(Received 12 April 2004; accepted 8 September 2004; published online 23 December 2004)

Surprisingly, differentiable functions are able to oscillate arbitrarily faster than their highest Fourier component would suggest. The phenomenon is called *superoscillation*. Recently, a practical method for calculating superoscillatory functions was presented and it was shown that superoscillatory quantum mechanical wave functions should exhibit a number of counter-intuitive physical effects. Following up on this work, we here present more general methods which allow the calculation of superoscillatory wave functions with custom-designed physical properties. We give concrete examples and we prove results about the limits to superoscillatory behavior. We also give a simple and intuitive new explanation for the exponential computational cost of superoscillations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1825076]

I. INTRODUCTION

It used to be believed that a function could not oscillate much faster than its highest Fourier component. Aharonov, Berry and others showed that this is not the case by giving explicit counter-examples which they named superoscillatory functions, see, e.g., Refs. 1–4. In fact, there are functions which on arbitrarily long stretches oscillate arbitrarily faster than their highest frequency Fourier component, see Ref. 5. In other words, the presence of localized fast oscillations in a continuous function need not be visible at all in the function's global Fourier transform. In a function's global Fourier transform, contributions from regions of fast oscillations can be cancelled perfectly by contributions from regions where the wave function is oscillating slowly.

In the context of quantum theory, wave functions that superoscillate are able to cause a number of counter-intuitive effects. Some of these may be of conceptual significance in quantum gravity, see Refs. 6 and 7. But effects of superoscillations also enter in the low energy realm of nonrelativistic quantum mechanics. Among such potentially observable low-energy effects is the counter-intuitive phenomenon that particles with superoscillatory wave functions can be made to accelerate when passing through a neutral slit.

Consider a particle which possesses a bounded momentum range, i.e., its momentum wave function vanishes for momenta that are larger than some $p_{\max}$. As will be explained below, we can arrange that in a certain region in space the particle's wave function superoscillates, i.e., that it oscillates with a much shorter wavelength than $h/p_{\max}$. Now let the wave function be incident onto a screen with a single slit in such a way that it is the superoscillatory part of the wave function which passes through the slit. Upon emerging from the slit the particle's wave function will then oscillate rapidly where the slit is and will be zero elsewhere. The very short wavelengths of the emerging wave function will be visible in its global Fourier transform. This is because the contributions to the global Fourier transform which come from the fast oscillations in the slit interval are no longer cancelled by contributions from outside the slit interval. Therefore, the particle will have gained momentum merely by passing the slit. The momentum gain is determined by the shortness of the wavelength of the superoscillations and, as explained below, there is no limit, in principle, to how short that wavelength can be made.

In order to facilitate the design of experiments that can realize the effects of superoscillatory wave functions it is desirable to possess methods for explicitly calculating superoscillatory wave functions with predetermined properties. In particular, one may wish to calculate those low-

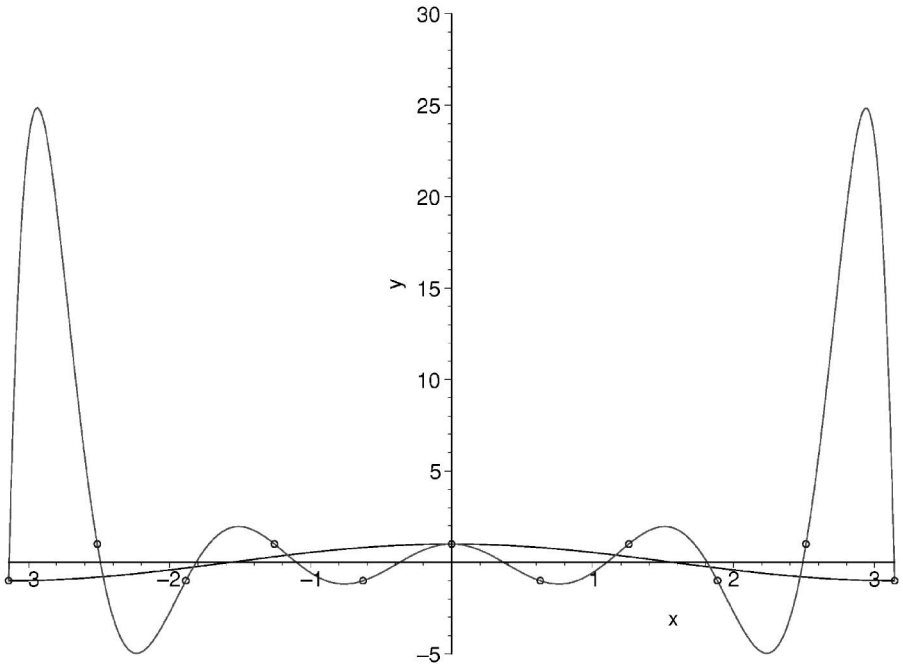

FIG. 1. Example of a superoscillation created by requiring the wave function to pass through certain points. A cosine function of the minimum wavelength/maximum frequency is shown for comparison.

momentum but superoscillatory wave functions which after passing through the slit yield wave functions with a predetermined arbitrarily large momentum and a momentum uncertainty that is as small as is allowed by the uncertainty relation. Our aim here is to develop methods that allow us to solve this and other problems.

Our starting point will be the method for calculating superoscillatory wave functions which was developed in Ref. 6 using results of Refs. 8 and 9. This method allows the construction of wave functions of arbitrarily low fixed frequency content that pass through an arbitrary finite number of prespecified points. Figures 1 and 2 show an example.

Our aim is to develop more general methods for designing superoscillatory functions with generic prespecified properties. We will also ask what the in-principle limits are for the construction of superoscillatory wave functions.

II. SELF-ACCELERATION THROUGH SINGLE SLIT

In order to motivate and formalize the mathematical problem that we will address, let us consider the illustrative example of particles that self-accelerate when passing through a slit.

A. Notation

The Fourier transform of a wave function ψ will be denoted by $\tilde{\psi}$,

$$\tilde{\psi}(p) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{\infty} \psi(x) e^{-ipx/\hbar} \, \mathrm{d}x. \tag{1}$$

We will often consider particles whose momentum is bounded by a finite value $p_{\max}$,

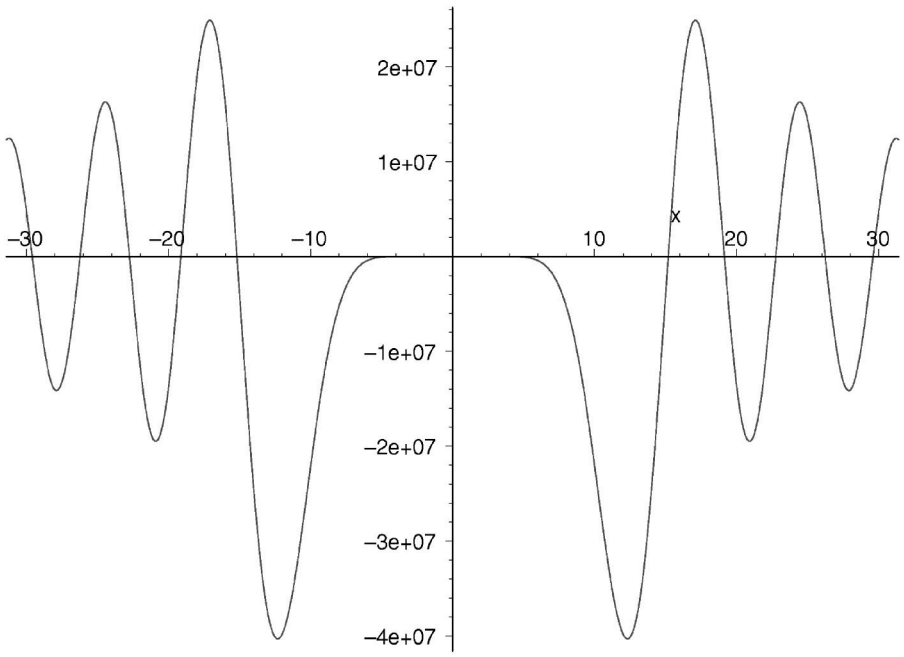

FIG. 2. A zoomed-out Fig. 1. Notice that, as is typical, the amplitudes in the superoscillating region are far smaller (here even unnoticable) than those on either side.

$$\psi(x) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\psi}(p) e^{ipx/\hbar}\, \mathrm{d}x. \tag{2}$$

Borrowing terminology from communication engineering and sampling theory, see, e.g., Ref. 10, we will speak of such a function $\psi(x)$ as having bandwidth $p_{\max}$, as being band limited, or in this case as being momentum limited. It will be convenient to define the sinc function as

$$\mathrm{sinc}(x) := \begin{cases} \dfrac{\sin(x)}{x} & \text{if } x \neq 0, \\ 1 \quad \text{if } x = 0. \end{cases} \tag{3}$$

Notice that definitions of the sinc function elsewhere may include a factor of π.

B. Gedanken experiment

Let us consider a particle in two dimensions which travels along the x_1 direction towards a screen which is parallel to the x_2 direction. Assume the particle passes through a slit with x_2-coordinate interval $[-L/2, L/2]$ in the screen. Henceforth, we will assume that the incident particle's momentum parallel to the screen, $\mathbf{p}_2$, has a finite bound $p_{2_{\max}}$,

$$\tilde{\psi}(p_1, p_2, t) = 0 \quad \text{if } p_2 \notin [-p_{2_{\max}}, p_{2_{\max}}]. \tag{4}$$

Our aim is to compare the particle's momentum parallel to the screen before and after the particle passes the slit. For simplicity, we will suppress the variables x_1, p_1, and t. From now on, x_2 is renamed x and p_2 is renamed p. We denote the incident wave function just before passing through the slit by $\psi(x)$ and we denote the wave function which emerges from the slit by $\Psi(x)$. The state $|\Psi\rangle$ is of course given by projection and renormalization,

$$|\Psi\rangle := \frac{P_s|\psi\rangle}{\|P_s|\psi\rangle\|}, \tag{5}$$

where P_s projects onto the slit,

$$P_s\psi(x) := \begin{cases} \psi(x), & \text{if } |x| \leqslant \frac{L}{2}, \\ 0, & \text{otherwise.} \end{cases} \tag{6}$$

Similarly, we define P_b as the projector onto a finite momentum interval,

$$P_b\tilde{\psi}(p) := \begin{cases} \tilde{\psi}(p), & \text{if } |p| \leqslant p_{\max}, \\ 0, & \text{otherwise.} \end{cases} \tag{7}$$

While the incident wave function is momentum limited, $P_b|\psi\rangle = |\psi\rangle$, the emerging wave function is position limited, obeying $P_s|\Psi\rangle = |\Psi\rangle$.

As was shown in Refs. 5 and 6, it is always possible to find incident wave functions $\psi(x)$ which obey the momentum bound $p_{\max}$ and which at any finite number of points in the slit interval take arbitrarily prescribed amplitudes (we will reproduce this result as a special case below). We will be able to arrange, therefore, that the wave function $\psi(x)$ takes, for example, the alternating values $(-1)^n$ at an arbitrarily large number of points in the slit interval—which enforces superoscillations. These $\psi(x)$ will be differentiable and square integrable. Then, if the particle passes the slit, only the superoscillating stretch of the wave function emerges from the slit. Renormalized, we denote it $\Psi(x)$. The Fourier transform $\tilde{\Psi}(p)$ of $\Psi(x)$ will show the presence of small wavelengths, implying that the particle emerges from the slit accelerated to a momentum beyond $p_{\max}$.

C. Template functions

As already mentioned, the results of Refs. 5 and 6 showed that functions of fixed bandwidth can always be found which at arbitrarily but finitely many points possess predetermined amplitudes. Therefore, the width or narrowness of the slit does not limit how short the wavelength of the superoscillations can be. As a consequence, there is no slit-dependent limit to the amount of self-acceleration that can be achieved in this way.

This leads us to ask more generally whether the process of self-acceleration can be designed virtually at will: is it always possible to construct incident wave functions $\psi(x)$ of fixed momentum limit $p_{\max}$ which on the slit interval $[-L/2, L/2]$ match any arbitrarily chosen template function, say $\Phi(x)$? This is of interest because, if true, we can optimize the predictability of the self-acceleration. To this end, we would choose the template function $\Phi(x)$ to be a wave function with a fixed arbitrarily large momentum expectation $\overline{p}$ whose momentum uncertainty Δp is as small as allowed by the uncertainty relation. If the incident superoscillatory wave function matched this template function in the slit interval (up to normalization), then the wave function would merge from the slit with the chosen momentum expectation $\overline{p}$ and lowest possible momentum uncertainty, Δp, for the given width of the slit. For later use, let us calculate these ideal template functions $\Phi(x)$.

1. Ideal template functions

Our aim is to find ideal template functions $\Phi(x)$ defined on the slit interval $[-L/2, L/2]$ which minimize the momentum uncertainty Δp, possess a predetermined momentum expectation $\langle\Phi|\mathbf{p}|\Phi\rangle = \overline{p}$ and are normalized $\langle\Phi|\Phi\rangle = 1$. To this end, we need to solve the constrained variational problem with the functional

$$\mathcal{L} = \langle \Phi|\mathbf{p}^2|\Phi\rangle + \mu_1\langle \Phi|\mathbf{p}|\Phi\rangle + \mu_2\langle \Phi|\Phi\rangle, \tag{8}$$

where μ_1 and μ_2 are Lagrange multipliers. Note that minimizing Δp is equivalent to minimizing $\langle \Phi|\mathbf{p}^2|\Phi\rangle$ because $\overline{p}$ is fixed. Hence the Euler–Lagrange equation in position space is

$$-\hbar^2\Phi''(x) - i\hbar\mu_1\Phi'(x) + \mu_2\Phi(x) = 0. \tag{9}$$

Since any wave function that emerges from the slit vanishes at the slit boundaries, we require $\Phi(\pm L/2)=0$. The solution, which is unique up to a phase, is

$$\Phi(x) = \sqrt{\frac{2}{L}}\cos\left(\frac{\pi}{L}x\right)e^{ix\overline{p}/\hbar}. \tag{10}$$

Its uncertainties are $\Delta x = L((\pi^2-6)/12\pi^2)^{1/2} \approx 0.18L$ and $\Delta p = \pi\hbar/L$. We have $\Delta x\Delta p \approx 0.57\hbar$ which is a little larger than what the uncertainty relation allows because our problem requires template functions $\Phi(x)$ to be zero outside the slit interval.

2. Superoscillatory wave functions cannot match arbitrary templates

Let us now come back to the question whether it is generally possible to find an incident wave function $\psi(x)$ which obeys a momentum bound $p_{\max}$ while in the interval $[-L/2, L/2]$ agreeing completely with an arbitrarily chosen template function $\Phi(x)$, such as the function $\Phi(x)$ just calculated in Sec. II C 1. Strictly speaking, the answer is no.

As is easily verified, all band-limited functions are entire functions. In particular, any momentum-limited incident wave function $\psi(x)$ is entire and it is, therefore, everywhere differentiable. Now choose, for example, a template function $\Phi(x)$ which is not differentiable at some point in the interval $[-L/2, L/2]$. Thus, there cannot exist a momentum-limited incident wave function which obeys $\psi(x)=\Phi(x)$ for all $x \in [-L/2, L/2]$. Nevertheless, a slightly weaker proposition does hold.

3. Convergence towards arbitrary template functions

Let $\Phi(x)$ be a continuous and square integrable template function. Let us ask whether one can always find a sequence of wave functions $\psi_N(x)$ of fixed momentum bound $p_{\max}$ which behave with more and more precision like $\Phi(x)$ over the region of the slit. To be precise, is it possible to find a sequence of momentum-limited incident waves $|\psi_N\rangle$ whose emerging wave functions $|\Psi_N\rangle$ have asymptotically vanishing L^2-distance $\||\Psi_N\rangle - |\Phi\rangle\|$ to an arbitrary template state $|\Phi\rangle$? This is indeed the case.

To see this, consider in the quantum mechanical Hilbert space of states $\mathcal{H}$ with scalar product

$$\langle \xi_1|\xi_2\rangle := \int_{-\infty}^{\infty} \xi_1^*(x)\xi_2(x)\mathrm{d}x, \tag{11}$$

and the following three subspaces:

$$\mathcal{H}_s := P_s\mathcal{H}, \tag{12}$$

$$\mathcal{H}_b := P_b\mathcal{H}, \tag{13}$$

$$\mathcal{H}_{sb} := P_sP_b\mathcal{H}. \tag{14}$$

That is, $\mathcal{H}_s$ is the subspace of states with position limitation to the slit, $\mathcal{H}_b$ is the subspace of states with fixed momentum limitation $p_{\max}$, and $\mathcal{H}_{sb}$ is the subspace of states obtained after passing the momentum-limited wave functions through the slit.

Proposition 1: $\mathcal{H}_{sb}$ is dense in $\mathcal{H}_s$, i.e.,

$$\forall |\Phi\rangle \in \mathcal{H}_s, \varepsilon > 0 \, \exists \, |\Psi\rangle \in \mathcal{H}_{sb} : \| |\Psi\rangle - |\Phi\rangle \| < \varepsilon. \tag{15}$$

Proof: If $|\Phi\rangle = 0$, then take $|\Psi\rangle = 0$. For $|\Phi\rangle \neq 0$ we must show that

$$\nexists |\Phi\rangle \in \mathcal{H}_s \setminus \{0\} : \langle \Psi | \Phi \rangle = 0 \; \forall \, |\Psi\rangle \in \mathcal{H}_{sb}. \tag{16}$$

Since $|\Phi\rangle$ is position limited, this is equivalent to showing that

$$\nexists |\Phi\rangle \in \mathcal{H}_s \setminus \{0\} : \langle \psi | \Phi \rangle = 0 \; \forall \, |\psi\rangle \in \mathcal{H}_b. \tag{17}$$

Assume, for a contradiction, that

$$\exists |\Phi\rangle \in \mathcal{H}_s \setminus \{0\} : \langle \psi | \Phi \rangle = 0 \; \forall \, |\psi\rangle \in \mathcal{H}_b. \tag{18}$$

This implies that $|\Phi\rangle \perp \mathcal{H}_b$. Thus, $\tilde{\Phi}(p) = 0$ on $[-p_{\max}, p_{\max}]$. But, since $\tilde{\Phi}(p)$ is entire and zero over a finite interval, $\tilde{\Phi}(p) = 0$ everywhere on $\mathbb{R}$, i.e., $|\Phi\rangle = 0$. This is a contradiction. Therefore, $\mathcal{H}_{sb}$ is dense in $\mathcal{H}_s$. □

While this result proves the existence of band-limited functions that are arbitrarily close in the L^2 topology to any template function within the window of the slit, the result does not provide explicit methods for constructing such band-limited functions.

III. CONSTRUCTIVE METHOD FOR GENERAL LINEAR CONSTRAINTS

We now focus on practical methods for calculating superoscillatory wave functions that approximate template functions in the slit interval. We begin with the method for constructing superoscillatory functions presented in Ref. 6. This method allows one to specify that the to-be-found superoscillatory function takes arbitrarily chosen amplitudes a_k at any finite number N of arbitrarily chosen points x_k,

$$\psi^{(u)}(x_k) = a_k \quad \text{for } k = 1, \ldots, N. \tag{19}$$

The superscript (u) is to indicate that the fuction will generally be unnormalized. Equation (19) specifies a function which possesses a superoscillating stretch. For example, we may choose the x_k spaced closer than $h/p_{\max}$ and the amplitudes alternating, e.g., $a_k = (-1)^k$. The normalized wave function $\psi(x) = \psi^{(u)}(x)/\|\psi^{(u)}\|$ then possesses superoscillations that are as rapid as those of $\psi^{(u)}$ but with a renormalized amplitude. Thus, in order to obtain the $\psi(x)$ with the most pronounced superoscillations, i.e., the superoscillations of largest possible amplitude, one needs to find that function $\psi^{(u)}(x)$ whose L^2 norm $\|\psi^{(u)}\|$ is minimal. The method of Ref. 6 solves this optimization problem.

We now generalize the method of Ref. 6. To this end, we begin by rewriting the requirement that $\psi^{(u)}(x)$ be band limited by $p_{\max}$ and pass through the points $\{(x_k, a_k)\}_{k=1}^N$, namely (19), in momentum space as

$$\frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} e^{i(x_k/\hbar)p} \tilde{\psi}^{(u)}(p) \mathrm{d}p = a_k. \tag{20}$$

Our aim is to obtain a method for constructing superoscillatory wave functions which not only pass through predetermined points but which obey also more generic types of constraints. To this end, let us allow constraints on the function $\tilde{\psi}^{(u)}$ which are of the general linear form,

$$a_k = \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\chi}_k^*(p) \tilde{\psi}^{(u)}(p) \mathrm{d}p \quad \forall \, k \in \{1, \ldots, N\}. \tag{21}$$

Here, the $\tilde{\chi}_k$ are arbitrary linearly independent differentiable functions. By choosing these, we will be able to prescribe for the superoscillatory wave function not only amplitudes but also arbitrary derivatives, integrals and any other linear constraint. In order to obtain the most pronounced

superoscillations in the normalized function $\tilde{\psi}$ we minimize the norm of $\tilde{\psi}^{(u)}$, subject to the constraints in Eq. (21). The to-be-optimized functional with Lagrange multipliers λ_k reads

$$\mathcal{L} = \int_{-p_{\max}}^{p_{\max}} \tilde{\psi}^{(u)*}(p)\tilde{\psi}^{(u)}(p)\mathrm{d}p - \sum_{k=1}^{N} \frac{\lambda_k^*}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\chi}_k^*(p)\tilde{\psi}^{(u)}(p)\mathrm{d}p + \text{c.c.}, \tag{22}$$

leading to the Euler–Lagrange equation,

$$\tilde{\psi}^{(u)}(p) = \frac{1}{\sqrt{2\pi\hbar}} \sum_{k=1}^{N} \lambda_k \tilde{\chi}_k(p). \tag{23}$$

Recall that $\tilde{\psi}^{(u)}$ is zero outside the interval $[-p_{\max}, p_{\max}]$ by assumption. Thus, using (23) in (21),

$$a_k = \sum_{r=1}^{N} T_{kr}\lambda_r, \tag{24}$$

where the Hermitian matrix T is defined by

$$T_{kr} := \frac{1}{2\pi\hbar} \int_{-p_{\max}}^{p_{\max}} \tilde{\chi}_k^*(p)\tilde{\chi}_r(p)\mathrm{d}p. \tag{25}$$

As we will show below, T is invertible. Thus, $\vec{\lambda} = T^{-1}\vec{a}$, i.e.,

$$\lambda_k = \sum_{r=1}^{N} T_{kr}^{-1} a_r. \tag{26}$$

Thus, using the Fourier transform of the constraint function

$$\chi_k(x) := \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\chi}_k(p) e^{ixp/\hbar}\, \mathrm{d}p \tag{27}$$

we obtain from (23) that the desired superoscillatory (still unnormalized) incident wave function in position space is given by

$$\psi^{(u)}(x) = \frac{1}{\sqrt{2\pi\hbar}} \sum_{k=1}^{N} \lambda_k \chi_k(x). \tag{28}$$

Existence of the solution: It remains to be shown that T is indeed invertible. To see this, let $\vec{u}$ be an arbitrary vector. Then

$$\vec{u}^{\dagger} T \vec{u} = \sum_{k,r=1}^{N} u_k^* T_{kr} u_r = \frac{1}{2\pi\hbar} \int_{-p_{\max}}^{p_{\max}} \sum_{k,r=1}^{N} u_k^* \tilde{\chi}_k^*(p)\tilde{\chi}_r(p) u_r \,\mathrm{d}p = \frac{1}{2\pi\hbar} \int_{-p_{\max}}^{p_{\max}} \left| \sum_{m=1}^{N} u_m \tilde{\chi}_m(p) \right|^2 \mathrm{d}p.$$

Since the $\tilde{\chi}_k$ are linearly independent the integrand is positive. Therefore, T is positive definite and hence invertible.

IV. THE COST OF SUPEROSCILLATIONS

As was shown in Ref. 6, one cost of superoscillations is that requiring more or faster superoscillations makes the matrix T increasingly difficult to invert numerically, as its smallest and largest eigenvalues differ by growing orders of magnitude. The condition number was found to increase exponentially with the number of superoscillations.

We here only remark that, in the sense of computational complexity, this makes it computationally hard to calculate superoscillations. Interestingly, this also means that any quantum effect

that naturally produces functions with arbitrarily large superoscillatory stretches constitutes an example of an exponential speed-up in the sense of quantum computing. Physical occurrences of superoscillations, e.g., in the context of evanescent waves, have been discussed, e.g., in Refs. 3 and 4. Also, for example (rather speculatively), the possibility of an unbounded production of superoscillations has been discussed in the context of the trans-Planckian problem of black holes in Refs. 11 and 12.

Here, we will focus on a more immediate cost of superoscillations, namely the need for an increasingly large dynamical range, a function's superoscillations are generally of low amplitude when compared to the function's amplitudes to the left and right of its superoscillatory stretch. To be precise, it was shown in Ref. 6 that the L^2 norm of the function increases polynomially with the frequency of the prescribed superoscillations, for fixed prescribed superoscillating amplitudes. In particular, it was also shown that the norm increases exponentially with the number of imposed superoscillations. Correspondingly, in normalized wave functions the amplitudes of superoscillations decrease exponentially with the number of superoscillations. (Of course, if the superoscillating stretch of the particle's wave function happens to pass through the slit then its wave function, however small, is renormalized whereby the superoscillating amplitudes will be restored to the amplitudes of the template function.)

By making use of the special properties of prolate functions these scaling results were derived for the type of superoscillations produced with the method of Ref. 6. In the following two sections we will show more directly the underlying reason for this exponential behavior of the norm of superoscillatory functions. Our argument will apply more generally to all superoscillatory functions that arise from linear constraints.

A. Derivatives and norms

If a function $\psi^{(u)}(x)$ is band limited, one would expect that there is a bound on its derivatives. Applying the Cauchy–Schwarz inequality, consider

$$\begin{aligned}\left|\frac{\mathrm{d}^n}{\mathrm{d}x^n}\psi^{(u)}(x)\right|^2 &= \frac{1}{2\pi\hbar}\left|\int_{-p_{\max}}^{p_{\max}}\tilde{\psi}^{(u)}(p)\left(\frac{ip}{\hbar}\right)^n e^{ipx/\hbar}\,\mathrm{d}p\right|^2 \\ &\leqslant \frac{1}{2\pi\hbar}\left(\int_{-p_{\max}}^{p_{\max}}\left|\tilde{\psi}^{(u)}(p)\left(\frac{ip}{\hbar}\right)^n\right|^2\mathrm{d}p\right)\left(\int_{-p_{\max}}^{p_{\max}}1\,\mathrm{d}p\right) \\ &\leqslant \frac{1}{2\pi\hbar}\left(\frac{p_{\max}}{\hbar}\right)^{2n}2p_{\max}\|\psi^{(u)}\|^2.\end{aligned}$$

Thus,

$$\left|\frac{\mathrm{d}^n}{\mathrm{d}x^n}\psi^{(u)}(x)\right| \leqslant \left(\frac{p_{\max}}{\hbar}\right)^n\sqrt{\frac{p_{\max}}{\pi\hbar}}\|\psi^{(u)}\|. \tag{29}$$

Thus arbitrarily large derivatives, as they can be produced with superoscillations, are consistent with a finite fixed bandwidth but we see that the cost must be an increase in the norm of the function $\|\psi^{(u)}\|$.

B. The norm of superoscillating functions

A precise expression for the norm $\|\psi^{(u)}\|$ of the superoscillatory functions obtained by our method can be derived,

$$\|\psi^{(u)}\|^2 = \frac{1}{2\pi\hbar}\int_{-p_{\max}}^{p_{\max}}\left|\sum_{k=1}^{N}\lambda_k\tilde{\chi}_k(p)\right|^2\mathrm{d}p = \frac{1}{2\pi\hbar}\int_{-p_{\max}}^{p_{\max}}\sum_{k,r=1}^{N}\lambda_k^*\tilde{\chi}_k^*(p)\tilde{\chi}_r(p)\lambda_r\,\mathrm{d}p = \vec{\lambda}^{\dagger}T\vec{\lambda}. \tag{30}$$

Hence,

$$\|\psi^{(u)}\|^2 = \vec{\lambda}^\dagger \vec{a} = \vec{a}^\dagger \vec{\lambda} = \vec{a}^\dagger T^{-1} \vec{a}. \tag{31}$$

Note that T^{-1} is a positive self-adjoint matrix. We now see that for given constraint functions, χ_k, the most norm-expensive superoscillatory functions are obtained if we choose the constraint parameters a_k such that $\vec{a}$ is the eigenvector of T^{-1} with largest eigenvalue. We will arrive at those extreme superoscillations also from independent momentum space considerations in Sec. VI.

C. Adding successive constraints

Consider a set of constraints, described by a set of functions $\{\tilde{\chi}_k\}_{k=1}^N$ and parameters $\{a_k\}_{k=1}^N$ and suppose that, using our method, the momentum-limited wave function which obeys all those constraints and is of minimum norm has been calculated. Let us ask how the norm of the solution to this problem changes if we add one additional constraint

$$a_{N+1} = \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\chi}_{N+1}(p) \tilde{\psi}(p) \mathrm{d}p, \tag{32}$$

where χ_{N+1} and a_{N+1} are chosen arbitrarily. Let us denote the solution to the initial problem of N constraints by $\tilde{\psi}_N$ and let us define,

$$c := \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\chi}_{N+1}(p) \tilde{\psi}_N(p) \mathrm{d}p. \tag{33}$$

Clearly, if we choose the $(N+1)$st constraint with $a_{N+1} := c$ then $\tilde{\psi}_N$ is also the function of minimum norm obeying the $N+1$ constraints, i.e., $\tilde{\psi}_{N+1} = \tilde{\psi}_N$, just as if we had not added a new constraint, or as if we had set the $(N+1)$st Lagrange multiplier to zero, $\lambda_{N+1} = 0$.

Now, let us allow the constraint parameter a_{N+1} to vary away from c. Correspondingly, our method will yield a family of functions, $\tilde{\psi}_{N+1}$ $(\neq \tilde{\psi}_N)$, parametrized by a_{N+1}. We observe from (31) (letting the sum run to $N+1$) that the norm squared of these functions is a quadratic (and of course positive) polynomial in a_m. Note that its minimum occurs if we choose the a_{N+1} value,

$$c = a_{N+1} = -\frac{1}{T^{-1}_{(N+1),(N+1)}} \sum_{r \neq (N+1)} T^{-1}_{(N+1),r} a_r, \tag{34}$$

because then $\Sigma_{s \neq (N+1)} T^{-1}_{(N+1),s} a_s = 0$. Using (24) we see that this choice of a_{N+1} leads to the vanishing of the Lagrange multiplier $\lambda_{N+1} = 0$, which is what we expected for if we add a new constraint that is already satisfied, $\tilde{\psi}$ will not change.

Crucially, we now see that as we tune a_{N+1} away from c, say in order to enforce an additional superoscillation twist, the squared norm of the solution increases quadratically. Therefore, if we keep adding new generic constraints, say in order to implement more and more superoscillations, this will generally increase the norm of the solution by a factor in each step. Thus, the norm of the solution will generically scale exponentially with an increase in the number of constraints N.

This finding widely generalizes the result of Ref. 6 which applied only to constraints of the special form (19) and among them only to those with equidistant spacings of the x_k.

V. APPLICATIONS TO AN IDEAL TEMPLATE FUNCTION

In Sec. II C 1, we asked how the wave function $\Psi(x)$ that emerges from the slit would have to look in order to describe a particle with an arbitrarily high predetermined momentum expectation value $\overline{p}$ and a momentum uncertainty Δp which is as small as is allowed by the uncertainty relation. This ideal template function was given in (10).

Let us consider the concrete example, $\hbar = 1$, $L = 2\pi$, $p_{\max} = 1$, and $\overline{p} = 2$. If the emerging wave function Ψ can be arranged to be equal or close to this template function Φ, this clearly exhibits

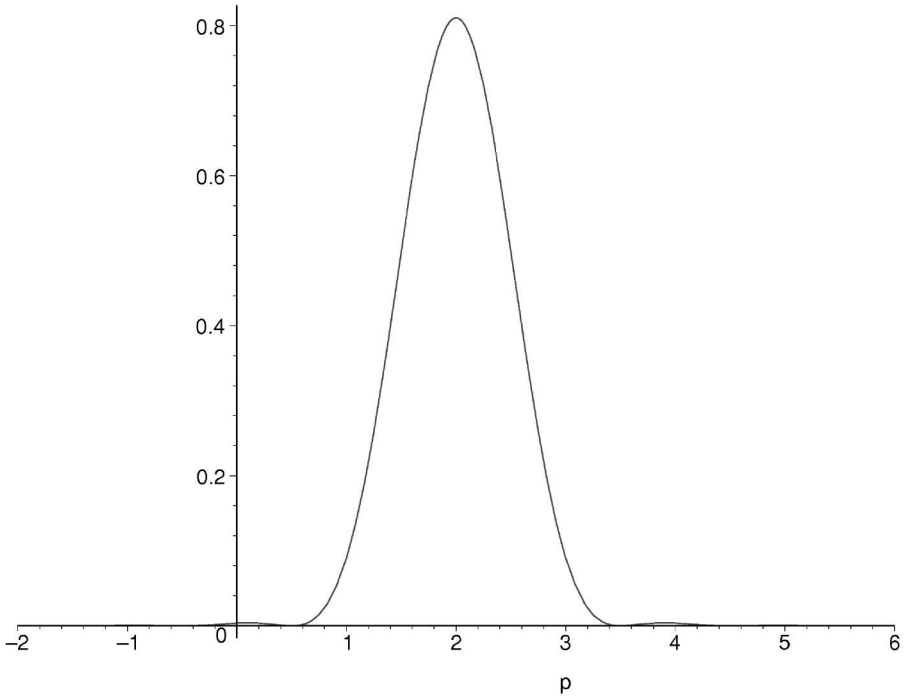

FIG. 3. The ideal template's momentum wave function $|\tilde{\Phi}(p)|^2$. Notice that it is centered well outside the original bandwidth $p_{\max}=1$.

the phenomenon of self-acceleration because the emerging momentum wave function would be peaked at $p \approx \overline{p}=2$, i.e., well outside the original bandwidth of $p_{\max}=1$, see Fig. 3.

We had shown that exact matching, $\Psi(x)=\Phi(x)$, is generally not possible, but we also saw that there always exists a sequence of incident waves ψ_N so that for the emerging waves Ψ_N we have $\Psi_N \to \Phi$ in the L^2 topology, which is here the only physically relevant topology. Thus, there are superoscillatory incident wave functions which achieve the prescribed self-acceleration properties to arbitrary precision. For illustration, let us explicitly calculate such superoscillatory incident wave functions.

A. Method of matching amplitudes

Let us begin by applying the method presented in Ref. 6, which is a special case of our method of general linear constraints. In this special case, we require the momentum-limited incident wave $\psi^{(u)}(x)$ to exactly match the amplitude of the ideal template function at several points x_k of the slit interval $[-L/2, L/2]$. The constraints in the variational problem are then given by the linearly independent constraint functions $\tilde{\chi}_k(p) := e^{-ipx_k/\hbar}$ and constraint parameters $a_k := \Phi(x_k)$. Thus,

$$T_{kr} = \frac{1}{2\pi\hbar}\int_{-p_{\max}}^{p_{\max}} e^{(ip/\hbar)(x_k - x_r)}\, \mathrm{d}p = \frac{p_{\max}}{\pi\hbar}\,\mathrm{sinc}\left(\frac{p_{\max}}{\hbar}[x_k - x_r]\right) \tag{35}$$

which leads to the solution

$$\psi^{(u)}(x) = \frac{1}{\sqrt{2\pi\hbar}}\sum_{k=1}^{N} \lambda_k \chi_k(x), \tag{36}$$

where $\vec{\lambda} = T^{-1}\vec{a}$ and where

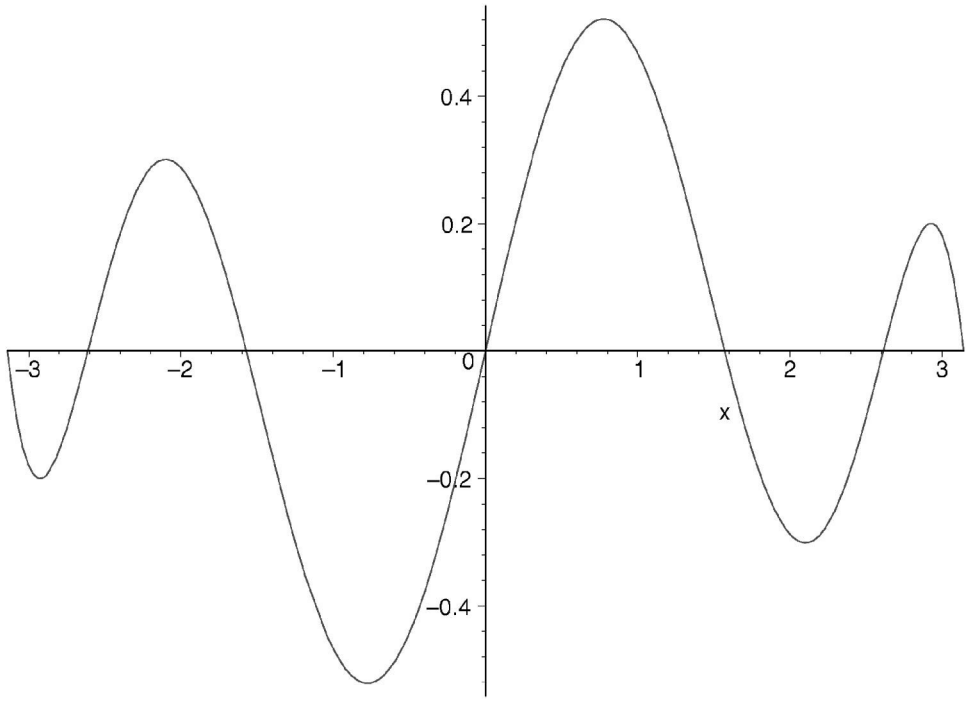

FIG. 4. $\mathrm{Im}(\psi^{(u)}(x))$ over the slit in the example of Sec. V A. The wavelength is about $0.5\lambda_{\min}$.

$$\chi_k(x) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} e^{(ip/\hbar)(x-x_k)}\, \mathrm{d}p = p_{\max} \sqrt{\frac{2}{\pi\hbar}}\, \mathrm{sinc}\left(\frac{p_{\max}}{\hbar}[x - x_k] \right). \tag{37}$$

We observe that the wave function $\psi^{(u)}(x)$ is a linear combination of sinc functions centered at the x_k and we note that $\psi(x)$ is square integrable, since the sinc functions are. In general, T is ill conditioned, i.e., care must be taken to invert it with enough numerical precision so as to satisfy the constraints with sufficient accuracy.

We used routines in Maple which calculate $\vec{\lambda} = T^{-1}\vec{a}$ by solving $T\vec{\lambda} = \vec{a}$ using Gaussian elimination. Concretely, we required $\psi^{(u)}(x)$ to match the ideal template function $\Phi(x)$ with $\overline{p} = 2$ at $N = 9$ equidistantly spaced points x_k from slit boundary to slit boundary. For example, Fig. 4 shows the imaginary part of the superoscillatory function $\psi^{(u)}$ over the slit interval. Figure 5 shows a zoomed-out view of $|\psi^{(u)}(x)|^2$, displaying the typical big amplitudes to the left and right of the superoscillating stretch.

The momentum expectation value for the ideal template function that we chose is $\overline{p} = 2p_{\max}$. Numerically, we found that the strictly momentum-limited incident wave function $\psi(x)$ for $N = 9$ yields an emerging wave function $\Psi(x)$ whose momentum expectation value is $\overline{p} \approx 1.92 p_{\max}$. Clearly, the momentum of particles which pass through the slit essentially doubles by self-acceleration, as intended. The momentum uncertainty of the emerging wave function is $\Delta p \approx 1.42 p_{\max}$.

Recall that for this slit size the momentum uncertainty could be significantly smaller, namely $\Delta p = 1/2$, as is precisely realized in the ideal template function. By increasing N, we can achieve that the incident wave function $\psi^{(u)}(x)$ better matches the template, leading to a lowering of Δp towards that limiting value. For example, for $N = 15$ we find $\overline{p} \approx 1.999\,47 p_{\max}$ and $\Delta p \approx 0.500\,25 p_{\max}$. For significantly larger N the exponential computational expense sets in. Our generalized method for linear constraints allows us to use other linear constraints which we found to be numerically more efficient in the sense of allowing us to reach larger values of N. We will discuss the use of these alternative constraints in Sec. V B.

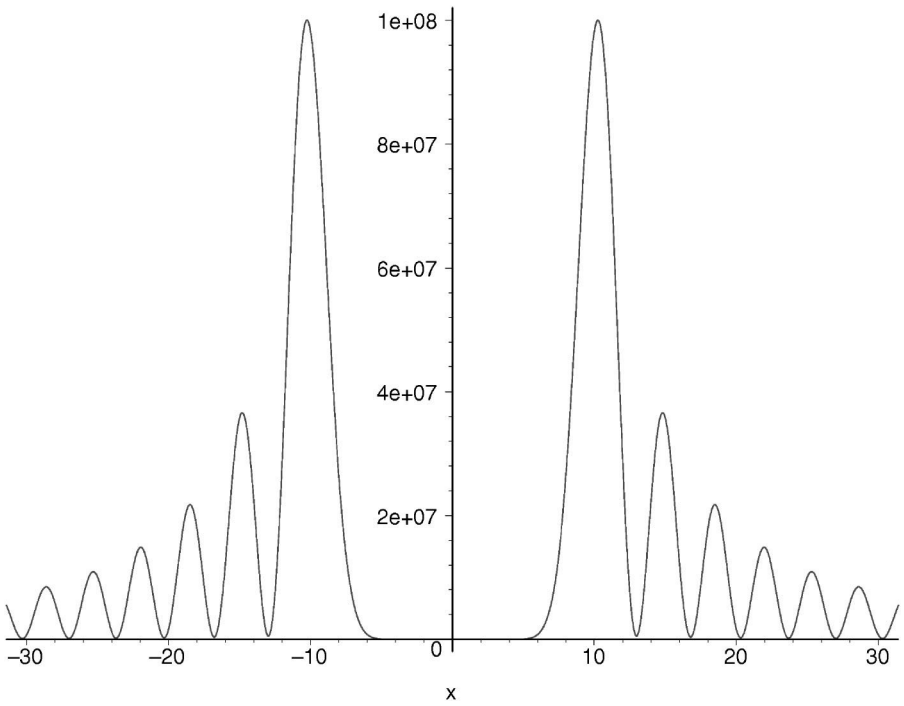

FIG. 5. $|\psi^{(u)}(x)|^2$ over the slit and surrounding regions in the example in Sec. V A.

Figure 6 shows the accuracy with which the $\psi^{(u)}(x)$ obtained by matching $N=9$ amplitudes of $\psi^{(u)}(x)$ to those of $\Phi(x)$ agrees with the ideal template function $\Phi(x)$ for arbitrary x in the slit interval. The behavior is similar for all values of N (that we tested). For general N, there are $N-1$ peaks and the height of the highest peak decreases with N.

B. Method of matching derivatives

In order to illustrate the generality of our new method of Sec. III, let us now construct superoscillatory wave functions by requiring that the wave function matches value and derivatives of the template at one point, instead of requiring, as we did in Sec. V A, that the wave function matches only the value of the template function at several points.

Concretely, let us require that the value and first $N-1$ derivatives of the to-be-found wave function $\psi^{(u)}$ agree at $x=0$ with those of the ideal template function Φ of above. In the equation for general linear constraints (21), we obtain a constraint on the $(k-1)$st derivative by choosing for the constraint function

$$\tilde{\chi}_k(p) = \left(-\frac{ip}{\hbar}\right)^{k-1}. \tag{38}$$

Matching the derivatives to those of the template is to choose the constraint parameters to be $a_k := \Phi^{(k-1)}(0)$, where $\Phi^{(k-1)}$ denotes the $(k-1)$st derivative. Since the $\tilde{\chi}_k$ are linearly independent,

$$T_{kr} = \frac{1}{2\pi\hbar}\int_{-p_{\max}}^{p_{\max}} \left(\frac{ip}{\hbar}\right)^{k-1}\left(-\frac{ip}{\hbar}\right)^{r-1} \mathrm{d}p \tag{39}$$

is invertible, yielding the solution

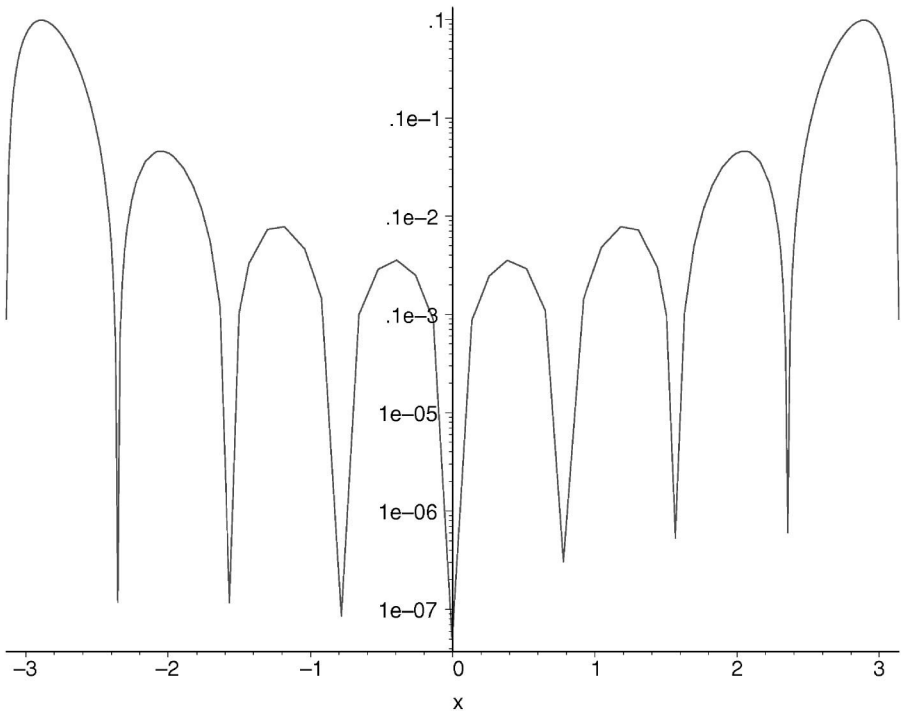

FIG. 6. $|\Psi(x)-\Phi(x)|^2$ over the slit in the example in Sec. V A.

$$\psi^{(u)}(x) = \frac{1}{\sqrt{2\pi\hbar}} \sum_{k=1}^{N} \lambda_k \chi_k(x), \tag{40}$$

where

$$\chi_k(x) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \left(-\frac{ip}{\hbar}\right)^{k-1} e^{ipx/\hbar}\, dp. \tag{41}$$

Note that $\psi(x)$ is a linear combination of derivatives of sinc functions, each of which is band limited. In this case, T is simpler to invert and we can go, for example, to the case $N=23$ before the exponential computational expense sets in. In this case, for large N the coefficients λ_k quickly grow large and hence the subtle cancellations in the Fourier transform require fast increasing numerical precision.

We considered the example where the value of the function and its first 22 derivatives is required to match those of the ideal template function at $x=0$. We found numerically that the momentum-limited superoscillating function, after passing through the slit, then exhibits a momentum expectation value of $\overline{p} \approx 2.0002 p_{\max}$ and momentum uncertainty $\Delta p \approx 0.500\,49$. Thus we reach the targeted momentum-doubling self-acceleration, with a momentum uncertainty which is only marginally above the uncertainty relation limit $\Delta p = 1/2$ for this slit size. Figure 7 displays the accuracy $|\Psi(x)-\Phi(x)|^2$.

VI. A MOMENTUM SPACE METHOD

In position space, superoscillatory wave functions $\psi(x)$ generally possess a characteristic shape: rapid but small oscillations in the superoscillating stretch and a few large long-wavelength amplitudes shortly before and after. Do these states also possess a characteristic shape in momentum space?

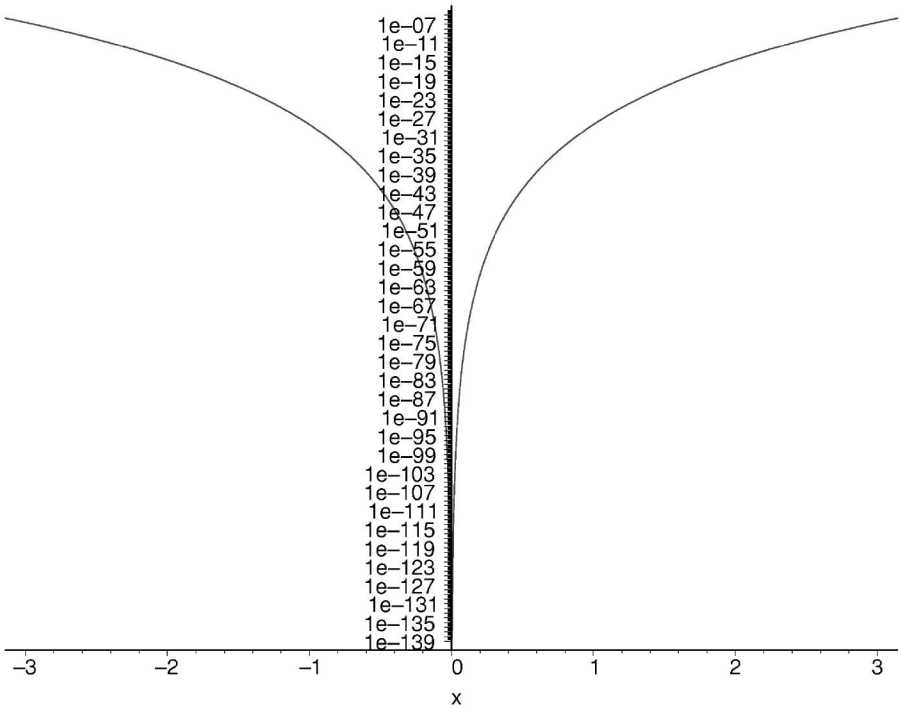

FIG. 7. $|\Psi(x)-\Phi(x)|^2$ over the slit in the example in Sec. V B.

Let us consider, for example, the superoscillations obtained by prescribing oscillating amplitude values a_k at close-by points x_k. We found that, in momentum space, such a state is a linear combination of plane waves $\exp(-ix_kp)$,

$$\tilde{\psi}(p) := \begin{cases} \frac{1}{\sqrt{2\pi\hbar}} \sum_{r=1}^{N} \lambda_r e^{-i(x_r/\hbar)p}, & \text{if } |p| \leqslant p_{\max}, \\ 0, & \text{if } |p| > p_{\max}. \end{cases} \tag{42}$$

It appears, see, e.g., Fig. 8, that these $\tilde{\psi}(p)$ generally possess small amplitudes in most of the momentum interval $[-p_{\max}, p_{\max}]$, except for near the boundaries $\pm p_{\max}$. We calculated the Fourier transforms of a number of superoscillatory wave functions and observed this as a general feature.

Thus, in momentum space, these superoscillations appear to be a linear combination of plane waves whose interference is close to being as strong as it can be, with the effect that the resulting function is of minimized norm.

If this assumption is correct, we should be able to derive superoscillatory wave functions by calculating that linear combination of plane waves in momentum space whose norm is minimal. To this end, let $\{x_r\}_{r=1}^N$ be points in $[-L/2, L/2]$. Our aim is to find a coefficient vector $\{q_r\}_{r=1}^N$ of fixed length, say $\|\vec{q}\|=1$ such that

$$\tilde{\psi}(p) := \begin{cases} \frac{1}{\sqrt{2\pi\hbar}} \sum_{r=1}^{N} q_r e^{-i(x_r/\hbar)p}, & \text{if } |p| \leqslant p_{\max}, \\ 0, & \text{if } |p| > p_{\max}, \end{cases} \tag{43}$$

is of minimum norm. The constrained optimization problem with Lagrange multiplier ν,

$$\mathcal{L} = \|\psi\|^2 + \nu(\|\vec{q}\|^2 - 1) \tag{44}$$

leads to

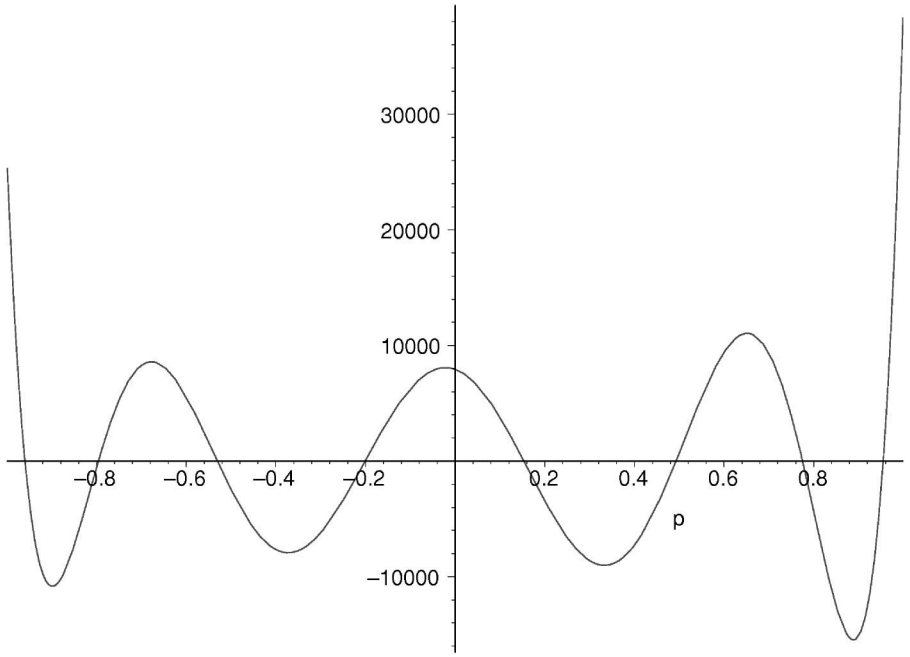

FIG. 8. $\mathrm{Re}(\tilde{\psi}(p))$ of the incident superoscillatory wave in the example in Sec. V A.

$$T\vec{q} = \nu\vec{q}. \tag{45}$$

Thus, the coefficient vector $\vec{q}$ which solves this optimization problem must be eigenvector to T. From Eq. (30), we obtain the general expression for the norm, $\|\psi\|^2 = \vec{q}^{\dagger} T\vec{q}$. Thus, $\vec{q}$ must be that eigenvector of T with the smallest eigenvalue.

Indeed, the position wave function determined by these coefficients $\vec{q}$ is superoscillatory: already in Sec. IV B, we encountered the wave functions whose coefficient vectors λ are the eigenvectors of T^{-1} of largest eigenvalue. There, we found that these are the superoscillatory wave functions which for a given set of constraint points $\{x_k\}$ are most norm expensive and which, therefore, possesses the most pronounced superoscillations.

VII. OPEN PROBLEMS

We know from Sec. II C 3 that it is always possible to find incident wave functions of fixed momentum bound that in the slit interval are matching any given template function arbitrarily closely in the L^2 norm topology. Thus, for all practical purposes, the self-acceleration phenomenon can be tailored at will. Our method of general linear constraints can be used to explicitly construct a sequence of momentum-limited superoscillatory wave functions $\psi_N(x)$ which more and more closely match any given template function Φ. The $\psi_N(x)$ approach $\Phi(x)$ in the slit interval in the sense that they obey more and more linear constraints that tie $\psi_N(x)$ to $\Phi(x)$.

In Sec. V A and Sec. V B we showed that a close approach to a fixed template function can be done numerically efficiently. Clearly, intuition and the easily achieved numerical accuracy lead us to conjecture that our methods for producing superoscillations, as used in Secs. V A and V B, do indeed always lead to convergence in the L^2 topology towards the template function. So far, however, we have no proof that our particular method for producing superoscillatory wave functions from linear constraints does indeed realize the L^2 convergence to generic template functions.

A. Quadratic constraints

Let us ask, therefore, if there is a choice of linear constraints that directly targets the area under the functions and that thereby directly guarantees convergence in the L^2 sense.

One may try, for example, constraints which require that the functions $\psi^{(u)}$ and Φ enclose equal areas on certain subintervals of the slit. This can be set into the form of a linear constraint: Let $\{x_k\}_{k=1}^{N+1}$ be equidistantly spaced points in $[-L/2, L/2]$. We require the linear constraints of (21) with the constraint functions

$$\tilde{\chi}_k(p) = \int_{x_k}^{x_{k+1}} e^{-ipx/\hbar}\, \mathrm{d}x \tag{46}$$

and the constraint parameters

$$a_k = \int_{x_k}^{x_{k+1}} \Phi(x)\mathrm{d}x. \tag{47}$$

While this can easily be carried out, these constraints are not directly guaranteeing L^2 convergence towards the template function by refining the partition of the slit interval into increasingly smaller subintervals: in principle, even functions that enclose equal areas on a very small interval may have very different amplitudes. Let us, therefore, consider to impose constraints which require the area of the function $|\Psi(x)-\Phi(x)|^2$ on small subintervals to be small. It is clear that to this end it would be necessary to implement also constraints that are quadratic in the field $\Psi(x)$. We will here not pursue this strategy to the end. As a preliminary step, however, let us generalize our method for constructing superoscillatory functions to include quadratic constraints.

To this end, we formulate the variational problem of finding the function $\tilde{\psi}^{(u)}$ of smallest norm and with momentum cutoff $p_{\max}$ which satisfies N linear and M quadratic constraints that tie it to a template function Φ,

$$a_k = \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\psi}^{(u)}(p)\tilde{\chi}_k^*(p)\mathrm{d}p \quad \text{for } k = 1, \ldots, N, \tag{48}$$

$$b_k = \frac{1}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\psi}^{(u)*}(p)\tilde{\psi}^{(u)}(p)\tilde{\Xi}_k^*(p)\mathrm{d}p \quad \text{for } k = 1, \ldots, M. \tag{49}$$

The to-be-optimized functional with Lagrange multipliers $\{\lambda_k\}_{k=1}^N$ and $\{\mu_k\}_{k=1}^M$, reads

$$\begin{aligned}\mathcal{L} = &\int_{-p_{\max}}^{p_{\max}} \tilde{\psi}^{(u)*}(p)\tilde{\psi}^{(u)}(p)\mathrm{d}p - \sum_{k=1}^{N} \frac{\lambda_k^*}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\psi}^{(u)}(p)\tilde{\chi}_k^*(p)\mathrm{d}p \\ &+ \sum_{k=1}^{N} \frac{\mu_k^*}{\sqrt{2\pi\hbar}} \int_{-p_{\max}}^{p_{\max}} \tilde{\psi}^{(u)*}(p)\tilde{\psi}^{(u)}(p)\tilde{\Xi}_k^*(p)\mathrm{d}p + \text{c.c.}\end{aligned} \tag{50}$$

and the Euler–Lagrange equation reduces to

$$\tilde{\psi}^{(u)}(p) = \frac{\frac{1}{\sqrt{2\pi\hbar}} \sum_{k=1}^{N} \lambda_k \tilde{\chi}_k(p)}{1 + \frac{1}{\sqrt{2\pi\hbar}} \sum_{k=1}^{N} \mu_k \tilde{\Xi}_k(p)}. \tag{51}$$

Although this may be difficult in practice, in principle, the substitution of (51) into (48) and (49) yields sufficient equations to solve for the $\{\lambda_k\}_{k=1}^N$ and $\{\mu_k\}_{k=1}^M$ in terms of the $\{a_k\}_{k=1}^N$ and $\{b_k\}_{k=1}^M$ and this yields the solution $\tilde{\psi}^{(u)}$.

B. A conjecture

Consider the case of a differentiable template function Φ whose derivative is bounded, $|\Phi'(x)| \leqslant K \forall x \in [-L/2, L/2]$, for some finite K. Assume that $\psi_N^{(u)}$ is a sequence of incident wave functions, calculated through the method of Sec. V A with the amplitudes of $\psi_N^{(u)}(x)$ and $\Phi(x)$ matched at N equidistantly spaced points x_k. We conjecture then that the supremum $|\psi_N'(x)|$ for all x and all N is finite as well,

$$|\psi_N'(x)| \leqslant M \quad \forall\, x \in \left[-\frac{L}{2}, \frac{L}{2}\right], \tag{52}$$

for some finite M. This is plausible because, else, $|\psi_N'(x)|$ would have to develop arbitrarily sharp spikes away from the template function in between some two points where its amplitudes are matched to those of the template function. From Sec. IV C, however, we expect large oscillations in the superoscillating stretch to be norm expensive and therefore be prevented from occurring, given that the $\psi_N^{(u)}$ are optimized to possess minimum norm for a given set of constraints.

C. Convergence

Proposition 2: Assume that the conjecture of Sec. VII B holds true. Then, $\{\psi_N(x)\}_N$ *converges uniformly and in the* L^2 *topology over the interval* $[-L/2, L/2]$ *to* $\Phi(x)$ *for* $N \to \infty$.

Proof: Partition the slit into $(N-1)$ equal-length intervals with the N endpoints $x_k^{(N)} := -(L/2) + (k-1)[L/(N-1)]$. Define $\{\alpha_N(x)\}_{N=2}^{\infty}$ by

$$\alpha_N(x) := \max\{x_k^{(N)} | k \in \{1, \ldots, N\}, x_k^{(N)} \leqslant x\}. \tag{53}$$

That is, $\alpha_N(x)$ is the closest point in the partition from the left to x. Then,

$$\begin{aligned} |\psi_N(x) - \Phi(x)| &\leqslant |\psi_N(x) - \Phi(\alpha_N(x))| + |\Phi(\alpha_N(x)) - \Phi(x)| \\ &= |\psi_N(x) - \psi_N(\alpha_N(x))| + |\Phi(\alpha_N(x)) - \Phi(x)| \\ &\leqslant M|x - \alpha_N(x)| + K|\alpha_N(x) - x| \leqslant \frac{(M+K)L}{N-1}, \end{aligned} \tag{54}$$

where we applied the triangle inequality and the mean value theorem. We therefore have uniform and L^2 convergence. □

VIII. SUMMARY

We started with the method for calculating superoscillatory wave functions introduced in Ref. 6 and applied it to concrete examples. We then generalized this method so that it now allows us to construct superoscillatory low-momentum wave functions with a wide range of predetermined properties. Namely, we can impose any arbitrary finite number of linear constraints. We calculated concrete examples.

Further, we addressed the question whether superoscillatory functions can be made to match any arbitrary continuous function on a finite interval. This would correspond to imposing an infinite number of constraints. Generally, the answer is no. However, we were able to prove that there always exists a sequence of superoscillatory wave functions which converges in the physically relevant L^2 topology towards any continuous template function over an arbitrarily large chosen interval.

This is of interest, for example, in the case of the single slit. We proved that the wave function of an incident low-momentum particle can be chosen to arbitrary precision such that, if the particle

passes through the slit, it will emerge with a predetermined arbitrarily large momentum expectation and with a momentum uncertainty that is as small as permitted by the width of the slit.

Our method for constructing superoscillating wave functions allows us to construct superoscillatory wave functions which match any *finite* number N of properties of a given template function (such as the template function's amplitudes or derivatives at specified points). This leads to the question if by letting the number of constraints, N, go to infinity we can obtain one of those sequences of superoscillatory wave functions which converge towards the template function in the L^2 topology.

We proved that such sequences exist but we have not proved that our particular method produces such sequences. The numerical evidence certainly suggests that this is the case. In fact, we found rather fast numerical convergence.

Nevertheless, it would be highly desirable to be able to prove that a given method for producing superoscillations can be used to calculate a sequence of superoscillatory functions that converges in the L^2 topology towards any given template function on an interval. An investigation based on Weierstrass' approximation theorem is in progress.[13]

Last, we found a method for identifying a class of superoscillatory functions by looking at their behavior in momentum space: superoscillatory functions can be viewed as functions which in momentum space are a linear combination of plane waves with coefficients such that their interference is maximal, i.e., such that their norm is minimal.

In this work we build a quantum logic that allows us to refer to physical magnitudes pertaining to different contexts from a fixed one without the contradictions with quantum mechanics expressed in no-go theorems. This logic arises from considering a sheaf over a topological space associated with the Boolean sublattices of the ortholattice of closed subspaces of the Hilbert space of the physical system. Different from standard quantum logics, the contextual logic maintains a distributive lattice structure and a good definition of implication as a residue of the conjunction. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1819525]

I. INTRODUCTION

Quantum mechanics has profound conceptual difficulties that may be posed in several ways. Nonetheless, almost every problem in the relation between the mathematical formalism and what may be called "our experience about the behavior of physical objects" can be encoded in the question about the possible meaning of the proposition "the physical magnitude *A* has a value and the value is this or that real number." Already from the first formalizations this point was recognized. For example, Dirac stated in his famous book: "The expression that an observable 'has a particular value' for a particular state is permissible in quantum mechanics in the special case when a measurement of the observable is certain to lead to the particular value, so that the state is an eigenstate of the observable. It may easily be verified from the algebra that, with this restricted meaning for an observable 'having a value,' if two observables have values for a particular state, then for this state the sum of the two observables (if the sum is an observable) has a value equal to the sum of the values of the two observables separately and the product of the two observables (if this product is an observable) has a value equal to the product of the values of the two observables separately."[10] This last point is the requirement of the functional compatibility condition (FUNC), to which we will return later. As long as we limit ourselves to speak about measuring results and avoid being concerned with what happens to nature when she is not measured, quantum mechanics carries out predictions with great accuracy. But, if we naively try to interpret eigenvalues as the possible or actual values of the physical properties of a system, we are faced with all kinds of no-go theorems that preclude this possibility. Most remarkable is the Kochen–Specker (KS) theorem, which rules out the noncontextual assignment of values to physical magnitudes.[17] Of course, to restrict the valuation to a subset of observables—typically to a complete set of commuting observables (CSCO) which constitutes a *context*—and refer to values of physical variables only in the sense allowed by the mathematical formalism, ensures no contradiction. So, a widely accepted position is to abandon seeking to describe what nature at the quantum level is and use the theory as a mere instrument of prediction. But, there are also different

[a)]Fellow of the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET); Electronic mail: domenech@iafe.uba.ar
[b)]Electronic mail: hfreytes@dm.uba.ar

proposals to investigate how to assign objective and measurable properties to a physical entity, i.e., how far we can refer to physical objects without contradiction with quantum theory. This paper is framed in that search.

Our proposal is to construct a logic to enable not only a Boolean valuation in each fixed context but also that, once chosen, certain set of projectors of the spectral decomposition of the operators (correspondingly, closed subspaces of Hilbert space $\mathcal{H}$) that admits a global Boolean valuation, to make it possible to refer at least partially to projectors pertaining to other contexts with the least arbitrariness.

Let us be concerned here with the simplest cases: pure states of the system are represented by normalized vectors of $\mathcal{H}$ and dynamical variables A by bounded self-adjoint operators $\mathbf{A}$ with discrete spectra. The possible results of the measurement of a (sharp) magnitude A are the eigenvalues a_i pertaining to the spectrum $\sigma(\mathbf{A})$ of its associated operator $\mathbf{A}$. To each of the eigenvalues a_i corresponds a projector $\mathbf{P}_i$ and correspondingly a closed subspace of $\mathcal{H}$. Every $\mathbf{A}$ admits a spectral decomposition

$$\mathbf{A} = \sum_i a_i \mathbf{P}_i,$$

where the equality is considered as a convergence in norm. So, observables may be discomposed to give an exhaustive and exclusive partition of the possible alternatives for the results of measurements. The probability to obtain one of them in an experimental procedure is given by the Born rule.

Now, let us suppose the state of the physical system is an eigenvector of a nondegenerate observable $\mathbf{A}$ (i.e., $\mathbf{A}$ constitutes a CSCO) so we know the eigenvalues of all projectors $\mathbf{P}_1, \mathbf{P}_2, \ldots, \mathbf{P}_n, \ldots$ of $\mathbf{A}$ for the system in this state. If any $\mathbf{P}_i$ lies in the spectral decomposition of another observable $\mathbf{B}$, then this "part" of B can be valued in a Boolean way. It is important to realize that this allows one to refer to observables pertaining to a CSCO from another CSCO. In categorical terms, this will be related to the possible local sections of a sheaf satisfying a certain kind of compatibility with respect to fixed contexts, to be exactly stated in what follows. From this formal analysis in terms of sheaves, we intend to build the mentioned logic, which we will call *contextual logic*. This *contextual logic* will allow us to formalize to what extent we can consider as objective properties of a physical system those properties represented by projectors pertaining to different contexts without facing no-go theorems. We will use a categorial frame to develop this logic, as has been the case during the last years, when applications of category theory tools to logical questions in standard quantum mechanics have begun to appear (for example, Isham and Butterfield,[15,16,13,6] also in the consistent histories approach,[14] in the interpretation of the Sasaki hook as an adjunction[8] and, in general, in the Geneve–Brussels approach[1,2,7]).

In Sec. II we introduce basic notions about lattice theory and topics in categories. We devote Sec. III to the problem of the valuations of physical magnitudes pertaining to different CSCCs. In Sec. IV we face the same problem from the point of view of sheaves, relating it to the dual spectral presheaf introduced in Ref. 15. In Sec. V we develop the contextual logic in a Kripke style and intuitionistic way. Finally, in Sec. VI we outline our conclusions.

II. BASIC NOTIONS

We recall from Refs. 3, 4, 11, and 18 some notions of the lattice theory and categories that will play an important role in what follows.

First, let $(A, \leqslant)$ be a poset and $X \subseteq A$. X is *decreasing set* if and only if for all $x \in X$, if $a \leqslant x$ then $a \in X$. For each $a \in A$ we define the *principal decreasing set* associated with a as $(a] = \{x \in A : x \leqslant a\}$. The set of all decreasing sets in A is denoted by A^+, and it is well known that $(A^+, \subseteq)$ is a complete lattice; thus $\langle A, A^+ \rangle$ is a topological space. We observe that if $G \in A^+$ and $a \in G$, then $(a] \subseteq G$. Therefore, $B = \{(a] : a \in A\}$ is a base of the topology A^+, which we will refer to as the *canonical base*. If $X \subseteq A$, we denote by ∂X the border of X, $C(X)$ the complement of X and X° the interior of X.

Let $\mathcal{A}$ be a category. We denote by $Ob(\mathcal{A})$ the class of objects and by $Ar(\mathcal{A})$ the class of arrows. Given an arrow $f:a\to b$, a is called domain of $f(a=\mathrm{dom}(f))$ and b is called codomain of $f(\mathrm{cod}(f))$. We denote by $[a,b]_{\mathcal{A}}$ the class of all arrows $a\to b$ in the category and by 1_A the identity arrow over the object A. $\mathcal{A}$ is said to be *small category* if and only if $Ob(\mathcal{A})$ is a set. A partially ordered set $(P,\leqslant)$ gives rise to a category with the elements of P as objects, and with precisely one arrow $p\to q$ if and only if $p\leqslant q$. In this case, $(P,\leqslant)$ is a small category. The category whose objects are sets and arrows are functions with the usual composition is denoted by *Ens*.

Let I be a topological space. A *sheaf* over I is a pair (A,p), where A is a topological space and $p:A\to I$ is a local homeomorphism. This means that each $a\in A$ has an open set G_a in A that is mapped homeomorphically by p onto $p(G_a)=\{p(x):x\in G_a\}$, and the latter is open in I. It is clear that p is a continuous and open map. If $p:A\to I$ is a sheaf over I, for each $i\in I$, the set $A_i=\{x\in A:p(x)=i\}$ is called the *fiber* over i. Each fiber has the discrete topology as subspace of A. *Local sections* of the sheaf p are continuous maps $\nu:U\to A$ defined over open proper subsets U of I such that the following diagram is commutative:

$$\begin{array}{ccc} U & \overset{\upsilon}{\longrightarrow} & A \\ & 1_U \searrow \equiv & \downarrow p \\ & & U \end{array}$$

In particular, we use the term *global section* only when $U=I$.

Given the category $\mathcal{A}$, one can form a new category $\mathcal{A}^{op}$, called *dual* category of $\mathcal{A}$, by taking the same objects but reversing the directions of all the arrows and the order of all compositions. $Ens^{\mathcal{A}^{op}}$ or $\hat{\mathcal{A}}$, where $\mathcal{A}$ is a small category, is the category whose objects are functors $F:\mathcal{A}^{op}\to Ens$ (also called *presheaves*) and whose arrows are natural transformations between presheaves. $\hat{\mathcal{A}}$ is a topos, i.e., has terminal object, pullbacks, exponentiation, and subobject classifier. The terminal object in $\hat{\mathcal{A}}$ is the functor $\mathbf{1}:\mathcal{A}^{op}\to Ens$ such that $\mathbf{1}(A)=\{*\}$ (the singleton) for each $A\in\mathcal{A}$ and for each arrow f, $\mathbf{1}(f)=\mathbf{1}_{\{*\}}$. For any presheaf $F:\mathcal{A}^{op}\to Ens$, the unique arrow $F\to\mathbf{1}$ is the natural transformation whose components are the unique functions $F(A)\to\{*\}$ for each object A in $\mathcal{A}$. Pullbacks, limits, and colimits are defined componentwise.

A *local section* of a presheaf $F:\mathcal{A}^{op}\to Ens$ is a natural transformation $\tau:U\to F$ such that U is a subfunctor of the presheaf $\mathbf{1}$. We only refer to *global sections* in the case that $U=\mathbf{1}$.

III. THE QUESTION OF VALUATION

Let $\mathcal{H}$ be the Hilbert space associated with the physical system and $L(\mathcal{H})$ be the set of closed subspaces on $\mathcal{H}$. If we consider the set of these subspaces ordered by inclusion, then $L(\mathcal{H})$ is a complete orthomodular lattice.[19] It is well known that each self-adjoint operator $\mathbf{A}$ has an associated Boolean sublattice W_A of $L(\mathcal{H})$. More precisely, W_A is the Boolean algebra of projectors $\mathbf{P}_i$ of the spectral decomposition $\mathbf{A}=\Sigma_i\, a_i\mathbf{P}_i$. We will refer to W_A as the spectral algebra of the operator $\mathbf{A}$. Any proposition about the system is represented by an element of $L(\mathcal{H})$ which is the algebra of quantum logic introduced by Birkhoff and von Neumann.[5]

Assigning values to a physical quantity A is equivalent to establishing a Boolean homomorphism $\upsilon:W_A\to\mathbf{2}$,[15] 2 being the two-element Boolean algebra. So, it is natural to consider the following definition.

Definition 3.1: Let $(W_i)_{i\in I}$ be the family of Boolean sublattices of $L(\mathcal{H})$. A global valuation over $L(\mathcal{H})$ is a family of Boolean homomorphisms $(\upsilon_i:W_i\to\mathbf{2})_{i\in I}$ such that $\upsilon_i|W_i\cap W_j=\upsilon_j|W_i\cap W_j$ for each $i,j\in I$.

This global valuation would give the values of all magnitudes at the same time maintaining a **compatibility condition** in the sense that whenever two magnitudes shear one or more projectors, the values assigned to those projectors are the same from every context.

But, KS theorem assures that we cannot assign real numbers pertaining to their spectra to operators $\mathbf{A}$ in such a way to satisfy the functional composition principle (FUNC), which is the expression of the "natural" requirement mentioned by Dirac that, for any operator $\mathbf{A}$ representing

a dynamical variable and any real-valued function $f(\mathbf{A})$, the value of $f(\mathbf{A})$ is the corresponding function of the value of $\mathbf{A}$. This is a very restrictive constraint because it does not allow assignment of values to all possible physical quantities or assignment of true–false as truth values to all propositions about the system, nor even noncontextual partial ones. KS theorem means that, if we demand a valuation to satisfy FUNC, then it is forbidden to define it in a noncontextual fashion for subsets of quantities represented by commuting operators. In the algebraic terms of the previous definition, KS theorem reads:

Theorem 3.2: *If $\mathcal{H}$ is a Hilbert space such that $dim(\mathcal{H})>2$, then a global valuation over $L(\mathcal{H})$ is not possible.* □

Of course, contextual valuations allow us to refer to different sets of actual properties of the system which define its state in each case. Algebraically, a *contextual valuation* is a Boolean valuation over one chosen spectral algebra. In classical particle mechanics it is possible to define a Boolean valuation of all propositions, that is to say, it is possible to give a value to all the properties in such a way of satisfying FUNC. This possibility is lost in the quantum case. And, it is not a matter of interpretation, it is the underlying mathematical structure that enables this possibility for classical mechanics and forbids it in the quantum case. The impossibility to assign values to the properties while at the same time satisfying FUNC is a weighty obstacle for almost any interpretation of the formalism as something more than a mere instrument.

IV. SPECTRAL SHEAF

$L(\mathcal{H})$ being the lattice of closed subspaces of the Hilbert space $\mathcal{H}$, we consider the family $\mathcal{W}$ of all Boolean subalgebras of the lattice $L(\mathcal{H})$ ordered by inclusion and the topological space $\langle \mathcal{W}, \mathcal{W}^+ \rangle$. On the set

$$E = \{(W,f): W \in \mathcal{W}, \quad f: W \to \mathbf{2} \text{ is a Boolean homomorphism}\},$$

we define a partial ordering given as

$$(W_1,f_1) \leqslant (W_2,f_2) \Leftrightarrow W_1 \subseteq W_2 \quad \text{and } f_1 = f_2|W_1.$$

Thus, we consider the topological space $\langle E, E^+ \rangle$ whose canonical base is given by the principal decreasing sets $((W,f)] = \{(G, f|G): G \subseteq W\}$. By simplicity $((W,f)]$ is noted as $(W,f]$.

Proposition 4.1: The map $p: E \to \mathcal{W}$ such that $(W,f) \mapsto W$ is a sheaf over $\mathcal{W}$.

Proof: Let $(W,f) \in E$. If we consider the open set $(W,f]$ in E, then $p((W,f]) = (W]$, and as a consequence $p((W,f])$ is an open set in $\mathcal{W}$. If we denote by p' the restriction $p|(W,f]$, then from the definition of p it is clear that $p': (W,f] \to (W]$ is a bijective map that preserves order inclusion. Thus, p' is a continuous map. Finally, p is a local homeomorphism. □

We refer to the sheaf $p: E \to \mathcal{W}$ as the *spectral sheaf*.

Proposition 4.2: Let $\nu: U \to E$ be a local section of the spectral sheaf p. Then, for each $W \in U$ we have

(1) $\nu(W) = (W,f)$ *for some Boolean homomorphism* $f: W \to \mathbf{2}$,
(2) *if* $W_0 \subseteq W$, *then* $\nu(W_0) = (W_0, f|W_0)$.

Proof: Since ν is a local section we consider the following commutative diagram:

$$\begin{array}{ccc} U & \xrightarrow{\upsilon} & E \\ & 1_U \searrow & \equiv \quad \downarrow p \\ & & U \end{array}$$

(1) It follows as an immediate consequence of the commutativity of the diagram.
(2) Since ν is continuous, $\nu^{-1}((W,f])$ is an open set in $\mathcal{W}$ (i.e., a decreasing set). Consequently, $W_0 \in \nu^{-1}((W,f])$ since $W_0 \subseteq W$ and $W \in \nu^{-1}((W,f])$. Thus, $\nu(W_0) \in (W,f]$, resulting in $\nu(W_0) = (W_0, f|W_0)$. □

From the physical perspective, we may state that the spectral sheaf takes into account the whole set of possible ways of assigning truth values to the propositions associated with the projectors of the spectral decomposition $\mathbf{A}=\Sigma_i a_i\mathbf{P}_i$. The continuity of a local section of p guarantees that the truth value of a proposition is maintained when considering the inclusion of subalgebras. In this way, the *compatibility condition* of the Boolean valuation with respect of intersection of pairs of Boolean sublattices of $L(\mathcal{H})$ is maintained.

A global section $\tau:\mathcal{W}\rightarrow E$ of p is interpreted as follows: the map assigns to every $W\in\mathcal{W}$ a fixed Boolean valuation $\tau_w:W\rightarrow\mathbf{2}$, obviously satisfying the compatibility condition. So, KS theorem in terms of the spectral sheaf reads:

Theorem 4.3: *If $\mathcal{H}$ is a Hilbert space such that $dim(\mathcal{H})>2$, then the spectral sheaf p has no global sections.* □

We may build a *contextual valuation* in terms of a local section as follows:

Let A be a physical magnitude with known value, i.e., we have been able to establish a Boolean valuation $f:W_A\rightarrow 2$. It is not very hard to see that the assignment

$$\nu:(W]\rightarrow E \text{ such that for each } W_i\in(W],\nu(W_i)=(W_i,\ f|W_i),$$

is a local section of p.

To extend contextual valuations we turn now to consider local sections. To do this we introduce the following definition:

Definition 4.4: Let ν be a local section of p and W_A the spectral algebra associated with the operator **A**. *Then, an extended valuation over A is given by the set*

$$\overline{\nu}(A)=\{W_B\in dom(\nu):W_B\subseteq W_A\}.$$

Given the previous definition, it is easy to prove the following proposition:

Proposition 4.5: If ν is a local section of p and W_A the spectral algebra associated to the operator **A**, *then*

(1) $\overline{\nu}(A)$ *is a decreasing set,*
(2) *if* $W_A\in U$ *then* $\overline{\nu}(A)=(W_A]$. □

We can start from the spectral sheaf to build a representation as presheaf such that local sections of the former are identifiable to local sections of the latter. When considering the family $\mathcal{W}$ ordered by inclusion, $\mathcal{W}$ can be regarded as a small category. Thus, we can take the topos presheaf $\hat{\mathcal{W}}$. Denoting E_W the fiber of the spectral sheaf p over W for each $W\in\mathcal{W}$, we consider the following presheaf:

$$D:\mathcal{W}^{op}\rightarrow Ens$$

such that

(i) $D(W)=E_W$ for each $W\in Ob(\mathcal{W})$;
(ii) if $i:W_1\subseteq W_2$ lies in $Ar(\mathcal{W})$, then $D_i:D(W_2)\rightarrow D(W_1)$ is such that $D_i(g)=g|W_1$.

It is clear that the presheaf acting over arrows satisfies the compatibility condition. Denoting Sec_p and Sec_D the sets of (global and local) sections of p and D, respectively, we can establish the following proposition:

Proposition 4.6:

$$Sec_p\simeq Sec_D.$$

Proof: Let $\nu:U\rightarrow E\in Sec_p$ and consider the presheaf $\tilde{U}:\mathcal{W}^{op}\rightarrow Ens$, whose action over $Ob(\mathcal{W})$ is given by

$$\widetilde{U}(W) = \begin{cases} \{*\}, & \text{if } W \in U \\ \varnothing, & \text{otherwise,} \end{cases}$$

and whose action over arrows is immediate. It is clear that $\widetilde{U}$ is a subfunctor of the presheaf **1**. From U we construct a natural transformation

$$\begin{array}{ccc} & & D \\ & & \rightarrow \\ \mathcal{W}^{op} & \tau_\nu \uparrow & Ens \\ & & \rightarrow \\ & & \widetilde{U} \end{array},$$

such that, for each $W \in \mathcal{W}$, $\tau_\nu(U(W)) = \nu(W)$. Thus, we have a map $Sec_p \rightarrow Sec_D$ given by $\nu \mapsto \tau_\nu$. It is not hard to see that this is an injective map. To see that it is also a surjective map, we consider a section of the presheaf D, namely $\tau: \widetilde{U} \rightarrow D$, and we prove that there exists a section ν of the spectral sheaf such that $\nu \mapsto \tau_\nu = \tau$. Let $U = \{W \in \mathcal{W}: \widetilde{U}(W) = \{*\}\}$. If $W \in U$ and $W_o \subseteq W$, then $\widetilde{U}(W_o) = \{*\}$, since $\widetilde{U}$ is a contravariant subfunctor of **1**. Thus, W_o lies in U, resulting in U, a decreasing set (i.e., an open set) in $\mathcal{W}$. Now, we consider the map $\nu: U \rightarrow E$ such that, for each $W \in U$, $\nu(W) = (W, \tau(\widetilde{U}(W)))$. It is clear that the following diagram is commutative:

$$\begin{array}{ccc} U & \overset{\upsilon}{\longrightarrow} & E \\ & 1_U \searrow \equiv & \downarrow p \\ & & U \end{array}$$

Now, we prove that ν is a continuous map. Let $(W_1, f]$ be an open set of the canonical base of E, $\nu^{-1}((W_1, f]) = \{W \in \mathcal{W}: \nu(W) \in (W_1, f]\}$, and we assume that $\nu^{-1}((W_1, f])$ is not the empty set. Let $W \in \nu^{-1}((W_1, f])$ and $W_x \subseteq W$. Since τ is a natural transformation, it follows that $\tau(\widetilde{U}(W_x)) = \tau(\widetilde{U}(W))|W_x$. Since $\nu(W) \in (W_1, f]$, it is clear that $\nu(W) = (W, f|W)$, resulting that $\widetilde{U}(W_x) = f|W_x$ and $W_x \in \nu^{-1}((W_1, f])$. This proves the continuity of the map. It is not very hard to see that $\tau = \tau_\nu$, thus it is proved that it is a surjective map. □

Remark 4.7: The presheaf D from the spectral sheaf is the dual spectral presheaf defined in Ref. 15.

Taking into account the last Proposition, we can write KS theorem in terms of presheaves from the spectral sheaf:

Theorem 4.8: *If $\mathcal{H}$ is a Hilbert space such that $dim(\mathcal{H}) > 2$, then the dual spectral presheaf D has no global sections.* □

Possible obstructions to the construction of global sections for the case of finite dimensional $\mathcal{H}$ are shown in Ref. 12.

On the other hand, in terms of a local section $\nu: U \rightarrow D$ of D, extended contextual valuations over an operator A may be defined as

$$\overline{\nu}(A) = \{W_B \subseteq W_A: U(W_B) = \{*\}\}.$$

Valuations are deeply connected to the election of particular local sections of the spectral sheaf. So, we see here once more that we cannot speak of the value of a physical magnitude without specifying this election, which clearly means the election of a particular context. This is in agreement with the statement that contextuality is "endemic" in any attempt to ascribe properties to quantities in quantum theories.[15]

V. CONTEXTUAL LOGIC

We know that if $\mathcal{W}$ is the family of Boolean subalgebras of $L(\mathcal{H})$, to take a local section ν of the spectral sheaf means an assignment of Boolean valuations to algebras in the proper subfamily $Dom(\nu)$ maintaining the compatibility condition. Now, an interesting question is to ask what ν can "tell us" about W when $W \notin Dom(\nu)$. Let us state more accurately this expression to precise our aim in the search of a *contextual logic*.

Definition 5.1: Let ν be a local section of the spectral sheaf. If $W_B \in Dom(\nu)$ and $W_B \subseteq W_A$, then we will say that W_B has *Boolean information* about *W_A*.

Clearly, this means that, in a given state of the system, the complete knowledge of the spectral decomposition of **B** lets us know the eigenvalue of one or more projectors in the spectral decomposition of **A**. *Contextual logic* allows some kind of "paste" among Boolean sublattices of $L(\mathcal{H})$ and so among CSCOs. A valuation in terms of decreasing sets maintains it "downstream" with respect to subalgebras, i.e., when the valuation of a subalgebra is given, all its subalgebras are automatically valuated. This makes it possible to have Boolean information of different contexts from the one chosen in the following sense: once fixed a local section ν, if $W_B \in Dom(\nu)$ and $W_A \notin Dom(\nu)$ then, referring to W_A from W_B takes into account the Boolean information that $W_B \cap W_A$ has about W_A.

We will now construct a propositional language *Self* for contextual logic whose atomic formulas refer to the physical magnitudes represented for bounded self-adjoint operators with discrete spectra. Intuitively, we can consider the set of atomic formulas $\mathcal{P}$ as

$$\mathcal{P} = \{A{:}A \text{ bounded self} - \text{adjoint operator}\}.$$

Then, this language is conformed as follows:

$$Self = \langle \mathcal{P}, \vee, \wedge, \rightarrow, \neg \rangle,$$

and it is clear that the formulas may be obtained in the usual way.

We will now turn to the use of Kripke models built starting from any local section of the spectral sheaf p because it allows us to naturally adapt the idea of Boolean knowledge. Thus, the obtained valuation will result in an extended contextual valuation.

Definition 5.2: We consider the poset $\langle \mathcal{W}, \subseteq \rangle$ as a *frame* for the Kripke model for *Self*. Let ν be a local section of p. Thus, we define the Kripke model $\mathcal{M} = \langle \mathcal{W}, \overline{\nu} \rangle$ with the following forcing:

(1) $\mathcal{M} \Vdash_W A$ if and only if $\mathcal{W} \in \overline{\nu}(\mathbf{A})$ with $A \in \mathcal{P}$;
(2) $\mathcal{M} \Vdash_W \alpha \vee \beta$ if and only if $\mathcal{M} \Vdash_W \alpha$ or $\mathcal{M} \Vdash_W \beta$;
(3) $\mathcal{M} \Vdash_W \alpha \wedge \beta$ if and only if $\mathcal{M} \Vdash_W \alpha$ and $\mathcal{M} \Vdash_W \beta$;
(4) $\mathcal{M} \Vdash_W \alpha \rightarrow \beta$ if and only if $\forall B \subseteq W$, if $\mathcal{M} \Vdash_B \alpha$, then $\mathcal{M} \Vdash_B \beta$;
(5) $\mathcal{M} \Vdash_W \neg \alpha$ if and only if $\forall B \subseteq W\ \mathcal{M} \nVdash_B \alpha$.

Given this forcing we can accurately define the idea of extended contextual valuation over *Self*.

Definition 5.3: Given a local section ν over p, an extended contextual valuation is the map $\overline{\nu}{:}Self \rightarrow \mathcal{W}^+$ defined as

$$\overline{\nu}(\alpha) = \{W{:}\mathcal{M} \Vdash_W \alpha\}.$$

Taking into account that $\mathcal{W}^+$ is a topological space, it is not very hard to see that $\overline{\nu}(\alpha)$ is an open set of $\mathcal{W}$. Now, we can to establish the following proposition:

Proposition 5.4: Let α be a formula in Self and consider the Kripke model $\mathcal{M} = \langle \mathcal{W}, \nu \rangle$. Then

(1) $\mathcal{M} \Vdash_W \neg \alpha$ if and only if $W \in (C\overline{\nu}(\alpha))^\circ$,
(2) $\mathcal{M} \nVdash_W \alpha$ and $\mathcal{M} \nVdash_W \neg \alpha$ if and only if $W \in \partial \overline{\nu}(\alpha)$.

Proof: (1) If $\mathcal{M} \Vdash_W \neg \alpha$, then $\forall B \subseteq W$, $\mathcal{M} \nVdash_B \alpha$ and $\forall B \subseteq W\ B \notin \overline{\nu}(\alpha)$. Thus $(W] \subseteq (C\overline{\nu}(\alpha))^\circ$ and $W \in (C\overline{\nu}(\alpha))^\circ$. On the other hand, if $W \in (C\overline{\nu}(\alpha))^\circ$, then there exists an open set G in $\mathcal{W}$ such

that $W \in G \subseteq C(\overline{\nu}(\alpha))$. Since G is a decreasing set, we have that $(W] \subseteq G \subseteq C(\overline{\nu}(\alpha))$ and $\mathcal{M}\| =_W \neg\alpha$. (2) It follows from (1) and the fact that $\mathcal{W} = \overline{\nu}(\alpha) \cup (C\overline{\nu}(\alpha))^\circ \cup \partial\overline{\nu}(\alpha))$. □

Remark 5.5: Following the usual interpretation of the Kripke model, the frame represents all possible states of knowledge that are preserved forward in time. In our case, the frame $\langle \mathcal{W}, \subseteq \rangle$, $\mathcal{W}$ represents all states of Boolean knowledge in the sense of all possible Boolean valuations of spectral algebras, and the usual notion of "preserving knowledge through time" must be understood in terms of $\subseteq$ as "preserving valuations in spectral subalgebras." The forcing $K\|=_W \alpha$ is interpreted as *the spectral algebra W has Boolean knowledge about* α, i.e., the complete Boolean valuation of W is known and W lies in the decreasing set associated with the formula α. By Proposition 4.5, to know the eigenvalue of $\mathbf{A}$ is expressed in terms of the forcing as $\mathcal{M}\|=_{(W_A]} A$.

$\mathcal{W}^+$ being a topological space, it is a Heyting algebra with meet and join operations, the classical ones and implication and negation defined as follows:

$$S \to T = \{P \in \mathcal{W}: \forall\, X \subseteq P, \textit{if } X \in S \textit{ then } X \in T\},$$

$$\neg S = \{P \in \mathcal{W}: \forall\, X \subseteq P, X \notin S\}.$$

Thus, the extended contextual valuation is a Heyting valuation of *Self* from the Heyting algebra $\mathcal{W}^+$ such that

(1) $\overline{\nu}(\alpha \vee \beta) = \overline{\nu}(\alpha) \cup \overline{\nu}(\beta)$;
(2) $\overline{\nu}(\alpha \wedge \beta) = \overline{\nu}(\alpha) \cap \overline{\nu}(\beta)$;
(3) $\overline{\nu}(\alpha \to \beta) = \overline{\nu}(\alpha) \to \overline{\nu}(\beta)$;
(4) $\overline{\nu}(\neg\alpha) = \neg\,\overline{\nu}(\alpha)$.

Taking into account the restrictions in the valuations imposed by the KS theorem, a Heyting valuation $v: Self \to \mathcal{W}^+$ such that $v(A) = (A]$ for each atomic formula A is not possible. So, it is clear that contextual logic is an intuitionistic logic in which not all of the Heyting valuations are allowed.

VI. CONCLUSIONS

Contextual logic is a formal language to deal with combinations of propositions about physical properties of a quantum system that are well defined in different contexts. These properties are regarded from a fixed context, which guarantees the avoidance of no-go theorems. This means that one can refer to contexts other than the chosen one by building a Kripke model in which each proposition is given a decreasing set as its truth value.

There are different formal languages on the orthomodular lattice of closed subspaces of $\mathcal{H}$ (such as orthologic or orthomodular quantum logic), but these logics give rise to different problems that lack an intuitive understanding, such as the "implication problem" (briefly, eight different connectives may represent the material conditional; see Ref. 9). On the contrary, as contextual logic is an intuitionistic one—with restrictions on the allowed valuations arising from the KS theorem—it has "good" properties as the distributive lattice structure and a nice definition of the implication as a residue of the conjunction. The price paid is it being a contextual language. But, this is not a difficulty, it is a main feature of quantum mechanics.

(Received 2 August 2004; accepted 13 September 2004; published online 27 December 2004)

Two and three dimensional Hamiltonians with generalized and ordinary shape invariance symmetry have been obtained by Fourier transforming over some coordinates of the SU(3) Casimir operator defined on SU(3)/SU(2) symmetric space. It is shown that the generalized shape invariance of the two dimensional Hamiltonian is equivalent to SU(3) symmetry while in the three dimensional one, the ordinary shape invariance is equivalent to contracted SU(3) and there is one to one correspondence between the representations of the generalized shape invariance symmetry of the two (three) dimensional Hamiltonian and SU(3) [contracted SU(3)] Verma bases. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1827325]

I. INTRODUCTION

Exactly solvable potentials are the central and fundamental problems of mathematical physics, consequently they have attracted much interest both in theoretical physics and mathematics. There are many methods of obtaining exactly solvable potentials in quantum mechanics. The most powerful methods are the algebraic method,[1] supersymmetric and shape invariant factorization of the Schrödinger equation in one and two or three dimensional exactly solvable models.[2–5] In all these works it is shown that there is a close connection between the shape invariance symmetry of one or higher dimensional Hamiltonians and some rank one semisimple Lie algebra or higher rank nonsemisimple algebras, where this equivalence between the one dimensional shape invariant and the rank one semisimple Lie algebra has been shown in Ref. 6.

Here in this work we introduce two and three dimensional Hamiltonians with a new kind of shape invariance. It is shown that the shape invariance symmetry of the two dimensional Hamiltonian is equivalent to SU(3) symmetry where we call it generalized shape invariance while the shape invariance associated with the three dimensional Hamiltonian is equivalent to contracted SU(3) ordinary shape invariance and there is one to one correspondence between the representation of the generalized shape invariance symmetry of two (three) dimensional Hamiltonians and SU(3) [contracted SU(3)] Verma bases.

The paper is organized as follows: In Sec. II after introducing the parametrization of SU(3) Lie group we derive its right invariant vector fields and Casimir operator on SU(3)/SU(2). In Sec. III, using the Fourier transformation together with the coset reduction we obtain the two dimensional Hamiltonian $H_l(m_1,m_2)$ of charged particle on S^2 sphere in the presence of an electric field. Section IV is devoted to SU(3) Verma basis,[7] and their connection with eigenspectrum and de-

generacy of the above Hamiltonian. In Sec. V we talk about the generalized shape invariance of this Hamiltonian. In Sec. V, through Inonu–Wigner contraction[8] of SU(3), we obtain three dimensional ordinary shape invariance Hamiltonians. The paper is ended with a conclusion and one appendix.

II. THE RIGHT INVARIANT VECTOR FIELDS AND QUADRATIC CASIMIR OPERATOR OF SU(3) GROUP OVER THE SU(3)/SU(2) COSET MANIFOLD

According to Ref. 9, we can parametrize an arbitrary element of the SU(3)/SU(2) coset manifolds in the following form:

$$U=\begin{pmatrix} \sin(\theta) & 0 & \cos(\theta)e^{i(\eta+\chi_1)} \\ -\cos(\theta)\cos(\varphi)e^{i(\chi_2-\chi_1)} & \sin(\varphi)e^{-i\eta} & \sin(\theta)\cos(\varphi)e^{i(\eta+\chi_2)} \\ -\cos(\theta)\sin(\varphi)e^{-i\chi_1} & -\cos(\varphi)e^{-i(\eta+\chi_2)} & \sin(\theta)\sin(\varphi)e^{i\eta} \end{pmatrix}, \tag{2.1}$$

where $0<\theta, \varphi\leqslant\pi/2$ and $0\leqslant\eta, \chi_1, \chi_2<2\pi$. Now, an arbitrary element of SU(3) group manifold can be obtained by multiplying the coset element given in (2.1) by an arbitrary element h of stability group SU(2) with the parametrization $h=\exp(i\lambda_3\alpha)\exp(i\lambda_2\beta)\exp(i\lambda_3\gamma)$ from left or right, where 3×3 Hermitian Gell–Mann matrices λ_i, $i=1,2,\ldots,8$ are defined as

$$\lambda_1=\begin{pmatrix}0&1&0\\1&0&0\\0&0&0\end{pmatrix},\quad \lambda_2=\begin{pmatrix}0&-i&0\\i&0&0\\0&0&0\end{pmatrix},\quad \lambda_3=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&0\end{pmatrix},$$

$$\lambda_4=\begin{pmatrix}0&0&1\\0&0&0\\1&0&0\end{pmatrix},\quad \lambda_5=\begin{pmatrix}0&0&-i\\0&0&0\\i&0&0\end{pmatrix},\quad \lambda_6=\begin{pmatrix}0&0&0\\0&0&1\\0&1&0\end{pmatrix}, \tag{2.2}$$

$$\lambda_7=\begin{pmatrix}0&0&0\\0&0&-i\\0&i&0\end{pmatrix},\quad \lambda_8=\frac{1}{\sqrt{3}}\begin{pmatrix}1&0&0\\0&1&0\\0&0&-2\end{pmatrix}.$$

Usually the right invariant vector fields of SU(3) group manifold can be obtained from the right invariant su(3) Lie algebra valued one forms $dG\,G^{-1}=e^i_\mu\,d\xi^\mu\,\lambda_i$ with $G=Uh$,[10] where e^i_μ are right invariant fiel-beins and $\xi^\mu=(\theta,\varphi,\eta,\chi_1,\chi_2,\alpha,\beta,\gamma)$ are coordinates of SU(3) group manifold. Then the right invariant vector field can be written as $R_i=e^\mu_i(\partial/\partial\xi^\mu)$, where e^μ_i are the inverse of the right invariant fiel-beins e^i_μ. Now, the SU(3) right invariant vector fields over the SU(3)/SU(2) coset manifold[11,12] can be obtained simply by projecting the SU(3) right invariant vector fields over the principal bundle SU(3) to the base manifold SU(3)/SU(2), where it leads to the vanishing of the components which are tangent to SU(2) fiber manifold (stability group).

Using the above prescription, after some lengthy and tedious calculation via Maple software we get the following expressions for the SU(3) right invariant vector fields over the SU(3)/SU(2) coset manifold:

$$R_\pm=\frac{1}{2}e^{\pm i(\chi_1-\chi_2)}\left[\mp\cos(\varphi)\frac{\partial}{\partial\theta}\pm\cot(\theta)\sin(\varphi)\frac{\partial}{\partial\varphi}+i\tan(\theta)\cos(\varphi)\frac{\partial}{\partial\chi_1}+i\frac{\cot(\theta)}{\cos(\varphi)}\frac{\partial}{\partial\chi_2}\right], \tag{2.3}$$

$$Y_\pm=\frac{1}{2}e^{\pm i\chi_1}\left[\pm\sin(\varphi)\frac{\partial}{\partial\theta}\pm\cot(\theta)\cos(\varphi)\frac{\partial}{\partial\varphi}-i\frac{\cot(\theta)}{\sin(\varphi)}\frac{\partial}{\partial\eta}\right.$$
$$\left.+2i\frac{\cos^2(\theta)-\sin^2(\theta)\sin^2(\varphi)}{\sin(2\theta)\sin(\varphi)}\frac{\partial}{\partial\chi_1}+i\frac{\cot(\theta)}{\sin(\varphi)}\frac{\partial}{\partial\chi_2}\right], \tag{2.4}$$

$$X_{\pm}=\frac{1}{2}e^{\mp i\chi_2}\left[\mp\frac{\partial}{\partial\varphi}-i\cot(\varphi)\left(\frac{\partial}{\partial\eta}-\frac{\partial}{\partial\chi_1}\right)+2i\cot(2\varphi)\frac{\partial}{\partial\chi_2}\right], \tag{2.5}$$

$$R_3=-\frac{i}{2}\left(\frac{\partial}{\partial\chi_1}-\frac{\partial}{\partial\chi_2}\right),\quad R_8=\frac{i\sqrt{3}}{2}\left(\frac{2}{3}\frac{\partial}{\partial\eta}-\frac{\partial}{\partial\chi_1}-\frac{\partial}{\partial\chi_2}\right), \tag{2.6}$$

where $R_{\pm}=\frac{1}{2}(R_1\pm iR_2)$, $Y_{\pm}=\frac{1}{2}(R_4\mp iR_5)$, and $X_{\pm}=\frac{1}{2}(R_6\pm iR_7)$. After some algebraic calculations one can show that, the above generators satisfy su(3) Lie algebra commutation relations. Also it is straightforward to show that the following defined su(3) quadratic Casimir operator commutes with all of the above generators

$$C=\tfrac{1}{2}(R_+R_-+R_-R_+)+\tfrac{1}{2}(Y_+Y_-+Y_-Y_+)+\tfrac{1}{2}(X_+X_-+X_-X_+)+R_3^2+R_8^2, \tag{2.7}$$

where after calculations, we obtain the following expression (by ignoring the factor $\frac{1}{4}$):

$$\begin{aligned}C=-\Bigg[&\frac{\partial^2}{\partial\theta^2}+\frac{1}{\sin^2(\theta)}\frac{\partial^2}{\partial\varphi^2}+\frac{4-\cos^2(\theta)\sin^2(\varphi)-\cos^2(\varphi)}{3\sin^2(\theta)\sin^2(\varphi)}\frac{\partial^2}{\partial\eta^2}+\frac{1-\sin^2(\theta)\cos^2(\varphi)}{\sin^2(\theta)\cos^2(\theta)\sin^2(\varphi)}\frac{\partial^2}{\partial\chi_1^2}\\&+\frac{1}{\sin^2(\theta)\sin^2(\varphi)\cos^2(\varphi)}\frac{\partial^2}{\partial\chi_2^2}-\frac{2}{\sin^2(\theta)\sin^2(\varphi)}\left(\frac{\partial^2}{\partial\eta\partial\chi_1}+\frac{\partial^2}{\partial\eta\partial\chi_2}-\frac{\partial^2}{\partial\chi_1\partial\chi_2}\right)\\&+\frac{2(4\cos^2(\theta)-1)}{\sin(2\theta)}\frac{\partial}{\partial\theta}+\frac{2\cot(2\varphi)}{\sin^2(\theta)}\frac{\partial}{\partial\varphi}\Bigg].\end{aligned} \tag{2.8}$$

Similarly we can calculate the SU(3) left invariant vector fields, where its structure constant, is minus the right invariant ones but its quadratic Casimir operator is the same as the right one. Here we need only the right invariant vector fields and we do not need to quote the left invariant ones here. Also one can show that the Casimir operator is the same as Laplace–Beltrami operator of adjoint invariant metric.

III. REDUCTION OF THE CASIMIR OPERATOR TO TWO-DIMENSIONAL HAMILTONIAN OF A CHARGED PARTICLE ON S^2 SPHERE

In order to reduce the SU(3) Casimir operator together with its right invariant vector fields defined on SU(3)/SU(2) coset manifold to a two-dimensional operator, first we eliminate the coordinate η by Fourier transforming over the coordinate η by kernel $e^{i\eta l}$, where after similarity transformation $R\to f^{-1}(\theta,\varphi)Rf(\theta,\varphi)$ with similarity function $f^{-1}(\theta,\varphi)=\sin(\theta)\sqrt{\cos(\theta)\sin(2\varphi)}$ the right invariant vector fields and their quadratic Casimir operator take the following form:

$$\begin{aligned}R_{\pm}=\frac{1}{2}e^{\pm i(\chi_1-\chi_2)}\Bigg[&\mp\cos(\varphi)\frac{\partial}{\partial\theta}\pm\cot(\theta)\sin(\varphi)\frac{\partial}{\partial\varphi}+i\tan(\theta)\cos(\varphi)\frac{\partial}{\partial\chi_1}\\&+i\frac{\cot(\theta)}{\cos(\varphi)}\frac{\partial}{\partial\chi_2}\pm\frac{\cos^2(\theta)-\cos^2(\varphi)\sin^2(\theta)}{\sin(2\theta)\cos(\varphi)}\Bigg],\end{aligned} \tag{3.1}$$

$$\begin{aligned}Y_{\pm}=\frac{1}{2}e^{\pm i\chi_1}\Bigg[&\pm\sin(\varphi)\frac{\partial}{\partial\theta}\pm\cot(\theta)\cos(\varphi)\frac{\partial}{\partial\varphi}+2i\frac{\cos^2(\theta)-\sin^2(\theta)\sin^2(\varphi)}{\sin(2\theta)\sin(\varphi)}\frac{\partial}{\partial\chi_1}\\&+i\frac{\cot(\theta)}{\sin(\varphi)}\frac{\partial}{\partial\chi_2}\mp\frac{\cos^2(\theta)-\sin^2(\varphi)\sin^2(\theta)}{\sin(2\theta)\sin(\varphi)}+l\frac{\cot(\theta)}{\sin(\varphi)}\Bigg],\end{aligned} \tag{3.2}$$

$$X_{\pm}=\frac{1}{2}e^{\mp i\chi_2}\left[\mp\frac{\partial}{\partial\varphi}+i\cot(\varphi)\frac{\partial}{\partial\chi_1}+2i\cot(2\varphi)\frac{\partial}{\partial\chi_2}\pm\cot(2\varphi)+l\cot(\varphi)\right], \tag{3.3}$$

$$R_3 = -\frac{i}{2}\left(\frac{\partial}{\partial\chi_1} - \frac{\partial}{\partial\chi_2}\right), \quad R_8 = -\frac{i\sqrt{3}}{2}\left(\frac{\partial}{\partial\chi_1} + \frac{\partial}{\partial\chi_2} - 2i\frac{l}{3}\right). \tag{3.4}$$

One can straightforwardly show that the above generators satisfy su(3) Lie algebra commutation relations

$$[R_3, R_\pm] = \pm R_\pm, \quad [R_3, Y_\pm] = \pm \tfrac{1}{2} Y_\pm, \quad [R_3, X_\pm] = \pm \tfrac{1}{2} X_\pm,$$

$$[R_8, Y_\pm] = \pm \frac{\sqrt{3}}{2} Y_\pm, \quad [R_8, X_\pm] = \mp \frac{\sqrt{3}}{2} X_\pm,$$

$$[R_+, R_-] = 2R_3, \quad [R_\pm, Y_\mp] = \pm X_\pm, \quad [R_\pm, X_\mp] = \mp Y_\pm,$$

$$[Y_+, Y_-] = R_3 + \sqrt{3}R_8, \quad [X_+, X_-] = R_3 - \sqrt{3}R_8, \quad [Y_\pm, X_\pm] = \mp R_\pm. \tag{3.5}$$

Also the Casimir operator reduces to

$$\begin{aligned} C = -\Bigg[& \frac{\partial^2}{\partial\theta^2} + \cot(\theta)\frac{\partial}{\partial\theta} + \frac{1}{\sin^2(\theta)}\frac{\partial^2}{\partial\varphi^2} + \frac{1}{\sin^2(\theta)\sin^2(\varphi)}\Bigg(\frac{1-\sin^2(\theta)\cos^2(\varphi)}{\cos^2(\theta)}\frac{\partial^2}{\partial\chi_1^2} \\ & + \frac{1}{\cos^2(\varphi)}\frac{\partial^2}{\partial\chi_2^2} + 2\frac{\partial^2}{\partial\chi_1\partial\chi_2} - 2il\left(\frac{\partial}{\partial\chi_1} + \frac{\partial}{\partial\chi_2}\right) - \frac{l^2}{3}(4 - \cos^2(\theta)\sin^2(\varphi) - \cos^2(\varphi))\Bigg) \\ & + \frac{1}{4}\tan^2(\theta) + \cot^2(\theta) + \frac{\cot^2(2\varphi)}{\sin^2(\theta)}\Bigg]. \end{aligned} \tag{3.6}$$

For convenience we have denoted the reduced generators with the same notation of the preceding section. Now we eliminate the coordinates χ_1 and χ_2 through Fourier transformation over them with the kernel $e^{i(m_1\chi_1 - m_2\chi_2)}$, then Casimir operator (3.6) reduces to the following Hamiltonian:

$$H_l(m_1, m_2) = -\left(\frac{1}{\sin(\theta)}\frac{\partial}{\partial\theta}\sin(\theta)\frac{\partial}{\partial\theta} + \frac{1}{\sin^2(\theta)}\frac{\partial^2}{\partial\varphi^2}\right) + V_{l,m_1,m_2}(\theta,\varphi) \tag{3.7}$$

with

$$\begin{aligned} V_{l,m_1,m_2}(\theta,\varphi) = \frac{1}{\sin^2(\theta)\sin^2(\varphi)}\Bigg(& \frac{m_1^2(1-\sin^2(\theta)\cos^2(\varphi))}{\cos^2(\theta)} + \frac{m_2^2}{\cos^2(\varphi)} - 2m_1m_2 - 2l(m_1 - m_2) \\ & + \frac{l^2}{3}(4 - \cos^2(\theta)\sin^2(\varphi) - \cos^2(\varphi))\Bigg) - \frac{1}{4}\tan^2(\theta) - \cot^2(\theta) - \frac{\cot^2(2\varphi)}{\sin^2(\theta)}. \end{aligned} \tag{3.8}$$

On the other hand, the dynamical symmetric of motion of a charged particle in the presence of an external electromagnetic field on the symmetric spaces can give the following nonrelativistic Hamiltonian for motion of a charged particle on the two dimensional manifold with metric $g_{\mu\nu}$ in the presence of static electromagnetic fields with vector potential $\vec{A}$ and scalar potential V as[13]

$$H = -\frac{1}{\sqrt{g}}(\partial_\mu - iA_\mu)(\sqrt{g}g^{\mu\nu}(\partial_\nu - iA_\nu)) + V, \tag{3.9}$$

where g is the determinant of metric $g_{\mu\nu}$. Therefore, the Hamiltonian (2.8) can be interpreted as the Hamiltonian of a charged particle on S^2 sphere with metric

$$g_{\mu\nu}=\begin{pmatrix}1 & 0\\ 0 & \sin^2(\theta)\end{pmatrix}, \tag{3.10}$$

in the presence of an electric field with scalar potential (3.8).

IV. THE ALGEBRAIC SOLUTION OF THE HAMILTONIAN BY USING VERMA BASES

Here in this section we try to solve our Hamiltonian algebraically, that is we will obtain its eigenspectrum by using the Verma bases of su(3) or A_2 Lie algebra. According to Ref. 7, Verma bases of the irreducible representation space $V(\Lambda)$ of A_2 over C Lie algebra, where $\Lambda=(p,q)$ is the highest weight, consist of all vectors

$$f_1^{a_3}f_2^{a_2}f_1^{a_1}|p,q\rangle, \tag{4.1}$$

such that

$$0\leqslant a_1\leqslant p,\quad 0\leqslant a_2\leqslant q+a_1,\quad 0\leqslant a_3\leqslant \min[q,a_2], \tag{4.2}$$

where e_i, f_i, h_i, $i=1$ and 2 are base of A_2 Lie algebra satisfying the commutation relations

$$[e_i,f_i]=h_i,\quad [h_i,e_i]=2e_i,\quad [h_i,f_i]=-2f_i,\quad i=1,2 \tag{4.3}$$

for each simple root $\alpha_1=(\frac{1}{2},\sqrt{3}/2)$ and $\alpha_2=(\frac{1}{2},-\sqrt{3}/2)$. Now, by comparing the commutation relations

$$[Y_+,Y_-]=R_3+\sqrt{3}R_8,\quad [R_3+\sqrt{3}R_8,Y_\pm]=\pm 2Y_\pm,$$

$$[X_+,X_-]=R_3-\sqrt{3}R_8,\quad [R_3-\sqrt{3}R_8,X_\pm]=\pm 2X_\pm \tag{4.4}$$

with (4.3) we have

$$h_1=R_3+\sqrt{3}R_8,\quad e_1=Y_+,\quad f_1=Y_-,$$

$$h_2=R_3-\sqrt{3}R_8,\quad e_2=X_+,\quad f_2=X_-. \tag{4.5}$$

In an arbitrary representation of A_2 with highest weight $\Lambda(p,q)$, the highest eigenweight satisfies

$$e_i|p,q\rangle=0,\quad i=1,2. \tag{4.6}$$

Therefore, the highest eigenfunction $\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2)=\langle\chi_2,\chi_1,\varphi,\theta|p,q\rangle$ satisfies the following first order linear differential equations:

$$\left[\sin(\varphi)\frac{\partial}{\partial\theta}+\cot(\theta)\cos(\varphi)\frac{\partial}{\partial\varphi}+2i\frac{\cos^2(\theta)-\sin^2(\theta)\sin^2(\varphi)}{\sin(2\theta)\sin(\varphi)}\frac{\partial}{\partial\chi_1}+i\frac{\cot(\theta)}{\sin(\varphi)}\frac{\partial}{\partial\chi_2}\right.$$
$$\left.-\frac{\cos^2(\theta)-\sin^2(\varphi)\sin^2(\theta)}{\sin(2\theta)\sin(\varphi)}+l\frac{\cot(\theta)}{\sin(\varphi)}\right]\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2)=0, \tag{4.7}$$

$$\left[-\frac{\partial}{\partial\varphi}+i\cot(\varphi)\frac{\partial}{\partial\chi_1}+2i\cot(2\varphi)\frac{\partial}{\partial\chi_2}+\cot(2\varphi)+l\cot(\varphi)\right]\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2)=0. \tag{4.8}$$

On the other hand, the highest eigenweight is the eigenstate of the Cartan subalgebra with R_3 and R_8 as its Gell–Mann basis,[14] where the bases h_{α_1} and h_{α_2} are associated with simple roots α_1 and α_2, and they can be written in terms of these bases in the following form:[15]

$$h_{\alpha_1} = R_3 + \sqrt{3}R_8, \quad h_{\alpha_2} = R_3 - \sqrt{3}R_8. \tag{4.9}$$

Writing the highest eigenweight in terms of fundamental weights, that is $\mu = p\mu^1 + q\mu^2$ and considering the following relation between the simple roots and fundamental weights:

$$2\frac{(\mu^i, \alpha_j)}{(\alpha_j, \alpha_j)} = \delta^i_j, \tag{4.10}$$

we can write

$$\begin{aligned}(R_3 + \sqrt{3}R_8)\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2) &= \langle \mu, R_3 + \sqrt{3}R_8\rangle \psi^{p,q}(\theta,\varphi,\chi_1,\chi_2) \\ &= \langle \mu, h_{\alpha_1}\rangle \psi^{p,q}(\theta,\varphi,\chi_1\chi_2) = 2\frac{(\mu,\alpha_1)}{(\alpha_1,\alpha_1)}\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2)\end{aligned}$$

or

$$(R_3 + \sqrt{3}R_8)\psi^{p,q}(\theta,\varphi,\chi_1\chi_2) = p\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2). \tag{4.11}$$

Similarly by acting out the other basis of Cartan subalgebra on highest eigenweight we obtain

$$(R_3 - \sqrt{3}R_8)\psi^{p,q}(\theta,\varphi,\chi_1\chi_2) = q\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2). \tag{4.12}$$

The above eigenvalue equations imply the following χ_1 and χ_2 dependence of highest eigenweight $\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2)$,

$$\psi^{p,q}(\theta,\varphi,\chi_1,\chi_2) = e^{(i/3)(2p+q+l)\chi_1} e^{-(i/3)(p+2q-l)\chi_2} \phi^{p,q}(\theta,\varphi). \tag{4.13}$$

Substituting (4.13) in (4.7) and (4.8), we see that the integrability of the latter equation requires that $p = q + l$, that is for given values of the parameter l, only the representations $(q+l, q)$ are relevant to the eigenspectrum of our Hamiltonian. Hence, integrating Eqs. (4.7) and (4.8) we get the following expression for the highest eigenweight in these particular representations:

$$\psi^{q,l}(\theta,\varphi,\chi_1,\chi_2) = e^{i((q+l)\chi_1 - q\chi_2)}(\cos^q(\varphi)\sin^{q+1}(\theta)\cos^{q+l}(\theta)\sqrt{\cos(\theta)\sin(2\varphi)}). \tag{4.14}$$

Now, using the formula (4.1) we can obtain the lower eigenweights or Verma bases,

$$\psi^{(a_3,a_2,a_1)}(\theta,\varphi,\chi_1,\chi_2) = Y_-^{a_3} X_-^{a_2} Y_-^{a_1} \psi^{q,l}(\theta,\varphi,\chi_1,\chi_2), \tag{4.15}$$

where $0 \leqslant a_1 \leqslant q+l$, $0 \leqslant a_2 \leqslant q + a_1$, $0 \leqslant a_3 \leqslant \min[q, a_2]$. In order to obtain eigenspectrum of the Hamiltonian (3.7), it is sufficient to eliminate χ_1 and χ_2 coordinates dependence of SU(3) Verma basis by Fourier transforming over them. This can be achieved simply by shifting the phase factor $e^{i((q+l)\chi_1 - q\chi_2)}$ to the left-hand side of lowering operators X_- and Y_- in the above relation and integrating over the coordinates χ_1 and χ_2. Hence, we obtain

$$\psi^{(a_3,a_2,a_1)}(\theta,\varphi,\chi_1,\chi_2) = e^{i(q+l-a_1-a_3)\chi_1} e^{-i(q-a_2)\chi_2} \chi^{q,l}_{q+l-a_1-a_3,q-a_2}(\theta,\varphi), \tag{4.16}$$

where

$$\chi^{q,l}_{q+l-a_1-a_3,q-a_2}(\theta,\varphi)=\left(\prod_{i=1}^{a_3}Y_-(q+l-a_1-i+1,q-a_2)\right)\left(\prod_{i=1}^{a_2}X_-(q+l-a_1,q-i+1)\right)$$
$$\times\left(\prod_{i=1}^{a_1}Y_-(q+l-i+1,q)\right)(\cos^q(\varphi)\sin^{q+1}(\theta)\cos^{q+l}(\theta)\sqrt{\cos(\theta)\sin(2\varphi)}), \tag{4.17}$$

and the operators appear in the products as $\Pi_{i=1}^{m}K(i)=K(m)K(m-1)\cdots K(1)$ also the Fourier transformed operators have the following form:

$$R_\pm(m_1,m_2)=\frac{1}{2}\Bigg[\mp\cos(\varphi)\frac{\partial}{\partial\theta}\pm\cot(\theta)\sin(\varphi)\frac{\partial}{\partial\varphi}-m_1\tan(\theta)\cos(\varphi)$$
$$+m_2\frac{\cot(\theta)}{\cos(\varphi)}\pm\frac{\cos^2(\theta)-\cos^2(\varphi)\sin^2(\theta)}{\sin(2\theta)\cos(\varphi)}\Bigg], \tag{4.18}$$

$$Y_\pm(m_1,m_2)=\frac{1}{2}\Bigg[\pm\sin(\varphi)\frac{\partial}{\partial\theta}\pm\cot(\theta)\cos(\varphi)\frac{\partial}{\partial\varphi}-2m_1\frac{\cos^2(\theta)-\sin^2(\theta)\sin^2(\varphi)}{\sin(2\theta)\sin(\varphi)}$$
$$+m_2\frac{\cot(\theta)}{\sin(\varphi)}\mp\frac{\cos^2(\theta)-\sin^2(\varphi)\sin^2(\theta)}{\sin(2\theta)\sin(\varphi)}+l\frac{\cot(\theta)}{\sin(\varphi)}\Bigg], \tag{4.19}$$

$$X_\pm(m_1,m_2)=\frac{1}{2}\Bigg[\mp\frac{\partial}{\partial\varphi}-m_1\cot(\varphi)+2m_2\cot(2\varphi)\pm\cot(2\varphi)+l\cot(\varphi)\Bigg], \tag{4.20}$$

$$R_3(m_1,m_2)=\tfrac{1}{2}(m_1+m_2),\quad R_8(m_1,m_2)=\frac{\sqrt{3}}{2}\left(m_1-m_2-\frac{2}{3}l\right). \tag{4.21}$$

Now, by defining $m_1=q+l-a_1-a_3$ and $m_2=q-a_2$, we see that due to the inequalities (4.2), the parameters m_1 and m_2 must satisfy $-q\leqslant m_1\leqslant q+l$ and $-(q+l)\leqslant m_2\leqslant q$. Also it is straightforward to see that an arbitrary Verma basis is proportional to $e^{i(m_1\chi_1-m_2\chi_2)}$ or we can write

$$\psi^{q,l}_{m_1,m_2}(\theta,\varphi,\chi_1,\chi_2)=e^{i(m_1\chi_1-m_2\chi_2)}\chi^{q,l}_{m_1,m_2}(\theta,\varphi). \tag{4.22}$$

Now, substituting (4.22) in (3.6) and Fourier transforming over the coordinates χ_1 and χ_2, the Casimir operator reduces to the required two dimensional Hamiltonian $H_l(m_1,m_2)$ given in (3.7). Therefore, the general eigenfunctions of the above Hamiltonian with eigenvalue $E(q,l)=\frac{1}{3}((q+l)(2q+l+3)+q(q+3))$ (for the degeneracy of these eigenvalues see the Appendix) can be written as

$$\chi^{q,l}_{m_1,m_2}(\theta,\varphi)=\left(\prod_{i=1}^{a_3}Y_-(m_1+a_3-i+1,m_2)\right)\left(\prod_{i=1}^{q-m_2}X_-(m_1+a_3,q-i+1)\right)$$
$$\times\left(\prod_{i=1}^{q+l-m_1-a_3}Y_-(q+l-i+1,q)\right)\left(\cos^q(\varphi)\sin^{q+1}(\theta)\cos^{q+l}(\theta)\sqrt{\cos(\theta)\sin(2\varphi)}\right). \tag{4.23}$$

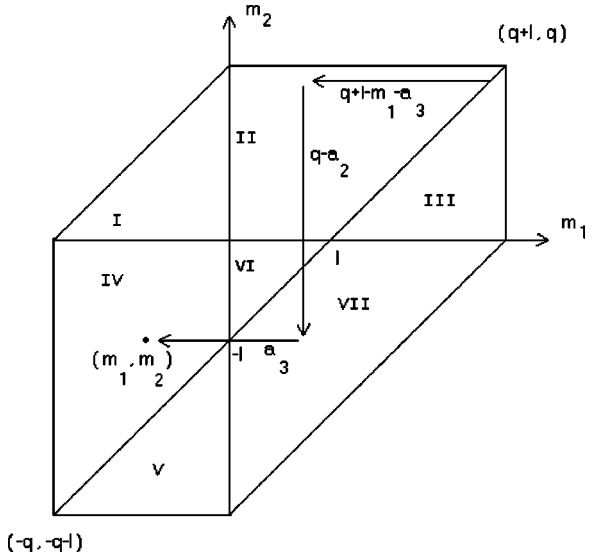

FIG. 1. Diagram of seven possible allowed regions of eigenspectrum of Hamiltonian $H_l(m_1,m_2)$ in the (m_1,m_2) plane for given values of integer parameters q, l, m_1, and m_2 with $l \geqslant 0$. Horizontal lines mean application of the lowering operator Y_- while the vertical line indicates the application of the lowering operator X_-.

V. GENERALIZED SHAPE INVARIANCE SYMMETRY

In this section we show that the Hamiltonian $H_l(m_1,m_2)$ possesses a new kind of shape invariance symmetry, we call it generalized shape invariance. Obviously SU(3) symmetry of the Casimir operator before the reduction generates this special shape invariance symmetry. Using this symmetry we will obtain below the eigenspectrum of Hamiltonian $H_l(m_1,m_2)$, that is the eigenfunctions $\chi^{q,l}_{m_1,m_2}(\theta,\varphi)$ corresponding to eigenvalue $E(q,l)$ by consecutive application of lowering operators over the state with $m_1=q+l$ and $m_2=q$. We will also obtain its degeneracy for given values of $(q+l,q)$, where it is the same as the one that can be obtained by using the inequalities (4.2) corresponding to Figs. 1 and 2.

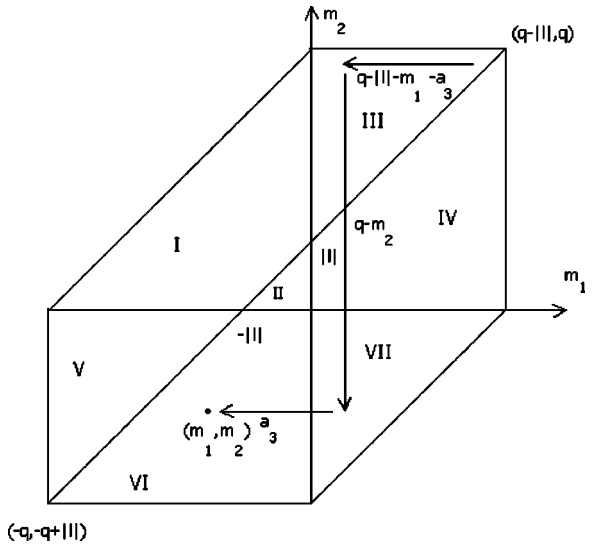

FIG. 2. Diagram of seven possible allowed regions of eigenspectrum of Hamiltonian $H_l(m_1,m_2)$ in the (m_1,m_2) plane for given values of integer parameters q, l, m_1, and m_2 with $l<0$. Horizontal lines mean application of the lowering operator Y_- while the vertical line indicates the application of the lowering operator X_-.

First we write the Hamiltonian $H_l(m_1,m_2)$ operator in terms of the Fourier transformed operators given in (4.18)–(4.21),

$$H_l(m_1,m_2)=\frac{1}{2}[R_+(m_1-1,m_2-1)R_-(m_1,m_2)+R_-(m_1+1,m_2+1)R_+(m_1,m_2)$$
$$+Y_+(m_1-1,m_2)Y_-(m_1,m_2)+Y_-(m_1+1,m_2)Y_+(m_1,m_2)+X_+(m_1,m_2-1)X_-(m_1,m_2)$$
$$+X_-(m_1,m_2+1)X_+(m_1,m_2)]+\frac{(m_1+m_2)^2}{4}+\frac{3\left(m_1-m_2-\frac{2}{3}l\right)^2}{4}. \tag{5.1}$$

Now, using the following commutation relations,

$$[R_3+\sqrt{3}R_8,Y_\pm]=\pm 2Y_\pm,\quad [R_3-\sqrt{3}R_8,Y_\pm]=\mp Y_\pm,$$
$$[R_3-\sqrt{3}R_8,X_\pm]=\pm 2X_\pm,\quad [R_3+\sqrt{3}R_8,X_\pm]=\mp X_\pm, \tag{5.2}$$

we can obtain the following relations:

$$(R_3(m_1\pm 1,m_2)+\sqrt{3}R_8(m_1\pm 1,m_2))Y_\pm(m_1,m_2)-Y_\pm(m_1,m_2)(R_3(m_1,m_2)$$
$$+\sqrt{3}R_8(m_1,m_2))=\pm 2Y_\pm(m_1,m_2),$$

$$(R_3(m_1\pm 1,m_2)-\sqrt{3}R_8(m_1\pm 1,m_2))Y_\pm(m_1,m_2)-Y_\pm(m_1,m_2)(R_3(m_1,m_2)$$
$$-\sqrt{3}R_8(m_1,m_2))=\mp Y_\pm(m_1,m_2),$$

$$(R_3(m_1,m_2\pm 1)-\sqrt{3}R_8(m_1,m_2\pm 1))X_\pm(m_1,m_2)-X_\pm(m_1,m_2)(R_3(m_1,m_2)$$
$$-\sqrt{3}R_8(m_1,m_2))=\pm 2X_\pm(m_1,m_2),$$

$$(R_3(m_1,m_2\pm 1)+\sqrt{3}R_8(m_1,m_2\pm 1))X_\pm(m_1,m_2)-X_\pm(m_1,m_2)(R_3(m_1,m_2)$$
$$+\sqrt{3}R_8(m_1,m_2))=\mp X_\pm(m_1,m_2). \tag{5.3}$$

The above relations imply that the Hamiltonian $H_l(m_1,m_2)$ possesses shape invariance symmetry. Since, through the left action of the operators $Y_\pm(m_1,m_2)$ and $X_\pm(m_1,m_2)$ on both sides of the following eigenvalue equations,

$$H_l(m_1,m_2)\chi^{q,l}_{m_1,m_2}(\theta,\varphi)=E(q,l)\chi^{q,l}_{m_1,m_2}(\theta,\varphi),$$

$$(R_3(m_1,m_2)+\sqrt{3}R_8(m_1,m_2))\chi^{q,l}_{m_1,m_2}(\theta,\varphi)=\left(2m_1-m_2-\frac{l}{2}\right)\chi^{q,l}_{m_1,m_2}(\theta,\varphi), \tag{5.4}$$

$$(R_3(m_1,m_2)-\sqrt{3}R_8(m_1,m_2))\chi^{q,l}_{m_1,m_2}(\theta,\varphi)=\left(-m_1+2m_2+\frac{l}{2}\right)\chi^{q,l}_{m_1,m_2}(\theta,\varphi),$$

we get

$$\chi^{q,l}_{m_1\pm 1,m_2}(\theta,\varphi)=Y_\pm(m_1,m_2)\chi^{q,l}_{m_1,m_2}(\theta,\varphi), \tag{5.5}$$

$$\chi^{q,l}_{m_1,m_2\pm 1}(\theta,\varphi)=X_\pm(m_1,m_2)\chi^{q,l}_{m_1,m_2}(\theta,\varphi). \tag{5.6}$$

Therefore, the operators $Y_\pm(m_1,m_2)$ shift the parameter m_1 by one unit or they push the unrenormalized eigenfunctions horizontally in Figs. 1 and 2, while the operators $X_\pm(m_1,m_2)$ shift the

parameter m_2 by one unit or they push the eigenfunctions vertically in Figs. 1 and 2. Obviously the eigenfunctions vanish in the forbidden regions of Figs. 1 and 2. Using the relations (5.5) and (5.6), we obtain the following relations:

$$Y_+(m_1-1,m_2)Y_-(m_1,m_2)\chi^{q,l}_{m_1,m_2}(\theta,\varphi)\simeq\chi^{q,l}_{m_1,m_2}(\theta,\varphi),$$

$$Y_-(m_1,m_2)Y_+(m_1-1,m_2)\chi^{q,l}_{m_1-1,m_2}(\theta,\varphi)\simeq\chi^{q,l}_{m_1-1,m_2}(\theta,\varphi) \tag{5.7}$$

and

$$X_+(m_1,m_2-1)X_-(m_1,m_2)\chi^{q,l}_{m_1,m_2}(\theta,\varphi)\simeq\chi^{q,l}_{m_1,m_2}(\theta,\varphi),$$

$$X_-(m_1,m_2)X_+(m_1,m_2-1)\chi^{q,l}_{m_1,m_2-1}(\theta,\varphi)\simeq\chi^{q,l}_{m_1,m_2-1}(\theta,\varphi), \tag{5.8}$$

which indicate that the Hamiltonian $H_l(m_1,m_2)$ possesses the shape invariance symmetry. Actually the first pair of equations given in (5.7) imply the horizontal shape invariance while the second pair of equations given in (5.8) imply the vertical shape invariance symmetry in Figs. 1 and 2, respectively. Therefore, using this symmetry we can obtain the eigenfunctions of the isospectral Hamiltonians $H_l(m_1,m_2)$ with the eigenvalue $E(q,l)$ simply by applying the lowering operators X_- and Y_- over the highest weight $\chi^{q,l}_{q+l,q}(\theta,\varphi)$, namely we obtain all the eigenstates for the values of parameters m_1 and m_2 given in the allowed region of Figs. 1 and 2, such that these eigenfunctions vanish for the values of the parameters corresponding to the forbidden region. Also one can show that in this way we obtain exactly the same eigenspectrum that we have obtained in Sec. IV by using the Verma basis.

Therefore, by consecutive application of lowering operators over highest eigenweight $\chi^{q,l}_{q+l,q}(\theta,\varphi)$, we can obtain an arbitrary eigenstate $\chi^{q,l}_{m_1,m_2}(\theta,\varphi)$, where the existence of different ordering of lowering operators or the different paths indicate the degeneracy of the Hamiltonian $H_l(m_1,m_2)$. It is straightforward to show that by this method we get exactly the eigenspectrum of the preceding section. For an illustration we explain below the real representation with $q=1$ and $l=0$ in detail. Using the relation (4.23), we get the following expression for highest eigenweight of (1,1) representation:

$$\chi^{1,0}_{1,1}(\theta,\varphi)=2\sin^2(\theta)\cos(\theta)\cos(\varphi)\sqrt{\cos(\theta)\sin(2\varphi)}, \tag{5.9}$$

then using (5.5) we get

$$\chi^{1,0}_{0,1}(\theta,\varphi)=Y_-(1,1)\chi^{1,0}_{1,1}(\theta,\varphi)=-\sin^3(\theta)\sin(2\varphi)\sqrt{\cos(\theta)\sin(2\varphi)}. \tag{5.10}$$

Now, we cannot lower the above eigenstate by acting the operator Y_- on it, since the function $\chi^{1,0}_{-1,1}(\theta,\varphi)$ corresponds to the values of parameters ($m_1=-1$, $m_2=1$) which is not allowed for $q=1$ and $l=0$. Therefore in order to get lower eigenstates we must act out the operator X_- on it, that is, we have

$$\chi^{1,0}_{0,0}(\theta,\varphi)=X_-(0,1)\chi^{1,0}_{0,1}(\theta,\varphi)=2\sin^3(\theta)\cos(2\varphi)\sqrt{\cos(\theta)\sin(2\varphi)}. \tag{5.11}$$

On the other hand, if we act out the lowering operator X_- on the highest eigenstate, we will obtain

$$\chi^{1,0}_{1,0}(\theta,\varphi)=X_-(1,1)\chi^{1,0}_{1,1}(\theta,\varphi)=-2\sin^2(\theta)\cos(\theta)\sin(\varphi)\sqrt{\cos(\theta)\sin(2\varphi)}, \tag{5.12}$$

where its further action will kill it, since the values of parameters ($m_1=1$, $m_2=-1$) are not allowed, hence we cannot have the eigenstate corresponding to these values of parameters. Similarly the action of Y_- will shift $\chi^{1,0}_{1,0}(\theta,\varphi)$ state to ($m_1=0$, $m_2=0$) or zero weight eigenstate,

$$\tilde{\chi}^{1}_{0,0}(\theta,\varphi) = Y_{-}(1,0)\chi^{1,0}_{1,0}(\theta,\varphi) = 2(\cos^2(\theta) - \sin^2(\varphi)\sin^2(\theta))\sin(\theta)\sqrt{\cos(\theta)\sin(2\varphi)}. \quad (5.13)$$

We see that zero weight is degenerate but other eigenvalues are nondegenerate which is in agreement with the results of the preceding section. With the same procedure we can obtain the remaining part of the spectrum, that is we have

$$\chi^{1,0}_{0,-1}(\theta,\varphi) = X_{-}(0,0)\chi^{1,0}_{0,0}(\theta,\varphi) = -2\sin(2\varphi)\sin^3(\theta)\sqrt{\cos(\theta)\sin(2\varphi)},$$

$$\chi^{1,0}_{-1,0}(\theta,\varphi) = Y_{-}(0,0)\chi^{1,0}_{0,0}(\theta,\varphi) = 2\sin(\varphi)\sin(2\theta)\sin(\theta)\sqrt{\cos(\theta)\sin(2\varphi)}, \quad (5.14)$$

and

$$\chi^{1,0}_{-1,-1}(\theta,\varphi) = Y_{-}(0,-1)\chi^{1,0}_{0,-1}(\theta,\varphi) = X_{-}(-1,0)\chi^{1,0}_{-1,0}(\theta,\varphi) = 2\sin(2\theta)\cos(\varphi)\sin(\theta)\sqrt{\cos(\theta)\sin(2\varphi)}. \quad (5.15)$$

We should remind that all eigenfunctions associated with the forbidden region of (m_1, m_2) plane vanish. For example, the action of the operators $X_{-}^3 Y_{-}$ and $Y_{-}^2 X_{-}^2 Y_{-}$ on highest eigenstate leads to vanishing functions $\chi^{1}_{0,-2}(\theta,\varphi)$ and $\chi^{1}_{-2,-1}(\theta,\varphi)$, respectively. Also one can show that by acting the operators $X_{-}Y_{-}X_{-}Y_{-}$ and $Y_{-}X_{-}Y_{-}X_{-}$ on the highest eigenstate we obtain eigenstates which are both proportional to Verma base $\chi^{1,0}_{-1,-1}(\theta,\varphi) = Y_{-}X_{-}^2 Y_{-}\chi^{1,0}_{1,1}(\theta,\varphi)$.

VI. THREE DIMENSIONAL HAMILTONIAN WITH ORDINARY SHAPE INVARIANCE SYMMETRY

Here in this section we first make Inonu–Wigner contraction[8] over the generators of su(3) Lie algebra given in (2.3)–(2.6), simply by making the change of coordinate $\theta = r/R$ and relating the new contracted generators to the old ones by $R^c_{\pm} = (1/R)R_{\pm}$, $R^c_3 = R_3$, $X^c_{\pm} = X_{\pm}$, $Y^c_{\pm} = (1/R)Y_{\pm}$, $R^c_8 = R_8$. Then in the limit of $R \to \infty$ the set of su (3) bases reduces to

$$R^c_{\pm} = \frac{1}{2}e^{\pm i(\chi_1 - \chi_2)}\left[\mp\cos(\varphi)\frac{\partial}{\partial r} \pm \frac{\sin(\varphi)}{r}\frac{\partial}{\partial\varphi} + \frac{i}{r\cos(\varphi)}\frac{\partial}{\partial\chi_2}\right], \quad (6.1)$$

$$Y^c_{\pm} = \frac{1}{2}e^{\pm i\chi_1}\left[\pm\sin(\varphi)\frac{\partial}{\partial r} \pm \frac{\cos(\varphi)}{r}\frac{\partial}{\partial\varphi} + \frac{i}{r\sin(\varphi)}\left(-\frac{\partial}{\partial\eta} + \frac{\partial}{\partial\chi_1} + \frac{\partial}{\partial\chi_2}\right)\right], \quad (6.2)$$

$$X^c_{\pm} = \frac{1}{2}e^{\mp i\chi_2}\left[\mp\frac{\partial}{\partial\varphi} - i\cot(\varphi)\left(\frac{\partial}{\partial\eta} - \frac{\partial}{\partial\chi_1}\right) + 2i\cot(2\varphi)\frac{\partial}{\partial\chi_2}\right], \quad (6.3)$$

$$R^c_3 = -\frac{i}{2}\left(\frac{\partial}{\partial\chi_1} - \frac{\partial}{\partial\chi_2}\right), \quad R^c_8 = \frac{i\sqrt{3}}{2}\left(\frac{2}{3}\frac{\partial}{\partial\eta} - \frac{\partial}{\partial\chi_1} - \frac{\partial}{\partial\chi_2}\right) \quad (6.4)$$

with the following commutation relations:

$$[R^c_3, R^c_{\pm}] = \pm R^c_{\pm}, \quad [R^c_3, Y^c_{\pm}] = \pm\tfrac{1}{2}Y^c_{\pm}, \quad [R^c_3, X^c_{\pm}] = \pm\tfrac{1}{2}X^c_{\pm},$$

$$[R^c_8, Y^c_{\pm}] = \pm\frac{\sqrt{3}}{2}Y^c_{\pm}, \quad [R^c_8, X^c_{\pm}] = \mp\frac{\sqrt{3}}{2}X^c_{\pm}, \quad (6.5)$$

$$[R^c_{\pm}, X^c_{\mp}] = \mp Y^c_{\pm}, \quad [X^c_{+}, X^c_{-}] = R^c_3 - \sqrt{3}R^c_8, \quad [Y^c_{\pm}, X^c_{\pm}] = \mp R^c_{\pm}.$$

Therefore, the generators R^c_{-}, R^c_{+}, Y^c_{-}, and Y^c_{+} commute with each other. Also the quadratic Casimir operator (2.8) reduces to

$$-C^c=\frac{\partial^2}{\partial r^2}+\frac{1}{r^2}\frac{\partial^2}{\partial\varphi^2}+\frac{1}{r^2\sin^2(\varphi)}\frac{\partial^2}{\partial\eta^2}+\frac{3}{r}\frac{\partial}{\partial r}+\frac{2\cot(2\varphi)}{r^2}\frac{\partial}{\partial\varphi}+\frac{1}{r^2\sin^2(\varphi)}$$
$$\times\left(\frac{\partial^2}{\partial\chi_1{}^2}+\frac{1}{\cos^2(\varphi)}\frac{\partial^2}{\partial\chi_2{}^2}+2\frac{\partial^2}{\partial\chi_1\partial\chi_2}-2\frac{\partial^2}{\partial\eta\partial\chi_1}-2\frac{\partial^2}{\partial\eta\partial\chi_2}\right), \tag{6.6}$$

where after the similarity transformation $\tilde{C}^c=f^{-1}(r,\varphi)C^cf(r,\varphi)$ with $f(r,\varphi)=1/\sqrt{r\cos(\varphi)}$ we get

$$-\tilde{C}^c=-\frac{1}{2}(\tilde{R}^c_-\tilde{R}^c_++\tilde{R}^c_+\tilde{R}^c_-+Y^c_-Y^c_++Y^c_+Y^c_-)$$
$$=+\frac{1}{r^2}\frac{\partial}{\partial r}r^2\frac{\partial}{\partial r}+\frac{1}{r^2\sin(\varphi)}\frac{\partial}{\partial\varphi}\sin(\varphi)\frac{\partial}{\partial\varphi}+\frac{1}{r^2\sin^2(\varphi)}\frac{\partial^2}{\partial\eta^2}+\frac{1}{4r^2\cos^2(\varphi)}$$
$$+\frac{1}{r^2\sin^2(\varphi)}\left(\frac{\partial^2}{\partial\chi_1^2}+\frac{1}{\cos^2(\varphi)}\frac{\partial^2}{\partial\chi_2^2}+2\frac{\partial^2}{\partial\chi_1\chi_2}-2\frac{\partial^2}{\partial\eta\partial\chi_1}-2\frac{\partial^2}{\partial\eta\partial\chi_2}\right), \tag{6.7}$$

where $\tilde{Y}^c_\pm=Y^c_\pm$ and $\tilde{R}^c_\pm=R^c_\pm\pm[1/4r\cos(\varphi)]e^{\pm i(\chi_1-\chi_2)}$. Now, by Fourier transforming over the coordinates χ_1 and χ_2 with the kernel $e^{i(m_1\chi_1-m_2\chi_2)}$, and the similarity transformation with function $e^{i(m_1-m_2)\eta}$, the above Casimir operator reduces to

$$H(m_2)=-\left[\frac{1}{r^2}\frac{\partial}{\partial r}r^2\frac{\partial}{\partial r}+\frac{1}{r^2\sin(\varphi)}\frac{\partial}{\partial\varphi}\sin(\varphi)\frac{\partial}{\partial\varphi}+\frac{1}{r^2\sin^2(\varphi)}\frac{\partial^2}{\partial\eta^2}-\frac{(m_2^2-\frac{1}{4})}{r^2\cos^2(\varphi)}\right]. \tag{6.8}$$

Also after Inonu–Wigner contraction together with the Fourier transformation, the Casimir eigenvalue equation $(C/R^2)\psi=[E(q,l)/R^2]\psi$ reduces to $H(m_2)\psi^{(k)}_{m_2}=k^2\psi^{(k)}_{m_2}$ provided that for finite l, we let $q\to\infty$, $R\to\infty$ such that $q/R=\text{finite}=k$, therefore, we have a hierarchy of isospectral Hamiltonians labeled by the parameter m_2 and one can show that this isospectral symmetry comes from the shape invariance symmetry of these Hamiltonians. To see this we first write the Hamiltonian $H(m_2)$ in terms of Fourier transformed and similarity transformed lowering and rising operators,

$$A_\pm(m_2)=\frac{1}{2}\left(\mp\cos(\varphi)\frac{\partial}{\partial r}\pm\frac{\sin(\varphi)}{r}\frac{\partial}{\partial\varphi}+\frac{2m_2-1}{2r\cos(\varphi)}\right),$$

$$B_+=\frac{1}{2}\left(\sin(\varphi)\frac{\partial}{\partial r}+\frac{\cos(\varphi)}{r}\frac{\partial}{\partial\varphi}-\frac{i}{r\sin(\varphi)}\frac{\partial}{\partial\eta}+\frac{1}{r\sin(\varphi)}\right), \tag{6.9}$$

$$B_-=\frac{1}{2}\left(-\sin(\varphi)\frac{\partial}{\partial r}-\frac{\cos(\varphi)}{r}\frac{\partial}{\partial\varphi}-\frac{i}{r\sin(\varphi)}\frac{\partial}{\partial\eta}\right),$$

in the following form:

$$H(m_2)=A_+(m_2)A_-(m_2)+B_+B_-, \tag{6.10}$$

$$H(m_2-1)=A_-(m_2)A_+(m_2)+B_+B_-. \tag{6.11}$$

Now, multiplying the eigenvalue equation

$$H(m_2)\psi^{(k)}_{m_2}=(A_+(m_2)A_-(m_2)+B_+B_-)\psi^{(k)}_{m_2} \tag{6.12}$$

from the left-hand side by the operator $A_-(m_2)$ and using the fact that $A_\pm(m_2)$ commute with $B_\pm$, we obtain

$$H(m_2-1)(A_-(m_2)\psi^{(k)}_{m_2}) = k^2(A_-(m_2))\psi^{(k)}_{m_2}), \tag{6.13}$$

therefore, $A_-(m_2)\psi^{(k)}_{m_2}$ is the eigenfunction of $H(m_2-1)$ with the same eigenvalue k^2, hence the operator $A_-(m_2)$ lowers the index m_2 by one unit. The similarity one shows that $A_+(m_2)$ raises m_2 by one unit, respectively. Therefore, the Hamiltonian $H(m_2)$ possesses ordinary shape invariance symmetry with respect to parameter m_2.

For half-integer value of the parameter m_2 we can obtain the continuous eigenspectrum of these Hamiltonians (since these Hamiltonians are positive definite), simply by acting these lowering and raising operators over the eigenfunction of the free particle as follows.

Since for $m_2=\frac{1}{2}$ the Hamiltonian $H(m_2)$ reduces to $H(\frac{1}{2})=-\nabla^2$ with the eigenvalue $E=k^2$ and eigenfunction $\psi^{(\vec{k})}_{1/2}=e^{i\vec{k}.\vec{x}}$ and for Hamiltonian $H(n_2+\frac{1}{2})$ with non-negative integer n_2, we have $H(n_2+\frac{1}{2})\psi^{(\vec{k})}_{n_2}=k^2\psi^{(\vec{k})}_{n_2}$ with

$$\psi^{(\vec{k})}_{n_2}=\prod_{j=1}^{n_2}A_+\left(j+\frac{1}{2}\right)e^{i\vec{k}.\vec{x}}. \tag{6.14}$$

VII. CONCLUSION

Here in this work we have generalized the ordinary exactly solvable shape invariance Hamiltonians to Hamiltonians with non-Abelian type of shape invariance symmetry and an ordinary shape invariance one. Again it is shown that the new kind of shape invariance symmetry has its origin in group theory or better to say, the exact solvability of Hamiltonians are related in some way to Lie algebras or Lie groups.

APPENDIX: DEGENERACY OF HAMILTONIAN $H_l(m_1, m_2)$

In order to determine the degeneracy of Hamiltonian $H_l(m_1,m_2)$ for a given value of integer parameters m_1 and m_2, we should determine the range of variation of integer a_3 by imposing the inequalities (4.2).

