Eq. (9) ahead], the joint distribution for the matrix elements will be a multivariate Gaussian. Thus all the information about EGUE(k) is in the covariance matrix or the matrix of second moments [Eq. (10) ahead]. PW have shown that the eigenvectors of this matrix are SU(N) Wigner [or Clebsch–Gordon (CG)] coefficients and derived the expression for their eigenvalues using a duality relation for EGUE(k). The purpose of this paper is to show that the eigenvalues can be written as SU(N) Racah coefficients and thus the matrix of second moments is solved completely by SU(N) Wigner–Racah algebra. To this end results for SU(N) Racah coefficients given in Refs. 7–9 are used. We will start with some basic results given in the PW paper.

II. BASIC DEFINITIONS AND RESULTS

Let us begin with m particles in N single particle states (unfortunately in PW ℓ is used in place of N but to keep the notations the same as in our earlier papers,[2,10] we use N). The single particle (sp) creation operator $a_i^\dagger$ for any ith sp state transforms as the irreducible representation $\{1\}$ of U(N) and similarly a product of r creation operators transform, as we have fermions, as the irrep $\{1^r\}$ in Young tableaux notation. Let us add that a U(N) irrep $\{\lambda_1,\lambda_2,\ldots,\lambda_N\}$ defines the corresponding SU(N) irrep as $\{\lambda_1-\lambda_N,\lambda_2-\lambda_N,\ldots,\lambda_{N-1}-\lambda_N\}$ with $N-1$ rows [there are also other equivalent ways of defining SU(N) irreps given a U(N) irrep (Ref. 6)]. This U(N)$\leftrightarrow$SU(N) correspondence is used throughout and therefore we use U(N) and SU(N) interchangeably. In PW, $\{1^r\}$ is denoted by f_r and we will follow this notation from now on. With v_r denoting irreps (and other multiplicity labels) of the groups in a subgroup chain of U(N) that supply the labels needed for a complete specification of any m-particle state (for the purpose of the present paper the subgroup chain need not be specified), the operator $\Pi_{i=1}^r a_i^\dagger$ and a normalized r-particle creation operator $A^\dagger(f_r v_r)$ behave as the SU(N) tensors $T^{f_r v_r}$ and $(1/\sqrt{r!})T^{f_r v_r}$, respectively. Using the composition formula,

$$T^{f_m v_m} = \sum_{v_k,v_s} C^{f_m v_m}_{f_k v_k f_s v_s} T^{f_k v_k} T^{f_s v_s}, \quad s = m-k, \tag{1}$$

where $C^{f_m v_m}_{f_k v_k f_s v_s}$ is a SU(N) CG coefficient, a m-particle state $|f_m v_m\rangle = A^\dagger(f_m v_m)|0\rangle$ can be written as a product of k and $s=m-k$ particle states as

$$|f_m v_m\rangle = \binom{m}{k}^{-1/2} \sum_{v_k v_s} A^\dagger(f_k v_k)|f_s v_s\rangle C^{f_m v_m}_{f_k v_k f_s v_s}. \tag{2}$$

Some properties of the CG coefficients, used later in simplifications, are

$$C^{f_{ab} v_{ab}}_{f_a v_a f_b v_b} = (-1)^{\phi(f_a,f_b,f_{ab})} C^{f_{ab} v_{ab}}_{f_b v_b f_a v_a}, \quad C^{f_{ab} v_{ab}}_{f_a v_a f_b v_b} = C^{\overline{f_{ab}} \overline{v_{ab}}}_{\overline{f_a} v_a \overline{f_b} v_b},$$

$$C^{f_{ab} v_{ab}}_{f_a v_a f_b v_b} = (-1)^{\phi(f_a,f_b,f_{ab})} \sqrt{\frac{d(f_{ab})}{d(f_a)}} C^{f_a v_a}_{f_{ab} v_{ab} \overline{f_b} v_b},$$

$$C^{f_a v_a}_{00 f_a v_a} = 1, \quad C^{00}_{f_a v_a \overline{f_a} v_a} = \frac{1}{\sqrt{d(f_a)}}, \quad (C^{f_{ab} v_{ab}}_{f_a v_a \overline{f_a} v_b})^* = C^{f_{ab} v_{ab}}_{f_a v_b \overline{f_a} v_a},$$

$$\sum_{v_a,v_b} (C^{f_{ab} v_{ab}}_{f_a v_a \overline{f_a} v_b})^* C^{f'_{ab} v'_{ab}}_{f_a v_a \overline{f_a} v_b} = \delta_{f_{ab} f'_{ab}} \delta_{v_{ab} v'_{ab}}. \tag{3}$$

In (3), ϕ is a function that defines the phase for the $1\leftrightarrow 2$ interchange in the CG coefficients, $d(f)$ is the dimension of the irrep f and $\overline{f}$ is the irrep conjugate to f. For $f_r=\{1^r\}$, $\overline{f_r}=\{1^{N-r}\}$ and it also contains a phase factor as given in Eq. (53) of Ref. 7 [this is also seen easily by comparing the second and third equalities in (3) with the corresponding relations for the standard CG coefficients for angular momentum[11]]. Similarly with $f_a=f_k$, $f_b=\overline{f_k}$, one has

$$f_{ab} = g_\nu = \{2^\nu 1^{N-2\nu}\}, \quad \nu = 0,1,\ldots,k.$$

Note that $g_0=\{0\}$ for SU(N) and also $g_\nu=\overline{g_{\nu'}}$. The function ϕ in Eq. (3) is of the form $\phi(\lambda_1,\lambda_2,\lambda_3)=F(\lambda_1)+F(\lambda_2)+F(\lambda_3)$ where F is some function with $F(\lambda)$ an integer and $F(\lambda)=F(\overline{\lambda})$; for SU($N$) irreps that appear in this paper these results are valid as can be seen from Eq. (60) of Ref. 7 except that there can be an overall N dependent factor which will not change any of the final results.

SU(N) irreducible tensors $B_k(g_\nu\omega_\nu)$ constructed out of $A^\dagger(f_k v_k)A(f_k v'_k)$ are defined by

$$B_k(g_\nu\omega_\nu) = \sum_{\upsilon_k,\upsilon_k'} A^\dagger(f_k\upsilon_k)A(f_k\upsilon_k')C^{g_\nu\omega_\nu}_{f_k\upsilon_k\ \overline{f_k}\overline{\upsilon_k'}}. \tag{4}$$

It is useful to note that the tensors B's in (4) multiplied by $k!$ are, to within a phase factor, the same as the tensors defined in Eq. (48) of Ref. 7. Wigner–Eckart theorem decomposes the matrix elements of $B_k(g_\nu\omega_\nu)$ in m-particle spaces into a reduced matrix element $\langle\|\ \|\rangle$ and a CG coefficient,

$$\langle f_m\upsilon_m|B_k(g_\nu\omega_\nu)|f_m\upsilon_m'\rangle = \langle f_m\|B_k(g_\nu)\|f_m\rangle C^{g_\nu\omega_\nu}_{f_m\upsilon_m\ \overline{f_m}\overline{\upsilon_m'}}. \tag{5}$$

Two important properties of $B_k(g_\nu\omega_\nu)$ are

$$\langle\langle B_k(g_\nu\omega_\nu)\rangle\rangle^k = \sqrt{N_k}\delta_{g_\nu,\{0\}},$$

$$\langle\langle B_k(g_\nu\omega_\nu)B_k(g_\mu\omega_\mu)\rangle\rangle^k = \delta_{g_\nu g_\mu}\delta_{\omega_\nu\omega_\mu}. \tag{6}$$

In (6), $\langle\langle\ \rangle\rangle^k$ denotes trace over the k-particle spaces. The first equality in Eq. (6) easily follows from the fact that here $g_\nu=\{0\}$ as traces are scalars with respect to SU(N) and then applying the fifth equality in Eq. (3). Similarly the second equality in Eq. (6) follows from the fact that only $g_\nu=g_\mu$ will give a scalar. Now we will turn to EGOE(k).

Consider a k-body Hamiltonian,

$$H(k) = \sum_{\upsilon_a,\upsilon_b} V_{\upsilon_a\upsilon_b}(k)A^\dagger(f_k\upsilon_a)A(f_k\upsilon_b), \tag{7}$$

where $V_{\upsilon_a\upsilon_b}(k)$ are matrix elements of $H(k)$ in k-particle space and form a GUE, i.e., $V_{\upsilon_a\upsilon_b}(k)$ are independent Gaussian variables with zero center and variance given by

$$\overline{V_{\upsilon_a\upsilon_b}(k)V_{\upsilon_c\upsilon_d}(k)} = \frac{\lambda^2}{N_k}\delta_{\upsilon_a\upsilon_d}\delta_{\upsilon_b\upsilon_c}. \tag{8}$$

In Eq. (8) the overline indicates ensemble average and λ^2 is ensemble averaged variance of $H(k)$ in k-particle space. The m-particle matrix elements of $H(k)$ are, with $s=m-k$,

$$H_{\upsilon_m^1\upsilon_m^2}(k) = \langle f_m\upsilon_m^1|H(k)|f_m\upsilon_m^2\rangle = \binom{m}{k}\sum_{\upsilon_a,\upsilon_b,\upsilon_s}(C^{f_m\upsilon_m^1}_{f_k\upsilon_a f_s\upsilon_s})^* C^{f_m\upsilon_m^2}_{f_k\upsilon_b f_s\upsilon_s}V_{\upsilon_a\upsilon_b}(k). \tag{9}$$

Equation (9) is obtained easily by substituting the definition (7) for $H(k)$, then inserting the complete set of states between $A^\dagger$ and A operators and applying Eq. (2). The EGUE(k) in $m\geqslant k$ spaces is defined by Eqs. (7)–(9). Now it is clear that for any analysis of EGUE(k) all one needs to know is the covariance between any two m-particle matrix elements $H_{\upsilon_m^1\upsilon_m^2}(k)$ and this defines the matrix of second moments,

$$A_{\upsilon_m^1\upsilon_m^4:\upsilon_m^3\upsilon_m^2} = \overline{H_{\upsilon_m^1\upsilon_m^2}(k)H_{\upsilon_m^3\upsilon_m^4}(k)}. \tag{10}$$

As stressed by PW, the most important step in EGUE(k) analysis is to derive a "generalized eigenvalue expansion" of A defined by $A_{ij}=\Sigma_k C_{ik}E_kC_{jk}$ with E_k the eigenvalues and C_{jk} the eigenvectors such that E_k are positive and C's Hermitian. To this end, it is useful to consider the unitary decomposition of $H(k)$ in terms of the SU(N) tensors $B_k(g_\nu\omega_\nu)$,

$$H(k) = \sum_{g_\nu,\omega_\nu} B_k(g_\nu\omega_\nu) W_{g_\nu\omega_\nu}(k). \tag{11}$$

The expansion coefficients $W_{g_\nu\omega_\nu}(k)$ are easily given by

$$W_{g_\nu\omega_\nu}(k) = \langle\langle H(k) B_k(g_\nu\omega_\nu)\rangle\rangle^k \tag{12}$$

and this follows by using the definition (11) and Eq. (6). The most significant property of the W coefficients is that they are independent Gaussian variables with zero center and variance given by [derived using Eqs. (11), (4), (7), and (8) in that order and using the orthonormal properties of the CG coefficients]

$$\overline{W_{g_\nu\omega_\nu}(k) W_{g_\mu\omega_\mu}(k)} = \frac{\lambda^2}{N_k} \delta_{g_\nu g_\mu} \delta_{\omega_\nu\omega_\mu}. \tag{13}$$

III. MATRIX OF SECOND MOMENTS

First we will derive an expression for the covariance $\overline{H^{\upsilon_m^1\upsilon_m^2}(k) H^{\upsilon_m^3\upsilon_m^4}(k)}$ in terms of SU(N) CG coefficients and Racah coefficients and then turn to the eigenvalues and eigenvectors of A, the matrix of second moments. Applying Eqs. (10), (11), and (5) in that order gives

$$\begin{aligned}
\overline{H^{\upsilon_m^1\upsilon_m^2}(k) H^{\upsilon_m^3\upsilon_m^4}(k)} &= \sum_{g_\nu,\omega_\nu,g_\mu,\omega_\mu} \overline{\langle f_m \upsilon_m^1 | B_k(g_\nu\omega_\nu) W_{g_\nu\omega_\nu}(k) | f_m \upsilon_m^2\rangle \langle f_m \upsilon_m^3 | B_k(g_\mu\omega_\mu) W_{g_\mu\omega_\mu}(k) | f_m \upsilon_m^4\rangle} \\
&= \sum_{g_\nu,\omega_\nu,g_\mu,\omega_\mu} \overline{W_{g_\nu\omega_\nu}(k) W_{g_\mu\omega_\mu}(k)} \langle f_m \upsilon_m^1 | B_k(g_\nu\omega_\nu) | f_m \upsilon_m^2\rangle \langle f_m \upsilon_m^3 | B_k(g_\mu\omega_\mu) | f_m \upsilon_m^4\rangle \\
&= \frac{\lambda^2}{N_k} \sum_{g_\nu\omega_\nu} \langle f_m \upsilon_m^1 | B_k(g_\nu\omega_\nu) | f_m \upsilon_m^2\rangle \langle f_m \upsilon_m^3 | B_k(g_\nu\omega_\nu) | f_m \upsilon_m^4\rangle \\
&= \frac{\lambda^2}{N_k} \sum_{g_\nu\omega_\nu} |\langle f_m \| B_k(g_\nu) \| f_m\rangle|^2 C^{g_\nu\omega_\nu}_{f_m \upsilon_m^1 \overline{f_m} \overline{\upsilon_m^2}} C^{g_\nu\omega_\nu}_{f_m \upsilon_m^3 \overline{f_m} \overline{\upsilon_m^4}}.
\end{aligned} \tag{14}$$

Equations (55) and (56) of Ref. 7 together with Eqs. (3) [see also the remark just after Eq. (4)] allows one to write the reduced matrix element in Eq. (14) as a SU(N) Racah or U-coefficient,

$$|\langle f_m \| B_k(g_\nu) \| f_m\rangle|^2 = \frac{(N_m)^2 \binom{m}{k}^2}{d(g_\nu)(N_{m-k})} [\mathrm{U}(f_m f_{N-k} f_m f_k; f_{m-k} g_\nu)]^2. \tag{15}$$

With $\{2^\nu 1^{N-2\nu}\} = \{1^\nu\} \otimes \{1^{N-\nu}\} - \{1^{\nu-1}\} \otimes \{1^{N-\nu+1}\}$ where $\otimes$ denotes Kronecker product, the dimension $d(g_\nu)$ is given by

$$d(g_\nu) = d(\nu) = (N_\nu)^2 - (N_{\nu-1})^2 = \frac{(N!)^2 (N+1)(N-2\nu+1)}{(\nu!)^2 (N-\nu+1!)^2}. \tag{16}$$

Before going further let us define, for a given (m,N), a function $\Lambda^\nu(k)$,

$$\Lambda^\nu(k) = \binom{m-\nu}{k} \binom{N-m+k-\nu}{k}. \tag{17}$$

Now, using Eq. (16) and substituting the expression given by Eq. (61) of Ref. 7 for the U-coefficient in (15), it is seen that

$$|\langle f_m||B_k(g_\nu)||f_m\rangle|^2 = \Lambda^\nu(m-k), \quad \nu = 0,1,2,\ldots,k. \tag{18}$$

Combining (14) with (18) yields an expression for the covariance between H matrix elements in m-particle spaces,

$$\overline{H_{v_m^1 v_m^2}(k) H_{v_m^3 v_m^4}(k)} = \frac{\lambda^2}{N_k} \sum_{\nu=0,1,\ldots,k;\omega_\nu} \frac{(N_m)^2 \binom{m}{k}^2}{d(g_\nu)(N_{m-k})} [\mathrm{U}(f_m f_{N-k} f_m f_k; f_{m-k} g_\nu)]^2 C^{g_\nu \omega_\nu}_{f_m v_m^1 \overline{f_m} \overline{v_m^2}} C^{g_\nu \omega_\nu}_{f_m v_m^3 \overline{f_m} \overline{v_m^4}}$$

$$= \frac{\lambda^2}{N_k} \sum_{\nu=0,1,\ldots,k;\omega_\nu} \{\Lambda^\nu(m-k)\} C^{g_\nu \omega_\nu}_{f_m v_m^1 \overline{f_m} \overline{v_m^2}} C^{g_\nu \omega_\nu}_{f_m v_m^3 \overline{f_m} \overline{v_m^4}}. \tag{19}$$

Equation (19) will be useful in deriving expressions for the moments of H spectrum, i.e., $\overline{\langle H^p \rangle^m}$. However the disadvantage of (19) is that it is not in a proper form to give the eigenvalues and eigenvectors of the matrix A in Eq. (10). In order to obtain them, the CG coefficients in Eq. (14) should be changed to $C^{g_\mu \omega_\mu}_{f_m v_m^1 \overline{f_m} \overline{v_m^4}} C^{g_\mu \omega_\mu}_{f_m v_m^3 \overline{f_m} \overline{v_m^2}}$ and this can be accomplished by a SU(N) Racah transform. Using Eq. (3.2.17) of Ref. 9 one has, for example,

$$\sum_{\omega_\nu} C^{g_\nu \omega_\nu}_{f_m v_m^1 \overline{f_m} \overline{v_m^2}} C^{f_m v_m^4}_{g_\nu \omega_\nu f_m v_m^3} = \sum_{g_\mu \omega_\mu} \mathrm{U}(f_m \overline{f_m} f_m f_m; g_\nu g_\mu) C^{g_\mu \omega_\mu}_{\overline{f_m} v_m^2 f_m v_m^3} C^{f_m v_m^4}_{f_m v_m^1 g_\mu \omega_\mu}. \tag{20}$$

Then Eqs. (20) and (3) will give

$$\sum_{\omega_\nu} C^{g_\nu \omega_\nu}_{f_m v_m^1 \overline{f_m} \overline{v_m^2}} C^{g_\nu \omega_\nu}_{f_m v_m^3 \overline{f_m} \overline{v_m^4}} = \sum_{g_\mu \omega_\mu} \sqrt{\frac{d(g_\nu)}{d(g_\mu)}} \mathrm{U}(f_m \overline{f_m} f_m f_m; g_\nu g_\mu) C^{g_\mu \omega_\mu}_{f_m v_m^1 \overline{f_m} \overline{v_m^4}} C^{g_\mu \omega_\mu}_{f_m v_m^3 \overline{f_m} \overline{v_m^2}}. \tag{21}$$

Finally Eqs. (21) and (15) combined with (14) produce the generalized eigenvalue expansion of the matrix of second moments A,

$$A_{v_m^1 v_m^4 : v_m^3 v_m^2} = \overline{H_{v_m^1 v_m^2}(k) H_{v_m^3 v_m^4}(k)} = \sum_{g_\mu \omega_\mu} C^{g_\mu \omega_\mu}_{f_m v_m^1 \overline{f_m} \overline{v_m^4}} C^{g_\mu \omega_\mu}_{f_m v_m^3 \overline{f_m} \overline{v_m^2}} \left\{ \frac{\lambda^2}{N_k} \frac{(N_m)^2 \binom{m}{k}^2}{(N_{m-k})} \left[\sum_{g_\nu} \sqrt{\frac{1}{d(g_\nu) d(g_\mu)}} \right.\right.$$

$$\left.\left. \times [\mathrm{U}(f_m f_{N-k} f_m f_k; f_{m-k} g_\nu)]^2 \mathrm{U}(f_m \overline{f_m} f_m f_m; g_\nu g_\mu) \right] \right\}. \tag{22}$$

Obviously the quantity in the curly brackets in Eq. (22) gives the eigenvalues of A and the C's are eigenvectors.

IV. EIGENVALUES AS SU(N) RACAH COEFFICIENTS AND THEIR APPLICATIONS

In order to proceed further, it is useful to consider $6j$ symbols of SU(N) and they are defined by [see Eq. (3.2.18) of Ref. 9],

$$\mathrm{U}(\lambda_1 \lambda_2 \lambda \lambda_3; \lambda_{12} \lambda_{23}) = \sqrt{d(\lambda_{12}) d(\lambda_{23})} (-1)^{\phi(\lambda_2, \overline{\lambda_2}, 0) + \phi(\lambda_{12}, \lambda_3, \overline{\lambda}) + \phi(\lambda_1, \lambda_2, \overline{\lambda_{12}})} \begin{Bmatrix} \lambda_1 & \lambda_{23} & \overline{\lambda} \\ \overline{\lambda_3} & \lambda_{12} & \lambda_2 \end{Bmatrix}. \tag{23}$$

In (23) λ's are SU(N) irreps and the four couplings involved in the U-coefficient are assumed to be multiplicity free (for the applications in the present paper this assumption is always valid). Symmetry properties of the $6j$-symbol appearing on the right-hand side of (23) are well known.[8,9] In the present analysis, the Biedenharn–Elliott sum rule extended to SU(N) (Refs. 8 and 9) plays a central role. This sum rule relates a product of three Racah coefficients (weighted appropriately

by dimension factors and phase factors with the irreps in the Racah coefficients appearing in some particular order) with sum over a common irrep label to a product of two Racah coefficients. After converting the Racah coefficients in (22) into 6j symbols of SU(N) using Eq. (23) and then applying the symmetry properties of the 6j symbols, it is seen that the sum in the square brackets in Eq. (22) is exactly in the required form. Applying the Biedenharn–Elliott sum rule, the sum then simplifies to

$$\frac{N_{m-k}}{N_k d(g_\mu)} \mathrm{U}^2(f_m f_{N-m+k} f_m f_{m-k}; f_k g_\mu).$$

Here $\mu = 0, 1, \ldots, m-k$. Now the eigenvalues of the matrix A, in terms of the U(N) Racah coefficients is given by

$$E_\mu = \frac{\lambda^2}{N_k} \frac{(N_m)^2 \binom{m}{k}^2}{d(g_\mu)(N_k)} [\mathrm{U}(f_m f_{N-m+k} f_m f_{m-k}; f_k g_\mu)]^2, \quad \mu = 0, 1, \ldots, m-k \tag{24}$$

with degeneracy $d(g_\mu)$ [see Eq. (16)]. Equation (24) is the central result of this paper. With this, the matrix A is completely specified by the U(N) Wigner and Racah coefficients. Now substituting the formula [Eq. (61) of Ref. 7] for the U-coefficients in Eq. (24) produces the result of PW,

$$A_{\upsilon_m^1 \upsilon_m^4 : \upsilon_m^3 \upsilon_m^2} = \overline{H_{\upsilon_m^1 \upsilon_m^2}(k) H_{\upsilon_m^3 \upsilon_m^4}(k)} = \sum_{g_\mu \omega_\mu} C^{g_\mu \omega_\mu}_{f_m \upsilon_m^1 \overline{f_m} \overline{\upsilon_m^4}} C^{g_\mu \omega_\mu}_{f_m \upsilon_m^3 \overline{f_m} \overline{\upsilon_m^2}} E_\mu, \tag{25}$$

where

$$E_\mu = \frac{\lambda^2}{N_k} \Lambda^\mu(k), \quad \mu = 0, 1, \ldots, m-k. \tag{26}$$

Note that the function $\Lambda^\mu(k)$ is defined by Eq. (17).

Information about EGUE(k) is contained in the ensemble averaged moments $M_p = \overline{\langle H^p \rangle^m}$ and the bivariate moments $\Sigma_{pq} = \overline{\langle H^p \rangle^m \langle H^q \rangle^m}$. In deriving the formulas for the lower order moments, we will show the usefulness of Eq. (19). Obviously, ensemble averaged centroid is zero and the variance is

$$\overline{\langle H^2 \rangle^m} = \frac{1}{N_m} \sum_{\upsilon_m^i, \upsilon_m^j} \overline{H_{\upsilon_m^i \upsilon_m^j} H_{\upsilon_m^j \upsilon_m^i}} = \frac{1}{N_m} \sum_{g_\mu, \omega_\mu} \Lambda^\mu(k) \sum_{\upsilon_m^i, \upsilon_m^j} C^{g_\mu \omega_\mu}_{f_m \upsilon_m^i \overline{f_m} \overline{\upsilon_m^i}} C^{g_\mu \omega_\mu}_{f_m \upsilon_m^j \overline{f_m} \overline{\upsilon_m^j}} = \Lambda^0(k). \tag{27}$$

The second equality follows from (25) and the final result follows by applying (3); note that $\Sigma_{\upsilon_m^i} C^{g_\mu \omega_\mu}_{f_m \upsilon_m^i \overline{f_m} \overline{\upsilon_m^i}} = \sqrt{N_m} \delta_{\mu,0}$. The variance in (27) is in λ^2/N_k units and this factor is dropped as all the quantities we consider from now on are all scaled with respect to $\{\overline{\langle H^2 \rangle^m}\}^{1/2}$. As the third moment is zero, we will turn to the fourth moment,

$$\begin{aligned}
\overline{\langle H^4 \rangle^m} &= \frac{1}{N_m} \sum_{\upsilon_m^i, \upsilon_m^j, \upsilon_m^{k'}, \upsilon_m^l} \overline{H_{\upsilon_m^i \upsilon_m^j} H_{\upsilon_m^j \upsilon_m^{k'}} H_{\upsilon_m^{k'} \upsilon_m^l} H_{\upsilon_m^l \upsilon_m^i}} \\
&= \frac{1}{N_m} \sum_{\upsilon_m^i, \upsilon_m^j, \upsilon_m^{k'}, \upsilon_m^l} \left\{ 2 \left[\sum_{g_\nu, \omega_\nu} \langle f_m \upsilon_m^i | B_k(g_\nu \omega_\nu) | f_m \upsilon_m^j \rangle \langle f_m \upsilon_m^j | B_k(g_\nu \omega_\nu) | f_m \upsilon_m^{k'} \rangle \right] \right. \\
&\quad \times \left[\sum_{g_\mu, \omega_\mu} \langle f_m \upsilon_m^{k'} | B_k(g_\mu \omega_\mu) | f_m \upsilon_m^l \rangle \langle f_m \upsilon_m^l | B_k(g_\mu \omega_\mu) | f_m \upsilon_m^i \rangle \right] + \left[\sum_{g_\nu, \omega_\nu} \langle f_m \upsilon_m^i | B_k(g_\nu \omega_\nu) | f_m \upsilon_m^j \rangle \right. \\
&\quad \left. \left. \times \langle f_m \upsilon_m^{k'} | B_k(g_\nu \omega_\nu) | f_m \upsilon_m^l \rangle \right] \left[\sum_{g_\mu, \omega_\mu} \langle f_m \upsilon_m^j | B_k(g_\mu \omega_\mu) | f_m \upsilon_m^{k'} \rangle \langle f_m \upsilon_m^l | B_k(g_\mu \omega_\mu) | f_m \upsilon_m^i \rangle \right] \right\}
\end{aligned}$$

$$= 2[\Lambda^0(k)]^2 + \frac{1}{N_m} \sum_{v_m^i, v_m^j, v_m^{k'}, v_m^l} \left\{ \sum_{\nu=0,1,\ldots,k;\omega_\nu} \{\Lambda^\nu(m-k)\} C^{g_\nu \omega_\nu}_{f_m v_m^i \overline{f_m} \overline{v_m^j}} C^{g_\nu \omega_\nu}_{f_m v_m^{k'} \overline{f_m} \overline{v_m^l}} \right\}$$

$$\times \left\{ \sum_{\mu=0,1,\ldots,m-k;\omega_\mu} \{\Lambda^\mu(k)\} C^{g_\mu \omega_\mu}_{f_m v_m^j \overline{f_m} \overline{v_m^i}} C^{g_\mu \omega_\mu}_{f_m v_m^l \overline{f_m} \overline{v_m^{k'}}} \right\}$$

$$= 2[\Lambda^0(k)]^2 + \frac{1}{N_m} \sum_{\nu=0}^{\min\{k,m-k\}} \Lambda^\nu(m-k)\Lambda^\nu(k) d(\nu). \tag{28}$$

The second equality in Eq. (28) follows by applying Eqs. (11) and (13). In the third equality, it is easy to recognize the first term. The second term follows by applying Eqs. (19) and (25) to the two pieces in the corresponding term in the second equality. The final result follows by applying the orthonormality of the CG coefficients. Equations (27) and (28) will give the excess (γ_2) parameter of the density of eigenvalues of EGUE(k),

$$\gamma_2 = \frac{\overline{\langle H^4 \rangle^m}}{[\overline{\langle H^2 \rangle^m}]^2} - 3 = \left[\frac{1}{N_m} \sum_{\nu=0}^{\min\{k,m-k\}} \frac{\Lambda^\nu(m-k)\Lambda^\nu(k) d(\nu)}{[\Lambda^0(k)]^2} \right] - 1. \tag{29}$$

Turning now to the lowest bivariate moment Σ_{11}, it is easily seen that

$$\Sigma_{11} = \overline{\langle H \rangle^m \langle H \rangle^m} = \frac{1}{(N_m)^2} \sum_{v_m^i, v_m^j} \overline{H_{v_m^i v_m^i} H_{v_m^j v_m^j}} = \frac{1}{N_m} \Lambda^0(m-k). \tag{30}$$

Applying (19) and recognizing that only $\nu=0$ will contribute to the traces give immediately Eq. (30). However Eq. (25) generates a different formula for Σ_{11} and equating it to (30) gives the identity (derived in PW using the duality transformation),

$$\frac{1}{N_m} \sum_{\nu=0}^{m-k} \Lambda^\nu(k) d(\nu) = \Lambda^0(m-k).$$

The variance of the distribution of centroids of the H spectra over the EGUE(k) ensemble is

$$\hat{\Sigma}_{11} = \frac{\Sigma_{11}}{\overline{\langle H^2 \rangle^m}} = \frac{1}{N_m} \frac{\Lambda^0(m-k)}{\Lambda^0(k)}. \tag{31}$$

Finally Σ_{22} is given by

$$\Sigma_{22} = \overline{\langle H^2 \rangle^m \langle H^2 \rangle^m} = \frac{1}{(N_m)^2} \sum_{v_m^i, v_m^j, v_m^{k'}, v_m^l} \overline{|H_{v_m^i v_m^j}|^2 |H_{v_m^{k'} v_m^l}|^2}$$

$$= \frac{1}{(N_m)^2} \sum_{v_m^i, v_m^j, v_m^{k'}, v_m^l} \overline{|H_{v_m^i v_m^j}|^2}\, \overline{|H_{v_m^{k'} v_m^l}|^2} + \frac{2}{(N_m)^2} \sum_{v_m^i, v_m^j, v_m^{k'}, v_m^l} [\overline{H_{v_m^i v_m^j} H_{v_m^{k'} v_m^l}}]^2$$

$$= [\Lambda^0(k)]^2 + \frac{2}{(N_m)^2} \sum_{\nu=0}^{m-k} [\Lambda^\nu(k)]^2 d(\nu). \tag{32}$$

Here in the second equality used is the property $\overline{x^2 y^2} = (\overline{x^2})(\overline{y^2}) + 2[\overline{xy}]^2$ of Gaussian variables x and y. Similarly the final result follows by applying (25) to the second term in the second equality and simplifying the CG coefficients using Eq. (3). Now, the variance of the distribution of the variances of the H spectra over the EGUE(k) ensemble is

$$\hat{\Sigma}_{22} = \frac{\Sigma_{22}}{[\overline{\langle H^2\rangle^m}]^2} - 1 = \frac{2}{(N_m)^2}\sum_{\nu=0}^{m-k}\left[\frac{\Lambda^\nu(k)}{\Lambda^0(k)}\right]^2 d(\nu). \tag{33}$$

Equations (27), (29), (31), and (33) are also given by Benet *et al.*;[5] this paper neither gives details of the derivations nor uses SU(N) Racah coefficients. Also in this work, $\hat{\Sigma}_{11}$, $\hat{\Sigma}_{22}$, and γ_2+1 are denoted by S, R, and Q, respectively, while we have followed Ref. 3.

V. CONCLUSIONS

Going beyond PW, matrix elements of the matrix of second moments are written explicitly in terms of SU(N) Wigner and Racah coefficients and this result is obtained by recognizing that the reduced matrix elements of $B_k(g_\nu)$ are SU(N) Racah coefficients. With this one has Eq. (19) and this is converted into the generalized eigenvalue expansion form by first applying a SU(N) Racah transform and then applying the Biedenharn–Elliott sum rule extended to SU(N). This gives the eigenvalues of the matrix of second moments explicitly in terms of SU(N) Racah coefficients [Eq. (24)]. The two different forms given by Eqs. (19) and (25) for the covariances of m-particle H matrix elements, give in a simple manner the formulas for the low order moments M_p that define the state density and the bivariate moments Σ_{pq} that give information about fluctuations.

Although EGUE(k) for only fermions is considered in this paper, all the results in fact translate to those of EGUE(k) for bosons by using the well known $N\rightarrow -N$ symmetry,[12,13] i.e., in the fermion results replace N by $-N$ and then take the absolute value of the final result. For example, the m boson space dimension is $d(m)=\left|\binom{-N}{m}\right|=\{(N-m+1)_m\}$. More importantly the eigenvalues of the matrix of the second moments are

$$\Lambda_B^\nu(k) \rightarrow \left|\binom{m-\nu}{k}\binom{-N-m+k-\nu}{k}\right| = \binom{m-\nu}{k}\binom{N+m+\nu-1}{k}. \tag{34}$$

This result was explicitly derived in Ref. 14; see Eq. (14) of this paper. Moreover for bosons, $\{k\}\otimes\{k^{N-1}\}\rightarrow g_\nu=\{2\nu,\nu^{N-2}\}$, $\nu=0,1,\ldots,k$. Also, the $N\rightarrow -N$ symmetry and Eq. (16) give $d(g_\nu)=\{(N+\nu-1)_\nu\}^2-\{(N+\nu-2)_{\nu-1}\}^2$ and this is same as Eq. (15) of Ref. 14. Similarly Eqs. (27), (29), (31), and (33) extend directly to the boson EGUE(k) with $\Lambda^\nu(k)$ replaced by $\Lambda_B^\nu(k)$ defined in Eq. (34). In addition, for fermions to bosons there is also a $m\leftrightarrow N$ symmetry and this connects fermion results (say for M_p and Σ_{pq}) in the dilute limit to boson results in the dense limit.[13]

Recently there is considerable interest in mesoscopic physics to study EGUE(k) for fermions with spin[15] and here the embedding algebra is $\mathrm{U}(2N)\supset\mathrm{U}(N)\otimes\mathrm{SU}(2)$ with SU(2) generating spin. The approach presented in Secs. II–IV is being applied to this system; some useful results for the $\mathrm{U}(2N)\supset\mathrm{U}(N)\otimes\mathrm{SU}(2)$ Wigner–Racah algebra are available in Refs. 16 and 17. Finally, Wigner–Racah algebra analysis of embedded ensembles with more general group symmetries (see Refs. 2, 6, 17, and 18 for examples) should be possible in the future, thus opening up a new direction in random matrix theory.

Darboux transformations and exact solutions of two dimensional $A_{2n}^{(2)}$ Toda equation

Zi-Xiang Zhou[a)]
Institute of Mathematics, Fudan University, Shanghai 200433, People's Republic of China

(Received 7 April 2004; accepted 16 December 2004; published online 16 February 2005)

The Darboux transformations for two dimensional $A_{2n}^{(2)}$ Toda equation are constructed. The lowest degree of the Darboux transformation is $2(2n+1)$ if all the spectral parameters are complex, or $2n+1$ if one spectral parameter is real. Exact solutions are written down by computing the Darboux transformations explicitly. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1857033]

I. INTRODUCTION

The two dimensional Toda equation is an important integrable system which has been studied widely (e.g., Refs. 1–15) and has applications to differential geometry.[4–7] A Toda equation corresponding to a Kac–Moody algebra g of affine type can be written as

$$w_{k,xt} = A_k \exp\left(\sum_{i=1}^{n} c_{ki} w_i\right) - A_0 v_k \exp\left(\sum_{i=1}^{n} c_{0i} w_i\right) \quad (k = 1, \ldots, n), \tag{1.1}$$

where $C=(c_{ij})_{0\leqslant i,j\leqslant n}$ is the generalized Cartan matrix of g, $v=(v_0, v_1, \ldots, v_n)^T$ is a nonzero vector such that $Cv=0$, and $A_0, A_1, \ldots, A_n$ are real constants.[8,9] There have been a lot of works on the two dimensional Toda equations which are infinite, or are periodic (with $g=A_n^{(1)}$),[5,10] or having fixed ends,[11,12] or with finite dimensional Lie algebras (Kac–Moody algebras of finite type).[13–15]

As a special case of $g=A_2^{(2)}$, the Tzitzeica equation is a typical equation in affine geometry describing indefinite affine spheres.[4,16] An expression of Darboux transformation of the Tzitzeica equation, whose spectral parameter is real, was discussed in Ref. 17, and the loop group decomposition was presented in Ref. 18.

In this paper, we consider the Toda equation with Kac–Moody algebra $g=A_{2n}^{(2)}$. It is neither periodic nor with fixed ends. It has an $(2n+1)\times(2n+1)$ Lax pair, and the Lax pair has a unitary symmetry, a reality symmetry and a cyclic symmetry of order $2n+1$. To get the Darboux transformations which generate solutions of the same equation, we need to consider all these symmetries in the construction. Therefore, Darboux transformations of high degree are necessary. We shall consider the case where all the spectral parameters are complex, as well as the case where one spectral parameter is real. The main results are presented in Theorem 1 of Sec. IV and Theorem 2 of Sec. V.

In Sec. II, we discuss the Lax pair of the $A_{2n}^{(2)}$ Toda equation. In Sec. III, the formulas of Darboux transformation are listed in terms of the standard construction. In Sec. IV, the Darboux transformation with complex spectral parameters is written down in an explicit way. Correspondingly, the Darboux transformation with a real spectral parameter is written down explicitly in Sec. V. In Sec. VI, the explicit solutions of the Tzitzeica equation are presented.

II. LAX PAIR AND EVOLUTION EQUATIONS

The $A_2^{(2)}$ Toda equation, or the Tzitzeica equation, is

a)Electronic mail: zxzhou@public6.sta.net.cn

$$w_{1,xt} = -A_0 e^{-w_1} + A_1 e^{2w_1}, \tag{2.1}$$

where A_0, A_1 are real constants. It corresponds to the generalized Cartan matrix $C=\left(\begin{smallmatrix} 2 & -1 \\ -4 & 2 \end{smallmatrix}\right)$ of $A_2^{(2)}$ with $C(\frac{1}{2},1)^T=0$.

For $n\geqslant 2$, the $A_{2n}^{(2)}$ Toda equation is

$$w_{1,xt} = -A_0 e^{-w_1} + A_1 e^{2w_1-w_2},$$

$$w_{j,xt} = -A_0 e^{-w_1} + A_j e^{2w_j-w_{j-1}-w_{j+1}} \quad (j=2,\ldots,n-1),$$

$$w_{n,xt} = -A_0 e^{-w_1} + A_n e^{2w_n-2w_{n-1}}, \tag{2.2}$$

where A_0, $A_1,\ldots,A_n$ are real constants. It corresponds to the generalized Cartan matrix

$$C = \begin{pmatrix} 2 & -1 & & & & \\ -2 & 2 & -1 & & & \\ & -1 & 2 & -1 & & \\ & & \ddots & \ddots & \ddots & \\ & & & -1 & 2 & -1 \\ & & & & -2 & 2 \end{pmatrix} \tag{2.3}$$

of $A_{2n}^{(2)}$ and $C(\frac{1}{2},1,\ldots,1)^T=0$.

For all $n\geqslant 1$, let $w_j=-(u_1+\ldots+u_j)$ $(j=1,\ldots,n)$, then (2.1) becomes

$$u_{1,xt} = A_0 e^{u_1} - A_1 e^{-2u_1}, \tag{2.4}$$

and (2.2) becomes

$$u_{1,xt} = A_0 e^{u_1} - A_1 e^{u_2-u_1},$$

$$u_{j,xt} = A_{j-1} e^{u_j-u_{j-1}} - A_j e^{u_{j+1}-u_j} \quad (2\leqslant j\leqslant n-1),$$

$$u_{n,xt} = A_{n-1} e^{u_n-u_{n-1}} - A_n e^{-2u_n}. \tag{2.5}$$

Hereafter, for any $(2n+1)\times(2n+1)$ matrix A or any $(2n+1)$-vector v, and for any integers i and j, define $A_{ij}=A_{i'j'}$ and $v_i=v_{i'}$ where $i\equiv i' \bmod 2n+1$, $j\equiv j' \bmod 2n+1$, and $1\leqslant i',j'\leqslant 2n+1$. Especially, denote

$$\delta_{ij} = \begin{cases} 1 & \text{if } i-j\equiv 0 \bmod 2n+1, \\ 0 & \text{otherwise.} \end{cases} \tag{2.6}$$

Let $\omega=e^{2\pi i/(2n+1)}$, $\Omega=\mathrm{diag}(1,\omega^{-1},\ldots,\omega^{-2n})$. Let $K=(K_{ij})=(\delta_{i,2n+1-j})_{(2n+1)\times(2n+1)}$ and $J=(J_{ij})=(\delta_{i,j-1})_{(2n+1)\times(2n+1)}$ be two constant matrices and

$$P = (p_i\delta_{ij})_{(2n+1)\times(2n+1)}, \quad Q = (q_i\delta_{i,j+1})_{(2n+1)\times(2n+1)}, \tag{2.7}$$

where

$$p_i = -p_{2n+1-i} = u_{i,x} \quad (1\leqslant i\leqslant n), \quad p_{2n+1}=0,$$

$$q_i = q_{2n-i} = A_i e^{u_{i+1}-u_i} \quad (1\leqslant i\leqslant n-1), \quad q_n = A_n e^{-2u_n}, \quad q_{2n}=q_{2n+1}=A_0 e^{u_1}. \tag{2.8}$$

From (2.7) and (2.8), $\det Q=q_1\ldots q_{2n+1}=A_0^2A_1^2\ldots A_{n-1}^2A_n$ is a constant.

Notice that

$$\Omega^* K = \omega^{-2} K \Omega. \tag{2.9}$$

Here A^* refers to the Hermitian conjugate of a matrix A.

Now consider the Lax pair

$$\Phi_x = U(x,t,\lambda)\Phi \equiv (\lambda J + P(x,t))\Phi, \quad \Phi_t = V(x,t,\lambda)\Phi \equiv \lambda^{-1} Q(x,t)\Phi. \tag{2.10}$$

Its integrability condition

$$U_t - V_x + [U,V] = 0 \tag{2.11}$$

is

$$Q_x = [P,Q], \quad P_t + [J,Q] = 0, \tag{2.12}$$

or equivalently

$$q_{i,x} = (p_{i+1} - p_i) q_i, \quad p_{i,t} = q_{i-1} - q_i. \tag{2.13}$$

These are just the $A_{2n}^{(2)}$ Toda equations (2.4) and (2.5) by considering (2.8).

It is easy to check that J, $P(x,t)$, $Q(x,t)$ satisfy the relations

$$\Omega P \Omega^{-1} = P, \quad \Omega J \Omega^{-1} = \omega J, \quad \Omega Q \Omega^{-1} = \omega^{-1} Q,$$

$$K P K^{-1} = -P^T, \quad K J K^{-1} = J^T, \quad K Q K^{-1} = Q^T. \tag{2.14}$$

Written equivalently in terms of U and V, (2.14) becomes

$$\overline{U(x,t,\lambda)} = U(x,t,\bar{\lambda}), \quad \overline{V(x,t,\lambda)} = V(x,t,\bar{\lambda}),$$

$$\Omega U(x,t,\lambda)\Omega^{-1} = U(x,t,\omega\lambda), \quad \Omega V(x,t,\lambda)\Omega^{-1} = V(x,t,\omega\lambda),$$

$$K U(x,t,\lambda) K^{-1} = -(U(x,t,-\bar{\lambda}))^*, \quad K V(x,t,\lambda) K^{-1} = -(V(x,t,-\bar{\lambda}))^*. \tag{2.15}$$

Conversely, if (P,Q) satisfies (2.12), then $\det Q$ is independent of x, since

$$(\det Q)_x = \det Q \, \mathrm{tr}(Q_x Q^{-1}) = \det Q \, \mathrm{tr}([PQ^{-1}, Q]) = 0. \tag{2.16}$$

Now suppose that $A_0, A_1, \ldots, A_{n-1} \neq 0$ are given constants and (P,Q) is a $(2n+1)\times(2n+1)$ matrix solution of (2.12) satisfying the constraints (2.14) and $\det Q$ is a constant. From (2.14), P and Q must be of form (2.7) with

$$p_i + p_{2n+1-i} = 0, \quad q_i = q_{2n-i} \quad (i = 1,2,\ldots,2n+1). \tag{2.17}$$

In the region where $q_i A_i > 0$ $(i=1,\ldots,n)$, let $q_i = A_i e^{u_{i+1}-u_i}$ $(1 \leqslant i \leqslant n-1)$, $q_{2n} = A_0 e^{u_1}$, then $q_n = A_n e^{-2u_n}$ where $A_n = \det Q / A_0^2 A_1^2 \cdots A_{n-1}^2$. Moreover, from the first equation of (2.12),

$$p_i = -p_{2n+1-i} = u_{i,x} \quad (1 \leqslant i \leqslant n), \quad p_{2n+1} = 0. \tag{2.18}$$

The second equation of (2.12) implies that $(u_1,\ldots,u_n)$ is a solution of the $A_{2n}^{(2)}$ Toda equation (2.4) or (2.5). Therefore, we have the following,

Lemma 1: *Suppose (P,Q) is a $(2n+1)\times(2n+1)$ matrix solution of (2.12) satisfying the constraints (2.14) and $\det Q$ is a constant. Then in the region where $q_i A_i > 0$ $(i=1,\ldots,n)$, $(u_1,\ldots,u_n)$ is a solution of the $A_{2n}^{(2)}$ Toda equation (2.4) or (2.5).*

In order to construct Darboux transformation, we need the following lemma, which is the direct consequence of (2.14).

Lemma 2: *Suppose $\mu \in \mathbf{C}$.*

(i) *If $\Phi(x,t)$ is a solution of (2.10) for $\lambda = \mu$, then $\overline{\Phi}(x,t)$ is a solution of (2.10) for $\lambda = \bar{\mu}$;*

(ii) *If* $\Phi(x,t)$ *is a solution of (2.10) for* $\lambda=\mu$*, then for any integer* k*,* $\Omega^k\Phi(x,t)$ *is a solution of (2.10) for* $\lambda=\omega^k\mu$.

(iii) *If* $\Phi(x,t)$ *is a solution of (2.10) for* $\lambda=\mu$*,* $\Psi(x,t)$ *is a solution of (2.10) for* $\lambda=-\bar{\mu}$*, then* $(\Psi^*K\Phi)_x=0$, $(\Psi^*K\Phi)_t=0$.

III. DARBOUX TRANSFORMATION

The Darboux matrix with unitary reduction can be constructed in the following known procedure.[19,20]

Let $\lambda_1,\ldots,\lambda_M$ be M complex numbers such that λ_j, $-\bar{\lambda}_j$ $(j=1,2,\ldots,M)$ are distinct. Let H_j be a column solution of the Lax pair (2.10) for $\lambda=\lambda_j$ $(j=1,2,\ldots,M)$. Denote

$$\Gamma_{ij}=\frac{H_i^*KH_j}{\bar{\lambda}_i+\lambda_j} \tag{3.1}$$

for $i,j=1,2,\ldots,M$, $\Gamma=(\Gamma_{ij})_{1\leqslant i,j\leqslant M}$,

$$G(x,t,\lambda)=\prod_{l=1}^{M}(\lambda+\bar{\lambda}_l)\left(1-\sum_{i,j=1}^{M}\frac{(\Gamma^{-1})_{ij}H_iH_j^*K}{\lambda+\bar{\lambda}_j}\right). \tag{3.2}$$

Then it can be checked directly that

$$G(x,t,\lambda)^{-1}=\prod_{l=1}^{M}(\lambda+\bar{\lambda}_l)^{-1}\left(1+\sum_{i,j=1}^{M}\frac{(\Gamma^{-1})_{ij}H_iH_j^*K}{\lambda-\lambda_i}\right). \tag{3.3}$$

$G(x,t,\lambda)$ is a polynomial of λ of degree M with matrix coefficients. Write

$$G(x,t,\lambda)=\sum_{j=0}^{M}(-1)^{M-j}G_{M-j}(x,t)\lambda^j,\quad G_0(x,t)=I, \tag{3.4}$$

and define

$$\tilde{U}=GUG^{-1}+G_xG^{-1},\quad \tilde{V}=GVG^{-1}+G_tG^{-1}. \tag{3.5}$$

Lemma 3: $\tilde{U}=\lambda J+\tilde{P}$, $\tilde{V}=(1/\lambda)\tilde{Q}$ *where* $\tilde{P}=P+[J,G_1]$, $\tilde{Q}=G_MQG_M^{-1}$.

Proof: Using (2.14) and the fact that H_j is a solution of the Lax pair (2.10) with $\lambda=\lambda_j$, we have

$$\Gamma_{ij,x}=H_i^*KJH_j,\quad \Gamma_{ij,t}=\frac{1}{\bar{\lambda}_i\lambda_j}H_i^*KQH_j. \tag{3.6}$$

Substituting (3.2), (3.3), and (3.6) into (3.5) and using the symmetries (2.14), we get the conclusion of the lemma by direct calculation.

Lemma 4:

$$G(x,t,-\bar{\lambda})^*KG(x,t,\lambda)=\prod_{l=1}^{M}(\bar{\lambda}_l+\lambda)(\lambda_l-\lambda)K. \tag{3.7}$$

Proof: The equality (3.7) follows from

$$G(x,t,-\bar{\lambda})^*=KG(x,t,\lambda)^{-1}K^{-1}\prod_{l=1}^{M}(\bar{\lambda}_l+\lambda)(\lambda_l-\lambda), \tag{3.8}$$

which is a direct result of (3.2), (3.3) and the fact that Γ is Hermitian. The lemma is proved.

The solution $\tilde{Q}$ has been expressed in terms of G_M. According to (3.2),

$$(-1)^M G_M = \prod_{l=1}^{M} \bar{\lambda}_l \left(1 - \sum_{i,j=1}^{M} \frac{(\Gamma^{-1})_{ij} H_i H_j^* K}{\bar{\lambda}_j} \right) = \prod_{l=1}^{M} \bar{\lambda}_l \left(1 - (2n+1) R^* \Gamma^{-1} S\right), \tag{3.9}$$

where R and S are $M \times (2n+1)$ matrices with

$$R_{ij} = (2n+1)^{-1/2} (\bar{H}_i)_j, \quad S_{ij} = (2n+1)^{-1/2} \bar{\lambda}_i^{-1} \sum_{k=1}^{2n+1} (\bar{H}_i)_{-k}. \tag{3.10}$$

IV. DARBOUX TRANSFORMATION WITH COMPLEX SPECTRAL PARAMETERS

Darboux matrix keeping the reductions (2.14) can be derived by above general construction together with some more constraints on the spectral parameters and the solutions of the Lax pair.

Let μ be a nonzero complex number such that $\arg(\mu) \neq k\pi/(4n+2)$ for any integer k. Let $\lambda_j = \omega^{j-1}\mu$, $\lambda_{2n+1+j} = \omega^{-j+1}\bar{\mu}$ $(j=1,2,\ldots,2n+1)$. Then all λ_j and $-\bar{\lambda}_j$ $(j=1,2,\ldots,2(2n+1))$ are distinct. Let h be a column solution of (2.10) for $\lambda=\mu$, $H_j = \Omega^{j-1} h$, $H_{2n+1+j} = \Omega^{-j+1}\bar{h}$ $(j=1,2,\ldots,2n+1)$. Then H_j is a solution of (2.10) for $\lambda=\lambda_j (j=1,2,\ldots,2(2n+1))$.

We construct Γ, $G(x,t,\lambda)$, $\tilde{U}(x,t,\lambda)$, $\tilde{V}(x,t,\lambda)$ according to Sec. III with $M=2(2n+1)$.

More explicit expressions of Γ_{ij} can be written down from their definition (3.1). For $1 \leqslant i,j \leqslant 2n+1$, let

$$A_{ij} = \Gamma_{ij} = \frac{h^*(\Omega^*)^{i-1} K \Omega^{j-1} h}{\omega^{-i+1}\bar{\mu} + \omega^{j-1}\mu} = \omega^{-i+1} \frac{h^* K \Omega^{i+j-2} h}{\bar{\mu} + \omega^{i+j-2}\mu},$$

$$B_{ij} = \Gamma_{i,2n+1+j} = \frac{h^*(\Omega^*)^{i-1} K \Omega^{-j+1} \bar{h}}{\omega^{-i+1}\bar{\mu} + \omega^{-j+1}\bar{\mu}} = \omega^{-i+1} \frac{h^* K \Omega^{i-j} \bar{h}}{\bar{\mu} + \omega^{i-j}\bar{\mu}},$$

$$C_{ij} = \Gamma_{2n+1+i,j} = \frac{\bar{h}^*(\Omega^*)^{-i+1} K \Omega^{j-1} h}{\omega^{i-1}\mu + \omega^{j-1}\mu} = \omega^{i-1} \frac{\bar{h}^* K \Omega^{j-i} h}{\mu + \omega^{j-i}\mu},$$

$$D_{ij} = \Gamma_{2n+1+i,2n+1+j} = \frac{\bar{h}^*(\Omega^*)^{-i+1} K \Omega^{-j+1} \bar{h}}{\omega^{i-1}\mu + \omega^{-j+1}\bar{\mu}} = \omega^{i-1} \frac{\bar{h}^* K \Omega^{-i-j+2} \bar{h}}{\mu + \omega^{-i-j+2}\bar{\mu}}. \tag{4.1}$$

Then Γ is written as a 2×2 block matrix $\Gamma = \left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$ where $A=(A_{ij})$, $B=(B_{ij})$, $C=(C_{ij})$, $D=(D_{ij})$ are $(2n+1)\times(2n+1)$ matrices, and $\Gamma^{-1} = \left(\begin{smallmatrix} \hat{A} & \hat{B} \\ \hat{C} & \hat{D} \end{smallmatrix}\right)$ where

$$\hat{A} = (A - BD^{-1}C)^{-1}, \quad \hat{B} = -A^{-1}B(D - CA^{-1}B)^{-1},$$

$$\hat{C} = -D^{-1}C(A - BD^{-1}C)^{-1}, \quad \hat{D} = (D - CA^{-1}B)^{-1}. \tag{4.2}$$

From (4.1), we know that $D=\bar{A}$, $C=\bar{B}$. Hence, (4.2) leads to $\hat{D}=\bar{\hat{A}}$, $\hat{C}=\bar{\hat{B}}$. Then, from (3.2), we have the following.

Lemma 5: $\overline{G(x,t,\bar{\lambda})} = G(x,t,\lambda)$. *Hence the coefficients of each power of* λ *in* $G(x,t,\lambda)$ *are all real matrices.*

From (4.1), we get

$$A_{i+1,j-1} = \omega^{-1} A_{ij}, \quad B_{i+1,j+1} = \omega^{-1} B_{ij}, \quad C_{i+1,j+1} = \omega C_{ij}, \quad D_{i+1,j-1} = \omega D_{ij}. \tag{4.3}$$

Written equivalently, they are

$$JAJ=\omega^{-1}A,\quad JBJ^{-1}=\omega^{-1}B,\quad J^{-1}CJ=\omega^{-1}C,\quad J^{-1}DJ^{-1}=\omega^{-1}D. \tag{4.4}$$

According to (4.2),

$$J\hat{A}J=\omega^{-1}\hat{A},\quad J\hat{B}J^{-1}=\omega^{-1}\hat{B},\quad J^{-1}\hat{C}J=\omega^{-1}\hat{C},\quad J^{-1}\hat{D}J^{-1}=\omega^{-1}\hat{D}. \tag{4.5}$$

Hence

$$\hat{A}_{i+1,j-1}=\omega^{-1}\hat{A}_{ij},\quad \hat{B}_{i+1,j+1}=\omega^{-1}\hat{B}_{ij},\quad \hat{C}_{i+1,j+1}=\omega\hat{C}_{ij},\quad \hat{D}_{i+1,j-1}=\omega\hat{D}_{ij}. \tag{4.6}$$

Lemma 6: $\Omega G(x,t,\lambda)\Omega^{-1}=G(x,t,\omega\lambda)$.

Proof:

$$\Omega\frac{\Omega^{i-1}h(\Omega^{j-1}h)^*K}{\lambda+\overline{\omega^{j-1}\mu}}\Omega^{-1}=\frac{\omega\Omega^{i}h(\Omega^{j-2}h)^*\Omega^*K\Omega^{-1}}{\omega\lambda+\overline{\omega^{j-2}\mu}}=\frac{\omega^{-1}\Omega^{i}h(\Omega^{j-2}h)^*K}{\omega\lambda+\overline{\omega^{j-2}\mu}}. \tag{4.7}$$

Hence,

$$\Omega\sum_{i,j=1}^{2n+1}\hat{A}_{ij}\frac{\Omega^{i-1}h(\Omega^{j-1}h)^*K}{\lambda+\overline{\omega^{j-1}\mu}}\Omega^{-1}=\sum_{i,j=1}^{2n+1}\hat{A}_{i+1,j-1}\frac{\Omega^{i}h(\Omega^{j-2}h)^*K}{\omega\lambda+\overline{\omega^{j-2}\mu}}=\sum_{i,j=1}^{2n+1}\hat{A}_{ij}\frac{\Omega^{i-1}h(\Omega^{j-1}h)^*K}{\omega\lambda+\overline{\omega^{j-1}\mu}} \tag{4.8}$$

by (4.6). Similar relations hold for the terms in G with B_{ij}, C_{ij}, and D_{ij}. Moreover, $\Pi_{l=1}^{2(2n+1)}(\lambda+\overline{\lambda}_l)=\Pi_{l=1}^{2(2n+1)}(\omega\lambda+\overline{\lambda}_l)$. Hence, by (3.2), the lemma is true.

From Lemma 4, Lemma 5, and Lemma 6, $\tilde{U}$ and $\tilde{V}$ defined by (3.5) are real and satisfy the relations (2.15). Moreover, after the Darboux transformation, they must satisfy the integrability condition (2.11). Hence, by Lemma 1, we have the following.

Proposition 1: $(\tilde{P},\tilde{Q})$ *generated by the Darboux transformation constructed above is a real solution of (2.12) satisfying the relations (2.14). Therefore, it gives a solution of the* $A_{2n}^{(2)}$ *Toda equation (2.4) or (2.5).*

In order to get explicit expressions of the solutions we should derive the explicit expression of $G_{2(2n+1)}$. Equation (3.2) is too complicated to be computed directly even by computer. Therefore, we need to represent the matrix Γ, regarded as a linear transformation, in another basis, so that its inverse can be computed explicitly.

Let $\xi_k=(2n+1)^{-1/2}\Omega^{k-1}(1,1,\ldots,1)^T$, then the ith component of ξ_k is

$$(\xi_k)_i=(2n+1)^{-1/2}\omega^{-(k-1)(i-1)}. \tag{4.9}$$

Using the fact

$$\sum_{j=1}^{2n+1}\omega^{jk}=\begin{cases}0 & \text{if } k\not\equiv 0 \bmod 2n+1,\\ 2n+1 & \text{if } k\equiv 0 \bmod 2n+1,\end{cases} \tag{4.10}$$

we know that $(\xi_1,\ldots,\xi_{2n+1})$ is an orthonormal basis of $\mathbf{C}^{2n+1}$.

From (4.1),

$$A\xi_k=\alpha_k\xi_{3-k},\quad B\xi_k=\overline{\gamma}_{2-k}\xi_{k+1},\quad C\xi_k=\gamma_k\xi_{k-1},\quad D\xi_k=\overline{\alpha}_{2-k}\xi_{1-k}, \tag{4.11}$$

where

$$\alpha_k=\sum_{j=1}^{2n+1}\frac{h^*K\Omega^jh}{\overline{\mu}+\omega^j\mu}\omega^{-(k-1)j},\quad \gamma_k=\sum_{j=1}^{2n+1}\frac{\overline{h}^*K\Omega^jh}{\mu+\omega^j\mu}\omega^{-(k-1)j}. \tag{4.12}$$

Using (2.9), we have $\overline{h^*K\Omega^jh}=(h^*K\Omega^jh)^*=\omega^{-2j}h^*K\Omega^jh$, $\overline{h}^*K\Omega^jh=(\overline{h}^*K\Omega^jh)^T=\omega^{2j}\overline{h}^*K\Omega^{-j}h$. Hence

$$\overline{\alpha}_k = \alpha_{3-k}, \quad \gamma_k = \gamma_{3-k}. \tag{4.13}$$

From (4.2) and (4.11), we obtain

$$\hat{A}\xi_k = \hat{\alpha}_k \xi_{3-k}, \quad \hat{B}\xi_k = \overline{\hat{\gamma}}_{2-k}\xi_{k+1}, \quad \hat{C}\xi_k = \hat{\gamma}_k \xi_{k-1}, \quad \hat{D}\xi_k = \overline{\hat{\alpha}}_{2-k}\xi_{1-k}, \tag{4.14}$$

where

$$\hat{\alpha}_k = \overline{\alpha}_{3-k}(|\alpha_{3-k}|^2 - |\gamma_{3-k}|^2)^{-1}, \quad \hat{\gamma}_k = -\gamma_{3-k}(|\alpha_{3-k}|^2 - |\gamma_{3-k}|^2)^{-1}. \tag{4.15}$$

Let $h=(h_1,\ldots,h_{2n+1})^T$, then the entries of $\overline{H}_i$, $\overline{H}_{2n+1+i}$ $(1\leqslant i\leqslant 2n+1)$ are $(\overline{H}_i)_j=\omega^{(i-1)(j-1)}\overline{h}_j$, $(\overline{H}_{2n+1+i})_j=\omega^{-(i-1)(j-1)}h_j$. Hence, from (3.10), for $1\leqslant i,j\leqslant 2n+1$,

$$R_{ij} = (2n+1)^{-1/2}\omega^{(i-1)(j-1)}\overline{h}_j, \quad R_{2n+1+i,j} = (2n+1)^{-1/2}\omega^{-(i-1)(j-1)}h_j,$$

$$S_{ij} = (2n+1)^{-1/2}\overline{\mu}^{-1}\omega^{-(i-1)j}\overline{h}_{-j}, \quad S_{2n+1+i,j} = (2n+1)^{-1/2}\mu^{-1}\omega^{(i-1)j}h_{-j}. \tag{4.16}$$

Written in matrices, the ith column of R is $(\overline{h}_i\xi_{2-i}, h_i\xi_i)^T$ and the jth column of S is $(\overline{\mu}^{-1}\overline{h}_{-j}\xi_{j+1}, \mu^{-1}h_{-j}\xi_{1-j})^T$.

Let

$$\mathcal{A}_l = \overline{h_l}h_{-l}, \quad \mathcal{C}_l = h_l h_{-l}. \tag{4.17}$$

Lemma 7: *$|\mu|^{-2(2n+1)}G_{2(2n+1)}=1-(2n+1)R^*\Gamma^{-1}S=\mathrm{diag}(g_1,\ldots,g_{2n+1})$ where*

$$g_j = 1 - 2(2n+1)\mathrm{Re}\left(\frac{1}{\mu}\frac{\mathcal{A}_j\alpha_{2-j} - \mathcal{C}_j\overline{\gamma}_{2-j}}{|\alpha_{2-j}|^2 - |\gamma_{2-j}|^2}\right). \tag{4.18}$$

Proof: Using the expressions (3.9) and (4.14), we have $|\mu|^{-2(2n+1)}G_{2(2n+1)}=1-(2n+1)R^*\Gamma^{-1}S$ and

$$(R^*\Gamma^{-1}S)_{ij} = \left(h_i\xi_{2-i}^*, \overline{h}_i\xi_i^*\right)\begin{pmatrix}\hat{A} & \hat{B}\\ \hat{C} & \hat{D}\end{pmatrix}\begin{pmatrix}\overline{\mu}^{-1}\overline{h}_{-j}\xi_{j+1}\\ \mu^{-1}h_{-j}\xi_{1-j}\end{pmatrix} = f_i\delta_{ij}, \tag{4.19}$$

where

$$f_j = \overline{\mu}^{-1}\overline{h}_{-j}(h_j\hat{\alpha}_{j+1} + \overline{h}_j\hat{\gamma}_{j+1}) + \mu^{-1}h_{-j}(\overline{h}_j\overline{\hat{\alpha}}_{j+1} + h_j\overline{\hat{\gamma}}_{j+1}) = \frac{1}{|\alpha_{2-j}|^2 - |\gamma_{2-j}|^2}\left(\overline{\mu}^{-1}\overline{\mathcal{A}}_j\overline{\alpha}_{2-j} - \overline{\mu}^{-1}\overline{\mathcal{C}}_j\gamma_{2-j}\right.$$

$$\left. - \mu^{-1}\mathcal{C}_j\overline{\gamma}_{2-j} + \mu^{-1}\mathcal{A}_j\alpha_{2-j}\right). \tag{4.20}$$

The lemma is proved.

According to Lemma 3, we get the entries $(\tilde{q}_1,\ldots,\tilde{q}_{2n+1})$ of $\tilde{Q}$ in (2.7) as

$$\tilde{q}_j = \frac{g_{j+1}}{g_j}q_j. \tag{4.21}$$

However, the expression of g_j in (4.18) is still not simple enough. To simplify the expressions of the solutions, we need the following two lemmas.

Lemma 8: *Suppose $k-2=(2n+1)s+r$ where s, r are integers, $1\leqslant r\leqslant 2n+1$, then*

$$\alpha_k = \frac{2n+1}{\overline{\mu}^{2n+1} + \mu^{2n+1}}\left(\sum_{l=1}^{r}\mathcal{A}_l(-\mu)^{r-l}\overline{\mu}^{2n+l-r} + \sum_{l=r+1}^{2n+1}\mathcal{A}_l(-\mu)^{2n+1+r-l}\overline{\mu}^{l-r-1}\right),$$

$$\gamma_k = \frac{2n+1}{2\mu^{2n+1}}\left(\sum_{l=1}^{r}\mathcal{C}_l(-\mu)^{r-l}\mu^{2n+l-r} + \sum_{l=r+1}^{2n+1}\mathcal{C}_l(-\mu)^{2n+1+r-l}\mu^{l-r-1}\right). \tag{4.22}$$

Proof: According to (4.12),

$$\alpha_k = \sum_{j=1}^{2n+1}\sum_{l=1}^{2n+1}\frac{\mathcal{A}_l\omega^{-j(k-l-2)}}{\overline{\mu}+\omega^j\mu}. \tag{4.23}$$

Let θ be a constant with $|\theta|<1$. Let

$$\alpha_k^{(\theta)} = \sum_{j=1}^{2n+1}\sum_{l=1}^{2n+1}\frac{\mathcal{A}_l\omega^{-j(k-l-2)}}{\overline{\mu}+\theta\omega^j\mu} = \sum_{j=1}^{2n+1}\sum_{l=1}^{2n+1}\sum_{\rho=0}^{+\infty}\overline{\mu}^{-1}\mathcal{A}_l\omega^{j(\rho+2+l-k)}(-\theta\mu\overline{\mu}^{-1})^{\rho}. \tag{4.24}$$

Using (4.10) we have $\Sigma_{j=1}^{2n+1}\omega^{j(\rho+2+l-k)}=0$ unless $\rho+2+l-k\equiv 0 \bmod 2n+1$. Let $\rho=k-l-2+(2n+1)\sigma$, then, using $k-2=(2n+1)s+r$,

$$\begin{aligned}(2n+1)^{-1}\alpha_k^{(\theta)} &= \sum_{l=1}^{2n+1}\sum_{\sigma\geqslant\frac{1}{2n+1}(l-k+2)}\overline{\mu}^{-1}\mathcal{A}_l(-\theta\mu\overline{\mu}^{-1})^{k-l-2+(2n+1)\sigma}\\ &= \sum_{l=1}^{r}\sum_{\sigma=-s}^{+\infty}\overline{\mu}^{-1}\mathcal{A}_l(-\theta\mu\overline{\mu}^{-1})^{k-l-2+(2n+1)\sigma} + \sum_{l=r+1}^{2n+1}\sum_{\sigma=-s+1}^{+\infty}\overline{\mu}^{-1}\\ &\quad\times\mathcal{A}_l(-\theta\mu\overline{\mu}^{-1})^{k-l-2+(2n+1)\sigma} = \sum_{l=1}^{r}\frac{\mathcal{A}_l(-\theta\mu)^{r-l}\overline{\mu}^{2n+l-r}}{\overline{\mu}^{2n+1}+(\theta\mu)^{2n+1}} + \sum_{l=r+1}^{2n+1}\frac{\mathcal{A}_l(-\theta\mu)^{2n+1+r-l}\overline{\mu}^{l-r-1}}{\overline{\mu}^{2n+1}+(\theta\mu)^{2n+1}}.\end{aligned} \tag{4.25}$$

Here a sum is zero if the lower bound is greater than the upper bound. Since $\arg(\mu)\notin\{k\pi/(4n+2)|k\in\mathbf{Z}\}$, by taking $\theta\to 1$, we get the expression of α_k in (4.22). The expression of γ_k in (4.22) is obtained similarly. The lemma is proved.

Lemma 9: *For any integer k,*

$$|\alpha_{2-k}|^2 - |\alpha_{1-k}|^2 - |\gamma_{2-k}|^2 + |\gamma_{1-k}|^2 = 2(2n+1)\mathrm{Re}\left(\mu^{-1}(\mathcal{A}_k\alpha_{2-k} - \mathcal{C}_k\overline{\gamma}_{2-k})\right). \tag{4.26}$$

Proof: First suppose $-k-1=(2n+1)s+r$, $1\leqslant r\leqslant 2n$, then $(2-k)-2=(2n+1)s+r+1$, $(1-k)-2=(2n+1)s+r$. According to Lemma 8,

$$\alpha_{2-k} = \frac{2n+1}{\overline{\mu}^{2n+1}+\mu^{2n+1}}\left(\sum_{l=1}^{r+1}\mathcal{A}_l(-\mu)^{r+1-l}\overline{\mu}^{2n-1+l-r} + \sum_{l=r+2}^{2n+1}\mathcal{A}_l(-\mu)^{2n+2+r-l}\overline{\mu}^{l-r-2}\right),$$

$$\alpha_{1-k} = \frac{2n+1}{\overline{\mu}^{2n+1}+\mu^{2n+1}}\left(\sum_{l=1}^{r}\mathcal{A}_l(-\mu)^{r-l}\overline{\mu}^{2n+l-r} + \sum_{l=r+1}^{2n+1}\mathcal{A}_l(-\mu)^{2n+1+r-l}\overline{\mu}^{l-r-1}\right). \tag{4.27}$$

Hence

$$\alpha_{1-k} = -\mu^{-1}\overline{\mu}(\alpha_{2-k} - (2n+1)\overline{\mu}^{-1}\mathcal{A}_{r+1}). \tag{4.28}$$

This implies

$$|\alpha_{2-k}|^2 - |\alpha_{1-k}|^2 = 2(2n+1)\mathrm{Re}\left(\mu^{-1}\overline{\mathcal{A}}_{r+1}\alpha_{2-k}\right) - (2n+1)^2|\mu|^{-2}|\mathcal{A}_{r+1}|^2. \tag{4.29}$$

Similarly, we have

$$-|\gamma_{2-k}|^2+|\gamma_{1-k}|^2=-2(2n+1)\mathrm{Re}(\overline{\mu}^{-1}\overline{\mathcal{C}}_{r+1}\gamma_{2-k})+(2n+1)^2|\mu|^{-2}|\mathcal{C}_{r+1}|^2. \tag{4.30}$$

Since $|\mathcal{C}_{r+1}|^2=|\mathcal{A}_{r+1}|^2$,

$$|\alpha_{2-k}|^2-|\alpha_{1-k}|^2-|\gamma_{2-k}|^2+|\gamma_{1-k}|^2=2(2n+1)\mathrm{Re}(\mu^{-1}\overline{\mathcal{A}}_{r+1}\alpha_{2-k})-2(2n+1)\mathrm{Re}(\mu^{-1}\mathcal{C}_{r+1}\overline{\gamma}_{2-k}). \tag{4.31}$$

According to (4.17), $\mathcal{A}_{r+1}=\overline{\mathcal{A}}_k$, $\mathcal{C}_{r+1}=\mathcal{C}_k$. Hence (4.26) holds.

If $-k-1\equiv 0 \bmod 2n+1$, (4.28) still holds. The same result is obtained. This proves the lemma.

From (4.18) and (4.26),

$$g_k=1-\frac{2(2n+1)}{|\alpha_{2-k}|^2-|\gamma_{2-k}|^2}\,\mathrm{Re}\left(\frac{\mathcal{A}_k\alpha_{2-k}-\mathcal{C}_k\overline{\gamma}_{2-k}}{\mu}\right)=\frac{|\alpha_{1-k}|^2-|\gamma_{1-k}|^2}{|\alpha_{2-k}|^2-|\gamma_{2-k}|^2}. \tag{4.32}$$

Using (4.21), we get the transformation of the solution of (2.12),

$$\tilde{q}_k=\frac{\eta_k\eta_{k+2}}{\eta_{k+1}^2}q_k, \tag{4.33}$$

Where $\eta_k=|\alpha_{2-k}|^2-|\gamma_{2-k}|^2$.

Remark 1: *From (4.13), the equality $\eta_{1-k}=\eta_k$ always holds. Hence $\tilde{q}_{-k-1}=\tilde{q}_k$ holds provided that $q_{-k-1}=q_k$ holds. This means that the Darboux transformation does not change the natural relation (2.17).*

η_k's can be written down explicitly. For $k=1,2,\ldots,n+1$, we have $(2-k)-2=-(2n+1)+2n+1-k$. The first equation of (4.27) can be written as

$$\alpha_{2-k}=\frac{2n+1}{\overline{\mu}^{2n+1}+\mu^{2n+1}}\left(\sum_{l=1}^{2n+1-k}\mathcal{A}_l(-\mu)^{2n+1-k-l}\overline{\mu}^{k+l-1}+\sum_{l=2n+2-k}^{2n+1}\mathcal{A}_l(-\mu)^{4n+2-k-l}\overline{\mu}^{k+l-2n-2}\right). \tag{4.34}$$

Similarly,

$$\begin{aligned}\gamma_{2-k}&=\frac{2n+1}{2\mu^{2n+1}}\left(\sum_{l=1}^{2n+1-k}\mathcal{C}_l(-\mu)^{2n+1-k-l}\mu^{k+l-1}+\sum_{l=2n+2-k}^{2n+1}\mathcal{C}_l(-\mu)^{4n+2-k-l}\mu^{k+l-2n-2}\right)\\&=-\frac{2n+1}{2\mu}\left(\sum_{l=1}^{2n+1-k}\mathcal{C}_l(-1)^{k+l}-\sum_{l=2n+2-k}^{2n+1}\mathcal{C}_l(-1)^{k+l}\right).\end{aligned} \tag{4.35}$$

Equation (4.33) leads to the transformation of the solution $(\tilde{u}_1,\ldots,\tilde{u}_n)$ of (2.4) or (2.5) as

$$\tilde{u}_k=u_k+\ln\frac{\eta_{k+1}}{\eta_k}\quad(1\leqslant k\leqslant n) \tag{4.36}$$

If $\eta_1,\ldots,\eta_n$ have the same sign.

In summary, we have the following theorem.

Theorem 1: *Suppose $(u_1,\ldots,u_n)$ is a solution of (2.4) or (2.5). Let $\mu\in\mathbf{C}\backslash\{0\}$ such that $\arg(\mu)\neq k\pi/(4n+2)$ for any inter k. Let $h=(h_1,\ldots,h_{2n+1})^T$ be a column solution of* (2.10) *for $\lambda=\mu$. Let $\lambda_j=\omega^{j-1}\mu$, $\lambda_{2n+1+j}=\omega^{-j+1}\overline{\mu}$, $H_j=\Omega^{j-1}h$, $H_{2n+1+j}=\Omega^{-j+1}\overline{h}(j=1,2,\ldots,2n+1)$. Define $\Gamma_{ij}=H_i^*KH_j/(\overline{\lambda}_i+\lambda_j)$ $(i,j=1,\ldots,2(2n+1))$. Let $G(x,t,\lambda)$ be defined by* (3.2) *with $M=2(2n+1)$. Then G is a Darboux matrix for (2.10) in the sense that for any solution Φ of (2.10), $\tilde{\Phi}=G\Phi$ satisfies*

$$\tilde{\Phi}_x=(\lambda J+\tilde{P})\tilde{\Phi},\quad \tilde{\Phi}_t=\lambda^{-1}\tilde{Q}\tilde{\Phi}, \tag{4.37}$$

where $\tilde{P}=P+[J,G_1]$, $\tilde{Q}=G_{2(2n+1)}QG_{2(2n+1)}^{-1}$.

Let

$$\zeta_k = \frac{1}{|\overline{\mu}^{2n+1} + \mu^{2n+1}|^2} \left| \sum_{l=1}^{2n+1-k} \overline{h}_l h_{-l} (-\mu)^{2n+1-k-l} \overline{\mu}^{k+l-1} + \sum_{l=2n+2-k}^{2n+1} \overline{h}_l h_{-l} (-\mu)^{4n+2-k-l} \overline{\mu}^{k+l-2n-2} \right|^2$$
$$- \frac{1}{4|\mu|^2} \left| \sum_{l=1}^{2n+1-k} h_l h_{-l} (-1)^{k+l} - \sum_{l=2n+2-k}^{2n+1} h_l h_{-l} (-1)^{k+l} \right|^2, \tag{4.38}$$

then in the region where $\zeta_1, \ldots, \zeta_n$ have the same sign, the new solution $(\tilde{u}_1, \ldots, \tilde{u}_n)$ of (2.4) or (2.5) is given by

$$\tilde{u}_k = u_k + \ln \frac{\zeta_{k+1}}{\zeta_k} \quad (k = 1, 2, \ldots, n). \tag{4.39}$$

V. DARBOUX TRANSFORMATION WITH A REAL SPECTRAL PARAMETER

Now suppose a spectral parameter in constructing Darboux matrix is real. Considering the symmetries in Lemma 2, the Darboux matrix can be derived as follows.

Let μ be a nonzero real number, $\lambda_j = \omega^{j-1}\mu (j = 1, 2, \ldots, 2n+1)$, then all λ_j, $-\overline{\lambda}_j$ $(j = 1, \ldots, 2n+1)$ are distinct. Let h be a column solution of (2.10) for $\lambda = \mu$, $H_j = \Omega^{j-1} h$, $(j = 1, 2, \ldots, 2n+1)$. Then H_j is a solution of (2.10) for $\lambda = \lambda_j$ $(j = 1, 2, \ldots, 2n+1)$.

According to Sec. III for $M = 2n+1$, we can also construct Γ and $G(x, t, \lambda)$. From (3.1),

$$\Gamma_{ij} = \frac{h^* (\Omega^*)^{i-1} K \Omega^{j-1} h}{\omega^{-i+1}\mu + \omega^{j-1}\mu} = \omega^{-i+1} \frac{h^* K \Omega^{i+j-2} h}{\mu + \omega^{i+j-2}\mu}. \tag{5.1}$$

Now

$$\Gamma \xi_k = \alpha_k \xi_{3-k}, \quad \alpha_k = \sum_{j=1}^{2n+1} \frac{h^* K \Omega^j h}{\mu + \omega^j \mu} \omega^{-(k-1)j}, \quad \Gamma^{-1} \xi_k = \hat{\alpha}_k \xi_{3-k}, \quad \hat{\alpha}_k = \alpha_{3-k}^{-1}. \tag{5.2}$$

Lemma 10: $\overline{G(x, t, \overline{\lambda})} = G(x, t, \lambda)$.

Proof: Since $\lambda_{2-i} = \overline{\lambda}_i$, $H_{2-i} = \overline{H}_i$, we have

$$\overline{\Gamma}_{2-i,2-j} = \frac{\overline{H}_{2-i}^* K \overline{H}_{2-j}}{\overline{\lambda}_{2-j} + \lambda_{2-i}} = \frac{H_i^* K H_j}{\overline{\lambda}_i + \lambda_j} = \Gamma_{ij}. \tag{5.3}$$

Let L be a constant matrix such that $L_{11} = 1$, $L_{i+1,1-i} = 1$ $(i = 1, 2, \ldots, 2n)$ and $L_{ij} = 0$ for other (i, j). Then Γ satisfies $L\Gamma L = \overline{\Gamma}$. This leads to $L\Gamma^{-1}L = \overline{\Gamma}^{-1}$. Therefore,

$$\sum_{i,j=1}^{2n+1} \overline{\left(\frac{(\Gamma^{-1})_{ij} H_i H_j^* K}{\overline{\lambda} + \overline{\lambda}_j} \right)} = \sum_{i,j=1}^{2n+1} \frac{(\Gamma^{-1})_{2-i,2-j} H_{2-i} H_{2-j}^* K}{\lambda + \overline{\lambda}_{2-j}} = \sum_{i,j=1}^{2n+1} \frac{(\Gamma^{-1})_{ij} H_i H_j^* K}{\lambda + \overline{\lambda}_j}. \tag{5.4}$$

The lemma is proved.

Hence, the coefficients of each power of λ in $G(x, t, \lambda)$ are all real matrices.

Similar to Lemma 6, we have

$$\Omega G(x, t, \lambda) \Omega^{-1} = G(x, t, \omega\lambda). \tag{5.5}$$

From Lemma 4, Lemma 10, and (5.5), $\tilde{U}$ and $\tilde{V}$ defined by (3.5) satisfy the relations (2.15).

Let $h = (h_1, \ldots, h_{2n+1})^T$, then

$$R_{ij} = (2n+1)^{-1/2} \omega^{(i-1)(j-1)} h_j, \quad S_{ij} = (2n+1)^{-1/2} \mu^{-1} \omega^{-(i-1)j} h_{-j}. \tag{5.6}$$

Written in matrices, the ith column of R is $h_i \xi_{2-i}$, and the jth column of S is $\mu^{-1} h_{-j} \xi_{j+1}$.

Therefore, $-\mu^{-2n-1}G_{2n+1}=1-(2n+1)R^*\Gamma^{-1}S=\mathrm{diag}(g_1,\ldots,g_{2n+1})$ where

$$g_j = 1-(2n+1)\mu^{-1}h_jh_{-j}/\alpha_{2-j}. \tag{5.7}$$

Similar to Lemma 8, α_k can be expressed as

$$\begin{aligned}\alpha_k &= \frac{2n+1}{2\mu^{2n+1}}\left(\sum_{l=1}^{r}\mathcal{A}_l(-\mu)^{r-l}\mu^{2n+l-r}+\sum_{l=r+1}^{2n+1}\mathcal{A}_l(-\mu)^{2n+1+r-l}\mu^{l-r-1}\right)\\ &= \frac{2n+1}{2\mu}\left(\sum_{l=1}^{r}(-1)^{r-l}\mathcal{A}_l-\sum_{l=r+1}^{2n+1}(-1)^{r-l}\mathcal{A}_l\right),\end{aligned} \tag{5.8}$$

where $\mathcal{A}_l=h_lh_{-l}$ and $k-2=(2n+1)s+r$ with $s,\ r\in\mathbf{Z}$ and $1\leqslant r\leqslant 2n+1$.

From (5.8), we get $\alpha_{2-k}+\alpha_{1-k}=(2n+1)\mu^{-1}\mathcal{A}_k$ corresponding to Lemma 9. From (5.7), $g_k=1-(2n+1)\mu^{-1}\mathcal{A}_k\alpha_{2-k}^{-1}=-\alpha_{1-k}\alpha_{2-k}^{-1}$. Hence, $\tilde{q}_k=(\eta_k\eta_{k+2}/\eta_{k+1}^2)q_k$ where $\eta_k=\alpha_{2-k}$.

Since $(2-k)-2=-(2n+1)s+2n+1-k$, (5.8) leads to

$$\eta_k=\alpha_{2-k}=-\frac{2n+1}{2\mu}\left(\sum_{l=1}^{2n+1-k}(-1)^{k+l}\mathcal{A}_l-\sum_{l=2n+2-k}^{2n+1}(-1)^{k+l}\mathcal{A}_l\right) \tag{5.9}$$

$(k=1,2,\ldots,n+1)$. Finally,

$$\tilde{u}_k=u_k+\ln\frac{\eta_{k+1}}{\eta_k}. \tag{5.10}$$

If $\eta_1,\ldots,\eta_n$ have the same sign.

The above results are summarized in the following theorem.

Theorem 2: *Suppose $(u_1,\ldots,u_n)$ is a solution of (2.4) or (2.5). Let $\mu\in\mathbf{R}\backslash\{0\}$. Let $h=(h_1,\ldots,h_{2n+1})^T$ be a real column solution of (2.10) for $\lambda=\mu$. Let $\lambda_j=\omega^{j-1}\mu$, $H_j=\Omega^{j-1}h$ $(j=1,2,\ldots,2n+1)$. Define $\Gamma_{ij}=H_i^*KH_j/(\bar{\lambda}_i+\lambda_j)$ $(i,j=1,\ldots,2n+1)$. Let $G(x,t,\lambda)$ be defined by (3.2) with $M=2n+1$. Then G is a Darboux matrix for (2.10) in the sense that for any solution Φ of (2.10), $\tilde{\Phi}=G\Phi$ satisfies*

$$\tilde{\Phi}_x=(\lambda J+\tilde{P})\tilde{\Phi},\quad \tilde{\Phi}_t=\lambda^{-1}\tilde{Q}\tilde{\Phi}, \tag{5.11}$$

Where $\tilde{P}=P+[J,G_1]$, $\tilde{Q}=G_{2n+1}QG_{2n+1}^{-1}$.

Let

$$\zeta_k=\sum_{l=1}^{2n+1-k}(-1)^{k+l}h_lh_{-l}-\sum_{l=2n+2-k}^{2n+1}(-1)^{k+l}h_lh_{-l} \tag{5.12}$$

then in the region where $\zeta_1,\ldots,\zeta_n$ have the same sign, the new solution $(\tilde{u}_1,\ldots,\tilde{u}_n)$ of (2.4) or (2.5) is given by

$$\tilde{u}_k=u_k+\ln\frac{\zeta_{k+1}}{\zeta_k}\quad (k=1,2,\ldots,n). \tag{5.13}$$

VI. APPLICATION TO THE TZITZEICA EQUATION

The Tzitzeica equation

$$u_{xt}=e^u-e^{-2u} \tag{6.1}$$

is a special two dimensional Toda equation with $n=1$.

Suppose u is a solution of (6.1) and $h=(h_1,h_2,h_3)^T$ is a column solution of its Lax pair for $\lambda=\mu$. Using Theorem 1 and Theorem 2, we get the new solution of (6.1). When μ is taken as a complex number,

$$\tilde{u}=u+\ln\frac{4|\mu|^2|\bar{\mu}^2\bar{h}_1h_2+\mu^2h_1\bar{h}_2-|\mu|^2|h_3|^3|^2-(\mu^3+\bar{\mu}^3)^2|2h_1h_2-h_3^2|^2}{(2|\mu|^2\bar{\mu}h_1\bar{h}_2-2|\mu|^2\mu\bar{h}_1h_2+(\mu^3-\bar{\mu}^3)|h_3|^2)^2}. \tag{6.2}$$

When μ is a real number,

$$\tilde{u}=u+\ln\frac{2h_1h_2-h_3^2}{h_3^2}. \tag{6.3}$$

Equation (6.3) is similar to that given by Ref. 17.

ACKNOWLEDGMENTS

The author is grateful to Professor C. H. Gu and Professor H. S. Hu for their helpful suggestions and discussions on constructing the Darboux transformations. He is also grateful to Dr. J. Inoguchi for his suggestion on studying the Tzitzeica equation together with helpful discussions. This work was supported by the special funds for Chinese major state basic research projects and the trans-century training program foundation for the talents by the Ministry of Education of China.

Representations of classical Lie subalgebras of quantum pseudodifferential operators

Carina Boyallian[a] and José I. Liberati[b]
Ciem-FAMAF, Universidad Nacional de Córdoba, Ciudad Universitaria, 5000 Córdoba, Argentina

(Received 29 July 2004; accepted 1 November 2004; published online 22 February 2005)

We show that there is a family of anti-involutions $\sigma_{\epsilon,k}$ ($\epsilon=\pm 1$ and $k\in\mathbb{Z}$), up to conjugation, of the Lie algebra $\mathcal{S}_q$ of quantum pseudodifferential operators preserving the principal gradation. We classify the irreducible quasifinite highest weight modules over the Lie subalgebras of $\mathcal{S}_q$, fixed by minus $\sigma_{\epsilon,k}$ (k even), and we realize them in terms of irreducible highest weight representations of the Lie algebra of infinite matrices with finitely many nonzero diagonals and its classical Lie subalgebras of B, C, and D types. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1845600]

I. INTRODUCTION

The W-infinity algebras naturally arise in various physical theories, such as conformal field theory, the theory of the quantum Hall effect, etc. The $W_{1+\infty}$ algebra, which is the central extension of the Lie algebra $\mathcal{D}$ of differential operators on the circle, is the most fundamental among these algebras.

When we study the representation theory of a Lie algebra of this kind, we encounter the difficulty that although it admits a $\mathbb{Z}$-gradation, each of the graded subspaces is still infinite dimensional, and therefore the study of highest weight modules which satisfy the quasifiniteness condition, that is, graded subspaces have finite dimension, becomes a nontrivial problem.

The study of representation theory of the Lie algebra $\hat{\mathcal{D}}$ (the universal central extension of the Lie algebra $\mathcal{D}$, also denoted by $\mathcal{W}_{1+\infty}$ in the physicists literature), was initiated in Ref. 5. In that paper, Kac and Radul classified the irreducible quasi-finite highest weight representations of $\hat{\mathcal{D}}$, and it was shown that they can be realized in terms of irreducible highest weight representations of the Lie algebra of infinite matrices. At the end of that article, they did, very briefly, the same for the Lie algebra $\widehat{\mathcal{S}_q}$, the central extension of the Lie algebra of quantum pseudodifferential operators, which contains as a subalgebra the q-analogue of the Lie algebra $\hat{\mathcal{D}}$, the algebra of all regular difference operators on $\mathbb{C}^\times$.

In Ref. 2 we extend the results obtained in Ref. 5, for the central extension of the Lie algebra of $M\times M$ matrix quantum pseudodifferential operators.

In this paper we get analogous results to those obtained in Ref. 6, for $\widehat{\mathcal{S}_q}$. That is, we show that there is a family of anti-involutions $\sigma_{\epsilon,k}$ ($\epsilon=\pm 1$ and $k\in\mathbb{Z}$), up to conjugation, of the Lie algebra $\mathcal{S}_q$, preserving the principal gradation. We classify the irreducible quasifinite highest weight modules over the Lie subalgebras of $\mathcal{S}_q$, fixed by minus $\sigma_{\epsilon,k}$ (k even), and we realize them in terms of irreducible highest weight representations of the Lie algebra of infinite matrices with finitely many nonzero diagonals and its classical Lie subalgebras of B, C, and D types. Here we get a larger family of subalgebras, and this makes the picture much richer than in the classical case.

[b]Electronic mail: liberati@mate.uncor.edu

The paper is organized as follows. In Sec. II we recall some definitions and notations of $\widehat{g\ell}_\infty$ and its classical subalgebras. In Sec. III we study the structure of $\widehat{\mathcal{S}_q}$, its involutions and we introduce the subalgebras $\widehat{\mathcal{S}_q^{\kappa,\epsilon}}$. In Sec. IV we characterize the quasifiniteness of highest weight modules over $\widehat{\mathcal{S}_q^{\kappa,\epsilon}}$. In Sec. V we establish the relation of this subalgebra with $\widehat{g\ell}(\infty,R_m)$ and finally in Sec. VI we realize and construct the quasifinite highest weight modules over $\widehat{\mathcal{S}_q}$.

II. LIE ALGEBRAS $\widehat{g\ell}_\infty^{[m]}$ AND ITS CLASSICAL SUBALGEBRAS

Denote by $R_m=\mathbb{C}[u]/(u^{m+1})$, the quotient algebra of the polynomial algebra $\mathbb{C}[u]$ by the ideal generated by u^{m+1} ($m\in\mathbb{Z}_+$). Let **1** be the identity element in R_m. Denote by $g\ell_\infty^{[m]}$ the complex Lie algebra of all infinite matrices $(a_{ij})_{i,j\in Z}$ with only finitely many nonzero diagonals with entries in R_m. Denote by E_{ij} the infinite matrix with 1 at (i,j)-place and 0 elsewhere. There is a natural automorphism ν of $g\ell_\infty^{[m]}$ given by

$$\nu(E_{i,j})=E_{i+1,j+1}. \tag{2.1}$$

Let the weight of $E_{i,j}$ be $j-i$. This defines the *principal* $\mathbb{Z}$-gradation $g\ell_\infty^{[m]}=\oplus_{j\in\mathbb{Z}}(g\ell_\infty^{[m]})_j$. Denote by $\widehat{g\ell}_\infty^{[m]}=g\ell_\infty^{[m]}\oplus R_m$ the cental extension of $g\ell_\infty^{[m]}$ given by the following 2-cocycle with values in R_m:

$$C(A,B)=\mathrm{Tr}([J,A]B), \tag{2.2}$$

where $J=\Sigma_{i\leqslant 0}E_{ii}$. The $\mathbb{Z}$-gradation of the Lie algebra $g\ell_\infty^{[m]}$ extends to $\widehat{g\ell}_\infty^{[m]}$ by setting the weight of R_m to be 0. In particular we have the *triangular decomposition*

$$\widehat{g\ell}_\infty^{[m]}=(\widehat{g\ell}_\infty^{[m]})_+\oplus(\widehat{g\ell}_\infty^{[m]})_0\oplus(\widehat{g\ell}_\infty^{[m]})_-, \tag{2.3}$$

where

$$(\widehat{g\ell}_\infty^{[m]})_\pm=\bigoplus_{j\in\mathbb{N}}(\widehat{g\ell}_\infty^{[m]})_{\pm j}\quad\text{and}\quad(\widehat{g\ell}_\infty^{[m]})_0=(g\ell_\infty^{[m]})_0\oplus R_m.$$

Given $\lambda\in(\widehat{g\ell}_\infty^{[m]})_0^*$, we let

$$c_i=\lambda(u^i),$$

$$^a\lambda_j^{(i)}=\lambda(u^iE_{j,j}), \tag{2.4}$$

$$^ah_j^{(i)}={}^a\lambda_j^{(i)}-{}^a\lambda_{1+j}^{(i)}+\delta_{j,0}c_i,$$

where $j\in\mathbb{Z}$ and $i=0,\ldots,m$. Let $L(\widehat{g\ell}_\infty^{[m]},\lambda)$ be the irreducible highest weight $\widehat{g\ell}_\infty^{[m]}$-module with highest weight λ. The $^a\lambda_j^{(i)}$ are called the *labels* and c_i are the *central charges* of $L(\widehat{g\ell}_\infty^{[m]},\lambda)$.

Consider the vector space $R_m[t,t^{-1}]$, and take the R_m-basis $v_i=t^{-i}$, $i\in\mathbb{Z}$. The Lie algebra $g\ell_\infty^{[m]}$ acts on this vector space via the usual formula

$$E_{ij}v_k=\delta_{j,k}v_i. \tag{2.5}$$

Now consider the following $\mathbb{C}$-bilinear form on $R_m[t,t^{-1}]$:

$$B^\pm(u^mv_i,u^nv_j)=u^m(-u^n)(\pm 1)^i\delta_{i,-j}. \tag{2.6}$$

Denote by $\overline{b}_\infty^{-[m]}$ (respectively, $\overline{b}_\infty^{+[m]}$) the Lie subalgebra of $g\ell_\infty^{[m]}$ which preserves the bilinear form $B^-(,)$ [respectively, $B^+(,)$]. We have

$$\overline{b}_\infty^{-[m]} = \{(a_{ij}(u))_{i,j\in\mathbb{Z}} \in g\ell_\infty^{[m]} | a_{ij}(u) = (-1)^{i+j+1} a_{-j,-i}(-u)\},$$

$$\overline{b}_\infty^{+[m]} = \{(a_{ij}(u))_{i,j\in\mathbb{Z}} \in g\ell_\infty^{[m]} | a_{ij}(u) = -a_{-j,-i}(-u)\}.$$

Denote by $b_\infty^{[m]} = \overline{b}_\infty^{-[m]} \oplus R_m$ (respectively, $\widetilde{b}_\infty^{[m]} = \overline{b}_\infty^{+[m]} \oplus R_m$), the central extension of $\overline{b}_\infty^{-[m]}$ (respectively, $\overline{b}_\infty^{+[m]}$) given by the corresponding restriction of the 2-cocycle in (2.2). These subalgebras inherit from $\widehat{g\ell}_\infty^{[m]}$ the principal $\mathbb{Z}$-gradation and the triangular decomposition (see Refs. 6 and 3 for notation),

$$b_\infty^{[m]} = \oplus_{j\in\mathbb{Z}} (b_\infty^{[m]})_j, \quad b_\infty^{[m]} = (b_\infty^{[m]})_+ \oplus (b_\infty^{[m]})_0 \oplus (b_\infty^{[m]})_-$$

and

$$\widetilde{b}_\infty^{[m]} = \oplus_{j\in\mathbb{Z}} (\widetilde{b}_\infty^{[m]})_j, \quad \widetilde{b}_\infty^{[m]} = (\widetilde{b}_\infty^{[m]})_+ \oplus (\widetilde{b}_\infty^{[m]})_0 \oplus (\widetilde{b}_\infty^{[m]})_-.$$

Note that the Lie algebra $\widetilde{b}_\infty^{[m]}$ is isomorphic to $b_\infty^{[m]}$ by mapping $u^k E_{ij} - (-u)^k E_{-j,-i}$ to $u^k E_{ij} + (-1)^{i+j+1}(-u)^k E_{-j,-i}$. When $m=0$, we have the usual Lie subalgebra of $g\ell_\infty$, denoted by b_∞.

Given $\lambda \in (b_\infty^{[m]})_0^*$, denote by $L(b_\infty^{[m]};\lambda)$ the irreducible highest weight module over $b_\infty^{[m]}$ with highest weight λ.

For each $\lambda \in (b_\infty^{[m]})_0^*$, we let

$$\begin{gathered} c_i = \lambda(u^i), \\ {}^b\lambda_0^{(i)} = \lambda(2u^i E_{0,0}) \quad (i \text{ odd}), \\ {}^b\lambda_j^{(i)} = \lambda(u^i E_{j,j} - (-u)^i E_{-j,-j}), \quad i \neq 0, \\ {}^bh_j^{(i)} = {}^b\lambda_j^{(i)} - {}^b\lambda_{1+j}^{(i)}, \\ {}^bh_0^{(i)} = -2\,{}^b\lambda_1^{(i)} + 2c_i \quad (i \text{ even}), \\ {}^bh_0^{(i)} = {}^b\lambda_0^{(i)} - {}^b\lambda_1^{(i)} + c_i \quad (i \text{ odd}), \end{gathered} \tag{2.7}$$

where $j \in \mathbb{N}$ and $i = 0, \ldots, m$. The superscript b stands for type B. The ${}^b\lambda_j^{(i)}$ are called the *labels* and c_i are the *central charges* of $L(b_\infty^{[m]}, \lambda)$.

As before, take the R_m-basis, $v_i = t^{-i}$, $i \in \mathbb{Z}$ of $R_m[t, t^{-1}]$, and consider $R_m[t, t^{-1}]$ equipped with the following $\mathbb{C}$-bilinear form:

$$C(u^m v_i, u^n v_j) = u^m(-u^n)(-1)^i \delta_{i,1-j}. \tag{2.8}$$

Denote by $\overline{c}_\infty^{\pm m]}$ the Lie subalgebra of $g\ell_\infty^{[m]}$ which preserves the bilinear form $C(,)$. We have

$$\overline{c}_\infty^{\pm m]} = \{(a_{ij}(u))_{i,j\in\mathbb{Z}} \in g\ell_\infty^{[m]} | a_{ij}(u) = (-1)^{i+j+1} a_{1-j,1-i}(-u)\}.$$

Denote by $c_\infty^{[m]} = \overline{c}_\infty^{\pm m]} \oplus R_m$ the central extension of $\overline{c}_\infty^{\pm m]}$ given by the restriction of the 2-cocycle (2.2), defined in $g\ell_\infty^{[m]}$. This subalgebra inherits from $\widehat{g\ell}_\infty^{[m]}$ the principal $\mathbb{Z}$-gradation and the triangular decomposition (see Refs. 6 and 3 for notation)

$$c_\infty^{[m]} = \oplus_{j\in\mathbb{Z}} (c_\infty^{[m]})_j, \quad c_\infty^{[m]} = (c_\infty^{[m]})_+ \oplus (c_\infty^{[m]})_0 \oplus (c_\infty^{[m]})_-.$$

In particular when $m=0$, we have the usual Lie subalgebra of $g\ell_\infty$, denoted by c_∞.

Given $\lambda \in (c_\infty^{[m]})_0^*$, denote by $L(c_\infty^{[m]};\lambda)$ the irreducible highest weight module over $c_\infty^{[m]}$ with highest weight λ.

For each $\lambda \in (c_\infty^{[m]})_0^*$, we let

$$c_i = \lambda(u^i),$$

$$\begin{aligned} {}^c\lambda_j^{(i)} &= \lambda(u^i E_{j,j} - (-u)^i E_{1-j,1-j}), \\ {}^c h_j^{(i)} &= {}^c\lambda_j^{(i)} - {}^c\lambda_{1+j}^{(i)}, \end{aligned} \tag{2.9}$$

$${}^c h_0^{(i)} = {}^c\lambda_1^{(i)} + c_i \quad (i \text{ even}),$$

where $j \in \mathbb{N}$ and $i=0,\ldots,m$. Here, the superscript c denotes type C. The ${}^c\lambda_j^{(i)}$ are called the *labels* and c_i are the *central charges* of $L(c_\infty^{[m]},\lambda)$.

Again, take the R_m-basis, $v_i=t^{-i}$, $i \in \mathbb{Z}$ of $R_m[t,t^{-1}]$, but consider $R_m[t,t^{-1}]$ equipped with the following C-bilinear form:

$$D(u^m v_i, u^n v_j) = u^m(-u^n)\delta_{i,1-j}. \tag{2.10}$$

Denote by $\overline{d}_\infty^{[m]}$ the Lie subalgebra of $g\ell_\infty^{[m]}$ which preserves the bilinear form $D(,)$. We have

$$\overline{d}_\infty^{[m]} = \{(a_{ij}(u))_{i,j\in\mathbb{Z}} \in g\ell_\infty^{[m]} | a_{ij}(u) = -a_{1-j,1-i}(-u)\}.$$

Denote by $d_\infty^{[m]} = \overline{d}_\infty^{[m]} \oplus R_m$ the central extension of $\overline{d}_\infty^{[m]}$ given by the restriction of the 2-cocycle (2.2). This subalgebra inherits from $\widehat{g\ell}_\infty^{[m]}$ the principal $\mathbb{Z}$-gradation and the triangular decomposition (see Refs. 6 and 3 for notation)

$$d_\infty^{[m]} = \oplus_{j\in\mathbb{Z}}(d_\infty^{[m]})_j, \quad d_\infty^{[m]} = (d_\infty^{[m]})_+ \oplus (d_\infty^{[m]})_0 \oplus (d_\infty^{[m]})_-.$$

In particular when $m=0$, we have the usual Lie subalgebra of $g\ell_\infty$, denoted by d_∞.

Given $\lambda \in (d_\infty^{[m]})_0^*$, denote by $L(d_\infty^{[m]};\lambda)$ the irreducible highest weight module over $d_\infty^{[m]}$ with highest weight λ.

For each $\lambda \in (d_\infty^{[m]})_0^*$, we let

$$c_i = \lambda(u^i),$$

$$\begin{aligned} {}^d\lambda_j^{(i)} &= \lambda(u^i E_{j,j} - (-u)^i E_{1-j,1-j}), \\ {}^d h_j^{(i)} &= {}^d\lambda_j^{(i)} - {}^d\lambda_{1+j}^{(i)}, \end{aligned} \tag{2.11}$$

$${}^d h_0^{(i)} = -{}^d\lambda_1^{(i)} - {}^d\lambda_2^{(i)} + 2c_i \quad (i \text{ even}),$$

where $j \in \mathbb{N}$ and $i=0,\ldots,m$. Here, the superscript d denotes type D.The ${}^d\lambda_j^{(i)}$ are called the *labels* and c_i are the *central charges* of $L(d_\infty^{[m]},\lambda)$.

III. THE SUBALGEBRA $\mathcal{S}_q$ AND ITS INVOLUTIONS

Denote by T_q, $q \in \mathbb{C}^\times = \mathbb{C}\backslash\{0\}$, the following operator on $\mathbb{C}[z,z^{-1}]$:

$$T_q f(z) = f(qz).$$

Denote by $\mathcal{S}_q^{qs}$ the associative algebra of all pseudodifferential operators, i.e., the operators on $\mathbb{C}[z,z^{-1}]$ of the form

$$E = \sum_{k \in Z} e_k(z) T_q^k, \quad \text{where } e_i(z) \in \mathbb{C}[z, z^{-1}] \quad \text{(sum is finite)}.$$

Any pseudodifferential operator can be written as linear combinations of elements of the form $z^k f(T_q)$, where $f \in \mathbb{C}[w, w^{-1}]$. The product in $\mathcal{S}_q^{as}$ is then given by

$$(z^r f(T_q))(z^s g(T_q)) = z^{r+s} f(q^s T_q) g(T_q).$$

Denote by $\mathcal{S}_q$ the Lie algebra obtained from $\mathcal{S}_q^{as}$ by taking the usual bracket. Let $\mathcal{S}_q' = [\mathcal{S}_q, \mathcal{S}_q]$. It is easy to check that we have

$$\mathcal{S}_q = \mathcal{S}_q' \oplus \mathbb{C} T_q^0 \quad \text{(direct sum of ideals)}.$$

Thus, the representation theory of $\mathcal{S}_q$ reduces to that of $\mathcal{S}_q'$. Taking the trace form in $\mathbb{C}[w, w^{-1}]$, namely $\mathrm{tr}_0(\Sigma_j c_j w^j) = c_0$, we obtain, by a general construction (cf. Sec. 1.3 in Ref. 5), the following 2-cocycle in $\mathcal{S}_q$:

$$\Psi(z^m f(T_q), z^k g(T_q)) = m \, \mathrm{tr}_0(f(q^{-m} w) g(w)) \delta_{m,-k}. \tag{3.1}$$

Let

$$\widehat{\mathcal{S}_q} = \mathcal{S}_q' + \mathbb{C} C$$

denote the central extension of $\mathcal{S}_q'$ corresponding to the cocycle (3.1).

The elements $z^k T_q^m$ $(k, m \in \mathbb{Z})$ form a basis of $\mathcal{S}_q$. Define the *weight* by

$$\mathrm{wt}\, z^k T_q^m = k, \ \mathrm{wt}\, C = 0.$$

This gives us the principal $\mathbb{Z}$-gradation of $\mathcal{S}_q^{as}$, $\mathcal{S}_q$, and $\widehat{\mathcal{S}_q}$,

$$\mathcal{S}_q^{as} = \bigoplus_{j \in \mathbb{Z}} (\mathcal{S}_q^{as})_j, \quad \widehat{\mathcal{S}_q} = \bigoplus_{j \in \mathbb{Z}} (\widehat{\mathcal{S}_q})_j.$$

An *anti-involution* σ of $\mathcal{S}_q^{as}$ is an involutive antiautomorphism of $\mathcal{S}_q^{as}$, i.e., $\sigma^2 = \mathrm{Id}$, $\sigma(ax + by) = a\sigma(x) + b\sigma(y)$ and $\sigma(xy) = \sigma(y)\sigma(x)$, for all $a, b \in \mathbb{C}$ and $x, y \in \mathcal{S}_q^{as}$. From now on we will assume that $|q| \neq 1$.

Proposition 3.1: Any anti-involution σ of $\mathcal{S}_q^{as}$ which preserves the principal $\mathbb{Z}$-gradation is of the following form:

$$\sigma_{A,B,k}(z) = A z T_q^k \quad \textit{and} \quad \sigma_{A,B,k}(T_q) = B T_q^{-1}$$

with $k \in \mathbb{Z}$ and $A, B \in \mathbb{C} - \{0\}$ such that $A^2 B^k = q^k$.

Proof: Since σ preserves $\mathbb{Z}$-gradation we may assume that $\sigma(z) = z f(T_q)$ and $\sigma(T_q) = g(T_q)$, where $f, g, \in \mathbb{C}[w, w^{-1}]$. Now, since T_q is an invertible element in our algebra, so is $g(T_q)$, and therefore of the form $g(T_q) = B T_q^l$ for some $B \in \mathbb{C} - \{0\}$ and $l \in \mathbb{Z}$. Similarly, $f(T_q) = A T_q^k$ with $A \in \mathbb{C} - \{0\}$ and $k \in \mathbb{Z}$. Using that $\sigma^2 = id$ we have

$$1 = f(g(T_q)) f(T_q) \quad \text{and } T_q = g(g(T_q)).$$

Combining the second equation and the expression of $g(T_q)$ we get $T_q = B^{l+1} T_q^{(l^2)}$. We can deduce that either $l = 1$, $B = \pm 1$ or $l = -1$ and $B \in \mathbb{C}$.

Now using the first equation and the expression for $f(T_q)$ we have $1 = A^2 B^k q^{lk} T_q^{(l+1)k}$, and hence $(l+1)k = 0$.

If $l = 1$, then $A = \pm 1$. Since we assumed that q is not a root of unity, it is easy to check that these are not antiautomorphisms. Therefore $l = -1$ and we have finished our proof. ■

It is immediate that $(h \in \mathbb{C}[w, w^{-1}])$,

$$\sigma_{A,B,k}(z^n h(T_q)) = A^n q^{[n(n-1)k]/2} z^n h(B q^{-n} T_q^{-1}) T_q^{nk}. \tag{3.2}$$

Given $s \in \mathbb{C}$, denote by Θ_s the automorphism of $\mathcal{S}_q$ given by sending $a \in \mathcal{S}_q$ to $z^{-s}az^s$. Therefore, using (3.2), we have

$$\theta_s \sigma_{A,B,k} \theta_{-s} = \sigma_{q^{-sk}A,q^{2s}B,k}. \tag{3.3}$$

Denote by $\mathcal{S}_q^{A,B,k}$ the fixed Lie subalgebra of $\mathcal{S}_q$ by $-\sigma_{A,B,k}$, namely

$$\mathcal{S}_q^{A,B,k} = \{a \in \mathcal{S}_q | \sigma_{A,B,k}(a) = -a\}.$$

It inherits a $\mathbb{Z}$-gradation from $\mathcal{S}_q$ since $\sigma_{A,B,k}$ preserves the principal $\mathbb{Z}$-gradation of $\mathcal{S}_q^{as}$: $\mathcal{S}_q^{A,B,k} = \oplus_{j\in\mathbb{Z}}(\mathcal{S}_q^{A,B,k})_j$, where $(\mathcal{S}_q^{A,B,k})_j = \{z^j f(T_q) | f(w) \in \mathbb{C}[w,w^{-1}]$ and $\sigma_{A,B,k}(z^j f(T_q)) = -z^j f(T_q)\}$.

Now, it is straightforward from (3.3) that we have the following.

Lemma 3.2: The Lie algebra $\mathcal{S}_q^{A,B,k}$ for arbitrary choices of A and B is isomorphic to $\mathcal{S}_q^{\epsilon,q,k}$ where ϵ is either 1 *or* -1.

We will write $\sigma_{\epsilon,k}$ and $\mathcal{S}_q^{\epsilon,k}$ instead of $\sigma_{\epsilon,q,k}$ and $\mathcal{S}_q^{\epsilon,q,k}$. From now on k is even.

Let us denote by $\mathbb{C}[w,w^{-1}]^{\epsilon,j}$ (where $\epsilon=1$ or $\epsilon=-1$) the set of Laurent polynomials such that $f(w^{-1}) = -(\epsilon)^j f(w)$.

Now, we can give a complete description of $(\mathcal{S}_q^{\epsilon,k})_j$.

Lemma 3.3: We have

$$(\mathcal{S}_q^{\epsilon,k})_j = \{z^j (q^{(j-1)/2}T_q)^{kj/2} f(q^{(j-1)/2}T_q) | f(w) \in \mathbb{C}[w,w^{-1}]^{\epsilon,j}\}. \tag{3.4}$$

Proof: By (3.2), an element of $(\mathcal{S}_q^{\epsilon,k})_j$ is of the form $(z^j h(T_q) \in \mathcal{S}_q)$,

$$z^j h(T_q) - \sigma_{\epsilon,k}(z^j h(T_q)) = z^j (h(T_q) - (\epsilon)^j (q^{(j-1)/2}T_q)^{jk} h(q^{-j+1}T_q^{-1})) = z^j (q^{(j-1)/2}T_q)^{jk/2} f(q^{(j-1)/2}T_q)$$

with $f(w) = h(q^{(-j+1)/2}w)w^{-jk/2} - (\epsilon)^j h(q^{(-j+1)/2}w^{-1})w^{jk/2}$. It is easy to see that $f(w^{-1}) = -(\epsilon)^j f(w)$, finishing the proof. ■

From this lemma we have that

$$\mathcal{B} = \{z^j (q^{(j-1)/2}T_q)^{jk/2} ((q^{(j-1)/2}T_q)^m - \epsilon^j (q^{(j-1)/2}T_q)^{-m}) | j \in \mathbb{Z}, m \in \mathbb{N}\}$$

form a $\mathbb{C}$-basis of $(\mathcal{S}_q^{\epsilon,k})$ if $\epsilon=1$ and $\mathcal{B} \cup \{z^j (q^{(j-1)/2}T_q)^{jk/2}\}$ is a basis if $\epsilon=-1$.

We denote again by Ψ the restriction of the 2-cocycle in (3.1) to $(\mathcal{S}_q^{\epsilon,k})$, namely

$$\begin{aligned}\Psi(z^m (q^{(m-1)/2}T_q)^{mk/2} f(q^{(m-1)/2}T_q), z^n (q^{(n-1)/2}T_q)^{nk/2} g(q^{(n-1)/2}T_q)) \\ = \delta_{m,-n} m \mathrm{tr}_0(f(q^{(m-1)/2}w) g(q^{(-m-1)/2}w)),\end{aligned} \tag{3.5}$$

where $z^m (q^{(m-1)/2}T_q)^{mk/2} f(q^{(m-1)/2}T_q)$ and $z^n (q^{(n-1)/2}T_q)^{nk/2} g(q^{(n-1)/2}T_q)$ are in $\mathcal{S}_q^{\epsilon,k}$. Denote by $\widehat{\mathcal{S}_q^{\epsilon,k}}$ the central extension of $\mathcal{S}_q^{\epsilon,k}$ by $\mathbb{C}C$ corresponding to the 2-cocycle Ψ. $\widehat{\mathcal{S}_q^{\epsilon,k}}$ is a Lie subalgebra of $\widehat{\mathcal{S}_q}$ by definition.

IV. CHARACTERIZATION OF QUASIFINITENESS OF HWMs OF $\widehat{\mathcal{S}_q^{\epsilon,k}}$

In order to characterize the quasifiniteness of the highest weight modules (HWMs) of $\widehat{\mathcal{S}_q^{\epsilon,k}}$ we will apply general results for quasifinite representations of $\mathbb{Z}$-graded Lie algebras obtained in Ref. 4. We refer to Ref. 4 for proofs and details. Let $\mathfrak{g}$ be a $\mathbb{Z}$-graded Lie algebra over $\mathbb{C}$:

$$\mathfrak{g} = \bigoplus_{j\in\mathbb{Z}} \mathfrak{g}_j, \quad [\mathfrak{g}_i, \mathfrak{g}_j] \subset \mathfrak{g}_{i+j},$$

where $\mathfrak{g}_i$ is not necessarily of finite dimension. Let $\mathfrak{g}_\pm = \oplus_{j>0}\mathfrak{g}_{\pm j}$. A subalgebra $\mathfrak{p}$ of $\mathfrak{g}$ is called *parabolic* if it contains $\mathfrak{g}_0 \oplus \mathfrak{g}_+$ as a proper subalgebra, that is

$$\mathfrak{p} = \bigoplus_{j\in\mathbb{Z}} \mathfrak{p}_j, \quad \text{where } \mathfrak{p}_j = \mathfrak{g}_j \text{ for } j \geqslant 0, \text{ and } \mathfrak{p}_j \neq 0 \text{ for some } j < 0.$$

We assume the following properties of $\mathfrak{g}$:

(P1) $\mathfrak{g}_0$ is commutative,

(P2) if $a \in \mathfrak{g}_{-k}$ $(k>0)$ and $[a,\mathfrak{g}_1]=0$, then $a=0$.

Given $a \in \mathfrak{g}_{-1}$, $a \neq 0$, we define $\mathfrak{p}^a = \oplus_{j\in\mathbb{Z}} \mathfrak{p}^a_j$, where $\mathfrak{p}^a_j = \mathfrak{g}_j$ for all $j \geqslant 0$, and

$$\mathfrak{p}^a_{-1} = \sum [\cdots[[a,\mathfrak{g}_0],\mathfrak{g}_0], \ldots], \quad \mathfrak{p}^a_{-k-1} = [\mathfrak{p}^a_{-1}, \mathfrak{p}^a_{-k}].$$

Lemma 4.1: (a) $\mathfrak{p}^a$ *is the minimal parabolic subalgebra containing* a. (b) $\mathfrak{g}^a_0 := [\mathfrak{p}^a, \mathfrak{p}^a] \cap \mathfrak{g}_0 = [a, \mathfrak{g}_1]$.

In the particular case of the central extension of the Lie algebra of matrix differential operators on the circle (see Ref. 1, Remark 2.2), we observed the existence of some parabolic subalgebras $\mathfrak{p}$ such that $\mathfrak{p}_{-j}=0$ for $j \gg 0$. Having in mind that example, we give the following definition.

Definition 4.2: (a) A parabolic subalgebra $\mathfrak{p}$ is called *nondegenerate* if $\mathfrak{p}_{-j}$ has finite codimension in $\mathfrak{g}_{-j}$, for all $j>0$.

(b) An element $a \in \mathfrak{g}_{-1}$ is called *nondegenerate* if $\mathfrak{p}^a$ is nondegenerate.

Now, we begin our study of quasifinite representations over $\mathfrak{g}$. A $\mathfrak{g}$-module V is called $\mathbb{Z}$*-graded* if $V = \oplus_{j\in\mathbb{Z}} V_j$ and $\mathfrak{g}_i V_j \subset V_{i+j}$. A $\mathbb{Z}$-graded $\mathfrak{g}$-module V is called *quasifinite* if $\dim V_j < \infty$ for all j.

Given $\lambda \in \mathfrak{g}_0^*$, a *highest weight module* is a $\mathbb{Z}$-graded $\mathfrak{g}$-module $V(\mathfrak{g},\lambda)$ generated by a highest weight vector $v_\lambda \in V(\mathfrak{g},\lambda)_0$ which satisfies

$$hv_\lambda = \lambda(h)v_\lambda \quad (h \in \mathfrak{g}_0), \quad \mathfrak{g}_+ v_\lambda = 0.$$

A nonzero vector $v \in V(\mathfrak{g},\lambda)$ is called *singular* if $\mathfrak{g}_+ v = 0$.

The *Verma module* over $\mathfrak{g}$ is defined as usual,

$$M(\mathfrak{g},\lambda) = \mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{g}_0 \oplus \mathfrak{g}_+)} \mathbb{C}_\lambda,$$

where $\mathbb{C}_\lambda$ is the one-dimensional $(\mathfrak{g}_0 \oplus \mathfrak{g}_+)$-module given by $h \mapsto \lambda(h)$ if $h \in \mathfrak{g}_0$, $\mathfrak{g}_+ \mapsto 0$, and the action of $\mathfrak{g}$ is induced by the left multiplication in $\mathcal{U}(\mathfrak{g})$. Here and further $\mathcal{U}(q)$ stands for the universal enveloping algebra of the Lie algebra $\mathfrak{q}$. Any highest weight module $V(\mathfrak{g},\lambda)$ is a quotient module of $M(\mathfrak{g},\lambda)$. The irreducible module $L(\mathfrak{g},\lambda)$ is the quotient of $M(\mathfrak{g},\lambda)$ by the maximal proper graded submodule. We shall write $M(\lambda)$ and $L(\lambda)$ in place of $M(\mathfrak{g},\lambda)$ and $L(\mathfrak{g},\lambda)$ if no ambiguity may arise.

Consider a parabolic subalgebra $\mathfrak{p} = \oplus_{j\in\mathbb{Z}} \mathfrak{p}_j$ of $\mathfrak{g}$ and let $\lambda \in \mathfrak{g}_0^*$ be such that $\lambda|_{\mathfrak{g}_0 \cap [\mathfrak{p},\mathfrak{p}]} = 0$. Then the $(\mathfrak{g}_0 \oplus \mathfrak{g}_+)$-module $\mathbb{C}_\lambda$ extends to a $\mathfrak{p}$-module by letting $\mathfrak{p}_j$ act as 0 for $j<0$, and we may construct the highest weight module

$$M(\mathfrak{g},\mathfrak{p},\lambda) = \mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{p})} \mathbb{C}_\lambda$$

called the *generalized Verma module*.

We will also require the following condition on $\mathfrak{g}$.

(P3) If $\mathfrak{p}$ is a nondegenerate parabolic subalgebra of $\mathfrak{g}$, then there exists a nondegenerate element a such that $\mathfrak{p}^a \subseteq \mathfrak{p}$.

Theorem 4.3: *The following conditions on* $\lambda \in \mathfrak{g}_0^*$ *are equivalent*:

(1) $M(\lambda)$ *contains a singular vector* $a \cdot v_\lambda$ *in* $M(\lambda)_{-1}$, *where* a *is nondegenerate*;
(2) *there exist a nondegenerate element* $a \in \mathfrak{g}_{-1}$, *such that* $\lambda([\mathfrak{g}_1, a]) = 0$;
(3) $L(\lambda)$ *is quasifinite*;
(4) *there exist a nondegenerate element* $a \in \mathfrak{g}_{-1}$, *such that* $L(\lambda)$ *is the irreducible quotient of the generalized Verma module* $M(\mathfrak{g},\mathfrak{p}^a,\lambda)$.

Now consider $\mathfrak{g} = \mathcal{S}_q^{\epsilon,k}$. Take a parabolic subalgebra $\mathfrak{p}$ of $\widehat{\mathcal{S}}_q^{\epsilon,k}$, namely, it is a subalgebra of the following form:

$$\mathfrak{p} = \bigoplus_{j\in z} \mathfrak{p}_j, \quad \text{where } \mathfrak{p}_j = (\widehat{\mathcal{S}}_q^{\epsilon,k})_j \text{ for } j \geqslant 0 \text{ and } \mathfrak{p}_j \neq 0 \text{ for some } j < 0.$$

Observe for each $j \in \mathbb{N}$ we have

$$\mathfrak{p}_{-j} = \{z^{-j}(q^{(-j-1)/2}T_q)^{-jk/2} f(q^{(-j-1)/2}T_q) : f \in I_{-j}\},$$

where I_{-j} is a subspace of $\mathbb{C}[w,w^{-1}]^{\epsilon,j}$. Given $f(w) \in \mathbb{C}[w,w^{-1}]^{\epsilon,0}$ and $p(w) \in \mathbb{C}[w,w^{-1}]^{\epsilon,j}$ we have that $[f(q^{-1/2}T_q), z^{-n}(q^{(-n-1)/2}T_q)^{-nk/2} p(q^{(-n-1)/2}T_q)] \in \widehat{\mathcal{S}_q^{\epsilon,k}}$. Computing

$$\begin{aligned}[f(q^{-1/2}T_q), z^{-n}(q^{(-n-1)/2}T_q)^{-nk/2} p(q^{(-n-1)/2}T_q)] &= z^{-n}(q^{(-n-1)/2}T_q)^{-nk/2}(f(q^{-n-1/2}T_q) \\ &\quad - f(q^{-1/2}T_q))p(q^{(-n-1)/2}T_q) \\ &= z^{-n}(q^{(-n-1)/2}T_q)^{-nk/2} g(q^{(-n-1)/2}T_q) p(q^{(-n-1)/2}T_q),\end{aligned} \tag{4.1}$$

where $g(w) = f(q^{-n/2}T_q) - f(q^{n/2}T_q)$. As f ranges over $\mathbb{C}[w,w^{-1}]^{\epsilon,0}$, $g(w)$ ranges over all Laurent polynomials such that $g(w^{-1}) = g(w)$. We denote this set by $\mathbb{C}[w,w^{-1}]^0$. Thus (4.1) implies that if $p(w) \in I_{-n}$, then $p(w)$ multiplied by any Laurent polynomial in $\mathbb{C}[w,w^{-1}]^0$ belongs to I_{-n}. This means that I_{-n} is a $\mathbb{C}[w,w^{-1}]^0$-submodule of $\mathbb{C}[w,w^{-1}]^{\epsilon,n}$, where $\mathbb{C}[w,w^{-1}]^{\epsilon,n}$ is regarded as a module over $\mathbb{C}[w,w^{-1}]^0$ by multiplication.

It is known that every nonzero $\mathbb{C}[w,w^{-1}]^0$-submodule of $\mathbb{C}[w,w^{-1}]^{\epsilon,n}$ is a free rank 1 submodule generated by a monic Laurent polynomial (meaning that the coefficient of the higher degree monomial is 1). Denote by b_n^ϵ such a generator for I_{-n} if $I_{-n} \neq 0$ and $b_n^\epsilon(w) = 0$ if $I_{-n} = 0$. We call $b_n^\epsilon(w)$, $k \in \mathbb{N}$ the *characteristic polynomial* of $\mathfrak{p}$.

Let us check conditions (P1), (P2), and (P3) for $\widehat{\mathcal{S}_q^{\epsilon,k}}$. We can immediately see that condition (P1) is satisfied since

$$(\mathcal{S}_q^{\epsilon,k})_0 = \{h(q^{-1/2}T_q) : h(w^{-1}) = h(w)\}$$

is abelian. Let us check (P2).

Lemma 4.4: If $a \in (\mathcal{S}_q^{\epsilon,k})_{-j}$, $(j>0)$ *such that* $[a, (\mathcal{S}_q^{\epsilon,k})_1] = 0$, *then* $a = 0$.

Proof: Take $a \in (\mathcal{S}_q^{\epsilon,k})_{-j}$, $(j>0)$, then $a = z^{-j}(q^{(-j-1)/2}T_q)^{-jk/2} h(q^{(-j-1)/2}T_q)$ with $h(w^{-1}) = -\epsilon^j h(w)$. Consider an arbitrary element of $(\mathcal{S}_q^{\epsilon,k})_1$, namely, $z(T_q)^{k/2} g(T_q)$ with $g(w^{-1}) = -\epsilon g(w)$. We have that

$$\begin{aligned}0 &= [z^{-j}(q^{(-j-1)/2}T_q)^{-jk/2} h(q^{(-j-1)/2}T_q), z(T_q)^{k/2} g(T_q)] \\ &= z^{-j+1}(q^{-j/2}T_q)^{[(-j+1)k]/2}(h(q^{(-j+1)/2}T_q)g(T_q) - h(q^{(-j-1)/2}T_q)g(q^{-j}T_q)) \\ &= z^{-j+1}(q^{-j/2}T_q)^{[(-j+1)k]/2} f(q^{-j/2}T_q)\end{aligned} \tag{4.2}$$

with $f(T_q) = h(q^{1/2}T_q)g(q^{j/2}T_q) - h(q^{-1/2}T_q)g(q^{-j/2}T_q)$. Suppose that $h(w) = a_n w^n + \textit{lower degree terms}$, with $a_n \neq 0$ and take $g(w) = w^m - \epsilon w^{-m}$ with $n \neq -mj$, then

$$0 = f(w) = a_n(q^{(n+mj)/2} - q^{(-n-mj)/2}) w^{m+n} + \textit{lower degree terms}$$

which is a contradiction, therefore $a = 0$. ∎

To check (P3) we will need the following lemma.

Lemma 4.5: Let $\{b_n^\epsilon : n \in \mathbb{N}\}$ *be the sequence of characteristic polynomials of a parabolic subalgebra* $\mathfrak{p}$ *of the Lie algebra* $\widehat{\mathcal{S}_q^{\epsilon,k}}$. *Then*

(1) $b_n^\epsilon(w) \in \mathbb{C}[w,w^{-1}]^{\epsilon,n}$;
(2) $b_n^\epsilon(w)$ *divides*

$$(q^{(-n-1)/2}w - \epsilon q^{(n+1)/2}w^{-1})((q^{-1}-1)q^{1/2}w - \epsilon^{-n-1}(q-1)q^{-1/2}w^{-1}) b_{n+1}^\epsilon(q^{-1/2}w);$$

(3) $b_{n+m}^\epsilon(w)$ *divides* $(q^{m/2} - q^{-m/2})(w + \epsilon^{-n}w^{-1}) b_n^\epsilon(q^{m/2}w) b_m^\epsilon(q^{n/2}w)$;

(4) $\mathfrak{p}_{-n} \neq 0$ for all $n \in \mathbb{N}$.

In particular all $b_n^\epsilon(w)$ *are nonzero.*

Proof: Part (1) follows from the definition of the characteristic polynomial. Computing

$$[z(T_q)^{k/2}(T_q - \epsilon T_q^{-1}), z^{-n-1}(q^{-n/2-1}T_q)^{[(-n-1)k]/2} b_{n+1}^\epsilon(q^{(-n/2)-1}T_q)]$$
$$= z^{-n}(q^{(-n-1)/2}T_q)^{-nk/2}((q^{-n-1}T_q - \epsilon q^{n+1}T_q^{-1})b_{n+1}^\epsilon(q^{(-n/2)-1}T_q) - (T_q - \epsilon T_q^{-1})b_{n+1}^\epsilon(q^{-n/2}T_q))$$

we see that $b_n^\epsilon(q^{(-n-1)/2}w)$ divides

$$(q^{-n-1}w - \epsilon q^{n+1}w^{-1})b_{n+1}^\epsilon(q^{(-n/2)-1}w) - (w - \epsilon w^{-1})b_{n+1}^\epsilon(q^{-n/2}w). \tag{4.3}$$

From the commutation relation

$$[z(T_q)^{k/2}(T_q - \epsilon T_q^{-1}), z^{-n-1}(q^{(-n/2)-1}T_q)^{[(-n-1)k]/2}(q^{(-n/2)-1}T_q - \epsilon^{-n-1}q^{(n/2)+1}T_q^{-1})b_{n+1}^\epsilon(q^{(-n/2)-1}T_q)]$$
$$= z^{-n}(q^{(-n-1)/2}T_q)^{-nk/2}((q^{-n-1}T_q - \epsilon q^{n+1}T_q^{-1})(q^{(-n/2)-1}T_q - \epsilon^{-n-1}q^{(n/2)+1}T_q^{-1})b_{n+1}^\epsilon(q^{(-n/2)-1}T_q)$$
$$- (T_q - \epsilon T_q^{-1})(q^{-n/2}T_q - \epsilon^{-n-1}q^{n/2}T_q^{-1})b_{n+1}^\epsilon(q^{-n/2}T_q))$$

we see that $b_n^\epsilon(q^{(-n-1)/2}w)$ divides

$$(q^{-n-1}w - \epsilon q^{n+1}w^{-1})((q^{(-n/2)-1}w - \epsilon^{-n-1}q^{(n/2)+1}w^{-1})b_{n+1}^\epsilon(q^{(-n/2)-1}w)$$
$$- (w - \epsilon w^{-1})(q^{-n/2}w - \epsilon^{-n-1}q^{n/2}w^{-1})b_{n+1}^\epsilon(q^{-n/2}w)). \tag{4.4}$$

Now, from (4.3) and (4.4) we see that $b_n^\epsilon(q^{(-n-1)/2}w)$ divides

$$(q^{-n-1}w - \epsilon q^{n+1}w^{-1})((q^{-1}-1)q^{-n/2}w - \epsilon^{-n-1}(q-1)q^{n/2}w^{-1})b_{n+1}^\epsilon(q^{(-n/2)-1}w).$$

This proves (2), and we can deduce that if $b_{n+1}^\epsilon(w) \neq 0$, then $b_n^\epsilon(w) \neq 0$.

Part (3) can be similarly proved by computing the following two commutators:

$$[z^{-n}(q^{(-n-1)/2}T_q)^{(-n)k/2}b_n^\epsilon(q^{(-n-1)/2}T_q), z^{-m}(q^{(-m-1)/2}T_q)^{(-m)k/2}b_m^\epsilon(q^{(-m-1)/2}T_q)]$$

and

$$[z^{-n}(q^{(-n-1)/2}T_q)^{(-n)k/2}(q^{(-n-1)/2}T_q - \epsilon^{-n}q^{(n+1)/2}T_q^{-1})b_n^\epsilon(q^{(-n-1)/2}T_q),$$
$$z^{-m}(q^{(-m-1)/2}T_q)^{(-m)k/2}b_m^\epsilon(q^{(-m-1)/2}T_q)].$$

In particular, if $b_k^\epsilon(w) \neq 0$ and $b_l^\epsilon(w) \neq 0$, then $b_{l+k}^\epsilon(w) \neq 0$. Part (4) follows immediately from (2) and (3). ■

Given $\mathfrak{p}$ a parabolic subalgebra of $\widehat{\mathcal{S}_q^{\epsilon,k}}$, by the lemma above, we have that it is nondegenerate. Take

$$a = z^{-1}(q^{-1}T_q)^{-k/2}b_1^\epsilon(q^{-1}T_q) \in \mathfrak{p}_{-1}, \tag{4.5}$$

where b_1^ϵ is the first characteristic polynomial of $\mathfrak{p}$. Then, $\mathfrak{p}^a$ is, by Lemma 4.1, the minimal parabolic subalgebra containing a. Using again the above lemma, we know that it is nondegenerate, therefore by definition a is nondegenerate, and by construction $\mathfrak{p}^a \subseteq \mathfrak{p}$, proving (P3).

Now, consider $\lambda \in (\widehat{\mathcal{S}_q^{\epsilon,k}})_0^*$. Let $L(\lambda) = L(\widehat{\mathcal{S}_q^{\epsilon,k}}, \lambda)$ denote the unique irreducible quotient of $M(\lambda) = M(\widehat{\mathcal{S}_q^{\epsilon,k}}, \lambda)$. A functional $\lambda \in (\widehat{\mathcal{S}_q^{\epsilon,k}})_0^*$ is described by its labels $\Delta_n = q(n)\lambda((q^{-1/2}T_q)^n - (q^{-1/2}T_q)^{-n})$ with $n \in \mathbb{Z}$, $q(n) = q^{n/2} - q^{-n/2}$, and the central charge $\lambda(C) = c$. We will consider the generating series

$$\Delta(x) = \sum_{n \in \mathbb{Z}} x^n \Delta_n.$$

Recall that a *quasipolynomial* is a linear combination of functions of the form $p(x)q^{\alpha x}$, where

$p(x)$ is a polynomial and $\alpha \in \mathbb{C}$. That is, it satisfies a nontrivial linear differential equation with constant coefficients. We also have the following well-known proposition.

Proposition 4.6: Given a quasipolynomial P, and a polynomial $B(x)=\Pi_i(x-A_i)$, *take* $b(x)=\Pi_i(x-a_i)$ *where* $a_i=e^{A_i}$, *then* $b(x)(\Sigma_{n\in\mathbb{Z}}P(n)x^{-n})=0$ *if and only if* $B(d/dx)P(x)=0$.

If the polynomial B is even we call P an *even quasipolynomial*. We will prove the main theorem of this section.

Theorem 4.7: *An irreducible highest weight* $\widehat{\mathcal{S}_q^{\epsilon,k}}$*-module* $L(\lambda)$ *is quasifinite if and only if one of the following equivalent conditions hold.*

(a) There exists a monic Laurent polynomial $b_1^\epsilon(w)\in\mathbb{C}^{\epsilon,1}[w,w^{-1}]$ *such that*

$$b_1^\epsilon(x)(\Delta(x)-2c)=0. \tag{4.6}$$

(b) There exists an even quasipolynomial $P_\epsilon(x)$ *such that*

$$P_\epsilon(n)=\Delta_n \quad \text{for } n\neq 0 \text{ and } P(0)=2c. \tag{4.7}$$

Proof: We can apply Theorem 4.3. Therefore the quasifiniteness of $L(\lambda)$ is equivalent to show that there exist a nondegenerate element $a\in(\widehat{\mathcal{S}_q^{\epsilon,k}})_{-1}$, such that $\lambda([(\widehat{\mathcal{S}_q^{\epsilon,k}})_1,a])=0$. Take a as in (4.5). Since $b_1^\epsilon(w)\in\mathbb{C}^{\epsilon,1}[w,w^{-1}]$, then we have that $b_1^\epsilon(w)=a_m(w^m-\epsilon w^{-m})+a_{m-1}(w^{m-1}-\epsilon w^{-m+1})+\ldots+a_1(w-\epsilon w^{-1})+a_0(1-\epsilon)$ with $a_m\neq 0$. Recall that a base for $(\widehat{\mathcal{S}_q^{\epsilon,k}})_1$ is

$$\mathcal{B}=\{z(T_q)^{k/2}(T_q^n-\epsilon T_q^{-n}):n\in\mathbb{N}\}$$

if $\epsilon=1$ and $\mathcal{B}\cup\{z(T_q)^{k/2}\}$ if $\epsilon=-1$. Therefore $(\forall n)$,

$$\begin{aligned}
0&=\lambda([z(T_q)^{k/2}(T_q^n-\epsilon T_q^{-n}),a])\\
&=\lambda(b_1^\epsilon(T_q)(T_q^n-\epsilon T_q^{-n})-(q^{-n}T_q^n-\epsilon q^n T_q^{-n})b_1^\epsilon(q^{-1}T_q)-\mathrm{tr}_0(b_1^\epsilon(w)(w^n-\epsilon w^{-n}))C)\\
&=\lambda\left(\sum_{j=0}^m a_j((T_q^j-\epsilon T_q^{-j})(T_q^n-\epsilon T_q^{-n})-(q^{-n}T_q^n-\epsilon q^n T_q^{-n})(q^{-j}T_q^j-\epsilon q^j T_q^{-j}))+\mathrm{tr}_0(b_1^\epsilon(w)(w^n-\epsilon w^{-n}))C\right)\\
&=\sum_{j=0}^m a_j(q\ (n+j)\lambda((q^{-1/2}T_q)^{j+n}-(q^{-1/2}T_q)^{-j-n})-\epsilon q(n-j)\lambda((q^{-1/2}T_q)^{n-j}-(q^{-1/2}T_q)^{-n+j})\\
&\quad-\lambda(\mathrm{tr}_0(b_1^\epsilon(w)(w^n-\epsilon w^{-n}))C)\\
&=\sum_{j=0}^m a_j(\Delta_{j+n}-\epsilon\Delta_{n-j})+2\epsilon a_n c.
\end{aligned} \tag{4.8}$$

We also have for the case $\epsilon=-1$,

$$0=\lambda[a,zT_q^{k/2}]=\lambda(b_1^\epsilon(T_q)-b_1^\epsilon(q^{-1}T_q))=\sum_{j=0}^m a_j\lambda(q(j)((q^{-1/2}T_q)^j-(q^{-1/2}T_q)^{-j}))=\sum_{j=0}^m a_j\Delta_j. \tag{4.9}$$

Multiplying the last equality in (4.8) by $x^n-\epsilon x^{-n}$, adding over $n\in\mathbb{Z}_{\geqslant 0}$, and using the fact that $\Delta_n=\Delta_{-n}$ and (4.9) when $\epsilon=-1$, we get

$$0=\sum_{j=0}^m a_j(x^{-j}-\epsilon x^j)\Delta(x)+2\epsilon b_1^\epsilon(x)c=-\epsilon b_1^\epsilon(x)(\Delta(x)-2c). \tag{4.10}$$

The equivalence of (a) and (b) follows from the fact that Eq. (4.6) holds, if and only if multiplying both sides of this formula by x^m this equation also holds, and now $\widetilde{b}^\epsilon(x)=x^m b_1^\epsilon(x)\in\mathbb{C}[x]$. Observe that $\widetilde{b}^\epsilon(0)=a_m\neq 0$, and since $b_1^\epsilon(x^{-1})=-\epsilon b_1^\epsilon(x)$ it is easy to see that if α is a root of $\widetilde{b}^\epsilon(x)$, then $1/\alpha$

is also a root of $\widetilde{b}^{\epsilon}(x)$. Now we can apply Proposition 4.6 and due to the relationship between the roots of B and b in this proposition it follows that the $B(x)$ corresponding to our $\widetilde{b}^{\epsilon}(x)$ is an even polynomial, finishing our proof. ■

Given a quasifinite irreducible highest weight $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module V by Theorem 4.7, we have that there exists an even quasipolynomial $P(x)$ satisfying (4.7). We will write

$$P(x) = \sum_i p_i(x)\cosh_q(e_i^+ x) + \sum_j q_j(x)\sinh_q(e_j^- x), \tag{4.11}$$

with $p_i(x)$ [respectively, $q_j(x)$] are nonzero even (respectively, odd) polynomials, e_i^+ and e_j^- are distinct complex numbers, $\cosh_q(x)=(q^x+q^{-x})/2$ and $\sin_q(x)=(q^x-q^{-x})/2$. The expression in (4.11) is unique up to a sign of e_i^+ or a simultaneous change of signs of e_j^- and $q_j(x)$. We call e_i^+ (respectively, e_j^-), *even type* (*respectively, odd type*) *exponents* of V with *multiplicities* $p_i(x)$ [respectively, $q_j(x)$]. As in Ref. 6, we denote e^+ the set of even type exponents with multiplicity $p_i(x)$ and by e^- the set of odd type of exponents with multiplicity $q_i(x)$. Therefore the pair $(e^+;e^-)$ uniquely determines V. We will denote this module by $L(\widehat{\mathcal{S}_q^{k,\epsilon}};e^+;e^-)$.

V. EMBEDDING OF $\widehat{\mathcal{S}_q^{\epsilon,k}}$ INTO INFINITE RANK CLASSICAL LIE ALGEBRAS

Let $\mathcal{O}$ be the algebra of all holomorphic functions on $\mathbb{C}^\times$ with the topology of uniform convergence on compact sets, and denote

$$\mathcal{O}^{\epsilon,j} = \{f \in \mathcal{O} | f(w) = -\epsilon^j f(w^{-1})\}.$$

We consider the vector space $\mathcal{S}_q^{\mathcal{O}^{as}}$ spanned by the quantum pseudodifferential operators (of infinite order) of the form $z^k f(T_q)$, where $f \in \mathcal{O}$. The product in $\mathcal{S}_q^{as}$ and its principal gradation extend to $\mathcal{S}_q^{\mathcal{O}^{as}}$. Denote by $\mathcal{S}_q^{\mathcal{O}}$ the corresponding Lie algebra. Then the cocycle Ψ extends by formula (3.1). Let $\widehat{\mathcal{S}}_q^{\mathcal{O}}=\mathcal{S}_q^{\mathcal{O}}+\mathbb{C}C$ be the corresponding central extension. Similarly we define

$$\widehat{\mathcal{S}_q^{k,\epsilon^{\mathcal{O}}}} = \mathcal{S}_q^{k,\epsilon^{\mathcal{O}}} + \mathbb{C}C$$

the central extension of $\mathcal{S}_q^{k,\epsilon^{\mathcal{O}}}$ by the restriction of the cocycle Ψ, where

$$\mathcal{S}_q^{k,\epsilon^{\mathcal{O}}} = \{z^l (q^{(l-1)/2}T_q)^{lk/2} f(q^{(l-1)/2}T_q) | l \in \mathbb{Z}, f \in \mathcal{O}^{\epsilon,l}\}.$$

We shall construct an embedding of $\widehat{\mathcal{S}_q^{\epsilon,k}}$ into the Lie algebra of infinite matrices with only finitely many nonzero diagonal, over the algebra of truncated polynomials and its classical Lie subalgebras of type B, C, and D.

As in Sec. II, consider the associative algebra $R_m=\mathbb{C}[t]/(t^{m+1})$ with $m \in \mathbb{Z}_+$. Recall that $g\ell_\infty^{[m]}$ is the $\mathbb{Z}$-graded complex Lie algebra of all infinite matrices $(a_{i,j})_{i,j\in\mathbb{Z}}$ with finitely many nonzero diagonals with entries in R_m.

Let us fix $s \in \mathbb{C}^\times$, then we have a family of homomorphism $\varphi_s: \mathcal{S}_q \to g\ell_\infty^{[m]}$ which is compatible with the principal gradation, defined by

$$\varphi_{s,t}(z^k f(T_q)) = \sum_{l\in\mathbb{Z}} f(sq^{-l+t})E_{(l-k),l}. \tag{5.1}$$

Observe that it naturally extends to a homomorphism $\varphi_{s,t}: \mathcal{S}_q^{\mathcal{O}} \to g\ell_\infty^{[m]}$. Let

$$I_s^{[m],\epsilon,l} = \{f(q^{(l-1)/2}T_q) | f \in \mathcal{O}^{\epsilon,l} \text{ and } f^{(i)}(sq^j) = 0 \text{ for all } j \in \mathbb{Z}, i = 0,1,\ldots,m\}$$

and

$$J_s^{[m],k,\epsilon} = \bigoplus_{l\in\mathbb{Z}} z^l (q^{(l-1)/2}T_q)^{lk/2} I_s^{[m],\epsilon,l} \in \mathcal{S}_q^{k,\epsilon^{\mathcal{O}}}.$$

Therefore, it follows by the Taylor formula for $\varphi_s^{[m]}: \mathcal{S}_q^{\epsilon,k} \to g\ell_\infty^{[m]}$, that

$$\operatorname{Ker} \varphi_s^{[m]} = J_s^{[m],k,\epsilon}. \tag{5.2}$$

Choose a branch of $\log q$. Let $\tau = \log q/2\pi i$. Then any $s \in \mathbb{C}^\times$ is uniquely written as $s = q^a$, $a \in \mathbb{C}/\tau^{-1}\mathbb{Z}$. Now, let fix $\mathbf{s} = (s_1, \ldots, s_n) \in \mathbb{C}^n$ such that if we write each $s_i = q^{a_i}$, we have

$$a_i - a_j \notin \mathbb{Z} + \tau^{-1}\mathbb{Z} \quad \text{for } i \neq j, \tag{5.3}$$

and fix $\mathbf{m} = (m_1, \ldots, m_n) \in \mathbb{Z}_+^n$.

Let $g\ell_\infty^{[\mathbf{m}]} = \oplus_{i=1}^n g\ell_\infty^{[m_i]}$. Consider the homomorphism

$$\varphi_{\mathbf{s}}^{[\mathbf{m}]} = \bigoplus_{i=1}^n \varphi_{s_i}^{[m_i]}: \mathcal{S}_q^{k,\epsilon^{\mathcal{O}}} \to g\ell_\infty^{[\mathbf{m}]}.$$

Proposition 5.1: Given $\mathbf{s}$ *and* $\mathbf{m}$ *as above, we have the exact sequence of* $\mathbb{Z}$*-graded Lie algebras, provided that* $|q| \neq 1$:

$$0 \to J_{\mathbf{s}}^{[\mathbf{m}],k,\epsilon} \to \mathcal{S}_q^{k,\epsilon^{\mathcal{O}}} \xrightarrow{\varphi_{\mathbf{s}}^{[\mathbf{m}]}} g\ell_\infty^{[\mathbf{m}]} \to 0$$

where $J_{\mathbf{s}}^{[\mathbf{m}],k,\epsilon} = \cap_{i=1}^n J_{s_i}^{[m_i],k,\epsilon}$.

Proof: The first part is clear from (5.2). For the sake of simplicity, we will prove the surjectivity of $\varphi_{\mathbf{s}}^{[\mathbf{m}]}$ in the case $N=1$, $\mathbf{m}=m$ and $\mathbf{s}=s=q^a$. We will use the following well-known fact: for every discrete sequence of points in $\mathbb{C}$ and a non-negative integer m there exists $f(w) \in \mathcal{O}$ having prescribed values of its first m derivatives at these points. By condition (5.3) and $|q| \neq 1$ we have that $\{q^{(n-1)/2-j+a}\}$ and $\{q^{-(n-1)/2+j-a}\}$ are discrete and disjoint sequences of points in $\mathbb{C}$. Therefore we can find $p \in \mathcal{O}$ such that $p^{(i)}(q^{(n-1)/2-j+a}) = p^{(i)}(q^{-(n-1)/2+j-a}) = 0$ for $i = 0, \ldots, m-1$ and $j \in \mathbb{Z}$,

$$p^{(m)}(q^{(n-1)/2-j+a}) = 1, \quad p^{(m)}(q^{-(n-1)/2+j-a}) = -\epsilon^j(-1)^m q^{2m\{[-(n-1)/2]+j-a\}}$$

for a fixed value of j and zero for the remaining points in the sequences. Now let $f(w) = [p(w) - \epsilon^n p(w^{-1})]/2$. Using Taylor formula for φ_s^m and the way we choose p it is a straightforward computation that the image of $z^n(q^{(n-1)/2}T_q)^{nk/2} f(q^{(n-1)/2}T_q)$ is up to a nonzero constant $(t^m/m!)E_{j-n,j}$. Similarly one can show that $[t^{m-1}/(m-1!)]E_{j-n,j}$ is also in the image, and then inductively completing the proof. ∎

Now we want to extend the homomorphism $\varphi_s^{[m]}$ to a homomorphism between the central extensions of the corresponding Lie algebras.

Proposition 5.2: The $\mathbb{C}$*-linear map* $\hat{\varphi}_s^{[m]}: \widehat{\mathcal{S}_q^{k,\epsilon}} \to \widehat{g\ell}_\infty^{[m]}$ *defined by* $(s = q^a)$,

$$\hat{\varphi}_s^{[m]}|_{(\widehat{\mathcal{S}_q^{k,\epsilon}})_j} = \varphi_s^{[m]}|_{(\mathcal{S}_q^{k\epsilon})_j} \quad \text{if } j \neq 0, \tag{5.4}$$

$$\widehat{\varphi_s^{[m]}}(q(n)(q^{-n/2}T_q^n - q^{n/2}T_q^{-n})) = \varphi_s^{[m]}(q(n)(q^{-n/2}T_q^n - q^{n/2}T_q^{-n})) - \sum_{j=1}^m \frac{q^{(a-1/2)n} + (-1)^j q^{(-a+1/2)n}}{q^{n/2} - q^{-n/2}} (n\log q)^j \frac{t^j}{j!} \quad (n \neq 0), \tag{5.5}$$

$$\hat{\varphi}_s^{[m]}(C) = 1 \in R_m, \tag{5.6}$$

is a homomorphism of Lie algebras over $\mathbb{C}$.

Proof: It is straightforward computation restricting the formula of $\widehat{\varphi_s^{[m]}}$ in (6.5) of Ref. 5, to $\widehat{\mathcal{S}_q^{k,\epsilon}}$. ∎

The homomorphism $\varphi_s^{[m]}: \mathcal{S}_q^{k,\epsilon} \to g\ell_\infty^{[m]}$ is defined for any $s \in \mathbb{C}^\times$. However if $s=q^a$ with $a \in \mathbb{Z}/2$, it is no longer surjective. The case $a=1$ is described by the following.

Proposition 5.3: We have the following exact sequences of Lie algebras:

$$0 \to J_q^{[m],k,1} \to \mathcal{S}_q^{k,1} \xrightarrow{\varphi_q^{[m]}} d_\infty^{[m]} \to 0,$$

$$0 \to J_q^{[m],k,-1} \to \mathcal{S}_q^{k,-1} \xrightarrow{\varphi_q^{[m]}} c_\infty^{[m]} \to 0.$$

Proof: By definition of $\varphi_q^{[m]}$, it is easy to see that its image lies in $d_\infty^{[m]}$ or $c_\infty^{[m]}$ depending if $\epsilon=1$ or -1. The proof of the rest is similar to that of Proposition 5.1. ■

Similarly, the case $a=1/2$, is described by the following.

Proposition 5.4: We have the following exact sequences of Lie algebras:

$$0 \to J_{q^{1/2}}^{[m],k,1} \to \mathcal{S}_q^{k,1} \xrightarrow{\varphi_{q^{1/2}}^{[m]}} \overline{b_\infty^{+}}^{[m]} \to 0,$$

$$0 \to J_{q^{1/2}}^{[m],k,-1} \to \mathcal{S}_q^{k,-1} \xrightarrow{\varphi_{q^{1/2}}^{[m]}} \overline{b_\infty^{-}}^{[m]} \to 0.$$

Remark 5.5: For arbitrary $a \in \mathbb{Z}$ the image of $\widehat{\mathcal{S}_q^{k,1}}$ by $\varphi_{q^a}^{[m]}$ is $\nu^{q^a}(d_\infty^{[m]})$ and the image of $\widehat{\mathcal{S}_q^{k,-1}}$ by $\varphi_{q^a}^{[m]}$ is $\nu^{q^a}(c_\infty^{[m]})$, where ν was defined in (2.1). Similarly, for $a \in \mathbb{Z}+1/2$ the image of $\widehat{\mathcal{S}_q^{k,\epsilon}}$ by $\varphi_{q^a}^{[m]}$ is $\nu^{q^a}(b_\infty^{[m]})$. Therefore it is enough to consider $a=1$ and $a=1/2$.

We will say that a vector $\mathbf{s}=(s_1,s_2,\ldots,s_N)=(q^{a_1},\ldots,q^{a_N}) \in \mathbb{C}^N$ satisfies the *condition* if $a_i \in \mathbb{Z}$, then $a_i=1$; if $a_i \in \mathbb{Z}+1/2$ then $a_i=1/2$, and $a_i-a_j \notin \mathbb{Z}+\tau^{-1}\mathbb{Z}$ for $i \neq j$.

Now, given $\mathbf{s}=(s_1,s_2,\ldots,s_N)=(q^{a_1},\ldots,q^{a_N}) \in \mathbb{C}^N$ satisfying the "condition" above and $\mathbf{m}=(m_1,\ldots,m_n) \in \mathbb{Z}^N$, and combining Propositions 5.1–5.4, we obtain a surjective Lie algebra homomorphism

$$\hat{\varphi}_{\mathbf{s}}^{[\mathbf{m}]} = \bigoplus_{i=1}^{n} \varphi_{s_i}^{[m_i]} : \widehat{\mathcal{S}_q^{k,\epsilon}}^{\mathcal{O}} \to \mathfrak{g}^{[\mathbf{m}]} := \bigoplus_{i=1}^{n} \mathfrak{g}^{[m_i]}, \tag{5.7}$$

where

$$\mathfrak{g}^{[m_i]} = \begin{cases} \widehat{g\ell}_\infty^{[m_i]} & \text{if } a_i \notin \mathbb{Z}/2, \\ b_\infty^{[m_i]} & \text{if } a_i = 1/2, \\ d_\infty^{[m_i]} & \text{if } a_i = 1 \text{ and } \epsilon = 1, \\ c_\infty^{[m_i]} & \text{if } a_i = 1 \text{ and } \epsilon = -1. \end{cases} \tag{5.8}$$

VI. REALIZATION OF QUASIFINITE HIGHEST WEIGHT MODULES OF $\widehat{\mathcal{S}_q^{\epsilon,k}}$

Here $\mathfrak{g}^{[m]}$ will be $\widehat{g\ell}_\infty^{[m]}$ or one of its classical subalgebras. The proof of the following result is in Ref. 3.

Proposition 6.1: The $\mathfrak{g}^{[m]}$*-module* $L(\mathfrak{g}^{[m]};\lambda)$ *is quasifinite if and only if all but finitely many of the* ${}^{\dagger}h_j^{(i)}$ *are zero, where* $\dagger$ *represents a, b, c or d depending on whether* $\mathfrak{g}^{[m]}$ *is* $\widehat{g\ell}_\infty^{[m]}$, $b_\infty^{[m]}$, $c_\infty^{[m]}$ *or* $d_\infty^{[m]}$.

Take a quasifinite $\lambda(i) \in (\mathfrak{g}_0^{[m_i]})^*$ for each $i=1,\ldots,N$, and let $L(\mathfrak{g}^{[m_i]};\lambda(i))$ be the corresponding irreducible $\mathfrak{g}^{[m_i]}$-module. The outer tensor product

$$L(\mathfrak{g}^{[\mathbf{m}]};\lambda)=\otimes_{i=1}^{n}L(\mathfrak{g}^{[m_i]};\lambda(i))$$

is an irreducible $\mathfrak{g}^{[\mathbf{m}]}$-module. The module $L(\mathfrak{g}^{[\mathbf{m}]};\lambda)$ can be regarded as $\widehat{\mathcal{S}_q^{\epsilon,k}}$-module via the homomorphism $\widehat{\varphi_{\mathbf{s}}^{[\mathbf{m}]}}$ given by (5.7), which we shall denote by $L_{\mathbf{s}}^{[\mathbf{m}],k,\epsilon}(\lambda)$.

We shall need the following Proposition, whose proof is completely similar to Proposition 4.3 in Ref. 5.

Proposition 6.2: Let V be a quasifinite $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module. Then the action of $\widehat{\mathcal{S}_q^{k,\epsilon}}$ on V naturally extends to the action of $(\widehat{\mathcal{S}_q^{k,\epsilon}}^{\mathcal{O}})_j$ on V for any $j\neq 0$.

Given $\mathbf{m}=(m_1,\ldots,m_n)\in\mathbb{Z}_+^n$, we let $\mathfrak{g}^{[\mathbf{m}]}=\oplus_{i=1}^{n}\mathfrak{g}^{[m_i]}$. Let $\mathbf{s}=(s_1,\ldots,s_n)$ satisfying the "condition." By Proposition 5.1(4), we have that $\hat{\varphi}_{\mathbf{s}}^{[\mathbf{m}]}:\widehat{\mathcal{S}_q^{k,\epsilon}}\to\mathfrak{g}^{[\mathbf{m}]}$ is a surjective homomorphism of Lie algebras over $\mathbb{C}$.

Now we have the following important result.

Theorem 6.3: *Let $\mathbf{s}=(s_1,\ldots,s_n)$ satisfying the "condition." Consider the embedding $\hat{\varphi}_{\mathbf{s}}^{[\mathbf{m}]}:\widehat{\mathcal{S}_q^{k,\epsilon}}\to\mathfrak{g}^{[\mathbf{m}]}$ and let V be a quasifinite $\mathfrak{g}^{[\mathbf{m}]}$-module. Then any $\widehat{\mathcal{S}_q^{k,\epsilon}}$-submodule of V is a $\mathfrak{g}^{[\mathbf{m}]}$-submodule as well. In particular, the $\widehat{\mathcal{S}_q^{k,\epsilon}}$-modules $L_{\mathbf{s}}^{[\mathbf{m}],k,\epsilon}(\lambda)$ are irreducible.*

Proof: The same proof as Theorem 4.5 in Ref. 5. ■

By Proposition 6.1 and Theorem 6.3, we have that the $\widehat{\mathcal{S}_q^{k,\epsilon}}$-modules $L_{\mathbf{s}}^{[\mathbf{m}],k,\epsilon}(\lambda)$ are irreducible quasifinite highest weight modules. Using the formulas (5.4) and (5.6), we can calculate the generating series $\Delta_{\mathbf{m},\mathbf{s},\lambda}^{k,\epsilon}(x)=\Sigma_n\Delta_n x^{-n}$ of the highest weight and the central charge c of the $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module $L_{\mathbf{s}}^{[\mathbf{m}],k,\epsilon}(\lambda)$. We will introduce the following notation:

$$\eta_i(\alpha,\beta):=\frac{q^{\alpha\beta}+(-1)^i q^{-\alpha\beta}}{q^{\alpha/2}-q^{-\alpha/2}}\frac{(\beta\log q)^i}{i!}. \tag{6.1}$$

Proposition 6.4: Take the embedding $\hat{\varphi}_s^{[m]}:\widehat{\mathcal{S}_q^{k,\epsilon}}\to\widehat{g\ell_\infty^{[m]}}$ with $s=q^a$ and $a\notin\mathbb{Z}/2$. The $\widehat{g\ell_\infty^{[m]}}$-module $L(\widehat{g\ell_\infty^{[m]}};\lambda)$ regarded as a $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module is isomorphic to $L(\widehat{\mathcal{S}_q^{k,\epsilon}};e^+,e^-)$ where e^+ and e^- consists of the exponents $a-j-1$, $(j\in\mathbb{Z})$ with multiplicities,

$$\sum_{0\leqslant i\leqslant m,\,i\ even}{}^a\tilde{h}_j^{(i)}\frac{x^i}{i!}\quad and\quad \sum_{0\leqslant i\leqslant m,\,i\ odd}{}^a\tilde{h}_j^{(i)}\frac{x^i}{i!}, \tag{6.2}$$

respectively, with ${}^a\tilde{h}_j^{(i)}=({}^ah_j^{(i)}-\delta_{0,j}c_i)(\log q)^i$.

Proof: By Proposition 6.1 and Theorem 6.3 the $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module $L_s^{[m],k,\epsilon}(\lambda)$ is an irreducible quasifinite highest weight module. By applying λ to (5.5) and using formulas (5.1) and (6.1), we obtain $(n\in\mathbb{Z})$

$$\begin{aligned}(\Delta_{m,s,\lambda}^{k,\epsilon})_n=&-q(n)\lambda\Bigg(\sum_{j\in\mathbb{Z}}\sum_{i=0}^{m}(q^{n(a-j-1/2)}-(-1)^iq^{-n(a-j-1/2)})(n\log q)^i\frac{t^i}{i!}E_{jj}\\&-\sum_{i=0}^{m}\frac{q^{(a-1)n}+(-1)^iq^{(-a+1)n}}{q^{n/2}-q^{-n/2}}\frac{(n\log q)^i}{i!}t^i\Bigg)\\=&-q(n)\lambda\Bigg(\sum_{j\in\mathbb{Z}}\sum_{i=0}^{m}(\eta_i(a-j,n)-\eta_i(a-j-1,n))t^iE_{jj}-\sum_{i=0}^{m}\eta_i(a-1,n)t^i\Bigg).\end{aligned} \tag{6.3}$$

Shifting the index j to $j+1$ in the first sum of the last identity in (6.3) we have

$$(\Delta_{m,s,\lambda}^{k,\epsilon})_n=-q(n)\Bigg(\sum_{j\in\mathbb{Z}}\sum_{i=0}^{m}\eta_i(a-j-1,n)^ah_j^{(i)}-\sum_{i=0}^{m}\eta_i(a-1,n)c_i\Bigg). \tag{6.4}$$

Using the definition of multiplicities and exponents for the quasipolynomial in Theorem 4.7 (b), we finish our proof. ■

Proposition 6.5: Take $s=q^a$, $a=1/2$ *and the embedding* $\hat{\varphi}_s^{[m]}:\widehat{\mathcal{S}_q^{k,\epsilon}}\to b_\infty^{[m]}$. *The* $b_\infty^{[m]}$*-module* $L(b_\infty^{[m]};\lambda)$ *regarded as a* $\widehat{\mathcal{S}_q^{k,\epsilon}}$*-module is isomorphic to* $L(\widehat{\mathcal{S}_q^{k,\epsilon}};e^+,e^-)$ *where* e^+ *and* e^- *consists of the exponents* $-j-1/2$, $(j\in\mathbb{Z}_{\geqslant 0})$ *with multiplicities*

$$\sum_{0\leqslant i\leqslant m,i\ even} {}^b\widetilde{h}_j^{(i)}\frac{x^i}{i!} \quad \text{and} \quad \sum_{0\leqslant i\leqslant m,i\ odd} {}^b\widetilde{h}_j^{(i)}\frac{x^i}{i!}, \tag{6.5}$$

respectively, where ${}^b\widetilde{h}_j^{(i)}={}^bh_j^{(i)}(\log q)^i$ *for* $j>0$ *and* ${}^b\widetilde{h}_0^{(i)}=1/2\,{}^bh_0^{(i)}(\log q)^i$.

Proof: Replacing $a=1/2$ in (6.3) and shifting the index j to $j+1$ in its first summation we get

$$(\Delta_{m,s,\lambda}^{k,\epsilon})_n=-q(n)\lambda\left(\sum_{j\in\mathbb{Z}}\sum_{i=0}^{m}\eta_i(-j-1/2,n)(t^iE_{j+1,j+1}-t^iE_{jj})-\sum_{i=0}^{m}(\eta_i(-1/2,n)t_i\right). \tag{6.6}$$

Now, splitting the summation $\Sigma_{j\in\mathbb{Z}}$ into two, namely $\Sigma_{j\geqslant 0}+\Sigma_{j\leqslant 0}$, changing j by $-j-1$ in the negative index sums, using the fact that $\eta_i(\alpha,\beta)=(-1)^i\eta_i(-\alpha,\beta)$ and formulas (2.7), we have

$$(\Delta_{m,s,\lambda}^{k,\epsilon})_n=-q(n)\sum_{j\geqslant 0}\sum_{i=0}^{m}\eta_i(-j-1/2,n)\,{}^b\widetilde{h}_j^{(i)}/(\log q)^i \tag{6.7}$$

now the proposition follows from the definition of multiplicities and exponents applied to the quasipolynomial given by Theorem 4.7. ■

Proposition 6.6: Consider $s=q^a$, $a=1$.

(*a*) ($\epsilon=1$). *Take the embedding* $\hat{\varphi}_s^{[m]}:\widehat{\mathcal{S}_q^{k,1}}\to d_\infty^{[m]}$. *The* $d_\infty^{[m]}$*-module* $L(d_\infty^{[m]};\lambda)$ *regarded as a* $\widehat{\mathcal{S}_q^{k,1}}$*-module is isomorphic to* $L(\widehat{\mathcal{S}_q^{k,1}};e^+,e^-)$ *where* e^+ *and* e^- *consists of the exponents* $-j$, $(j\in\mathbb{Z}_{\geqslant 0})$ *with multiplicities,*

$$\sum_{0\leqslant i\leqslant m,i\ even} {}^d\widetilde{h}_j^{(i)}\frac{x^i}{i!} \quad \text{and} \quad \sum_{0\leqslant i\leqslant m,i\ odd} {}^d\widetilde{h}_j^{(i)}\frac{x^i}{i!}, \tag{6.8}$$

respectively, with ${}^d\widetilde{h}_j^{(i)}={}^dh_j^{(i)}(\log q)^i$ *if* $j>0$ *and* ${}^0\widetilde{h}_j^{(i)}=1/2({}^dh_0^{(i)}-{}^dh_1^{(i)})(\log q)^i$.

(*b*) ($\epsilon=-1$). *Take the embedding* $\hat{\varphi}_s^{[m]}:\widehat{\mathcal{S}_q^{k,1}}\to c_\infty^{[m]}$. *The* $c_\infty^{[m]}$*-module* $L(c_\infty^{[m]};\lambda)$ *regarded as a* $\widehat{\mathcal{S}_q^{k,1}}$*-module is isomorphic to* $L(\widehat{\mathcal{S}_q^{k,1}};e^+,e^-)$ *where* e^+ *and* e^- *consists of the exponents* $-j$, $(j\in\mathbb{Z}_{\geqslant 0})$ *with multiplicities*

$$\sum_{0\leqslant i\leqslant m,i\ even} {}^c\widetilde{h}_j^{(i)}\frac{x^i}{i!} \quad \text{and} \quad \sum_{0\leqslant i\leqslant m,i\ odd} {}^c\widetilde{h}_j^{(i)}\frac{x^i}{i!}, \tag{6.9}$$

respectively, with ${}^c\widetilde{h}_j^{(i)}={}^ch_j^{(i)}(\log q)^i$.

Proof: We leave the details of the proof to the reader since it is completely similar to the proof of Proposition (6.5). ■

Consider an irreducible quasifinite highest weight $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module V and denote by $P(x)$ its corresponding quasipolynomial. We will write

$$P(x)=\sum_{s=q^a\in\mathbb{C}}\sum_{i=0}^{m_s}a_{s,i}\eta_i(x,a-1)\frac{\sinh_q(x/2)}{2} \tag{6.10}$$

with $a_{s,i}\in\mathbb{C}$, and $a_{s,i}\neq 0$ for only finitely many $s\in\mathbb{C}$. We can fix ambiguities in expressing $P(x)$ in the form (6.10) caused by symmetries of (6.1) [namely $\eta_i(\alpha,\beta)=(-1)^i\eta_i(\alpha,-\beta)$], by the following rule inthe choice of the parameter s: when $s=q^a$, with $a\in\mathbb{Z}$ we require $a\leqslant 0$; when $a\in 1/2+\mathbb{Z}$, we ask $a\leqslant 1/2$; when $a\notin 1/2\mathbb{Z}$ we require that $\mathrm{Im}\,a>0$ if $\mathrm{Im}\,a\neq 0$, or $a>1$ if $a\in\mathbb{R}$, where Im denote the imaginary part of a complex number and [ ] denote the closest integer to the number which is not larger than itself.

Now, we decompose the set $\{s \in \mathbb{C} | a_{s,i} \neq 0 \text{ for some } i\}$ into a disjoint union of equivalence classes S under the relation

$$s = q^a \sim s' = q^{a'} \quad \text{if and only if } a - a' \in \mathbb{Z} + \tau^{-1}\mathbb{Z},$$

Then, we choose a representative s of each equivalence class S such that $s=q$ if a lies in $\mathbb{Z}$ and $s=q^{1/2}$ if a lies in $\mathbb{Z}+1/2$. Let $S=\{s=q^a, s_1=q^{a+k_1}, s_2=q^{a+k_2}, \ldots\}$. Take $k_0=0$ and $m=\max_{s\in S} m_s$. It is easy to see by the rules in picking the parameter s that if $a=1$ or $1/2$, then $k_i \in \mathbb{N}$.

Now, we attach to S a $\mathfrak{g}^{[m]}$-module $L_s^{[m]}(\lambda_S)$ in one of the following ways.

If $a \notin \mathbb{Z}/2$, let ${}^a h_{k_r}^{(i)} = a_{s+k_r,i}(\log q)^i$ with $i=0,\ldots,m_s$ and $r=0,1,2,\ldots$. We associate to S the $\widehat{g\ell}_\infty^{[m]}$-module $L_s^{[m]}(\lambda_S)$ with central charges and labels

$$c_i = \sum_{k_r} {}^a h_{k_r}^{(i)}, \quad {}^a\lambda_j^{(i)} = \sum_{k_r \geqslant j} {}^a\widetilde{h}_{k_r}^{(i)},$$

where ${}^a\widetilde{h}_k^{(i)} = {}^a h_k^{(i)} - c_i \delta_{k,0}$.

If $a=1/2$ let ${}^b h_{k_r}^{(i)} = a_{s+k_r,i}(\log q)^i$ with $i=0,\ldots,m_{q^{1/2}}$ and $r=0,1,2,\ldots$. We associate to S the $b_\infty^{[m]}$-module $L_s^{[m]}(\lambda_S)$ with central charges and labels

$$c_i = \sum_{k_r} {}^b h_{k_r}^{(i)}, \quad (i \text{ even}), \quad c_i = 0, \quad (i \text{ odd}),$$

$${}^b\lambda_j^{(i)} = \sum_{k_r \geqslant j} {}^b h_{k_r}^{(i)}, \quad {}^b\lambda_0^{(i)} = \sum_{k_r \geqslant 0} {}^b h_{k_r}^{(i)} \quad (i \text{ odd}),$$

where $j \in \mathbb{N}$ and $i=0,\ldots,m_{q^{1/2}}$.

If $a=1$ and $\epsilon=-1$, let ${}^c h_{k_r}^{(i)} = a_{s+k_r,i}(\log q)^i$ with $j=0,\ldots,m_q$ and $r=0,1,2,\ldots$. We associate to S the $c_\infty^{[m]}$-module $L_s^{[m]}(\lambda_S)$ with central charges and labels

$$c_i = \sum_{k_r} {}^c h_{k_r}^{(i)} \quad (i \text{ even}), \quad c_i = 0 \quad (i \text{ odd}),$$

$${}^c\lambda_j^{(i)} = \sum_{k_r \geqslant j} {}^c h_{k_r}^{(i)},$$

where $j \in \mathbb{N}$ and $i=0,\ldots,m_q$. If $a=1$ and $\epsilon=1$, let ${}^c h_{k_r}^{(i)} = a_{s+k_r,i}(\log q)^i$ with $j=0,\ldots,m_1$ and $r=0,1,2,\ldots$. We associate to S the $d_\infty^{[m]}$-module $L_s^{[m]}(\lambda_S)$ with central charges and labels

$$c_i = \sum_{k_r} {}^d h_{k_r}^{(i)} \quad (i \text{ even}), \quad c_i = 0 \quad (i \text{ odd}),$$

$${}^d\lambda_j^{(i)} = \sum_{k_r \leqslant i} {}^d h_{k_r}^{(i)},$$

where $j \in \mathbb{N}$ and $i=0,\ldots,m_1$.

Denote by $\{s_1, s_2, \ldots, s_N\}$ a set of representatives of the equivalence classes in the set $\{s \in \mathbb{C} | a_{s,j} \neq 0 \text{ for some } j\}$. Theorem 6.3, the $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module $L_{\mathbf{s}}^{[\mathbf{m}],k,\epsilon}(\lambda)$ is irreducible for $\mathbf{s}=(s_1,\ldots,s_N)$ satisfying the "condition." Then by the above discussion, Theorem 6.3, and Propositions 6.4–6.6 we have proved the following.

Theorem 6.7: *Let V be an irreducible quasifinite highest weight $\widehat{\mathcal{S}_q^{k,\epsilon}}$-module with central charge c and let $P(x)$ be the quasipolynomial given by Theorem 4.7 written in the form (6.10). Then V is isomorphic to the tensor product of the modules $L_s^{[m],k,\epsilon}(\lambda_S)$ with distinct equivalence classes S.*

Remark 6.8: A different choice of representatives $s=q^a$ with $a \notin \mathbb{Z}/2$ in the equivalence class

S has the effect of shifting $\widehat{g\ell}_{\infty}^{[m]}$ via the automorphism ν^i for some i. It is not difficult to see that any irreducible quasifinite highest weight module $L(\widehat{\mathcal{S}_q^{k,\epsilon}}, \zeta)$ can be obtained as above in an essentially unique way up to this shift.

In order to find an accurate expression for the inversion probability of a large spin, an asymptotic expansion in series of Bessel functions is found, and a formula for the inversion time is obtained. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1860593]

I. INTRODUCTION

Spin dynamics plays a very important role in the study of molecular magnetic clusters. In particular, if Mössbauer spectroscopy is used, the inversion time of the spin is one of the most important parameters in the structure of the experimental spectra.[1] In a pictorial, intuitive description, as the total electronic spin of the surrounding neighbors inverts its direction, the magnetic field on the iron nucleus also changes. Thus, the nuclear energy levels are modified and we are in the presence of the "Mössbauer relaxation spectrum," with a structure that depends on the frequency of the inversion.[2]

In Ref. 3 the coefficient $|b_n(t)|^2$, which gives the probability of finding the system in the nth spin state, has been calculated and it is found to be a somewhat involute trigonometric sum. An approximate expression for $b_n(t)$ by means of the corresponding Bessel functions was obtained only if $n \ll N$, $\alpha t \ll N$ (N is the total number of spin states, α is a parameter), since the trigonometric sum which runs through all the spin states can be replaced by an integral in a careful way only in this case. Using a heuristic argumentation, this form has been assumed to be valid also for $n=N$, which corresponds to the transition from spin-up to spin-down, and the inversion time has been calculated in this way. It is given by the first maximum of $|b_N(t)|^2$. However, due to the important role of the inversion time, which connects the theory with the experimental spectra, a better calculation is in order, thus justifying in a strict way the approach used in Ref. 3.

In this paper a new formula for the probability amplitude $b_N(t)$, for $N \geqslant 2$ and for any t, is obtained. This exact expression in terms of the Bessel functions with large indexes allows the effective computation of $b_N(t)$ with increasing accuracy (see Fig. 1 in Sec. III).

An asymptotically exact expression is obtained for the spin inversion time. An application of this useful formula is shown in the example of the Fe8 cluster.

II. POSITION OF THE PROBLEM

The Hamiltonian of our system, which involves an entire spin S, has the form: $H=H_0+V$, where H_0 is a static Hamiltonian (e.g., a magnetic field) and V is the term responsible for the transitions between spin states.

Starting from the discrete set of the $N(N=2S+1)$ spin eigenstates $|n\rangle$ of H_0 with energies E_n, we can write the wave function as

a)Electronic mail: p.moretti@ifac.cnr.it

$$\psi(t) = \sum_{n=1}^{N} a_n(t)|n\rangle \exp(-iE_n t/\hbar). \tag{1}$$

From the Schrödinger equation, the coefficients $a_n(t)$ result:

$$i\hbar \dot{a}_n(t) = \sum_{l=1}^{N} a_l(t) V_{nl} \exp(i\omega_{nl} t), \quad \omega_{nl} = \frac{E_n - E_l}{\hbar}. \tag{2}$$

Some simplifications are in order. First, we can assume that V connects only neighboring states, and does not have diagonal elements; moreover, $|\omega_{n,n\pm1}| = \omega$, independent of n, and $V^*_{n,n+1} = V_{n,n-1} = k$.

The initial conditions of interest are

$$a_1(0) = 1,$$

$$a_n(0) = 0, \quad n = 2,3,\ldots,N,$$

which correspond to the spin up (or down).

The substitution

$$b_n(t) = a_n(t) \mathrm{e}^{-in\omega t} \tag{3}$$

leads to a set of equations that can be solved by Laplace transform. By considering $n = N$, namely the probability amplitude of the spin inversion, the following result can be obtained:

$$b_N(t) = -2\frac{(-1)^N}{N+1} \sum_{s=1}^{N} \sin\frac{s\pi}{N+1} \sin\frac{Ns\pi}{N+1} \exp\left(2\pi i\beta \cos\frac{s\pi}{N+1}\right), \tag{4}$$

where

$$\beta = \frac{kt}{\pi\hbar} = \alpha\frac{t}{2\pi}, \quad \alpha = \frac{2k}{\hbar}. \tag{5}$$

This equation works for small values of ω; more precisely, if in the full calculation an expansion up to the first order in ω is performed, the coefficient b_N is again given by (4) within a phase factor only.[3]

III. THE ASYMPTOTIC EXPANSION OF b_N

The aim of the present work is to study the function $b_N(t)$ where $N \geqslant 2$.

Theorem: *For $b_N(t)$ holds the formula:*

$$b_N(t) = (-1)^N \frac{2}{\alpha t} \sum_{\nu=1}^{+\infty} i^{(N+1)(2\nu-1)} \{[(N+1)(2\nu-1) - 1] J_{(N+1)(2\nu-1)-1}(\alpha t) + [(N+1)(2\nu-1) + 1] J_{(N+1)(2\nu-1)+1}(\alpha t)\}, \quad N \geqslant 2.$$

To prove the theorem it is necessary to prove three lemmas.

Lemma 1: The following relation is valid for $b_N(t)$:

$$b_N(t) = \frac{(-1)^N}{2(N+1)} [S_1 - S_2 - (S_3 - S_4)],$$

where

$$S_1 = \sum_{j=1}^{N+1} \exp\left[2\pi i\left(\frac{2j-1}{N+1} + \beta\cos\frac{(2j-1)\pi}{N+1}\right)\right],$$

$$S_2 = \sum_{j=1}^{N+1} \exp\left[2\pi i\left(\frac{2j}{N+1} + \beta\cos\frac{2j\pi}{N+1}\right)\right],$$

$$S_3 = \sum_{j=1}^{N+1} \exp\left[2\pi i\beta\cos\frac{(2j-1)\pi}{N+1}\right],$$

$$S_4 = \sum_{j=1}^{N+1} \exp\left(2\pi i\beta\cos\frac{2j\pi}{N+1}\right).$$

Proof: First, one easily verifies that

$$2b_N(t) = -2\frac{(-1)^N}{N+1}\sum_{s=1}^{2(N+1)} \sin\frac{s\pi}{N+1}\sin\frac{Ns\pi}{N+1}\exp\left(2\pi i\beta\cos\frac{s\pi}{N+1}\right),$$

and after straightforward calculations we obtain that

$$b_N(t) = \frac{(-1)^N}{4(N+1)}\sum_{s=1}^{2(N+1)} (-1)^{s+1}\left\{\exp\left[2\pi i\left(\frac{s}{N+1} + \beta\cos\frac{s\pi}{N+1}\right)\right]\right.$$
$$\left. + \exp\left[-2\pi i\left(\frac{s}{N+1} - \beta\cos\frac{s\pi}{N+1}\right)\right] - 2\exp\left[2\pi i\beta\cos\frac{s\pi}{N+1}\right]\right\}. \tag{6}$$

Since the function

$$(-1)^{s+1}\exp\left[2\pi i\left(\frac{s}{N+1} + \beta\cos\frac{s\pi}{N+1}\right)\right]$$

is periodic in s, with the period $2(N+1)$,

$$\sum_{s=1}^{2(N+1)} (-1)^{s+1}\exp\left[2\pi i\left(\frac{s}{N+1} + \beta\cos\frac{s\pi}{N+1}\right)\right] = \sum_{s=1}^{2(N+1)} (-1)^{s+1}\exp\left[-2\pi i\left(\frac{s}{N+1} - \beta\cos\frac{s\pi}{N+1}\right)\right],$$

and therefore

$$b_N(t) = \frac{(-1)^N}{2(N+1)}\sum_{s=1}^{2(N+1)} (-1)^{s+1}\left\{\exp\left[2\pi i\left(\frac{s}{N+1} + \beta\cos\frac{s\pi}{N+1}\right)\right] - \exp\left[2\pi i\beta\cos\frac{s\pi}{N+1}\right]\right\}. \tag{7}$$

We represent (7) in the form of the sum of two sums, one over odd s: $s=2j-1$; $j=1,2,3,\ldots,N+1$; another one over even s: $s=2j$; $j=1,2,3,\ldots,N+1$. From here we have the statement of the lemma.

We consider the function

$$f(x) = e^{2\pi i\beta\cos 2\pi x}, \tag{8}$$

which is a periodic function with the period 1. We expand $f(x)$ as a Fourier series

$$f(x) = \sum_{k=-\infty}^{+\infty} c(k) e^{2\pi i k x}, \tag{9}$$

with the coefficients

$$c(k) = \int_0^1 f(x) e^{-2\pi i k x} \mathrm{d}x = 2 \int_0^{1/2} e^{2\pi i \beta \cos 2\pi x} \cos 2\pi k x \, \mathrm{d}x. \tag{10}$$

Lemma 2: *For* $|k| > 0$, *the following estimate is valid:*

$$|c(k)| \leqslant \frac{(2\pi\beta)^2 + 2\pi|\beta|}{k^2},$$

and, in particular, the Fourier series for the function $f(x)$ *converges absolutely.*

Proof: From (10), $c(k) = c(-k)$. For $k \neq 0$, we find

$$c(k) = \int_0^1 f(x) \frac{\mathrm{d}e^{-2\pi i k x}}{-2\pi i k} = \frac{1}{(2\pi i k)^2} \int_0^1 f''(x) e^{-2\pi i k x} \mathrm{d}x,$$

$$|c(k)| \leqslant \frac{1}{(2\pi k)^2} \int_0^1 |f''(x)| \mathrm{d}x \leqslant \frac{1}{(2\pi k)^2} \max_{0 \leqslant x \leqslant 1} |f''(x)|.$$

Since from (8)

$$f''(x) = -16\pi^4 \beta^2 \sin^2 2\pi x e^{2\pi i \beta \cos 2\pi x} - 8\pi^3 i \beta \cos 2\pi x e^{2\pi i \beta \cos 2\pi x},$$

then

$$|f''(x)| \leqslant (2\pi)^4 \beta^2 + (2\pi)^3 |\beta|.$$

From here we have the statement of the lemma.

Lemma 3: *Assume that* M *and* m *are integers,* $M > 1$, $0 \leqslant m \leqslant M$; *the sums* A *and* B *are defined by the equalities:*

$$A = \sum_{j=1}^{M} \exp\left[2\pi i \left(\frac{m}{M} \left(j - \frac{1}{2} \right) + \beta \cos 2\pi \frac{\left(j - \frac{1}{2} \right)}{M} \right) \right],$$

$$B = \sum_{j=1}^{M} \exp\left[2\pi i \left(\frac{m}{M} j + \beta \cos 2\pi \frac{j}{M} \right) \right].$$

Then the following relations hold:

$$A = M \sum_{r=-\infty}^{+\infty} (-1)^r c(rM - m),$$

$$B = M \sum_{r=-\infty}^{+\infty} c(rM - m),$$

where $c(k)$ *are the Fourier coefficients of the function* $f(x) = e^{2\pi i \beta \cos 2\pi x}$.

Proof: Representing the factor $e^{2\pi i \beta \cos 2\pi x}$ of each summand of the sums A and B in the form of the Fourier series, we find

$$A=\sum_{j=1}^{M}\exp\left[2\pi i\frac{m}{M}\left(j-\frac{1}{2}\right)\right]\sum_{k=-\infty}^{+\infty}c(k)\exp\left(2\pi i\frac{j-\frac{1}{2}}{M}k\right)=\sum_{k=-\infty}^{+\infty}c(k)\sum_{j=1}^{M}\exp\left[2\pi i\frac{m+k}{M}\left(j-\frac{1}{2}\right)\right], \tag{11}$$

$$B=\sum_{j=1}^{M}\exp\left(2\pi i\frac{m}{M}j\right)\sum_{k=-\infty}^{+\infty}c(k)\exp\left(2\pi i\frac{j}{M}k\right)=\sum_{k=-\infty}^{+\infty}c(k)\sum_{j=1}^{M}\exp\left(2\pi i\frac{m+k}{M}j\right). \tag{12}$$

Since

$$\sum_{j=1}^{M}\exp\left[2\pi i\frac{m+k}{M}\left(j-\frac{1}{2}\right)\right]=\begin{cases}(-1)^{r}M & \text{if } m+k=rM, r \text{ is an integer}, -\infty<r<+\infty\\ 0 & \text{if } m+k \text{ is not a multiple of } M,\end{cases}$$

$$\sum_{j=1}^{M}\exp\left(2\pi i\frac{m+k}{M}j\right)=\begin{cases}M & \text{if } m+k=rM, r \text{ is an integer}, -\infty<r<+\infty\\ 0 & \text{if } m+k \text{ is not a multiple of } M,\end{cases}$$

then we have from (11) and (12), respectively,

$$A=M\sum_{r=-\infty}^{+\infty}(-1)^{r}c(rM-m),$$

$$B=M\sum_{r=-\infty}^{+\infty}c(rM-m).$$

The lemma is proved.