For $l\geqslant 0$ and $0\leqslant m_2\leqslant q$ we have the following three different regions for integer parameter m_1:

(I) $-m_1\leqslant a_3\leqslant q-m_2$, $m_2-m_1\leqslant q$, $-q\leqslant m_1<0$, degeneracy$=q-m_2+m_1+1$,
(II) $0\leqslant a_3\leqslant q-m_2$, $0\leqslant m_1<l+m_2$, degeneracy$=q-m_2+1$,
(III) $0\leqslant a_3\leqslant q+l-m_1$, $l+m_2\leqslant m_1\leqslant q+l$, degeneracy$=q+l-m_1+1$,
while for $-q-l\leqslant m_2<0$ there are another four different regions for m_1,
(IV) $-m_1\leqslant a_3\leqslant q$, $-q\leqslant m_1<l+m_2<0$, $-q-l\leqslant m_2<0$, degeneracy$=q+m_1+1$,
(V) $-m_1\leqslant a_3\leqslant q+l-m_1+m_2$, $l+m_2\leqslant m_1<0$, $-q-l\leqslant m_2<-l$, degeneracy$=q+l+m_2+1$,
(VI) $0\leqslant a_3\leqslant q$, $0\leqslant m_1<l+m_2$, $-l\leqslant m_2<0$, degeneracy$=q+1$,
(VII) $0\leqslant a_3\leqslant q+l-m_1+m_2$, $l\leqslant m_1-m_2\leqslant q+l$, $0\leqslant m_1\leqslant q+l$, $-l-q\leqslant m_2<0$, degeneracy $=q+l-m_1+m_2+1$.

For $l<0$ and $0\leqslant m_2\leqslant q$ we have the following four different regions for integer parameter m_1:

(I) $-m_1\leqslant a_3\leqslant q-m_2$, $|l|<m_2-m_1\leqslant q$, $-q\leqslant m_1\leqslant 0$, $0\leqslant m_2\leqslant q$, degeneracy$=q-m_2+m_1+1$,
(II) $-m_1\leqslant a_3\leqslant q-|l|-m_1$, $m_2-|l|\leqslant m_1<0$, $0\leqslant m_2<|l|$, degeneracy$=q-|l|+1$,
(III) $0\leqslant a_3\leqslant q-m_2$, $0\leqslant m_1\leqslant m_2-|l|$, $|l|\leqslant m_2\leqslant q$, degeneracy$=q-m_2+1$,
(IV) $0\leqslant a_3\leqslant q-|l|-m_1$, $0\leqslant m_2-|l|\leqslant m_1\leqslant q-|l|$, $0\leqslant m_2\leqslant q$, degeneracy$=q-|l|-m_1+1$,
while for $-q+|l|\leqslant m_2<0$ there are another three different regions for m_1,
(V) $-m_1\leqslant a_3\leqslant q$, $-q\leqslant m_1<m_2-|l|$, degeneracy$=q+m_1+1$,
(VI) $-m_1\leqslant a_3\leqslant q-|l|-m_1+m_2$, $m_2-|l|\leqslant m_1<0$, degeneracy$=q-|l|+m_2+1$,
(VII) $0\leqslant a_3\leqslant q-|l|-m_1+m_2$, $m_1-m_2\leqslant q-|l|$, $0\leqslant m_1<q-|l|$, degeneracy$=q-|l|-m_1+m_2+1$.

For given values of the integer parameters q, l, m_1, and m_2 the eigenspectrum of Hamiltonian $H_l(m_1,m_2)$ exists in the above seven regions of the (m_1,m_2) plane (see Fig. 1 for $l \geqslant 0$ and Fig. 2 for $l<0$). Therefore for given values of m_1 and m_2 the eigenspectrum can be obtained simply by consecutive application of lowering operators over the highest eigenweight according to the paths shown in Figs. 1 and 2.

(Received 21 July 2004; accepted 20 September 2004; published online 27 December 2004)

We consider group-covariant positive operator valued measures (POVMs) on a finite dimensional quantum system. Following Neumark's theorem a POVM can be implemented by an orthogonal measurement on a larger system. Accordingly, our goal is to find a quantum circuit implementation of a given group-covariant POVM which uses the symmetry of the POVM. Based on representation theory of the symmetry group we develop a general approach for the implementation of group-covariant POVMs which consist of rank-one operators. The construction relies on a method to decompose matrices that intertwine two representations of a finite group. We give several examples for which the resulting quantum circuits are efficient. In particular, we obtain efficient quantum circuits for a class of POVMs generated by Weyl–Heisenberg groups. These circuits allow to implement an approximative simultaneous measurement of the position and crystal momentum of a particle moving on a cyclic chain. © *2005 American Institute of Physics.*

I. INTRODUCTION

General measurements of quantum systems are described by positive operator-valued measures (POVMs).[1,2] For several optimality criteria the use of POVMs can be advantageous as compared to projector valued measurements. This is true, e.g., for the mean square error, the minimum probability of error,[3] and the mutual information.[4] POVMs are more flexible than orthogonal von Neumann measurements and can consist of finite as well as of an infinite number of elements. An example for the latter is given in Ref. 5 where a POVM for measuring the spin direction is proposed. Here we restrict our attention to the finite case where a POVM is described by a set of positive operators which sum up to the identity. Such a POVM is called group-covariant if the set is invariant under the action of a group. The example of POVMs for the Weyl–Heisenberg groups as well as an example given in Ref. 5 show that POVMs are needed to describe phenomenologically the mesoscopic scale of quantum systems. They allow *approximatively* simultaneous measurements of quantum observables which are actually incompatible. For instance, the classical phase space of a particle can be approximatively reproduced by simultaneous measurements of momentum and position. Descriptions of quantum particles which have strong analogy to the classical phase space are helpful to understand the relations between the classical and the quantum world.[6] Also for several other tasks in quantum information processing the implementation of POVMs is of interest.[7–9]

Neumark's theorem[10,11] states that in principle every POVM can be implemented by an orthogonal measurement of the joint system consisting of the system and an ancilla system. However, the orthogonal measurement required by this construction may not be a "natural" observable of the joint system. One may need an additional unitary transform to obtain a reduction to a more natural observable which henceforth will be called the measurement in the computational basis of the quantum system.

Therefore, the question arises how to actually implement a POVM in terms of a quantum circuit which itself is composed of a sequence of elementary quantum gates.[12] So far, only little is known about the implementation of POVMs even in quantum systems with a small number of dimensions. While some rather specific single-qubit measurements have been studied,[4,13,14] not much is known about the general problem of how to implement a POVM by a unitary transform on the quantum register of a possibly larger space followed by an orthogonal measurement in the computational basis.

When studying quantum circuits for families of POVMs questions about the complexity of the required unitary transforms arise. In some cases we can exploit the fact that they admit some additional symmetry. This leads to the study of group-covariant POVMs which has been studied extensively in the literature.[4,15–17] As a recent example we mention the construction of symmetric informationally complete POVMs by means of suitable finite symmetry groups.[18]

The main contribution of this paper is a general method which computes an embedding of group-covariant POVMs into orthogonal measurements on a larger Hilbert space. A particular feature of the computed embedding is that it uses the symmetry. This in turn allows to apply known techniques for decomposing matrices with symmetry to the unitary matrices obtained by this embedding. For several cases this leads to families of *efficient* quantum circuits implementing the given POVMs.

Outline: In Sec. II we briefly recall the definition of POVMs. In Sec. III we consider the decomposition of matrices that have a symmetry with respect to a group. This type of decomposition is a basic tool for our constructions. We also define group-covariance of POVMs with respect to a symmetry group and a group representation. Furthermore, we explain how POVMs with this group covariance are related to so-called monomial representations of the symmetry group. In Sec. IV we explain the general scheme for the construction of a unitary transform that implements a group-covariant POVM. The basis for this construction is the analysis of the intertwining space between the group representation that is given by the group covariance of the POVM and the monomial representation. This is the starting point for methods using fast quantum Fourier transforms as described in Sec. V. Finally, in Sec. VI we give several examples of implementations of group-covariant POVMs.

Notations: We denote the field of complex numbers by $\mathbb{C}$. The group of invertible $n\times n$ matrices is denoted by $\mathrm{GL}_n(\mathbb{C})$ and the subgroup consisting of the unitary $n\times n$ matrices is denoted by $\mathcal{U}(n)$. We denote the identity matrix in $\mathcal{U}(n)$ by $\mathbf{1}_n$. If not denoted otherwise all matrices are matrices over the complex numbers. The cyclic group of order n is denoted by $\mathbb{Z}_n$. Representations are denoted by small greek letters, e. g., φ, ψ, etc. By abuse of notation we also denote the trivial representation of dimension n (i.e., dimension n) by $\mathbf{1}_n$. The direct sum of matrices and representations is denoted by $A\oplus B$ and $\varphi\oplus\psi$ and the tensor product is denoted by $A\otimes B$ and $\varphi\otimes\psi$, respectively. We make frequent use of the Pauli matrices

$$\sigma_x=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_y=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma_z=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

A diagonal matrix with diagonal entries $\lambda_1,\ldots,\lambda_n$ is abbreviated by $\mathrm{diag}(\lambda_1,\ldots,\lambda_n)$. We denote the symmetric group on n symbols by $\mathcal{S}_n$. To each permutation $\sigma\in\mathcal{S}_n$ naturally corresponds the permutation matrix $\Sigma_i|\sigma(i)\rangle\langle i|$. By abuse of notation we identify σ with the corresponding permutation matrix. We often use the permutation matrix S_m which corresponds to the m-cycle $(1,2,\ldots,m)$ and the matrix$T_m=\mathrm{diag}(1,\omega_m,\ldots,\omega_m^{m-1})$ which contains the eigenvalues of $\mathcal{S}_m$. The basis states of an n-qubit system correspond to binary strings of length n. Quantum circuits are

written from the left to the right, and the qubits are arranged such that the most significant qubit (characterizing the left-most symbol of a binary string) is on top. Throughout the paper a matrix entry "·" stands for zero.

II. POVMs AND ORTHOGONAL MEASUREMENTS

A POVM for a quantum system with Hilbert space $\mathbb{C}^d$ is a set $P=\{A_1,\ldots,A_n\}\subseteq\mathbb{C}^{d\times d}$ of non-negative operators, where $\Sigma_k A_k=\mathbf{1}_d$. For a more general definition for POVMs with an infinite number of operators we refer to Ref. 19. For example, the set of matrices

$$P_2=\left\{\frac{1}{3}\begin{pmatrix}1&1\\1&1\end{pmatrix},\frac{1}{3}\begin{pmatrix}1&\omega\\\omega^2&1\end{pmatrix},\frac{1}{3}\begin{pmatrix}1&\omega^2\\\omega&1\end{pmatrix}\right\}\subseteq\mathbb{C}^{2\times 2},$$

where $\omega=\exp(2\pi i/3)$ is a third root of unity, defines a POVM on a system with corresponding Hilbert space $\mathbb{C}^2$. Suppose that the state of the system is described by the density matrix $\rho\in\mathbb{C}^{d\times d}$. Then for a general POVM the probability p_k for the result k is given by $p_k=\mathrm{tr}(\rho A_k)$. An *orthogonal* measurement is a POVM with mutually orthogonal operators A_k, i. e., we have that $A_kA_l=A_lA_k=0$ for $k\neq l$.

In the following we restrict ourselves to rank-one operators $A_k=|\Psi_k\rangle\langle\Psi_k|$. Note that the POVM vectors $|\Psi_k\rangle$ need not be normalized and that the restriction to operators of rank one is for some applications justified by Davies' theorem.[15] It states that we can always find a POVM with rank-one operators that maximizes the mutual information. The example P_2, which consists of three rank-one operators, can be written as $P_2=\{|\Psi_1\rangle\langle\Psi_1|,|\Psi_2\rangle\langle\Psi_2|,|\Psi_3\rangle\langle\Psi_3|\}$, where

$$|\Psi_1\rangle=\frac{1}{\sqrt{3}}\begin{pmatrix}1\\1\end{pmatrix},\quad |\Psi_2\rangle=\frac{1}{\sqrt{3}}\begin{pmatrix}1\\\omega^2\end{pmatrix},\quad \text{and } |\Psi_3\rangle=\frac{1}{\sqrt{3}}\begin{pmatrix}1\\\omega\end{pmatrix}$$

are the corresponding POVM vectors in $\mathbb{C}^2$. Neumark's theorem[11] states that it is possible to implement a POVM by reducing it to an orthogonal measurement on a larger system. We briefly recall this construction. Let $P=\{A_k\}=\{|\Psi_k\rangle\langle\Psi_k|\}$ be a POVM with n operators that acts on the Hilbert space $\mathbb{C}^d$. For $n>d$ the vectors $|\Psi_k\rangle$ cannot be mutually orthogonal. Consequently, we must extend the system by at least $n-d$ dimensions in order to define an orthogonal measurement with n different measurement outcomes. We want to implement an orthogonal measurement $\tilde{P}=\{\tilde{A}_k\}=\{|\tilde{\Psi}_k\rangle\langle\tilde{\Psi}_k|\}$ on the system with n dimensions such that $\tilde{P}$ corresponds to the POVM P on the subsystem with d dimensions, i.e., $p_k=\mathrm{tr}(\rho A_k)=\mathrm{tr}(\tilde{\rho}\tilde{A}_k)$. Here we have that the embedding of the state into the larger system is $\tilde{\rho}=\rho\oplus 0_{n-d}\in\mathbb{C}^{n\times n}$ where 0_{n-d} denotes the zero matrix of size $n-d$.

We write the POVM vectors $|\Psi_k\rangle$ as columns of the matrix $M=(|\Psi_1\rangle\cdots|\Psi_n\rangle)\in\mathbb{C}^{d\times n}$. In the following we refer to M as the defining matrix for the POVM P. Now, the vectors $|\tilde{\Psi}_k\rangle=|\Psi_k\rangle\oplus|\Phi_k\rangle$ corresponding to $\tilde{A}_k=|\tilde{\Psi}_k\rangle\langle\tilde{\Psi}_k|\in\mathbb{C}^{n\times n}$ are the columns of the matrix

$$\tilde{M}=\begin{pmatrix}|\Psi_1\rangle&\cdots&|\Psi_n\rangle\\|\Phi_1\rangle&\cdots&|\Phi_n\rangle\end{pmatrix}\in\mathcal{U}(n).$$

Note that $\tilde{M}$ can be an arbitrary unitary matrix which contains M as upper part of size $d\times n$. Since P is a POVM we have $MM^\dagger=\Sigma_k|\Psi_k\rangle\langle\Psi_k|=\Sigma_k A_k=\mathbf{1}_d$, i. e., finding a suitable $\tilde{M}$ is always possible. For example, in case of P_2 we obtain the defining matrix

$$M=\frac{1}{\sqrt{3}}\begin{pmatrix}1&1&1\\1&\omega^2&\omega\end{pmatrix}\in\mathbb{C}^{2\times 3}$$

and one possible choice for $\tilde{M}$ is to add the row given by $(1/\sqrt{3})(1,\omega,\omega^2)$. Hence the rank-one projectors corresponding to the orthogonal measurement $\tilde{M}$ are

$$|\tilde{\Psi}_1\rangle = \frac{1}{\sqrt{3}}\begin{pmatrix}1\\1\\1\end{pmatrix}, \quad |\tilde{\Psi}_2\rangle = \frac{1}{\sqrt{3}}\begin{pmatrix}1\\\omega^2\\\omega\end{pmatrix}, \quad \text{and } |\tilde{\Psi}_3\rangle = \frac{1}{\sqrt{3}}\begin{pmatrix}1\\\omega\\\omega^2\end{pmatrix}.$$

The probability distribution $\tilde{p}_k = \mathrm{tr}(\tilde{\rho}\tilde{A}_k)$ of the constructed orthogonal measurement equals the distribution p_k of the original POVM since

$$\tilde{p}_k = \mathrm{tr}(\tilde{\rho}\tilde{A}_k) = \mathrm{tr}\left((\rho \oplus 0_{n-d})\begin{pmatrix}|\Psi_k\rangle\langle\Psi_k| & |\Psi_k\rangle\langle\Phi_k|\\ |\Phi_k\rangle\langle\Psi_k| & |\Phi_k\rangle\langle\Phi_k|\end{pmatrix}\right) = \mathrm{tr}(\rho A_k) = p_k.$$

The embedding into a larger system can be realized by using an ancilla register of a quantum computer. It consists of l qubits such that $2^l \geqslant n-d$. They are initially in the state $|0\cdots0\rangle$. Then the space $\mathbb{C}^d \otimes |0\cdots0\rangle$ is the subspace where the POVM acts on and $\mathbb{C}^d \otimes (\mathbb{C}^2)^{\otimes l}$ is the extension. The density operator $\tilde{\rho}$ acts on an n-dimensional subspace of the joint system consisting of the original system and the ancilla register. In the following we will assume that also the system space $\mathbb{C}^d$ is embedded into the state space of some qubits.

As explained above, we can implement the POVM with corresponding matrix M by applying the unitary transform $\tilde{M}^\dagger$ to the initial state $\tilde{\rho}$ of the joint system followed by a measurement in the computational basis. Note that for the special case where the columns of M are already orthogonal we have that $\tilde{M} = M$. In this case by implementing the matrix $M^\dagger$ followed by a measurement in the computational basis we can perfectly distinguish between the columns of M.

In principle, the construction of an appropriate matrix $\tilde{M}$ is simple since we just have to find mutually orthogonal rows that lead to a unitary matrix. However, k qubits allow POVMs with $n = 2^k$ operators. Hence the size of $\tilde{M}$ is exponential in k. The complexity to implement a unitary matrix on k qubits can be upper bounded[20] by $O(4^k)$ and a generic element of $\mathcal{U}(2^k)$ will indeed require an exponential number of elementary transforms (e.g., one- and two-qubit gates). Therefore we are interested in the construction of a matrix $\tilde{M}$ that can be implemented efficiently, if such a construction exists at all. While finding efficient factorizations is a hard problem in general, the situation becomes easier in some cases where we are given the additional structure of a group-covariant POVM. In the following sections we will give a definition of group covariance and the related notion of symmetry. Later, we exploit the symmetry of the matrix M and give several examples of POVMs that have efficient quantum circuit implementations.

III. GROUP-COVARIANT POVMs AND MATRICES WITH SYMMETRY

In the following we give a precise mathematical definition of the notion of *symmetry* of a matrix $M \in \mathbb{C}^{m\times n}$. Later we define group covariance of a POVM and show that the group covariance in a natural way leads to matrices with symmetry. For the necessary background on finite groups and representations we refer to standard textbooks such as Refs. 21 and 22.

We start with a finite group G and a pair (φ, ψ) of matrix representations of G which are compatible with the size of M, i.e., $\varphi: G \to \mathrm{GL}_m(\mathbb{C})$ and $\psi: G \to \mathrm{GL}_n(\mathbb{C})$. Following Refs. 23 and 24 we call the triple (G, φ, ψ) a symmetry of M if the identity $\varphi(g)M = M\psi(g)$ holds for all $g \in G$. Sometimes we abbreviate this by using the shorthand notation $\varphi M = M\psi$. Note that if M is not a square matrix the representations φ and ψ have different dimensions.

To give an example we let $\omega = \exp(2\pi i/3)$ and let $\alpha, \beta, \gamma \in \mathbb{C}$. Then for all $j \in \{0,1,2\}$ we have that

$$\begin{pmatrix}1&\cdot&\cdot\\ \cdot&\omega&\cdot\\ \cdot&\cdot&\omega^2\end{pmatrix}^j \begin{pmatrix}\alpha&\alpha&\alpha\\ \beta&\beta\omega&\beta\omega^2\\ \gamma&\gamma\omega^2&\gamma\omega\end{pmatrix} = \begin{pmatrix}\alpha&\alpha&\alpha\\ \beta&\beta\omega&\beta\omega^2\\ \gamma&\gamma\omega^2&\gamma\omega\end{pmatrix} \begin{pmatrix}\cdot&\cdot&1\\ 1&\cdot&\cdot\\ \cdot&1&\cdot\end{pmatrix}^j.$$

Hence we obtain a symmetry which is given by the cyclic group $\mathbb{Z}_3 = \{0,1,2\}$ together with the two representations $\varphi, \sigma: \mathbb{Z}_3 \to \mathcal{U}(3)$ given by $\varphi(1) = \mathrm{diag}(1, \omega, \omega^2)$ and $\sigma(1) = (1,3,2)$.

Note that given two representations φ, ψ of a group G the set of all matrices M which fulfill $\varphi(g)M=M\psi(g)$ for all $g\in G$ is a vector space. It turns out that the matrices in this vector space have a special form. Hence we explore its structure in more detail in the following.

Definition 1 (intertwining space): Let G be a group and let φ, ψ be representations of G of dimensions n and m, respectively. Then

$$\mathrm{Int}(\varphi,\psi) := \{M:\varphi(g)M = M\psi(g),\ \textit{for all } g\in G\}$$

with $M\in\mathbb{C}^{n\times m}$ is called the intertwining space of φ and ψ.

In the following we denote by $\varphi_1,\ldots,\varphi_k$ a complete list of pairwise inequivalent irreducible representations of G. Recall that for any representation of a finite group it is always possible to find a base change such that the corresponding representation is a direct sum of irreducible representations.[22] For representations which are completely decomposed into a direct sum of irreducibles the structure of the intertwining space is known. This is the content of the following theorem which follows directly from Schur's lemma (see Ref. 26, Sec. 29).

Theorem 2: *Let G be a finite group and $\varphi=\oplus_{i=1}^{k}(\mathbf{1}_{n_i}\otimes\varphi_i)$ and $\psi=\oplus_{i=1}^{k}(\mathbf{1}_{m_i}\otimes\varphi_i)$ two representations of G which have been completely decomposed into pairwise inequivalent representations φ_i with $i=1,\ldots,k$. Then the intertwining space of φ and ψ has the following structure:*

$$\mathrm{Int}(\varphi,\psi) = (\mathbb{C}^{n_1\times m_1}\otimes\mathbf{1}_{\deg(\varphi_1)})\oplus\cdots\oplus(\mathbb{C}^{n_k\times m_k}\otimes\mathbf{1}_{\deg(\varphi_k)}).$$

A matrix A is called *block permuted* if there are permutation matrices P and Q such that $PAQ=B_1\oplus\cdots\oplus B_k$, where $B_1,\ldots,B_k$ are (rectangular) matrices. For all $n,m,k\in\mathbb{N}$ there exist permutation matrices $P_{n,m,k}$ and $Q_{n,m,k}$ such that for all $A\in\mathbb{C}^{n\times m}$ we have $P_{n,m,k}(A\otimes\mathbf{1}_k)Q_{n,m,k}=\mathbf{1}_k\otimes A$. Hence we have shown that the elements of the intertwining space of completely reduced representations are block permuted.

We continue with an easy observation which turns out to be essential for the approach of extending the symmetry of a given group-covariant POVM to a measurement on a larger space. Suppose that $M\in\mathrm{Int}(\varphi,\psi)$ and that the matrices U and W decompose the representations φ and ψ into the direct sums, i.e., $U\varphi U^\dagger=\varphi_1\oplus\cdots\oplus\varphi_n$ and $V\psi V^\dagger=\psi_1\oplus\cdots\oplus\psi_m$. Then we can rewrite $\varphi M=M\sigma$ as

$$U^\dagger(\varphi_1\oplus\cdots\oplus\varphi_n)UM = MW^\dagger(\psi_1\oplus\cdots\oplus\psi_m)W.$$

Multiplying this from the left by U and from the right by $W^\dagger$ shows that $C:=UMW^\dagger$ is an element of the intertwining space $\mathrm{Int}(\varphi_1\oplus\cdots\oplus\varphi_n,\psi_1\oplus\cdots\oplus\psi_m)$ of two completely reduced representations. In particular, we can apply Theorem 2 to determine the structure of C. In particular we obtain that C is block permuted and the size of the blocks depend on the multiplicities and dimensions of the irreducible representations contained in φ and ψ.

Matrices with symmetry arise naturally in context of group-covariant POVMs. We first give a definition of these POVMs and then establish a connection between the notions of group covariance and symmetry.

Definition 3 (group-covariant POVMs): A POVM $P=\{A_1,\ldots,A_n\}\subseteq\mathbb{C}^{d\times d}$ with $A_k\neq A_l$ for $k\neq l$ is group-covariant with respect to the group G if there exists a projective unitary representation $\varphi:G\to\mathcal{U}(d)$ with $\varphi(g)A_k\varphi(g)^\dagger\in P$ for all $g\in G$ and all k.

Note that a group-covariant POVM is also group covariant for all subgroups $H\leqslant G$ and the restriction of the representation φ to H. As a special case, the choice of the trivial subgroup $H=\{1\}$ means that we do not use the symmetry of the POVM at all.

A minor complication arises due to the fact that while the notion of symmetry of matrices relies on ordinary, i.e., nonprojective representations, the definition of group-covariant POVMs relies on projective representations. Therefore, we need a construction which allows to transform the projective representation of the symmetry group of a group-covariant POVM into a nonprojective representation. This connection is established using so-called *central extensions* which is a method going back to Schur. We briefly recall this construction [see also Ref. 22, Lemma (11.16)]. Let $\varphi:G\to\mathrm{GL}_d(\mathbb{C})$ be a projective representation of the group G. More precisely, we have

$\varphi(gh)=\gamma_{gh}\varphi(g)\varphi(h)$ for $g,h\in G$, where γ_{gh} is a factor system. Let $H=\langle\gamma_{gh}:g,h\in G\rangle$ be the group generated by the γ_{gh}. We consider the group $\hat{G}$ consisting of the elements (g,h) with $g\in G$ and $h\in H$. The multiplication of two elements (g,h) and (g',h') of $\hat{G}$ is defined by $(g,h)(g',h')=(gg',\gamma_{gg'}hh')$. Then the map $\tilde{\varphi}((g,h))=h\varphi(g)$ is a representation with $\tilde{\varphi}((g,1))=\varphi(g)$, i.e., the representation $\tilde{\varphi}$ equals φ on the elements $(g,1)$ and the group $\hat{G}$ is a central extension of the group G.

In the following we always assume φ to be a nonprojective representation of the symmetry group G by this construction. This is justified since the set of POVM operators does not change by switching from G to a central extension $\hat{G}$ because scalar multiples of the identity transform trivially under conjugation.

We now analyze the structure of the matrix M corresponding to the group-covariant POVM $P=\{|\Psi_k\rangle\langle\Psi_k|\}$ with rank-one operators. Note that the phases of the vectors $|\Psi_k\rangle$ can be chosen arbitrarily without changing the POVM. Let $\varphi:G\to\mathcal{U}(d)$ be the representation corresponding to the symmetry of P. We then have the equation

$$\varphi(g)|\Psi_k\rangle\langle\Psi_k|\varphi(g)^\dagger=|\Psi_{\pi(g)k}\rangle\langle\Psi_{\pi(g)k}|,$$

where $\pi:G\to S_n$ denotes a permutation representation of the group G. Indeed, the equation $|\Psi_{\pi(g)j}\rangle\langle\Psi_{\pi(g)j}|=|\Psi_{\pi(g)k}\rangle\langle\Psi_{\pi(g)k}|$ implies $|\Psi_j\rangle\langle\Psi_j|=|\Psi_k\rangle\langle\Psi_k|$ by conjugation with $\varphi(g)^\dagger$ since $A_j\neq A_k$ for $j\neq k$. Therefore, the map $\pi(g)$ is injective for all $g\in G$. Since an injective map on a finite set is also surjective the map $\pi(g)$ defines a permutation.

Next, we consider the action of φ on the columns of the matrix M. As stated above the columns $|\Psi_k\rangle$ of M can have arbitrary phase factors. The action of $\varphi(g)$ on the columns of M can be described by the equation $\varphi(g)|\Psi_k\rangle=e^{i\phi(g,k)}|\Psi_{\pi(g)k}\rangle$ where $\phi(g,k)$ depends on k, g and the fixed phase factors of the vectors $|\Psi_k\rangle$. We identify the columns $|\Psi_k\rangle$ with a basis b_k of the vector space $\mathbb{C}^n$ in order to construct a representation that describes the action of φ on the columns of M. With this identification the action of $\varphi(g)$ corresponds to the map $b_k\mapsto e^{i\phi(g,k)}b_{\pi(g)k}$.

By writing down the matrix corresponding to this map, we see that in each row and each column there is precisely one entry different from zero. Matrices having a structure like this are called *monomial matrices*[25] (Ref. 26, Sec. 43). Whenever the images under a representation consist entirely of monomial matrices, we denote this with a subscript, i.e., we write $\varphi_{\mathrm{mon}}(g)$. Now, the two representations φ and φ_{mon} define the symmetry $\varphi M=M\varphi_{\mathrm{mon}}$ of the matrix M. The monomial representation φ_{mon} acts on the columns of M. For each $g\in G$ it permutes the columns of M and multiplies each column with a phase factor.

Example 4: As an example in two dimensions we consider the following POVM:

$$P=\left\{\begin{pmatrix}|\alpha|^2 & \alpha\overline{\beta}\\ \overline{\alpha}\beta & |\beta|^2\end{pmatrix},\begin{pmatrix}|\alpha|^2 & -\alpha\overline{\beta}\\ -\overline{\alpha}\beta & |\beta|^2\end{pmatrix},\begin{pmatrix}|\beta|^2 & \overline{\alpha}\beta\\ \alpha\overline{\beta} & |\alpha|^2\end{pmatrix},\begin{pmatrix}|\beta|^2 & -\overline{\alpha}\beta\\ -\alpha\overline{\beta} & |\alpha|^2\end{pmatrix}\right\}\subseteq\mathbb{C}^{2\times 2}$$

with $\alpha,\beta\in\mathbb{C}$ and $|\alpha|^2+|\beta|^2=1/2$. Then P is covariant with respect to $\mathbb{Z}_2\times\mathbb{Z}_2$. The corresponding projective representation $\varphi:\mathbb{Z}_2\times\mathbb{Z}_2\to\mathcal{U}(2)$ is defined by the equations

$$\varphi(0,0)=\mathbf{1}_2,\quad \varphi(0,1)=\sigma_z,\quad \varphi(1,0)=\sigma_x,\quad \varphi(1,1)=\sigma_z\sigma_x,$$

where (0,0), (0,1), (1,0), and (1,1) denote the elements of the group $\mathbb{Z}_2\times\mathbb{Z}_2$.

For this projective representation of $\mathbb{Z}_2\times\mathbb{Z}_2$ a simple computation shows that the central extension $\hat{G}$ of $\mathbb{Z}_2\times\mathbb{Z}_2$ is isomorphic to the dihedral group with eight elements. In the following it is sufficient to consider the definition of the representation on the elements ((0,1),1) and ((1,0),1) since these elements generate $\hat{G}=\{(g,h):g\in\mathbb{Z}_2\times\mathbb{Z}_2,h\in\{\pm 1\}\}$. We can choose

$$M = \begin{pmatrix} \alpha & \alpha & \beta & \beta \\ \beta & -\beta & \alpha & -\alpha \end{pmatrix} \in \mathbb{C}^{2\times 4}$$

or a matrix with the same columns (up to an arbitrary phase factor for each column). This leads to a symmetry group given by the monomial representation

$$\varphi_{\mathrm{mon}}((0,1),1) = \begin{pmatrix} \cdot & 1 & \cdot & \cdot \\ 1 & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & 1 \\ \cdot & \cdot & 1 & \cdot \end{pmatrix} \quad \text{and} \quad \varphi_{\mathrm{mon}}((1,0),1) = \begin{pmatrix} \cdot & \cdot & 1 & \cdot \\ \cdot & \cdot & \cdot & -1 \\ 1 & \cdot & \cdot & \cdot \\ \cdot & -1 & \cdot & \cdot \end{pmatrix}.$$

For a different choice of phase factors we obtain another representation φ_{mon}. The modified pair of representations φ, φ_{mon} also defines a symmetry of M.

An important special case of group-covariant POVMs are *group-generated* POVMs which we describe next. Let G be a group and $\varphi: G \to \mathbb{C}^{d\times d}$ an (ordinary) unitary representation. A group-generated POVM is described by the POVM vectors $\varphi(g)|\Psi\rangle$ for $g \in G$ and an initial vector $|\Psi\rangle \in \mathbb{C}^d$. The corresponding operators of the POVM are given by $A_g = \varphi(g)|\Psi\rangle\langle\Psi|\varphi(g)^\dagger$ for $g \in G$. In other words, all POVM vectors are obtained by the initial vector $|\Psi\rangle$ under the operation of the group G, i.e., they form an orbit. Obviously, a group-generated POVM is a group-covariant POVM with a single orbit under the action of the group. With this construction, the phase factors of the POVM vectors $\varphi(g)|\Psi\rangle$ are fixed by the phase factor of the initial vector $|\Psi\rangle$. The phase factors $e^{i\phi(g,k)}$ of the monomial representation φ_{mon} corresponding to φ equal 1. As a consequence, the monomial representation φ_{mon} equals the regular representation of G with respect to a fixed order of the elements of G.

Note that the operators $\{\varphi(g)|\Psi\rangle\langle\Psi|\varphi(g)^\dagger\}$ in general do not define a POVM for arbitrary representations φ and initial vectors $|\Psi\rangle$. However, if φ acts irreducibly one has (after appropriate normalization) for every vector $|\Psi\rangle$ the equation $\Sigma_{g\in G}\varphi(g)|\Psi\rangle\langle\Psi|\varphi(g)^\dagger = \mathbf{1}_d$.

IV. CONSTRUCTION OF THE ORTHOGONAL MEASUREMENT

Following the preceding section we can arrange the vectors which correspond to the elements of a POVM with rank-one projectors into the columns of a matrix M. We have seen that in case of a group-covariant POVM the matrix $M \in \mathbb{C}^{d\times n}$ always has the symmetry $\varphi M = M\varphi_{\mathrm{mon}}$ where φ is the given representation and φ_{mon} is a monomial representation. Both representations are representations of the symmetry group of the group-covariant POVM. We know that both representations are equivalent to direct sums of irreducible representations. Hence we can find unitary matrices U and W such that $U\varphi U^\dagger = \varphi_1 \oplus \cdots \oplus \varphi_n$ and $W\varphi_{\mathrm{mon}}W^\dagger = \sigma_1 \oplus \cdots \oplus \sigma_m$ where the φ_k and the σ_l denote irreducible representations of the group G. In general, we can write the equation $\varphi M = M\varphi_{\mathrm{mon}}$ as

$$U^\dagger(\varphi_1 \oplus \cdots \oplus \varphi_n)UM = MW^\dagger(\sigma_1 \oplus \cdots \oplus \sigma_m)W.$$

This is equivalent to $C = UMW^\dagger \in T := \mathrm{Int}(\varphi_1 \oplus \cdots \oplus \varphi_n, \sigma_1 \oplus \cdots \oplus \sigma_m)$. Conversely, a matrix C which is contained in this intertwining space and has orthogonal rows defines (up to an appropriate normalization) a group-covariant POVM with corresponding matrix $M = U^\dagger CW$.

For a given matrix $M \in \mathbb{C}^{d\times n}$ we now consider the construction of a unitary matrix $\tilde{M} \in \mathcal{U}(n)$ such that $\tilde{M}$ contains M as the upper part, i.e., we are looking for a matrix $\tilde{M}$ such that

$$\tilde{M} = \begin{pmatrix} M \\ N \end{pmatrix},$$

where $N \in \mathbb{C}^{(n-d)\times n}$. In addition to this we intend to get the symmetry $(\varphi \oplus \varphi')\tilde{M} = \tilde{M}\varphi_{\mathrm{mon}}$ with an appropriate representation $\varphi': G \to \mathcal{U}(n-d)$. If we succeed in constructing an appropriate representation φ' and matrix $\tilde{M}$ then we have the equation $\varphi \oplus \varphi' = \tilde{M}\varphi_{\mathrm{mon}}\tilde{M}^\dagger$, i.e., the representation

$\varphi \oplus \varphi'$ must be equivalent to φ_{mon}. In other words, each irreducible representation of G is contained the same number of times in $\varphi \oplus \varphi'$ and in φ_{mon}. Furthermore, from the decompositions $(U \oplus \mathbf{1}_{n-d})(\varphi \oplus \varphi')(U^\dagger \oplus \mathbf{1}_{n-d}) = \sigma_{\pi(1)} \oplus \cdots \oplus \sigma_{\pi(m)}$ and $W\varphi_{\mathrm{mon}}W^\dagger = \sigma_1 \oplus \cdots \oplus \sigma_m$ we obtain that

$$(U \oplus \mathbf{1})\widetilde{M}W^\dagger \in \widetilde{T} := \mathrm{Int}(\sigma_{\pi(1)} \oplus \cdots \oplus \sigma_{\pi(m)}, \sigma_1 \oplus \cdots \oplus \sigma_m) \subseteq \mathbb{C}^{n\times n}. \tag{1}$$

The permutation τ used in Eq. (1) is a suitable reordering of the irreducible representations. The structure of the intertwining space $\widetilde{T}$ is known from Theorem 2 since we can compute the irreducible representations σ_j from φ_{mon}.

In the following discussion we consider the construction of φ' and $\widetilde{M}$. Our goal is to show that the construction of φ' that makes $U\varphi U^\dagger \oplus \varphi'$ equal to $W\varphi_{\mathrm{mon}}W^\dagger$ up to a permutation τ of the irreducible components is always possible.

Important for the extension of M to $\widetilde{M}$ will be the following theorem which characterizes the relations of two representations in case there is an intertwiner of maximal possible rank. Recall that ψ_1 is a constituent of ψ_2 if and only if there is a base change U such that $U^{-1}\psi_2(g)U = \psi_1(g) \oplus \psi_1'(g)$ where ψ_1' is a representation of G.

Theorem 5: *Let G be a finite group and let ψ_1, ψ_2 be representations of G of dimensions $d_1 = \deg(\psi_1)$ and $d_2 = \deg(\psi_2)$, respectively. Let $M \in \mathbb{C}^{d_1\times d_2}$ be a matrix with $\psi_1(g)M = M\psi_2(g)$ for all $g \in G$ and $\mathrm{rk}(M) = \deg(\psi_1)$. Then ψ_1 is a constituent of ψ_2.*

Proof: Let M be such that $\psi_1(g)M = M\psi_2(g)$ and let $\varphi_1, \ldots, \varphi_k$ be a complete set of pairwise inequivalent irreducible representations of G. Since ψ_1, ψ_2 are representations of a finite group over the field of complex numbers we find unitary matrices U, W such that $U\psi_1 U^\dagger = \oplus_{i=1}^k m_i\varphi_i$ and $W\psi_2 W^\dagger = \oplus_{i=1}^k n_i\varphi_i$, where the multiplicities m_i and n_i are non-negative integers. We must show that actually $m_i \leq n_i$ for all $i = 1, \ldots, k$.

From $\psi_1 M = M\psi_2$ and the choice of U and W we obtain $(\oplus m_i\varphi_i)(UMW^\dagger) = (UMW^\dagger)(\oplus n_i\varphi_i)$, i.e., we have that $UMW^\dagger \in \mathrm{Int}(\oplus_{i=1}^k m_i\varphi_i, \oplus_{i=1}^k n_i\varphi_i)$. By the remarks following Theorem 2 we know that there are permutation matrices P and Q such that $M_0 := P(UMW^\dagger)Q = (\mathbf{1}_{\deg(\varphi_1)} \otimes B_1) \oplus \cdots \oplus (\mathbf{1}_{\deg(\varphi_k)} \otimes B_k)$ where each $B_i \in \mathbb{C}^{m_i\times n_i}$. Multiplication with invertible matrices preserves the property that M and hence also M_0 have full rank [given by $\deg(\psi_1)$]. On the other hand, we know that the rank of a block diagonal matrix is given by the sum of the ranks of the blocks. Hence $\mathrm{rk}(M_0) = \Sigma_{i=1}^k \deg(\varphi_i) \cdot \mathrm{rk}(B_i)$ which shows that each B_i must have full rank. Since B_i is an $m_i \times n_i$ matrix this in particular implies that $m_i \leq n_i$. This shows that ψ_1 is a constituent of ψ_2.

We now use Eq. (1) to construct the matrix $\widetilde{M}$ for the implementation of a group-covariant POVM. Having determined U and W we can compute the matrix $C = UMW^\dagger \in \mathrm{Int}(U\varphi U^\dagger, W\varphi_{\mathrm{mon}}W^\dagger)$. The multiplicity of each irreducible representation in φ' can be computed. Since the structure of the intertwining space $\widetilde{T} = \mathrm{Int}(U\varphi U^\dagger \oplus \varphi', W\varphi_{\mathrm{mon}}W^\dagger)$ is known we can extend C to an arbitrary unitary matrix $\widetilde{C}$ of the intertwining space $\widetilde{T}$. This extension is always possible since both representations $U\varphi U^\dagger \oplus \varphi'$ and $W\varphi_{\mathrm{mon}}W^\dagger$ contain each irreducible representation the same number of times. The matrix C defines some of the rows of A. Since M defines a POVM the rows are mutually orthogonal. Consequently, the matrix components of $\widetilde{C}$ corresponding to an irreducible representation can be chosen under the constraint that they are orthogonal. We now have that for any $V \in \mathcal{U}(n-d)$ the matrix $\widetilde{M} = (U^\dagger \oplus V^\dagger)\widetilde{C}W$ yields a unitary that extends the matrix M and has the symmetry we wanted to construct.

Hence, we obtain the following algorithm to construct an orthogonal measurement which realizes the given POVM and preserves the symmetry.

Algorithm 6: Let $P = \{A_1, \ldots, A_n\} \subseteq \mathbb{C}^{d\times d}$ be a POVM. Then the following steps implement P by a von Neumann measurement on a larger space.

(1) Write the rank-one operators $A_k = |\Psi_k\rangle\langle\Psi_k|$ of the POVM as columns of the matrix $M \in \mathbb{C}^{d\times n}$.
(2) Determine an appropriate symmetry group with corresponding representation $\varphi: G \to \mathcal{U}(d)$.
(3) Compute the monomial representation $\varphi_{\mathrm{mon}}: G \to \mathcal{U}(n)$.

(4) Find a matrix $U \in \mathcal{U}(d)$ that decomposes φ into irreducible representations where equivalent ones are equal.
(5) Find a matrix $W \in \mathcal{U}(n)$ that decomposes φ_{mon} into irreducible representations where equivalent ones are equal.
(6) Construct the representation φ' such that $U\varphi U^\dagger \oplus \varphi'$ is equal to $W\varphi_{\mathrm{mon}}W^\dagger$ up to a permutation τ of the irreducibles.
(7) Construct $\widetilde{C} \in \mathcal{U}(n)$ that contains $C = UMW^\dagger \in \mathbb{C}^{d\times n}$ as upper part and is in the intertwining space $\widetilde{T}$ of $U\varphi U^\dagger \oplus \varphi'$ and $W\varphi_{\mathrm{mon}}W^\dagger$.
(8) Choose an arbitrary unitary matrix $V \in \mathcal{U}(n-d)$.
(9) Compute $\widetilde{M} = (U^\dagger \oplus V^\dagger)\widetilde{C}W \in \mathcal{U}(n)$.

Then $\widetilde{M}^\dagger$ implements the POVM P by a von Neumann measurement on a larger space, i.e., for any state ρ on the original d-dimensional system we have that $p_k = \mathrm{tr}(\widetilde{\rho}\widetilde{A}_k) = \langle \widetilde{\Psi}_k | \widetilde{\rho} | \widetilde{\Psi}_k \rangle$. Here $|\widetilde{\Psi}_k\rangle$ denote the rows of $\widetilde{M}$ and $\widetilde{\rho} = \rho \oplus 0_{n-d}$ is the embedding of ρ to a state of an n-dimensional system.

Example 7: We consider the example of the preceding section with the matrix

$$M = \begin{pmatrix} \alpha & \alpha & \beta & \beta \\ \beta & -\beta & \alpha & -\alpha \end{pmatrix} \in \mathbb{C}^{2\times 4}$$

and the group $G = \{(g,h) : g \in \mathbb{Z}_2 \times \mathbb{Z}_2, h \in \{\pm 1\}\}$ which is isomorphic to the dihedral group of order eight. The representation $\varphi : G \to \mathcal{U}(2)$ is given by $\varphi((0,1),1) = \sigma_z$ and $\varphi((1,0),1) = \sigma_x$. We have $U = \mathbf{1}_2$ and $U\varphi U^\dagger = \varphi$ since the representation φ is already irreducible. An elementary computation shows that the corresponding monomial representation φ_{mon} is given by

$$W\varphi_{\mathrm{mon}}((0,1),1)W^\dagger = \begin{pmatrix} 1 & \cdot & \cdot & \cdot \\ \cdot & -1 & \cdot & \cdot \\ \cdot & \cdot & 1 & \cdot \\ \cdot & \cdot & \cdot & -1 \end{pmatrix}, \quad W\varphi_{\mathrm{mon}}((1,0),1)W^\dagger = \begin{pmatrix} \cdot & 1 & \cdot & \cdot \\ 1 & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & 1 \\ \cdot & \cdot & 1 & \cdot \end{pmatrix}$$

with the unitary matrix

$$W = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 & \cdot & \cdot \\ \cdot & \cdot & 1 & -1 \\ \cdot & \cdot & 1 & 1 \\ 1 & -1 & \cdot & \cdot \end{pmatrix} \in \mathcal{U}(4).$$

Therefore, φ_{mon} contains the irreducible representation φ twice, i.e., $W\varphi_{\mathrm{mon}}W^\dagger = \varphi \oplus \varphi$.

With the matrices $M \in \mathbb{C}^{2\times 4}$, $U \in \mathcal{U}(2)$ and $W \in \mathcal{U}(4)$ as above we find that $C = UMW^\dagger = \sqrt{2}(\alpha\ \beta) \otimes \mathbf{1}_2 \in \mathbb{C}^{2\times 4}$, which is an element of the intertwining space

$$\mathrm{Int}(\varphi, W\varphi_{\mathrm{mon}}W^\dagger) = \mathrm{Int}(\varphi, \varphi \oplus \varphi).$$

Since we have $W\varphi_{\mathrm{mon}}W^\dagger = \varphi \oplus \varphi$, we must choose $\varphi' = \varphi$. The intertwining space $\widetilde{T}$ is given by

$$\widetilde{T} = \mathrm{Int}(\varphi \oplus \varphi, \varphi \oplus \varphi) = \left\{ \begin{pmatrix} \lambda_{11} & \cdot & \lambda_{12} & \cdot \\ \cdot & \lambda_{11} & \cdot & \lambda_{12} \\ \lambda_{21} & \cdot & \lambda_{22} & \cdot \\ \cdot & \lambda_{21} & \cdot & \lambda_{22} \end{pmatrix} : \lambda_{ij} \in \mathbb{C} \right\} \subseteq \mathbb{C}^{4\times 4}.$$

In our example, the matrix $C = UMW^\dagger$ defines the first two rows of the matrix $\widetilde{C} \in \widetilde{T} = \mathrm{Int}(\varphi \oplus \varphi, \varphi \oplus \varphi)$.

In particular, we have the equations $\lambda_{11} = \sqrt{2}\alpha$ and $\lambda_{12} = \sqrt{2}\beta$. For example, it is possible to choose $\lambda_{21} = \sqrt{2}\overline{\beta}$ and $\lambda_{22} = -\sqrt{2}\overline{\alpha}$ for $\alpha, \beta \in \mathbb{C}$ to obtain the unitary matrix

$$\tilde{C} = \sqrt{2}\begin{pmatrix} \alpha & \cdot & \beta & \cdot \\ \cdot & \alpha & \cdot & \beta \\ \overline{\beta} & \cdot & -\overline{\alpha} & \cdot \\ \cdot & \overline{\beta} & \cdot & -\overline{\alpha} \end{pmatrix} \in \mathcal{U}(4),$$

which has the symmetry $(\varphi \oplus \varphi)\tilde{C} = \tilde{C}(\varphi \oplus \varphi)$. With $\tilde{M} = (U^\dagger \oplus V^\dagger)\tilde{C}W$ and $V = \mathbf{1}_2$ we compute the matrix

$$\tilde{M} = \begin{pmatrix} \alpha & \alpha & \beta & \beta \\ \beta & -\beta & \alpha & -\alpha \\ \overline{\beta} & \overline{\beta} & -\overline{\alpha} & -\overline{\alpha} \\ -\overline{\alpha} & \overline{\alpha} & \overline{\beta} & -\overline{\beta} \end{pmatrix} \in \mathcal{U}(4)$$

that contains M as the upper part and has the symmetry $(\varphi \oplus \varphi)\tilde{M} = \tilde{M}\varphi_{\mathrm{mon}}$. Note that all unitary matrices $V \in \mathcal{U}(2)$ give rise to possible extensions $\tilde{M}$.

V. EFFICIENT IMPLEMENTATIONS OF GROUP-COVARIANT POVMs

From the general construction of a von Neumann measurement which realizes a given POVM using the symmetry of the POVM we now turn to the question of decomposing the unitary $\tilde{M}$ into gates. This can be seen as a first step towards the more general question of how POVMs can be implemented efficiently on a quantum computer.

When speaking about the efficiency, we mean the cost of implementing the POVM as a von Neumann measurement on a larger Hilbert space, i.e., the number of elementary gates we need to actually implement the necessary unitary operation on this bigger space. First note that the discussed construction of $\tilde{M}$ has several degrees of freedom:

(i) The matrix $\tilde{C}$ that contains C as upper part can be chosen arbitrarily. The matrix $\tilde{C}$ has to be a unitary matrix in the intertwining space $\tilde{T}$.
(ii) The matrix $V \in \mathcal{U}(n-d)$ can be an arbitrary unitary matrix.
(iii) The order and phase factors of the POVM vectors in the matrix M can be chosen arbitrarily. However, it must be possible to deduce the applied POVM operator from the result of the orthogonal measurement efficiently.
(iv) The permutation τ of the irreducible representations in $U\varphi U^\dagger \oplus \varphi'$ can be chosen arbitrarily.
(v) The symmetry group G can be restricted to subgroups $H \leqslant G$ which might lead to different realizations of the POVM.

The constructions depend on the symmetry group G we consider for the POVM. Sometimes, we can obtain simple implementations by restricting the symmetry group to a subgroup $H \leqslant G$. If we consider a subgroup H of G and construct the POVM with respect to H we have several changes in the construction compared to the construction with the group G. On the one hand, the number of occurrences of the irreducible representations in φ_{mon} increase. On the other hand, the number of inequivalent irreducible representations of the symmetry group decreases. Consequently, the matrices of the intertwining spaces are more complex since there are more irreducible representations in φ and φ_{mon} that are equivalent. As a tradeoff we have that the complexity of the transform W decreases. The circuits constructed in Ref. 14 show that the restriction of the symmetry group to a cyclic subgroup can lead to efficient algorithms in some cases.

Let G be a finite group and $\{\varphi_1, \ldots, \varphi_k\}$ a system of representatives for the irreducible representations of G. Let the coefficients of these representation be indexed by the list $L' := [(m;i,j), 1 \leqslant m \leqslant k, 1 \leqslant i,j \leqslant \deg(\varphi_m)]$. Furthermore, let the elements of G be indexed by the list L. Then the matrix

$$1/\sqrt{|G|}(\sqrt{\deg(\varphi_m)}\varphi_m(g)_{ij})_{(m;i,j),g}$$

is unitary and is called a Fourier transform (or DFT for short) for G (Refs. 27 and 28) (with respect to L and L').

For several groups it is known how to realize a DFT efficiently on a quantum computer.[29–31] In these cases the symmetry φ_{mon} can be decomposed efficiently whenever we have that (i) φ_{mon} is a regular representation of G and that (ii) the DFT for G can be computed efficiently. Note that the computational complexity of this von Neumann measurement depends essentially on the complexity of implementing DFT_G in terms of elementary quantum gates. Hence we obtain several families of POVMs for which the monomial representation φ_{mon} can be decomposed efficiently. The complexity of the corresponding POVM then depends on the remaining matrices C, U, and W used in Algorithm 6.

VI. EXAMPLES

In this section we apply the methods discussed in the preceding sections to some examples of group-covariant POVMs. We exploit the symmetry of group-covariant POVMs with respect to cyclic groups, dihedral groups, and Weyl–Heisenberg groups in order to construct quantum circuits for the implementation of these POVMs. Quantum circuits for the implementation of group-covariant POVMs on a single qubit with respect to the cyclic and dihedral groups are also discussed in Ref. 14.

A. Cyclic groups

Let $\mathbb{Z}_n=\{0,1,\ldots,n-1\}$ be a cyclic group with n elements and let $\omega=\exp(2\pi i/n)$ be a primitive nth root of unity. On a d-dimensional Hilbert space we consider a group-generated POVM with respect to the representation $\varphi:\mathbb{Z}_n\to\mathcal{U}(d)$ that is defined on the generator by $\varphi(1)=\mathrm{diag}(1,\omega,\omega^2,\ldots,\omega^{d-1})$. With an appropriate initial vector $|\Psi\rangle\in\mathbb{C}^d$ the elements $\varphi(g)|\Psi\rangle$ for $g\in\mathbb{Z}_n$ define a POVM. In the following, we only consider the vector $|\Psi\rangle=1/\sqrt{n}(1,\ldots,1)^T\in\mathbb{C}^d$. This vector leads to the POVM with the defining matrix

$$M=\frac{1}{\sqrt{n}}\begin{pmatrix}1 & 1 & 1 & \ldots & 1\\ 1 & \omega & \omega^2 & \ldots & \omega^{n-1}\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ 1 & \omega^{d-1} & \omega^{2(d-1)} & \ldots & \omega^{(n-1)(d-1)}\end{pmatrix}\in\mathbb{C}^{d\times n}. \tag{2}$$

The matrix $M\in\mathbb{C}^{d\times n}$ has the symmetry $\varphi M=M\varphi_{\mathrm{mon}}$ where $\varphi_{\mathrm{mon}}(1)=(1,2,\ldots,n)$. The representation φ_{mon} is the regular representation of the cyclic group where the elements are ordered as $[0,1,\ldots,(n-1)]$. With the Fourier matrix

$$F_n=\frac{1}{\sqrt{n}}(\omega^{jk})_{j,k=0}^{n-1}\in\mathcal{U}(n)$$

we can write $F_n\varphi_{\mathrm{mon}}(1)F_n^\dagger=\mathrm{diag}(1,\omega,\omega^2,\ldots,\omega^{n-1})$. This shows that the Fourier transform decomposes the regular representation of $\mathbb{Z}_n$ into a direct sum of irreducible representations.

According to the preceding discussion (and notation) we have that $U=\mathbf{1}_d$ and $W=F_n$. As a consequence we have the equation $\mathbf{C}=UMW^\dagger=MF_n^\dagger$. More precisely, we have $C=MF_n^\dagger=\mathrm{diag}(1,1,\ldots,1)\in\mathbb{C}^{d\times n}$.

We now consider the construction of the matrices $\tilde{C}$ and $\tilde{M}$. The representation $\varphi:\mathbb{Z}_n\to\mathcal{U}(d)$ with $\varphi(1)=\mathrm{diag}(1,\omega,\omega^2,\ldots,\omega^{d-1})$ contains the irreducible representations $1\mapsto(\omega^k)$ for all $k\in\{0,\ldots,d-1\}$. The representation $F_n\varphi_{\mathrm{mon}}F_n^\dagger:\mathbb{Z}_n\to\mathcal{U}(n)$ with $F_n\varphi_{\mathrm{mon}}(1)F_n^\dagger=\mathrm{diag}(1,\omega,\omega^2,\ldots,\omega^{n-1})$ contains the irreducible representations $1\mapsto(\omega^k)$ for all $k\in\{0,1,\ldots,n-1\}$. Following Algorithm 6 from Sec. IV, we choose φ' with $\varphi'(1)=\mathrm{diag}(\omega^d,\ldots,\omega^{n-1})$ in order

to obtain $\varphi \oplus \varphi' = F_n \varphi_{\mathrm{mon}} F_n^\dagger$. Since each irreducible representation $1 \mapsto (\omega^k)$ with $k \in \{0,1,\ldots,n-1\}$ has dimension one and the irreducible representations defined by $1 \mapsto (\omega^k)$ are inequivalent for different k we have the intertwining space

$$\widetilde{T} = \mathrm{Int}(\varphi \oplus \varphi', F_n \varphi_{\mathrm{mon}} F_n^\dagger) = \{\mathrm{diag}(\lambda_1, \ldots, \lambda_n) : \lambda_j \in \mathbb{C}\} \subseteq \mathbb{C}^{n \times n}.$$

We have to find a matrix $\widetilde{C} \in \mathcal{U}(n)$ in the intertwining space $\widetilde{T}$ that has the matrix $C \in \mathbb{C}^{d \times n}$ as upper part. As stated above, the matrix $M \in \mathbb{C}^{d \times n}$ defines $\lambda_j = 1$ for $j \in \{0,1,\ldots,d-1\}$. Since $\widetilde{C}$ has to be a unitary matrix we must choose λ_j with the absolute value $|\lambda_j| = 1$ for $j \in \{d,\ldots,n-1\}$.

In order to simplify the matrices we set $\lambda_j = 1$ for all $j \in \{d,\ldots,n-1\}$. With these elements λ_j we have the equation $\widetilde{C} = \mathbf{1}_n$. Furthermore, we choose $V = \mathbf{1}_{n-d}$ in Algorithm 6 from Sec. IV leading to $U \oplus V = \mathbf{1}_n$. Consequently, we obtain the equation

$$\widetilde{M}^\dagger = W^\dagger \widetilde{C}^\dagger (U \oplus V) = F_n^\dagger \mathbf{1}_n \mathbf{1}_n = F_n^\dagger.$$

This equation shows that the inverse Fourier transform $\widetilde{M}^\dagger = F_n^\dagger$ is a unitary transform that implements the group-covariant POVM with defining matrix (2). Recall that for $n = 2^k$ where $k \in \mathbb{N}$ the Fourier transform can be implemented efficiently on a qubit register.[32,33]

B. Dihedral groups

Let $D_{2m} = \langle r, s : r^m = 1, s^2 = 1, srs^{-1} = r^{-1} \rangle$ be the dihedral group[34] with $n = 2m = 2^{k+1}$ elements for a fixed $m = 2^k \geqslant 4$. The element r denotes the rotation and s the reflection of the dihedral group. We consider the irreducible representation $\varphi : D_{2m} \to \mathcal{U}(2)$ that is defined by

$$\varphi(r) = \begin{pmatrix} \omega & 0 \\ 0 & \omega^{-1} \end{pmatrix} \quad \text{and} \quad \varphi(s) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

The element $\omega = \exp(2\pi i/m)$ is an mth root of unity. For $\alpha, \beta \in \mathbb{C}$ with $|\alpha|^2 + |\beta|^2 = 1/m$ we consider the POVM with the corresponding matrix

$$M = \begin{pmatrix} \alpha & \ldots & \alpha & \beta & \ldots & \beta \\ \beta & \ldots & \beta\omega^{m-1} & \alpha & \ldots & \alpha\omega^{m-1} \end{pmatrix} \in \mathbb{C}^{2 \times n}.$$

The matrix $M \in \mathbb{C}^{2 \times n}$ has the symmetry $\varphi M = M \varphi_{\mathrm{mon}}$ where φ_{mon} is defined by the equations $\varphi_{\mathrm{mon}}(r) = \mathbf{1}_2 \otimes \omega S_m^{-2}$ and $\varphi_{\mathrm{mon}}(s) = \sigma_x \otimes F_m^2 T_m$. The matrices $S_m, T_m \in \mathbb{C}^{m \times m}$ are defined by the equations (indices are taken modulo m)

$$S_m = \sum_{i=0}^{m-1} |i+1\rangle\langle i|, \quad T_m = \sum_{i=0}^{m-1} \omega^i |i\rangle\langle i|,$$

and F_m denotes the discrete Fourier transform defined in the preceding section. In order to decompose φ_{mon} into irreducibles the following permutation Q_k is useful. Denoting by $\overline{x}$ the binary complement of the binary vector x of length k we define $Q_k : |x,0\rangle \mapsto |x,0\rangle$ and $Q_k : |x,1\rangle \mapsto |\overline{x},1\rangle$. Furthermore, we introduce the representations φ_l defined by

$$\varphi_l(r) = \begin{pmatrix} \omega^l & 0 \\ 0 & \omega^{-l} \end{pmatrix} \quad \text{and} \quad \varphi_l(s) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

With this notation we have $\varphi = \varphi_1$. The two-dimensional representations φ_l are irreducible and inequivalent[34] for different $l \in \{1,\ldots,m/2\}$. Now, using the base change $W := Q_m(\mathbf{1}_2 \otimes F_m^\dagger) \in \mathbb{C}^{n \times n}$ we obtain that

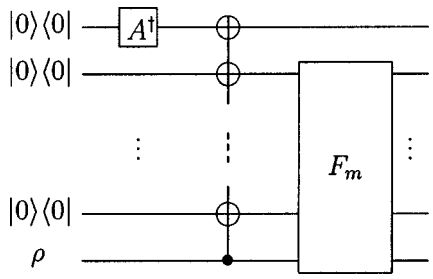

FIG. 1. Quantum circuit for the implementation of the dihedral POVM.

$$W\varphi_{\mathrm{mon}}W^\dagger = \psi \oplus \psi \oplus \psi \oplus \psi,$$

where ψ is a direct sum of all representations φ_j with odd j. The first component of ψ is φ_1, the other components φ_j appear in a specific order which is irrelevant in the sequel. We choose the representation

$$\varphi' = \psi' \oplus \psi \oplus \psi \oplus \psi,$$

where ψ' is obtained from ψ by dropping φ_1. This leads to $\varphi \oplus \varphi' = W\varphi_{\mathrm{mon}}W^\dagger$. The matrix $C = MW^\dagger = (\sqrt{m}\alpha\ 0\cdots 0 \,|\, \sqrt{m}\beta\ 0\cdots 0) \otimes \mathbf{1}_2 \in \mathbb{C}^{2\times n}$ defines the first two rows of the intertwining matrix $\widetilde{C}$ we want to construct according to Algorithm 6 from Sec. IV. A possible extension of the intertwining matrix $C \in \mathbb{C}^{2\times n}$ to a unitary matrix $\widetilde{C} \in \mathcal{U}(n)$ is $\widetilde{C} = A \otimes \mathbf{1}_{m/2}$ with the matrix

$$A = \sqrt{m}\begin{pmatrix} \alpha & \beta \\ \overline{\beta} & -\overline{\alpha} \end{pmatrix} \in \mathcal{U}(2).$$

According to Algorithm 6 from Sec. IV we must define the matrices $U \in \mathcal{U}(2)$ and $V \in \mathcal{U}(n-2)$. The equations $\varphi = \varphi_1$ and $W\varphi_{\mathrm{mon}}W^\dagger = (\varphi_1 \oplus \psi') \oplus \psi \oplus \psi \oplus \psi$ show that $U = \mathbf{1}_2$. Furthermore, we choose $V = \mathbf{1}_{n-2}$. Then we have the matrix $U \oplus V = \mathbf{1}_n$. To summarize, we must implement the matrix

$$\widetilde{M}^\dagger = W^\dagger \widetilde{C}^\dagger = (\mathbf{1}_2 \otimes F_m) Q_k (A^\dagger \otimes \mathbf{1}_4) \in \mathcal{U}(n)$$

in order to measure the POVM corresponding to the dihedral group D_m. The scheme of the circuit corresponding to $\widetilde{M}^\dagger$ is shown in Fig. 1.

C. Weyl–Heisenberg groups

In the following we introduce the finite Weyl–Heisenberg groups which are matrix groups acting on a finite-dimensional vector space. For our purposes we consider vector spaces of dimension $m = 2^k$ only, where $k \geq 2$. Then the Weyl–Heisenberg group G_m is the group generated by the matrices $S_m = (1, 2, \ldots, m)$ and $T_m = \mathrm{diag}(1, \omega, \omega^2, \ldots, \omega^{m-1})$ where $\omega = \exp(2\pi i/m) \in \mathbb{C}$ is a primitive mth root of unity. It is known that G_m contains m^3 elements.[35] POVMs that are covariant with respect to the Weyl–Heisenberg groups have a physical motivation. Since the position and momentum of a particle cannot be measured simultaneously by any projection-valued measurement one must construct POVMs which measure both observables with a certain inaccuracy. This idea has already been described in Ref. 19 starting from a wave packet, i.e., a unit vector $|\psi\rangle \in L^2(\mathbb{R})$ we define a set $\{M_{s,t}\}$ of operators by

$$M_{s,t} := \frac{1}{2\pi} e^{isP+tQ} |\psi\rangle\langle\psi| e^{-isP-tQ},$$

where $s,t \in \mathbb{R}$ and P and Q are the position and momentum operators, respectively. Explicitly, they are defined by $(P\psi)(x) := -i(d/\mathrm{d}x)\psi(x)$ and $(Q\psi)(x) := x\psi(x)$. We then have that

$$\int_{s,t} M_{s,t}\, \mathrm{d}s\, \mathrm{d}t = 1.$$

The POVM $\{M_{s,t}\}$ provides an approximative realization of the classical phase space since the measurement outcome (s,t) can be interpreted as the point (s,t) in the phase space. In the following we are interested in finite-dimensional approximations of this. Assume that we want to measure the position and crystal momentum of a particle on a lattice with m points for $m=2^k$.[36] Furthermore, we assume that it is possible to transfer the state of such a system into k qubits of a quantum register in the sense that one can implement the SWAP operations,

$$|j\rangle \otimes |i\rangle \leftrightarrow |i\rangle \otimes |j\rangle.$$

Here the left-hand vector denotes a joint state of particle and register where the particle is at position j in the lattice and the register is in its ith canonical basis state. The states corresponding to the vectors $\Sigma_{j=0}^{m-1} e^{2\pi i l j/m} |j\rangle$ with $l=0,\ldots,m-1$ are the eigenstates of the crystal momentum. Explicitly, the crystal momentum p can be defined by $p := 2\pi l/m - \pi$. With this definition the values of p are in the interval $[-\pi,\pi]$ that meets the usual physical intuition of the one-dimensional Brillouin zone of an infinite one-dimensional crystal. Here we characterize the position and momentum simply by the integer values j, $l=0,\ldots,m-1$. The cyclic translation of the position is given by the action of S_m and a change of crystal momentum by the action of T_m. Consider a rank-one positive operator $|\psi\rangle\langle\psi|$ with the property that neither the position nor the momentum of the corresponding state is completely undefined. Set

$$M_{j,l} := \frac{1}{m} S_m^j T_m^l |\psi\rangle\langle\psi| T_m^{-l} S_m^{-j}.$$

Due to irreducible group action the equation $\Sigma_{j,l} M_{j,l} = \mathbf{1}_m$ holds and the operators $M_{j,l}$ define a POVM. For large m we can find states with corresponding state vectors $|\psi\rangle$ such that both values j and l are approximately defined. Here the word "approximately" is understood with respect to the cyclic topology, i.e., $m-1$ and 0 are "almost" the same value. A good choice for the POVM will be the following. Set $|\psi\rangle := \Sigma_j c_j |j\rangle$ where the coefficients c_j are chosen such that the function $j \mapsto |c_j|^2$ has a unique maximum at j_0 and the modulus of the values c_j decrease with increasing distance from j_0 in the cyclic topology. If all values c_j are real and they decrease not too quickly the momentum l of the state is around j_0, too. Then the measurement values j,l can directly be interpreted as a good estimation for the position and momentum values. We will show that an efficient implementation of the POVM can be found in the case where $|\Psi\rangle = 1/\sqrt{\kappa}(1,\alpha,\alpha^2,\ldots,\alpha^{m/2-2},\alpha^{m/2-1},\alpha^{m/2-1},\alpha^{m/2-2},\ldots,\alpha^2,\alpha,1)^T \in \mathbb{C}^m$ with $\alpha \in \mathbb{C}$ and an appropriate normalization factor $1/\sqrt{\kappa}$.

In the following we consider the group-generated POVMs with respect to G_m and the natural representation φ defined by $\varphi(g)=g$ for all $g \in G_m$. This representation is irreducible. Therefore, following Algorithm 6 from Sec. IV we can set $U=\mathbf{1}_m$ since $\mathbf{1}_m$ decomposes φ into a direct sum of irreducible representations. The vector $|\Psi\rangle = (v_1,\ldots,v_m)^T \in \mathbb{C}^m$ with the normalization $|v_1|^2 + \cdots + |v_m|^2 = 1/m$ leads to the POVM where the defining matrix $M \in \mathbb{C}^{m\times n}$ is given by

$$\begin{pmatrix} v_1 & v_1 & \cdots & v_1 & v_m & \cdots & v_m & \cdots & v_2 & \cdots & v_2 \\ v_2 & v_2\omega & \cdots & v_2\omega^{m-1} & v_1 & \cdots & v_1\omega^{m-1} & \cdots & v_3 & \cdots & v_3\omega^{m-1} \\ & \vdots & \ddots & & & \ddots & & \ddots & & \ddots & \\ v_m & v_m\omega^{m-1} & \cdots & v_m\omega & v_{m-1} & \cdots & v_{m-1}\omega & \cdots & v_1 & \cdots & v_1\omega \end{pmatrix}.$$

Note that we identify vectors $g|\Psi\rangle$ and $h|\Psi\rangle$ for different $g,h \in G_m$ that are equal up to a global phase factor. Consequently, the POVM consists of at most $n=m^2$ different operators. For example, when $m=4$ the vector $|\Psi\rangle=(v_1,v_2,v_3,v_4)^T \in \mathbb{C}^4$ with $|v_1|^2+|v_2|^2+|v_3|^2+|v_4|^2=1/4$ leads to the POVM with $n=16$ operators and the corresponding matrix $M \in \mathbb{C}^{4\times 16}$ where M is defined by

$$\begin{pmatrix} v_1 & v_1 & v_1 & v_1 & v_4 & v_4 & v_4 & v_4 & \cdots & v_2 & v_2 & v_2 & v_2 \\ v_2 & v_2 i & -v_2 & -v_2 i & v_1 & v_1 i & -v_1 & -v_1 i & \cdots & v_3 & v_3 i & -v_3 & -v_3 i \\ v_3 & -v_3 & v_3 & -v_3 & v_2 & -v_2 & v_2 & -v_2 & \cdots & v_4 & -v_4 & v_4 & -v_4 \\ v_4 & -v_4 i & -v_4 & v_4 i & v_3 & -v_3 i & -v_3 & v_3 i & \cdots & v_1 & -v_1 i & -v_1 & v_1 i \end{pmatrix}.$$

The symmetry of $M \in \mathbb{C}^{m\times n}$ can be described on the generators by the equations $T_m M = M(\mathbf{1}_m \otimes S_m)$ and $S_m M = M(S_m \otimes T_m^\dagger)$. Therefore the representation $\varphi_{\mathrm{mon}}: G_m \to \mathcal{U}(n)$ is defined by $\varphi_{\mathrm{mon}}(T_m)=\mathbf{1}_m \otimes S_m$ and $\varphi_{\mathrm{mon}}(S_m)=S_m \otimes T_m^\dagger$. The symmetry of M can also be written as

$$T_m M = M(\mathbf{1}_m \otimes T_m)^{F_m^\dagger \otimes F_m} \quad \text{and} \quad S_m M = M(T_m^\dagger \otimes S_m)^{F_m^\dagger \otimes F_m},$$

where we use the notation $A^X = X^\dagger A X$ and the Fourier transform F_m as defined in Sec. VI A. We can write $(\mathbf{1}_m \otimes T_m)$ and $(T_m^\dagger \otimes S_m)$ as direct sums

$$(\mathbf{1}_m \otimes T_m) = T_m \oplus T_m \oplus \cdots \oplus T_m \quad \text{and} \quad (T_m^\dagger \otimes S_m) = S_m \oplus \omega^{m-1} S_m \oplus \cdots \oplus \omega S_m.$$

By using the equations $T_m S_m T_m^\dagger = \omega S_m$ and $(\mathbf{1}_m \otimes S_m)^{Z^\dagger} = (T_m^\dagger \otimes S_m)$ we can conjugate these matrices with the diagonal matrix $Z = \mathbf{1}_m \oplus T_m^{m-1} \oplus T_m^{m-2} \oplus \cdots \oplus T_m^2 \oplus T_m$ in order to obtain the equations

$$T_m M = M(\mathbf{1}_m \otimes T_m)^{Z^\dagger (F_m^\dagger \otimes F_m)} \quad \text{and} \quad S_m M = M(\mathbf{1}_m \otimes S_m)^{Z^\dagger (F_m^\dagger \otimes F_m)}.$$

These equations show that we have the decomposition $W \varphi_{\mathrm{mon}} W^\dagger = \varphi \oplus \cdots \oplus \varphi$ with the matrix $W = Z^\dagger (F_m^\dagger \otimes F_m)$. The representation $W \varphi_{\mathrm{mon}} W^\dagger$ contains m components φ. Following Algorithm 6 from Sec. IV we must find a representation φ' that leads to the direct sum $\varphi \oplus \varphi' = \varphi \oplus \cdots \oplus \varphi$ with m components φ. Consequently, we choose $\varphi' = \varphi \oplus \cdots \oplus \varphi$ with $m-1$ components φ. We now consider the extension of the matrix $C = MW^\dagger = M(F_m \otimes F_m^\dagger)Z \in \mathbb{C}^{m\times n}$ to a unitary matrix $\widetilde{C} \in \mathcal{U}(n)$. The matrix C is an element of the intertwining space,

$$\mathrm{Int}(\varphi, \varphi \oplus \cdots \oplus \varphi) = \{(\alpha_1, \ldots, \alpha_n) \otimes \mathbf{1}_m : \alpha_j \in \mathbb{C}\} \subseteq \mathbb{C}^{m\times n}.$$

More precisely, we have $C = ((\sqrt{m}v_1, \ldots, \sqrt{m}v_m)F_m^\dagger) \otimes \mathbf{1}_m \in \mathbb{C}^{m\times n}$. For example, for $m=4$ we obtain the group $G_4 = \langle S_4, T_4 \rangle$ with $S_4 = (1,2,3,4)$ and $T_4 = \mathrm{diag}(1,i,-1,-i)$ that contains 64 elements. In this example we have the equation

$$C = \left((v_1,v_2,v_3,v_4) \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & -i & -1 & i \\ 1 & -1 & 1 & -1 \\ 1 & i & -1 & -i \end{pmatrix} \right) \otimes \begin{pmatrix} 1 & \cdot & \cdot & \cdot \\ \cdot & 1 & \cdot & \cdot \\ \cdot & \cdot & 1 & \cdot \\ \cdot & \cdot & \cdot & 1 \end{pmatrix} \in \mathbb{C}^{4\times 16}.$$

The matrix $C \in \mathbb{C}^{m\times n}$ determines the first m rows of the matrix $\widetilde{C}$ we want to construct. The matrix $\widetilde{C}$ is a unitary matrix of the intertwining space,

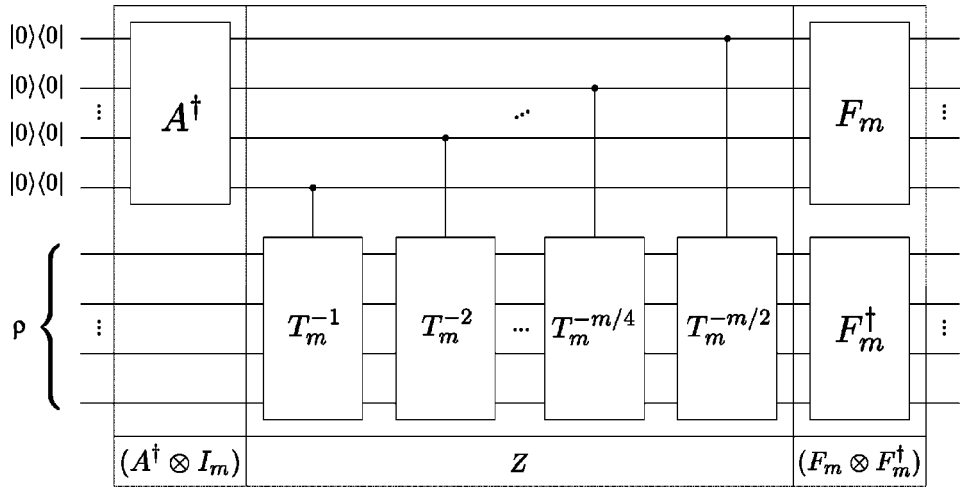

FIG. 2. Circuit for the implementation of the POVM with respect to the Weyl–Heisenberg group and the vector $|\Psi\rangle = (v_1, \ldots, v_m)^T$. The vector $|\Psi\rangle$ determines the matrix $A^\dagger$.

$$\mathrm{Int}(\varphi \oplus \cdots \oplus \varphi, \varphi \oplus \cdots \oplus \varphi) = \{A \otimes \mathbf{1}_m : A \in \mathbb{C}^{m\times m}\} \subseteq \mathbb{C}^{n\times n}.$$

When we write $\tilde{C} = A \otimes \mathbf{1}_m$ then the matrix C determines the first row of A. Explicitly, the first row of A is

$$(\sqrt{m}v_1, \ldots, \sqrt{m}v_m)F_m^\dagger. \tag{3}$$

The operation $\tilde{M}^\dagger$ for the implementation of the POVM is defined by

$$\tilde{M}^\dagger = W^\dagger \tilde{C}^\dagger (U \oplus V) = (F_m \otimes F_m^\dagger) Z (A^\dagger \otimes \mathbf{1}_m) \in \mathcal{U}(n).$$

In this equation we have $V = \mathbf{1}_{n-m}$ leading to $U \oplus V = \mathbf{1}_m \oplus \mathbf{1}_{n-m} = \mathbf{1}_n$. The general scheme for the implementation of the matrix $\tilde{M}^\dagger$ is shown in Fig. 2. For $m = 2^k$ the circuit contains the k controlled operations

$$T_m^{-1}, T_m^{-2}, \ldots, T_m^{-m/4}, T_m^{-m/2}$$

for the implementation of the matrix Z. The matrix $T_m = \mathrm{diag}(1, \omega, \omega^2, \ldots, \omega^{m-1})$ can be written as Kronecker product

$$T_m = \begin{pmatrix} 1 & 0 \\ 0 & \omega^{m/2} \end{pmatrix} \otimes \begin{pmatrix} 1 & 0 \\ 0 & \omega^{m/4} \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 1 & 0 \\ 0 & \omega \end{pmatrix} \in \mathcal{U}(m).$$

Therefore, the matrices T_m^j of the circuit in Fig. 2 can be implemented efficiently on a register of qubits.

The circuit in Fig. 2 is efficient if the matrix A that contains the vector (3) as the first row can be implemented efficiently. We can find such a matrix for the POVM with the vector

$$|\Psi\rangle = \frac{1}{\sqrt{\kappa}}(1, \alpha, \alpha^2, \ldots, \alpha^{m/2-2}, \alpha^{m/2-1}, \alpha^{m/2-1}, \alpha^{m/2-2}, \ldots, \alpha^2, \alpha, 1)^T \in \mathbb{C}^m, \tag{4}$$

where we have $\alpha \in \mathbb{C}$ and the normalization $\kappa = 2m(1 + |\alpha|^2 + |\alpha|^4 + \cdots + |\alpha|^{m-2})$. A matrix $A \in \mathcal{U}(m)$ that contains the vector (3) as the first row is given by

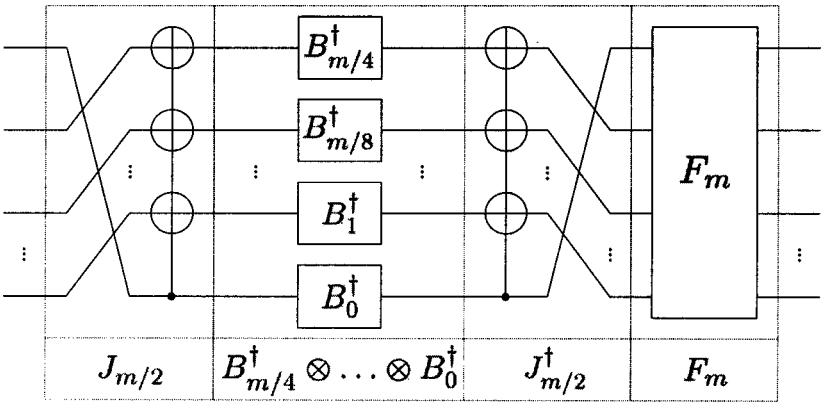

FIG. 3. Implementation of the matrix $A^\dagger$ where A is a matrix that contains the vector (3) as the first row. This matrix is part of the circuit in Fig. 2 for the vectors (4).

$$A = J^\dagger_{m/2}(B_{m/4} \otimes B_{m/8} \otimes \cdots \otimes B_4 \otimes B_2 \otimes B_1 \otimes B_0)J_{m/2}F^\dagger_m,$$

where we use the unitary matrices

$$B_j = \frac{1}{\sqrt{1+|\alpha|^{2j}}}\begin{pmatrix} 1 & \alpha^j \\ \overline{\alpha^j} & -1 \end{pmatrix} \in \mathcal{U}(2).$$

Here J_k is defined to be the permutation matrix which maps $2i \mapsto i$ and $(2i-1) \mapsto -i$ for $i = 0, \ldots, k$. In our example with $m=4$ we have the matrix

$$J^\dagger_2(B_1 \otimes B_0)J_2 = \frac{1}{\sqrt{2+2|\alpha|^2}}\begin{pmatrix} 1 & \alpha & \alpha & 1 \\ \overline{\alpha} & -1 & -1 & \overline{\alpha} \\ \overline{\alpha} & -1 & 1 & -\overline{\alpha} \\ 1 & \alpha & -\alpha & -1 \end{pmatrix}.$$

The circuit scheme for the implementation of the matrix

$$A^\dagger = F_m J^\dagger_{m/2}(B^\dagger_{m/4} \otimes B^\dagger_{m/8} \otimes \cdots \otimes B^\dagger_4 \otimes B^\dagger_2 \otimes B^\dagger_1 \otimes B^\dagger_0)J_{m/2}$$

is shown in Fig. 3.

VII. CONCLUSIONS AND OUTLOOK

We have shown that a group-covariant POVM can be reduced to an orthogonal measurements by a unitary transform which is symmetric in the sense that it intertwines two different group representations. The symmetry of the unitary transform can be used to derive decompositions which in several cases of interest (as the Weyl–Heisenberg group) leads to an efficient quantum circuit for the implementation of the POVM.

We have argued that POVMs are often necessary in order to understand why large quantum systems show typically classical behavior on the phenomenological level. The POVM with Weyl–Heisenberg symmetry as well as the example in Ref. 5 show that the POVMs which appear in this context are often covariant with respect to some group.

Besides the physical motivation to study implementations of POVMs by means of orthogonal measurements in terms of quantum circuits there is also a motivation from computer science. The so-called *hidden subgroup problem*[37] is an attractive generalization of the quantum algorithms for discrete logarithms and factoring.[38] The standard approach for the hidden subgroup problem consists in a Fourier transform for the respective group followed by a suitable post-processing on the Fourier coefficients.[39] For Abelian groups this post-processing consists simply in an orthogo-

nal measurement in the computational basis. However, for non-Abelian group measurements which are in fact POVMs are often more advantageous, see, e.g., Ref. 40. The POVMs which appear to be useful to solve hidden subgroup problems for non-Abelian groups are naturally group covariant. The methods presented in this paper might be useful to find quantum algorithms for the hidden subgroup problem for new classes of non-Abelian groups.

(Received 12 December 2003; accepted 28 July 2004; published online 3 January 2005)

We consider a Schrödinger operator with a constant magnetic field in a one-half three-dimensional space, with Neumann-type boundary conditions. It is known from the works by Lu–Pan and Helffer–Morame that the lower bound of its spectrum is less than b, the intensity of the magnetic field, provided that the magnetic field is not normal to the boundary. We prove that the spectrum under b is a finite set of eigenvalues (each of infinite multiplicity). In the case when the angle between the magnetic field and the boundary is small, we give a sharp asymptotic expansion of the number of these eigenvalues. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1827922]

I. INTRODUCTION

Let us consider, for (t,x,y) in the half-space $E=\mathbb{R}_+\times\mathbb{R}^2$, the Neumann realization of the operator with magnetic field

$$H=(D_t-A_1)^2+(D_x-A_2)^2+(D_y-A_3)^2,$$

where $D_s=-i(\partial/\partial s)$.

We will assume that the magnetic field $B=\mathrm{d}A$, seen as a three-dimensional vector field, is not tangent to the boundary ∂E, and denote by θ the angle between B and the plane $t=0$ and by b the norm of B.

This implies that a suitable choice for the gauge A is the 1-form,

$$A=b(x\sin\theta-t\cos\theta)\mathrm{d}y$$

(so that $A_1=A_2=0$), since the condition $B=\mathrm{d}A$ leads to the 2-form,

$$B=b\sin\theta\,\mathrm{d}x\wedge\mathrm{d}y-b\cos\theta\,\mathrm{d}t\wedge\mathrm{d}y\quad\left(\theta\in\left[0,\frac{\pi}{2}\right]\right).$$

Now the operator H can be written as

$$H_\theta=D_t^2+D_x^2+(D_y-b(x\sin\theta-t\cos\theta))^2. \tag{1.1}$$

The spectrum of the Neumann operator H_0 (corresponding to the case $\theta=0$) is absolutely continuous, as proved by Lu and Pan.[10–12] More precisely one has

$$\sigma(H_0)=\sigma_{ac}(H_0)=[b\mu_0+\infty[, \tag{1.2}$$

[a)]Electronic mail: morame@math.univ-nantes.fr
[b)]Electronic mail: francoise.truc@ujf-grenoble.fr

$$\mu_0 = \inf_{\xi \in \mathbb{R}} \mu(\xi), \tag{1.3}$$

where $\mu(\xi)$ denotes the first eigenvalue of the Neumann operator $Q_\xi = D_t^2 + (t-\xi)^2$ on $L^2(\mathbb{R}_+)$,

$$\mu(\xi) = \inf \sigma(Q_\xi) = \inf_{\|f\|_{L^2(\mathbb{R}_+)}=1} \int_{\mathbb{R}_+} [|D_t f|^2 + (t-\xi)^2 |f|^2] \mathrm{d}t. \tag{1.4}$$

It is also shown in Refs. 10–12 that, if $\theta = \pi/2$, the spectrum of $H_{\pi/2}$ is absolutely continuous,

$$\sigma(H_{\pi/2}) = \sigma_{ac} = [b, +\infty[. \tag{1.5}$$

When $\theta \in]0, \pi/2[$, the spectrum of H_θ is no longer absolutely continuous (see Refs. 8–12). We are precisely interested in that case,

$$0 < \theta < \frac{\pi}{2}. \tag{1.6}$$

First, performing a partial Fourier transform in the variable y we observe that

$$\sigma(H_\theta) = \bigcup_{\tau \in \mathbb{R}} \sigma(H_{\theta,\tau}), \tag{1.7}$$

where $H_{\theta,\tau}$ denotes the Neumann realization in the half-plane $F = \mathbb{R}_+ \times \mathbb{R}$ of the operator,

$$H_{\theta,\tau} = D_t^2 + D_x^2 + (\tau - b(x \sin\theta - t\cos\theta))^2. \tag{1.8}$$

Furthermore, using for any τ the change of coordinates $x \to x - (\tau/b \sin\theta)$, we see that $\sigma(H_{\theta,\tau}) = \sigma(H_{\theta,0})$, and then the spectrum of H_θ is essential and given by

$$\sigma(H_\theta) = \sigma_{\mathrm{ess}}(H_\theta) = \sigma(H_{\theta,0}) = b \times \sigma(P_\theta), \tag{1.9}$$

if $P_\theta = D_t^2 + D_x^2 + (t\cos\theta - x\sin\theta)^2$ is the Neumann operator on the half-plane $F = \mathbb{R}_+ \times \mathbb{R}$.

In Refs. 9 and 12 it was proved that

$$\inf \sigma(P_\theta) = \nu(\theta) < 1 = \inf \sigma_{\mathrm{ess}}(P_\theta), \tag{1.10}$$

so there exists a countable set of eigenvalues of P_θ, $(\nu_j(\theta))_{j\in I}$, $(I \subset \mathbb{N})$, in $[\nu(\theta), 1[$. Each eigenvalue is of finite multiplicity, so we will assume that each one is repeated according to its multiplicity. The associated orthonormalized sequence of eigenfunctions will be denoted by $(\psi_{\theta,j})_{j\in I}$,

$$P_\theta \psi_{\theta,j} = \nu_j(\theta)\psi_{\theta,j},$$

$$\langle \psi_{\theta,j} | \psi_{\theta,k} \rangle = \delta_{jk},$$

$$E_{]-\infty,1[}(P_\theta) f = \sum_j \langle \psi_{\theta,j} | f \rangle \psi_{\theta,j}$$

[$\langle g | f \rangle = \int_F \overline{g} f \, \mathrm{d}t \, \mathrm{d}x$ and $E_J(P_\theta)$ denotes the spectral projection of P_θ on J]. Coming back to the operator (H_θ) we can write

$$\sigma(H_\theta) \cap \,]-\infty, b[= \{b\nu_1(\theta), b\nu_2(\theta), \ldots, b\nu_j(\theta), b\nu_{j+1}(\theta), \ldots\}, \tag{1.11}$$

where each $b\nu_j(\theta)$ is now an eigenvalue of infinite multiplicity of H_θ.

For any $d \leqslant 1$ let us denote by $N(d, P_\theta)$ the number of eigenvalues of P_θ in $]-\infty, d[$,

$$N(d, P_\theta) = \mathrm{Tr}(E_{]-\infty,d[}(P_\theta) = \#\{j; \nu_j(\theta) < d\}. \tag{1.12}$$

The aim of this work is first to prove that for any $\theta \in]0,\pi/2[$, the number of eigenvalues of P_θ in $]-\infty,1[$ is finite. This is the purpose of Sec. II. Another interesting question is to get the asymptotic behavior of $N(d,P_\theta)$ as θ goes to zero, when $d<1$. This is done in Sec. IV. Section III is devoted to a survey of preliminary results about the function $\mu(\xi)$ defined in (1.4), which are required in the computation of the asymptotics in Sec. IV.

II. FINITENESS OF THE DISCRETE SPECTRUM

The purpose of this section is to prove the following theorem.

Theorem 2.1: *There exists a constant $C \geqslant 1$ such that, for any $\theta \in]0,\pi/2[$,*

$$N(1,P_\theta) \leqslant \frac{C}{\sin\theta}. \tag{2.1}$$

Proof: We have the following conventions.

Convention 2.2: $\theta \in]0,\pi/2[$ is fixed.

Convention 2.3: From now on, any constant depending only on θ will be denoted invariably as C_θ.

If the constant does not depend on θ, it will be denoted invariably as C.

Let us denote by q_θ the quadratic form associated to P_θ,

$$q_\theta(u) = \int_F [|D_t u|^2 + |D_x u|^2 + (t\cos\theta - x\sin\theta)^2 |u|^2]\mathrm{d}t\,\mathrm{d}x, \tag{2.2}$$

$$\forall u \in H^1(F) \cap L^2(F;(t\cos\theta - x\sin\theta)^2\,\mathrm{d}t\,\mathrm{d}x)\ (F = \mathbb{R}_{+,t}\times\mathbb{R}_x).$$

There exists a partition of unity $(\chi_0(t),\chi_1(t))$ satisfying

$$\chi_0(t) = 1 \quad \text{if } t<1,$$

$$\chi_0(t) = 0 \quad \text{if } t>2, \tag{2.3}$$

$$\chi_0^2(t) + \chi_1^2(t) = 1.$$

Let $R>1$ be fixed. We consider the following covering of F:

$$O_{0,R} = \{(t,x) \in \mathbb{R}_+ \times \mathbb{R},\ 0<t<2R\},$$

$$O_{1,R} = \{(t,x) \in \mathbb{R}_+ \times \mathbb{R},\ R<t\}. \tag{2.4}$$

We define the partition of unity $(\chi_{0,R}(t),\chi_{1,R}(t))$ by

$$\chi_{j,R}(t) = \chi_t\left(\frac{t}{R}\right). \tag{2.5}$$

Let us recall that

$$q_\theta(u) = \sum_j q_\theta(\chi_{j,R}u) - \sum_j \|\chi'_{j,R}u\|^2. \tag{2.6}$$

We define the following quadratic forms:

$$q_{\theta,0}(u) = \int_{O_{0,R}} [|D_t u|^2 + |D_x u|^2 + ((t\cos\theta - x\sin\theta)^2 - V_R(t))|u|^2]\mathrm{d}t\,\mathrm{d}x, \tag{2.7}$$

$$\forall u \in H^1(O_{0,R}) \cap L^2(O_{0,R}; x^2\,\mathrm{d}t\,\mathrm{d}x), \quad u/\{t = 2R\} = 0,$$

with $V_R(t) = \Sigma_j |\chi'_{j,R}(t)|^2$, and

$$q_{\theta,1}(u) = \int_{O_{1,R}} [|D_t u|^2 + |D_x u|^2 + ((t\cos\theta - x\sin\theta)^2 - V_R(t))|u|^2]\mathrm{d}t\,\mathrm{d}x, \tag{2.8}$$

$$\forall u \in H^1(O_{1,R}) \cap L^2(O_{1,R}; (t\cos\theta - x\sin\theta)^2\,\mathrm{d}t\,\mathrm{d}x), \quad u/\{t = R\} = 0.$$

By min–max principle, we have

$$N(1, q_\theta) \leqslant N(1, q_{\theta,0}) + N(1, q_{\theta,1}). \tag{2.9}$$

This estimate remains if we change $O_{1,R}$ into $\mathbb{R}^2$ in the definition of $q_{\theta,1}$,

$$q_{\theta,1}(u) = \int_{\mathbb{R}^2} [|D_t u|^2 + |D_x u|^2 + ((t\cos\theta - x\sin\theta)^2 - V_R(t))|u|^2]\mathrm{d}t\,\mathrm{d}x, \tag{2.10}$$

$$\forall u \in H^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2; (t\cos\theta - x\sin\theta)^2\,\mathrm{d}t\,\mathrm{d}x).$$

The operator $P_{\theta,0}$, associated to $q_{\theta,0}$ has compact resolvent, and

$$q_{\theta,0}(u) \geqslant \int_{O_{0,R}} \left[|D_t u|^2 + |D_x u|^2 + \left(\frac{1}{2}x^2\sin^2\theta - 4R^2\cos^2\theta - \frac{C}{R^2}\right)|u|^2 \right]\mathrm{d}t\,\mathrm{d}x.$$

So, if we denote by ρ_j^0 the eigenvalues of $|D_t u|^2$ on [0,1] with Neumann conditions on 0 and Dirichlet conditions on 1, we have

$$N(1, q_{\theta,0}) \leqslant \#\left\{ (k;j) \in \mathbb{N}^2; \frac{2k+1}{\sqrt{2}}\sin\theta + \frac{\rho_j^0}{4R^2} \leqslant 1 + 4R^2\cos^2\theta + \frac{C}{R^2} \right\}. \tag{2.11}$$

Using that $\rho_j^0 \sim j^2$ as $j \to \infty$, we get easily

$$N(1, q_{\theta,0}) \leqslant \frac{CR}{\sin\theta}[1 + R^2\cos^2\theta]^{3/2}. \tag{2.12}$$

Using the orthonormal change of coordinates, $(t,x) \to (s,y)$ with $s = t\cos\theta - x\sin\theta$, and $y = t\sin\theta + x\cos\theta$, we can take for $q_{\theta,1}$ the following expression:

$$q_{\theta,1}(u) = \int_{\mathbb{R}^2} [|D_s u|^2 + |D_y u|^2 + (s^2 - V_R(s,y))|u|^2]\mathrm{d}s\,\mathrm{d}y, \tag{2.13}$$

$\forall u \in H^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2;\ s^2\,\mathrm{d}s\,\mathrm{d}y)$, with

$$V_R(s,y) = \frac{1}{R^2}\sum_j \left| \chi'_j\left(\frac{s\cos\theta + y\sin\theta}{R}\right)\right|^2. \tag{2.14}$$

Let us consider the orthogonal projections

$$\Pi_1(u)(s,y) = e^{-s^2/2}\int_{\mathbb{R}} u(\tau,y)e^{-\tau^2/2}\frac{\mathrm{d}\tau}{\sqrt{\pi}},$$

$$\Lambda_1 u = u - \Pi_1 u, \tag{2.15}$$

so that, for any $u \in L^2(\mathbb{R}^2)$, we get $\|u\|^2 = \|\Pi_1 u\|^2 + \|\Lambda_1 u\|^2$.

Writing $\Pi_1 u(s,y) = (e^{-s^2/2}/\pi^{1/4})\psi(y)$ and

$$W_R(y) = \frac{1}{\sqrt{\pi}}\int_{\mathbb{R}} e^{-s^2}V_R(s,y)\mathrm{d}s,$$

we obtain that

$$q_{\theta,1}(\Pi_1 u) = \int_{\mathbb{R}} [|D_y\psi|^2 + (1 - W_R(y))|\psi|^2]\mathrm{d}y. \tag{2.16}$$

We have also

$$q_{\theta,1}(\Lambda_1 u) \geqslant \int_{\mathbb{R}^2}\left[|D_y\Lambda_1 u|^2 + \left(3 - \frac{C}{R^2}\right)|\Lambda_1 u|^2\right]\mathrm{d}s\,\mathrm{d}y. \tag{2.17}$$

But

$$q_{\theta,1}(u) = q_{\theta,1}(\Pi_1 u) + q_{\theta,1}(\Lambda_1 u) - 2\,\mathcal{R}e\int_{\mathbb{R}^2} V_R(s,y)\Pi_1 u \cdot \overline{\Lambda_1 u}\,\mathrm{d}s\,\mathrm{d}y, \tag{2.18}$$

so, for any $\epsilon \in]0,1[$,

$$q_{\theta,1}(u) \geqslant q_{\theta,1}(\Pi_1 u) - \frac{1}{\epsilon}\int_{\mathbb{R}^2} V_R^2(s,y)|\Pi_1 u|^2\,\mathrm{d}s\,\mathrm{d}y + q_{\theta,1}(\Lambda_1 u) - \epsilon\|\Lambda_1 u\|^2. \tag{2.19}$$

Thanks to (2.17), we can take $\epsilon = 1$ and R large enough such that

$$q_{\theta,1}(\Lambda_1 u) - \|\Lambda_1 u\|^2 > \|\Lambda_1 u\|^2, \tag{2.20}$$

for example, R satisfying $2 - (C/R^2) > 1$.

Then, by (2.16), (2.18), and (2.20), we get that

$$N(1, q_{\theta,1}) \leqslant N(0, q_{\theta,1,0}), \tag{2.21}$$

if

$$q_{\theta,1,0}(\psi) = \int_{\mathbb{R}} [|D_y\psi|^2 - W_{R,1}(y)|\psi|^2]\mathrm{d}y, \tag{2.22}$$

$\forall\,\psi \in H^1(\mathbb{R})$, with

$$W_{R,1}(y) = \frac{1}{\sqrt{\pi}}\int_{\mathbb{R}} e^{-s^2}[V_R(s,y) + V_R^2(s,y)]\mathrm{d}s.$$

From (2.3) and the formula (2.14), the following bound holds:

$$0 \leqslant W_{R,1}(y) \leqslant \frac{C}{R^2}\int_{(R-y\sin\theta)/\cos\theta}^{(2R-y\sin\theta)/\cos\theta} e^{-s^2}\,\mathrm{d}s$$

[we used the fact that, for any fixed y, $V_R(s,y)=0$ for s outside the interval defined by $R<s\cos\theta+y\sin\theta<2R$], so

$$0 \leqslant W_{R,1}(y) \leqslant \frac{C}{R^2}\chi_{[R/2\sin\theta,3R/\sin\theta]}(y) + \frac{C}{R\cos\theta}[e^{-[(y\sin\theta-R)^2]/\cos^2\theta} + e^{-[(y\sin\theta-2R)^2]/\cos^2\theta}]. \tag{2.23}$$

As the operators on $L^2(\mathbb{R})$, $\frac{1}{3}D_y^2-(C/R\cos\theta)e^{-[(y\sin\theta-R)^2]/\cos^2\theta}$, $\frac{1}{3}D_y^2-(C/R\cos\theta)\times e^{-[(y\sin\theta-2R)^2]/\cos^2\theta}$, and $(\sin^2\theta/3\cos^4\theta)D_y^2-(C/R\cos\theta)e^{-y^2}$ have the same spectrum, we get from (2.21)–(2.23) that

$$N(1,q_{\theta,1}) \leqslant 2N(0,q_{\theta,1,1}) + N(0,q_{\theta,1,2}), \tag{2.24}$$

if

$$q_{\theta,1,1}(\psi) = \int_{\mathbb{R}}\left[\frac{\sin^2\theta}{3\cos^4\theta}|D_y\psi|^2 - \frac{C}{R\cos\theta}e^{-y^2}|\psi|^2\right]\mathrm{d}y, \tag{2.25}$$

and

$$q_{\theta,1,2}(\psi) = \int_{\mathbb{R}}\left[\frac{1}{3}|D_y\psi|^2 - \frac{C}{R^2}\chi_{[R/2\sin\theta,3R/\sin\theta]}(y)|\psi|^2\right]\mathrm{d}y, \tag{2.26}$$

$\forall\psi\in H^1(\mathbb{R})$, for some $R>1$ independent of $\theta\in\,]0,\pi/2[$.

It is now possible to deduce from Theorem 1 in the work of Egorov and Kondrat'ev[5] the following estimates: $N(0,q_{\theta,1,1})\leqslant C(\cos^{3/2}\theta/\sin\theta)$ and $N(0,q_{\theta,1,2})\leqslant C/\sin\theta$, so

$$N(1,q_{\theta,1}) \leqslant \frac{C}{\sin\theta}. \tag{2.27}$$

We conclude from (2.9), (2.12), and (2.27) that the estimate (2.1) is valid.

III. SOME PROPERTIES OF $\mu(\xi)$

The properties of the first eigenvalue, $\mu(\xi)$, of the Neumann operator on $L^2(\mathbb{R}_+)$, $Q_\xi=D_t^2+(t-\xi)^2$, can be found in Refs. 3, 7, 11, and 13 (also see Refs. 2, 4, and 6).

The main ones are

$$\mu\in C^\infty(\mathbb{R}),$$

$$\mu'(\xi)\neq 0 \quad \text{if } \xi\neq\xi_0,$$

$$\mu(\xi)>1 \quad \text{if } \xi<0, \tag{3.1}$$

$$\mu(\xi)<1 \quad \text{if } \xi>0,$$

$$\lim_{\xi\to-\infty}\mu(\xi)=+\infty, \quad \lim_{\xi\to+\infty}\mu(\xi)=1$$

[$\xi_0>0$ is such that $\xi_0^2=\mu(\xi_0)$].

Let φ_ξ be a normalized eigenfunction associated to $\mu(\xi)$,

$$\|\varphi_\xi\|_{L^2(\mathbb{R}_+)} = 1, \quad \varphi'_\xi(0) = 0, \quad Q_\xi\varphi_\xi = \mu(\xi)\varphi_\xi, \tag{3.2}$$

then

$$\mu'(\xi) = -(\mu(\xi) - \xi^2)\varphi_\xi^2(0). \tag{3.3}$$

It is easy to see that φ_ξ is exponentially decreasing. More precisely we have the following.

Lemma 3.1: There exists $C_0 > 1$ such that

$$1 - C_0 e^{-|\xi|^2/C_0} \leqslant \mu(\xi). \tag{3.4}$$

Moreover, if $\mu_2(\xi)$ is the second eigenvalue of Q_ξ, then we have also

$$3 - C_0 e^{-|\xi|^2/C_0} \leqslant \mu_2(\xi). \tag{3.5}$$

Proof: We proceed as in Ref. 4 to get first the following bound: For any $\xi > 1$ and $\eta \in]0,1[$,

$$\int_{\mathbb{R}_+} [\eta(t-\xi)^2 - \mu(\xi)]_+ e^{(1-\eta)^{1/2}(t-\xi)^2} |\varphi_\xi(t)|^2 \, dt \leqslant \mu(\xi) e^{\mu(\xi)/\eta}. \tag{3.6}$$

For any Lipschitz and real function Φ, with compact support,

$$\|D_t(e^\Phi \varphi_\xi)\|^2_{L^2(\mathbb{R}_+)} = \langle [\mu(\xi) - (t-\xi)^2 + (\Phi')^2] e^\Phi \varphi_\xi | e^\Phi \varphi_\xi \rangle$$

so

$$\langle [(t-\xi)^2 - \mu(\xi) - (\Phi')^2]_+ e^\Phi \varphi_\xi | e^\Phi \varphi_\xi \rangle \leqslant \langle [\mu(\xi) - (t-\xi)^2 + (\Phi')^2]_+ e^\Phi \varphi_\xi | e^\Phi \varphi_\xi \rangle.$$

This estimate is still valid for Φ with noncompact support, provided that the right-hand side of the inequality is finite; so we can take $\Phi(t) = (1-\eta)^{1/2}(t-\xi)^2/2$ to get (3.6). Now, let χ be a smooth cutoff function on $\mathbb{R}$,

$$\begin{gathered} \chi \in C^\infty(\mathbb{R}), \\ \chi(t) = 1 \quad \text{if } -1 < t < 1, \\ \chi(t) = 0 \quad \text{if } |t| > 2, \\ 0 \leqslant \chi \leqslant 1. \end{gathered} \tag{3.7}$$

If $\xi > 1$, we define the function $\tilde{\varphi}_{1,\xi}(t) = \chi(4[(t-\xi)/\xi])\varphi_\xi(t)$.

So,

$$\|D_t\tilde{\varphi}_{1,\xi}\|^2 + \|(t-\xi)\tilde{\varphi}_{1,\xi}\|^2 = \mu(\xi))\|\tilde{\varphi}_{1,\xi}\|^2 + \frac{16}{\xi^2}\left\|\chi'\left(4\frac{t-\xi}{\xi}\right)\tilde{\varphi}_\xi\right\|^2.$$

As $\tilde{\varphi}_{1,\xi}$ is of compact support and the first eigenvalue of $D_t^2 + (t-\xi)^2$ on $L^2(\mathbb{R})$ is 1, then

$$\|\tilde{\varphi}_{1,\xi}\|^2 \leqslant \mu(\xi))\|\tilde{\varphi}_{1,\xi}\|^2 + \frac{16}{\xi^2}\left\|\chi'\left(4\frac{t-\xi}{\xi}\right)\varphi_\xi\right\|^2,$$

then we use the estimate (3.6) to see that, for some constant $C > 1$, $1 \leqslant \mu(\xi) + Ce^{-\xi^2/C}$, the estimate (3.4) follows.

If $\mu_2(\xi)$ is the second eigenvalue of Q_ξ and $\varphi_{2,\xi}$ the associated normalized eigenfunction, then we have in the same way, for any real function Φ,

$$\langle[(t-\xi)^2-\mu_2(\xi)-(\Phi')^2]_+e^{\Phi}\varphi_{2,\xi}|e^{\Phi}\varphi_{2,\xi}\rangle \leqslant \langle[\mu_2(\xi)-(t-\xi)^2+(\Phi')^2]_+e^{\Phi}\varphi_{2,\xi}|e^{\Phi}\varphi_{2,\xi}\rangle,$$

so $\varphi_{2,\xi}$ is exponentially decreasing as φ_{ξ}, and if $\tilde{\varphi}_{2,\xi}(t)=\chi(4[(t-\xi)/\xi])\varphi_{2,\xi}(t)$, then

$$\|D_t\tilde{\varphi}_{2,\xi}\|^2+\|(t-\xi)\tilde{\varphi}_{2,\xi}\|^2 \leqslant \mu_2(\xi)+Ce^{-\xi^2/C}$$

and

$$|\|\tilde{\varphi}_{2,\xi}\|-1| \leqslant Ce^{-\xi^2/C},$$

$$|\langle\tilde{\varphi}_{1,\xi}|\tilde{\varphi}_{2,\xi}\rangle| \leqslant Ce^{-\xi^2/C}. \tag{3.8}$$

Those estimates, (3.4) and the min–max principle show that $\mu_2(\xi)+Ce^{-\xi^2/C}$ is greater than the second eigenvalue of $D_t^2+(t-\xi)^2$ on $L^2(\mathbb{R})$, so $3\leqslant\mu_2(\xi)+Ce^{-\xi^2/C}$. This ends the proof of the lemma.

IV. THE CASE OF SMALL θ

We are still investigating the spectrum of the operator P_θ, defined in the Introduction as follows:

$$P_\theta=D_t^2+D_x^2+(t\cos\theta-x\sin\theta)^2.$$

Performing the scaling $(t,x)\to(t\sqrt{\cos\theta},-x\sin\theta/\sqrt{\cos\theta})$, we observe that this operator has the same spectrum as

$$P_\theta=\cos\theta[D_t^2+(t-x)^2]+\frac{\sin^2\theta}{\cos\theta}D_x^2$$

(we keep on the same notation for simplification).

It has been proved in Ref. 8 that for small values of $\theta>0$ the following asymptotics hold:

$$\inf\sigma(P_\theta)\sim\mu_0+\sum_{j\geqslant 1}c_j\theta^j.$$

Therefore let us consider a set,

$$I_d=\,]-\infty,d[\quad\text{with } d\in\,]\mu_0,1[.$$

The goal of this section is to get information about

$$N(d,P_\theta)=\#\,\sigma(P_\theta)\cap\,]-\infty,d[, \tag{4.1}$$

which denotes the number of eigenvalues of P_θ included in the set I_d.

For a fixed $a>1$ let us consider the following sets:

$$J_0=[-a,+\infty[\,,\quad J_1=\left]-\infty,-\frac{a}{2}\right],$$

and a partition of unity

$$\chi_0^2(x)+\chi_1^2(x)=1,\quad \text{support}\,(\chi_j)\subset J_j,\quad \sum_j|\chi_j'(x)|^2<C.$$

For $j=0,1$ let us denote by Ω_j the domains $\mathbb{R}_+\times J_j$, $\Omega_0=\mathbb{R}_+\times\,]-a,+\infty[$ and $\Omega_1=\mathbb{R}_+\times\,]-\infty,-a/2[$. We take now the realization of the operators P_θ^j on each domain Ω_j, associated to the quadratic form q_{Ω_j}, with Neumann conditions on $\Gamma_N=\{0\}\times J_j$ and Dirichlet conditions on $\Gamma_D=\mathbb{R}_+\times\partial J_j$.

The quadratic forms are defined as follows:

$$q_{\Omega_j}(u) = \int_{\Omega_j} \left\{ \cos\theta\,[|D_t u|^2 + (t-x)^2|u|^2] + \frac{\sin^2\theta}{\cos\theta}|D_x u|^2 - \frac{\sin^2\theta}{\cos\theta}\sum_{j=0}^{1} |\chi_j'(x)|^2|u|^2 \right\} \mathrm{d}t\,\mathrm{d}x.$$

Let us first explain why q_{Ω_1} will not give any contribution to the term $N(d,P_\theta)$.

According to Sec. III we know that $\mu(x)$, the first eigenvalue of $D_t^2+(t-x)^2$ is decreasing on J_1, so we have

$$q_{\Omega_1}(u) \geqslant \left[\mu\left(-\frac{a}{2}\right)\cos\theta - C\frac{\sin^2\theta}{\cos\theta} \right] \|u\|^2_{L^2(\Omega_1)}.$$

But $\mu(-a/2)>1$, so for small θ the preceding minoring ensues

$$q_{\Omega_1}(u) \geqslant \|u\|^2_{L^2(\Omega_1)} \quad \text{if } 0<\theta<\theta_0, \tag{4.2}$$

for some $\theta_0 \in]0,\pi/4[$.

In order to study the form q_{Ω_0}, it is convenient to use the normalized eigenfunction φ_x, associated to $\mu(x)$, in the following way.

Let us denote by $\Pi_0(u)$ the orthogonal projection on the set

$$F_0 = \{\varphi_x(t)\psi(x);\ \psi \in L^2(J_0)\}, \tag{4.3}$$

defined by

$$\Pi_0(u) = \varphi_x(t)\left(\int_{\mathbb{R}_+} u(s,x)\varphi_x(s)\mathrm{d}s \right), \tag{4.4}$$

and by $F_1=(F_0)^\perp$ the orthogonal set of F_0. The corresponding orthogonal projection is

$$\Pi_1 = I - \Pi_0.$$

A direct computation gives

$$\partial_x(\Pi_0 u) = \Pi_0(\partial_x u) + R(u),$$

where R is defined by

$$R(u) = \varphi_x(t)\left(\int_{\mathbb{R}_+} u(s,x)\partial_x\varphi_x(s)\mathrm{d}s \right) + \partial_x\varphi_x(t)\left(\int_{\mathbb{R}_+} u(s,x)\varphi_x(s)\mathrm{d}s \right). \tag{4.5}$$

The additional fact that

$$\partial_x(\Pi_1 u) = \Pi_1(\partial_x u) - R(u)$$

yields the following bounds:

$$(1-\epsilon)[\|\partial_x(\Pi_0 u)\|^2_{L^2(\Omega_0)} + \|\partial_x(\Pi_1 u)\|^2_{L^2(\Omega_0)}] + 2\left(1-\frac{1}{\epsilon}\right)\|R(u)\|^2_{L^2(\Omega_0)}$$

$$\leqslant \|\partial_x u\|^2_{L^2(\Omega_0)} \leqslant (1+\epsilon)[\|\partial_x(\Pi_0 u)\|^2_{L^2(\Omega_0)} + \|\partial_x(\Pi_1 u)\|^2_{L^2(\Omega_0)}] + 2\left(1+\frac{1}{\epsilon}\right)\|R(u)\|^2_{L^2(\Omega_0)}.$$

Let us establish now the following lemma.

Lemma 4.1:

$$\exists C_0>0, \quad s.t.\ \forall\, u \in L^2(\Omega_0), \quad \|R(u)\|_{L^2(\Omega_0)} \leqslant C_0\|u\|_{L^2(\Omega_0)}. \tag{4.6}$$

Taking norms in (4.5) we have

$$\|R(u)\|^2_{L^2(\Omega_0)} \leqslant 2\int_{\Omega_0} |u(s,x)(\partial_x\varphi_x(s))|^2 \,\mathrm{d}s\,\mathrm{d}x + 2\sup_{x\in J_0}\|\partial_x\varphi_x(t)\|^2_{L^2(\mathbb{R}_+)}\|u\|^2_{L^2(\Omega_0)}$$
$$\leqslant 4\sup_{x\in J_0}\|\partial_x\varphi_x(t)\|^2_{L^2(\mathbb{R}_+)}\|u\|^2_{L^2(\Omega_0)}.$$

The lemma will then be proved if we show that $\sup_{x\in J_0}\|\partial_x\varphi_x(t)\|^2_{L^2(\mathbb{R}_+)}\|$ is finite.

We recall that some elementary technique of perturbation shows that

$$\frac{\partial}{\partial x}\varphi_x(t) = 2[Q_x - \mu(x)]^{-1}\psi_x, \tag{4.7}$$

with

$$\psi_x(t) = (t-x)\varphi_x(t) - \langle (t-x)\varphi_x|\varphi_x\rangle\varphi_x(t).$$

Now using

$$\|D_t^2\varphi_x\|^2_{L^2(\mathbb{R}^2_+)} + \|(t-x)\varphi_x\|^2_{L^2(\mathbb{R}^2_+)} = \mu(x)\|\varphi_x\|^2_{L^2(\mathbb{R}^2_+)} = \mu(x),$$

we get that

$$\|(t-x)\varphi_x\|_{L^2(\mathbb{R}^2_+)} \leqslant \sqrt{\mu(x)},$$

and then

$$|\langle (t-x)\varphi_x|\varphi_x\rangle_{L^2(\mathbb{R}^2_+)}| \leqslant \sqrt{\mu(x)},$$

so

$$\|\psi_x\|_{L^2(\mathbb{R}^2_+)} \leqslant 2\sqrt{\mu(x)}.$$

Since ψ_x lives on the orthogonal space of φ_x, let us consider the norm N_x of the restriction of $[Q_x-\mu(x)]^{-1}$ to this orthogonal space. It is given by

$$N_x = \frac{1}{\mu_2(x)-\mu_1(x)} = \frac{1}{\mu_2(x)-\mu(x)},$$

where $(\mu_j(x))_j$ is the increasing sequence of the eigenvalues of Q_x.

According to (3.1) and (3.5), $\mu(x)$ and N_x are uniformly bounded on J_0, so there exists $C_0 > 0$ such that

$$\sup_{x\in J_0}\|\partial_x\varphi_x(t)\|_{L^2(\mathbb{R}^2_+)} \leqslant 2\sup_{x\in J_0}\frac{\sqrt{\mu(x)}}{\mu_2(x)-\mu(x)} \leqslant C_0, \tag{4.8}$$

so the Lemma 4.1 follows.

From Lemma 4.1, we see that we can find a constant $C_1>0$, such that, for any $\epsilon\in\,]0,1[$,

$$(1-\epsilon)[\|\partial_x(\Pi_0 u)\|^2_{L^2(\Omega_0)} + \|\partial_x(\Pi_1 u)\|^2_{L^2(\Omega_0)}] - \frac{C_1}{\epsilon}\|u\|^2_{L^2(\Omega_0)}$$
$$\leqslant \|\partial_x u\|^2_{L^2(\Omega_0)} \leqslant (1+\epsilon)[\|\partial_x(\Pi_0 u)\|^2_{L^2(\Omega_0)} + \|\partial_x(\Pi_1 u)\|^2_{L^2(\Omega_0)}] + \frac{C_1}{\epsilon}\|u\|^2_{L^2(\Omega_0)}.$$

From that we obtain the corresponding bounds on the quadratic form q_{Ω_0},

$$q^{\epsilon,-}_{\Omega_0}(\Pi_0 u) + q^{\epsilon,-}_{\Omega_0}(\Pi_1 u) \leqslant q_{\Omega_0}(u) \leqslant q^{\epsilon,+}_{\Omega_0}(\Pi_0 u) + q^{\epsilon,+}_{\Omega_0}(\Pi_1 u), \tag{4.9}$$

where we used the natural notations

$$q^{\epsilon,-}_{\Omega_0}(u) = \int_{\Omega_0} \left\{ \cos\theta \left[|D_t u|^2 + (t-x)^2 |u|^2 \right] + (1-\epsilon) \frac{\sin^2\theta}{\cos\theta} |D_x u|^2 \right\} \mathrm{d}t\, \mathrm{d}x - \frac{\sin^2\theta}{\cos\theta} \left[C + \frac{C_1}{\epsilon} \right] \|u\|^2_{L^2(\Omega_0)}$$

and

$$q^{\epsilon,+}_{\Omega_0}(u) = \int_{\Omega_0} \left\{ \cos\theta \left[|D_t u|^2 + (t-x)^2 |u|^2 \right] + (1+\epsilon) \frac{\sin^2\theta}{\cos\theta} |D_x u|^2 \right\} \mathrm{d}t\, \mathrm{d}x + \frac{\sin^2\theta}{\cos\theta} \frac{C_1}{\epsilon} \|u\|^2_{L^2(\Omega_0)}.$$

Writing

$$h = \frac{\sin\theta}{\sqrt{\cos\theta}}, \tag{4.10}$$

taking into account (4.3), we define

$$W(x) = \int_{\mathbb{R}_+} \left| \frac{\partial}{\partial x} \varphi_x(t) \right|^2 \mathrm{d}t,$$

and we get, using (4.4) that

$$q^{\epsilon,-}_{\Omega_0}(\Pi_0 u) = q^{\epsilon,-}(\psi) = \int_{J_0} \left\{ \left[\mu(x)\cos\theta + (1-\epsilon) h^2 W(x) \right] |\psi(x)|^2 + (1-\epsilon) h^2 |D_x \psi(x)|^2 - h^2 \left[C + \frac{C_1}{\epsilon} \right] |\psi(x)|^2 \right\} \mathrm{d}x.$$

In the same way we have

$$q^{\epsilon,+}_{\Omega_0}(\Pi_0 u) = q^{\epsilon,+}(\psi) = \int_{J_0} \left\{ \left[\mu(x)\cos\theta + (1+\epsilon) h^2 W(x) \right] |\psi(x)|^2 + (1+\epsilon) h^2 |D_x \psi(x)|^2 + h^2 \frac{C_1}{\epsilon} |\psi(x)|^2 \right\} \mathrm{d}x.$$

Now we must deal with the terms involving the second projection $\Pi_1 u$. But the definition of $\Pi_1 u$, the min–max principle and the estimate $1-\cos\theta \leqslant h^2 C$ give the following lower bound:

$$q^{\epsilon,\pm}_{\Omega_0}(\Pi_1 u) \geqslant \left[\inf_{x \in J_0} \mu_2(x) - h^2 \left(C + \frac{C_1}{\epsilon} \right) \right] \|\Pi_1 u\|_{L^2(\Omega_0)},$$

where $\mu_2(x)$ denotes the second eigenvalue defined in the Lemma 3.1. This eigenvalue must be greater than the first eigenvalue of the corresponding Dirichlet problem, so

$$\mu_2(x) > 1.$$

Let us take $\epsilon = h$. We get that

$$N(d, q^{h,\pm}_{\Omega_0}) = N(d, q^{h,\pm}).$$

Let us take an extension $\tilde{\mu}(x)$ of $\mu(x)$ outside of

$$J_{0,d} = \{x \in J_0,\ \mu(x) < d + (1-d)/2\}, \tag{4.11}$$

such that

$$\tilde{\mu}(x) = \mu(x) \quad \text{if } x \in J_{0,d},$$

$$\tilde{\mu}(x) \geqslant (1+d)/2, \quad \forall\, x \notin J_{0,d}, \tag{4.12}$$

$$\tilde{\mu}(x) = 1 \quad \text{if } |x| > C_d,$$

for some constant $C_d > 0$. Let us define

$$q_0^{h,\pm}(\psi) = \int_{\mathbb{R}} [\tilde{\mu}(x)|\psi(x)|^2 + (1 \pm h)h^2|D_x\psi(x)|^2]\mathrm{d}x.$$

We will need the following lemma.

Lemma 4.2: Let $U(x) \in C^\infty(\mathbb{R};\mathbb{R})$, $E \in \mathbb{R}$ and $\eta > 0$ such that $U^{-1}(]-\infty, E+\eta])$ is bounded.

Then for any interval I of $\mathbb{R}$ satisfying $\mathbb{R}\backslash I \subset [E+(\eta/2), +\infty[$, there exists a constant $C = C_\eta > 0$ such that

$$N(E, q_{h,U,I}) \leqslant N(E, q_{h,U}) \leqslant N(E + h^2C, q_{h,U,I}), \tag{4.13}$$

if

$$q_{h,U}(\psi) = \int_{\mathbb{R}} [h^2|D_x\psi(x)|^2 + U(x)|\psi(x)|^2]\mathrm{d}x, \quad \forall\, \psi \in C_0^\infty(\mathbb{R}),$$

and

$$q_{h,U,I}(\psi) = \int_I [h^2|D_x\psi(x)|^2 + U(x)|\psi(x)|^2]\mathrm{d}x, \ \forall\, \psi \in C_0^\infty(I).$$

From the estimate (4.13) we get

$$N(d - hC, q_0^{\epsilon,\pm}) \leqslant N(d, q^{\epsilon,\pm}) \leqslant N(d + hC, q_0^{\epsilon,\pm}) \tag{4.14}$$

[we have used that $W(x)$ is bounded in J_0, thanks to (4.8), then we apply the left-hand side of (4.13) to $N(d+hC, q_0^{\epsilon,\pm})$ and the right-hand side of (4.13) to $N(d-hC, q_0^{\epsilon,\pm})$, both with $I = J_0$].

Applying a classical estimate of $N(d, q_0^{h,\pm})$ (see, for example, Ref. 13, Theorem V-11, p. 263), we have that, for any $\lambda < (1+d)/2$, there exists $C_\lambda > 0$ such that, for any $h \in]0, 1/2[$,

$$\left| N(\lambda, q_0^{h,\pm}) - \frac{1}{2\pi h\sqrt{1 \pm h}} \int_{\mathbb{R}} [\lambda - \mu(x)]_+^{1/2}\, \mathrm{d}x \right| \leqslant C_\lambda. \tag{4.15}$$

According to the choice of d and (3.1), we can use the fact that $\mu'(x) \neq 0$ for $\mu(x) = d$ and get from (4.9)–(4.12), (4.14), and (4.15) with $\lambda = d \pm hC$, that there exists $C_d > 0$, depending only on d, such that

$$\left| N(d, q_{\Omega_0}) - \frac{1}{2\pi \sin\theta} \int_{\mathbb{R}} [d - \mu(x)]_+^{1/2}\, \mathrm{d}x \right| \leqslant C_d. \tag{4.16}$$

We get easily from the above discussion the following theorem.

Theorem 4.3: *For any $d \in]\mu_0, 1[$, there exists $C_d > 0$ such that*

$$\left| N(d, P_\theta) - \frac{1}{2\pi \sin\theta} \int_{\mathbb{R}} [d - \mu(x)]_+^{1/2}\, \mathrm{d}x \right| \leqslant C_d. \tag{4.17}$$

Sketch of the proof of Lemma 4.2: The min–max principle proves the left-hand side of (4.13). For the right-hand side, take a partition of unity of $\mathbb{R}$, $\chi_0^2(x)+\chi_1^2(x)=1$ such that χ_0 is supported in I and χ_1 supported $J\subset U^{-1}([E+\eta_0,+\infty[)$, for some $\eta_0>0$. Then $q_{h,U}(\psi)=q_{h,U_h}(\chi_0\psi)+q_{h,U_h}(\chi_1\psi)$, with $U_h(x)=U(x)-h^2[(\chi_0'(x))^2+(\chi_1'(x))^2]$. From the min–max principle, we get that

$$N(E,q_{h,U})\leqslant N(E,q_{h,U_h,I})+N(E,q_{h,U_h,J}).$$

If h is small enough, then $N(E,q_{h,U_h,J})=0$ and we get the right-hand side of (4.13).

Remark 4.4: The condition $\theta<\theta_0$ (4.2) *can be removed since* $N(d,P_\theta)$ *is finite for fixed* θ *according to Theorem 2.1.*

Remark 4.5: It should be possible to apply the technique of Balazard–Konlein[1] *to get the asymptotics of* $N(d,P_\theta)$*, but the result would be rough, compared to our result in Theorem 4.3: our remainder is an* $\mathbf{O}(1)$ *and the result of Ref. 1 would give* $\mathbf{O}(\sin^{-\rho}\theta)$ *with* $\rho>1/2$.

Moreover the assumptions in Ref. 1 are not satisfied in our case.

(Received 30 July 2004; accepted 23 September 2004; published online 5 January 2005)

The Wigner–Weyl isomorphism for quantum mechanics on a compact simple Lie group G is developed in detail. Several features are shown to arise which have no counterparts in the familiar Cartesian case. Notable among these is the notion of a semiquantized phase space, a structure on which the Weyl symbols of operators turn out to be naturally defined and, figuratively speaking, located midway between the classical phase space T^*G and the Hilbert space of square integrable functions on G. General expressions for the star product for Weyl symbols are presented and explicitly worked out for the angle-angular momentum case. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1825078]

I. INTRODUCTION

It is well known that the method of Wigner distributions,[1] which describes every state of a quantum mechanical system by a corresponding real quasiprobability density on the classical phase space, is dual to the Weyl mapping[2] of classical dynamical variables to quantum mechanical operators. Together they provide the Wigner–Weyl isomorphism, whereby both states and operators in quantum mechanics can be given c-number descriptions on the classical phase space. The trace of the product of two operators is then calculable as the integral of the product of the two corresponding Weyl symbols or phase space functions. Combined with the work of Moyal,[3] which shows how products and commutators of operators are expressed in phase space language, this entire development may be called the Wigner–Weyl–Moyal or WWM method in quantum mechanics and has been instrumental in giving rise to the fertile subject of deformation quantization.[4] An important feature of the Wigner distribution is that while it is not by itself a phase space probability density, its marginals obtained by, respectively, integrating over momenta or over coordinates do reproduce the quantum mechanical expressions for probability densities in coordinate and in momentum space, respectively.

The WWM method has been studied most extensively in the case of Cartesian systems in quantum mechanics. By this we mean those systems whose configuration space Q is $\mathbb{R}^n$ for some integer $n \geqslant 1$. The classical phase space is then $T^*Q \simeq \mathbb{R}^{2n}$. While Schrödinger wave functions are

square integrable functions on $\mathbb{R}^n$, both Wigner distributions and Weyl symbols are functions on $\mathbb{R}^{2n}$. Quantum kinematics can be expressed via the Heisenberg canonical commutation relations for Cartesian coordinates and their conjugate momenta, or via the exponentiated Weyl form using families of unitary operators. An important feature in this case is that as far as their eigenvalue spectra are concerned, the momenta do not experience any quantization on their own; they account for the second factor in $T^*Q \simeq \mathbb{R}^{2n} \simeq \mathbb{R}^n \times \mathbb{R}^n$. Furthermore we have in this case the Stone–von Neumann theorem on the uniqueness of the irreducible representation of the Heisenberg commutation relations, and the important roles of the groups $\mathrm{Sp}(2n,R)$ and $\mathrm{Mp}(2n)$ corresponding to linear canonical transformations on coordinates and momenta.

There has been for some time considerable interest in developing the Wigner–Weyl isomorphism for other kinds of quantum systems, that is, for non-Cartesian systems.[5–16] In these cases, typically the underlying quantum kinematics cannot be expressed by Heisenberg-type commutation relations. The situations studied include the quantum mechanics of an angle-angular momentum pair, where the configuration space is $Q=\mathbb{S}^1$,[17,18] and finite state quantum systems corresponding to a finite dimensional Hilbert space.[19,20] More recently, the method of Wigner distributions has been developed for quantum systems whose configuration space is a compact simple Lie group; and in the discrete case when it is a finite group of odd order.[21,22] In all these departures from the Cartesian situation, an important aspect is the occurrence of new features which do not show up at all with Cartesian variables.

The aim of the present work is to develop in detail the Wigner–Weyl isomorphism for quantum mechanics on a compact simple Lie group. Here the configuration space Q is a (compact simple) Lie group G, so the corresponding classical phase space is $T^*G \simeq G \times \underline{G}^*$, where $\underline{G}^*$ is the dual to the Lie algebra $\underline{G}$ of G. In the quantum situation, Schrödinger wave functions are complex square integrable functions on G, and observables or dynamical variables are linear Hermitian operators acting on such functions. The replacements for the canonical Heisenberg commutation relations are best formulated using the (commutative) algebra of suitable smooth functions on G, and (say) the left regular representation of G acting on functions on itself. The natural question that arises in trying to set up a Wigner–Weyl isomorphism in this case is whether quantum states and operators are to be described using suitable functions on the classical phase space T^*G. In Ref. 21 an overcomplete Wigner distribution formalism for quantum states, which transforms in a reasonable way under left and right group actions and also reproduces the natural marginal probability distributions, has been developed. The methods developed there are here exploited to set up a Wigner–Weyl isomorphism in full detail, disclosing many interesting differences compared to the Cartesian case. In particular we find that this isomorphism does not directly utilize c-number functions on T^*G at all, but instead uses a combination of functions on G and operators on a simpler Hilbert space, standing in a sense midway between T^*G and the Hilbert space of the quantum system. This feature is traceable to the non-Abelian nature of G, something which is absent in the Cartesian case when Q is the Abelian group $\mathbb{R}^n$.

The material of this paper is organized as follows. In Sec. II we briefly recapitulate key features of the Wigner–Weyl isomorphism for the Cartesian and angle-angular momentum cases. This sets the stage for Sec. III where we develop the quantum kinematics for situations where the configuration space is a compact Lie group and thus go beyond the Abelian cases discussed in Sec. I. This analysis leads to a proper identification of the analogues of the momenta of the Cartesian case and helps set up the Wigner distribution for such situations possessing properties expected of a Wigner distribution. The Wigner distributions so defined have a certain degree of overcompleteness about them, a circumstance forced by the non-Abelian nature of the underlying group G. A key ingredient in this construction is the notion of the midpoint of two group elements introduced in an earlier work.[21] In Sec. IV a more compact description in terms of Weyl symbols devoid of any redundances is developed and correspondences facilitating transition from the Cartesian case to more general situations are established. The results of Sec. IV are exploited in Sec. V towards defining a star product between Weyl symbols for operators and the general expression for the star product is explicitly worked out for the non-Cartesian, albeit Abelian case of angle-angular momentum. Section VI is devoted to analyzing the minimal structure on which the Weyl symbols for

operators find their natural definition. This leads to the concept of a noncommutative cotangent space or a semiquantized phase space the ramifications of which are examined further towards highlighting the structural similarity between classical phase space functions and the Weyl symbols. A short appendix contains some technical details concerning results used in Sec. V.

II. THE WIGNER–WEYL ISOMORPHISM: CARTESIAN AND ANGLE-ANGULAR MOMENTUM CASES

In this section we recall briefly the relevant structures needed to set up the Wigner–Weyl isomorphism for Cartesian quantum mechanics. This is to facilitate comparison with the Lie group case later on. For simplicity we choose one degree of freedom only, as the extension to $Q=\mathbb{R}^n$ is straightforward. We also recall the angle-angular momentum case, $Q=\mathbb{S}^1$, where we already see significant differences from the Cartesian case; these increase when we go to $Q=G$.

One-dimensional Cartesian quantum mechanics: The canonical Heisenberg commutation relation between Hermitian coordinate and momentum operators $\hat{q}$ and $\hat{p}$, fixing the kinematics, is

$$[\hat{q},\hat{p}] = i. \tag{2.1}$$

In the unitary Weyl form this is expressed as follows:

$$U(p) = \exp(ip\hat{q}), \quad V(q) = \exp(-iq\hat{p}),$$

$$U(p)V(q) = V(q)U(p)e^{iqp}, \quad q,p \in \mathbb{R}. \tag{2.2}$$

In the Cartesian case the exponentials can be combined to define a phase space displacement operator

$$D(q,p) = U(p)V(q)e^{-iqp/2} = V(q)U(p)e^{iqp/2} = \exp(ip\hat{q} - iq\hat{p}). \tag{2.3}$$

However this cannot be done even in the single angle-angular momentum pair case, and also when we treat the Lie group case. We therefore use expressions in which the exponentials are kept separate.

The standard form of the unique irreducible representation of Eqs. (2.1) and (2.2) uses the Hilbert space of square integrable functions $\psi(q)$ on $\mathbb{R}$. Introducing as usual an ideal basis of eigenvectors of $\hat{q}$ we have

$$\mathcal{H} = L^2(\mathbb{R}) = \left\{ \psi(q) \mid \|\psi\|^2 = \int_{\mathbb{R}} \mathrm{d}q |\psi(q)|^2 < \infty \right\},$$

$$\psi(q) = \langle q|\psi\rangle, \quad \hat{q}|q\rangle = q|q\rangle, \tag{2.4}$$

$$\langle q'|q\rangle = \delta(q'-q).$$

On such $\psi(q)$ (subject to relevant domain conditions) the actions of $\hat{q}$, $\hat{p}$, $U(p)$, $V(q)$ are

$$(\hat{q}\psi)(q) = q\psi(q), \quad (\hat{p}\psi)(q) = -i\frac{\mathrm{d}}{\mathrm{d}q}\psi(q),$$

$$(U(p')\psi)(q) = e^{ip'q}\psi(q), \quad (V(q')\psi)(q) = \psi(q-q'). \tag{2.5}$$

The momentum space description of $|\psi\rangle$ uses the Fourier transform of $\psi(q)$; in terms of the ideal eigenstates $|p\rangle$ for $\hat{p}$,

$$\tilde{\psi}(p) = \langle p|\psi\rangle = \int_{\mathbb{R}} \frac{\mathrm{d}q}{\sqrt{2\pi}} \exp(-ipq)\psi(q),$$

$$\|\psi\|^2 = \int_{\mathbb{R}} \mathrm{d}p |\tilde{\psi}(p)|^2. \tag{2.6}$$

The displacement operators (2.2) form a complete trace orthonormal set (in the continuum sense) in the space of operators on $\mathcal{H}$,

$$\mathrm{Tr}((U(p')V(q'))^\dagger U(p)V(q)) = 2\pi\delta(q'-q)\delta(p'-p). \tag{2.7}$$

The completeness property will be used later.

The definitions of the Wigner distribution for a normalized pure state $|\psi\rangle \in \mathcal{H}$, or more generally for a mixed state with density operator $\hat{\rho}$, are

$$W(q,p) = \frac{1}{2\pi}\int_{\mathbb{R}} \mathrm{d}q'\ \psi\left(q - \frac{1}{2}q'\right)\psi\left(q + \frac{1}{2}q'\right)^* \exp(ipq'),$$

$$W(q,p) = \frac{1}{2\pi}\int_{\mathbb{R}} \mathrm{d}q' \left\langle q - \frac{1}{2}q'|\hat{\rho}|q + \frac{1}{2}q'\right\rangle \exp(ipq'). \tag{2.8}$$

(The dependences on $|\psi\rangle$, $\hat{\rho}$ are left implicit.) While $W(q,p)$ is real though not always nonnegative, the recovery of the marginal position and momentum space probability densities is assured by

$$\int_{\mathbb{R}} \mathrm{d}p\ W(q,p) = \langle q|\hat{\rho}|q\rangle, \quad \int_{\mathbb{R}} \mathrm{d}q\ W(q,p) = \langle p|\hat{\rho}|p\rangle. \tag{2.9}$$

It is possible to express $W(q,p)$ in a more compact form by introducing a family of Hermitian operators $\hat{W}(q,p)$ on $\mathcal{H}$ with interesting algebraic properties. They are essentially the double Fourier transforms of the displacement operators (2.2),

$$W(q,p) = \mathrm{Tr}(\hat{\rho}\hat{W}(q,p)),$$

$$\hat{W}(q,p) = \hat{W}(q,p)^\dagger = \frac{1}{(2\pi)^2}\int_{\mathbb{R}}\int_{\mathbb{R}} \mathrm{d}q'\ \mathrm{d}p'\ U(p')V(q')e^{ipq'-ip'(q+(1/2)q')}. \tag{2.10}$$

It has been shown in Ref. 17 that, apart from sharing the trace orthonormality property (2.7) which is preserved by the Fourier transformation,

$$\mathrm{Tr}(\hat{W}(q',p')\hat{W}(q,p)) = \frac{1}{2\pi}\delta(q'-q)\delta(p'-p), \tag{2.11}$$

we have the following behaviors under anticommutation with $\hat{q}$ and $\hat{p}$:

$$\tfrac{1}{2}\{\hat{q}, \hat{W}(q,p)\} = q\hat{W}(q,p), \quad \tfrac{1}{2}\{\hat{p}, \hat{W}(q,p)\} = p\hat{W}(q,p). \tag{2.12}$$

Thus we may regard $\hat{W}(q,p)$ as operator analogues of Dirac delta functions concentrated at individual phase space points. In Ref. 19 they have been called phase point operators.

Turning to the Weyl map, it takes a general classical dynamical variable, a (square integrable) function $a(q,p)$ on the classical phase space, to a corresponding (Hilbert–Schmidt) operator $\hat{A}$ on $\mathcal{H}$:

$$a(q,p) \to \tilde{a}(p',q') = \int_{\mathbb{R}} \int_{\mathbb{R}} \mathrm{d}q\, \mathrm{d}p\, a(q,p) e^{i(pq'-qp')}$$

$$\to \hat{A} = \frac{1}{2\pi} \int_{\mathbb{R}} \int_{\mathbb{R}} \mathrm{d}q'\, \mathrm{d}p'\, \tilde{a}(p',q') U(p') V(q') e^{-iq'p'/2}. \tag{2.13}$$

The important property of this map is that traces of operators on $\mathcal{H}$ go into integrals over phase space,

$$\mathrm{Tr}(\hat{A}^{\dagger}\hat{B}) = \int_{\mathbb{R}} \int_{\mathbb{R}} \mathrm{d}q\, \mathrm{d}p\, a(q,p) * b(q,p). \tag{2.14}$$

One can immediately see that the relation between $a(q,p)$ and $\hat{A}$ is given by

$$\hat{A} = 2\pi \int_{\mathbb{R}} \int_{\mathbb{R}} \mathrm{d}q\, \mathrm{d}p\, a(q,p) \hat{W}(q,p), \tag{2.15}$$

thus establishing that the Wigner and Weyl maps are inverses of one another. Indeed extending the definition of the Wigner distribution (2.10) to a general operator $\hat{A}$ on $\mathcal{H}$, we have

$$a(q,p) = \mathrm{Tr}(\hat{A}\hat{W}(q,p)). \tag{2.16}$$

It is this kind of isomorphism that we wish to develop when $\mathbb{R}$ is replaced by a compact simple Lie group G.

The angle-angular momentum case: We now trace the changes which appear if we replace the Cartesian variable $q \in \mathbb{R}$ by an angle $\theta \in (-\pi, \pi)$. The corresponding Hermitian operator is denoted by $\hat{\theta}$, with eigenvalues θ; its canonical conjugate $\hat{M}$ has integer eigenvalues $m = 0, \pm 1, \pm 2, \ldots$. Thus $m \in \mathbb{Z}$ unlike the Cartesian p, so $\hat{M}$ is already quantized. The replacements for Eqs. (2.4) and (2.6) are

$$\mathcal{H} = L^2(\mathrm{S}^1) = \left\{ \psi(\theta) \,|\, \|\psi\|^2 = \int_{-\pi}^{\pi} \mathrm{d}\theta |\psi(\theta)|^2 < \infty \right\},$$

$$\psi(\theta) = \langle \theta | \psi \rangle, \quad \langle \theta' | \theta \rangle = \delta(\theta' - \theta), \quad \hat{\theta} | \theta \rangle = \theta | \theta \rangle,$$

$$\psi_m = \langle m | \psi \rangle = \frac{1}{2\pi} \int_{-\pi}^{\pi} \mathrm{d}\theta\, e^{-im\theta} \psi(\theta), \tag{2.17}$$

$$\|\psi\|^2 = \sum_{m \in \mathbb{Z}} |\psi_m|^2,$$

$$\hat{M} | m \rangle = m | m \rangle, \quad \langle \theta | m \rangle = \frac{1}{\sqrt{2\pi}} e^{im\theta}.$$

In place of the Heisenberg commutation relation (2.1), we have only the exponentiated Weyl version,

$$U(m) = \exp(im\hat{\theta}), \quad V(\theta) = \exp(-i\theta\hat{M}),$$

$$U(m)V(\theta) = V(\theta)U(m)e^{im\theta}. \tag{2.18}$$

With the actions

$$(U(m')\psi)(\theta) = e^{im'\theta}\psi(\theta),$$

$$(V(\theta')\psi)(\theta) = \psi([\theta - \theta']), \tag{2.19}$$

$$[\theta - \theta'] = \theta - \theta' \bmod 2\pi,$$

we have an irreducible system on $\mathcal{H}=L^2(\mathbb{S}^1)$. The analogues of the displacement operators (2.3) are now

$$U(m)V(\theta)e^{-im\theta/2} = V(\theta)U(m)e^{im\theta/2}, \tag{2.20}$$

but here the exponents cannot be combined. They do however form a complete trace orthonormal system,

$$\mathrm{Tr}((U(m')V(\theta'))^{\dagger}U(m)V(\theta)) = 2\pi\delta_{mm'}\delta(\theta' - \theta). \tag{2.21}$$

With this preparation we can turn to the definition of the Wigner distribution and the Weyl map. For a given density operator $\hat{\rho}$ on $\mathcal{H}$, the former is

$$W(\theta,m) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathrm{d}\theta' \left\langle \theta - \frac{1}{2}\theta' \middle| \hat{\rho} \middle| \theta + \frac{1}{2}\theta' \right\rangle \exp(im\theta'). \tag{2.22}$$

We see immediately that this is not a function on the classical phase space $T^*\mathbb{S}^1 \simeq \mathbb{S}^1 \times \mathbb{R}$, which is a cylinder, but on a partially quantized space $\mathbb{S}^1 \times \mathbb{Z}$. We may regard this space as standing somewhere in between $T^*\mathbb{S}^1$ and the fully quantum mechanical Hilbert space and operator setup. The marginals are properly reproduced in the sense that

$$\int_{-\pi}^{\pi} \mathrm{d}\theta\, W(\theta,m) = \langle m|\hat{\rho}|m\rangle,$$

$$\sum_{m\in\mathbb{Z}} W(\theta,m) = \langle \theta|\hat{\rho}|\theta\rangle. \tag{2.23}$$

We can display $W(\theta,m)$ as

$$W(\theta,m) = \mathrm{Tr}(\hat{\rho}\hat{W}(\theta,m)),$$

$$\hat{W}(\theta,m) = \hat{W}(\theta,m)^{\dagger} = \frac{1}{(2\pi)^2}\sum_{m'\in\mathbb{Z}}\int_{-\pi}^{\pi} \mathrm{d}\theta'\; U(m')V(\theta')e^{im\theta' - im'(\theta + 1/2\theta')}, \tag{2.24}$$

and like their Cartesian counterparts these operators form a trace orthonormal system,

$$\mathrm{Tr}(\hat{W}(\theta',m')\hat{W}(\theta,m)) = \frac{1}{2\pi}\delta(\theta' - \theta)\delta_{mm'}. \tag{2.25}$$

In a similar spirit, the Weyl map now takes any classical function $a(\theta,m)$ on $\mathbb{S}^1 \times \mathbb{Z}$ into an operator on $L^2(\mathbb{S}^1)$,

$$a(\theta,m) \to \tilde{a}(m',\theta') = \sum_{m\in\mathbb{Z}} \int_{-\pi}^{\pi} \mathrm{d}\theta\, a(\theta,m) e^{i(m\theta'-m'\theta)}$$

$$\to \hat{A} = \frac{1}{2\pi} \sum_{m'\in\mathbb{Z}} \int_{-\pi}^{\pi} \mathrm{d}\theta'\, \tilde{a}(m',\theta') U(m') V(\theta') e^{-im'\theta'/2}. \tag{2.26}$$

Then the trace operation becomes, as in (2.14),

$$\mathrm{Tr}(\hat{A}^{\dagger}\hat{B}) = \sum_{m\in\mathbb{Z}} \int_{-\pi}^{\pi} \mathrm{d}\theta\, a(\theta,m) * b(\theta,m). \tag{2.27}$$

Combining Eqs. (2.24) and (2.26) we are able to get the analogue to (2.15),

$$\hat{A} = 2\pi \sum_{m\in\mathbb{Z}} \int_{-\pi}^{\pi} \mathrm{d}\theta\, a(\theta,m) \hat{W}(\theta,m). \tag{2.28}$$

In this way the similarities as well as important differences compared to the Cartesian case are easily seen.

III. QUANTUM KINEMATICS IN THE LIE GROUP CASE AND THE WIGNER DISTRIBUTION

Let G be a (non-Abelian) compact simple Lie group of order n, with elements $g, g', \ldots$ and composition law $g', g \to g'g$. To set up the kinematics appropriate for a quantum system with configuration space $Q=G$, it is simplest to begin with the Hilbert space of Schrödinger wave functions. The normalized left and right invariant volume element on G is written as $\mathrm{d}g$. For suitable functions $f(g)$ on G we have the invariances and normalization condition

$$\int_G \mathrm{d}g\, f(g) = \int_G \mathrm{d}g\, (f(g'g) \quad \text{or } f(gg') \text{ or } f(g^{-1})),$$

$$\int_G \mathrm{d}g = 1. \tag{3.1}$$

Correspondingly we can introduce a Dirac delta function on G characterized by

$$\int_G \mathrm{d}g (\delta(g'^{-1}g) \quad \text{or } \delta(gg'^{-1}) \quad \text{or } \delta(g^{-1}g') \quad \text{or } \delta(g'g^{-1})) f(g) = f(g'). \tag{3.2}$$

Thus $\delta(g)$ is a delta function concentrated at the identity element $e \in G$.

We take the Hilbert space $\mathcal{H}$ for the quantum system to be made up of all complex square integrable functions on G:

$$\mathcal{H} = L^2(G) = \left\{ \psi(g) \in C \mid \|\psi\|^2 = \int_G \mathrm{d}g |\psi(g)|^2 < \infty \right\}. \tag{3.3}$$

A convenient basis of ideal vectors $|g\rangle$ can be introduced such that for a general $|\psi\rangle \in \mathcal{H}$ we may write

$$\psi(g) = \langle g|\psi\rangle, \quad \langle g'|g\rangle = \delta(g'g^{-1}). \tag{3.4}$$

The notion of position coordinates is intrinsically captured by the commutative algebra representing real valued smooth functions $f(g)$ on G, i.e., $f \in \mathcal{F}(G)$. To each such function we associate a Hermitian multiplicative operator $\hat{f}$ on $\mathcal{H}$:

$$f \in \mathcal{F}(G) \to \hat{f} = \int_G \mathrm{d}g\, f(g)|g\rangle\langle g|,$$

$$(\hat{f}\psi)(g) = f(g)\psi(g). \tag{3.5}$$

Thus all these operators commute with one another, being diagonal in the position description $\psi(g)$ of $|\psi\rangle$.