Corollary 1: From lemma 1 and lemma 3 we obtain that

$$b_N(t)=(-1)^{N+1}\sum_{\nu=1}^{+\infty}\{c[(N+1)(2\nu-1)-2]+c[(N+1)(2\nu-1)+2]-2c[(N+1)(2\nu-1)]\}. \tag{13}$$

Proof of the theorem: The terms of this series, the functions $c(k)$, are defined by the integrals (10) and can be transformed into a convenient form. By making the change of variable of integration $y=2\pi x$, $\varphi=y-\pi/2$, in (10), we obtain

$$c(k)=\frac{1}{\pi}\int_0^{\pi}e^{i\alpha t\cos y}\cos ky\,\mathrm{d}y=\frac{i^k}{2\pi}\int_0^{2\pi}e^{i(k\varphi-\alpha t\sin\varphi)}\mathrm{d}\varphi,$$

$\alpha=2\pi\beta/t$.

The integral

$$J_k(\alpha t)=\frac{1}{2\pi}\int_0^{2\pi}e^{i(k\varphi-\alpha t\sin\varphi)}\mathrm{d}\varphi \tag{14}$$

is the Bessel function of the kth order; using well-known recurrence formulas,[4] we represent the series (13) in the form

$$b_N(t)=(-1)^{N}\frac{2}{\alpha t}\sum_{\nu=1}^{+\infty}i^{(N+1)(2\nu-1)}\{[(N+1)(2\nu-1)-1]J_{(N+1)(2\nu-1)-1}(\alpha t)+[(N+1)(2\nu-1)+1]J_{(N+1)(2\nu-1)+1}(\alpha t)\},\quad N\geqslant 2. \tag{15}$$

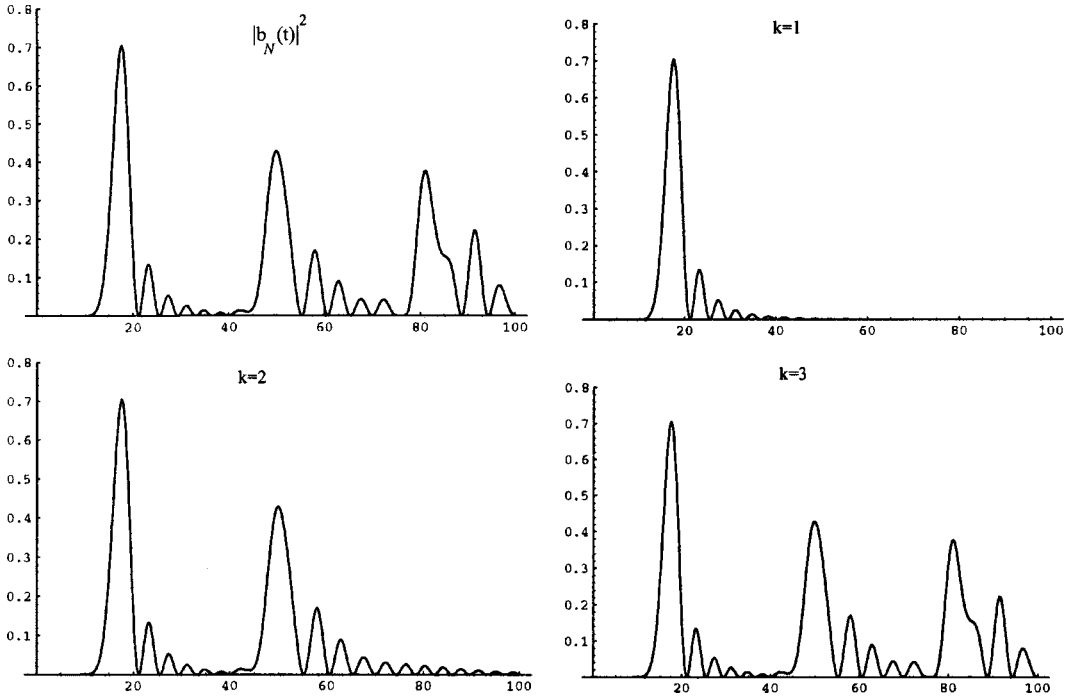

FIG. 1. The value of $|b_N(t)|^2 (N=15, \alpha=1)$ as given by (4), and by approximation (16), with $k=1, 2, 3$.

The theorem is proved.

Remark: Since $J_\nu(\alpha t)$ decreases exponentially as ν increases, and in (15) the summing is over ν, belonging to an arithmetic progression with the difference $2(N+1)$, then the first summands of the sum (15) give already a very good approximation to $b_N(t)$.

Let $k \geqslant 1$, and

$$b_N^{(k)}(t) = (-1)^N \frac{2}{\alpha t} \sum_{\nu=1}^{k} i^{(N+1)(2\nu-1)} \{[(N+1)(2\nu-1)-1] J_{(N+1)(2\nu-1)-1}(\alpha t) + [(N+1)(2\nu-1) + 1] J_{(N+1)(2\nu-1)+1}(\alpha t)\}, \quad N \geqslant 2. \tag{16}$$

We note at once that, also stopping to $k=1$, the result is very satisfactory up to the first maximum, and the expression used in Ref. 3, with a single Bessel function, is improved significantly. This is shown in Fig. 1 for a typical value $N=15$.

IV. CALCULATION OF THE INVERSION TIME

Since function (16) reproduces the behavior of $b_N(\alpha t)$ very well also for $k=1$ in the range of interest, we use this approximate form to find the position of the first maximum of its squared modulus, which gives the inversion time. This maximum corresponds to the first zero of $d/d\tau[b_N^{(1)}(\alpha t)]$, and is given by the equation $(\tau = \alpha t)$

$$0 = \frac{\mathrm{d}}{\mathrm{d}\tau}\left[N\frac{J_N(\tau)}{\tau} + (N+2)\frac{J_{N+2}(\tau)}{\tau} \right] = \frac{\mathrm{d}}{\mathrm{d}\tau}\left[\frac{2N(N+1)}{\tau} J_{N+1}(\tau) + 2J_{N+2}(\tau) \right]$$

and since[4]

$$\frac{\mathrm{d}}{\mathrm{d}\tau} J_{N+2}(\tau) = J_{N+1}(\tau) - \frac{N+2}{\tau} J_{N+2}(\tau),$$

$$J_{N+2}(\tau) = -\frac{\mathrm{d}}{\mathrm{d}\tau}J_{N+1}(\tau) + \frac{N+1}{\tau}J_{N+1}(\tau),$$

we eventually obtain

$$0 = \frac{\mathrm{d}\ J_{N+1}(\tau)}{\mathrm{d}\tau} - \frac{J_{N+1}(\tau)}{\tau}\left[\frac{2N(N+1)+(N+3)(N+1)-\tau^2}{N^2+2N+3}\right] \tag{17}$$

as can easily be verified. By expanding in the neighborhood of the first zero of $\mathrm{d}/\mathrm{d}\tau[J_{N+1}]$, as given by Abramowitz,[5] a straightforward calculation leads to the result

$$\overline{\tau} = N + 1 + 0.8N^{1/3} - 1.16N^{-1/3} + O(N^{-2/3}). \tag{18}$$

V. CONCLUSIONS

The difference between expression (18) and that of Ref. 3, for a typical value of $N \sim 10-20$, is remarkable. With reference to the Fe8 cluster,[6] the value of the experimental parameter (k/D), where D is the anisotropy constant, is found to be about 0.22, less than the value 0.25 given in Ref. 3. It is, therefore, closer to the experimental value 0.16, thus confirming that a precise determination of the inversion time is of fundamental importance in correlating the structure of Mössbauer spectra to the spin Hamiltonian parameters.

We would like to stress that in this system the inversion takes place by means of jumps between the degenerate lowest doublets, and therefore the use of formulas (4) and (18) is well justified. The accurate asymptotic formula (18) would be useless, in the presence of an indeterminate error due to a large value of ω.

An even better calculation can be worked out by observing that, in many cases, the spin states are degenerate in energy only to a first approximation. As indicated in Ref. 3, a full investigation taking into account the energy differences leads to the Laplace transform of Lommel's polynomials, and work is in progress in this direction.

In the framework of geometric quantization, filaments of vorticity in a two-dimensional, ideal incompressible superfluid belong to certain coadjoint orbits of the group of area-preserving diffeomorphisms. The Poisson structure for such vortex strings is analyzed in detail. While the Lie algebra associated with area-preserving diffeomorphisms is noncanonical, we can nevertheless find canonical coordinates and their conjugate momenta that describe these systems. We then introduce a Fock-like space of quantum states for the simplest case of bosonic vortex loops, with natural, nonlocal creation and annihilation operators for the quantized vortex filaments. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1853504]

I. INTRODUCTION

In this paper we discuss quantized vortex filaments—open or closed strings of vorticity—in the context of a model of an incompressible, inviscid fluid. Vortices are excitations descriptive of the collective motion of the fluid. Such collective coordinates have played an essential role in understanding a variety of quantum many-body systems, of which superfluids are a prominent example.

Quantized vortex configurations in two or three spatial dimensions can be described by means of unitary representations of the group $G=S\,\mathrm{Diff}(\mathbf{R}^n)$, for $n=2$ or 3. Here G is the group (under composition) of area- or volume-preserving diffeomorphisms of the plane or of three-space, respectively, where the diffeomorphisms are compactly supported or become rapidly trivial at infinity. To exploit the full physical content of the representation theory, we would like to have a description that makes use of the ideas associated with canonical creation and annihilation operators in Fock space. Here we take some important steps in this direction, writing canonically conjugate coordinates to describe filaments of vorticity in an idealized thin planar film of fluid, and introducing a Fock-like space of states, with creation and annihilation field operators, to describe bosonic vortex loops.

Knowledge of the symmetry group of a classical system generally permits use of some variant of geometric quantization, where the Hilbert space of quantum states carries an appropriate unitary, irreducible representation of the symmetry group. Thus we construct the quantized vortices so

[a)]Electronic mail: gagoldin@dimacs.rutgers.edu

as to respect the classical symmetry of the fluid. The configuration space for the fluid can be identified with the underlying manifold of G, and the symmetry is also described by G, acting on its own group manifold by left multiplication.

Unitary representations are obtained from coadjoint orbits or families of orbits, which serve as reduced phase spaces for the classical system. For $n=2$ we consider the Poisson structure on those coadjoint orbits of G that are associated with filaments of vorticity. Ordinarily the description is noncanonical. However, using a coordinatization intrinsic to the filaments themselves, we are able to write canonically conjugate coordinates for the coadjoint orbits. These turn out to be the position $\Gamma(s)$ of the filament in $\mathbf{R}^2$, parametrized by its own arc length s, and the *cumulative vorticity* function $\tilde{\gamma}(s)$ along the filament.

We next introduce a Fock-like space for bosonic vortex loops. The arguments of the field operators are extended configurations (unparametrized loops), so that the operators are, in a sense, nonlocal. Our formal construction also assumes the existence of a suitable measure on the space of unparametrized loops. We show that the desired measure for systems of loops (i.e., multiloop configurations) should satisfy a multiplicative property with respect to the creation of new loops, in order to yield an appropriate hierarchy of unitary group representations. We give some simple prescriptions for constructing such measures from single-loop measures.

Section II briefly surveys some related research. In Sec. III we review the symplectic structure on coadjoint orbits of diffeomorphism groups, establish notation, and discuss the Poisson structure on coadjoint orbits associated with vortex filaments. Section IV introduces the formal construction of the Fock space, while Sec. V contains conclusions and suggestions for future research directions.

II. BACKGROUND

The diffeomorphism group $G=S\,\mathrm{Diff}(\mathbf{R}^n)$ is taken as the classical symmetry group of an ideal, incompressible fluid by Arnold.[1] Marsden and Weinstein[2] consider coadjoint orbits with point vortices (for $n=2$). We refer to the book by Arnold and Khesin,[3] and references therein.

Goldin, Menikoff, and Sharp examine the quantizability of particular vortex structures from the point of view of geometric quantization on coadjoint orbits.[4,5] They demonstrate that not all the coadjoint orbits of G permit quantization, in the sense of obtaining an irreducible, unitary representation of G. A necessary condition is existence of a polarization which, roughly speaking, encodes the uncertainy principle. It expresses the condition that the coordinates of the orbit (regarded as a reduced, classical phase space) can be partitioned into some maximal set of "configuration space" variables together with another set of "momentum" variables. When a polarization is found, the quantum states can be written as functions of configuration space coordinates only.

For point vortices in two dimensions, and one-dimensional vortex filaments in three dimensions, the requisite polarizations do not exist. However, polarizations do exist for coadjoint orbits containing vortex dipoles, loops (closed strings), and arcs (open strings) in the plane, and for orbits containing vortex ribbons and tubes in three-space.

Owczarek[6,7] obtains similar results in three dimensions using an approach based formally on a field theoretic interpretation of knot theory,[8,9] proposed by Peradzyński.[10] He also discusses the role of topological degrees of freedom for knotted and linked vortices in the thermodynamics of critical superfluid helium,[11] as anticipated in Ref. 5. Brylinski[12] studies the symplectic structure on orbits associated with vortex filaments in three dimensions, noting too that vortex ribbons are better suited for quantization than vortex filaments. He proves that vortex ribbons describe Lagrange manifolds with respect to the standard symplectic structure, remarking that this could be a starting point for geometric quantization. Penna and Spera[13] reconstruct the Poisson structure that generates Hamiltonian dynamics for vortex filaments, within the current algebra framework used here, as a limit of the standard brackets for smooth velocity fields. They also discuss differences between this framework and the canonical quantization of point vortices.

The geometric ideas we use also underlie the so-named α-Euler equation,[14–18] which can be understood as an averaged Euler equation—or, in more functional analytic terms, an H^1-Euler

equation in contrast to the standard L^2-Euler equation. The latter terminology is associated with the variational derivation of the equations. Recall that the elements of the Lie algebra of G are divergenceless velocity fields. Taking the L^2-norm on the space of velocity fields, one obtains the standard Euler equation by variation of this norm with respect to the velocity field. Taking the H^1-norm instead, one obtains the α-Euler equation by the analogous variational procedure. In defining the H^1-norm, one must introduce a constant factor with the dimension of length (which is where α comes into play). One motivation for the modified theory is to achieve greater stability by filtering out short-wavelength modes from the system. The interesting feature of this approach for us is that the diffeomorphism invariance is not destroyed by this change. The geometric framework of Shkoller, Marsden, and Ratiu[19,20] may be as valuable for quantization of vortex solutions to α-Euler equations as the earlier Marsden–Weinstein work[2] is for quantum vortices in the standard Euler fluid.

Questions similar to those addressed in the present paper about the quantum kinematics of vortex filaments are already answered for systems of nonrelativistic, quantum point particles, which are classified by the unitary representations of the group Diff ($\mathbf{R}^n$) of (not necessarily volume-preserving) diffeomorphisms.[21,22] In particular Goldin, Menikoff, and Sharp predict "anyons," particles obeying intermediate statistics modeled on the braid group, using this approach,[22] confirming an earlier idea of Leinaas and Myrheim.[23] More recently Goldin and Sharp propose a general construction of creation and annihilation field operators as intertwining operators in a hierarchy of unitary representations of the diffeomorphism group. For the case of anyons they construct such field operators explicitly, showing how q-commutation rules enter for the operators without having been assumed from the outset.[24] We adopt the same spirit here in our Fock space construction, but for ease of discussion we treat only the bosonic case. We expect to be able to generalize our results to anyonic statistics for systems of planar vortex loops and filaments.

The above-mentioned facts regarding the quantizability of certain vortex structures highlight the possibility of interesting effects on the quantum level associated with the more complicated topology of vortex configuration spaces. Thus there can be "internal statistics" for individual, two-dimensional vortex loops, and effects associated with twistedness, knottedness, and linkedness of vortex ribbons in three dimensions.

Speliotopoulos constructs creation and annihilation operators for vortices in superfluid helium with a heuristic approach that starts from a rule for quantization of vorticity.[25] Treating the vortices as point-like excitations, he postulates an approximate bilinear one-vortex Hamiltonian $H=\epsilon c^* c$, where c^* and c are one-vortex creation and annihilation operators. To avoid singularities in the corresponding wave function, he then modifies the creation and annihilation operators in a way that he interprets as a transition from point vortices to vortex patches. However the vortex patches are homogeneous, and in our framework are also not susceptible to geometric quantization.[4]

Taking coadjoint orbits that allow polarizations, the unitarity of the resulting representations of G further depends on having measures on the configuration space that are quasi-invariant under G. Construction of such measures is difficult, but not essential for our present results on the kinematics of such systems. However, we expect the details to be very important to quantum dynamics. Some ideas regarding properties of measures appropriate to the description of quantum vortices are given in Ref. 26. Related questions about measures are discussed by Ismagilov[27] and Goldin and Moschella;[28,29] a mathematical construction of such measures is proposed by Shavgulidze.[30]

III. POISSON STRUCTURE FOR VORTEX FILAMENTS IN R^2

A. Symplectic structure on coadjoint orbits of diffeomorphism groups

The present notation is a compromise between that used in our previous publications, and the notation of the textbook by Arnold and Khesin.[3] We begin with the general formula for the

Kirillov–Kostant–Souriau (KKS) symplectic structure on coadjoint orbits of a Lie group G. We then take G to be $S\,\mathrm{Diff}(\mathbf{R}^n)$, with $n=2$ or 3 as needed for discussing incompressible hydrodynamics.

Let $\mathcal{G}$ be the Lie algebra of G and $\mathcal{G}^*$ be its dual, with the pairing $\langle\cdot,\cdot\rangle$ mapping $\mathcal{G}^*\times\mathcal{G}\to\mathbf{R}$. Let $[\cdot,\cdot]$ denote the bracket in $\mathcal{G}$. For finite-dimensional groups $\mathcal{G}^*$ is isomorphic as a vector space to $\mathcal{G}$, while if G is an infinite-dimensional group of the sort we consider, then $\mathcal{G}^*$ is in a sense larger than $\mathcal{G}$; they are no longer isomorphic. Denote left translation in G by $L_g(h)=gh$, right translation by $R_g(h)=hg$, and the adjoint action $R_{g^{-1}}\circ L_g$ by $\mathrm{Ad}_g: G\to G$ (where $\circ$ denotes composition); Ad_g (like L_g) is a left action on G.

Given a manifold M and $F: M\to M$, its derivative at the point $x\in M$ is a linear operator $F_*|_x$ from T_xM to $T_{F(x)}M$. The derivative of Ad_g at the identity $e\in G$ is the adjoint representation of G acting in $\mathcal{G}$, denoted also as Ad_g. For $\xi\in\mathcal{G}$, we write

$$\mathrm{ad}_\xi = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=0} \mathrm{Ad}_{g(t)},$$

where $g(t)$ is a curve in G with $g(0)=e$ and

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=0} g(t) = \xi;$$

then $[\xi,\eta]=\mathrm{ad}_\xi\eta$.

Define the coadjoint representation of $\mathcal{G}$ acting in $\mathcal{G}^*$, for $\xi,\eta\in\mathcal{G}$ and $\mu\in\mathcal{G}^*$, by

$$\langle \mathrm{coad}_\xi\mu,\eta\rangle = \langle \mathrm{ad}^*_\xi\mu,\eta\rangle = \langle \mu,\mathrm{ad}_\xi\eta\rangle = \langle \mu,[\xi,\eta]\rangle. \tag{1}$$

This is the infinitesimal version of the coadjoint representation of G on $\mathcal{G}^*$,

$$\langle \mathrm{Ad}^*_g(\mu),\xi\rangle = \langle \mu,\mathrm{Ad}_g\xi\rangle, \tag{2}$$

which is a right action: $\langle \mathrm{Ad}^*_{g_1g_2}\mu,\xi\rangle = \langle (\mathrm{Ad}^*_{g_2}\circ\mathrm{Ad}^*_{g_1})(\mu),\xi\rangle$. For $\mu\in\mathcal{G}^*$, the coadjoint orbit containing μ is the set $\mathcal{O}_\mu := \{\mathrm{Ad}^*_g(\mu): g\in G\}$. Given an element $\xi\in\mathcal{G}$, the coadjoint representation of G associates to it a vector field $\xi_{\mathcal{G}^*}$ on $\mathcal{O}_\mu$. The KKS symplectic form on $\mathcal{O}_\mu$ is given by

$$\Omega_\mu(\xi_{\mathcal{G}^*}(\mu),\eta_{\mathcal{G}^*}(\mu)) := \langle \mu,[\xi,\eta]\rangle, \tag{3}$$

where $\xi_{\mathcal{G}^*}(\mu)$ is the value of $\xi_{\mathcal{G}^*}$ at μ.

To describe idealized, incompressible hydrodynamics, one considers G to be $S\,\mathrm{Diff}(M)$, where M is a manifold equipped with a volume form. Usually $M=\mathbf{R}^2$ or $\mathbf{R}^3$, with the standard Euclidean metric and volume element, so that $S\,\mathrm{Diff}(M)$ consists of volume-preserving C^∞ diffeomorphisms of M. For M not compact, diffeomorphisms are usually further assumed to be compactly supported, or else to become trivial sufficiently rapidly at infinity. The group law is defined by composition of diffeomorphisms: $\phi_1\phi_2=\phi_1\circ\phi_2$, for $\phi_1,\phi_2\in G$. With this convention we follow Refs. 2 and 3, instead of our previous papers where the opposite order was used. With the present convention, the bracket in $\mathcal{G}$ is the negative of the usual Lie bracket of vector fields (see the following). Now $\mathcal{G}$ can be identified with divergenceless vector fields on M vanishing rapidly at infinity, the space that we call $s\,\mathrm{Vect}(M)$. The left group action in G is $L_{\phi_1}(\phi_2)=\phi_1\phi_2=\phi_1\circ\phi_2$, while $R_{\phi_1}(\phi_2)=\phi_2\circ\phi_1$, so that $(\mathrm{Ad}\,\phi)(\psi)=\phi\psi\phi^{-1}=\phi\circ\psi\circ\phi^{-1}$. Let $\psi^{\mathbf{v}}_t$ be a one-parameter subgroup in G generated by a vector field $\mathbf{v}(x)$ on the manifold M. Then from $(\mathrm{Ad}\,\phi)(\psi^{\mathbf{v}}_t)=\phi\circ\psi^{\mathbf{v}}_t\circ\phi^{-1}$, we have

$$\mathrm{Ad}\;\phi_*|_e\mathbf{v} = (D_\phi\mathbf{v})\circ\phi^{-1}, \tag{4}$$

or in Cartesian coordinates (summing over repeated indices),

$$(\mathrm{Ad}(\phi)v)^j(x) = \left[\left(\frac{\partial\phi(y)^j}{\partial y^k}v^k\right)\circ\phi^{-1}\right](x) = \left.\frac{\partial\phi(y)^j}{\partial y^k}\right|_{y=\phi^{-1}(x)} v^k(\phi^{-1}(x)) = \frac{\partial x^j}{\partial[\phi^{-1}(x)]^k}v^k(\phi^{-1}(x)). \tag{5}$$

Thus the matrix D_ϕ at x is given by

$$[D_\phi]^j_k(x) = \frac{\partial\phi(x)^j}{\partial x^k}, \tag{6}$$

and at $\phi^{-1}(x)$ by

$$[D_\phi]^j_k(\phi^{-1}(x)) = \frac{\partial x^j}{\partial[\phi^{-1}(x)]^k}. \tag{7}$$

This specifies how diffeomorphisms act in the space of velocity fields of the fluid.

The transformation has a counterpart in the adjoint action of diffeomorphisms on stream functions. For divergenceless velocity fields in $\mathbf{R}^3$, the stream function $\chi_\mathbf{v}$ is defined so that $\mathbf{v}=-\mathrm{curl}\,\chi_\mathbf{v}$. In $\mathbf{R}^2$, $\chi_\mathbf{v}$ is a scalar function, and we have $v^i=-\epsilon^{ij}\partial\chi_\mathbf{v}/\partial x_j$, where ϵ_{ij} is the usual antisymmetric symbol with $\epsilon_{12}=1$. The stream function is defined only up to the gradient of a function on $\mathbf{R}^3$, or up to an additive constant on $\mathbf{R}^2$. In the latter case one can obtain $\chi_\mathbf{v}$ from $\mathbf{v}$ by introducing $\mathbf{w}=\nabla^{(2)}\chi_\mathbf{v}=(v_2,-v_1)=\mathbf{v}^\perp$. Then $\chi_\mathbf{v}=\int_\infty^x\mathbf{w}\cdot\mathrm{d}\mathbf{s}$, where the integration is along any path from infinity to x (and is independent of the path); this choice sets $\chi_\mathbf{v}=0$ at infinity. An interesting and convenient relation satisfied by such a stream function is

$$\chi_{[\mathbf{v}_1,\mathbf{v}_2]_L} = \mathbf{v}_2 \times \mathbf{v}_1, \tag{8}$$

where $[\cdot,\cdot]_L$ denotes the standard Lie bracket of vector fields, $[\mathbf{v}_1,\mathbf{v}_2]_L=(\mathbf{v}_1\nabla)\mathbf{v}_2-(\mathbf{v}_2\nabla)\mathbf{v}_1$. We use the subscript L to distinguish this from the bracket in the Lie algebra $\mathcal{G}$ obtained in Eq. (15). The action of diffeomorphisms (in three dimensions), given by

$$\chi_i' = [(\mathrm{Ad}\,\phi)\chi]_i = \left(\frac{\partial y^j}{\partial[\phi(y)]^i}\chi_j\right)\circ\phi^{-1} \tag{9}$$

or

$$\chi_i'(x) = \frac{\partial[\phi^{-1}(x)]^j}{\partial x^i}\chi_j(\phi^{-1}(x)), \tag{10}$$

and (in two dimensions) given by

$$\chi_i'(x) = \chi_i(\phi^{-1}(x)), \tag{11}$$

leads to the correct adjoint representation on the velocity fields.

Now $\mathcal{G}^*$ consists of *generalized* (co-)vector fields; that is, fields $\mathbf{A}(x)$ whose components are generalized functions (distributions). The duality is expressed by the pairing

$$\langle\mathbf{A}(x),\mathbf{v}(x)\rangle := \int_{\mathbf{R}^n}\mathbf{A}(x)\cdot\mathbf{v}(x)\mathrm{d}^n x = \int_{\mathbf{R}^n}A_i(x)v^i(x)\mathrm{d}^n x. \tag{12}$$

For $n=3$, we have

$$\langle\mathbf{A}(x),\mathbf{v}(x)\rangle = -\int_{\mathbf{R}^3}\omega(x)\cdot\chi_\mathbf{v}(x)\mathrm{d}^3x, \tag{13}$$

where $\omega(x)=\mathrm{curl}\,\mathbf{A}(x)$ is a generalized vorticity field.

Now the adjoint action of G on $\mathcal{G}$ should be such that infinitesimally it reduces to the adjoint action of $\mathcal{G}$ on $\mathcal{G}$; this requirement is satisfied by (4) and (5). Consider the one-parameter subgroup $\phi_t^{\mathbf{u}}$ of G, which is the solution of the ordinary differential equation

$$\frac{\mathrm{d}\phi_t^{\mathbf{u}}(x)}{\mathrm{d}t} = \mathbf{u}(\phi_t^{\mathbf{u}}(x)),$$

$$\phi_{t=0}^{\mathbf{u}}(x) = x,$$

describing the flow under the vector field $\mathbf{u}(x) \in s\,\mathrm{Vect}(\mathbf{R}^n)$. Then

$$(\mathrm{Ad}(\phi_t^{\mathbf{u}})\mathbf{v})^j = \frac{\partial[\phi_t^{\mathbf{u}}(x)]^j}{\partial x^k} v^k \circ (\phi_t^{\mathbf{u}})^{-1}, \tag{14}$$

and as a result

$$[\mathbf{u},\mathbf{v}] = \mathrm{ad}(\mathbf{u})\mathbf{v} = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=0} [\mathrm{Ad}(\phi_t^{\mathbf{u}})\mathbf{v}] = -[\mathbf{u},\mathbf{v}]_L, \tag{15}$$

so we see that the bracket in the Lie algebra $\mathcal{G}$ is the negative of the Lie bracket of the vector fields.

Next we write the symplectic form explicitly. We work in the three-dimensional case, because two-dimensional vector fields can be embedded in three dimensions so that the same formulas are applicable.

For $\mu \in \mathcal{G}^*$ we take the generalized velocity field $\mathbf{A}(x) \in s\,\mathrm{Vect}(\mathbf{R}^n)^*$. For $\xi, \eta \in \mathcal{G}$ we take two divergenceless vector fields $\mathbf{u}_1(x)$, $\mathbf{u}_2(x)$. Then the formula for the KKS form on the coadjoint orbit containing $\mathbf{A}(x)$, taken at $\mathbf{A}(x)$, is

$$\Omega_{\mathbf{A}(x)}(\mathbf{u}_{1\mathcal{G}^*}(\mathbf{A}(x)), u_{2\mathcal{G}^*}(\mathbf{A}(x))) = \langle \mathbf{A}(x), [\mathbf{u}_1(x), \mathbf{u}_2(x)]\rangle = -\int_{\mathbf{R}^3} \mathbf{A}(x) \cdot [\mathbf{u}_1(x), \mathbf{u}_2(x)]_L \mathrm{d}^3x. \tag{16}$$

Using (8) and integration by parts, we obtain

$$\Omega_{\mathbf{A}(x)}(\mathbf{u}_{1\mathcal{G}^*}(\mathbf{A}(x)), u_{2\mathcal{G}^*}(\mathbf{A}(x))) = \int_{\mathbf{R}^3} \omega(x) \cdot [\mathbf{u}_1(x) \times \mathbf{u}_2(x)] \mathrm{d}^3x. \tag{17}$$

B. Vortex filaments

Next we consider the case of coadjoint orbits associated with vortex loops or arcs in $\mathbf{R}^2$. We shall use the term "filament" to refer to either a loop or an arc. For a vortex filament in $\mathbf{R}^2$, the vorticity field can be written as

$$\omega(x) = \kappa \mathbf{e}_z \int_0^{2\pi} \mathrm{d}\alpha\, \delta(x^1 - C^1(\alpha))\delta(x^2 - C^2(\alpha)), \tag{18}$$

where $\mathbf{C}(\alpha)$ is a parametrized filament in $\mathbf{R}^2$; i.e., $\mathbf{C}:[0,2\pi] \to \mathbf{R}^2$; and where κ is proportional to the total vorticity of the filament. The KKS symplectic form is given by

$$
\begin{aligned}
&\Omega_{\mathbf{A}(x)}(\mathbf{u}_{1\mathcal{G}^*}(\mathbf{A}(x)),\mathbf{u}_{2\mathcal{G}^*}(\mathbf{A}(x)))\\
&\quad=\kappa\int_{\mathbf{R}^2}\mathrm{d}x^1\,\mathrm{d}x^2\,\mathbf{e}_z\cdot\int_0^{2\pi}\mathrm{d}\alpha\,\delta(x^1-C^1(\alpha))\delta(x^2-C^2(\alpha))(\mathbf{u}_1(x)\times\mathbf{u}_2(x))\\
&\quad=\kappa\int_0^{2\pi}\mathrm{d}\alpha\,u_1^1(C^1(\alpha),C^2(\alpha))u_2^2(C^1(\alpha),C^2(\alpha))\\
&\qquad-\kappa\int_0^{2\pi}\mathrm{d}\alpha\,u_2^1(C^1(\alpha),C^2(\alpha))u_1^2(C^1(\alpha),C^2(\alpha))\\
&\quad=\kappa\int_0^{2\pi}\mathrm{d}\alpha\,(\delta C^1(\alpha)\wedge\delta C^2(\alpha))(\mathbf{u}_1(\mathbf{C}(\alpha)),\mathbf{u}_2(\mathbf{C}(\alpha))),
\end{aligned}
\tag{19}
$$

where $C^1(\alpha)$, $C^2(\alpha)$ are the first and second components of $\mathbf{C}(\alpha)$ in $\mathbf{R}^2$, and $\delta C^1(\alpha)$, $\delta C^2(\alpha)$ denote the respective infinitesimal variations.

Thus the KKS form on the coadjoint orbit characterized by $\mathbf{C}(\alpha)$ can be written as the two-form

$$
\Omega_{\mathbf{C}(\alpha)}=\kappa\int_0^{2\pi}\mathrm{d}\alpha\,\delta C^1(\alpha)\wedge\delta C^2(\alpha).
\tag{20}
$$

Taking a geometric point of view, it is natural to consider unparametrized filaments instead of parametrized ones. An unparametrized filament is just the *image* of the map $\mathbf{C}(\alpha)$. As remarked in Ref. 4, the unparametrized filaments should serve as the quantum configurations. Given a (sufficiently smooth) unparametrized filament Γ, a naturally available intrinsic parametrization is with respect to its own arc length s (in the case of the loop, calculated from an arbitrary initial point). Then we can use a description of the vortex filament in which the original parametrized filament $\mathbf{C}(\alpha)$ is replaced by the pair (Γ,γ), where γ is the vorticity distribution written as a function of s. The function $\gamma(s)$ is defined from $\mathbf{C}(\alpha)$ by

$$
\gamma(s):=\frac{\mathrm{d}\alpha}{\mathrm{d}s}.
\tag{21}
$$

Thus Γ describes just the shape of the filament; the remaining information is coded in $\gamma(s)$. One expects that the canonical coordinates on the coadjoint orbits can be expressed in terms of these quantities. Therefore, it is desirable to write the principal formulas in terms of them.

To calculate the action of the symplectic form on two vector fields in the intrinsic coordinates, we can introduce internal tangent and normal components of the vector fields. In these coordinates $\mathbf{u}_i(x)=(u_{it}(x),u_{in}(x))$, for $i=1,2$; where x is a point on the filament, $u_{it}(x)$ is the component of $\mathbf{u}_i(x)$ tangent to the curve, and $u_{in}(x)$ the component normal to the curve. Using (19), the action of the symplectic form on the pair of vector fields $\mathbf{u}_1(x)$, $\mathbf{u}_2(x)$ is given by

$$
\Omega_{\mathbf{A}(x)}(\mathbf{u}_{1\mathcal{G}^*}(\mathbf{A}(x)),\mathbf{u}_{2\mathcal{G}^*}(\mathbf{A}(x)))=\int_{\mathbb{R}^2}\mathrm{d}^2x\,\mathbf{e}_z\kappa\int\mathrm{d}s\;\gamma(s)\delta(x-\Gamma(s))(\mathbf{u}_1(x)\times\mathbf{u}_2(x)).
\tag{22}
$$

In intrinsic coordinates, the symplectic form reads

$$
\Omega_{(\gamma(s),\Gamma(s))}=\kappa\int\mathrm{d}s\;\gamma(s)\delta s\wedge\delta\Gamma(s).
\tag{23}
$$

This suggests that we introduce the *cumulative vorticity* function $\tilde{\gamma}(s):=\int_0^s\gamma(s')\mathrm{d}s'$, where the zero in the lower limit of the integral can be taken arbitrarily, so that $\mathrm{d}\tilde{\gamma}(s)=\gamma(s)\mathrm{d}s$. Then

$$\Omega_{(\tilde{\gamma}(s),\Gamma(s))} = \kappa \int \mathrm{d}s\, \delta\tilde{\gamma}(s) \wedge \delta\Gamma(s), \tag{24}$$

which is the canonical form of the symplectic structure.

Next we calculate the Poisson bracket for the coadjoint orbit of a vortex filament, in both systems of coordinates. First, let us consider the parametrization by $\mathbf{C}(\alpha) = (C^1(\alpha), C^2(\alpha))$. For any two functions $F(\mathbf{C})$, $G(\mathbf{C})$ on the coadjoint orbit, one defines the Poisson bracket by

$$\{F,G\}(\mathbf{C}(\alpha)) = \Omega_{\mathbf{C}(\alpha)}(X_F, X_G), \tag{25}$$

where X_F and X_G are the vector fields on the coadjoint orbit associated with F and G. They are given by the formula

$$i_{X_F}(\Omega_{\mathbf{C}(\alpha)}) = -\,\mathrm{d}F(\mathbf{C}(\alpha)), \tag{26}$$

where i_X is the interior product; that is, $i_X(\Omega)$ is here the one-form satisfying $[i_X(\Omega)](Y) = \Omega(X,Y)$ for any vector field Y on the coadjoint orbit.

In general

$$\mathrm{d}F(\mathbf{C}(\alpha)) = \int_0^{2\pi} \mathrm{d}\alpha \left[\frac{\delta F}{\delta C^1(\alpha)} \delta C^1(\alpha) + \frac{\delta F}{\delta C^2(\alpha)} \delta C^2(\alpha) \right], \tag{27}$$

so the vector field associated with $F(\mathbf{C}(\alpha))$ is given by

$$X_F = \int_0^{2\pi} \mathrm{d}\alpha \left[X_F^1(\alpha) \frac{\delta}{\delta C^1(\alpha)} + X_F^2(\alpha) \frac{\delta}{\delta C^2(\alpha)} \right], \tag{28}$$

where $\delta/\delta C^1(\alpha)$ and $\delta/\delta C^2(\alpha)$ are defined to be the basis dual to $\delta C^1(\alpha)$ and $\delta C^2(\alpha)$ as specified by the formulas

$$\begin{aligned}
&\frac{\delta}{\delta C^1(\alpha)} \rfloor \delta C^1(\beta) = \delta(\alpha - \beta), \\
&\frac{\delta}{\delta C^2(\alpha)} \rfloor \delta C^1(\beta) = 0, \\
&\frac{\delta}{\delta C^1(\alpha)} \rfloor \delta C^2(\beta) = 0, \\
&\frac{\delta}{\delta C^2(\alpha)} \rfloor \delta C^2(\beta) = \delta(\alpha - \beta).
\end{aligned} \tag{29}$$

Next we express the components of X_F in terms of derivatives of $F(\mathbf{C})$. Since

$$i_{X_F}(\Omega_{\mathbf{C}(\alpha)}) = \kappa \int_0^{2\pi} \mathrm{d}\alpha [X_F^1 \delta C^2(\alpha) - X_F^2 \delta C^1(\alpha)], \tag{30}$$

we obtain by comparison with (27)

$$X_F^1(\alpha) = -\frac{1}{\kappa} \frac{\delta F}{\delta C^2(\alpha)}, \tag{31}$$

$$X_F^2(\alpha) = \frac{1}{\kappa}\frac{\delta F}{\delta C^1(\alpha)}. \tag{32}$$

As a result,

$$X_F = \int_0^{2\pi} \mathrm{d}\alpha \frac{1}{\kappa}\left[-\frac{\delta F}{\delta C^2(\alpha)}\frac{\delta}{\delta C^1(\alpha)} + \frac{\delta F}{\delta C^1(\alpha)}\frac{\delta}{\delta C^2(\alpha)} \right]. \tag{33}$$

Thus we obtain the Poisson bracket of two functions on our coadjoint orbit,

$$\{F,G\}(\mathbf{C}(\alpha)) = \Omega_{\mathbf{C}(\alpha)}(X_F,X_G) = -\int_0^{2\pi} \mathrm{d}\alpha \frac{1}{\kappa}\left[\frac{\delta F}{\delta C^1(\alpha)}\frac{\delta G}{\delta C^2(\alpha)} - \frac{\delta F}{\delta C^2(\alpha)}\frac{\delta G}{\delta C^1(\alpha)} \right]. \tag{34}$$

Applying a similar procedure, we obtain the formula for the Poisson bracket with respect to the intrinsic coordinates $\tilde{\gamma}(s)$ and $\Gamma(s)$,

$$\{F,G\}(\tilde{\gamma}(s),\Gamma(s)) = \Omega_{(\tilde{\gamma}(s),\Gamma(s))}(X_F,X_G) = \frac{1}{\kappa}\int \mathrm{d}s \left[\frac{\delta F}{\delta \Gamma(s)}\frac{\delta G}{\delta \tilde{\gamma}(s)} - \frac{\delta F}{\delta \tilde{\gamma}(s)}\frac{\delta G}{\delta \Gamma(s)} \right]. \tag{35}$$

Thus the coordinates $\Gamma(s)$ and $\tilde{\gamma}(s)$ serve as canonical coordinates and momenta of the coadjoint orbit. Formula (35) agrees with the result of Ref. 4 concerning the polarization of the orbits. The quantum configuration space is the space of *unparametrized* filaments $\Gamma(s)$. The stability subgroup, or little group, consists of those area-preserving diffeomorphisms which preserve the filament as a set, but which can change arbitrarily the cumulative vorticity distribution $\tilde{\gamma}(s)$, preserving only the total vorticity of the loop.

C. Evaluation of a Poisson bracket

Let us consider the calculation of the Poisson bracket for a concrete, illustrative pair of functions on the coadjoint orbit of vortex filaments, using Eqs. (25) and (26). Suppose first that the vector fields X_F, X_G can be identified with $\mathbf{u}_{\mathcal{G}^*}$ and $\mathbf{v}_{\mathcal{G}^*}$, respectively, for vector fields $\mathbf{u}$ and $\mathbf{v}$ on $\mathbf{R}^2$. We then have Eq. (19), which we write more concisely as

$$\Omega(\mathbf{u}_{\mathcal{G}^*},\mathbf{v}_{\mathcal{G}^*}) = \kappa\int_0^{2\pi} \mathrm{d}\alpha[(u^1\circ\mathbf{C})(v^2\circ\mathbf{C}) - (u^2\circ\mathbf{C})(v^1\circ\mathbf{C})](\alpha). \tag{36}$$

Next introduce a local coordinate system in $\mathbf{R}^2$ defined in a sufficiently narrow, ribbon-like neighborhood of the filament. Such coordinates can be defined locally using integral curves of the vector fields obtained via parallel transport of the tangent and normal vector fields on the filament. We can thus write the coordinates for a point in such a neighborhood as $(s,x^\perp)$, where s is the arclength along the filament, and $x^\perp$ is locally the arclength coordinate along the integral curve of the normal vector field, taking the value 0 on the filament. In this notation, the symplectic form can be formally rewritten

$$\Omega(\mathbf{u}_{\mathcal{G}^*},\mathbf{v}_{\mathcal{G}^*}) = \kappa\int\int \mathrm{d}^2x\,\delta^{(1)}(x^\perp)I_{[0,L_{\mathrm{tot}}]}(s)\gamma(s)[u^1(x)v^2(x) - u^2(x)v^1(x)], \tag{37}$$

where $\mathrm{d}^2x = \mathrm{d}s\,\mathrm{d}x^\perp$, $I_{[0,L_{\mathrm{tot}}]}$ is the indicator function that is 1 on the interval $[0,L_{\mathrm{tot}}]$ and 0 outside it, L_{tot} is the length of the filament, and the integration is taken over a neighborhood of the filament in which the coordinates are defined. Now let us regard F as given, with $X_F = \mathbf{u}_{\mathcal{G}^*}$, and contract both sides of Eq. (34) with an arbitrary vector field $\mathbf{v}_{\mathcal{G}^*}$. The right-hand side becomes

$$\mathrm{d}F(\mathbf{v}_{\mathcal{G}^*})|_{\mathbf{C}} = \mathbf{v}_{\mathcal{G}^*}(F)|_{\mathbf{C}} = \left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=0} F(\phi_t^{\mathbf{v}} \circ \mathbf{C}), \tag{38}$$

where $\phi_t^{\mathbf{v}}$ is the flow generated by $\mathbf{v}$, while the left-hand side of (34) becomes just $\Omega(\mathbf{u}_{\mathcal{G}^*}, \mathbf{v}_{\mathcal{G}^*})|_{\mathbf{C}}$ which is (37). Equating (37) and (38), we now consider a particular, highly instructive choice of functions F: let us define $F^j_\beta(\mathbf{C}) = C^j(\beta)$ for $j=1,2$, where β is a fixed value of the parameter α. That is, for each β the F^j_β are coordinate functions on the space of filaments. Then

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\right|_{t=0} F^j_\beta(\phi_t^{\mathbf{v}} \circ \mathbf{C}) = v^j(\mathbf{C}(\beta)), \tag{39}$$

which may be rewritten as

$$\int\int \mathrm{d}^2x\, v^j(x)\, \delta^{(1)}(x^\perp)\, \delta^{(1)}(s - s(\beta)). \tag{40}$$

Setting (37) equal to (40), and recalling that $\mathbf{v}$ was chosen arbitrarily, the resulting equations are easily solved to obtain formal expressions for $\mathbf{u}$: For $j=1$, we have

$$\begin{aligned} u^1(0,s) &= 0, \\ u^2(0,s) &= -\frac{1}{\kappa\gamma(s)}\,\delta^{(1)}(s - s(\beta)), \end{aligned} \tag{41}$$

while for $j=2$,

$$\begin{aligned} u^1(0,s) &= \frac{1}{\kappa\gamma(s)}\,\delta^{(1)}(s - s(\beta)), \\ u^2(0,s) &= 0. \end{aligned} \tag{42}$$

We make two remarks about these formulas:

1. The vector field $\mathbf{u}$ is singular (a distribution), so that from a rigorous point of view it does not belong to the Lie algebra $\mathcal{G}$. It is, however, straightforward to regularize it. In place of $F^j_\beta(\mathbf{C})$ consider

$$F^{j(a)}_\beta(\mathbf{C}) = \int_0^{2\pi} \mathrm{d}\alpha\; \delta^{(1)}_a(\alpha - \beta) C^j(\beta), \tag{43}$$

   where $\delta^{(1)}_a$ is a family of smooth functions parametrized by a such that the weak limit of $\delta^{(1)}_a(\alpha)$ as $a \to 0$ is $\delta^{(1)}(\alpha)$; we then obtain formulas corresponding to (41) and (42) with $\delta^{(1)}$ replaced by $\delta^{(1)}_a$.
2. The solutions for $\mathbf{u}$ describe it only on the filament, and not in the local neighborhood. Nevertheless, one can extend $\mathbf{u}$ to the neighborhood in a smooth but otherwise arbitrary way.

Finally we calculate the Poisson bracket for the functions

$$F(\mathbf{C}) = C^1(\beta_1), \quad G(\mathbf{C}) = C^2(\beta_2), \tag{44}$$

defined on the coadjoint orbit. Let $\mathbf{u}_1$ and $\mathbf{u}_2$ be vector fields in the plane whose components on the filament $\mathbf{C}$ are given by the formulas (41) and (42), respectively. The Poisson bracket of F and G is then given by

$$
\begin{aligned}
\{F,G\}|_{\mathbf{C}} &= \Omega(X_F,X_G)|_{\mathbf{C}} \\
&= \Omega(\mathbf{u}_{1\mathcal{G}^*},\mathbf{u}_{2G^*})|_{\mathbf{C}} \\
&= \kappa\int_0^{2\pi} \mathrm{d}\alpha[u_1^1(\mathbf{C}(\alpha))u_2^2(\mathbf{C}(\alpha)) - u_1^2(\mathbf{C}(\alpha))u_2^1(\mathbf{C}(\alpha))] \\
&= \kappa\int_0^{L_{\mathrm{tot}}} \mathrm{d}s\ \gamma(s)\frac{1}{\kappa\gamma(s)}\delta^{(1)}(s-s(\beta_1))\frac{1}{\kappa\gamma(s)}\delta^{(1)}(s-s(\beta_2)) \\
&= \frac{1}{\kappa\gamma(s(\beta_1))}\delta(s(\beta_1)-s(\beta_2)).
\end{aligned} \tag{45}
$$

This result confirms the formal expression (34) obtained for the Poisson bracket.

IV. FOCK SPACE FOR BOSONIC VORTEX LOOPS

In this section we construct a Fock space of states for planar vortex loops. We do this for the simplest case of bosonic loops. Despite its relative simplicity, this case is quite rich and illustrates some of the general features. It will serve as a fundamental construction in our continuing study of vortex structures in ideal quantum fluids. Our consideration is formal to the extent that we make no commitment to a specific quasi-invariant measure on the configuration space, which is necessary for the construction of unitary representations; see Ref. 30, however, where a class of such measures is constructed. We expect the particular choice of measure to describe the dynamics of the theory,[31] while here we consider only the kinematics.

In the approach to nonrelativistic quantum systems based on local current algebras and diffeomorphism groups,[21,32,33] the states are vectors in a Hilbert space carrying a unitary representation of the group Diff (M), of (not necessarily volume-preserving) diffeomorphisms of the spatial manifold M that become rapidly trivial at infinity. The states are square-integrable functions defined on the configuration space, with values in a complex inner product space. In quantum mechanics, the configuration space typically consists of N-point subsets of M, while in statistical physics it consists of countably infinite but locally finite subsets.

The representations take the general form

$$
(V(\phi)\Psi)(\Gamma) = \chi_\phi(\Gamma)\Psi(\phi\Gamma)\sqrt{\frac{\mathrm{d}\mu_\phi}{\mathrm{d}\mu}(\Gamma)}, \tag{46}
$$

where ϕ is a diffeomorphism, Γ is an element of the configuration space Δ (on which diffeomorphisms of M act naturally), μ is a measure on Δ quasi-invariant under diffeomorphisms, and $\chi_\phi(\Gamma)$ denotes a unitary cocycle, satisfying (almost everywhere) the relation

$$
\chi_{\phi_1\circ\phi_2}(\Gamma) = \chi_{\phi_2}(\Gamma)\chi_{\phi_1}(\phi_2\Gamma). \tag{47}
$$

In the applications of diffeomorphism groups to the nonrelativistic quantum mechanics of finitely many particles, inequivalent cocycles describe distinct quantum statistics (bosonic, fermionic, anyonic, or plektonic), and can be obtained by inducing from unitary representations of the stability subgroup.[21,22,34] The square root of the Radon–Nikodym derivative in (46) ensures that $V(\phi)$ is unitary with respect to the measure μ; note that this expression also satisfies a cocycle condition.

Our purpose here is to generalize the earlier construction to include configurations that are extended objects—in particular, the quantum vortex filaments in an ideal, incompressible fluid discussed in Sec. III. Thus we consider unitary representations of the subgroup $S\,\mathrm{Diff}(\mathbf{R}^n)$, here with $n=2$.

In general, the configuration space consists of unparametrized loops. It can be decomposed into the disjoint union of submanifolds, each of which consists of configurations having a specified number N of component loops; we call such configurations "multiloops." There is a corresponding

decomposition of the full Hilbert space $\mathcal{H}$ into a direct sum of component subspaces $\mathcal{H}_N$, characterized by the number of loops in a configuration. So far, this is similar to the case of point particles. The new ingredient with extended objects is the further decomposition of the subspace of N-loop configuration space into components invariant under area-preserving diffeomorphisms. These are the topological sectors discussed, for example, in Ref. 26. There is a corresponding decomposition of the Hilbert spaces $\mathcal{H}_N$.

When studying point particles, it is useful to consider creation and annihilation operators. For the diffeomorphism group these intertwine the corresponding N-particle unitary group representations, and the cocycles impose the algebra of canonical commutation, anticommutation, or q-commutation relations on the creation and annihilation fields.[24] We anticipate that this scheme will also work for nonrelativistic extended objects such as vortex filaments.

We now construct representations of creation and annihilation field operators for bosonic vortex loops, where the cocycles are assumed to be trivial. This removes complications due to the different topological sectors in each N-loop subspace—when a loop is created, the operator need not "know" whether it intersects with or overlaps existing loops. For that reason, this case is formally very similar to the case of bosonic point particles. Nevertheless we have the new feature that the arguments of the creation and annihilation operators are extended, unparametrized loops, rather than points in the physical space.

Now the wave functions of this quantum theory are complex-valued functions of multiloops. The N-loop representation of the diffeomorphism group is given by

$$[V(\phi)\Psi]_N(\{\Gamma_1, \ldots, \Gamma_N\}) = \Psi(\{\phi\Gamma_1, \ldots, \phi\Gamma_N\}) \sqrt{\frac{\mathrm{d}\mu_\phi^{(N)}}{\mathrm{d}\mu^{(N)}}(\{\Gamma_1, \ldots, \Gamma_N\})}, \tag{48}$$

with $\{\Gamma_1, \ldots, \Gamma_N\}$ being a multiloop comprised of N unparametrized loops (possibly intersecting, overlapping, knotted, and so forth, according to the number of dimensions of the space). Here $\phi\Gamma_j$ denotes the natural action of the area-preserving diffeomorphism ϕ on the loop Γ_j embedded in $\mathbf{R}^2$.

We define the operators $\psi^*(\Gamma): \mathcal{H}_N \to \mathcal{H}_{N+1}$ and $\psi(\Gamma): \mathcal{H}_{N+1} \to \mathcal{H}_N$ by

$$[\psi(\Gamma)\Psi]_N(\{\Gamma_1, \ldots, \Gamma_N\}) := \Psi_{N+1}(\{\Gamma_1, \ldots, \Gamma_N, \Gamma\}), \tag{49}$$

$$[\psi^*(\Gamma)\Psi]_N(\{\Gamma_1, \ldots, \Gamma_N\}) := \sum_{j=1}^{N} \delta(\Gamma, \Gamma_j)\Psi_{N-1}(\{\Gamma_1, \ldots, \hat{\Gamma}_j, \ldots, \Gamma_N\}), \tag{50}$$

where $\hat{\Gamma}_j$ means that Γ_j is omitted, and where $\delta(\Gamma, \Gamma')$ is formally defined as a distribution over functions $h(\Gamma)$ on the one-loop configuration space by

$$\int \mathrm{d}\mu(\Gamma')\,\delta(\Gamma, \Gamma')h(\Gamma') = h(\Gamma). \tag{51}$$

Straightforward calculation gives the commutation relations for these creation and annihilation operators:

$$[\psi(\Gamma), \psi(\Gamma')] = 0, \quad [\psi^*(\Gamma), \psi^*(\Gamma')] = 0, \quad [\psi(\Gamma), \psi^*(\Gamma')] = \delta(\Gamma, \Gamma'). \tag{52}$$

Necessary conditions for the operators $\psi(\Gamma)$, $\psi^*(\Gamma)$ and the representations $V(\phi)$ to form a hierarchy are the intertwining properties of the form proposed in Ref. 24:

$$\begin{aligned} V_{N+1}(\phi)\psi^*(h) &= \psi^*(V_{N=1}(\phi)h)V_N(\phi), \\ V_N(\phi)\psi(h) &= \psi(V_{N=1}(\phi)h)V_{N+1}(\phi), \end{aligned} \tag{53}$$

where $\psi(h) = \int \mathrm{d}\mu(\Gamma)h(\Gamma)\psi(\Gamma)$ and $\psi^*(h) = \int \mathrm{d}\mu(\Gamma)h(\Gamma)\psi^*(\Gamma)$ are the creation and annihilation operators averaged with respect to $h \in \mathcal{H}_{N=1}$. These intertwining properties restrict the quasi-

invariant measures in an interesting way. Thus, a condition on the $\mu^{(N)}$ sufficient to satisfy (53) is

$$\forall j \in \{1, \ldots, N\}, \quad \frac{\mathrm{d}\mu_\phi^{(N)}}{\mathrm{d}\mu^{(N)}}(\{\Gamma_1, \ldots, \Gamma_j, \ldots, \Gamma_N\}) = \frac{\mathrm{d}\mu_\phi^{(N-1)}}{\mathrm{d}\mu^{(N-1)}}(\{\Gamma_1, \ldots, \hat{\Gamma}_j, \ldots, \Gamma_N\}) \frac{\mathrm{d}\mu_\phi^{(1)}}{\mathrm{d}\mu^{(1)}}(\{\Gamma_j\}). \tag{54}$$

Iteration of this formula leads to the following multiplicative property of the Radon–Nikodym derivatives:

$$\frac{\mathrm{d}\mu_\phi^{(N)}}{\mathrm{d}\mu^{(N)}}(\{\Gamma_1, \ldots, \Gamma_N\}) = \prod_{j=1}^{N} \frac{\mathrm{d}\mu_\phi^{(1)}}{\mathrm{d}\mu^{(1)}}(\{\Gamma_j\}). \tag{55}$$

This is the condition which, when satisfied by the quasi-invariant measure, ensures existence of a hierarchy of representations of the diffeomorphism group. The representations from the hierarchy are indexed by the numbers of loops. The simplest examples of such measures are, of course, products of one-loop measures, so that

$$\mathrm{d}\mu^{(N)}(\{\Gamma_1, \ldots, \Gamma_N\}) = \mathrm{d}\mu^{(1)}(\{\Gamma_1\}) \ldots \mathrm{d}\mu^{(1)}(\{\Gamma_N\}). \tag{56}$$

However, we are mainly interested in more general measures, which can distinguish nonoverlapping and overlapping vortex loops. Such measures should depend on the areas of the overlap regions, which are preserved by the diffeomorphisms in our group. For complicated overlaps there can be many such regions, on whose areas the measures may explicitly depend; some general properties that should be satisfied are discussed in Ref. 26. In particular, suppose that some multiloops $\{\Gamma_1, \ldots, \Gamma_N\}$ consist of N overlapping loops with r distinguished regions of overlap; let the areas be $\beta_1, \ldots, \beta_r$. Then let

$$\mathrm{d}\mu^{(N)}(\{\Gamma_1, \ldots, \Gamma_N\}) = f(\beta_1, \ldots \beta_r)\mathrm{d}\mu^{(1)}(\{\Gamma_1\}) \ldots \mathrm{d}\mu^{(1)}(\{\Gamma_N\}), \tag{57}$$

where f is a general, measurable function of $\beta_1, \ldots, \beta_r$. One can assume that for $\beta_1 = \ldots = \beta_r = 0$, $f(\beta_1, \ldots \beta_r) = 1$. It is easy to prove that for a measure satisfying this condition, (55) is satisfied.

V. SUMMARY AND OUTLOOK

We have written down and analyzed the Poisson structure for coadjoint orbits associated with two-dimensional vortex filaments, and introduced canonical coordinates and momenta—the unparametrized filaments, and the cumulative vorticity functions, respectively. This result confirms the results of Ref. 4, which were obtained by requiring the existence of a polarization for geometric quantization.

We have also constructed a space of quantum states for bosonic vortex loops. This construction is at a formal level, but acquires concrete meaning when an appropriate quasi-invariant measure is chosen.

Similar constructions should be valid for other nonrelativistic extended objects. These may include vortex dipoles in two space dimensions, vortex ribbons and tubes in three space dimensions, or nonrelativistic bosonic strings. We also anticipate further study of the dynamics for extended vortex configurations, where the dynamical role of topological degrees of freedom should become apparent.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 042103 (2005)

Bounds on integrals of the Wigner function: The hyperbolic case

J. G. Wood and A. J. Bracken
Centre for Mathematical Physics, University of Queensland, Brisbane, Australia 4072

(Received 4 November 2004; accepted 6 December 2004; published online 18 March 2005)

Wigner functions play a central role in the phase space formulation of quantum mechanics. Although closely related to classical Liouville densities, Wigner functions are not positive definite and may take negative values on subregions of phase space. We investigate the accumulation of these negative values by studying bounds on the integral of an arbitrary Wigner function over noncompact subregions of the phase plane with hyperbolic boundaries. We show using symmetry techniques that this problem reduces to computing the bounds on the spectrum associated with an exactly solvable eigenvalue problem and that the bounds differ from those on classical Liouville distributions. In particular, we show that the total "quasiprobability" on such a region can be greater than 1 or less than zero. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1851971]

I. INTRODUCTION

Since its introduction,[1] the Wigner function has been the subject of extensive study in the fields of quantum physics, quantum chemistry and signal analysis (see Refs. 2–10 and references therein). Since Wigner functions represent quantum states on phase space, they play a key role in the phase space formulation of quantum mechanics. They are also designed to closely resemble the joint densities of position and momentum, known as Liouville densities, that are used in classical mechanics. In quantum physics, such studies have been stimulated in recent times by the development of quantum tomography, which has enabled the reconstruction of Wigner functions corresponding to states of a variety of quantum systems.[11] Such experimental observations have confirmed that Wigner functions can be negative on subregions of phase space. This is one of several properties that can be used to distinguish Wigner functions from classical Liouville densities.

The study of these "quantum properties" has been approached in a number of ways including calculations of pointwise bounds on Wigner functions and bounds on various moments.[12–16] A more recent development has been the study of bounds on integrals of the Wigner function over subregions of the phase space,[17–19] which we denote by Γ. We call such integrals *quasiprobability integrals* (qpis). For a given subregion S of Γ, the problem of determining best possible upper and lower bounds on all possible qpis over S has been shown to be equivalent to the problem of determining the supremum and infimum of the spectrum of the *region operator* associated with S. This operator is just the image under Weyl's quantization map[20] of the characteristic function of S, namely the function that equals 1 on S and 0 elsewhere on Γ. In the special case of a quantum system with one linear degree of freedom, it has been shown that for any subregion of the phase plane enclosed by an ellipse, the eigenvalue problem is exactly solvable and the bounds on qpis can be obtained analytically for ellipses of arbitrary size.[17]

The determination of bounds on qpis is important not only because it provides information about the structure of theoretically possible Wigner functions, which is a question of mathematical interest, but also because an understanding of that structure provides checks on experimentally determined Wigner functions. It is therefore of interest to know if there are other subregions of the phase plane, and more generally of phase space, for which the spectrum of the associated region operators, and hence the best-possible upper and lower bounds on all possible associated qpis, can

be determined exactly. In this paper, we show that an exact formula for the spectrum of the region operator, from which the bounds are easily obtained numerically, can be derived for subregions of the phase plane with hyperbolic symmetry. The solvability of the eigenvalue problems for the corresponding region operators, as in the case of elliptical subregions discussed earlier, relies on the invariance of these regions under one-parameter subgroups of the metaplectic group $Mp(2,\mathbb{R})$ of transformations of the phase plane. This group consists of all real transformations of the form

$$T:(q,p) \to (q',p') = (\alpha q + \beta p + q_0, \gamma q + \delta p + p_0), \tag{1}$$

where $\alpha\delta - \beta\gamma = 1$. In this paper, the subgroup of $Mp(2,\mathbb{R})$ formed by the transformations $T_\sigma:(q,p) \to (\sigma q, p/\sigma), \sigma > 0$ is of particular importance.

Several illustrative examples of eigenvalue problems for hyperbolic regions are considered in what follows, including the interesting limiting case of an infinite wedge. We shall be concerned with quantum systems with one linear degree of freedom, described in terms of a Hilbert space of states $\mathcal{H}$, and with the properties of Wigner functions on the associated (q,p) phase plane Γ. We are not concerned with dynamics, and consider each Wigner function at a fixed time. Dimensionless phase plane coordinates (q,p) are used, and in effect we set $\hbar = 1$. Finally, we note that in the absence of limits of integration, integrals are assumed to run from $-\infty$ to ∞.

II. BOUNDS ON QUASIPROBABILITY INTEGRALS

The Wigner function corresponding to a pure state $\psi \in \mathcal{H}$ has the definition

$$W_\psi(q,p) = \frac{1}{\pi} \int \overline{\psi}(q+\tau)\psi(q-\tau)e^{2ip\tau}\,\mathrm{d}\tau. \tag{2}$$

For a mixed state, the Wigner function is a convex linear combination of such integrals. It is known that Wigner functions are bounded at every point $(q,p) \in \Gamma$ such that $-1/\pi \leqslant W(q,p) \leqslant 1/\pi$ and that they satisfy the normalization conditions

$$\int_\Gamma W\,\mathrm{d}q\,\mathrm{d}p = 1, \quad 0 \leqslant \int_\Gamma W^2\,\mathrm{d}q\,\mathrm{d}p \leqslant \frac{1}{2\pi},$$

where the value $1/2\pi$ is attained if and only if W corresponds to a pure state.

More generally, an operator $\hat{A}$ is unitarily related to a phase space function $A(q,p)$ by the Weyl–Wigner transform[21] and its inverse,

$$A = \mathcal{W}(\hat{A}), \quad \hat{A} = \mathcal{W}^{-1}(A). \tag{3}$$

Here $\mathcal{W}^{-1}$ is Weyl's quantization map and $\mathcal{W}$ is such that the Wigner function corresponding to a quantum density operator $\hat{\rho}$ is given by $W_\rho = \mathcal{W}(\hat{\rho})/(2\pi)$. In this paper we make extensive use of the configuration realization, in which $\hat{A}$ can be expressed as an integral operator

$$(\hat{A}\psi)(x) = \int A_K(x,y)\psi(y)\mathrm{d}y. \tag{4}$$

We refer to the function $A_K(x,y)$ as the configuration kernel of $\hat{A}$. It is related to the phase space function $A(q,p)$ by the formulas[22,23]

$$A(q,p) = \int A_K(q-y/2, q+y/2)e^{ipy}\,\mathrm{d}y, \tag{5}$$

$$A_K(x,y) = \frac{1}{2\pi}\int A((x+y)/2,p)e^{ip(x-y)}\,\mathrm{d}p, \tag{6}$$

which provide an explicit realization of the transformations (3).

An important property of Wigner functions is that quantum averages on phase space take the same form as classical averages, if $A(q,p)$ is the phase space representation of a quantum observable $\hat{A}$, then its quantum average in the state with density operator $\hat{\rho}$ and corresponding Wigner function W_ρ is given by

$$\langle\hat{A}\rangle = \mathrm{Tr}(\hat{A}\hat{\rho}) = \int_\Gamma W_\rho(q,p)A(q,p)\mathrm{d}q\,\mathrm{d}p. \tag{7}$$

The qpi of a Wigner function W over a subregion S of Γ may be written as the functional

$$Q_S[W] = \int_S W(q,p)\mathrm{d}q\,\mathrm{d}p. \tag{8}$$

Note that the integral on the right-hand side can be rewritten in terms of the characteristic function $\chi_S(q,p)$ that equals 1 on S and 0 on its complement,

$$Q_S[W] = \int_\Gamma W(q,p)\chi_S(q,p)\mathrm{d}q\,\mathrm{d}p,$$

and, by comparing with (7), we can write

$$Q_S[W] = \langle\hat{\chi}_s\rangle, \tag{9}$$

where we have introduced the *region operator* $\hat{\chi}_S = \mathcal{W}^{-1}(\chi_S)$,[17] with configuration kernel [as given by (6)]

$$\chi_{S,K}(x,y) = \frac{1}{2\pi}\int \chi_S((x+y)/2,p)e^{ip(x-y)}\,\mathrm{d}p. \tag{10}$$

Since the expectation value of a quantum operator always lies between the extremal values of its spectrum, we deduce from (9) that $Q_S[W]$ must lie between the infimum and the supremum of the spectrum of $\hat{\chi}_S$. Moreover, as the spectral bounds on the expectation value of an operator can be approached arbitrarily closely with normalized states in $\mathcal{H}$, these bounds are best-possible. Hence the best-possible bounds on the qpi functional Q_S are provided by the extremal solutions to the integral equation

$$(\hat{\chi}_S\psi)(x) = \int \chi_{S,K}(x,y)\psi(y)\mathrm{d}y = \lambda\psi(x) \tag{11}$$

that defines the eigenvalue problem for $\hat{\chi}_S$.

For a general region S, the integral equation (11) is not exactly solvable and the bounds on its spectrum must be obtained by using computational methods. However, there is a subclass of regions for which the (generalized) eigenvalues and eigenfunctions can be determined exactly. This subclass is the set of regions that are each invariant under a one-parameter subgroup of the metaplectic (or linear canonical) group of transformations (1) of the phase plane. Any such transformation U has the special property that its inverse Weyl–Wigner transform $\hat{U} = \mathcal{W}^{-1}(U)$ is a unitary (and thus spectrum preserving) operator acting on $\mathcal{H}$. If a subregion S of Γ is invariant under a metaplectic transformation, then it follows that the associated region operator $\hat{\chi}_S$ is invariant under the corresponding unitary operation $\hat{U}$, that is generated by an operator $\hat{r}$ of no

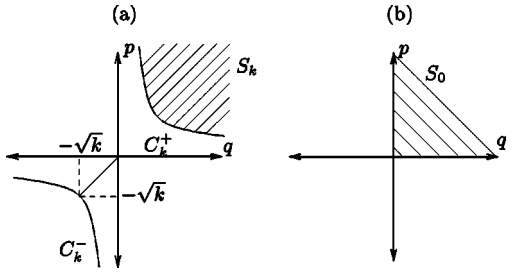

FIG. 1. Graphs of hyperbolic regions and their boundaries, in (a) the hyperbolic region S_k is shown as are the boundary curves C_k^+ and C_k^-, while in (b) the infinite wedge S_0 is depicted.

greater than the second degree in $\hat{q}$ and $\hat{p}$. It follows that $[\hat{\chi}_S, \hat{r}]=0$ and hence that the eigenfunctions of $\hat{\chi}_S$ may be chosen so that they are also eigenfunctions of $\hat{r}$. These are readily obtained by solving the eigenvalue problem for $\hat{r}$.

This approach can be applied to regions that are bounded by ellipses, hyperbolas, parabolas, and straight lines. [If the boundary is composed of several curves, then each curve must be invariant under the same one-parameter subgroup of $Mp(2,\mathbb{R})$.] In the case of elliptical regions, the best-possible bounds have already been described,[17] while the fact that the marginal distributions of the Wigner function are true probability density functions[24] implies that integrals over regions bounded by parallel straight lines must lie in the interval $[0, 1]$. In this paper, we consider the problem of determining the best-possible bounds on qpis over regions with hyperbolic boundaries.

III. BEST-POSSIBLE BOUNDS ON QPIS FOR HYPERBOLIC REGIONS

In order to demonstrate our technique for constructing the bounds on qpis, we begin with a simple example. Let C_k be the hyperbolic curve consisting of all points that satisfy

$$qp = k, \quad k \geqslant 0, \tag{12}$$

as depicted in part (a) of Fig. 1. Note that C_k is itself composed of two curves, namely C_k^+, which lies in the positive (q,p) quadrant of Γ and C_k^-, which lies in the negative (q,p) quadrant of Γ. It is clear that the curves $C_k^\pm$ are separately invariant under the action of the transformation $T_\sigma: (q,p) \to (\sigma q, p/\sigma)$ for all $\sigma > 0$.

Now consider the subregion S_k that contains all points in Γ such that $qp \geqslant k$, $q \geqslant 0$, which is indicated by the shaded region in part (a) of Fig. 1. Since this region can be viewed as the union of all hyperbolic curves C_l^+ with $l \geqslant k$, it is itself invariant under the action of T_σ. In order to apply this symmetry to the problem of determining the bounds on qpis over S_k, we must first construct the corresponding region operator, which we denote by $\hat{\chi}_k$. Note that the characteristic function on S_k, may be written as

$$\chi_k = \begin{cases} 1, & qp \geqslant k, \quad q \geqslant 0 \\ 0, & \text{otherwise} \end{cases} = H(q)H(p - k/q), \tag{13}$$

where H is the Heaviside function. Using (6), the configuration kernel for the region operator can be determined (see the Appendix for details):

$$\chi_{k,K}(x,y) = H\left(\frac{x+y}{2}\right) e^{2ik[(x-y)/(x+y)]} \left[\frac{1}{2}\delta(x-y) - \frac{1}{2\pi i(x-y)}\right], \tag{14}$$

and hence the bounds on qpis are given by the spectral bounds associated with the integral equation

$$\int_{-x}^{\infty} e^{2ik[(x-y)/(x+y)]}\left[\frac{1}{2}\delta(x-y)-\frac{1}{2\pi i(x-y)}\right]\psi(y)\mathrm{d}y=\mu\psi(x). \tag{15}$$

We know, however, that the region operator $\hat{\chi}_k$ is invariant under the set of operator transformations that correspond to the subgroup of $Mp(2,\mathbb{R})$ formed by $T_\sigma, \sigma>0$. Since the effect of T_σ is to squeeze position and stretch momentum (or vice versa) while preserving the canonical commutation relations, the corresponding operator transformation, up to an unimportant phase, is given by the squeezing operator $\hat{U}_\sigma=\exp(i\log\sigma(\hat{q}\hat{p}+\hat{p}\hat{q})/2)$. This implies that $\hat{\chi}_k$ commutes with $\hat{U}_\sigma$ for all $\sigma>0$, and hence

$$[\hat{\chi}_k,\hat{\omega}]=0, \quad \hat{\omega}=(\hat{q}\hat{p}+\hat{p}\hat{q})/2.$$

It follows that the eigenfunctions of $\hat{\chi}_k$ can be chosen such that they are also eigenfunctions of $\hat{\omega}$. We can then obtain a partial solution to the integral equation (15) by solving the equation $\hat{\omega}\psi=\omega\psi$. A number of results connected with this problem can be found in a paper of Chruscinski.[25] On configuration space, this equation appears as the first order differential equation

$$x\frac{\mathrm{d}\psi}{\mathrm{d}x}=\left(i\omega-\frac{1}{2}\right)\psi. \tag{16}$$

The solutions of this equation are complex-valued linear combinations of the functions

$$\psi_\omega^+(x)=\begin{cases}\dfrac{1}{\sqrt{2\pi}}\dfrac{e^{i\omega\log|x|}}{|x|^{1/2}}, & x>0,\\ 0, & x<0,\end{cases} \qquad \psi_\omega^-(x)=\begin{cases}0, & x>0,\\ \dfrac{1}{\sqrt{2\pi}}\dfrac{e^{i\omega\log|x|}}{|x|^{1/2}}, & x<0.\end{cases} \tag{17}$$

Here ω can take any real value. These solutions are generalized functions and are elements of the space of tempered distributions $\mathcal{G}'$,[26] of which $\mathcal{H}$ is a proper subspace. The factor $1/\sqrt{2\pi}$ is inserted to ensure that $(\psi_\omega^\pm,\psi_{\omega'}^\pm)=\delta(\omega-\omega')$. Since they have disjoint support, ψ_ω^+ and $\psi_{\omega'}^-$ are orthogonal for all $\omega,\omega'\in\mathbb{R}$. Note that, since $\log|x|\to-\infty$ as $|x|\to0$, the eigenfunctions become highly oscillatory in the neighborhood of the origin and are undefined at $|x|=0$, due to the $|x|^{1/2}$ term in the denominator.

Since the $\psi_\omega^\pm$ form two independent families of solutions to (16), the eigenfunctions of $\hat{\chi}_k$ are not yet fully determined. In order to construct these solutions, we must solve the reduced eigenvalue problem

$$\hat{\chi}_k\psi_\omega=\mu(\omega,k)\psi_\omega, \quad \psi_\omega=\alpha_\omega\psi_\omega^+ +\beta_\omega\psi_\omega^-, \tag{18}$$

where $\alpha_\omega,\beta_\omega\in\mathbb{C}$. In order to solve (18), we must first determine the action of $\hat{\chi}_k$ on the two-dimensional subspace $\mathcal{G}'_\omega$ of $\mathcal{G}'$ spanned by ψ_ω^+ and ψ_ω^-, $\hat{\chi}_k(\psi_\omega^+,\psi_\omega^-)^T=A(\omega,k)(\psi_\omega^+,\psi_\omega^-)^T$, where $A(\omega,k)$ is given by the matrix

$$A(\omega,k)=\begin{pmatrix}A_{11}(\omega,k) & A_{12}(\omega,k)\\ A_{21}(\omega,k) & A_{22}(\omega,k)\end{pmatrix}. \tag{19}$$

The matrix elements of $A(\omega,k)$ can be computed by using the configuration realization of $\hat{\chi}_k$, details of which are presented in the Appendix. It so happens that the matrix elements of $A(\omega,k)$ depend on the functions $d(\omega,k)$ and $a(\omega,k)$, that are given by

$$d(\omega,k)=\frac{1}{2}\left[\tanh(\pi\omega)+\frac{1}{4\pi}\Im\left\{\oint_{C_0}\frac{e^{i\omega z-2ik\coth(z/2)}}{\cosh(z/2)}\mathrm{d}z\right\}\right], \tag{20}$$

where C_0 is any closed path in the complex plane that contains only the pole at $z=0$, and

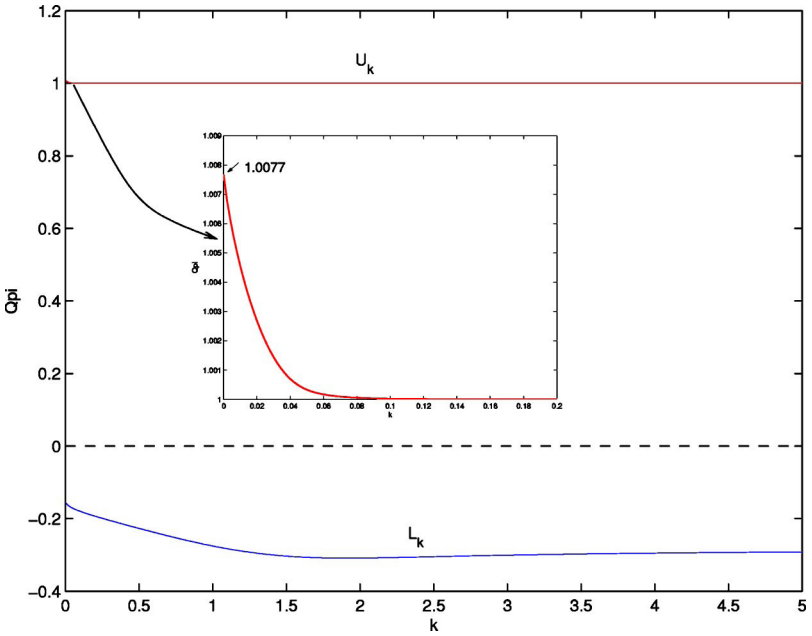

FIG. 2. (Color online) Graph of the best-possible bounds on qpis over S_k for k in the range 0 to 5. The inset graph, with k in the range 0 to 0.2, shows that the upper bound lies above 1, but converges rapidly to 1 as k increases.

$$a(\omega,k)=\frac{e^{-\pi\omega}}{2\pi}\left(\int_0^{\pi}\left(\frac{e^{\omega t-2k\tan(t/2)}}{\sin(t/2)}-\frac{\cos(\omega t-2k\tanh(t/2))}{\sinh(t/2)}\right)\mathrm{d}t-\int_{\pi}^{\infty}\frac{\cos(\omega t-2k\tanh(t/2))}{\sinh(t/2)}\mathrm{d}t\right). \tag{21}$$

The above formula is written in this way, because the individual terms in the first integral are singular at $t=0$, whereas their difference is well defined. In terms of these functions, we may expand $A(\omega,k)$ as

$$A(\omega,k)=\begin{pmatrix}\frac{1}{2}+d(\omega,k) & \frac{1}{2}\left[a(\omega,k)+ie^{-\pi\omega}\left(\frac{1}{2}+d(\omega,k)\right)\right]\\ \frac{1}{2}\left[a(\omega,k)-ie^{-\pi\omega}\left(\frac{1}{2}+d(\omega,k)\right)\right] & 0\end{pmatrix}. \tag{22}$$

Hence the spectrum of the region operator $\hat{\chi}_k$ splits into positive and negative parts, which we label by $\mu_+(\omega,k)$ and $\mu_-(\omega,k)$, respectively,

$$\mu_{\pm}(\omega,k)=\tfrac{1}{2}\left[\tfrac{1}{2}+d(\omega,k)\pm\sqrt{\left(\tfrac{1}{2}+d(\omega,k)\right)^2(1+e^{-2\pi\omega})+a(\omega,k)^2}\right]. \tag{23}$$

Of particular interest are the functions $L_k=\inf_{\omega\in\mathbb{R}}\mu_-(\omega,k)$ and $U_k=\sup_{\omega\in\mathbb{R}}\mu_+(\omega,k)$, since they provide the best-possible bounds on qpis over the hyperbolic regions S_k. Although it does not seem possible to obtain exact expressions for these functions, it is not difficult to compute the bounds after first evaluating a and d numerically.

These bounds are graphed in Fig. 2 for k in the range $[0, 5]$ from which we conclude that the upper bound on qpis over S_k remains close to but greater to 1 for all k and that this difference is greatest when $k=0$ (see inset). The lower bound displays a more marked difference from the classical bound of 0, reaching a minimum value of -0.3089 at approximately $k=1.9$, before rising again. A surprising result is that the lower bound does not approach 0 for large values of k. Nonetheless, this appears to be a characteristic feature of bounds on qpis for many classes of regions.[27]

The infinite wedge: An interesting subclass of hyperbolic regions is provided by taking the limit as $k\to 0$. The region S_0 so obtained is precisely the positive (q,p) quadrant of Γ, as depicted

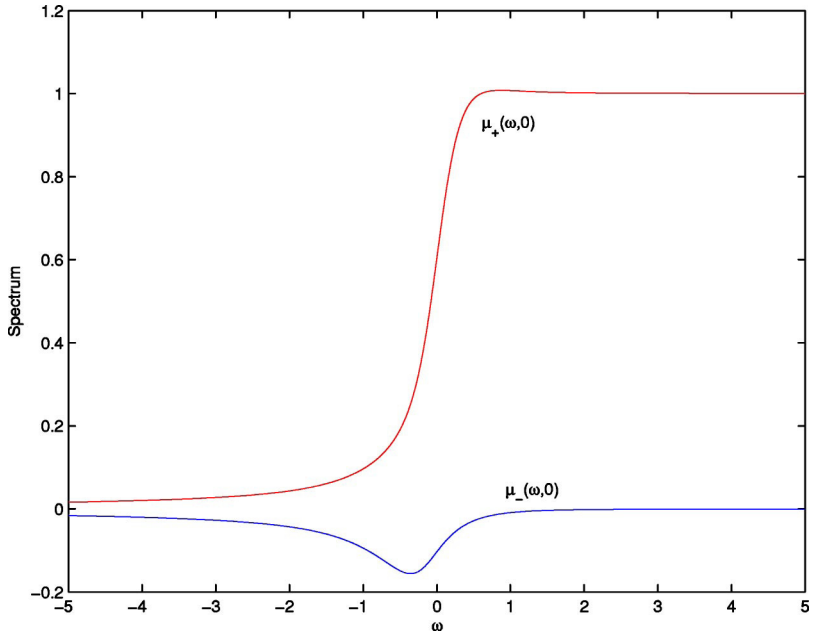

FIG. 3. (Color online) Graph of the spectrum of $\hat{\chi}_0$ which, as labeled, splits into the curves $\mu_+(\omega,0)$ and $\mu_-(\omega,0)$.

in part (b) of Fig. 1. Note that when $k=0$, the functions d and a take a simplified form,

$$d(\omega,0)) = \tfrac{1}{2}\tanh(\pi\omega), \quad a(\omega,0) = -\tfrac{1}{2}\tanh(\pi\omega) + u(\omega), \tag{24}$$

where $u(\omega)$ may be expressed as an infinite sum,[28]

$$u(\omega) = \frac{8\omega}{\pi}\sum_{n=0}^{\infty}\frac{1}{\omega^2 + (4n+1)^2}.$$

If we now apply these simplifications to the spectral formula (23), we obtain the spectrum for $\hat{\chi}_0$:

$$\mu_\pm(\omega,0) = \tfrac{1}{4}(1 + \tanh(\pi\omega) \pm \sqrt{(2u(\omega) - \tanh(\pi\omega))^2 + (1 + \tanh(\pi\omega))^2}), \tag{25}$$

which is graphed in Fig. 3. The infimum and supremum can then be determined numerically, and to an accuracy of $\pm 5\times 10^{-10}$, we have that

$$-0.155\,939\,843 < Q_0[W] < 1.007\,679\,970. \tag{26}$$

An interesting point is that these bounds are also best-possible when applied to regions defined by infinite wedges. This equivalence is due to two factors: first, by an appropriate metaplectic transformation T, the region S_0 can be transformed into any infinite wedge with half-angle $\alpha < \pi/2$. Second, the operator transformation $\hat{U}_T$ that corresponds to T is unitary, and thus the spectrum of $\hat{\chi}_0$ is preserved under its action. This implies that the spectrum of any region operator corresponding to an infinite wedge is given by (25). As a consequence, the integral of a Wigner function over any infinite wedge must lie between the bounds given in (26). Bounds on the spectrum of similar operators have been considered before, in the context of the quantum phase operator[21] and in connection with studies of probability backflow[29] but not to the same level of precision.

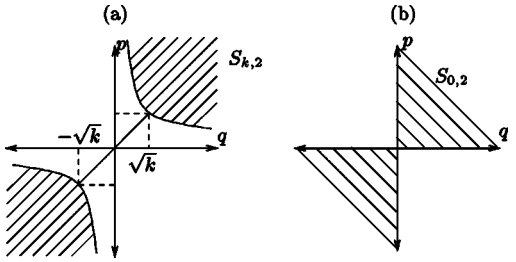

FIG. 4. Regions bounded by two hyperbolic curves, in (a) the hyperbolic region $S_{k,2}$ is shown while in (b) the double wedge $S_{0,2}$ is depicted.

IV. EXAMPLES INVOLVING TWO BOUNDARY CURVES

As a second example, consider the slightly more complicated case of a region with a boundary composed of two curves with T_σ symmetry. There are several possible forms that such a region can take,[27] however, we will concentrate on just the subcase for which the boundary curves lie in positive and negative (q,p) quadrants, as shown in part (a) of Fig. 4.

In order to further simplify matters, we assume that both curves are labeled by the variable k. We label the class of regions that remain by $S_{k,2}$ and note that this region may be written in terms of the region S_k as

$$S_{k,2} = S_k + R_\pi(S_k), \tag{27}$$

where R_π denotes a rotation through an angle π. Note that $R_\pi:(q,p)\to(-q,-p)$ and that the operator that corresponds to this transformation under the Weyl–Wigner transform is just the parity operator $\hat{P}$, which acts on the canonical coordinate and momentum operators according to

$$\hat{P}\hat{q}\hat{P} = -\hat{q}, \quad \hat{P}\hat{p}\hat{P} = -\hat{p}.$$

Due to the linearity of the Weyl quantization map, this implies that the region operator that corresponds to $S_{k,2}$ may be expressed as

$$\hat{\chi}_{k,2} = \hat{\chi}_k + \hat{P}\hat{\chi}_k\hat{P}. \tag{28}$$

This operator also commutes with $\hat{\omega}$, and hence its eigenstates can be chosen such that they are some linear combination of $\psi^\pm_\omega$. In order to find the correct linear combination, we must first determine the matrix representation of $\hat{\chi}_{k,2}$ on the subspace spanned by $\psi^\pm_\omega$. This turns out to quite simple, since the action of $\hat{P}$ on this subspace is given by $\hat{P}\psi^\pm_\omega = \psi^\mp_\omega$. Thus the matrix representation of $\hat{\chi}_{k,2}$ is given by

$$A_2(\omega,k) = A(\omega,k) + \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} A(\omega,k) \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} \frac{1}{2} + d(\omega,k) & a(\omega,k) \\ a(\omega,k) & \frac{1}{2} + d(\omega,k) \end{pmatrix}. \tag{29}$$

The simple form of this matrix representation leads to the following expression for the spectrum of $\hat{\chi}_{k,2}$:

$$\mu_{2,\pm}(\omega,k) = \tfrac{1}{2} + d(\omega,k) \pm |a(\omega,k)|, \tag{30}$$

In this case, the eigenfunctions are odd and even combinations of $\psi^\pm_\omega$, and are independent of k,

$$\psi^\pm_{2,\omega}(x;k) \equiv \psi^\pm_{2,\omega}(x) = \frac{1}{\sqrt{2}}(\psi^+_\omega(x) \pm \psi^-_\omega(x)), \tag{31}$$

which indicates that the operators $\hat{\chi}_{k,2}$ commute for all $k \geqslant 0$.

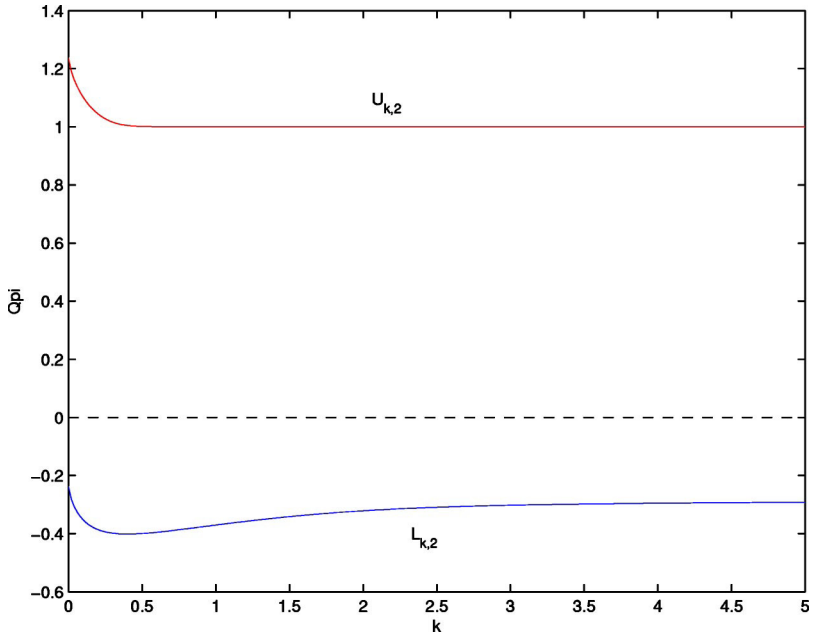

FIG. 5. (Color online) Graph of the best-possible bounds on qpis over $S_{k,2}$ for k in the range 0 to 5.

The properties of the spectrum in this case vary somewhat from the preceding example. In particular, $\mu_{2,-}(\omega,k)$ is not restricted to negative values and, similarly, $\mu_{2,+}(\omega,k)$ is not strictly positive, although clearly the inequality $\mu_{2,+}(\omega,k)\geqslant\mu_{2,-}(\omega,k)$ holds for all $\omega\in\mathbb{R}$, $k\geqslant 0$. Since the bounds on qpis over $S_{k,2}$ are given by the infimum $L_{k,2}$ and supremum $U_{k,2}$ of the spectrum of $\hat{\chi}_{k,2}$, it is these functions that are of primary importance in the context of this paper. Again, closed-form expressions do not appear to exist, so we must resort to computational techniques in evaluating these functions, the results of which are graphed in Fig. 5. In this case, the upper bound is well in excess of 1 for small values of k, but rapidly approaches 1 as k increases. The lower bound, on the other hand, dips initially, reaching a minimum of -0.4014 at $k=0.4$ before rising again, and appears to approach a finite negative value near to -0.3 as $k\rightarrow\infty$.

Double wedges: It is again of interest to consider in more detail the limit as $k\rightarrow 0$ of the region $S_{k,2}$. The resulting region $S_{0,2}$ is the union of the positive and negative (q,p) quadrants [as shown in part (b) of Fig. 4], and one might guess that qpis over such a region should be positive,[24] since it appears to be composed from the union of a set of infinite straight lines, over which the integral of the Wigner function is known to be positive. However, since these lines cross at the origin one cannot immediately apply this result and it will be shown that the true bounds on qpis lie significantly outside the [0,1] interval to which classical probabilities are restricted.

The region operator that corresponds to $\hat{\chi}_{0,2}$ may be expressed in terms of $\hat{\chi}_0$ as $\hat{\chi}_{0,2}=\hat{\chi}_0+\hat{P}\hat{\chi}_0\hat{P}$. The spectrum for this operator can be derived from (30) upon substitution of (24), from which we obtain

$$\mu_{2,\pm}(\omega,0)=\frac{1+\tanh(\pi\omega)}{2}\pm\left|u(\omega)-\frac{\tanh(\pi\omega)}{2}\right|. \tag{32}$$

This spectrum is graphed in Fig. 6, and from this one sees that the function $\mu_2=\frac{1}{2}+u(\omega)$ passes through both the infimum and the supremum of the spectrum of $\hat{\chi}_{0,2}$. Since $u(\omega)$ is an odd function, we need only calculate its global maximum in order to determine the bounds on qpis over $S_{0,2}$. Using computational techniques, this value can be obtained to great accuracy, and we find that the best-possible bounds (accurate to $\pm 5\times 10^{-10}$) on qpis over $S_{0,2}$ are

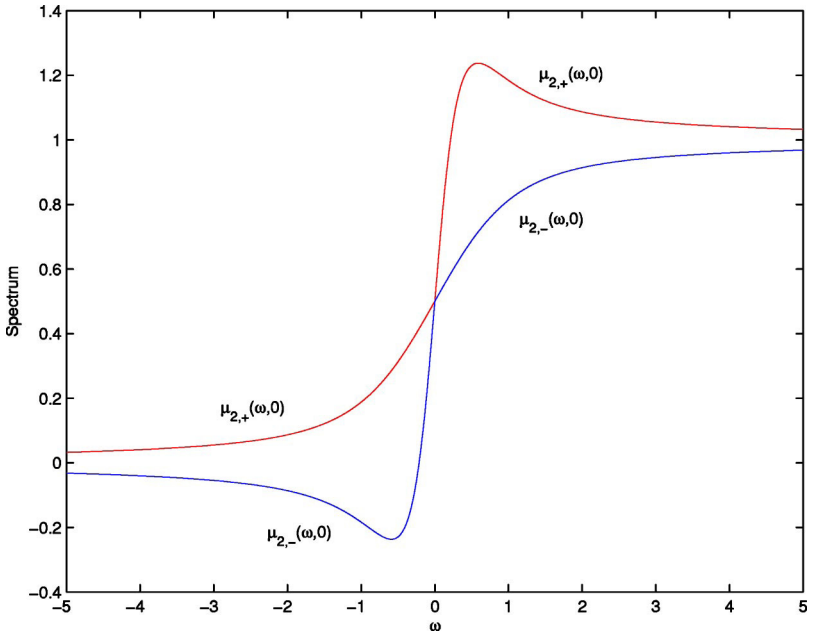

FIG. 6. (Color online) Spectrum of the double wedge operator $\hat{\chi}_{0,2}$.

$$-0.236\,823\,652 < Q_{\alpha,2}[W] < 1.236\,823\,652. \tag{33}$$

Note that the upper and lower bounds sum to 1 since they are symmetric about $1/2$. This symmetry can be explained by noting that if one rotates the region $S_{0,2}$ through an angle $\pi/2$, then one obtains its complement: i.e., $R_{\pi/2}(S_{0,2})=\Gamma/S_{0,2}=S_{0,2}^c$. Note that the integral of a Wigner function over $\Gamma=S\cup S^c$ is normalized to 1. Now, since the operator equivalent of a rotation is a unitary transformation, the region operator that corresponds to the complement of $S_{0,2}$ has precisely the spectrum given in (32). Accordingly, the spectrum of $\hat{\chi}_{0,2}$ must consist of pairs that sum to 1 and, in particular, the upper and lower bounds on this spectrum must be symmetric about $1/2$.

As in the case of the region S_0, the bounds on qpis over $S_{0,2}$ can be applied to a wider class of regions. We shall refer to elements of this wider class as double wedges, since they are formed by taking the union of an infinite wedge with its rotation through an angle π. By applying the appropriate metaplectic transformation, we can transform $S_{0,2}$ into any double wedge. The corresponding operator transformation is unitary and preserves the spectrum of $\hat{\chi}_{0,2}$, so that the spectrum of any region operator corresponding to a double wedge is given by (32). Accordingly, the integral of any Wigner function over an arbitrary double wedge must satisfy the inequality given in (33).

V. CONCLUSION

The problem of constructing best-possible bounds on integrals of the Wigner function is not only of mathematical interest, but should be of practical significance in providing checks on experimentally reconstructed quantum states. Since our approach to the problem relies on specifying the region to be integrated over, it is important to identify the types of region for which the bounds can be easily computed. In this paper, we have considered several examples of regions with a hyperbolic symmetry for which the bounds can be computed numerically from the spectrum of an exactly solvable integral equation. We have demonstrated that the bounds on integrals of the Wigner function for these regions are not equivalent to those on integrals of true probability density functions. In particular, the lower bound is significantly below zero in all cases, although it lacks the scalloped effect arising from eigenvalue crossings as seen in the bounds for elliptical

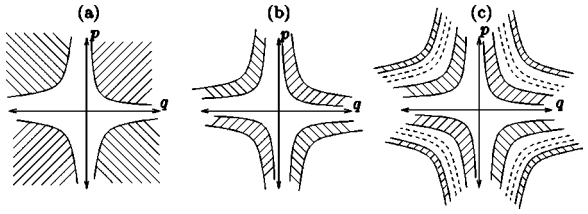

FIG. 7. Examples of generalized hyperbolic regions are shown in (a)–(c).

discs.[17] The upper bound also rises above 1 although for the most part the difference between its value and the classical bound is very small. This contrasts with the case of the disc, for which the upper bound always remains below 1.

The results herein can also be extended to more complicated regions with boundaries given by an arbitrary number of hyperbolic curves sharing the same symmetry,[27] for example, the regions shown in Fig. 7. The problem of determining the spectrum is essentially the same but the matrix representations for operators corresponding to regions with many boundaries are functions of many variables and hence the behavior of the bounds is much more difficult to characterize.

APPENDIX

The configuration kernels that correspond to (13) take the form

$$\chi_{k,K}(x,y) = \frac{H\left(\frac{x+y}{2}\right)}{2\pi}\int_{-\infty}^{\infty} H\left(p - \frac{2k}{x+y}\right)e^{i(x-y)p}\,\mathrm{d}p. \tag{A1}$$

This integral can be computed in a generalized sense,[30] and we find that

$$\chi_{k,K}(x,y) = H\left(\frac{x+y}{2}\right)e^{2ik[(x-y)/(x+y)]}\left[\frac{1}{2}\delta(x-y) - \frac{1}{2\pi i(x-y)}\right]. \tag{A2}$$

This expression for the configuration kernel of $\hat{\chi}_k$ enables us to determine the action of $\hat{\chi}_k$ on the space $\mathcal{G}'_\omega$ [recall that this is given by the matrix $A(\omega,k)$ defined in (19)]. In this representation $\hat{\chi}_k$ acts on ψ_ω as

$$(\hat{\chi}_k\psi_\omega)(x) = \int_{-x}^{\infty} e^{2ik[(x-y)/(x+y)]}\left[\frac{1}{2}\delta(x-y) - \frac{1}{2\pi i(x-y)}\right]\psi_\omega(y)\,\mathrm{d}y. \tag{A3}$$

If we substitute $\psi_\omega = \alpha_\omega\psi^+_\omega + \beta_\omega\psi^-_\omega$, then we find that the action of $\hat{\chi}_k$ when $x<0$ differs from that when $x>0$. Thus, for $x>0$,

$$\begin{aligned}(\hat{\chi}_k\psi_\omega)(x) = {}& \alpha_\omega\int_0^{\infty} e^{2ik[(x-y)/(x+y)]}\left[\frac{1}{2}\delta(x-y) - \frac{1}{2\pi i(x-y)}\right]\frac{e^{i\omega\log y}}{\sqrt{2\pi y}}\mathrm{d}y \\ & + \beta_\omega\int_{-x}^{0} e^{2ik[(x-y)/(x+y)]}\left[\frac{1}{2}\delta(x-y) - \frac{1}{2\pi i(x-y)}\right]\frac{e^{i\omega\log|y|}}{\sqrt{2\pi|y|}}\mathrm{d}y\end{aligned}$$

and for $x<0$,

$$(\hat{\chi}_k\psi_\omega)(x) = \alpha_\omega\int_{|x|}^{\infty} e^{2ik[(x-y)/(x+y)]}\left[\frac{1}{2}\delta(x-y) - \frac{1}{2\pi i(x-y)}\right]\frac{e^{i\omega\log y}}{\sqrt{2\pi y}}\mathrm{d}y.$$

It is immediately clear that $A_{22}(\omega,k)=0$, since the $x>0$ case involves only α_ω.

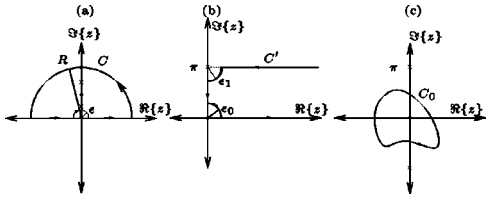

FIG. 8. The contours used in evaluating the functions $b(\omega,k)$, $a(\omega,k)$, and $d(\omega,k)$, in (a) the semicircular contour C, in (b) the contour C' used to relate $b(\omega,k)$ to $d(\omega,k)$, and in (c) an example of a contour C_0 for evaluating $R(\omega,k)$.

The other integrals can be simplified and this process leads to the following expression for the matrix elements of A:

$$A(\omega,k)=\begin{pmatrix} \frac{1}{2}+d(\omega,k) & \frac{1}{2}[a(\omega,k)+ib(\omega,k)] \\ \frac{1}{2}[a(\omega,k)-ib(\omega,k)] & 0 \end{pmatrix}, \tag{A4}$$

where the functions d, a, and b are given by

$$d(\omega,k)=\frac{1}{2\pi}\int_0^\infty \frac{\sin(\omega t-2k\tanh(t/2))}{\sinh(t/2)}\mathrm{d}t, \tag{A5}$$

$$a(\omega,k)=\frac{1}{2\pi}\int_0^\infty \frac{\sin(\omega t-2k\coth(t/2))}{\cosh(t/2)}\mathrm{d}t, \tag{A6}$$

$$b(\omega,k)=\frac{1}{2\pi}\int_0^\infty \frac{\cos(\omega t-2k\coth(t/2))}{\cosh(t/2)}\mathrm{d}t. \tag{A7}$$

Note, however, that although the integrands of a and b are bounded for all t, they become highly oscillatory in the neighborhood of the origin, which poses difficulties for numerical schemes. These problems can be alleviated by using the technique of contour integration.

In the case of $b(\omega,k)$, we consider the following contour integral in the complex plane:

$$I_C=\frac{1}{2\pi}\oint_C \frac{e^{i\omega z-2ik\coth(z/2)}}{\cosh(z/2)}\mathrm{d}z, \tag{A8}$$

where C is the contour shown in part (a) of Fig. 8. Although the contour is divided into four parts, only the integrals along the real axis contribute, since the contributions from the semicircular segments vanish in the respective limits as $\epsilon\to 0$ and $R\to\infty$. Thus one has that

$$\lim_{R\to\infty,\epsilon\to 0} I_C=2\frac{1}{2\pi}\int_0^\infty \frac{e^{i\omega t-2ik\coth(t/2)}}{\cosh(t/2)}\mathrm{d}t, \tag{A9}$$

and as a result, $b(\omega,k)=\Re\{I_C\}/2$.

We can make use of the residue theorem in evaluating I_C,

$$I_C=2\pi i\sum \mathrm{Res}\, f(z), \tag{A10}$$

where $f(z)$ is the integrand in (A8). Note that $f(z)$ has two distinct classes of residues, simple poles at $z=(2n+1)\pi i$ and essential singularities at $z=2m\pi i$, with $m\in\mathbb{Z}$. The contour C encloses only the simple poles with $n\geqslant 0$ and the essential singularities with $m\geqslant 1$, and hence the sum in (A10) is over the residues at these points.

It is easy to evaluate the residues at the simple poles and we find that the total contribution from the simple poles inside C is given by

$$\mathrm{Res}_s = \frac{1}{2\pi i}\sum_{n=0}^{\infty}(-1)^n e^{-(2n+1)\pi\omega} = \frac{\mathrm{sech}(\pi\omega)}{2\pi i}. \tag{A11}$$

The sum of the residues associated with the essential singularities can also be simplified,

$$\mathrm{Res}_e = \frac{1}{2\pi}\sum_{n=1}^{\infty}(-1)^n e^{-2n\pi\omega} R(\omega,k) = \frac{e^{-\pi\omega}\,\mathrm{sech}(\pi\omega)}{2} R(\omega,k), \tag{A12}$$

where $R(\omega,k)$ is the residue of $f(z)$ associated with the essential singularity at the origin.

Ordinarily, one might try to evaluate this residue by constructing the Laurent series for $f(z)$, however in this case the coth term in the exponential makes this extremely difficult. However, one may use the residue theorem in reverse and evaluate $R(\omega,k)$ by considering the integral of $f(z)$ over a closed contour enclosing the origin (and no other poles),

$$R(\omega,k) = \frac{1}{2\pi i}\oint_{C_1} \frac{e^{i\omega z - 2ik\,\coth(z/2)}}{\cosh(z/2)}\mathrm{d}z. \tag{A13}$$

The rapid oscillations due to the coth term do not appear in this calculation, and due to its finite range this integral can be rapidly evaluated to a high degree of accuracy using numerical techniques.

If we now collect the results for the residues together, we discover that

$$b(\omega,k) = \frac{\mathrm{sech}(\pi\omega)}{2}\left[1 + \frac{e^{-\pi\omega}}{2}\Im\{R(\omega,k)\}\right]. \tag{A14}$$

Note that in deriving these results it has been assumed that $\omega \geqslant 0$. A similar procedure (with the semicircular contour defined in the lower half-plane) enables us to extend the validity of (A14) to all $\omega \in \mathbb{R}$.

In order to obtain superior expressions for the functions $a(\omega,k)$ and $d(\omega,k)$, we choose another contour [see part (b) of Fig. 8], this time involving five curves. However, we know from the above calculation that the integral over ϵ_0 vanishes, which leaves four curves to consider. Of these, the integral over the imaginary axis from 0 to π results in a pure imaginary contribution I_π, while the integral over ϵ_1 contributes $-1/2$ in the limit as $\epsilon_1 \to 0$. The integral over the positive real axis is equal to $b(\omega,k)+a(\omega,k)i$ in the limit as $\epsilon_0 \to 0$, while the contribution from the line $(\pi i, \pi i + \infty)$ can be expressed as $-\exp(-\pi\omega)(d(\omega,k)+I_\infty i)$.

By equating the real parts, we find that

$$b(\omega,k) = e^{-\pi\omega}\left(\tfrac{1}{2} + d(\omega,k)\right). \tag{A15}$$

This leads to the expression (20) for $d(\omega,k)$ and the expression (22) for the matrix A. If we equate the imaginary parts, then we discover that

$$a(\omega,k) = e^{-\pi\omega}(I_\pi - I_\infty), \tag{A16}$$

where

$$I_\pi = \frac{1}{2\pi}\int_0^{\pi} \frac{e^{\omega t - 2k\,\tan(t/2)}}{\sin(t/2)}\mathrm{d}t, \tag{A17}$$

$$I_\infty = \frac{1}{2\pi}\int_0^{\infty} \frac{\cos(\omega t - 2k\,\tanh(t/2))}{\sinh(t/2)}\mathrm{d}t. \tag{A18}$$

Neither I_π nor I_∞ are well defined, but their difference is, and provided one expresses $a(\omega,k)$ as in (21), the singularities of these integrals are avoided.

(Received 21 July 2004; accepted 10 January 2005; published online 21 March 2005)

We characterize the quasianti-Hermitian quaternionic operators in quaternionic quantum mechanics by means of their spectra; moreover, we state a necessary and sufficient condition for a set of quasianti-Hermitian quaternionic operators to be anti-Hermitian with respect to a uniquely defined positive scalar product in a infinite dimensional (right) quaternionic Hilbert space. According to such results we obtain two alternative descriptions of a quantum optical physical system, in the realm of quaternionic quantum mechanics, while no alternative can exist in complex quantum mechanics, and we discuss some differences between them. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1873040]

I. INTRODUCTION

Many attempts have been made in the past in order to formulate quantum mechanics in Hilbert spaces over the skew-field **Q** of quaternions. In the early 1960s a systematic approach began to quaternionic quantum mechanics (QQM);[1] at present, a clear and detailed review of this theory, together with the foundations of quaternionic quantum field theory, can be found in Ref. 2.

It is worth noting that an important difference exists between complex and quaternionic quantum mechanics about Hamiltonians operators and observables. In both theories, observables are associated with self-adjoint (or Hermitian) operators, whereas Hamiltonians are Hermitian in complex quantum mechanics (CQM), but they are anti-Hermitian in QQM, and the same happens for the symmetry generators, like the angular momentum operators. Moreover, in CQM any anti-Hermitian operator can be made Hermitian (and vice versa) by multiplying by i. In QQM in contrast, an anti-Hermitian operator cannot be trivially converted to a Hermitian one by multiplying by a c-number; actually in this context in order to obtain such a conversion one needs a "phase" operator.[2]

Thus, if one wishes to enlarge the theoretical framework and to generalize standard quaternionic Hamiltonians and symmetry generators (as happened in CQM where pseudo-Hermiticity has been fruitfully introduced), in QQM one rather needs to deal with *pseudoanti-Hermitian* quaternionic operators.

Definition (Ref. 3): A quaternionic linear operator H is said to be (η-) pseudoanti-Hermitian if a linear invertible Hermitian operator η exists such that

$$\eta H \eta^{-1} = -H^{\dagger}. \tag{1}$$

If Eq. (1) holds with a bounded positive definite η, H is said *quasianti-Hermitian*.

Of course, several η can exist which verify Eq. (1). The properties of pseudoanti-Hermitian Hamiltonians in QQM are analogous to the ones of pseudo-Hermitian in CQM. In particular, a

[a]Electronic mail: blasi@le.infn.it
[b]Electronic mail: scolarici@le.infn.it
[c]Electronic mail: solombrino@le.infn.it

new inner product in the Hilbert space can be associated with any bounded positive definite η which fulfills Eq. (1), and different η's give rise to alternative descriptions.[4]

In this paper, we preliminarly characterize in Sec. II the subclass of quasianti-Hermitian quaternionic operators with discrete spectrum (in finite dimensional vector spaces), showing that they are necessarily diagonalizable operators with imaginary eigenvalues (and vice versa). Next, facing the unity problem, we derive in Sec. III a necessary and sufficient condition for a set of quasianti-Hermitian operators to be anti-Hermitian with respect to a uniquely defined scalar product in quaternionic Hilbert spaces. Finally, we consider in Sec. IV two alternative descriptions of a physical system in quantum optics, which are possible only in the realm of QQM, according with the previous result, and we discuss some differences between them.

II. QUASIANTI-HERMITIAN QUATERNIONIC OPERATORS

In this section, we characterize the subclass of quasianti-Hermitian quaternionic operators by means of their spectra, in strict analogy with similar statements in CQM.[5,6] The following proposition, which holds in finite dimensional Hilbert spaces, provides a necessary and sufficient condition for a quaternionic operator with discrete spectrum to be quasianti-Hermitian.

Proposition 1: Let H be a quaternionic linear operator with discrete spectrum. Then, a definite operator η exists such that H is η-pseudoanti-Hermitian (hence, η-quasianti-Hermitian) if and only if H is diagonalizable with imaginary spectrum.

Proof: Let H be a pseudoanti-Hermitian operator. We preliminarily observe that, being in any case η an invertible operator, all its eigenvalues must be different from zero, so that either η is definite or it is indefinite. Now, let us suppose that a positive (respectively, negative) definite operator η exists which fulfills condition (1); then, an R exists such that $\eta = R^\dagger R$ (Ref. 7) (respectively, $\eta = -R^\dagger R$), and by Eq. (1) we obtain

$$RHR^{-1} = -R^{\dagger -1} H^\dagger R^\dagger = -(RHR^{-1})^\dagger,$$

i.e., RHR^{-1} is anti-Hermitian, hence it is diagonalizable and it has an imaginary spectrum.[2] The same conclusion holds obviously with regard to H, since on a right quaternionic vector space the similarity transformations preserve the properties of the spectrum, in the sense that the real part and the moduli of the imaginary part of the eigenvalues do not change under (quaternionic) similarity transformations.

Conversely, if H is diagonalizable with imaginary spectrum, then by proposition 2 of Ref. 3, a positive definite operator $\eta = SS^\dagger$ exists which fulfills condition (1). ■

We remark that the above Proposition still holds in infinite dimensional Hilbert spaces $\mathcal{H}^Q$ if one assumes that the eigenvalues of H have finite multiplicity and there is a basis on $\mathcal{H}^Q$ in which H is block diagonal with finite dimensional blocks (see also Ref. 6).

As a consequence of Proposition 1, any quasianti-Hermitian operator H with discrete spectrum can be written by means of a set of biorthonormal vectors (if we suitably fix their phases) as[3,2]

$$H = \sum_n \sum_{a=1}^{d_n} |\psi_n, a\rangle i E_n \langle \phi_n, a|, \quad E_n \geqslant 0,$$

where d_n denotes the degeneracy associated to the nth eigenvalue, a is a degeneracy label, and the usual relations for a biorthonormal basis hold,

$$\langle \phi_m, b|\psi_n, a\rangle = \delta_{mn}\delta_{ba},$$

$$\sum_n \sum_{a=1}^{d_n} |\psi_n, a\rangle\langle \phi_n, a| = \sum_n \sum_{a=1}^{d_n} |\phi_n, a\rangle\langle \psi_n, a| = \mathbf{1}.$$

III. ALTERNATIVE DESCRIPTIONS OF QUANTUM SYSTEMS

As we already pointed out in the Introduction, different (alternative) description of the same physical system in a quaternionic Hilbert space $\mathcal{H}^Q$ are possible whenever different η's fulfill condition (1). Indeed, *for any bounded self-adjoint positive definite* η*, the space* H^Q *endowed with the scalar product* $\langle\varphi|\psi\rangle_\eta=\langle\varphi|\eta|\psi\rangle$ *is a Hilbert space* H^Q_η.

We do not report here the explicit proof of this property, which was already stated in CQM;[8] indeed the proof easily follows from the one in the complex case since all the key steps in it still hold in a quaternionic Hilbert space, as for instance the closed graph theorem[9] and the uniticity of the decomposition $\eta=S^2$, with S positive and self-adjoint.[10]

Hence, an undesirable ambiguity can arise, as we will explicitly show in the next section by means of a physical example; in order to remove that and obtain a proper (quaternionic) quantum mechanical interpretation, we will resort to the concept of irreducibility of the physical operators on $\mathcal{H}^Q$.

As a preliminary step, we state the following lemma, which actually is very similar to the quaternionic version of the corollary of the Schur lemma (on the irreducible quaternionic group representations of unitary operators)[10] and can be easily proven in the same way.

Lemma: Let $\{H_i\}$ $(i=1,2,\ldots,N)$ *be an irreducible set of anti-self-adjoint bounded quaternionic linear operators on the (right) quaternionic Hilbert space* $\mathcal{H}^Q$*. Then, the commutant of* $\{H_i\}$*, i.e., the set of all bounded quaternionic linear operators which commute with each* H_i *is composed of the operators* $T=h\mathbf{1}+a\mathbf{I}_a$ (*where* h, $a\in\mathbf{R}$, *and* $\mathbf{I}_a$ *is a unitary, anti-Hermitian operator on* $\mathcal{H}^Q$).

Thus, the following proposition provides a necessary and sufficient condition for a set of η-quasianti-Hermitian quaternionic operators to admit a unique positive definite operator η which satisfy the quasianti-Hermiticity condition.

Proposition 2: Let $\{H_i\}$ *be a set of bounded* η*-quasianti-Hermitian operators on a right quaternionic Hilbert space* $\mathcal{H}^Q$*, where* η *denotes a bounded positive self-adjoint operator. Then,* η *is uniquely determined up to a global normalization factor if and only if the set* $\{H_i\}$ *is irreducible on* $\mathcal{H}^Q$.

Proof: First, we observe that, by assumption, all the quasianti-Hermitian operators in the set $\{H_i\}$ are bounded both on $\mathcal{H}^Q$ and on $\mathcal{H}^Q_\eta$, since $\|H_ix\|_\eta=\|SH_ix\|\leqslant\|SH_iS^{-1}\|\|Sx\|=\|SH_iS^{-1}\|\|x\|_\eta$ (where the decomposition $\eta=S^2$, with S positive, self-adjoint has been used[10]); furthermore, they are anti-self-adjoint on $\mathcal{H}^Q_\eta$ because $\eta H_i=-H_i^\dagger\eta\ \forall i=1,2,\ldots,N$. Assume now that an η' exists with the same properties as η. Then, it follows that $[\eta'^{-1}\eta,H_i]=0\ \forall i=1,2,\ldots,N$. Hence, by the previous lemma, $\eta=\eta'(h\mathbf{1}+a\mathbf{I}_a)$. But imposing the Hermiticity condition on η, one easily obtains $\eta'(h\mathbf{1}+a\mathbf{I}_a)=(h\mathbf{1}-a\mathbf{I}_a)\eta'$, which implies either $a=0$ or $\{\eta',\mathbf{I}_a\}=0$. Denoting by $|\eta'\rangle$ an eigenvector of η': $\eta'|\eta'\rangle=|\eta'\rangle\alpha$ (where $\alpha>0$, since η' is positive) the condition $\{\eta',\mathbf{I}_a\}=0$ would imply $\eta'(\mathbf{I}_a|\eta'\rangle)=-(\mathbf{I}_a|\eta'\rangle)\alpha$, i.e., an eigenvector of η' would exist associated with a negative eigenvalue, contradicting thus the hypothesis on the positive definiteness of η'. Then, $a=0$ and $\eta=\eta'h$.

The converse is easily proven by merely paraphrasing the analogous proof in complex Hilbert spaces.[8] ■

As a consequence of the above proposition, any reducible set $\{H_i\}$ of quasianti-Hermitian operators admits at least two quite different positive operators η and η' which fulfill the quasianti-Hermiticity condition for any operator belonging to this set. This allows us to construct two different Hilbert spaces $\mathcal{H}^Q_\eta$ and $\mathcal{H}^Q_{\eta'}$, endowed with scalar products $\langle\varphi|\eta|\psi\rangle$ and $\langle\varphi|\eta'|\psi\rangle$, respectively, such that any H_i is anti-Hermitian on $\mathcal{H}^Q_\eta$ as well as on $\mathcal{H}^Q_{\eta'}$.

In particular, any reducible set of anti-Hermitian operators $\{H_i\}$ on $\mathcal{H}^Q$ will appear at the same time as a set of anti-Hermitian operators on the Hilbert space $\mathcal{H}^Q_\eta$ where η denotes a bounded, nontrivial, positive operator which commutes with any element of $\{H_i\}$.

This is just the scenario of the example we will study in the next section, which exactly mimics an analogous situation in CQM, where alternative descriptions arise in correspondence with different η's which fulfill the quasi-Hermiticity condition for a set $\{H_i\}$.[4,8]

IV. A PHYSICAL EXAMPLE

Let us consider a two level quantum optical system in the *complex* Hilbert space $\mathcal{H}$ whose dynamics is described by the complex anti-Hermitian time-dependent Hamiltonian,

$$H = 2\Omega_0(t)J_1 + 2\Omega_1(t)J_2 + \omega(t)J_3 \quad (\hbar = 1), \tag{2}$$

where $\Omega_0(t)$, $\Omega_1(t)$, and $\omega(t)$ are real valued functions of the time t, and the anti-Hermitian operators J_l ($l=1,2,3$) obey the usual rules of commutation of the su(2) algebra

$$[J_l, J_m] = -\varepsilon_{lmn}J_n.$$

As we already noted in the Introduction, H times i is of course an observable in CQM, and it coincides with the one introduced in order to describe the interaction of a chirped classical electromagnetic field with a two level atomic system in a complex Hilbert space.[11] This model has been extensively studied also to explain the Berry phase.[12]

By resorting to the irreducible two-dimensional representation of the J operators

$$J_1 = \frac{i}{2}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad J_2 = \frac{1}{2}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad J_3 = \frac{i}{2}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{3}$$

and setting $\Omega = \Omega_0 + i\Omega_1$, we can write the Hamiltonian (2) as a 2×2 anti-Hermitian complex matrix,

$$H = i\begin{pmatrix} \dfrac{\omega(t)}{2} & \Omega^*(t) \\ \Omega(t) & -\dfrac{\omega(t)}{2} \end{pmatrix}. \tag{4}$$

The set $\mathfrak{h}$ of anti-Hermitian complex operators obtained by changing the entries in Eq. (4), is of course irreducible in the two-dimensional (complex) Hilbert space $\mathcal{H}$, since such is the spinorial representation (3) of the J_l's.

From a different point of view, we can interpret the Hamiltonian (4) as a *anti-Hermitian quaternionic operator* in a (right) quaternionic Hilbert space $\mathcal{H}^Q$, and the dynamics of our quantum system is then described by the Schrödinger equation[2]

$$\frac{d}{dt}|\boldsymbol{\Psi}\rangle = -H|\boldsymbol{\Psi}\rangle, \tag{5}$$

where $|\boldsymbol{\Psi}\rangle$ belongs to $\mathcal{H}^Q$. (We recall that in QQM the eigenvalues of a anti-Hermitian Hamiltonian are imaginary quaternions, whose moduli represent the values of the energy of the system.)

Roughly speaking, $\mathcal{H}^Q$ can be obtained from $\mathcal{H}$ by simply adding to each complex vector $|v\rangle \in \mathcal{H}$ a term $|v'\rangle j$, where $|v'\rangle \in \mathcal{H}$ and $j : j^2 = -1$ is a quaternionic unity different from i; note that $\dim \mathcal{H}^Q = \dim \mathcal{H} = 2$. Actually the various manner in which one can *quaternionify* a complex Hilbert space are all equivalent to this one.[13]

Now, let us denote by $|\boldsymbol{\Psi}\rangle = \begin{pmatrix} \boldsymbol{\Psi}_{\alpha,+} + \boldsymbol{\Psi}_{\beta,+}j \\ \boldsymbol{\Psi}_{\alpha,-} + \boldsymbol{\Psi}_{\beta,-}j \end{pmatrix} \equiv \begin{pmatrix} \boldsymbol{\Psi}_+ \\ \boldsymbol{\Psi}_- \end{pmatrix}$ (where $\boldsymbol{\Psi}_{\alpha,\pm}, \boldsymbol{\Psi}_{\beta,\pm}$ are complex functions of t) the quaternionic state vector representing the system; the components $\boldsymbol{\Psi}_-$ and $\boldsymbol{\Psi}_+$ can be interpreted from a physical point of view as the probability amplitudes for the system of being in the lowest or in the excited state, respectively. From the Schrödinger equation one immediately gets the time evolution of the components $\Psi_\pm$,

$$\boldsymbol{\Psi}'_{\alpha,+} = \frac{i}{2}\omega(t)\boldsymbol{\Psi}_{\alpha,+} + i\Omega^*(t)\boldsymbol{\Psi}_{\alpha,-}, \tag{6a}$$

$$\boldsymbol{\Psi}'_{\alpha,-} = -\frac{i}{2}\omega(t)\boldsymbol{\Psi}_{\alpha,-} + i\Omega(t)\boldsymbol{\Psi}_{\alpha,+}, \tag{6b}$$

$$\boldsymbol{\Psi}'_{\beta,+} = \frac{i}{2}\omega(t)\boldsymbol{\Psi}_{\beta,+} + i\Omega^*(t)\boldsymbol{\Psi}_{\beta,-}, \tag{7a}$$

$$\boldsymbol{\Psi}'_{\beta,-} = -\frac{i}{2}\omega(t)\boldsymbol{\psi}_{\beta,-} + i\Omega(t)\boldsymbol{\Psi}_{\beta,+}. \tag{7b}$$

where the prime denotes a time derivative.

Since the systems in (6) and (7) are identical, and they represent a rotation of the vector $\boldsymbol{\Psi}$ in the complex space, we can write their solutions as a whole using the Cayley–Klein (CK) matrix, *independently on the quaternionic or complex character of* $\boldsymbol{\Psi}_{\pm}$,

$$\begin{pmatrix} \boldsymbol{\Psi}_+ \\ \boldsymbol{\Psi}_- \end{pmatrix} = \begin{pmatrix} F^* & G \\ -G^* & F \end{pmatrix} \begin{pmatrix} \boldsymbol{\Psi}_+(0) \\ \boldsymbol{\Psi}_-(0) \end{pmatrix}, \tag{8}$$

where $F(t)$ and $G(t)$ are complex functions depending on ω and Ω in a rather involved way; furthermore $F(0)=1$, $G(0)=0$, and $|F|^2+|G|^2=1$.[11]

The CK matrix can be regarded as the matrix representation of the time evolution operator U associated with the time-dependent Hamiltonian (4), and it belongs to a two-dimensional (complex) unitary representation of the SU(2) group; by varying H in $\mathfrak{h}$, we correspondingly obtain a set $\mathfrak{U}=\{U\}$.

We remark once again that the form of any element $U \in \mathfrak{U}$ does not depend on the scalar field, **C** or **Q**, adopted. Now, as long as we study the two-level system in $\mathcal{H}$, the set $\mathfrak{U}$ is clearly irreducible, hence, by the corollary of the Schur lemma, no nontrivial η exists which commutes with it. Recalling the discussion at the end of the preceding section, we can conclude that the description of the system in $\mathcal{H}$ is unique.

On the contrary, if we now consider $\mathfrak{U}$ as a quaternionic group representation acting on $\mathcal{H}^Q$, it can be proven that this representation is reducible into the direct sum of two equivalent unidimensional irreducible quaternionic representations on $\mathcal{H}^Q$,[14,15] so that $\mathfrak{U}$ admits a nontrivial commutant. By a direct computation, the most general quaternionic Hermitian matrix η commuting with any $U \in \mathfrak{U}$ (hence with any $H \in \mathfrak{h}$) is

$$\eta = \begin{pmatrix} a & jz \\ -jz & a \end{pmatrix}, \quad z \in \mathbf{C}. \tag{9}$$

Since its matrix elements are independent of ω and Ω, η is a *secular* metric in the sense of Ref. 16.

Moreover, η is positive definite whenever $a > |z|$, as one can prove by solving the eigenvalue problem associated with it.[17]

We can conclude that any element $U \in \mathfrak{U}$ is unitary on $\mathcal{H}^Q$,

$$U^\dagger U = \mathbf{1}, \tag{10}$$

and, moreover, it is η-unitary on $\mathcal{H}^Q_\eta$,[18] i.e.,

$$U^\dagger \eta U = \eta. \tag{11}$$

Alternatively, we can say that the Hamiltonian H given in Eq. (4) is anti-Hermitian on $\mathcal{H}^Q$ as well as on the Hilbert space $\mathcal{H}^Q_\eta$ endowed with the scalar product $\langle\Psi|\eta|\Phi\rangle$, since

$$H = \eta H \eta^{-1} = -H^\dagger, \tag{12}$$

where η is given in Eq. (9).

Then, we may describe the dynamics of our system in $\mathcal{H}^Q$ or in $\mathcal{H}^Q_\eta$. Moreover, if the value $a=1$ is chosen in Eq. (9), one obtains that for each vector $|\psi_c\rangle$ with *complex components* $\langle\psi_c|\psi_c\rangle=\langle\psi_c|\eta|\psi_c\rangle$. The relevant physical quantities with respect to both the alternative descriptions can now be easily computed.

Let us compute first the diagonal matrix elements of the angular momentum operators and of the Hamiltonian when the system is described by the vector $|+\rangle=\binom{1}{0}$ and $|-\rangle=\binom{0}{1}$. (In the sequel by an abuse of language, we will call them *expectation values.*) One easily obtains

$$\langle\pm|J_1|\pm\rangle=0, \quad \langle\pm|\eta J_1|\pm\rangle=\mp\tfrac{1}{2}kz,$$

$$\langle\pm|J_2|\pm\rangle=0, \quad \langle\pm|\eta J_2|\pm\rangle=\mp\tfrac{1}{2}jz,$$

$$\langle\pm|J_3|\pm\rangle=\langle\pm|\eta J_3|\pm\rangle=\pm\frac{i}{2},$$

$$\langle\pm|H|\pm\rangle=\pm\frac{i}{2}\omega, \quad \langle+|\eta H|+\rangle=\frac{i}{2}\omega-kz\Omega, \quad \langle-|\eta H|-\rangle=-\frac{i}{2}\omega-kz\Omega^*.$$

All these values are obviously imaginary quaternions. In particular the moduli of the mean values of H are

$$|\langle\pm|H|\pm\rangle|=\frac{|\omega|}{2}, \quad |\langle\pm|\eta H|\pm\rangle|=\sqrt{\frac{\omega^2}{4}+|z|^2|\Omega|^2}, \tag{13}$$

showing then a sharp difference between the two descriptions, which however vanishes as $|z|\to 0$.

More generally, by using the previous results, one can compute all the expectation values associated with any vector $|\mathbf{\Psi}\rangle=\binom{\mathbf{\Psi}_+}{\mathbf{\Psi}_-}$ ($\mathbf{\Psi}_\pm\in\mathbf{Q}$), being trivially $|\mathbf{\Psi}\rangle=|+\rangle\mathbf{\Psi}_++|-\rangle\mathbf{\Psi}_-$. The only obvious warning concerns the norm of $|\mathbf{\Psi}\rangle$, since (as one can obtain by an easy calculation)

$$\langle\mathbf{\Psi}|\eta|\mathbf{\Psi}\rangle=|\mathbf{\Psi}_+|^2+|\mathbf{\Psi}_-|^2+2\,\mathrm{Re}\{\overline{\mathbf{\Psi}}_+jz\mathbf{\Psi}_-\}\neq\langle\mathbf{\Psi}|\mathbf{\Psi}\rangle. \tag{14}$$

(Here, $\overline{\mathbf{\Psi}}_+$ denotes the quaternionic conjugate of $\mathbf{\Psi}_+$.)

Finally, making resort to the form (8) of the evolution operator U, we can also compute the transition probabilities in both the descriptions. Let us for instance assume that the system is in the excited state $|+\rangle$ at $t=0$; the probability of finding the system in the ground state $|-\rangle$ at the time t is given by

$$\mathcal{P}_{+\to-}(t)=|\langle-|U|+\rangle|^2=|G|^2 \tag{15}$$

according to the first description, and by

$$\mathcal{P}'_{+\to-}(t)=|\langle-|\eta U|+\rangle|^2=|z|^2|F|^2+|G|^2. \tag{16}$$

according to the alternative description.[19]

We emphasize in conclusion that the possibility of an alternative description for this model can only occur in QQM, which then appears as a theory intrinsically different from CQM, and not a mere trascription of it.

(Received 24 November 2004; accepted 4 January 2005; published online 22 March 2005; publisher error corrected 9 May 2005)

We introduce a condition for memoryless quantum channels which, when satisfied guarantees the multiplicativity of the maximal ℓ_p-norm with p a fixed integer. By applying the condition to qubit channels, it can be shown that it is not a necessary condition, although some known results for qubits can be recovered. When applied to the Werner-Holevo channel, which is known to violate multiplicativity when p is large relative to the dimension d, the condition suggests that multiplicativity holds when $d \geqslant 2^{p-1}$. This conjecture is proved explicitly for $p=2,3,4$. Finally, a new class of channels is considered which generalizes the depolarizing channel to maps which are combinations of the identity channel and a noisy one whose image is an arbitrary density matrix. It is shown that these channels are multiplicative for $p=2$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1862094]

I. INTRODUCTION

A noisy quantum channel can be described by[9,26,29] means of a completely positive, trace-preserving (CPT) map $\mathcal{E}$ which transforms the density matrices γ on the Hilbert space $\mathcal{H}$ into the output states $\mathcal{E}(\gamma)$. Such maps can always be represented[8,26,29] in the form

$$\mathcal{E}(\gamma) = \sum_k A_k \gamma A_k^\dagger, \quad \sum_k A_k^\dagger A_k = \mathbb{1}, \tag{1}$$

with $\{A_k\}$ called a set of Kraus operators associated with $\mathcal{E}$. When the channel is memoryless,[6] m successive uses are described by the map $\mathcal{E}^{\otimes m}$. It is natural to ask if entangled inputs can decrease the effects of noise for memoryless channels[5] in some way.

One measure of the effect of noise is the maximal ℓ_p-norm of a channel, which is defined as

$$\nu_p(\mathcal{E}) \equiv \sup_{\gamma \in \mathcal{D}(\mathcal{H})} \|\mathcal{E}(\gamma)\|_p, \quad p \geqslant 1, \tag{2}$$

where $\|A\|_p \equiv (\mathrm{Tr}|A|^p)^{1/p}$ is the p-norm of the operator A and where the supremum is taken over all $\mathcal{D}(\mathcal{H})$, the set of density matrices. The quantity $\mathrm{Tr}[\mathcal{E}(\gamma)^p]$ is a measure of the closeness of the output to a pure state, and $\nu_p(\mathcal{E})=1$ if and only if some output state $\mathcal{E}(\gamma)$ is pure. Because the Rényi entropy[30] can be written as $S_p(\rho)=[-1/(p-1)]\log\|\rho\|_p^p$ one could define a maximal output Rényi entropy[2,13,14] satisfying $(p-1)S_{p,\max}(\mathcal{E})=-p\log\nu_p(\mathcal{E})$.

Amosov, Holevo, and Werner (AHW) conjectured[4] that $\nu_p(\mathcal{E})$ is multiplicative for tensor product channels

$$\nu_p(\mathcal{E}^{\otimes m}) \equiv \sup_{\Gamma \in \mathcal{D}(\mathcal{H}^{\otimes m})} \|\mathcal{E}^{\otimes m}(\Gamma)\|_p = [\nu_p(\mathcal{E})]^m, \tag{3}$$

where $\mathcal{E}^{\otimes m}$ is the CPT map which describes m successive memoryless uses of the channel $\mathcal{E}$, and where the maximization in the second term of Eq. (3) is now performed over the density matrices $\Gamma \in \mathcal{D}(\mathcal{H}^{\otimes m})$. The AHW conjecture requires that a product state Γ saturates the supremum of $\nu_p(\mathcal{E}^{\otimes m})$ for the memoryless channel $\mathcal{E}^{\otimes m}$ so that entangled input states Γ do not increase the output norm. One rationale for the multiplicativity hypothesis[4] is the physical intuition that quantum coherence among successive channel uses should be degraded by the action of a memoryless channel. Since the ℓ_p-norm "measures" the purity of the states emerging from the channel, one might expect separable inputs to perform better than entangled inputs. The multiplicativity of $\nu_p(\mathcal{E}^{\otimes m})$ is equivalent to additivity for the minimum Rényi entropy with the same p.[2,13,14] Moreover, if (3) holds for p arbitrarily close to 1, then it implies[4] the additivity of the minimum output von Neumann entropy,[24] another measure of output purity. This has been shown[33] to be related to a conjectured additivity property of the Holevo information,[15] and to conjectures about additivity and superadditivity of the entanglement of formation.[1,27]

Subsequently, Werner and Holevo[34] showed that the general multiplicativity conjecture is false by producing a channel that violates (3) for $p > 4.79$. Nevertheless, one might still expect multiplicativity to hold for some range of p, most notably $1 \leqslant p \leqslant 2$ and this would suffice for many applications in quantum information theory. However, even the case $p=2$ is still not resolved. It is hence important to understand under which circumstances and for which values of p a given channel satisfies Eq. (3). Many authors have tackled this problem by discussing special situations for which the conjecture can be proved.[2,3,10,13,18–23,25,28,32] In the case of a fixed integer p, we provide an upper bound for $\nu_p(\mathcal{E}^{\otimes m})$, and derive a pair of sufficient conditions, either of which ensures that $\mathcal{E}$ satisfies the multiplicativity conjecture (3).

The material is organized as follows. In Sec. II we introduce some notation and present a linearization technique that allows one to compute the ℓ_p-norm of integer order as the expectation value of an operator defined on an extended Hilbert space. In Sec. III we derive our upper bound and show how it leads to a sufficient condition for the multiplicativity of the ℓ_p-norm. Then we apply our condition to several classes of channels. By considering qubit channels in the case $p=2$, we show in Sec. IV A that our sufficient condition is not necessary. We also obtain new proofs of multiplicativity when the two shortest axes of the image ellipsoid (whether or not shifted) are equal. In Sec. IV B we prove multiplicativity when $p=2$ for a shifted depolarizing channel and further generalizations which do not seem to have been considered in the literature. Finally, in Sec. IV C we consider the Werner–Holevo channel[34] for $p=2,3,4$, and obtain new results about multiplicativity when $p=3,4$. We also conjecture that the channel is multiplicative for *any* p when it acts on a space of dimension $d \geqslant 2^{p-1}$.

We include several appendices. The first reviews useful facts about operators, including Hilbert–Schmidt duality, shift and permutation operators, and double stochastic matrices. Appendix A also contains information about the notation, and the proof of an important identity. Appendix B discusses properties and alternative forms of the linearizing operators we use. Appendix C provides details needed for our analysis of the Werner–Holevo channel.

II. LINEARIZATION OF *p*-NORM FUNCTIONS

A. Basic linearization strategy

In this section we present a method, introduced in Ref. 13, that allows one to compute the ℓ_p-norm from the expectation value of a operator defined in an extended Hilbert space. For any integer p, it is possible to find a linear operator $X(\mathcal{E},p)$ defined in the extended Hilbert space $\mathcal{H}^{\otimes p}$ such that, for any density matrix $\gamma \in \mathcal{H}$, we have

$$\mathrm{Tr}[\mathcal{E}(\gamma)]^p = \mathrm{Tr}[(\underbrace{\gamma \otimes \gamma \otimes \cdots \otimes \gamma}_{p\text{-times}})X(\mathcal{E},p)], \tag{4}$$

where the trace on the left-hand side is computed with respect to an orthonormal basis of $\mathcal{H}$, while

the trace on the right-hand side is computed with respect to an orthonormal basis of $\mathcal{H}^{\otimes p}$. In other words, we can represent the p-purity functionTr$[\mathcal{E}(\gamma)]^p$ as the expectation value of $X(\mathcal{E},p)$ on p copies of γ. The operator $X(\mathcal{E},p)$ is not uniquely defined; in fact, it can be realized by the action of tensor products of the dual map of $\mathcal{E}$ on any permutation operator acting on $\mathcal{H}^{\otimes p}$ whose shortest cycle is length p.

To make this explicit, we need some notation, which is explained in more detail in Appendix A, particularly Appendixes A 1 and A 2. We will use a hat to denote the dual, or adjoint, map $\hat{\mathcal{E}}$ with respect to the Hilbert–Schmidt inner product. Let L_p and R_p denote the left and right cyclic shifts which can be defined by their action on an orthonormal product basis as

$$L_p|\xi_1\xi_2\cdots\xi_{p-1}\xi_p\rangle = |\xi_2\cdots\xi_p\xi_1\rangle, \tag{5a}$$

$$R_p|\xi_1\xi_2\cdots\xi_{p-1}\xi_p\rangle = |\xi_p\xi_1\cdots\xi_{p-1}\rangle, \tag{5b}$$

where $|\xi_1\xi_2\cdots\xi_{p-1}\xi_p\rangle = \otimes_{j=1}^{p}|\xi_j\rangle$ and $\{|\xi_k\rangle\}$ is an orthonormal basis for $\mathcal{H}$. Then the operator

$$\Omega(\mathcal{E},p) = \hat{\mathcal{E}}^{\otimes p}(L_p) \tag{6}$$

satisfies (4). This follows from

$$\begin{aligned}\mathrm{Tr}\ \gamma^{\otimes p}\Omega(\mathcal{E},p) &= \mathrm{Tr}(\gamma\otimes\ \gamma\otimes\ \cdots\ \otimes\ \gamma)\hat{\mathcal{E}}^{\otimes p}(L_p)\\ &= \mathrm{Tr}[\mathcal{E}(\gamma)\otimes\mathcal{E}(\gamma)\otimes\ \cdots\ \otimes\mathcal{E}(\gamma)]L_p = \mathrm{Tr}[\mathcal{E}(\gamma)]^p,\end{aligned} \tag{7}$$

where the last step used (A12). It follows from (A14) that L_p could be replaced by another permutation; however, it is important to make a definite choice for later use.

In previous work,[13,14] a different realization of $X(\mathcal{E},p)$ was used which is valid only for pure states. Let

$$\Theta(\mathcal{E},p) = \Omega(\mathcal{E},p)R_p = \hat{\mathcal{E}}^{\otimes p}(L_p)R_p \tag{8}$$

$$= \sum_{k_1,\ldots,k_p} A_{k_1}^{\dagger}A_{k_2}\otimes A_{k_2}^{\dagger}A_{k_3}\otimes\ \cdots\ \otimes A_{k_p}^{\dagger}A_{k_1}, \tag{9}$$

where $\{A_k\}$ form a set of Kraus operators for $\mathcal{E}$ as in (1). The operator $\Theta(\mathcal{E},p)$ satisfies (4) when $\gamma=|\psi\rangle\langle\psi|$ is a pure state. This relation is proved in Appendix B 1, and implicitly shows that it does not depend on the chosen Kraus representation (1) of $\mathcal{E}$. For $p=2$, (9) and (8) were obtained earlier in Ref. 35.

In general, the operator $\Omega(\mathcal{E},p)$ will not be Hermitian. We have already observed that $X(\mathcal{E},p)$ is not unique and that whenever P_p is a permutation operator whose shortest cycle is length p, the operator $\hat{\mathcal{E}}^{\otimes p}(P_p)$ provides another realization. Since $L_p=R_p^{\dagger}$,

$$[\hat{\mathcal{E}}^{\otimes p}(L_p)]^{\dagger} = \hat{\mathcal{E}}^{\otimes p}(L_p^{\dagger}) = \hat{\mathcal{E}}^{\otimes p}(R_p). \tag{10}$$

This implies that $\Omega(\mathcal{E},2)$ is Hermitian for $p=2$, and that the operator

$$\tfrac{1}{2}[\Omega(\mathcal{E},p) + [\Omega(\mathcal{E},p)]^{\dagger}] = \tfrac{1}{2}[\hat{\mathcal{E}}^{\otimes p}(L_p) + \hat{\mathcal{E}}^{\otimes p}(R_p)] \tag{11}$$

gives a Hermitian realization of $X(\mathcal{E},p)$ for any p. However, we do not expect (11) to have the important multiplicity property (14) for repeated uses of the channel. Further discussion of other realizations $X(\mathcal{E},p)$ is given in Appendixes B 2 and B 3.

Linear operators satisfying (4) provide a useful tool for studying the p-purity functions, which are intrinsically nonlinear objects; it reduces some associated problems to the analysis of the linear operator $X(\mathcal{E},p)$ acting on the extended Hilbert space $\mathcal{H}^{\otimes p}$ obtained by adding $p-1$ "fictitious" copies of the input Hilbert space $\mathcal{H}$. In Refs. 13 and 14, this approach was used to obtain some

additivity properties of Gaussian Bosonic channels. For $p=2$, Eq. (4) was used in Ref. 7 to study the fidelity obtainable in continuous-variable teleportation with finite two-mode squeezing, and in Ref. 35 to analyze the purity of generic quantum channels.

B. Tensor product maps

The results derived in the preceding section can also be applied when the basic CPT map is itself a tensor product. Then Eq. (4) becomes

$$\mathrm{Tr}[\mathcal{E}^{\otimes m}(\Gamma)]^p = \mathrm{Tr}[(\underbrace{\Gamma\otimes\Gamma\otimes\cdots\Gamma}_{p\text{-times}})X(\mathcal{E}^{\otimes m},p)], \tag{12}$$

where Γ is a generic density matrix in the input Hilbert space $\mathcal{H}^{\otimes m}$ and $X(\mathcal{E}^{\otimes m},p)$ is a linear operator on $(\mathcal{H}^{\otimes m})^{\otimes p}=\mathcal{H}^{\otimes mp}$. Following the strategy of Sec. II A, we now choose $X(\mathcal{E}^{\otimes m},p)$ to be the operator,

$$\Omega(\mathcal{E}^{\otimes m},p) \equiv (\widehat{\mathcal{E}^{\otimes m}})^{\otimes p}(\mathbb{L}_p) = (\widehat{\mathcal{E}^{\otimes m}})^{\otimes p}(L_p^{\otimes m}). \tag{13}$$

The operator $\mathbb{L}_p$ is described in more detail in Appendix A 3 where it is proved that $\mathbb{L}_p=L_p^{\otimes m}=(L_{mp})^m$. Using $(\widehat{\mathcal{E}^{\otimes m}})^{\otimes p}=(\hat{\mathcal{E}})^{\otimes mp}$, we find

$$\Omega(\mathcal{E}^{\otimes m},p) = \hat{\mathcal{E}}^{\otimes mp}(L_p^{\otimes m}) = [\hat{\mathcal{E}}^{\otimes p}(L_p)]^{\otimes m} = [\Omega(\mathcal{E},p)]^{\otimes m}. \tag{14}$$

Equation (14) is a key result whose simplicity hides a great deal of subtlety. The essential point is that the linear operator $X(\mathcal{E}^{\otimes m},p)$ which satisfies (1) for the tensor product channel $\mathcal{E}^{\otimes m}$ can be realized by the action of the dual of $\mathcal{E}^{\otimes m}$ on the permutation $L_p^{\otimes m}$.

III. CONDITIONS FOR MULTIPLICATIVITY

A. Upper bound

We now use the singular value decomposition[16,17] to observe that one can write

$$\Omega(\mathcal{E},p) = \sum_j \mu_j |\eta_j\rangle\langle\omega_j|, \tag{15}$$

where $\{|\eta_j\rangle\}$ and $\{|\omega_j\rangle\}$ denote orthonormal bases for $\mathcal{H}^{\otimes p}$ and $\mu_j>0$ are the singular values of $\Omega(\mathcal{E},p)$, i.e., the nonzero eigenvalues of $|\Omega(\mathcal{E},p)| \equiv \sqrt{[\Omega(\mathcal{E},p)]^\dagger\Omega(\mathcal{E},p)}$. Before applying this, it is convenient to introduce the convention of using bold uppercase greek letters to denote tensor product vectors as in $|\mathbf{\Psi}\rangle \equiv |\psi\rangle^{\otimes p} = |\psi\rangle\otimes|\psi\rangle\otimes\cdots\otimes|\psi\rangle \in \mathcal{H}^{\otimes p}$. Then

$$\begin{aligned}
\mathrm{Tr}[\mathcal{E}(|\psi\rangle\langle\psi|)]^p &= \langle\mathbf{\Psi}|\Omega(\mathcal{E},p)|\mathbf{\Psi}\rangle \\
&= \sum_j \mu_j \langle\mathbf{\Psi}|\eta_j\rangle\langle\omega_j|\mathbf{\Psi}\rangle \\
&\leqslant \mu_{\max}\sum_j |\langle\mathbf{\Psi}|\eta_j\rangle\langle\omega_j|\mathbf{\Psi}\rangle| \\
&\leqslant \mu_{\max}\|\mathbf{\Psi}\|^2 = \|\Omega(\mathcal{E},p)\|_\infty,
\end{aligned} \tag{16}$$

where $\mu_{\max}=\sup_j \mu_j=\|\Omega(\mathcal{E},p)\|_\infty$ is the largest singular value of $\Omega(\mathcal{E},p)$. Applying this analysis to multiple uses of the channel, one can similarly conclude that

$$\mathrm{Tr}[\mathcal{E}^{\otimes m}(|\Psi\rangle\langle\Psi|)]^p \leqslant \|\Omega(\mathcal{E}^{\otimes m},p)\|_\infty, \tag{17}$$

where $|\Psi\rangle$ is now an arbitrary vector in $\mathcal{H}^{\otimes m}$. However, it follows from (14) that the singular values of $\Omega(\mathcal{E}^{\otimes m},p)$ are products of those of $\Omega(\mathcal{E},p)$ so that

$$\|\Omega(\mathcal{E}^{\otimes m},p)\|_\infty = (\|\Omega(\mathcal{E},p)\|_\infty)^m = (\mu_{\max})^m. \tag{18}$$

Combining (17) and (18), one finds

$$\mathrm{Tr}[\mathcal{E}^{\otimes m}(|\Psi\rangle\langle\Psi|)]^p \leqslant (\|\Omega(\mathcal{E},p)\|_\infty)^m = (\mu_{\max})^m. \tag{19}$$

Since, the supremum in (2) is attained using a pure state input and (19) holds for all pure inputs $|\Psi\rangle$, we conclude that the upper bound

$$\nu_p(\mathcal{E}^{\otimes m}) \leqslant (\mu_{\max})^{m/p}, \tag{20}$$

holds for all pairs of integers m and p.

B. Multiplicativity condition

The bound (20) leads to a sufficient condition for multiplicativity. We state this formally, and give a condition as a corollary.

Theorem 1: *The channel $\mathcal{E}$ has the multiplicativity property (3) if the largest singular value of $\Omega(\mathcal{E},p)$ satisfies*

$$\|\Omega(\mathcal{E},p)\|_\infty = [\nu_p(\mathcal{E})]^p. \tag{21}$$

Corollary 2: *The channel $\mathcal{E}$ has the multiplicativity property (3) if the largest singular value of $\Omega(\mathcal{E},p)$ is also an eigenvalue of $\Omega(\mathcal{E},p)$ with a product eigenvector of the form $|\phi\rangle^{\otimes p}$.*

To prove Theorem 1, observe that in the notation of the preceding section (21) can be written as $\mu_{\max}=[\nu_p(\mathcal{E})]^p$. Then (20) implies

$$\nu_p(\mathcal{E}^{\otimes m}) \leqslant (\mu_{\max})^{m/p} = [\nu_p(\mathcal{E})]^m. \tag{22}$$

On the other hand, one always has

$$\nu_p(\mathcal{E}^{\otimes m}) \geqslant \|\mathcal{E}^{\otimes m}(\gamma_{\max}^{\otimes m})\|_p = \|\mathcal{E}(\gamma_{\max})\|_p^m = [\nu_p(\mathcal{E})]^m,$$

where $\gamma_{\max}$ denotes the state which achieves the supremum for $\nu_p(\mathcal{E})$. Combining these inequalities gives $\nu_p(\mathcal{E}^{\otimes m})=[\nu_p(\mathcal{E})]^m$. QED

To prove the corollary, observe that its hypothesis holds if and only if there is a state $|\phi\rangle$ in $\mathcal{H}$ such that

$$\mu_{\max} = \langle\mathbf{\Phi}|\Omega(\mathcal{E},p)|\mathbf{\Phi}\rangle = \mathrm{Tr}[\mathcal{E}(|\phi\rangle\langle\phi|)]^p, \tag{23}$$

where the second equality used (7) and our convention that $|\mathbf{\Phi}\rangle=|\phi\rangle^{\otimes p}$. But it is always true that

$$\mathrm{Tr}[\mathcal{E}(|\phi\rangle\langle\phi|)]^p \leqslant \sup_\gamma \mathrm{Tr}[\mathcal{E}(\gamma)]^p \equiv [\nu_p(\mathcal{E})]^p \tag{24}$$

so that $\mu_{\max}\leqslant[\nu_p(\mathcal{E})]^p$. Combining this with (20) when $m=1$, implies that $\mu_{\max}=[\nu_p(\mathcal{E})]^p$ so that the hypothesis of Theorem 1 holds. QED

In Sec. IV A we will see that the condition in Theorem 1 is not necessary. There are unital qubit CPT maps, which are known to be multiplicative, but do not satisfy (21). Verifying the hypothesis of Corollary 2 requires that one find an eigenvector as well as the largest singular value of an operator, but does not require knowledge of $\nu_p(\mathcal{E})$; condition (21) does require the latter, but does not require computation of any eigenvectors. In general, (21) seems easier to check. However, in the examples we analyzed, both conditions hold and the process of verifying one easily yields the other. It would be interesting to know if (21) implies that the singular value of $\Omega(\mathcal{E},p)$ is also an eigenvector with a product eigenvalue as in Corollary 2.

IV. APPLICATIONS

A. Qubit channels

1. Notation

We illustrate our condition by looking at some examples of qubit channels, for which we will use notation similar to that introduced in Refs. 25 and 31. Any 2×2 matrix can be represented in the basis consisting of the 2×2 identity matrix $\mathbb{1}$ and the three Pauli matrices which we often write as a formal vector $\vec{\sigma}\equiv(\sigma_1,\sigma_2,\sigma_3)$. In this basis a density matrix can be written as $\gamma=\frac{1}{2}[\mathbb{1}+\vec{w}\cdot\vec{\sigma}]$ with $\vec{w}$ in $\mathbf{R}^3$ and $|\vec{w}|\leqslant 1$. The density matrix is pure if and only if $|\vec{w}|=1$. Any linear map Φ on a qubit, can be described by two real vectors $\vec{s}$, $\vec{t}\in\mathbf{R}^3$ and by a 3×3 real matrix T, through the expression

$$\Phi(z_0\mathbb{1}+\vec{z}\cdot\vec{\sigma})=(z_0+\vec{s}\cdot\vec{z})\mathbb{1}+(z_0\vec{t}+T\cdot\vec{z})\cdot\vec{\sigma}, \tag{25}$$

which holds for all $z_0\in\mathbb{C}$ and $\vec{z}\in\mathbb{C}^3$. This corresponds to representing Φ in the basis $\{\mathbb{1},\vec{\sigma}\}$ by the 4×4 matrix $\left(\begin{smallmatrix}1 & \vec{s}^{\,t}\\ \vec{t} & T\end{smallmatrix}\right)$ which we have written in block form (with the convention that $\vec{t}$ corresponds to a column vector and $\vec{s}^{\,t}$ a row vector, using the superscript t to denote transpose). It was shown in Ref. 24 that it suffices to consider T diagonal with real elements $\{\lambda_1,\lambda_2,\lambda_3\}$. [In essence, a variant of the SVD (which leads to negative as well as positive λ_k) can be applied to T corresponding to rotations on the input and output bases, respectively.]

In this notation, Φ is trace preserving (TP) if and only if $\vec{s}=0$ and it is unital if and only if $\vec{t}=0$. Additional conditions under which the map is positivity preserving or completely positive (CP) are more complex. A complete set of conditions for the map to be CPT was obtained in Ref. 31. When $t_1=t_2=0$, these CPT conditions reduce to $(\lambda_1\pm\lambda_2)^2\leqslant(1\pm\lambda_3)^2-t_3^2$, as shown in Refs. 11 and 31. Since the dual map of Φ is represented by the adjoint matrix, it satisfies,

$$\hat{\Phi}(z_0\mathbb{1}+\vec{z}\cdot\vec{\sigma})=(z_0+\vec{t}\cdot\vec{z})\mathbb{1}+(z_0\vec{s}+T^t\cdot\vec{z})\cdot\vec{\sigma}. \tag{26}$$

Since $\mathcal{H}$ is now two dimensional, the left shift L_2 is simply the SWAP operator S which satisfies

$$S=\tfrac{1}{2}[\mathbb{1}\otimes\mathbb{1}+\sigma_1\otimes\sigma_1+\sigma_2\otimes\sigma_2+\sigma_3\otimes\sigma_3]. \tag{27}$$

It is then straightforward to use (6) to show that

$$\Omega(\Phi,2)=\hat{\Phi}^{\otimes 2}(S)=\frac{1}{2}\left[(1+|\vec{t}|^2)\mathbb{1}\otimes\mathbb{1}+\sum_{j=1}^{3}\lambda_j^2\sigma_j\otimes\sigma_j+\sum_{j=1}^{3}\lambda_j t_j(\mathbb{1}\otimes\sigma_j+\sigma_j\otimes\mathbb{1})\right]. \tag{28}$$

2. Unital maps

For qubit channels the conjecture (2) has been extensively studied in Refs. 18, 19, 22, and 24. Multiplicativity has been proven for all p for unital qubit channels[18] and for $p=2$ for all qubit channels (Theorem 2 of Ref. 18). Here we will use the case $p=2$ to illustrate the multiplicativity criterion presented in Sec. III B.

It will be useful to choose the subscript "max" in {1, 2, 3} so that $|\lambda_{\max}|=\max_k|\lambda_k|$. For unital qubits maps, the maximum ℓ_2-norm of Φ can be achieved with an input state of the form $\frac{1}{2}[\mathbb{1}\pm\sigma_{\max}]$ for which the output $\frac{1}{2}[\mathbb{1}\pm\lambda_{\max}\sigma_{\max}]$ has eigenvalues $\frac{1}{2}[1\pm\lambda_{\max}]$ and

$$\nu_2(\Phi)=\frac{1}{\sqrt{2}}\sqrt{1+\lambda_{\max}^2}. \tag{29}$$

When Φ is unital, $\vec{t}=0$ and the third term in the expression (28) vanishes. It then follows that in the product basis $\{|00\rangle,|01\rangle,|10\rangle,|11\rangle\}$, the operator $\Omega(\Phi,2)$ is represented by the matrix

$$\frac{1}{2}\begin{pmatrix} 1+\lambda_3^2 & 0 & 0 & \lambda_1^2-\lambda_2^2 \\ 0 & 1-\lambda_3^2 & \lambda_1^2+\lambda_2^2 & 0 \\ 0 & \lambda_1^2+\lambda_2^2 & 1-\lambda_3^2 & 0 \\ \lambda_1^2-\lambda_2^2 & 0 & 0 & 1+\lambda_3^2 \end{pmatrix}. \tag{30}$$

This is easily seen to have two nonzero 2×2 blocks. The "inner" block has eigenvalues $\frac{1}{2}[1-\lambda_3^2\pm(\lambda_1^2+\lambda_2^2)]$ with eigenvectors $2^{-1/2}(0,1,\pm 1,0)^t$ corresponding to the Bell states $2^{-1/2}(|01\rangle\pm|10\rangle)$. The "outer" block has eigenvalues $\frac{1}{2}[1+\lambda_3^2\pm(\lambda_1^2-\lambda_2^2)]$ with eigenvectors $2^{-1/2}(1,0,0,\pm 1)^t$ corresponding to the Bell states $2^{-1/2}(|00\rangle\pm|11\rangle)$. Since $\Omega(\Phi,2)$ is Hermitian, its singular values are simply the absolute values of the eigenvalues above.

When the $|\lambda_k|$ are distinct for $k=1,2,3$, the singular values of $\Omega(\Phi,2)$ are all distinct and correspond to maximally entangled, rather than product, states. Moreover, one of the singular values is always strictly greater than $\nu_2(\Phi)$. For example, when $|\lambda_{\max}|=|\lambda_3|$, one of the "outer" eigenvalues equals $\nu_2(\Phi)^2+\frac{1}{2}(\lambda_1^2-\lambda_2^2)$ which is strictly greater than (29) unless $|\lambda_1|=|\lambda_2|$. Therefore, although Φ is multiplicative, it does not satisfy (21). This establishes that (21) is not a necessary condition for multiplicativity.

Now consider the case $\lambda_3>\lambda_1=\lambda_2\geqslant 0$; such channels are sometimes called "two-Pauli" channels.[5] The image of the Bloch sphere is an ellipsoid shaped like an American football. For these channels, the "outer" block in (30) is diagonal, its (degenerate) eigenvalue $\frac{1}{2}(1+\lambda_3^2)=[\nu_2(\Phi)]^2$ is the largest singular value of $\Omega(\Phi,2)$ and the corresponding eigenvectors $|00\rangle$ and $|11\rangle$ are product states. Thus, Theorem 1 implies that the channel satisfies (3).

3. Nonunital maps

We now consider channels similar to those above, but with the image ellipsoid shifted along the longest axis. It suffices to consider $|\lambda_3|\geqslant\lambda_1=\lambda_2\geqslant 0$ and $t_1=t_2=0$. The same results hold for permutations of 1,2,3 and for $\lambda_1=\lambda_2\leqslant 0$. However, the analysis in the basis we have chosen to represent $\Omega(\Phi,2)$ is simplest when $|\lambda_{\max}|=|\lambda_3|$. The matrix representing $\Omega(\Phi,2)$ is

$$\frac{1}{2}\begin{pmatrix} 1+(t_3+\lambda_3)^2 & 0 & 0 & 0 \\ 0 & 1+t_3^2-\lambda_3^2 & 2\lambda_1^2 & 0 \\ 0 & 2\lambda_1^2 & 1+t_3^2-\lambda_3^2 & 0 \\ 0 & 0 & 0 & 1+(t_3-\lambda_3)^2 \end{pmatrix} \tag{31}$$

which has an "inner" block with eigenvalues $\frac{1}{2}[1+t_3^2-\lambda_3^2\pm 2\lambda_1^2]$ and a diagonal "outer" block with eigenvalues $\frac{1}{2}[1+(t_3\pm\lambda_3)^2]$ and product eigenvectors. One can verify that the largest singular value is $\frac{1}{2}[1+(|t_3|+|\lambda_3|)^2]$. To see that this equals $[\nu_2(\Phi)]^2$, observe that the optimal input state is $\frac{1}{2}[\mathbb{1}+(t_3/|t_3|)\sigma_3]$ for which the output state has eigenvalues $\frac{1}{2}[1\pm(|t_3|+|\lambda_3|)^2]$. Thus, we can again use Theorem 1 to conclude that (3) holds.

The methods introduced here are able to handle qubit channels for which the image of the Bloch sphere is an elongated ellipsoid with a symmetry axis, i.e., in the shape of an American football, both when the channel is unital and when it is shifted in the direction of the longest axis. However, it cannot handle these channels if the shift is orthogonal to the longest axis, i.e., if $t_3=0$ but $t_2\neq 0$ above. When the ellipsoid has a symmetry axis but $|\lambda_1|=|\lambda_2|\geqslant|\lambda_3|$ so that it is shaped like a flying saucer, the methods used here cannot prove multiplicativity. Even for unital channels, for which multiplicativity has been established,[19] neither of the conditions in Theorem 1 holds.

B. Shifted depolarizing channels

1. Shifting and generalizing the depolarizing channel

The unital qubit map with $\lambda_k = \pm|\lambda_{\max}|$ for all k, is a special case of the depolarizing channel which has the form $\mathcal{E}(\gamma) = (1-x)(\mathrm{Tr}\,\gamma)\frac{1}{d}\mathbb{1} + x\gamma$. It is CPT for $-\frac{1}{3} \leqslant x \leqslant 1$. The nonunital qubit map which takes

$$\gamma = \tfrac{1}{2}[\mathbb{1} + \vec{w}\cdot\vec{\sigma}] \mapsto \tfrac{1}{2}[\mathbb{1} + (\vec{t} + \lambda\vec{w})\cdot\vec{\sigma}] = (1 - |\vec{t}| - \lambda)\tfrac{1}{2}\mathbb{1} + |\vec{t}|\tfrac{1}{2}[\mathbb{1} + \hat{t}\cdot\vec{\sigma}] + \lambda\gamma \tag{32}$$

can be regarded as a shifted depolarizing channel because it shifts the output toward the point $\hat{t}$ on the Bloch sphere. By rotating coordinates so that $\vec{t} = (0,0,t_3)$, this is a special case of the qubit maps considered in Sec. IV A 3 above. It is then natural to define a shifted depolarizing channel in dimension d by

$$\mathcal{E}(\gamma) = a(\mathrm{Tr}\,\gamma)\frac{1}{d}\mathbb{1} + b(\mathrm{Tr}\,\gamma)|\psi\rangle\langle\psi| + c\gamma \tag{33}$$

with the state $|\psi\rangle$ fixed and $a+b+c=1$. When a,b,c are positive, this channel is a convex combination of the identity map and two completely noisy channels which maps all states to $\frac{1}{d}\mathbb{1}$ and to $|\psi\rangle\langle\psi|$, respectively.

We now consider the more general class of channels of the form

$$\mathcal{E}(\gamma) = (1-c)(\mathrm{Tr}\,\gamma)\rho + c\gamma, \tag{34}$$

where ρ is a fixed density matrix. For $\rho = (1/d)\mathbb{1}$, this is the usual depolarizing channel; for $\rho = [1/(a+b)][(a/d)\mathbb{1} + b|\psi\rangle\langle\psi|]$ it is the shifted depolarizing channel (33).

When $c \geqslant 0$ additivity was proved for the depolarizing channel in d dimensions using a majorization argument[12] from which multiplicativity immediately follows; for $-[1/(d^2-1)] \leqslant c \leqslant 1$ (which is the range for which the map is CPT) multiplicativity of the depolarizing channel in d dimensions was proved in Ref. 21. Neither shifted depolarizing channels nor the generalization (34) seem to have been explicitly considered in the literature before. One could obtain a proof of multiplicativity for $p=2$ when $c>0$ by verifying that the positive element condition in Ref. 25 is satisfied. (In fact, these maps satisfy the stronger condition considered in Ref. 23.) However, neither of these positive element conditions can be verified when $c<0$. By contrast, the method presented here can establish multiplicativity when $p=2$ for all CPT maps of the form (34), including those with $c<0$.

2. Convex combinations of the identity and completely noisy maps

It will be useful to write the spectral decomposition of ρ as $\rho = \Sigma_j a_j |j\rangle\langle j|$ with the eigenvalues a_j in decreasing order. Then, for $c>0$, the state $\mathcal{E}(|1\rangle\langle 1|)$ majorizes all outputs so that $[\nu_p(\mathcal{E})]^p = [ca_1 + (1-c)]^p + c^p \Sigma_{j>1}^d a_j^p$.

Since, $\hat{\mathcal{E}}(B) = (1-c)[\mathrm{Tr}\,B\rho]\mathbb{1} + cB$, we have

$$\hat{\mathcal{E}}(|j\rangle\langle k|) = (1-c)\langle k|\rho|j\rangle\mathbb{1} + c|j\rangle\langle k| = (1-c)\,\delta_{jk}a_k\mathbb{1} + c|j\rangle\langle k| \tag{35}$$

and

$$\begin{aligned}\Omega(\mathcal{E},2) &= (\hat{\mathcal{E}}\otimes\hat{\mathcal{E}})(S) = \sum_{jk}\hat{\mathcal{E}}(|j\rangle\langle k|)\otimes\hat{\mathcal{E}}(|k\rangle\langle j|)\\ &= \sum_{jk}[(1-c)^2\delta_{jk}a_k^2\mathbb{1}\otimes\mathbb{1} + c(1-c)\,\delta_{jk}a_k(\mathbb{1}\otimes|k\rangle\langle k| + |k\rangle\langle k|\otimes\mathbb{1}) + c^2|j\rangle\langle k|\otimes|k\rangle\langle j|]\\ &= (1-c)^2(\mathrm{Tr}\,\rho^2)\mathbb{1}\otimes\mathbb{1} + c(1-c)[\mathbb{1}\otimes\rho + \rho\otimes\mathbb{1}] + c^2 S.\end{aligned} \tag{36}$$

From this it is easy to see that $\Omega(\mathcal{E},2)$ has d product eigenvectors of the form $|kk\rangle$ with eigenvalues

$$(1-c)^2(\mathrm{Tr}\,\rho^2)+2c(1-c)a_k+c^2=[(1-c)a_k+c]^2+(1-c)^2\sum_{j\neq k}a_j^2, \tag{37}$$

and $\binom{d}{2}$ blocks of the form $[(1-c)^2(\mathrm{Tr}\,\rho^2)+c(1-c)(a_j+a_k)]\mathbb{1}_2+c^2\sigma_x$, with eigenvalues

$$(1-c)^2(\mathrm{Tr}\,\rho^2)+c(1-c)(a_j+a_k)\pm c^2 \tag{38}$$

and entangled eigenvectors $2^{-1/2}(|jk\rangle\pm|kj\rangle)$. When $c>0$ all eigenvalues are non-negative and the largest singular value is $[(1-c)a_1+c]^2+(1-c)^2\Sigma_{j>1}a_j^2=[\nu_2(\mathcal{E})]^2$ associated with the product eigenvector $|11\rangle$. Therefore, one can use Theorem 1, or Corollary 2, to conclude that the channel (34) is multiplicative for $p=2$ when $c>0$.

3. CPT maps with a negative contribution from the identity

To analyze the case $c<0$, write $c=-x$ with $x=|c|>0$, and recall that we assumed that the $\{a_j\}$ are decreasing. It can still happen that all eigenvalues of $\Omega(\mathcal{E},2)$ are non-negative, in which case the largest singular value is $[(1+x)a_d-x]^2+(1+x)^2\Sigma_{j<d}a_j^2$ associated with the product eigenvector $|dd\rangle$. It turns out that the requirement that $\mathcal{E}$ be CPT suffices to ensure that the eigenvalues of $\Omega(\mathcal{E},2)$ are non-negative. Therefore, any CPT map of the form (34) is multiplicative for $p=2$.

To see the relevance of the CPT condition, observe that the CP requirement that $(\mathcal{E}\otimes\mathbb{1})(\Sigma_{jk}|j\rangle\langle k|\otimes|j\rangle\langle k|)$ (which is the Choi matrix) is positive semidefinite holds if and only if

$$B=(1+x)\rho-x\begin{pmatrix}1&\cdots&1\\ \vdots&&\vdots\\ 1&\cdots&1\end{pmatrix}$$

is positive semidefinite. Then B has non-negative diagonal elements, which gives

$$(1+x)a_j-x\geqslant 0\Rightarrow x\leqslant\frac{a_j}{1-a_j}\Rightarrow\frac{x}{1+x}\leqslant a_j. \tag{39}$$

All 2×2 principle minors of B are non-negative, which implies

$$(1+x)^2a_1a_2-x(1+x)(a_1+a_2)\geqslant 0. \tag{40}$$

Now, all eigenvalues of $\Omega(\mathcal{E},2)$ will be positive if $(1-c)^2(\mathrm{Tr}\,\rho^2)+c(1-c)(a_j+a_k)-c^2\geqslant 0$ for all j,k. But the most negative of these is

$$\begin{aligned}(1+x)^2(\mathrm{Tr}\,\rho^2)-x(1+x)(a_1+a_2)-x^2&\geqslant(1+x)^2(a_1^2+a_2^2)-(1+x)^2a_1a_2-x^2\\&=(1+x)^2\left[a_1^2+a_2^2-a_1a_2-\left(\frac{x}{1+x}\right)^2\right]\\&\geqslant(1+x)^2[a_1^2+a_2^2-2a_1a_2]=(1+x)^2(a_1-a_2)^2\geqslant 0,\end{aligned} \tag{41}$$

where the second inequality used (39) with $j=1,2$ to conclude that $[x/(1+x)]^2\leqslant a_1a_2$.

C. The Werner–Holevo channel

In our final example, we apply our condition for $p=3,4$ as well as $p=2$. We study the channels $\mathcal{W}_d$ introduced in Ref. 34 to show that multiplicativity does not hold for sufficiently large p. The channel $\mathcal{W}_d$ is defined on a d dimensional Hilbert space as

$$\mathcal{W}_d(\gamma) \equiv \frac{1}{d-1}[(\mathrm{Tr}\,\gamma)\mathbb{1}_d - \gamma^T] = \frac{1}{(d-1)}\sum_{j<k} W_{jk}^\dagger \gamma W_{jk} \tag{42}$$

with $\mathbb{1}_d$ the identity operator on $\mathcal{H}$, γ^T the matrix transpose with respect to some fixed basis $\{|i\rangle\}$, and W_{jk} the anti-Hermitian operator $|j\rangle\langle k| - |k\rangle\langle j|$. (We will often suppress the subscript d and simply write $\mathcal{W}$ for $\mathcal{W}_d$.) As observed in Ref. 34, any pure input state yields an output state $\mathcal{W}(|\psi\rangle\langle\psi|)$ with eigenvalues$1/(d-1)$ with multiplicity $d-1$. This implies

$$\nu_p(\mathcal{W}_d) = (d-1)^{(1-p)/p}. \tag{43}$$

Werner and Holevo showed that for $d=3$ and $p>4.79$ this map is not ℓ_p multiplicative, by showing that maximally entangled inputs yield output ℓ_p-norm greater than $(d-1)^{(1-p)/p}$. For $d>3$, they also showed that multiplicativity fails for sufficiently large p. Although their results strongly suggest that multiplicativity does hold for smaller p, they do not preclude the possibility that it fails with inputs that are partially entangled. Our results show that this cannot happen when $p=2,3,4$ and $d\geqslant 2^{p-1}$.

The multiplicativity of $\mathcal{W}$ for $p=2$ was established in Ref. 25; the additivity of minimal output entropy and Holevo capacity was proved in Refs. 28 and 10; and, recently, a short elegant proof of multiplicativity for all $1\leqslant p\leqslant 2$ was given in Ref. 2. Here we use Theorem 1 to give another proof of (3) for $p=2$, and then consider multiplicativity of $\Omega(\mathcal{W},p)$ for integer $p>2$.

For $p=2$ it is straightforward to show that (or see Appendix C 1)

$$\Omega(\mathcal{W},2) = (\mathcal{W}\otimes\mathcal{W})(S) = \frac{1}{(d-1)^2}[(d-2)\mathbb{1}\otimes\mathbb{1} + S]. \tag{44}$$

with S the SWAP on $\mathcal{H}\otimes\mathcal{H}$. The eigenvalues of $\Omega(\mathcal{W},2)$ can be computed from those of S which has a diagonal block with d product states $|jj\rangle$ as eigenvectors with eigenvalue 1, and $\binom{d}{2}$ blocks of the form $\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$ with eigenvalues $+1$ and -1 corresponding to the entangled states $2^{-1/2}(|jk\rangle \pm |kj\rangle)$. This yields eigenvalues $1/(d-1)$ with multiplicity $d(d+1)/2$ and $(d-3)/(d-1)$ with multiplicity $d(d-1)/2$. For $d\geqslant 3$, these are also the singular values of $\Omega(\mathcal{W},2)$; for $d=2$, $1/(d-1)$ is the only singular value. In both cases $\|\Omega(\mathcal{W},2)\|_\infty = 1/(d-1) = \nu_2(\mathcal{W})$. Therefore, (21) is satisfied and the result follows from Theorem 1.

To study $p>2$, we first observe that (C2) implies that $\Omega(\mathcal{W},p)$ is a linear combination of permutation matrices. This has some important consequences.

(a) $\Omega(\mathcal{W},p)$ has a large number of invariant subspaces, giving it a block diagonal structure. Each block describes the restriction of $\Omega(\mathcal{W},p)$ to a subspace spanned by all permutations of a vector $|\xi_{k_1}\xi_{k_2}\cdots\xi_{k_p}\rangle$ with indices $k_1\leqslant k_2\leqslant\cdots\leqslant k_p$.

(b) All row and column sums are equal. Moreover, (C3) implies that every row and column sum of $\Omega(\mathcal{W},p)$ or, equivalently, of each block, is exactly $(d-1)^{1-p}$, which is also the value of $[\nu_p(\mathcal{W})]^p$.

It follows immediately from (b) that $(d-1)^{1-p}$ is an eigenvalue of each block of $\Omega(\mathcal{W},p)$ and hence, an eigenvalue of $\Omega(\mathcal{W},p)$ with very high degeneracy. Therefore, $\Omega(\mathcal{W},p)$ can have a singular value greater that $[\nu_p(\mathcal{W})]^p$ only if some block has a singular value greater than $(d-1)^{1-p}$. The following lemma, which is proved in Appendix C 5, shows that it will suffice to consider this question for one of the largest blocks.

Lemma 3: When $d\geqslant p$, the largest singular value of $\Omega(\mathcal{W},p)$ is a singular value of each of the $p!\times p!$ blocks representing the restriction of $\Omega(\mathcal{W},p)$ to a subspace of $(\mathbb{C}^d)^{\otimes p}$ spanned by all permutations of a vector $|\xi_{k_1}\xi_{k_2}\cdots\xi_{k_p}\rangle$ with distinct k_p.

Based on this and the structure of the largest blocks as described in Appendx C 4, we make the following conjecture.

Conjecture 4: The ℓ_p multiplicativity relation (3) holds for the channel $\mathcal{W}_d$ when the dimension $d\geqslant 2^{p-1}$.

TABLE I. Block structure of $\Omega(\mathcal{W},p)$.

Number of blocks	Size	Type of vectors	Non-neg elements	max sing value $\times(d-1)^p$		
				$d=3$	$d=4$	$d\geqslant 5$
			$p=3$			
d	1×1	$\|kkk\rangle$	yes	2	3	$d-1$
$d(d-1)$	3×3	$\|jjk\rangle$	yes	2	3	$d-1$
$\binom{d}{3}$	6×6	$\|ijk\rangle$	no	4	3	$\max\{d-1,\|7-d\|\}$
			$p=4$			
d	1×1	$\|kkkk\rangle$	yes	2	3	$d-1$
$d(d-1)$	4×4	$\|jjjk\rangle$	yes	2	3	$d-1$
$\binom{d}{2}$	6×6	$\|jjkk\rangle$	yes	2	3	$d-1$
$\frac{1}{2}d(d-1)(d-2)$	12×12	$\|ijkk\rangle$	no	$\sqrt{18}$	$\sqrt{13}$	$\max\{d-1,\sqrt{d^2-12d+45}\}$
$\binom{d}{4}$	24×24	$\|ijk\ell\rangle$	no		11	$\max\{d-1,\|15-d\|\}$

This conjecture is proved for $p=2,3,4$. For larger p we have shown in Appendix C 4 that the largest block of $\Omega(\mathcal{W},p)$ has two eigenvectors which transform as the two one-dimensional representations of $\mathcal{S}_p$. The corresponding eigenvalues are $(d-1)^{1-p}$ and $(d-1)^{-p}(d-2^p+1)$. When $d\geqslant 2^{p-1}$, $|d-2^p+1|\leqslant d-1$. Moreover, no other singular values have the symmetry associated with a one-dimensional representation of $\mathcal{S}_p$. Thus, if we knew that the largest singular value of $\Omega(\mathcal{W},p)$ must be associated with a one-dimensional irreducible representation, we could conclude that the largest singular value of $\Omega(\mathcal{W},p)$ is $d-1$, proving the conjecture.

Now we consider $p=3,4$. The results in Appendix C 1 can be used to write $\Omega(\mathcal{W},p)$ explicitly as

$$\Omega(\mathcal{W},3)=\frac{1}{(d-1)^3}\left[(d-3)\mathbb{1}+\sum_{a<b}S_{ab}-R_3\right], \tag{45}$$

$$\Omega(\mathcal{W},4)=\frac{1}{(d-1)^4}\left[(d-4)\mathbb{1}+\sum_{a<b}S_{ab}-\sum_{a<b<c}R_3(a,b,c)+R_4\right], \tag{46}$$

where the shift $R_3(a,b,c)$ is defined in Appendix A 2. The block structure of $\Omega(\mathcal{W},p)$ for $p=3,4$ is summarized in Table I. In this table, i,j,k,ℓ always denote distinct indices. For readability, $(d-1)^p\mu_{\max}$ is reported in the last three columns, and should be compared to $(d-1)^p[\nu_p(\mathcal{W})]^p=(d-1)$. For $\Omega(\mathcal{W},3)$ and $\Omega(\mathcal{W},4)$, all singular values can be found explicitly with the help of Mathematica, with the largest for each block shown in Table I. The multiplicativity condition (21) holds if the largest singular value is $(d-1)^{1-p}$. For $p=3$, this holds for $d\geqslant 4$; for $p=4$, it holds for $d\geqslant 8$. For $p=3$, an analytic argument, which does not require determining the eigenvalues of $\Omega(\mathcal{W},3)$, is presented in Appendix C 2.

V. CONCLUSION

We have extended the method introduced in Refs. 13 and 14 to study the maximal ℓ_p-norms of a CPT map when p is a fixed integer. This yields a sufficient condition for multiplicativity which requires only that one find the singular values of a particular matrix, rather than performing

a full optimization. Although the matrix will be $d^p \times d^p$, it often has a block structure which makes the problems quite tractable, as shown in several examples. The condition is not necessary, but does allow us to prove new results about multiplicativity in several interesting cases, as well as providing alternative proofs of known results.

APPENDIX A: SOME OPERATOR PROPERTIES

1. Hilbert–Schmidt duality

For a Hilbert space $\mathcal{H}$ the subspace of operators satisfying $\mathrm{Tr}\, A^\dagger A < \infty$ also forms a Hilbert space (the space of Hilbert–Schmidt operators) with respect to the inner product,

$$\langle A, B\rangle = \mathrm{Tr}\, A^\dagger B. \tag{A1}$$

An operator (sometimes referred to as a "superoperator") $\mathcal{E}$ acting on this space has an adjoint which we will denote $\hat{\mathcal{E}}$ and which satisfies

$$\mathrm{Tr}[\mathcal{E}(A)]^\dagger B = \mathrm{Tr}\, A^\dagger \hat{\mathcal{E}}(B) \quad \forall\, A, B. \tag{A2}$$

Because $[\mathcal{E}(A)]^\dagger = \mathcal{E}(A^\dagger)$, by writing C for $A^\dagger$ one easily sees that (A2) is equivalent to to the condition

$$\mathrm{Tr}[\mathcal{E}(C)]B = \mathrm{Tr}\, C\hat{\mathcal{E}}(B) \quad \forall\, B, C. \tag{A3}$$

The map $\hat{\mathcal{E}}$ is often called the dual of $\mathcal{E}$ because it is defined by the duality property of the Riesz representation theorem applied to the inner product (A1). When $\mathcal{E}$ is a CPT map of the form (1), its dual is the unital CP map with the form

$$\hat{\mathcal{E}}(\gamma) = \sum_k A_k^\dagger B A_k. \tag{A4}$$

One can verify, either directly from (A1) or by using (A4), that the dual of the map $\mathcal{E}^{\otimes m}$ is given by the m-fold tensor product of the dual map of $\mathcal{E}$; i.e., $\widehat{\mathcal{E}^{\otimes m}} = (\hat{\mathcal{E}})^{\otimes m}$.

2. Shift operators

The shift operators defined in (5) are unitary and satisfy $L_p R_p = \mathbb{1}$ so that $L_p^\dagger = L_p^{-1} = R_p$. Moreover, if a vector $|\Psi\rangle$ in $\mathcal{H}^{\otimes p}$ has the expansion

$$|\Psi\rangle = \sum_{j_1 j_2 \cdots j_p} c_{j_1 j_2 \cdots j_p} |\xi_{j_1} \xi_{j_2} \cdots \xi_{j_p}\rangle \tag{A5}$$

then

$$L_p|\Psi\rangle = \sum_{j_1 j_2 \cdots j_p} c_{j_1 j_2 \cdots j_p} |\xi_{j_2} \xi_{j_3} \cdots \xi_p \xi_{j_1}\rangle \tag{A6}$$

$$= \sum_{j_1 j_2 \cdots j_p} c_{j_p j_1 \cdots j_{p-1}} |\xi_{j_1} \xi_{j_2} \cdots \xi_{j_p}\rangle \tag{A7}$$

so that L_p induces a right shift on the expansion coefficients. From this, it follows that L_p and R_p induce left and right shifts on all product states, e.g.,

$$L_p|\phi_1, \phi_2, \ldots, \phi_p\rangle = |\phi_2, \phi_3, \ldots, \phi_p, \phi_1\rangle, \tag{A8a}$$

$$R_p|\phi_1, \phi_2, \ldots, \phi_p\rangle = |\phi_p, \phi_1, \ldots, \phi_{p-1}\rangle, \tag{A8b}$$

where $|\phi_1, \phi_2, \ldots, \phi_p\rangle$ denotes $|\phi_1\rangle \otimes |\phi_2\rangle \otimes \cdots \otimes |\phi_p\rangle$. It also follows from (A8) that the shift operators are independent of the choice of orthonormal basis in (5).

To compute operators associated with the WH channel, it will be useful to observe that

$$L_p = \sum_{m_1 \cdots m_p} |m_2 \cdots m_p m_1\rangle\langle m_1 m_2 \cdots m_p|, \tag{A9a}$$

$$R_p = \sum_{m_1 \cdots m_p} |m_p m_1 \cdots m_{p-1}\rangle\langle m_1 m_2 \cdots m_p|, \tag{A9b}$$

where $|m_j\rangle$ denotes any orthonormal basis of $\mathcal{H}$. It will also be useful to introduce some notation for shift operators on a subset of $\mathcal{H}^{\otimes p}$. For example, write $\mathcal{H}^{\otimes 4} = \mathcal{H}_a \otimes \mathcal{H}_b \otimes \mathcal{H}_c \otimes \mathcal{H}_d$. Then $L_3(a,b,d)$ denotes the operator which acts as a left shift on $\mathcal{H}_a \otimes \mathcal{H}_b \otimes \mathcal{H}_d$ and the identity on $\mathcal{H}_c$, i.e.,

$$L_3(a,b,d) = \sum_{m_1 \cdots m_4} |m_2 m_4 m_3 m_1\rangle\langle m_1 m_2 m_3 m_4|. \tag{A10}$$

The SWAP operators $L_2(a,b) = R_2(a,b)$ play such a special role that we denote them as S_{ab}. Using the standard method for writing any permutation as a product of cycles, one can see that any shift can be written as a product of SWAP operators, e.g., $L_3(a,b,d) = S_{ab} S_{ad}$ and $L_4(a,b,c,d) = S_{ab} S_{ac} S_{ad}$.

3. Tensor products of shifts

When the underlying Hilbert is itself a tensor product $\mathcal{H}^{\otimes m}$, we will let $\mathbb{L}_p$ denote the shift operator acting on p copies of $\mathcal{H}^{\otimes m}$, e.g., $\mathbb{L}_3|x,y,z\rangle = |y,z,x\rangle$ with x,y,z denoting vectors in $\mathcal{H}^{\otimes m}$. Then, $\mathbb{L}_p = L_p^{\otimes m} = (L_{mp})^m$. To avoid notation with double subscripts, we prove this in the case $p = 3$. Then

$$\begin{aligned} \mathbb{L}_3|x,y,z\rangle &= \mathbb{L}_3|x_1,x_2, \ldots, x_m, y_1, y_2, \ldots, y_m, z_1, z_2, \ldots, z_m\rangle \\ &= |y_1, y_2, \ldots, y_m, z_1, z_2, \ldots, z_m, x_1, x_2, \ldots, x_m\rangle \\ &= L_3^{\otimes m}|x_1,x_2, \ldots, x_m, y_1, y_2, \ldots, y_m, z_1, z_2, \ldots, z_m\rangle, \end{aligned} \tag{A11}$$

where the last line follows by writing

$$L_3^{\otimes m} = (L_3 \otimes \mathbb{1} \otimes \cdots \otimes \mathbb{1})(\mathbb{1} \otimes L_3 \otimes \mathbb{1} \otimes \cdots \otimes \mathbb{1}) \cdots (\mathbb{1} \otimes \mathbb{1} \otimes \mathbb{1} \otimes \cdots \otimes \mathbb{1} \otimes L_3)$$

and observing that

$$\begin{aligned} &(L_3 \otimes \mathbb{1} \otimes \cdots \otimes \mathbb{1})|x_1,x_2, \ldots, x_m, y_1, y_2, \ldots, y_m, z_1, z_2, \ldots, z_m\rangle \\ &\quad = |y_1, x_2, \ldots, x_m, z_1, y_2, \ldots, y_m, x_1, z_2, \ldots, z_m\rangle. \end{aligned}$$

Note that it is also evident from (A11) that $L_p^{\otimes m} = (L_{mp})^m$.

4. An important trace identity

We now show that for any set of operators $\{B_1, B_2, \ldots, B_p\}$ acting on $\mathcal{H}$,

$$\mathrm{Tr}_{\mathcal{H}}[B_1 B_2 B_3 \cdots B_p] = \mathrm{Tr}_{\mathcal{H}^{\otimes p}}[B_1 \otimes B_2 \otimes \cdots \otimes B_p] L_p, \tag{A12}$$

where we have introduced subscripts to emphasize that the trace on the left-hand side of Eq. (A12) is performed on $\mathcal{H}$, while the trace on the right-hand side is performed on $\mathcal{H}^{\otimes p}$. To verify (A12) observe that

$$\begin{aligned}
\mathrm{Tr}[B_1 B_2 \cdots B_p] &= \sum_{\xi_1} \langle \xi_1 | B_1 B_2 \cdots B_{p-1} B_p | \xi_1 \rangle \\
&= \sum_{\xi_1, \ldots, \xi_p} \langle \xi_1 | B_1 | \xi_2 \rangle \langle \xi_2 | B_2 | \xi_3 \rangle \cdots \langle \xi_{p-1} | B_{p-1} | \xi_p \rangle \langle \xi_p | B_p | \xi_1 \rangle \\
&= \sum_{\xi_1, \ldots, \xi_p} \langle \xi_1, \xi_2, \ldots, \xi_p | B_1 \otimes B_2 \otimes \cdots \otimes B_p | \xi_2, \ldots, \xi_p, \xi_1 \rangle \\
&= \mathrm{Tr}[B_1 \otimes B_2 \otimes \cdots \otimes B_p] L_p,
\end{aligned}$$

where a resolution of the identity operator $\mathbb{1}$ of $\mathcal{H}$ was inserted between the products $B_j B_{j+1}$.