To complete the kinematics and to obtain an irreducible system of operators on $\mathcal{H}$ we have to adjoin suitable momenta. Here we have two choices, corresponding to the left and right translations of G on itself by group action. We choose the former, and so define a family of unitary operators $V(g)$ to give the left regular representation of G:

$$(V(g')\psi)(g) = \psi(g'^{-1}g),$$

$$V(g')|g\rangle = |g'g\rangle. \tag{3.6}$$

They obey

$$V(g')V(g) = V(g'g),$$

$$V(g)^\dagger V(g) = I. \tag{3.7}$$

To identify their Hermitian generators, we introduce a basis $\{e_r\}$ in the Lie algebra $\underline{G}$ of G. Using the exponential map $\underline{G} \to G$, we write a general $g \in G$ as

$$g = \exp(\alpha^r e_r), \tag{3.8}$$

the sum on r being from 1 to n. The generators $\hat{J}_r$ of $V(g)$ are then identified by

$$V(\exp(\alpha^r e_r)) = \exp(-i\alpha^r \hat{J}_r). \tag{3.9}$$

These are Hermitian operators on the Hilbert space $\mathcal{H}$, obeying commutation relations involving the structure constants C_{rs}^t of G:

$$[\hat{J}_r, \hat{J}_s] = iC_{rs}{}^t \hat{J}_t. \tag{3.10}$$

On Schrödinger wave functions $\psi(g)$ each $\hat{J}_r$ acts as a first order partial differential operator; indeed if the (right invariant) vector fields generating the left action of G on itself are written as X_r, then we have

$$\hat{J}_r\psi(g) = iX_r\psi(g). \tag{3.11}$$

The commutation relations (3.10) are direct consequences of similar commutation relations among the vector fields X_r.

The analogue of the Cartesian Heisenberg–Weyl system (2.1) and (2.2) is now obtained by setting together the following ingredients:

$$f_1, f_2 \in \mathcal{F}(G) \to \hat{f}_1\hat{f}_2 = \hat{f}_2\hat{f}_1,$$

$$f \in \mathcal{F}(G), \quad g' \in G \to V(g')\hat{f}V(g')^{-1} = \hat{f}', \tag{3.12}$$

$$f'(g) = f(g'^{-1}g),$$

along with the representation property (3.7) for $V(g)$. This is in the spirit of the unitary Weyl system (2.2). In infinitesimal terms we have

$$[\hat{J}_r, \hat{f}] = i\widehat{(X_r f)}, \tag{3.13}$$

combined with (3.10). The space $\mathcal{H}$ is indeed irreducible with respect to the family of operators $\{\hat{f}, V(\cdot)\}$ or equivalently $\{\hat{f}, \hat{J}_r\}$.

We can express functions of position also via unitary operators in the Weyl spirit as follows: for each real $f \in \mathcal{F}(G)$, we define the unitary operator $U(f)$ by

$$U(f) = e^{i\hat{f}}\colon\ (U(f)\psi)(g) = e^{if(g)}\psi(g). \tag{3.14}$$

It is then easy to see that we have the relations

$$\begin{aligned}
(U(f)V(g')\psi)(g) &= e^{if(g)}\psi(g'^{-1}g),\\
(V(g')U(f)\psi)(g) &= e^{if(g'^{-1}g)}\psi(g'^{-1}g),\\
(U(f)V(g')(V(g')U(f))^{\dagger}\psi)(g) &= e^{if(g)-if(g'^{-1}g)}\psi(g),
\end{aligned} \tag{3.15}$$

which is in the spirit of Eqs. (2.2) and (2.18), except that f is not restricted to be linear in any coordinate variables.

We see here that unlike in the n-dimensional Cartesian case the canonical momenta are a noncommutative system. Therefore the analogue or generalization of the single momentum eigenstate $|\underline{p}\rangle$ in the Cartesian situation will turn out to be a generally multidimensional Hermitian irreducible representation of (3.10), namely the generators of some unitary irreducible representation (UIR) of G. We will see this in detail as we proceed.

For completeness we should mention the operators giving the right regular representation of G. These are, say, $\tilde{V}(g)$, defined by and obeying

$$\begin{aligned}
(\tilde{V}(g')\psi)(g) &= \psi(gg'),\\
\tilde{V}(g')|g\rangle &= |gg'^{-1}\rangle,\\
\tilde{V}(g')\tilde{V}(g) &= \tilde{V}(g'g),\\
V(g')\tilde{V}(g) &= \tilde{V}(g)V(g').
\end{aligned} \tag{3.16}$$

However as is well known their generators $\hat{\tilde{J}}_r$ are determined by $\hat{J}_r$ and the matrices $(\mathcal{D}^s_r(g))$ of the adjoint representation of G, by

$$\hat{\tilde{J}}_r = -\mathcal{D}^s_r(g)\hat{J}_s. \tag{3.17}$$

Therefore it suffices to regard the collection of operators $\{\hat{f}, V(\cdot)\}$ as providing the replacement for the Heisenberg–Weyl system in the present case.

Complementary to the position basis $|g\rangle$ for $\mathcal{H}$ is a momentum basis. This can be set up using the Peter–Weyl theorem involving all the UIR's of G. We denote the various UIR's by j, with dimension N_j; we label rows and columns within the jth UIR by magnetic quantum numbers m, n. Thus the unitary matrix representing $g \in G$ in the jth UIR is

$$g \to (D^j_{mn}(g)). \tag{3.18}$$

In general each of j,m,n is a collection of several independent discrete quantum numbers, and there is a freedom of unitary changes in the choice of m,n. In addition to unitarity and the composition law,

$$\sum_n D^j_{mn}(g) * D^j_{m'n}(g) = \delta_{mm'},$$

$$\sum_n D^j_{mn}(g')D^j_{nn'}(g) = D^j_{mn'}(g'g), \tag{3.19}$$

we have orthogonality and completeness properties,

$$\int_G \mathrm{d}g\, D^j_{mn}(g)D^{j'}_{m'n'}(g)\, * \,= \delta_{jj'}\delta_{mm'}\delta_{nn'}/N_j,$$

$$\sum_{jmn} N_j D^j_{mn}(g)D^j_{mn}(g')\, * \,= \delta(g^{-1}g'). \tag{3.20}$$

Then a simultaneous complete reduction of both representations $V(\cdot)$, $\tilde{V}(\cdot)$ of G is achieved by passing to a new orthonormal basis $|jmn\rangle$ for $\mathcal{H}$. Its definition and basic properties are

$$|jmn\rangle = N_j^{1/2}\int_G \mathrm{d}g\, D^j_{mn}(g)|g\rangle,$$

$$\langle j'm'n'|jmn\rangle = \delta_{j'j}\delta_{m'm}\delta_{n'n},$$

$$V(g)|jmn\rangle = \sum_{m'} D^j_{mm'}(g^{-1})|jm'n\rangle, \tag{3.21}$$

$$\tilde{V}(g)|jmn\rangle = \sum_{n'} D^j_{n'n}(g)|jmn'\rangle.$$

Therefore in $|jmn\rangle$ the index n counts the multiplicity of occurrence of the jth UIR in the reduction of $V(\cdot)$ and m performs a similar function in the reduction of $\tilde{V}(\cdot)$.

We now regard the sets of N_j^2 states $\{|jmn\rangle\}$ for each fixed j as momentum eigenstates in the present context. This means that the n-dimensional real momentum eigenvalue $\underline{p}$ in Cartesian quantum mechanics is now replaced by a collection of (discrete) quantum numbers jmn. A vector $|\psi\rangle \in \mathcal{H}$ with wave function $\psi(g)$ is given in the momentum description by a set of expansion coefficients ψ_{jmn},

$$\psi \in \mathcal{H} \to \psi_{jmn} = \langle jmn|\psi\rangle = N_j^{1/2}\int_G \mathrm{d}g\, D^j_{mn}(g) * \psi(g),$$

$$\|\psi\|^2 = \sum_{jmn} |\psi_{jmn}|^2. \tag{3.22}$$

A normalized $|\psi\rangle$ then determines two complementary probability distributions, $|\psi(g)|^2$ on G and $|\psi_{jmn}|^2$ on momentum space.

In this situation a (provisional and overcomplete) Wigner distribution $\tilde{W}(g;jmn\,m'n')$ can be defined for each $|\psi\rangle \in \mathcal{H}$ (or for any mixed state $\hat{\rho}$ as well). (Here we depart slightly from the

notation in Ref. 21, so that our later expressions are more concise.) It transforms in a reasonable manner when $|\psi\rangle$ is acted upon by $V(\cdot)$ or $\tilde{V}(\cdot)$; and it reproduces in a simple and direct way the two probability distributions determined by $|\psi\rangle$, as marginals. We give only the latter property here,

$$\sum_{jmn} \tilde{W}(g;jmn\ mn) = |\psi(g)|^2,$$

$$\int_G \mathrm{d}g\ \tilde{W}(g;jmn\ m'n') = \psi_{jm'n'}\ \psi^*_{jmn}. \tag{3.23}$$

The right-hand side of the second relation is a natural generalization of $|\psi_{jmn}|^2$, to allow for freedom in the choice of labels m,n within each UIR j. The expression for this Wigner distribution involves a function s, $G\times G\to G$ obeying certain conditions and is

$$\tilde{W}(g;jmn\ m'n') = N_j \int_G \mathrm{d}g' \int_G \mathrm{d}g''\ \psi(g'')\psi(g') * D^j_{m'n'}(g'') * D^j_{mn}(g')\,\delta(g^{-1}s(g',g'')). \tag{3.24}$$

Reality in the Cartesian or single angle-angular momentum cases is replaced here by Hermiticity,

$$\tilde{W}(g;jmn\ m'n') * = \tilde{W}(g;jm'n'\ mn). \tag{3.25}$$

The conditions on $s(g',g'')$ to ensure that all the above properties are secured are

$$g',g'' \in G \to s(g',g'') = s(g'',g') \in G,$$

$$s(g_1g'g_2,g_1g''g_2) = g_1\ s(g',g'')g_2, \tag{3.26}$$

$$s(g',g') = g'.$$

We can simplify the problem of constructing such a function by exploiting the second of these relations to write

$$s(g',g'') = g's(e,g'^{-1}g'') = g's_0(g'^{-1}g''), \tag{3.27}$$

so the function $s_0(g)$ of a single group element must satisfy

$$s_0(e) = e,$$

$$s_0(g^{-1}) = g^{-1}s_0(g) = s_0(g)g^{-1}, \tag{3.28}$$

$$s_0(g'gg'^{-1}) = g'\ s_0(g)g'^{-1}.$$

The solution proposed in Ref. 21 is to take $s_0(g)$ to be the midpoint along the geodesic from the identity $e\in G$ to g. These geodesics are determined starting from the invariant Cartan–Killing metric on G, and have the necessary behaviors under left and right group actions to ensure that all of Eqs. (3.26) and (3.28) are obeyed. In the exponential notation of Eq. (3.8) we have

$$s_0(\exp(\alpha^r\ e_r)) = \exp(\tfrac{1}{2}\alpha^r\ e_r), \tag{3.29}$$

since it is true that geodesics passing through the identity are one parameter subgroups. With this explicit construction we have the additional relation

$$s_0(g^{-1}) = s_0(g)^{-1},$$

i.e.,

$$s_0(g)\ s_0(g) = g. \tag{3.30}$$

Thus $s_0(g)$ is the (almost everywhere unique) square root of g and $s(g',g'')$ is a kind of symmetric square root of g' and g''.

We shall explore the properties of $\tilde{W}(g;jmn\,m'n')$ in the next section, especially the sense in which it contains information about $|\psi\rangle\langle\psi|$ in an overcomplete manner. This will then lead to the Wigner–Weyl isomorphism for quantum mechanics on a (compact simple) Lie group.

IV. THE WIGNER–WEYL ISOMORPHISM IN THE LIE GROUP CASE

The definition (3.24) can be immediately extended to associate an object $\tilde{W}_{\hat{A}}(g;jmn\,m'n')$ with every linear operator $\hat{A}$ on $\mathcal{H}$ (of Hilbert–Schmidt class). In terms of the integral kernel $\langle g''|\hat{A}|g'\rangle$ of $\hat{A}$ we have

$$\tilde{W}_{\hat{A}}(g;jmn\,m'n') = N_j \int_G \mathrm{d}g' \int_G \mathrm{d}g'' \langle g''|\hat{A}|g'\rangle D^j_{m'n'}(g'') * D^j_{mn}(g')\,\delta(g^{-1}s(g',g'')). \tag{4.1}$$

It is indeed the case that this expression describes or determines $\hat{A}$ completely, however this happens in an overcomplete manner. There are certain linear relations obeyed by $\tilde{W}_{\hat{A}}(g;jmn\,m'n')$ which have an $\hat{A}$ independent form. We now obtain these relations, then proceed to construct a simpler expression which contains complete information about $\hat{A}$ without redundancy.

The Dirac delta function in the integral on the right-hand side of Eq. (4.1) means that the only contributions to the integral are from the points where

$$s(g',g'') = g. \tag{4.2}$$

Writing this as

$$s_0(g'^{-1}g'') = g'^{-1}g, \tag{4.3}$$

and then using Eq. (3.30), we see that, say, in the g'' integration the delta function picks out the single point determined by

$$g'^{-1}g'' = (g'^{-1}g)^2,$$

i.e.,

$$g'' = gg'^{-1}g. \tag{4.4}$$

This means that $\delta(g^{-1}s(g',g''))$ is some Jacobian factor times $\delta(g''^{-1}gg'^{-1}g)$. We are therefore permitted to use this value for g'' elsewhere in the integrand, so

$$\tilde{W}_{\hat{A}}(g;jmn\,m'n') = N_j \int_G \mathrm{d}g' \int_G \mathrm{d}g'' \langle gg'^{-1}g|\hat{A}|g'\rangle D^j_{m'n'}(gg'^{-1}g) * D^j_{mn}(g')\,\delta(g^{-1}s(g',g'')). \tag{4.5}$$

Transferring the g-dependent representation matrices from the right-hand side to the left-hand side and using unitarity, we get

$$\sum_{m'n'} D^j_{m'm''}(g)D^j_{n''n'}(g)\tilde{W}_{\hat{A}}(g;jmn\ m'n') = N_j \int_G \mathrm{d}g' \int_G \mathrm{d}g''\ \delta(g^{-1}s(g',g'')) \times \langle gg'^{-1}g|\hat{A}|g'\rangle D^j_{n''m''}(g')D^j_{mn}(g'). \tag{4.6}$$

It is now clear we have symmetry of the expression on the left-hand side under the simultaneous interchanges $m \leftrightarrow n''$, $n \leftrightarrow m''$, a statement independent of $\hat{A}$. This is the sense in which $\tilde{W}_{\hat{A}}(g;jmn\ m'n')$ contains information about $\hat{A}$ in an overcomplete manner, and this happens only when G is non-Abelian.

Taking advantage of this, we now associate to $\hat{A}$ the simpler quantity

$$W_{\hat{A}}(g;jmm') = N_j^{-1}\sum_n \tilde{W}_{\hat{A}}(g;jmn\ m'n) = \int_G \mathrm{d}g' \int_G \mathrm{d}g''\langle g''|\hat{A}|g'\rangle D^j_{mm'}(g'g''^{-1})\delta(g^{-1}s(g',g'')). \tag{4.7}$$

We shall call this the Weyl symbol corresponding to the operator $\hat{A}$. The passage $\hat{A} \to \hat{A}^\dagger$ results in

$$W_{\hat{A}^\dagger}(g;jmm') = W_{\hat{A}}(g;jm'm)^*. \tag{4.8}$$

It is easy to obtain the transformation properties of the Weyl symbol under conjugation of $\hat{A}$ by either the left or the right regular representation,

$$\hat{A}' = V(g_0)\hat{A}V(g_0)^{-1},$$

$$W_{\hat{A}'}(g;jmm') = \sum_{m_1m_1'} D^j_{mm_1}(g_0)D^j_{m'm_1'}(g_0)^* W_{\hat{A}}(g_0^{-1}g;jm_1m_1'), \tag{4.9}$$

$$\hat{A}'' = \tilde{V}(g_0)\hat{A}\tilde{V}(g_0)^{-1},$$

$$W_{\hat{A}''}(g;jmm') = W_{\hat{A}}(gg_0;jmm').$$

Next we can verify that if $\hat{A}$ and $\hat{B}$ are any two Hilbert–Schmidt operators on $\mathcal{H}$, then $\mathrm{Tr}(\hat{A}\hat{B})$ can be simply expressed in terms of their Weyl symbols,

$$\mathrm{Tr}(\hat{A}\hat{B}) = \sum_{jmm'} N_j \int_G \mathrm{d}g\ W_{\hat{A}}(g;jmm')W_{\hat{B}}(g;jm'm). \tag{4.10}$$

The proof exploits the completeness relation in (3.20) and the properties (3.26) of $s(g',g'')$. This key result proves that $\hat{A}$ is indeed completely determined by its Weyl symbol: $\hat{A}$ is certainly determined by the values of $\mathrm{Tr}(\hat{A}\hat{B})$ for all $\hat{B}$, and the latter are known once the Weyl symbols are known.

Before expressing the Weyl symbol of $\hat{A}$ in a form analogous to Eq. (2.16), we give examples for some simple choices of $\hat{A}$,

$$\begin{array}{cc} \hat{A} & W_{\hat{A}}(g;jmm') \\ \hline \hat{f}=\int_G \mathrm{d}g\, f(g)|g\rangle\langle g| & f(g)\delta_{mm'} \\ V(g_0) & D^j_{mm'}(g_0^{-1}) \\ \tilde{V}(g_0) & D^j_{mm'}(gg_0g^{-1}) \\ \hat{f}V(g_0) & f(s_0(g_0)g)D^j_{mm'}(g_0^{-1}) \\ V(g_0)\hat{f} & f(s_0(g_0)^{-1}g)D^j_{mm'}(g_0^{-1}) \end{array} \tag{4.11}$$

We shall comment later on the structure of these Weyl symbols. However it is already instructive to compare these results with the Cartesian situation

$$\begin{array}{cc} \hat{A} & W(q,p) \\ \hline \hat{f}=f(\hat{q}) & f(q) \\ V(q') & \exp(-ipq') \\ \hat{f}V(q')=f(\hat{q})V(q') & f(q+q'/2)\exp(-ipq') \\ V(q')f(\hat{q}) & f(q-q'/2)\exp(-ipq') \end{array} \tag{4.12}$$

Now we turn to the problem of expressing the Weyl symbol of $\hat{A}$ in the form

$$W_{\hat{A}}(g;jmm')=\mathrm{Tr}(\hat{A}\hat{W}(g;jmm')) \tag{4.13}$$

for a suitable operator $\hat{W}(g;jmm')$. This would be the analogue of $\hat{W}(q,p)$ in Eq. (2.10). Since the kernel $\langle g''|\hat{A}|g'\rangle$ is quite general, Eq. (4.13) and Eq. (4.7) imply

$$\langle g'|\hat{W}(g;jmm')|g''\rangle = D^j_{mm'}(g'g''^{-1})\,\delta(g^{-1}s(g',g'')) = D^j_{mm'}(g'g''^{-1})\,\delta(g^{-1}s_0(g''g'^{-1})g'). \tag{4.14}$$

We shall synthesize $\hat{W}(g;jmm')$ in steps. We begin by defining a family of commuting operators $U(jmn)$ in the manner of Eq. (3.5), all of them diagonal in the position basis,

$$(U(jmn)\psi)(g)=D^j_{mn}(g)\psi(g). \tag{4.15}$$

These are analogous to the Cartesian $U(p')$, labeled by a momentum eigenvalue jmn, functions of position alone. They are unitary in the matrix sense,

$$\sum_m U(jmn)^\dagger U(jmn')=\sum_m U(jnm)^\dagger U(jn'm)=\delta_{n'n}I. \tag{4.16}$$

These operators allow us to express the map $f\in\mathcal{F}(G)\to\hat{f}$ of Eq. (3.5) more explicitly as follows:

$$f(g)=\sum_{jmn} f_{jmn}D^j_{mn}(g)\Rightarrow \hat{f}=\sum_{jmn} f_{jmn}U(jmn). \tag{4.17}$$

Upon conjugation by $V(g)$ we have

$$V(g)^{-1}U(jmn)V(g)=\sum_{m'} D^j_{mm'}(g)U(jm'n). \tag{4.18}$$

Combining Eqs. (3.16), (3.20), and (4.15) we easily obtain the trace orthonormality property

$$\mathrm{Tr}((U(j'm'n')V(g'))^{\dagger}U(jmn)V(g)) = N_j^{-1}\delta_{j'j}\delta_{m'm}\delta_{n'n}\delta(g^{-1}g'), \tag{4.19}$$

analogous to Eqs. (2.7) and (2.5). The action of $U(j'm'n')$ on the momentum eigenstates $|jmn\rangle$ can be worked out; it involves the Clebsch–Gordan coefficients for the reduction of direct products of two general UIR's of G and reads

$$U(j'm'n')|jmn\rangle = \sum_{j''m''n''\lambda} \sqrt{\frac{N_j}{N_{j''}}} C^{j'jj''\lambda}_{m'mm''} * C^{j'jj''\lambda}_{n'nn''} |j''m''n''\rangle. \tag{4.20}$$

Here λ is a multiplicity index keeping track of the possibly multiple occurrences of the UIR $D^{j''}$ in the reduction of the direct product $D^{j'} \times D^{j}$. The significance of this relation is similar in spirit to the statement in the Cartesian case that $U(p') = \exp(ip'\hat{q})$ generates a translation in $\hat{p}$, in other words that in the momentum description $\hat{q}$ is given by the differential operator $i(\mathrm{d}/\mathrm{d}p)$. The result (4.20) however involves discrete labels since G is compact, unlike continuous Cartesian variables, and incorporates non-Abelianness as well. Therefore translating the momentum jmn by the amount $j'm'n'$ yields several final momenta $j''m''n''$ according to the contents of the direct product $D^{j'} \times D^{j}$ of UIR's of G.

Now multiply both sides of Eq. (4.14) by $D^{j_1}_{m_1m_1'}(g)$ and integrate with respect to g, this is Fourier transformation with respect to g and gives

$$\langle g'| \int_G \mathrm{d}g\, D^{j_1}_{m_1m_1'}(g) \hat{W}(g;jmm')|g''\rangle = D^{j}_{mm'}(g'g''^{-1}) D^{j_1}_{m_1m_1'}(s_0(g''g'^{-1})g'). \tag{4.21}$$

Now perform an inverse Fourier transformation with respect to the momenta jmm' to get

$$\begin{aligned} &\sum_{jmm'} N_j D^{j}_{mm'}(g_1) * \langle g'| \int_G \mathrm{d}g\, D^{j_1}_{m_1m_1'}(g) \hat{W}(g;jmm')|g''\rangle \\ &\quad = D^{j_1}_{m_1m_1'}(s_0(g''g'^{-1})g')\,\delta(g_1g''g'^{-1}) = D^{j_1}_{m_1m_1'}(s_0(g_1^{-1})g')\,\delta(g_1g''g'^{-1}) \\ &\quad = \langle g'|g_1g''\rangle D^{j_1}_{m_1m_1'}(s_0(g_1^{-1})g') = \sum_{m_2} \langle g'|U(j_1m_2m_1')V(g_1)|g''\rangle D^{j_1}_{m_1m_2}(s_0(g_1^{-1})). \end{aligned} \tag{4.22}$$

Comparing the two sides and peeling off $\langle g'|$ and $|g''\rangle$ gives

$$\sum_{jmm'} N_j D^{j}_{mm'}(g_1) * \int_G \mathrm{d}g\, D^{j_1}_{m_1m_1'}(g) \hat{W}(g;jmm') = \sum_{m_2} D^{j_1}_{m_1m_2}(s_0(g_1^{-1})) U(j_1m_2m_1')V(g_1). \tag{4.23}$$

Then Fourier inversion twice yields the result

$$\hat{W}(g;jmm') = \sum_{j_1m_1m_2} N_{j_1} \int_G \mathrm{d}g_1\, U(j_1m_2m_1)V(g_1) D^{j}_{mm'}(g_1) D^{j_1}_{m_1m_2}(g^{-1}s_0(g_1^{-1})). \tag{4.24}$$

This may be compared in every detail with the Cartesian result in Eq. (2.10), the correspondence of arguments and integration/summation variables is (including the factors representing momentum eigenfunctions)

$$q \to g, \quad p \to jmm', \quad q' \to g_1, \quad p' \to j_1m_1m_2,$$

$$e^{ipq'} \to D^{j}_{mm'}(g_1), \quad e^{-ip'(q+q'/2)} \to D^{j_1}_{m_1m_2}(g^{-1}s_0(g_1^{-1})). \tag{4.25}$$

Giving due attention to the new matrix features, the correspondence is quite remarkable.

Combining Eqs. (3.28) and (4.14) we obtain the relation

$$\hat{W}(g;jmn)^{\dagger} = \hat{W}(g;jnm). \tag{4.26}$$

Similarly combining Eqs. (4.24) and (4.19) and carrying out quite elementary operations leads to analogues to the Cartesian relations (2.11) and (2.15) in the forms

$$\mathrm{Tr}(\hat{W}(g';j'm'n')^{\dagger}\hat{W}(g;jmn)) = N_j^{-1}\delta_{jj'}\delta_{mm'}\delta_{nn'}\delta(g^{-1}g'),$$

$$\hat{A} = \sum_{jmn} N_j \int_G \mathrm{d}g\; W_{\hat{A}}(g;jnm)\hat{W}(g;jmn). \tag{4.27}$$

We may thus conclude that we have succeeded in setting up a Wigner–Weyl isomorphism for quantum mechanics on a compact simple Lie group with reasonable properties.

V. THE STAR PRODUCT FOR WEYL SYMBOLS

In this section we sketch the derivation of the expression for noncommutative operator multiplication in terms of the corresponding Weyl symbols, relegating some details to the Appendix. Thus, for two operators $\hat{A}$ and $\hat{B}$ we seek an expression for the Weyl symbol of $\hat{A}\hat{B}$ in terms of those of $\hat{A}$ and $\hat{B}$ in the form

$$W_{\hat{A}\hat{B}}(g;jmn) = (W_{\hat{A}} \star W_{\hat{B}})(g;jmn). \tag{5.1}$$

From Eq. (4.13) we have

$$(W_{\hat{A}} \star W_{\hat{B}})(g;jmn) = \mathrm{Tr}(\hat{A}\hat{B}\hat{W}(g;jmn)), \tag{5.2}$$

so using Eq. (4.27) for $\hat{A}$ as well as for $\hat{B}$ we have

$$(W_{\hat{A}} \star W_{\hat{B}})(g;jmn) = \sum_{\substack{j'm'n' \\ j''m''n''}} N_{j'}N_{j''} \int_G \mathrm{d}g'' \int_G \mathrm{d}g'\; W_{\hat{A}}(g'';j''n''m'')W_{\hat{B}}(g';j'n'm') \times \mathrm{Tr}(\hat{W}(g'';j''m''n'')\hat{W}(g';j'm'n')\hat{W}(g;jmn)). \tag{5.3}$$

We therefore need to compute the trace of the product of three $\hat{W}$'s, which is a nonlocal integral kernel defining the (associative but noncommutative) star product on the left-hand side. The two ingredients for this calculation are expressions for the product $U(jmn)V(g)$ in terms of $\hat{W}(g';j'm'n')$, and for the product $U(j'm'n')V(g')U(jmn)V(g)$ in terms of similar products UV. These are

$$U(jmn)V(g) = \sum_{j'm'n'} N_{j'} D^{j'}_{m'n'}(g) * \int_G \mathrm{d}g'\; D^{j}_{mn}(s_0(g)g')\hat{W}(g';j'm'n'), \tag{5.4a}$$

$$U(j'm'n')V(g')U(jmn)V(g) = \sum_{j''m''n''k} C^{j'\ j\ j''}_{m'n'\ kn\ m''n''} D^{j}_{mk}(g'^{-1})U(j''m''n'')V(g'g). \tag{5.4b}$$

The derivations are given in the Appendix, and the C-symbol on the right-hand side in the second equation is a sum of products of Clebsch–Gordan coefficients of the type occurring in Eq. (4.20).

Starting from Eq. (4.24) and using Eq. (5.4b) we have for the product of two $\hat{W}$'s,

$$\hat{W}(g';j'm'n')\hat{W}(g;jmn)$$

$$= \sum_{\substack{j_0,m_0,n_0\\ j_0'm_0'n_0'}} N_{j_0}N_{j_0'}\int_G \mathrm{d}g_0 \int_G \mathrm{d}g_0'\, D^{j}_{mn}(g_0)D^{j'}_{m'n'}(g_0')$$

$$\times D^{j_0}_{n_0m_0}(g^{-1}s_0(g_0^{-1}))D^{j_0'}_{n_0'm_0'}(g'^{-1}s_0(g_0'^{-1}))U(j_0'm_0'n_0')V(g_0')U(j_0m_0n_0)V(g_0)$$

$$= \sum_{\substack{j_0m_0n_0k_0\\ j_0'm_0'n_0'\\ j_0''m_0''n_0''}} N_{j_0}N_{j_0'}C^{j_0'}_{m_0'n_0'\ k_0n_0}\ {}^{j_0''}_{m_0''n_0''}\int_G \mathrm{d}g_0 \int_G \mathrm{d}g_0'\, D^{j}_{mn}(g_0)D^{j'}_{m'n'}(g_0')$$

$$\times D^{j_0}_{m_0k_0}(g_0'^{-1})D^{j_0}_{n_0m_0}(g^{-1}s_0(g_0^{-1}))D^{j_0'}_{n_0'm_0'}(g'^{-1}s_0(g_0'^{-1}))\times U(j_0''m_0''n_0'')V(g_0'g_0). \tag{5.5}$$

If here we use Eq. (5.4a) and then Eq. (4.27) we obtain for the kernel in Eq. (5.3),

$$\mathrm{Tr}(\hat{W}(g'';j''m''n'')\hat{W}(g';j'm'n')\hat{W}(g;jmn))$$

$$= \sum_{\substack{j_0m_0n_0k_0\\ j_0'm_0'n_0'\\ j_0''m_0''n_0''}} N_{j_0}N_{j_0'}C^{j_0'}_{m_0'n_0'\ k_0n_0}\ {}^{j_0''}_{m_0''n_0''}\int_G \mathrm{d}g_0 \int_G \mathrm{d}g_0'\, D^{j}_{mn}(g_0)D^{j'}_{m'n'}(g_0')D^{j''}_{n''m''}(g_0'g_0)\ *$$

$$\times D^{j_0}_{m_0k_0}(g_0'^{-1})D^{j_0}_{n_0m_0}(g^{-1}s_0(g_0^{-1}))D^{j_0'}_{n_0'm_0'}(g'^{-1}s_0(g_0'^{-1}))D^{j_0''}_{m_0''n_0''}(s_0(g_0'g_0)g''). \tag{5.6}$$

The star product of Eq. (5.3) is then obtained by inserting this integral kernel on the right-hand side.

A slightly simpler expression—which amounts to trading four of the D-functions for Dirac delta functions—results from direct use of Eq. (4.14),

$$\mathrm{Tr}(\hat{W}(g'';j''m''n'')\hat{W}(g';j'm'n')\hat{W}(g;jmn))$$

$$= \int_G \mathrm{d}g_0 \int_G \mathrm{d}g_0' \int_G \mathrm{d}g_0'' \langle g_0|\hat{W}(g'';j''m''n'')|g_0'\rangle\langle g_0'|\hat{W}(g';j'm'n')|g_0''\rangle\langle g_0''|\hat{W}(g;jmn)|g_0\rangle$$

$$= \int_G \mathrm{d}g_0 \int_G \mathrm{d}g_0' \int_G \mathrm{d}g_0''\, D^{j''}_{m''n''}(g_0g_0'^{-1})D^{j'}_{m'n'}(g_0'g_0''^{-1})$$

$$\times D^{j}_{mn}(g_0''g_0^{-1})\,\delta(g''^{-1}s(g_0,g_0'))\,\delta(g'^{-1}s(g_0',g_0''))\,\delta(g^{-1}s(g_0'',g_0)). \tag{5.7}$$

These expressions for the star product show an unavoidable complexity for general compact non-Abelian G. In the one-dimensional Abelian (but non-Cartesian) case $Q=\mathbb{S}^1$, there are some simplifications. Referring to Sec. II, we have the rule for Weyl symbols given by Eq. (2.25) and (2.28),

$$a(\theta;m) = \mathrm{Tr}(\hat{A}\hat{W}(\theta;m)),$$

$$\hat{A} = 2\pi \sum_{m\in\mathbb{Z}} \int_{-\pi}^{\pi} \mathrm{d}\theta\, a(\theta;m)\hat{W}(\theta;m). \tag{5.8}$$

The star product then appears as

$$(a \star b)(\theta;m) = \sum_{m',m'' \in \mathbb{Z}} \int_{-\pi}^{\pi} \mathrm{d}\theta'' \int_{-\pi}^{\pi} \mathrm{d}\theta' \ \mathrm{Tr}(\hat{W}(\theta'';m'')\hat{W}(\theta';m')\hat{W}(\theta;m))a(\theta'';m'')b(\theta';m'),$$

$$\mathrm{Tr}(\hat{W}(\theta'';m'')\hat{W}(\theta';m')\hat{W}(\theta;m)) = \frac{1}{4\pi^2} \sum_{m_0,m_0' \in \mathbb{Z}} \int_{-\pi}^{\pi} d\theta_0' \int_{-\pi}^{\pi} d\theta_0 e^{i/2(m_0'\theta_0 - m_0\theta_0')} \exp[i(m\theta_0 - m_0\theta + m'\theta_0' - m_0'\theta' + (m_0 + m_0')\theta'' - m''(\theta_0 + \theta_0'))]. \tag{5.9}$$

This expression for the kernel results from Eq. (5.6) if we first drop the magnetic quantum numbers $m,n,m',n',m'',n'',m_0,n_0,k_0,m_0',n_0',m_0'',n_0''$; then set the dimensionalities N_{j0}, $N_{j_0'}$ equal to unity; next make the replacements $j \to m, j' \to m', j'' \to m'', j_0 \to m_0, j_0' \to m_0', g_0 \to \theta_0, g_0' \to \theta_0'$, and use for the C coefficient the Kronecker delta $\delta_{j_0'',m_0+m_0'}$. Even with some simplifications, the kernel in Eq. (5.9) remains nonlocal because of (among other things) the occurrence of half-angles in the exponent.

VI. DISCUSSION AND CONCLUDING REMARKS

The characteristic feature revealed by our analysis is that for quantum mechanics on a Lie group G as configuration space, the concept of canonical momentum is a collection of noncommuting operators $\hat{J}_r$, in fact constituting the Lie algebra of the left regular representation of G on $L^2(G)$. This in itself is known, but it results in the analogues of momentum eigenvalue being a set of discrete labels jmn, and the single Cartesian momentum eigenvector $|p\rangle$ being replaced by a multidimensional set of vectors $\{|jmn\rangle\}$. Other consequences of this non-Abelianness should be noted. One needs to work with both overcomplete and with complete nonredundant Weyl symbols for general operators $\hat{A}$: the former are useful for reproducing in a simple manner the two complementary marginal probability distributions associated with a pure or mixed quantum state from its Wigner distribution as shown in Eq. (3.23); while the latter lead to the Wigner–Weyl isomorphism in a reasonable manner.

It is interesting that the Weyl symbols $W_{\hat{A}}(g;jmm')$ are not complex valued functions on the classical phase space T^*G. They may be more compactly viewed as follows. Whereas by the Peter–Weyl theorem the Hilbert space $\mathcal{H}=L^2(G)$ carries each UIR $\mathcal{D}^{(j)}(\cdot)$ of G as often as its dimension N_j, the structure of Eq. (4.7) leads us to define a smaller Hilbert space $\mathcal{H}_0$ carrying each UIR of G exactly once:

$$\mathcal{H}_0 = \sum_j \oplus \mathcal{H}^{(j)},$$

$$\mathcal{H}^{(j)} = \mathrm{Sp}\{|jm)\}, \quad \dim \mathcal{H}^{(j)} = N_j, \tag{6.1}$$

$$(j'm'|jm) = \delta_{j'j}\delta_{m'm},$$

with $\mathcal{H}^{(j)}$ carrying the UIR $\mathcal{D}^{(j)}(\cdot)$ of G. Then the Weyl symbol of a general operator $\hat{A}$, $W_{\hat{A}}(g;jmm')$, may be regarded as a function of $g \in G$ and an operator on $\mathcal{H}_0$. This is evident from the examples of Weyl symbols given in Eq. (4.11); in the Cartesian case in Eq. (4.12) such features are of course absent. This can be understood also from the following point of view. In the normal quantum description an operator $\hat{A}$ on $\mathcal{H}=L^2(G)$ can be given via its kernel $\langle g''|\hat{A}|g'\rangle$, or via its complementary diagonal plus off-diagonal matrix elements $\langle j'm'n'|\hat{A}|jmn\rangle$. If in the latter we trade half of the labels for a dependence on a group element g, we arrive at the Weyl symbol $W_{\hat{A}}(g;jmm')$ viewed as a block diagonal operator on $\mathcal{H}_0$ with simultaneously a dependence on g. Thus while the Wigner–Weyl isomorphism does not work directly with the true classical phase

space T^*G, it seems to use what may be called a noncommutative cotangent space, standing somewhere between T^*G and operators on $L^2(G)$.

Nevertheless the link to functions on the classical phase space T^*G can be established, as we will see below.

We may use the phrase "semiquantized phase space" for the space on which the Weyl symbols $W_{\hat{A}}(g;jmn)$ of operators $\hat{A}$ are defined. It is to be understood that this phrase includes the restriction that only (g-dependent) block-diagonal operators on $\mathcal{H}_0$ are encountered. This may be viewed as a superselection rule. In detail, given an operator $\hat{A}$ on $\mathcal{H}=L^2(G)$, we associate with it the g-dependent block-diagonal operator,

$$\tilde{A}(g) = \sum_j \sum_{m,n} \sqrt{N_j} W_{\hat{A}}(g;jmn)|jm)(jn|, \tag{6.2}$$

acting on $\mathcal{H}_0$, and we then have the connection

$$\mathrm{Tr}_{\mathcal{H}}(\hat{A}\hat{B}) = \int_G \mathrm{d}g\, \mathrm{Tr}_{\mathcal{H}_0}(\tilde{A}(g)\tilde{B}(g)). \tag{6.3}$$

The Weyl symbol $\tilde{A}(g)$ is simpler than $\hat{A}$ both in that it acts on the much smaller Hilbert space $\mathcal{H}_0$, and in that it is block diagonal.

To finally establish the link to suitable functions on the classical phase space T^*G, we exploit both the fact that the representation of G on $\mathcal{H}_0$ has a multiplicity-free reduction into UIR's, and the fact that $\tilde{A}(g)$ is block diagonal. Let us denote the generators of G on $\mathcal{H}_0$ by $\hat{J}^{(0)}_r$, $r=1,2,\ldots,n$. The Weyl symbol $\tilde{A}(g)$ may initially be written as the direct sum of symbols $\tilde{A}_j(g)$ acting within each subspace $\mathcal{H}^{(j)}$ in $\mathcal{H}_0$,

$$\tilde{A}(g) = \sum_j \oplus \tilde{A}_j(g),$$

$$\tilde{A}_j(g) = \sum_{m,n} \sqrt{N_j} W_{\tilde{A}}(g;jmn)|jm)(jn|. \tag{6.4}$$

Next, using the irreducibility of $\{\hat{J}^{(0)}_r\}$ acting on $\mathcal{H}^{(j)}$, we can expand $\tilde{A}_j(g)$ uniquely as a sum of symmetrized polynomials in $\hat{J}^{(0)}_r$,

$$\tilde{A}_j(g) = \sum_{N=0,1,\ldots} \sum_{r_1,r_2,\ldots,r_N} a_{r_1\ldots r_N}(g;j)\{\hat{J}^{(0)}_{r_1}\hat{J}^{(0)}_{r_2}\cdots\hat{J}^{(0)}_{r_N}\}^{(j)}_S,$$

$$\{\hat{J}^{(0)}_{r_1}\hat{J}^{(0)}_{r_2}\cdots\hat{J}^{(0)}_{r_N}\}^{(j)}_S = \frac{1}{N!}\sum_{P\in S_N}(\hat{J}^{(0)}_{r_{P(1)}}\cdots\hat{J}^{(0)}_{r_{P(N)}})^{(j)}. \tag{6.5}$$

Here the upper limit of N is determined by the UIR D^j; S_N is the permutation group on N symbols; and the superscript (j) denotes the restriction to $\mathcal{H}^{(j)}$. The coefficients $a_{r_1,\ldots,r_N}(g;j)$ are c-number quantities symmetric in $r_1,\ldots,r_N$. If we now replace their j dependences by dependences on the independent mutually commuting Casimir operators $\hat{\mathcal{C}}$ of G, themselves symmetric homogeneous polynomials in $\hat{J}^{(0)}_r$, we can use (6.5) in (6.4) and write

$$\tilde{A}(g) = \sum_{N=0}^{\infty} \sum_{r_1,\ldots,r_N} a_{r_1,\ldots,r_N}(g;\hat{\mathcal{C}})\{\hat{J}^{(0)}_{r_1}\cdots\hat{J}^{(0)}_{r_N}\}_S. \tag{6.6}$$

This expression for the Weyl symbol $\tilde{A}(g)$ of $\hat{A}$ can now be set into one-to-one correspondence with the classical phase space function

$$a(g;J) = \sum_{N=0}^{\infty} \sum_{r_1,\ldots,r_N} a_{r_1,\ldots,r_N}(g;\mathcal{C}) J_{r_1} \cdots J_{r_N}, \tag{6.7}$$

where the commuting classical variables J_r are the canonical momentum coordinates of the classical phase space T^*G,[21] while $\mathcal{C}$ are invariant (Casimir) homogeneous polynomials in them. Thus we have the two-stage sequence of correspondences

$$\hat{A} \text{ on } \mathcal{H} = L^2(G) \Leftrightarrow \tilde{A}(g) = \text{block-diagonal operator on } \mathcal{H}_0 \leftrightarrow a(g;J) \in \mathcal{F}(T^*G). \tag{6.8}$$

The importance of the multiplicity-free nature of the representation of G on $\mathcal{H}_0$, and the superselection rule, is evident. In contrast to the Cartesian case in Sec. II, the appearance of the semiquantized phase space as an intermediate step is to be noted. We hope to return to this aspect in a future publication.

APPENDIX

We indicate here the derivations of Eqs. (5.4a) and (5.4b). For Eq. (5.4a), we begin with Eq. (4.23) and use the unitarity of the D-matrices to shift the D-matrix on the right-hand side to the left-hand side. This immediately gives Eq. (5.4a). For Eq. (5.4b) we begin with the decomposition of the product of two U's; from Eq. (4.15), using Eq. (A29) in Ref. 21,

$$U(j'm'n')U(jmn)|g\rangle = D^{j'}_{m'n'}(g)D^{j}_{mn}(g)|g\rangle = \sum_{j''m''n''\lambda} C^{j'\ j\ j''\lambda *}_{m'\ m\ m''} C^{j'\ j\ j''\lambda}_{n'\ n\ n''} D^{j''}_{m''n''}(g)|g\rangle. \tag{A1}$$

Here the C's are the usual Clebsch–Gordan coefficients for the decomposition of the direct product $D^{j'} \times D^{j}$ of two UIR's into UIR's $D^{j''}$, with a multiplicity index λ to keep track of multiple occurrences of a given $D^{j''}$. If we introduce the short-hand notation

$$C^{j'\ \ j\ \ j''}_{m'n'\ mn\ m''n''} = \sum_{\lambda} C^{j'\ j\ j''\lambda *}_{m'\ m\ m''} C^{j'\ j\ j''\lambda}_{n'\ n\ n''}, \tag{A2}$$

we get from (A1):

$$U(j'm'n')U(jmn) = \sum_{j''m''n''} C^{j'\ \ j\ \ j''}_{m'n'\ mn\ m''n''} U(j''m''n''). \tag{A3}$$

We can now tackle the product of four factors in Eq. (5.4b). First using Eqs. (3.7) and (4.18) and then using (A3) above gives

$$\begin{aligned} U(j'm'n')V(g')U(jmn)V(g) &= U(j'm'n') \sum_{k} D^{j}_{mk}(g'^{-1}) U(jkn) V(g'g) \\ &= \sum_{j''m''n''k} D^{j}_{mk}(g'^{-1}) C^{j'\ \ j\ \ j''}_{m'n'\ kn\ m''n''} U(j''m''n'') V(g'g), \end{aligned} \tag{A4}$$

which is Eq. (5.4b).

(Received 6 August 2004; accepted 1 October 2004; published online 5 January 2005)

A set of ordinary differential equations is derived employing the method of differentiable forms so as to describe the quantum mechanics of a particle constrained to move on a general two-dimensional surface of revolution. Eigenvalues and eigenstates are calculated quasianalytically in the case of a finite cylinder (finite along the axis) and compared with the eigenvalues and eigenstates of a full three-dimensional Schrödinger problem corresponding to a hollow cylinder in the limit where the inner and outer radii approach each other. Good agreement between the two models is obtained for a relative difference less than 20% in inner and outer radii. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1829376]

I. INTRODUCTION

With the recent advances in nanotechnology,[1] it is now possible to grow quasi-two-dimensional surfaces of almost arbitrary shape where quantum effects play a major role.[2] Examples include single crystal $NbSe_3$ Möbius strips,[3] spherical CdSe–ZnS core-shell quantum dots,[4] and Si nanowire and nanoribbon transistors.[5] Due to the confinement of the quantum-mechanical particle to a two-dimensional surface, differential geometry methods offer certain advantages above the usual three-dimensional treatment of Schrödinger-equation problems in determining eigenvalues and eigenstates. Several publications have appeared on the constrainment of quantum-mechanical particles (with applications in, e.g., standard Schrödinger equation problems and relativistic Dirac equation problems) to a two-dimensional surface since the original works by Jensen and Koppe, da Costa[6–8] clarified that physical properties of two-dimensional systems in general depend on the surrounding three-dimensional space.

In the present work, we derive the three-dimensional Schrödinger equation in curvilinear coordinates u^1, u^2, u^3 with $u^3=0$ defining the two-dimensional surface to which the particle is confined. The resulting representation of the Schrödinger equation in u^1, u^2, u^3 can be separated into three ordinary differential equations (one for each u^i, $i=1,2,3$) for any surface of revolution. In doing this, simple equations are obtained relevant to the more general case of surfaces than those considered in Ref. 9 where the surface was restricted to obey the relation $z=S(r)$ where z, r are the axial and radial cylinder coordinates, respectively.

Next, we solve the problem of a particle confined to the surface of a finite cylinder and determine eigenvalues and eigenstates analytically. The corresponding eigenvalues and eigenstates of a hollow cylinder in three dimensions is also solved quasianalytically. In particular, we show that three-dimensional results for a thin hollow cylinder agree very well with results obtained by performing a quasi-two-dimensional differential form analysis of the Schrödinger equation.

II. SCHRÖDINGER's EQUATION IN CURVED COORDINATES

Let (u^1,u^2,u^3) be *normal coordinates* in $\mathbb{R}^3$ with respect to a surface Σ embedded in $\mathbb{R}^3$, i.e., u^1,u^2 are coordinates on the surface and u^3 is the distance to the surface. A simple calculation

shows that the volume element in $\mathbb{R}^3$ is $F\sqrt{g}\,\mathrm{d}u^1\,\mathrm{d}u^2\,\mathrm{d}u^3$, where $F=1-2Mu^3+K(u^3)^2$, and M and K denote the mean and Gaussian curvature, respectively. If we let $\chi=\sqrt{F}\phi$, then we can write the Laplacian in $\mathbb{R}^3$ acting on ψ as

$$\sqrt{F}\Delta_{\mathbb{R}^3}\psi=(\Delta_0+u^3\Delta_1+(u^3)^2\Delta_2+\cdots)\chi+\partial_3^2\chi, \tag{1}$$

where Δ_k, $k=0,1,2,\ldots$ are operators on Σ. In particular,

$$\Delta_0=\Delta_\Sigma+(M^2-K), \tag{2}$$

see Ref. 7, where Δ_Σ is the Laplace–Beltrami operator on Σ,

$$\Delta_\Sigma=g^{-1/2}\partial_\beta g^{\alpha\beta}g^{1/2}\partial_\beta=g^{\alpha\beta}\partial_\alpha\partial_\beta+\left(\frac{g^{\alpha\beta}}{2}\frac{\partial_\beta g}{g}+\partial_\beta g^{\alpha\beta}\right)\partial_\alpha, \tag{3}$$

and $\partial_\alpha=\partial/\partial u^\alpha$, $g_{\alpha\beta}$ are the components of the metric tensor, $g=\det[g_{\alpha\beta}]$ and $[g^{\alpha\beta}]=[g_{\alpha\beta}]^{-1}$ (see Ref. 6).

We now specialize to a *surface of revolution*. It can be parametrized as $\mathbf{x}(u^1,u^2)=(r(u^1)\cos u^2, r(u^1)\sin u^2, z(u^1))$, where $(r(u^1),z(u^1))$ is a curve in the xz plane. The metric tensor is given by $g_{11}=r'(u^1)^2+z'(u^1)^2$, $g_{22}=r(u^1)^2$, and $g_{12}=g_{21}=0$, and the principal curvatures are $\kappa_1=\kappa(u^1)=(r'z''-z'r'')/(r'^2+z'^2)^{3/2}$ and $\kappa_2=z'/r\sqrt{r'^2+z'^2}$, see Ref. 10. The mean and Gaussian curvature are $\frac{1}{2}(\kappa_1+\kappa_2)$ and $\kappa_1\kappa_2$, respectively, so $M^2-K=\frac{1}{4}(\kappa_1-\kappa_2)^2$ and

$$\Delta_0=\frac{\partial_1^2}{r'^2+z'^2}+\frac{\partial_2^2}{r^2}+\left(\frac{r'}{r(r'^2+z'^2)}-\frac{r'r''+z'z''}{(r'^2+z'^2)^2}\right)\partial_1+\frac{1}{4}\frac{1}{r'^2+z'^2}\left(\frac{r'z''-z'r''}{r'^2+z'^2}-\frac{z'}{r}\right)^2. \tag{4}$$

If the curve $(r(u^1),z(u^1))$ is parametrized by arc length, i.e., $r'^2+z'^2=1$, the expression simplifies to

$$\Delta_0=\partial_1^2+\frac{\partial_2^2}{r^2}-\frac{r'}{r}\partial_1+\frac{1}{4}\left(r'z''-z'r''-\frac{z'}{r}\right)^2. \tag{5}$$

For the sake of completeness, let us next write the Schrödinger equation in curved coordinates for a particle confined to the surface $(u^1,u^2,u^3=0)$,

$$\frac{-\hbar^2}{2m}(\Delta_0+\partial_3^2)\chi(u^1,u^2,u^3)+V(u^1,u^2,u^3)\chi(u^1,u^2,u^3)=E\chi(u^1,u^2,u^3), \tag{6}$$

where the Laplacian is as given by Eq. (2), and

$$V(u^1,u^2,u^3)=\begin{cases}0 & \text{if } |u^3|\leqslant\epsilon_3,\\ \infty & \text{otherwise.}\end{cases} \tag{7}$$

For a surface of revolution, the Schrödinger equation can be written as three ordinary differential equations using the separation-of-variables method. Hence, assuming $\chi(u^1,u^2,u^3)=\chi_1(u^1)\chi_2(u^2)\chi_3(u^3)$ and inserting into Eq. (6) leads to [by use of the more general expression for Δ_0 given by Eqs. (4) and (7)]

$$\partial_1^2\chi_1+\left(\frac{r'}{r}-\frac{r'r''+z'z''}{r'^2+z'^2}\right)\partial_1\chi_1+\left(\frac{1}{4}\left(\frac{r'z''-z'r''}{r'^2+z'^2}-\frac{z'}{r}\right)^2-\left(c_1+\frac{c_2}{r^2}\right)(r'^2+z'^2)\right)\chi_1=0, \tag{8}$$

$$\partial_2^2\chi_2+c_2\chi_2=0, \tag{9}$$

$$\partial_3^2\chi_3+\left(\frac{2m(E-V(u^3))}{\hbar^2}+c_1\right)\chi_3=0. \tag{10}$$

III. ENERGY SPECTRUM OF A PARTICLE CONFINED TO THE SURFACE OF A FINITE CYLINDER

In the following, the possible energy eigenvalues of a particle obeying Schrödinger's equation confined to the surface of a finite cylinder with radius R and length L will be determined. First, a parametrization of the cylinder surface is defined by

$$(r(u^1),z(u^1)) = (R,u^1), \quad 0 \leqslant u^1 \leqslant L. \tag{11}$$

Inserting this into Eqs. (8)–(10) immediately yields

$$\partial_1^2\chi_1 + \left(\frac{1}{4R^2} - \frac{c_2}{R^2} - c_1\right)\chi_1 = 0, \tag{12}$$

$$\partial_2^2\chi_2 + c_2\chi_2 = 0, \tag{13}$$

$$\partial_3^2\chi_3 + \left(\frac{2m}{\hbar^2}E + c_1\right)\chi_3 = 0, \tag{14}$$

where c_1, c_2 are separation constants and $\chi(u^1,u^2,u^3) \equiv \chi_1(u^1)\chi_2(u^2)\chi_3(u^3)$.

Consider first the equation in u^2. The solution satisfying the periodic condition $\chi_2(2\pi) = \chi_2(0)$, is

$$\chi_2(u^2) = \exp(\pm i\sqrt{c_2}u^2) = \exp(ilu^2), \tag{15}$$

where l is an integer (positive or negative), i.e.,

$$c_2 = l^2. \tag{16}$$

Next, c_1 is determined from Eq. (12) by imposing the boundary conditions

$$\chi_1(u^1 = 0) = \chi_1(u^1 = L) = 0. \tag{17}$$

The corresponding solution is

$$\chi_1(u^1) = \sin\left(\sqrt{-\frac{c_2}{R^2} - c_1 + \frac{1}{4R^2}}u^1\right) = \sin\left(\frac{k\pi}{L}u^1\right), \quad k = 1,2,3,\ldots, \tag{18}$$

i.e.,

$$c_1 = -\left(\frac{k\pi}{L}\right)^2 - \frac{c_2}{R^2} + \frac{1}{4R^2} = -\left(\frac{k\pi}{L}\right)^2 - \frac{l^2}{R^2} + \frac{1}{4R^2}. \tag{19}$$

The remaining equation in u^3 can finally be solved—subject to the boundary conditions $\chi(u^1,u^2,u^3 = \pm\epsilon_3) = 0$,

$$\chi_3(u^3) = \sin\left(\frac{n\pi}{2\epsilon_3}(u^3 - \epsilon_3)\right), \quad n = 1,2,3,\ldots. \tag{20}$$

In other words, the energy spectrum is found from Eqs. (14), (19), and (20) and reads

$$E_{\mathrm{DG}} = \frac{\hbar^2}{2m}\left[\left(\frac{n\pi}{2\epsilon_3}\right)^2 + \left(\frac{k\pi}{L}\right)^2 + \frac{l^2}{R^2} - \frac{1}{4R^2}\right], \tag{21}$$

where $n = 1,2,3,\ldots$, $k = 1,2,3,\ldots$, and $l = 0,1,2,3,\ldots$ are quantum indices.

IV. ENERGY SPECTRUM OF A PARTICLE CONFINED TO A HOLLOW CYLINDER—THREE-DIMENSIONAL TREATMENT

The Schrödinger equation in cylindrical coordinates reads

$$\frac{\partial^2\psi}{\partial r^2}+\frac{1}{r}\frac{\partial\psi}{\partial r}+\frac{1}{r^2}\frac{\partial^2\psi}{\partial\theta^2}+\frac{\partial^2\psi}{\partial z^2}+\kappa(r)^2\psi=0, \tag{22}$$

where

$$\kappa(r)^2=\frac{2m}{\hbar^2}(E-V(r)), \tag{23}$$

for a potential depending on the radial coordinate r only. Here, $V(r)$ is a step potential confining the particle to the hollow cylinder, i.e.,

$$V(r)=\begin{cases}0 & \text{if } R_i\leqslant r\leqslant R_o,\\ \infty & \text{otherwise,}\end{cases} \tag{24}$$

and R_i (R_o) is the inner (outer) radius of the hollow cylinder. A separable solution in the region $R_i\leqslant r\leqslant R_o$ is sought in the form

$$\psi(r,\theta,z)=\rho(r)\Theta(\theta)Z(z), \tag{25}$$

where

$$\frac{\mathrm{d}^2Z}{\mathrm{d}z^2}=-k_{zk}^2Z, \tag{26}$$

$$\frac{\mathrm{d}^2\Theta}{\mathrm{d}\theta^2}=-l^2\Theta, \tag{27}$$

$$r^2\frac{\mathrm{d}^2\rho}{\mathrm{d}r^2}+r\frac{\mathrm{d}\rho}{\mathrm{d}r}+(k_{ln}^2r^2-l^2)\rho=0, \tag{28}$$

and $\kappa^2=k_{ln}^2+k_{zk}^2$. The potential $V(r)$ in Eq. (24) ensures that the wave function vanishes at the inner and outer radii positions, $\psi(r=R_i,\theta,z)=\psi(r=R_o,\theta,z)=0$. The solution for $Z(z)$ amenable with the boundary conditions $Z(z=0)=Z(z=L)=0$, is

$$Z(z)=\sin(k_{zk}z)=\sin\left(\frac{k\pi}{L}z\right),\quad k=1,2,3,\ldots\ . \tag{29}$$

The general solution to the Bessel equation [Eq. (28)] is

$$\rho(r)=AJ_l(k_{ln}r)+BY_l(k_{ln}r), \tag{30}$$

where A, B are numbers and J_l, Y_l are Bessel functions of order l of the first and second kind, respectively. Hence, the boundary conditions lead to the determinental equation for nontrivial solutions,

$$J_l(k_{ln}R_i)Y_l(k_{ln}R_o)-J_l(k_{ln}R_o)Y_l(k_{ln}R_i)=0. \tag{31}$$

Equation (31) can be easily solved for k_{ln}. Thus, the eigenstates correspond to an energy in the form,

$$E_{\mathrm{HC}}=\frac{\hbar^2(k_{ln}^2+k_{zk}^2)}{2m}=\frac{\hbar^2}{2m}\left(k_{ln}^2+\left(\frac{k\pi}{L}\right)^2\right). \tag{32}$$

TABLE I. Energy gaps ΔE_{DG} and the relative error $\delta(\epsilon)$, for a quantum-mechanical particle with mass m confined to a set of hollow cylinders with $R_i=(1-\epsilon)$ nm and $R_0=(1+\epsilon)$ nm, as calculated employing Eqs. (33) and (35), respectively. Length is measured in nm and other units are chosen such that $\hbar^2/2m\equiv 1$.

V. NUMERICAL RESULTS AND DISCUSSIONS

In this section, we compare results for eigenstates of electrons confined to a thin cylindrical shell employing the full three-dimensional Schrödinger equation and the quasi-two-dimensional Schrödinger equation based on differential-form methods using curvilinear coordinates (u^1,u^2,u^3) with u^3 nearly zero in the cylindrical shell. The energies E_{DG} and E_{HC} of the two theories are given by Eqs. (21) and (32), respectively, and we see that they have the term $(\hbar/2m)(k\pi/L)^2$ in common. The dominating term in (21) is $E_n=(\hbar/2m)(n\pi/2\epsilon)^2$ which is order of magnitudes larger than the other terms so in order to compare the two theories we will consider E_n as a reference energy and define the energy gap

$$\Delta E_{\mathrm{DG}} = E_{\mathrm{DG}} - E_n - \frac{\hbar}{2m}\left(\frac{k\pi}{L}\right)^2 = \frac{\hbar}{2m}\frac{4l^2-1}{4R^2}, \tag{33}$$

$$\Delta E_{\mathrm{HC}} = E_{\mathrm{HC}} - E_n - \frac{\hbar}{2m}\left(\frac{k\pi}{L}\right)^2 = \frac{\hbar}{2m}\left(k_{ln}^2 - \left(\frac{n\pi}{2\epsilon}\right)^2\right), \tag{34}$$

and the relative error

$$\delta = \frac{\Delta E_{\mathrm{HC}} - \Delta E_{\mathrm{DG}}}{\Delta E_{\mathrm{DG}}} = \frac{E_{\mathrm{HC}} - E_{\mathrm{DG}}}{\Delta E_{\mathrm{DG}}}. \tag{35}$$

The relative error δ can now be used to rewrite Eq. (32) so as to obtain the form

$$E_{\mathrm{HC}} = \frac{\hbar}{2m}\left[\left(\frac{n\pi}{2\epsilon}\right)^2 + \left(\frac{k\pi}{L}\right)^2 + (1+\delta)\frac{4l^2-1}{4R^2}\right], \tag{36}$$

where $R_o=R+\epsilon$ and $R_i=R-\epsilon$. Except for the term δ, which in most cases can be neglected, this is the same as Eq. (21). In Table I, we list the energy gap ΔE_{DG} and the relative error δ, as obtained for a hollow cylinder with $R=1$ nm and $\epsilon=10^{-4}R$, $10^{-3}R$, $10^{-2}R$, and $10^{-1}R$.

Evidently, the agreement is surprisingly good between the two models even for the case where ϵ is 10% of R. The eigenstates for the full three-dimensional problem are

$$\psi(r,\theta,z) = \sin\left(\frac{k\pi}{L}z\right)\exp(il\theta)\left(J_l(k_{ln}r) - \frac{J_l(k_{ln}R_o)}{Y_l(k_{ln}R_o)}Y_l(k_{ln}r)\right), \tag{37}$$

corresponding to the energy eigenvalues given by Eq. (32). Similarly, the eigenstates for the two-dimensional problem are

$$\chi(r,\theta,z) = \sin\left(\frac{k\pi}{L}u^1\right)\exp(ilu^2)\chi_3(u^3), \tag{38}$$

with

$$\chi_3(u^3) = \sin\left(\frac{n\pi}{2\epsilon_3}(u^3-\epsilon_3)\right), \quad n = 1,2,3,\ldots, \tag{39}$$

corresponding to the energy eigenvalues given by Eq. (21). Note that these eigenstates are exactly the same in their z and θ dependencies (or u^1 and u^2 dependencies) since $u^1 \in [0;L]$, $u^2 \in [0;2\pi[$, $\theta \in [0;2\pi[$, and $z \in [0;L]$ with k, l, and n integers. This could in fact have been seen beforehand. Indeed, for the cylinder we have $u^1=z$, $u^2=\theta$, and $u^3=R-r$. So the equation $\chi = \sqrt{F}\psi = \sqrt{1-u^3/R}\psi$ gives us in the limit $\epsilon^3 \to 0$ that $\chi_1(u^1)=Z(z)$ and $\chi_2(u^2)=\Theta(\theta)$. For the sake of completeness we note that the exact equation for χ is

$$-\frac{\hbar^2}{2m}\left(\partial_1^2 + \frac{1}{(R-u^3)^2}\partial_2^2 + \partial_3^2 - \frac{1}{4(R-u^3)^2}\right)\chi + V(u^3)\chi = E\chi, \tag{40}$$

and in Sec. III the factor $(R-u^3)^{-2}$ in Eq. (40) is replaced with the zeroth order term R^{-2}.

We would like to point out that we obtain the same result for an annulus in $\mathbb{R}^2$ as for the hollow cylinder in $\mathbb{R}^3$, except that in the former case, the u^1 dependence disappears in the eigenstates as does the term $(k\pi/L)^2$ in the corresponding energy eigenvalue expressions. However, the $1/4R^2$ contribution to the energy also appears in the annulus problem as this term reflects radial confinement of the quantum-mechanical particle.

VI. CONCLUSIONS

The Schrödinger equation in curvilinear coordinates (u^1,u^2,u^3) is derived where $(u^1,u^2,u^3=0)$ describes the two-dimensional surface to which a quantum-mechanical particle is confined. In the case of a surface of revolution it is possible to separate the Schrödinger equation in curvilinear coordinates so as to obtain three ordinary differential equations. As an example, energy eigenvalues and eigenstates are determined quasianalytically for the case of confinement to a finite cylindrical surface. Results are in good agreement with corresponding full three-dimensional results of a hollow cylinder in the case where the inner and outer radii approach each other.

Quantum integrability of bosonic massive Thirring model in continuum

Tanaya Bhattacharyya[a)]
Theory Group, Saha Institute of Nuclear Physics, 1/AF Bidhan Nagar, Kolkata 700 064, India

(Received 16 June 2004; accepted 8 September 2004; published online 23 December 2004)

By using a variant of the quantum inverse scattering method, commutation relations between all elements of the quantum monodromy matrix of the bosonic massive Thirring (BMT) model are obtained. Using those relations, the quantum integrability of BMT model is established and the *S*-matrix of two-body scattering between the corresponding quasiparticles has been obtained. It is observed that for some special values of the coupling constant, there exists an upper bound on the number of quasiparticles that can form a quantum-soliton state of the BMT model. We also calculate the binding energy for a *N*-soliton state of the quantum BMT model. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1818722]

I. INTRODUCTION

Quantum integrable field models in $1+1$ dimensions are objects of interest due to their close connections with different areas of physics as well as mathematics.[1–10] These integrable theories have played an important role in understanding the basic nonperturbative aspects of physical theories relevant in the realistic $3+1$ dimensional models. Through quantum inverse scattering method (QISM) one can establish the integrability property of these models and obtain the spectrum as well as different correlation functions of the corresponding models.[4]

Massive Thirring model in $1+1$ dimensions has been widely studied as a toy counterpart to low energy QCD, since it does not include many of the complications arising in $3+1$ dimensions. The study of a nonlocal massless Thirring model is relevant, not only from a purely field theoretical point of view but also because of its connection with the physics of strongly correlated systems in one spatial dimension. This model describes an ensemble of nonrelativistic particles coupled through a two-body forward-scattering potential and displays Luttinger-liquid behavior[11] that can play a role in real one-dimensional semiconductors.[12]

Massive Thirring model in $1+1$ dimensions can be treated through QISM for both bosonic and fermionic field operators.[6] In this paper, we shall focus our attention to the bosonic massive Thirring (BMT) model. The classical version of the BMT model is described by the Hamiltonian

$$H=\int_{-\infty}^{\infty}\mathrm{d}x\left[-\frac{i}{2}\left\{\left(\phi_1^*\frac{\partial\phi_1}{\partial x}-\frac{\partial\phi_1^*}{\partial x}\phi_1\right)-\left(\phi_2^*\frac{\partial\phi_2}{\partial x}-\frac{\partial\phi_2^*}{\partial x}\phi_2\right)\right\}-(\phi_1^*\phi_2+\phi_2^*\phi_1)-4\xi\phi_1^*\phi_2^*\phi_2\phi_1\right] \tag{1.1}$$

with the equal time Poisson bracket (PB) relations,

$$\{\phi_1(x),\phi_1(y)\}=\{\phi_1^*(x),\phi_1^*(y)\}=0,\ \ \{\phi_1(x),\phi_1^*(y)\}=-i\delta(x-y),$$

a)Electronic mail: tanaya@theory.saha.ernet.in

$$\{\phi_2(x),\phi_2(y)\}=\{\phi_2^*(x),\phi_2^*(y)\}=0,\ \ \{\phi_2(x),\phi_2^*(y)\}=-i\delta(x-y). \tag{1.2}$$

It is well known that this BMT model is intimately connected with the derivative nonlinear Schrödinger (DNLS) model. In fact, one can generate the Lax operator of the BMT model by "fusing" two Lax operators of DNLS model with different spectral parameters.[13] The integrability of the classical DNLS model, possessing ultralocal PB structure, can be established from the fact that the corresponding monodromy matrix satisfies the classical Yang–Baxter equation.[14] The quantized version of this DNLS model also preserves the integrability property. By applying QISM, the quantum integrability of DNLS model is established and the Bethe eigenstates for all conserved quantities have been constructed.[14,15]

In an earlier work by Kulish and Sklyanin,[6] the Lax operator and the corresponding *R*-matrix for the quantum BMT model has been given, though the detailed calculations are not being explicitly shown. Moreover, the quantum Yang–Baxter equation (QYBE) at the infinite interval limit and hence the corresponding commutation relation between the creation and annihilation operators have not been studied. However, it is evident that taking the infinite interval limit of the monodromy matrix and corresponding QYBE is necessary to get the spectrum for the quantum version of the Hamiltonian (1.1). In this context it may be mentioned that, by applying a variant of the QISM[3] which is directly applicable to field theoretical models, the quantum DNLS model has been shown to be integrable.[15,16] The infinite interval limit of the corresponding QYBE enabled us to obtain the spectrum of all the conserved quantities including the Hamiltonian and also the two-particle *S*-matrix. Therefore, it is interesting to explore the integrability property of the quantum BMT model by using the same variant of QISM that we applied for the DNLS model. It may be noted that the one-dimensional Hubbard model has been treated earlier through algebraic Bethe ansatz in the infinite interval limit. As an advantage of taking this infinite interval limit, the commutation relations among various elements of the corresponding monodromy matrix are obtained in a much simpler form.[17] In this paper our aim is to establish the integrability property of the quantum BMT model and to obtain the spectrum of all conserved quantities including the Hamiltonian by using the QISM at an infinite interval limit.

The arrangement of this paper is as follows. In Sec. II, we consider the classical BMT model and evaluate the PB relations among the various elements of the corresponding monodromy matrix at the infinite interval limit. Using these PB relations, the integrability of the classical BMT model can be established in the Liouville sense. In this section we also derive the expressions for the classical conserved quantities of the BMT model. In Sec. III, we construct the quantum monodromy matrix of the BMT model on a finite interval and derive the corresponding QYBE. In Sec. IV, we consider the infinite interval limit of QYBE and obtain the commutation relations among the various elements of the corresponding quantum monodromy matrix. Such commutation relations allow us to construct exact eigenstates for the quantum conserved quantities of the BMT model by using the prescription of algebraic Bethe ansatz. In particular we are able to obtain the spectrum for the quantum version of the Hamiltonian (1.1). Furthermore we obtain the commutation relation between creation and annihilation operators of quasiparticles associated with the BMT model and find out the *S*-matrix of two-body scattering among such quasiparticles. In this section we also calculate the binding energy for a *N*-soliton state of the quantum BMT model. Section V is the concluding section.

II. INTEGRABILITY OF THE CLASSICAL MASSIVE THIRRING MODEL

The classical version of the BMT model is described by the Lax operator,[6]

$$U(x,\lambda)=i\begin{pmatrix}\xi\{\rho_1(x)-\rho_2(x)\}-\frac{1}{4}\left\{\lambda^2-\frac{1}{\lambda^2}\right\} & \xi\left\{\lambda\phi_1^*(x)-\frac{1}{\lambda}\phi_2^*(x)\right\}\\ \lambda\phi_1(x)-\frac{1}{\lambda}\phi_2(x) & -\xi\{\rho_1(x)-\rho_2(x)\}+\frac{1}{4}\left\{\lambda^2-\frac{1}{\lambda^2}\right\}\end{pmatrix}, \tag{2.1}$$

where $\rho_1(x)=\phi_1^*(x)\phi_1(x)$, $\rho_2(x)=\phi_2^*(x)\phi_2(x)$, λ is the spectral parameter and ξ is the coupling constant of the theory. The bosonic fields $\phi_1(x)$, $\phi_2(x)$ satisfy the PB relations (1.2) and vanish at

$|x| \to \infty$ limit. The monodromy matrix on finite and infinite intervals are defined as

$$T_{x_1}^{x_2}(\lambda) = \mathcal{P} \exp \int_{x_1}^{x_2} U(x,\lambda) \mathrm{d}x \tag{2.2}$$

and

$$T(\lambda) = \lim_{\substack{x_2 \to +\infty \\ x_1 \to -\infty}} e(-x_2,\lambda) \left\{ \mathcal{P} \exp \int_{x_1}^{x_2} U(x,\lambda) \mathrm{d}x \right\} e(x_1,\lambda), \tag{2.3}$$

respectively, where $\mathcal{P}$ denotes the path ordering and $e(x,\lambda) = e^{-(i/4)\{\lambda^2 - (1/\lambda^2)\}\sigma_3 x}$.

First, we want to investigate the symmetry properties of the monodromy matrix (2.3). It is easy to check that, the Lax operator (2.1) satisfies the relations

$$U(x,\lambda)^* = K U(x,\lambda^*) K, \tag{2.4a}$$

$$U(x,-\lambda) = K' U(x,\lambda) K', \tag{2.4b}$$

where $K = \begin{pmatrix} 0 & \sqrt{-\xi} \\ 1/\sqrt{-\xi} & 0 \end{pmatrix}$ and $K' = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. By using these relations, we find that the symmetries of the monodromy matrix $T(\lambda)$ (2.3) are given by

$$T(\lambda)^* = K T(\lambda^*) K, \tag{2.5a}$$

$$T(-\lambda) = K' T(\lambda) K'. \tag{2.5b}$$

Due to the relation (2.5a), $T(\lambda)$ can be expressed in the form

$$T(\lambda) = \begin{pmatrix} a(\lambda) & -\xi b^*(\lambda) \\ b(\lambda) & a^*(\lambda) \end{pmatrix}, \tag{2.6}$$

where λ is taken as a real parameter. Moreover, by using the symmetry relation (2.5b), it is easy to see that $a(-\lambda) = a(\lambda)$ and $b(-\lambda) = -b(\lambda)$. Therefore, it is sufficient to derive the PB relations among the elements of $T(\lambda)$ only for $\lambda \geqslant 0$.

Next, our aim is to calculate the classical conserved quantities of the BMT model by using the approach described in Ref 2. From (2.2), one obtains the differential equation followed by the monodromy matrix $T_{x_1}^{x_2}(\lambda)$ as

$$\frac{\partial}{\partial x_2} T_{x_1}^{x_2}(\lambda) = U(x_2,\lambda) T_{x_1}^{x_2}(\lambda). \tag{2.7}$$

Now, let us decompose the monodromy matrix in the form

$$T_{x_1}^{x_2}(\lambda) = (1 + W(x_2,\lambda)) \exp Z(x_2,x_1,\lambda) (1 + W(x_1,\lambda)), \tag{2.8}$$

where $Z(x_2,x_1,\lambda)$ is a diagonal matrix and $W(x,\lambda)$ is a nondiagonal one. The Lax operator of the classical BMT model can be expressed as $U(x,\lambda) = U_d(x,\lambda) + U_{nd}(x,\lambda)$, where $U_d(x,\lambda)$ is the diagonal part and $U_{nd}(x,\lambda)$ is the nondiagonal part of $U(x,\lambda)$. Using the above expression of the Lax operator $U(x,\lambda)$ (2.1), the differential equation (2.7) can be decomposed into

$$\frac{\mathrm{d}Z}{\mathrm{d}x} = U_d + U_{nd} W, \tag{2.9a}$$

$$\frac{dW}{dx} - 2U_d W - U_{nd} + WU_{nd}W = 0. \tag{2.9b}$$

The structure of the Lax operator (2.1) ensures that $W(x_2,\lambda)$ and $Z(x_2,x_1,\lambda)$ can be written in the form

$$W(x_2,\lambda) = -\xi w^*(x_2,\lambda)\sigma_+ + w(x_2,\lambda)\sigma_-,$$

$$Z(x_2,x_1,\lambda) = z(x_2,x_1,\lambda)\sigma_3.$$

Substituting Eqs. (2.6) and (2.8) in the expression (2.3), and using $W(x,\lambda)\to 0$ at $|x|\to\infty$ limit, one obtains

$$\ln a(\lambda) = \lim_{\substack{x_2\to+\infty \\ x_1\to-\infty}} \left\{ z(x_2,x_1,\lambda) + \frac{i\lambda^2}{4}(x_2 - x_1) \right\}.$$

Substituting the explicit form of $z(x_2,x_1,\lambda)$ [as obtained by integrating Eq. (2.9a)] to the above expression, we get the following form of $\ln a(\lambda)$:

$$\ln a(\lambda) = i\xi \int_{-\infty}^{+\infty} \{\phi_1^*\phi_1 - \phi_2^*\phi_2\}dx + i\xi\lambda \int_{-\infty}^{+\infty} \phi_1^* w dx - \frac{i\xi}{\lambda}\int_{-\infty}^{+\infty} \phi_2^* w dx. \tag{2.10}$$

Next, we expand $w(x,\lambda)$ in inverse powers of λ as

$$w(x,\lambda) = \sum_{j=0}^{\infty} \frac{w_j}{\lambda^{2j+1}}.$$

Using the differential Eq. (2.9b) followed by $W(x,\lambda)$, the expansion coefficient w_j's can be obtained explicitly in a recursive way. The first few nonzero w_j's are given by

$$w_0 = -2\phi_1, \quad w_2 = 4i\phi_{1_x} + 8\xi\phi_1(\phi_2^*\phi_2) + 2\phi_2.$$

Substituting w_j's in the expression of $\ln a(\lambda)$ (2.10), one gets

$$\ln a(\lambda) = \sum_{n=0}^{\infty} \frac{iC_n}{\lambda^{2n}},$$

where C_n's represent an infinite set of conserved quantities. The first two of them are explicitly given by

$$C_0 = -\xi \int_{-\infty}^{+\infty} \{\phi_1^*\phi_1 + \phi_2^*\phi_2\}dx, \tag{2.11a}$$

$$C_1 = 4i\xi \int_{-\infty}^{+\infty} \phi_1^*\phi_{1x}\, dx + 2\xi \int_{-\infty}^{+\infty} \{\phi_1^*\phi_2 + \phi_2^*\phi_1\}dx + 8\xi^2 \int_{-\infty}^{+\infty} (\phi_1^*\phi_1)(\phi_2^*\phi_2)dx. \tag{2.11b}$$

Next we expand $w(x,\lambda)$ in powers of λ as

$$w(x,\lambda) = \sum_{j=0}^{\infty} \tilde{w}_j \lambda^{2j+1}.$$

In a similar way as above, using (2.9b), the first few nonzero $\tilde{w}_j$'s can be obtained as

$$\tilde{w}_0 = -2\phi_2, \quad \tilde{w}_2 = -4i\phi_{2_x} + 8\xi(\phi_1^*\phi_1)\phi_2 + 2\phi_1.$$

Correspondingly, Eq. (2.10) yields

$$\ln a(\lambda) = \sum_{n=0}^{\infty} i\tilde{C}_n\lambda^{2n},$$

where $\tilde{C}_n$'s represent another infinite set of conserved quantities. The first two of them are explicitly given by

$$\tilde{C}_0 = \xi\int_{-\infty}^{+\infty}\{\phi_1^*\phi_1 + \phi_2^*\phi_2\}\mathrm{d}x, \tag{2.12a}$$

$$\tilde{C}_1 = 4i\xi\int_{-\infty}^{+\infty}\phi_2^*\phi_{2_x}\,\mathrm{d}x - 2\xi\int_{-\infty}^{+\infty}\{\phi_1^*\phi_2 + \phi_2^*\phi_1\}\mathrm{d}x - 8\xi^2\int_{-\infty}^{+\infty}(\phi_1^*\phi_1)(\phi_2^*\phi_2)\mathrm{d}x. \tag{2.12b}$$

Now by combining these two sets of conserved quantities, the mass, momentum, and the Hamiltonian of classical BMT model can be expressed in the following way:

$$N = -\frac{1}{2\xi}(C_0 - \tilde{C}_0) = \int_{-\infty}^{+\infty}(\phi_1^*\phi_1 + \phi_2^*\phi_2)\mathrm{d}x,$$

$$P = -\frac{1}{4\xi}(C_1 + \tilde{C}_1) = \int_{-\infty}^{+\infty}(\phi_1^*\phi_{1x} + \phi_2^*\phi_{2x})\mathrm{d}x$$

$$H = -\frac{1}{4\xi}(C_1 - \tilde{C}_1) = \int_{-\infty}^{\infty}[-i(\phi_1^*\phi_{1_x} - \phi_2^*\phi_{2_x}) - \{\phi_1^*\phi_2 + \phi_2^*\phi_1\} - 4\xi\phi_1^*\phi_2^*\phi_2\phi_1]\mathrm{d}x.$$

Next, we want to derive the PB relations among the elements of $T(\lambda)$ (2.6). We apply the equal time PB relations (1.2) between the basic field variables to evaluate the PB relations among the elements of the Lax operator (2.1) and find that

$$\{U(x,\lambda) \overset{\otimes}{,} U(y,\mu)\} = [r(\lambda,\mu), U(x,\lambda)\otimes 1 + 1\otimes U(y,\mu)]\delta(x-y), \tag{2.13}$$

where

$$r(\lambda,\mu) = -\xi\{t^c\sigma_3\otimes\sigma_3 + s^c(\sigma_+\otimes\sigma_- + \sigma_-\otimes\sigma_+)\} \tag{2.14}$$

with

$$t^c = \frac{\lambda^2+\mu^2}{2(\lambda^2-\mu^2)}, \quad s^c = \frac{2\lambda\mu}{\lambda^2-\mu^2}.$$

Now, by using Eqs. (2.13) and (2.3), one obtains

$$\{T(\lambda) \overset{\otimes}{,} T(\mu)\} = r_+(\lambda,\mu)T(\lambda)\otimes T(\mu) - T(\lambda)\otimes T(\mu)r_-(\lambda,\mu), \tag{2.15}$$

where

$$r_\pm = -\xi(t^c\sigma_3\otimes\sigma_3 + s_\pm^c\sigma_+\otimes\sigma_- + s_\mp^c\sigma_-\otimes\sigma_+),$$

with $s_\pm^c = \pm 2i\pi\lambda^2\delta(\lambda^2-\mu^2)$. By substituting the symmetric form of $T(\lambda)$ (2.6) to Eq. (2.15) and comparing the individual elements in both sides, we obtain

$$\{a(\lambda),a(\mu)\}=0, \tag{2.16a}$$

$$\{a(\lambda),a^*(\mu)\}=0, \tag{2.16b}$$

$$\{b(\lambda),b(\mu)\}=0, \tag{2.16c}$$

$$\{a(\lambda),b(\mu)\}=\xi\left(\frac{\lambda^2+\mu^2}{\lambda^2-\mu^2}\right)a(\lambda)b(\mu)-2i\pi\xi\lambda^2\delta(\lambda^2-\mu^2)b(\lambda)a(\mu), \tag{2.16d}$$

$$\{a(\lambda),b^*(\mu)\}=-\xi\left(\frac{\lambda^2+\mu^2}{\lambda^2-\mu^2}\right)a(\lambda)b^*(\mu)+2i\pi\xi\lambda^2\delta(\lambda^2-\mu^2)b^*(\lambda)a(\mu), \tag{2.16e}$$

$$\{b(\lambda),b^*(\mu)\}=-4i\pi\lambda^2\delta(\lambda^2-\mu^2)|a(\lambda)|^2. \tag{2.16f}$$

From Eq. (2.16a) it follows that all expansion coefficients occurring in the expansions of $\ln a(\lambda)$ will have vanishing PB relations among themselves. Hence, the following expressions will hold true

$$\{C_m,C_n\}=\{\tilde{C}_m,\tilde{C}_n\}=\{C_m,\tilde{C}_n\}=0,$$

for all values of m and n. Since the mass, momentum, and the Hamiltonian of the classical BMT model has been expressed in terms of the expansion coefficients C_n and $\tilde{C}_n$'s, all of them will have vanishing PB relations among themselves. Thus the integrability property of the classical BMT model, described by the Hamiltonian (1.1), is established in the Liouville sense.

III. COMMUTATION RELATIONS FOR THE QUANTUM MONODROMY MATRIX ON A FINITE INTERVAL

By using a version of QISM which is directly applicable to field models,[3] in this section we shall show that the quantum monodromy matrix of the BMT model on a finite interval satisfies QYBE. The basic field operators of the quantum BMT model satisfy the following equal time commutation relations:

$$[\phi_1(x),\phi_1(y)]=[\phi_1^\dagger(x),\phi_1^\dagger(y)]=0,\ \ [\phi_1(x),\phi_1^\dagger(y)]=\hbar\delta(x-y),$$

$$[\phi_2(x),\phi_2(y)]=[\phi_2^\dagger(x),\phi_2^\dagger(y)]=0,\ \ [\phi_2(x),\phi_2^\dagger(y)]=\hbar\delta(x-y), \tag{3.1}$$

and the vacuum state is defined through the relations $\phi_1(x)|0\rangle=\phi_2(x)|0\rangle=0$.

In analogy with the classical Lax operator (2.1), we assume that the quantum Lax operator of BMT model is given by

$$\mathcal{U}_q(x,\lambda)=i\begin{pmatrix} f_1\rho_1(x)-f_2\rho_2(x)-\dfrac{\lambda^2}{4}+\dfrac{1}{4\lambda^2} & \xi\lambda\phi_1^\dagger(x)-\dfrac{\xi}{\lambda}\phi_2^\dagger(x) \\ \lambda\phi_1(x)-\dfrac{1}{\lambda}\phi_2(x) & -g_1\rho_1(x)+g_2\rho_2(x)+\dfrac{\lambda^2}{4}-\dfrac{1}{4\lambda^2}\end{pmatrix}, \tag{3.2}$$

where $\rho_1(x)=\phi_1^\dagger(x)\phi_1(x)$, $\rho_2(x)=\phi_2^\dagger(x)\phi_2(x)$ and f_1,f_2,g_1,g_2 are four parameters which will be determined later in this section through QYBE. Using the Lax operator (3.2), the quantum monodromy matrix on a finite interval is defined as

$$\mathcal{T}_{x_1}^{x_2}(\lambda) =: \mathcal{P}\exp\int_{x_1}^{x_2}\mathcal{U}_q(x,\lambda)\mathrm{d}x:, \tag{3.3}$$

where the symbol $::$ denotes the normal ordering of operators. This quantum monodromy matrix (3.3) satisfies a differential equation given by

$$\begin{aligned}\frac{\partial}{\partial x_2}\mathcal{T}_{x_1}^{x_2}(\lambda) =: \mathcal{U}_q(x_2,\lambda)\mathcal{T}_{x_1}^{x_2}(\lambda): = &-\frac{i}{4}\left\{\lambda^2-\frac{1}{\lambda^2}\right\}\sigma_3\mathcal{T}_{x_1}^{x_2}(\lambda)+i\xi\lambda\phi_1^\dagger(x_2)\sigma_+\mathcal{T}_{x_1}^{x_2}(\lambda)\\ &-\frac{i\xi}{\lambda}\phi_2^\dagger(x_2)\sigma_+\mathcal{T}_{x_1}^{x_2}(\lambda)+i\lambda\sigma_-\mathcal{T}_{x_1}^{x_2}(\lambda)\phi_1(x_2)-\frac{i}{\lambda}\sigma_-\mathcal{T}_{x_1}^{x_2}(\lambda)\phi_2(x_2)\\ &+if_1\phi_1^\dagger(x_2)e_{11}\mathcal{T}_{x_1}^{x_2}(\lambda)\phi_1(x_2)-if_2\phi_2^\dagger(x_2)e_{11}\mathcal{T}_{x_1}^{x_2}(\lambda)\phi_2(x_2)\\ &-ig_1\phi_1^\dagger(x_2)e_{22}\mathcal{T}_{x_1}^{x_2}(\lambda)\phi_1(x_2)+ig_2\phi_2^\dagger(x_2)e_{22}\mathcal{T}_{x_1}^{x_2}(\lambda)\phi_2(x_2),\end{aligned} \tag{3.4}$$

where $e_{11}=\frac{1}{2}(1+\sigma_3)$ and $e_{22}=\frac{1}{2}(1-\sigma_3)$. Now, to apply QISM, we must find out the differential equation satisfied by the product $\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu)$. By using the basic commutation relations (3.1) and the method of "extension,"[3] we find that the product of two monodromy matrices satisfies the following differential equation (detail calculations are given in the Appendix):

$$\frac{\partial}{\partial x_2}(\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu)) = \vdots\ \mathcal{L}(x_2;\lambda,\mu)\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu)\ \vdots\ , \tag{3.5}$$

where

$$\mathcal{L}(x;\lambda,\mu)=\mathcal{U}_q(x,\lambda)\otimes\mathbb{1}+\mathbb{1}\otimes\mathcal{U}_q(x,\mu)+\mathcal{L}_\Delta(x;\lambda,\mu), \tag{3.6}$$

with

$$\mathcal{L}_\Delta(x;\lambda,\mu)=\begin{pmatrix}-\hbar f_1^2\rho_1(x) & -\hbar\xi\mu f_1\phi_1^\dagger(x) & 0 & 0\\ -\hbar f_2^2\rho_2(x) & -\dfrac{\hbar\xi}{\mu}f_2\phi_2^\dagger(x) & & \\ 0 & \hbar g_1 f_1\rho_1(x) & 0 & 0\\ & +\hbar g_2 f_2\rho_2(x) & & \\ -\hbar\lambda f_1\phi_1(x) & -\hbar\xi\left\{\lambda\mu+\dfrac{1}{\lambda\mu}\right\} & \hbar g_1 f_1\rho_1(x) & \hbar\xi\mu g_1\phi_1^\dagger(x)\\ -\dfrac{\hbar f_2}{\lambda}\phi_2(x) & & +\hbar g_2 f_2\rho_2(x) & +\dfrac{\hbar\xi g_2}{\mu}\phi_2^\dagger(x)\\ 0 & \hbar\lambda g_1\phi_1(x) & 0 & -\hbar g_1^2\rho_1(x)\\ & +\dfrac{\hbar g_2}{\lambda}\phi_2(x) & & -\hbar g_2^2\rho_2(x)\end{pmatrix}. \tag{3.7}$$

In the expression (3.5), the sign of normal arrangement of operator factors is taken as $\vdots\,\vdots$. The sign $\vdots\,\vdots$, applied to the product of several operator factors (including ϕ_1, ϕ_2, $\phi_1^\dagger$, and $\phi_2^\dagger$), ensures the arrangement of all $\phi_1^\dagger$, $\phi_2^\dagger$ on the left, and all ϕ_1, ϕ_2 on the right, *without altering the order of the remaining factors*. For example,

$$:X\phi_1\phi_2\phi_1^\dagger\phi_2^\dagger Y: = \phi_1^\dagger\phi_2^\dagger XY\phi_1\phi_2,$$

where X and Y may in general be taken as some functions of the basic field operators.

Now one can easily check that $\mathcal{L}(x;\lambda,\mu)$ (3.6) follows an equation given by

$$R(\lambda,\mu)\mathcal{L}(x;\lambda,\mu) = \mathcal{L}(x;\mu,\lambda)R(\lambda,\mu), \tag{3.7}$$

where $R(\lambda,\mu)$ is a (4×4) matrix of the form

$$R(\lambda,\mu) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & s(\lambda,\mu) & t(\lambda,\mu) & 0 \\ 0 & t(\lambda,\mu) & s(\lambda,\mu) & 0 \\ 0 & 0 & 0 & 1, \end{pmatrix}, \tag{3.8}$$

with

$$t(\lambda,\mu) = \frac{\lambda^2-\mu^2}{\lambda^2 q-\mu^2 q^{-1}},\quad s(\lambda,\mu) = \frac{(q-q^{-1})\lambda\mu}{\lambda^2 q-\mu^2 q^{-1}}$$

and $q=e^{-i\alpha}$. The above equation (3.7) enables us to determine the exact expressions of the parameters f_1, f_2, g_1, g_2, α in terms of the coupling constant ξ. We obtain

$$\hbar\xi = -\sin\alpha, \tag{3.9a}$$

$$f_1 = g_2 = \frac{\xi e^{-i\alpha/2}}{\cos\alpha/2}, \tag{3.9b}$$

$$g_1 = f_2 = \frac{\xi e^{i\alpha/2}}{\cos\alpha/2}. \tag{3.9c}$$

Using Eqs. (3.5) and (3.7), we find that the monodromy matrix (3.3) satisfies QYBE given by

$$R(\lambda,\mu)\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu) = \mathcal{T}_{x_1}^{x_2}(\mu)\otimes\mathcal{T}_{x_1}^{x_2}(\lambda)R(\lambda,\mu). \tag{3.10}$$

Using the above QYBE (3.10), the commutation relations among all elements of the quantum monodromy matrix (3.3) can be obtained easily.

Equations (3.9a), (3.9b), and (3.9c), describing the relations between f_1, f_2, g_1, g_2, α and the coupling constant ξ, provide the necessary conditions for the Lax operator (3.2) to satisfy QYBE (3.10). From Eq. (3.9a) we can conclude that, the above method of deriving QYBE for quantum BMT model is applicable only when the coupling constant ξ lies within the range $|\xi|\leqslant 1/\hbar$. The parameter α has a one-to-one correspondence with the coupling constant ξ for $-\pi/2\leqslant\alpha\leqslant\pi/2$. For the purpose of investigating the classical limit of the quantum Lax operator (3.2), we take the $\alpha\to 0$ limit which is equivalent to the $\hbar\to 0$ limit for a fixed value of ξ. From Eqs. (3.9b) and (3.9c), it follows that at this limit $f_1, f_2\to\xi$ and $g_1, g_2\to\xi$. Hence we find that the quantum Lax operator (3.2) correctly reproduces the classical Lax operator (2.1) at $\hbar\to 0$ limit.

IV. ALGEBRAIC BETHE ANSATZ FOR THE QUANTUM MONODROMY MATRIX ON AN INFINITE INTERVAL

The quantum monodromy matrix in an infinite interval is defined as

$$\mathcal{T}(\lambda) = \lim_{\substack{x_2 \to +\infty \\ x_1 \to -\infty}} e(-x_2,\lambda)\mathcal{T}_{x_1}^{x_2}(\lambda)e(x_1,\lambda), \tag{4.1}$$

where $\mathcal{T}_{x_1}^{x_2}(\lambda)$ is given by Eq. (3.3). Just as in the classical case, the quantum Lax operator (3.2) also satisfies the symmetry relations

$$\mathcal{U}_q(x,\lambda)^* = K\mathcal{U}_q(x,\lambda^*)K, \tag{4.2a}$$

$$\mathcal{U}_q(x,-\lambda) = K'\mathcal{U}_q(x,\lambda)K', \tag{4.2b}$$

where K and K' matrices have appeared earlier in Eq. (2.4). Using Eq. (4.2a), the quantum monodromy matrix (4.1) can be expressed in a symmetric form given by

$$\mathcal{T}(\lambda) = \begin{pmatrix} A(\lambda) & -\xi B^\dagger(\lambda) \\ B(\lambda) & A^\dagger(\lambda) \end{pmatrix}, \tag{4.3}$$

where λ is a real parameter. From Eq. (4.2b), it follows that $A(-\lambda)=A(\lambda)$ and $B(-\lambda)=-B(\lambda)$. So it is sufficient to obtain the commutation relations among the elements of the quantum monodromy matrix (4.3) only for $\lambda \geqslant 0$.

Now we aim to obtain the infinite interval limit of the QYBE satisfied by $\mathcal{T}(\lambda)$ (4.3). To this end, we split the $\mathcal{L}(x;\lambda,\mu)$ matrix (3.6) into two parts:

$$\mathcal{L}(x;\lambda,\mu) = \mathcal{L}_0(\lambda,\mu) + \mathcal{L}_1(x;\lambda,\mu),$$

where $\mathcal{L}_0(\lambda,\mu)$ is given by

$$\mathcal{L}_0(\lambda,\mu) = \lim_{|x|\to\infty} \mathcal{L}(x;\lambda,\mu) = \begin{pmatrix} -\frac{i}{4}(\lambda^2+\mu^2) + \frac{i}{4}\left(\frac{1}{\lambda^2}+\frac{1}{\mu^2}\right) & 0 & 0 & 0 \\ 0 & -\frac{i}{4}(\lambda^2-\mu^2) + \frac{i}{4}\left(\frac{1}{\lambda^2}-\frac{1}{\mu^2}\right) & 0 & 0 \\ 0 & -\hbar\xi\lambda\mu - \frac{\hbar\xi}{\lambda\mu} & \frac{i}{4}(\lambda^2-\mu^2) - \frac{i}{4}\left(\frac{1}{\lambda^2}-\frac{1}{\mu^2}\right) & 0 \\ 0 & 0 & 0 & \frac{i}{4}(\lambda^2+\mu^2) - \frac{i}{4}\left(\frac{1}{\lambda^2}+\frac{1}{\mu^2}\right) \end{pmatrix},$$

and $\mathcal{L}_1(x;\lambda,\mu)$ is the field dependent part of $\mathcal{L}(x;\lambda,\mu)$, which vanishes at $x \to \pm\infty$. From Eq. (3.7) we get

$$R(\lambda,\mu)\varepsilon(x;\lambda,\mu) = \varepsilon(x;\mu,\lambda)R(\lambda,\mu), \tag{4.4}$$

where $\varepsilon(x;\lambda,\mu)=e^{\mathcal{L}_0(\lambda,\mu)x}$. By using the above mentioned splitting of $\mathcal{L}(x;\lambda,\mu)$, we derive the integral form of the differential equation (3.5) as

$$\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu)=\varepsilon(x_2-x_1;\lambda,\mu)+\int_{x_1}^{x_2}\mathrm{d}x\,\varepsilon(x_2-x;\lambda,\mu)\,{:}\,\mathcal{L}_1(x,\lambda,\mu)\mathcal{T}_{x_1}^{x}(\lambda)\otimes\mathcal{T}_{x_1}^{x}(\mu)\,{:}\ .$$

From this integral relation it is clear that at the asymptotic limit $x_1,x_2\to\pm\infty$, $\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu)\to\varepsilon(x_2-x_1;\lambda,\mu)$, which is an oscillatory term. To get rid of this problem, we define an operator like

$$W(\lambda,\mu)=\lim_{\substack{x_2\to+\infty\\ x_1\to-\infty}}\varepsilon(-x_2;\lambda,\mu)\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu)\varepsilon(x_1;\lambda,\mu). \tag{4.5}$$

In the above defined operator, the oscillatory nature of $\mathcal{T}_{x_1}^{x_2}(\lambda)\otimes\mathcal{T}_{x_1}^{x_2}(\mu)$ has been removed and $W(\lambda,\mu)$ is perfectly well behaved at the limit $x_1,x_2\to\pm\infty$. By using (3.10) and (4.4), it is easy to verify that the operator $W(\lambda,\mu)$ (4.5) satisfies an equation given by

$$R(\lambda,\mu)W(\lambda,\mu)=W(\mu,\lambda)R(\lambda,\mu). \tag{4.6}$$

The above equation represents the QYBE of the BMT model at an infinite interval limit.

Next, we want to express the QYBE (4.6) directly in terms of the monodromy matrices (4.1) defined in an infinite interval. For this purpose, $W(\lambda,\mu)$ (4.5) can be rewritten as

$$W(\lambda,\mu)=C_+(\lambda,\mu)\mathcal{T}(\lambda)\otimes\mathcal{T}(\mu)C_-(\lambda,\mu), \tag{4.7}$$

where

$$C_+(\lambda,\mu)=\lim_{x\to\infty}\varepsilon(-x;\lambda,\mu)E(x;\lambda,\mu), \tag{4.8a}$$

$$C_-(\lambda,\mu)=\lim_{x\to-\infty}E(-x;\lambda,\mu)\varepsilon(x;\lambda,\mu), \tag{4.8b}$$

with $E(x;\lambda,\mu)=e(x,\lambda)\otimes e(x,\mu)$. Substituting the explicit forms of $E(x;\lambda,\mu)$ and $\varepsilon(x;\lambda,\mu)$ to (4.8a) and (4.8b), and taking the limits in the principal value sense: $\lim_{x\to\pm\infty}P(e^{ikx}/k)=\pm i\pi\delta(k)$, we obtain

$$C_+(\lambda,\mu)=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&\rho_+(\lambda,\mu)&1&0\\0&0&0&1\end{pmatrix},\quad C_-(\lambda,\mu)=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&\rho_-(\lambda,\mu)&1&0\\0&0&0&1\end{pmatrix}, \tag{4.9}$$

where

$$\begin{aligned}\rho_\pm(\lambda,\mu)&=\mp\frac{2i\hbar\xi\left(\lambda\mu+\frac{1}{\lambda\mu}\right)}{\lambda^2-\mu^2-\frac{1}{\lambda^2}+\frac{1}{\mu^2}}+2\pi\hbar\xi\left(\lambda\mu+\frac{1}{\lambda\mu}\right)\delta\left(\lambda^2-\mu^2-\frac{1}{\lambda^2}+\frac{1}{\mu^2}\right)\\&=\mp\frac{2i\hbar\xi\left\{\lambda\mu+\frac{1}{\lambda\mu}\right\}}{\lambda^2-\mu^2-\frac{1}{\lambda^2}+\frac{1}{\mu^2}\mp i\epsilon}.\end{aligned} \tag{4.10}$$

Substituting the expression of $W(\lambda,\mu)$ (4.7) in Eq. (4.6), we can express this QYBE for the infinite interval in the form

$$R(\lambda,\mu)C_+(\lambda,\mu)\mathcal{T}(\lambda)\otimes\mathcal{T}(\mu)C_-(\lambda,\mu)=C_+(\mu,\lambda)\mathcal{T}(\mu)\otimes\mathcal{T}(\lambda)C_-(\mu,\lambda)R(\lambda,\mu). \tag{4.11}$$

By inserting the explicit forms of $R(\lambda,\mu)$ (3.8), $C_{\pm}(\lambda,\mu)$ (4.9), and $\mathcal{T}(\lambda)$ (4.3) to the above QYBE (4.11) and comparing the matrix elements from both sides of this equation, we obtain the following commutation relations:

$$[A(\lambda),A(\mu)]=0, \tag{4.12a}$$

$$[A(\lambda),A^{\dagger}(\mu)]=0, \tag{4.12b}$$

$$[B(\lambda),B(\mu)]=0, \tag{4.12c}$$

$$A(\lambda)B^{\dagger}(\mu)=\frac{\mu^2q-\lambda^2q^{-1}}{\mu^2-\lambda^2-i\epsilon}B^{\dagger}(\mu)A(\lambda)=\frac{\mu^2q-\lambda^2q^{-1}}{\mu^2-\lambda^2}B^{\dagger}(\mu)A(\lambda)-2\pi\hbar\xi\lambda\mu\delta(\lambda^2-\mu^2)B^{\dagger}(\lambda)A(\mu), \tag{4.12d}$$

$$B(\mu)A(\lambda)=\frac{\mu^2q-\lambda^2q^{-1}}{\mu^2-\lambda^2-i\epsilon}A(\lambda)B(\mu)=\frac{\mu^2q-\lambda^2q^{-1}}{\mu^2-\lambda^2}A(\lambda)B(\mu)-2\pi\hbar\xi\lambda\mu\delta(\lambda^2-\mu^2)A(\mu)B(\lambda), \tag{4.12e}$$

$$B(\mu)B^{\dagger}(\lambda)=\tau(\lambda,\mu)B^{\dagger}(\lambda)B(\mu)+4\pi\hbar\xi\lambda\mu\delta(\lambda^2-\mu^2)A^{\dagger}(\lambda)A(\lambda), \tag{4.12f}$$

where

$$\tau(\lambda,\mu)=\left[1+\frac{8\hbar^2\xi^2\lambda^2\mu^2}{(\lambda^2-\mu^2)^2}-\frac{4\hbar^2\xi^2\left\{\lambda\mu+\frac{1}{\lambda\mu}\right\}^2}{\left(\lambda^2-\mu^2-\frac{1}{\lambda^2}+\frac{1}{\mu^2}-i\epsilon\right)\left(\lambda^2-\mu^2-\frac{1}{\lambda^2}+\frac{1}{\mu^2}+i\epsilon\right)}\right].$$

It is interesting to note that, for the case $\lambda\neq\mu$, Eq. (4.12f) gives $[B(\lambda),B^{\dagger}(\mu)]\neq 0$, whereas from Eq. (2.16f), one obtains that $\{b(\lambda),b^{*}(\mu)\}=0$ for $\lambda\neq\mu$. Thus the correspondence principle is not manifest here in a straightforward manner. However the $\hbar\to 0$ limit of $\tau(\lambda,\mu)$, gives the correct classical counterpart of the commutation relation (4.12f).

Due to Eq. (4.12a), all the operator valued coefficients occuring in the expansion of $\ln A(\lambda)$ will commute among themselves. As a consequence the BMT model described by the Lax operator (3.2) turn out to be a quantum integrable system. By applying the method of algebraic Bethe ansatz, one can also construct the exact eigenstates for all commuting operators which are generated through the expansion of $\ln A(\lambda)$. With the help of Eq. (4.1), it is easy to find that $A(\lambda)|0\rangle=|0\rangle$. By using this relation and Eq. (4.12d), it can be shown that

$$A(\lambda)|\mu_1,\mu_2,\ldots,\mu_N\rangle=\prod_{r=1}^{N}\left(\frac{\mu_r^2q-\lambda^2q^{-1}}{\mu_r^2-\lambda^2-i\epsilon}\right)|\mu_1,\mu_2,\ldots,\mu_N\rangle, \tag{4.13}$$

where μ_j's are all distinct real or complex numbers and $|\mu_1,\mu_2,\ldots,\mu_N\rangle \equiv B^{\dagger}(\mu_1)B^{\dagger}(\mu_2)\ldots B^{\dagger}(\mu_N)|0\rangle$ represents a Bethe eigenstate. Using the commutation relation (4.12f) one can also calculate the norm of the eigenstates $B^{\dagger}(\mu_1)B^{\dagger}(\mu_2)\cdots B^{\dagger}(\mu_N)|0\rangle$. However, the commutation relation (4.12f) contains product of singular functions

$$\left(\lambda^2-\mu^2-\frac{1}{\lambda^2}+\frac{1}{\mu^2}-i\epsilon\right)^{-1}\left(\lambda^2-\mu^2-\frac{1}{\lambda^2}+\frac{1}{\mu^2}+i\epsilon\right)^{-1},$$

which is undefined at the limit $\lambda\to\mu$. As a result, eigenstates like $B^{\dagger}(\mu_1)B^{\dagger}(\mu_2)\cdots B^{\dagger}(\mu_N)|0\rangle$ are not normalized on the δ-function. To solve this problem, we consider a reflection operator given by

$$R^{\dagger}(\lambda) = B^{\dagger}(\lambda)(A^{\dagger}(\lambda))^{-1} \tag{4.14}$$

and its adjoint $R(\lambda)$. By using Eqs. (4.12a), (4.12b), (4.12c), (4.12d), (4.12e), and (4.12f), we find that such reflection operators satisfy well-defined commutation relations like

$$R^{\dagger}(\lambda)R^{\dagger}(\mu) = S^{-1}(\lambda,\mu)R^{\dagger}(\mu)R^{\dagger}(\lambda),$$

$$R(\lambda)R(\mu) = S^{-1}(\lambda,\mu)R(\mu)R(\lambda), \tag{4.15}$$

$$R(\lambda)R^{\dagger}(\mu) = S(\lambda,\mu)R^{\dagger}(\mu)R(\lambda) + 4\pi\hbar\lambda^2\delta(\lambda^2-\mu^2),$$

where

$$S(\lambda,\mu) = \frac{\lambda^2 q - \mu^2 q^{-1}}{\lambda^2 q^{-1} - \mu^2 q}. \tag{4.16}$$

The $S(\lambda,\mu)$ defined above represents the nontrivial S-matrix element of two-body scattering among the related quasiparticles. We find that this $S(\lambda,\mu)$ satisfies the following conditions:

$$S^{-1}(\lambda,\mu) = S(\mu,\lambda) = S^{*}(\lambda,\mu), \tag{4.17}$$

and remains nonsingular at the limit $\lambda \to \mu$. Consequently, the action of the operators like $R^{\dagger}(\lambda)$ on the vacuum would produce well-defined states which can be normalized on the δ-function.

The point to be noted here is that in Eq. (4.13), the eigenvalues of $A(\lambda)$ are in general complex. To get real eigenvalues, we define a new operator $\ln \hat{A}(\lambda)$ through the relation $\ln \hat{A}(\lambda) \equiv \ln A(\lambda e^{-i\alpha/2})$ and expand this operator in inverse powers of λ,

$$\ln \hat{A}(\lambda) = \sum_{n=0}^{\infty} \frac{i\mathcal{C}_n}{\lambda^{2n}}. \tag{4.18}$$

Using Eqs. (4.13) and (4.18), it is easy to see that $\mathcal{C}_n$'s satisfy eigenvalue equations like

$$\mathcal{C}_n|\mu_1,\mu_2,\ldots,\mu_N\rangle = \chi_n|\mu_1,\mu_2,\ldots,\mu_N\rangle,$$

where the first few χ_n's are explicitly given by

$$\chi_0 = \alpha N, \quad \chi_1 = 2\sin\alpha\sum_{j=1}^{N}\mu_j^2, \quad \chi_2 = \sin 2\alpha\sum_{j=1}^{N}\mu_j^4. \tag{4.19}$$

It may be noted that these eigenvalues are all real when μ_j's are taken as real numbers. Next we expand the operator $\ln \hat{A}(\lambda)$ in powers of λ as

$$\ln \hat{A}(\lambda) = \sum_{n=0}^{\infty} i\tilde{\mathcal{C}}_n\lambda^{2n}, \tag{4.20}$$

and by using (4.13) we obtain

$$\tilde{\mathcal{C}}_n|\mu_1,\mu_2,\ldots,\mu_N\rangle = \tilde{\chi}_n|\mu_1,\mu_2,\ldots,\mu_N\rangle.$$

The first few $\tilde{\chi}_n$'s are explicitly given by

$$\tilde{\chi}_0 = -\alpha N,\ \ \tilde{\chi}_1 = -2\sin\alpha\sum_{j=1}^{N}\frac{1}{\mu_j^2},\ \ \tilde{\chi}_2 = -\sin 2\alpha\sum_{j=1}^{N}\frac{1}{\mu_j^4}. \tag{4.21}$$

In analogy with the classical case, one can now define the momentum and Hamiltonian of the quantum BMT model as

$$\mathcal{P} = -\frac{1}{4\xi}(C_1 + \tilde{C}_1),\ \ \mathcal{H} = -\frac{1}{4\xi}(C_1 - \tilde{C}_1).$$

By using (4.19) and (4.21), the eigenvalue equations corresponding to the above momentum and Hamiltonian are obtained as

$$\mathcal{P}|\mu_1,\mu_2,\ldots,\mu_N\rangle = \frac{\hbar}{2}\sum_{j=1}^{N}\left(\mu_j^2 - \frac{1}{\mu_j^2}\right)|\mu_1,\mu_2,\ldots,\mu_N\rangle,$$

$$\mathcal{H}|\mu_1,\mu_2,\ldots,\mu_N\rangle = \frac{\hbar}{2}\sum_{j=1}^{N}\left(\mu_j^2 + \frac{1}{\mu_j^2}\right)|\mu_1,\mu_2,\ldots,\mu_N\rangle. \tag{4.22}$$

In the above expressions, μ_j's are taken as real numbers and $|\mu_1,\mu_2,\ldots,\mu_N\rangle$ represents a scattering state. Now to construct quantum N-soliton states of the BMT model, complex values of μ_j can be chosen in such a way so that the eigenvalues corresponding to different expansion coefficients of $\ln\hat{A}(\lambda)$ still remains real. Such a choice is given by

$$\mu_j = \mu\exp\left[-i\alpha\left(\frac{N+1}{2} - j\right)\right], \tag{4.23}$$

where μ is a real parameter and $j \in [1,2,\ldots,N]$. For the above choice of μ_j, Eq. (4.13) takes the form

$$A(\lambda)|\mu_1,\mu_2,\ldots,\mu_N\rangle = q^{-N}\left(\frac{\lambda^2 - \mu^2 q^{N+1}}{\lambda^2 - \mu^2 q^{-N+1}}\right)|\mu_1,\mu_2,\ldots,\mu_N\rangle. \tag{4.24}$$

Consequently, the energy eigenvalue equation corresponding to the quantum N-soliton state can be obtained as $\mathcal{H}|\mu_1,\mu_2,\ldots,\mu_N\rangle = E|\mu_1,\mu_2,\ldots,\mu_N\rangle$, where

$$E = \frac{\hbar}{2}\left(\mu^2 + \frac{1}{\mu^2}\right)\frac{\sin\alpha N}{\sin\alpha}. \tag{4.25}$$

Thus we find that quantum N-soliton states can be constructed for the BMT model for $N > 1$. Now we assume a particular value of the coupling constant ξ given by $\hbar\xi = -\sin\alpha = -\sin(2\pi m/n)$, where m and n are nonzero integers which do not have any common factor. From Eq. (4.23), we obtain $\mu_j = \mu_{j+n}$ for the above choice of ξ. Since all the μ_j's must be distinct, we get $N \leqslant n$ as a restriction on the number of quasiparticles that can form a quantum soliton state for the BMT model when $\xi = -(1/\hbar)\sin(2\pi m/n)$.

Next we aim to calculate the binding energy for a N-soliton state of the quantum BMT model. Substituting the expression of μ_j (4.23) to the first relation in Eq. (4.22), the momentum eigenvalue of a N-soliton state is obtained as

$$P = \frac{\hbar}{2}\left(\mu^2 - \frac{1}{\mu^2}\right)\frac{\sin\alpha N}{\sin\alpha}. \tag{4.26}$$

It is interesting to observe that the energy (4.25) and the momentum eigenvalue (4.26) of a N-soliton state satisfy the dispersion relation $E^2 = P^2 + m^2$, where $m = \hbar\sin\alpha N/\sin\alpha$. To calculate binding energy we assume that the momentum P (4.26) is equally distributed among N number of

single-particle scattering states. The real wave number associated with each of these single particle states is denoted by μ_0. With the help of Eqs. (4.22) and (4.26), we find that

$$\mu_0^2 - \frac{1}{\mu_0^2} = \left(\mu^2 - \frac{1}{\mu^2}\right)\frac{\sin \alpha N}{N \sin \alpha}. \tag{4.27}$$

Using Eq. (4.22), the total energy for N number of such single particle states is obtained as

$$E' = \frac{\hbar N}{2}\left(\mu_0^2 + \frac{1}{\mu_0^2}\right) = \frac{\hbar N}{2}\left\{\left(\mu^2 - \frac{1}{\mu^2}\right)^2 \frac{\sin^2 \alpha N}{N^2 \sin^2 \alpha} + 4\right\}^{1/2}. \tag{4.28}$$

Subtracting E (4.25) from E' (4.28), we obtain the binding energy of the quantum N-soliton state as

$$E_B(\alpha, N) = E' - E = \frac{\hbar N}{2}\left\{\left(\mu^2 - \frac{1}{\mu^2}\right)^2 \frac{\sin^2 \alpha N}{N^2 \sin^2 \alpha} + 4\right\}^{1/2} - \frac{\hbar}{2}\left(\mu^2 + \frac{1}{\mu^2}\right)\frac{\sin \alpha N}{\sin \alpha}. \tag{4.29}$$

Note that the above expression of $E_B(\alpha, N)$ remains invariant under the transformation $\alpha \to -\alpha$. So it is sufficient to analyze the nature of binding energy within the range $0 < \alpha \leqslant \pi/2$. Now, for $E_B(\alpha, N)$ to represent the energy of a real bound state, E' must be greater than E. Since E' (4.28) is always positive, it is evident that $E' > E$ for $E < 0$. So we will restrict our attention only for the case $E > 0$, when the condition $E' > E$ is equivalent to $E'^2 > E^2$. Substituting the explicit expressions for E' (4.28) and E (4.25), the above condition takes the form

$$N \sin \alpha > \sin \alpha N. \tag{4.30}$$

Substituting $N = 2$ in (4.30), we get the trivial inequality $1 > \cos \alpha$ for $\alpha > 0$. So the condition (4.30) is satisfied for the $N = 2$ case within our chosen range of α. By using the method of induction, we can easily prove that the condition (4.30) is valid for arbitrary values of N. Thus we get an N-soliton bound state when α lies in the range $0 < |\alpha| \leqslant \pi/2$.

V. CONCLUDING REMARKS

In this paper we consider the classical Lax operator of the BMT model and obtain the PB relations among various elements of the classical monodromy matrix at the infinite interval limit. By using these PB relations, the classical integrability of the BMT model is established in the Liouville sense. We also calculate the classical conserved quantities of BMT model. Next, we quantize the Lax operator of the BMT model. By using a variant of QISM, that can be directly applied to the field theoretic models, we obtain the QYBE for the quantum monodromy matrix at a finite interval. This QYBE enables us to determine the various parameters of the quantum Lax operator in terms of the coupling constant ξ. Then we take the infinite interval limit of this QYBE and derive all possible commutation relations among the various elements of the corresponding quantum monodromy matrix. These commutation relations enable us to establish the quantum integrability of the BMT model and also to construct the exact eigenstates for the quantum version of the Hamiltonian (1.1) as well as other conserved quantities by using algebraic Bethe ansatz. We also obtain the commutation relation between creation and annihilation operators associated with quasiparticles of the BMT model and find out the S-matrix for two-body scattering.

In this context, we consider the BMT model with some special values of coupling constant given by $\xi = -(1/\hbar)\sin \alpha = -(1/\hbar)\sin(2\pi m/n)$, where m and n are nonzero integers with no common factor. It turns out that the number of quasiparticles, which form a bound state for such quantum BMT model, cannot exceed the value of n. We have also derived the exact expression of binding energy for a N-soliton state of the quantum BMT model. The binding energy turns out to be positive for all allowed values of α.

The commutation relation between creation and annihilation operators will play an important role in the future study, since by using it one might be able to calculate the norm of Bethe eigenstates and various correlation functions of the BMT model. In the future, we would also like

to obtain the quantum conserved quantities of the BMT model in terms of the field operators by using a method which was used earlier in the case of the nonlinear Schrödinger model[18] and DNLS model.[16]

ACKNOWLEDGMENT

The author would like to thank Dr. B. Basu-Mallick for many valuable suggestions and careful reading of the paper.

APPENDIX

Here we give the details of deriving Eq. (3.5). Direct attempt to calculate $(\partial/\partial x_2)(\mathcal{T}_{x_1}^{x_2}(\lambda) \otimes \mathcal{T}_{x_1}^{x_2}(\mu))$ by using Eq. (3.4), leads to indeterminate expressions of the form $[\mathcal{T}_{x_1}^{x_2}(\lambda), \phi_1^\dagger(x_2)]$ and $[\mathcal{T}_{x_1}^{x_2}(\lambda), \phi_2^\dagger(x_2)]$. To avoid this problem by using the method of extension,[3] we shift the upper limit of the monodromy matrix $\mathcal{T}_{x_1}^{x_2}(\lambda)$ by a small amount ϵ and take $\epsilon \to 0$ limit only after differentiating the product $\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes \mathcal{T}_{x_1}^{x_2}(\mu)$ with respect to x_2. So, using Eq. (3.4), we obtain

$$\frac{\partial}{\partial x_2}(\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes \mathcal{T}_{x_1}^{x_2}(\mu)) = :(\mathcal{U}_q(x_2+\epsilon;\lambda) \otimes \mathbb{1} + \mathbb{1} \otimes \mathcal{U}_q(x_2;\mu))\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes \mathcal{T}_{x_1}^{x_2}(\mu):\ + K_+ + K_-, \tag{A1}$$

where

$$\begin{aligned} K_+ = {} & i\xi\mu[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_1^\dagger(x_2)] \otimes \sigma_+ \mathcal{T}_{x_1}^{x_2}(\mu) - \frac{i\xi}{\mu}[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_2^\dagger(x_2)] \otimes \sigma_+ \mathcal{T}_{x_1}^{x_2}(\mu) + if_1[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_1^\dagger(x_2)] \\ & \otimes e_{11}\mathcal{T}_{x_1}^{x_2}(\mu)\phi_1(x_2) - if_2[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_2^\dagger(x_2)] \otimes e_{11}\mathcal{T}_{x_1}^{x_2}(\mu)\phi_2(x_2) - ig_1[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_1^\dagger(x_2)] \\ & \otimes e_{22}\mathcal{T}_{x_1}^{x_2}(\mu)\phi_1(x_2) + ig_2[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_2^\dagger(x_2)] \otimes e_{22}\mathcal{T}_{x_1}^{x_2}(\mu)\phi_2(x_2), \end{aligned}$$

$$\begin{aligned} K_- = {} & i\lambda\sigma_- \mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes [\phi_1(x_2+\epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)] - \frac{i}{\lambda}\sigma_- \mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes [\phi_2(x_2+\epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)] + if_1\phi_1^\dagger(x_2 \\ & + \epsilon)e_{11}\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes [\phi_1(x_2+\epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)] - if_2\phi_2^\dagger(x_2+\epsilon)e_{11}\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes [\phi_2(x_2+\epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)] \\ & - ig_1\phi_1^\dagger(x_2+\epsilon)e_{22}\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes [\phi_1(x_2+\epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)] + ig_2\phi_2^\dagger(x_2+\epsilon)e_{22}\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda) \otimes [\phi_2(x_2 \\ & + \epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)]. \end{aligned}$$

Now we consider the case, $\epsilon > 0$. Since $\phi_1(x_2+\epsilon)$ and $\phi_2(x_2+\epsilon)$ commute with $\phi_1(x)$, $\phi_1^\dagger(x)$, $\phi_2(x)$, $\phi_2^\dagger(x)$ for all x lying within x_1 and x_2, we get $[\phi_1(x_2+\epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)] = [\phi_2(x_2+\epsilon), \mathcal{T}_{x_1}^{x_2}(\mu)] = 0$. Thus we can conclude that for a positive ϵ, $K_- = 0$. So we must calculate only the nontrivial commutators $[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_1^\dagger(x_2)]$ and $[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_2^\dagger(x_2)]$ appearing in the expression of K_+.

First let us calculate the commutator $[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_1^\dagger(x_2)]$. For this purpose, we consider a "transformation" Ω, which replaces the classical variables $\phi_1(x)$, $\phi_2(x)$, and $\phi_1^*(x)$, $\phi_2^*(x)$ by quantum operators $\phi_1(x)$, $\phi_2(x)$ and $\phi_1^\dagger(x)$, $\phi_2^\dagger(x)$, respectively. Next we use a correspondence principle,[3]

$$[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda), \phi_1^\dagger(x_2)] = i\hbar :\Omega\{T_{x_1}^{x_2+\epsilon}(q;\lambda), \phi_1^*(x_2)\}: , \tag{A2}$$

where $T_{x_1}^{x_2+\epsilon}(q;\lambda)$ represents a classical monodromy matrix given by

$$T_{x_1}^{x_2+\epsilon}(q;\lambda) = \mathcal{P}\exp\int_{x_1}^{x_2} U_q(x,\lambda)\mathrm{d}x,$$

and $U_q(x,\lambda)=\Omega^{-1}\mathcal{U}_q(x,\lambda)$. By using the fundamental PB relations (1.2), it is easy to find that

$$\begin{aligned}\{T_{x_1}^{x_2+\epsilon}(q;\lambda),\phi_1^*(x_2)\} &= \int_{x_1}^{x_2+\epsilon} \mathrm{d}x\, T_x^{x_2+\epsilon}(q;\lambda)\{U_q(x,\lambda),\phi_1^*(x_2)\}T_{x_1}^{x}(q,\lambda)\\ &= T_{x_2}^{x_2+\epsilon}(q;\lambda)(f_1\phi_1^*(x_2)e_{11} - g_1\phi_1^*(x_2)e_{22} + \lambda\sigma_-)T_{x_1}^{x_2}(q;\lambda).\end{aligned}$$

Taking $\epsilon\to 0$ limit of the above expression and substituting it in (A2), we obtain

$$\lim_{\epsilon\to 0}[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda),\phi_1^\dagger(x_2)] = i\hbar(f_1\phi_1^\dagger(x_2)e_{11} - g_1\phi_1^\dagger(x_2)e_{22} + \lambda\sigma_-)\mathcal{T}_{x_1}^{x_2}(\lambda). \tag{A3}$$

Next we must calculate the commutator $[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda),\phi_2^\dagger(x_2)]$. Using the same correspondence principle as before and finally taking the $\epsilon\to 0$ limit one obtains

$$\lim_{\epsilon\to 0}[\mathcal{T}_{x_1}^{x_2+\epsilon}(\lambda),\phi_2^\dagger(x_2)] = i\hbar\left(-f_2\phi_2^\dagger(x_2)e_{11} + g_2\phi_2^\dagger(x_2)e_{22} - \frac{1}{\lambda}\sigma_-\right)\mathcal{T}_{x_1}^{x_2}(\lambda). \tag{A4}$$

Taking the $\epsilon\to 0$ limit of Eq. (A1) and using (A3) and (A4), we finally obtain the differential equation (3.5). Note that, instead of $\epsilon>0$, we could have chosen $\epsilon<0$ in Eq. (A1). In that case only the commutators $[\phi_1(x_2+\epsilon),\mathcal{T}_{x_1}^{x_2}(\mu)]$ and $[\phi_2(x_2+\epsilon),\mathcal{T}_{x_1}^{x_2}(\mu)]$ give nontrivial contributions. However, by repeating similar steps as outlined above and finally taking the $\epsilon\to 0$ limit, we would have obtained the same differential equation (3.5).

(Received 4 June 2004; accepted 27 September 2004; published online 27 December 2004)

We discuss the relativistic top theory from the point of view of the de Sitter (or anti–de Sitter) group. Our treatment rests on the Hanson–Regge spherical relativistic top Lagrangian formulation. We propose an alternative method for studying spinning objects via Kaluza–Klein theory. In particular, we derive the relativistic top equations of motion starting with the geodesic equation for a point particle in $4+N$ dimensions. We compare our approach with Fukuyama's formulation of spinning objects, which is also based on Kaluza–Klein theory. We also report a generalization of our approach to a $4+N+D$ dimensional theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1827923]

I. INTRODUCTION

If one compares Regge's work[1,2] published in 1959 and 1960, respectively, with the Hanson–Regge work of 1974 about the relativistic spherical top theory[3] (see also Ref. 4), one gets the feeling that Regge thought of the trajectory constraint linking mass and the spin of a relativistic spinning object as a deep physical concept of nature. Through the years it has become clear that Regge was right. In fact, such a constraint, now called Regge trajectory, plays a fundamental role not only in the dual string models[5] and the relativistic rotator theory,[6,7] but also in string theory[8] and in the black holes approach.[9] It seems that even Regge is in the sky[10] in connection with the mass and the internal angular momentum of celestial objects.

One of the simplest Regge trajectory for a spherical relativistic top is provided by the expression[3,4]

$$H \equiv P^{\mu}P_{\mu} + \frac{1}{2r^2}\Sigma^{\mu\nu}\Sigma_{\mu\nu} + m_0^2 \approx 0, \tag{1}$$

where P^{μ} and $\Sigma^{\mu\nu}=-\Sigma^{\nu\mu}$ are the linear momentum and the internal angular momentum, respectively, associated with some spinning object. Here, m_0 and r are constants determining the properties of the system and the symbol "≈ 0" means weakly equal zero in the sense of the terminology of Dirac's constraints Hamiltonian formalism.[11] (Here the indices μ,ν run from 0 to 3.)

One of the interesting aspects of (1) is that it resembles one of the Casimir operator's of the de Sitter group,

$$C_1 = \tfrac{1}{2}S^{AB}S_{AB}, \tag{2}$$

where the indices A,B run from 0 to 4. In fact, if classically it is possible to make the identifications

a)Electronic mail: nieto@uas.uasnet.mx

$$S^{4\mu} \to rP^{\mu}, \quad S^{\mu\nu} \to \Sigma^{\mu\nu}, \quad C_1 \to -r^2 m_0^2, \tag{3}$$

then the spherical relativistic top may lead naturally to a de Sitter relativistic top and several properties of the de Sitter group can be applied to such a system. The problem, however, it is not so simple because the momenta P^{μ} and $\Sigma^{\mu\nu}$ are restricted to satisfy the so-called Tulczyjew constraint[12]

$$\Sigma^{\mu\nu} P_{\nu} \approx 0 \tag{4}$$

and it seems that there is not a counterpart in the de Sitter group formalism of this constraint. One of the main goals of this work is to use a Lagrangian analysis of the relativistic top in order to shed some light on this and other related problems.

As soon as we make the identification (3) the parameter r, measuring the "size" of the top, may acquire a particular interesting meaning, namely, it can be identified with the Planck length $l_P=(\hbar G/c^3)^{1/2}$ or with the radius of the universe R. In the first case, the relativistic top may have contact not only with elementary particles through the superstring top theory,[13,14] but also with gravity itself.[15] In fact, it has been shown[15] that extending the Poincaré group to the de Sitter group through a Wigner contraction with l_P as a parameter one can make sense of a gravitational theory as a gauge theory. Similar conclusion is provided by the MacDowell–Mansouri formalism.[16]

In the second case, one may find a connection between the relativistic top with accelerated universe via the de Sitter space–time. In some sense, one may say that Regge is not only in the sky but in the cosmos as well.

The central idea of this work is to develop different aspects of the de Sitter top theory using the spherical relativistic top theory as a guide. For this purpose in Secs. II and III we show explicitly how the first order and second order formalisms of a particular spherical top system are related. In Sec. IV, we show how the Kaluza–Klein formalism may lead to de Sitter top theory. In Sec. V, we make some final remarks. In Appendix B we report a generalization of our formalism to $4+N+D$ dimensions.

II. FROM THE FIRST ORDER TO THE SECOND ORDER LAGRANGIAN

Let us describe the motion of the top by four coordinates $x^{\mu}(\tau)$ and a tetrad $e^{\mu}_{(\alpha)}(\tau)$ where τ is an arbitrary parameter along the world line of the top. Here $x^{\mu}(\tau)$ is used to describe the position of the system, while $e^{\mu}_{(\alpha)}(\tau)$ is attached to the top in order to describe its rotations. We shall assume that the tetrad $e^{\mu}_{(\alpha)}(\tau)$ satisfies the orthonormal relations

$$\eta_{\mu\nu} e^{\mu}_{(\alpha)} e^{\nu}_{(\beta)} = \eta_{(\alpha\beta)},$$

$$\eta^{(\alpha\beta)} e^{\mu}_{(\alpha)} e^{\nu}_{(\beta)} = \eta^{\mu\nu}, \tag{5}$$

where $\eta_{\mu\nu}=\mathrm{diag}(-1,1,1,1)$ is the Minkowski metric. We shall associate the canonical linear momentum P_{μ} to the linear velocity $u^{\mu}=\mathrm{d}x^{\mu}/\mathrm{d}\tau$ and the spin tensor $\Sigma^{\mu\nu}=-\Sigma^{\nu\mu}$ to the angular velocity $\sigma^{\mu\nu}=e^{\mu}_{(\alpha)}(\mathrm{d}e^{\nu}_{(\alpha)}/\mathrm{d}\tau)$.

Consider the first order Lagrangian corresponding to a special type of a relativistic top,[3,4]

$$L = u^{\mu} P_{\mu} + \frac{1}{2}\sigma^{\mu\nu}\Sigma_{\mu\nu} - \frac{\lambda}{2}\left(P^{\mu}P_{\mu} + \frac{1}{2r^2}\Sigma^{\mu\nu}\Sigma_{\mu\nu} + m_0^2\right) + \xi_{\mu}\Sigma^{\mu\nu}P_{\nu}, \tag{6}$$

where λ and ξ_{μ} are Lagrange multipliers. Varying L with respect to P_{μ} gives

$$u^{\mu} = \lambda P^{\mu} + V^{\mu}, \tag{7}$$

where

$$V^{\mu} = \Sigma^{\mu\nu}\xi_{\nu}, \tag{8}$$

while varying L with respect to $\Sigma_{\mu\nu}$ yields

$$\sigma^{\mu\nu} = \frac{\lambda}{r^2}\Sigma^{\mu\nu} + P^{\mu}\xi^{\nu} - P^{\nu}\xi^{\mu}. \tag{9}$$

Similarly varying L with respect to ξ_{μ} leads to the constraint

$$\Sigma^{\mu\nu}P_{\nu} = 0, \tag{10}$$

while varying L with respect to λ one obtains

$$P^{\mu}P_{\mu} + \frac{1}{2r^2}\Sigma^{\mu\nu}\Sigma_{\mu\nu} + m_0^2 = 0. \tag{11}$$

Since $\Sigma^{\mu\nu}$ is antisymmetric, we observe from (6) that if ξ_{μ} is parallel to P_{μ} the last term in (6) vanishes identically. Therefore, we may set

$$\xi^{\mu}P_{\mu} = 0. \tag{12}$$

This condition must be added to the Lagrangian (6) in the form $\eta(\xi^{\mu}P_{\mu})$, where η is another Lagrange multiplier. Varying the resultant extended Lagrangian with respect to η leads to (12). While arbitrary variations with respect to ξ^{μ} leads to the equation $\Sigma^{\mu\nu}P_{\nu} + \eta P^{\mu} = 0$ which, after multiplying it by P_{μ}, gives $\eta = 0$ and therefore one recovers the Lagrangian (6).

Our goal is to derive the second order Lagrangian associated with the Lagrangian (6). Our proof consists of some elementary algebra and for that reason in this section we shall only mention the main results. Nevertheless, since in such an algebra there are some key steps, in Appendix A we present the computation in more detail.

The main idea is to compute from (7)–(12) the combination $u\sigma\sigma u - r^2 \det\sigma$, where

$$u\sigma\sigma u \equiv u_{\mu}\sigma^{\mu\nu}\sigma_{\nu}{}^{\alpha}u_{\alpha} \tag{13}$$

and

$$\det\sigma = \frac{1}{4!}\varepsilon^{\mu\nu\alpha\beta}\varepsilon^{\tau\lambda\sigma\rho}\sigma_{\mu\tau}\sigma_{\nu\lambda}\sigma_{\alpha\sigma}\sigma_{\beta\rho}. \tag{14}$$

One finds the following result (for details see Appendix A):

$$u\sigma\sigma u - r^2 \det\sigma = \frac{m_0^2}{r^2}\left[\left(u^2 + \frac{r^2\sigma^2}{2}\right)\lambda^2 + \frac{1}{r^2}\lambda^4 m_0^2\right], \tag{15}$$

where we used the notation $a^2 = a^{\mu}a_{\mu}$, for any dynamical variable a^{μ}. Using once again the constraint (11) we find that (15) leads to the expression

$$\lambda^4 + \frac{\lambda^2}{m_0^2}\left(u^2 + \frac{1}{2}r^2\sigma^2\right) - \frac{r^2}{m_0^4}(u\sigma\sigma u - r^2 \det\sigma) = 0. \tag{16}$$

This expression can be solved for λ in terms of the Lorentz scalars u^2, σ^2, $u\sigma\sigma u$, and $\det\sigma$. But before solving for λ, let us show that λ and the Lagrangian L are related by the expression

$$L = -m_0^2\lambda. \tag{17}$$

First using the constraints (10) and (11) the Lagrangian (6) becomes

$$L = u^{\mu}P_{\mu} + \tfrac{1}{2}\sigma^{\mu\nu}\Sigma_{\mu\nu}.$$

From (7) and (9) we find the results

$$u^\mu P_\mu = \lambda P^2 \tag{18}$$

and

$$\frac{1}{2}\sigma^{\mu\nu}\Sigma_{\mu\nu} = \lambda\frac{\Sigma^2}{2r^2}. \tag{19}$$

So, we get

$$L = u^\mu P_\mu + \frac{1}{2}\sigma^{\mu\nu}\Sigma_{\mu\nu} = \lambda\left(P^2 + \frac{1}{2r^2}\Sigma^2\right). \tag{20}$$

By using (11) once again, we see that (20) leads to (17).

Thus, (16) and (17) leads to the Lagrangian

$$L = -m_0\left[\frac{-(u^2 + \frac{1}{2}r^2\sigma^2) \pm \sqrt{(u^2 + \frac{1}{2}r^2\sigma^2)^2 + r^2(u\sigma\sigma u - r^2 \det\sigma)}}{2}\right]^{1/2}. \tag{21}$$

Observe that if σ vanishes only the minus sign in the symbol $\pm\sqrt{}$ makes sense. In this case (21) is reduced to

$$L = -m_0[-u^2]^{1/2}, \tag{22}$$

which is the well-known Lagrangian for a relativistic point particle.

Since the Lagrangian (21) is a function of the all Lorentz scalars that can be formed from the velocities u and σ, namely u^2, σ^2, $u\sigma\sigma u$, and $\det\sigma$ we observe that such a Lagrangian has manifest Lorentz invariance. In fact, the Lagrangian (21) has a Poincaré invariance under the infinitesimal transformations $\delta x^\mu = a^\mu + \omega^\mu_\nu x^\nu$ and $\delta e^\mu_{(\alpha)} = \omega^\mu_\nu e^\nu_{(\alpha)}$, for arbitrary $\omega_{\mu\nu} = -\omega_{\nu\mu}$. By explicit computation, one can show by applying Noether's procedure to these transformations that P^μ and $M^{\mu\nu} = x^\mu P^\nu - x^\nu P^\mu + \Sigma^{\mu\nu}$ are conserved generators obeying the Poincaré group algebra (see Refs. 3 and 4 for details).

III. THE CONSTRAINTS FROM THE SECOND ORDER LAGRANGIAN

The central idea in this section is to derive the set of constraints associated with (21) which, of course, should correspond to (10) and (11). Instead of starting with the Lagrangian given in (21) we shall take advantage of the formulas (16) and (17). From this perspective one may assume that $\lambda = \lambda(u, \sigma)$ and define a "linear momentum" p_μ and an "internal angular momentum" $l_{\mu\nu}$ as

$$p_\mu = \frac{\partial\lambda}{\partial u^\mu} \tag{23}$$

and

$$l_{\mu\nu} = \frac{\partial\lambda}{\partial\sigma^{\mu\nu}}, \tag{24}$$

respectively. According to (17) we have the relations: $P_\mu = -m_0^2 p_\mu$ and $\Sigma_{\mu\nu} = -m_0^2 l_{\mu\nu}$. One of the reasons to define p_μ and $l_{\mu\nu}$ is to avoid carrying all the time the factor m_0^2.

Taking the derivative of (16) with respect to u^μ leads to

$$\left[\lambda^3 + \frac{\lambda}{2m_0^2}\left(u^2 + \frac{1}{2}r^2\sigma^2\right)\right]p_\mu = -\frac{\lambda^2}{2m_0^2}u_\mu + \frac{r^2}{2m_0^4}u^\alpha\sigma_{\alpha\beta}\sigma^\beta{}_\mu. \tag{25}$$

Let us define

$$A = \left[\lambda^3 + \frac{\lambda}{2m_0^2}\left(u^2 + \frac{1}{2} r^2 \sigma^2 \right) \right]. \tag{26}$$

We find

$$A^2 p^2 = \frac{\lambda^4 u^2}{4m_0^4} - \frac{\lambda^2 r^2}{2m_0^6} u\sigma\sigma u + \frac{r^4}{4m_0^8} u^\alpha \sigma_{\alpha\beta} \sigma^\beta{}_\mu \sigma^\mu{}_\tau \sigma^\tau{}_\lambda u^\lambda. \tag{27}$$

But the identity (A19) leads to

$$u^\alpha \sigma_{\alpha\beta} \sigma^\beta{}_\mu \sigma^\mu{}_\tau \sigma^\tau{}_\lambda u^\lambda = u^\alpha \sigma_{\alpha\beta} [-\tfrac{1}{2} \sigma^\beta{}_\lambda \sigma^2 - \tfrac{1}{4} \sigma^{*\beta}{}_\lambda (\sigma * \sigma)] u^\lambda \tag{28}$$

and therefore we have

$$A^2 p^2 = \frac{\lambda^4}{4m_0^4} u^2 - \frac{\lambda^2 r^2}{2m_0^6} u\sigma\sigma u - \frac{r^4}{8m_0^8} u\sigma\sigma u \sigma^2 + \frac{1}{64} \frac{r^4}{m_0^8} u^2 (\sigma \cdot \sigma *)^2, \tag{29}$$

where we used the fact that

$$\sigma_{\alpha\beta} \sigma^{*\beta}{}_\lambda = -\tfrac{1}{4} \eta_{\alpha\lambda} (\sigma \cdot \sigma *). \tag{30}$$

Similarly, applying to (16) the derivative with respect to $\sigma^{\mu\nu}$ we obtain

$$\left[\lambda^3 + \frac{\lambda}{2m_0^2}\left(u^2 + \frac{1}{2} r^2 \sigma^2 \right) \right] l_{\mu\nu} = -\frac{\lambda^2 r^2}{2m_0^2} \sigma_{\mu\nu} + \frac{r^2}{2m_0^4} (u^\alpha \sigma_{\alpha\mu} u_\nu - u^\alpha \sigma_{\alpha\nu} u_\mu) + \frac{r^4}{8m_0^4} \sigma^*_{\mu\nu} (\sigma \cdot \sigma *), \tag{31}$$

where we used (A18). This expression yields

$$A^2 l^2 = \frac{\lambda^4 r^4}{4m_0^4} \sigma^2 - \frac{\lambda^2 r^4}{m_0^6} u\sigma\sigma u - \frac{\lambda^2 r^6}{8m_0^6} (\sigma \cdot \sigma *)^2 - \frac{r^4}{2m_0^8} u\sigma\sigma u u^2 - \frac{r^6}{16m_0^8} u^2 (\sigma \cdot \sigma *)^2 - \frac{r^8 \sigma^2}{64 m_0^8} (\sigma \cdot \sigma *)^2, \tag{32}$$

where we used the identities $\sigma^* \sigma^* = -\sigma\sigma$ and (30).

Adding (29) and (32) leads to

$$\begin{aligned} A^2 \left(p^2 + \frac{1}{2r^2} l^2 \right) = {} & \frac{\lambda^4}{4m_0^4} \left(u^2 + \frac{1}{2} r^2 \sigma^2 \right) - \frac{\lambda^2 r^2}{m_0^6} (u\sigma\sigma u - r^2 \det \sigma) \\ & - \frac{r^4}{4m_0^8} \left(u^2 + \frac{1}{2} r^2 \sigma^2 \right) (u\sigma\sigma u - r^2 \det \sigma), \end{aligned} \tag{33}$$

where we used (A18).

Using (16) and (26) we discover that

$$p^2 + \frac{1}{2r^2} l^2 = -\frac{1}{m_0^2}. \tag{34}$$

Since $P_\mu = -m_0^2 p_\mu$ and $\Sigma_{\mu\nu} = -m_0^2 l_{\mu\nu}$ we finally get from (34) the constraint

$$P^2 + \frac{1}{2r^2} \Sigma^2 + m_0^2 = 0. \tag{35}$$

Let us now derive from (25) and (31) the constraint $\Sigma^{\mu\nu} P_\nu = 0$. We have

$$A^2 l^{\mu\nu} p_\nu = \frac{\lambda^4 r^2}{2m_0^2}\sigma^{\mu\nu}u_\nu + \frac{\lambda^2 r^2 u^2}{2m_0^6}\sigma^{\mu\nu}u_\nu - \frac{\lambda^2 r^4}{8m_0^6}(\sigma\cdot\sigma^*)\sigma^{*\mu\nu}u_\nu - \frac{\lambda^2 r^4}{2m_0^6}\sigma^{\mu\nu}\sigma_{\nu\alpha}\sigma^{\alpha\beta}u_\beta - \frac{r^4(u\sigma\sigma u)}{2m_0^8}\sigma^{\mu\nu}u_\nu + \frac{r^4 u^\mu}{2m_0^8}u_\tau\sigma^{\tau\nu}\sigma_{\nu\alpha}\sigma^{\alpha\beta}u_\beta + \frac{r^6}{2m_0^8}(\sigma\cdot\sigma^*)\sigma^{*\mu\nu\tau\nu}\sigma_{\nu\alpha}\sigma^{\alpha\beta}u_\beta. \tag{36}$$

The sixth term on the right-hand side of (36) vanishes due to the identity $u_\tau\sigma^{\tau\nu}\sigma_{\nu\alpha}\sigma^{\alpha\beta}u_\beta \equiv 0$. Using (A19) and (30) it is not difficult to show that (36) is reduced to

$$A^2 l^{\mu\nu} p_\nu = \frac{\lambda^4 r^2}{2m_0^2}\sigma^{\mu\nu}u_\nu + \frac{\lambda^2 r^2}{2m_0^6}\left(u^2 + \frac{r^2}{2}\sigma^2\right)\sigma^{\mu\nu}u_\nu - \frac{r^4}{2m_0^8}(u\sigma\sigma u - r^2\det\sigma)\sigma^{\mu\nu}u_\nu. \tag{37}$$

Solving the factor $(u\sigma\sigma u - r^2\det\sigma)$ in (16) and substituting the result in (37) we finally discover that $l^{\mu\nu}p_\nu = 0$. This leads to the constraint

$$\Sigma^{\mu\nu}P_\nu = 0, \tag{38}$$

which is the Tulczyjew constraint.

Summarizing, we have shown that the Lagrangian (21) leads to the constraints (35) and (38) which were the starting point in the first order formalism of Sec. II.

IV. FROM A POINT PARTICLE IN HIGHER DIMENSIONS TO THE DE SITTER RELATIVISTIC TOP

Let us start writing the higher dimensional metric γ_{MN} in terms of the vielbien field E_M^A,

$$\gamma_{MN} = E_M^A E_N^B \eta_{AB}, \tag{39}$$

where η_{AB} is a *flat metric* in $4+N$ dimensions. Here we are considering the vielbien field E_M^A as a the function of the coordinates x^M.

The Lagrangian of a point particle moving in a background determined by the metric γ_{MN} is

$$L = -M_0(-\gamma_{MN}\dot{x}^M\dot{x}^N)^{1/2}, \tag{40}$$

where M_0 is the analogue of the mass of the object and $\dot{x}^M \equiv \mathrm{d}x^M/\mathrm{d}\tau$. From this Lagrangian one gets the Euler–Lagrange equations of motion

$$\frac{DP^M}{D\tau} \equiv \dot{P}^M + \Gamma_{RS}^M \dot{x}^R P^S = 0, \tag{41}$$

where

$$P_M = \frac{\partial L}{\partial \dot{x}^M} \tag{42}$$

and Γ_{RS}^M are the Christoffel symbols associated with γ_{MN}. We can write E_M^A in the form

$$E_M^A = \begin{pmatrix} E_\mu^a(x,y) & E_\mu^{a'}(x,y) \\ E_i^a(x,y) & E_i^{a'}(x,y) \end{pmatrix}, \tag{43}$$

where we used the notation $x^M = (x^\mu, y^i) = (x, y)$.

Using the Kaluza–Klein mechanism it is well known that E_M^A can be written in the form

$$E_M^A = \begin{pmatrix} e_\mu^a(x) & \omega_\mu^{a'}(x) \\ 0 & e_i^{a'}(y) \end{pmatrix}. \tag{44}$$

Here, for later convenience, we used the notation $\omega_\mu^{a'} \equiv E_\mu^{a'}$, $e_\mu^a \equiv E_\mu^a$, and $e_i^{a'} \equiv E_i^{a'}$.

Using (44) we can brake the metric (39) in the form

$$\gamma_{\mu\nu} = g_{\mu\nu} + \omega_\mu^{a'}\omega_\nu^{b'}\eta_{a'b'},$$

$$\gamma_{\mu i} = \omega_\mu^{a'} e_i^{b'}\eta_{a'b'}, \tag{45}$$

$$\gamma_{ij} = e_i^{a'} e_j^{b'}\eta_{a'b'} = g_{ij}(y),$$

where $g_{\mu\nu}(x) = e_\mu^a(x)e_\nu^b(x)\eta_{ab}$.