5. General permutations

Shifts are special cases of permutation operators. Let Π_p denote a permutation of $\{1, 2, \ldots, p\}$ and $\mathcal{S}_p$ the set of all such permutations. We will write $\Pi(j) = k_j$ for the permutation that takes $j \mapsto k_j$. For example, $L_p(j) = j + 1$. One can then define a permutation operator on $\mathcal{H}^{\otimes p}$ by

$$\Pi_p |\xi_{j_1} \xi_{j_2} \cdots \xi_{j_p}\rangle = |\xi_{\Pi(j_1)} \xi_{\Pi(j_2)} \cdots \xi_{\Pi(j_p)}\rangle \tag{A13}$$

with $\{|\xi_j\rangle\}$ an orthonormal basis for $\mathcal{H}$ as in (5). A permutation of the indices $\{1, 2, \ldots, p\}$ induces a permutation on the d^p product basis vectors $\mathcal{H}^{\otimes p}$ via (A13). Although we abuse notation by using the same letter for both, there should be no confusion. The permutation operator on $\mathcal{H}^{\otimes p}$ is represented by a $d^p \times d^p$ matrix which has precisely one 1 and $d^p - 1$ 0's in each row and column.

The permutation which takes $k_1 \mapsto k_2 \mapsto \cdots \mapsto k_q \mapsto k_1$ is called a cycle and written $P = (k_1, k_2, \ldots, k_q)$, i.e., $P(k_j) = (k_{j+1})$ with the understanding that $P(k_q) = k_1$ and $\Pi(j) = j$ if j does not appear as one of the k_i in the cycle. Any permutation can be written uniquely as a product of *disjoint* cycles, and the length of the disjoint cycles in $\Pi P \Pi^\dagger$ are the same as those in P. For example $(13) L_5 (13) = (14532)$. If a permutation of $\{1, 2, \ldots, p\}$ has a cycle decomposition with cycles whose length is strictly less than p, then some subset of $\{1, 2, \ldots, p\}$ is invariant. A permutation Π_p whose shortest cycle is of length p has no invariant subsets. Permutations satisfying this condition, which is equivalent to $(\Pi_p)^s(j) \neq j$ for $s < p$ and $(\Pi_p)^p(j) = j$ for all j, are of particular interest.

In fact, when all operators $B_i = B$ are identical, (A12) can be extended to any permutation Π_p of $\{1, 2, \ldots, p\}$ whose shortest cycle is length p. One finds

$$\begin{aligned}
\mathrm{Tr}_{\mathcal{H}} B^p &= \sum_{\xi_1, \ldots, \xi_p} \langle \xi_1 | B | \xi_{\Pi_p(1)} \rangle \langle \xi_{\Pi_p(1)} | B | \xi_{\Pi_p^2(1)} \rangle \cdots \langle \xi_{(\Pi_p)^p(1)} | B | \xi_1 \rangle \\
&= \sum_{\xi_1, \ldots, \xi_p} \langle \xi_1 | B | \xi_{\Pi_p(1)} \rangle \langle \xi_2 | B | \xi_{\Pi_p(2)} \rangle \cdots \langle \xi_p | B | \xi_{\Pi_p(p)} \rangle \\
&= \sum_{\xi_1, \ldots, \xi_p} \langle \xi_1, \xi_2, \ldots, \xi_p | B \otimes B \otimes \cdots \otimes B | \xi_{k_1}, \xi_{k_2}, \ldots, \xi_{k_p} \rangle \\
&= \mathrm{Tr}_{\mathcal{H}^{\otimes p}}[B \otimes B \otimes \cdots \otimes B] \Pi_p = \mathrm{Tr}_{\mathcal{H}^{\otimes p}} B^{\otimes p} \Pi_p.
\end{aligned} \tag{A14}$$

To see where the invariance condition is used, consider the permutation (153) (24). Attempting to apply the process above yields

$$\mathrm{Tr}_{\mathcal{H}} B^5 = \sum_{\xi_1,\xi_3,\xi_5} \langle\xi_1|B|\xi_5\rangle\langle\xi_5|B|\xi_3\rangle\langle\xi_3|B^3|\xi_1\rangle$$
$$= \sum_{\xi_1,\xi_3,\xi_5} \langle\xi_1,\xi_5,\xi_3|B\otimes B\otimes B^3|\xi_5,\xi_3,\xi_1\rangle = \mathrm{Tr}_{\mathcal{H}_a\otimes\mathcal{H}_c\otimes\mathcal{H}_e}[B\otimes B\otimes B^3]L_3$$

or $\mathrm{Tr}_{\mathcal{H}} B^5 = \mathrm{Tr}_{\mathcal{H}^{\otimes 3}}[B\otimes B^3\otimes B]L_3$ or $\mathrm{Tr}_{\mathcal{H}} B^5 = \mathrm{Tr}_{\mathcal{H}^{\otimes 2}}[B\otimes B^4]L_2$.

6. Double stochastic matrices

A double stochastic matrix[16] is a matrix with non-negative elements whose row and column sums are all 1, i.e., B is double stochastic if and only if $b_{jk}\geqslant 0\,\forall\, j,k$ and $\Sigma_j b_{jk}=\Sigma_k b_{jk}=1$. The vector $(1,1,\ldots,1)$ is always an eigenvector with eigenvalue 1. Moreover, all other eigenvalues satisfy $|\lambda_j|\leqslant 1$. A permutation of $\{1,2,\ldots,p\}$ can be represented by a matrix which has precisely one 1 and $p-1$ 0's in each row and column. This is a special type of double stochastic matrix called a "permutation matrix." Moreover, a permutation Π_p of $\{1,2,\ldots,p\}$ has no nontrivial invariant subspaces if and only if its permutation matrix is indecomposable. Note that the corresponding permutation operator on $\mathcal{H}^p$, represented by a $d^p\times d^p$ matrix with precisely one 1 and d^p-1 0's in each row and column, can have invariant subspaces. In fact, it will be block diagonal.

APPENDIX B: PROPERTIES OF LINEARIZING OPERATORS $X(\mathcal{E},p)$

1. Kraus operator form of $\Omega(\mathcal{E},p)$

We first observe that conjugation of a tensor product of operators by a shift operation induces a shift on the tensor product, e.g.,

$$L_p[B_1\otimes B_2\otimes\cdots\otimes B_p]L_p^{-1} = B_2\otimes\cdots\otimes B_p\otimes B_1. \tag{B1}$$

More generally,

$$\Pi_p[B_1\otimes B_2\otimes\cdots\otimes B_p]\Pi_p^{-1} = B_{\Pi(1)}\otimes B_{\Pi(2)}\cdots\otimes B_{\Pi(p)}. \tag{B2}$$

To prove (9), one can use (1) and (B1) to see that

$$[\hat{\mathcal{E}}^{\otimes p}(L_p)]R_p = \left[\sum_{k_1,\ldots,k_p}(A_{k_1}^\dagger\otimes A_{k_2}^\dagger\otimes\cdots\otimes A_{k_p}^\dagger)L_p(A_{k_1}\otimes A_{k_2}\otimes\cdots\otimes A_{k_p})\right]L_p^{-1}$$
$$= \sum_{k_1,\ldots,k_p}(A_{k_1}^\dagger\otimes A_{k_2}^\dagger\otimes\cdots\otimes A_{k_p}^\dagger)(A_{k_2}\otimes A_{k_3}\otimes\cdots\otimes A_{k_p}\otimes A_{k_1})$$
$$= \sum_{k_1,\ldots,k_p} A_{k_1}^\dagger A_{k_2}\otimes A_{k_2}^\dagger A_{k_3}\otimes\cdots\otimes A_{k_p}^\dagger A_{k_1} \tag{B3}$$

which gives the desired result. Moreover, using a similar argument and (B2), one finds

$$R_p[\hat{\mathcal{E}}^{\otimes p}(L_p)] = R_p\left[\sum_{k_1,\ldots,k_p}(A_{k_1}^\dagger\otimes A_{k_2}^\dagger\otimes\cdots\otimes A_{k_p}^\dagger)L_p^{-1}(A_{k_1}\otimes A_{k_2}\otimes\cdots\otimes A_{k_p})\right]$$
$$= \sum_{k_1,\ldots,k_p} A_{k_p}^\dagger A_{k_1}\otimes A_{k_1}^\dagger A_{k_2}\otimes\cdots\otimes A_{k_{p-1}}^\dagger A_{k_p}. \tag{B4}$$

Then by observing that both (B3) and (B4) involve tensor products of operators of the form $A_{k_j}^\dagger A_{k_{j+1}}$, one sees that after a change of variable in the summation indices, e.g., $k_j\to k_{j-1}$ in (B4), the two expressions are identical. Therefore, R_P commutes with $\hat{\mathcal{E}}^{\otimes p}(L_p)$ and $\Theta(\mathcal{E},p)=\Omega(\mathcal{E},p)R_p=R_p\Omega(\mathcal{E},p)$.

2. General permutations

Define $\mathcal{X}(\mathcal{E},p)$ the set of operators $X(\mathcal{E},p)$ of $\mathcal{H}^{\otimes p}$ that satisfy the property (4) for all the input states γ of $\mathcal{H}$. We have already seen that $\hat{\mathcal{E}}^{\otimes p}(L_p)$ is in $\mathcal{X}(\mathcal{E},p)$ which implies that it is nonempty. Moreover, the linearity of Eq. (4) with respect to $X(\mathcal{E},p)$ implies that whenever $X(\mathcal{E},p)$ and $Y(\mathcal{E},p)$ are in $\mathcal{X}(\mathcal{E},p)$, then $aX(\mathcal{E},p)+(1-a)Y(\mathcal{E},p)$ is in $X(\mathcal{E},p)$ is also. This is true for any real number a including $a<0$ and $a>1$, and even for complex a. By choosing $0<a<1$, we can also conclude that $\mathcal{X}(\mathcal{E},p)$ is convex; however, $\mathcal{X}(\mathcal{E},p)$ is not compact. Because $\mathrm{Tr}[\mathcal{E}(\gamma)]^p$ is real,

$$\mathrm{Tr}\ \gamma^{\otimes p}X(\mathcal{E},p) = \overline{\mathrm{Tr}\ \gamma^{\otimes p}X(\mathcal{E},p)} = \mathrm{Tr}[\gamma^{\otimes p}X(\mathcal{E},p)]^\dagger = \mathrm{Tr}[X(\mathcal{E},p)]^\dagger\gamma^{\otimes p} = \mathrm{Tr}\ \gamma^{\otimes p}[X(\mathcal{E},p)]^\dagger \tag{B5}$$

for all density matrices γ. Therefore, whenever $X(\mathcal{E},p)$ is in $\mathcal{X}(\mathcal{E},p)$ so are $[X(\mathcal{E},p)]^\dagger$ and the self-adjoint operator $\frac{1}{2}(X(\mathcal{E},p)+[X(\mathcal{E},p)]^\dagger)$.

In view of the discussion in Appendix A 4 we can also conclude that the operator $\hat{\mathcal{E}}^{\otimes p}(\Pi_p)$ is in $\mathcal{X}$ whenever Π_p is a permutation whose shortest cycle is length p. Moreover, a modification of the argument in the preceding section shows that, for these permutations,

$$\hat{\mathcal{E}}^{\otimes p}(\Pi_p)\Pi_p^\dagger = \Pi_p^\dagger\hat{\mathcal{E}}^{\otimes p}(\Pi_p) = \sum_{k_1,\ldots,k_p} A_{k_1}^\dagger A_{\Pi(k_1)} \otimes A_{k_2}^\dagger A_{\Pi(k_2)} \otimes \cdots \otimes A_{k_p}^\dagger A_{\Pi(k_p)}. \tag{B6}$$

Since $\Pi_p\gamma^{\otimes p}\Pi_p^\dagger=\Pi_p$ for any permutation,

$$\mathrm{Tr}[\gamma^{\otimes p}(\Pi_p X(\mathcal{E},p)\Pi_p^\dagger)] = \mathrm{Tr}[(\Pi_p^\dagger\gamma^{\otimes p}\Pi_p)X(\mathcal{E},p)] = \mathrm{Tr}\ \gamma^{\otimes p}X(\mathcal{E},p) = \mathrm{Tr}[\mathcal{E}(\gamma)^p]. \tag{B7}$$

Note that the map $P_p\mapsto\Pi_pP_p\Pi_p^\dagger$ does not change the cycle structure of P_p, e.g., if P_p is a product of a 3-cycle and a disjoint 2-cycle, then so is $\Pi_pP_p\Pi_p^\dagger$. Thus, $\Pi_pL_p\Pi_p^\dagger$ is a permutation whose shortest cycle is length p irrespective of the cycle structure of Π_p. One can show that $\Pi_p[\hat{\mathcal{E}}^{\otimes p}(L_p)]\Pi_p^\dagger=\hat{\mathcal{E}}^{\otimes p}(\Pi_pL_p\Pi_p^\dagger)$, with a similar result when L_p is replaced by any permutation whose shortest cycle is length p.

3. Linearizing operators for pure inputs

The set $\mathcal{X}(\mathcal{E},p)$ is a subset of $\mathcal{X}_{\mathrm{pure}}(\mathcal{E},p)$, the set of operators, which satisfy the property (4) when $\gamma=|\psi\rangle\langle\psi|$ is pure. We have already observed that $\Theta(\mathcal{E},p)=\Omega(\mathcal{E},p)R_p$ belongs to $\mathcal{X}_{\mathrm{pure}}(\mathcal{E},p)$ but need not belong to $\mathcal{X}(\mathcal{E},p)$. It follows from (B6) that the operators $\hat{\mathcal{E}}^{\otimes p}(\Pi_p)\Pi_p^\dagger$ are also in $\mathcal{X}_{\mathrm{pure}}(\mathcal{E},p)$. In addition, for any $X(\mathcal{E},p)\in\mathcal{X}_{\mathrm{pure}}(\mathcal{E},p)$ the operators $X(\mathcal{E},p)\Pi_p$ and $\Pi_pX(\mathcal{E},p)$ are also in $\mathcal{X}_{\mathrm{pure}}(\mathcal{E},p)$ for all permutations Π_p. This follows from

$$\begin{aligned}\mathrm{Tr}[\gamma\otimes\gamma\otimes\cdots\otimes\gamma]X(\mathcal{E},p)\Pi_p &= \mathrm{Tr}|\psi\rangle\langle\psi|\otimes|\psi\rangle\langle\psi|\otimes\cdots\otimes|\psi\rangle\langle\psi|X(\mathcal{E},p)\Pi_p\\ &= \mathrm{Tr}\,\Pi_p|\psi,\ldots,\psi\rangle\langle\psi,\ldots,\psi|X(\mathcal{E},p)\\ &= \mathrm{Tr}|\psi,\ldots,\psi\rangle\langle\psi,\ldots,\psi|X(\mathcal{E},p)\\ &= \mathrm{Tr}[\gamma\otimes\gamma\otimes\cdots\otimes\gamma]X(\mathcal{E},p) = \mathrm{Tr}\,\mathcal{E}(\gamma)^p,\end{aligned}$$

whenever $\gamma=|\psi\rangle\langle\psi|$ is pure.

APPENDIX C: OPERATORS FOR WERNER–HOLEVO CHANNEL

1. General form of $\Omega(\mathcal{W},p)$

It follows from (42), (A9), and (6) that for the WH channel,

$$\Omega(\mathcal{W},p) = \sum_{\xi_1\cdots\xi_p} \mathcal{W}(|\xi_2\rangle\langle\xi_1|) \otimes \mathcal{W}(|\xi_3\rangle\langle\xi_2|) \otimes \cdots \mathcal{W}(|\xi_p\rangle\langle\xi_{p-1}|)\mathcal{W}(|\xi_1\rangle\langle\xi_p|)$$

$$= \frac{1}{(d-1)^p} \sum_{\xi_1\cdots\xi_p} (\delta_{\xi_2\xi_1}\mathbb{1} - |\overline{\xi_1}\rangle\langle\overline{\xi_2}|) \otimes (\delta_{\xi_3\xi_2}\mathbb{1} - |\overline{\xi_2}\rangle\langle\overline{\xi_3}|) \otimes \cdots \otimes (\delta_{\xi_1\xi_p}\mathbb{1} - |\overline{\xi_p}\rangle\langle\overline{\xi_1}|)$$

$$= \frac{1}{(d-1)^p}\Bigg[d\mathbb{1} - \Bigg(\sum_{\xi_1} |\overline{\xi_1}\rangle\langle\overline{\xi_1}| + \sum_{\xi_2} |\overline{\xi_1}\rangle\langle\overline{\xi_2}| + \cdots + \sum_{\xi_p} |\overline{\xi_1}\rangle\langle\overline{\xi_p}|\Bigg)$$

$$+ \sum_{a<b} \Bigg(\sum_{\xi_a\xi_b} |\overline{\xi_a}\overline{\xi_b}\rangle\langle\overline{\xi_b}\overline{\xi_a}|\Bigg) - \cdots + (-1)^p \sum_{\xi_1\cdots\xi_p} |\overline{\xi_1}\overline{\xi_2}\cdots\overline{\xi_{p-1}}\overline{\xi_p}\rangle\langle\overline{\xi_2}\overline{\xi_3}\cdots\overline{\xi_p}\overline{\xi_1}| \qquad \text{(C1)}$$

$$= \frac{1}{(d-1)^p}\Bigg[(d-p)\mathbb{1} + \sum_{a<b} S_{ab} - \sum_{a<b<c} R_3(a,b,c) + \cdots + (-1)^p R_p \Bigg], \qquad \text{(C2)}$$

where we have used the notation introduced at the end of Appendix A 2. Note that the orthonormal basis $\{|\xi_j\rangle\}$ can be chosen real, but even if it is not, $\{|\overline{\xi_j}\rangle\}$ gives another orthonormal basis for $\mathcal{H}$ for which the representation (A9) is also valid.

It is useful to compare the structure of (C2) to that of a binomial expansion. The term in square brackets is a sum of shift operators R_k of order $k=0,1,2,\ldots,p$. For $k\geqslant 2$ the number of R_k is $\binom{p}{k}$ with coefficient $(-1)^k$. In view of (C1), the $(d-p)\mathbb{1}$ term should be regarded as the sum of a $k=0$ term $d\mathbb{1}$ and a $k=1$ term $-p\mathbb{1}$. The coefficient of the $k=0$ term is anomalous, since it has the value d rather than 1. This implies that the row and column sums of the matrix representing $\Omega(\mathcal{W},p)$ in the orthonormal basis $\{|\overline{\xi_{j1}}\overline{\xi_{j2}}\cdots\overline{\xi_{jp}}\rangle\}$ of $\mathcal{H}^{\otimes p}$ are

$$\frac{1}{(d-1)^p}\left[d + \sum_{k=1}^{p} (-1)^k \binom{p}{k} \right] = \frac{d-1}{(d-1)^p}. \qquad \text{(C3)}$$

One similarly finds that the sum of the absolute values of elements in any row or column sum is bounded above by

$$\frac{1}{(d-1)^p}\left[d + \sum_{k=1}^{p} \binom{p}{k} \right] = \frac{(d-1+2^p)}{(d-1)^p},$$

and will use the fact that

$$\sum_{k=2}^{p} \binom{p}{k} = 2^p - p - 1.$$

2. Singular value analysis for $p=3$

We first remark that one can reduce the analysis of $\Omega(\mathcal{W},3)$ to that of its 6×6 blocks without using Lemma 3. When $p=3$, all blocks with basis vectors $|jjk\rangle$ with $j\neq k$ have only non-negative elements. To see why, note that the only negative contribution comes from R_3, for which $\langle jjk|R_3|jkj\rangle=-1$ is the only nonzero element of the row corresponding to jjk. But $\langle jjk|\Omega|jkj\rangle \geqslant \langle jjk|(S_{ac}-R_3)|jkj\rangle=0$. Therefore, every 3×3 block is represented by a stochastic matrix and, hence, its column sum $(d-1)^{1-p}$ is also its largest singular value. Thus, only the 6×6 blocks of $\Omega(\mathcal{W},3)$ can have negative elements and, hence, a singular value greater than $(d-1)^{1-p}$.

Using an ordered basis whose first three elements are $\{|ijk\rangle, L_3|ijk\rangle, L_3^2|ijk\rangle\}$ and last three $S_{ab}\{|ijk\rangle, S_{bc}|ijk\rangle, S_{ac}|ijk\rangle\}$, one can write each 6×6 block as $(d-1)^{-3}F$ with

TABLE II. Singular value decomposition of $\Omega(\mathcal{W},4)$ on the 12-dimensional subspace generated by the vectors $\{|ijkk\rangle,|jikk\rangle,\ldots,|kjik\rangle\}$ and the 24-dimensional subspace generated by $\{|ijk\ell\rangle,|jjk\ell\rangle,\ldots,|kji\ell\rangle\}$.The singular values $\Omega(\mathcal{W},4)$ are given in the left column, with the corresponding degeneracies in the central and right columns.

Singular value $\times(d-1)^4$	Degeneracy (12×12 blocks)	Degeneracy (24×24 blocks)
$\sqrt{d^2-12d+45}$	2	6
$\lvert d-5\rvert$	1	3
$\lvert d-3\rvert$	3	5
$\sqrt{d^2-4d+5}$	4	6
$\lvert d-1\rvert$	2	3
$\lvert d-15\rvert$	0	1

$$F=(d-3)\mathbb{1}_6+\begin{pmatrix}-L_3 & V\\ V & -L_3\end{pmatrix}\quad\text{and } V=\begin{pmatrix}1&1&1\\1&1&1\\1&1&1\end{pmatrix}. \tag{C4}$$

Then

$$\begin{aligned}F^\dagger F&=(d-3)^2\mathbb{1}+(d-3)[G+G^\dagger]+G^\dagger G\\&=(d^2-5d+7)\mathbb{1}_6+\begin{pmatrix}-d+6 & 2d-8\\ 2d-8 & -d+6\end{pmatrix}\otimes V.\end{aligned} \tag{C5}$$

Since the eigenvalues of V are 3, 0, 0, the nonzero eigenvalues of $F^\dagger F$ are d^2-5d+7 (with fourfold degeneracy) and $(d^2-5d+7)+3[(6-d)\pm(2d-8)]$ or $(d-7)^2$ and $(d-1)^2$. Now $(d^2-5d+7)\leqslant(d-1)^2$ when $d\geqslant2$ and $(d-7)^2\leqslant(d-1)^2$ if and only if $d\geqslant4$. Therefore, when $d\geqslant4$ the largest singular value of this block is $d-1$ which implies that the largest singular value of $\|\Omega(\mathcal{W},3)\|_\infty=(d-1)^{-2}$.

3. Singular value analysis for $p=4$

For $p=4$, one can show that the 4×4 and 6×6 blocks have only non-negative elements. Therefore, their largest singular value is the same as the column sum $(d-1)^{-3}$. $\Omega(\mathcal{W},4)$ also has 12×12 blocks corresponding to permutations of $|ijkk\rangle$, with i,j,k distinct and 24×24 blocks corresponding to permutations of $|ijk\ell\rangle$, with i,j,k,ℓ distinct. By Lemma 3, the largest singular value is associated with the latter. Nevertheless, an analysis of all blocks was performed using Mathematica, yielding the results summarized in Table II. This confirms that the largest singular value of $\Omega(\mathcal{W},4)$ is $(d-1)^{-3}$ when $d\geqslant8$.

4. Structure of largest block

a. Preliminaries

Recall that every permutation P in $\mathcal{S}_p$ can be classified as even or odd, depending on the number of transpositions (or SWAP) operators needed to write it as a product $P=S_{a_1b_1}S_{a_2b_2}\cdots S_{a_mb_m}$. Although this decomposition is not unique, m is either always even or always odd. Let $|P|$ be the minimal number of swaps needed so that

$$(-)^{|P|}=\begin{cases}+1 & \text{if } P \text{ is even}\\ -1 & \text{if } P \text{ is odd}\end{cases}.$$

Note that $S(a,b)$ and $R_4(a,b,c,d)$ are odd and $R_3(a,b,c)$ is even. More generally, a shift of j elements is even when j is odd and odd when j is even. Thus, one can write

$$\Omega(\mathcal{W},p) = \frac{1}{(d-1)^p}[(d-p)\mathbb{1} + \tilde{\Omega}_{\text{odd}} - \tilde{\Omega}_{\text{even}}], \tag{C6}$$

where $\tilde{\Omega}_{\text{odd}}$ is the sum over odd permutations (even shifts) in (C2) and $\tilde{\Omega}_{\text{even}}$ the sum over even permutations (odd shifts) in (C2).

Fix $k_1<k_2<\cdots<k_p$ and let $\mathcal{K}$ denote the subspace spanned by $\{P|\xi_{k_1},\xi_{k_2},\ldots,\xi_{k_p}\rangle : P\in\mathcal{S}_p\}$ where $|\xi_k\rangle$ is an orthonormal basis for $\mathbb{C}^d$ and the action of P is as defined in (A13). The matrix representing a particular permutation operator Π has elements

$$\pi_{st} = \langle \xi_{k_1},\xi_{k_2},\ldots,\xi_{k_p}|P_s^\dagger \Pi P_t|\xi_{k_1},\xi_{k_2},\ldots,\xi_{k_p}\rangle \tag{C7}$$

which depends *only* on the labeling P_s, $s=1,2,\ldots,p!$ of elements of $\mathcal{S}_p$ and not on the choice of indices k_j or vectors ξ_j. It will be convenient to simply use $|k\rangle$ to denote $|\xi_k\rangle$, and to write $|\Pi(k_1,k_2,\ldots,k_p)\rangle$ for $\Pi|\xi_{k_1},\xi_{k_2},\ldots,\xi_{k_p}\rangle$. (The condition $k_j<k_{j+1}$ is only a convenient convention; the essential requirement is that the k_j are distinct.)

b. Irreducible representation structure

The matrix representing the action of a permutation Π on the vectors $\{P|k_1,k_2,\ldots,k_p\rangle : P\in\mathcal{S}_p\}$ is identical to its matrix in the regular representation of $\mathcal{S}_p$. Therefore, one can find a unitary transformation to a basis whose components form disjoint subsets which transform as the irreducible representation of $\mathcal{S}_p$. This basis change simultaneously converts all permutations to a block diagonal form. Thus, $\Omega(\mathcal{W},p)$, is also block diagonal with each block corresponding to an irreducible representation of $\mathcal{S}_p$. The two one-dimensional representations, therefore, yield eigenvectors of $\Omega(\mathcal{W},p)$. In fact

$$\Omega(\mathcal{W},p)|\phi_{\text{sym}}\rangle = \frac{d-1}{(d-1)^p}|\phi_{\text{sym}}\rangle, \tag{C8a}$$

$$\Omega(\mathcal{W},p)|\phi_{\text{anti}}\rangle = \frac{d-2^p+1}{(d-1)^p}|\phi_{\text{anti}}\rangle, \tag{C8b}$$

where

$$|\phi_{\text{sym}}\rangle = \frac{1}{\sqrt{p!}}\sum_{P\in\mathcal{S}_p}|P(k_1,k_2,\ldots,k_p)\rangle = \frac{1}{\sqrt{2}}(|u_{\text{even}}\rangle + |u_{\text{odd}}\rangle), \tag{C9a}$$

$$|\phi_{\text{anti}}\rangle = \frac{1}{\sqrt{p!}}\sum_{P\in\mathcal{S}_p}(-)^{|P|}|P(k_1,k_2,\ldots,k_p)\rangle = \frac{1}{\sqrt{2}}(|u_{\text{even}}\rangle - |u_{\text{odd}}\rangle), \tag{C9b}$$

with

$$|u_{\text{even}}\rangle = \sqrt{\frac{2}{p!}}\sum_{p_{\text{even}}}|P(k_1,k_2,\ldots,k_p)\rangle,$$

and

$$|u_{\text{odd}}\rangle = \sqrt{\frac{2}{p!}}\sum_{p_{\text{odd}}}|P(k_1,k_2,\ldots,k_p)\rangle.$$

If we could conclude that the largest singular value of $(d-1)^p\Omega(\mathcal{W},p)$ is associated with a one-dimensional representation of $\mathcal{S}_p$, then we could conclude that $(d-1)^p\|\Omega(\mathcal{W},p)\|_\infty = \max\{d-1,|d-2^p+1|\}$. Note that this maximum is clearly $d-1$ when $d\geqslant 2^p-1$. For $d<2^p$, the maximum is $d-1$ if and only if $2^p-d-1\leqslant d-1\Leftrightarrow 2d\geqslant 2^p$.

c. Odd/even structure

We now describe the odd/even structure of $\Omega(\mathcal{W},p)$. We can divide the $p!$ basis vectors of $\mathcal{K}$ into two equal subsets, those of the form $P_{\text{even}}|k_1,k_2,\ldots,k_p\rangle$ and those of the form $P_{\text{odd}}|k_1,k_2,\ldots,k_p\rangle$. We will denote their spans as $\mathcal{K}_{\text{even}}$ and $\mathcal{K}_{\text{odd}}$, respectively. Now $\langle k_1,k_2,\ldots,k_p|\Pi|k_1,k_2,\ldots,k_p\rangle=0$ unless Π is the identity permutation. Therefore $\langle P_s(k_1,k_2,\ldots,k_p)|\Pi|P_t(k_1,k_2,\ldots,k_p)\rangle=0$ unless $\Pi=P_sP_t^\dagger=I$. Moreover, since the identity is an even permutation

$$\langle P_{\text{even}}(k_1,k_2,\ldots,k_p)|\Pi_{\text{odd}}|\tilde{P}_{\text{even}}(k_1,k_2,\ldots,k_p)\rangle=\langle P_{\text{odd}}(k_1,k_2,\ldots,k_p)|\Pi_{\text{odd}}|\tilde{P}_{\text{odd}}(k_1,k_2,\ldots,k_p)\rangle=0, \tag{C10}$$

$$\langle P_{\text{even}}(k_1,k_2,\ldots,k_p)|\Pi_{\text{even}}|\tilde{P}_{\text{odd}}(k_1,k_2,\ldots,k_p)\rangle=\langle P_{\text{odd}}(k_1,k_2,\ldots,k_p)|\Pi_{\text{even}}|\tilde{P}_{\text{even}}(k_1,k_2,\ldots,k_p)\rangle=0. \tag{C11}$$

Thus, the largest block of $(d-1)^p\Omega(\mathcal{W},p)$ can be written in the form

$$B=(d-p)\mathbb{1}+\begin{pmatrix}-B_{\text{ee}} & B_{\text{oe}}\\ B_{\text{eo}} & -B_{\text{oo}}\end{pmatrix}$$

with B_{ee} and B_{oo} determined by $\tilde{\Omega}_{\text{even}}$ and B_{eo} and B_{oe} determined by $\tilde{\Omega}_{\text{odd}}$.

It is useful to relate the order of elements within the bases associated with odd and even permutations. Let $P_1,P_2,\ldots,P_M$ with $M=p!/2$ denote the even permutations (with $P_1=\mathbb{1}$) and $P_{t+M}=P_tS$ the odd, where S denotes the swap operator $S(k_1,k_2,k_3,\ldots,k_p)=k_2,k_1,k_3,\ldots,k_p$. (There is nothing special about applying SWAP to the first two elements. Any fixed choice would do.) Then

$$\begin{aligned}b_{s,t+M}&=\langle P_s(k_1,k_2,\ldots,k_p)|\Pi|P_tS(k_1,k_2,\ldots,k_p)\rangle\\&=\langle P_sS(k_2,k_1,\ldots,k_p)|\Pi|P_t(k_2,k_1,\ldots,k_p)\rangle=b_{s+M,t},\end{aligned} \tag{C12}$$

where we used the fact that the matrix representing a permutation is independent of the initial choice of k_i. Thus, $B_{\text{eo}}=B_{\text{oe}}$ and, for the same reason, $B_{\text{ee}}=B_{\text{oo}}$, and we can write

$$B=(d-p)\mathbb{1}+\begin{pmatrix}-W_{\text{e}} & W_{\text{o}}\\ W_{\text{o}} & -W_{\text{e}}\end{pmatrix}=(d-p)\mathbb{1}+B_{\text{off}}, \tag{C13}$$

where W_{e} and W_{o} are determined by $\tilde{\Omega}_{\text{even}}$ and $\tilde{\Omega}_{\text{odd}}$, respectively. By conjugating with $\left(\begin{smallmatrix}1&0\\0&-1\end{smallmatrix}\right)$, one finds that B has the same singular values as

$$G=(d-p)\mathbb{1}-\begin{pmatrix}W_{\text{e}} & W_{\text{o}}\\ W_{\text{o}} & W_{\text{e}}\end{pmatrix}=(d-p)\mathbb{1}-G_{\text{off}}. \tag{C14}$$

Note that we have shown that the restriction of $\Omega(\mathcal{W},p)$ to $\mathcal{K}$ is similar to $1/(d-1)^p[(d-p)\mathbb{1}-\tilde{\Omega}_{\text{odd}}-\tilde{\Omega}_{\text{even}}]$ which differs from (C6) by a sign. Although this may seem surprising, it could easily be established directly by observing that any vector $|v\rangle\in\mathcal{K}$ can be written as $|v\rangle=|v_{\text{even}}\rangle+|v_{\text{odd}}\rangle$ with $|v_{\text{even}}\rangle\in\mathcal{K}_{\text{even}}$ and $|v_{\text{odd}}\rangle\in\mathcal{K}_{\text{odd}}$. Using (C3) and related combinatorics, one finds that the row and column sums of B, G, W_{e}, and W_{o} are, respectively, $d-1$, $d-2^p+1$, $2^{p-1}-p$, and $2^{p-1}-1$. It follows that $d-1$ and $d-2^p+1$ are eigenvalues of B and G,

$$B\begin{pmatrix}1\\1\end{pmatrix}=(d-1)\begin{pmatrix}1\\1\end{pmatrix},\quad B\begin{pmatrix}1\\-1\end{pmatrix}=(d-2^p+1)\begin{pmatrix}1\\-1\end{pmatrix}, \tag{C15a}$$

$$G\begin{pmatrix} 1 \\ -1 \end{pmatrix} = (d-1)\begin{pmatrix} 1 \\ -1 \end{pmatrix}, \quad G\begin{pmatrix} 1 \\ 1 \end{pmatrix} = (d-2^p+1)\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \tag{C15b}$$

where 1 denotes a vector with all 1's. These are easily seen to be equivalent to (C8).

The main reason for changing B to the form (C14) is that G_{off} is a multiple of a double stochastic matrix, its column sum 2^p-p-1 is both its largest eigenvalue and its largest singular value. Therefore, $d-2^p+1$ is the smallest eigenvalue of G; however, even when it is the most negative eigenvalue, we cannot conclude that it is also the largest singular value because G could have a positive, or complex, eigenvalue of greater magnitude.

Remark: Conjugating B with the block Hadamard transform $H=2^{-1/2}\begin{pmatrix} \mathbb{1} & \mathbb{1} \\ \mathbb{1} & -\mathbb{1} \end{pmatrix}$ corresponds to making the change of basis to (C18). One finds

$$HFH^\dagger = (d-p)\mathbb{1} + \begin{pmatrix} -W_e + W_o & 0 \\ 0 & -W_e - W_o \end{pmatrix}. \tag{C16}$$

5. Proof that $\|\Omega(\mathcal{W},p)\|_\infty$ is attained on the largest blocks

As above, fix $k_1<k_2<\cdots<k_p$ and let B denote the block of $\Omega(\mathcal{W},p)$ corresponding to their span $\mathcal{K}$.

For simplicity, we first compare the singular values of B to those for a block spanned by vectors of the form

$$\{\Pi|j,j,k_3,\ldots,k_p\rangle : \Pi \in \mathcal{S}_p\} \tag{C17}$$

with $j<k_3<\cdots<k_p$. Observe that

$$\left\{ \frac{1}{\sqrt{2}}\Pi(|k_1,k_2,k_3,\ldots,k_p\rangle \pm |k_2,k_1,k_3,\ldots,k_p\rangle) : \Pi \in \mathcal{S}_p,\ \Pi \neq S_{12} \right\} \tag{C18}$$

is another orthonormal basis for $\mathcal{K}$, and let V be the unitary matrix for the basis change from $\{P|k_1,k_2,\ldots,k_p\rangle, P\in\mathcal{S}_p\}$ to (C18). Let $\mathcal{K}_\pm$ denote the subspace spanned by vectors with a $\pm$ sign in (C18), and $\tilde{B}_{++}$ the submatrix for the restriction of $VBV^\dagger$ to the subspace $\mathcal{K}_+$. The effect of any permutation on vectors of the form (C17) and those with a $+$ sign in (C18) is the same. Therefore, $\tilde{B}_{++}$ is identical to the matrix for the restriction of $\Omega(\mathcal{W},p)$ to the span of (C17), and the largest singular value of the latter is the same as

$$\|\tilde{B}_{++}\|_\infty = \sup_{\phi\in\mathcal{K}_+} \frac{\langle\phi,\tilde{B}_{++}^\dagger\tilde{B}_{++}\phi\rangle}{\|\phi\|^2} = \sup_{\phi\in\mathcal{K}_+} \frac{\langle\phi,VB^\dagger BV^\dagger\phi\rangle}{\|\phi\|^2} \leqslant \sup_{\phi\in\mathcal{K}} \frac{\langle\phi,VB^\dagger BV^\dagger\phi\rangle}{\|\phi\|^2} = \|B\|_\infty^2. \tag{C19}$$

In (C16) we showed that $\tilde{B}_{++}=-W_e+W_o$ and that B is block diagonal, which immediately implies that the singular values of $\tilde{B}_{++}$ are a subset of those for B. This is stronger than (C19), but does not necessarily generalize.

Next, consider a block for a subspace spanned by vectors of the form

$$\{\Pi|j,j,\ldots,j,k_{m+1},\ldots,k_p\rangle : \Pi \in \mathcal{S}_p\} \tag{C20}$$

with m occurences of j and $j<k_{m+1}\cdots k_p$. We adopt the convention that $Q\in\mathcal{S}_m$ denotes a permutation of $\{1,2,\ldots,m\}$. Choose $p!/m!$ permutations $P_t\in\mathcal{S}_p$ such that each P_t is in a distinct coset of $\mathcal{S}_p/\mathcal{S}_m$ or, equivalently $P_sP_t^{-1}\notin\mathcal{S}_m\,\forall\, s\neq t$. Then the vectors

$$|\phi_t\rangle = \frac{1}{\sqrt{m!}} \sum_{Q \in \mathcal{S}_m} P_t Q |k_1, \ldots, k_m, k_{m+1}, \ldots, k_p\rangle \tag{C21}$$

transform under permutations exactly as those in (C20). Therefore, the restriction of B to the span of (C21) is represented by the same matrix as the block of $\Omega(\mathcal{W}, p)$ corresponding to (C20). Then, as in (C19), its largest singular value is bounded above by $\|B\|_\infty$.

To deal with the general case, note that the restriction $j < k_{m+1} < k_{m+2} < \cdots < k_p$ does not play an essential role. The same argument works whenever j is distinct from the remaining k_i with $i > m$. Then, for example, the

largest singular value of the block for permutations of $|i,i,i,j,j,k_6, \ldots, k_p\rangle$

$\leqslant$ largest singular value of the block for permutations of $|i,i,i,k_4,k_5, \ldots, k_p\rangle$

$\leqslant$ largest singular value of the block for permutations of $|k_1,k_2, \ldots, k_p\rangle = \|B\|_\infty$.

Proceeding in this way, one can complete the argument by induction. Alternatively, one could consider cosets for repeated indices, such as $\mathcal{S}_p/(\mathcal{S}_3 \times \mathcal{S}_2)$ in this example.

(Received 9 March 2004; accepted 13 December 2004; published online 23 March 2005)

Recently, Avron *et al.* in a series of papers shed new light on the question of quantum transport in mesoscopic samples coupled to particle reservoirs by semi-infinite leads. They rigorously treat the case, when the sample undergoes an adiabatic evolution thus generating a current through the leads, and prove the so-called BPT formula. Using a discrete model, we complement their work by giving a rigorous proof of the Landauer–Büttiker formula, which deals with the current generated by an adiabatic evolution on the leads. As is well known from physics, both of these formulas link the conductance coefficients for such systems to the *S*-matrix of the associated scattering problem. As an application, we discuss resonant transport through a quantum dot. The single charge tunneling processes are mediated by extended edge states, simultaneously localized near several leads. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1862324]

I. INTRODUCTION

Mesoscopic systems have been extensively studied in the last two decades, both from theoretical and experimental points of view. Much effort has been devoted to the understanding of transport phenomena through quantum rings, wires, or dots (see the monographs, Refs. 15 and 18). These nano-devices display several nontrivial effects, for example, Aharonov–Bohm conductance oscillations, quantum Hall effect, and single charge tunneling. Consequently, various theories have been developed in order to explain them. Among such theories, the scattering approach to the transport problem initiated by Landauer,[23,24] and accomplished by Büttiker,[10,11] is perhaps the most frequently utilized one in the physics literature. The basic idea in the Landauer–Büttiker (LB) formalism is that the charge transport through a finite system connected to several (usually semi-infinite) leads is a scattering process. The incident electrons are either transmitted between leads or reflected in the same lead. By a counting argument, the conductance G of a two-lead system is related to its transmittance $\mathcal{T}$ (which still remains to be computed from the S matrix of the problem) by the Landauer formula at zero temperature,

$$G = \frac{e^2}{h}\mathcal{T}. \tag{1}$$

As shown by Büttiker, this formula admits a generalization to a multilead geometry, and also to the case, when a magnetic field is present. In particular, a four-terminal setup is the natural way to put into evidence the quantization of the Hall resistance in strong magnetic fields.

Alternatively, the conductance G can be found from the linear response theory. It is then a natural question, whether the Landauer formula can be derived directly from the Kubo formalism. This problem was addressed in a series of papers in the 1980s (see Refs. 17, 20, 25, and 22). All those papers used the Kubo formula as given for macroscopic samples. Later on, Baranger and

[a]MaPhySto–A Network in Mathematical Physics and Stochastics, funded by The Danish National Research Foundation.

Stone[6] argued for a Kubo formula adapted to mesoscopic systems with leads. They also presented a formal justification of the equivalence between the linear response theory, and the LB approach.

The main aim of our work is to provide a rigorous derivation of this equivalence, following their ideas. Second, we use the LB formalism to describe the resonant transport through a mesoscopic sample weakly coupled to leads, the so-called quantum dot (see Ref. 21 for a review). These steps are behind the formulas used in Ref. 26 for studying specific properties of such systems.

Now let us describe the strategy followed to achieve the results. First, we establish a Kubo formula for the conductance, and then we perform the thermodynamic and adiabatic limits. Second, we compute the transmission between different leads from scattering theory. A comparison of the two results leads us to the Landauer–Büttiker formula.

We stress that in the present approach we use a tight-binding representation (i.e., a discrete model) for Hamiltonians. This makes some of the delicate technical points easier to handle. For instance, due to the particular form of the current operator (which has finite rank), the trace implied by the Kubo formula is reduced to a simple product of matrix elements of an effective resolvent R_{eff} that comes from the Feshbach formula. Its associated Hamiltonian acts only in the Hilbert space of the finite system, and is non-Hermitian, due to a supplementary term that embodies the effects of the leads. This term is well known in the physics literature as the self-energy of the leads (see Ref. 15). Roughly speaking, it controls the imaginary part of the effective Hamiltonian coming from the Feshbach formula, and is proportional to the square of the hopping integral between the leads and the sample. As a consequence, a weak coupling generates resonances located near the real axis, and a peak in the conductance, as given by the LB formula, each time the energy of the incident electron equals an eigenvalue of the isolated dot. These peaks are the so-called Coulomb oscillations in quantum dots (see Ref. 21 for an introduction to the subject). In fact, our approach shows that the peaks are *not* of Coulomb origin, but a purely resonant effect (as shown numerically in Ref. 26, they are very sensitive to the lead-dot coupling, the interaction adding quantitative differences only).

Other interesting geometric, topological, and adiabatic aspects of transport problems through mesoscopic samples were given by Avron *et al.* in Refs. 1–4. Note that the authors work with adiabatic pumps, i.e., the perturbation occurs on the sample, and not on the leads (the analog of LB formula in that case is the so-called BPT formula[12]).

In Ref. 5 the authors rigorously prove the BPT formula. They chose to work from the beginning with infinite leads. A difficulty in that approach is that the one particle fermionic density matrix is no longer trace class, and one has to be careful when defining the currents. We manage to bypass this difficulty, by starting with the grand canonical density matrix in the associated Fock spaces for *finite* leads. Due to the absence of self-interactions, we manage to define one particle currents in a natural way. Then we let the lengths of the leads go to infinity, and finally we perform the adiabatic limit.

We note that Cohen in Ref. 13 investigates the connection between the BPT and Landauer formulas on one hand, and linear response theory on the other hand. By starting with the Kubo formalism, Cohen found expressions for both the dissipative and nondissipative parts of the response.

Application to pumping of the BPT formula can be traced back to several other authors. Probably the first one to use this tool was Brouwer.[9] Then Moskalets and Büttiker in Ref. 27 investigated dissipation and noise in adiabatic quantum pumps, while in Ref. 28 they extended the theory to nonadiabatic situations.

The paper is organized as follows. Section II sets notation and gives the main result, Section III presents some relevant spectral properties of our system, while Sec. IV contains the proof of our main theorem. Section V is devoted to a simple application of the formalism to the resonant transport through noninteracting quantum dots. Several technical tools are left to appendices.

II. PRELIMINARIES AND RESULTS

A. The model

We use the tight-binding approximation, and thus a discrete model, throughout the paper. The system, through which the current will run, is modeled by Γ, chosen to be a finite subset of $\mathbb{Z}^2$ (we can also identify it with a finite subset of $\mathbb{N}$). We couple Γ to several "one-dimensional" leads. The sites of each lead are modeled by $\mathcal{N}\subseteq\mathbb{N}$; when $\mathcal{N}=\mathbb{N}$ the lead is semi-infinite. In the sequel the finite system described by Γ will be named sample while the name "system" will be given to the whole structure consisting of "sample+leads."

The total one-particle Hilbert space is a direct sum of the space modeling the sample, and M spaces corresponding to the leads,

$$\mathcal{H} = l^2(\Gamma) \oplus l^2(\mathcal{N}) \oplus \cdots l^2(\mathcal{N}). \tag{2.1}$$

Let us describe the one-particle Hamiltonian. In the sample we may have any self-adjoint bounded operator H^S. For example, we can choose H^S to be the restriction of a Harper-type operator to $l^2(\Gamma)$ with Dirichlet boundary conditions,

$$H^S = \sum_{(m,n)\in\mathbb{Z}^2} (E_0|m,n\rangle\langle m,n| + t_1(e^{-i(Bm/2)}|m,n\rangle\langle m,n+1| + \text{H.c.}) + t_2(e^{-i(Bn/2)}|m,n\rangle\langle m+1,n| + \text{H.c.})). \tag{2.2}$$

Here H.c. means Hermitian conjugate, E_0 is the reference energy, B is a magnetic field, from which the magnetic phases appear (the symmetric gauge was used), while t_1 and t_2 are hopping integrals between nearest neighbor sites.

As for the leads, the dynamics in each of them is governed by the one-dimensional discrete Laplacian on $l^2(\mathcal{N})$ with Dirichlet boundary conditions (see Appendix A). The Hamiltonian on the leads will be ($t_L>0$ is the hopping integral on leads)

$$H^L = \sum_{\alpha=1}^{M} H^L_\alpha, \quad H^L_\alpha = \sum_{n_\alpha\in\mathcal{N}} t_L\cdot(|n_\alpha\rangle\langle n_\alpha+1| + \text{H.c.}), \tag{2.3}$$

acting on functions, which by convention are extended with value zero at the sites -1 and $N+1$.

The "coupling" between the sample and leads is described by the tunneling Hamiltonian,

$$H^T = \tau\sum_{\alpha=1}^{M} |0_\alpha\rangle\langle\mathcal{S}^\alpha| + \tau\sum_{\alpha=1}^{M} |\mathcal{S}^\alpha\rangle\langle 0_\alpha| =: H^{LS} + H^{SL}. \tag{2.4}$$

Here $\tau>0$ is the hopping integral between each lead and the sample, and simulates a quantum point constriction, or a tunneling barrier. Here $|0_\alpha\rangle$ is the first site on the lead α, and $|\mathcal{S}^\alpha\rangle$ is the site from the sample, through which the coupling with the lead α is realized.

Then the total one-particle Hamiltonian is the sum $H^S+H^L+H^T$, with obvious identifications. In the case when the leads are *semi-infinite*, we introduce a special notation for it,

$$K := H^S + \sum_{\alpha=1}^{M} H^L_\alpha + H^T = H^S + H^L + H^{LS} + H^{SL}. \tag{2.5}$$

B. Adiabatic currents and conductivity

Here we deal with electronic transport through the system. We first take the leads to be finite (i.e., each lead consists of $N<\infty$ sites), although their length can be arbitrarily large. However, the thermodynamic limit $N\to\infty$ is to be taken at a certain point in our argument.

We will only work in the grand canonical ensemble. This means that our system is in contact with a reservoir of energy and particles. Having this in mind, we will study the linear response of

a system of noninteracting fermions at temperature T and chemical potential μ subjected to a perturbation, which is switched on adiabatically (to insure that the system is at equilibrium at all times).

Let χ_η, $\eta>0$, be a smooth switching function $0\leqslant\chi_\eta(t)\leqslant 2$,

$$\chi_\eta(t)=\begin{cases} e^{\eta t} & \text{if } t\leqslant 0,\\ 1 & \text{if } t>1. \end{cases} \tag{2.6}$$

Then the perturbation is given by (i_α denotes the ith site on the lead α)

$$V(N,t) := \chi_\eta(t)\sum_{\alpha=1}^{M} V_\alpha \sum_{i_\alpha=0}^{N} |i_\alpha\rangle\langle i_\alpha|. \tag{2.7}$$

Notice that $V(N,t)$ models the adiabatic application of a constant voltage V_α on the lead α. This will generate a charge transfer between the leads via the sample.

The relevant one-particle Hamiltonians then are given by

$$H_0(N) := H^S + H^L(N) + H^T,$$

$$H(N,t) := H_0(N) + V(N,t). \tag{2.8}$$

Here $H^L(N)$ is the Hamiltonian acting on the finite leads, while $H_0(N)$ is the same operator as in (2.5), but the different notation indicates that it describes the initial equilibrium state for finite leads.

Now we are interested in deriving the current response of the system due to the perturbation. Since we work in the grand canonical ensemble, we have to consider all our operators in the second quantization, see Appendix B for further notation and properties.

At $t=-\infty$ our system is characterized by the Gibbs equilibrium state, and its corresponding statistical operator (density matrix) is the well known one [see (B2)]. The statistical operator describing the equilibrium state at time t for the sample coupled with the finite leads is denoted by $\hat{\rho}^{(N)}(t)$, and is defined as the (trace class) solution of the quantum Liouville equation

$$i\frac{\partial\hat{\rho}^{(N)}(t)}{\partial t}=[\mathrm{d}\Gamma(H(N,t)),\hat{\rho}^{(N)}(t)], \tag{2.9}$$

which satisfies the initial condition $\lim_{t\to-\infty}\hat{\rho}^{(N)}(t)=\hat{\rho}_0^{(N)}$, where $\hat{\rho}_0^{(N)}$ is as in (B2), but with $H_0(N)$ instead of H. We stress here the fact that if the leads are infinite, these operators are no longer of trace class.

Let us now write the perturbation in the "interaction picture,"

$$\tilde{V}(N,s) := e^{isH_0(N)}V(N,s)e^{-isH_0(N)}. \tag{2.10}$$

To describe the solution of the Liouville equation we consider the following equation:

$$\frac{\mathrm{d}W}{\mathrm{d}s}(s)=iW(s)\mathrm{d}\Gamma(\tilde{V}(N,s)),\quad W(-\infty)=\mathrm{Id},$$

where the unitary $W(s)$ is given by the usual Dyson series with respect to $\mathrm{d}\Gamma(\tilde{V}(N,s))$. By direct computation, and using (B5) for $\tilde{V}(N,s)$, one can verify that

$$\hat{\rho}^{(N)}(t)=e^{-it\ \mathrm{d}\Gamma(H_0(N))}W^*(t)\hat{\rho}_0^{(N)}W(t)e^{it\ \mathrm{d}\Gamma(H_0(N))} \tag{2.11}$$

is the unique solution to the Liouville equation, providing us with a positive operator of trace class. Expanding the Dyson series up to the first order, and using (B4) and (B5), a straightforward computation gives

$$\hat{\rho}^{(N)}(t) = \hat{\rho}_0^{(N)} - i\int_{-\infty}^{t} [\mathrm{d}\Gamma(e^{i(s-t)H_0(N)}V(N,s)e^{-i(s-t)H_0(N)}), \hat{\rho}_0^{(N)}]\mathrm{d}s + \mathcal{O}(V^2). \tag{2.12}$$

Let us introduce the one-particle charge operator in a given lead α (which is just minus the projection corresponding to the lead, the sign taking into account the fact that we deal with electrons)

$$Q_\alpha^{(N)} = -\sum_{i=0}^{N} |i_\alpha\rangle\langle i_\alpha|. \tag{2.13}$$

Denote by $\mathbf{Q}_\alpha^{(N)} = \mathrm{d}\Gamma(Q_\alpha^{(N)})$ its second quantization. Since we work in the grand canonical ensemble, the average charge in the lead α is given by

$$\mathcal{Q}_\alpha^{(N)}(t) := \mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}^{(N)}(t)\mathbf{Q}_\alpha^{(N)}). \tag{2.14}$$

Then the average charge is smooth in t, and we can define the current in the lead α as the charge transfer per unit of time, namely

$$\mathcal{I}_\alpha(t) := \frac{\mathrm{d}}{\mathrm{d}t}\mathcal{Q}_\alpha(t). \tag{2.15}$$

We will see that at $t=0$, this current can be written as

$$\mathcal{I}_\alpha(0) = \sum_\beta g_{\alpha\beta}(T,\mu,\eta,N)V_\beta + \mathcal{O}(V^2), \tag{2.16}$$

where $g_{\alpha\beta}(T,\mu,\eta,N)$ are the so-called conductance coefficients.[15] At this stage they depend on the temperature, the chemical potential, the adiabatic coefficient, and the length of the leads. The point of this paper is then to study the connection between $g_{\alpha\beta}$ and the transmittance of the problem, defined below.

Let us stress once again, as we have already done it in the introduction, that the above current is derived in a linear response regime. As it is well known, this approach does not allow one to perform the adiabatic limit first, since the error in (2.16) is in fact $\mathcal{O}(V^2/\eta^2)$. Such a result would demand a different approach, as done, for example, in Avron *et al.*[5] Nevertheless, the linear response theory gives relevant results, if the amplitude of the external perturbation is weaker than its rate of adiabaticity.

For the mathematical treatment of linear response theory, together with an analysis of its physical applicability, we cite a recent paper by Bouclet *et al.*[7]

C. The transmittance

Now we briefly switch to an apparently unrelated scattering problem, associated with the pair of Hamiltonians (K,H_0), where $H_0=H^L$ and $K=H_0+W=H_0+H^S+H^T$. Thus the "free" system consists here of the *semi-infinite* leads, while the complete evolution is that of the coupled system (leads and sample).

The operator K is defined on the full space $\mathcal{H}$, see (2.1), and the operator H_0 is defined on the subspace $\mathcal{H}_0=\oplus_{\alpha=1}^{M} l^2(\mathbb{N})$. We denote by $J:\mathcal{H}_0\to\mathcal{H}$ the identification operator. We obviously have $J^*J=\mathrm{Id}$, the identity on $\mathcal{H}_0$. Note that H_0 has purely absolutely continuous spectrum. The operator $KJ-JH_0$ is of finite rank, hence the (two space) trace class scattering theory (see Refs. 30–32) implies that the wave operators

$$\Omega_\pm = s - \lim_{t\to\mp\infty} e^{itK}Je^{-itH_0} \tag{2.17}$$

exist and are asymptotically complete.

In the sequel we will return to the notation H^L, instead of H_0. It will be clear from the context, whether we regard it as an operator on $\mathcal{H}$, or on $\mathcal{H}_0$. The (normalized) generalized eigenfunctions of H^L on the semi-infinite leads are [here $k \in (0,\pi)$, $\lambda = 2t_L \cos(k)$, and $1 \leqslant \alpha \leqslant M$] given by

$$\Psi_\alpha(\lambda) = \sum_{m \geqslant 0} \Psi(\lambda;m)|m\rangle, \quad \Psi(\lambda;m) = \frac{\sin(k(m+1))}{\sqrt{\pi t_L \sin(k)}}.$$

The generalized Fourier transform associated to these eigenvectors is defined as

$$F: \overset{M}{\underset{\alpha=1}{\oplus}} l^2(\mathbb{N}) \to \overset{M}{\underset{\alpha=1}{\oplus}} L^2([-2t_L, 2t_L]), \tag{2.18}$$

$$[F(\Phi)]_\alpha(\lambda) = \langle \Psi_\alpha(\lambda), \Phi_\alpha \rangle_{l^2(\mathbb{N})} = \sum_{m \geqslant 0} \overline{\Psi(\lambda;m)} \Phi_\alpha(m). \tag{2.19}$$

Its adjoint is given by

$$F^*: \overset{M}{\underset{\alpha=1}{\oplus}} L^2([-2t_L, 2t_L]) \to \overset{M}{\underset{\alpha=1}{\oplus}} l^2(\mathbb{N}), \tag{2.20}$$

$$[F^*(\Xi)]_\alpha(m) = \int_{-2t_L}^{2t_L} \Xi_\alpha(\lambda) \Psi(\lambda;m) \mathrm{d}\lambda. \tag{2.21}$$

We see that F is a unitary operator, and that $FH^L F^*$ is just multiplication by λ, i.e.,

$$FH^L F^* = 2t_L \cos(k) \mathrm{Id}. \tag{2.22}$$

The scattering operator is unitary, and is given by $S = \Omega_-^* \Omega_+$. The T-operator is defined by $T := S - \mathrm{Id}$. In the spectral representation of H_0, the T-operator is a λ-dependent $M \times M$ matrix, the T-matrix. Thus [see (4.4)

$$\sum_\beta t_{\alpha\beta}(\lambda) \Xi_\beta(\lambda) = [F(S - \mathrm{Id}) F^* \Xi]_\alpha(\lambda). \tag{2.23}$$

The transmittance between the leads α and β at energy λ is finally defined as

$$\mathcal{T}_{\alpha\beta}(\lambda) := |t_{\alpha\beta}(\lambda)|^2. \tag{2.24}$$

D. The Landauer–Büttiker formula and the main theorem

We can finally give the main result of our paper.

Theorem 2.1: *Consider the conductance $g_{\alpha\beta}(T, \mu, \eta, N)$ between the leads α and β ($\alpha \neq \beta$), at temperature $T > 0$, chemical potential $\mu \in (-2t_L, 2t_L)$, adiabatic switch-on coefficient $\eta > 0$ and length of the leads $N < \infty$. Assume that the point spectrum of K [the one from (2.5), with $N = \infty$] is disjoint from the thresholds $-2t_L$ and $2t_L$. Then if we first take the limit $N \to \infty$, and after that $\eta \searrow 0$, we have*

$$g_{\alpha\beta}(T, \mu) := \lim_{\eta \searrow 0} [\lim_{N \to \infty} g_{\alpha\beta}(T, \mu, \eta, N)] = -\frac{1}{2\pi} \int_{-2t_L}^{2t_L} \mathrm{d}E \frac{\partial f_{\mathrm{FD}}(E)}{\partial E} \mathcal{T}_{\alpha\beta}(E), \tag{2.25}$$

where $\mathcal{T}_{\alpha\beta}(\cdot)$ is real analytic on $(-2t_L, 2t_L)$ and equal to zero outside this interval. The function f_{FD} is the usual Fermi–Dirac function [see (B3)]. If $T \to 0$ in (2.25) (limit taken at last), we obtain the Landauer formula

$$g_{\alpha\beta}(0_+,\mu) = \frac{1}{2\pi}\mathcal{T}_{\alpha\beta}(\mu). \tag{2.26}$$

III. THE FESHBACH FORMULA AND SPECTRAL ANALYSIS FOR THE SYSTEM WITH SEMI-INFINITE LEADS

We assume throughout this section that the leads are semi-infinite. We denote by $R^L(z)$ the resolvent of the leads as a block diagonal matrix in $\oplus_{\alpha=1}^{M} l^2(\mathbb{N})$. Some of its properties are given in Appendix A.

We use the Feshbach formula[19,29] in order to express the full resolvent in terms of an effective Hamiltonian, which describes the mesoscopic system in the presence of the leads.

If Π^S denotes the projection onto the subspace corresponding to the "system" $l^2(\Gamma)$, and $\Pi^L = \mathrm{Id} - \Pi^S$ denotes the projection onto the leads, then we can rewrite (2.1) as

$$\mathcal{H} = \Pi^S\mathcal{H} \oplus \Pi^L\mathcal{H}. \tag{3.1}$$

To simplify, we write

$$R^L(z) = (\Pi^L K \Pi^L - z\Pi^L)^{-1},$$

as an operator acting on $\Pi^L\mathcal{H}$.

The effective Hamiltonian is defined as

$$H_{\mathrm{eff}}(z) := H^S - H^{SL}R^L(z)H^{LS}, \quad z \in \mathbb{C}\setminus\mathbb{R}, \tag{3.2}$$

acting on $\Pi^S\mathcal{H}$. We abuse notation slightly, and write

$$R_{\mathrm{eff}}(z) = (H_{\mathrm{eff}}(z) - z)^{-1}$$

on this space.

Using the identity (A1) from Nenciu's paper,[29] the total resolvent reads in operator matrix notation [see also (2.5)],

$$R(z) = (K-z)^{-1} = \begin{bmatrix} R_{\mathrm{eff}}(z) & -R_{\mathrm{eff}}(z)H^{SL}R^L(z) \\ -R^L(z)H^{LS}R_{\mathrm{eff}}(z) & R^L(z) + R^L(z)H^{LS}R_{\mathrm{eff}}(z)H^{SL}R^L(z) \end{bmatrix}. \tag{3.3}$$

Using (2.4), the explicit expression for the matrix elements of $R^L(z)$ that we gave in (A1), and Proposition 6.1(iii), we can write

$$H_{\mathrm{eff}}(z) = H^S - \tau^2\sum_{\alpha=1}^{M} |\mathcal{S}^\alpha\rangle\langle 0_\alpha|R^L(z)|0_\alpha\rangle\langle\mathcal{S}^\alpha| = H^S - \frac{\tau^2}{t_L}\zeta_1(z)\sum_{\alpha=1}^{M}|\mathcal{S}^\alpha\rangle\langle\mathcal{S}^\alpha|. \tag{3.4}$$

The spectral problem for K is thus reduced to the spectral problem for H^L and H_{eff}. Note that $H_{\mathrm{eff}}(z)$ is not Hermitian. We also have

$$(H_{\mathrm{eff}}(z) - z)^{-1} = \Pi^S(K-z)^{-1}\Pi^S, \quad \mathrm{Im}\, z \neq 0, \tag{3.5}$$

again with a slight abuse of the notation Π^S.

We need some more notation. For $\epsilon > 0$, define the strip

$$\Omega_\epsilon := \{x + iy \in \mathbb{C} : -2t_L + \epsilon < x < 2t_L - \epsilon, |y| < 1/\epsilon\}. \tag{3.6}$$

Finally, introduce the orthogonal projection

$$\Pi^T := \sum_{\alpha=1}^{M} |\mathcal{S}^\alpha\rangle\langle\mathcal{S}^\alpha|. \tag{3.7}$$

We can then write

$$H_{\text{eff}}(z) = H^S - \frac{\tau^2}{t_L}\zeta_1(z)\Pi^T.$$

The main result of this section is stated as follows.

Proposition 3.1: Let $|S^\beta\rangle$ *and* $|S^\gamma\rangle$ *be the coupling points between the sample, and leads* β *and* γ. *Define*

$$u_{\beta\gamma}(z) = \langle\mathcal{S}^\beta, [H^S - z - (\tau^2/t_L)\zeta_1(z)\Pi^T]^{-1}\mathcal{S}^\gamma\rangle, \quad \text{Im } z > 0. \tag{3.8}$$

Then for all positive τ *and* ϵ, *the function* $u_{\beta\gamma}$ *admits a meromorphic extension* $u^+_{\beta\gamma}$ *to* $\mathbb{C}_+ \cup \Omega_\epsilon$, *and all its poles have negative imaginary part. In particular, the restriction of* $u^+_{\alpha\beta}$ *to the interval* $(-2t_L, 2t_L)$ *is real analytic.*

Proof: First note that $u^+_{\beta\gamma}$ is the key term appearing in the transmittance formula [see (4.6)]. Now introduce the notation [see (A4)]

$$H_+(z) := H^S - \frac{\tau^2}{t_L}\zeta_+(z)\Pi^T. \tag{3.9}$$

Then $u^+_{\beta\gamma}(z) = \langle\mathcal{S}^\beta, [H_+(z) - z]^{-1}\mathcal{S}^\gamma\rangle$ is the meromorphic extension we are looking for. Since $l^2(\Gamma)$ is finite dimensional, the set of poles is included in the set of solutions of $\det(H_+(z) - z) = 0$. Due to (3.5), the poles cannot be in the upper complex half-plane.

Now let us prove that the poles are neither on the real axis. If there are no solutions for $\det(H_+(z) - z) = 0$ in $(-2t_L, 2t_L)$, then we are done. Now assume that there exists $\lambda \in (-2t_L, 2t_L)$, such that $H_+(\lambda) - \lambda$ is not invertible. Then $H_+(\lambda) - \lambda$ is not injective. Denote by p_λ the orthogonal projection onto to the null space of $H_+(\lambda) - \lambda$. For every $\phi_\lambda \in \text{Ran}(p_\lambda)$ we have

$$(H^S - \lambda)\phi_\lambda - \frac{\tau^2}{t_L}\zeta_+(\lambda)\Pi^T\phi_\lambda = 0.$$

Taking the scalar product with ϕ_λ and estimating the imaginary part, we have [use (A4)]

$$\langle\phi_\lambda, \Pi^T\phi_\lambda\rangle = \|\Pi^T\phi_\lambda\|^2 = 0.$$

This implies that $\Pi^T\phi_\lambda = 0$, and thus ϕ_λ must also be an eigenfunction for H^S, corresponding to the eigenvalue λ. Notice that this does not say that all eigenvectors of H^S corresponding to λ are in the range of p_λ.

Because $p_\lambda\Pi^T = (\Pi^T p_\lambda)^* = 0$, and because $\text{Ran}(p_\lambda)$ is spanned by eigenvectors of H^S, it means that p_λ commutes with $H_+(z)$, and we can write (here $q_\lambda = \text{Id} - p_\lambda$)

$$H_+(z) - z = p_\lambda(H_+(z) - z)p_\lambda + q_\lambda(H_+(z) - z)q_\lambda = (\lambda - z)p_\lambda + q_\lambda(H_+(z) - z)q_\lambda. \tag{3.10}$$

The range of q_λ is generated by eigenvectors of H^S, which either correspond to other eigenvalues than λ, or correspond to λ but are orthogonal to $\text{Ran}(p_\lambda)$. Now $q_\lambda(H_+(\lambda) - \lambda)q_\lambda$ is one to one on $\text{Ran}(q_\lambda)$, thus invertible, and so is $q_\lambda(H_+(z) - z)q_\lambda$ for z close to λ (by simple perturbation theory and the Neumann series). Moreover, its inverse is holomorphic near λ. Therefore,

$$(H_+(z) - z)^{-1} - (\lambda - z)^{-1}p_\lambda \tag{3.11}$$

is holomorphic around λ. In conclusion, since $p_\lambda\mathcal{S}^\gamma = 0$,

$$u^{+}_{\beta\gamma}(z) = \langle \mathcal{S}^{\beta}, [H_{+}(z) - z]^{-1}\mathcal{S}^{\gamma} - (\lambda - z)^{-1} p_{\lambda}\mathcal{S}^{\gamma}\rangle \tag{3.12}$$

is also holomorphic near λ, and we are done. A similar reasoning gives a meromorphic extension to $\mathbb{C}_{-} \cup \Omega_{\epsilon}$, which we denote by $u^{-}_{\beta\gamma}$. It is also easy to see [use (3.5) and (3.8)] that

$$\overline{u^{+}_{\beta\gamma}(\overline{z})} = u^{-}_{\gamma\beta}(z). \tag{3.13}$$

■

Remark: The above proposition does not rule out real poles for the effective Hamiltonian. It only says that its eventual real poles are not singularities for functions like $u_{\beta\gamma}$. Notice that we allowed τ to be arbitrarily large.

Another important observation is that K cannot have an infinite number of discrete eigenvalues outside $[-2t_L, 2t_L]$. Assume the contrary. Then the equation $\det[H_{\text{eff}}(\lambda) - \lambda] = 0$ would have infinitely many solutions, which accumulate either at $-2t_L$, or at $2t_L$. Since the determinant is continuous at $\pm 2t_L$, it would mean that either $-2t_L$ or $2t_L$ is also a zero. This would imply that K has an eigenvalue at the thresholds, contradicting our hypothesis in Theorem 2.1.

IV. PROOF OF THE MAIN THEOREM

As we have already announced in the introduction, the strategy of the proof is to compute the conductance and transmittance separately, and then to show that they are related as in (2.25). Since the transmittance involves less work, we start with it.

A. A formula for the transmittance

We will use the notation introduced in Sec. II C. The scattering operator $S: \mathcal{H}^L \to \mathcal{H}^L$ can be written as

$$S = \Omega^{*}_{-}\Omega_{+} = \text{Id} + \frac{2i}{\pi}\int_{-2t_L}^{2t_L} \text{Im}[(H^L - x + i0)^{-1}]X(x + i0)\text{Im}[(H^L - x + i0)^{-1}]\text{d}x, \tag{4.1}$$

where we used the fact that H^L has purely absolutely continuous spectrum, and introduced

$$X(z) = J^{*}H^{LS}J - J^{*}H^{LS}(K - z)^{-1}H^{SL}J$$

with the usual abuse of notation. See Ref. 34 for a proof of this formula in general two space trace class scattering theory.

Note that $J^{*}H^{LS}J = 0$. Using the Feshbach formula we get

$$S = \text{Id} - \frac{2i\tau^2}{\pi}\sum_{\alpha,\beta=1}^{M}\int_{-2t_L}^{2t_L} (\text{Im}[(H^L - x + i0)^{-1}]|0_{\alpha}\rangle) \times \langle \mathcal{S}^{\alpha}, R_{\text{eff}}(x + i0)\mathcal{S}^{\beta}\rangle (\langle 0_{\beta}|\text{Im}[(H^L - x + i0)^{-1}])\text{d}x. \tag{4.2}$$

Take $\Xi \in \oplus_{\alpha=1}^{M} C_0^{\infty}((-2t_L, 2t_L))$. Using the formulas (2.22); (2.18), (2.20), and (3.8), we have

$$[F(S - \text{Id})F^{*}\Xi]_{\alpha}(\lambda) = -\frac{2i\tau^2}{\pi}\sum_{\beta=1}^{M}\int_{-2t_L}^{2t_L}\text{d}x(\text{Im}[(\lambda - x + i0)^{-1}]\Psi(\lambda;0))u^{+}_{\alpha\beta}(x) \times \left(\int_{-2t_L}^{2t_L}\text{Im}[(\lambda' - x + i0)^{-1}]\Psi(\lambda';0)\Xi_{\beta}(\lambda')\text{d}\lambda'\right). \tag{4.3}$$

Using twice Sohotsky's formula $1/(t + i0) = \text{P.V.}(1/t) - i\pi\delta$, we get

$$[F(S-\mathrm{Id})F^*\Xi]_\alpha(\lambda) = 2\pi\tau^2 i\sum_{\beta=1}^{M}|\Psi(\lambda;0)|^2 u^+_{\alpha\beta}(\lambda)\Xi_\beta(\lambda). \tag{4.4}$$

Therefore, the T-matrix in the spectral representation of H^L is given by the elements

$$t_{\alpha\beta}(\lambda) = \frac{2\tau^2}{t_L} i\sin(k)u^+_{\alpha\beta}(\lambda). \tag{4.5}$$

Then the transmittance between the leads α and β at energy $\mu =: 2t_L\cos(k_\mu)$ is [see (2.24)] expressed as

$$\mathcal{T}_{\alpha\beta}(\mu) = \frac{4\tau^4}{t_L^2}\sin^2(k_\mu)|u^+_{\alpha\beta}(\mu)|^2. \tag{4.6}$$

B. Conductivities via the linear response theory

We now concentrate on the left-hand side of (2.25). Our main goal here is to obtain a more detailed version of formula (2.16), and to put into evidence the conductivities $g_{\alpha\beta}$ between different leads. Then we perform the thermodynamic and adiabatic limits.

1. Deriving the linear response: a Kubo formula

Differentiating in (2.15), using the Liouville equation (2.9), trace properties [i.e., $\mathrm{Tr}([A,B]C) = -\mathrm{Tr}(B[A,C])$], and (B4), we have

$$\begin{aligned}\mathcal{I}_\alpha(t) &= \mathrm{Tr}_{\mathcal{F}_a}\left(\frac{\mathrm{d}\hat{\rho}^{(N)}(t)}{\mathrm{d}t}\mathbf{Q}^{(N)}_\alpha\right) = i\,\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}^{(N)}(t)[\mathbf{H}(N,t),\mathbf{Q}^{(N)}_\alpha])\\ &= i\,\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}^{(N)}(t)\mathrm{d}\Gamma([H(N,t),Q^{(N)}_\alpha])) = \mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}^{(N)}(t)\mathrm{d}\Gamma(j_\alpha(t))),\end{aligned} \tag{4.7}$$

where the one-particle current operator is

$$j_\alpha(t) =: i[H(N,t),Q^{(N)}_\alpha], \tag{4.8}$$

and has a simple explicit form, independent of time [because $Q^{(N)}_\alpha$ and $V(N,t)$ commute],

$$j_\alpha = i\tau(|0_\alpha\rangle\langle\mathcal{S}^\alpha| - |\mathcal{S}^\alpha\rangle\langle 0_\alpha|). \tag{4.9}$$

Note that j_α is a rank two operator. Notice also that even if the leads are semiinfinite, j_α is the *same*, this fact justifying the absence of N in its notation.

Now we continue to compute the current, using the decomposition (2.12). Introduce the notation [see also (2.8) and (B3), and set $t=0$]

$$\mathcal{I}^{(0)}(0) =: \mathrm{Tr}_{\mathcal{H}}(f_{\mathrm{FD}}(H_0(N))j_\alpha),$$

$$\mathcal{I}^{(1)}(0) =: i\int_{-\infty}^{0}\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}^{(N)}_0[\mathrm{d}\Gamma(\tilde{V}(N,s)),\mathrm{d}\Gamma(j_\alpha)])\mathrm{d}s. \tag{4.10}$$

Inserting (2.12) in (4.7), and using (B6) for the first term and trace commutation properties for the second one, we obtain

$$\mathcal{I}_\alpha(0) = \mathcal{I}^{(0)}(0) + \mathcal{I}^{(1)}(0) + \mathcal{O}(V^2). \tag{4.11}$$

Introduce the notation

$$Q_\beta^{(N)}(-s) := e^{-isH_0(N)} Q_\beta^{(N)} e^{+isH_0(N)}. \tag{4.12}$$

We continue rewriting $\mathcal{I}^{(1)}(0)$ employing (B4)–(B6), which leads to

$$\begin{aligned}
\mathcal{I}^{(1)}(0) &= i\int_{-\infty}^{0} \mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}_0^{(N)}[\mathrm{d}\Gamma(e^{isH_0(N)}V(N,s)e^{-isH_0(N)}),\mathrm{d}\Gamma(j_\alpha)])\mathrm{d}s \\
&= -i\sum_\beta \int_0^\infty \chi_\eta(-s)\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}_0^{(N)}[\mathrm{d}\Gamma(Q_\beta(-s),\mathrm{d}\Gamma(j_\alpha)])V_\beta\,\mathrm{d}s \\
&= -i\sum_\beta \int_0^\infty \mathrm{d}s\ \chi_\eta(-s)\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}_0^{(N)}\,\mathrm{d}\Gamma[Q_\beta(-s),j_\alpha])V_\beta \\
&= -i\sum_\beta \int_0^\infty \mathrm{d}s\ \chi_\eta(-s)\mathrm{Tr}_{\mathcal{H}}(f_{\mathrm{FD}}(H_0(N))[Q_\beta(-s),j_\alpha])V_\beta.
\end{aligned}$$

Notice that the minus sign appears, because the charge is negative, and we replaced the projection on each lead with the corresponding charge operator. The average current at time $t=0$ then becomes

$$\begin{aligned}
\mathcal{I}_\alpha(0) = \mathcal{I}^{(0)}(0) + \mathcal{I}^{(1)}(0) + \mathcal{O}(V^2) &= \mathrm{Tr}_{\mathcal{H}}(f_{\mathrm{FD}}(H_0(N))j_\alpha) - i\sum_\beta \int_0^\infty \mathrm{d}s\ e^{-\eta s}\,\mathrm{Tr}_{\mathcal{H}}(f_{\mathrm{FD}}(H_0(N)) \\
&\quad \times[Q_\beta^{(N)}(-s),j_\alpha])V_\beta + \mathcal{O}(V^2).
\end{aligned} \tag{4.13}$$

If we compare this expression with the one announced in (2.16), we see that we are almost in place with the exception of the term $\mathcal{I}^{(0)}(0)$. This term represents the current in the equilibrium state when all V_α's are zero. Let us now prove that this term is always zero. Indeed,

$$\mathcal{I}^{(0)}(0) = i\,\mathrm{Tr}\{f_{\mathrm{FD}}(H_0(N))[H_0(N),Q_\alpha(N)]\} = i\,\mathrm{Tr}\{[f_{\mathrm{FD}}(H_0(N)),H_0(N)]Q_\alpha(N)] = 0. \tag{4.14}$$

Therefore, we have finally obtained an expression for the total current as it was announced in (2.16), where the conductivities are given by

$$g_{\alpha\beta}(T,\mu,\eta,N) := -i\int_0^\infty \mathrm{d}s\ e^{-\eta s}\,\mathrm{Tr}_{\mathcal{H}}(f_{\mathrm{FD}}(H_0(N))[Q_\beta^{(N)}(-s),j_\alpha]). \tag{4.15}$$

What we do in the next paragraphs is to perform the various limits required by Theorem 2.25.

2. Making the leads semi-infinite: N→∞

Define the quantity which is the natural candidate for the limit $N\to\infty$

$$g_{\alpha\beta}(T,\mu,\eta,\infty) := -i\int_0^\infty \mathrm{d}s\ e^{-\eta s}\,\mathrm{Tr}_{\mathcal{H}}(f_{\mathrm{FD}}(K)[Q_\beta^{(\infty)}(-s),j_\alpha]). \tag{4.16}$$

Notice that in the limit $N=\infty$, we have $H_0(\infty)=K$ [see (2.8) and (2.5)]. Neither $f_{\mathrm{FD}}(K)$ nor $Q_\beta^{(\infty)}\times(-s)$ are of trace class anymore, but since j_α is the same as in (4.9) (thus of rank two), the total operator is of trace class with trace uniformly bounded with respect to s. It is easy to see that $g_{\alpha\beta}(T,\mu,\eta,N)$ converges to (4.16), since $H_0(N)$ converges strongly to K, and j_α is trace class. The hard part is to say something about the rate of convergence.

The main result of this paragraph is contained in the following lemma, which states that the speed of convergence when N grows to infinity is faster than any inverse power of N.

Lemma 4.1: For every $J>0$, there exists $C>0$, which may depend on all other parameters but N, so that

$$|g_{\alpha\beta}(T,\mu,\eta,N) - g_{\alpha\beta}(T,\mu,\eta,\infty)| \leqslant CN^{-J}. \tag{4.17}$$

Proof: We will need the formula (3.3), where we replace H^L with $H^L(N)$ [see below (2.8) for the definition of $H^L(N)$]. We introduce the obvious notation $R^L(N,z)$ and $H_{\text{eff}}(N,z)$, to indicate that the leads have finite length. For future reference, formula (3.3) leads to

$$\langle \mathcal{S}^\alpha, (H_0(N)-z)^{-1}0_\alpha\rangle = -\langle \mathcal{S}^\alpha, (H_{\text{eff}}(N,z)-z)^{-1}\mathcal{S}^\alpha\rangle\langle 0_\alpha, R^L(N,z)0_\alpha\rangle = \langle 0_\alpha, (H_0(N)-z)^{-1}\mathcal{S}^\alpha\rangle. \tag{4.18}$$

We first reduce (4.15) to a form which is easier to work with. Replacing the expression for $Q_\beta^{(N)}(-s)$ [see (4.12) and (2.13)] we have (using trace commutation properties)

$$g_{\alpha\beta}(T,\mu,\eta,N) = -i\int_0^\infty \mathrm{d}s\, e^{-\eta s}\{\mathrm{Tr}(f_{\text{FD}}(H_0(N))e^{-isH_0(N)}Q_\beta^{(N)}e^{isH_0(N)}j_\alpha) - \mathrm{Tr}(f_{\text{FD}}(H_0(N))e^{isH_0(N)}j_\alpha e^{-isH_0(N)}Q_\beta^{(N)})\}. \tag{4.19}$$

It is clear that it is enough to prove an estimate as in (4.17) for just one of the terms in (4.19). Define

$$A_{\alpha\beta}(N) := \int_0^\infty e^{-\eta s}\,\mathrm{Tr}(f_{\text{FD}}(H_0(N))e^{-isH_0(N)}Q_\beta^{(N)}e^{isH_0(N)}j_\alpha)\mathrm{d}s. \tag{4.20}$$

Since $\|H_0(N)\| \leqslant \text{const}$ uniformly in N, it means that we can find an interval $[a,b]$, independent of N, which contains the spectrum of $H_0(N)$. Define the function $\phi_0 \in C_0^\infty(\mathbb{R})$, $0 \leqslant \phi_0 \leqslant 1$, $\mathrm{supp}(\phi_0) \subset (-1+a, b+1)$ and

$$\phi_0(x) = \frac{1}{e^{\beta(x-\mu)}+1}, \quad x \in (a,b). \tag{4.21}$$

Also define for every $s>0$ the function

$$\phi_s(x) := \phi_0(x)e^{-isx}. \tag{4.22}$$

Clearly, $f_{\text{FD}}(H_0(N))e^{-isH_0(N)} = \phi_s(H_0(N))$. Assume that $\tilde{\phi}_0$ is an almost analytic extension of ϕ_0, supported in the strip,

$$\mathrm{supp}(\tilde{\phi}_0) \subset (-1+a, b+1) \times (-\eta/2, \eta/2) \subset \mathbb{C}, \tag{4.23}$$

and such that

$$\sup_{-1+a\leqslant x\leqslant b+1} |\overline{\partial}\tilde{\phi}_0(x+iy)| \leqslant \text{const}\cdot|y|^P, \quad |y| \leqslant \eta/2, \tag{4.24}$$

where P is any previously given positive integer. Because e^{-isz} is entire as function of z, an almost analytic extension for ϕ_s is simply $\tilde{\phi}_s(z) := \tilde{\phi}_0(z)e^{-isz}$. The Helffer–Sjöstrand formula is the formula (see, for example, Ref. 16)

$$\phi_s(H_0(N)) = \frac{1}{\pi}\int_{\mathrm{supp}(\tilde{\phi}_0)} (\overline{\partial}\tilde{\phi}_0(x+iy))e^{-isx+sy}(H_0(N)-x-iy)^{-1}\,\mathrm{d}x\,\mathrm{d}y.$$

We will use the following technical result.

Proposition 4.2: Let $F:\mathbb{C}\to\mathbb{C}\backslash\mathbb{R}$ be smooth. Assume that for $x+iy$ in the support of $\tilde{\phi}_0$, we can find two positive integers $k_1 \leqslant P$ and $k_2 \leqslant P$, such that we have the estimate

$$|F(x+iy)| \leqslant \text{const}\cdot\frac{1}{N^{k_1}|y|^{k_2}}, \quad x+iy \in \mathrm{supp}(\tilde{\phi}_0), \quad y \neq 0. \tag{4.25}$$

Then

$$\int_{\mathrm{supp}(\tilde{\phi}_0)} |\overline{\partial\tilde{\phi}_0}(z)| \cdot |F(z)| \mathrm{d}x\, \mathrm{d}y \leqslant \mathrm{const} \cdot \frac{1}{N^{k_1}}. \tag{4.26}$$

Clearly, the proposition is immediately implied by (4.24) and (4.25) and it does not require further details.

We can introduce the expression of $\phi_s(H_0(N))$ in (4.20) and perform the integral with respect to s; the interchange of integrals is permitted because on the support of $\tilde{\phi}_0$ we have $|y| < \eta$. In order to simplify the writing, we denote $x+iy=z$ and $\mathrm{d}x\,\mathrm{d}y$ by d^2z. Then, up to constants, we have that $A_{\alpha\beta}(N)$ is proportional to

$$\int_{\mathrm{supp}(\tilde{\phi}_0)} \overline{\partial\tilde{\phi}_0}(z) \mathrm{Tr}((H_0(N)-z)^{-1} Q_\beta^{(N)} (H_0(N)-z+i\eta)^{-1} j_\alpha) \mathrm{d}^2 z. \tag{4.27}$$

Next we want to simplify the above trace, by expressing Q_β with the help of the current operator j_β. Let $z'=z-i\eta$. We have [see (4.8) and (4.9)]

$$j_\beta = -i[Q_\beta^{(N)}, H_0(N)] = -i(Q_\beta^{(N)}(H_0(N)-z') - (H_0(N)-z)Q_\beta^{(N)}) - i(z'-z)Q_\beta^{(N)},$$

then using obvious notation for the resolvents

$$R_0(N,z)Q_\beta^{(N)}R_0(N,z') = \frac{1}{z'-z}\{iR_0(N,z)j_\beta R_0(N,z') + Q_\beta^{(N)}R_0(N,z') - R_0(N,z)Q_\beta^{(N)}\}. \tag{4.28}$$

Inserting this back into (4.27), we have a number of terms, which must be treated separately. We only deal with one of them, namely the term given (up to constants) by

$$\int_{\mathrm{supp}(\tilde{\phi}_0)} \overline{\partial\tilde{\phi}_0}(z) \mathrm{Tr}(R_0(N,z) Q_\beta^{(N)} j_\alpha) \mathrm{d}^2 z. \tag{4.29}$$

Since $Q_\beta^{(N)} j_\alpha = -i\tau\delta_{\alpha\beta}|0_\alpha\rangle\langle\mathcal{S}^\alpha|$, introducing it back again and performing the trace, we obtain up to constants [see (4.18)]

$$\delta_{\alpha\beta}\int_{\mathrm{supp}(\tilde{\phi}_0)} \overline{\partial\tilde{\phi}_0}(z) \langle\mathcal{S}^\alpha, (H_{\mathrm{eff}}(N,z)-z)^{-1}\mathcal{S}^\alpha\rangle \langle 0_\alpha, R^L(N,z)0_\alpha\rangle \mathrm{d}^2 z. \tag{4.30}$$

The next step is to replace the quantities involving finite leads with the ones corresponding to semi-infinite leads. Let J be an arbitrarily large integer. We see that one term we have to look at in connection with (4.30) is

$$F_1(z) := \langle\mathcal{S}^\alpha, (H_{\mathrm{eff}}(N,z)-z)^{-1}\mathcal{S}^\alpha\rangle \cdot (\langle 0_\alpha, R^L(N,z)0_\alpha\rangle - \langle 0_\alpha, R^L(z)0_\alpha\rangle).$$

An application of (C3) and (C6) yields the estimate

$$|\langle 0_\alpha, R^L(N,z)0_\alpha\rangle - \langle 0_\alpha, R^L(z)0_\alpha\rangle| \leqslant \mathrm{const} \cdot \frac{1}{|\mathrm{Im}\, z|^2} e^{-2cN|\mathrm{Im}\, z|}, \tag{4.31}$$

uniformly in z on the support of $\tilde{\phi}_0$, with $\mathrm{Im}\, z \neq 0$. Notice that (3.5) is also true at finite N, and this gives an upper bound of order $1/|\mathrm{Im}\, z|$ on the first factor in $F_1(z)$. We finally obtain

$$|F_1(z)| \leqslant \mathrm{const} \cdot \frac{1}{|\mathrm{Im}\, z|^3} e^{-2cN|\mathrm{Im}\, z|}, \tag{4.32}$$

uniformly in z on the support of $\tilde{\phi}_0$, with $\mathrm{Im}\, z \neq 0$. But this implies

$$|F_1(z)| \leqslant \text{const} \cdot \frac{1}{|\text{Im } z|^{3+J}} N^{-J}. \tag{4.33}$$

Now choose $\tilde{\phi}_0$ to have a decay in y near the real axis with an exponent P larger than $J+3$ [see (4.24)]. Then (4.26) implies that the integral of F_1 times $\overline{\partial\tilde{\phi}_0}$ will decay at least like N^{-J}.

Another type of term one needs to estimate can be set into the form

$$F_2(z) := \langle 0_\alpha, R^L(z) 0_\alpha \rangle [\langle \mathcal{S}^\alpha (H_{\text{eff}}(N,z) - z)^{-1} \mathcal{S}^\alpha \rangle - \langle \mathcal{S}^\alpha (H_{\text{eff}}(z) - z)^{-1} \mathcal{S}^\alpha \rangle]. \tag{4.34}$$

Using the identity $A^{-1} - B^{-1} = A^{-1}(B-A)B^{-1}$, and the expression (3.2), which is valid for both effective Hamiltonians, we reduce the problem to the estimate from (4.31), but in addition we have some other terms which are each bounded from above by $1/|\text{Im } z|$. We eventually get the estimate

$$|F_2(z)| \leqslant \text{const} \cdot \frac{1}{|\text{Im } z|^5} e^{-2cN|\text{Im } z|}, \tag{4.35}$$

and then we argue as before.

Concluding, we proved that the difference between a term as in (4.30) at finite N, and a similar term "with infinite leads," decays faster than any inverse power of N. We consider that (4.17), thus the lemma, to be proven. ■

3. Taking the adiabatic limit: $\eta \searrow 0$

The next limit to be performed is the adiabatic limit. Thus we define

$$g_{\alpha\beta}(T,\mu) := \lim_{\eta \searrow 0} g_{\alpha\beta}(T,\mu,\eta,\infty), \tag{4.36}$$

where $g_{\alpha\beta}(T,\mu,\eta,\infty)$ is given by (4.16). The idea is again to use the resolvent properties, as we did in the preceding section, one important difference now being that we have to use Stone's formula instead of the Helffer–Sjöstrand formula. The computations will also be more involved in this case. From (4.16) we have

$$g_{\alpha\beta}(T,\mu,\eta,\infty) = -i \int_0^\infty \text{ds } e^{-\eta s} \text{Tr}_{\mathcal{H}} (f_{\text{FD}}(K) e^{-isK} Q_\beta e^{isK} j_\alpha - j_\alpha e^{-isK} Q_\beta e^{isK} f_{\text{FD}}(H)).$$

We note that in the above formula appears again $f_{\text{FD}}(K)e^{-isK}$ and its adjoint. We will express them using Stone's formula. Recall now that K can have point spectrum outside the interval $[-2t_L, 2t_L]$; we also assumed that $\pm 2t_L$ are not eigenvalues. This implies that K can only have a finite number of eigenvalues outside $[-2t_L, 2t_L]$ [see the remarks following (3.13)]. We will see in the next section that K might have embedded eigenvalues in $(-2t_L, 2t_L)$ (see Proposition 5.4).

Consider without loss of generality that there is only one eigenvalue E_1 outside $[-2t_L, 2t_L]$, P_1 being the corresponding projection. Then from Stone's formula one has

$$f_{\text{FD}}(K)e^{-isK} = \lim_{\varepsilon \to 0} \int_{-2t_L}^{2t_L} \text{d}E \, f_{\text{FD}}(E) e^{-isE} \frac{1}{\pi} \text{Im } R(E + i\varepsilon) + f_{\text{FD}}(E_1) e^{-isE_1} P_1. \tag{4.37}$$

Now we follow the same steps as in Sec. IV B 2, namely we perform the integrals over s and we get

$$g_{\alpha\beta}(T,\mu,\eta,\infty) = \frac{i}{2\pi} \lim_{\varepsilon \to 0} \int_{-2t_L}^{2t_L} \text{d}E \, f_{\text{FD}}(E) \, \text{Tr}_{\mathcal{H}} (M_{\alpha\beta}(E,\eta,\varepsilon)) + f_{\text{FD}}(E_1) \, \text{Tr}_{\mathcal{H}} (P_1 Q_\beta R(E_1 - i\eta) j_\alpha$$
$$+ j_\alpha R(E_1 + i\eta) Q_\beta P_1), \tag{4.38}$$

where we wrote

$$M_{\alpha\beta}(E,\eta,\varepsilon) := (R(E+i\varepsilon)-R(E-i\varepsilon))Q_\beta R(E-i\eta)j_\alpha + j_\alpha R(E+i\eta)Q_\beta(R(E+i\varepsilon)-R(E-i\varepsilon)). \tag{4.39}$$

We start with the terms arising from the eigenvalue E_1, and show that in the limit $\eta \searrow 0$ they give no contribution. First we use again a trick to introduce current operators instead of charge operators, namely we write

$$P_1 j_\beta R(E_1 - i\eta) = iP_1[K-(E_1-i\eta),Q_\beta]R(E_1-i\eta) = -\eta P_1 Q_\beta R(E_1-i\eta) - iP_1 Q_\beta,$$

from which we get

$$P_1 Q_\beta R(E_1-i\eta) = -\frac{1}{\eta}P_1 j_\beta R(E_1-i\eta) - \frac{i}{\eta}P_1 Q_\beta. \tag{4.40}$$

Then replacing $P_1 Q_\beta R(E_1 - i\eta)$ and its adjoint in the second term from (4.38) we obtain for the second term in this expression

$$-\mathrm{Tr}_{\mathcal{H}}(P_1 Q_\beta R(E_1-i\eta)j_\alpha + j_\alpha R(E_1+i\eta)Q_\beta P_1) = \frac{1}{\eta}\mathrm{Tr}_{\mathcal{H}}(j_\alpha R(E_1+i\eta)j_\beta P_1 + j_\alpha P_1 j_\beta R(E_1-i\eta) + i(P_1 Q_\beta j_\alpha - j_\alpha Q_\beta P_1)), \tag{4.41}$$

and we can see right away that the last term disappears, when $\alpha \neq \beta$.

The singularities appearing in resolvents can be isolated by writing

$$R(E_1 \pm i\eta) = \pm i\frac{P_1}{\eta} + \frac{1}{2\pi i}\int_{|z-E_1|=\epsilon}\frac{1}{z-(E_1\pm i\eta)}(K-z)^{-1}\,\mathrm{d}z \quad \text{with } \epsilon > \eta. \tag{4.42}$$

We also write P_1 as a Riesz integral,

$$P_1 = \frac{i}{2\pi}\int_{|z'-E_1|=\epsilon'} R(z')\mathrm{d}z' \quad \text{with } \epsilon' < \epsilon. \tag{4.43}$$

By looking at (4.41) we see that the singular term equal to

$$\frac{1}{\eta^2}\mathrm{Tr}_{\mathcal{H}}\{j_\alpha P_1 j_\beta P_1\}$$

is in fact identically zero, due to

$$P_1 j_\alpha P_1 = iP_1[K,Q_\alpha]P_1 = iP_1[K-E_1,Q_\alpha]P_1 = 0. \tag{4.44}$$

Thus we are only left with the regular part from (4.42). Substitute it into (4.41), together with P_1 expressed as in (4.43). We have

$$\frac{1}{\eta}\mathrm{Tr}_{\mathcal{H}}\{j_\alpha R(E_1+i\eta)j_\beta P_1 + j_\alpha P_1 j_\beta R(E_1-i\eta)\} = \frac{1}{4\pi^2\eta}\int_{|z-E_1|=\epsilon}\mathrm{d}z\int_{|z'-E_1|=\epsilon'}\mathrm{d}z'\,F_{\alpha\beta}(z,z',\eta), \tag{4.45}$$

where we used the notation

$$F_{\alpha\beta}(z,z',\eta) := \frac{1}{z-(E_1+i\eta)}\mathrm{Tr}_{\mathcal{H}}(j_\alpha R(z)j_\beta R(z')) + \frac{1}{z-(E_1-i\eta)}\mathrm{Tr}_{\mathcal{H}}(j_\alpha R(z')j_\beta R(z)). \tag{4.46}$$

To go further with the computations we need a technical lemma that gives a general expression for $\mathrm{Tr}_{\mathcal{H}}(j_\alpha R(z)j_\beta R(z'))$.

Lemma 4.3: Let $u_{\alpha\beta}(z)$ *be the function introduced in Proposition* 3.1. *Then the following identity holds* ($\alpha \neq \beta$):

$$\mathrm{Tr}_{\mathcal{H}}(j_\alpha R(z) j_\beta R(z')) = \frac{\tau^4}{t_L^2}(\zeta_1(z) - \zeta_1(z'))^2 u_{\alpha\beta}(z) u_{\beta\alpha}(z'). \tag{4.47}$$

Proof: Taking into account the explicit form of j_α and j_β, we have

$$\mathrm{Tr}_{\mathcal{H}}(j_\alpha R(z) j_\beta R(z')) = -\tau^2\{\langle \mathcal{S}^\alpha, R(z)0_\beta\rangle\langle \mathcal{S}^\beta, R(z')0_\alpha\rangle - \langle \mathcal{S}^\alpha, R(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R(z')0_\alpha\rangle - \langle 0_\alpha, R(z)0_\beta\rangle \times\langle \mathcal{S}^\beta, R(z')\mathcal{S}^\alpha\rangle + \langle 0_\alpha, R(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R(z')\mathcal{S}^\alpha\rangle\}.$$

Each term is then computed using the Feshbach formula for $R(z)$,

$$\langle \mathcal{S}^\alpha, R(z)0_\beta\rangle\langle \mathcal{S}^\beta, R(z')0_\alpha\rangle = \tau^2\langle \mathcal{S}^\alpha, R_{\mathrm{eff}}(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R^L(z)0_\beta\rangle\langle \mathcal{S}^\beta, R_{\mathrm{eff}}(z')\mathcal{S}^\alpha\rangle\langle 0_\alpha, R^L(z')0_\alpha\rangle,$$

$$\langle \mathcal{S}^\alpha, R(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R(z')0_\alpha\rangle = \tau^2\langle \mathcal{S}^\alpha, R_{\mathrm{eff}}(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R^L(z')0_\beta\rangle\langle \mathcal{S}^\beta, R_{\mathrm{eff}}(z')\mathcal{S}^\alpha\rangle\langle 0_\alpha, R^L(z')0_\alpha\rangle,$$

$$\langle 0_\alpha, R(z)0_\beta\rangle\langle \mathcal{S}^\beta, R(z')\mathcal{S}^\alpha\rangle = \tau^2\langle 0_\alpha, R^L(z)0_\alpha\rangle\langle \mathcal{S}^\alpha, R_{\mathrm{eff}}(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R^L(z)0_\beta\rangle\langle \mathcal{S}^\beta, R_{\mathrm{eff}}(z')\mathcal{S}^\alpha\rangle,$$

$$\langle 0_\alpha, R(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R(z')\mathcal{S}^\alpha\rangle = \tau^2\langle 0_\alpha, R^L(z)0_\alpha\rangle\langle \mathcal{S}^\alpha, R_{\mathrm{eff}}(z)\mathcal{S}^\beta\rangle\langle 0_\beta, R^L(z')0_\beta\rangle\langle \mathcal{S}^\beta, R_{\mathrm{eff}}(z')\mathcal{S}^\alpha\rangle.$$

Moreover, we can also use the expression for the matrix elements of the resolvent R^L, which proves the lemma. ■

Now turning back to (4.46), and using the lemma above, we arrive at

$$\frac{t_L^2}{\tau^4}F_{\alpha\beta}(z,z',\eta) = \frac{1}{z-(E_1+i\eta)}(\zeta_1(z)-\zeta_1(z'))^2 u_{\alpha\beta}(z)u_{\beta\alpha}(z') + \frac{1}{z-(E_1-i\eta)} \times(\zeta_1(z)-\zeta_1(z'))^2 u_{\alpha\beta}(z')u_{\beta\alpha}(z).$$

Now we must handle the contour integrals in (4.45). Notice that $u_{\alpha\beta}(z)$ is singular around E_1. However, due to the equivalence (3.5) and relation (4.42), we have (with $\epsilon_1 > \epsilon$)

$$u_{\alpha\beta}(z) = \langle \mathcal{S}^\alpha, P_1\mathcal{S}^\beta\rangle\frac{1}{E_1-z} + \frac{1}{2\pi i}\int_{|z_1-E_1|=\epsilon_1} \mathrm{d}z_1 \frac{1}{z_1-z}\langle \mathcal{S}^\alpha, R(z_1)\mathcal{S}^\beta\rangle. \tag{4.48}$$

Remember that we have $\epsilon_1 > \epsilon > \epsilon'$. Substituting the u's in (4.46) we obtain a lot of terms. The most singular one is of the form (we omit the contours and constants for simplicity)

$$A_1 := \frac{1}{\eta}\int \mathrm{d}z \int \mathrm{d}z' \left(\frac{1}{z-(E_1+i\eta)} + \frac{1}{z-(E_1-i\eta)}\right)\frac{(\zeta_1(z)-\zeta_1(z'))^2}{(E_1-z)\cdot(E_1-z')}. \tag{4.49}$$

By the residue theorem

$$A_1 = \frac{(2\pi)^2 i}{\eta^2}((\zeta_1(E_1-i\eta)-\zeta_1(E_1))^2 - (\zeta_1(E_1+i\eta)-\zeta_1(E_1))^2).$$

Writing the Taylor series for $\zeta_1(E_1 \pm i\eta)$, one is left inside the parentheses with an expression of order η^3, and A_1 vanishes in the limit $\eta \to 0$.

Next, take one of the terms involving the singular part of $u_{\alpha\beta}(z)$ and the regular part of $u_{\alpha\beta}(z')$ (we omit for the moment the constants t_L, τ as well as the matrix elements of P_1),

$$A_2 = \frac{1}{\eta}\int \mathrm{d}z \int \mathrm{d}z' \frac{(\zeta_1(z)-\zeta_1(z'))^2}{z-(E_1+i\eta)} \cdot \frac{1}{E_1-z}\int \frac{\mathrm{d}z_1}{z_1-z'} u_{\alpha\beta}(z_1). \tag{4.50}$$

We see that the integral with respect to z' only involves analytic functions in the disk $|E_1-z'| < \epsilon'$, therefore the integral vanishes.

Another term coming from the singular part of $u_{\alpha\beta}(z')$ and the regular part of $u_{\alpha\beta}(z)$ is the following:

$$\begin{aligned} A_3 &:= \frac{1}{\eta}\int \mathrm{d}z \int \mathrm{d}z' \frac{(\zeta_1(z)-\zeta_1(z'))^2}{z-(E_1+i\eta)} \cdot \frac{1}{E_1-z'}\int \frac{\mathrm{d}z_1}{z_1-z} u_{\alpha\beta}(z_1) \\ &= -\frac{2\pi i}{\eta}\int \mathrm{d}z \frac{(\zeta_1(z)-\zeta_1(E_1))^2}{z-(E_1+i\eta)}\int \frac{\mathrm{d}z_1}{z_1-z} u_{\alpha\beta}(z_1), \end{aligned} \tag{4.51}$$

where in the second line we performed the integral with respect to z'. We can also perform the integral with respect to z and get up to constants the term

$$\frac{1}{\eta}(\zeta_1(E_1+i\eta)-\zeta_1(E_1))^2 \int \frac{\mathrm{d}z_1}{z_1-E_1} u_{\alpha\beta}(z_1).$$

Using again the Taylor series we see that $A_3 \sim \eta$, thus it will disappear as well. The same thing happens with all the other terms.

Looking back at (4.38), we continue with the contribution of $M_{\alpha\beta}$. Let us first bring $M_{\alpha\beta}(E,\eta,\varepsilon)$ to a suitable form. Using (4.28) it turns out that

$$M_{\alpha\beta}(E,\eta,\varepsilon) = M^{(1)}_{\alpha\beta}(E,\eta,\varepsilon) + M^{(2)}_{\alpha\beta}(E,\eta,\varepsilon), \tag{4.52}$$

where

$$\begin{aligned} M^{(1)}_{\alpha\beta}(E,\eta,\varepsilon) &:= \frac{1}{\eta-\varepsilon}(j_\alpha R(E-i\varepsilon) j_\beta R(E-i\eta) - j_\alpha R(E+i\eta) j_\beta R(E+i\varepsilon)) - \frac{1}{\eta+\varepsilon} \\ &\times (j_\alpha R(E+i\varepsilon) j_\beta R(E-i\eta) - j_\alpha R(E+i\eta) j_\beta R(E-i\varepsilon)), \end{aligned} \tag{4.53}$$

while $M^{(2)}_{\alpha\beta}$ includes all terms with only one resolvent. Since $\alpha \neq \beta$, and using the trace cyclicity, the trace of $M^{(2)}_{\alpha\beta}$ is zero and we are only left with $M^{(1)}_{\alpha\beta}$,

$$g_{\alpha\beta}(T,\mu) = \lim_{\eta \searrow 0}\lim_{\epsilon \searrow 0} \frac{i}{2\pi}\int_{-2t_L}^{2t_L} \mathrm{d}E f_{\mathrm{FD}}(E) \mathrm{Tr}_{\mathcal{H}}(M^{(1)}_{\alpha\beta}(E,\eta,\epsilon)). \tag{4.54}$$

Now we apply again the identity (4.47) and we use the meromorphic extensions of $u_{\alpha\beta}(z)$ (see Proposition 3.1), and the properties of $\zeta_1(z)$. The result is

$$g_{\alpha\beta}(T,\mu) = \lim_{\eta \searrow 0}\lim_{\epsilon \searrow 0} \frac{\tau^4}{t_L^2}\frac{i}{2\pi}\int_{-2t_L}^{2t_L} \mathrm{d}E\, f_{\mathrm{FD}}(E)\left(\frac{C_{\alpha\beta}(E,\eta,\epsilon)}{\eta-\epsilon} - \frac{D_{\alpha\beta}(E,\eta,\epsilon)}{\eta+\epsilon}\right), \tag{4.55}$$

with the following notation [see also (3.8) and (3.13)]

$$\begin{aligned} C_{\alpha\beta}(E,\eta,\epsilon) &:= (\zeta_-(E-i\epsilon)-\zeta_-(E-i\eta))^2 u^-_{\alpha\beta}(E-i\epsilon) u^-_{\beta\alpha}(E-i\eta) - (\zeta_+(E+i\eta)-\zeta_+(E+i\epsilon))^2 \\ &\times u^+_{\alpha\beta}(E+i\eta) u^+_{\beta\alpha}(E+i\epsilon), \end{aligned} \tag{4.56}$$

$$\begin{aligned} D_{\alpha\beta}(E,\eta,\epsilon) &:= (\zeta_+(E+i\epsilon)-\zeta_-(E-i\eta))^2 u^+_{\alpha\beta}(E+i\epsilon) u^-_{\beta\alpha}(E-i\eta) - (\zeta_+(E+i\eta)-\zeta_-(E-i\epsilon))^2 \\ &\times u^+_{\alpha\beta}(E+i\eta) u^-_{\beta\alpha}(E-i\epsilon). \end{aligned} \tag{4.57}$$

Since the $u^{\pm}(z)$ are smooth near the real axis, and the $\zeta_{\pm}$ have good behavior, one can take at once

the limit $\epsilon \searrow 0$ in (4.56) and (4.57). In the following we show that $C_{\alpha\beta}$ vanishes in the limit $\eta \searrow 0$. To see this we write, for example,

$$\zeta_+(E + i\eta) - \zeta_+(E) = -i\int_0^\eta (\partial_y \zeta_+(E + iy))\mathrm{d}y \tag{4.58}$$

and use the explicit form of ζ_+ to obtain the estimate

$$|\partial_y \zeta_+(E + iy)| \leqslant \text{const} \cdot \frac{1}{\sqrt{4t_L^2 - E^2}}, \tag{4.59}$$

which shows that $(1/\eta)C_{\alpha\beta} \sim \eta$ and the result follows.

The last step is to deal with

$$g_{\alpha\beta}(T,\mu) = -\lim_{\eta \searrow 0} \frac{\tau^4}{t_L^2}\frac{i}{2\pi}\int_{-2t_L}^{2t_L} f_{\mathrm{FD}}(E)\frac{D_{\alpha\beta}(E,\eta,0_+)}{\eta}\mathrm{d}E. \tag{4.60}$$

One notes that with the notation

$$F(E,\eta) := (\zeta_+(E + i\eta) - \zeta_-(E))^2 u^+_{\alpha\beta}(E + i\eta)u^-_{\beta\alpha}(E),$$

we have $D_{\alpha\beta}(E,\eta,0_+) = -2i\,\mathrm{Im}\,F(E,\eta)$ and

$$g_{\alpha\beta}(T,\mu) = -\lim_{\eta \searrow 0} \frac{\tau^4}{t_L^2}\frac{1}{\pi}\int_{-2t_L}^{2t_L} f_{\mathrm{FD}}(E)\frac{\mathrm{Im}\,F(E,\eta)}{\eta}\mathrm{d}E. \tag{4.61}$$

Using (3.13) and (A4) we see that $\mathrm{Im}\,F(E,i0_+) = 0$ and

$$\mathrm{Re}\,F(E,0_+) = -4[\mathrm{Im}\,\zeta_+(E)]^2 \cdot |u^+_{\alpha\beta}(E)|^2.$$

Taking the limit $\eta \searrow 0$, we obtain in the integral the term $(\partial_\eta \mathrm{Im}\,F)(E,0_+)$. Using the Cauchy–Riemann equations for u^+ and ζ_+, we get after some work that we can replace $(\partial_\eta \mathrm{Im}\,F)(E,0_+)$ by $(1/2)\times\partial_E \mathrm{Re}\,F(E,0_+)$. This also shows that F is not analytic.

Integrating by parts and noticing that $\zeta_+(\pm 2t_L) - \zeta_-(\pm 2t_L) = 0$ we proved the following lemma.

Lemma 4.4: The conductance coefficients $g_{\alpha\beta}(T,\mu)$ defined in (4.36) are given by the relation

$$g_{\alpha\beta}(T,\mu) = -\frac{4\tau^4}{t_L^2}\frac{1}{2\pi}\int_{-2t_L}^{2t_L} \mathrm{d}E\frac{\partial f_{\mathrm{FD}}(E)}{\partial E}(\mathrm{Im}\,\zeta_+(E))^2|u^+_{\alpha\beta}(E)|^2. \tag{4.62}$$

C. Completion of the proof of the main theorem

Before giving the final step in the proof of the Landauer–Büttiker formula, let us briefly review what we have done in this section. We started with the scattering problem associated to the semi-infinite leads case, the transmission between two leads being found in (4.6). The rest of the work has been done to obtain explicit expressions for the conductance coefficients given by the Kubo-type formula (4.15), when the thermodynamic and adiabatic limits are taken.

To finish the proof of Theorem 2.1 there is not much to be done. First, use the explicit expressions for $\zeta_\pm(\cdot)$, together with the definition of the Fermi "momentum," $E = 2t_L\cos(k_E)$, in (4.62). The result is

$$g_{\alpha\beta}(T,\mu) = -\frac{4\tau^4}{t_L^2}\frac{1}{2\pi}\int_{-2t_L}^{2t_L} \mathrm{d}E\frac{\partial f_{\mathrm{FD}}(E)}{\partial E}\sin^2(k_E)|u^+_{\alpha\beta}(E)|^2. \tag{4.63}$$

Now comparing (4.63) and (4.6) one obtains (2.25), and we are done. Notice that when $T \to 0$, we have $-\partial_E f_{\mathrm{FD}} \to \delta(E-\mu)$, and (2.26) follows.

The presence of $1/2\pi$ in those equations is not an accident. It makes more sense, if one carefully includes in computations the physical constants e and $\hbar$ (we have been working until now with the convention $e=\hbar=1$). Without giving details, we assure the reader that in the end the equality in (2.26) becomes

$$g_{\alpha\beta}(0_+,\mu)=\frac{e^2}{2\pi\hbar}\mathcal{T}_{\alpha\beta}(\mu)=\frac{e^2}{h}\mathcal{T}_{\alpha\beta}(\mu), \tag{4.64}$$

which is nothing but the well-known Landauer formula at zero temperature. Note that when the total particle density is fixed, then μ represents the Fermi energy of our system. When the leads become infinite, the sample does not contribute to the thermodynamic limit, thus the Fermi energy is fixed by the leads. The proof of Theorem 2.1 is completed. ■

V. RESONANT TRANSPORT IN A QUANTUM DOT

Up to now we allowed τ to be arbitrarily large, together with the assumption that the Hamilton operator for the system with semi-infinite leads K had no eigenvalues at $\pm 2t_L$. In this section we are interested in small coupling, i.e., the limit $\tau\to 0$.

We now assume that the sample Hamiltonian H^S *does not have eigenvalues* $\pm 2t_L$. This assumption implies, through a simple perturbation argument, and the explicit form of the effective Hamiltonian, that the full Hamiltonian K does not have eigenvalues $\pm 2t_L$, provided τ is sufficiently small.

Assume that H^S has $J\geqslant 1$ (possibly degenerate) eigenvalues, denoted by $\{E_1,\ldots,E_J\}$, such that

$$\sigma(H^S)\cap[-2t_L,2t_L]=\{E_1,\ldots,E_J\}\subset(-2t_L,2t_L). \tag{5.1}$$

We are not interested in possible eigenvalues outside $[-2t_L,2t_L]$, since for small τ they will still remain discrete eigenvalues for K, and we saw that they do not contribute to transport. Now we focus on the influence of $\{E_1,\ldots,E_J\}$ on the transport properties, when τ is small.

Let us give the main result of this section. We consider the transmittance [see (4.6)] between the leads β and γ. Assume that all eigenvalues $\{E_1,\ldots,E_J\}\subset(-2t_L,2t_L)$ of H^S are nondegenerate. The normalized eigenvector corresponding to E_j is denoted by ϕ_j.

Proposition 5.1: (i) *For every* $\lambda\in(-2t_L,2t_L)\backslash\{E_1,\ldots,E_J\}$ *we have*

$$\lim_{\tau\searrow 0}\mathcal{T}_{\beta\gamma}(\lambda,\tau)=0. \tag{5.2}$$

(ii) *Fix* $\lambda=E_j$. *If either* $\langle\mathcal{S}^\beta,\phi_j\rangle$ *or* $\langle\mathcal{S}^\gamma,\phi_j\rangle$ *is zero, then*

$$\lim_{\tau\searrow 0}\mathcal{T}_{\beta\gamma}(E_j,\tau)=0. \tag{5.3}$$

(iii) *Fix* $\lambda=E_j$. *If both* $\langle\mathcal{S}^\beta,\phi_j\rangle$ *and* $\langle\mathcal{S}^\gamma,\phi_j\rangle$ *are different from zero, then there exists a positive constant* $C(E_j)$ *such that*

$$\lim_{\tau\searrow 0}\mathcal{T}_{\beta\gamma}(E_j,\tau)=C(E_j)\left|\frac{\langle\mathcal{S}^\beta,\phi_j\rangle\cdot\langle\mathcal{S}^\gamma,\phi_j\rangle}{\sum_{\alpha=1}^{M}|\langle\mathcal{S}^\alpha,\phi_j\rangle|^2}\right|^2. \tag{5.4}$$

Remark: The physical significance of this proposition is quite transparent. It states that at small coupling, the following things happen: (i) If the energy of the incident electron is not close to the eigenvalues of H^S, it will not contribute to the current. (ii) If the incident energy is close to some eigenvalue E_j, but the eigenfunction ϕ_j is not localized around both coupling points $\mathcal{S}^\gamma$ and $\mathcal{S}^\beta$, then again there is no current. (iii) In order to have a peak in the current, it is necessary for H^S to have extended edge states, which couple several leads. A numerical analysis of the Harper operator on large domains with Dirichlet boundary conditions puts into evidence such extended

edge states, as well as the existence of bulk states concentrated in the middle of the dot (see Refs. 26 and 33).

Proof: We split the proof into several technical results. We will not assume that the E_j's are nondegenerate, unless stated otherwise.

Lemma 5.2: Consider $u_{\beta\gamma}$ given in (3.8), and $u^+_{\beta\gamma}$ its meromorphic extension. Then

$$\lim_{\tau\searrow 0}(\tau^2 \sup_{\lambda\in(-2t_L,2t_L)}|u^+_{\beta\gamma}(\lambda,\tau)|)<\infty.$$

Proof: The lemma roughly says that $u^+_{\beta\gamma}(\lambda)$ cannot blow up worse than $1/\tau^2$, when τ is small. In other words, its poles (if any) have an imaginary part of order τ^2, when τ is small.

Clearly, if τ is smaller than some $\delta_0>0$, then by the usual perturbation theory we get that for all λ located outside some small disks (with radii determined by δ_0) centered at $\{E_j\}_{j=1}^J$ (the eigenvalues of H^S), we have

$$\|(H_+(\lambda)-\lambda)^{-1}\|\leqslant C\max_{j\in\{1,\ldots,J\}}|E_j-\lambda|^{-1},$$

thus we only need to look at what happens in each interval of the form $(E_j-\epsilon,E_j+\epsilon)$.

Assume that E_j is n-fold degenerate. Denote by Π_j the n-dimensional projection corresponding to E_j. The operator $\Pi_j\Pi^T\Pi_j$ has a (possibly trivial) null space in $\mathrm{Ran}(\Pi_j)$. Let p_j be the projection onto this space. Let $\tilde{p}_j=\Pi_j-p_j$ be the projection onto the orthogonal complement of $\mathrm{Ran}(p_j)$ in $\mathrm{Ran}(\Pi_j)$. It is easy to see that there exists a positive constant C_j, such that

$$\tilde{p}_j\Pi^T\tilde{p}_j\geqslant C_j\tilde{p}_j^2. \tag{5.5}$$

Indeed, this is implied by the fact that the operator is non-negative, and with a trivial null space.

Let $q_j=\mathrm{Id}-p_j$. Since $\Pi^Tp_j=0$, and arguing as in (3.10), we have

$$(H_+(\lambda)-\lambda)^{-1}-(E_j-\lambda)^{-1}p_j=q_j[q_j(H_+(\lambda)-\lambda)q_j]^{-1}q_j.$$

Only the right-hand side will contribute to $u^+_{\beta\gamma}$, since $p_j\mathcal{S}^\gamma=0$. The proposition will be proven, if we can show the estimate [on $\mathrm{Ran}(q_j)$]

$$\|[q_j(H_+(\lambda)-\lambda)q_j]^{-1}\|\leqslant C/\tau^2 \tag{5.6}$$

for λ near E_j.

Notice that $q_j=\tilde{p}_j+(\mathrm{Id}-\Pi_j)$, i.e., it is the orthogonal sum of some part of Π_j and the projections corresponding to all other eigenvalues of H^S different from E_j. Let $A_j:=q_j(H_+(\lambda)-\lambda)q_j$.

Note further that $(\mathrm{Id}-\Pi_j)A_j(\mathrm{Id}-\Pi_j)$ is well-behaved when λ is close to E_j, because it essentially equals $(\mathrm{Id}-\Pi_j)(H^S-\lambda)(\mathrm{Id}-\Pi_j)$ plus a perturbation of order τ^2. Applying the Neumann series again, we get that on $\mathrm{Ran}(\mathrm{Id}-\Pi_j)$,

$$\|[(\mathrm{Id}-\Pi_j)A_j(\mathrm{Id}-\Pi_j)]^{-1}\|\leqslant\mathrm{const} \tag{5.7}$$

for λ close to E_j and τ small enough. Hence if $\tilde{p}_j=0$, this estimate implies

$$\|[q_j(H_+(\lambda)-\lambda)q_j]^{-1}\|\leqslant\mathrm{const}, \tag{5.8}$$

which implies (5.6), and we are done.

If $\tilde{p}_j\neq 0$, we again apply the Feshbach lemma for the operator A_j, intending to reduce the problem to the subspace $\mathrm{Ran}(\tilde{p}_j)$. Then A_j is invertible in $\mathrm{Ran}(q_j)$, if and only if the operator

$$X_j:=\tilde{p}_jA_j\tilde{p}_j-\tilde{p}_jA_j(\mathrm{Id}-\Pi_j)[(\mathrm{Id}-\Pi_j)A_j(\mathrm{Id}-\Pi_j)]^{-1}(\mathrm{Id}-\Pi_j)A_j\tilde{p}_j \tag{5.9}$$

is invertible in $\mathrm{Ran}(\tilde{p}_j)$, and their inverses will have the same estimate for their norm, when τ is small. It is not difficult to see that the second term in (5.9) is of order τ^4, when λ is near E_j. We can then write

$$X_j = \tilde{p}_j A_j \tilde{p}_j + \mathcal{O}(\tau^4). \tag{5.10}$$

But the operator

$$\tilde{p}_j A_j \tilde{p}_j = E_j - \lambda - (\tau^2/t_L)\zeta_+(\lambda)\tilde{p}_j \Pi^T \tilde{p}_j \tag{5.11}$$

is one to one (thus invertible), because for every $f \in \mathrm{Ran}(\tilde{p}_j)$ with norm one we have [see also (A4)]

$$\|\tilde{p}_j A_j \tilde{p}_j f\| \geqslant |\langle f, A_j f\rangle| \geqslant |\mathrm{Im}(\langle f, A_j f\rangle)| = (\tau^2/t_L)\sqrt{1-\lambda^2/(4t_L^2)}\langle f, \Pi^T f\rangle,$$

and using (5.5) we get

$$\|\tilde{p}_j A_j \tilde{p}_j f\| \geqslant (\tau^2/t_L)\sqrt{1-\lambda^2/(4t_L^2)}C_j,$$

which leads to

$$\|[\tilde{p}_j A_j \tilde{p}_j]^{-1}\| \leqslant \mathrm{const} \cdot 1/\tau^2.$$

Using this in (5.10) by employing again the Neumann series, we get that for τ small and λ near E_j we have

$$\|X_j^{-1}\| \leqslant \mathrm{const} \cdot 1/\tau^2,$$

thus (5.6) is proven, and so is the lemma. ■

Remark: We see that if $p_j \neq 0$, its range is spanned by eigenvectors of K corresponding to E_j. But they do not contribute in any way to $u^+_{\beta\gamma}$.

Corollary 5.3: We use the notation introduced in the previous lemma. Assume that E_j is n-fold degenerate.

(i) *For every $\lambda \in (-2t_L, 2t_L)$ with $\lambda \notin \{E_1, \ldots, E_J\}$ we have*

$$\lim_{\tau \searrow 0} \tau^2 |u^+_{\beta\gamma}(\lambda, \tau)| = 0. \tag{5.12}$$

(ii) *Fix $\lambda = E_j$. Assume $\tilde{p}_j = 0$. Then*

$$\lim_{\tau \searrow 0} \tau^2 |u^+_{\beta\gamma}(E_j, \tau)| = 0. \tag{5.13}$$

(iii) *Fix $\lambda = E_j$. Assume that $\tilde{p}_j \neq 0$. Then $\tilde{p}_j \Pi^T \tilde{p}_j$ is positive on* $\mathrm{Ran}(\tilde{p}_j)$ *and*

$$\lim_{\tau \searrow 0} \tau^2 |u^+_{\beta\gamma}(E_j, \tau)| = t_L |\langle \mathcal{S}^\beta, \tilde{p}_j [\tilde{p}_j \Pi^T \tilde{p}_j]^{-1} \tilde{p}_j \mathcal{S}^\gamma\rangle|. \tag{5.14}$$

Proof: (i) By regular perturbation theory, we see that $|u^+_{\beta\gamma}(\lambda, \tau)|$ remains bounded when τ tends to zero, while λ is fixed and away from the eigenvalues of H^S. Hence (5.12) is straightforward.

(ii) If $\tilde{p}_j = 0$ and $\lambda = E_j$, the estimate (5.8) implies again that $|u^+_{\beta\gamma}(E_j, \tau)|$ remains bounded when τ tends to zero, thus (5.13) follows.

(iii) If $\tilde{p}_j \neq 0$ and $\lambda = E_j$, we rely on the properties of the inverse on $\mathrm{Ran}(\tilde{p}_j)$ of the operator $\tilde{p}_j A_j \tilde{p}_j$ introduced in (5.11). A consequence of the arguments presented in the previous proposition is that for λ close to E_j we have

$$u^+_{\beta\gamma}(\lambda) - \langle \mathcal{S}^\beta, \tilde{p}_j [\tilde{p}_j A_j \tilde{p}_j]^{-1} \tilde{p}_j \mathcal{S}^\gamma\rangle = \mathcal{O}_\tau(1). \tag{5.15}$$

Then using (5.11) with $\lambda = E_j$, and the fact that $|\zeta_+(\lambda)| = 1$, the result follows easily. The corollary is proven. ■

Completing the proof of Proposition 5.1: The proof is easily obtained by replacing (5.12)–(5.14) in (4.6), in the nondegenerate case. Details are omitted.

We see that in the degenerate case it is not that simple to give clear criteria, for which the current is zero, or not, in the small coupling regime. Assume that E_j is n-fold degenerate. Denote by $\{\phi_j^{(s)}\}_{s=1}^n$ the normalized eigenvectors of H^S spanning the range of Π_j. A sufficient condition for the right-hand side of (5.14) to be zero for every β and γ, is Π_j to be orthogonal to Π^T. In other words, $\langle S^\alpha, \phi_j^{(r)}\rangle = 0$ for every $1 \leqslant \alpha \leqslant M$ and $1 \leqslant r \leqslant n$. Physically, this means no contact at all between the leads and the mode E_j. A necessary but not sufficient condition for the right-hand side of (5.14) to be different from zero is to have $\tilde{p}_j \neq 0$. The proposition is proven. ■

We continue this section with a result giving more information about the poles in the case, when τ is small, and we are near a nondegenerate eigenvalue of H^S.

Assume that the eigenvalue $E_1 \in (-2t_L, 2t_L)$ of H^S is nondegenerate. We denote the corresponding normalized eigenvector with ϕ_1, i.e., $H^S\phi_1 = E_1\phi_1$. It is clear that one of the following two alternatives is true:

(1) A_1, there exists $\alpha_1 \in \{1, \ldots, M\}$ such that $\langle \phi_1, \mathcal{S}^{\alpha_1}\rangle \neq 0$;
(2) A_2, for all $\alpha \in \{1, \ldots, M\}$ we have $\langle \phi_1, \mathcal{S}^{\alpha}\rangle = 0$.

If A_1 holds, then ϕ_1 is "coupled" with at least one lead. If A_2 holds, then the coupling is absent.

Define the projection $\Pi^L = \Sigma_{\alpha=1}^M |0_\alpha\rangle\langle 0_\alpha|$. By direct computation we have [see (3.8) and (3.3)]

$$\Pi^L(K-z)^{-1}\Pi^L = \frac{\zeta_1(z)}{t_L}\sum_{\alpha=1}^M |0_\alpha\rangle\langle 0_\alpha| + \frac{\zeta_1^2(z)}{t_L^2}\sum_{\alpha,\beta=1}^M |0_\alpha\rangle u_{\alpha\beta}(z)\langle 0_\beta|. \tag{5.16}$$

Then the weighted resolvent $\Pi^L(K-z)^{-1}\Pi^L$ admits a meromorphic extension to any domain of the form $\mathbb{C}_+ \cup \Omega_\epsilon$ [see (3.6)].

Proposition 5.4: (i) *For small enough τ, the weighted resolvent $\Pi^L(K-z)^{-1}\Pi^L$ has a simple pole near E_1* [*denoted by $\tilde{E}_1(\tau)$*].

(ii) *If A_1 holds true, then for $\tau > 0$ small enough the pole $\tilde{E}_j(\tau)$ is a resonance for K with*

$$\lim_{\tau \searrow 0}(\mathrm{Re}\,\tilde{E}_1(\tau) - E_1)/\tau^2 = -\frac{E_1}{2t_L^2}\sum_{\alpha=1}^M |\langle \phi_1, \mathcal{S}^\alpha\rangle|^2$$

and

$$\lim_{\tau \searrow 0}\mathrm{Im}\,\tilde{E}_1(\tau)/\tau^2 = -\frac{\sqrt{4t_L^2 - E_1^2}}{2t_L^2}\sum_{\alpha=1}^M |\langle \phi_1, \mathcal{S}^\alpha\rangle|^2.$$

(iii) *If A_2 holds for ϕ_1, then $\tilde{E}_1(\tau) = E_1$ and ϕ_1 remains an eigenvector for K, i.e., $K\phi_1 = \tilde{E}_1\phi_1$.*

Proof: Let us focus on what happens near E_1, when A_1 holds. Denote by P_1 the spectral projection of H^S corresponding to ϕ_1, and let $Q_1 = \mathrm{Id} - P_1$. The Feshbach lemma gives [using a compact notation, cf. (3.3)]

$$\begin{aligned}(H_+(z) - z)^{-1} = (Q_1H_+Q_1 - z)^{-1} + (1 - (Q_1H_+Q_1 - z)^{-1}Q_1H_+P_1)\\ \times (\tilde{H}_+(z) - z)^{-1} \cdot (1 - P_1H_+Q_1(Q_1H_+Q_1 - z)^{-1}),\end{aligned} \tag{5.17}$$

where the new effective Hamiltonian $\tilde{H}_+(z)$ is defined by

$$\tilde{H}_+(z) := P_1H_+(z)P_1 - P_1H_+Q_1(Q_1H_+Q_1 - z)^{-1}Q_1H_+P_1, \tag{5.18}$$

and lives in a one-dimensional space. With the notation

$$f_1(z,\tau) := \sum_{\alpha,\beta=1}^{M} \sum_{i,i'\neq 1} \frac{\tau^4}{t_L^2} \zeta_+^2(z) \langle \phi_1, \mathcal{S}^\alpha \rangle \langle \mathcal{S}^\alpha, \phi_i \rangle \times \langle \phi_i, (Q_1 H_+ Q_1 - z)^{-1} \phi_{i'} \rangle \langle \phi_{i'}, \mathcal{S}^\beta \rangle \langle \mathcal{S}^\beta, \phi_1 \rangle,$$

we have that for small enough τ, $H_+(z)-z$ is invertible, if and only if the function

$$F_1(z,\tau) := E_1 - z - \frac{\tau^2}{t_L} \zeta_+(z) \sum_{\alpha=1}^{M} |\langle \phi_j, \mathcal{S}^\alpha \rangle|^2 - f_1(z,\tau)$$

is different from zero. Notice that for τ small enough, and z near E_1, we have $f_1(z,\tau)=\mathcal{O}(\tau^4)$.

For small τ, and with z near E_1, the implicit function theorem provides us with a unique solution $\tilde{E}_1(\tau)$ to the equation $F_1(z,\tau)=0$.

If we define

$$\begin{aligned}\mathcal{T}_1(z,\tau) := &- (Q_1 H_+ Q_1 - z)^{-1} Q_1 H_+ P_1 - P_1 H_+ Q_1 (Q_1 H_+ Q_1 - z)^{-1} \\ &+ (Q_1 H_+ Q_1 - z)^{-1} Q_1 H_+ P_1 H_+ Q_1 (Q_1 H_+ Q_1 - z)^{-1},\end{aligned}$$

then we can write

$$(H_+ - z)^{-1} = \frac{1}{F_1(z,\tau)} [P_1 + \mathcal{T}_1] + (Q_1 H_+ Q_1 - z)^{-1}. \tag{5.19}$$

It is easy to see that $\mathcal{T}_1$ is analytic in z near E_1, and of order $\mathcal{O}(\tau^2)$. Now we must take the matrix elements $\langle \mathcal{S}^\alpha, (H_+(z)-z)^{-1} \mathcal{S}^\beta \rangle$ to obtain $u_{\alpha\beta}(z)$ in (5.16). It turns out that

$$\Pi^L (K-z)^{-1} \Pi^L = \text{bounded and analytic term} + \frac{\zeta_+^2(z)}{t_L^2} \sum_{\alpha,\beta=1}^{M} \left\{ \frac{\langle \mathcal{S}^\alpha, \psi_1 \rangle \langle \psi_1, \mathcal{S}^\beta \rangle + \langle \mathcal{S}^\alpha, \mathcal{T}_1 \mathcal{S}^\beta \rangle}{F_1(z,\tau)} \right\} |0_\alpha\rangle\langle 0_\beta|.$$

Moreover, since we can show that

$$F_1(z,\tau)/(E_1(\tau) - z) = 1 + \mathcal{O}(\tau^2)$$

for z in a small neighborhood of E_1, we conclude that

$$\begin{aligned}\Pi^L (K-z)^{-1} \Pi^L = &\text{ bounded and analytic term} + (1 + \mathcal{O}(\tau^2)) \frac{\zeta_+^2(z)}{t_L^2} \sum_{\alpha,\beta=1}^{M} \frac{\langle \mathcal{S}^\alpha, \psi_1 \rangle \langle \psi_1, \mathcal{S}^\beta \rangle + \mathcal{O}(\tau^2)}{\tilde{E}_1(\tau) - z} \\ &\times |0_\alpha\rangle\langle 0_\beta|.\end{aligned}$$

Therefore the second statement of the proposition is now proved up to a straightforward application of the implicit function theorem for the claimed properties of $\tilde{E}_1(\tau)$. The third statement is also straightforward. ■

APPENDIX A: THE DISCRETE LAPLACIAN ON THE HALF-LINE

Denote by $\{|n\rangle\}_{n\geq 0}$ the standard basis in $l^2(\mathbb{N})$. For $t_L>0$, consider the operator H_α^L, which acts on $\psi \in l^2(\mathbb{N})$ as follows:

$$(H_\alpha^L \psi)(j) = t_L \psi(j+1) + t_L \psi(j-1), \quad j \geq 0, \quad \psi(-1) := 0.$$

It is well known that the spectrum of H_α^L is purely absolutely continuous, and moreover $\sigma(H_\alpha^L)=[-2t,2t]$. We are interested in the matrix elements of the resolvent of H_α^L. If $\mathrm{Im}\, z>0$, one can easily compute

$$\langle m,R_\alpha^L(z)n\rangle = \frac{1}{t_L(\zeta_2-\zeta_1)}(\zeta_1(z)^{|m-n|}-\zeta_1(z)^{m+n+2}), \tag{A1}$$

where $\zeta_{1,2}$ are solutions of the equation

$$t_L\zeta^2 - z\zeta + t = 0, \tag{A2}$$

and ζ_1 is chosen, such that $|\zeta_1|\sim 1/|z|$ at infinity (note that $\zeta_1\zeta_2=1$).

We give several explicit representations for ζ_1. By $\ln(x)=\ln(|x|)+i\arg(x)$ we understand the principal branch of the natural logarithm defined on $\mathbb{C}\backslash(-\infty,0]$, with $\arg(x)\in(-\pi,\pi)$. Thus $\sqrt{x}=\sqrt{|x|}e^{(i/2)\arg(x)}$.

Proposition 6.1: We have the following properties.

(i) *Assume that* $z\notin[-2t_L,2t_L]$. *Then*

$$\zeta_1(z) = \frac{z}{2t_L}(1-\sqrt{1-4t_L^2/z^2}). \tag{A3}$$

(ii) *Consider the holomorphic functions*

$$\zeta_\pm(z) = \frac{z}{2t_L} \mp i\sqrt{1-z^2/(4t_L^2)}, \quad z\notin(-\infty,-2t_L]\cup[2t_L,\infty). \tag{A4}$$

Then $\zeta_1(z)=\zeta_+(z)$ *if* $\mathrm{Im}\, z>0$, *and* $\zeta_1(z)=\zeta_-(z)$ *if* $\mathrm{Im}\, z<0$.

(iii) *We have* $\zeta_2(z)=1/\zeta_1(z)$.

Proof: We see that ζ_1 in (A3) solves the equation, and behaves like $1/z$ for large $|z|$. Furthermore, since ζ_1 and $\tilde{\zeta}_\pm$ are holomorphic, it is enough to verify their equality at points of the form $\pm it$ with $t>0$, which is trivial. ■

APPENDIX B: THE SECOND QUANTIZATION OF AN IDEAL FERMI GAS

The results in this section are well known, see for example Ref. 8. We recall the results to fix the notation.

Given a separable Hilbert space $\mathcal{H}$, the associated antisymmetric Fock space is given by

$$\mathcal{F}_a(\mathcal{H}) = \bigoplus_{n=0}^{\infty} \mathcal{H}^{\otimes_a n}, \quad \mathcal{H}^{\otimes_a 0} := \mathbb{C}.$$

Here the subscript a indicates the total antisymmetrization of the tensor products. Let $\mathcal{B}=\{e_k\}_{k\geqslant 1}$ be an orthonormal basis in $\mathcal{H}$. Then we can construct the "occupation number" basis in $\mathcal{F}_a(\mathcal{H})$ associated to $\mathcal{B}$. We denote a generic vector by $\Psi_{N_1,N_2,\ldots}$, where the N_k's are numbers (either 0 or 1) showing how many times e_k appears in the tensor products defining Ψ. For example, $\Psi_{0,0,\ldots}=1\in\mathbb{C}$ is the vacuum.

The annihilation operators associated with this particular basis are defined as

$$a_\alpha\Psi_{N_1,N_2,\ldots,N_\alpha=0,\ldots} = 0,$$

$$a_\alpha\Psi_{N_1,N_2,\ldots,N_\alpha=1,\ldots} = (-1)^{\Sigma_{\beta<\alpha}N_\beta}\Psi_{N_1,N_2,\ldots,N_\alpha=0,\ldots},$$

while their adjoints (the creation operators) are given by

$$a_\alpha^\dagger\Psi_{N_1,N_2,\ldots,N_\alpha=1,\ldots} = 0,$$

$$a_\alpha^\dagger \Psi_{N_1,N_2,\ldots,N_\alpha=0,\ldots} = (-1)^{\Sigma_{\beta<\alpha} N_\beta} \Psi_{N_1,N_2,\ldots,N_\alpha=1,\ldots}.$$

If A is a bounded linear operator in $\mathcal{H}$, its second quantization $\mathbf{A}=\mathrm{d}\Gamma(A)$ is the operator on $\mathcal{F}_a$, whose restriction to $\mathcal{H}^{\otimes_a n}$ is given by

$$A \otimes \mathrm{Id} \otimes \cdots \otimes \mathrm{Id} + \ldots + \mathrm{Id} \otimes \cdots \otimes \mathrm{Id} \otimes A,$$

where the above sum has n terms. Using the particular basis $\mathcal{B}$, we have

$$\mathbf{A} = \mathrm{d}\Gamma(A) = \sum_{k,j\geqslant 1} \langle e_k, Ae_j\rangle a_k^+ a_j. \tag{B1}$$

For example, the total Hamiltonian is $\mathbf{H}=\mathrm{d}\Gamma(H)$, and the number operator is $\mathbf{N}=\mathrm{d}\Gamma(\mathrm{Id})$.

Now assume that $\mathcal{H}$ is finite dimensional. The grand canonical partition function Ξ and the density matrix operator in the grand canonical ensemble $\hat{\rho}_0$ are defined as

$$\Xi := \mathrm{Tr}_{\mathcal{F}_a} e^{-\beta(\mathbf{H}-\mu\mathbf{N})}, \quad \hat{\rho}_0 := \frac{1}{\Xi} e^{-\beta(\mathbf{H}-\mu\mathbf{N})}. \tag{B2}$$

Finally, we define

$$f_{\mathrm{FD}}(x) = \frac{1}{e^{\beta(x-\mu)}+1}, \quad \rho_0 := f_{\mathrm{FD}}(H). \tag{B3}$$

The following proposition will be used extensively in Sec. III.

Proposition 6.2: Let A and B be bounded operators in $\mathcal{H}$. Denote by $[A,B]=AB-BA$ their commutator. Then

$$\mathrm{d}\Gamma([A,B]) = [\mathbf{A},\mathbf{B}], \tag{B4}$$

$$e^{\mathbf{A}}\mathbf{B}e^{-\mathbf{A}} = \mathrm{d}\Gamma(e^A B e^{-A}), \tag{B5}$$

$$\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}_0 \mathbf{A}) = \mathrm{Tr}_{\mathcal{H}}(\rho_0 A). \tag{B6}$$

Proof: The first identity is easily proven using the anticommutation relations

$$\begin{aligned}[\mathbf{A},\mathbf{B}] &= \sum_{k,j,m,n} \langle e_k, Ae_j\rangle\langle e_m, Be_n\rangle [a_k^\dagger a_j a_m^\dagger a_n - a_m^\dagger a_n a_k^\dagger a_j] \\ &= \sum_{k,j,m,n} \langle e_k, Ae_j\rangle\langle e_m, Be_n\rangle [a_k^\dagger a_n \delta_{jm} - a_m^\dagger a_n \delta_{kn}] = \sum_{k,j} \langle e_k, (AB-BA)e_j\rangle = \mathrm{d}\Gamma([A,B]),\end{aligned}$$

while the second one is implied by the first equality, the Baker–Cambell–Hausdorff formula

$$e^{\mathbf{A}}\mathbf{B}e^{-\mathbf{A}} = \mathbf{B} + [\mathbf{A},\mathbf{B}] + \tfrac{1}{2}[\mathbf{B},[\mathbf{B},\mathbf{A}]] + \cdots,$$

and the linearity of $\mathrm{d}\Gamma(\cdot)$.

Concerning the third identity (see also Proposition 5.2.23 in Ref. 8) we first note that the trace is invariant with respect to the basis used, so we may assume that the basis $\mathcal{B}=\{e_k\}$ is the set of eigenvectors of H. We consider the occupation number basis derived from it. The eigenvalues of H are denoted by $\{\lambda_k\}$. Then

$$\Xi = \Pi_k (1 + e^{-\beta(\lambda_k-\mu)}) < \infty, \tag{B7}$$

and we can write

$$\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}_0\mathbf{A}) = \sum_{N_1,N_2,\ldots\in\{0,1\}} \langle \Psi_{N_1,N_2,\ldots}, \hat{\rho}_0\mathbf{A}\Psi_{N_1,N_2,\ldots}\rangle.$$

Since

$$\hat{\rho}_0\Psi_{N_1,N_2,\ldots} = \frac{1}{\Xi}e^{-\beta\Sigma_j N_j(\lambda_j-\mu)}\Psi_{N_1,N_2,\ldots} = \frac{1}{\Xi}\Pi_j e^{-\beta N_j(\lambda_j-\mu)}\Psi_{N_1,N_2,\ldots},$$

and

$$\langle \Psi_{N_1,N_2,\ldots}, \mathbf{A}\Psi_{N_1,N_2,\ldots}\rangle = \sum_{k,m}\langle e_k, Ae_m\rangle \delta_{N_k,1}\delta_{N_m,1}\delta_{k,m},$$

we have

$$\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}_0\mathbf{A}) = \sum_k \langle e_k, Ae_k\rangle \frac{1}{\Xi}\sum_{N_1,N_2,\ldots\in\{0,1\}} \Pi_j e^{-\beta N_j(\lambda_j-\mu)}\delta_{N_k,1}.$$

Note that

$$\sum_{N_1,N_2,\ldots\in\{0,1\}} \Pi_j e^{-\beta N_j(\lambda_j-\mu)}\delta_{N_k,1} = (1+e^{-\beta(\lambda_1-\mu)})(1+e^{-\beta(\lambda_2-\mu)})\cdots e^{-\beta(\lambda_k-\mu)}\cdots(1+e^{-\beta(\lambda_j-\mu)})\cdots, \tag{B8}$$

hence

$$\frac{1}{\Xi}\sum_{N_1,N_2,\ldots\in\{0,1\}} \Pi_j e^{-\beta N_j(\lambda_j-\mu)}\delta_{N_k,1} = f_{\mathrm{FD}}(\lambda_k),$$

and therefore

$$\mathrm{Tr}_{\mathcal{F}_a}(\hat{\rho}_0\mathbf{A}) = \sum_k \langle e_k, Ae_k\rangle f_{\mathrm{FD}}(\lambda_k) = \mathrm{Tr}_{\mathcal{H}}(\rho_0 A).$$

■

APPENDIX C: A DISCRETE KREIN FORMULA AND EXPONENTIAL DECAY

We now give a formula relating the resolvent of the discrete Laplacian defined on $l^2(\mathcal{N})$, $\mathcal{N}=\{0,1,\ldots,N\}$, with the resolvent of the Laplacian defined on $l^2(\mathbb{N})$; both operators are with Dirichlet boundary conditions. We denote by $r^L(N,z)$ the resolvent on the finite segment, and by $r^L(z)$ the resolvent on the semi-infinite lead. We use lower case letters to emphasize that we model only one lead. The operator itself is denoted by $h^L(N)$ when restricted to a segment, and by h^L on $l^2(\mathbb{N})$. The vector δ_m is the vector in $l^2(\mathcal{N})$ having 1 in the mth position, and 0 elsewhere. Define for every $z\in\mathbb{C}\backslash\mathbb{R}$ the "integral kernels"

$$g_{m,n}(N,z) = \langle \delta_m, r^L(N,z)\delta_n\rangle, \quad g_{m,n}(z) = \langle \delta_m, r^L(z)\delta_n\rangle. \tag{C1}$$

The Dirichlet boundary condition means

$$g_{-1,n}(N,z) = g_{N+1,n}(N,z) = g_{-1,n}(z) = 0, \tag{C2}$$

with analogous equalities for the second argument, due to the symmetry property $g_{m,n}(N,z) = \overline{g_{n,m}(N,\bar{z})}$.

Proposition 6.3: For all $0\leqslant m,n\leqslant N$ *we have the following Krein formula:*

$$g_{m,n}(N,z) - g_{m,n}(z) = t_L g_{m,N}(N,z) g_{N+1,n}(z). \tag{C3}$$

Proof: The proof is outlined here. For every fixed n, the vectors $g_{\cdot,n}(N,z)$ ($g_{\cdot,n}(z)$) are in $l^2(\mathcal{N})$ ($l^2(\mathbb{N})$). Then

$$[(h^L(N)-z)g_{\cdot,n}(N,z)](m)=\delta_{m,n},$$

$$[(h^L-z)g_{\cdot,n}(z)](m)=\delta_{m,n}. \tag{C4}$$

Using summation by parts, we get the identity [the scalar products are in $l^2(\mathcal{N})$]

$$\langle[(h^L(N)-\overline{z})g_{\cdot,m}(N,\overline{z})],g_{\cdot,n}(z)\rangle=\langle g_{\cdot,m}(N,\overline{z}),(h^L-z)g_{\cdot,n}(z)\rangle-t_L g_{m,N}(N,z)g_{N+1,n}(z), \tag{C5}$$

where we employed various symmetry properties of the kernels, together with (C2). The use of (C4) finishes the proof. ■

Finally, we need an exponential decay estimate for the resolvents.

Proposition 6.4: There exist constants $0<c<C$, *such that uniformly in* N *and* z *with* $0<|\mathrm{Im}\, z|<1$ *we have*

$$|g_{m,n}(N,z)|\leqslant\frac{C}{|\mathrm{Im}\, z|}\exp(-c|\mathrm{Im}\, z||m-n|), \tag{C6}$$

for all $m,n\in\mathcal{N}$. *The same estimate holds, when* $N=\infty$.

Proof: This proof is a discrete (and simpler) version of the usual Combes–Thomas argument (see Ref. 14), which leads to boundedness of resolvents between spaces with exponential weights. Define the discrete dilation for $\alpha>0$ by

$$(W_\alpha\psi)(n)=e^{\alpha n}\psi(n). \tag{C7}$$

Then, by a direct computation, the dilated Hamiltonian $H(\alpha)=W_\alpha H W_{-\alpha}$ is given by

$$\begin{aligned}(H(\alpha)\psi)(n)&=e^{-\alpha}\psi(n+1)+e^{\alpha}\psi(n-1)\\&=(H\psi)(n)+(e^{-\alpha}-1)\psi(n+1)+(e^{\alpha}-1)\psi(n-1)=((H+V(\alpha))\psi)(n),\end{aligned}$$

where the perturbation $V(\alpha):=(e^{-\alpha}-1)T_1+(e^{\alpha}-1)T_{-1}$, $T_{\pm1}$ being the shift operators. Noting that $V(\alpha)$ is of order $\mathcal{O}(\alpha)$. If c is a sufficiently small positive constant, and $\alpha\leqslant c|\mathrm{Im}\, z|$, we can write

$$(H(\alpha)-z)^{-1}=(H-z)^{-1}(1+V(\alpha)(H-z)^{-1})^{-1}, \tag{C8}$$

where the second part is invertible, and its norm is less than a chosen constant (for example, 2). Hence,

$$\|(H(\alpha)-z)^{-1}\|\leqslant\|(H-z)^{-1}\|\cdot\|(1+V(\alpha)(H-z)^{-1})^{-1}\|\leqslant\frac{2}{|\mathrm{Im}\, z|}. \tag{C9}$$

Define the following vectors in $l^2(\mathcal{N})$ (the exponential is in the mth position)

$$\Psi_{mn}=(0,0,\ldots,e^{i\arg(g_{mn}(N,z))},\ldots,0,0),\quad m\geqslant n. \tag{C10}$$

Then

$$\langle\Psi_{mn},W_\alpha(H-z)^{-1}W_{-\alpha}\delta_n\rangle=e^{\alpha(m-n)}|g_{mn}(N,z)|=\langle\Psi_{mn},(H(\alpha)-z)^{-1}\delta_n\rangle\leqslant\frac{C}{|\mathrm{Im}\, z|},$$

from which the claimed estimate follows. ■

(Received 25 November 2004; accepted 6 December 2004; published online 24 March 2005)

The theory of operator integrals is used to determine the moment operators of the Cartesian margins of the phase space observables generated by the mixtures of the number states. The moments of the x-margin are polynomials of the position operator and those of the y-margin are polynomials of the momentum operator. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1851957]

I. INTRODUCTION

According to the theory developed in Ref. 7, each complex valued measurable function f and operator measure E determine a unique, possibly unbounded, linear operator $L(f,E)$, the operator integral of f with respect to E. In the case of real valued functions and phase space operator measures, a natural application of this theory is quantization.

In general, quantization means any procedure which associates a quantum mechanical observable to a given classical dynamical variable, the latter being represented by a real valued measurable function on the phase space $\mathbb{R}^{2n}$ of the classical system. Phase space quantization schemes are often realized by associating to a given classical variable f the operator $\int f(q,p)\Delta(q,p)\mathrm{d}q\,\mathrm{d}p$, where Δ is some operator valued phase space function and the integral is interpreted, e.g., in the weak or strong sense on a suitable domain (cf., e.g., Refs. 6, 10, and 13).

Consider the quantization determined by the operator density $(q,p)\mapsto\Delta(q,p):=(2\pi)^{-1}W(-q,p)TW(-q,p)^*$, where the $W(-q,p)$ are the Weyl operators acting in a separable Hilbert space and T is a state, i.e., a positive operator of trace one. Now the map $\mathcal{B}(\mathbb{R}^{2n})\ni B\mapsto E(B):=\int_B\Delta\in L(\mathcal{H})$ is a phase space observable, so that any classical variable f can be integrated with respect to it. On its natural domain, the operator integral $L(f,E)$ coincides with the (weak) quantization integral $\int f\Delta$. In this way, $L(f,E)$ can be interpreted as a quantization of the classical variable f. It can be noted that this approach differs from the Weyl quantization, which is obtained by replacing T in the above density $\Delta(q,p)$ by (a constant times) the parity operator in $L^2(\mathbb{R})$ (cf., e.g., Ref. 3, Sec. IV.1, Ref. 6, p. 199, and Ref. 10, pp. 140–141).

In this paper, we consider the phase space observables on $\mathbb{R}^2$ associated with certain pure states and their convex combinations, with the state vectors being taken from a fixed countable orthonormal basis of the separable Hilbert space. The moment operators of the Cartesian margins of these operator measures will be determined using the theory of operator integrals. The results sharpen and extend some of those obtained previously in Ref. 9.

II. OPERATOR INTEGRALS AND PHASE SPACE OBSERVABLES

A. The operator integral

In the following, we review the basic results of Ref. 7 on the theory of operator integrals and prove a proposition concerning integration with respect to sequences of positive operator measures.

Let $\mathcal{H}$ be a Hilbert space, with inner product $\langle\cdot|\cdot\rangle$, and $L(\mathcal{H})$ the set of bounded operators on $\mathcal{H}$. Let Ω be a nonempty set, $\mathcal{A}$ a σ-algebra of subsets of Ω, and $E:\mathcal{A}\to L(\mathcal{H})$ a positive operator measure (a positive operator valued set function σ-additive with respect to the strong, or, equivalently, the weak operator topology). For all φ, $\psi\in\mathcal{H}$, the map $\mathcal{A}\ni X\mapsto\langle\psi|E(X)\varphi\rangle\in\mathbb{C}$ is a complex measure, and it is denoted by $E_{\psi,\varphi}$. Let $f:\Omega\to\mathbb{C}$ be an $\mathcal{A}$-measurable function and let $D(f,E)$ be the set of those vectors $\varphi\in\mathcal{H}$ for which f is integrable with respect to the complex measure $E_{\psi,\varphi}$ for all $\psi\in\mathcal{H}$. The set $D(f,E)$ is a vector subspace of $\mathcal{H}$, and there is a unique linear operator $L(f,E)$ on the domain $D(f,E)$ such that

$$\langle\psi|L(f,E)\varphi\rangle=\int f\,\mathrm{d}E_{\psi,\varphi}$$

for all $\varphi\in D(f,E)$ and $\psi\in\mathcal{H}$ (cf. Ref. 7). We call $L(f,E)$ the *(operator) integral* of f with respect to E.

Let $\tilde{D}(f,E)$ be the set of those vectors $\varphi\in\mathcal{H}$ for which $|f|^2$ is integrable with respect to the positive measure $E_{\varphi,\varphi}$. We have the following results, proved in Ref. 7.

Theorem 1: (a) *$\tilde{D}(f,E)$ is a vector subspace of $D(f,E)$.* (b) *If $E(X)$ is a projection for all $X\in\mathcal{A}$, then $\tilde{D}(f,E)=D(f,E)$.* It is well known that, in case (b), the domain is dense.

Theorem 2: *If f is real valued, then $L(f,E)$ is a symmetric operator, that is, $\langle\psi|L(f,E)\varphi\rangle=\langle L(f,E)\psi|\varphi\rangle$ for all $\psi,\varphi\in D(f,E)$.* The following general lemma will be used in the proof of Proposition 1.

Lemma 1: Let $\mu_n:\mathcal{A}\to\mathbb{C}$ be a complex measure for each $n\in\mathbb{N}$ such that the series $\Sigma_{n\in\mathbb{N}}\mu_n$ converges absolutely in the total variation norm. Let μ and ν denote the measures $\Sigma_{n\in\mathbb{N}}\mu_n$ and $\Sigma_{n\in\mathbb{N}}|\mu_n|$, respectively. Here $|\cdot|$ stands for the total variation.

(a) *f is ν-integrable, if and only if $\Sigma_{n=1}^{\infty}\int|f|d|\mu_n|<\infty$.*
(b) *If f is ν-integrable, then f is integrable with respect to μ and all the measures μ_n, and*

$$\int f\,\mathrm{d}\mu=\sum_{n=1}^{\infty}\int f\,\mathrm{d}\mu_n.$$

Proof: (a) Assume that f is ν-integrable (i.e., $|f|$ is such). Since $|\mu_n(B)|\leqslant\nu(B)$ for all $B\in\mathcal{A}$ and $n\in\mathbb{N}$, $|f|$ is μ_n-integrable for each $n\in\mathbb{N}$. Now

$$\sum_{n=1}^{k}\int|f|d|\mu_n|=\int|f|d\left(\sum_{n=1}^{k}|\mu_n|\right)\leqslant\int|f|\mathrm{d}\nu$$

for each $k\in\mathbb{N}$, so that $\Sigma_{n=1}^{\infty}\int|f|d|\mu_n|<\infty$. The converse follows from Lemma A.5. of Ref. 7.

(b) Clearly μ and all the μ_n are ν-continuous. Let g and g_n be their Radon–Nikodým derivatives with respect to ν, respectively. Since

$$\left(\sum_{n=1}^{k}\mu_n-\mu\right)(B)=\int_B\left(\sum_{n=1}^{k}g_n-g\right)\mathrm{d}\nu$$

for all $B\in\mathcal{A}$ and $k\in\mathbb{N}$, we have

$$\lim_{k\to\infty}\int\left|\sum_{n=1}^{k}g_n-g\right|\mathrm{d}\nu=\lim_{k\to\infty}\left\|\sum_{n=1}^{k}\mu_n-\mu\right\|=0,$$

where $\|\cdot\|$ denotes the total variation norm. This means that the series $\Sigma_n g_n$ converges in $L^1(\nu)$ to the function g. Thus some subsequence $(\Sigma_{n=1}^{k_m}g_n)$ converges to g ν-almost everywhere. In addition, the monotone convergence theorem gives

$$\nu(B)=\sum_{n=1}^{\infty}\int_B|g_n|\mathrm{d}\nu=\int_B\left(\sum_n|g_n|\right)\mathrm{d}\nu$$

for all $B\in\mathcal{A}$, so that

$$\left|f(x)\sum_{n=1}^{k_m}g_n(x)\right|\leqslant|f(x)|\sum_n|g_n|=|f(x)| \tag{1}$$

for ν-almost all $x\in\Omega$.

Assume now that f is ν-integrable. Then by (a), f is μ_n-integrable for each $n\in\mathbb{N}$, and the series $\Sigma_{n=1}^{\infty}\int f\,\mathrm{d}\mu_n$ converges absolutely. Because of (1), the dominated convergence theorem implies that fg is ν-integrable, i.e., f is μ-integrable, and

$$\int f\,\mathrm{d}\mu=\int fg\,\mathrm{d}\nu=\lim_{m\to\infty}\sum_{n=1}^{k_m}\int fg_n\,\mathrm{d}\nu=\sum_{n=1}^{\infty}\int f\,\mathrm{d}\mu_n.$$

■

Proposition 1: Let $E^n:\mathcal{A}\to L(\mathcal{H})$ be a positive operator measure for each $n\in\mathbb{N}$ such that the range of E^n is bounded in norm by $M_n>0$, with $\Sigma_n M_n<\infty$. Then the norm limit $\Sigma_n E^n(B)$, $B\in\mathcal{A}$, defines a positive operator measure E, for which

$$L(f,E)|_{\tilde{D}(f,E)}\subset\sum_n L(f,E^n)|_{\tilde{D}(f,E^n)},$$

where the series is understood to converge in the weak sense to an operator, whose domain consists of those vectors $\varphi\in\cap_{n\in\mathbb{N}}\tilde{D}(f,E^n)$ for which the vector series $\Sigma_n L(f,E^n)\varphi$ converges weakly.

Proof: Let $\psi,\varphi\in\mathcal{H}$. Since $\|E^n_{\psi,\varphi}\|\leqslant 4\sup_{B\in\mathcal{A}}|E^n_{\psi,\varphi}(B)|\leqslant 4\|\psi\|\,\|\varphi\|M_n$, the series $\Sigma_n E^n_{\psi,\varphi}$ converges absolutely in the total variation norm. The above inequality also implies that for every $B\in\mathcal{A}$, the sesquilinear functional $(\varphi,\psi)\mapsto\Sigma_n E^n_{\psi,\varphi}(B)$ is bounded, so that there is a (clearly positive) operator $E(B)\in L(\mathcal{H})$, for which $\langle\psi|E(B)\varphi\rangle=\Sigma_n E^n_{\psi,\varphi}(B)$. Thus the map $B\mapsto E(B)$ is a positive operator measure, for which $E(B)=\Sigma_n E^n(B)$ in the operator norm and $E_{\psi,\varphi}=\Sigma_n E^n_{\psi,\varphi}$ in the total variation norm.

By applying Lemma 1 (b) to the finite positive measures $E^n_{\varphi,\varphi}$ and the function $|f|^2$, we see that if $\varphi\in\tilde{D}(f,E)$, then $\varphi\in\tilde{D}(f,E^n)$ for all $n\in\mathbb{N}$, and $\Sigma_n\int|f|^2\,\mathrm{d}E^n_{\varphi,\varphi}=\int|f|^2\,\mathrm{d}E_{\varphi,\varphi}<\infty$. Now let F^n denote the positive operator measure $M_n^{-1}E^n$. We have $\Sigma_n M_n\sqrt{\int|f|^2\,\mathrm{d}F^n_{\psi,\varphi}}\leqslant\Sigma_n M_n(1+\int|f|^2\,\mathrm{d}F^n_{\psi,\varphi})<\infty$. Using the inequality

$$\int|f|d|F^n_{\psi,\varphi}|\leqslant\|\psi\|\sqrt{\int|f|^2\,\mathrm{d}F^n_{\varphi,\varphi}}$$

from Ref. 7, we get $\Sigma_n\int|f|d|E^n_{\psi,\varphi}|=\Sigma_n M_n\int|f|d|F^n_{\psi,\varphi}|<\infty$, from which it follows by Lemma 1 (a) and (b) that

$$\langle\psi|L(f,E)\varphi\rangle = \sum_n \langle\psi|L(f,E^n)\varphi\rangle.$$

■

B. Phase space observables

We assume that the Hilbert space $\mathcal{H}$ is separable. For any $\varphi,\psi\in\mathcal{H}$, let $|\varphi\rangle\langle\psi|$ denote the operator $\xi\mapsto\langle\psi|\xi\rangle\varphi$. Let $\{|n\rangle|n\geqslant 0\}$ be a fixed orthonormal basis of $\mathcal{H}$. We call it the number basis. Let $A_+=\Sigma_{n\geqslant 0}\sqrt{n+1}|n+1\rangle\langle n|$ and $A_-=\Sigma_{n\geqslant 0}\sqrt{n+1}|n\rangle\langle n+1|$ be the raising and lowering operators associated with this basis. They are closed operators with the domain

$$\mathcal{D}(A_+)=\mathcal{D}(A_-)=\left\{\varphi\in\mathcal{H}\middle|\sum_k k|\langle\varphi|k\rangle|^2<\infty\right\},$$

and they satisfy the relation $A_+=A_-^*$. The symmetric operators $(1/\sqrt{2})(A_++A_-)$ and $(1/\sqrt{2})i(A_+-A_-)$ are essentially self-adjoint on $\mathcal{D}(A_+)$ and their closures Q and P are unitarily equivalent to the canonical position and momentum operators, respectively, acting in $L^2(\mathbb{R})$. The operators A_+ and A_- can be expressed in terms of Q and P according to

$$A_+=\frac{1}{\sqrt{2}}(Q-iP),\qquad A_-=\frac{1}{\sqrt{2}}(Q+iP) \tag{2}$$

(cf. Ref. 2, p. 283 and Ref. 12, p. 73). The number operator $N:=\Sigma_{n\geqslant 0}n|n\rangle\langle n|=A_+A_-$, with the domain

$$D(N)=\left\{\varphi\in\mathcal{H}\middle|\sum_k k^2|\langle\varphi|k\rangle|^2<\infty\right\},$$

is self-adjoint and satisfies

$$N+\tfrac{1}{2}I=\tfrac{1}{2}(Q^2+P^2). \tag{3}$$

[The last equality is a simple consequence of (2) and the fact that $D(N)=D(A_+A_-)=D(A_-A_+)$.]

The operators Q and P generate strongly continuous one parameter unitary groups $p\mapsto V(p):=e^{ipQ}$ and $q\mapsto \mathrm{U}(q):=e^{iqP}$ which satisfy the Weyl relation $\mathrm{U}(q)V(p)=e^{iqp}V(p)\mathrm{U}(q)$ for all $q,p\in\mathbb{R}$. The Weyl operators $W(q,p)$ are defined by $W(q,p)=e^{-(1/2)iqp}\mathrm{U}(q)V(p)$ for $q,p\in\mathbb{R}$. The map $(q,p)\mapsto W(-q,p)$ is a projective representation of $\mathbb{R}^2$.

Let T be a state operator. Then

$$I=\frac{1}{2\pi}\int_{\mathbb{R}^2} W(-q,p)TW(-q,p)^*\,\mathrm{d}q\,\mathrm{d}p,$$

and the map $E^T:\mathcal{B}(\mathbb{R}^2)\to L(\mathcal{H})$ defined by

$$E^T(B)=\frac{1}{2\pi}\int_B W(-q,p)TW(-q,p)^*\,\mathrm{d}q\,\mathrm{d}p$$

is a normalized positive operator measure, a phase space observable. Here $\mathcal{B}(\mathbb{R}^2)$ denotes the σ-algebra of Borel subsets of $\mathbb{R}^2$ and the integrals are understood in the weak sense. The construction of the operator measures E^T can be found for instance in Refs. 5 or 14. The operator measure E^T is covariant with respect to the projective representation $(q,p)\mapsto W(-q,p)$ in the sense that $E^T(B+(q_0,p_0))=W(-q_0,p_0)E^T(B)W(-q_0,p_0)^*$ for all $B\in\mathcal{B}(\mathbb{R}^2)$ and $(q,p)\in\mathbb{R}^2$.

The following characterization is obtained in Refs. 4 and 15: every normalized positive operator measure $E:\mathcal{B}(\mathbb{R}^2)\to L(\mathcal{H})$, which is covariant with respect to the representation $(q,p)\mapsto W(-q,p)$, is of the form E^T for some state T.

We let $E^{|s\rangle}$ denote the phase space observable associated with the number state $|s\rangle\langle s|$. Consider the mixed states

$$T=\sum_{n=0}^{\infty} w_n|n\rangle\langle n|, \tag{4}$$

where $w_n\geqslant 0$ and $\Sigma w_n=1$. These states are the ones for which the observable E^T is covariant also with respect to the phase shifts in the sense that

$$e^{i\theta N}E^T([0,\infty)\times X)e^{-i\theta N}=E^T([0,\infty)\times(X+\theta))$$

for all $\theta\in[0,2\pi)$ and $X\in\mathcal{B}([0,2\pi))$, where $\mathbb{R}^2=[0,\infty)\times[0,2\pi)$ and the sum $X+\theta$ is understood modulo 2π. (cf. Ref. 8).

Since $w_n\|E^{|n\rangle}(B)\|\leqslant w_n$ for all $n\in\mathbb{N}$ and $B\in\mathcal{B}(\mathbb{R}^2)$, Proposition 1 can be applied to the positive operator measures $w_nE^{|n\rangle}$. That the norm limit $\Sigma_n w_nE^{|n\rangle}(B)$ equals $E^T(B)$, follows from the identity

$$\langle\varphi|E^T(B)\varphi\rangle=\frac{1}{2\pi}\int_B\left(\sum_n w_n|\langle\varphi|W(-q,p)|n\rangle|^2\right)\mathrm{d}q\,\mathrm{d}p=\sum_n w_n\langle\varphi|E^{|n\rangle}(B)\varphi\rangle,$$

where $\varphi\in\mathcal{H}$ is arbitrary and the monotone convergence theorem has been used.

III. MOMENT OPERATORS OF THE CARTESIAN MARGINS OF THE PHASE SPACE OBSERVABLES ASSOCIATED WITH THE NUMBER STATES

Let x and y denote the functions $(q,p)\mapsto q$ and $(q,p)\mapsto p$, respectively. In Ref. 7, the moment operators $L((x\pm iy)^k,E^{|n\rangle})$ and $L((x^2+y^2)^k,E^{|n\rangle})$ were determined. In Ref. 9, these results were used to obtain the operator relations

$$\begin{aligned} L(x,E^{|n\rangle})&\subset Q,\\ L(y,E^{|n\rangle})&\subset P,\\ L(x^2,E^{|n\rangle})&\subset\left(n+\tfrac{1}{2}\right)I+Q^2,\\ L(y^2,E^{|n\rangle})&\subset\left(n+\tfrac{1}{2}\right)I+P^2. \end{aligned} \tag{5}$$

In this section, we determine directly the moment operators $L(x^k,E^T)$ and $L(y^k,E^T)$, where the state T is taken to be of the form $\Sigma_n w_n|n\rangle\langle n|$. The results show, among other things, that the inclusions (5) are in fact equalities.

A. The operators $L(x^k,E^{|n\rangle})$ and $L(y^k,E^{|n\rangle})$

Let $U:L^2(\mathbb{R})\to\mathcal{H}$ be the unitary operator which maps the Hermite function basis $\{h_n\}_{n\geqslant 0}$ of $L^2(\mathbb{R})$ onto the number basis of $\mathcal{H}$ according to the rule $Uh_n=|n\rangle$. The position and momentum operators in $L^2(\mathbb{R})$ correspond to the operators Q and P via the unitary transformation U, so that the operators $W_0(q,p)$, defined by $W_0(q,p)=U^{-1}W(q,p)U$, act in $L^2(\mathbb{R})$ according to the formula

$$(W_0(q,p)f)(t)=e^{i(1/2)qp}e^{ipt}f(t+q).$$

We need the following well-known result (see, e.g., Ref. 14, pp. 47 and 49).

Lemma 2: Let $F:L^2(\mathbb{R})\to L^2(\mathbb{R})$ denote the Fourier–Plancherel operator. Let $u\in L^2(\mathbb{R})$ be a

unit vector and $f \in L^2(\mathbb{R})$. *Then* $\overline{u}(\cdot - q)f \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ *for almost all* $q \in \mathbb{R}$ *and* $\overline{Fu}(\cdot - p)Ff \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ *for almost all* $p \in \mathbb{R}$. *In addition,*

$$\frac{1}{\sqrt{2\pi}}\langle W_0(-q,p)u|f\rangle = e^{i(1/2)qp}F(\overline{u}(\cdot - q)f)(p)$$

for almost all $q \in \mathbb{R}$ *and all* $p \in \mathbb{R}$, *and*

$$\frac{1}{\sqrt{2\pi}}\langle W_0(-q,p)u|f\rangle = e^{-i(1/2)qp}F^{-1}(\overline{Fu}(\cdot - p)Ff)(q)$$

for almost all $p \in \mathbb{R}$ *and all* $q \in \mathbb{R}$.

Proof: Since u, $f \in L^2(\mathbb{R})$, the function $\overline{u}(\cdot - q)f$ is integrable. Because $\|f\|^2 = \int |\overline{u}(t-q)f(t)|^2 \, dt \, dq$ by Fubini's theorem, $\overline{u}(\cdot - q)f \in L^2(\mathbb{R})$ for almost all q. Similarly, $\overline{Fu}(\cdot - p)Ff \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ for almost all $p \in \mathbb{R}$. The rest of the proof follows from straightforward calculations.

■

First we determine the square integrability domains corresponding to the functions x^k and y^k.

Lemma 3: $\tilde{D}(x^k, E^{|n\rangle}) = D(Q^k)$ *and* $\tilde{D}(y^k, E^{|n\rangle}) = D(P^k)$ *for all* $k \in \mathbb{N}$.

Proof: Let $k \in \mathbb{N}$ be fixed. Let $\varphi \in \mathcal{H}$ and $f = U^{-1}\varphi \in L^2(\mathbb{R})$. If $\varphi \in \tilde{D}(x^k, E^{|n\rangle})$, the function $(q,p) \mapsto q^{2k}|\langle f|W_0(-q,p)h_n\rangle|^2 = q^{2k}|\langle \varphi|W(-q,p)|n\rangle|^2$ is integrable over $\mathbb{R}^2$, and

$$\begin{aligned}
\int_{\mathbb{R}^2} q^{2k} \, dE^{|n\rangle}_{\varphi,\varphi}(q,p) &= \frac{1}{2\pi}\int q^{2k}\left(\int |\langle \varphi|W(-q,p)|n\rangle|^2 \, dp\right)dq \\
&= \int q^{2k}\left(\int |F(\overline{h_n}(\cdot - q)f)(p)|^2 \, dp\right)dq \\
&= \int q^{2k}\left(\int |h_n(t-q)|^2|f(t)|^2 \, dt\right)dq \\
&= \int \left(\int q^{2k}|h_n(t-q)|^2|f(t)|^2 \, dq\right)dt \\
&= \int\int (t-q)^{2k}|h_n(q)|^2|f(t)|^2 \, dq \, dt \\
&= \int\int (t-q)^{2k}|h_n(q)|^2|f(t)|^2 \, dt \, dq,
\end{aligned}$$

where Lemma 2, the unitarity of the Fourier–Plancherel operator, and Fubini's theorem have been used. The existence of the last integral implies that $t \mapsto (t-q)^{2k}|f(t)|^2$ is integrable over $\mathbb{R}$ for almost all $q \in \mathbb{R}$. Thus also $t \mapsto t^{2k}|f(t)|^2$ must be integrable. [In fact, take one $q \in \mathbb{R}$ for which $t \mapsto (t-q)^{2k}|f(t)|^2$ is integrable and use the fact that there exist positive constants A, B, M, such that $At^{2k} \leqslant (t-q)^{2k} \leqslant Bt^{2k}$ for $|t| \geqslant M$.] This means that f belongs to the domain of the kth power of the position operator in $L^2(\mathbb{R})$ and hence $\varphi = Uf \in D(Q^k)$. Conversely, if $\varphi = Uf \in D(Q^k)$, the functions $t \mapsto |t^l||f(t)|^2$ and $q \mapsto |q^l||h_n(q)|^2$ are integrable over $\mathbb{R}$ for all $l \leqslant 2k$ and hence $(t,q) \mapsto (t-q)^{2k}|h_n(q)|^2|f(t)|^2$ is integrable over $\mathbb{R}^2$. The preceding calculation now shows that $\varphi \in \tilde{D}(x^k, E^{|n\rangle})$. The equality $\tilde{D}(x^k, E^{|n\rangle}) = D(Q^k)$ is thus proved.

The results $\tilde{D}(y^k, E^{|n\rangle}) = D(P^k)$ is obtained in an analogous manner by using the fact that the position and momentum operators in $L^2(\mathbb{R})$ are unitarily equivalent via the Fourier–Plancherel operator F.

■

Now we can determine the operators $L(x^k, E^{|n\rangle})$ and $L(y^k, E^{|n\rangle})$.

Theorem 3: *$L(x^k, E^{|n\rangle}) = p_k^{|n\rangle}(Q)$ and $L(y^k, E^{|n\rangle}) = p_k^{|n\rangle}(P)$, where $p_k^{|n\rangle}: \mathbb{R} \to \mathbb{R}$ is the polynomial*

$$p_k^{|n\rangle}(t) = \langle n|(t-Q)^k|n\rangle = \sum_{l=0}^{k} \left(\binom{k}{l} (-1)^{k-l} \langle n|Q^{k-l}|n\rangle \right) t^l.$$

Proof: Since $p_k^{|n\rangle}$ is a polynomial of order k and Q is unitarily equivalent to the position operator in $L^2(\mathbb{R})$, the natural domain of the operator $p_k^{|n\rangle}(Q)$ [which is the set $D(Q^k) \cap D(Q^{k-1}) \cap \cdots D(Q)$] is equal to that of Q^k. Because Q and P are unitarily equivalent, also $D(p_k^{|n\rangle}(P)) = D(P^k)$. Thus by the preceding lemma, we have $D(p_k^{|n\rangle}(Q)) = D(Q^k) = \tilde{D}(x^k, E^{|n\rangle})$ and $D(p_k^{|n\rangle}(P)) = D(P^k) = \tilde{D}(y^k, E^{|n\rangle})$.

Let $\varphi,\ \psi \in \tilde{D}(x^k, E^{|n\rangle}) \subset D(x^k, E^{|n\rangle})$. Let $f = U^{-1}\varphi$, $g = U^{-1}\psi$. Since the function

$$(q,p) \mapsto q^k \langle \psi|W(-q,p)|n\rangle \overline{\langle \varphi|W(-q,p)|n\rangle}$$

is integrable over $\mathbb{R}^2$, we get

$$\begin{aligned}
\langle \psi|L(x^k, E^{|n\rangle})\varphi\rangle &= \int_{\mathbb{R}^2} q^k \, \mathrm{d}E^{|n\rangle}_{\psi,\varphi}(q,p) \\
&= \frac{1}{2\pi} \int q^k \left(\int \langle \psi|W(-q,p)|n\rangle \overline{\langle \varphi|W(-q,p)|n\rangle} \mathrm{d}p \right) \mathrm{d}q \\
&= \int q^k \left(\int \overline{F(\overline{h_n}(\cdot - q)g)(p)} F(\overline{h_n}(\cdot - q)f)(p) \mathrm{d}p \right) \mathrm{d}q \\
&= \int q^k \left(\int \overline{h_n(t-q)g(t)} h_n(t-q) f(t) \mathrm{d}t \right) \mathrm{d}q \\
&= \int \left(\int q^k |h_n(t-q)|^2 \mathrm{d}q \right) \overline{g(t)} f(t) \mathrm{d}t \\
&= \int \left(\int (t-q)^k |h_n(q)|^2 \mathrm{d}q \right) \overline{g(t)} f(t) \mathrm{d}t, \\
&= \int \langle n|(t-Q)^k|n\rangle \overline{g(t)} f(t) \mathrm{d}t \\
&= \langle \psi|p_k^{|n\rangle}(Q)\varphi\rangle.
\end{aligned}$$

The fifth equality follows from Fubini's theorem, since $(q,t) \mapsto q^k |h_n(t-q)|^2 \overline{g(t)} f(t)$ is integrable [because of the inequality

$$|q^k |h_n(t-q)|^2 \overline{g(t)} f(t)| \leqslant \tfrac{1}{2}(1 + q^{2k})(|f(t)|^2 + |g(t)|^2) |h_n(t-q)|^2$$

and the proof of Lemma 3]. The unitarity of F is also used. Since ψ was taken arbitrarily from the dense set $D(Q^k) = \tilde{D}(f, E^{|n\rangle})$, we have $p_k^{|n\rangle}(Q) \subset L(x^k, E^{|n\rangle})$.

The equality $p_k^{|n\rangle}(Q) = L(x^k, E^{|n\rangle})$ follows from the fact that being self-adjoint, the operator $p_k^{|n\rangle}(Q)$ cannot have a proper symmetric extension.

The statement $p_k^{|n\rangle}(P) = L(y^k, E^{|n\rangle})$ is obtained in the same manner, since $p_k^{|n\rangle}$ can also be written in the form $p_k^{|n\rangle}(t) = \langle n|(t-P)^k|n\rangle$ and $p_k^{|n\rangle}(P)$ is self-adjoint. ■

Remark: Since $\langle n|Q^m|n\rangle = 0$ for odd m, and $\langle n|Q^m|n\rangle > 0$ for even m, only the terms with even $k-l$ are present in the sum defining the polynomial $p_k^{|n\rangle}$, and the coefficients of the corresponding x^l are all strictly positive. In particular, $L(x^k, E^{|n\rangle}) \neq Q^k$ and $L(y^k, E^{|n\rangle}) \neq P^k$ for $k > 1$ and $n \geqslant 0$, reflecting the difference from the Weyl quantization (Ref. 6, p. 229), as well as the fact that the Cartesian margins of $E^{|n\rangle}$ are not the spectral measures of Q and P.

Using Theorem 3, all the operators $L(x^k, E^{|n\rangle})$ and $L(x^k, E^{|n\rangle})$ can be written in terms of Q and P, respectively. In particular, the first and second moment operators are the following:

$$\begin{aligned} L(x, E^{|n\rangle}) &= Q, \\ L(y, E^{|n\rangle}) &= P, \\ L(x^2, E^{|n\rangle}) &= \left(n + \tfrac{1}{2}\right) I + Q^2, \\ L(y^2, E^{|n\rangle}) &= \left(n + \tfrac{1}{2}\right) I + P^2. \end{aligned} \tag{6}$$

For the special case of $n=0$, these results were already obtained by formal computations in Ref. 1, pp. 28–29 (without addressing the question on the domains of the operators). A related result of Ref. 10, p. 140, however, seems to lack a constant term.

B. The operators $L(x^k, E^T)$ and $L(y^k, E^T)$ with $T=\Sigma_n w_n |n\rangle\langle n|$

In the next theorem, we need to consider the expressions $\langle n|Q^{2k}|n\rangle$. These integrals are well known and can be calculated, e.g., as instructed in Ref. 11, p. 60. We need here only the following fact.

Lemma 4: For $n \geqslant k$, the expression $\langle n|Q^{2k}|n\rangle$ can be written as a polynomial in n of order k.

Proof: Expressing Q in terms of A_+ and A_-, we get $\langle n|Q^{2k}|n\rangle = (1/2^k)\|(A_+ + A_-)^k|n\rangle\|^2$. Because $A_- A_+ = N + I$, we can write

$$(A_+ + A_-)^k |n\rangle = \sum_{m=0}^{k} a_m |n + k - 2m\rangle,$$

where $a_m|n+k-2m\rangle = A_+^{k-2m} q_m^+(N)|n\rangle$ for $0 \leqslant m \leqslant k/2$ and $a_m|n+k-2m\rangle = A_-^{2m-k} q_m^-(N)|n\rangle$ for $k/2 \leqslant m \leqslant k$, where $q_m^{\pm}$ are some polynomials with $2\deg(q_m^{\pm}) \pm (k-2m) \leqslant k$. Now $a_m^2 = (n+1)(n+2)\cdots(n+k-2m) q_m^+(n)^2$ for $0 \leqslant m \leqslant k/2$ and $a_m^2 = n(n-1)\cdots(n-(2m-k)+1) q_m^-(n)^2$ for $k/2 \leqslant m \leqslant k$, so that each a_m^2 is a polynomial in n of order at most k, with the coefficient of the highest power positive. Since $a_0^2 = (n+1)(n+2)\cdots(n+k)$, we see that $\langle n|Q^{2k}|n\rangle = (1/2^k)\Sigma_{m=0}^k a_m^2$ is a polynomial in n of order exactly k.

■

Theorem 4: *Let $T = \Sigma_n w_n |n\rangle\langle n|$ be a mixture of the number states and $k \in \mathbb{N}$. Let $p_k^{|n\rangle}$ denote the polynomials defined in Theorem 3, and define*

$$s_{kl} = \binom{k}{l} \sum_{n=0}^{\infty} w_n \langle n|Q^{k-l}|n\rangle (\leqslant \infty)$$

for $0 \leqslant l \leqslant k$.

(a) $\tilde{D}(x^k, E^T) \neq \{0\}$ *if and only if*

$$\sum_n n^k w_n < \infty, \tag{7}$$

in which case $s_{kl} < \infty$ for all $0 \leqslant l \leqslant k$, $D(x^k, E^T) = \tilde{D}(x^k, E^T) = D(Q^k)$, and

$$L(x^k, E^T) = \sum_{l=0}^{k} s_{kl} Q^l.$$

In particular, the operator $L(x^k, E^T)$ is then self-adjoint.

(b) *The statement (a) holds true when "x" and "Q" are replaced by "y" and "P."*

Proof: Let $k \in \mathbb{N}$ be fixed. According to Proposition 1, Lemma 3 and Theorem 3 we have

$$L(x^k,E^T)|_{\tilde{D}(x^k,E^T)} \subset \sum_n w_n L(x^k,E^{|n\rangle}) = \sum_n w_n p_k^{|n\rangle}(Q) \tag{8}$$

(where the series of operators are understood in the same sense as in Proposition 1). Let $\varphi \in D(Q^k) \supset D(\Sigma_n w_n p_k^{|n\rangle}(Q))$ and $\varphi \neq 0$. Let $A_{\varphi,\varphi}^{|n\rangle}$ be the density function of the positive measure $E_{\varphi,\varphi}^{|n\rangle}$. By the definition of the square integrability domain, $\varphi \in \tilde{D}(x^k,E^T)$ if and only if the function $x^{2k}\Sigma_n w_n A_{\varphi,\varphi}^{|n\rangle}$ is integrable. By the monotone convergence theorem, the latter statement is equivalent to

$$\sum_n w_n \int x^{2k}\, \mathrm{d}E_{\varphi,\varphi}^{|n\rangle} < \infty. \tag{9}$$

According to the proof of Lemma 3,

$$\begin{aligned}\int x^{2k}\, \mathrm{d}E_{\varphi,\varphi}^{|n\rangle} &= \int\int (t-q)^{2k}|h_n(q)|^2|(U^{-1}\varphi)(t)|^2\, \mathrm{d}t\, \mathrm{d}q \\ &= \sum_{l=0}^{2k}\binom{2k}{l}(-1)^{2k-1}\left(\int t^l|(U^{-1}\varphi)(t)|^2\, \mathrm{d}t\right)\langle n|Q^{2k-l}|n\rangle.\end{aligned}$$

Since $\langle n|Q^m|n\rangle = 0$ for odd $m \in \mathbb{N}$, only the terms with even l are present in the above sum. Because $U^{-1}\varphi \neq 0$, these terms are all strictly positive. Since $0 < \langle n|Q^{2l}|n\rangle \leqslant \int(1+q^{2k})|h_n(q)|^2\, \mathrm{d}q = 1 + \langle n|Q^{2k}|n\rangle$ for all $l \leqslant k$ and $\Sigma_n w_n = 1$, the convergence of the series $\Sigma_n w_n\langle n|Q^{2k}|n\rangle$ implies the convergence of each series $\Sigma_n w_n\langle n|Q^{2l}|n\rangle$ and s_{kl}, $l \leqslant k$. Thus, it follows that a nonzero vector in $D(Q^k)$ belongs to $\tilde{D}(x^k,E^T)$ if and only if the series

$$\sum_n w_n\langle n|Q^{2k}|n\rangle \tag{10}$$

converges. By the preceding lemma, this is equivalent to (7). Since $\tilde{D}(x^k,E^T) \subset D(Q^k)$ by (8), we have shown that $\tilde{D}(x^k,E^T) \neq \{0\}$ if and only if (7) holds, and in that case, $\tilde{D}(x^k,E^T) = D(Q^k)$ and $s_{kl} < \infty$ for $l \leqslant k$.

From the definition of the polynomials $p_k^{|n\rangle}$ we see that if (10) converges, then [using (8)] we get

$$\langle\psi|L(x^k,E^T)\varphi\rangle = \sum_n w_n\langle\psi|p_k^{|n\rangle}(Q)\varphi\rangle = \sum_{l=0}^{k} s_{kl}\langle\psi|Q^l\varphi\rangle$$

for each $\varphi \in D(Q^k)$ and $\psi \in \mathcal{H}$. Thus, $\Sigma_{l=0}^k s_{kl}Q^l \subset L(x^k,E^T)$ [now $D(\Sigma_{l=0}^k s_{kl}Q^l) = D(Q^k)$, because $s_{kk} = 1$]. Since the operator $\Sigma_{l=0}^k s_{kl}Q^l$ is self-adjoint and $L(x^k,E^T)$ is symmetric, the statement (a) has been proved.

The result (b) is obtained in the same manner, since

$$L(y^k,E^T)|_{\tilde{D}(y^k,E^T)} \subset \sum_n w_n L(y^k,E^{|n\rangle}) = \sum_n w_n p_k^{|n\rangle}(P),$$

$\langle n|Q^m|n\rangle = \langle n|P^m|n\rangle$ for all m, $n \geqslant 0$ and

$$\int y^{2k}\,\mathrm{d}E^{|n\rangle}_{\varphi,\varphi} = \int\int (t-p)^{2k}|Fh_n(p)|^2|(FU^{-1}\varphi)(t)|^2\,\mathrm{d}t\,\mathrm{d}p$$
$$= \sum_{l=0}^{2k}\binom{2k}{l}(-1)^{2k-l}\left(\int t^l|(FU^{-1}\varphi)(t)|^2\,\mathrm{d}t\right)\langle n|P^{2k-l}|n\rangle$$

for all $\varphi \in D(P^k)$. ∎

Remark: For each $k \in \mathbb{N}$, there are states T of the form (4) such that (7) does not converge [so that $\widetilde{D}(x^k,E^T)=\{0\}$], but all the series s_{kl} do. In that case, $\Sigma_{l=0}^k s_{kl}Q^l$ is still a well-defined self-adjoint operator with the domain $D(Q^k)$. An example of such a state for $k \in \mathbb{N}$ is given by $t_n = 1/(Sn^{k+1})$, where $S=\Sigma_n n^{-(k+1)}$. We do not know whether there are any nonzero vectors in the domain $D(x^k,E^T)$ then.

IV. OPERATOR INTEGRALS OF SOME POLYNOMIALS

In this last section, we use Theorem 3 to determine the operator integrals for certain types of polynomials. To that end, let h, h_1, h_2 be real polynomials defined by $h(t)=\Sigma_{l=0}^k a_l t^l$, $a_k \neq 0$, and $h_i(t)=\Sigma_{l=0}^{k_i} a_{i,l}t^l$, $a_{i,k_i}\neq 0$, $i=1,2$.

The operators $L(h\circ x,E^{|n\rangle})$ and $L(h\circ y,E^{|n\rangle})$: Let ψ, $\varphi \in \mathcal{H}$. There exist positive constants M, A, B such that $A|t^k| \leqslant |h(t)| \leqslant B|t^k|$ for $|t| \geqslant M$, which implies that the function $h\circ x$ [i.e., $(q,p)\mapsto h(q)$] is $E^{|n\rangle}_{\psi,\varphi}$-integrable if and only if x^k is such, and in that case, $\int h\circ x\,\mathrm{d}E^{|n\rangle}_{\psi,\varphi} = \Sigma_{l=0}^k a_l \int x^l\,\mathrm{d}E^{|n\rangle}_{\psi,\varphi}$. Since $D(x^k,E^{|n\rangle})=D(Q^k)\subset D(Q^l)=D(x^l,E^{|n\rangle})$ for $l\leqslant k$, it follows that $D(h\circ x,E^{|n\rangle})=D(Q^k)$, and

$$L(h\circ x,E^{|n\rangle}) = \sum_{l=0}^{k} a_l p_l^{|n\rangle}(Q). \tag{11}$$

Naturally, a similar result holds for the function $h\circ y$.

The operators $L(h_1\circ x+ih_2\circ y,E^{|n\rangle})$: Let ψ, $\varphi \in \mathcal{H}$. The function $h_1\circ x+ih_2\circ y$ is $E^{|n\rangle}_{\psi,\varphi}$-integrable if and only if both $h_1\circ x$ and $h_2\circ y$ are such, and in that case $\int(h_1\circ x+ih_2\circ y)\mathrm{d}E^{|n\rangle}_{\psi,\varphi} = \int h_1\circ x\,\mathrm{d}E^{|n\rangle}_{\psi,\varphi} + i\int h_2\circ y\,\mathrm{d}E^{|n\rangle}_{\psi,\varphi}$. Thus, we have $D(h_1\circ x+ih_2\circ y,E^{|n\rangle})=D(Q^{k_1})\cap D(P^{k_2})$, and

$$L(h_1\circ x + ih_2\circ y,E^{|n\rangle}) = \sum_{l=0}^{k_1} a_{1,l}p_l^{|n\rangle}(Q) + i\sum_{l=0}^{k_2} a_{2,l}p_l^{|n\rangle}(P). \tag{12}$$

The operators $L(h_1\circ x+h_2\circ y,E^{|n\rangle})$ with k_i even and $a_{i,k_i}>0$: Assume that k_i is even, and $a_{i,k_i}>0$, $i=1,2$. Then we can choose positive constants M, A_i, B_i such that $h_i(t)\geqslant 0$ and $A_i t^{k_i} \leqslant h_i(t) \leqslant B_i t^{k_i}$ for $|t|\geqslant M$ and $i=1,2$. This implies that the function $h_1\circ x+h_2\circ y$ is $E^{|n\rangle}_{\psi,\varphi}$-integrable for ψ, $\varphi \in \mathcal{H}$ if and only if both x^{k_1} and y^{k_2} are such. We get $D(h_1\circ x+h_2\circ y,E^{|n\rangle}) = D(Q^{k_1})\cap D(P^{k_2})$, and

$$L(h_1\circ x + h_2\circ y,E^{|n\rangle}) = \sum_{l=0}^{k_1} a_{1,l}p_l^{|n\rangle}(Q) + \sum_{l=0}^{k_2} a_{2,l}p_l^{|n\rangle}(P). \tag{13}$$

A note on the operators $L(x\pm iy,E^{|n\rangle})$ and $L(x^2+y^2,E^{|n\rangle})$: The above observations show that, in particular, $L((1/\sqrt{2})(x\pm iy),E^{|n\rangle})=(1/\sqrt{2})(Q\pm iP)$, and $L\left(\frac{1}{2}(x^2+y^2),E^{|n\rangle}\right)=\frac{1}{2}(Q^2+P^2)+\left(n+\frac{1}{2}\right)I$. These operator integrals have already been determined in Ref. 7 (using a different method) to be the following: $L((1/\sqrt{2})(x\pm iy),E^{|n\rangle})=A_{\mp}$ and $L\left(\frac{1}{2}(x^2+y^2),E^{|n\rangle}\right)=N+(n+1)I$. The fundamental operator equalities (2) and (3) now show that the results are indeed consistent.

ACKNOWLEDGMENTS

The authors thank Dr. Daniel Dubin and Dr. Mark Hennings for pointing out some details concerning the validity of the operator equality (3).

Initial states and decoherence of histories

Artur Scherer[a] and Andrei N. Soklakov
Department of Mathematics, Royal Holloway, University of London, Egham, Surrey, TW20 0EX, United Kingdom

(Received 14 September 2004; accepted 8 February 2005; published online 24 March 2005)

We study decoherence properties of arbitrarily long histories constructed from a fixed projective partition of a finite dimensional Hilbert space. We show that decoherence of such histories for all initial states that are naturally induced by the projective partition implies decoherence for arbitrary initial states. In addition we generalize the simple necessary decoherence condition [Scherer *et al.*, Phys. Lett. A **326**, 307 (2004)] for such histories to the case of arbitrary coarse graining. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1888030]

I. INTRODUCTION

In the Copenhagen interpretation of quantum mechanics all properties of a quantum system are defined with respect to measurements performed by an external observer using classical measuring devices. This interpretation, however, cannot be used in the case of closed quantum systems, such as the Universe as a whole. In this case any observer must be a part of the system itself. A self-contained theory of closed quantum systems that does not rely on either the external observer nor on the existence of classical devices is still under development. The decoherent histories approach[1–5] is probably the most promising candidate for such a theory. This approach predicts probabilities for quantum histories, i.e., ordered sequences of quantum-mechanical "propositions." Mathematically, these propositions are represented by projectors, the same projectors that would define a quantum measurement in the Copenhagen approach. In particular, an exhaustive set of mutually exclusive propositions corresponds to a complete set of mutually orthogonal projectors.

Due to quantum interference, one cannot always assign probabilities to a set of histories in a consistent way. For this to be possible, the set of histories must be decoherent. Whether the corresponding decoherence condition is fulfilled or not depends on the initial state, the unitary dynamics of the system and the propositions from which the histories are constructed. The dependence on the initial state is connected to one of the central questions in quantum cosmology, the question of how the classical features of our world evolve from the initial quantum state of the Universe. This question provides the main motivation for the research presented in this paper.

Here we consider histories that are constructed from a *fixed* exhaustive set of mutually exclusive propositions, $\{P_\mu\}$, and investigate the question of how the choice of the initial state affects decoherence of such histories. We show that decoherence of arbitrarily long histories for all initial states that are induced by the projectors $\{P_\mu\}$ via normalization implies the decoherence for arbitrary initial states. It is relevant to note that, unlike the set of all possible states, the set $\{P_\mu\}$ is discrete and may contain as few as just two elements (for "yes–no" propositions). As an additional result, we obtain a generalization of the simple necessary decoherence condition that was derived for fine-grained histories in Ref. 6. The condition is applicable to arbitrary coarse grainings.

The paper is organized as follows. After introducing our framework we present the mathematical content of our results in the form of a theorem. We prove the theorem, infer the results, and conclude with a short summary.

II. OUR FRAMEWORK

Definition 1: A set of projectors $\{P_\mu\}$ on a Hilbert space $\mathcal{H}$ is called a projective *partition* of $\mathcal{H}$, if $\forall \mu,\mu' : P_\mu P_{\mu'} = \delta_{\mu\mu'} P_\mu$ and $\Sigma_\mu P_\mu = \mathbb{1}_\mathcal{H}$. Here, $\mathbb{1}_\mathcal{H}$ denotes the unit operator. We call a projective partition *fine-grained* if all projectors are one dimensional, i.e., $\forall \mu$ $\dim(\mathrm{supp}(P_\mu))=1$,[7] and *coarse-grained* otherwise.

Definition 2: Given a projective partition $\{P_\mu\}$ of a Hilbert space $\mathcal{H}$, we denote by $\mathcal{K}[\{P_\mu\};k] := \{h_\alpha : h_\alpha = (P_{\alpha_1}, P_{\alpha_2}, \ldots, P_{\alpha_k}) \in \{P_\mu\}^k\}$ the corresponding exhaustive set of mutually exclusive histories of length k. Histories are thus defined to be ordered sequences of projection operators, corresponding to quantum-mechanical propositions. Note that we restrict ourselves to histories constructed from a *fixed* projective partition, the projectors P_{α_j} within the sequences are all chosen from the same partition for all "times" $j=1,\ldots,k$.

Definition 3: Given a Hilbert space $\mathcal{H}$ and a projective partition $\{P_\mu\}$ of $\mathcal{H}$, we denote by $\mathcal{S}$ the set of all density operators on $\mathcal{H}$ and by $\mathcal{S}_{\{P_\mu\}}$ the discrete set of "*partition states*" induced by the partition $\{P_\mu\}$ via normalization,

$$\mathcal{S}_{\{P_\mu\}} := \left\{ \frac{P_\nu}{\mathrm{Tr}[P_\nu]} : P_\nu \in \{P_\mu\} \right\}. \tag{1}$$

An initial state $\rho \in \mathcal{S}$ and a unitary dynamics generated by a unitary map $U:\mathcal{H}\to\mathcal{H}$ induce a probabilistic structure on the event algebra associated with $\mathcal{K}[\{P_\mu\};k]$, if certain consistency conditions are fulfilled. These are given in terms of properties of the *decoherence functional* $\mathcal{D}_{U,\rho}[\cdot,\cdot]$ on $\mathcal{K}[\{P_\mu\};k]\times\mathcal{K}[\{P_\mu\};k]$, defined by

$$\mathcal{D}_{U,\rho}[h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}}] := \mathrm{Tr}[C_{\boldsymbol{\alpha}} \rho C_{\boldsymbol{\beta}}^\dagger], \tag{2}$$

where

$$C_{\boldsymbol{\alpha}} := (U^{\dagger k} P_{\alpha_k} U^k)(U^{\dagger k-1} P_{\alpha_{k-1}} U^{k-1}) \cdots (U^\dagger P_{\alpha_1} U) = U^{\dagger k} P_{\alpha_k} U P_{\alpha_{k-1}} U \cdots P_{\alpha_2} U P_{\alpha_1} U. \tag{3}$$

The set $\mathcal{K}[\{P_\mu\};k]$ is said to be *decoherent* or *consistent* with respect to a given unitary map $U:\mathcal{H}\to\mathcal{H}$ and a given initial state $\rho\in\mathcal{S}$, if

$$\mathcal{D}_{U,\rho}[h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}}] \propto \delta_{\boldsymbol{\alpha}\boldsymbol{\beta}} \equiv \prod_{j=1}^{k} \delta_{\alpha_j \beta_j} \tag{4}$$

for all $h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}} \in \mathcal{K}[\{P_\mu\};k]$. These are the consistency conditions. If they are fulfilled, probabilities may be assigned to the histories and are given by the diagonal elements of the decoherence functional, $p[h_{\boldsymbol{\alpha}}] = \mathcal{D}_{U,\rho}[h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\alpha}}]$.

What we have just described is a slightly simplified version of the general decoherent histories formalism. In general, both the partition and the unitary may depend on the parameter $j=1,\ldots,k$. Our setting based on a fixed partition and a fixed unitary is motivated by the analogy with the classical symbolic dynamics.[6,8] Various generalizations of this setting will be addressed in forthcoming publications. In the literature several consistency conditions of different strength can be found.[9] The conditions given above are known as *medium decoherence*.[5] It has recently been shown that consideration of the weaker decoherence conditions is problematic.[10]

III. RESULTS

Theorem: *Let a projective partition $\{P_\mu\}$ of a finite dimensional Hilbert space $\mathcal{H}$ and a unitary map U on $\mathcal{H}$ be given. Then the following three statements are equivalent:*

(a) $\forall \rho \in \mathcal{S}_{\{P_\mu\}} \forall k \in \mathbb{N}\ \forall h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}} \in \mathcal{K}[\{P_\mu\};k] : \mathcal{D}_{U,\rho}[h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}}] \propto \delta_{\boldsymbol{\alpha}\boldsymbol{\beta}}$,
(b) $\forall P_{\mu'}, P_{\mu''} \in \{P_\mu\} \forall n \in \mathbb{N} : [U^n P_{\mu'} (U^\dagger)^n, P_{\mu''}] = 0$,
(c) $\forall \rho \in \mathcal{S}\ \forall k \in \mathbb{N}\ \forall h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}} \in \mathcal{K}[\{P_\mu\};k] : \mathcal{D}_{U,\rho}[h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}}] \propto \delta_{\boldsymbol{\alpha}\boldsymbol{\beta}}$.

Proof: We will prove the theorem by showing that (a) implies (b), (b) implies (c), and (c) implies (a). The last implication, (c)$\Rightarrow$(a), is trivial, and the second implication, (b)$\Rightarrow$(c), can be easily shown using the notation of Eq. (3). It remains to prove the implication (a)$\Rightarrow$(b).

The proof is constructed as follows. We first show that the proposition

$$\forall \rho \in \mathcal{S}_{\{P_\mu\}} \forall n \in \mathbb{N} \ \ \forall \mu_0, \mu', \mu'' \quad \text{with } \mu' \neq \mu'' : \mathrm{Tr}[P_{\mu''}(U^n P_{\mu_0} U^{\dagger n}) P_{\mu'}(U^n \rho U^{\dagger n}) P_{\mu''}] = 0 \tag{5}$$

is a necessary consequence of the decoherence condition (a) and then conclude that this proposition implies the commutativity condition (b) of the theorem.

The first part of the proof will be accomplished by contradiction, i.e., we will assume that (5) is not satisfied, and then show that this assumption contradicts the decoherence condition (a) of the theorem.

Assume condition (5) is not satisfied. This means there exist a partition state $\tilde{\rho} \in \mathcal{S}_{\{P_\mu\}}$, an integer $\tilde{n} \in \mathbb{N}$, and partition-element labels μ_0, μ', μ'', with $\mu' \neq \mu''$, such that

$$\mathrm{Tr}[P_{\mu''}(U^{\tilde{n}} P_{\mu_0} U^{\dagger \tilde{n}}) P_{\mu'}(U^{\tilde{n}} \tilde{\rho} U^{\dagger \tilde{n}}) P_{\mu''}] = c \neq 0. \tag{6}$$

This, as we will see, is in contradiction to decoherence condition (a). Written out, the decoherence condition (a) is

$$\mathrm{Tr}[P_{\alpha_k} U P_{\alpha_{k-1}} U \cdots P_{\alpha_1} U \rho_0 U^\dagger P_{\beta_1} \cdots P_{\beta_{k-1}} U^\dagger P_{\beta_k}] \propto \prod_{j=1}^{k} \delta_{\alpha_j \beta_j} \tag{7}$$

for all $k \in \mathbb{N}$, all initial states $\rho_0 \in \mathcal{S}_{\{P_\mu\}}$, and arbitrary histories $h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}}$. Since the length k of the histories is arbitrary, we may choose $k = q\tilde{n}$ with arbitrary $q \in \mathbb{N}$. By summing over $\alpha_1, \ldots, \alpha_{\tilde{n}-1}, \alpha_{\tilde{n}+1}, \ldots, \alpha_{q\tilde{n}-1}$ and $\beta_1, \ldots, \beta_{\tilde{n}-1}, \beta_{\tilde{n}+1}, \ldots, \beta_{q\tilde{n}-1}$, and using $\Sigma_\mu P_\mu = \mathbb{1}_{\mathcal{H}}$, we obtain

$$\mathrm{Tr}[P_{\alpha_{q\tilde{n}}} (U^{q-1})^{\tilde{n}} P_{\alpha_{\tilde{n}}} U^{\tilde{n}} \rho_0 U^{\dagger \tilde{n}} P_{\beta_{\tilde{n}}} (U^{\dagger q-1})^{\tilde{n}} P_{\beta_{q\tilde{n}}}] \propto \delta_{\alpha_{q\tilde{n}} \beta_{q\tilde{n}}} \delta_{\alpha_{\tilde{n}} \beta_{\tilde{n}}} \tag{8}$$

for all $q \in \mathbb{N}$, and $\rho_0 \in \mathcal{S}_{\{P_\mu\}}$, and arbitrary $\alpha_{\tilde{n}}, \beta_{\tilde{n}}, \alpha_{q\tilde{n}}, \beta_{q\tilde{n}}$. In order to proceed we will need the following lemma.[6]

Lemma: Let $\mathcal{H}$ be a finite dimensional Hilbert space and $U : \mathcal{H} \to \mathcal{H}$ any unitary map on $\mathcal{H}$. Then $\forall \epsilon > 0 \ \exists q \in \mathbb{N}$ such that $\|U^q - \mathbb{1}_{\mathcal{H}}\| < \epsilon$, $\|\cdot\|$ meaning the conventional operator norm, which is $\|A\| := \sup\{\|Av\| : v \in \mathcal{H}, \|v\| = 1\}$ for an operator A on $\mathcal{H}$.

According to this lemma, for any given arbitrarily small $\epsilon > 0$ we can always find a $q \in \mathbb{N}$ such that $U^q = \mathbb{1}_{\mathcal{H}} + \hat{\mathcal{O}}(\epsilon)$, where $\hat{\mathcal{O}}(\epsilon)$ is some operator whose norm is of order ϵ, $\|\hat{\mathcal{O}}(\epsilon)\| < \epsilon$. Using the submultiplicativity property of operator norms, we have

$$\|U^{-1}\hat{\mathcal{O}}(\epsilon)\| \leqslant \|U^{-1}\| \times \|\hat{\mathcal{O}}(\epsilon)\| = \|\hat{\mathcal{O}}(\epsilon)\| \tag{9}$$

and hence $U^{q-1} = U^{-1} + \hat{\mathcal{O}}'(\epsilon)$, where $\|\hat{\mathcal{O}}'(\epsilon)\| < \epsilon$.

Now we are in a position to derive a contradiction. We let our histories start with the initial state $\rho_0 = \tilde{\rho}$. Furthermore we choose $\alpha_{\tilde{n}} = \mu'$, $\beta_{\tilde{n}} = \mu''$, and $\alpha_{q\tilde{n}} = \beta_{q\tilde{n}} = \mu_0$. Since $\mu' \neq \mu''$, condition (8) becomes

$$\forall q \in \mathbb{N} : \mathrm{Tr}[P_{\mu_0} (U^{q-1})^{\tilde{n}} P_{\mu'} U^{\tilde{n}} \tilde{\rho} U^{\dagger \tilde{n}} P_{\mu''} (U^{\dagger q-1})^{\tilde{n}} P_{\mu_0}] = 0. \tag{10}$$

Choosing q such that $\|U^q - \mathbb{1}_{\mathcal{H}}\| < \epsilon$ for a given *arbitrarily small* $\epsilon > 0$, we get a situation where the expressions $(U^{q-1})^{\tilde{n}}$ and $(U^{\dagger q-1})^{\tilde{n}}$ in Eq. (10) can be replaced by $(U^\dagger + \hat{\mathcal{O}}'(\epsilon))^{\tilde{n}}$ and $(U + \hat{\mathcal{O}}'^\dagger(\epsilon))^{\tilde{n}}$, respectively. In the following it will be convenient to use the definition

$$A_{r_1,r_2,\ldots,r_{\tilde{n}}} := \prod_{i=1}^{\tilde{n}} (U^{\dagger r_i}(\hat{\mathcal{O}}'(\epsilon))^{1-r_i}), \tag{11}$$

where the operators inside the product are written out from left to right in the order of increasing index i. Using this definition we have

$$(U^\dagger + \hat{\mathcal{O}}'(\epsilon))^{\tilde{n}} = \sum_{r_1,\ldots,r_{\tilde{n}}\in\{0,1\}} A_{r_1,\ldots,r_{\tilde{n}}}. \tag{12}$$

This yields for the left-hand side of Eq. (10),

$$\begin{aligned}
&\mathrm{Tr}[P_{\mu_0}(U^{q-1})^{\tilde{n}}P_{\mu'}U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}}P_{\mu''}(U^{\dagger q-1})^{\tilde{n}}P_{\mu_0}] \\
&\quad = \mathrm{Tr}\left[P_{\mu_0}\left(\sum_{r_1,\ldots,r_{\tilde{n}}\in\{0,1\}} A_{r_1,\ldots,r_{\tilde{n}}}\right)P_{\mu'}U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}}P_{\mu''}\left(\sum_{s_1,\ldots,s_{\tilde{n}}\in\{0,1\}} A^\dagger_{s_1,\ldots,s_{\tilde{n}}}\right)P_{\mu_0}\right] \\
&\quad = \sum_{r_1,\ldots,r_{\tilde{n}}\in\{0,1\}}\ \sum_{s_1,\ldots,s_{\tilde{n}}\in\{0,1\}} \mathrm{Tr}[P_{\mu_0}A_{r_1,\ldots,r_{\tilde{n}}}P_{\mu'}U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}}P_{\mu''}A^\dagger_{s_1,\ldots,s_{\tilde{n}}}P_{\mu_0}].
\end{aligned} \tag{13}$$

According to (10) the left-hand side of this equation must be zero. Hence we have

$$\begin{aligned}
&\mathrm{Tr}[P_{\mu_0}(U^\dagger)^{\tilde{n}}P_{\mu'}U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}}P_{\mu''}U^{\tilde{n}}P_{\mu_0}] \\
&\quad = -\sum_{\substack{r_1,\ldots,r_{\tilde{n}}\in\{0,1\}\\ r_1+\cdots+r_{\tilde{n}}<\tilde{n}}}\ \sum_{\substack{s_1,\ldots,s_{\tilde{n}}\in\{0,1\}\\ s_1+\cdots+s_{\tilde{n}}<\tilde{n}}} \mathrm{Tr}[P_{\mu_0}A_{r_1,\ldots,r_{\tilde{n}}}P_{\mu'}U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}}P_{\mu''}A^\dagger_{s_1,\ldots,s_{\tilde{n}}}P_{\mu_0}].
\end{aligned} \tag{14}$$

Using the cyclic permutation-invariance property of the trace and the triangle inequality, we obtain

$$\begin{aligned}
&|\mathrm{Tr}[P_{\mu''}(U^{\tilde{n}}P_{\mu_0}U^{\dagger\tilde{n}})P_{\mu'}(U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}})P_{\mu''}]| \\
&\quad \leqslant \sum_{\substack{r_1,\ldots,r_{\tilde{n}}\in\{0,1\}\\ r_1+\cdots+r_{\tilde{n}}<\tilde{n}}}\ \sum_{\substack{s_1,\ldots,s_{\tilde{n}}\in\{0,1\}\\ s_1+\cdots+s_{\tilde{n}}<\tilde{n}}} |\mathrm{Tr}[A^\dagger_{s_1,\ldots,s_{\tilde{n}}}P_{\mu_0}A_{r_1,\ldots,r_{\tilde{n}}}P_{\mu'}U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}}P_{\mu''}]|.
\end{aligned} \tag{15}$$

Utilizing the inequality $|\mathrm{Tr}[BT]| \leqslant \|B\|\mathrm{Tr}\sqrt{T^\dagger T}$ for bounded operators $B:\mathcal{H}\to\mathcal{H}$ and operators $T:\mathcal{H}\to\mathcal{H}$ with finite trace norm $\|T\|_1 := \mathrm{Tr}\sqrt{T^\dagger T}$, see Ref. 11, we deduce from Eq. (15),

$$|\mathrm{Tr}[P_{\mu''}(U^{\tilde{n}}P_{\mu_0}U^{\dagger\tilde{n}})P_{\mu'}(U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}})P_{\mu''}]| \leqslant \sum_{\substack{r_1,\ldots,r_{\tilde{n}}\in\{0,1\}\\ r_1+\cdots+r_{\tilde{n}}<\tilde{n}}}\ \sum_{\substack{s_1,\ldots,s_{\tilde{n}}\in\{0,1\}\\ s_1+\cdots+s_{\tilde{n}}<\tilde{n}}} \|B^{s_1,\ldots,s_{\tilde{n}}}_{r_1,\ldots,r_{\tilde{n}}}\|\mathrm{Tr}\sqrt{T^\dagger T}, \tag{16}$$

where we defined

$$B^{s_1,\ldots,s_{\tilde{n}}}_{r_1,\ldots,r_{\tilde{n}}} := A^\dagger_{s_1,\ldots,s_{\tilde{n}}}P_{\mu_0}A_{r_1,\ldots,r_{\tilde{n}}}, \tag{17}$$

$$T := P_{\mu'}U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}}P_{\mu''}. \tag{18}$$

Using the fact that $\|B^\dagger\| = \|B\|$ for any bounded operator B and it's adjoint $B^\dagger$,[12] we have $\|\hat{\mathcal{O}}'^\dagger(\epsilon)\| = \|\hat{\mathcal{O}}'(\epsilon)\| < \epsilon$. Utilizing the submultiplicativity property of operator norms we deduce that the norms of the operators $B^{s_1,\ldots,s_{\tilde{n}}}_{r_1,\ldots,r_{\tilde{n}}}$ are all bounded from above by ϵ, except in the case where all $s_1,\ldots,s_{\tilde{n}}$ and all $r_1,\ldots,r_{\tilde{n}}$ are equal 1, which is excluded from the sum on the right-hand side of Eq. (16). Indeed we have

$$\|B^{s_1,\ldots,s_{\tilde{n}}}_{r_1,\ldots,r_{\tilde{n}}}\| \leqslant \left(\prod_{i=1}^{\tilde{n}} \|U\|^{s_i}\|\hat{\mathcal{O}}'^{\dagger}(\epsilon))\|^{1-s_i}\right)\|P_{\mu_0}\|\left(\prod_{i=1}^{\tilde{n}} \|U^{\dagger}\|^{r_i}\|\hat{\mathcal{O}}'(\epsilon))\|^{1-r_i}\right)$$
$$\leqslant \left(\prod_{i=1}^{\tilde{n}} \epsilon^{1-s_i}\right)\left(\prod_{j=1}^{\tilde{n}} \epsilon^{1-r_j}\right) \leqslant \epsilon^2 < \epsilon, \quad \text{if } s_1 + \cdots + s_{\tilde{n}} < \tilde{n}, \quad r_1 + \cdots + r_{\tilde{n}} < \tilde{n}, \tag{19}$$

where we used $\|P_{\mu_0}\| = \|U\| = \|U^{\dagger}\| = 1$ and $\epsilon \ll 1$. With the definition $M := \mathrm{Tr}\sqrt{T^{\dagger}T}$ we finally conclude from Eq. (16),

$$|\mathrm{Tr}[P_{\mu''}(U^{\tilde{n}}P_{\mu_0}U^{\dagger\tilde{n}})P_{\mu'}(U^{\tilde{n}}\tilde{\rho}U^{\dagger\tilde{n}})P_{\mu''}]| < 2^{2\tilde{n}}M\epsilon. \tag{20}$$

Since c, $\tilde{n}$, and M are fixed constants, we can always arrange $2^{2\tilde{n}}M\epsilon < |c|$ by choosing a sufficiently small $\epsilon > 0$. This contradicts the assumption (6) and thus proves our proposition (5).

We are now in a position to derive the commutativity condition (b) of the theorem. It is a straightforward consequence of proposition (5) we have just proven. Taking condition (5) and choosing in it the state $\rho \in \mathcal{S}_{\{P_\mu\}}$ to be proportional to the projector sandwiched between U^n and $U^{\dagger n}$ within the first bracket,

$$\rho = \frac{P_{\mu_0}}{\mathrm{Tr}[P_{\mu_0}]}, \tag{21}$$

where P_{μ_0} is still arbitrary, we necessarily get the condition

$$\forall n \in \mathbb{N} \ \forall \mu_0, \mu', \mu'' \quad \text{with } \mu' \neq \mu'' : \mathrm{Tr}[P_{\mu''}(U^n P_{\mu_0} U^{\dagger n})P_{\mu'}(U^n P_{\mu_0} U^{\dagger n})P_{\mu''}] = 0. \tag{22}$$

With the definition $A := P_{\mu'}(U^n P_{\mu_0} U^{\dagger n})P_{\mu''}$ Eq. (22) becomes $\mathrm{Tr}[A^{\dagger}A] = 0$. Since $A^{\dagger}A$ is a positive operator, this is possible if and only if $A = 0$. Hence condition (22) is equivalent to

$$\forall n \in \mathbb{N} \ \forall \mu_0, \mu', \mu'' \quad \text{with } \mu' \neq \mu'' : P_{\mu'}(U^n P_{\mu_0} U^{\dagger n})P_{\mu''} = 0. \tag{23}$$

This condition implies

$$\sum_{\mu'} P_{\mu'}(U^n P_{\mu_0} U^{\dagger n})P_{\mu''} = P_{\mu''}(U^n P_{\mu_0} U^{\dagger n})P_{\mu''} \tag{24}$$

for any μ_0 and μ'', and arbitrary $n \in \mathbb{N}$. But since $\Sigma_{\mu'} P_{\mu'} = \mathbb{1}_{\mathcal{H}}$, the left-hand side of the last equation must be equal to $(UP_{\mu_0}U^{\dagger})P_{\mu''}$. Hence we obtain

$$P_{\mu''}(U^n P_{\mu_0} U^{\dagger n})P_{\mu''} = (U^n P_{\mu_0} U^{\dagger n})P_{\mu''} \tag{25}$$

on the one hand and by taking the adjoint of Eq. (25),

$$P_{\mu''}(U^n P_{\mu_0} U^{\dagger n})P_{\mu''} = P_{\mu''}(U^n P_{\mu_0} U^{\dagger n}) \tag{26}$$

on the other hand, for any $n \in \mathbb{N}$ and arbitrary μ_0 and μ''. Therefore

$$(U^n P_{\mu_0} U^{\dagger n})P_{\mu''} = P_{\mu''}(U^n P_{\mu_0} U^{\dagger n}) \tag{27}$$

for any $n \in \mathbb{N}$ and arbitrary μ_0, μ'', and so $[U^n P_{\mu_0} U^{\dagger n}, P_{\mu''}] = 0$ for any $n \in \mathbb{N}$ and all $P_{\mu_0}, P_{\mu''} \in \{P_\mu\}$. □

The implication (a) $\Rightarrow$ (c) of the theorem constitutes the main result of this paper: the decoherence of histories of arbitrary length for all initial states from the set $\mathcal{S}_{\{P_\mu\}}$ implies decoherence of such histories for arbitrary initial states $\rho \in \mathcal{S}$. It should be mentioned that the set $\mathcal{S}_{\{P_\mu\}}$ can be viewed as the smallest natural set of states that is associated with our framework. It is discrete and

may consist of just two elements (in the case of "yes–no" propositions). The set $\mathcal{S}$, on the other hand, contains the continuum of all possible states that are allowed in our framework.

In Ref. 6 the notion of classical states with respect to a partition $\{P_\mu\}$ was introduced.

Definition 4: A state represented by the density operator ρ is called *classical with respect to (w.r.t.) a partition* $\{P_\mu\}$ of the Hilbert space $\mathcal{H}$, if it is block-diagonal w.r.t. $\{P_\mu\}$, i.e., if $\rho = \Sigma_\mu P_\mu \rho P_\mu$. We denote by $\mathcal{S}^{\mathrm{cl}}_{\{P_\mu\}}$ the set of all density operators that are classical w.r.t. $\{P_\mu\}$.

In Ref. 6 it was shown that in the case of fine-grained partitions sets of histories of arbitrary length decohere for all classical initial states *only if* the unitary dynamics preserves the classicality of states, i.e., *only if*

$$\forall \rho \in \mathcal{S}^{\mathrm{cl}}_{\{P_\mu\}}: U\rho U^\dagger \in \mathcal{S}^{\mathrm{cl}}_{\{P_\mu\}}. \tag{28}$$

It is a single-iteration criterion, to verify that it holds for a particular unitary map U, only a single iteration of the map needs to be taken into account, which can be much easier than establishing decoherence directly by computing the off-diagonal elements of the decoherence functional. This is especially useful for studying chaotic quantum maps, for which typically only the first iteration is known in a closed analytical form.[13] Unfortunately, condition (28) fails to be necessary in the coarse-grained case. The following simple corollary of our theorem provides a necessary single-iteration condition that applies to arbitrary coarse grainings and is equivalent to (28) in the fine-grained case.

Corollary: Let a projective partition $\{P_\mu\}$ *of a finite dimensional Hilbert space* $\mathcal{H}$ *and a unitary map* U *on* $\mathcal{H}$ *be given. The medium decoherence condition is then satisfied for all classical initial states and arbitrarily long histories, i.e.,*

$$\forall \rho \in \mathcal{S}^{\mathrm{cl}}_{\{P_\mu\}}\ \forall k \in \mathbb{N}\ \ \forall h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}} \in \mathcal{K}[\{P_\mu\};k]: \mathcal{D}_{U,\rho}[h_{\boldsymbol{\alpha}}, h_{\boldsymbol{\beta}}] \propto \delta_{\boldsymbol{\alpha}\boldsymbol{\beta}}, \tag{29}$$

only if the following necessary condition is fulfilled:

$$\forall P_{\mu'}, P_{\mu''} \in \{P_\mu\}: [UP_{\mu'}U^\dagger, P_{\mu''}] = 0. \tag{30}$$

Proof: Follow trivially from the implication (a)$\Rightarrow$(b) of the theorem, as $\mathcal{S}_{\{P_\mu\}} \subset \mathcal{S}^{\mathrm{cl}}_{\{P_\mu\}}$. □

IV. SUMMARY

We have investigated decoherence properties of sets of quantum histories constructed from a fixed projective partition $\{P_\mu\}$ of a finite dimensional Hilbert space. We have found that if decoherence is established for arbitrary history lengths and all initial states from $\mathcal{S}_{\{P_\mu\}}$, which is the smallest natural set induced by $\{P_\mu\}$, then any set of histories constructed from $\{P_\mu\}$ is decoherent for all possible initial states. In addition, we have provided a necessary single-iteration criterion for decoherence of arbitrarily long histories that generalizes the condition of Ref. 6 to the case of arbitrary coarse grainings.

(Received 13 October 2004; accepted 31 January 2005; published online 29 March 2005)

We study a possible improvement of uncertainty relations. The Heisenberg uncertainty relation employs commutator of a pair of conjugate observables to set the limit of quantum measurement of the observables. The Schrödinger uncertainty relation improves the Heisenberg uncertainty relation by adding the correlation in terms of anti-commutator. However both relations are insensitive whether the state used is pure or mixed. We improve the uncertainty relations by introducing additional terms which measure the mixtureness of the state. For the momentum and position operators as conjugate observables and for the thermal state of quantum harmonic oscillator, it turns out that the equalities in the improved uncertainty relations hold. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1876874]

I. INTRODUCTION

Soon after Heisenberg and Schrödinger invented Quantum Mechanics around 1925, Heisenberg discovered the uncertainty relation in 1927.[1] The standard form of Heisenberg's uncertainty relation for any pair of observables A and B and a density matrix ρ is expressed as

$$\frac{1}{4}|\langle [A,B]\rangle_\rho|^2 \leqslant \mathrm{Var}_\rho(A)\mathrm{Var}_\rho(B), \tag{1.1}$$

where $\mathrm{Var}_\rho(A)=\mathrm{tr}(\rho A^2)-(\mathrm{tr}(\rho A))^2$ is the variance of A in the state defined by ρ, and $\mathrm{Var}_\rho(B)$ is defined analogously, $\langle [A,B]\rangle_\rho=\mathrm{tr}(\rho[A,B])$ is the expectation of the commutator $[A,B]=AB-BA$. The relation (1.1) states the fundamental limitation on quantum measurement for incompatible (noncommuting) observables and has played a fundamental role in quantum theory.

In 1930, Schrödinger[2] improved the uncertainty relation (1.1) by including the correlation between observables:

$$\frac{1}{4}|\langle [A,B]\rangle_\rho|^2+\frac{1}{4}|\langle \{A_0,B_0\}\rangle_\rho|^2 \leqslant \mathrm{Var}_\rho(A)\mathrm{Var}_\rho(B), \tag{1.2}$$

where $\langle \{A_0,B_0\}\rangle_\rho=\mathrm{tr}(\rho\{A_0,B_0\})$ denotes the expectation of anticommutator $\{A_0,B_0\}=A_0B_0+B_0A_0$ and $A_0=A-\langle A\rangle_\rho$, $B_0=B-\langle B\rangle_\rho$. The first term on the left-hand side of (1.2) encodes incompatibility, while the second term encodes correlation between observables A and B.

In recent years in the field of quantum computation and quantum information, the strong correlation, such as the phenomenon of entanglement, in the quantum world that cannot occur in classical mechanics, has been intensively studied.[3] Thus one expects that the Schrödinger uncertainty relation will play an important role in quantum theory.[4]

In this paper, we improved the uncertainty relations (1.1) and (1.2) by introducing additional terms in the lower bounds of (1.1) and (1.2), respectively. We will show that for any observables A and B, and any density matrix ρ, the following uncertainty relations hold:

a)Electronic mail: ympark@yonsei.ac.kr

$$\frac{1}{4}|\langle [A,B]\rangle_\rho|^2 + \mathrm{tr}(A_0\rho^{1/2}A_0\rho^{1/2})(\mathrm{tr}(B_0\rho^{1/2}B_0\rho^{1/2})) \leqslant \mathrm{Var}_\rho(A)\mathrm{Var}_\rho(B) \tag{1.3}$$

and

$$\frac{1}{4}|\langle [A,B]\rangle_\rho|^2 + \frac{1}{4}|\langle \{A_0,B_0\}\rangle_\rho|^2 + M(A_0,B_0;\rho) \leqslant \mathrm{Var}_\rho(A)\mathrm{Var}_\rho(B), \tag{1.4}$$

where the quantity $M(A_0,B_0;\rho)$ is defined in Theorem 2.2 explicitly. Notice that the relations (1.3) and (1.4) are improved versions of the relations (1.1) and (1.2), respectively. If the density matrix ρ is pure, then the second term on the left-hand side of (1.3) and the third term in (1.4) are vanished, and so (1.3) and (1.4) are reduced to the original relations (1.1) and (1.2), respectively.

It may be worth mentioning that for any observable A the functional,

$$\rho \mapsto \mathrm{tr}(A\rho^{1/2}A\rho^{1/2}),$$

is concave by Lieb's concavity theorem,[5] and so in a sense the values of additional terms in the above measure the mixturedness of ρ. We also note that the Wigner–Yanase skew information[6] is given by

$$I(\rho,A) = -\frac{1}{2}\mathrm{tr}([\rho^{1/2},A]^2) = \mathrm{tr}(\rho A^2) - \mathrm{tr}(A\rho^{1/2}A\rho^{1/2}), \tag{1.5}$$

and so the terms we introduced are related to the Wigner–Yanase information. See Sec. III for the details.

In order to show that the uncertainty relations (1.3) and (1.4) are optimal in some special situations, we consider the position and momentum operators as a pair of conjugate observables in $L^2(\mathbb{R})$, and choose the density operator ρ corresponding to the thermal state (quasi-free state) for a quantum harmonic oscillator. In this case, we show that the equalities in (1.3) and (1.4) hold. See Theorem 4.2.

Let us describe the main idea employed in this paper. Let A and B be self-adjoint operators (observables) acting on a separable Hilbert space. Let $\langle\cdot,\cdot\rangle$ be the Hilbert–Schmidt inner product defined on the class of Hilbert Schmidt operators:

$$\langle A,B\rangle := \mathrm{tr}(A^*B).$$

Then the left-hand side of (1.2) equals $|\langle A_0\rho^{1/2},B_0\rho^{1/2}\rangle|^2$. In order to make ρ play the same role as A and B, we introduce orthogonal decompositions:

$$\begin{aligned} A\rho^{1/2} &= A_{\rho,+} + A_{\rho,-}, \\ B\rho^{1/2} &= B_{\rho,+} + B_{\rho,-}, \end{aligned} \tag{1.6}$$

where

$$\begin{aligned} A_{\rho,+} &:= \frac{1}{2}(A\rho^{1/2} + \rho^{1/2}A), \\ A_{\rho,-} &:= \frac{1}{2}(A\rho^{1/2} - \rho^{1/2}A), \end{aligned} \tag{1.7}$$

and $B_{\rho,+}$ and $B_{\rho,-}$ are defined analogously. Notice that $\langle A_{\rho,-},A_{\rho,+}\rangle = 0$ and $\langle B_{\rho,-},B_{\rho,+}\rangle = 0$. One observes that

$$|\langle A_{\rho,+}, B_{\rho,-}\rangle| = |\langle A_{\rho,-}, B_{\rho,+}\rangle| = \frac{1}{4}|\langle [A,B]\rangle_\rho|.$$

The relation (1.3) will be followed from the above relation and the Schwarz inequality. See the proof of Theorem 2.1 in Sec. III. The proof of (1.4) is a little complicated. Let S be the subspace spanned by $B_{\rho,+}$ and $B_{\rho,-}$ and let P_S be the projection onto S. Denote by $\|\cdot\|_2$ the norm induced by $\langle\cdot,\cdot\rangle$. Notice that $\|P_S A\rho^{1/2}\|_2 \leqslant \|A\rho^{1/2}\|_2$. We will estimate $\|P_S A_\rho\|_2$ to prove the relation (1.4). See Sec. III for details.

There have been several proposals to quantify uncertainty by many authors. A prominent one is the Shanon entropy,[7,8] and another one is the Fisher information arising in Statistical Inference.[9,10] Recently Luo and Zhang[11] tried to characterize uncertainty relations by the Wigner–Yanase skew information.[6] Also, there are other families of uncertainty relations for mixed states. See Ref. 12 and the references therein. However, the results and the method used differ from those in this paper.

The paper is organized as follows: In Sec. II, we list our main results, Theorem 2.1 and Theorem 2.2. In Sec. III, we produce the proofs of main theorems by introducing the concept of orthogonal decompositions of $A\rho^{1/2}$ and $B\rho^{1/2}$. In Sec. IV, we give a brief discussion on the possible optimal improvement. Then, we give an example of a mixed state (and a pair of conjugate observables) for which the equalities in (1.3) and (1.4) hold.

II. IMPROVEMENT OF UNCERTAINTY RELATIONS: MAIN RESULTS

In this section we first list our main results, Theorem 2.1 and Theorem 2.2, and then give some remarks on the content of the results.

Let $\mathcal{H}$ be a separable Hilbert space. Denote by $\mathcal{L}(\mathcal{H})$ the algebra of all bounded linear operators on $\mathcal{H}$. An operator $T \in \mathcal{L}(\mathcal{H})$ is called Hilbert–Schmidt if $\mathrm{tr}(T^*T) < \infty$, where $\mathrm{tr}(T^*T)$ is the trace of T^*T. The class of all Hilbert–Schmidt operators is denoted by $\mathcal{L}_2(\mathcal{H})$.

We consider a pair of self-adjoint operators A and B acting on $\mathcal{H}$. Denote by $D(A)$ [resp., $D(B)$] the domain of A (resp., B). Let ρ be a density matrix (operator) on $\mathcal{H}$; $\rho \geqslant 0$ and $\mathrm{tr}(\rho) = 1$. In order to care for the domain problems arising from the unboundedness of A and B, we assume that the properties in the following assumption hold.

Assumption 2.1: Let A and B be self-adjoint operators acting on a separable Hilbert space $\mathcal{H}$ and let $\rho \in \mathcal{L}(\mathcal{H})$ be a density matrix. We assume that the following properties hold:

(a) *The inclusions* $\rho^{1/2}\mathcal{H} \subset \mathbf{(}D(A) \cap D(B)\mathbf{)}$, $A\rho^{1/2}\mathcal{H} \subset \mathbf{(}D(A) \cap D(B)\mathbf{)}$ *and* $B\rho^{1/2}\mathcal{H} \subset \mathbf{(}D(A) \cap D(B)\mathbf{)}$, *hold.*

(b) *The composition maps* $A\rho^{1/2}$, $B\rho^{1/2}$, $BA\rho^{1/2}$, $AB\rho^{1/2}$, $A^2\rho^{1/2}$, and $B^2\rho^{1/2}$ *define Hilbert–Schmidt operators on* $\mathcal{H}$.

(c) *There is a dense set* $D \subset \mathbf{(}D(A) \cap D(B)\mathbf{)}$ *such that the following inclusions hold:* $AD \subset \mathbf{(}D(A) \cap D(B)\mathbf{)}$ *and* $BD \subset \mathbf{(}D(A) \cap D(B)\mathbf{)}$.

We now list our main results. For notational simplicity, put

$$\langle T\rangle_\rho := \mathrm{tr}(T\rho), \quad \|T\|_\rho^2 = \mathrm{tr}(T^*T\rho),$$

for any (unbounded) operator, whenever the expressions in the above are well defined. Let $[A,B] := AB - BA$ and $\{A,B\} := AB + BA$ be the commutator and anticommutator of A and B, respectively. The following results are improved versions of the uncertainty relations (1.1) and (1.2):

Theorem 2.1: *Let A and B be self-adjoint operators acting on a separable Hilbert space $\mathcal{H}$ and let ρ be a density matrix. Under Assumption 2.1, the relation*

$$\frac{1}{4}|\langle [A,B]\rangle_\rho|^2 + \mathrm{tr}(A\rho^{1/2}A\rho^{1/2})\mathrm{tr}(B\rho^{1/2}B\rho^{1/2}) \leqslant \|A\|_\rho^2\|B\|_\rho^2 \tag{2.1}$$

holds.

Theorem 2.2: *Let A, B, and ρ be the operators as in Theorem 2.1. Under Assumption 2.1, the relation,*

$$\frac{1}{4}|\langle [A,B]\rangle_\rho|^2 + \frac{1}{4}|\langle \{A,B\}\rangle_\rho|^2 + M(A,B;\rho) \leqslant \|A_\rho\|^2\|B\|_\rho^2 \tag{2.2}$$

holds, where $M(A,B;\rho)=max\{M_1(A,B;\rho),M_1(B,A;\rho)\}$ *and* $M_1(A,B;\rho)$ *is given by*

$$M_1(A,B;\rho) := \frac{1}{4}\frac{(|\langle [A,B]\rangle_\rho|\mathrm{tr}(B\rho^{1/2}B\rho^{1/2}))^2}{\|B\|_\rho^4 - (\mathrm{tr}(B\rho^{1/2}B\rho^{1/2}))^2} \tag{2.3}$$

if $\mathrm{tr}(B\rho^{1/2}B\rho^{1/2}) < \|B\|_\rho^2$, *and* $M_1(A,B;\rho)=0$ *otherwise.*

Under Assumption 2.1, one can check that each term in the relations (2.1) and (2.2) is well defined. It may be possible to weaken Assumption 2.1 to get the relations (2.1) and (2.2). Put

$$A_0 := A - \langle A\rangle_0, \quad B_0 := B - \langle B\rangle_\rho.$$

If one replaces A and B by A_0 and B_0 in the relations (2.1) and (2.2), one can see that Theorem 2.1 and Theorem 2.2 are improvements of Heisenberg's uncertainty relation (1.1) and Schrödinger's uncertainty relation (1.2), respectively. Notice that if ρ is pure, $\mathrm{tr}(A_0\rho^{1/2}A_0\rho^{1/2})=\mathrm{tr}(B_0\rho^{1/2}B_0\rho^{1/2})=0$, and so the relations (2.1) and (2.2) are reduced to the relations (1.1) and (1.2), respectively, for any pure states.

It may be worth giving discussions on the content of Theorem 2.1 and Theorem 2.2 in more detail.

Remark 2.1: The Wigner–Yanase skew information[6] for any observable A and a density matrix ρ is defined by

$$I(\rho,A) := \frac{1}{2}\mathrm{tr}([\rho^{1/2},A][A,\rho^{1/2}]) = \mathrm{tr}(A^2\rho) - \mathrm{tr}(A\rho^{1/2}A\rho^{1/2}). \tag{2.4}$$

Thus, the terms we introduced in Theorem 2.1 and Theorem 2.2 are related to the above skew information. Since $0 \leqslant I(\rho,A)$, we see that $\mathrm{tr}(A\rho^{1/2}A\rho^{1/2}) \leqslant \|A\|_\rho^2$ and the equality holds if and only if $[\rho,A]=0$. If ρ commutes with either A or else B, then $\langle [A,B]\rangle_\rho=0$. Thus, if A and B are conjugate observables, there does not exist such a density matrix, and the strict inequalities $\mathrm{tr}(A\rho^{1/2}A\rho^{1/2}) < \|A\|_\rho^2$ and $\mathrm{tr}(B\rho^{1/2}B\rho^{1/2}) < \|B\|_\rho^2$ hold for any conjugate observables A and B.

Remark 2.2: The inequality (2.2) is not optimal. In fact, we discarded complicated non-negative terms in the derivation of (2.2). We will give a discussion on the optimal lower bound of (2.2). See Theorem 4.1 in Sec. IV.

Remark 2.3: As an application of the uncertainty relations (2.1) and (2.2), we considered the position and momentum operators on $L^2(\mathbb{R})$ as a pair of conjugate observables and the density matrix ρ corresponding to the thermal state for a quantum harmonic oscillator. We proved that the equalities in the uncertainty relations in (2.1) and (2.2) hold in this case. See Theorem 4.2.

III. PROOFS OF THEOREM 2.1 AND THEOREM 2.2

We produce the proofs of Theorem 2.1 and Theorem 2.2 in this section. Let A and B be self-adjoint operators and ρ a density matrix satisfying the properties in Assumption 2.1. For notational brevity, we write

$$A_\rho := A\rho^{1/2}, \quad B_\rho := B\rho^{1/2}. \tag{3.1}$$

We decompose A_ρ and B_ρ as

$$A_\rho = A_{\rho,+} + A_{\rho,-},$$

$$B_\rho = B_{\rho,+} + B_{\rho,-}, \tag{3.2}$$

where

$$\begin{aligned} A_{\rho,+} &:= \frac{1}{2}(A\rho^{1/2} + \rho^{1/2}A) = \frac{1}{2}\{A, \rho^{1/2}\}, \\ A_{\rho,-} &:= \frac{1}{2}(A\rho^{1/2} - \rho^{1/2}A) = \frac{1}{2}[A, \rho^{1/2}], \\ B_{\rho,+} &:= \frac{1}{2}(B\rho^{1/2} + \rho^{1/2}B) = \frac{1}{2}\{B, \rho^{1/2}\}, \\ B_{\rho,-} &:= \frac{1}{2}(B\rho^{1/2} - \rho^{1/2}B) = \frac{1}{2}[B, \rho^{1/2}]. \end{aligned} \tag{3.3}$$

Denote by $\langle T,S\rangle, T,S \in \mathcal{L}_2(\mathcal{H})$, the Hilbert–Schmidt inner product on $\mathcal{L}_2(\mathcal{H})$:

$$\langle T,S\rangle := \mathrm{tr}(T^*S), \quad \forall\, T,S \in \mathcal{L}_2(\mathcal{H}), \tag{3.4}$$

and $\|T\|_2$ the induced norm:

$$\|T\|_2^2 := \mathrm{tr}(T^*T). \tag{3.5}$$

Here we have used the norm $\|T\|_2$ to distinguish it from the operator norm $\|T\|$. In the sequel, we assume that the properties in Assumption 2.1 hold.

Lemma 3.1: (a) The composite maps $\rho^{1/2}A$, $\rho^{1/2}B$, $\rho^{1/2}AB$, $\rho^{1/2}BA$, $\rho^{1/2}A^2$, *and* $\rho^{1/2}B^2$ *are bounded on* D. *The bounded extensions of those operators, denoted by the same symbols, are adjoint operators of* $A\rho^{1/2}$, $B\rho^{1/2}$, $BA\rho^{1/2}$, $AB\rho^{1/2}$, $A^2\rho^{1/2}$, *and* $B^2\rho^{1/2}$, respectively.

(b) The equalities,

$$\rho^{1/2}(A^2\rho^{1/2}) = (\rho^{1/2}A)(A\rho^{1/2}), \quad \rho^{1/2}(B^2\rho^{1/2}) = (\rho^{1/2}B)(B\rho^{1/2}),$$

$$\rho^{1/2}(AB\rho^{1/2}) = (\rho^{1/2}A)(B\rho^{1/2}), \quad \rho^{1/2}(BA\rho^{1/2}) = (\rho^{1/2}B)(A\rho^{1/2}),$$

hold, where $\rho^{1/2}(A^2\rho^{1/2})$ *is the composite map (operator product) of* $\rho^{1/2}$ *and* $A^2\rho^{1/2}$, *and* $(\rho^{1/2}A)\times(A\rho^{1/2})$ *the composite map of* $\rho^{1/2}A$ *and* $A\rho^{1/2}$, *etc.*

(c) $\langle A_{\rho,+}, A_{\rho,-}\rangle = 0$ *and* $\langle B_{\rho,+}, B_{\rho,-}\rangle = 0$.

Proof: (a) By Assumption 2.1 (b)–(c), one has that for any $\varphi \in D$ and $\eta \in \mathcal{H}$,

$$(\varphi, A\rho^{1/2}\eta) = (\rho^{1/2}A\varphi, \eta),$$

and so $\rho^{1/2}A = (A\rho^{1/2})^*$ on D. Since D is dense, the relation extends to $\mathcal{H}$. The rest of the part (a) follows from a similar method used above.

(b) Those equalities follow from Assumption 2.1 (b) and the part (a) of the lemma.

(c) Part (c) of the lemma follows from the definitions of $A_{\rho,\pm}$ and $B_{\rho,\pm}$ in (3.3) and the trace property; $\mathrm{tr}(TS) = \mathrm{tr}(ST)$. □

It follows from Lemma 3.1 (c) that the decompositions in (3.2) are orthogonal decompositions. Also, Lemma 3.1 (a) shows that $A_{\rho,+}$ and $B_{\rho,+}$ are self-adjoint, and $(A_{\rho,-})^* = -A_{\rho,-}$ and $(B_{\rho,-})^* = -B_{\rho,-}$.

Lemma 3.2: The equalities,

$$\langle A_{\rho,\pm}, A_{\rho,\pm}\rangle = \frac{1}{2}\{\mathrm{tr}(A^2\rho) \pm \mathrm{tr}(A\rho^{1/2}A\rho^{1/2})\},$$

$$\langle B_{\rho,\pm}, B_{\rho,\pm}\rangle = \frac{1}{2}\{\mathrm{tr}(B^2\rho) \pm \mathrm{tr}(B\rho^{1/2}B\rho^{1/2})\},$$

$$\langle B_{\rho,\pm}, A_{\rho,\pm}\rangle = \frac{1}{4}\{\mathrm{tr}(\{A,B\}\rho) \pm 2\mathrm{tr}(B\rho^{1/2}A\rho^{1/2})\},$$

$$\langle B_{\rho,\pm}, A_{\rho,\mp}\rangle = \frac{1}{4}\{\mathrm{tr}([B,A]\rho)\ ,$$

hold.

Proof: The equalities follow from the definitions of $A_\pm$ and $B_\pm$ in (3.3) and direct computations. □

Notice that by the first and second equalities in Lemma 3.2, one has that

$$\|A_{\rho,\pm}\|_2^2 = \frac{1}{2}\{\|A\|_\rho^2 \pm \mathrm{tr}(A\rho^{1/2}A\rho^{1/2})\},$$

$$\|B_{\rho,\pm}\|_2^2 = \frac{1}{2}\{\|B\|_\rho^2 \pm \mathrm{tr}(B\rho^{1/2}B\rho^{1/2})\}. \tag{3.6}$$

Also one recognizes that the Wigner–Yanase skew information $I(\rho,A)$ and $\|A_{\rho,-}\|$ are related by

$$I(\rho,A) = 2\|A_{\rho,-}\|^2. \tag{3.7}$$

See the definition of $I(\rho,A)$ in (2.4).

We are now ready to prove Theorem 2.1 and Theorem 2.2. It follows from (3.1) that

$$\langle B_\rho, A_\rho\rangle = \mathrm{tr}(BA\rho) = \frac{1}{2}\mathrm{tr}(\{B,A\}\rho) + \frac{1}{2}\mathrm{tr}([B,A]\rho).$$

Since the first term on the rhs of the above is real and the second term is pure imaginary,

$$|\langle B_\rho, A_\rho\rangle|^2 = \frac{1}{4}|\mathrm{tr}(\{B,A\}\rho)|^2 + \frac{1}{4}|\mathrm{tr}([B,A]\rho)|^2, \tag{3.8}$$

and so by the Schwarz inequality, the Schrödinger uncertainty relation,

$$\frac{1}{4}(\mathrm{tr}([B,A]\rho)|^2 + \frac{1}{4}|\mathrm{tr}(\{B,A\}\rho)|^2 \leqslant \|A_\rho\|_2^2\|B_\rho\|_2^2, \tag{3.9}$$

holds. Recall that $\|A_\rho\|_2^2 = \|A\|_\rho^2$ and $\|B_\rho\|_2^2 = \|B\|_\rho^2$.

Proof of Theorem 2.1: It follows from the Schwarz inequality and (3.6) that

$$|\langle B_{\rho,+}, A_{\rho,-}\rangle|^2 \leqslant \|B_{\rho,+}\|_2^2\|A_{\rho,-}\|_2^2 = \frac{1}{4}(\|B\|_\rho^2 + \mathrm{tr}(B\rho^{1/2}A\rho^{1/2}))(\|A\|_\rho^2 - \mathrm{tr}(A\rho^{1/2}A\rho^{1/2})),$$

$$|\langle B_{\rho,-}, A_{\rho,+}\rangle|^2 \leqslant \|B_{\rho,-}\|_2^2\|A_{\rho,+}\|_2^2 = \frac{1}{4}(\|B\|_\rho^2 - \mathrm{tr}(B\rho^{1/2}A\rho^{1/2}))(\|A\|_\rho^2 + \mathrm{tr}(A\rho^{1/2}A\rho^{1/2})).$$

Thus, by the fourth equality in Lemma 3.2 and the above inequality. we have

$$\frac{1}{8}|\mathrm{tr}([B,A]\rho)|^2 = |\langle B_{\rho,+}, A_{\rho,-}\rangle|^2 + |\langle B_{\rho,-}, A_{\rho,+}\rangle|^2 \leqslant \frac{1}{2}\{\|B\|_\rho^2\|A\|_\rho^2 - \mathrm{tr}(B\rho^{1/2}B\rho^{1/2})\mathrm{tr}(A\rho^{1/2}A\rho^{1/2})\}.$$

The above relation equals that in Theorem 2.1. □.

Now, let us turn to the proof of Theorem 2.2. Recall that the class $\mathcal{L}_2(\mathcal{H})$ of the Hilbert–Schmidt operator is a Hilbert space with the Hilbert–Schmidt inner product $\langle\cdot,\cdot\rangle$ defined in (3.4). Denote by $\hat{A}_{\rho,\pm}$ and $\hat{B}_{\rho,\pm}$ the normalized vectors in $\mathcal{L}_2(\mathcal{H})$ in the direction of $A_{\rho,\pm}$ and $B_{\rho,\pm}$, respectively:

$$\hat{A}_{\rho,\pm} = A_{\rho,\pm}/\|A_{\rho,\pm}\|_2, \quad \hat{B}_{\rho,\pm} = B_{\rho,\pm}/\|B_{\rho,\pm}\|_2. \tag{3.10}$$

If $\|A_{\rho,-}\|_2=0$ (resp., $\|B_{\rho,-}\|_2=0$), we set $\hat{A}_{\rho,-}=0$ (resp., $\hat{B}_{\rho,-}=0$). By (3.2) and (3.10),

$$\begin{aligned} A_\rho &= \|A_{\rho,+}\|_2\hat{A}_{\rho,+} + \|A_{\rho,-}\|_2\hat{A}_{\rho,-}, \\ B_\rho &= \|B_{\rho,+}\|_2\hat{B}_{\rho,+} + \|B_{\rho,-}\|_2\hat{B}_{\rho,-}. \end{aligned} \tag{3.11}$$

We introduce vectors orthogonal to A_ρ and B_ρ by

$$\begin{aligned} A_\rho^\perp &= \|A_{\rho,-}\|_2\hat{A}_{\rho,+} - \|A_{\rho,+}\|_2\hat{A}_{\rho,-}, \\ B_\rho^\perp &= \|B_{\rho,-}\|_2\hat{B}_{\rho,+} - \|B_{\rho,+}\|_2\hat{B}_{\rho,-}. \end{aligned} \tag{3.12}$$

It is easy to check that

$$\begin{aligned} &\|A_\rho^\perp\|_2 = \|A_\rho\|_2, \quad \|B_\rho^\perp\|_2 = \|B_\rho\|_2, \\ &\langle A_\rho^\perp, A_\rho\rangle = 0, \quad \langle B_\rho^\perp, B_\rho\rangle = 0. \end{aligned} \tag{3.13}$$

Denote by $\tilde{S}$ and S the subspace of $\mathcal{L}_2(\mathcal{H})$ spanned by $\{\hat{A}_{\rho,+},\hat{A}_{\rho,-}\}$ and $\{\hat{B}_{\rho,+},\hat{B}_{\rho,-}\}$, respectively, and let P_S be the projection to S.

Proposition 3.1: The inequality,

$$|\langle B_\rho, A_\rho\rangle|^2 + |\langle B_\rho^\perp, A_\rho\rangle|^2 \leqslant \|B_\rho\|_2^2\|A_\rho\|_2^2,$$

holds.

Proof: Let $\hat{B}_\rho$ and $\hat{B}_\rho^\perp$ be normalized vectors in the directions of B_ρ and $B_\rho^\perp$, respectively:

$$\hat{B}_\rho = B_\rho/\|B_\rho\|_2, \quad \hat{B}_\rho^\perp = B_\rho^\perp/\|B_\rho\|_2.$$

Since $\{\hat{B}_\rho, \hat{B}_\rho^\perp\}$ is an orthonormal basis of S, we have

$$\|P_S A_\rho\|^2 = |\langle \hat{B}_\rho, P_S A_\rho\rangle|^2 + |\langle \hat{B}_\rho^\perp, P_S A_\rho\rangle|^2, \tag{3.14}$$

and so

$$|\langle \hat{B}_\rho, A_\rho\rangle|^2 + |\langle \hat{B}_\rho^\perp, A_\rho\rangle|^2 = \|P_S A_\rho\|_2^2 \leqslant \|A_\rho\|_2^2.$$

By multiplying $\|B_\rho\|_2^2$ to both sides of the above inequality, we proved the lemma. □

Lemma 3.3: The equality,

$$|\langle B_\rho^\perp, A\rangle|^2 = M_1(A,B;\rho) + M_2(A,B;\rho),$$

holds, where $M_1(A,B;\rho)$ is given by (2.3) in Theorem 2.2 and

$$M_2(A,B;\rho) = \frac{1}{4}(\|B_{\rho,+}\|_2\|B_{\rho,-}\|_2)^{-2}\left[\|B\|_\rho^2 \mathrm{tr}(B\rho^{1/2}A\rho^{1/2}) - \frac{1}{2}\langle\{B,A\}\rangle_\rho \mathrm{tr}(B\rho^{1/2}B\rho^{1/2})\right]^2, \tag{3.15}$$

if $\mathrm{tr}(B\rho^{1/2}B\rho^{1/2}) < \|B\|_\rho^2$, *and* $M_2(A,B;\rho)=0$ *otherwise.*

Proof: By the definition of $B_\rho^\perp$ in (3.12),

$$\begin{aligned}\langle B_\rho^\perp, A_\rho\rangle &= \langle \|B_{\rho,-}\|_2 \hat{B}_{\rho,+} - \|B_{\rho,+}\|_2 \hat{B}_{\rho,-}, A_{\rho,+} + A_{\rho,-}\rangle \\ &= \left\{ \frac{\|B_{\rho,-}\|_2}{\|B_{\rho,+}\|_2}\langle B_{\rho,+}, A_{\rho,+}\rangle - \frac{\|B_{\rho,+}\|_2}{\|B_{\rho,-}\|_2}\langle B_{\rho,-}, A_{\rho,-}\rangle \right\} \\ &\quad + \left\{ \frac{\|B_{\rho,-}\|_2}{\|B_{\rho,+}\|_2}\langle B_{\rho,+}, A_{\rho,-}\rangle - \frac{\|B_{\rho,+}\|_2}{\|B_{\rho,-}\|_2}\langle B_{\rho,-}, A_{\rho,+}\rangle \right\}.\end{aligned}$$

Since the first term on the rhs of the last equality in the above is real and the second term is pure imaginary, we have

$$|\langle B_\rho^\perp, A_\rho\rangle|^2 = M_1(A,B;\rho) + M_2(A,B;\rho),$$

where

$$M_1(A,B;\rho) = \left| \frac{\|B_{\rho,-}\|_2}{\|B_{\rho,+}\|_2}\langle B_{\rho,+}, A_{\rho,-}\rangle - \frac{\|B_{\rho,+}\|_2}{\|B_{\rho,-}\|_2}\langle B_{\rho,-}, A_{\rho,+}\rangle \right|^2,$$

$$M_2(A,B;\rho) = \left| \frac{\|B_{\rho,-}\|_2}{\|B_{\rho,+}\|_2}\langle B_{\rho,+}, A_{\rho,+}\rangle - \frac{\|B_{\rho,+}\|_2}{\|B_{\rho,-}\|_2}\langle B_{\rho,-}, A_{\rho,-}\rangle \right|^2. \tag{3.16}$$

By Lemma 3.2,

$$M_1(A,B;\rho) = \frac{1}{4^2}|\langle [B,A]\rangle_\rho|^2 (\|B_{\rho,+}\|_2 \|B_{\rho,-}\|_2)^{-2} (\|B_{\rho,-}\|_2^2 - \|B_{\rho,+}\|)^2.$$

Substituting (3.6) into the above expression, we proved that $M_1(A,B;\rho)$ in the above equals that in (2.3).

Next, we consider $M_2(A,B;\rho)$ in (3.16). $M_2(A,B;\rho)$ can be expressed as

$$M_2(A,B;\rho) = (\|B_{\rho,+}\|_2 \|B_{\rho,-}\|_2)^{-2} [\|B_{\rho,-}\|_2^2 \langle B_{\rho,+}, A_{\rho,-}\rangle - \|B_{\rho,+}\|_2^2 \langle B_{\rho,-}, A_{\rho,-}\rangle]^2.$$

Using Lemma (3.2) and (3.6), one can check that the above expression equals that in (3.15). Notice that, if $\|B_{\rho,-}\|_2 = 0$, then $B_\rho^\perp = 0$ by (3.12). Thus, $M_1(A,B;\rho) = M_2(A,B;\rho) = 0$ in this case. This proved the lemma completely. □

Proof of Theorem 2.2: Since $M_2(A,B;\rho) \geqslant 0$, Theorem 2.2 for $M_1(A,B;\rho)$ follows from Proposition 3.1, (3.8), and Lemma 3.3. By interchanging the role of A_ρ and B_ρ, we proved the theorem completely. □

IV. OPTIMAL IMPROVEMENT AND APPLICATION

We give a brief discussion on the optimal improvement of Theorem 2.2, which can be obtained by the method used in Sec. III. Then, as an application of Theorem 2.1 and Theorem 2.2, we consider the thermal states of a quantum harmonic oscillator.

A. Possible optimal improvement

Recall that S is the subspace of $\mathcal{L}_2(\mathcal{H})$ spanned by $\{\hat{B}_{\rho,+}, \hat{B}_{\rho,-}\}$ and P_S is the projection onto S. In the proof of Theorem 2.2, we have used the identity (3.14). The quantity $\|P_S A_\rho\|$ is the length of the projection of A_ρ onto S. Thus, it is clear that, in order to obtain the optimal improvement one has to find the vector X with $\|X\|_2 = \|A_\rho\|_2$ in the subspace $\tilde{S}$ spanned by $\{\hat{A}_{\rho,+}, \hat{A}_{\rho,-}\}$, which has the biggest component in S.

In order to find such a vector in $\tilde{S}$, put

$$X = \alpha A_\rho + \beta A_\rho^\perp,$$

where α and β are complex constants satisfying

$$|\alpha|^2 + |\beta|^2 = 1.$$

One has that

$$\|P_S X\|_2^2 = \alpha^2 \|P_S A_\rho\|_2^2 + \overline{\alpha}\beta\langle P_S A_\rho, P_S A_\rho^\perp\rangle + \alpha\overline{\beta}\langle P_S A_\rho^\perp, P_S A_\rho\rangle + |\beta|^2 \|P_S A_\rho^\perp\|_2^2.$$

One can choose α such that $\alpha \geqslant 0$. The first and last terms on the rhs of the above are non-negative. To make the other terms non-negative, we choose β as

$$\beta = \gamma\langle P_S A_\rho^\perp, P_S A_\rho\rangle / |\langle P_S A_\rho^\perp, P_S A_\rho\rangle|,$$

where $\gamma \geqslant 0$. We then have

$$\|P_S X\|_2^2 = \alpha^2 \|P_S A_\rho\|_2^2 + 2\alpha\gamma|\langle P_S A_\rho, P_S A_\rho^\perp\rangle| + \gamma^2 \|P_S A_\rho^\perp\|_2^2, \tag{4.1}$$

where α and γ are non-negative real numbers satisfying

$$\alpha^2 + \gamma^2 = 1. \tag{4.2}$$

Thus, the problem is to maximize (4.1) under the constraint (4.2). The problem can be solved by the method of the Lagrange multiplier.

We use the following notation:

$$a = \|P_S A_\rho\|_2^2,\ b = \|P_S A_\rho^\perp\|_2^2,\ c = |\langle P_S A_\rho, P_S A_\rho^\perp\rangle|. \tag{4.3}$$

Put

$$d = (a - b)/2c. \tag{4.4}$$

The method of the Lagrange multiplier implies that

$$a\alpha + c\gamma = \lambda\alpha,$$

$$b\gamma + c\alpha = \lambda\gamma,$$

where λ is the Lagrange multiplier. The above relations imply

$$\alpha^2 - 2d\alpha\gamma - \gamma^2 = 0. \tag{4.5}$$

Since $\alpha > 0$, one has that

$$\alpha = (d + \sqrt{d^2 + 1})\gamma. \tag{4.6}$$

From (4.2) and (4.6), α and γ can be solved explicitly. One may check that

$$\gamma^2 = 1/(1 + (d + \sqrt{d^2 + 1})^2) = 1/[2(d^2 + 1) + 2d\sqrt{d^2 + 1}]. \tag{4.7}$$

The relations (4.5) and (4.2) imply

$$\alpha\gamma = (1 - 2\gamma^2). \tag{4.8}$$

We substitute (4.7) and (4.8) into

$$\|P_S X\|_2^2 = a(1 - \gamma^2) + 2c\alpha\gamma + b\gamma^2$$

to obtain

$$\|P_S X\|_2^2 = a + c(\sqrt{d^2+1} - d) = a + \frac{1}{2}\{[(a-b)^2 + 4c^2]^{1/2} - (a-b)\}. \tag{4.9}$$

We leave that detailed derivation of (4.9) to the reader.

Let us denote by

$$m_3(A,B;\rho) := \frac{1}{2}\{[(a-b)^2 + 4c^2]^{1/2} - (a-b)\}, \tag{4.10}$$

where a, b, and c are given by (4.3). Put

$$M_3(A,B;\rho) := \|B\|_\rho^2 m_3(A,B;\rho). \tag{4.11}$$

We then obtain the following result.

Theorem 4.1: *The relation*

$$\frac{1}{4}|\langle [A,B]\rangle_\rho|^2 + \frac{1}{4}|\langle \{A,B\}\rangle_\rho|^2 + \tilde{M}(A,B;\rho) \leqslant \|A\|_\rho^2 \|B\|_\rho^2.$$

holds, where

$$\tilde{M}(A,B;\rho) = \max\left\{\sum_{k=1}^{3} M_k(A,B;\rho), \sum_{k=1}^{3} M_k(B,A;\rho)\right\},$$

and $M_1(A,B;\rho)$, $M_2(A,B;\rho)$ and $M_3(A,B;\rho)$ are given as in (2.3), (3.15), and (4.11), respectively.

Proof: It follows from (4.9) that

$$\|B\|_\rho^2 \|P_S A_\rho\|_2^2 + M_3(A,B;\rho) = \|B\|_\rho^2 \|P_S X\|_2^2 \leqslant \|B\|_\rho^2 \|X\|_2^2 = \|B\|_\rho^2 \|A\|_\rho^2. \tag{4.12}$$

We recall from the (3.14) and Lemma 3.3 that

$$\|B\|_\rho^2 \|P_S A_\rho\|_2^2 = |\langle B_\rho, A_\rho\rangle|^2 + M_1(A,B;\rho) + M_2(A,B;\rho). \tag{4.13}$$

Thus, the theorem follows from (4.12), (4.13), and (3.8) together with interchanging the role of A and B. □

Even if $M_3(A,B;\rho)$ can be expressed explicitly in terms of $\|A_{\rho,\pm}\|_2$, $\|B_{\rho,\pm}\|_2$, etc., the expression is complicated and so we do not present it here.

B. An Application

In $L^2(\mathbb{R})$, the momentum operator P and the position operator Q are represented by

$$P = i\frac{d}{dx}, \quad Q = x. \tag{4.14}$$

It is convenient to introduce the annihilation and creation operators that are defined as

$$a = \frac{1}{\sqrt{2}}\left(x + \frac{d}{dx}\right), \quad a^* = \frac{1}{\sqrt{2}}\left(x - \frac{d}{dx}\right).$$

Those operators satisfy the canonical commutation relations

$$[a,a^*] = 1, \quad [a,a] = [a,a^*] = 0, \tag{4.15}$$

and P and Q can be written as

$$P = \frac{i}{\sqrt{2}}(a - a^*), \quad Q = \frac{1}{\sqrt{2}}(a + a^*). \tag{4.16}$$

Let N be the number operator defined by

$$N = a^* a. \tag{4.17}$$

The Hamiltonian for quantum harmonic oscillator is given by

$$H = \frac{1}{2}(P^2 + Q^2) = N + \frac{1}{2}. \tag{4.18}$$

Let Ω be the ground state of H and let $\mathcal{F}_0$ be the dense subset consisting of finite linear combinations of vectors $\{(a^*)^n\Omega, n \in \mathbb{N}\}$. Then $\mathcal{F}_0$ is a common core for a, a^*, and N. For the details, we refer to Sec. 5.2 of Ref. 13.

The density operator ρ corresponding to the thermal state is given by

$$\rho = \frac{1}{Z}\exp(-\beta H) = \frac{1}{Z}\exp\left(-\beta\left(N + \frac{1}{2}\right)\right), \tag{4.19}$$

where $Z = \mathrm{tr}(\exp(-\beta H))$ and $\beta > 0$ the inverse of the temperature.

Theorem 4.2: *Let $A = P$ and $B = Q$ and let ρ be given by (4.19). Then the properties in Assumption 2.1 hold (with $D = \mathcal{F}_0$). Moreover each side of (2.1) and (2.2) equals* $\cosh^2(\beta/2))/4\sinh^2(\beta/2)$, *and so the equalities in the uncertainty relations in Theorem 2.1 and Theorem 2.2 hold.*

Proof: Let $a_k^{\#}$, $k = 1, 2, \ldots, n$, be either a^* or else a. It can be checked that

$$\left\| \prod_{k=1}^{n} a_k^{\#} \varphi \right\| \leqslant \|(N + n + 1)^{n/2}\varphi\|,$$

for any $\varphi \in \mathcal{F}_0$.[13] Thus $(\Pi_{k=1}^n a_k^{\#})(N+n+1)^{-n/2}$ is bounded operator for each n. Thus the properties (a) and (b) in Assumption 2.1 hold.

Notice that the equalities

$$a(N + 1) = (N + 2)a, \quad a^*(N + 2) = (N + 1)a^*,$$

hold on $\mathcal{F}_0$. The above equalities imply

$$(N + 2)^{-1}a = a(N + 1)^{-1}, \quad (N + 1)^{-1}a^* = a^*(N + 2)^{-1}.$$

Using the above relations repeatedly, one can check that property (c) in Assumption 2.1 holds. We leave the details to the reader.

Next, we compute each side of (2.1) and (2.2). A direct computation shows that

$$\langle a^* a\rangle_\rho = e^{-\beta}/(1 - e^{-\beta}). \tag{4.20}$$

It follows from (4.20) and the canonical commutation relations (4.15) that

$$\|Q\|_\rho^2 = \frac{1}{2}\mathrm{tr}((a + a^*)(a + a^*)\rho) = \frac{1}{2} + e^{-\beta}/(1 - e^{-\beta}) = \frac{1}{2}\cosh(\beta/2)/\sinh(\beta/2). \tag{4.21}$$

The method used in the above gives

$$\|P\|_\rho^2 = \frac{1}{2}\cosh(\beta/2)/\sinh(\beta/2). \tag{4.22}$$

It can be checked that

$$\rho^{1/2}a = e^{\beta/2}a\rho^{1/2}, \quad \rho^{1/2}a^* = e^{-\beta/2}a^*\rho^{1/2}. \tag{4.23}$$

We use (4.23) to obtain

$$\begin{aligned}\mathrm{tr}(Q\rho^{1/2}Q\rho^{1/2}) &= \frac{1}{2}\mathrm{tr}((a+a^*)(e^{\beta/2}a + e^{-\beta/2}a^*)\rho) = \frac{1}{2}\mathrm{tr}(e^{-\beta/2}aa^* + e^{\beta/2}a^*a) \\ &= \frac{1}{2}\{e^{-\beta/2} + (e^{\beta/2} + e^{-\beta/2})e^{-\beta}/(1-e^{-\beta})\} = 1/2\,\sinh(\beta/2),\end{aligned} \tag{4.24}$$

$$\mathrm{tr}(P\rho^{1/2}P\rho^{1/2}) = 1/2\,\sinh(\beta/2). \tag{4.25}$$

A direct computation yields

$$\langle\{P,Q\}\rangle_\rho = 0, \quad \mathrm{tr}(P\rho^{1/2}Q\rho^{1/2}) = 0. \tag{4.26}$$

Thus (4.21) and (4.22) imply

$$\|P\|_\rho^2\|Q\|_\rho^2 = \cosh^2(\beta/2)/4\,\sinh^2(\beta/2). \tag{4.27}$$

Since $[P,Q]=i$, (4.24) and (4.25) imply that

$$\text{lhs of (2.1)} = \frac{1}{4} + \frac{1}{4\,\sinh^2(\beta/2)} = \cosh^2(\beta/2)/4\,\sinh^2(\beta/2). \tag{4.28}$$

Next, we compute the lhs of (2.2). We use (4.21) and (4.24) to obtain

$$\begin{aligned}\|Q\|_\rho^4 - (\mathrm{tr}(Q\rho^{1/2}Q\rho^{1/2}))^2 &= \frac{1}{4}\left\{\frac{\cosh^2(\beta/2)}{\sinh^2(\beta/2)} - \frac{1}{\sinh^2(\beta/2)}\right\}, \\ &= \frac{1}{4},\end{aligned}$$

and so

$$M_1(P,Q;\rho) = (\mathrm{tr}(Q\rho^{1/2}Q\rho^{1/2}))^2 = 1/4\,\sinh^2(\beta/2).$$

Thus, we conclude that

$$\text{lhs of (2.2)} = \cosh^2(\beta/2)/4\,\sinh^2(\beta/2). \tag{4.29}$$

Combining (4.27)–(4.29), we complete the proof of Theorem 4.2. □

Construction of the dual family of Gazeau–Klauder coherent states via temporally stable nonlinear coherent states

R. Roknizadeh[a] and M. K. Tavassoly[b]
Quantum Optics Group, Physics Department, University of Isfahan, Isfahan, Iran

(Received 22 November 2004; accepted 23 December 2004;
published online 30 March 2005)

Using the *analytic representation* of the so-called Gazeau–Klauder coherent states (CSs), we shall demonstrate that how a new class of generalized CSs, namely the *family of dual states* associated with theses states, can be constructed through viewing these states as *temporally stable nonlinear CSs*. Also we find that the ladder operators, as well as the displacement type operator corresponding to these two pairs of generalized CSs, may be easily obtained using our formalism, without employing the *supersymmetric quantum mechanics* (SUSYQM) techniques. Then, we have applied this method to some physical systems with known spectrum, such as Pöschl–Teller, infinite well, Morse potential and hydrogenlike spectrum as some quantum mechanical systems. Finally, we propose the generalized form of the Gazeau–Klauder CS and the corresponding dual family. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1861276]

I. INTRODUCTION

Coherent states (CSs) play an important role in various fields of physics, quantum technologies and especially in quantum optics (see, for instance, Refs. 1–4). Therefore efforts along generalizations and applications have been appreciably increased in recent years.[5] Recently, Gazeau and Klauder have introduced an important class of generalized CSs, the so-called "*Gazeau–Klauder CSs*" have been denoted by $|J,\gamma\rangle$, corresponding to any arbitrary quantum mechanical system.[6,7] Keeping in mind that Gazeau–Klauder CSs are really CSs, we will refer to them as "*GK states*." These states have attracted much attention in literature (see, e.g., Refs. 8–13). More recently, along generalization of GK states, the vector CSs of the GK type have been constructed and some physical applications of them have been addressed.[14]

In another direction, a new way of generalization has been proposed to construct the so-called *family of the dual states* corresponding to some particular known classes of CSs such as nonlinear CSs.[15,16] In an extended framework we have recently studied this idea, rederived basically and well developed.[16] The construction of the dual pairs may be actually performed for all classes of generalized CSs, obtained by each of the three ways of generalizations; i.e., *algebraic*, *symmetric*, and *dynamics*. We have found that the canonical CSs are the only *self-dual* family (a useful check point for our future construction in this paper). Also we have already established the dual states associated with KPS,[17] PS,[18] and SU (1,1) group CSs successfully, of course, after demonstrating the nonlinearity nature of these states.[8] Unfortunately, as we have stated in earlier works, employing either our previous approaches in Ref. 16 or the formalism proposed in Ref. 15 for constructing the dual of GK state, do not lead to full consistent CSs with the Gazeau–Klauder criteria. For instance according to the proposition in Ref. 16 the $\hat{T}^{-1}$ operator, whose action on canonical CS

[a]Electronic mail: rokni@sci.ui.ac.ir
[b]Electronic mail: mk.tavassoly@sci.ui.ac.ir

yields $|J,\gamma\rangle$ may be obtained trivially. But when one acts the related $\hat{T}$-operator on the standard CS, the output state which was expected to be of the GK type (in fact the dual set of GK states), encounters some difficulties. For example, apart from the ill-definition of the $\hat{T}$ (and so $\hat{T}^{-1}$) operator, the obtained states do not fulfill *temporal stability*. Consequently, the important property of the GK states, *the action identity* evolves some problems. Therefore one must try some *radically different method* from the previous ones.

This paper is organized as follows: first, after imposing a *second modification* on the *modified* GK states $|z,\alpha\rangle$ (*to be distinguished from "GK states," by abuse of notation we shall call them as GKCSs*) introduced by El Kinani and Daoud,[11] we shall clarify the nonlinearity of these states. Second, in view of establishing the GKCS as an extension of "*KPS nonlinear CS*"[17] to "*temporally stable CS*," together with the fact that the dual family of KPS nonlinear CS has already been introduced appropriately, we attempt to find the dual of GKCS (we shall refer to it as DGKCS) through generalization of "the dual of KPS nonlinear CS" to state that it possesses the "*temporal stability*" characteristic. Upon generalizing this result, we shall introduce the $\hat{S}(\alpha)$-operator ($\alpha \in \mathbb{R}$) which transfers any generalized nonlinear CS, corresponding to a Hamiltonian with known spectrum (which does not preserve temporal stability) to a situation in which it nicely restores this property.

Additionally, a set of new interesting results such as the explicit form of annihilation, creation, and displacement type operators corresponding to each of the two generalized CSs (GKCSs and DGKCSs) will be obtained. Also, by using the dual family of GKCS, the even, odd, and Schrödinger cat CSs have been introduced. We then apply the method to some well-known solvable systems, i.e., harmonic oscillator, Pöschl–Teller, infinite well and Morse potential and hydrogenlike spectrum as some examples of quantum mechanical systems. Finally, we outline a scheme for *generalization of the GKCSs* as well as *DGKCSs*.

II. ANALYTICAL REPRESENTATIONS OF GAZEAU–KLAUDER CS AS NONLINEAR CS

In this section, we first revisit the analytical representations of GKCSs and then impose a second modification on them. At last, we establish their nonlinearity nature.

A. Analytical representations of GK states

The GK states, $|J,\gamma\rangle$, corresponding to any Hamiltonian with discrete (nondegenerate) eigenvalues $e_n \geqslant 0$, are defined as[6,7,19]

$$|J,\gamma\rangle \doteq \mathcal{N}(J)^{-1/2}\sum_{n=0}^{\infty}\frac{J^{n/2}e^{-i\gamma e_n}}{\sqrt{\rho(n)}}|n\rangle, \quad J \geqslant 0, \quad -\infty < \gamma < \infty, \tag{1}$$

where $\mathcal{N}$ is a normalization constant may be determined (for a new and interesting formalism related to degenerate Hamiltonian see Ref. 14). The orthonormal set $\{|n\rangle\}_{n=0}^{\infty}$ satisfy the eigenvalue equation

$$\hat{H}|n\rangle = E_n|n\rangle \equiv \hbar\omega e_n|n\rangle = e_n|n\rangle, \quad \hbar \equiv 1, \quad \omega \equiv 1. \tag{2}$$

The eigenvalues of the Hamiltonian $\hat{H}$ are such that

$$0 = e_0 < e_1 < e_2 < \cdots < e_n < e_{n+1} < \cdots . \tag{3}$$

These states should satisfy the following properties: (i) *continuity of labeling*, (ii) *resolution of the identity*, (iii) *temporal stability*, and (iv) *action identity*. The last two conditions require $\rho(n) = [e_n]!$.

Along the works on GK states, El Kinani and Daoud in a series of papers,[11–13] imposed a minor modification on these states via generalizing the Bargman representation for the standard harmonic oscillator.[20] The authors introduced the *analytical representations of GK states*, denoted by us as GKCSs,

$$|z,\alpha\rangle \doteq \mathcal{N}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n e^{-i\alpha e_n}}{\sqrt{\rho(n)}}|n\rangle, \quad z\in\mathbb{C}, \quad \alpha\in\mathbb{R}, \tag{4}$$

where the normalization constant and the function $\rho(n)$ are given by

$$\mathcal{N}(|z|^2)=\sum_{n=0}^{\infty}\frac{|z|^{2n}}{\rho(n)}, \quad \rho(n)=[e_n]!\,. \tag{5}$$

Briefly speaking, they replaced $-\infty<\gamma<\infty$ and $J>0$ in (1) by $\alpha\in\mathbb{R}$ and $z\in\mathbb{C}$, respectively. We must emphasize the main difference between the GKCSs presented in (4) and GK states in (1) in view of the significance and the role of γ and α, particularly in the integration procedure, in order to establish the resolution of unity. For this purpose, it is required to find an appropriate positive measure $\mathrm{d}\lambda(z)$ such that

$$\int_0^R |z,\alpha\rangle\langle z,\alpha|\mathrm{d}\lambda(z)=\sum_{n=0}^{\infty}|n\rangle\langle n|=\hat{I}, \quad 0<R\leqslant\infty. \tag{6}$$

Inserting (4) in (6), writing $z=xe^{i\theta}$ and expressing the measure as

$$\mathrm{d}\lambda(z)=\mathrm{d}\lambda(|z|^2)=\pi\mathcal{N}(x^2)\sigma(x^2)x\,\mathrm{d}x\,\mathrm{d}\theta, \tag{7}$$

performing the integration over $\theta\in[0,2\pi]$, the over-completeness relation (6) finally reduced to the following moment problem (see Ref. 17 and references therein)

$$\int_0^R x^n\sigma(x)\mathrm{d}x=\rho(n), \quad 0<R\leqslant\infty. \tag{8}$$

B. A discussion about the modification of GK states

As it is observed in the preceding section, in the modification imposed by El Kinani and Daoud on the GKCSs, the parameter α has been *implicitly* considered as a constant, whose presence in the exponential factor of the introduced CSs preserves the temporal stability requirement (it is not now an integration *variable*). Meanwhile, for the temporal stability of the states in (4) one reads

$$e^{-i\hat{H}t}|z,\alpha\rangle=|z,\alpha'\rangle, \quad \alpha'=\alpha+\omega t. \tag{9}$$

Upon a closer inspection, one can see that the latter relation is indeed inconsistent with the resolution of the identity. By this, we mean that when α is considered as a constant parameter, it really labels any over-complete set of GKCSs, $\{|z,\alpha\rangle\}$. But the time evolution operator in (9) maps the over-complete set of states $\{|z,\alpha\rangle\}$ to another over-complete set $\{|z,\alpha'\rangle\}$. These are two *distinct sets of CSs*, each of them labeled with a specific α, if one considers the El Kinani-Daoud formalism. But the temporal stability precisely means that under the chosen dynamics, the time evolution of a CS remains CS, *of the same family*. In this manner, the states introduced in (4) are not of the Gazeau–Klauder type, exactly.

To overcome this problem, we redefine the resolution of the identity as follows:

$$\lim_{\Gamma\to\infty}\frac{1}{2\Gamma}\int_{-\Gamma}^{\Gamma}\mathrm{d}\alpha\int_0^R |z,\alpha\rangle\langle z,\alpha|\mathrm{d}\lambda(z)=\sum_{n=0}^{\infty}|n\rangle\langle n|=\hat{I}, \quad 0<R\leqslant\infty. \tag{10}$$

We can simplify the left-hand side (LHS) of (10) which interestingly led us exactly to the LHS of (6). Indeed we have

$$\int_0^R |z,\alpha\rangle\langle z,\alpha| \mathrm{d}\lambda(z) = \lim_{\Gamma\to\infty} \frac{1}{2\Gamma} \int_{-\Gamma}^{\Gamma} \mathrm{d}\alpha \int_0^R |z,\alpha\rangle\langle z,\alpha| \mathrm{d}\lambda(z), \tag{11}$$

where $\mathrm{d}\lambda(z)$ is determined as in (7).

By this fact we want to conclude that both of the over-complete collection of states $\{|z,\alpha\rangle\}$ and $\{|z,\alpha'\rangle\}$, with *fixed* α and $\alpha' \equiv \alpha + \omega t$, belong to a large set of over-complete states with an arbitrary α,

$$\{|z,\alpha\rangle, z \in C, -\infty \leqslant \alpha \leqslant \infty\}. \tag{12}$$

Note that by replacing $\alpha \in R$ with $-\infty \leqslant \alpha \leqslant \infty$ in (12) we want to emphasize that the parameter α is relaxed from the constraint of being fixed. But we will encounter other difficulty, that is the *variability* of α destroys the well definition of the "*operator valued function*" $f(\alpha,\hat{n})$, which will be introduced later in (14), in addition to the deformed annihilation and creation operators $A = af(\alpha,\hat{n})$ and $A^\dagger = f^\dagger(\alpha,\hat{n})a^\dagger$. To overcome this difficulty we may bridge the gap between these two situations: variability and constancy of α. We define the set of operators $A = af(\alpha,\hat{n})$, $A^\dagger = f^\dagger(\alpha,\hat{n})a^\dagger$ and any other operator which explicitly depends on α, in each *sector* (*subspace*) $\mathfrak{H}_\alpha$, labeled by a specific α parameter, of the whole Hilbert space $\mathfrak{H}$ which contains all GKCSs $\{|z,\alpha\rangle\}$. Indeed, the whole Hilbert space foliates by each α (remember the continuity of α). Moreover, the action of the time evolution operator on any state on a specific sector, transfer it to another sector, both belong to a large Hilbert space. So, *when we deal with the operators that depend on the* α *parameter, it should necessarily be fixed, while this is not the case when we are dealing with the states*.

We notify here that taking α as a *constant* in somewhere and as a *variable* in another may be confused and seems to be problematic. However, it is similar to the case which one encounters in the contexts of general relativity and quantum field theory, where the covariant formulation of the theory is required. In these cases one considers in the whole space with the dimension n, the spacelike Cauchy hypersurface Σ is defined with the dimension $n-1$. Fixing α is similar to the so-called gauge fixing (e.g., a section in time). For instance by gauge fixing one may calculate the evolution of metric in solving the *Einstein equation* in general relativity or the commutation relation in quantum field theory. So in the present case, although the operators are typically true operators over the whole Hilbert space $\mathfrak{H}$, but the calculations and their commutation relations are done with a fixed α in the subspace $\mathfrak{H}_\alpha$.

C. The relation between nonlinear CS and GKCS

On the other hand, the notion of nonlinear CSs introduced in Refs. 21–23 has attracted much attention in the recent decade, especially in quantum optics. The realization of a special class of these states has been proposed in the quantized motion of a trapped ion in a Paul trap.[22,24] The nonlinear CS defined as eigenvector of the deformed annihilation operator has the following expansion over the Fock space:

$$|z\rangle_f = \mathcal{N}_f(|z|^2)^{-1/2} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{n![f(n)]!}} |n\rangle, \quad [f(n)]! \doteq f(n)f(n-1)f(n-2)\cdots f(1), \tag{13}$$

where $f(0) \equiv 1$ and $\mathcal{N}_f$ in some appropriate normalization constant may be determined. We recall that by replacing $f(n)$ with $1/f(n)$ in the relation (13) one immediately gets the nonlinear CSs introduced in Ref. 15. We have called these states as the dual family of nonlinear CSs of Man'ko's type.[16]

Following the formalism given in Ref. 8 for the states expressed in (4) one may obtain

$$f_{\mathrm{GK}}(\alpha,\hat{n}) = e^{i\alpha(\hat{e}_n-\hat{e}_{n-1})}\sqrt{\frac{\rho(\hat{n})}{\hat{n}\rho(\hat{n}-1)}}, \quad \alpha, \quad \text{being fixed.} \tag{14}$$

where we have chosen the notation $\hat{e}_n \equiv \rho(\hat{n})/\rho(\hat{n}-1)$.

Moreover, we gain the opportunity to find raising and lowering operators in a safe manner

$$A_{\mathrm{GK}} = af_{\mathrm{GK}}(\alpha,\hat{n}), \quad A_{\mathrm{GK}}^{\dagger} = f_{\mathrm{GK}}^{\dagger}(\alpha,\hat{n})a^{\dagger}. \tag{15}$$

It is easy to verify that $A_{\mathrm{GK}}|z,\alpha\rangle = z|z,\alpha\rangle$. Obviously the commutation relation between these two (f-deformed) ladder operators obeys[23] the relation

$$\begin{aligned}[A_{\mathrm{GK}},A_{\mathrm{GK}}^{\dagger}] &= \frac{\rho(\hat{n}+1)}{\rho(\hat{n})} - \frac{\rho(\hat{n})}{\rho(\hat{n}-1)} \\ &= \hat{e}_{n+1} - \hat{e}_n. \end{aligned} \tag{16}$$

The special case $\rho(n)=n!$ recovers the standard bosonic commutation relation $[a,a^{\dagger}]=\hat{I}$. Using the "*normal-ordered*" form of the Hamiltonian as in Ref. 8 and taking $\hbar=1=\omega$, for the Hamiltonian of GKCSs we get

$$\hat{H}_{\mathrm{GK}} \equiv \hat{\mathcal{H}} = A_{\mathrm{GK}}^{\dagger}A_{\mathrm{GK}} = \hat{n}|f_{\mathrm{GK}}(\alpha,\hat{n})|^2 = \frac{\rho(\hat{n})}{\rho(\hat{n}-1)} = \hat{e}_n \tag{17}$$

which clearly shows that the dynamics of the system is independent of α.

III. THE DUAL FAMILY OF GKCS AS THE TEMPORALLY STABLE CS OF THE DUAL OF KPS CS

The KPS coherent states, introduced by Klauder, Penson, and Sixdeniers[17] have the following form:

$$|z\rangle_{\mathrm{KPS}} = \mathcal{N}_{\mathrm{KPS}}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{\rho(n)}}|n\rangle, \quad z\in\mathbb{C}. \tag{18}$$

As demonstrated in Ref. 8, all of the various sets of CSs introduced in Ref. 17, constructed by diverse $\rho(n)$'s, are nonlinear CSs in nature. Also the appropriate nonlinearity function $f(n)$ as well as the deformed annihilation, creation, and Hamiltonian operators were introduced there. Especially, it is found that $\rho(n)$ in (18) must satisfy the relation $\rho(n)=[nf^2(n)]!=[e_n]!$, where e_n's are the eigenvalues of the associated factorized Hamiltonian. Taking into account the above results, comparing (18) with GKCS in (4) and keeping $\hbar$ and ω in the formulas, one may conclude that

$$e^{-i(\alpha/\hbar\omega)\hat{\mathcal{H}}}|z\rangle_{\mathrm{KPS}} = |z,\alpha\rangle, \quad 0\neq\alpha\in\mathbb{R}, \quad z\in\mathbb{C}. \tag{19}$$

While $|z\rangle_{\mathrm{KPS}}$ states are not temporally stable, $|z,\alpha\rangle$ states enjoy this property.

Now we may outline a relatively evident physical meaning to the arbitrary real α in (4) or (19) as $\alpha\equiv\omega t$, where by t we mean the time that the operator acts on the KPS coherent states. It should be mentioned that, in a sense this interpretation has been presented for the GKCSs in a compact form.[10] If so, then $|z,\alpha\rangle$ can be considered as the evolution of $|z\rangle_{\mathrm{KPS}}$. Therefore in a more general framework, we claim that the action of the evolution type operator

$$\hat{S}(\alpha) = e^{-i(\alpha/\hbar\omega)\hat{\mathcal{H}}}, \quad \hat{S}\hat{S}^{\dagger} = \hat{S}^{\dagger}\hat{S} = \hat{I}, \quad 0\neq\alpha\in\mathbb{R}, \tag{20}$$

on any nontemporally stable CSs, makes it temporally stable CSs. So, $\hat{S}(\alpha)$ *is a nice operator which transfers any generalized CS to a situation which it restores the temporal stability property*. Here, we stress the fact that in (20) the Hamiltonian, $\hat{\mathcal{H}}$, should satisfy $\hat{\mathcal{H}}|n\rangle=\hbar\omega e_n|n\rangle$.

At this point we are ready to find a suitable way to define the dual family of GKCS. First, we note that the dual family of KPS CSs introduced in (18) has already been established in Ref. 8, via the following exact form:

$$|\widetilde{z}\rangle_{\mathrm{KPS}} = \widetilde{\mathcal{N}}_{\mathrm{KPS}}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{\mu(n)}}|n\rangle, \quad z \in \mathbb{C}, \tag{21}$$

where

$$\mu(n) \equiv \widetilde{\rho}(n) = \frac{(n\,!\,)^2}{\rho(n)}. \tag{22}$$

Hereafter, the sign "tilde" over the operators and states, assign them to the corresponding dual operators and states, respectively. For instance $\widetilde{\rho}(n)$ is dual correspondence of $\rho(n)$. Equation (22) expresses the relation between KPS and the associated dual CSs, in a simple way. Obviously $\mathcal{N}_{\mathrm{KPS}}$ and $\widetilde{\mathcal{N}}_{\mathrm{KPS}}$ in (18) and (21) are the normalization constants obtained. Employing the formalism led to (19), for "the dual of KPS states" in (21) naturally results in the following superposition of Fock states for the dual family of GKCSs (we shall refer to them as DGKCS):

$$\begin{aligned}\widetilde{\hat{S}}(\alpha)|\widetilde{z}\rangle_{\mathrm{KPS}} &= e^{-i(\alpha/\hbar\omega)\widetilde{\hat{H}}}|\widetilde{z}\rangle_{\mathrm{KPS}} \\ &= \widetilde{\mathcal{N}}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n e^{-i\alpha\varepsilon_n}}{\sqrt{\mu(n)}}|n\rangle = |\widetilde{z,\alpha}\rangle, \quad z \in \mathbb{C}, \quad 0 \neq \alpha \in \mathbb{R},\end{aligned} \tag{23}$$

where $\widetilde{\mathcal{N}}=\widetilde{\mathcal{N}}_{\mathrm{KPS}}$ [because of the unitarity of $\hat{S}(\alpha)$, which preserves the norm] is given by

$$\widetilde{\mathcal{N}}(|z|^2) = \sum_{n=0}^{\infty}\frac{|z|^{2n}}{\mu(n)}. \tag{24}$$

The special case of $\varepsilon_n=n$ in (23) recovers the canonical CSs, correctly. Note also that setting $\alpha=\omega t$ in (20) and (23) reduces the operators $\hat{S}(\alpha)$ and $\widetilde{\hat{S}}(\alpha)$ to the well-known *time evolution operators* $\mathcal{U}(t)$ and $\widetilde{\mathcal{U}}(t)$, respectively. The case $\alpha=0$ for the states in (4) and (23) recovers KPS and the corresponding dual CSs (which certainly are not temporally stable), respectively. The overlap between two states of the DGKCSs takes the following form:

$$\langle\widetilde{z,\alpha}|\widetilde{z',\alpha'}\rangle = \widetilde{\mathcal{N}}(|z|^2)^{-1/2}\widetilde{\mathcal{N}}(|z'|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{(z^*z')^n e^{-i\varepsilon_n(-\alpha+\alpha')}}{\mu(n)}, \tag{25}$$

which means that the states are essentially nonorthogonal.

It should be noticed that the produced states [$|\widetilde{z,\alpha}\rangle$ introduced in (23)] form a *new class of generalized CSs*, essentially different from $|z,\alpha\rangle$ in (4). Also, it is apparent that for our introduction of DGKCSs, we have obtained directly the analytic representation of DGKCS for any arbitrary quantum mechanical system. Using the formalism proposed in Ref. 8, one can deduce the nonlinearity function for the dual states in (23) as

$$\widetilde{f}_{\mathrm{GK}}(\alpha,\hat{n}) = e^{i\alpha(\hat{\varepsilon}_n-\hat{\varepsilon}_{n-1})}\sqrt{\frac{\mu(\hat{n})}{\hat{n}\mu(\hat{n}-1)}}, \quad \alpha \text{ being fixed}, \tag{26}$$

where we have used the notation $\hat{\varepsilon}_n \equiv \mu(\hat{n})/\mu(\hat{n}-1)$. Therefore, analogous to (17) the deformed annihilation and creation operators of the dual system may be expressed explicitly as

$$\widetilde{A}_{\mathrm{GK}} = a e^{i\alpha(\hat{\varepsilon}_n - \hat{\varepsilon}_{n-1})} \sqrt{\frac{\mu(\hat{n})}{\hat{n}\mu(\hat{n}-1)}}, \tag{27}$$

$$\widetilde{A}^{\dagger}_{\mathrm{GK}} = e^{-i\alpha(\hat{\varepsilon}_n - \hat{\varepsilon}_{n-1})} \sqrt{\frac{\mu(\hat{n})}{\hat{n}\mu(\hat{n}-1)}} a^{\dagger}. \tag{28}$$

The normal-ordered Hamiltonian of *dual oscillator* in the same manner stated in (17) is

$$\widetilde{\hat{\mathcal{H}}}_{\mathrm{GK}} \equiv \widetilde{\hat{\mathcal{H}}} = \widetilde{A}^{\dagger}_{\mathrm{GK}} \widetilde{A}_{\mathrm{GK}} = \frac{\mu(\hat{n})}{\mu(\hat{n}-1)} = \frac{\hat{n}^2}{\hat{e}_n}, \tag{29}$$

which is again independent of α. As a result

$$\widetilde{\hat{\mathcal{H}}}|n\rangle = \widetilde{\mathcal{E}}_n|n\rangle \equiv \hbar\omega\varepsilon_n|n\rangle = \varepsilon_n|n\rangle, \quad \varepsilon_n \equiv \widetilde{e}_n = \frac{n^2}{e_n}, \tag{30}$$

where again we have used the units $\omega = 1 = \hbar$. The first equation in (30) illustrates clearly the relation between the eigenvalues of the two mutual dual systems. Also, the DGKCSs are required to satisfy the following inequalities:

$$0 = \varepsilon_0 < \varepsilon_1 < \varepsilon_2 < \cdots < \varepsilon_n < \varepsilon_{n+1} < \cdots, \tag{31}$$

the same as that of e_n's in (3). At this point a question may have arisen: to what extent one may be sure that the DGKCSs in (23) are of the Gazeau–Klauder type? Let us briefly investigate this question.

(1) *Continuity of labeling*, it is clearly satisfied.
(2) *Resolution of unity*,

$$\int_0^{\widetilde{R}} |\widetilde{z,\alpha}\rangle\langle\widetilde{z,\alpha}| \mathrm{d}\lambda(z) = \sum_{n=0}^{\infty} |n\rangle\langle n| = \hat{I}, \quad 0 < \widetilde{R} \leqslant \infty, \tag{32}$$

where the measure $\mathrm{d}\lambda(z)$ is defined as in (7). The radius of convergence of DGKCS is determined as $\widetilde{R} = \lim_{n\to\infty} \sqrt[n]{\mu(n)}$ and $\mu(n)$ is defined as positive constants assumed to be appearing as moments of a probability distribution. Similar calculations that led to the result in (8) are needed to arrive at the new moment problem associated with the DGKCSs,

$$\mu(n) \equiv \widetilde{\rho}(n) = \int_0^{\widetilde{R}} x^n \widetilde{\sigma}(x) \mathrm{d}x, \quad 0 < \widetilde{R} \leqslant \infty, \tag{33}$$

which must be solved with the help of the previously mentioned techniques. As for the GKCSs, we assume that $\mu(0) = 1$ and $\mu(n) < \infty$ for all n.
(3) *Temporal stability*, using (23) and the relevant Hamiltonian (30) gives us

$$\begin{aligned} e^{-i\widetilde{\hat{\mathcal{H}}}t}|\widetilde{z,\alpha}\rangle &= \widetilde{\mathcal{N}}(|z|^2)^{-1/2} \sum_{n=0}^{\infty} \frac{z^n e^{-i\varepsilon_n(\alpha+\omega t)}}{\sqrt{\mu(n)}} |n\rangle \\ &= |z, \widetilde{\alpha+\omega t}\rangle, \end{aligned} \tag{34}$$

which illustrates that DGKCSs remain coherent, as time goes on.
(4) *Action identity:* from the condition (iii) we find that the time evolution of a CS is a map given by $(z,\alpha) \mapsto (z, \alpha+\omega t)$. The new states $|\widetilde{z,\alpha}\rangle$ satisfy the relation

$$\langle\widetilde{z,\alpha}|\widetilde{\hat{\mathcal{H}}}|\widetilde{z,\alpha}\rangle = \omega|z|^2, \tag{35}$$

in consistence with Gazeau–Klauder's criteria, which is the so-called action identity. This is a strong requirement which uniquely specifies the weights $\{\mu(n)\}_{n\geqslant 0}$ in the denominator of the expansion coefficients of the DGKCS. Using (23), (24), and (30) on the LHS of (35) we obtain

$$\sum_{n=0}^{\infty}\frac{\varepsilon_n|z|^{2n}}{\mu(n)} = |z|^2\sum_{n=0}^{\infty}\frac{|z|^{2n}}{\mu(n)}, \tag{36}$$

by which we arrive at the following condition;

$$\varepsilon_n = \frac{\mu(n)}{\mu(n-1)}. \tag{37}$$

By conventional choice of $\mu(0)\equiv 1$, we thus deduce

$$\mu(n) = \varepsilon_n\varepsilon_{n-1}\cdots\varepsilon_1 = \Pi_{k=1}^{n}\varepsilon_k \equiv [\varepsilon_n]\,!\,. \tag{38}$$

So, we have established that the DGKCSs in (23) are exactly of the Gazeau–Klauder type. It should be noted that the same arguments we presented in Sec. II B about the resolution of the identity (and the integration procedures), the α parameter (the states and the operators which depend on it) and the corresponding Hilbert spaces must also be considered for the DGKCSs have been built in the present section.

A. The introduction of temporally stable nonlinear CS

Let us now outline the main idea in a general framework. It is believed that the property of the temporal stability is intrinsic to the *harmonic oscillator* and the systems which are *unitarily equivalent* to it.[25] But in what follows we shall demonstrate how this important property can be restored by a redefinition of any generalized CSs which can be classified in the nonlinear CSs category. Recall that the nonlinear CSs we introduced in (13) do not generally have the temporal stability property.[23] So, by considering the results obtained in the previous work[8] and the above explanations, we want to proceed and introduce generally the notion of "*temporally stable nonlinear CSs*" as

$$|z,\alpha\rangle_f = \mathcal{N}_f(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n e^{-i\alpha e_n}}{\sqrt{n!}[f(n)]!}|n\rangle, \quad e_n = nf^2(n), \quad 0\neq\alpha\in\mathbb{R}, \quad z\in\mathbb{C}. \tag{39}$$

We can also define the dual of the latter states by the following expression:

$$|\widetilde{z,\alpha}\rangle_f = \widetilde{\mathcal{N}}_f(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n[f(n)]\,!\,e^{-i\alpha\varepsilon_n}}{\sqrt{n!}}|n\rangle, \quad \varepsilon_n = \frac{n}{f^2(n)}, \quad 0\neq\alpha\in\mathbb{R}, \quad z\in\mathbb{C}, \tag{40}$$

which are indeed the temporally stable version of the nonlinear CSs that have been introduced in Ref. 15. In both sets of the CSs given by (39) and (40), α is a real constant and the normalization factors are independent of α. Setting $\alpha=0$ in (39) and (40), we recover the old form of Man'ko's and Roy's nonlinear CSs, respectively, which clearly are not temporally stable.

B. Temporally stable CS of SU (1,1) group

An instructive example of the families of nonlinear CSs is provided by the Gilmore–Perelomov (GP)[26] and Barut–Girardello (BG) CSs[27], defined for the discrete series representations of the group SU (1,1). Using the results of Ref. 8 for GP states, and then imposing the proposed

formalism on them, the "*temporally stable CSs of GP type associated with SU* (1,1) *group*" can be defined as

$$|z,\alpha\rangle_{\mathrm{GP}}^{\mathrm{SU}(1,1)}=\mathcal{N}_{\mathrm{GP}}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n e^{-i\alpha[n/(n+2\kappa-1)]}}{[n\,!\,/\Gamma(n+2\kappa)]^{1/2}}|n\rangle,\quad |z|<1, \tag{41}$$

where $\mathcal{N}_{\mathrm{GP}}$ is a normalization factor and the parameter $\kappa=1,3/2,2,5/2,\ldots$, labels the SU (1,1) representation being used. Analogously, applying the presented extension to the BG type of CSs, gives immediately "*temporally stable CSs of BG type associated with SU* (1,1) *group*" as follows:

$$|z,\alpha\rangle_{\mathrm{BG}}^{\mathrm{SU}(1,1)}\equiv|\widetilde{z,\alpha}\rangle_{\mathrm{GP}}^{\mathrm{SU}(1,1)}=\mathcal{N}_{\mathrm{BG}}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n e^{-i\alpha n(n+2\kappa-1)}}{[n\,!\,\Gamma(n+2\kappa)]^{1/2}}|n\rangle,\quad z\in\mathbb{C}, \tag{42}$$

where once more, $\mathcal{N}_{\mathrm{BG}}$ is chosen by normalization of the states.

C. Temporally stable CS of Penson–Solomon type and its dual

As established in Ref. 8, the generalized CSs introduced by Penson and Solomon[18] as

$$|q,z\rangle=\mathcal{N}(q,|z|^2)\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{\sqrt{n!}}z^n|n\rangle, \tag{43}$$

are also nonlinear with $f(n)=q^{(1-n)}$ and therefore the factorized Hamiltonian reads $\hat{\mathcal{H}}_{\mathrm{PS}}=\hat{n}q^{2(1-\hat{n})}$. It is stated in Ref. 18 that under the action of $\exp(-i\hat{H}t)$ these states are temporally stable, where the Hamiltonian $\hat{H}=a^{\dagger}a=\hat{n}$ expresses the (shifted) quantum harmonic oscillator with the corresponding canonical CS. Seemingly to verify the invariance under time evolution operator, it may be more realistic to act the operator, $\exp(-i\hat{\mathcal{H}}_{\mathrm{PS}}t)$, on the PS states in (43), where $\hat{\mathcal{H}}_{\mathrm{PS}}|n\rangle=\hat{n}q^{2(1-\hat{n})}|n\rangle=nq^{2(1-n)}|n\rangle$. Clearly by such proposition these states are not temporally stable. But the presented formalism in this paper allows one to construct the temporally stable CS of PS type as follows:

$$|q,z,\alpha\rangle\equiv e^{-i(\alpha/\hbar\omega)\hat{\mathcal{H}}_{\mathrm{PS}}}|q,z\rangle=\mathcal{N}_{\mathrm{PS}}(q,|z|^2)\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{\sqrt{n!}}e^{-i\alpha e_n}z^n|n\rangle, \tag{44}$$

where $e_n=nq^{2(1-n)}$.

We have already introduced the dual family of the PS states of Eq. (43) $\widetilde{|q,z\rangle}$ in Ref. 8. So the temporally stable dual of these states may also be obtained immediately as

$$\widetilde{|q,z,\alpha\rangle}\equiv e^{-i(\alpha/\hbar\omega)\tilde{\hat{\mathcal{H}}}_{\mathrm{PS}}}\widetilde{|q,z\rangle}=\tilde{\mathcal{N}}_{\mathrm{PS}}(q,|z|^2)\sum_{n=0}^{\infty}\frac{q^{-n(n-1)/2}}{\sqrt{n!}}e^{-i\alpha\varepsilon_n}z^n|n\rangle, \tag{45}$$

where $\varepsilon_n=n/q^{2(1-n)}$.

D. Some remarkable points

We end this section with some remarkable points.

(i) First, one can prove that the f-deformed annihilation operator given by (14) is just the same as the one derived earlier in Ref. 10, denoted by $a(\alpha)$,

$$a(\alpha)=e^{-i\alpha\hat{H}(\hat{n})/\hbar\omega}\breve{a}e^{i\alpha\hat{H}(\hat{n})/\hbar\omega}, \tag{46}$$

or in terms of the introduced evolution operator $\hat{S}(\alpha)$,

$$a(\alpha) = \hat{S}(\alpha)\check{a}\hat{S}^{\dagger}(\alpha). \tag{47}$$

It must be noticed that $\check{a}$ and its adjoint $\check{a}^{\dagger}$ in Eqs. (46) and (47) have been defined as follows:

$$\check{a}|n\rangle = \sqrt{e_n}|n-1\rangle, \quad \check{a}^{\dagger}|n\rangle = \sqrt{e_{n+1}}|n+1\rangle. \tag{48}$$

Now using the relations $f^{\dagger}(\hat{n})a = af^{\dagger}(\hat{n}-1)$ and $\hat{n}a = a(\hat{n}-1)$, we have

$$e^{-i\alpha\hat{H}(\hat{n})/\hbar\omega}\check{a} = \check{a}e^{-i\alpha\hat{H}(\hat{n}-1)/\hbar\omega} = \check{a}e^{-i\alpha\hat{e}_{n-1}}, \tag{49}$$

where we have used Eq. (2) in the last step. Upon replacing (49) on the right-hand side (RHS) of (46) and taking into account (2) we are readily led to the equality $a(\alpha) \equiv A_{\mathrm{GK}} = af_{\mathrm{GK}}(\alpha, \hat{n})$.

(ii) In light of the presented explanations the annihilation operator eigenstate (algebraic definition) for GKCSs and DGKCS are such that

$$A_{\mathrm{GK}}|z,\alpha\rangle = z|z,\alpha\rangle, \quad \widetilde{A}_{\mathrm{GK}}|\widetilde{z,\alpha}\rangle = z|\widetilde{z,\alpha}\rangle. \tag{50}$$

The deformed annihilation and creation operators $\widetilde{A}_{\mathrm{GK}}$ and $\widetilde{A}^{\dagger}_{\mathrm{GK}}$ of the dual oscillator algebra, satisfy the following eigenvector equations:

$$\widetilde{A}_{\mathrm{GK}}|n\rangle = \sqrt{\varepsilon_n}e^{i\alpha(\varepsilon_n-\varepsilon_{n-1})}|n-1\rangle, \tag{51}$$

$$\widetilde{A}^{\dagger}_{\mathrm{GK}}|n\rangle = \sqrt{\varepsilon_{n+1}}e^{i\alpha(\varepsilon_{n+1}-\varepsilon_n)}|n+1\rangle, \tag{52}$$

$$[\widetilde{A}_{\mathrm{GK}}, \widetilde{A}^{\dagger}_{\mathrm{GK}}]|n\rangle = (\varepsilon_{n+1}-\varepsilon_n)|n\rangle, \tag{53}$$

$$[\widetilde{A}_{\mathrm{GK}}, \hat{n}] = \widetilde{A}_{\mathrm{GK}}, \quad [\widetilde{A}^{\dagger}_{\mathrm{GK}}, \hat{n}] = -\widetilde{A}^{\dagger}_{\mathrm{GK}}. \tag{54}$$

Upon looking on the actions defined in (51) and (52) one can interpret $\widetilde{A}_{\mathrm{GK}}$ and $\widetilde{A}^{\dagger}_{\mathrm{GK}}$ as the operators which correctly annihilate and create one quanta of *deformed photon*, respectively. A closer look at the basis of the involved Hilbert space $\mathfrak{H}_{\alpha}$ in each over-complete set $\{|z,\alpha\rangle\}$, shows that it is spanned by the vectors

$$|n,\alpha\rangle = \frac{(\widetilde{A}^{\dagger}_{\mathrm{GK}})^n e^{i\alpha\varepsilon_n}}{\sqrt{[e_n]!}}|0\rangle \equiv |n\rangle, \quad \widetilde{A}_{\mathrm{GK}}|0\rangle = 0. \tag{55}$$

Moreover, we have omitted the α parameter from the basis for simplicity. At last, we are able to introduce the generators of the deformed oscillator algebra[28] of Gazeau–Klauder and the corresponding dual family as $\{A_{\mathrm{GK}}, A^{\dagger}_{\mathrm{GK}}, \hat{\mathcal{H}}\}$ and $\{\widetilde{A}_{\mathrm{GK}}, \widetilde{A}^{\dagger}_{\mathrm{GK}}, \widetilde{\hat{\mathcal{H}}}\}$, respectively.

(iii) One may expect that the inequalities for ε_n given in (31) corresponding to any solvable system do not hold for DGKCSs [the restriction which also exists in (3) for GKCSs]. This generally may be true, but fortunately many cases—if not all—such as all physical systems considered in this paper are of this sort (both of ε_n and e_n are strictly increasing). So it must be mentioned that before making use of our formalism for dual states associated with any set of GKCSs one should be sure about the condition (31). If both of the inequalities in (3) and (31) hold simultaneously, then one has

$$1 > \frac{e_n}{e_{n+1}} > \frac{n^2}{(n+1)^2} \tag{56}$$

which can be expressed in terms of the nonlinearity function $f_{\mathrm{GK}}(\alpha, \hat{n})$ as follows:

$$\sqrt{\frac{n+1}{n}} > \sqrt{\left|\frac{f_{\mathrm{GK}}(\alpha,\hat{n})}{f_{\mathrm{GK}}(\alpha,\hat{n}+1)}\right|^2} > \sqrt{\frac{n}{n+1}}, \tag{57}$$

for all $n>0$.

(iv) As it may be clear, when one wants to work with one of the dual pairs singly, they can be considered on their relevant domains. But to deal with their mutual relation, calculations must be done only in the intersection of the domains of the pair of CSs (in this case GKCSs and DGKCSs); i.e., generally on a unit disk, unless the CS is defined on a finite dimensional Hilbert space. As we shall see later, the latter is the case for Morse potential.

(v) Finally, the probability distribution for the DGKCSs is defined as

$$\widetilde{\mathbf{P}}(n) = |\langle n|\widetilde{z,\alpha}\rangle|^2 = \widetilde{\mathcal{N}}(|z|^2)^{-1}\frac{|z|^{2n}}{\mu(n)}, \tag{58}$$

which is independent of the α parameter.

We terminate this section with recalling that there exists also a set of equations such as (51)–(54) related to GKCSs which may be obtained just by replacing $\widetilde{A}_{\mathrm{GK}}$, $\widetilde{A}^{\dagger}_{\mathrm{GK}}$, and ε_n with A_{GK}, $A^{\dagger}_{\mathrm{GK}}$, and e_n, respectively. The latter have been already derived by applying SUSYQM techniques,[12] but rederivation of them are very easy by our formalism. According to their results, the one-dimensional SUSYQM provides a mathematical tool to define ladder operators for an exactly solvable potential. But the authors did not express the *explicit* form of the ladder operators, and only the concerning actions were expressed there. Therefore besides the simplicity of our method, it is more complete in the sense that as we found the *explicit* form of the raising and lowering operators in terms of the standard bosonic creation and annihilation operators and the photon number (intensity of the field) have been found easily [see Eqs. (15), (27), and (28)].

IV. DISPLACEMENT OPERATORS ASSOCIATED WITH GKCS AND THE CORRESPONDING DUAL FAMILY

Now that we introduced the explicit form of the deformed annihilation operator and hence the annihilation operator definition for GKCSs and DGKCSs according to Eqs. (50), we are in the position to extract the CSs of Klauder–Perelomov type for an arbitrary quantum mechanical system. For this purpose, we introduce the following auxiliary operators related to GKCSs:

$$B_{\mathrm{GK}} = a\frac{1}{f_{\mathrm{GK}}(-\alpha,\hat{n})}, \quad B^{\dagger}_{\mathrm{GK}} = \frac{1}{f^{\dagger}_{\mathrm{GK}}(-\alpha,\hat{n})}a^{\dagger}, \tag{59}$$

and those for the dual families DGKCSs,

$$\widetilde{B}_{\mathrm{GK}} = a\frac{1}{\widetilde{f}_{\mathrm{GK}}(-\alpha,\hat{n})}, \quad \widetilde{B}^{\dagger}_{\mathrm{GK}} = \frac{1}{\widetilde{f}^{\dagger}_{\mathrm{GK}}(-\alpha,\hat{n})}a^{\dagger}. \tag{60}$$

Notice that the minus sign in the argument of the f-function is needed in both cases, since only in such cases we have $f^{\dagger}_{\mathrm{GK}}(-\alpha,\hat{n}) = f_{\mathrm{GK}}(\alpha,\hat{n})$.

The f-deformed operators given by (59) and (60) are canonically conjugate of the f-deformed creation and annihilation operators $(A_{\mathrm{GK}},A^{\dagger}_{\mathrm{GK}})$ and $(\widetilde{A}_{\mathrm{GK}},\widetilde{A}^{\dagger}_{\mathrm{GK}})$, respectively; i.e., they satisfy the algebras $[A_{\mathrm{GK}},B^{\dagger}_{\mathrm{GK}}]=[B_{\mathrm{GK}},A^{\dagger}_{\mathrm{GK}}]=\hat{I}$ and $[\widetilde{A}_{\mathrm{GK}},\widetilde{B}^{\dagger}_{\mathrm{GK}}]=[\widetilde{B}_{\mathrm{GK}},\widetilde{A}^{\dagger}_{\mathrm{GK}}]=\hat{I}$, respectively. Now we have all mathematical tools to construct the displacement operators for GKCS,

$$D_{\mathrm{GK}}(z,\alpha) = \exp(zB^{\dagger}_{\mathrm{GK}} - z^{*}A_{\mathrm{GK}}), \tag{61}$$

and for DGKCS,

$$\widetilde{D}_{\mathrm{GK}}(z,\alpha)=\exp(z\widetilde{B}^{\dagger}_{\mathrm{GK}}-z^{*}\widetilde{A}_{\mathrm{GK}}). \tag{62}$$

The actions of $D_{\mathrm{GK}}(z,\alpha)$ and $\widetilde{D}_{GK}(z,\alpha)$ on the vacuum state $|0\rangle$ yield the GKCSs and DGKCS, up to some normalization constant, respectively, as we demand. From the group theoretical point of view, one can see that the sets $\{A_{\mathrm{GK}},B^{\dagger}_{\mathrm{GK}},B^{\dagger}_{\mathrm{GK}},A_{\mathrm{GK}},\hat{I}\}$ and $\{\widetilde{A}_{\mathrm{GK}},\widetilde{B}^{\dagger}_{\mathrm{GK}},\widetilde{B}^{\dagger}_{\mathrm{GK}}\widetilde{A}_{\mathrm{GK}},\hat{I}\}$, which are, respectively, associated with GKCSs and DGKCSs, form the Lie algebra h_4 and the corresponding Lie group is the well-known Weyl–Heisenberg (WH) group. Also, the action of the latter operators in (61) and (62) on the vacuum state are the orbits of the projective *nonunitary* representations of the WH group.[16] It must be understood that as we pointed out earlier, we have applied neither the formalism in Ref. 16 nor the equivalent formalism of Ref. 15 for constructing the dual states, since the states obtained from the earlier formalisms were not completely consistent with the Gazeau–Klauder criteria. Indeed, we proposed a way, through viewing the GKCSs $|z,\alpha\rangle$ and its dual pair $|\widetilde{z,\alpha}\rangle$ as generalization of KPS nonlinear CSs $|z\rangle_{\mathrm{KPS}}$ and its dual $|\tilde{z}\rangle_{\mathrm{KPS}}$ to the two distinct temporally stable CSs, respectively. Speaking otherwise, the operators introduced in (61) and (62) do not have the relation $\widetilde{D}_{\mathrm{GK}}(-z,\alpha)=D_{\mathrm{GK}}(z,\alpha)=[D_{\mathrm{GK}}(z,\alpha)^{-1}]^{\dagger}$, which is the characteristic of the earlier formalisms. To this end, it is possible to build the following displacement type operators, $V_{\mathrm{GK}}(z,\alpha)=\exp(zA^{\dagger}_{\mathrm{GK}}-z^{*}B_{\mathrm{GK}})$ for GKCSs, and in a similar manner, $\widetilde{V}_{\mathrm{GK}}(z,\alpha)=\exp(z\widetilde{A}^{\dagger}_{\mathrm{GK}}-z^{*}\widetilde{B}_{\mathrm{GK}})$ for DGKCSs, whose actions on the vacuum state yield two new sets of states. But it is easy to investigate that none of them can be classified in the Gazeau–Klauder CSs.

V. THE CONSTRUCTION OF EVEN, ODD AND SCHRÖDINGER CAT COHERENT STATES FROM THE INTRODUCED DGKCS

Various superpositions of CSs may result in different nonclassical states of light. Recently, there has been much interest in the construction as well as generation of these states, in the regard of their applications in the context of quantum optics. Their different characteristics are due to the various quantum interference between summands. As an example, the even and odd CSs associated with canonical CSs as well as other classes of generalized CSs such as nonlinear CSs extensively studied in the literature[29] exhibit nonclassical features, such as squeezing, sub-Poissonian statistics (antibunching), and oscillatory number distribution. The symmetric (antisymmetric) combinations of GKCSs have been introduced in Ref. 11. Similarly, using the unnormalized DGKCSs we are led to the even (odd) CSs denoted by + (−),

$$\begin{aligned}|\widetilde{z,\alpha}\rangle_{\pm}&=\widetilde{\mathcal{N}'}_{\pm}(|z|^2)^{-1/2}(|\widetilde{z,\alpha}\rangle\pm|\widetilde{-z,\alpha}\rangle)\\&=\widetilde{\mathcal{N}'}_{\pm}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{e^{-i\alpha\varepsilon_n}[z^n\pm(-z)^n]}{\sqrt{\mu(n)}}|n\rangle,\end{aligned} \tag{63}$$

where $z\in\mathbb{C}$ and $\alpha\in\mathbb{R}$. For the normalization factors we get

$$\widetilde{N'}_{\pm}(|z|^2)=2\left(\sum_{n=0}^{\infty}\frac{|z|^{2n}}{\mu(n)}+\sum_{n=0}^{\infty}\frac{(-1)^n|z|^{2n}}{\mu(n)}\right)^{-1}. \tag{64}$$

A few simplifications imposed on the states in (63) will clarify the name even (odd) associated with these states

$$|\widetilde{z,\alpha}\rangle_{+}=\widetilde{\mathcal{N}'}_{+}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^{2n}e^{-i\alpha\varepsilon_{2n}}}{\sqrt{\mu(2n)}}|2n\rangle, \tag{65}$$

$$|\widetilde{z,\alpha}\rangle_- = \widetilde{\mathcal{N}'}_-(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^{2n+1}e^{-i\alpha\varepsilon_{2n+1}}}{\sqrt{\mu(2n+1)}}|2n+1\rangle. \tag{66}$$

Finally the (±) states in (65) and (66) satisfy the following eigenvalue equations:

$$(\tilde{A}_{\mathrm{GK}})^2|\widetilde{z,\alpha}\rangle_\pm = z^2|\widetilde{z,\alpha}\rangle_\pm. \tag{67}$$

The probability distributions for the even-DGKCS (+) and odd-DGKCS (−) are derived as

$$\tilde{\mathbf{P}}_\pm(n) = |\langle n|\widetilde{z,\alpha}\rangle_\pm|^2 = \widetilde{\mathcal{N}'}_\pm(|z|^2)^{-1}\frac{|z|^{2n}}{\mu(n)}, \tag{68}$$

which clearly are independent of the α parameter.

Now, we pay attention to another specific superposition of the DGKCSs $|\widetilde{z,\alpha}\rangle$, by which we may obtain the *real* (+) and *imaginary* (−) *Schrödinger cat states as*

$$|\widetilde{z,\alpha}\rangle_\pm^{\mathrm{Cat}} = \widetilde{\mathcal{N}''}_\pm(|z|^2)^{-1/2}(|\widetilde{z,\alpha}\rangle \pm |\widetilde{z^*,\alpha}\rangle), \tag{69}$$

where z^* is the complex conjugate of z. Inserting $z=re^{i\theta}$ in the last equations give us the following explicit forms:

$$|\widetilde{z,\alpha}\rangle_+^{\mathrm{Cat}} = \widetilde{\mathcal{N}''}_+(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{r^n\cos(n\theta)}{\sqrt{\mu(n)}}e^{-i\alpha\varepsilon_n}|n\rangle \tag{70}$$

and

$$|\widetilde{z,\alpha}\rangle_-^{\mathrm{Cat}} = \widetilde{\mathcal{N}''}_-(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{r^{n+1}\sin[(n+1)\theta]}{\sqrt{\mu(n+1)}}e^{-i\alpha\varepsilon_{n+1}}|n+1\rangle, \tag{71}$$

where the normalization constants would be

$$\widetilde{\mathcal{N}''}_+(|z|^2) = \sum_{n=0}^{\infty}\frac{r^{2n}\cos^2(n\theta)}{\mu(n)} \tag{72}$$

and

$$\widetilde{\mathcal{N}''}_-(|z|^2) = \sum_{n=0}^{\infty}\frac{r^{2(n+1)}\sin^2[(n+1)\theta]}{\mu(n+1)}. \tag{73}$$

The probability distribution for the real (+) and imaginary (−) Schrödinger cat CSs in (70) and (71) can be calculated as

$$\tilde{\mathbf{P}}_\pm^{\mathrm{Cat}}(n) = |\langle n|\widetilde{z,\alpha}\rangle_\pm^{\mathrm{Cat}}|^2 = \widetilde{\mathcal{N}''}_\pm(r^2)^{-1}\frac{r^{2n}(1\pm\cos(2n\theta))}{\mu(n)}, \tag{74}$$

which are again independent of α.

VI. SOME PHYSICAL APPLICATIONS OF THE DGKCS

In order to illustrate the presented idea in this paper, let us apply the formalism on some physical examples which the associated GKCSs have already been known. To economize in the space the complete form of DGKCSs have not been given in what follows and it will be enough for our intention to present ε_n, $\mu(n)$, and $\tilde{\mathcal{N}}(|z|^2)$, since substituting these quantities into (23) gives readily the explicit form of the DGKCSs, $|\widetilde{z,\alpha}\rangle$.

Example 1, harmonic oscillator: As the simplest example we apply the formalism to the

harmonic oscillator Hamiltonian, whose nonlinearity function is equal to 1, hence $\varepsilon_n=n=e_n$ which results in the moments as $\mu(n)=n!=\rho(n)$. Note that we have considered a shifted Hamiltonian to lower the zero-point energy to zero ($e_0=0=\varepsilon_0$). Eventually

$$|\widetilde{z,\alpha}\rangle_{\mathrm{CCS}}=e^{-|z|^2/2}\sum_{n=0}^{\infty}\frac{z^n e^{-i\alpha n}}{\sqrt{n!}}|n\rangle=|z,\alpha\rangle_{\mathrm{CCS}} \tag{75}$$

ensures the *self-duality* of canonical CS. For this example all the Gazeau–Klauder's requirements are satisfied, trivially.

Example 2, Pöschl–Teller potential: The interest in this potential and its CSs is due to various applications in many fields of physics particularly in atomic and molecular physics. The usual GKCSs for the Pöschl–Teller potential have been demonstrated nicely by Antoine *et al.*[10] Their obtained results are as follows:

$$e_n=n(n+\nu),\quad \rho(n)=\frac{n!\,\Gamma(n+\nu+1)}{\Gamma(\nu+1)},\quad \nu>2 \tag{76}$$

with the radius of convergence $R=\infty$. Consequently using the equations given by (76) in (22) and (30) we are able to construct DGKCSs associated with this particular potential by the new quantities obtained as

$$\varepsilon_n=\frac{n}{n+\nu},\quad \mu(n)=\frac{n!\,\Gamma(\nu+1)}{\Gamma(n+\nu+1)},\quad \nu>2 \tag{77}$$

and for the normalization constant we obtain from (24),

$$\widetilde{\mathcal{N}}(|z|^2)=(1-|z|^2)^{-1-\nu}, \tag{78}$$

whose region of convergence is determined as the open unit disk. The overlap between two of these states when $\alpha=\alpha'$ is obtained from (25) as

$$\langle\widetilde{z,\alpha}|\widetilde{z',\alpha}\rangle=[(1-|z|^2)(1-|z'|^2)]^{(1+\nu)/2}(1-zz')^{(-1-\nu)}. \tag{79}$$

For these dual states we only investigate the resolution of the identity; since the other three requirements are obviously satisfied. As required, we must find $\widetilde{\sigma}(x)$ such that the moment integral

$$\int_0^1 x^n\widetilde{\sigma}(x)\mathrm{d}x=\frac{n!\,\Gamma(\nu+1)}{\Gamma(n+\nu+1)} \tag{80}$$

holds. It may be checked that the proper weight function $\widetilde{\sigma}(x)$ is determined as $\nu(1-x)^{\nu-1}$.

At this point we recall that e_n's in (76) denotes the eigenvalues of different Hamiltonians. The characteristics of the dynamical system has been shown by the parameter ν. For instance, the eigenvalues of the anharmonic (nonlinear) oscillator, well studied in literature and the related GKCSs and GK states have been discussed in Refs. 11 and 30 in detail, respectively. In the current example the parameter ν is related to two other parameters, namely λ and κ through the relation $\nu=\lambda+\kappa$, which determine the height and the depth of the well potential. However, when one deals with the nonlinear oscillator it has another meaning; e.g., we refer to Ref. 30, in which the interest was due to its usefulness in the study of laser light propagation in a *nonlinear Kerr medium*. In particular, ν in this case is related to the nonlinear susceptibility of the medium. So, the obtained results in (77) and (78) can be exactly used for the anharmonic oscillator, too. To this end, we shall see in the next example that the case of $\nu=2$ in (76) is the eigenvalues of the infinite well potential.

Example 3, infinite well potential: The GKCSs for the infinite well, have been established by Antoine *et al.* in Ref. 10. The related quantities are

$$e_n = n(n+2), \quad \rho(n) = \frac{n!\,(n+2)!}{2}, \tag{81}$$

with radius of convergence as $R=\infty$. Consequently inserting (81) in (22) and (30) one can construct the dual of these states by the quantities

$$\varepsilon_n = \frac{n}{n+2}, \quad \mu(n) = \frac{2}{(n+1)(n+2)}, \tag{82}$$

and the normalization factor can be obtained from (24) as

$$\widetilde{\mathcal{N}}(|z|^2) = (1-|z|^2)^{-3}, \tag{83}$$

whose region of convergence is determined as the open unit disk. The overlap between two of these states for the special case $\alpha=\alpha'$ is obtained from (25) as

$$\langle \widetilde{z,\alpha} | \widetilde{z',\alpha} \rangle = [(1-|z|^2)(1-|z'|^2)]^{3/2} \frac{1}{1-zz'}. \tag{84}$$

To clarify the fact that these dual states are actually CSs, we only investigate the resolution of the identity, since the other three requirements are satisfied straightforwardly. For this condition we must find $\tilde{\sigma}(x)$ such that the integral

$$\int_0^1 x^n \tilde{\sigma}(x)\mathrm{d}x = \frac{2}{(n+1)(n+2)} \tag{85}$$

holds. It is easy to verify that $\tilde{\sigma}(x)=2(1-x)$ is the solution.

Example 4, Morse potential: The GKCSs for the Morse potential, which is the simplest type of anharmonic oscillator and is useful in various problems in different fields of physics (for example, spectroscopy, diatomic, and polyatomic molecule vibrations and scattering), can be obtained using the related quantities given in Ref. 9:

$$e_n = \frac{n(M+1-n)}{M+2}, \quad \rho(n) = \frac{\Gamma(n+1)\Gamma(M+1)}{(M+2)^n \Gamma(M+1-n)}, \tag{86}$$

where $n=0,1,2,\ldots<(M+1)$. Therefore taking into account (86) in (22) and (30) the dual of these states can be produced by the following quantities:

$$\varepsilon_n = \frac{n(M+2)}{M-n+1}, \quad \mu(n) = \frac{(M+2)^n \Gamma(n+1)\Gamma(M-n+1)}{\Gamma(M+1)}. \tag{87}$$

For the normalization factor in this case one obtains

$$\widetilde{\mathcal{N}}(|z|^2) = \left[1 + \frac{|z|^2}{2+M}\right]^M, \tag{88}$$

where again Eq. (24) has been used. Noticing that the series led to $\widetilde{\mathcal{N}}(|z|^2)$ in (88) is finite, it is readily found that it is absolutely convergent. i.e., $x=\sqrt{|z|^2}\geqslant 0$, $z\in\mathbb{C}$. For evaluating the overlap between two of these states, when $\alpha=\alpha'$, the formula (25) is not useful and one must calculate especially the overlap between the Morse states for themselves, because of the upper bound of the summation

$$\langle \widetilde{z,\alpha}|\widetilde{z',\alpha}\rangle = \widetilde{\mathcal{N}}(|z|^2)^{-1/2}\widetilde{\mathcal{N}}(|z'|^2)^{-1/2}\sum_{n=0}^{M+1}\frac{(z^*z')^n}{\mu(n)}$$
$$= \left[\left(1+\frac{|z|^2}{2+M}\right)\left(1+\frac{|z'|^2}{2+M}\right)\right]^{-M/2}\left[\frac{2+M+zz'}{2+M}\right]^M. \tag{89}$$

We need only to verify the resolution of the identity. As before, we must find a function $\tilde{\sigma}(x)$ such that

$$\int_0^\infty x^n\tilde{\sigma}(x)\mathrm{d}x = \frac{(M+2)^n\Gamma(n+1)\Gamma(M-n+1)}{\Gamma(M+1)}. \tag{90}$$

Using the definition of Meijer's G-function and the inverse Mellin theorem, it follows that[31]

$$\int_0^\infty \mathrm{d}x\, x^{s-1}G_{p,q}^{m,n}\left(\alpha x\middle|\begin{matrix}a_1, & \ldots, & a_n, & a_{n+1}, & \ldots, & a_p\\ b_1, & \ldots, & b_m, & b_{m+1}, & \ldots, & b_q\end{matrix}\right)$$
$$= \frac{1}{\alpha^s}\frac{\Pi_{j=1}^m\Gamma(b_j+s)\Pi_{j=1}^n\Gamma(1-a_j-s)}{\Pi_{j=n+1}^p\Gamma(a_j+s)\Pi_{j=m+1}^q\Gamma(1-b_j-s)}. \tag{91}$$

Comparing (90) and (91), one can find the function $\tilde{\sigma}(x)$ needed in (90), in terms of the Meijer's G-function by the expression

$$\tilde{\sigma}(x) = (M+2)\Gamma(M+1)G_{0,0}^{1,1}\left(x(M+2)^{-1}\middle|\begin{matrix}-(M+1), & .\\ 0, & .\end{matrix}\right). \tag{92}$$

Example 5, hydrogenlike spectrum: As the final physical example, we choose the hydrogenlike spectrum where the corresponding CS has been a long-standing subject and discussed frequently in the literature. For instance in Refs. 6 and 32 the one-dimensional model of such a system with the Hamiltonian $\hat{H}=-\omega/(\hat{n}+1)^2$ and the eigenvalues $E_n=-\omega/(n+1)^2$ has been considered ($\omega=me^4/2$, and $n=0,1,2,\ldots$). But to be consistent with the GKCSs, as it has been done in Ref. 32, the energy levels should be shifted by a constant amount, such that after taking $\omega=1$ one has the eigenvalues e_n and therefore the functions $\rho(n)$ as follows:

$$e_n = 1-\frac{1}{(n+1)^2}, \quad \rho(n) = \frac{(n+2)}{2(n+1)} \tag{93}$$

with unit disk centered at the origin as the region of convergence, i.e., $R=1$. Therefore the related dual family of GKCSs for a bound state portion of the hydrogenlike atom can be constructed. For this purpose, we take into account (93) in (22) and (30), so the corresponding quantities for the DGKCSs can be easily obtained as

$$\varepsilon_n = \frac{n(n+1)^2}{n+2}, \quad \mu(n) = \frac{2n!\,(n+1)!}{n+2}. \tag{94}$$

In this case $\widetilde{R}=\infty$ as the radius of convergence. For the normalization factor, using Eq. (24) obtains

$$\widetilde{\mathcal{N}}(|z|^2) = \frac{1}{2\sqrt{|z|^2}}[2I_1(2\sqrt{|z|^2}) + \sqrt{|z|^2}I_2(2\sqrt{|z|^2})], \tag{95}$$

where $I_\nu(z)$ is the modified Bessel function of the first kind. Similar to the preceding examples, we only verify the resolution of the identity. In the present case we must find a function $\tilde{\sigma}(x)$ such that

$$\int_0^\infty x^n \tilde{\sigma}(x)\mathrm{d}x = 2\frac{n\,!\,(n+1)!}{n+2}. \tag{96}$$

The integral in (91) is again helpful, if we rewrite the RHS of (96) as $2n![(n+1)!]^2/(n+2)!$. The suitable measure is then found to be

$$\tilde{\sigma}(x) = G^{3,1}_{0,0}\left(x \left| \begin{matrix} 0,\ 1,\ 1,\ . \\ \qquad 2,\ . \end{matrix} \right.\right). \tag{97}$$

The overlap between these states for the special case $\alpha=\alpha'$ is obtained from (25) in the closed form

$$\langle\widetilde{z,\alpha}|\widetilde{z',\alpha}\rangle = \tilde{\mathcal{N}}(|z|^2)^{-1/2}\tilde{\mathcal{N}}(|z'|^2)^{-1/2}\frac{1}{2\sqrt{z^* z'}}(2I_1(2\sqrt{z^* z'}) + \sqrt{z^* z'}I_2(2\sqrt{z^* z'})), \tag{98}$$

where $\tilde{\mathcal{N}}(|z|^2)$ and $\tilde{\mathcal{N}}(|z'|^2)$ are determined by Eq. (95).

VII. INTRODUCING THE GENERALIZED GKCS AND THE ASSOCIATED DUAL FAMILY

In light of the above explanations we are now in a position to propose the generalized GKCSs, by which we may recover the GKCSs given by Eq. (4) (also the associated dual family, DGKCSs) and the nonlinear CSs given by Eq. (13) as some special cases. In the following scheme, the physical meaning of the α parameter which enters in the GKCS and DGKCS will be more clear, the case we have already mentioned [in the explanations after Eq. (19)] as $\alpha=\omega t$.

A. Time evolved CSs as the generalized GKCSs

Consider the Hamiltonian $\hat{H}$ whose eigenvectors and eigenvalues are $|\phi_n\rangle$ and e_n, respectively, such that

$$\hat{H} = \omega\sum_{n=0}^{\infty} e_n|\phi_n\rangle\langle\phi_n|, \quad \text{where} \quad \hat{H}|\phi_n\rangle = \omega e_n|\phi_n\rangle, \tag{99}$$

where ω is a constant with the dimension of energy (taking $\hbar=1$). Let $\mathfrak{H}$ be a separable, infinite dimensional and complex Hilbert space spanned by orthonormal set $\{|\phi_n\rangle\}_{n=0}^{\infty}$. Also suppose $0=e_0<e_1<e_2<\cdots<e_n<e_{n+1}<\cdots$, be such that the sum $\Sigma_{n=0}^{\infty}(x^n/[e_n]!)$ converges in some interval $0<x\leqslant L$. For $z\in\mathbb{C}$, such that $|z|^2<L\leqslant\infty$, we define the generalized CSs as follows:

$$|z\rangle \doteq \mathcal{N}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{[e_n]!}}|\phi_n\rangle, \tag{100}$$

where $\mathcal{N}(|z|^2)$ is a normalization factor. As it is clear, these states known as nonlinear CSs, with the nonlinearity function $f(n)=\sqrt{e_n/n}$. Setting $z=re^{i\theta}$ with $r=J^{1/2}$, it is reasonable to write $|z\rangle \equiv |J,\theta\rangle$. Now if $\mathrm{d}\nu$ be a measure which solves the moment problem

$$\int_0^L J^n\,\mathrm{d}\nu(J) = [e_n]\,!\,, \quad \int_0^L \mathrm{d}\nu(J) = 1, \tag{101}$$

then these CSs satisfy the resolution of the identity

$$\int_0^L\left[\int_0^{2\pi}|J,\theta\rangle\langle J,\theta|\mathcal{N}(J)\frac{\mathrm{d}\theta}{2\pi}\right]\mathrm{d}\nu(J) = I_{\mathfrak{H}}. \tag{102}$$

The CSs in (100) evolve with time in the manner

$$|z,t\rangle = e^{-i\hat{H}t}|z\rangle = \mathcal{N}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n e^{-i\omega e_n t}}{\sqrt{[e_n]!}}|\phi_n\rangle, \tag{103}$$

or equivalently in terms of the new variables J and θ,

$$|J,\theta,t\rangle = e^{-i\hat{H}t}|J,\theta\rangle = \mathcal{N}(J)^{-1/2}\sum_{n=0}^{\infty}\frac{J^{n/2}e^{in\theta}e^{-i\omega e_n t}}{\sqrt{[e_n]!}}|\phi_n\rangle. \tag{104}$$

This larger set of GKCSs, we will call them "*generalized GKCSs*," defined for all t, satisfies the resolution of the identity,

$$\begin{aligned}
&\int_{\mathbb{R}}\left[\int_0^L\left\{\int_0^{2\pi}|J,\theta,t\rangle\langle J,\theta,t|\mathcal{N}(J)\frac{\mathrm{d}\theta}{2\pi}\right\}\mathrm{d}\nu(J)\right]\mathrm{d}\mu_{\mathcal{B}}\\
&\quad=\int_0^L\left[\int_0^{2\pi}|J,\theta,t\rangle\langle J,\theta,t|\mathcal{N}(J)\frac{\mathrm{d}\theta}{2\pi}\right]\mathrm{d}\nu(J)\\
&\quad=\int_{\mathbb{R}}\left[\int_0^L|J,\theta,t\rangle\langle J,\theta,t|\mathcal{N}(J)\mathrm{d}\nu(J)\right]\mathrm{d}\mu_{\mathcal{B}}\\
&\quad=\sum_{n=0}^{\infty}|\phi_n\rangle\langle\phi_n| = I_{\mathfrak{H}},
\end{aligned} \tag{105}$$

where $\mathrm{d}\mu_{\mathcal{B}}$ which is really a functional (not a measure) is referred to as the *Bohr measure*,

$$\langle\mu_{\mathcal{B}};f\rangle \doteq \lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{T}f(x)\mathrm{d}x = \int_{\mathbb{R}}f(x)\mathrm{d}\mu_{\mathcal{B}}(x), \tag{106}$$

and f is a suitably chosen function over $\mathbb{R}$. In particular, if $f(x)=1$ for all x, then $\langle\mu_{\mathcal{B}};f\rangle=1$, so that $\mu_{\mathcal{B}}$ resembles a probability measure. Therefore writing the Bohr measure as an integral has only a symbolic meaning.

Setting $t=0$ in the "generalized GKCSs" of Eq. (103), we shall recover the nonlinear CSs and for $\theta=0$, the generalized CSs of Eq. (104) reduce to the GKCSs $|J,\alpha\rangle$ in (1) with $\alpha\equiv\omega t$, which the latter states satisfy the resolution of the identity,

$$\int_{\mathbb{R}}\left[\int_0^L|J,\alpha\rangle\langle J,\alpha|\mathcal{N}(J)\mathrm{d}\nu(J)\right]\mathrm{d}\mu_{\mathcal{B}}(t) = I_{\mathfrak{H}}. \tag{107}$$

The generalized GKCSs $|J,\theta,t\rangle$ in (104) satisfy the temporal stability condition and the action identity, as well as the continuity in the labels and resolution of the identity,

$$e^{-i\hat{H}t'}|J,\theta,t\rangle = |J,\theta,t+t'\rangle, \quad \langle J,\theta,t|\hat{H}|J,\theta,t\rangle = \omega J, \tag{108}$$

and so do the states $|z,t\rangle$ in (103).

B. The dual family of the "generalized GKCS"

Let us now write $e_n=nf^2(n)$, so using our previous results in the present paper, there is a *dual set* of numbers $\tilde{e}_n\equiv\varepsilon_n=n/f^2(n)$, associated with the *dual Hamiltonian* $\tilde{\hat{H}}$. Correspondingly this Hamiltonian has eigenvectors $|\phi_n\rangle$ and eigenvalues ε_n, such that

$$\widetilde{\hat{H}} = \omega \sum_{n=0}^{\infty} \varepsilon_n |\phi_n\rangle\langle\phi_n|, \quad \text{where } \widetilde{\hat{H}}|\phi_n\rangle = \omega\varepsilon_n|\phi_n\rangle. \tag{109}$$

Also assume that $0=\varepsilon_0<\varepsilon_1<\varepsilon_2<\cdots<\varepsilon_n<\varepsilon_{n+1}<\cdots$, such that the sum $\Sigma_{n=0}^{\infty}(x^n/[\varepsilon_n]!)$ converges in some interval $0<x\leqslant\tilde{L}$. We can now define the *dual family* of generalized CSs introduced in (100) by

$$|\tilde{z}\rangle \doteq \tilde{\mathcal{N}}(|z|^2)^{-1/2} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{[\varepsilon_n]!}} |\phi_n\rangle, \tag{110}$$

which are the well-known (dual) nonlinear CSs of Ref. 15. The time evolution of these states reads as

$$\widetilde{|z,t\rangle} = e^{-i\hat{H}t}|\tilde{z}\rangle = \tilde{\mathcal{N}}(|z|^2)^{-1/2} \sum_{n=0}^{\infty} \frac{z^n e^{-i\omega\varepsilon_n t}}{\sqrt{[\varepsilon_n]!}} |\phi_n\rangle. \tag{111}$$

Again, setting $z=re^{i\theta}$ with $r=J^{\frac{1}{2}}$, we can write $|\tilde{z}\rangle \equiv \widetilde{|J,\theta\rangle}$. So, equivalently the states in (111) can be rewritten in terms of the new variables J and θ as

$$\widetilde{|J,\theta,t\rangle} = e^{-i\hat{H}t}\widetilde{|J,\theta\rangle} = \tilde{\mathcal{N}}(J)^{-1/2} \sum_{n=0}^{\infty} \frac{J^{n/2} e^{in\theta} e^{-i\omega\varepsilon_n t}}{\sqrt{[\varepsilon_n]!}} |\phi_n\rangle. \tag{112}$$

We call this large set of states as the "*dual of the generalized GKCS*." Setting $\theta=0$ in (112) will reduce it to the dual of the GKCSs we introduced in (23) with $\alpha=\omega t$. Provided the moment problem

$$\int_0^{\tilde{L}} J^n \, \mathrm{d}\tilde{\nu}(J) = [\varepsilon_n]\,!\,, \quad \int_0^{\tilde{L}} \mathrm{d}\tilde{\nu}(J) = 1, \tag{113}$$

has a solution, we also have expressions for the resolution of the identity of the type (102), (105), and (107). The GK criteria may immediately be verified for the dual of the generalized GKCS in Eq. (112), as it was down for the "generalized GKCSs" in Eq. (104).

C. Generalized creation and annihilation operators

We define two sets of the generalized annihilation operators

$$A|\phi_n\rangle = \sqrt{e_n}|\phi_{n-1}\rangle, \quad \tilde{A}|\phi_n\rangle = \sqrt{\varepsilon_n}|\phi_{n-1}\rangle, \tag{114}$$

and the corresponding generalized creation operators

$$A^\dagger|\phi_n\rangle = \sqrt{e_{n+1}}|\phi_{n+1}\rangle, \quad \tilde{A}^\dagger|\phi_n\rangle = \sqrt{\varepsilon_{n+1}}|\phi_{n+1}\rangle, \tag{115}$$

where $\varepsilon_n=\tilde{e}_n$. Therefore, the Hamiltonian of the system and its associated dual are

$$\hat{H} = \omega A^\dagger A, \quad \widetilde{\hat{H}} = \omega\tilde{A}^\dagger\tilde{A}. \tag{116}$$

Note that we have dropped the GK indices from all the operators in this last section because the discussion is exclusively related to the GK states. Then, for the states in (100) and (110) we have clearly

$$A|z\rangle = z|z\rangle, \quad \tilde{A}|\tilde{z}\rangle = z|\tilde{z}\rangle. \tag{117}$$

In the Heisenberg picture the generalized annihilation operators A and $\tilde{A}$ evolve in time as

$$A(t) = e^{i\hat{H}t}Ae^{-i\hat{H}t}, \quad \tilde{A}(t) = e^{i\tilde{\hat{H}}t}\tilde{A}e^{-i\tilde{\hat{H}}t}, \tag{118}$$

and similarly for the generalized creation operators. At any time t one may obtain,

$$A(t)|z,-t\rangle = z|z,-t\rangle, \quad \tilde{A}(t)\widetilde{|z,-t\rangle} = z\widetilde{|z,-t\rangle}. \tag{119}$$

D. Interpolating between generalized GKCSs and their dual

Following the approach proposed in Ref. 16 we can define the operator $\hat{T}$ on $\mathfrak{H}$ as

$$\hat{T} \doteq \sum_{n=0}^{\infty} \sqrt{\frac{[e_n]!}{[\varepsilon_n]!}}|\phi_n\rangle\langle\phi_n|, \tag{120}$$

with the action

$$\hat{T}|\phi_n\rangle = \sqrt{\frac{[e_n]!}{[\varepsilon_n]!}}|\phi_n\rangle, \quad n = 0,1,2\ldots . \tag{121}$$

Then, writing $\eta_z = \mathcal{N}(|z|^2)^{1/2}|z\rangle$ and similarly defining $\tilde{\eta}_z$, $\eta_{J,\theta,t}$, and $\tilde{\eta}_{J,\theta,t}$ as the unnormalized CSs, we have

$$\hat{T}\eta_z = \tilde{\eta}_z. \tag{122}$$

Since $\hat{T}$, $\hat{H}$, and $\tilde{\hat{H}}$ commute, we have the interpolation rule at any fixed time t; i.e., fixed α,

$$e^{-i(\tilde{\hat{H}}-\hat{H})t}\hat{T}\eta_{J,\theta,t} = \tilde{\eta}_{J,\theta,t}. \tag{123}$$

VIII. CONCLUDING REMARKS

Finally we present a summary of our results. After imposing a second modification on GK states, we showed that both the GKCSs and DGKCSs are essentially of the type of the so-called nonlinear (f-deformed) CSs. In each of the two cases the relevant nonlinearity function is an *operator valued function* which depends on the intensity of light ($\tilde{n}$), but is labeled by a constant real parameter (α). The introduced nonlinearity function which contains an intensity dependent phase factor, has not appeared in literature up to now. This feature originates from the temporal stability requirement imposed on GKCSs and DGKCSs. Meanwhile, using the two nonlinearity functions we constructed the raising and lowering operators, by which one can create and annihilate the *deformed photons*. After all, we proposed a general evolution operator $\hat{S}(\alpha)$, whose action on any generalized CS with known spectrum transforms it to a temporally stable CS. This *physically* makes the generalized CS more useful in practical experiments.

Adding the results presented in Sec. VI we show that, at least in most of the considered physical systems, i.e., when the CS deals with the whole Fock space $\{|n\rangle\}_{n=0}^{\infty}$, while the GKCSs is defined on the whole complex plane (unit disk) the DGKCSs are restricted to unit disk (whole plane), and vice versa. This situation does not hold for Morse potential in which there is a cutoff in the summation (finite dimensional Hilbert space: $\{|n\rangle\}_{n=0}^{M+1}$). So based on the results in Ref. 33 in which the authors relate the radius of convergence to the physical quantities, it can be concluded that GKCSs and DGKCSs can be produced under different physical conditions.

We emphasize the fact that the Hamiltonian involved in the operator $\hat{S}(\alpha)$ must be the one that expresses the dynamics of the system. Using this proposition we introduced the dual family of GKCS. Also it may be understood that the GKCSs can be rewritten in terms of the associated f_{GK} function, explicitly as

$$|z,\alpha\rangle_f = \mathcal{N}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{n!}[f_{\mathrm{GK}}(\alpha,\hat{n})]!}|n\rangle,$$

and similarly for the DGKCSs in terms of the same nonlinearity function $f_{\mathrm{GK}}(\alpha,\hat{n})$,

$$\widetilde{|z,\alpha\rangle}_f = \tilde{\mathcal{N}}(|z|^2)^{-1/2}\sum_{n=0}^{\infty}\frac{z^n[f_{\mathrm{GK}}(\alpha,\hat{n})]!}{\sqrt{n!}}|n\rangle.$$

Hence, we have established that the latter states are indeed a special class of nonlinear CSs which are temporally stable. This property is preserved, using a particular set of nonlinearity functions as introduced in (14) and (26). Also, the map

$$|z,\alpha\rangle \mapsto \widetilde{|z,\alpha\rangle}$$

may be obtained by the following map:

$$f_{\mathrm{GK}}(\alpha,\hat{n}) \mapsto \frac{1}{f_{\mathrm{GK}}(\alpha,\hat{n})}.$$

Note that this map converts even the normalization factor correctly. Keeping in mind the above explanation, a certain class of nonlinear CS and its dual, determined on a specified point of the phase space ($z \in \mathbb{C}$), including the fact that the standard CS is self-dual, may be similar to the image of a state by the map defined above. While the images of standard canonical CS are the same in any arbitrary point of the phase space, i.e., the usual CS does not destroy the flatness of the mirror (or the linearity of the medium), this is not so for the nonlinear CSs. It may be recognized that the operator f in the CSs affect the flatness of the mirror (or the linearity of the medium), and makes it to be curved (or nonlinear). As much as the state is far from the harmonic oscillator CSs, the effect of the f-function is more strong and the dual state (image) is far from the state itself. So the role of the nonlinearity in the nonlinear CSs may be related to the medium, instead of the source of light. In other words, corresponding to any nonlinear CSs there exist an equivalent situation, "a linear source (ordinary photon) with a *nonlinear optical medium*," such as Kerr medium. This particular interpretation of the nonlinear CSs has already been realized in Refs. 34 and 35.

Finally, we confined ourselves to the general introduction of the new type of Gazeau–Klauder CSs in this paper. Although it would be interesting for further applications in quantum optics to investigate in detail, minimization of Robertson–Schrödinger uncertainty equation, the intelligent states and the statistical properties, quadrature squeezing, etc., of DGKCSs and the special superpositions of them have been introduced associated with various exactly solvable quantum mechanical systems and compared with those of the old one (GKCSs type). Also it seems that the vector CSs of DGKCSs may be constructed, as it was done for GK states.[14] These matters are under consideration for future works.

ACKNOWLEDGMENTS

The authors would like to express their thanks to Professor S. Twareque Ali from the Department of Mathematics and Statistics of Concordia University, for his intuitive and useful comments and suggestions, in addition to his rigorous look at the paper, in all its stages during preparation. The authors thank Professor M. Soltanolkotabi and Dr. M. H. Naderi for reading the paper carefully and useful discussions. Estimates on Green functions of second order differential operators with singular coefficients

Z. Haba[a)]
Institute of Theoretical Physics, University of Wroclaw, 50-204 Wroclaw, Plac Maxa Borna 9, Poland

(Received 6 October 2004; accepted 10 December 2004; published online 4 March 2005)

We investigate the Green functions $G(x;x')$ of some second order differential operators on R^{d+1} with singular coefficients depending only on one coordinate x_0. We express the Green functions by means of the Brownian motion. Applying probabilistic methods we prove that when $x=(0,\mathbf{x})$ and $x'=(0,\mathbf{x}')$ (here $x_0=0$) lie on the singular hyperplanes, then $G(0,\mathbf{x};0,\mathbf{x}')$ is more regular than the Green function of operators with regular coefficients. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1855934]

I. INTRODUCTION

We discuss Green functions of some second order differential operators with singular coefficients appearing in quantum physics.

As a first example consider the Lagrangian for a scalar field in $(d+1)$-dimensions interacting with gravity

$$\mathcal{L} = g^{\mu\nu}\partial_\mu\phi\partial_\nu\phi + (m^2 + \xi R)\phi^2, \tag{1}$$

where $g^{\mu\nu}$ is the metric tensor and R is the scalar curvature. Such a Lagrangian with $m=0$ and the minimal coupling $\xi=0$ appears also in the theory of structure formation (cosmological perturbations).[1] We discuss the Euclidean version of a spatially homogeneous metric [we write $x=(t,\mathbf{x})$ or $x=(x_0,\mathbf{x})$ depending on whether the first coordinate has an interpretation of time or space],

$$ds^2 = dt^2 + g_{jk}(t)dx^j dx^k.$$

The Laplace–Beltrami operator resulting from the bilinear form in Eq. (1) reads

$$\Delta_g = \tfrac{1}{2}g^{-1/2}\partial_\mu(g^{\mu\nu}g^{1/2}\partial_\nu) \tag{2}$$

[here $g=\det(g_{\mu\nu})$]. In cosmological models $g_{jk}\simeq t^{2\alpha}$ and $g^{jk}\simeq t^{-2\alpha}$ when $t\to 0$ with $\alpha>0$. Such a singular behavior can appear also in models describing collapse phenomena in general relativity.[2]

As a second example we consider quantum mechanics on a (topologically trivial) manifold with the Hamiltonian

$$H = -\Delta_g + U(x_0) \tag{3}$$

[in some global coordinates $x=(x_0,\mathbf{x})$].

The Green functions of (Euclidean) quantum scalar fields (1) with $m=0$ and the minimal coupling $\xi=0$ are solutions of the equation

a)Electronic mail: zhab@ift.uni.wroc.pl

$$-\Delta_g G = g^{-1/2}\delta. \tag{4}$$

These Green functions are also relevant for classical field theory because they describe a propagation of disturbances. In quantum mechanics (3) we are interested in the propagator kernels

$$\exp(-\tau H)(x_0,\mathbf{x};x_0',\mathbf{x}'), \tag{5}$$

where τ is purely imaginary.

In this paper we prove that if the coefficients of the Laplace–Beltrami operator have a power-law singularity at a certain point $t=t_0$, then the Green functions $G(t_0,\mathbf{x};t_0,\mathbf{x}')$ are more regular than the ones of operators with regular coefficients (for regular coefficients the Green function can be expressed by the geodesic distance[3,4]). In quantum field theory these Green functions have the meaning of expectation values of quantum fields at equal times. In quantum mechanics the propagator (5) will have an anomalous behavior in τ. The Green function (4) can be obtained from the propagator (5) by means of an integration over τ.

II. THE GREEN FUNCTIONS

Let us change coordinates

$$\frac{dt}{d\eta} = \sqrt{g}. \tag{6}$$

The Laplace–Beltrami operator (2) takes the form

$$2\Delta_g = g^{-1}\partial_\eta^2 + g^{jk}\partial_j\partial_k. \tag{7}$$

The bilinear form in Eq. (1) determines an operator $\mathcal{A}$ which is of the same form as H in quantum mechanics [Eq. (3)]:

$$\mathcal{A} = -\Delta_g + w. \tag{8}$$

Here, $w=\frac{1}{2}m^2+\frac{1}{2}\xi R$ for the scalar field and $w=U$ for quantum mechanics. The Green function of $\mathcal{A}$ is a solution of the equation

$$-(\partial_\eta^2 + gg^{jk}\partial_j\partial_k - W)G = 2\delta(\eta-\eta')\delta(\mathbf{x}-\mathbf{x}'), \tag{9}$$

where we write

$$W = gw. \tag{10}$$

Together with Eq. (9) we consider the differential equation

$$-\partial_\tau P_\tau = \mathcal{A}P_\tau \tag{11}$$

with the initial condition $P_0(\eta,\mathbf{x};\eta',\mathbf{x}')=\delta(\eta-\eta')\delta(\mathbf{x}-\mathbf{x}')$. Equation (11) defines the transition function of a stochastic process.[5]

We can formulate the problem of solving the equation

$$\mathcal{A}G = \delta \tag{12}$$

as a problem in the Hilbert space of square integrable functions $L^2(d\eta d\mathbf{x})$.[6] We assume that W is a non-negative function. The operator $\mathcal{A}$ can be considered as a self-adjoint non-negative operator in L^2 if gg^{jk} and W are locally integrable functions [then we can define the Friedrichs extension[6] of the symmetric differential operator (8)]. The transition function P_τ of Eq. (11) can be defined as the integral kernel of $\exp(-\tau\mathcal{A})$. Then, the kernel of the inverse

$$\mathcal{A}^{-1} = \int_0^\infty d\tau \exp(-\tau\mathcal{A})$$

is the solution of Eq. (9). It follows that the Fourier transform $\tilde{G}$ of G has the representation

$$\tilde{G}(\eta, \eta'; \mathbf{p}) = \int_0^\infty d\tau \tilde{P}_\tau(\eta, \eta', \mathbf{p}), \tag{13}$$

where $\tilde{P}$ is a solution of the equation

$$-\partial_\tau \tilde{P}_\tau = \tilde{\mathcal{A}}\tilde{P}_\tau \tag{14}$$

with the initial condition $\tilde{P}_0(\eta, \eta', \mathbf{p}) = \delta(\eta - \eta')$ (the fundamental solution). Here

$$\tilde{\mathcal{A}} = -\tfrac{1}{2}\partial_\eta^2 + \tfrac{1}{2}p_j g^{jk}(\eta)g(\eta)p_k + W \equiv -\tfrac{1}{2}\partial_\eta^2 + V(\eta) + W(\eta). \tag{15}$$

Equation (14) is a Schrödinger-type equation with the Hamiltonian $\tilde{\mathcal{A}}$ and the potential $V+W$ where

$$V(\eta) = \tfrac{1}{2}p_j g^{jk}(\eta)g(\eta)p_k \equiv \mathbf{p}\tilde{V}\mathbf{p}(\eta). \tag{16}$$

If the potentials V and W belong to $L^1_{loc}(d\eta)$, then $\tilde{\mathcal{A}}$ is a well-defined essentially self-adjoint operator in $L^2(d\eta)$.[7]

We can express the kernel $\tilde{P}$ by means of the Brownian motion b (the Feynman–Kac formula;[8] a discussion of the probabilistic representation for singular potentials can be found in Ref. 9):

$$\tilde{P}_\tau(\eta, \eta', \mathbf{p}) = E\left[\delta(\eta' - \eta - b(\tau))\exp\left(-\int_0^\tau V(\eta + b(s))ds - \int_0^\tau W(\eta + b(s))ds\right)\right], \tag{17}$$

where $E[.]$ denotes an average over the Brownian paths. Now, the kernel of $\exp(-\tau\mathcal{A})$ has the representation

$$P_\tau(\eta, \mathbf{x}, \eta', \mathbf{x}') = (2\pi)^{-d}\int d\mathbf{p}\, \exp(i\mathbf{p}(\mathbf{x}' - \mathbf{x})) \times E\left[\delta(\eta' - \eta - b(\tau))\exp\left(-\int_0^\tau V(\eta + b(s))ds - \int_0^\tau W(\eta + b(s))ds\right)\right]. \tag{18}$$

In order to eliminate the δ function in Eq. (17) it is useful to express the expectation value over the Brownian motion by means of an expectation value over the Brownian bridge γ. Let q be a path connecting η with η'

$$q\left(\frac{s}{\tau}\right) = \eta + (\eta' - \eta)\frac{s}{\tau} + \sqrt{\tau}\gamma\left(\frac{s}{\tau}\right), \tag{19}$$

where γ is the Gaussian process on the interval $[0, 1]$ (the Brownian bridge) starting from 0 and ending in 0 with the covariance

$$E[\gamma(s)\gamma(s')] = s'(1 - s)$$

for $s' \leqslant s$. Then, Eq. (17) can be rewritten in the form[8]

$$\widetilde{P}_\tau(\eta,\eta',\mathbf{p}) = (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)E\left[\exp\left(-\tau\int_0^1 ds(V(q(s))+W(q(s))\right)\right]. \tag{20}$$

Applying the Jensen inequality (see Refs. 10 and 11) to the $E[..]$ integral we obtain the inequality

$$\widetilde{P}_\tau(\eta,\eta',\mathbf{p}) \geqslant (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)\exp\left(-\tau\int_0^1 ds\, E[V(q(s))+W(q(s))]\right) \equiv \widetilde{P}^L. \tag{21}$$

This integral is

$$\widetilde{P}^L_\tau(\eta,\eta',\mathbf{p}) = (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)\exp\left(-\tau\int_0^1 ds\int dy(2\pi s(1-s))^{-1/2}\exp\left(-\frac{y^2}{2s(1-s)}\right)\right.$$
$$\left.\times(V+W)(\eta+s(\eta'-\eta)+\sqrt{\tau}y)\right). \tag{22}$$

As a simple application of the inequality (21) we note that if

$$V+W \leqslant A'\mathbf{p}^2+B', \tag{23}$$

then

$$\widetilde{P}^L_\tau(\eta,\eta',\mathbf{p}) \geqslant (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)\exp(-\tau A'\mathbf{p}^2-\tau B'). \tag{24}$$

Hence, we obtain a bound from below by the transition function for the d-dimensional Brownian motion.

On the other hand, we may apply the Jensen inequality in the opposite direction to the s-integral

$$\widetilde{P}_\tau(\eta,\eta',\mathbf{p}) \leqslant (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)\int_0^1 ds\, E[\exp(-\tau V(q(s))-\tau W(q(s)))] \equiv \widetilde{P}^U. \tag{25}$$

This integral takes the form

$$\widetilde{P}^U_\tau(\eta,\eta',\mathbf{p}) = (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)\int_0^1 ds\int dy(2\pi s(1-s))^{-1/2}\exp\left(-\frac{y^2}{2s(1-s)}\right)$$
$$\times\exp(-\tau(V+W)(\eta+s(\eta'-\eta)+\sqrt{\tau}y)). \tag{26}$$

If

$$V+W \geqslant A\mathbf{p}^2+B,$$

then

$$\widetilde{P}^U_\tau(\eta,\eta',\mathbf{p}) \leqslant (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)\exp(-\tau A\mathbf{p}^2-\tau B). \tag{27}$$

Hence, we estimate the transition function from above by the Wiener transition function.

III. SCALE INVARIANT METRICS

We consider in this section a power-law cosmological expansion. Such an expansion is an exact solution of coupled Einstein equations for a metric and for the scalar field with an exponential self-interaction. Some consequences for a structure formation with such an expansion are discussed in Refs. 12 and 13. If $g_{jk}(t)$ has an isotropic power-law behavior, then V is scale invariant. Let us assume here that V and W are non-negative and scale invariant around $\eta=0$ [there is nothing special in the choice of $\eta=0$ as a singular point, see a discussion at Eq. (44)]:

$$\tilde{V}^{jk}(\lambda\eta) = \lambda^{2\nu}\tilde{V}^{jk}(\eta) \tag{28}$$

and

$$W(\lambda\eta) = \lambda^{2\sigma}W(\eta). \tag{29}$$

Let us denote $\theta=\tau^{-1/2}\eta$. We apply the scaling properties of the Brownian bridge (19). Then, for V of the form (28) and W in (29) we obtain

$$\tilde{P}_\tau(\eta,\eta',\mathbf{p}) = (2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta'-\eta)^2\right)E\left[\exp\left(-\tau^{1+\nu}\int_0^1 \mathbf{p}\tilde{V}\mathbf{p}(\theta+s(\theta'-\theta)+\gamma(s))ds\right)\right.$$
$$\left.\times\exp\left[\left(-\tau^{1+\sigma}\int_0^1 W(\theta+s(\theta'-\theta)+\gamma(s))ds\right)\right]\right]. \tag{30}$$

The bounds (22) and (26) become simple if $\eta=\eta'=0$. Then, the bound (22) reads

$$\tilde{P}^L_\tau(0,0,\mathbf{p}) = (2\pi\tau)^{-1/2}\exp\left(-\tau^{1+\nu}\int_0^1 ds\int dy(2\pi s(1-s))^{-1/2}V(y)\exp\left(-\frac{y^2}{2s(1-s)}\right)\right.$$
$$\left.-\tau^{1+\sigma}\int_0^1 ds\int dy(2\pi s(1-s))^{-1/2}W(y)\exp\left(-\frac{y^2}{2s(1-s)}\right)\right)$$
$$= (2\pi\tau)^{-1/2}\exp\left(-\tau^{1+\nu}\mathbf{p}h\mathbf{p}\int_0^1 ds(s(1-s))^\nu - B\tau^{1+\sigma}\int_0^1 ds(s(1-s))^\sigma\right), \tag{31}$$

where the bilinear form h in $\mathbf{p}$ is defined by

$$\mathbf{p}h\mathbf{p} = (2\pi)^{-1/2}\int dy\exp\left(-\frac{y^2}{2}\right)\mathbf{p}\tilde{V}(y)\mathbf{p} \tag{32}$$

and the constant B in Eq. (31) is

$$B = (2\pi)^{-1/2}\int dy\exp\left(-\frac{y^2}{2}\right)W(y). \tag{33}$$

The integral (32) is finite if $\nu>-\frac{1}{2}$ and (33) is finite if $\sigma>-\frac{1}{2}$. In such a case the lower bound (31) is nontrivial. The upper bound (26) takes the form

$$\tilde{P}^U_\tau(0,0,\mathbf{p}) = (2\pi\tau)^{-1/2}\int_0^1 ds\int dy(2\pi s(1-s))^{-1/2}\exp\left(-\frac{y^2}{2s(1-s)}\right)\exp(-\tau^{1+\nu}V(y)-\tau^{1+\sigma}W(y)). \tag{34}$$

We are interested in the Green functions (9) of the operator $\mathcal{A}$ which according to Eqs. (13) and (18) are expressed by a τ integration upon P_τ. As the simplest example of the integral (13) let $V+W=A\mathbf{p}^2+B$. Then performing the τ integration upon the rhs of Eq. (13) we obtain

$$\widetilde{G}_0(0,0;\mathbf{p}) = (2A\mathbf{p}^2 + 2B)^{-1/2}. \tag{35}$$

This is the standard behavior of equal-time Green functions for the quantum free field.

In Eq. (31) let us first discuss the case $W=B=0$. Then, the integral over τ of Eq. (31) gives the lower bound on the Green function

$$\widetilde{G}(0,0;\mathbf{p}) \geqslant K_1(\mathbf{p}h\mathbf{p})^{-\omega}, \tag{36}$$

where

$$\omega = \frac{1}{2(1+\nu)}. \tag{37}$$

In order to estimate the upper bound (34) (for $W=0$) let us assume a lower bound $|\widetilde{V}|_0$ on $\widetilde{V}$, i.e., for $\mathbf{p}\neq 0$

$$\mathbf{p}\widetilde{V}\mathbf{p} \geqslant \mathbf{p}^2|\widetilde{V}|_0 > 0. \tag{38}$$

Now, we change variables in Eqs. (13) and (34), $(\tau,y)\to(\rho,u)$, where

$$\rho = \tau|\mathbf{p}|^{2/(1+\nu)}|\widetilde{V}(y)|_0^{1/(1+\nu)},$$

$$u = y(s(1-s))^{-1/2}.$$

Then, the upper bound takes the form

$$\widetilde{G}(0,0;\mathbf{p}) \leqslant |\mathbf{p}|^{-2\omega}\int_0^\infty d\rho(2\pi\rho)^{-1/2}\int_0^1 ds\int du(2\pi)^{-1/2}(s(1-s))^{-\nu/(1+\nu)}|\widetilde{V}(u)|_0^{-\omega}$$
$$\times\exp\left(-\frac{u^2}{2}\right)\exp(-\rho^{1+\nu}). \tag{39}$$

We can see that the integral on the rhs of Eq. (39) is finite if $-1<\nu<\infty$.

We can summarize our results as follows.

Theorem 1: Assume that $W=0$ and the potential V in Eq. (15) is non-negative and scale invariant with $\nu>-\frac{1}{2}$ [Eq. (28)]. Then, the operator $\widetilde{\mathcal{A}}$ is essentially self-adjoint and the integral kernel of $\exp(-\tau\widetilde{\mathcal{A}})$ has the probabilistic representation (20). The Green function G of Eq. (9) can be defined as an integral kernel of $\mathcal{A}^{-1}$. Assume that the potential V satisfies the lower bound (38). Then the Fourier transform $\widetilde{G}(\eta,\eta';\mathbf{p})$ of $G(\eta,\eta',\mathbf{x}-\mathbf{x}')$ at $\eta=\eta'=0$ for any $\mathbf{p}$ satisfies the inequalities

$$K_1(\mathbf{p}h\mathbf{p})^{-\omega} \leqslant \widetilde{G}(0,0;\mathbf{p}) \leqslant K_2|\mathbf{p}|^{-2\omega}, \tag{40}$$

where h is defined in Eq. (32) and K_1 and K_2 are some positive constants.

For $\nu<0$ the Fourier transform $\widetilde{G}$ is decaying to zero faster than the Green function for operators with constant coefficients. As a consequence G is less singular than the one for operators with constant coefficients [see Eq. (43) below].

In the configuration space, if $W=0$, then we can extract the τ dependence from V using its scale invariance. Then, changing the integration variable in Eq. (18), $\mathbf{p}=\tau^{-(1/2)(1+\nu)}\mathbf{k}$, we can conclude that P has the form

$$P_\tau(\eta,\mathbf{x},\eta',\mathbf{x}') = \tau^{-(1/2)(1+\nu)d-1/2}F(\tau^{-1/2}\eta,\tau^{-1/2}\eta',\tau^{-(1/2)(1+\nu)}(\mathbf{x}-\mathbf{x}')) \tag{41}$$

with a certain function F. Integration over τ with a rescaled $\tau=r|\mathbf{x}-\mathbf{x}'|^{2/(1+\nu)}$ brings the Green function at equal time to the form

$$G(\eta,\mathbf{x},\eta,\mathbf{x}') = |\mathbf{x}-\mathbf{x}'|^{-d+1/(1+\nu)} f(|\mathbf{x}-\mathbf{x}'|^{1/(1+\nu)}\eta, (\mathbf{x}-\mathbf{x}')|\mathbf{x}-\mathbf{x}'|^{-1}). \tag{42}$$

It follows

$$G(0,\mathbf{x},0,\mathbf{x}') = |\mathbf{x}-\mathbf{x}'|^{-d+1/(1+\nu)} f((\mathbf{x}-\mathbf{x}')|\mathbf{x}-\mathbf{x}'|^{-1}). \tag{43}$$

We obtain such a behavior in $|\mathbf{x}-\mathbf{x}'|$ if we apply the inverse Fourier transform to the functions on both sides of the inequalities (40).

Let us note that if V is singular at $\eta_0 \neq 0$ (e.g., $V \simeq |\eta-\eta_0|^{2\nu}$), then all our results concerning the transition functions and Green functions still hold true but instead of setting $\eta=\eta'=0$ we set $\eta=\eta'=\eta_0$ [this conclusion follows directly from Eq. (30)]. So, e.g., the formula (43) reads

$$G(\eta_0,\mathbf{x},\eta_0,\mathbf{x}') = |\mathbf{x}-\mathbf{x}'|^{-d+1/(1+\nu)} f((\mathbf{x}-\mathbf{x}')|\mathbf{x}-\mathbf{x}'|^{-1}). \tag{44}$$

We admit now $W \neq 0$

Theorem 2: Let $W \geqslant 0$ be scale invariant [Eq. (29)] and $\sigma > -\frac{1}{2}$. Then (under the assumptions of Theorem 1 concerning V) for any $\Lambda > 0$, if $|\mathbf{p}| > \Lambda$, then there exist positive constants K_1 and K_2 such that the inequalities (40) hold true.

Proof: Setting $W=0$ in Eq. (34) we obtain the upper bound (39). For the lower bound we note that the exponential in Eq. (31) is dominated by the term quadratic in the momenta. We change the integration variable in Eqs. (13) and (34):

$$\tau = r(\mathbf{p}h\mathbf{p})^{-1/(1+\nu)}.$$

Then, we can see that for any $\Lambda > 0$, if $|\mathbf{p}| > \Lambda$, then there exists a constant C such that in the exponential of Eq. (31) $B\tau^{1+\sigma} < Cr^{1+\sigma}$. Then

$$\int d\tau \, \tilde{P}^L_\tau(0,0,\mathbf{p}) \geqslant (\mathbf{p}h_2\mathbf{p})^{-\omega} \int dr (2\pi r)^{-1/2} \exp\left(- r^{1+\nu} \int_0^1 ds (s(1-s))^\nu - Cr^{1+\sigma} \int_0^1 ds (s(1-s))^\sigma \right).$$

From this lower bound and from the upper bound (39) we obtain the results of the theorem.

If $W > 0$, then the lower bound in Eq. (40) cannot be true for arbitrarily small $\mathbf{p}$ because as follows from Eq. (34) ($V=0$ for $\mathbf{p}=0$)

$$\tilde{G}(0,0,\mathbf{0}) \leqslant \int_0^\infty d\tau (2\pi\tau)^{-1/2} \int_0^1 ds \int dy (2\pi s(1-s))^{-1/2} \exp\left(- \frac{y^2}{2s(1-s)} \right) \exp(-\tau^{1+\sigma} W(y)) < \infty. \tag{45}$$

If we imposed the condition that $t \geqslant 0$ (which is quite artificial in the Euclidean framework), then we would need to impose boundary conditions at $\eta=0$ on the Brownian motion in the path integral (17). The Dirichlet boundary conditions can easily be imposed in the functional integration framework. We just insert the characteristic function of the positive real axis in the path integral (17), rejecting all the Brownian paths which leave the positive real axis. With the Dirichlet boundary conditions our estimates on the upper bound remain unchanged whereas the estimates on the lower bound require some minor modifications.

Let us consider an example of a three-dimensional space. By a change of coordinates we can diagonalize the matrix (g_{jk}):

$$g_{jk} = \delta_{jk} a_j^2. \tag{46}$$

Let $a = (a_1 a_2 a_3)^{1/3}$ and

$$\delta_j = a_j^{-1} a^{-2} \partial_\eta a_j,$$

$$\delta = a^{-3} \partial_\eta a,$$

$$Q = \frac{1}{18}\sum_{j<k} (\delta_j - \delta_k)^2.$$

Then, in the potential W of Eq. (9),[14]

$$gR = 6a^4(a^{-2}\partial_\eta \delta + \delta^2 + Q) \tag{47}$$

and

$$m^2 g = m^2 a^6. \tag{48}$$

We obtain a scale invariant V and W if a_j are scale invariant. Let us consider the simplest case when all a_j are equal, $t \in R$, and

$$a(t) = |t|^\alpha. \tag{49}$$

We have

$$\eta = (1 - 3\alpha)^{-1} t|t|^{-3\alpha}.$$

Note that for $\alpha > \frac{1}{3}$ the point $t=0$ corresponds to $\eta = -\infty$ and $t = \infty$ to $\eta = 0$.

Then

$$V(y) = \kappa \mathbf{p}^2 |y|^{2\nu},$$

where $\kappa > 0$ is a certain constant and

$$\nu = 2\alpha(1 - 3\alpha)^{-1}. \tag{50}$$

For a scale invariant metric

$$W = m^2 g(\eta) + \xi g R = C_1 m^2 |\eta|^{6\alpha/(1-3\alpha)} + \xi C_2 \eta^{-2}.$$

De Sitter space can be obtained as a limit $\alpha \to \infty$. Then, we have $V(\eta) = c\mathbf{p}^2|\eta|^{-4/3}$ and $m^2 g = c' \eta^{-2}$, hence $W(\eta) = \tilde{c}\eta^{-2}$. This is a singular perturbation which goes beyond our analysis. It can be treated by means of the path integral methods. However, in such a case W needs a regularization, then a renormalization and a subsequent removal of the regularization.[9] The η^{-2} singularity comes also from the term gR. Hence, the results of this section apply only to $\xi = 0$. Then, in Eq. (29) $\sigma = 3\alpha(1-3\alpha)^{-1}$. B in Eq. (33) is finite if $|\alpha| < \frac{1}{3}$.