The line element ds^2 associated with γ_{MN} is

$$ds^2 = \gamma_{MN}\,dx^M\,dx^N = \gamma_{\mu\nu}\,dx^\mu\,dx^\nu + 2\gamma_{\mu i}\,dx^\mu\,dy^i + \gamma_{ij}\,dy^i\,dy^j. \tag{46}$$

Substituting (45) within (46) one gets

$$ds^2 = (g_{\mu\nu} + \omega_\mu^{a'}\omega_\nu^{b'}\eta_{a'b'})dx^\mu\,dx^\nu + 2(\omega_\mu^{a'}e_i^{b'}\eta_{a'b'})dx^\mu\,dy^i + (e_i^{a'}e_j^{b'}\eta_{a'b'})dy^i\,dy^j. \tag{47}$$

This expression can be rewritten in the following form:

$$ds^2 = g_{\mu\nu}dx^\mu\,dx^\nu + (\omega_\mu^{a'}\,dx^\mu + e_i^{a'}\,dy^i)^2, \tag{48}$$

which is the Fukuyama starting point in the study of spinning particles.[17] If we choose the base[18,19]

$$\theta^\mu = dx^\mu \tag{49a}$$

and

$$\theta^{a'} = \omega_\mu^{a'}\,dx^\mu + e_i^{a'}\,dy^i, \tag{49b}$$

then we have that the line element (48) becomes

$$ds^2 = g_{\mu\nu}\theta^\mu\theta^\nu + \eta_{a'b}\theta^{a'}\theta^{b'}. \tag{50}$$

Therefore, in the base (49) the metric takes the form

$$\hat{\gamma}_{MM} = \begin{pmatrix} g_{\mu\nu} & 0 \\ 0 & \eta_{a'b'} \end{pmatrix}. \tag{51}$$

The dual base is given by

$$D_\mu = \partial_\mu - \omega_\mu^{a'}e_{a'}^i\partial_i \tag{52a}$$

and

$$D_{a'} = e_{a'}^i\partial_i. \tag{52b}$$

In fact, one can verify that

$$\langle\theta^\mu, D_\nu\rangle = \langle dx^\mu, \partial_\nu - \omega_\nu^{a'}e_{a'}^i\partial_i\rangle = \delta_\nu^\mu \tag{53}$$

and

$$\langle\theta^{a'}, D_{b'}\rangle = \langle\omega_\mu^{a'}\,dx^\mu + e_i^{a'}\,dx^i, u_{b'}^j\partial_j\rangle = e_i^{a'}e_{b'}^i = \delta_{b'}^{a'}. \tag{54}$$

Similarly, one can check that

$$\langle \theta^{a'}, D_\nu \rangle = \langle \omega_\mu^{a'}\, \mathrm{d}x^\mu + e_i^{a'}\, \mathrm{d}x^i, \partial_\nu - \omega_\nu^{b'} e_{b''}^j \partial_j \rangle = \omega_\nu^{a'} - e_j^{a'} e^{jb'} \omega_{b'\nu} = \omega_\nu^{a'} - \eta^{a'b'} \omega_{b'\nu} = 0. \quad (55)$$

Let us compute the commutator $[D_\mu, D_\nu]$. From (52a) we have

$$[D_\mu, D_\nu] = [\partial_\mu - \omega_\mu^{a'} e_{a'}^i \partial_i, \partial_\nu - \omega_\nu^{b'} e_{b''}^j \partial_j] = \partial_\mu(\partial_\nu - \omega_\nu^{b'} e_{b''}^j \partial_j) - \omega_\mu^{a'} e_{a'}^i \partial_i(\partial_\nu - \omega_\nu^{b'} e_{b''}^j \partial_j)$$
$$= -\partial_\nu(\partial_\mu - \omega_\mu^{a'} e_{a'}^i \partial_i) + \omega_\nu^{b'} e_{b''}^j \partial_j(\partial_\mu - \omega_\mu^{a'} e_{a'}^i \partial_i). \quad (56)$$

Considering that $[\partial_\mu, \partial_\nu]=0$, $[\partial_i, \partial_j]=0$ and $[\partial_\mu, \partial_i]=0$ we find that the expression (56) reduces to

$$[D_\mu, D_\nu] = (-\partial_\mu \omega_\nu^{b'} + \partial_\nu \omega_\mu^{b'}) e_{b'}^j \partial_j + (\omega_\mu^{a'} e_{a'}^i \omega_\nu^{b'} - \omega_\nu^{c'} e_{c'}^i \omega_\mu^{b'})(\partial_i e_{b'}^j)\partial_j. \quad (57)$$

The second term in (57) can be rewritten as

$$(\omega_\mu^{a'} e_{a'}^i \omega_\nu^{b'} - \omega_\nu^{c'} e_{c'}^i \omega_\mu^{b'})(\partial_i e_{b'}^j)\partial_j = \omega_\mu^{a'} \omega_\nu^{b'} (e_{a'}^i \partial_i e_{b'}^j - e_{b''}^l \partial_l e_{a'}^j). \quad (58)$$

Let us write $e_{a'} \equiv e_{a'}^i \partial_i$, thus we have

$$(e_{a'}^i \partial_i e_{b'}^j - e_{b''}^l \partial_l e_{a'}^j) = [e_{a'}, e_{b'}]. \quad (59)$$

We assume that

$$[e_{a'}, e_{b'}] = -C_{a'b'}^{d'} e_{d'}, \quad (60)$$

where $C_{a'b'}^{d'}$ are the structure constants associated with some group G. Substituting (60) into (57) we find the expression

$$[D_\mu, D_\nu] = (-\partial_\mu \omega_\nu^{b'} + \partial_\nu \omega_\mu^{b'}) e_{b'} - \omega_\mu^{a'} \omega_\nu^{b'} C_{a'b'}^{d'} e_{d'}, \quad (61)$$

which by means of the definition

$$R_{\mu\nu}^{b'} = \partial_\mu \omega_\nu^{b'} - \partial_\nu \omega_\mu^{b'} + C_{c'd'}^{b'} \omega_\mu^{c'} \omega_\nu^{d'} \quad (62)$$

becomes

$$[D_\mu, D_\nu] = -R_{\mu\nu}^{b'} e_{b'}. \quad (63)$$

Following similar procedure we find that

$$[D_\mu, D_{a'}] = 0 \quad (64)$$

and

$$[D_{a'}, D_{b'}] = -C_{a'b'}^{d'} e_{d'}. \quad (65)$$

Thus, from (63)–(65) we see that the only nonvanishing structure constants related to the commutator $[D_M, D_N]$ are $C_{\mu\nu}^{b'} = -R_{\mu\nu}^{b'}$ and $C_{a'b'}^{d'}$.

In general, in a nonbase frame, the connection Γ_{MNP} is given by

$$\Gamma_{MNP} = \tfrac{1}{2}(D_P \hat{\gamma}_{MN} + D_N \hat{\gamma}_{MP} - D_M \hat{\gamma}_{NP}) + \tfrac{1}{2}(C_{MNP} + C_{MPN} - C_{NPM}). \quad (66)$$

Since $C_{\mu\nu\alpha}=0$ and $\hat{\gamma}_{\mu\nu}=g_{\mu\nu}(x)$ we get

$$\Gamma_{\mu\nu\alpha} = \tfrac{1}{2}(D_\alpha \hat{\gamma}_{\mu\nu} + D_\nu \hat{\gamma}_{\nu\alpha} - D_\mu \hat{\gamma}_{\nu\alpha}) = \tfrac{1}{2}(\partial_\alpha g_{\mu\nu} + \partial_\nu g_{\nu\alpha} - \partial_\mu g_{\nu\alpha}) \equiv \{\mu\nu\alpha\}. \quad (67)$$

In the same way, since $C_{\mu\nu a'} = -R_{\mu\nu a'}$ we obtain

$$\Gamma_{\mu\nu a'} = \tfrac{1}{2}(C_{\mu\nu a'} + C_{\mu a'\nu} - C_{\nu a'\mu}) = -\tfrac{1}{2}R_{\mu\nu a'}. \tag{68}$$

We also get

$$\Gamma_{\mu a'b'} = 0 \tag{69}$$

and

$$\Gamma_{a'b'c'} = -\tfrac{1}{2}C_{a'b'c'}. \tag{70}$$

With these results in hand for Γ_{MNP} we shall proceed to see their consequences in the equations of motion (41). Let us start splitting (41) in the following form:

$$\dot{P}^{\mu} + \Gamma^{\mu}_{\nu\alpha}\dot{x}^{\nu}P^{\alpha} + \Gamma^{\mu}_{\nu a'}\dot{x}^{\nu}P^{a'} + \Gamma^{\mu}_{a'\nu}\dot{x}^{a'}P^{\nu} = 0 \tag{71}$$

and

$$\dot{P}^{a'} + \Gamma^{a'}_{b'c'}\dot{x}^{b'}P^{c'} = 0, \tag{72}$$

where we used the fact that the only nonvanishing components of Γ_{MNP} are $\Gamma_{\mu\nu\alpha}$, $\Gamma_{\mu\nu a'}$ and $\Gamma_{a'b'c'}$.

Using (67) and (68) we discover that (71) and (72) yields

$$\frac{\overline{D}P^{\mu}}{\overline{D}\tau} = R^{\mu}_{\nu a'}\dot{x}^{\nu}P^{a'} \tag{73}$$

and

$$\dot{P}^{a'} = 0, \tag{74}$$

respectively, where $\overline{D}/\overline{D}\tau$ means covariant derivative in terms of the Christoffel symbols $\{\mu\nu\alpha\}$. Here we used the fact that

$$P_M = \frac{M_0\gamma_{MN}\dot{x}^N}{(-\gamma_{PQ}\dot{x}^P\dot{x}^Q)^{1/2}}, \tag{75}$$

which means that $P^M = \lambda\dot{x}^M$, with $\lambda = M_0(-\gamma_{PQ}\dot{x}^P\dot{x}^Q)^{-1/2}$.

We shall show now that (73) and (74) are equivalent to the relativistic top equations of motion (RTEM) in a gravitational field.[20–25] For that purpose we shall make the indices identification $a' \to (a,b)$ where the pair (a,b) is antisymmetric. Thus, the equations of motion (73) and (74) become

$$\frac{\overline{D}P^{\mu}}{\overline{D}\tau} = \frac{1}{2}R^{\mu}_{\nu ab}\dot{x}^{\nu}S^{ab} \tag{76}$$

and

$$\dot{S}^{ab} = 0, \tag{77}$$

where we used the notation $S^{ab} \equiv P^{ab}$ and introduced in (76) the quantity $\frac{1}{2}$ in order to avoid counting twice.

The last step is to write $S^{ab} = e^a_{\mu}e^b_{\nu}S^{\mu\nu}$ in order to write (76) and (77) in the form

$$\frac{\overline{D}P^{\mu}}{\overline{D}\tau} = \frac{1}{2}R^{\mu}_{\nu\alpha\beta}\dot{x}^{\nu}S^{\alpha\beta} \tag{78}$$

and

$$\frac{\overline{D}S^{\mu\nu}}{\overline{D}\tau} = 0, \tag{79}$$

which are the traditional forms given to the RTEM in a gravitational field.

It is interesting to clarify the meaning of the constant M_0. From (75) it follows the constraint

$$P^M P^N \hat{\gamma}_{MM} = -M_0^2, \tag{80}$$

which in virtue of the form of the metric $\hat{\gamma}_{MM}$, given in (51), we see that (80) can be written as

$$g_{\mu\nu}P^{\mu}P^{\nu} + \eta_{a'b'}P^{a'}P^{b'} = -M_0^2 \tag{81}$$

or

$$g_{\mu\nu}P^{\mu}P^{\nu} + \frac{1}{2r^2}S^{\mu\nu}S_{\mu\nu} = -m_0^2, \tag{82}$$

where we used the relation $S^{ab}=e^a_{\mu}e^b_{\nu}S^{\mu\nu}$ and redefined P^{μ} as rP^{μ} and M_0 as rm_0 with r a constant of the motion. If we compare the expression (82) with (1) we observe their great similarity. However, they are not exactly the same because the constraint $\Sigma^{\mu\nu}P_{\nu}\approx 0$ given in (4) is not satisfied by P^{μ} and $S^{\mu\nu}$. Instead of the constraint (4) we can define the vector

$$S^{\mu} = \tfrac{1}{2}\epsilon^{\mu\nu\alpha\beta}P_{\nu}S_{\alpha\beta} \tag{83}$$

and, as a consequence of this formula, we have

$$S^{\mu}P_{\mu} = 0. \tag{84}$$

Nevertheless, the relation between $\Sigma^{\mu\nu}$ and $S^{\mu\nu}$ is subtle and requires a careful analysis. First of all, let us write the first order Lagrangian

$$L = \dot{x}^M P_M - \frac{\lambda'}{2}(P^M P_M + M_0^2), \tag{85}$$

corresponding to (40). Using (82) we see that (40) can be written as

$$L = \dot{x}^{\mu}P_{\mu} + \frac{1}{2}\dot{x}^{\mu\nu}S_{\mu\nu} - \frac{\lambda}{2}\left(P^{\mu}P_{\mu} + \frac{1}{2r^2}S^{\mu\nu}S_{\mu\nu} + m_0^2\right), \tag{86}$$

where $\dot{x}^{\mu\nu}=e^{\mu}_a e^{\nu}_b \dot{x}^{ab}$ and $\lambda \equiv r^2\lambda'$. Comparing (86) with (6) one observes the close similarity between both Lagrangians. We can even try to go from (86) to (6) by using the transformation

$$S^{\mu\nu} = \Sigma^{\mu\nu} + \xi^{\mu}P^{\nu} - \xi^{\nu}P^{\mu}. \tag{87}$$

But this implies to redefine the velocities u^{μ} and $\sigma^{\mu\nu}$ in terms of the velocities $\dot{x}^{\mu}$ and $\dot{x}^{\mu\nu}$. This is related to the fact that the motion of a relativistic top can be described, in an equivalent way, by two position vectors, namely, the center of mass and the center of charge. (An extensive discussion about the meaning of these two position vectors of a relativistic top can be found in Ref. 26.) The center of mass can be associated with $\Sigma^{\mu\nu}$ via the constraint $\Sigma^{\mu\nu}P_{\nu}\approx 0$, while the center of charge with $S^{\mu\nu}$. Thus, the transformation (87) suggests to identify the variable ξ^{μ} with the difference between the center of mass and the center of charge. In fact, multiplying (87) by P_{μ} one gets

$$S^{\mu\nu}P_{\nu} = \xi^{\mu}P^{\nu}P_{\nu}, \tag{88}$$

where we assumed $\xi^{\mu}P_{\mu}=0$. Substituting this expression into (87) one discovers that $\Sigma^{\mu\nu}$ can be obtained from $S^{\mu\nu}$ using the projector $\eta^{\mu\alpha}-(1/P^2)P^{\mu}P^{\alpha}$.

Summarizing, we have shown that using the Kaluza–Klein theory it is possible to obtain the relativistic top theory from a point particle in higher dimensions. This is in fact a very interesting result because it means that although the top does not follow geodesics in four dimensions, it does in higher dimensions.

V. FINAL COMMENTS

In this paper we have shown different aspects of a particular relativistic top, namely the top satisfying (1) and (4). First, we showed the equivalence between the first and second order Lagrangians (6) and (21). Then, the form of the Lagrangian (6) motivated us to look for a higher dimensional description of the top, and as a matter of fact we discovered that it is possible to obtain the relativistic top equations of motion starting from a geodesic equation of motion of a point particle in higher dimensions. This is an interesting result that deserves to be analyzed in terms of a fiber bundle scenario.

First we notice that such a result is similar to the case of the Lorentz force associated with a charged particle which can be obtained from a geodesic in five dimensions. More generally, our result is similar to the generalized Lorentz force associated with a Yang–Mills gauge field which can be obtained by a geodesic in $4+D$-dimensions. In this case, the traditional method is to consider a $4+D$-dimensional principle fiber bundle P, which locally looks like $M^4\times B$, where M^4 is a four-dimensional base space and B is a group manifold whose dimension is D. The key object to connect the geodesic in $4+D$-dimensions with the generalized Lorentz force in four dimensions is the one-form in the cotangent space $T^*(P)$,

$$\omega = g^{-1}\,\mathrm{d}g + g^{-1}Ag, \tag{89}$$

where $A=A^{a}_{\mu}T_a\,\mathrm{d}x^{\mu}$ can eventually be identified with the Yang–Mills gauge field. Here, T_a are the generators of some group G acting transitively on B and having the properties

$$[T_a,T_b] = C^{c}_{ab}T_c. \tag{90}$$

In principle, if we consider the fiber space $M^4\times Q$, where Q corresponds also to a four-dimensional manifold, one may apply similar description to the case of a spinning object (see Ref. 17). In this case the connection one-form reads as

$$\omega = g^{-1}\,\mathrm{d}g + g^{-1}\Omega g, \tag{91}$$

where Ω is given by

$$\Omega = \tfrac{1}{2}\omega^{AB}_{\mu}S_{AB}\,\mathrm{d}x^{\mu}. \tag{92}$$

Here, we shall assume that S_{AB} are the generators of the de Sitter group SO(1,4) [or anti–de Sitter group SO(2,3)]. If we compare (49b) with (91) we observe that both expressions are very similar. In fact, since g is an element of SO(1,4) we can write g as a matrix in the form Λ^{A}_{B} and therefore the one-form (91) yields

$$\omega^{AB} = \omega^{AB}_{i}\,\mathrm{d}y^{i} + \omega^{AB}_{\mu}\,\mathrm{d}x^{\mu}, \tag{93}$$

where $\omega^{AB}_{i}=\Lambda^{CA}\partial_i\Lambda^{B}_{C}$. This expression can be written as

$$\omega^{5a} = \omega^{5a}_{i}\,\mathrm{d}y^{i} + \omega^{5a}_{\mu}\,\mathrm{d}x^{\mu} \tag{94}$$

and

$$\omega^{ab} = \omega_i^{ab}\, \mathrm{d}y^i + \omega_\mu^{ab}\, \mathrm{d}x^\mu. \tag{95}$$

The base (49a) and (49b) arises from (94) and (95) by defining $e_i^{a'} \equiv \omega_i^{ab}$, $e_\mu^a \equiv \omega_\mu^{5a}$ and setting ω_i^{5a} equal to zero. This means that we can write (44) in the following form:

$$\omega_M^{AB} = \begin{pmatrix} \omega_\mu^{5a}(x) & \omega_\mu^{ab}(x) \\ 0 & \omega_i^{ab}(y) \end{pmatrix}. \tag{96}$$

Therefore, the metric γ_{MN} in (39) becomes

$$\gamma_{MN} = \tfrac{1}{2}\omega_M^{AB}\omega_{NAB} \tag{97}$$

and consequently the Lagrangian (40) can be written as

$$L = -M_0(-\tfrac{1}{2}\omega_M^{AB}\omega_{NAB}\dot{x}^M\dot{x}^N)^{1/2}. \tag{98}$$

Thus, the corresponding line element is

$$\mathrm{d}s^2 = \tfrac{1}{2}\omega_M^{AB}\omega_{NAB}\, \mathrm{d}x^M\, \mathrm{d}x^N, \tag{99}$$

which is in agreement with the Fukuyama's suggestion.[17] We shall call the system described by the Lagrangian (98) with ω_M^{AB} given by (96) the *de Sitter top*.

There are several observations that one can make from our analysis but perhaps one of the most important is the fact that the top theory leads naturally to consider the de Sitter group SO(1,4) [or anti–de Sitter group SO(2,3)] via the connection ω_M^{AB}. As it is well known, this group structure appears in several fronts of current interest, including Maldacena's conjecture in string theory, accelerated universe, and the gravitational gauge approach of MacDowell–Mansouri. For this reason it turns out to be of particular interest for further research to study the possible connection between the de Sitter top and these lines of research.

On the other hand, since in the Kaluza–Klein $4+N+D$-dimensional space the metric gives gravity, Yang–Mills, and scalar fields, a top moving in this space will be acted on by these fields. It may be interesting to see how the Yang–Mills field, which can be understood as the field which generates rotations in the isospace, affects the motion of the top. In Ref. 27 some computations in this direction were reported. We attach a brief review of such computations as an appendix (see Appendix B). Part of our task, for further research, is to analyze these computations from the point of view of the present work.

Finally, the Regge trajectory (1) which lead us to the de Sitter relativistic top concept is a very particular relation between the mass and the spin of a particle. In general, a singular Lagrangian can lead to more general Regge trajectories of the form (B5). In particular, by using group theoretical methods, Atre and Mukunda[7] have developed a systematic procedure for other possible Regge trajectories. In those cases one should expect generalizations or alternatives of the de Sitter relativistic top which is based in the de Sitter group. From the group theoretical point of view, however, such a generalization or alternative appears as an intriguing possibility motivating further research on the subject.

ACKNOWLEDGMENT

The authors would like to thank M. C. Marín for helpful comments.

APPENDIX A

In this appendix we present the proof of formula (15). From (7) and (10) we get

$$u^2 = \lambda^2 P^2 + V^2. \tag{A1}$$

Similarly, from (9), (10), and (12) we find

$$\sigma^2 = \frac{\lambda^2}{r^4}\Sigma^2 + 2\xi^2 P^2. \tag{A2}$$

Here we also used the notation $b^2 = b^{\mu\nu}b_{\mu\nu}$, for any tensor $b^{\mu\nu}$.

We shall compute

$$\sigma^4 \equiv \sigma_{\mu\nu}\sigma^{\nu}{}_{\alpha}\sigma^{\alpha}{}_{\beta}\sigma^{\beta\mu}. \tag{A3}$$

Observe first that

$$\sigma^{\mu\alpha}\sigma_{\alpha}{}^{\nu} = \frac{\lambda^2}{r^4}\Sigma^{\mu\alpha}\Sigma_{\alpha}{}^{\nu} - \frac{\lambda}{r^2}(V^{\mu}P^{\nu} + V^{\nu}P^{\mu}) - \xi^2 P^{\mu}P^{\nu} - P^2\xi^{\mu}\xi^{\nu}, \tag{A4}$$

where we used (10) and (12). The expression (A4) leads to

$$\sigma^4 = \frac{\lambda^4}{r^8}\Sigma^4 + 4\frac{\lambda^2}{r^4}P^2V^2 + 2\xi^2\xi^2P^2P^2, \tag{A5}$$

where once again we used (10) and (12) and antisymmetric properties, such as $\Sigma^{\mu\nu}\xi_{\mu}\xi_{\nu} \equiv 0$.

We also need to compute

$$u\sigma\sigma u \equiv u_{\mu}\sigma^{\mu\nu}\sigma_{\nu}{}^{\alpha}u_{\alpha}. \tag{A6}$$

From (7), (9), (10), and (12) we find

$$\sigma^{\mu\nu}u_{\nu} = \frac{\lambda}{r^2}\Sigma^{\mu\nu}V_{\nu} - \lambda P^2\xi^{\mu}. \tag{A7}$$

Therefore, we have

$$u\sigma\sigma u = -\lambda^2\left(-\frac{1}{r^4}V_{\mu}\Sigma^{\mu\nu}\Sigma_{\nu}{}^{\alpha}V_{\alpha} + \frac{2}{r^2}P^2V^2 + P^2P^2\xi^2\right) \tag{A8}$$

or

$$u\sigma\sigma u = -\lambda^2\left(\frac{1}{r^4}\xi_{\alpha}\Sigma^{\alpha\nu}\Sigma_{\nu\tau}\Sigma^{\tau\lambda}\Sigma_{\lambda}{}^{\beta}\xi_{\beta} + \frac{2}{r^2}P^2V^2 + P^2P^2\xi^2\right). \tag{A9}$$

Now, let us define the dual of any antisymmetric tensor $A_{\alpha\beta}$ as

$$A^{*\mu\nu} = \tfrac{1}{2}\epsilon^{\mu\nu\alpha\beta}A_{\alpha\beta}, \tag{A10}$$

where $\varepsilon^{\mu\nu\alpha\beta}$ is the completely antisymmetric Levi–Cività tensor.

It turns out that from the constraint (10) it follows

$$\Sigma^{*\mu\nu}\Sigma_{\mu\nu} = 0. \tag{A11}$$

Using (A11) it is not difficult to show that

$$\Sigma^{\mu\nu}\Sigma_{\nu\alpha}\Sigma^{\alpha\tau} = -\tfrac{1}{2}\Sigma^{\mu\tau}(\Sigma^2). \tag{A12}$$

Thus, using (A12) one finds that (A9) becomes

$$u\sigma\sigma u = -\lambda^2\left(\frac{1}{2r^4}V^2\Sigma^2 + \frac{2}{r^2}P^2V^2 + P^2P^2\xi^2\right). \tag{A13}$$

On the other hand, from (A2) we obtain

$$\sigma^2\sigma^2 = \frac{\lambda^4}{r^8}\Sigma^2\Sigma^2 + \frac{4\lambda^2}{r^4}\xi^2P^2\Sigma^2 + 4\xi^2\xi^2P^2P^2. \tag{A14}$$

Therefore, (A5) and (14) imply

$$\sigma^2\sigma^2 - 2\sigma^4 = \frac{4\lambda^2}{r^4}\xi^2P^2\Sigma^2 - \frac{8\lambda^2}{r^4}P^2V^2, \tag{A15}$$

where we used the fact that from (A12) it follows that

$$2\Sigma^4 - \Sigma^2\Sigma^2 = 0. \tag{A16}$$

Now, define

$$\det\sigma = \frac{1}{4!}\varepsilon^{\mu\nu\alpha\beta}\varepsilon^{\tau\lambda\sigma\rho}\sigma_{\mu\lambda}\sigma_{\nu\lambda}\sigma_{\alpha\sigma}\sigma_{\beta\rho}. \tag{A17}$$

It is not difficult to show that

$$\det\sigma = -\tfrac{1}{16}(\sigma * \sigma)^2. \tag{A18}$$

From the identity

$$\sigma^{\mu\alpha}\sigma_{\alpha\beta}\sigma^{\beta\nu} = -\tfrac{1}{2}\sigma^{\mu\nu}(\sigma^2) - \tfrac{1}{4}\sigma^{*\mu\nu}(\sigma * \sigma), \tag{A19}$$

we find

$$\sigma^4 = \tfrac{1}{2}\sigma^2\sigma^2 + \tfrac{1}{4}(\sigma * \sigma)(\sigma * \sigma). \tag{A20}$$

Therefore, by combining (A18) and (A20) we obtain

$$\det\sigma = \tfrac{1}{8}(\sigma^2\sigma^2 - 2\sigma^4). \tag{A21}$$

From (A15) we see that (A21) implies

$$\det\sigma = \frac{\lambda^2}{2r^4}\xi^2P^2\Sigma^2 - \frac{\lambda^2}{r^4}P^2V^2. \tag{A22}$$

Now, from (A13) and (A22) we see that

$$u\sigma\sigma u - r^2\det\sigma = \lambda^2\left[\frac{-1}{2r^4}V^2\Sigma^2 - \frac{2}{r^2}P^2V^2 - \xi^2r^2P^2 - \frac{1}{2r^2}\xi^2P^2\Sigma^2 + \frac{1}{r^2}P^2V^2\right] = \lambda^2\left[\frac{m_0^2}{r^2}V^2 + m_0^2\xi^2P^2\right]. \tag{A23}$$

Using (A1) and (A2) one finally sees that (A23) leads to (15).

APPENDIX B

In $4+N'$ dimensions, with $N'=N+D$, a top can be described by the variables $x^M(\tau)$ and $E_A^M(\tau)$, where x^M are $4+N'$ coordinates, $E_A^M(\tau)$ are $4+N'$ orthonormal vectors, τ is an arbitrary parameter and the index A in parentheses labels the name of the vector. The vectors E_A^M satisfy the condition

$$\gamma_{MN} = E_M^A E_N^B \eta_{AB}, \tag{B1}$$

where $\eta_{AB}=\mathrm{diag}(-1,1,\ldots,1)$ is a scalar matrix and γ_{MN} is the curved metric generalized to $4+N'$ dimensions.

Define the linear velocity u^M and the angular velocity σ^{MN} as follows:

$$u^M \equiv \frac{\mathrm{d}x^M}{\mathrm{d}\tau} = \dot{x}^M, \tag{B2}$$

$$\sigma^{MN} = \eta^{AB} E_A^M \frac{\Delta}{\mathrm{d}\tau} E_B^N = -\sigma^{NM}. \tag{B3}$$

Here, the symbol $\Delta/\mathrm{d}\tau$ means covariant derivative with respect to τ, having the Christoffel symbols Γ_{NP}^M as the connection. One sees that σ^{MN} is again antisymmetric by virtue of the condition (B1).

Consider a top with linear velocity u^M, angular velocity σ^{MN}, linear momentum P^M, and internal angular momentum S^{MN}. We will assume that the dynamics of the system is generated by the Lagrangian

$$L = -u^M P_M - \tfrac{1}{2}\sigma^{MN} S_{MN} + \lambda H + \lambda_M H^M, \tag{B4}$$

where

$$H \equiv P^M P_M - f(\tfrac{1}{2} S^{MN} S_{MN}) \tag{B5}$$

and

$$H^M \equiv S^{MN} P_N \tag{B6}$$

corresponds to the Regge and Tulcyzjew constraints, respectively, generalized to $4+N'$ dimensions. Here, λ and λ_M are Lagrange multipliers.

Using the Lagrangian (B4) and assuming the equivalence principle in $4+N'$ dimensions leads to the RTEM equations of motion generalized to higher dimensions,

$$\frac{\Delta P^M}{\mathrm{d}\tau} = -\frac{1}{2} R^M_{NPQ} u^N S^{PQ} \tag{B7}$$

and

$$\frac{\Delta S^{MN}}{\mathrm{d}\tau} = P^M u^N - P^N u^M. \tag{B8}$$

Here, $\Delta A^M/\mathrm{d}\tau = (\mathrm{d}A^M/\mathrm{d}\tau) + \Gamma^M_{NP} A^N u^P$, where A^M is any vector and R^M_{NPQ} is the Riemann tensor.

Using the constraint $H^M = 0$ one sees from (B8) that $J^2 = \frac{1}{2} S^{MN} S_{MN}$ is a constant of the motion. Using this fact and the constraint $H = 0$ one can show that $P^M P_M = -M^2$ is also a constant of the motion.

We will follow the strategy of doing the computations in the *horizontal lift base* defined by the commutators[18,19]

$$[D_\mu, D_\nu] = -F^a_{\mu\nu} D_a,$$

$$[D_\mu, D_a] = 0, \tag{B9}$$

$$[D_a, D_b] = f^c_{ab} D_c.$$

Therefore the only nonvanishing commutation coefficients are

$$C^c_{\mu\nu} = -F^c_{\mu\nu} \tag{B10}$$

and

$$C_{ab}^{c} = f_{ab}^{c}. \tag{B11}$$

In the base (B9) the metric associated with $M^4 \times N'$ is

$$\hat{\gamma}_{MN} = \begin{pmatrix} g_{\mu\nu} & 0 \\ 0 & g_{ab} \end{pmatrix}, \tag{B12}$$

with

$$D_a g_{\mu\nu} = 0,$$

$$D_c g_{ab} = f_{cab} + f_{cba},$$

$$D_\mu g_{ab} = \partial_\mu g_{ab} - A_\mu^c D_c g_{ab} = g_{\ ab|\mu},$$

$$D_\alpha g_{\mu\nu} = g_{\mu\nu,\alpha}. \tag{B13}$$

The Christoffel symbols are given in a noncoordinate base by

$$\hat{\Gamma}_{MNP} = \tfrac{1}{2}(D_P \hat{\gamma}_{MN} + D_N \hat{\gamma}_{MP} - D_N \hat{\gamma}_{NP}) + \tfrac{1}{2}(C_{MNP} + C_{MPN} - C_{NPM}), \tag{B14}$$

and the Riemann tensor is given by

$$\hat{R}_{NPQ}^{M} = D_P \hat{\Gamma}_{NQ}^{M} - D_Q \hat{\Gamma}_{NQ}^{M} + \hat{\Gamma}_{RP}^{M} \hat{\Gamma}_{NQ}^{R} - \hat{\Gamma}_{RQ}^{M} \Gamma_{NP}^{R} - \hat{\Gamma}_{NR}^{M} C_{PQ}^{R}. \tag{B15}$$

The linear velocity u^M, angular velocity σ^{MN}, linear momentum P^M, and internal angular momentum S^{MN} will be referred to below with respect to the "horizontal lift base" defined in (B9). By using (B12)–(B15) one may reduce the equations of motion (B7) to four dimensions,

$$\frac{D\Pi^\mu}{\mathrm{d}\tau} = -\tfrac{1}{2} R_{\nu\alpha\beta}^{\mu} u^\nu S^{\alpha\beta} + Q_a F_\nu^{\mu a} u^\nu + \tfrac{1}{4} F_{\alpha\beta}^{a}{}^{;\mu} M_a^{\alpha\beta} + Z^\mu. \tag{B16}$$

Here the following definitions were used:

$$\Pi^\mu \equiv P^\mu - \tfrac{1}{2} g_{ab} F_\nu^{\mu a} S^{\nu b}, \tag{B17}$$

$$Q_a \equiv g_{ab} P^b + \tfrac{1}{4} g_{ab} f_{ce}^{b} S^{ce} + \tfrac{1}{4} g_{ab} F_{\alpha\beta}^{b} S^{\alpha\beta} + \tfrac{1}{2} g_{\ ab|\alpha} S^{\alpha b}, \tag{B18}$$

$$M_a^{\alpha\beta} \equiv g_{ab} u^a S^{\alpha\beta} + g_{ab} u^\beta S^{\alpha b} - g_{ab} u^\alpha S^{\beta b}, \tag{B19}$$

and

$$Z^\mu = [(\tfrac{1}{2} u^a P^b - \tfrac{1}{4} F_{\alpha\beta}^{a} u^\alpha S^{\beta b} + \tfrac{1}{4} F_{\alpha\beta}^{a} S^{\alpha\beta} u^b - \tfrac{1}{4} g^{af} g_{\ fe|\alpha} u^e S^{\alpha b}) - \tfrac{1}{4} g^{af} g_{\ fe|\alpha} u^\alpha S^{eb} + (f_{ec}^{a} + f_{ce}^{a} + f_{ec}^{a}) u^e S^{cb}$$
$$- (f_{ec}^{b} u^a S^{ec})] g_{ab}{}^{|\mu} + \tfrac{1}{2} g_{ab}{}^{|\mu}{}_{;\alpha} S^{\alpha b} u^a. \tag{B20}$$

Here, the symbol $g_{ab}{}^{|\mu}{}_{;\alpha}$ means

$$g_{ab}{}^{|\mu}{}_{;\alpha} = g_{ab}{}^{|\mu}{}_{|\alpha} + \begin{Bmatrix} \mu \\ \beta\alpha \end{Bmatrix} g_{ab}{}^{|\beta},$$

where $g_{ab}{}^{|\mu}$ is defined in (B13), while the symbol $F_\alpha^{\mu a}{}_{;\beta}$ means

$$F_\alpha^{\mu a}{}_{;\beta} = F_\alpha^{\mu a}{}_{,\beta} + \begin{Bmatrix} \mu \\ \sigma\beta \end{Bmatrix} F_\alpha^{\sigma a} - \begin{Bmatrix} \sigma \\ \beta\alpha \end{Bmatrix} F_\sigma^{\mu a}.$$

In terms of the definitions (B17) and (B19) the equation of motion (B8) leads to

$$\frac{DS^{\mu\nu}}{d\tau} = \Pi^{\mu}u^{\nu} - \Pi^{\nu}u^{\mu} + \frac{1}{2}(F^{\mu\alpha a}M^{\nu}_{\alpha a} - M^{\mu\alpha}_{a}F^{\nu a}_{\alpha}) + H^{\mu\nu}, \tag{B21}$$

where

$$H^{\mu\nu} = S^{\mu a}u^{b}g_{ab}{}^{|\nu} - S^{\nu a}u^{b}g_{ab}{}^{|\mu}.$$

Clearly, Eqs. (B16) and (B21) are generalizations of the usual four-dimensional case. One can show that the quantity Q_a given in (B18) is a constant of the motion. It turns out that Q_a can be interpreted as charges of the system. For details the reader is referred to Ref. 27.

(Received 21 July 2004; accepted 11 September 2004; published online 3 January 2005)

We investigate the problem of introducing consistent self-couplings in free theories for mixed tensor gauge fields whose symmetry properties are characterized by Young diagrams made of two columns of arbitrary (but different) lengths. We prove that, in flat space, these theories admit no local, Poincaré-invariant, smooth, self-interacting deformation with at most two derivatives in the Lagrangian. Relaxing the derivative and Lorentz-invariance assumptions, there still is no deformation that modifies the gauge algebra, and in most cases no deformation that alters the gauge transformations. Our approach is based on a Becchi-Rouet-Stora-Tyutin (BRST) -cohomology deformation procedure. © *2005 American Institute of Physics.*

I. INTRODUCTION

These last few years, mixed symmetry gauge fields (i.e., that are neither completely symmetric nor antisymmetric) have attracted some renewed attention,[1–10] thereby reviving the efforts made in this direction during the 1980s, under the prompt of string field theory.[11–14] Mixed-symmetry fields appear in a wide variety of higher-dimensional ($D>4$) contexts. Indeed, group theory imposes that first-quantized particles propagating in flat background should provide representations of the Poincaré group. The cases $D=3,4$ are very particular in the sense that each tensor irreducible representation (irrep) of the little groups O(2) and O(3) is equivalent to a completely symmetric tensor irrep (pictured by a one-row Young diagram with S columns for a spin-S particle). When $D>4$, more complicated Young diagrams are allowed. For instance, all critical string theory spectra contain massive fields in mixed symmetry representations of the Lorentz group. In the tensionless limit ($\alpha' \to \infty$) all these massive excitations become massless. Another way to generate various mixed symmetry fields is by dualizing totally symmetric fields in higher dimensions.[3,6]

An irrep of the general linear group $\mathrm{GL}(D,\mathbb{R})$ is denoted by $[c_1,c_2,\ldots,c_L]$, where c_i indicates the number of boxes in the ith column of the Young diagram characterizing the corresponding irrep. We will focus on theories describing gauge fields $\phi_{\mu_1\cdots\mu_p|\nu_1\cdots\nu_q}$ whose symmetries correspond to the Young diagram $[p,q]$ formed by two columns of arbitrary (but different) lengths p and q ($p>q$). The physical degrees of freedom for such theories correspond to a traceless tensor carrying an irrep of the little group $\mathrm{O}(D-2)$ associated with the Young diagram $[p,q]$. Therefore,

we will work in space–time dimension $D \geqslant p+q+2$ so that the field carries local physical degrees of freedom. Such fields were studied recently at the free level in anti–de Sitter background.[9,10] In the sequel, we will frequently use a loose terminology by referring to a tensor irrep by its Young diagram.

In the present paper, we address the natural problem of switching on consistent self-interactions among $[p,q]$-type tensor gauge fields in flat background, where $p \neq q$. As in Refs. 15–20, we use the BRST-cohomological reformulation of the Noether method for the problem of consistent interactions.[21] For an alternative Hamiltonian-based deformation point of view, see Ref. 22. The question of consistent self-interactions in flat background has already been investigated in the case of vector (i.e., [1,0]) gauge fields in Ref. 15, p-forms (i.e., $[p,0]$-fields) in Ref. 16, Fierz–Pauli [1,1]-fields in Ref. 17, $[p,1]$-fields ($p>1$) in Ref. 18, [2,2]-fields in Ref. 19, and $[p,p]$-fields ($p>1$) in Ref. 20. Here, we extend and strengthen the results of Ref. 18 by relaxing some assumptions on the number of derivatives in the interactions. The present work is thus the completion of the analysis of self-interactions for *arbitrary* $[p,q]$-type tensor gauge fields in flat space.

Our main (no-go) result can be stated as follows, spelling out explicitly our assumptions.

Theorem: *In flat space and under the assumptions of locality and translation-invariance, there is no consistent smooth deformation of the free theory for* $[p,q]$*-type tensor gauge fields with* $p \neq q$ *that modifies the gauge algebra. Furthermore, for* $q>1$*, when there is no positive integer* n *such that* $p+2=(n+1)(q+1)$*, there exists no smooth deformation that alters the gauge transformations either. Finally, if one excludes deformations that involve four derivatives or more in the Lagrangian and that are not Lorentz-invariant, then there is no smooth deformation at all.*

The paper is organized as follows. In Sec. II, we review the free theory of $[p,q]$-type tensor gauge fields. In Sec. III, we introduce the BRST construction for the theory. Sections IV–VII are devoted to the proof of cohomological results. We compute $H(\gamma)$ in Sec. IV, an invariant Poincaré lemma is proved in Sec. V, the cohomologies $H_k^D(\delta|\mathrm{d})$ and $H_k^{D\ \mathrm{inv}}(\delta|\mathrm{d})$ are computed, respectively, in Secs. VI and VII. The self-interaction question is answered in Sec. VIII. A brief concluding section is finally followed by three appendixes containing the proofs of three theorems presented in the core of the paper.

II. FREE THEORY

As stated above, we consider theories for mixed tensor gauge fields $\phi_{\mu_1\cdots\mu_p|\nu_1\cdots\nu_q}$ whose symmetry properties are characterized by two columns of arbitrary (but different) lengths. In other words, the gauge field obeys the conditions

$$\phi_{\mu_1\cdots\mu_p|\nu_1\cdots\nu_q} = \phi_{[\mu_1\cdots\mu_p]|\nu_1\cdots\nu_q} = \phi_{\mu_1\cdots\mu_p|[\nu_1\cdots\nu_q]},$$

$$\phi_{[\mu_1\cdots\mu_p|\nu_1]\nu_2\cdots\nu_q} = 0,$$

where the square brackets denote strength-one complete antisymmetrization.

A. Lagrangian and gauge invariances

The Lagrangian of the free theory is

$$\mathcal{L} = -\frac{1}{2(p+1)!q!}\delta^{[\rho_1\cdots\rho_q\mu_1\cdots\mu_{p+1}]}_{[\nu_1\cdots\nu_q\sigma_1\cdots\sigma_{p+1}]}\partial^{[\sigma_1}\phi^{\ \sigma_2\cdots\sigma_{p+1}]|}_{\rho_1\cdots\rho_q}\partial_{[\mu_1}\phi_{\ \mu_2\cdots\mu_{p+1}]|}^{\ \ \ \ \ \ \nu_1\cdots\nu_q},$$

where the generalized Kronecker delta has strength one. This Lagrangian was obtained for [2,1]-fields in Ref. 11, for $[p,1]$-fields in Ref. 12 and, for the general case of $[p,q]$-fields, in the second paper of Ref. 5.

The quadratic action

$$S_0[\phi] = \int \mathrm{d}^D x\, \mathcal{L}(\partial\phi) \tag{1}$$

is invariant under gauge transformations with gauge parameters $\alpha^{(1,0)}$ and $\alpha^{(0,1)}$ that have respective symmetries $[p-1,q]$ and $[p,q-1]$. In the same manner as p-forms, these gauge transformations are *reducible*, their order of reducibility growing with p. We identify the gauge field ϕ with $\alpha^{(0,0)}$, the zeroth order parameter of reducibility. The gauge transformations and their reducibilities are (we introduce the short notation $\mu_{[p]} \equiv [\mu_1 \cdots \mu_p]$; a comma stands for a derivative, $\alpha_{,\nu} \equiv \partial_\nu \alpha$)

$$\delta\alpha^{(i,j)}_{\mu_{[p-i]}|\nu_{[q-j]}} = \partial_{[\mu_1}\alpha^{(i+1,j)}_{\mu_2\cdots\mu_{p-i}]|\nu_{[q-j]}} + b_{i,j}\left(\alpha^{(i,j+1)}_{\mu_{[p-i]}|[\nu_{[q-j-1]},\nu_{q-j}]} + a_{i,j}\alpha^{(i,j+1)}_{\nu_{[q-j]}[\mu_{q-j+1}\cdots\mu_{p-i}|\mu_{[q-j-1]},\mu_{q-j}]}\right), \tag{2}$$

where $i=0,\ldots,p-q$ and $j=0,\ldots,q$. The coefficients $a_{i,j}$ and $b_{i,j}$ are given by

$$a_{i,j} = \frac{(p-i)!}{(p-i-q+j+1)!(q-j)!}, \quad b_{i,j} = (-)^i \frac{(p-q+j+2)}{(p-i-q+j+2)}.$$

To the above formulas, we must add the convention that, for all j, $\alpha^{(p-q+1,j)} = 0 = \alpha^{(i,q+1)}$. The symmetry properties of the parameters $\alpha^{(i,j)}$ are those of Young diagrams with two columns of lengths $p-i$ and $q-j$. More details on the reducibility parameters $\alpha^{(i,j)}_{\mu_1\cdots\mu_{p-i}|\nu_1\cdots\nu_{q-j}}$ will be given in Sec. III B.

The fundamental gauge-invariant object is the field strength K, the $[p+1,q+1]$-tensor defined as the double curl of the gauge field

$$K_{\mu_1\cdots\mu_{p+1}|\nu_1\cdots\nu_{q+1}} \equiv \partial_{[\mu_1}\phi_{\mu_2\cdots\mu_{p+1}]|[\nu_1\cdots\nu_q,\nu_{q+1}]}.$$

By definition, it satisfies the Bianchi (BII) identities

$$\partial_{[\mu_1}K_{\mu_2\cdots\mu_{p+2}]|\nu_1\cdots\nu_{q+1}} = 0, \quad K_{\mu_1\cdots\mu_{p+1}|[\nu_1\cdots\nu_{q+1},\nu_{q+2}]} = 0. \tag{3}$$

The field strength tensor K plays a crucial role in the determination of the physical degrees of freedom described by the action $S_0[\phi]$.

B. Equations of motion

The equations of motion are expressed in terms of the field strength,

$$G^{\mu_1\cdots\mu_p|}{}_{\nu_1\ldots\nu_q} \equiv \frac{\delta\mathcal{L}}{\delta\phi_{\mu_1\ldots\mu_p|}{}^{\nu_1\ldots\nu_q}} = \frac{1}{(p+1)!q!}\delta^{[\rho_1\cdots\rho_{q+1}\mu_1\cdots\mu_p]}_{[\nu_1\cdots\nu_q\sigma_1\cdots\sigma_{p+1}]}K^{\sigma_1\cdots\sigma_{p+1}|}{}_{\rho_1\cdots\rho_{q+1}} \approx 0,$$

where a weak equality "$\approx$" means "equal on the surface of the solutions of the equations of motion." This is a generalization of vacuum Einstein equations, linearized around the flat background. Taking successive traces of the equations of motion, one can show that they are equivalent to the tracelessness of the field strength,

$$\eta^{\sigma_1\rho_1}K_{\sigma_1\cdots\sigma_{p+1}|\rho_1\cdots\rho_{q+1}} \approx 0. \tag{4}$$

This equation generalizes the vanishing of the Ricci tensor (in the vacuum), and is nontrivial only when $p+q+2 \leqslant D$. Together with the "Ricci equation" (4), the Bianchi identities (3) imply[3]

$$\partial^{\sigma_1}K_{\sigma_1\cdots\sigma_{p+1}|\rho_1\cdots\rho_{q+1}} \approx 0 \approx \partial^{\rho_1}K_{\sigma_1\cdots\sigma_{p+1}|\rho_1\cdots\rho_{q+1}}. \tag{5}$$

The gauge invariance of the action is equivalent to the divergenceless of the tensor $G^{\mu_{[p]}|\nu_{[q]}}$, that is, the latter satisfies the Noether identities

$$\partial^{\sigma_1} G_{\sigma_1 \cdots \sigma_{p+1} | \rho_1 \cdots \rho_{q+1}} = 0 = \partial^{\rho_1} G_{\sigma_1 \cdots \sigma_{p+1} | \rho_1 \cdots \rho_{q+1}} . \tag{6}$$

These identities are a direct consequence of the Bianchi ones (3). The Noether identities (6) ensure that the equations of motion can be written as

$$0 \approx G^{\mu_1 \cdots \mu_p | \nu_1 \cdots \nu_q} = \partial_\alpha H^{\alpha \mu_1 \cdots \mu_p | \nu_1 \cdots \nu_q} ,$$

where

$$H^{\alpha \mu_1 \cdots \mu_p |}{}_{\nu_1 \cdots \nu_q} = \frac{1}{(p+1)! q!} \delta^{[\rho_1 \cdots \rho_q \alpha \mu_1 \cdots \mu_p]}_{[\nu_1 \cdots \nu_q \beta \sigma_1 \cdots \sigma_p]} \partial^{[\beta} \phi^{\sigma_1 \cdots \sigma_p] |}{}_{\rho_1 \cdots \rho_q} .$$

The symmetries of the tensor H correspond to the Young diagram $[p+1,q]$. This property will be useful in the computation of the local BRST cohomology.

C. Physical degrees of freedom

The "Ricci equation" (4) states that, on-shell, the field strength belongs to the irrep $[p+1,q+1]$ of $\mathrm{O}(D-1,1)$. The Bianchi identities together with (5) further imply that the on-shell nonvanishing components of the field strength belong to the unitary irrep $[p,q]$ of the little group $\mathrm{O}(D-2)$. Indeed, on-shell, gauge fields in the light-cone gauge are essentially field strengths,[13] and the "Ricci equation" takes the form

$$\delta^{i_1 j_1} \phi_{i_1 \cdots i_p | j_1 \cdots j_q} \approx 0 ,$$

where i and j denote light-cone indices $(i,j=1,\ldots,D-2)$. As a consistency check, one can note that the latter equation is nontrivial only when $p+q \geqslant D-2$. The theory describes the correct physical degrees of freedom of a first-quantized massless particle propagating in flat space, i.e., the latter particle provides a unitary irrep of the group $\mathrm{IO}(D-1,1)$.

We should stress that the exact analogue of all the previous properties hold for arbitrary mixed symmetry fields. This result was obtained by two of us and was mentioned in Ref. 7 but the detailed proof was not given there. [The proof presented in this paper (Appendix A) provides an indirect proof that the light-cone gauge is reachable (so that the theory describes the correct number of physical degrees of freedom). We would like to underline the fact that Refs. 3 and 5 assume (but do not contain any rigorous proof of) this fact. It would not be straightforward to prove it directly because the tower of ghosts is extremely complicated in the general case.] We take the opportunity to provide this extremely simple proof in Appendix A for the particular case of two-column gauge fields, since it already covers all the features of the general case for arbitrary mixed tensor gauge fields.

III. BRST CONSTRUCTION

A. BRST deformation technique

Once one has a consistent free theory, it is natural to try to deform it into an interacting theory. The traditional Noether deformation procedure assumes that the deformed action can be expressed as a power series in a coupling constant g, the zeroth-order term in the expansion describing the free theory S_0. The procedure is perturbative: one tries to construct the deformations order by order in the deformation parameter g.

Some physical requirements naturally come out.

(i) *Nontriviality:* We reject *trivial* deformations arising from field redefinitions that reduce to the identity at order g^0,

$$\phi \to \phi' = \phi + g\theta(\phi, \partial\phi, \ldots) + \mathcal{O}(g^2) . \tag{7}$$

(ii) *Consistency:* A deformation of a theory is called *consistent* if the deformed theory possesses the same number of (possibly deformed) independent gauge symmetries, reducibility

identities, etc., as the system we started with. In other words, the number of physical degrees of freedom is unchanged.

(iii) *Locality:* The deformed action $S[\phi]$ must be a *local* functional. The deformation of the gauge transformations, etc., must be local functions, as well as the field redefinitions.

We remind the reader that a local function of some set of fields φ^i is a smooth function of the fields φ^i and their derivatives $\partial\varphi^i$, $\partial^2\varphi^i$,… up to some *finite* order, say k, in the number of derivatives. Such a set of variables φ^i, $\partial\varphi^i$, …, $\partial^k\varphi^i$ will be collectively denoted by $[\varphi^i]$. Therefore, a local function of φ^i is denoted by $f([\varphi^i])$. A local p-form $(0\leqslant p\leqslant D)$ is a differential p-form, the components of which are local functions,

$$\omega = \frac{1}{p!}\omega_{\mu_1\cdots\mu_p}(x,[\phi^i])\mathrm{d}x^{\mu_1}\wedge\cdots\wedge\mathrm{d}x^{\mu_p}.$$

A local functional is the integral of a local D-form.

As shown in Ref. 21, the Noether procedure can be reformulated in a BRST-cohomological formalism: the first-order nontrivial consistent local interactions are in one-to-one correspondence with elements of the cohomology $H^{D,0}(s|\mathrm{d})$ of the BRST differential s modulo the total derivative d, in maximum form-degree D and in ghost number 0. That is, one must compute the general solution of the cocycle condition

$$sa^{D,0} + \mathrm{d}b^{D-1,1} = 0, \tag{8}$$

where $a^{D,0}$ is a top-form of ghost number zero and $b^{D-1,1}$ a $(D-1)$-form of ghost number one, with the understanding that two solutions of (8) that differ by a trivial solution should be identified,

$$a^{D,0} \sim a^{D,0} + sm^{D,-1} + \mathrm{d}n^{D-1,0},$$

as they define the same interactions up to field redefinitions (7). The cocycles and coboundaries a, b, m, n,… are local forms of the field variables (including ghosts and antifields).

B. BRST spectrum

In the theories under consideration and according to the general rules of the BRST-antifield formalism, one associates with each gauge parameter $\alpha^{(i,j)}$ a ghost, and then to any field (including ghosts) a corresponding antifield (or antighost) of opposite Grassmann parity. More precisely, the spectrum of fields (including ghosts) and antifields is given by

(i) *the fields*, $A^{(i,j)}_{\mu_{[p-i]}|\nu_{[q-j]}}$, where $A^{(0,0)}$ is identified with ϕ;

(ii) *the antifields*, $A^{*(i,j)\,\mu_{[p-i]}|\nu_{[q-j]}}$,

where $i=0,\ldots,p-q$ and $j=0,\ldots,q$. The symmetry properties of the fields $A^{(i,j)}_{\mu_{[p-i]}|\nu_{[q-j]}}$ and antifields $A^{*(i,j)\,\mu_{[p-i]}|\nu_{[q-j]}}$ are those of Young diagrams with two columns of lengths $p-i$ and $q-j$. To each field and antifield are associated a pure ghost number and an antifield (or antighost) number. The pure ghost number is given by $i+j$ for the fields $A^{(i,j)}$ and 0 for the antifields, while the antifield number is 0 for the fields and $i+j+1$ for the antifields $A^{*(i,j)}$. The Grassmann parity is given by the pure ghost number (or the antighost number) modulo 2. All this is summarized in Table I.

TABLE I. Symmetry, pure ghost and antighost numbers, and parity of the (anti)fields.

	Young	puregh	antigh	Parity
$A^{(i,j)}$	$[p-i,q-j]$	$i+j$	0	$i+j$
$A^{*(i,j)}$	$[p-i,q-j]$	0	$i+j+1$	$i+j+1$

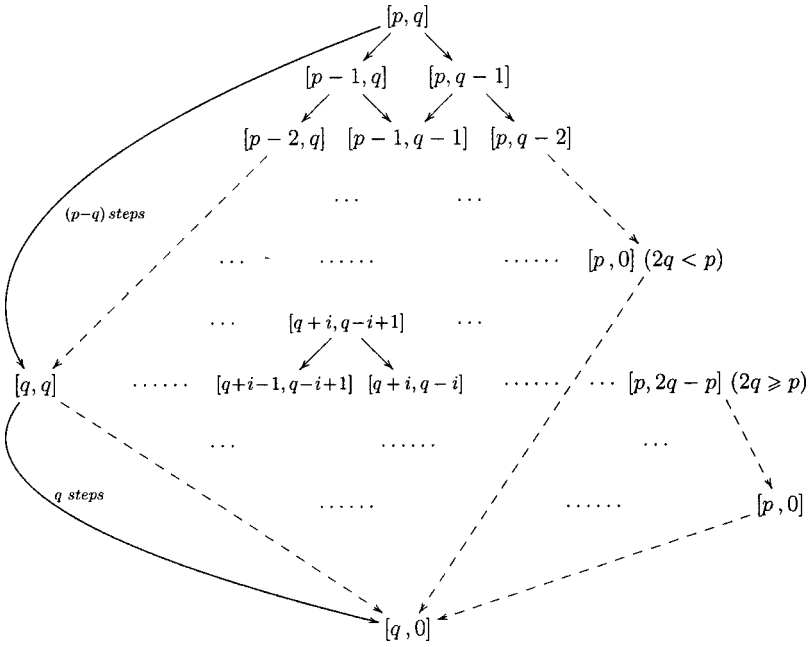

FIG. 1. Antighost-zero BRST spectrum of $[p,q]$-type gauge field.

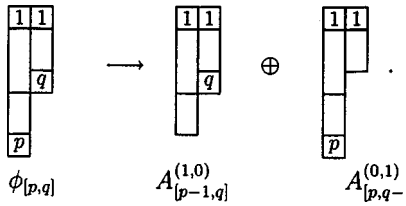
One can visualize the whole BRST spectrum in vanishing antighost number as well as the procedure that gives all the ghosts starting from $\phi_{\mu_{[p]}|\nu_{[q]}}$ in Fig. 1, where the pure ghost number increases from top down, by one unit at each line.

At the top of Fig. 1 lies the gauge field $\phi_{\mu_{[p]}|\nu_{[q]}}$ with pure ghost number zero. At the level below, one finds the pure ghost number one "gauge parameters" $A^{(1,0)}_{\mu_{[p-1]}|\nu_{[q]}}$ and $A^{(0,1)}_{\mu_{[p]}|\nu_{[q-1]}}$ whose respective symmetries are obtained by removing a box in the first (respectively, second) column of the Young diagram $[p,q]$ corresponding to the gauge field $\phi_{\mu_{[p]}|\nu_{[q]}}$ [the rules that give the $(i+1)$th generation ghosts from the ith generation ones can be found in Refs. 4 and 14],



In pure ghost number $p-q$, we obtain a set of ghosts containing $A^{(p-q,0)}_{\mu_{[q]}|\nu_{[q]}} \sim [q,q]$. The Young diagram corresponding to the latter ghost is obtained by removing $p-q$ boxes from the first column of $[p,q]$.

If $q<p-q$, we do not have to reach the pure ghost level $p-q$ to find the p-form ghost $A^{(0,q)}_{\mu_{[p]}} \sim [p,0]$. If $2q \geqslant p$, we must remove additional boxes from the second column of $[p,q]$ in order to empty it completely and obtain the p-form ghost $A^{(0,q)}_{\mu_{[p]}}$. The Young diagrams of the remaining ghosts are obtained by further removing boxes from the Young diagram corresponding to the ghost $A^{(0,q)}_{\mu_{[p]}}$ with puregh$=q$. This procedure will terminate at pure ghost number p with the q-form ghost $A^{(p-q,q)}_{\mu_{[q]}} \sim [q,0]$. It is not possible to find ghosts $A_{\mu_{[r]}|\nu_{[s]}}$ with r and $s<q$, since it would mean that two boxes from a same row would have been removed from $[p,q]$, which is not allowed.[4,14]

The antighost sector has exactly the same structure as the ghost sector in Fig. 1, where each ghost $A^{(i,j)}$ is replaced by its antighost $A^{*(i,j)}$.

C. BRST differential

The BRST differential s of the free theory (1) and (2) is generated by the functional

$$W_0 = S_0[\phi] + \int \mathrm{d}^D x \left[\sum_{i=0}^{p-q} \sum_{j=0}^{q} (-)^{i+j} A^{*(i,j)\mu_1 \cdots \mu_{p-i}|\nu_1 \cdots \nu_{q-j}} \times (\partial_{[\mu_1} A^{(i+1,j)}_{\mu_2 \cdots \mu_{p-i}]|\nu_1 \cdots \nu_{q-j}} - b_{i+1,j} A^{(i,j+1)}_{\mu_1 \cdots \mu_{p-i}|[\nu_1 \cdots \nu_{q-j-1}, \nu_{q-j}]}) \right],$$

with the convention that $A^{(p-q+1,j)} = A^{(i,q+1)} = A^{*(-1,j)} = A^{*(i,-1)} = 0$. More precisely, W_0 is the generator of the BRST differential s of the free theory through

$$sA = (W_0, A)_{a.b.},$$

where the antibracket $(,)_{a.b.}$ is defined by

$$(A,B)_{a.b.} = \frac{\delta^R A}{\delta \Phi^I} \frac{\delta^L B}{\delta \Phi^*_I} - \frac{\delta^R A}{\delta \Phi^*_I} \frac{\delta^L B}{\delta \Phi^I},$$

Φ^I collectively denoting all fields and ghosts, and Φ^*_I the antighosts. The functional W_0 is a solution of the *master equation*

$$(W_0, W_0)_{a.b.} = 0.$$

The BRST-differential s decomposes into $s = \gamma + \delta$. The first piece γ, the differential along the gauge orbits, increases the pure ghost number by one unit, whereas the Koszul–Tate differential δ decreases the antighost (or antifield) number by one unit. A $\mathbb{Z}$-grading called *ghost number* (or gh) corresponds to the differential s. We have

$$\mathrm{gh} = \mathrm{puregh} - \mathrm{antigh}.$$

The action of γ and δ on the BRST variables is zero, except

$$\gamma A^{(i,j)}_{\mu_{[p-i]}|\nu_{[q-j]}} = \partial_{[\mu_1} A^{(i+1,j)}_{\mu_2 \cdots \mu_{p-i}]|\nu_{[q-j]}} + b_{i,j} (A^{(i,j+1)}_{\mu_{[p-i]}|[\nu_{[q-j-1]}, \nu_{q-j}]} + a_{i,j} A^{(i,j+1)}_{\nu_{[q-j]}[\mu_{q-j+1} \cdots \mu_{p-i}|\mu_{[q-j-1]}, \mu_{q-j}]}),$$

$$\delta A^{*(0,0)\mu_{[p]}|\nu_{[q]}} = G^{\mu_{[p]}|\nu_{[q]}},$$

$$\delta A^{*(i,j)\mu_{[p-i]}|\nu_{[q-j]}} = (-)^{i+j} \left(\partial_\sigma A^{*(i-1,j)\sigma\mu_{[p-i]}|\nu_{[q-j]}} - \frac{1}{p-i+1} \partial_\sigma A^{*(i-1,j)\nu_1 \mu_{[p-i]}|\sigma\nu_2 \cdots \nu_{q-j}} \right) + (-)^{i+j+1} b_{i+1,j-1} \partial_\sigma A^{*(i,j-1)\mu_{[p-i]}|\nu_{[q-j]}\sigma},$$

where the last equation holds only for (i,j) different from (0, 0).

For later computations, it is useful to define a unique antifield for each antighost number,

$$C^*_{p+1-j}{}^{\mu_1 \cdots \mu_q|\nu_1 \cdots \nu_j} = \sum_{k=0}^{j} \epsilon_{k,j} A^{*(p-q-j+k,q-k)\mu_1 \cdots \mu_q[\nu_{k+1} \cdots \nu_j|\nu_1 \cdots \nu_k]}$$

for $0 \leqslant j \leqslant p$, and, in antighost zero, the following specific combination of single derivatives of the field:

TABLE II. Young representation, pure ghost and antighost numbers, and parity of C_k^*.

	Young diagram	puregh	antigh	Parity
C_k^*	$[q]\otimes[p+1-k]-[p+1]\otimes[q-k]$	0	k	k

$$C_0^{*\mu_1\cdots\mu_q|\nu_1\cdots\nu_{p+1}} = \epsilon_{q,p+1} H^{\mu_1\cdots\mu_q[\nu_{q+1}\cdots\nu_{p+1}|\nu_1\cdots\nu_q]},$$

where $\epsilon_{k,j}$ vanishes for $k>q$ and for $j-k>p-q$, and is given in the other cases by

$$\epsilon_{k,j} = (-)^{pk+j(k+p+q)+[k(k+1)/2]} \frac{\binom{k}{p+1}\binom{k}{j}}{\binom{k}{q}},$$

where $\binom{m}{n}$ are the binomial coefficients ($n \geqslant m$). Some properties of the new variables C_k^* are summarized in Table II.

The symmetry properties of C_k^* are denoted by

$$[q]\otimes[p+1-k]-[p+1]\otimes[q-k]$$

which means that they have the symmetry properties corresponding to the tensor product of a column $[q]$ by a column $[p+1-k]$ from which one should substract (when $k\leqslant q$) all the Young diagrams appearing in the tensor product $[p+1]\otimes[q-k]$.

The antifields $C_k^{*\mu[q]|\nu[p+1-k]}$ have been defined in order to obey the following relations:

$$\delta C_{p+1-j}^{*\mu_1\cdots\mu_q|\nu_1\cdots\nu_j} = \partial_\sigma C_{p-j}^{*\mu_1\cdots\mu_q|\nu_1\cdots\nu_j\sigma} \quad \text{for } 0\leqslant j\leqslant p,$$

$$\delta C_0^{*\mu_1\cdots\mu_q|\nu_1\cdots\nu_{p+1}} = 0. \tag{9}$$

If we further define the inhomogeneous form

$$\tilde{H}^{\mu_1\cdots\mu_q} \equiv \sum_{j=0}^{p+1} C_{p+1-j}^{*D-j\mu_1\cdots\mu_q},$$

where

$$C_{p+1-j}^{*D-j\mu_1\cdots\mu_q} \equiv (-)^{jp+j(j+1)/2} \frac{1}{j!(D-j)!} C_{p+1-j}^{*\mu_1\cdots\mu_q|\nu_1\cdots\nu_j} \epsilon_{\nu_1\cdots\nu_D}\, \mathrm{d}x^{\nu_{j+1}}\cdots \mathrm{d}x^{\nu_D},$$

then, as a consequence of (9), any polynomial $P(\tilde{H})$ in $\tilde{H}^{\mu_1\cdots\mu_q}$ will satisfy

$$(\delta+d)P(\tilde{H}) = 0. \tag{10}$$

The polynomial $\tilde{H}$ is not invariant under gauge transformations. It is therefore useful to still introduce another polynomial, $\tilde{\mathcal{H}}$, with an explicit x dependence, that *is* invariant. $\tilde{\mathcal{H}}$ is defined by

$$\tilde{\mathcal{H}}_{\mu_{[q]}} \equiv \sum_{j=1}^{p+1} C_{j\mu_{[q]}}^{*D-p-1+j} + \tilde{a}\epsilon_{[\mu_{[q]}\sigma_{[p+1]}\tau_{[D-p-q-1]}]} K^{q+1\sigma_{[p+1]}} x^{\tau_1}\, \mathrm{d}x^{\tau_2}\cdots \mathrm{d}x^{\tau_{D-p-q-1}},$$

where $\tilde{a}=(-)^{[p(p-1)+q(q-1)/2]}[1/q!q!(p+q+1)!(p+1-q)!(D-p-q-1)!]$. One can check that $\tilde{\mathcal{H}}=\tilde{H}+\mathrm{d}m_0^{D-p-2}$. This fact has the consequence that polynomials in $\tilde{\mathcal{H}}$ also satisfy $(\delta+d)P(\tilde{\mathcal{H}})=0$.

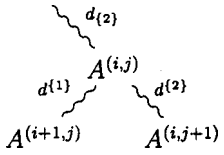


FIG. 2. Ghost $A^{(i,j)}$ appearing in only one reducibility relation.

IV. COHOMOLOGY OF γ

We hereafter give the content of $H(\gamma)$. Subsequently, we explain the procedure that we followed in order to obtain that result.

Theorem 4.1: *The cohomology of* γ *is isomorphic to the space of functions depending on*

(i) *the antifields and their derivatives* $[A^{*(i,j)}]$,
(ii) *the curvature and its derivatives* $[K]$,
(iii) *the pth generation ghost* $A^{(p-q,q)}$, *and*
(iv) *the curl* $D^0_{\mu_1\cdots\mu_{p+1}} \equiv (-)^q \partial_{[\mu_1} A^{(0,q)}_{\mu_2\cdots\mu_{p+1}]}$ *of the qth generation ghost* $A^{(0,q)}$,

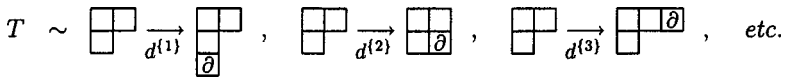
$$H(\gamma) \simeq \{f([A^{*(i,j)}],[K],A^{(p-q,q)},D^0_{\mu_1\cdots\mu_{p+1}})\}.$$

Proof: The antifields and all their derivatives are annihilated by γ. Since they carry no pure ghost degree by definition, they cannot be equal to the γ-variation of any quantity. Hence, they obviously belong to the cohomology of γ.

To compute the γ-cohomology in the sector of the field, the ghosts and all their derivatives, we split the variables into three sets of *independent* variables obeying, respectively, $\gamma u^\ell = v^\ell$, $\gamma v^\ell = 0$, and $\gamma w^i = 0$. The variables u^ℓ and v^ℓ form so-called "contractible pairs" and the cohomology of γ is therefore generated by the variables w^i (see, e.g., Ref. 23, Theorem 8.2).

We decompose the spaces spanned by the derivatives $\partial_{\mu_1\cdots\mu_k} A^{(i,j)}$, $k \geqslant 0$, $0 \leqslant i \leqslant p-q$, $0 \leqslant j \leqslant q$, into irreps of $\mathrm{GL}(D,\mathbb{R})$ and use the structure of the reducibility conditions (see Figs. 2 and 3) in order to group the variables into contractible pairs.

We use the differential operators $d^{\{i\}}$, $i=1,2,\ldots$ (see Ref. 4 for a general definition) which act, for instance, on Young-symmetry-type tensor fields $T_{[2,1]}$, as follows:



For fixed i and j the set of ghosts $A^{(i,j)}$ and all their derivatives decompose into three types of independent variables,

$$[A^{(i,j)}] \leftrightarrow \mathcal{O}A^{(i,j+1)}, \mathcal{O}d^{\{1\}}A^{(i,j+1)}, \mathcal{O}d^{\{2\}}A^{(i,j+1)}, \mathcal{O}d^{\{1\}}d^{\{2\}}A^{(i,j+1)},$$

where $\mathcal{O}$ denotes any operator of the type $\Pi_{m\geqslant 3} d^{\{m\}}$ or the identity.

Different cases arise depending on the position of the field $A^{(i,j)}$ in Fig. 1. We must consider fields that sit in the interior, on a border or at a corner of the diagram.

Interior: In this case, all the ghosts $A^{(i,j)}$ and their derivatives form u^ℓ or v^ℓ variables. Indeed, we have the relations

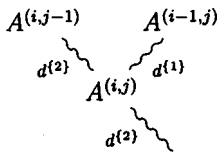


FIG. 3. Ghost $A^{(i,j)}$ the reducibility relation of which involves only one ghost.

$$\gamma A^{(i,j)} \propto [d^{\{1\}}A^{(i+1,j)} - d^{\{2\}}A^{(i,j+1)}],$$

$$\gamma[d^{\{1\}}A^{(i+1,j)} - d^{\{2\}}A^{(i,j+1)}] = 0,$$

$$\gamma[d^{\{1\}}A^{(i+1,j)} + d^{\{2\}}A^{(i,j+1)}] \propto d^{\{1\}}d^{\{2\}}A^{(i+1,j+1)},$$

$$\gamma[d^{\{1\}}d^{\{2\}}A^{(i,j+1)}] = 0,$$

and $\mathcal{O}$ commutes with γ. From which we conclude that one can perform a change of variable from the sets $[A^{(i,j)}]$ to the contractible pairs

$$u^{\ell} \leftrightarrow \mathcal{O}A^{(i,j)}, \mathcal{O}[d^{\{1\}}A^{(i+1,j)} + d^{\{2\}}A^{(i,j+1)}],$$

$$v^{\ell} \leftrightarrow \mathcal{O}[d^{\{1\}}A^{(i+1,j)} - d^{\{2\}}A^{(i,j+1)}], \mathcal{O}d^{\{1\}}d^{\{2\}}A^{(i+1,j+1)},$$

so that the ghosts $A^{(i,j)}$ in the interior and all their derivatives do not appear in $H(\gamma)$.

Border: If a ghost $A^{(i,j)}$ stands on a border of Fig. 1, it means that either (i) its reducibility relation involves only one ghost (see, e.g., Fig. 3), or (ii) there exists only one field whose reducibility relation involves $A^{(i,j)}$ (see, e.g., Fig. 2).

(i) Suppose $A^{(i,j)}$ stands on the left-hand (lower) edge of Fig. 1. We have the relations

$$\gamma A^{(i,j)} \propto d^{\{2\}}A^{(i,j+1)},$$

$$\gamma[d^{\{2\}}A^{(i,j+1)}] = 0,$$

$$\gamma[d^{\{1\}}A^{(i,j)}] \propto d^{\{1\}}d^{\{2\}}A^{(i,j+1)},$$

$$\gamma[d^{\{1\}}d^{\{2\}}A^{(i,j+1)}] = 0,$$

so that the corresponding sets $[A^{(i,j)}]$ on the left-hand edge do not contribute to $H(\gamma)$. We reach similar conclusion if $A^{(i,j)}$ lies on the right-hand (higher) border of Fig. 1, substituting $d^{\{1\}}$ for $d^{\{2\}}$ when necessary.

(ii) Since, by assumption, $A^{(i,j)}$ does not sit in a corner of Fig. 1 (but on the higher left-hand or lower right-hand border), its reducibility transformation involves two ghosts, and we proceed as if it were in the interior. The only difference is that $\mathcal{O}d^{\{1\}}d^{\{2\}}A^{(i,j)}$ will be equal to either $\gamma\mathcal{O}d^{\{1\}}A^{(i,j-1)}$ or $\gamma\mathcal{O}d^{\{2\}}A^{(i-1,j)}$, depending whether the field above $A^{(i,j)}$ is $A^{(i-1,j)}$ or $A^{(i,j-1)}$.

Lower corner: On the one hand, we have $\gamma A^{(p-q,q)}_{[q,0]} = 0$. As the operator γ introduces a derivative, $A^{(p-q,q)}_{[q,0]}$ cannot be γ-exact. As a result, $A^{(p-q,q)}_{[q,0]}$ is a w^i-variable and thence belongs to $H(\gamma)$. On the other hand, we find $\partial_{\nu}A^{(p-q,q)}_{\mu_1\cdots\mu_q} = \gamma[A^{(p-q-1,q)}_{\nu\mu_1\cdots\mu_q} + (-)^{p-q}[q/(p+1)]A^{(p-q,q-1)}_{\mu_1\cdots\mu_q|\nu}]$, which implies that all the derivatives of $A^{(p-q,q)}$ do not appear in $H(\gamma)$.

Left-hand corner: In this case, the ghost $A^{(i,j)}$ is characterized by a squared-shape Young diagram (it is the only one with this property). Its reducibility transformation involves only one ghost and there exists only one field whose reducibility transformation involves $A^{(i,j)}$. Because of its symmetry properties, $d^{\{2\}}A^{(i,j)} \sim d^{\{1\}}A^{(i,j)}$. Better, $d^{\{2\}}$ is not well-defined on $A^{(i,j)}$, it is only well defined on $d^{\{1\}}A^{(i,j)}$. Therefore, the derivatives $\partial_{\mu_1\cdots\mu_k}A^{(i,j)}$ decompose into $\mathcal{O}A^{(i,j)}$, $\mathcal{O}d^{\{1\}}A^{(i,j)}$, and $\mathcal{O}d^{\{1\}}d^{\{2\}}A^{(i,j)}$. The first set $\mathcal{O}A^{(i,j)}$ forms u^{ℓ}-variables associated with $\mathcal{O}d^{\{2\}}A^{(i,j+1)}$. The second set is grouped with $\mathcal{O}d^{\{1\}}d^{\{2\}}A^{(i,j+1)}$, and the third one forms v^{ℓ}-variables with $\mathcal{O}d^{\{2\}}A^{(i-1,j)}$.

Upper corner: In the case where $A^{(i,j)}$ is the gauge field, we proceed exactly as in the "interior" case, except that the variables $\mathcal{O}d^{\{1\}}d^{\{2\}}A^{(0,0)} = 0$ are not grouped with any other variables any

longer. They constitute true w^i-variables and are thus present in $H(\gamma)$. Recalling the definition of the curvature K, we have $\mathcal{O}d^{\{1\}}d^{\{2\}}A^{(0,0)} \propto [K]$.

Right-hand corner: In this case, the field $A^{(i,j)}$ is the p-form ghost $A^{(0,q)}_{[p]}$. We have the (u,v)-pairs $(\mathcal{O}d^{\{2\}}A^{(0,q)}, \mathcal{O}d^{\{1\}}d^{\{2\}}A^{(1,q)})$, $(\mathcal{O}d^{\{1\}}A^{(0,q-1)}, \mathcal{O}d^{\{1\}}d^{\{2\}}A^{(0,q)})$.

The derivative $d^{\{1\}}A^{(0,q)}_{[p]} \propto D^0_{[p+1]}$ is a w^i-variable since it is invariant and no other variable $\partial_{\mu_1 \cdots \mu_k} A^{(i,j)}$ possesses the same symmetry. □

In the sequel, the polynomials $\alpha([K],[A^*])$ in the curvature, the antifields and all their derivatives will be called "invariant polynomials." We will denote by $\mathcal{N}$ the algebra generated by all the ghosts and the noninvariant derivatives of the field ϕ. The entire algebra of the fields and antifields is then generated by the invariant polynomials and the elements of $\mathcal{N}$.

V. INVARIANT POINCARÉ LEMMA

The space of *invariant* local forms is the space of (local) forms that belong to $H(\gamma)$. The algebraic Poincaré lemma tells us that any closed form is exact (except top forms and constants). However, if the form is furthermore invariant, it is not guaranteed that the form is exact in the space of invariant forms. The following lemma tells us more about this important subtlety, in a limited range of form degree.

Lemma 5.1 (invariant Poincaré lemma in form degree $k<p+1$): Let α^k be an invariant local k-form, $k<p+1$,

$$\textit{if } \mathrm{d}\alpha^k = 0, \ \textit{then } \alpha^k = Q(K^{q+1}_{\mu_1 \cdots \mu_{p+1}}) + \mathrm{d}\beta^{k-1},$$

where Q is a polynomial in the $(q+1)$-forms,

$$K^{q+1}_{\mu_1 \cdots \mu_{p+1}} \equiv K_{\mu_1 \cdots \mu_{p+1}|\nu_1 \cdots \nu_{q+1}} \, \mathrm{d}x^{\nu_1} \cdots \mathrm{d}x^{\nu_{q+1}},$$

while β^{k-1} is an invariant local form.

A closed invariant local form of form-degree $k<p+1$ and of strictly positive antighost number is always exact in the space of invariant local forms.

The proof is directly inspired from the one given in Ref. 24 (Theorem 6).

A. Beginning of the proof of the invariant Poincaré lemma

The second statement of the lemma [i.e., the case antigh $(\alpha^k) \neq 0$] is part of a general theorem (see, e.g., Ref. 25) which holds without any restriction on the form degree. It will not be reviewed here.

We will thus assume that antigh$(\alpha^k)=0$, and prove the first part of Lemma 5.1 by induction.

Induction basis: For $k=0$, the invariant Poincaré lemma is trivially satisfied, $\mathrm{d}\alpha^0=0$ implies that α^0 is a constant by the usual Poincaré lemma.

Induction hypothesis: The lemma holds in form degree k' such that $0 \leqslant k' < k < p+1$.

Induction step: We will prove in the sequel that under the induction hypothesis, the lemma holds in form degree k.

Because $\mathrm{d}\alpha^k=0$ and $\gamma\alpha^k=0$, we can build a descent as follows:

$$\mathrm{d}\alpha^k = 0 \Rightarrow \alpha^k = \mathrm{d}a^{k-1,0}, \tag{11}$$

$$0 = \gamma a^{k-1,0} + \mathrm{d}a^{k-2,1}, \ldots, \tag{12}$$

$$0 = \gamma a^{k-j,j-1} + \mathrm{d}a^{k-j-1,j}, \tag{13}$$

$$0 = \gamma a^{k-j-1,j}, \tag{14}$$

where $a^{r,i}$ is a r-form of pure ghost number i. The pure ghost number of $a^{r,i}$ must obey $0 \leqslant i \leqslant k-1$. Of course, since we assume $k < p+1$, we have $i < p$. The descent stops at (14) either because $k-j-1=0$ or because $a^{k-j-1,j}$ is invariant. The case $j=0$ is trivial since it gives immediately $\alpha^k = \mathrm{d}\beta^{k-1}$, where $\beta^{k-1} \equiv a^{k-1,0}$ is invariant. Accordingly, we assume from now on that $j > 0$.

Since we are dealing with a descent, it is helpful to introduce one of its building blocks, which is the purpose of the next section. We will complete the induction step in Sec. V C.

B. A descent of γ modulo d

Let us define the following differential forms built up from the ghosts:

$$D^l_{\mu_1\cdots\mu_{p+1}} \equiv (-)^{l(q+1)+q} \partial_{[\mu_1} A^{(0,q-l)}_{\mu_2\cdots\mu_{p+1}]|\nu_1\cdots\nu_l} \, \mathrm{d}x^{\nu_1} \cdots \mathrm{d}x^{\nu_l},$$

for $0 \leqslant l \leqslant q$. It is easy to show that these fields verify the following descent:

$$\gamma(D^0_{\mu_1\cdots\mu_{p+1}}) = 0, \tag{15}$$

$$\gamma(D^{l+1}_{\mu_1\cdots\mu_{p+1}}) + \mathrm{d}D^l_{\mu_1\cdots\mu_{p+1}} = 0, \quad 0 \leqslant l \leqslant q-1,$$

$$\mathrm{d}D^q_{\mu_1\cdots\mu_{p+1}} = K^{q+1}_{\mu_1\cdots\mu_{p+1}}. \tag{16}$$

It is convenient to introduce the inhomogeneous form

$$D_{\mu_1\cdots\mu_{p+1}} = \sum_{l=0}^{q} D^l_{\mu_1\cdots\mu_{p+1}}$$

because it satisfies a so-called "Russian formula,"

$$(\gamma + \mathrm{d}) D_{\mu_1\cdots\mu_{p+1}} = K^{q+1}_{\mu_1\cdots\mu_{p+1}}, \tag{17}$$

which is a compact way of writing the descent (15) to (16).

Let $\omega_{(n,m)}$ be a homogeneous polynomial of degree m in D and of degree n in K. Its decomposition is

$$\omega_{(n,m)}(K,D) = \omega^{n(q+1)+mq,0} + \cdots + \omega^{n(q+1)+j,mq-j} + \cdots + \omega^{n(q+1),mq},$$

where $\omega^{n(q+1)+j,mq-j}$ has form degree $n(q+1)+j$ and pure ghost number $mq-j$. Due to (17), the polynomial satisfies

$$(\gamma + \mathrm{d})\omega_{(n,m)} = K^{q+1}_{\mu_1\cdots\mu_{p+1}} \frac{\partial^L \omega_{(n,m)}}{\partial D_{\mu_1\cdots\mu_{p+1}}}, \tag{18}$$

the form-degree decomposition of which leads to the descent

$$\gamma(\omega^{n(q+1),mq}) = 0,$$

$$\gamma(\omega^{n(q+1)+j+1,mq-j-1}) + \mathrm{d}\omega^{n(q+1)+j,mq-j} = 0, \quad 0 \leqslant j \leqslant q-1,$$

$$\gamma(\omega^{n(q+1)+q+1,(m-1)q-1}) + \mathrm{d}\omega^{n(q+1)+q,(m-1)q} = K^{q+1}_{\mu_1\cdots\mu_{p+1}}\left[\frac{\partial^L \omega}{\partial D_{\mu_1\cdots\mu_{p+1}}}\right]^{n(q+1),(m-1)q}, \tag{19}$$

where $[\partial\omega/\partial D]^{n(q+1),(m-1)q}$ denotes the component of form degree $n(q+1)$ and pure ghost equal to $(m-1)q$ of the derivative $\partial\omega/\partial D$. This component is the homogeneous polynomial of degree $m-1$ in the variable D^0,

$$\left[\frac{\partial\omega}{\partial D_{\mu_1\cdots\mu_{p+1}}}\right]^{n(q+1),(m-1)q} = \left.\frac{\partial\omega}{\partial D_{\mu_1\cdots\mu_{p+1}}}\right|_{D=D^0}.$$

The right-hand side of (19) vanishes if and only if the right-hand side of (18) does.

Two cases arise depending on whether the right-hand side (rhs) of (18) vanishes or not.

(i) The rhs of (18) vanishes, then the descent is said not to be obstructed in any strictly positive pure ghost number and goes all the way down to the bottom equations

$$\gamma(\omega^{n(q+1)+mq,0}) + \mathrm{d}\omega^{n(q+1)+mq+1,1} = 0, \quad 0 \leqslant j \leqslant q-1,$$

$$\mathrm{d}(\omega^{n(q+1)+mq,0}) = 0.$$

(ii) The rhs of (18) is not zero, then the descent is obstructed after q steps. It is not possible to find an $\tilde{\omega}^{n(q+1)+q+1,(m-1)q-1}$ such that

$$\gamma(\tilde{\omega}^{n(q+1)+q+1,(m-1)q-1}) + \mathrm{d}\omega^{n(q+1)+q,(m-1)q} = 0,$$

because the rhs of (19) is an element of $H(\gamma)$. This element is called the *obstruction* to the descent. One also says that this obstruction cannot be lifted more than q times, and $\omega^{n(q+1),mq}$ is the top of the ladder [in this case it must be an element of $H(\gamma)$].

This covers the general type of ladder (descent as well as lift) that does not contain the pth generation ghost $A^{(p-q,q)}$.

C. End of the proof of the invariant Poincaré lemma

As $j<p$, Theorem 4.1 implies that the equation (14) has nontrivial solutions only when $j=mq$ for some integer m

$$a^{k-mq-1,mq} = \sum_I \alpha_I^{k-mq-1}\omega_I^{0,mq}, \tag{20}$$

up to some γ-exact term. The α_I^{k-mq-1}'s are invariant forms, and $\{\omega_I^{0,mq}\}$ is a basis of polynomials of degree m in the variable D^0. The ghost $A^{(p-q,q)}$ is absent since the pure ghost number is $j=mq<p$.

The equation (13) implies $\mathrm{d}\alpha_I^{k-mq-1}=0$. Together with the induction hypothesis, this implies

$$\alpha_I^{k-mq-1} = P_I(K^{q+1}_{\mu_1\cdots\mu_{p+1}}) + \mathrm{d}\beta_I^{k-mq-2}, \tag{21}$$

where the polynomials P_I of order n are present iff $k-mq-1=n(q+1)$. Inserting (21) into (20) we find that, up to trivial redefinitions, $a^{k-j-1,j}$ is a polynomial in $K^{q+1}_{\mu_1\cdots\mu_{p+1}}$ and $D^0_{\mu_1\cdots\mu_{p+1}}$.

From the analysis performed in Sec. V B, we know that such an $a^{k-j-1,j}$ can be lifted at most q times. Therefore, $a^{k-j-1,j}$ belongs to a descent of type (11)–(14) only if $j=q$. Without loss of generality we can thus take $a^{k-q-1,q}=P(K^{q+1}_{\mu_1\cdots\mu_{p+1}},D^0)$ where P is a homogeneous polynomial with a linear dependence in D^0 (since $m=1$). In such a case, it can be lifted up to (11). Furthermore, because $a^{k-1,0}$ is defined up to an invariant form $\beta^{k-1,0}$ by the equation (12), the term $\mathrm{d}a^{k-1,0}$ of (11) must be equal to the sum

$$\mathrm{d}a^{k-1,0} = \underbrace{P(K^{q+1},K^{q+1})}_{\equiv Q(K^{q+1}_{\mu_1\cdots\mu_{p+1}})} + \mathrm{d}\beta^{k-1,0}$$

of a homogeneous polynomial Q in K^{q+1} (the lift of the bottom) and a form d-exact in the invariants. □

VI. COHOMOLOGY OF δ MODULO d: $H_k^D(\delta|\mathrm{d})$

In this section, we compute the cohomology of δ modulo d in top form degree and antighost number k, for $k \geqslant q$. We will also restrict ourselves to $k>1$. The group $H_1^D(\delta|\mathrm{d})$ describes the infinitely many conserved currents and will not be studied here.

Let us first recall a general theorem (Theorem 9.1 in Ref. 26).

Theorem 6.1: *For a linear gauge theory of reducibility order* $p-1$,

$$H_k^D(\delta|\mathrm{d}) = 0 \quad \text{for } k > p+1.$$

The computation of the cohomology groups $H_k^D(\delta|\mathrm{d})$ for $q \leqslant k \leqslant p+1$ follows closely the procedure used for p-forms in Ref. 24. It relies on the following theorems.

Theorem 6.2: *Any solution of* $\delta a^D + \mathrm{d}b^{D-1} = 0$ *that is at least bilinear in the antifields is necessarily trivial.*

The proof of Theorem 6.2 is similar to the proof of Theorem 11.2 in Ref. 26 and will not be repeated here.

Theorem 6.3: *A complete set of representatives of* $H_{p+1}^D(\delta|\mathrm{d})$ *is given by the antifields* $C^{*D}_{p+1\mu_1\cdots\mu_q}$, *i.e.,*

$$\delta a^D_{p+1} + \mathrm{d}a^{D-1}_p = 0 \Rightarrow a^D_{p+1} = \lambda^{\mu_{[q]}} C^{*D}_{p+1\mu_{[q]}} + \delta b^D_{p+2} + \mathrm{d}b^{D-1}_{p+1},$$

where the $\lambda^{[\mu_1\cdots\mu_q]}$ *are constants.*

Proof: Candidates: any polynomial of antighost number $p+1$ can be written

$$a^D_{p+1} = \Lambda^{[\mu_1\cdots\mu_q]} C^{*D}_{p+1[\mu_1\cdots\mu_q]} + \mu^D_{p+1} + \delta b^D_{p+2} + \mathrm{d}b^{D-1}_{p+1},$$

where Λ does not involve the antifields and where μ^D_{p+1} is at least quadratic in the antifields. The cocycle condition $\delta a^D_{p+1} + \mathrm{d}a^{D-1}_p = 0$ then implies

$$-\Lambda^{[\mu_1\cdots\mu_q]}\,\mathrm{d}C^{*D-1}_{p[\mu_1\cdots\mu_q]} + \delta(\mu^D_{p+1} + \mathrm{d}b^{D-1}_{p+1}) + da^{D-1}_p = 0.$$

By taking the Euler–Lagrange derivative of this equation with respect to $C^*_{p[\mu_1\cdots\mu_q]|\nu}$, one gets the weak equation $\partial^\nu \Lambda^{[\mu_1\cdots\mu_q]} \approx 0$. Considering ν as a form index, one sees that Λ belongs to $H_0^0(\mathrm{d}|\delta)$. The isomorphism $H_0^0(\mathrm{d}|\delta)/\mathbb{R} \cong H_D^D(\delta|\mathrm{d})$ (see Ref. 26) combined with the knowledge of $H_D^D(\delta|\mathrm{d}) \cong 0$ (by Theorem 6.1) implies $\Lambda^{[\mu_1\cdots\mu_q]} = \lambda^{[\mu_1\cdots\mu_q]} + \delta\nu_1^{[\mu_1\cdots\mu_q]}$ where $\lambda^{[\mu_1\cdots\mu_q]}$ is a constant. The term $\delta\nu_1^{[\mu_1\cdots\mu_q]} C^{*D}_{p+1[\mu_1\cdots\mu_q]}$ can be rewritten as a term at least bilinear in the antifields up to a δ-exact term. Inserting $a^D_{p+1} = \lambda^{[\mu_1\cdots\mu_q]} C^{*D}_{p+1\mu_1\cdots\mu_q} + \mu^D_{p+1} + \delta b^D_{p+2} + \mathrm{d}b^{D-1}_{p+1}$ into the cocycle condition, we see that μ^D_{p+1} must be a solution of $\delta\mu^D_{p+1} + \mathrm{d}b^{D-1} = 0$ and is therefore trivial by Theorem 6.2.

Nontriviality: It remains to show that the cocycles $a^D_{p+1} = \lambda C^{*D}_{p+1}$ are nontrivial. Indeed one can prove that $\lambda C^{*D}_{p+1} = \delta u^D_{p+2} + \mathrm{d}v^{D-1}_{p+1}$ implies that λC^{*D}_{p+1} vanishes. It is straightforward when u^D_{p+2} and v^{D-1}_{p+1} do not depend explicitly on x: δ and d bring in a derivative while λC^{*D}_{p+1} does not contain any. If u and v depend explicitly on x, one must expand them and the equation $\lambda C^{*D}_{p+1} = \delta u^D_{p+2} + \mathrm{d}v^{D-1}_{p+1}$ according to the number of derivatives of the fields and antifields to reach the conclusion. Explicitly, $u^D_{p+2} = u^D_{p+2,0} + \cdots + u^D_{p+2,l}$ and $v^{D-1}_{p+1} = v^{D-1}_{p+1,0} + \cdots + v^{D-1}_{p+1,n}$. If $n>l$, the equation in degree $n+1$ reads $0 = \mathrm{d}' v^{D-1}_{p+1,n}$ where d' does not differentiate with respect to the explicit dependence in x. This in turn implies that $v^{D-1}_{p+1,n} = \mathrm{d}'\tilde{v}^{D-1}_{p+1,n-1}$ and can be removed by redefining $v^{D-1}_{p+1}: v^{D-1}_{p+1} \to v^{D-1}_{p+1} - \mathrm{d}\tilde{v}^{D-1}_{p+1,n-1}$. If $l>n$, the equation in degree $l+1$ is $0 = \delta u^D_{p+2,l}$ and implies, together with the acy-

clicity of δ, that one can remove $u^D_{p+2,l}$ by a trivial redefinition of u^D_{p+2}. If $l=n>0$, the equation in degree $l+1$ reads $0=\delta u^D_{p+2,l}+\mathrm{d}' v^{D-1}_{p+1,l}$. Since there is no cohomology in antighost number $p+2$, this implies that $u^D_{p+2,l}=\delta \overline{u}^D_{p+3,l-1}+\mathrm{d}'\overline{u}^{D-1}_{p+2,l-1}$ and can be removed by trivial redefinitions: $u^D_{p+2}\to u^D_{p+2}-\delta\overline{u}^D_{p+3,l-1}$ and $v^{D-1}_{p+1}\to v^{D-1}_{p+1}-\mathrm{d}\tilde{u}^{D-1}_{p+2,l-1}$. Repeating the steps above, one can remove all $u^D_{p+2,l}$ and $v^{D-1}_{p+1,n}$ for $l,n>0$. One is left with $\lambda C^{*D}_{p+1}=\delta u^D_{p+2,0}+\mathrm{d}' v^{D-1}_{p+1,0}$. The derivative argument used in the case without explicit x dependence now leads to the desired conclusion. □

Theorem 6.4: *The cohomology groups $H^D_k(\delta|\mathrm{d})$ $(k>1)$ vanish unless $k=D-r(D-p-1)$ for some strictly positive integer r. Furthermore, for those values of k, $H^D_k(\delta|\mathrm{d})$ has at most one nontrivial class.*

Proof: We already know that $H^D_k(\delta|\mathrm{d})$ vanishes for $k>p+1$ and that $H^D_{p+1}(\delta|\mathrm{d})$ has one nontrivial class. Let us assume that the theorem has been proved for all k's strictly greater than K (with $K<p+1$) and extend it to K. Without loss of generality we can assume that the cocycles of $H^D_K(\delta|\mathrm{d})$ take the form (up to trivial terms) $a^D_K=\lambda^{\mu_1\cdots\mu_{p+1-K}|\nu_1\cdots\nu_q}C^{*D-p-1+K}_{K\ \nu_1\cdots\nu_q|\mu_1\cdots\mu_{p+1-K}}+\mu^D_K$, where λ does not involve the antifields and μ is at least bilinear in the antifields. Taking the Euler–Lagrange derivative of the cocycle condition with respect to C^*_{K-1} implies that $\lambda^{p+1-K}_{\nu_1\cdots\nu_q}\equiv\lambda_{\mu_1\cdots\mu_{p+1-K}|\nu_1\cdots\nu_q}\,\mathrm{d}x^{\mu_1}\cdots\mathrm{d}x^{\mu_{p+1-K}}$ defines an element of $H_0^{p+1-K}(\mathrm{d}|\delta)$. If λ is d-trivial modulo δ, then it is straightforward to check that $\lambda C^{*D-p-1+K}_K$ is trivial or bilinear in the antifields. Using the isomorphism $H_0^{p+1-K}(\mathrm{d}|\delta)\cong H^D_{D-p-1+K}(\delta|\mathrm{d})$, we see that λ must be trivial unless $D-p-1+K=D-r(D-p-1)$, in which case $H^D_{D-p-1+K}(\delta|\mathrm{d})$ has one nontrivial class. Since $K=D-(r+1)(D-p-1)$ is also of the required form, the theorem extends to K. □

Theorem 6.5: *Let r be a strictly positive integer. A complete set of representatives of $H^D_k(\delta|\mathrm{d})$ $[k=D-r(D-p-1)\geqslant q]$ is given by the terms of form-degree D in the expansion of all possible homogeneous polynomials $P(\tilde{H})$ of degree r in $\tilde{H}$ [or equivalently $P(\tilde{\mathcal{H}})$ of degree r in $\tilde{\mathcal{H}}$].*

The proof of this theorem is given in Appendix B.

These theorems give us a complete description of all the cohomology groups $H^D_k(\delta|\mathrm{d})$ for $k\geqslant q$ (with $k>1$).

VII. INVARIANT COHOMOLOGY OF δ MODULO d, $H^{\mathrm{inv}}_k(\delta|\mathrm{d})$

In this section, we compute the set of invariant solutions a^D_k $(k\geqslant q)$ of the equation $\delta a^D_k+\mathrm{d}b^{D-1}_{k-1}=0$, up to trivial terms $a^D_k=\delta b^D_{k+1}+\mathrm{d}c^{D-1}_k$, where b^D_{k+1} and c^{D-1}_k are invariant. This space of solutions is the invariant cohomology of δ modulo d, $H^{\mathrm{inv}}_k(\delta|\mathrm{d})$. We first compute representatives of all the cohomology classes of $H^{\mathrm{inv}}_k(\delta|\mathrm{d})$, then we find out the cocycles without explicit x dependence.

Theorem 7.1: *For $k\geqslant q$, a complete set of invariant solutions of the equation $\delta a^D_k+\mathrm{d}b^{D-1}_{k-1}=0$ is given by the proper component in the expansion of the polynomials in the curvature K^{q+1} and in $\tilde{\mathcal{H}}$ (modulo trivial solutions),*

$$\delta a^D_k+\mathrm{d}b^{D-1}_{k-1}=0\Rightarrow a^D_k=P(K^{q+1},\tilde{\mathcal{H}})|^D_k+\delta\mu^D_{k+1}+\mathrm{d}\nu^{D-1}_k,$$

where μ^D_{k+1} and ν^{D-1}_k are invariant forms.

Proof: From the preceding section, we know that for $k\geqslant q$ the general solution of the equation $\delta a^D_k+\mathrm{d}b^{D-1}_{k-1}=0$ is $a^D_k=Q(\tilde{\mathcal{H}})|^D_k+\delta m^D_{k+1}+\mathrm{d}n^{D-1}_k$ where $Q(\tilde{\mathcal{H}})$ is a homogeneous polynomial of degree r in $\tilde{\mathcal{H}}$ [it exists only when $k=D-r(D-p-1)$]. Note that m^D_{k+1} and n^{D-1}_k are not necessarily invariant. However, one can prove the following theorem (the lengthy proof of which is given in Appendix C).

Theorem 7.2: *Let α^D_k be an invariant polynomial $(k\geqslant q)$. If $\alpha^D_k=\delta m^D_{k+1}+\mathrm{d}n^{D-1}_k$, then*

$$\alpha^D_k=R^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|^D_k+\delta\mu^D_{k+1}+\mathrm{d}\nu^{D-1}_k,$$

where $R^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})$ is a polynomial of degree s in K^{q+1} and r in $\tilde{\mathcal{H}}$, such that the strictly positive integers s, r satisfy $D=r(D-p-1)+k+s(q+1)$ and μ^D_{k+1} and ν^{D-1}_k are invariant forms.

As a^D_k and $Q(\tilde{\mathcal{H}})|^D_k$ are invariant, this theorem implies that

$$a_k^D = P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_k^D + \delta\mu_{k+1}^D + \mathrm{d}\nu_k^{D-1},$$

where $P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})$ is a polynomial of non-negative degree s in K^{q+1} and of strictly positive degree r in $\tilde{\mathcal{H}}$. Note that the polynomials of nonvanishing degree in K^{q+1} are trivial in $H_k^D(\delta|\mathrm{d})$ but not necessarily in $H_k^{D\ \mathrm{inv}}(\delta|\mathrm{d})$. □

Part of the solutions found in Theorem 7.1 depend explicitly on the coordinate x, because $\tilde{\mathcal{H}}|_0$ does. Therefore the question arises whether there exist other representatives of the same nontrivial equivalence class $[P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_k^D] \in H_k^{D\ \mathrm{inv}}(\delta|\mathrm{d})$ that *do not* depend explicitly on x. The answer is negative when $r>1$. In other words, we can prove the general theorem.

Theorem 7.3: *When $r>1$, there is no nontrivial invariant cocycle in the equivalence class $[P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_k^D] \in H_k^{D\ \mathrm{inv}}(\delta|\mathrm{d})$ without explicit x* dependence.

To do so, we first prove the following lemma.

Lemma 7.1: Let $P(K^{q+1},\tilde{\mathcal{H}})$ be a homogeneous polynomial of order s in the curvature K^{q+1} and r in $\tilde{\mathcal{H}}$. If $r\geqslant 2$, then the component $P(K^{q+1},\tilde{\mathcal{H}})|_k^D$ always contains terms of order $r-1(\neq 0)$ in $\tilde{\mathcal{H}}|_0$.

Proof: Indeed, $P(K^{q+1},\tilde{\mathcal{H}})$ can be freely expanded in terms of $\tilde{\mathcal{H}}|_0$ and the undifferentiated antighost forms. The Grassmann parity is the same for all terms in the expansion of $\tilde{\mathcal{H}}$, therefore the expansion is the binomial expansion up to the overall coefficient of the homogeneous polynomial and up to relative signs obtained when reordering all terms. Hence, the component $P(K^{q+1},\tilde{\mathcal{H}})|_k^D$ always contains a term that is a product of $(r-1)$ $\tilde{\mathcal{H}}|_0^{D-p-1}$'s, a single antighost $C_k^{*D-p-1+k}$ and s curvatures, which possesses the correct degrees as can be checked straightforwardly. □

Proof of Theorem 7.3: Let us assume that there exists a nonvanishing invariant x-independent representative $\alpha_k^{D,\mathrm{inv}}$ of the equivalence class $[P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_k^D] \in H_k^{D\ \mathrm{inv}}(\delta|\mathrm{d})$, i.e.,

$$P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_k^D + \delta\rho_{k+1}^D + \mathrm{d}\sigma_k^{D-1} = \alpha_k^{D,\mathrm{inv}}, \tag{22}$$

where ρ_{k+1}^D and σ_k^{D-1} are invariant and allowed to depend explicitly on x.

We define the descent map $f:\alpha_m^n \to \alpha_{m-1}^{n-1}$ such that $\delta\alpha_m^n + \mathrm{d}\alpha_{m-1}^{n-1} = 0$, for $n \leqslant D$. This map is well defined on equivalence classes of $H^{\mathrm{inv}}(\delta|\mathrm{d})$ when $m>1$. Hence, going down $k-1$ steps, it is clear that the equation (22) implies

$$P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_1^{D-k+1} + \delta\rho_2^{D-k+1} + \mathrm{d}\sigma_1^{D-k} = \alpha_1^{D-k+1,\mathrm{inv}},$$

with $\alpha_1^{D-k+1,\mathrm{inv}} \neq 0$.

We can decompose this equation in the polynomial degree in the fields, antifields, and all their derivatives. Since δ and d are linear operators, they preserve this degree; therefore

$$P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_{1,r+s}^{D-k+1} + \delta\rho_{2,r+s}^{D-k+1} + \mathrm{d}\sigma_{1,r+s}^{D-k} = \alpha_{1,r+s}^{D-k+1,\mathrm{inv}}, \tag{23}$$

where $r+s$ denotes the polynomial degree. The homogeneous polynomial $\alpha_{1,r+s}^{D-k+1,\mathrm{inv}}$ of polynomial degree $r+s$ is linear in the antifields of antighost number equal to one, and depends on the fields only through the curvature.

Finally, we introduce the number operator N defined by

$$N = r\partial_{\rho_1}\cdots\partial_{\rho_r}\phi_{\mu_1\cdots\mu_p|\nu_1\cdots\nu_q}\frac{\partial}{\partial(\partial_{\rho_1}\cdots\partial_{\rho_r}\phi_{\mu_1\cdots\mu_p|\nu_1\cdots\nu_q})} + (r+1)\partial_{\rho_1}\cdots\partial_{\rho_r}\Phi^*_A\frac{\partial}{\partial(\partial_{\rho_1}\cdots\partial_{\rho_r}\Phi^*_A)} - x^\mu\frac{\partial}{\partial x^\mu},$$

where $\{\Phi^*_A\}$ denotes the set of all antifields. It follows immediately that δ and d are homogeneous of degree one and the degree of $\tilde{\mathcal{H}}$ is also equal to one,

$$N(\delta) = N(d) = 1 = N(\tilde{\mathcal{H}}).$$

Therefore, the decomposition in N-degree of the equation (23) reads in N-degree equal to $n=r+2s$,

$$P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|^{D-k+1}_{1,r+s} + \delta\rho^{D-k+1}_{2,r+s,r+2s-1} + \mathrm{d}\sigma^{D-k}_{1,r+s,r+2s-1} = \alpha^{D-k+1,\mathrm{inv}}_{1,r+s,r+2s} \tag{24}$$

and, in N-degree equal to $n>r+2s$,

$$\delta\rho^{D-k+1}_{2,r+s,n-1} + \mathrm{d}\sigma^{D-k}_{1,r+s,n-1} = \alpha^{D-k+1,\mathrm{inv}}_{1,r+s,n}.$$

The component $\alpha^{D-k+1,\mathrm{inv}}_{1,r+s,r+2s}$ of N-degree equal to $r+2s$ is x-independent, depends linearly on the (possibly differentiated) antighost of antifield number 1, and is of order $r+s-1$ in the (possibly differentiated) curvatures. Direct counting shows that there is no polynomial of N-degree equal to $r+2s$ satisfying these requirements when $r\geqslant 2$. Thus for $r\geqslant 2$ the component $\alpha^{D-k+1,\mathrm{inv}}_{1,r+s,r+s}$ vanishes, and then the equation (24) implies that $P^{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|^{D-k+1}_{1,r+s}$ is trivial (and even vanishes when $s=0$, by Theorem 6.5).

In conclusion, if $P(K^{q+1},\tilde{\mathcal{H}})$ is a polynomial that is quadratic or more in $\tilde{\mathcal{H}}$, then there exists no nontrivial invariant representative without explicit x dependence in the cohomology class $[P(K^{q+1},\tilde{\mathcal{H}})]$ of $H^{\mathrm{inv}}(\delta|\mathrm{d})$. □

This leads us to the following theorem.

Theorem 7.4: *The invariant solutions a^D_k $(k\geqslant q)$ of the equation $\delta a^D_k+\mathrm{d}b^{D-1}_{k-1}=0$ without explicit x dependence are all trivial in $H^{\mathrm{inv}}_k(\delta|\mathrm{d})$ unless $k=p+1-s(q+1)$ for some non-negative integer s. For those values of k, the nontrivial representatives are given by polynomials that are linear in $C^{*D-p-1+k}_k$ and of order s in K^{q+1}.*

Proof: By Theorem 7.1, invariant solutions of the equation $\delta a^D_k+\mathrm{d}b^{D-1}_{k-1}=0$ are polynomials in K^{q+1} and $\tilde{\mathcal{H}}$ modulo trivial terms. When the polynomial is quadratic or more in $\tilde{\mathcal{H}}$, then Theorem 7.3 states that there is no representative without explicit x dependence in its cohomology class, which implies that it should be rejected. The remaining solutions are the polynomials linear in $\tilde{\mathcal{H}}|_k=C^{*D-p-1+k}_k$ and of arbitrary order in K^{q+1}. They are invariant and x independent, they thus belong to the set of looked-for solutions. □

VIII. SELF-INTERACTIONS

As explained in Sec. III, the nontrivial first order deformations of the free theory are given by the elements of $H^{D,0}(s|\mathrm{d})$, the cohomological group of the BRST differential s in the space of local forms in top form degree and in ghost number zero. The purpose of this section is to compute this group. As the computation is very similar to the computation of similar groups in the case of p-forms,[16] gravity,[17] dual gravity,[18] and $[p,p]$-fields,[20] we will not reproduce it here entirely and refer to the works just cited (e.g., Ref. 17) for technical details. We just present the main steps of the procedure and the calculations that are specific to the case of $[p,q]$-fields.

The proof is given for a single $[p,q]$-field ϕ but extends trivially to a set $\{\phi^a\}$ containing a finite number n of them (with fixed p and q) by writing some internal index $a=1,\ldots,n$ everywhere.

The group $H(s|\mathrm{d})$ is the group of solutions a of the equation $sa+\mathrm{d}b=0$, modulo trivial solutions of the form $a=sm+\mathrm{d}n$. The basic idea to compute such a group is to use homological perturbation techniques by expanding the quantities and the equations according to the antighost number.

Let $a^{D,0}$ be a solution of $sa^{D,0}+\mathrm{d}b^{D-1,1}=0$ with ghost number zero and top form degree. For convenience, we will frequently omit to write the upper indices. One can expand $a(=a^{D,0})$ as $a=a_0+a_1+\cdots+a_k$ where a_i has antighost number i. The expansion can be assumed to stop at some finite value of the antighost number under the sole hypothesis that the first-order deformation of the Lagrangian has a finite derivative order.[27] Let us recall[21] that (i) the antifield-independent piece a_0 is the deformation of the Lagrangian; (ii) the terms linear in the ghosts contain the information about the deformation of the reducibility conditions; (iii) the other terms give the information about the deformation of the gauge algebra.

Under the assumption of locality, the expansion of b also stops at some finite antighost number. Without loss of generality, one can assume that $b_j=0$ for $j\geqslant k$. Decomposing the BRST differential as $s=\gamma+\delta$, the equation $sa+\mathrm{d}b=0$ is equivalent to

$$\begin{aligned}
&\delta a_1+\gamma a_0+\mathrm{d}b_0=0,\\
&\delta a_2+\gamma a_1+\mathrm{d}b_1=0,\ \ldots,\\
&\delta a_k+\gamma a_{k-1}+\mathrm{d}b_{k-1}=0,\\
&\gamma a_k=0.
\end{aligned}\tag{25}$$

The next step consists in the analysis of the term a_k with highest antighost number and the determination of whether it can be removed by trivial redefinitions or not. We will see in the sequel under which assumptions this can be done.

A. Computation of a_k for $k>1$

The last equation of the descent (25) is $\gamma a_k=0$. It implies that $a_k=\alpha_J\omega^J$ where α_J is an invariant form and ω^J is a polynomial in the ghosts of $H(\gamma)$: $A^{(p-q,q)}_{\mu_{[q]}}$ and $D^0_{\mu_{[p+1]}}$. Inserting this expression for a_k into the second to last equation leads to the result that α_J should be an element of $H^{D,\mathrm{inv}}_k(\delta|\mathrm{d})$. Furthermore, if α_J is trivial in this group, then a_k can be removed by trivial redefinitions. The vanishing of $H^{D,\mathrm{inv}}_k(\delta|\mathrm{d})$ is thus a sufficient condition to remove the component a_k from a. It is however not a necessary condition, as we will see in the sequel.

We showed that nontrivial interactions can arise only if some $H^{D,\mathrm{inv}}_k(\delta|\mathrm{d})$ do not vanish. The requirement that the Lagrangian should not depend explicitly on x implies that we can restrict ourselves to x-independent elements of this group. Indeed, it can be shown[23] that, when a_0 does not depend explicitly on x, the whole cocycle $a=a_0+a_1+\cdots+a_k$ satisfying $sa+\mathrm{d}b=0$ is x independent (modulo trivial redefinitions). By Theorem 7.4, $H^{D,\mathrm{inv}}_k(\delta|\mathrm{d})$ contains nontrivial x-independent elements only if $k=p+1-s(q+1)$ for some non-negative integer s. The form of the nontrivial elements is then $\alpha^D_k=C^{*D-p-1+k}_k(K^{q+1})^s$. In order to be (possibly) nontrivial, a_k must thus be a polynomial linear in $C^{*D-p-1+k}_k$, of order s in the curvature K^{q+1} and of appropriate orders in the ghosts $A^{(p-q,q)}_{\mu_{[q]}}$ and $D^0_{\mu_{[p+1]}}$.

As a_k has ghost number zero, the antighost number of a_k should match its pure ghost number. Consequently, as the ghosts $A^{(p-q,q)}_{\mu_{[q]}}$ and $D^0_{\mu_{[p+1]}}$ have puregh$=p$ and q, respectively, the equation $k=np+mq$ should be satisfied for some positive integers n and m. If there is no couple of integers n, m to match k, then no a_k satisfying the relevant equations of the descent (25) can be constructed and a_k thus vanishes.

In the sequel, we will consider the case where n and m satisfying $k=np+mq$ can be found and classify the different cases according to the following values of n and m: (i) $n\geqslant 2$, (ii) $n=1$, (iii)

$n=0$, $m>1$, and (iv) $n=0$, $m=1$. We will show that the corresponding candidates a_k are either obstructed in the lift to a_0 or that they are trivial, except in the case (iv). In this case, a_k can be lifted but a_0 depends explicitly on x and contains more than two derivatives.

(i) Candidates with $n\geqslant 2$: The constraints $k\leqslant p+1$ and $k=np+mq$ have no solutions. (There is a solution in the case previously considered in Ref. 17, where $p=q=1$, $n=2$. As shown in Ref. 17, this solution gives rise to Einstein's theory of gravity.)

(ii) Candidates with $n=1$: The conditions $k=mq+p\leqslant p+1$ are only satisfied for $q=1=m$. As shown in Ref. 18, the lift of these candidates is obstructed after one step without any additional assumption.

(iii) Candidates with $n=0$, $m>1$: For a nontrivial candidate to exist at $k=mq$, Theorem 7.4 tells us that p and q should satisfy the relation $p+1=mq+s(q+1)$ for some positive or null integer s. The candidate then has the form

$$a^D_{mq}=C^{*D-p-1+mq}_{mq\nu_{[q]}}\omega^{\nu_{[q]}}_{(s,m)}(K,D),$$

where what is meant by a polynomial $\omega_{(s,m)}$ is explained in Sec. V B.

We will show that these candidates are either trivial or that there is an obstruction to lift them up to a^D_0 after q steps.

It is straightforward to check that, for $1\leqslant j\leqslant q$, the terms

$$a^D_{mq-j}=C^{*D-p-1+mq-j}_{mq-j}\omega^{s(q+1)+j,mq-j}$$

satisfy the descent equations, since, as $m>1$, all antifields $C^{*D-p-1+mq-j}_{mq-j}$ are invariant. The set of summed indices $\nu_{[q]}$ is implicit as well as the homogeneity degree of the generating polynomials $\omega_{(s,m)}$. We can thus lift a^D_{mq} up to $a^D_{(m-1)q}$. As $m>1$, this is not yet a_0.

There is however no $a^D_{(m-1)q-1}$ such that

$$\gamma(a^D_{(m-1)q-1})+\delta a^D_{(m-1)q}+\mathrm{d}\beta^{D-1}_{(m-1)q-1}=0. \tag{26}$$

Indeed, we have

$$\delta a^D_{(m-1)q}=-\gamma(C^{*D-(s+1)(q+1)}_{(m-1)q-1}\omega^{(s+1)(q+1),(m-1)q-1})+(-)^{D-mq}C^{*D-(s+1)(q+1)}_{(m-1)q-1}K^{q+1}\left[\frac{\partial^L\omega}{\partial D}\right]^{s(q+1),(m-1)q}.$$

Without loss of generality, we can suppose that

$$a^D_{(m-1)q-1}=C^{*D-(s+1)(q+1)}_{(m-1)q-1}\bar{a}^{(s+1)(q+1)}_0+\bar{a}^D_{(m-1)q-1},$$

where there is an implicit summation over all possible coefficients $\bar{a}^{(s+1)(q+1)}_0$, and most importantly the two $\bar{a}$'s *do not* depend on $C^*_{(m-1)q-1}$. (This is not true in the case—excluded in this paper—where $p=q=1$ and $m=2$: since $C^*_{(m-1)q-1}\equiv C^*_0$ has antighost number zero, the antighost number counting does not forbid that the $\bar{a}$'s depend on C^*_0. Candidates arising in this way are treated in Ref. 28 and give rise to a consistent deformation of the Fierz–Pauli theory in $D=3$.) Taking the Euler–Lagrange derivative of (26) with respect to $C^*_{(m-1)q-1}$ yields

$$\gamma(\bar{a}^{(s+1)(q+1)}_0-\omega^{(s+1)(q+1),(m-1)q-1})\propto K^{q+1}\left[\frac{\partial^L\omega}{\partial D}\right]^{s(q+1),(m-1)q}.$$

The product of nontrivial elements of $H(\gamma)$ in the rhs is not γ-exact and constitutes an obstruction to the lift of the candidate, unless it vanishes. The latter happens only when the polynomial $\omega_{(s,m)}$ can be expressed as

$$\omega^{\nu_{[q]}}_{(s,m)}(K,D) = K^{q+1}\mu_{[p+1]}\frac{\partial^L \widetilde{\omega}^{\nu_{[q]}}_{(s-1,m+1)}(K,D)}{\partial D^{\mu_{[p+1]}}},$$

for some polynomial $\widetilde{\omega}^{\nu_{[q]}}_{(s-1,m+1)}(K,D)$ of order $s-1$ in K^{q+1} and $m+1$ in D. However, in this case, a^D_{mq} can be removed by the trivial redefinition

$$a^D \to a^D + s(\widetilde{H}_{\nu_{[q]}}\widetilde{\omega}^{\nu_{[q]}}_{(s-1,m+1)}|^D).$$

This completes the proof that these candidates are either trivial or that their lift is obstructed. As a consequence, they do not lead to consistent interactions and can be rejected. Let us stress that no extra assumptions are needed to get this result. In the particular case $q=1$, this had already been guessed but not proved in Ref. 18.

(iv) Candidates with $n=0$, $m=1$: These candidates exist only when the condition $p+2=(s+1)(q+1)$ is satisfied, for some strictly positive integer s. It is useful for the analysis to write the indices explicitly,

$$a^D_q = g^{\nu_{[q]}\|\mu^1_{[p+1]}|\cdots|\mu^{s+1}_{[p+1]}}C^{*D-p-1+q}_{q\nu_{[q]}}\left(\prod_{i=1}^{s}K^{q+1}_{\mu^i_{[p+1]}}\right)D^0_{\mu^{s+1}_{[p+1]}},$$

where g is a constant tensor.

We can split the analysis into two cases: (i) $g\to(-)^q g$ under the exchange $\mu^s_{[p+1]}\leftrightarrow\mu^{s+1}_{[p+1]}$, and (ii) $g\to(-)^{q+1}g$ under the same transformation.

In the case (i), a^D_q can be removed by adding the trivial term $s\,m^D$ where $m^D=\Sigma^{2q}_{j=q}m^D_j$ and

$$m^D_j = (-)^{D-q}\frac{1}{2}g^{\nu_{[q]}\|\mu^1_{[p+1]}|\cdots|\mu^{s+1}_{[p+1]}}C^{*D-p-1+j}_{j\nu[q]}\left(\prod_{i=1}^{s-1}K^{q+1}_{\mu^i_{[p+1]}}\right)[D_{\mu^s_{[p+1]}}D_{\mu^{s+1}_{[p+1]}}]^{2q+1-j}.$$

This construction does not work in the case (ii) where the symmetry of g makes m^D vanish.

In the case (ii), the candidate a^D_q can be lifted up to a^D_0,

$$a^D_0 \propto f^{\sigma_{[p+1]}\|\mu^1_{[p+1]}|\cdots|\mu^{s+1}_{[p+1]}}_{\tau_{[D-p-q-1]}}x^{\tau_1}\,\mathrm{d}x^{\tau_2}\cdots\mathrm{d}x^{\tau_{D-p-q-1}}K^{q+1}_{\sigma_{[p+1]}}\left(\prod_{i=1}^{s}K^{q+1}_{\mu^i_{[p+1]}}\right)D^q_{\mu^{s+1}_{[p+1]}},$$

where the constant tensor f is defined by

$$f^{\sigma_{[p+1]}\|\mu^1_{[p+1]}|\cdots|\mu^{s+1}_{[p+1]}}_{\tau_{[D-p-q-1]}} \equiv g^{\nu_{[q]}\|\mu^1_{[p+1]}|\cdots|\mu^{s+1}_{[p+1]}}\epsilon^{\sigma_{[p+1]}}{}_{\nu_{[q]}\tau_{[D-p-q-1]}}.$$

Let us first note that this deformation does not affect the gauge algebra, since it is linear in the ghosts.

The Lagrangian deformation a^D_0 depends explicitly on x, which is not a contradiction with translation invariance of the physical theory if the x dependence of the Lagrangian can be removed by adding a total derivative and/or a δ-exact term. If it were the case, a^D_0 would have the form $a^D_0=xG(\cdots)+x^\alpha\mathrm{d}(\cdots)_\alpha$. We have no complete proof that a^D_0 does not have this form, but we think it very unlikely. In any case, this deformation is ruled out by the requirement that the deformation of the Lagrangian contains at most two derivatives.

To summarize the results obtained in this section, we have proved that, under the hypothesis of translation invariance of the first-order vertex a^D_0, all a^D_k $(k>1)$ can be removed by trivial redefinitions of a, except when $p+2=(s+1)(q+1)$ for some positive integer s. In that case, the supplementary assumption that the deformed Lagrangian contains no more than two derivatives is needed to reach the same conclusion, and the only possible deformation (without the latter assumption) does not modify the gauge algebra.

B. Computation of a_1

The term a_1 vanishes without any further assumption when $q>1$. Indeed, when $q>1$, the vanishing of the cohomology of γ in puregh 1 implies that there is no nontrivial a_1.

This is not true when $q=1$, as there are some nontrivial cocycles with pure ghost number equal to one. However, it can be shown[18] that any nontrivial a_1^D leads to a deformation of the Lagrangian with at least four derivatives.

C. Computation of a_0

This leaves us with the problem of solving the equation $\gamma a_0^D + \mathrm{d} b_0^{D-1} = 0$ for a_0^D. Such solutions correspond to deformations of the Lagrangian that are invariant up to a total derivative. Proceeding as in Ref. 20 and asking for Lorentz invariance and that a_0^D should not contain more than two derivatives leaves only (when $p=q$, there exists also a cosmological-like term,[20] $a_0 = \Lambda \eta_{\mu_1\nu_1} \cdots \eta_{\mu_p\nu_p} \phi^{\mu_1 \cdots \mu_p | \nu_1 \cdots \nu_p}$) the Lagrangian itself. This deformation is of course trivial.

IX. CONCLUSIONS

Assembling the results of the present paper ($p \neq q$) with those previously obtained in Ref. 20 ($p=q \neq 1$), we can state general conclusions for $[p,q]$-tensor gauge fields where p and q are now arbitrary but not both equal to one. Under the hypothesis of locality and translation invariance, there is no smooth deformation of the free theory that modifies the gauge algebra, which remains Abelian. This result strengthens the conclusions of Ref. 18 as no condition on the number of derivative is needed any longer. Furthermore, for $q>1$, when there is no positive integer s such that $p+2=(s+1)(q+1)$, there exists also no smooth deformation that alters the gauge transformations. Finally, if one excludes deformations that involve more than two derivatives in the Lagrangian and are not Lorentz invariant, then the only smooth deformation of the free theory is a cosmological-like term for $p=q$.[20]

These no-go results complete the search for self-interactions of $[p,q]$-tensor gauge fields. It is still an open question whether interactions are possible between N different $[p,q]$-type fields (where "different" means $[p_1,q_1] \neq [p_2,q_2]$ for $N=2$), or with other types of fields.

As a conclusion, one can reformulate the results in more physical terms by saying that no analogue of Yang–Mills nor Einstein theories seems to exist for more exotic fields (at least not in the range of local perturbative theories).

U. Leuven.

APPENDIX A: GOING TO THE LIGHT CONE

Theorem A.1: *Let K be a tensor in the irreducible representation $[p+1,q+1]$ of $O(D-1,1)$. The space of such harmonic multiforms K, i.e., solutions of*

$$\left.\begin{aligned} \partial_{[\mu_0} K_{[\mu_1 \cdots \mu_{p+1}]|\nu_1 \cdots \nu_{q+1}} = 0 = K_{\mu_1 \cdots \mu_{p+1}|[\nu_1 \cdots \nu_{q+1}, \nu_0]} \quad \text{(closed)} \\ \partial^{\mu_1} K_{\mu_1 \cdots \mu_{p+1}|\nu_1 \cdots \nu_{q+1}} = 0 = \partial^{\nu_1} K_{\mu_1 \cdots \mu_{p+1}|\nu_1 \cdots \nu_{q+1}} \quad \text{(coclosed)} \end{aligned}\right\} \Rightarrow \Box K = 0$$

is a unitary irreducible module of $O(D-2)$ associated to the Young diagram $[p,q]$.

Proof: Since $\Box K(x)=0$ then, after Fourier transform, $K(p)\neq 0$ iff $p^2=0$. In the light-cone frame, the lightlike momentum p^μ decomposes into

$$p^\mu = (p^+, p^-, \underbrace{0, \cdots, 0}_{D-2}), \quad p^- = 0.$$

(i) The condition that K is closed implies

$$p_\mu \varepsilon^{\mu\nu_1\cdots\nu_{D-p-2}\mu_1\cdots\mu_{p+1}} K_{\mu_1\cdots\mu_{p+1}|\alpha_1\cdots\alpha_{q+1}} = 0,$$

$$p_\mu \varepsilon^{\mu\nu_1\cdots\nu_{D-q-2}\mu_1\cdots\mu_{q+1}} K_{\alpha_1\cdots\alpha_{p+1}|\mu_1\cdots\mu_{q+1}} = 0,$$

i.e.,

$$\varepsilon^{-\nu_1\cdots\nu_{D-p-2}\mu_1\cdots\mu_{p+1}} K_{\mu_1\cdots\mu_{p+1}|\alpha_1\cdots\alpha_{q+1}} = 0,$$

$$\varepsilon^{-\nu_1\cdots\nu_{D-q-2}\mu_1\cdots\mu_{q+1}} K_{\alpha_1\cdots\alpha_{p+1}|\mu_1\cdots\mu_{q+1}} = 0.$$

The italic indices will run over the $D-2$ transverse values. Assigning $\nu_1=+$, $\nu_2=j_2,\ldots,\ \nu_{D-\ell-2}=j_{D-\ell-2}$ (where $\ell=p$ or q, respectively), one finds

$$K_{i_1\cdots i_{p+1}|\alpha_1\cdots\alpha_{q+1}} = 0 = K_{\alpha_1\cdots\alpha_{p+1}|i_1\cdots i_{q+1}}.$$

In other words, K vanishes whenever one of its columns contains only transverse indices.

(ii) The fact that K is coclosed on-shell implies

$$p_{[-} K_{+\mu_2\cdots\mu_{p+1}]|\alpha_1\cdots\alpha_{q+1}} = 0 = K_{\alpha_1\cdots\alpha_{p+1}|[+\mu_2\cdots\mu_{q+1}} p_{-]},$$

i.e.,

$$K_{+\mu_2\cdots\mu_{p+1}|\alpha_1\cdots\alpha_{q+1}} = 0 = K_{\alpha_1\cdots\alpha_{p+1}|+\mu_2\cdots\mu_{q+1}}.$$

In other words, K vanishes whenever one of its columns contains a "+" index.

Once it has been observed that each column of K must contain at least one "−" index and no "+" index, one finds that the tensor

$$\phi_{i_1\cdots i_p|j_1\cdots j_q} \equiv \frac{(p+1)(q+1)}{p_-^2} K_{-i_1\cdots i_p|j_1\cdots j_q-}$$

obeys

$$0 = \frac{p+2}{p_-^2} K_{[-i_1\cdots i_p|j_1]\cdots j_q-} = \phi_{[i_1\cdots i_p|j_1]\cdots j_q},$$

$$0 = \eta^{\mu_1\nu_1} K_{\mu_1\mu_2\cdots\mu_{p+1}|\nu_1\cdots\nu_{q+1}} \Rightarrow 0 = \frac{(p+1)(q+1)}{p_-^2} \delta^{i_1j_1} K_{-i_1i_2\cdots i_p|j_1\cdots j_q-} = \delta^{i_1j_1}\phi_{i_1i_2\cdots i_p|j_1\cdots j_q}.$$

□

APPENDIX B: PROOF OF THEOREM 6.5

In this appendix, we give the proof of Theorem 6.5.

Let r be a strictly positive integer. A complete set of representatives of $H_k^D(\delta|\mathrm{d})$ [$k>1$ and $k=D-r(D-p-1)\geqslant q$] is given by the terms of form-degree D in all homogeneous polynomials

$P^{(r)}(\tilde{H})$ *of degree r in* $\tilde{H}$ [*or equivalently* $P^{(r)}(\tilde{\mathcal{H}})$ *of degree r in* $\tilde{\mathcal{H}}$].

It is obvious from the definition of $\tilde{\mathcal{H}}$ and from Eq. (10) that the term of form-degree D in $P^{(r)}(\tilde{H})$ has the right antighost number and is a cocycle of $H_k^D(\delta|\mathrm{d})$. Furthermore, as $\tilde{\mathcal{H}}=\tilde{H}+d(\cdots)$, $P^{(r)}(\tilde{\mathcal{H}})$ belongs to the same cohomology class as $P^{(r)}(\tilde{H})$ and can as well be chosen as a representative of this class. To prove the theorem, it is then enough, by Theorem 6.4, to prove that the cocycle $P^{(r)}(\tilde{H})|_k^D$ is nontrivial. The proof is by induction: we know the theorem to be true for $r=1$ by Theorem 6.3, supposing that the theorem is true for $r-1$ [i.e., $[P^{(r-1)}(\tilde{H})]_{k+D-p-1}^D$ is not trivial in $H_{k+D-p-1}^D(\delta|\mathrm{d})$] we prove that $[P^{(r)}(\tilde{H})]_k^D$ is not trivial either.

Let us assume that $[P^{(r)}(\tilde{H})]_k^D$ is trivial: $[P^{(r)}(\tilde{H})]_k^D=\delta(u_{k+1}\,\mathrm{d}^Dx)+\mathrm{d}v_k^{D-1}$. We take the Euler–Lagrange derivative of this equation with respect to $C^*_{k,\mu_{[q]}|\nu_{[p+1-k]}}$. For $k>q$, it reads

$$\alpha_{\mu_{[q]}|\nu_{[p+1-k]}}=(-)^k\delta(Z_{1\,\mu_{[q]}|\nu_{[p+1-k]}})-Z_{0\,\mu_{[q]}[\nu_{[p-k]},\nu_{p+1-k}]}, \tag{B1}$$

where

$$\alpha_{\mu_{[q]}|\nu_{[p+1-k]}}\,\mathrm{d}^Dx\equiv\frac{\delta^L[P^{(r)}(\tilde{H})]_k^D}{\delta C_k^{*\,\mu_{[q]}|\nu_{[p+1-k]}}},$$

$$Z_{k+1-j\,\mu_{[q]}|\nu_{[p+1-j]}}\equiv\frac{\delta^L u_{k+1}}{\delta C_j^{*\,\mu_{[q]}|\nu_{[p+1-j]}}}\quad\text{for } j=k,k+1.$$

For $k=q$, there is an additional term,

$$\alpha_{\mu_{[q]}|\nu_{[p+1-q]}}=(-)^q\delta(Z_{1\,\mu_{[q]}|\nu_{[p+1-q]}})-(Z_{0\,\mu_{[q]}[\nu_{[p-q]},\nu_{p+1-q}]}-Z_{0[\,\mu_{[q]}|\nu_{[p-q]},\nu_{p+1-q}]}). \tag{B2}$$

The origin of the additional term lies in the fact that $C_q^{*\mu_{[q]}|\nu_{[p+1-q]}}$ does not possess all the irreducible components of $[q]\otimes[p+1-q]$: the completely antisymmetric component $[p+1]$ is missing. Taking the Euler–Lagrange derivative with respect to this field thus involves projecting out this component.

We will first solve the equation (B1) for $k>q$, then come back to (B2) for $k=q$.

Explicit computation of $\alpha_{\mu_{[q]}|\nu_{[p+1-k]}}$ for $k>q$ yields

$$\alpha_{\mu_{[q]}|\nu_{[p+1-k]}}=[\tilde{H}^{\rho^1_{[q]}}]_{0,\sigma^1_{[D-p-1]}}\cdots[\tilde{H}^{\rho^{r-1}_{[q]}}]_{0,\sigma^{r-1}_{[D-p-1]}}a_{\mu_{[q]}|\rho^1_{[q]}|\cdots|\rho^{r-1}_{[q]}}\delta^{[\sigma^1_{[D-p-1]}\cdots\sigma^{r-1}_{[D-p-1]}]}_{\nu_{[p+1-k]}},$$

where a is a constant tensor and the notation $[A]_{k,\nu_{[p]}}$ means the coefficient $A_{k,\nu_{[p]}}$, with antighost number k, of the p-form component of $A=\Sigma_{k,I}A_{k,\nu_{[I]}}\,\mathrm{d}x^{\nu_1}\cdots\mathrm{d}x^{\nu_I}$. Considering the indices $\nu_{[p+1-k]}$ as form indices, (B1) reads

$$\begin{aligned}\alpha^{p+1-k}_{\mu_{[q]}}&=[\tilde{H}^{\rho^1_{[q]}}]_0^{D-p-1}\cdots[\tilde{H}^{\rho^{r-1}_{[q]}}]_0^{D-p-1}a_{\mu_{[q]}|\rho^1_{[q]}|\cdots|\rho^{r-1}_{[q]}}\\&=\left[\prod_{i=1}^{(r-1)}\tilde{H}^{i\,\rho_{[q]}}\right]_0^{p+1-k}a_{\mu_{[q]}|\rho^1_{[q]}|\cdots|\rho^{r-1}_{[q]}}=(-)^k\delta(Z^{p+1-k}_{1\mu_{[q]}})+(-)^{p-k+1}\,\mathrm{d}Z^{p-k}_{0\mu_{[q]}}.\end{aligned}$$

The latter equation is equivalent to

$$\left[\prod_{i=1}^{(r-1)}\tilde{H}^{i\,\rho_{[q]}}\right]_{D-p-1+k}^{D}a_{\mu_{[q]}|\rho^1_{[q]}|\cdots|\rho^{r-1}_{[q]}}=\delta(\cdots)+\mathrm{d}(\cdots),$$

which contradicts the induction hypothesis. The assumption that $[P^{(r)}(\tilde{H})]_k^D$ is trivial is thus wrong, which proves the theorem for $k>q$.

The philosophy of the resolution of (B2) for $k=q$ is inspired by the proof of Theorem 3.3 in Ref. 20 and goes as follows: first, one must constrain the last term of (B2) in order to get an equation similar to the equation (B1) treated previously, then one solves this equation in the same way as for $k>q$.

Let us constrain the last term of (B2). Equation (B2) and explicit computation of $\alpha_{\mu_{[q]}|\nu_{[p+1-k]}}$ imply

$$\partial_{[\nu_{p+1-q}}\alpha_{\ \mu_{[q]}|\nu_{[p-q]}]\lambda} = (-)^q\delta(\partial_{[\nu_{p+1-q}}Z_{1\ \mu_{[q]}|\nu_{[p-q]}]\lambda}) - b\partial_{[\nu_{p+1-q}}Z_{0\ \mu_{[q]}|\nu_{[p-q]}],\lambda}$$
$$\approx b\partial_\lambda([\tilde{H}^{\rho^1_{[q]}}]_{0,\sigma^1_{[D-p-1]}}\cdots[\tilde{H}^{\rho^{r-1}_{[q]}}]_{0,\sigma^{r-1}_{[D-p-1]}}\delta^{[\sigma^1_{[D-p-1]}\cdots\sigma^{r-1}_{[D-p-1]}]}_{[\nu_{p+1-k}]}a_{[\mu_{[q]}]|\rho^1_{[q]}|\cdots|\rho^{r-1}_{[q]}}),$$

where $b=q/(p+1)(p+1-q)$. By the isomorphism $H_0^0(\mathrm{d}|\delta)/\mathbb{R}\cong H_D^D(\delta|\mathrm{d})\cong 0$, the latter equation implies

$$Z_{0[\mu_{[q]}|\nu_{[p-q]},\nu_{p+1-q}]} \approx -[\tilde{H}^{\rho^1_{[q]}}]_{0,\sigma^1_{[D-p-1]}}\cdots[\tilde{H}^{\rho^{r-1}_{[q]}}]_{0,\sigma^{r-1}_{[D-p-1]}}a_{\mu_{[q]}|\rho^1_{[q]}|\cdots|\rho^{r-1}_{[q]}}\delta^{[\sigma^1_{[D-p-1]}\cdots\sigma^{r-1}_{[D-p-1]}]}_{\nu_{[p+1-k]}}$$

(the constant solutions are removed by considering the equation in polynomial degree $r-1$ in the fields and antifields). Inserting this expression for $Z_{0[\mu_{[q]}|\nu_{[p-q]},\nu_{p+1-q}]}$ into (B2) and redefining Z_1 in a suitable way yields (B1) for $k=q$. The remaining proof is then the same as for $k>q$. □

APPENDIX C: PROOF OF THEOREM 7.2

In this appendix, we give the complete (and lengthy) proof of Theorem 7.2.

Let a_k^D be an invariant polynomial. If $a_k^D=\delta b_{k+1}^D+\mathrm{d}c_k^{D-1}$, then

$$a_k^D = P_{(s,r)}(K^{q+1},\tilde{\mathcal{H}})|_k^D + \delta\mu_{k+1}^D + \mathrm{d}\nu_k^{D-1},$$

where $P_{(s,r)}(K^{q+1},\tilde{\mathcal{H}})$ is a polynomial of degree s in K^{q+1} and r in $\tilde{\mathcal{H}}$, such that the integers $s,r\geqslant 1$ satisfy $D=r(D-p-1)+k+s(q+1)$ and μ_{k+1}^D and ν_k^{D-1} are invariant polynomials.

The proof is by induction and follows closely the steps of the proof of similar theorems in the case of 1-forms,[26,27] p-forms,[24] gravity[17] or $[p,p]$-fields.[20]

There is a general procedure to prove that Theorem 7.2 holds for $k>D$, that can be found, e.g., in Ref. 17 and will not be repeated here. We assume that the theorem has been proved for any $k'>k$, and show that it is still valid for k.

The proof of the induction step is rather lengthy and is decomposed into several steps.

(i) The Euler–Lagrange derivatives of a_k with respect to the fields ϕ and C_j^* $(1\leqslant j\leqslant p+1)$ are computed in terms of the Euler–Lagrange derivatives of b_{k+1} (Appendix C 1).
(ii) It is shown that the Euler–Lagrange derivatives of b_{k+1} can be replaced by invariant quantities in the expression for the Euler–Lagrange derivative of a_k with the lowest antighost number, up to some additional terms (Appendix C 2).
(iii) The preceding step is extended to all the Euler–Lagrange derivatives of a_k (Appendix C 3).
(iv) The Euler–Lagrange derivative of a_k with respect to the field ϕ is re-expressed in terms of invariant quantities (Appendix C 4).
(v) A homotopy formula is used to reconstruct a_k from its Euler–Lagrange derivatives (Appendix C 5).

1. Euler–Lagrange derivatives of a_k

We define

$$Z_{k+1-j\,\mu_{[q]}|\nu_{[p+1-j]}} = \frac{\delta^L b_{k+1}}{\delta C_j^{*\,\mu_{[q]}|\nu_{[p+1-j]}}},\quad 1\leqslant j\leqslant p+1,$$

$$Y_{k+1}^{\mu_{[p]}|\nu_{[q]}} = \frac{\delta^L b_{k+1}}{\delta \phi_{\mu_{[p]}|\nu_{[q]}}}.$$

Then, the Euler–Lagrange derivatives of a_k are given by

$$\frac{\delta^L a_k}{\delta C^{*\mu_{[q]}}_{p+1}} = (-)^{p+1} \delta Z_{k-p\mu_{[q]}}, \tag{C1}$$

$$\frac{\delta^L a_k}{\delta C^{*}_{j\,\mu_{[q]}|\nu_{[p+1-j]}}} = (-)^j \delta Z_{k+1-j\,\mu_{[q]}|\nu_{[p+1-j]}} - Z_{k-j\,\mu_{[q]}[\nu_{[p-j]},\nu_{p+1-j]}}, \quad q < j \leqslant p,$$

$$\frac{\delta^L a_k}{\delta C^{*}_{j\,\mu_{[q]}|\nu_{[p+1-j]}}} = (-)^j \delta Z_{k+1-j\,\mu_{[q]}|\nu_{[p+1-j]}} - Z_{k-j\,\mu_{[q]}[\nu_{[p-j]},\nu_{p+1-j]}}\big|_{\text{sym of } C^*_j}, \quad 1 \leqslant j \leqslant q,$$

$$\frac{\delta^L a_k}{\delta \phi^{\mu_{[p]}|\nu_{[q]}}} = \delta Y_{k+1\,\mu_{[p]}|\nu_{[q]}} + \beta D_{\mu_{[p]}|\nu_{[q]}|\rho_{[p]}|\sigma_{[q]}} Z_k^{\sigma_{[q]}|\rho_{[p]}}, \tag{C2}$$

where

$$\beta \equiv (-)^{(q+1)[p+(q/2)]} \frac{(p+1)!}{q!(p-q+1)!}$$

and

$$D^{\nu_{[q]}|}{}_{\rho_{[p]}|\mu_{[p]}|}{}^{\sigma_{[q]}} \equiv \frac{1}{(p+1)!q!} \delta^{[\sigma_{[q]}\alpha\mu_{[p]}]}_{[\nu_{[q]}\beta\rho_{[p]}]} \partial_\alpha \partial^\beta$$

is the second-order self-adjoint differential operator defined by $G_{\mu_{[p]}|\nu_{[q]}} \equiv D_{\mu_{[p]}|\nu_{[q]}|\rho_{[p]}|\sigma_{[q]}} \times C^{\rho_{[p]}|\sigma_{[q]}}$.

As in Appendix B, the projection on the symmetry of the indices of C_j^* is needed when $j \leqslant q$, since in that case the variables C_j^* do not possess all the irreducible components of $[q] \otimes [p+1-j]$, but only those where the length of the first column is smaller or equal to p. When $j > q$, the projection is trivial.

2. Replacing *Z* by an invariant in the Euler–Lagrange derivative of a_k with the lowest antighost number

We should first note that, when $k < p+1$, some of the Euler–Lagrange derivatives of a_k vanish identically: indeed, as there is no negative antighost-number field, a_k cannot depend on C_j^* if $j > k$. Some terms on the right-hand side of (C1) and (C2) also vanish, Z_{k+1-j} vanishes when $j > k+1$. This implies that the $p+1-k$ top equations of (C1) and (C2) are trivially satisfied, the $p-k$ first equations involve only vanishing terms, and the $(p-k+1)$th involves in addition the δ of an antighost-zero term, which also vanishes trivially. The first nontrivial equation is then

$$\frac{\delta^L a_k}{\delta C^{*}_{k\mu_{[q]}|\nu_{[p+1-k]}}} = (-)^k \delta(Z_{1\mu_{[q]}|\nu_{[p+1-k]}}) - Z_{0\mu_{[q]}[\nu_{[p-k]},\nu_{p+1-k]}}\big|_{\text{sym of } C^*_k}. \tag{C3}$$

Let us now define $[T^q_{\rho_{[p+1]}}]_{\nu_{[q]}} \equiv (-)^q \partial_{[\rho_1} \phi_{\rho_2 \cdots \rho_{p+1}]|\nu_{[q]}}$. We will prove the following lemma for $k \geqslant q$.

Lemma C.1: In the first nontrivial equation of the system (C1) to (C2) [i.e., (C1) when $k \geqslant p+1$ *and (C3) when* $p+1 > k \geqslant q$*], respectively,* Z_{k-p} *or* Z_1 *satisfies*

$$Z_{l\mu_{[q]}|\nu_{[p+l-k]}} = Z'_{l\mu_{[q]}|\nu_{[p+l-k]}} + (-)^{k-l}\delta\beta_{l+1\mu_{[q]}|\nu_{[p+l-k]}} + \beta_{l\mu_{[q]}|[\nu_{[p+l-k-1]},\nu_{p+l-k}]}\Big|_{\text{sym of } C^*_{k-l+1}}$$
$$+ A_l\left[P^{(n)}_{\mu_{[q]}}(\tilde{\mathcal{H}}) + \frac{1}{s}T^q_{\rho_{[p+1]}}\frac{\partial^L R^{(s,r)}_{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}_{\rho_{[p+1]}}}\right]_{l,\nu_{[p+l-k]}}\Bigg|_{\text{sym of } C^*_{k-l+1}}, \tag{C4}$$

where Z'_l is invariant, the β_l's are at least linear in $\mathcal{N}$ and possess the same symmetry of indices as Z_{l-1}, $A_l \equiv (-)^{lp+p+1+[l(l+1)/2]}$, $P^{(n)}$ is a polynomial of degree n in $\tilde{\mathcal{H}}$ and $R^{(s,r)}$ is a polynomial of degree s in K^{q+1} and r in $\tilde{\mathcal{H}}$. The polynomials are present only when $p-k=n(D-p-1)$ or $p+1-k=s(q+1)+r(D-p-1)$, respectively.

Moreover, when $p+1>k\geqslant q$, the first nontrivial equation can be written

$$\frac{\delta^L a_k}{\delta C^*_{k\mu_{[q]}|\nu_{[p+1-k]}}} = (-)^k\delta Z'_{1\mu_{[q]}|\nu_{[p+1-k]}} - Z'_{0\mu_{[q]}|[\nu_{[p-k]},\nu_{p+1-k}]}\Big|_{\text{sym of } C^*_k}$$
$$+ \left([Q^{(m)}_{\mu_{[q]}}(K^{q+1})]_{\nu_{[p+1-k]}} + (-)^k[R^{(s,r)}_{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]_{0,\nu_{[p+1-k]}}\right)\Big|_{\text{sym of } C^*_k},$$

where Z'_0 is an invariant and $Q^{(m)}_{\mu_{[q]}}(K^{q+1})$ is a polynomial of degree m in K^{q+1}, present only when $p+1-k=m(q+1)$.

The lemma will be proved in this Appendix Secs. C 2 a–C 2 c, respectively, for the cases $k\geqslant p+1$, $q<k<p+1$, and $k=q$.

a. Proof of Lemma C.1 for k⩾p+1

As $k-p>0$, there is no trivially satisfied equation and we start with the top equation of (C1) to (C2).

The Lemma C.1 is a direct consequence of the well-known Lemma C.2 (see, e.g., Ref. 17).

Lemma C.2: Let α be an invariant local form that is δ-exact, i.e., $\alpha=\delta\beta$. Then $\beta=\beta'+\delta\sigma$, where β' is invariant and we can assume without loss of generality that σ is at least linear in the variables of $\mathcal{N}$.

b. Proof of Lemma C.1 for q<k<p+1

The first nontrivial equation is (as $k>q$)

$$\frac{\delta^L a_k}{\delta C^*_{k\mu_{[q]}|\nu_{[p+1-k]}}} = (-)^k\delta(Z_{1\mu_{[q]}|\nu_{[p+1-k]}}) - Z_{0\mu_{[q]}|[\nu_{[p-k]},\nu_{p+1-k}]}. \tag{C5}$$

We will first prove that Z_1 has the required form, then we will prove the first nontrivial equation can indeed be re-expressed as stated in Lemma C.1.

First part: Defining

$$\alpha_{0\mu_{[q]}|\nu_{[p+1-k]}} \equiv \frac{\delta^L a_q}{\delta C^*_{q\mu_{[q]}|\nu_{[p+1-q]}}},$$

the above equation can be written as

$$\alpha_0^{p+1-k} = (-)^k\delta(Z_1^{p+1-k}) + (-)^{p+1-k}\,\mathrm{d}Z_0^{p-k}, \tag{C6}$$

where we consider the indices $\nu_{[p+1-k]}$ as form indices and omit to write the indices $\mu_{[q]}$. Acting with d on this equation yields $\mathrm{d}\alpha_0^{p+1-k}=(-)^{k+1}\delta(\mathrm{d}Z_1^{p+1-k})$. Due to Lemma C.2, this implies that

$$\alpha_1^{p+2-k} = \mathrm{d}Z_1^{p+1-k} + \delta Z_2^{p+2-k}, \tag{C7}$$

for some invariant α_1^{p+2-k} and some Z_2^{p+2-k}. These steps can be reproduced to build a descent of equations ending with

$$\alpha^D_{D-p-1+k} = \mathrm{d}Z^{D-1}_{D-p-1+k} + \delta Z^D_{D-p+k},$$

where $\alpha^D_{D-p-1+k}$ is invariant. As $D-p-1+k>k$, the induction hypothesis can be used and implies

$$\alpha^D_{D-p-1+k} = \mathrm{d}Z'^{D-1}_{D-p-1+k} + \delta Z'^D_{D-p+k} + [R(K^{q+1},\tilde{\mathcal{H}})]^D_{D-p-1+k},$$

where Z'^D_{D-p+k} and $Z'^{D-1}_{D-p-1+k}$ are invariant, and $R(K^{q+1},\tilde{\mathcal{H}})$ is a polynomial of order s in K^{q+1} and r in $\tilde{\mathcal{H}}$ (with $r,s>0$), present when $p+1-k=s(q+1)+r(D-p-1)$. This equation can be lifted and implies that

$$\alpha_1^{p+2-k} = \mathrm{d}Z_1'^{p+1-k} + \delta Z_2'^{p+2-k} + [R(K^{q+1},\tilde{\mathcal{H}})]_1^{p+2-k},$$

for some invariant quantities $Z_1'^{p+1-k}$ and $Z_2'^{p+2-k}$. Substracting the last equation from (C7) yields

$$\mathrm{d}\left(Z_1^{p+1-k} - Z_1'^{p+1-k} - \frac{1}{s}T^q\left[\frac{\partial^L R(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}}\right]_1^{p+1-k-q}\right) + \delta(\cdots) = 0.$$

As $H_1^{p+1-k}(\mathrm{d}|\delta) \cong H^D_{D-(p-k)}(\delta|\mathrm{d})$, by Theorem 6.5 the solution of this equation is

$$Z_1^{p+1-k} = Z_1'^{p+1-k} + \frac{1}{s}T^q\left[\frac{\partial^L R(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}}\right]_1^{p+1-k-q} + \mathrm{d}\beta_1^{p-k} + \delta\beta_2^{p+1-k} + [P^{(n)}(\tilde{\mathcal{H}})]_1^{p+1-k},$$

where the last term is present only when $p-k=n(D-p-1)$.

This proves the first part of the induction basis, regarding Z_1.

Second part: We insert the above result for Z_1 into (C6). Knowing that $\delta([P(\tilde{\mathcal{H}})]_1^{p+1-k}) + \mathrm{d}([P(\tilde{\mathcal{H}})]_0^{p-k}) = 0$ and defining

$$W_0^{p-k} = (-)^{k+1}\left((-)^p Z_0^{p-k} + \delta\beta_1^{p-k} + [P^{(n)}(\tilde{\mathcal{H}})]_0^{p-k} + \frac{1}{s}T^q\left[\frac{\partial^L R(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}}\right]_0^{p-k-q}\right),$$

we get

$$\alpha_0^{p+1-k} = (-)^k\delta(Z_1'^{p+1-k}) + \mathrm{d}(W_0^{p-k}) + (-)^k[R(K^{q+1},\tilde{\mathcal{H}})]_0^{p-k}.$$

Thus $\mathrm{d}(W_0^{p-k})$ is an invariant and the invariant Poincaré Lemma 5.1 then states that

$$\mathrm{d}(W_0^{p-k}) = \mathrm{d}(Z_0'^{p-k}) + Q(K^{q+1})$$

for some invariant $Z_0'^{p-k}$ and some polynomial in K^{q+1}, $Q(K^{q+1})$. This straightforwardly implies

$$\alpha_0^{p+1-k} = (-)^k\delta(Z_1'^{p+1-k}) + \mathrm{d}(Z_0'^{p-k}) + Q(K^{q+1}) + (-)^k[R(K^{q+1},\tilde{\mathcal{H}})]_0^{p-k},$$

which completes the proof of Lemma C.1 for $q<k<p+1$. □

c. Proof of Lemma C.1 for k=q

The first nontrivial equation is

$$\frac{\delta^L a_q}{\delta C^*_{q\mu_{[q]}|\nu_{[p+1-q]}}} = (-)^q \delta(Z_{1\mu_{[q]}|\nu_{[p+1-q]}}) - (Z_{0\mu_{[q]}[\nu_{[p-q]},\nu_{p+1-q}]} - Z_{0[\,\mu_{[q]}|\nu_{[p-q]},\nu_{p+1-q}]}). \tag{C8}$$

This equation is different from the equations treated in the previous cases because the operator acting on Z_0 cannot be seen as a total derivative, since it involves the projection on a specific Young diagram. The latter problem was already faced in the $[p,p]$ case and the philosophy of the resolution goes as follows:[20]

(1) one first constrains the last term of (C8) to get an equation similar to Eq. (C3) treated previously,
(2) one solves it in the same way as for $q<k<p+1$.