In quantum mechanics x_0 is interpreted as a space variable. The metric takes the form ($d+1=3$)

$$ds^2 = dx_0^2 + |x_0|^{2\alpha}(dx_1^2 + dx_2^2).$$

Then, $\eta = (1-2\alpha)^{-1} x_0 |x_0|^{-2\alpha}$. The Hamiltonian (3) is symmetric in $L^2(\sqrt{g}dx)$. The change of coordinates $x_0 \to \eta$ associates with H the operator $\tilde{A} = g\tilde{H}$ which is symmetric in $L^2(d\eta d\mathbf{x})$,

$$\tilde{A} = -\partial_\eta^2 + V + W,$$

where

$$V(\eta) = C_1 \mathbf{p}^2 |\eta|^{2\alpha/(1-2\alpha)} \tag{51}$$

with $\mathbf{p}^2 = p_1^2 + p_2^2$ and

$$W = gU(\eta) = C_2 |\eta|^{4\alpha/(1-2\alpha)} U(\eta). \tag{52}$$

The anomalous behavior of $\tilde{P}_\tau$ has the following as a consequence.

Corollary 3: Let $\tilde{P}_\tau(\eta,\eta',\mathbf{p})$ be the fundamental solution of Eq. (14) with $W=0$ and V defined in Eq. (51). If $\nu=\alpha/(1-2\alpha)>-\frac{1}{2}$, then for any $\tau\geqslant 0$

$$\int d\mathbf{x}\, P_\tau(0,\mathbf{x},0,\mathbf{x}')|\mathbf{x}-\mathbf{x}'|^2=(-\Delta_{\mathbf{p}})\tilde{P}_\tau(0,0,\mathbf{p})_{|\mathbf{p}=0}=B_1\tau^{1/2+\nu} \tag{53}$$

and

$$\int d\mathbf{x}d\eta'\, P_\tau(0,\mathbf{x},\eta',\mathbf{x}')|\mathbf{x}-\mathbf{x}'|^2=\int d\eta'(-\Delta_{\mathbf{p}})\tilde{P}_\tau(0,\eta',\mathbf{p})_{|\mathbf{p}=0}=B_2\tau^{1+\nu}. \tag{54}$$

If $W(\eta)\geqslant 0$ defined in Eq. (52) belongs to $L^1_{loc}(d\eta)$, then instead of the equalities in Eqs. (53) and (54) we have bounds from above by $B_1\tau^{1/2+\nu}$ in Eq. (53) and $B_2\tau^{1+\nu}$ in Eq. (54).

Proof: We prove Eq. (54) [Eq. (53) is simpler and proved in a similar way]. Let us calculate

$$(-\Delta_{\mathbf{p}})\int d\eta'\,\tilde{P}_\tau(0,\eta',\mathbf{p})_{|\mathbf{p}=0}=\int d\eta'(2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta')^2\right)$$
$$\times E\left[\tau^{1+\nu}\int_0^1 Tr\tilde{V}(s\tau^{-1/2}\eta'+\gamma(s))ds\right]=B_2\tau^{1+\nu}. \tag{55}$$

If $W\geqslant 0$, then instead of the expectation value (55) we have

$$\int d\eta'(2\pi\tau)^{-1/2}\exp\left(-\frac{1}{2\tau}(\eta')^2\right)E\left[\tau^{1+\nu}\int_0^1 Tr\tilde{V}(s\tau^{-1/2}\eta'+\gamma(s))ds\right.$$
$$\left.\times\exp\left(-\int_0^\tau W\left(s\tau^{-1}\eta'+\sqrt{\tau}\gamma\left(\frac{s}{\tau}\right)\right)ds\right)\right]\leqslant B_2\tau^{1+\nu},$$

where the inequality follows from $W\geqslant 0$.

Corollary 3 means that if $\nu<0$, then the sample paths of diffusions generated by operators with singular coefficients have worse continuity properties than the Brownian paths (for Brownian paths see Ref. 8).

IV. MORE GENERAL METRICS

We study the lower bound on G following from Eq. (22)

$$\tilde{G}^L(0,0,\mathbf{p})=\int_0^\infty d\tau(2\pi\tau)^{-1/2}\exp\left(-\tau\int_0^1 ds\int dy(2\pi s(1-s))^{-1/2}\exp\left(-\frac{y^2}{2s(1-s)}\right)\mathcal{V}(\sqrt{\tau}y)\right),$$

and the upper bound following from Eq. (26)

$$\tilde{G}^U(0,0,\mathbf{p})=\int_0^\infty d\tau(2\pi\tau)^{-1/2}\int_0^1 ds\int dy(2\pi s(1-s))^{-1/2}\exp\left(-\frac{y^2}{2s(1-s)}\right)\exp(-\tau\mathcal{V}(\sqrt{\tau}y))$$

for more general $\mathcal{V}$.

A generalization of Theorem 1 reads as follows.

Theorem 4: Let us consider $\mathcal{V}=\mathbf{p}\tilde{\mathcal{V}}\mathbf{p}$, which is not scale invariant but of the form

$$\tilde{\mathcal{V}}(\eta)=\tilde{V}(\eta)f(\eta)+l(\eta), \tag{56}$$

where $\tilde{V}$ is a matrix scale invariant function (28) satisfying the conditions of Theorem 1 with $-\frac{1}{2}<\nu<0$, f is a bounded function with a strictly positive lower bound, and l is a non-negative bounded matrix function. Assume in addition that

$$\int dy \exp\left(-\frac{y^2}{2}\right) f(y)\tilde{V}(y) \geqslant cI > 0, \tag{57}$$

where c is a positive number. Under our assumptions (56) and (57) for any $\Lambda > 0$, if $|\mathbf{p}| > \Lambda$, then there exist a positively definite bilinear form h_2 and constants K_1 and K_2 such that

$$K_1(\mathbf{p}h_2\mathbf{p})^{-\omega} \leqslant \tilde{G}(0,0;\mathbf{p}) \leqslant K_2|\mathbf{p}|^{-2\omega}. \tag{58}$$

If $\nu \geqslant 0$ for $\tilde{V}$ in Eq. (56), then for $|\mathbf{p}| > \Lambda$ the inequalities (58) hold true with $\omega = \frac{1}{2}$.

Proof: Our assumptions (56) on $\tilde{\mathcal{V}}$ mean that it satisfies the inequalities

$$\tau^{\nu}\mathbf{p}\tilde{V}_1(y)\mathbf{p} + \mathbf{p}l_1\mathbf{p} \leqslant \mathcal{V}(\sqrt{\tau}y) \leqslant \tau^{\nu}\mathbf{p}\tilde{V}_2(y)\mathbf{p} + \mathbf{p}l_2\mathbf{p} \tag{59}$$

with certain matrix functions $\tilde{V}_1$ and $\tilde{V}_2$ independent of τ and bilinear forms l_1 and l_2 (independent of y). It follows that the integral of $\tilde{P}_\tau$ satisfies the bounds

$$\int d\tau\, \tilde{P}_\tau^{L_2} \exp(-\tau\mathbf{p}l_2\mathbf{p}) \leqslant \int d\tau\, \tilde{P}_\tau \leqslant \int d\tau\, \tilde{P}_\tau^{U_1} \exp(-\tau\mathbf{p}l_1\mathbf{p}), \tag{60}$$

where in the lower bound $\tilde{P}^{L_2}$ the potential V_2 from the rhs of Eq. (59) is applied and in $\tilde{P}^{U_1}$ the one from the lhs of Eq. (59). The integral (57) defines h of Eq. (32) [and the h_2 from the upper bound (59)]. Let us change the integration variable $\tau = r(\mathbf{p}h_2\mathbf{p})^{-1/(1+\nu)}$ on the lhs of Eq. (60) and $\tau = \rho|\mathbf{p}|^{-4\omega}|\tilde{V}_1(y)|_0^{-2\omega}$ on the rhs. Then, the lower and upper bounds read [from Eqs. (31), (34), and (38)]

$$\begin{aligned}
&(\mathbf{p}h_2\mathbf{p})^{-\omega}\int_0^\infty dr(2\pi r)^{-1/2} \exp(-r^{1+\nu} - r(\mathbf{p}h_2\mathbf{p})^{-2\omega}\mathbf{p}l_2\mathbf{p}) \\
&\quad \leqslant \tilde{G}(0,0,\mathbf{p}) \leqslant |\mathbf{p}|^{-2\omega}\int_0^\infty d\rho(2\pi\rho)^{-1/2}\int_0^1 ds \int du(2\pi)^{-1/2}(s(1-s))^{-\nu/(1+\nu)}|\tilde{V}_1(u)|_0^{-\omega} \\
&\quad \times \exp\left(-\frac{u^2}{2}\right)\exp(-\rho^{1+\nu} - \rho|\mathbf{p}|^{-4\omega}|\tilde{V}_1(u\sqrt{s(1-s)})|_0^{-2\omega}\mathbf{p}l_1\mathbf{p}).
\end{aligned} \tag{61}$$

The condition (57) implies that the bilinear form h_2 is strictly positive. Hence, there exists a constant K such that

$$K\mathbf{p}h_2\mathbf{p} \geqslant \mathbf{p}l_2\mathbf{p}.$$

Then, for $-\frac{1}{2} < \nu < 0$ and $|\mathbf{p}| > \Lambda$, there exists c_1 such that

$$r(\mathbf{p}h_2\mathbf{p})^{-1/(1+\nu)}\mathbf{p}l_2\mathbf{p} < rc_1$$

in the exponential on the lhs of Eq. (61). The l_1 term can be set zero for the upper bound. In such a case for each $\Lambda > 0$ there exist constants c_1 and c_2 such that if $|\mathbf{p}| > \Lambda$, then the inequalities (61) take the form

$$\begin{aligned}
&(\mathbf{p}h_2\mathbf{p})^{-\omega}\int_0^\infty dr(2\pi r)^{-1/2} \exp(-r^{1+\nu} - rc_1) \\
&\quad \leqslant \tilde{G}(0,0,\mathbf{p}) \leqslant |\mathbf{p}|^{-2\omega}\int_0^\infty d\rho(2\pi\rho)^{-1/2}\int_0^1 ds \int du(2\pi)^{-1/2} \\
&\quad \times (s(1-s))^{-\nu/(1+\nu)}|\tilde{V}_1(u)|_0^{-\omega} \exp\left(-\frac{u^2}{2}\right)\exp(-\rho^{1+\nu}).
\end{aligned} \tag{62}$$

The inequalities (62) coincide with (58) because under our assumptions the integrals in Eq. (62) are finite. The last statement of Theorem 4 follows from the inequalities (60) because the behavior for large $\mathbf{p}$ follows from the behavior of $\tilde{P}_\tau$ for a small τ. If $\nu>0$, then in Eq. (60) $\tau^{1+\nu}<A\tau$ for any A and a sufficiently small τ. Hence, we obtain the same behavior of $\tilde{G}$ for large momenta as in the case $\tilde{V}=1$.

We would like to note that the restrictive form (56) of $\mathcal{V}$ is not necessary. As an example we could consider $\mathcal{V}$ which has singularities at several points, e.g.,

$$\mathcal{V}(\eta)=\mathbf{p}^2(a_0|\eta-\eta_0|^{2\nu_0}+\kappa|\eta|^{2\nu}) \tag{63}$$

with $|\nu_0|<|\nu|$ (only negative indices are nontrivial). An application of the lower and upper bounds (31) and (34) to the potential (63) leads to the conclusion that after an integration upon τ the inequalities (40) hold true for $|\mathbf{p}|>\Lambda$. Hence, the leading singularity ν determines the behavior at large momenta.

V. DISCUSSION AND SUMMARY

As we pointed out in the Introduction our results concerning the Green functions can find an application to quantum field theory in an expanding universe. The stronger damping in momenta [Eq. (40)] in the inflationary models ($\alpha>1$) at $\eta=\eta'=0$ indicates that it would be promising to start quantization at this time ($\eta=0$ corresponds to $t=\infty$ in cosmological models with $\alpha>\frac{1}{3}$). The exponential inflation can be obtained as a limit $\alpha\to\infty$ which corresponds to $\nu=-\frac{2}{3}$. This limit is beyond our rigorous approach but it could be treated by means of more sophisticated methods of Ref. 9. By a formal scaling argument we obtain again the behavior (40) which in inflationary cosmological models is known as the Harrison–Zeldovich spectrum of scalar fluctuations.[1,15] The Green functions can be applied in order to derive a solution of Einstein equations linearized around the homogeneous background.[12,13] In such a case in addition to the scalar Green function the tensor Green function must be studied as well. Further consequences of our estimates concerning the spectrum of $\tilde{G}$ for the complete theory still need to be explored. For this purpose a detailed dependence of the Green function on η and η' would be useful. It is much harder to derive such estimates than the ones for the time zero case. In the Appendix we investigate the upper bound G^U for general η. In particular, calculations performed there suggest that it is only the behavior of $\mathcal{V}(y)$ for small y which is relevant for Theorem 4 and that the upper bound is valid for all $\nu>-1+1/d$. For the lower bound G^L we can also obtain an integral representation. However, it is quite complicated.

Another motivation for a study of the $(d+1)$-dimensional Green functions comes from the problem of a dimensional reduction of quantum fields defined on a brane.[16] In such a case we restrict ourselves to a d-dimensional submanifold imposing the condition $\eta=\eta'=0$. We have proved here that if the metric has a power-law behavior, then the Green functions of the restricted quantum field theory are decaying faster in the momentum space than the standard $|\mathbf{p}|^{-1}$. In particular, for $\nu=-\frac{1}{2}$ we obtain the propagator $|\mathbf{p}|^{-2}$ in d-dimensions which is the same as the one of the Euclidean massless free field.

APPENDIX

We calculate the upper bound for the Green function $\tilde{G}$ following the form of Eqs. (26) and (13) in more detail. Set $u=\sqrt{\tau}y$ and let us perform the integration upon τ in Eq. (26) with $W=0$. Then

$$\tilde{G}^U(\eta,\eta',\mathbf{p})=2(2\pi)^{-1/2}\int_0^1 ds\int du(2\pi s(1-s))^{-1/2}K_0(\sqrt{2M\mathbf{p}\tilde{V}\mathbf{p}(u)}), \tag{A1}$$

where

$$M = (\eta' - \eta)^2 + (s(1-s))^{-1}(u - \eta - s(\eta' - \eta))^2 \tag{A2}$$

and K_ρ is the modified Bessel function of order ρ.[17]

The integral is simpler if $\eta = \eta'$

$$\tilde{G}^U(\eta, \eta, \mathbf{p}) = \pi^{-1} \int_0^1 ds \int du\, K_0(N\sqrt{2\mathbf{p}\tilde{V}\mathbf{p}(u)}), \tag{A3}$$

where

$$N = (s(1-s))^{-1/2}\eta - u. \tag{A4}$$

If $\eta' = \eta = 0$, then the integral (A1) further simplifies. If additionally V is scale invariant, then we can calculate it exactly as in Sec. III.

For arbitrary η and η' the behavior of $\tilde{G}^U$ is much more complicated because the decay of $\tilde{G}^U$ substantially depends on η. In the simplest case, when $\tilde{V} = \frac{1}{2}$

$$\tilde{G}(\eta, \eta', \mathbf{p}) = |\mathbf{p}|^{-1} \exp(-|\mathbf{p}||\eta' - \eta|). \tag{A5}$$

Let us consider an arbitrary V and assume that it behaves as

$$V(\lambda y) = \lambda^{2\nu} B_\lambda(y) \tag{A6}$$

when $\lambda \to 0$ with a certain B_λ, which as a function of λ is bounded from above and from below, i.e., $C_2(y) \geqslant B_\lambda(y) \geqslant C_1(y) > 0$ for a small λ. Let us change variables in Eq. (A1)

$$u = |\mathbf{p}|^{-1/(1+\nu)} y. \tag{A7}$$

Assume that $|\mathbf{p}| \to \infty$, $\eta \to 0$, and $\eta' \to 0$ in such a way that $\theta = |\mathbf{p}|^{1/(1+\nu)}\eta$ and $\theta' = |\mathbf{p}|^{1/(1+\nu)}\eta'$ remain finite. In such a case from Eq. (A1) we can conclude that

$$\tilde{G}(|\mathbf{p}|^{-1/(1+\nu)}\theta, |\mathbf{p}|^{-1/(1+\nu)}\theta', \mathbf{p}) \simeq |\mathbf{p}|^{-2\omega} \tag{A8}$$

for large $\mathbf{p}$ in agreement with Eqs. (40) and (A5) ($\nu = 0$ for a constant $\tilde{V}$).

Equations (A1)–(A4) give an integral representation of the upper bound which is expected to approximate the exact Green function $\tilde{G}$ for large $\mathbf{p}$. We suppose that the Fourier transform G^U of $\tilde{G}^U$ is a reliable approximation to G at short distances. After the Fourier transform of Eq. (26) with $W = 0$ we can calculate the τ integral in Eq. (13) exactly. We obtain

$$G^U(\eta, \mathbf{x}, \eta', \mathbf{x}') = (2\pi)^{-(d+2)/2} \int_0^1 ds (s(1-s))^{-1/2} \int dy (\det \tilde{V}(y))^{-1/2} ((\mathbf{x} - \mathbf{x}')\tilde{V}^{-1}(y)(\mathbf{x} - \mathbf{x}')$$
$$+ (\eta - \eta')^2 + (s(1-s))^{-1}(y - \eta - s(\eta' - \eta))^2)^{-d/2}. \tag{A9}$$

If $\tilde{V}^{ij}(y) = \delta^{ij} v(y)$, then the formula (A9) can be expressed in a simpler form

$$G^U(\eta, \mathbf{x}, \eta', \mathbf{x}') = (2\pi)^{-(d+2)/2} \int_0^1 ds (s(1-s))^{-1/2} \int dy (|\mathbf{x} - \mathbf{x}'|^2 + v(y)(\eta - \eta')^2$$
$$+ (s(1-s))^{-1} v(y)(y - \eta - s(\eta' - \eta))^2)^{-d/2}. \tag{A10}$$

If $v = 1$, then Eq. (A10) gives

$$(2\pi)^{-(d+1)/2}(|\mathbf{x} - \mathbf{x}'|^2 + (\eta - \eta')^2)^{-(d-1)/2}, \tag{A11}$$

as it should.

The integrals (A9) and (A10) suggest some generalizations of the theorems proved in the main part. First, assume that $V(y) \simeq |y|^{2\rho}$ for a large $|y|$. Then the integrals (A9) and (A10) are finite (for $|\mathbf{x}-\mathbf{x}'| \neq 0$) if $\rho > -1+1/d$. Next, it can be shown from Eq. (A10) that if $v(y) \simeq |y|^{2\nu}$ for $y \to 0$ and $\eta = \eta' = 0$, then

$$G^U(0,\mathbf{x},0,\mathbf{x}') \simeq |\mathbf{x}-\mathbf{x}'|^{-d+1/(1+\nu)}$$

for $\mathbf{x}-\mathbf{x}' \to 0$. The derivation of the result (44) based on Eq. (A10) suggests that for Theorem 4 only the behavior of $V(y)$ for a small y is relevant [assuming the integral (A10) is finite].

For general v and arbitrary $\mathbf{x}, \mathbf{x}', \eta$ and η' it is harder to obtain usable estimates. Let us mention some special cases. It follows directly from Eq. (41) that

$$G(\eta,\mathbf{x},0,\mathbf{x}) \simeq |\eta|^{-d(1+\nu)+1}$$

and

$$G(0,\mathbf{x},\eta',\mathbf{x}) \simeq |\eta'|^{-d(1+\nu)+1},$$

whereas from Eq. (A10) we obtain that if $v(\eta) \neq 0$, then

$$G^U(\eta,\mathbf{x},\eta,\mathbf{x}') \simeq v(\eta)^{-1/2}|\mathbf{x}-\mathbf{x}'|^{-d+1} \tag{A12}$$

when $\mathbf{x} \to \mathbf{x}'$.

If $V(y) \geqslant c|y|^{2\rho}$ with $c > 0$ and $\rho > -1+1/d$ for large y, then changing the integration variable $y = |\mathbf{x}-\mathbf{x}'|^{1/(1+\rho)}z$ we can show that for any η and η' there exists A such that if $|\mathbf{x}-\mathbf{x}'| \geqslant A$, then

$$G^U(\eta,\mathbf{x},\eta',\mathbf{x}') \leqslant K|\mathbf{x}-\mathbf{x}'|^{-d+1/(1+\rho)}. \tag{A13}$$

When $\rho > 0$, then Eq. (A13) gives a nontrivial estimate saying that the Green function has a stronger decay for large distances than the one for operators with constant coefficients. However, such a decay at large distances will be changed by most perturbations W whereas the behavior for short distances is remarkably stable with respect to perturbations.

(Received 21 October 2003; accepted 12 November 2004; published online 15 March 2005)

In nonrelativistic quantum electrodynamics the charge of an electron equals its bare value, whereas the self-energy and the mass must be renormalized. In our contribution we study perturbative mass renormalization, including second order in the fine structure constant α, in the case of a single, spinless electron. As is well known, if m denotes the bare mass and m_{eff} the mass computed from the theory, to order α one has $m_{\mathrm{eff}}/m=1+(8\alpha/3\pi)\log(1+\frac{1}{2}(\Lambda/m))+O(\alpha^2)$ which suggests that $m_{\mathrm{eff}}/m=(\Lambda/m)^{8\alpha/3\pi}$ for small α. If correct, in order α^2 the leading term should be $\frac{1}{2}((8\alpha/3\pi)\log(\Lambda/m))^2$. To check this point we expand m_{eff}/m to order α^2. The result is $\sqrt{\Lambda/m}$ as leading term, suggesting a more complicated dependence of m_{eff} on m. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1852699]

I. INTRODUCTION

Nonperturbative renormalization in relativistic quantum electrodynamics (QED) remains as a mathematical challenge. Thus it is of interest to study simplified candidates, an obvious one being nonrelativistic QED. In this theory, with comparable little effort, one can start from a self-adjoint Hamiltonian operator and thus has a well-defined mathematical framework. As an additional simplification, there is no charge renormalization because of the absence of positrons. Nevertheless, even in nonrelativistic QED, energy and mass renormalization remain poorly understood. Our, admittedly modest, contribution is to study mass renormalization including order α^2.

Let us first explain the basic Hamiltonian. We consider a single, spinless free electron coupled to the quantized radiation field. We will use relativistic units and employ immediately the total momentum representation. Then the Hilbert space of states is the symmetric Fock space, $\mathcal{F}$, over the one-particle space $L^2(\mathbb{R}^3\times\{1,2\})$, i.e.,

$$\mathcal{F}=\oplus_{n=0}^{\infty}[\otimes_s^n L^2(\mathbb{R}^3\times\{1,2\})].$$

The inner product in $\mathcal{F}$ is denoted by $(\cdot,\cdot)$ and the Fock vacuum by Ω. On $\mathcal{F}$ we introduce the Bose field

$$a(f)=\sum_{j=1,2}\int f(k,j)^* a(k,j)\mathrm{d}k, \quad f\in L^2(\mathbb{R}^3\times\{1,2\}). \tag{1.1}$$

Operators $a(f)$ and $a(f)^*=a^*(f)$ are densely defined and satisfy the CCR,

$$[a(f),a^*(g)]=(f,g)_{L^2(\mathbb{R}^3\times\{1,2\})},$$

a)Electronic mail: hiroshima@mpg.setsunan.ac.jp
b)Electronic mail: spohn@ma.tum.de

$$[a(f),a(g)]=0,$$

$$[a^*(f),a^*(g)]=0.$$

The kinetic energy of the photon is given by

$$H_f=\sum_{j=1,2}\int \omega(k)a^*(k,j)a(k,j)\mathrm{d}k, \tag{1.2}$$

which is the second quantization of $\omega(k)=|k|$ considered as a multiplication operator on $L^2(\mathbb{R}^3)$. Similarly the momentum of the photon field is

$$P_f=\sum_{j=1,2}\int ka^*(k,j)a(k,j)\mathrm{d}k. \tag{1.3}$$

The coupling of the electron to the Maxwell field is mediated through the transverse vector potential $A_{\hat{\varphi}}$ defined by

$$A_{\hat{\varphi}}=\frac{1}{\sqrt{2}}(a(f_{\hat{\varphi}})+a^*(f_{\hat{\varphi}})), \tag{1.4}$$

where

$$f_{\hat{\varphi}}(k,j)=\frac{1}{\sqrt{\omega}}\hat{\varphi}(k)e(k,j),\quad k\in\mathbb{R}^3,\quad j=1,2, \tag{1.5}$$

with $k/|k|$, $e(k,1)$, $e(k,2)$ forming a right-handed dreibein in $\mathbb{R}^3$. $\hat{\varphi}$ is the form factor which, as a minimal assumption, satisfies

$$\int_{\mathbb{R}^3}|\hat{\varphi}(k)|^2(\omega(k)^{-2}+\omega(k))\mathrm{d}k<\infty. \tag{1.6}$$

Later on, we will make a more specific choice of $\hat{\varphi}$.

With these definitions the Hamiltonian under study is

$$H_{\hat{\varphi}}(p)=\tfrac{1}{2}:(p-P_f-eA_{\hat{\varphi}})^2:+H_f,\quad p\in\mathbb{R}^3, \tag{1.7}$$

where p is the total momentum, e the charge, to be definite $e\geqslant 0$, and $:X:$ denotes the Wick order of X. $H_{\hat{\varphi}}(p)$ with domain $D(H_f+\frac{1}{2}P_f^2)=D(H_f)\cap D(\frac{1}{2}P_f^2)$ is self-adjoint for e and p with $|e|<e_0$ and $|p|<p_0$ for some e_0 and p_0, provided (1.6) holds. The energy-momentum relation is defined as the bottom of the spectrum of $H_{\hat{\varphi}}(p)$,

$$E_{\hat{\varphi}}(p)=\inf\sigma(H_{\hat{\varphi}}(p)). \tag{1.8}$$

In (1.7) the bare mass m of the electron is still missing. It appears in two places. First the form factor depends on m. Let us assume a sharp ultraviolet cutoff Λ. Then

$$\hat{\varphi}(k)=\hat{\varphi}_0(mck/\Lambda),\quad \Lambda>0,$$

$$\hat{\varphi}_0(k)=\begin{cases}(2\pi)^{-3/2} & \text{for } |k|\leqslant 1,\\ 0 & \text{for } |k|>1,\end{cases} \tag{1.9}$$

with $1/mc$ the Compton wavelength. Second, energy is to be measured in units of mc^2 and momentum in units of mc. We henceforth set $c=1$ (and also $\hbar=1$). Thus the true energy-momentum relation of the Pauli–Fierz Hamiltonian is

$$E_{m,\Lambda}(p) = mE_{\hat{\varphi}}(p/m), \quad \hat{\varphi} \text{ of (1.9)}. \tag{1.10}$$

Note that equivalently $E_{m,\Lambda}(p)$ is given through

$$E_{m,\Lambda}(p) = \inf \sigma\left(\frac{1}{2m} :(p - P_f - eA_{\hat{\varphi}_0(\cdot/\Lambda)})^2: + H_f \right).$$

Removal of the ultraviolet cutoff Λ through mass renormalization means to find sequences

$$\Lambda \to \infty, \quad m \to 0 \tag{1.11}$$

such that $E_{m,\Lambda}(p) - E_{m,\Lambda}(0)$ has a nondegenerate limit. A convenient criterion for nondegeneracy is the curvature of $E_{m,\Lambda}(p)$ at $p=0$, in other words the inverse effective mass. Let us assume for a moment an infrared cutoff,

$$\hat{\varphi}(k) = 0 \quad \text{for } |k| < \kappa/m$$

with some $0 < \kappa$. Then it is known[1] that, for $|e| < e_*$, $|p| < p_*$ with suitable $e_* > 0$ and $p_* > 0$, $H_{\hat{\varphi}}(p)$ has a nondegenerate ground state $\psi_g(p)$ separated by a gap from the continuum, i.e.,

$$H_{\hat{\varphi}}(p)\psi_g(p) = E_{\hat{\varphi}}(p)\psi_g(p), \quad \psi_g(p) \in \mathcal{F},$$

has a unique solution. Let us set

$$E_{m,\Lambda}(p) - E_{m,\Lambda}(0) = \frac{1}{2m_{\text{eff}}} p^2 + \mathcal{O}(|p|^3) \tag{1.12}$$

for small p. Then, using second order perturbation theory in (1.10), one obtains

$$\frac{m}{m_{\text{eff}}} = 1 - \frac{2}{3} \sum_{\mu=1,2,3} \frac{(\psi_g(0), (P_f + eA_{\hat{\varphi}})_\mu (H_{\hat{\varphi}}(0) - E_{\hat{\varphi}}(0))^{-1} (P_f + eA_{\hat{\varphi}})_\mu \psi_g(0))}{(\psi_g(0), \psi_g(0))}. \tag{1.13}$$

We assume that this formula remains valid also when $\kappa = 0$.

On the basis of (1.13), mass renormalization can be discussed more precisely. From (1.13) it trivially follows that m/m_{eff} depends only on the ratio Λ/m. It is convenient to express this dependence in the form

$$\frac{m_{\text{eff}}}{m} = h(\Lambda/m). \tag{1.14}$$

Clearly $h \geqslant 1$ and $h(0) = 1$. Let us set

$$\lambda = \frac{\Lambda}{m}. \tag{1.15}$$

One expects that h is increasing in λ, because with increasing Λ more photons are bound to the electron which makes m_{eff} larger.

Let us distinguish several cases. If h has a finite limit as $\lambda \to \infty$, then the mass renormalization is finite,

$$m_{\text{eff}} = h(\infty)m.$$

Such kind of behavior occurs in the Nelson model.[2] Second, let us consider the case that $h(\lambda)$ increases linearly for large λ. We set

$$h(\lambda) = 1 + b_0\lambda$$

with $b_0 > 0$. Then

$$m_{\text{eff}} = m + b_0\Lambda. \tag{1.16}$$

Hence mass renormalization is additive. This behavior is found in the dipole approximation to the Pauli–Fierz Hamiltonian, e.g., Ref. 3, and in the classical Abraham model.[4] If $m_{\text{eff}} > 0$ is imposed, then as $\Lambda \to \infty$ necessarily $m \to -\infty$. As soon as $m < 0$, $mH_{\hat{\varphi}}(p/m)$ is not bounded from below. Therefore we regard the theory as not renormalizable. Thus the case of interest is when for large λ,

$$h(\lambda) \simeq b_0\lambda^{\gamma}, \quad b_0 > 0, \quad 0 < \gamma < 1, \tag{1.17}$$

which defines the scaling exponent γ and the amplitude b_0. γ depends on e, as does b_0. Inserting (1.17) in (1.14), one obtains for sufficiently large λ,

$$\frac{m_{\text{eff}}}{m} \simeq b_0\left(\frac{\Lambda}{m}\right)^{\gamma}. \tag{1.18}$$

Thus the choice

$$m = \Lambda^{-\gamma/(1-\gamma)} b_1^{1/(1-\gamma)} \tag{1.19}$$

yields

$$\lim_{\Lambda\to\infty} m_{\text{eff}}(\Lambda) = m^* = b_0 b_1. \tag{1.20}$$

Here b_0 is fixed by $h(\lambda)$ and b_1 is a parameter which can be adjusted to yield the experimentally determined mass of the electron.

Of course, the difficulty with our discussion is that, while the scaling function is well defined, at present we have no technique to find out its behavior for large λ. For that reason we turn to perturbative renormalization which, through the interchange of the limits $\Lambda \to \infty$ and $e \to 0$, tries to guess the proper value of γ. The details will be given in the following sections, but let us summarize briefly our findings. The fine structure constant is defined through

$$\alpha = \frac{e^2}{4\pi}. \tag{1.21}$$

To first order one finds

$$h(\lambda) = 1 + \frac{8\alpha}{3\pi}\log\left(1 + \frac{1}{2}\lambda\right) + \mathcal{O}(\alpha^2), \tag{1.22}$$

which suggests

$$h(\lambda) \simeq \lambda^{8\alpha/3\pi} \tag{1.23}$$

for sufficiently large λ and therefore

$$\gamma = \frac{8\alpha}{3\pi}, \quad \alpha \ll 1. \tag{1.24}$$

To have a control check, one assumes that to second order

$$h(\lambda) \simeq \lambda^{(8/3\pi)\alpha + b\alpha^2} \simeq 1 + \frac{8\alpha}{3\pi}\log\lambda + \frac{1}{2}\left(\frac{8\alpha}{3\pi}\log\lambda\right)^2 + b\alpha^2\log\lambda + \mathcal{O}(\alpha^3) \tag{1.25}$$

for small α. Therefore by expanding m_{eff}/m to order α^2, one should find a term $(\log\lambda)^2$ with an already determined prefactor and a term proportional to $\log\lambda$, together with lower order terms. As to explain, this guess is not confirmed. *Instead* we prove that

$$h(\lambda) = 1 + \frac{8\alpha}{3\pi}\log\left(1 + \frac{1}{2}\lambda\right) + c_0\alpha^2\sqrt{\lambda} + \mathcal{O}(\alpha^3), \quad c_0 > 0, \tag{1.26}$$

for $|\alpha|$ small enough *depending on* Λ, which could suggest $\gamma = \frac{1}{2}$ independent of e.

Note added in proof: Since the completion of this work, Hiroshima and Ito[5] extended the investigation to include the spin of the electron. The number of terms in the perturbation series up to the same order as studied here is then multiplied by a factor of 4. As a net result one finds that the leading divergence is proportional to λ^2, rather than $\lambda^{1/2}$. Because of the interaction with the quantized magnetic field the effective mass (at the order considered) is more strongly ultraviolet divergent when spin is included.

Some aspects of the effective mass and its renormalization have been studied before. Spohn[6] investigates the effective mass of the Nelson model[2] from a functional integral point of view. Lieb and Loss[7,8] study mass renormalization and binding energies for various models of matter coupled to the radiation field including the Pauli–Fierz model. Hainzl[9] and Hainzl and Seiringer[10] compute the leading order of the effective mass of the Pauli–Fierz Hamiltonian with spin $1/2$.

Our paper is organized in the following way. In Sec. II we review under which conditions $E_{\hat{\varphi}}(p) = E_{\hat{\varphi}}(p,e)$ is jointly analytic in p and e. In Sec. III we set up the perturbation theory for the effective mass and work out explicitly the terms including α^2. Their asymptotics with $\Lambda \to \infty$ is studied in Sec. IV.

II. GROUND STATE AND ITS ANALYTIC PROPERTIES

Throughout this paper we assume that

$$\hat{\varphi}(k) = \begin{cases} 0 & \text{for } |k| < \kappa/m, \\ (2\pi)^{-3/2} & \text{for } \kappa/m \leqslant |k| \leqslant \Lambda/m, \\ 0 & \text{for } |k| > \Lambda/m. \end{cases}$$

For notational convenience, we shall use notations $H(p)$, A, and $E(p)$ instead of $H_{\hat{\varphi}}(p)$, $A_{\hat{\varphi}}$, and $E_{\hat{\varphi}}(p)$, respectively. Let $\mathcal{F}_\kappa$ (respectively, $\mathcal{F}_{\kappa,0}$) be the symmetric Fock space over $L^2(\mathbb{R}^3_{\kappa/m} \times \{1,2\})$ [respectively, $L^2(\mathbb{R}^{3\perp}_{\kappa/m} \times \{1,2\})$], where $\mathbb{R}^3_{\kappa/m} = \{k \in \mathbb{R}^3 \| k| \geqslant \kappa/m\}$. Then it follows that

$$\mathcal{F} \cong \mathcal{F}_\kappa \otimes \mathcal{F}_{\kappa,0}. \tag{2.1}$$

It is seen that $\mathcal{F}_\kappa$ reduces $H(p)$ and, under the identification (2.1),

$$H(p) \cong \left(H(p)\lceil_{\mathcal{F}_\kappa}\right) \otimes 1 + 1 \otimes \left(H_f\lceil_{\mathcal{F}_{\kappa,0}}\right). \tag{2.2}$$

The bottom of the continuous spectrum of $H(p)\lceil_{\mathcal{F}_\kappa}$ is denoted by $E_c(p)$. Note that $\inf \sigma(H(p)\lceil_{\mathcal{F}_\kappa}) = E(p)$. The following lemma can be proven in the similar manner as in Ref. 11.

Lemma 2.1 (Ref. 11): There exists a constant $p_* > 0$ independent of e with $|e| < e_0$ such that for $p \in \mathbb{R}^3$ with $|p| < p_*$,

$$E_c(p) - E(p) > 0.$$

In particular there exists a ground state $\psi_{g,\kappa}(p) \in \mathcal{F}_\kappa$ of $H(p)\lceil_{\mathcal{F}_\kappa}$ for $p \in \mathbb{R}^3$ provided $|p| < p_*$.

By Lemma 2.1, we see that $H(p)$ has the ground state

$$\psi_g(p) = \psi_{g,\kappa}(p) \otimes \Omega_{\kappa,0}$$

for $p \in \mathbb{R}^3$ provided $|p| < p_*$, where $\Omega_{\kappa,0}$ denotes the vacuum of $\mathcal{F}_{\kappa,0}$. To have uniqueness, one proves that for any ground state $\psi_g(p)$, one has

$$(\psi_g(p), \Omega) > 0$$

provided $|p| < p_*$ and $|e| < e_*$ with some e^*.

Lemma 2.2 (Ref. 1): There exists a constant $e_* > 0$ such that for $(p,e) \in \mathbb{R}^3 \times \mathbb{R}$ with

$|p|<p_*$ *and* $|e|<e_*$, *the ground state of* $H(p)$ *is unique up to multiple constants.*

Remark 2.3: In the case $\kappa=0$ *and for sufficiently small* e, *Chen*[12] *proves the absence of a ground state of* $H(p)$ *in* $\mathcal{F}$ *for* $p\neq 0$ *and the existence of a ground state of* $H(0)$.

We also need the analytic properties of $\psi_g(p)=\psi_g(p,e)$ and $E(p)=E(p,e)$ with respect to $(p,e)\in\mathbb{R}^3\times\mathbb{R}$ in a neighborhood of $(0,0)\in\mathbb{R}^3\times\mathbb{R}$.

Lemma 2.4: There exists an open neighborhood $\mathcal{O}$ *of* $(0,0)\in\mathbb{R}^3\times\mathbb{R}$ *such that* $\psi_g(p,e)$ *is strongly analytic and* $E(p,e)$ *analytic on* $\mathcal{O}$.

Proof: Let $\psi_{g,\kappa}(p)\in\mathcal{F}_\kappa$ be the ground state of $H(p)\restriction_{\mathcal{F}_\kappa}$. Since $\psi_g(p)=\psi_{g,\kappa}(p)\otimes\Omega_{\kappa,0}$, it is enough to show that $\psi_{g,\kappa}(p)$ is strongly analytic on $\mathcal{O}$. We split $H(p)$ as

$$H(p)=H_0(p)+H_I(p), \tag{2.3}$$

where

$$H_0(p)=\tfrac{1}{2}(p-P_f)^2+H_f,$$

$$H_I(p)=-e(p-P_f)\cdot A+\frac{e^2}{2}{:}A^2{:}\,.$$

Then we obtain that

$$\|H_I(p)\Psi\|_{\mathcal{F}_\kappa}\leqslant c_4\|H_0(p)\Psi\|_{\mathcal{F}_\kappa}+c_5\|\Psi\|_{\mathcal{F}_\kappa} \tag{2.4}$$

for $\Psi\in D(H_0(p)\restriction_{\mathcal{F}_\kappa})=D(H_f)\cap D(P_f{}^2)\cap\mathcal{F}_\kappa$. Then $H(p)\restriction_{\mathcal{F}_\kappa}$ is an analytic family of type (A) for e near $e=0$ (see Ref. 13, p. 16). Thus by Ref. 13, Theorem XII.9, $H(p)\restriction_{\mathcal{F}_\kappa}$ is an analytic family in the sense of Kato, which implies that by Ref. 13, Theorem XII.8, together with Lemmas 2.1 and 2.2, $\psi_{g,\kappa}(p,e)$ is strongly analytic and $E(p,e)$ analytic for e near $e=0$. Alternatively we split $H(p)$ as

$$H(p)=H_0'+p\cdot H_I'+\tfrac{1}{2}p^2,$$

where

$$H_0'=\tfrac{1}{2}{:}(P_f+eA_{\hat{\varphi}})^2{:}+H_f,\quad H_I'=-(P_f+eA_{\hat{\varphi}}).$$

Then we have

$$\|H_I'\Psi\|_{\mathcal{F}_\kappa}\leqslant c_6\|H_0'\Psi\|_{\mathcal{F}_\kappa}+c_7\|\Psi\|_{\mathcal{F}_\kappa} \tag{2.5}$$

with some constants c_6 and c_7 for $\Psi\in D(H_f)\cap D(P_f{}^2)\cap\mathcal{F}_\kappa$. Thus $H(p)\restriction_{\mathcal{F}_\kappa}$ is an analytic family of type (A) for $p\in\mathbb{R}^3$ near $p=0$. We can see that $\psi_{g,\kappa}(p,e)$ is strongly analytic and $E(p,e)$ analytic for p near $p=0$ in the similar manner as for e. ■

III. EFFECTIVE MASS

A. Formulas

In what follows we assume that $(p,e)\in\mathcal{O}$. By the definition of $E(p,e)$, we have

$$\frac{m}{m_{\text{eff}}}=\frac{1}{3}\Delta_p E(p,e)\restriction_{p=0}. \tag{3.1}$$

Actually we can see in Ref. 1 that $H(p)$ is unitarily equivalent to $H(|p|n_z)$, where $n_z=(0,0,1)$. Thus $E(p,e)=\tilde{E}(|p|,e)=\inf\sigma(H(|p|n_z))$ and

$$\frac{m}{m_{\text{eff}}}=\partial_{|p|}^2\tilde{E}(|p|,e)\restriction_{|p|=0}.$$

Moreover we see that $\tilde{E}(-|p|,e)=\tilde{E}(|p|,e)$. Then

$$\partial p_\mu E(p,e)\big|_{p_\mu=0} = 0, \quad \mu = 1,2,3. \tag{3.2}$$

Since $E(p,e)$ also has the symmetry, $E(p,-e)=E(p,e)$, $E(p,e)$ is a function of e^2. In particular it follows that

$$\partial_e^{2m+1} E(p,e)\big|_{e=0} = 0, \quad m \geqslant 0. \tag{3.3}$$

Lemma 3.1: The ratio m/m_{eff} can be expressed as

$$\frac{m}{m_{\text{eff}}} = 1 - \frac{2}{3}\sum_{\mu=1,2,3} \frac{(\psi_g(0),(P_f+eA)_\mu (H(0)-E(0))^{-1}(P_f+eA)_\mu \psi_g(0))}{(\psi_g(0),\psi_g(0))}.$$

Proof: Since

$$(H(p)\Psi,\psi_g(p)) = E(p)(\Psi,\psi_g(p)),$$

for $\Psi \in D(H(p))$, taking a derivative with respect to p_μ on the both sides above, we have

$$(H'_\mu(p)\Psi,\psi_g(p)) + (H(p)\Psi,\psi'_{g_\mu}(p)) = E'_\mu(p)(\Psi,\psi_g(p)) + E(p)(\Psi,\psi'_{g_\mu}(p)) \tag{3.4}$$

and

$$\begin{aligned}(H''_\mu(p)\Psi,\psi_g(p)) + 2(H'_\mu(p)\Psi,\psi'_{g_\mu}(p)) + (H(p)\Psi,\psi''_{g_\mu}(p))\\ = E''_\mu(p)(\Psi,\psi_g(p)) + 2E'_\mu(p)(\Psi,\psi'_{g_\mu}(p)) + E(p)(\Psi,\psi''_{g_\mu}(p)).\end{aligned} \tag{3.5}$$

Here $E'_\mu(p)$ [respectively, $\psi'_{g_\mu}(p)$] denotes the derivative (respectively, strong derivative) in p_μ, and $H'_\mu(p)=(p-P_f-eA_{\hat{\varphi}})_\mu$, $H''_\mu(p)=1$. By (3.2) it follows that $E'_\mu(0)=0$, and by (3.4) with $p=0$,

$$(P_f+eA)_\mu \psi_g(0) \in D((H(0)-E(0))^{-1}),$$

and

$$\psi'_{g_\mu}(0) = (H(0)-E(0))^{-1}(P_f+eA)_\mu \psi_g(0).$$

Therefore, using (3.1) and (3.5), we have

$$\begin{aligned}\frac{m}{m_{\text{eff}}} &= \frac{1}{3}\sum_{\mu=1,2,3} \frac{(\psi_g(0),E''(0)_\mu \psi_g(0))}{(\psi_g(0),\psi_g(0))}\\ &= \frac{1}{3}\sum_{\mu=1,2,3}\left\{1 + \frac{(\psi_g(0),2H'_\mu(0)\psi'_{g_\mu}(0))}{(\psi_g(0),\psi_g(0))}\right\}\\ &= 1 - \frac{2}{3}\sum_{\mu=1,2,3} \frac{((P_f+eA)_\mu\psi_g(0),(H(0)-E(0))^{-1}(P_f+eA)_\mu\psi_g(0))}{(\psi_g(0),\psi_g(0))}.\end{aligned} \tag{3.6}$$

Thus the lemma follows. ■

From this lemma we obtain the following corollary.

Corollary 3.2: Let $|e|<e_*$. Then $m_{\text{eff}} \geqslant m$.

B. Perturbative expansions

Let

$$\psi_g(0) = \sum_{n=0}^{\infty} \frac{e^n}{n!}\varphi_n, \quad E(0) = \sum_{n=0}^{\infty} \frac{e^{2n}}{(2n)!}E_{2n}.$$

We want to get the explicit form of φ_n. Let

$$\mathcal{F}_{\rm fin} = \{\{\Psi^{(n)}\}_{n=0}^{\infty} \in \mathcal{F} | \Psi^{(m)} = 0 \quad \text{for } m \geqslant \ell \text{ with some } \ell\},$$

$$\mathcal{F}_0 = \{\Psi \in \mathcal{F}_{\rm fin} | ({\rm i}) \Psi^{(0)} = 0, ({\rm ii}) {\rm supp}_{k \in \mathbb{R}^{3n}} \Psi^{(n)}(k,j) \not\ni \{0\}, n \geqslant 1, j \in \{1,2\}^n\}.$$

Lemma 3.3: It follows that $\mathcal{F}_0 \subset D(H_0^{-1})$.

Proof: Let $\Psi = \{\Psi^{(n)}\}_{n=0}^{\infty} \in \mathcal{F}_0$. Since

$$(H_0^{-1}\Psi)^{(n)}(k_1, \ldots, k_n, j_1, \ldots, j_n) = \left[\frac{1}{2}(k_1 + \cdots + k_n)^2 + \sum_{i=1}^{n} \omega(k_i)\right]^{-1} \Psi^{(n)}(k_1, \ldots, k_n, j_1, \ldots, j_n),$$

and ${\rm supp}_{(k_1,\ldots,k_n) \in \mathbb{R}^{3n}} \Psi^{(n)}(k_1, \ldots, k_n, j_1, \ldots, j_n) \not\ni \{(0, \ldots, 0)\}$, we obtain that

$$\|H_0^{-1}\Psi\|_{\mathcal{F}}^2 = \sum_{n=1}^{\infty} \|(H_0^{-1}\Psi)^{(n)}\|_{\mathcal{F}^{(n)}}^2 < \infty$$

and the lemma follows. ■

We define A^- and A^+ by

$$A^- = \frac{1}{\sqrt{2}} a(f_{\hat{\varphi}}), \quad A^+ = \frac{1}{\sqrt{2}} a^*(f_{\hat{\varphi}}).$$

Then $A = A^+ + A^-$. Moreover A_μ^- and A_μ^+ are defined by A^- and A^+ with $e(k,j) = (e^1(k,j), e^2(k,j), e^3(k,j))$ replaced by $e^\mu(k,j)$. We split $H(0)$ as

$$H(0) = H_0 + eH_1 + \frac{e^2}{2} H_2,$$

where

$$H_0 = \tfrac{1}{2} P_f^2 + H_f,$$

$$H_1 = \tfrac{1}{2}(P_f \cdot A + A \cdot P_f) = P_f \cdot A = A \cdot P_f,$$

$$H_2 = :A^2: = A^+ \cdot A^+ + A^- \cdot A^- + 2A^+ \cdot A^-.$$

Lemma 3.4: It follows that $E_0 = E_2 = 0$, *and there exists a ground state* $\psi_g(0) = \Sigma_{n=0}^{\infty}(e^n/n!)\varphi_n$ *such that*

$$\varphi_0 = \Omega, \quad \varphi_1 = 0, \quad \varphi_2 = -H_0^{-1} H_2 \Omega, \quad \varphi_3 = 3H_0^{-1} H_1 H_0^{-1} H_2 \Omega. \tag{3.7}$$

In particular $\varphi_2 \in \mathcal{F}^{(2)}$ *and* $\varphi_3 \in \mathcal{F}^{(1)} \oplus \mathcal{F}^{(3)}$.

Proof: It is obvious that $E_0 = 0$. Let $\psi_g(0) = \Sigma_{n=0}^{\infty}(e^n/n!)\varphi_n$ be an arbitrary strongly analytic ground state of $H(0)$ with $(\varphi_0, \Omega) \neq 0$. Let $\rho(e) = \Sigma_{n=0}^{\infty}(e^n/n!)\rho_n$ be an analytic function on e and set $\psi_g^\rho = \rho(e)\psi_g(0)$. Then ψ_g^ρ is also a strongly analytic ground state of $H(0)$ and

$$\psi_g^\rho = \underbrace{\rho_1 \varphi_0}_{=\varphi_0^\rho} + \underbrace{e(\rho_0\varphi_1 + \rho_1\varphi_0)}_{=\varphi_1^\rho} + e^2 \frac{1}{2!} \underbrace{(\rho_0\varphi_2 + 2\rho_1\varphi_1 + \rho_2\varphi_0)}_{=\varphi_2^\rho}$$

$$+ e^3 \frac{1}{3!} \underbrace{(\rho_0\varphi_3 + 3\rho_1\varphi_2 + 3\rho_2\varphi_1 + \rho_3\varphi_0)}_{=\varphi_3^\rho} + \mathcal{O}(e^4).$$

Set

$$\rho_0 = 1/(\varphi_0,\Omega), \quad \rho_1 = -\rho_0(\varphi_1,\Omega)/(\varphi_0,\Omega),$$

$$\rho_2 = -\{\rho_0(\varphi_2,\Omega) + 2\rho_1(\varphi_1,\Omega)\}/(\varphi_0,\Omega),$$

$$\rho_3 = -\{\rho_0(\varphi_3,\Omega) + 3\rho_1(\varphi_2,\Omega) + 3\rho_2(\varphi_1,\Omega)\}/(\varphi_0,\Omega).$$

Then $\psi_g^\rho = \Sigma_{n=0}^\infty (e^n/n!)\varphi_n^\rho$ satisfies that

$$(\varphi_n^\rho,\Omega) = \delta_{0,n}, \quad n = 0,1,2,3. \tag{3.8}$$

We reset ψ_g^ρ (respectively, φ_n^ρ) with (3.8) as $\psi_g(0)$ (respectively, φ_n). Let us write $H(0)$, $E(0)$, and $\psi_g(0)$ as H, E, and ψ_g, respectively. Take derivative in e on the both sides of $(H\Psi,\psi_g) = E(\Psi,\psi_g)$, $\Psi \in D(H)$. Then we have

$$(H'\Psi,\psi_g) + (H\Psi,\psi_g') = E'(\Psi,\psi_g) + E(\Psi,\psi_g'), \tag{3.9}$$

$$(H''\Psi,\psi_g) + 2(H'\Psi,\psi_g') + (H\Psi,\psi_g'') = E''(\Psi,\psi_g) + 2E'(\Psi,\psi_g') + E(\Psi,\psi_g''), \tag{3.10}$$

$$3(H''\Psi,\psi_g') + 3(H'\Psi,\psi_g'') + (H\Psi,\psi_g''') = E'''(\Psi,\psi_g) + 3E''(\Psi,\psi_g') + 3E'(\Psi,\psi_g'') + E(\Psi,\psi_g'''), \tag{3.11}$$

where E' (respectively, ψ_g') denotes the derivative (respectively, strong derivative) in e, and $H' = P_f(P_f + eA)$ and $H'' = P_f \cdot A$. Set $\Psi = \Omega$ and $e = 0$ in (3.10). Then

$$0 = E_2(\Omega,\Omega), \tag{3.12}$$

which shows that $E_2 = 0$. From (3.9) with $e = 0$ it follows that

$$H_1\Omega + H_0\varphi_1 = 0,$$

from which it holds that $H_0\varphi_1 = 0$. Hence $\varphi_1 = b\Omega$ with some constant b. By (3.8) we have, however, $b = 0$. Then $\varphi_1 = 0$ follows. By (3.10) with $e = 0$, we have

$$H_2\Omega + H_0\varphi_2 = 0.$$

Since $H_2\Omega \in \mathcal{F}_0$, we see that by Lemma 3.3, $H_2\Omega \in D(H_0^{-1})$. Thus we have $\varphi_2 = -H_0^{-1}H_2\Omega + c\Omega$ with some constant c. Since $(-H_0^{-1}H_2\Omega,\Omega) = 0$, it follows that $c = 0$ from (3.8). From (3.11) it follows that in $e = 0$,

$$3H_1\varphi_2 + H_0\varphi_3 = 0.$$

Since $H_1\varphi_2 = -H_1H_0^{-1}H_2\Omega \in \mathcal{F}_0$, Lemma 3.3 ensures that $H_1\varphi_2 \in D(H_0^{-1})$. Hence $\varphi_3 = -3H_0^{-1}H_1\varphi_2 + d\Omega = 3H_0^{-1}H_1H_0^{-1}H_2\Omega + d\Omega$ with some constant d. Since $(3H_0^{-1}H_1H_0^{-1}H_2\Omega,\Omega) = 0$, it follows that $d = 0$ from (3.8). Then the lemma is proven. ■

In the similar manner as Lemma 3.4, we can prove the following proposition.

Proposition 3.5: There exists a ground state $\psi_g(0) = \Sigma_{n=0}^\infty (e^n/n!)\varphi_n$ such that

$$\varphi_{2m} = H_0^{-1}\left\{ -\sum_{j=1,2} \binom{2m}{j} H_1\varphi_{2m-j} + \sum_{j=2}^{m} \binom{2m}{2j} E_{2j}\varphi_{2m-2j} \right\}, \quad m \geqslant 2,$$

$$\varphi_{2m+1} = H_0^{-1}\left\{ -\sum_{j=1,2} \binom{2m+1}{j} H_j\varphi_{2m+1-j} + \sum_{j=2}^{m-1} \binom{2m+1}{2j} E_{2j}\varphi_{2m-2j+1} \right\}, \quad m \geqslant 2,$$

with $\varphi_{2m} \in \mathcal{F}^{(2)} \oplus \mathcal{F}^{(4)} \oplus \cdots \oplus \mathcal{F}^{(2m)}$ and $\varphi_{2m+1} \in \mathcal{F}^{(1)} \oplus \mathcal{F}^{(3)} \oplus \cdots \oplus \mathcal{F}^{(2m+1)}$, and E_{2m} is given by

$$E_{2m} = \binom{2m}{2}(\Omega, H_2\varphi_{2m-2}), \quad m \geqslant 2.$$

C. Effective mass up to order e^4

In this section we expand m/m_{eff} up to order e^4.

Lemma 3.6: The ratio m/m_{eff} can be expanded as

$$\begin{aligned}\frac{m}{m_{\text{eff}}} = 1 &- e^2\frac{2}{3}\sum_{\mu=1,2,3}(\Omega, A_\mu H_0^{-1}A_\mu\Omega) \\ &- e^4\frac{2}{3}\sum_{\mu=1,2,3}\Big\{2(\Psi_3^\mu, H_0^{-1}\Psi_1^\mu) + (\Psi_2^\mu, H_0^{-1}\Psi_2^\mu) - 2(\Psi_2^\mu, H_0^{-1}H_1H_0^{-1}\Psi_1^\mu) \\ &\qquad - \frac{1}{2}(\Psi_1^\mu, H_0^{-1}H_2H_0^{-1}\Psi_1^\mu) + (\Psi_1^\mu, H_0^{-1}H_1H_0^{-1}H_1H_0^{-1}\Psi_1^\mu)\Big\} + \mathcal{O}(e^6),\end{aligned} \tag{3.13}$$

where

$$\Psi_1^\mu = A_\mu\Omega,$$

$$\Psi_2^\mu = -\tfrac{1}{2}P_{f\mu}H_0^{-1}(A^+\cdot A^+)\Omega,$$

$$\Psi_3^\mu = \tfrac{1}{2}\big\{-A_\mu H_0^{-1}(A^+\cdot A^+)\Omega + \tfrac{1}{2}P_{f\mu}H_0^{-1}(P_f\cdot A + A\cdot P_f)H_0^{-1}(A^+\cdot A^+)\Omega\big\}.$$

Proof: Since by (3.6),

$$\frac{m}{m_{\text{eff}}} = 1 - \frac{2}{3}\sum_{\mu=1,2,3}\frac{((P_f+eA)_\mu\psi_g(0), \psi_{g_\mu}'(0))}{(\psi_g(0),\psi_g(0))}, \tag{3.14}$$

where $\psi_{g_\mu}'(0) = s\text{-}\partial_{p_\mu}\psi_g(p)\big|_{p=0}$, we expand $\psi_{g_\mu}'(0)$ and $\psi_g(0)$ in e. Assume that $\psi_g(0) = \sum_{n=0}^\infty (e^n/n!)\varphi_n$ satisfies (3.7), i.e., $\varphi_0 = \Omega$, $\varphi_1 = 0$, $\varphi_2 = -H_0^{-1}H_2\Omega$, and $\varphi_3 = 3H_0^{-1}H_1H_0^{-1}H_2\Omega$. We have

$$\begin{aligned}(P_f+eA)_\mu\psi_g(0) &= eA_\mu\Omega + e^2\big(\tfrac{1}{2}P_{f\mu}\varphi_2\big) + e^3\big(\tfrac{1}{2}A_\mu\varphi_2 + \tfrac{1}{6}P_{f\mu}\varphi_3\big) + \mathcal{O}(e^4) \\ &= e\Psi_1^\mu + e^2\Psi_2^\mu + e^3\Psi_3^\mu + \mathcal{O}(e^4).\end{aligned} \tag{3.15}$$

Note that by Proposition 3.5,

$$\varphi_0 \in \mathcal{F}^{(0)}, \quad \varphi_2 \in \mathcal{F}^{(2)}, \quad \varphi_3 \in \mathcal{F}^{(3)}\oplus\mathcal{F}^{(1)}, \quad \varphi_4 \in \mathcal{F}^{(4)}\oplus\mathcal{F}^{(2)}.$$

In particular

$$\frac{1}{(\psi_g,\psi_g)} = 1 - e^4(\frac{1}{2}\varphi_2, \frac{1}{2}\varphi_2) - e^4(\Omega, \frac{1}{24}\varphi_4) + \mathcal{O}(e^6) = 1 - e^4\frac{1}{4}(\varphi_2,\varphi_2) + \mathcal{O}(e^6). \tag{3.16}$$

Let

$$\psi_{g_\mu}'(0) = \sum_{n=0}^\infty \frac{e^n}{n!}\Phi_n^\mu. \tag{3.17}$$

Since

$$((H(0)-E(0))\Psi,\psi'_{g_\mu}(0))=((P_f+eA)_\mu\Psi,\psi_g(0)),\quad \Psi\in D(H(0)),\tag{3.18}$$

setting $e=0$ on the both sides of (3.18), we have

$$H_0\Phi_0^\mu=0.$$

Then

$$\Phi_0^\mu=b_0\Omega\tag{3.19}$$

with some constant b_0. From taking derivative of the both sides of (3.18) at $e=0$, we see that by (3.7),

$$H_0\Phi_1^\mu=A_\mu\Omega,$$

$$H_2\Phi_0^\mu+2H_1\Phi_1^\mu+H_0\Phi_2^\mu=P_{f\mu}\varphi_2,$$

$$3H_2\Phi_1^\mu+3H_1\Phi_2^\mu+H_0\Phi_3^\mu=3A_\mu\varphi_2+P_{f\mu}\varphi_3.$$

From them it follows that

$$\Phi_1^\mu=H_0^{-1}\Psi_1^\mu+b_1\Omega,\tag{3.20}$$

$$\begin{aligned}\Phi_2^\mu&=H_0^{-1}(2\Psi_2^\mu-2H_1\Phi_1^\mu-H_2\Phi_0^\mu)+b_2\Omega\\&=2H_0^{-1}(\Psi_2^\mu-H_1H_0^{-1}\Psi_1^\mu)+(-b_0H_0^{-1}H_2\Omega+b_2\Omega),\end{aligned}\tag{3.21}$$

$$\begin{aligned}\Phi_3^\mu&=H_0^{-1}(6\Psi_3^\mu-3H_1\Phi_2^\mu-3H_2\Phi_1^\mu)+b_3\Omega\\&=6H_0^{-1}\left\{\Psi_3^\mu-H_1H_0^{-1}\Psi_2^\mu+\left(H_1H_0^{-1}H_1H_0^{-1}-\tfrac{1}{2}H_2H_0^{-1}\right)\Psi_1^\mu\right\}\\&\quad+(3b_0H_0^{-1}H_1H_0^{-1}H_2\Omega-3b_1H_0^{-1}H_2\Omega+b_3\Omega),\end{aligned}\tag{3.22}$$

where b_1, b_2, b_3 are some constants. Here we used that $H_1\Omega=0$. By (3.14) (3.15) (3.16) and (3.17) we have

$$\begin{aligned}\frac{m}{m_{\text{eff}}}=1-\frac{2}{3}\sum_{\mu=1}^{3}\Bigg\{&e^2((\Psi_1^\mu,\Phi_1^\mu)+(\Psi_2^\mu,\Phi_0^\mu))\\&+e^4\left(\frac{1}{6}(\Psi_1^\mu,\Phi_3^\mu)+\frac{1}{2}(\Psi_2^\mu,\Phi_2^\mu)+(\Psi_3^\mu,\Phi_1^\mu)\right)\Bigg\}+\mathcal{O}(e^6).\end{aligned}\tag{3.23}$$

Substitute (3.20)–(3.22) into (3.23). No contribution of constants $b_0,\ldots,b_3$ exists, i.e., we can directly see that

$$e^2\{b_1(\Psi_1^\mu,\Omega)+b_0(\Psi_2^\mu,\Omega)\}=0$$

and

$$\begin{aligned}e^4\Bigg\{&\frac{1}{6}b_3(\Psi_1^\mu,\Omega)+\frac{1}{6}b_1(\Psi_1^\mu,-3H_0^{-1}H_2\Omega)+\frac{1}{6}b_0(\Psi_1^\mu,3H_0^{-1}H_1H_0^{-1}H_2\Omega)\\&+\frac{1}{2}b_2(\Psi_2^\mu,\Omega)+\frac{1}{2}b_0(\Psi_2^\mu,-H_0^{-1}H_2\Omega)+b_1(\Psi_3^\mu,\Omega)\Bigg\}=0.\end{aligned}$$

Then the lemma follows. ■

Remark 3.7: By Lemma 3.1 we have seen that

$$\frac{m}{m_{\text{eff}}} = 1 - \frac{2}{3}\sum_{\mu=1,2,3} \frac{((P_f + eA)_\mu \psi_g(0), (H(0) - E(0))^{-1}(P_f + eA)_\mu \psi_g(0))}{(\psi_g(0), \psi_g(0))}. \tag{3.24}$$

We "informally" expand $(H(0)-E(0))^{-1}$ *as*

$$\begin{aligned}(H(0) - E(0))^{-1} &= \sum_{n=0}^{\infty} \left(- H_0^{-1} \sum_{l=1}^{\infty} \frac{e^l}{l!} H_l \right)^n H_0^{-1} \\ &= \sum_{n=0}^{\infty} (-1)^n \sum_{k=n}^{\infty} e^k \sum_{\substack{l_1,\ldots,l_n=1 \\ l_1+\cdots+l_n=k}}^{k} \frac{1}{l_1! \cdots l_n!} H_0^{-1} H_{l_1} H_0^{-1} H_{l_2} \cdots H_0^{-1} H_{l_n} H_0^{-1}. \end{aligned} \tag{3.25}$$

Here we set

$$H_j = \begin{cases} H_j, & j = 1,2, \\ -E_j, & j \geqslant 3. \end{cases}$$

Then we have

$$\begin{aligned}(H(0) - E(0))^{-1} &= H_0^{-1} - eH_0^{-1} H_1 H_0^{-1} \\ &\quad + e^2 \left(-\tfrac{1}{2} H_0^{-1} H_2 H_0^{-1} + H_0^{-1} H_1 H_0^{-1} H_1 H_0^{-1} \right) + \mathcal{O}(e^3). \end{aligned} \tag{3.26}$$

Substitute (3.26) into (3.24). Then the result coincides with (3.13).

D. Explicit expressions

For each $k \in \mathbb{R}^3$ let us define the projection $Q(k)$ on $\mathbb{R}^3$ by

$$Q(k) = \sum_{j=1,2} |e_j(k)\rangle\langle e_j(k)|.$$

We also set

$$m = 1,$$

since it can easily be reintroduced at the end of the computation. We set

$$\hat{\varphi}_j = \hat{\varphi}(k_j), \quad \omega_j = \omega(k_j), \quad Q(k_j) = Q_j, \quad j = 1,2.$$

Let

$$\frac{1}{E_j} = \frac{1}{|k_j|^2/2 + \omega_j}, \quad j = 1,2,$$

$$\frac{1}{E_{12}} = \frac{1}{|k_1 + k_2|^2/2 + \omega_1 + \omega_2}, \quad k_1, k_2 \in \mathbb{R}^3,$$

$$\frac{1}{F_j} = \frac{1}{r_j^2/2 + r_j}, \quad j = 1,2,$$

$$\frac{1}{F_{12}} = \frac{1}{(r_1^2 + 2r_1 r_2 X + r_2^2)/2 + r_1 + r_2}, \quad r_1, r_2 \geqslant 0, \quad -1 \leqslant X \leqslant 1.$$

Lemma 3.8: It follows that

$$\frac{m}{m_{\mathrm{eff}}} = 1 - \alpha a_1(\Lambda,\kappa) - \alpha^2 a_2(\Lambda,\kappa) + \mathcal{O}(\alpha^3),$$

where

$$a_1(\Lambda,\kappa) = \frac{8}{3\pi}\log\left(\frac{\Lambda+2}{\kappa+2}\right) \tag{3.27}$$

and

$$\begin{aligned} a_2(\Lambda,\kappa) = (4\pi)^2\frac{2}{3}\int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat{\varphi}_1|^2}{2\omega_1}\frac{|\hat{\varphi}_2|^2}{2\omega_2} \\ \times\Bigg\{-\left(\frac{1}{E_1}+\frac{1}{E_2}\right)\frac{1}{E_{12}}(1+s^2)+\left(\frac{1}{E_{12}}\right)^3\frac{|k_1+k_2|^2}{2}(1+s^2) \\ +\left(\frac{1}{E_1}+\frac{1}{E_2}\right)\left(\frac{1}{E_{12}}\right)^2(k_1\cdot k_2)(-1+s^2)-\frac{1}{E_1}\frac{1}{E_2}(1+s^2) \\ +\left(\frac{|k_1|^2}{E_1^2}+\frac{|k_2|^2}{E_2^2}\right)\frac{1}{E_{12}}(1-s^2)+\frac{1}{E_1}\frac{1}{E_2}\frac{1}{E_{12}}(k_1\cdot k_2)(-1+s^2)\Bigg\}, \end{aligned} \tag{3.28}$$

where $s=(\hat{k}_1,\hat{k}_2)$. *Changing variables to polar coordinates we also have*

$$\begin{aligned} a_2(\Lambda,\kappa) = \frac{(4\pi)^2}{(2\pi)^6}\frac{2}{3}\int_{-1}^{1}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r_1\int_{\kappa}^{\Lambda}\mathrm{d}r_2\,2\pi^2 r_1 r_2 \\ \times\Bigg\{-\left(\frac{1}{F_1}+\frac{1}{F_2}\right)\frac{1}{F_{12}}(1+X^2)+\left(\frac{1}{F_{12}}\right)^3\frac{r_1^2+2r_1r_2X+r_2^2}{2}(1+X^2) \\ +\left(\frac{1}{F_1}+\frac{1}{F_2}\right)\left(\frac{1}{F_{12}}\right)^2 r_1r_2X(-1+X^2)-\frac{1}{F_1}\frac{1}{F_2}(1+X^2)+\left(\frac{r_1^2}{F_1^2}+\frac{r_2^2}{F_2^2}\right)\frac{1}{F_{12}}(1-X^2) \\ +\frac{1}{F_1}\frac{1}{F_2}\frac{1}{F_{12}}r_1r_2X(-1+X^2)\Bigg\}. \end{aligned} \tag{3.29}$$

Proof: Note that

$$\begin{aligned} a_1(\Lambda,\kappa) &= \frac{2}{3}(\sqrt{4\pi})^2(A_\mu^+\Omega, H_0^{-1}A_\mu^+\Omega) \\ &= \frac{2}{3}(\sqrt{4\pi})^2 2\int\frac{\hat{\varphi}(k)^2}{2\omega(k)}\frac{1}{|k|^2/2+|k|}\mathrm{d}^3k \\ &= \frac{2}{3}(\sqrt{4\pi})^2\frac{1}{(2\pi)^3}4\pi\int_{\kappa}^{\Lambda}\frac{1}{r/2+1}\mathrm{d}r \\ &= \frac{8}{3\pi}\log\left(\frac{\Lambda+2}{\kappa+2}\right). \end{aligned}$$

Thus (3.27) follows. To check $a_2(\Lambda,\kappa)$ we exactly compute the five terms on the right-hand side of (3.13) separately.

(1) We have

$$2(\Psi_3^\mu, H_0^{-1}\Psi_1^\mu) = (\Omega, -(A^-\cdot A^-)H_0^{-1}A_\mu H_0^{-1}A_\mu^+\Omega) + \tfrac{1}{2}(\Omega,(A^-\cdot A^-)H_0^{-1}(P_f\cdot A + A\cdot P_f)H_0^{-1}P_{f\mu}H_0^{-1}A_\mu^+\Omega). \tag{3.30}$$

Since $P_{f\mu}H_0^{-1}A_\mu\Omega = H_0^{-1}A_\mu P_{f\mu}\Omega = 0$, the second term of the right-hand side of (3.30) vanishes, we have

$$2(\Psi_3^\mu, H_0^{-1}\Psi_1^\mu) = -(\Omega,(A^-\cdot A^-)H_0^{-1}A_\mu^+H_0^{-1}A_\mu^+\Omega) = -\int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat\varphi_1|^2}{2\omega_1}\frac{|\hat\varphi_2|^2}{2\omega_2}\frac{1}{E_{12}}\left(\frac{1}{E_1}+\frac{1}{E_2}\right)\mathrm{tr}(Q_1Q_2). \tag{3.31}$$

(2) We have

$$\begin{aligned}(\Psi_2^\mu, H_0^{-1}\Psi_2^\mu) &= \left(\frac{1}{2}\right)^2 (P_{f\mu}H_0^{-1}(A^+\cdot A^+)\Omega, H_0^{-1}P_{f\mu}H_0^{-1}(A^+\cdot A^+)\Omega)\\ &= \left(\frac{1}{2}\right)^2 (\Omega,(A^-\cdot A^-)(H_0^{-1})^3(P_f\cdot P_f)(A^+\cdot A^+)\Omega)\\ &= \left(\frac{1}{2}\right)^2 \int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat\varphi_1|^2}{2\omega_1}\frac{|\hat\varphi_2|^2}{2\omega_2}\left(\frac{1}{E_{12}}\right)^3 |k_1+k_2|^2\,2\,\mathrm{tr}(Q_1Q_2).\end{aligned} \tag{3.32}$$

(3) We have

$$\begin{aligned}&-2(\Psi_2^\mu, H_0^{-1}H_1H_0^{-1}\Psi_1^\mu)\\ &= \frac{1}{2}(P_{f\mu}H_0^{-1}(A^+\cdot A^+)\Omega, H_0^{-1}(P_f\cdot A + A\cdot P_f)H_0^{-1}A_\mu^+\Omega)\\ &= \sum_{\nu=1,2,3}(\Omega,(A^-\cdot A^-)H_0^{-1}P_{f\mu}H_0^{-1}P_{f\nu}A_\nu^+H_0^{-1}A_\mu^+\Omega)\\ &= \int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat\varphi_1|^2}{2\omega_1}\frac{|\hat\varphi_2|^2}{2\omega_2}\left(\frac{1}{E_{12}}\right)^2\left(\frac{1}{E_1}+\frac{1}{E_2}\right)(k_2, Q_1Q_2k_1).\end{aligned} \tag{3.33}$$

(4) We have

$$\begin{aligned}&-\frac{1}{2}(\Psi_1^\mu, H_0^{-1}H_2H_0^{-1}\Psi_1^\mu)\\ &= -\frac{1}{2}(A_\mu^+\Omega, H_0^{-1}((A^+\cdot A^+) + 2(A^+\cdot A^-) + (A^-\cdot A^-))H_0^{-1}A_\mu^+\Omega)\\ &= -(\Omega, A_\mu^- H_0^{-1}(A^+\cdot A^-)H_0^{-1}A_\mu^+\Omega)\\ &= -\int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat\varphi_1|^2}{2\omega_1}\frac{|\hat\varphi_2|^2}{2\omega_2}\frac{1}{E_1}\frac{1}{E_2}\mathrm{tr}(Q_1Q_2).\end{aligned} \tag{3.34}$$

(5) We have

$$(\Psi_1^\mu, H_0^{-1}H_1H_0^{-1}H_1H_0^{-1}\Psi_1^\mu) = \left(\frac{1}{2}\right)^2 (A_\mu^+\Omega, H_0^{-1}(P_f\cdot A + A\cdot P_f)H_0^{-1}(P_f\cdot A + A\cdot P_f)H_0^{-1}A_\mu^+\Omega)$$
$$= (A_\mu^+\Omega, H_0^{-1}(P_f\cdot A)H_0^{-1}(P_f\cdot A)H_0^{-1}A_\mu^+\Omega)$$
$$= \sum_{\nu,\kappa=1,2,3} (A_\mu^+\Omega, H_0^{-1}P_{f\nu}A_\nu^+H_0^{-1}P_{f\kappa}A_\kappa^-H_0^{-1}A_\mu^+\Omega)$$
$$+ \sum_{\nu,\kappa=1,2,3} (A_\mu^+\Omega, H_0^{-1}P_{f\nu}A_\nu^-H_0^{-1}P_{f\kappa}A_\kappa^+H_0^{-1}A_\mu^+\Omega). \tag{3.35}$$

Since

$$P_{f\kappa}A_\kappa^-H_0^{-1}A_\mu^+\Omega = 0,$$

the first term on the last line in (3.35) vanishes. Then we have

$$(\Psi_1^\mu, H_0^{-1}H_1H_0^{-1}H_1H_0^{-1}\Psi_1^\mu) = \sum_{\nu,\kappa=1,2,3} (\Omega, A_\mu^-H_0^{-1}P_{f\nu}A_\nu^-H_0^{-1}P_{f\kappa}A_\kappa^+H_0^{-1}A_\mu^+\Omega)$$
$$= \int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat\varphi_1|^2}{2\omega_1}\frac{|\hat\varphi_2|^2}{2\omega_2}\frac{1}{E_{12}}\left\{\left(\frac{1}{E_2}\right)^2 2(k_2, Q_1k_2) + \frac{1}{E_1}\frac{1}{E_2}(k_2, Q_1Q_2k_1)\right\}$$
$$= \int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat\varphi_1|^2}{2\omega_1}\frac{|\hat\varphi_2|^2}{2\omega_2}\frac{1}{E_{12}}\left\{\left(\frac{1}{E_1}\right)^2 (k_1, Q_2k_1) + \left(\frac{1}{E_2}\right)^2 (k_2, Q_1k_2)\right\}$$
$$+ \int\int \mathrm{d}^3k_1\,\mathrm{d}^3k_2 \frac{|\hat\varphi_1|^2}{2\omega_1}\frac{|\hat\varphi_2|^2}{2\omega_2}\frac{1}{E_{12}}\frac{1}{E_1}\frac{1}{E_2}(k_2, Q_1Q_2k_1). \tag{3.36}$$

Equation (3.28) follows from Lemma 3.6, (3.31), (3.32), (3.33), (3.34), (3.36) and the facts

$$\mathrm{tr}[Q(k_1)Q(k_2)] = \sum_{j,j'=1,2} (e_j(k_1)e_{j'}(k_2))^2 = 1 + (\hat k_1, \hat k_2)^2,$$

$$(k_1, Q(k_2)Q(k_1)k_2) = (k_1, k_2)((\hat k_1, \hat k_2)^2 - 1),$$

$$(k_1, Q(k_2)k_1) = |k_1|^2(1 - (\hat k_1, \hat k_2)^2).$$

Thus the proof is complete. ■

IV. MAIN THEOREM

By (3.29) we can see that

$$a_2(\Lambda, \kappa) = \frac{(4\pi)^2}{(2\pi)^6}\frac{2}{3}\sum_{j=1}^{6} b_j(\Lambda), \tag{4.1}$$

where

$$b_1(\Lambda) = -\int_{-1}^{1}\mathrm{d}X(1+X^2)\int_\kappa^\Lambda \mathrm{d}r_1\int_\kappa^\Lambda \mathrm{d}r_2\, 2\pi^2 r_1r_2\left(\frac{1}{F_1}+\frac{1}{F_2}\right)\frac{1}{F_{12}},$$

$$b_2(\Lambda) = \int_{-1}^{1}\mathrm{d}X(1+X^2)\int_\kappa^\Lambda \mathrm{d}r_1\int_\kappa^\Lambda \mathrm{d}r_2\, 2\pi^2 r_1r_2\left(\frac{1}{F_{12}}\right)^3\frac{r_1^2+2r_1r_2X+r_2^2}{2},$$

$$b_3(\Lambda) = \int_{-1}^{1} \mathrm{d}X\, X(-1+X^2) \int_{\kappa}^{\Lambda} \mathrm{d}r_1 \int_{\kappa}^{\Lambda} \mathrm{d}r_2\, 2\pi^2 r_1^2 r_2^2 \left(\frac{1}{F_1} + \frac{1}{F_2}\right)\left(\frac{1}{F_{12}}\right)^2,$$

$$b_4(\Lambda) = -\int_{-1}^{1} \mathrm{d}X(1+X^2) \int_{\kappa}^{\Lambda} \mathrm{d}r_1 \int_{\kappa}^{\Lambda} \mathrm{d}r_2\, 2\pi^2 r_1 r_2 \frac{1}{F_1}\frac{1}{F_2},$$

$$b_5(\Lambda) = \int_{-1}^{1} \mathrm{d}X(1-X^2) \int_{\kappa}^{\Lambda} \mathrm{d}r_1 \int_{\kappa}^{\Lambda} \mathrm{d}r_2\, 2\pi^2 r_1 r_2 \left(\frac{r_1^2}{F_1^2} + \frac{r_2^2}{F_2^2}\right)\frac{1}{F_{12}},$$

$$b_6(\Lambda) = \int_{-1}^{1} \mathrm{d}X\, X(-1+X^2) \int_{\kappa}^{\Lambda} \mathrm{d}r_1 \int_{\kappa}^{\Lambda} \mathrm{d}r_2\, 2\pi^2 r_1^2 r_2^2 \frac{1}{F_1}\frac{1}{F_2}\frac{1}{F_{12}}.$$

Our main theorem is stated as follows.

Theorem 4.1: *There exist strictly positive constants c_1 and c_2 such that*

$$c_1 \leqslant \lim_{\Lambda\to\infty} \frac{a_2(\Lambda,\kappa)}{\sqrt{\Lambda}} \leqslant c_2.$$

To prove Theorem 4.1 we estimate the lower and upper bounds of $a_2(\Lambda,\kappa)/\sqrt{\Lambda}$ as $\Lambda\to\infty$ in what follows.

Let $\rho_\Lambda(\cdot,\cdot)$: $[0,\infty)\times[-1,1]\to\mathbb{R}$ be defined by

$$\rho_\Lambda = \rho_\Lambda(r,X) = r^2 + 2\Lambda r X + \Lambda^2 + 2r + 2\Lambda = (r + \Lambda X + 1)^2 + \Delta,$$

where

$$\Delta = \Lambda^2(1-X^2) + 2\Lambda(1-X) - 1. \tag{4.2}$$

Lemma 4.2: There exist constants C_1, C_2, C_3, and C_4 such that for sufficiently large $\Lambda > 0$,

$$(1)\ \int_{-1}^{1} \mathrm{d}X \int_{0}^{\Lambda} \mathrm{d}r \frac{1}{\rho_\Lambda(r,X)} \leqslant C_1 \frac{1}{\Lambda},$$

$$(2)\ \int_{-1}^{1} \mathrm{d}X \int_{0}^{\Lambda} \mathrm{d}r \left(\frac{1}{\rho_\Lambda(r,X)}\right)^2 \leqslant C_2 \frac{1}{\Lambda^{5/2}},$$

$$(3)\ \int_{-1}^{1} \mathrm{d}X \int_{0}^{\Lambda} \mathrm{d}r \frac{1}{\rho_\Lambda(r,X)}\frac{1}{r+2} \leqslant C_3 \frac{\log\Lambda}{\Lambda^2},$$

$$(4)\ \int_{-1}^{1} \mathrm{d}X \int_{0}^{\Lambda} \mathrm{d}r \left(\frac{1}{\rho_\Lambda(r,X)}\right)^2 (1-X^2) \leqslant C_4 \frac{1}{\Lambda^3}.$$

Proof: See Appendix A. ∎

A. Upper bounds

Lemma 4.3: There exists a constant $C_{\max}$ such that

$$\lim_{\Lambda\to\infty} \left| \frac{a(\Lambda,\kappa)}{\sqrt{\Lambda}} \right| < C_{\max}.$$

Proof: Note that for a continuous function f,

$$\frac{\mathrm{d}}{\mathrm{d}\Lambda}\int_\kappa^\Lambda \mathrm{d}r_1 \int_\kappa^\Lambda \mathrm{d}r_2\, f(r_1,r_2) = \int_\kappa^\Lambda f(\Lambda,r)\mathrm{d}r + \int_\kappa^\Lambda f(r,\Lambda)\mathrm{d}r. \tag{4.3}$$

In this proof, C denotes some sufficiently large constant and is not necessarily the same number.

(1) We have

$$\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_1(\Lambda) = 16\pi^2\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho_\Lambda(r,X)}\left(\frac{\Lambda}{r+2}+\frac{r}{\Lambda+2}\right)(1+X^2).$$

Since by Lemma 4.2 (3) and (1),

$$\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho_\Lambda(r,X)}\frac{\Lambda}{r+2} \leqslant C\frac{\log\Lambda}{\Lambda},$$

$$\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho_\Lambda(r,X)}\frac{r}{\Lambda+2} \leqslant C\frac{1}{\Lambda},$$

we have

$$\left|\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_1(\Lambda)\right| \leqslant C\frac{\log\Lambda}{\Lambda}. \tag{4.4}$$

(2) We see that by Lemma 4.2 (2),

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_2(\Lambda) &= 16\pi^2\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r\left(\frac{1}{\rho_\Lambda(r,X)}\right)^3 r\Lambda(\Lambda^2+r^2+2\Lambda rX)(1+X^2)\\ &\leqslant 16\pi^2\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r\left(\frac{1}{\rho_\Lambda(r,X)}\right)^2 r\Lambda(1+X^2)\\ &\leqslant 16\pi^2\Lambda^2\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r\left(\frac{1}{\rho_\Lambda(r,X)}\right)^2 (1+X^2) \leqslant C\frac{1}{\sqrt{\Lambda}}.\end{aligned}$$

Hence

$$\left|\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_2(\Lambda)\right| \leqslant C\frac{1}{\sqrt{\Lambda}}. \tag{4.5}$$

(3) We have

$$\left|\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_3(\Lambda)\right| = 32\pi^2\left|\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r\, X(X^2-1)\left(\frac{1}{\rho_\Lambda(r,X)}\right)^2\left(\frac{\Lambda^2 r}{r+2}+\frac{r^2\Lambda}{\Lambda+2}\right)\right|.$$

Since by Lemma 4.2 (3) and (4),

$$\left|\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r\, X(X^2-1)\left(\frac{1}{\rho_\Lambda(r,X)}\right)^2\frac{\Lambda^2 r}{r+2}\right| \leqslant C\frac{1}{\Lambda},$$

$$\left|\int_{-1}^1 \mathrm{d}X\int_\kappa^\Lambda \mathrm{d}r\, X(X^2-1)\left(\frac{1}{\rho_\Lambda(r,X)}\right)^2\frac{r^2\Lambda}{\Lambda+2}\right| \leqslant C\frac{1}{\Lambda},$$

we have

$$\left|\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_3(\Lambda)\right| \leqslant C\frac{1}{\Lambda}. \tag{4.6}$$

(4) It is trivial that

$$|b_4(\Lambda)| \leqslant C[\log \Lambda]^2. \tag{4.7}$$

(5) We have

$$\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_5(\Lambda) = 32\pi^2\int_{-1}^{1}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho_\Lambda(r,X)}(1-X^2)r\Lambda\left\{\left(\frac{1}{\Lambda+2}\right)^2+\left(\frac{1}{r+2}\right)^2\right\}.$$

Since by Lemma 4.2 (1),

$$\int_{-1}^{1}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho_\Lambda(r,X)}(1-X^2)r\Lambda\left(\frac{1}{\Lambda+2}\right)^2 \leqslant C\frac{1}{\Lambda},$$

$$\int_{-1}^{1}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho_\Lambda(r,X)}(1-X^2)r\Lambda\left(\frac{1}{r+2}\right)^2 \leqslant C\frac{1}{\Lambda},$$

we see that

$$\left|\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_5(\Lambda)\right| \leqslant C\frac{1}{\Lambda}. \tag{4.8}$$

(6) We have by Lemma 4.2 (1)

$$\left|\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_6(\Lambda)\right| = 32\pi^2\left|\int_{-1}^{1}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r(X^2-1)X\frac{1}{\rho_\Lambda(r,X)}\frac{r}{r+2}\frac{\Lambda}{\Lambda+2}\right| \leqslant C\frac{1}{\Lambda}.$$

Then we have

$$\left|\frac{\mathrm{d}}{\mathrm{d}\Lambda}b_6(\Lambda)\right| \leqslant C\frac{1}{\Lambda}. \tag{4.9}$$

From (4.4)–(4.9) it follows that

$$|b_j(\Lambda)| \leqslant C[\log \Lambda]^2, \quad j=1,4,$$

$$|b_2(\Lambda)| \leqslant C\Lambda^{1/2}, \quad |b_j(\Lambda)| \leqslant C\log\Lambda, \quad j=3,5,6. \tag{4.10}$$

Then the lemma follows. ■

B. Lower bounds

Lemma 4.4: There exists a positive constant $C_{\min}>0$ *such that*

$$C_{\min} \leqslant \lim_{\Lambda\to\infty}\frac{b_2(\Lambda)}{\sqrt{\Lambda}}.$$

From this lemma and (4.10), i.e.,

$$\lim_{\Lambda\to\infty}\frac{b_j(\Lambda)}{\sqrt{\Lambda}} = 0, \quad j=1,3,4,5,6,$$

the following corollary follows.

Corollary 4.5: It follows that

$$C_{\min} \leqslant \lim_{\Lambda\to\infty} \frac{a_2(\Lambda,\kappa)}{\sqrt{\Lambda}}.$$

Proof of Lemma 4.4: We have

$$\frac{\mathrm{d}}{\mathrm{d}\Lambda} b_2(\Lambda) = 16\pi^2 \int_{-1}^{1} \mathrm{d}X \int_{\kappa}^{\Lambda} \mathrm{d}r (1+X^2) \left(\frac{1}{\rho_\Lambda(r,X)}\right)^3 (r^2 + 2r\Lambda X + \Lambda^2) r\Lambda, \tag{4.11}$$

where, recall that

$$\rho_\Lambda(r,X) = (r + \Lambda X + 1)^2 + \Delta,$$

$$\Delta = \Lambda^2(1-X^2) + 2\Lambda(1-X) - 1.$$

Note that $\Delta > 0$ for $X \leqslant 0$ and a sufficiently large Λ. Since the integrand of (4.11),

$$T_R(r) = \left(\frac{1}{\rho_\Lambda(r,X)}\right)^3 (r^2 + 2r\Lambda X + \Lambda^2) r\Lambda$$

is positive, it is enough to prove that

$$\lim_{\Lambda\to\infty} \sqrt{\Lambda} \frac{\mathrm{d}}{\mathrm{d}\Lambda} b_2(\Lambda) \geqq \lim_{\Lambda\to\infty} \sqrt{\Lambda} \int_{-1+(1/\Lambda)}^{0} \mathrm{d}X \int_{\kappa}^{\Lambda} \mathrm{d}r\, T_R(r)(1+X^2) > 0. \tag{4.12}$$

We simply set $\rho = \rho_\Lambda(r,X)$. Since

$$(r^2 + 2r\Lambda X + \Lambda^2) r\Lambda = \Lambda\{(r-2)\rho + (4 + 4\Lambda X - 2\Lambda) r + 2(\Lambda^2 + 2\Lambda)\},$$

we have

$$\begin{aligned}\int_{\kappa}^{\Lambda} \mathrm{d}r\, T_R(r) &= \Lambda \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{r-2}{\rho^2} + \Lambda(4 + 4\Lambda X - 2\Lambda) \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{r}{\rho^3} + 2\Lambda(\Lambda^2 + 2\Lambda) \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{1}{\rho^3} \\ &= \Lambda \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{r}{\rho^2} + \Lambda^2(4X - 2) \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{r}{\rho^3} + 2\Lambda^3 \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{1}{\rho^3} + t_1(\Lambda),\end{aligned}$$

where

$$t_1(\Lambda) = -2\Lambda \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{1}{\rho^2} + 4\Lambda \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{r}{\rho^3} + 2\Lambda^2 \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{1}{\rho^3}.$$

Moreover since

$$\int_{\kappa}^{\Lambda} \mathrm{d}r \frac{r}{\rho^2} = -\frac{1}{2}\left[\frac{1}{\rho}\right]_{\kappa}^{\Lambda} - \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{\Lambda X + 1}{\rho^2},$$

$$\int_{\kappa}^{\Lambda} \mathrm{d}r \frac{r}{\rho^3} = -\frac{1}{4}\left[\frac{1}{\rho^2}\right]_{\kappa}^{\Lambda} - \int_{\kappa}^{\Lambda} \mathrm{d}r \frac{\Lambda X + 1}{\rho^3},$$

we have

$$\int_\kappa^\Lambda \mathrm{d}r\, T_R(r) = -\Lambda^2 X \int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho^2} + \Lambda^3(2 - X(4X-2)) \int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho^3} + t_1(\Lambda) + t_2(\Lambda),$$

where

$$t_2(\Lambda) = \Lambda\left(-\frac{1}{2}\right)\left[\frac{1}{\rho}\right]_\kappa^\Lambda - \Lambda \int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho^2} + \Lambda^2(4X-2)\left(-\frac{1}{4}\right)\left[\frac{1}{\rho^2}\right]_\kappa^\Lambda - \Lambda^2(4X-2)\int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho^3}.$$

Note that

$$\int \frac{1}{(x^2+a^2)^{n+1}}\mathrm{d}x = \frac{1}{2na^2}\frac{x}{(x^2+a^2)^n} + \frac{2n-1}{2n}\frac{1}{a^2}\int \frac{1}{(x^2+a^2)^n}\mathrm{d}x, \quad n \geqslant 1.$$

Then

$$\int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho^2} = \left[\frac{r+\Lambda X+1}{2\Delta}\frac{1}{\rho}\right]_\kappa^\Lambda + \frac{1}{2\Delta^{3/2}}\left[\arctan\frac{r+\Lambda X+1}{\sqrt{\Delta}}\right]_\kappa^\Lambda,$$

$$\int_\kappa^\Lambda \mathrm{d}r \frac{1}{\rho^3} = \left[\frac{r+\Lambda X+1}{4\Delta}\frac{1}{\rho^2}\right]_\kappa^\Lambda + \frac{3}{8}\left[\frac{r+\Lambda X+1}{\Delta^2}\frac{1}{\rho}\right]_\kappa^\Lambda + \frac{3}{8}\frac{1}{\Delta^{5/2}}\left[\arctan\frac{r+\Lambda X+1}{\sqrt{\Delta}}\right]_\kappa^\Lambda.$$

Hence we have

$$\begin{aligned}\int_\kappa^\Lambda \mathrm{d}r\, T_R(r) = &-\Lambda^2 X \frac{1}{2\Delta^{3/2}}\left\{\left[\arctan\frac{r+\Lambda X+1}{\sqrt{\Delta}}\right]_\kappa^\Lambda + \left[\sqrt{\Delta}\frac{r+\Lambda X+1}{\rho}\right]_\kappa^\Lambda\right\} \\ &+ \frac{3}{8}\Lambda^3 2(2X+1)(1-X)\frac{1}{\Delta^{5/2}}\left\{\left[\arctan\frac{r+\Lambda X+1}{\sqrt{\Delta}}\right]_\kappa^\Lambda + \left[\sqrt{\Delta}\frac{r+\Lambda X+1}{\rho}\right]_\kappa^\Lambda\right\} \\ &+ t_1(\Lambda) + t_2(\Lambda) + t_3(\Lambda),\end{aligned}$$

where

$$t_3(\Lambda) = \Lambda^3 2(2X+1)(1-X)\left[\frac{r+\Lambda X+1}{4\Delta}\frac{1}{\rho^2}\right]_\kappa^\Lambda.$$

It is proven in Lemma B.1 of Appendix B that

$$\lim_{\Lambda\to\infty}\sqrt{\Lambda}\int_{-1+1/\Lambda}^0 (1+X^2)(t_1(\Lambda)+t_2(\Lambda)+t_3(\Lambda))\mathrm{d}X = 0. \tag{4.13}$$

From this it is enough to show that

$$\begin{aligned}\lim_{\Lambda\to\infty}\sqrt{\Lambda}\Lambda^2 \int_{-1+1/\Lambda}^0 \mathrm{d}X(1+X^2)\frac{1}{\Delta^{3/2}}&\left[\sqrt{\Delta}\frac{r+\Lambda X+1}{\rho}\right]_\kappa^\Lambda \\ &\times\frac{1}{4}\left\{-2X+3(1-X)(2X+1)\frac{\Lambda}{\Delta}\right\} \geqslant 0\end{aligned} \tag{4.14}$$

and that there exists a positive constant $\xi > 0$ such that

$$\lim_{\Lambda\to\infty}\sqrt{\Lambda}\int_{-1+1/\Lambda}^{0} dX(1+X^2)\left\{-\Lambda^2 X\frac{1}{2\Delta^{3/2}}\left[\arctan\frac{r+\Lambda X+1}{\sqrt{\Delta}}\right]_{\kappa}^{\Lambda}\right.$$
$$\left.+\frac{3}{8}\Lambda^3 2(2X+1)(1-X)\frac{1}{\Delta^{5/2}}\left[\arctan\frac{r+\Lambda X+1}{\sqrt{\Delta}}\right]_{\kappa}^{\Lambda}\right\}$$
$$=\lim_{\Lambda\to\infty}\sqrt{\Lambda}\Lambda^2\int_{-1+1/\Lambda}^{0} dX(1+X^2)\frac{1}{\Delta^{3/2}}\left[\arctan\frac{r+\Lambda X+1}{\sqrt{\Delta}}\right]_{\kappa}^{\Lambda}$$
$$\times\frac{1}{4}\left\{-2X+3(1-X)(2X+1)\frac{\Lambda}{\Delta}\right\}>\xi. \tag{4.15}$$

Changing variable X to $-y$, we shall prove (4.15), i.e.,

$$\lim_{\Lambda\to\infty}\sqrt{\Lambda}\Lambda^2\int_{0}^{1-(1/\Lambda)} dy(1+y^2)\frac{1}{\Delta^{3/2}}\left[\arctan\frac{r-\Lambda y+1}{\sqrt{\Delta}}\right]_{\kappa}^{\Lambda}\frac{1}{4}a_{\Lambda}(y)dy>\xi,$$

where

$$a_{\Lambda}(y)=2y+\frac{6}{\Lambda}+b_{\Lambda}(y),$$

$$b_{\Lambda}(y)=\frac{3}{\Lambda}\left(1+\frac{4}{\Lambda}\right)\frac{y+\dfrac{\Lambda^2+4\Lambda-2}{\Lambda(\Lambda+4)}}{\left(y-\dfrac{1}{\Lambda}\right)^2-\dfrac{\Lambda+2}{\Lambda}}.$$

The function $b_{\Lambda}(\cdot)$ satisfies the following properties.

(1) $b_{\Lambda}''(y)<0$ for $0\leqslant y\leqslant 1-1/\Lambda$, i.e., $b_{\Lambda}(y)$ is concave for $0\leqslant y\leqslant 1-1/\Lambda$.
(2) $\lim_{\Lambda\to\infty} b_{\Lambda}(1-1/\Lambda)=-1$.
(3) $\lim_{\Lambda\to\infty} b_{\Lambda}(y)=0$ for $y\neq 1$ and $\lim_{\Lambda\to\infty} b_{\Lambda}(1)=-3/2$.

By (1)–(3) we have

$$\inf_{0\leqslant y\leqslant 1-1/\Lambda} b_{\Lambda}(y)=\min\{b_{\Lambda}(0),b_{\Lambda}(1-1/\Lambda)\}$$

and then for sufficiently large Λ,

$$\inf_{0\leqslant y\leqslant 1-1/\Lambda} b_{\Lambda}(y)=b_{\Lambda}(1-1/\Lambda)>-\tfrac{7}{4}.$$

Hence

$$\inf_{15/16\leqslant y\leqslant 1-1/\Lambda} a_{\Lambda}(y)\geqslant \tfrac{15}{8}-\tfrac{7}{4}=\tfrac{1}{8}>0.$$

Moreover

$$\left[\arctan\frac{r-\Lambda y+1}{\sqrt{\Delta}}\right]_{\kappa}^{\Lambda}=\arctan\frac{(1-y)\Lambda+1}{\sqrt{\Delta}}-\arctan\frac{\kappa-\Lambda y+1}{\sqrt{\Delta}}>0,$$

$$\lim_{\Lambda\to\infty}\left[\arctan\frac{r-\Lambda y+1}{\sqrt{\Delta}}\right]_{\kappa}^{\Lambda}=\arctan\frac{1-y}{\sqrt{1-y^2}}+\arctan\frac{y}{\sqrt{1-y^2}}>0$$

for $0\leqslant y\leqslant 1$. Then

$$\delta = \inf_{\Lambda>1} \inf_{0\leqslant y\leqslant 1} \left[\arctan \frac{r-\Lambda y+1}{\sqrt{\Delta}} \right]_\kappa^\Lambda > 0.$$

Then we have

$$\begin{aligned}
&\lim_{\Lambda\to\infty} \sqrt{\Lambda}\Lambda^2 \int_0^{1-(1/\Lambda)} dy(1+y^2) \frac{1}{\Delta^{3/2}} \left[\arctan \frac{r-\Lambda y+1}{\sqrt{\Delta}} \right]_\kappa^\Lambda \frac{1}{4} a_\Lambda(y) \\
&\geqslant \lim_{\Lambda\to\infty} \sqrt{\Lambda}\Lambda^2 \int_{15/16}^{1-(1/\Lambda)} dy(1+y^2) \frac{1}{\Delta^{3/2}} \left[\arctan \frac{r-\Lambda y+1}{\sqrt{\Delta}} \right]_\kappa^\Lambda \frac{1}{4} a_\Lambda(y) \\
&\geqslant \frac{1}{8} \times \frac{1}{4} \times \delta \times \lim_{\Lambda\to\infty} \sqrt{\Lambda}\Lambda^2 \int_{15/16}^{1-(1/\Lambda)} dy \frac{1}{\Delta^{3/2}}.
\end{aligned}$$

Furthermore,

$$\begin{aligned}
&\lim_{\Lambda\to\infty} \sqrt{\Lambda}\Lambda^2 \int_{15/16}^{1-(1/\Lambda)} dy \frac{1}{\Delta^{3/2}} \\
&= \lim_{\Lambda\to\infty} \frac{1}{\sqrt{\Lambda}} \int_{15/16}^{1-(1/\Lambda)} dy \frac{1}{\left\{ (1-y^2) + \frac{2}{\Lambda}(1+y) - \frac{1}{\Lambda^2} \right\}^{3/2}} \\
&\geqslant \lim_{\Lambda\to\infty} \frac{1}{\sqrt{\Lambda}} \int_{15/16}^{1-(1/\Lambda)} dy \frac{1}{\left\{ (1-y) + \frac{2}{\Lambda} \right\}^{3/2}} \frac{1}{(1+y)^{3/2}} \\
&\geqslant \lim_{\Lambda\to\infty} \frac{1}{\sqrt{\Lambda}} \int_{15/16}^{1-(1/\Lambda)} dy \frac{1}{\left\{ (1-y) + \frac{2}{\Lambda} \right\}^{3/2}} \frac{1}{2^{3/2}} \\
&= \lim_{\Lambda\to\infty} \frac{1}{\sqrt{2}} \frac{1}{\sqrt{\Lambda}} \left(\frac{1}{\sqrt{3/\Lambda}} - \frac{1}{\sqrt{1/16+2/\Lambda}} \right) = \frac{1}{\sqrt{6}}.
\end{aligned}$$

Then we proved that

$$\lim_{\Lambda\to\infty} \sqrt{\Lambda} \frac{\mathrm{d}}{\mathrm{d}\Lambda} b_2(\Lambda) > 4\pi \times \tfrac{1}{8} \times \tfrac{1}{4} \times \tfrac{1}{\sqrt{6}} \times \delta = \frac{\pi\delta}{8\sqrt{6}} > 0.$$

Then (4.15) follows. We shall show (4.14). Since the left-hand side of (4.14) is

$$\lim_{\Lambda\to\infty} \sqrt{\Lambda}\Lambda^2 \int_0^{1-(1/\Lambda)} dy(1+y^2) \frac{1}{\Delta^{3/2}} \left[\sqrt{\Delta} \frac{r-\Lambda y+1}{\rho} \right]_\kappa^\Lambda \frac{1}{4} a_\Lambda(y) dy, \tag{4.16}$$

it is enough to show that $[\cdots]_\kappa^\Lambda$ in (4.16) is non-negative. We can directly see that

$$\left[\sqrt{\Delta} \frac{r-\Lambda y+1}{\rho} \right]_\kappa^\Lambda = \frac{\sqrt{\Delta} K}{\{(\Lambda+\Lambda X+1)^2+\Delta\}\{(\kappa+\Lambda X+1)^2+\Delta\}},$$

where, for $0\leqslant y\leqslant 1$,

$$K = (-2y^2+y+1)\Lambda^3 + (1+4y)\Lambda^2 - 2\Lambda + \kappa((y^2-2)\Lambda^2 + (-2y-2)\Lambda + 1) + \kappa^2((-y+1)\Lambda+1).$$

Since $K>0$ for a sufficiently large Λ, (4.14) follows. ■

Proof of Theorem 4.1: The theorem follows from Lemma 4.3 and Corollary 4.5. ■

Remark 4.6: (1) $a_2(\Lambda,\kappa)/\sqrt{\Lambda}$ *converges to a non-negative constant as* $\Lambda\to\infty$. *(2) By (4.1), we can define* $a_2(\Lambda,0)$ *since* $b_j(\Lambda)$ *with* $\kappa=0$ *are finite. Moreover* $a_2(\Lambda,0)$ *also satisfies Theorem 4.1.*

APPENDIX A: PROOF OF LEMMA 4.2

Proof of Lemma 4.2: By the definition of Δ it follows that for sufficiently large Λ,

$$\frac{1}{\Delta}\leqslant\frac{1}{\Lambda}\quad\text{for } X\leqslant 0.$$

Let

$$\delta=\delta(k)=\frac{1}{\Lambda^k},\quad 0<k\leqslant 2.$$

Then for sufficiently large Λ,

$$\Delta\geqslant\Lambda^2(1-X^2)-1>0\quad\text{for } -1+\delta(k)<X\leqslant 0,\quad 0<k\leqslant 2.$$

In particular we obtain

$$\frac{1}{\Delta}\leqslant\frac{a}{\Lambda^2}\frac{1}{1-X^2}\quad\text{for } -1+\delta(k)\leqslant X\leqslant 0,\quad 0<k\leqslant 2,$$

with some constant a independent of Λ. In this proof C denotes some sufficiently large constant and it is not necessarily the same number. We divide $\int_{-1}^{1}\cdots dX$ as

$$\int_{-1}^{1}\cdots dX=\int_{0}^{1}+\int_{-1+\delta}^{0}+\int_{-1}^{-1+\delta}.$$

(1) It is trivial that $|\int_0^1\cdots dX|\leqslant C/\Lambda$. Note that

$$\left|\int_0^\Lambda dr\frac{1}{\rho_\Lambda(r,X)}\right|=\frac{1}{\sqrt{\Delta}}\left|\arctan\frac{\Lambda+\Lambda X+1}{\sqrt{\Delta}}-\arctan\frac{\Lambda X+1}{\sqrt{\Delta}}\right|\leqslant\pi\frac{1}{\sqrt{\Delta}}.$$

Let $\delta=\delta(1/2)=1/\sqrt{\Lambda}$. Hence we have

$$\left|\int_{-1+\delta}^{0}\cdots dX\right|\leqslant\frac{C}{\Lambda}\arcsin(1-\delta),$$

$$\left|\int_{-1}^{-1+\delta}\cdots dX\right|\leqslant\frac{C}{\sqrt{\Lambda}}\delta.$$

Thus (1) follows.

(2) It is trivial that $|\int_0^1\cdots dX|\leqslant C/\Lambda^3$. Note that

$$\left|\int_0^\Lambda \mathrm{d}r \frac{1}{\rho_\Lambda(r,X)^2}\right| = \frac{1}{2\Delta}\left|\int_0^\Lambda \frac{1}{\rho_\Lambda(r,X)}\mathrm{d}r + \left(\frac{\Lambda+\Lambda X+1}{(\Lambda+\Lambda X+1)^2+\Delta} - \frac{\Lambda X+1}{(\Lambda X+1)^2+\Delta}\right)\right|$$
$$\leqslant \begin{cases} \dfrac{C}{\Lambda^2}\left(\dfrac{1}{\Lambda(1-X^2)^{3/2}}+\dfrac{1}{\Lambda}\right), & -1+\delta \leqslant X \leqslant 0, \\ \dfrac{C}{\Lambda}\left(\dfrac{1}{\sqrt{\Lambda}}+\dfrac{1}{\Lambda}\right), & -1 \leqslant X \leqslant -1+\delta. \end{cases}$$

Let $\delta=\delta(1)=1/\Lambda$. Hence we have

$$\left|\int_{-1+\delta}^0 \cdots \mathrm{d}X\right| \leqslant \frac{C}{\Lambda^3}\int_{-1+\delta}^0 \mathrm{d}X\left(\frac{1}{(1-X^2)^{3/2}}+1\right) \leqslant \frac{C}{\Lambda^3}\left(\frac{1}{\sqrt{\delta}}+1\right),$$

$$\left|\int_{-1}^{-1+\delta} \cdots \mathrm{d}X\right| \leqslant \frac{C}{\Lambda}\left(\frac{1}{\sqrt{\Lambda}}+\frac{1}{\Lambda}\right)\delta.$$

Then (2) follows.

(3) We see that

$$\frac{1}{\rho_\Lambda(r,X)}\frac{1}{r+2} = \frac{\ell_1}{r+2} + \frac{\ell_2}{\rho_\Lambda(r,X)},$$

where

$$\ell_1 = \frac{1}{\Lambda^2}\frac{1}{(4X-1)/\Lambda-1}, \quad \ell_2 = \frac{1}{\Lambda^2}\frac{r+2\Lambda X}{(4X-1)/\Lambda-1}.$$

We have

$$\left|\int_{-1}^1 \mathrm{d}X\int_0^\Lambda \mathrm{d}r\frac{\ell_1}{r+2}\right| \leqslant \frac{\log(\Lambda+2)}{\Lambda^2}\int_{-1}^1 \mathrm{d}X\frac{1}{(4X-1)/\Lambda-1} \leqslant C\frac{\log\Lambda}{\Lambda^2},$$

$$\left|\int_{-1}^1 \mathrm{d}X\int_0^\Lambda \mathrm{d}r\frac{\ell_2}{\rho_\Lambda(r,X)}\right| \leqslant \frac{\Lambda}{\Lambda^2}\int_{-1}^1 \mathrm{d}X\int_0^\Lambda \frac{1}{\rho_\Lambda(r,X)}\frac{1+2X}{(4X-1)/\Lambda-1} \leqslant \frac{C}{\Lambda^2}.$$

Hence (3) follows.

(4) It is trivial that $|\int_0^1 \cdots \mathrm{d}X| \leqslant C/\Lambda^3$. Let $\delta=\delta(3/2)=1/\Lambda^{3/2}$. From the proof of (2) it follows that

$$\left|\int_{-1+\delta}^0 \cdots \mathrm{d}X\right| \leqslant \frac{C}{\Lambda^3}\int_{-1+\delta}^0 \mathrm{d}X\left\{\frac{(1-X^2)}{(1-X^2)^{3/2}}+(1-X^2)\right\} \leqslant \frac{C}{\Lambda^3}(\arcsin(1-\delta)+1),$$

$$\left|\int_{-1}^{-1+\delta} \cdots \mathrm{d}X\right| \leqslant \frac{C}{\Lambda}\left(\frac{1}{\sqrt{\Lambda}}+\frac{1}{\Lambda}\right)\delta.$$

Hence (4) follows. ■

APPENDIX B: PROOF OF (4.13)

Lemma B.1: It follows that

$$\lim_{\Lambda\to\infty}\sqrt{\Lambda}\int_{-1+1/\Lambda}^{0}(1+X^2)(t_1(\Lambda)+t_2(\Lambda)+t_3(\Lambda))\mathrm{d}X=0, \tag{B1}$$

where

$$t_1(\Lambda)=-2\Lambda\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho^2}+4\Lambda\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{r}{\rho^3}+2\Lambda^2\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho^3},$$

$$t_2(\Lambda)=\Lambda\left(-\frac{1}{2}\right)\left[\frac{1}{\rho}\right]_{\kappa}^{\Lambda}-\Lambda\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho^2},$$

$$t_3(\Lambda)=\Lambda^3 2(2X+1)(1-X)\left[\frac{r+\Lambda X+1}{4\Delta}\frac{1}{\rho^2}\right]_{\kappa}^{\Lambda}.$$

Proof: In this proof C also denotes some sufficiently large constant, which is not necessarily the same number. We have

$$\sqrt{\Lambda}\Lambda\left|\int_{-1+(1/\Lambda)}^{0}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho^2}\right|\leqslant C\sqrt{\Lambda}\Lambda\frac{1}{\Lambda^{5/2}}=C\frac{1}{\Lambda},$$

$$\sqrt{\Lambda}\Lambda\left|\int_{-1+(1/\Lambda)}^{0}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{r}{\rho^3}\right|\leqslant C\sqrt{\Lambda}\Lambda^2\frac{1}{\Lambda^{7/2}}=C\frac{1}{\Lambda},$$

$$\sqrt{\Lambda}\Lambda^2\left|\int_{-1+(1/\Lambda)}^{0}\mathrm{d}X\int_{\kappa}^{\Lambda}\mathrm{d}r\frac{1}{\rho^3}\right|\leqslant C\sqrt{\Lambda}\Lambda^2\frac{1}{\Lambda^{7/2}}=C\frac{1}{\Lambda}.$$

Then

$$\lim_{\Lambda\to\infty}\sqrt{\Lambda}\int_{-1+1/\Lambda}^{0}\mathrm{d}X(1+X^2)t_1(\Lambda)=0$$

follows. Next we shall show that

$$\lim_{\Lambda\to\infty}\sqrt{\Lambda}\int_{-1+1/\Lambda}^{0}\mathrm{d}X(1+X^2)t_2(\Lambda)=0. \tag{B2}$$

Note that

$$\left|\left[\frac{1}{\rho}\right]_{\kappa}^{\Lambda}\right|=\left|\frac{1}{(\Lambda+\Lambda X+1)^2+\Delta}-\frac{1}{(\kappa+\Lambda X+1)^2+\Delta}\right|\leqslant\frac{2}{\Delta}\leqslant\frac{2}{\Lambda^2}\frac{1}{1-X^2}.$$

Then

$$\left|\int_{-1+1/\Lambda}^{0}\mathrm{d}X\left[\frac{1}{\rho}\right]_{\kappa}^{\Lambda}\right|\leqslant C\frac{\log\Lambda}{\Lambda^2}.$$

Similarly we can see that

$$\left| \int_{-1+1/\Lambda}^{0} \mathrm{d}X \left[\frac{1}{\rho^2} \right]_\kappa^\Lambda \right| \leqslant C \frac{1}{\Lambda^3},$$

which implies that

$$\sqrt{\Lambda}\Lambda \left| \int_{-1+1/\Lambda}^{0} \mathrm{d}X \left[\frac{1}{\rho} \right]_\kappa^\Lambda \right| \leqslant C \frac{\log \Lambda}{\sqrt{\Lambda}},$$

$$\sqrt{\Lambda}\Lambda^2 \left| \int_{-1+1/\Lambda}^{0} \mathrm{d}X \left[\frac{1}{\rho^2} \right]_\kappa^\Lambda \right| \leqslant C \frac{1}{\sqrt{\Lambda}}.$$

Hence (B2) follows. Finally we shall show that

$$\lim_{\Lambda \to \infty} \sqrt{\Lambda} \int_{-1+1/\Lambda}^{0} \mathrm{d}X (1 + X^2) t_3(\Lambda) = 0. \tag{B3}$$

We divide $\int_{-1+1/\Lambda}^{0} \mathrm{d}X$ as

$$\int_{-1+1/\Lambda}^{0} \mathrm{d}X = \int_{-1+1/\Lambda}^{-1/2} \mathrm{d}X + \int_{-1/2}^{0} \mathrm{d}X.$$

Since

$$\frac{1}{\Delta} \leqslant \frac{1}{\Lambda^2} \frac{1}{1 - X^2} \leqslant \frac{1}{\Lambda^2} \frac{4}{3} \quad \text{for } -\frac{1}{2} \leqslant X \leqslant 0,$$

we see that

$$\sqrt{\Lambda}\Lambda^3 \left| \int_{-1/2}^{0} \mathrm{d}X \left[\frac{r + \Lambda X + 1}{\Delta} \frac{1}{\rho^2} \right]_\kappa^\Lambda \right| \leqslant C \sqrt{\Lambda}\Lambda^3 \frac{\Lambda}{\Lambda^2} \frac{1}{\Lambda^3} = C \frac{1}{\sqrt{\Lambda}}. \tag{B4}$$

On the other hand,

$$\left[\frac{r + \Lambda X + 1}{\Delta} \frac{1}{\rho^2} \right]_\kappa^\Lambda = \frac{\Lambda + \Lambda X + 1}{\Delta} \frac{1}{\{(\Lambda + \Lambda X + 1)^2 + \Delta\}^2} - \frac{\kappa + \Lambda X + 1}{\Delta} \frac{1}{\{(\kappa + \Lambda X + 1)^2 + \Delta\}^2}.$$

Since

$$\left| \frac{\Lambda + \Lambda X + 1}{\Delta} \right| \leqslant \frac{C}{\Lambda}, \quad \left| \frac{\kappa + \Lambda X + 1}{(\kappa + \Lambda X + 1)^2 + \Delta} \right| \leqslant \frac{C}{\Lambda},$$

we have

$$\left| \int_{-1+1/\Lambda}^{-1/2} \mathrm{d}X \left[\frac{r + \Lambda X + 1}{\Delta} \frac{1}{\rho^2} \right]_\kappa^\Lambda \right| \leqslant C \frac{1}{\Lambda} \int_{-1+1/\Lambda}^{-1/2} \frac{1}{\Delta^2} \leqslant C \frac{1}{\Lambda^4}.$$

Then we obtain that

$$\sqrt{\Lambda}\Lambda^3 \left| \int_{-1+1/\Lambda}^{-1/2} \mathrm{d}X \left[\frac{r + \Lambda X + 1}{\Delta} \frac{1}{\rho^2} \right]_\kappa^\Lambda \right| \leqslant C \frac{1}{\sqrt{\Lambda}}. \tag{B5}$$

Thus (B3) follows from (B4) and (B5). ■

(Received 14 June 2004; accepted 21 December 2004; published online 17 March 2005)

We consider the Bogomol'nyi equations of the Abelian Chern–Simons–Higgs model with $SU(N)_{global} \otimes U(1)_{local}$ symmetry. This is a generalization of the well-known Abelian Chern–Simons–Higgs model with $U(1)_{local}$ symmetry. We prove existence of both topological and nontopological multivortex solutions of the system on the plane. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1868858]

I. INTRODUCTION

The Abelian Chern–Simons–Higgs model with $SU(N)_{global} \otimes U(1)_{local}$ symmetry is defined by the Lagrangian,

$$\mathcal{L} = \frac{\kappa}{4}\epsilon^{\mu\nu\lambda}F_{\mu\nu}A_\lambda + (D_\mu\Phi)^\dagger(D^\mu\Phi) - \frac{1}{\kappa^2}|\Phi|^2(|\Phi|^2-1)^2,$$

where $A_\mu(\mu=0,1,2)$ is the gauge field on $\mathbb{R}^3$, $F_{\mu\nu}=(\partial/\partial x^\mu)A_\nu-(\partial/\partial x^\nu)A_\mu$ is the corresponding gauge curvature tensor, $D_\mu=(\partial/\partial x^\mu)-iA_\mu$ is the gauge covariant derivative, $\Phi=(\Phi_1,\Phi_2,\ldots,\Phi_N)$ is a $\mathbb{C}^N$ valued function on $\mathbb{R}^3$, called the Higgs multiplet, $\epsilon_{\mu\nu\rho}$ is the totally skewsymmetric tensor with $\epsilon_{012}=1$, and finally $\kappa>0$ is the Chern–Simons coupling constant. Our metric on $\mathbb{R}^3$ is $(g_{\mu\nu})=\mathrm{diag}(1,-1,-1)$. This model was suggested by Khare,[6] generalizing the original Abelian Chern–Simons–Higgs model, due to Hong–Kim–Pac[4] and Jackiw–Weinberg.[5] We also mention that there are also studies of the corresponding Abelian Higgs model with $SU(N)_{global} \otimes U(1)_{local}$ symmetry in Refs. 14 and 3. Similar to the case of Abelian Chern–Simons–Higgs model, in the static case, the following Bogomol'nyi system in $\mathbb{R}^2$ is obtained:[6]

$$(D_1 \pm iD_2)\Phi_k = 0, \quad \forall\, k=1,\ldots,N,$$

$$F_{12} = \pm\frac{2}{\kappa^2}|\Phi|^2(|\Phi|^2-1). \tag{1.1}$$

This system is equipped with one of the following boundary conditions: either

$$|\Phi(z)|^2 \to 1 \quad \text{as } |z|\to\infty, \tag{1.2}$$

or

$$|\Phi(z)|^2 \to 0 \quad \text{as } |z|\to\infty \tag{1.3}$$

Following the standard Jaffe–Taubes reduction procedure,[13] we introduce new variable $(u_1,\ldots,u_N)$ by

a)Electronic mail: chae@skku.edu

$$\Phi_k(z) = \exp\left[\frac{1}{2}u_k + i\sum_{j=1}^{M_k} \mathrm{Arg}(z - z_{k,j})\right], \quad z = x_1 + ix_2 \in \mathbb{C}^1 = \mathbb{R}^2,$$

where $\mathbb{Z}_k = \{z_{k,j}\}_{j=1}^{M_k}$ is the set of zeros of $\Phi_k(z)$. Then, the system (1.1) becomes the following semilinear elliptic system for $(u_1, \ldots, u_N)$ in $\mathbb{R}^2$:

$$\Delta u_k = \left(\sum_{j=1}^{N} e^{u_j}\right)\left(\sum_{j=1}^{N} e^{u_j} - 1\right) + 4\pi\sum_{j=1}^{M_k} \delta(z - z_{k,j}), \quad k = 1, \ldots, N, \tag{1.4}$$

where we set $\kappa = 2$ for simplicity. In terms of $(u_1, \ldots, u_N)$, the boundary condition (1.2) reads

$$e^{u_k} \to \sigma_k \quad \text{as } |z| \to \infty$$

$$\text{with } \sigma_k \geqslant 0 \quad \text{for all } k = 1, \ldots, N, \text{and} \sum_{k=1}^{N} \sigma_k = 1, \tag{1.5}$$

while (1.3) reads

$$e^{u_k} \to 0 \quad \text{as } |z| \to \infty \quad \text{for all } k = 1, \ldots, N. \tag{1.6}$$

The boundary condition (1.5) is called topological, while the boundary condition (1.6) is called nontopological. We observe that when $N = 1$, the system (1.4) reduces to the well-known (scalar) Chern–Simons equation, for which there are many studies for topological vortices,[11,15] nontopological vortices,[1,2,10] periodic vortex condensates,[9,8,12,16] respectively. We first consider the nontopological case. In the system (1.4) equipped with (1.3), without loss of generality, we assume $M_1 \geqslant M_k$ for all $k = 1, \ldots, N$. Let us define

$$f_k(z) = (M_k + 1)\prod_{j=1}^{M_k} (z - z_{k,j}), \quad F_k(z) = \int_0^z f_k(\xi)\mathrm{d}\xi. \tag{1.7}$$

Given $\varepsilon > 0$, $a = a_1 + ia_2 \in \mathbb{C}$, let us introduce the functions $\rho_{\varepsilon,a}^{(k)}(z)$ by

$$\rho_{\varepsilon,a}^{(k)}(z) = \frac{8\varepsilon^{2M_k+2}|f_k(z)|^2}{\left(1 + \varepsilon^{2M_1+2}\left|F_1(z) + \dfrac{a}{\varepsilon^{M_1+1}}\right|^2\right)^2}. \tag{1.8}$$

We note that for any $\varepsilon > 0$ and $a \in \mathbb{C}^1$, $\ln \rho_{\varepsilon,a}^{(1)}(z)$ is a solution of the Liouville equation,

$$\Delta \ln \rho_{\varepsilon,a}^{(1)}(z) = -\rho_{\varepsilon,a}^{(1)}(z) + 4\pi\sum_{j=1}^{M_1} \delta(z - z_{1,j}). \tag{1.9}$$

We state the existence theorem for the nontopological vortices.

Theorem 1.1 (Existence of nontopological vortices): *Let $N \geqslant 2$. For each $k = 1, \ldots, N$ let $M_k \in \mathbb{N}$ with $M_1 \geqslant M_k$ for all $k = 1, \ldots, N$, and let $\mathbb{Z}_1, \ldots, \mathbb{Z}_N$ be given with $\mathbb{Z}_k = \{z_{k,j}\}_{j=1}^{M_k} \in \mathbb{R}^2$. Then, there exists a constant $\varepsilon_1 > 0$ such that for any $\varepsilon \in (0, \varepsilon_1)$ there exists a family of solutions to (1.4) $(u_1, u_2, \ldots, u_N)$ equipped with the boundary condition (1.6). Moreover, the solutions we constructed have the following representations:*

$$u_1(z) = \ln \rho_{\varepsilon,a_\varepsilon^*}^{(1)}(z) + \varepsilon^2 w(\varepsilon|z|) + \varepsilon^2 v_\varepsilon^*(\varepsilon z), \tag{1.10}$$

$$u_k(z) = \ln \rho_{\varepsilon,a_\varepsilon^*}^{(k)}(z) + \varepsilon^2 w(\varepsilon|z|) + \varepsilon^2 v_\varepsilon^*(\varepsilon z) + \ln \varepsilon^4, \tag{1.11}$$

for all $k = 2, \ldots, N$.

In (1.10) and (1.11), the function $\varepsilon \mapsto a_\varepsilon^*$ *is continuous in a neighborhood of* 0, *and* $|a_\varepsilon^*| \to 0$ *as* $\varepsilon \to 0$. *The radial function w in (1.10) and (1.11) has the following asymptotic behavior:*

$$w(|z|) = -C_0 \ln|z| + O(1), \tag{1.12}$$

as $|z| \to \infty$ *with the constant* $C_0 > 0$ *defined by*

$$C_0 = \frac{4\pi M_1^2 (2M_1+1)^6}{15(M_1+1)^5 \sin\left(\frac{\pi M_1}{M_1+1}\right)}. \tag{1.13}$$

The function v_ε^* *in (1.10) and (1.11) satisfies*

$$\sup_{z\in\mathbb{R}^2} \frac{|v_\varepsilon^*(\varepsilon z)|}{\ln(1+|z|)} \leqslant o(1) \quad \text{as } \varepsilon \to 0. \tag{1.14}$$

Next, we consider the system (1.4) equipped with the topological boundary condition (1.5). Without loss of generality, we assume that for $m \in \{1, \ldots, N\}$,

$$e^{u_k} \to \sigma_k \quad \text{as } |z| \to \infty \quad \text{for } k = 1, \ldots, m, \tag{1.15}$$

$$e^{u_k} \to 0 \quad \text{as } |z| \to \infty \quad \text{for all } k = m+1, \ldots, N, \tag{1.16}$$

where $\Sigma_{k=1}^m \sigma_k = 1$, and $\sigma_k \in (0,1]$ for each $k = 1, \ldots, m$. The following is our second main theorem.

Theorem 1.2 (Existence of topological vortices): *In order to have solution to the system (1.4) equipped with (1.15) and (1.16), it is necessary that*

$$M_1 = M_2 = \cdots = M_m (\equiv M) \quad \text{and } M_k < M \quad \text{for all } k = m+1, \ldots, N. \tag{1.17}$$

If the condition (1.17) is satisfied, then there exists a solution $(u_1, \ldots, u_N)$ *to the problem. Moreover, the solutions we constructed have the following representations:*

$$u_k(z) = \ln\left(\sigma_k \prod_{j=1}^{M} \frac{|z - z_{k,j}|^2}{(\mu + |z - z_{1,j}|^2)} \right) + v \quad \text{for } k = 1, \ldots, m, \tag{1.18}$$

while

$$u_k(z) = \ln\left(\frac{\prod_{j=1}^{M_k} |z - z_{k,j}|^2}{\prod_{j=1}^{M} (\mu + |z - z_{1,j}|^2)} \right) + v \quad \text{for } k = m+1, \ldots, N \tag{1.19}$$

for a function $v \in \cap_{q=1}^{\infty} H^q(\mathbb{R}^2)$.

II. EXISTENCE OF NONTOPOLOGICAL VORTICES

In this section our aim is to prove Theorem 1.1. From the equation, $\Delta \ln|z - z_0|^2 = 4\pi\delta(z - z_0)$ in $\mathbb{R}^2$ we find that

$$\Delta\left(u_k - u_1 - \sum_{j=1}^{M_k} \ln|z - z_{k,j}|^2 + \sum_{j=1}^{M_1} \ln|z - z_{1,j}|^2 \right) = 0.$$

Hence, we obtain the relations between u_1 and u_k,

$$u_k = u_1 + \ln\left(\frac{\prod_{j=1}^{M_k}|z-z_{k,j}|^2}{\prod_{j=1}^{M_1}|z-z_{1,j}|^2}\right) + h_k(z) \tag{2.1}$$

for all $k=1,\dots,N$, where $h_k(z)$ is a harmonic function in $\mathbb{R}^2$. We choose

$$h_k(z) \equiv \ln \varepsilon^{4+2M_k-2M_1}.$$

Then, (2.1) becomes

$$u_k = u_1 + \ln\left(\frac{\varepsilon^{4+2M_k-2M_1}\prod_{j=1}^{M_k}|z-z_{k,j}|^2}{\prod_{j=1}^{M_1}|z-z_{1,j}|^2}\right). \tag{2.2}$$

We introduce $g^{(k)}_{\varepsilon,a}(z)$, $\rho_k(r)$, $k=1,\dots,N$ as follows:

$$g^{(k)}_{\varepsilon,a}(z) = \frac{1}{\varepsilon^2}\rho^{(k)}_{\varepsilon,a}\left(\frac{z}{\varepsilon}\right), \quad \rho_k(r) = \frac{8(M_k+1)^2 r^{2M_k}}{(1+r^{2M_1+2})^2} \quad \left[=\lim_{\varepsilon\to 0} g^{(k)}_{\varepsilon,0}(z)\right]. \tag{2.3}$$

Let us make a change of variables from u_1 to v by the following formula:

$$u_1(z) = \ln \rho^{(1)}_{\varepsilon,a}(z) + \varepsilon^2 w(\varepsilon|z|) + \varepsilon^2 v(\varepsilon x), \tag{2.4}$$

where $w(\cdot)$ is a radial function to be determined below. Then, after elementary computations we find that combination of (2.2) and (2.4) implies the following representation formula for u_k:

$$u_k(z) = \ln \rho^{(k)}_{\varepsilon,a}(z) + \varepsilon^2 w(\varepsilon|z|) + \varepsilon^2 v(\varepsilon x) + \ln \varepsilon^4 \tag{2.5}$$

for all $k=2,\dots,N$.

Then, the equation for u_1 in (1.4) can be written as the functional equation $P(v,a,\varepsilon)=0$, where

$$P(v,a,\varepsilon) = \Delta v + \frac{1}{\varepsilon^2} g^{(1)}_{\varepsilon,a}(z)(e^{\varepsilon^2(v+w)}-1) - [g^{(1)}_{\varepsilon,a}(z)]^2 e^{2\varepsilon^2(v+w)} + \varepsilon^2 \sum_{k=2}^{N} g^{(k)}_{\varepsilon,a}(z) e^{\varepsilon^2(v+w)} - \varepsilon^4 \sum_{k=2}^{N} g^{(1)}_{\varepsilon,a}(z) g^{(k)}_{\varepsilon,a}$$

$$\times(z) e^{2\varepsilon^2(v+w)} - \varepsilon^8 \sum_{k,l=2}^{N} g^{(l)}_{\varepsilon,a}(z) g^{(k)}_{\varepsilon,a}(z) e^{2\varepsilon^2(v+w)}. \tag{2.6}$$

Now we introduce the functions spaces introduced in Ref. 1. Let us fix $\alpha \in (0, \frac{1}{2})$ throughout this paper. Following Ref. 1, we introduce the Banach spaces X_α and Y_α as

$$X_\alpha = \left\{ u \in L^2_{\mathrm{loc}}(\mathbb{R}^2) \Big| \int_{\mathbb{R}^2} (1+|x|^{2+\alpha})|u(x)|^2 \, \mathrm{d}x < \infty \right\}$$

equipped with the norm $\|u\|^2_{X_\alpha} = \int_{\mathbb{R}^2}(1+|x|^{2+\alpha})|u(x)|^2 \, \mathrm{d}x$, and

$$Y_\alpha = \left\{ u \in W^{2,2}_{\mathrm{loc}}(\mathbb{R}^2) \Big| \|\Delta u\|^2_{X_\alpha} + \left\| \frac{u(x)}{1+|x|^{1+(\alpha/2)}} \right\|^2_{L^2(\mathbb{R}^2)} < \infty \right\}$$

equipped with the norm

$$\|u\|^2_{Y_\alpha} = \|\Delta u\|^2_{X_\alpha} + \left\| \frac{u(x)}{1+|x|^{1+(\alpha/2)}} \right\|^2_{L^2(\mathbb{R}^2)}.$$

We recall the following propositions proved in Ref. 1.

Proposition 2.1: Let Y_α be the function space introduced above. Then we have the followings:

(i) *If $v \in Y_\alpha$ is a harmonic function, then $v \equiv$ constant.*
(ii) *There exists a constant $C_1 > 0$ such that for all $v \in Y_\alpha$,*

$$|v(x)| \leqslant C_1 \|v\|_{Y_\alpha} \ln(e + |x|), \quad \forall\, x \in \mathbb{R}^2.$$

Proposition 2.2: Let $\alpha \in (0, \frac{1}{2})$, and let us set

$$L = \Delta + \rho_1 : Y_\alpha \to X_\alpha. \tag{2.7}$$

We have

$$\operatorname{Ker} L = \operatorname{Span}\{\varphi_+, \varphi_-, \varphi_0\}, \tag{2.8}$$

where we denoted

$$\varphi_+(r,\theta) = \frac{r^{M_1+1}\cos(M_1+1)\theta}{1 + r^{2M_1+2}}, \quad \varphi_-(r,\theta) = \frac{r^{M_1+1}\sin(M_1+1)\theta}{1 + r^{2M_1+2}}, \tag{2.9}$$

and

$$\varphi_0 = \frac{1 - r^{2M_1+2}}{1 + r^{2M_1+2}}. \tag{2.10}$$

Moreover, we have

$$\operatorname{Im} L = \left\{ f \in X_\alpha \,\middle|\, \int_{\mathbb{R}^2} f\varphi_\pm = 0 \right\}. \tag{2.11}$$

We can check easily that P is a well-defined continuous mapping from $B_{\varepsilon_0} \subset Y_\alpha \times \mathbb{C} \times \mathbb{R}_+$ into X_α, where $B_{\varepsilon_0} = \{\|v\|_{Y_\alpha} + |a| \leqslant \varepsilon < \varepsilon_0\}$ for sufficiently small ε_0. In order to have a continuous extension to $\varepsilon = 0$ of $P(\cdot)$ we require that $\lim_{\varepsilon \to 0} P(0,0,\varepsilon) = 0$, which implies the following equation for w:

$$\Delta w + \rho_1 w - \rho_1^2 = 0. \tag{2.12}$$

We first note the following lemma about asymptotic behaviors of the solutions $w \in Y_\alpha$, the proof of which is in the Appendix.

Lemma 2.1: Let C_0 be the number introduced in (1.13). Then, there exist radial solutions $w(|z|)$ of (2.12) belonging to Y_α, and satisfying the asymptotic formula in (1.12).

In order to obtain the linearized operator $P'_{(v,a)}(0,0,0) = \mathcal{A}$ we first compute,

$$\left.\frac{\partial g^{(k)}_{\varepsilon,a}(z)}{\partial a_1}\right|_{\varepsilon=0,a=0} = -4\rho_k\varphi_+, \qquad \left.\frac{\partial g^{(k)}_{\varepsilon,a}(z)}{\partial a_2}\right|_{\varepsilon=0,a=0} = -4\rho_k\varphi_-,$$

for all $k = 1, \ldots, N$, where ■ ■

Using these we find

$$\mathcal{A}[\nu,\beta] = L\nu - 4(\rho_1 w - 2\rho_1^2)(\varphi_+\beta_1 + \varphi_-\beta_2).$$

For the linearized operator $\mathcal{A}[\cdot]$ we need the following key lemma.

Lemma 2.2: The operator $\mathcal{A}: Y_\alpha \times \mathbb{R}^2 \to X^2_\alpha$ defined above is onto. Moreover, kernel of $\mathcal{A}$ is given by

$$\operatorname{Ker} A = \operatorname{Span}\{\varphi_+, \varphi_-, \varphi_0\} \times \{(0,0)\}. \tag{2.13}$$

Thus, if we decompose $Y_\alpha \times \mathbb{R}^2 = U_\alpha \oplus \operatorname{Ker}\mathcal{A}$, where we set $U_\alpha = (\operatorname{Ker}\mathcal{A})^\perp$, then $\mathcal{A}$ is an isomorphism from U_α onto X_α.

For the proof of Lemma 2.2 we need the following proposition, the proof of which is in the Appendix.

Proposition 2.3:

$$I_{\pm} := \int_{\mathbb{R}^2} (\rho_1 w - 2\rho_1^2)\varphi_{\pm}^2 \, dx \neq 0.$$

With Proposition 2.3 equipped, the proof of Lemma 2.2 is the same as the one in Ref. 1, since the linearized operator, $\mathcal{A}$ is the same as the one in it. We are now ready to prove our main theorem.

Proof of Theorem 1.1: Let us set

$$U_\alpha = (\mathrm{Ker}\, L)^{\perp} \times \mathbb{R}^2.$$

Then, Lemma 2.2 shows that $P'_{(v,\xi,\beta)}(0,0,0,0): U_\alpha \to X_\alpha \times X_\alpha$ is an isomorphism for $\alpha \in (0, \frac{1}{2})$. Then, the standard implicit function theorem (see, e.g., Ref. 17), applied to the functional $P: U_\alpha \times (-\varepsilon_0, \varepsilon_0) \to X_\alpha \times X_\alpha$, implies that there exists a constant $\varepsilon_1 \in (0, \varepsilon_0)$ and a continuous function $\varepsilon \mapsto \psi_\varepsilon^* := (v_\varepsilon^*, a_\varepsilon^*)$ from $(0, \varepsilon_1)$ into a neighborhood of 0 in U_α such that

$$P(v_\varepsilon^*, a_\varepsilon^*, \varepsilon) = 0 \quad \text{for all } \varepsilon \in (0, \varepsilon_1).$$

This completes the proof of Theorem 1.1. Since $M_1 \geqslant M_k$ for all $k = 1, \cdots, N$, the representation of solutions u_k, and the explicit form of

$$\ln[\rho^{(k)}_{\varepsilon, a_\varepsilon^*}(z)] = -[(4M_1 - 2M_k) + 4]\ln|z| + O(1)$$

as $|z| \to \infty$, together with the asymptotic behaviors of $w(\cdot)$ described in Lemma 2.1, the fact that $v_\varepsilon^* \in Y_\alpha$, combined with Proposition 2.1, implies that the solutions satisfy the boundary condition in (1.6). Now, from Proposition 2.1 we obtain that

$$|v_\varepsilon^*(z)| \leqslant C\|v_\varepsilon^*\|_{Y_\alpha}(\ln^+|z| + 1) \leqslant C\|\psi_\varepsilon\|_{U_\alpha}(\ln^+|z| + 1).$$

This implies then

$$|v_\varepsilon^*(\varepsilon x)| \leqslant C\|\psi_\varepsilon\|_{U_\alpha}(\ln^+|\varepsilon x| + 1) \leqslant C\|\psi_\varepsilon\|_{U_\alpha}(\ln^+|x| + 1). \tag{2.14}$$

From the continuity of the function $\varepsilon \mapsto \psi_\varepsilon$ from $(0, \varepsilon_0)$ into U_α and the fact $\psi_0^* = 0$ we have

$$\|\psi_\varepsilon\|_{U_\alpha} \to 0 \quad \text{as } \varepsilon \to 0. \tag{2.15}$$

The proof of (1.14) follows from (2.15) combined with (2.14). This completes the proof of Theorem 1.1. ■

III. EXISTENCE OF TOPOLOGICAL VORTICES

Our aim in this section is to prove Theorem 1.2.

Proof of Theorem 1.2: We first establish that in order to have existence of solution $(u_1, \cdots, u_N)$ satisfying (1.4) and (1.15) and (1.16), it is necessary to have (1.17). Without loss of generality we may assume $M_1 \geqslant M_k$ for all $k = 1, \cdots, m$. Suppose that there exists $M_k < M_1$ for some $k \in \{1, \cdots, m\}$. Then, from (1.4) we have

$$\Delta(u_k - u_1 - \sum_{j=1}^{M_k} \ln|z - z_{k,j}|^2 + \sum_{j=1}^{M_1} \ln|z - z_{l,j}|^2) = 0$$

and

$$u_k = u_1 + \ln\left(\frac{\prod_{j=1}^{M_k}|z-z_{k,j}|^2}{\prod_{j=1}^{M_1}|z-z_{l,j}|^2}\right) + h_k(z) \tag{3.1}$$

for some harmonic function $h_k(z)$. Since

$$u_k \to \ln\sigma_k, \quad u_1 \to \ln\sigma_1, \quad \ln\left(\frac{\prod_{j=1}^{M_k}|z-z_{k,j}|^2}{\prod_{j=1}^{M_1}|z-z_{l,j}|^2}\right) \to O((M_k - M_1)\ln|z|),$$

as $|z|\to\infty$, (3.1) implies $h_k \equiv C_k$ (constant), and provides an absurd relation. Hence, $M_1 = \cdots = M_m \equiv M$. Similarly, the relation (3.1) with $k=m+1,\cdots,N$ implies $M_k < M$ for all $k=m+1,\cdots,N$, since for all $k=m+1,\cdots,N$, $u_k \to -\infty$, while $u_1 \to \ln\sigma_1$ as $|z|\to\infty$.

Then, choosing $C_k = \ln(\sigma_k/\sigma_1)$ for all $k=1,\cdots,m$, (2.1) becomes

$$u_k = u_1 + \ln\left(\frac{\sigma_k}{\sigma_1}\prod_{j=1}^{M}\frac{|z-z_{k,j}|^2}{|z-z_{1,j}|^2}\right) \tag{3.2}$$

for $k=1,\cdots,N$. Let us set

$$\eta_k(z) = \begin{cases} \sigma_k\displaystyle\prod_{j=1}^{M}\frac{|z-z_{k,j}|^2}{(\mu+|z-z_{1,j}|^2)} & \text{for } k\in\{1,\cdots,m\}, \\ \dfrac{\prod_{j=1}^{M_k}|z-z_{k,j}|^2}{\prod_{j=1}^{M}(\mu+|z-z_{1,j}|^2)} & \text{for } k\in\{m+1,\cdots,N\}, \end{cases}$$

where $\mu>$ is a sufficiently large parameter. We introduce new unknown v by

$$u_1 = v + \ln\,\eta_1. \tag{3.3}$$

Then, (3.2) combined with (3.3) implies the representation for u_k, $k=1,\cdots,N$ by

$$u_k = v + \ln\,\eta_k.$$

We introduce

$$g(z) = \sum_{j=1}^{M}\frac{4\mu}{(\mu+|z-z_{1,j}|^2)^2}.$$

We note that

$$\Delta\ln\,\eta_1(z) = 4\pi\sum_{j=1}^{M}\delta(z-z_{1,j}) - g(z). \tag{3.4}$$

We also introduce the function u_0 defined by

$$\sum_{k=1}^{N}\eta_k = e^{u_0}. \tag{3.5}$$

Note that since $e^{u_0}\to\Sigma_{k=1}^{m}\sigma_k=1$, we have $u_0\to 0$ as $|z|\to\infty$.

Using (3.4) and (3.5), we can rewrite the equation for u_1 in (1.4) as follows:

$$\Delta v = e^{v+u_0}(e^{v+u_0}-1) + g,$$

which is the Euler–Lagrange equation of the functional

$$F(v)=\int_{\mathbb{R}^2}\left[\frac{1}{2}|\nabla v|^2+\frac{1}{2}(e^{u+u_0}-1)^2+gv\right]\mathrm{d}x. \tag{3.6}$$

After this step the arguments for the existence of solution by minimization of the functional $F(v)$ by showing the coercivity and the weak lower semicontinuity in $H^1(\mathbb{R}^2)$ for sufficiently large μ, is exactly the same as in Refs. 15 and 11 or 16 and we do not repeat them here. This finishes the proof of Theorem 1.2. ■

APPENDIX

Here we prove Lemma 2.1 and Proposition 2.3. We begin with the following elementary integration lemma.

Lemma 4.1: Let $m\geqslant k+1$, then we have

$$\int_0^\infty \frac{r^{k(2N+2)-3}}{(1+r^{2N+2})^m}\mathrm{d}r=\frac{\pi\prod_{j=1}^{k-1}(Nj+j-1)\prod_{j=1}^{m-k}[Nj+j-1]}{2(m-1)!(N+1)^m\sin\left(\frac{\pi N}{N+1}\right)}. \tag{A1}$$

Proof:

$$\begin{aligned}\int_0^\infty \frac{r^{k(2N+2)-3}}{(1+r^{2N+2})^m}\mathrm{d}r&=\frac{1}{2N+2}\int_0^\infty \frac{t^{k-1-[1/(N+1)]}}{(1+t)^m}\mathrm{d}t \quad (\text{setting } t=r^{2N+2})\\ &=-\frac{1}{2N+2}\int_0^\infty \frac{t^{k-1-[1/(N+1)]}}{(m-1)}\frac{\mathrm{d}}{\mathrm{d}t}\frac{1}{(1+t)^{m-1}}\mathrm{d}t\\ &=\frac{1}{(2N+2)}\frac{1}{(m-1)}\left(k-1-\frac{1}{N+1}\right)\int_0^\infty \frac{t^{k-2-[1/(N+1)]}}{(1+t)^{m-1}}\mathrm{d}t=\cdots\\ &=\frac{\left(k-1-\frac{1}{N+1}\right)\left(k-2-\frac{1}{N+1}\right)\cdots\left(1-\frac{1}{N+1}\right)}{2(N+1)(m-1)(m-2)\cdots(m-k+1)}\int_0^\infty \frac{t^{-1/(N+1)}}{(1+t)^{m-k+1}}\mathrm{d}t.\end{aligned} \tag{A2}$$

Now we use the well-known formula from the Mellin transform (see, e.g., Ref. 7),

$$\int_0^\infty \frac{t^{a-1}}{(1+t)^n}\mathrm{d}t=\frac{\pi|(a-1)(a-2)\cdots(a-(n-1))|}{(n-1)!\sin(\pi a)},\quad a\in(0,1)$$

in order to evaluate

$$\int_0^\infty \frac{t^{-1/(N+1)}}{(1+t)^{m-k+1}}\mathrm{d}t=\int_0^\infty \frac{t^{a-1}}{(1+t)^{m-k+1}}\mathrm{d}t=\frac{\pi|(a-1)(a-2)\cdots(a-m+k)|}{(m-k)!\sin(\pi a)}, \tag{A3}$$

where we set $a=N/(N+1)$. Substituting (A3) into (A2), we obtain (A1). ■

Proof of Lemma 2.1: Let us set $f(r)=\rho_1(r)$. Then, it is found in Ref. 1 that the ordinary differential equation (with respect to r), $\Delta w+\rho_1 w=f(r)$ has a solution $w(r)\in Y_\alpha$ given by

$$w(r) = \varphi_0(r)\left\{ \int_0^r \frac{\phi_f(s) - \phi_f(1)}{(1-s)^2} \mathrm{d}s + \frac{\phi_f(1) r}{1-r} \right\} \tag{A4}$$

with

$$\phi_f(r) := \left(\frac{1 + r^{2M_1+2}}{1 - r^{2M_1+2}} \right)^2 \frac{(1-r)^2}{r} \int_0^r \varphi_0(t) t f(t) \mathrm{d}t,$$

where $\phi_f(1)$ and $w(1)$ are defined as limits of $\phi_f(r)$ and $w(r)$ as $r \to 1$. From the formula (A4) we find that

$$w(r) = \varphi_0(r) \int_2^r \left(\frac{1 + s^{2M_1+2}}{1 - s^{2M_1+2}} \right)^2 \frac{I(s)}{s} \mathrm{d}s + (\text{bounded function of } r) \tag{A5}$$

as $r \to \infty$, where

$$I(s) = \int_0^s \varphi_0(t) t \rho_1(t) \mathrm{d}t.$$

Since $\varphi_0(r) \to -1$ as $r \to \infty$, (1.12) follows if we show

$$I = I(\infty) = \int_0^\infty \varphi_0(r) r \rho_1(r) \mathrm{d}r = C_0.$$

We evaluate the integral,

$$\begin{aligned}
I &= \int_0^\infty \varphi_0(r) f(r) r \, \mathrm{d}r = \int_0^\infty \varphi_0(r) \rho_1(r)^2 r \, \mathrm{d}r = 64(M_1+1)^4 \int_0^\infty \frac{(1 - r^{2M_1+2}) r^{4M_1+1}}{(1 + r^{2M_1+2})^5} \mathrm{d}r \\
&= 64(M_1+1)^4 \left[\int_0^\infty \frac{r^{4M_1+1}}{(1 + r^{2M_1+2})^5} \mathrm{d}r - \int_0^\infty \frac{r^{6M_1+3}}{(1 + r^{2M_1+2})^5} \mathrm{d}r \right] \\
&= 64(M_1+1)^4 \left[\frac{\pi M_1^2 (2M_1+1)(3M_1+2)}{2 \times 4! (M_1+1)^5 \sin\left(\frac{\pi M_1}{M_1+1} \right)} - \frac{\pi M_1^2 (2M_1+1)^2}{2 \times 4! (M_1+1)^5 \sin\left(\frac{\pi M_1}{M_1+1} \right)} \right] \\
&= \frac{4\pi M_1^2 (2M_1+1)^6}{15(M_1+1)^5 \sin\left(\frac{\pi M_1}{M_1+1} \right)} = C_0,
\end{aligned}$$

where we used (A1) with $(k,m) = (2,5)$ and (3,5) in the fourth line. This completes the proof of Lemma 2.1. ■

Proof of Proposition 2.3: In order to transform the integral we use the formula

$$L\left[\frac{1}{16(1 + r^{2M_1+2})^2} \right] = \frac{(M_1+1)^2 r^{4M_1+2}}{(1 + r^{2M_1+2})^4},$$

which can be verified by an elementary computation. Using this, we have the following:

$$
\begin{aligned}
I_{\pm} &= \int_{\mathbb{R}^2} (\rho_1 w - 2\rho_1^2)\varphi_{\pm}^2 \, \mathrm{d}x = \int_0^{2\pi}\int_0^{\infty} (\rho_1 w - 2\rho_1^2) \frac{r^{2M_1+2}}{(1+r^{2M_1+2})^2} \begin{Bmatrix} \cos^2(M_1+1)\theta \\ \sin^2(M_1+1)\theta \end{Bmatrix} r \, \mathrm{d}r \, \mathrm{d}\theta \\
&= \pi \int_0^{\infty} \left[\frac{8(M_1+1)^2 r^{2M_1}}{(1+r^{2M_1+2})^2} w - 2\rho_1^2 \right] \frac{r^{2M_1+2}}{(1+r^{2M_1+2})^2} r \, \mathrm{d}r = \pi \int_0^{\infty} \left[\frac{1}{2} L \left\{ \frac{1}{(1+r^{2M_1+2})^2} \right\} w \right. \\
&\quad \left. - \frac{2\rho_1^2 r^{2M_1+2}}{(1+r^{2M_1+2})^2} \right] r \, \mathrm{d}r = \pi \int_0^{\infty} \left[\frac{1}{2} L w \cdot \frac{1}{(1+r^{2M_1+2})^2} - \frac{2\rho_1^2 r^{2M_1+2}}{(1+r^{2M_1+2})^2} \right] r \, \mathrm{d}r \\
&= \pi \int_0^{\infty} \left[\frac{\rho_1^2}{2(1+r^{2M_1+2})^2} - \frac{2\rho_1^2 r^{2M_1+2}}{(1+r^{2M_1+2})^2} \right] r \, \mathrm{d}r = \pi \int_0^{\infty} \left[\frac{5\rho_1^2}{2(1+r^{2M_1+2})^2} - \frac{2\rho_1^2}{(1+r^{2M_1+2})} \right] r \, \mathrm{d}r \\
&= 64\pi (M_1+1)^4 \int_0^{\infty} \left[\frac{5 r^{4M_1+1}}{2(1+r^{2M_1+2})^6} - \frac{2 r^{4M_1+1}}{(1+r^{2M_1+2})^5} \right] \mathrm{d}\, r \\
&= 64\pi (M_1+1)^4 \left[\frac{\pi M_1^2 (2M_1+1)(3M_1+2)(4M_1+3)}{4 \times 4! (M_1+1)^6 \sin\left(\dfrac{\pi M_1}{M_1+1} \right)} - \frac{\pi M_1^2 (2M_1+1)(3M_1+2)}{4! (M_1+1)^5 \sin\left(\dfrac{\pi M_1}{M_1+1} \right)} \right] \\
&= - \frac{2\pi^2 M_1^2 (2M_1+1)(3M_1+2)}{3(M_1+1)^2 \sin\left(\dfrac{\pi M_1}{M_1+1} \right)} < 0,
\end{aligned}
$$

where we used (A1) with $(k,m)=(2,6)$ and $(2,5)$, respectively, in order to evaluate the integrals in the seventh line. This completes the proof of the proposition. ■

The topology of the electroweak interaction

Jürgen Tolksdorf[a)]
Max Planck Institute for Mathematics in the Sciences, Germany

(Received 16 August 2004; accepted 25 January 2005; published online 21 March 2005)

In this paper we show that the Higgs boson of the (minimal) standard model has at most three gauge inequivalent ground states. One of these states is related to ordinary electromagnetism and the other two to electromagnetism within magnetically charged vacua. If space–time is assumed to be rotationally symmetric then the charged electroweak vacua may be identified with Dirac monopoles of magnetic charge $g=\pm 1/2$. This offers a physical interpretation of magnetic monopoles and Dirac's quantization condition of electric charge in terms of the electroweak interaction. Moreover, in the case of the (minimal) standard model the three possible gauge inequivalent ground states of the Higgs boson are shown to fully determine the topological structure of the gauge bundle which underlies the electroweak interaction. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1883312]

I. INTRODUCTION

In this paper we discuss the topological structure that underlies the electroweak interaction as it is described by the (minimal) standard model. More specifically, we shall show that the topological structure of the principal $\mathrm{SU}(2)\times\mathrm{U}(1)$ bundle of the electroweak interaction is fully determined by the hypercharge of the Higgs boson.

In Ref. 15 it has been shown that the symmetry of electromagnetism under charge conjugation is equivalent to the triviality of the electroweak gauge bundle. The aim of this paper is to discuss the topology of the electroweak gauge bundle $\mathcal{P}$ over an arbitrary space–time $(\mathcal{M},g_{\mathrm{M}})$ when charge conjugation is not taken into account. We will show that the structure of $\mathcal{P}$ is fully determined by Dirac's famous quantization condition of electric charge. It follows that in the case of the (minimal) standard model the Higgs boson has at most three gauge inequivalent ground states, one of which corresponds to ordinary electromagnetism and the other two correspond to electromagnetism within a "magnetically charged vacuum." Thus, the latter spoil charge conjugation. The fact that there are two charged vacua corresponds to the $\mathbb{Z}_2$-grading of charge conjugation of ordinary electromagnetism. To prove this, we will first summarize the basic geometrical setup in the next section. In the third section we present the proof of the above statements and discuss some consequences. In the fourth section we propose a specific generalization of the moduli space of all electroweak vacua that has been introduced in Ref. 15 and discuss Dirac monopoles from the geometrical viewpoint presented in this paper. We finish with a summary of the results presented.

In the following we summarize the motivation and the physical terminology used in this paper (see also Ref. 15). This paper is part of a sequence of papers dealing with a globally geometrical analysis of spontaneously broken gauge theories. The discussion is based on a geometrical understanding of the "two shifts" usually performed in order to make perturbation theory on Minkowski space–time $\mathbb{R}^{1,3}$

$$d \mapsto d + A,$$

[a)]Electronic mail: juergen.tolksdorf@mis.mpg.de

$$\mathbf{z}_0 \mapsto \mathbf{z}_0 + \phi. \tag{1}$$

For example, in the semiclassical approximation ("tree-level") of the (minimal) standard model $A = B + W \in \Omega^1(\mathbb{R}^{1,3}, \mathbb{R} \oplus \mathbb{R}^3)$ denotes the electroweak gauge potential and $\phi \in \Omega^0(\mathbb{R}^{1,3}, \mathbb{C}^2)$ represents the Higgs boson. Moreover, the Higgs boson and the electroweak gauge boson are assumed to represent the following "particle multiplets:"

$$A = (A_{\mathrm{elm}}, W^{\pm}, Z^0),$$

$$\phi = (\phi_{\mathrm{G}}, \phi_{\mathrm{H,phys}}). \tag{2}$$

When "quantized" A_{elm} is identified with the photon and $W^{\pm}$ and Z^0 with the electroweak vector bosons; ϕ_{G} denotes the Goldstone boson and $\phi_{\mathrm{H,phys}}$ the physical Higgs boson.

In the unitary gauge the pair $(A, \phi_{\mathrm{H,phys}})$ is physically interpreted as a "fluctuation" of a ground state ("semiclassical vacuum") of the electroweak interaction. From a geometrical perspective such a ground state may be described as a particular "Yang–Mills–Higgs pair" $(d, \mathbf{z}_0)$, where "d" is considered as the exterior covariant derivative with respect to the trivial connection on $\mathbb{C}^2$. The chosen minimum $\mathbf{z}_0 \in \mathbb{C}^2$ of the Higgs potential V_{H} can be regarded as the canonical smooth mapping

$$\mathbf{z}_0 : \mathbb{R}^{1,3} \to \mathrm{orbit}(\mathbf{z}_0),$$

$$x \mapsto \mathbf{z}_0. \tag{3}$$

Here, the submanifold orbit $(\mathbf{z}_0) \subset \mathbb{C}^2$ is the orbit of $\mathbf{z}_0$ with respect to a unitary group action of $\mathrm{G} \equiv \mathrm{SU}(2) \times \mathrm{U}(1)$ on $\mathbb{C}^2$.

Of course, the decomposition (2) and the physical interpretation of $(A, \phi_{\mathrm{H,phys}})$ only makes sense if either the topology of space–time $(\mathcal{M}, g_{\mathrm{M}})$ or the topology of the underlying gauge bundle $\mathcal{P}$ is assumed to be trivial. But what do we know about the global properties of the respective spaces? And what kind of phenomena can we expect if the respective topologies are nontrivial? Usually, one argues that physics can only make local statements. Consequently, the above given interpretation may be considered as local relations for locally space–time and any (gauge) bundle are topologically trivial. Then, for example, the gauge classes of mappings (3) are known to be classified by $\pi_1(\mathrm{G}/\mathrm{H})$, where the closed subgroup $\mathrm{H} \subset \mathrm{G}$ is isomorphic to the isotropy group of $\mathbf{z}_0$. However, the notion of locality is physically meaningless in the context of gauge theories for the latter do not give rise to a scale (in contrast to gravity). Therefore, the mathematical fact that every bundle is locally trivial has no physical meaning. We are thus forced to consider a bundle as a global geometrical object. This holds true in particular with respect to a gauge bundle $\mathcal{P}$. Likewise, because of the local nature of our experiments it seems more appropriate to determine the topological structure of space–time only by physical reasoning and not by *a priori* assumptions.

The assumption that the topology of $(\mathcal{M}, g_{\mathrm{M}})$ and of $\mathcal{P}$ is quite general naturally rises the question about the moduli space of gauge classes of semiclassical vacua. This moduli space is related to the topology of space–time and the underlying gauge bundle. One may thus learn something about the global structure of the latter by investigating the moduli space of semiclassical vacua. Notice that the topological structure of space–time and of the gauge bundle also determines the global structure of every associated bundle (up to equivalence). That the moduli space of semiclassical vacua actually provides a good tool to study the possible topolological structure of $\mathcal{P}$ is demonstrated in this paper for the special case of the electroweak interaction. Although restricted to the semiclassical approximation the results presented may also have nontrivial consequences for quantizing the electroweak/electromagnetic interaction on curved space–time. Indeed, our discussion is also intended as a preliminary step towards a geometrical understanding of perturbation theory.

II. THE ELECTROWEAK INTERACTION AS A SPECIFIC YANG–MILLS–HIGGS GAUGE THEORY

For the convenience of the reader we summarize in this section the basic geometrical notions used to geometrically formulate the bosonic sector of the electroweak interaction as a specific Yang–Mills–Higgs (YMH) gauge theory. For the terminology used and the details we refer to Refs. 13 and 15. A corresponding discussion of fermions can be found in Ref. 14.

In what follows $(\mathcal{M},g_{\mathrm{M}})$ denotes a smooth orientable (semi-)Riemannian manifold of arbitrary signature and dimension. As a topological space, $\mathcal{M}$ is assumed to be paracompact, connected and Hausdorff. In addition we shall assume that either the cohomology of $\mathcal{M}$ is torsion free, or all cohomological statements presented are regarded "modulo torsion." Since we are mainly interested in the case where $(\mathcal{M},g_{\mathrm{M}})$ denotes a four dimensional Lorentzian manifold of signature -2, we call $\mathcal{M}$ "space–time." Likewise, by $\mathcal{P}$ we mean a smooth principal G bundle over space–time $\mathcal{M}$,

$$\pi_{\mathrm{P}}:\mathrm{P}\to\mathcal{M},$$

$$p\mapsto x, \tag{4}$$

with structure group $\mathrm{G}:=\mathrm{SU}(2)\times\mathrm{U}(1)$. We call $\mathcal{P}$ the "electroweak gauge bundle." Its topological structure is thought to be given but so-far arbitrary. We will show that the actual bundle structure is fully determined (up to equivalence) by physical reasoning.

We call $(\mathcal{P},\rho_{\mathrm{H}},V_{\mathrm{H}})$ the geometrical data which permit to describe the electroweak interaction as a specific YMH gauge theory. Here,

$$\rho_{\mathrm{H}}:\mathrm{G}\to\mathrm{GL}(2,\mathbb{C}),$$

$$g=(g_{(2)},g_{(1)})\mapsto g_{(2)}g_{(1)}^{\mathrm{y}}, \tag{5}$$

with $y\in\mathbb{Q}$ denoting the so-called "hypercharge;"

$$V_{\mathrm{H}}:\mathbb{C}^2\to\mathbb{R},$$

$$\mathbf{z}\mapsto\lambda|\mathbf{z}|^4-\mu^2|\mathbf{z}|^2 \tag{6}$$

is the well-known Higgs potential $(\lambda,\mu>0)$. Note that the unitary representation ρ_{H} is faithful and the Higgs potential is rotationally symmetric, i.e., $V_{\mathrm{H}}=f_{\mathrm{H}}\circ r$ with $r(\mathbf{z}):=|\mathbf{z}|$ the "radial function."

The "Higgs bundle" ξ_{H} and the "Yang–Mills bundle" $\xi_{\mathrm{YM}}:=\tau_{\mathrm{M}}^{*}\otimes\mathfrak{ad}(\mathcal{P})$ are naturally associated with the geometrical data $(\mathcal{P},\rho_{\mathrm{H}},V_{\mathrm{H}})$. The Higgs bundle is defined by

$$\pi_{\mathrm{H}}:E_{\mathrm{H}}:=\mathrm{P}\times_{\rho_{\mathrm{H}}}\mathbb{C}^2\to\mathcal{M},$$

$$\mathfrak{z}\equiv[(p,\mathbf{z})]\mapsto\pi_{\mathrm{P}}(p) \tag{7}$$

and the adjoint bundle $\mathfrak{ad}(\mathcal{P})$ is given by

$$\pi_{\mathrm{ad}}:\mathrm{ad}(\mathrm{P}):=\mathrm{P}\times_{\mathrm{ad}}\mathrm{Lie}(\mathrm{G})\to\mathcal{M},$$

$$\tau\equiv[(p,T)]\mapsto\pi_{\mathrm{P}}(p). \tag{8}$$

The latter is always considered as a real vector bundle of rank four. Also the Higgs bundle will be mainly regarded as a real vector bundle of rank four. The real vector bundle τ_{M}^{*} denotes the cotangent bundle of space–time $\mathcal{M}$.

Each minimum $\mathbf{z}_0\in\mathbb{C}^2$ of the Higgs potential induces a specific fiber sub-bundle $\xi_{\mathrm{orb}}\subset\xi_{\mathrm{H}}$, which we call the "orbit bundle" with respect to $\mathbf{z}_0$,

$$\pi_{\mathrm{orb}}:\mathrm{Orbit}(\mathbf{z}_0) := \mathrm{P}\times_{\rho_{\mathrm{orb}}} \mathrm{orbit}(\mathbf{z}_0) \to \mathcal{M}$$

$$\mathfrak{z} \equiv [(p,\mathbf{z})] \mapsto \pi_{\mathrm{P}}(p), \tag{9}$$

with $\rho_{\mathrm{orb}} := \rho_{\mathrm{H}}|_{\mathrm{orbit}(\mathbf{z}_0)}$. Note that in the case at hand the Higgs potential has only one orbit of minima. Also, for two different minima the corresponding orbit bundles are equivalent. We therefore refer to (9) as the orbit bundle with respect to the data $(\mathcal{P},\rho_{\mathrm{H}},V_{\mathrm{H}})$. For rotationally symmetric Higgs potentials the orbit bundle can be thought of as a sphere sub-bundle of the Higgs bundle.

Each section $\mathcal{V}\in\Gamma(\xi_{\mathrm{orb}})$ is in one-to-one correspondence with a smooth principal H bundle $\mathcal{Q}$ over $\mathcal{M}$

$$\pi_{\mathrm{Q}}:\mathrm{Q}\to\mathcal{M},$$

$$q\mapsto x. \tag{10}$$

The structure group $\mathrm{H}\equiv\mathrm{U}_{\mathrm{elm}}(1)$ of $\mathcal{Q}$ is isomorphic to the isotropy group $I(\mathbf{z}_0)\subset\mathrm{G}$ of the minimum $\mathbf{z}_0\in\mathbb{C}^2$

$$I(\mathbf{z}_0)\equiv\{\exp(\theta[T+iy])|T=T(\mathbf{z}_0)\in\mathrm{su}(2),\mathrm{tr}[(T+iy)^2]=-n^2,n\in\mathbb{N}\}. \tag{11}$$

Moreover, there is an equivariant embedding of principal bundles $\iota:\mathcal{Q}\hookrightarrow\mathcal{P}$, such that $(\iota,\mathcal{Q})$ is an H reduction of $\mathcal{P}$ (see, Ref. 9). For a discussion of spontaneously broken gauge theories in terms of bundle reductions see, for example, Refs. 4, 5, 12, and 17. We call the principal H bundle $\mathcal{Q}$ the "electromagnetic gauge bundle" with respect to the "vacuum section" $\mathcal{V}$. The relation between a section $\mathcal{V}$ of the orbit bundle and the appropriate H reduction $(\iota,\mathcal{Q})$ of $\mathcal{P}$ is given by $\mathcal{V}(x)=[(\iota(q),\mathbf{z}_0)]|_{q\in\pi_{\mathrm{Q}}^{-1}(x)}$ for all $x\in\mathcal{M}$.

Each $\mathcal{V}\in\Gamma(\xi_{\mathrm{orb}})$ gives rise to a distinguished subset of principal connections on $\mathcal{P}$. They are determined by the requirement

$$d_{\mathrm{A}}\mathcal{V}=0, \tag{12}$$

where $\mathcal{A}\in\mathcal{A}(\xi_{\mathrm{H}})$ is the corresponding associated connection on ξ_{H}. The connections on $\mathcal{P}$ which satisfy the condition (12) are called compatible with the vacuum section $\mathcal{V}$ [respectively, with the H reduction $(\iota,\mathcal{Q})$ of $\mathcal{P}$]. These connections have the crucial property that they are flat when restricted to the "physical space–time" $\mathcal{M}_{\mathrm{phys}}:=\mathcal{V}(\mathcal{M})\subset E_{\mathrm{H}}$.

A YMH pair $(\mathcal{A},\Phi)\in\mathcal{A}(\xi_{\mathrm{H}})\times\Gamma(\xi_{\mathrm{H}})$ is called a "vacuum (pair)" iff $\Phi=\mathcal{V}$ is a vacuum section and $\mathcal{A}=\Theta$ is associated with a flat connection on $\mathcal{P}$ which is compatible with $\mathcal{V}$. Each vacuum defines an absolute minimum of the energy functional (if globally defined) that is associated with the well-known YMH functional. The moduli space of gauge classes of vacua is denoted by $\mathfrak{M}_{\mathrm{vac}}$. The latter turns out to be nontrivial iff $\mathcal{P}$ is trivial. In this case, $\mathfrak{M}_{\mathrm{vac}}$ can be canonically identified with $\mathrm{H}^1_{\mathrm{deR}}(\mathcal{M})$. In other words, the moduli space of the electroweak vacua only depends on the topology of space–time. In particular, if $\mathcal{M}$ is simply connected then there is a natural vacuum (pair) $(\Theta_0,\mathcal{V}_0)$ which generates $\mathfrak{M}_{\mathrm{vac}}$. This vacuum corresponds to the vacuum usually introduced in perturbation theory via the "shift" (1).

Since $\mathfrak{M}_{\mathrm{vac}}=\emptyset$ for nontrivial $\mathcal{P}$, we have to appropriately generalize the notion of the moduli space of electroweak vacua. This will be achieved by use of the fact that $\mathfrak{M}_{\mathrm{vac}}\neq\emptyset$ iff electromagnetism is symmetric with respect to charge conjugation. Before we introduce a generalization of $\mathfrak{M}_{\mathrm{vac}}$, however, we shall prove in the next section that Dirac's quantization condition of electric charge fully determines the topological structure of the electroweak gauge bundle.

III. THE TOPOLOGY OF THE ELECTROWEAK GAUGE BUNDLE

When charge conjugation is taken into account the existence of vacuum sections is equivalent to the triviality of the electroweak gauge bundle. We therefore consider in this section the situation where charge conjugation is spoiled. Physically, this is the case if an absolute magnetic field exists which, for example, is generated by a magnetic monopole. We show that in the case of the standard model the Higgs boson may also provide such a state.

Proposition 3.1: Let $\mathcal{Q}$ be a principal H bundle over a smooth manifold $\mathcal{M}$ and let $\lambda:\mathrm{H}\hookrightarrow\mathrm{G}$ be a homomorphism which is also a smooth embedding of Lie groups. Up to isomorphism there is a unique principal G bundle $\mathcal{P}$ over $\mathcal{M}$ together with a smooth embedding $\iota:\mathcal{Q}\hookrightarrow\mathcal{P}$ such that $(\iota,\mathcal{Q})$ is an H reduction of $\mathcal{P}$.

Proof: For this let $\{(U_i,\varphi_i)\,|\,i\in\Lambda\}$ be a family of local trivializations of the principal H bundle $\mathcal{Q}:\pi_\mathrm{Q}:\mathrm{Q}\to\mathcal{M}$. That is, $U_i\subset\mathcal{M}$ is an open subset such that $\mathcal{M}\subset\cup_{i\in\Lambda}U_i$, and

$$\varphi_i:\pi_\mathrm{Q}^{-1}(U_i)\to U_i\times\mathrm{H},$$

$$p\mapsto(x:=\pi_\mathrm{Q}(q),h_i:=\varphi_{i,x}(q)) \tag{13}$$

is an equivariant diffeomorphism for all $i\in\Lambda$.

Accordingly, for $U_i\cap U_j\neq\emptyset$ we denote by the mappings

$$h_{ij}:U_i\cap U_j\to\mathrm{H},$$

$$x\mapsto\varphi_{i,x}(q)(\varphi_{j,x}(q))^{-1}, \tag{14}$$

the transition functions with respect to the local trivialization $\{(U_i,\varphi_i)\,|\,i\in\Lambda\}$.

For all $i,j\in\Lambda$ such that $U_i\cap U_j\neq\emptyset$ we define smooth mappings

$$g_{ij}:U_i\cap U_j\to\mathrm{G},$$

$$x\mapsto\lambda(h_{ij}(x)) \tag{15}$$

which satisfy the co-cycle condition $g_{ij}(x)g_{jk}(x)g_{ki}(x)=e$ for all $x\in U_i\cap U_j\cap U_k$. Therefore, up to equivalence there is a unique principal G bundle $\mathcal{P}:\pi_\mathrm{P}:\mathrm{P}\to\mathcal{M}$ with local trivialization $\{(U_i,\psi_i)\,|\,i\in\Lambda\}$ such that $g_{ij}(x)=\psi_{i,x}(p)(\psi_{j,x}(p))^{-1}$.

We define a smooth family $\{(U_i,\iota_i\,|\,i\in\Lambda)\}$ of mappings

$$\iota_i:\pi_\mathrm{Q}^{-1}(U_i)\to\pi_\mathrm{P}^{-1}(U_i),$$

$$q\mapsto\psi_i^{-1}\,(x,\lambda(\varphi_{i,x}(q)))|_{x=\pi_\mathrm{Q}(q)}. \tag{16}$$

Since λ is an embedding, these mappings have maximal rank and fulfill $\iota_i(q)=\iota_j(q)$ for all $q\in\pi_\mathrm{Q}^{-1}(U_i\cap U_j)$. Therefore, they define a global immersion $\iota:\mathrm{Q}\to\mathrm{P}$ which is a homeomorphism onto $\iota(\mathrm{Q})$. Moreover, since λ is a homomorphism, the embedding ι is equivariant and fulfill $\pi_\mathrm{P}\circ\iota=\pi_\mathrm{Q}$. Consequently, $(\iota,\mathcal{Q})$ is an H reduction of $\mathcal{P}$ and thus $\mathcal{P}$ a G extension of $\mathcal{Q}$. Any other G-extension $\mathcal{P}'$ must be equivalent to $\mathcal{P}$, for the structure functions of $\mathcal{P}'$ are equivalent to those of $\mathcal{P}$. □

Therefore, for given data $(\mathcal{Q},\mathrm{G},\lambda)$ there is (up to equivalence) a unique G-extension $\mathcal{P}$ of the principal H bundle $\mathcal{Q}$. Since every principal U(1) bundle is characterized by an integer we may apply the Proposition 3.1 to prove our main result.

Proposition 3.2: Let $(\mathcal{P},\rho_\mathrm{H},V_\mathrm{H})$ be the geometrical data which specifies the electroweak interaction of the (minimal) standard model as a YMH gauge theory. Up to equivalence the topological structure of the electroweak gauge bundle is fully determined by the hypercharge of the Higgs boson. Moreover, for a given hypercharge $y>0$ there are $2|n|+1$ gauge inequivalent sections of the orbit bundle where

$$y = \sqrt{\tfrac{1}{2}\left(n^2 - \tfrac{1}{2}\right)}, \quad n \in \mathbb{Z}^*. \tag{17}$$

Proof: To prove the statement we make use of the fact that every principal U(1) bundle is characterized by its Chern number $n \in \mathbb{Z}$, where $n=0$ corresponds to the trivial bundle (see Ref. 7). For a given hypercharge $y \in \mathbb{Q}$, the definition (11) of the isotropy group of a minimum $\mathbf{z}_0 \in \mathbb{C}^2$ of the Higgs potential V_{H} determines an integer $n \in \mathbb{Z}^* \equiv \mathbb{Z}\backslash\{0\}$ which is unique modulo $\mathbb{Z}_2$. For example, one may assume that $\mathbf{z}_0 = (0,0,0,r_0)$ with $r_0 := \sqrt{\mu^2/2\lambda}$ and $T(\mathbf{z}_0) = i\tau_3/2 \in \mathrm{su}(2)$ to prove the relation (17). In the case where $y<0$, we may replace y by $-|y|$ in the definition of the hypercharge. So, we may assume $y>0$ without loss of generality. The relation (17) is Dirac's quantization condition of electric charge in terms of the hypercharge of the Higgs boson. Modulo $\mathbb{Z}_2$, this condition fixes a specific principal $\mathrm{U}_{\mathrm{elm}}(1)$ bundle $\mathcal{Q}$ over $\mathcal{M}$, where $h \in \mathrm{U}_{\mathrm{elm}}(1)$ is given by $h = \det \exp(\theta[T+iy])$. Accordingly, the embedding λ reads

$$\lambda : U_{\mathrm{elm}}(1) \hookrightarrow \mathrm{SU}(2) \times \mathrm{U}(1),$$

$$h = \exp(in\theta) \mapsto (\exp(\theta T), \exp(i\theta y)). \tag{18}$$

Therefore, the structure of the electroweak gauge bundle $\mathcal{P}$ is fully determined by the hypercharge of the Higgs boson. Moreover, if the case $n=0$ is taken into account one obtains $2|n|+1$ $\mathrm{U}_{\mathrm{elm}}(1)$ reductions of the principal $\mathrm{SU}(2)\times\mathrm{U}(1)$ bundle $\mathcal{P}$. □

The case $n=0$ is special in several respects and has been thoroughly discussed in Ref. 15. For instance, as already mentioned, the corresponding electromagnetic gauge bundle equals the trivial principal $\mathrm{U}_{\mathrm{elm}}(1)$ bundle independently from the topology of space–time,

$$\mathrm{pr}_1 : \mathcal{M} \times \mathrm{U}_{\mathrm{elm}}(1) \to \mathcal{M},$$

$$q = (x,h) \mapsto x. \tag{19}$$

This electromagnetic gauge bundle is the only one which possesses a flat connection. Moreover, it has a natural flat connection that is induced by the Maurer–Cartan form on $\mathrm{U}_{\mathrm{elm}}(1)$. Since the electroweak gauge bundle is trivial too, the corresponding embedding $\iota : \mathcal{Q} \hookrightarrow \mathcal{P}$ is given by

$$\iota : \mathcal{M} \times \mathrm{U}_{\mathrm{elm}}(1) \hookrightarrow \mathcal{M} \times (\mathrm{SU}(2) \times \mathrm{U}(1)),$$

$$(x,h) \mapsto (x, \lambda(h)). \tag{20}$$

Accordingly, the vacuum section $\mathcal{V}_0$ reads

$$\mathcal{V}_0 : \mathcal{M} \to \mathcal{M} \times \mathrm{orbit}(\mathbf{z}_0),$$

$$x \mapsto (x, \mathbf{z}_0). \tag{21}$$

Indeed, it has been shown that, for the trivial electroweak gauge bundle, any other vacuum section $\mathcal{V}$ must be gauge equivalent to the canonical section $\mathcal{V}_0$. It follows that $\mathfrak{M}_{\mathrm{vac}} \simeq \mathrm{H}^1_{\mathrm{deR}}(\mathcal{M})$, which turns out to be equivalent to the existence of charge conjugation. Therefore, the case $n=0$ corresponds to ordinary electromagnetism generated by the ground state $\mathcal{V}_0$ of the Higgs boson.

Since for $n \neq 0$ the corresponding electromagnetic gauge bundles possess no flat connection, we call the appropriate ground states of the Higgs boson "magnetically charged." They spoil the symmetry of ordinary electromagnetism under charge conjugation like a magnetic monopole. However, the $\mathbb{Z}_2$ symmetry of charge conjugation is hidden in the two-to-one relation (17) between the Chern number and the hypercharge of the Higgs boson. Physically this means that it is possible

to absolutely distinguish between positive and negative electrically charged particles if we know the gauge class of the ground states of the Higgs boson. We stress that for $n \neq 0$ the electroweak gauge bundle $\mathcal{P}$ is nontrivial and possesses no flat connection.

When the Gell–Mann–Nishijima relation between the hypercharges and the electric charges of the fermions is taken into account, the hypercharge of the Higgs boson yields $y=1/2$ (cf., for instance, Refs. 1,11, or 20). Thus, in the case of the (minimal) standard model the Higgs boson has exactly three gauge inequivalent ground states, which are parametrized by the Chern numbers $n=0,\pm 1$. These ground states correspond to the lowest nonvanishing electric charge a particle may have.

Let $\mathcal{O} \in \Gamma(\xi_{\mathrm{H}})$ be the zero section and $\Gamma^*(\xi_{\mathrm{H}}) \equiv \Gamma(\xi_{\mathrm{H}}) \backslash \{\mathcal{O}\}$. Then, the Proposition 3.2 shows that the Higgs bundle ξ_{H} has at least $2|n|+1$ nonvanishing sections. Therefore, $\Gamma^*(\xi_{\mathrm{H}}) \neq \emptyset$, and for each $\Phi \in \Gamma^*(\xi_{\mathrm{H}})$ there is a unique $n \in \mathbb{Z}$ and a nonvanishing function $\varphi \in \mathcal{C}^\infty(\mathcal{M})$ such that

$$\Phi: \mathcal{M} \to E_{\mathrm{H}},$$

$$x \mapsto \varphi(x)\mathcal{V}(x). \tag{22}$$

Consequently, also for $n \neq 0$ every nonvanishing section of the Higgs bundle is fully determined by its length. This is but a geometrical variant of what is usually referred to as "unitary gauge." In fact, despite the chosen terminology the unitary gauge is not a choice of gauge (which may not exist globally). Instead, it refers to the moduli space of ground states of the Higgs boson.

IV. MAGNETICALLY CHARGED VACUA AND MONOPOLES

As discussed in the preceding section, ordinary electromagnetism corresponds to the $n=0$ ground states of the Higgs boson. Moreover, the moduli space of electroweak vacua is related to the topology of space–time via the isomorphism $\mathfrak{M}_{\mathrm{vac}} \simeq \mathrm{H}^1_{\mathrm{deR}}(\mathcal{M})$.

As we have already mentioned, in the case of $n \neq 0$ the electroweak gauge bundle possesses no flat connection and thus $\mathfrak{M}_{\mathrm{vac}} = \emptyset$. One may therefore ask for an appropriate generalization of $\mathfrak{M}_{\mathrm{vac}}$. For this we call a solution $F_{\mathrm{mag}} \in \Omega^2(\mathcal{M})$ of the Maxwell equations a "Dirac–Higgs (DH) monopole," provided it satisfies the following conditions: (a) $[F_{\mathrm{mag}}]/2\pi \in \mathrm{H}^2_{\mathrm{deR}}(\mathcal{M})$ is integral; (b) the Chern number n of the isomorphism class of principal U(1) bundles defined by F_{mag} is either zero or related to the hypercharge of the Higgs boson via Dirac's quantization condition (17); (c) for each $x \in \mathcal{M}$ there is a geodesic normal coordinate system (U,φ) such that $i_{\partial_t} F_{\mathrm{mag}} = 0$, where ∂_t is the (local) timelike vector field that is induced by (U,φ). In particular, for $n=0$ it is assumed that condition (c) holds true for every geodesic normal coordinate system. We let $\mathfrak{M}_{\mathrm{mag}}$ be the moduli space of all gauge classes of YMH pairs $(\mathcal{A},\mathcal{V}) \in \mathcal{A}(\xi_{\mathrm{H}}) \times \Gamma(\xi_{\mathrm{H}})$ such that $\mathcal{A}$ is associated with a connection on $\mathcal{P}$ which is compatible with the vacuum section $\mathcal{V}$ and whose curvature corresponds to F_{mag}.

The condition (c) physically means that there is always an inertial reference system (U,φ) such that with respect to this system F_{mag} is purely magnetic, $\imath_t^* F_{\mathrm{mag}} = B_t \in \Omega^2(\Sigma_t)$ with $\imath_t: \Sigma_t \hookrightarrow U \subset \mathcal{M}$ is defined by the local spacelike hypersurface $t=$const. Moreover, for $n=0$ we have $F_{\mathrm{mag}}=0$.

For $n \neq 0$ we call $\mathfrak{M}_{\mathrm{mag}}$ the "(magnetically) charged sector" of the moduli space of the electroweak vacua. Accordingly, for $n=0$ we call $\mathfrak{M}_{\mathrm{mag}} = \mathfrak{M}_{\mathrm{vac}}$ the "(magnetically) uncharged sector" of the electroweak vacua. Note that the charged sector of $\mathfrak{M}_{\mathrm{mag}}$ also depends on the geometry of space–time. (We would like to thank G. Naber for an appropriate hint).

To present an example which demonstrates the nontriviality of the magnetically charged sector of $\mathfrak{M}_{\mathrm{mag}}$ we consider the exterior Schwarzschild space–time $(\mathcal{M}, g_{\mathrm{M}})$. Here, $\mathcal{M} \simeq \mathbb{R} \times [r_0, \infty[\times S^2$ with $r_0 \in \mathbb{R}_+$ the Schwarzschild radius. Consequently, $\mathcal{M} \approx S^2$ where the latter is a spacelike submanifold of $(\mathcal{M}, g_{\mathrm{M}})$. Since the pull-back of g_{M} to this submanifold equals the Riemannian standard metric on $S^2 \subset \mathbb{R}^3$ it is straightforward to check that

$$F_{\mathrm{mag}} = \frac{n}{2} \sin\vartheta \, \mathrm{d}\vartheta \wedge \mathrm{d}\varphi \tag{23}$$

defines a Dirac–Higgs monopole provided $n \neq 0$ satisfies Dirac's quantization condition (17). The corresponding electromagnetic gauge bundle $(\mathcal{Q}, \iota)$ over $(\mathcal{M}, g_{\mathrm{M}})$ is equivalent to the (generalized) Hopf bundle (see, for instance, Refs. 10, 17, and 18 for a very readable approach)

$$\pi_n : S^3/\mathbb{Z}_n \to S^2, \tag{24}$$

where $\mathbb{Z}_n := \{e^{2k\pi i/n} \,|\, k = 0, 1, \ldots, n-1\} \subset \mathrm{U}(1)$ and π_n generalizes the famous Hopf map π_1 between spheres (cf. Ref. 8; for a recent discussion of the various physical meanings of the Hopf fibration see Ref. 19).

In classical electrodynamics the DH monopole field (23) is regarded as being created by a massive magnetically charged pointlike particle ("Dirac monopole") moving in Minkowski space–time $\mathbb{R}^{1,3}$. In this context the monopole field $F_{\mathrm{mag}} \in \Omega^2(\mathcal{M})$ is known as the Dirac monopole field on $\mathcal{M} := \mathbb{R}^{1,3} \backslash \Gamma$, where $\Gamma \subset \mathcal{M}$ denotes the worldline of the Dirac monopole, see Ref. 6. However, in the context of the standard model the physical interpretation of (23) is different. Notice that in either case $(g_{\mathrm{M}}, F_{\mathrm{mag}})$ is not a solution of the combined Einstein–Maxwell equations. Also notice that the DH monopole has finite energy since the Schwarzschild radius r_0 acts like an ultraviolet cutoff. Indeed, the energy-momentum current $\tau \in \Gamma(\mathrm{End}(\tau_{\mathrm{M}}))$ of the DH monopole field (23) reads $\tau = (n^2/2r^4)\mathrm{Id}_{\mathrm{TM}}$. Hence, the "vacuum energy" Λ is given by the magnetical analogue of the electrostatic energy of an electrically charged sphere

$$\Lambda = 4\pi \frac{g^2}{r_0}, \tag{25}$$

where $g \equiv n/2$ is the magnetic charge of the DH monopole. Notice that the vacuum energy either is zero or uniquely determined by the Schwarzschild radius and the hypercharge of the Higgs boson, i.e., by the topology of space–time and the electroweak gauge bundle. In particular, in the case of the standard model one has $\Lambda \in \{0, \pi/r_0\}$.

The given example of a DH monopole also demonstrates that the electroweak gauge bundle $\mathcal{P}$ is nontrivial in general. However, to determine the structure of the moduli space $\mathfrak{M}_{\mathrm{mag}}$ of electroweak vacua for more general space–times $(\mathcal{M}, g_{\mathrm{M}})$ is certainly a major challenge. The geometry of (static) monopoles (in Minkowski space–time) is thoroughly discussed, for example, in Refs. 2 and 3 (see also, in Ref. 16). However, the point here is to not regard magnetic monopoles as individual "classical (pointlike) particles" in space–time but instead to consider monopoles as specific ground states of the Higgs boson whose realizations depend on both the topology and the geometry of space–time. Indeed, the notion of a world line $\Gamma \subset \mathcal{M}$ is a purely classical concept which seems to make no sense within (quantum) field theory. Also, Dirac's famous quantization condition $qn \in \mathbb{Z}$ of electric charge $q \in \mathbb{Q}$ (again, when measured in appropriate units, see again Ref. 6) holds true only if the appropriate monopole bundle (which is characterized by $n \in \mathbb{Z}^*$) is identified with the electromagnetic gauge bundle. However, this is consistent with the standard model only if the monopole bundle is regarded as a specific $\mathrm{U}_{\mathrm{elm}}(1)$ reduction of the electroweak gauge bundle $\mathcal{P}$. That is, the monopole is identified with a specific gauge class of ground states of the Higgs boson which are not gauge equivalent to those considered in perturbation theory.

In Ref. 15 it has been shown that, with respect to any electroweak vacuum, the Yang–Mills bundle decomposes as

$$\xi_{\mathrm{YM}} = \xi_{\mathrm{elm}} \oplus \xi_{Z^0} \oplus \xi_{W^\pm}. \tag{26}$$

Here, respectively, ξ_{elm} and ξ_{Z^0} are trivial line bundles which geometrically represent an (asymptotically free) photon and an electrically neutral massive weak vector boson. In contrast, $\xi_{W^\pm} := \tau_{\mathrm{M}}^* \otimes \xi_W$, with $\xi_W \subset \mathfrak{ad}(\mathcal{P})$ denoting a rank two vector bundle, simultaneously represents both of the electrically charged and massive weak vector bosons $W^\pm$ iff electromagnetism is symmetric with respect to charge conjugation. Of course, one may expect that only electrically charged

particles permit a physical distinction between the magnetically charged and uncharged ground states of the Higgs boson. With respect to a magnetically charged vacuum, the (massive) vector bosons W^+ and W^- are no longer charge conjugate to each other due to their electromagnetic interaction with the corresponding DH monopole. Geometrically, this is expressed by the nontriviality of ξ_W and that the asymptotically free states of the $W^\pm$ bosons must satisfy the field equation (see also Eq. 35 in Ref. 15)

$$\delta_A d_A W^\pm + m_W^2 W^\pm = 0. \tag{27}$$

Here, respectively, d_A and δ_A is the exterior covariant derivative and its formal adjoint with respect to a DH monopole connection $\mathcal{A}$ and $W^\pm \in \Gamma(\xi_{W^\pm})$ is (the electrically charged part of) a smooth "fluctuation" of $\mathcal{A}$. Moreover, $m_W^2 \in \mathbb{R}_+$ is a nonvanishing eigenvalue of the Yang–Mills mass matrix (for the terminology used please see Ref. 15) $\mathcal{V}^* M_{\mathrm{YM}}^2 \in \Gamma(\mathrm{End}(\xi_{\mathrm{YM}}))$ with $[(\mathcal{A},\mathcal{V})] \in \mathfrak{M}_{\mathrm{mag}}$.

However, in the case of a magnetically charged vacuum the $\mathbb{Z}_2$ symmetry of charge conjugation is restored in the two-to-one correspondence between the charge of the vacuum and the hypercharge of the Higgs boson. Of course, it is interesting to also ask for appropriate physical effects which permit to distinguish between the gauge inequivalent ground states of the Higgs boson. Though we do not want to discuss this question here, we would like to stress again that such an interaction can only occur for a topologically nontrivial space–time. Moreover, such an interaction also depends on the space–time geometry, i.e., on the gravitational field. Consequently, appropriate physical effects caused by the interaction of the electrically charged weak vector bosons (respectively, fermions) with the electroweak vacuum may provide the possibility to gain some insight into the topology and the geometry of space–time.

V. CONCLUSION

We have shown that the topological structure of the electroweak gauge bundle either is trivial or fully determined by the hypercharge of the Higgs boson. This is a geometrical variant of Dirac's quantization condition within the realm of the electroweak interaction. For this it is crucial, however, that in the case of the (minimal) standard model "charge comes with mass." Indeed, it is a remarkable fact that no massless electrically charged particles are known to exist in nature. In general, the moduli space of the electroweak vacua consists of a magnetically charged and an uncharged sector. The uncharged sector corresponds to ordinary electromagnetism. It is determined by the assumption that the electrically charged massive weak vector bosons are charge conjugate to each other. The uncharged sector is fixed by the topology of space–time via the first de Rham cohomology group of $\mathcal{M}$. In contrast, a necessary condition for the existence of the charged sector (i.e., the existence of DH monopoles) is the nontriviality of the second de Rham cohomology group of space–time provided there is no (algebraic) torsion (the author thanks R. Vitolo for appropriate discussion on the occurrence of torsion) [e.g., $\mathrm{H}_1(\mathcal{M},\mathbb{Z})=0$]. Moreover, a charged ground state of the Higgs boson can only exist if it also fits with the geometry of space–time.

In the case of the (minimal) standard model the physical Higgs boson geometrically appears as a fluctuation of any of the three gauge inequivalent ground states of the Higgs boson which are characterized by the Chern numbers $n=0,\pm 1$. These ground states correspond to the lowest possible nonvanishing electric charge a particle may assume. However, the magnetically charged ground states $n=\pm 1$ can be realized only if space–time possesses a nontrivial topology as, for example, in the case of a rotationally symmetric space–time. In this case, the corresponding electromagnetic gauge bundles are equivalent to Hopf fibrations. The appropriate DH monopoles generalize the well-known Dirac monopoles of magnetic charge $g=\pm 1/2$ to the electroweak interaction within the (minimal) standard model. This example may also motivate the terminology of "magnetically charged electroweak vacua." In general, these topologically nontrivial ground states of the Higgs boson yield electric charge quantization analogous to ordinary Dirac monopoles. Clearly, whether these ground states of the Higgs boson can be actually realized for a

general space–time manifold $(\mathcal{M}, g_{\mathrm{M}})$ needs a more thorough analysis of the space of solutions $F_{\mathrm{mag}} \in \Omega^2(\mathcal{M})$ of the corresponding Maxwell equations. Moreover, like in the usual discussion of magnetic monopoles also the definition of DH monopoles does not refer to some field equation of gravity. Of course, this seems unsatisfying from a physical viewpoint. However, to mathematically discuss the structure of the correspondingly enlarged moduli space of electroweak vacua is obviously even more challenging. In any case, the geometrical viewpoint presented here with respect to the electroweak interaction of the (minimal) standard model suggests that the mechanism of spontaneous symmetry breaking may provide a better understanding of the link between topology and geometry.

(Received 1 October 2004; accepted 24 January 2005; published online 22 March 2005)

By making use of the potentials of the heat conduction equation the integral equations are derived which determine the heat kernel for the Laplace operator $-a^2\Delta$ in the case of compound media. In each of the media the parameter a^2 acquires a certain constant value. At the interface of the media the conditions are imposed which demand the continuity of the temperature and the heat flows. The integration in the equations is spread out only over the interface of the media. As a result the dimension of the initial problem is reduced by 1. The perturbation series for the integral equations derived are nothing else as the multiple scattering expansions for the relevant heat kernels. Thus a rigorous derivation of these expansions is given. In the one dimensional case the integral equations at hand are solved explicitly (Abel equations) and the exact expressions for the regarding heat kernels are obtained for diverse matching conditions. Derivation of the asymptotic expansion of the integrated heat kernel for a compound media is considered by making use of the perturbation series for the integral equations obtained. The method proposed is also applicable to the configurations when the same medium is divided, by a smooth compact surface, into internal and external regions, or when only the region inside (or outside) this surface is considered with appropriate boundary conditions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1870734]

I. INTRODUCTION

The heat kernel technique[1–5] is widely used for constructing the quantum field theory in gravitational background and with allowance for nontrivial boundary conditions. Of a particular interest is the asymptotic expansion of the heat kernel it terms of evolution parameter for its small values. The coefficients of this expansion pertain to divergences and anomalies in the relevant quantum field theory models. Proceeding from this one can develop the renormalization procedure needed.

For well posed spectral problems the heat kernel coefficients are expressed, in an polynomial way, through the local geometric characteristics of the manifold D and its boundary S. Not only the contributions of D and S are independent but the contributions of individual regions of D and S are also additive.

The spectral problem is well posed for the goal of constructing the heat kernel if the second oder elliptic differential operator in question is close to the Laplace operator defined on a smooth manifold with a smooth boundary, if any.

[c]Electronic mail: michael.bordag@itp.uni-leipzig.de

There are no universal methods for constructing the heat kernel and its asymptotic expansion. The development of different approaches to this problem is the subject of many works (see, for example, the reviews[1–5] and references therein).

The initial definition of the heat kernel is the Green function of the heat-conduction equation with an elliptic operator under study. In many physical problems it is worth going from the differential equation, defining the solution to be found or the relevant Green's function, to the equivalent integral equation. In the dynamical evolution problems the integral equations manifestly show the reason–consequence relations governing the physical process under study. Reducing the problem to the integral equation, as a rule, allows one to develop the method of successive approximations (perturbation theory).

Transforming the initial differential equation into the integral form is in the general case a nontrivial problem. Special attention should be paid here to incorporating the boundary conditions into the integral equation. When constructing the integral equations governing the Green's function of the heat equation we shall use the surface potentials for this equation. The volume potential and the potentials of single and double layers naturally arise in the theory of the Laplace equation. In this case they are referred to as the Newtonian (or electrostatic) potentials. This idea proved to be fruitful also in studies of the Helmholtz equation describing, for example, steady harmonic oscillations, the wave equation, and the heat-conduction equation. The potentials are particular solutions of these homogeneous equations, and they are constructed in a universal way in terms of the fundamental (or elementary) solution of the initial equation. The potential technique has turned out to be effective both for consideration of the general properties of the equations under study (for example, the prove of the solution uniqueness) and for deriving particular solutions with given properties and for obtaining the Green's functions.

This paper seeks to demonstrate the efficiency of using the heat potentials when constructing the integral equations for the heat kernel (Green functions) at first in the case of manifolds with boundary. It is worth noting that integration in these equations is spread out over the boundary only. As a result the dimensionality of the initial problem is reduced by co-dimension of the boundary S. Further this approach is extended to the compound media, where the principal part of the differential operator has a discontinuity at the interface between different media. A typical example here is the electrodynamics of continuous media.[6] The velocity of light has, in the general case, a jump discontinuity on the border between two media with different characteristics (for example, on the border between dielectric and vacuum). In the both media the Maxwell equations are well defined, and at the interface the matching conditions (or boundary conditions) should be satisfied. The concrete form of these conditions is determined by the physical content of the problem in question. In the same way the conduction of heat in compound media is treated.[7] As far as we are aware, the heat kernel for compound media is not investigated yet.[4]

The layout of the paper is as follows. In Sec. II the essentials of the potential theory are recalled first for the Laplace equation (Newtonian potentials) and then for the heat-conduction equation (heat potentials). By making use of the heat potentials the integral equation for the Green function (heat kernel) is derived for a compact region of Euclidean space bounded by a smooth surface. The perturbative series for this equation is developed which is nothing else as the multiple scattering expansion for the heat kernel. Thus a rigorous derivation of this expansion is presented. The convenience to use here the Laplace transform is shown. In Sec. III the integral equations are derived that determine the heat kernel for compound media. The efficiency of the approach proposed is demonstrated by deriving the t-small asymptotics of the first three terms of the perturbation series for the heat kernel in the case of compound media (Sec. IV). In Sec. V the heat kernel on an infinite line is constructed in an exact form for diverse matching conditions. In the Conclusion (Sec. VI) the obtained results are briefly summarized and the possibility of extending the approach proposed is discussed. In the Appendix the general conditions at the interface are found which result in self-adjoint boundary value problem for the Laplace operator considered in compound media.

II. HEAT POTENTIALS

In order to recall the basic facts from the potential theory, we first address the Laplace equation

$$\Delta u = 0 \tag{2.1}$$

considered in the d-dimensional Euclidean space $\mathbb{R}_d$, which is divided by a smooth closed surface S into a compact internal domain D_+ and external one D_-. On the surface S the relevant boundary conditions should be imposed, that depend on the physical content of the problem in question. For example, it may be a mathematical formulation of the electrostatic problem.[6] The surface S is supposed to possess the properties of smoothness needed. In the potential theory[8–11] this implies that S is the Lyapunov type surface. The points of Euclidean space $\mathbb{R}_d$ are denoted by $x,y,z,\ldots$, and r_{xy} is the Euclidean distance between x and y. At any point x on S there exists a unit normal n_x or $n(x)$. For definiteness we choose the inward directed normal. It is possible because we are dealing with closed surfaces S.

For a linear homogeneous differential equation the fundamental (or elementary) solution is defined, which is the Green function of this equation in an unbounded space. By definition, the fundamental solution obeys the initial equation with a δ-like source on its right-hand side. In the case of the Laplace equation in $\mathbb{R}_d$ the fundamental solution is

$$E_d(x;x') = -\frac{\Gamma(d/2)(r_{xx'})^{-d+2}}{(2d-4)\pi^{d/2}}, \quad d \geqslant 3, \quad E_3(x;x') = -\frac{1}{4\pi r_{xx'}} \tag{2.2}$$

with the properties

$$\Delta_x E_d(x;x') = \Delta_{x'} E_d(x;x') = \delta^{(d)}(x,x'), \quad E_d(x;x') = E_d(x';x). \tag{2.3}$$

The potentials for the Laplace equation are constructed by making use of the fundamental solution, namely, the volume potential

$$U(x) = -\frac{1}{4\pi}\int_D \frac{w(y)}{r_{xy}}\mathrm{d}y, \tag{2.4}$$

the single-layer potential

$$V(x) = -\frac{1}{4\pi}\int_S \frac{\nu(y)}{r_{xy}}\mathrm{d}S_y, \tag{2.5}$$

and the potential of a double layer

$$W(x) = -\frac{1}{4\pi}\int_S \mu(y)\frac{\partial}{\partial n_y}\frac{1}{r_{xy}}\mathrm{d}S_y. \tag{2.6}$$

These formulas are written for $\acute{d}=3$, and the following notations are used: $\mathrm{d}y$ and $\mathrm{d}S_y$ are, respectively, the elements of the volume and of the surface at the point $y, w(y), \mu(y)$, and $\nu(y)$ are the densities of these potentials. It is convenient to consider the densities $w(y), \mu(y)$, and $\nu(y)$ to be continuous functions.

All three potentials are solutions of the Laplace equation (2.1), namely, the volume potential (2.4) is harmonic outside $D, V(x)$, and $W(x)$ are harmonic outside S. The single-layer potential $V(x)$ is continuous everywhere in $\mathbb{R}_d$, specifically, on passing through S. The potential of a double layer $W(x)$ has a discontinuity on S, namely,

$$W_i(x) = W(x) - \tfrac{1}{2}\mu(x),$$

$$W_e(x) = W(x) + \tfrac{1}{2}\mu(x), \quad x \in S. \tag{2.7}$$

Here $W(x)$ is the value of the integral (2.6), when the point x belongs to S [$W(x)$ is a continuous function for x varying along S], $W_i(x)$ is the value of the double-layer potential (2.6), when the point x tends to S from D_+, and $W_e(x)$ is the same when the point x approaches at S from D_-.

In what follows we shall frequently use the derivative along the normal to the surface S at the point y, which belongs to S. This derivative acts on the function the argument of which is the distance r_{xy} between the points x and y, the point x being not obliged to lay on S. Simple calculation gives

$$\frac{\partial}{\partial n_y} r_{xy} = \cos\varphi, \tag{2.8}$$

where φ is the angle between the vector $\mathbf{r}_{xy}$, which starts at x and ends at y, and the normal $\mathbf{n}_y$. In the same way we have

$$\frac{\partial}{\partial n_y} f(r_{xy}) = f'(r_{xy})\cos\varphi, \quad \frac{\partial}{\partial n_y}\left(\frac{1}{r_{xy}}\right) = -\frac{\cos\varphi}{r_{xy}^2}. \tag{2.9}$$

Equations (2.8) and (2.9) are obviously valid for both inward and outward directed normals.

The application of the potentials (2.4)–(2.7) for transforming the boundary problems for the Laplace equation (2.1) to the integral equations can be found in many textbooks on mathematical physics.[8–10,12–15]

Let us proceed to consideration of the heat-conduction equation,

$$\frac{\partial u}{\partial t} - a^2\Delta u = 0. \tag{2.10}$$

The fundamental (or elementary) solution to this equation in $\mathbb{R}_d$ is

$$E_d(x,t;x',t') = \theta(t-t')K_0(x,t;x',t'), \tag{2.11}$$

where

$$K_0(x,t;x',t') = \frac{1}{(2a\sqrt{\pi(t-t')})^d}\exp\left[-\frac{r_{xx'}^2}{4a^2(t-t')}\right]. \tag{2.12}$$

The function $K_0(x,t;x',t')$ (the propagator[14] or the heat kernel) obeys the homogeneous heat equations,

$$\left(\frac{\partial}{\partial t} - a^2\Delta_x\right)K_0(x,t;x',t') = 0,$$

$$\left(\frac{\partial}{\partial t'} + a^2\Delta_{x'}\right)K_0(x,t;x',t') = 0, \tag{2.13}$$

and inhomogeneous initial condition

$$K_0(x,t;x',t') \to \delta^{(d)}(x-x'), \quad \text{when } t-t'. \tag{2.14}$$

This condition enables one to construct the solution of the Cauchy problem for the nonhomogeneous heat equation

$$\left(\frac{\partial}{\partial t} - a^2\Delta_x\right)u(x,t) = f(x,t) \tag{2.15}$$

considered in an unbounded space

$$u(x,t) = \int \mathrm{d}x'\, K_0(x,t;x',t')u_0(x') + \int_{t'}^{t}\mathrm{d}\theta \int \mathrm{d}x'\, K_0(x,t;x',\theta)f(x',\theta), \tag{2.16}$$

where $u_0(x)=u(x,t=t')$. In the classical mathematical physics[8] the representation (2.16) of the solution to the heat-conduction equation (2.15) is known as the Poisson formula. The last term in (2.16) can be considered as an analog of Eq. (2.4) defining the volume potential for the Laplace equation.

In a complete agreement with the definitions (2.5) and (2.6) the heat surface potentials are introduced, namely, the simple-layer potential,

$$V(x,t) = a^2\int_0^t \mathrm{d}\theta \int_S \mathrm{d}S_y\, K_0(x,t;y,\theta)\,\nu(y,\theta) \tag{2.17}$$

and the potential of a double layer,

$$W(x,t) = a^2\int_0^t \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial K_0}{\partial n_y}(x,t;y,\theta)\mu(y,\theta) = -\int_0^t \frac{\mathrm{d}\theta}{2(t-\theta)}\int_S \mathrm{d}S_y r_{xy}\cos\varphi\, K_0(x,t;y,\theta)\mu(y,\theta), \tag{2.18}$$

where the functions $\nu(y,\theta)$ and $\mu(y,\theta)$ are the surface densities of these potentials. By the construction the heat potentials $V(x,t)$ and $W(x,t)$ vanish at $t=0$.

For bounded density $\nu(x,t)$ the heat potential of a single layer $V(x,t)$ is continuous everywhere in $\mathbb{R}_d$, also on passing through the surface S, and satisfies the homogeneous heat-conduction equation (2.10) outside S, i.e., it is parabolic outside S. The normal derivatives of $V(x,t)$ have jump discontinuities on S. For continuous in S density $\nu(x,t)$ these discontinuities are given by

$$\left(\frac{\partial V(x,t)}{\partial n_x}\right)_i = \frac{\partial V(x,t)}{\partial n_x} - \frac{1}{2}\nu(x,t),$$

$$\left(\frac{\partial V(x,t)}{\partial n_x}\right)_e = \frac{\partial V(x,t)}{\partial n_x} + \frac{1}{2}\nu(x,t), \quad x \in S. \tag{2.19}$$

For bounded density $\mu(x,t)$ the heat potential of a double layer (2.18) is continuous everywhere outside of S (in $\mathbb{R}_d\backslash S$) and in S. Outside S the potential $W(x,t)$ is parabolic. On passing through S it has discontinuities. For continuous in S density $\mu(x,t)$ these discontinuities are given by $(d=3)$

$$W_i(x,t) = W(x,t) + \tfrac{1}{2}\mu(x,t),$$

$$W_e(x,t) = W(x,t) - \tfrac{1}{2}\mu(x,t), \quad x \in S. \tag{2.20}$$

The normal derivatives of the double-layer potential are continuous on passing through S.

The employment of the Newtonian and heat potentials for transforming the boundary-value problems for Laplace and heat equations into the integral ones is based on the discontinuity properties on the boundary of the double-layer potential and the normal derivatives of the single-layer potential. Let us consider a simple example, namely, construction of the solution to the Dirichlet problem for the heat equation in a compact domain D bounded by a smooth surface S,

$$\left(\frac{\partial}{\partial t} - a^2\Delta\right)u(x,t) = 0, \quad x \in D, \quad t > 0,$$

$$u(x,0) = 0, \quad x \in D,$$

$$u(x,t) = \psi(x,t), \quad x \in S, \quad t > 0, \tag{2.21}$$

where the function $\psi(x,t)$ specifies the temperature on the boundary S at different time instants t. We shall look for the solution $u(x,t)$ in terms of the heat potential of a double layer (2.18),

$$u(x,t) = W(x,t). \tag{2.22}$$

With account of Eq. (2.20) we have on the boundary S,

$$\frac{1}{2}\mu(x,t) = -a^2\int_0^t dt' \int_S dS_{x'} \frac{\partial K_0}{\partial n_{x'}}(x,t;x',t')\mu(x',t') + \psi(x,t), \quad x,x' \in S. \tag{2.23}$$

Thus, the problem under consideration is reduced to the solution of the linear integral equation of the second kind. With respect to the variable t these equations are of the Volterra type and with respect to the spatial variables x and x' they are of the Fredholm type, the variables x and x' ranging on the boundary S.

In an analogous way the integral equations for the Green's function of the heat equation can be deduced. Let us consider this technique in the case of the first boundary-value problem (the Dirichlet problem) for this equation. The Green function $K(x,t;x',t')$ is specified by the following conditions:[8] it should satisfy the homogeneous heat equation with respect to the first pair of its arguments

$$\left(\frac{\partial}{\partial t} - a^2\Delta_x\right)K(x,t;x',t') = 0, \tag{2.24}$$

it should obey the inhomogeneous initial condition

$$K(x,t;x',t) = \delta(x,x'), \quad t \geqslant 0, \tag{2.25}$$

and the homogeneous boundary condition

$$K(x,t;x',t') = 0, \quad x \in S. \tag{2.26}$$

Strictly speaking, the function $K(x,t;x',t')$ is the propagator of the heat equation. It should be multiplied by the step function $\theta(t-t')$ in order to get the Green function.[14] This point should be kept in mind when dealing with the parabolic equations.

We represent the Green function $K(x,t;x',t')$ as the sum of a free propagator and the heat potential of a double layer,

$$K(x,t;x',t') = K_0(x,t;x',t') + a^2\int_{t'}^t d\theta \int_S dS_y \frac{\partial K_0}{\partial n_y}(x,t;y,\theta)\mu(y,\theta;x',t'). \tag{2.27}$$

The right-hand side of this equation obviously satisfies Eq. (2.24). When $t=t'$ the double-layer potential in (2.27) (the second term) vanishes. The free propagator in this formula K_0 enables one to obey the initial condition (2.25). The density of the double-layer potential $\mu(y,\theta;x',t')$ is determined from the boundary condition (2.26). On substituting Eq. (2.27) into (2.26) the following integral equation is obtained for the potential density μ:

$$\frac{1}{2}\mu(x,t;x',t') = -K_0(x,t;x',t') - a^2\int_{t'}^{t} d\theta \int_S dS_y \frac{\partial K_0}{\partial n_y}(x,t;y,\theta)\mu(y,\theta;x',t'), \quad x \in S. \tag{2.28}$$

For Eq. (2.28) and consequently for Eq. (2.27) the method of successive approximations can be developed, as Eq. (2.28) is an integral equation of the second kind. It has been proved, that the series arising here is uniformly convergent.[16] The first terms of this series for Eq. (2.27) are

$$\begin{aligned} K(x,t;x',t') = {} & K_0(x,t;x',t') + (-2a^2)^1 \int_{t'}^{t} d\theta \int_S dS_y \frac{\partial K_0}{\partial n_y}(x,t;y,\theta)K_0(y,\theta;x',t') \\ & + (-2a^2)^2 \int_{t'}^{t} d\theta \int_S dS_y \frac{\partial K_0}{\partial n_y}(x,t;y,\theta) \int_{t'}^{\theta} d\theta_1 \int dS_{y_1} \frac{\partial K_0}{\partial n_{y_1}}(y,\theta;y_1,\theta_1) \\ & \times K_0(y_1,\theta_1;x',t') + \cdots . \end{aligned} \tag{2.29}$$

Obviously, this series is a result of successive approximations applied to the integral equation for the complete propagator

$$K(x,t;x',t') = K_0(x,t;x',t') - 2a^2 \int_{t'}^{t} d\theta \int_S dS_y \frac{\partial K_0}{\partial n_y}(x,t;y,\theta)K(y,\theta;x',t'). \tag{2.30}$$

The series (2.29) is nothing else as the multiple scattering expansion for the heat kernel in the problems under consideration.[17,18] Thus we have derived this expansion in a rigorous way.

By making use of the Laplace transform in Eq. (2.29) one can remove the integrations over the intermediate time variables θ's,

$$\begin{aligned} \overline{K}(x,x';p) = {} & \overline{K_0}(r_{xx'};p) + (-2a^2)^1 \int_S dS_y\, \overline{K_1}(r_{xy};p)\overline{K_0}(r_{yx'};p) \\ & + (-2a^2)^2 \int_S dS_y\, \overline{K_1}(r_{xy};p) \int_S dS_{y_1}\, \overline{K_1}(r_{yy_1};p)\overline{K_0}(r_{y_1x'};p) + \cdots , \end{aligned} \tag{2.31}$$

where

$$\overline{K}(x,x';p) = \int_0^{\infty} e^{-pt}K(x,t;x',0)dt, \tag{2.32}$$

$$\overline{K_0}(r_{xy};p) = \int_0^{\infty} e^{-pt}K_0(x,t;y,0)dt = \frac{1}{2\pi a^2}K_0\left(\frac{r_{xy}}{a}\sqrt{p}\right), \tag{2.33}$$

$$\overline{K_1}(r_{xy};p) = \int_0^{\infty} e^{-pt}\frac{\partial K_0}{\partial n_y}(x,t;y,0)dt = -\frac{\cos\varphi}{2\pi a^3}\sqrt{p}K_1\left(\frac{r_{xy}}{a}\sqrt{p}\right), \quad y \in S. \tag{2.34}$$

In Eq. (2.34) φ is the angle between the vectors $\mathbf{r}_{xy}$ and $\mathbf{n}_y$. The Laplace transforms $\overline{K_0}$ and $\overline{K_1}$ are calculated for $d=2$. They are expressed in terms of the modified Bessel functions[19] $K_0(z)$ and $K_1(z)$. We hope that our notations will not lead to confusion because the free propagator $K_0(x,t;x',t')$ and the Bessel function $K_0(z)$ have a different number of arguments. The series (2.31) is the perturbative solution to the following integral equation:

$$\overline{K}(x,x';p) = \overline{K}_0(r_{xx'};p) - 2a^2 \int_S \mathrm{d}S_y\, \overline{K}_1(r_{xy};p)\overline{K}(r_{yx'};p). \tag{2.35}$$

The series (2.29) or (2.31) contains complete information about the Green function (heat kernel) in the problem at hand. However, extracting it from here is not a simple task.

The second term on the right-hand side of Eq. (2.31) is responsible for one reflection from the boundary (the Born approximation). Its contribution into the heat kernel can be expressed in terms of the confluent hypergeometric function[19] $W_{\alpha\beta}$. By making use of the convolution theorem for the Laplace transform[7,19–21] we obtain

$$\overline{K}^{(1)}(x,x';p) = \frac{2a^2\sqrt{p}}{(2\pi)^2 a^5} \int_S \mathrm{d}S_y \cos\varphi\, K_0\left(\frac{r_{xy}}{a}\sqrt{p}\right) K_1\left(\frac{r_{yx'}}{a}\sqrt{p}\right). \tag{2.36}$$

The inverse Laplace transform gives[22]

$$K^{(1)}(x,x;t) = \frac{1}{2^{5/2}\pi^{3/2}a^2 t} \int_S \mathrm{d}S_y \frac{\cos\varphi}{r_{xy}} \exp\left(-\frac{r_{xy}^2}{2a^2 t}\right) W_{\frac{1}{2}\frac{1}{2}}\left(\frac{r_{xy}^2}{a^2 t}\right), \tag{2.37}$$

where φ is the angle between the vector $\mathbf{r}_{xy}$ and the inward directed normal to the boundary S at the point y.

The perturbation series (2.31) can be employed, for example, to find the asymptotic expansion of the heat kernel trace.

III. COMPOUND MEDIA

An important advantage of the heat potential technique for constructing the integral equations is the possibility of applying it to compound media. We show this by considering first the solution of the heat-conduction equation instead of the relevant Green's function.

Thus, in both the regions D_+ and D_- the heat equations are defined

$$\left(\frac{\partial}{\partial t} - a_+^2\Delta\right) u_+(x,t) \equiv \hat{T}_{tx}(a_+)u_+(x,t) = 0, \quad x \in D_+, \tag{3.1}$$

$$\left(\frac{\partial}{\partial t} - a_-^2\Delta\right) u_-(x,t) \equiv \hat{T}_{tx}(a_-)u_-(x,t) = 0, \quad x \in D_-, \tag{3.2}$$

with the matching conditions at the interface S, namely, when crossing S the following quantities should be continuous: temperature

$$u_+(x,t) = u_-(x,t), \quad x \in S \tag{3.3}$$

and heat current

$$\lambda_+ \frac{\partial u_+(x,t)}{\partial n_+(x)} + \lambda_- \frac{\partial u_-(x,t)}{\partial n_-(x)} = 0, \quad x \in S, \tag{3.4}$$

where $n_+(x)$ and $n_-(x)$ are inward normals to the surface S at the point x for the regions D_+ and D_-, respectively. These matching conditions imply, in particular, that there are no heat sources on S. The parameters a_+, a_-, λ_+, and λ_- specify the material characteristics of the media.

We shall look for the solution to this problem in terms of the heat potentials of single layer and double layer. Here the following feature proves to be important. If the solution $u_+(x,t)$ in the internal region D_+ is represented as the heat potential of a single layer,

$$u_+(x,t) = a_+^2 \int_0^t \mathrm{d}t' \int_S \mathrm{d}S_{x'}\, K_0^{(+)}(x,t;x',t')\,\nu(x',t'), \tag{3.5}$$

then the solution $u_-(x,t)$ in the external region D_- should be looked for in terms of the heat potential of a double layer,

$$u_-(x,t) = a_-^2 \int_0^t \mathrm{d}t' \int_S \mathrm{d}S_{x'} \frac{\partial K_0^{(-)}}{\partial n_-(x')}(x,t;x',t')\,\mu(x',t'), \tag{3.6}$$

where $K_0^{(+)}$ and $K_0^{(-)}$ are the fundamental solutions of the heat equations (3.1) and (3.2), which are defined by the formula (2.12) with $a=a_+$ and $a=a_-$, respectively.

Substituting Eqs. (3.5) and (3.6) into the first matching condition (3.3) we obtain

$$a_+^2 \int_0^t \mathrm{d}t' \int_S \mathrm{d}S_{x'}\, K_0^{(+)}(x,t;x',t')\,\nu(x',t') = \frac{1}{2}\mu(x,t) + a_-^2 \int_0^t \mathrm{d}t' \int_S \mathrm{d}S_{x'} \frac{\partial K_0^{(-)}}{\partial n_-(x')}(x,t;x',t')\,\mu(x',t'), \quad x,x' \in S. \tag{3.7}$$

The second matching condition (3.4) results in another integral equation,

$$\lambda_+ a_+^2 \int_0^t \mathrm{d}t' \int_S \mathrm{d}S_{x'} \frac{\partial K_0^{(+)}}{\partial n_+(x)}(x,t;x',t')\,\nu(x',t') - \frac{1}{2}\lambda_+\nu(x,t) + \lambda_- a_-^2 \int_0^t \mathrm{d}t' \int_S \mathrm{d}S_{x'} \frac{\partial^2 K_0^{(+)}}{\partial n_-(x)\,\partial n_-(x')}(x,t;x',t')\,\mu(x',t') = 0, \quad x,x' \in S. \tag{3.8}$$

Thus the problem under consideration is reduced to the solution of the system of two linear integral equations of the second kind (3.7) and (3.8). It is worth noting that we have obtained homogeneous equations, because there are not any heat sources in the problem under study. Hence, we are dealing here with the eigenfunctions only.

Let us proceed to the Green's function $K(x,t;x',t')$ in this problem. In what follows, it is convenient to represent this function in terms of the following four components depending on the range of the arguments:

$$K(x,t;x',t') = \begin{cases} K_{++}(x,t;x',t'), & x,x' \in D_+, \\ K_{+-}(x,t;x',t'), & x \in D_+, x' \in D_-, \\ K_{-+}(x,t;x',t'), & x \in D_-, x' \in D_+, \\ K_{--}(x,t;x',t'), & x,x' \in D_-. \end{cases} \tag{3.9}$$

The conditions, which specify the Green function $K(x,t;x',t')$, can be found in the following way. This function should provide the solution $\overline{u}(x,t)$ of the inhomogeneous boundary-value problem (3.1)–(3.4) with the heat source $f(x,t)$ in the form

$$\overline{u}(x,t) = -\,\theta(t-t') \int_{t'}^t \mathrm{d}\tau \int_{\mathbb{R}_d} K(x,t;\xi,\tau) f(\xi,\tau)\mathrm{d}\xi, \tag{3.10}$$

where $\theta(t-t')$ is the step function. The function $\overline{u}(x,t)$ will satisfy the inhomogeneous heat-conduction equation

$$f(x,t)=\begin{cases}\hat{T}_{tx}(a_+)\overline{u}(x,t), & x\in D_+,\\ \hat{T}_{tx}(a_-)\overline{u}(x,t), & x\in D_-,\end{cases} \tag{3.11}$$

if the Green function $K(x,t;x',t')$ obeys the corresponding homogeneous heat equations with respect to the first pair of its arguments

$$\hat{T}_{tx}(a_+)K(x,t;x',t')=0, \quad x\in D_+,$$

$$\hat{T}_{tx}(a_-)K(x,t;x',t')=0, \quad x\in D_-, \tag{3.12}$$

and the inhomogeneous initial condition (2.25) with respect to both pairs of its arguments. In terms of the components (3.9) the initial condition (2.25) acquires the form

$$K_{++}(x,t;x',t)=\delta(x,x'), \quad x,x'\in D_+, \tag{3.13}$$

$$K_{--}(x,t;x',t)=\delta(x,x'), \quad x,x'\in D_-, \tag{3.14}$$

$$K_{+-}(x,t;x',t)=K_{-+}(x,t;x',t)=0. \tag{3.15}$$

On the right-hand side of the initial conditions (3.15) the delta function $\delta(x,x')$ with $x,x'\in S$ is absent. Thus in our consideration we eliminate the treatment of heat sources at the interface. The point is such sources alter the matching conditions instead of the initial conditions. In the next section the solution to the heat-conduction equation, defined on a line, will be constructed for such a configuration by making use of the heat potential technique.

The matching conditions (3.3) and (3.4) are directly transformed into the conditions for the Green function $K(x,t;x',t')$ with respect to the first pair of its arguments,

$$K_{++}(x,t;x',t')=K_{-+}(x,t;x',t'), \tag{3.16}$$

$$\lambda_+\frac{\partial K_{++}}{\partial n_+(x)}(x,t;x',t')+\lambda_-\frac{\partial K_{-+}}{\partial n_-(x)}(x,t;x',t')=0, \tag{3.17}$$

$$K_{+-}(x,t;x',t')=K_{--}(x,t;x',t'), \tag{3.18}$$

$$\lambda_+\frac{\partial K_{+-}}{\partial n_+(x)}(x,t;x',t')+\lambda_-\frac{\partial K_{--}}{\partial n_-(x)}(x,t;x',t')=0, \tag{3.19}$$

$$x\in S.$$

It turns out that the heat equations (3.12), the initial conditions (3.13)–(3.15), and the matching conditions (3.16)–(3.19) are enough for construction of the Green function in the case of compound media in a unique way.

We shall look for the components of the Green function (3.9) in terms of the heat potentials of single and double layers with respect to the first pair of their arguments, the components K_{++} and K_{+-} being expressed through the heat potentials of single layers and the components K_{--} and K_{-+} through the heat potentials of double layers. In order to take into account the inhomogeneous initial conditions (3.13) and (3.14) for the components K_{++} and K_{--} we add to the chosen heat potentials (nonsingular part of the Green function) the free propagator $K_0^{(+)}$ or $K_0^{(-)}$ (singular part of this function)

$$K_{++}(x,t;x',t') = K_0^{(+)}(x,t;x',t') + a_+^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \, K_0^{(+)}(x,t;y,\theta)\, \nu_{++}(y,\theta;x',t'), \tag{3.20}$$

$$K_{+-}(x,t;x',t') = a_+^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \, K_0^{(+)}(x,t;y,\theta)\, \nu_{+-}(y,\theta;x',t'), \tag{3.21}$$

$$K_{--}(x,t;x',t') = K_0^{(-)}(x,t;x',t') + a_-^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial K_0^{(-)}}{\partial n_-(y)}(x,t;y,\theta)\, \nu_{--}(y,\theta;x',t'), \tag{3.22}$$

$$K_{-+}(x,t;x',t') = a_-^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial K_0^{(-)}}{\partial n_-(y)}(x,t;y,\theta)\, \nu_{-+}(y,\theta;x',t'). \tag{3.23}$$

The matching conditions (3.16) and (3.17) give

$$\begin{aligned} &K_0^{(+)}(x,t;x',t') + a_+^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \, K_0^{(+)}(x,t;y,\theta)\, \nu_{++}(y,\theta;x',t') \\ &\quad = \frac{1}{2}\nu_{-+}(x,t;x',t') + a_-^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial K_0^{(-)}}{\partial n_-(y)}(x,t;y,\theta)\, \nu_{-+}(y,\theta;x',t'), \end{aligned} \tag{3.24}$$

$$\begin{aligned} &\lambda_+ \frac{\partial K_0^{(+)}}{\partial n_+(x)}(x,t;x',t') + \lambda_+ a_+^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial K_0^{(+)}}{\partial n_+(x)}(x,t;y,\theta)\, \nu_{++}(y,\theta;x',t') - \frac{1}{2}\lambda_+ \nu_{++}(y,\theta;x',t') \\ &\quad + \lambda_- a_-^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial^2 K_0^{(-)}}{\partial n_-(x)\, \partial n_-(y)}(x,t;y,\theta)\, \nu_{-+}(y,\theta;x',t') = 0, \quad x \in S. \end{aligned} \tag{3.25}$$

In the same way we deduce from (3.18) and (3.19)

$$\begin{aligned} a_+^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \, K_0^{(+)}(x,t;y,\theta)\, \nu_{+-}(y,\theta;x',t') &= K_0^{(-)}(x,t;x',t') + \frac{1}{2}\nu_{--}(x,t;x',t') \\ &\quad + a_-^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial K_0^{(-)}}{\partial n_-(y)}(x,t;y,\theta)\, \nu_{--}(y,\theta;x',t'), \end{aligned} \tag{3.26}$$

$$\begin{aligned} &-\frac{1}{2}\lambda_+ \nu_{+-}(x,t;x',t') + \lambda_+ a_+^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial K_0^{(+)}}{\partial n_+(x)}(x,t;y,\theta)\, \nu_{+-}(y,\theta;x',t') \\ &\quad + \lambda_- a_-^2 \int_{t'}^{t} \mathrm{d}\theta \int_S \mathrm{d}S_y \frac{\partial^2 K_0^{(-)}}{\partial n_-(x)\, \partial n_-(y)}(x,t;y,\theta)\, \nu_{--}(y,\theta;x',t') + \lambda_- \frac{\partial K_0^{(-)}}{\partial n_-(x)}(x,t;x',t') = 0, \quad x \in S. \end{aligned} \tag{3.27}$$

The sets of integral equations of the second kind (3.24), (3.25) and (3.26), (3.27) define the heat kernel for compound media in full. With respect to spatial variables these equations are of Fredholm type while regarding time variable they are of Volterra type. It is essential that the integration over the spatial variables is restricted by the interface S only. Hence the dimension of the initial problem is reduced by 1. By making use of the Laplace transform one can remove the integration over the time variables in Eqs. (3.24)–(3.27) as it has been done in Sec. II.

Obviously the integral equations for the heat kernel derived here can be also applied when the surface S divides the same medium into the regions D_+ and D_+, i.e., when the constants a_+^2 and a_-^2 equal.

For constructing the solutions to the integral equations (3.24)–(3.27) the perturbation theory can be employed (see Sec. II). The expansion parameters in this case prove to be the constants $a_\pm^2$ and $\lambda_\pm$. The perturbation series generated here are nothing else as the multiple scattering expansion for the heat kernel.[17,18] Thus we have proposed a rigorous derivation of these expansions both for homogeneous media and compact regions and for compound media.

IV. ASYMPTOTIC EXPANSION OF HEAT KERNEL FROM PERTURBATION SERIES

In practical applications, especially in QFT, the asymptotic expansion of the integrated heat kernel when $t \to +0$ proves to be important.[1–4] It has the form

$$K(t) \equiv \int \mathrm{d}x\, K(x,t;x,0) = (4\pi t)^{-d/2} \sum_{n=0,1,2,\ldots}^{\infty} t^{n/2} B_{n/2} + \mathrm{ES}. \tag{4.1}$$

In this expansion d is the dimension of the configuration space and ES stands for the exponentially small corrections as $t \to +0$. We show how to derive this expansion proceeding from the perturbation series for the integral equations (3.24)–(3.27). The functions K_{-+} and K_{+-} do not contribute to integrated heat kernel (see Sec. V C), thus we must consider only K_{++} and K_{--}.

For our purposes it is convenient to use such coordinates that in the vicinity of the surface S the metric is $g_{ij}\,\mathrm{d}x^i\,\mathrm{d}x^j = (\mathrm{d}x^3)^2 + g_{ab}\,\mathrm{d}x^a\,\mathrm{d}x^b$ where x^3 is a coordinate on the normal to S, $x^3=0$ on S. In view of the exact form of the free propagator (2.12), one can infer that in each term of the perturbation series for integral equations (3.24)–(3.27) the power in t contributions are given only at the following conditions: when evaluating the heat kernel trace, the integration over dx should be spread over the region immediately adjacent to the boundary S and in the course of the multiple integration over the boundary S the respective distances $r_{yy'}$ should be also small. Therefore in the vicinity of S we may replace the squared distance $(x-z)^2$ by several terms of its expansion in powers of the corresponding geodesic distance σ on the surface S,

$$(x-z)^2 = (x_3-z_3)^2 + \sigma^2\{1-(x_3+y_3)k_1 + x_3 z_3(k_1^2+k_2^2)\} + \sigma^3\left\{-\tfrac{1}{3}(2z_3+x_3)k_1' + x_3 z_3(k_1 k_1' + k_2 k_2')\right\} + \cdots,$$

$$k_1 = L_{ab}\xi^a\xi^b, \quad k_2 = \frac{1}{2}(\varepsilon_{ac}L_b^c + \varepsilon_{bc}L_a^c)\xi^a\xi^b, \quad \varepsilon_{ac} = -\varepsilon_{ca}, \quad k_1' \equiv \frac{\mathrm{d}k_1}{\mathrm{d}\sigma}, \quad k_2' \equiv \frac{\mathrm{d}k_2}{\mathrm{d}\sigma}. \tag{4.2}$$

The surface area element is $\mathrm{d}S_z = \left(1-\frac{1}{12}R_{ab}\xi^a\xi^b\sigma^2+\cdots\right)\sigma\,\mathrm{d}\sigma\,\mathrm{d}\Omega$, Ω parametrizes a unit sphere, L_{ab} is the second fundamental form on S, R_{ab} is intrinsic Ricci curvature, ξ is a unit tangent vector at x to the geodesics with the length σ joining z to x on S (see, for example, Ref. 23).

Here we present the first three terms of the perturbation series under consideration when $t \to +0 (d=3)$,

$$K^{(0)}(t) = K_{++}^{(0)}(t) + K_{--}^{(0)}(t) = \frac{t^{-3/2}}{(4\pi a_+^2)^{3/2}}D_+ + \frac{t^{-3/2}}{(4\pi a_-^2)^{3/2}}D_-,$$

$$K_{++}^{(1)}(t) = \frac{t^{-1}S}{8\pi a_+^2} + \frac{t^{-1/2}}{8\pi^{3/2}a_+}\int_S \mathrm{d}S\, L_a^a + \frac{t^0}{2^8\pi}\int_S \mathrm{d}S\left[5(L_a^a)^2 + L_a^b L_b^a - \frac{2}{3}R_a^a\right] + \cdots,$$

$$K_{++}^{(2)}(t) = -\frac{t^{-1}}{8\pi}\frac{\lambda_-}{\lambda_+}\frac{S}{a_+^2} - \frac{1}{8\pi^{3/2}}\frac{\lambda_-}{\lambda_+}\frac{t^{-1/2}}{a_+}\int_S dS\, L_a^a + \frac{t^0}{32\pi}\left\{ a_-\frac{\lambda_-}{\lambda_+}\frac{(a_+ + 2a_-)}{(a_+ + a_-)^2}\int_S dS\left[-(L_a^a)^2 + 4L_a^b L_b^a - \frac{1}{3}R_a^a\right] + \left[\frac{1}{8} - \frac{\lambda_-}{\lambda_+}\frac{1}{(a_+ + a_-)^3}\left(\frac{35}{12}a_-^3 + \frac{11}{4}a^2 a_+ + 2a_+^2 a_- + \frac{2}{3}a_+^3 + \frac{9}{4}\frac{a_-^4}{a_+} + \frac{3}{4}\frac{a_-^5}{a_+^2}\right)\right]\int_S dS[(L_a^a)^2 + 2L_a^b L_b^a]\right\} + \cdots . \tag{4.3}$$

To obtain $K_{--}^{(1)}(t)$ and $K_{--}^{(2)}(t)$ one should replace $a_+ \leftrightarrow a_-, \lambda_+ \leftrightarrow \lambda_-, L_a^b \to -L_a^b$. The asymptotics of the subsequent terms of perturbation series may be found in a similar way. After that all factors appearing with the same powers of t are added up to give the heat kernel coefficients. The latter are expressed through the integrals of the surface geometric invariants. The asymptotics (4.3) were presented in Ref. 24 without considering the derivation of the relevant integral equations.

V. HEAT KERNEL ON A LINE

In this section we demonstrate the efficiency of our approach based on integral equations for constructing the heat kernel on a line. In this case the interface between the media reduces to a point. As a result we are dealing with the Volterra integral equations in respect of one (time) variable. These equations are of a special type (Abel equations), and their solutions can be found in an exact form.

A. Homogeneous media with gluing conditions

By making use of the heat potential technique we construct here, in an exact form, the heat kernel $K(x,y;t)$ for the Laplace operator on an infinite line for homogeneous medium with a nonstandard gluing conditions at the origin (these conditions will be specified below). From the physical point of view $K(x,y;t)$ is the temperature at the point x which is generated by a unit instantaneous heat source placed at the point y at the moment $t=0$.

As in the preceding sections we first formulate the conditions that define the heat kernel in the problem under consideration. With respect to the first argument $K(x,y;t)$ should satisfy the one-dimensional heat-conduction equation

$$\left(\frac{\partial}{\partial t} - \frac{\partial^2}{\partial x^2}\right)K(x,y;t) = 0, \quad t > 0, \quad -\infty < x < \infty \tag{5.1}$$

and special conditions at the interface $x=0$

$$lK(-0,y;t) = l^{-1}K(+0,y;t), \tag{5.2}$$

$$l^{-1}\frac{\partial}{\partial x}K(x,y;t)\bigg|_{x=-0} = l\frac{\partial}{\partial x}K(x,y;t)\bigg|_{x=+0}, \tag{5.3}$$

where l is a dimensionless parameter. We shall refer to these conditions as to gluing ones. In the Appendix it is shown that such conditions lead to a self-adjoint spectral problem for the Laplace operator in any dimension. The initial condition for $K(x,y;t)$ involves its both space arguments

$$K(x,y;0) = \delta(x,y). \tag{5.4}$$

We shall seek for $K(x,y;t)$ in terms of free heat kernel and single-layer heat potentials. The solution is decomposed in four components related to different positions of the heat source and the observer

$$K_{-+}(x,y;t) = \int_0^t \mathrm{d}\tau\, K_0(x,0;t-\tau)\alpha_1(\tau,y), \quad x<0, \quad y>0, \tag{5.5}$$

$$K_{++}(x,y;t) = K_0(x,y;t) + \int_0^t \mathrm{d}\tau\, K_0(x,0;t-\tau)\alpha_2(\tau,y), \quad x,y>0, \tag{5.6}$$

$$K_{+-}(x,y;t) = \int_0^t \mathrm{d}\tau\, K_0(x,0;t-\tau)\alpha_3(\tau,y), \quad x>0, \quad y<0, \tag{5.7}$$

$$K_{--}(x,y;t) = K_0(x,y;t) + \int_0^t \mathrm{d}\tau\, K_0(x,0;t-\tau)\alpha_4(\tau,y), \quad x,y<0, \tag{5.8}$$

where $K_0(x,y;t)$ is the free heat kernel (propagator) on an infinite line

$$K_0(x,y;t) = \frac{1}{2\sqrt{\pi t}} e^{-[(x-y)^2/4t]}. \tag{5.9}$$

In multi-dimensional problems we may also choose single-layer potential for internal region and double-layer potential for external region. However when $d=1$ such a choice may lead to divergent integrals.

First we substitute Eqs. (5.5) and (5.6) into the gluing conditions (5.2) and (5.3). Then we take into account that the single-layer potential changes smoothly across the boundary, while the normal derivative of this potential undergoes a jump

$$K_{-+}(-0,y;t) = \frac{1}{2\sqrt{\pi}} \int_0^t \mathrm{d}\tau\, \frac{\alpha_1(y,\tau)}{\sqrt{t-\tau}}, \tag{5.10}$$

$$K_{++}(+0,y;t) = K_0(0,y;t) + \frac{1}{2\sqrt{\pi}} \int_0^t \mathrm{d}\tau\, \frac{\alpha_2(y,\tau)}{\sqrt{t-\tau}}, \tag{5.11}$$

$$\frac{\partial}{\partial x} K_{-+}(x,y;t)\bigg|_{x=-0} = -\frac{1}{2}\alpha_1(y,t), \tag{5.12}$$

$$\frac{\partial}{\partial x} K_{++}(x,y;t)\bigg|_{x=+0} = -\frac{1}{2}\alpha_2(y,t) + \frac{\partial}{\partial x} K_0(x,y;t)\bigg|_{x=0}. \tag{5.13}$$

Inserting Eqs. (5.10) and (5.11) into Eq. (5.2) one obtains the Abel integral equation

$$\frac{1}{2\sqrt{\pi}} \int_0^t \frac{\mathrm{d}\tau}{\sqrt{t-\tau}} [l^2\alpha_1(y,\tau) - \alpha_2(y;\tau)] = K_0(0,y;t) \tag{5.14}$$

with the solution

$$\alpha_1(y,t) - l^{-2}\alpha_2(y;t) = \frac{2}{l^2\sqrt{\pi}} \frac{d}{\mathrm{d}t} \int_0^t \frac{K_0(0,y;\tau)}{\sqrt{t-\tau}} \mathrm{d}\tau = \frac{1}{2\sqrt{\pi} l^2} \frac{y}{t^{3/2}} \exp\left(-\frac{y^2}{4t}\right). \tag{5.15}$$

When considering the gluing conditions the use of the single-layer potentials leads to the exactly solvable (no iterations needed) Abel equation only in one-dimensional case. The substitution of Eqs. (5.12) and (5.13) into Eq. (5.3) gives

$$\alpha_1(y,t) = -l^2\alpha_2(y,t) + \frac{l^2}{2\sqrt{\pi}}\frac{y}{t^{3/2}}e^{-y^2/4t}. \tag{5.16}$$

From (5.15) and (5.16) it follows that

$$\alpha_1(y,t) = \frac{l^2}{l^4+1}\frac{y}{\sqrt{\pi}t^{3/2}}e^{-y^2/4t}, \quad \alpha_2(y,t) = \frac{l^4-1}{l^4+1}\frac{y}{2\sqrt{\pi}t^{3/2}}e^{-y^2/4t}. \tag{5.17}$$

And finally

$$K_{-+}(x,y;t) = \frac{l^2}{l^4+1}\frac{1}{\sqrt{\pi t}}e^{-[(x-y)^2/4t]}, \tag{5.18}$$

$$K_{++}(x,y;t) = \frac{1}{2\sqrt{\pi t}}e^{-[(x-y)^2/4t]} + \frac{l^4-1}{l^4+1}\frac{1}{2\sqrt{\pi t}}e^{-[(x+y)^2/4t]}. \tag{5.19}$$

In a similar way one gets

$$K_{+-}(x,y;t) = \frac{l^2}{l^4+1}\frac{1}{\sqrt{\pi t}}e^{-[(x-y)^2/4t]}, \tag{5.20}$$

$$K_{--}(x,y;t) = \frac{1}{2\sqrt{\pi t}}e^{-[(x-y)^2/4t]} - \frac{l^4-1}{l^4+1}\frac{1}{2\sqrt{\pi t}}e^{-[(x+y)^2/4t]}. \tag{5.21}$$

These formulas are in complete agreement with the result of a combined employment of the Lemma 5.2 argued in Ref. 25 and Lemma 4.1 from Ref. 26,

$$K_{++}(x,y;t) = \cos^2\theta K_N(x,y;t) + \sin^2\theta K_D(x,y;t), \tag{5.22}$$

$$K_{--}(x,y;t) = \sin^2\theta K_N(x,y;t) + \cos^2\theta K_D(x,y;t), \tag{5.23}$$

$$K_{+-}(x,y;t) = \sin\theta\cos\theta[K_N(x,y;t) - K_D(x,y;t)], \tag{5.24}$$

where

$$\cos^2\theta = \frac{l^4}{l^4+1}, \quad \sin^2\theta = \frac{1}{l^4+1},$$

and $K_D(x,y;t)$ and $K_N(x,y;t)$ are the heat kernels for Dirichlet and Neumann boundary conditions, respectively.

B. Dielectriclike conditions on a line

We construct here the heat kernel for the Laplace operator defined on an infinite line with dielectriclike matching conditions at the origin $x=0$. The heat kernel is defined by the heat-conduction equation

$$\left(\frac{\partial}{\partial t} - a^2(x)\frac{\partial^2}{\partial x^2}\right)K(x,y;t) = 0, \quad t>0, \quad -\infty < x < +\infty, \quad x \neq 0, \tag{5.25}$$

where

$$a^2(x) = \begin{cases} a_-^2, & x < 0, \\ a_+^2, & x > 0, \end{cases}$$

a_+^2 and a_-^2 being positive constants. At the interface of dielectric media the matching conditions

$$K(-0,y;t) = K(+0,y;t), \tag{5.26}$$

$$\lambda_- \frac{\partial}{\partial x} K(x,y;t)\Big|_{x=-0} = \lambda_+ \frac{\partial}{\partial x} K(x,y;t)\Big|_{x=+0} \tag{5.27}$$

should be met. As usual, the initial condition for $K(x,y;t)$ is given by (5.4).

We call the boundary conditions (5.26) and (5.27) the dielectriclike conditions. The use of this term requires some explanations. When two dielectric media D_+ and D_- possessing different characteristics are separated by the interface S of an arbitrary form then in Maxwell theory we have on the surface S the set of coupled boundary conditions involving all the components of the electromagnetic potential $A_\mu(t,\mathbf{x})$, $\mu = 0,\cdots,d$. If one disregards the vector character of the electromagnetic field and confine oneself to oscillations described by a sole scalar potential (for example, sound waves which are described by a scalar velocity potential) then at the interface between different media the conditions (5.26) and (5.27) should be satisfied. In other words, these boundary conditions hold in the theory of scalar "photons" in compound media.

Again we seek for the solution in terms of a relevant free propagator and single-layer heat potentials,

$$K_{-+}(x,y;t) = a_-^2 \int_0^t d\tau\, K_0(x,0;a_-^2(t-\tau))\beta_1(\tau,y), \quad x<0, \quad y>0, \tag{5.28}$$

$$K_{++}(x,y;t) = K_0(x,y;a_+^2 t) + a_+^2 \int_0^t d\tau\, K_0(x,0;a_+^2(t-\tau))\beta_2(\tau,y), \quad x,y>0, \tag{5.29}$$

$$K_{+-}(x,y;t) = a_+^2 \int_0^t d\tau\, K_0(x,0;a_+^2(t-\tau))\beta_3(\tau,y), \quad x>0, \quad y<0, \tag{5.30}$$

$$K_{--}(x,y;t) = K_0(x,y;a_-^2 t) + a_-^2 \int_0^t d\tau\, K_0(x,0;a_-^2(t-\tau))\beta_4(\tau,y), \quad x,y<0. \tag{5.31}$$

First we insert Eqs. (5.28) and (5.29) into the matching conditions (5.26) and (5.27). The single-layer potential changes smoothly across the boundary, while its normal derivative undergoes a jump,

$$K_{-+}(-0,y;t) = \frac{a_-}{2\sqrt{\pi}} \int_0^t d\tau \frac{\beta_1(y,\tau)}{\sqrt{t-\tau}}, \tag{5.32}$$

$$K_{++}(+0,y;t) = K_0(0,y;a_+^2 t) + \frac{a_+}{2\sqrt{\pi}} \int_0^t d\tau \frac{\beta_2(y,\tau)}{\sqrt{t-\tau}}, \tag{5.33}$$

$$\frac{\partial}{\partial x} K_{-+}(x,y;t)\Big|_{x=-0} = -\frac{1}{2}\beta_1(y,t), \tag{5.34}$$

$$\frac{\partial}{\partial x}K_{++}(x,y;t)\bigg|_{x=+0} = -\frac{1}{2}\beta_2(y,t) + \frac{\partial}{\partial x}K_0(x,y;a_+^2t)\bigg|_{x=0}. \tag{5.35}$$

Substituting Eqs. (5.32) and (5.33) into Eq. (5.26) one obtains the Abel integral equation,

$$\frac{1}{2\sqrt{\pi}}\int_0^t \frac{\mathrm{d}\tau}{\sqrt{t-\tau}}[a_-\beta_1(y,\tau) - a_+\beta_2(y;\tau)] = K_0(0,y;a_+^2t) \tag{5.36}$$

with the solution

$$a_-\beta_1(y,t) - a_+\beta_2(y;t) = \frac{2}{\sqrt{\pi}}\frac{d}{\mathrm{d}t}\int_0^t \frac{\mathrm{d}\tau}{\sqrt{t-\tau}}K_0(0,y;a_+^2\tau) = \frac{1}{2\sqrt{\pi}}\frac{y}{a_+^2t^{3/2}}\exp\left(-\frac{y^2}{4a_+^2t}\right). \tag{5.37}$$

The substitution of Eqs. (5.34) and (5.35) into Eq. (5.27) gives

$$\lambda_-\beta_1(y,t) = -\lambda_+\beta_2(y,t) + \lambda_+\frac{1}{2\sqrt{\pi}}\frac{y}{a_+^3t^{3/2}}e^{-(y^2/4a_+^2t)}. \tag{5.38}$$

From Eqs. (5.37) and (5.38) it follows that

$$\beta_1(y,t) = \frac{\frac{\lambda_+}{a_+}}{\frac{\lambda_+}{a_+}+\frac{\lambda_-}{a_-}}\frac{y}{\sqrt{\pi}a_+^3t^{3/2}}e^{-y^2/4a_+^2t}, \quad \beta_2(y,t) = \frac{\frac{\lambda_+}{a_+}-\frac{\lambda_-}{a_-}}{\frac{\lambda_+}{a_+}+\frac{\lambda_-}{a_-}}\frac{y}{2\sqrt{\pi}a_+^3t^{3/2}}e^{-y^2/4a_+^2t}. \tag{5.39}$$

And finally

$$K_{-+}(x,y;t) = \frac{\frac{\lambda_+}{a_+}}{\frac{\lambda_+}{a_+}+\frac{\lambda_-}{a_-}}\frac{1}{\sqrt{\pi a_+^2t}}e^{-[(x-y\ a_-/a_+)^2/4a_-^2t]}, \tag{5.40}$$

$$K_{++}(x,y;t) = \frac{1}{2\sqrt{\pi\ a_+^2t}}e^{-[(x-y)^2/4\ a_+^2t]} + \frac{\frac{\lambda_+}{a_+}-\frac{\lambda_-}{a_-}}{\frac{\lambda_+}{a_+}+\frac{\lambda_-}{a_-}}\frac{1}{2\sqrt{\pi\ a_+^2t}}e^{-[(x+y)^2/4\ a_+^2t]}. \tag{5.41}$$

In a similar way one gets

$$K_{+-}(x,y;t) = \frac{\frac{\lambda_-}{a_-}}{\frac{\lambda_-}{a_-}+\frac{\lambda_+}{a_+}}\frac{1}{\sqrt{\pi\ a_-^2t}}e^{-[(x-ya_+/a_-)^2/4\ a_+^2t]}, \tag{5.42}$$

$$K_{--}(x,y;t) = \frac{1}{2\sqrt{\pi\ a_-^2t}}e^{-[(x-y)^2/4\ a_-^2t]} + \frac{\frac{\lambda_-}{a_-}-\frac{\lambda_+}{a_+}}{\frac{\lambda_-}{a_-}+\frac{\lambda_+}{a_+}}\frac{1}{2\sqrt{\pi\ a_-^2t}}e^{-[(x+y)^2/4\ a_-^2t]}. \tag{5.43}$$

The solution obtained here exactly reproduces the results obtained in this problem by other methods.[7,27]

C. δ-like heat source at the interface

In the preceding considerations we excluded the configuration when the δ-like heat source is placed at the interface of the media $y=0$. For completeness we have to check whether this configuration contributes to the trace $\int_{-\infty}^{\infty}K(x,x;t)\mathrm{d}x$. To this end we use the approach of Ref. 28. The idea is to modify the boundary conditions (5.26) and (5.27) so that they allow for the heat source placed at the interface

$$K_-(-0;t) = K_+(+0;t), \tag{5.44}$$

$$\lambda_- \frac{\partial}{\partial x} K_-(x;t)\bigg|_{x=-0} - \lambda_+ \frac{\partial}{\partial x} K_+(x;t)\bigg|_{x=+0} = Q\ \delta(t). \tag{5.45}$$

The condition (5.45) means that the heat Q instantly generated by the source is divided into two flows which are proportional to λ_- and λ_+. We represent the solution in the form

$$K_-(x;t) = a_-^2 \int_0^t \mathrm{d}\tau\, K_0(x,0;a_-^2(t-\tau))\beta_1(\tau), \quad x<0, \tag{5.46}$$

$$K_+(x;t) = a_+^2 \int_0^t \mathrm{d}\tau\, K_0(x,0;a_+^2(t-\tau))\beta_2(\tau), \quad x>0. \tag{5.47}$$

The functions $\beta_1(\tau)$ and $\beta_2(\tau)$ can be determined by making use of the Laplace transform. We denote by $\overline{K}(x;s)$ the transform of $K(x;t)$, i.e.,

$$\overline{K}(x;p) = \int_0^\infty \mathrm{d}t\, e^{-p\ t} K(x;t).$$

Transforming (5.45) and (5.47) we obtain

$$\overline{K}_-(x;p) = a_-\overline{\beta}_-(p)\sqrt{\pi/p}\,\exp(-x\sqrt{p}/a_-), \tag{5.48}$$

$$\overline{K}_+(x;p) = a_+\overline{\beta}_+(p)\sqrt{\pi/p}\,\exp(-x\sqrt{p}/a_+). \tag{5.49}$$

Then Eq. (5.44) leads to the relation between the Laplace transforms $\overline{\beta}_-$ and $\overline{\beta}_+$,

$$a_-\overline{\beta}_-(p) - a_+\overline{\beta}_+(p) = 0. \tag{5.50}$$

The substitution of Eqs. (5.46) and (5.47) into Eq. (5.45) gives

$$\lambda_-\beta_-(t) + \lambda_+\beta_+(t) = 2\ Q\ \delta(t). \tag{5.51}$$

After the Laplace transform one arrives at the second relation between $\overline{\beta}_1$ and $\overline{\beta}_2$,

$$\lambda_1\overline{\beta}_-(p) + \lambda_2\beta_+(p) = 2\ Q\ \overline{\delta}(p). \tag{5.52}$$

How to apply the Laplace transform to the singular δ function can be found in appropriate handbooks.[20,21] The essence of the matter comes to defining the integration rule

$$\int_0^\infty f(t)\delta(t)\mathrm{d}t = f(0),$$

whence it follows in particular

$$\overline{\delta}(p) = \int_0^\infty e^{-pt}\delta(t)\mathrm{d}t = 1.$$

In the problems treated by the integral Laplace transform the semiaxis $t>0$ (or $t>t_0$) is usually considered. Therefore the δ-function should be defined here in a nonsymmetric way, for example, as the limit when $\varepsilon \to +0$ of the function

$$\delta_\varepsilon(t) = \begin{cases} 0, & t<0, \quad t>\varepsilon, \\ 1/\varepsilon, & 0<t<\varepsilon. \end{cases}$$

The solution of the system (5.50) and (5.52) is

$$\overline{\beta}_-(p) = \frac{2\,a_+Q\,\overline{\delta}(p)}{\lambda_+a_- + \lambda_-a_+}, \quad \overline{\beta}_+(p) = \frac{2\,a_-Q\,\overline{\delta}(p)}{\lambda_+a_- + \lambda_-a_+}. \tag{5.53}$$

By the inverse Laplace transform we find from (5.53)

$$\beta_-(t) = \frac{2\,a_+Q\,\delta(t)}{\lambda_+a_- + \lambda_-a_+}, \quad \beta_+(t) = \frac{2\,a_-Q\,\delta(t)}{\lambda_+a_- + \lambda_-a_+}. \tag{5.54}$$

Having inserted (5.54) into (5.46) and (5.47) we derive

$$K_-(x;t) = \frac{1}{\sqrt{\pi t}} e^{-x^2/4a_-^2 t} \frac{Q}{\frac{\lambda_+}{a_+} + \frac{\lambda_-}{a_-}}, \quad x < 0, \tag{5.55}$$

$$K_+(x;t) = \frac{1}{\sqrt{\pi t}} e^{-x^2/4a_+^2 t} \frac{Q}{\frac{\lambda_+}{a_+} + \frac{\lambda_-}{a_-}}, \quad x > 0. \tag{5.56}$$

These formulas show that for $t>0$ the heat kernel is finite notwithstanding the δ-like heat source situated at the interface between two media. Therefore the neighborhood of the point $x=0$ gives no contribution to the heat kernel trace $\int_{-\infty}^{\infty} K(x,x;t)\mathrm{d}x$.

VI. CONCLUSION

For a broad set of boundary conditions the finding of the heat kernel is reduced to the solution of integral equations defined on the boundary (or at the interface) of the manifolds. As a result the dimension of the initial problem is brought down by 1. Remarkably this technique is applicable to compound media where the standard methods for the investigation of heat kernel do not work because in this case the principal part of the elliptic operator in question is not smooth.

The perturbation series for the integral equations derived are nothing else as the multiple scattering expansions for the relevant heat kernels. Thus a rigorous derivation of these expansions both for homogeneous media and compact regions and for compound media has been done.

The efficiency of this approach is convincingly demonstrated by constructing, in an exact form, the heat kernel on an infinite line with diverse matching conditions and by deriving the first terms of the asymptotic expansion for integrated heat kernel in the case of three-dimensional compound media.

APPENDIX : SELF-ADJOINTNESS OF BOUNDARY VALUE PROBLEMS FOR COMPOUND MEDIA

Often it is helpful to use the spectral representation for the Green's function of the heat-conduction equation (2.10),

$$K(x,t;x',0) = \sum_k e^{-\omega_k t} f_k(x) f_k^*(x'), \tag{A1}$$

where $f_k(x)$ are the eigenfunctions of the spectral problem at hand

$$-a^2\Delta f_k(x) = \omega_k f_k(x), \quad x \in D \tag{A2}$$

obeying the relevant boundary conditions on S. Apparently, the representation (A1) is well defined if the spectral problem (A2) is Hermitian and positive definite. In this connection it is worth

elucidating the boundary conditions for compound media that lead to the self-adjoint spectral problem [see Eqs. (3.1)–(3.4)]. In this case we have instead of (A2),

$$-a^2(x)\Delta f_k(x) = \omega_k f_k(x), \tag{A3}$$

where

$$a^2(x) = \begin{cases} a_+^2, & x \in D_+, \\ a_-^2, & x \in D_-, \end{cases} \tag{A4}$$

a_+^2 and a_-^2 being constants. At the interface S the natural modes $f_k(x)$ obey the dielectriclike conditions

$$f_{k+}(x) = f_{k-}(x),$$

$$\lambda_+ \frac{\partial f_{k+}(x)}{\partial n_+(x)} + \lambda_- \frac{\partial f_{k-}(x)}{\partial n_-(x)} = 0,$$

$$x \in S. \tag{A5}$$

Here we are using the same notations as in Eqs. (3.1)–(3.4).

Since the outer region D_- is not bounded the spectrum ω_k is continuous. For example, we can assume that at the spatial infinity $|\mathbf{x}| \to \infty$ the natural modes $f_k(x)$ satisfy the scattering problem conditions and decrease sufficiently fast. The explicit form of these conditions will not be needed below.

The differential operator in Eq. (A3) apparently coincides with its adjoint

$$[-a^2(x)\Delta]\dagger = \begin{cases} -a_+^2\Delta, & x \in D_+, \\ -a_-^2\Delta, & x \in D_-. \end{cases} \tag{A6}$$

The boundary value problem with the operator $-a^2(x)\Delta$ will be self-adjoint when the integral for two sufficiently smooth functions $u(x)$ and $v(x)$,

$$I = \int_{D_+ \cup D_-} \mathrm{d}x\, a^2(x)(v\Delta u - u\Delta v) \tag{A7}$$

vanishes. Applying the Green integral formula for the domains D_+ and D_- separately we obtain

$$I = \int_S \mathrm{d}S \left[a_+^2 \left(u_+ \frac{\partial v_+}{\partial n_+} - v_+ \frac{\partial u_+}{\partial n_+} \right) + a_-^2 \left(u_- \frac{\partial v_-}{\partial n_-} - v_- \frac{\partial u_-}{\partial n_-} \right) \right]. \tag{A8}$$

The functions $u(x)$ and $v(x)$ are assumed to diminish at the infinity in such a way that the region $|\mathbf{x}| \to \infty$ does not contribute to the integral (A8). The integral I is equal to zero, for example, for the following conditions at the interface S:

$$u_+(x) = u_-(x),$$

$$a_+^2 \frac{\partial u_+(x)}{\partial n_+(x)} + a_-^2 \frac{\partial u_-(x)}{\partial n_-(x)} = 0, \quad x \in S. \tag{A9}$$

The function $v(x)$ should satisfy the same boundary conditions on S. Thus the dielectriclike conditions (A5) lead to self-adjoint boundary value problem if

$$\frac{\lambda_+}{a_+^2} = \frac{\lambda_-}{a_-^2}.$$

Of course, conditions (A9) do not exhaust all the cases when the boundary value problem under consideration is self-adjoint. Let the surface S divides the same medium into the domains D_+ and D_-, i.e., $a_+^2 = a_-^2$. We get the self-adjoint spectral problem if we impose at the interface S the following gluing conditions:

$$lu_+(x) = l^{-1}u_-(x),$$

$$l^{-1}\frac{\partial u_+(x)}{\partial n_+(x)} + l\frac{\partial u_-(x)}{\partial n_-(x)} = 0, \quad x \in S, \tag{A10}$$

where l is a dimensionless constant. The one-dimensional version of this problem has been considered in Sec. V.

(Received 19 October 2004; accepted 6 December 2004; published online 24 March 2005)

The properties of Q-balls in the general case of a sixth order potential have been studied using analytic methods. In particular, for a given potential, the initial field value that leads to the soliton solution has been derived and the corresponding energy and charge have been explicitly evaluated. The proposed scheme is found to work reasonably well for all allowed values of the model parameters. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1851972]

I. INTRODUCTION

A scalar field theory with a spontaneously broken U(1) symmetry may contain stable nontopological solitons, the so-called Q-balls.[1,2] Q-balls are coherent states of complex scalar fields that carry a global U(1) charge and can be understood as bound states of scalar particles which appear as stable classical solutions carrying a rotating time dependent internal phase. They are characterized by a conserved nontopological charge Q (Noether charge) that ensures existence and stability.[3,4]

The concepts associated with these solutions are quite general and occur in a wide variety of physical contexts.[5] Q-balls are allowed in supersymmetric extensions of the standard model that allow flat directions in the scalar potential. Flat directions in the minimal supersymmetric standard model (MSSM)[6] have been shown to exist. The conserved charge is associated with the U(1) symmetries of baryons and leptons, while, the relevant U(1) fields correspond to either squark or slepton particles. Thus, Q-balls can be thought of as condensates of a large number of either squark or slepton particles which can affect baryogenesis via the Affleck–Dine mechanism[7] during the post-inflationary period of the early universe. The Q-ball stability is cosmologically important since if stable Q-balls are formed in the early universe they can contribute to its dark matter content. These can be huge balls with charges of order 10^{20}; however, very small Q-balls can also be considered as dark matter constituents.[8] Decaying Q-balls can also be of crucial cosmological significance. If Q-balls decay after the electroweak phase transition, they can protect baryons from the erasure of baryon number due to sphaleron transitions. Furthermore, the Q-ball decay may contribute to dark matter production in the form of the lightest supersymmetric particle, explaining the baryon to dark matter ratio of the universe.[9]

Consider the U(1) Goldstone model Lagrangian describing a single complex scalar field ϕ in three spatial dimensions given by

[a)]Electronic mail: ti3@gen.auth.gr
[b)]Electronic mail: kouirouki@astro.auth.gr
[c)]Electronic mail: vlachos@physics.auth.gr

$$\mathcal{L} = \tfrac{1}{2}\partial_\mu \phi \partial^\mu \overline{\phi} - \mathrm{U}(|\phi|). \tag{1}$$

$\mathrm{U}(|\phi|)$ has a single minimum at $\phi=0$ which is equivalent of stating that there is a sector of scalar particles (mesons) carrying U(1) charge with mass equal to $\sqrt{\frac{1}{2}\mathrm{U}''(0)}$. The corresponding energy functional is given by

$$E = \int \left(\frac{1}{2}|\dot{\phi}|^2 + \frac{1}{2}|\nabla \phi|^2 + \mathrm{U}(|\phi|) \right) \mathrm{d}^3x \tag{2}$$

while the conserved Noether current [due to the global U(1) symmetry] is

$$J_\mu = \frac{1}{2i}(\overline{\phi}\partial_\mu \phi - \phi \partial_\mu \overline{\phi}) \tag{3}$$

with charge given by

$$Q = \frac{1}{2i} \int (\overline{\phi}\partial_t \phi - \phi \partial_t \overline{\phi}) \mathrm{d}^3x. \tag{4}$$

The stationary Q-ball solution can be obtained by assuming that

$$\phi = e^{i\omega t} f(r), \tag{5}$$

where $f(r)$ is a real radial profile function that satisfies the ordinary differential equation,

$$\frac{\mathrm{d}^2 f}{\mathrm{d}r^2} + \frac{2}{r}\frac{\mathrm{d}f}{\mathrm{d}r} = -\omega^2 f + \mathrm{U}'(f), \tag{6}$$

with boundary conditions $f(\infty)=0$ and $f'(0)=0$. In each case, the effective potential is defined as $\mathrm{U}_{\mathrm{eff}}(f) = \omega^2 f^2/2 - \mathrm{U}(f)$, while, the existence of Q-ball solutions leads to constraints on the potential $\mathrm{U}(f)$ and the frequency ω, (i) the effective mass of f must be negative, so, by assuming that $\mathrm{U}(0)=\mathrm{U}'(0)=0$ and $\mathrm{U}''(0)=\omega_+^2>0$ one can deduce that $\omega<\omega_+$. (ii) The minimum of $\mathrm{U}(f)/f^2$ must be attained at some positive value of f (say $0<f_0<\infty$) and existence of the solution requires that $\omega>\omega_-$ where $\omega_-^2 = 2\mathrm{U}(f_0)/f_0^2$. Hence, Q-balls exist for all ω in the range $\omega_- < |\omega| < \omega_+$.

The charge (4) and energy (2) of a stationary Q-ball solution (5) take the simple form

$$Q = 4\pi\omega \int r^2 f^2(r) \mathrm{d}r, \tag{7}$$

$$E = \frac{1}{2}\omega^2 Q^2 + 4\pi \int \left(\frac{f'^2}{2} + \mathrm{U}(f) \right) r^2 \mathrm{d}r. \tag{8}$$

Numerical and analytical methods have shown that when the internal frequency is close to the minimal value ω_- the profile function is almost constant, implying that the charge (7) is large (thin-wall approximation). On the other hand, when the internal frequency approaches the maximal value ω_+ the profile function falls off very quickly (thick-wall approximation). In the thick-wall approximation the behavior of Q depends on the particular form of the potential and the number of dimensions.[10]

The choice of the potential is not unique since the only requirement is that the ratio $\mathrm{U}(f)/f^2$ has a local minimum at some value of f different from zero. There are several natural types to be considered, two of which are shown below,

$$\text{(I)} \quad U(f) = \frac{m_1^2}{2} f^2 - \lambda_1 f^4 + \mu_1 f^6,$$

$$\text{(II)} \quad U(f) = m_3 f^2 (1 - K \log(\lambda_3 f^2)) + \mu_3 f^{2p}. \tag{9}$$

In each case, two of the parameters can be removed by rescaling, thus, the potentials of type I have one free parameter while potentials of type II have two for fixed p. The type I potential is the simplest allowed one which is a polynomial in f^2, while type II mimics the D-flat direction in MSSM. Here, $p \geqslant 6$ is some integer that ensures the growth of the potential for large f, but does not destroy the flatness property for intermediate values of f. None of these types are the kind which might be associated with a renormalizable quantum field theory, but, they are typical of effective theories incorporating radiative or finite temperature corrections to a bare potential. In this paper, we shall be dealing with type I potentials only, for which $\omega_+ = m_1$ and $\omega_- = \sqrt{(2m_1^2\mu_1 - \lambda_1^2)/2\mu_1}$. Stable Q-balls exist for $\sqrt{(2m_1^2\mu_1 - \lambda^2)/2\mu_1} < \omega < m_1$. The equation of motion (6) is

$$\frac{d^2 f}{dr^2} + \frac{2}{r}\frac{df}{dr} = \alpha^2 f - 4\lambda_1 f^3 + 6\mu_1 f^5, \tag{10}$$

where we have defined $\alpha^2 = m_1^2 - \omega^2$.

Q-balls can be studied either analytically,[1,10,11] or numerically.[3–10,12–14] In a recent work,[15,16] we employed analytic arguments in order to construct an approximate profile function of the symmetrized Woods–Saxon type, expected to be valid in the thin-wall limit. This approximate profile led to an explicit energy-charge relation which, to our surprise, was found to yield valid results for a region far exceeding the expected limits of the thin-wall approximation. The calculation was carried out for a specific form of type I potential, i.e., $\lambda_1 = 2$, $\mu_1 = 1$, and $m = 2$. In this paper, the aforementioned work is being extended to include the general case of type I potentials (where the parameters are taken to be arbitrary) in *both* regimes, thin-wall and thick-wall, respectively. This way, the soliton energy and charge as well as the initial field value $f(0)$ can be accurately derived as functions of α for the whole allowed range of the model parameters.

II. POTENTIAL ENERGY

From a mechanical point of view, a Q-ball solution describes the motion of a particle moving with friction in the potential

$$U_{\text{eff}}(f) = -\tfrac{1}{2}\alpha^2 f^2 + \lambda_1 f^4 - \mu_1 f^6, \quad \lambda_1, \mu_1 > 0. \tag{11}$$

The corresponding equation of motion is given by (10). Upon rescaling $r \to r/\alpha$ and letting $f(r) = f(0)\psi(ar)$ for $\psi(0) = 1$, Eq. (10) transforms to

$$\frac{d^2\psi}{dr^2} + \frac{2}{r}\frac{d\psi}{dr} = \psi - 4\lambda\psi^3 + 6\mu\psi^5, \tag{12}$$

where $\lambda = \lambda_1 f(0)^2/\alpha^2$ and $\mu = \mu_1 f(0)^4/\alpha^2$ and the effective potential (11) becomes

$$U(\psi) = -\tfrac{1}{2}\psi^2 + \lambda\psi^4 - \mu\psi^6. \tag{13}$$

After some algebra, it can be shown that Eq. (12) implies that

$$\int_0^\infty r^{n-1}\left(\frac{d\psi}{dr}\right)^2 dr = \frac{2n}{4-n}\int_0^\infty r^{n-1}\left(-\frac{1}{2}\psi^2 + \lambda\psi^4 - \mu\psi^6\right)dr, \quad n \neq 0. \tag{14}$$

For the special cases $n = 3$ and $n = 0$, we get that

$$\frac{1}{2}\int_0^\infty r^2\left(\frac{\mathrm{d}\psi}{\mathrm{d}r}\right)^2 \mathrm{d}r = 3\int_0^\infty r^2\left(-\frac{1}{2}\psi^2 + \lambda\psi^4 - \mu\psi^6\right)\mathrm{d}r, \tag{15}$$

$$2\int_0^\infty r^{-1}\left(\frac{\mathrm{d}\psi}{\mathrm{d}r}\right)^2 \mathrm{d}r = -\frac{1}{2}\psi(0)^2 + \lambda\psi(0)^4 - \mu\psi(0)^6 \equiv \mathrm{U}(1). \tag{16}$$

The first condition is Derrick's (or virial) theorem which states that, for a three-dimensional model, the kinetic energy equals three times the potential energy; the second condition describes the energy dissipation of the mechanical system.

The mechanical analogue imposes several constraints on U(1). Consider a particle initially located at the point $\psi(0)=1$ which starts rolling down the potential wall to eventually stop at the point $\psi(\infty)=0$. (Here r corresponds to the time variable). Then, the potential energy (13) at the origin $\mathrm{U}(1)=-\frac{1}{2}+\lambda-\mu$ must be consumed by the friction term $(2/r)(\mathrm{d}\psi/\mathrm{d}r)$, therefore U(1) must be bounded both from below and above, since for U(1) large the particle will overshoot the top point while for U(1) small it will not reach it.

The initial potential energy U(1) must be positive implying that

$$\mu \leqslant \lambda - \tfrac{1}{2} \tag{17}$$

and, also, $\mathrm{U}'(1)$ must be positive (attractive "force") leading to

$$\mu \leqslant \tfrac{1}{6}(4\lambda - 1). \tag{18}$$

These conditions are satisfied for $\lambda > 1$ when (18) holds while for $1/2 < \lambda < 1$ when (17) holds. Note that for $\lambda < 1$ no Q-ball solutions can be found. Depending on the shape of the potential (i.e., the actual values of λ and μ) the following two distinct cases occur.

(I) *Thin-wall approximation:* In this case, $\psi(0)$ lies near the maximum of the effective potential which is deep. Then $\mathrm{U}'(1)=-1+4\lambda-6\mu\approx 0$ must be positive and close to zero (slow roll) while $\mathrm{U}''(1)$ is negative (convex region) and of order unity. The Q-ball solutions lie approximately on the line

$$\mu = \tfrac{1}{6}(4\lambda - 1) \tag{19}$$

and the initial potential energy depends linearly on λ,

$$\mathrm{U}(1) = \tfrac{1}{3}(\lambda - 1), \quad \lambda > 1. \tag{20}$$

(II) *Thick-wall approximation:* Here, the potential is shallow and the maxima are high up while $\mathrm{U}''(1)$ is positive and large (concave region) and μ is small. The initial potential energy U(1) increases with λ and reaches its maximal value when $\mu \to 0$. This value can be determined numerically and is found to be $\lambda_{\max} \simeq 4.701\,37$. The actual functional dependence of U(1) on λ however, is unknown and needs to be determined.

To that end, let us assume a leading power law behavior

$$\mathrm{U}(1) = \kappa\lambda^n. \tag{21}$$

Then, (13) implies that the Q-ball solutions lie on the line

$$\mu = -\tfrac{1}{2} + \lambda - \kappa\lambda^n \tag{22}$$

which determines κ in terms of $\lambda_{\max}$ [since $\mu(\lambda_{\max})=0$],

$$\kappa = \frac{2\lambda_{\max} - 1}{2\lambda_{\max}^n}. \tag{23}$$

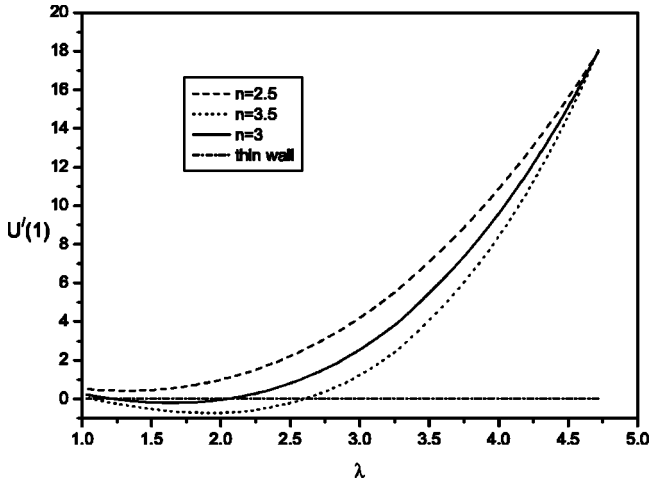

FIG. 1. The potential energy gradient in terms of λ for different values of n.

In order to determine the value of n in (21), we require that the transition from the thick-wall region to the thin-wall one be smooth implying that, $U'(1)$ is small for small values of λ ($\simeq 1$), i.e.,

$$U'(1) = 2(1-\lambda) + 6\kappa\lambda^n \approx 0. \tag{24}$$

Its minimum value occurs at the point $\lambda_{\min} = (3n\kappa)^{1/(1-n)}$. Substituting $\lambda_{\min}$ in (24) one gets that $U'(1)$ vanishes for $n = 2.821\,87$ in which case $\lambda_{\min} = 1.548\,89$ (in agreement to our hypothesis). Assuming that n can only take integer or half-integer values (otherwise the structure of the model on the complex plane would be very complicated), Fig. 1 shows that for $n=3$, the transition is indeed satisfactorily smooth. For this case, we get that $\kappa = 1/24.75$. This way, we get the $\mu(\lambda)$ relation for the thin-wall (19) and thick-wall (22) limits depicted in Fig. 2 against numerical data.

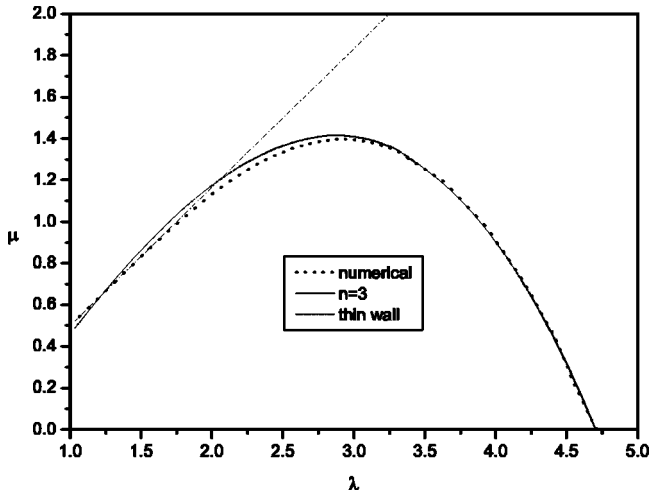

FIG. 2. The $\mu(\lambda)$ relation for $n=3$ against numerical data.

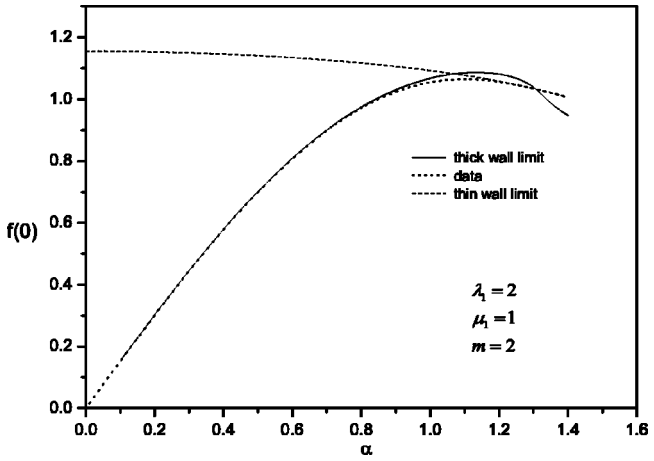

FIG. 3. Predicted initial field values $f(0)$ against numerical data.

III. PROPERTIES OF Q-BALLS

Using the rescaling formulas of the preceding section, the α dependence of the functions E, Q, and $f(0)$ can now be analytically determined. The initial field value $f(0)$ that leads to a Q-ball solution is given by

$$f(0) = \alpha\sqrt{\frac{\lambda}{\lambda_1}}, \quad \alpha = \sqrt{\frac{\mu}{\mu_1}}\frac{\lambda_1}{\lambda}. \tag{25}$$

Figure 3 depicts predicted values of $f(0)$ in terms of α against numerically calculated ones for sample values $\lambda_1=2$, $\mu_1=1$, $m=2$ (as in Ref. 16).

The corresponding charge (7) and energy (8) functionals are given by

$$Q = \frac{4\pi\omega}{\alpha}\frac{\lambda}{\lambda_1}\int_0^\infty \psi^2 r^2\,\mathrm{d}r, \tag{26}$$

$$E = \frac{\alpha^2+2\omega^2}{2\omega}Q + 4\pi\alpha\frac{\lambda}{\lambda_1}\int_0^\infty \left(\frac{1}{2}\psi'^2 - \lambda\psi^4 + \mu\psi^6\right)r^2\,\mathrm{d}r. \tag{27}$$

It was shown in Ref. 16 that a trial function satisfying the boundary conditions and having the right asymptotic behavior, is the symmetrized Woods–Saxon profile

$$\phi(r) = \frac{c}{\sqrt{1+c_1\cosh(br)}}. \tag{28}$$

This function satisfies the exact differential equation

$$\phi'' = \frac{b^2}{4}\phi - \frac{b^2}{c^2}\phi^3 + \frac{3}{4}\frac{b^2}{c^4}(1-c_1^2)\phi^5 \tag{29}$$

and the approximate one

$$\phi'' + \frac{2}{r}\phi' = \frac{b^2}{4}\left(1-\frac{4}{br}\right)\phi - \frac{b^2}{c^2}\left(1-\frac{1}{br}\right)\phi^3 + \frac{3b^2}{4c^4}\left((1-c_1^2)+\frac{2}{3}\frac{c_1^2}{br}\right)\phi^5 + O(\phi^7). \tag{30}$$

Here, c, c_1, and b are arbitrary parameters which need to be determined in order that (28) fits the exact profile function $\psi(r)$ in the best possible way. Note that only two of the three parameters in

(28) are independent since the initial condition $\phi(0)=1$ implies that $c=\sqrt{1+c_1}$.

First note that (28) satisfies the following relations:

$$\phi'^2=\frac{b^2}{4}\phi^2-\frac{1}{2}\frac{b^2}{c^2}\phi^4+\frac{1}{4}\frac{b^2}{c^4}(1-c_1^2)\phi^6,$$

$$\phi^4=c^2\phi^2+c^2c_1\frac{\mathrm{d}}{\mathrm{d}c_1}\phi^2, \tag{31}$$

$$\phi^6=c^4\phi^2+2c^4c_1\frac{\mathrm{d}}{\mathrm{d}c_1}\phi^2+\frac{1}{2}c^4c_1^2\frac{\mathrm{d}^2}{\mathrm{d}c_1^2}\phi^2,$$

in terms of which the charge (26) and energy (27) functionals can be explicitly evaluated,

$$Q=\frac{4\pi\omega}{\alpha}\frac{\lambda}{\lambda_1}\frac{c^2}{3b^3}i_0, \tag{32}$$

$$E=4\pi\frac{c^2}{3b^3}\sqrt{\frac{\mu}{\mu_1}}\left\{\left(\frac{(m^2+\omega^2)}{2\alpha}\frac{\lambda}{\lambda_1}\sqrt{\frac{\mu_1}{\mu}}+\mu c^4-\lambda c^2-\frac{1}{8}b^2c_1^2\right)i_0+\left(2\mu c^4-\lambda c^2-\frac{1}{4}b^2c_1^2\right)c_1\frac{\mathrm{d}i_0}{\mathrm{d}c_1}\right.$$
$$\left.+\frac{1}{2}\left(\mu c^4+\frac{1}{8}b^2(1-c_1^2)\right)c_1^2\frac{\mathrm{d}^2i_0}{\mathrm{d}c_1^2}\right\}. \tag{33}$$

Here i_0 is a function of c_1 given by

$$i_0(c_1)=\frac{1}{\sqrt{1-c_1^2}}\operatorname{arccosh}\left(\frac{1}{c_1}\right)\left[\pi^2+\operatorname{arccosh}\left(\frac{1}{c_1}\right)^2\right],\quad \text{for } c_1<1. \tag{34}$$

Note that λ_1, μ_1, m are fixed external parameters, λ varies continuously between 1 and 4.701 37 and μ is a known function of λ given by (19) and (22) depending on the regime.

The profile parameters b and c_1 can be determined by imposing the conditions (15) and (16) on $\phi(r)$, that is

$$\frac{1}{2}b^2c_1^2c^2\int_0^\infty\frac{\mathrm{d}r}{r}\frac{\sinh^2 r}{(1+c_1\cosh r)^3}=\mathrm{U}(1), \tag{35}$$

$$\left(\frac{1}{2}-\lambda c^2+\mu c^4-\frac{b^2c_1^2}{24}\right)i_0+\left(2\mu c^4-\frac{b^2c_1^2}{12}-\lambda c^2\right)c_1\frac{\mathrm{d}i_0}{\mathrm{d}c_1}+\frac{c_1^2}{2}\left(\mu c^4+\frac{b^2}{24}(1-c_1^2)\right)\frac{\mathrm{d}^2i_0}{\mathrm{d}c_1^2}=0. \tag{36}$$

Equation (35) can be written in a compact form

$$b=\frac{1}{c_1c}\sqrt{\frac{2\mathrm{U}(1)}{i_1}}, \tag{37}$$

where

$$i_1=\int_0^\infty\frac{\mathrm{d}r}{r}\frac{\sinh^2 r}{(1+c_1\cosh r)^3} \tag{38}$$

in terms of which (36) becomes

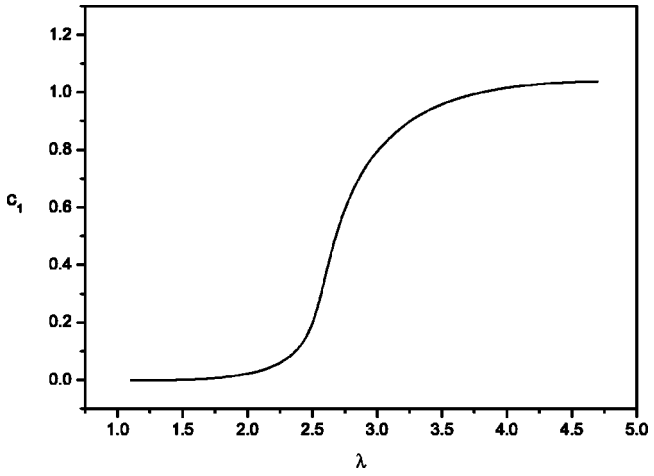

FIG. 4. The $c_1(\lambda)$ relation obtained from (39).

$$\left(\frac{1}{2}-\lambda c^2+\mu c^4-\frac{1}{12c^2}\frac{\mathrm{U}(1)}{i_1}\right)i_0+\left(2\mu c^4-\frac{1}{6c^2}\frac{\mathrm{U}(1)}{i_1}-\lambda c^2\right)c_1\frac{\mathrm{d}i_0}{\mathrm{d}c_1}+\frac{c_1^2}{2}\left(\mu c^4+\frac{(1-c_1^2)}{12c_1^2c^2}\frac{\mathrm{U}(1)}{i_1}\right)\frac{\mathrm{d}^2 i_0}{\mathrm{d}c_1^2}=0. \tag{39}$$

Equation (39) determines c_1 in terms of λ and is depicted in Fig. 4. Note that the values of c_1 and b obtained this way are universal since they do not depend on the geometrical parameters of the potential. Nevertheless, the values of the energy and charge do depend on the specific form of the potential, i.e., the values of λ_1, μ_1, and m. These values tend to infinity in both limits since (i) in the thin-wall limit $c_1\to 0$ while (ii) in the thick-wall limit $\alpha\to 0$.

Figures 5 and 6 present the α dependence of the charge (32) and energy (33) against values obtained numerically, for $\lambda_1=2$, $\mu_1=1$, $m=2$. It is interesting to realize that the range of validity of the thick-wall approximation is very wide and gives satisfactory results even in the thin-wall region. It appears that in this class of theories the Q-balls prefer to be "thick."

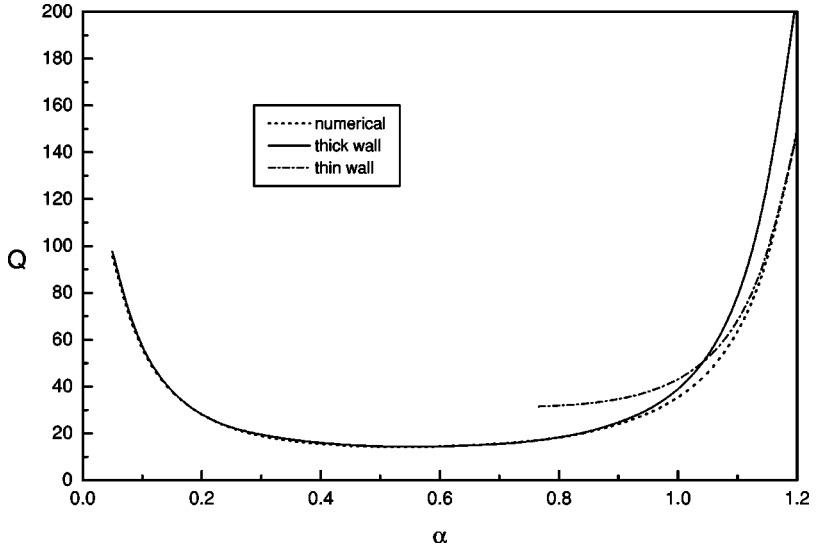

FIG. 5. The α dependence of Q given by (32).

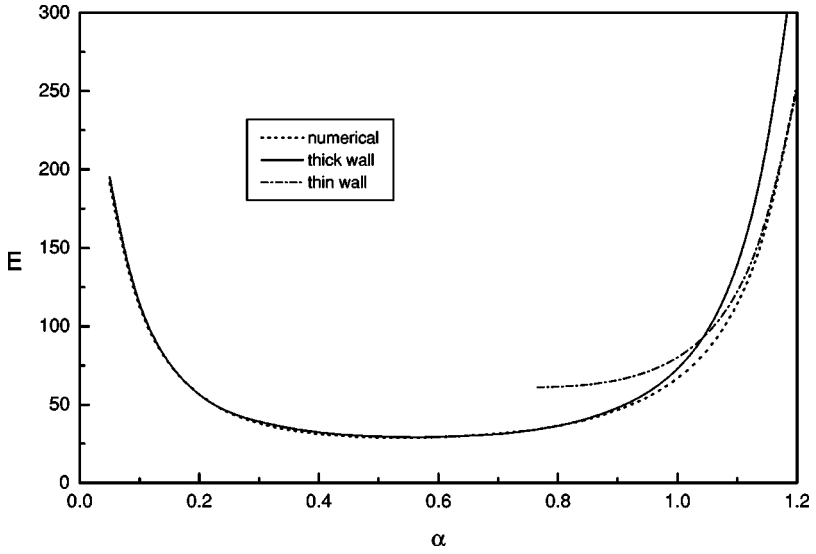

FIG. 6. The α dependence of E given by (33).

IV. CONCLUSIONS

In this paper we have extended our earlier work[16] and investigated phenomenologically relevant properties of Q-balls in a universal way. In particular, we have addressed the following problem: Given the geometrical characteristics of the scalar potential find the initial field value that will lead to a Q-ball solution as well as the corresponding charge and energy of the soliton. For a particular class of potentials (sixth order polynomials), after parameter rescaling, the problem can be tackled in a universal way. The Q-ball profile can be accurately approximated by means of a two-parameter symmetrized Woods–Saxon function which can be analytically calculated in all cases. This scheme is found to yield satisfactory results in the whole parameter region so that we do not have to rely on approximations like thin-wall or thick-wall. The soliton energy and charge can subsequently be analytically calculated and compared against numerically calculated values taken from an earlier work.[15]

We believe that a similar line of argument can be applied to study the profile function and the energy-charge dependence in all types of potentials.

(Received 1 June 2004; accepted 13 December 2004; published online 25 March 2005)

The two approaches of consistent quantum field theory for systems of the trapped Bose–Einstein condensates are known, one is the Bogoliubov–de Gennes approach and the other is the generalized Bogoliubov approach. In this paper, we investigate the relation between the two approaches and show that they are formally equivalent to each other. To do this one must carefully treat the Nambu–Goldstone mode which plays a crucial role in the condensation. It is emphasized that the choice of vacuum is physically relevant. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1865322]

I. INTRODUCTION

The Bose–Einstein condensation is associated with the appearance of the Nambu–Goldstone (NG) mode[1] which is gapless. This is because the phenomenon is a manifestation of a spontaneous breakdown of a global phase (gauge) symmetry in quantum field theory (QFT) and then the Goldstone theorem requires that there must be a gapless mode. The NG mode plays a crucial role in creating and maintaining an ordered state such as the Bose–Einstein condensate (BEC).

For systems of the trapped BECs,[2–4] there are two approaches in QFT involving the NG mode explicitly. They are called the Bogoliubov–de Gennes (BdG)[5,6] and the generalized Bogoliubov (GB)[7,8] approaches. Both seem to offer consistent formulations in the sense that the canonical commutation relations are respected and that the unperturbed Hamiltonian is diagonalized. The purpose of this paper is to study the relation between them. We can prove that they are formally equivalent to each other, finding the explicit linear transformation in operators from one to the other. The treatment of the NG mode is subtle. We will clarify this point.

After the formal equivalence of the two approaches are established, we emphasize that the choice of vacuum is relevant physically while the choice of approach is not.

The paper is organized as follows. In Sec. II, the model action and Hamiltonian are given. An artificial breaking term is introduced there. Sections III and IV are devoted to reviews of the GB and BdG approaches, respectively. Section V is a central part of this paper, in which first the equivalence in the excitation modes is proved and then the correspondence between the NG modes in the two approaches is established. It will be found that the two sets of the NG modes are related through a squeezing transformation. In Sec. VI, we give a summary and discuss implications of

[a)]Electronic mail: mine@toki.waseda.jp
[b)]Electronic mail: okumura@aoni.waseda.jp
[c)]Electronic mail: yamanaka@waseda.jp

our conclusion. Finally we comment that the two different types of vacua lead to different observable results. In the Appendix, we give expressions for free propagators when the unperturbed vacuum associated with quantum coordinates is chosen.

II. MODEL ACTION AND HAMILTONIAN

We start with the following action to describe the trapped BEC of neutral atoms:

$$S = \int \mathrm{d}t\, \mathrm{d}^3x \left[\psi^\dagger(x)(T - K - V + \mu)\psi(x) - \frac{g}{2}\psi^\dagger(x)\psi^\dagger(x)\psi(x)\psi(x) \right], \tag{1}$$

where

$$T = i\frac{\partial}{\partial t}, \tag{2a}$$

$$K = -\frac{1}{2m}\nabla^2, \tag{2b}$$

$$V = \tfrac{1}{2}m\omega^2(x^2 + y^2 + z^2). \tag{2c}$$

with the chemical potential μ and the coupling constant g. Here we assumed for simplicity the isotropic trapping potential with its frequency ω, but the essences of the present paper are not lost even in anisotropic trapping potentials. Throughout this paper $\hbar$ is set to unity. This action is invariant under the global phase transformation,

$$\psi(x) \to e^{i\eta}\psi(x) \quad \text{and} \quad \psi^\dagger(x) \to e^{-i\eta}\psi^\dagger(x), \tag{3}$$

where η is an arbitrary constant phase.

When a continuous symmetry is broken spontaneously and the NG mode is present, one usually needs an artificial breaking interaction to control an infrared behavior of the system. In the system of the BEC, we add

$$\Delta S = \varepsilon\overline{\epsilon}\int \mathrm{d}t\, \mathrm{d}^3x [e^{-i\theta}v(\mathbf{x})\psi(x) + e^{i\theta}v(\mathbf{x})\psi^\dagger(x)] \tag{4}$$

to the original action (1),[8]

$$S_\varepsilon = S + \Delta S. \tag{5}$$

Here ε is an infinitesimal dimensionless parameter which is taken to be vanishing at the final stage of calculation, and $\overline{\epsilon}$ is a typical energy scale of the system given by ω. As we will see below, such a breaking term is necessary for the GB formalism, while it seems that the BdG formalism can be formulated without it.

Let us divide the original field $\psi(x)$ into the classical and quantum parts as

$$\psi(x) = e^{i\theta}v(\mathbf{x}) + e^{i\theta}\varphi(x), \tag{6}$$

where it is assumed that the c-number real function $v(\mathbf{x})$, whose square is a distribution function of condensed particle, is time independent, and that θ is real, time and space independent, corresponding to the situation without vortices. We factorize $e^{i\theta}$ in $\varphi(x)$ so that there appears no phase factor in the following formulations. Equation (6) is substituted into Eq. (5), which is rewritten in terms of $v(\mathbf{x})$ and $\varphi(x)$ as follows:

$$S_\varepsilon = S_0 + S_1 + S_2 + S_{3,4}, \tag{7}$$

where

$$S_0 = \int \mathrm{d}t\, \mathrm{d}^3x \left[v(\mathbf{x})(-K - V + \mu + 2\varepsilon\overline{\epsilon})v(\mathbf{x}) - \frac{g}{2}v^4(x) \right], \tag{8a}$$

$$S_1 = \int \mathrm{d}t\, \mathrm{d}^3x \{v(\mathbf{x})[-K - V + \mu - gv^2(\mathbf{x}) + \varepsilon\overline{\epsilon}]\varphi(x) + \varphi^\dagger(x)[-K - V + \mu - gv^2(\mathbf{x}) + \varepsilon\overline{\epsilon}]v(\mathbf{x})\}, \tag{8b}$$

$$S_2 = \int \mathrm{d}t\, \mathrm{d}^3x \left\{ \varphi^\dagger(x)[T - K - V + \mu]\varphi(x) - \frac{g}{2}v^2(\mathbf{x})[4\varphi^\dagger(x)\varphi(x) + \varphi^2(x) + \varphi^{\dagger 2}(x)] \right\}, \tag{8c}$$

$$S_{3,4} = \int \mathrm{d}t\, \mathrm{d}^3x \left\{ -gv(\mathbf{x})[\varphi^\dagger(x)\varphi^\dagger(x)\varphi(x) + \varphi^\dagger(x)\varphi(x)\varphi(x)] - \frac{g}{2}\varphi^\dagger(x)\varphi^\dagger(x)\varphi(x)\varphi(x) \right\}. \tag{8d}$$

At the tree level, the c-number function $v(\mathbf{x})$ satisfies

$$[K + V - \mu + gv^2(\mathbf{x}) - \varepsilon\overline{\epsilon}]v(\mathbf{x}) = 0, \tag{9}$$

which, at the limit of vanishing ε, is reduced to the Gross–Pitaevskii (GP) equation:[9]

$$[K + V - \mu + gv^2(\mathbf{x})]v(\mathbf{x}) = 0. \tag{10}$$

We rewrite $v(\mathbf{x})$ as

$$v(\mathbf{x}) = \sqrt{N_c} f_\varepsilon(\mathbf{x}), \tag{11}$$

since the condensate particle number N_c is given by

$$N_c = \int \mathrm{d}^3x\, v^2(\mathbf{x}), \tag{12}$$

and $f_\varepsilon(\mathbf{x})$ can be normalized to unity,

$$\int \mathrm{d}^3x\, f_\varepsilon^2(\mathbf{x}) = 1. \tag{13}$$

The suffix ε in $f_\varepsilon(\mathbf{x})$ is put to remind us that it is ε-dependent, which will be relevant in later sections.

The total Hamiltonian of the system is now written as

$$\hat{H} = \hat{H}_0 + \hat{H}_{\mathrm{int}}, \tag{14}$$

where

$$\hat{H}_0 = \int \mathrm{d}^3x \left\{ \hat{\varphi}^\dagger(x)(K + V - \mu)\hat{\varphi}(x) + \frac{gN_c}{2} f_\varepsilon^2(\mathbf{x})[4\hat{\varphi}^\dagger(x)\hat{\varphi}(x) + \hat{\varphi}^2(x) + \hat{\varphi}^{\dagger 2}(x)] \right\}, \tag{15}$$

$$H_{\mathrm{int}} = \int \mathrm{d}^3x \left\{ g\sqrt{N_c} f_\varepsilon(\mathbf{x})[\hat{\varphi}^\dagger(x)\hat{\varphi}^\dagger(x)\hat{\varphi}(x) + \hat{\varphi}^\dagger(x)\hat{\varphi}(x)\hat{\varphi}(x)] + \frac{g}{2}\hat{\varphi}^\dagger(x)\hat{\varphi}^\dagger(x)\hat{\varphi}(x)\hat{\varphi}(x) \right\}. \tag{16}$$

It is emphasized that the canonical commutation relations

$$[\hat{\varphi}(\mathbf{x},t), \hat{\varphi}^\dagger(\mathbf{x}',t)] = \delta^3(\mathbf{x} - \mathbf{x}') \tag{17}$$

and $[\hat{\varphi}(\mathbf{x},t), \hat{\varphi}(\mathbf{x}',t)] = [\hat{\varphi}^\dagger(\mathbf{x},t), \hat{\varphi}^\dagger(\mathbf{x}',t)] = 0$, must hold for consistent QFT.

III. GENERALIZED BOGOLIUBOV APPROACH

First let us review the GB approach, in which the field operator $\hat{\varphi}(x)$ and $\hat{\varphi}^\dagger(x)$ are expanded as

$$\hat{\varphi}(x) = \sum_{n=0}^{\infty} \hat{a}_n(t) w_n^{(\varepsilon)}(\mathbf{x}), \tag{18a}$$

$$\hat{\varphi}^\dagger(x) = \sum_{n=0}^{\infty} \hat{a}_n^\dagger(t) w_n^{(\varepsilon)}(\mathbf{x}), \tag{18b}$$

where the complete orthonormal set of real functions $\{w_n^{(\varepsilon)}(\mathbf{x})\}$,

$$\int \mathrm{d}^3x w_n^{(\varepsilon)}(\mathbf{x}) w_m^{(\varepsilon)}(\mathbf{x}) = \delta_{nm}, \tag{19}$$

$$\sum_{n=0}^{\infty} w_n^{(\varepsilon)}(\mathbf{x}) w_n^{(\varepsilon)}(\mathbf{x}') = \delta^3(\mathbf{x}-\mathbf{x}'), \tag{20}$$

is obtained from the following eigenequation:

$$(\mathcal{L}-\mathcal{M}) w_n^{(\varepsilon)}(\mathbf{x}) = (\epsilon_n + \varepsilon\overline{\epsilon}) w_n^{(\varepsilon)}(\mathbf{x}). \tag{21}$$

For later convenience, we have introduced the abbreviated notations of

$$\mathcal{L} = K + V - \mu + 2gN_c f_\varepsilon^2(\mathbf{x}), \tag{22a}$$

$$\mathcal{M} = gN_c f_\varepsilon^2(\mathbf{x}), \tag{22b}$$

and the index (ε) in $\{w_n^{(\varepsilon)}(\mathbf{x})\}$ indicates that they are ε-dependent, and $\{w_n^{(\varepsilon)}(\mathbf{x})\}$ are expanded as

$$w_n^{(\varepsilon)}(\mathbf{x}) = w_n^{(0)}(\mathbf{x}) + \varepsilon w_n^{(1)}(\mathbf{x}) + \cdots . \tag{23}$$

So in the limit $\varepsilon \to 0$, the functions $\{w_n^{(\varepsilon)}(\mathbf{x})\}$ reduce to $\{w_n^{(0)}(\mathbf{x})\}$, which are the solutions of the eigenequations

$$(\mathcal{L}-\mathcal{M}) w_n^{(0)}(\mathbf{x}) = \epsilon_n w_n^{(0)}(\mathbf{x}). \tag{24}$$

The eigenequation (21) with $n=0$ is identical with the (ε-modified) GP equation (9), and $w_0^{(\varepsilon)}(\mathbf{x})$ is nothing but $f_\varepsilon(\mathbf{x})$ defined in Eq. (11). Hereafter the index (ε) in $\{w^{(\varepsilon)}(\mathbf{x})\}$ is omitted otherwise mentioned.

For the operators $\hat{a}_n(t)$ and $\hat{a}_n^\dagger(t)$ the following commutation relations are assumed:

$$[\hat{a}_n(t), \hat{a}_m^\dagger(t)] = \delta_{nm} \tag{25}$$

and $[\hat{a}_n(t), \hat{a}_m(t)] = [\hat{a}_n^\dagger(t), \hat{a}_m^\dagger(t)] = 0$. Combining these with the completeness condition in Eq. (20), one can reproduce the canonical commutation relations of Eq. (17). In the formulation under the "Bogoliubov" approximation, meaning that the term $\hat{a}_0 w_n(\mathbf{x})$ is absent in the expansion of Eq. (18), the canonical commutation relations are violated as

$$[\hat{\varphi}(\mathbf{x},t), \hat{\varphi}^\dagger(\mathbf{x}',t)] = \delta^3(\mathbf{x}-\mathbf{x}') - w_0(\mathbf{x}) w_0(\mathbf{x}'). \tag{26}$$

Substituting Eq. (18) into Eq. (15), we rewrite $\hat{H}_0$ in terms of the $\hat{a}$-operators,

$$\hat{H}_0 = \sum_{n=0}^{\infty} \epsilon_n \hat{a}_n^\dagger \hat{a}_n + \sum_{n,m=0}^{\infty} [2\hat{a}_n^\dagger U_{nm} \hat{a}_m + \hat{a}_n U_{nm} \hat{a}_m + \hat{a}_n^\dagger U_{nm} \hat{a}_m^\dagger], \tag{27}$$

where

$$U_{nm} = \frac{gN_c}{2} \int \mathrm{d}^3x \, f_\varepsilon^2(\mathbf{x}) w_n(\mathbf{x}) w_m(\mathbf{x}). \tag{28}$$

This Hamiltonian can be diagonalized by introducing the generalized Bogoliubov transformation,

$$\hat{b}_n = \sum_{m=0}^{\infty} (C_{nm} \hat{a}_m + S_{nm} \hat{a}_m^\dagger), \tag{29a}$$

$$\hat{b}_n^\dagger = \sum_{m=0}^{\infty} (C_{nm} \hat{a}_m^\dagger + S_{nm} \hat{a}_m), \tag{29b}$$

and

$$\hat{H}_0 = \sum_{n=0}^{\infty} [E_{G,n} \hat{b}_n^\dagger \hat{b}_n + (\text{c-numbers})]. \tag{30}$$

Here the real matrices C and S in the matrix notation are given by

$$C = \tfrac{1}{2}(E_G^{1/2} \mathcal{O} \boldsymbol{\epsilon}^{-1/2} + E_G^{-1/2} \mathcal{O} \boldsymbol{\epsilon}^{1/2}), \tag{31a}$$

$$S = \tfrac{1}{2}(E_G^{1/2} \mathcal{O} \boldsymbol{\epsilon}^{-1/2} - E_G^{-1/2} \mathcal{O} \boldsymbol{\epsilon}^{1/2}), \tag{31b}$$

with

$$(E_G)_{nm} = E_{G,n} \delta_{nm}, \tag{32a}$$

$$(\boldsymbol{\epsilon})_{nm} = (\epsilon_n + \varepsilon \overline{\epsilon}) \delta_{nm}, \tag{32b}$$

and the orthogonal matrix $\mathcal{O}$ diagonalizes the real symmetric matrix W with eigenvalues of $E_{G,n}^2 (n = 0, 1, 2, \ldots)$,

$$\mathcal{O} W \mathcal{O}^T = E_G^2, \tag{33}$$

where

$$W = \begin{pmatrix} 4(\varepsilon \overline{\epsilon}) U_{00} + O(\varepsilon^2) & \sqrt{\varepsilon \overline{\epsilon}} u'^T + O(\varepsilon^{3/2}) \\ \sqrt{\varepsilon \overline{\epsilon}} u' + O(\varepsilon^{3/2}) & W' + O(\varepsilon) \end{pmatrix}, \tag{34}$$

with

$$u' = \begin{pmatrix} 4\sqrt{\epsilon_1} U_{10} \\ 4\sqrt{\epsilon_2} U_{20} \\ \vdots \end{pmatrix}, \tag{35a}$$

$$W'_{nm} = \epsilon_n^2 \delta_{nm} + 4\sqrt{\epsilon_n} U_{nm} \sqrt{\epsilon_m} \; (n, m = 1, 2, \ldots). \tag{35b}$$

We use the following notations for matrices such as A and A': A' stands for a matrix A_{nm} with $n, m = 1, 2, \ldots$ while A does for one with $n, m = 0, 1, 2, \ldots$. And we notice that when we investigate

the leading order behavior of ε, it does not matter if we use $\{w_n^{(0)}(\mathbf{x})\}$ for U_{nm} instead of $\{w_n^{(\varepsilon)}(\mathbf{x})\}$ [see Eq. (28)].

One can easily check the properties of C and S from Eq. (31),

$$\sum_{m=0}^{\infty}(C_{nm}C_{n'm}-S_{nm}S_{n'm})=\delta_{nn'}, \tag{36a}$$

$$\sum_{m=0}^{\infty}(C_{nm}S_{n'm}-S_{nm}C_{n'm})=0. \tag{36b}$$

The above expressions are expanded with respect to the infinitesimal parameter ε. We note that the zeroth eigenvalue,

$$E_{G,0}=\sqrt{\varepsilon\epsilon}\sqrt{\overline{E_0}}+O(\varepsilon^{3/2}), \tag{37a}$$

$$\overline{E_0}\equiv 4U_{00}-u'^{T}W'^{-1}u', \tag{37b}$$

approaches zero as it should be, but is kept nonvanishing due to ε, which enables us to diagonalize $\hat{H}_0$.

The matrix $\mathcal{O}$ is obtained explicitly as

$$\mathcal{O}=\begin{pmatrix}1-\frac{1}{2}(\varepsilon\overline{\epsilon})u'^{T}W'^{-2}u'+O(\varepsilon^2) & -\sqrt{\varepsilon\overline{\epsilon}}u'^{T}W'^{-1}\mathcal{O}'^{T}+O(\varepsilon^{3/2})\\ \sqrt{\varepsilon\overline{\epsilon}}\mathcal{O}'W'^{-1}u'+O(\varepsilon^{3/2}) & \mathcal{O}'+O(\varepsilon)\end{pmatrix}, \tag{38}$$

where $\mathcal{O}'$ is an orthogonal matrix diagonalizing the matrix W',

$$\mathcal{O}'W'\mathcal{O}'^{T}=E_G'^{2}, \tag{39}$$

with the diagonal matrix

$$(E_G'^{2})_{nm}=E_{G,n}^2\delta_{nm}+O(\varepsilon^{1/2})\quad(n,m=1,2,\dots). \tag{40}$$

Thus the mixing among $\hat{a}_n$ $(n=1,2,\dots)$ is regular with respect to ε, only the mixing between $\hat{a}_0$ and other $\hat{a}_n$'s gives rise to a singularity.

Thus the field operators in the GB approach are expanded in terms of $\hat{b}$-operators diagonalizing the unperturbed Hamiltonian as

$$\hat{\varphi}(\mathbf{x})=\sum_{n=0}^{\infty}[\hat{b}_n w_{Cn}(\mathbf{x})-\hat{b}_n^{\dagger}w_{Sn}(\mathbf{x})], \tag{41a}$$

$$\hat{\varphi}^{\dagger}(\mathbf{x})=\sum_{n=0}^{\infty}[\hat{b}_n^{\dagger}w_{Cn}(\mathbf{x})-\hat{b}_n w_{Sn}(x)] \tag{41b}$$

with

$$w_{Cn}(\mathbf{x})=\sum_{m=0}^{\infty}C_{nm}w_m(\mathbf{x}), \tag{42a}$$

$$w_{Sn}(\mathbf{x})=\sum_{m=0}^{\infty}S_{nm}w_m(\mathbf{x}). \tag{42b}$$

IV. BOGOLIUBOV–DE GENNES APPROACH

Next we review the BdG approach. The parameter ε is set to be zero throughout this section, so all the quantities are those of $\varepsilon=0$.

One sets up the coupled eigenequations,

$$\mathcal{L}u_n(\mathbf{x}) - \mathcal{M}v_n(\mathbf{x}) = E_{B,n}u_n(\mathbf{x}), \tag{43a}$$

$$\mathcal{L}v_n(\mathbf{x}) - \mathcal{M}u_n(\mathbf{x}) = -E_{B,n}v_n(\mathbf{x}), \tag{43b}$$

where the notations in Eq. (22) are used and we assume the functions $u_n(\mathbf{x})$ and $v_n(\mathbf{x})$ to be real. The orthonormal condition reads as

$$\int \mathrm{d}^3x[u_n(\mathbf{x})u_m(\mathbf{x}) - v_n(\mathbf{x})v_m(\mathbf{x})] = \delta_{nm}, \tag{44a}$$

$$\int \mathrm{d}^3x[u_n(\mathbf{x})v_m(\mathbf{x}) - v_n(\mathbf{x})u_m(\mathbf{x})] = 0. \tag{44b}$$

Several authors have already made remarks on states with zero eigenvalue for Eq. (43).[10–12] It is easy to see that $u_0(\mathbf{x})=v_0(\mathbf{x})=f(\mathbf{x})$ [the normalized solution of GP equation, see Eqs. (10) and (11)] are eigenfunctions with $E_B=0$. However, the set of $f(\mathbf{x})$ and $\{u_n(\mathbf{x}),v_n(\mathbf{x})\}$ with $E_{B,n}\neq 0$ is not complete. One needs one more state denoted by $h(\mathbf{x})$ for the completeness,[12] which is a solution of

$$(\mathcal{L}+\mathcal{M})h(\mathbf{x}) = \frac{1}{I}f(\mathbf{x}), \tag{45}$$

where I is a positive constant. The orthonormal properties are, in addition to Eqs. (13) and (44) for eigenfunctions of nonzero eigenvalues,

$$0 = \int \mathrm{d}^3x[\{u_n(\mathbf{x}) - v_n(\mathbf{x})\}f(\mathbf{x})], \tag{46a}$$

$$0 = \int \mathrm{d}^3x[\{u_n(\mathbf{x}) + v_n(\mathbf{x})\}h(\mathbf{x})], \tag{46b}$$

$$\tfrac{1}{2} = \int \mathrm{d}^3x\, f(\mathbf{x})h(\mathbf{x}). \tag{46c}$$

The last line fixes the value of I. The completeness condition now reads as

$$\sum_{n=1}^{\infty}[u_n(\mathbf{x})u_n(\mathbf{x}') - v_n(\mathbf{x})v_n(\mathbf{x}')] + [f(\mathbf{x})h(\mathbf{x}') + h(\mathbf{x})f(\mathbf{x}')] = \delta^3(\mathbf{x}-\mathbf{x}'), \tag{47a}$$

$$\sum_{n=1}^{\infty}[u_n(\mathbf{x})v_n(\mathbf{x}') - v_n(\mathbf{x})u_n(\mathbf{x}')] + [f(\mathbf{x})h(\mathbf{x}') - h(\mathbf{x})f(\mathbf{x}')] = 0. \tag{47b}$$

Consider the field operators. We introduce the oscillator-operators $\hat{\alpha}_n(t)=\hat{\alpha}_n e^{-iE_{B,n}t}$ and $\hat{\alpha}_n^{\dagger}(t) = \hat{\alpha}_n^{\dagger}e^{iE_{B,n}t}$ associated with $u_n(\mathbf{x})$ and $v_n(\mathbf{x})$, respectively, and also a set of canonical variables $\{\hat{\mathcal{Q}}(t),\hat{\mathcal{P}}(t)\}$ for $f(\mathbf{x})$ and $h(\mathbf{x})$,

$$[\hat{\alpha}_n, \hat{\alpha}_m^\dagger] = \delta_{nm}, \tag{48}$$

$$[\hat{\mathcal{Q}}(t), \hat{\mathcal{P}}(t)] = i, \tag{49}$$

and other vanishing commutation relations. Then the field operators are expanded as

$$\hat{\varphi}(x) = \hat{\mathcal{P}}(t)h(\mathbf{x}) - i\hat{\mathcal{Q}}(t)f(\mathbf{x}) + \sum_{n=1}^{\infty} [\hat{\alpha}_n(t)u_n(\mathbf{x}) - \hat{\alpha}_n^\dagger(t)v_n(\mathbf{x})], \tag{50a}$$

$$\hat{\varphi}^\dagger(x) = \hat{\mathcal{P}}(t)h(\mathbf{x}) + i\hat{\mathcal{Q}}(t)f(\mathbf{x}) + \sum_{n=1}^{\infty} [\hat{\alpha}_n^\dagger(t)u_n(\mathbf{x}) - \hat{\alpha}_n(t)v_n(\mathbf{x})]. \tag{50b}$$

It is easy to check that the canonical commutation relations are derived from these expressions and the completeness condition in Eq. (47). Also the substitution of Eq. (50) into the $\hat{H}_0$ in Eq. (15) leads to

$$\hat{H}_0 = \frac{\hat{\mathcal{P}}^2}{2I} + \sum_{n=1}^{\infty} [E_{B,n}\hat{\alpha}_n^\dagger\hat{\alpha}_n + (c\text{-numbers})], \tag{51}$$

where we have employed the orthonormal conditions, (13), (44), and (46). Important observations here are that the canonical commutation relations would be violated without introducing $h(\mathbf{x})$ and that we have the term $\hat{\mathcal{P}}^2/(2I)$ in the Hamiltonian as a result of the existence of the NG mode.

V. RELATION BETWEEN GENERALIZED BOGOLIUBOV AND BOGOLIUBOV–DE GENNES APPROACHES

We have reviewed the GB and BdG approaches in the preceding two sections. Both of them seem to be consistent canonical theories in which the NG mode is taken account of properly.

On the other hand, the two approaches follow different procedures. For example, one sees in the BdG approach the appearance of canonical variables $\hat{\mathcal{P}}$ and $\hat{\mathcal{Q}}$, while one does not in the GB approach. Furthermore, in the BdG approach one apparently sees no problem of infrared divergence associated with the NG modes, while one encounters it in the GB approach.

Then arises a natural question whether the two approaches are equivalent. In this section, we first show that these two approaches are equivalent in the excitation modes. After that, we find a correspondence in the zero-mode eigenspaces of the two approaches, investigating the functions $f(\mathbf{x})$ and $h(\mathbf{x})$ in the BdG approach in terms of $w_n(\mathbf{x})$ in the GB one. Then the limit of $\varepsilon \to 0$ in the GB approach must be taken carefully.

First, let us deal with the following simultaneous equations for excited states with $n \geqslant 1$, equivalent to Eq. (43),[13]

$$(\mathcal{L} - \mathcal{M})u_{+,n}(\mathbf{x}) = E_{B,n}u_{-,n}(\mathbf{x}), \tag{52a}$$

$$(\mathcal{L} + \mathcal{M})u_{-,n}(\mathbf{x}) = E_{B,n}u_{+,n}(\mathbf{x}), \tag{52b}$$

where

$$u_{\pm,n}(\mathbf{x}) = u_n(\mathbf{x}) \pm v_n(\mathbf{x}). \tag{53}$$

Then we have

$$(\mathcal{L} + \mathcal{M})(\mathcal{L} - \mathcal{M})u_{+,n}(\mathbf{x}) = E_{B,n}^2 u_{+,n}(\mathbf{x}) \tag{54a}$$

$$(\mathcal{L} - \mathcal{M})(\mathcal{L} + \mathcal{M})u_{-,n}(\mathbf{x}) = E_{B,n}^2 u_{-,n}(\mathbf{x}). \tag{54b}$$

Suppose that the eigenfunctions $u_{\pm,n}(\mathbf{x})$ $(n=1,2,\ldots)$ in the BdG approach can be expanded in terms of $w_n^{(\varepsilon)}(\mathbf{x})$ $(n=0,1,\ldots)$ in the GB approach,

$$u_{\pm,n}(\mathbf{x}) = \sum_{m=0}^{\infty} R_{\pm,nm} w_m^{(\varepsilon)}(\mathbf{x}). \tag{55}$$

Substitute Eq. (55) into Eq. (52), apply Eq. (21), multiply $w_{n'}^{(\varepsilon)}(\mathbf{x})$ from the left and integrate over $\mathbf{x}$, then we derive the matrix equations

$$R_+ \boldsymbol{\epsilon} = E_B R_-, \tag{56a}$$

$$R_-(\boldsymbol{\epsilon} + 4U) = E_B R_+, \tag{56b}$$

where the matrix notations are $(E_B)_{nm}=E_{B,nm}$ and $(U)_{nm}=U_{nm}$ in Eq. (28), and $(\boldsymbol{\epsilon})_{nm}$ is defined in Eq. (32). Remark that the indices of $(R_\pm)_{nm}$ run from $n=1$ and $m=0$. From these equations derive the equations,

$$R_+ \boldsymbol{\epsilon}(\boldsymbol{\epsilon} + 4U) = E_B^2 R_+, \tag{57a}$$

$$R_-(\boldsymbol{\epsilon} + 4U)\boldsymbol{\epsilon} = E_B^2 R_-. \tag{57b}$$

One can easily find the solutions for $R_\pm$ by using $\mathcal{O}$ satisfying Eq. (33), that is,

$$R_+ = H_+ \mathcal{O} \boldsymbol{\epsilon}^{-1/2}, \tag{58a}$$

$$R_- = H_- \mathcal{O} \boldsymbol{\epsilon}^{1/2}, \tag{58b}$$

where $H_\pm$ are arbitrary matrices $(n=1,2,\ldots;m=0,1,2,\ldots)$ whose off-diagonal elements are vanishing. In fact we have from Eqs. (31)–(33),

$$R_+ \boldsymbol{\epsilon}(\boldsymbol{\epsilon} + 4U) = E_G^2 R_+, \tag{59a}$$

$$R_-(\boldsymbol{\epsilon} + 4U)\boldsymbol{\epsilon} = E_G^2 R_-, \tag{59b}$$

where $(E_G')_{nm}=E_{G,n}\delta_{nm}$ $(n,m=1,2,\ldots)$. The comparison of Eqs. (57) and (59) clearly shows that the energy spectra E_B and E_G are identical for excited states, so let us denote them simply by E. If we take

$$H_+ = E^{1/2}, \tag{60a}$$

$$H_- = E^{-1/2}, \tag{60b}$$

we can find in the limit of $\varepsilon \to 0$ from arguments in Sec. IV that

$$u_n(\mathbf{x}) = w_{Cn}^{(0)}(\mathbf{x}), \tag{61a}$$

$$v_n(\mathbf{x}) = w_{Sn}^{(0)}(\mathbf{x}). \tag{61b}$$

Thus it has been proved that the two approaches are essentially equivalent to each other in the excited modes.

Next, in order to include the zero-mode eigenspace, we introduce a new function $h_\varepsilon(\mathbf{x})$, corresponding to Eq. (45), through the relation,

$$(\mathcal{L}+\mathcal{M})h_\varepsilon(\mathbf{x})=\frac{1}{I_\varepsilon}f_\varepsilon(\mathbf{x}). \tag{62}$$

Here $f_\varepsilon(\mathbf{x})$ is defined in Eq. (11) with Eq. (9), and the constant I_ε is determined from the condition

$$\frac{1}{2}=\int \mathrm{d}^3x\, f_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}). \tag{63}$$

It is clear from their definitions that the functions $f_\varepsilon(\mathbf{x})$ and $h_\varepsilon(\mathbf{x})$ and the constant I_ε reduce to $f(\mathbf{x})$, $h(\mathbf{x})$, and I, respectively, as ε goes to zero.

We attempt to expand $h_\varepsilon(\mathbf{x})$ in terms of $\{w_n^{(\varepsilon)}\}$,

$$h_\varepsilon(\mathbf{x})=\sum_{n=0}^{\infty}k_n w_n^{(\varepsilon)}(\mathbf{x}). \tag{64}$$

Remark that $w_0^{(\varepsilon)}(\mathbf{x})$ is included in this summation. Substitute this into Eq. (45),

$$(\mathcal{L}+\mathcal{M})h_\varepsilon(\mathbf{x})=\sum_{n=0}^{\infty}k_n[(\epsilon_n+\varepsilon\overline{\epsilon})+2\mathcal{M}]w_n^{(\varepsilon)}(\mathbf{x})=\frac{1}{I_\varepsilon}f_\varepsilon(\mathbf{x}), \tag{65}$$

and multiply it by $\int \mathrm{d}^3x\, w_m^{(\varepsilon)}(\mathbf{x})$, one obtains in the matrix notation

$$[\boldsymbol{\epsilon}+4U]k=\frac{1}{I_\varepsilon}e_0, \tag{66}$$

with $(e_0)_n=\delta_{0n}$ and $(k)_n=k_n$. We manipulate this as

$$[\boldsymbol{\epsilon}^2+4\boldsymbol{\epsilon}^{1/2}U\boldsymbol{\epsilon}^{1/2}]\boldsymbol{\epsilon}^{-1/2}k=W\boldsymbol{\epsilon}^{-1/2}k=\frac{1}{I_\varepsilon}\boldsymbol{\epsilon}^{1/2}e_0, \tag{67}$$

where W is defined in Eq. (34), and we have

$$k=\frac{1}{I_\varepsilon}\boldsymbol{\epsilon}^{1/2}W^{-1}\boldsymbol{\epsilon}^{1/2}e_0. \tag{68}$$

We remark that $(\boldsymbol{\epsilon})_{nm}$ should be interpreted not as $\epsilon_n\delta_{nm}$ but as $(\epsilon_n+\varepsilon\overline{\epsilon})\delta_{nm}$. Since $\mathcal{O}W^{-1}\mathcal{O}^T=E_G^{-2}$ from Eq. (33) and $C-S=E_G^{-1/2}\mathcal{O}\boldsymbol{\epsilon}^{1/2}$ from Eq. (31), Eq. (68) reduces to

$$k=\frac{1}{I_\varepsilon}(C-S)^TE_G^{-1}(C-S)e_0. \tag{69}$$

The behaviors of the matrices E_G^{-1}, $(C-S)$, and $(C+S)=E_G^{1/2}\mathcal{O}\boldsymbol{\epsilon}^{-1/2}$ with respect to ε can be estimated from Sec. III,

$$E_G^{-1}=\begin{pmatrix}O(\varepsilon^{-1/2}) & 0\\ 0 & O(\varepsilon^0)\end{pmatrix} \tag{70a}$$

$$C-S=\begin{pmatrix}O(\varepsilon^{1/4}) & O(\varepsilon^{1/4})\\ O(\varepsilon) & O(\varepsilon^0)\end{pmatrix} \tag{70b}$$

$$C+S=\begin{pmatrix}O(\varepsilon^{-1/4}) & O(\varepsilon^{3/4})\\ O(\varepsilon^0) & O(\varepsilon^0)\end{pmatrix}, \tag{70c}$$

where the first rows and columns correspond to $n=0$, and the second ones to $n=1,2,\ldots$. Therefore, up to the leading order of ε, we have after some manipulations

$$E_G^{-1}(C-S)e_0 = \overline{E_0}^{-3/4}(\varepsilon\overline{\epsilon})^{-1/4}e_0 + O(\varepsilon). \tag{71}$$

Recall the definition of Eq. (37) for $\overline{E_0}$ which is independent of ε. Finally k becomes

$$k = \frac{1}{I_\varepsilon}\overline{E_0}^{-3/4}(\varepsilon\overline{\epsilon})^{-1/4}(C-S)^T e_0 + O(\varepsilon), \tag{72}$$

implying that

$$\begin{aligned} h_\varepsilon(\mathbf{x}) &= \frac{1}{I_\varepsilon}(\overline{E_0})^{-3/4}(\varepsilon\overline{\epsilon})^{-1/4}(w_{C0}^{(\varepsilon)}(\mathbf{x}) - w_{S0}^{(\varepsilon)}(\mathbf{x})) + O(\varepsilon) \\ &= \frac{1}{I_\varepsilon}\overline{E_0}^{-1}\left[w_0^{(\varepsilon)}(\mathbf{x}) - \sum_{n=1}^{\infty}(u'^T W'^{-1})_n \epsilon_n^{1/2} w_n^{(\varepsilon)}(\mathbf{x}) \right] + O(\varepsilon^{1/2}). \end{aligned} \tag{73}$$

The constant I_ε can be evaluated from Eq. (73), Eq. (63), and $f_\varepsilon(\mathbf{x}) = w_0^{(\varepsilon)}(\mathbf{x})$,

$$I_\varepsilon = \frac{2}{\overline{E_0}} + O(\varepsilon^{1/2}). \tag{74}$$

Then we have an explicit form of $h_\varepsilon(\mathbf{x})$ as

$$h_\varepsilon(\mathbf{x}) = \frac{1}{2}\left[w_0^{(0)}(\mathbf{x}) - \sum_{n=1}^{\infty}(u'^T W'^{-1})_n \epsilon_n^{1/2} w_n^{(0)}(\mathbf{x}) \right] + O(\varepsilon^{1/2}). \tag{75}$$

We rewrite the function $f_\varepsilon(\mathbf{x})$, which is $w_0^{(0)}(\mathbf{x})$ in the limit of $\varepsilon \to 0$, as

$$f_\varepsilon(\mathbf{x}) = w_0^{(\varepsilon)}(\mathbf{x}) = (\overline{E_0})^{-1/4}(\varepsilon\overline{\epsilon})^{1/4}[(w_{C0}(\mathbf{x}) + w_{S0}(\mathbf{x})) + O(\varepsilon^{1/2})], \tag{76}$$

since then the completeness condition becomes evident [see Eqs. (20) and (47) with Eq. (61)],

$$\begin{aligned} \delta^3(\mathbf{x}-\mathbf{x}') &= \sum_{n=0}^{\infty} w_n^{(\varepsilon)}(\mathbf{x}) w_n^{(\varepsilon)}(\mathbf{x}') \\ &= \sum_{n=1}^{\infty}[w_{Cn}^{(\varepsilon)}(\mathbf{x}) w_{Cn}^{(\varepsilon)}(\mathbf{x}') - w_{Sn}^{(\varepsilon)}(\mathbf{x}) w_{Sn}^{(\varepsilon)}(\mathbf{x}')] + [f_\varepsilon(\mathbf{x}) h_\varepsilon(\mathbf{x}') + h_\varepsilon(\mathbf{x}) f_\varepsilon(\mathbf{x}')]. \end{aligned} \tag{77}$$

This way it has been confirmed that $f_\varepsilon(\mathbf{x})$ and $h_\varepsilon(\mathbf{x})$ thus defined in the GB approach correspond to $f(\mathbf{x})$ and $h(\mathbf{x})$ in the BdG approach in the limit of $\varepsilon \to 0$.

As the next step, we rewrite the oscillatorlike operator $\hat{b}_0$ by a new set of canonical operators $\{\hat{\mathcal{Q}}_b, \hat{\mathcal{P}}_b\}$,

$$\hat{b}_0 = \frac{1}{\sqrt{2}}(\hat{\mathcal{P}}_b - i\hat{\mathcal{Q}}_b), \tag{78a}$$

$$\hat{b}_0^\dagger = \frac{1}{\sqrt{2}}(\hat{\mathcal{P}}_b + i\hat{\mathcal{Q}}_b), \tag{78b}$$

with

$$[\hat{\mathcal{Q}}_b, \hat{\mathcal{P}}_b] = i \tag{79}$$

and

$$[\hat{\mathcal{Q}}_b, \hat{\mathcal{Q}}_b] = [\hat{\mathcal{P}}_b, \hat{\mathcal{P}}_b] = 0. \tag{80}$$

Using Eqs. (73), (76), and (75) one can express the field operator in the GB approach as

$$\hat{\varphi}(x) = \hat{b}_0(t) w_{C0}^{(\varepsilon)}(\mathbf{x}) - \hat{b}_0^\dagger(t) w_{S0}^{(\varepsilon)}(\mathbf{x}) + \hat{\varphi}_{\mathrm{exc}}(x) = \xi \hat{\mathcal{P}}_b(t) h_\varepsilon(\mathbf{x}) - i\xi^{-1} \hat{\mathcal{Q}}_b(t) f_\varepsilon(\mathbf{x}) + \hat{\varphi}_{\mathrm{exc}}(x) + O(\varepsilon^{1/2}), \tag{81}$$

where

$$\xi = \sqrt{2}\overline{E_0}^{-1/4} (\varepsilon \overline{\epsilon})^{1/4}, \tag{82}$$

$$\hat{\varphi}_{\mathrm{exc}}(x) = \sum_{n=1}^{\infty} [\hat{b}_n(t) w_{Cn}^{(\varepsilon)}(\mathbf{x}) - \hat{b}_n^\dagger(t) w_{Sn}^{(\varepsilon)}(\mathbf{x})]. \tag{83}$$

Recall Eq. (74) and that $\varphi_{\mathrm{exc}}(x)$ is common, which has been proved in the first part of this section, and we see that Eqs. (81) and (50) become identical to each other in the limit of $\varepsilon \to 0$, if we identify

$$\hat{\mathcal{P}} = \xi \hat{\mathcal{P}}_b, \tag{84a}$$

$$\hat{\mathcal{Q}} = \xi^{-1} \hat{\mathcal{Q}}_b. \tag{84b}$$

Namely, the field operators in the GB approach may be expressed as

$$\hat{\varphi}(x) = \hat{\mathcal{P}}(t) h_\varepsilon(\mathbf{x}) - i \hat{\mathcal{Q}}(t) f_\varepsilon(\mathbf{x}) + \hat{\varphi}_{\mathrm{exc}}(x) + O(\varepsilon^{1/2}), \tag{85a}$$

$$\hat{\varphi}^\dagger(x) = \hat{\mathcal{P}}(t) h_\varepsilon(\mathbf{x}) + i \hat{\mathcal{Q}}(t) f_\varepsilon(\mathbf{x}) + \hat{\varphi}_{\mathrm{exc}}^\dagger(x) + O(\varepsilon^{1/2}). \tag{85b}$$

The Hamiltonian (30) in the GB approach is in terms of $\hat{\mathcal{P}}$ and $\hat{\mathcal{Q}}$,

$$\begin{aligned} \hat{H}_0 &= \frac{1}{2I_\varepsilon} \xi^2 \hat{\mathcal{P}}_b^2 + (\varepsilon \overline{\epsilon}) \xi^{-2} \hat{\mathcal{Q}}_b^2 + \sum_{n=1}^{\infty} E_n \hat{b}_n^\dagger \hat{b}_n + (c\text{-numbers}) \\ &= \frac{1}{2I_\varepsilon} \hat{\mathcal{P}}^2 + (\varepsilon \overline{\epsilon}) \hat{\mathcal{Q}}^2 + \sum_{n=1}^{\infty} E_n \hat{b}_n^\dagger \hat{b}_n + (c\text{-numbers}) \to \frac{1}{2I} \hat{\mathcal{P}}^2 + \sum_{n=1}^{\infty} E_n \hat{b}_n^\dagger \hat{b}_n + (c\text{-numbers}), \end{aligned} \tag{86}$$

which is the same as Eq. (51).

Thus Eqs. (78), (82), and (84) reveal the correspondence between the two sets of operators representing the NG modes in the two approaches, $\{\hat{b}_0, \hat{b}_0^\dagger\}$ and $\{\hat{\mathcal{P}}, \hat{\mathcal{Q}}\}$, in the limit of $\varepsilon \to 0$.

VI. SUMMARY AND DISCUSSIONS

It was shown explicitly in this paper that in the unperturbed representation for systems of the trapped BECs (i) the operators of excitation modes in the GB and BdG approaches are identical, and (ii) the operators $\hat{b}_0$ and $\hat{b}_0^\dagger$ of the NG mode in the GB approach are related to the quantum coordinates $\hat{\mathcal{P}}$ and $\hat{\mathcal{Q}}$ in the BdG approach through the linear relations (78) and (84) with Eq. (82). The introduction of the breaking term in Eq. (4) and the parameter ε in the GB is very important to find the relations. The formal equivalence of the two approaches is established since the operators turned out to be related to each other linearly.

We note that the scale transformation [see Eq. (84)],

$$\hat{\mathcal{P}}_b \to \hat{\mathcal{P}} = \xi \hat{\mathcal{P}}_b, \tag{87a}$$

$$\hat{\mathcal{Q}}_b \to \hat{\mathcal{Q}} = \xi^{-1} \hat{\mathcal{Q}}_b, \tag{87b}$$

which is canonical, corresponds to the squeezing, although it is singular as ξ^{-1} diverges in the limit of $\varepsilon \to 0$.

Let us discuss on vacuum states. Because of the result (i), the vacuum structures with respect to the excitation modes are identical in the two approaches, we simply require

$$\hat{b}_n |\Omega_{\text{exc}}\rangle = 0 \quad (n \geqslant 1). \tag{88}$$

But there are two ways to determine the vacuum structure in the NG mode sector. One is a prescription, naturally adopted in the GB approach, to have the vacuum defined by

$$\hat{b}_0 |\Omega_0\rangle = 0. \tag{89}$$

Here the operator $\hat{b}_0$ is treated as a gapless mode. The other is to have no unique vacuum but a quantum mechanical state associated with the quantum coordinates $\{\hat{\mathcal{P}}, \hat{\mathcal{Q}}\}$, denoted by $|Q\rangle$. Although this state must satisfy

$$\langle Q|\hat{\mathcal{Q}}|Q\rangle = \langle Q|\hat{\mathcal{P}}|Q\rangle = 0, \tag{90}$$

due to the condition

$$\langle \Omega|\hat{\varphi}(x)|\Omega\rangle = 0, \tag{91}$$

where $|\Omega\rangle$ is the total vacuum, it cannot be determined completely from general considerations. As an example, one may take for it a Gaussian wave function, centered at $Q=0$. Here Q is a quantum number associated with the operator $\hat{\mathcal{Q}}$.

In summary, we have the two types of total vacuum, depending on whether the NG mode is treated as a gapless mode or as quantum coordinates,

$$|\Omega\rangle = \begin{cases} |\Omega_0\rangle \otimes |\Omega_{\text{exc}}\rangle & \text{(as gapless mode)}, \\ |Q\rangle \otimes |\Omega_{\text{exc}}\rangle & \text{(as quantum coordinate)}. \end{cases} \tag{92}$$

One should not confuse the choice of approach and that of vacuum. We can develop in the GB approach a consistent formulation with the vacuum $|Q\rangle \otimes |\Omega_{\text{exc}}\rangle$ as quantum coordinates, guided by the relations (78) and (84) with Eq. (82). What matters physically is the choice of vacuum but not that of approach. We are discussing the unperturbed representation in this paper. The choice of unperturbed vacuum affects the unperturbed (free) propagator and inevitably all of the higher order effects. The corrections at one-loop level to the original GP equation have been evaluated when the vacuum $|\Omega_0\rangle \otimes |\Omega_{\text{exc}}\rangle$ is chosen.[8] We have reported the evaluation of the same corrections with the choice of $|Q\rangle \otimes |\Omega_{\text{exc}}\rangle$ in Ref. 14. The expressions for free propagators with $|Q\rangle \otimes |\Omega_{\text{exc}}\rangle$ are given in the Appendix, while those with $|\Omega_0\rangle \otimes |\Omega_{\text{exc}}\rangle$ are found in Ref. 8.

APPENDIX: PROPAGATORS USING QUANTUM COORDINATES

In this Appendix, we construct unperturbed (free) propagators with $|Q\rangle\otimes|\Omega_{\rm exc}\rangle$. These are necessary to calculate quantum and thermal corrections.

The time dependence of $\hat{\mathcal{Q}}$ and $\hat{\mathcal{P}}$ are governed by the Hamiltonian (86),

$$\hat{\mathcal{Q}}(t)=\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{Q}}+\frac{1}{\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}}\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{P}}, \tag{A1a}$$

$$\hat{\mathcal{P}}(t)=\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{P}}-(\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon})\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{P}}, \tag{A1b}$$

where $\bar{\mathcal{E}}=\sqrt{\bar{\epsilon}\bar{E}_0}+O(\varepsilon)$.

We substitute Eq. (A1) into the field operators in Eq. (85),

$$\hat{\varphi}(x)=[\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{P}}-\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{Q}}]h_\varepsilon(\mathbf{x})-i\left[\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{Q}}+\frac{1}{\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}}\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{P}}\right]f_\varepsilon(\mathbf{x})$$
$$+\hat{\varphi}_{\rm exc}(x)+O(\varepsilon), \tag{A2a}$$

$$\hat{\varphi}^\dagger(x)=[\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{P}}-\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{Q}}]h_\varepsilon(\mathbf{x})+i\left[\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{Q}}+\frac{1}{\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}}\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\hat{\mathcal{P}}\right]f_\varepsilon(\mathbf{x})$$
$$+\hat{\varphi}^\dagger_{\rm exc}(x)+O(\varepsilon). \tag{A2b}$$

When the limit $\varepsilon\to 0$ is taken, they are

$$\hat{\varphi}(x)=\hat{\mathcal{P}}h(\mathbf{x})-i\left(\hat{\mathcal{Q}}+\frac{1}{I}\hat{\mathcal{P}}t\right)f(\mathbf{x})+\hat{\varphi}_{\rm exc}(x), \tag{A3a}$$

$$\hat{\varphi}^\dagger(x)=\hat{\mathcal{P}}h(\mathbf{x})+i\left(\hat{\mathcal{Q}}+\frac{1}{I}\hat{\mathcal{P}}t\right)f(\mathbf{x})+\hat{\varphi}^\dagger_{\rm exc}(x). \tag{A3b}$$

These representations are the same as in Ref. 12.

Next, let us construct the propagators with Eq. (A2) and the vacuum $|Q\rangle\otimes|\Omega_{\rm exc}\rangle$. The 2×2-matrix propagator is derived as

$$\mathbf{G}_Q(\mathbf{x},\mathbf{x}';t,t')=\begin{pmatrix}G_{Q,11}(\mathbf{x},\mathbf{x}';t,t') & G_{Q,12}(\mathbf{x},\mathbf{x}';t,t')\\ G_{Q,21}(\mathbf{x},\mathbf{x}';t,t') & G_{Q,22}(\mathbf{x},\mathbf{x}';t,t')\end{pmatrix}, \tag{A4}$$

where

$$G_{Q,11}(\mathbf{x},\mathbf{x}';t,t')\equiv\langle\Omega|\mathcal{T}[\hat{\varphi}(x)\hat{\varphi}^\dagger(x')]|\Omega\rangle=\Bigg[\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t')h_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}')$$
$$+\left(\frac{1}{\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}}\right)^2\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t')f_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}')$$
$$+i\frac{1}{\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}}\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t')h_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}')$$
$$-i\frac{1}{\sqrt{\varepsilon\bar{\mathcal{E}}I_\varepsilon}}\sin(\sqrt{\varepsilon\bar{\mathcal{E}}}t)\cos(\sqrt{\varepsilon\bar{\mathcal{E}}}t')f_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}')\Bigg]\langle Q|\hat{\mathcal{P}}^2|Q\rangle$$

$$
\begin{aligned}
&+ [\cos(\sqrt{\varepsilon\mathcal{E}}t)\cos(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}') + (\sqrt{\varepsilon\mathcal{E}}I_\varepsilon)^2\sin(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')h_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}') \\
&+ i(\sqrt{\varepsilon\mathcal{E}}I_\varepsilon)\cos(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}') \\

&+ \frac{1}{\sqrt{\varepsilon\mathcal{E}I_\varepsilon}}\cos(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}') + i\sin(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')h_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}') \\
&- i\cos(\sqrt{\varepsilon\mathcal{E}}t)\cos(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}')\Bigg]\Bigg\}\langle Q|\hat{\mathcal{P}}\hat{\mathcal{Q}}|Q\rangle \\
&+ \Bigg\{\theta(t-t')\Bigg[-(\sqrt{\varepsilon\mathcal{E}I_\varepsilon})\sin(\sqrt{\varepsilon\mathcal{E}}t)\cos(\sqrt{\varepsilon\mathcal{E}}t')h_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}') \\
&+ \frac{1}{\sqrt{\varepsilon\mathcal{E}I_\varepsilon}}\cos(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}') - i\cos(\sqrt{\varepsilon\mathcal{E}}t)\cos(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}') \\
&+ i\sin(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')h_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}')\Bigg] + \theta(t'-t) \\
&\times\Bigg[-(\sqrt{\varepsilon\mathcal{E}I_\varepsilon})\cos(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')h_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}') \\
&+ \frac{1}{\sqrt{\varepsilon\mathcal{E}I_\varepsilon}}\sin(\sqrt{\varepsilon\mathcal{E}}t)\cos(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}') - i\cos(\sqrt{\varepsilon\mathcal{E}}t)\cos(\sqrt{\varepsilon\mathcal{E}}t')h_\varepsilon(\mathbf{x})f_\varepsilon(\mathbf{x}') \\
&+ i\sin(\sqrt{\varepsilon\mathcal{E}}t)\sin(\sqrt{\varepsilon\mathcal{E}}t')f_\varepsilon(\mathbf{x})h_\varepsilon(\mathbf{x}')\Bigg]\Bigg\}\langle Q|\hat{\mathcal{Q}}\hat{\mathcal{P}}|Q\rangle \qquad \text{(A7)}
\end{aligned}
$$

$$
G_{Q,21}(\mathbf{x},\mathbf{x}';t,t') = G_{Q,12}(\mathbf{x}',\mathbf{x};t',t). \qquad \text{(A8)}
$$

In the above definitions, we use the notation for propagators without NG mode,

$$
G_{\mathrm{exc},11}(\mathbf{x},\mathbf{x}';t-t') \equiv \langle\Omega_{\mathrm{exc}}|T[\hat{\varphi}_{\mathrm{exc}}(x)\hat{\varphi}^\dagger_{\mathrm{exc}}(x')]|\Omega_{\mathrm{exc}}\rangle, \qquad \text{(A9a)}
$$

$$G_{\mathrm{exc},12}(\mathbf{x},\mathbf{x}';t-t') \equiv \langle \Omega_{\mathrm{exc}}|T[\hat{\varphi}_{\mathrm{exc}}(\mathbf{x})\hat{\varphi}_{\mathrm{exc}}(\mathbf{x}')]|\Omega_{\mathrm{exc}}\rangle, \tag{A9b}$$

$$G_{\mathrm{exc},21}(\mathbf{x},\mathbf{x}';t-t') \equiv \langle \Omega_{\mathrm{exc}}|T[\hat{\varphi}^{\dagger}_{\mathrm{exc}}(\mathbf{x})\hat{\varphi}^{\dagger}_{\mathrm{exc}}(x')]|\Omega_{\mathrm{exc}}\rangle, \tag{A9c}$$

$$G_{\mathrm{exc},22}(\mathbf{x},\mathbf{x}';t-t') \equiv \langle \Omega_{\mathrm{exc}}|T[\hat{\varphi}^{\dagger}_{\mathrm{exc}}(x)\hat{\varphi}_{\mathrm{exc}}(x')]|\Omega_{\mathrm{exc}}\rangle. \tag{A9d}$$

One can find their explicit forms in Ref. 8.

In the limit of $\varepsilon \to 0$, the propagators become

$$\begin{aligned} G_{Q,11}(\mathbf{x},\mathbf{x}';t,t') = & \left[h(\mathbf{x})h(\mathbf{x}') + f(\mathbf{x})f(\mathbf{x}')\left(\frac{t}{I}\right)\left(\frac{t'}{I}\right) + ih(\mathbf{x})f(\mathbf{x}')\left(\frac{t'}{I}\right) - if(\mathbf{x})h(\mathbf{x}')\left(\frac{t}{I}\right)\right]\langle Q|\hat{\mathcal{P}}^2|Q\rangle \\ & + f(\mathbf{x})f(\mathbf{x}')\langle Q|\hat{\mathcal{Q}}^2|Q\rangle + \left\{ \theta(t-t')\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t}{I}\right) + ih(\mathbf{x})f(\mathbf{x}')\right] + \theta(t'-t)\right. \\ & \left.\times\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t'}{I}\right) - if(\mathbf{x})h(\mathbf{x}')\right]\right\}\langle Q|\hat{\mathcal{P}}\hat{\mathcal{Q}}|Q\rangle + \left\{ \theta(t-t')\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t'}{I}\right)\right.\right. \\ & \left.\left. - if(\mathbf{x})h(\mathbf{x}')\right] + \theta(t'-t)\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t}{I}\right) + ih(\mathbf{x})f(\mathbf{x}')\right]\right\}\langle Q|\hat{\mathcal{Q}}\hat{\mathcal{P}}|Q\rangle \\ & + G_{\mathrm{exc},11}(\mathbf{x},\mathbf{x}';t-t'), \end{aligned} \tag{A10}$$

$$G_{Q,22}(\mathbf{x},\mathbf{x}';t,t') = G_{Q,11}(\mathbf{x}',\mathbf{x};t',t), \tag{A11}$$

$$\begin{aligned} G_{Q,12}(\mathbf{x},\mathbf{x}';t,t') = & \left[h(\mathbf{x})h(\mathbf{x}') + f(\mathbf{x})f(\mathbf{x}')\left(\frac{t}{I}\right)\left(\frac{t'}{I}\right) - ih(\mathbf{x})f(\mathbf{x}')\left(\frac{t'}{I}\right) - if(\mathbf{x})h(\mathbf{x}')\left(\frac{t}{I}\right)\right]\langle Q|\hat{\mathcal{P}}^2|Q\rangle \\ & + f(\mathbf{x})f(\mathbf{x}')\langle Q|\hat{\mathcal{Q}}^2|Q\rangle + \left\{ \theta(t-t')\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t}{I}\right) - ih(\mathbf{x})f(\mathbf{x}')\right] + \theta(t'-t)\right. \\ & \left.\times\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t'}{I}\right) - if(\mathbf{x})h(\mathbf{x}')\right]\right\}\langle Q|\hat{\mathcal{P}}\hat{\mathcal{Q}}|Q\rangle + \left\{ \theta(t-t')\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t'}{I}\right)\right.\right. \\ & \left.\left. - if(\mathbf{x})h(\mathbf{x}')\right] + \theta(t'-t)\left[f(\mathbf{x})f(\mathbf{x}')\left(\frac{t}{I}\right) - ih(\mathbf{x})f(\mathbf{x}')\right]\right\}\langle Q|\hat{\mathcal{Q}}\hat{\mathcal{P}}|Q\rangle \\ & + G_{\mathrm{exc},12}(\mathbf{x},\mathbf{x}';t-t'), \end{aligned} \tag{A12}$$

$$G_{Q,21}(\mathbf{x},\mathbf{x}';t,t') = G_{Q,12}(\mathbf{x}',\mathbf{x};t',t). \tag{A13}$$

On extensions of superconformal algebras

Jasbir Nagi[a)]
DAMTP, University of Cambridge, Cambridge CB3 0WA, United Kingdom

(Received 22 December 2004; accepted 7 January 2005; published online 25 March 2005)

Starting from vector fields that preserve a differential form on a Riemann sphere with Grassmann variables, one can construct a superconformal algebra by considering central extensions of the algebra of vector fields. In this paper, the $N=4$ case is analyzed closely, where the presence of weight zero operators in the field theory forces the introduction of noncentral extensions. How this modifies the existing field theory, representation theory, and Gelfand–Fuchs constructions is discussed. It is also discussed how graded Riemann sphere geometry can be used to give a geometrical description of the central charge in the $N=1$ theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1863652]

I. INTRODUCTION

Two-dimensional conformal symmetry in quantum field theory has, over the last 30 years, touched many parts of mathematics and theoretical physics. A quantum field theory that is conformally invariant is called a conformal field theory (CFT), and in this paper, only the case of two dimensions is examined. Lying at the heart of CFT is understanding how to treat the infinite conformal symmetry on the quantum level, and understanding the representation theory of the algebra. If one wants a nontrivial, unitary representation of the symmetry algebra (known as the DeWitt algebra), then a central extension must be introduced into the algebra, yielding the Virasoro algebra.[3] Hence, when considering any algebra which has the Virasoro algebra as a subalgebra, the understanding of how and what extensions can be added is of crucial importance. Two-dimensional CFTs present an example of a quantum field theory where there is a rich interplay between the geometry of the theory and the quantum theory. As a result, many aspects of the quantum theory can be described elegantly by the geometry. This is a point of view that this paper will use repeatedly.

In this paper, the case of the conformal symmetries of a Riemann sphere and graded Riemann sphere are examined. In Ref. 7 it was found that a graded Riemann sphere is a sensible space on which to try and construct a superconformal field theory (SCFT). On this space many results can be obtained, and primary fields (fields that "generate" the space of states) can be built in a natural manner associated to the geometry of the space. These spaces give rise to lie graded algebras of vector fields that contain the DeWitt algebra. Much work has been done on the extensions of these algebras in Ref. 6. Here, the $N=4$ case is revisited, with particular attention paid to the weight 0 fields that arise in the theory. These fields give unusual behavior, giving logarithms in the super OPE, and exhibiting some Jordan block structure in the adjoint representation. The structure, however, turns out to be quite manageable, since the behavior turns out to be quite similar to that of a free boson. The understanding of how to construct bosonic primary fields geometrically, as sections of a line bundle is extremely well covered in the CFT literature. However, it is also known, in the bosonic theory, how to construct central extensions geometrically.[10] Here, this is extended to the $N=1$ case, and is discussed how this might extend to higher N.

In Sec. II, the vector fields for the $N=4$ case are found, and extensions of the algebra considered, using just the graded Jacobi identity. In particular, it is found that if the algebra is not

[a)]Electronic mail: j.s.nagi@damtp.cam.ac.uk

reduced to its simple subalgebra, then the Jacobi identity implies that algebra must be extended by noncentral elements, if it is to contain the Virasoro algebra with nontrivial central charge. Section III examines how this fits into the operator formalism of CFT, where the starting point is usually an operator product expansion. There the subtlety arises from understanding what mode expansions to take for operators, and how to treat logarithms in the operator product expansion. Section IV looks at how the usual representation theory of the $N=4$ algebra will be altered with the noncentral extension found. Section V then considers how the algebra obtained fits into the formalism of Gelfand–Fuchs extensions, and how superspace techniques can be used to write them. Section VI then looks at the $N=1$ Gelfand–Fuchs cocycle, i.e., the $N=1$ central charge, and considers how to realize the cocycle as a geometric object on a graded Riemann sphere.

II. THE ALGEBRA OF VECTOR FIELDS

On a Riemann sphere, one obtains the DeWitt algebra by looking at the vector fields that preserve the one-form dz, a basis of which is given by

$$l_n = -z^{n+1}\frac{\partial}{\partial z}. \tag{1}$$

Calculating the commutation relations given by the lie bracket yields the DeWitt algebra

$$[l_n, l_m] = (n-m)l_{n+m}. \tag{2}$$

Similarly, on a graded Riemann sphere, with $N=4$ and the usual one-form $\omega = \mathrm{d}z + \Sigma_{i=1}^{4}\theta_i\,\mathrm{d}\theta_i$, one finds a basis of vector fields that preserve ω (Ref. 6),

$$l_n = -z^n\left(z\partial + \tfrac{1}{2}(n+1)\,\theta_i\partial_i\right),$$

$$g_r^j = z^{r+1/2}\left(\theta_j\partial - \partial_j + \frac{\left(r+\frac{1}{2}\right)}{z}\theta_j\theta_k\partial_k\right),$$

$$t_n^{ml} = z^n\left(\theta_l\partial_m - \theta_m\partial_l + \frac{n}{z}\theta_m\theta_l\theta_p\partial_p\right), \tag{3}$$

$$\psi_r^k = -z^{r-1/2}\left(\tfrac{1}{6}\epsilon_{kpqr}\theta_p\theta_q\theta_r\partial + \frac{\left(r-\frac{1}{2}\right)}{z}\theta_1\theta_2\theta_3\theta_4\partial_k + \tfrac{1}{2}\epsilon_{kpqr}\theta_p\theta_q\partial_r\right),$$

$$u_n = -z^{n-1}\left(\theta_1\theta_2\theta_3\theta_4\partial + \tfrac{1}{12}\epsilon_{ijkl}\theta_i\theta_j\theta_k\partial_l\right).$$

These vector fields give rise to the graded commutation relations under the graded Lie bracket,

$$[l_n, l_m] = (n-m)l_{m+n}, \quad [l_n, g_r^j] = \left(\frac{n}{2} - r\right)g_{n+r}^j, \quad [l_n, t_m^{pq}] = -mt_m^{pq},$$

$$[l_n, \psi_r^k] = \left(-\frac{n}{2} - r\right)\psi_{n+r}^k, \quad [l_n, u_m] = -(n+m)u_{m+n},$$

$$\begin{gathered}[g_r^j, g_s^k] = 2\delta_{jk}l_{r+s} + (s-r)t_{r+s}^{jk}, \quad [t_n^{ml}, g_r^j] = \delta_{mj}g_{n+r}^l - \delta_{lj}g_{n+r}^m + n\epsilon_{mljk}\psi_{n+r}^k, \\ [g_r^j, \psi_s^k] = \delta_{jk}2(r+s)u_{r+s} + \tfrac{1}{2}\epsilon_{jkpq}t_{r+s}^{pq}, \quad [g_r^j, u_n] = -\tfrac{1}{2}\psi_{n+r}^j,\end{gathered} \tag{4}$$

$$[t_n^{ml}, t_r^{pq}] = \delta_{mq} t_{n+r}^{pl} + \delta_{mp} t_{n+r}^{lq} + \delta_{lq} t_{n+r}^{mp} + \delta_{lp} t_{n+r}^{qm}, \quad [t_n^{ml}, u_p] = 0,$$

$$[t_n^{ml}, \psi_r^k] = \delta_{mk} \psi_{n+r}^l - \delta_{kl} \psi_{n+r}^m, \quad [\psi_r^k, \psi_s^j] = 0, \quad [\psi_r^k, u_n] = 0, \quad [u_m, u_n] = 0.$$

Note that this algebra is not simple, and that $[\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}/\langle u_o \rangle$ (quotient taken in the vector space sense) is simple. This simple algebra is the large $N=4$ algebra, without its three central elements. The t_n^{ml} form an so(4) loop algebra. This loop algebra may be written explicitly as so(4) = su(2) $\oplus$ su(2) by the change of basis

$$t_m^1 = \tfrac{1}{2}(t_m^{12} + t_m^{34}), \quad t_m^2 = \tfrac{1}{2}(t_m^{13} - t_m^{24}), \quad t_m^3 = \tfrac{1}{2}(t_m^{14} + t_m^{23}),$$

$$\overline{t}_m^1 = \tfrac{1}{2}(t_m^{34} - t_m^{12}), \quad \overline{t}_m^2 = \tfrac{1}{2}(-t_m^{13} - t_m^{24}), \quad \overline{t}_m^3 = \tfrac{1}{2}(t_m^{23} - t_m^{14}).$$

These su(2)s can then be centrally extended, to affine currents, with extension c and $\overline{c}$. Defining $c^+ = c + \overline{c}$ and $c^- = c - \overline{c}$, one finds the modified commutation relation,

$$[t_n^{ml}, t_r^{pq}] = \delta_{mq} t_{n+r}^{pl} + \delta_{mp} t_{n+r}^{lq} + \delta_{lq} t_{n+r}^{mp} + \delta_{lp} t_{n+r}^{qm} + (\delta_{mp}\delta_{lq} - \delta_{mq}\delta_{lp}) c^+ n \delta_{n+r,0} + \epsilon_{mlpq} c^- n \delta_{n+r,0}.$$

The c^- also modifies, by the Jacobi identity, the relations

$$[g_r^j, \psi_s^k] = \delta_{jk} 2(r+s) u_{r+s} + \tfrac{1}{2} \epsilon_{jkpq} t_{r+s}^{pq} + c^- \left(r + \tfrac{1}{2}\right) \delta_{jk} \delta_{r+s,0},$$

$$[l_n, u_m] = -(n+m) u_{m+n} - \frac{c^-}{4} (n+1) \delta_{m+n,0}.$$

The c^+ also modifies, by the Jacobi identity, the relations

$$[l_m, l_n] = (m-n) l_{m+n} - \frac{c^+}{4} m(m^2-1) \delta_{m+n,0},$$

$$[g_r^j, g_s^k] = 2\delta_{jk} l_{r+s} + (s-r) t_{r+s}^{jk} - c^+ \left(r^2 - \tfrac{1}{4}\right) \delta_{jk} \delta_{r+s,0},$$

$$[\psi_r^k, \psi_s^j] = c^+ \delta_{jk} \delta_{r+s,0}, \quad [u_m, u_n] = -\frac{c^+}{4m} \delta_{m+n,0} \quad \text{for } m \neq 0.$$

As it stands, the $\{g_r^j, \psi_s^j, u_0\}$ Jacobi identity implies $c^+ = 0$. This offending Jacobi identity is usually bypassed by working in $[\mathfrak{g}, \mathfrak{g}]$ rather than in $\mathfrak{g}$, but this is not the route that will be taken here. Nonzero c^+ can be obtained by adding another extension, denoted v_0. From the $[l_n, u_m]$ commutator, it can be seen that the u_m form a current of weight zero. This current can be deformed to include a logarithmic term, so that $u(z) = -\Sigma_n u_n z^{-n} + v_0 \log z$. This then modifies the commutation relations,

$$\begin{aligned} [l_n, u_m] &= -(m+n) u_{m+n} - v_0 \delta_{m+n,0}, \\ [g_r^j, \psi_s^k] &= 2\delta_{jk}((r+s) u_{r+s} + v_0 \delta_{r+s,0}) + \tfrac{1}{2} \epsilon_{jkpq} t_{r+s}^{pq}. \end{aligned} \tag{5}$$

Using the Jacobi identity, one can see that v_0 commutes with all elements, except u_0. The $\{g_r^j, \psi_s^j, u_0\}$ Jacobi identity now yields $[u_0, v_0] = c^+/4$. This algebra now realizes centrally extended $K'(4)$ (also known as large $N=4$) with the u_0 operator put back in. Note that in $K'(4)$, v_0 is a central extension.[6] The behavior of the u_m, v_0 is very similar to that of the modes of a free boson, identifying v_0 with momentum and u_0 with position. The commutation relations then become

$$[l_m,l_n]=(m-n)l_{m+n}-\frac{c^+}{4}m(m^2-1)\delta_{m+n,0},\quad [l_n,g_r^j]=\left(\frac{n}{2}-r\right)g_{n+r}^j,$$

$$[l_n,\psi_r^k]=\left(-\frac{n}{2}-r\right)\psi_{n+r}^k,\quad [l_n,u_m]=-(n+m)u_{m+n}-\left(\frac{c^-}{4}(n+1)+v_0\right)\delta_{m+n,0},$$

$$[g_r^j,g_s^k]=2\delta_{jk}l_{r+s}+(s-r)t_{r+s}^{jk}-c^+\left(r^2-\tfrac{1}{4}\right)\delta_{jk}\delta_{r+s,0},\quad [l_n,t_m^{pq}]=-mt_m^{pq},$$

$$[t_n^{ml},g_r^j]=\delta_{mj}g_{n+r}^l-\delta_{lj}g_{n+r}^m+n\epsilon_{mljk}\psi_{n+r}^k,\quad [g_r^j,u_n]=-\tfrac{1}{2}\psi_{n+r}^j,$$

$$[g_r^j,\psi_s^k]=\delta_{jk}2(r+s)u_{r+s}+\tfrac{1}{2}\epsilon_{jkpq}t_{r+s}^{pq}+\left(c^-\left(r+\tfrac{1}{2}\right)+2v_0\right)\delta_{jk}\delta_{r+s,0}, \tag{6}$$

$$[t_n^{ml},t_r^{pq}]=\delta_{mq}t_{n+r}^{pl}+\delta_{mp}t_{n+r}^{lq}+\delta_{lq}t_{n+r}^{mp}+\delta_{lp}t_{n+r}^{qm}+(\delta_{mp}\delta_{lq}-\delta_{mq}\delta_{lp})c^+n\delta_{n+r,0}+\epsilon_{mlpq}c^-n\delta_{n+r,0},$$

$$[t_n^{ml},u_p]=0,\quad [t_n^{ml},\psi_r^k]=\delta_{mk}\psi_{n+r}^l-\delta_{kl}\psi_{n+r}^m,\quad [\psi_r^k,\psi_s^j]=c^+\delta_{jk}\delta_{r+s,0},$$

$$[\psi_r^k,u_n]=0,\quad [u_m,u_n]=-\frac{c^+}{4m}\delta_{m+n,0},\quad [u_0,v_0]=\frac{c^+}{4}$$

with $c^{\pm}$ central, and v_0 has only one nontrivial commutator, namely $[u_0,v_0]$. Thus, while u_0,v_0 can both be considered to be operators at level 0, they cannot both be in the Cartan subalgebra. If v_0 is nonzero, one can choose it to be in the Cartan subalgebra. Usually, in a conformal field theory, one finds that the space of operators at level zero can be identified with the Cartan subalgebra. This is not the case here, and can potentially lead to Jordan blocks. In this sense, the $N=4$ theory can be thought of as a logarithmic theory, with the logarithmic character coming from $u(z)$. The usual large algebra comes from looking at the simple subalgebra obtained from identifying $u_0 \sim 0$, i.e., considering the field $\partial u(z)$ as fundamental rather than $u(z)$. To see where the logarithms actually come in, one must look at the operator formalism.

III. THE OPERATOR APPROACH

The super operator product expansion of the super Virasoro operator with a primary superfield for the $N=4$ case is given by[5]

$$\begin{aligned}\mathbb{T}(Z_1)\Phi(Z_2)\sim{}&\frac{h\theta_{12,1}\theta_{12,2}\theta_{12,3}\theta_{12,4}}{Z_{12}^2}\Phi(Z_2)+\frac{\theta_{12,1}\theta_{12,2}\theta_{12,3}\theta_{12,4}}{Z_{12}}\partial\Phi(Z_2)\\&+\frac{1}{12}\frac{\epsilon_{ijkl}\theta_{12,i}\theta_{12,j}\theta_{12,k}}{Z_{12}}D_l\Phi(Z_2)+\frac{1}{4}\frac{\epsilon_{ijkl}\theta_{12,i}\theta_{12,j}J^{kl}}{Z_{12}}\Phi(Z_2)+p\log(Z_{12})\Phi(Z_2),\end{aligned} \tag{7}$$

where $Z_1=(w,\chi_i)$, $Z_2=(z,\theta_i)$, $\theta_{12,i}=(\chi_i-\theta_i)$, $Z_{12}=(w-z-\chi_i\theta_i)$,

$$\mathbb{T}(Z_2)=\theta_1\theta_2\theta_3\theta_4L(z)+\tfrac{1}{12}\epsilon_{ijkl}\theta_i\theta_j\theta_kG^l(z)+\tfrac{1}{8}\epsilon_{ijkl}\theta_i\theta_jT^{kl}(z)+\tfrac{1}{2}\theta_k\psi^k(z)-U(z) \tag{8}$$

and the J^{ab} form an so (4) algebra with commutation relations given by $\frac{1}{2}t_0^{ab}$. $\log(Z_{12})$ is defined by

$$\log(Z_{12})=\log(w-z)-\sum_{p=1}^{4}\frac{1}{p}\left(\frac{\chi_i\theta_i}{(w-z)}\right)^p. \tag{9}$$

The χ_i components of each side can be taken, giving

$$L(w)\Phi(Z_2)\sim\left(\frac{h}{(w-z)^2}+\frac{1}{(w-z)}\partial+\frac{1}{2(w-z)^2}\theta_i\partial_i-\frac{\theta_i\theta_jJ^{ij}}{(w-z)^2}-\frac{6\theta_1\theta_2\theta_3\theta_4}{(w-z)^4}p\right)\Phi(Z_2),$$

$$\frac{1}{2}G^i(w)\Phi(Z_2)\sim\left(\frac{-h\theta_i}{(w-z)^2}-\frac{\theta_i\partial}{2(w-z)}+\frac{\partial_i}{2(w-z)}-\frac{\theta_i\theta_j\partial_j}{2(w-z)^2}+\frac{\theta_i\theta_j\theta_kJ^{jk}}{(w-z)^3}+\frac{\theta_jJ^{ji}}{(w-z)^2}-\frac{\epsilon_{ijkl}\theta_j\theta_k\theta_l}{3(w-z)^3}p\right)\Phi(Z_2),$$

$$\frac{1}{2}T^{ab}(w)\Phi(Z_2)\sim\left(\frac{h\theta_a\theta_b}{(w-z)^2}+\frac{\theta_b\partial_a-\theta_a\partial_b}{2(w-z)}+\frac{\theta_a\theta_b\theta_j\partial_j}{2(w-z)^2}-\frac{\theta_1\theta_2\theta_3\theta_4}{(w-z)^3}\epsilon_{abjk}J^{jk}+\frac{1}{(w-z)^2}(\theta_a\theta_jJ^{bj}-\theta_b\theta_jJ^{aj})+\frac{1}{(w-z)}J^{ab}+\frac{\epsilon_{abjk}\theta_j\theta_k}{2(w-z)^2}p\right)\Phi(Z_2),\tag{10}$$

$$\frac{1}{2}\psi^k(w)\Phi(Z_2)\sim\left(\frac{-h\epsilon_{klmn}\theta_l\theta_m\theta_n}{6(w-z)^2}+\frac{\epsilon_{klmn}\theta_l\theta_m\theta_n}{12(w-z)}\partial+\frac{\theta_1\theta_2\theta_3\theta_4}{2(w-z)^2}\partial_k+\frac{\epsilon_{klmn}\theta_l\theta_m}{4(w-z)}\partial_n-\frac{\epsilon_{klmn}\theta_l}{2(w-z)}J^{mn}+\frac{\theta_k\epsilon_{lmnp}\theta_l\theta_m}{4(w-z)^2}J^{np}-\frac{\theta_k}{(w-z)}p\right)\Phi(Z_2),$$

$$-U(w)\Phi(Z_2)\sim\left(\frac{h\theta_1\theta_2\theta_3\theta_4}{(w-z)^2}-\frac{\theta_1\theta_2\theta_3\theta_4}{(w-z)}\partial-\frac{\epsilon_{klmn}\theta_k\theta_l\theta_m}{12(w-z)}\partial_n+\frac{\epsilon_{klmn}\theta_k\theta_l}{4(w-z)}J^{mn}+\log(w-z)p\right)\Phi(Z_2)$$

from which the vector fields of (3) can be recovered. Note that logarithms only appear in OPEs containing $U(z)$. Clearly, in this last OPE, a contour integral can only be taken if $\partial U(w)\Phi(z)$ is considered. Taking $U(z)=\Sigma_nU_nz^{-n}+V_0\log z$, it can be shown that $[V_0,\Phi]=p\Phi$. Allowing V_0 to annihilate the vacuum[11] then yields $V_0|\Phi\rangle=p|\Phi\rangle$. The $[V_0,\Phi]$ commutator is unusual, in that it contains no differential operators. Hence, it is not obvious how to associate a conformal vector field of the form of (3) to V_0. The logarithm in the last OPE of (10) prevents one from obtaining an action from U_0. If one looks at a representation where $V_0=0$, then it can be seen that $p=0$ and that the w contour integral in $U(w)\Phi(z)$ can be performed, to give

$$[U_0,\Phi(Z)]\sim\left(\frac{h\theta_1\theta_2\theta_3\theta_4}{z^2}+\frac{\theta_1\theta_2\theta_3\theta_4\partial}{z}+\frac{\epsilon_{klmn}\theta_k\theta_l\theta_m\partial_n}{12z}-\frac{\epsilon_{klmn}\theta_k\theta_lJ^{mn}}{4z}\right)\Phi(Z).$$

However, its action on the highest weight from this approach is unclear, and a more careful approach to the representation theory is warranted.

The logarithmic character can also be examined by looking at the $\mathbb{T}(Z_1)\mathbb{T}(Z_2)$ OPE, given by

$$\mathbb{T}(Z_1)\mathbb{T}(Z_2)\sim\frac{c^+\log(Z_{12})}{4}-\frac{c^-\theta_{12,1}\theta_{12,2}\theta_{12,3}\theta_{12,4}}{4Z_{12}^2}+\frac{\theta_{12,1}\theta_{12,2}\theta_{12,3}\theta_{12,4}}{Z_{12}}\partial\mathbb{T}(Z_2)+\frac{1}{12}\frac{\epsilon_{ijkl}\theta_{12,i}\theta_{12,j}\theta_{12,k}}{Z_{12}}D_l\mathbb{T}(Z_2).\tag{11}$$

Using (9), one can see that the only term involving logarithms is the term,

$$U(w)U(z)\sim\frac{c^+}{4}\log(w-z).\tag{12}$$

Therefore, if $c^+\neq0$, $U(z)$ must have a logarithmic component in its mode expansion. This can easily be verified by taking the contour integrals in (12) to get the commutation relations. If there is no logarithmic component in $U(z)$, then from the computation one can deduce that $c^+=0$, the

same result found when using the Jacobi identity in the preceding section. The field $U(z)$ behaves in a very similar way to a free boson. In particular, $[V_0, U_0] = c^+/4$, and hence they are not mutually diagonalizable, as was reflected by the above manipulations of the last OPE in (10).

One can ask if the field, $U(z)$, can be written in a logarithmic form[1]

$$L(w)D(z) \sim \frac{hD(z) + E(z)}{(z-w)^2} + \frac{\partial D(z)}{(w-z)},$$

$$L(w)E(z) \sim \frac{hE(z)}{(z-w)^2} + \frac{\partial E(z)}{(w-z)}.$$

From (11) one can read off the $L(w)U(z)$ OPE to find

$$L(w)U(z) \sim \frac{\partial U(z)}{(w-z)} - \frac{c^-}{4(w-z)^2}. \tag{13}$$

Regarding $-c^-/4$ as a constant field of weight zero, one then gets the desired form. While the V_0 operator gives rise to an eigenvalue, this analysis does not yield a conformal transformation associated to V_0. The previous analysis shows that v_0 had to be introduced as an extension of the algebra. This suggests that rather than thinking of the p eigenvalue as being associated to a primary field, one should instead think of the V_0 operator as appearing in a similar way to a central extension.

IV. A LITTLE REPRESENTATION THEORY

A closer look at the level zero operators is warranted. These are normally defined as those operators with $\mathrm{ad}l_0$ eigenvalue being zero. Considering the commutation relations (6), one can see that clearly $\{l_0, t_0^{ml}, v_0, c^{\pm}\}$ fall into this category. However, u_0 has a strange action under $\mathrm{ad}l_0$, namely

$$[l_0, u_0] = -\left(\frac{c^-}{4} + v_0\right).$$

If one were to define a basis $e_1 = -(c^-/4) - v_0$, $e_2 = u_0$ and write down the matrix for $\mathrm{ad}l_0$ with respect to this basis, one would find the Jordan block

$$(\mathrm{ad}l_0) = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

In this manner, u_0 can be considered as an operator at level zero that is not in the Cartan subalgebra.

The algebra here differs slightly from the usual large $N=4$ algebra, by the mode u_0. This affects the representation theory. The Fock space will be enlargened, due to the presence of polynomials in u_0 acting on the highest weight. Using the analogy of v_0 as momentum, and u_0 as position, instead of considering the states $u_0^n|h\rangle$, the "momentum" eigenstates $|k,h\rangle = e^{-ku_0}|h\rangle$ can be considered. From the fact that the only nontrivial commutators u_0 has are with l_n, g_r^j, v_0, one can show

$$v_0|k,h\rangle = \left(\frac{c^+k}{4} + p\right)|k,h\rangle, \quad g_r^j|k,h\rangle = e^{-ku_0}g_r^j|h\rangle + \frac{k}{2}\psi_r^j|k,h\rangle,$$
$$l_n|k,h\rangle = \begin{cases} e^{-ku_0}l_n|h\rangle + knu_n|k,h\rangle, & n \neq 0, \\ \left(h + k\left(\frac{c^-}{4} + p\right) + k^2\frac{c^+}{8}\right)|k,h\rangle, & n = 0 \end{cases} \tag{14}$$

from which it can be seen that $|k,h\rangle$ obeys highest weight conditions, with potentially different v_0 and l_0 eigenvalues from $|h\rangle$. In analogy with a free boson, the u_n. $n>0$ annihilate the vacuum and the highest weight state and v_0 annihilates the vacuum. For nonzero c^+, u_0 annihilates neither.