We need the useful Lemma C.3, proved in Ref. 20.

Lemma C.3: If α_0^1 is an invariant polynomial of antighost number 0 and form degree 1 that satisfies $\alpha_0^1=\delta Z_1^1+\mathrm{d}W_0^0$, then, for some invariant polynomials $Z_1'^1$ and $W_0'^0$, $Z_1^1=Z_1'^1+\delta\phi_2^1+\mathrm{d}\chi_1^0$ and $W_0^0=W_0'^0+\delta\chi_1^0$

As explained above, we now constrain the last term of (C8). Equation (C8) implies

$$\partial_{[\rho}\,\alpha_{0\mu_{[q]}|\,\nu_{[p-q]}]\nu_{p+1-q}} = (-)^q\delta(\partial_{[\rho}\,Z_{1\mu_{[q]}|\,\nu_{[p-q]}]\nu_{p+1-q}}) - b\partial_{[\rho}\,Z_{0\mu_{[q]}|\,\nu_{[p-q]}],\nu_{p+1-q}},$$

where $b\equiv q/(p+1)(p+1-q)$. Defining

$$\tilde{\alpha}^1_{0[\rho\mu_{[q]}\nu_{[p-q]}]} = \partial_{[\rho}\,\alpha_{0\mu_{[q]}|\,\nu_{[p-q]}]\nu_{p+1-q}}\,\mathrm{d}x^{\nu_{p+1-q}},$$

$$\tilde{Z}^1_{1[\rho\mu_{[q]}\nu_{[p-q]}]} = (-)^q\partial_{[\rho}\,Z_{1\mu_{[q]}|\,\nu_{[p-q]}]\nu_{p+1-q}}\mathrm{d}x^{\nu_{p+1-q}},$$

$$\tilde{W}^0_{0[\rho\mu_{[q]}\nu_{[p-q]}]} = -\,a\partial_{[\rho}Z_{0\mu_{[q]}|\,\nu_{[p-q]}]},$$

and omitting to write the indices $[\rho\mu_{[q]}\nu_{[p-q]}]$, the above equation reads $\tilde{\alpha}_0^1=\delta\tilde{Z}_1^1+\mathrm{d}\tilde{W}_0^0$. Lemma C.3 then implies that $\tilde{W}_0^0=I_0'^0+\delta m_1^0$ for some invariant $I_0'^0$. By the definition of $\tilde{W}_0^0$, this statement is equivalent to

$$\partial_{[\rho}\,Z_{0\mu_{[q]}|\,\nu_{[p-q]}]} = I'_{0[\mu_{[q]}\nu_{[p-q]}\rho]} + \delta m_{1[\mu_{[q]}\nu_{[p-q]}\rho]}.$$

Inserting this result into (C8) yields

$$\alpha_{0\mu_{[q]}|\nu_{[p+1-q]}} - I'_{0[\mu_{[q]}\nu_{[p+1-q]}]} = \delta((-)^q Z_{1\mu_{[q]}|\nu_{[p+1-q]}} + m_{1[\mu_{[q]}\nu_{[p+1-q]}]}) - Z_{0\mu_{[q]}[\nu_{[p-q]},\nu_{p+1-q}]}.$$

This equation has the same form as (C5) and can be solved in the same way to get the following result:

$$Z_{1\mu_{[q]}|\nu_{[p+1-q]}} = (-)^{q+1}m_{1[\mu_{[q]}\nu_{[p+1-q]}]} + Z'_{1\mu_{[q]}|\nu_{[p+1-q]}} + \beta_{1\mu_{[q]}[\nu_{[p-q]},\nu_{p+1-q}]} + \delta\beta_{2\mu_{[q]}|\nu_{[p+1-q]}}$$
$$+\frac{1}{s}\left[T^q_{\rho_{[p+1]}}\frac{\partial^L R_{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}_{\rho_{[p+1]}}}\right]_{1,\nu_{[p+1-q]}} + [P(\tilde{\mathcal{H}})]_{1,\nu_{[p+1-k]}},$$

$$\alpha_{0\mu_{[q]}|\nu_{[p+1-q]}} = I'_{0[\,\mu_{[q]}|\nu_{[p+1-q]}]} + (-)^q\delta(Z'_{1\mu_{[q]}|\nu_{[p+1-q]}}) + Z'_{0\mu_{[q]}[\nu_{[p-q]},\nu_{p+1-q}]} + [Q_{\mu_{[q]}}(K^{q+1})]_{\nu_{[p+1-q]}}$$
$$+(-)^k[R(K^{q+1},\tilde{\mathcal{H}})]_{0,\nu_{[p+1-q]}}.$$

Removing the completely antisymmetric parts of these equations yields the desired result. □

This ends the proof of Lemma C.1 for $k \geqslant q$.

3. Replacing all *Z* and *Y* by invariants

We will now prove the following lemma.

Lemma C.4: The Euler–Lagrange derivatives of a_k can be written

$$\frac{\delta^L a_k}{\delta C^{*\mu_{[q]}}_{p+1}} = (-)^{p+1}\delta(Z'_{k-p\mu_{[q]}}),$$

$$\frac{\delta^L a_k}{\delta C_j^{*\mu_{[q]}|\nu_{[p+1-j]}}} = (-)^j \delta(Z'_{k+1-j\mu_{[q]}|\nu_{[p+1-j]}}) - Z'_{k-j\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}, \quad q < j \leqslant p,$$

$$\frac{\delta^L a_k}{\delta C_j^{*\mu_{[q]}|\nu_{[p+1-j]}}} = (-)^j \delta(Z'_{k+1-j\mu_{[q]}|\nu_{[p+1-j]}}) - Z'_{k-j\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}\big|_{\text{sym of } C_j^*}, \quad 1 \leqslant j \leqslant q,$$

$$\frac{\delta^L a_k}{\delta \phi^{\mu_{[q]}|\nu_{[q]}}} = \delta(Y'_{k+1\,\mu_{[q]}|\nu_{[q]}}) + \beta D_{\mu_{[q]}|\nu_{[q]}|\rho_{[p]}|\sigma_{[q]}} Z'^{\,\sigma_{[q]}|\rho_{[p]}}_{k},$$

where Z'_l $(k-p \leqslant l \leqslant k)$ and Y'_{k+1} are invariant polynomials, except in the following cases. When $k=p+1-m(q+1)$ for some strictly positive integer m, there is an additional term in the first nontrivial equation,

$$\frac{\delta^L a_k}{\delta C_k^{*\mu_{[q]}|\nu_{[p+1-k]}}} = (-)^k \delta Z'_{1\mu_{[q]}|\nu_{[p+1-k]}} - Z'_{0\mu_{[q]}|[\nu_{[p-k]},\nu_{p+1-k}]} + [Q_{\mu_{[q]}}(K^{q+1})]_{\nu_{[p+1-k]}}\big|_{\text{sym of } C_k^*},$$

where Q is a polynomial of degree m in K^{q+1}. Furthermore, when $k=p+1-r(D-p-1)-s(q+1)$ for a couple of integer $r,s>0$, then there is an additional term in each Euler–Lagrange derivative,

$$\frac{\delta^L a_k}{\delta C_j^{*\mu_{[q]}|\nu_{[p+1-j]}}} = (-)^j \delta(Z'_{k+1-j\mu_{[q]}|\nu_{[p+1-j]}}) - Z'_{k-j\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}\big|_{\text{sym of } C_j^*} + (-)^{k+p+1} A_{k-j}\,[R_{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]_{k-j\nu_{[p+1-j]}}\big|_{\text{sym of } C_j^*},$$

$$\frac{\delta^L a_k}{\delta \phi^{\mu_{[q]}|\nu_{[q]}}} = \delta(Y'_{k+1\mu_{[q]}|\nu_{[q]}}) + \beta D_{\mu_{[q]}|\nu_{[q]}|\rho_{[p]}|\sigma_{[q]}} Z'^{\,\sigma_{[q]}|\rho_{[p]}}_{k} + A\delta^{[\sigma_{[q]}\alpha\mu_{[p]}\xi]}_{[\nu_{[q]}\beta\rho_{[p+1]}]}\partial_\alpha\partial^\beta(x_\xi[R_{\sigma_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{\rho_{[p+1]}}_k),$$

where

$$A = \beta\frac{p+q+2}{(D-p-q-1)(p+1)!q!}A_k(-)^{p+k+1}.$$

Proof: By Lemma C.1, we know that the Z's involved in the first nontrivial equation satisfy (C4) and that this equation has the required form. We will proceed by induction and prove that when Z_{k-j} (where $k-j \geqslant 1$) satisfies (C4), then the equation for $\delta^L a_k/\delta C_j^*$ also has the desired form and Z_{k-j+1} also satisfies (C4).

Let us assume that Z_{k-j} satisfies (C4) and consider the following equation:

$$\frac{\delta^L a_k}{\delta C^*_{j\mu_{[q]}|\nu_{[p+1-j]}}} = (-)^j \delta(Z^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j}) - \left. Z^{\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}_{k-j}\right|_{\text{sym of } C^*_j}. \tag{C9}$$

Inserting (C4) for Z_{k-j} into this equation yields

$$\begin{aligned}\frac{\delta^L a_k}{\delta C^*_{j\mu_{[q]}|\nu_{[p+1-j]}}} &= (-)^j \delta(Z^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j} - \left.\beta^{\mu_{[q]}|[\nu_{[p-j]},\nu_{p-j+1}]}_{k-j+1}\right|_{\text{sym of } C^*_j}) \\ &\quad + (-)^{k+p} a_{k-j}\delta\left[P^{\mu_{[q]}}(\tilde{\mathcal{H}}) + \frac{1}{s} T^q_{\rho_{[p+1]}} \frac{\partial^L R^{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}_{\rho_{[p+1]}}}\right]^{\nu_{[p+1-j]}}_{k-j+1 \ \text{sym of } C^*_j} \\ &\quad + \left(-Z'^{\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}_{k-j} + (-)^{p+k+1} A_{k-j}[R^{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{\nu_{[p+1-j]}}_{k-j}\right)\Big|_{\text{sym of } C^*_j}. \end{aligned} \tag{C10}$$

Note that one can omit to project on the symmetries of C^*_{j+1} when inserting (C4) into (C9). Indeed the Young components that are removed by this projection would be removed later anyway by the projection on the symmetries of C^*_j.

Defining the invariant

$$\begin{aligned} Z'^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j} &\equiv \left. Z^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j}\right|_{\mathcal{N}=0} + (-)^{k+p+j} A_{k-j} \\ &\quad \times \left[P^{\mu_{[q]}}(\tilde{\mathcal{H}}) + \frac{1}{s} T^q_{\rho_{[p+1]}} \frac{\partial^L R^{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}_{\rho_{[p+1]}}}\right]^{\nu_{[p+1-j]}}_{k-j+1} \Bigg|_{\text{sym of } C^*_j} \Bigg|_{\mathcal{N}=0} \end{aligned}$$

and setting $\mathcal{N}=0$ in the last equation yields, as β_{k-j+1} is at least linear in $\mathcal{N}$,

$$\begin{aligned}\frac{\delta^L a_k}{\delta C^*_{j\mu_{[q]}|\nu_{[p+1-j]}}} &= (-)^j \delta(Z'^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j}) - \left. Z'^{\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}_{k-j}\right|_{\text{sym of } C^*_j} \\ &\quad + (-)^{p+k+1} A_{k-j} \left. [R^{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{\nu_{[p+1-j]}}_{k-j}\right|_{\text{sym of } C^*_j}. \end{aligned} \tag{C11}$$

This proves the part of the induction regarding the equations for the Euler–Lagrange derivatives. We now prove that Z_{k-j+1} verifies (C4).

Substracting (C11) from (C10), we get

$$\begin{aligned} 0 &= (-)^j \delta\Bigg(\left. Z^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j} - Z'^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j} - \beta^{\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}_{k+1-j}\right|_{\text{sym of } C^*_j} \\ &\quad + (-)^{j+k+p} A_{k-j}\left[P^{\mu_{[q]}}(\tilde{\mathcal{H}}) + \frac{1}{s} T^q_{\rho_{[p+1]}} \frac{\partial^L R^{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}_{\rho_{[p+1]}}}\right]^{\nu_{[p+1-j]}}_{k+1-j} \Bigg|_{\text{sym of } C^*_j} \Bigg). \end{aligned}$$

As $k+1-j>0$, this implies

$$\begin{aligned} Z^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j} &= Z'^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j} + (-)^{j-1}\delta\beta^{\mu_{[q]}|\nu_{[p+1-j]}}_{k-j} + \left.\beta^{\mu_{[q]}|[\nu_{[p-j]},\nu_{p+1-j}]}_{k-j+1}\right|_{\text{sym of } C^*_j} \\ &\quad + A_{k+1-j}\left[P^{\mu_{[q]}}(\tilde{\mathcal{H}}) + \frac{1}{s} T^q_{\rho_{[p+1]}} \frac{\partial^L R^{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}_{\rho_{[p+1]}}}\right]^{\nu_{[p+1-j]}}_{k+1-j} \Bigg|_{\text{sym of } C^*_j}, \end{aligned}$$

which is the expression (C4) for Z_{k+1-j}.

Assuming that Z_{k-j} satisfies (C4), we have thus proved that the equation for $\delta^L a_k/\delta C_j^*$ has the desired form and that Z_{k+1-j} also satisfies (C4). Iterating this step, one shows that all Z's satisfy (C4) and that the equations involving only Z's have the desired form.

It remains to be proved that the Euler–Lagrange derivative with respect to the field takes the right form. Inserting the expression (C4) for Z_k into (C2) and some algebra yield

$$\frac{\delta^L a_k}{\delta\phi^{\mu_{[q]}|\nu_{[q]}}} = \delta(\tilde{Y}_{k+1\mu_{[q]}|\nu_{[q]}}|_{\text{sym of }\phi}) + \beta D_{\mu_{[q]}|\nu_{[q]}|\rho_{[p]}|\sigma_{[q]}} Z'^{\sigma_{[q]}|\rho_{[p]}}_{k} + A\delta^{[\sigma_{[q]}\alpha\mu_{[p]}\xi]}_{[\nu_{[q]}\beta\rho_{[p+1]}]}\partial_\alpha\partial^\beta\,(x_\xi[R_{\sigma_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{\rho_{[p+1]}}_k)|_{\text{sym of }\phi},$$

where

$$\tilde{Y}_{k+1\mu_{[q]}|\nu_{[q]}} \equiv Y_{k+1\mu_{[q]}|\nu_{[q]}} + \beta D_{\mu_{[q]}|\nu_{[q]}|\rho_{[p]}|\sigma_{[q]}}\beta^{\sigma_{[q]}|\rho_{[p]}}_{k+1} + c\delta^{[\sigma_{[q]}\alpha\mu_{[p]}]}_{[\nu_{[q]}\beta\rho_{[p]}]}\partial_\alpha\left[P_{\sigma_{[q]}}(\tilde{\mathcal{H}}) + \frac{1}{s}T^q_{\lambda_{[p+1]}}\frac{\partial^L R^{\sigma_{[q]}}(K^{q+1},\tilde{\mathcal{H}})}{\partial K^{q+1}_{\lambda_{[p+1]}}}\right]^{[\rho_{[p]}\beta]}_{k+1} + (-)^{k+q+1}A\delta^{[\sigma_{[q]}\alpha\mu_{[p]}\xi]}_{[\nu_{[q]}\beta\rho_{[p+1]}]}\partial_\alpha(x_\xi[R_{\sigma_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{[\rho_{[p+1]}\beta]}_{k+1})$$

and $c\equiv\beta[1/(p+1)!q!]A_k(-)^{p+k+1}$. Defining $Y'_{k+1\mu_{[p]}|\nu_{[q]}}\equiv \tilde{Y}_{k+1\mu_{[q]}|\nu_{[q]}}|_{\text{sym of }\phi}|_{\mathcal{N}=0}$ and setting $\mathcal{N}=0$ in the above equation completes the proof of Lemma C.4. □

4. Euler–Lagrange derivative with respect to the field

In this section, we manipulate the Euler–Lagrange derivative of a_k with respect to the field ϕ. We have proved in the preceding section that it can be written in the form

$$\frac{\delta^L a_k}{\delta\phi^{\mu_{[p]}|\nu_{[q]}}} = \delta(Y'_{k+1\mu_{[p]}|\nu_{[q]}}) + \beta D_{\mu_{[p]}|\nu_{[q]}|\rho_{[p]}|\sigma_{[q]}} Z'^{\sigma_{[q]}|\rho_{[p]}}_{k} + A\delta^{[\sigma_{[q]}\alpha\mu_{[p]}\xi]}_{[\nu_{[q]}\beta\rho_{[p+1]}]}\partial_\alpha\partial^\beta\,(x_\xi[R_{\sigma_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{\rho_{[p+1]}}_k)|_{\text{sym of }\phi}.$$

As a_k is invariant, it can depend on $\phi_{\mu_{[p]}|\nu_{[q]}}$ only through $K_{\mu_{[p]}\alpha|\nu_{[q]}\beta}$, which implies that $\delta^L a_k/\delta\phi^{\mu_{[p]}|\nu_{[q]}} = \partial^{\alpha\beta}X_{[\mu_{[p]}\alpha][\nu_{[q]}\beta]}$, where X has the symmetry of the curvature. This in turn implies that $\delta(Y'_{k+1\mu_{[p]}|\nu_{[q]}}) = \partial^{\alpha\beta}W_{\mu_{[p]}\alpha|\nu_{[q]}\beta}$ for some W with the Young symmetry $[p+1,q+1]$. Let us consider the indices $\mu_{[p]}$ as form indices. As $H^{D-p}_{k+1}(\delta|\mathrm{d})\cong H^D_{p+1+k}(\delta|\mathrm{d})\cong 0$ for $k>0$, the last equation implies

$$Y'_{k+1\mu_{[p]}|\nu_{[q]}} = \delta A_{k+2\mu_{[p]}|\nu_{[q]}} + \partial^\lambda T_{k+1[\lambda\mu_{[p]}]|\nu_{[q]}}. \tag{C12}$$

By the induction hypothesis for $p+1+k$, we can take A_{k+2} and T_{k+1} invariant. Antisymmetrizing (C12) over the indices $\mu_q\cdots\mu_p\nu_1\cdots\nu_q$ yields

$$0 = \delta A_{k+2\mu_1\cdots\mu_{q-1}[\mu_q\cdots\mu_p|\nu_1\cdots\nu_q]} + \partial^\lambda T_{k+1\lambda\mu_1\cdots\mu_{q-1}[\mu_q\cdots\mu_p|\nu_1\ldots\nu_q]}.$$

The solution of this equation for T_{k+1} is

$$T_{k+1\mu_0\cdots\mu_{q-1}[\mu_q\cdots\mu_p|\nu_1\cdots\nu_q]} = \delta Q_{k+2\mu_0\cdots\mu_{q-1}|[\mu_q\cdots\mu_p\nu_1\cdots\nu_q]} + \partial^\alpha S_{k+1\alpha\mu_0\cdots\mu_{q-1}|[\mu_q\cdots\mu_p\nu_1\cdots\nu_q]} + [U^{(u)}_{[\mu_q\cdots\mu_p\nu_1\cdots\nu_q]}(\tilde{\mathcal{H}})]^{\rho_{[D-q]}}_{k+1}\epsilon_{\mu_0\cdots\mu_{q-1}\rho_{[D-q]}},$$

where $U^{(u)}$ is a polynomial of degree u in $\tilde{\mathcal{H}}$, present when $k+q+1=D-u(D-p-1)$ for some

strictly positive integer u. As T and $U^{(u)}(\tilde{\mathcal{H}})$ are invariant, we can use the induction hypothesis for $k'=k+1+q$. This implies

$$T_{k+1\mu_0\cdots\mu_{q-1}[\mu_q\cdots\mu_p|\nu_1\cdots\nu_q]} = \delta Q'_{k+2\mu_0\cdots\mu_{q-1}|[\mu_q\cdots\mu_p\nu_1\cdots\nu_q]} + \partial^\alpha S'_{k+1\alpha\mu_0\cdots\mu_{q-1}|[\mu_q\cdots\mu_p\nu_1\cdots\nu_q]} + [U^{(u)}_{[\mu_q\cdots\mu_p\nu_1\cdots\nu_q]}(\tilde{\mathcal{H}}) + V^{(v,w)}_{[\mu_q\cdots\mu_p\nu_1\cdots\nu_q]}(K^{q+1},\tilde{\mathcal{H}})]^{\rho_{[D-q]}}_{k+1}\epsilon_{\mu_0\cdots\mu_{q-1}\rho_{[D-q]}}, \tag{C13}$$

where Q'_{k+2} and S'_{k+1} are invariants and $V^{(v,w)}$ is a polynomial of order v and w in K^{q+1} and $\tilde{\mathcal{H}}$, respectively, present when $D-q=v(q+1)+w(D-p-1)+k+1$ for some strictly positive integers v,w.

We define the invariant tensor $E_{\alpha\mu_{[p]}|\beta\nu_{[q]}}$ with Young symmetry $[p+1,q+1]$ by

$$E_{\alpha\mu_{[p]}|\beta\nu_{[q]}} = \sum_{i=0}^{q+1} \alpha_i S'_{k+1\rho_0\cdots\rho_{i-1}[\nu_i\cdots\nu_q|\beta\nu_1\cdots\nu_{i-1}]\rho_i\cdots\rho_p}\delta^{[\rho_0\cdots\rho_p]}_{[\alpha\mu_{[p]}]},$$

where $\alpha_i=\alpha_0[(q+1)!/(q+1-i)!i!]$ and $\alpha_0=(-)^{pq}\{((p+1)!)^2/(p-q)!(q!)^2(p-q+1)(p+2)\Sigma_{j=0}^{q}[(p-j)!/(q-j)!]\}$.

Writing $\partial^{\alpha\beta}E_{k+1\alpha\mu_{[p]}|\beta\nu_{[q]}}$ in terms of S'_{k+1} and using (C13) and (C12) yields

$$Y'_{k+1\mu_{[p]}|\nu_{[q]}} = \partial^{\alpha\beta}E_{k+1\alpha\mu_{[p]}|\beta\nu_{[q]}} + \delta F_{k+2\mu_{[p]}|\nu_{[q]}} + \partial^\alpha\sum_{i=0}^{q}\beta_i[V^{(v,w)}_{[\alpha\nu_{[i]}\mu_{i+1}\cdots\mu_p]}(K^{q+1},\tilde{\mathcal{H}})]^{\rho_{[D-q]}}_{k+1}\epsilon_{\mu_{[i]}\nu_{i+1}\cdots\nu_q\rho_{[D-q]}}, \tag{C14}$$

where F_{k+2} is invariant, $\beta_i\equiv\alpha_0[(p+2)q!/(p+1)i!(q-i)!]$ and v is allowed to take the value $v=0$ to cover also the case of the polynomial $U^{(w)}(\tilde{\mathcal{H}})$.

5. Homotopy formula

We will now use the homotopy formula to reconstruct a_k from its Euler–Lagrange derivatives,

$$a^D_k = \int_0^1 \mathrm{d}t\left[\phi_{\mu_{[p]}|\nu_{[q]}}\frac{\delta^L a_k}{\delta\phi_{\mu_{[p]}|\nu_{[q]}}} + \sum_{j=1}^{p+1} C^*_{j\mu_{[q]}|\nu_{[p+1-j]}}\frac{\delta^L a_k}{\delta C^*_{j\mu_{[q]}|\nu_{[p+1-j]}}}\right]\mathrm{d}^Dx.$$

Inserting the expressions for the Euler–Lagrange derivatives given by Lemma C.4 yields

$$a^D_k = \int_0^1 \mathrm{d}t\left[\delta(\phi_{\mu_{[p]}|\nu_{[q]}}Y'^{\mu_{[p]}|\nu_{[q]}}_{k+1}) + \sum_{j=1}^{p+1}\delta(C^*_{j\mu_{[q]}|\nu_{[p+1-j]}}Z'^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j}) + \sum_{j=1}^{k} C^*_{j\mu_{[q]}|\nu_{[p+1-j]}} \times(-)^{k+p+1}A_{k-j}[R^{\mu_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{\nu_{[p+1-j]}}_{k-j} + \phi_{\mu_{[p]}|\nu_{[q]}}A\delta^{[\sigma_{[q]}\alpha\mu_{[p]}\xi]}_{[\nu_{[q]}\beta\rho_{[p+1]}]}\partial_\alpha\partial^\beta(x_\xi[R_{\sigma_{[q]}}(K^{q+1},\tilde{\mathcal{H}})]^{\rho_{[p+1]}}_k) + C^*_{k\mu_{[q]}|\nu_{[p+1-k]}}[Q^{(m)\mu_{[q]}}(K^{q+1})]^{\nu_{[p+1-k]}}\right]\mathrm{d}^Dx + \mathrm{d}n^{D-1}_k.$$

Using the result (C14) for Y'_{k+1} and some algebra, one finds

$$a_k^D = \int_0^1 \mathrm{d}t \Bigg[\delta(K_{\mu_{[p+1]}|\nu_{[q+1]}} E_{k+1}^{\mu_{[p+1]}|\nu_{[q+1]}} \mathrm{d}^D x) + a_v K_{\mu_{[p+1]}}^{q+1} [V^{(v,w)\mu_{[p+1]}}(K^{q+1}, \tilde{\mathcal{H}})]_k^{D-q-1}$$
$$+ \sum_{j=1}^{p+1} \delta(C^*_{j\mu_{[q]}|\nu_{[p+1-j]}} Z'^{\mu_{[q]}|\nu_{[p+1-j]}}_{k+1-j} \mathrm{d}^D x) + a_r [\tilde{\mathcal{H}}^{\sigma_{[q]}} R_{\sigma_{[q]}}(K^{q+1}, \tilde{\mathcal{H}})]_k^D$$
$$+ a_q [\tilde{\mathcal{H}}^{\sigma_{[q]}}]_k^{D-m(q+1)} Q^{(m)}_{\sigma_{[q]}}(K^{q+1}) \Bigg] + \mathrm{d}\bar{n}_k^{D-1},$$

where $a_v = (-)^{k(q+1)} \Sigma_{i=0}^q \beta_i [i!(p-i)!/p!]$, $a_r = (-)^{D(p+k+1)+\{[p(p+1)+k(k+1)]/2\}}$ and $a_q = (-)^k a_r$. In short,

$$a_k^D = [P(K^{q+1}, \tilde{\mathcal{H}})]_k^D + \delta \mu_{k+1}^D + \mathrm{d}\bar{n}_k^{D-1}$$

for some invariant μ_{k+1}^D, and some polynomial P of strictly positive order in K^{q+1} and $\tilde{\mathcal{H}}$.

We must still prove that $\bar{n}_k^{D-1}$ can be taken invariant.

Acting with γ on the last equation yields $\mathrm{d}(\gamma \bar{n}_k^{D-1}) = 0$. By the Poincaré lemma, $\gamma \bar{n}_k^{D-1} = \mathrm{d}(r_k^{D-2})$. Furthermore, a well-known result on $H(\gamma|\mathrm{d})$ for positive antighost number k (see e.g., Appendix A.1 of Ref. 17) states that one can redefine $\bar{n}_k^{D-1}$ in such a way that $\gamma \bar{n}_k^{D-1} = 0$. As the pure ghost number of $\bar{n}_k^{D-1}$ vanishes, the last equation implies that $\bar{n}_k^{D-1}$ is an invariant polynomial.

This completes the proof of Theorem 7.2 for $k \geqslant q$. □

(Received 30 June 2004; accepted 30 September 2004; published online 5 January 2005)

We investigate the critical behavior of the N-component Euclidean $\lambda\phi^4$ model, in the large N limit, in three situations: confined between two parallel planes a distance L apart from one another; confined to an infinitely long cylinder having a square transversal section of area L^2; and to a cubic box of volume L^3. Taking the mass term in the form $m_0^2=\alpha(T-T_0)$, we retrieve Ginzburg–Landau models which are supposed to describe samples of a material undergoing a phase transition, respectively, in the form of a film, a wire and of a grain, whose bulk transition temperature (T_0) is known. We obtain equations for the critical temperature as functions of L and of T_0, and determine the limiting sizes sustaining the transition. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1828589]

I. INTRODUCTION

Models with fields confined in spatial dimensions play important roles both in field theory and in quantum mechanics. Relevant examples are the Casimir effect and superconducting films, where confinement is carried on by appropriate boundary conditions. For Euclidean field theories, imaginary time and the spatial coordinates are treated exactly on the same footing, so that an extended Matsubara formalism can be applied for dealing with the breaking of invariance along any one of the spatial directions.

Relying on this fact, in the present work we discuss the critical behavior of the Euclidean $\lambda\varphi^4$ model compactified in one, two, and three spatial dimensions. We implement the spontaneous symmetry breaking by taking the bare mass coefficient in the Lagrangian parametrized as $m_0^2=\alpha(T-T_0)$, with $\alpha>0$ and the parameter T varying in an interval containing T_0. With this choice, considering the system confined between two parallel planes a distance L apart from one another, in an infinitely long square cylinder with transversal section area $A=L^2$, and in a cube of volume $V=L^3$, in dimension $D=3$, we obtain Ginzburg–Landau models describing phase transitions in samples of a material in the form of a film, a wire and a grain, respectively, T_0 standing for the bulk transition temperature. Such descriptions apply to physical circumstances where no gauge fluctuations need to be considered.

We start recapitulating the general procedure developed in Ref. 1 to treat the massive $(\lambda\varphi^4)_D$ theory in Euclidean space, compactified in a d-dimensional subspace, with $d\leqslant D$. This permits to extend to an arbitrary subspace some results in the literature for finite temperature field theory[2] and for the behavior of field theories in the presence of spatial boundaries.[3,4] We shall consider the vector N-component $(\lambda\varphi^4)_D$ Euclidean theory at leading order in $1/N$, thus allowing for nonper-

turbative results, the system being submitted to the constraint of compactification of a d-dimensional subspace. After describing the general formalism, we readdress the renormalization procedure we use treating the simpler situation of $d=1$, which corresponds to the system confined between parallel planes (a film), analyzed in Ref. 5 for the case of two components, $N=2$. We then focus on two other particularly interesting cases of $d=2$ and $d=3$, in the three-dimensional Euclidean space, corresponding, respectively, to the system confined to an infinitely long cylinder with square transversal section (a wire) and to a finite cubic box (a grain). Extending the investigation to these new cases demands further developments in the subject of multidimensional Epstein functions.

For these situations, in the framework of the Ginzburg–Landau model we derive equations for the critical temperature as a function of the confining dimensions. For a film, we show that the critical temperature decreases linearly with the inverse of the film thickness while, for a square wire and for a cubic grain, we obtain that the critical temperatures decrease linearly with the inverse of the side of the square and with the inverse of the edge of the cube, respectively, but with larger coefficients. In all cases, we are able to calculate the minimal system size (thickness, transversal section area, or volume) below which the phase transition does not take place.

II. THE COMPACTFIED MODEL

In this section we review the analytical methods of compactification of the N-component Euclidean $\lambda\varphi^4$ model developed in Ref. 1 We consider the model described by the Hamiltonian density,

$$\mathcal{H}=\frac{1}{2}\partial_\mu\varphi_a\partial^\mu\varphi_a+\frac{1}{2}\overline{m}_0^2\varphi_a\varphi_a+\frac{\lambda}{N}(\varphi_a\varphi_a)^2, \tag{1}$$

in Euclidean D-dimensional space, confined to a d-dimensional spatial rectangular box of sides L_j, $j=1,2,\ldots,d$. In the above equation λ is the *renormalized* coupling constant, $\overline{m}_0^2$ is a boundary-modified mass parameter depending on $\{L_i\}$ $i=1,2,\ldots,d$, in such a way that

$$\lim_{\{L_i\}\to\infty}\overline{m}_0^2(L_1,\ldots,L_d)=m_0^2(T)\equiv\alpha(T-T_0), \tag{2}$$

$m_0^2(T)$ being the constant mass parameter present in the usual free-space Ginzburg–Landau model. In Eq. (2), T_0 represents the bulk transition temperature. Summation over repeated "color" indices a is assumed. To simplify the notation in the following we drop out the color indices, summation over them being understood in field products. We will work in the approximation of neglecting boundary corrections to the coupling constant. A precise definition of the boundary-modified mass parameter will be given later for the situation of $D=3$ with $d=1$, $d=2$, and $d=3$, corresponding, respectively, to a film of thickness L_1, to a wire of rectangular section $L_1\times L_2$ and to a grain of volume $L_1\times L_2\times L_3$.

We use Cartesian coordinates $\mathbf{r}=(x_1,\ldots,x_d,\mathbf{z})$, where $\mathbf{z}$ is a $(D-d)$-dimensional vector, with corresponding momentum $\mathbf{k}=(k_1,\ldots,k_d,\mathbf{q})$, $\mathbf{q}$ being a $(D-d)$-dimensional vector in momentum space. Then the generating functional of correlation functions has the form

$$\mathcal{Z}=\int\mathcal{D}\varphi^\dagger\,\mathcal{D}\varphi\exp\left(-\int_0^{\mathbf{L}}\mathrm{d}^dr\int\mathrm{d}^{D-d}\mathbf{z}\,\mathcal{H}(\varphi,\nabla\varphi)\right), \tag{3}$$

where $\mathbf{L}=(L_1,\ldots,L_d)$, and we are allowed to introduce a generalized Matsubara prescription, performing the following multiple replacements (compactification of a d-dimensional subspace):

$$\int \frac{\mathrm{d}k_i}{2\pi} \to \frac{1}{L_i} \sum_{n_i=-\infty}^{+\infty}, \quad k_i \to \frac{2n_i\pi}{L_i}, \quad i = 1,2,\ldots,d. \tag{4}$$

A simpler situation is the system confined simultaneously between two parallel planes a distance L_1 apart from one another normal to the x_1 axis and two other parallel planes, normal to the x_2 axis separated by a distance L_2 (a "wire" of rectangular section).

We start from the well-known expression for the one-loop contribution to the zero-temperature effective potential,[6]

$$U_1(\varphi_0) = \sum_{s=1}^{\infty} \frac{(-1)^{s+1}}{2s} [12\lambda\varphi_0^2]^s \int \frac{\mathrm{d}^D k}{(2\pi)^D} \frac{1}{(k^2+m^2)^s}, \tag{5}$$

where m is the physical mass and φ_0 is the normalized vacuum expectation value of the field (the classical field). In the following, to deal with dimensionless quantities in the regularization procedures, we introduce parameters

$$c = \frac{m}{2\pi\mu}, \quad b_i = \frac{1}{L_i\mu}, \quad g = \frac{\lambda}{4\pi^2\mu^{4-D}}, \quad \phi_0^2 = \frac{\varphi_0^2}{\mu^{D-2}}, \tag{6}$$

where μ is a mass scale. In terms of these parameters and performing the replacements (4), the one-loop contribution to the effective potential can be written in the form

$$U_1(\phi_0, b_1, \ldots, b_d) = \mu^D b_1 \cdots b_d \sum_{s=1}^{\infty} \frac{(-1)^s}{2s} [12g\phi_0^2]^s \sum_{n_1,\ldots,n_d=-\infty}^{+\infty} \int \frac{\mathrm{d}^{D-d} q'}{(b_1^2 n_1^2 + \cdots + b_d^2 n_d^2 + c^2 + \mathbf{q}'^2)^s}, \tag{7}$$

where $\mathbf{q}' = \mathbf{q}/2\pi\mu$ is dimensionless. Using a well-known dimensional regularization formula[7] to perform the integration over the $(D-d)$ noncompactified momentum variables, we obtain

$$U_1(\phi_0, b_1, \ldots, b_d) = \mu^D b_1 \cdots b_d \sum_{s=1}^{\infty} f(D,d,s) [12g\phi_0^2]^s A_d^{c^2}\left(s - \frac{D-d}{2}; b_1, \ldots, b_d\right), \tag{8}$$

where

$$f(D,d,s) = \pi^{(D-d)/2} \frac{(-1)^{s+1}}{2s\Gamma(s)} \Gamma\left(s - \frac{D-d}{2}\right) \tag{9}$$

and

$$\begin{aligned} A_d^{c^2}(\nu; b_1, \ldots, b_d) &= \sum_{n_1,\ldots,n_d=-\infty}^{+\infty} (b_1^2 n_1^2 + \cdots + b_d^2 n_d^2 + c^2)^{-\nu} \\ &= \frac{1}{c^{2\nu}} + 2\sum_{i=1}^{d} \sum_{n_i=1}^{\infty} (b_i^2 n_i^2 + c^2)^{-\nu} \\ &\quad + 2^2 \sum_{i<j=1}^{d} \sum_{n_i,n_j=1}^{\infty} (b_i^2 n_i^2 + b_j^2 n_j^2 + c^2)^{-\nu} + \cdots \\ &\quad + 2^d \sum_{n_1,\ldots,n_d=1}^{\infty} (b_1^2 n_1^2 + \cdots + b_d^2 n_d^2 + c^2)^{-\nu}. \end{aligned} \tag{10}$$

Next we can proceed generalizing to several dimensions the mode-sum regularization prescription described in Ref. 8. This generalization has been done in Ref. 1 and we briefly describe here its principal steps. From the identity

$$\frac{1}{\Delta^{\nu}} = \frac{1}{\Gamma(\nu)} \int_0^{\infty} \mathrm{d}t\, t^{\nu-1} e^{-\Delta t}, \tag{11}$$

and using the following representation for Bessel functions of the third kind, K_{ν},

$$2(a/b)^{\nu/2} K_{\nu}(2\sqrt{ab}) = \int_0^{\infty} \mathrm{d}x\, x^{\nu-1} e^{-(a/x)-bx}, \tag{12}$$

we obtain after some rather long but straightforward manipulations,[1]

$$\begin{aligned} A_d^{c^2}(\nu; b_1, \ldots, b_d) = \frac{2^{\nu-(d/2)+1}\pi^{2\nu-(d/2)}}{b_1 \cdots b_d \Gamma(\nu)} \Bigg[& 2^{\nu-(d/2)-1}\Gamma\left(\nu - \frac{d}{2}\right)(2\pi c)^{d-2\nu} \\ & + 2\sum_{i=1}^{d}\sum_{n_i=1}^{\infty} \left(\frac{n_i}{2\pi c b_i}\right)^{\nu-(d/2)} K_{\nu-(d/2)}\left(\frac{2\pi c n_i}{b_i}\right) + \cdots \\ & + 2^d \sum_{n_1,\ldots,n_d=1}^{\infty} \left(\frac{1}{2\pi c}\sqrt{\frac{n_1^2}{b_1^2} + \cdots + \frac{n_d^2}{b_d^2}}\right)^{\nu-(d/2)} K_{\nu-(d/2)}\left(2\pi c \sqrt{\frac{n_1^2}{b_1^2} + \cdots + \frac{n_d^2}{b_d^2}}\right) \Bigg]. \end{aligned} \tag{13}$$

Taking $\nu = s - (D-d)/2$ in Eq. (13) and inserting it in Eq. (8), we obtain the one-loop correction to the effective potential in D dimensions with a compactified d-dimensional subspace in the form (recovering the dimensionful parameters)

$$\begin{aligned} U_1(\varphi_0, L_1, \ldots, L_d) = \sum_{s=1}^{\infty} [12 g \phi_0^2]^s h(D,s) \Bigg[& 2^{s-(D/2)-2}\Gamma\left(s - \frac{D}{2}\right) m^{D-2s} \\ & + \sum_{i=1}^{d}\sum_{n_i=1}^{\infty} \left(\frac{m}{L_i n_i}\right)^{(D/2)-s} K_{(D/2)-s}(m L_i n_i) \\ & + 2\sum_{i<j=1}^{d}\sum_{n_i,n_j=1}^{\infty} \left(\frac{m}{\sqrt{L_i^2 n_i^2 + L_j^2 n_j^2}}\right)^{(D/2)-s} K_{(D/2)-s}(m\sqrt{L_i^2 n_i^2 + L_j^2 n_j^2}) + \cdots \\ & + 2^{d-1} \sum_{n_1,\ldots,n_d=1}^{\infty} \left(\frac{m}{\sqrt{L_1^2 n_1^2 + \cdots + L_d^2 n_d^2}}\right)^{(D/2)-s} K_{(D/2)-s}(m\sqrt{L_1^2 n_1^2 + \cdots + L_d^2 n_d^2}) \Bigg], \end{aligned} \tag{14}$$

with

$$h(D,s) = \frac{1}{2^{D/2+s-1}\pi^{D/2}} \frac{(-1)^{s+1}}{s\Gamma(s)}. \tag{15}$$

Criticality is attained when the inverse squared correlation length, $\xi^{-2}(L_1, \ldots, L_d, \varphi_0)$, vanishes in the large-$N$ gap equation,

$$\xi^{-2}(L_1,\ldots,L_d,\varphi_0)=\overline{m}_0^2+12\lambda\varphi_0^2+\frac{24\lambda}{L_1\cdots L_d}\sum_{n_1,\ldots,n_d=-\infty}^{\infty}\int\frac{\mathrm{d}^{D-d}q}{(2\pi)^{D-d}}\times\frac{1}{\mathbf{q}^2+\left(\frac{2\pi n_1}{L_1}\right)^2+\cdots+\left(\frac{2\pi n_d}{L_d}\right)^2+\xi^{-2}(L_1,\ldots,L_d,\varphi_0)},\tag{16}$$

where φ_0 is the normalized vacuum expectation value of the field (different from zero in the ordered phase). In the disordered phase, φ_0 vanishes and the inverse correlation length equals the physical mass, given below by Eq. (18). Recalling the condition,

$$\left.\frac{\partial^2}{\partial\varphi_0^2}U(D,L_1,L_2)\right|_{\varphi_0=0}=m^2,\tag{17}$$

where U is the sum of the tree-level and one-loop contributions to the effective potential (remembering that at the large-N limit it is enough to take the one-loop contribution to the mass), we obtain

$$\begin{aligned}m^2(L_1,\ldots,L_d)=\overline{m}_0^2(L_1,\ldots,L_d)+\frac{24\lambda}{(2\pi)^{D/2}}\Bigg[&\sum_{i=1}^{d}\sum_{n_i=1}^{\infty}\left(\frac{m}{L_in_i}\right)^{(D/2)-1}K_{(D/2)-1}(mL_in_i)\\&+2\sum_{i<j=1}^{d}\sum_{n_i,n_j=1}^{\infty}\left(\frac{m}{\sqrt{L_i^2n_i^2+L_j^2n_j^2}}\right)^{(D/2)-1}K_{(D/2)-1}(m\sqrt{L_i^2n_i^2+L_j^2n_j^2})+\cdots\\&+2^{d-1}\sum_{n_1,\ldots,n_d=1}^{\infty}\left(\frac{m}{\sqrt{L_1^2n_1^2+\cdots+L_d^2n_d^2}}\right)^{(D/2)-1}K_{(D/2)-1}(m\sqrt{L_1^2n_1^2+\cdots+L_d^2n_d^2})\Bigg].\end{aligned}\tag{18}$$

Notice that, in writing Eq. (18), we have suppressed the parcel $2^{-(D/2)-1}\Gamma[1-(D/2)]m^{D-2}$ from its square brackets, the parcel that emerges from the first term in the square bracket of Eq. (14). This expression, which does not depend explicitly on L_i, diverges for D even due to the poles of the gamma function; in this case, this parcel is subtracted to get a renormalized mass equation. For D odd, $\Gamma[1-(D/2)]$ is finite but we also subtract this term (corresponding to a finite renormalization) for sake of uniformity; besides, for $D\geqslant 3$, the factor m^{D-2} does not contribute in the criticality.

The vanishing of Eq. (18) defines criticality for our compactified system. We claim that, taking $d=1$, $d=2$, and $d=3$ with $D=3$, we are able to describe, respectively, the critical behavior of samples of materials in the form of films, wires, and grains. Notice that the parameter m on the right-hand side of Eq. (18) is the boundary-modified mass $m(L_1,\ldots,L_d)$, which means that Eq. (18) is a self-consistency equation, a very complicated modified Schwinger–Dyson equation for the mass, not soluble by algebraic means. Nevertheless, as we will see in the next sections, a solution is possible at criticality, which allows us to obtain a closed formula for the boundary-dependent critical temperature.

III. CRITICAL BEHAVIOR FOR FILMS

We now consider the simplest particular case of the compactification of only one spatial dimension, with the system confined between two parallel planes a distance L apart from one another. This case, which has already been considered in Ref. 5 concerning with the two-component model, is reanalyzed here to set the required renormalization procedure in the proper large-N grounds and, also, for the sake of completeness. Thus, from Eq. (18), taking $d=1$, we get in the disordered phase

$$m^2(L) = \overline{m}_0^2(L) + \frac{24\lambda}{(2\pi)^{D/2}} \sum_{n=1}^{\infty} \left(\frac{m}{nL}\right)^{(D/2)-1} K_{(D/2)-1}(nLm), \tag{19}$$

where L $(=L_1)$ is the separation between the planes, the film thickness. If we limit ourselves to the neighborhood of criticality $(m^2 \approx 0)$ and consider L finite and sufficiently small, we may use an asymptotic formula for small values of the argument of Bessel functions,

$$K_\nu(z) \approx \frac{1}{2}\Gamma(|\nu|)\left(\frac{z}{2}\right)^{-|\nu|} \quad (z \approx 0), \tag{20}$$

and Eq. (19) reduces, for $D>3$, to

$$m^2(L) \approx \overline{m}_0^2(L) + \frac{6\lambda}{\pi^{D/2} L^{D-2}} \Gamma\left(\frac{D}{2} - 1\right) \zeta(D-2), \tag{21}$$

where $\zeta(D-2)$ is the Riemann *zeta*-function, defined for $\mathrm{Re}\{D-2\}>1$ by the series

$$\zeta(D-2) = \sum_{n=1}^{\infty} \frac{1}{n^{D-2}}. \tag{22}$$

It is worth mentioning that for $D=4$, taking $m^2(L)=0$ and making the appropriate changes $(L \to \beta, \lambda \to \lambda/4!)$, Eq. (21) is *formally identical* to the high-temperature (low values of β) critical equation obtained in Ref. 9, thus providing a check of our calculations.

For $D=3$, Eq. (21) can be made physically meaningful by a regularization procedure as follows. We consider the analytic continuation of the *zeta*-function, leading to a meromorphic function having only one simple pole at $z=1$, which satisfies the reflection formula

$$\zeta(z) = \frac{1}{\Gamma(z/2)} \Gamma\left(\frac{1-z}{2}\right) \pi^{z-1/2} \zeta(1-z). \tag{23}$$

Next, remembering the formula

$$\lim_{z \to 1} \left[\zeta(z) - \frac{1}{z-1} \right] = \gamma, \tag{24}$$

where $\gamma \approx 0.5772$ is the Euler–Mascheroni constant, we define the L-dependent bare mass for $D \approx 3$, in such a way that the pole at $D=3$ in Eq. (21) is suppressed, that is we take

$$\overline{m}_0^2(L) \approx M - \frac{1}{(D-3)} \frac{6\lambda}{\pi L}, \tag{25}$$

where M is independent of D. To fix the finite term, we make the simplest choice satisfying (2),

$$M = m_0^2(T) = \alpha(T - T_0), \tag{26}$$

T_0 being the bulk critical temperature. In this case, using Eq. (25) in Eq. (21) and taking the limit as $D \to 3$, the L-dependent renormalized mass term in the vicinity of criticality becomes

$$m^2(L) \approx \alpha(T - T_c(L)), \tag{27}$$

where the modified, L-dependent, transition temperature is given by

$$T_c(L) = T_0 - C_1 \frac{\lambda}{\alpha L}, \tag{28}$$

L being the thickness of the film, with the constant C_1 given by

$$C_1 = \frac{6\gamma}{\pi} \approx 1.1024. \tag{29}$$

From this equation, we see that for L smaller than

$$L_{\min} = C_1 \frac{\lambda}{\alpha T_0}, \tag{30}$$

$T_c(L)$ becomes negative, meaning that the transition does not occur.[5]

IV. CRITICAL BEHAVIOR FOR WIRES

We now focus on the situation where two spatial dimensions are compactified. From Eq. (18), taking $d=2$, we get (in the disordered phase)

$$\begin{aligned} m^2(L_1,L_2) = \overline{m}_0^2(L_1,L_2) + \frac{24\lambda}{(2\pi)^{D/2}}\Bigg[& \sum_{n=1}^{\infty}\left(\frac{m}{nL_1}\right)^{(D/2)-1} K_{(D/2)-1}(nL_1 m) \\ & + \sum_{n=1}^{\infty}\left(\frac{m}{nL_2}\right)^{(D/2)-1} K_{(D/2)-1}(nL_2 m) \\ & + 2\sum_{n_1,n_2=1}^{\infty}\left(\frac{m}{\sqrt{L_1^2 n_1^2 + L_2^2 n_2^2}}\right)^{(D/2)-1} K_{(D/2)-1}(m\sqrt{L_1^2 n_1^2 + L_2^2 n_2^2})\Bigg]. \end{aligned} \tag{31}$$

If we limit ourselves to the neighborhood of criticality, $m^2 \approx 0$, and taking both L_1 and L_2 finite and sufficiently small, we may use Eq. (20) to rewrite Eq. (31) as

$$m^2(L_1,L_2) \approx \overline{m}_0^2(L_1,L_2) + \frac{6\lambda}{\pi^{D/2}}\Gamma\left(\frac{D}{2}-1\right)\left[\left(\frac{1}{L_1^{D-2}} + \frac{1}{L_2^{D-2}}\right)\zeta(D-2) + 2E_2\left(\frac{D-2}{2};L_1,L_2\right)\right], \tag{32}$$

where $E_2[(D-2)/2;L_1,L_2]$ is the generalized (multidimensional) Epstein *zeta*-function defined by

$$E_2\left(\frac{D-2}{2};L_1,L_2\right) = \sum_{n_1,n_2=1}^{\infty}[L_1^2 n_1^2 + L_2^2 n_2^2]^{-[(D-2)/2]}, \tag{33}$$

for $\mathrm{Re}\{D\} > 3$.

As mentioned before, the Riemann *zeta*-function $\zeta(D-2)$ has an analytical extension to the whole complex D-plane, having a unique simple pole (of residue 1) at $D=3$. One can also construct analytical continuations (and recurrence relations) for the multidimensional Epstein functions which permit to write them in terms of Kelvin and Riemann *zeta*-functions. To start one considers the analytical continuation of the Epstein–Hurwitz *zeta*-function given by[8]

$$\sum_{n=1}^{\infty}(n^2+p^2)^{-\nu} = -\frac{1}{2}p^{-2\nu} + \frac{\sqrt{\pi}}{2p^{2\nu-1}\Gamma(\nu)}\left[\Gamma\left(\nu-\frac{1}{2}\right) + 4\sum_{n=1}^{\infty}(\pi p n)^{\nu-1/2}K_{\nu-1/2}(2\pi p n)\right]. \tag{34}$$

Using this relation to perform one of the sums in (33) leads immediately to the question of which sum is first evaluated. As it is done in Ref. 10, whatever the sum one chooses to perform first, the manifest $L_1 \leftrightarrow L_2$ symmetry of Eq. (33) is lost; to overcome such an obstacle, in order to preserve this symmetry, we adopt here a symmetrized summation generalizing the prescription introduced in Ref. 1 for the case of many variables.

To derive an analytical continuation and symmetrized recurrence relations for the multidimensional Epstein functions, we start by taking these functions defined as the symmetrized summations

$$E_d(\nu;L_1,\ldots,L_d)=\frac{1}{d!}\sum_{\sigma}\sum_{n_1=1}^{\infty}\cdots\sum_{n_d=1}^{\infty}[\sigma_1^2n_1^2+\cdots+\sigma_d^2n_d^2]^{-\nu}, \tag{35}$$

where $\sigma_i=\sigma(L_i)$, with σ running in the set of all permutations of the parameters $L_1,\ldots,L_d$, and the summations over $n_1,\ldots,n_d$ being taken in the given order. Applying (34) to perform the sum over n_d, one gets

$$E_d(\nu;L_1,\ldots,L_d)=-\frac{1}{2d}\sum_{i=1}^{d}E_{d-1}(\nu;\ldots,\widehat{L_i},\ldots)+\frac{\sqrt{\pi}}{2\,\mathrm{d}\Gamma(\nu)}\Gamma\left(\nu-\frac{1}{2}\right)\sum_{i=1}^{d}\frac{1}{L_i}E_{d-1}\left(\nu-\frac{1}{2};\ldots,\widehat{L_i},\ldots\right)$$
$$+\frac{2\sqrt{\pi}}{\mathrm{d}\Gamma(\nu)}W_d\left(\nu-\frac{1}{2},L_1,\ldots,L_d\right), \tag{36}$$

where the hat over the parameter L_i in the functions E_{d-1} means that it is excluded from the set $\{L_1,\ldots,L_d\}$ (the others being the $d-1$ parameters of E_{d-1}), and

$$W_d(\eta;L_1,\ldots,L_d)=\sum_{i=1}^{d}\frac{1}{L_i}\sum_{n_1,\ldots,n_d=1}^{\infty}\left(\frac{\pi n_i}{L_i\sqrt{(\cdots+\widehat{L_i^2n_i^2}+\cdots)}}\right)^{\eta}K_{\eta}\left(\frac{2\pi n_i}{L_i}\sqrt{(\cdots+\widehat{L_i^2n_i^2}+\cdots)}\right), \tag{37}$$

with $(\cdots+\widehat{L_i^2n_i^2}+\cdots)$ representing the sum $\Sigma_{j=1}^{d}L_j^2n_j^2-L_i^2n_i^2$. In particular, noticing that $E_1(\nu;L_j)=L_j^{-2\nu}\zeta(2\nu)$, one finds

$$E_2\left(\frac{D-2}{2};L_1^2,L_2^2\right)=-\frac{1}{4}\left(\frac{1}{L_1^{D-2}}+\frac{1}{L_2^{D-2}}\right)\zeta(D-2)+\frac{\sqrt{\pi}\Gamma\left(\frac{D-3}{2}\right)}{4\Gamma\left(\frac{D-2}{2}\right)}\left(\frac{1}{L_1L_2^{D-3}}+\frac{1}{L_1^{D-3}L_2}\right)\zeta(D-3)$$
$$+\frac{\sqrt{\pi}}{\Gamma\left(\frac{D-2}{2}\right)}W_2\left(\frac{D-3}{2};L_1,L_2\right), \tag{38}$$

which is a meromorphic function of D, symmetric in the parameters L_1 and L_2 as Eq. (33) suggests.

Using the above expression, Eq. (32) can be rewritten as

$$m^2(L_1,L_2)\approx\overline{m}_0^2(L_1,L_2)+\frac{3\lambda}{\pi^{D/2}}\left[\left(\frac{1}{L_1^{D-2}}+\frac{1}{L_2^{D-2}}\right)\Gamma\left(\frac{D-2}{2}\right)\zeta(D-2)\right.$$
$$\left.+\sqrt{\pi}\left(\frac{1}{L_1L_2^{D-3}}+\frac{1}{L_1^{D-3}L_2}\right)\Gamma\left(\frac{D-3}{2}\right)\zeta(D-3)+2\sqrt{\pi}W_2\left(\frac{D-3}{2};L_1,L_2\right)\right]. \tag{39}$$

This equation presents no problems for $3<D<4$ but, for $D=3$, the first and second terms between the square brackets of Eq. (39) are divergent due to the ζ-function and Γ-function, respectively. We can deal with divergences remembering the property in Eq. (24) and using the expansion of $\Gamma[(D-3)/2]$ around $D=3$,

$$\Gamma\left(\frac{D-3}{2}\right)\approx\frac{2}{D-3}+\Gamma'(1), \tag{40}$$

$\Gamma'(z)$ standing for the derivative of the Γ-function with respect to z. For $z=1$ it coincides with the Euler digamma-function $\psi(1)$, which has the particular value $\psi(1)=-\gamma$. We notice however, that differently from the case treated in the preceding section, where a renormalization procedure was

needed, here the two divergent terms generated by the use of formulas (24) and (40) cancel exactly between them. No renormalization is needed. Thus, for $D=3$, taking the bare mass given by $\overline{m}_0^2(L_1,L_2)=\alpha(T-T_0)$, we obtain the renormalized boundary-dependent mass term in the form

$$m^2(L_1,L_2) \approx \alpha(T - T_c(L_1,L_2)), \tag{41}$$

with the boundary-dependent critical temperature given by

$$T_c(L_1,L_2) = T_0 - \frac{9\lambda\gamma}{2\pi\alpha}\left(\frac{1}{L_1}+\frac{1}{L_2}\right) - \frac{6\lambda}{\pi\alpha}W_2(0;L_1,L_2), \tag{42}$$

where

$$W_2(0;L_1,L_2) = \sum_{n_1,n_2=1}^{\infty}\left\{\frac{1}{L_1}K_0\left(2\pi\frac{L_2}{L_1}n_1n_2\right)+\frac{1}{L_2}K_0\left(2\pi\frac{L_1}{L_2}n_1n_2\right)\right\}. \tag{43}$$

The quantity $W_2(0;L_1,L_2)$, appearing in Eq. (42), involves complicated double sums, very difficult to handle for $L_1\neq L_2$; in particular, it is not possible to take limits such as $L_i\to\infty$. For this reason we will restrict ourselves to the case $L_1=L_2$. For a wire with the square transversal section, we have $L_1=L_2=L=\sqrt{A}$ and Eq. (42) reduces to

$$T_c(A) = T_0 - C_2\frac{\lambda}{\alpha\sqrt{A}}, \tag{44}$$

where C_2 is a constant given by

$$C_2 = \frac{9\gamma}{\pi}+\frac{12}{\pi}\sum_{n_1,n_2=1}^{\infty}K_0(2\pi n_1n_2) \approx 1.6571. \tag{45}$$

We see that the critical temperature of the square wire depends on the bulk critical temperature and the Ginzburg–Landau parameters α and λ (which are characteristics of the material constituting the wire), and also on the area of its cross section. Since T_c decreases linearly with the inverse of the side of the square, this suggests that there is a minimal area for which $T_c(A_{\min})=0$,

$$A_{\min} = \left(C_2\frac{\lambda}{\alpha T_0}\right)^2; \tag{46}$$

for square wires of the transversal section areas smaller than this value, in the context of our model the transition should be suppressed. On topological grounds, we expect that (apart from appropriate coefficients) our result should be independent of the transverse section shape of the wire, at least for transversal sectional regular polygons.

V. CRITICAL BEHAVIOR FOR GRAINS

We now turn our attention to the case where all three spatial dimensions are compactified, corresponding to the system confined in a box of sides L_1,L_2,L_3. Taking $d=3$ in Eq. (18) and using Eq. (20), we obtain (for sufficiently small L_1,L_2,L_3 and in the neighborhood of classicality, $m^2\approx 0$)

$$m^2(L_1,L_2,L_3) \approx \overline{m}_0^2(L_1,L_2,L_3) + \frac{6\lambda}{\pi^{D/2}}\Gamma\left(\frac{D-2}{2}\right)\left[\sum_{i=1}^{3}\frac{\zeta(D-2)}{L_i^{D-2}} + 2\sum_{i<j=1}^{3}E_2\left(\frac{D-2}{2};L_i,L_j\right) + 4E_3\left(\frac{D-2}{2};L_1,L_2,L_3\right)\right], \tag{47}$$

where $E_3(\nu;L_1,L_2,L_3)=\Sigma_{n_1,n_2,n_3=1}^{\infty}[L_1^2n_1^2+L_2^2n_2^2+L_3^2n_3^2]^{-\nu}$ and the functions E_2 are given by Eq. (38).

The analytical structure of the function $E_3[(D-2)/2;L_1,L_2,L_3]$ can be obtained from the general symmetrized recurrence relation given by Eqs. (36) and (37); explicitly, one has

$$E_3\left(\frac{D-2}{2};L_1,L_2,L_3\right) = -\frac{1}{6}\sum_{i<j=1}^{3}E_2\left(\frac{D-2}{2};L_i,L_j\right) + \frac{\sqrt{\pi}\Gamma\left(\frac{D-3}{2}\right)}{6\Gamma\left(\frac{D-2}{2}\right)}\sum_{i,j,k=1}^{3}\frac{(1+\varepsilon_{ijk})}{2}\frac{1}{L_i} \times E_2\left(\frac{D-2}{2};L_j,L_k\right) + \frac{2\sqrt{\pi}}{3\Gamma\left(\frac{D-2}{2}\right)}W_3\left(\frac{D-3}{2};L_1,L_2,L_3\right), \tag{48}$$

where ε_{ijk} is the totally antisymmetric symbol and the function W_3 is a particular case of Eq. (37). Using Eqs. (38) and (48), the boundary dependent mass can be written as

$$m^2(L_1,L_2,L_3) \approx \overline{m}_0^2(L_1,L_2,L_3) + \frac{6\lambda}{\pi^{D/2}}\left[\frac{1}{3}\Gamma\left(\frac{D-2}{2}\right)\sum_{i=1}^{3}\frac{1}{L_i^{D-2}}\zeta(D-2) + \frac{\sqrt{\pi}}{6}\zeta(D-3) \times \sum_{i<j=1}^{3}\left(\frac{1}{L_i^{D-3}L_j}+\frac{1}{L_j^{D-3}L_i}\right)\Gamma\left(\frac{D-3}{2}\right) + \frac{4\sqrt{\pi}}{3}\sum_{i<j=1}^{3}W_2\left(\frac{D-3}{2};L_i,L_j\right) + \frac{\pi}{6}\zeta(D-4)\Gamma\left(\frac{D-4}{2}\right)\sum_{i,j,k=1}^{3}\frac{(1+\varepsilon_{ijk})}{2}\frac{1}{L_i}\left(\frac{1}{L_j^{D-4}L_k}+\frac{1}{L_k^{D-4}L_j}\right) + \frac{2\pi}{3}\sum_{i,j,k=1}^{3}\frac{(1+\varepsilon_{ijk})}{2}\frac{1}{L_i}W_2\left(\frac{D-4}{2};L_j,L_k\right) + \frac{8\sqrt{\pi}}{3}W_3\left(\frac{D-3}{2};L_1,L_2,L_3\right)\right]. \tag{49}$$

The first two terms in the square brackets of Eq. (49) diverge as $D\to 3$ due to the poles of the Γ and ζ-functions. However, as it happens in the case of wires, using Eqs. (24) and (40) it can be shown that these divergences cancel exactly one another. After some simplifications, for $D=3$, the boundary dependent mass (49) becomes

$$m^2(L_1,L_2,L_3) \approx \overline{m}_0^2(L_1,L_2,L_3) + \frac{6\lambda}{\pi}\left[\frac{\gamma}{2}\sum_{i=1}^{3}\frac{1}{L_i} + \frac{4}{3}\sum_{i<j=1}^{3}W_2(0;L_i,L_j) + \frac{\pi}{18}\sum_{i,j,k=1}^{3}\frac{(1+\varepsilon_{ijk})}{2}\frac{L_i}{L_jL_k} + \frac{2\sqrt{\pi}}{3}\sum_{i,j,k=1}^{3}\frac{(1+\varepsilon_{ijk})}{2}\frac{1}{L_i}W_2\left(-\frac{1}{2};L_j,L_k\right) + \frac{8}{3}W_3(0;L_1,L_2,L_3)\right]. \tag{50}$$

As before, since no divergences need to be suppressed, we can take the bare mass given by $\overline{m}_0^2(L_1,L_2,L_3)=\alpha(T-T_0)$ and rewrite the renormalized mass as $m^2(L_1,L_2,L_3)\approx\alpha(T-T_c(L_1,L_2,L_3))$. The expression of $T_c(L_1,L_2,L_3)$ can be easily obtained from Eq. (50), but it is a very complicated formula, involving multiple sums, which makes almost impossible a general

analytical study for arbitrary parameters L_1, L_2, L_3; thus, we restrict ourselves to the situation where $L_1=L_2=L_3=L$, corresponding to a cubic box of volume $V=L^3$. In this case, the boundary dependent critical temperature reduces to

$$T_c(V) = T_0 - C_3 \frac{\lambda}{\alpha V^{1/3}}, \tag{51}$$

where the constant C_3 is given by [using that $K_{-1/2}(z)=\sqrt{\pi/2z}e^{-z}$]

$$C_3 = 1 + \frac{9\gamma}{\pi} + \frac{12}{\pi}\sum_{n_1,n_2=1}^{\infty}\frac{e^{-2\pi n_1 n_2}}{n_1} + \frac{48}{\pi}\sum_{n_1,n_2=1}^{\infty} K_0(2\pi n_1 n_2) + \frac{48}{\pi}\sum_{n_1,n_2,n_3=1}^{\infty} K_0(2\pi n_1\sqrt{n_2^2+n_3^2}) \approx 2.7657. \tag{52}$$

One sees that the minimal volume of the cubic grain sustaining the transition is

$$V_{\min} = \left(C_3 \frac{\lambda}{\alpha T_0}\right)^3. \tag{53}$$

VI. CONCLUSIONS

In this paper we have discussed the spontaneous symmetry breaking of the $(\lambda\phi^4)_D$ theory compactified in $d \leqslant D$ Euclidean dimensions, extending some results of Ref. 1. We have parametrized the bare mass term in the form $m_0^2(T-T_0)$, thus placing the analysis within the Ginzburg–Landau framework. We focused on the situations with $D=3$ and $d=1,2,3$, corresponding (in the context of condensed matter systems) to films, wires, and grains, respectively, undergoing phase transitions which may be described by (mean-field) Ginzburg–Landau models. This generalizes to more compactified dimensions of previous investigations on the superconducting transition in films, both without[5] and in the presence of a magnetic field.[11] In all cases studied here, in the absence of gauge fluctuations, we found that the boundary-dependent critical temperature decreases linearly with the inverse of the linear dimension L: $T_c(L)=T_0-C_d\lambda/\alpha L$, where α and λ are the Ginzgurg–Landau parameters, T_0 is the bulk transition temperature, and C_d is a constant equal to 1.1024, 1.6571, and 2.6757 for $d=1$ (film), $d=2$ (square wire), and $d=3$ (cubic grain), respectively. Such behavior suggests the existence of a minimal size of the system below which the transition is suppressed. It is worth mentioning that having the transition temperature scaling with the inverse of the relevant length L for all the cases analyzed (films, wires, and grains) is in accordance with what one learns from finite-size scaling arguments.[12]

These findings seems to be in *qualitative* agreement with results for the existence of a minimal thickness for disappearance of superconductivity in films.[13–16] Experimental investigations in nanowires searching to establish whether there is a limit to how thin a superconducting wire can be, while retaining its superconducting character, have also drawn the attention of researchers; for example, in Ref. 17 the behavior of nanowires has been studied. Similar questions have also been raised concerning the behavior of superconducting nanograins.[18,19] Nevertheless, an important point to be emphasized is that our results are obtained in a field-theoretical framework and do not depend on microscopic details of the material involved nor account for the influence of manufacturing aspects of the sample; in other words, our results emerge solely as a topological effect of the compactification of the Ginzburg–Landau model in a subspace. Detailed microscopic analysis is required if one attempts to account quantitatively for experimental observations which might deviate from our mean field results.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 012305 (2005)

Uniqueness of the topological multivortex solution in the self-dual Chern–Simons theory

Kwangseok Choe[a)]
Department of Mathematics, Seoul National University, Seoul 151-747, Korea

(Received 7 July 2004; accepted 24 September 2004; published online 5 January 2005)

We establish a uniqueness result for the topological multivortex solution to the self-dual equations of the Abelian relativistic self-dual Chern–Simons–Higgs model. We prove that the topological multivortex solution is unique if the Chern–Simons coupling parameter $\kappa>0$ is sufficiently small. We also establish a uniqueness result for $\kappa>0$ sufficiently large. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1834694]

I. INTRODUCTION

Chern–Simons theories have attracted much attention as they are believed relevant to physical phenomena such as high-temperature superconductivity and anyon physics. In particular, Hong–Kim–Pac[18] and Jackiw–Weinberg[19] proposed an Abelian Chern–Simons–Higgs model whose dynamics is governed only by the Chern–Simons term. This model is given in the $(2+1)$-dimensional Minkowski space with metric $g_{\mu\nu}=\mathrm{diag}(1,-1,-1)$. When a suitable Higgs potential is chosen, this model admits a self-dual structure which enables us to study the static solutions rigorously.

The Lagrangian density[18,19] is given by

$$\mathcal{L}=\frac{\kappa}{4}\varepsilon^{\mu\nu\rho}F_{\mu\nu}A_\rho+g^{\mu\nu}D_\mu\phi\overline{D_\nu\phi}-\frac{1}{\kappa^2}|\phi|^2(1-|\phi|^2)^2,$$

where A_μ $(\mu=0,1,2)$ is a real gauge field on $\mathbb{R}^3$, ϕ is the complex-valued Higgs field, $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$ is the curvature tensor, $D_\mu=\partial_\mu-\sqrt{-1}A_\mu$ is the gauge covariant derivative, $\varepsilon^{\mu\nu\rho}$ is totally skew symmetric tensor with $\varepsilon^{012}=1$, and $\kappa>0$ is the Chern–Simons coupling constant. Hereafter, we let $i=\sqrt{-1}$.

The Euler–Lagrange equations corresponding to $\mathcal{L}$ are given by

$$\begin{aligned}&\frac{\kappa}{2}\varepsilon^{\mu\nu\rho}F_{\mu\nu}=i(\phi\overline{D^\rho\phi}-\overline{\phi}D^\rho\phi),\\&D_\mu D^\mu\phi=-\frac{1}{\kappa^2}(|\phi|^2-1)(3|\phi|^2-1)\phi.\end{aligned}\tag{1.1}$$

We seek the static configuration of (1.1). Then, the $\rho=0$ component of (1.1) yields $\kappa F_{12}=-2A_0|\phi|^2$, which in turn implies that the corresponding static energy density is given by

a)Electronic mail: kschoe@math.snu.ac.kr

$$\mathcal{E} = \frac{\kappa^2 F_{12}^2}{4|\phi|^2} + |D_1\phi|^2 + |D_2\phi|^2 + \frac{1}{\kappa^2}|\phi|^2(1-|\phi|^2)^2$$
$$= \left| \frac{\kappa F_{12}}{2|\phi|} \pm \frac{1}{\kappa}|\phi|(|\phi|^2-1) \right|^2 + |D_1\phi \pm iD_2\phi|^2 \pm F_{12} \mp i\varepsilon^{jk}\partial_j(\bar{\phi}D_k\phi).$$

By taking the conjugate $(\bar{\phi}, -A_\mu)$ of (ϕ, A_μ) if necessary, we may choose the upper sign in the above formula. If $|\phi||D\phi| = o(|x|^{-1})$ as $|x| \to \infty$, then $E = \int_{\mathbb{R}^2} \mathcal{E} dx \geqslant \int_{\mathbb{R}^2} F_{12} dx$, and the minimum is saturated if and only if (ϕ, A_μ) satisfies the following self-dual equations:

$$D_1\phi + iD_2\phi = 0,$$

$$F_{12} + \frac{2}{\kappa^2}|\phi|^2(|\phi|^2-1) = 0, \tag{1.2}$$

$$\kappa F_{12} + 2A_0|\phi|^2 = 0.$$

In order to make the total energy E finite, we impose a suitable boundary condition on ϕ; either $\lim_{|x|\to\infty}|\phi(x)| = 1$ or $\lim_{|x|\to\infty}|\phi(x)| = 0$. The former boundary condition is called topological, the latter one nontopological.

In this paper, we prove that the self-dual equations (1.2) admit a unique topological solution if $\kappa > 0$ is sufficiently small. As (1.2) admits the invariance $A_\mu \to A_\mu + \partial_\mu \eta$ and $\phi \to \phi e^{i\eta}$ for any smooth function $\eta = \eta(x_1, x_2)$, our uniqueness result is established in the sense of equivalence class. (See Main Theorem below.)

It follows from the argument of Jaffe–Taubes[20] that ϕ admits a discrete set of zeros. Then, we can establish existence results for the self-dual equations (1.2) such that ϕ vanishes at any prescribed points $p_1, \ldots, p_m \in \mathbb{R}^2$ with multiplicities $n_1, \ldots, n_m \in \mathbb{Z}_+$, respectively. For this purpose, we follow the argument in Ref. 20 to reduce the self-dual equations (1.2) to a single elliptic equation. Introduce a real-valued function u by

$$\phi = \exp\left[\frac{u}{2} + \sum_{j=1}^{m} i \arg(z - p_j) \right]. \tag{1.3}$$

Then, u satisfies

$$\Delta u = \frac{4}{\kappa^2} e^u (e^u - 1) + 4\pi \sum_{j=1}^{m} n_j \delta_{p_j}, \quad \mathbb{R}^2. \tag{1.4}$$

Once a solution u of (1.4) is found, we can construct a solution (ϕ, A_μ) by (1.3) and

$$A_1 = -\operatorname{Re}(i\partial^* \ln \phi), \quad A_2 = -\operatorname{Im}(i\partial^* \ln \phi) \quad \text{with} \quad \partial^* = \partial_1 + i\partial_2. \tag{1.5}$$

A solution u of (1.4) is topological if $\lim_{|x|\to\infty} u(x) = 0$, and nontopological if $\lim_{|x|\to\infty} u(x) = -\infty$. In both cases, it turns out that $|\phi||D\phi| = o(|x|^{-2})$ as $|x| \to \infty$. In the sequel, we let

$$N = \sum_{j=1}^{m} n_j.$$

Then, it is well known $E = \int_{\mathbb{R}^2} F_{12}\, dx = 2\pi N$ if $u = \ln|\phi|^2$ is topological. However, if u is nontopological, E may take all the values in an interval (see, e.g., Lemma 2.2 below). Moreover, it is also well known that the magnetic flux Φ and electric charge Q are given by $\Phi = \int F_{12}\, dx = E$ and $Q = \kappa \int F_{12}\, dx$, respectively. We refer to the books Refs. 15 and 31 for detailed description of self-dual Chern–Simons theories.

Several existence results are now available for the equation (1.4). The existence result for a topological solution was first established by Wang.[30] Spruck–Yang[28] constructed a topological solution via the iterative method, which is an efficient algorithm for a numerical solution.

For a nontopological solution, Spruck–Yang[27] constructed a radially symmetric solution for the special case $p_1=\cdots=p_m=0$. The result in Ref. 27 was refined by Chen *et al.*[10] and later by Chan *et al.*[8] In Ref. 8, they have established a uniqueness result for radial solutions: If $p_1=\cdots=p_m=0$ and a constant $\beta>2N+4$ is given, (1.4) admits a unique radial solution $u(r)$ such that $u(r)=-\beta \ln r+O(1)$ near ∞. The existence result for the general case where $p_1,\ldots,p_m$ is arbitrary was established by Chae–Imanuvilov.[7] It also turns out in Ref. 7 that if $N>0$, (1.4) admits a one-parameter family of nonradial solutions even if the vortex points p_j's are located at the origin. Hence, we cannot expect the uniqueness of nontopological solutions of (1.4) for $N>0$. It is believed that multiple existence for nontopological solutions depends on the total vortex number N and the location of vortex points p_j. If $N=0$, for instance, it can be proved by the method of moving planes[27] that every nontopological zero-vortex solution is radially symmetric with respect to some point in $\mathbb{R}^2$. If $N>0$, we cannot expect such symmetry any longer. Moreover, Chan *et al.*[8] recently constructed a nontopological solution concentrating at each vortex point $\{p_1,\ldots,p_m\}$ if $\Pi_{j\neq k}|p_j-p_k|$ is independent of k.

Then, it is quite natural to ask if Eq. (1.4) admits a unique topological solution for each $\kappa>0$. The uniqueness of a radial topological solution has been proved in Ref. 10. If $p_1=\cdots=p_m=0$ in (1.4), it has been proved by Han[17] that every topological solution is radially symmetric. Therefore, the uniqueness for the special case $p_1=\cdots=p_m=0$ has been established.

In this paper, we establish uniqueness for a topological solution for $\kappa>0$ sufficiently small.

Theorem 1.1: *Let $p_1,\ldots,p_m\in\mathbb{R}^2$ and $n_1,\ldots,n_m\in\mathbb{Z}_+$ be given. Then, there is a constant $\kappa_0=\kappa_0(p_1,\ldots,p_m,n_1,\ldots,n_m)>0$ such that for $0<\kappa<\kappa_0$, Eq. (1.4) admits a unique topological solution.*

Given $p_1,\ldots,p_m\in\mathbb{R}^2$ and $n_1,\ldots,n_m\in\mathbb{Z}_+$, we also establish a uniqueness result for $\kappa>0$ sufficiently large.

Theorem 1.2: *There is a constant $\kappa_1=\kappa_1(p_1,\ldots,p_m,n_1,\ldots,n_m)>0$ such that for $\kappa>\kappa_1$ Eq. (1.4) admits a unique topological solution.*

Once Theorem 1.1 is proved, we can state the uniqueness result for a solution (ϕ,A_μ) of the self-dual equations (1.2). Assume that (ϕ,A_μ) and $(\hat{\phi},\hat{A}_\mu)$ are two solutions subject to the topological boundary condition $\lim_{|x|\to\infty}|\phi(x)|=\lim_{|x|\to\infty}|\hat{\phi}(x)|=1$. Then, it is obvious that $\hat{A}_0=A_0$. Since $\nabla\times(\hat{A}-A)=0$ with $\hat{A}-A=(\hat{A}_1-A_1,\hat{A}_2-A_2)$, there is a smooth function η such that $\hat{A}-A=\nabla\eta$. Let $\alpha=A_1+iA_2$ and $\hat{\alpha}=\hat{A}_1+i\hat{A}_2$ for simplicity. Then, we can rewrite the first equation of the self-dual equations (1.2) as

$$\partial^*\phi=i\alpha\phi \quad \text{and} \quad \partial^*\hat{\phi}=i\hat{\alpha}\hat{\phi}.$$

Then, we obtain that $\partial^*(\hat{\phi}e^{-i\eta})=i\alpha\hat{\phi}e^{-i\eta}$, which in turn implies that $\partial^*(\hat{\phi}e^{-i\eta}/\phi)=0$. If ϕ and $\hat{\phi}$ have zeros in common, we conclude that $\hat{\phi}=\phi e^{i\eta+h}$ for some holomorphic function h. Due to the topological boundary condition, h must be a constant. Then, we have the uniqueness result for the topological solutions of the self-dual equations (1.2).

Main Theorem: *Given a topological solution u_κ of (1.4), let $(\phi^{(\kappa)},A_\mu^{(\kappa)})$ be given by (1.3) and (1.5) and $A_0^{(\kappa)}=(1/\kappa)|\phi^{(\kappa)}|^2(1-|\phi^{(\kappa)}|^2)$. Then, there are constants $\kappa_0,\kappa_1>0$ such that if $\kappa\in(0,\kappa_0)\cup(\kappa_1,\infty)$ then any topological solution $(\tilde{\phi}^{(\kappa)},\tilde{A}_\mu^{(\kappa)})$ of (1.2) satisfies $\tilde{A}_0^{(\kappa)}=A_0^{(\kappa)}$, $\tilde{A}^{(\kappa)}-A^{(\kappa)}=\nabla\eta_\kappa$ and $\tilde{\phi}^{(\kappa)}=\phi^{(\kappa)}e^{i\eta_\kappa}$ for a real-valued smooth function η_κ.*

We will prove Theorem 1.1 in Sec. III, but we sketch the proof here. We first prove that if $\kappa>0$ is sufficiently small, then any topological solution u_κ is approximated by the sum of rescaled radial topological solutions. More precisely, given $n_j\in\mathbb{Z}_+$, we let ϕ_j be the radial topological solution of $(1.4)_{\kappa=2}$. Then, we will show that if we define z_κ by

$$z_\kappa(x) = \frac{1}{\kappa^3}\left[u_\kappa(x) - \sum_{j=1}^{m} \chi_j(x)\phi_j\left(\frac{2(x-p_j)}{\kappa}\right)\right], \quad x \in \mathbb{R}^2,$$

then $\|z_\kappa\|_{H^2(\mathbb{R}^2)} = o(1)$ as $\kappa \to 0^+$. Here, $\chi_j \in C_0^\infty(\mathbb{R}^2)$ is a cutoff function which is identically 1 near the vortex point p_j. Then, we will construct a functional $\Phi_\kappa : H^2(\mathbb{R}^2) \to H^2(\mathbb{R}^2)$ in such a way that z_κ is a fixed point of Φ_κ for $\kappa > 0$ sufficiently small. Indeed, it will turn out that Φ_κ is a well-defined contraction mapping on a suitable closed subset $\mathcal{B}$ of $H^2(\mathbb{R}^2)$, and $z_\kappa \in \mathcal{B}$ for $\kappa > 0$ sufficiently small. Then, Theorem 1.1 immediately follows from uniqueness of a fixed point in $\mathcal{B}$. Thus, it is a crucial step to obtain the asymptotic behavior of a topological solution u_κ as $\kappa \to 0^+$.

It has been proved by Tarantello[29] that the "maximal" topological solution $\overline{u_\kappa}$ satisfies

$$\frac{4}{\kappa^2} e^{\overline{u}_\kappa}(1 - e^{\overline{u}_\kappa}) \to 4\pi \sum_{j=1}^{m} n_j \delta_{p_j} \quad \text{in the measure sense} \quad \text{as} \quad \kappa \to 0^+.$$

Thus, given any topological solution u_κ, we need to look into the concentration phenomena for u_κ near each p_j for $\kappa > 0$ sufficiently small. For this purpose, we divide $\mathbb{R}^2$ into two disjoint sets, $\Omega_d = \cup_j B_d(p_j)$ and the complement of Ω_d, and apply well-known arguments for uniform estimates and concentration phenomena to u_κ in Ω_d. (See, e.g., Refs. 5, 23, 22, 9, and 3, and references therein.)

Instead of typical topological/nontopological boundary conditions, one may impose the 't Hooft periodic boundary condition on the static configuration of (1.1) and study the equation on a flat torus, $\Omega = \mathbb{R}^2/(a\mathbb{Z} \times b\mathbb{Z})$ with $a, b > 0$. We can also derive self-dual equations (1.2) under the periodic boundary condition, and study the following equation for an unknown $u = \ln|\phi|^2$:

$$\Delta u = \frac{4}{\kappa^2} e^u (e^u - 1) + 4\pi \sum_{j=1}^{m} n_j \delta_{p_j} \quad \text{in} \quad \Omega. \tag{1.6}$$

An existence result for (1.6) was established by Caffarelli–Yang[6] (type I below), and later refined by Tarantello.[29] Tarantello, among other things, established multiple existence results for (1.6). In particular, Tarantello proved that if $N = 1$ then the self-dual equations admit at least two solutions $(\phi^{(\kappa)}, A^{(\kappa)})$ and $(\tilde{\phi}^{(\kappa)}, \tilde{A}^{(\kappa)})$ such that

(a) $|\phi^{(\kappa)}| \to 1$ a.e. as $\kappa \to 0^+$ (type I),

(b) $\forall q \geqslant 0$, $(1/\kappa^2)\|\tilde{\phi}^{(\kappa)}\|_{C^q(\Omega)} \leqslant C_q$ for some constant $C_q > 0$ (type II).
If $N \geqslant 2$, the situation becomes more delicate, and it requires a different approach to establish such multiple existence results. In this case, Eq. (1.4) may admit bubble solutions $\phi^{(\kappa)}$ such that

(c) $F_{12}(\phi^{(\kappa)}, A^{(\kappa)}) \to \Sigma_{k=1}^{l} m_k \delta_{q_k}$ as $\kappa \to 0^+$ in the sense of measure for some $m_k > 0$ and $q_k \in \Omega$. Moreover, $1/\kappa^2 \|\phi^{(\kappa)}\|_{C^0(K)} \to 0$ for any $K \subset\subset \Omega \setminus \{q_1, \ldots, q_l\}$ (type III).

Many experts have pointed out[29,25,12,13] that it is related to the concentration phenomena for a mean-field equation to classify and construct solutions of type II and type III. Recently, it was reported by Nolasco[24] that Eq. (1.4) admits a solution concentrating at the vortex points for $\kappa > 0$ sufficiently small. We also refer to Refs. 5, 23, 22, 9, and 3 for the concentration phenomena for a mean-field equation.

We are interested in the solution of type I. In the following theorem we establish uniqueness result for the solution of type I.

Theorem 1.3: *Let $\Omega = \mathbb{R}^2/(a\mathbb{Z} \times b\mathbb{Z})$ be a flat 2-torus. Then, there exists a constant $\kappa_1 = \kappa_1(p_1, \ldots, p_m, n_1, \ldots, n_m) > 0$ such that for $0 < \kappa < \kappa_1$ Eq. (1.6) admits unique periodic solution $u = \ln|\phi|^2$ which satisfies $u \to 0$ a.e. as $\kappa \to 0^+$.*

From the mathematical point of view, it would be interesting to consider the general situation where Eq. (1.6) is given on a Riemannian 2-manifold (Ω, γ) without boundary. (See Ref. 14.) In

Sec. IV, we will consider such a general situation and establish uniqueness result for $\kappa>0$ sufficiently small. See Theorem 4.1. Theorem 1.3 is indeed a direct consequence of Theorem 4.1. The proof of Theorem 4.1 is similar to that of Theorem 1.1, and we will sketch the proof in Sec. IV.

Theorem 1.3 shows that if $\kappa>0$ is sufficiently small, any solution u_κ of type I is indeed the maximal solution constructed by Caffarelli–Yang.[6] Moreover, the second solution $(\tilde{\phi}^{(\kappa)},\tilde{A}^{(\kappa)})$ found by Tarantello[29] satisfies $|\tilde{\phi}^{(\kappa)}|\to 0$ a.e. as $\kappa\to 0^+$. Theorems 1.1, 1.2, and 1.3 give a partial affirmative answer to the questions raised by Yang[31] and Ding *et al.*[14] The above uniqueness result would also be useful when we classify the solutions of (1.4) or (1.6) for $\kappa>0$ sufficiently small.

This paper is organized as follows. In Sec. II, we collect some well-known results on the solutions of Eq. (1.4). Section III is devoted to the proof of Theorem 1.1 and Theorem 1.2. In Sec. IV, we will sketch the proof of Theorem 1.3.

II. PRELIMINARIES

Hereafter, we let $\epsilon=\kappa/2$ for the sake of simplicity, and rewrite Eq. (1.4) as

$$\Delta u=\frac{1}{\epsilon^2}e^u(e^u-1)+4\pi\sum_{j=1}^{m}n_j\delta_{p_j},\quad \mathbb{R}^2 \tag{2.1}$$

$$u(x)\to 0\quad \text{as}\quad |x|\to\infty. \tag{2.2}$$

We will prove that given $p_1,\ldots,p_m\in\mathbb{R}^2$ and $n_1,\ldots,n_m\in\mathbb{Z}_+$, there is a constant $\epsilon_0=\epsilon_0(p_1,\ldots,p_m,n_1,\ldots,n_m)>0$ such that for $0<\epsilon<\epsilon_0$, Eqs. (2.1) and (2.2) admit a unique solution.

We begin this section by recalling some useful lemmas. Lemma A below is found in Ref. 16.

Lemma A: Given a domain $\Omega\subset\mathbb{R}^2$, let $d_x=\mathrm{dist}(x,\partial\Omega)$ for $x\in\Omega$. Then, $u\in C^2(\Omega)$ satisfies the estimate

$$\sup_\Omega d_x|\nabla u(x)|\leqslant C(\sup_\Omega|u|+\sup_\Omega d_x^2|\Delta u(x)|).$$

In the following two lemmas we collect well-known results for the special case where $p_1=\cdots=p_m=0$ in Eq. (2.1). Instead of the topological boundary condition (2.2), we impose a weaker condition on (2.1).

Lemma 2.1: Let n be a non-negative integer, and u be a solution of the following equation:

$$\begin{cases}\Delta u=e^u(e^u-1)+4\pi n\delta_{p=0}, & \mathbb{R}^2\\ \displaystyle\int_{\mathbb{R}^2}e^u(1-e^u)dx\leqslant C,\end{cases} \tag{2.3}$$

for some constant $C>0$. Then, either

$$\lim_{|x|\to\infty}u(x)=0$$

or

$$\lim_{|x|\to\infty}u(x)=-\infty.$$

Moreover, we have

(i) *if $u\to 0$ near ∞, then u is radially symmetric. Moreover, for each $R>1$ there is a constant $C_R>0$ such that $|u(x)|+|\nabla u(x)|\leqslant C_Re^{-|x|}$ for $|x|>R$.*

(ii) *if $u\to-\infty$ near ∞, then $\int_{\mathbb{R}^2}e^u(1-e^u)dx>8\pi(1+n)$.*

Proof: The proof may be well known to many experts, but we sketch it for completeness. It

follows from the argument of Spruck–Yang[27] that $u<0$ in $\mathbb{R}^2$. Hence, either $\lim_{|x|\to\infty}u(x)=0$ or $\liminf_{|x|\to\infty} u(x)<0$. In the latter case, we claim $\liminf_{|x|\to\infty} u(x)=-\infty$. Otherwise, Lemma A would imply that $\int_{\mathbb{R}^2} e^u(1-e^u)dx=\infty$, which yields a contradiction.

Moreover, it follows from the argument of Chen–Li[11] that there is a constant $\beta=\beta(u)>2$ such that $u(x)=-\beta\ln|x|+O(1)$ near ∞. Therefore, we conclude that if $\liminf_{|x|\to\infty} u(x)<0$ then $u(x)=-\beta\ln|x|+O(1)$ near ∞ for some constant $\beta>2$.

(i) If $\lim_{|x|\to\infty}u(x)=0$, it follows from the method of moving planes that u is radially symmetric.[17] Moreover, it is well known that $u(x)\leqslant C_R e^{-(2/3)|x|}$ for $|x|\geqslant R$, with $R>0$ sufficiently large. Notice that $\Delta u-u=O(u^2)$ near ∞. Comparing u with the comparison function $e^{-|x|}$, we can verify by maximum principle that $|u(x)|\leqslant C_R e^{-|x|}$ for $|x|\geqslant R$ with $R>0$ sufficiently large. The estimate for $|\nabla u(x)|$ follows from Lemma A.

(2) If $\lim_{|x|\to\infty}u(x)=-\infty$, then we have $\int_{\mathbb{R}^2}(e^u-e^{2u})dx=\pi(4n+2\beta)$. The inequality in (ii) follows from the Pohozaev identity. Indeed, multiplying (2.1) by $x\cdot\nabla u$ and integrating by parts on the domain $\Sigma_{\delta,R}=\{x|\delta<|x|<R\}$ with $\delta,R>0$, we obtain

$$\int_{\partial\Sigma_{\delta,R}}\left[\frac{1}{2}(x\cdot\nu)|\nabla u|^2-(x\cdot\nabla u)(\nu\cdot\nabla u)+\frac{1}{2}(x\cdot\nu)e^{2u}-(x\cdot\nu)e^u\right]d\sigma=\int_{\Sigma_{\delta,R}}(e^{2u}-2e^u)dx,$$

where ν is the outward normal vector on $\partial\Sigma_{\delta,R}$. Since $\nabla u(x)=\beta x/|x|^2+o(|x|^{-1})$ near ∞, and $u(x)=2n\ln|x|+v$ near $y=0$ for some smooth function v, we obtain

$$\int_{|x|=\delta}\frac{1}{|x|}(x\cdot\nabla u)^2d\sigma=\frac{1}{\delta}\int_{|x|=\delta}(2n+x\cdot\nabla v)^2d\sigma=8\pi n^2+O(\delta),$$

$$\int_{|x|=\delta}\frac{1}{2}|x||\nabla u|^2d\sigma=\frac{\delta}{2}\int_{|x|=\delta}\left(\frac{4n^2}{\delta^2}+O\left(\frac{1}{\delta}\right)\right)d\sigma=4\pi n^2+O(\delta),$$

as $\delta\to0$, and

$$\int_{|x|=R}\left[\frac{1}{2}(x\cdot\nu)|\nabla u|^2-(x\cdot\nabla u)(\nu\cdot\nabla u)\right]d\sigma=-\pi\beta^2+o(1)\quad\text{as}\quad R\to\infty.$$

Letting $\delta\to0^+$ and $R\to\infty$, we obtain $\pi(4n^2-\beta^2)=\int_{\mathbb{R}^2}(e^{2u}-2e^u)dx$. Then, we have $\int_{\mathbb{R}^2}e^{2u}dx=\pi((\beta-2)^2-4(n+1)^2)>0$. Hence, $\beta>2n+4$ and the desired inequality immediately follows. □

Remark: The Pohozaev identity also implies that if $u\to0$ near ∞ then $\int_{\mathbb{R}^2}(e^u-1)^2dx=4\pi n^2$. Indeed, proceeding as above, we obtain

$$\int_{\partial\Sigma_{\delta,R}}\left(\frac{1}{2}(x\cdot\nu)|\nabla u|^2-(x\cdot\nabla u)(\nu\cdot\nabla u)+\frac{1}{2}(x\cdot\nu)(e^u-1)^2\right)d\sigma=\int_{\partial\Sigma_{\delta,R}}(e^u-1)^2dy.$$

Letting $\delta\to0$ and $R\to\infty$, we obtain the desired result.

Spruck–Yang[27] proved that if $n=0$ then every nontrivial solution of (2.3) is radially symmetric with respect to some point. However, if $n>0$, it has been proved by Chae–Imanuvilov[7] that Eq. (2.3) admits a nonradial solution. If we limit our attention to the radial solutions of (2.3) for $n\geqslant0$, we have the uniqueness result (2.3) established by Chen *et al.*[10] and Chan *et al.*;[8] the topological radial solution is unique. Moreover, given a constant $\beta>2n+4$, (2.3) admits a unique radial solution $u(r)$ such that $u(x)-2n\ln|x|$ is smooth, and $u(r)=-\beta\ln r+O(1)$ as $r\to\infty$. More precisely, we have

Lemma 2.2 (Chen et al.[10]): Given a non-negative integer n, let $u(r;n,s)$ be the radial solution of (2.3) such that $\lim_{r\to0}(u(r;n,s)-2n\ln r)=s$ and $\lim_{r\to0}(u_r(r;n,s)-2n/r)=0$. Then, there is a constant $s_n\in\mathbb{R}$ such that

(i) $u(r;n,s_n)\to0$ *as* $r\to\infty$,

(ii) *If* $s<s_n$, $u(r;n,s_n)\to-\infty$ *as* $r\to\infty$,
(iii) *If* $s>s_n$, $u(r;n,s_n)$ *blows up at some* $r=r(s)$.

Moreover, if we define a function $\beta_n:(-\infty,s_n)\to\mathbb{R}_+=(0,\infty)$ *by*

$$\beta_n(s)=\int_0^\infty e^{u(r;n,s)}(1-e^{u(r;n,s)})r\,dr, \tag{2.4}$$

then $\lim_{s\to s_n}\beta_n(s)=\infty$, $\lim_{s\to-\infty}\beta_n(s)=2n+4$, *and* $\{\beta_n(s)|s<s_n\}=(2n+4,\infty)$.

(Chan et al.[8]*):* β_n *is differentiable and strictly increasing in the interval* $(-\infty,s_n)$.

Remark: It is obvious that $s_n=0$ if $n=0$ in (2.3).

Before proceeding, we fix some notations. For simplicity, we let $\mathcal{Z}=\{p_1,\ldots,p_m\}$ be the set of vortex points. Given a positive constant $r>0$, we let

$$\Omega_r=\bigcup_{j=1}^m B_r(p_j).$$

Hereafter, we denote by χ a cutoff function such that $0\leqslant\chi\leqslant1$, $\chi(x)=1$ for $|x|\leqslant1$, and $\chi(x)=0$ for $|x|\geqslant2$. Given a set Σ, we denote by Σ^c the complement of Σ. $C,c_0,\ldots$ will denote constants independent of ϵ. Throughout this paper, d is a fixed constant such that $0<d<\frac{1}{4}\min\{|p_k-p_j|1\leqslant k<j\leqslant m\}$.

Denote by ϕ_j the radial topological solution of the equation

$$\Delta\phi_j=e^{\phi_j}(e^{\phi_j}-1)+4\pi n_j\delta_{p=0},$$

$$\phi_j\to0\quad\text{near}\quad\infty. \tag{2.5}$$

We will prove in the following section that any solution u_ϵ of (2.1) and (2.2) is "close" to the rescaled radial solution $\phi_j(\epsilon^{-1}(x-p_j)+p_j)$ near each vortex point p_j. Then, we need an estimate for the linearized operator at ϕ_j in order to obtain *a priori* estimates for u_ϵ near $x=p_j$.

Lemma 2.3: Let $L_j:H^2(\mathbb{R}^2)\to L^2(\mathbb{R}^2)$ *be the linearized operator*

$$L_j=\Delta-e^{\phi_j}(2e^{\phi_j}-1).$$

Then, $L_j:H^2(\mathbb{R}^2)\to L^2(\mathbb{R}^2)$ *is one-to-one, and moreover, there is a constant* $c>0$ *such that* $\|L_ju\|_{L^2(\mathbb{R}^2)}\geqslant c\|u\|_{H^2(\mathbb{R}^2)}$ *for all* $u\in H^2(\mathbb{R}^2)$.

Proof: We first show that $L_j:H^2(\mathbb{R}^2)\to L^2(\mathbb{R}^2)$ is one-to-one. Assume that $u\in H^2(\mathbb{R}^2)$ satisfies $L_ju=0$. By Fourier expansion, it suffices to study the following eigenvalue problem:

$$u_k''+\frac{u_k'}{r}-\frac{k^2}{r^2}u_k=e^{\phi_j}(2e^{\phi_j}-1)u_k,$$

$$u_k(r)=r^k(1+O(r))\quad\text{near}\quad r=0,\quad k=0,1,\ldots.$$

We first claim that u_k is positive in $\mathbb{R}_+$ for all $k\geqslant0$. Let $\psi(r)=r\phi_j'(r)$. Then, ψ is positive in $\mathbb{R}_+$, and $\psi(r)=2N+O(r^{2n_j+2})$ near $r=0$. By comparing ψ with u_0, we obtain that $u_0>0$ in $\mathbb{R}_+$. Indeed, it is easily checked that

$$\psi''+\frac{\psi'}{r}=e^{\phi_j}(2e^{\phi_j}-1)\psi+2e^{\phi_j}(e^{\phi_j}-1).$$

Suppose that u_0 has a first zero at $r=r_0>0$, namely, $u_0(r_0)=0$ and $u_0>0$ in the interval $(0,r_0)$. Then, integration by parts gives that

$$0 < \int_0^{r_0} 2e^{\phi_j}(1-e^{\phi_j})u_0\, rdr = [r\psi u_0' - ru_0\psi']_0^{r_0} \leqslant 0,$$

which yields a contradiction. Hence, u_0 is positive in $\mathbb{R}_+$. A comparison lemma also shows that $u_k > 0$ in $\mathbb{R}_+$ for each $k \geqslant 1$. Indeed, if we suppose that u_k has a first zero at $r = r_k > 0$, then we obtain

$$0 < \int_0^{r_k} \frac{k^2}{r} u_0 u_k\, dr = [ru_0 u_k' - ru_k u_0']_0^{r_k} \leqslant 0,$$

which leads to a contradiction. Then, it is easily checked that $\lim_{r\to\infty}[u_k(r)/r] = \infty$. Therefore, we conclude that $ker\ L_j \cap H^2(\mathbb{R}^2) = \{0\}$.

We now prove the second part. We argue by contradiction and suppose that there exists a sequence $\{u_n\} \subset H^2(\mathbb{R}^2)$ such that $\|u_n\|_{H^2(\mathbb{R}^2)} = 1$ while $\|L_j u_n\|_{L^2(\mathbb{R}^2)} = o(1)$ as $n \to \infty$. Passing to a subsequence, we may assume that there exists $u_* \in H^2(\mathbb{R}^2)$ such that $u_n \rightharpoonup u_*$ weakly in $H^2(\mathbb{R}^2)$ and strongly in $W^{1,p}(\Omega)$ for $1 < p < \infty$ and any bounded domain Ω. It is obvious that $L_j u_* = 0$, and hence $u_* \equiv 0$. Consequently, $\|u_n\|_{H^1(\Omega)} = o(1)$ as $n \to \infty$ for each bounded domain $\Omega \subset \mathbb{R}^2$.

Fix a constant $R > 0$ such that $e^{\phi_j(R)} \geqslant 2/3$. Let $B_r^c = \{|x| \geqslant r\}$ and $A_r = \{r \leqslant |x| \leqslant r+1\}$ for a constant $r > 0$. Choose a cutoff function σ such that $0 \leqslant \sigma \leqslant 1$, $\sigma \equiv 1$ in $B_R(0)$, and $\sigma(x) = 0$ for $|x| \geqslant R+1$. Let $u_{1n} = \sigma u_n$ and $u_{2n} = (1-\sigma)u_n$. Then, it is easy to check that

$$L_j u_{2n} = (1-\sigma)L_j u_n - 2\nabla u_n \cdot \nabla \sigma - u_n \Delta\sigma, \tag{2.6}$$

and $\|u_{1n}\|_{H^1(B_{R+1}(0))} = o(1)$ as $n \to \infty$. Multiplying (2.6) by u_{2n}, and integrating by parts, we obtain

$$\|\nabla u_{2n}\|_{L^2(B_R^c)} + \|u_{2n}\|_{L^2(B_R^c)} \leqslant C(\|u_n\|_{H^1(A_R)} + \|L_j u_n\|_{L^2(B_R^c)}) = o(1).$$

In particular, $\|u_n\|_{H^1(B_{R+1}^c)} = o(1)$, which in turn implies that $\|u_n\|_{H^1(\mathbb{R}^2)} = o(1)$ as $n \to \infty$. Consequently, we obtain

$$\|D^2 u_n\|_{L^2(\mathbb{R}^2)} = \|\Delta u_n\|_{L^2(\mathbb{R}^2)} \leqslant \|u_n\|_{L^2(\mathbb{R}^2)} + \|L_j u_n\|_{L^2(\mathbb{R}^2)} = o(1),$$

which yields a contradiction. The proof of Lemma 2.3 is complete. □

Remark: Since $L_j : H^2(\mathbb{R}^2) \to L^2(\mathbb{R}^2)$ is self-adjoint, it follows from Lemma 2.3 that L_j is an isomorphism from $H^2(\mathbb{R}^2)$ onto $L^2(\mathbb{R}^2)$.

III. UNIQUENESS OF A TOPOLOGICAL SOLUTION

We first prove Theorem 1.1. To this end, we first obtain the *a priori* estimates for a solution u_ϵ of (2.1) and (2.2) as $\epsilon \to 0^+$. Those estimates will be given in the following two lemmas.

Lemma 3.1: Let u_ϵ be any topological solution of (2.1). *Then, there is a constant $\epsilon_0 = \epsilon_0(d) > 0$ such that if $0 < \epsilon < \epsilon_0$ then*

$$\|u_\epsilon\|_{H^2(\Omega_d^c)} \leqslant c_0 \exp[-c_1/\epsilon], \tag{3.1}$$

for some positive constants c_0, c_1 depending only on d.

Proof: We divide the proof into three steps.

Step 1: We claim that for each compact subset $K \subset \mathbb{R}^2 \setminus \mathcal{Z}$, there are constants $\epsilon_* > 0$ and $\gamma_0(K) < 0$ such that $\gamma_0(K) \leqslant u_\epsilon < 0$ in K for $0 < \epsilon < \epsilon_*$.

Let

$$u_*(x) = \sum_j 2n_j \ln|x - p_j|,$$

and $v_\epsilon = u_\epsilon - u_*$. Fix a constant $R > \sup_j |p_j|$. Then, it suffices to prove that if $\epsilon > 0$ is sufficiently small then $\inf_{B_R(0)} v_\epsilon \geqslant \gamma_0$ for some constant $\gamma_0(R) < 0$.

We argue by contradiction and suppose that there are sequences $\{\epsilon_n\}$ and $\{x_n\}\subset B_R(0)$ such that $\epsilon_n\to 0^+$ and $v_{\epsilon_n}(x_n)=\inf_{B_R(0)}v_{\epsilon_n}\to-\infty$. For simplicity, we let $v_n:=v_{\epsilon_n}$.

Decompose $v_n=v_{1n}+v_{2n}$, where

$$\begin{cases}\Delta v_{1n}=\dfrac{1}{\epsilon_n^2}e^{u_*+v_n}(e^{u_*+v_n}-1), & B_R(0)\\ v_{1n}=0, & \partial B_R(0)\end{cases}$$

and

$$\begin{cases}\Delta v_{2n}=0, & B_R(0)\\ v_{2n}=v_n, & \partial B_R(0).\end{cases}$$

By the Harnack inequality, we may assume $v_{2n}\to-\infty$ uniformly on $B_R(0)$.

On the other hand, following the argument of Tarantello,[29] we can verify that v_{1n} is bounded in $W_0^{1,q}(B_R(0))$ for each $1<q<2$. By passing to a subsequence, we may assume that $v_{1n}\rightharpoonup v_\infty$ weakly in $W_0^{1,q}(B_R(0))$, and strongly in $L^p(B_R(0))$ for $1\leqslant p<2q/(2-q)$. Consequently, $v_n\to-\infty$ almost everywhere on $B_R(0)$.

Consider the function $\beta_0(s)$ defined in (2.4), and fix a constant $s_0<0$ such that $\beta_0(s_0)>2N$. Let $u_n=v_n+u_*$. For each n, choose $y_n\in\mathbb{R}^2$ such that

$$u_n(y_n)=s_0 \quad\text{and}\quad |y_n|=\sup\{|x|\,|\,u_n(x)=s_0.$$

Notice that $\inf_{|x|\geqslant r}u_n(x)=\inf_{|x|=r}u_n(x)$ for each $r>\sup_j|p_j|$. Since $u_n\to-\infty$ almost everywhere on each compact subset, $|y_n|\to\infty$.

Let $\overline{u_n}(x)=u_n(\epsilon_n x+y_n)$. Then, $\overline{u_n}$ satisfies

$$\begin{cases}\Delta\overline{u_n}=e^{\overline{u_n}}(e^{\overline{u_n}}-1), & \Omega_n:=\{|x|<|y_n|/2\epsilon_n\}\\ \displaystyle\int_{\Omega_n}e^{\overline{u_n}}(1-e^{\overline{u_n}})dx\leqslant 4\pi N.\end{cases}$$

Since $\overline{u_n}(0)=s_0$ and $\overline{u_n}<0$, the argument of Brezis–Merle[5] implies that $\overline{u_n}$ is bounded in $C^0_{loc}(\Omega_n)$. Then, we may assume that $\overline{u_n}$ converges in $C^2_{loc}(\mathbb{R}^2)$ to $\overline{u_*}$ which is a solution of

$$\begin{cases}\Delta\overline{u_*}=e^{\overline{u_*}}(e^{\overline{u_*}}-1), & \mathbb{R}^2,\\ \displaystyle\int_{\mathbb{R}^2}e^{\overline{u_*}}(1-e^{\overline{u_*}})dx\leqslant 4\pi N.\end{cases}$$

Since $\overline{u_*}(0)=s_0<0$, Lemma 2.1 implies that $\overline{u_*}$ is radially symmetric with respect to some point in $\mathbb{R}^2$. Consequently

$$\int_{\mathbb{R}^2}e^{\overline{u_*}}(1-e^{\overline{u_*}})dx\geqslant 2\pi\beta_0(s_0)>4\pi N,$$

which yields a contradiction.

Step 2: Recall that $\Omega_d=\cup_j B_d(p_j)$. We claim that $u_\epsilon\to 0$ in $C^0(\Omega_d^c)$ as $\epsilon\to 0^+$. Moreover, if $\epsilon>0$ is sufficiently small, then

$$\|u_\epsilon\|_{L^\infty(\Omega_d^c)}\leqslant c_2\,\exp[-c_3/\epsilon] \tag{3.2}$$

for some constants $c_2(d),c_3(d)>0$. We note that for each $d>0$, $\|u_\epsilon\|_{L^\infty(\Omega_d^c)}$ is attained on $\partial\Omega_d$. Thus, it suffices to prove $\|u_\epsilon\|_{L^\infty(\partial\Omega_d)}\leqslant\exp[-c_3/\epsilon]$.

The second claim follows from the maximum principle. Indeed, fix two constants $\epsilon_*>0$ and $m<0$ such that $u_\epsilon\geqslant m$ on $\Omega_{d/2}^c$ for $0<\epsilon<\epsilon_*$. Then, it follows that

$$-\epsilon^2\Delta u_\epsilon + e^{2m}u_\epsilon \geqslant 0 \quad \text{on} \quad \Omega^c_{d/2}.$$

For each $x_0 \in \partial\Omega_d$, we define a comparison function w_ϵ by

$$w_\epsilon(x) = (1-m)\exp\left[\frac{e^m}{2d\epsilon}(|x-x_0|^2 - d^2/4)\right] \quad \text{for} \quad |x-x_0| \leqslant d/2.$$

It is easy to check that if $\epsilon > 0$ is sufficiently small

$$-\epsilon^2\Delta(u_\epsilon + w_\epsilon) + e^{2m}(u_\epsilon + w_\epsilon) > 0 \quad \text{on} \quad B_{d/2}(x_0).$$

Then, the maximum principle implies that $(u_\epsilon + w_\epsilon)(x) > (u_\epsilon + w_\epsilon)|_{|x-x_0|=d/2} > 0$ for $|x-x_0| \leqslant d/2$. In particular, there is a constant $c > 0$ such that $u_\epsilon(x) > -\exp[-c/\epsilon]$ for $|x-x_0| \leqslant d/4$. Since the constant c is indepedent of the choice of $x_0 \in \partial\Omega_d$, (3.2) immediately follows.

Step 3: We now prove (3.1). Notice that $\|u_\epsilon\|_{L^\infty(\Omega^c_{d/2})} \leqslant c_2\exp[-c_3/\epsilon]$, and

$$\epsilon^2\Delta u_\epsilon - u_\epsilon = O(1)|u_\epsilon|^2 \quad \text{in} \quad \Omega^c_{d/2}, \tag{3.3}$$

where $O(1)$ denotes a quantity which is uniformly bounded in $C^0(\Omega^c_{d/2})$. Let σ be a smooth function such that $0 \leqslant \sigma \leqslant 1$, $\sigma(x) = 1$ for $x \in \Omega^c_{3d/4}$, and $\sigma(x) = 0$ for $x \in \Omega_{d/2}$. Multiplying (3.3) by σu_ϵ and integrating by parts, we obtain

$$\begin{aligned}\epsilon^2\|\nabla u_\epsilon\|^2_{L^2(\Omega^c_{3d/4})} + \|u_\epsilon\|^2_{L^2(\Omega^c_{3d/4})} &\leqslant C(d)\left[\int_{\Omega_d\setminus\Omega_{d/2}} (\epsilon^2|\Delta\sigma|u_\epsilon^2 + \sigma|u_\epsilon|^3)dx + \int_{\Omega^c_d}|u_\epsilon|^3 dx\right] \\ &\leqslant C(d)[\exp(-c/\epsilon) + \|u_\epsilon\|_{L^\infty(\Omega^c_d)}\|u_\epsilon\|^2_{L^2(\Omega^c_d)}],\end{aligned}$$

which in turn implies that if $\epsilon > 0$ is sufficiently small

$$\epsilon\|\nabla u_\epsilon\|_{L^2(\Omega^c_{3d/4})} + \|u_\epsilon\|_{L^2(\Omega^c_{3d/4})} \leqslant C(d)\epsilon\,\exp[-c_3/\epsilon]. \tag{3.4}$$

Choose a smooth function $\tilde{\sigma}$ such that $0 \leqslant \tilde{\sigma} \leqslant 1$, $\tilde{\sigma}(x) = 1$ for $x \in \Omega^c_d$ and $\tilde{\sigma}(x) = 0$ for $x \in \Omega_{3d/4}$. We note that

$$\|D^2(\tilde{\sigma}u_\epsilon)\|_{L^2(\mathbb{R}^2)} = \|\Delta(\tilde{\sigma}u_\epsilon)\|_{L^2(\mathbb{R}^2)} \leqslant C(\|\Delta u_\epsilon\|_{L^2(\Omega^c_{3d/4})} + \|u_\epsilon\|_{H^1(\Omega^c_{3d/4})}). \tag{3.5}$$

Then, Lemma 3.1 is an immediate consequence of (3.4) and (3.5). □

We now investigate the asymptotic behavior of u_ϵ in each ball $B_d(p_j)$. For each $1 \leqslant j \leqslant m$, let $\hat{u}_{\epsilon,j}(x) = u_\epsilon(\epsilon x + p_j)$ for $|x| \leqslant 2d/\epsilon$. Then, $\hat{u}_{\epsilon,j}$ satisfies

$$\Delta\hat{u}_{\epsilon,j} = e^{\hat{u}_{\epsilon,j}}(e^{\hat{u}_{\epsilon,j}} - 1) + 4\pi n_j\delta_{p=0} \quad \text{for} \quad |x| \leqslant 2d/\epsilon, \tag{3.6}$$

and $|\hat{u}_{\epsilon,j}(x)| = O(e^{-c/\epsilon})$ for $|x| = 2d/\epsilon$. It follows from the Pohozaev identity that

$$\int_{|y|\leqslant 2d/\epsilon} (1 - e^{\hat{u}_{\epsilon,j}})^2 dy = 4\pi n_j^2 + o(e^{-c/\epsilon}), \tag{3.7}$$

for some constant $c > 0$.

The following lemma shows the asymptotic behavior of $\hat{u}_{\epsilon,j}$ in the ball $B_{d/\epsilon}(0)$.

Lemma 3.2: There is a constant $\epsilon_1 = \epsilon_1(d) > 0$ such that if $0 < \epsilon < \epsilon_1$, then

$$\sup_j \|\hat{u}_{\epsilon,j} - \phi_j\|_{H^2(|x|\leqslant d/\epsilon)} \leqslant C_0\,\exp[-C_1/\epsilon], \tag{3.8}$$

for some positive constants C_0 and C_1 depending only on d.

Proof: It follows from Lemma 3.1 that if $\epsilon > 0$ is sufficiently small, then there are positive constants c_0, c_1 such that $\|\hat{u}_{\epsilon,j}\|_{H^2(d/\epsilon\leqslant|x|\leqslant 2d/\epsilon)} \leqslant c_0\,\exp[-c_1/\epsilon]$. The proof of Lemma 3.2 will be given in three steps.

Step 1: We claim that $\hat{u}_{\epsilon,j}-\phi_j\to 0$ in $C^2_{loc}(\mathbb{R}^2)$ as $\epsilon\to 0^+$.

Let $\hat{v}_{\epsilon,j}=\hat{u}_{\epsilon,j}-2n_j\ln|x|$. Then, $\hat{v}_{\epsilon,j}$ satisfies

$$\Delta\hat{v}_{\epsilon,j}=|x|^{2n_j}e^{\hat{v}_{\epsilon,j}}(|x|^{2n_j}e^{\hat{v}_{\epsilon,j}}-1)\quad\text{for}\quad|x|\leqslant 2d/\epsilon,$$

$$\int_{|x|\leqslant 2d/\epsilon}|x|^{2n_j}e^{\hat{v}_{\epsilon,j}}(1-|x|^{2n_j}e^{\hat{v}_{\epsilon,j}})dx=4\pi n_j+o(e^{-c/\epsilon}).$$

We claim that $\hat{v}_{\epsilon,j}$ is bounded in $C^0_{loc}(\mathbb{R}^2)$.

Indeed, since $|x|^{2n_j}e^{\hat{v}_{\epsilon,j}}\leqslant 1$, it follows from the Harnack inequality that either $\hat{v}_{\epsilon,j}$ is bounded in $C_{loc}(\mathbb{R}^2)$, or $\hat{v}_{\epsilon,j}\to-\infty$ uniformly on any compact subset of $\mathbb{R}^2$. If $\hat{v}_{\epsilon,j}\to-\infty$ on any compact subset, then it follows that $\int_{|y|\leqslant R}(1-e^{\hat{u}_{\epsilon,j}})^2dy=\pi R^2+o(1)$ as $\epsilon\to 0^+$ for each $R>0$, which contradicts (3.7). Therefore, $\hat{v}_{\epsilon,j}$ is bounded in $C^0_{loc}(\mathbb{R}^2)$.

By passing to a subsequence, we may assume that $\hat{v}_{\epsilon,j}$ converges uniformly in $C^2_{loc}(\mathbb{R}^2)$ to a function $v_*\in C^2(\mathbb{R}^2)$, which satisfies

$$\Delta v_*=|x|^{2n_j}e^{v_*}(|x|^{2n_j}e^{v_*}-1)\quad\text{in}\quad\mathbb{R}^2,$$

$$\int_{\mathbb{R}^2}|x|^{2n_j}e^{v_*}(1-|x|^{2n_j}e^{v_*})dx\leqslant 4\pi n_j.$$

Let $u_*(x)=v_*(x)+2n_j\ln|x|$. Then, Lemma 2.1 implies that $u_*(x)\to 0$ as $|x|\to\infty$, and hence u_* is radially symmetric. It follows from the uniqueness of radial topological solution[10] that $u_*=\phi_j$.

Step 2: We claim $\sup_{|x|\leqslant 2d/\epsilon}|(\hat{u}_{\epsilon,j}-\phi_j)(x)|\to 0$ as $\epsilon\to 0^+$.

For simplicity, we let

$$\hat{w}_{\epsilon,j}=\hat{u}_{\epsilon,j}-\phi_j,$$

and fix a constant $R_0>0$ such that $e^{\phi_j(R_0)}\geqslant 2/3$. We argue by contradiction and suppose that there exist sequences $\{\epsilon_n\}$ and $\{x_n\}\subset B_{2d/\epsilon_n}(0)$ such that $\epsilon_n\to 0^+$ and

$$|\hat{w}_{\epsilon_n,j}(x_n)|=\sup_{|x|\leqslant 2d/\epsilon_n}|\hat{w}_{\epsilon_n,j}(x)|\geqslant\gamma_0$$

for some constant $\gamma_0>0$. It follows from the previous step that $|x_n|\to\infty$, and we may assume that $R_0<|x_n|<2d/\epsilon_n$. Let $\hat{w}_n=\hat{w}_{\epsilon_n,j}$ for simplicity.

If $\hat{w}_n(x_n)>0$, then we have

$$0\geqslant\Delta\hat{w}_n(x_n)=e^{\phi_j(x_n)+\hat{w}_n(x_n)}(e^{\phi_j(x_n)+\hat{w}_n(x_n)}-1)-e^{\phi_j(x_n)}(e^{\phi_j(x_n)}-1)>0,$$

which yields a contradiction. Consequently, $\hat{w}_n(x_n)<0$. Since $\Delta\hat{w}_n(x_n)\geqslant 0$, we have

$$e^{\phi_j(x_n)+\hat{w}_n(x_n)}+e^{\phi_j(x_n)}\leqslant 1.$$

Then, it follows from Lemma 2.1 that $\hat{w}_n(x_n)\leqslant\ln(e^{-\phi_j(x_n)}-1)\leqslant-|x_n|+C$ for some constant C. In particular, $\hat{w}_n(x_n)\to-\infty$ as $n\to\infty$.

Since $\phi_j<0$ and $\phi_j+w_n<0$, it follows from the Harnack inequality that $\phi_j+\hat{w}_n\to-\infty$ uniformly on $B_R(x_n)$. Then, it follows that $\int_{|x-x_n|<R}(1-e^{\phi_j+\hat{w}_n})^2dx=\pi R^2+o(1)$, which contradicts (3.7).

Step 3: We are now ready to prove the inequality (3.8). Recall that χ is a cutoff function such that $0\leqslant\chi\leqslant 1$, $\chi\equiv 1$ on $B_1(0)$ and $\chi\equiv 0$ outside $B_2(0)$. Let $\sigma_\epsilon(x)=\chi(\epsilon x/d)$.

Since $0\leqslant e^t-1-t\leqslant(t^2/2)e^{\max\{0,t\}}$ for $t\in\mathbb{R}$, we have $L_j\hat{w}_{\epsilon,j}=O(1)|\hat{w}_{\epsilon,j}|^2$ pointwise for $|x|\leqslant 2d/\epsilon$. Then, it is easy to check that

$$L_j(\sigma_\epsilon\hat{w}_{\epsilon,j})=2\nabla\hat{w}_{\epsilon,j}\cdot\nabla\sigma_\epsilon+\hat{w}_{\epsilon,j}\Delta\sigma_\epsilon+O(1)\sigma_\epsilon|\hat{w}_{\epsilon,j}|^2.$$

Let $\hat{A}_\epsilon=\{d/\epsilon\leqslant|x|\leqslant 2d/\epsilon\}$. Then, Lemma 2.3 implies that

$$\|\sigma_\epsilon \hat{w}_{\epsilon,j}\|_{H^2(\mathbb{R}^2)} \leq C(\epsilon\|\nabla \hat{w}_{\epsilon,j}\|_{L^2(\hat{A}_\epsilon)} + \epsilon^2\|\hat{w}_{\epsilon,j}\|_{L^2(\hat{A}_\epsilon)} + \sup_{|x|\leq 2d/\epsilon}|\hat{w}_{\epsilon,j}(x)|\|\sigma_\epsilon \hat{w}_{\epsilon,j}\|_{L^2(\mathbb{R}^2)})$$

for some constant $C=C(d)>0$. Since $\sup_{|x|\leq 2d/\epsilon}|\hat{w}_{\epsilon,j}(x)|=o(1)$ as $\epsilon\to 0^+$, we obtain

$$\begin{aligned}\|\hat{w}_{\epsilon,j}\|_{H^2(|x|\leq d/\epsilon)} \leq \|\sigma_\epsilon \hat{w}_{\epsilon,j}\|_{H^2(\mathbb{R}^2)} &\leq C(\epsilon\|\nabla \hat{w}_{\epsilon,j}\|_{L^2(\hat{A}_\epsilon)} + \epsilon^2\|\hat{w}_{\epsilon,j}\|_{L^2(\hat{A}_\epsilon)}) \\ &\leq C\epsilon\|\hat{w}_{\epsilon,j}\|_{H^2(d/\epsilon\leq|x|\leq 2d/\epsilon)} \leq C_0\exp[-C_1/\epsilon]\end{aligned}$$

for some constants $C_0, C_1>0$ if $\epsilon>0$ is sufficiently small. The proof of Lemma 3.2 is complete.□

For each $1\leq j\leq m$, let $\chi_j(x)=\chi((x-p_j)/d)$. Given a solution u_ϵ of (2.1) and (2.2), let

$$z_\epsilon(x) = \frac{1}{\epsilon^3}\left[u_\epsilon(x) - \sum_{j=1}^m \chi_j(x)\phi_j\left(\frac{x-p_j}{\epsilon}\right)\right], \quad x\in\mathbb{R}^2. \tag{3.9}$$

For the sake of simplicity, we let $\phi_{j,\epsilon}(x)=\phi_j((x-p_j)/\epsilon)$ for $1\leq j\leq m$ and $\epsilon>0$. Then, $z_\epsilon \in H^2(\mathbb{R}^2)$ satisfies

$$\begin{aligned}\Delta z_\epsilon = \frac{1}{\epsilon^5}\exp\left[\sum_j \chi_j\phi_{j,\epsilon} + \epsilon^3 z_\epsilon\right]\left(\exp\left[\sum_j \chi_j\phi_{j,\epsilon} + \epsilon^3 z_\epsilon\right] - 1\right) - \frac{1}{\epsilon^5}\sum_j \chi_j e^{\phi_{j,\epsilon}}(e^{\phi_{j,\epsilon}}-1) \\ - \frac{1}{\epsilon^3}\sum_j [2\nabla\chi_j\cdot\nabla\phi_{j,\epsilon} + \phi_{j,\epsilon}\Delta\chi_j] \quad \text{in} \quad \mathbb{R}^2,\end{aligned} \tag{3.10}$$

and, moreover, it follows from Lemma 3.1 and Lemma 3.2 that $\|z_\epsilon\|_{H^2(\mathbb{R}^2)}=o(1)$ as $\epsilon\to 0^+$.

Given a solution u_ϵ of (2.1) and (2.2), we construct a functional $\Phi_\epsilon: H^2(\mathbb{R}^2)\to H^2(\mathbb{R}^2)$ in such a way that z_ϵ defined in (3.9) is a fixed point of Φ_ϵ. For this purpose, we define an auxiliary functional $F_\epsilon: H^2(\mathbb{R}^2)\to L^2(\mathbb{R}^2)$ by

$$\begin{aligned}F_\epsilon(v) = \Delta v - \frac{1}{\epsilon^5}\exp\left[\sum_j \chi_j\phi_{j,\epsilon} + \epsilon^3 v\right]\left(\exp\left[\sum_j \chi_j\phi_{j,\epsilon} + \epsilon^3 v\right] - 1\right) \\ + \frac{1}{\epsilon^5}\sum_j \chi_j e^{\phi_{j,\epsilon}}(e^{\phi_{j,\epsilon}}-1) + \frac{1}{\epsilon^3}\sum_j [2\nabla\chi_j\cdot\nabla\phi_{j,\epsilon} + \phi_{j,\epsilon}\Delta\chi_j].\end{aligned} \tag{3.11}$$

Indeed, Φ_ϵ will be defined in terms of F_ϵ and $DF_\epsilon(0)$. In order to prove that Φ_ϵ has a unique fixed point in $H^2(\mathbb{R}^2)$, we show that Φ_ϵ is a well-defined contraction mapping on a suitable bounded subset $\mathcal{B}$ of $H^2(\mathbb{R}^2)$. Thus, we need to obtain some estimates for F_ϵ and $DF_\epsilon(0)$. We prove in the following lemma useful properties of F_ϵ for $\epsilon>0$ sufficiently small.

Lemma 3.3: If $\epsilon>0$ is sufficiently small, we have

(a) $\|F_\epsilon(0)\|_{L^2(\mathbb{R}^2)}\leq c_0\exp[-c_1/\epsilon]$ *for some constants* $c_0, c_1>0$.

(b) $DF_\epsilon(0)$ *is an isomophism from* $H^2(\mathbb{R}^2)$ *onto* $L^2(\mathbb{R}^2)$, *and there is a constant* $C>0$ *such that*

$$\|DF_\epsilon(0)h\|_{L^2(\mathbb{R}^2)} \geq C\|h\|_{H^2(\mathbb{R}^2)} \quad \textit{for all} \quad h\in H^2(\mathbb{R}^2). \tag{3.12}$$

(c) $\|DF_\epsilon(z)h - DF_\epsilon(0)h\|_{L^2(\mathbb{R}^2)}\leq C\epsilon\|h\|_{H^2(\mathbb{R}^2)}$ *for* $\|z\|_{H^2(\mathbb{R}^2)}\leq 1$.

Proof:

(a) Estimate for $F_\epsilon(0)$: We note that $F_\epsilon(0)\equiv 0$ both on $\Omega_d=\cup_j B_d(p_j)$ and on Ω_{2d}^c. Moreover, if we set $\Sigma_j=B_{2d}(p_j)\setminus B_d(p_j)$ for each $1\leq j\leq m$, it follows from Lemma 2.1 that

$$\sup_{1\leq j\leq m}(\|\phi_{j,\epsilon}\|_{L^\infty(\Sigma_j)} + \|\nabla\phi_{j,\epsilon}\|_{L^\infty(\Sigma_j)}) \leq c_0\exp[-c_1/\epsilon]$$

for some constants $c_0, c_1>0$. Then (a) follows from the inequality $|e^t-1|\leq|t|e^{|t|}$.

(b) Estimate for $\|DF_\epsilon(0)\|$: Notice that for $h\in H^2(\mathbb{R}^2)$

$$DF_\epsilon(0)h = \Delta h - \frac{1}{\epsilon^2}\exp\left[\sum_j \chi_j \phi_{j,\epsilon}\right]\left(2\,\exp\left[\sum_j \chi_j \phi_{j,\epsilon}\right] - 1\right)h.$$

The proof of (b) is essentially similar to that of Lemma 2.3. We argue by contradiction and suppose there are sequences $\{\epsilon_n\}$ and $\{h_n\} \subset H^2(\mathbb{R}^2)$ such that $\epsilon_n \to 0^+$, $\|h_n\|_{H^2(\mathbb{R}^2)} = 1$, and $\|DF_{\epsilon_n}(0)h_n\|_{L^2(\mathbb{R}^2)} = o(1)$ as $n \to \infty$.

For each $1 \leqslant j \leqslant m$, we let $\tilde{\sigma}_j(x) = \chi(4(x-p_j)/d)$ and $\tilde{h}_n = (1 - \Sigma_j\, \tilde{\sigma}_j)h_n$. Then, $\tilde{h}_n$ satisfies

$$\begin{aligned}\Delta\tilde{h}_n - \frac{1}{\epsilon_n^2}\exp\left[\sum_j \chi_j \phi_{j,\epsilon_n}\right]\left(2\,\exp\left[\sum_j \chi_j \phi_{j,\epsilon_n}\right] - 1\right)\tilde{h}_n \\ = -\sum_j 2\,\nabla h_n \cdot \nabla \tilde{\sigma}_j - \sum_j h_n \Delta\tilde{\sigma}_j + \left(1 - \sum_j \tilde{\sigma}_j\right)DF_{\epsilon_n}(0)h_n. \qquad (3.13)\end{aligned}$$

Recall $\Omega_r^c = [\cup_j B_r(p_j)]^c$ for a constant $r > 0$. Multiplying (3.13) by $\tilde{h}_n$ and integrating by parts, we obtain for n sufficiently large

$$\|\nabla\tilde{h}_n\|^2_{L^2(\Omega^c_{d/4})} + \frac{1}{\epsilon_n^2}\|\tilde{h}_n\|^2_{L^2(\Omega^c_{d/4})} \leqslant C\|\tilde{h}_n\|_{L^2(\Omega^c_{d/4})}(\|h_n\|_{H^1(\Omega^c_{d/4})} + \|DF_{\epsilon_n}(0)h_n\|_{L^2(\Omega^c_{d/4})}) \quad (3.14)$$

for some constant $C = C(d) > 0$. Then, it follows from the assumption that

$$\begin{aligned}\|\nabla h_n\|_{L^2(\Omega^c_{d/2})} + \frac{1}{\epsilon_n}\|h_n\|_{L^2(\Omega^c_{d/2})} &\leqslant \|\nabla\tilde{h}_n\|_{L^2(\Omega^c_{d/4})} + \frac{1}{\epsilon_n}\|\tilde{h}_n\|_{L^2(\Omega^c_{d/4})} \\ &\leqslant C\epsilon_n(\|h_n\|_{H^1(\Omega^c_{d/4})} + \|DF_{\epsilon_n}(0)h_n\|_{L^2(\Omega^c_{d/4})}) \leqslant C\epsilon_n. \qquad (3.15)\end{aligned}$$

Let $\sigma_j^*(x) = \chi(2(x-p_j)/d)$ and $h_n^* = (1 - \Sigma_j\, \sigma_j^*)h_n$. By repeating the above argument (3.13) and (3.14) on $\Omega^c_{d/2}$, we obtain

$$\|\nabla h_n^*\|_{L^2(\Omega^c_{d/2})} + \frac{1}{\epsilon_n}\|h_n^*\|_{L^2(\Omega^c_{d/2})} \leqslant C\epsilon_n(\|h_n\|_{H^1(\Omega^c_{d/2})} + \|DF_{\epsilon_n}(0)h_n\|_{L^2(\Omega^c_{d/2})}) = o(\epsilon_n) \quad \text{as} \quad n \to \infty. \qquad (3.16)$$

Then, it follows that $\|h_n^*\|_{L^2(\Omega^c_{d/2})} = o(\epsilon_n^2)$ and hence $\|\Delta h_n^*\|_{L^2(\Omega^c_{d/2})} = o(1)$. Consequently, $\|h_n\|_{H^2(\Omega_d)} = 1 + o(1)$ as $n \to \infty$.

On the other hand, for each $j = 1, \ldots, m$, let $\chi_j(x) = \chi((x-p_j)/d)$ and $h_{jn} = \chi_j h_n$. Let $\hat{h}_n(x) = h_n(\epsilon_n x + p_j)$, $\hat{\chi}_j(x) = \chi_j(\epsilon_n x + p_j)$, and $\hat{h}_{jn} = \hat{\chi}_j \hat{h}_n$. We also let $\Sigma_j = \{d \leqslant |x - p_j| \leqslant 2d\}$ and $\hat{\Sigma}_0 = \{d/\epsilon_n \leqslant |x| \leqslant 2d/\epsilon_n\}$.

Then it is easily checked that $\hat{h}_{jn}$ satisfies

$$\begin{aligned}L_j\hat{h}_{jn} = 2\,\nabla\hat{h}_n \cdot \nabla\hat{\chi}_j + \hat{h}_n\Delta\hat{\chi}_j + \epsilon_n^2\hat{\chi}_j(x)[DF_{\epsilon_n}(0)h_n](\epsilon_n x + p_j) \\ + [e^{\hat{\chi}_j\phi_j}(2e^{\hat{\chi}_j\phi_j} - 1) - e^{\phi_j}(2e^{\phi_j} - 1)]\hat{h}_{jn} \quad \text{for} \quad |x| \leqslant 2d/\epsilon_n. \qquad (3.17)\end{aligned}$$

Notice that the last term in (3.17) vanishes outside $\hat{\Sigma}_0$. Then, it follows from (3.16) and Lemma 2.3 that

$$\begin{aligned}\|\hat{h}_{jn}\|_{H^2(\mathbb{R}^2)} &\leqslant C(\epsilon_n\|\nabla\hat{h}_n\|_{L^2(\hat{\Sigma}_0)} + \|\hat{h}_n\|_{L^2(\hat{\Sigma}_0)} + \epsilon_n\|DF_{\epsilon_n}(0)h_n\|_{L^2(B_d(p_j))}) \\ &\leqslant C(\epsilon_n\|\nabla h_n\|_{L^2(\Sigma_j)} + \epsilon_n^{-1}\|h_n\|_{L^2(\Sigma_j)} + \epsilon_n\|DF_{\epsilon_n}(0)h_n\|_{L^2(B_d(pj))}) = o(\epsilon_n) \quad \text{as} \quad n \to \infty.\end{aligned}$$

Consequently, $\|h_n\|_{H^2(B_d(pj))} \leqslant \|h_{jn}\|_{H^2(\mathbb{R}^2)} = o(1)$ for each $1 \leqslant j \leqslant m$, which yields a contradiction. Therefore (3.12) is proved.

Since $DF_\epsilon(0): H^2(\mathbb{R}^2) \to L^2(\mathbb{R}^2)$ is self-adjoint (3.12) implies that $DF_\epsilon(0)$ is indeed an iso-

morphism from $H^2(\mathbb{R}^2)$ onto $L^2(\mathbb{R}^2)$, and moreover, $\|[DF_\epsilon(0)]^{-1}\| \leq C$ for $\epsilon > 0$ sufficiently small.

(c) Estimate for $\|DF_\epsilon(z) - DF_\epsilon(0)\|$: Notice that

$$DF_\epsilon(z)h - DF_\epsilon(0)h = -\frac{2}{\epsilon^2}\exp\left[\sum_j 2\chi_j\phi_{j,\epsilon}\right](\exp[2\epsilon^3 z] - 1)h + \frac{1}{\epsilon^2} \times \exp\left[\sum_j \chi_j\phi_{j,\epsilon}\right](\exp[\epsilon^3 z] - 1)h.$$

Then (c) immediately follows from the embedding $H^2(\mathbb{R}^2) \hookrightarrow L^\infty(\mathbb{R}^2)$. □

We are now in a position to prove Theorem 1.1

Proof of Theorem 1.1: Following Ref. 24, we define a functional $\Phi_\epsilon : H^2(\mathbb{R}^2) \to H^2(\mathbb{R}^2)$ by

$$\Phi_\epsilon(v) = v - [DF_\epsilon(0)]^{-1}F_\epsilon(v). \tag{3.18}$$

Then, it suffices to prove that Φ_ϵ admits a unique fixed point in $H^2(\mathbb{R}^2)$ for $\epsilon > 0$ sufficiently small. Let $\mathcal{B} = \{u \in H^2(\mathbb{R}^2) \,|\, \|u\|_{H^2(\mathbb{R}^2)} \leq 1\}$. Then, it follows from Lemma 3.1 and Lemma 3.2 that for each topological solution u_ϵ of (2.1), $z_\epsilon \in H^2(\mathbb{R}^2)$ defined in (3.9) is a fixed point of Φ_ϵ, and moreover, $z_\epsilon \in \mathcal{B}$ for $\epsilon > 0$ sufficiently small.

We claim that $\Phi_\epsilon : \mathcal{B} \to \mathcal{B}$ is a well-defined contraction mapping for $\epsilon > 0$ sufficiently small.

Observe that

$$D\Phi_\epsilon(z)h = -[DF_\epsilon(0)]^{-1}(DF_\epsilon(z) - DF_\epsilon(0))h \quad \text{for} \quad z \in \mathcal{B}, \quad h \in H^2(\mathbb{R}^2).$$

Then, it follows from Lemma 3.3 that if $\epsilon > 0$ is sufficiently small

$$\|D\Phi_\epsilon(z)h\|_{L^2(\mathbb{R}^2)} \leq \|[DF_\epsilon(0)]^{-1}\| \, \|(DF_\epsilon(z) - DF_\epsilon(0))h\|_{L^2(\mathbb{R}^2)} \leq C\epsilon\|h\|_{L^2(\mathbb{R}^2)}$$

for $z \in \mathcal{B}$. Moreover, it also follows from Lemma 3.3 that

$$\|\Phi_\epsilon(0)\|_{H^2(\mathbb{R}^2)} \leq C\|F_\epsilon(0)\|_{L^2(\mathbb{R}^2)} \leq C\exp[-c/\epsilon].$$

Assume that $v, v_1, v_2 \in \mathcal{B}$ are given. If $\epsilon > 0$ is sufficiently small we obtain

$$\begin{aligned}\|\Phi_\epsilon(v)\|_{H^2(\mathbb{R}^2)} &\leq \|\Phi_\epsilon(0)\|_{H^2(\mathbb{R}^2)} + \|\Phi_\epsilon(v) - \Phi_\epsilon(0)\|_{H^2(\mathbb{R}^2)} \\ &\leq \|\Phi_\epsilon(0)\|_{H^2(\mathbb{R}^2)} + (\sup_{z\in\mathcal{B}} \|D\Phi_\epsilon(z)\|)\|v\|_{H^2(\mathbb{R}^2)} \leq C(\exp[-c/\epsilon] + \epsilon),\end{aligned}$$

and

$$\|\Phi_\epsilon(v_1) - \Phi_\epsilon(v_2)\|_{H^2(\mathbb{R}^2)} \leq (\sup_{z\in\mathcal{B}} \|D\Phi_\epsilon(z)\|)\|v_1 - v_2\|_{H^2(\mathbb{R}^2)} \leq C\epsilon\|v_1 - v_2\|_{H^2(\mathbb{R}^2)}.$$

Therefore, if $\epsilon > 0$ is sufficiently small, $\Phi_\epsilon : \mathcal{B} \to \mathcal{B}$ is well-defined contraction mapping, which in turn implies that Φ_ϵ has the unique fixed point $\omega_\epsilon \in \mathcal{B}$.

On the other hand, recall the function z_ϵ defined in (3.9) is also the fixed point of the mapping Φ_ϵ and $\|z_\epsilon\|_{H^2(\mathbb{R}^2)} = o(1)$ as $\epsilon \to 0^+$. Therefore, by the uniqueness of the fixed point, $z_\epsilon = \omega_\epsilon$ for $\epsilon > 0$ sufficiently small.

The proof of Theorem 1.1 is complete. □

We will prove Theorem 1.2 in the rest of this section.

For simplicity, we let $\alpha = 2/\kappa$. Then, it suffices to prove that the following equation:

$$\Delta u = e^u(e^u - 1) + 4\pi\sum_{j=1}^{m} n_j \delta_{\alpha p_j}, \quad \mathbb{R}^2, \tag{3.19}$$

admits a unique topological solution if $\alpha > 0$ is sufficiently small. To this end, we follow the argument in the proof of Theorem 1.1, and show that any topological solution of (3.19) satisfies a specific asymptotic behavior for $\alpha > 0$ sufficiently small. Throughout the rest of this section, $\overline{u}_\alpha$ will denote a topological solution of (3.19).

The following lemma will be very useful when we prove Lemma 3.5.

Lemma 3.4: Let $\alpha > 0$. *There is a constant* $C = C(\{p_j\},\{n_j\}) > 0$ *such that*

$$\int_{\mathbb{R}^2} (e^{\overline{u}_\alpha} - 1)^2 dx \leqslant C.$$

Proof: Let $\overline{v}_{\alpha,j}(x) = \overline{u}_\alpha(x) - 2n_j \ln|x - \alpha p_j|$ for $x \in \mathbb{R}^2$ and $j = 1, \ldots, m$. Then, we claim that

$$\int_{\mathbb{R}^2} (e^{\overline{u}_\alpha} - 1)^2 dx = 4\pi\sum_{j=1}^{m} (n_j^2 + \alpha n_j p_j \cdot \nabla \overline{v}_{\alpha,j}(\alpha p_j)). \tag{3.20}$$

Indeed, (3.20) follows from the Pohozaev identity. Choose a small constant $\varepsilon > 0$ such that $\varepsilon < (1/2)\inf\{|\alpha p_j - \alpha p_k| | j \neq k\}$. Multiplying both sides of (3.19) by $x \cdot \nabla \overline{u}_\alpha$ and integrating on the domain $\mathbb{R}^2 \setminus \cup_j B_\varepsilon(\alpha p_j)$, we obtain

$$\begin{aligned}\sum_{j=1}^{m} \int_{|x-\alpha p_j|=\varepsilon} \left[\frac{1}{\varepsilon}(x \cdot \nabla \overline{u}_\alpha)((x - \alpha p_j) \cdot \nabla \overline{u}_\alpha) - \frac{1}{2\varepsilon}(x \cdot (x - \alpha p_j))|\nabla \overline{u}_\alpha|^2\right] d\sigma \\ = \int_{\mathbb{R}^2 \setminus \cup_j B_\varepsilon(\alpha p_j)} (e^{\overline{u}_\alpha} - 1)^2 dx + \frac{1}{2\varepsilon}\sum_{j=1}^{m} \int_{|x-\alpha p_j|=\varepsilon} (x \cdot (x - \alpha p_j))(e^{\overline{u}_\alpha} - 1)^2 d\sigma. \end{aligned} \tag{3.21}$$

Since $\overline{u}_\alpha(x) = \overline{v}_{\alpha,j}(x) + 2n_j \ln|x - \alpha p_j|$ for each $1 \leqslant j \leqslant m$, it is easily checked that for $|x - \alpha p_j| = \varepsilon$

$$\begin{aligned}&\frac{1}{\varepsilon}(x \cdot \nabla \overline{u}_\alpha)((x - \alpha p_j) \cdot \nabla \overline{u}_\alpha) - \frac{1}{2\varepsilon}(x \cdot (x - \alpha p_j))|\nabla \overline{u}_\alpha|^2 \\ &\quad = \frac{2n_j^2}{\varepsilon} + \frac{2n_j}{\varepsilon}\alpha p_j \cdot \nabla \overline{v}_{\alpha,j}(\alpha p_j) + \frac{2n_j^2}{\varepsilon^3}\alpha p_j \cdot (x - \alpha p_j) + O(1) \quad \text{as} \quad \varepsilon \to 0^+. \end{aligned} \tag{3.22}$$

Then (3.20) is an immediate consequence of (3.21) and (3.22).

Let $\overline{w}_\alpha(x) = \overline{u}_\alpha(x) - \Sigma_{j=1}^m 2n_j \ln|x - \alpha p_j|$. We note that

$$\nabla \overline{w}_\alpha(x) = \frac{1}{2\pi}\int_{\mathbb{R}^2} \frac{x - y}{|x - y|^2} e^{\overline{u}_\alpha(y)}(e^{\overline{u}_\alpha(y)} - 1) dy \quad \text{for} \quad x \in \mathbb{R}^2.$$

If $|x| \leqslant 1$, then we obtain that

$$\begin{aligned}2\pi|\nabla \overline{w}_\alpha(x)| &\leqslant \int_{|y|\leqslant 2} \frac{1}{|x - y|} e^{\overline{u}_\alpha(y)}(1 - e^{\overline{u}_\alpha(y)}) dy + \int_{|y|\geqslant 2} \frac{1}{|x - y|} e^{\overline{u}_\alpha(y)}(1 - e^{\overline{u}_\alpha(y)}) dy \\ &\leqslant \int_{|y|\leqslant 2} \frac{1}{|x - y|} dy + \int_{|y|\geqslant 2} \frac{2}{|y|} e^{\overline{u}_\alpha(y)}(1 - e^{\overline{u}_\alpha(y)}) dy \leqslant C \end{aligned} \tag{3.23}$$

for some constant C depending on $\Sigma_{j=1}^m n_j$. We also note that

$$\nabla \overline{v}_{\alpha,j}(\alpha p_j) = \sum_{k \neq j} \frac{2n_k(p_j - p_k)}{\alpha |p_j - p_k|^2} + \nabla \overline{w}_\alpha(\alpha p_j) \quad \text{for} \quad j = 1, \ldots, m.$$

Then, Lemma 3.4 immediately follows from (3.20) and (3.23). □

Before we proceed, we fix some notations. For $\mu \in \mathbb{R}$, we let

$$f_\mu(x) = \sum_{j=1}^m n_j \ln\left(\frac{|x - \mu p_j|^2}{1 + |x - \mu p_j|^2}\right), \quad g_\mu(x) = \sum_{j=1}^m \frac{4n_j}{(1 + |x - \mu p_j|^2)^2}.$$

Let ϕ be the unique (radial) topological solution of

$$\Delta \phi = e^\phi(e^\phi - 1) + 4\pi\left(\sum_{j=1}^m n_j\right)\delta_{p=0} \quad \text{in} \quad \mathbb{R}^2.$$

Then, it is easily checked that $\overline{u}_\alpha - f_\alpha \in H^2(\mathbb{R}^2)$ and $\phi - f_0 \in H^2(\mathbb{R}^2)$. The following lemma shows the asymptotic behavior of $\overline{u}_\alpha$ for $\alpha > 0$ sufficiently small.

Lemma 3.5: For $\alpha > 0$ sufficiently small, $\overline{u}_\alpha$ can be decomposed as

$$\overline{u}_\alpha = f_\alpha - f_0 + \phi + z_\alpha, \quad z_\alpha \in H^2(\mathbb{R}^2), \tag{3.24}$$

where $\|z_\alpha\|_{H^2(\mathbb{R}^2)} = O(\alpha)$ as $\alpha \to 0^+$.

Proof: The proof of Lemma 3.5 is similar to that of Lemma 3.2, and we just sketch the proof. Let $v_\alpha = \overline{u}_\alpha - f_\alpha$ for simplicity.

Step 1: $v_\alpha \to \phi - f_0$ in $C^2_{loc}(\mathbb{R}^2)$ as $\alpha \to 0^+$.

Indeed, since $e^{\overline{u}_\alpha} \leqslant 1$, it follows from Harnack's inequality (see, e.g., Ref. 5) that either $\{v_\alpha\}$ is bounded in $C^0_{loc}(\mathbb{R}^2)$ or $v_\alpha \to -\infty$ uniformly on any compact subset as $\alpha \to 0^+$. By Lemma 3.4, we conclude that $\{v_\alpha\}$ is bounded in $C^0_{loc}(\mathbb{R}^2)$. Then, the standard diagonal process, Lemma 3.4, and the uniqueness of a radial topological solution imply that $v_\alpha \to \phi - f_0$ in $C^2_{loc}(\mathbb{R}^2)$ as $\alpha \to 0^+$.

Step 2: $\sup_{|x| \geqslant 1} |\overline{u}_\alpha(x) - \phi(x)| \to 0$ as $\alpha \to 0^+$.

Indeed, we note that if $\alpha > 0$ is sufficiently small

$$|f_\alpha(x) - f_0(x)| \leqslant C\alpha(1 + |x|)^{-3} \quad \text{for} \quad |x| \geqslant 1.$$

Consequently, it follows from Step 1 that $\sup_{|x|=1} |\overline{u}_\alpha(x) - \phi(x)| \to 0$ as $\alpha \to 0^+$. Moreover, the maximum principle implies that $\inf_{|x| \geqslant 1} \overline{u}_\alpha$ is bounded below by a fixed constant for $\alpha > 0$ sufficiently small. Therefore, Step 2 follows from Lemma 3.4 and the argument in the proof of Lemma 3.2.

Step 1 and Step 2 imply that $\|v_\alpha - (\phi - f_0)\|_{L^\infty(\mathbb{R}^2)} \to 0$ as $\alpha \to 0^+$. Since

$$|e^{f_\alpha(x)} - e^{f_0(x)}| + |g_\alpha(x) - g_0(x)| \leqslant C\alpha(1 + |x|)^{-3} \quad \text{for} \quad x \in \mathbb{R}^2, \tag{3.25}$$

it follows that

$$|(\Delta - e^\phi(2e^\phi - 1))(v_\alpha - (\phi - f_0))| \leqslant C(|v_\alpha - (\phi - f_0)|^2 + \alpha(1 + |x|)^{-3}).$$

Consequently, Lemma 2.3 implies that

$$\|v_\alpha - (\phi - f_0)\|_{H^2(\mathbb{R}^2)} \leqslant C\alpha$$

for $\alpha > 0$ sufficiently small. Lemma 3.5 is proved. □

We are now in a position to prove Theorem 1.2.

Proof of Theorem 1.2: Fix a small constant $\mu_0 > 0$ and define a mapping $P: H^2(\mathbb{R}^2) \times (-\mu_0, \mu_0) \to L^2(\mathbb{R}^2)$ by

$$P(\psi, \mu) = \Delta\psi - e^{f_\mu - f_0 + \phi + \psi}(e^{f_\mu - f_0 + \phi + \psi} - 1) + e^\phi(e^\phi - 1) - g_\mu + g_0.$$

Then, it is easily checked that (3.19) admits a solution $\overline{u}_\mu$ of the form (3.24) if and only if $P(z_\mu, \mu) = 0$.

Lemma 2.3 implies that $D_\psi P(0,0)$ is an isomorphism from $H^2(\mathbb{R}^2)$ onto $L^2(\mathbb{R}^2)$. Since $P(0,0)=0$, it follows from the implicit function theorem that there is a positive constant $\mu_1 < \mu_0$ such that for each $-\mu_1 < \mu < \mu_1$ the mapping $P(\cdot,\mu)$ admits a unique zero $v=v(\mu)$ in $H^2(\mathbb{R}^2)$. In other words, if $\alpha>0$ is sufficiently small then Eq. (3.19) admits a unique solution which takes the form (3.24) with $\|z_\alpha\|_{H^2(\mathbb{R}^2)} \to 0$ as $\alpha \to 0^+$.

The proof of Theorem 1.2 is complete. □

IV. UNIQUENESS RESULT FOR COMPACT DOMAINS

In the previous section, we obtained *a priori* estimates for the topological solution u_ϵ for $\epsilon > 0$ sufficiently small by dividing $\mathbb{R}^2$ into two disjoint sets, $\Omega_d = U_j B_d(p_j)$ and Ω_d^c. Actually, by making use of the topological boundary condition (2.2), we have proved that u_ϵ is bounded below on Ω_d^c, which is the first step for the proof of Lemma 3.1 and Lemma 3.2.

In this section, we consider a general situation for (2.1), and study (2.1) on a compact Riemannian 2-manifold (Ω, γ) without boundary

$$\Delta_0 u = \frac{1}{\epsilon^2} e^{u_\epsilon}(e^{u_\epsilon} - 1) + 4\pi \sum_{j=1}^{m} n_j \delta_{p_j} \quad \text{in} \quad \Omega, \tag{4.1}$$

where Δ_0 is the Laplace–Beltrami operator on (Ω, γ). In this case, every solution of (4.1) is not bounded below on a compact subset K of $\Omega \backslash \{p_1, \ldots, p_m\}$ because we do not have the topological boundary condition (2.2) anymore. Indeed, it has been proved by Ding *et al.*[14] that for $\epsilon > 0$ sufficiently small (4.1) admits at least two solutions $u_{\epsilon,1}$ and $u_{\epsilon,2}$ such that

(a) $u_{\epsilon,1} \to 0$ a.e. as $\epsilon \to 0^+$ (type I);
(b) $u_{\epsilon,2} \to -\infty$ a.e. as $\epsilon \to 0^+$.

In what follows, we will call u_ϵ a type-I solution if u_ϵ satisfies (4.1) and the above-mentioned asymptotic behavior (a).

Let $G(x,y)$ be the Green function which satisfies

$$\Delta_x G(x,y) = \delta_y - \frac{1}{|\Omega|}, \quad \Omega$$

$$\int_\Omega G(x,y) dV_g(x) = 0.$$

Then, it follows from the arguments in Refs. 29 and 14 that u_ϵ is a type-I solution of (4.1) if and only if $u_\epsilon - \Sigma_j 4\pi n_j G(x,p_j)$ is bounded below by a constant for $\epsilon > 0$ sufficiently small.

We limit our attention to the type-I solutions, and establish a uniqueness result for $\epsilon > 0$ sufficiently small. More precisely, we have

Theorem 4.1: *Fix any constant* $C_* < \inf_{x\in\Omega}(-\Sigma_j 4\pi n_j G(x,p_j))$. *Then, there is a constant* $\epsilon_* > 0$ *such that for each* $0 < \epsilon < \epsilon_*$ (4.1) *admits a unique solution* u_ϵ *which satisfies* $u_\epsilon - \Sigma_j 4\pi n_j G(x,p_j) \geqslant C_*$.

Remark: The constant ϵ_* in Theorem 4.1 depends on C_*, $\{p_j\}$, $\{n_j\}$ and the Riemannian manifold (Ω, γ).

Theorem 1.3 is a direct consequence of Theorem 4.1. We can prove Theorem 4.1 by making use of the argument used in Sec. III. Indeed, every crucial estimate in the previous section is essentially local. We will choose a suitable atlas $\{(U_l, \varphi_l)\}_{l=1}^k$ on Ω, and repeat the proof of Theorem 1.1 on each local chart (U_l, φ_l).

Theorem 4.1 will be proved in several steps, and we will just present the outline of the proof. To this end, we choose an atlas $\{(U_l, x_l)\}_{l=1}^k$ on Ω with the property that

(i) For $1 \leqslant l \leqslant k$, $x_l(U_l)$ is an open neighborhood of the origin in $\mathbb{R}^2$. Moreover, $p_j \in U_j$ and $x_j(p_j) = 0$ for each $1 \leqslant j \leqslant m$.

(ii) For $1 \leqslant l \leqslant k$, (U_l, x_l) is an isothermal coordinate, and there is a smooth function ξ_l such that $\xi_l(0)=0$, $\nabla \xi_l(0)=0$ and $ds^2 = e^{\xi_l(x)}|dx|^2$ on (U_l, x_l).

(iii) For $1 \leqslant j \leqslant m$, there is a constant $0 < d < 1/2$ such that $\{x \in \mathbb{R}^2 | |x| \leqslant 2d\} \subset x_j(U_j)$ and $\|\nabla \xi_j\|_{L^\infty(|x| \leqslant 2d)} \leqslant 1$. Moreover, we assume that $x_j^{-1}(\{|x| \leqslant 2d\}) \cap U_l = \emptyset$ for $l \neq j$.

In what follows, we let

$$V_d = \cup_{j=1}^m x_j^{-1}(\{x \in \mathbb{R}^2 | |x| \leqslant d\}.$$

We first present the following lemma similar to Lemma 3.1.

Lemma 4.1: For $\epsilon > 0$ sufficiently small, there are constants $C, c > 0$ such that

$$\|u_\epsilon\|_{H^2(V_d^c)} \leqslant Ce^{-c/\epsilon}.$$

Proof: On each (U_l, x_l), Eq. (4.1) can be written as

$$\Delta u_\epsilon = \frac{1}{\epsilon^2} e^{\xi_l} e^{u_\epsilon}(e^{u_\epsilon} - 1), \quad |x| \neq 0,$$

where $\Delta = \partial_1^2 + \partial_2^2$ stands for a Laplacian in $\mathbb{R}^2$. Then, the proof is similar to that of Lemma 3.1 (Steps 2, 3). We skip the details. □

We now investigate the asymptotic behavior of u_ϵ near each $p_j \in \Omega$. For each $1 \leqslant j \leqslant m$ (4.1) may be written as

$$\Delta u = \frac{1}{\epsilon^2} e^{\xi_j} e^u (e^u - 1) + 4\pi n_j \delta_{p=0}, \quad \text{for} \quad |x| \leqslant 2d. \tag{4.2}$$

For each $1 \leqslant j \leqslant m$, let $\hat{\xi}_j(x) = \xi_j(\epsilon x)$ for $|x| < 2d/\epsilon$, and

$$\hat{f}_{j,\epsilon}(x) = \begin{cases} e^{\hat{\xi}_j} e^{\phi_j}(2e^{\phi_j} - 1), & |x| \leqslant 2d/\epsilon, \\ e^{\phi_j}(2e^{\phi_j} - 1), & |x| > 2d/\epsilon. \end{cases}$$

The following corollary is the direct consequence of Lemma 2.3.

Corollary 4.1: For $1 \leqslant j \leqslant m$, there are constants $c > 0$ and $\epsilon_1 > 0$ such that

$$\|(\Delta - \hat{f}_{j,\epsilon})v\|_{L^2(\mathbb{R}^2)} \geqslant c\|v\|_{H^2(\mathbb{R}^2)}$$

for all $v \in H^2(\mathbb{R}^2)$ and $0 < \epsilon < \epsilon_1$. Therefore, $\Delta - \hat{f}_{j,\epsilon}$ is an isomorphism from $H^2(\mathbb{R}^2)$ onto $L^2(\mathbb{R}^2)$ for $0 < \epsilon < \epsilon_1$.

For each $1 \leqslant j \leqslant m$ and $0 < \epsilon < \epsilon_1$, let $\hat{\psi}_{j,\epsilon} \in H^2(\mathbb{R}^2)$ be the unique solution of

$$(\Delta - \hat{f}_{j,\epsilon})\hat{\psi}_{j,\epsilon} = g_{j,\epsilon} \quad \text{in} \quad \mathbb{R}^2, \tag{4.3}$$

where $g_{j,\epsilon} \in L^2(\mathbb{R}^2)$ is defined by

$$g_{j,\epsilon}(x) = \begin{cases} (e^{\hat{\xi}_j} - 1)e^{\phi_j}(e^{\phi_j} - 1), & |x| \leqslant 2d/\epsilon \\ 0, & |x| > 2d/\epsilon. \end{cases}$$

Let

$$\alpha_j(\epsilon) = \|g_{j,\epsilon}\|_{L^2(\mathbb{R}^2)}.$$

Since $\xi_j(0) = 0$ and $\nabla \xi_j(0) = 0$, it follows that $\alpha_j(\epsilon) \leqslant C\epsilon^2$ for all $1 \leqslant j \leqslant m$.

Lemma 4.2: There are positive constants C, ϵ_1, and c_1 such that for $0 < \epsilon < \epsilon_1$

$$|\hat{\psi}_{j,\epsilon}(x)| \leqslant C\alpha_j(\epsilon)e^{-c_1|x|}, \quad x \in \mathbb{R}^2. \tag{4.4}$$

Proof: Corollary 4.1 implies that $\|\hat{\psi}_{j,\epsilon}\|_{L^\infty} \leqslant C\|\hat{\psi}_{j,\epsilon}\|_{H^2(\mathbb{R}^2)} \leqslant C\alpha_j(\epsilon)$. Choose two constants R_0 and $0<c_0<1$ such that $\hat{f}_{j,\epsilon}(x) \geqslant 2c_0^2$ for $|x| \geqslant R_0$. Consider a comparison function

$$\varphi(x) = C_0\alpha_j(\epsilon)e^{-c_0|x|}, \quad x \in \mathbb{R}^2.$$

Since $|\phi_j(x)| \leqslant Ce^{-|x|}$ for $x \in \mathbb{R}^2$, there are constants $R>R_0$ and $\epsilon_0>0$ such that

$$(\Delta - \hat{f}_{j,\epsilon})(\hat{\psi}_{j,\epsilon} - \varphi) > 0 \quad \text{for} \quad |x| > R \quad \text{and} \quad 0 < \epsilon < \epsilon_1.$$

Fix a constant $C_0>0$ such that $\hat{\psi}_{j,\epsilon} - \varphi < 0$ for $|x|=R$. Then, the weak maximum principle implies that $\hat{\psi}_{j,\epsilon} \leqslant \varphi$ for $|x|>R$.

Similarly, we can choose positive constants R_1 and C_1 such that $\hat{\psi}_{j,\epsilon} > -C_1\alpha_j(\epsilon)e^{-c_0|x|}$ for $|x| > R_1$ and $0<\epsilon<\epsilon_1$. □

Let $u_{\epsilon,j}$ be a solution of (4.2) such that $\sup_{|x|=2d}|u_{\epsilon,j}(x)| \to 0$ as $\epsilon \to 0^+$. Let $\hat{u}_{\epsilon,j}(x) = u_{\epsilon,j}(\epsilon x)$ for $|x| \leqslant 2d/\epsilon$.

Lemma 4.3: For $\epsilon>0$ sufficiently small, there are constants $C, c>0$ such that

$$\|\hat{u}_{\epsilon,j} - \phi_j - \hat{\psi}_{j,\epsilon}\|_{H^2(|x|\leqslant d/\epsilon)} \leqslant C(e^{-c/\epsilon} + \epsilon^2\alpha_j(\epsilon)). \tag{4.5}$$

Proof: It follows from the Pohozaev identity and the gradient estimate (Lemma A) that

$$\frac{1}{\epsilon^2}\int_{|x|<2d}\left(1 + \frac{1}{2}(x \cdot \nabla \xi_j)\right)e^{\xi_j}(e^{u_{\epsilon,j}} - 1)^2 dx = 4\pi n_j^2 + o(e^{-c/\epsilon})$$

for some constant $c>0$. Since $\|x \cdot \nabla \xi_j\|_{L^\infty(|x|<2d)} \leqslant 1$, it follows that

$$\int_{|x|<2d/\epsilon} e^{\hat{\xi}_j}(e^{\hat{u}_{\epsilon,j}} - 1)^2 dx \leqslant C. \tag{4.6}$$

Step 1: We claim $\sup_{|x|\leqslant 2d/\epsilon}|\hat{u}_{\epsilon,j}(x) - \phi_j(x)| \to 0$ as $\epsilon \to 0^+$.

Indeed, it follows from the argument in Lemma 3.2 (Step 1) and (4.6) that $\hat{u}_{\epsilon,j} - \phi_j \to 0$ in $C^2_{loc}(\mathbb{R}^2)$. For the sake of simplicity, we let $\hat{w}_{\epsilon,j} = \hat{u}_{\epsilon,j} - \phi_j$. Suppose that there are sequences $\{\epsilon_n\}$ and $\{x_n\}$ such that $\epsilon_n \to 0$, $|x_n| < 2d/\epsilon_n$, and

$$|\hat{w}_{\epsilon_n,j}(x_n)| = \sup_{|x|\leqslant 2d/\epsilon_n}|\hat{w}_{\epsilon_n,j}(x)| \geqslant \gamma_0$$

for some constant $\gamma_0>0$. It is easy to check that $|x_n| \to \infty$ and $\epsilon_n|x_n| \to 0$. Since $\hat{\xi}_j(x_n) = o(1)$, we can follow the argument in Lemma 3.2 (Step 2) and conclude that $\hat{w}_{\epsilon_n,j}(x_n) \to -\infty$. Then it follows from the Harnack inequality that $\hat{w}_{\epsilon_n,j} \to -\infty$ uniformly on $B_R(x_n)$ for any constant $R>0$, which contradicts (4.6). Therefore, our claim is proved.

Step 2: We now prove (4.5). Making use of the inequality $0 \leqslant e^t - 1 - t \leqslant t^2 e^{|t|}$, $t \in \mathbb{R}$, we can verify that

$$(\Delta - \hat{f}_{j,\epsilon})(\hat{\psi}_{\epsilon,j} - \hat{\psi}_{j,\epsilon}) = O(1)|\hat{w}_{\epsilon,j}|^2 \quad \text{for} \quad |x| \leqslant 2d/\epsilon. \tag{4.7}$$

Consider a cutoff function $\sigma \in C_0^\infty(\mathbb{R}^2)$ such that $0 \leqslant \sigma \leqslant 1$, $\sigma \equiv 1$ for $|x| \leqslant d$, and $\sigma \equiv 0$ for $|x| \geqslant 2d$. Let $\sigma_\epsilon(x) = \sigma(\epsilon x)$. Then, we obtain

$$(\Delta - \hat{f}_{j,\epsilon})(\sigma_\epsilon(\hat{w}_{\epsilon,j} - \hat{\psi}_{j,\epsilon})) = \sigma_\epsilon((\Delta - \hat{f}_{\epsilon,j})(\hat{w}_{\epsilon,j} - \hat{\psi}_{j,\epsilon})) + [\Delta, \sigma_\epsilon]\hat{w}_{\epsilon,j} - [\Delta, \sigma_\epsilon]\hat{\psi}_{\epsilon,j},$$

where $[\Delta, \sigma_\epsilon]f = f\Delta\sigma_\epsilon + 2\nabla\sigma_\epsilon \cdot \nabla f$. Corollary 4.1 and (4.7) imply that

$$\|\sigma_\epsilon(\hat{w}_{\epsilon,j}-\hat{\psi}_{j,\epsilon})\|_{H^2(\mathbb{R}^2)} \leqslant C(\|[\Delta,\sigma_\epsilon]\hat{w}_{\epsilon,j}\|_{L^2(\mathbb{R}^2)} + \|[\Delta,\sigma_\epsilon]\hat{\psi}_{j,\epsilon}\|_{L^2(\mathbb{R}^2)} + \|\hat{\psi}_{j,\epsilon}\|^2_{L^4(\mathbb{R}^2)}) + C\|\hat{w}_{\epsilon,j}+\hat{\psi}_{j,\epsilon}\|_{L^\infty}\|\sigma_\epsilon(\hat{w}_{\epsilon,j}-\hat{\psi}_{j,\epsilon})\|_{L^2(\mathbb{R}^2)}. \tag{4.8}$$

Moreover, it follows from elliptic estimates that

$$\|\nabla\hat{\psi}_{j,\epsilon}\|_{L^\infty(d/\epsilon\leqslant|x|\leqslant 2d/\epsilon)} \leqslant Ce^{-c/\epsilon}.$$

Then (4.5) is an immediate consequence of (4.4) and (4.8), and Lemma 4.1. □

Recall that ϕ_j is the (unique) radial solution of (2.5). Let $\sigma\in C_0^\infty(\mathbb{R}^2)$ be a cutoff function such that $0\leqslant\sigma\leqslant 1$, $\sigma\equiv 1$ on $B_d(0)$, and $\sigma\equiv 0$ on $B^c_{2d}(0)$. Let $\psi_{j,\epsilon}(x)=\hat{\psi}_{j,\epsilon}(x/\epsilon)$ and $\phi^*_{j,\epsilon}(x)=\phi_j(x/\epsilon)$ for $x\in\mathbb{R}^2$.

For each $1\leqslant j\leqslant m$, we let

$$\overline{\sigma_j}=\sigma\circ x_j,\quad \overline{\phi}_{j,\epsilon}=\phi^*_{j,\epsilon}\circ x_j \quad\text{and}\quad \overline{\psi}_{j,\epsilon}=\psi_{j,\epsilon}\circ x_j.$$

Then, Lemma 4.1 and Lemma 4.3 imply that

Proposition 4.1: Let u_ϵ be a type-I solution of (4.1). *For $\epsilon>0$ sufficiently small, u_ϵ is decomposed as*

$$u_\epsilon=\sum_{j=1}^m \overline{\sigma_j}(\overline{\phi}_{j,\epsilon}+\overline{\psi}_{j,\epsilon})+\epsilon^{5/2}v_\epsilon \tag{4.9}$$

for some $v_\epsilon\in H^2(\Omega)$ such that $\|v_\epsilon\|_{H^2(\Omega)}=o(1)$ as $\epsilon\to 0^+$.

In what follows, we prove that (4.1) admits a unique solution of the form (4.9) if $\epsilon>0$ is sufficiently small.

Construction of a contraction mapping

Define $F_\epsilon: H^2(\Omega)\to L^2(\Omega)$ by

$$F_\epsilon(v)=\Delta_0 v-\frac{1}{\epsilon^{9/2}}\exp\left[\epsilon^{5/2}v+\sum_{j=1}^m\overline{\sigma_j}(\overline{\phi}_{j,\epsilon}+\overline{\psi}_{j,\epsilon})\right]\left(\exp\left[\epsilon^{5/2}v+\sum_{j=1}^m\overline{\sigma_j}(\overline{\phi}_{j,\epsilon}+\overline{\psi}_{j,\epsilon})\right]-1\right) + \frac{1}{\epsilon^{5/2}}\sum_{j=1}^m(\overline{\sigma_j}\Delta_0\overline{\phi}_{j,\epsilon}-4\pi n_j\delta_{p_j})+\frac{1}{\epsilon^{5/2}}\sum_{j=1}^m\overline{\sigma_j}\Delta_0\overline{\psi}_{j,\epsilon}+\frac{1}{\epsilon^{5/2}}\sum_{j=1}^m[\Delta_0,\overline{\sigma_j}](\overline{\phi}_{j,\epsilon}+\overline{\psi}_{j,\epsilon}),$$

where $[\Delta_0,\overline{\sigma_j}]f=f\Delta_0\overline{\sigma_j}+2\nabla f\cdot\nabla\overline{\sigma_j}$. It is easily checked that (4.1) admits a solution u_ϵ of the form (4.9) if and only if $F_\epsilon(v_\epsilon)=0$.

We have the following lemma similar to Lemma 3.3.

Lemma 4.4: There is a constant $\epsilon_1>0$ such that if $0<\epsilon<\epsilon_1$ then we have

(a) $\|F_\epsilon(0)\|_{L^2(\Omega)}\leqslant C(\epsilon^{-3/2}\max_{1\leqslant j\leqslant m}\alpha_j(\epsilon)+e^{-c/\epsilon})$ *for some constants $C,c>0$.*

(b) $DF_\epsilon(0)$ *is an isomophism from $H^2(\Omega)$ onto $L^2(\Omega)$, and there is a constant $C>0$ such that*

$$\|DF_\epsilon(0)h\|_{L^2(\Omega)}\geqslant C\|h\|_{H^2(\Omega)} \quad \textit{for all} \quad h\in H^2(\Omega). \tag{4.10}$$

(c) $\|DF_\epsilon(z)h-DF_\epsilon(0)h\|_{L^2(\Omega)}\leqslant C\epsilon^{1/2}\|h\|_{H^2(\Omega)}$ *for* $\|z\|_{H^2(\Omega)}\leqslant 1$.

Proof: The proof of Lemma 4.4 is similar to that of Lemma 3.3, and we sketch it in brief.

Lemma 4.2 implies that there are some constants $C,c>0$ such that $|F_\epsilon(0)|\leqslant Ce^{-c/\epsilon}$ on V_d^c. For each $1\leqslant j\leqslant m$, it follows that on each local coordinate chart (U_j,x_j)

$$F_\epsilon(0) = -\frac{1}{\epsilon^{9/2}} e^{\phi^*_{j,\epsilon^+}\psi_{j,\epsilon}}(e^{\phi^*_{j,\epsilon^+}\psi_{j,\epsilon}} - 1) + \frac{1}{\epsilon^{9/2}} e^{-\xi_j} e^{\phi^*_{j,\epsilon}}(e^{\phi^*_{j,\epsilon}} - 1) + \frac{1}{\epsilon^{9/2}} e^{\phi^*_{j,\epsilon}}(2e^{\phi^*_{j,\epsilon}} - 1)\psi_{j,\epsilon}$$

$$+ \frac{1}{\epsilon^{9/2}}(1 - e^{-\xi_j}) e^{\phi^*_{j,\epsilon}}(e^{\phi^*_{j,\epsilon}} - 1) = \frac{1}{\epsilon^{9/2}} O(1)|\psi_{j,\epsilon}|^2 \quad \text{for} \quad |x| \leqslant d.$$

Since $\alpha_j(\epsilon) \leqslant C\epsilon^2$, we obtain

$$\|F_\epsilon(0)\|_{L^2(x_j^{-1}(B_d(0)))} \leqslant C\epsilon^{-7/2} \|\hat{\psi}_{j,\epsilon}\|^2_{L^4(B_{d/\epsilon}(0))} \leqslant C\epsilon^{-3/2}\alpha_j(\epsilon).$$

Therefore (a) is proved. In particular, $\|F_\epsilon(0)\|_{L^2(\Omega)} = O(\epsilon^{1/2})$ as $\epsilon \to 0^+$.

Making use of (4.4) and the argument in the proof of Lemma 3.3, we can also prove (b) and (c). We skip the details. See Refs. 1, 2, 4, 21, and 26. □

We are now in a position to prove Theorem 4.1.

Proof of Theorem 4.1: Let $\mathcal{B} = \{v \in H^2(\Omega) | \|v\|_{H^2(\Omega)} \leqslant 1\}$, and define a mapping $\Phi_\epsilon : H^2(\Omega) \to H^2(\Omega)$ by

$$\Phi_\epsilon(v) = v - [DF_\epsilon(0)]^{-1} F_\epsilon(v).$$

It is easily checked that (4.1) admits a solution u_ϵ of the form (4.9) if and only if $v_\epsilon \in H^2(\Omega)$ is a fixed point of Φ_ϵ.

It follows from Lemma 4.4 that Φ_ϵ is a well-defined contraction mapping from $\mathcal{B}$ into $\mathcal{B}$ if $\epsilon > 0$ is sufficiently small. Therefore, if $\epsilon > 0$ is sufficiently small then Φ_ϵ admits a unique fixed point in $\mathcal{B}$.

On the other hand, Proposition 4.1 implies that v_ϵ defined in (4.9) is a fixed point of Φ_ϵ, and moreover, $v_\epsilon \in \mathcal{B}$ if $\epsilon > 0$ is sufficiently small. Therefore, v_ϵ in (4.9) is the unique fixed point of Φ_ϵ for $\epsilon > 0$ sufficiently small.

The proof of Theorem 1.3 is complete. □

Weak field reduction in teleparallel coframe gravity: Vacuum case

Yakov Itin[a)]
Institute of Mathematics, Hebrew University of Jerusalem, Givat Ram, Jerusalem 91904, Israel

(Received 11 March 2004; accepted 11 September 2004;
published online 17 December 2004)

The teleparallel coframe gravity may be viewed as a generalization of the standard GR. A coframe (a field of four independent 1-forms) is considered, in this approach, to be a basic dynamical variable. The metric tensor is treated as a secondary structure. The general Lagrangian, quadratic in the first order derivatives of the coframe field is not unique. It involves three dimensionless free parameters. We consider a weak field approximation of the general coframe teleparallel model. In the linear approximation, the field variable, the coframe, is covariantly reduced to the superposition of the symmetric and antisymmetric field. We require this reduction to be preserved on the levels of the Lagrangian, of the field equations, and of the conserved currents. This occurs if and only if the pure Yang–Mills-type term is removed from the Lagrangian. The absence of this term is known to be necessary and sufficient for the existence of the viable (Schwarzschild) spherical-symmetric solution. Moreover, the same condition guarantees the absence of ghosts and tachyons in particle content of the theory. The condition above is shown recently to be necessary for a well-defined Hamiltonian formulation of the model. Here we derive the same condition in the Lagrangian formulation by means of the weak field reduction. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1819523]

I. INTRODUCTION

Einstein's general relativity (GR) is very successful in describing the long distance (macroscopic) gravity phenomena. This theory, however, encounters serious difficulties on microscopic distances. So far essential problems appear in all attempts to quantize the standard GR (for recent review, see, e.g., Ref. 1). Also, the Lagrangian structure of GR differs, in principle, from the ordinary microscopic gauge theories. In particular, a covariant conserved energy-momentum tensor for the gravitational field cannot be constructed in the framework of GR. Consequently, the study of alternative models of gravity is justified from the physical as well as from the mathematical point of view. Even in the case when GR is unique true theory of gravity, consideration of close alternative models can shed light on the properties of GR itself.

Among various alternative constructions, the Poincaré gauge theory of gravity, see Refs. 2–11, is of a special interest. This theory proposes a natural bridge between gauge and geometrical theories. Moreover, it has a straightforward generalization to the metric-affine theory of gravity,[5] which involves a wide spectra of space–time geometries. However, it was elucidated recently that even the restriction of the Poincaré gauge theory to the teleparallel model provides a reasonable alternative to GR.

A. Coframe (teleparallel) gravity—basic facts and notations

We start with a brief account of the coframe (teleparallel) model of gravity and establish the notations used in this paper. Details, different approaches, and additional references can be found in Refs. 12–28.

Let a four-dimensional (4D) differential manifold $\mathcal{M}$ be endowed with two smooth fields: a frame field e_a and a coframe field ϑ^a. In a local coordinate chart,

$$e_a = e_a{}^\mu(x)\,\partial/\partial x^\mu, \quad \vartheta^a = \vartheta^a_\mu(x)\mathrm{d}x^\mu, \quad a,\mu = 0,1,2,3. \tag{1.1}$$

These fields allow to compare two vectors (more generally, two tensors) attached to different points of the manifold. It is referred to as the *teleparallel structure* on $\mathcal{M}$. The two basic fields are assumed to fulfill the dual relation: $e_a \rfloor \vartheta^b = \delta^b_a$. We denote by $\rfloor$ the interior product operator $\mathcal{X}\times\Lambda^p \to \Lambda^{p-1}$ that, for an arbitrary vector field $X \in \mathcal{X}$ and a p-form field $w \in \Lambda^p$, $X \rfloor w := w(X,\ldots)$. So only one of the fields, e_a or ϑ^a, is independent. Thus, two alternative (but, principle, equivalent) representations of the teleparallel geometry are possible.

The *frame representation* is based on a complex $\{\mathcal{M}, e_a\}$ and applies the tensorial calculus as the main mathematical tool similar to the Einstein tensorial representation of GR.

The *coframe representation*, which deals with a complex $\{\mathcal{M}, \vartheta^a\}$, applies the exterior form technique. In the present paper, we use this approach and call it the *coframe gravity*, in contrast to the metric gravity of GR.

In a wider context, the coframe field appears as one of the basic dynamical variables in the Poincaré gauge gravity and in the metric-affine gravity. To extract the pure coframe sector, in these theories, one must require vanishing of the curvature. Here, we treat the coframe field as a self-consistent dynamical variable with its own covariant operators: wedge product, Hodge map and exterior derivative. These two approaches (one with a trivial connection and the other without explicit exhibition of a connection) are principally equivalent.

The indices in (1.1) are basically different. The greek indices refer to the coordinate space and describe the behavior of tensors under the group of diffeomorphisms of the manifold $\mathcal{M}$. The italic indices denote different 1-forms of the coframe. The corresponding group of transformations, SO(1,3), comes together with its natural invariant $\eta_{ab} = \mathrm{diag}(1,-1,-1,-1)$.

The metric tensor on $\mathcal{M}$ is expressed via the coframe as

$$g = \eta_{ab}\vartheta^a \otimes \vartheta^b, \tag{1.2}$$

i.e., the coframe is postulated to be pseudo-orthonormal. The coframe field and all the objects constructed from it are assumed to be global (rigid) covariant. In other words, all the constructions are required to be covariant under the global transformations $\vartheta^a \to A^a{}_b\vartheta^b$ with a constant matrix $A^a{}_b \in \mathrm{SO}(1,3)$. The metric tensor (1.2) is invariant under a wider group of transformation: local (pointwise) transformations of the coframe with $A^a{}_b = A^a{}_b(x)$.

Consider a Lagrangian density, which is (i) diffeomorphism invariant, (ii) invariant under global SO(1,3) transformations of the coframe, and (iii) quadratic in the exterior derivatives of the coframe. The most general Lagrangian of this form is a linear combination,[23,26]

$$\mathcal{L} = \frac{1}{2}\sum_{i=1}^{3} \rho_i{}^{(i)}\mathcal{L}, \tag{1.3}$$

where ρ_1, ρ_2, ρ_3 are free dimensionless parameters. The linear independent 4-forms appearing here are expressed via the coframe *field strength*, $\mathcal{C}^a := \mathrm{d}\vartheta^a$,

$${}^{(1)}\mathcal{L} = \mathcal{C}^a \wedge {}^*\,\mathcal{C}_a, \tag{1.4}$$

$${}^{(2)}\mathcal{L} = (\mathcal{C}_a \wedge \vartheta^a) \wedge {}^*\,(\mathcal{C}_b \wedge \vartheta^b), \tag{1.5}$$

$$^{(3)}\mathcal{L} = (\mathcal{C}_a \wedge \vartheta^b) \wedge * (\mathcal{C}_b \wedge \vartheta^a). \tag{1.6}$$

The Hodge dual operator * is defined by the pseudo-orthonormal coframe ϑ^a or, equivalently, by the metric (1.2). One may try to include in the Lagrangian some invariant expressions of the second order (similarly to the Hilbert–Einstein Lagrangian). Such terms, however, are reduced to total derivatives and do not affect the field equations and the Noether conserved currents. So (1.3) is the most general Lagrangian that generates the field equations of the second order.

Let us introduce the notion of the *field strength*

$$\mathcal{F}^a := {}^{(1)}\mathcal{F}^a + {}^{(2)}\mathcal{F}^a + {}^{(3)}\mathcal{F}^a, \tag{1.7}$$

with

$${}^{(1)}\mathcal{F}^a := (\rho_1 + \rho_3)\mathcal{C}^a, \tag{1.8}$$

$${}^{(2)}\mathcal{F}^a := \rho_2\, e^a \rfloor (\vartheta^m \wedge \mathcal{C}_m), \tag{1.9}$$

$${}^{(3)}\mathcal{F}^a := -\rho_3 \vartheta^a \wedge (e_m \rfloor \mathcal{C}^m). \tag{1.10}$$

Such separation of the strength $\mathcal{F}^a$ involves two scalar-valued forms $\vartheta^m \wedge \mathcal{C}_m$ and $e_m \rfloor \mathcal{C}^m$. So some calculations are simplified. For irreducible decomposition of $\mathcal{F}^a$, see Refs. 5 and 23.

In the notations (1.8)–(1.10), the coframe Lagrangian (1.3) takes a form similar to the Maxwell Lagrangian,

$$\mathcal{L} = \tfrac{1}{2}\mathcal{C}^a \wedge * \mathcal{F}_a. \tag{1.11}$$

The free variation of (1.11) relative to the coframe ϑ^a must take into account also the variation of the Hodge dual operator, which implicitly depends on the coframe. It yields the field equation of the form[23]

$$\mathrm{d} * \mathcal{F}^a = \mathcal{T}^a, \tag{1.12}$$

where the 3-form $\mathcal{T}^a$ is the energy-momentum current of the coframe field

$$\mathcal{T}_a = (e_a \rfloor \mathcal{C}_m) \wedge * \mathcal{F}^m - e_a \rfloor \mathcal{L}. \tag{1.13}$$

The conservation law for this 3-form: $\mathrm{d}\mathcal{T}_a = 0$ is a straightforward consequence of (1.12).

B. Viable models—a problem of physical motivation

A general quadratic coframe model, which is global SO(1,3) invariant, involves three parameters,

$$\rho_1, \quad \rho_2, \quad \rho_3 \text{ — free}. \tag{1.14}$$

The ordinary GR is extracted from this family by requiring of the *local* SO(1,3) invariance, which is realized by the following restrictions of the parameters:

$$\rho_1 = 0, \quad 2\rho_2 + \rho_3 = 0. \tag{1.15}$$

The analysis of exact solutions[28] to the field equation (1.12) shows that the Schwarzschild solution appears even for a wider set of parameters (viable set),

$$\rho_1 = 0, \quad \rho_2, \quad \rho_3 \text{ — free}. \tag{1.16}$$

Moreover, for $\rho_1 \neq 0$, spherical-symmetric static solutions to (1.12) do not have the Newtonian behavior at infinity.[28]

So a problem arises: *Which physical motivated requirement extracts the viable set of parameters?*

The quantum-theory solution to this problem is known for a long time. In Refs. 29–33 it was shown that the requirement (1.16) is necessary and sufficient for the absence of ghosts and tachyons in particle content of the theory. Another motivation for (1.16) comes from the requirement that the theory must have a well-defined Hamiltonian formulation (Ref. 34).

In this paper we look for a motivation of (1.16) on a classical Lagrangian level. We deal with linear approximation of the general coframe model. The coframe variable can be treated, in this approximation, as a regular 4×4 matrix. Consequently, it reduced to a composition of two independent variables: the symmetric and the antisymmetric fields.

Our main result is as follows: Only for (1.16), the coframe model is reduced to two independent models, every one with its own Lagrangian, field equation, and conserved current. In other words, the viable model is exactly this one that approaches the *free-field limit*, i.e., any interaction between the approximately independent fields appears only in higher orders.

Linear approximation of coframe models was usually applied for studying the deviation of teleparallel gravity from the standard GR, and for comparison with the observation data, see Refs. 3, 4, 30, and 31. In our approach the reduction of the lower order terms is used as a theoretical device. We show that this condition is enough to distinguish the set of viable models. The relation between these two approaches requires a further consideration.

II. WEAK FIELD REDUCTION

A. Linear approximations

To study the approximate solutions to (1.12), we start with a trivial exact solution, a *holonomic coframe*, for which,

$$\mathrm{d}\vartheta^a = 0. \tag{2.1}$$

Consequently, $\mathcal{F}^a=\mathcal{C}^a=0$, so both sides of Eq. (1.12) vanish. By Poincaré's lemma, the solution of (2.1) can be locally expressed as $\vartheta^a=\mathrm{d}\tilde{x}^a(x)$, where $\tilde{x}^a(x)$ is a set of four smooth functions defined in some neighborhood U of a point $x\in\mathcal{M}$. The functions $\tilde{x}^a(x)$, being treated as the components of a coordinate map $\tilde{x}^a: U\to\mathbb{R}^4$, generate a local coordinate system on U. The metric tensor (1.2) reduces, in this coordinate chart, to the flat Minkowskian metric $g=\eta_{ab}\mathrm{d}\tilde{x}^a\otimes\mathrm{d}\tilde{x}^b$. Thus the holonomic coframe plays, in the teleparallel background, the same role as the Minkowskian metric in the (pseudo-)Riemannian geometry. Moreover, a manifold endowed with a (pseudo-)orthonormal holonomic coframe is flat. The weak perturbations of the basic solution $\vartheta^a=\mathrm{d}x^a$ are

$$\vartheta^a = \mathrm{d}x^a + h^a = (\delta^a_b + h^a{}_b)\mathrm{d}x^b. \tag{2.2}$$

"Weak" means

$$\|h^a{}_b\| = \epsilon = o(1), \quad \|h^a{}_{b,c}\| = O(\epsilon), \quad \|h^a{}_{b,c,d}\| = O(\epsilon), \tag{2.3}$$

where $\|\cdots\|$ denotes the maximal tensor norm. We accept that the coframe ϑ^a and the holonomic coframe $\mathrm{d}x^a$ have the same physical dimension of [*length*]. Thus, the components of the matrix $h^a{}_b$ and the parameter ϵ are dimensionless. Consequently, the approximation conditions (2.3) are invariant under rescaling of the coordinates.

In this paper we will take into account only the first order approximation in the perturbations $h^a{}_b$ and in their derivatives (i.e., in the parameter ϵ). Note that, in this approximation, the difference between coframe and coordinate indices completely disappears. This justifies our choice, in (2.2) and in the sequel, of the same notation for these (basically different) indices.

In accordance with (2.3), only weak coordinate transformations are considered. Under a shift

$$x^a \mapsto x^a + \xi^a(x), \tag{2.4}$$

the components of the coframe are transformed as

$$h^a{}_b \mapsto h^a{}_b - \xi^a{}_{,b}. \tag{2.5}$$

Thus, in order to preserve the weakness of the fluctuation, it is necessary to require $\xi^a{}_{,b}=O(\|h^a{}_b\|)$. We will use the term *approximately covariant*[35] for the expressions which are covariant only to the first order of the perturbations. Observe that this assumption restricts only the amplitudes of the perturbations and of their derivatives. It does not restrict, however, the local freedom to transform the coordinates. An appropriative coordinate system can still be chosen in a small neighborhood of the identity transformation in order to simplify the (local) field equations.

Similarly, in order to be in agreement with the approximation condition (2.3), the global SO(1,3) transformations of the coframe field, $\vartheta^a \mapsto A^a{}_b \vartheta^b$, must also be restricted. It is enough to require the transformations to be in a small neighborhood of the identity

$$A^a{}_b = \delta^a_b + \alpha^a_b, \quad \|\alpha^a_b\| = o(1). \tag{2.6}$$

B. Reduction of the field

In (2.2), $h^a{}_b$ is a perturbation of the flat coframe. Thus we have the following.

(i) To the first order, the holonomic coframe is expressed by the unholonomic one as

$$\mathrm{d}x^a = (\delta^a_b - h^a{}_b)\vartheta^b. \tag{2.7}$$

(ii) The indices in $h^a{}_b$ can be lowered and raised by the Minkowskian metric,

$$h_{ab} := \eta_{am} h^m{}_b, \quad h^{ab} := \eta^{bm} h^a{}_m. \tag{2.8}$$

The first operation is exact (covariant to all orders of approximations), while the second is covariant only to the first order, when $g^{ab} \approx \eta^{ab}$.

(iii) The symmetric and the antisymmetric combinations of the perturbations,

$$\theta_{ab} := h_{(ab)} = \tfrac{1}{2}(h_{ab} + h_{ba}) \quad \text{and} \quad w_{ab} := h_{[ab]} = \tfrac{1}{2}(h_{ab} - h_{ba}) \tag{2.9}$$

as well as the trace $\theta := h^m{}_m = \theta^m{}_m$ are covariant to the first order.

(iv) The components of the metric tensor, in the linear approximation, involve only the symmetric combination of the coframe perturbations,

$$g_{ab} = \eta_{ab} + 2\theta_{ab}. \tag{2.10}$$

(v) Under the transformations (2.4), two covariant pieces of the fluctuation change as

$$\theta_{ab} \mapsto \theta_{ab} - \xi_{(a,b)} \quad \text{and} \quad w_{ab} \mapsto w_{ab} - \xi_{[a,b]}. \tag{2.11}$$

Thus the approximately covariant irreducible decomposition of the dynamical variable

$$h_{ab} = \theta_{ab} + w_{ab} \tag{2.12}$$

is obtained. Thus, instead of one field h_{ab}, we have, in this approximation, two independent fields: a symmetric field θ_{ab} and an antisymmetric field w_{ab}.

C. Gauge conditions

The actual values of the components of the fields θ_{ab} and w_{ab} depend on a choice of a coordinate system. Thus four arbitrary relations between the components (equal to the number of coordinates) may be imposed. We require these relations to be Lorentz invariant, i.e., covariant in the first order approximation. Thus the most general form of constraints (gauge conditions) that involve the first order derivatives is

$$\alpha\theta_{am}{}^{,m} + \beta\theta_{,a} + \gamma w_{am}{}^{,m} = 0, \tag{2.13}$$

where α, β, γ are dimensionless parameters.

Certainly, for some special values of the parameters, these conditions cannot be realized. Indeed, under the coordinate transformations (2.4), Eq. (2.13) changes, in the lowest order, to

$$\alpha\tilde{\theta}_{am}{}^{,m} + \beta\tilde{\theta}_{,a} + \gamma\tilde{w}_{am}{}^{,m} = (\alpha\xi_{(a,m)} + \beta\xi_{m,a} + \gamma\xi_{[a,m]})^{,m}. \tag{2.14}$$

Thus the conditions (2.13) can be realized, by the coordinate transformations (2.4), if and only if the system of PDE (2.14) has a solution $\xi(x)$ for a given left-hand side (LHS).

Let us check the integrability of this system. Equation (2.14) results in

$$(\alpha\xi_{(a,m),b} + \beta\xi_{m,a,b} + \gamma\xi_{[a,m],b})^{,m} = \alpha\tilde{\theta}_{am,b}{}^{,m} + \beta\tilde{\theta}_{,a,b} + \gamma\tilde{w}_{am,b}{}^{,m}. \tag{2.15}$$

Commuting the indices a and b, we obtain

$$(\alpha + \gamma)\,\Box\,\xi_{[a,b]} = 2(\alpha\theta_{m[a,b]} - \gamma w_{m[a,b]})^{,m}. \tag{2.16}$$

Thus, the gauge condition (2.13) with $\alpha = -\gamma \neq 0$ cannot be realized by any change of the coordinate system. Now, take the trace of (2.15),

$$(\alpha + \beta)\,\Box\,\xi_{m}{}^{,m} = \alpha\theta_{mn}{}^{,m,n} + \beta\,\Box\,\theta. \tag{2.17}$$

Thus $\alpha = -\beta \neq 0$ is also forbidden.

We will apply, in the sequel, two separate gauge conditions: for the symmetric field

$$\theta_{am}{}^{,m} - \tfrac{1}{2}\theta_{,a} = 0, \tag{2.18}$$

and for the antisymmetric field

$$w_{am}{}^{,m} = 0. \tag{2.19}$$

Observe, that (2.18) and (2.19) cannot be realized simultaneously by the same coordinate transformation. Indeed, for this, the coordinate functions must satisfy

$$\Box\,\xi_a = 2\theta_{am}{}^{,m} - \theta_{,a} \quad \text{and} \quad \Box\,\xi_a - (\xi_m{}^{,m})_{,a} = w_{am}{}^{,m}. \tag{2.20}$$

The integrability conditions for these equations yield

$$\Box\,\xi_{[a,b]} = 2\theta_{m[a,b]}{}^{,m} = -\,w_{m[a,b]}{}^{,m}. \tag{2.21}$$

For arbitrary independent fields θ_{ab} and w_{ab}, these conditions are not satisfied.

Certainly, the conditions (2.18) and (2.19) can be realized, separately, by transformation of the coordinates.

D. Reduction of the field strengths

By (2.3), let us decompose the field strengths (1.8)–(1.10). The 2-form $\mathcal{C}_a$ is approximated by

$$\mathcal{C}_a = h_{ab,c}\,\mathrm{d}x^c \wedge \mathrm{d}x^b = -\,h_{a[b,c]}\vartheta^b \wedge \vartheta^c = -\,(\theta_{a[b,c]} + w_{a[b,c]})\,\vartheta^b \wedge \vartheta^c. \tag{2.22}$$

Consequently, the first part of the field strength (1.8), takes the form

$${}^{(1)}\mathcal{F}_a = -\,(\rho_1 + \rho_3)(\theta_{a[b,c]} + w_{a[b,c]})\,\vartheta^b \wedge \vartheta^c. \tag{2.23}$$

As for the second part (1.9), it involves only the antisymmetric field,

$${}^{(2)}\mathcal{F}_a = -\,3\rho_2 w_{[ab,c]}\;\vartheta^b \wedge \vartheta^c. \tag{2.24}$$

The third part (1.10), takes the form

$$^{(3)}\mathcal{F}_a = \rho_3 \eta_{ac}(h_{mb}{}^{,m} - h_{,b})\ \vartheta^b \wedge \vartheta^c = \rho_3 \eta_{ac}(\theta_{bm}{}^{,m} - \theta_{,b} - w_{bm}{}^{,m})\vartheta^b \wedge \vartheta^c. \tag{2.25}$$

Therefore, the field strength is reduced to the sum of two independent strengths—one defined by the symmetric field θ_{ab} and the second one defined by the antisymmetric field w_{ab},

$$\mathcal{F}_a(\theta_{mn}, w_{mn}) = {}^{(\mathrm{sym})}\mathcal{F}_a(\theta_{mn}) + {}^{(\mathrm{ant})}\mathcal{F}_a(w_{mn}), \tag{2.26}$$

where

$$^{(\mathrm{sym})}\mathcal{F}_a = -[(\rho_1 + \rho_3)\theta_{a[b,c]} + \rho_3 \eta_{a[b}\ \theta_{c]m}{}^{,m} - \rho_3 \eta_{a[b}\ \theta_{,\,c]}]\vartheta^b \wedge \vartheta^c \tag{2.27}$$

and

$$^{(\mathrm{ant})}\mathcal{F}_a = -[(\rho_1 + \rho_3)w_{a[b,c]} + 3\rho_2 w_{[ab,c]} - \rho_3 \eta_{a[b}\, w_{\,c]m}{}^{,m}]\vartheta^b \wedge \vartheta^c. \tag{2.28}$$

Hence, for arbitrary values of the parameters ρ_i, the field strengths are independent.

E. Reduction of the field equations

The field equation (1.12) includes the second order derivatives of the perturbations on its LHS and the squares of the first order derivatives on both sides. In the linear approximation (2.3), the quadratic terms can be neglected. Thus, (1.12) is approximated by

$$\mathrm{d} * \mathcal{F}^a = 0. \tag{2.29}$$

The covector valued 2-form $\mathcal{F}_a$ can be expressed in the unholonomic basis as $\mathcal{F}_a = \mathcal{F}_{abc}\vartheta^b \wedge \vartheta^c/2$. Accordingly, we derive

$$\mathrm{d} * \mathcal{F}^a = \tfrac{1}{2}F_{abc,m}\ \mathrm{d}x^m \wedge *\,(\vartheta^b \wedge \vartheta^c) = -\tfrac{1}{2}F_{abc}{}^{,m} * [\, e_m \rfloor (\vartheta^b \wedge \vartheta^c) \rfloor = \tfrac{1}{2}F_{a[bc]}{}^{,c} * \vartheta^b.$$

Consequently, Eq. (2.29) reads

$$F_{a[bc]}{}^{,c} = 0. \tag{2.30}$$

Applying the antisymmetrization of the corresponding indices to the expression (2.26) we derive the linearized field equation

$$\begin{aligned}(\rho_1 + \rho_3)(\Box\,\theta_{ab} - \theta_{am,b}{}^{,m}) + \rho_3(-\,\eta_{ab}\,\Box\,\theta - \theta_{mb}{}^{,m}{}_{,a} + \theta_{,a,b} + \eta_{ab}\theta_{mn}{}^{,m,n}) \\ + (\rho_1 + 2\rho_2 + \rho_3)(\Box w_{ab} - w_{am,b}{}^{,m}) + (2\rho_2 + \rho_3)w_{bm,a}{}^{,m} = 0.\end{aligned} \tag{2.31}$$

Proposition 1: For the case $\rho_1 = 0$, *the linearized coframe field equation (2.31), in arbitrary coordinates, splits into two independent systems,*

$$^{(\mathrm{sym})}\mathcal{E}_{(ab)}(\theta_{mn}) = 0 \quad \text{and} \quad {}^{(\mathrm{ant})}\mathcal{E}_{[ab]}(w_{mn}) = 0.$$

If $\rho_1 \neq 0$, *Eq. (2.31) does not split in any coordinate system.*

Proof: The equation (2.31) is tensorial to the first order. Thus, by applying symmetrization and antisymmetrization operations, it is reduced covariantly to a system of two independent tensorial (to the first order) equations. The symmetrization yields a system of 10 independent equations,

$$\Box[(\rho_1 + \rho_3)\theta_{ab} - \rho_3 \eta_{ab}\theta] - (\rho_1 + 2\rho_3)\theta_{m(a,b)}{}^{,m} + \rho_3(\theta_{,a,b} + \eta_{ab}\theta_{mn}{}^{,m,n}) + \rho_1 w_{m(a,b)}{}^{,m} = 0. \tag{2.32}$$

The antisymmetrization yields a system of six independent equations,

$$(\rho_1 + 2\rho_2 + \rho_3)\,\Box\, w_{ab} + (\rho_1 + 4\rho_2 + 2\rho_3) w_{m[a,b]}{}^{,m} - \rho_1 \theta_{m[a,b]}{}^{,m} = 0. \tag{2.33}$$

Evidently, the condition $\rho_1 = 0$ removes the "mixed terms" and yields the separation of the system. Such splitting holds in arbitrary system of coordinates.

Suppose now $\rho_1 \neq 0$. Thus, the "mixed terms" remain in both equations—the w term in (2.32) and the θ term in (2.33). Let us try to remove these terms by an appropriative choice of a coordinate system. For this we must require the equations

$$\theta_{m[a,b]}{}^{,m} = 0 \quad \text{and} \quad w_{m(a,b)}{}^{,m} = 0$$

to hold simultaneously. These equations can be satisfied only if

$$\theta_{ma}{}^{,m} = 0 \quad \text{and} \quad w_{ma}{}^{,m} = 0. \tag{2.34}$$

The actual values of the variables θ_{ab} and w_{ab} depend on a choice of a coordinate system. Recall that the approximation conditions (2.3) do not restrict the freedom to choose the local coordinate transformations. Therefore, by (2.4), four additional conditions (equal to the number of coordinates), can still be applied to the perturbations in order to satisfy (2.34). We need, however, to eliminate eight independent expressions $w_{ma}{}^{,m}$ and $\theta_{ma}{}^{,m}$. This cannot be done by four independent functions of the coordinates. Indeed, under the transformations (2.4),

$$\theta_{ma}{}^{,m} \mapsto \theta_{ma}{}^{,m} - \xi_{(m,a)}{}^{,m}, \tag{2.35}$$

$$w_{ma}{}^{,m} \mapsto w_{ma}{}^{,m} - \xi_{[m,a]}{}^{,m}. \tag{2.36}$$

Hence the coordinate transformations must satisfy

$$\xi_{(m,a)}{}^{,m} = \theta_{ma}{}^{,m} \quad \text{and} \quad \xi_{[m,a]}{}^{,m} = w_{ma}{}^{,m} \tag{2.37}$$

simultaneously. Therefore,

$$\xi_{m,a}{}^{,m} = h_{ma}{}^{,m}. \tag{2.38}$$

The consistency condition for (2.38) is

$$h_{ma,b}{}^{,m} = h_{mb,a}{}^{,m},$$

which it is not satisfied in general. ■

Consequently, for $\rho_1 = 0$ and generic values of the parameters ρ_2, ρ_3, the field equation of the coframe field is reduced to two independent field equations for independent field variables.

(i) The symmetric field θ_{ab} of 10 independent variables satisfies the system of 10 independent equations,

$$^{(\mathrm{sym})}\mathcal{E}_{(ab)}(\theta_{mn}) := \rho_3[\Box(\theta_{ab} - \eta_{ab}\theta) - \theta_{m(a,b)}{}^{,m} + \theta_{,a,b} + \eta_{ab}\theta_{mn}{}^{,m,n}] = 0. \tag{2.39}$$

We rewrite it as

$$\Box(\theta_{ab} - \eta_{ab}\theta) - (\theta_{am}{}^{,m} - \tfrac{1}{2}\theta_{,a})_{,b} - (\theta_{bm}{}^{,m} - \tfrac{1}{2}\theta_{,b})_{,a} + \eta_{ab}\theta_{mn}{}^{,m,n} = 0. \tag{2.40}$$

Substituting here the condition (2.18) and its consequence

$$\theta_{mn}{}^{,m,n} = \tfrac{1}{2}\,\Box\,\theta \tag{2.41}$$

we obtain

$$\Box(\theta^{ab} - \tfrac{1}{2}\eta^{ab}\theta) = 0. \tag{2.42}$$

Equation (2.42) results in $\Box\theta = 0$. Then it is equivalent to

$$\Box\theta_{ab}=0. \tag{2.43}$$

Consequently, in the coordinates associated with (2.18), the symmetric field satisfied the wave equation.

(ii) The antisymmetric system of six independent equations for six independent variables,

$$^{(\mathrm{ant})}\mathcal{E}_{[ab]}(w_{mn}):=(2\rho_2+\rho_3)(\Box w_{ab}+2w_{m[a,b]}{}^{,m})=0. \tag{2.44}$$

In the coordinates associated with (2.19) it is reduced to the wave equation,

$$\Box w_{ab}=0. \tag{2.45}$$

F. Reduction of the Lagrangian

In the sequel of this paper, we consider the models with parameter $\rho_1=0$. Let us examine now the reduction of the Lagrangian (1.3).

Proposition 2: For $\rho_1=0$, the Lagrangian of the coframe field is reduced, up to a total derivative term, to the sum of two independent Lagrangians,

$$\mathcal{L}(\theta_{ab},w_{ab})=^{(\mathrm{sym})}\mathcal{L}(\theta_{ab})+^{(\mathrm{ant})}\mathcal{L}(w_{ab}). \tag{2.46}$$

Proof: With $\rho_1=0$ the term $^{(1)}\mathcal{L}$ does not appear in the Lagrangian. Calculate in the linear approximation (we use the abbreviation $\vartheta^{ab\cdots}=\vartheta^a\wedge\vartheta^b\wedge\cdots$),

$$^{(2)}\mathcal{L}=(\mathrm{d}\vartheta^a\wedge\vartheta_a)\wedge *(\mathrm{d}\vartheta_b\wedge\vartheta^b)=h^{am,n}h_{bp,q}\vartheta_{nma}\wedge *\vartheta^{qpb}. \tag{2.47}$$

Applying the formula

$$\vartheta_{abc}\wedge *\vartheta^{a'b'c'}=6\delta_a^{[a'}\delta_b^{b'}\delta_c^{c']}*1 \tag{2.48}$$

we derive

$$^{(2)}\mathcal{L}=2w^{ab,c}(w_{ab,c}+w_{ca,b}+w_{bc,a})*1. \tag{2.49}$$

So $^{(2)}\mathcal{L}$ depends only on the antisymmetric field. Consider now the linear approximation to the term $^{(3)}\mathcal{L}$,

$$^{(3)}\mathcal{L}=(\mathrm{d}\vartheta_a\wedge\vartheta_b)\wedge *(\mathrm{d}\vartheta^b\wedge\vartheta^a)=h_a{}^{m,n}h^b{}_{p,q}\vartheta_{nmb}\wedge *\vartheta^{qpa}. \tag{2.50}$$

Use (2.48) to get

$$^{(3)}\mathcal{L}=[h_{ab,c}(h^{ab,c}-h^{ac,b})-h_{ab}{}^{,a}h^{cb}{}_{,c}+\theta^a(2h_{ba}{}^{,b}-\theta_{,a})]*1. \tag{2.51}$$

Insert here the splitting (2.12). It follows that the Lagrangian (2.51) is reduced to the sum

$$^{(3)}\mathcal{L}=^{(3)}\mathcal{L}(\theta)+^{(3)}\mathcal{L}(w)+^{(3)}\mathcal{L}(\theta,w), \tag{2.52}$$

where

$$^{(3)}\mathcal{L}(\theta)=[\theta_{ab,c}(\theta^{ab,c}-\theta^{ac,b})-\theta_{ab}{}^{,a}\theta^{cb}{}_{,c}+\theta^a(2\theta_{ba}{}^{,b}-\theta_{,a})]*1, \tag{2.53}$$

$$^{(3)}\mathcal{L}(w)=[w_{ab,c}(w^{ab,c}-w^{ac,b})-w_{ab}{}^{,a}w^{cb}{}_{,c}]*1, \tag{2.54}$$

$$^{(3)}\mathcal{L}(\theta,w)=2[-\theta_{ab,c}w^{ac,b}+\theta^a w_{ba}{}^{,b}-\theta_{ab}{}^{,a}w^{cb}{}_{,c}]*1. \tag{2.55}$$

Extracting the total derivatives in the mixed term (2.55) we obtain

$$^{(3)}\mathcal{L}(\theta,w)=(\theta_{ab}(w^{ac,b}-w^{bc,a})_{,c}-\theta w_{ba}{}^{,a,b})*1+\text{exact terms}. \tag{2.56}$$

The terms in the square brackets vanish identically as a product of symmetric and antisymmetric tensors. Thus the mixed term $^{(3)}\mathcal{L}(\theta,w)$ is a total derivative. Consequently, desired reduction of the Lagrangian is obtained. ■

The Lagrangian of the symmetric field $^{(\text{sym})}\mathcal{L}=^{(3)}\mathcal{L}(\theta)$ may be rewritten in a more compact form. Observing the identity

$$\theta_{ab}{}^{,a}\theta^{cb}{}_{,c}=\theta_{ab}{}^{,c}\theta^{cb}{}_{,a}+\text{exact terms}, \tag{2.57}$$

and extracting the total derivatives, we obtain

$$^{(\text{sym})}\mathcal{L}=\tfrac{1}{2}\rho_3[\theta_{ab,c}(\theta^{ab,c}-2\theta^{ac,b})+\theta^a(2\theta_{ba}{}^{,b}-\theta_{,a})]*1. \tag{2.58}$$

This form of the Lagrangian is acceptable in arbitrary coordinates. In the coordinates associated with the condition (2.18), the last parentheses in (2.58) vanish. In the first parentheses, we extract the total derivatives and use (2.18) to derive (symbol $\approx$ used here for equality up to total derivatives)

$$\theta_{ab,c}\theta^{ac,b}=(\theta_{ab}\theta^{ac,b})_{,c}-\theta_{ab}\theta^{ac,b}{}_{,c}\approx-\tfrac{1}{2}\theta_{ab}\theta^{a,b}\approx\tfrac{1}{2}\theta_{ab}{}^{,b}\theta^a\approx\tfrac{1}{4}\theta_{,a}\theta^a.$$

Consequently the symmetric field Lagrangian (2.53) is reduced to

$$^{(\text{sym})}\mathcal{L}=\tfrac{1}{2}\kappa(\theta_{ab,c}\theta^{ab,c}-\tfrac{1}{2}\theta_{,a}\theta^a)*1. \tag{2.59}$$

Analogously, for the Lagrangian of the antisymmetric field $^{(\text{ant})}\mathcal{L}=^{(2)}\mathcal{L}+^{(3)}\mathcal{L}(w)$, we use the identity

$$w_{ab}{}^{,a}w^{cb}{}_{,c}=w_{ab,c}w^{ac,b}+\text{exact terms} \tag{2.60}$$

and rewrite it, in an arbitrary system of coordinates, as

$$^{(\text{ant})}\mathcal{L}=\tfrac{1}{2}(2\rho_2+\rho_3)[w_{ab,c}(w^{ab,c}-2w^{ac,b})]*1, \tag{2.61}$$

or, equivalently, as

$$\mathcal{L}(w)=\tfrac{1}{2}(2\rho_2+\rho_3)(w_{ab,c}(w^{ab,c}-w^{ac,b})-w_{ab}{}^{,a}w^{cb}{}_{,c})*1.$$

The gauge condition (2.19) removes the last term while the second term is rewritten as

$$w_{ab,c}w^{ac,b}\approx-w_{ab}w^{ac,b}{}_{,c}\approx0.$$

Thus, the Lagrangian of the antisymmetric field is

$$\tilde{\mathcal{L}}(w)=\tfrac{1}{2}(2\rho_2+\rho_3)w_{ab,c}w^{ab,c}*1. \tag{2.62}$$

G. Reduction of the energy-momentum current

The Lagrangian of the coframe field is decomposed, in the first order approximation, to a sum of two independent Lagrangians for two independent fields. The Noether current expression, being derivable from the Lagrangian, must have the same splitting.

Proposition 3: The coframe energy-momentum current is reduced, on shell, in the first order approximation, as

$$\mathcal{T}_a(\theta_{mn},w_{mn})=^{(\text{sym})}\mathcal{T}_a(\theta_{mn})+^{(\text{ant})}\mathcal{T}_a(w_{mn}), \tag{2.63}$$

up to a total derivative.

Proof: The coframe energy-momentum current is of the form

$$\mathcal{T}_a = (e_a \rfloor \mathcal{C}_m) \wedge {}^*\mathcal{F}^m - e_a \rfloor \mathcal{L}. \tag{2.64}$$

Due to Proposition 2, the second term, in the first order approximation, does not contain the mixed terms $\theta' \cdot w'$. Hence, it already has the reduced form. To treat the first term, we write the strengths in the component

$$\mathcal{C}_m = \mathcal{C}_{m[bc]}\vartheta^b \wedge \vartheta^c, \quad \mathcal{F}^m = F^m{}_{[pq]}\vartheta^p \wedge \vartheta^q. \tag{2.65}$$

Thus, the first term of (2.64) is approximated by

$$(e_a \rfloor \mathcal{C}_m) \wedge {}^*\mathcal{F}^m = \mathcal{C}_{m[bc]}F^m{}_{[pq]}(e_a \rfloor \vartheta^{bc}) \wedge {}^*\vartheta^{pq} = 4C_{m[an]}F^{m[bn]} * \vartheta_b = 4h_{m[a,n]}F^{m[bn]} * \vartheta_b. \tag{2.66}$$

The 3-form $*\vartheta_b$, in the lowest order approximation, is an exact form. Thus, it is enough to show that the scalar factor, on the right-hand side (RHS) of (2.66), has the desired splitting. This expression is a sum of two terms. The first one is proportional to

$$h_{ma,n}F^{m[bn]} = -h_{ma}F^{m[bn]}{}_{,n} + \text{total derivatives},$$

i.e., it is, on shell, an exact form. Now we must show that the second term, which is proportional to $h_{ma,n}F^{m[bn]}$, does not involve the mixed products of a type $\theta \cdot w$. The mixed product expression in the latter term is proportional to

$$\theta_{mn,a}(w^{mb,n} + 2\eta^{m[n}w^{b]k}{}_{,k}) + w_{mn,a}(\theta^{mb,n} + \eta^{mb}\theta^{nk}{}_{,k} - \eta^{mb}\theta^{,n}). \tag{2.67}$$

By recollection of the terms, we rewrite this expression as

$$(\theta_{mn,a}w^{mb,n} + \theta_{mn}{}^{,n}w^{bm}{}_{,a}) + (\theta_{,a}w^{bm}{}_{,m} - \theta_{,m}w^{bm}{}_{,a}) + (\theta^{mb,n}w_{mn,a} - \theta^{bm}{}_{,a}w_{mn}{}^{,n}). \tag{2.68}$$

The three brackets above are total derivatives, namely,

$$[(\theta_{mn,a}w^{mb})^{,n} + (\theta_{mn}{}^{,n}w^{bm})_{,a}] + [(\theta w^{bm}{}_{,m})_{,a} - (\theta w^{bm}{}_{,a})_{,m}] + [(\theta^{mb,n}w_{mn})_{,a} - (\theta^{bm}{}_{,a}w_{mn})^{,n}]. \tag{2.69}$$

Thus, (2.66) and, consequently, (2.64) do not involve the mixed terms. The desired splitting is proved. ■

The energy-momentum tensor $T_a{}^b$ can be derived from the Noether current $\mathcal{T}_a$ by applying the relations

$$\mathcal{T}_a = T_a{}^b * \vartheta_b, \quad T_{ab} = e_b \rfloor * \mathcal{T}_a. \tag{2.70}$$

Proposition 4: For the field θ_{ab} in the coordinate system associated with the gauge condition

$$\theta_{am}{}^{,m} - \tfrac{1}{2}\theta_{,a} = 0, \tag{2.71}$$

the energy-momentum tensor is

$$T_{ab} = \tfrac{1}{2}\kappa[(\theta_{mn,a}\theta^{mn}{}_{,b} - \tfrac{1}{4}\eta_{ab}\theta_{lm,n}\theta^{lm,n}) - \tfrac{1}{2}(\theta_{,a}\theta_{,b} - \tfrac{1}{4}\eta_{ab}\theta_{,m}\theta^{,m})]. \tag{2.72}$$

This tensor is symmetric and traceless.

Proof: We start with the energy-momentum current for the coframe field

$$\mathcal{T}_a = (e_a \rfloor \mathcal{C}_m) \wedge {}^*\mathcal{F}^m - e_a \rfloor \mathcal{L}.$$

Due to Proposition 3, in the first order approximation, this current is decomposed to two independent currents. Thus we may assume $w_{ab}=0$ in order to derive the expression for $\mathcal{T}_a(\theta)$.

In the coordinates associated with the gauge condition (2.71), by (2.59),

$$e_a\mathcal{L}=\tfrac{1}{2}\rho_3(\theta_{mn,p}\theta^{mn,p}-\tfrac{1}{2}\theta_{,m}\theta^{m})*\vartheta_a.$$

The first term of $\mathcal{T}_a$ is derived from (2.64),

$$(e_a\rfloor\mathcal{C}_m)\wedge *\mathcal{F}^m=4\theta_{m[a,n]}F^{m[bn]}*\vartheta_b=2(\theta_{ma,n}F^{m[bn]}*\vartheta_b-\theta_{mn,a}F^{m[bn]}*\vartheta_b).$$

Observe that, on shell, up to a total derivative

$$\theta_{ma,n}F^{m[bn]}\approx-\theta_{ma}F^{m[bn]}{}_{,n}=0.$$

Thus,

$$(e_a\rfloor\mathcal{C}_m)\wedge *\mathcal{F}^m=-2\theta_{mn,a}F^{m[bn]}*\vartheta_b.$$

Applying the gauge condition to (2.26) we get

$$\mathcal{F}_a=-\rho_3[\theta_{a[b,c]}+\eta_{a[b}\,(\theta_{\,c]m}{}^{,m}-\theta_{,\,c]})\vartheta^{bc}=-\rho_3(\theta_{a[b,c]}-\tfrac{1}{2}\eta_{a[b}\,\theta_{,\,c]})\vartheta^{bc}.$$

Consequently,

$$(e_a\rfloor\mathcal{C}_m)\wedge *\mathcal{F}^m=2\rho_3\theta_{mn,a}(\theta^{m[b,n]}-\tfrac{1}{2}\eta^{m[b}\,\theta^{\,n]})*\vartheta_b.$$

Extracting the total derivatives

$$\theta_{mn,a}\theta^{mb,n}\approx\theta_{mn}{}^{,n}\theta^{mb}{}_{,a}\approx\tfrac{1}{2}\theta_{,m}\theta^{mb}{}_{,a}\approx\tfrac{1}{4}\theta_{,a}\theta^{b},$$

$$\theta_{mn,a}\eta^{mb}\theta^{n}\approx\theta_{mn}{}^{,n}\theta_{,a}\approx\tfrac{1}{4}\theta_{,a}\theta^{b},$$

it follows that

$$(e_a\rfloor\mathcal{C}_m)\wedge *\mathcal{F}^m=\rho_3(-2\theta_{mn,a}\theta^{mn,b}+\theta_{,a}\theta^{b})*\vartheta_b.$$

Collecting the terms into $\mathcal{T}_a$ and extracting the energy-momentum tensor $T_a{}^b$ from the current $\mathcal{T}_a$ by $T_{ab}=e_b\rfloor*\mathcal{T}_a$ we get the desired expression. It is clear that energy-momentum tensor is symmetric and traceless. ■

In GR, the behavior of small perturbations of the metric tensor is managed by the wave equation. Thus, for a wave propagating in the positive direction of the x axis, only two independent components of the matrix θ_{ab} remain,

$$\theta_{23}=\mu(\tau),\quad \theta_{22}=-\theta_{33}=\nu(\tau),\quad \text{where}\quad \tau=t-x. \tag{2.73}$$

The calculation of the energy-momentum tensor for the symmetric field by use of the tensor (2.72) yields

$$T_{ab}=k(\mu_{,a}\mu_{,b}+\nu_{,a}\nu_{,b}). \tag{2.74}$$

The energy flux reads

$$T_{01}=-\rho_3(\dot{\theta}_{23}^2+\tfrac{1}{4}(\dot{\theta}_{22}-\dot{\theta}_{33})^2). \tag{2.75}$$

Observe that the expressions (2.74) and (2.75) are the same as the expressions obtained in GR from the energy-momentum pseudotensors.

Let us turn now to the antisymmetric field.

Proposition 5: In the coordinate system associated with the gauge condition

$$w_{am}{}^{,m}=0, \tag{2.76}$$

the energy-momentum tensor of the antisymmetric field is

$$T_{ab} = -(2\rho_2 + \rho_3)(w_{mn,a}w^{mn}{}_{,b} - \tfrac{1}{4}\eta_{ab}w_{mn,p}w^{mn,p}). \tag{2.77}$$

This tensor is traceless and symmetric.

Proof: The current of the symmetric and of the antisymmetric fields are decoupled. Thus we may assume $\theta_{ab}=0$. In the coordinates associated with the gauge condition (2.76),

$$e_a \rfloor \mathcal{L} = \tfrac{1}{2}(2\rho_2 + \rho_3)w_{ab,c}w^{ab,c} * \vartheta_b.$$

As for the first term of $\mathcal{T}_a(w)$ we derive from (2.66),

$$(e_a \rfloor \mathcal{C}_m) \wedge * \mathcal{F}^m = 4w_{m[a,n]}F^{m[bn]} * \vartheta_b = 2(w_{ma,n}F^{m[bn]} - w_{mn,a}F^{m[bn]}) * \vartheta_b.$$

The first term vanishes, on shell, up to a total derivative,

$$w_{ma,n}F^{m[bn]} \approx -w_{ma}F^{m[bn]}{}_{,n} = 0.$$

Thus,

$$(e_a \rfloor \mathcal{C}_m) \wedge * \mathcal{F}^m = -2w_{mn,a}F^{m[bn]} * \vartheta_b.$$

Inserting the gauge condition (2.76) into (2.26) we derive

$$\mathcal{F}_a = -(\rho_3 w_{a[b,c]} + 3\rho_2 w_{[ab,c]})\vartheta^{bc}.$$

Hence,

$$(e_a \rfloor \mathcal{C}_m) \wedge * \mathcal{F}^m = 2(\rho_3 w_{ma,n}w^{m[b,n]} + 3\rho_2 w_{ma,n}w^{[mb,n]}) * \vartheta_b.$$

Extract the total derivatives and use the gauge condition to get

$$w_{mn,a}w^{mb,n} \approx w_{mn}{}^{,n}w^{mb}{}_{,a} \approx 0,$$

$$w_{mn,a}w^{bn,m} \approx w_{mn}{}^{,m}w^{bn}{}_{,a} \approx 0.$$

Consequently,

$$(e_a \rfloor \mathcal{C}_m) \wedge * \mathcal{F}^m = -(2\rho_2 + \rho_3)w_{mn,a}w^{mn,b}.$$

The desired expression (2.77) is obtained now by collecting the terms. ■

III. THE ROLE OF THE PARAMETERS ρ_1

The case $\rho_1=0$ is extracted in coframe models by existence of a unique spherical symmetric static solution. Since the exact solution yields the Schwarzschild metric this condition generates a viable subclass of gravity coframe models.

We have involved an independent criteria. Namely, we have shown that only in the case $\rho_1=0$ the weak perturbations of the coframe reduce to two independent fields with their own Lagrangian dynamics. Consequently the models have a free field limit. This effect is correlated to the recently obtained result [34] concerning the Hamiltonian dynamics behavior.

It is interesting to note that in the two-dimensional coframe gravity only one term in the Lagrangian preceded by ρ_1 appears. Thus the corresponding reduction of fields is impossible.

Odd-type spin-2 perturbations of Einstein's equation can be reduced to the scalar Regge–Wheeler equation. We show that the weighted norms of solutions are in L^2 of time and space. This result uses commutator methods and applies uniformly to all relevant spherical harmonics. © *2005 American Institute of Physics.*

I. INTRODUCTION

Recently, it has been shown that the wave equation for a scalar field on the exterior part of the Schwarzschild manifold satisfies local decay estimates useful for scattering theory and global existence.[2] The extension for the linearized Einstein equation is considered here. In 1957, Regge and Wheeler investigated spin-2 tensor fields on the Schwarzschild manifold.[4] They classified such fields into two types, which they called even and odd. For the odd fields, they were able to reduce the problem to an equation for a scalar field very similar to the wave equation for scalar fields on the Schwarzschild manifold. In 1970, Zerilli extended their results to include the even case; although, the equation for the even case is significantly more complicated and shows less resemblance to the wave equation for a scalar field.[9] Teukolsky has done a related reduction for the rotating Kerr black hole[6] which has been used to investigate the stability of the black holes.[8]

This paper extends the local decay estimate for the scalar wave equation of Ref. 2 to the Regge–Wheeler equation. Many of the proofs used here follow Ref. 2. We obtain the following: for r_* the standard Regge–Wheeler coordinate and $\beta > \frac{3}{2}$, there is a constant C, depending on the initial condition through the energy norm, so that

$$\int_0^\infty \left\| \left(1 + \left(\frac{r_*}{2M}\right)^2\right)^{-\beta/2} u \right\|^2 \mathrm{d}t < C.$$

II. COORDINATES AND EQUATIONS

The Schwarzschild manifold describes a static black hole solution to the Einstein equation. The exterior of the black hole is most easily described by $(t, r, \theta, \phi) \in \mathbf{R} \times (2M, \infty) \times S^2$ with the metric

$$\mathrm{d}s^2 = \left(1 - \frac{2M}{r}\right)\mathrm{d}t^2 - \left(1 - \frac{2M}{r}\right)^{-1} \mathrm{d}r^2 - r^2\, \mathrm{d}s^2_{S^2}. \tag{2.1}$$

To simplify the analysis of linear stability, Regge and Wheeler[4] introduced a new radial coordinate, r_*, satisfying

$$\frac{\partial r}{\partial r_*} = \left(1 - \frac{2M}{r}\right). \tag{2.2}$$

This allows the definition of a spacelike manifold

$$\mathfrak{M} = \mathbf{R} \times S^2. \tag{2.3}$$

The old coordinate r is now treated as a function of r_*.

In these new coordinates, the Regge–Wheeler equation for a scalar field $u: \mathbf{R} \times \mathfrak{M} \to \mathbf{R}$ which determines the behavior of the odd-type tensor fields is

$$\ddot{u} + Hu = 0, \tag{2.4}$$

where

$$H = \sum_{j=1}^{3} H_j, \tag{2.5}$$

$$H_1 = -\frac{\partial^2}{\partial r_*^2}, \tag{2.6}$$

$$H_2 = (1 - s^2)V, \tag{2.7}$$

$$V = \frac{2M}{r^3}\left(1 - \frac{2M}{r}\right), \tag{2.8}$$

$$H_3 = V_L(-\Delta_{S^2}) = V_L \sum_{l=0}^{\infty} l(l+1)P_l, \tag{2.9}$$

$$V_L = \frac{1}{r^2}\left(1 - \frac{2M}{r}\right) \tag{2.10}$$

and where $s=2$ for the case of the tensor field and P_l is projection onto spherical harmonics with total angular momentum l. The case $s=0$ is the scalar field previously considered and $s=1$ is for the odd-type vector (Maxwell) fields.

Because of the way the scalar field u is defined it is not possible for it to have any component with spherical harmonic component $l=0$. It has also been shown that the $l=1$ component corresponds to changing the nonrotating Schwarzschild background to a rotating Kerr solution and to gauge transformations.[3,5] For this reason, we only consider u with no $l=0$ or $l=1$ spherical harmonic component. This provides a lower bound on the spherical Laplace–Beltrami operator,

$$-\Delta_{S^2} \geqslant 2(2+1) = 6. \tag{2.11}$$

For the scalar wave equation, Bachelot and Nicolas have proven global existence[1] in both an energy space and in C^∞. The assumption of global existence in C^∞ greatly simplifies all the following arguments and will be assumed; although, we are not yet aware of a published paper. However, the method of Bachelot and Nicolas should extend to the Regge–Wheeler equation without difficulty. The assumption of global existence in C^∞ means that all solutions are assumed to be $C^\infty(\mathfrak{M}) \cap H^1(\mathfrak{M}, \mathrm{d}r_* \, \mathrm{d}^2\omega_{S^2})$, are infinitely differentiable in t and have time derivative in $C^\infty(\mathfrak{M}) \cap L^2(\mathfrak{M}, \mathrm{d}r_* \, \mathrm{d}^2\omega_{S^2})$. The notation $u(t)$ denotes the function from $\mathfrak{M} \to \mathbf{R}$ corresponding to u evaluated at time t. The measure $\mathrm{d}r_* \, \mathrm{d}^2\omega_{S^2}$ is used for all norms and inner products unless otherwise specified, and the norm $\|\cdot\|$ refers to the L^2 norm.

III. THE HEISENBERG-TYPE RELATION AND PRELIMINARY ESTIMATES

For the Schrödinger equation, the Heisenberg relation describes the time evolution of expectation values for an operator and gives conserved quantities from symmetries of the Hamiltonian. A similar relation exists for the wave equation.[2]

Theorem III.1 (Heisenberg-type relation): *For a time independent operator A and a solution to the linear wave equation* $\ddot{u}+Hu=0$ *such that u and Hu are in the domain of A, and u and Au are in the domain of H,*

$$\frac{\mathrm{d}}{\mathrm{d}t}(\langle u,A\dot{u}\rangle - \langle \dot{u},Au\rangle) = \langle u,[H,A]u\rangle. \tag{3.1}$$

Proof: The proof is found in Theorem 1 of Ref. 2.

The first and most important application of Theorem III.1 is conservation of energy. As usual it is generated by time translation symmetry. This result is already well known.[7]

Theorem III.2 (energy conservation): *The Regge–Wheeler equation, Eq. (2.4), has a conserved quantity* $\|u\|_{\mathcal{H}}^2$ *which we call the energy.*

$$\|u\|_{\mathcal{H}}^2 = \langle \dot{u},\dot{u}\rangle + \langle u',u'\rangle + \langle u,-3Vu\rangle + \sum_{l=2}^{\infty} \langle P_l u, l(l+1)V_L P_l u\rangle. \tag{3.2}$$

This acts as a metric on the space $\mathcal{H}=\{u\in L^2_{\mathrm{loc}}:\|u\|_{\mathcal{H}}<\infty\}$.

Proof: The conservation of energy follows from the Heisenberg-type relation with the multiplier $A=\mathrm{d}/\mathrm{d}t$. This acts as a metric because the $\langle u,(H_2+H_3)u\rangle$ term is positive. The positivity of this potential was known to Regge and Wheeler[4] and is verified here.

Since only functions orthogonal to the spherical harmonics with $l=0$ and $l=1$ are considered

$$\langle u,-3Vu\rangle + \sum_{l=2}^{\infty} \langle P_l u, l(l+1)V_L P_l u\rangle \geqslant \langle u,-3Vu\rangle + \langle u,6V_L u\rangle \geqslant \left\langle u,\left(\frac{-6M}{r^3}+\frac{6}{r^2}\right)\left(1-\frac{2M}{r}\right)u\right\rangle$$
$$\geqslant \left\langle u,\frac{6}{r^2}\left(1-\frac{M}{r}\right)\left(1-\frac{2M}{r}\right)u\right\rangle.$$

Since

$$\frac{6}{r^2}\left(1-\frac{M}{r}\right)\left(1\frac{2M}{r}\right)$$

is always positive, $\langle u,(H_2+H_3)u\rangle$ is positive definite. Since $\langle \dot{u},\dot{u}\rangle$, $\langle u',u'\rangle$, and $\langle u,(H_2+H_3)u\rangle$ are all positive each is defined if $\|u\|_{\mathcal{H}}$ is finite, and $\|u\|_{\mathcal{H}}$ is a metric. □

As stated in the proof of energy conservation, the energy controls certain derivative norms and this can be used to control the growth of the L^2 norm.

Theorem III.3: *If u is a real valued solution of the Regge–Wheeler equation [Eq. (2.4)] and* $\|u(t)\|_{L^2}$ *is the norm of u at time t, then for* $t\geqslant 0$,

$$\|\dot{u}\|_{L^2} \leqslant \|u\|_{\mathcal{H}},$$

$$\|u(t)\| \leqslant t\|u\|_{\mathcal{H}} + \|u(0)\|_{L^2}.$$

Proof: Since $\langle u',u'\rangle$ and $\langle u,(H_2+H_3)u\rangle$ are strictly positive, $\|\dot{u}(t)\|$ is controlled by the energy. This is used to control the growth rate of $\|u(t)\|_{L^2}$,

$$\frac{\mathrm{d}}{\mathrm{d}t}\|u(t)\|_{L^2}^2 = \frac{\mathrm{d}}{\mathrm{d}t}\langle u,u\rangle = 2\langle u,\dot{u}\rangle,$$

$$2\|u\|_{L^2}\frac{\mathrm{d}}{\mathrm{d}t}\|u\|_{L^2} \leqslant 2\|u\|_{L^2}\|\dot{u}\|_{L^2},$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\|u\|_{L^2} \leqslant \|\dot{u}\|_{L^2} \leqslant \|u\|_{\mathcal{H}}.$$

□

IV. LOCAL DECAY

For the scalar wave equation, a radial differential operator γ was introduced to prove the local decay estimate.[2] It is used here for the same purpose. This multiplier is centered at the peak of the angular potential V_L. To simplify calculations the standard r_* coordinate is translated to a new one, $\rho_* = r_* - \alpha_*$, so that $\rho_* = 0$ at the peak of V_L. This centrifugal tortoise coordinate satisfies the same differential definition as r_*, Eq. (2.2).

Definition IV.1: The centrifugal origin α, centrifugal tortoise origin α_*, and centrifugal tortoise radius ρ_* are defined by

$$\alpha \equiv 3M, \tag{4.1}$$

$$\alpha_* \equiv r_*|_{r=\alpha=3M}, \tag{4.2}$$

$$\rho_* \equiv r_* - \alpha_*. \tag{4.3}$$

Definition IV.2: Given $\sigma \in (\frac{1}{2}, 1]$, the Morawetz-type multiplier γ_σ is defined by

$$g_\sigma(r_*) \equiv \int_0^{(r_*-\alpha_*)/2M} (1+\tau^2)^{-\sigma}\,\mathrm{d}\tau, \tag{4.4}$$

$$\gamma_\sigma \equiv -\frac{i}{2}\left(g_\sigma\frac{\partial}{\partial r_*} + \frac{\partial}{\partial r_*}g_\sigma\right). \tag{4.5}$$

As before, C^∞ solutions are assumed so that there are no domain issues. In all cases, the value of σ will be fixed and the notation $g = g_\sigma$ and $\gamma = \gamma_\sigma$ will be used.

Theorem IV.3: If $u \in H^1(\mathfrak{M})$ and $\sigma \in (\frac{1}{2}, 1]$, then

$$\langle u, \gamma_\sigma u\rangle = 0 \tag{4.6}$$

and there is a constant $C_\sigma = \lim_{r_*\to\infty} g(r_*)$ such that

$$\|\gamma u\| \leqslant C_\sigma\|u\|_{\mathcal{H}} + \frac{1}{2}\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-\sigma} u\right\|_{L^2}. \tag{4.7}$$

Proof: Equation (4.6) is proven in Theorem 16 of Ref. 2 (the statement of which includes the additional, but unnecessary, assumption that u satisfy the scalar wave equation). For Eq. (4.7), Theorem 17 of Ref. 2 does not directly apply since the space $\mathcal{H}$ defined there involves different potentials. However, the same argument applies. It is first noted that since $\sigma > \frac{1}{2}$ and the integrand in the definition of g is positive and even, $|g|$ is bounded by $C_\sigma = \lim_{r_*\to\infty} g(r_*)$. Now, by direct computation,

$$\|\gamma u\| = \left\|gu' + \frac{1}{2}g'u\right\| \leqslant \|gu'\| + \frac{1}{2}\|g'u\| \leqslant C_\sigma\|u\|_{\mathcal{H}} + \frac{1}{2}\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-\sigma} u\right\|_{L^2}.$$

□

The Heisenberg-type relation will be applied to the multiplier γ. To do this it is necessary to estimate the commutator $[\Sigma_{j=1}^{3} H_j, \gamma]$.

Lemma IV.4: For $\sigma \in (\frac{1}{2}, 1]$,

$$i\left[\frac{-1}{r^2}\left(1-\frac{2M}{r}\right)\Delta_{S^2}, \gamma\right] = -g(r_*)\left[\frac{3M}{r}-1\right]\frac{2}{r^3}\left(1-\frac{2M}{r}\right)\Delta_{S^2} \geqslant 0. \tag{4.8}$$

Proof: The proof is found in Lemma 18 of Ref. 2.

Lemma IV.5: For $\sigma \in (\frac{1}{2}, 1]$ *and u in the domain of* γ *and H,*

$$\left\langle u, i\left[-\frac{\partial^2}{\partial r_*^2}, \gamma\right]u\right\rangle \geqslant \left\langle u, \frac{\sigma}{\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{\sigma+2}}\frac{1}{(2M)^3}\left[5+(3-2\sigma)\left(\frac{r_*-\alpha_*}{2M}\right)^2\right]u\right\rangle. \tag{4.9}$$

Proof: The proof is found in Lemma 20 of Ref. 2.

Lemma IV.6: For $\sigma \in (\frac{1}{2}, 1]$ *and u in the domain of H and* γ*, there is a constant* c_σ *so that*

$$\left\langle u, i\left[\sum_{i=j}^{3} H_j, \gamma\right]u\right\rangle \geqslant \left\langle u, \frac{c_\sigma}{\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{\sigma+1}}u\right\rangle. \tag{4.10}$$

Proof: Since $\sigma \leqslant 1$,

$$\frac{\sigma}{\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{\sigma+2}}\frac{1}{(2M)^3}\left[5+(3-2\sigma)\left(\frac{r_*-\alpha_*}{2M}\right)^2\right] < \frac{\sigma}{\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{\sigma+1}}.$$

In the proof of Lemma 21 of Ref. 2 it is shown that

$$i[V, \gamma] = g\left(3-\frac{8M}{r}\right)\frac{2M}{r^4}\left(1-\frac{2M}{r}\right). \tag{4.11}$$

Since $g<0$ for $r<3M$ and $g>0$ for $r>3M$, $i[H_2, \gamma]=-3i[V, \gamma]$ is negative for $r<8M/3$, positive for $8M/3<r<3M$, and negative for $3M<r$. In the region $8M/3<r<3M$, all the terms of the form $i[H_j, \gamma]$ are positive so an estimate of the form (4.10) holds. The other r values are now treated.

It is useful to note that a term relating H_2 to H_3 is decreasing since

$$\frac{\mathrm{d}}{\mathrm{d}r}\frac{3-\frac{8M}{r}}{1-\frac{3M}{r}} = -\frac{M}{(r-3M)^2} < 0.$$

At $r=2M$, $3-(8M/r)=-1=2[1-(3M/r)]$. Therefore in $2M<r\leqslant 8M/3$ and for $l \geqslant 2$,

$$\left|3-\frac{8M}{r}\right| < 2\left|1-\frac{3M}{r}\right|,$$

$$\left|g\frac{1}{r^3}\left(1-\frac{2M}{r}\right)\left(\frac{2M}{r}\right)\left(3-\frac{8M}{r}\right)\right| < \left|g\frac{1}{r^3}\left(1-\frac{2M}{r}\right)2\left(1-\frac{3M}{r}\right)\right|,$$

$$|i[H_2,\gamma]| < \frac{3}{6} i[H_3,\gamma].$$

The $\frac{3}{6}$ factor is present due to the restriction that $l \geqslant 2$ and hence that $-\Delta_{S^2} \geqslant 6$ and to the factor of -3 relating V to H_2.

At $r=3.3M$,

$$\left| \frac{2\left(1-\frac{3M}{r}\right)6}{-3\left(3-\frac{8M}{r}\right)} \right| = \frac{12}{19} > \frac{2M}{3.3M}.$$

Therefore for $r>3.3M$ and $l \geqslant 2$

$$\left| -3\left(3-\frac{8M}{r}\right)\frac{2M}{3.3M} \right| < 2\left(1-\frac{3M}{r}\right)6,$$

$$\left| \frac{g}{r^3}\left(1-\frac{2M}{r}\right)(-3)\left(3-\frac{8M}{r}\right)\frac{2M}{r} \right| < \frac{g}{r^3}\left(1-\frac{2M}{r}\right)\left(1-\frac{3M}{r}\right)(-\Delta_{S^2}),$$

$$|i[H_2,\gamma]| < i[H_3,\gamma].$$

Finally for $3M \leqslant r \leqslant 3.3M$, since $i[H_3,\gamma]$ vanishes quadratically in $(r-3M)$ where as $i[H_2,\gamma]$ vanishes only linearly it is necessary to bound $i[H_2,\gamma]$ by $i[H_1,\gamma]$. On this interval $F^{-1}<3$, $\rho_* < 0.9M$, and $g<0.9M$. Again, assuming $l \geqslant 2$,

$$\begin{aligned} |i[H_2,\gamma]| &= 3g\left(3-\frac{8M}{r}\right)\left(\frac{2M}{r}\right)^4 \frac{1}{(2M)^3}\left(1-\frac{2M}{r}\right) \\ &< (3)(0.9)\left(\frac{19}{33}\right)\left(\frac{2}{3}\right)^4\left(\frac{13}{33}\right)\frac{1}{(2M)^3} < 0.121\frac{1}{(2M)^3}, \end{aligned}$$

$$i[H_1,\gamma] > \frac{5\sigma}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{\sigma+2}}\frac{1}{(2M)^3} > \frac{5\sigma}{(1.2025)^{\sigma+2}}\frac{1}{(2M)^3} > 1.43\frac{1}{(2M)^3}.$$

In summary, for $r<3M$ and for $r>3.3M$, $i[H_2+H_3,\gamma]>0$, and for $3M \leqslant r \leqslant 3.3M$, $i[H_1+H_2,\gamma]$ is strictly positive. Since for $r<3M$ and for $r>3.3M$, $i[H,\gamma]>i[H_1,\gamma]>C(1+(\rho_*/2M)^2)^{-\sigma-1}$ and since for $3M \leqslant r \leqslant 3.3M$, $i[H,\gamma]$ is strictly positive, there is a constant C so that

$$\langle u, i[H,\gamma]u\rangle \geqslant \left\langle u, \frac{C}{\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{\sigma+1}}u \right\rangle.$$

□

It is now possible to apply the Heisenberg-type relation to γ and integrate the result to prove local decay.

Theorem IV.7 (local decay): *If u is a solution to the Regge–Wheeler equation [Eq. (2.4)], $\|u\|^2_{\mathcal{H}}=E$, $u(0)=f$, and $\beta>\frac{3}{2}$, then there is a constant D_σ such that*

$$\int_0^\infty \left\| \left(1+\left(\frac{r_*}{2M}\right)^2\right)^{-\beta/2} u \right\|^2 \mathrm{d}t \leqslant D_\sigma E^{1/2}(E^{1/2}+\|f\|_{L^2}). \tag{4.12}$$

Proof: Initially the result will be proven with $\beta=\sigma+1$ and $\sigma\in\left(\frac{1}{2},1\right]$ and ρ_* in place of r_*. By integrating Lemma IV.6 and applying the Heisenberg-type relation, Theorem III.1, it is possible to bound the time integral of the local decay term by an inner product evaluated at time T. Despite the explicit factors of i appearing in the following, all terms are real valued:

$$\begin{aligned}\int_0^T\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-(\sigma+1)/2}u\right\|^2\mathrm{d}t &\leqslant \int_0^T\langle u,i[H,\gamma]u\rangle\mathrm{d}t\leqslant\int_0^T\frac{\mathrm{d}}{\mathrm{d}t}(\langle u,i\gamma\dot{u}\rangle-\langle\dot{u},i\gamma u\rangle)\mathrm{d}t\\ &\leqslant\int_0^T i\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathrm{d}}{\mathrm{d}t}\langle u,\gamma u\rangle-2\langle\dot{u},\gamma u\rangle\right)\mathrm{d}t\leqslant\int_0^T-2i\frac{\mathrm{d}}{\mathrm{d}t}\langle\dot{u},\gamma u\rangle\mathrm{d}t\\ &\leqslant 2(\|\dot{u}\|\,\|\gamma u\|)|_{t=T}+2(\|\dot{u}\|\,\|\gamma u\|)|_{t=0}\\ &\leqslant E^{1/2}\left(4C_\sigma E^{1/2}+\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-\sigma}f\right\|\right)\\ &\quad+E^{1/2}\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-\sigma}u(T)\right\|.\end{aligned}\tag{4.13}$$

Since $\sigma>\frac{1}{2}$, q can be chosen so that $(1/2\sigma)+\frac{1}{2}<q<\frac{3}{2}$. If p is the conjugate exponent to q and $\kappa\equiv 2/p$, then

$$\frac{1}{p}<1-\frac{2}{3}=\frac{1}{3},\quad\frac{2-\kappa}{2}q=1,\quad q\sigma>\frac{\sigma+1}{2}.$$

Hölder's inequality can now be applied to the last norm in line (4.13),

$$\begin{aligned}\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-\sigma}u\right\|^2&=\int_{\mathfrak{M}}\frac{|u|^\kappa|u|^{2-\kappa}}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{2\sigma}}\mathrm{d}r_*\,\mathrm{d}^2\omega_{S^2}\\ &\leqslant\left(\int_{\mathfrak{M}}|u|^{p\kappa}\,\mathrm{d}r_*\,\mathrm{d}^2\omega_{S^2}\right)^{1/p}\left(\int_{\mathfrak{M}}\frac{|u|^{(2-\kappa)q}}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{2\sigma q}}\mathrm{d}r_*\,\mathrm{d}^2\omega_{S^2}\right)^{1/q},\end{aligned}$$

$$\begin{aligned}\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-\sigma}u\right\|&\leqslant\|u\|^{1/p}\left\|\frac{|u|}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{\sigma q}}\right\|^{1-(1/p)}\\ &\leqslant(E^{1/2}T+\|f\|)^{1/p}\left\|\frac{u}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{(\sigma+1)/2}}\right\|^{1-(1/p)}.\end{aligned}$$

For sufficiently large T, there is a constant F so that

$$\begin{aligned}\left\|\left(1+\left(\frac{r_*-\alpha_*}{2M}\right)^2\right)^{-\sigma}u\right\|&\leqslant FT^{1/p}\left\|\frac{u}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{(\sigma+1)/2}}\right\|^{1-(1/p)},\\ \int_0^T\left\|\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{-(\sigma+1)/2}u\right\|^2\mathrm{d}t&\leqslant E^{1/2}(4C_\sigma E^{1/2}+\|f\|)+FT^{1/p}\left\|\frac{u}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{(\sigma+1)/2}}\right\|^{1-(1/p)}.\end{aligned}\tag{4.14}$$

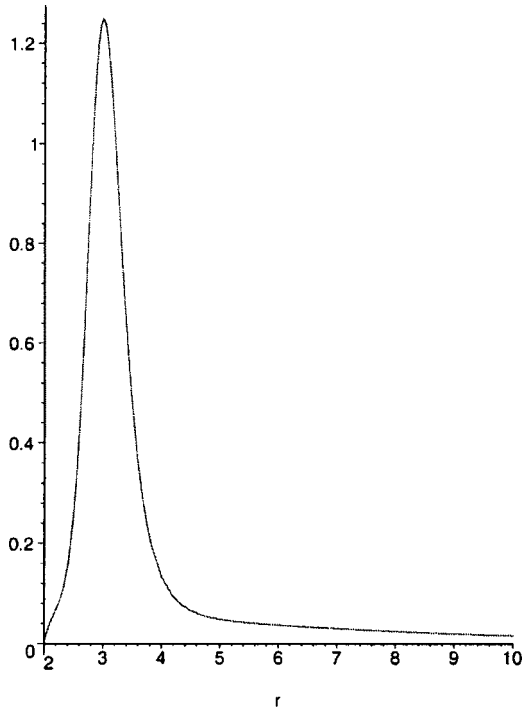

FIG. 1. Plot of a lower bound for $i[H,\gamma]$ as a function of r.

This establishes an integral relation between the local decay norm and its square integral. The local decay norm has bounded derivative since

$$\frac{\mathrm{d}}{\mathrm{d}t}\left\|\frac{u}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{(\sigma+1)/2}}\right\|^2 = 2\left\langle \frac{u}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{(\sigma+1)2}}, \frac{\dot{u}}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{(\sigma+1)2}} \right\rangle$$
$$\leqslant 2\left\|\frac{u}{\left(1+\left(\frac{\rho_*}{2M}\right)^2\right)^{(\sigma+1)/2}}\right\| E^{1/2}. \tag{4.15}$$

These two conditions are sufficient to apply Lemma 25 of Ref. 2. That lemma states that for $\theta:\mathbf{R}\to\mathbf{R}^+$ with uniformly bounded derivative, $\epsilon\in\left(0,\frac{1}{3}\right)$, if $\int_0^t\theta(\tau)^2\,\mathrm{d}\tau\leqslant C_1+C_2t^\epsilon\theta^{1-\epsilon}$ then $t^\epsilon\theta(t)^{1-\epsilon}$ goes to zero sequentially and hence $\int_0^t\theta(\tau)^2\,\mathrm{d}\tau\leqslant C_1$. The lemma can be applied with θ as the local decay norm, $1/p=\epsilon$, and C_1 and C_2 as in (4.14).

This proves the result for $\beta\in\left(\frac{3}{2},2\right]$ and for ρ_* instead of r_*. Since $(1+(\rho_*/2M)^2)^{-\beta}$ is a decreasing function of β, the result holds for all $\beta>\frac{3}{2}$. Finally since for any β there is a constant so that for all r_*, $(1+[(r_*-\alpha_*)/2M]^2)^{-\beta}\leqslant C(1+(r_*/2M)^2)^{-\beta}$ the statement of the theorem holds. □

APPENDIX: NUMERICAL VERIFICATION OF THE POSITIVITY OF THE COMMUTATOR

The key step in proving the local decay estimate is the lower bound for the commutator $i[H,\gamma]$ proven in Lemma IV.6. From the asymptotics of $i[H_2,\gamma]\approx r^{-4}$ and $i[H_3,\gamma]\approx r^{-3}$ it is clear that the negative contributions from $i[H_2,\gamma]$ will be dominated eventually and it is sufficient to show $i[H,\gamma]$ is positive in some finite domain. To verify positivity of the commutator, the sum of the exact form for $i[H_2,\gamma]$ from Eq. (4.11), the lower bounds for $i[H_1,\gamma]$ from Eq. (4.9), and the lower bound for $i[H_3,\gamma]$ from Eq. (4.8) with $l=2$ is plotted for $M=1$ and $\sigma=1$ in Fig. 1. From the graph it is clear that the total commutator is positive. The graph decays because all the terms involved decay. This provides an alternate, numerical verification of the result proven in Lemma IV.6.

Necessary and sufficient conditions for *n*-dimensional conformal Einstein spaces via dimensionally dependent identities

S. Brian Edgar[a)]
Matematiska Institutionen, Linköpings Universitet, Linköping S-581 83, Sweden

(Received 3 August 2004; accepted 7 September 2004; published online 27 December 2004)

Listing has recently extended results of Kozameh, Newman, and Tod for four-dimensional space–times and presented a set of necessary and sufficient conditions for a metric to be locally conformally equivalent to an Einstein metric in all semi-Riemannian spaces of dimension $n \geqslant 4$—subject to a nondegeneracy restriction on the Weyl tensor. By exploiting dimensionally dependent identities we demonstrate how to construct two alternative versions of these necessary and sufficient conditions which we believe will be useful in applications. The four-dimensional case is discussed in detail and examples are also given in five and six dimensions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1823011]

I. INTRODUCTION

Kozameh, Newman, and Tod[7] have shown that a certain pair of necessary conditions are also sufficient for a *four-dimensional space–time* to be conformal to an Einstein space–time—with the exception of those space–times whose complex Weyl scalar invariant $J=0$. (In the conformal Einstein space with metric g_{ab}, $R^{ab}{}_{cd}$ represents the Riemann tensor, $C^{ab}{}_{cd}$ represents the Weyl conformal tensor, $R^{ab}{}_{cd}$ represents the Ricci tensor, $R=R^{a}{}_{a}$ the Ricci scalar, and $\tilde{R}_{ab}=R_{ab}-Rg_{ab}/n$ the trace-free Ricci tensor where $2\nabla_{[a}\nabla_{b]}V^{c}=-R_{abcd}V^{d}$ for an arbitrary vector V^{a}. I, J are the usual complex Weyl scalar invariants in four dimensions, and $\underset{2}{C}\equiv C^{ab}{}_{cd}C^{cd}{}_{ab}$. More details of the notation are given in the next section.) Implicit in their paper was another result: a *four-dimensional space–time* with metric g_{ab} can be transformed into an Einstein space by a conformal transformation if and only if the vector K^{a} given by

$$K^{a}=4C^{ac}{}_{ij}\nabla^{k}C^{ij}{}_{ck}/\underset{2}{C} \tag{1a}$$

satisfies (the $n=4$ dimension version of)

$$\tilde{R}_{ab}+(n-2)(\nabla_{a}K_{b}-K_{a}K_{b}-(\nabla^{c}K_{c}-K^{c}K_{c})g_{ab}/n)=0 \tag{2a}$$

for the class of space–times where $\underset{2}{C}\neq 0$. The essential ideas in Ref. 7 were to exploit the properties that Einstein spaces are a subset of C spaces (spaces whose Weyl tensor is divergence free, $\nabla_{a}C^{ab}{}_{cd}=0$) and that spaces conformal to C spaces satisfy (the $n=4$ dimension version of)

$$\nabla^{k}C^{ab}{}_{ck}+(n-3)C^{ab}{}_{ck}K^{k}=0 \tag{3}$$

and hence to extract the explicit expression (1a) for K^{a} by using the *four-dimensional* dimensionally dependent identity

a)Electronic mail: bredg@mai.liu.se

$$C^{cj}{}_{ab}C^{ab}{}_{ck} = \delta^{j}_{k}C/4. \tag{4a}$$

The principles underlying the techniques used in Ref. 7 originated in a study of conformal transformations by spinor methods by Szekeres,[12] and although most of the work in Ref. 7 was tensor based, some lemmas were proven by spinor methods; this is probably why Kozameh, Newman, and Tod have commented that their method in Ref. 7 does not seem to be extendible to higher dimensions $n>4$. However, recently Listing[8] has exploited the same principles more generally and shows that the condition that a particular vector $\mathbf{T}^a$ obtained from (3) satisfies (2a) is a necessary and sufficient condition for conformal Einstein spaces in *all semi-Riemannian spaces with dimensions* $n\geqslant 4$—subject to a nondegenerate determinant condition on a matrix representation of the Weyl tensor. On the other hand, when the four-dimensional results from Ref. 8 are compared with Ref. 7, the explicit form of the vector $\mathbf{T}^a$ in Ref. 8 differs considerably from its counterpart K^a used in Ref. 7 and quoted above in (1a); furthermore, the nondegenerate determinant condition in Ref. 8 is not easily translated into a condition on the real Weyl invariant scalars in the n-dimensional case, although Listing states that this condition is equivalent in four dimensions to the complex scalar invariant Weyl scalar $J\neq 0$.

It is well known that we can write $\mathbf{C}^{A}{}_{C}\equiv C^{ab}{}_{cd}$ where $A\equiv[ab]$, $C\equiv[cd]$ so that $A,C=1,2,\ldots,N(=n(n-1)/2)$ and so consider $\mathbf{C}$ as an $N\times N$ trace-free matrix. (Note that we are not making use of the symmetries, $C_{abcd}=C_{cdab}$ and $C_{a[bcd]}=0$, and in fact this construction is valid for any trace-free double 2-form; also, we are not defining a metric for the N-dimensional space, nor even making use of the n-dimensional space metric g_{ab} in this construction.)

Instead of exploiting higher dimensional counterparts of identities such as (4a), Listing's result and proof[8] assumed $\det(\mathbf{C})\neq 0$ and then used the inverse matrix $\mathbf{C}^{-1}$ to solve (3) for K^a; however $\mathbf{C}^{-1}$ cannot be easily interpreted in tensor notation without some translation and, in that form, does not seem to be very useful in practical applications. In the illustrative example in Ref. 8 Listing restricted himself to *four-dimensional Riemann space*, where he followed the technique in Ref. 7 of using the *four-dimensional* identity (4a) to extract K^a, and also used properties dependent on the *positive definite metric*; this avoided having to deal with $\mathbf{C}^{-1}$ directly.

Although the four-dimensional identity (4a) is well known, the existence of higher dimensional analogues (Ref. 2) seems less well known and one purpose of this paper is to draw attention again to the power and usefulness of such dimensionally dependent tensor identities.[2] (See also Refs. 9, 3, and 13.)

We shall show in this paper how to exploit dimensionally dependent identities[2] to obtain results valid in all dimensions $n\geqslant 4$ and automatically in all signatures; in particular we will

(i) reformulate Listing's results in Ref. 8, and in particular, $\det(\mathbf{C})\neq 0$ and the inverse matrix $\mathbf{C}^{-1}$ in the tensor notation of Ref. 7;
(ii) obtain explicit solutions for K^a which avoid the use of $\mathbf{C}^{-1}$ altogether.

We shall also show explicitly how the four-dimensional results implicit in Ref. 7 can be seen as special cases of this formulation of Listing's result, and are valid for all signatures.

To demonstrate the usefulness of our versions, we will consider the four-, five-, and six-dimensional cases, independent of signature. The higher dimensional analogues[2] of the four-dimensional identity (4a) will be the basis for our applications in five and six dimensions.

II. NOTATION

We begin with some notation which we will use to link algebraic and tensor notation, and prove a simple lemma. Let us define, for $p\geqslant 1$ Weyl tensors, a *chain of the zeroth kind*,[13]

$$\underset{p}{C}{}^{ab}{}_{cd} \equiv C^{ab}{}_{i_1j_1}C^{i_1j_1}{}_{i_2j_2}C^{i_2j_2}{}_{i_3j_3}\cdots C^{i_{p-2}j_{p-2}}{}_{i_{p-1}j_{p-1}}C^{i_{p-1}j_{p-1}}{}_{cd},$$

noting that $\underset{1}{C}{}^{ab}{}_{cd}\equiv C^{ab}{}_{cd}$.

A useful relation is

$$\underset{p}{C}{}^{ab}{}_{cd}\underset{q}{C}{}^{cd}{}_{ef} = \underset{p+q}{C}{}^{ab}{}_{ef}$$

and the following scalar invariants arise naturally:

$$\underset{p}{C} \equiv \underset{p}{C}{}^{ab}{}_{ab}.$$

Of course there are other Weyl scalar invariants (e.g., $C^{a}{}_{b}{}^{c}{}_{d}C^{b}{}_{e}{}^{d}{}_{f}C^{e}{}_{a}{}^{f}{}_{c}$) which do not fall into this pattern. The simple obvious identifications which we will exploit are

$$\mathbf{C}^p = \underset{p}{C}{}^{ab}{}_{cd},$$

$$\langle \mathbf{C}^p \rangle = \underset{p}{C}, \tag{5}$$

where $\langle\ \rangle$ denotes the trace of a matrix; but note that expressions like $\underset{2}{C}{}^{cj}{}_{ci}$ have no such obvious identification in the matrix notation.

The Cayley–Hamilton theorem for the trace-free $N\times N$ matrix $\mathbf{C}$ is given by

$$c_0\mathbf{C}^N + c_2\mathbf{C}^{N-2} + c_3\mathbf{C}^{N-3} + \cdots + c_{N-2}\mathbf{C}^2 + c_{N-1}\mathbf{C} + c_N\mathbf{I} = 0, \tag{6}$$

where $\mathbf{I}$ is the $N\times N$ identity matrix, and

$$c_0 = 1,\ \ c_2 = -\tfrac{1}{2}\langle\mathbf{C}^2\rangle,\ \ c_3 = -\tfrac{1}{3}\langle\mathbf{C}^3\rangle,\ \ c_4 = -\tfrac{1}{4}\left(\langle\mathbf{C}^4\rangle - \tfrac{1}{2}\langle\mathbf{C}^2\rangle^2\right),$$

$$c_5 = -\tfrac{1}{5}\left(\langle\mathbf{C}^5\rangle - \tfrac{5}{6}\langle\mathbf{C}^2\rangle\langle\mathbf{C}^3\rangle\right),$$

$$c_6 = -\tfrac{1}{6}\left(\langle\mathbf{C}^6\rangle - \tfrac{3}{4}\langle\mathbf{C}^2\rangle\langle\mathbf{C}^4\rangle - \tfrac{1}{3}\langle\mathbf{C}^3\rangle^2 + \tfrac{1}{8}\langle\mathbf{C}^2\rangle^3\right),\ \ \ldots\ ,$$

$$c_N = -\frac{1}{N}(\langle\mathbf{C}^N\rangle + \cdots + \cdots) \tag{7}$$

are the usual characteristic coefficients; since $\mathbf{C}$ is trace free, $c_1 = 0$. This theorem can easily be rewritten in chain notation as

$$c_0\underset{N}{C}{}^{ab}{}_{cd} + c_2\underset{N-2}{C}{}^{ab}{}_{cd} + c_3\underset{N-3}{C}{}^{ab}{}_{cd} + \cdots + c_{N-2}\underset{2}{C}{}^{ab}{}_{cd} + c_{N-1}\underset{1}{C}{}^{ab}{}_{cd} + c_N\delta^{a}_{[c}\delta^{b}_{d]} = 0, \tag{6′}$$

where the characteristic coefficients are now given in terms of Weyl scalar invariants by

$$c_0 = 1,\ \ c_2 = -\tfrac{1}{2}\underset{2}{C},\ \ c_3 = -\tfrac{1}{3}\underset{3}{C},\ \ c_4 = -\tfrac{1}{4}(\underset{4}{C} - \tfrac{1}{2}\underset{2}{C}{}^2),$$

$$c_5 = -\tfrac{1}{5}(\underset{5}{C} - \tfrac{5}{6}\underset{2}{C}\underset{3}{C}),$$

$$c_6 = -\tfrac{1}{6}(\underset{6}{C} - \tfrac{3}{4}\underset{2}{C}\underset{4}{C} - \tfrac{1}{3}\underset{3}{C}{}^2 + \tfrac{1}{8}\underset{2}{C}{}^3),\ \ \ldots\ ,$$

$$c_N = -\frac{1}{N}(\underset{N}{C} + \cdots + \cdots). \tag{7′}$$

From the well-known result $(-1)^N\det(\mathbf{C}) = c_N$ the required translation of $\det(\mathbf{C}) \neq 0$ into tensor language follows immediately:

$$0 \neq (-1)^{N+1} N \det(\mathbf{C}) = \underset{N}{C} + \cdots + \cdots . \tag{8}$$

Lemma: In n-dimensional spaces, the inhomogeneous algebraic equation for the vector V^d,

$$C^{ab}{}_{cd} V^d = H^{ab}{}_c,$$

has a unique solution when condition (8) holds; the solution is given by

$$V^a = \frac{2}{(n-1)c_N} H^{ij}{}_b (c_0 \underset{N-1}{C}{}^{ab}{}_{ij} + c_2 \underset{N-3}{C}{}^{ab}{}_{ij} + c_3 \underset{N-4}{C}{}^{ab}{}_{ij} + \cdots + c_{N-2} C^{ab}{}_{ij}),$$

where $N = n(-1)/2$ The coefficients $c_0, c_2, c_3, \ldots, c_{N-2}, c_N$ are the usual characteristic coefficients of the Cayley–Hamilton theorem given in (7′).

Proof: We consider the Cayley–Hamilton theorem for the $N \times N$ trace-free matrix $\mathbf{C}$ in tensor notation in (6′), with characteristic coefficients given by (7′).

Multiplying by V_a gives

$$\begin{aligned} 0 &= V_a (c_0 \underset{N}{C}{}^{ab}{}_{cd} + c_2 \underset{N-2}{C}{}^{ab}{}_{cd} + c_3 \underset{N-3}{C}{}^{ab}{}_{cd} + c_4 \underset{N-4}{C}{}^{ab}{}_{cd} + \cdots + c_{N-2} \underset{2}{C}{}^{ab}{}_{cd} + c_{N-1} \underset{1}{C}{}^{ab}{}_{cd}) + c_N V_{[c} \delta^b_{d]} \\ &= V_a \underset{1}{C}{}^{ab}{}_{ij} (c_0 \underset{N-1}{C}{}^{ij}{}_{cd} + c_2 \underset{N-3}{C}{}^{ij}{}_{cd} + c_3 \underset{N-4}{C}{}^{ij}{}_{cd} + c_4 \underset{N-5}{C}{}^{ij}{}_{cd} + \cdots + c_{N-2} \underset{1}{C}{}^{ij}{}_{cd}) + c_{N-1} V_a \underset{1}{C}{}^{ab}{}_{cd} + c_N V_{[c} \delta^b_{d]}. \end{aligned}$$

From which, by taking the trace and remembering $\underset{1}{C}{}^{ab}{}_{cd} \equiv C^{ab}{}_{cd}$ is trace free, we obtain

$$0 = V_a C^{ab}{}_{ij} (c_0 \underset{N-1}{C}{}^{ij}{}_{cb} + c_2 \underset{N-3}{C}{}^{ij}{}_{cb} + c_3 \underset{N-4}{C}{}^{ij}{}_{cb} + c_4 \underset{N-5}{C}{}^{ij}{}_{cb} + \cdots + c_{N-2} C^{ij}{}_{cb}) + \frac{n-1}{2} c_N V_c.$$

Rearranging gives the solution in the lemma. □

For future reference, we note that the *four-dimensional identity* (4a) can be written in the chain notation as

$$\underset{2}{C}{}^{cj}{}_{ck} = \delta^j_k \underset{2}{C}/4$$

and this is actually a special case of the more general identity[13] *in four dimensions only*

$$\underset{p}{C}{}^{cj}{}_{ck} = \delta^j_k \underset{p}{C}/4, \quad p = 2,3,4, \ldots . \tag{4b}$$

We have preferred the notation $\underset{2}{C}, \underset{3}{C}, \ldots, \underset{p}{C}, \ldots$ to the (possibly confusing) notation $C^2, C^3, \ldots, C^p, \ldots$ used in Refs. 7 and 8 and elsewhere for these Weyl scalar invariants.

Finally we note a very useful dimensionally *independent* identity (a direct consequence of the first Bianchi identity),

$$4 C_{a[ij]b} C^{cijd} = C_{abij} C^{cdij}.$$

III. REFORMULATING LISTING's RESULT AND REDERIVING THE IMPLICIT RESULTS IN REF. 7

With this lemma we determine the vector K^a from (3),

$$K^a = \frac{2}{(n-3)(n-1)c_N} \nabla^k C^{ij}{}_{kb} (c_0 \underset{N-1}{C}{}^{ab}{}_{ij} + c_2 \underset{N-3}{C}{}^{ab}{}_{ij} + c_3 \underset{N-4}{C}{}^{ab}{}_{ij} + \cdots + c_{N-2} C^{ab}{}_{ij}) \tag{9}$$

providing restriction (8) holds, where $N = n(n=1)/2$.

Substituting this value for K^a back into (2a) gives necessary and sufficient conditions defined only in terms of the geometry.

We can therefore reformulate Theorem 4.5 in Ref. 8 as follows.

Theorem 1: *A semi-Riemannian manifold, with a Weyl tensor subject to the restriction (8), is locally conformally related to an Einstein space if and only if the vector field K^a given in (9) satisfies (2a).*

Four dimensions: We now will retrieve the four-dimensional results implicit in Ref. 7 from this theorem in a signature independent manner. Instead of substituting for K^a with the expression (1a) as used in Ref. 7, or the four-dimensional version of the expression involving $\mathbf{C}^{-1}$ in Ref. 8, we can now use the $n=4$ version of (9),

$$K^a = \frac{2}{3c_6}\nabla^k C^{ij}{}_{kb}(c_0 \underset{5}{C}{}^{ab}{}_{ij} + c_2 \underset{3}{C}{}^{ab}{}_{ij} + c_3 \underset{2}{C}{}^{ab}{}_{ij} + c_4 C^{ab}{}_{ij}) \tag{10}$$

providing $c_6 \neq 0$ with the characteristic coefficients given by (7′) in terms of Weyl scalars. However, since the solution for K^a is unique we should be able to see precisely the links between these two expressions in (1a) and (10). To retrieve the result (1a) from (10) we simply substitute (3) back into the right-hand side of (a slightly rearranged) (10), for all terms except the last one, and use identity (4a) on each of these terms,

$$\begin{aligned} 3c_6 K^a &= -2K^k C^{ij}{}_{kb}(\underset{5}{C}{}^{ab}{}_{ij} + c_2 \underset{3}{C}{}^{ab}{}_{ij} + c_3 \underset{2}{C}{}^{ab}{}_{ij}) + 2c_4 C^{ab}{}_{ij}\nabla^k C^{ij}{}_{kb} \\ &= -2K^k(\underset{6}{C}{}^{cb}{}_{kb} + c_2 \underset{4}{C}{}^{cb}{}_{kb} + c_3 \underset{3}{C}{}^{cb}{}_{kb}) + 2c_4 C^{ab}{}_{ij}\nabla^k C^{ij}{}_{kb} \\ &= -\tfrac{1}{2}K^a(\underset{6}{C} + c_2 \underset{4}{C} + c_3 \underset{3}{C}) + 2c_4 C^{ij}{}_{cb}\nabla^k C^{ij}{}_{kb} \end{aligned}$$

which rearranges to

$$(6c_6 + \underset{6}{C} + c_2 \underset{4}{C} + c_3 \underset{3}{C})K_c = 4c_4 C^{ij}{}_{cb}\nabla_k C^{kb}{}_{ij}$$

and via (7′) to

$$c_4 \underset{2}{C} K^a = -4c_4 C^{ab}{}_{ij}\nabla^k C^{ij}{}_{kb}$$

and hence to (1a)—providing $\underset{2}{C} \neq 0 \neq \underset{4}{C} - \underset{2}{C}{}^2/2$.

Kozameh, Newman, and Tod[7] have shown that it is possible to obtain three alternative versions to (1a) for K^a consisting of

$$K^a = 4\underset{2}{C}{}^{ac}{}_{ij}\nabla^k C^{ij}{}_{ck}/\underset{3}{C} \quad \text{for } \underset{3}{C} \neq 0$$

together with two other similar expressions with invariants involving the dual of the Weyl tensor. We do not wish to depend on expressions with duals in this work since we wish to generalize the four-dimensional case to all higher dimensions. Instead, from the general identity (4b) we see that we can obtain the various expressions for K^a for all integers $p \geqslant 2$,

$$K^a = 4\,\underset{p-1}{C}{}^{ac}{}_{ij}\nabla^k C^{ij}{}_{ck}/\underset{p}{C} \quad \text{for } \underset{p}{C} \neq 0. \tag{1b}$$

So, in an analogous manner to which we retrieved (1a) from (10), we can also retrieve (1b) for $p=3, 4, 6$; by use of the Cayley–Hamilton theorem we could also retrieve the results for $p=5$ and $p \geqslant 7$, although after $p=6$ these expressions are not independent precisely because of the Cayley–Hamilton theorem. We note that we cannot retrieve the version of (1b) directly with $p=5$ from (10) due to the fact that the relevant term involved the coefficient c_1 which is identically zero, being the trace of $C_{ab}{}^{cd}$.

It is well known that in four dimensions there exist only four algebraically independent Weyl scalar invariants: these are usually given in terms of the well-known complex invariants I and J,

which come naturally from considerations in terms of spinors or complex Weyl tensors (which exploit the very simple and unique structure of the Weyl dual in four dimensions). If we wish to only employ structures which can be exploited in higher dimensions, we would consider instead the four algebraically independent scalars C, C, C, C (or any four from C, C, C, C, C)[10] (see also Refs. 11 and 5); and providing there is at least one Weyl scalar invariant which is nonzero, we can calculate K^a explicitly.

Higher dimensions: Theorem 1 gives an explicit tensor expression for K^a for all dimensions. So, for example, in *five dimensions*, $N=10$ and we obtain

$$K^a = \frac{1}{4c_{10}}\nabla^k C^{ij}{}_{kb}(c_0 C^{ab}{}_{ij} + c_2 C^{ab}{}_{ij} + c_3 C^{ab}{}_{ij} + \cdots + c_7 C^{ab}{}_{ij} + c_8 C^{ab}{}_{ij})$$

providing $c_{10} \neq 0$ with the characteristic coefficients given by (7′) in terms of Weyl scalars. Clearly this expression involves quite high order terms in the Weyl tensor, and we note that in the four-dimensional case, we were able to get lower order expressions for K^a by exploiting the individual dimensionally dependent identities (4b) rather than the Cayley–Hamilton theorem implicit in Theorem 1. So, in higher dimensions, we would also expect to exploit individual dimensional identities, analogous to the four-dimensional identities (4b), in order to obtain alternative lower order forms in the Weyl tensor for K^a in n dimensions.

IV. LOWER ORDER VERSIONS OF K^a IN n-DIMENSIONS

In four dimensions, providing we pay the price that at least one scalar invariant is nonzero, we are able to solve the four-dimensional version of (3), and obtain K^a. The versions from the individual identities (4b) are more concise and manageable than the versions from the Cayley–Hamilton theorem; on the other hand, in four dimensions, the latter include all the simpler results as special cases, and are more general, in the sense of weaker restrictions on the Weyl scalar invariants. Of course also the Cayley–Hamilton approach is applicable in all dimensions. However, we now will show how to obtain alternative simpler versions for K^a in dimensions other than four, by direct application of dimensionally dependent identities analogous to those used in four dimensions in Ref. 7.

The set of identities (4b) are all consequences of the well-known four-dimensional identity [it is interesting to note, in this notation, that the underlying identity for the Cayley–Hamilton theorem for the trace-free 6×6 matrix $\mathbf{C}$ is $\mathbf{C}^{[A}{}_{[P}\delta^{BCDEF]}_{QRSTU]}=0$ (Ref. 2)],[3]

$$C^{[ab}{}_{[cd}\delta^{e]}_{f]} = 0, \tag{11}$$

and we shall now exploit their higher dimensional analogues in the same way as in Ref. 7 for the four-dimensional case. For five dimensions we have

$$C^{[ab}{}_{[cd}\delta^{ef]}_{hi]} = 0, \tag{12}$$

and for six dimensions,

$$C^{[ab}{}_{[cd}\delta^{efg]}_{hij]} = 0, \tag{13}$$

and so on.[2]

These lead to

$$C^{cd}{}_{pe}C^{ph}{}_{ab}C^{[ab}{}_{[cd}\delta^{ef]}_{hi]} = 0 \tag{14}$$

for five dimensions, and

$$C^{cd}{}_{ef}C^{hi}{}_{ab}C^{[ab}{}_{[cd}\delta^{efg]}_{hij]} = 0 \tag{15}$$

for six dimensions, and so on. Of course, these are just representative for each dimension of the various identities that can be created; but it is of interest to note that for the lowest order in Weyl in each dimension—in five dimensions cubic, in six dimensions cubic, in seven dimensions quartic, and so on—there is only one possibility, but as we look at higher orders—in five dimensions quartic, in six dimensions quartic, in seven dimensions quintic, and so on—there will be many more possibilities. Unfortunately, when expanded, such two-index identities in higher dimensions will not have such a simple form as the four-dimensional identities (4b).

In higher dimensions there exist greater numbers of algebraically independent Weyl scalar invariants, and so there will be greater numbers of two-index tensor identities analogous to (4b) for each dimension $n>4$; furthermore, the tensor identities analogous to (4b) will be based on (14) and (15), … and so will also require more Weyl tensors as the dimension increases. Since, in higher dimensions, a product of three or more Weyl tensors yields more than one Weyl scalar algebraically independent of each other and of invariants of lower order (e.g., in general, $\underset{3}{C}$ and $C^{a\ b}_{i\ j}C^{i\ j}_{c\ d}C^{c\ d}_{a\ b}$ are algebraically independent in $n\geqslant 6$ dimensions), and more than one algebraically independent two-index tensor, we expect the higher dimensional analogues of identities (4b) to consist of linear combinations of Weyl tensors on both sides of the identity.

However, it is important to note that, although these higher order two-index identities will have more terms, and higher products, they will have the same crucial structure, which we can represent by

$$\underset{p}{L\{C\}}{}^{j}{}_{k} = \delta^{j}_{k}\underset{p}{L\{C\}}/n, \tag{16}$$

where $\underset{p}{L\{C\}}{}^{j}{}_{k}$ represents a two-index tensor consisting of a linear combination of products of p Weyl tensors, and $\underset{p}{L\{C\}}\equiv\underset{p}{L\{C\}}{}^{i}{}_{i}$ represents a linear combination of scalar products of p Weyl tensors. (Note that each term is unlikely to be just a simple chain.) It follows, for $\underset{p}{L\{C\}}\neq 0$ from (16),

$$K^{j} = n\underset{p}{L\{C\}}{}^{j}{}_{k}K^{k}/\underset{p}{L\{C\}}, \tag{17}$$

and hence all the terms involving the vector K^k on the right-hand side—which will each contain a factor of the form $C^{\cdot\cdot}{}_{.k}K^{k}$—can be replaced using (3) by

$$C^{\cdot\cdot}{}_{.k}K^{k} = -\frac{1}{n-3}\nabla^{k}C^{\cdot\cdot}{}_{.k}. \tag{18}$$

We can summarize these new results as follows.

Theorem 2: *An n-dimensional semi-Riemannian manifold with a nondegenerate Weyl tensor restricted by* $\underset{p}{L\{C\}}\neq 0$ *[where* $\underset{p}{L\{C\}}$ *is associated with an identity of the form (16)] is locally conformally related to an Einstein space if and only if the vector field* K^a *given in (17), with the appropriate substitutions (18), satisfies (2a).*

Clearly from Theorem 2 we will obtain for K^a much lower order expressions in the Weyl tensor than from Theorem 1; for example, in five dimensions using Theorem 1 will require terms involving products of 10 Weyl tensors, whereas if we use Theorem 2 it looks possible to use terms with only three Weyl tensors, from (14).

V. FIVE- AND SIX-DIMENSIONAL SPACES

For higher dimensional spaces we can use Theorem 1 with the respective substitutions $n=5,6,\ldots$ into (9). But for spaces where we know dimensionally dependent identities of the form (14) and (15), etc., we can use Theorem 2.

So for spaces with dimension $n>4$ there is the need to systematically write out explicitly the two-index identities such as (14) and (15), etc., for $n=5,6,\ldots$. In this section we give just a few examples in five and six dimensions as illustrations.

Five dimensions: After a straightforward calculation we find that (14) expands as follows:

$$C^{aj}{}_{bc}C^{bc}{}_{de}C^{de}{}_{ak}-2C^{aj}{}_{bk}C^{bc}{}_{de}C^{de}{}_{ac}-4C^{aj}{}_{bc}C^{bd}{}_{ek}C^{ce}{}_{ad}=\tfrac{1}{5}(C^{ab}{}_{cd}C^{cd}{}_{ef}C^{ef}{}_{ab}-4C^{ab}{}_{cd}C^{ce}{}_{af}C^{df}{}_{be})\delta^{j}_{k}. \tag{19}$$

Although this appears to have the structure of (16), unfortunately when we also consider the scalar identity closely related to (14),

$$C^{cd}{}_{ab}C^{ki}{}_{ej}C^{[ab}{}_{[cd}\delta^{ej]}_{ki]}=0$$

we find

$$C^{ab}{}_{cd}C^{cd}{}_{ef}C^{ef}{}_{ab}=4C^{ab}{}_{cd}C^{ce}{}_{af}C^{df}{}_{be}. \tag{20}$$

(This five-dimensional scalar identity was also noted in Ref. 6, where it was obtained from the *five-dimensional* identity $C^{ab}{}_{[cd}C^{cd}{}_{ef}C^{ef}{}_{ab]}\equiv 0$.) This means that (19) does not have the structure of (16) as we hoped, since its right-hand side is identically zero. However, we do have an interesting two-index *five-dimensional* identity which will be useful in other contexts,

$$C^{aj}{}_{bc}C^{bc}{}_{de}C^{de}{}_{ak}-2C^{aj}{}_{bk}C^{bc}{}_{de}C^{de}{}_{ac}-4C^{aj}{}_{bc}C^{bd}{}_{ek}C^{ce}{}_{ad}=0. \tag{21}$$

On the other hand, if we consider one (of a number of) quartic identity in five dimensions,

$$C^{qg}{}_{ip}C^{ip}{}_{qe}C^{ab}{}_{cd}C^{[cd}{}_{[ab}\delta^{ef]}_{gh]}=0 \tag{22}$$

we obtain

$$\begin{aligned}5C^{qj}{}_{ip}C^{ip}{}_{qk}C^{ab}{}_{cd}C^{cd}{}_{ab}-8C^{qg}{}_{ip}C^{ip}{}_{qk}C^{ab}{}_{cg}C^{cj}{}_{ab}+8C^{qg}{}_{ip}C^{ip}{}_{qe}C^{be}{}_{ag}C^{aj}{}_{bk}-4C^{qg}{}_{ip}C^{ip}{}_{qe}C^{ab}{}_{gk}C^{ej}{}_{ab}\\ -8C^{qg}{}_{ip}C^{ip}{}_{qe}C^{ae}{}_{bk}C^{bj}{}_{ag}=(C^{qg}{}_{ip}C^{ip}{}_{qg}C^{ab}{}_{cd}C^{cd}{}_{ab}-4C^{qg}{}_{ip}C^{ip}{}_{qd}C^{ab}{}_{cg}C^{cd}{}_{ab})\delta^{j}_{k}\end{aligned} \tag{23}$$

which again appears to have the structure of (16). [The use of the identity (21) does not give any simplification.] We need to determine whether the right-hand side of (23) is nonzero. Unlike in the cubic case where there was only one possible scalar identity (20), there will be a number of quartic scalar identities in five dimensions; so although we will return to examine these another time, for now we simply note, via a counterexample, that the right-hand side cannot be identically zero.[14]

Hence, via the substitution (18), we obtain the following form for K^j:

$$\begin{aligned}K^{j}=&-(5C^{qj}{}_{ip}C^{ab}{}_{cd}C^{cd}{}_{ab}\nabla^{k}C^{ip}{}_{qk}-8C^{qg}{}_{ip}C^{ab}{}_{cg}C^{cj}{}_{ab}\nabla^{k}C^{ip}{}_{qk}+8C^{qg}{}_{ip}C^{ip}{}_{qe}C^{be}{}_{ag}\nabla^{k}C^{aj}{}_{bk}\\ &-4C^{qg}{}_{ip}C^{ip}{}_{qe}C^{ej}{}_{ab}\nabla^{k}C^{ab}{}_{gk}-8C^{qg}{}_{ip}C^{ip}{}_{qe}C^{bj}{}_{ag}\nabla^{k}C^{ae}{}_{bk})/2(C^{qg}{}_{ip}C^{ip}{}_{qg}C^{ab}{}_{cd}C^{cd}{}_{ab}\\ &-4C^{qg}{}_{ip}C^{ip}{}_{qe}C^{ab}{}_{cg}C^{ce}{}_{ab}).\end{aligned} \tag{24}$$

We can then substitute this value for K^j into the five-dimension version of (2a),

$$\widetilde{R}_{ab}+3(\nabla_{a}K_{b}-K_{a}K_{b}-(\nabla^{c}K_{c}-K^{c}K_{c})g_{ab}/5)=0 \tag{2b}$$

to obtain the required necessary and sufficient condition.

Six dimensions: When we expand (15) we obtain

$$C_{ak}{}^{bc}C^{aj}{}_{de}C_{bc}{}^{de}-2C_{ak}{}^{bj}C^{ac}{}_{de}C_{bc}{}^{de}-4C_{ak}{}^{bc}C^{dj}{}_{be}C_{cd}{}^{ae}=\tfrac{1}{6}(C_{ab}{}^{cd}C_{cd}{}^{ef}C_{ef}{}^{ab}-4C_{ab}{}^{cd}C^{ae}{}_{cf}C_{de}{}^{bf})\delta^{j}_{k}. \tag{25}$$

Unlike for the case of the five-dimensional two-index identity (19), there is no related scalar identity cubic in Weyl tensors, analogous to (20). So therefore we do not need to worry about the

possibility of the right-hand side of (25) being zero, and so we have an identity which has precisely the structure (16).

Hence, via the substitution (18), we obtain the following form for K^j:

$$K^j = -2(C^{aj}{}_{de}C_{bc}{}^{de}\nabla^k C_{ak}{}^{bc} - 2C^{ac}{}_{de}C_{bc}{}^{de}\nabla^k C_{ak}{}^{bj} - 4C^{dj}{}_{be}C_{cd}{}^{ae}\nabla^k C_{ak}{}^{bc})/(C_{ab}{}^{cd}C_{cd}{}^{ef}C_{ef}{}^{ab} - 4C_{ab}{}^{cd}C^{ae}{}_{cf}C_{de}{}^{bf}). \tag{26}$$

We can then substitute this value for K^j into the six-dimensional version of (2a),

$$\tilde{R}_{ab} + 4(\nabla_a K_b - K_a K_b - (\nabla^c K_c - K^c K_c)g_{ab}/6) = 0, \tag{2c}$$

to obtain the required necessary and sufficient condition.

There do not seem to be many explicit examples of identities for the Weyl tensor in higher dimensions in the literature. However, there does exist a six-dimensional two-index tensor identity quartic in the Weyl tensor which was identified some time ago by Lovelock.[9] A double three-form with the antisymmetric and trace-free properties, respectively,

$$H_{abk}{}^{def} = H_{[abk]}{}^{[def]},$$

$$H_{abi}{}^{dei} = 0 \tag{27}$$

in six dimensions (and lower) satisfies the identity

$$H_{abk}{}^{def}H_{def}{}^{abj} = \tfrac{1}{6}\delta^j_k H_{abc}{}^{def}H_{def}{}^{abc}. \tag{28}$$

This then becomes a quartic identity for Weyl with the choice

$$H_{ijk}{}^{abc} = A_{ijk}{}^{abc} - \tfrac{9}{8}A_{r[jk}{}^{r[bc}\delta_{i]}^{a]} + 3A_{rs[i}{}^{rs[c}\delta_i^a\delta_{k]}^{b]} - \tfrac{1}{4}A_{rst}{}^{rst}\delta^{[a}_{[i}\,\delta^b_j\delta^{c]}_{k]}, \tag{29}$$

where

$$A_{ijk}{}^{abc} = 4C_{[ij}{}^{h[a}C_{k]h}{}^{bc]}. \tag{30}$$

By substituting (29) into (28) we obtain

$$A_{abk}{}^{cde}A_{cde}{}^{abj} + 3A_{abk}{}^{abc}A_{cde}{}^{dej} + 6A_{abk}{}^{acd}A_{cde}{}^{bej} - 3A_{abc}{}^{ade}A_{dek}{}^{bcj} - A_{abc}{}^{abc}A_{dek}{}^{dej} + 6A_{abc}{}^{abd} = \delta^j_k(A_{abc}{}^{abc}A_{def}{}^{def} + 9A_{abc}{}^{ade}A_{def}{}^{bcf} - 9A_{abc}{}^{abd}A_{def}{}^{cef} - A_{abc}{}^{def}A_{def}{}^{abc})/6, \tag{31}$$

which is precisely the structure of (16). Hence, we obtain the following form for K^j,

$$K^j = -6(K^k A_{kab}{}^{cde}A_{cde}{}^{abj} + 3K^k A_{kab}{}^{abc}A_{cde}{}^{dej} + 6K^k A_{kab}{}^{acd}A_{cde}{}^{bej} - 3A_{abc}{}^{ade}K^k A_{kde}{}^{bcj} - A_{abc}{}^{abc}K^k A_{kde}{}^{dej} + 6A_{abc}{}^{abd}K^k A_{kde}{}^{cej})/(A_{abc}{}^{abc}A_{def}{}^{def} + 9A_{abc}{}^{ade}A_{def}{}^{bcf} - 9A_{abc}{}^{abd}A_{def}{}^{cef} - A_{abc}{}^{def}A_{def}{}^{abc}), \tag{32}$$

where all terms involving K^k on the right-hand side are replaced via the substitution

$$K^k A_{kab}{}^{cde} = \nabla^k C_{k[a}{}^{p[c}C_{b]p}{}^{de]} - \nabla^k C_{kp}{}^{[de}C_{ab}{}^{c]p} \tag{33}$$

and all other terms replaced with (30). We then substitute the value for K^j from (32) into (2c) to obtain the required necessary and sufficient condition. It is of course necessary to check that the right-hand side of (32) is not identically zero; this can be confirmed with a simple counterexample.[14]

VI. SUMMARY AND DISCUSSION

We have demonstrated the power of dimensionally dependent identities [either as the Cayley–Hamilton theorem, or as individual identities in specific dimensions such as (4b), (23), (25), and (31)] to translate the existence result of Listing[8] into versions which can be applied directly; furthermore, these applications are completely independent of signature. Theorem 1 gives a general reformulation of Listing's result on the existence of necessary and sufficient conditions in a form which can be directly exploited. So if one wishes to test if a particular metric is conformally Einstein, then it is a simple procedure to find its Weyl and trace-free Ricci tensor and to test directly—for instance, using GRTENSOR II (Ref. 14)—if condition (2a) is satisfied.

We have drawn attention to the higher dimensional analogues (23), (25), and (31), etc., of identities (4b), which are the basis for Theorem 2; for applications, Theorem 2 would seem to provide a simpler and more manageable tool—providing the appropriate identities are known.

A major complication when we move to dimensions $n>4$ is that there are many more Weyl invariant scalars, and of course they cannot all be written in the form C. The same sort of detailed analysis of the Weyl invariant scalars for $n=5,6\ldots$, as has been (partly) carried out for $n=4$, as well as a systematic presentation of two-index identities, is a necessary prerequisite for a systematic examination of all possible versions of the vector K^a. As Bonanos has pointed out,[1] existing detailed studies such as Ref. 4 do not take into account invariants formed from duals, or identities from the Cayley–Hamilton theorem. There are still a number of interesting issues to be investigated further.

There appears to be an important difference between even and odd dimensions: for even dimensions $n=4,6,8,\ldots$ the simplest two-index identity involves products of 2,3,4,… Weyl tensors, respectively, such as (4a) and (25), with a "delta term" on the right-hand side; for odd $n=5,7,\ldots$ the simplest two-index identity involves products of 3, 4,… Weyl tensors, respectively, such as (19), but it would seem likely that as in (21) the "delta term" on the right-hand side disappears because of an identically zero coefficient. For the investigations in this paper we need an identity of the former type, so in general it appears that for even dimensions $n=2m$ we will be able to exploit comparatively simple identities involving products of m Weyl tensors, while for odd dimensions $n=2m-1$ we will only have more complicated identities involving products of $m+1$ Weyl tensors. On the other hand, we anticipate that in other investigations the simple identities such as (21) will be very useful.

Listing[8] has stated that the condition $\det \mathbf{C} \neq 0$ *in four dimensions* is equivalent to the complex Weyl invariant scalar $J \neq 0$; by a little manipulation this can be shown to be equivalent to at least one of C and C being nonzero. It would be useful to know this condition in higher dimensions in terms of the real Weyl invariant scalars, and hence understand it better. The fact that the right-hand side of identity (19) is identically zero should alert us to the possibility of identically zero scalars arising in some situations.

The use of the dual Weyl tensor makes work in four dimensions comparatively easy—for instance there is a basis of four Weyl scalar invariants none of which is higher than cubic in Weyl, compared to having a basis with invariants up to fifth order in Weyl if the dual tensor is not used; in higher dimensions the major advantage (the dual Weyl tensor is also a double two form) does not apply, and work gets more complicated. However, we believe that it is still possible to take advantage of other benefits of the dual tensor, and we will discuss this possibility, together with the other points mentioned here, elsewhere.

Finally, we note that the necessary and sufficient conditions investigated by Listing[8] and in this paper were different from the necessary and sufficient conditions investigated explicitly in Ref. 7 in four dimensions. In Ref. 7 these conditions involved the Bach tensor which of course is only defined in four dimensions. It will be shown elsewhere how the techniques in Ref. 8 and in this paper can be used to investigate these alternative conditions as well as to generate an n-dimensional generalization of the Bach tensor.

(Received 17 February 2004; accepted 10 September 2004; published online 3 January 2005)

In this paper we study for a given azimuthal quantum number κ the eigenvalues of the Chandrasekhar–Page angular equation with respect to the parameters $\mu := am$ and $\nu := a\omega$, where a is the angular momentum per unit mass of a black hole, m is the rest mass of the Dirac particle and ω is the energy of the particle (as measured at infinity). For this purpose, a self-adjoint holomorphic operator family $A(\kappa;\mu,\nu)$ associated to this eigenvalue problem is considered. At first we prove that for fixed $\kappa \in \mathbb{R}\setminus(-\frac{1}{2},\frac{1}{2})$ the spectrum of $A(\kappa;\mu,\nu)$ is discrete and that its eigenvalues depend analytically on $(\mu,\nu) \in \mathbb{C}^2$. Moreover, it will be shown that the eigenvalues satisfy a first order partial differential equation with respect to μ and ν, whose characteristic equations can be reduced to a Painlevé III equation. In addition, we derive a power series expansion for the eigenvalues in terms of $\nu-\mu$ and $\nu+\mu$, and we give a recurrence relation for their coefficients. Further, it will be proved that for fixed $(\mu,\nu) \in \mathbb{C}^2$ the eigenvalues of $A(\kappa;\mu,\nu)$ are the zeros of a holomorphic function Θ which is defined by a relatively simple limit formula. Finally, we discuss the problem if there exists a closed expression for the eigenvalues of the Chandrasekhar–Page angular equation. © *2005 American Institute of Physics.*

I. INTRODUCTION

The angular eigenvalue problem of a spin-$\frac{1}{2}$ particle in the Kerr–Newman geometry is given by the Chandrasekhar–Page angular equation

$$\mathcal{L}^{+}_{1/2} S_{+1/2} = (am\cos\theta - \lambda) S_{-1/2}, \tag{1}$$

$$\mathcal{L}^{-}_{1/2} S_{-1/2} = (am\cos\theta + \lambda) S_{+1/2}, \tag{2}$$

see Chandrasekhar (1998, Chap. 10, Sec. 104), where the Kerr parameter a is the angular momentum per unit mass of a black hole and m is the rest mass of the Dirac particle. Moreover, the differential operators $\mathcal{L}^{\pm}_{1/2}$ are defined by

$$\mathcal{L}^{\pm}_{1/2} = \partial_\theta \pm Q(\theta) + \frac{\cot\theta}{2}, \quad Q(\theta) := a\omega\sin\theta + \frac{\kappa}{\sin\theta}, \quad \theta \in (0,\pi),$$

where ω is the energy of the particle (as measured at infinity) and κ is a half-integer, i.e., $\kappa = k - \frac{1}{2}$ with some $k \in \mathbb{Z}$. A parameter $\lambda \in \mathbb{R}$ is called an *eigenvalue* of this spectral problem if the

[b]Electronic mail: harald.schmid@mathematik.uni-regensburg.de
[c]Electronic mail: winklmeier@math.uni-bremen.de

system given by (1)-(2) has a nontrivial solution which is square-integrable on $(0,\pi)$ with respect to the weight function $\sin\theta$. In this paper we study for fixed κ the eigenvalues of the Chandrasekhar–Page angular equation as a function of the parameters $\mu := am$ and $\nu := a\omega$. As a main result, we will prove that the eigenvalues satisfy a first order quasilinear partial differential equation, and we will derive a power series expansion for the eigenvalues in terms of $\nu-\mu$ and $\nu+\mu$.

For this purpose it is necessary to consider the system (1)-(2) in a more general context where κ is real, $|\kappa| \geqslant \frac{1}{2}$, and μ, ν are complex numbers. At first we rewrite this system for fixed $\kappa \in \mathbb{R}\backslash(-\frac{1}{2},\frac{1}{2})$ as an eigenvalue problem for some self-adjoint holomorphic operator family $A=A(\kappa;\mu,\nu)$ depending on the parameters $(\mu,\nu)\in\mathbb{C}^2$. In the special case where $(\mu,\nu)\in\mathbb{R}^2$ the differential operator $A(\kappa;\mu,\nu)$ is self-adjoint and has purely discrete spectrum. In Sec. II we prove that for a given κ the eigenvalues $\lambda_j(\kappa;\mu,\nu)$ of A are holomorphic functions in (μ,ν), and we derive some basic estimates for them. Furthermore, we transform the system (1)-(2) to a matrix differential equation

$$y'(x) = \left[\frac{1}{x}B_0 + \frac{1}{x-1}B_1 + C\right]y(x) \tag{3}$$

on the interval $(0,1)$ with coefficient matrices

$$B_0 = \begin{pmatrix} -\frac{\kappa}{2}-\frac{1}{4} & \mu-\lambda \\ 0 & \frac{\kappa}{2}+\frac{1}{4} \end{pmatrix}, \quad B_1 = \begin{pmatrix} \frac{\kappa}{2}+\frac{1}{4} & 0 \\ \mu-\lambda & -\frac{\kappa}{2}-\frac{1}{4} \end{pmatrix}, \quad C = \begin{pmatrix} -2\nu & -2\mu \\ 2\mu & 2\nu \end{pmatrix},$$

which can be extended to the complex domain $\mathbb{C}\backslash\{0,1\}$. In this way we obtain a further characterization of the eigenvalues of A and some useful estimates for the corresponding eigenfunctions. Applying analytic perturbation theory, we show in Sec. III that the eigenvalues $\lambda_j(\kappa;\mu,\nu)$ satisfy the partial differential equation

$$(\mu-2\nu\lambda)\frac{\partial\lambda}{\partial\mu} + (\nu-2\mu\lambda)\frac{\partial\lambda}{\partial\nu} + 2\kappa\mu + 2\mu\nu = 0. \tag{4}$$

In particular, this result can be used to obtain a recurrence relation for the coefficients $c_{m,n}$ of a power series expansion

$$\lambda_j(\kappa;\mu,\nu) = \sum_{m,n=0}^{\infty} c_{m,n}(\nu-\mu)^m(\nu+\mu)^n.$$

In Sec. IV we solve the PDE (4) by the method of characteristics. First, we derive an explicit formula for the eigenvalues in the case $|\mu|=|\nu|$. Moreover, in the regions where $|\mu|\neq|\nu|$ we reduce the characteristic equations of (4) to a Painlevé III equation

$$vv' + tvv'' - t(v')^2 - 2\kappa(v^2\pm 1)v - t(v^4-1) = 0$$

with parameters $\alpha=\pm\beta=2\kappa$ and $\gamma=-\delta=1$ according to the notation in Milne *et al.* (1997) and Mansfield and Webster (1998). As this differential equation is in general not solvable in terms of elementary functions, we cannot expect a closed expression for the eigenvalues of the Chandrasekhar–Page angular equation for all $(\mu,\nu)\in\mathbb{R}^2$. However, if κ is a half-integer, i.e., $\kappa=k-\frac{1}{2}$ with some positive integer k, then $\alpha\pm\beta=2(2k-1)$, and there are integrals of polynomial type for the third Painlevé equation in this special case, cf. Milne *et al.* (1997). Hence, if $\kappa=\pm\frac{1}{2},\pm\frac{3}{2},\ldots$, there exist algebraic solutions of the partial differential equation (4), and the question arises if these explicit solutions are in fact eigenvalues of the Chandrasekhar–Page angular equation. It turns out that there is another type of "special values" associated to the operator A, called *monodromy eigenvalues*, which belong to the algebraic solutions of the PDE

(4). For a half-integer κ, the monodromy eigenvalues are introduced in Sec. V by requiring that the system (3) has a fundamental matrix of the form

$$[x(1-x)]^{-(\kappa/2)-1/4}H(x)$$

with an entire matrix function $H:\mathbb{C}\to \mathrm{M}_2(\mathbb{C})$. This property turns out to be equivalent to the existence of special solutions of the form

$$[x(1-x)]^{-(\kappa/2)-1/4}p^{\pm}(x)e^{\pm 2tx},$$

where $p^{\pm}:\mathbb{C}\to\mathbb{C}^2$ are polynomials and $t=\pm\sqrt{\nu^2-\mu^2}$. For comparison purposes, an eigenvalue of A can be characterized by the property that (3) possesses a nontrivial solution of the form

$$[x(1-x)]^{(\kappa/2)+1/4}\eta(x)$$

with some entire vector function $\eta:\mathbb{C}\to\mathbb{C}^2$. We prove that the monodromy eigenvalues are zeros of a polynomial with degree $2k-1$ whose coefficients are polynomials in μ and ν. Moreover, it can be shown that monodromy eigenvalues and "classical" eigenvalues are distinct at least in a neighborhood of $(\mu,\nu)=(0,0)$. Nevertheless, they are both characterized by the fact that certain monodromy data of the system (3) are preserved for all parameters (μ,ν). In fact, λ is a monodromy eigenvalue of A if and only if the monodromy matrices of (3) at the regular-singular points 0 and 1 are diagonal, whereas λ is a classical eigenvalue of A if and only if a certain nondiagonal entry of the connection matrix for the fundamental matrices at 0 and 1 vanishes. Hence, for the Chandrasekhar–Page angular equation the monodromy as well as the classical eigenvalue problem is closely related to the isomonodromy problem for the differential equation (3). Monodromy preserving deformations for such a system were studied by Jimbo *et al.* (1981), but only if the eigenvalues of B_0 and B_1 do not differ by an integer, i.e., $\kappa+\frac{1}{2}\notin\mathbb{Z}$. In Sec. VI we consider the isomonodromy problem for (3) in the case that κ is a half-integer. As a consequence, we show that the monodromy eigenvalues of A satisfy the partial differential equation (4), and we obtain an alternative derivation of (4) for the classical eigenvalues of A. Unlike the proof in Sec. III, which relies on the particular structure of the Chandrasekhar–Page angular equation, the method presented in Sec. V is more general and based on finding suitable deformation equations for parameter-dependent differential equations. Thus, we expect that this technique is applicable to other eigenvalue problems as well.