V. GELFAND–FUCHS 2-COCYCLES

For an algebra of vector fields, where a function can be associated to each vector field, it is often useful to construct central extensions by considering Gelfand–Fuchs 2-cocycles.[4] Here, superfield formalisms are used, which yield similar results to Ref. 4. For instance, in the bosonic case, one has[10]

$$l_m = -z^{m+1}\frac{\partial}{\partial z}, \quad l(z) = z^{m+1}, \text{ then}$$
$$c(l_m,l_n) = \frac{1}{24\pi i}\oint_0 \mathrm{d}z\left(\frac{\partial^3}{\partial z^3}z^{m+1}\right)z^{n+1} = \frac{c}{12}m(m^2-1)\delta_{m+n,0} \tag{15}$$

or for a general polynomial $l(z)$

$$c(l_{(1)},l_{(2)}) = \frac{1}{24\pi i}\oint_0 \mathrm{d}z\, l'''_{(1)}l_{(2)}, \tag{16}$$

where the contour is a closed loop around the origin, say the unit circle, beginning and ending at $z=1$. Since the extensions are known for the $N=1$, 2,3,4 algebras, they can be set in Gelfand–Fuchs 2-cocycle form. For the $N=1$ case

$$l_n = -z^n\left(z\partial_z + \tfrac{1}{2}(n+1)\theta\partial_\theta\right), \quad l(z) = z^{n+1},$$
$$g_r = z^{r+1/2}(\partial_\theta - \theta\partial_z), \quad g(z) = z^{r+1/2}. \tag{17}$$

Defining the graded field $X_{(i)} = \frac{1}{2}l_{(i)} + \theta g_{(i)}$ with l and g graded even polynomials in z, z^{-1}, one finds the central extension is given by the 2-cocycle,

$$c(X_{(1)},X_{(2)}) = \frac{1}{6\pi i}\oint_0 \mathrm{d}z\,\mathrm{d}\theta(DX''_{(1)})X_{(2)}, \tag{18}$$

where $D = \partial_\theta + \theta\partial_z$, and, as usual, $\int \mathrm{d}\theta$ really means $\partial/\partial\theta$. Similarly, for $N=2$, the vector fields and associated fields are

$$l_n = -z^n\left(z\partial_z + \tfrac{1}{2}(n+1)\theta_i\partial_{\theta_i}\right), \quad l(z) = z^{m+1},$$
$$g_r^i = z^{r-1/2}\left(z\theta_i\partial_z - z\partial_{\theta_i} + \left(r+\tfrac{1}{2}\right)\theta_i\theta_j\partial_{\theta_j}\right), \quad g^i(z) = z^{r+1/2}, \tag{19}$$
$$t_m = -z^m(\theta_2\partial_{\theta_1} - \theta_1\partial_{\theta_2}), \quad t(z) = z^m.$$

Introducing the graded field,

$$X_{(i)} = \tfrac{1}{2} l_{(i)} + \theta_j g^j_{(i)} + \theta_1\theta_2 t_{(i)} \tag{20}$$

the 2-cocycle is given by

$$c(X_{(1)},X_{(2)}) = \frac{1}{6\pi i}\oint_0 \mathrm{d}z\, \mathrm{d}\theta_2\, \mathrm{d}\theta_1 (D_1 D_2 X'_{(1)}) X_{(2)}, \tag{21}$$

where $D_i = \partial_{\theta_i} + \theta_i \partial_z$. For $N=3$,

$$\begin{gathered}
l_n = -z^n\left(z\partial_z + \tfrac{1}{2}(n+1)\theta_i\partial_{\theta_i}\right), \quad l(z) = z^{m+1}, \\
g^i_r = z^{r-1/2}\left(z\theta_i\partial_z - z\partial_{\theta_i} + \left(r+\tfrac{1}{2}\right)\theta_i\theta_j\partial_{\theta_j}\right), \quad g^i(z) = z^{r+1/2}, \\
t^i_m = z^{m-1}(z\epsilon_{ijk}\theta_j\partial_{\theta_k} - m\theta_1\theta_2\theta_3\partial_{\theta_i}), \quad t^i(z) = z^m, \\
\psi_r = -z^{r-1/2}\left(\theta_1\theta_2\theta_3\partial_z + \tfrac{1}{2}\epsilon_{ijk}\theta_i\theta_k\partial_{\theta_k}\right), \quad \psi(z) = z^{r-1/2},
\end{gathered} \tag{22}$$

$$X_{(i)} = \tfrac{1}{2} l_{(i)} + \theta_j g^j_{(i)} + \tfrac{1}{2}\epsilon_{klm}\theta_k\theta_l t^m_{(i)} + \theta_1\theta_2\theta_3\psi_{(i)}, \tag{23}$$

$$c(X_{(1)},X_{(2)}) = \frac{1}{6\pi i}\oint_0 \mathrm{d}z\, \mathrm{d}\theta_3\, \mathrm{d}\theta_2\, \mathrm{d}\theta_1 (D_1 D_2 D_3 X_{(1)}) X_{(2)}. \tag{24}$$

Now, for $N=4$, $X_{(i)}$ is given by

$$X_{(i)} = \tfrac{1}{2} l_{(i)} + \theta_j g^j_{(i)} + \tfrac{1}{2}\theta_a\theta_b t^{ab}_{(i)} - \tfrac{1}{6}\epsilon_{abcd}\theta_a\theta_b\theta_c\psi^d_{(i)} - \theta_1\theta_2\theta_3\theta_4 \tfrac{1}{2} u_{(i)}, \tag{25}$$

where $u_{(i)} = z^{n-1}$ corresponds to the vector u_m in (3), and similarly for the other fields in $X_{(i)}$. In the cases so far, given an $X_{(i)}$, a conformal vector field can be obtained. It is worth considering what $X_{(i)}$ means in the operator approach. To this end, recall the super stress-energy tensor $\mathbb{T}$ from (8). From the OPE (11), it can be shown that $L(z)$ scales like a field of weight 2, and hence expansion $L(z) = \Sigma_m L_m z^{-m-2}$. Similarly, the other operators have scaling dimensions-G^i is $\frac{3}{2}$, T^{ij} is 1, ψ^j is $\frac{1}{2}$ and U is 0. In fact, the G^i, T^{ij}, ψ^j are primary fields. Now, rather than obtain the vector field associated to $X_{(i)}$, the operator associated to it can be obtained by computing

$$\frac{1}{\pi i}\oint_0 \mathrm{d}z\, \mathrm{d}\theta_4\, \mathrm{d}\theta_3\, \mathrm{d}\theta_2\, \mathrm{d}\theta_1\, X_{(i)}\mathbb{T}. \tag{26}$$

A similar formula[12] holds for the smaller N. Since V_0 is a part of $\mathbb{T}$, one can ask how to obtain the operator V_0 from the above integral, and see if it sheds light on how the $[u_0, v_0] = c^+/4$ commutator might be obtained. To this end, consider the logarithmic part of

$$\begin{aligned}
\frac{1}{\pi i}\int_{1+i\epsilon}^{1-i\epsilon} \mathrm{d}z \frac{1}{2} u(z) U(z) &= \frac{1}{\pi i}\int_{1+i\epsilon}^{1-i\epsilon} \mathrm{d}z \frac{1}{2} u(z) V_0 \log(z) \\
&= -\frac{1}{2\pi i}\int_{1+i\epsilon}^{1-i\epsilon} \mathrm{d}z \frac{1}{z} V_0 \int u + \frac{1}{2\pi i} V_0 \left[\log(z)\int u\right]_{1+i\epsilon}^{1-i\epsilon}.
\end{aligned} \tag{27}$$

Concentrating on the first part of the expression, it seems very suggestive to associate the constant part of $\int u$, which arises as an integration constant, to the algebra element v_0 (assuming $\int u$ is single valued around the origin, i.e., u has no $1/z$ term). This turns out to be precisely what is needed to obtain the c^+ 2-cocycle,

$$c^+(X_{(1)},X_{(2)}) = \frac{-1}{2\pi i}\oint_0 \mathrm{d}z\,\mathrm{d}\theta_4\,\mathrm{d}\theta_3\,\mathrm{d}\theta_2\,\mathrm{d}\theta_1\left(D_1D_2D_3D_4\int X_{(1)}\right)X_{(2)} \tag{28}$$

assuming the integrand is single valued around the origin. On expanding out the $X_{(i)}$ and applying all the superderivatives, the only component of $X_{(1)}$ that is actually integrated in $D_1D_2D_3D_4\int X_{(1)}$ is the $u_{(1)}$ component. This essentially means that $c^+(u_0,u_0)$ cannot be explicitly obtained, since the integrand would have logs in it. This, however, is not a problem, since $[u_0,u_0]=0$ by antisymmetry of the commutator. Also, $c^+(v_0,v_0)$ is not obtained, but by the same argument is clearly zero. Most importantly, if the integration constant is taken to be 1, then one can obtain $c^+(v_0,u_0)=-\frac{1}{4}$. The c^- cocycle can also be found,

$$c^-(X_{(1)},X_{(2)}) = -\frac{1}{2\pi i}\oint_0 \mathrm{d}z\,\mathrm{d}\theta_4\,\mathrm{d}\theta_3\,\mathrm{d}\theta_2\,\mathrm{d}\theta_1 X'_{(1)}X_{(2)} \tag{29}$$

as well as an expression for the v_0 extension,

$$v_0(X_{(1)},X_{(2)}) = \frac{2}{\pi i}\oint_0 \mathrm{d}z\,\mathrm{d}\theta_4\,\mathrm{d}\theta_3\,\mathrm{d}\theta_2\,\mathrm{d}\theta_1\left(\frac{1}{z}\left(1-\tfrac{1}{2}\theta_i\partial_{\theta_i}\right)X_{(1)}\right)X_{(2)}. \tag{30}$$

All of the extensions here for all N are consistent with the operator formalism. Apart from c^+ in $N=4$, which has a problem with logs, all the extensions can be obtained from the super OPE by calculating

$$-\frac{1}{4\pi}\oint_0 \mathrm{d}z\,\mathrm{d}\theta_N\cdots\mathrm{d}\theta_1\oint_z \mathrm{d}w\,\mathrm{d}\chi_N\cdots\mathrm{d}\chi_1\,X_{(1)}(Z_1)X_{(2)}(Z_2)\mathbb{T}(Z_1)\mathbb{T}(Z_2) \tag{31}$$

and give rise to the same formulas. The formulas also suggest that the extensions should be described by a map from two vector fields into something proportional to the volume form

$$C:\mathcal{D}^1\mathcal{A}_N\times\mathcal{D}^1\mathcal{A}_N\to \mathrm{d}z\otimes_i\frac{\partial}{\partial\theta_i}. \tag{32}$$

VI. *N*=1 GELFAND–FUCHS 2-COCYCLE

In (17), a parametrization of a vector field in terms of a field was written. One can try and explore how these fields are related to a graded Riemann sphere. First, redefine $X=\frac{1}{2}f(z)+g(z)\theta$, where now f and g need not have a defined parity, i.e., they are each a sum of an even part and an odd part. Now, introduce the map

$$l:X\mapsto -\left(f(z)\frac{\partial}{\partial z}+\frac{1}{2}f'(z)\theta D\right)-g(z)\left(2\theta\frac{\partial}{\partial z}-D\right). \tag{33}$$

Under this identification, (18) holds. In components (18) now reads

$$c(X_{(1)},X_{(2)}) = \frac{1}{6\pi i}\oint \mathrm{d}z\left(\frac{1}{4}f'''_{(1)}f_{(2)}+(-1)^{g_{(2)}}g''_{(1)}g_{(2)}\right), \tag{34}$$

where[13] $(-1)^{g_{(2)}}g_{(2)}=(-1)^{g_{(2)0}}g_{(2)0}+(-1)^{g_{(2)1}}g_{(2)1}=g_{(2)0}-g_{(2)1}$ with $g_{(2)0}$ and $g_{(2)1}$ being, respectively, the even and odd parts of $g_{(2)}$. Recall that any invertible superconformal transformation can be parametrized by $\Phi:(z,\theta)\mapsto(w,\pi)$,

$$w = w_0 + \theta w_1 (w_0')^{1/2},$$

$$\chi = w_1 + \theta (w_0' + w_1 w_1')^{1/2}, \tag{35}$$

where $w_0 = w_0(z)$ is even and with body, and $w_1 = w_1(z)$ is odd. Restricting to invertible transformations, and using the superconformal condition $Dw = \chi D\chi$, one can show that

$$\Phi^* \begin{pmatrix} \frac{\partial}{\partial w} \\ D_\chi \end{pmatrix} = \begin{pmatrix} (D_\theta \chi)^{-2} & -\left(\frac{\partial \chi}{\partial z}\right)(D_\theta \chi)^{-3} \\ 0 & (D_\theta \chi)^{-1} \end{pmatrix} \begin{pmatrix} \frac{\partial}{\partial z} \\ D_\theta \end{pmatrix}. \tag{36}$$

Plugging in the parametrization (35), and looking at the pull-pack of the vector field $l(X)$, one finds the induced transformation law for X,

$$X(w, \chi) \mapsto (D_\theta \chi)^{-2} (X \circ \Phi)(z, \theta) =: \hat{X}(z, \theta) \tag{37}$$

showing that X can in fact be identified with components of sections of the locally rank one sheaf ω^{-1},[7,9] where $\omega = \mathrm{d}z + \theta\, \mathrm{d}\theta$. Thus, in local coordinates, it reads as the tensor $\mathbf{X} = X\omega^{-1}$, yielding the transformation law

$$\Phi^*(X(w, \chi)\omega^{-1}) = (X \circ \Phi)(z, \theta)\omega^{-1}(D_\theta \chi)^{-2} = \hat{X}(z, \theta)\omega^{-1}. \tag{38}$$

A bracket can be introduced on $\Gamma(\omega^{-1})$[6]as

$$[X_{(1)}, X_{(2)}] = -2X_{(1)}X_{(2)}' + 2X_{(1)}'X_{(2)} - (-1)^{X_{(1)}}(DX_{(1)})(DX_{(2)}). \tag{39}$$

The bracket represents graded antisymmetric and obeys the graded Jacobi identity, and hence defines a Lie graded algebra structure. The map $l: \Gamma(\omega^{-1}) \to \Gamma(\mathcal{D}^1 \mathcal{A}_1)$ is then a Lie graded algebra homomorphism, with the brackets on vector fields given by the usual Lie bracket. Equation (18) can be rewritten as

$$c(X_{(1)}, X_{(2)}) = \frac{1}{12\pi i} \oint_0 \mathrm{d}z\, \mathrm{d}\theta ((DX_{(1)}'')X_{(2)} - (-1)^{X_{(1)}X_{(2)}}(DX_{(2)}'')X_{(1)}). \tag{40}$$

The integration measure, transforms, according to the Berezinian as

$$\Phi^* \left[\mathrm{d}w \frac{\partial}{\partial \chi} \right] = \left[\mathrm{d}z \frac{\partial}{\partial \theta} \right] (D_\theta \chi). \tag{41}$$

Knowing how X transforms from (37), one can compute

$$\begin{aligned} \Phi^*((D_\chi X_{(1)}'')X_{(2)} - (-1)^{X_{(1)}X_{(2)}}(D_\chi X_{(2)}'')X_{(1)}) = (D_\theta \chi)^{-1} &((D_\theta \hat{X}_{(1)}'')\hat{X}_{(2)} - (-1)^{X_{(1)}X_{(2)}}(D_\theta \hat{X}_{(2)}'')\hat{X}_{(1)} \\ &+ 2\{\chi, \theta\}[\hat{X}_{(1)}, \hat{X}_{(2)}] + D_\theta(\{\chi, \theta\}((D_\theta \hat{X}_{(1)}'')\hat{X}_{(2)} \\ &- (-1)^{X_{(1)}X_{(2)}}(D_\theta \hat{X}_{(2)}'')\hat{X}_{(1)})\ ), \end{aligned} \tag{42}$$

where the primes on the left-hand side are derivatives with respect to w, and on the right-hand side with respect to z. Also, $(-1)^X \hat{X} = (-1)^{\hat{X}} \hat{X}$ on virtue of $D_\theta \chi$ being even and

$$\{\chi, \theta\} = \frac{\chi''}{D_\theta \chi} - 2\frac{\chi' D_\theta \chi'}{(D_\theta \chi)^2} \tag{43}$$

is the $N = 1$ Schwarzian.[8] Notice that the last term in (42) is a total derivative in D_θ, and hence will vanish under the integral. Hence, it is most useful to look at sections of $\mathrm{d}z \otimes \partial/\partial\theta$ modulo exact derivatives. More explicitly,

$$\oint_0 \mathrm{d}z\, \mathrm{d}\theta (f_0 + f_1\theta) = (-1)^{f_1} \oint_0 \mathrm{d}z\, f_1 \tag{44}$$

and modulo exact derivatives means that if f_1 has an antiderivative, then $(f_0+f_1\theta)\sim 0$. In particular, this means

$$f_0 + f_1\theta = f_0 + F_1'\theta = D_\theta((-1)^{F_1}F_1 + (-1)^{f_0}f_0\theta) \sim 0 \tag{45}$$

as required.

Given $\Phi:(z,\theta)\mapsto(w,\chi)$, a contravariant map can be defined as

$$U_{\chi,\theta}:\begin{pmatrix} \frac{c}{6}((D_\chi X''_{(1)})X_{(2)} - (-1)^{X_{(1)}X_{(2)}}(D_\chi X''_{(2)})X_{(1)}) \\ [X_{(1)},X_{(2)}] \end{pmatrix} \mapsto \begin{pmatrix} \frac{c}{6}((D_\theta \hat{X}''_{(1)})\hat{X}_{(2)} - (-1)^{X_{(1)}X_{(2)}}(D_\theta \hat{X}''_{(2)})\hat{X}_{(1)}) \\ [\hat{X}_{(1)},\hat{X}_{(2)}] \end{pmatrix} \tag{46}$$

by

$$\begin{aligned} &U_{\chi,\theta}\begin{pmatrix} \frac{c}{6}((D_\chi X''_{(1)})X_{(2)} - (-1)^{X_{(1)}X_{(2)}}(D_\chi X''_{(2)})X_{(1)}) \\ [X_{(1)},X_{(2)}] \end{pmatrix} \\ &= \begin{pmatrix} (D_\theta\chi) & -\frac{c}{3}\{\chi,\theta\}(D_\theta\chi)^{-2} \\ 0 & (D_\theta\chi)^{-2} \end{pmatrix} \Phi^* \begin{pmatrix} \frac{c}{6}((D_\chi X''_{(1)})X_{(2)} - (-1)^{X_{(1)}X_{(2)}}(D_\chi X''_{(2)})X_{(1)}) \\ [X_{(1)},X_{(2)}] \end{pmatrix}, \end{aligned} \tag{47}$$

recalling that the first term is only defined up to exact derivatives. Given, in addition, a map $\Psi:(w,\chi)\mapsto(u,\rho)$, and using the property of the Schwarzian $\{\rho,\theta\}=\{\rho,\chi\}(D_\theta\chi)^3+\{\chi,\theta\}$ which can be deduced from (43), one can show

$$U_{\chi,\theta}\circ U_{\rho,\chi} = U_{\rho,\theta}. \tag{48}$$

Associating the necessary open sets to the maps Φ and Ψ then realizes (48) as the requirement on restriction maps. This then, locally, represents a nontrivial extension of

$$\left[\mathrm{d}z\frac{\partial}{\partial\theta}\right] \oplus \omega^{-1} \tag{49}$$

modulo exact derivatives in the first slot and for $c\neq 0$. If $c=0$, the extension becomes trivial. The graded Lie brackets can then be defined on sections of this extension as

$$\left[\begin{pmatrix} \lambda \\ X_{(1)} \end{pmatrix},\begin{pmatrix} \mu \\ X_{(2)} \end{pmatrix}\right] = \begin{pmatrix} \frac{c}{6}((D_\chi X''_{(1)})X_{(2)} - (-1)^{X_{(1)}}X_{(1)}(D_\chi X''_{(2)})) \\ [X_{(1)},X_{(2)}] \end{pmatrix}, \tag{50}$$

where the grade is given by the lower component. Note that, although it looks like the top component has a different parity to the bottom component, after performing the $\int \mathrm{d}z\, \mathrm{d}\theta$ integral to get the central charge, it will have the same parity. The graded Jacobi identity is already satisfied by the lower component, it remains to verify the upper component.

$$(-1)^{X_{(1)}X_{(3)}}\left[\left[\begin{pmatrix} \lambda \\ X_{(1)} \end{pmatrix},\begin{pmatrix} \mu \\ X_{(2)} \end{pmatrix}\right],\begin{pmatrix} \sigma \\ X_{(3)} \end{pmatrix}\right] + \text{cyclic} = \begin{pmatrix} U \\ 0 \end{pmatrix} \tag{51}$$

has top component

$$
\begin{aligned}
U = {} & (-1)^{X_{(1)}X_{(3)}}((-(DX_{(1)})X'''_{(2)} + (-1)^{X_{(1)}}X'''_{(1)}(DX_{(2)}) - 3(-1)^{X_{(1)}}X'_{(1)}(DX''_{(2)}) + 3(DX''_1)X'_2 \\
& - 2(-1)^{X_{(1)}}X_1(DX'''_2) + 2(DX'''_{(1)})X_{(2)})X_3 + (-1)^{X_{(1)}+X_{(2)}}(2X_{(1)}X'_{(2)} - 2X'_{(1)}X_{(2)} \\
& + (-1)^{X_{(1)}}(DX_{(1)}DX_{(2)})))(DX''_3) + \text{cyclic} \\
= {} & (-1)^{X_{(1)}X_{(3)}}\partial(2(DX'_{(1)})X'_{(2)}X_{(3)} - 2(DX'_{(1)})X_{(2)}X'_{(3)} + 2(-1)^{(X_1)}X_{(1)}(DX'_{(2)})X'_{(3)} \\
& - 2(-1)X_{(1)}(DX'_{(2)})X_{(3)} + 2(-1)^{X_{(1)}+X_{(2)}}X'_{(1)}X_{(2)}(DX'_{(3)}) - 2(-1)^{X_{(1)}+X_{(2)}}X_{(1)}X'_{(2)}(DX'_{(3)}) \\
& - (-1)^{X_{(2)}}\partial((DX_{(1)})(DX_{(2)})(DX_{(3)}))) + (-1)^{X_{(1)}X_{(3)}}D(2(-1)^{X_{(1)}}(DX'_{(1)}) \\
& - 2(-1)^{X_{(1)}+X_{(2)}}(DX'_{(1)})X_{(2)}(DX'_{(3)}) + 2(-1)^{X_{(2)}}X_{(1)}(DX'_{(2)})(DX'_{(3)}) + (-1)^{X_{(1)}}(DX''_{(1)})(DX_{(2)})X_{(3)} \\
& - (-1)^{X_{(1)}+X_{(2)}}(DX''_{(1)})X_{(2)}(DX_{(3)}) + (-1)^{X_{(1)}}(DX_{(1)})(DX''_{(2)})X_{(3)} + (-1)^{X_{(2)}}X_{(1)}(DX''_{(2)})(DX_{(3)}) \\
& + (-1)^{X_{(2)}}X_{(1)}(DX_{(2)})(DX''_{(3)}) - (-1)^{X_{(1)}+X_{(2)}}(DX_{(1)})X_{(2)}(DX''_{(3)})) \sim 0, \qquad (52)
\end{aligned}
$$

where the equivalence follows since the term is a total derivative (recall $\partial = D^2$), and the brackets obey the graded Jacobi identity. Hence, the algebra of conformal vector fields admits an extension on the graded Riemann sphere to accommodate the central charge, which realizes a map of the form (32) using (18). The construction precisely mirrors that done for the bosonic case in Ref. 10. Given the list of Schwarzians in Ref. 8, it should be possible to extend the construction to all $N \leqslant 4$.

VII. CONCLUSIONS

If one wishes to study all of the conformal symmetries on an $N=4$ graded Riemann sphere at the quantum level, and not neglect any symmetries, then one is forced to look at adding noncentral extensions to the algebra. If the u_0 symmetry is neglected, then all of the extensions are central. To the author's knowledge, this has not been observed before, and the author is unaware of the $N=4$ algebra given by (6) having appeared previously in the literature. It was found that this extension was completely consistent with the usual CFT treatments of the quantum theory, i.e., with the operator product expansions of the $N=4$ theory, and in fact explained why the logarithms appeared in the OPE. The effect on the representation theory was discussed, as was the description of the Gelfand–Fuchs extensions for $N=1,\ldots,4$, given by the superfield formalism. There, it was found that the extra extension explained the appearance of the indefinite integral inside the contour integral in (28). It was then described for the $N=1$ case how the central extension arises from the geometry of an $N=1$ graded Riemann sphere, and how it might be expected that the central extensions for the higher N might be obtained.

As well as exploiting graded Riemann sphere geometry to describe extensions of superconformal algebras, these calculations also shed some light on how one might try to treat noncentral extensions in a CFT. In this case, the field theory exhibited an, albeit mild, logarithmic behavior, not unrelated to the manner in which zero modes are modified in Ref. 2. For higher N, the requirement of having a Virasoro subalgebra with nonzero central extension could force noncentral extensions to appear that enrich the zero mode structure. $N=5$ would have a graded odd weight $-\frac{1}{2}$ field whose zero mode structure might give unavoidable Jordan cells in the representation theory. In the $N=4$ case, the modified zero mode structure was reflected by the appearance of indefinite integrals in the Gelfand–Fuchs extensions.

Jinsung Park[b)]
Mathematisches Institut, Universität Bonn, Beringstrasse 1, D-53115 Bonn, Germany

(Received 28 July 2004; accepted 27 November 2004; published online 28 March 2005)

In this note, we explicitly compute the functional determinant of a Dirac Laplacian with nonlocal *pseudodifferential* boundary conditions over a finite cylinder in terms of the ζ-function of the Dirac operator on the cross section and the pseudodifferential operators defining the boundary conditions. In particular, this result reduces to our previous formula [J. Phys. A **37**, 7381 (2004)] for the special case of generalized Atiyah–Patodi–Singer conditions. To prove our main result, we use the gluing and comparison formulas established by the present authors in Refs 14 and 15.
 [DOI: 10.1063/1.1860591]

I. INTRODUCTION

Recent advances in quantum field theory have necessitated the explicit evaluation of functional determinants of Dirac operators over a variety of space–time configurations. In fact, at the one-loop order, any such theory can be reduced to the theory of determinants. We refer the reader to the works of Dowker and Critchley[1] and Hawking.[2] See also Elizalde *et al.*,[3] Kirsten,[4] and Scott and Wojciechowski,[5] for recent reviews. Because of their increasingly important role in mathematical physics, over the past several years there has been intense research to compute functional ζ-determinants of Dirac Laplacians. Of great significance is the Dirac Laplacian with spectral pseudodifferential boundary conditions; the Atiyah–Patodi–Singer (henceforth APS) boundary conditions being the most well-known example. Such boundary conditions arise in, for instance, one-loop quantum cosmology,[6–8] spectral branes,[9] and the study of Dirac fields in the background of a magnetic flux.[10]

However, only recently was the open problem of explicitly computing the ζ-determinant of a Dirac Laplacian with APS conditions over a finite cylinder solved.[11] One reason this problem withstood the efforts of existing mathematical methods is that it is impossible to find explicit formulas for the eigenvalues of such a Dirac operator. For this reason, we had to attack the problem using the method of *adiabatic decomposition* pioneered by Douglas and Wojciechowski[12] for the eta invariant and by the second author and Wojciechowski[13] for the ζ-determinant. The purpose of this current paper is twofold. First, we extend the result of Ref. 11 to a general class of pseudodifferential conditions that generalize the APS condition up to operators of *arbitrary* finite rank. To compute the ζ-determinant in this generalized framework, which in some sense possesses eigenvalues that are even more enigmatic, we use the gluing and comparison formulas for ζ-determinants proved by the authors in Refs. 14 and 15 to break up this general framework into tangible parts which can be explicitly computed. The second purpose of this paper is to elucidate

[a)]Electronic mail: paul@math.binghamton.edu
[b)]Electronic mail: jpark@math.uni.bonn.de

the effectiveness of these gluing and comparison formulas to compute ζ-determinants that have eluded explicit evaluations due to the perplexity of their eigenvalues. This also exemplifies the aim of gluing and comparison formulas: Breaking up complex problems into simpler more tractable ones.

We now describe our setup. Fix $R>0$ and let $\mathcal{D}:C^\infty(N_R,S)\to C^\infty(N_R,S)$ be a Dirac type operator where $N_R=[-R,R]\times Y$ is a finite cylinder with $R>0$, Y a closed compact Riemannian manifold (of arbitrary dimension), and S a Clifford bundle over N_R. We assume that $\mathcal{D}$ is of product form

$$\mathcal{D}=G(\partial_u+D_Y), \tag{1.1}$$

where G is a unitary bundle isomorphism of S and D_Y is a Dirac operator acting on $C^\infty(Y,S)$ such that $G^2=-\mathrm{Id}$ and $GD_Y=-D_YG$. Furthermore, we assume that

$$\dim(\ker(G+i)\cap\ker(D_Y))=\dim(\ker(G-i)\cap\ker(D_Y)). \tag{1.2}$$

Let Π_+,Π_-, and Π_0 denote the orthogonal projections onto the positive, negative, and zero eigenspaces of D_Y. Since N_R has boundaries, we have to impose boundary conditions. Let $\mathrm{Gr}^*_\infty(D_Y)$ denote the space of pairs $(\mathcal{P}_1,\mathcal{P}_2)$, where $\mathcal{P}_1$ and $\mathcal{P}_2$ are orthogonal pseudodifferential projections on $L^2(Y,S)$ such that

$$\mathcal{P}_1-\Pi_+,\quad \mathcal{P}_2-\Pi_-\ \text{are smoothing operators},$$

and for $i=1,2$,

$$\mathcal{P}_iG=G(\mathrm{Id}-\mathcal{P}_i),\quad D_Y\mathcal{P}_i=\mathcal{P}_iD_Y.$$

An important class of such boundary conditions are the renowned generalized APS spectral conditions,[16] which are defined as follows. Let σ_1,σ_2 be involutions (that is, $\sigma_i^2=\mathrm{Id}$) over $\ker(D_Y)$ such that $\sigma_1G=-G\sigma_1$ and $\sigma_2G=-G\sigma_2$. Note that such involutions exist because of the assumption (1.2). Then

$$\Pi_+^{\sigma_1}:=\Pi_++\frac{1+\sigma_1}{2}\Pi_0,\quad \Pi_-^{\sigma_2}:=\Pi_-+\frac{1+\sigma_2}{2}\Pi_0 \tag{1.3}$$

are called *generalized APS spectral projections*, and $(\Pi_+^{\sigma_1},\Pi_-^{\sigma_2})\in\mathrm{Gr}^*_\infty(D_Y)$. These generalized APS boundary conditions were considered in our paper (Ref. 11), but elements of $\mathrm{Gr}^*_\infty(D_Y)$ are much more general and can differ from APS projections by operators of *arbitrary* finite rank. Let $P=(\mathcal{P}_1,\mathcal{P}_2)\in\mathrm{Gr}^*_\infty(D_Y)$ and impose boundary conditions for $\mathcal{D}$ at $\{-R\}\times Y$ and $\{R\}\times Y$ via

$$\mathcal{P}_1\quad\text{at}\ \{-R\}\times Y,\quad \mathcal{P}_2\quad\text{at}\ \{R\}\times Y.$$

We denote by $\mathcal{D}_P$ the resulting operator with these boundary conditions, that is,

$$\mathcal{D}_P:=\mathcal{D}:\mathrm{dom}(\mathcal{D}_P)\to L^2(N_R,S), \tag{1.4}$$

where

$$\mathrm{dom}(\mathcal{D}_P):=\{\phi\in H^1(N_R,S)\,|\,\mathcal{P}_1(\phi|_{u=-R})=0,\quad \mathcal{P}_2(\phi|_{u=R})=0\}.$$

By the fundamental work of Seeley,[17,18] the spectrum of the Dirac operator $\mathcal{D}_P$ consists of discrete real eigenvalues $\{\lambda_k\}$. The ζ-function of $\mathcal{D}_P^2$ is defined by

$$\zeta_{\mathcal{D}_P^2}(s)=\sum_{\lambda_k\neq0}\lambda_k^{-2s},$$

which is *a priori* defined for $\Re(s)\gg0$, and by the work of Grubb[19,20] and Wojciechowski[21] (cf. Lei[22] and Loya and Park[15]), has a meromorphic extension to $\mathbb{C}$ with 0 as a regular point. The ζ-determinant of $\mathcal{D}_P^2$ is defined by

$$\det_\zeta \mathcal{D}_P^2 := \exp(-\zeta'_{\mathcal{D}_P^2}(0)).$$

This definition first appeared in Ray and Singer's seminal paper[23] on the analytic torsion. Since we imposed nonlocal pseudodifferential boundary conditions, it is impossible to compute the eigenvalues $\{\lambda_k\}$ of $\mathcal{D}_P$ explicitly, so there is no direct way to compute the ζ-determinant $\det_\zeta \mathcal{D}_P^2$ from the eigenvalues. However, we shall give two derivations of the formula for $\det_\zeta \mathcal{D}_P^2$:

(1) Using the gluing formula proved in Ref. 14.
(2) Using the comparison/relative invariant formula proved in Ref. 15.

See Sec. II for more on these results. The formula for $\det_\zeta \mathcal{D}_P^2$ is described as follows. Since the $\mathcal{P}_i$'s are orthogonal projectors such that $\mathcal{P}_i G = G(\mathrm{Id} - \mathcal{P}_i)$ by assumption, with respect to the decomposition

$$L^2(Y,S) = L^2(Y,S^+) \oplus L^2(Y,S^-) \tag{1.5}$$

with $S^\pm$ denoting the $(\pm i)$-eigenspaces of G in S (recall that $G^2 = -\mathrm{Id}$), we can write

$$\mathcal{P}_i = \frac{1}{2}\begin{pmatrix} \mathrm{Id} & \kappa_i^{-1} \\ \kappa_i & \mathrm{Id} \end{pmatrix},$$

where $\kappa_i : L^2(Y,S^+) \to L^2(Y,S^-)$ are corresponding isometries. In particular,

$$U_P := -\kappa_1 \kappa_2^{-1} : L^2(Y,S^-) \to L^2(Y,S^-)$$

is a unitary operator. Let $\hat{U}_P$ denote the restriction of U_P to the orthogonal complement of its (-1)-eigenspace. Let $W := \mathrm{Im}(\mathrm{Id} - \mathcal{P}_1) \cap \mathrm{Im}(\mathrm{Id} - \mathcal{P}_2)$. Then our assumptions on $(\mathcal{P}_1, \mathcal{P}_2)$ imply that W is a finite-dimensional vector space and that $D_Y : \mathrm{Im}(\mathcal{P}_i) \to \mathrm{Im}(\mathcal{P}_i)$ and $D_Y : \mathrm{Im}(\mathrm{Id} - \mathcal{P}_i) \to \mathrm{Im}(\mathrm{Id} - \mathcal{P}_i)$. We define a map T_P over W by

$$T_P := \begin{cases} \frac{\sinh(2RD_Y)}{D_Y} & \text{on } W \cap \ker(D_Y)^\perp, \\ 2R & \text{on } W \cap \ker(D_Y). \end{cases}$$

We also define $T_{\mathcal{P}_1}$ and $T_{\mathcal{P}_2}$ over the finite-dimensional vector spaces $\mathrm{Im}(\Pi_+) \cap \mathrm{Im}(\mathrm{Id} - \mathcal{P}_1)$ and $\mathrm{Im}(\Pi_+) \cap \mathrm{Im}(\mathcal{P}_2)$, respectively, by

$$T_{\mathcal{P}_1} := e^{4RD_Y}, \quad T_{\mathcal{P}_2} := e^{4RD_Y}.$$

The following theorem is the main result of this note.

Theorem 1.1. *The following equality holds:*

$$\det_\zeta \mathcal{D}_P^2 = e^{2CR} 2^{\zeta_{D_Y^2}(0) + h_Y} \frac{(\det T_P)^2}{(\det T_{\mathcal{P}_1})^2 (\det T_{\mathcal{P}_2})^2} \cdot \det_F\left(\frac{2\,\mathrm{Id} + \hat{U}_P + \hat{U}_P^{-1}}{4} \right),$$

where $C = (\Gamma(s)^{-1} \zeta_{D_Y^2}(s - 1/2))'(0)$ *with* $\zeta_{D_Y^2}(s)$ *the* ζ*-function of* D_Y^2, $h_Y = \dim \ker(D_Y)$ *and* $\det_F$ *denotes the Fredholm determinant.*

More explicitly, if we let E_μ denote the eigenspace of D_Y associated to the eigenvalue $\mu \in \mathrm{spec}(D_Y)$, then we can write

$$\det{}_\zeta \mathcal{D}_P^2 = e^{2CR} 2^{\zeta_{D_Y^2}(0)+h_Y} \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{-4\mu R} \right) \cdot \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathcal{P}_2)\neq 0}} e^{-4\mu R} \right)$$
$$\cdot \left(\prod_{\substack{\mu \in \mathrm{spec}(D_Y) \\ E_\mu \cap W \neq 0}} \frac{\sinh^2(2\mu R)}{\mu^2} \right) \cdot \det{}_F \left(\frac{2\mathrm{Id} + \hat{U}_P + \hat{U}_P^{-1}}{4} \right), \tag{1.6}$$

where if $\mu=0$ in the product in the second line, we replace $[\sinh^2(2\mu R)]/\mu^2$ by its limit as $\mu \to 0$, that is, $(2R)^2$. In particular, when $\mathcal{P}_1=\Pi_+^{\sigma_1}$ and $\mathcal{P}_2=\Pi_-^{\sigma_2}$, the generalized APS spectral projectors in (1.3), then Theorem 1.1 reduces to the main result of Ref. 11.

$$\det{}_\zeta \mathcal{D}^2_{\Pi_+^{\sigma_1},\Pi_-^{\sigma_2}} = e^{2CR} 2^{\zeta_{D_Y^2}(0)+h_Y} (2R)^{2h} \det{}^* \left(\frac{2\mathrm{Id} - (\sigma_1\sigma_2)_- - (\sigma_1\sigma_2)_-^{-1}}{4} \right), \tag{1.7}$$

where $(\sigma_1\sigma_2)_-$ is the restriction of the unitary map $\sigma_1\sigma_2$ to $L^2(Y,S^-) \cap \ker(D_Y)$, h is the number of $(+1)$-eigenvalues of $(\sigma_1\sigma_2)_-$, and where $\det^*(L)$ denotes the determinant of $(L|_{\ker(L)^\perp})$ for an operator L over a finite-dimensional vector space.

The structure of this paper is as follows. In Sec. II, we review the gluing formula from Ref. 14 and the comparison/relative invariant formula from Ref. 15, which we shall use in the subsequent sections. In Sec. III, we derive new formulas for ζ-determinant ratios of Dirac Laplacians with boundary conditions of special types. Finally, in Sec. IV we combine these special ζ-determinant ratios and the gluing and comparison formulas from Refs. 14 and 15 to derive our main Theorem 1.1.

II. THE GLUING AND COMPARISON FORMULAS FROM REFS. 14 and 15

In this section we review the gluing formula from Ref. 14 and the comparison/relative invariant formula from Ref. 15.

Let $\mathcal{D}$ be a Dirac type operator acting on $C^\infty(M,S)$ where M is a closed compact Riemannian manifold of arbitrary dimension and S is a Clifford bundle over M. Suppose that $M=M_- \cup M_+$ is partitioned into a union of manifolds with a common boundary $Y=\partial M_-=\partial M_+$. We assume that all geometric structures are of product type over a tubular neighborhood N of Y where $\mathcal{D}$ takes the product form (1.1). By restriction of $\mathcal{D}$, we obtain Dirac type operators $\mathcal{D}_\pm$ over $M_\pm$. We impose the boundary conditions given by the orthogonalized Calderón projectors $\mathcal{C}_\pm$ for $\mathcal{D}_\pm$ and we denote by $\mathcal{D}_{\mathcal{C}_\pm}$ the resulting operators,

$$\mathcal{D}_{\mathcal{C}_\pm} = \mathcal{D}_\pm : \mathrm{dom}(\mathcal{D}_{\mathcal{C}_\pm}) := \{\phi \in H^1(M_\pm,S) | \mathcal{C}_\pm(\phi|_Y) = 0\} \to L^2(M_\pm,S).$$

Here, we recall that the Calderón projectors $\mathcal{C}_\pm$ are the projectors defined intrinsically as the unique orthogonal projectors onto the closures in $L^2(Y,S)$ of the infinite-dimensional *Cauchy data spaces* of $\mathcal{D}_\pm$:

$$\{\phi|_Y | \phi \in C^\infty(M_\pm,S), \quad \mathcal{D}_\pm\phi = 0\} \subset C^\infty(Y,S).$$

The *gluing problem* for the ζ-determinant is to describe the "defect"

$$\frac{\det_\zeta \mathcal{D}^2}{\det_\zeta \mathcal{D}^2_{\mathcal{C}_+} \cdot \det_\zeta \mathcal{D}^2_{\mathcal{C}_-}} = \boxed{?}$$

in terms of recognizable data. To describe the solution in Ref. 14, we need to introduce some notations. With respect to the decomposition as in (1.5), the Calderón projectors $\mathcal{C}_\pm$ have the matrix forms

$$\mathcal{C}_\pm = \frac{1}{2}\begin{pmatrix} \mathrm{Id} & \kappa_\pm^{-1} \\ \kappa_\pm & \mathrm{Id} \end{pmatrix}, \tag{2.1}$$

where the maps $\kappa_\pm : L^2(Y,S^+) \to L^2(Y,S^-)$ are corresponding isometries, so that $\mathcal{U} := -\kappa_- \kappa_+^{-1}$ is a unitary operator over $L^2(Y,S^-)$. Furthermore, $\mathcal{U}$ is of Fredholm determinant class. We denote by $\hat{\mathcal{U}}$ the restriction of $\mathcal{U}$ to the orthogonal complement of its (-1)-eigenspace. We also put

$$\mathcal{L} := \sum_{k=1}^{h_M} \gamma U_k \otimes \gamma U_k : \gamma \ker(\mathcal{D}) \to \gamma \ker(\mathcal{D}),$$

where $h_M = \dim \ker(\mathcal{D})$, γ is the restriction map from M to Y, and $\{U_k\}$ is an orthonormal basis of $\ker(\mathcal{D})$. Then $\mathcal{L}$ is a positive operator on the finite-dimensional vector space

$$\gamma \ker(\mathcal{D}) \equiv \mathrm{Im}(\mathcal{C}_-) \cap \mathrm{Im}(\mathcal{C}_+).$$

We now have all the ingredients to state the following *gluing formula*:[14]

$$\frac{\det_\zeta \mathcal{D}^2}{\det_\zeta \mathcal{D}^2_{\mathcal{C}_-} \cdot \det_\zeta \mathcal{D}^2_{\mathcal{C}_+}} = 2^{-\zeta_{D_Y^2}(0)-h_Y} (\det \mathcal{L})^{-2} \det_F\left(\frac{2\mathrm{Id} + \hat{\mathcal{U}} + \hat{\mathcal{U}}^{-1}}{4}\right), \tag{2.2}$$

where $h_Y = \dim \ker(D_Y)$ and $\det_F$ denotes the Fredholm determinant. There is a similar formula for manifolds with cylindrical ends.[24]

We now explain the comparison/relative invariant formula proved in Ref. 15 for $(M_-, \mathcal{D}_-)$. To this end, we consider the space $\mathrm{Gr}^*_\infty(\mathcal{D}_-)$, which consists of orthogonal projections $\mathcal{P}$ such that $\mathcal{P} - \mathcal{C}_-$ are smoothing operators and $G\mathcal{P} = (\mathrm{Id} - \mathcal{P})G$. Let us fix $\mathcal{P} \in \mathrm{Gr}^*_\infty(\mathcal{D}_-)$ and let $\kappa_\mathcal{P} : L^2(Y,S^+) \to L^2(Y,S^-)$ be the map that determines $\mathcal{P}$ as $\kappa_\pm$ does $\mathcal{C}_\pm$ in (2.1). Let $\mathcal{D}_\mathcal{P}$ denote the operator $\mathcal{D}_-$ on M_- with the boundary condition given by $\mathcal{P}$. Let P_W be the orthogonal projection of $L^2(Y,S)$ onto the finite-dimensional vector space

$$W := \gamma \ker(\mathcal{D}_\mathcal{P}) \equiv \mathrm{Im}(\mathcal{C}_-) \cap \mathrm{Im}(\mathrm{Id} - \mathcal{P}).$$

Then we introduce a linear map

$$L := -P_W G \mathcal{R}^{-1} G P_W : \gamma \ker(\mathcal{D}_\mathcal{P}) \to \gamma \ker(\mathcal{D}_\mathcal{P}), \tag{2.3}$$

where $\mathcal{R}$ is the sum of the Dirichlet to Neumann maps on an extension of M_- defined as follows. Fix *any* invertible extension $\widetilde{\mathcal{D}}$ of $\mathcal{D}$ to a manifold $\widetilde{M}$ that contains M_-. (The *double* of $\mathcal{D}$ would do nicely.) Then for any $\varphi \in C^\infty(Y,S)$, there are unique $\phi_1 \in C^\infty(M_-,S)$ and $\phi_2 \in C^\infty(\widetilde{M} \setminus M_-, S)$ that are continuous at Y with value φ such that $\widetilde{\mathcal{D}}^2 \phi_i = 0$, $i = 1, 2$, off of Y. Then

$$\mathcal{R}\varphi := \partial_u \phi_1|_Y - \partial_u \phi_2|_Y. \tag{2.4}$$

In Ref. 15, we prove that L is a positive operator so that $\det L$ is a positive real number. Now the main result of Ref. 15 states that

$$\frac{\det_\zeta \mathcal{D}^2_\mathcal{P}}{\det_\zeta \mathcal{D}^2_{\mathcal{C}_-}} = (\det L)^2 \cdot \det_F\left(\frac{2\mathrm{Id} + \hat{U} + \hat{U}^{-1}}{4}\right), \tag{2.5}$$

where $\hat{U}$ is the restriction of $U := \kappa_- \kappa_\mathcal{P}^{-1}$ to the orthogonal complement of its (-1)-eigenspace. The formula (2.5) extends the work of Scott[25] for the invertible case (cf. Scott and Wojciechowski[26]), and has recently been further extended to noncompact manifolds whose boundaries are manifolds with multi-cylindrical ends.[27]

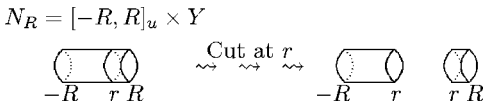

FIG. 1. Cutting N_R at r into two pieces.

III. THE ζ-DETERMINANT FOR SPECIAL BOUNDARY CONDITIONS

If $(\mathcal{P}_1,\mathcal{P}_2)\in \mathrm{Gr}^*_\infty(D_Y)$, then for the sake of clarity we shall denote the operator $\mathcal{D}_P$ in the introduction with these boundary conditions by $\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}$. Thus, over $N_R=[-R,R]\times Y$ we impose boundary conditions at $\{-R\}\times Y$ and $\{R\}\times Y$ via

$$\mathcal{P}_1 \text{ at } \{-R\}\times Y, \quad \mathcal{P}_2 \text{ at } \{R\}\times Y,$$

and $\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}$ is the operator with domain

$$\mathrm{dom}(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}) := \{\phi\in H^1(N_R,S)\,|\,\mathcal{P}_1(\phi|_{u=-R})=0,\quad \mathcal{P}_2(\phi|_{u=R})=0\}. \tag{3.1}$$

Let $\mathcal{P}$ be a projection on $L^2(Y,S)$ with $(\mathcal{P},\mathrm{Id}-\mathcal{P})\in \mathrm{Gr}^*_\infty(D_Y)$. By definition of $\mathrm{Gr}^*_\infty(D_Y)$, the image of $\mathcal{P}\Pi_0$ is a Lagrangian subspace in $\mathrm{Im}(\Pi_0)=\ker(D_Y)$. Let σ be the involution over $\mathrm{Im}(\Pi_0)$ such that $[(1+\sigma)/2]\Pi_0=\mathcal{P}\Pi_0$. Recalling $\Pi^\sigma_+:=\Pi_+ +[(\mathrm{Id}+\sigma)/2]\Pi_0$, it follows that $(\mathcal{P},\mathrm{Id}-\Pi^\sigma_+)\in \mathrm{Gr}^*_\infty(D_Y)$. Recall that we can write

$$\mathcal{P}=\frac{1}{2}\begin{pmatrix}\mathrm{Id} & \kappa_{\mathcal{P}}^{-1}\\ \kappa_{\mathcal{P}} & \mathrm{Id}\end{pmatrix},\quad \Pi^\sigma_+=\frac{1}{2}\begin{pmatrix}\mathrm{Id} & \kappa_{\sigma}^{-1}\\ \kappa_{\sigma} & \mathrm{Id}\end{pmatrix}$$

for corresponding isometries $\kappa_{\mathcal{P}},\kappa_\sigma: L^2(Y,S^+)\to L^2(Y,S^-)$, and define $\hat{U}_{\mathcal{P}}$ as the restriction of $U_{\mathcal{P}}:=\kappa_{\mathcal{P}}\kappa_\sigma^{-1}$ over $L^2(Y,S^-)$ to the orthogonal complement of its (-1)-eigenspace. Note that $-\kappa_{\mathcal{P}}$ and $-\kappa_\sigma$ are the isometries corresponding to $\mathrm{Id}-\mathcal{P}$ and $\mathrm{Id}-\Pi^\sigma_+$, respectively. We begin by computing the following ratio.

Lemma 3.1: We have

$$\frac{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\Pi^\sigma_+}}{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}}}=\left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}}\frac{e^{4\mu R}\sinh^2(2\mu R)}{\mu^2}\right)\cdot \det_F\left(\frac{2\mathrm{Id}+\hat{U}_{\mathcal{P}}+\hat{U}_{\mathcal{P}}^{-1}}{4}\right),$$

where E_μ denotes the eigenspace of D_Y associated to the eigenvalue $\mu\in\mathrm{spec}(D_Y)$.

Proof: We give two proofs, first using the gluing formula (2.2) then using the comparison formula (2.5), in order to demonstrate the effectiveness of these formulas.

Gluing proof of Lemma 3.1: Let us decompose N_R into two parts $[-R,r]\times Y$ and $[r,R]\times Y$ as shown in Fig. 1. Then the restrictions of $\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi^\sigma_+}$ over the decomposed parts $[-R,r]\times Y$ and $[r,R]\times Y$ define two Dirac type operators with boundary conditions given by $\mathcal{P}$ at $\{-R\}\times Y$ and $\mathrm{Id}-\Pi^\sigma_+$ at $\{R\}\times Y$. It is easy to check that the Calderón projections of these two operators are, respectively, just $\mathcal{C}_-=\mathrm{Id}-\mathcal{P}$ and $\mathcal{C}_+=\Pi^\sigma_+$ over $\{r\}\times Y$. We denote the operators over the decomposed parts $[-R,r]\times Y$ and $[r,R]\times Y$, with the new boundary conditions given by these Calderón projectors over $\{r\}\times Y$, by $\mathcal{D}_{\mathcal{P},\mathrm{Id}-\mathcal{P}}(r)$ and $\mathcal{D}_{\Pi^\sigma_+,\mathrm{Id}-\Pi^\sigma_+}(r)$, respectively. Applying the gluing formula (2.2) to this situation, we obtain

$$\frac{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\Pi^\sigma_+}}{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}}(r)\cdot \det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\Pi^\sigma_+}(r)}=2^{-\zeta_{D_Y^2}(0)-h_Y}(\det \mathcal{L}_r)^{-2}\det_F\left(\frac{2\,\mathrm{Id}+\hat{U}_{\mathcal{P}}+\hat{U}_{\mathcal{P}}^{-1}}{4}\right), \tag{3.2}$$

where $\zeta_{D_Y^2}(s)$ is the ζ-function of D_Y^2 and $h_Y=\dim\ker(D_Y)$, where we used that the $\hat{\mathcal{U}}$ in (2.2) for this situation is $-(-\kappa_{\mathcal{P}})(\kappa_\sigma^{-1})=\kappa_{\mathcal{P}}\kappa_\sigma^{-1}=:\hat{U}_{\mathcal{P}}$, and where

$$\mathcal{L}_r := \sum_{k=1}^{h_{\mathcal{P}}} \gamma_r U_k \otimes \gamma_r U_k : \gamma_r \ker(\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma}) \to \gamma_r \ker(\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma}),$$

where $h_{\mathcal{P}}=\dim \ker(\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma})$, γ_r is the restriction map from N_R to $\{r\}\times Y$, and $\{U_k\}$ is an orthonormal basis of $\ker(\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma})$. From the main result of Ref. 11 [that is, the formula (1.7)], we have

$$\det{}_\zeta \mathcal{D}^2_{\Pi_+^\sigma,\mathrm{Id}-\Pi_+^\sigma}(r) = e^{C(R-r)} 2^{\zeta_{D_Y^2}(0)+h_Y},$$

where $C=(\Gamma(s)^{-1}\zeta_{D_Y^2}(s-1/2))'(0)$. Thus, $\det_\zeta \mathcal{D}^2_{\Pi_+^\sigma,\mathrm{Id}-\Pi_+^\sigma}(r) \to 2^{\zeta_{D_Y^2}(0)+h_Y}$ as $r\to R$, so taking $r\to R$ in (3.2), we see that

$$\frac{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma}}{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}}} = (\det \mathcal{L}_R)^{-2} \det{}_F\left(\frac{2\,\mathrm{Id} + \hat{U}_{\mathcal{P}} + \hat{U}_{\mathcal{P}}^{-1}}{4}\right).$$

It remains to compute $(\det \mathcal{L}_R)^{-2}$. To do so, we note that

$$\ker(\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma}) \equiv \mathrm{Im}(\mathrm{Id}-\mathcal{P}) \cap \mathrm{Im}(\Pi_+^\sigma) = \mathrm{Im}(\mathrm{Id}-\mathcal{P}) \cap \mathrm{Im}(\Pi_+),$$

since $\mathrm{Im}(\mathrm{Id}-\mathcal{P})$ and $\mathrm{Im}(\Pi_+^\sigma)$ have zero intersection in $\ker(D_Y)$ by definition of σ. Let $\{\psi_\mu\}$ be an orthonormal basis of $\mathrm{Im}(\mathrm{Id}-\mathcal{P})\cap\mathrm{Im}(\Pi_+)$ where $\psi_\mu \in E_\mu$. (Here, we recall that $D_Y\mathcal{P}=\mathcal{P}D_Y$, so D_Y preserves $\mathrm{Im}(\mathrm{Id}-\mathcal{P})$ and obviously $\mathrm{Im}(\Pi_+)$ as well. It follows that D_Y can be diagonalized within the finite-dimensional space $\mathrm{Im}(\mathrm{Id}-\mathcal{P})\cap\mathrm{Im}(\Pi_+)$. This elementary fact will be used quite often in the sequel.) Then $\phi_\mu = e^{-\mu u}\psi_\mu \in \ker(\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma})$ and

$$\|\phi_\mu\|^2 = \int_{-R}^{R} e^{-2\mu u} du = \frac{e^{2\mu R} - e^{-2\mu R}}{2\mu} = \frac{\sinh(2\mu R)}{\mu}.$$

It follows that

$$\mathcal{L}_R = \sum_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \frac{\phi_\mu(R)}{\|\phi_\mu\|} \otimes \frac{\phi_\mu(R)}{\|\phi_\mu\|} = \sum_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \frac{e^{-2\mu R}}{\|\phi_\mu\|^2} \psi_\mu \otimes \psi_\mu.$$

Hence,

$$(\det \mathcal{L}_R)^{-2} = \prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \left(\frac{e^{-2\mu R}}{\|\phi_\mu\|^2}\right)^{-2} = \prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} e^{4\mu R} \frac{\sinh^2(2\mu R)}{\mu^2}.$$

This completes the Gluing proof of Lemma 3.1.

Comparison proof of Lemma 3.1: We shall apply the comparison formula (2.5) to the pair $(\mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma}, \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}})$. Here we regard $\mathrm{Id}-\mathcal{P}$ as the Calderón projector at the boundary $\{R\}\times Y$ of the operator

$$D : \mathrm{dom}(D) \to L^2(N_R, S),$$

where

$$\mathrm{dom}(D) := \left\{\phi \in H^1(N_R,S) \,|\, \mathcal{P}(\phi|_{u=-R}) = 0\right\}.$$

Then $D_{\mathrm{Id}-\Pi_+^\sigma} = \mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi_+^\sigma}$ and $D_{\curvearrowright} = \mathcal{D}_{\mathcal{P},\mathrm{Id}-\mathcal{P}}$, so by the comparison formula (2.5),

$$\frac{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\Pi^\sigma_+}}{\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}}} = (\det L)^2 \cdot \det_F\left(\frac{2\,\mathrm{Id} + \hat{U}_\mathcal{P} + \hat{U}_\mathcal{P}^{-1}}{4}\right),$$

where we used that the U in (2.5) for this situation is $(-\kappa_\mathcal{P})(-\kappa_\sigma^{-1}) = \kappa_\mathcal{P}\kappa_\sigma^{-1} =: U_\mathcal{P}$, and where L is the map over $\{R\}\times Y$ defined in (2.3):

$$L = -P_W G \mathcal{R}^{-1} G P_W : W \to W$$

with

$$W := \gamma_R \ker(\mathcal{D}_{\mathcal{P},\mathrm{Id}-\Pi^\sigma_+}) \equiv \mathrm{Im}(\mathrm{Id}-\mathcal{P}) \cap \mathrm{Im}(\Pi^\sigma_+) = \mathrm{Im}(\mathrm{Id}-\mathcal{P}) \cap \mathrm{Im}(\Pi_+).$$

To determine $(\det L)^2$, we need to find $\mathcal{R}$. An invertible extension $\tilde{D}$ of D is just $G(\partial_u + D_Y)$ over $[-R,2R]\times Y$ with boundary condition $\mathcal{P}$ at $-R$ and $\mathrm{Id}-\mathcal{P}$ at $2R$. Let $\{\psi_\mu\}$ be an orthonormal basis of $W = \mathrm{Im}(\mathrm{Id}-\mathcal{P}) \cap \mathrm{Im}(\Pi_+)$ where $\psi_\mu \in E_\mu$, and for each such μ, define $\varphi_\mu := G\psi_\mu \in GW$. Since $GD_Y = -D_Y G$ and $\mathcal{P}G = G(\mathrm{Id}-\mathcal{P})$, it follows that $\varphi_\mu = G\psi_\mu \in E_{-\mu} \cap \mathrm{Im}(\mathcal{P})$. Using this, it is straightforward to check that

$$\phi_1 := \frac{\sinh(\mu(u+R))}{\sinh(2\mu R)}\varphi_\mu \quad \text{over} \quad [-R,R]\times Y,$$

and

$$\phi_2 := e^{\mu(u-R)}\varphi_\mu \quad \text{over} \quad [R,2R]\times Y,$$

are continuous at $u=R$ with value φ_μ and satisfy $\tilde{D}^2\phi_i = 0$, $i=1,2$. Thus, by the definition of $\mathcal{R}$ in (2.4), we have

$$\mathcal{R}\varphi_\mu := \partial_u\phi_1|_{u=R} - \partial_u\phi_2|_{u=R} = \left(\mu\frac{\cosh(2\mu R)}{\sinh(2\mu R)} - \mu\right)\varphi_\mu = \frac{\mu e^{-2\mu R}}{\sinh(2\mu R)}\varphi_\mu.$$

Therefore,

$$-G\mathcal{R}G\psi_\mu = -G\mathcal{R}\varphi_\mu = -G\frac{\mu e^{-2\mu R}}{\sinh(2\mu R)}\varphi_\mu = \frac{\mu e^{-2\mu R}}{\sinh(2\mu R)}\psi_\mu.$$

It follows that

$$L = -P_W G \mathcal{R}^{-1} G P_W = \sum_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \frac{e^{2\mu R}\sinh(2\mu R)}{\mu}\psi_\mu \otimes \psi_\mu.$$

Hence,

$$(\det L)^2 = \prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} e^{4\mu R}\frac{\sinh^2(2\mu R)}{\mu^2},$$

which completes the Comparison proof of Lemma 3.1. □

Next, we compute a related ζ-determinant ratio.

Lemma 3.2: With the notations above, the following equality holds:

$$\frac{\det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\mathcal{P}}}{\det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\Pi^\sigma_+}} = \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \frac{e^{-4\mu R}\sinh^2(2\mu R)}{\mu^2}\right) \cdot \det_F\left(\frac{2\,\mathrm{Id} + \hat{U}_\mathcal{P} + \hat{U}_\mathcal{P}^{-1}}{4}\right).$$

Proof: Observe that $\mathrm{Id}-\Pi_+^\sigma$ is the Calderón projector at $\{R\}\times Y$ of the operator

$$D:\mathrm{dom}(D)\to L^2(N_R,S),$$

where

$$\mathrm{dom}(D):=\{\phi\in H^1(N_R,S)\,|\,\Pi_+^\sigma(\phi|_{u=-R})=0\}.$$

Then $D_{\mathrm{Id}-\mathcal{P}}=\mathcal{D}_{\Pi_+^\sigma,\mathrm{Id}-\mathcal{P}}$ and $D_{\mathcal{C}_-}=\mathcal{D}_{\Pi_+^\sigma,\mathrm{Id}-\Pi_+^\sigma}$, so the comparison formula (2.5) applied to this situation gives us

$$\frac{\det_\zeta\mathcal{D}^2_{\Pi_+^\sigma,\mathrm{Id}-\mathcal{P}}}{\det_\zeta\mathcal{D}^2_{\Pi_+^\sigma,\mathrm{Id}-\Pi_+^\sigma}}=(\det L)^2\cdot\det_F\left(\frac{2\,\mathrm{Id}+\hat{U}_{\mathcal{P}}^{-1}+\hat{U}_{\mathcal{P}}}{4}\right),$$

where we used that the U in (2.5) for this situation is $(-\kappa_\sigma)(-\kappa_{\mathcal{P}}^{-1})=\kappa_\sigma\kappa_{\mathcal{P}}^{-1}=(\kappa_{\mathcal{P}}\kappa_\sigma^{-1})^{-1}=U_{\mathcal{P}}^{-1}$, and where L is the map over $\{R\}\times Y$ defined in (2.3):

$$L:=-P_W G\mathcal{R}^{-1}GP_W:W\to W$$

with

$$W:=\gamma_R\ker(\mathcal{D}_{\Pi_+^\sigma,\mathrm{Id}-\mathcal{P}})\equiv\mathrm{Im}(\mathrm{Id}-\Pi_+^\sigma)\cap\mathrm{Im}(\mathcal{P})=\mathrm{Im}(\mathcal{P})\cap\mathrm{Im}(\Pi_-).$$

To compute $(\det L)^2$ for this example, we proceed in much the same way as for the Comparison proof of Lemma 3.1. An invertible extension $\tilde{D}$ of D is just $G(\partial_u+D_Y)$ over $[-R,2R]\times Y$ with boundary condition Π_+^σ at $-R$ and $\mathrm{Id}-\Pi_+^\sigma$ at $2R$. Let $\{\psi_\nu\}$ be an orthonormal basis of $W=\mathrm{Im}(\mathcal{P})\cap\mathrm{Im}(\Pi_-)$ where $\psi_\nu\in E_\nu$. It is important to note that, in contrast to the Comparison proof of Lemma 3.1, the ν's are *negative* (rather than positive) and that $\psi_\nu\in E_\nu\cap\mathrm{Im}(\mathcal{P})$ [rather than $\mathrm{Im}(\mathrm{Id}-\mathcal{P})$]. Following the Comparison proof of Lemma 3.1 almost verbatim, it is straightforward to check that

$$L=-P_W G\mathcal{R}^{-1}GP_W=\sum_{\substack{\nu<0\\ E_\nu\cap\mathrm{Im}(\mathcal{P})\neq 0}}\frac{e^{2\nu R}\sinh(2\nu R)}{\nu}\psi_\nu\otimes\psi_\nu,$$

so

$$(\det L)^2=\prod_{\substack{\nu<0\\ E_\nu\cap\mathrm{Im}(\mathcal{P})\neq 0}}e^{4\nu R}\frac{\sinh^2(2\nu R)}{\nu^2}.$$

Finally, using that G maps $E_\nu\cap\mathrm{Im}(\mathcal{P})$ isomorphically onto $E_{-\nu}\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P})$, where we used that $GD_Y=-D_YG$ and $\mathcal{P}G=G(\mathrm{Id}-\mathcal{P})$, we finally get

$$(\det L)^2=\prod_{\substack{\mu>0\\ E_\mu\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}}e^{4(-\mu)R}\frac{\sinh^2(-2\mu R)}{(-\mu)^2}=\prod_{\substack{\mu>0\\ E_\mu\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}}e^{-4\mu R}\frac{\sinh^2(2\mu R)}{\mu^2},$$

which completes our proof. □

We are now ready to prove the following

Lemma 3.3: With the notations above, the following equality holds:

$$\det_\zeta\mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}}=e^{2CR}2^{\zeta_{D_Y^2}(0)+h_Y}\cdot\left(\prod_{\substack{\mu>0\\ E_\mu\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}}e^{-8\mu R}\right),$$

where $C=(\Gamma(s)^{-1}\zeta_{D_Y^2}(s-1/2))'(0)$ *with* $\zeta_{D_Y^2}(s)$ *the* ζ*-function of* D_Y^2 *and* $h_Y=\dim\ker(D_Y)$.

Proof: Solving for $\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}}$ in Lemma 3.1, we obtain

$$\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{P}} = \det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\Pi^\sigma_+} \cdot \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \frac{e^{-4\mu R}\mu^2}{\sinh^2(2\mu R)} \right) \cdot \det_F \left(\frac{2\,\mathrm{Id} + \hat{U}_\mathcal{P} + \hat{U}_\mathcal{P}^{-1}}{4} \right)^{-1}. \tag{3.3}$$

On the other hand, from Lemma 3.2, we know that

$$\frac{\det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\mathcal{P}}}{\det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\Pi^\sigma_+}} = \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \frac{e^{-4\mu R}\sinh^2(2\mu R)}{\mu^2} \right) \cdot \det_F \left(\frac{2\,\mathrm{Id} + \hat{U}_\mathcal{P} + \hat{U}_\mathcal{P}^{-1}}{4} \right)$$

and from the main result of Ref. 11 [see formula (1.7)], we also have

$$\det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\Pi^\sigma_+} = e^{2CR} 2^{\zeta_{D_Y^2}(0)+h_Y}.$$

Hence,

$$\det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\mathcal{P}} = e^{2CR} 2^{\zeta_{D_Y^2}(0)+h_Y} \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P})\neq 0}} \frac{e^{-4\mu R}\sinh^2(2\mu R)}{\mu^2} \right) \cdot \det_F \left(\frac{2\mathrm{Id} + \hat{U}_\mathcal{P} + \hat{U}_\mathcal{P}^{-1}}{4} \right).$$

Substituting this expression into (3.3), using that

$$\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\Pi^\sigma_+} = \det_\zeta \mathcal{D}^2_{\Pi^\sigma_+,\mathrm{Id}-\mathcal{P}}, \tag{3.4}$$

concludes the proof of our result once we show that (3.4) holds. In fact, (3.4) holds in the more general setting: $\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{Q}} = \det_\zeta \mathcal{D}^2_{\mathcal{Q},\mathrm{Id}-\mathcal{P}}$ for all $(\mathcal{P},\mathrm{Id}-\mathcal{Q}) \in \mathrm{Gr}^*_\infty(D_Y)$. To prove this, we simply observe that

$$G(\partial_u + D_Y)\phi = \lambda\phi, \quad \mathcal{P}\phi(-R) = 0, \quad (\mathrm{Id}-\mathcal{Q})\phi(R) = 0$$

if and only if $\psi(u) := G\phi(-u)$ satisfies

$$G(\partial_u + D_Y)\psi = -\lambda\psi, \quad (\mathrm{Id}-\mathcal{P})\psi(R) = 0, \quad \mathcal{Q}\psi(-R) = 0,$$

where we used that $G^2 = -\mathrm{Id}$, $GD_Y = -D_Y G$, $\mathcal{P}G = G(\mathrm{Id}-\mathcal{P})$, and $\mathcal{Q}G = G(\mathrm{Id}-\mathcal{Q})$. It follows that $\mathrm{spec}(\mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{Q}}) = \mathrm{spec}(\mathcal{D}^2_{\mathcal{Q},\mathrm{Id}-\mathcal{P}})$, which implies that $\det_\zeta \mathcal{D}^2_{\mathcal{P},\mathrm{Id}-\mathcal{Q}} = \det_\zeta \mathcal{D}^2_{\mathcal{Q},\mathrm{Id}-\mathcal{P}}$. □

IV. PROOF OF THEOREM 1.1

As we already mentioned, in order to demonstrate the effectiveness of the gluing formula (2.2) and the comparison formula (2.5), we shall give separate proofs of Theorem 1.1 exploiting both formulas.

Gluing proof of Theorem 1.1: Recall that the operator $\mathcal{D}_P$ as defined in (1.4) written using the notation (3.1) is

$$\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2} := \mathcal{D}:\mathrm{dom}(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}) \to L^2(N_R,S),$$

where

$$\mathrm{dom}(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}) := \{\phi \in H^1(N_R,S) | \mathcal{P}_1(\phi|_{u=-R}) = 0, \quad \mathcal{P}_2(\phi|_{u=R}) = 0\}.$$

Let us decompose N_R into two parts $[-R,0]\times Y$ and $[0,R]\times Y$ as shown in Fig. 2. Then the restrictions of $\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}$ over the decomposed parts define two Dirac type operators with boundary

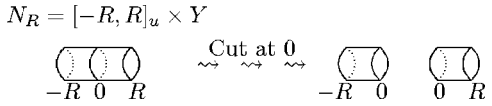

FIG. 2. Cutting N_R at 0 into two pieces.

conditions given by $\mathcal{P}_1$ at $\{-R\}\times Y$ and $\mathcal{P}_2$ at $\{R\}\times Y$. It is easy to check that the Calderón projections of these operators are, respectively, just $\mathrm{Id}-\mathcal{P}_1$ and $\mathrm{Id}-\mathcal{P}_2$ over $\{0\}\times Y$. We denote the operators over the decomposed parts $[-R,0]\times Y$ and $[0,R]\times Y$ with the new boundary conditions given by these Calderón projectors over $\{0\}\times Y$ by $D_{\mathcal{P}_1,\mathrm{Id}-\mathcal{P}_1}$ and $D_{\mathrm{Id}-\mathcal{P}_2,\mathcal{P}_2}$, respectively. Now applying the gluing formula (2.2) to this situation, we obtain

$$\frac{\det_\zeta \mathcal{D}^2_{\mathcal{P}_1,\mathcal{P}_2}}{\det_\zeta D^2_{\mathcal{P}_1,\mathrm{Id}-\mathcal{P}_1}\cdot \det_\zeta D^2_{\mathrm{Id}-\mathcal{P}_2,\mathcal{P}_2}} = 2^{-\zeta_{D_Y^2}(0)-h_Y}(\det \mathcal{L})^{-2}\det_F\left(\frac{2\,\mathrm{Id}+\hat{U}_P+\hat{U}_P^{-1}}{4}\right), \tag{4.1}$$

where the $\hat{\mathcal{U}}$ in (2.2) for this situation is the restriction of $-(-\kappa_1)(-\kappa_2^{-1})=-\kappa_1\kappa_2^{-1}=:U_P$ over $L^2(Y,S^-)$ to the orthogonal complement of its (-1)-eigenspace, noting that $-\kappa_i$ is the isometry corresponding to $\mathrm{Id}-\mathcal{P}_i$ for $i=1$, 2, and where

$$\mathcal{L} := \sum_{k=1}^{h_P} \gamma_0 U_k \otimes \gamma_0 U_k : \gamma_0 \ker(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}) \to \gamma_0 \ker(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}), \tag{4.2}$$

where $h_P=\dim\ker(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2})$, γ_0 is the restriction map from N_R to $\{0\}\times Y$, and $\{U_k\}$ is an orthonormal basis of $\ker(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2})$. By Lemma 3.3 (here we need to replace R with $R/2$ since the lengths of $[-R,0]$ and $[0,R]$ are half that of $[-R,R]$, which is the interval considered in Lemma 3.3),

$$\det_\zeta D^2_{\mathcal{P}_1,\mathrm{Id}-\mathcal{P}_1} = e^{CR}2^{\zeta_{D_Y^2}(0)+h_Y}\cdot\left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{-4\mu R}\right),$$

and

$$\det_\zeta D^2_{\mathrm{Id}-\mathcal{P}_2,\mathcal{P}_2} = e^{CR}2^{\zeta_{D_Y^2}(0)+h_Y}\cdot\left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathcal{P}_2)\neq 0}} e^{-4\mu R}\right).$$

Now to complete the Gluing proof of Theorem 1.1, it remains to compute $(\det\mathcal{L})^{-2}$ over $\gamma_0\ker(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2})\equiv \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P}_2)$. To do so, we note that

$$\ker(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}) \equiv \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P}_2) := W.$$

Let $\{\psi_\mu\}$ be an orthonormal basis of W where $\psi_\mu\in E_\mu$. Then $\phi_\mu := e^{-\mu u}\psi_\mu \in \ker(\mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2})$ and

$$\|\phi_\mu\|^2 = \int_{-R}^{R} e^{-2\mu u}du = \frac{\sinh(2\mu R)}{\mu},$$

where if $\mu=0$, then we replace $[\sinh(2\mu R)]/\mu$ by its limit as $\mu\to 0$, that is, $2R$. It follows that

$$\mathcal{L} = \sum_{\substack{\mu\in\mathrm{spec}(D_Y)\\ E_\mu\cap W\neq 0}} \frac{\phi_\mu(0)}{\|\phi_\mu\|}\otimes\frac{\phi_\mu(0)}{\|\phi_\mu\|} = \sum_{\substack{\mu\in\mathrm{spec}(D_Y)\\ E_\mu\cap W\neq 0}} \frac{1}{\|\phi_\mu\|^2}\psi_\mu\otimes\psi_\mu.$$

Hence,

$$(\det \mathcal{L})^{-2} = \prod_{\substack{\mu \in \operatorname{spec}(D_Y) \\ E_\mu \cap W \neq 0}} \left(\frac{1}{\|\phi_\mu\|^2} \right)^{-2} = \prod_{\substack{\mu \in \operatorname{spec}(D_Y) \\ E_\mu \cap W \neq 0}} \frac{\sinh^2(2\mu R)}{\mu^2}.$$

This completes the Gluing proof of Theorem 1.1.

Comparison proof of Theorem 1.1: We now prove Theorem 1.1 using the comparison formula (2.5) applied to the pair $(\mathcal{D}^2_{\mathcal{P}_1,\mathcal{P}_2}, \mathcal{D}^2_{\mathcal{P}_1,\mathrm{Id}-\mathcal{P}_1})$. Here we regard $\mathrm{Id}-\mathcal{P}_1$ as the Calderón projector at the boundary $\{R\}\times Y$ of the operator

$$D{:}\operatorname{dom}(D) \to L^2(N_R, S),$$

where

$$\operatorname{dom}(D) := \{\phi \in H^1(N_R, S) | \mathcal{P}(\phi|_{u=-R}) = 0\}.$$

Then $D_{\mathcal{P}_2} = \mathcal{D}_{\mathcal{P}_1,\mathcal{P}_2}$ and $D_{c_-} = \mathcal{D}_{\mathcal{P}_1,\mathrm{Id}-\mathcal{P}_1}$, so applying the comparison formula (2.5) to this situation, we obtain

$$\frac{\det_\zeta \mathcal{D}^2_{\mathcal{P}_1,\mathcal{P}_2}}{\det_\zeta \mathcal{D}^2_{\mathcal{P}_1,\mathrm{Id}-\mathcal{P}_1}} = (\det L)^2 \cdot \det_F\left(\frac{2\mathrm{Id} + \hat{U}_P + \hat{U}_P^{-1}}{4} \right), \tag{4.3}$$

where we used that the U in (2.5) for this situation is $(-\kappa_1)\kappa_2^{-1} =: U_P$ noting that $-\kappa_1$ corresponds to $\mathrm{Id}-\mathcal{P}_1$, and where L is the operator defined in (2.3) for this situation, which we will investigate in detail soon. Now, by Lemma 3.3,

$$\det_\zeta \mathcal{D}^2_{\mathcal{P}_1,\mathrm{Id}-\mathcal{P}_1} = e^{2CR} 2^{\zeta_{D_Y^2}(0)+h_Y} \cdot \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{-8\mu R} \right),$$

therefore by (4.3),

$$\det_\zeta \mathcal{D}^2_{\mathcal{P}_1,\mathcal{P}_2} = e^{2CR} 2^{\zeta_{D_Y^2}(0)+h_Y} \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{-8\mu R} \right) \cdot (\det L)^2 \cdot \det_F\left(\frac{2\mathrm{Id} + \hat{U}_P + \hat{U}_P^{-1}}{4} \right).$$

To compute $\det L$, we use almost the exact same argument found in Lemma 3.2 to show that with $W := \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1) \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_2)$,

$$(\det L)^2 = \prod_{\substack{\mu \in \operatorname{spec}(D_Y) \\ E_\mu \cap W \neq 0}} e^{4\mu R} \frac{\sinh^2(2\mu R)}{\mu^2},$$

where in the product, when $\mu = 0$ we replace $[\sinh^2(2\mu R)]/\mu^2$ by its limit as $\mu \to 0$, that is, $(2R)^2$. Therefore,

$$\begin{aligned} \det_\zeta \mathcal{D}^2_{\mathcal{P}_1,\mathcal{P}_2} = e^{2CR} 2^{\zeta_{D_Y^2}(0)+h_Y} & \left(\prod_{\substack{\mu>0 \\ E_\mu \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{-8\mu R} \right) \cdot \left(\prod_{\substack{\mu \in \operatorname{spec}(D_Y) \\ E_\mu \cap W \neq 0}} e^{4\mu R} \right) \\ & \cdot \left(\prod_{\substack{\mu \in \operatorname{spec}(D_Y) \\ E_\mu \cap W \neq 0}} \frac{\sinh^2(2\mu R)}{\mu^2} \right) \cdot \det_F\left(\frac{2\mathrm{Id} + \hat{U}_P + \hat{U}_P^{-1}}{4} \right). \end{aligned} \tag{4.4}$$

Since $W = \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1) \cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_2)$, we have

$$\prod_{\substack{\mu\in\mathrm{spec}(D_Y)\\ E_\mu\cap W\neq 0}} e^{4\mu R} = \left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P}_2)\neq 0}} e^{4\mu R}\right)\cdot\left(\prod_{\substack{\mu<0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P}_2)\neq 0}} e^{4\mu R}\right)$$

$$= \left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{4\mu R}\right)\cdot\left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathcal{P}_2)\neq 0}} e^{-4\mu R}\right)$$

$$\cdot\left(\prod_{\substack{\mu<0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P}_2)\neq 0}} e^{4\mu R}\right).$$

Since $D_Y G=-GD_Y$ and $\mathcal{P}_i G=G(\mathrm{Id}-\mathcal{P}_i)$, we have

$$E_\mu\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathrm{Id}-\mathcal{P}_2)\neq 0\Leftrightarrow E_{-\mu}\cap\mathrm{Im}(\mathcal{P}_1)\cap\mathrm{Im}\mathcal{P}_2\neq 0,$$

as G maps the first space isomorphically onto the second space, therefore

$$\prod_{\substack{\mu\in\mathrm{spec}(D_Y)\\ E_\mu\cap W\neq 0}} e^{4\mu R} = \left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{4\mu R}\right)\cdot\left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\cap\mathrm{Im}(\mathcal{P}_2)\neq 0}} e^{-4\mu R}\right)$$

$$\cdot\left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathcal{P}_1)\cap\mathrm{Im}(\mathcal{P}_2)\neq 0}} e^{-4\mu R}\right)$$

$$= \left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathrm{Id}-\mathcal{P}_1)\neq 0}} e^{4\mu R}\right)\cdot\left(\prod_{\substack{\mu>0\\ E_\mu\cap \mathrm{Im}(\mathcal{P}_2)\neq 0}} e^{-4\mu R}\right).$$

Putting this expression into (4.4) completes the Comparison proof of Theorem 1.1.

In this paper we prove the existence of the radially symmetric nontopological bare solutions in the relativistic self-dual Maxwell–Chern–Simons–Higgs model. We also verify the Chern–Simons limit for those solutions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1861277]

I. INTRODUCTION

In this paper we are concerned with the relativistic Maxwell–Chern–Simons–Higgs model (MCSH).[1] Consider $(2+1)$-dimensional Minkowski space $\mathbb{R}^{1,2}$ with the metric $\mathrm{diag}(1,-1,-1)$. The metric is used to raise or lower indices. The Lagrangian density of the relativistic MCSH is given by

$$\mathcal{L} = (D_\alpha\phi)\overline{(D^\alpha\phi)} - \frac{1}{4}F_{\alpha\beta}F^{\alpha\beta} + \frac{\kappa}{4}\epsilon^{\alpha\beta\gamma}A_\alpha F_{\beta\gamma} + \frac{1}{2}\partial_\alpha N\partial^\alpha N - q^2|\phi|^2N^2 - \frac{1}{2}(q|\phi|^2 + \kappa N - q)^2, \tag{1.1}$$

where all the greek indices run over 0,1,2. Here $q>0$ is the charge of electron, $\kappa>0$ is the Chern–Simons coupling constant, $\phi:\mathbb{R}\times\mathbb{R}^2\to\mathbb{C}$ is the Higgs field, $A_\alpha:\mathbb{R}\times\mathbb{R}^2\to\mathbb{R}$ is the gauge field, $N:\mathbb{R}\times\mathbb{R}^2\to\mathbb{R}$ is the neutral scalar field, $D_\alpha=\partial_\alpha-iqA_\alpha$ is the covariant derivative with $i=\sqrt{-1}$, and $F_{\alpha\beta}=\partial_\alpha A_\beta-\partial_\beta A_\alpha$ is the field strength.

We say that (ϕ,A_α) is gauge equivalent to (ψ,B_α), if there exists a function χ such that

$$(\psi,B_\alpha) = (e^{i\chi}\phi, A_\alpha + \partial_\alpha\chi).$$

It is easily verified that the $\mathcal{L}$ and its Euler–Lagrange equations are invariant under the gauge transformation.

We consider the stationary solutions of the Euler–Lagrange equations for (1.1). The variational equation for A_0, often called the Gauss constraint equation, gives

$$-\Delta A_0 + 2q^2|\phi|^2A_0 = -\kappa F_A. \tag{1.2}$$

Using this equation, we can write the static MCSH energy functional as

$$\mathcal{E}(\phi,A,N) = \int_{\mathbb{R}^2} |D_A\phi|^2 + \frac{1}{2}|F_A|^2 + q^2|\phi|^2A_0^2 + \frac{1}{2}|\nabla A_0|^2 + q^2|\phi|^2N^2 + \frac{1}{2}|\nabla N|^2 + \frac{1}{2}(q|\phi|^2 + \kappa N - q)^2. \tag{1.3}$$

Here we used the notations as follows: $A=(A_1,A_2)$, $D_A\phi=\nabla\phi-iq\phi A$, and $F_A=\partial_1A_2-\partial_2A_1$.

Using (1.2) and integrating by parts, we obtain

[a]Electronic mail: jmhan@hufs.ac.kr
[b]Electronic mail: jdjang@hufs.ac.kr

$$\mathcal{E}(\phi,A,N)=\int_{\mathbb{R}^2}\Big(|D_1\phi\pm iD_2\phi|^2+q^2|\phi|^2|A_0\pm N|^2+\frac{1}{2}|\nabla A_0\pm\nabla N|^2$$
$$+\frac{1}{2}|F_A\pm(q|\phi|^2+\kappa N-q)|^2\Big)\mathrm{d}x\pm\Lambda,$$

where

$$\Lambda=q\int_{\mathbb{R}^2}F_A\,\mathrm{d}x. \tag{1.4}$$

If Λ is positive (negative), then choose the upper (lower) sign. This yields the lower bound of the energy functional,

$$\mathcal{E}(\phi,A,N)\geqslant|\Lambda|,$$

which is saturated by the following system of self-dual equations:

$$D_1\phi\pm iD_2\phi=0, \tag{1.5}$$

$$A_0\pm N=0, \tag{1.6}$$

$$F_A\pm(q|\phi|^2+\kappa N-q)=0. \tag{1.7}$$

Since the solutions of (1.5)–(1.7) are the global minimizer of $\mathcal{E}$ over a suitable function space,[2] they are solutions of the Euler–Lagrange equations of the Lagrangian $\mathcal{L}$. It is not yet proved whether the converse is true, i.e., the self-dual equations (1.5)–(1.7) are equivalent to the Euler–Lagrange equations.

The boundary conditions are given by the finite energy condition of (1.3) as $|x|\to\infty$, either

$$|\phi|\to1\quad\text{and }N\to0,$$

or

$$|\phi|\to0\quad\text{and }N\to\frac{q}{\kappa}.$$

The former is called topological, while the latter nontopological.

Let us take the upper signs in (1.5)–(1.7). The lower sign case can be obtained by the conjugate transformation $(\phi,A,N)\to(\overline{\phi},-A,N)$. To examine the self-dual equations further, we use the classical Jaffe–Taubes arguments.[3] In fact, Eq. (1.5) implies that ϕ is holomorphic up to a nonvanishing multiple factor and has exactly m zeros allowing multiplicities. Thus we may assume that ϕ takes the form

$$\phi(z)=\exp\left(\frac{1}{2}u(x)+i\sum_{j=1}^{k}n_j\arg(x-p_j)\right), \tag{1.8}$$

where the points $p_1,\ldots,p_k$, called the vortex points, are the distinct zeros of ϕ with multiplicities $n_1,\ldots,n_k$, respectively. Clearly, $n_1+\cdots+n_k=m$. We observe that the arbitrary choice on the imaginary part of ϕ merely reflects the gauge invariance of (1.2)–(1.7). Now the equations (1.2), (1.6), and (1.7) are transformed into

$$\Delta u=2q^2(e^u-1)+2\kappa qN+4\pi\sum_{j=1}^{k}n_j\delta_{p_j},\quad\text{in }\mathbb{R}^2, \tag{1.9}$$

$$\Delta N = \kappa q(e^u - 1) + (\kappa^2 + 2q^2 e^u)N \quad \text{in } \mathbb{R}^2. \tag{1.10}$$

The boundary conditions are rewritten as

$$\text{topological}, \quad u \to 0 \quad \text{and } N \to 0, \tag{1.11}$$

$$\text{nontopological}, \quad u \to -\infty \quad \text{and } N \to \frac{q}{\kappa}, \tag{1.12}$$

as $|x| \to \infty$. Conversely, once we find a solution (u, N) of (1.9) and (1.10), we may recover A and A_0 from (1.5) and (1.6) by the formula

$$qA_1 + iqA_2 = -2i\overline{\partial} \ln \phi,$$

where $\overline{\partial} = (\partial_1 + i\partial_2)/2$.

It was proved that the equations (1.9) and (1.10) allow both topological[4] and nontopological[5] solutions. On the other hand, one can consider the self-dual equations (1.5)–(1.7) on the 't Hooft type periodic domain, of which solutions are called condensate solutions. There has been several results for the condensate solutions.[6–8]

It is an interesting question that there exists a radially symmetric solution to (1.9) and (1.10) if $k=0$ or 1. Such a radial solution has been studied in several self-dual gauge models.[9,10] Concerning the Maxwell–Chern–Simons–Higgs model, if $k=0$, then the only solution of (1.9) and (1.10) with the topological boundary condition (1.11) is proved to be $u \equiv N \equiv 0$ by the maximum principle, while there is no result for the nontopological solution. For the case $k=1$, every topological solution is radially symmetric about the only vortex point.[11] Although the existence of nontopological multivortex solutions was established by Chae–Imanuvilov,[5] their solutions are not radially symmetric about the vortex point for the case $k=1$. In this context, when $k=0$ or $k=1$, it is an interesting problem to consider nontopological solutions which is radially symmetric about a point. In this paper we are interested in the radially symmetric nontopological solutions when there are no vortex points, i.e., $k=0$. In this case, the solutions are called bare solutions.[12] For the case $k=1$, we postpone the study of nontopological radial solutions to a forthcoming paper.

From now on we assume $m=0$ and let us rewrite (1.9) as

$$\Delta u = 2q^2(e^u - 1) + 2\kappa q N. \tag{1.13}$$

Our first result in this paper is to establish the radial solutions of (1.10) and (1.13) as follows.

Theorem 1.1: *For any $x_0 \in \mathbb{R}^2$ and $a<0$, there exists a unique number $b=b(a) \in (0, q/\kappa)$ such that the equations (1.10) and (1.13) with the boundary condition (1.12) admit a unique solution which is radially symmetric about x_0. The corresponding solution (ϕ, A, N) of the self-dual equations (1.5)–(1.7) is of finite energy. Furthermore, we have the following.*

(i) *There exists a constant $\gamma = \gamma(a) > 4$ such that*

$$\mathcal{E}(\phi, A, N) = \pi\gamma.$$

(ii) *(ϕ, A, N) is radially symmetric about x_0.*

(iii) *ϕ has no zeros in $\mathbb{R}^2$.*

(iv) $\max_{x \in \mathbb{R}^2} |\phi(x)|^2 = |\phi(x_0)|^2 = e^a, \quad \min_{x \in \mathbb{R}^2} N(x) = N(x_0) = b.$

(v) $|\phi(x)|^2, \quad q - \kappa N(x) = O(|x|^{-\gamma}).$

On the other hand, if we set

$$\kappa = 0, \quad q = 1/\sqrt{2}, \quad N \equiv 0, \tag{1.14}$$

then the equations (1.9) and (1.10) reduce to

$$\Delta u = e^u - 1 + 4\pi \sum_{j=1}^{k} n_j \delta_{p_j},$$

which is the self-dual equation of the Abelian–Higgs model.[13] Similarly, if we set

$$\kappa = \mu q^2, \quad \mu > 0, \quad N = q(1 - e^u)/\kappa, \quad q \to \infty, \tag{1.15}$$

then the equations (1.9) and (1.10) tend formally to

$$\Delta u = \frac{1}{\mu^2} e^u (e^u - 1) + 4\pi \sum_{j=1}^{k} n_j \delta_{p_j}, \tag{1.16}$$

which is the self-dual equation of the Chern–Simons–Higgs model.[14,15] Therefore, one can formally consider the Maxwell–Chern–Simons–Higgs model as a unification of the Abelian–Higgs model and the Chern–Simons–Higgs model.[1] The first limit is called the Maxwell limit (or Abelian–Higgs limit), while the second one the Chern–Simons limit. There have been several results about the mathematically rigorous proof for the convergence of the topological solutions[4] and the condensate[6–8] solutions. See Ref. 2 for the Chern–Simons limit of the solutions of the Euler–Lagrange equations on a bounded domain. However, there have been no results about the verification of the limits for the nontopological solutions on $\mathbb{R}^2$, as far as we know. For the nontopological solutions on $\mathbb{R}^2$, only the Chern–Simons limit is meaningful because the self-dual equations of the Abelian–Higgs model permits only the topological boundary conditions at infinity. In the following theorem we verify the Chern–Simons limit for the radially symmetric nontopological bare solutions, which is the main contribution of the present paper.

Theorem 1.2 (Chern–Simons limit): *Let $a<0$ be fixed and set $\kappa=\mu q^2$. Let (u_q, N_q) be the unique solution of the equations (1.10) and (1.13) with the boundary condition (1.12) which is radially symmetric about a point $x_0 \in \mathbb{R}^2$ with $u(x_0)=a$ and $N(x_0)=b(a)$. Let $\tilde{N}_q = qN_q$. Then, as $q \to \infty$, $(u_q, \tilde{N}_q)$ converges to (u_*, N_*) such that (u_*, N_*) satisfies*

$$\Delta u_* = \frac{1}{\mu^2} e^{u_*}(e^{u_*} - 1), \quad u(x_0) = a, \quad u_* \to -\infty \quad \text{as } |x| \to \infty, \tag{1.17}$$

and $N_* = (1 - e^{u_*})/\mu$. More precisely, for any $R>0$,

$$\|u_q - u_*\|_{C^2(B_R)} = O(q^{-2}), \quad \|\tilde{N}_q - N_*\|_{C^0(B_R)} = O(q^{-2}).$$

The solutions of the equation (1.17) are well known.[10] In fact, every solution of (1.17) is radially symmetric about a point $x_0 \in \mathbb{R}^2$ with the property $u<0$ on $\mathbb{R}^2$, and for each $a<0$ (1.17) allows a unique radial solution with $u(x_0)=a$. In this point of view it is an interesting question whether every nontopological bare solution of (1.10) and (1.13) is radially symmetric about a point.

In the next two sections, we will prove Theorems 1.1 and 1.2.

II. EXISTENCE OF RADIAL SOLUTIONS

In this section we prove Theorem 1.1 following the argument in Refs. 9 and 10, which was used to prove the existence of several kind of self-dual equations of nontopological type. We will develop the argument in Refs. 9 and 10 into a system of equations. We begin with the following lemma.

Lemma 2.1: Let (u, N) be a solution of (1.10) and (1.13) with the boundary, condition (1.12). Then

$$0 < N < \frac{q}{\kappa}(1 - e^u). \tag{2.1}$$

Proof: Although this lemma is well known,[6] we provide a proof for the sake of completeness.

We first show that $N \geqslant 0$. Suppose that x_0 is a negative minimum point of N. Then by the maximum principle,

$$0 > N(x_0) > \frac{\kappa q(1 - e^{u(x_0)})}{\kappa^2 + 2q^2 e^{u(x_0)}}.$$

In particular, $u(x_0) > 0$, and hence if x_1 is a maximum point of u, then $u(x_1) > 0$. Again the maximum principle implies,

$$N(x_1) < q(1 - e^{u(x_1)}).$$

Combining these two inequalities, we obtain

$$\frac{\kappa^2}{\kappa^2 + 2q^2 e^{u(x_0)}}(1 - e^{u(x_0)}) < (1 - e^{u(x_0)}).$$

Since $u(x_0) > 0$, this lead us to a contradiction.

Now let $v = q(e^u - 1) + \kappa N$. A short computation gives

$$\Delta v - (4q^2 e^u + \kappa^2)v = 2\kappa q^2 e^u N + qe^u |\nabla u|^2 > 0.$$

Since $v \to 0$ as $|x| \to \infty$, the maximum principle implies (2.1). ■

We will study solutions of (1.10) and (1.13) which is radially symmetric about a point $x_0 \in \mathbb{R}^2$, say $x_0 = 0$. If we set $r = |x|$, $u = u(r)$, and $N = N(r)$, then (1.10) and (1.13) become

$$u_{rr} + \frac{1}{r}u_r = 2q^2(e^u - 1) + 2\kappa qN, \quad r > 0, \tag{2.2}$$

$$N_{rr} + \frac{1}{r}N_r = \kappa q(e^u - 1) + (\kappa^2 + 2q^2 e^u)N, \quad r > 0, \tag{2.3}$$

$$u(0) = a, \quad N(0) = b. \tag{2.4}$$

Furthermore, if we make a change of variables $t = \ln r$, then with $u = u(t)$ and $N = N(t)$, we obtain

$$u'' = 2q^2 e^{2t}(e^u - 1) + 2\kappa qe^{2t}N, \quad t \in \mathbb{R}, \tag{2.5}$$

$$N'' = \kappa qe^{2t}(e^u - 1) + (\kappa^2 + 2q^2 e^u)e^{2t}N, \quad t \in \mathbb{R}, \tag{2.6}$$

$$u(t) = a + o(1), \quad N(t) = b + o(1) \text{ near } -\infty. \tag{2.7}$$

Here, prime denotes the derivative with respect to the variable t.

In view of Lemma 2.1, a necessary condition of the existence of a global solution to (2.5)–(2.7) with the boundary condition (1.12) is

$$0 < b < \frac{q}{\kappa}(1 - e^a). \tag{2.8}$$

In particular, $a < 0$. Moreover, we can rewrite (2.5) and (2.6) as

$$u'' = 2q^2 e^{2t} f(u) + 2\kappa qe^{2t}N \equiv e^{2t}\Phi(u, N), \tag{2.9}$$

$$N'' = \kappa q e^{2t} f(u) + (\kappa^2 + 2q^2 g(u)) e^{2t} N \equiv e^{2t} \Psi(u, N), \tag{2.10}$$

where $f(u) = e^u - 1$ and $g(u) = e^u$ for $u \leqslant 0$, and both f and g are smoothly defined for $u > 0$ in such a way that

$$\alpha = \sup_{u \in \mathbb{R}} (1 + |f(u)| + |f'(u)| + |g(u)| + |g'(u)|) < \infty.$$

We observe that both Φ and Ψ are increasing in u and N, and $\Phi < 2q\Psi/\kappa$ for $N > 0$. This fact plays an important role on the analysis of the above equations with the following identity:

$$u'' = \frac{2q}{\kappa} N'' - \frac{4q^3}{\kappa} e^{2t} e^u N. \tag{2.11}$$

We also define a number

$$\beta = \max\{1, \kappa, q\}.$$

Lemma 2.2: For $a < 0$ and $b > 0$, the equations (2.9) and (2.10) admits a unique solution satisfying

$$\lim_{t \to -\infty} u(t) = a, \quad \lim_{t \to -\infty} N(t) = b. \tag{2.12}$$

Proof: It is easy to show that (u, N) is a solution of (2.9) and (2.10) satisfying (2.12) if and only if (u, N) verifies

$$u(t) = a + \int_{-\infty}^{t} (t - s) e^{2s} \Phi(u(s), N(s)) \mathrm{d}s, \tag{2.13}$$

$$N(t) = b + \int_{-\infty}^{t} (t - s) e^{2s} \Psi(u(s), N(s)) \mathrm{d}s. \tag{2.14}$$

Let $T \in \mathbb{R}$ be a constant satisfying

$$e^{2T}(\beta^2 + \alpha\beta^2 + \beta^2 b + \alpha\beta^2 b) < \min\left\{\tfrac{1}{2}, b\right\}.$$

In order to find a solution in the interval $(-\infty, T]$, we construct a Picard iterative sequence (u_j, N_j) with the initial data $u_0 = a$, and $N_0 = b$,

$$u_j(t) = a + \int_{-\infty}^{t} (t - s) e^{2s} \Phi(u_{j-1}(s), N_{j-1}(s)) \mathrm{d}s,$$

$$N_j(t) = b + \int_{-\infty}^{t} (t - s) e^{2s} \Psi(u_{j-1}(s), N_{j-1}(s)) \mathrm{d}s.$$

Inductively, for $t \in (-\infty, T]$,

$$|N_j(t)| \leqslant b + (\kappa q \sup_{\mathbb{R}} |f| + (\kappa^2 + 2q^2 \sup_{\mathbb{R}} |g|) \sup_{(-\infty, T]} |N_{j-1}|) \int_{-\infty}^{T} (T - s) e^{2s} \, \mathrm{d}s \leqslant b$$

$$+ \frac{1}{4} e^{2T} (\alpha\beta^2 + 2b(\beta^2 + 2\alpha\beta^2)) \leqslant 2b.$$

Now for $t \in (-\infty, T]$,

$$|u_{j+1}(t)-u_j(t)| \leqslant \tfrac{1}{4}e^{2T}(2q^2 \sup_{\mathbb{R}}|f'| \cdot \sup_{(-\infty,T]}|u_j-u_{j-1}| + 2\kappa q \sup_{(-\infty,T]}|N_j-N_{j-1}|)$$
$$\leqslant \tfrac{1}{2}e^{2T}(\beta^2+\alpha\beta^2)(\sup_{(-\infty,T]}|u_j-u_{j-1}| + \sup_{(-\infty,T]}|N_j-N_{j-1}|),$$

and, since $|N_{j-1}(t)| \leqslant 2b$,

$$|N_{j+1}(t)-N_j(t)| \leqslant \tfrac{1}{4}e^{2T}(\alpha\beta^2 \sup_{(-\infty,T]}|u_j-u_{j-1}| + \beta^2 \sup_{(-\infty,T]}|N_j-N_{j-1}|) + \int_{-\infty}^{t} 2q^2e^{2s}(t-s)[g(u_j)(N_j$$
$$-N_{j-1}) + (g(u_j)-g(u_{j-1}))N_{j-1}]\mathrm{d}s \leqslant \tfrac{1}{4}e^{2T}((\alpha\beta^2+4\alpha\beta^2b) \sup_{(-\infty,T]}|u_j-u_{j-1}| + (\beta^2$$
$$+2\alpha\beta^2) \sup_{(-\infty,T]}|N_j-N_{j-1}|).$$

Consequently,

$$\sup_{(-\infty,T]}(|u_{j+1}-u_j| + |N_{j+1}-N_j|) \leqslant \tfrac{1}{4}e^{2T}(3\beta^2+4\alpha\beta^2+4\alpha\beta^2b)) \sup_{(-\infty,T]}(|u_j-u_{j-1}| + |N_j-N_{j-1}|)$$
$$\leqslant \tfrac{1}{2} \sup_{(-\infty,T]}(|u_j-u_{j-1}| + |N_j-N_{j-1}|),$$

and thus we obtain a solution on $(-\infty,T]$. Since $\alpha<\infty$, the solution can be extended in $\mathbb{R}$. Moreover, it is easily verified that the solution is unique on $(-\infty,T]$, and hence in $\mathbb{R}$. ■

Given $a<0$ and $b\in(0,q/\kappa)$, let us denote by $(u(t,a,b),N(t,a,b))$ the solutions of (2.9) and (2.10) constructed in Lemma 2.2. For $a<0$, let us define

$$\mathcal{S}^+(a)=\{b\in(0,q/\kappa): N(t_0,a,b)>q/\kappa \text{ for some } t_0\},$$

$$\mathcal{S}^0(a)=\{b\in(0,q/\kappa): 0\leqslant N(t,a,b)\leqslant q/\kappa,\ \forall\, t\in\mathbb{R}\},$$

$$\mathcal{S}^-(a)=\{b\in(0,q/\kappa): N(t,a,b)\leqslant q/\kappa\ \forall\, t \text{ and } N(t_0,a,b)<0 \text{ for some } t_0\}.$$

From now on let $a<0$ be fixed and set

$$b_1(a)\equiv\frac{\kappa q}{\kappa^2+2q^2e^a}(1-e^a),\quad b_2(a)\equiv\frac{q}{\kappa}(1-e^a). \tag{2.15}$$

We note that $\Phi(a,b_2)=0$ and $\Psi(a,b_1)=0$.

Lemma 2.3: (i) *If* $b\in(0,b_1)$, *then* $b\in\mathcal{S}^-(a)$. (ii) *If* $b\in(b_2,q/\kappa)$, *then* $b\in\mathcal{S}^+(a)$. (iii) $\mathcal{S}^-(a)$ *and* $\mathcal{S}^+(a)$ *are open*. (iv) $\mathcal{S}^0(a)$ *is a closed nonempty set.*

Proof: Note that

$$u'(t)=\int_{-\infty}^{t} e^{2s}\Phi(u(s),N(s))\mathrm{d}s, \tag{2.16}$$

$$N'(t)=\int_{-\infty}^{t} e^{2s}\Psi(u(s),N(s))\mathrm{d}s. \tag{2.17}$$

We observe that if $b\in(0,b_1)$, then $\Phi(a,b)<0$ and $\Psi(a;b)<0$. Hence there exists $T\in\mathbb{R}$ such that $u'',u',N'',N'<0$ for all $t>T$. Since $\Phi(u,N)$ and $\Psi(u,N)$ are monotone increasing in both $u<0$ and N, it holds that $u'',u',N'',N'<0$ for all $t\in\mathbb{R}$, which implies that $b\in\mathcal{S}^-(a)$. This establishes (i).

On the other hand, it is easy to check that if $b \in (b_2, q/\kappa)$, then $\Phi(a,b)>0$ and $\Psi(a,b)>0$. Then by the same argument as above, it remains that $u'', u', N'', N' > 0$ until the graph of u touches the t-axis. Once $u(t)>0$, we see that $u''(t)>0$ by the definition of Φ, and hence $u'', u', N'', N' > 0$ for all $t \in \mathbb{R}$. Thus $b \in \mathcal{S}^+(a)$, which proves (ii).

The assertion (iii) comes from the continuous dependence of solutions on b. Finally, the statement (iv) is derived from the fact that

$$\left(0, \frac{q}{\kappa}\right) = \mathcal{S}^-(a) \cup \mathcal{S}^0(a) \cup \mathcal{S}^+(a).$$

■

Lemma 2.4: There exist two numbers $b^-(a)$ and $b^+(a)$ satisfying $b^- \geqslant b_1$ and $b^+ \leqslant b_2$ such that

$$\mathcal{S}^-(a) = (0, b^-), \quad \mathcal{S}^0(a) = [b^-, b^+], \quad \mathcal{S}^+(a) = (b^+, q/\kappa).$$

Proof: We notice from Lemma 2.3 (i) and (ii) that

$$\{b:(0,b] \subset \mathcal{S}^-(a)\} \neq \emptyset, \quad \{b:[b, q/\kappa) \subset \mathcal{S}^+(a)\} \neq \emptyset.$$

We claim that

$$b \in \mathcal{S}^-(a)(b \in \mathcal{S}^+(a), \text{resp.}) \Rightarrow (0,b] \subset \mathcal{S}^-(a)([b, q/\kappa) \subset \mathcal{S}^+(a), \text{resp.}). \tag{2.18}$$

Then the numbers defined by

$$b^-(a) = \sup\{b:(0,b] \subset \mathcal{S}^-(a)\}, \quad b^+(a) = \inf\{b:[b, q/\kappa) \subset \mathcal{S}^+(a)\}$$

satisfy the assertion.

It remains to prove (2.18). Since $\mathcal{S}^-(a)$ is open, it suffices to show that if $(d_1, d_2] \subset \mathcal{S}^-(a)$, then $d_1 \in \mathcal{S}^-(a)$. Suppose that $d_1 \notin \mathcal{S}^-(a)$. Since $\mathcal{S}^-(a)$ and $\mathcal{S}^+(a)$ are open, $d_1 \in \mathcal{S}^0(a)$ and thus $N(t) \geqslant 0$ for all $t \in \mathbb{R}$. Let $u_i(t) = u(t, a, d_i)$ and $N_i(t) = N(t, a, d_i)$ for $i = 1, 2$. Note that $\Phi(a, d_1) < \Phi(a, d_2)$ and $\Psi(a, d_1) < \Psi(a, d_2)$. Since $\Phi(u, N)$ and $\Psi(u, N)$ are increasing functions of u and N, $u_1(t) < u_2(t)$ and $N_1(t) < N_2(t)$ for all $t \ll -1$ by the formulas (2.13) and (2.14). On the other hand, since $d_1 \in \mathcal{S}^0(a)$ and $d_2 \in \mathcal{S}^-(a)$, there exists $T \in \mathbb{R}$ such that $N_1(T) = N_2(T)$ and $N_1(t) < N_2(t)$ for all $t < T$.

We claim that $u_1(t) < u_2(t)$ for all $t < T$. Otherwise, there would exist a number $T_1 < T$ such that $u_1(T_1) = u_2(T_1)$ and $u_1(t) < u_2(t)$ for all $t < T_1$. Hence $(u_2 - u_1)''(t) < 0$ for all $t < T_1$ by the monotonicity of $\Phi(u, N)$ in u and N. Consequently, $u_2(T_1) - u_1(T_1) > u_2(-\infty) - u_1(-\infty) = 0$, a contradiction. Now, since $u_1(t) < u_2(t)$ and $N_1(t) < N_2(t)$ for all $t < T$, we conclude that $(N_2 - N_1)'' > 0$ for $t < T$, and hence $N_1(T) < N_2(T)$, which violates the fact that $N_1(T) = N_2(T)$. This completes the proof of the lemma. ■

Lemma 2.5: If $b \in \mathcal{S}^0(a)$, then a and b satisfy (2.8). Furthermore,

$$N'(t) \geqslant 0, \quad u'(t) \leqslant 0, \quad \forall\, t \in \mathbb{R}, \tag{2.19}$$

$$\lim_{t \to \infty} u(t) = -\infty, \quad \lim_{t \to \infty} N(t) = \frac{q}{\kappa}. \tag{2.20}$$

In addition, N'' changes signs only once, from $+$ to $-$.

Proof: Let $b \in \mathcal{S}^0(a)$. Then $0 \leqslant N(t) \leqslant q/\kappa$ for all $t \in \mathbb{R}$. Since $b_1 \leqslant b \leqslant b_2$, it holds that $\Phi(a,b) \leqslant 0$ and $\Psi(a,b) \geqslant 0$. We split the proof into three steps.

Step 1: If $b \in \mathcal{S}^0(a)$, then (2.19) holds.

We have three cases, $b_1 < b < b_2$, $b = b_2$, and $b = b_1$. If $b_1 < b < b_2$, then $\Phi(a,b) < 0$ and $\Psi(a,b) > 0$. Hence there exists $T_0 \in \mathbb{R}$ such that $u'(t) < 0$, $u''(t) < 0$, $N''(t) > 0$, and $N'(t) > 0$ for all $t < T_0$. Therefore if $N'(T) < 0$ for some T, then there exist two numbers T_1 and T_2 such that $N'(t) < 0$ and $N''(t) < 0$ on (T_1, T_2). We note from (2.11) that

$$u'(t) = \frac{2q}{\kappa}N'(t) - \int_{-\infty}^{t} \frac{4q^3}{\kappa}e^{u(s)}N(s)\mathrm{d}s.$$

Hence $u'(t)<0$ and $u''(t)<0$ on (T_1,T_2). Consequently, the monotonicity of Φ and Ψ implies that $b\in\mathcal{S}^-(a)$, a contradiction. Therefore, $N'(t)>0$ for all $t\in\mathbb{R}$. On the other hand, if $u'>0$ at some point, since $u',u''<0$ near $-\infty$, there exists an interval (T_3,T_4) such that $u',u''>0$ on (T_3,T_4). This would imply that $N',N''>0$ on (T_3,T_4), and thus $b\in\mathcal{S}^+(a)$. Hence $u'(t)\leqslant 0$ for all $t\in\mathbb{R}$. This proves (2.19).

We now turn to the second case, $b=b_2$. Since $\Phi(a,b)=0$ and $\Psi(a,b)>0$, we have $N'',N'>0$ near $-\infty$. Thus $u'',u'\leqslant 0$ near $-\infty$, otherwise $b\in\mathcal{S}^+(a)$. Now the similar argument as above shows (2.19).

Finally if $b=b_1$, then $\Phi(a,b)<0$ and $\Psi(a,b)=0$. By a similar argument as the second case, we arrive at (2.19).

Step 2: (2.20) holds.

Let $\lambda=\limsup\{N(t):t\in\mathbb{R}\}\leqslant q/\kappa$. Since $N'(t)\geqslant 0$ for all $t\in\mathbb{R}$,

$$\lambda = \lim_{t\to\infty} N(t), \quad \lim_{t\to\infty} N''(t) = 0. \tag{2.21}$$

If $\tau=\liminf\{u(t):t\in\mathbb{R}\}>-\infty$, by (2.19),

$$\tau = \lim_{t\to\infty} u(t), \quad \lim_{t\to\infty} u''(t) = 0.$$

Thus $\Phi(\tau,\lambda)=\Psi(\tau,\lambda)=0$ and this implies that $\lambda e^{\tau}=0$, which is absurd. In the sequel, the first part of (2.20) is proved. The second identity is now the consequence of (2.21).

Step 3: N'' changes signs only once, from $+$ to $-$.

Since (u,N) is a solution of (2.5)–(2.7) satisfying (2.20), it comes from (2.1) that $\Phi(a,b)<0$, namely, a and b satisfy (2.8). Since $\Psi(a,b)>0$, $N''>0$ for all $t\ll -1$. Moreover, since $N'\geqslant 0$ and $N(t)$ is convergent as $t\to\infty$, $N''(t)<0$ for all $t\gg 1$. If N'' changes signs twice, there exist two numbers $T_1<T_2$ such $u'',u',N'',N'<0$ on (T_1,T_2), which means $b\in\mathcal{S}^-(a)$, a contradiction. This completes the proof. ■

It follows from (2.8) and (2.20) that $b_2\notin\mathcal{S}^0(a)$, namely, $b^+<b_2$.

Lemma 2.6: $\mathcal{S}^0(a)$ consists of only one point.

Proof: Suppose that $d_1,d_2\in\mathcal{S}^0(a)$ with $d_1<d_2$. Let (u_i,N_i) be the unique solutions of (2.5)–(2.7) corresponding to d_i, $i=1,2$. Since $\Phi(u,N)$ and $\Psi(u,N)$ are increasing functions of u and N, there exists $T\in\mathbb{R}$ such that $u_1(t)<u_2(t)$ and $N_1(t)<N_2(t)$ for all $t\leqslant T$.

We claim that $u_1<u_2$ for all $t\in\mathbb{R}$. Assume the contrary. Then there exists a number $T_1\in\mathbb{R}$ such that $u_1(T_1)=u_2(T_1)$ and $u_1(t)<u(t)$ for all $t<T_1$. We note that $N_1(t)<N_2(t)$ for all $t<T_1$. Otherwise there would be a number $T_2<T_1$ such that $N_1(T_2)=N_2(T_2)$ and $N_1(t)<N_2(t)$ for all $t<T_2$, which implies that $(N_2-N_1)''(t)>0$ for all $t<T_2$ by the monotonicity of $\Psi(u,N)$ with respect to u and N. Consequently, $N_2(T_2)-N_1(T_2)>d_2-d_1>0$, a contradiction. Since $N_1(t)<N_2(t)$ for all $t<T_1$, we conclude that $(u_2-u_1)''>0$ for $t<T_1$, and hence $u_1(T_1)<u_2(T_1)$, a contradiction. Thus the claim follows.

It now follows that $N_1(t)<N_2(t)$ for all $t\in\mathbb{R}$ by a similar argument as above. However, this implies that

$$(N_2-N_1)''(t)>0 \quad \forall\, t\in\mathbb{R}, \quad \lim_{t\to\infty}(N_2-N_1)=0,$$

a contradiction. ■

It follows from Lemma 2.5 and Lemma 2.6 that for each $a<0$, there exists a unique $b=b(a)\in(0,q/\kappa)$ such that the equations (2.5)–(2.7) satisfying (2.20). Moreover, $b\in(b_1,b_2)$ by Lemma 2.4. Hereafter let $(u(t,a),N(t,a))$ be the unique solution to (2.5)–(2.7) with the boundary condition (1.12).

Lemma 2.7: There exists a constant $\gamma=\gamma(a)>4$ such that

$$\lim_{t\to\infty} u'(t) = -\gamma. \tag{2.22}$$

Proof: Since $u''<0$ by Lemma 2.1, there exists a constant $\gamma\in(0,\infty]$ such that $u'(t)\to-\gamma$ as $t\to\infty$. If $\gamma=\infty$, then there is a number T satisfying that $u'(t)<-3$ for all $t>T$. Thus $u(t)<-3t+C$ for all $t>T$, and

$$\int_{-\infty}^{\infty} e^{2s}e^{u(s)}\,\mathrm{d}s<\infty.$$

Since $b<N(t)<q/\kappa$ for all $t\in\mathbb{R}$ and $\lim_{t\to\infty}N'(t)=0$, we see from (2.11) that

$$\lim_{t\to\infty} u'(t) = \frac{2q}{\kappa}\lim_{t\to\infty}N'(t) - \frac{4q^3}{\kappa}\int_{-\infty}^{\infty} e^{2s}e^{u(s)}N(s)\mathrm{d}s \geqslant -\frac{4q^4}{\kappa^2}\int_{-\infty}^{\infty} e^{2s}e^{u(s)}\,\mathrm{d}s > -\infty,$$

a contradiction. Hence $\gamma<\infty$.

Set $w=u-2qN/\kappa$. Then

$$w'' = -\frac{4q^3}{\kappa}e^{2t}e^{u}N, \quad \lim_{t\to\infty} w'(t) = -\gamma. \tag{2.23}$$

Since $u''<0$ and

$$\gamma = \frac{4q^3}{\kappa}\int_{-\infty}^{\infty} e^{2s}e^{u(s)}N(s)\mathrm{d}s<\infty, \tag{2.24}$$

we conclude that $\gamma>2$ and thus $e^{2t+u}\to 0$ as $t\to\infty$. Using this fact and integrating by parts after multiplication of (2.23) by w', we are led to

$$\frac{\gamma^2}{2}-2\gamma = \frac{4q^3}{\kappa}\int_{-\infty}^{\infty} e^{2t+u}N'\left(1+\frac{2q}{\kappa}N\right)\mathrm{d}t>0. \tag{2.25}$$

Hence $\gamma>4$. ■

We are now in a position to prove Theorem 1.1. We have constructed a unique solution (u,N) of the equations (2.5)–(2.7) satisfying (2.20). In terms of $r=e^t$ variable, (u,N) is a solution of (2.2)–(2.4) with the boundary condition (1.12). Then we can recover the nontopological solution (u,A,N) of (1.5)–(1.7) as mentioned in the Introduction. In other words, we have proved the statements (ii)–(iv) of Theorem 1.1. To complete the proof of Theorem 1.1, it remains to show that (u,A,N) is a finite energy solution and verify the statements (i) and (v).

It follows from (2.22) that

$$\lim_{t\to\infty}\frac{u(t)}{t} = \lim_{t\to\infty} u'(t) = -\gamma.$$

Hence $u(x)=O(-\gamma\ln|x|)$ near ∞, which proves the first part of (v). We also observe that

$$\Delta N = e^u(\kappa q + 2q^2N) - \kappa(q-\kappa N)\to 0$$

as $|x|\to\infty$. This proves the second part of (v).

Next, we show that (u,A,N) is a finite energy solution. Using the self-dual equations (1.6) and (1.7), we can rewrite (1.3) as

$$\mathcal{E}(\phi,A,N) = \int_{\mathbb{R}^2} |D_A\phi|^2 + (q|\phi|^2+\kappa N-q)^2 + 2q^2|\phi|^2N^2 + |\nabla N|^2.$$

Since $ru_r=u_t=O(1)$, we have $u_r=O(r^{-1})$. Then

$$|D_A\phi|^2 = \tfrac{1}{2}|u_r|^2 e^u = O(r^{-\gamma-2}) \in L^1(\mathbb{R}^2),$$

$$(q|\phi|^2 + \kappa N - q)^2 = O(r^{-2\gamma}) \in L^1(\mathbb{R}^2),$$

$$2q^2|\phi|^2 N^2 = O(r^{-\gamma}) \in L^1(\mathbb{R}^2).$$

Meanwhile, multiplying (1.10) by N and integrating by parts, we are led to

$$\|\nabla N\|_{L^2} \leqslant C(\|e^u\|_{L^1} + \|q - \kappa N\|_{L^1}) < \infty.$$

Consequently, (u,A,N) is of finite energy.

Finally, we prove the statement (i). By means of (1.7), the magnetic flux given by (1.4) is computed as

$$\Lambda = -q\int_{\mathbb{R}^2}(q|\phi|^2 + \kappa N - q)\mathrm{d}x = -2\pi q\int_{-\infty}^{\infty} e^{2t}(qe^u + \kappa N - q)\mathrm{d}t = -\pi u'(\infty) = \pi\gamma.$$

Here we used the $t=\ln r$ variable. Since (ϕ,A,N) satisfies the self-dual equations, we conclude that

$$\mathcal{E}(\phi,A,N) = \Lambda = \pi\gamma.$$

This completes the proof of Theorem 1.1.

In the remaining part of this section, we make an observation of γ given by (2.22). We are going to prove that the lower bound of γ in Lemma 2.7 is optimal. In fact, we show that there exists a solution of (2.5)–(2.7) satisfying (2.20) such that the corresponding γ is arbitrarily close to 4. We begin with the following lemma.

Lemma 2.8: $b=b(a)$ is a continuous decreasing function such that

$$\lim_{a\to 0} b = 0, \quad \lim_{a\to-\infty} b = \frac{q}{\kappa}. \tag{2.26}$$

Proof: If $a_k \to a_0 < 0$, then up to a subsequence $b(a_k) \to b_0$. It follows from the continuous dependence of solutions to the initial data that $(u(t,a_0),N(t,a_0))$ is the unique solution of (2.5) and (2.6) with the boundary condition (2.20) satisfying $u(-\infty,a_0)=a_0$ and $N(-\infty,a_0)=b_0$. By virtue of the uniqueness result of Lemma 2.6, $b_0=b(a_0)$ and hence $b(a)$ is a continuous function.

The decreasing property of $b=b(a)$ follows from similar arguments of the proof of Lemma 2.6. Indeed, if $a_1<a_2$ and $b(a_1)\leqslant b(a_2)$, then we arrive at a contradiction by virtue of the monotonicity of $\Phi(u,N)$ and $\Psi(u,N)$ as in the proof of Lemma 2.6.

Finally, it is easily seen from (2.15) that

$$\lim_{a\to 0} b_1(a) = \lim_{a\to 0} b_2(a) = 0, \quad \lim_{a\to-\infty} b_1(a) = \lim_{a\to-\infty} b_2(a) = \frac{q}{\kappa}.$$

Since $b_1 \leqslant b \leqslant b_2$, this implies (2.26). ■

Proposition 2.9: $\gamma=\gamma(a)$ is a continuous function and

$$\lim_{a\to-\infty} \gamma(a) = 4. \tag{2.27}$$

Proof: We first show the continuity of $\gamma(a)$. For $a<0$, let $a_k \to a$. Let T_0 be such that $u'(T_0,a) = -7/2$. Since $u'(t,a)$ is continuous in a, we may assume that $u'(T_0,a_k) < -3$ for all k. Since u' is decreasing, we deduce that $u'(t,a_k) < -3$ for all $t > T_0$. Thus for $t \geqslant T_0$,

$$u(t,a_k) < u(T_0,a_k) - 3(t-T_0) \leqslant a_k - 3(t-T_0).$$

Now

$$\int_{-\infty}^{\infty} e^{2t}e^{u(t,a_k)}N(t,a_k)\mathrm{d}t \leqslant \frac{q}{\kappa}e^{a_k}\int_{-\infty}^{T_0} e^{2t}\,\mathrm{d}t + \frac{q}{\kappa}e^{a_k+3T_0}\int_{T_0}^{\infty} e^{-t}\,\mathrm{d}t = \frac{q}{2\kappa}e^{\alpha_k}e^{2T_0} + \frac{q}{\kappa}e^{a_k}e^{2T_0} \leqslant C$$

as $a_k \to a$. Since γ is given by the formula (2.24), it comes from the Lebesgue convergence theorem that $\gamma(a_k)\to\gamma(a)$. This implies the continuity of $\gamma(a)$.

To show (2.27), we observe from (2.25) that

$$\gamma^2(a) - 4\gamma(a) \leqslant C_1\int_{-\infty}^{\infty} e^{2t}e^{u(t,a)}N'(t,a)\mathrm{d}t, \quad C_1 = \frac{8q^3}{\kappa}\left(1+\frac{2q^2}{\kappa^2}\right). \tag{2.28}$$

Let $h(t,a)=N'(t,a)$. A simple calculation gives

$$h'' - (\kappa^2 + 2q^2e^u)h = (\kappa q + 2q^2N)e^u u'.$$

We recall that $h>0$. Let $T_1=T_1(a)$ be the positive maximum point of $h(t,a)$. Since $u'(t)>-\gamma$ for all $t\in\mathbb{R}$, we have

$$h(T_1;a) \leqslant \left(\frac{\kappa q + 2q^2N}{\kappa^2 + 2q^2e^u}e^u(-u')\right)(T_1,a) \leqslant \frac{1}{\kappa^2}\left(\kappa q + \frac{2q^3}{\kappa}\right)e^a\gamma(a) = C_2e^a\gamma(a)$$

as $a\to-\infty$. Thus by (2.28),

$$\gamma^2(a) - 4\gamma(a) \leqslant C_1C_2e^a\gamma(a)\int_{-\infty}^{\infty} e^{2t}e^{u(t,a)}\,\mathrm{d}t$$

as $a\to-\infty$. On the other hand, it comes from (2.24) and (2.26) that

$$\int_{-\infty}^{\infty} e^{2t}e^{u(t,a)}\,\mathrm{d}t \leqslant \frac{1}{b}\int_{-\infty}^{\infty} e^{2t}e^{u(t,a)}N(t,a)\mathrm{d}t = \left(\frac{\kappa^2}{4q^4} + o(1)\right)\gamma(a)$$

as $a\to-\infty$. In the sequel,

$$\gamma^2(a) - 4\gamma(a) \leqslant Ce^a\gamma^2(a),$$

and hence $\gamma(a)-4=o(1)$ as $a\to-\infty$. This establishes (2.27). ■

III. CHERN–SIMONS LIMIT

This section is devoted to the proof of Theorem 1.2. Throughout this section, let $a<0$ be fixed. Let (u_q,N_q) be the unique solution of (2.5)–(2.7) satisfying (2.20) corresponding to $(\kappa,q)=(\mu q^2,q)$ such that $b_q=\lim_{t\to-\infty}N_q(t)$ is uniquely determined by a and q. Set

$$\widetilde{N}_q = qN_q, \quad \widetilde{b}_q = qb_q, \quad w_q = u_q + \frac{2}{\mu q^2}\left(\frac{1}{\mu} - \widetilde{N}_q\right).$$

We notice that

$$\widetilde{N}_q < \mu^{-1}, \quad \|w_q - u_q\|_{L^\infty(\mathbb{R})} = O(q^{-2}), \quad w_q'' = -\frac{4}{\mu}e^{2t}e^{u_q}\widetilde{N}_q < 0. \tag{3.1}$$

Since w_q' is decreasing, it follows from (2.22) that $w_q' \searrow -\gamma_q$ with $\gamma_q>4$ as $t\to\infty$.

On the other hand, we recall from Lemma 2.4 that

$$\frac{\kappa q}{\kappa^2 + 2q^2e^a}(1-e^a) \leqslant b_q \leqslant \frac{q}{\kappa}(1-e^a).$$

Hence

$$b_* \equiv \lim_{q\to\infty} \tilde{b}_q = \frac{1}{\mu}(1-e^a) > 0.$$

It was proved[10] that every solution of (1.17) is radially symmetric about a point $x_0 \in \mathbb{R}^2$, say $x_0=0$, with the property $u<0$. In addition, for each $a<0$, there exists a unique radial solution such that $u(x_0)=a$. Let us rewrite (1.17) in the t variable as

$$u'' = \frac{4}{\mu^2} e^{2t} e^u (e^u - 1), \quad t \in \mathbb{R}. \tag{3.2}$$

Let u_* be the unique solution satisfying $u_*(t)=a+o(1)$ near $-\infty$. Then we can write

$$u_*(t) = a + \frac{4}{\mu^2}\int_{-\infty}^{t} (t-s) e^{2s} e^{u_*(s)} (e^{u_*(s)} - 1) \mathrm{d}s.$$

In this section we will prove that u_q converges to u_* as $q\to\infty$.

Lemma 3.1: γ_q is uniformly bounded in q.

Proof: Let $T_1=T_1(q)$ be the number such that $w_q'(T_1)=-2$. We claim that $\{T_1(q)\}$ is bounded above for all large q. Suppose that $T_1>0$. It follows that $w_q(t)+2t>w(0)$ for $t\in(0,T_1)$. Thus for all large q,

$$2 > \int_0^{T_1} w'' \,\mathrm{d}t = \frac{4}{\mu}\int_0^{T_1} e^{2t} e^{u_q} \tilde{N}_q \,\mathrm{d}t > \frac{4\tilde{b}_q}{\mu}\int_0^{T_1} e^{2t} e^{u_q}\,\mathrm{d}t > \frac{2\tilde{b}_q}{\mu}\int_0^{T_1} e^{2t+w_q}\,\mathrm{d}t > \frac{2\tilde{b}_q}{\mu} e^{w_q(0)} T_1.$$

Hence if q is large enough, then $T_1 < \mu \tilde{b}_q^{-1} e^{-w_q(0)}$. Let $z_q(t)=\mu^{-2}e^{2t}-a+w_q(t)$. Then $z_q''=4\mu^{-1}e^{2t}(\mu^{-1}-e^{u_q}\tilde{N}_q)>0$. Since $z_q(-\infty)>0$ and $z_q'(-\infty)=0$, it is seen that $z_q(0)>0$. As a consequence, we conclude that $T_1 \leqslant C$.

Set $T_2=T_2(q)=(w_q')^{-1}(-3)$. Then for $t>T_2$,

$$-w_q'(t) - 3 = -\int_{T_2}^{t} w_q''(s)\mathrm{d}s \leqslant \frac{4}{\mu^2}\int_{T_2}^{t} e^{2s} e^{u_q(s)}\,\mathrm{d}s \leqslant \frac{4}{\mu^2}\int_{T_2}^{t} e^{2s+w_q(s)}\,\mathrm{d}s.$$

Since $-w_q'(t)>3$ for $t>T_2$, it follows that $w_q(t)<-3(t-T_2)+w_q(T_2)$. Hence for $t>T_2$,

$$-w_q'(t) - 3 < \frac{4}{\mu^2}\int_{T_2}^{t} e^{-s+3T_2+w_q(T_2)}\,\mathrm{d}s.$$

Letting $t\to\infty$, we find that $\gamma_q<3+4\mu^{-2}e^{2T_2+w_q(T_2)}$. Since $-w_q'(t)>2$ for $t>T_1$, it follows that $2t+w_q(t)<2T_1+w_q(T_1)$. Since $T_1<T_2$, we obtain

$$\gamma_q < 3 + 4\mu^{-2} e^{2T_1+w_q(T_1)} \leqslant C.$$

■

Lemma 3.2: As $q\to\infty$, we have

$$e^{u_q} - 1 + \mu\tilde{N}_q = O(q^{-2}). \tag{3.3}$$

Proof: We first observe from (2.16) that $|u'(t)| \leqslant Cq^2 e^{2t}$ for all $t\in\mathbb{R}^2$. In particular,

$$e^{-2t}|u'(t)| \leqslant Cq^2 \tag{3.4}$$

for all $t\in\mathbb{R}$. Let us write $u_q''=2e^{2t}v_q$, where $v_q=q^2(e^{u_q}-1+\mu\tilde{N}_q)$. Then $v_q<0$ and

$$v_q'' - e^{2t}v_q(2q^2e^{u_q}+\mu^2q^4) = q^2e^{u_q}|u_q'|^2 + 2\mu q^4 e^{2t} e^{u_q}\tilde{N}_q.$$

If $T_3=T_3(q)$ is a minimum point of v_q, then by Lemma 3.1 and (3.4),

$$0 > v_q(T_3) \geqslant -\frac{e^{-2t}|u_q'|^2 e^{u_q} + 2\mu q^2 e^{u_q}\tilde{N}_q}{2e^{u_q} + \mu^2 q^2}(T_3) \geqslant -\frac{Cq^2\gamma_q e^{u_q} + 2\mu q^2 e^{u_q}\tilde{N}_q}{2e^{u_q} + \mu^2 q^2}(T_3) \geqslant -C$$

for some positive constant. This finishes the proof. ■

Lemma 3.3: For any $T \in \mathbb{R}$, we have

$$\sup_{t\leqslant T}|u_q - u_*| = O(q^{-2}), \quad \sup_{t\leqslant T}|\tilde{N}_q - N_*| = O(q^{-2}), \tag{3.5}$$

where $N_* = \mu^{-1}(1-e^{u_*})$.

Proof: Let $T \in \mathbb{R}$ be fixed. It comes from (3.3) that

$$w_q'' = \frac{4}{\mu^2}e^{2t}e^{u_q}(e^{u_q}-1) - \frac{4}{\mu^2}e^{2t}e^{u_q}(e^{u_q}-1+\mu\tilde{N}_q) = \frac{4}{\mu^2}e^{2t}e^{u_q}(e^{u_q}-1) + O(q^{-2})\cdot e^{2t} \tag{3.6}$$

as $q\to\infty$. Let $T_0 \leqslant T$. For any $t \leqslant T_0$, by (3.1) and (3.6),

$$\begin{aligned}|w_q(t) - u_*(t)| &\leqslant O(q^{-2}) + \int_{-\infty}^{t} e^{2t}(t-s)\left(\frac{4}{\mu^2}|e^{u_q}(e^{u_q}-1) - e^{u_*}(e^{u_*}-1)| + O(q^{-2})\right)ds \\ &\leqslant Ce^{2T_0}\sup_{t\leqslant T_0}|u_q - u_*| + Cq^{-2}e^{2T_0} + O(q^{-2}) \\ &\leqslant Ce^{2T_0}\sup_{t\leqslant T_0}|w_q - u_*| + Cq^{-2}e^{2T_0} + O(q^{-2}).\end{aligned}$$

Hence if T_0 is small enough, then

$$\sup_{t\leqslant T_0}|w_q - u_*| = O(q^{-2}).$$

Applying the standard continuation argument, we obtain

$$\sup_{t\leqslant T}|w_q - u_*| = O(q^{-2}),$$

and thus by (3.1), we have

$$\sup_{t\leqslant T}|u_q - u_*| = O(q^{-2}).$$

Finally for $t \leqslant T$, by (3.3),

$$|\tilde{N}_q - N_*| = \frac{1}{\mu}|e^{\mu_q} - e^{u_*}| + O(q^{-2}) = O(q^{-2}).$$

■

Lemma 3.4: As $q\to\infty$, we have

$$\mu q^2(e^{u_q} - 1 + \mu\tilde{N}_q) + 2e^{u_q}\tilde{N}_q = O(q^{-2}). \tag{3.7}$$

Proof: Let us write $\tilde{N}_q'' = e^{2t}h_q$, where

$$h_q = q^2[\mu q^2(e^{u_q} - 1 + \mu\tilde{N}_q) + 2e^{u_q}\tilde{N}_q].$$

It suffice to show that $\|h_q(t)\|_{L^\infty(\mathbb{R})} \leqslant C$ as $q\to\infty$. A simple calculation yields that

$$h_q'' - q^2e^{2t}h_q(\mu^2q^2 + 2e^{u_q}) = \mu q^4 e^{u_q}|u_q'|^2 + 2\mu q^4 e^{2t}e^{u_q}v_q + 2q^2e^{u_q}|u_q'|^2\tilde{N}_q + 4q^2e^{2t}e^{u_q}\tilde{N}_q v_q + 4q^2u_q'e^{u_q}\tilde{N}_q'.$$

Here v_q is defined by $v_q = q^2(e^{u_q} - 1 + \mu\tilde{N}_q)$ as in the proof of Lemma 3.2. Since $v_q < 0$, if $T_4 = T_4(q)$ is a positive maximum point of h_q, then

$$0 < h_q(T_4) \leqslant -\frac{2\mu q^2 e^{u_q}v_q + 4e^{u_q}\tilde{N}_q v_q + 4e^{-2t}\tilde{N}_q'u_q'e^{u_q}}{\mu^2q^2 + 2e^{u_q}}(T_4).$$

We observe from (2.17) and (3.3) that $|\tilde{N}_q'(t)| \leqslant Cq^2e^{2t}$ for all $t \in \mathbb{R}$. Combining this and Lemma 3.1 with the above inequality, we conclude that $h_q(T_4) \leqslant C$.

Similarly, if $T_5 = T_5(q)$ is a negative minimum point of h_q, then

$$0 > h_q(T_5) \geqslant -\frac{\mu q^2 e^{-2t}e^{u_q}|u_q'|^2 + 2e^{-2t}e^{u_q}|u_q'|^2\tilde{N}_q}{\mu^2q^2 + e^{u_q}}(T_5). \tag{3.8}$$

We claim that T_5 is bounded below. On the contrary, suppose that $T_5 \to -\infty$. We recall from Lemma 2.5 that $\tilde{N}_q''$ changes signs only once, from $+$ to $-$. Let $T_6 = T_6(q)$ be the unique zero of h_q. Then $h_q > 0$ for $t < T_6$ and $h_q < 0$ for $t > T_6$. Thus $T_6 \to -\infty$. Fix $T_0 \in \mathbb{R}$ such that $T_6 < T_0$ for all large q. For $t \geqslant T_0$,

$$0 < \tilde{N}_q'(t) = \int_{-\infty}^{t} e^{2t}h_q(t)\mathrm{d}t \leqslant \int_{-\infty}^{T_6} e^{2t}h_q(t)\mathrm{d}t \leqslant \frac{1}{2}h_q(T_4)e^{2T_6}.$$

Integrating this inequality on (T_0, t), we have

$$\tilde{N}_q(t) - \tilde{N}_q(T_0) = \tfrac{1}{2}h_q(T_4)e^{2T_6}(t - T_0).$$

Letting $q \to \infty$, we have $N_*(t) = N_*(T_0)$ for all $t \geqslant T_0$. Since T_0 was arbitrary, N_* is a constant, which gives a contradiction.

Now since T_6 is bounded below, it follows from Lemma 3.1 and (3.8) that $0 > h_q(T_5) \geqslant -C$. This completes the proof. ■

Lemma 3.5: For any $T \in \mathbb{R}^2$, we have

$$\sup_{t \leqslant T}|u_q'' - u_*''| = O(q^{-2}). \tag{3.9}$$

Proof: Fix $T \in \mathbb{R}^2$. Combining (3.2) and (3.6) with (3.5), we obtain

$$\sup_{t \leqslant T}|w_q'' - u_*''| \leqslant Ce^{2T}\sup_{t \leqslant T}|u_q - u_*| + O(q^{-2}) \cdot e^{2T} = O(q^{-2}) \cdot e^{2T}.$$

Since $\sup_{t \leqslant T}\tilde{N}_q'' \leqslant C$ by (3.7), we are led to

$$\sup_{t \leqslant T}|u_q'' - u_*''| \leqslant \sup_{t \leqslant T}|u_q'' - u_*''| + \sup_{t \leqslant T}|w_q'' - u_*''| \leqslant Cq^{-2}\sup_{t \leqslant T}\tilde{N}_q'' + O(q^{-2}) \cdot e^{2T} = O(q^{-2}),$$

and thus the proof is complete. ■

It now follows from (3.5) and (3.9) that for any $T \in \mathbb{R}^2$,

$$\|u_q - u_*\|_{C^2(-\infty,T]} = O(q^{-2}).$$

This finishes the proof of Theorem 1.2.

We construct a nonperturbative approach based on quantum averaging combined with resonant transformations to detect the resonances of a given Hamiltonian and to treat them. This approach, which generalizes the rotating-wave approximation, takes into account the resonances at low field and also at high field (nonlinear resonances). This allows us to derive effective Hamiltonians that contain the qualitative features of the spectrum, i.e., crossings and avoided crossings, as a function of the coupling constant. At a second stage the precision of the spectrum can be improved quantitatively by standard perturbative methods like contact transformations. We illustrate this method by determining the spectrum of a two-level atom interacting with a single-mode quantized field. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1864252]

I. INTRODUCTION

Some important features of classical and quantum systems are determined by resonances of the system which cannot be treated by perturbative approaches. In the vicinity of resonances the perturbative formulas display small denominators that lead to the divergence of the perturbative expansions. A widely used model that incorporates a one-photon resonance is the Jaynes-Cummings Hamiltonian extracted from the full dressed Hamiltonian that describes a two-level system coupled with a single mode of a quantized field.[1] Its counterpart for an interaction with a semiclassical laser field is the RWA Hamiltonian (rotating-wave approximation).[2]

In this article we give a systematic method that allows us to construct effective Hamiltonians and determine their spectrum by treating the resonances with an adaptation of resonant transformations that were introduced in Ref. 3 in the context of laser-driven quantum systems in the Floquet representation. The semiclassical model with several incommensurate frequencies[4] has been treated by different methods in Refs. 5–8.

The goal is to obtain the spectrum for a whole interval of values of a parameter like the coupling constant. This is needed, e.g., in applications where the coupling changes adiabatically,[9] corresponding, e.g., to envelopes of laser pulses or to transversal spatial profiles of cavity fields. The method is based on the detection of resonances by a projector derived from quantum averaging. We illustrate it on the problem of a two-level atom interacting with a quantized field and show that a treatment of all the relevant resonances of the system in a given range of parameters allows us to reproduce with good accuracy the spectrum of this system. The treatment of the resonances yields the qualitative structure of the spectrum—the crossings and avoided

crossings—as a function of the coupling constant. Once this main structure is obtained, one can systematically improve the quantitative accuracy of the spectrum by applying perturbative methods. We use contact transformations with a Kolmogorov-Arnold-Moser (KAM) iteration,[3] which are particularly efficient due to its superconvergent properties.

The paper is structured as follows. In Sec. II, we describe the method of resonance analysis and the construction of effective Hamiltonians. Section III contains the presentation of the model and some preliminary considerations. In Sec. IV, taking into account the resonances of this model in the weak-coupling regime, we extract the effective Hamiltonians by quantum averaging techniques and resonant transformations. In the weak-coupling regime we have to iterate this procedure several times to derive the essential structure of the spectrum in larger ranges of the coupling constant. In Sec. V we extract the effective Hamiltonians in the strong-coupling regime where the qualitative properties of the spectrum can be globally obtained by some preliminary unitary transformations and one resonant transformation which treats the zero-field resonances. We obtain an accurate approximation valid for all values of the coupling constant that contains all the qualitative structures. Finally, in Sec. VI we give some conclusions.

II. PRINCIPLE OF THE METHOD

We consider a Hamiltonian $H=H_0+\epsilon V$, where H_0 is the reference (unperturbed) Hamiltonian, ϵV is the perturbation, and ϵ is an ordering parameter. The first analysis of this problem is in terms of perturbation theory: we look for a KAM-type unitary transformation $e^{\epsilon W}$ close to the identity that allows us to reduce the order of the perturbation from ϵ to ϵ^2:

$$e^{-\epsilon W}He^{\epsilon W}=H_0+\epsilon D+\epsilon^2V_2. \tag{1}$$

ϵD is a remaining term of order ϵ that satisfies $[H_0,D]=0$. The unknown W and D are solutions of the following equations:[3,10]

$$[H_0,W]+V=D, \tag{2a}$$

$$[H_0,D]=0. \tag{2b}$$

The remaining perturbation of order ϵ^2 is given by

$$\epsilon^2V_2=\sum_{m=2}^{\infty}\frac{\epsilon^m}{m!}((m-1)L_W^{m-1}V+L_W^{m-1}D), \tag{3}$$

where L_W is defined as

$$L_WB=[B,W]. \tag{4}$$

The solutions of Eqs. (2) can be written in terms of averaging:[3,11]

$$D=\overline{V}\equiv\Pi_{H_0}V:=\lim_{\tau\to\infty}\frac{1}{\tau}\int_0^{\tau}dse^{-iH_0s}Ve^{iH_0s}=\sum_{\nu,j,j'}|\nu,j\rangle\langle\nu,j|V|\nu,j'\rangle\langle\nu,j'|, \tag{5a}$$

$$W=\lim_{\tau\to\infty}\frac{-i}{\tau}\int_0^{\tau}ds\int_0^{s}ds'e^{-iH_0s'}(V-\Pi_{H_0}V)e^{iH_0s'}=-\sum_{\nu,j,j',\nu'\neq\nu}\frac{|\nu,j\rangle\langle\nu,j|V|\nu',j'\rangle\langle\nu',j'|}{E_\nu^{(0)}-E_{\nu'}^{(0)}}, \tag{5b}$$

where ν labels the different eigenvalues $E_\nu^{(0)}$ of H_0, and j is a degeneracy index which distinguishes different basis vectors $|\nu,j\rangle$ of the degeneracy eigenspace. The operator Π_{H_0} is the projector on the kernel of the application $A\mapsto[H_0,A]$. We remark that the integral representation of D,W in Eqs. (5) can be also well defined in cases where H_0 has a continuum spectrum. We can

iterate the KAM procedure taking $H_0+\epsilon D$ as the new reference Hamiltonian and $\epsilon^2 V_2$ as the new perturbation. The units are chosen such that $\hbar=1$. In the following discussion, we do not write explicitly the ordering parameter ϵ.

A *resonance* is defined as a degeneracy of an eigenvalue $E_\nu^{(0)}$ of H_0 and is said to be *active* if the perturbation V has nonzero matrix elements in the degeneracy subspace of $E_\nu^{(0)}$: $\langle \nu,j|V|\nu,j'\rangle \neq 0$ for some j,j'. Otherwise the resonance is called *passive* or *mute*. Equation (5b) shows that in the case of quasi-resonance (as opposed to exact resonance) where the denominator would be different from zero but very small with respect to the numerator, W can be very large, and thus the expansion cannot be expected to converge. The method we present here is a construction designed to avoid such divergences. We remark that the concept of resonance is defined intrinsically for H_0, while the distinction between active and passive depends on the relation between H_0 and V. The analysis of the resonances thus involves three aspects:

- Decomposition of the Hamiltonian into $H=H_0+V$. Different decompositions can be considered for different regimes of the parameters of H.
- Determination of degenerate eigenvalues of H_0.
- Detection of the *resonant terms* in the perturbation V that couple these degenerate eigenstates.

The resonant terms of V can be detected by projectors of type Π_{H_0} that extract a block-diagonal part of V relative to H_0, where the blocks are generated by the degeneracy subspaces. In the absence of active resonances, when all the eigenvalues of H_0 are nondegenerate or when the resonances are mute, the matrix representation of $\Pi_{H_0}V$ is in fact diagonal in the eigenbasis of H_0. In the presence of active resonances, the block-diagonal effective Hamiltonian that takes into account the considered resonance of the original Hamiltonian can be written as

$$H^{\text{eff}} = H_0 + \Pi_{H_0} V. \tag{6}$$

We will call the transformation that diagonalizes H^{eff} *resonant transformation* (RT). The Hamiltonian $H=H^{\text{eff}}+(V-\Pi_{H_0}V)$ is transformed under RT (denoted $\mathcal{R}$) as follows:

$$H_1 = \mathcal{R}^\dagger H \mathcal{R} = \mathcal{R}^\dagger H^{\text{eff}} \mathcal{R} + \mathcal{R}^\dagger (V - \Pi_{H_0} V)\mathcal{R} =: H_1^{(0)} + V_1, \tag{7}$$

where $H_1^{(0)}$ is defined as the new renormalized reference Hamiltonian and V_1 is the new perturbation. The effect of $\Pi_{H_0}V$ in (6) is to lift the degeneracy of H_0. This can happen in two ways: either the active resonance is transformed into a passive one (e.g., in the case of zero-field resonances) or the resonance disappears completely (when a crossing is transformed into an avoided crossing). The new Hamiltonian H_1 can, however, have other resonances at different values of the coupling parameter. If $H_1^{(0)}+V_1$ does not have any other active resonance in the considered range of the coupling constant, we can, at a second stage, improve the spectrum by a KAM-type perturbative expansion which is expected to converge. If there are other active resonances, we have to iterate the renormalization procedure by applying another RT. We remark that there are cases of multiphoton resonances where the active resonances appear only after applying one or several contact transformations.

III. DESCRIPTION OF THE MODEL AND PRELIMINARY CONSIDERATIONS

We consider as an illustration a two-level atom interacting with a single mode of a quantized field described by

$$H = \omega(a^\dagger a + 1/2) \otimes \mathbb{1}_2 + \frac{\omega_0}{2}\mathbb{1} \otimes \sigma_z + g(a + a^\dagger) \otimes \sigma_x, \tag{8}$$

where a, $a^\dagger$ are the annihilation and creation operators for the field mode with the commutation relation $[a,a^\dagger]=\mathbb{1}=\Sigma_{n=0}^{\infty}|n\rangle\langle n|$, σ_z,σ_x are Pauli matrices, and $\mathbb{1}_2$ is the 2×2 identity matrix. Here ω is the frequency of the field mode, ω_0 is the energy difference of the two atomic states, and g is the

dipole-coupling between the field mode and the atom. This Hamiltonian acts on the Hilbert space $\mathcal{K}=\mathcal{F}\otimes\mathcal{H}$ where $\mathcal{H}=\mathbb{C}^2$ is the Hilbert space of the atom generated by $|\pm\rangle$ (eigenvectors of σ_z) and $\mathcal{F}$ is the Fock space of the field mode generated by the orthonormal basis $\{|n\rangle; n=0,1,2,\ldots\}$, n being the photon number of the field.

For this system there is a parity operator

$$P = e^{i\pi a^\dagger a} \otimes \sigma_z = \sum_{n=0}^{\infty} (-1)^n |n\rangle\langle n| \otimes \sigma_z, \tag{9}$$

with the properties

$$[P,H] = 0, \quad P = P^\dagger, \quad P^2 = \mathbb{1}_{\mathcal{K}} \equiv \mathbb{1} \otimes \mathbb{1}_2. \tag{10}$$

As a consequence, the eigenstates of H can be separated into two symmetry classes, even or odd, under P:

$$P|\phi_{n,\pm}\rangle = \pm|\phi_{n,\pm}\rangle, \quad H|\phi_{n,\pm}\rangle = E_{n,\pm}|\phi_{n,\pm}\rangle. \tag{11}$$

The parity operator also commutes with any operator that depends only on $N=a^\dagger a$ and σ_z.

In spite of the simple form of (8), its exact solutions are not known. This can be related to the fact that the classical limit of this model is nonintegrable.[12] This model is of great interest as a physical model in quantum optics[13–16] and quantum chaos.[17,18] Some approximate solutions of this model have been studied among many others in Refs. 19 and 20 using different formalisms.

The conceptual framework for the solution of this system based on the construction of unitary transformations can be described as follows: First, we decompose the Hamiltonian in two terms as $H=H_0+V$. Depending on the considered ranges of the parameters of the system, different decompositions may be considered. H_0 is *a priori* an operator that is a regular function exclusively of the operators N and σ_z. The operators N and σ_z can be considered in the present model as quantum analogs of classical *global actions*,[21] and H_0 can be labeled *integrable*. The perturbation V contains functions that involve also the other operators $a, a^\dagger, \sigma_x, \sigma_y$. The goal is to determine a unitary transformation U, which should be expressed in terms of well-behaved regular functions of $a, a^\dagger, \sigma_x, \sigma_y, \sigma_z$, such that

$$U^\dagger(H_0(N,\sigma_z) + V(a,a^\dagger,\sigma_x,\sigma_y,\sigma_z))U = H'(N,\sigma_z), \tag{12}$$

where H' is a regular function f exclusively of the action operators N, σ_z: $H'(N,\sigma_z)=f(N,\sigma_z)$. With this transformation the eigenvectors of H can be expressed as $|\phi_{n,\pm}\rangle = U(|n\rangle\otimes|\pm\rangle)$ and the corresponding eigenvalues as $E_{n,\pm}=f(n,\pm1)$ where $N|n\rangle=n|n\rangle$ and $\sigma_z|\pm\rangle=\pm|\pm\rangle$.

We remark that in our context the important property for singling out the operators N, σ_z is that they commute with each other and their spectrum and eigenvectors are explicitly available. The question of whether for a given model there exists a regular unitary transformation U that accomplishes the above requirement is, to our knowledge, an open problem.

Most of the perturbative approaches can be interpreted as methods to find approximations of the transformation U. The presence of resonances is one of the central difficulties in the construction of U, as will be made precise below. In this paper we discuss an iterative approach that consists of constructing first some approximations of U that take into account the dominating effects of a certain number of resonances. The transformations involved in this stage are far from the identity and have a clearly nonperturbative character. Once we have a transformation that takes into account the main effect of a set of resonances that are relevant in a considered interval of the coupling constant g, a perturbative approach (like the KAM, Van Vleck, or other types of the contact transformation) can be applied to improve the approximation quantitatively. The transformations involved in this second stage can be considered as deformations of the identity, since they can be written in the form e^W. This stage cannot be implemented if the resonances are not taken care of beforehand. Indeed the perturbative formulations diverge close to resonances due to the appearance of *small denominators* as can be seen in Eq. (5b).

As in classical mechanics, the construction of the transformation U leading to a Hamiltonian that contains only action variables can often be considered in two steps: $U=U_1U_2$. In the first step, which is called *reduction*, the Hamiltonian is transformed by U_1 into a form that contains functions of $\sigma_z, \sigma_x, \sigma_y$ and N, but not of a and $a^\dagger$. The degree of freedom of the field is made trivial and the number of nontrivial degrees of freedom is thus reduced by one. When we apply this reduction to the effective Hamiltonian (6), we obtain a *reduced effective Hamiltonian*. We remark that in the literature, this "reduced effective Hamiltonian" is often called simply "effective Hamiltonian." In the second step, the reduced Hamiltonian is transformed under U_2 into a form that contains functions of only N and σ_z. For the model (8), the reduction step corresponds to diagonalization in the Fock space and the second step corresponds to diagonalization in the atomic Hilbert space which in this case is trivial. The construction of the RT is based on this reduction procedure.

IV. EFFECTIVE HAMILTONIANS IN THE WEAK-COUPLING REGIME

In this section we consider the Hamiltonian (8) at resonance $\omega_0=\omega$ in the weak coupling regime, so that H can be decomposed as follows:

$$H = H_0 + V,$$

$$H_0(N,\sigma_z) = \omega(N+1/2)\otimes \mathbb{1}_2 + \frac{\omega_0}{2}\mathbb{1}\otimes\sigma_z, \tag{13}$$

$$V(a,a^\dagger,\sigma_x,g) = g(a+a^\dagger)\otimes\sigma_x.$$

The eigenvalues and eigenvectors of H_0 are

$$E^{(0)}_{n,\pm} = \omega(n+1/2) \pm \frac{\omega_0}{2},$$

$$|\phi^{(0)}_{n,\pm}\rangle = |n,\pm\rangle = |n\rangle\otimes|\pm\rangle, \tag{14}$$

$$|n,+\rangle = \begin{pmatrix} |n\rangle \\ 0 \end{pmatrix}, \quad |n,-\rangle = \begin{pmatrix} 0 \\ |n\rangle \end{pmatrix}.$$

For $\omega_0=\omega$ there is a one photon resonance which corresponds to the degeneracies $E^{(0)}_{n,+}=E^{(0)}_{n+1,-}$. The degeneracy eigenspaces are spanned by the vectors $|\phi^{(0)}_{n,+}\rangle$ and $|\phi^{(0)}_{n+1,-}\rangle$. The resonant part of V is obtained by (5a):

$$V_{res} := \Pi_{H_0}V = \sum_{n=0}^{\infty}\left(|n,+\rangle\langle n,+|V|n+1,-\rangle\langle n+1,-| + |n+1,-\rangle\langle n+1,-|V|n,+\rangle\langle n,+|\right)$$
$$= g\begin{pmatrix} 0 & a \\ a^\dagger & 0 \end{pmatrix}, \tag{15}$$

where we have used the relations

$$a = \sum_{n=0}^{\infty}\sqrt{n+1}|n\rangle\langle n+1|, \quad a^\dagger = \sum_{n=0}^{\infty}\sqrt{n+1}|n+1\rangle\langle n|. \tag{16}$$

The effective Hamiltonian containing the one-photon resonance is the so-called Jaynes-Cummings Hamiltonian that can be written as

$$H_0^{\text{eff}} = H_{JC} = H_0 + \Pi_{H_0} V = \omega(N + 1/2) \otimes \mathbb{1}_2 + \frac{\omega}{2}\mathbb{1} \otimes \sigma_z + g\begin{pmatrix} 0 & a \\ a^\dagger & 0 \end{pmatrix}. \tag{17}$$

H_{JC} is a good approximation of (8) for low energies in the limit $g \ll \omega_0, |\omega - \omega_0| \ll \omega_0$. In this limit, the so-called counter-rotating terms $g\left(\begin{smallmatrix} 0 & a^\dagger \\ a & 0 \end{smallmatrix}\right)$ can be discarded (rotating-wave approximation). H can thus be written as $H = H_0^{\text{eff}}(N, a, a^\dagger, \sigma_x, \sigma_y; g) + (V - \Pi_{H_0} V)$. Next we transform H_0^{eff} by a resonant transformation $\mathcal{R}_1$ to a regular function of exclusively the action operators N, σ_z. Every resonant transformation is performed in two steps. To diagonalize H_0^{eff} in the Fock space (the reduction step of the RT denoted R_1) we define a transformation in such a way that the following condition is satisfied:

$$R_1^\dagger V_{res} R_1 = f(N) \otimes \sigma_x, \tag{18}$$

where f is a regular function of N which has to be determined. We require furthermore that $R_1^\dagger H_0 R_1$ stays a function of only N and σ_z. A suitable transformation satisfying these conditions is

$$R_1 := \begin{pmatrix} (aa^\dagger)^{-1/2} a & 0 \\ 0 & \mathbb{1} \end{pmatrix} \equiv \begin{pmatrix} \sum_{n=0}^{\infty} |n\rangle\langle n+1| & 0 \\ 0 & \mathbb{1} \end{pmatrix}. \tag{19}$$

This transformation is not unitary but *isometric*:[22]

$$R_1 R_1^\dagger = \mathbb{1}_{\mathcal{K}}, \quad R_1^\dagger R_1 = \mathbb{1}_{\mathcal{K}} - \begin{pmatrix} |0\rangle\langle 0| & 0 \\ 0 & 0 \end{pmatrix}, \tag{20}$$

where we have used the identity $a^\dagger (N+1)^{-1} a = \mathbb{1} - |0\rangle\langle 0|$. Applying this transformation on the resonant term gives

$$R_1^\dagger V_{res} R_1 = g a^\dagger (aa^\dagger)^{-1/2} a \otimes \sigma_x = g\sqrt{N} \otimes \sigma_x \tag{21}$$

and H is transformed under R_1 as

$$H_{R_1} = R_1^\dagger H R_1 = \omega N \otimes \mathbb{1}_2 + g\sqrt{N} \otimes \sigma_x + g\begin{pmatrix} 0 & A^\dagger \\ A & 0 \end{pmatrix}, \tag{22}$$

where

$$A = a(aa^\dagger)^{-1/2} a = \sum_{n=0}^{\infty} \sqrt{n+1} |n\rangle\langle n+2|, \tag{23}$$

with the properties

$$AA^\dagger = aa^\dagger, \quad A^\dagger A = a^\dagger a - \mathbb{1} + |0\rangle\langle 0|. \tag{24}$$

To each eigenvector $|\phi\rangle$ of H corresponds an eigenvector $R_1^\dagger|\phi\rangle$ of H_{R_1}, since

$$H_{R_1} R_1^\dagger |\phi\rangle = R_1^\dagger H R_1 R_1^\dagger |\phi\rangle = \lambda R_1^\dagger |\phi\rangle. \tag{25}$$

We remark that $R_1^\dagger|\phi\rangle \neq 0 \ \forall |\phi\rangle \in \mathcal{K}$. Every eigenvalue of the original Hamiltonian H is also an eigenvalue of the transformed Hamiltonian H_{R_1}. However, since $R_1|0,+\rangle = 0$, there is a difference in the spectrum between H and H_{R_1}: H_{R_1} has an extra zero eigenvalue with eigenvector $|0,+\rangle$. The spurious eigenvalue can be detected and eliminated after applying the transformation. Indeed, since $|0,+\rangle$ is not coupled to any vector in its orthogonal complement, one can eliminate it from the rest of the calculation by taking the projection of H_{R_1} into the orthogonal complement $H_{R_1,\perp(0,+)} = P_{\perp(0,+)} H_{R_1} P_{\perp(0,+)}$ with $P_{\perp(0,+)} = \mathbb{1}_{\mathcal{K}} - |0,+\rangle\langle 0,+|$. This difference between unitary and

isometric transformations was not taken into account in Ref. 23 in diagonalizing the Jaynes-Cummings Hamiltonian.

The second step of the RT is the diagonalization of $R_1^\dagger H_0^{\text{eff}} R_1 = \omega N \otimes \mathbb{1}_2 + \sqrt{N} \otimes \sigma_x$ in the atomic Hilbert space. This can be performed by a $\pi/2$ rotation around the y-axis:

$$T = e^{-i(\pi/4)\sigma_y} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \tag{26}$$

with the properties

$$T^\dagger \sigma_x T = \sigma_z, \quad T^\dagger \sigma_z T = -\sigma_x. \tag{27}$$

However, since the spurious eigenvector $|0,+\rangle$ can be separated and $|0,-\rangle$ is already an eigenvector of $R_1^\dagger H_0^{\text{eff}} R_1$, the transformation T must be applied only on the subspace with $n \geqslant 1$ photons. The complete transformation (denoted T_1) reads thus

$$T_1 = P_0 \otimes \mathbb{1}_2 + P_{\perp 0} \otimes T, \tag{28}$$

where

$$P_0 = |0\rangle\langle 0|, \quad P_{\perp 0} = \sum_{n=1}^{\infty} |n\rangle\langle n|. \tag{29}$$

Applying T_1 gives

$$H_1 := T_1^\dagger R_1^\dagger H R_1 T_1 = H_1^{(0)}(N, \sigma_z; g) + V_1(a, a^\dagger, \sigma_z, \sigma_x, \sigma_y; g), \tag{30}$$

with

$$H_1^{(0)} = \omega N \otimes \mathbb{1}_2 + g\sqrt{N} \otimes \sigma_z,$$

$$V_1 = \frac{g}{2} \begin{pmatrix} A_{\perp 0} + A_{\perp 0}^\dagger & -A_{\perp 0} + A_{\perp 0}^\dagger \\ A_{\perp 0} - A_{\perp 0}^\dagger & -A_{\perp 0} - A_{\perp 0}^\dagger \end{pmatrix} + \frac{g}{\sqrt{2}} \begin{pmatrix} 0 & |2\rangle\langle 0| \\ |0\rangle\langle 2| & -|2\rangle\langle 0| - |0\rangle\langle 2| \end{pmatrix}, \tag{31}$$

where

$$A_{\perp 0} = P_{\perp 0} A P_{\perp 0} = \sum_{n=1}^{\infty} \sqrt{n+1}\, |n\rangle\langle n+2|, \tag{32}$$

and use has been made of the relations

$$AP_0 = P_0 A^\dagger = 0, \quad P_0 A P_{\perp 0} = |0\rangle\langle 2|. \tag{33}$$

The first RT is thus the combination of $R_1 T_1$. Since the transformation R_1 dresses the upper atomic state by (-1) photon,[15] $\mathcal{R}_1 = R_1 T_1$ can be called a one-photon RT.

$H_1^{(0)}$ is in fact the diagonalized Jaynes-Cummings Hamiltonian in the resonant case with the eigenvalues

$$E_{1,(n,\pm)}^{(0)}(g) = \omega n \pm g\sqrt{n}, \quad n = 0, 1, 2, \ldots . \tag{34}$$

The eigenvalues and therefore the degeneracies of $H_1^{(0)}$ depend on the coupling constant g. For small enough g and low energies, $H_1^{(0)}$ does not have other degeneracies besides the ones at $g = 0$ for which the new perturbation V_1 does not have resonant terms, and we can apply a finite number of KAM-type transformations to improve quantitatively the precision of the spectrum by iteration. We apply a finite number of KAM-type transformations with a cutoff in energy to improve iteratively the precision of the spectrum at small energies. This iteration cannot be

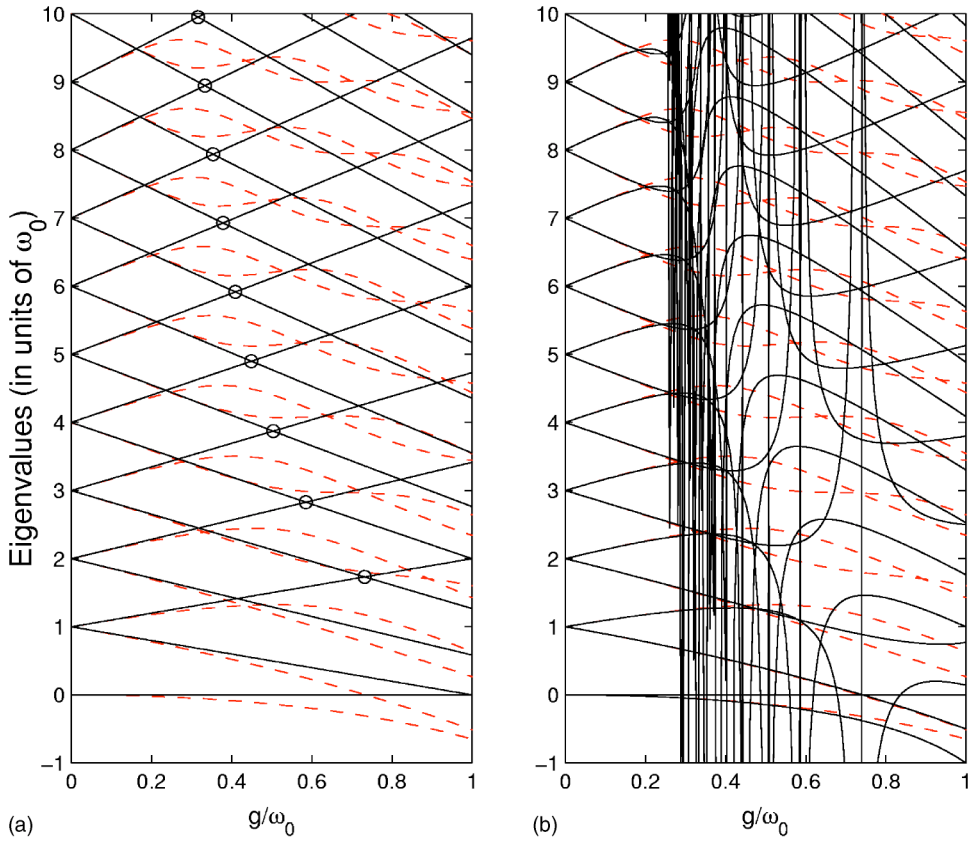

FIG. 1. Comparison of exact numerical eigenvalues (dashed lines) of (8) for one-photon resonance $\omega=\omega_0$ with the approximate ones (solid lines) obtained after (a) one one-photon RT given by (34) and (b) one one-photon RT plus one iteration of KAM-type perturbative expansion. The divergence observed around $g/\omega_0=0.3$ in panel (b) is due to the active nonlinear resonances of $H_1^{(0)}$ that occurred at the degeneracies marked by circles in panel (a). One can see clearly that the locations of these resonances depend on n according to Eq. (35).

expected to converge for all values of g in an interval $[0,g_0]$, because of the presence of a countable number of resonances at high energies at arbitrarily small values of g. A single KAM transformation (which is essentially equivalent to second-order perturbation theory) already gives quite good precision, as shown in Fig. 1(b) for $g/\omega_0<0.25$ for energies smaller than $10\omega_0$. If we take large enough g or larger energies, we encounter new resonances which appear at some specific finite values of g. These resonances are called *field-induced resonances* or *nonlinear resonances*. For larger values of the coupling $[g/\omega_0\approx 0.3$ for the shown energy interval in Fig. 1(b)], where we encounter nonlinear resonances, the KAM iteration diverges. The eigenvalues of $H_1^{(0)}$ are degenerate at $g_n=\omega/(\sqrt{n}+\sqrt{n+1})$ as $E^{(0)}_{1,(n,+)}(g_n)=E^{(0)}_{1,(n+1,-)}(g_n)$. But the corresponding resonant terms in V_1 are zero due to parity (mute resonances). The next degeneracies appear at

$$g_n = 2\omega/(\sqrt{n}+\sqrt{n+2}), \tag{35}$$

as

$$E^{(0)}_{1,(n,+)}(g_n) = E^{(0)}_{1,(n+2,-)}(g_n), \tag{36}$$

which have been marked by circles in Fig. 1(a). All the other resonances are mute. There is an infinite family of nonlinear resonances located at different values of the coupling g_n. We observe from (35) that for higher energies the nonlinear resonances appear for arbitrary small coupling $(\lim_{n\to\infty} g_n=0)$. We can extract the resonant terms corresponding to the whole family in a single

step by working with the combined projector $\Sigma_n \Pi_{H_1^{(0)}(g_n)}$. The resonant terms in V_1 corresponding to the degeneracies (36) are

$$\sum_n \Pi_{H_1^{(0)}(g_n)} V_1 = -\frac{g}{2}\begin{pmatrix} 0 & A_{\perp 0} \\ A_{\perp 0}^\dagger & 0 \end{pmatrix} - \frac{g}{\sqrt{2}}\begin{pmatrix} 0 & 0 \\ 0 & |2\rangle\langle 0| + |0\rangle\langle 2| \end{pmatrix}, \tag{37}$$

and the new effective Hamiltonian is thus

$$H_1^{\text{eff}} = \omega N \otimes \mathbb{1}_2 + g\sqrt{N} \otimes \sigma_z + \sum_n \Pi_{H_1^{(0)}(g_n)} V_1. \tag{38}$$

To diagonalize H_1^{eff}, it can be decomposed according to three orthogonal subspaces:

$$H_1^{\text{eff}} = P_{(0,2,-)} H_1^{\text{eff}} P_{(0,2,-)} + P_{(0,+)} H_1^{\text{eff}} P_{(0,+)} + P_\perp H_1^{\text{eff}} P_\perp = H_1^{\text{eff}} P_{(0,2,-)} + H_1^{\text{eff}} P_{(0,+)} + H_1^{\text{eff}} P_\perp, \tag{39}$$

where the projectors, which commute with H_1^{eff}, are defined by

$$P_{(0,2,-)} = \begin{pmatrix} 0 & 0 \\ 0 & |0\rangle\langle 0| + |2\rangle\langle 2| \end{pmatrix}, \quad P_{(0,+)} = \begin{pmatrix} |0\rangle\langle 0| & 0 \\ 0 & 0 \end{pmatrix},$$

$$P_\perp = \mathbb{1}_{\mathcal{K}} - P_{(0,2,-)} - P_{(0,+)} = \begin{pmatrix} \sum_{n=1}^{\infty} |n\rangle\langle n| & 0 \\ 0 & \sum_{n=1,\neq 2}^{\infty} |n\rangle\langle n| \end{pmatrix}, \tag{40}$$

which leads to

$$H_1^{\text{eff}} P_{(0,+)} = 0, \quad H_1^{\text{eff}} P_{(0,2,-)} = \left[(2\omega - g\sqrt{2})|2\rangle\langle 2| - \frac{g}{\sqrt{2}}(|2\rangle\langle 0| + |0\rangle\langle 2|) \right] \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix},$$

$$H_1^{\text{eff}} P_\perp = \omega \begin{pmatrix} \sum_{n=1}^{\infty} n|n\rangle\langle n| & 0 \\ 0 & + \sum_{n=1,n\neq 2}^{\infty} n|n\rangle\langle n| \end{pmatrix} + g \begin{pmatrix} \sum_{n=1}^{\infty} \sqrt{n}|n\rangle\langle n| & 0 \\ 0 & \sum_{n=1,n\neq 2}^{\infty} \sqrt{n}|n\rangle\langle n| \end{pmatrix}$$
$$- \frac{g}{2}\begin{pmatrix} 0 & A_{\perp 0} \\ A_{\perp 0}^\dagger & 0 \end{pmatrix}. \tag{41}$$

$H_1^{\text{eff}} P_{(0,2,-)}$ can be directly diagonalized by

$$R_{(0,2,-)} = P_{(0,2,-)} \begin{pmatrix} 0 & 0 \\ 0 & \cos\theta(|2\rangle\langle 2| - |0\rangle\langle 0|) - \sin\theta(|2\rangle\langle 0| + |0\rangle\langle 2|) \end{pmatrix} P_{(0,2,-)}, \tag{42}$$

where the angle θ is defined by the relation

$$\tan 2\theta = \frac{g\sqrt{2}}{2\omega - g\sqrt{2}}, \quad 0 \leqslant \theta < \frac{\pi}{2}, \tag{43}$$

and the corresponding eigenvalues are

$$E^{\text{eff}}_{1,(0,+)} = 0, \quad E^{\text{eff}}_{1,(n=0,2,-)} = \omega - \frac{g}{\sqrt{2}} \pm \frac{1}{2}\sqrt{(2\omega - g\sqrt{2})^2 + 2g^2}. \tag{44}$$

The reduction step of the second RT to diagonalize $H_1^{\text{eff}} P_\perp$ in the Fock space can be defined as

$$R_{2,\perp} := P_\perp \begin{pmatrix} (A_{\perp 0} A_{\perp 0}^\dagger)^{-1/2} A_{\perp 0} & 0 \\ 0 & \mathbb{1} \end{pmatrix} P_\perp = \begin{pmatrix} \sum_{n=1}^{\infty} |n\rangle\langle n+2| & 0 \\ 0 & \sum_{n=1,\neq 2}^{\infty} |n\rangle\langle n| \end{pmatrix} \tag{45}$$

with the properties

$$R_{2,\perp} R_{2,\perp}^\dagger = P_\perp, \quad R_{2,\perp}^\dagger R_{2,\perp} = P_\perp - \begin{pmatrix} |1\rangle\langle 1| + |2\rangle\langle 2| & 0 \\ 0 & 0 \end{pmatrix}. \tag{46}$$

Equation (45) shows that $R_{2,\perp}$ dresses the upper atomic state by (-2) photons. Therefore $\mathcal{R}_{2,\perp}$ can be called a two-photon RT. Since $R_{2,\perp}|1,+\rangle = 0 = R_{2,\perp}|2,+\rangle$, the spectrum of $R_{2,\perp}^\dagger H_1^{\text{eff}} P_\perp R_{2,\perp}$ has two extra zero eigenvalues relative to the spectrum of $H_1^{\text{eff}} P_\perp$. Applying $R_{2,\perp}$ gives

$$R_{2,\perp}^\dagger H_1^{\text{eff}} P_\perp R_{2,\perp} = \omega \begin{pmatrix} \sum_{n=3}^{\infty} (n-2)|n\rangle\langle n| & 0 \\ 0 & \sum_{n=1,\neq 2}^{\infty} n|n\rangle\langle n| \end{pmatrix} + g \begin{pmatrix} \sum_{n=3}^{\infty} \sqrt{n-2}|n\rangle\langle n| & 0 \\ 0 & -\sum_{n=1,\neq 2}^{\infty} \sqrt{n}|n\rangle\langle n| \end{pmatrix}$$
$$- g/2 \sum_{n=3}^{\infty} \sqrt{n-1}|n\rangle\langle n| \otimes \sigma_x. \tag{47}$$

Combining the transformations on the different subspaces we can write the transformation that diagonalizes H_1^{eff} in the Fock space as

$$R_2 = R_{2,\perp} + R_{(0,2,-)} + P_{(0,+)}. \tag{48}$$

At the right-hand side of (47), the three matrices have entries that commute with each other so we can diagonalize the sum of them in the atomic Hilbert space (the second step of $\mathcal{R}_{2,\perp}$) as if they had scalar entries. The eigenvalues of $R_{2,\perp}^\dagger H_1^{\text{eff}} P_\perp R_{2,\perp}$ are thus

$$E^{\text{eff}}_{1,(n=1,-)} = \omega - g, \quad E^{\text{eff}}_{1,(n=1,+)} = 0, \quad E^{\text{eff}}_{1,(n=2,+)} = 0,$$

$$E^{\text{eff}}_{1,(n\geqslant 3,\pm)} = \omega(n-1) + \frac{g}{2}(\sqrt{n-2} - \sqrt{n}) \pm \frac{1}{2}[(-2\omega + g(\sqrt{n-2} + \sqrt{n}))^2 + g^2(n-1)]^{1/2}. \tag{49}$$

As it can be seen from (49), there are two extra zero eigenvalues which have been added by $R_{2,\perp}$ to the spectrum of H_1^{eff}.

Figures 2(a) and 2(b) compare respectively the exact spectrum of H calculated numerically with the spectrum of $H_0^{\text{eff}} = H_{JC}$ given by (34) and of H_1^{eff} given by (49) and (44). The crossings of the exact spectrum are all among the eigenvalues with different parities. It is found that the spectrum of H_0^{eff} coincides with the exact one only in the range of quite small coupling. The spectrum of H_1^{eff} has been modified with respect to the one of H_0^{eff} by transforming the encircled crossings between eigenvalues with the same parity into avoided crossings in the small g region. This procedure to treat resonances can be iterated to take into account other resonances appearing at larger values of g. Figures 2(a)–2(e) show how the combination of a one-photon RT and

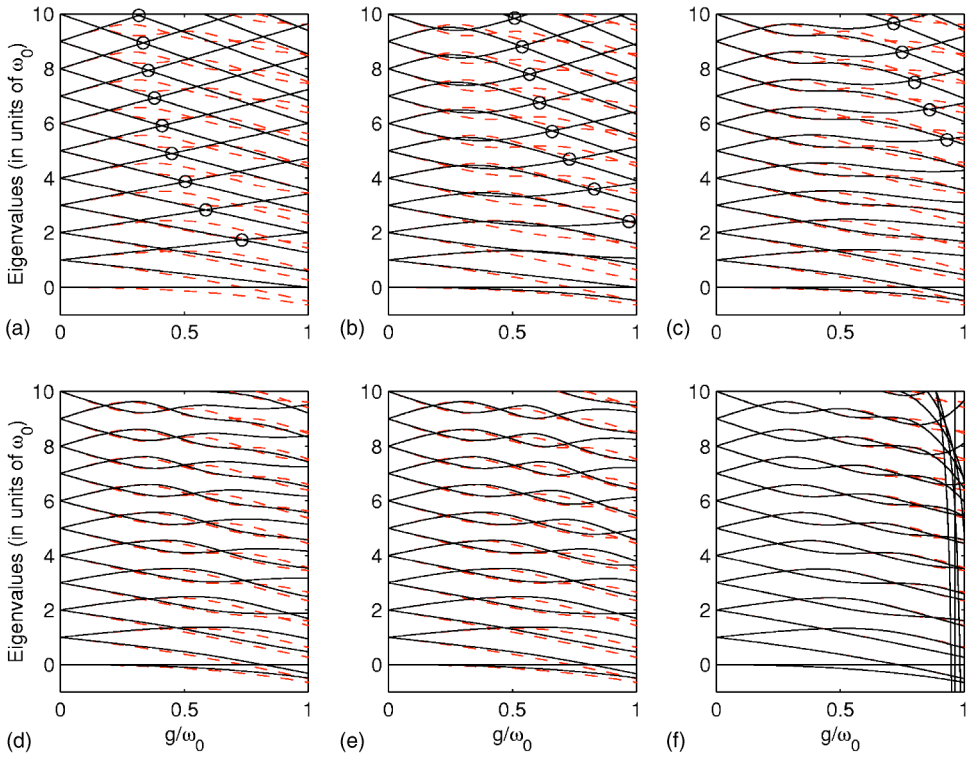

FIG. 2. Comparison of the exact numerical eigenvalues (dashed lines) of (8) for one-photon resonance $\omega=\omega_0$ with the approximate ones (solid lines) obtained respectively after (a) one one-photon RT given by (34), (b) one one-photon RT plus one two-photon RTs given by (49), (c) one one-photon RT plus two two-photon RTs, (d) one one-photon RT plus three two-photon RTs, (e) one one-photon RT plus four two-photon RTs, (f) one one-photon RT plus four two-photon RTs plus one iteration of KAM-type perturbative expansion. The divergence of the KAM transformation observed close to $g/\omega_0=1$ in panel (f) is due to the presence of active resonances at larger values of g.

consecutive two-photon RTs lift the artificial degeneracies (marked by circles) of the effective Hamiltonians. The successive steps, which we have implemented numerically, transform eigenvalue crossings into avoided crossings. We observe that these RTs also produce an improvement of the approximations of the spectrum. Figure 2(f) shows the effect of a KAM transformation after the fourth two-photon RT which improves quantitatively the result of Fig. 2(e). The divergence of the KAM transformation close to $g=1$ in Fig. 2(e) is due to the presence of active resonances at larger values of g.