II. A SELF-ADJOINT HOLOMORPHIC OPERATOR FAMILY ASSOCIATED TO THE CHANDRASEKHAR–PAGE ANGULAR EQUATION

By introducing the notations

$$\mu := am, \quad \nu := a\omega, \quad S(\theta) := \sqrt{\sin\,\theta}\begin{pmatrix} S_{+1/2}(\theta) \\ S_{-1/2}(\theta)\end{pmatrix}, \quad \theta\in(0,\pi),$$

the Chandrasekhar–Page angular equation (1)-(2) takes the form

$$(\mathfrak{A}S)(\theta) := \begin{pmatrix} 0 & 1 \\ -1 & 0\end{pmatrix}S'(\theta) + \begin{pmatrix} -\mu\cos\,\theta & -\dfrac{\kappa}{\sin\,\theta}-\nu\sin\,\theta \\ -\dfrac{\kappa}{\sin\,\theta}-\nu\sin\,\theta & \mu\cos\,\theta\end{pmatrix}S(\theta) = \lambda S(\theta) \tag{5}$$

with fixed $\kappa\in\mathbb{R}\setminus\left(-\frac{1}{2},\frac{1}{2}\right)$ and parameters $(\mu,\nu)\in\mathbb{C}^2$. We can associate the so-called minimal operator A_0 to the formal differential expression $\mathfrak{A}$, which acts in the Hilbert space $\mathcal{H}:=\mathcal{L}^2((0,\pi),\mathbb{C}^2)$ of square integrable vector functions with respect to the scalar product

$$(S_1,S_2) := \int_0^\pi S_2(\theta)^* S_1(\theta)\mathrm{d}\theta, \quad S_1,S_2 \in \mathcal{H}. \tag{6}$$

The operator A_0 given by $\mathcal{D}(A_0)=\mathrm{C}_0^\infty((0,\pi),\mathbb{C}^2)$ and $A_0S:=\mathfrak{A}S$ for $S\in\mathcal{D}(A_0)$ is densely defined and closable. For $|\kappa|\geqslant\frac{1}{2}$ and $(\mu,\nu)\in\mathbb{R}^2$ the formal differential operator in (5) is in the limit point case at 0 and π, hence A_0 is even essentially self-adjoint. In the following we denote the closure of A_0 by $A=A(\kappa;\mu,\nu)$. According to Weidmann (1987, Theorem 5.8) the domain of $A(\kappa;0,0)$ is given by

$$\mathcal{D}(A)=\{S\in\mathcal{H} : S \text{ is absolutely continuous and } A(\kappa;0,0)S\in\mathcal{H}\}.$$

Since $A(\kappa;\mu,\nu)=A(\kappa;0,0)+T(\mu,\nu)$ with the bounded multiplication operator

$$T(\mu,\nu)=\begin{pmatrix} -\mu\cos\theta & -\nu\sin\theta \\ -\nu\sin\theta & \mu\cos\theta \end{pmatrix},$$

its domain of definition $\mathcal{D}(A)$ is independent of $(\mu,\nu)\in\mathbb{C}^2$, see Kato (1966, Chap. IV, §1, Theorem 1.1). Moreover, if $(\mu,\nu)\in\mathbb{R}^2$, then $T(\mu,\nu)$ is a symmetric perturbation of $A(\kappa;0,0)$, and Theorem 4.10 in Kato (1966, Chap. V, §4) yields that $A(\kappa;\mu,\nu)$ is self-adjoint. Thus, according to the classification in Kato (1966, Chap. VII, §3), $A(\kappa;\mu,\nu)$ forms a self-adjoint holomorphic operator family of type (A) in the variables $(\mu,\nu)\in\mathbb{C}^2$. Further, the spectrum of $A(\kappa;0,0)$ is discrete and consists of simple eigenvalues given by

$$\lambda_j(\kappa;0,0)=\mathrm{sgn}(j)(|\kappa|-\tfrac{1}{2}+|j|), \quad j\in\mathbb{Z}\setminus\{0\} \tag{7}$$

(for the details we refer to Appendix A). This means, in particular, that $A(\kappa;0,0)$ has compact resolvent, and from Theorem 2.4 in Kato (1966, Chap. V, §2) it follows that $A(\kappa;\mu,\nu)$ has compact resolvent for all $(\mu,\nu)\in\mathbb{C}^2$. As a consequence, the spectrum of $A(\kappa;\mu,\nu)$, $(\mu,\nu)\in\mathbb{C}^2$, is discrete, and since $A(\kappa;\mu,\nu)$ is in the limit point case at $\theta=0$ and $\theta=\pi$, its spectrum consists of simple eigenvalues for $(\mu,\nu)\in\mathbb{R}^2$. Now, Theorem 3.9 in Kato (1966, Chap. V, §3) implies that the eigenvalues $\lambda_j=\lambda_j(\kappa;\mu,\nu)$, $j\in\mathbb{Z}\setminus\{0\}$, of $A(\kappa;\mu,\nu)$ are simple and depend holomorphically on (μ,ν) in a complex neighborhood of $\mathbb{R}^2$. Moreover, the partial derivatives of A with respect to μ and ν are given by

$$\frac{\partial A}{\partial\mu}=\begin{pmatrix} -\cos\theta & 0 \\ 0 & \cos\theta \end{pmatrix}, \quad \frac{\partial A}{\partial\nu}=\begin{pmatrix} 0 & -\sin\theta \\ -\sin\theta & 0 \end{pmatrix},$$

which yields the following estimates for the growth rate of the eigenvalues, compare Kato (1966, Chap. VII, §3, Sec. 4):

$$\left|\frac{\partial\lambda_j}{\partial\mu}\right|\leqslant\left\|\frac{\partial A}{\partial\mu}\right\|\leqslant 1, \quad \left|\frac{\partial\lambda_j}{\partial\nu}\right|\leqslant\left\|\frac{\partial A}{\partial\nu}\right\|\leqslant 1.$$

Here $\|\cdot\|$ denotes the operator norm of a (2×2) matrix. In addition, by Theorem 4.10 in Kato (1966, Chap. V, §3), we have

$$\min_{j\in\mathbb{Z}\setminus\{0\}}|\lambda-\lambda_j(\kappa;0,0)|\leqslant\|T(\mu,\nu)\|\leqslant\max\{|\mu|,|\nu|\} \tag{8}$$

for each eigenvalue λ of $A(\kappa;\mu,\nu)$. Finally, by interchanging the components of $S(\theta)$, we obtain that a point λ is an eigenvalue of $A(\kappa;\mu,\nu)$ if and only if $-\lambda$ is an eigenvalue of $A(-\kappa;\mu,-\nu)$. Since the eigenvalues depend holomorphically on μ and ν, the identity

$$\lambda_j(\kappa;\mu,\nu) = -\lambda_{-j}(-\kappa;\mu,-\nu)$$

holds for all (μ,ν) in a neighborhood of $\mathbb{R}^2$. Therefore, we restrict our attention to the case $\kappa \in \left[\frac{1}{2},\infty\right)$. Note that $\lambda \in \mathbb{C}$ is an eigenvalue of $A(\kappa;\mu,\nu)$ if and only if the system (5) has a nontrivial solution $S(\theta)$ satisfying

$$\int_0^\pi |S(\theta)|^2 \, \mathrm{d}\theta < \infty. \tag{9}$$

By means of the transformation

$$S(\theta) = \begin{pmatrix} \sqrt{\tan\frac{\theta}{2}} & 0 \\ 0 & \sqrt{\cot\frac{\theta}{2}} \end{pmatrix} y\left(\sin^2\frac{\theta}{2}\right), \quad \theta \in (0,\pi), \tag{10}$$

the differential equation (5) is equivalent to the system

$$y'(x) = \left[\frac{1}{x}B_0 + \frac{1}{x-1}B_1 + C\right] y(x) \tag{11}$$

on the interval $(0,1)$ with coefficient matrices

$$B_0 := \begin{pmatrix} -\frac{\kappa}{2}-\frac{1}{4} & \mu-\lambda \\ 0 & \frac{\kappa}{2}+\frac{1}{4} \end{pmatrix}, \quad B_1 := \begin{pmatrix} \frac{\kappa}{2}+\frac{1}{4} & 0 \\ \mu-\lambda & -\frac{\kappa}{2}-\frac{1}{4} \end{pmatrix}, \quad C := \begin{pmatrix} -2\nu & -2\mu \\ 2\mu & 2\nu \end{pmatrix}, \tag{12}$$

and the normalization condition (9) becomes

$$\int_0^1 y(x)^* \begin{pmatrix} \frac{1}{1-x} & 0 \\ 0 & \frac{1}{x} \end{pmatrix} y(x)\mathrm{d}x < \infty. \tag{13}$$

If we consider the differential equation (11) for a fixed $\kappa \in (0,\infty)$ in the complex plane, then it has two regular singular points, one at $x=0$ and one at $x=1$ with characteristic values $\pm\left[(\kappa/2)+\frac{1}{4}\right]$. From the theory of asymptotic expansions [see Wasow (1965), for example], it follows that for each $\lambda \in \mathbb{C}$ there exists a nontrivial solution

$$y_0(x,\lambda) = x^{(\kappa/2)+1/4} h(x,\lambda), \quad x \in \mathfrak{B}_0 \tag{14}$$

of (11) in the open unit disk $\mathfrak{B}_0 \subset \mathbb{C}$ with center 0, where $h(\cdot,\lambda): \mathfrak{B}_0 \to \mathbb{C}^2$ is a holomorphic function,

$$h(x,\lambda) = \sum_{n=0}^{\infty} x^n h_n(\lambda), \quad h_0(\lambda) := \begin{pmatrix} \mu-\lambda \\ \kappa+\frac{1}{2} \end{pmatrix}. \tag{15}$$

Here $h_0(\lambda)$ is an eigenvector of B_0 for the eigenvalue $(\kappa/2)+\frac{1}{4}$, and the coefficients $h_n(\lambda)$, $n>1$, are uniquely determined by the recurrence relation

$$(B_0 - \alpha - n)h_n(\lambda) = (B_0 + B_1 - C + 1 - \alpha - n)h_{n-1}(\lambda) + C\, h_{n-2}(\lambda) \tag{16}$$

with $\alpha := (\kappa/2)+\frac{1}{4}$ and $h_{-1}(\lambda) := 0$. Since the matrices B_0 and B_1 depend holomorphically on λ, the coefficients $h_n: \mathbb{C} \to \mathbb{C}^2$ are holomorphic functions. By slightly modifying the proof of Theorem 5.3

in Wasow (1965), it can be shown that the series (15) converges uniformly in every compact subset of $\mathfrak{B}_0 \times \mathbb{C}$. Thus, by a theorem of Weierstrass, $h: \mathfrak{B}_0 \times \mathbb{C} \to \mathbb{C}^2$ is a holomorphic vector function in the variables (x, λ). Now, let

$$h\left(\frac{1}{2}, \lambda\right) =: \begin{pmatrix} f(\lambda) \\ g(\lambda) \end{pmatrix},$$

and we define the holomorphic function $\Delta: \mathbb{C} \to \mathbb{C}$ by

$$\Delta(\lambda) := f(\lambda)^2 - g(\lambda)^2, \quad \lambda \in \mathbb{C}. \tag{17}$$

The following lemma provides a connection between the eigenvalues of A and the zeros of Δ.

Lemma 1: For fixed $\kappa \in \left[\frac{1}{2}, \infty\right)$ and $(\mu, \nu) \in \mathbb{C}^2$, a point $\lambda \in \mathbb{C}$ is an eigenvalue of $A(\kappa; \mu, \nu)$ if and only if λ is a zero of the function Δ given by (17). This is equivalent to the statement that the differential equation (11) has a nontrivial solution of the form

$$y(x) = [x(1-x)]^{(\kappa/2)+1/4} \eta(x), \quad x \in \mathbb{C} \setminus \{0, 1\}, \tag{18}$$

where $\eta: \mathbb{C} \to \mathbb{C}^2$ is an entire vector function. As a consequence, if S is an eigenfunction of $A(\kappa; \mu, \nu)$ for some eigenvalue λ, then

$$|S(\theta)| \leqslant C \sin^{\kappa} \theta, \quad \theta \in (0, \pi), \tag{19}$$

with some constant $C > 0$.

Proof: Defining

$$K := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{20}$$

we have $K^{-1} = K$ and $KB_0K = B_1$, $KCK = -C$. Hence, y is a solution of the system (11) if and only if the function $Ky(1-x)$ satisfies (11). In particular, $y_1(x) := Ky_0(1-x)$ is a solution of (11) in the unit disk $\mathfrak{B}_1 \subset \mathbb{C}$ with center 1, and y_1 has the form

$$y_1(x, \lambda) = (1-x)^{(\kappa/2)+1/4} K h(1-x, \lambda), \quad x \in \mathfrak{B}_1.$$

Moreover, by the Levinson theorem, see Eastham (1989, Theorem 1.3.1), any solution of (11) which is linearly independent of y_0 in $(0,1)$ behaves asymptotically like $x^{-(\kappa/2)-1/4}[v_0 + o(1)]$ as $x \to 0$, where v_0 is an eigenvector of B_0 for the eigenvalue $-(\kappa/2) - \frac{1}{4}$. Similarly, any solution of (11) which is linearly independent of y_1 in $(0,1)$ has the asymptotic behavior $(x-1)^{-(\kappa/2)-1/4} \times [v_1 + o(1)]$ as $x \to 1$ with an eigenvector v_1 of B_1 for the eigenvalue $-(\kappa/2) - \frac{1}{4}$. Now, if λ is an eigenvalue of $A(\kappa; \mu, \nu)$, then the system (11) has a nontrivial solution y satisfying (13), and it follows that $y(x) = y_a(x, \lambda) c_a$ holds in $(0,1)$ with some constants $c_a \in \mathbb{C} \setminus \{0\}$, $a \in \{0, 1\}$. Thus, y_0 and y_1 are linearly dependent, and the Wronskian $W(x, \lambda) := \det(y_0(x, \lambda), y_1(x, \lambda))$ vanishes identically for all $x \in (0,1)$. In particular, $0 = W\left(\frac{1}{2}, \lambda\right) = 2^{-\kappa - 1/2} \Delta(\lambda)$. Conversely, if $\Delta(\lambda) = 0$, then $W\left(\frac{1}{2}, \lambda\right) = 0$, which implies that y_0 and y_1 are linearly dependent. Hence, $y_0(x) = y_1(x) c$ with some constant $c \in \mathbb{C} \setminus \{0\}$, and therefore y_0 is a solution of (11) satisfying the condition (13) on the interval $(0,1)$. Moreover, we immediately obtain that y_0 has the form (18) with a holomorphic vector function $\eta: \mathfrak{B}_0 \cup \mathfrak{B}_1 \to \mathbb{C}^2$, and since (11) is regular in $\mathbb{C} \setminus \{0, 1\}$, we can extend $\eta: \mathbb{C} \to \mathbb{C}^2$ to an entire function by the existence and uniqueness theorem. Finally, by means of the transformation (10), an eigenfunction S of $A(\kappa; \mu, \nu)$ has to be a constant multiple of

$$\sin^{\kappa}\theta \begin{pmatrix} \sin\frac{\theta}{2} & 0 \\ 0 & \cos\frac{\theta}{2} \end{pmatrix} \eta\left(\sin^2\frac{\theta}{2}\right), \quad \theta \in (0,\pi),$$

and this yields the estimate (19). □

Lemma 2: For fixed $\kappa \in \left[\frac{1}{2},\infty\right)$ *and* $j \in \mathbb{Z}\backslash\{0\}$*, the jth eigenvalue* $\lambda_j(\kappa;\mu,\nu)$ *of* $A(\kappa;\mu,\nu)$ *has a power series expansion of the form*

$$\lambda_j(\kappa;\mu,\nu) = \sum_{m,n=0}^{\infty} \lambda_{m,n}\mu^m\nu^n, \quad \lambda_{0,0} = \lambda_j(\kappa;0,0), \tag{21}$$

which is uniformly convergent in the polydisc $\mathfrak{C} := \{(\mu,\nu) \in \mathbb{C}^2 : |\mu|,|\nu| \leqslant \frac{1}{2}\}$*. Moreover, for all integers m and n, the following estimate holds:*

$$|\lambda_{m,n}| \leqslant (|\kappa| + |j|)2^{n+m}. \tag{22}$$

Proof: Since the coefficient matrices in (11) depend holomorphically on $(\lambda,\mu,\nu) \in \mathbb{C}^3$, we can modify Theorem 5.3 in Wasow (1965) appropriately in order to obtain that h in (14) and therefore $\Delta = \Delta(\lambda,\mu,\nu)$ as given by (17) are holomorphic functions on $\mathbb{C}^3$. By a similar reasoning as in the proof of Lemma 1, we can show that for fixed $(\mu,\nu) \in \mathbb{C}^2$ the eigenvalues of $A(\kappa;\mu,\nu)$ coincide with the zeros of the function $\lambda \mapsto \Delta(\lambda,\mu,\nu)$. In particular for the case $(\mu,\nu) \in \mathbb{R}^2$ these zeros are simple because $A(\kappa;\mu,\nu)$ has only simple eigenvalues. Hence, by solving the equation $\Delta(\lambda,\mu,\nu)=0$ and using the implicit function theorem, an eigenvalue $\lambda_j(\kappa;\mu,\nu)$ of the operator $A(\kappa;\mu,\nu)$ depends holomorphically on (μ,ν) in a complex neighborhood of $\mathbb{R}^2$. Furthermore, the estimate (8) implies that the set $\{\lambda \in \mathbb{C} : \min_{j\neq 0}|\lambda - \lambda_j(\kappa;0,0)| \geqslant \frac{1}{2}\}$ contains no eigenvalues of $A(\kappa;\mu,\nu)$ for all $(\mu,\nu) \in \mathfrak{C}$. Thus there exists a holomorphic solution $\lambda : \mathfrak{C} \to \mathbb{C}$ of the equation $\Delta(\lambda,\mu,\nu)=0$, which is uniquely determined by $\lambda(0,0) = \lambda_j(\kappa;0,0)$. Consequently, $\lambda_j(\kappa;\mu,\nu)$ is holomorphic in $\mathfrak{C}$, and therefore it has a power series expansion in $\mathfrak{C}$ of the form (21). In addition, by Cauchy's formula,

$$\lambda_{m,n} = -\frac{1}{4\pi^2}\oint_{\partial\mathfrak{C}} \frac{\lambda_j(\kappa;\mu,\nu)}{\mu^{m+1}\nu^{n+1}} \mathrm{d}\mu\, \mathrm{d}\nu,$$

and applying (8) and (7), it follows that

$$|\lambda_j(\kappa;\mu,\nu)| \leqslant |\lambda_j(\kappa;0,0)| + \max\{|\mu|,|\nu|\} \leqslant |\kappa| + |j|,$$

which gives the estimate (22). □

According to Lemma 1, for fixed parameters $(\mu,\nu) \in \mathbb{C}^2$ the eigenvalues of $A(\kappa;\mu,\nu)$ are exactly the zeros of the function $\Delta(\lambda)$ given by (17). In principle, this result can be used for numerical computation of the eigenvalues. However, in order to calculate $\Delta(\lambda)$ at some point $\lambda \in \mathbb{C}$, we first have to determine the coefficients $h_n(\lambda)$ with the help of the recurrence relation (16) and subsequently we need to evaluate $h(x,\lambda)$ at $x=\frac{1}{2}$ by means of the power series expansion (15). Unfortunately, this method requires the calculation of two consecutive limits, making things rather complicated. In the remaining part of this section we show that there is yet another function Θ which encodes the eigenvalues of $A(\kappa;\mu,\nu)$. The main advantage of Θ is, that it can be obtained by only one limit process.

By setting $y(x) := x^{\alpha}(1-x)^{1-\alpha}\hat{y}(x)$ with $\alpha := (\kappa/2) + \frac{1}{4}$, the system (11) becomes

$$\hat{y}'(x) = \left[\frac{1}{x}\hat{B}_0 + \frac{1}{x-1}\hat{B}_1 + C\right]\hat{y}(x) \tag{23}$$

with the coefficient matrices

$$\hat{B}_0 := \begin{pmatrix} -\kappa - \frac{1}{2} & \mu - \lambda \\ 0 & 0 \end{pmatrix}, \quad \hat{B}_1 := \begin{pmatrix} \kappa - \frac{1}{2} & 0 \\ \mu - \lambda & -1 \end{pmatrix}, \quad C = \begin{pmatrix} -2\nu & -2\mu \\ 2\mu & 2\nu \end{pmatrix}.$$

Now, there exists a holomorphic solution of (23) in $\mathfrak{B}_1$ given by

$$\hat{y}(x,\lambda) = \sum_{n=0}^{\infty} x^n d_n(\lambda), \quad d_0(\lambda) := \begin{pmatrix} \mu - \lambda \\ \kappa + \frac{1}{2} \end{pmatrix}, \tag{24}$$

where $d_0(\lambda)$ is an eigenvector of $\hat{B}_0$ for the eigenvalue 0. In addition, the coefficients $d_n(\lambda)$, $n > 1$, are uniquely determined by the recurrence relation

$$d_n(\lambda) = (\hat{B}_0 - n)^{-1}[(E - n)d_{n-1}(\lambda) + Cd_{n-2}(\lambda)]$$

with

$$E := \begin{pmatrix} 2\nu & 3\mu - \lambda \\ -\mu - \lambda & -2\nu \end{pmatrix}, \quad d_{-1}(\lambda) := 0.$$

Finally, we denote by $\Theta_n(\lambda)$ the second component of $d_n(\lambda)$.

Lemma 3: Let $\kappa \in \left[\frac{1}{2}, \infty\right)$ *and* $(\mu, \nu) \in \mathbb{C}^2$ *be fixed. Then, for each* $\lambda \in C$, *the limit*

$$\Theta(\lambda) := \lim_{n \to \infty} \Theta_n(\lambda) \tag{25}$$

exists, and $\Theta : \mathbb{C} \to \mathbb{C}$ *is a holomorphic function. Moreover, a point* $\lambda \in \mathbb{C}$ *is an eigenvalue of* $A(\kappa; \mu, \nu)$ *if and only if* $\Theta(\lambda) = 0$.

Proof: For fixed $\lambda \in \mathbb{C}$, the differential equation (23) has a regular singular point at $x = 1$ with characteristic values -1 and $\kappa - \frac{1}{2}$. First, let us assume that their difference $\kappa + \frac{1}{2}$ is not an integer. In this case the system (23) has a fundamental system of solutions in a complex neighborhood of $x = 1$, which can be written as

$$\hat{y}_1(x,\lambda) = (1-x)^{-1} \sum_{n=0}^{\infty} (1-x)^n d_n^1(\lambda), \quad \hat{y}_2(x,\lambda) = (1-x)^{\kappa - 1/2} \sum_{n=0}^{\infty} (1-x)^n d_n^2(\lambda), \tag{26}$$

where

$$d_0^1(\lambda) = \begin{pmatrix} 0 \\ 1 \end{pmatrix} =: e_2, \quad d_0^2(\lambda) = \begin{pmatrix} \kappa + \frac{1}{2} \\ \mu - \lambda \end{pmatrix}$$

are eigenvectors of $\hat{B}_1$ for the eigenvalues -1 and $\kappa - \frac{1}{2}$, respectively. Now, $\hat{y}$ can be written as a linear combination

$$\hat{y}(x,\lambda) = \gamma_1(\lambda)\hat{y}_1(x,\lambda) + \gamma_2(\lambda)\hat{y}_2(x,\lambda)$$

with connection coefficients $\gamma_1(\lambda), \gamma_2(\lambda) \in \mathbb{C}$. Applying Corollary 1.6 in Schäfke and Schmidt (1980) to the system (23) gives

$$\lim_{n \to \infty} d_n(\lambda) = \gamma_1(\lambda) e_2, \tag{27}$$

and therefore the limit (25) exists. Furthermore, λ is an eigenvalue of $A(\kappa; \mu, \nu)$ if and only if $\gamma_1(\lambda) = 0$, i.e., if and only if $\Theta(\lambda)$ becomes zero. Finally, it can be shown that the functions d_n converge uniformly in every compact subset of $\mathbb{C}$, and Weierstrass' theorem implies that Θ is an entire function.

Now, suppose that $k := \kappa + \frac{1}{2}$ is a positive integer. In this case, a fundamental system of the form (26) may not exist. Nevertheless, it can be proved (see Lemma 6 in Sec. VI) that the system (23) has a fundamental matrix,

$$\hat{Y}(x,\lambda) = G(\lambda)\sum_{n=0}^{\infty} H_n(\lambda)(1-x)^n(1-x)^D(1-x)^{J(\lambda)},$$

in a complex neighborhood of $x=1$, where $D:=\mathrm{diag}(-1,k-1)$, $H_0(\lambda)=I$, and

$$G(\lambda) = \begin{pmatrix} 0 & \kappa+\frac{1}{2} \\ 1 & \mu-\lambda \end{pmatrix}, \quad J(\lambda) = \begin{pmatrix} 0 & 0 \\ q(\lambda) & 0 \end{pmatrix}$$

with some $q(\lambda)\in\mathbb{C}$. In particular, we can write $\hat{Y}$ in the form

$$\hat{Y}(x,\lambda) = \hat{H}(x,\lambda)(1-x)^{\tilde{J}(\lambda)}, \quad \hat{H}(x,\lambda) = \sum_{n=0}^{\infty}(1-x)^n D_n(\lambda),$$

where

$$D_0(\lambda) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \tilde{J}(\lambda) = \begin{pmatrix} -1 & 0 \\ q(\lambda) & -1 \end{pmatrix}.$$

Since $\hat{y}$ solves the system (23), there exists a vector $c(\lambda)\in\mathbb{C}^2$ such that $\hat{y}(x,\lambda)=\hat{Y}(x,\lambda)c(\lambda)$, and Theorem 1.1 in Schäfke (1980) implies

$$d_n(\lambda) = D_0(\lambda)\frac{1}{\Gamma}(-\tilde{J}(\lambda))\Gamma(n+1)\frac{1}{\Gamma}(n-\tilde{J}(\lambda))c(\lambda) + O(n^{\delta-1}) \tag{28}$$

for arbitrary $\delta>0$. For the definition and discussion of the reciprocal gamma function for matrices we refer to the Appendix in Schäfke (1980). Particularly, for the Jordan-type matrices $-\tilde{J}(\lambda)$ and $n-\tilde{J}(\lambda)$ we obtain

$$\frac{1}{\Gamma}(-\tilde{J}(\lambda)) = \begin{pmatrix} 1 & 0 \\ * & 1 \end{pmatrix}, \quad \frac{1}{\Gamma}(n-\tilde{J}(\lambda)) = \begin{pmatrix} \dfrac{1}{\Gamma(n+1)} & 0 \\ * & \dfrac{1}{\Gamma(n+1)} \end{pmatrix}.$$

Now, if $\gamma_1(\lambda)$ denotes the first component of $c(\lambda)$, then (28) implies (27). Since λ is an eigenvalue of $A(\kappa;\mu,\nu)$ if and only if $\gamma_1(\lambda)=0$, the proof of Lemma 3 is complete. □

III. A PARTIAL DIFFERENTIAL EQUATION FOR THE EIGENVALUES

Theorem 1: *For fixed $\kappa\in[\frac{1}{2},\infty)$ and $j\in\mathbb{Z}\backslash\{0\}$, the jth eigenvalue $\lambda=\lambda_j(\kappa;\mu,\nu)$ of A is an analytical function in $(\mu,\nu)\in\mathbb{R}^2$ satisfying the first order quasilinear partial differential equation*

$$(\mu-2\nu\lambda)\frac{\partial\lambda}{\partial\mu} + (\nu-2\mu\lambda)\frac{\partial\lambda}{\partial\nu} + 2\kappa\mu + 2\mu\nu = 0, \tag{29}$$

where $\lambda_j(\kappa;0,0)$ is given by (7).

Proof: Let

$$S(\theta) =: \begin{pmatrix} S_1(\theta) \\ S_2(\theta) \end{pmatrix}, \quad \theta\in(0,\pi),$$

be that eigenfunction of $A(\kappa;\mu,\nu)$ for the eigenvalue $\lambda=\lambda_j(\kappa;\mu,\nu)$ which is normalized by the condition $(S,S)=1$. Introducing the functions

$$U(\theta) := S_1(\theta)^2 + S_2(\theta)^2, \quad V(\theta) := S_2(\theta)^2 - S_1(\theta)^2, \quad W(\theta) := 2S_1(\theta)S_2(\theta),$$

a straightforward calculation shows that U, V, and W are solutions of the system of differential equations

$$U'(\theta) = 2\left(\nu \sin\theta + \frac{\kappa}{\sin\theta}\right)V(\theta) + 2\mu\cos\theta W(\theta), \tag{30}$$

$$V'(\theta) = 2\left(\nu \sin\theta + \frac{\kappa}{\sin\theta}\right)U(\theta) + 2\lambda W(\theta), \tag{31}$$

$$W'(\theta) = 2\mu\cos\theta U(\theta) - 2\lambda V(\theta). \tag{32}$$

Now, from analytic perturbation theory, compare Kato (1966, Chap. VII, §3, Sec. 4), it follows that

$$\frac{\partial\lambda}{\partial\mu} = \left(\frac{\partial A}{\partial\mu}S,S\right) = \int_0^\pi S(\theta)^*\begin{pmatrix}-\cos\theta & 0\\ 0 & \cos\theta\end{pmatrix}S(\theta)\mathrm{d}\theta = \int_0^\pi \cos\theta V(\theta)\mathrm{d}\theta, \tag{33}$$

$$\frac{\partial\lambda}{\partial\nu} = \left(\frac{\partial A}{\partial\nu}S,S\right) = \int_0^\pi S(\theta)^*\begin{pmatrix}0 & -\sin\theta\\ -\sin\theta & 0\end{pmatrix}S(\theta)\mathrm{d}\theta = -\int_0^\pi \sin\theta W(\theta)\mathrm{d}\theta. \tag{34}$$

In addition, from (19) we obtain the estimates

$$|U(\theta)|,|V(\theta)|,|W(\theta)| \leqslant C\sin^{2\kappa}\theta$$

with some constant $C>0$. Since κ is positive, U, V, and W vanish at $\theta=0$ and $\theta=\pi$. If we integrate (33) by parts and replace $V'(\theta)$ with the right-hand side (rhs) of (31), then we get

$$\begin{aligned}\frac{\partial\lambda}{\partial\mu} &= -\int_0^\pi \sin\theta V'(\theta)\mathrm{d}\theta = -\int_0^\pi (2\nu\sin^2\theta + 2\kappa)U(\theta) + 2\lambda\sin\theta W(\theta)\mathrm{d}\theta\\ &= -(2\nu+2\kappa)\int_0^\pi U(\theta)\mathrm{d}\theta - 2\lambda\int_0^\pi \sin\theta W(\theta)\mathrm{d}\theta + 2\nu\int_0^\pi \cos^2\theta U(\theta)\mathrm{d}\theta.\end{aligned}$$

Taking into account that

$$\int_0^\pi U(\theta)\mathrm{d}\theta = (S,S) = 1, \quad \int_0^\pi \sin\theta W(\theta)\mathrm{d}\theta = -\frac{\partial\lambda}{\partial\nu},$$

we have

$$\mu\frac{\partial\lambda}{\partial\mu} = -\mu(2\nu+2\kappa) + 2\mu\lambda\frac{\partial\lambda}{\partial\nu} + 2\mu\nu\int_0^\pi \cos^2\theta U(\theta)\mathrm{d}\theta. \tag{35}$$

Moreover, Eq. (32) implies

$$2\mu\cos^2\theta U(\theta) = \cos\theta W'(\theta) + 2\lambda\cos\theta V(\theta),$$

and integration by parts gives

$$2\mu\nu\int_0^\pi \cos^2\theta U(\theta)\mathrm{d}\theta = \nu\int_0^\pi \cos\theta W'(\theta)\mathrm{d}\theta + 2\nu\lambda\int_0^\pi \cos\theta V(\theta)\mathrm{d}\theta$$

$$= \nu\int_0^\pi \sin\theta W(\theta)\mathrm{d}\theta + 2\nu\lambda\int_0^\pi \cos\theta V(\theta)\mathrm{d}\theta = -\nu\frac{\partial\lambda}{\partial\nu} + 2\nu\lambda\frac{\partial\lambda}{\partial\mu}. \quad (36)$$

Replacing the last term on the rhs of (35) with (36), we obtain exactly the partial differential equation (29). □

The PDE (29) can be used in order to derive a power series expansion for λ_j with respect to μ and ν. For this purpose we introduce the new coordinates,

$$\alpha := \nu - \mu, \quad \beta := \nu + \mu,$$

compare Suffern *et al.* (1983). Then $\hat{\lambda}(\alpha,\beta) := \lambda_j(\kappa;(\beta-\alpha)/2,(\beta+\alpha)/2)$ is a solution of the transformed partial differential equation

$$\alpha(1+2\hat{\lambda})\frac{\partial\hat{\lambda}}{\partial\alpha} + \beta(1-2\hat{\lambda})\frac{\partial\hat{\lambda}}{\partial\beta} = \kappa(\alpha-\beta) + \frac{1}{2}(\alpha^2-\beta^2), \quad (37)$$

where $\hat{\lambda}(0,0)=\lambda_j(\kappa;0,0)$ is given by (7). As $\hat{\lambda}$ depends analytically on (α,β), there exists a series expansion for $\hat{\lambda}$ of the form

$$\hat{\lambda}(\alpha,\beta) = \sum_{m,n=0}^{\infty} c_{m,n}\alpha^m\beta^n \quad (38)$$

(for clarity, the indices κ and j in the coefficients $c_{m,n}$ and in the function $\hat{\lambda}$ have been omitted). Furthermore, (37) is equivalent to

$$\alpha\left(\frac{\partial\hat{\lambda}}{\partial\alpha} + \frac{\partial\hat{\lambda}^2}{\partial\alpha}\right) + \beta\left(\frac{\partial\hat{\lambda}}{\partial\beta} - \frac{\partial\hat{\lambda}^2}{\partial\beta}\right) = \kappa(\alpha-\beta) + \frac{1}{2}(\alpha^2-\beta^2), \quad (39)$$

and since

$$\hat{\lambda}(\alpha,\beta)^2 = \sum_{m,n=0}^{\infty}\left(\sum_{r=0}^{m}\sum_{s=0}^{n} c_{r,s}c_{m-r,n-s}\right)\alpha^m\beta^n,$$

we obtain the identity

$$\sum_{m,n=0}^{\infty}\left((m+n)c_{m,n} + (m-n)\sum_{r=0}^{m}\sum_{s=0}^{n} c_{r,s}c_{m-r,n-s}\right)\alpha^m\beta^n = \kappa(\alpha-\beta) + \frac{1}{2}(\alpha^2-\beta^2).$$

Comparing the terms of equal order in α and β, it follows that

$$c_{0,0} = \lambda_j(\kappa;0,0) =: c_0, \quad c_{1,0} = \frac{\kappa}{2c_0+1}, \quad c_{0,1} = \frac{\kappa}{2c_0-1},$$

$$c_{2,0} = \frac{(2c_0+1)^2-4\kappa^2}{4(2c_0+1)^3}, \quad c_{1,1} = 0, \quad c_{0,2} = \frac{(2c_0-1)^2-4\kappa^2}{4(2c_0-1)^3},$$

and for $m+n>2$ the coefficients $c_{m,n}$ satisfy

$$((m+n)+2c_0(m-n))c_{m,n} = (n-m)\sum_{(r,s)\in[\![m,n]\!]} c_{r,s}c_{m-r,n-s}, \tag{40}$$

where $[\![m,n]\!]$ denotes the set of all pairs $(r,s)\in\mathbb{Z}^2$ with $0\leqslant r\leqslant m$, $0\leqslant s\leqslant n$ and $0<r+s<m+n$. In particular, if $m=n>0$, then we get $2n\ c_{n,n}=0$, which implies

$$c_{n,n}=0 \quad \text{for all } n>0. \tag{41}$$

Moreover, if κ is not a rational number, i.e., $\kappa\in\left[\frac{1}{2},\infty\right)\setminus\mathbb{Q}$, then the initial value c_0 is not a rational number, and we have $(m+n)+2c_0(m-n)\neq 0$ for all $(m,n)\in\mathbb{Z}^2$ with $m+n>2$. In this case (40) gives a recurrence formula for all coefficients of the power series expansion (38).

Now, suppose that $\kappa\in\left[\frac{1}{2},\infty\right)\cap\mathbb{Q}$. Then c_0 is a rational number with $|c_0|\geqslant 1$, and we get $(2c_0-1)/(2c_0+1)=p/q$ with some coprime integers p and q. Now, the prefactor on the left-hand side (lhs) of (40) becomes zero if and only if $m=\ell p$, $n=\ell q$ with some positive integer ℓ, and thus the coefficients $c_{\ell p,\ell q}$ are not determined by (40). However, we can by-pass this problem if we regard κ as an additional parameter in our eigenvalue problem. Since the coefficient matrix of (11) depends holomorphically on $\kappa\in\mathbb{C}^+:=\{z\in\mathbb{C}:\mathrm{Re}\ z>0\}$ and $(\lambda,\mu,\nu)\in\mathbb{C}^3$, we obtain in a similar way as described in Sec. I that h in (14) and therefore $\Delta=\Delta(\kappa;\lambda;\mu,\nu)$ given by (17) is a holomorphic function on $\mathbb{C}^+\times\mathbb{C}^3$. Moreover, in the same way as in the proof of Lemma 1, we can show that for fixed $\kappa\in\left[\frac{1}{2},\infty\right)$ and $(\mu,\nu)\in\mathbb{C}^2$ the eigenvalues of $A(\kappa;\mu,\nu)$ coincide with the zeros of the function $\lambda\mapsto\Delta(\kappa;\lambda;\mu,\nu)$. In the case $(\kappa,\mu,\nu)\in\left[\frac{1}{2},\infty\right)\times\mathbb{R}^2$ these zeros are simple, since $A(\kappa;\mu,\nu)$ has only simple eigenvalues. Hence, by solving the equation $\Delta(\kappa;\lambda;\mu,\nu)=0$, we find that an eigenvalue $\lambda_j(\kappa;\mu,\nu)$ is a holomorphic function in a complex neighborhood of $\left[\frac{1}{2},\infty\right)\times\mathbb{R}^2$. In particular, $\hat{\lambda}$ depends holomorphically on $(\kappa;\alpha,\beta)$, and for a given $\kappa\in\left[\frac{1}{2},\infty\right)$, there exists a power series expansion of the form

$$\hat{\lambda}(\kappa+\varepsilon;\alpha,\beta)=\sum_{l,m,n=0}^{\infty} c_{m,n}^{(l)}\varepsilon^l\alpha^m\beta^n$$

in a neighborhood of $(\kappa,0,0)$. In the following we derive a recurrence relation for the coefficients $c_{m,n}^{(l)}$. Since

$$\hat{\lambda}(\kappa+\varepsilon;\alpha,\beta)^2=\sum_{l,m,n=0}^{\infty}\left(\sum_{t=0}^{l}\sum_{r=0}^{m}\sum_{s=0}^{n} c_{r,s}^{(t)}c_{m-r,n-s}^{(l-t)}\right)\varepsilon^l\alpha^m\beta^n,$$

from (39) it follows that

$$\sum_{l,m,n=0}^{\infty}\left((m+n)c_{m,n}^{(l)}+(m-n)\sum_{t=0}^{l}\sum_{r=0}^{m}\sum_{s=0}^{n} c_{r,s}^{(t)}c_{m-r,n-s}^{(l-t)}\right)\varepsilon^l\alpha^m\beta^n=\kappa(\alpha-\beta)+\varepsilon(\alpha-\beta)+\frac{1}{2}(\alpha^2-\beta^2). \tag{42}$$

Moreover, (7) implies that

$$c_{0,0}^{(l)}=\frac{1}{l!}\frac{\partial^l\lambda}{\partial\kappa^l}(\kappa;0,0)=\begin{cases}\mathrm{sgn}(j)(\kappa-\frac{1}{2}+|j|), & \text{if } l=0,\\ \mathrm{sgn}(j), & \text{if } l=1,\\ 0, & \text{if } l>1.\end{cases}$$

Comparing the terms of equal order in (42), we obtain

$$c_{0,0}^{(0)}=\lambda_j(\kappa;0,0)=:c_0,\quad c_{1,0}^{(0)}=\frac{\kappa}{2c_0+1},\quad c_{0,1}^{(0)}=\frac{\kappa}{2c_0-1},$$

$$c_{2,0}^{(0)} = \frac{(2c_0+1)^2 - 4\,\kappa^2}{4(2c_0+1)^3}, \quad c_{1,1}^{(0)} = 0, \quad c_{0,2}^{(0)} = \frac{(2c_0-1)^2 - 4\,\kappa^2}{4(2c_0-1)^3},$$

$$c_{1,0}^{(1)} = \frac{2c_0+1-2\,\mathrm{sgn}(j)\kappa}{(2c_0+1)^2}, \quad c_{0,1}^{(1)} = \frac{2c_0-1-2\,\mathrm{sgn}(j)\kappa}{(2c_0-1)^2},$$

while the remaining coefficients are determined by the identity

$$((m+n)+2c_0(m-n))c_{m,n}^{(l)} + (m-n)\sum_{(t,r,s)\in[\![l,m,n]\!]} c_{r,s}^{(t)} c_{m-r,n-s}^{(l-t)} = 0, \quad l+m+n>2. \tag{43}$$

Here $[\![l,m,n]\!]$ denotes the set of all triples $(t,r,s)\in\mathbb{Z}^3$ with $0\leqslant t\leqslant l$, $0\leqslant r\leqslant m$, $0\leqslant s\leqslant n$, and $0<t+r+s<l+m+n$. In the case $(m+n)+2c_0(m-n)=0$, the prefactor of $c_{m,n}^{(l)}$ in (43) vanishes, and since $m-n\neq 0$, we get for $l>0$

$$0 = \sum_{(t,r,s)\in[\![l,m,n]\!]} c_{r,s}^{(t)} c_{m-r,n-s}^{(l-t)} = 2c_{0,0}^{(1)} c_{m,n}^{(l-1)} + \sum_{(t,r,s)\in[\![l,m,n]\!]^*} c_{r,s}^{(t)} c_{m-r,n-s}^{(l-t)}, \tag{44}$$

where $[\![l,m,n]\!]^* := [\![l,m,n]\!]\backslash\{(1,0,0),(l-1,m,n)\}$. Now, for all coefficients $c_{m,n}^{(l)}$ with $l+m+n>2$, (43) implies

$$c_{m,n}^{(l)} = \frac{n-m}{(m+n)+2c_0(m-n)} \sum_{(t,r,s)\in[\![l,m,n]\!]} c_{r,s}^{(t)} c_{m-r,n-s}^{(l-t)} \quad \text{if } (m+n)+2c_0(m-n)\neq 0,$$

whereas (44) and $c_{0,0}^{(1)} = \mathrm{sgn}(j)$ yield

$$c_{m,n}^{(l-1)} = -\frac{\mathrm{sgn}(j)}{2} \sum_{(t,r,s)\in[\![l,m,n]\!]^*} c_{r,s}^{(t)} c_{m-r,n-s}^{(l-t)} \quad \text{if } (m+n)+2c_0(m-n)=0 \text{ and } l>1.$$

These recurrence relations can be used to determine all the coefficients $c_{m,n} = c_{m,n}^{(0)}$ of the power series expansion (38) in the case that κ is a rational number.

Remark 1: A series expansion for the eigenvalues $\hat{\lambda}$ with respect to (α,β) has been given by Suffern et al. (1983, Sec. 8), however, only the coefficients $c_{m,n}$ with $m+n\leqslant 5$ have been determined. Furthermore, Kalnins and Miller (1992) studied a series expansion $\lambda = \Sigma_{n=0}^{\infty} \lambda_n a^n$ for the eigenvalues in terms of the Kerr parameter a, but also in this paper only a finite number of coefficients $\lambda_0,\ldots,\lambda_3$ have been explicitly computed. A general recurrence relation for the coefficients of (38) could not be found in the literature. Moreover, the problem of dividing by numbers which may be zero has not been noticed in Suffern et al. (1983) and Kalnins and Miller (1992). Finally, it should be noted that some of the diagonal entries $c_{n,n}$ for $n>0$ in Suffern et al. (1983, Table I) are not equal to zero, in contrast to our result (41).

IV. SOLUTION OF THE PDE BY THE METHOD OF CHARACTERISTICS

In this section the PDE (29) for real parameters $(\mu,\nu)\in\mathbb{R}^2$ and fixed $\kappa\in\left[\frac{1}{2},\infty\right)$ is studied by the method of characteristics. In particular, we obtain an exact formula for the eigenvalues in the case $|\mu|=|\nu|$, and for $|\mu|\neq|\nu|$, it turns out that the characteristic equations can be reduced to the third Painlevé equation.

Theorem 2: *Let $\kappa\in\left[\frac{1}{2},\infty\right)$, $j\in\mathbb{Z}\backslash\{0\}$ and $\tau\in\{-1,+1\}$ be fixed. Then*

$$\lambda_j(\kappa;\mu,\tau\mu) = \frac{\tau}{2} + \mathrm{sgn}(j)\sqrt{\left(\lambda_j(\kappa;0,0)-\frac{\tau}{2}\right)^2 + 2\tau\kappa\mu + \mu^2}, \tag{45}$$

where $\lambda_j(\kappa;0,0) = \mathrm{sgn}(j)\left(\kappa-\frac{1}{2}+|j|\right)$. In particular, if $j=\tau$, then

$$\lambda_j(\kappa;\mu,\tau\mu) = \tau\left(\kappa+\tfrac{1}{2}\right)+\mu.$$

Proof: According to Theorem 1, the function $\lambda(\mu,\nu) := \lambda_j(\kappa;\mu,\nu)$ solves the partial differential equation (29). Defining $w(\mu) := \lambda(\mu,\tau\mu)$, $\mu \in \mathbb{R}$, for some fixed $\tau \in \{-1,+1\}$, we obtain

$$w'(\mu) = \frac{\partial \lambda}{\partial \mu}(\mu,\tau\mu) + \tau \frac{\partial \lambda}{\partial \nu}(\mu,\tau\mu),$$

and with the help of (29) it can be shown that

$$\mu w'(\mu) - 2\tau\mu w(\mu) w'(\mu) = -2\kappa\mu - 2\tau\mu^2.$$

Dividing the above differential equation by $-\tau\mu$ and integrating gives

$$\left(w(\mu) - \frac{\tau}{2}\right)^2 = C + 2\tau\kappa\mu + \mu^2, \quad \mu \in \mathbb{R}, \tag{46}$$

where the constant of integration C is uniquely determined by

$$C = \left(w(0) - \frac{\tau}{2}\right)^2 = \left(\lambda_j(\kappa;0,0) - \frac{\tau}{2}\right)^2.$$

Now, from (46) it follows that

$$w(\mu) = \frac{\tau}{2} + \varepsilon \sqrt{\left(\lambda_j(\kappa;0,0) - \frac{\tau}{2}\right)^2 + 2\tau\kappa\mu + \mu^2} \tag{47}$$

with some $\varepsilon \in \{-1,+1\}$ and the square root assumed to be non-negative. We have to take the sign of ε such that the lhs of (47) is analytic and coincides with $\lambda_j(\kappa;0,0)$ at the point $\mu=0$. If $j=\tau$, then $\lambda_j(\kappa;0,0) = \tau\left(\kappa+\frac{1}{2}\right)$, and (47) implies $w(\mu) = (\tau/2) + \varepsilon(\tau\kappa+\mu)$. Inserting $\mu=0$, it follows that $\varepsilon=\tau$, i.e., $w(\mu) = \tau\left(\kappa+\frac{1}{2}\right)+\mu$. In the case $j \neq \tau$ we have $|\lambda_j(\kappa;0,0) - (\tau/2)| \geqslant \kappa+1$ and thus the radicand in (47) is positive for all $\mu \in \mathbb{R}$. Moreover, by means of

$$\lambda_j(\kappa;0,0) = w(0) = \frac{\tau}{2} + \varepsilon \sqrt{\left(\lambda_j(\kappa;0,0) - \frac{\tau}{2}\right)^2} = \frac{\tau}{2} + \varepsilon \left|\lambda_j(\kappa;0,0) - \frac{\tau}{2}\right|$$

and (7), we get $\varepsilon = \operatorname{sgn}(\lambda_j(\kappa;0,0) - (\tau/2)) = \operatorname{sgn}(j)$, which completes the proof. □

Remark 2: For a given half-integer κ and $\mu=\nu$, this result has been shown by Suffern, Fackerell, and Cosgrove using a power series expansion for the eigenfunctions of (1) and (2) in terms of hypergeometric functions, see Suffern et al. (1983, Secs. 3–5). Here, we obtained the formula for $\lambda_j(\kappa;\mu,\pm\mu)$ as an immediate consequence of the partial differential equation (29). Moreover, it should be noted that the formula (54) in Chakrabarti (1984) is not correct.

Now, let us consider the case $|\mu| \neq |\nu|$. To this purpose, we introduce new coordinates $(t,v) \in (0,\infty) \times (\mathbb{R}\setminus\{0\})$ by

$$\mu(t,v) = \frac{t}{2}\left(v + \frac{\sigma}{v}\right), \quad \nu(t,v) = \frac{t}{2}\left(v - \frac{\sigma}{v}\right) \tag{48}$$

with some fixed $\sigma \in \{-1,+1\}$ [note that $\sigma = \pm 1$ corresponds to the cases $|\mu| > |\nu|$ and $|\mu| < |\nu|$, respectively; moreover, this transformation maps $v=\text{const}$ onto lines in the (μ,ν)-plane starting at the origin, while the curves $t=\text{const}$ are mapped onto hyperboles]. By setting $w(t,v) = \lambda(\mu,\nu)$, we have

$$\frac{\partial w}{\partial t} = \frac{1}{2}\left(v + \frac{\sigma}{v}\right)\frac{\partial \lambda}{\partial \mu} + \frac{1}{2}\left(v - \frac{\sigma}{v}\right)\frac{\partial \lambda}{\partial \nu} = \frac{1}{t}\left(\mu\frac{\partial \lambda}{\partial \mu} + \nu\frac{\partial \lambda}{\partial \nu}\right),$$

$$\frac{\partial w}{\partial v} = \frac{t}{2}\left(1 - \frac{\sigma}{v^2}\right)\frac{\partial \lambda}{\partial \mu} + \frac{t}{2}\left(1 + \frac{\sigma}{v^2}\right)\frac{\partial \lambda}{\partial \nu} = \frac{1}{v}\left(\nu\frac{\partial \lambda}{\partial \mu} + \mu\frac{\partial \lambda}{\partial \nu}\right),$$

and (29) becomes

$$\frac{\partial w}{\partial t} - \frac{2vw}{t}\frac{\partial w}{\partial v} + \kappa\left(v + \frac{\sigma}{v}\right) + \frac{t}{2}\left(v^2 - \frac{1}{v^2}\right) = 0. \tag{49}$$

The characteristic equations of this PDE are given by

$$v'(t) = -\frac{2v(t)w(t)}{t}, \tag{50}$$

$$w'(t) = -\kappa\left(v(t) + \frac{\sigma}{v(t)}\right) - \frac{t}{2}\left(v(t)^2 - \frac{1}{v(t)^2}\right). \tag{51}$$

From (50) we obtain that $w(t) = -tv'(t)/2v(t)$, and (51) implies

$$\frac{v'(t)}{2v(t)} + \frac{tv''(t)}{2v(t)} - \frac{tv'(t)^2}{2v(t)^2} = \kappa\left(v(t) + \frac{\sigma}{v(t)}\right) + \frac{t}{2}\left(v(t)^2 - \frac{1}{v(t)^2}\right).$$

Multiplying the above differential equation with $2v(t)^2$, we get the following third Painlevé equation:

$$tvv'' - t(v')^2 + vv' - 2\kappa(v^2 + \sigma)v - t(v^4 - 1) = 0, \tag{52}$$

with parameters $\alpha = \sigma\beta = 2\kappa$ and $\gamma = -\delta = 1$ [see Milne *et al.* (1997) or Mansfield and Webster (1998), for example]. For further details on the Painlevé III we refer to, e.g., McCoy *et al.* (1977), Widom (2000), and Iwasaki *et al.* (1991).

In general, Painlevé III is not solvable in terms of elementary functions, and therefore we cannot expect a closed expression for the eigenvalues of $A(\kappa;\mu,\nu)$ in the case $|\mu| \neq |\nu|$. On the other hand, for particular values of κ there exist so-called special integrals of polynomial type for this equation, i.e., polynomials Q in t, v, and v' with the property that every solution of the differential equation $Q(t,v,v') = 0$ satisfies (52). As it will be shown below, such special integrals are related to algebraic solutions of the PDE (29), i.e., solutions, which are zeros of a polynomial in λ with rational coefficients in μ and ν. Moreover, taking into account that the eigenvalues $\lambda_j(\kappa;\mu,\tau\mu)$, $\tau \in \{-1,1\}$, of $A(\kappa;\mu,\tau\mu)$ satisfy the quadratic equation

$$\left(\lambda - \frac{\tau}{2}\right)^2 = C + 2\tau\kappa\mu + \mu^2 \quad \text{with} \quad C := \left(\lambda_j(\kappa;0,0) - \frac{\tau}{2}\right)^2,$$

the question arises if such an algebraic expression for the eigenvalues of $A(\kappa;\mu,\nu)$ exists in the case $|\mu| \neq |\nu|$. A first step towards the answer of this problem is given by the next lemma.

Lemma 4: Suppose that there exists a polynomial

$$P(\lambda;\mu,\nu) = \sum_{n=0}^{N} P_n(\mu,\nu)\lambda^n, \quad P_N \equiv 1,$$

of degree $N > 0$ *in* λ *with rational coefficients* P_n *in* μ *and* ν *such that the zeros* $z_j(\mu,\nu)$, $j = 1,\ldots,N$, *of* $P(\cdot;\mu,\nu)$ *are simple, and that the functions* $\lambda = z_j$ *are solutions of the partial differential equation* (29). *Then* κ *is a half-integer. Moreover, if* $N = 1$ *or* $N = 2$, *then* $\kappa = \frac{1}{2}$ *and* $P(\lambda;\mu,\nu) = (\lambda + \mu)^N$.

Proof: Let $Q(t,v,v') = \Sigma_{n=0}^{N} Q_n(t,v)(v')^n$ be the polynomial in v' with coefficients

$$Q_n(t,v) := \left(-\frac{2v}{t}\right)^{N-n} P_n(\mu(t,v),\nu(t,v)), \quad n=0,\ldots,N,$$

where $\mu(t,v)$ and $\nu(t,v)$ are given by (48). Note that the Q_n are again rational functions in t and v. Moreover, let $v:\mathfrak{D}\to\mathbb{R}\setminus\{0\}$ be any solution of the first order ODE $Q(t,v,v')=0$ on some interval $\mathfrak{D}\subset\mathbb{R}\setminus\{0\}$. For the function

$$w(t) = -\frac{tv'(t)}{2v(t)}, \quad t\in\mathfrak{D}, \tag{53}$$

we obtain

$$0 = Q(t,v(t),v'(t)) = \sum_{n=0}^{N} Q_n(t,v(t))\left(-\frac{2v(t)w(t)}{t}\right)^n = \left(-\frac{2v(t)}{t}\right)^N P(w(t);\mu(t,v(t)),\nu(t,v(t))),$$

and thus $w(t)$ is a zero of $P(\cdot;\mu(t,v(t)),\nu(t,v(t)))$ for each $t\in\mathfrak{D}$. Since the zeros of this polynomial depend analytically on the parameter t according to the implicit function theorem, there exists an index $j\in\{1,\ldots,N\}$ such that $w(t)=z_j(\mu(t,v(t)),\nu(t,v(t)))$ for all $t\in\mathfrak{D}$. Furthermore, as z_j solves the PDE (29), it follows that $(t,v(t),w(t))$, $t\in\mathfrak{D}$, is a characteristic curve of (49), and thus v is a solution of (52). Hence, $Q(t,v,v')=0$ implies (52), and therefore Q is a special integral of rational type for this Painlevé III. Multiplying $Q(t,v,v')$ by an appropriate polynomial $r(t,v)$ in t and v, we obtain that the function $\widetilde{Q}(t,v,v') := r(t,v)Q(t,v,v')$ is a special integral of polynomial type of degree N with respect to v'. Now, Theorem 2 in Mansfield and Webster (1998) yields that such a special integral exists if and only if $2\kappa\pm 2\sigma\kappa = 2(2k-1)$ with some integer k, i.e., $\kappa = k-\frac{1}{2}$ is a half-integer. In addition, by Lemma 3 in Mansfield and Webster (1998), the relation $(\sigma q-p)\kappa = N$ must be satisfied for some integers $p,q\in\{-N,-N+2,\ldots,N-2,N\}$. In the case $N=1$ or $N=2$, these conditions imply $\kappa=\frac{1}{2}$, and the corresponding special integrals of polynomial type are explicitly known, namely $r(t)v^s(v'+v^2+\sigma)^N$, where r is some polynomial in t, and s is an integer, compare Sec. II in Mansfield and Webster (1998). Hence, $Q(t,v,v')=(v'+v^2+\sigma)^N$ and

$$P(w(t);\mu(t,v(t)),\nu(t,v(t))) = \left(-\frac{t}{2v(t)}\right)^N Q(t,v(t)) = (w(t)+\mu((t,v(t))))^N, \quad t\in\mathfrak{D},$$

which yields $P(\lambda;\mu,\nu)=(\lambda+\mu)^N$ if $N=1$ or $N=2$. □

As a consequence of this lemma, if a solution $\lambda(\mu,\nu)$ of the PDE (29) is a zero of a linear or quadratic polynomial with rational coefficients in μ and ν, then $\kappa=\frac{1}{2}$ and $\lambda(\mu,\nu)=-\mu$. In fact, the function $\lambda(\mu,\nu)=-\mu$ solves (29) for $\kappa=\frac{1}{2}$, but since $\lambda(0,0)=0$ and the spectrum of $A(\frac{1}{2};0,0)$ is given by $\mathbb{Z}\setminus\{0\}$, it is not an eigenvalue of $A(\frac{1}{2};\mu,\nu)$ for any $(\mu,\nu)\in\mathbb{R}^2$. The following considerations show that this solution is nevertheless of interest.

V. MONODROMY EIGENVALUES

In this section we consider the case that κ is a positive half-integer, i.e., $\kappa=k-\frac{1}{2}$ with some positive integer k, and we assume that the matrix C defined in (12) has distinct eigenvalues, i.e., $\mu^2\neq\nu^2$. For such κ and (μ,ν) there is in addition to the classical eigenvalues of $A(\kappa;\mu,\nu)$ another type of "special values" which we call monodromy eigenvalues. In order to introduce this concept, we first recall the characterization of eigenvalues according to Lemma 1: A point λ is an eigenvalue of $A(\kappa;\mu,\nu)$ if and only if the system (11) has a nontrivial solution of the form

$$y(x) = [x(1-x)]^{(\kappa/2)+1/4}\eta(x), \tag{54}$$

where $\eta:\mathbb{C}\to\mathbb{C}^2$ is an entire vector function. Now, as the difference of the characteristic values $\pm[(\kappa/2)+\frac{1}{4}]$ at 0 and 1 is an integer, the differential equation (11) has a fundamental matrix of the form

$$Y(x) = [x(1-x)]^{-(\kappa/2)-1/4} H(x), \tag{55}$$

where $H(x) = H_a(x)(x-a)^{J_a}$ holds in $\mathfrak{B}_a$, $a \in \{0,1\}$, with some holomorphic function $H_a : \mathfrak{B}_a \to M_2(\mathbb{C})$ and a Jordan matrix J_a, see Theorem 5.6 in Wasow (1965). Hence, the matrix function H is in general not holomorphic in $\mathfrak{B}_0 \cup \mathfrak{B}_1$ since it involves logarithmic terms. In the following, a point $\lambda \in \mathbb{C}$ is called *monodromy eigenvalue* of $A(\kappa;\mu,\nu)$ if and only if the system (11) has a fundamental matrix of the form (55) with the property that $H : \mathbb{C} \to \mathrm{M}_2(\mathbb{C})$ is an entire matrix function. Monodromy eigenvalues are characterized by the following lemma.

Lemma 5: For a given half-integer $\kappa > 0$ and $(\mu,\nu) \in \mathbb{C}^2$ with $\mu^2 \neq \nu^2$, a point $\lambda \in \mathbb{C}$ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$ if and only if the system (11) has a nontrivial solution of the form

$$[x(1-x)]^{-(\kappa/2)-1/4} p(x) e^{2tx}, \tag{56}$$

where $p : \mathbb{C} \to \mathbb{C}^2$ is a polynomial vector function and $t = \pm\sqrt{\nu^2-\mu^2}$.

Proof: By means of the transformation $y(x) = x^{\alpha}(1-x)^{\alpha}\tilde{y}(x)$ with $\alpha := (\kappa/2) + \frac{1}{4}$, the differential equation (11) is equivalent to the system

$$\tilde{y}'(x) = \left[\frac{1}{x}\tilde{B}_0 + \frac{1}{x-1}\tilde{B}_1 + C\right]\tilde{y}(x), \tag{57}$$

where

$$\tilde{B}_0 = \begin{pmatrix} 0 & \mu-\lambda \\ 0 & k \end{pmatrix}, \quad \tilde{B}_1 = \begin{pmatrix} k & 0 \\ \mu-\lambda & 0 \end{pmatrix}. \tag{58}$$

Now, if λ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$, then the system (57) has a holomorphic fundamental matrix $H : \mathbb{C} \to \mathrm{M}_2(\mathbb{C})$. Since the coefficient matrix of (57) is a rational matrix function which is bounded at infinity, an extension of Halphen's theorem, see Theorem 2.4 in Gesztesy *et al.* (2000), implies that the system (57) has a fundamental matrix of the form $R(x)e^{Dx}$ with some rational matrix function R and $D := \mathrm{diag}(-2t, 2t)$ (note that $\pm 2t$ are the eigenvalues of C). Moreover, $R(x)e^{Dx} = H(x)Q$ with some invertible matrix Q, and therefore $R(x) = H(x)Qe^{-Dx}$ is an entire matrix function in $\mathbb{C}$. This implies that $R : \mathbb{C} \to \mathrm{M}_2(\mathbb{C})$ is a polynomial. Vice versa, suppose that the system (11) has a nontrivial solution $y(x) = [x(1-x)]^{-\alpha} p(x) e^{2tx}$ with some polynomial vector function $p : \mathbb{C} \to \mathbb{C}^2$. Defining

$$\tilde{y}(x) := e^{-2t} K y(1-x) = [x(1-x)]^{-\alpha} K p(1-x) e^{-2tx}$$

with K given by (20), it follows that $\tilde{y}$ is a solution of (11) which is linearly independent of y. Therefore, (11) has a fundamental matrix of the type (55), where H is the entire matrix function $H(x) = (p(x)e^{2tx}, Kp(1-x)e^{-2tx})$. □

Theorem 3: *For fixed $\kappa = k - \frac{1}{2}$ with a positive integer k there exists a polynomial $P(\kappa;\lambda;\mu,\nu)$ of degree $2k-1$ in λ with polynomial coefficients in μ and ν such that for each $(\mu,\nu) \in \mathbb{C}^2$ with $\mu^2 \neq \nu^2$ a point $\lambda \in \mathbb{C}$ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$ if and only if λ is a zero of $P(\kappa;\cdot;\mu,\nu)$. Moreover, the integers $1-k, \ldots, k-1$ are the zeros of $P(\kappa;\cdot;0,0)$, and for $\kappa = \frac{1}{2}$ we obtain $P(\frac{1}{2};\lambda;\mu,\nu) = \lambda + \mu$.*

Proof: A point λ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$ if and only if the differential equation (57) has a nontrivial solution $p(x)e^{2tx}$, where $p(x) = \sum_{n=0}^{N} p_n x^n$, $p_N \neq 0$, is a polynomial vector function, and $t = \pm\sqrt{\nu^2-\mu^2}$. In the following we assume $t = \sqrt{\nu^2-\mu^2}$ (the main branch of the square root) but all considerations remain valid if we replace t with $-t$. If we set $\Lambda := \lambda - \mu$ and $\tilde{C} := C - t$, then the polynomial p satisfies the differential equation

$$p'(x) = \left[\frac{1}{x}\widetilde{B}_0 + \frac{1}{x-1}\widetilde{B}_1 + \widetilde{C}\right]p(x), \tag{59}$$

where the coefficient matrices take the form

$$\widetilde{B}_0 = \begin{pmatrix} 0 & -\Lambda \\ 0 & k \end{pmatrix}, \quad \widetilde{B}_1 = \begin{pmatrix} k & 0 \\ -\Lambda & 0 \end{pmatrix}, \quad \widetilde{C} = \begin{pmatrix} -2\nu - 2t & -2\mu \\ 2\mu & 2\nu - 2t \end{pmatrix}.$$

It is easy to see that the coefficients $p_n \in \mathbb{C}^2$, $n=0,\ldots,N$, form a nontrivial solution of the linear system of equations

$$\widetilde{B}_0 p_0 = 0, \quad (\widetilde{B}_0 - 1)p_1 + \widetilde{S}p_0 = 0, \tag{60}$$

$$(\widetilde{B}_0 - n)p_n + (\widetilde{S} + n - 1)p_{n-1} - \widetilde{C}p_{n-2} = 0 \quad (n = 2, \ldots, N), \tag{61}$$

$$(\widetilde{S} + N)p_N - \widetilde{C}p_{N-1} = 0, \quad -\widetilde{C}p_N = 0, \tag{62}$$

where

$$\widetilde{S} := \widetilde{C} - \widetilde{B}_0 - \widetilde{B}_1 = \begin{pmatrix} -2\nu - 2t - k & -2\mu + \Lambda \\ 2\mu + \Lambda & 2\nu - 2t - k \end{pmatrix}.$$

Multiplying the first equation in (62) from the left with the matrix $\widetilde{C}+4t$ and observing that $(\widetilde{C}+4t)\widetilde{C}=0$, we get

$$0 = (\widetilde{C} + 4t)(\widetilde{S} + N)p_N = \begin{pmatrix} N-k & -\Lambda \\ -\Lambda & N-k \end{pmatrix}\widetilde{C}p_N + 4t(N-k)p_N = 4t(N-k)p_N.$$

Since $t \neq 0$ and $p_N \neq 0$, it follows that $N=k$. Due to technical reasons we must distinguish between the cases $k \geqslant 2$ and $k=1$. We will proceed at first with a detailed proof for the more complicated case $k \geqslant 2$. Adding the second equation in (62) to the first one and then both equations in (62) to (61) for $n=N$, we obtain

$$\widetilde{B}_0 p_0 = 0, \quad (\widetilde{B}_0 - 1)p_1 + \widetilde{S}p_0 = 0, \tag{63}$$

$$(\widetilde{B}_0 - n)p_n + (\widetilde{S} + n - 1)p_{n-1} - \widetilde{C}p_{n-2} = 0 \quad (n = 2, \ldots, k-1), \tag{64}$$

$$-\widetilde{B}_1 p_k + \begin{pmatrix} -1 & \Lambda \\ \Lambda & -1 \end{pmatrix}p_{k-1} - \widetilde{C}p_{k-2} = 0, \tag{65}$$

$$\begin{pmatrix} 0 & \Lambda \\ \Lambda & 0 \end{pmatrix}p_k - \widetilde{C}p_{k-1} = 0, \quad -\widetilde{C}p_k = 0. \tag{66}$$

The system above consists of $2k+6$ linear equations for $2k+2$ unknowns. In the following we prove that only $2k+2$ of these equations are linearly independent. Summation of all equations (60)–(62) yields $-\widetilde{B}_1\Sigma_{n=0}^{k}p_n=0$. Because of rank $(\widetilde{B}_1)=1$, it is possible to eliminate the second line of the first equation in (65) by means of line transformations, and since also rank $(\widetilde{B}_0)=1$, we can delete the first line of the first equation in (63). Thus, the system (63)–(66) consists of at most $2k+4$ linearly independent equations. In order to reduce the equations (66) further, we must consider the cases $\nu - t \neq 0$ and $\nu - t = 0$ separately. First, let us assume that $\nu - t \neq 0$. Multiplying the equations in (66) from the left by the invertible matrix

$$T := \begin{pmatrix} \nu - t & \mu \\ 0 & 1 \end{pmatrix},$$

it follows that (66) is equivalent to

$$\begin{pmatrix} 0 & 0 \\ \Lambda & 0 \end{pmatrix} p_k - \begin{pmatrix} 0 & 0 \\ 2\mu & 2\nu - 2t \end{pmatrix} p_{k-1} = 0, \quad \begin{pmatrix} 0 & 0 \\ 2\mu & 2\nu - 2t \end{pmatrix} p_k = 0. \tag{67}$$

Now, we can represent the system of the linear equations (63)–(65), (67) as a matrix equation $\tilde{\Gamma}\tilde{p}=0$ with $\tilde{p}=(p_0,\ldots,p_k)\in\mathbb{C}^{2k+2}$ and the $(2k+2)\times(2k+2)$ matrix

$$\tilde{\Gamma} := \left(\begin{array}{cc|cc|ccc|cc} 0 & k & 0 & 0 & \cdots & & & \cdots & 0 & 0 \\ \hline \tilde{S} & & \tilde{B}_0 - I & & 0 & & & & 0 & \\ -\tilde{C} & & \tilde{S} + I & & \tilde{B}_0 - 2I & 0 & & & \vdots & \\ 0 & & -\tilde{C} & & \tilde{S} + 2I & \tilde{B}_0 - 3I & 0 & & & \\ \vdots & & \ddots & & \ddots & \ddots & \ddots & \ddots & \vdots & \\ 0 & & \cdots & & 0 & -\tilde{C} & \tilde{S} + (k-2)I & \tilde{B}_0 - (k-1)I & 0 & \\ \hline 0 & 0 & \cdots & & \cdots & 0 & 0 & 2\nu + 2t & 2\mu & -1 & \Lambda & -k & 0 \\ 0 & 0 & \cdots & & \cdots & 0 & 0 & 0 & 0 & -2\mu & 2t - 2\nu & \Lambda & 0 \\ 0 & 0 & \cdots & & \cdots & 0 & 0 & 0 & 0 & 0 & 0 & -2\mu & 2t - 2\nu \end{array}\right).$$

Let $\hat{\Gamma}$ be the $(2k+1)\times(2k+1)$-matrix obtained from $\tilde{\Gamma}$ by deleting the last row and column. Then λ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$ if and only if $0=\det\tilde{\Gamma}=(2t-2\nu)\det\hat{\Gamma}$, i.e., $\det\hat{\Gamma}=0$ since $\nu-t\neq 0$. Now, suppose that $\nu-t=0$. We will prove that also in this case λ is a monodromy eigenvalue if and only if $\det\hat{\Gamma}=0$. Note that $\nu=t$ implies $\mu=0$, and therefore the equations in (66) are equivalent to

$$\begin{pmatrix} 0 & \Lambda \\ \Lambda & 0 \end{pmatrix} p_k + \begin{pmatrix} 4t & 0 \\ 0 & 0 \end{pmatrix} p_{k-1} = 0, \quad \begin{pmatrix} -4t & 0 \\ 0 & 0 \end{pmatrix} p_k = 0. \tag{68}$$

If λ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$, then the vector $\tilde{p}=(p_0,\ldots,p_k)$ is a nontrivial solution of the matrix equation $\tilde{\Gamma}\tilde{p}=0$ even though T is not invertible for $\nu-t=0$. If we assume $\det\hat{\Gamma}\neq 0$, it follows that $\Lambda\neq 0$ and the first $2k+1$ components of $\tilde{p}$ must be zero. In particular, $p_1=\cdots=p_{k-1}=0$, and the first equation in (68) yields $p_k=0$. Thus $\tilde{p}=0$, and this contradiction implies $\det\hat{\Gamma}=0$. Conversely, if $\det\hat{\Gamma}=0$, then either $\Lambda=0$, and $\tilde{p}:=(0,\ldots,0,1)\in\mathbb{C}^{2k+2}$ is a nontrivial solution of (63)–(65) and (68), or $\Lambda\neq 0$. In the latter case, there exists a vector $\hat{p}\neq 0$ with components $\hat{p}_1,\ldots,\hat{p}_{2k+1}\in\mathbb{C}$ such that $\hat{\Gamma}\hat{p}=0$. Defining $q:=(4t/\Lambda)\hat{p}_{2k-1}$, then $\tilde{p}:=(\hat{p},q)\in\mathbb{C}^{2k+2}$ is a nontrivial solution of the equations (63)–(65) and (68), i.e., λ is a monodromy eigenvalue. Hence, we have shown that for all $(\mu,\nu)\in\mathbb{C}^2$ with $\mu^2\neq\nu^2$ a point $\lambda\in\mathbb{C}$ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$ if and only if $\det\hat{\Gamma}=0$. In order to prove that $\det\hat{\Gamma}$ is a polynomial in Λ of degree $2k-1$, we apply once more appropriate line transformations to $\hat{\Gamma}$. Adding successively the second to the fourth line, the fourth to the sixth line and so on up to the $2k$th line, then $\det\hat{\Gamma}=\det\Gamma$ with the $(2k+1)\times(2k+1)$-matrix

$$\Gamma(\kappa;\Lambda;\mu,\nu;t) := \left(\begin{array}{cccccccc}
0 & k & 0 & 0 & \cdots & & & 0 \\
\hline
\widetilde{S}_0 & \widetilde{B}_0 - I & 0 & & & & & \vdots \\
-\widetilde{R} & \widetilde{S}_1 & \widetilde{B}_0 - 2I & 0 & & & & \\
\widetilde{Q} & -\widetilde{R} & \widetilde{S}_2 & \widetilde{B}_0 - 3I & 0 & & & \\
\widetilde{Q} & \widetilde{Q} & -\widetilde{R} & \widetilde{S}_3 & \widetilde{B}_0 - 4I & 0 & & \\
\vdots & & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\
\widetilde{Q} & & & \widetilde{Q} & -\widetilde{R} & \widetilde{S}_{k-2} & \widetilde{B}_0 - (k-1)I & 0 \\
\hline
\widetilde{Q} & \cdots & & & \widetilde{Q} & \widetilde{Q} & -\widetilde{R} & -k \\
 & & & & & & & \Lambda
\end{array}\right)$$

where

$$\widetilde{Q} := \begin{pmatrix} -k & 0 \\ 0 & 0 \end{pmatrix}, \quad \widetilde{R} := \begin{pmatrix} k & 0 \\ 2\mu & 2\nu - 2t \end{pmatrix},$$

$$\widetilde{S}_n := \begin{pmatrix} -2\nu - 2t - k & -2\mu \\ 2\mu + \Lambda & 2\nu - 2t + n - k \end{pmatrix}, \quad n = 0, \ldots, k-2.$$

Now, Λ appears at most once in each row and each column, whereas only the first and the $2k$th line contain no entry involving Λ. It is easy to verify that $\det \Gamma(\Lambda;\mu,\nu;t)$ has the form $\pm k^2 \Lambda^{2k-1} +$ (terms of lower order in Λ), and therefore $\det \Gamma(\Lambda;\mu,\nu;t)$ is a polynomial in Λ with polynomial coefficients in μ, ν, and t. Moreover, for all $(\mu,\nu) \in \mathbb{C}^2$ with $\mu^2 \neq \nu^2$ a point λ is a monodromy eigenvalue of $A(\kappa;\mu,\nu)$ if and only if the determinant of $\Gamma(\kappa;\Lambda;\mu,\nu;t)$ vanishes. As mentioned at the beginning of the proof, this result remains valid if we replace t with $-t$. Hence, the zeros of the polynomials $\det \Gamma(\kappa;\Lambda;\mu,\nu;t)$ and $\det \Gamma(\kappa;\Lambda;\mu,\nu;-t)$ coincide, which implies that $\det \Gamma(\kappa;\Lambda;\mu,\nu;t) = \det \Gamma(\kappa;\Lambda;\mu,\nu;-t)$. Consequently, the polynomial $P(\kappa;\lambda;\mu,\nu) := \det \Gamma(\kappa;\Lambda;\mu,\nu;t)$ contains no terms in t of odd order, and the terms of even order in t depend only on $t^2 = \nu^2 - \mu^2$. It follows that P is a polynomial of degree $2k-1$ in λ with polynomial coefficients in μ and ν, and the zeros of P are exactly the monodromy eigenvalues of $A(\kappa;\mu,\nu)$.

Next, we prove that the integers $1-k, \ldots, k-1$ are the zeros of the polynomial $P(\kappa;\lambda;0,0)$. To this aim, let Γ_0 be the $(2k \times 2k)$ matrix obtained from $\hat{\Gamma}$ for $(\mu,\nu) = (0,0)$ by deleting the last row and column. Then

$$\Gamma_0 = \left(\begin{array}{cccccccc}
0 & k & 0 & 0 & \cdots & & 0 & 0 \\
\hline
Q & \widetilde{B}_0 - I & 0 & \cdots & & & 0 & \\
0 & Q + I & \widetilde{B}_0 - 2I & 0 & & & \vdots & \\
0 & 0 & Q + 2I & \widetilde{B}_0 - 3I & 0 & & & \\
\vdots & & \ddots & \ddots & \ddots & \ddots & \vdots & \\
\vdots & & & 0 & Q + (k-3)I & \widetilde{B}_0 - (k-2)I & 0 & \\
0 & \cdots & & & 0 & Q + (k-2)I & \widetilde{B}_0 - (k-1)I & \\
\hline
0 & 0 & \cdots & & & 0 & 0 & -1 \quad \lambda
\end{array}\right),$$

$$Q := \begin{pmatrix} -k & \lambda \\ \lambda & -k \end{pmatrix},$$

and $\det \hat{\Gamma} = \lambda \det \Gamma_0$. Moreover, $\det \Gamma_0 = 0$ if and only if the equation $\Gamma_0 (p_n)_{n=0}^{k-1} = 0$ has a nontrivial solution. Such a nontrivial solution is a constant multiple of the vector given by the recurrence formula

$$p_0 := \begin{pmatrix} (k-1)! \\ 0 \end{pmatrix},$$

$$p_n = (n - \tilde{B}_0)^{-1}(Q+n-1)p_{n-1} = -\frac{1}{n(k-n)}\begin{pmatrix} (k-n)(k+1-n)-\lambda^2 & \lambda \\ n\lambda & -n(k+1-n) \end{pmatrix} p_{n-1}$$

for $n=1,\ldots,k-1$. By induction, it can be shown that

$$p_n = (-1)^n \frac{(k-n-1)!}{n!}\prod_{j=1}^{n-1}[(k-j)^2-\lambda^2]\begin{pmatrix} k(k-n)-\lambda^2 \\ n\lambda \end{pmatrix}.$$

Multiplying the vector $(p_n)_{n=0}^{k-1}$ from the left by the last line of Γ_0, we get

$$0 = (-1)^{k-1}\frac{1}{(k-1)!}\prod_{j=1}^{k-2}[(k-j)^2-\lambda^2](-k+\lambda^2+(k-1)\lambda^2) = \frac{k(-1)^k}{(k-1)!}\prod_{j=1}^{k-1}[(k-j)^2-\lambda^2].$$

Hence, $\det \Gamma_0 = 0$ if and only if $\lambda^2 \in \{1,\ldots,(k-1)^2\}$, and therefore $1-k,\ldots,k-1$ are the zeros of $P(\kappa;\cdot;0,0)$.

It remains to deal with the case $k=1$, where we must consider only the equations (60) and (62). Adding both equations in (62) to the second equation in (60) gives (65) with $p_{-1} := 0$. Hence, we can replace (60)–(62) with the linear system of equations consisting of the first equation in (63) and Eqs. (65) and (66). Now, by applying a similar reduction procedure as in the case $k \geqslant 2$, we obtain the polynomial

$$P(\tfrac{1}{2};\lambda;\mu,\nu) = \det\begin{pmatrix} 0 & 1 & 0 \\ -1 & \Lambda & -1 \\ -2\mu & 2t-2\nu & \Lambda \end{pmatrix} = \Lambda + 2\mu = \lambda + \mu,$$

whose zero $\lambda = -\mu$ is the uniquely determined monodromy eigenvalue of $A(\frac{1}{2};\mu,\nu)$ for each $(\mu,\nu) \in \mathbb{C}^2$, $\mu^2 \neq \nu^2$. □

Corollary 1: For a fixed half-integer $\kappa = k - \frac{1}{2}$ with a positive integer k, there exists a neighborhood $\mathfrak{U} \subset \mathbb{C}^2$ of $(0,0)$ such that $A(\kappa;\mu,\nu)$ has exactly $2k-1$ many monodromy eigenvalues $\lambda_0^j(\kappa;\mu,\nu)$, $j=1-k,\ldots,k-1$, for all $(\mu,\nu) \in \mathfrak{U}$ with $\mu^2 \neq \nu^2$. Moreover, $\lambda_0^j(\kappa;\mu,\nu)$ depends holomorphically on (μ,ν), and $\lim_{(\mu,\nu)\to(0,0)} \lambda_0^j(\kappa;\mu,\nu) = j$. In particular, monodromy eigenvalues and classical eigenvalues are distinct near $(\mu,\nu)=(0,0)$.

Remark 3: Monodromy eigenvalues also appear in the context of spheroidal wave equations. In Sec. 3.54 in Meixner and Schäfke (1954) they are characterized by a similar property as given in Lemma 5, but they are not specified in detail.

In view of Theorem 3 and Corollary 1 we could alternatively define the monodromy eigenvalues of $A(\kappa;\mu,\nu)$ to be the zeros of the polynomial $P(\kappa;\cdot;\mu,\nu)$ for each $(\mu,\nu) \in \mathbb{C}^2$ (without the restriction $\mu^2 \neq \nu^2$). Then the monodromy eigenvalues $\lambda_0^j(\kappa;0,0) = j$, $j=1-k,\ldots,k-1$, fill in the gap of integers appearing in the spectrum of $A(\kappa;0,0)$. Moreover, $P(\frac{1}{2};\lambda;\mu,\nu) = \lambda+\mu$ is just the polynomial given by Lemma 4 in the case $N=1$, and its zero $\lambda_0^0(\frac{1}{2};\mu,\nu) = -\mu$ satisfies the partial differential equation (29) for $\kappa = \frac{1}{2}$. In the next section we prove that the monodromy eigenvalues of $A(\kappa;\mu,\nu)$ are solutions of the PDE (29) for each half-integer $\kappa \in \{\frac{1}{2},\frac{3}{2},\frac{5}{2},\ldots\}$.

VI. MONODROMY PRESERVING DEFORMATIONS

In Jimbo *et al.* (1981), Jimbo and Miwa (1981a, 1981b), these authors developed a general theory for monodromy preserving deformations of linear ordinary differential equations with rational coefficients. As a main result, they proved that the monodromy data (Stokes multipliers, connection matrices, and exponents of formal monodromy) do not depend on the deformation parameters if and only if certain nonlinear differential equations, the so-called deformation equa-

tions, are satisfied. This result, however, was proved under the restriction that the characteristic values at regular singular points do not differ by an integer. On the other hand, in the theory of special functions and in many physical applications the case where the characteristic values differ by an integer is of great significance. In this section we consider the isomonodromy problem for linear systems with two fixed regular singular points and coefficients which depend on one parameter t. Assuming that the characteristic values at the singular points are distinct and independent of t, we will show that certain components of the monodromy data are constant with respect to t if a deformation equation of the type (1.18) in Jimbo *et al.* (1981) is satisfied. Since the monodromy components in question determine the existence of solutions of the form (54) and (55), they are relevant to monodromy and classical eigenvalue problems. Applying the results to the system (11) with an eigenvalue t of C as deformation parameter, it finally turns out that the deformation equation is in principle the characteristic equation of the partial differential equation (29).

We start with some basic facts about parameter-dependent regular singular systems. At first, let us consider a family of (2×2) systems of differential equations

$$\frac{\partial y}{\partial x}(x,t)=\Phi(x,t)y(x,t),\quad (x,t)\in(\mathfrak{B}\setminus\{0\})\times\mathfrak{D}, \tag{69}$$

in an open disk $\mathfrak{B}\subset\mathbb{C}$ with center 0 that depends on a parameter t varying in some real or complex domain $\mathfrak{D}$. It is assumed that (69) has a regular singular point at 0 for all $t\in\mathfrak{D}$. More precisely, we suppose that the coefficient matrix Φ of (69) has the following properties:

(a) $\Phi(x,t)=(1/x)\Psi(x,t)$, where $\Psi:\mathfrak{B}\times\mathfrak{D}\to \mathrm{M}_2(\mathbb{C})$ is an analytical matrix function.
(b) The eigenvalues α and β of $\Psi(0,t)$ are distinct and independent of $t\in\mathfrak{D}$; $\mathrm{Re}\alpha\leqslant\mathrm{Re}\beta$.
(c) There is an analytical function $G:\mathfrak{D}\to\mathrm{M}_2(\mathbb{C})$ such that $G(t)$ is invertible and

$$G(t)^{-1}\Psi(0,t)G(t)=\mathrm{diag}(\alpha,\beta)=:D,\quad t\in\mathfrak{D},$$

Note that such a matrix function G always exists since the eigenvalues of $\Psi(0,t)$ are distinct, see Theorem 25.1 in Wasow (1965, Chap. VII, Sec. 25).

Lemma 6: If the conditions (a)–(c) are satisfied, then the system (69) has a fundamental matrix of the form

$$Y(x,t)=G(t)H(x,t)x^{D}x^{J(t)},$$

where $H:\mathfrak{B}\times\mathfrak{D}\to\mathrm{M}_2(\mathbb{C})$ *is analytic,* $H(0,t)=I$ *for all* $t\in\mathfrak{D}$, *and*

$$J(t)=\begin{pmatrix}0 & 0\\ p(t) & 0\end{pmatrix} \tag{70}$$

with some analytical function $p:\mathfrak{D}\to\mathbb{C}$. *Moreover, if* $\beta-\alpha$ *is not an integer, then* $p\equiv 0$.

Proof: If $\beta-\alpha$ is not an integer, the existence of such a fundamental matrix with $J\equiv 0$ is well known, cf. Schäfke (1951). Hence, we have to consider only the case that $k:=\beta-\alpha$ is a positive integer. By the transformation

$$y(x,t)=x^{\alpha}G(t)y_0(x,t), \tag{71}$$

the system (69) is equivalent to the differential equation

$$x\frac{\partial y_0}{\partial x}(x,t)=\Psi_0(x,t)y_0(x,t),\quad (x,t)\in(\mathfrak{B}\setminus\{0\})\times\mathfrak{D}, \tag{72}$$

where $\Psi_0(x,t):=G(t)^{-1}\Psi(x,t)G(t)-\alpha$ is an analytical matrix function,

$$\Psi_0(x,t) = \sum_{n=0}^{\infty} x^n \Psi_{0,n}(t), \quad (x,t) \in \mathfrak{B} \times \mathfrak{D},$$

with $\Psi_{0,0}(t) = \mathrm{diag}(0,k)$ for all $t \in \mathfrak{D}$. Now, for $j = 1, \ldots, k-1$ we recursively apply the transformations

$$y_{j-1}(x,t) = \begin{pmatrix} 1 & 0 \\ \dfrac{x}{j-k}\psi_{j-1}(t) & x \end{pmatrix} y_j(x,t), \tag{73}$$

where ψ_{j-1} denotes the (2,1)-coefficient of the matrix $\Psi_{j-1,1}$. At each step, $y_j(x,t)$ is a solution of a system

$$x\frac{\partial y_j}{\partial x}(x,t) = \Psi_j(x,t) y_j(x,t), \quad (x,t) \in (\mathfrak{B} \setminus \{0\}) \times \mathfrak{D}, \tag{74}$$

where the coefficient matrix Ψ_j is analytic in $\mathfrak{B} \times \mathfrak{D}$,

$$\Psi_j(x,t) = \sum_{n=0}^{\infty} x^n \Psi_{j,n}(t), \quad (x,t) \in \mathfrak{B} \times \mathfrak{D},$$

with $\Psi_{j,0}(t) = \mathrm{diag}(0, k-j)$ for all $t \in \mathfrak{D}$, and $\Psi_{j,n}(t), n = 1, \ldots, j-1$, are lower triangular matrix functions [that means, the (1,2) component is identically zero]. Finally, by the shearing transformation

$$y_{k-1}(x,t) = \begin{pmatrix} 1 & 0 \\ 0 & x \end{pmatrix} y_k(x,t), \tag{75}$$

we obtain a differential equation

$$x\frac{\partial y_k}{\partial x}(x,t) = \Psi_k(x,t) y_k(x,t), \quad (x,t) \in (\mathfrak{B} \setminus \{0\}) \times \mathfrak{D}, \tag{76}$$

where $\Psi_k : \mathfrak{B} \times \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$ is an analytical matrix function,

$$\Psi_k(x,t) = \sum_{n=0}^{\infty} x^n \Psi_{k,n}(t), \quad (x,t) \in \mathfrak{B} \times \mathfrak{D},$$

satisfying

$$\Psi_{k,0}(t) = \begin{pmatrix} 0 & 0 \\ p(t) & 0 \end{pmatrix} =: J(t), \quad t \in \mathfrak{D},$$

with some analytical function $p : \mathfrak{D} \to \mathbb{C}$. Note that p is just the $(2,1)$-component of $\Psi_{k-1,1}$. Moreover, $\Psi_{k,n}(t), n = 0, \ldots, k$, are lower triangular matrices for all $t \in \mathfrak{D}$. Now, the system (76) has a fundamental matrix of the form

$$\tilde{Y}(x,t) = \tilde{H}(x,t) x^{J(t)}$$

provided that $\tilde{H}$ is a solution of the matrix differential equation

$$x\frac{\partial \widetilde{H}}{\partial x}(x,t) = \Psi_k(x,t)\widetilde{H}(x,t) - \widetilde{H}(x,t)J(t), \quad (x,t) \in \mathfrak{B} \times \mathfrak{D}, \tag{77}$$

such that for each $t \in \mathfrak{D}$ the matrix $\widetilde{H}(x,t)$ is invertible for some, and hence all, $x \in \mathfrak{B}$. Obviously, (77) has a formal solution

$$\widetilde{H}(x,t) = \sum_{n=0}^{\infty} x^n \widetilde{H}_n(t), \quad (x,t) \in \mathfrak{B} \times \mathfrak{D}, \tag{78}$$

where $\widetilde{H}_0(t) = I$ and the coefficients $\widetilde{H}_n$, $n > 0$, are uniquely determined by the recurrence relation

$$(J(t) - n)\widetilde{H}_n(t) - \widetilde{H}_n(t)J(t) = -\sum_{j=0}^{n-1} \Psi_{k,n-j}(t)\widetilde{H}_j(t). \tag{79}$$

Following the proof of Theorem 5.3 in the book of Wasow (1965), it can be shown that the series (78) converges uniformly in every compact subset of $\mathfrak{B} \times \mathfrak{D}$. Thus, a Weierstrass theorem implies that $\widetilde{H}$ is analytic in $\mathfrak{B} \times \mathfrak{D}$, and therefore $\widetilde{H}$ is an actual solution of (77). Further, since $J(t)$ has the special form (70) and $\Psi_{k,j}(t), j = 0, \ldots, k$, are lower triangular matrices, it is easy to verify that $\widetilde{H}_j(t)$ are lower triangular matrices for $j = 0, \ldots, k$. Now, by combining the transformations (71), (73), and (75), it follows that the differential equation (69) has a fundamental matrix of the form

$$Y(x,t) = x^{\alpha} G(t) \begin{pmatrix} 1 & 0 \\ xq(x,t) & x^k \end{pmatrix} \widetilde{H}(x,t) x^{J(t)}, \tag{80}$$

where $q(x,t)$ is a polynomial in x of degree $n-1$ with coefficients depending analytically on t, and $\widetilde{H}(x,t)$ is an analytical matrix function of the type

$$\widetilde{H}(x,t) = \begin{pmatrix} h_{11}(x,t) & x^{k+1}h_{12}(x,t) \\ h_{21}(x,t) & h_{22}(x,t) \end{pmatrix}$$

satisfying $h_{11}(0,t) = h_{22}(0,t) = 1$. Now, if we define

$$H(x,t) := \begin{pmatrix} h_{11}(x,t) & xh_{12}(x,t) \\ xq(x,t)h_{11}(x,t) + x^{k+1}h_{21}(t) & x^2 q(x,t)h_{12}(x,t) + h_{22}(x,t) \end{pmatrix},$$

then $H: \mathfrak{B} \times \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$ is analytic, $H(0,t) = I$ for all $t \in \mathfrak{D}$, and

$$\begin{pmatrix} 1 & 0 \\ xq(x,t) & x^k \end{pmatrix} \widetilde{H}(x,t) = H(x,t) \begin{pmatrix} 1 & 0 \\ 0 & x^k \end{pmatrix}.$$

Hence, we can write the fundamental matrix (80) in the form $Y(x,t) = G(t)H(x,t)x^D x^{J(t)}$, where H has the properties stated in the lemma. □

Now, we consider a family of (2×2) differential systems,

$$\frac{\partial y}{\partial x}(x,t) = \Phi(x,t)y(x,t), \quad (x,t) \in (\mathfrak{G} \setminus \{0,1\}) \times \mathfrak{D}, \tag{81}$$

in a domain $\mathfrak{G}$, $\mathfrak{B}_0 \cup \mathfrak{B}_1 \subset \mathfrak{G} \subset \mathbb{C}$, with regular singular points at $x = 0$ and $x = 1$ and a parameter t varying in some domain $\mathfrak{D} \subset \mathbb{R}$ or $\mathfrak{D} \subset \mathbb{C}$. Further, we assume that the coefficient matrix Φ in (81) has the form

$$\Phi(x,t) = \frac{1}{x(x-1)}\Psi(x,t), \quad (x,t) \in (\mathfrak{G} \setminus \{0,1\}) \times \mathfrak{D},$$

where $\Psi: \mathfrak{G} \times \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$ is an analytical matrix function with the following properties.

(I) The eigenvalues α, β of $\Psi(a,t)$ are distinct and independent of $t \in \mathfrak{D}$ and $a \in \{0,1\}$; in addition, $\mathrm{Re}\alpha \leqslant \mathrm{Re}\beta$.

(II) There are analytical functions $G_a: \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$, $a \in \{0,1\}$, such that $G_a(t)$ is invertible for all $t \in \mathfrak{D}$ and

$$G_a(t)^{-1}\Psi(a,t)G_a(t) = (-1)^a \operatorname{diag}(\alpha,\beta).$$

From Lemma 6 it follows that the system (81) possesses a fundamental matrix of the form

$$Y_a(x,t) = G_a(t)H_a(x,t)(x-a)^D(x-a)^{J_a(t)} \tag{82}$$

in the unit disk $\mathfrak{B}_a \subset \mathfrak{G}$ with center $a \in \{0,1\}$, where $H_a: \mathfrak{B}_a \times \mathfrak{D} \to M_2(\mathbb{C})$ is an analytical matrix function satisfying $H_a(0,t)=I$ for all $t \in \mathfrak{D}$, $D=\operatorname{diag}(\alpha,\beta)$, and

$$J_a(t) = \begin{pmatrix} 0 & 0 \\ p_a(t) & 0 \end{pmatrix} \tag{83}$$

with some analytical function $p_a: \mathfrak{D} \to \mathbb{C}$. By analytic continuation along curves, we can assume that Y_a is defined on the universal covering $\mathfrak{R}$ of the set $\mathfrak{G}\setminus\{0,1\}$. Since $Y_a(xe^{2i\pi}+a,t)=Y_a(x+a,t)e^{2i\pi D}[I+2\pi i J_a(t)]$ for all $(x,t) \in (\mathfrak{B}_0\setminus\{0\}) \times \mathfrak{D}$, the diagonal matrix D and the Jordan-type matrix $J_a(t)$ represent the monodromy behavior of Y_a corresponding to a circuit around $a \in \{0,1\}$. Moreover, as Y_0 and Y_1 are both fundamental matrices of the same differential equation (81), there exists an analytical matrix function $Q: \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$ such that $Y_0(x,t)=Y_1(x,t)Q(t)$ for all $(x,t) \in (\mathfrak{G}\setminus\{0,1\}) \times \mathfrak{D}$, which is called the connection matrix for Y_0 and Y_1. The next result gives a sufficient condition that certain components of the monodromy data J_a and Q are constant in $\mathfrak{D}$. For this reason, we establish in addition to (I) and (II) the following assumptions on the coefficient matrix Φ.

(III) There exists an analytical function $\Omega: \mathfrak{G} \times \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$ such that

$$\frac{\partial \Phi}{\partial t}(x,t) + \Phi(x,t)\Omega(x,t) = \Omega(x,t)\Phi(x,t) + \frac{\partial \Omega}{\partial x}(x,t), \quad (x,t) \in (\mathfrak{G}\setminus\{0,1\}) \times \mathfrak{D}. \tag{84}$$

(IV) The matrix functions G_a, $a \in \{0,1\}$, satisfy the linear differential equations

$$\frac{\partial G_a}{\partial t}(t) = \Omega(a,t)G_a(t), \quad t \in \mathfrak{D}. \tag{85}$$

Theorem 4: *If the conditions (I)–(IV) are satisfied, then*

$$\frac{\partial J_a}{\partial t} \equiv \frac{\partial Q_{21}}{\partial t} \equiv 0 \text{ in } \mathfrak{D}, \tag{86}$$

where the Jordan matrices J_a, $a \in \{0,1\}$, are given by (83) and $Q_{12}: \mathfrak{D} \to \mathbb{C}$ denotes the (1,2)-component of the connection matrix Q for Y_0 and Y_1.

Proof: Let $\gamma := \beta - \alpha$, and for fixed $a \in \{0,1\}$ we define

$$Z_a(x,t) := \frac{\partial Y_a}{\partial t}(x,t) - \Omega(x,t)Y_a(x,t), \quad (x,t) \in \mathfrak{R} \times \mathfrak{D}.$$

From (81) and the deformation equation (84) it follows that

$$\frac{\partial Z_a}{\partial x} = \frac{\partial^2 Y_a}{\partial x\,\partial t} - \frac{\partial \Omega}{\partial x} Y_a - \Omega \frac{\partial Y_a}{\partial x} = \frac{\partial (\Phi Y_a)}{\partial t} - \frac{\partial \Omega}{\partial x} Y_a - \Omega \Phi Y_a$$
$$= \Phi \frac{\partial Y_a}{\partial t} + \left(\frac{\partial \Phi}{\partial t} - \frac{\partial \Omega}{\partial x} - \Omega \Phi \right) Y_a = \Phi \left(\frac{\partial Y_a}{\partial t} - \Omega Y_a \right) = \Phi Z_a,$$

and therefore Z_a is a matrix solution of the differential equation (81) in $\mathfrak{R}$. Hence, there exists an analytical function $C_a : \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$ such that

$$Z_a(x,t) = Y_a(x,t) C_a(t), \quad (x,t) \in \mathfrak{R} \times \mathfrak{D}.$$

Now, by means of the differential equation (85), we get

$$\frac{\partial Y_a}{\partial t} = \frac{\partial G_a}{\partial t} H_a (x-a)^D (x-a)^{J_a} + G_a \frac{\partial H_a}{\partial t} (x-a)^D (x-a)^{J_a} + \log(x-a) G_a H_a (x-a)^D \frac{\partial J_a}{\partial t} (x-a)^{J_a}$$
$$= \left(\Omega(a, \cdot) G_a H_a + G_a \frac{\partial H_a}{\partial t} + (x-a)^\gamma \log(x-a) G_a H_a \frac{\partial J_a}{\partial t} \right) (x-a)^D (x-a)^{J_a},$$

and since $C_a = Y_a^{-1} Z_a$, it results that

$$\begin{aligned}
&(x-a)^D (x-a)^{J_a} C_a (x-a)^{-J_a} (x-a)^{-D} \\
&\quad = (x-a)^D (x-a)^{J_a} Y_a^{-1} \left(\frac{\partial Y_a}{\partial t} - \Omega Y_a \right) (x-a)^{-J_a} (x-a)^{-D} \\
&\quad = H_a^{-1} G_a^{-1} (\Omega(a, \cdot) - \Omega) G_a H_a + H_a^{-1} \frac{\partial H_a}{\partial t} + (x-a)^\gamma \log(x-a) \frac{\partial J_a}{\partial t} \\
&\quad = (x-a) F_a + (x-a)^\gamma \log(x-a) \begin{pmatrix} 0 & 0 \\ \dfrac{\partial p_a}{\partial t} & 0 \end{pmatrix}
\end{aligned} \tag{87}$$

with some analytical function $F_a : \mathfrak{G} \times \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$. Further, by setting

$$C_a(t) =: \begin{pmatrix} C_{11}(t) & C_{12}(t) \\ C_{21}(t) & C_{22}(t) \end{pmatrix}, \quad t \in \mathfrak{D}$$

(for clarity, we omit the index a in the entries of C_a), we have

$$\begin{aligned}
&(x-a)^D (x-a)^{J_a} C_a (x-a)^{-J_a} (x-a)^{-D} \\
&\quad = \begin{pmatrix} 1 & 0 \\ (x-a)^\gamma \log(x-a) p_a & (x-a)^\gamma \end{pmatrix} \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\log(x-a) p_a & (x-a)^{-\gamma} \end{pmatrix} \\
&\quad = \begin{pmatrix} C_{11} - \log(x-a) p_a C_{12} & (x-a)^{-\gamma} C_{12} \\ * & C_{22} + \log(x-a) p_a C_{12} \end{pmatrix}.
\end{aligned} \tag{88}$$

Comparing (87) to (88), it follows that $C_{12} \equiv 0$ in $\mathfrak{D}$ since the function in (87) is bounded at $x=a$. This in turn implies $C_{11} \equiv C_{22} \equiv 0$ as the diagonal entries in (87) have a zero at $x=a$ for all $t \in \mathfrak{D}$. Finally, we obtain that

$$(x-a)^D (x-a)^{J_a} C_a (x-a)^{-J_a} (x-a)^{-D} = \begin{pmatrix} 0 & 0 \\ (x-a)^\gamma C_{21} & 0 \end{pmatrix} \tag{89}$$

has no logarithmic singularity at $x=a$ and therefore the last term (87) vanishes identically. Hence, $\partial J_a / \partial t \equiv 0$ in $\mathfrak{D}$.

Next, we prove that $\partial Q_{12} / \partial t \equiv 0$. Since $Y_0(x,t) = Y_1(x,t) Q(t)$, it follows that

$$\frac{\partial Y_0}{\partial t} = \frac{\partial Y_1}{\partial t} Q + Y_1 \frac{\partial Q}{\partial t}. \tag{90}$$

Further, from $Z_a(x,t) = Y_a(x,t) C_a(t)$ we get

$$\frac{\partial Y_0}{\partial t} Y_0^{-1} - \Omega = Y_0 C_0 Y_0^{-1}, \quad \frac{\partial Y_1}{\partial t} Y_1^{-1} - \Omega = Y_1 C_1 Y_1^{-1}. \tag{91}$$

By means of (90) and $Y_0^{-1} = Q^{-1} Y_1^{-1}$, the first equation in (91) becomes

$$\frac{\partial Y_1}{\partial t} Y_1^{-1} - \Omega = Y_1 Q C_0 Q^{-1} Y_1^{-1} - Y_1 \frac{\partial Q}{\partial t} Q^{-1} Y_1^{-1}. \tag{92}$$

Now, (92) and the second equation in (91) imply

$$Y_1 C_1 Y_1^{-1} = Y_1 Q C_0 Q^{-1} Y_1^{-1} - Y_1 \frac{\partial Q}{\partial t} Q^{-1} Y_1^{-1}$$

and therefore

$$\frac{\partial Q}{\partial t} = Q C_0 - C_1 Q. \tag{93}$$

Note that the matrix function C_a has the form

$$C_a(t) = \begin{pmatrix} 0 & 0 \\ c_a(t) & 0 \end{pmatrix}, \quad a \in \{0,1\}.$$

Hence, if we set

$$Q(t) =: \begin{pmatrix} Q_{11}(t) & Q_{12}(t) \\ Q_{21}(t) & Q_{22}(t) \end{pmatrix}, \quad t \in \mathfrak{D},$$

then (93) is equivalent to the system

$$\frac{\partial}{\partial t} \begin{pmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{pmatrix} = \begin{pmatrix} c_0 Q_{12} & 0 \\ c_0 Q_{22} - c_1 Q_{11} & c_1 Q_{12} \end{pmatrix},$$

and we immediately obtain that $\partial Q_{12} / \partial t \equiv 0$ in $\mathfrak{D}$. □

In the following we apply the results of Lemma 6 and Theorem 4 to a family of (2×2) differential systems

$$\frac{\partial y}{\partial x}(x,t) = \left[\frac{1}{x} B_0(t) + \frac{1}{x-1} B_1(t) + C(t) \right] y(x,t), \quad (x,t) \in (\mathbb{C} \setminus \{0,1\}) \times \mathfrak{D}, \tag{94}$$

where $t \in \mathfrak{D}$ with some domain $\mathfrak{D} \subset \mathbb{R}$ or $\mathfrak{D} \subset \mathbb{C}$, and we suppose that the coefficients $B_0, B_1, C : \mathfrak{D} \to M_2(\mathbb{C})$ are analytical functions. Further, we assume that the following conditions hold.

(i) The eigenvalues α, β of $B_0(t)$ are distinct and independent of $t \in \mathfrak{D}$. Moreover, they coincide with the eigenvalues of $B_1(t)$, and $\mathrm{Re}\,\alpha \leqslant \mathrm{Re}\,\beta$.

(ii) There are analytical functions $G_a : \mathfrak{D} \to M_2(\mathbb{C})$, $a \in \{0,1\}$, such that $G_a(t)$ is invertible and

$$G_0(t)^{-1} B_0(t) G_0(t) = -G_1(t)^{-1} B_1(t) G_1(t) = \mathrm{diag}(\alpha, \beta) =: D, \quad t \in \mathfrak{D}.$$

Let Y_a, $a \in \{0,1\}$, be fundamental matrices of (94) in the open disk $\mathfrak{B}_a \subset \mathbb{C}$ with center a and radius 1 having the form (82), where $H_a : \mathfrak{B} \times \mathfrak{D} \to \mathrm{M}_2(\mathbb{C})$ is analytical, $H_a(0,t) = I$ for all $t \in \mathfrak{D}$, and $J_a(t)$ is given by (83) with some analytical function $p_a : \mathfrak{D} \to \mathbb{C}$. Again, by analytic continua-

tion, we assume that Y_a is defined on the universal covering $\mathfrak{R}$ of $\mathbb{C}\setminus\{0,1\}$, and we denote by $Q:\mathfrak{D}\to M_2(\mathbb{C})$ the connection matrix for Y_0 and Y_1. In the sequel we are looking for conditions such that for fixed $t\in\mathfrak{D}$ the system (94) has one of the following properties.

(P) There exists a fundamental matrix Y of the form

$$Y(x)=[x(1-x)]^{\alpha}P(x)e^{C(t)x},\quad x\in\mathbb{C}\setminus\{0,1\},\tag{95}$$

where $P:\mathbb{C}\to\mathrm{M}_2(\mathbb{C})$ is a polynomial matrix function.

(H) There exists a nontrivial solution y of the form

$$y(x)=[x(1-x)]^{\beta}h(x),\quad x\in\mathbb{C}\setminus\{0,1\},\tag{96}$$

where $h:\mathbb{C}\to\mathbb{C}^2$ is an entire vector function.

Lemma 7: Suppose that the conditions (i) and (ii) are satisfied, and let $t\in\mathfrak{D}$. Then the system (94) has the property (P) if and only if $\beta-\alpha$ is an integer and $p_0(t)=p_1(t)=0$, and it has the property (H) if and only if $Q_{21}(t)=0$.

Proof: By means of the transformation $y(x)=x^{\alpha}(x-1)^{\alpha}\tilde{y}(x)$, the differential equation (94) is equivalent to the system

$$\frac{\partial\tilde{y}}{\partial x}(x,t)=\left[\frac{1}{x}\tilde{B}_0(t)+\frac{1}{x-1}\tilde{B}_1(t)+C(t)\right]\tilde{y}(x,t),\quad (x,t)\in(\mathbb{C}\setminus\{0,1\})\times\mathfrak{D},\tag{97}$$

where $\tilde{B}_0(t):=B_0(t)-\alpha$ and $\tilde{B}_1(t):=B_1(t)-\alpha$. Moreover,

$$\tilde{Y}_a(x,t)=G_a(t)H_a(x,t)\begin{pmatrix}1&0\\0&(x-a)^{\beta-\alpha}\end{pmatrix}(x-a)^{J_a(t)}\tag{98}$$

are fundamental matrices of (97) in a neighborhood of $a\in\{0,1\}$. First, suppose that $\beta-\alpha$ is an integer and that $p_0(t)=p_1(t)=0$ holds. In this case $J_0(t)=J_1(t)=0$, and the system (97) has a holomorphic fundamental matrix since $(x-a)^{\beta-\alpha}$ is holomorphic and $\tilde{Y}_0(\cdot,t)$, $\tilde{Y}_1(\cdot,t)$ contain no logarithmic terms. Moreover, as the coefficient matrix $\Phi(\cdot,t)$ of (94) is a rational function which is bounded at infinity, the extension of Halphen's theorem, Theorem 2.4 in Gesztesy *et al.* (2000), implies that the system (97) has a fundamental matrix of the form $\tilde{Y}(x)=R(x)e^{C(t)x}$ with some rational (and hence polynomial) matrix function $R:\mathbb{C}\to\mathrm{M}_2(\mathbb{C})$. Conversely, if (94) has a fundamental matrix of the form (95), then $\tilde{Y}_0(\cdot,t)$ and $\tilde{Y}_1(\cdot,t)$ are holomorphic matrix functions, which gives $\beta-\alpha\in\mathbb{Z}$ and $J_0(t)=J_1(t)=0$.

Next, let us assume that $Q_{12}(t)=0$. If we define

$$y(x):=Y_0(x,t)\begin{pmatrix}0\\1\end{pmatrix}=x^{\beta}G_0(t)H_0(x,t)\begin{pmatrix}0\\1\end{pmatrix},$$

then y is a nontrivial solution of (94), and $x^{-\beta}y(x)$ is analytic at $x=0$. Since $Y_0(x,t)=Y_1(x,t)Q(t)$ and $Q_{12}(t)=0$, we obtain

$$y(x)=Y_1(x,t)Q(t)\begin{pmatrix}0\\1\end{pmatrix}=(x-1)^{\beta}G_1(t)H_1(x,t)\begin{pmatrix}0\\Q_{22}(t)\end{pmatrix},$$

and therefore $(1-x)^{-\beta}y(x)$ is analytic in a neighborhood of $x=1$. Now, by the existence and uniqueness theorem, $h(x):=[x(1-x)]^{-\beta}y(x)$ can be extended to an entire vector function. Conversely, suppose that (94) has a nontrivial solution of the form (96). Then

$$y(x)=Y_0(x,t)\begin{pmatrix}0\\c_0\end{pmatrix}=Y_1(x,t)\begin{pmatrix}0\\c_1\end{pmatrix}$$

with some constants $c_0,c_1\in\mathbb{C}\setminus\{0\}$. Since $Y_0(x,t)=Y_1(x,t)Q(t)$, it follows that

$$Q(t)\begin{pmatrix}0\\ c_0\end{pmatrix}=\begin{pmatrix}0\\ c_1\end{pmatrix},$$

which gives $Q_{21}(t)=0$.

Now, in addition to (i) and (ii), we assume that the coefficients of (94) satisfy the following conditions.

(iii) There exists an analytical function $\Omega:\mathbb{C}\times\mathfrak{D}\to M_2(\mathbb{C})$ such that the deformation equation (84) holds in $(\mathbb{C}\setminus\{0,1\})\times\mathfrak{D}$, where Φ is given by

$$\Phi(x,t):=\frac{1}{x}B_0(t)+\frac{1}{x-1}B_1(t)+C(t),\quad (x,t)\in(\mathbb{C}\setminus\{0,1\})\times\mathfrak{D}.$$

(iv) The matrix functions G_a, $a\in\{0,1\}$, satisfy the differential equations

$$\frac{\partial G_a}{\partial t}(t)=\Omega(a,t)G_a(t),\quad t\in\mathfrak{D}.$$

The next result is an immediate consequence of Theorem 4 and Lemma 7.

Corollary 2: Suppose that the conditions (i)–(iv) are satisfied. If (P) holds for one $t_0\in\mathfrak{D}$, then (94) has the property (P) for all $t\in\mathfrak{D}$, and if (H) holds for one $t_0\in\mathfrak{D}$, then (94) has the property (H) for all $t\in\mathfrak{D}$.

Finally, we apply the results of this section to prove that the classical as well as the monodromy eigenvalues of the Chandrasekhar–Page angular equation in dependence of $(\mu,\nu)\in\mathbb{R}^2$ are (locally) solutions of the partial differential equation (29).

Lemma 8: Let $\kappa\in\left[\frac{1}{2},\infty\right)$ and $\sigma\in\{-1,+1\}$ be fixed. Moreover, suppose that the functions $v:\mathfrak{D}\to\mathbb{R}\setminus\{0\}$ and $w:\mathfrak{D}\to\mathbb{R}$ are solutions of the system (50) and (51) on some interval $\mathfrak{D}\subset(0,\infty)$. Finally, let

$$\mu(t):=\frac{t}{2}\left(v(t)+\frac{\sigma}{v(t)}\right),\quad \nu(t):=\frac{t}{2}\left(v(t)-\frac{\sigma}{v(t)}\right),\quad t\in\mathfrak{D},\tag{99}$$

and $t_0\in\mathfrak{D}$. If $w(t_0)$ is an eigenvalue of $A(\kappa;\mu(t_0),\nu(t_0))$, then $w(t)$ is an eigenvalue of $A(\kappa;\mu(t),\nu(t))$ for each $t\in\mathfrak{D}$. Furthermore, if κ is a half-integer and $w(t_0)$ is a monodromy eigenvalue of $A(\kappa;\mu(t_0),\nu(t_0))$, then $w(t)$ is a monodromy eigenvalue of $A(\kappa;\mu(t),\nu(t))$ for each $t\in\mathfrak{D}$.

Proof: In terms of (99) and $\lambda(t):=w(t)$, the coefficient matrices (12) of the system (11) take the form

$$B_0(t)=\begin{pmatrix}-\frac{\kappa}{2}-\frac{1}{4} & \frac{t}{2}\left(v(t)+\frac{\sigma}{v(t)}\right)-w(t)\\ 0 & \frac{\kappa}{2}+\frac{1}{4}\end{pmatrix},$$

$$B_1(t)=\begin{pmatrix}\frac{\kappa}{2}+\frac{1}{4} & 0\\ \frac{t}{2}\left(v(t)+\frac{\sigma}{v(t)}\right)-w(t) & -\frac{\kappa}{2}-\frac{1}{4}\end{pmatrix},$$

$$C(t) = \frac{t}{v(t)} \begin{pmatrix} -(v(t)^2+1) & -(v(t)^2-1) \\ (v(t)^2-1) & (v(t)^2+1) \end{pmatrix},$$

where the condition (i) is satisfied with $\alpha = -(\kappa/2) - \frac{1}{4}$ and $\beta = (\kappa/2) + \frac{1}{4}$. Now, if we define the matrix function

$$\Omega(x,t) := \frac{1}{v(t)} \begin{pmatrix} (v(t)^2-\sigma)\left(\frac{1}{2}-x\right) & (v(t)^2+\sigma)(1-x) \\ (v(t)^2+\sigma)x & (v(t)^2-\sigma)\left(x-\frac{1}{2}\right) \end{pmatrix}, \quad (x,t) \in \mathbb{C} \times \mathfrak{D},$$

then, by a straightforward calculation using the characteristic equations (50) and (51), it follows that the deformation equation in (iii) holds. Finally, by setting

$$G_0(t) := \begin{pmatrix} e^{\phi(t)} & \left[\frac{t}{2}\left(v(t) + \frac{\sigma}{v(t)}\right) - w(t)\right] e^{-\phi(t)} \\ 0 & (\kappa + \frac{1}{2}) e^{-\phi(t)} \end{pmatrix}, \quad G_1(t) := KG_0(t)K,$$

where K is the matrix (20) and

$$\phi(t) := \int_{t_0}^{t} \frac{v(\tau)^2 - \sigma}{2v(\tau)} \mathrm{d}\tau, \quad t \in \mathfrak{D},$$

the conditions (ii), (iv) are satisfied. Since $w(t)$ is a monodromy eigenvalue of $A(\kappa;\mu(t),\nu(t))$ if and only if (11) has the property (P), and $w(t)$ is a classical eigenvalue of $A(\kappa;\mu(t),\nu(t))$ if and only if (11) has the property (H), the assertion follows from Corollary 2. □

Theorem 5: *For a fixed $\kappa = k - \frac{1}{2}$ with a positive integer k, let $(0,0) \in \mathfrak{S} \subset \mathbb{R}^2$ be a simply connected domain such that for each $(\mu,\nu) \in \mathfrak{S}$ all monodromy eigenvalues $\lambda_0^j(\kappa;\mu,\nu)$, $j = 1-k,\ldots,k-1$, of $A(\kappa;\mu,\nu)$ are simple zeros of the polynomial $P(\kappa;\cdot,\mu,\nu)$ given by Theorem 3. Then each function $\lambda = \lambda_0^j$, $j = 1-k,\ldots,k-1$, satisfies the partial differential equation (29) in $\mathfrak{S}$.*

Proof: Let $j \in \{1-k,\ldots,k-1\}$ be fixed. The monodromy eigenvalues of $A(\kappa;\mu,\nu)$ are exactly the zeros of the polynomial $P(\kappa;\cdot;\mu,\nu)$, and since all zeros of $P(\kappa;\cdot;\mu,\nu)$ are simple, the implicit function theorem implies that $\lambda_0^j(\kappa;\mu,\nu)$ depends analytically on (μ,ν) in $\mathfrak{S}$. In order to show that the function $\lambda = \lambda_0^j$ satisfies the PDE (29), we make use of the unique continuation property of analytical functions. That means, it suffices to prove that (29) holds for $\lambda = \lambda_0^j$ in a neighborhood of some point $(\mu,\nu) = (\tau,0) \in \mathfrak{S}$, $\tau > 0$. Now, in view of the coordinate transformation (99), we must verify that the function $\lambda_0^j(\kappa;\mu(t,v),\nu(t,v))$ is a solution of the partial differential equation (49) in a neighborhood of the point $(t,v) = (\tau,1)$. To this end, let us consider the characteristic equations of (49),

$$\frac{\partial v}{\partial t}(t,u) = -\frac{2v(t,u)w(t,u)}{t},$$

$$\frac{\partial w}{\partial t}(t,u) = -\kappa\left(v(t,u) + \frac{1}{v(t,u)}\right) - \frac{t}{2}\left(v(t,u)^2 - \frac{1}{v(t,u)^2}\right)$$

together with the initial values

$$v(\tau,u) = u, \quad w(\tau,u) = \lambda_0^j(\kappa;\mu(\tau,u),\nu(\tau,u)),$$

which depend analytically on the parameter $u \in (0,\infty)$. The solutions $v(t,u)$ and $w(t,u)$ of this initial value problem are analytical functions in a neighborhood of $(\tau,1)$, and since $(\partial v/\partial u)(\tau,u) = 1$, they form locally an integral surface for the PDE (49), compare John (1982, Chap. 1, Sec. 5). More precisely, there exists an analytical function U defined on a neighborhood

$\mathfrak{V}$ of $(t,v)=(\tau,1)$ such that $U(\tau,v)=v$, and $W(t,v):=w(t,U(t,v))$ is a solution of (49) in $\mathfrak{V}$. Now, Lemma 8 implies that $W(t,v)$ is a monodromy eigenvalue of $A(\kappa;\mu(t,v),\nu(t,v))$ for all $(t,v)\in\mathfrak{V}$, and since $W(\tau,v)=\lambda_0^j(\kappa;\mu(\tau,v),\nu(\tau,v))$, it follows that $W(t,v)=\lambda_0^j(\kappa;\mu(t,v),\nu(t,v))$ holds identically on $\mathfrak{V}$. This completes the proof of the theorem. □

In a similar way we can apply Lemma 8 to prove that for fixed $\kappa\in(0,\infty)$ the zeros of the function $\lambda\mapsto\Delta(\kappa;\lambda,\mu,\nu)$ defined in Sec. II and therefore the eigenvalues of $A(\kappa;\mu,\nu)$ satisfy the partial differential equation (29). This alternative proof of Theorem 1 is based on monodromy preserving deformation—a general technique, which should be applicable to other eigenvalue problems as well. Potential candidates and associated Ω-matrices for solving the deformation equations can be found in Jimbo and Miwa (1981a, Appendix C).

Finally, as a consequence of Theorem 5, the zeros of the polynomial $P(\kappa;\cdot;\mu,\nu)$ given by Theorem 3 satisfy the PDE (29) and do not coincide with any eigenvalue of $A(\kappa;\mu,\nu)$ in a neighborhood of $(\mu,\nu)=(0,0)$. Moreover (see the proof of Lemma 4), $P(\kappa;\cdot;\mu,\nu)$ gives rise to a special integral of polynomial type for the Painlevé III (52). Now, the results of Mansfield and Webster (1998) suggest that these special integrals are unique in some sense, which in turn implies that classical eigenvalues of the Chandrasekhar–Page angular equation are not algebraic.

APPENDIX A: EIGENVALUES AND EIGENFUNCTIONS IN THE CASE $\mu=\nu=0$

For fixed $\kappa\in[\frac{1}{2},\infty)$, a point $\lambda\in\mathbb{C}$ is an eigenvalue of $A(\kappa;0,0)$ if and only if the system (5) with $(\mu,\nu)=(0,0)$ has a nontrivial solution $S(\theta)$ satisfying

$$\int_0^\pi |S(\theta)|^2\,\mathrm{d}\theta<\infty. \tag{A1}$$

Introducing the functions $u,v:(-1,1)\to\mathbb{C}$ by

$$S(\theta) =: \sin^{\kappa+1/2}\theta\begin{pmatrix}\sqrt{\tan\frac{\theta}{2}}\,u(\cos\theta)\\ \sqrt{\cot\frac{\theta}{2}}\,v(\cos\theta)\end{pmatrix}, \tag{A2}$$

then (5) with $(\mu,\nu)=(0,0)$ is transformed into

$$(1-x)u'(x)=(\kappa+\tfrac{1}{2})u(x)+\lambda v(x),\quad (1+x)v'(x)=-\lambda u(x)-(\kappa+\tfrac{1}{2})v(x), \tag{A3}$$

and the normalization condition (A1) is equivalent to

$$\int_{-1}^1 u(x)^2(1-x)^{\kappa+1/2}(1+x)^{\kappa-1/2}\,\mathrm{d}x<\infty,\quad \int_{-1}^1 v(x)^2(1-x)^{\kappa-1/2}(1+x)^{\kappa+1/2}\,\mathrm{d}x<\infty. \tag{A4}$$

If $\lambda=0$, then the differential equations (A3) imply that there are constants $c_1,c_2\in\mathbb{C}$ such that $u(x)=c_1(1-x)^{-\kappa-1/2}$ and $v(x)=c_2(1+x)^{-\kappa-1/2}$, and from the condition (A4) it follows that $c_1=c_2=0$. Hence, $\lambda=0$ is not an eigenvalue of $A(\kappa;0,0)$, and we assume in what follows that $\lambda\neq0$. In this case, the second equation in (A3) gives

$$u(x) = -\frac{1+x}{\lambda}v'(x) - \frac{\kappa+\frac{1}{2}}{\lambda}v(x), \tag{A5}$$

and for v we obtain the second order differential equation

$$(1-x^2)v''(x) + [1-2(\kappa+1)x]v'(x) + \left[\lambda^2 - \left(\kappa+\frac{1}{2}\right)^2\right]v(x) = 0.$$

If we set $\alpha := \kappa - \frac{1}{2}$, $\beta := \kappa + \frac{1}{2}$, and $\Lambda := \lambda - \kappa - \frac{1}{2}$, this differential equation becomes

$$(1-x^2)v''(x) + [\beta - \alpha - (\alpha+\beta+2)x]v'(x) + \Lambda(\Lambda+\alpha+\beta+1)v(x) = 0, \tag{A6}$$

and the second condition in (A4) takes the form

$$\int_{-1}^{1} v(x)^2(1-x)^\alpha(1+x)^\beta \, dx < \infty. \tag{A7}$$

Note that (A6) and (A7) is the eigenvalue problem associated to the Jacobi polynomials. More precisely, the solutions of the differential equation (A6) which are square integrable with respect to the weight function $(1-x)^\alpha(1+x)^\beta$ are constant multiples of the Jacobi polynomials $P_n^{(\alpha,\beta)}$ with some non-negative integer n, and the corresponding eigenvalues $\lambda_n^\pm$ are determined by the equation $\lambda^2 - (\kappa+\frac{1}{2})^2 = n(n+\alpha+\beta+1)$, i.e., $\lambda_n^\pm = \pm(\kappa+\frac{1}{2}+n)$. Now, if we define $v(x) := -P_n^{(\alpha,\beta)}(x)$, $x \in (-1,1)$, then (A5) yields

$$\begin{aligned}
\lambda_n^\pm u(x) &= (1+x)\frac{d}{dx}P_n^{(\alpha,\beta)} + \beta P_n^{(\alpha,\beta)} = \frac{\alpha+\beta+n+1}{2}(1+x)P_{n-1}^{(\alpha+1,\beta+1)} + \beta P_n^{(\alpha,\beta)} \\
&= \frac{\alpha+\beta+n+1}{\alpha+\beta+2n+1}[(\beta+n)P_{n-1}^{(\alpha+1,\beta)} + nP_n^{(\alpha+1,\beta)}] + \beta P_n^{(\alpha,\beta)} \\
&= (\alpha+\beta+n+1)P_n^{(\alpha+1,\beta)} - (\alpha+n+1)P_n^{(\alpha,\beta)} \\
&= (\beta+n)P_n^{(\alpha+1,\beta-1)} = |\lambda_n^\pm| P_n^{(\alpha+1,\beta-1)},
\end{aligned}$$

where we applied the differentiation formulas and contiguous relations for Jacobi polynomials, see Magnus *et al.* (1966, Sec. 5.2). Hence, $u(x) = \pm P_n^{(\alpha+1,\beta-1)}(x)$, $x \in (-1,1)$, and since u satisfies the first condition in (A4), the numbers $\lambda_n^\pm$ are in fact eigenvalues of $A(\kappa;0,0)$. Moreover, the corresponding eigenfunctions are constant multiples of

$$\sin^\kappa\theta \begin{pmatrix} \pm\sqrt{\tan\frac{\theta}{2}}\, P_n^{(\kappa+1/2,\kappa-1/2)}(\cos\theta) \\ -\sqrt{\cot\frac{\theta}{2}}\, P_n^{(\kappa-1/2,\kappa+1/2)}(\cos\theta) \end{pmatrix}, \quad \theta \in (0,\pi),$$

which form a complete orthogonal set in $\mathcal{L}^2((0,\pi),\mathbb{C}^2)$. In particular, the spectrum of $A(\kappa;0,0)$ is given by $\{\lambda_n^\pm : n = 0,1,2,\ldots\}$.

APPENDIX B: A NUMERICAL EXAMPLE

As a numerical example, we have computed the coefficients $c_{m,n}$ of the power series expansion (38) up to and including $m+n=8$ for $\kappa=\frac{1}{2}$ and $j=1$ using the recurrence relation given in Sec. III. The coefficients have been rounded to six significant figures and listed in Table I. It should be noted that they are to some extent different from the coefficients displayed in Suffern *et al.* (1983, Table I). Evaluating the power series expansion (38) at $\alpha=0.01$ and $\beta=0.02$, i.e., $(\mu,\nu) = (0.005, 0.015)$, yields $\tilde{\lambda}_1 = 1.011\,67$ as a numerical approximation for the eigenvalue λ_1, and this result coincides with the value given in Suffern *et al.* (1983, Table II). For a second pair of

TABLE I. The coefficients $c_{m,n}$, $0 \leqslant m+n \leqslant 8$, of the power series expansion (38) in the case $\kappa = \frac{1}{2}$ and $j=1$.

8	7.108 56e−06								

parameters $(\alpha,\beta)=(0.5,1.0)$, i.e., $(\mu,\nu)=(0.25,0.75)$, we obtain $\tilde{\lambda}_1=1.597\,45$, which differs slightly from the value $\hat{\lambda}_1=1.597\,64$ listed in Suffern *et al.* (1983, Table II). In order to test the reliability of our numerical result, we can use the statement of Lemma 3. That means, we approximate $\Theta(\lambda)$ defined in (25) by the second component $\Theta_n(\lambda)$ of $d_n(\lambda)$ for $n=8$, and we compare $\Theta_8(\tilde{\lambda}_1)$ and $\Theta_8(\hat{\lambda}_1)$ with the theoretical result $\Theta(\lambda_1)=0$. As $\Theta_8(\tilde{\lambda}_1)=3.608\,82e-05$ and $\Theta_8(\hat{\lambda}_1)=-2.511\,64e-04$, our result seems to be more trustworthy. Finally, let $(\mu,\nu)=(0.02,0.1)$. The coefficients of the polynomial Θ_8 are given in Table II. For these parameters, our power series approximation gives $\tilde{\lambda}_1=1.073\,79$ which differs significantly from the value $\hat{\lambda}_1=1.061\,04$ given by Chakrabarti (1984, Table I). Despite his claiming of an accuracy of six decimals, the evaluation of Θ_8 at the eigenvalues in question gives $\Theta_8(\tilde{\lambda}_1)=5.688\,99e-12$ and $\Theta_8(\hat{\lambda}_1)=1.527\,70e-02$ in favor of our result. Thus, Chakrabarti's calculations should be taken with some caution.

APPENDIX C: EIGENFUNCTIONS IN THE CASE $|\mu| \neq |\nu|$

Eliminating the second component of y in the system (11), we get a linear second-order differential equation for the first component y_1 given by

$$\frac{\mathrm{d}^2 y_1}{\mathrm{d}x^2}(x) + \left(\frac{1}{x} - \frac{1}{x-b}\right)\frac{\mathrm{d}y_1}{\mathrm{d}x}(x) + \left(\tau_0 + \frac{\tau_1}{x} + \frac{\tau_2}{x^2} + \frac{\tau_3}{x-1} + \frac{\tau_4}{(x-1)^2} + \frac{\tau_5}{x-b}\right) y_1(x) = 0$$

with

$$b := \frac{\mu-\lambda}{2\mu}, \quad \tau_0 := 4(\mu^2-\nu^2),$$

TABLE II. The coefficients δ_n of the polynomial $\Theta_8(\lambda)=\sum_{n=0}^{16}\delta_n\lambda^n$ for $\kappa=\frac{1}{2}$, $\mu=0.02$, $\nu=0.1$.

$n=0$	1.221 51e+00	$n=9$	4.911 51e−06
1	1.443 47e−02	10	−4.220 48e−04
2	−1.705 25e+00	11	−9.466 10e−08
3	−7.922 97e−03	12	1.026 43e−05
4	6.721 14e−01	13	6.889 33e−10
5	1.460 03e−03	14	−1.264 70e−07
6	−1.123 51e−01	15	−1.000 00e−26
7	−1.210 28e−04	16	6.151 19e−10
8	9.396 64e−03		

$$\tau_1 := \lambda^2 - 2\alpha^2 + 2\nu + \alpha - \mu^2 - 4\alpha\nu + \frac{2\alpha\mu}{\mu - \lambda}, \quad \alpha := \frac{\kappa}{2} + \frac{1}{4},$$

$$\tau_2 := -\alpha^2, \quad \tau_3 := \frac{4\alpha\mu^2}{\mu^2 - \lambda^2} + 2\nu - \tau_1, \quad \tau_4 := \alpha(1-\alpha), \quad \tau_5 := \frac{2(\nu\mu^2 + 2\alpha\mu^2 - \nu\lambda^2)}{\lambda^2 - \mu^2}.$$

Now by means of the transformation

$$y_1(x) := x^\alpha (x-1)^\alpha \psi(x) e^{2tx}, \quad t = \pm\sqrt{\nu^2 - \mu^2},$$

we find that $\psi(x)$ satisfies the generalized Heun equation,

$$\frac{d^2\psi(x)}{dx^2} + \left(\frac{1-\mu_0}{x} + \frac{1-\mu_1}{x-1} + \frac{1-\mu_2}{x-b} + 4t\right)\frac{d\psi(x)}{dx} + \frac{\beta_0 + \beta_1 x + \beta_2 x^2}{x(x-1)(x-b)}\psi(x) = 0, \tag{C1}$$

where

$$\mu_0 = -2\alpha, \quad \mu_1 = 1 - 2\alpha, \quad \mu_2 = 2, \quad \beta_2 := 8\alpha t,$$

and

$$\beta_1 = \mu^2 - \lambda^2 - 2t[b + 2\alpha(1+2b)] + 2\alpha(\alpha - 1) + 2\nu(2\alpha - b) - \frac{2\alpha\mu(b-1)}{\lambda + \mu} + \frac{2\alpha\mu b}{\mu - \lambda},$$

$$\beta_0 = b(\lambda^2 - \mu^2) + b[2(\nu + t) - 4\alpha(\nu - t) - 4\alpha^2] + \alpha - \frac{2\mu\alpha b}{\lambda - \mu}.$$

We observe that 0, 1, and b are simple singularities with characteristic exponents $(0, \mu_0)$, $(0, \mu_1)$, and $(0, \mu_2)$, respectively, while ∞ is (at most) an irregular singularity of rank 1. To stress the importance of Eq. (C1), it is sufficient to remark that it contains the ellipsoidal wave equation as well as Heun's equation and thus the Mathieu, spheroidal, Lamé, Whittaker-Hill, and Ince equations as special cases.

(Received 24 May 2004; accepted 7 September 2004; published online 23 December 2004)

We investigate integrable two-dimensional Hamiltonian systems with scalar and vector potentials, admitting second invariants which are linear or quadratic in the momenta. In the case of a linear second invariant, we provide some examples of weakly integrable systems. In the case of a quadratic second invariant, we recover the classical strongly integrable systems in *Cartesian and polar coordinates* and provide some new examples of integrable systems in *parabolic and elliptical coordinates*. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1818721]

I. INTRODUCTION

The direct approach to investigate integrable Hamiltonian systems is a very classical subject.[1,2] It consists in determining the class of potentials supporting additional invariants within some specified family of phase-space functions. This method produced several interesting results in the 1980s, as illustrated in the review by Hietarinta.[3] Recently[4–6] the approach has been applied to treat in a unified way both invariants at arbitrary and fixed energy, where the second possibility is related to the existence of additional "weak" invariants only on given energy hypersurfaces.

Many results are known for natural reversible Hamiltonians. One of the reasons for this is that the search for additional invariants can be restricted to functions with a definite parity in the momenta. This property leads to a substantial reduction in the usually very complicated set of equations. Much less is known in the case of Hamiltonians with vector potentials. For a long time, the only systematic attempt to cope with this case was that of Dorizzi *et al.*[7] providing a set of solutions in Cartesian coordinates. Recently, McSween and Winternitz[8] obtained some new solutions in polar coordinates and Bérubé and Winternitz[9] extended the results to the corresponding quantum problem. In both works the authors also identify the subset of superintegrable systems. In an attempt to extend these results to include weak integrability, we have provided[10] a general solution for linear invariants and analyzed some new classes of weakly integrable systems.

The physical applications of Hamiltonians with terms linear in the momenta are of great relevance. Just to mention one of the most important, we recall the ubiquitous role of rotation in astrophysical problems like those of galactic dynamics. The purpose of the present paper is to reinvestigate Hamiltonian systems with both scalar and vector potentials, trying to identify those admitting the existence of a second invariant which is a quadratic polynomial in the momenta. We state the general approach at arbitrary and fixed value of the first invariant (Jacobi constant) and show that, in the case of strong integrability, it is possible to get a general formal solution. This is valid for every standard coordinate systems which are the same as the separable ones in the purely scalar case. Therefore, in addition to the above-mentioned Cartesian and polar case, solutions in parabolic and elliptical coordinates can be looked for. In all cases, the potentials are defined in terms of a pair of scalar functions for which we get the integrability conditions: solving them

[a)]Electronic mail: pucacco@roma2.infn.it
[b)]Electronic mail: kr@physto.se

determines the vector potential, whereas the scalar potential is subject to an additional linear differential equation. We provide some new examples of integrable systems with a vector potential whose existence can be discovered working in parabolic and elliptical coordinates. The case of quadratic invariants was also addressed by Yehia[11,12] who obtained integrable systems with Riemannian configuration space and applications to rigid body dynamics: the examples with a flat configuration space can be reproduced with the procedure devised here. The issue of separation of the Hamilton–Jacobi equation in presence of a vector potential has been recently faced by Benenti, Chanu, and Rastelli.[13] Their general approach requires an extended configuration space, preventing the application of the approach adopted here which heavily resides on the use of conformal coordinate transformation in two dimensions.

The plan of the paper is as follows: in Sec. II we recall the structure of Hamiltonian systems with terms linear in the velocities; in Sec. III we illustrate a version of the direct approach to find polynomial invariants which is particularly efficient in treating two-dimensional systems; in Sec. IV, for the sake of completeness, we recall systems admitting a second invariant which is a linear polynomial in the momenta; in Sec. V we treat the case of the quadratic second invariant; in Sec. VI we illustrate all known strongly integrable solutions in the quadratic case; and in Sec. VII we conclude.

II. HAMILTONIANS WITH SCALAR AND VECTOR POTENTIALS

We are interested in finding integrable examples of systems generated by a Hamiltonian function of the type

$$\mathcal{H} = \tfrac{1}{2}(p_x^2 + p_y^2) + A_1(x,y)p_x + A_2(x,y)p_y + V(x,y), \tag{1}$$

where the function V is the ordinary "scalar" potential and A_1 and A_2 are the components of a "vector" potential $\mathbf{A}$ in two dimensions. Under the canonical transformation

$$p_x \to p_x + \partial_x F, \quad p_y \to p_y + \partial_y F, \tag{2}$$

where $F(x,y)$ is an arbitrary function, the Hamiltonian remains invariant if $\mathbf{A}$ and V are changed according to

$$\mathbf{A} \to \mathbf{A} + \nabla F, \tag{3}$$

$$V \to V + \mathbf{A} \cdot \nabla F + \tfrac{1}{2}|\nabla F|^2. \tag{4}$$

However, the two quantities

$$\Omega(x,y) = \tfrac{1}{2}(\partial_y A_1 - \partial_x A_2) \tag{5}$$

and

$$W(x,y) = V - \tfrac{1}{2}|\mathbf{A}|^2 \tag{6}$$

are "gauge invariants" and can therefore be used to uniquely characterize the model system. The Hamiltonian to be worked on becomes then

$$\mathcal{H} = \tfrac{1}{2}(p_x + A_1(x,y))^2 + \tfrac{1}{2}(p_y + A_2(x,y))^2 + W(x,y). \tag{7}$$

Ω, the "curl" of the vector potential, has several physical interpretations: in astrophysical and celestial mechanical applications, it usually denotes an angular velocity field; it is a magnetic field in electrodynamics and plasma physics and so on. We remark that in general it is easier to attempt to solve directly for Ω and W. To recover the scalar V, one must have A_1 and A_2 and this can be another difficult problem.[3]

We can first write the canonical equations provided by (1),

$$\dot{x} = p_x + A_1, \tag{8}$$

$$\dot{y} = p_y + A_2, \tag{9}$$

$$\dot{p}_x = -\partial_x A_1 p_x - \partial_x A_2 p_y - \partial_x V, \tag{10}$$

$$\dot{p}_y = -\partial_y A_1 p_x - \partial_y A_2 p_y - \partial_y V, \tag{11}$$

and then simplify them by exploiting the functions introduced above to get the equations of motion

$$\ddot{x} - 2\Omega\dot{y} = -\partial_x W, \tag{12}$$

$$\ddot{y} + 2\Omega\dot{x} = -\partial_y W. \tag{13}$$

It is readily verified that under the phase-space flow generated by (12) and (13), there exists a conserved function that is the first invariant of the system (*Jacobi constant*),

$$J = \tfrac{1}{2}(\dot{x}^2 + \dot{y}^2) + W. \tag{14}$$

In the investigation of the integrability properties of Hamiltonian (7), it turns out to be very helpful to work with complex variables. We perform then the canonical point transformation given by

$$z = x + iy, \quad p_z = p = \tfrac{1}{2}(p_x - ip_y), \tag{15}$$

$$\overline{z} = x - iy, \quad p_{\overline{z}} = \overline{p} = \tfrac{1}{2}(p_x + ip_y), \tag{16}$$

so that Hamiltonian (7) turns out to be

$$\mathcal{H} = 2(p + \Phi)(\overline{p} + \overline{\Phi}) + W(z, \overline{z}), \tag{17}$$

where the complex function

$$\Phi = \tfrac{1}{2}(A_1 - iA_2) \tag{18}$$

has been introduced. In these variables, Ω is given by

$$\Omega = 2\Im\{\partial_z \Phi\}, \tag{19}$$

where $\Im$ denotes the imaginary part. Equations (15) and (16) display a nice space-saving feature of using complex variables: even if an expression is not real, it is enough to write a single relation between complex functions [like, e.g., (15)]. The remaining information is provided by the corresponding complex conjugate expression, which we therefore do not write explicitly. For example, the canonical equations given by (17) are

$$\dot{z} = 2(\overline{p} + \overline{\Phi}), \tag{20}$$

$$\dot{p} = -2(\overline{p} + \overline{\Phi})\partial_z \Phi - 2(p + \Phi)\partial_z \overline{\Phi} - \partial_z W, \tag{21}$$

and the equations of motion corresponding to (12) and (13) are

$$\ddot{z} + 2i\Omega\dot{z} = -2\partial_{\overline{z}} W. \tag{22}$$

The Jacobi constant now is

$$J = \tfrac{1}{2}\dot{z}\dot{\overline{z}} + W. \tag{23}$$

III. POLYNOMIAL INVARIANTS

We are working with a Hamiltonian system with two degrees of freedom of which we already know an invariant, the Jacobi constant. In order to identify integrable systems in the usual Liouville–Arnold sense, we must find a second independent phase-space function conserved along the flow. The standard direct method to solve the problem consists in making a suitable ansatz about this function and trying to solve the system of differential equations ensuing by the conservation condition. For several reasons, the ansatz of a polynomial in the generalized momenta is the most common.[3] It is well suited from the mathematical point of view, since it allows one to get a system of PDEs in the coordinates only and is also well grounded on the basis of experience with already known integrable systems.

Since we are looking for a real function, we make the following assumption:

$$I^{(M)} = \sum_{k=0}^{M} (D_k(p+\Phi)^k + \overline{D}_k(\overline{p}+\overline{\Phi})^k). \tag{24}$$

Although it is common, in the vector potential case, to see the invariant written in terms of the velocities, this is the correct interpretation of $I^{(M)}$ as a phase-space function of the canonical variables. In order to satisfy the conservation of function (24), we impose that its Poisson bracket with the Hamiltonian vanishes,

$$\{I^{(M)}, \mathcal{H}\} = 0, \tag{25}$$

and try to solve for the complex functions $D_k(z,\overline{z})$. In the presentation of the results, for easy comparisons with existing works, we will revert to the usual expressions in terms of the velocities, replacing the momenta in (24) according to (20). In this case, conservation of the invariant can be checked by means of the condition

$$\frac{\mathrm{d}I^{(M)}}{\mathrm{d}t} = 0, \tag{26}$$

along the solution of the equations of motion (22).

Following the approach already used in the scalar case,[4–6] we consistently apply the trick of the energy constraint even in the present case. Here, with energy, we mean the Jacobi constant (23). This method has the advantage of allowing the simultaneous treatment of "strong" invariants (the usual ones which are conserved for arbitrary values of the energy) and "weak" invariants (functions which are conserved only on some energy surfaces). In the papers cited above, we have moreover shown how the energy constraint simplifies the structure of the system of PDEs that must be solved. The essential remark is that, to identify the cases of strong integrability, it is sufficient that in the final results a subset can be isolated which is independent of the energy parameter, in the present situation the given value of the first invariant, let us say C. If we are interested in a "strongly integrable system," in the end we must get a solution independent of C. The procedure may appear more involute, but, at least in the scalar case, it reveals to be very effective.

Formally, the idea of operating with the energy constraint is very simple. It consists first in introducing the "null" Hamiltonian,

$$\mathcal{H}_0 = \mathcal{H} - C \equiv 0, \tag{27}$$

or, on the same footing, the "null" Jacobi invariant,

$$J_0 = J - C = \tfrac{1}{2}\dot{z}\dot{\overline{z}} - G \equiv 0, \tag{28}$$

where C as usual denotes the given fixed value of the Jacobi constant and

$$G = C - W \tag{29}$$

is the so-called "Jacobi potential." Second, using in a consistent way the constraint

$$2(p + \Phi)(\overline{p} + \overline{\Phi}) = G, \tag{30}$$

wherever it appears in the computations. This essentially occurs when, implementing the conservation condition (25), a polynomial relation in the generalized momenta appears and the constraint (30) is used to eliminate powers of the mixed variables $(p+\Phi)(\overline{p}+\overline{\Phi})$ in favor of powers of G. One minor shortcoming of this approach is that, in view of the explicit appearance of the function G, rather than simply the potential W, some of the coefficients of the invariant in general depend on the energy parameter too,

$$D_j = D_j(z, \overline{z}; C), \quad 0 \leqslant j \leqslant M - 2. \tag{31}$$

Therefore, to obtain the standard expression in terms of phase-space coordinates only, in the end we must remember to perform the substitution

$$C \to \mathcal{H}(p, \overline{p}, z, \overline{z}), \tag{32}$$

wherever the parameter C appears. In view of (31), we see that this replacement does not affect the degree of the polynomial in the momenta.

In practice, computing the Poisson bracket (25), using the constraint, collecting the coefficients of the various powers of $p+\Phi$ (they are accompanied by their complex conjugates) and imposing their vanishing, we get the system

$$\partial_{\overline{z}} D_{k-1} + ik\Omega D_k + \frac{1}{2G^k}\partial_z(G^{k+1} D_{k+1}) = 0, \quad k = 0, 1, \ldots, M, \tag{33}$$

where it is implicitly assumed that $D_j = 0$ for $j < 0$ and for $j > M$. The set of equation (33) must be supplemented by the closure equations

$$\partial_{\overline{z}} D_M = 0 \tag{34}$$

and

$$\Re\{\partial_z(G D_1)\} = 0, \tag{35}$$

where $\Re$ denotes the real part. For sake of space, we do not write the expressions of the standard direct approach in real coordinates and without the energy constraint. To compare with, we refer to Sec. IV of Hietarinta[3] and recall the work of Hall,[14] where the study of weak invariants was first addressed and of Sarlet *et al.*,[15] where some wrong deductions contained in Hall's work were corrected. A systematic analysis of the cases with $M = 1$ (linear invariant) and $M = 2$ (quadratic invariant) was started in Ref. 7 and recently taken up again in Ref. 8. A more general version of the problem concerned with quadratic invariants is mentioned in a different context in Ref. 16.