V. EFFECTIVE HAMILTONIANS IN THE STRONG-COUPLING REGIME

In this section we use quantum averaging techniques and RT to obtain the effective Hamiltonians of (8) by starting the analysis from the strong-coupling regime. We derive a formula that reproduces the spectrum quite accurately in the whole range of g and for all energies. We consider an alternative decomposition of the Hamiltonian (8) in a way suggested by the strong coupling regime $g \gg \omega_0 > 0$,

$$H = H_0 + V,$$

$$H_0 = \omega(N + 1/2) \otimes \mathbb{1}_2 + g(a + a^\dagger) \otimes \sigma_x, \tag{50}$$

$$V = \frac{\omega_0}{2}\mathbb{1} \otimes \sigma_z$$

which can be interpreted as the system of a quantized field plus the coupling term perturbed by the two-level atom. We will use this decomposition as an alternative starting point. As it will be seen later, this approach will allow us to obtain the spectral data for the whole range of values of the coupling $g \in [0,\infty)$. We remark that in this decomposition, H_0 contains all the unbounded operators of the complete model and that the perturbation V is a bounded operator. In this case $H_0(N,a,a^\dagger,\sigma_z,\sigma_x;g)$ is integrable since we can explicitly transform it into a form involving a regular function exclusively of the action operators N,σ_z [given below in Eq. (55)]. To transform H_0 to a function of action operators, first we diagonalize the term $g(a+a^\dagger)\otimes\sigma_x$ in the atomic Hilbert space by the transformation (26):

$$T^\dagger H T = \omega(N + 1/2) \otimes \mathbb{1}_2 + g(a + a^\dagger) \otimes \sigma_z - \frac{\omega_0}{2}\mathbb{1} \otimes \sigma_x. \tag{51}$$

Next we apply a second unitary transformation,

$$U = \begin{pmatrix} e^{-(g/\omega)(a^\dagger - a)} & 0 \\ 0 & e^{(g/\omega)(a^\dagger - a)} \end{pmatrix}, \tag{52}$$

to transform $\omega(N+1/2)\otimes\mathbb{1}_2+g(a+a^\dagger)\otimes\sigma_z$ into a function of only N,σ_z (in this case only of N):

$$H_1 := U^\dagger T^\dagger H T U = \left[\omega(N + 1/2) - \frac{g^2}{\omega}\right] \otimes \mathbb{1}_2 - \frac{\omega_0}{2}\begin{pmatrix} 0 & e^{2(g/\omega)(a^\dagger - a)} \\ e^{-2(g/\omega)(a^\dagger - a)} & 0 \end{pmatrix}, \tag{53}$$

where use has been made of the commutation relations among a, $a^\dagger$, N, and the Hausdorff formula:

$$e^B C e^{-B} = C + [B,C] + \frac{1}{2!}[B,[B,C]] + \cdots. \tag{54}$$

We decompose H_1 as

$$H_1 = H_1^{(0)} + V_1,$$

$$H_1^{(0)} = U^\dagger T^\dagger H_0 T U = \left[\omega(N + 1/2) - \frac{g^2}{\omega}\right] \otimes \mathbb{1}_2, \tag{55}$$

$$V_1 = -\omega_0/2\begin{pmatrix} 0 & e^{2(g/\omega)(a^\dagger - a)} \\ e^{-2(g/\omega)(a^\dagger - a)} & 0 \end{pmatrix}.$$

The effective Hamiltonian of the system for strong-coupling regime can thus be written as

$$H_1^{\text{eff}} = H_1^{(0)} + \Pi_{H_1^{(0)}} V_1. \tag{56}$$

The eigenvalues of $H_1^{(0)}$ have a twofold degeneracy for every value of n as

$$E^{(0)}_{1,(n,\pm)} = \omega(n + 1/2) - \frac{g^2}{\omega}. \tag{57}$$

The average of V_1 relative to $H_1^{(0)}$ is thus

$$\begin{aligned}\Pi_{H_1^{(0)}} V_1 &= \sum_{n=0}^{\infty} \{|n,+\rangle\langle n,+|V_1|n,-\rangle\langle n,-| + |n,-\rangle\langle n,-|V_1|n,+\rangle\langle n,+|\} \\ &= -\frac{\omega_0}{2}\sum_{n=0}^{\infty} f_n |n\rangle\langle n| \otimes \sigma_x,\end{aligned} \tag{58}$$

with

$$\begin{aligned}f_n &= \langle n|e^{(-2g/\omega)(a^\dagger - a)}|n\rangle = \langle n|e^{(+2g/\omega)(a^\dagger - a)}|n\rangle = e^{-2g^2/\omega^2}\langle n|e^{(-2g/\omega)a^\dagger}e^{(+2g/\omega)a}|n\rangle \\ &= e^{-2g^2/\omega^2}\left(\sum_{j=0}^{n}\frac{(-2g/\omega)^j}{j!}\sqrt{\frac{n!}{(n-j)!}}\langle n-j|\right)\left(\sum_{i=0}^{n}\frac{(+2g/\omega)^i}{i!}\sqrt{\frac{n!}{(n-i)!}}|n-i\rangle\right) \\ &= e^{-2g^2/\omega^2}\sum_{j=0}^{n}\frac{(2g/\omega)^{2j}(-1)^j}{(j!)^2}\frac{n!}{(n-j)!} = e^{-2g^2/\omega^2}L_n\left(\frac{4g^2}{\omega^2}\right)\end{aligned} \tag{59}$$

where the L_n are the Laguerre polynomials. We remark that in the limit of a large photon number $(n\to\infty)$, f_n can be expressed as a zeroth-order Bessel function $J_0(4g\sqrt{n}/\omega)$.[15] H_1 can be reorganized as

$$H_1 = H_1^{\text{eff}} + (V_1 - \Pi_{H_1^{(0)}} V_1),$$

$$H_1^{\text{eff}} = \left(\omega(N + 1/2) - \frac{g^2}{\omega}\right)\otimes 1_2 - \frac{\omega_0}{2}F \otimes \sigma_x, \tag{60}$$

$$(V_1 - \Pi_{H_1^{(0)}} V_1) = -\frac{\omega_0}{2}\begin{pmatrix} 0 & G - F \\ G^\dagger - F & 0\end{pmatrix},$$

where

$$G = e^{(+2g/\omega)(a^\dagger - a)}, \quad F = \sum_{n=0}^{\infty} f_n |n\rangle\langle n|. \tag{61}$$

H_1^{eff} can easily be diagonalized by applying the transformation (26) that diagonalizes σ_x:

$$H_2 := T^\dagger H_1 T = H_2^{(0)} + V_2, \tag{62}$$

with

$$H_2^{(0)} = T^\dagger H_1^{\text{eff}} T = \left(\omega(N + 1/2) - \frac{g^2}{\omega}\right)\otimes 1_2 - \frac{\omega_0}{2}F \otimes \sigma_z, \tag{63}$$

and

$$V_2 = T^\dagger(V_1 - \Pi_{H_1^{(0)}} V_1)T = -\omega_0/4\begin{pmatrix} G + G^\dagger - 2F & G - G^\dagger \\ -G + G^\dagger & -G - G^\dagger + 2F\end{pmatrix}. \tag{64}$$

The eigenvalues of $H_2^{(0)}$ are therefore

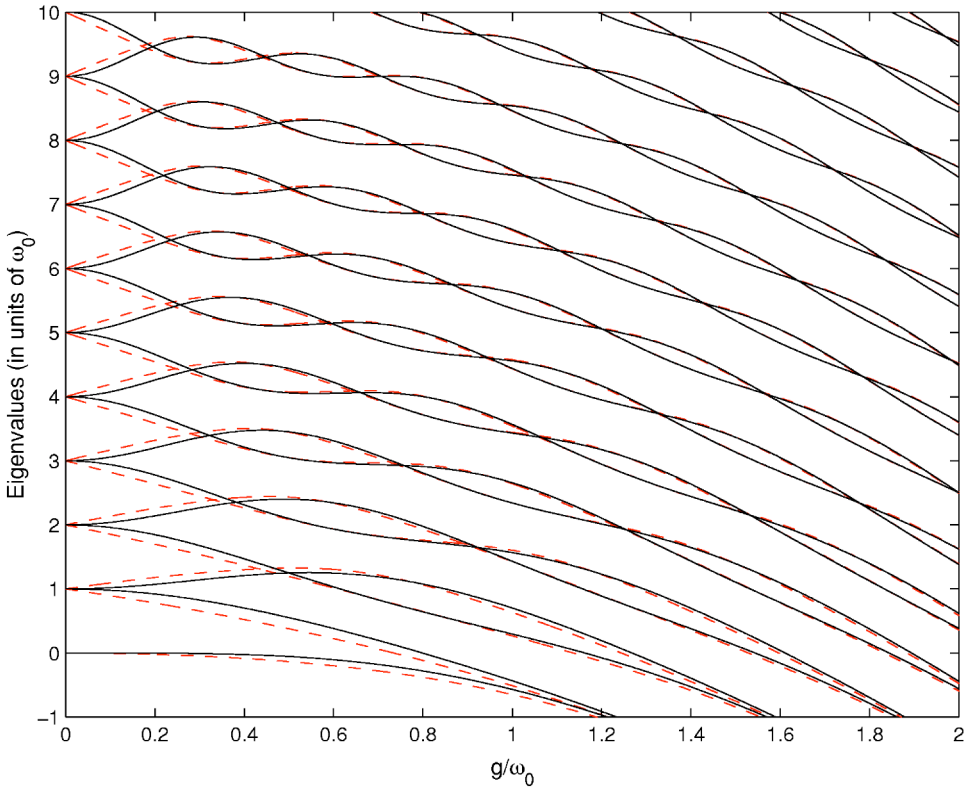

FIG. 3. Comparison of exact numerical eigenvalues (dashed lines) of (8) as a function of the coupling constant in the resonant case ($\omega=\omega_0$), with the approximate eigenvalues (solid lines) obtained from (65).

$$E^{(0)}_{2,(n,\pm)} = \omega(n+1/2) - \frac{g^2}{\omega} \mp \frac{\omega_0}{2} e^{-2g^2/\omega^2} L_n\left(\frac{4g^2}{\omega^2}\right), \tag{65}$$

which is the same result obtained in Refs. 17, 19, and 20 by other methods. Figure 3 compares the exact numerical spectrum of (8) with the approximation (65) for the resonant case $\omega=\omega_0$. One can see that for large enough g, the formula (65) reproduces the spectrum well. It is not very accurate for small values of g because of the presence of the one-photon zero-field resonances that we analyze as follows. In the limit $g\to 0$, we have

$$H_2^{(0),g\to 0} \rightsquigarrow \omega(N+1/2)\otimes \mathbb{1}_2 - \frac{\omega}{2}\mathbb{1}\otimes\sigma_z,$$

$$V_2^{g\to 0} \rightsquigarrow g\begin{pmatrix} 0 & a-a^\dagger \\ -(a-a^\dagger) & 0 \end{pmatrix}. \tag{66}$$

Thus degeneracies of $H_2^{(0),g\to 0}$ occur as

$$E^{(0),g\to 0}_{2,(n,+)} = E^{(0),g\to 0}_{2,(n-1,-)}. \tag{67}$$

They are made active by the resonant terms of $V_2^{g\to 0}$:

$$V_{2,res}^{g\to 0} = \Pi_{H_2^{(0)}}^{g\to 0} V_2^{g\to 0} = -g\begin{pmatrix} 0 & a^\dagger \\ a & 0 \end{pmatrix}. \tag{68}$$

The transformation (the reduction step of the RT) which transforms this resonant term to a regular function of N is

$$R_1 := \begin{pmatrix} \mathbb{1} & 0 \\ 0 & (aa^\dagger)^{-1/2}a \end{pmatrix} = \begin{pmatrix} \mathbb{1} & 0 \\ 0 & \sum_{n=0}^{\infty} |n\rangle\langle n+1| \end{pmatrix}, \tag{69}$$

with the properties

$$R_1 R_1^\dagger = \mathbb{1}_{\mathcal{K}}, \quad R_1^\dagger R_1 = \mathbb{1}_{\mathcal{K}} - \begin{pmatrix} 0 & 0 \\ 0 & |0\rangle\langle 0| \end{pmatrix}. \tag{70}$$

We remark that the definition of R_1 depends on the type of resonant terms. The reduction step of the RT presented here is different from (19). The Hamiltonian transformed under this RT has an extra zero eigenvalue corresponding to spurious eigenvector $|0, -\rangle$, while for the Hamiltonian transformed under (19), the extra zero eigenvalue corresponds to $|0, +\rangle$. Applying R_1 on H_2 gives

$$\begin{aligned} H_3 := R_1^\dagger H_2 R_1 &= \left(\omega N - \frac{g^2}{\omega}\right) \otimes \mathbb{1}_2 + R_1^\dagger V_2 R_1 \\ &+ \begin{pmatrix} \frac{\omega}{2}\left(1 - \sum_{n=0}^{\infty} f_n |n\rangle\langle n|\right) & 0 \\ 0 & -\frac{\omega}{2}\left(1 - \sum_{n=1}^{\infty} f_{n-1}|n\rangle\langle n|\right) - \left(\frac{\omega}{2} + \frac{g^2}{\omega}\right)|0\rangle\langle 0| \end{pmatrix}. \end{aligned} \tag{71}$$

Next, we take $H_3^{(0)} = \omega N \otimes \mathbb{1}_2$ and the rest of H_3 as V_3. Since $H_3^{(0)}$ has a twofold degeneracy as $E_{3,(n,+)}^{(0)} = E_{3,(n,-)}^{(0)}$, the average of V_3 relative to $H_3^{(0)}$ is thus

$$\Pi_{H_3^{(0)}} V_3 = \begin{pmatrix} \frac{\omega}{2} - \frac{g^2}{\omega} - \frac{\omega}{2}\sum_{n=0}^{\infty} f_n |n\rangle\langle n| & \sum_{n=1}^{\infty} -\frac{g}{\sqrt{n}} e^{-2g^2/\omega^2} L_{n-1}^{(1)}\left(\frac{4g^2}{\omega^2}\right)|n\rangle\langle n| \\ \sum_{n=1}^{\infty} -\frac{g}{\sqrt{n}} e^{-2g^2/\omega^2} L_{n-1}^{(1)}\left(\frac{4g^2}{\omega^2}\right)|n\rangle\langle n| & -\left(\frac{\omega}{2} + \frac{g^2}{\omega}\right)(1 - |0\rangle\langle 0|) + \frac{\omega}{2}\sum_{n=1}^{\infty} f_{n-1}|n\rangle\langle n| \end{pmatrix}, \tag{72}$$

where we have used the relation[16]

$$\langle m|e^{\pm(2g/\omega)(a^\dagger - a)}|n\rangle = \sqrt{\frac{n!}{m!}}\left(\frac{\pm 2g}{\omega}\right)^{m-n} e^{-(2g^2/\omega^2)} L_n^{(m-n)}\left(\frac{4g^2}{\omega^2}\right), \tag{73}$$

with $L_n^{(m-n)}(x)$ the associated Laguerre polynomials and $m \geqslant n$. The new effective Hamiltonian can thus be written as

$$H_3^{\text{eff}} = \omega N \otimes \mathbb{1}_2 + \Pi_{H_3^{(0)}} V_3. \tag{74}$$

Since all the entries of H_3^{eff} commute with N, it can be diagonalized in the atomic Hilbert space as if its entries were scalars. The eigenvalues of H_3^{eff} are thus

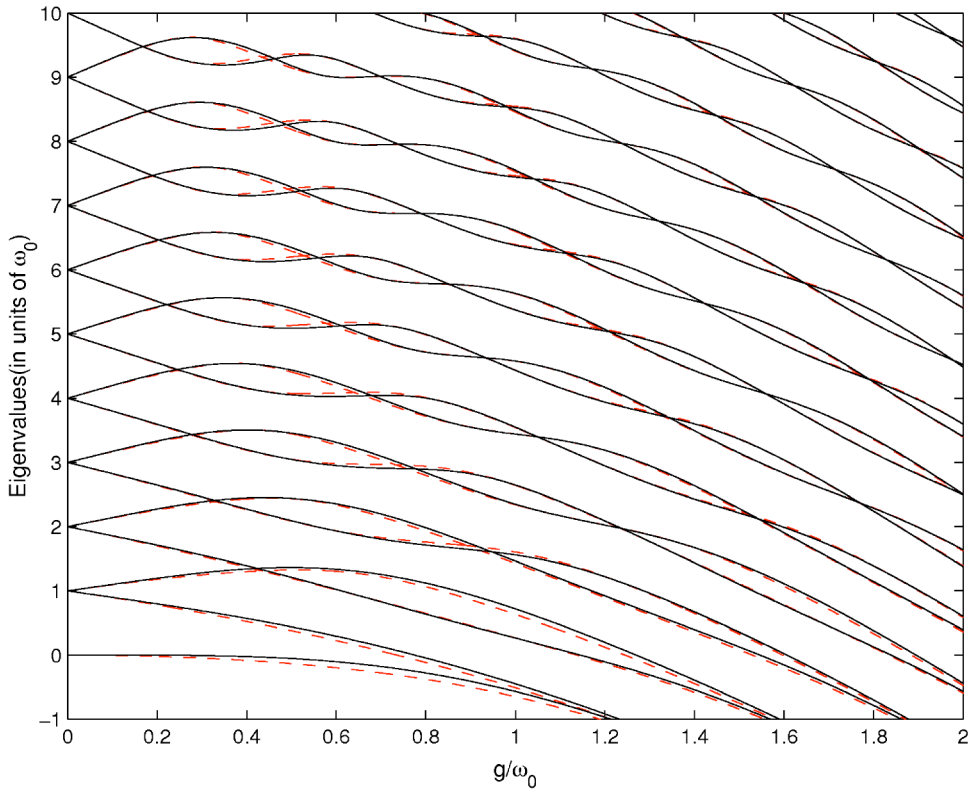

FIG. 4. Comparison of exact numerical spectrum of (8) (dashed lines) as a function of the coupling constant in the resonant case ($\omega=\omega_0$), with the quite accurate result (75) which has treated the zero-field resonances by a RT (solid lines).

$$E^{\mathrm{eff}}_{3,(0,-)}=0,\quad E^{\mathrm{eff}}_{3,(0,+)}=\frac{\omega}{2}-\frac{g^2}{\omega}-\frac{\omega}{2}e^{-2g^2/\omega^2},$$

$$E^{\mathrm{eff}}_{3,(n\geqslant 1,\pm)}=n\omega-\frac{g^2}{\omega}-\frac{\omega}{4}e^{-2g^2/\omega^2}\left(L_n\left(\frac{4g^2}{\omega^2}\right)-L_{n-1}\left(\frac{4g^2}{\omega^2}\right)\right)$$
$$\pm\frac{1}{2}\left[\left(\omega-\frac{\omega}{2}e^{-2g^2/\omega^2}\left(L_n\left(\frac{4g^2}{\omega^2}\right)+L_{n-1}\left(\frac{4g^2}{\omega^2}\right)\right)\right)^2+\frac{4g^2}{n}e^{-4g^2/\omega^2}\left(L^{(1)}_{n-1}\left(\frac{4g^2}{\omega^2}\right)\right)^2\right]^{1/2}. \tag{75}$$

The zero eigenvalue is the extra spurious one that has been added by the RT to the spectrum. Figure 4 compares the exact numerical spectrum of (8) and the approximation (75) which has treated the zero-field resonances by a RT. The figure shows that treating all the active resonances of the system allows us to obtain all the qualitative features of the spectrum in the whole range of the coupling constant and for all energies. At a second stage, since we have treated all the active resonances, we can improve further this spectrum quantitatively by a KAM-type perturbative iteration.

VI. CONCLUSIONS

We have presented a nonperturbative method based on the quantum averaging technique to determine the spectral properties of systems containing resonances. It consists in the construction of unitary or isometric transformations that leads to an effective reduced Hamiltonian. These transformations are composed of two qualitatively distinct stages. The first one consists of non-

perturbative transformations (RTs) that are adapted to the structure of the resonances. Their role is to construct a first effective Hamiltonian that contains the main qualitative features of the spectrum—crossings and avoided crossings—in a given range of the coupling parameter. The diagonalized form of this effective Hamiltonian, which depends parametrically on the coupling constant, is then taken as a new reference Hamiltonian around which one can apply perturbative techniques to improve the quantitative accuracy of the spectrum. We formulate the perturbative approach in terms of a KAM-type iteration of contact transformations. Similar results can be obtained with other formulations of perturbation theory.

We have illustrated the method with a model of a two-level atom interacting with a single mode of a quantized field. The method can be applied to more general systems with several field modes. It can also be adapted to the treatment of semiclassical models in which the field is described as a time-dependent function.

We have analyzed the resonances in two regimes of weak and strong coupling. The results we obtained in the weak-coupling regime can be expected to be applicable to quite general models. The analysis of the strong-coupling regime of this model leads to results that are valid for all values of the coupling and for all energies. The possibility to obtain such a global result is due to a particular property of the model, and one cannot expect to obtain it for general models. The particular property is that the part we selected as the reference Hamiltonian H_0 in the strong-coupling regime contains all the unbounded operators of the complete model and is explicitly solvable. The term that was left to be treated by RT and perturbation theory is a bounded operator.

An abstract interface to higher spin gauge field theory

A. K. H. Bengtsson[a)]
School of Engineering, University College of Borås, Allégatan 1, S-50190 Borås, Sweden

(Received 15 October 2004; accepted 18 January 2005; published online 1 April 2005)

A comprehensive approach to the theory of higher spin gauge fields is proposed. By explicitly separating out details of implementation from general principles, it becomes possible to focus on the bare minimum of requirements that such a theory must satisfy. The abstraction is based on a survey of the progress that has been achieved since relativistic wave equations for higher spin fields were first considered in the 1930s. As a byproduct, a formalism is obtained that is abstract enough to describe a wide class of classical field theories. The formalism, viewed as syntax, can then be semantically mapped to a category of strongly homotopy Lie algebras, thus showing that the theory in some sense exists, at least as an abstract mathematical structure. Still, a concrete physicslike, implementation remains to be constructed. Lacking deep physical insight into the problem, an implementation in terms of generalized vertex operators is set up within which a brute force iterative determination of the first few orders in the interaction can be attempted. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1867976]

I. INTRODUCTION

On a very high level of abstraction, the theory of self-interacting higher spin gauge fields becomes either trivial or void. This might seem like a preposterous statement about a problem, the solution of which has eluded theoretical physics since the 1970s, when the problem was first explicitly raised.[1] In this paper, we will try to explain the intuition behind this claim.

Theoretical physics in general, and high energy physics in particular, rest on a tremendous body of knowledge about reality. The nature of this knowledge is manifold, one aspect is the general principles like the relativity principle, the equivalence principle, various gauge principles and the quantum paradigm. Another aspect is the many elaborate calculational schemes employed in particular models, realistic or of the toy variant. This is the nuts and bolts of the science. Whereas the principles are lofty and beautiful to contemplate, the nuts and bolts are often ugly and boring to struggle with. Of course, this is a matter of taste and outlook. But in the end, the nuts and bolts must be there in the right place in order to make contact with experiment, and ensure eventual mathematical consistency.

In computer science, we also find this division between a high level abstract approach to problems, and a low level nuts and bolts code grinding. But in computer science the division is more explicitly pronounced. The complexity of modern software development has forced an approach where one must get the principles right first.

One purpose of the present paper is to adopt this mode of working with respect to the problem of introducing self-interactions for higher spin massless gauge fields. Substantial progress notwithstanding, the problem is still not completely solved, and far less understood. It is not even clear how to recognize or evaluate a purported solution. Massless higher spin fields appear in many contexts related to string theory, membrane theory and M-theory and theories deriving from these.

a)Electronic mail: anders.bengtsson@hb.se

This makes it interesting to find out if higher spin gauge fields can stand on their own, without crutches, so to speak, from circumstantial theoretical constructs. Furthermore, a problem so simple to formulate, but so difficult to solve, is intriguing in itself.

We will approach the problem by formulating an as general as possible *interface* to higher spin gauge field theory. In the process, specifications that the theory must meet, will be cataloged. The interface will then turn out to be quite trivial. Then comes the question of implementing the interface. This is where the nuts and bolts enters. Perhaps there is no implementation, in which case the theory is void.

Now, what do we gain by adopting this strategy? First, we get a framework where we can discuss the general aspects of the theory without worrying at the same time whether they can be implemented or not. We do not have to fix space–time dimension or signature, or worry about background geometry and coupling to gravity. Indeed, we do not have to worry about space–time at all. Second, it might be possible to separate the issue of existence from the issue of construction. Third, if the theory exists, there might be several, in some sense different implementations, thus avoiding the so common pattern of thinking in terms of uniqueness. Fourth, it might be possible to implement the theory computationally in some set of abstract data types. (In that case, considerations of finite definition enters, but that can presumably be taken care of relying on lazy evaluation, thus effectively allowing enumerably infinite data structures.) And last, and perhaps not completely independent of the previous points, we can separate physics from mathematics. The problem is so difficult that we cannot *a priori* know if all our cherished physical principles can be retained. Better then to keep an open mind and treat the problem purely mathematically.

There is one further point to be made. When solving hard problems in theoretical physics, it is natural to search through mathematics in the hope of finding a pre-existing structure that can be used. However, one could imagine a physics problem for which there is no mathematical structure available as yet. That this situation could be encountered in fundamental physics is not at all unthinkable. It seems to me that computer science has tools to tackle this situation, or at least to formulate it. Thus, again borrowing from computer science, the approach to higher spin theory proposed here can also be viewed as an attempt to provide a *syntax* for the problem. Then implementation corresponds to providing the syntactical model with *semantics*. Now syntax and semantics are concepts normally applied to programming languages, or formal languages in general, so we use the concepts in a slightly transferred sense. Continuing this train of thought, of the different semantical schemes, *denotational* semantics, where the syntactical structures are mapped to mathematical objects in a pre-existing (and well understood) semantical domain,[2] seems to be the most appropriate. If a semantical domain cannot be found, then research should perhaps be directed towards inventing new mathematics, rather than trying to solve a theoretical physics problem. If the domain exists, we might be able to target this mathematical structure more precisely. This is one reason for adopting computer science inspired thinking rather than working directly within a mathematical structure from the outset.

If it seems strange to use computer science concepts in high energy physics, one should consider the fact that the subject of theoretical computer science is, in essence, *data* and *processes* in general, and therefore it can be useful in various scientific contexts where one must deal with complex systems.

Parts of the discussion in this paper are quite elementary. That is inherent in the formal, syntactic approach. We want to focus on the abstract and general issues involved, not taking, at least not consciously so, to much pre-existing mathematics on board. But as the present work is mainly conceptual and in a creative phase, the formalization will not be pushed to far. A pure syntactic approach would almost certainly obscure the main idea. In order to communicate, we will compromise by using a somewhat unprincipled mix of syntax, semantics, and mathematics. If the approach is fruitful, an exact formulation can be set up later.

Perhaps a simple example helps to further explicate this point of view. Consider the real numbers. The axioms for this structure are well known and used almost subconsciously in everyday calculating. When working in calculus or real analysis, for example solving differential equations, these axioms and the theorems are used throughout. We never worry about their relevance

or their truth. But of course, if there was no implementation of the axioms, the exercise would be void, i.e., just formal manipulations. Now we know that there are different implementations of the real numbers in terms of, for example, Dedekind cuts or limits of Cauchy sequences. These implementations are in their turn based on implementations of the rational numbers in terms of the natural numbers. The story is well known. But one more point can be made. If numerical calculations must be done, then a detailed implementation of the real numbers in terms of floating point numbers is necessary.

Now, we never start with a completely blank mind. We have some knowledge about the problem at hand and we often have more or less strong intuitions. There might also be folklore on the subject, but in my opinion, folklore is often too prejudiced to be useful in a creative way.

The first step will be to abstract from what we already know. The scope of the present paper is to set up a general enough framework within which the problem of self-interactions can be analyzed, while allowing for various forms for the free theory and allowing for different implementational ideas as regards interactions.

Two other sources of ideas for the present paper should be mentioned. One is string field theory,[3,4] in particular the nonpolynomial closed string field theory,[5,6] and the other is the mathematical theory of higher homotopy Lie algebras (see Ref. 7 for further references). Classical string field theory can be seen as an implementation of the framework presented here, although we have actually worked the other way, abstracting what is nonparticular to strings. The various algebraic structures, on the other hand, can be considered as (themselves quite abstract, but understood) semantical domains for the syntax presented here. In fact, there is an enormous amount of mathematics that might be relevant. We do not understand higher spin gauge fields well enough to target the appropriate mathematics with precision yet, although it seems possible to semantically map to higher homotopy Lie algebras. Still we need a concrete, physics like, implementation. Thus, we envisage a four-tier structure: syntactic formulation of the theory $\rightarrow$semantical map into a known mathematical structure$\rightarrow$concrete physicslike implementation $\rightarrow$computational implementation.

II. NOTES ON THE FREE FIELD THEORY

The free field theory of higher spin gauge fields is a simple generalization of the lower spin gauge theories for spin 1 and spin 2. There are many variations, developed and proposed during the last five decades.[8–14] Indeed, the literature on higher spin fields is enormous, and we will not attempt to review it. However, it seems to be that certain approaches stand out as particularly simple and, perhaps for that reason, suited as a basis for interactions. One is the original formulation[15–18] in terms of field equations and Lagrangians for symmetric tensor fields, perfected by Fronsdal.[9] Another is the formulation of Freedman and deWit[12] in terms of generalized Christoffel symbols (see also Ref. 19). A third is the BRST approach developed by Siegel and Zwiebach,[20] Ouvry and Stern,[21] and independently by the author.[22] This approach was inspired by and adapted from the, at that time, very active work on string field theory. The reader is referred to the review[4] for a list of references. The BRST approach has been rediscovered[23–26] several times during the years since it was first written down in 1986. Then there is the light-front formulation,[27–29] which, in a way, is the simplest formulation of all, if not for the intricate mixing of gauge symmetry with Poincaré symmetry which makes higher order interactions untractable. Then we have the approach of Vasiliev[13] which has lead to a dramatic progress on interactions in an AdS background geometry. See Refs. 30 and 31 for recent reviews and further references, as well as a view on the higher spin problem that is complementary to the one given in the present paper. For completeness, the twistor approach should be noted.[8,32]

A detailed discussion of the BRST formulation of the free field theory, suitable for our present purposes, can be found in Ref. 33. Here, the notation that will be needed when discussing the BRST implementation will be reviewed.

Consider a phase space spanned by bosonic variables (x_μ, p_μ) and $(\alpha_\mu, \alpha_\mu^\dagger)$ and ghost variables (c^+, b_+), (c^-, b_-), and (c^0, b_0) with commutation relations

$$[x_\mu, p_\nu] = i\eta_{\mu\nu}, \quad [\alpha_\mu, \alpha_\nu^\dagger] = \eta_{\mu\nu}, \tag{1}$$

$$\{c^+, b_+\} = \{c^-, b_-\} = \{c^0, b_0\} = 1. \tag{2}$$

The ghosts have the following properties under Hermitian conjugation

$$(c^-)^\dagger = c^+, \quad (b_-)^\dagger = b_+, \quad (c^0)^\dagger = c^0, \quad (b_0)^\dagger = b_0. \tag{3}$$

The vacuum is degenerate

$$\alpha_\mu|+\rangle = \alpha_\mu|-\rangle = 0, \tag{4}$$

$$\langle +|-\rangle = \langle -|+\rangle = 1, \tag{5}$$

$$\langle +|+\rangle = \langle -|-\rangle = 0, \tag{6}$$

with properties

$$b_0|+\rangle = 0, \quad b_0|-\rangle = |+\rangle, \tag{7}$$

$$c^0|-\rangle = 0, \quad c^0|+\rangle = |-\rangle, \tag{8}$$

$$c^-|+\rangle = c^-|-\rangle = 0, \tag{9}$$

$$b_+|+\rangle = b_+|-\rangle = 0. \tag{10}$$

The ghost variables are Grassmann odd, while the bosonic are Grassmann even. The equations $b_0|-\rangle = |+\rangle$ and $c^0|+\rangle = |-\rangle$ relating the vacua, then implies that either one of the two vacua must be odd. Here, we will choose $|-\rangle$ Grassmann even and $|+\rangle$ Grassmann odd. A peculiar consequence is that $\langle +|-\rangle$ becomes odd.

Ghost numbers, gh, are assigned according to

$$\begin{gathered} x_\mu, p_\mu, \alpha_\mu, \alpha_\mu^\dagger \quad 0 \\ c^0, c^+, c^- \quad 1 \\ b_0, b_+, b_- \quad -1 \\ |+\rangle \quad -1/2 \\ |-\rangle \quad 1/2. \end{gathered} \tag{11}$$

The higher spin fields are collected into the ket $|\Phi\rangle$ with expansion

$$|\Phi\rangle = \Phi(p)|+\rangle + F(p)c^+b_-|+\rangle + H(p)b_-|-\rangle, \tag{12}$$

where $\Phi(p)$ contains the symmetric higher spin gauge fields, and $F(p)$ and $H(p)$ are certain auxiliary fields. These fields are further expanded in terms of the oscillators

$$\Phi = \Phi_0 + i\Phi^\mu\alpha_\mu^\dagger + \Phi^{\mu\nu}\alpha_\mu^\dagger\alpha_\nu^\dagger + \cdots, \tag{13}$$

$$F = F_0 + iF^\mu\alpha_\mu^\dagger + F^{\mu\nu}\alpha_\mu^\dagger\alpha_\nu^\dagger + \cdots, \tag{14}$$

$$H = H_0 + iH^{\mu}\alpha_{\mu}^{\dagger} + H^{\mu\nu}\alpha_{\mu}^{\dagger}\alpha_{\nu}^{\dagger} + \cdots . \tag{15}$$

The gauge parameters are expanded as

$$|\Xi\rangle = (\xi_0 - i\xi^{\mu}\alpha_{\mu}^{\dagger} + \xi^{\mu\nu}\alpha_{\mu}^{\dagger}\alpha_{\nu}^{\dagger} + \cdots)b_{-}|+\rangle. \tag{16}$$

Note that the field $|\Phi\rangle$ is odd while the $|\Xi\rangle$ is even. The Grassmann properties are carried by the vacua. When abstracting the free theory, the vacua will be dropped, and the Grassmann properties of Φ and Ξ will be interchanged. They can be defined either way in the abstract theory.

The BRST operator Q is expressed in terms of the generators

$$G_0 = \tfrac{1}{2}p^2, \quad G_{-} = \alpha \cdot p, \quad G_{+} = \alpha^{\dagger} \cdot p, \tag{17}$$

spanning the simple algebra

$$[G_{-}, G_{+}] = 2G_0, \tag{18}$$

with all other commutators zero.

In terms of these generators, the BRST operator reads (signs are chosen so that the component field actions works out as in Ref. 34)

$$Q = c^0 G_0 - c^{+}G_{+} - c^{-}G_{-} - 2c^{+}c^{-}b_0. \tag{19}$$

The action

$$A = \langle\Phi|Q|\Phi\rangle, \tag{20}$$

is invariant under the gauge transformations,

$$\delta_{\Xi}|\Phi\rangle = Q|\Xi\rangle, \tag{21}$$

as is the field equation

$$Q|\Phi\rangle = 0. \tag{22}$$

There is one, somewhat puzzling aspect, of this theory. When expanding the equations (20)–(22), everything works out nicely for the component fields, except the fact that the theory contains auxiliary fields which cannot be solved for without introducing a further constraint. This constraint is applied to both the field and the gauge parameter

$$T|\Phi\rangle = 0, \quad T|\Xi\rangle = 0, \tag{23}$$

where T is the operator

$$T = \frac{1}{2}\alpha \cdot \alpha + b_{+}c^{-}. \tag{24}$$

When expanded, the constraint equation yields the double tracelessness constraint for component fields of spin $s \geqslant 4$ and the tracelessness constraint for the corresponding component gauge parameters. The free field theory is still gauge invariant without imposing these constraints, but the constraints are needed in order to get the correct number of physical degrees of freedom. These questions are discussed in Ref. 33.

So the bottom line of the BRST treatment of the free field theory is that the action can be written as $\langle\Phi|Q|\Phi\rangle$ with Q a nilpotent kinetic operator and $|\Phi\rangle$ a certain expansion over internal and ghost degrees of freedom. Below, when discussing an abstract approach to the theory, we will not use this notation, instead inventing a new syntax. The reason is to keep bra and ket vectors, oscillators, and commutator brackets, etc., where they belong, namely in the implementation.

It is neither particularly difficult, nor very interesting at the present stage of investigation to write down more complicated free field theories than the one reviewed here. For our present purpose, it suffices to consider this particular free theory, which is presumable the simplest one, as an example to abstract.

A note on units: Working in mass units, i.e., with dimensionality $\mathrm{d}(p)=1$, all configuration space fields have $\mathrm{d}(\Phi(x))=(D-2)/2$ where D is the space–time dimension, while momentum space fields have $\mathrm{d}(\Phi(p))=-(D+2)/2$. All in all we get dimensionalities d according to

$$\begin{array}{ll} p,c^{+},c^{-} & 1 \\ \alpha,\alpha^{\dagger},c^{0},b^{0} & 0 \\ |+\rangle,|-\rangle & 0 \\ x,b^{+},b^{-} & -1. \end{array} \tag{25}$$

Consequently, $\mathrm{d}(|\Phi\rangle)=-(D+2)/2$ and $\mathrm{d}(Q)=2$.

III. NOTES ON SELF-INTERACTIONS

There is a large amount of work on interactions for higher spin gauge fields. We will certainly not try to review the full body of knowledge on the matter. Instead, we will outline a few salient features that we think are significant with respect to the self-interaction problem. We will do this based on a brief overview of the subject, well aware of the prejudices this might entail. (In particular, we will leave out all references to work on coupling point particles to background higher spin gauge fields, not because the topic is uninteresting, but because it lies somewhat outside the main thrust of the present paper. The same comment goes for all occurrences of massless higher spin fields in string theory and its descendants).

As far as we know, the question of introducing self-interactions (electromagnetic and gravitational interactions will be briefly discussed at the end of this section) for higher spin massless fields was first published in Ref. 1, reviewing the so named Gupta program. This program belongs to the attempts to quantize gravity in terms of an interacting spin 2 field.[35,36] It can be approached via two paths, either by linearizing Einstein gravity, or by starting with a free spin 2 field and attempting to introduce self-consistent interactions in an iterative way. This latter approach soon acquired immediacy of its own, more or less independent of the quantization problem. Indeed, the question of self-coupling a free spin 2 field into a nonlinear theory can be studied as a problem in classical field theory. Some of the often cited early works on this subject are Refs. 37–40.

That general relativity can be derived from requiring a consistent self-interacting theory of spin 2 fields, was shown by Deser in Ref. 41 (see also Ref. 42). In that paper, it is shown that the Einstein and Yang–Mills theories can both be derived from the requirement of self-interaction in just one iterative step. The resulting theories are cubic in the first order form, i.e., where pairs of independent fields $(g^{\mu\nu},\ \Gamma^{\alpha}_{\mu\nu})$ and $(A_{\mu},\ F_{\mu\nu})$ are used, respectively. In this approach, the further nonlinearities of the theories are hidden in the choice of first order field variables, since upon relating to the standard formulation, the field $\Gamma^{\alpha}_{\mu\nu}$ must be solved in terms $g^{\mu\nu}$, and $F_{\mu\nu}$ in terms of A_{μ} in the well known way. This derivation uses only the Abelian local gauge invariance of the free theory, and the full non-Abelian local gauge invariance is a result rather than an input.

But in the course of this work on Yang–Mills theory and gravity, it became apparent that gauge invariance is a crucial concept. By iteratively adding nonlinear terms to the free spin 2 action and Abelian gauge transformations, it could be proved[1] that a consistent, gauge invariant theory of self-interacting spin 2 fields can be constructed that is equivalent to Einstein gravity. This derivation relied on starting from Minkowski space–time, and a free spin 2 field $h_{\mu\nu}$ propagating in this flat background. That the condition of a Minkowski background can be lifted was shown in Ref. 43.

It was only natural then to try and extend the program to spin 3 fields and higher. The general idea behind this approach is to take a free field theory and its Abelian gauge symmetry and then *deform* it into a nonlinear theory. The problem was from the outset[1] put in a deformation theoretic context.[44] Most authors express the hope that the so constructed nonlinear theory, if it exists, will turn out to be unique. A first requirement for this method to succeed is that a general enough ansatz for the nonlinear theory can be written down. This is a nontrivial problem in general. As soon as we go beyond spin 2, the problem explodes in a potential complexity of fields, multiplets, background manifolds, dimensions, symmetry groups, etc., and any ansatz runs the risk of being to restrictive.

Returning to the historical path, at roughly the same time, another approach to gravity appeared, more closely modeled on Yang–Mills theory. The Yang–Mills interaction of spin 1 fields was introduced by gauging of a global symmetry algebra like SU (N) in the well-known way.[45] A natural question was whether gravity could likewise be obtained by gauging an appropriate global space–time symmetry. The candidate global space–time symmetries are the Lorentz or Poincaré symmetries. It turns out that gravity can indeed be obtained by gauging the Poincaré group using techniques of vierbeins and spin connections.[46–50] The gauging approach is different from the deformation approach in that the gauge algebra is fixed, but it is promoted from being global to becoming local. In deformation theory, the algebra is already local, but it is promoted from being Abelian to becoming non-Abelian. The question then is whether the two approaches yield the same result. In the case of spin 1 the answer is definitely positive.[51,52] In the case of spin 2, there are conceptual problems involved, at least if one is strongly prejudiced towards a geometrical view, but barring this, the results agree.

The subsequent work on the higher spin problem followed these two paths, either deforming the free theory Abelian gauge group, or gauging a global (but non-Abelian) symmetry algebra. The impressive work of Vasiliev falls in the second category. The far less advanced BRST program falls in the first category, as does the light-front approach and the approach of Berends, Burgers, and van Dam referred to below. Note also that these methods have been extensively used for obtaining various supergravity theories (for reviews, see Refs. 53 and 54).

As regards higher spin gauge field interactions, the first positive result was the light-front construction of cubic interaction terms for arbitrary spin.[27] When going from spin 1 and spin 2 in the light-front approach to higher spin, nothing strange happens. Quite to the contrary, the generalization seems very natural. In four dimensions, where each and every integer spin gauge field has just two physical helicity degrees of freedom, parametrized by a natural number λ, the cubic interaction term can be written

$$g\int \mathrm{d}^4x\sum_{n=0}^{\lambda}(-1)^n\binom{\lambda}{n}(\partial^+)^\lambda\phi\left[\frac{\partial}{\partial^+}\right]^{(\lambda-n)}\bar{\phi}\left[\frac{\partial}{\partial^+}\right]^n\bar{\phi}+\text{complex conjugate}, \tag{26}$$

where the two components of the complex field $(\phi,\bar{\phi})$ correspond to the two helicities λ and $-\lambda$, and where $(\partial,\bar{\partial})$ are complex transverse partial derivatives. The interaction is essentially a binominal expansion. In the case of odd λ, the fields entering the interaction term carry an index contracted into an antisymmetric symbol f_{abc} reminiscent of the situation for spin 1. How this generalizes to higher orders in the interaction is not known, since the quartic interaction term has resisted attempts at construction.

From the cubic interaction term, we can read the following information:

(i) There are λ transverse derivatives.
(ii) The coupling constant g has mass dimension $1-\lambda$.
(iii) The odd spin fields carry an antisymmetrized index.

The covariant spin 3 vertex constructed in Ref. 55 is consistent with these general properties. Furthermore, fixing the light-front gauge in the covariant cubic interaction for spin 3 yields precisely the light-front cubic interaction term for spin 3.[56]

In a way, the light-front result is a bit odd. If it turns out, as claimed by Vasiliev, that higher spin interactions require an anti-deSitter background, then why does the nonlinear Minkowski Poincaré algebra allow this term? Is it just a coincidence, and the theory breaks down at the quartic level? We do not know. Note, though, that there are other cubic interaction terms on the light-front, involving fields of different helicities.[29] Whether any of these terms describe higher spin interaction with gravity to lowest order in the spin 2 field, is at least to my knowledge, not known. The same situation occurs in covariant approach of Berends, Burgers, and van Dam.[55]

These latter authors found that upon commuting two spin 3 gauge transformations, the commutator did not close on spin 3, but produced terms that could be interpreted as gauge transformations for fields of spin >3. This is a clear hint that once one goes beyond spin 2, an infinite tower of higher spin fields will be needed (see also Refs. 57 and 58). Berends, Burgers, and van Dam[59,60] furthermore made an extensive analysis of the higher spin problem that is still highly relevant. Their analysis is within the deformation approach and is based on the original formulation of the free field theory mentioned in Sec. II.

Higher spin fields in electromagnetic and gravitational backgrounds: Self-interactions was not the first type of interaction discussed for higher spin fields. Rather, it was electromagnetic and gravitational interactions. To begin with, massive higher spin fields, i.e., matter, in particular spin $3/2$, was studied. Later the discussion included massless higher spin gauge fields. There is a huge literature on this subject, and here we will just point out a list of original references (hopefully not to incomplete) as well as some recent papers that might be helpful to the reader wishing to pursue this topic.

To make a long story short, minimally coupling higher spin gauge fields to gravity violates the higher spin gauge invariances. In the special case of supergravity, nonminimal terms can be added that saves the theory. But in general, higher spin fields coupled to gravity suffer from a consistency problem that cannot be alleviated by nonminimal couplings. Similar problems arise in attempts to couple higher spin fields to electromagnetism. There thus seems to be no consistent way of introducing higher spin fields into a pre-existing spin 1 and 2 system. The problem was first noted already by Fierz and Pauli,[16] and there exist a long series of papers discussing these problems.[61–72] A modern reference is Ref. 73.

In view of these discouraging results it is reasonable to ask if it is at all useful to pursue investigations into higher spin gauge field interactions. The authors' own point of view is based on the following three observations, being well aware of the fact that this is a weak spot; (i) negative (so-called no-go results) have been circumvented before, (ii) as soon as spin 2 is passed, all spins must be included, and presumably all be treated on a common ground, and it is not clear what happens then, (iii) all negative results derived within a space–time setting, this might be misguided if higher spins play any fundamental role at all.

The reader should note that the present paper does not purport to solve these problems, but rather proposes a way to work around them, by setting up a framework with as few as possible restrictions.

IV. ABSTRACTING DYNAMICS

Physics concerns itself with the dynamics of physical systems. A physical system is a part of the universe with a well-defined interface towards the rest of the universe which becomes the environment. One of the standard paradigms of dynamics is to describe the system in terms of an action. The action in its turn depends on a set of dynamical variables. Often the action possess symmetries, i.e., parameter dependent variations of the variables that leave the action essentially invariant. Equations of motion are obtained by varying the action with respect to the dynamical variables. The scheme is well known to every physicist, and clearly, it can be formalized. Here we will choose a moderate level of formalization, sufficient as a backdrop to the formalization we will need for higher spin gauge fields.

Thus, abstract dynamics can be described as follows.

Let the description of the system be in terms of a set of variables $\{\phi_i\}$ where the index i runs

over an index set $\mathcal{I}$. Dynamics is governed by the action A. The action is a function $A(\{\phi_i\})$ of the set of variables $\{\phi_i\}$. The equations of motion follows from varying the action with respect to the variables. Formally we have

$$\forall j \in \mathcal{I}:(\delta_{\phi_j} A(\{\phi_i\}) = 0 \rightarrow \exists\, W_j : W_j(\{\phi_i\}) = 0). \tag{27}$$

Here, W denotes the equations of motion,

$$\forall j \in \mathcal{I}: W_j(\{\phi_i\}) = 0. \tag{28}$$

Defining the variation δ_{ϕ_j} requires some care, but we will rely on the standard application of this operation.

Invariance of the action under symmetry transformations

$$\delta_\xi \phi = f(\{\phi_n\}, \xi), \tag{29}$$

is the demand that the variation of the action evaluates to zero

$$\delta_\xi A = 0. \tag{30}$$

We also demand that the transformation close and form an algebra, possibly modulo the field equations,

$$[\delta_{\xi_1}, \delta_{\xi_2}]\phi = f(\{\delta_{\xi_1}\phi_n\}, \xi_2) - f(\{\delta_{\xi_2}\phi_n\}, \xi_1) = \delta_{\xi(\{\phi_n\},\xi_1,\xi_2)}\phi (\text{mod } W). \tag{31}$$

The algebra can be field dependent, as signaled by the field dependent gauge parameter $\xi(\{\phi_n\}, \xi_1, \xi_2)$ in the commutator of two gauge transformations.

V. ABSTRACTING THE FREE FIELD THEORY

All higher spin gauge fields, as well as auxiliary fields, are packaged into one master field Φ. Let such a field be called an HS field. The explicit representation is left to the implementation. However, we need a way to extract the component fields. Let us write this formally as

$$\textbf{get}(\Phi, s) \rightarrow \phi_s, \tag{32}$$

where we can think of **get** as either an operator acting on Φ or as a function call in the case that the theory is implemented computationally. **get** applied to the field equation for Φ should yield the component field equations. In practice, in order to make contact with conventional field theory, the component fields will be ordinary symmetric tensors, so that

$$\phi_s(p) = \phi_{\mu_1\mu_2\cdots\mu_s}(p). \tag{33}$$

Here, p denotes a momentum space coordinate and the indices μ are space–time indices. It should be kept in mind, though, that there might be situations where we want to hide the space–time representation, or where we want to extract an entirely different representation. There is also the possibility that there is no space–time representation. (A deep reason for the severe problems in constructing interactions might be that space–time is not the proper arena for higher spins. Assuming that the very concept of spin can be given a reasonable definition independent of a background space–time geometry, such a representation is currently under investigation.)

Furthermore, we need a way to distinguish different fields. Here we will build in one piece of classical field theory. Fields depend on variables, in general space–time coordinates and possibly extra variables. All these will be collected into one indexed symbol σ_i, which as already noted, need not be related to space–time at all. Thus we will write HS fields as $\Phi(\sigma_i)$, sometimes abbreviated to Φ_i for convenience.

Implicit in the above discussion on the HS fields is that they belong to some set $\mathcal{H}$. Eventually $\mathcal{H}$ might be a Hilbert space, but we need not presuppose that as yet. We write $\Phi :: \mathcal{H}$. One can think of this equation as stating the *type* of Φ.

Furthermore, to the extent to which we need to be able to multiply fields by numbers and add them, we may assume that the set $\mathcal{H}$ of HS fields is a vector space. The scalars of the vector space can be complex numbers of even or odd Grassmann parity. The fields might carry a Grassmann parity $\varrho(\Phi) \in \{0,1\}$, so that

$$\Phi_1\Phi_2 = (-)^{\varrho(\Phi_1)\varrho(\Phi_2)}\Phi_2\Phi_1. \tag{34}$$

The product involved here is just a direct product $\otimes$. This equation could also be regarded as a purely textual ordering of symbols. It will be used subsequently when a proper field product is defined.

A minimum requirement in order to write down a free field theory action is that we can write a real bilinear form containing some kind of kinetic operator K. Contemplating this, it becomes clear that we need to enforce the structure of an inner product $\mathbf{in}(\cdot,\cdot)$ on the vector space,

$$\mathbf{in}(\cdot,\cdot) :: \mathcal{H}^2 \to \mathrm{C}. \tag{35}$$

Finally, we need a structure of linear operators acting on the fields. Let K be one such operator

$$K :: \mathcal{H} \to \mathcal{H}, \tag{36}$$

then the free field theory action is written

$$A(\Phi) = \mathbf{in}(\Phi, K\Phi). \tag{37}$$

It is clearly interesting to analyze what is the weakest possible structure that needs to be introduced. The above assumptions are more based on intuition than on a systematic study. As already noted in the introduction, a pure syntactic formulation should presumably be pursued, but it is not useful at the present exploratory stage of investigation.

In this context, it can be discussed how general the equation (37) for the free action is. It is clearly an abstraction of the $\langle\Phi|Q|\Phi\rangle$ action in the BRST approach. However, that the free action should be a bilinear in the abstract field Φ is hard to dispute. Furthermore, the field equations should involve some operators, differential (or momentum) in a space–time description, so it is hard to escape some linear operator K acting on Φ and in some way extracting a concrete kinetic operator acting on the component fields. But the reader must judge for herself/himself.

VI. ABSTRACTING INTERACTIONS

In any field theory, interactions between different fields enter the field equations with nonlinear terms, corresponding to nonquadratic contributions to the action. To accommodate this in our scheme, we need a way to form products between fields. It is immediately clear that ordinary naive school products are insufficient in the general case. That only works in scalar polynomial theories like the ϕ^3-model. All other field theories, electrodynamics, gravity, string field theory, etc., requires more elaborate schemes. For example, the Yang–Mills three field interaction term reads

$$g f_{abc} A^a_\mu(x) A^b(x) \cdot \partial A(x)^{c\mu}. \tag{38}$$

Superficially, the three fields seem to enter the interaction term in an unsymmetric way. But if the term is transformed to momentum space, it can be written as

$$g f_{abc} A^a(p_1) \cdot A^b(p_2)(p_1 - p_2) \cdot A^c(p_3) + \text{cyclic permutations}. \tag{39}$$

The configuration space interaction term is local in space–time, whereas in momentum space, the fields entering the interaction term carry their own momenta. This is the form of interaction that we want to abstract, since then each field carries a unique label encoded in σ_i.

A product of n HS fields is a multilinear map $\mathbf{pr} :: \mathcal{H}^{\otimes n} \to \mathrm{H}$,

$$\Phi(\sigma_{n+1}) = \mathbf{pr}(\Phi(\sigma_1), \Phi(\sigma_2), \ldots, \Phi(\sigma_n)). \tag{40}$$

A priori, this product has no symmetries, an issue to which we will return below. A shorthand notation is useful when the field arguments are not needed

$$\mathbf{pr}(\Phi^n) \equiv \mathbf{pr}(\Phi(\sigma_1),\Phi(\sigma_2),\ldots,\Phi(\sigma_n)) \equiv \mathbf{pr}(\Phi_1,\ldots,\Phi_n). \tag{41}$$

We will also need expressions like $\mathbf{pr}(\Phi^k,\Psi^l)$, which are naturally expanded as need be

$$\mathbf{pr}(\Phi^k,\Psi^l) = \mathbf{pr}(\Phi_1,\ldots,\Phi_k,\Psi_1,\ldots,\Psi_l). \tag{42}$$

Multilinearity entails

$$\begin{aligned}\mathbf{pr}(\Phi_1,\ldots,a_n\Phi_n + b_n\Psi_n,\ldots,\Phi_m) = a_n(-)^{\iota(a_n,n)}\mathbf{pr}(\Phi_1,\ldots,\Phi_n,\ldots,\Phi_m)\\ + b_n(-)^{\iota(b_n,n)}\mathbf{pr}(\Phi_1,\ldots,\Psi_n,\ldots,\Phi_m),\end{aligned} \tag{43}$$

where

$$\iota(a_n,n) = \varrho(a_n)(\varrho(\Phi_1) + \cdots + \varrho(\Phi_{n-1}) \ . \tag{44}$$

Upon reordering adjacent fields in the product, there might be a sign flip in the case where they anticommute,

$$\mathbf{pr}(\Phi_1,\ldots,\Phi_n,\Psi_{n+1},\ldots,\Phi_m) = (-)^{\varrho(\Phi_n)\varrho(\Psi_{n+1})}\mathbf{pr}(\Phi_1,\ldots,\Psi_{n+1},\Phi_n,\ldots,\Phi_m). \tag{45}$$

The HS fields themselves can be chosen as Grassmann even, as seen from the free field theory (where the odd parity derives from the vacuum). But we need this generality, taking grading into account, since the gauge parameters are odd, and there will occur odd operators like Q. This also derives from the BRST free theory. The product itself is assumed to carry no intrinsic Grassmann parity.

Now, flipping the order of adjacent fields in the product, all permutations of the fields can be reached. In the case of Grassmann even fields, the product is therefore independent of the particular order in which the fields are written, and the product is strictly commutative. This might sound confusing, since we certainly do not expect an Abelian theory. However, noncommutativity enters when one considers the nested products that appear when studying gauge invariance and commutators of gauge transformations. Furthermore, associativity is not an issue at this stage. Here we are considering primitive n-ary products, and associativity only enters upon discussing, for example, expressing a product of three factors in terms of successive products of two factors.

It should be clear that in order for this product to serve as a basis for introducing interactions, it must have further properties. This is precisely the subject of our study. The bare minimum of such properties will be derived from the requirement of gauge invariance of the action.

The low indices $n=0$ and $n=1$ merit simplified notation. Thus we define

$$\mathbf{pr}(\Phi^0) \equiv \mathbf{pr}(\ ) = 0, \tag{46}$$

where Φ^0 is defined to be a void argument, and

$$\mathbf{pr}(\Phi) = K\Phi. \tag{47}$$

Since for $n=1$, **pr** is of type $\mathcal{H}\to\mathcal{H}$, it makes sense to define it as linear transformation. If any of the fields is identically zero for all values of the labels σ_i, then the product is zero.

We now have the abstract tools for writing interactions. By taking the product between $n-1$ HS fields and then the inner product with an nth field, a candidate for an n-field interaction term can be written

$$\mathbf{in}(\Phi_n,\mathbf{pr}(\Phi_1,\Phi_2,\ldots,\Phi_{n-1})). \tag{48}$$

It makes sense to introduce a special notation for this expression

$$\mathbf{vx}(\Phi_1,\Phi_2,\ldots,\Phi_n) = \mathbf{in}(\Phi_n,\mathbf{pr}(\Phi_1,\Phi_2,\ldots,\Phi_{n-1})) \tag{49}$$

so that **vx** is a multilinear map $\mathbf{vx} :: \mathcal{H}^{\otimes n} \to C$.

Just as the product (40), **vx** has no *a priori* symmetries. However, if this is to be useful in an interaction term, it must at least be cyclic symmetric in the field [compare to the Yang–Mills three field interaction term above (39)]. This can be fixed by explicitly summing over all permutations of the fields. Alternatively, one could just sum over all cyclic permutations. It turns out, though, that summing over all permutations leads to simpler formulas. Computationally, it is inefficient to sum over all permutations. However, in actual implementations, the permutation symmetries will be explicit, and the combinatorial sums collapse into at most $\mathcal{O}(n^2)$ terms.

To that end, let $\pi[0..n]$ denote the set of all permutations of the list $[0..n]$ of natural numbers between 0 and n. Then $\Sigma_{\pi[n]}$ will denote a sum over permutations.

This finishes setting up of the basic syntax of the theory. In the following sections, we will perform calculations within this syntax. That might seem a bit strange, since we have not defined any rules of calculation or rewrite rules. However, close scrutiny of the manipulations that follow shows that we only need to do substitutions and rearrangements of sums. This is a weak form of equational reasoning that we certainly want to do in any formalism, but strictly speaking, rewrite rules, belong to semantics.

VII. THE ACTION AND GAUGE INVARIANCE

Since we are working within the deformation tradition it makes sense to write an ansatz for the action as a formal power series in the polymorphic map **vx**. The action then reads

$$A(\Phi) = \sum_{i=2}^{\infty} \frac{g^{i-2}}{i!} \sum_{\pi[i]} \mathbf{vx}(\Phi_1, \Phi_2, \ldots, \Phi_i). \tag{50}$$

To clean up notation, introduce a new summation symbol $\Sigma^{\infty}_{\pi(i=m)} \equiv \Sigma^{\infty}_{i=m} \Sigma_{\pi[i]}$.

The action can written, highlighting the kinetic term explicitly and expanding **vx**, in the form

$$\begin{aligned} A(\Phi) &= \mathbf{in}(\Phi, K\Phi) + \sum_{\pi(i=3)}^{\infty} \frac{g^{i-2}}{i!} \mathbf{in}(\Phi_i, \mathbf{pr}(\Phi_1, \Phi_2, \ldots, \Phi_{i-1}) \\ &= \mathbf{in}(\Phi, K\Phi) + \sum_{\pi(i=3)}^{\infty} \frac{g^{i-2}}{i!} \mathbf{in}(\Phi, \mathbf{pr}(\Phi^{i-1})), \end{aligned} \tag{51}$$

where

$$\mathbf{in}(\Phi, K\Phi) = \tfrac{1}{2}(\mathbf{in}(\Phi_1, K_2\Phi_2) + \mathbf{in}(\Phi_2, K_1\Phi_1)). \tag{52}$$

The gauge transformation will also be written as a formal power series. At this stage we have a choice either to introduce a new abstract product $\mathbf{pr}_\mathbf{g}$ (renaming the previously introduced product $\mathbf{pr}_\mathbf{a}$), or use the same product as the one used for the action. This is one of the points where one is confronted with a dilemma as to the generality of the ansatz. We will be conservative here and use the same product. The gauge transformation then reads

$$\delta_\Xi \Phi = \sum_{\pi(i=0)}^{\infty} \frac{g^i}{i!} \mathbf{pr}(\Phi^i, \Xi) = K\Xi + \sum_{\pi(i=1)}^{\infty} \frac{g^i}{i!} \mathbf{pr}(\Phi^i, \Xi). \tag{53}$$

Gauge invariance of the action to all orders of interaction amounts to

$$\delta_\Xi A(\Phi) = 0. \tag{54}$$

By demanding this to be true, we can derive the requisite demands on the maps **in**, **pr**, and **vx**. We must go through this calculation meticulously as we must note all steps where required properties of the maps must be recorded. To that aim, apply δ_Ξ to the action (50),

$$\delta_\Xi A(\Phi) = \sum_{i=2}^{\infty} \frac{g^{i-2}}{i!} \delta_\Xi \sum_{\pi[i]} \mathbf{vx}(\Phi^i). \tag{55}$$

We immediately run into the problem of how to perform this operation. However, by analyzing how the operation of varying the action is normally done in standard field theories, we see that this can be done by just textually substituting $\delta_\Xi\Phi$ for all the occurences of Φ one at a turn so to speak. Indeed

$$\begin{aligned}\delta_\Xi \mathbf{vx}(\Phi_1, \Phi_2, \ldots, \Phi_i) = \mathbf{vx}(\delta_\Xi\Phi_1, \Phi_2, \ldots, \Phi_i) + \mathbf{vx}(\Phi_1, \delta_\Xi\Phi_2, \ldots, \Phi_i) \\ + \cdots + \mathbf{vx}(\Phi_1, \Phi_2, \ldots, \delta_\Xi\Phi_i),\end{aligned} \tag{56}$$

so that we get

$$\delta_\Xi \sum_{\pi[n]} \mathbf{vx}(\Phi^n) = n \sum_{\pi[n]} \mathbf{vx}(\delta_\Xi\Phi, \Phi^{n-1}). \tag{57}$$

Thus continuing the calculation (55), we get

$$\delta_\Xi A(\Phi) = \sum_{\pi(i=2)}^{\infty} \frac{g^{i-2}}{(i-1)!} \mathbf{vx}(\delta_\Xi\Phi, \Phi^{i-1}). \tag{58}$$

Then, upon substituting (53) for $\delta_\Xi\Phi$ and shifting the i-sum, $i \to i-1$,

$$\sum_{\pi(i=1)}^{\infty} \frac{g^{i-1}}{i!} \sum_{\pi(j=0)}^{\infty} \frac{g^j}{j!} \mathbf{vx}(\mathbf{pr}(\Phi^j, \Xi), \Phi^i). \tag{59}$$

Here, we can use the definition (49) of **vx**,

$$\sum_{\pi(i=1)}^{\infty} \sum_{\pi(j=0)}^{\infty} \frac{g^{i+j-1}}{i!j!} \mathbf{in}(\mathbf{pr}(\Phi^j, \Xi), \mathbf{pr}(\Phi^i)). \tag{60}$$

No harm is done by extending the i-sum to start at $i=0$. Assuming that it is allowed to rearrange the double sum, it can be written as

$$\sum_{i=0}^{\infty} \sum_{\substack{\pi(k=0) \\ \pi(l=0)}}^{k+l=i} \frac{g^{i-1}}{k!l!} \mathbf{in}(\mathbf{pr}(\Phi^k, \Xi), \mathbf{pr}(\Phi^l)), \tag{61}$$

i.e., we are summing order by order in the total power of the field, corresponding to how an order by order checking of invariance would be performed. Thus, for any fixed $i=n$, study

$$\sum_{\substack{\pi(k=0) \\ \pi(l=0)}}^{k+l=n} \frac{g^{n-1}}{k!l!} \mathbf{in}(\mathbf{pr}(\Phi^k, \Xi), \mathbf{pr}(\Phi^l)) = \sum_{\substack{\pi(k=0) \\ \pi(l=0)}}^{k+l=n} \frac{g^{n-1}}{k!l!} \mathbf{in}(\mathbf{pr}(\Phi^l), \mathbf{pr}(\Phi^k, \Xi)). \tag{62}$$

Again using the definition (49) of **vx**,

$$\sum_{\substack{\pi(k=0) \\ \pi(l=0)}}^{k+l=n} \frac{g^{n-1}}{k!l!} \mathbf{vx}(\mathbf{pr}(\Phi^l), \Phi^k, \Xi) = \sum_{\substack{\pi(k=0) \\ \pi(l=0)}}^{k+l=n} \frac{g^{n-1}}{k!l!} \mathbf{vx}(\Xi, \Phi^k, \mathbf{pr}(\Phi^l)) = \sum_{\substack{\pi(k=0) \\ \pi(l=0)}}^{k+l=n} \frac{g^{n-1}}{k!l!} \mathbf{in}(\Xi, \mathbf{pr}(\Phi^k, \mathbf{pr}(\Phi^l))). \tag{63}$$

Normally, invariance should not depend on the gauge parameter Ξ, so in order for this sum to vanish, we must require for all $n \in N$,

$$\sum_{\substack{\pi(k=0)\\ \pi(l=0)}}^{k+l=n} \frac{1}{k!l!}\mathbf{pr}(\Phi^k,\mathbf{pr}(\Phi^l)) = 0. \tag{64}$$

This is a nontrivial demand on the map **pr**. The other demands can be considered as part of the syntax, but this one involves the semantics of the theory. We will refer to this requirement as the *product identity*.

Low level special cases of the product identity: The first four levels, i.e., values of n, are of immediate importance.

When $n=0$ the identity trivializes to

$$\mathbf{pr}(\mathbf{pr}(\,)) = \mathbf{pr}(0) = 0. \tag{65}$$

The case $n=1$ becomes

$$\mathbf{pr}(\Phi,\mathbf{pr}(\,)) + \mathbf{pr}(\mathbf{pr}(\Phi)) = KK\Phi = 0. \tag{66}$$

This equation expresses gauge invariance for the free theory.

When $n=2$, taking permutations into account and noting that $\mathbf{pr}(\Phi_1,\Phi_2)$ is actually symmetric, we get

$$\mathbf{pr}(\mathbf{pr}(\Phi_1,\Phi_2)) + \mathbf{pr}(\Phi_1,\mathbf{pr}(\Phi_2)) + \mathbf{pr}(\Phi_2,\mathbf{pr}(\Phi_1)) = 0, \tag{67}$$

or

$$K\mathbf{pr}(\Phi_1,\Phi_2) + \mathbf{pr}(\Phi_1,K\Phi_2) + \mathbf{pr}(K\Phi_1,\Phi_2) = 0. \tag{68}$$

This equation expresses gauge invariance of the cubic interaction term. Granting that we already know how to implement the $n=1$ equation in terms of an appropriate field and a kinetic operator, the $n=2$ equation is the first nontrivial equation to implement. It involves the two-product $\mathbf{pr}(\cdot,\cdot)$ which so far is undefined. This is the product that was partially studied in Ref. 33.

The next level, $n=3$ involves the quartic interaction term

$$\begin{aligned} &K\mathbf{pr}(\Phi_1,\Phi_2,\Phi_3) + \mathbf{pr}(K\Phi_1,\Phi_2,\Phi_3) + \mathbf{pr}(\Phi_1,K\Phi_2,\Phi_3) + \mathbf{pr}(\Phi_1,\Phi_2,K\Phi_3) + \mathbf{pr}(\Phi_1,\mathbf{pr}(\Phi_2,\Phi_3))\\ &\quad + \mathbf{pr}(\Phi_2,\mathbf{pr}(\Phi_3,\Phi_1)) + \mathbf{pr}(\Phi_3,\mathbf{pr}(\Phi_1,\Phi_2)) = 0. \end{aligned} \tag{69}$$

This equation expresses gauge invariance up to the quartic level. In order to solve it, the full two-product $\mathbf{pr}(\cdot,\cdot)$ must have been obtained first. Clearly, it can then be seen as a differential equation for the three-product $\mathbf{pr}(\cdot,\cdot,\cdot)$ with K acting as differential operator.

It follows that a necessary condition for the interaction to be cubic is that the two-product satisfies a Jacobi identity. In the cubic case, the three-product $\mathbf{pr}(\cdot,\cdot,\cdot)$ is zero, and the first four terms in (69) vanishes.

The field equations: Varying the action (50) with respect to the field Φ yields the field equation

$$\delta_\Phi A(\Phi) = \sum_{\pi(i=2)}^{\infty} \frac{g^{i-2}}{(i-1)!}\mathbf{vx}(\delta_\Phi,\Phi^{i-1}) = \mathbf{in}\left(\delta_\Phi, \sum_{\pi(i=1)}^{\infty} \frac{g^{i-1}}{i!}\mathbf{pr}(\Phi^i)\right). \tag{70}$$

According to the abstract dynamics, we get the field equation

$$W(\Phi) = \sum_{\pi(i=1)}^{\infty} \frac{g^{i-1}}{i!}\mathbf{pr}(\Phi^i) = 0, \tag{71}$$

thus expressing the basic intuition that the product captures the interactions.

VIII. THE GAUGE ALGEBRA

In order to examine the gauge algebra, we do the standard calculation,

$$\begin{aligned}
[\delta_{\Xi_1},\delta_{\Xi_2}]\Phi &= \delta_{\Xi_1}\delta_{\Xi_2}\Phi - (1\leftrightarrow 2)\\
&= \delta_{\Xi_1}\left(\sum_{\pi(i=0)}^{\infty}\frac{g^i}{i!}\mathbf{pr}(\Phi^i,\Xi_2)\right) - (1\leftrightarrow 2)\\
&= \sum_{\pi(i=1)}^{\infty}\frac{g^i}{(i-1)!}\mathbf{pr}(\delta_{\Xi_1}\Phi,\Phi^{i-1},\Xi_2) - (1\leftrightarrow 2)\\
&= \sum_{\pi(i=0)}^{\infty}\sum_{\pi(j=0)}^{\infty}\frac{g^{i+j+1}}{i!j!}\mathbf{pr}(\mathbf{pr}(\Phi^j,\Xi_1),\ \Phi^i,\Xi_2)) - (1\leftrightarrow 2)\\
&= \sum_{i=0}^{\infty}\sum_{\substack{\pi(k=0)\\ \pi(l=0)}}^{k+l=i}\frac{g^{k+l+1}}{k!l!}\mathbf{pr}(\Phi^k,\Xi_1,\mathbf{pr}(\Phi^l,\Xi_2)) - (1\leftrightarrow 2).
\end{aligned} \tag{72}$$

This is as far as we can get without invoking semantics for the product. Experience with field theory, shows that the commutator of two gauge transformations should close on a new, possibly field dependent gauge transformation, possibly modulo the field equations.

The form of Eq. (72) suggests considering

$$\mathbf{pr}(\Phi^k,\mathbf{pr}(\Xi_1,\Xi_2,\Phi^l)). \tag{73}$$

If we could establish the following identity,

$$\begin{aligned}
&\sum_{\substack{\pi(k=0)\\ \pi(l=0)}}^{k+l=i}\frac{g^{k+l+1}}{k!l!}\{\mathbf{pr}(\Phi^k,\mathbf{pr}(\Xi_1,\Xi_2,\Phi^l)) + \mathbf{pr}(\Phi^k,\Xi_1,\Xi_2,\mathbf{pr}(\Phi^l)) + \mathbf{pr}(\Phi^k,\Xi_1,\mathbf{pr}(\Xi_2,\Phi^l))\\
&\quad - \mathbf{pr}(\Phi^k,\Xi_2,\mathbf{pr}(\Xi_1,\Phi^l))\} = 0,
\end{aligned} \tag{74}$$

then the calculation (72) could be continued with

$$\begin{aligned}
&-\sum_{n=0}^{\infty}\sum_{\substack{\pi(k=0)\\ \pi(l=0)}}^{k+l=n}\frac{g^{k+l+1}}{k!l!}(\mathbf{pr}(\Phi^k,\mathbf{pr}(\Xi_1,\Xi_2,\Phi^l)) + \mathbf{pr}(\Phi^k,\Xi_1,\Xi_2,\mathbf{pr}(\Phi^l)\ )\\
&= -\sum_{\pi(k=0)}^{\infty}\frac{g^k}{k!}\mathbf{pr}\left(\Phi^k,\sum_{\pi(l=0)}^{\infty}\frac{g^{l+1}}{l!}\mathbf{pr}(\Xi_1,\Xi_2,\Phi^l)\right) - \sum_{\pi(k=0)}^{\infty}\frac{g^k}{k!}\mathbf{pr}\left(\Phi^k,\Xi_1,\Xi_2,\sum_{\pi(l=0)}^{\infty}\frac{g^{l+1}}{l!}\mathbf{pr}(\Phi^l)\right).
\end{aligned} \tag{75}$$

The first term can be recognized as a field dependent gauge transformation and the second as being proportional to the field equations, thus

$$[\delta_{\Xi_1},\delta_{\Xi_2}]\Phi = \delta_{\Xi(\Phi,\Xi_1,\Xi_2)}\Phi - g^2\sum_{\pi(k=0)}^{\infty}\frac{g^k}{k!}\mathbf{pr}(\Phi^k,\Xi_1,\Xi_2,W(\Phi)), \tag{76}$$

where the new gauge parameter is

$$\Xi(\Phi,\Xi_1,\Xi_2) = -\sum_{\pi(l=0)}^{\infty}\frac{g^{l+1}}{l!}\mathbf{pr}(\Xi_1,\Xi_2,\Phi^l). \tag{77}$$

We can now record the required properties of the product. Apart from being able to make substitutions, add and compare equal terms, i.e., use standard equational reasoning, the product identity (64) is the only nontrivial demand on **pr**. The equation (74) that is needed in the gauge algebra calculation, can be subsumed in a generalization of the product identity (64). Let us see how this can be done.

The product identity was derived under the assumption that all the fields were Grassmann even, and that the only odd object was the gauge parameter. Therefore, the Grassmann properties could be ignored. We must generalize (64) to include the case of fields with even and odd parities. To that end, let $\{\Gamma_i\}$ denote a set of n fields with $\varrho(\Gamma_i) \in \{0,1\}$.

The sum in the product identity runs over all permutations just for convenience. The different terms are cyclic permutations of the split of the string of fields $\Phi_1 \cdots \Phi_n$ into two strings with k and l fields, respectively, and the factor $1/k!l!$ is cancelled against the number of equal permutations in each split. Therefore (64) can be written as

$$\sum_{\substack{k=0,l=0 \\ \text{cycl.perm.}}}^{k+l=n} \mathbf{pr}(\Phi^k, \mathbf{pr}(\Phi^l)) = 0. \tag{78}$$

Another way to express this is to consider the index set $\{1,\ldots,n\}$ as split into the two sets $\{i_1,\ldots,i_k\}$ and $\{j_1,\ldots,j_l\}$.

Denote the split $\{\{i_1,\ldots,i_k\},\{j_1,\ldots,j_l\}\}$ by $\chi(k,l)$. The sum then runs over all different such splits

$$\sum_{\substack{k=0,l=0 \\ \chi(k,l)}}^{k+l=n} \mathbf{pr}(\Phi_{i_1} \cdots \Phi_{i_k}, \mathbf{pr}(\Phi_{j_1} \cdots \Phi_{j_l})) = 0. \tag{79}$$

The order of the indices does not matter when all the fields are Grassmann even. When arbitrary parities are involved, we need a convention as to the order. Instead of sets $\{i_1,\ldots,i_k\}$ and $\{j_1,\ldots,j_l\}$ we use ordered lists $[i_1..i_k]$ and $[j_1..j_l]$. This pair of ordered lists is denoted by $\pi(k,l)$. It is a particular permutation of the index set into two lists with $i_1 < \cdots < i_k$ and $j_1 < \cdots < j_l$.

If the fields carry arbitrary Grassmann parity, the weakest generalization is to record a sign picked up when the order of the fields $\Gamma_{i_1} \cdots \Gamma_{i_k} \cdots \Gamma_{j_1} \cdots \Gamma_{j_l}$ are reordered lexicographically into $\Gamma_1 \Gamma_2 \cdots \Gamma_n$. Denote this sign by $\epsilon(\pi(k,l))$.

We must sum over all such splittings, keeping track of the signs

$$\sum_{\substack{k=0,l=0 \\ \pi(k,l)}}^{k+l=n} \epsilon(\pi(k,l)) \mathbf{pr}(\Gamma_{i_1} \cdots \Gamma_{i_k}, \mathbf{pr}(\Gamma_{j_1} \cdots \Gamma_{j_l})) = 0. \tag{80}$$

We can then return to the equation (74) that governs the closure of the gauge algebra. Consider first the last expression of the commutator calculation (72). Expanding the permutations we have

$$\sum_{\substack{k=0,l=0 \\ \text{cycl.perm.}}}^{k+l=n} \mathbf{pr}(\Phi^k, \Xi_1, \mathbf{pr}(\Phi^l, \Xi_2)) - (1 \leftrightarrow 2). \tag{81}$$

Consider applying the identity (80) to the string of fields $\Gamma^n = \Phi^{k'} \Xi_1 \Xi_2 \Phi^{l'}$. Of the terms in the sum, there are terms where both Ξ_1 and Ξ_2 are in the first list, both Ξ_1 and Ξ_2 in the second list, and terms where $\Xi_1(\Xi_2)$ is in the first and $\Xi_2(\Xi_1)$ in the second. Writing this out explicitly yields

$$\sum_{\substack{k=0,l=0\\ \chi(k,l)}}^{k+l=n} \{\mathbf{pr}(\Phi^k,\mathbf{pr}(\Xi_1,\Xi_2,\Phi^l)) + \mathbf{pr}(\Phi^k,\Xi_1,\Xi_2,\mathbf{pr}(\Phi^l)) + \mathbf{pr}(\Phi^k,\Xi_1,\mathbf{pr}(\Xi_2,\Phi^l)) - \mathbf{pr}(\Phi^k,\Xi_2,\mathbf{pr}(\Xi_1,\Phi^l))\} = 0. \tag{82}$$

Thus, the identity (74) we used in the gauge algebra calculation follows from the generalized product identity (80) taking Grassmann parities into account.

Therefore, given a particular type of free gauge fields Φ, gauge parameter Ξ, a kinetic operator K and the inner product **in**, construction of the map **pr** satisfying (80) is the only nontrivial task.

In this way, the vaguely defined problem of introducing interactions for higher spin gauge fields, has been focused on implementing the product map **pr** satisfying the product identity (80). Since very little has been assumed as to the particulars of such an implementation, we are quite free to explore various implementational schemes. These vary from finding pre-existing mathematical domains to setting up concrete data structures within which computerized explorations can be performed. In the last two paragraphs, we will outline examples of these two extreme approaches.

IX. STRONGLY HOMOTOPY LIE ALGEBRAS

The product identities we have found are similar to the defining identities for strongly homotopy Lie algebras (sh-Lie algebras or L_∞ algebras).[74,75] This opens the possibility to map the syntax set up here onto such an algebra. Furthermore, in a recent paper[76] it is shown that if the gauge algebra of the Lagrangian higher spin field theory of Berends, Burgers, and van Dam[59] actually exists, then it has the structure of an sh-Lie algebra. The approach of the present paper is more direct in that the gauge algebra falls into an sh-Lie algebra pattern without further analysis. In both these approaches, the problem is that we do not know which particular algebra to choose. Or phrased differently, we do not know if the deformed gauge algebra of the interacting fields exist, starting from the gauge field theory of the free fields.

There are a few variants of the basic definitions of strongly homotopy Lie algebras in the literature, but the following, mildly technical, is sufficient for our purpose to bring out the similarity to the product identity.

Definition: Consider a $\mathbf{Z_2}$ graded vector space $V=V_0\oplus V_1$ over some number field, and denote the elements by x. The grading is given by ϱ with $\varrho(x)=0$ if $x\in V_0$ and $\varrho(x)=1$ if $x\in V_1$. V is supposed to carry a sequence of n-linear products denoted by brackets. The graded n-linearity is expressed by

$$[x_1,\ldots,x_n,x_{n+1},\ldots,x_m] = (-)^{\varrho(x_n)\varrho(x_{n+1})}[x_1,\ldots,x_{n+1},x_n,\ldots,x_m], \tag{83}$$

$$[x_1,\ldots,a_nx_n+b_nx_n'\ldots,x_m] = a_n(-)^{\iota(a_n,n)}[x_1,\ldots,x_n,\ldots,x_m] + b_n(-)^{\iota(b_n,n)}[x_1,\ldots,x_n',\ldots,x_m], \tag{84}$$

where $\iota(a_n,n)=\varrho(a_n)(\varrho(x_1)+\cdots+\varrho(x_{n-1})$.

The defining identities for the algebra are, for all $n\in N$,

$$\sum_{\substack{k=0\\ l=0}}^{k+l=n} \sum_{\pi(k,l)} \epsilon(\pi(k,l))[[x_{\pi(1)},\ldots,x_{\pi(k)}],x_{\pi(k+1)},\ldots,x_{\pi(k+l)}] = 0, \tag{85}$$

where $\pi(k,l)$ stands for (k,l)-unshuffles. A (k,l)-unshuffle is a permutation π of the indices $1,2,\ldots,k+l$ such that $\pi(1)<\cdots<\pi(k)$ and $\pi(k+1)<\cdots<\pi(k+l)$. $\epsilon(\pi(k,l))$ is the sign picked up during the unshuffle as the points x_i with indices $0\leqslant i\leqslant k$ are taken through the points x_j with indices $k+1\leqslant j\leqslant l$. This is just the normal procedure in superalgebras.

The low index, $n=0$ and $n=1$ brackets are treated separately, thus

$$[\cdot] = 0, \tag{86}$$

$$[x] = \partial x, \tag{87}$$

with ∂ a derivation.

This is a definition. Given that such algebras do exist, it is clear that they provide a possible semantic target for abstract higher spin gauge field theory. It is obvious that the image of a field Φ_n is a point x_n, and that the products $\mathbf{pr}(\cdot)$ map into the brackets $[\cdot]$. A technical detail is that in order for the mapping to be complete, the sh-Lie algebra must be supplied with an inner product.

The details of setting up this mapping would require some care, but it should be essentially straightforward. The problem lies elsewhere, we still do not know which particular algebra to map to. Had we known the correct concrete algebra, then we would have had a solution to the higher spin problem.

A way out of this dilemma is to, as a first step, map the corresponding categories instead. By formalizing the syntax given here, a category of interacting fields, say **IField** is set up. The same is done for strongly homotopy Lie algebras, denoted by **shLie**. The interpretation map $[|\cdot|]$ is then a functor from the interacting fields to the sh-Lie algebras.

$$[|\cdot|] :: \mathbf{IField} \to \mathbf{shLie}.$$

Clearly, there is much work to done here and many technical details to work out. It should be noted that category theory can in fact be used in denotational semantics for programming languages.[77] Given that a programming language is just an example of a formal language, and that abstract field theory also can be formulated as a formal language, it should be clear that this point of view is feasible. Whether it helps in the quest to obtain a concrete physicslike implementation remains to be seen. At least, we are able to put interacting higher spin gauge fields in a context where models can be systematically searched for.

From a physics point of view it is clear that the abstract view given here must be supplemented by physical insight into the problem. That is, what are higher spin gauge fields? What kind of physics do they describe? What is the proper context to set them in? Lacking that understanding, we will in the next section set up a framework for a concrete implementation within which the problem can at least be pursued by brute force computerized calculation.

X. VERTEX IMPLEMENTATION

With the free field theory implemented using the BRST technique briefly reviewed in Sec. II, it is natural to try to implement the interacting field products in terms of vertex operators. This is how string field theory is done. Taking the open string as an example, the three string vertex is a product of a bosonic vertex and a ghost vertex. The bosonic vertex is

$$|V_3\rangle = \exp\left(\frac{1}{2}\sum_{r,s=1}^{3}\sum_{n,m=0}^{\infty}\alpha_{-n}^{\mu,r}N_{nm}^{rs}\alpha_{-m}^{\mu,s}\right)|-\rangle_3,$$

in terms of bosonic string oscillators $\alpha_{-n}^{\mu,r}$ and the Neumann function matrices N_{nm}^{rs}. There has been attempts to use this form of three vertex for higher spin gauge fields, but that fails since such a vertex do not reproduce the spin 1 Yang–Mills cubic interaction term.[78]. It is known from the light-front form of the cubic interaction term[29] that the vertex must at least contain terms of the generic form $\alpha^\dagger\alpha^\dagger\alpha^\dagger p$ (indices suppressed), i.e., with three oscillators and one momentum label. Such a covariant vertex was partially determined in Ref. 33 and it correctly reproduces the Yang–Mills cubic interaction term. Further progress was halted by a lack of an effective way of calculating higher order terms in the three vertex. In this section, higher spin vertices will be discussed from the point of view of the abstract approach presented here.

The intention is to define the field products in terms of vertex operators. An n-vertex operator is an object that takes $n-1$ fields, labeled by $\{\sigma_i\}_1^{n-1}$ and outputs a new field, labeled by σ_n. Each field $\Phi(\sigma_i)$ is represented as a ket vector $|\Phi(\sigma_i)\rangle$ in the oscillator and ghost Fock space corresponding to the label σ_i as in Eqs. (12)–(15). The product is defined in terms of the n-vertex $|V(\sigma_1,\ldots,\sigma_{n-1},\sigma_n)\rangle$ by

$$\mathbf{pr}(\Phi(\sigma_1),\ldots,\Phi(\sigma_{n-1})) \equiv \langle\Phi(\sigma_1)|\cdots\langle\Phi(\sigma_{n-1})||V(\sigma_1,\ldots,\sigma_{n-1},\sigma_n)\rangle. \tag{88}$$

The notation makes it explicit that the product evaluates to a ket field $|\Phi(\sigma_n)\rangle$, or

$$\langle\Phi(\sigma_1)|\cdots\langle\Phi(\sigma_{n-1})||V(\sigma_1,\ldots,\sigma_{n-1},\sigma_n)\rangle \to |\Phi(\sigma_n)\rangle. \tag{89}$$

Note that the fields $|\Phi\rangle$ are now Grassmann odd due to the vacuum $|+\rangle$, whereas the gauge parameters are Grassmann even. As will be seen below, the vertex can be built from Grassmann even objects, so that it has full permutational symmetry in all the n field labels.

Likewise the map **vx** is represented by

$$\mathbf{vx}(\Phi(\sigma_1),\ldots,\Phi(\sigma_n)) \equiv \langle\Phi(\sigma_1)|\cdots\langle\Phi(\sigma_n)||V(\sigma_1,\ldots,\sigma_n)\rangle, \tag{90}$$

which evaluates to a combination of component fields and momentum labels. In the abstract action, **vx** is summed over all permutations of the fields. If we allow ourselves the trick of moving all the $\langle+|_n$ vacua to the left, we get

$$\begin{aligned}\frac{1}{n!}\sum_{\pi[1..n]}\mathbf{vx}(\Phi(\sigma_1),\ldots,\Phi(\sigma_n)) &= \frac{1}{n!}(\otimes_{i=1}^n\langle+|_i)\Big(\sum_{\pi[1..n]}\Phi(\sigma_1)\cdots\Phi(\sigma_n)\Big)|V(\sigma_1,\ldots,\sigma_n)\rangle \\ &= \langle\Phi(\sigma_1)|\cdots\langle\Phi(\sigma_n)||V(\sigma_1,\ldots,\sigma_n)\rangle,\end{aligned} \tag{91}$$

i.e., one term, in that particular order. With ${}_{1\cdots n}\langle+|$ as a shorthand for $\otimes_{i=1}^n\langle+|_i$, this can also be written keeping all the vacua to the left,

$${}_{1\cdots n}\langle+|\Phi(\sigma_1)\cdots\Phi(\sigma_n)|V(\sigma_1,\ldots,\sigma_n)\rangle, \tag{92}$$

a form that is convenient for explicit calculations.

When implementing the abstract gauge transformation, some care is needed considering the permutations. The vertex implementation of the gauge transformation becomes

$$\delta_\Xi|\Phi(\sigma_n)\rangle = Q(n)|\Phi(\sigma_n)\rangle + \frac{n}{2}\sum_{\substack{\text{cycl.perm}\\ [\sigma_1..\sigma_{n-1}]}}{}_{1\cdots n}\langle+|\Phi(\sigma_1)\cdots\Phi(\sigma_{n-2})\Xi(\sigma_{n-1})|V(\sigma_1,\ldots,\sigma_{n-1},\sigma_n)\rangle, \tag{93}$$

where the coefficient $n/2$ is an artefact of the permutations.

When evaluating expressions such as (88), (90), and (93), the explicit oscillator and ghost representations of Sec. II is used.

In order for the vertex to encode nontrivial interaction information, we introduce an n-ary function $\mathcal{F}$ of the labels $\{\sigma_i\}_1^n$. Then we write the vertex as

$$|V(\sigma_1,\ldots,\sigma_n)\rangle = \mathcal{F}(\sigma_1,\ldots,\sigma_n)\int \mathrm{d}^Dp_1|-\rangle_1\cdots\int \mathrm{d}^Dp_n|-\rangle_n\delta^D(\Sigma_{i=1}^n p_i), \tag{94}$$

where $\delta^D(\Sigma_{i=1}^n p_i)$ enforces momentum conservation.

For notational convenience, write

$$|-\rangle_{1\cdots n} = \int \mathrm{d}^Dp_1|-\rangle_1\cdots\int \mathrm{d}^Dp_n|-\rangle_n\delta^D(\Sigma_{i=1}^n p_i). \tag{95}$$

The n-order interaction term can now be written

$$g^{n-2}\langle\Phi|^{\otimes n}\mathcal{F}_n|-\rangle_{1\cdots n}. \tag{96}$$

With this form for the vertex, mass dimensions and ghost number counting should work out correctly. It is natural to demand $\mathrm{gh}(\mathcal{F})=0$, i.e., the ghost number is zero, but it must carry mass dimension, as will be calculated shortly.

The ghost number count works out

$$\mathrm{gh}(\langle\Phi|^{\otimes n}) + \mathrm{gh}(|-\rangle_{1\cdots n}) = n\left(-\frac{1}{2}\right) + \frac{n}{2} = 0.$$

The mass dimension count yields

$$(n-2)\mathrm{d}(g) + \mathrm{d}(\mathcal{F}_n) + n\left(-\frac{D+2}{2}\right) + nD - D = 0. \tag{97}$$

There is no compelling reason to let g carry nonzero dimensionality, thus we set $\mathrm{d}(g)=0$, so that

$$\mathrm{d}(\mathcal{F}_n) = D + n - \frac{nD}{2} \tag{98}$$

in four dimensions, the dimension is simply $4-n$.

Ansatz for the vertex function: The ansatz for the vertex function $\mathcal{F}_n$ is based on the following clauses:

(i) $\mathrm{gh}(\mathcal{F}_n)=0$,
(ii) $\mathcal{F}_n$ does not contain annihilators c^0, c^-, b_+ or α_μ,
(iii) $\mathcal{F}_n$ is a space–time scalar,
(iv) $\mathrm{d}(\mathcal{F}_n)=\frac{1}{2}(2D+2n-nD)$.

The first three clauses imply that $\mathcal{F}_n$ can be built from the following bilinears:

$$\alpha_r^\dagger\cdot\alpha_s^\dagger, \quad \alpha_r^\dagger\cdot p_s, \quad c_r^+ b_{s-}, \quad c_r^+ b_{s0},$$

where the indices r,s label HS fields. The fourth clause requires that we introduce at least one-dimensional constant κ to balance the dimensions for the second and last bilinear. Choose $\mathrm{d}(\kappa)=-1$. Introduce a symbol η_{rs}^a to denote the dimensionless bilinears according to

$$\eta_{rs}^1 = \alpha_r^\dagger\cdot\alpha_s^\dagger, \quad \eta_{rs}^2 = \kappa\alpha_r^\dagger\cdot p_s, \quad \eta_{rs}^3 = c_r^+ b_{s-}, \quad \eta_{rs}^4 = \kappa c_r^+ b_{s0}. \tag{99}$$

As already noted, the higher spin vertices cannot be built out of these bilinears alone, rather, powers of the bilinears must be considered. To that end, introduce a symbol Δ_{2m}^n where n denotes the order of the vertex and m denotes the homogenous power of bilinears,

$$\Delta_{2m}^n = {}^nY_{a_1\cdots a_m}^{r_1 s_1\cdots r_m s_m}\eta_{r_1 s_1}^{a_1}\cdots\eta_{r_m s_m}^{a_m}, \tag{100}$$

where there are implicit summations according to

(i) all r_i and s_i, $i\in[1..m]$ are summed over the list $[1..n]$,
(ii) all a_i, $i\in[1..m]$ are summed over the list $[1..4]$,

and where the coefficients ${}^nY_{a_1\cdots a_m}^{r_1 s_1\cdots r_m s_m}$ are algebraic numbers to be determined.

Finally, $\mathcal{F}_n$ can be synthesized as

$$\mathcal{F}_n = \sum_m^\infty \kappa^{[(nD/2)-D-n]}\Delta_{2m}^n. \tag{101}$$

In this framework, the countable set of functions $\{\mathcal{F}_n\}_{n=3}^{\infty}$, if they exist, encode the full interacting theory of higher spin gauge fields. The same information can therefore also be considered as encoded into the countable set of numbers $\{{}^nY^{r_1s_1\cdots r_ms_m}_{a_1\cdots a_m}\}$.

Summarizing, we have the action

$$A = \langle\Phi|Q|\Phi\rangle + \sum_{n=2}^{\infty} g^{n-2}\langle\Phi|^{\otimes n}\mathcal{F}_n|-\rangle_{1\cdots n}, \tag{102}$$

and the gauge transformations

$$\delta_{\Xi}|\Phi\rangle = Q|\Xi\rangle + \sum_{n=3}^{\infty}\frac{n}{2}g^{n-2}\sum_{\text{cycl.perm}}{}_{1\cdots n}\langle+|\Phi^{\otimes(n-2)}\Xi\mathcal{F}_n|-\rangle_{1\cdots n}. \tag{103}$$

It is clear that when formulated in this manner, the gauge invariance of the action can be checked order by order by computerized calculation. At least it should be possible to work out the quartic vertex up to and including spin 3 fields. This would make it possible to compare with the known spin 1 and spin 2 cubic and quartic interaction terms, and with the covariant cubic interaction term for spin 3 derived by Berends, Burgers, and van Dam.[55] Furthermore, it is likely that any obstructions that might make the theory inconsistent should crop up beyond the cubic term.

In order to organize such a calculation a few more points need clarifying. These are the issues of field redefinitions, global symmetries and the tracelessness constraints. A brief discussion of these points can be found in Ref. 33. Setting up the concrete data structures can be done in a functional language like Haskell. But the details of this belong to a computer science journal rather then a physics journal. Therefore this paper defers a thorough discussion to a more appropriate context.

XI. CONCLUSIONS AND OUTLOOK

It is clear that the framework constructed here is not specific to higher spin gauge fields. Higher spin gauge fields enter in the specifications of the fields Φ and the kinetic BRST operator Q, thus essentially in the free field theory. The rest of the abstract structure is independent of the detailed form of Φ and Q. Whether there is an implementation of the structure or not, depends, consequently, on the form of the free theory.

In particular, the abstract structure is silent on the question of multiplet structure, global symmetries, group theory factors, etc. The free field theory contemplated in Sec. II is special in that it contains just one component field of each integer spin s. This is perhaps the most simple situation to envision. We do not know yet if the interacting theory can be constructed in this case. It might be that more complicated multiplet structures are needed, perhaps accompanied by supersymmetry.

There is one peculiarity about the theory outlined here. What is the role of the spin 2 gauge field that appears in the free field theory? The question is connected to the role of gravity and space–time background. Presumably, the free field theory can be cast in any fixed spacetime background. The kinetic operator Q is known in Minkowski space and in AdS space.

The author is reluctant at the moment to speculate on a fundamental role for higher spin gauge fields. But one line of thought seems appropriate to air in the present context. The ubiquity of gravity at all scales of physics is one of the standard tenets of fundamental physics. In particular, this is one of the motivations behind the many attempts to quantize gravity and unify gravity with the spin 1 Yang–Mills forces. On the other hand, there is something glaringly macroscopic about gravity. The force is weak and long range. It is fair to say that we do not know much about gravity on extreme submicroscopic scales. There is a strand of research based on the assumption that gravity is not a fundamental force at all, but just an effective force that manifests itself above submicroscopic scales. Furthermore, as is clear from the cited work on deriving the gravitational equations either by deforming the free field theory, or by gauging the Poincaré group, that the nonlinearities can be understood without building it on a geometrical interpretation. This squares

well with the present day folklore that space–time breaks down at the Planck scale. But if space–time breaks down, then so does physical geometry. This emphasizes the intuition that arithmetic is more fundamental than geometry. Arithmetic is completely scale independent, and since the abstraction of arithmetic is algebra, it can be argued that an algebraic approach to the fundamental theory is more natural than a geometric. Should it furthermore turn out that there is a fundamentally discrete substructure to reality, we think physical geometry is out at the most minute scales.

There are no-go theorems[79,80,34] to the effect that massless fields of spin greater than 2 cannot generate long range forces. This is also consistent with everyday experience. One, admittedly sweeping, scenario would be that in a theory containing massless fields of all integer (and perhaps half-integer) spin, all the fields with spin $s>2$ just generate extreme submicroscopic forces, while the spin 2 field gets effectively self-coupled to generate gravity, and the spin 1 fields generate the standard model forces, one of them surviving as long-range electrodynamics.

Related to the issues discussed here, there is one advantage of the abstract approach to higher spin fields. It makes it very natural to reconsider, as already noted, the higher spin problem in a non-space–time context.

To conclude, there is at least three areas where research is needed. First, the semantic mapping into generalized Lie algebras need to be clarified. Second, a brute force calculation within the vertex implementation should be undertaken for experimental reasons. And third, physical insight into the significance of higher spin gauge fields is badly needed.

New spherically symmetric monopole and regular solutions in Einstein–Born–Infeld theories

D. J. Cirilo Lombardo[a)]
Bogoliubov Laboratory of Theoretical Physics, Joint Institute of Nuclear Research, Dubna, Moscow Region, 141980, Russia

(Received 3 May 2004; accepted 6 December 2004; published online 4 March 2005)

In this work a new asymptotically flat solution of the coupled Einstein–Born–Infeld equations for a static spherically symmetric space–time is obtained. When the intrinsic mass is zero the resulting space–time is regular everywhere, in the sense given by Hoffmann and Infeld in 1937, and the Einstein–Born–Infeld theory leads to the identification of the gravitational with the electromagnetic mass. This means that the metric, the electromagnetic field, and their derivatives do not have discontinuities in all the manifold. In particular, there are not conical singularities at the origin, in contrast to the well-known monopole solution studied by Hoffmann in 1935. The lack of uniqueness of the action function in nonlinear electrodynamics is discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1862308]

I. INTRODUCTION AND RESULTS

The four-dimensional solutions with spherical symmetry of the Einstein equations coupled to Born–Infeld fields have been well studied in the literature.[1–4] In particular, the electromagnetic field of the Born–Infeld monopole, in contrast to Maxwell's counterpart, contributes to the ADM mass of the system (it is the four momentum of asymptotic flat manifolds). Hoffmann was the first to study such static solutions in the context of general relativity with the idea of obtaining consistent particle-like model.[2] Unfortunately, these static Einstein–Born–Infeld (EBI) models generate conical singularities at the origin[2,3] that cannot be removed as in global monopoles or other nonlocalized defects of the space–time.[5,6] With the existence of these types of singularities in the space–time of the monopole we cannot identify the gravitational with the electromagnetic mass. In this work a *new* static spherically symmetric solution with Born–Infeld charge is obtained. The new metric, when the intrinsic mass of the system is zero, is *regular* everywhere in the sense that was given by Hoffmann and Infeld[3] in 1937 and the EBI theory leads to identification of the gravitational with the electromagnetic mass. This means that the metric, the electromagnetic field, and their derivatives do not have singularities and discontinuities in all the manifold. The fundamental feature of this solution is the lack of conical singularities at the origin. A distant observer will associate with this solution an electromagnetic mass that is twice the mass of the electromagnetic geon found by Demianski[4] in 1986. The energy–momentum tensor and the electric field are both regular with zero value at the origin and new parameters appear, given to the new metric surprising behaviors. The convention[7,8] used is the *spatial* of Landau and Lifshitz (1962), with signatures of the metric, Riemann, and Einstein tensors all positives $(+++)$.

The plan of this paper is as follows: in Sec. II we give a short introduction to the Born–Infeld theory: properties and principal features. In Sec. III the regularity condition as was given by Hoffmann and Infeld[3] in 1937. Sections IV–VII are devoted to finding the new solution and analyzing its properties. Finally, the conclusion and comments of the results are presented in Sec. VIII.

II. THE BORN–INFELD THEORY

The most significant nonlinear theory of electrodynamics is, by excellence, the Born–Infeld theory.[1,9] Among its many special properties is an exact SO(2) electric-magnetic duality invariance. The Lagrangian density describing Born–Infeld theory (in arbitrary space–time dimensions) is

$$\mathcal{L}_{\mathrm{BI}} = \sqrt{-g}L_{\mathrm{BI}} = \frac{b^2}{4\pi}\{\sqrt{-g} - \sqrt{|\det(g_{\mu\nu} + b^{-1}F_{\mu\nu})|}\}, \tag{1}$$

where b is a fundamental parameter of the theory with field dimensions. In open superstring theory,[10] for example, loop calculations lead to this Lagrangian with $b^{-1}=2\pi\alpha'$ ($\alpha' \equiv$ inverse of the string tension). In four space–time dimensions the determinant in (1) may be expanded out to give

$$L_{\mathrm{BI}} = \frac{b^2}{4\pi}\left\{1 - \sqrt{1 + \frac{1}{2}b^{-2}F_{\mu\nu}F^{\mu\nu} - \frac{1}{16}b^{-4}(F_{\mu\nu}\widetilde{F}^{\mu\nu})^2}\right\}, \tag{2}$$

which coincides with the usual Maxwell Lagrangian in the weak field limit.

It is useful to define the second rank tensor $P^{\mu\nu}$ by

$$P^{\mu\nu} = -\frac{1}{2}\frac{\partial L_{\mathrm{BI}}}{\partial F_{\mu\nu}} = \frac{F^{\mu\nu} - \frac{1}{4}b^{-2}(F_{\rho\sigma}\widetilde{F}^{\rho\sigma})\widetilde{F}^{\mu\nu}}{\sqrt{1 + \frac{1}{2}b^{-2}F_{\rho\sigma}F^{\rho\sigma} - \frac{1}{16}b^{-4}(F_{\rho\sigma}\widetilde{F}^{\rho\sigma})^2}} \tag{3}$$

(so that $P^{\mu\nu} \approx F^{\mu\nu}$ for weak fields) satisfying the electromagnetic equations of motion

$$\nabla_\mu P^{\mu\nu} = 0, \tag{4}$$

which are highly nonlinear in $F_{\mu\nu}$. The energy–momentum tensor may be written as

$$T_{\mu\nu} = \frac{1}{4\pi}\left\{\frac{F_\mu{}^\lambda F_{\nu\lambda} + b^2\left[\mathbb{R} - 1 - \frac{1}{2}b^{-2}F_{\rho\sigma}F^{\rho\sigma}\right]g_{\mu\nu}}{\mathbb{R}}\right\},$$
$$\mathbb{R} \equiv \sqrt{1 + \tfrac{1}{2}b^{-2}F_{\rho\sigma}F^{\rho\sigma} - \tfrac{1}{16}b^{-4}(F_{\rho\sigma}\widetilde{F}^{\rho\sigma})^2}. \tag{5}$$

Although it is by no means obvious, it may be verified that Eqs. (3)–(5) are invariant under electric-magnetic rotations of duality $F \leftrightarrow *G$. We can show that the SO(2) structure of the Born–Infeld theory is more easily seen in quaternionic form,[11,12]

$$\frac{1}{R}(\sigma_0 + i\sigma_2\overline{\mathbb{P}})L = \mathbb{L},$$

$$\frac{\mathbb{R}}{(1+\overline{\mathbb{P}^2})}(\sigma_0 - i\sigma_2\overline{\mathbb{P}})\mathbb{L} = L,$$

$$\overline{\mathbb{P}} \equiv \frac{\mathbb{P}}{b},$$

where we defined

$$L = F - i\sigma_2\widetilde{F},$$

$$\mathbb{L} = P - i\sigma_2\widetilde{P},$$

the pseudoescalar of the electromagnetic tensor $F^{\mu\nu}$,

$$\mathbb{P} = -\tfrac{1}{4}F_{\mu\nu}\widetilde{F}^{\mu\nu},$$

and σ_0, σ_2 the well-known Pauli matrix.

In flat space, and for purely electric configurations, the Lagrangian (2) reduces to

$$L_{\mathrm{BI}} = \frac{4\pi}{b^2}\{1 - \sqrt{1 - b^{-2}\vec{E}^2}\}$$

so there is an upper bound on the electric field strength $\vec{E}$,

$$|\vec{E}| \leqslant b. \tag{6}$$

III. THE REGULARITY CONDITION

The new field theory initiated in 1934 by Born[9] introduces in the classical equations of the electromagnetic field a characteristic length r_0 representing the radius of the elementary particle through

$$r_0 = \sqrt{\frac{e}{b}},$$

where e is the elementary charge and b the fundamental field strength entering in a nonlinear Lagrangian function. It was originally thought that the Lagrangian (1) was the simplest choice which would lead to a finite energy for an electric particle. This is, however, not the case. It is possible to find an infinite number of quite different action functions, each giving simple algebraic relations between the fields and each leading to a finite energy for an electric particle.

In 1937 Hoffmann and Infeld[3] introduced a regularity condition on the new field theory of Born[9] with the main idea to solve the lack of uniqueness of the function action. They had already seen that the condition of regularity of the field gives the restriction in the spherically symmetric electrostatic case $E_r = 0$ for $r = 0$.

In the general theory they applied the regularity condition not only to the $F_{\mu\nu}$ field but also to the $g_{\mu\nu}$ field. The regularity condition for the general theory was that:

Only those solutions of the fields equations may have physical meaning for which space–time is everywhere regular and for which the $F_{\mu\nu}$ and the $g_{\mu\nu}$ fields and those of their derivatives which enter in the field equations and the conservation laws exist everywhere.

In the general theory of relativity the spherically symmetric solution of the purely gravitational field equations is given by the Schwarzschild line element

$$\mathrm{d}s^2 = -A\,\mathrm{d}t^2 + A^{-1}\mathrm{d}r^2 + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\varphi^2),$$

$$A \equiv 1 - \frac{2M}{r},$$

where $(-2M)$ is a constant of integration M having the significance of the gravitational mass of the body source of the field (we take the gravitational constant $G = 1$). This line element has an essential singularity at $r = 0$ and does not satisfy the regularity condition.

In the general relativity form of the original new field theory the requirement that there be no infinities in the $g_{\mu\nu}$ forces the identification of gravitational with electromagnetic mass. In Ref. 3 Hoffmann and Infeld have used for such identification the line element of the well-known monopole solution studied by Hoffmann[2] in 1935,

$$A \equiv 1 - \frac{8\pi}{r}\int_0^r [(r^4+1)^{1/2} - r^2]\mathrm{d}r,$$

which is originated by an Einstein–Born–Infeld action as in Eq. (1). This line element approximates the Schwarzschild form for r greater than the electronic radius but avoids the infinities of that line element for $r=0$. However it is still a singularity of conical type at the pole. When $r \to 0$ the above expression for A gives

$$A \to (1 - 8\pi) \equiv \beta$$

so $\mathrm{d}s^2$ becomes

$$\mathrm{d}s^2 = -\beta\,\mathrm{d}t^2 + \beta^{-1}\,\mathrm{d}r^2 + r^2(\mathrm{d}\theta^2 + \sin^2\theta \mathrm{d}\varphi^2).$$

Thus the radius of the circumference to the radius of a small circle having its center at the pole is, in the limit, $2\pi\beta$ and not 2π. Therefore the origin (it is at $r=0$) is a conical point and not regular. Note that because of the conical point no coordinate can be introduced which will be nonsingular at $r=0$ and derivatives are actually undefined at this point.

This problem with the conical singularities at $r=0$, which destroys the regularity condition, makes that in Ref. 3 change the action of the Born–Infeld form as in Eq. (1) for other nonlinear Lagrangian of logarithmic type. The new logarithmic action does not present such difficulties at $r=0$, and makes many people change the very nice form of the Einstein–Born–Infeld action (1) for other nonlinear Lagrangians that solved the problem of the self-energy of the electron and the regularity condition given above.

In this work we present an *exact* spherically symmetric solution of the Einstein–Born–Infeld equations. The metric, when the intrinsic mass of the system is zero, is *regular* everywhere in the sense that was given by Hoffmann and Infeld[3] in 1937, and the EBI theory leads to identification of the gravitational with the electromagnetic mass. In this manner we also show that stronger conditions are needed to solve the problem of lack of uniqueness of the function action.

IV. STATEMENT OF THE PROBLEM

We propose the following line element for the static Born–Infeld monopole:

$$\mathrm{d}s^2 = -e^{2\Lambda}\,\mathrm{d}t^2 + e^{2\Phi}\mathrm{d}r^2 + e^{2F(r)}\mathrm{d}\theta^2 + e^{2G(r)}\sin^2\theta\,\mathrm{d}\varphi^2, \tag{7}$$

where the components of the metric tensor are

$$g_{tt} = -e^{2\Lambda}, \quad g^{tt} = -e^{-2\Lambda},$$

$$g_{rr} = e^{2\Phi}, \quad g^{rr} = e^{-2\Phi},$$

$$g_{\theta\theta} = e^{2F}, \quad g^{\theta\theta} = e^{-2F},$$

$$g_{\varphi\varphi} = \sin^2\theta e^{2G}, \quad g^{\varphi\varphi} = \frac{e^{-2G}}{\sin^2\theta}. \tag{8}$$

For the obtention of the Einstein–Born-Infeld equation system we use Cartan's structure equations method,[13] which is most powerful and direct where we work with differential forms and in an orthonormal frame (tetrad). The line element (7) in the one-forms basis takes the following form:

$$\mathrm{d}s^2 = -(\omega^0)^2 + (\omega^1)^2 + (\omega^2)^2 + (\omega^3)^2, \tag{9}$$

where the forms are

$$\omega^0 = e^{\Lambda}\mathrm{d}t \Rightarrow \mathrm{d}t = e^{-\Lambda}\omega^0,$$

$$\omega^1 = e^{\Phi}\mathrm{d}r \Rightarrow \mathrm{d}r = e^{-\Phi}\omega^1,$$

$$\omega^2 = e^{F(r)}\mathrm{d}\theta \Rightarrow \mathrm{d}\theta = e^{-F(r)}\omega^2, \tag{10}$$

$$\omega^3 = e^{G(r)}\sin\theta\,\mathrm{d}\varphi \Rightarrow \mathrm{d}\varphi = e^{-G(r)}(\sin\theta)^{-1}\omega^3.$$

Now, following the standard procedure of the structure equations (Appendix) to obtain easily the components of the Riemann tensor, we can construct the Einstein equations

$$G^1{}_2 = -e^{-(F+G)}\frac{\cos\theta}{\sin\theta}\partial_r(G-F), \tag{11}$$

$$G^0{}_0 = e^{-2\Phi}\Psi - e^{-2F},$$

$$\Psi \equiv [\partial_r\partial_r(F+G) - \partial_r\Phi\partial_r(F+G) + (\partial_r F)^2 + (\partial_r G)^2 + \partial_r F\partial_r G], \tag{12}$$

$$G^1{}_1 = e^{-2\Phi}[\partial_r\Lambda\partial_r(F+G) + \partial_r F\partial_r G] - e^{-2F}, \tag{13}$$

$$G^2{}_2 = e^{-2\Phi}[\partial_r\partial_r(\Lambda+G) - \partial_r\Phi\partial_r(\Lambda+G) + (\partial_r\Lambda)^2 + (\partial_r G)^2 + \partial_r\Lambda\partial_r G], \tag{14}$$

$$G^3{}_3 = e^{-2\Phi}[\partial_r\partial_r(F+\Lambda) - \partial_r\Phi\partial_r(F+\Lambda) + (\partial_r\Lambda)^2 + (\partial_r F)^2 + \partial_r F\partial_r\Lambda], \tag{15}$$

$$G^1{}_3 = G^2{}_3 = G^0{}_3 = G^0{}_2 = G^0{}_1 = 0. \tag{16}$$

In the tetrad defined by (10), the energy–momentum tensor of Born–Infeld takes a diagonal form, its components being the following:

$$-T_{00} = T_{11} = \frac{b^2}{4\pi}\left(\frac{\mathbb{R}-1}{\mathbb{R}}\right), \tag{17}$$

$$T_{22} = T_{33} = \frac{b^2}{4\pi}(1-\mathbb{R}), \tag{18}$$

where

$$\mathbb{R} \equiv \sqrt{1-\left(\frac{F_{01}}{b}\right)^2}. \tag{19}$$

In this manner, one can see from the Einstein equation (11) the characteristic property of the spherically symmetric space–times,[14]

$$G^1{}_2 = -e^{-(F+G)}\frac{\cos\theta}{\sin\theta}\partial_r(G-F) = 0 \Rightarrow G = F. \tag{20}$$

Notice that for the interval to be a spherically symmetric one, the functions $F(r)$ and $G(r)$ must be equal. As we saw in the precedent paragraph the components of the energy–momentum tensor of BI assures this condition is in a natural form. Also it is interesting to see from Eqs. (17) and (18) that the energy–momentum tensor of Born–Infeld has the same form as the energy–momentum tensor of an anisotropic fluid.

V. EQUATIONS FOR THE ELECTROMAGNETIC FIELDS OF BORN–INFELD IN THE TETRAD

The equations that describe the dynamic of the electromagnetic fields of Born–Infeld in a curved space–time are

$$\nabla_a \mathbb{F}^{ab} = \nabla_a \left[\frac{F^{ab}}{\mathbb{R}} + \frac{P}{b^2 \mathbb{R}} \widetilde{F}^{ab} \right] = 0 \quad \text{(field equations)}, \tag{21}$$

$$\nabla_a \widetilde{F}^{ab} = 0 \quad \text{(Bianchi's identity)}, \tag{22}$$

where

$$P \equiv -\tfrac{1}{4} F_{\alpha\beta} \widetilde{F}^{\alpha\beta}, \tag{23}$$

$$S \equiv -\tfrac{1}{4} F_{\alpha\beta} F^{\alpha\beta}, \tag{24}$$

$$\mathbb{R} \equiv \sqrt{1 - \frac{2S}{b^2} - \left(\frac{P}{b^2} \right)^2}. \tag{25}$$

The above equations can be solved explicitly giving the follow result:

$$F_{01} = A(r), \tag{26}$$

$$\mathbb{F}_{01} = f e^{-2G}, \tag{27}$$

where f is a constant. We can see from Eqs. (19) and (21) that

$$\mathbb{F}_{01} = \frac{F_{01}}{\sqrt{1 - (\overline{F}_{01})^2}},$$

where we obtain the following form for the electric field of the self-gravitating BI monopole:

$$F_{01} = \frac{b}{\sqrt{\left(\frac{b}{f} e^{2G} \right)^2 + 1}}. \tag{28}$$

We can associate[1]

$$f = b r_0^2 \equiv Q \Rightarrow F_{01} = \frac{b}{\sqrt{\left(\frac{e^G}{r_0} \right)^4 + 1}}, \tag{29}$$

where r_0 is a constant with units of longitude that in Ref. 1 were associated with the radius of the electron. Finally the components of the energy–momentum tensor of BI takes its explicit form reemplacing the F_{01} that was found in Eq. (29) in expressions (17) and (18)

$$-T_{00} = T_{11} = \frac{b^2}{4\pi} \left(1 - \sqrt{\left(\frac{r_0}{e^G} \right)^4 + 1} \right), \tag{30}$$

$$T_{22} = T_{33} = \frac{b^2}{4\pi}\left(1 - \frac{1}{\sqrt{\left(\frac{r_0}{e^G}\right)^4 + 1}}\right). \tag{31}$$

Expressions (11)–(16) together with (30), (31), and (20) are the full set of Einstein equations in explicit form.

VI. REDUCTION AND SOLUTIONS OF THE SYSTEM OF EINSTEIN–BORN–INFELD EQUATIONS

Of the above-noted expressions, we can see that $G^0{}_0 = G^1{}_1$ then

$$\partial_r\partial_r G + (\partial_r G)^2 - \partial_r G\partial_r(\Phi + \Lambda) = 0. \tag{32}$$

In order to reduce Eq. (32) we will proceed as follows. First we make

$$\partial_r G \equiv \xi \tag{33}$$

with this change of variables, in Eq. (32) we have first derivatives only

$$\partial_r\xi + \xi^2 - \xi\partial_r(\Phi + \Lambda) = 0. \tag{34}$$

Dividing expression (34) by ξ and making the substitution

$$\chi \equiv \ln \xi \tag{35}$$

we obtain the following inhomogeneous equation:

$$\partial_r\chi + e^{\chi} = \partial_r(\Phi + \Lambda). \tag{36}$$

The homogeneous part of the last equation is easy to integrate,

$$\chi_h = -\ln r. \tag{37}$$

Now, as usual, we make the following substitution in Eq. (36):

$$\chi = \chi_h + \chi_p = -\ln r + \ln \mu = -\ln r + \ln(1 + \eta). \tag{38}$$

Then

$$\partial_r \ln(1 + \eta) + \frac{\eta}{r} = \partial_r(\Phi + \Lambda) \Rightarrow \partial_r[\ln(1 + \eta) + \mathcal{F}(r) - (\Phi + \Lambda)] = 0 \tag{39}$$

$$\ln(1 + \eta) + \mathcal{F}(r) - (\Phi + \Lambda) = cte = 0,$$

where $d\mathcal{F}(r)/dr \equiv \eta(r)/r$. The constant must be put equal to zero to obtain the correct limit. Finally the form of the exponent G is

$$G = \ln r + \mathcal{F}(r). \tag{40}$$

The next step is to put Φ in function of Λ and G in expression (13). After tedious but straightforward computations and integrations, we obtain

$$e^{2\Lambda} = 1 + a_0 e^{-G} + e^{2G}\frac{2b^2}{3} - 2b^2 e^{-G}\int^{Y(r)} \sqrt{Y^4 + (r_0)^4}\,dY, \tag{41}$$

where we define

$$Y(r) = e^{G}$$

and $a(0)$ is an integration constant.

Hitherto, we know that $\mathcal{F}$ is an arbitrary function of the radial coordinate r, but to be sure of it, we must introduce the function Λ given for the above equation in the Einstein equations (14) and (15) and verify that $G_{22}=G_{33}$. This equality is verified successfully and the functions Λ, Φ, and G remain mathematically determinate. In this manner the line element of our problem (7) takes the following form:

$$ds^2 = -e^{2\Lambda}dt^2 + e^{2\mathcal{F}(r)}[e^{-2\Lambda}(1 + r\partial_r\mathcal{F}(r))^2 dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\varphi^2)]. \tag{42}$$

A. Analysis of the function $\mathcal{F}(r)$ from the physical point of view

The function $\mathcal{F}(r)$ must, to have the behavior in the form of the electric field of the configuration, obey the following requirements to give a regular solution in the sense that was given by Hoffmann and Infeld,[3]

$$F_{01}|_{r=r_0} < b, \tag{43}$$

$$F_{01}|_{r=0} = 0, \tag{44}$$

$$F_{01}|_{r\to\infty} = 0 \quad \text{asymptotically Coulomb} \tag{45}$$

the simplest function $\mathcal{F}(r)$ that obey the above conditions is of the type

$$e^{2\mathcal{F}(r)} = \left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]^{2m}, \tag{46}$$

where a is an arbitrary constant, and the exponents n and m will obey the following relation:

$$mn > 1 \quad (m,n \in \mathbb{N}) \tag{47}$$

with

$$0 < a < 1 \text{ or } -1 < a < 0$$

depending on whether $m(n)$ is even or odd and

$$a \neq 0$$

that ensure a consistent regularization condition not only for the electric (magnetic) field but for the energy-momentum tensor (30) and (31) and the line element (42).

The analysis of the Riemann tensor indicates to us that it is regular everywhere and its components go faster than $1/r^3$ when $r\to\infty$. With all these considerations, the metric solution to the problem is

$$ds^2 = -e^{2\Lambda}dt^2 + \left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]^{2m}\left\{e^{-2\Lambda}dr^2\left[\frac{1 - \left(\frac{r_0}{a|r|}\right)^n (mn-1)}{\left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]}\right]^2 + r^2(d\theta^2 + \sin^2\theta\, d\varphi^2)\right\} \tag{48}$$

and the electric field takes the form

$$F_{01} = \frac{b}{\sqrt{1 + \left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]^{4m} \left(\frac{r}{r_0}\right)^4}}. \tag{49}$$

It is interesting to note that if we violate condition (43) taking $a=1$ and $F_{01}|_{r=r_0}=b$ (limit value for the electric field in BI theory) the energy momentum diverges automatically at $r=r_0$. Strictly, the regularity conditions for the energy–momentum tensor (without divergences and discontinuities in the neighborhood of r_0, physical radius of the spherical source of the nonlinear electromagnetic field) are

$$T_{ab}|_{r=r_0} = \text{finite} \Rightarrow -1 < a < 0 \text{ or } 0 < a < 1$$

depending on parity of m, n; and

$$T_{ab}|_{r=0} \to 0 \Rightarrow \mathbb{R} \to 1.$$

For the magnetic monopole case the line element is as expression (48) with the following obvious definition for the magnetic charge,

$$br_0^2 \equiv Q_m.$$

The magnetic field takes the following form:

$$F_{23} = \frac{b}{\left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]^{2m} \left(\frac{r}{r_0}\right)^2} = \frac{Q_m}{\left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]^{2m} r^2}$$

and considerations concerning the regularity conditions on the energy momentum tensor are as in the electric monopole case.

B. Interesting cases for particular values of *n* and *m*

Because

$$\exp 2\mathcal{F}(r) = \left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]^{2m}$$

it is easy to see that for $m=0$,

$$e^G = r.$$

We obtain the spherically symmetric line element of Hoffmann,[2] the electric field F_{01}, and the energy–momentum tensor T_{ab} takes the form of the well-known EBI solution for the electromagnetic geon of Demiánski.[4]

On the other hand, in the *limit* when: $a \to 1$, $n \to 4$, and $m \to \frac{1}{4}$ we have

$$F_{01} \to \frac{b}{\sqrt{1 + \left[1 - \left(\frac{r_0}{|r|}\right)^4\right] \left(\frac{r}{r_0}\right)^4}} = \frac{Q}{r^2},$$

where (as is usually taken) $br_0^2 \equiv Q$. How we see, we obtain as solution in the *limit* the Maxwellian linear field. Note that the values of a and the exponents m and n are restricted by conditions (47).

VII. ANALYSIS OF THE METRIC

We have the metric (42)

$$ds^2 = -e^{2\Lambda}dt^2 + e^{2\mathcal{F}(r)}[e^{-2\Lambda}(1 + r\partial_r\mathcal{F}(r))^2dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\varphi^2)]$$

if we make the substitution

$$Y \equiv re^{\mathcal{F}(r)},$$

and differentiating it

$$dY \equiv e^{\mathcal{F}(r)}(1 + r\partial_r\mathcal{F}(r))dr$$

the interval (7) takes the form

$$ds^2 = -e^{2\Lambda}dt^2 + e^{-2\Lambda}dY^2 + Y^2(d\theta^2 + \sin^2\theta\, d\varphi^2)$$

we can see that the metric (in particular the g_{tt} coefficient), in the new coordinate $Y(r)$, takes the similar form like a Demianski solution for the Born–Infeld monopole space–time:

$$e^{2\Lambda} = 1 - \frac{2M}{Y} - \frac{2b^2r_0^4}{3(\sqrt{Y^4 + r_0^4} + Y^2)} - \frac{4}{3}b^2r_{02}^2F_1\left[1/4, 1/2, 5/4; -\left(\frac{Y}{r_0}\right)^4\right].$$

Here M is an integration constant, which can be interpreted as an intrinsic mass, and ${}_2F_1$ is the Gauss hypergeometric function.[15] We have pass

$$g_{rr} \to g_{YY}, \quad g_{tt}(r) \to g_{tt}(Y).$$

Specifically, for the form of the $\mathcal{F}(r)$ given by (46), Y is

$$Y^2 \equiv \left[1 - \left(\frac{r_0}{a|r|}\right)^n\right]^{2m} r^2.$$

Now, with the metric coefficients fixed to an asymptotically Minkowskian form, one can study the asymptotic behavior of our solution. A regular, asymptotically flat solution with the electric field and energy–momentum tensor both regular, in the sense of Hoffmann and Infeld, is when the exponent numbers of $Y(r)$ take the following particular values:

$$n = 3, \quad m = 1.$$

In this case, and for $r \gg r_0/a$, we have the following asymptotic behavior for $Y(r)$ and $-g_{tt}$, which does not depend on the a parameter

$$Y(r) \to r \quad \left(r \gg \frac{r_0}{a}\right),$$

$$e^{2\Lambda} \simeq 1 - \frac{2M}{r} - \frac{8b^2r_0^4K(1/2)}{3r_0r} + 2\frac{b^2r_0^4}{r^2} + \cdots.$$

A distant observer will associate with this solution a total mass

$$M_{\text{eff}} = M + \frac{4b^2r_0^4K(1/2)}{3r_0}$$

and total charge

$$Q^2 = 2b^2 r_0^2.$$

Notice that when the intrinsic mass M is zero the line element is regular everywhere, the Riemann tensor is also regular everywhere and hence the space–time is singularity free. The electromagnetic mass

$$M_{\mathrm{el}} = \frac{4b^2 r_0^4 K(1/2)}{3r_0} \tag{50}$$

and the charge Q are *twice* that of the electromagnetic charge and mass of the Demianski solution[4] for the static electromagnetic geon. Notice that the M_{el} is necessarily positive, which was not the case in the Schwarzschild line element. The other important reason for us to take the constant $M=0$ is that we must regard the quantity (let us restore for one moment the gravitational constant G)

$$4\pi G \int_{Y(r=0)}^{Y(r)} T_0^0(Y) Y^2 \mathrm{d}Y$$

as the *gravitational mass* causing the field at coordinate distance r from the pole. In our case T_0^0 is given by expression (30). This quantity is precisely (in gravitational units) M_{el} given by (50), the *total electromagnetic mass* within the sphere having its center at $r=0$ and coordinate r. We will take $M=0$ in the rest of the analysis.

On the other hand, the function $Y(r)$ for the values of the m and n parameters given above has the following behavior near the origin:

$$\text{for } a<0 \quad \text{when } r\to 0, Y(r)\to\infty,$$

$$\text{for } a>0 \quad \text{when } r\to 0, Y(r)\to -\infty.$$

Notice that the case $a>0$ will be excluded because in any value $r_0 \to Y(r_0)=0$, the electric field takes the limit value b and condition (43) is violated. For $M=0$ and $a<0$, expanding the hypergeometric function, we can see that the $-g_{tt}$ coefficient has the following behavior near the origin:

$$e^{2\Lambda} \simeq 1 - \frac{8b^2 r_0^4 K(1/2)}{3r_0} r^2 \left(\frac{|a|}{r_0}\right)^3 + 2b^2 r_0^4 r^4 \left(\frac{|a|}{r_0}\right)^6 + \cdots .$$

The metric (see figures) and the energy–momentum tensor *both* remain regulars at the origin (it is: $g_{tt}\to -1$, $T_{\mu\nu}\to 0$ for $r\to 0$). It is not very difficult to check that (for $m=1$ and $n=3$) the maximum of the electric field (see the figures) is not in $r=0$, but in the *physical border* of the spherical configuration source of the electromagnetic fields (this point is located around $r_B = 2^{1/3} r_0/|a|$). It means that $Y(r)$ maps correctly the internal structure of the source in the same form as the quasiglobal coordinate of Ref. 16 for the global monopole in general relativity. The lack of conical singularities at the origin is due to the very good description of the manifold in the neighborhood of $r=0$ given by $Y(r)$.

Because the metric is regular ($g_{tt}=-1$, at $r=0$ and at $r=\infty$), its derivative must change sign. In the usual gravitational theory of general relativity the derivative of g_{tt} is proportional to the gravitational force which would act on a test particle in the Newtonian approximation. In Einstein–Born–Infeld theory with this new static solution, it is interesting to note that although this force is attractive for distances of the order $r_0 \ll r$, it is actually a repulsion for very small r. For r greater than r_0, the line element closely approximates to the Schwarzschild form. Thus the regularity condition shows that the electromagnetic and gravitational mass are the same and, as in the Newtonian theory, we now have the result that the attraction is zero in the center of the spherical configuration source of the electromagnetic field.

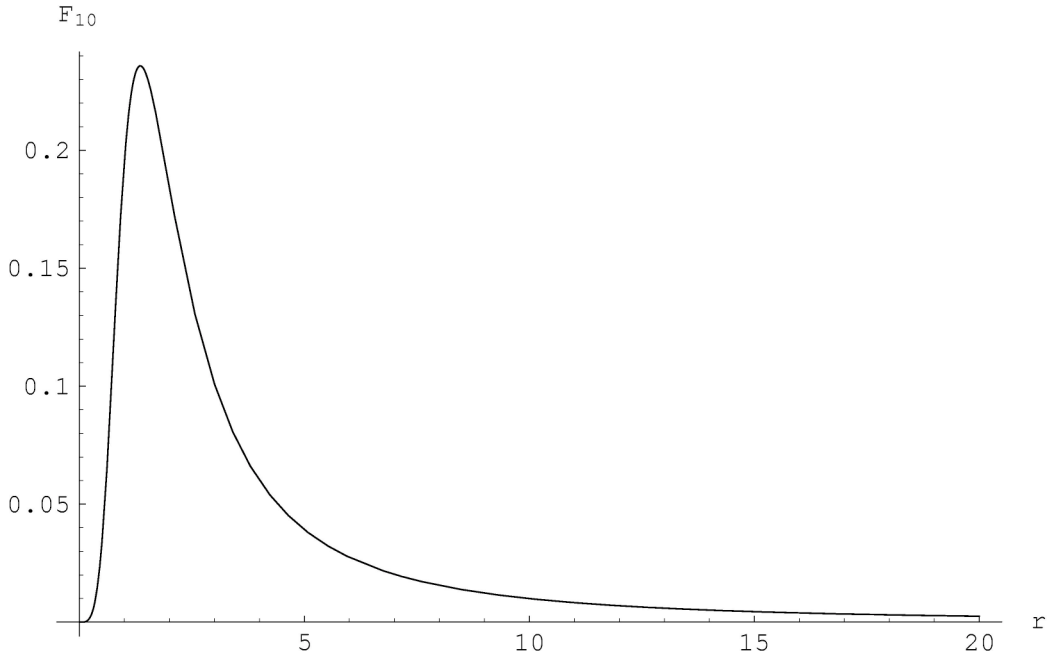

FIG. 1. Electric field F_{10} of the EBI - monopole in function of r, for $M=0$, $r_0=1$, $m=1$, $n=3$ and $a=-0.9$

VIII. CONCLUSIONS

In this report a *new* exact solution of the Einstein–Born–Infeld equations for a static spherically symmetric monopole is presented. The general behavior of the geometry is strongly modified according to the value that r_0 takes (Born–Infeld radius[1,9]) and three new parameters: a, m, and n.

The fundamental feature of this solution is the lack of conical singularities at the origin when $-1<a<0$ or $0<a<1$ (depends on parity of m and n) and $mn>1$. In particular, for $m=1$ and $n=3$, with the parameter a in the range given above and the intrinsic mass of the system M being zero, the strong regularity conditions given by Hoffmann and Infeld in Ref. 3 hold in all the space–time. For the set of values for the above-given parameters, the solution is asymptotically flat, free of singularities in the electric field, metric, energy–momentum tensor and their derivatives (with derivative values zero for $r\to 0$); and the electromagnetic mass (ADM) of the system is twice that of the electromagnetic mass of other well-known[2,4] solutions for the Einstein–Born–Infeld monopole. The electromagnetic mass M_{el} asymptotically is necessarily positive, which was not the case in the Schwarzschild line element (See Figs. 1 and 2).

This solution has a surprising similitude with the metric for the global monopole in general relativity given in Refs. 16 and 17 in the sense that the physics of the problem has a correct description only by means of a new radial function $Y(r)$.

Because the metric is regular ($g_{tt}=-1$, at $r=0$ and at $r=\infty$), its derivative (that is proportional to the force in Newtonian approximation) must change sign. In Einstein–Born–Infeld theory with this new static solution, it is interesting to note that although this force is attractive for distances of the order $r_0 \lll r$, it is actually repulsive for very small r.

With this new regular solution, we also show that stronger conditions are needed to solve the problem of the lack of uniqueness of the function action in nonlinear electrodynamics.

APPENDIX: CONNECTIONS AND CURVATURE FORMS FROM THE GEOMETRICAL CARTAN'S FORMULATION

The standard procedure of Cartan has its start point in the following:

$$\mathrm{d}\omega^{\alpha} = -\,\omega^{\alpha}{}_{\beta} \wedge \omega^{\beta}, \tag{A1}$$

$$\mathcal{R}^{\alpha}{}_{\beta} = d\omega^{\alpha}{}_{\beta} + \omega^{\alpha}{}_{\lambda} \wedge \omega^{\lambda}{}_{\beta}. \tag{A2}$$

These are denominated *the structure equations*. The procedure to obtain the Einstein equations is as follows.

(i) Making the exterior derivatives of ω^{α} we compute the connection one-forms $\omega^{\alpha}{}_{\beta}$:

$$\omega^{0}{}_{1} = \omega^{1}{}_{0} = e^{-\Phi}\partial_r \Lambda \omega^{0},$$

$$\omega^{2}{}_{1} = -\,\omega^{1}{}_{2} = e^{-\Phi}\partial_r F(r)\omega^{2},$$

$$\omega^{3}{}_{1} = -\,\omega^{1}{}_{3} = e^{-\Phi}\partial_r G(r)\omega^{3}, \tag{A3}$$

$$\omega^{3}{}_{2} = -\,\omega^{2}{}_{3} = \frac{\cos\theta}{\operatorname{sen}\theta} e^{-F(r)}\omega^{3}.$$

(ii) Making the exterior derivatives of $\omega^{\alpha}{}_{\beta}$ we compute the curvature two-forms $\mathcal{R}^{\alpha}{}_{\beta}$:

$$\mathcal{R}^{0}{}_{1} = e^{-2\Phi}(\partial_r\partial_r\Lambda - \partial_r\Phi\partial_r\Lambda + (\partial_r\Lambda)^2)\omega^{1} \wedge \omega^{0},$$

$$\mathcal{R}^{2}{}_{1} = e^{-2\Phi}(\partial_r\partial_r F - \partial_r\Phi\partial_r F + (\partial_r F)^2)\omega^{1} \wedge \omega^{2},$$

$$\mathcal{R}^3{}_2 = e^{-(F+\Phi)}\partial_r(G-F)\frac{\cos\theta}{\operatorname{sen}\theta}\omega^1\wedge\omega^3 + (e^{-2\Phi}\partial_r G\partial_r F - e^{-2F})\omega^2\wedge\omega^3,$$

$$\mathcal{R}^3{}_1 = e^{-2\Phi}(\partial_r\partial_r G - \partial_r\Phi\partial_r G + (\partial_r G)^2)\omega^1\wedge\omega^3 + e^{-(F+\Phi)}\partial_r(G-F)\frac{\cos\theta}{\operatorname{sen}\theta}\omega^2\wedge\omega^3, \tag{A4}$$

$$\mathcal{R}^0{}_2 = -e^{-2\Phi}\partial_r\Lambda\partial_r F\omega^0\wedge\omega^2,$$

$$\mathcal{R}^0{}_3 = -e^{-2\Phi}\partial_r\Lambda\partial_r G\omega^0\wedge\omega^3.$$

(iii) The components of the Riemann tensor are easily obtained from the well-know geometrical relation of Cartan:

$$\mathcal{R}^\alpha{}_\beta = R^\alpha{}_{\beta\rho\sigma}\omega^\rho\wedge\omega^\sigma,$$

where we obtain explicitly

$$R^0{}_{110} = e^{-2\Phi}(\partial_r\partial_r\Lambda - \partial_r\Phi\partial_r\Lambda + (\partial_r\Lambda)^2),$$

$$R^2{}_{112} = e^{-2\Phi}(\partial_r\partial_r F - \partial_r\Phi\partial_r F + (\partial_r F)^2),$$

$$R^3{}_{113} = e^{-2\Phi}(\partial_r\partial_r G - \partial_r\Phi\partial_r G + (\partial_r G)^2),$$

$$R^3{}_{213} = e^{-(F+\Phi)}\partial_r(G-F)\frac{\cos\theta}{\sin\theta},$$

$$R^3{}_{123} = e^{-(F+\Phi)}\partial_r(G-F)\frac{\cos\theta}{\sin\theta}, \tag{A5}$$

$$R^3{}_{223} = e^{-2\Phi}\partial_r G\partial_r F - e^{-2F},$$

$$R^0{}_{330} = e^{-2\Phi}\partial_r\Lambda\partial_r G,$$

$$R^0{}_{220} = e^{-2\Phi}\partial_r\Lambda\partial_r F,$$

from which we can construct the Einstein equations of the usual manner.

Conformal symmetries of Einstein's field equations and initial data

Ramesh Sharma[a)]
Department of Mathematics, University of New Haven, West Haven, Connecticut 06516

(Received 30 November 2004; accepted 19 January 2005; published online 17 March 2005)

This paper examines the initial data for the evolution of the space–time solution of Einstein's equations admitting a conformal symmetry. Under certain conditions on the extrinsic curvature of the initial complete spacelike hypersurface and sectional curvature of the space–time with respect to sections containing the normal vector field, we have shown that the initial hypersurface is conformally diffeomorphic to a sphere or a flat space or a hyperbolic space or the product of an open real interval and a complete 2-manifold. It has been further shown that if the initial hypersurface is compact, then it is conformally diffeomorphic to a sphere. Finally, the conformal symmetries of a generalized Robertson–Walker space–time have been described. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1868372]

I. INTRODUCTION

Most of the known solutions of Einstein's field equations (that are highly nonlinear) are based on the assumption that they admit one or more Killing vector fields (infinitesimal isometries) or homothetic vector fields. These solutions provide many clues and insights into astrophysical and cosmological questions. However, it would be interesting to analyze space–time solutions with weaker symmetries, such as, conformal symmetries. This would be further supported by the fact that Robertson–Walker space–times (which provide a satisfactory cosmological model) do admit a G_6 of Killing vectors and a G_9 of conformal Killing vector fields (see Maartens and Maharaj[14]). One may also note that conformal symmetries preserve the causal character of space–times. One little drawback with conformal symmetries lies in the fact that unlike isometries and homotheties, conformal symmetries do not leave Einstein tensor invariant, and in this respect, may be regarded unnatural or accidental. Nevertheless, some solutions with conformal symmetries are known (for details we refer to Duggal and Sharma[6]). We note that the existence of a proper conformal symmetry places severe restrictions on the space–times, as indicated by the results proven by Collinson and French,[5] Garfinkle and Tian,[10] and Sharma.[17] The work reported in this paper is primarily intrigued by the following significant result of Eardley, Isenberg, Marsden, and Moncrief:[8] "*Let* (M,g) *be a globally hyperbolic spacetime which (a) satisfies the Einstein equations for a stress tensor T obeying the mixed energy condition and the dominant energy condition; (b) admits a homothetic Killing vector field* ξ *of g*; *and (c) admits a compact hypersurface of constant mean curvature (CMC). Then either* (M,g) *is an expanding hyperbolic model with T vanishing everywhere, or* ξ *is Killing*." In this paper we characterize a space–time solution of Einstein's equation with a conformal symmetry, in terms of a spacelike hypersurface as an initial data. *As this is a formidable task, we have assumed a curvature condition on the space–time*. This assumption is motivated by the fact that this holds on a generalized Robertson–Walker space–time (in particular, Robertson–Walker space–time) as indicated in Example (1) of Sec. II. First we derive the constraint and evolution equations for a conformal Killing vector (CKV) field on the space–time solution of Einstein's equations. Assuming that the space–time solution M admits a proper CKV field ξ, and is evolved out of a spacelike hypersurface Σ such that (a) Σ is complete

a)Electronic mail: rsharma@newhaven.edu

and totally umbilical in M, (b) the normal sectional curvature of the space–time is independent of the normal section at each point of Σ, and (c) the normal component of ξ is nonvanishing and nonconstant on Σ, we prove that such a hypersurface is conformally diffeomorphic to one of the following: (i) sphere S^3, (ii) Euclidean space E^3, (iii) hyperbolic space H^3, (iv) the Riemannian product of a real open interval and a complete 2-manifold. Then we prove the main result of this paper, i.e., if a space–time solution M of Einstein's equation admits a CKV field ξ and is evolved out of a compact spacelike CMC hypersurface Σ such that (a) ξ is nowhere tangential and nonvanishing on Σ, (b) the normal component of ξ is nonconstant over Σ, and (c) the normal sectional curvature of M is independent of the normal section at each point of Σ, then Σ is totally umbilical in M, and conformally diffeomorphic to a 3-sphere. Finally we describe CKV fields on a generalized Robertson–Walker space–time (see example (1) under Sec. II).

II. PRELIMINARIES AND NOTATIONS

We would like to follow the ADM 3+1 splitting formalism due to Arnowitt, Deser, and Misner[2] that slices the space–time (M,g) into a one-parameter family of spacelike hypersurfaces and considers that the space–time geometry evolve out of an initial spacelike hypersurface $\Sigma(t=\text{constant})$ with initial data as its Riemannian metric γ and the second fundamental form (extrinsic curvature) k. Let us denote arbitrary vector fields tangential to Σ by X,Y,Z,W, and the timelike unit vector field normal to Σ by N. Then the Gauss and Weingarten formulas are

$$\bar{\nabla}_X Y = \nabla_X Y + k(X,Y)N, \quad \bar{\nabla}_X N = KX, \tag{1}$$

where K is the Weingarten (shape) operator of Σ defined by $k(X,Y)=\langle KX,Y\rangle$ ($\langle,\rangle$ denotes the inner product with respect to the 3-metric γ of Σ as well as the space–time metric g), and $\bar{\nabla},\nabla$ the Levi–Civita connections of the metrics g,γ, respectively. We write the Gauss and Codazzi equations as

$$\langle \bar{R}(X,Y)Z,W\rangle = \langle R(X,Y)Z,W\rangle + k(Y,Z)k(X,W) - k(X,Z)k(Y,W), \tag{2}$$

$$\langle \bar{R}(X,Y)N,Z\rangle = (\nabla_X k)(Y,Z) - (\nabla_Y k)(X,Z), \tag{3}$$

where $\bar{R}$ and R denote curvature tensors of g and γ, respectively. Let $(e_a)(a=1,2,3)$ denote a local orthonormal frame on an open neighborhood $\mathcal{O}$ in Σ. Then (e_a,N) is a local orthonormal basis of the tangent space of M at each point of $\mathcal{O}$. Contracting (2) and (3) with respect to this basis one gets

$$\overline{\mathrm{Ric}}(X,Y) + \langle \bar{R}(N,X)Y,N\rangle = \mathrm{Ric}(X,Y) + \tau\langle KX,Y\rangle - \langle KX,KY\rangle, \tag{4}$$

$$\overline{\mathrm{Ric}}(X,N) = (\mathrm{div}\, K)X - X\tau, \tag{5}$$

where $\overline{\mathrm{Ric}}$ and Ric are the Ricci tensors of g and γ, respectively, and $\tau=\mathrm{Tr}\,K=3$ times the mean curvature of Σ. Denoting the scalar curvature and the energy-momentum tensor of the space–time solution of the Einstein's field equations

$$\overline{\mathrm{Ric}} - \frac{\bar{r}}{2}g = 8\pi T \tag{6}$$

by $\bar{r}$ and T, respectively, and using (4)–(6) yields the constraint equations

$$r + \frac{2\tau^2}{3} - |L|^2 = 16\pi T_{nn}, \tag{7}$$

$$(\operatorname{div} L)X - \tfrac{2}{3}X\tau = 8\pi T(X,N), \tag{8}$$

where r is the scalar curvature of γ, $\|$ the norm operator with respect to γ, $L=K-(\tau/3)I$ and $T_{nn}=T(N,N)$.

At this point we assume that (M,g) admits a conformal Killing vector field ξ, i.e.,

$$\mathfrak{L}_{\xi} g = \sigma g \tag{9}$$

for a sufficiently smooth function σ on (M,g), and decompose ξ along Σ as

$$\xi = V + \rho N, \tag{10}$$

where V is the tangential component of ξ. A straightforward calculation using Eqs. (1), (9), and (10) provides

$$\mathfrak{L}_V \gamma = \sigma\gamma - 2\rho k. \tag{11}$$

Next, differentiating $\rho=-g(\xi,N)$ twice along Σ, and following the procedure given on p. 103 of Ref. 18, we obtain

$$(\nabla\,\nabla\,\rho)(X,Y) = \frac{N\sigma}{2}\langle X,Y\rangle + \langle \bar{R}(V,X)Y,N\rangle + \rho\langle \bar{R}(N,X)Y,N\rangle + \frac{\sigma}{2}k(X,Y) - \langle \nabla_Y V, KX\rangle - \rho\langle KX,KY\rangle - \langle \nabla_X KV, Y\rangle. \tag{12}$$

The use of (3) and (4) in the above equation shows

$$\langle (\mathfrak{L}_V K)X,Y\rangle = -(\nabla\,\nabla\,\rho)(X,Y) + \frac{N\sigma}{2}\langle X,Y\rangle - \left(\frac{\sigma}{2} - \rho\tau\right)\langle KX,Y\rangle + \rho\,\mathrm{Ric}(X,Y) - \rho\,\overline{\mathrm{Ric}}(X,Y). \tag{13}$$

Going back to the Einstein's Eqs. (6) we observe that $\bar{r}=8\pi(T_{nn}-T^m_m)$, where $T^m_m=\langle Te_m,e_m\rangle$. The use of (6) in (13) gives rise to

$$(\mathfrak{L}_V K)X = -\nabla_X D\rho + \frac{N\sigma}{2}X + \left(\rho\tau - \frac{\sigma}{2}\right)KX + \rho QX - 8\pi\rho TX + 4\pi\rho(T^m_m - T_{nn})X, \tag{14}$$

where D is the spatial gradient operator, and Q is the Ricci operator of γ, and $\nabla^2=\nabla^a\nabla_a$ (a summed over 1,2,3). Equations (7), (11), and (14) provide the following evolution equations:

$$(\mathfrak{L}_V\gamma)(X,Y) = \sigma\gamma(X,Y) - 2\rho\langle LX,Y\rangle - \frac{2\rho\tau}{3}\gamma(X,Y), \tag{15}$$

$$(\mathfrak{L}_V L)X = -\left(\nabla_X D\rho - \frac{\nabla^2\rho}{3}X\right) - 8\pi\rho\left(TX - \frac{T^m_m}{3}X\right) + \left(\rho\tau - \frac{\sigma}{2}\right)LX + \rho\left(QX - \frac{r}{3}X\right), \tag{16}$$

$$\mathfrak{L}_V\tau = \frac{3N\sigma}{2} - \frac{\sigma\tau}{2} - \nabla^2\rho + \rho\left[\frac{\tau^2}{3} + |L|^2 + 4\pi(T^m_m + T_{nn})\right]. \tag{17}$$

These evolution equations were derived in Ref. 8 through a different approach using Berger's trick[4] that sets the evolution vector field equal to the CKV field.

Let us now define the concept of normal sectional curvature of the space–time with respect to a normal section. A normal section of (M,g) at a point p of a spacelike hypersurface Σ is the timelike plane section spanned by the normal N and a tangential vector, say X, at p. The normal sectional curvature $\bar{K}(N,X)$ of M at a point p and along a unit tangent vector X of Σ is defined as $\langle \bar{R}(N,X)N,X\rangle$ (see p. 331 of Ref. 3 for the definition of sectional curvature of a timelike plane

section). If $\bar{K}(N,X)$ is independent of the choice of X at each point of Σ, then it follows that $\bar{R}(N,X)N=fN$ for some smooth function f and arbitrary vector field X tangent to Σ. This normal sectional curvature condition is a weakening of constant curvature condition for M, and holds when M is Minkowski, de Sitter, anti-de Sitter, and Robertson–Walker space–times. The normal sectional curvature has been termed a principal sectional curvature of the Robertson–Walker space–time by O'Neill (p. 345 of Ref. 16). Next we provide three examples of space–times satisfying this condition.

Example 1: The normal sectional curvature condition holds for generalized Robertson–Walker (GRW) space–times defined by Alias, Romero, and Sanchez in Ref. 1 as the warped product $I\times_f\Sigma$ of the timeline I with an *arbitrary* three-dimensional Riemannian manifold (Σ,γ) through the warping function $f>0$ on I such that the metric of the warped product space–time (M,g) is

$$ds^2=-dt^2+(f(t))^2\gamma_{ab}\,dx^a\,dx^b,$$

where $x^a(a=1,2,3)$ are the coordinates on the fiber Σ. Note that, when (Σ,γ) is of constant curvature; the GRW space–time reduces to the Robertson–Walker space–time. Here $N=\partial/\partial t$. For the GRW space–time, it is known (see p. 210 of Ref. 16) that $\bar{R}(X,N)N$ is a multiple of X, where $\bar{R}$ denotes the curvature tensor of g and X is an arbitrary vector field on the fiber Σ. Each slice $t=$constant, is homothetic to the fiber Σ, and totally umbilical in (M,g).

Example 2: Consider a conformally flat perfect fluid solution of Einstein's equations, admitting a spacelike hypersurface Σ orthogonal to the 4-velocity. In this case the 4-velocity vector is N, the energy-momentum tensor is $T=(\mu+p)N^*N^*+pg$, where N^* denotes the 1-form metrically (g) equivalent to N, and μ,p denote, respectively, the energy density and pressure of the perfect fluid. It turns out, after a straightforward calculation, that $\langle\bar{R}(N,X)N,X\rangle=-(4\pi/3)(\mu+3p)$ for an arbitrary unit vector field X tangent to Σ.

Example 3: Classically, we know that the shape operator K of an (orientable) hypersurface of a space–time of constant curvature (Minkowski, de Sitter, and anti-de Sitter) is a Codazzi tensor, i.e., satisfies $(\nabla_X K)Y=(\nabla_Y K)X$ [which follows from the Codazzi Eq. (3)]. This need not be true for a general ambient space–time. A hypersurface Σ of a space–time (M,g) is said to be Codazzi if its shape tensor is Codazzi. A totally umbilical CMC hypersurface of M is obviously Codazzi. One can also verify that if a three-dimensional space Σ of constant curvature c is a hypersurface of (M,g) with $K=cfI+\nabla Df$ for a smooth function f on Σ, and where D denotes the gradient operator of Σ, then Σ is Codazzi in (M,g). However, the converse holds only locally, i.e., if K is a Codazzi tensor on a space of constant curvature c, then locally, $K=cfI+\nabla Df$, for a smooth function f (see Ref. 9). Now let (M,g) denote a space–time with a closed CKV field ξ, and a spacelike hypersurface Σ such that Σ is Codazzi in (M,g) and ξ is nowhere tangential to Σ. We then have $\bar{\nabla}_{\bar{X}}\xi=\sigma\bar{X}$ for a smooth function σ and arbitrary vector field $\bar{X}$ on M. A straightforward computation shows

$$\bar{R}(\bar{X},\bar{Y})\xi=(\bar{X}\sigma)\bar{Y}-(\bar{Y}\sigma)\bar{X}$$

for arbitrary vector fields $\bar{X}$, $\bar{Y}$ on M. Substituting $\bar{X}=N$, $\bar{Y}=Y$(an arbitrary vector field tangent to Σ), and using the orthogonal splitting $\xi=\rho N+V$ (V being the tangential component of ξ) we have

$$\rho\bar{R}(N,Y)N+\bar{R}(N,Y)V=(N\sigma)Y-(Y\sigma)N$$

on Σ. Taking its inner product with an arbitrary tangent vector field X on Σ, and noting

$$g(\bar{R}(N,Y)V,X)=g(\bar{R}(V,X)N,Y)=0$$

(in view of Codazzi equation and the assumption that Σ is a Codazzi hypersurface), we find

$$\rho g(\bar{R}(N,Y)N,X) = (N\sigma)g(X,Y).$$

As per our assumption, ρ vanishes nowhere on Σ. Hence $\bar{R}(N,Y)N=(N\sigma/\rho)Y$, i.e., the normal sectional curvature of M is independent of the choice of the arbitrary vector field Y at each point of Σ.

III. RESULTS AND THEIR PROOFS

From a cosmological point of view, it makes sense to assume that space–time is spatially homogeneous (e.g., Robertson–Walker, Bianchi I, and Taub-NUT space–times are so) and since a homogeneous Riemannian manifold is complete (see p. 127 of Ref. 3), one may assume that space–time is spatially complete. Recently, Duggal and Sharma[7] considered the Example 3 of the preceding section, with Σ as a totally umbilical CMC hypersurface and proved "*Let* (M,g) *be a space–time evolved out of a complete initial hypersurface* Σ *that is totally umbilical and has nonzero CMC. If M admits a closed CKV field* ξ *nonvanishing on* Σ*, then either* ξ *is orthogonal to* Σ*, or* Σ *is conformally diffeomorphic to* E^3, S^3, H^3*, or the Riemannian product of an open interval and a complete Riemannian 2-manifold*." This result assumes that the CKV field is closed, which implies in view of Example 3, that the normal sectional curvature condition holds. We would like to consider the case when the CKV is not necessarily closed, but the normal sectional curvature condition holds. Omitting the CMC condition, and assuming completeness of Σ we state our first result.

Theorem 1: *Let* (M,g) *be a space–time solution of Einstein's field equations admitting a CKV field* ξ *and be evolved out of a complete spacelike hypersurface* Σ *such that (a)* Σ *is totally umbilical in M, (b) the normal component* ρ *of* ξ *is nonconstant on* Σ*, and (c) the normal sectional curvature of M is independent of the tangential direction at each point of* Σ*. Then* Σ *is conformally diffeomorphic to (i) a 3-sphere* S^3*, or (ii) Euclidean space* E^3*, or (iii) hyperbolic space* H^3*, or (iv) the Riemannian product of a complete two-dimensional manifold and an open real interval. If* Σ *is compact, then only (i) holds.*

Proof: By hypothesis,we have that $\bar{R}(N,X)N=fX$ for some function f and any vector field X tangent to Σ, at each point of Σ. This implies, upon contraction, that $f=(-1/3)\overline{\mathrm{Ric}}(N,N)$. Also, as Σ is totally umbilical, Eq. (4) assumes the form

$$\overline{\mathrm{Ric}}(X,Y) = \mathrm{Ric}(X,Y) + \frac{1}{3}\left(\frac{2\tau^2}{3} - \overline{\mathrm{Ric}}(N,N)\right)\langle X,Y\rangle. \tag{18}$$

Contracting this one gets

$$\bar{r} + 2\,\overline{\mathrm{Ric}}(N,N) = r + \frac{2\tau^2}{3}.$$

Further, (6) implies

$$\bar{r} + 2\,\overline{\mathrm{Ric}}(N,N) = 16\pi T_{nn}.$$

Using (6) in (18) we have

$$8\pi TX = QX + \left(\frac{2\tau^2}{9} - 8\pi T_{nn} + \frac{2\,\overline{\mathrm{Ric}}(N,N)}{3}\right)X.$$

Its trace-free part is

$$8\pi\left(TX - \frac{T_m^m}{3}X\right) = QX - \frac{r}{3}X. \tag{19}$$

By hypothesis, $L=0$, and hence we have from (16) that

$$\nabla_X D\rho = \frac{\nabla^2\rho}{3} X. \tag{20}$$

Now we recall the following result of Kuehnel (pp. 133 and 135 of Ref. 13) "Let (Σ, g) be a complete connected n-dimensional Riemannian manifold admitting a nonconstant solution ρ of $\nabla\nabla\rho = (\nabla^2\rho/n)g$. Then the number of critical points of ρ is $N \leqslant 2$, and Σ is conformally diffeomorphic to (i) the sphere (S^n, g_1) if $N=2$, (ii) the Euclidean space (E^n, g_0) or hyperbolic space (H^n, g_{-1}) if $N=1$, and (iii) the Riemannian product of an $(n-1)$-dimensional Riemannian manifold and an open real interval, if $N=0$. In case when Σ is compact, only (i) holds." According to our hypothesis, ρ is nonconstant. Since ρ satisfies Eq. (20), the above result is applicable and therefore applying it completes the proof.

Our next result assumes the existence of a compact spacelike CMC hypersurface. This is well motivated because such hypersurfaces have been shown to exist in a Lorentzian manifold by Gerhardt.[11] Before stating our next result we state the following lemma.

Lemma: Let (M, g) be a space–time manifold admitting a CKV field ξ and be evolved out of a compact spacelike CMC hypersurface Σ such that the normal vector field to Σ is an eigenvector of the Ricci tensor of M, at each point of Σ and ξ is nonvanishing and nowhere tangent to Σ. Then Σ is totally umbilical in M.

This lemma is the Lorentzian analog and a slight extension of the corresponding result of Katsurada[12] for an Einstein Riemannian (M, g), and its proof is similar to that of the Riemannian case.

Before stating our main theorem we would like to recall the following notions. The geometrodynamic field momentum dynamically conjugate to the geometrodynamic field coordinate g_{ab} is defined as $\pi^{ab} = \gamma^{1/2}(K^{ab} - \tau\gamma^{ab})$. The supermomentum in the ADM formalism is defined as $\mathcal{H}^a = 2\nabla_b[\sqrt{\gamma}(\tau\gamma^{ab} - K^{ab})]$, where γ is the determinant of the 3-metric γ_{ab} and ∇ acts a covariant derivative of a tensor density (see p. 521 of Ref. 15 for details). Our main result is as follows.

Theorem 2: *Let (M, g) be a space–time solution of Einstein's equations admitting a CKV field ξ and evolved out of a compact spacelike CMC hypersurface Σ such that (i) the supermomentum $\mathcal{H}^a$ vanishes on Σ, (ii) the normal component ρ of ξ is nonvanishing and nonconstant on Σ, and (iii) the normal sectional curvature of M is independent of the tangential direction at each point of Σ. Then Σ is totally umbilical in M, and conformally diffeomorphic to the 3-sphere.*

Proof: As $\mathcal{H}^a = 0$ on Σ, it follows that

$$\nabla_a\tau - \nabla_b K^b_a = 0.$$

In view of this and Eq. (5) we observe that N is an eigenvector of the Ricci tensor of (M, g) at each point of Σ. Hence the lemma stated above is applicable here and hence Σ is totally umbilical. Now Theorem 1 becomes applicable and hence Σ being compact, is conformally diffeomorphic to S^3. This completes the proof.

Remark: The metrics of Σ in the conclusions of Theorems 1 and 2 can be expressed as

$$du^2 + (\rho'(u))^2\, d\psi^2,$$

globally for case (iv), and except at critical points of ρ for cases (i), (ii), and (iii); where $d\psi^2$ denotes the metric of the complete two-dimensional space orthogonal to $\partial/\partial u$ (for details see Ref. 13). Also, one may note that Σ is quasi-Einstein, because the Ricci tensor of $d\psi^2$ (which is the metric of a two-dimensional Riemannian manifold S) is just a scalar multiple of its metric.

IV. CONFORMAL SYMMETRIES OF GRW SPACE–TIMES.

Let ξ be a CKV field on a generalized Robertson–Walker space–time (M, g), as described in Example 1. Setting $\xi = \rho\,\partial/\partial t + V^a\,\partial/\partial x^a$ (where x^a are the coordinates on the fiber Σ), and decomposing the CKV equations into normal–normal components [note that $\partial/\partial t$ is the unit timelike vector normal to spacelike slice $\Sigma_t(t = \text{constant})$] we find that

$$\sigma = 2\,\partial\rho/\partial t. \tag{21}$$

Similarly, decomposing the CKV equation into tangential–normal, and tangential–tangential components gives

$$\partial\rho/\partial x^a = f^2(\partial V^b/\partial t)\gamma_{ab}, \tag{22}$$

$$\mathfrak{L}_V\gamma_{ab} = \left(\sigma - 2\frac{\rho}{f}\,\partial f/\partial t\right)\gamma_{ab}. \tag{23}$$

If $V=0$, i.e., ξ is orthogonal to the slices Σ_t, then from (22) ρ is a function of only t and from (21) we have $\sigma=2\dot{\rho}$, where an overdot means derivative with respect to t. Using this expression of σ in (23), and noting that $V=0$, shows $\dot{\rho}=(\dot{f}/f)\rho$. Integrating it provides $\rho=cf$ for an arbitrary constant c, and hence we obtain $\xi=cf\,\partial/\partial t$. This is the well known[14] timelike CKV normal to the slices Σ_t of a Robertson–Walker space–time. On the other hand, if $\rho=0$, i.e., ξ is tangent to each slice Σ_t, then from Eq. (21) it follows that $\sigma=0$, i.e., ξ is Killing on (M,g). *This generalizes the fact* (see Ref. 14) *that the CKV fields that are tangential to the constant curvature slices* Σ_t *of a Robertson–Walker space–time, are Killing*. More generally, if ρ is a function of only spatial coordinates x^a, then (21) implies $\sigma=0$ and hence ξ is Killing, though ξ is not tangential to Σ_t. Now suppose that ρ is a function of only t, i.e., constant on each slice Σ_t. Then Eq. (22) shows that V^a are functions of only x^a, and hence Eqs. (21) and (23) show that $\dot{\rho}-(\dot{f}/f)\rho=c_1$(a constant). Solving this linear equation provides

$$\rho = f(t)\left(c_1\int_{t_0}^{t}\frac{1}{f(\tau)}\mathrm{d}\tau + c_2\right), \tag{24}$$

where c_2 is an arbitrary constant. The value of σ is gotten by using this expression of ρ in (21). *If* ρ *is a nonvanishing function of all the four coordinates* t,x^a, *then from Theorem 1 (note that all the hypotheses of Theorem 1 are satisfied by GRW space–times) it follows that each slice is conformally diffeomorphic to one of the model spaces mentioned in the conclusion of Theorem 1, and has the line element* $du^2+(\rho'(u))^2\,d\psi^2$ *where* $d\psi^2$ *is the 2-metric orthogonal to* $\partial/\partial u$. *This does compare with the line element of the spatial slice of the Robertson–Walker space–time where the 2-metric* $d\psi^2$ *is the standard metric of the unit 2-sphere*. Finally we note that if the GRW space–time admits a maximal conformal group G_{15}, then it is conformally flat, and hence Σ has constant curvature, i.e., GRW space–time reduces to Robertson–Walker space–time.

V. CONCLUDING REMARKS

In the hypotheses of Theorems 1 and 2, we have assumed that the normal component ρ of the CKV field ξ is nonvanishing and nonconstant on Σ. If we just assume that (M,g) is a space–time admitting a CKV field ξ and a spacelike hypersurface Σ such that ρ is zero, i.e., ξ is everywhere tangential to Σ, then we observe from Eqs. (11) and (16) that V is conformal on Σ and L is preserved by V up to the factor $-\sigma/2$. Next, suppose that a space–time solution (M,g) of Einstein's equations admits a CKV field ξ and a totally umbilical spacelike hypersurface Σ such that the normal component ρ of ξ is a nonzero constant on Σ. Then one can show using Eqs. (3), (9), and (12) that $\langle\bar{R}(N,X)N,X\rangle=-4\pi/3(T_{nn}+T^m_m)$ for any unit tangent vector field X on Σ, i.e., the normal sectional curvature of M is independent of the tangential direction at each point of Σ. Conversely, this consequence need not imply that ρ is constant on Σ. This intrigued us to include this normal sectional curvature condition as a hypothesis in Theorems 1 and 2. This is further motivated by the fact that the normal sectional curvature condition holds for GRW space–times.

Exact solutions with noncommutative symmetries in Einstein and gauge gravity

Sergiu I. Vacaru[a)]
Instituto de Matematicas y Fisica Fundamental, Consejo Superior de Investigaciones Cientificas, Calle Serrano 123, Madrid 28006, Spain

(Received 27 July 2004; accepted 22 December 2004; published online 21 March 2005)

We present new classes of exact solutions with noncommutative symmetries constructed in vacuum Einstein gravity (in general, with nonzero cosmological constant), five-dimensional (5D) gravity and (anti) de Sitter gauge gravity. Such solutions are generated by anholonomic frame transforms and parametrized by generic off-diagonal metrics. For certain particular cases, the new classes of metrics have explicit limits with Killing symmetries but, in general, they may be characterized by certain anholonomic noncommutative matrix geometries. We argue that different classes of noncommutative symmetries can be induced by exact solutions of the field equations in commutative gravity modeled by a corresponding moving real and complex frame geometry. We analyze two classes of black ellipsoid solutions (in the vacuum case and with cosmological constant) in four-dimensional gravity and construct the analytic extensions of metrics for certain classes of associated frames with complex valued coefficients. The third class of solutions describes 5D wormholes which can be extended to complex metrics in complex gravity models defined by noncommutative geometric structures. The anholonomic noncommutative symmetries of such objects are analyzed. We also present a descriptive account how the Einstein gravity can be related to gauge models of gravity and their noncommutative extensions and discuss such constructions in relation to the Seiberg–Witten map for the gauge gravity. Finally, we consider a formalism of vielbeins deformations subjected to noncommutative symmetries in order to generate solutions for noncommutative gravity models with Moyal (star) product. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1869538]

I. INTRODUCTION

In the last 15 years much effort has been made to elaborate a consistent formulation of noncommutative gravity theory generalizing the standard Einstein theory but up to now the problem is quite difficult to approach (see, for instance, Refs. 1–8 for details related to existing models). The proposed theories are for the spaces with Euclidean signatures, and, in general, result in models of complex gravity in noncommutative spaces provided with complex and/or nonsymmetric metrics and anholonomic frames. There were also derived some effective noncommutative gravity models from string/brane theory, by considering quantum group structures and/or by proposing noncommutative gaugelike generalizations of gravity.

In this paper, we pursue the idea that noncommutative geometric structures are present in the Einstein, five-dimensional (in brief, 5D) gravity and gauge gravity models. Such noncommutative symmetries are emphasized if the anholonomic moving frames[9–12] are introduced into consideration. This hidden noncommutativity is nontrivial for various classes of generic off-diagonal metrics admitting effective diagonalizations by anholonomic transforms with associated nonlinear connection structure.[13–19] The metrics may be subjected to the condition to define exact solutions

[a)]Electronic mail: vacaru@imaff.cfmac.csic.es and sergiu_vacaru@yahoo.com

of the vacuum field equations with certain possible extensions to matter sources. The noncommutative anhlonomic geometries can be derived even from the commutative general relativity theory and admit a natural embedding into different models of complex noncommutative gravity. The metric and frame (vielbein) coefficients corresponding to off-diagonal solutions depend on two, three or four variables and define space–times with associated noncommutative symmetries. Such classes of exact solutions are very different from the well-known examples of metrics with Killing symmetry (like the Schwarzschild or Kerr–Newmann solutions; see a detailed analysis in Ref. 20).

Our aim is to prove, by constructing and analyzing three classes of exact solutions, that certain noncommutative geometric structures can be defined in the framework of the Einstein (in general, with the cosmological term) and 5D gravity. We emphasize classes of anholonomic real and complex deformations of metrics possessing associated noncommutative symmetries. Contrary to other approaches to noncommutative gravity and field interactions theory elaborated by substituting the commutative algebras of functions with noncommutative algebras and/or by postulating any complex noncommutative relations for coordinates, we try to derive noncommutative structures from associated symmetries of metrics and frames subjected to anholonomy relations. We shall propose a classification of such space–times and state a method of complexification of exact solutions preserving the noncommutative symmetry for black hole and wormhole metrics in real and complex gravity.

The study of anholonomic noncommutative symmetries of gravitational field interactions is more involved in the moving frame formalism conventionally adapted to equivalent redefinitions of the Einstein equations as Yang–Mills equations for nonsemisimple gauge groups like in the Poincare gauge gravity.[21,22] This construction has direct generalizations to various type of gauge gravity models with nondegenerate metrics in the total bundle spaces, in both commutative and noncommutative forms.[23–29,6] The connection between the general relativity theory and gauge gravity models is emphasized in order to apply and compare with a set of results from noncommutative gauge theory.

Among our static solutions we find geometries having a structure as have Schwarzschild, Reissner–Nordstrem, and (anti) de Sitter spaces but with the coefficients redefined (with certain polarization constants) with respect to anholonomic real/complex frames which make possible definition of such objects in noncommutative models of gravity. There are equally interesting applications to black hole physics, quantum gravity, and string gravity.

Next, the emerged anholonomic noncommutative symmetries of off-diagonal metrics prescribe explicit rules of deformation the solutions on small noncommutative parameters and connect the results to quantum deformations of gravity and gauge models. So, even a generally accepted version of noncommutative gravity theory has been not yet formulated, we know how to generate particular classes of real and complex stable metrics with noncommutative symmetries and possessing properties very similar to the usual black hole and wormhole solutions. In particular, we present a systematic procedure for constructing exact solutions both in commutative and noncommutative gravity models, to define black hole and wormhole objects with noncommutative symmetries and quantum corrections. We are able to investigate the physical properties of such objects subjected to certain classes of anholonomic and/or quantum deformations.

The paper is organized as follows.

We begin in Sec. II with a brief introduction into the geometry of space–times provided with anholonomic frame structure and associated nonlinear connections. Such geometries are characterized by corresponding anholonomy relations induced by nonlinear connection coefficients related to certain off-diagonal metric components. This also induces a corresponding noncommutative space–time structure.

In Sec. III, we illustrate that such noncommutative anholonomic geometries can be associated even to real space–times and that a simple realization holds within the algebra for complex matrices. We emphasize that a corresponding noncommutative differential calculus can be derived from the anholonomy coefficients deforming the structure constants of the related Lie algebras.

Section IV is devoted to a rigorous analysis of two classes of static black ellipsoid solutions [the first and second type metrics defining, respectively, four-dimensional (4D) vacuum Einstein

and induced by cosmological constant configurations]. We prove that such metrics can be complexified in order to admit associated complex frame/nonlinear connection structures inducing noncommutative matrix geometries and show how analytic extensions of such real and complexified space–times can be constructed.

In Sec. V, a class of 5D wormhole solutions with anisotropic elliptic polarizations is considered for the 5D gravity. We argue that such generic off-diagonal metrics may be also complexified as to preserve the wormhole configurations being additionally characterized by complex valued coefficients for the associated nonlinear connection. Such objects possess the same noncommutative symmetry for both types of real and complex solutions.

Section VI is a discussion of how the Einstein gravity and its higher dimension extensions can be incorporated naturally into commutative and noncommutative gauge models. A new point is that the proposed geometric formalism is elaborated in order to include anholonomic complex vielbeins.

In Sec. VII, we define the Seiberg–Witten map for the de Sitter gauge gravity and state a prescription how the exact solutions possessing anholonomic noncommutative symmetries can be adapted to deformations via star products with noncommutative relations for coordinates.

We conclude and discuss the results in Sec. VIII. For convenience, we summarize the necessary results from Refs. 13–19 and 30–32 in Appendixes A–C and state some definitions on "star" products and enveloping algebras in Appendix D.

II. OFF-DIAGONAL METRICS AND ANHOLONOMIC FRAMES

We consider a $(n+m)$-dimensional space–time manifold V^{n+m} provided with a (pseudo) Riemannian metric $\mathbf{g}=\{g_{\mu\nu}\}$ and denote the local coordinates $u=(x,y)$, or in component form, $u^{\alpha}=(x^i,y^a)$, where the greek indices are conventionally split into two subsets, $x=\{x^i\}$ and $y=\{y^a\}$, labelled, correspondingly, by italic indices of type $i,j,k,\ldots=1,2,\ldots,n$, and $a,b,\ldots=1,2,\ldots,m$. In general, the geometric objects on such space–times may possess some nontrivial Killing symmetries (the Killing case is emphasized by the condition $L_X\mathbf{g}=0$, where L_X is the Lie derivative with respect to a vector field X on V^{n+m}, see, for instance, Ref. 20) or some deformations of such symmetries, for instance, by frame transforms. The space–times may have some additional frame structures with associated nonlinear connection, bundle structure, and even nontrivial torsions being adapted to the frame structure.

We shall define our constructions for a general metric ansatz of type

$$\mathbf{g}=g_{\mu\nu}\delta u^{\mu}\otimes\delta u^{\nu}=g_{ij}(x^k)\mathrm{d}x^i\otimes\mathrm{d}x^j+h_{ab}(x^k,v)\delta y^a\otimes\delta y^b \tag{1}$$

with respect to a locally adapted basis $[\mathrm{d}x^i,\delta y^a]$, where the Einstein's summation rule is applied and by v we emphasize the dependence on a so-called anisotropic coordinate from the set $\{y^a\}$. The local basis

$$e^{\mu}_{[N]}=\delta^{\mu}=\delta u^{\mu}=[\mathrm{d}x^i,\delta y^a]=[\mathrm{d}x^i,\mathrm{d}y^a=\mathrm{d}y^a+N^a_i(x^k,v)\mathrm{d}x^i] \tag{2}$$

(called to be N-elongated; we shall provide an additional index $[N]$ if necessary to distinguish such objects) is dual to the local basis

$$e^{[N]}_{\alpha}=\delta_a=\frac{\delta}{\delta u^a}=\left[\frac{\delta}{\partial x^i}=\frac{\partial}{\partial x^i}-N^a_i(x^k,v)\frac{\partial}{\partial y^a},\frac{\partial}{\partial y^b}\right]. \tag{3}$$

We consider an off-diagonal metric ansatz for (1) having the components

$$\hat{g}_{\alpha\beta}=\begin{bmatrix} g_{ij}+N^a_iN^b_jh_{ab} & N^e_jh_{ae} \\ N^e_ih_{be} & h_{ab}\end{bmatrix}. \tag{4}$$

So, we can write equivalently $\mathbf{g}=\hat{g}_{\alpha\beta}\,\mathrm{d}u^{\alpha}\,\mathrm{d}u^{\beta}$ if the metric is rewritten with respect to the local dual coordinate basis $\mathrm{d}u^{\mu}=[\mathrm{d}x^i,\mathrm{d}y^a]$, the dual to $\partial/\partial u^{\alpha}=[\partial/\partial x^i,\partial/\partial y^b]$ (defined correspondingly by usual partial derivatives and differentials).

A very surprising fact is that the off-diagonal metric ansatz (4) for dimensions $n+m=3,4,5$ and certain imbedding of such configurations in extra dimension (super) spaces results in completely integrable systems of partial differential equations (see details in Refs. 13–19 with a review of results in Refs. 30 and 31 and Theorems 1–3 in Appendix B). In this paper, we shall consider that any metric (4), or equivalently (1) and frames (vielbeins) (2) and (3), parametrizes an exact solution of the Einstein equations in a commutative gravity theory.

Let us state the main geometric properties of space–times provided with off-diagonal metrics which can be effectively diagonalized with respect to the *N*-elongated frames (2) and (3).

(1) Such space–times are characterized by certain anholonomic frame relations (anholonomy conditions)

$$e_{\alpha}^{[N]}e_{\beta}^{[N]}-e_{\beta}^{[N]}e_{\alpha}^{[N]}=w_{\alpha\beta}^{[N]\gamma}e_{\gamma}^{[N]} \tag{5}$$

with some nontrivial anholonomy coefficients $w_{\alpha\beta}^{[N]\gamma}$ computed as

$$w^{k}{}_{ij}=0,\ w^{k}{}_{aj}=0,\quad w^{k}{}_{ab}=0,\ w^{c}{}_{ab}=0,$$

$$w^{a}{}_{bj}=-w^{a}{}_{jb}=\partial_{b}N_{j}^{a},\quad w^{a}{}_{ij}=-\Omega_{ij}^{a}=\delta_{i}N_{j}^{a}-\delta_{j}N_{i}^{a} \tag{6}$$

(we shall omit the label $[N]$ if this will not result in any confusion; as a matter of principle, we can consider arbitrary anholonomy coefficients not related to any off-diagonal metric terms). If the values $w_{\alpha\beta}^{[N]\gamma}$ do not vanish, it is not possible to diagonalize the metric (4) by any coordinate transforms: such space–times are generic off diagonal. The holonomic frames (in particular the coordinate ones) consist of a subclass of vielbeins with vanishing anholonomy coefficients.

(2) To any frame (vielbein) transform defined by the coefficients of $e_{\alpha}^{[N]}$ decomposed with respect to usual coordinate frames, we can associate a nonlinear connection structure (in brief, *N* connection) **N** with the coefficients $\{N_{j}^{a}\}$ [in global form the *N* connection was defined in Ref. 33 by developing previous ideas from Finsler geometry,[9–12,34–36] investigated in details for vector bundle spaces in Refs. 37 and 38; see also Refs. 13–19 and 30–32 on definition of such objects in (pseudo) Riemannian and Riemann–Cartan–Weyl geometry or on superspaces]. Here we note that the *N*-connection structure is characterized by its curvature (*N* curvature) $\Omega=\{\Omega_{ij}^{a}\}$ with the coefficients computed as in (6). The well-known class of linear connections is to be distinguished as a particular case when $N_{j}^{a}(x,y)=\Gamma_{jb}^{a}(x)y^{b}$. On (pseudo) Riemannian spaces, the *N* connection is a geometric object completely defined by anholonomic frames when the vielbein transforms $e_{\alpha}^{[N]}$ are parametrized explicitly via certain values $(N_{i}^{a},\delta_{i}^{j},\delta_{b}^{a})$, where δ_{i}^{j} and δ_{b}^{a} are the Kronecker symbols, like in (3).

(3) The *N* coefficients define a conventional global horizontal–vertical (in brief, $h-v$) splitting of space–time V^{n+m} into holonomic–anholonomic subsets of geometrical objects labeled by *h* components with indices $i,j,\ldots$ and *v* components with indices $a,b,\ldots$; see details in Refs. 13–19 and 30–32. The necessary formulas for the $h-v$ decompositions of the curvature, Ricci and Einstein tensors are contained in Appendix A.

(4) Such generic "off-diagonal" space–times may be characterized by the so-called canonical *N*-adapted linear connection $\Gamma^{[c]}=\{L^{i}{}_{jk},L^{a}{}_{bk},C^{i}{}_{jc},C^{a}{}_{bc}\}$ satisfying the metricity condition $D_{\gamma}^{[c]}g_{\alpha\beta}=0$ and being adapted to the $h-v$ distribution. The coefficients of $\Gamma^{[c]}$ are

$$L^{i}{}_{jk}=\tfrac{1}{2}g^{in}(\delta_{k}g_{nj}+\delta_{j}g_{nk}-\delta_{n}g_{jk}),$$

$$L^{a}{}_{bk}=\partial_{b}N_{k}^{a}+\tfrac{1}{2}h^{ac}(\delta_{k}h_{bc}-h_{dc}\partial_{b}N_{k}^{d}-h_{db}\partial_{c}N_{k}^{d}), \tag{7}$$

$$C^i_{jc} = \tfrac{1}{2} g^{ik} \partial_c g_{jk}, \quad C^a_{bc} = \tfrac{1}{2} h^{ad} (\partial_c h_{db} + \partial_b h_{dc} - \partial_d h_{bc}),$$

where $\delta_k = \delta / \partial x^k$ and $\partial_c = \partial / \partial y^a$; they are constructed from the coefficients (and their partial derivatives) of the metric and N connection. This connection is an anholonomic deformation (by N coefficients) of the Levi–Civita connection.

(5) The torsion of the connection $\Gamma^{[c]}$ is defined (for simplicity, we omit the label $[c]$)

$$T^\alpha_{\beta\gamma} = \Gamma^\alpha_{\beta\gamma} - \Gamma^\alpha_{\gamma\beta} + w^\alpha_{\beta\gamma}, \tag{8}$$

with $h-v$ components

$$T^i_{.jk} = T^i_{jk} = L^i_{jk} - L^i_{kj} = 0 \quad \text{in the canonical case,}$$

$$T^a_{.bc} = S^a_{.bc} = C^a_{bc} - C^a_{cb} = 0 \quad \text{in the canonical case,} \tag{9}$$

$$T^i_{.ja} = 0, \quad T^i_{ja} = -T^i_{aj} = -C^i_{ja}, \quad T^a_{.ij} = -\Omega^a_{ij}, \quad T^a_{.bi} = -T^a_{.bi} = \partial_b N^a_i - L^a_{.bi}.$$

The nonvanishing components of torsion are induced as an anholonomic frame effect which is obtained by vielbien transforms (2) and (3) even for a (pseudo) Riemannian metric (4). In this paper, we shall also consider some nontrivial torsion structures existing in extra dimension gravity.

(6) By straightforward calculations with respect to the frames (2) and (3) (see for instance, Refs. 39 and 40) we can compute the coefficients of the Levi–Civita connection ∇, i.e., $\Gamma^{[\nabla]}_{\alpha\beta\gamma} = g(e^{[N]}_\alpha, \nabla_\gamma e^{[N]}_\beta) = g_{\alpha\tau} \Gamma^{[\nabla]\tau}_{\beta\gamma}$, satisfying the metricity condition $\nabla_\gamma g_{\alpha\beta} = 0$ for $g_{\alpha\beta} = (g_{ij}, h_{ab})$,

$$\Gamma^{[\nabla]}_{\alpha\beta\gamma} = \tfrac{1}{2} (e^{[N]}_\beta g_{\alpha\gamma} + e^{[N]}_\gamma g_{\beta\alpha} - e^{[N]}_\alpha g_{\gamma\beta} + g_{\alpha\tau} w^\tau{}_{\gamma\beta} + g_{\beta\tau} w^\tau{}_{\alpha\gamma} - g_{\beta\tau} w^\tau{}_{\beta\alpha}).$$

Using the values (6) and (3), we can write

$$\Gamma^{[\nabla]\tau}_{\beta\gamma} = \left\{ L^i_{jk}, L^a_{bk} + \frac{\partial N^a_k}{\partial y^b}, C^i_{jc} + \frac{1}{2} g^{ik} \Omega^a_{jk} h_{ca}, C^a_{bc} \right\}. \tag{10}$$

Comparing the coefficients of $\Gamma^{[c]}$ and $\Gamma^{[\nabla]}$, we conclude that both connections have the same coefficients with respect to the N-adapted frames (2) and (3) if and only if $\partial N^a_k / \partial y^b = 0$ and $\Omega^a_{jk} = 0$.

(7) The ansatz of type (4) have been largely used in Kaluza–Klein theories (see, for instance, Refs. 41–43). For the corresponding compactifications, the coefficients N^a_i may be associated to the potential of certain gauge fields but, in general, they belong to some noncompactified metric and vielbein gravitational fields. There were elaborated general methods for constructing exact solutions without compactification and arbitrary N^a_i in various types of gravity models.[13–19]

Any ansatz of type (4) with the components satisfying the conditions of the Theorems 1–3 from Appendix B define a new class of exact solutions, vacuum and nonvacuum ones, in three- through five-dimensional gravity parametrized by generic off-diagonal metrics with the coefficients depending on two, three or even four variables. These solutions can be constructed in explicit form by using corresponding boundary and symmetry conditions following the so-called anholonomic frame method elaborated and developed in Refs. 13–19, 30, and 31 (for instance, they can describe black elipsoid/tori configurations, two- through three-dimensional solitonic–spinor–dilaton interactions, polarized wormhole/flux tube solutions, locally anisotropic Taub NUT space–times and so on).

Perhaps, by using the anholonomic frame method, we can construct the most general known class of exact solutions in Einstein gravity and its extra dimension and string generalizations. From a formal point of view, we can use superpositions of anholonomic maps in order to construct integral varieties of the Einstein equations with the metric/frame coefficients being functions of necessary smooth class depending on arbitrary number of variables but parametrized as products

of functions depending on one, two, three, and four real, or some complex, variables with real and complex valued functions. The physical meaning of such classes of solutions should be stated following explicit physical models. We note that the bulk of the well-known black hole and cosmological solutions (for instance, the Schwarzschild, Kerr–Newman, Reissner–Nordström, and Friedmann–Roberston–Walker solutions) are with metrics being diagonalizable by coordinate transforms and depending only on one variable (radial or timelike), with imposed spherical or cylindrical symmetries and subjected to the conditions of Killing symmetry being asymptotically flat.

In general, the solutions with anholonomic configurations do not possess Killing symmetries (for instance, they are not restricted by "black hole uniqueness theorems," proved for Killing space–times satisfying corresponding asymptotic conditions, see details and references in Ref. 20) but have new properties like the (1)–(7) stated above. There is a subclass of off-diagonal solutions resulting in corresponding limits into the well-known asymptotically flat space–times, or with (anti) de Sitter symmetries.[13–19,30,31] We are interested to investigate possible symmetries of such non-Killing exact solutions.

The purpose of the next section is to prove that the space–times with a nontrivial anholonomic and associated N-connection structure possess a natural noncommutative symmetry.

III. ANHOLONOMIC NONCOMMUTATIVE STRUCTURES

We shall analyze two simple realizations of noncommutative geometry of anholonomic frames within the algebra of complex $k\times k$ matrices, $M_k(\mathrm{IC},u^\alpha)$ depending on coordinates u^α on space–time V^{n+m} connected to complex Lie algebras SL (k,IC) and SU_k. We shall consider matrix valued functions of a necessary smooth class derived from the anholonomic frame relations (5) (being similar to the Lie algebra relations) with the coefficients (6) induced by off-diagonal metric terms in (4) and by N-connection coefficients N_i^a. We shall use algebras of complex matrices in order to have the possibility for some extensions to complex solutions. Usually, for commutative gravity models, the anholonomy coefficients $w_{\alpha\beta}^{[N]\gamma}$ are real functions but in Sec. VII we shall consider also complex space–times related to noncommutative gravity.[3–5]

We start with the basic relations for the simplest model of noncommutative geometry realized with the algebra of complex $(k\times k)$ noncommutative matrices,[44], $M_k(\mathrm{IC})$. An element $M\in M_k(\mathrm{IC})$ can be represented as a linear combination of the unit $(k\times k)$ matrix I and (k^2-1) Hermitian traceless matrices $q_{\underline{\alpha}}$ with the underlined index $\underline{\alpha}$ running values $1,2,\ldots,k^2-1$, i.e.,

$$M=\alpha I+\sum\beta^{\underline{\alpha}}q_{\underline{\alpha}}$$

for some constants α and $\beta^{\underline{\alpha}}$. It is possible to choose the basis matrices $q_{\underline{\alpha}}$ satisfying the relations

$$q_{\underline{\alpha}}q_{\underline{\beta}}=\frac{1}{k}\rho_{\underline{\alpha}\underline{\beta}}I+Q_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}q_{\underline{\gamma}}-\frac{i}{2}f^{\underline{\gamma}}{}_{\underline{\alpha}\underline{\beta}}q_{\underline{\gamma}}, \tag{11}$$

where $i^2=-1$ and the real coefficients satisfy the properties

$$Q_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}=Q_{\underline{\beta}\underline{\alpha}}^{\underline{\gamma}},\quad Q_{\underline{\gamma}\underline{\beta}}^{\underline{\gamma}}=0,\quad f^{\underline{\gamma}}{}_{\underline{\alpha}\underline{\beta}}=-f^{\underline{\gamma}}{}_{\underline{\beta}\underline{\alpha}},\quad f^{\underline{\gamma}}{}_{\underline{\gamma}\underline{\alpha}}=0$$

with $f^{\underline{\gamma}}{}_{\underline{\alpha}\underline{\beta}}$ being the structure constants of the Lie group SL (k,IC) and the Killing–Cartan metric tensor $\rho_{\underline{\alpha}\underline{\beta}}=f^{\underline{\tau}}{}_{\underline{\alpha}\underline{\gamma}}f^{\underline{\gamma}}{}_{\underline{\tau}\underline{\beta}}$. The interior derivatives $\hat{\partial}_{\underline{\gamma}}$ of this algebra can be defined as

$$\hat{\partial}_{\underline{\gamma}}q_{\underline{\beta}}=ad(iq_{\underline{\gamma}})q_{\underline{\beta}}=i[q_{\underline{\gamma}},q_{\underline{\beta}}]=f^{\underline{\alpha}}{}_{\underline{\gamma}\underline{\beta}}q_{\underline{\alpha}}. \tag{12}$$

Following the Jacobi identity, we obtain

$$\hat{\partial}_{\underline{\alpha}}\hat{\partial}_{\underline{\beta}}-\hat{\partial}_{\underline{\beta}}\hat{\partial}_{\underline{\alpha}}=f^{\underline{\gamma}}{}_{\underline{\alpha}\underline{\beta}}\hat{\partial}_{\underline{\gamma}}. \tag{13}$$

Our idea is to construct a noncommutative geometry starting from the anholonomy relations of frames (5) by adding to the structure constants $f^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$ the anholonomy coefficients $w^{[N]\tau}_{\alpha\gamma}$ (6). Such deformed structure constants consist from N-connection coefficients N^a_i and their first partial derivatives, i.e., they are induced by some off-diagonal terms in the metric (4) being a solution of the gravitational field equations. We note that there is a rough analogy between formulas (13) and (5) because the anholonomy coefficients do not satisfy, in general, the condition $w^{[N]\tau}_{\tau\alpha}=0$. There is also another substantial difference, the anholonomy relations are defined for a manifold of dimension $n+m$, with greek indices $\alpha,\beta,\ldots$ running values from 1 to $n+m$ but the matrix noncommutativity relations are stated for traceless matrices labeled by underlined indices $\underline{\alpha},\underline{\beta}$, running values from 1 to k^2-1. It is not possible to satisfy the condition $k^2-1=n+m$ by using integer numbers for arbitrary $n+m$. We suggest to extend the dimension of space–time from $n+m$ to any $n'\geqslant n$ and $m'\geqslant m$ when the condition $k^2-1=n'+m'$ can be satisfied by a trivial embedding of the metric (4) into higher dimension, for instance, by adding the necessary number of unities on the diagonal by writing

$$\hat{g}_{\underline{\alpha}\underline{\beta}}=\begin{bmatrix} 1 & \cdots & 0 & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & \cdots & 1 & 0 & 0 \\ 0 & \cdots & 0 & g_{ij}+N^a_iN^b_jh_{ab} & N^e_jh_{ae} \\ 0 & \cdots & 0 & N^e_ih_{be} & h_{ab} \end{bmatrix}$$

and $e^{[N]}_{\underline{\alpha}}=\delta_{\underline{\alpha}}=(1,1,\ldots,e^{[N]}_{\alpha})$, where, for simplicity, we preserve the same type of underlined greek indices, $\underline{\alpha},\underline{\beta},\ldots=1,2,\ldots,k^2-1=n'+m'$. The anholonomy coefficients $w^{[N]\gamma}_{\alpha\beta}$ can be extended with some trivial zero components and for consistency we rewrite them without labeled indices, $w^{[N]\gamma}_{\alpha\beta}\to W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$. The set of anholonomy coefficients $w^{[N]\gamma}_{\alpha\beta}$ (6) may result in degenerated matrices, for instance for certain classes of exact solutions of the Einstein equations. Nevertheless, we can consider an extension $w^{[N]\gamma}_{\alpha\beta}\to W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$ when the coefficients $w^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}(u^{\underline{\tau}})$ for any fixed value $u^{\underline{\tau}}=u^{\underline{\tau}}_{[0]}$ would be some deformations of the structure constants of the Lie algebra SL (k,IC), like

$$W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}=f^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}+w^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}, \tag{14}$$

being nondegenerate.

Instead of the matrix algebra $M_k(\mathrm{IC})$, constructed from constant complex elements, we shall consider dependencies on coordinates $u^{\underline{\alpha}}=(0,\ldots,u^{\alpha})$, for instance, like a trivial matrix bundle on $V^{n'+m'}$, and denote this space $M_k(\mathrm{IC},u^{\underline{\alpha}})$. Any element $B(u^{\underline{\alpha}})\in M_k(\mathrm{IC},u^{\underline{\alpha}})$ with a noncommutative structure induced by $W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$ is represented as a linear combination of the unit $(n'+m')\times(n'+m')$ matrix I and the $[(n'+m')^2-1]$ Hermitian traceless matrices $q_{\underline{\alpha}}(u^{\underline{\tau}})$ with the underlined index $\underline{\alpha}$ running values $1,2,\ldots,(n'+m')^2-1$,

$$B(u^{\underline{\tau}})=\alpha(u^{\underline{\tau}})I+\sum\beta^{\underline{\alpha}}(u^{\underline{\tau}})q_{\underline{\alpha}}(u^{\underline{\tau}})$$

under condition that the following relation holds:

$$q_{\underline{\alpha}}(u^{\underline{\tau}})q_{\underline{\beta}}(u^{\underline{\gamma}})=\frac{1}{n'+m'}\rho_{\underline{\alpha}\underline{\beta}}(u^{\underline{\nu}})+Q^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}q_{\underline{\gamma}}(u^{\underline{\mu}})-\frac{i}{2}W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}q_{\underline{\gamma}}(u^{\underline{\mu}})$$

with the same values of $Q^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$ from the Lie algebra for SL (k,IC) but with the Killing–Cartan-type metric tensor defined by anholonomy coefficients, i.e., $\rho_{\underline{\alpha}\underline{\beta}}(u^{\underline{\nu}})=W^{\underline{\tau}}_{\underline{\alpha}\underline{\gamma}}(u^{\underline{\alpha}})W^{\underline{\gamma}}_{\underline{\tau}\underline{\beta}}(u^{\underline{\alpha}})$. For complex space–times, we shall consider that the coefficients $N^{\underline{a}}_{\underline{i}}$ and $W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$ may be some complex valued functions of necessary smooth (in general, with complex variables) class. In result, the Killing–Cartan-type metric tensor $\rho_{\underline{\alpha}\underline{\beta}}$ can also be complex.

We rewrite (5) as

$$e_{\underline{\alpha}}e_{\underline{\beta}} - e_{\underline{\beta}}e_{\underline{\alpha}} = W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}e_{\underline{\gamma}} \tag{15}$$

being equivalent to (13) and defining a noncommutative anholonomic structure (for simplicity, we use the same symbols $e_{\underline{\alpha}}$ as for some N-elongated partial derivatives, but with underlined indices). The analogs of derivation operators (12) are stated by using $W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$,