The first result one easily gets with this approach is that Eq. (34) is readily solved as

$$D_M = D_M(z), \tag{36}$$

that is, the leading order coefficient in the invariant is an *arbitrary analytical function*. This result, already known in the inertial case, still holds here. In Ref. 4 it was shown how, in the purely scalar case, the strong conservation condition restricts the form of this function. In what follows we will get analogous results when also a vector potential is present.

One fundamental difference with what happens in the scalar case, is that equations for coefficients with even and odd indexes do not decouple. This fact is due to the Hamiltonian not being reversible in the present instance. System (33) is therefore very awkward to solve in the general case. In the next two sections we present the solutions in the linear and quadratic cases at fixed and arbitrary values of the Jacobi constant.

IV. LINEAR INVARIANTS

We start the investigation looking for systems admitting a second invariant which is a linear function in the momenta. The ansatz is

$$I^{(1)} = S(p + \Phi) + \overline{S}(\overline{p} + \overline{\Phi}) + K, \tag{37}$$

where for the three coefficients we have used a notation which conforms with that in previous works. The system of equations ensuing from the conservation condition is the following:

$$S_{\overline{z}} = 0, \tag{38}$$

$$K_{\overline{z}} + i\Omega S = 0, \tag{39}$$

$$\Re\{(GS)_z\} = 0. \tag{40}$$

In order to compactify formulas, from hereinafter with the subscript we denote the partial derivative with respect to the corresponding variable.

A. The general solution for linear invariants

Equation (38) agrees with (34), confirming that S can be an arbitrary analytic function,

$$S = S(z). \tag{41}$$

To complete the treatment, given an arbitrary $S(z)$, we must solve (39) and (40). This task is more efficiently achieved by performing a coordinate transformation that trivializes the differential equations. Let us consider a conformal transformation $z=F(w)$ to the new complex variable $w=X+iY$ given by

$$\frac{\mathrm{d}z}{\mathrm{d}w} = F'(w) \equiv S(z(w)). \tag{42}$$

The explicit form of the transformation is then

$$w = \int \frac{\mathrm{d}z}{S(z)} \tag{43}$$

and we have the relation between the differential operators

$$\frac{d}{\mathrm{d}w} = F'(w)\frac{d}{\mathrm{d}z} = S\frac{d}{\mathrm{d}z}. \tag{44}$$

Multiplying (40) by the real factor $S\overline{S}$, the content of the curly brackets can be modified in the following way:

$$S\overline{S}(SG)_z = S(S\overline{S}G)_z = (S\overline{S}G)_w. \tag{45}$$

Introducing the "conformal" potential

$$\tilde{G} = |F'|^2 G = |S|^2 G = S\bar{S}G, \tag{46}$$

Eq. (40) reduces to

$$\Re\{\tilde{G}_w\} = 0, \tag{47}$$

which is readily solved in

$$\tilde{G} = g(Y), \tag{48}$$

where g is an arbitrary real function and, according to the definition of the coordinate transformation, Y is the imaginary part of w.

In the new variables w, Eq. (39), together with its complex conjugate, can be rewritten as

$$K_w = i\tilde{\Omega}, \tag{49}$$

$$K_{\bar{w}} = -i\tilde{\Omega}, \tag{50}$$

where the conformal field

$$\tilde{\Omega} = |S|^2 \Omega \tag{51}$$

has been introduced. The integrability condition for the real function K is

$$\Re\{K_w\} = 0, \tag{52}$$

with solution

$$K = k(Y), \tag{53}$$

where k is another arbitrary real function. The conformal vector potential is then given by

$$\tilde{\Omega} = -\frac{k'(Y)}{2}. \tag{54}$$

An inversion of the coordinate transformation allows one to express the solution in the original variables. The second invariant can be expressed as

$$I^{(1)} = \Re\{S\}\dot{x} + \Im\{S\}\dot{y} + K. \tag{55}$$

B. Linear invariants at arbitrary energy

Equation (40), in view of (41) and recalling the definition of G in (29), can be rewritten as

$$\Re\{S'(C - W) - SW_z\} = 0. \tag{56}$$

If we are interested in strong integrability, namely in an invariant which is conserved for arbitrary values of the Jacobi constant, Eq. (56) must be independent of C. Therefore, it decouples in two independent equations: the first is

$$\Re\{S'(z)\} = 0. \tag{57}$$

The second turns out to be

$$\Re\{(SW)_z\} = 0. \tag{58}$$

Equation (57) means that at arbitrary energy, we are no longer free in the choice of the coordinate transformation: we must comply with this condition which actually imposes very strong limitations. It can be integrated to give

$$S(z) = ikz + \alpha, \tag{59}$$

where k is a real constant and α a complex constant. We can prove that it essentially allows only two kinds of new coordinates, (a) polar coordinates, (b) rotated Cartesian coordinates. To show this, we first observe that we can exploit translations and scaling of the complex plane to further reduce the freedom contained in (59). If k is not zero, a translation allows us to set $\alpha=0$. A scaling allows us then to set $k=1$. We have then the two possibilities,

$$\text{(a)} \quad S(z) = iz, \quad F(w) = e^{iw}, \quad x = e^{-Y}\cos X, \quad y = e^{-Y}\sin X, \tag{60}$$

$$\text{(b)} \quad S(z) = \alpha, \quad F(w) = \alpha w, \quad x = aX - bY, \quad y = bX + aY. \tag{61}$$

Case (a) can be recognized as the transformation to *polar* coordinates. In fact, with the usual notation, they are defined as

$$r = e^{-Y}, \quad \theta = X. \tag{62}$$

Solutions (48)–(54), in view of (28), are

$$W = W(r) = \frac{g(r)}{r^2}, \quad K = k(r), \quad \Omega = \frac{k'(r)}{2r}, \tag{63}$$

and the second invariant turns out to be

$$I^{(1)} = i(z\dot{z} - \overline{z\,\dot{z}}) + K = r^2\dot{\theta} + k(r). \tag{64}$$

The problem is rotationally symmetric and the corresponding invariant is a generalization of the angular momentum.

Case (b) can be recognized as the transformation to *rotated Cartesian* coordinates. Solutions (48)–(54), in view of (28), then give

$$W = W(ay - bx), \quad K = k(ay - bx), \quad \Omega = -\frac{k'(ay - bx)}{2}. \tag{65}$$

The second invariant now is

$$I^{(1)} = \dot{z} + \dot{\overline{z}} + K = a\dot{x} + b\dot{y} + k(ay - bx). \tag{66}$$

The problem is invariant under translation along the family of straight lines $ax+by=$const. These two solutions are already well known,[7] and the above procedure can be appreciated in its effectiveness.

C. Examples of weakly integrable systems with linear invariants

We may provide two interesting classes of weakly integrable systems admitting linear invariants.

The first is obtained by the simple observation that, if we choose the level surface $C=0$, it is no longer necessary that condition (57) be satisfied. *Any* analytic function $S=S(z)$ provides a solution through the corresponding conformal transformation. If Y, as above, denotes the new coordinate

$$Y = \Im\left\{\int \frac{dz}{S(z)}\right\}, \tag{67}$$

then the solution is given by

$$W = \frac{g(Y(x,y))}{|S|^2}, \quad K = k(Y(x,y)), \quad \Omega = -\frac{k'(Y(x,y))}{2|S|^2}, \tag{68}$$

with g and k arbitrary real functions.

The second class of weakly integrable systems is obtained with the following trick. Let us consider the analytic function $f(z)$ and consider then the conformal transformation (42) with $S(z)$ given by

$$S = \frac{1}{c + f'(z)}, \tag{69}$$

with c constant. Recalling definition (46), let us consider the "flat" conformal potential $\tilde{G}=1$. In this case, relation (46), using (69), gives

$$G = C - W = \frac{1}{|S|^2} = c^2 + c(f' + \overline{f'}) + |f'|^2. \tag{70}$$

We can therefore interpret c^2 as the fixed value of the Jacobi constant,

$$c^2 \equiv C, \tag{71}$$

and get as a consequence the family of potentials,

$$W(z,\overline{z};c) = -c(f'(z) + \overline{f'}(\overline{z})) - |f'(z)|^2. \tag{72}$$

We remark that the dynamics given by potentials (72) is defined for arbitrary values of C, but it happens to be integrable only on the surface singled out by condition (71).

To complete the solution, we must write explicitly the coordinate transformation generated by (69), that is

$$w = \int \frac{dz}{S(z)} = cz + f(z). \tag{73}$$

Again, an arbitrary function $k(Y)$, with

$$Y = \Im\{cz + f(z)\}, \tag{74}$$

will do the work. For further details on these systems we refer to Ref. 10.

V. QUADRATIC INVARIANTS

We now look for systems admitting a second invariant which is a quadratic function in the momenta. The ansatz is

$$I^{(2)} = S(p + \Phi)^2 + \overline{S}(\overline{p} + \overline{\Phi})^2 + R(p + \Phi) + \overline{R}(\overline{p} + \overline{\Phi}) + K, \tag{75}$$

where, besides S and the real function K, we now must determine the complex function R. The system of equations ensuing from the conservation condition is the following:

$$S_{\overline{z}} = 0, \tag{76}$$

$$R_{\overline{z}} + 2i\Omega S = 0, \tag{77}$$

$$K_{\bar{z}} + SG_z + \tfrac{1}{2}S'G + i\Omega R = 0, \tag{78}$$

$$\Re\{(RG)_z\} = 0, \tag{79}$$

where, in (78) we have already exploited (76), that, as usual, embodies the fact that S is an arbitrary analytic function.

A. Towards a general solution for quadratic invariants

System (76)–(79) is much more difficult to solve than the previous linear case. Indeed we lack a general solution. The main reason for this difficulty is that the coupling between G, R, and Ω produces an integrability condition for K, through Eq. (78) and its complex conjugate, that is a *nonlinear* PDE. However, we can implement the strategy to arrive as close as possible to a general solution and, what is of great importance, we can solve the problem in the strongly integrable case, developing an effective way to construct solutions.

This time we use a conformal transformation to the complex variable $w=X+iY$ given by

$$\frac{\mathrm{d}z}{\mathrm{d}w} = F'(w) \equiv \sqrt{S(z(w))}, \tag{80}$$

so that the explicit form of the transformation is

$$w = \int \frac{\mathrm{d}z}{\sqrt{S(z)}}. \tag{81}$$

Introducing the conformal potential

$$\widetilde{G} = |F'|^2 G = |S|G = \sqrt{S\bar{S}}G, \tag{82}$$

and the new complex function

$$\widetilde{R} = \frac{R}{\sqrt{\bar{S}}}, \tag{83}$$

Eq. (79) keeps its form in the transformed coordinates

$$\Re\{(\widetilde{R}\widetilde{G})_w\} = 0. \tag{84}$$

The solution of this equation is

$$\widetilde{R}\widetilde{G} = i\mathcal{K}_{\bar{w}}, \tag{85}$$

where $\mathcal{K}$ is an arbitrary real function.

Let us now multiply both sides of (77) by

$$\sqrt{\frac{\bar{S}}{S}}. \tag{86}$$

Using (83) and introducing the conformal field

$$\widetilde{\Omega} = |S|\Omega, \tag{87}$$

Eq. (77) transforms into

$$\widetilde{R}_{\bar{w}} + 2i\widetilde{\Omega} = 0. \tag{88}$$

Since the conformal field is real, the solution of (88) is

$$\tilde{R} = -4i\xi_w, \tag{89}$$

where ξ is another arbitrary real function. The factor -4 appears for later convenience. In this way, the conformal field is given by

$$\tilde{\Omega} = 2\xi_{w\bar{w}}. \tag{90}$$

At this point, to get the general solution of the unified treatment of weak and strong integrability, one should try to solve the integrability condition for Eq. (78) in the light of the results (85)–(89). Let us write the integrability condition for K which, computing $K_{z\bar{z}}=K_{\bar{z}z}$ from (78), is

$$\mathfrak{J}\{S''G + 3S'G_z + 2SG_{zz} + 2i(\Omega R)_z\} = 0. \tag{91}$$

In the transformed coordinates, this becomes

$$\mathfrak{J}\{\tilde{G}_{ww}\} + \mathfrak{R}\{(\tilde{R}\tilde{\Omega})_w\} = 0. \tag{92}$$

From (85) and (88) we have

$$\tilde{R}\tilde{\Omega} = \frac{i}{2}\tilde{R}\tilde{R}_{\bar{w}} = \frac{i}{4}(\tilde{R}^2)_{\bar{w}} = -\frac{i}{4}(\tilde{G}^{-2}\mathcal{K}_{\bar{w}}^{-2})_{\bar{w}} \tag{93}$$

so that (92) can be rewritten as

$$\mathfrak{J}\{\tilde{G}_{ww}\} = \tfrac{1}{4}\mathfrak{R}\{i(\tilde{G}^{-2}\mathcal{K}_{\bar{w}})_{\bar{w}w}\}. \tag{94}$$

We can try to solve this equation after specifying $\mathcal{K}$. Unfortunately, the equation is highly nonlinear except in the rather trivial case when $\mathcal{K}$ is constant, so it appears to be very difficult to solve it in the general case. We direct our attention attempting to solve the more limited but fundamental case of strong integrability.

B. Quadratic invariants at arbitrary energy

Starting again with (79), we see that, in view of definition (29), it can be rewritten as

$$\mathfrak{R}\{R_z(C - W) - RW_z\} = 0. \tag{95}$$

If R is independent of C, as is the case under study, in order to satisfy this equation at arbitrary values of the energy, it decouples in two independent equations, the first is

$$\mathfrak{R}\{R_z\} = 0, \tag{96}$$

the second is

$$\mathfrak{R}\{RW_z\} = 0. \tag{97}$$

Equation (96) is solved by introducing the arbitrary real function η so that

$$R = -4i\eta_{\bar{z}}. \tag{98}$$

This allows us to solve equation (97) for W in the form

$$W = W(\eta), \tag{99}$$

that is W is, at this stage, an arbitrary function of the argument.

Comparing (98) with (89) and taking into account definition (83), we get the relation

$$\sqrt{S\bar{S}}\xi_w = |S|\xi_w = \eta_{\bar{w}}. \tag{100}$$

Solving the integrability condition for η with a given form of S allows us to find ξ (and vice versa): Eq. (100) is deceivingly simple; we will see later that it is of some concern. Here we remark that the route followed to treat Eq. (79) reverted to the original physical coordinates z, $\bar{z}$, since they lead to the simple result in (98). However, Eq. (90) is valid in general, it is the simplest way in which we can solve for the vector potential and is expressed in the new coordinates w, $\bar{w}$. This result and the development below show how working in the new coordinates is advantageous in this context too.

In the meantime we must determine the forms of S imposed by strong integrability. Examining the integrability condition (91), the usual condition of independence of the results from C imposes the following constraints on the form of S:

$$\Im\{S''(z)\} = 0. \tag{101}$$

This result, which is valid in the scalar case also, is a natural extension of what was found in the linear case.

Coming back to Eq. (100), we note that, using real coordinates, we have

$$|S|\xi_X = \eta_X, \tag{102}$$

$$|S|\xi_Y = -\eta_Y. \tag{103}$$

It can be proven[17] that condition (101) is equivalent to

$$|S|_{XY} = 0, \tag{104}$$

so that we can also write

$$|S| = A(X) + B(Y), \tag{105}$$

with A and B determined by the specific form of S. Therefore, Eqs. (102) and (103) generate the following differential equations for the functions η and ξ:

$$A'\eta_Y + B'\eta_X - 2(A+B)\eta_{XY} = 0, \tag{106}$$

$$A'\xi_Y + B'\xi_X + 2(A+B)\xi_{XY} = 0. \tag{107}$$

In view of (98), that can be rewritten as

$$|S|\tilde{R} = -4i\eta_{\bar{w}} \tag{108}$$

and of (87), integrability condition (92) can be written in the form

$$\Im\{\tilde{G}_{ww}\} + |S|\Re\{\tilde{R}\Omega_w\} = 0, \tag{109}$$

or, in real coordinates,

$$\tilde{G}_{XY} + 2(\eta_X\Omega_Y - \eta_Y\Omega_X) = 0. \tag{110}$$

If we want to exploit the result established by (99), we must resume the physical potential W through

$$\tilde{G} = |S|(C - W). \tag{111}$$

Using (105) we have

$$\tilde{G}_{XY} = -A'W_Y - B'W_X - (A+B)W_{XY} \tag{112}$$

and so (110) is

$$(A+B)W_{XY} + A'W_Y + B'W_X = 2(\eta_X\Omega_Y - \eta_Y\Omega_X). \tag{113}$$

But (99) tells us that

$$W_X = \eta_X W'(\eta), \quad W_Y = \eta_Y W'(\eta), \quad W_{XY} = \eta_X\eta_Y W'' + \eta_{XY}W', \tag{114}$$

so that (113) becomes

$$W''(\eta) + 3\frac{\eta_{XY}}{\eta_X\eta_Y}W'(\eta) = \frac{2}{A+B}\left(\frac{\Omega_Y}{\eta_Y} - \frac{\Omega_X}{\eta_X}\right). \tag{115}$$

This is the best form we attain to express the integrability condition for the potential: we see that in general it implies that

$$\frac{\eta_{XY}}{\eta_X\eta_Y} = \Phi(\eta), \tag{116}$$

where Φ is arbitrary.

Therefore, the strategy to find strongly integrable systems with scalar and vector potentials supporting quadratic invariants is to choose a suitable S in the class determined by condition (101) (and therefore A and B) and solve (106) and (107) to find $\eta(X,Y)$ and $\xi(X,Y)$; to solve (90) to find

$$\tilde{\Omega} = \tfrac{1}{2}(\xi_{XX} + \xi_{YY}) \tag{117}$$

and use (87) to find

$$\Omega(X,Y) = \frac{\tilde{\Omega}}{A+B} \tag{118}$$

and, finally, try to solve (115) for

$$W = W(\eta(X,Y)) \tag{119}$$

taking into account (116).

C. General form of the quadratic invariant

In the next section we apply the strategy delineated above illustrating how already known and new integrable systems are determined. We end this section with a closer look at the structure of the quadratic invariant.

In the new variables, w, $\overline{w}$, together with the conformal transformation, it is natural to introduce the new time variable τ such that

$$\mathrm{d}\tau = \frac{\mathrm{d}t}{|F'|^2}. \tag{120}$$

We can use the apex to also denote the derivative with respect to τ without risk of confusion with other derivatives with respect to coordinates. Equations of motion (22) then assume the following form:

$$w'' + 2i\tilde{\Omega}w' = 2\tilde{G}_{\overline{w}}. \tag{121}$$

In view of the above positions, the quadratic invariant is most simply expressed as

$$I^{(2)} = \Re\{\tfrac{1}{2}(w')^2 + \widetilde{R}\overline{w'}\} + K, \tag{122}$$

or, in terms of real variables,

$$I^{(2)} = \tfrac{1}{2}[(X')^2 - (Y')^2] - 2(\xi_X Y' + \xi_Y X') + K. \tag{123}$$

We recall that the scalar K, to be found by integrating the transformed version of (78), namely

$$K_{\overline{w}} + \widetilde{G}_w + i\widetilde{\Omega}\widetilde{R} = 0, \tag{124}$$

is a function of the form

$$K = K(w, \overline{w}; C). \tag{125}$$

In the present case of strong integrability, in view of (105), it turns out that this function can be expressed as

$$K = k + C(B - A), \tag{126}$$

and k can be found by integrating the system

$$k_X - \widetilde{W}_X + 4\widetilde{\Omega}\xi_X = 0, \tag{127}$$

$$k_Y + \widetilde{W}_Y - 4\widetilde{\Omega}\xi_Y = 0, \tag{128}$$

where $\widetilde{W} = (A+B)W$. From (123), using (126) and

$$C = \frac{1}{2}\frac{(X')^2 + (Y')^2}{A + B} + W, \tag{129}$$

the general form of the invariant is then

$$I^{(2)} = \frac{1}{A + B}[B(X')^2 - A(Y')^2] - 2(\xi_X Y' + \xi_Y X') + (B - A)W + k. \tag{130}$$

Observing that the relations between velocities in the two gauges are given by

$$X' = \Re\{F'\}\dot{x} + \Im\{F'\}\dot{y}, \tag{131}$$

$$Y' = -\Im\{F'\}\dot{x} + \Re\{F'\}\dot{y}, \tag{132}$$

we can eventually transform the invariant in Cartesian coordinates. Transformation rules automatically account also for the change of the time variable according to (120).

VI. SOLUTIONS WITH QUADRATIC INVARIANTS

Let us recall the coordinate systems given by the condition for the existence of strong quadratic invariants. We observe that the function S we must use is obtained by integrating (101) so that

$$S(z) = cz^2 + \beta z + \alpha, \tag{133}$$

where c is a real constant and β, α complex constants. Exploiting the freedom of making translations, rotations and scaling in the complex plane, we have the following four inequivalent cases (for further details we refer to Refs. 4 and 18):

$$\text{(a)} \quad S(z) = \alpha, \quad F(w) = \alpha w, \quad x = aX - bY, \quad y = bX + aY, \tag{134}$$

$$\text{(b)} \quad S(z) = z^2, \quad F(w) = e^w, \quad x = e^X \cos Y, \quad y = e^X \sin Y, \tag{135}$$

$$\text{(c)} \quad S(z) = 4z, \quad F(w) = w^2, \quad x = X^2 - Y^2, \quad y = 2XY, \tag{136}$$

$$\text{(d)} \quad S(z) = z^2 + \Delta^2, \quad F(w) = \Delta \sinh w, \tag{137}$$

$$x = \Delta \sinh X \cos Y, \quad y = \Delta \cosh X \sin Y. \tag{138}$$

Case (a) gives the rotated Cartesian coordinates (standard Cartesian coordinates if $\alpha=1$). Case (b) gives again the polar coordinates. Case (c) gives the parabolic coordinates which are also referred to as *Levi–Cività* coordinates (the factor 4 in the definition of S appears just for this reason). Finally, case (d) produces the elliptical coordinates. For the sake of completeness, we list, for each of the four cases, the conformal factor and functions A and B introduced in (105):

$$\text{(a)} \quad |S| = 1, \quad A = B = \tfrac{1}{2}, \tag{139}$$

$$\text{(b)} \quad |S| = e^{2X}, \quad A = e^{2X}, \quad B = 0, \tag{140}$$

$$\text{(c)} \quad |S| = 4(X^2 + Y^2), \quad A = 4X^2, \quad B = 4Y^2, \tag{141}$$

$$\text{(d)} \quad |S| = \Delta^2(\sinh^2 X + \cos^2 Y), \tag{142}$$

$$A = \Delta^2 \sinh^2 X, \quad B = \Delta^2 \cos^2 Y. \tag{143}$$

A. Cartesian coordinates

Let us start with the simplest case (a), the Cartesian one. As the structure of the solution will show in the end, there is no need to work with rotated coordinates, therefore we can set $\alpha=1$ and make the trivial identification $X=x$ and $Y=y$. Equations (102) and (103) are

$$\eta_x = \xi_x, \tag{144}$$

$$\eta_y = -\xi_y. \tag{145}$$

The solution is

$$\xi = f(x) + g(y), \tag{146}$$

$$\eta = f(x) - g(y), \tag{147}$$

with f and g arbitrary. From (117) and (118), the vector field is

$$\Omega = \tfrac{1}{2}(f'' + g'') \tag{148}$$

and the R function

$$R = -2(g' + if'). \tag{149}$$

Equation (113) is

$$W_{xy} - (g' f''' + f' g''') = 0. \tag{150}$$

From (99) we have that $W=W(f(x)-g(y))$, so that

$$W_{xy} = -f'g'W'' \tag{151}$$

and (150) becomes

$$W'' + \frac{f'''}{f'} + \frac{g'''}{g'} = 0. \tag{152}$$

A further differentiation by x and y gives

$$\frac{1}{f'}\frac{d}{dx}\frac{f'''}{f'} = -\frac{1}{g'}\frac{d}{dy}\frac{g'''}{g'} = 2a = -W''' \tag{153}$$

with a real constant. We then get two equations for f and g,

$$f'' = af^2 + bf + c, \tag{154}$$

$$g'' = -ag^2 + dg + e, \tag{155}$$

in agreement with the work of Dorizzi *et al.*,[7] that can be integrated for various choices of the constants a, b, c, d, e. The potentials in terms of f and g are

$$W = \frac{a}{3}(g-f)^3 - \frac{b+d}{2}(g-f)^2 + (c-e+m)(g-f), \tag{156}$$

$$2\Omega = a(f^2 - g^2) + bf + dg + c + e, \tag{157}$$

where m is another constant. Integrating Eqs. (127) and (128) gives then

$$K = afg(f+g) + (b-d)fg - a(f^3+g^3) - \tfrac{1}{2}(3b+d)f^2 + \tfrac{1}{2}(3d+b)g^2 - (3c+m+e)f + (c-m+3e)g. \tag{158}$$

The fundamental example of the harmonic oscillator is obtained with the choice

$$a = b = d = 0, \tag{159}$$

so that

$$f = \tfrac{1}{2}cx^2, \tag{160}$$

$$g = \tfrac{1}{2}ey^2, \tag{161}$$

and the potentials are

$$W = \tfrac{1}{2}(c-e+m)(ey^2 - cx^2), \tag{162}$$

$$2\Omega = c + e. \tag{163}$$

We remark that, in this case, the vector field is a *constant angular velocity* and that the isotropic oscillator only exists when the angular velocity vanishes. The second invariant in this case is

$$I^{(2)} = \tfrac{1}{2}(\dot{x}^2 - \dot{y}^2) - 2(cx\dot{y} + ey\dot{x}) + \tfrac{1}{2}[(c-m+3e)ey^2 - (3c+m+e)cx^2]. \tag{164}$$

B. Polar coordinates

In case (b), the polar coordinates, we recall that now

$$r = e^X, \quad \theta = Y \tag{165}$$

and remark the difference of this relation with respect to (62) obtained in the linear case. We have

$$|S| = A = e^{2X} = r^2, \quad B = 0. \tag{166}$$

Equation (106) becomes

$$2e^{2X}(\eta_{XY} - \eta_Y) = 0, \tag{167}$$

which is solved by

$$\eta = e^X g(Y) + f(X), \tag{168}$$

with f and g arbitrary. From (100) we then have

$$\xi = -e^X g + \int e^{-2X} f'(X) \mathrm{d}X. \tag{169}$$

From (117) and (118), the velocity field is

$$2\Omega = e^{-2X}\Delta\xi = e^{-4X}(f'' - 2f') - e^{-3X}(g'' + g). \tag{170}$$

Condition (116) says that

$$\eta_X = e^X g(Y) + f'(X) = \Phi(e^X g(Y) + f(X)). \tag{171}$$

There are two ways in which (171) can be accomplished: the first is $g = \text{const}$ and it is easy to see that in this way we are actually taken back to the spherically symmetric case to which actually a linear invariant is associated. We can take $\eta(X)$ and $W(X)$ arbitrarily whereas, to find the vector field, we observe that

$$\xi'(X) = e^{-2X}\eta'(X), \tag{172}$$

so that

$$2\Omega = e^{-2X}\xi'' = e^{-4X}(\eta'' - 2\eta') = e^{-2X}(e^{-2X}\eta')'. \tag{173}$$

To show that this solution is equivalent to that obtained in the linear case, we compute the scalar k by integrating (127) to get

$$k^{(2)}(X) = e^{2X}W - (e^{-2X}\eta')^2. \tag{174}$$

Observing that, in polar coordinates, relation (120) between old and new time is

$$\mathrm{d}\tau = \frac{\mathrm{d}t}{r^2} \tag{175}$$

and using

$$Y' = r^2\dot{\theta}, \tag{176}$$

expression (130) becomes

$$I^{(2)} = -r^4\dot{\theta}^2 - 2\eta'\dot{\theta} - \frac{(\eta')^2}{r^4}. \tag{177}$$

In the linear case, recalling solution (64), we obtain

$$I^{(1)} = r^2\dot{\theta} + k^{(1)}(r), \tag{178}$$

where, from (63),

$$k^{(1)}(r) = 2\int r\Omega\, \mathrm{d}r = 2\int e^{2X}\Omega\, \mathrm{d}X. \tag{179}$$

Using (173) this becomes

$$k^{(1)}(r) = e^{-2X}\eta' = r^{-2}\eta', \tag{180}$$

so that, comparing (177) with (178), we see that

$$I^{(2)} = -(I^{(1)})^2. \tag{181}$$

The second possibility of satisfying condition (171) is to have $f=\text{const}$ and the constant, without any loss of generality, can be set equal to zero. Therefore, we have

$$\eta = e^X g(Y) \tag{182}$$

and

$$\xi = -e^{-X}g. \tag{183}$$

To find the potential, we must solve (115) which, using (182) and (170), is

$$W''(\eta) + \frac{3}{\eta}W'(\eta) = -\frac{1}{e^{6X}gg'}(g'''g + 3g''g' + 4g'g). \tag{184}$$

The simplest way in which the right-hand side is also a function of η is given by the condition

$$g'''g + 3g''g' + 4g'g = \alpha\frac{g'}{g^5}, \tag{185}$$

with α constant, so that (184) becomes

$$W''(\eta) + \frac{3}{\eta}W'(\eta) + \frac{\alpha}{\eta^6} = 0 \tag{186}$$

with solution

$$W = \frac{\beta}{\eta^2} - \frac{\alpha}{8\eta^4}. \tag{187}$$

To find explicit solution we must determine the possible forms of g which can be obtained by integrating (185) twice,

$$(g')^2 + g^2 + \frac{\alpha}{4g^4} + \frac{\gamma}{g^2} = \delta, \tag{188}$$

with γ and δ constants. All this is in agreement with the results in McSween and Winternitz[8] to which we refer.

Since in the approach with the energy constraint, the coefficients appearing in the invariant must be supplemented by a further substitution in order to get the final physical expression, for the sake of completeness, we work out a specific example. To ease the comparison with the results in Ref. 8, we use explicitly polar coordinates as in (165). The simplest case in the solution above is given by the choice $\alpha=0$. Equation (188) has the solution

$$g(\theta) = \sqrt{a + b\cos 2\theta} \tag{189}$$

with the constants a and b given by

$$\gamma = a^2 - b^2, \quad \delta = 2a. \tag{190}$$

From (187) and (170), the potential and velocity field are given, respectively, by

$$W = \frac{\beta}{r^2(a + b\cos 2\theta)} \tag{191}$$

and

$$\Omega = \frac{b^2 - a^2}{2r^3(a + b\cos 2\theta)^{3/2}}. \tag{192}$$

To find the invariant, we can use (130). Equations (127) and (128) can easily be integrated to get

$$k = -r^2 W - r^{-2} g(g + g''). \tag{193}$$

so that expression (130) becomes

$$I^{(2)} = r^4\dot{\theta}^2 + 2(rg\dot{\theta} - \dot{r}g') + \frac{2\beta}{g^2} + \frac{g(g + g'')}{r^2}. \tag{194}$$

In the specific example of (189) we get

$$I^{(2)} = r^4\dot{\theta}^2 + \frac{2b\sin\theta}{\sqrt{a + b\cos 2\theta}}\dot{r} + 2\sqrt{a + b\cos 2\theta}\, r\dot{\theta} + \frac{1}{a + b\cos 2\theta}\left(\frac{a^2 - b^2}{r^2} + 2\beta\right). \tag{195}$$

We remark that the small discrepancy in (195) with respect to the analogous expression reported in Ref. 8 is due to a difference of a factor of 2 in the definition of Ω as can be seen from Eq. (192).

C. Parabolic coordinates

We use the Levi–Cività representation of the parabolic coordinates introduced in case (c) above and mostly used in celestial mechanical applications. As a first step, the general strategy we depicted at the end of Sec. V B prescribes to determine the functions η and ξ satisfying equations (106) and (107). According to (141), we have

$$A = 4X^2, \quad B = 4Y^2, \tag{196}$$

so that Eq. (106) becomes

$$X\eta_Y + Y\eta_X - (X^2 + Y^2)\eta_{XY} = 0. \tag{197}$$

A fairly general solution of this PDE can be represented in the following form:

$$\eta(X,Y) = \int F(a)\sqrt{(X^2 + a)(Y^2 - a)}\,\mathrm{d}a + \int G(a)\frac{(X^2 + Y^2)^2}{((X^2 + a)(Y^2 - a))^{3/2}}\mathrm{d}a, \tag{198}$$

where a is an arbitrary real parameter and F and G two arbitrary smooth functions.

The subsequent steps should consist in determining the functions ξ and Ω and finally to solve for the potential $W(\eta)$. However, we observe that it is not easy to satisfy the constraint (116) with a too general expression for η: therefore, we first find a suitable form of this function and then proceed as above. A simple but nontrivial possibility is that given by the position

$$F = c\,\delta(a-b), \quad G = 0 \tag{199}$$

in (198), where $\delta(a)$ is the Dirac function. This choice gives the simplest separable solution of the differential equation (197). Therefore, we have

$$\eta(X,Y) = c\sqrt{(X^2+b)(Y^2-b)}, \tag{200}$$

which is easily shown to satisfy condition (116) in the form

$$\frac{\eta_{XY}}{\eta_X \eta_Y} = \frac{1}{\eta}. \tag{201}$$

With solution (200), Eqs. (106) and (107) are readily solved for ξ,

$$\xi(X,Y) = \frac{c}{4}\arctan\sqrt{\frac{X^2+b}{Y^2-b}}, \tag{202}$$

so that, from (117), the conformal vector field is

$$\tilde{\Omega} = \frac{bc}{8}\frac{X^2+Y^2}{((X^2+b)(Y^2-b))^{3/2}}. \tag{203}$$

From this, Eq. (118) gives

$$\Omega = \frac{\tilde{\Omega}}{4(X^2+Y^2)} = \frac{c^4 b}{32}\frac{1}{\eta^3}. \tag{204}$$

This result suggests to set

$$c = 2 \tag{205}$$

in order to simplify formulas and we have the physical vector field from

$$2\Omega = \frac{b}{\eta^3}, \quad \eta(X,Y) = 2\sqrt{(X^2+b)(Y^2-b)}. \tag{206}$$

An important consequence of this result is that, together with W, Ω too depends on the coordinates only through η. This implies that the right-hand side of Eq. (115) for W vanishes, so that, taking into account (201), we get simply

$$W''(\eta) + \frac{3}{\eta}W'(\eta) = 0. \tag{207}$$

The solution for the scalar potential is then

$$W = \frac{\beta}{\eta^2} \tag{208}$$

and we are actually led to a situation analogous to that encountered above in the example examined in polar coordinates. It is interesting to remark that potential (208) is separable if considered in the purely scalar situation, since, using (200), we get

$$W = \frac{\beta}{4(X^2+Y^2)}\left(\frac{1}{X^2+b} + \frac{1}{Y^2-b}\right). \tag{209}$$

Reverting to Cartesian coordinates through

$$X = \sqrt{\frac{r+x}{2}}, \quad Y = \sqrt{\frac{r-x}{2}}, \tag{210}$$

the scalar and vector potentials are, respectively, given by

$$W = \frac{\beta}{y^2 - 4b(x+b)} \tag{211}$$

and

$$\Omega = \frac{b}{2(y^2 - 4b(x+b))^{3/2}}. \tag{212}$$

The second invariant using parabolic coordinates is

$$I^{(2)} = \frac{1}{X^2+Y^2}[Y^2(X')^2 - X^2(Y')^2] + \frac{Y(X^2+b)X' - X(Y^2-b)Y'}{(X^2+Y^2)\sqrt{(X^2+b)(Y^2-b)}} + \frac{b + 8\beta(Y^2 - X^2 - b)}{4(X^2+b)(Y^2-b)}, \tag{213}$$

where the τ time variable is used and, therefore, it is conserved along the solution of the transformed equations of motion of the form (121). Using relations (131) and (132) between velocities in the two gauges,

$$X' = \sqrt{2(r+x)}\dot{x} + \sqrt{2(r-x)}\dot{y}, \tag{214}$$

$$Y' = \sqrt{2(r+x)}\dot{y} - \sqrt{2(r-x)}\dot{x}, \tag{215}$$

we can transform the invariant into Cartesian coordinates,

$$I^{(2)} = (y\dot{x} - x\dot{y})\dot{y} + \frac{y\dot{x} + 2b\dot{y}}{2\sqrt{y^2 - 4b(x+b)}} + \frac{b - 8\beta(x+b)}{4(y^2 - 4b(x+b))}. \tag{216}$$

D. Elliptical coordinates

It turns out that even in elliptical coordinates it is possible to find nontrivial solutions with a structure closely related to that seen in the examples detailed above in polar and parabolic coordinates. In addition, in elliptical coordinates, a solution with a constant vector field also exists (constant angular velocity), whereas this possibility appears to be absent in parabolic coordinates.

A common feature of all these cases is that both the scalar and vector potentials, W and Ω, can be expressed only in terms of η. This implies that the right-hand side of Eq. (115) for W vanishes, so that, taking into account (116), this common feature is embodied in the equation

$$W''(\eta) + \Phi(\eta)W'(\eta) = 0, \tag{217}$$

with suitable Φ. Analogously to what is seen in the polar cases, other solutions may very well exist but they are not so easy to find.

According to (143), we now have

$$A = \Delta^2 \sinh^2 X, \quad B = \Delta^2 \cos^2 Y. \tag{218}$$

In this case Eq. (106) becomes

$$\sinh X \cosh X \eta_Y - \sin Y \cos Y \eta_X - (\sinh^2 X + \cos^2 Y)\eta_{XY} = 0. \tag{219}$$

A simple solution of this PDE is the following:

$$\eta(X,Y) = a\Delta^2(\sinh^2 X - \cos^2 Y) + b\Delta^4(\sinh^2 X + \cos^2 Y)^2, \tag{220}$$

with a and b constants. Using this solution, Eqs. (106) and (107) give for ξ,

$$\xi(X,Y) = a\,\ln[\Delta^2(\sinh^2 X + \cos^2 Y)] + \tfrac{1}{2}b\Delta^2(\cosh 2X - \cos 2Y). \tag{221}$$

Computing the conformal vector potential from (117), we see that the first solution is trivial since its Laplacian vanishes giving a null vector field. We remark that the analogous phenomenon also occurs in the parabolic coordinates case, where it is possible to find several additional solutions of Eq. (197) generating a vanishing vector field.

The second solution appearing in (221) instead gives

$$\tilde{\Omega} = b\Delta^2(\cosh 2X + \cos 2Y) = 2b\Delta^2(\sinh^2 X + \cos^2 Y). \tag{222}$$

We get that the conformal field is proportional to the conformal factor $|S|$ so that, from (118), we have that the vector field is constant

$$\Omega = 2b \equiv \Omega_0. \tag{223}$$

Condition (116) for the nontrivial solution (220) with $a=0$ is

$$\frac{\eta_{XY}}{\eta_X \eta_Y} = \frac{1}{2\eta}, \tag{224}$$

so that Eq. (115) for W is

$$W''(\eta) + \frac{3}{2\eta}W'(\eta) = 0, \tag{225}$$

whose solution is

$$W = \frac{\alpha}{\sqrt{\eta}}, \tag{226}$$

or, using again (220),

$$W(X,Y) = \frac{\beta}{|S|} = \frac{\beta}{\Delta^2(\sinh^2 X + \cos^2 Y)}, \tag{227}$$

where α and β are arbitrary constants. This solution is the simplest separable scalar potential in elliptical coordinates, which is therefore shown to be integrable also in a uniformly rotating system: this result is already known for its application in the modeling of rotating galaxies.[19] The second invariant (130) using elliptical coordinates is

$$I^{(2)} = \frac{1}{\sinh^2 X + \cos^2 Y}[\cos^2 Y(X')^2 - \sinh^2(Y')^2] + \frac{1}{2}\Omega_0(\sin 2YX' - \sinh 2XY') - \beta\frac{\sinh^2 X - \cos^2 Y}{\sinh^2 X + \cos^2 Y} - \Omega_0^2(\sinh^2 X + \cos^2 Y)^2. \tag{228}$$

Reverting to Cartesian coordinates through

$$2\Delta^2 \sinh^2 X = r^2 - \Delta^2 + \sqrt{(r^2+\Delta^2)^2 - 4\Delta^2 y^2}, \tag{229}$$

$$2\Delta^2 \sin^2 Y = r^2 + \Delta^2 - \sqrt{(r^2+\Delta^2)^2 - 4\Delta^2 y^2}, \tag{230}$$

the scalar potential becomes

$$W(x,y) = \frac{\beta}{\sqrt{r^4 + 2\Delta^2(x^2 - y^2) + \Delta^4}} \tag{231}$$

and, using relations (131) and (132) between velocities in the two gauges, we can transform the invariant into Cartesian coordinates,

$$\begin{aligned} I^{(2)} = (y\dot{x} - x\dot{y})^2 - \Delta^2\dot{x}^2 + (\Delta^2 - r^2)(2\Omega_0 y\dot{x} - W(x,y)) \\ + 2\Omega_0(\Delta^2 + r^2)x\dot{y} + \Omega_0^2(r^4 + 2\Delta^2(x^2 - y^2) + \Delta^4). \end{aligned} \tag{232}$$

We pass now to investigate a more complex class of systems. A general solution of Eq. (219) is

$$\begin{aligned} \eta(X,Y) = \int F(a)\sqrt{(\Delta^2 \sinh^2 X + a)(a - \Delta^2 \cos^2 Y)}\mathrm{d}a \\ + \int G(a)\frac{(\Delta^2 \sinh^2 X + \Delta^2 \cos^2 Y)^2}{((\Delta^2 \sinh^2 X + a)(a - \Delta^2 \cos^2 Y))^{3/2}}\mathrm{d}a, \end{aligned} \tag{233}$$

where a is an arbitrary real parameter and F and G are two arbitrary smooth functions. Comparing this solution with that of (198) we can guess analogous developments. Therefore we try with the simple solution

$$F = \delta(a - b), \quad G = 0, \tag{234}$$

which corresponds to the simplest separable solution of the differential equation (219). Therefore, we have

$$\eta(X,Y) = \sqrt{(\Delta^2 \sinh^2 X + b)(b - \Delta^2 \cos^2 Y)}, \tag{235}$$

which satisfies condition (116) in the same form as in (201). With solution (235), Eqs. (106) and (107) give the following expression for ξ:

$$\xi(X,Y) = -\operatorname{arctanh}\sqrt{\frac{b + \Delta^2 \sinh^2 X}{b - \Delta^2 \cos^2 Y}}, \tag{236}$$

so that, from (117), the conformal vector field is

$$\tilde{\Omega} = \frac{b\Delta^2(b - \Delta^2)(\sinh^2 X + \cos^2 Y)}{((\Delta^2 \sinh^2 X + b)(b - \Delta^2 \cos^2 Y))^{3/2}}. \tag{237}$$

From this, Eq. (118) gives

$$\Omega = \frac{\tilde{\Omega}}{\Delta^2(\sinh^2 X + \cos^2 Y)} = \frac{b(b - \Delta^2)}{2\eta^3}. \tag{238}$$

As remarked above, from this result it follows that the right-hand side of Eq. (115) for W vanishes, so that, taking into account (201), we get again (207) so that the solution for the scalar potential is

$$W = \frac{\beta}{\eta^2} = \frac{\beta}{(\Delta^2 \sinh^2 X + b)(b - \Delta^2 \cos^2 Y)}. \tag{239}$$

Even potential (239) is separable if considered in the purely scalar situation, since it can be written in the form

$$W = \frac{\beta}{\Delta^2(\sinh^2 X + \cos^2 Y)}\left(\frac{1}{b - \Delta^2 \cos^2 Y} - \frac{1}{\Delta^2 \sinh^2 X + b}\right). \tag{240}$$

Using the explicit coordinate transformation (229) and (230), the scalar and vector potentials are, respectively, given by

$$W = \frac{\beta}{by^2 + (b - \Delta^2)(x^2 + b)} \tag{241}$$

and

$$\Omega = \frac{b(b - \Delta^2)}{2(by^2 + (b - \Delta^2)(x^2 + b))^{3/2}}. \tag{242}$$

Finally, the second invariant using elliptical coordinates is

$$I^{(2)} = \frac{\cos^2 Y (X')^2 - \sinh^2 (Y')^2}{\sinh^2 X + \cos^2 Y} + \frac{1}{\sinh^2 X + \cos^2 Y}\left(\sin 2Y \sqrt{\frac{b + \Delta^2 \sinh^2 X}{b - \Delta^2 \cos^2 Y}} X' - \sinh 2X \sqrt{\frac{b - \Delta^2 \cos^2 Y}{b + \Delta^2 \sinh^2 X}} Y'\right) + \frac{b(\Delta^2 - b) + 2\beta(\Delta^2(\cos^2 Y - \sinh^2 X) - b)}{(\Delta^2 \sinh^2 X + b)(b - \Delta^2 \cos^2 Y)},$$

whereas using Cartesian coordinates is given by

$$I^{(2)} = (y\dot{x} - x\dot{y})^2 - \Delta^2 \dot{x}^2 + 2\frac{by\dot{x} + (\Delta^2 - b)x\dot{y}}{\sqrt{by^2 + (b - \Delta^2)(x^2 + b)}} + \frac{b(b - \Delta^2) + 2\beta(b - \Delta^2 + x^2 + y^2)}{by^2 + (b - \Delta^2)(x^2 + b)}. \tag{243}$$

VII. CONCLUDING REMARKS

We have investigated Hamiltonian systems with vector potentials admitting a second invariant which is linear or quadratic in the momenta. In our approach, weak and strong invariants are treated in a unified setting where the strong invariants emerge as special cases. As for scalar potentials, the integrable systems can be greatly simplified by introducing certain standardized coordinates, as given in (134)–(138). It is a striking result that these standardized coordinate systems for systems with strong invariants exactly coincide with the classical separable coordinates for scalar potentials.

This work is an extension and improvement of the approach to integrable vector potential Hamiltonians which was proposed in Ref. 10. However, there still remain issues which need clarification. In particular, it should be possible to obtain a better understanding of the integrability conditions, especially the role of the condition (116) for the structure of the strongly invariant case.

I. INTRODUCTION

There are some attempts to study a constrained system in the framework of first order Lagrangian.[1,2] The coordinates appearing in a first order Lagrangian are in fact the phase space coordinates. The Euler–Lagrange equations of motion of a first order Lagrangian in an ordinary (nonconstrained) system are the same as the canonical equations of motion. The kinetic term in a first order Lagrangian constitutes of a one-form whose exterior derivative appears in the equations of motion. The resulted two-form, called the symplectic tensor, is singular for a constrained system. If the system is not constrained, usually the inverse of the symplectic tensor exists and provides the fundamental Poisson brackets (we exclude degenerate systems discussed in Refs. 3 and 4 in which the symplectic tensor may have a lower rank in some regions of the phase space).

The properties of a constrained system can be determined by trying to overcome the singularity of the symplectic tensor. Faddeev and Jackiw[5] used the Darboux theorem to separate canonical and noncanonical coordinates. They solved the equations of motion for noncanonical coordinates either to decrease the degrees of singularity of the symplectic tensor or to find the next level constraints.

Then using a special system of coordinates, the authors of Ref. 6 showed that the Faddeev–Jackiw approach is essentially equivalent to the usual Dirac method.[7] In a parallel approach, known as symplectic analysis[8–11] one extends the phase space to include the Lagrange multipliers. In this approach the consistency of constraints at each level adds some additional elements to the symplectic tensor. In other words, the kinetic part of the (first order) Lagrangian is responsible to impose the consistency conditions.

The important point in most papers written in the Faddeev–Jackiw method or symplectic analysis is that they often show their results for the constraints in the first level and then *deduce* that the same thing would be repeated at any level. However, the whole procedure of studying the singularities of symplectic tensor, demonstrates some global aspects. For example, some questions that may arise are as follows:

What happens, after all, to the symplectic tensor? Is it ultimately singular? How many degrees of singularity may it have? What is the relation of ultimate singularities with the gauge symmetries of the system and so on? In Ref. 12 we showed that the symplectic analysis gives, at each step, the same results as the traditional Dirac method (in the framework of *the level by level approach*). The

[a]Electronic mail: shirzad@ipm.ir
[b]Electronic mail: mojiri@sepahan.iut.ac.ir

symplectic analysis may also be studied in the framework of *the chain by chain approach*[13] to obtain the Dirac constraints.

Meanwhile, some recent observation[14] shows that in some examples the result of symplectic analysis and the well-established method of Dirac are not the same. This creates serious doubt about the validity of the symplectic analysis. Therefore, it is worth studying the origin of the difference between this approach and that of Dirac.[7] This is the aim of this paper. In the next section we first review the basic concept of symplectic approach as given in Ref. 12. As we will show the symplectic analysis is equivalent to a special procedure in the Dirac approach in which one uses the extended Hamiltonian at each level of consistency. In Sec. III we will show that in the framework of the Dirac method one is not allowed to use an extended Hamiltonian when there exist second class constraints. The important point to be emphasized is that this result can be understood more clearly in the framework of the chain by chain method. In Sec. IV we show that for a one chain system with second class constraints the symplectic analysis as proposed in the literature fails. This result can be simply generalized to the general case of a multichain system. When recognizing the origin of the problem, we give our prescription to solve it in Sec. V. Finally in Sec. VI we give an example.

The last point to be noticed is that the problem would not show itself for systems with two levels of constraints. As we will show, this is the case for second class systems with at least four levels of constraints. That is the reason for the fact that the problem does not appear if one considers just first level constraints.

II. REVIEW OF SYMPLECTIC APPROACH

Consider a phase space with coordinates y^i $(i=1,\ldots,2K)$ specified by the first order Lagrangian,

$$L = a_i(y)\dot{y}^i - H(y), \tag{1}$$

where $H(y)$ is the canonical Hamiltonian of the system. The equations of motion read

$$f_{ij}\dot{y}^j = \partial_i H, \tag{2}$$

where $\partial_i \equiv \partial/\partial y^i$ and the presymplectic tensor f_{ij} is defined as

$$f_{ij} \equiv \partial_i a_j(y) - \partial_j a_i(y). \tag{3}$$

We denote it in matrix notation as f. This matrix is invertible for a regular system. Let f^{ij} be the components of the inverse, f^{-1}. From (2) we have

$$\dot{y}^i = \{y^i, H\}, \tag{4}$$

where the Poisson brackets $\{,\}$ are defined as

$$\{F(y), G(y)\} = f^{ij}\partial_i F \partial_j G. \tag{5}$$

If f is singular, then using the Darboux theorem, as shown in Ref. 5, one can choose the independent coordinates (y'^α, λ^l) such that

$$L = a'_\alpha \dot{y}'^\alpha - \lambda^l \Phi_l(y') - H(y'), \tag{6}$$

where $f'_{\alpha\beta} = \partial_\alpha a'_\beta - \partial_\beta a'_\alpha$ is invertible. This shows that one can consider a system with a singular tensor f_{ij}, as a regular one described by

$$L = a'_\alpha \dot{y}'^\alpha - H(y') \tag{7}$$

together with the primary constraints $\Phi_l(y')$. In other words, without losing the generality one can assume that one is at first given the first order Lagrangian (1) with a regular presymplectic

two-form (3), and then the set of primary constraints $\Phi_\mu^{(1)}$ $(\mu=1,\ldots,M)$ are applied to the system. In this way the system is described by the Lagrangian,

$$L = a_i\dot{y}^i - \lambda^\mu\Phi_\mu^{(1)} - H(y), \tag{8}$$

in the extended space (y^i,λ^μ). The equations of motion (2) should be replaced in matrix form by

$$\begin{pmatrix} f & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} \dot{y} \\ \dot{\lambda} \end{pmatrix} = \begin{pmatrix} \partial H \\ \Phi^{(1)} \end{pmatrix}, \tag{9}$$

which is equivalent to Eq. (2) together with the constraint equations $\Phi_\mu^{(1)}=0$ $(\mu=1,\ldots,M)$.

Now one should impose the consistency conditions $\dot{\Phi}_\mu^{(1)}=0$. To do this, one should extend the space to include new variables η^μ and add the term $\eta^\mu\dot{\Phi}_\mu^{(1)}$ (or equivalently $-\dot{\eta}^\mu\Phi_\mu^{(1)}$) to the Lagrangian (8). This leads in the extended space (y,λ,η) to the equations

$$\begin{pmatrix} f & 0 & A \\ 0 & 0 & 0 \\ -\tilde{A} & 0 & 0 \end{pmatrix}\begin{pmatrix} \dot{y} \\ \dot{\lambda} \\ \dot{\eta} \end{pmatrix} = \begin{pmatrix} \partial H \\ \Phi^{(1)} \\ 0 \end{pmatrix}, \tag{10}$$

where the elements of the rectangular matrix A are given by

$$A_{\mu i} = \partial_i\Phi_\mu^{(1)}. \tag{11}$$

However, nothing would be lost if one forgets about the variables λ^μ and reduces the system to the Lagrangian

$$L^{(1)} = a_i\dot{y}^i - \dot{\eta}^\mu\Phi_\mu^{(1)} - H(y). \tag{12}$$

This leads to the symplectic two-form,

$$F = \begin{pmatrix} f & A \\ -\tilde{A} & 0 \end{pmatrix}, \tag{13}$$

in the $(2K+M)$-dimensional space of variables $Y\equiv(y^i,\eta^\mu)$. It should be noted that the Lagrangian $L^{(1)}$ in Eq. (12) is the same as Eq. (8) in which λ^μ is replaced by $\dot{\eta}^\mu$. This means that the derivatives $\dot{\eta}^\mu$ have the same role as Lagrangian multipliers λ^μ corresponding to primary constraints in the total Hamiltonian

$$H_T = H + \lambda^\mu\Phi_\mu^{(1)}. \tag{14}$$

In other words, if some of $\dot{\eta}^\mu$'s are found by the dynamical equations of the system, then the corresponding Lagrange multipliers are obtained. In the Dirac approach[15] this would be the case if there exist some second class constraints.

The equations of motion due to the Lagrangian $L^{(1)}$ can be written in matrix notation as

$$F\dot{Y} = \partial H. \tag{15}$$

Using operations that keep the determinant invariant, it is easy to show that

$$\det F = \det\begin{pmatrix} f & A \\ 0 & \tilde{A}f^{-1}A \end{pmatrix} = (\det f)(\det\tilde{A}f^{-1}A). \tag{16}$$

Since $\det f\neq 0$, F would be singular if $C\equiv\tilde{A}f^{-1}A$ is singular. Using (5) and (11) we have

$$C_{\mu\nu} = \{\Phi^{(1)}_{\mu}, \Phi^{(1)}_{\nu}\}. \tag{17}$$

Suppose rank $(C) = M''$ where $M'' \leqslant M$. This means that F possesses $M' = M - M''$ null-eigenvectors. One can, in principle, divide $\Phi^{(1)}_{\mu}$'s in two sets $\Phi^{(1)}_{\mu'}$ and $\Phi^{(1)}_{\mu''}$ such that

$$\{\Phi^{(1)}_{\mu'}, \Phi^{(1)}_{\nu}\} \approx 0,$$

$$\{\Phi^{(1)}_{\mu''}, \Phi^{(1)}_{\nu''}\} \approx C_{\mu''\nu''}, \quad \det C_{\mu''\nu''} \neq 0, \tag{18}$$

where the weak equality symbol $\approx$ means equality on the surface of the constraints already known (here, the primary constraints). The matrix A can be decomposed to A' and A'' such that

$$A_{\mu' i} = \partial_i \Phi^{(1)}_{\mu'},$$

$$A_{\mu'' i} = \partial_i \Phi^{(1)}_{\mu''}. \tag{19}$$

Accordingly the symplectic tensor F can be written as

$$F = \begin{pmatrix} f & A'' & A' \\ -\tilde{A}'' & 0 & 0 \\ -\tilde{A}' & 0 & 0 \end{pmatrix}. \tag{20}$$

Consider the rectangular matrix

$$(\tilde{A}' f^{-1}, 0, 1), \tag{21}$$

which has M' rows and $2K+M$ columns. Using (18) one can show that its rows are left null-eigenvectors of F. Multiplying (21) with the equations of motion (15) gives the second level constraints as

$$\Phi^{(2)}_{\mu'} \approx \{\Phi^{(1)}_{\mu'}, H\} = 0. \tag{22}$$

On the other hand, F in (20) has an invertible sub-block

$$F_{\text{inv}} = \begin{pmatrix} f & A'' \\ -\tilde{A}'' & 0 \end{pmatrix} \tag{23}$$

with the inverse

$$F^{-1}_{\text{inv}} = \begin{pmatrix} f^{-1} - f^{-1}A''C''^{-1}\tilde{A}''f^{-1} & -f^{-1}A''C''^{-1} \\ C''^{-1}\tilde{A}''f^{-1} & C''^{-1} \end{pmatrix}. \tag{24}$$

This can solve the equations of motion (15) for variables $\dot{\eta}^{\mu''}$ to give

$$\dot{\eta}^{\mu''} = -C^{\mu''\nu''}\{\Phi^{(1)}_{\nu''}, H\}, \tag{25}$$

where $C^{\mu''\nu''}$ is the inverse of $C_{\mu''\nu''}$. Inserting this in the Lagrangian (12) gives

$$L^{(1)} = a_i(y)\dot{y}^i - \dot{\eta}^{\mu'}\Phi^{(1)}_{\mu'} - H^{(1)}(y), \tag{26}$$

where

$$H^{(1)} = H - \{H, \Phi^{(1)}_{\mu''}\}C^{\mu''\nu''}\Phi^{(1)}_{\nu''}. \tag{27}$$

In this way a number of Lagrange multipliers corresponding to the second class constraints are derived whose effect is only replacing the canonical Hamiltonian H with $H^{(1)}$. Now we can forget about them and suppose that we are given the primary constraints $\Phi_\mu^{(1)}$ and the second level constraints $\phi_\mu^{(2)}$. Next, we should consider the consistency of $\Phi_\mu^{(2)}$ and add the term $-\dot{\eta}_2^\mu \Phi_\mu^{(2)}$ to the Lagrangian $L^{(1)}$. Renaming the previous $\eta^{\mu'}$'s as η_1^μ, the new Lagrangian would be

$$L^{(2)} = a_i(y)\dot{y}^i - \dot{\eta}_1^\mu \Phi_\mu^{(1)} - \dot{\eta}_2^\mu \Phi_\mu^{(2)} - H^{(1)}(y) \tag{28}$$

this gives the symplectic two-form

$$F^{(2)} = \begin{pmatrix} f & A^{(1)} & A^{(2)} \\ -\tilde{A}^{(1)} & 0 & 0 \\ -\tilde{A}^{(2)} & 0 & 0 \end{pmatrix} \tag{29}$$

in the space (y, η_1, η_2). Assuming that the composed matrix $A \equiv (A^{(0)}, A^{(1)})$, $F^{(2)}$ has the same form as (13). One should again proceed in the same way to find the null-eigenvectors as well as the invertible sub-block of $F^{(2)}$. The process goes on in this and the subsequent steps as explained in more detail in Ref. 12.

The important point to be emphasized is that the Lagrangian,

$$L^{(n)} = a_i(y)\dot{y}^i - \sum_{k=1}^{n} \dot{\eta}_k^\mu \Phi_\mu^{(k)} - H^{(n)}(y), \tag{30}$$

at the nth level, say, is equivalent to a system with extended Hamiltonian,

$$H_E^{(n)} = H^{(n-1)} + \sum_{k=1}^{n} \lambda_k^\mu \Phi_\mu^{(k)}, \tag{31}$$

at that level. In other words, the symplectic analysis is equivalent to the Dirac approach in the context of the level by level method provided that at each level one adds the new constraints with the corresponding Lagrange multipliers to the Hamiltonian. In fact this slight difference with the standard Dirac method may lead to some difficulties as we will see in the following section.

III. THE PROBLEM WITH EXTENDED HAMILTONIAN

The extended Hamiltonian formalism is well known in the context of first class constraints.[15,16] In fact, it can be shown that the dynamical equation

$$\dot{g} = \{g, H_E\}, \tag{32}$$

leads to the correct equation of motion provided that g is a gauge invariant quantity. In Eq. (32) the extended Hamiltonian H_E is defined as

$$H_E = H + \lambda^m \Phi_m, \tag{33}$$

where Φ_m are only first class constraints (primary or secondary). For a first class system, the extended Hamiltonian can also be used step by step during the process of producing the constraints. In other words, when all of the constraints are first class, there is no difference whether one uses $\dot{\Phi} = \{\Phi, H_T\}$ or $\dot{\Phi} = \{\Phi, H_E\}$.

Now we show that the extended Hamiltonian formalism in the Dirac approach is not suitable when second class constraints are present. We show this point for a system with only one primary constraint, i.e., a one-chain system in the language of chain by chain method. We remember that for such a system level by level and chain by chain methods coincide.

Consider a system with the canonical Hamiltonian $H(y)$ and one primary constraint $\Phi^{(1)}$. The total Hamiltonian reads

$$H_T = H + \lambda\Phi^{(1)}. \tag{34}$$

Suppose the consistency of $\Phi^{(1)}$ leads to $\Phi^{(2)}=\{\Phi^{(1)},H\}$. Then $\Phi^{(3)}$ emerges as $\{\Phi^{(2)},H\}$, and so on. The iterative process that produces the constraints is described by

$$\Phi^{(n+1)} = \{\Phi^{(n)},H\}. \tag{35}$$

The above procedure progresses unless $\{\Phi^{(N)},H_T\}\approx 0$ or $\{\Phi^{(N)},\Phi^{(1)}\}\neq 0$ at the last step N. In the former case the constraints in the chain are first class, i.e., commute with each other;[13] while in the latter all the constraints are second class which means that the matrix

$$C^{nm} = \{\Phi^{(n)},\Phi^{(m)}\} \tag{36}$$

is invertible. In this case the Lagrange multiplier λ would finally be determined as

$$\lambda = \frac{\{\Phi^{(N)},H\}}{\{\Phi^{(N)},\Phi^{(1)}\}}. \tag{37}$$

Using the Jacobi identity, it is shown in Ref. 13 that the matrix C^{nm} in Eq. (36) has the following form:

$$C \approx \begin{pmatrix} 0 & 0 & \cdots & 0 & C^{1N} \\ 0 & 0 & \cdots & C^{2(N-1)} & C^{2N} \\ \vdots & \vdots & & \vdots & \cdots \\ 0 & C^{(N-1)2} & \cdots & C^{(N-1)(N-1)} & C^{(N-1)N} \\ C^{N1} & C^{N2} & \cdots & C^{N(N-1)} & C^{NN} \end{pmatrix}. \tag{38}$$

In other words,

$$\{\Phi^{(i)},\Phi^{(j)}\} \approx 0 \quad \text{if } i+j \leqslant N. \tag{39}$$

Moreover using the Jacobi identity one can show from (35) that

$$\{\Phi^{(1)},\Phi^{(N)}\} \approx -\{\Phi^{(2)},\Phi^{(N-1)}\} \approx \cdots \approx (-1)^{[(N/2)-1]}\{\Phi^{N/2},\Phi^{[(N/2)+1]}\} \neq 0. \tag{40}$$

Remember that N is the number of second class constraints and necessarily should be even.

Now suppose that in order to define the dynamics of the system at some level n, one wishes to use the extended Hamiltonian,

$$H_E^{(n)} = H + \sum_{k=1}^{n} \lambda_k \Phi^{(k)}. \tag{41}$$

If $n \leqslant N/2$ then from (38) the consistency of the constraint $\Phi^{(n)}$ gives

$$\dot{\Phi}^{(n)} = \{\Phi^{(n)},H_E^{(n+1)}\} \approx \{\Phi^{(n)},H\}, \tag{42}$$

which by (35), is the same as $\Phi^{(n+1)}$. However at level $(N/2)+1$ the consistency of $\Phi^{[(N/2)+1]}$, using $H_E^{[(N/2)+1]}$ gives

$$\dot{\Phi}^{[(N/2)+1]} = \{\Phi^{[(N/2)+1]},H\} + \lambda_{N/2}\{\Phi^{[(N/2)+1]},\Phi^{N/2}\}. \tag{43}$$

As is apparent from (40) the above equation solves the Lagrange multiplier $\lambda_{N/2}$. There is no justification to keep $\{\Phi^{[(N/2)+1]},H\}$ as the next constraint $\Phi^{[(N/2)+2]}$. In order to knit the second class chain up to the last element $\Phi^{(N)}$, one is just allowed to use the total Hamiltonian (34). In other words, the second half of the chain can be derived if only the primary constraint $\Phi^{(1)}$ is present in the corresponding Hamiltonian. As explained in the preceding section, using the standard symplectic analysis is equivalent to using the extended Hamiltonian formalism described above. So

one should expect some contradiction in symplectic analysis when second class constraints are present. In the next section we will show the essence of this contradiction for a one chain system and propose a method to resolve it.

IV. SECOND CLASS ONE CHAIN IN SYMPLECTIC ANALYSIS

According to the algorithm given in Sec. II, given the canonical Hamiltonian $H(y)$ and the primary constraint $\Phi_{\mu}^{(1)}$, at the first step of consistency one should consider the Lagrangian (see Ref. 14)

$$L^{(1)} = a_i \dot{y}^i - \dot{\eta}_1 \Phi^{(1)} - H(y). \tag{44}$$

The equations of motion can be written in matrix form as

$$\begin{pmatrix} f & A^{(1)} \\ -\tilde{A}^{(1)} & 0 \end{pmatrix} \begin{pmatrix} \dot{y} \\ \dot{\eta}_1 \end{pmatrix} = \begin{pmatrix} \partial H \\ 0 \end{pmatrix}. \tag{45}$$

It is easy to see that

$$u^1 \equiv (\tilde{A}^{(1)} f^{-1}, 1) \tag{46}$$

is the null-eigenvector of the matrix

$$F = \begin{pmatrix} f & A^{(1)} \\ -\tilde{A}^{(1)} & 0 \end{pmatrix}. \tag{47}$$

Implying u^1 on both sides of (45) and using (5) gives the new constraint

$$\Phi^{(2)} = \{\Phi^{(1)}, H\}. \tag{48}$$

Adding the term $-\dot{\eta}_2 \Phi^{(2)}$ to the Lagrangian (to perform consistency) gives

$$L^{(2)} = a_i \dot{y}^i - \dot{\eta}_1 \Phi^{(1)} - \dot{\eta}_2 \Phi^{(2)} - H(y). \tag{49}$$

The equations of motion are

$$\begin{pmatrix} f & A^{(1)} & A^{(2)} \\ -\tilde{A}^{(1)} & 0 & 0 \\ -\tilde{A}^{(2)} & 0 & 0 \end{pmatrix} \begin{pmatrix} \dot{y} \\ \dot{\eta}_1 \\ \dot{\eta}_2 \end{pmatrix} = \begin{pmatrix} \partial H \\ 0 \\ 0 \end{pmatrix}. \tag{50}$$

Assuming $\{\Phi^{(1)}, \Phi^{(2)}\} \approx 0$, one can find the new null-eigenvector,

$$u^2 \equiv (\tilde{A}^{(2)} f^{-1}, 0, 1). \tag{51}$$

Multiplying u^2 by (50) gives the new constraint $\Phi^{(3)} = \{\Phi^{(2)}, H\}$, and so on.

Suppose one wishes to proceed in this way to find the constraints of the chain discussed in the preceding section, i.e., the second class chain $\Phi^{(1)}, \ldots, \Phi^{(N)}$ with the algebra given in (38)–(40). Suppose the above procedure has been proceeded up to the step $(N/2)+1$ where the equations of motion are

$$\begin{pmatrix} f & A^{(1)} & \cdots & A^{[(N/2)+1]} \\ -\tilde{A}^{(1)} & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ -\tilde{A}^{[(N/2)+1]} & 0 & \cdots & 0 \end{pmatrix} \begin{pmatrix} \dot{y} \\ \dot{\eta}_1 \\ \vdots \\ \dot{\eta}_{(N/2)+1} \end{pmatrix} = \begin{pmatrix} \partial H \\ 0 \\ \vdots \\ 0 \end{pmatrix}. \tag{52}$$

Clearly no more null-eigenvector can be found. In fact adding the column and row corresponding to the constraint $\Phi^{[(N/2)+1]}$ has increased the rank of the matrix F by two. This means that the equations of motion can be solved to find $\dot{\eta}^{N/2}$ and $\dot{\eta}^{[(N/2)+1]}$. There is no way in the context of symplectic analysis to proceed further to find the remaining constraints $\Phi^{[(N/2)+1]},\ldots,\Phi^{(N)}$ of the chain. This is really the failure of traditional symplectic analysis. In fact this is the reason why the symplectic analysis has failed in the example given in Ref. 14 (particle in hypersphere). We will discuss this example in Sec. VI.

What we showed here is the failure of symplectic analysis for a second class system with only one primary constraint (i.e., a one chain system). However, one can easily observe that for an arbitrary system with several primary constraints again the symplectic analysis would fail. The reason is that for such a system some of the constraints driven at level n, i.e., $\Phi_{\mu}^{(n)}$, may have nonvanishing Poisson brackets with constraints of previous levels while commuting with primary constraints. As we know from the Dirac approach, in such a case the Poisson brackets of these constraints with Hamiltonian give the next level constraints. Meanwhile, a little care on symplectic analysis shows that in this case a number of Lagrange multipliers corresponding to nonprimary constraints would be determined and there is no way to find the next level constraints. In this way, we conclude that *the symplectic analysis would fail whenever second class constraints emerge at third level or higher*.

V. HOW TO SOLVE THE PROBLEM

In this section we try to find a way to maintain the symplectic analysis by imposing some modifications. The origin of the problem is the fact that $\Phi^{[(N/2)+1]}$ has nonvanishing Poisson brackets with $\Phi^{N/2}$. As a result, the symplectic two-form on the left-hand side of Eq. (52), i.e.,

$$F=\begin{pmatrix} f & A^{(1)} & \cdots & A^{[(N/2)+1]} \\ -\tilde{A}^{(1)} & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ -\tilde{A}^{[(N/2)+1]} & 0 & \cdots & 0 \end{pmatrix}, \tag{53}$$

does not possess a new null-eigenvector. If one could consider the vector

$$u^{[(N/2)+1]}\equiv(\tilde{A}^{[(N/2)+1]}f^{-1},0,\ldots,0,1) \tag{54}$$

as a null-eigenvector, then by multiplying $u^{[(N/2)+1]}$ on the right-hand side of (52), one would obtain the next constraint as

$$\Phi^{[(N/2)+2]}=\{\Phi^{[(N/2)+1]},H\}. \tag{55}$$

To reach this goal one should truncate those columns of F which are located after $A^{(1)}$. In other words, instead of F in Eq. (53) one should consider the rectangular matrix

$$\tilde{F}=\begin{pmatrix} f & A^{(1)} \\ -\tilde{A}^{(1)} & 0 \\ \vdots & \vdots \\ -\tilde{A}^{[(N/2)+1]} & 0 \end{pmatrix}. \tag{56}$$

Clearly $u^{[(N/2)+1]}$ in Eq. (54) is the null-eigenvector of $\tilde{F}$. It is obvious that if one does the same thing in the subsequent steps, one can produce all the remaining constraints of the chain, i.e., $\Phi^{[(N/2)+1]},\ldots,\Phi^{(N)}$. In the last step the chain terminates, since $\{\Phi^{(N)},\Phi^{(1)}\}\neq 0$.

But what is the justification to find the null-eigenvectors of $\tilde{F}$, i.e., the *truncated F*. In fact using Eq. (5) the set of equations

$$\begin{pmatrix} f & A^{(1)} \\ -\tilde{A}^{(1)} & 0 \\ \vdots & \vdots \\ -\tilde{A}^{(N)} & 0 \end{pmatrix} \begin{pmatrix} \dot{y} \\ \dot{\eta}_1 \end{pmatrix} = \begin{pmatrix} \partial H \\ 0 \\ \vdots \\ 0 \end{pmatrix} \tag{57}$$

is equivalent to

$$\dot{y}_i = \{y_i, H + \dot{\eta}_1 \Phi^{(1)}\}, \quad i = 1, \ldots, 2K,$$

$$\dot{\Phi}^{(j)} = 0, \quad j = 1, \ldots, N. \tag{58}$$

Remembering that $\dot{\eta}_1$ has the same role as the Lagrange multiplier λ_1 corresponding to the primary constraint $\Phi^{(1)}$, we see that Eq. (58) is the correct equation of motion

$$\dot{y}_i = \{y_i, H_T\}. \tag{59}$$

On the other hand, it is easy to see that the equations of motion resulting from Eq. (52) can be written as

$$\dot{y}_i = \{y_i, H_E\}, \tag{60}$$

where H_E contains all derived constraints (including second class ones). In fact as we explained before, the correct equations of motion are (58) and not (60).

Therefore, if one wishes to proceed in the context of symplectic analysis, one should consider Eq. (57) instead of Eq. (52).

VI. EXAMPLE

Consider the Lagrangian

$$L = \tfrac{1}{2}\dot{\mathbf{q}}^2 + v(\mathbf{q}^2 - 1), \tag{61}$$

where $\mathbf{q} \equiv (q_1, \ldots, q_n)$. The primary constraint is P_v. The corresponding Hamiltonian is

$$H = \tfrac{1}{2}\mathbf{p}^2 - v(\mathbf{q}^2 - 1), \tag{62}$$

where $\mathbf{p} \equiv (p_1, \ldots, p_n)$. In the usual Dirac approach, using the total Hamiltonian $H_T = H + \lambda P_v$, the consistency of $\Phi^{(1)} = P_v$ gives the following chain of constraints

$$\Phi^{(1)} = P_v,$$

$$\Phi^{(2)} = \mathbf{q}^2 - 1,$$

$$\Phi^{(3)} = 2\mathbf{q} \cdot \mathbf{p},$$

$$\Phi^{(4)} = 2(\mathbf{p}^2 + 2v\mathbf{q}^2). \tag{63}$$

As is apparent, $\Phi^{(4)}$ and $\Phi^{(3)}$ are conjugate to $\Phi^{(1)}$ and $\Phi^{(2)}$, respectively. It is worth remembering that although $\Phi^{(3)}$ is second class, when reaching at third level, the process of consistency should not stop, i.e., it should be proceeded one level more to find $\Phi^{(4)}$ which is conjugate to the primary constraint $\Phi^{(1)}$. In the symplectic approach the corresponding first order Lagrangian is

$$L = \mathbf{p}\dot{\mathbf{q}} + P_v\dot{v} - \tfrac{1}{2}\mathbf{p}^2 + v(\mathbf{q}^2 - 1) - \lambda P_v. \tag{64}$$

This gives the singular presymplectic tensor

$$F=\begin{pmatrix} f & 0 \\ 0 & 0 \end{pmatrix}, \tag{65}$$

where f is the usual $(2n+2)\times(2n+2)$ symplectic tensor,

$$f=\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \tag{66}$$

The equations of motion for $y^i=(\mathbf{q},v,\mathbf{p},P_v,\lambda)$ are $f_{ij}\dot{y}^j=\partial_i H_T$ where $H_T=H+\lambda P_v$. Clearly this gives the canonical equation of motion with Hamiltonian H_T, together with the constraint equation $P_v=0$. Adding the consistency term $-\dot{\eta}_1 P_v$ to the Lagrangian (64), where η_1 is a new variable and forgetting about the term proportional to λ (which just reproduces the primary constraint) one finds

$$L^{(1)}=\mathbf{p}\dot{\mathbf{q}}+P_v\dot{v}-\dot{\eta}_1 P_v-\tfrac{1}{2}\mathbf{p}^2+v(\mathbf{q}^2-1). \tag{67}$$

This gives the equations of motion

$$F^{(1)}_{ij}\dot{Y}^j=\partial_i H, \tag{68}$$

where $Y^i\equiv(\mathbf{q},v,\mathbf{p},P_v,\eta_1)$. In the matrix form we have

$$F^{(1)}=\begin{pmatrix} f & A^{(1)} \\ -\tilde{A}^{(1)} & 0 \end{pmatrix}, \tag{69}$$

where $\tilde{A}^{(1)}=(\mathbf{0},0,\mathbf{0},1)$. Here, bold zero ($\mathbf{0}$) means a row vector with n zero components. Clearly $u^{(1)}=(\mathbf{0},-1,\mathbf{0},0,1)$ is the left null-eigenvector of $F^{(1)}$. Multiplying the equations of motion (68) from the left by $u^{(1)}$ gives the constraint $\Phi^{(2)}=\mathbf{q}^2-1$.

In the next level we have the Lagrangian

$$L^{(2)}=L-\dot{\eta}_1 P_v-\dot{\eta}_2(\mathbf{q}^2-1) \tag{70}$$

written in the space $Y^i\equiv(\mathbf{q},v,\mathbf{p},P_v,\eta_1,\eta_2)$. The corresponding symplectic tensor reads

$$F^{(2)}=\begin{pmatrix} f & A^{(1)} & A^{(2)} \\ -\tilde{A}^{(1)} & 0 & 0 \\ -\tilde{A}^{(2)} & 0 & 0 \end{pmatrix}, \tag{71}$$

where $\tilde{A}^{(2)}=(2\mathbf{q},0,\mathbf{0},0)$. Clearly $u^{(2)}=(\mathbf{0},0,2\mathbf{q},0,0,1)$ is the null-eigenvector of F^2. Multiplying the equations of motion $F^{(2)}_{ij}\dot{Y}^j=\partial_i H_T$ from the left by $u^{(2)}$ gives the next level constraint $\Phi^{(3)}=2\mathbf{q}\cdot\mathbf{p}$. Again considering another variable η_3, the third level Lagrangian would be

$$L^{(3)}=L-\dot{\eta}_1 P_v-\dot{\eta}_2(\mathbf{q}^2-1)-\dot{\eta}_3(2\mathbf{q}\cdot\mathbf{p}). \tag{72}$$

This gives the following symplectic tensor:

$$F^{(3)}=\begin{pmatrix} f & A^{(1)} & A^{(2)} & A^{(3)} \\ -\tilde{A}^{(1)} & 0 & 0 & 0 \\ -\tilde{A}^{(2)} & 0 & 0 & 0 \\ -\tilde{A}^{(3)} & 0 & 0 & 0 \end{pmatrix}, \tag{73}$$

where $\tilde{A}^{(3)}=(2\mathbf{p},0,2\mathbf{q},0)$. Now the crucial point appears. That is, $F^{(3)}$ has no new null-eigenvector. In fact one expects that multiplying $u^{(3)}=(-2\mathbf{q},0,2\mathbf{p},0,0,0,1)$ by the equations of motion due to $L^{(3)}$ gives the next constraint $\Phi^{(4)}=2(\mathbf{p}^2+2v\mathbf{q}^2)$. However, it can be easily checked

that $u^{(3)}F^{(3)}\neq 0$. Moreover, $u^{(2)}$ (with one additional zero as the last element) is no more the null-eigenvector of $F^{(3)}$. This means that adding the $(2n+5)$th row and columns to $F^{(2)}$ has led to increasing the rank of $F^{(3)}$ by two. In other words, the equations of motion for $\dot{\eta}_2$ and $\dot{\eta}_3$ can be solved. Unfortunately without any modification there is no way to find the Lagrangian,

$$L^{(4)}=L-\dot{\eta}_1 P_v-\dot{\eta}_2(\mathbf{q}^2-1)-\dot{\eta}_3(2\mathbf{q}\cdot\mathbf{p})-\dot{\eta}_4(2(\mathbf{p}^2+2v\mathbf{q}^2)). \tag{74}$$

If we could find $L^{(4)}$, then we would be able to have

$$F^{(4)}=\begin{pmatrix} f & A^{(1)} & A^{(2)} & A^{(3)} & A^{(4)} \\ -\tilde{A}^{(1)} & 0 & 0 & 0 & 0 \\ -\tilde{A}^{(2)} & 0 & 0 & 0 & 0 \\ -\tilde{A}^{(3)} & 0 & 0 & 0 & 0 \\ -\tilde{A}^{(4)} & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{75}$$

where $\tilde{A}^{(4)}=(8v\mathbf{q},4\mathbf{q}^2,4\mathbf{p},0)$. If we had somehow derived (74) and (75), then the singularity of symplectic tensor would completely disappear and $\dot{\eta}_1,\ldots,\dot{\eta}_4$ would be obtained. However, using the *truncated symplectic tensor* at the second step as

$$\tilde{F}^{(2)}=\begin{pmatrix} f & A^{(1)} \\ -\tilde{A}^{(1)} & 0 \\ -\tilde{A}^{(2)} & 0 \end{pmatrix} \tag{76}$$

and similarly $\tilde{F}^{(3)}$ at the third level as

$$\tilde{F}^{(3)}=\begin{pmatrix} f & A^{(1)} \\ -\tilde{A}^{(1)} & 0 \\ -\tilde{A}^{(2)} & 0 \\ -\tilde{A}^{(3)} & 0 \end{pmatrix} \tag{77}$$

makes it possible to introduce again $u^{(2)}$ and $u^{(3)}$ as the corresponding left null-eigenvectors of $\tilde{F}^{(2)}$ and $\tilde{F}^{(3)}$, respectively. This makes us able to find $\Phi^{(4)}$ as explained before. It should be noted that one can after all write the complete symplectic tensor $F^{(4)}$.

This example has also been discussed in Ref. 14, where some other reason is proposed as the origin of failure of the symplectic analysis. The same results as what we derived here can be found in every second class system possessing at least four levels of constraints. For example, one can study the simpler Lagrangian $L=\dot{x}\dot{y}-z(x+y)$ as well as the more complicated example of the bosonized Schwinger model in $(1+1)$ dimensions[17,18] given by

$$\mathcal{L}=\tfrac{1}{2}\partial_\mu\phi\partial^\mu\phi+(g^{\mu\nu}-\varepsilon^{\mu\nu})\partial_\mu\phi A_\nu-\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}+\tfrac{1}{2}A_\mu A^\mu. \tag{78}$$

One can see that the main feature of the above calculations will more or less appear in all such examples.

(Received 7 October 2004; accepted 19 October 2004; published online 5 January 2005)

We construct static and time dependent exact soliton solutions for a theory of scalar fields taking values on a wide class of two dimensional target spaces, and defined on the four dimensional space–time $S^3 \times \mathbb{R}$. The construction is based on an ansatz built out of special coordinates on S^3. The requirement for finite energy introduce boundary conditions that determine an infinite discrete spectrum of frequencies for the oscillating solutions. For the case where the target space is the sphere S^2, we obtain static soliton solutions with nontrivial Hopf topological charges. In addition, such Hopfions can oscillate in time, preserving their topological Hopf charge, with any of the frequencies belonging to that infinite discrete spectrum. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1829911]

I. INTRODUCTION

In this paper we consider a nonlinear theory of a complex scalar field u, on the space–time $S^3 \times \mathbb{R}$. Our considerations apply to a wide class of target spaces, but the case of most interest is that of the sphere S^2, in which case the field u parametrizes a plane corresponding to the stereographic projection of S^2. The action is the integral of the square of the pull-back of the area form on the target space. Therefore, it is quartic in derivatives, but only quadratic in time derivatives. The theory is integrable in the sense that it possesses a generalized zero curvature representation of its equations of motion and an infinite number of local conservation laws.[1,2] The conserved currents are associated to the invariance of the theory under the area preserving diffeomorphisms on the target space.

We construct an infinite number of static and time dependent exact soliton solutions using an ansatz[2,3] that reduces the four dimensional nonlinear equations of motion into linear ordinary differential equations for the profile function. In the case of the target space S^2 the solitons carry nontrivial Hopf topological charges. Although the topology is the same as that of other models possessing Hopfion solutions,[3–5] the Derrick's scaling argument is circumvented in a different manner. The stability of the static three dimensional solutions comes from the fact that the physical space is S^3 and that introduces a length scale given by its radius. A model in Euclidean space where a similar stability mechanism occurs is discussed in Ref. 6.

The requirement for finite energy leads to boundary conditions that determine an infinite discrete set of allowed frequencies for the oscillations of the solutions. Those solutions can be linearly superposed since the profile function satisfies a linear equation. It turns out that the energy of the superposed solution is the sum of the energies of the modes, and in this sense the modes are decoupled. However, the profile function can take values only on some intervals on the real line, which depend on the choice of the target space. Therefore, not all superpositions are allowed and that introduces some sort of coupling among the modes. The allowed superpositions for the case of the target space S^2 are discussed in detail. One of the most interesting superpositions corre-

sponds to oscillating Hopfion solutions. We show that it is possible to superpose to the static Hopfion soliton any number of oscillating modes with any of the frequencies belonging to that infinite discrete spectrum. Although the solution oscillates in time, its topological Hopf charge is preserved. The only constraint on such superposition appears on the intensity of each mode.

The paper is organized as follows: in Sec. II we introduce the model and discuss its integrability properties, in Sec. III we propose the ansatz and construct the exact soliton solutions, in Sec. IV we discuss the energy, boundary conditions and allowed frequencies. The case of the target space S^2 is discussed in Sec. V.

II. THE MODEL

The metric on the space–time $S^3\times\mathbb{R}$ is given by

$$\mathrm{d}s^2 = \mathrm{d}t^2 - r_0^2\left(\frac{\mathrm{d}z^2}{4z(1-z)} + (1-z)\mathrm{d}{\varphi_1}^2 + z\,\mathrm{d}{\varphi_2}^2\right), \tag{1}$$

where t is the time, z, and φ_i, $i=1$, 2, are coordinates on the sphere S^3, and $0\leqslant z\leqslant 1$, $0\leqslant\varphi_i\leqslant 2\pi$, and r_0 is the radius of the sphere S^3. Embedding S^3 on $\mathbb{R}^4$ we get that the Cartesian coordinates of the points of S^3 are

$$x_1 = r_0\sqrt{z}\cos\varphi_2, \quad x_3 = r_0\sqrt{1-z}\cos\varphi_1,$$

$$x_2 = r_0\sqrt{z}\sin\varphi_2, \quad x_4 = r_0\sqrt{1-z}\sin\varphi_1. \tag{2}$$

The model is defined by the action

$$S = \int \mathrm{d}t\int_{S^3}\mathrm{d}\Sigma\,\frac{h_{\mu\nu}^2}{\gamma^2}, \tag{3}$$

where the volume element on S^3 is $\mathrm{d}\Sigma=(r_0^3/2)\mathrm{d}z\,\mathrm{d}\varphi_1\,\mathrm{d}\varphi_2$, and

$$h_{\mu\nu}\equiv\partial_\mu u\partial_\nu u^* - \partial_\nu u\partial_\mu u^*, \tag{4}$$

where ∂_μ denotes partial derivatives with respect to the four coordinates on $S^3\times\mathbb{R}$, namely $\zeta^\mu\equiv(t,z,\varphi_1,\varphi_2)$, u is a complex scalar field, and $\gamma\equiv\gamma(|u|^2)$, is a real functional of the squared modulus of u, and it defines the geometry of the target space. The metric on target space is given by

$$\mathrm{d}\sigma^2 = \frac{\mathrm{d}u\,\mathrm{d}u^*}{\gamma}. \tag{5}$$

Some cases of interest are the following: (a) $\gamma=1$ corresponding to the plane with coordinates being the real and imaginary parts of u, (b) $\gamma=(1-|u|^2)^2$, with $|u|^2<1$, corresponding to the Poincaré hyperbolic disc, and (c) $\gamma=(1+|u|^2)^2$ corresponding to the sphere S^2. In such case, u is related to the three dimensional unit vector $\vec{n}$ ($\vec{n}^2=1$) defining the sphere, through the stereographic projection

$$\vec{n} = \frac{1}{1+|u|^2}(u+u^*,-i(u-u^*),|u|^2-1). \tag{6}$$

Notice that in the case of the target space being S^2, the action (3) corresponds to the quartic term of the Skyrme–Faddeev action[4] which has been studied on the space–time $S^3\times\mathbb{R}$ in Ref. 7.

The Euler–Lagrange equations following from (3) are given by

$$\partial^\mu\left(\frac{K_\mu}{\gamma}\right)=0 \tag{7}$$

together with its complex conjugate, and where

$$K_\mu = h_{\mu\nu}\partial^\nu u = (\partial u\partial u^*)\partial_\mu u - (\partial u)^2\partial_\mu u^*. \tag{8}$$

The model (3) possesses an infinite number of local conserved currents given by

$$J_\mu = \frac{K_\mu}{\gamma}\frac{\delta G}{\delta u} - \frac{K_\mu^*}{\gamma}\frac{\delta G}{\delta u^*}, \tag{9}$$

where G is a function of u and u^* but not of its derivatives. Using the equations of motion (7) and the identities

$$K_\mu\partial^\mu u = 0, \quad K_\mu\partial^\mu u^* - K_\mu^*\partial^\mu u = 0 \tag{10}$$

one can check that (9) is indeed conserved, i.e., $\partial^\mu J_\mu = 0$. The symmetries associated to such conservation laws are the area preserving diffeomorphisms of the target manifold. Indeed, the tensor $h_{\mu\nu}/\gamma$ is the pull-back of the area form on the target space

$$\mathrm{d}A = i\frac{\mathrm{d}u\wedge\mathrm{d}u^*}{\gamma}. \tag{11}$$

Therefore, the action (3) is invariant under diffeomorphisms preserving the area (11) and (9) are the corresponding Noether currents.[2,8]

III. THE ANSATZ

Following Refs. 2 and 3 we introduce the ansatz

$$u = f(t,z)e^{i(m_1\varphi_1+m_2\varphi_2)}, \tag{12}$$

where m_i, $i=1, 2$, are arbitrary integers, and f is a real profile function. Replacing it into the equation of motion (7) one gets

$$\partial_t\left(\frac{\partial_t f^2}{\gamma}\right) - \frac{4z(1-z)}{r_0^2\Omega}\partial_z\left(\Omega\frac{\partial_z f^2}{\gamma}\right) = 0, \tag{13}$$

where

$$\Omega \equiv m_1^2 z + m_2^2(1-z). \tag{14}$$

We now make a change of variable in the profile function, introducing a function g by

$$\mathrm{d}g \sim \frac{\mathrm{d}f^2}{\gamma}. \tag{15}$$

For instance, in the particular cases discussed below (5) we get that (a) for the plane where $\gamma=1$ one has $g=f^2$, and $g\geqslant 0$; (b) for the Poincaré hyperbolic disk where $\gamma=(1-|u|^2)^2$, one has $g=1/(1-f^2)$, and $g\geqslant 1$; (c) for the sphere S^2 where $\gamma=(1+|u|^2)^2$ one has $g=1/(1+f^2)$, and $0\leqslant g\leqslant 1$.

So, with the change (15) one gets that (13) becomes a linear partial differential equation in g

$$\partial_t^2 g - \frac{4z(1-z)}{r_0^2\Omega}\partial_z(\Omega\partial_z g) = 0. \tag{16}$$

The solutions can be obtained by separation of variables introducing

$$g(t,z) = J(t)H(z) \tag{17}$$

and then J and H must satisfy

$$\partial_t^2 J + \omega^2 J = 0 \tag{18}$$

and

$$z(1-z)\partial_z\big[\big(q^2 z + (1-z)\big)\partial_z H\big] + \frac{r_0^2\omega^2}{4}\big(q^2 z + (1-z)\big)H = 0, \tag{19}$$

where ω^2 is the separation of variables constant, and where q is

$$q \equiv \frac{|m_1|}{|m_2|}. \tag{20}$$

Equation (19) is what is called a Heun equation.[9] It is a generalization of Gauss hypergeometric equation in the sense that it has one extra regular singular point. Indeed, (19) reduces to the hypergeometric equation for $q=1$. Notice that (19) is invariant under the joint transformations $q \leftrightarrow 1/q$ and $z \leftrightarrow 1-z$. Therefore, if $H_{q,\omega}(z)$ is a solution of (19) for some value of q, so is

$$H_{1/q,\omega}(z) = H_{q,\omega}(1-z) \tag{21}$$

for the inverse value $1/q$. One can obtain solutions of (19) in powers series around $z=0$ and for $0 \leqslant q \leqslant 1$. The solutions for $q \geqslant 1$, are then obtained from those using the above symmetry. The power series solutions are given by

$$H_{q,\omega}(z) = \frac{1}{v_{q,\omega}}\left(z + \sum_{n=2}^{\infty} c_n z^n\right), \tag{22}$$

where the positive constants $v_{q,\omega}$ are chosen such that the maximum absolute value of $H_{q,\omega}(z)$ in the interval $0 \leqslant z \leqslant 1$, is unity. The coefficients, for $n \geqslant 2$, are determined by the recursion relation (with $c_0=0$, and $c_1=1$)

$$c_n = \frac{-1}{n(n-1)}\left[(q^2-1)\left(\frac{\omega^2 r_0^2}{4} - (n-2)^2\right)c_{n-2} + \left(\frac{\omega^2 r_0^2}{4} - (n-1)(n-2) + (q^2-1)(n-1)^2\right)c_{n-1}\right]. \tag{23}$$

We will be interested in solutions with ω real, and therefore the solutions of (18) are trigonometric functions. Of course, if g is a solution of (16), so is $\alpha g + \beta$, with α and β constants. We will then use the following normalization for the solutions of (16):

$$g_{q,\omega} = \tfrac{1}{2}[\sin(\omega t + \delta)H_{q,\omega}(z) + 1], \quad \omega \neq 0 \tag{24}$$

with $H_{q,\omega}(z)$ given by (22). The advantage of such normalization is that the solutions (24) take values on the real line from zero to unity only. Therefore, they are admissible solutions for the case where the target space is the sphere S^2 [see discussion below (15)].

We normalize the static solutions of (16) as

$$g_{q,0} = \frac{\ln(q^2 z + 1 - z)}{\ln q^2}. \tag{25}$$

So, $g_{q,0}$ is a monotonic function varying from zero at $z=0$ to unity at $z=1$. Notice that $g_{q,0} \to z$ as $q \to 1$. A decreasing function can be obtained by the interchange $g_{q,0} \to 1 - g_{q,0}$. Therefore, (25) are also admissible solutions for the case where the target space is the sphere S^2.

The admissible solutions for the cases of the plane or the Poincaré hyperbolic disk can then be written as

TABLE I. The first three frequencies leading to solutions (22) satisfying the boundary conditions (30) for some chosen values of q. Due to the symmetry (21) the frequencies are invariant under the interchange $q\leftrightarrow 1/q$.

q	$\omega_1^2 r_0^2/4$	$\omega_2^2 r_0^2/4$	$\omega_3^2 r_0^2/4$
1	2	6	12
3/4	1.983 765 266 031	5.987 866 563 654	11.988 820 961 965

$$g_{q,\omega}^{\text{plane}} = \alpha g_{q,\omega}, \quad g_{q,\omega}^{\text{Poinc.disk}} = \alpha g_{q,\omega} + 1 \tag{26}$$

with α being a real and positive constant, and $g_{q,\omega}$ being given either by (24) or (25) (see Tables I–III).

IV. THE ENERGY AND BOUNDARY CONDITIONS

The energy for the solutions obtained through the ansatz (12) and (15) is given by

$$E = \int_{S^3} \mathrm{d}\Sigma\, \mathcal{H} = 16\pi^2 r_0 \int_0^1 \mathrm{d}z\, \Omega\left(\frac{(\partial_t g)^2}{4z(1-z)} + \frac{1}{r_0^2}(\partial_t g)^2\right), \tag{27}$$

where $\mathcal{H}$ is the Hamiltonian density associated to (3). Using the equation of motion (16) one gets that the energy of static configurations is

$$E_{\text{static}} = \frac{16\pi^2}{r_0}(\Omega g \partial_z g)\big|_{z=0}^{z=1}. \tag{28}$$

Therefore, the energy of the static solutions (25) is

$$E(g_{q,0}) = \frac{16\pi^2}{r_0}|m_1 m_2|\frac{(q-1/q)}{\ln q^2}. \tag{29}$$

Notice that the solutions of (19), for $\omega\neq 0$, which do not vanish at $z=0$ or $z=1$, have a logarithmic divergence on its first derivative, at those points. We then observe from (27) that such solutions do not have finite energy. Consequently, we shall impose the following boundary conditions:

$$H_{q,\omega}(0) = H_{q,\omega}(1) = 0 \quad \text{for } \omega \neq 0. \tag{30}$$

In addition, using the equation of motion (16) one obtains that

TABLE II. Numerical values of Λ_{q,ω_i}, as defined in (34), for some chosen values of q and for the three frequencies given in Table I. Due to (21), $\Lambda_{q,\omega}$ is invariant under the interchange $q\leftrightarrow 1/q$.

q	Λ_{q,ω_1}	Λ_{q,ω_2}	Λ_{q,ω_3}
1	4/3	27/5	64/7
3/4	1.362 643	4.693 750	9.501 984
1/2	1.505 658	4.275 566	9.428 440
1/4	2.065 180	4.819 658	8.855 009
1/10	3.739 188	7.930 185	13.004 162

TABLE III. Numerical values of the normalization constant v_{q,ω_i}, as defined in (22), for some chosen values of q and for the three frequencies given in Table I. Due to (21), $v_{q,\omega}$ is invariant under the interchange $q \leftrightarrow 1/q$.

q	v_{q,ω_1}	v_{q,ω_2}	v_{q,ω_3}
1	1/4	$1/6\sqrt{3}$	1/16
3/4	0.285 189 93	0.119 156 83	0.070 789 33
1/2	0.332 611 65	0.152 779 52	0.087 010 28
1/4	0.409 991 03	0.204 149 92	0.126 957 32
1/10	0.502 749 25	0.256 726 47	0.167 310 92

$$\frac{\mathrm{d}E}{\mathrm{d}t} = \frac{32\pi^2}{r_0}\,(\Omega\partial_t g\partial_z g)\big|_{z=0}^{z=1}\,. \tag{31}$$

Therefore, the energy is conserved for the static solutions, and for those solutions (24) satisfying the boundary conditions (30).

Multiplying (19) by $H_{q,\omega}$ and integrating in z, one gets that

$$\int_0^1 \mathrm{d}z \frac{\omega^2\Omega}{4z(1-z)}\,H_{q,\omega}^2 - \frac{1}{r_0^2}\int_0^1 \mathrm{d}z\,\Omega\,(H'_{q,\omega})^2 = -\frac{1}{r_0^2}\,(\Omega H_{q,\omega}\,H'_{q,\omega})\big|_{z=0}^{z=1}. \tag{32}$$

Consequently, the energy (27) for the solutions (24) satisfying (30) is

$$E(g_{q,\omega}) = \frac{16\pi^2}{r_0}\,|m_1\,m_2|\Lambda_{q,\omega}\,, \tag{33}$$

where

$$\Lambda_{q,\omega} = \Lambda_{1/q,\omega} = \frac{\omega^2 r_0^2}{16}\int_0^1 \mathrm{d}z\left(\frac{q}{1-z}+\frac{1}{qz}\right)H_{q,\omega}^2 = \frac{1}{4}\int_0^1 \mathrm{d}z\left(qz+\frac{1-z}{q}\right)(H'_{q,\omega})^2. \tag{34}$$

The fact that $\Lambda_{q,\omega}$ is invariant under $q \leftrightarrow 1/q$, follows from the symmetry (21). In Table II we give the values of $\Lambda_{q,\omega}$ for some chosen values of q and some allowed frequencies ω. So, the energies (29) and (33) do not depend upon the signs of the integers m_1 and m_2 and it is invariant under the interchange $m_1 \leftrightarrow m_2$ [see (20)].

Multiplying (19) by $H_{q,\varpi}$, subtracting from the same relation with ω interchanged with $\overline{\omega}$, and integrating in z, one gets that

$$(\omega^2-\overline{\omega}^2)\int_0^1 \mathrm{d}z\frac{\Omega}{4z(1-z)}H_{q,\omega}H_{q,\varpi} = \frac{1}{r_0^2}\,(\Omega(H_{q,\omega}H'_{q,\varpi} - H'_{q,\omega}H_{q,\varpi}))\big|_{z=0}^{z=1}. \tag{35}$$

Similarly, differentiating (19) with respect to z once, multiplying by $H'_{q,\varpi}$, subtracting from the same relation with ω interchanged with $\overline{\omega}$, and integrating in z, one gets that

$$(\omega^2-\overline{\omega}^2)\int_0^1 \mathrm{d}z\,\Omega H'_{q,\omega}H'_{q,\varpi} = \frac{1}{r_0^2}\,(4z(1-z)\Omega(H'_{q,\omega}H''_{q,\varpi} - H''_{q,\omega}H'_{q,\varpi}))\big|_{z=0}^{z=1}. \tag{36}$$

Consequently, for the solutions (24) satisfying (30), and having finite first and second z-derivatives at $z=0$ and $z=1$, one gets the orthogonality relations

$$\int_0^1 \mathrm{d}z \frac{\Omega}{4z(1-z)} H_{q,\omega} H_{q,\varpi} = \int_0^1 \mathrm{d}z\, \Omega H'_{q,\omega} H'_{q,\varpi} = 0 \quad \text{for } \omega \neq \overline{\omega}. \tag{37}$$

It then follows that the energy (27) of a linear combination of solutions (24) satisfying (30), is just the sum of the energies of each solution, i.e.,

$$E(Ag_{q,\omega} + Bg_{q,\varpi}) = A^2 E(g_{q,\omega}) + B^2 E(g_{q,\varpi}) \quad \text{for } \omega \neq \overline{\omega}. \tag{38}$$

Therefore, in that sense, the modes for the same value of q are decoupled. However, the intensities in which they enter in the superposition are not independent. As discussed below (15) the real values that the profile function g can take depend on the target space under consideration. So, when we take linear combinations of the solutions we have to respect those constraints. In Sec V we discuss those constrained linear combinations in detail in the case where the target space is the sphere S^2.

The boundary conditions (30) lead to a discrete spectrum of allowed frequencies ω. Indeed, for the case where $q=1$ the series (23) truncates whenever

$$\frac{r_0^2\omega^2}{4} = n(\mathrm{n}+1), \quad n = 1,2,3,\ldots, \tag{39}$$

and the corresponding polynomials satisfy the boundary conditions (30). The first four of those polynomials are given by [with the normalization as in (22)]

$$H_{1,2} = 4(z - z^2),$$

$$H_{1,6} = 6\sqrt{3}(z - 3z^2 + 2z^3),$$

$$H_{1,12} = 16(z - 6z^2 + 10z^3 - 5z^4),$$

$$H_{1,20} = \frac{2450(z - 10z^2 + 30z^3 - 35z^4 + 14z^5)}{\sqrt{7}(3\sqrt{5} + 5\sqrt{6})\sqrt{15 - 2\sqrt{30}}}, \tag{40}$$

where the first index refers to $q=1$ and the second to $n(n+1)$ as given by (39).

For $q \neq 1$ the series (22) does not truncate, and the frequencies ω leading to solutions satisfying (30) can be found numerically. We give in Table I the first three frequencies for some chosen values of q. In addition, the same frequencies hold true under the exchange $q \leftrightarrow 1/q$ due to the symmetry (21). Therefore, the frequencies become smaller as q departs from unity, either to smaller or greater values than unity.

In Fig. 1 we exemplify the shape of the functions $H_{q,\omega}$, by plotting the first three modes H_{q,ω_i}, for $q=3/4$ and $q=1/10$ and the frequencies ω_i, $i=1,2,3$, given in Table I. Due to the symmetry (21), $H_{1/q,\omega_i}$ can be obtained by reflecting the plots around $z=1/2$. Notice that the polynomial solutions for $q=1$, given in (40), are invariant under (21). One observes that as q decreases, the functions $H_{q,\omega}$ get deformed in a way that their first derivatives at $z=1$ increase. For $q>1$, it follows, due to (21), that the first derivative of $H_{q,\omega}$ at $z=0$ increases as q increases.

V. THE CASE OF S^2 AS TARGET SPACE

According to the comments below (15), in the case where the target space is the two dimensional sphere S^2, we have that $\gamma=(1+|u|^2)^2$, and so $g=1/(1+f^2)$ and $0\leqslant g\leqslant 1$. The ansatz (12) becomes

$$u = \sqrt{\frac{1-g}{g}}\, e^{i(m_1\varphi_1 + m_2\varphi_2)}. \tag{41}$$

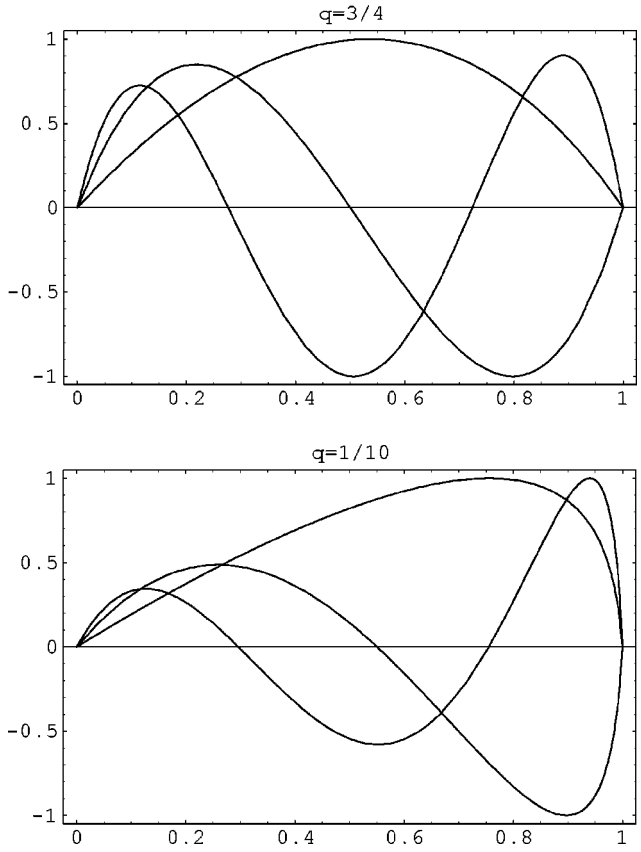

FIG. 1. Plots of $H_{q,\omega_i}(z)$, $i=1, 2, 3$, as normalized in (22), for $q=3/4$ (top) and $q=1/10$ (bottom) and for the three frequencies given in Table I. The number of zeroes increase with the increase of ω_i. The plots of $H_{q,\omega}$ and $H_{1/q,\omega}$ are related by reflection around $z=1/2$ due to the symmetry (21).

As we have discussed, the solutions (24) and (25) are admissible solutions for the case where the target space is S^2. However, one can construct more admissible solutions, i.e., with $0 \leqslant g \leqslant 1$, by taking linear combinations of the solutions (24) and (25). An interesting case corresponds to linear combinations of the static solution $g_{q,0}$ given by (25), with one or more time dependent solutions of the type (24). It leads to oscillating (in time) Hopfion solutions. Let us consider the case $q \leqslant 1$ first. The static solution $g_{q,0}$ vanishes at $z=0$, and has z-derivative equals to $(q^2-1)/\ln q^2$ there. The function $f_q(z) \equiv [(q^2-1)/\ln q^2] v_{q,\omega} H_{q,\omega}(z)$, with $H_{q,\omega}$ given by (23) and satisfying (30), has the same behavior at $z=0$ as $g_{q,0}$. In addition, c_2 given by (23), is negative for the case of $H_{q,\omega}$ satifying (30), and so $f_q(z)$ grows slower than $g_{q,0}$ for small z. We do not have rigorous proof, but by careful direct inspection we found that, as z increases from zero to unity the absolute value of $f_q(z)$ never exceeds the value of $g_{q,0}$, which is a positive monotonic function of z. It then follows that the combination

$$g_{q,0} + \alpha \frac{(q^2-1)}{\ln q^2} v_{q,\omega} \sin(\omega t + \delta) H_{q,\omega}(z) \tag{42}$$

with $0 \leqslant \alpha \leqslant 1$, takes values between zero and unity only, and so it is an admissible time dependent solution for the target space S^2. Therefore, by adding up such types of solutions and dividing by their number, one gets that the time dependent solutions

$$g_q^{(N)}(t,z)=\frac{\ln(q^2z+1-z)}{\ln q^2}+\frac{1}{N}\frac{(q^2-1)}{\ln q^2}\sum_{\omega_i}\alpha_i v_{q,\omega_i}\sin(\omega_i t+\delta_i)H_{q,\omega_i}(z), \tag{43}$$

where N is the number of modes (frequencies) entering into the sum, and α_i's are real coefficients satisfying $0\leqslant\alpha_i\leqslant 1$, are admissible solutions for the target space S^2. The energy of such solutions, according to (24), (25), (29), (33), and (38), is given by

$$E=\frac{16\pi^2}{r_0}|m_1m_2|\frac{(q-1/q)}{\ln q^2}\left(1+4\frac{q^2}{N^2}\frac{(q-1/q)}{\ln q^2}\sum_{\omega_i}\alpha_i^2v_{q,\omega_i}^2\Lambda_{q,\omega_i}\right) \tag{44}$$

with Λ_{q,ω_i} given by (34).

Solutions of the type (43) for $q\geqslant 1$ can be obtained using the symmetry (21), i.e., $g_{1/q}^{(N)}(t,z)=g_q^{(N)}(t,1-z)$. Solutions that decrease from unity at $z=0$ to zero at $z=1$ can be obtained by the symmetry $g_q^{(N)}(t,z)\to 1-g_q^{(N)}(t,z)$. The energy (44) is invariant under those two types of transformations. As we now show, all these solutions correspond to oscillating Hopfions, i.e., solutions that oscillate in time and have a constant (in time) nontrivial Hopf number.

For any fixed time t our solutions define a map from the physical space S^3 to the target space S^2, and so it is a Hopf map.[10] We now show that the Hopf invariant (the linking number) is independent of time for the admissible solutions we have constructed. In order to calculate the Hopf index of the solution we introduce

$$\Phi_1=\sqrt{g}\cos(m_2\varphi_2),\quad \Phi_3=\sqrt{1-g}\cos(m_1\varphi_1),$$

$$\Phi_2=-\sqrt{g}\sin(m_2\varphi_2),\quad \Phi_4=\sqrt{1-g}\sin(m_1\varphi_1), \tag{45}$$

which defines another 3-sphere S^3_Φ, since $\Phi_1^2+\Phi_2^2+\Phi_3^2+\Phi_4^2=1$. The field u in (41) can be written as

$$u=\frac{\Phi_3+i\Phi_4}{\Phi_1+i\Phi_2}. \tag{46}$$

Since u parametrizes the sphere S^2 through the stereographic projection (6), we have that (46) gives the map $S^3_\Phi\to S^2$. So, the Hopf index is in fact evaluated through the map $S^3\to S^3_\Phi\to S^2$, as we now explain. We introduce the potential

$$\vec{A}-\frac{i}{2}(Z^\dagger\vec{\nabla}Z-\vec{\nabla}Z^\dagger Z), \tag{47}$$

where

$$Z=\begin{pmatrix}Z_1\\Z_2\end{pmatrix},\quad Z_1=\Phi_3+i\Phi_4,\quad Z_2=\Phi_1+i\Phi_2 \tag{48}$$

and the differential operator $\vec{\nabla}$ is the gradient on the physical space S^3. The Hopf index is defined by the integral[10]

$$Q_H=\frac{1}{4\pi^2}\int \mathrm{d}\Sigma\,\vec{A}\cdot\mathrm{curl}\,\vec{A}, \tag{49}$$

where $\mathrm{d}\Sigma$ is the volume element on the physical space S^3. Evaluating we get

$$\vec{A}=-m_1\frac{(1-g)}{\sqrt{1-z}}\hat{\mathbf{e}}_{\varphi 1}+m_2\frac{g}{\sqrt{z}}\hat{\mathbf{e}}_{\varphi 2} \tag{50}$$

and

$$\text{curl}\,\vec{A} = 2\partial_z g(-m_2\sqrt{1-z}\hat{\mathbf{e}}_{\varphi 1} + m_1\sqrt{z}\hat{\mathbf{e}}_{\varphi 2}). \tag{51}$$

Consequently we get that

$$Q_H = m_1 m_2[g(t,z=1) - g(t,z=0)]. \tag{52}$$

Therefore, the solutions (25) have Hopf index

$$Q_H(g_{q,0}) = m_1 m_2 \tag{53}$$

and so they are static Hopfion soliton solution. The time dependent solutions (24) are constant at $z=0$ and $z=1$ due to the boundary condition (30), i.e., $g_{q\omega}(t,0)=g_{q\omega}(t,1)=1/2$. Therefore, they carry no Hopf number

$$Q_H(g_{q,\omega}) = 0, \quad \omega \neq 0. \tag{54}$$

The solutions (43) although time dependent, also have contant values at $z=0$ and $z=1$, determined by their static component. It then follows that

$$Q_H\left(g_q^{(N)}\right) = m_1 m_2 \tag{55}$$

and so they do correspond to oscillating Hopfion soliton solutions.

The Hopf index can also be calculated as the linking number of the preimages of two points of S^2.[10] Notice, from (6), that the north pole of S^2, $\vec{n}=(0,0,1)$, corresponds to $u\to\infty$, and so from (41) to $g=0$. On the other hand, the south pole of S^2, $\vec{n}=(0,0,-1)$, corresponds to $u=0$, and so to $g=1$. Therefore, from (45) and (48), we see that the pre-image on S^3_Φ of the north pole of S^2 correponds to $Z_1=e^{im_1\varphi_1}$ and $Z_2=0$, while the preimage of the south pole to $Z_1=0$ and $Z_2=e^{-im_2\varphi_2}$. For the static solution (25) and the time dependent solutions (43), the preimages in the spacial S^3 of these two circles in S^3_Φ are constant in time. In addition, those two circles in S^3_Φ pass through each other m_1m_2 times as φ_1 and φ_2 varies from 0 to 2π in S^3. So their linking number is m_1m_2, and that is the Hopf index. For the time dependent solutions (24) it is not possible to have $g=0$ and $g=1$ on different points on the spatial S^3 at the same time t. Therefore, the preimages of the north and south poles of S^2 never link, and so the Hopf index of such solutions vanishes.

We analyze the canonical treatment of classical constrained mechanical systems formulated with a discrete time. We prove that under very general conditions, it is possible to introduce nonsingular canonical transformations that preserve the constraint surface and the Poisson or Dirac bracket structure. The conditions for the preservation of the constraints are more stringent than in the continuous case and as a consequence some of the continuum constraints become second class upon discretization and need to be solved by fixing their associated Lagrange multipliers. The gauge invariance of the discrete theory is encoded in a set of arbitrary functions that appear in the generating function of the evolution equations. The resulting scheme is general enough to accommodate the treatment of field theories on the lattice. This paper attempts to clarify and put on sounder footing a discretization technique that has already been used to treat a variety of systems, including Yang–Mills theories, BF theory, and general relativity on the lattice. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1823030]

I. INTRODUCTION

We have recently introduced[1,2] a technique for treating the theories that arise when one discretizes (space)–time in a constrained mechanical system or a continuum field theory. We have shown that this technique works for Yang–Mills and BF theories and implemented it for the gravitational case. Previous attempts to studying systems with discrete time had concentrated mostly on systems without constraints or with holonomic constraints only (for a review with a comprehensive reference list see Ref. 3).

The idea consists on starting from a discretized action, constructing discrete Lagrange equations and introducing a symplectic structure in the discrete space. The evolution is implemented via canonical transformations and the consistency of the discrete theory determines in part the Lagrange multipliers. In some totally constrained systems, like general relativity, the resulting discrete theories are constraint-free since the constraints are solved for the Lagrange multipliers. This makes the quantization of the discrete theories considerably simpler than the continuum cases. This was exploited to make progress in solving the problem of time in quantum gravity[4,5] and to implement the Page–Wootters relational time[5,6] and show that a fundamental decoherence arises in quantum mechanics from quantum gravity.

In this paper, we want to address in a more systematic way the issue of the canonical formulation of discrete constrained systems. Up to now, most of the analysis has been made on specific examples, and a canonical analysis, à la Dirac,[7,8] is still lacking. In particular, the technique relied

heavily on defining a canonical transformation that was initially singular (and therefore not a true canonical transformation) and showing that one could eliminate variables and end up with a true canonical transformation. Up to now this was shown in a case by case basis. This paper determines the general conditions needed for the construction of a proper canonical transformation by following a close analogue of the Dirac procedure, adapted to the discrete case. In particular, we note that there are several ways to proceed that yield equivalent results, but that may offer different advantages for particular systems.

In Sec. II we will lay out the framework of how to deal with mechanical systems where time is discrete, including singular and nonsingular systems. In Sec. III we will develop a classification of constraints into first and second class suitable for the discrete context. In Sec. IV we work out a specific example that exhibits the details of the formalism. In Sec. V we discuss an alternative formulation of the formalism and we end with conclusions and discussion.

II. MECHANICS WITH DISCRETE TIME

We start by considering a continuum theory representing a mechanical system. Its Lagrangian will be denoted by $\hat{L}(q^a,\dot{q}^a)$, $a=1,\ldots,M$. This setting is general enough to accommodate, for instance, totally constrained systems. In such case $\dot{q}$ will be the derivative of the canonical variables with respect to the evolution parameter. It is also general enough to include the systems that result from formulating on a discrete space–time lattice a continuum field theory.

We discretize the evolution parameter in intervals (possibly varying upon evolution) $t_{n+1}-t_n=\epsilon_n$ and we label the generalized coordinates evaluated at t_n as q_n. We define the discretized Lagrangian as

$$L(n,n+1)\equiv L(q_n^a,q_{n+1}^a)\equiv \epsilon_n \hat{L}(q^a,\dot{q}^a), \tag{1}$$

where

$$q^a=q_n^a \quad \text{and} \quad \dot{q}^a\equiv \frac{q_{n+1}^a-q_n^a}{\epsilon_n}. \tag{2}$$

Of course, one could have chosen to discretize things in a different fashion, for instance using a different approximation for the derivative, or by choosing to write the continuum Lagrangian in terms of different variables. The resulting discrete theories generically will be different and will approximate the continuum theory in different ways. However, given a discrete theory, the treatment we outline in this paper is unique. For instance, in the method we introduce in order for constraints to be preserved we will fix the values of the Lagrange multipliers. However, if one has constraints that are only function of either the configuration or the momentum variables (but not mixed) the method preserves the constraints automatically. Therefore the determination of the Lagrange multipliers will depend on the particular form chosen for the continuum theory. If one can find a canonical transformation that makes all the constraints only dependent on configuration variables, for example, then the Lagrange multipliers will not be determined and the symmetries implemented by the constraints will be preserved automatically without the need to determine the Lagrange multipliers.

The action can then be written as

$$S=\sum_{n=0}^{N} L(n,n+1). \tag{3}$$

It should be noted that in previous treatments[1,2] we have written the Lagrangian in first order form, i.e., $L=\int \mathrm{d}t(p\dot{q}-H(p,q))$. It should be emphasized that this is contained as a particular case in the treatment we are presenting in this paper. In this case one takes both q and p to be configuration variables, and one is faced with a Lagrangian that involves q_n, p_n, and q_{n+1} as variables, being independent of p_{n+1}. In Sec. IV we discuss an example where in fact we apply the

technique to a Lagrangian of this type. Although in simple examples as these the first order form may appear as a bit of an overkill, since dynamical variables and constraints proliferate, it nevertheless shows that the method is applicable as outlined without problems.

If the continuum theory is invariant under reparametrizations of the evolution parameter, one can show that the information about the intervals ϵ_n may be absorbed in the Lagrange multipliers. In the case of standard mechanical systems it is simpler to use an invariant interval $\epsilon_n = \epsilon$.

The Lagrange equations of motion are obtained by requiring the action to be stationary under variations of the configuration variables q^a fixed at the endpoints of the evolution interval $n=0$, $n=N+1$,

$$\frac{\partial L(n,n+1)}{\partial q_n^a} + \frac{\partial L(n-1,n)}{\partial q_n^a} = 0. \tag{4}$$

These equations define a unique evolution if the determinant is

$$\left| \frac{\partial^2 L(n,n+1)}{\partial q_{n+1}^b \partial q_n^a} \right| \neq 0. \tag{5}$$

We will refer to this case as the nonsingular case. When the determinant vanishes, one must analyze the situation differently. Let us start with the nonsingular case.

A. Nonsingular case

In this case one can solve the Lagrange equations explicitly and the q_{n+1} are uniquely given as a function of q_n and q_{n-1}. This is the equivalent of the Hessian condition for the nonsingular Lagrangian theories in the continuum. The resulting equations are "second order" in the sense that the q_n's are determined provided one knows two previous time levels. One can introduce a "first order" formulation by introducing canonically conjugate variables as is usually done when introducing a Hamiltonian formulation in the continuum theories.

We introduce the following definition of variables that we will later show end up being canonically conjugate momenta of the configuration variables:

$$p_{n+1}^a \equiv \frac{\partial L(n,n+1)}{\partial q_{n+1}^a}, \tag{6}$$

$$p_n^a \equiv \frac{\partial L(n-1,n)}{\partial q_n^a} = -\frac{\partial L(n,n+1)}{\partial q_n^a}, \tag{7}$$

where we have used Eq. (4). Equations (6) and (7) define a canonical transformation for the variables q_n, p_n to q_{n+1}, p_{n+1} with the type 1 generating function $F_1 = -L(q_n^a, q_n^a + 1)$ provided that condition (5) is fulfilled. Notice that the evolution scheme is implicit, one can use the bottom equation (since we are in the nonsingular case) to give an expression for q_{n+1} in terms of q_n, p_n, which in turn can be substituted in the top equation to get an equation for p_{n+1} purely in terms of q_n, p_n.

It should be noted that there are several other possible choices, when going from the set of equations (6) and (7) to an explicit evolution scheme. For example, one can choose to do things in a way that yields a closer analogy with the standard Hamiltonian description in the continuum by introducing type 2 canonical transformations. To do this, we choose to invert Eq. (6) for $q_{n+1}^a \equiv q_{n+1}^a(q_n^b, p_{n+1}^b)$, which is possible only if

$$\left| \frac{\partial^2 L(n,n+1)}{\partial q_{n+1}^a \partial q_{n+1}^b} \right| \neq 0. \tag{8}$$

We can now introduce a Legendre transform and define

$$F_2(q_n,p_{n+1}) \equiv \sum_a q^a_{n+1}p^a_{n+1} - L(q_n,q_{n+1}). \tag{9}$$

From here it is immediate to obtain

$$q^b_{n+1} = \frac{\partial F_2}{\partial p^b_{n+1}}, \tag{10}$$

$$\frac{\partial F_2}{\partial q^b_n} = \frac{-\partial L(n,n+1)}{\partial q^b_n} = p^b_n, \tag{11}$$

where we have used the Lagrange equation in order to obtain the last equality. We easily recognize from here that F_2 behaves as a type 2 generating function of the canonical transformation connecting level n with level $n+1$.

We may define now a sort of "type 2" Hamiltonian [in the sense that it depends on p_{n+1} and q_n, $H_2(p_{n+1},q_n)$] given by

$$H_2(q_n,p_{n+1}) \equiv \sum_a p^a_{n+1}(q^a_{n+1} - q^a_n) - L(q_n,q_{n+1}) = F_2(q_n,p_{n+1}) - \sum_a p^a_{n+1}q^a_n, \tag{12}$$

which leads to the discrete Hamilton equations,

$$q^b_{n+1} = q^b_n + \frac{\partial H_2}{\partial p^b_{n+1}}, \tag{13}$$

$$p^b_n = p^b_{n+1} + \frac{\partial H_2}{\partial q^b_n}. \tag{14}$$

It should be noted that although this formulation has a degree of analogy with the traditional Hamiltonian formulation, there are significant differences due to the fact that the conjugate variables live at different time slices. It would not be possible therefore to use this formulation to attempt to construct a Schrödinger equation starting from the above Hamiltonian.

Provided that the canonical map defined by F_2 is invertible we end up with a discrete evolution implemented by a canonical transformation. It can be easily seen by using the Legendre transform that F_2 will be invertible if and only if

$$\left|\frac{\partial^2 F_2(n,n+1)}{\partial q^a_n p^b_{n+1}}\right| = -\left|\frac{\partial^2 L(n,n+1)}{\partial q^a_n q^b_{n+1}}\right| \times \left|\frac{\partial^2 L(n,n+1)}{\partial q^a_{n+1} q^b_{n+1}}\right|^{-1} \neq 0. \tag{15}$$

Thus, in order to have canonical transformations generated by type 2 functions, the Hessian condition in the continuum time mechanics leads to two independent conditions in the discrete theory given by Eqs. (5) and (8). Notice however that (8) is not necessary for introducing a symplectic structure.

It is clear that when one builds a canonical discrete theory there are four possibilities depending on which pair of variables one chooses to construct the generating functional of the canonical transformation, either q_n,q_{n+1}, q_n,p_{n+1}, p_n,q_{n+1}, p_n,p_{n+1}. In this section we considered only two, but the others can be easily generalized from the discussion here.

B. The singular case

Let us consider as before the generic discrete Lagrangian $L(n,n+1)=L(q^a_n,q^a_{n+1})$ with $a=1,\ldots,M$. It leads to the equations we already discussed,

$$p^a_{n+1} = \frac{\partial L(n,n+1)}{\partial q^a_{n+1}}, \tag{16}$$

$$p_n^a = -\frac{\partial L(n,n+1)}{\partial q_n^a}. \tag{17}$$

If $|\partial^2 L(n,n+1)/\partial q_{n+1}^a \partial q_n^b|$ vanishes and its rank is K, the system is singular and has $M-K$ constraints of the form

$$\Phi_A(q_n^a, p_n^a) = 0 \tag{18}$$

that result from Eq. (17), and $M-K$ constraints,

$$\Psi_A(q_{n+1}^a, p_{n+1}^a) = 0, \tag{19}$$

resulting from Eq. (16). The evolution of the configuration variables from level n to $n+1$ is given by solving for q_{n+1}^a the equation (17). As the system is singular the evolution depends on ($M-K$) arbitrary functions V_n^A,

$$q_{n+1}^a = f^a(q_n^b, p_n^b, V_n^A). \tag{20}$$

We shall follow closely the standard Dirac canonical procedure of continuum mechanics. In this case, the analysis of a constraint system goes through two steps. The first step consists in the definition of a set of evolution equations that weakly preserve the constraints and the Poisson symplectic structure. To do that one defines the total Hamiltonian $H_T = H_0 + V^\alpha \phi_\alpha$, where ϕ_α are the primary constraints, and the V^α are partially determined in order to preserve all the constraints of the system. Even though some of the V's may be arbitrary functions, once they are specified, the evolution generated by H_T preserves the Poisson brackets and the dynamical evolution is consistent at the classical level with the constraint structure. The second step is only required to quantize the system and consists in the identification of the first and second class constraints and the introduction of the Dirac brackets that enforce strongly the second class constraints.

As we shall see, the same procedure may be followed in the discrete case. The main difference is the implementation of the canonical transformation that is not generated by a Hamiltonian but by a canonical transformation of types 2, 3, or 4.

Let us start by completing the evolution equations. We need to add to Eq. (20) an equation for p_{n+1},

$$p_{n+1}^a = \left.\frac{\partial L(q_n, q_{n+1})}{\partial q_{n+1}^a}\right|_{q_{n+1}^a = f^a(q_n^b, p_n^b, V_n^A)}. \tag{21}$$

We now impose the preservation of the constraints

$$\Phi_A(q_{n+1}^a, p_{n+1}^a) = \Phi_A\left(f^a{}_n, \frac{\partial L(q_n, f_n^a)}{\partial q_{n+1}^a}\right) = 0. \tag{22}$$

Furthermore, we need to impose the $n+1$ level constraints at level n, $\Psi_A(q_n^a, p_n^a) = 0$ and impose the consistency conditions

$$\Psi_A\left(f^a{}_n, \frac{\partial L(q_n, f_n^a)}{\partial q_{n+1}^a}\right) = 0. \tag{23}$$

Three different cases may occur.

(a) Equations (22) and (23) vanish automatically, and therefore we are not led to new conditions.
(b) They lead to inconsistencies, and the dynamical system is inconsistent.
(c) New secondary constraints $C(q_n^a, p_n^a)$ appear or/and some of the arbitrary functions V_n^A are determined, that is $V_n^A = V^A(q_n^a, p_n^a, v_n^\alpha)$ with $\alpha = 1, \ldots, R \leqslant (N-K)$, and v_n^α arbitrary functions. The process is repeated until consistency is achieved. That is, until the consistency conditions are automatically satisfied without further constraints and conditions for V.

Substituting V_n^A in (20) and (21) we get the evolution equations that preserve all the constraints: primary, secondary, tertiary, and so on,

$$q_{n+1}^a = f^a(q_n^b, p_n^b, V^A(q,p,v)) = \tilde{f}^a(q_n^b, p_n^b, v^\alpha), \tag{24}$$

$$p_{n+1}^a = g^a(q_n^b, p_n^b, v^\alpha). \tag{25}$$

Initial values need to be restricted by the $n=0$ level constraints,

$$\Phi_A(q_0^a, p_0^a) = \Psi_A(q_0^a, p_0^a) = 0. \tag{26}$$

In order to have a complete analogy with the continuum case, we still need to analyze under what conditions this evolution also preserves the Poisson bracket structure. As in the continuum case we assume that the arbitrary functions v have been fixed. Three different cases may arise depending on if one chooses to implement things in terms of a canonical transformation of types 2, 3 or 4.

Case I: Equation (24) is invertible for q_n^a, that is, $|\partial q_{n+1}^a / \partial q_n^b| \neq 0$ and therefore one can write

$$q_n^a = h^a(q_{n+1}^b, p_n^b). \tag{27}$$

Notice that, under these hypotheses, there are no pseudoconstraints of the form $G(q_{n+1}^a, p_n^a) = 0$. We call these pseudoconstraints because they involve variables at different instants of time.

We may define a type 3 generating function of canonical transformations,

$$F_3(q_{n+1}^b, p_n^b) = [p_n^b q_n^b + L(q_n, q_{n+1})]|_{q_n^b = h^b}. \tag{28}$$

Then we have

$$\frac{\partial F_3(q_{n+1}^a, p_n^a)}{\partial p_n^b} = q_n^b = h^b(q_{n+1}^a, p_n^a) \tag{29}$$

and

$$\frac{\partial F_3(q_{n+1}^a, p_n^a)}{\partial q_{n+1}^b} = \left.\frac{\partial L(q_n^a, q_{n+1}^a)}{\partial q_{n+1}^b}\right|_{q_n = h} = p_{n+1}^b. \tag{30}$$

Notice that in the last equality there are also contributions coming from the dependence on q_{n+1} of the level n variables q_n, but these contributions cancel because of the definition of the canonical momenta. The information about the momenta is completely encoded in the evolution equations $q_{n+1}^a = h^a$ and the constraints. As the first equation is equivalent to (24) one ends up recovering the fundamental evolution equations as a canonical transformation generated by F_3. Furthermore,

$$\left| \frac{\partial F_3(q_{n+1}^a, p_n^a)}{\partial p_n^b \partial q_{n+1}^a} \right| = \left| \frac{\partial q_n^b}{\partial q_{n+1}^a} \right| \neq 0 \tag{31}$$

due to the fact that we have assumed that $|\partial q_{n+1}^b / \partial q_n^a| \neq 0$, and consequently F_3 is a nonsingular generating function and therefore the resulting canonical transformation preserves the Poisson bracket structure.

Case II: Equation (25) is invertible for p_n^a, that is $|\partial p_{n+1}^a / \partial p_n^b| \neq 0$ and therefore one can write

$$p_n^a = g^a(q_n^b, p_{n+1}^b). \tag{32}$$

Notice that, under these hypotheses, there are no pseudoconstraints of the form $G(q_n^a, p_{n+1}^a) = 0$. By substituting (32) in (24), one gets

$$q_{n+1}^a = k^a(q_n^b, p_{n+1}^b), \tag{33}$$

which allows one to introduce a type 2 generating function,

$$F_2(q_n^b, p_{n+1}^b) = [p_{n+1}^b q_{n+1}^b - L(q_n, q_{n+1})]|_{q_{n+1}^b = k^b}. \tag{34}$$

One can now easily check that this generating function reproduces the evolution equations (24) and (25) and defines a nonsingular canonical transformation that preserves the Poisson brackets in the evolution.

Case III: Even when the system has pseudoconstraints of the form $G(q_{n+1}^a, p_n^a)=0$ and $F(q_n^a, p_{n+1}^a)=0$ one may be able to find a canonical transformation provided that the system does not have pseudoconstraints of the form $F(p_n^a, p_{n+1}^a)=0$.

In fact, by using Eq. (25) one can invert for

$$q_n^a = l^a(p_n^b, p_{n+1}^b), \tag{35}$$

and substituting in (24) get

$$q_{n+1}^a = m^a(p_n^b, p_{n+1}^b). \tag{36}$$

A generating function of type 4 that does the same job as the two previous ones may now be introduced,

$$F_4(p_n^b, p_{n+1}^b) = [-p_{n+1}^b q_{n+1}^b + p_n^b q_n^b + L(q_n, q_{n+1})]|_{q_n^b = l^b}^{q_{n+1}^b = m^b}. \tag{37}$$

All of the discrete systems that have been treated up to now in the literature may be analyzed by following this canonical procedure, allowing one to preserve the constraints and the Poisson bracket structure. Later on we will show an example of a system of this type in order to analyze how this procedure works in a concrete case.

It should be noted that there may exist mechanical systems that do not fall into any of the above classifications. For instance, a system could have pseudoconstraints of all the types listed above. In such cases one will need to develop further techniques to treat them. For instance one could introduce canonical transformations of a given type for some of the variables and of a different type for other variables. This would require further study and it does not appear necessary for the systems that have been analyzed up to present.

III. CLASSIFICATION OF THE CONSTRAINTS

At this point we have a set of constraints primary, secondary, tertiary, etc., of the form $\chi_Z(q^a, p^a)=0$ with $Z=1,\ldots,A$ with A the total number of independent constraints, that are preserved under the evolution given by Eqs. (24) and (25) provided part or all of the arbitrary functions V are conveniently fixed.

As in the continuum case it is convenient to introduce the notion of first and second class constraints, in order to quantize the theory. A constraint is of first class if it commutes with all the constraints, if that is not the case it is of second class. As in the continuum case one can define first class functions of the canonical variables $f(q,p)$ that are not necessarily constraints. Such a function will be first class if it commutes with all the constraints. Second class constraints may be imposed strongly by introducing Dirac brackets. As the evolution equations preserve the Poisson structure, they will preserve the Dirac structure because Dirac brackets are defined in terms of Poisson brackets. One ends up with a theory with a set of evolution equations that preserve the symplectic structure of the system, and therefore may be quantized by describing the evolution in terms of unitary operators.

In the discrete case there is not a straightforward relation between the number of first and second class constraints and the number of phase space degrees of freedom. This is due to the fact that now the evolution of the constraints is not directly related with their Poisson brackets with a total Hamiltonian. Thus, the fact that a constraint does not commute with others is not easily

related with the determination of an arbitrary function. It is still very easy to determine the number of phase space degrees of freedom. In fact this number is given by two times the number of configuration variables minus the total number of constraints minus the number of arbitrary functions v.

IV. AN EXAMPLE OF CONSTRAINED SYSTEM WITH SECOND CLASS CONSTRAINTS

To illustrate the techniques elaborated above, we would like to discuss a model that is simple, yet addresses in a nontrivial way the main points we discussed. This example had been treated using ad-hoc techniques in Ref. 4. The model consists of a parametrized free particle in a two-dimensional space–time under the influence of a linear potential. The discrete Lagrangian is given by

$$L_n \equiv L(q_n^a, \pi_n^a, N_n, q_{n+1}^a, \pi_{n+1}^a, N_{n+1}) = \pi_n^a(q_{n+1}^a - q_n^a) - N_n[\pi_n^0 + \tfrac{1}{2}(\pi_n^1)^2 + \alpha q_n^1]. \tag{38}$$

We have chosen a first order formulation for the particle. However, this Lagrangian is of the type we considered in this paper, one simply needs to consider all variables, q^a, π^a, N as configuration variables. The system is clearly singular since the π's and N only appear at level n (or in the continuum Lagrangian, their time derivatives are absent). When considered as a type I generating function, the above Lagrangian leads to the equations

$$p_{\pi,n+1}^a = \frac{\partial L_n}{\partial \pi_{n+1}^a} = 0, \tag{39}$$

$$p_{q,n+1}^a = \frac{\partial L_n}{\partial q_{n+1}^a} = \pi_n^a, \tag{40}$$

$$p_{N,n+1} = \frac{\partial L_n}{\partial N_{n+1}} = 0, \tag{41}$$

and

$$p_{\pi,n}^a = -\frac{\partial L_n}{\partial \pi_n^a} = -(q_{n+1}^a - q_n^a) + \pi_n^1 N_n \delta_1^a + N_n \delta_0^a, \tag{42}$$

$$p_{q,n}^a = -\frac{\partial L_n}{\partial q_n^a} = \pi_n^a + \delta_1^a \alpha N_n, \tag{43}$$

$$p_{N,n} = -\frac{\partial L_n}{\partial N_n} = \pi_n^0 + \frac{1}{2}(\pi_n^1)^2 + \alpha q_n^1. \tag{44}$$

One can easily recognize that the system has six constraints: three at the $n+1$ level, and three at the n level. They are

$$\psi_1^a \equiv p_{\pi,n+1}^a = 0, \tag{45}$$

$$\psi_2 \equiv p_{N,n+1} = 0, \tag{46}$$

$$\Phi_1^a \equiv p_{q,n}^a - (\pi_n^a + \delta_1^a \alpha N_n), \tag{47}$$

$$\Phi_2 \equiv p_{N,n} - [\pi_n^0 + \tfrac{1}{2}(\pi_n^1)^2 + \alpha q_n^1]. \tag{48}$$

Therefore the evolution depends on three arbitrary functions $V_{N,n}, V_{\pi,n}^a$,

$$q_{n+1}^a = q_n^a + \pi_n^1 N_n \delta_1^a + N_n \delta_0^a - p_{\pi,n}^a, \tag{49}$$

$$\pi_{n+1}^a = \pi_n^a + V_{\pi,n}^a, \tag{50}$$

$$N_{n+1} = N_n + V_{N,n}. \tag{51}$$

The preservation of the ψ constraints from level n to level $n+1$ is automatically ensured from (23). Now we impose the preservation of the Φ constraints upon evolution. Let us begin with Φ_1^0,

$$\Phi_{1n+1}^0 \equiv p_{q,n+1}^0 - \pi_{n+1}^0 = p_{q,n}^0 - \pi_n^0 - V_{\pi,n}^0 = 0, \tag{52}$$

which taking into account the constraint Φ_{1n}^0 implies $V_{\pi,n}^0 = 0$.

For the Φ_2 one gets the equation

$$\Phi_{2n+1} = \pi_n^0 + \alpha(q_n^1 + \pi_n^1 N_n) + (\pi_n^1 + V_n^{\pi 1})^2/2 = 0, \tag{53}$$

that taking into account the constraint Φ_{2n} implies that

$$V_{\pi,n}^1 = -\pi_n^1 + \epsilon\sqrt{(\pi_n^1)^2 - 2\pi_n^1 N_n \alpha}, \tag{54}$$

where $\epsilon = \pm 1$.

Finally we have

$$\Phi_{1n+1}^1 = p_{q,n}^1 - N_n\alpha - \pi_n^1 - V_{\pi,n}^1 - \alpha(N_n + V_{N,n}) = 0, \tag{55}$$

that after imposing the constraint at level n leads to

$$V_{N,n} = -\frac{1}{\alpha} V_{\pi,n}^1 - N_n. \tag{56}$$

Thus, the evolution equations for the configuration variables are

$$q_{n+1}^a = q_n^a + \pi_n^1 N_n \delta_1^a + N_n \delta_0^a, \tag{57}$$

$$\pi_{n+1}^0 = \pi_n^0, \tag{58}$$

$$\pi_{n+1}^1 = \epsilon\sqrt{(\pi_n^1)^2 - 2\pi_n^1 N_n \alpha}, \tag{59}$$

$$N_{n+1} = \frac{1}{\alpha}[\pi_n^1 - \epsilon\sqrt{(\pi_n^1)^2 - 2\pi_n^1 N_n \alpha}]. \tag{60}$$

We are now ready to define an invertible canonical transformation with the help of a type 3 generating function. Notice that these evolution equations are invertible for q_n^a, and therefore we are in the case I. The inverse is given by a set of equations of the form $q_n(q_{n+1})$, explicitly given by

$$q_n^1 = q_{n+1}^1 - \pi_{n+1}^1 N_{n+1} - \frac{\alpha}{2}(N_{n+1})^2, \tag{61}$$

$$q_n^0 = q_{n+1}^0 - \frac{\pi_{n+1}^1 N_{n+1} + \frac{\alpha}{2}(N_{n+1})^2}{\pi_{n+1}^1 + \alpha N_{n+1}}, \tag{62}$$

$$\pi_n^0 = \pi_{n+1}^0, \tag{63}$$

$$\pi_n^1 = \pi_{n+1}^1 + \alpha N_{n+1}, \tag{64}$$

$$N_n = \frac{\pi_{n+1}^1 N_{n+1} + \frac{\alpha}{2}(N_{n+1})^2}{\pi_{n+1}^1 + \alpha N_{n+1}}. \tag{65}$$

Recalling that F_3 is given by Eq. (28) we obtain

$$F_3 = p_{\pi,n}^0 \pi_{n+1}^0 + p_{\pi,n}^1(\alpha N_{n+1} + \pi_{n+1}^1) + p_{q,n}^0 q_{n+1}^0 + \frac{1}{2} N_{n+1}[\alpha^2 N_{n+1}^2 + 3\alpha N_{n+1}\pi_{n+1}^1 + 2(\pi_{n+1}^1)^2]$$
$$- \frac{N_{n+1}(\alpha N_{n+1} + 2\pi_{n+1}^1)}{2(\alpha N_{n+1} + \pi_{n+1}^1)}\left[p_{q,n}^0 - p_{N,n} + \frac{1}{2}(\pi_{n+1}^1)^2 + \alpha q_{n+1}^1\right] + p_{q,n}^1\left(q_{n+1}^1 - \frac{\alpha}{2} N_{n+1}^2 - N_{n+1}\pi_{n+1}^1\right). \tag{66}$$

One can check that Eqs. (61)–(65) are easily recovered by taking the partial derivative with respect to p_n^a. By differentiating with respect to q_{n+1}^a one gets

$$p_{q,n+1}^0 = p_{q,n}^0, \tag{67}$$

$$p_{q,n+1}^1 = p_{q,n}^1 - \frac{\alpha}{2} A_n N_{n+1}(\alpha N_{n+1} + 2\pi_{n+1}^1), \tag{68}$$

$$p_{\pi,n+1}^0 = p_{\pi,n}^0, \tag{69}$$

$$p_{\pi,n+1}^1 = p_{\pi,n}^1 + \frac{N_{n+1}}{2}[3\alpha N_{n+1} - 2p_{q,n}^1 + 4\pi_{n+1}^1 + 2B_n A_n - A_n(\pi_{n+1}^1 + B_n A_n)(\alpha N_{n+1} + 2\pi_{n+1}^1)], \tag{70}$$

$$p_{N,n+1} = \tfrac{3}{2}\alpha^2 N_{n+1}^2 + \alpha p_{\pi,n}^1 - p_{q,n}^1 \pi_{n+1}^1 + (\pi_{n+1}^1)^2 + B_n$$
$$+ \alpha N_{n+1}[-p_{q,n}^1 + 3\pi_{n+1}^1 - \tfrac{1}{2} B_n A_n^2(\alpha N_{n+1} + 2\pi_{n+1}^1)], \tag{71}$$

where we have introduced

$$A_n \equiv (\alpha N_{n+1} + \pi_{n+1}^1)^{-1}, \tag{72}$$

$$B_n \equiv p_{N,n} - p_{q,n}^0 - \tfrac{1}{2}(\pi_{n+1}^1)^2 - \alpha q_{n+1}^1. \tag{73}$$

By substituting in Eqs. (67)–(71) the variables q_{n+1} and using the level n constraints one gets Eqs. (39)–(41), which is a canonical transformation that reproduces, on the constraint surface, the evolution equations of the discrete particle.

What remains to be done is to identify the second class constraints and impose them strongly. The complete set of six constraints of this model ψ and Φ are second class and allow one to solve for π^a and N and eliminate completely these variables and their complex conjugates P_π and P_N.

One can proceed in two different ways. The first alternative is to start by observing that P_π and P_N vanish strongly, and then to solve for π and N in terms of the $n+1$ level variables, leading to

$$\pi_n^0 = p_{q,n+1}^0, \tag{74}$$

$$\pi_n^1 = p_{q,n+1}^1, \tag{75}$$

$$N_n = \frac{C_{n+1}}{\alpha p_{q,n+1}^1}, \tag{76}$$

where $C_{n+1}=p_{q,n+1}^0+(p_{q,n+1}^1)^2/2+\alpha q_{n+1}^1$. The relevant evolution equations are obtained from (57), (67), and (68), and are given by

$$q_{n+1}^0 = q_n^0 + N_n = q_n^0 + \frac{C_{n+1}}{\alpha p_{q,n+1}^1}, \tag{77}$$

$$q_{n+1}^1 = q_n^1 + N_n \pi_n^1 = q_n^1 + \frac{C_{n+1}}{\alpha}, \tag{78}$$

$$p_{q,n}^0 = p_{q,n+1}^0, \tag{79}$$

$$p_{q,n}^1 = p_{q,n+1}^1 + \alpha N_n = p_{q,n+1}^1 + \frac{C_{n+1}}{p_{q,n+1}^1}, \tag{80}$$

and we recover the evolution equations obtained in Ref. 4.

The second alternative consists in solving for π and N in terms of the n level variables, leading to

$$\pi_n^0 = p_{q,n}^0, \tag{81}$$

$$\pi_n^1 = \epsilon\sqrt{-2(p_{q,n}^0 + \alpha q_n^1)}, \tag{82}$$

$$N_n = \frac{1}{\alpha}(p_{q,n}^1 - \epsilon\sqrt{-2(p_{q,n}^0 + \alpha q_n^1)}), \tag{83}$$

and from here, computing the evolution equations by using (57), (67), and (68). The two methods yield evolution schemes of different functional form since one propagates "forward" in time and the other "backward." The inequivalence in the functional form stems from the fact that the discretization of the time derivatives chosen in the Lagrangian is not centered. It should be emphasized that if one starts from given initial data and propagates forward with the first system of equations and then backward using the second, one will return to the same initial data.

Notice that we have six second class constraints, and the initial number of phase space degrees of freedom was 10. By noticing that there are no arbitrary functions left, one is left with four degrees of freedom on the constraint surface. The continuum model had two degrees of freedom.

The procedure we have followed here is completely general and may be simplified when one is treating specific cases. For instance, as it happens in the continuum theory[8] it is sometimes possible to implement the canonical analysis by first solving the constraints for the unphysical degrees of freedom N, π, p^N, p^π and then introducing a generating functional on the physical degrees of freedom by following the procedure of the preceding sections. In this particular case it is easy to show that, for $p^{q^1} \neq 0$, $|\partial q_{n+1}^a / \partial q_n^b| \neq 0$, where $q^a \equiv (q^1, q^0)$, and thus it is possible to

construct an F_3 generating functional. In all the models treated up to now in the literature the unphysical degrees of freedom were eliminated before obtaining the canonical transformation for the evolution of the physical degrees of freedom. In order to keep the analysis general in a simple model, here we have kept all the variables involved in this approach.

V. TREATMENT IN TERMS OF TYPE II GENERATING FUNCTIONS

Up to now, we have taken as the starting point a singular type I generating function given by $F_1=-L(q_n^a,q_{n+1}^a)$. It is interesting to analyze how singular systems may be described in terms of other types of generating functions.

Let us assume that neither condition (8) nor condition (5) are fulfilled by the discrete system and, therefore, we are in the singular case. Then, it may be immediately seen, by using (16), and taking into account that the determinant that appears in (8) now vanishes, that singular systems with first order Lagrangians in the continuum lead to the presence of pseudoconstraints $\phi_\alpha(q_n,p_{n+1})=0$, in the theory. Recall that these pseudoconstraints are similar to the constraints that arise in the continuum case, but mixing configuration variables at one level with momenta in the next level. As in the continuum case, one can then introduce the pseudoconstraint surface S_ϕ which we shall assume has well-defined functions,

$$\tilde{\nabla}\phi_\alpha=\left(\cdots\frac{\partial\phi}{\partial q_n^a}\cdots,\cdots\frac{\partial\phi}{\partial p_{n+1}^a}\cdots\right), \tag{84}$$

where a vector $\tilde{\tau}$ in the tangent space of S_ϕ, $T_{(q,p)}S_\phi$, is such that

$$\tilde{\tau}\cdot\tilde{\nabla}\phi_\alpha=0\ \forall\ \alpha. \tag{85}$$

Let us introduce now as before the type 2 Hamiltonian (12),

$$H_2\equiv\sum_a p_{n+1}^a(q_{n+1}^a-q_n^a)-L(q_n,q_{n+1}). \tag{86}$$

It is easy to see, using the pseudoconstraints, that Eq. (86) is a function of q_n,p_{n+1}. Let us consider now an infinitesimal variation of H_2 along the pseudoconstraint surface,

$$\begin{aligned}\mathrm{d}H_2&=\sum_a\left[(q_{n+1}^a-q_n^a)\mathrm{d}p_{n+1}^a+\left(p_{n+1}^a-\frac{\partial L}{\partial q_{n+1}^a}\right)\mathrm{d}q_{n+1}^a-\left(p_{n+1}^a+\frac{\partial L}{\partial q_n^a}\right)\mathrm{d}q_n^a\right]\\&=\sum_a\left[(q_{n+1}^a-q_n^a)\mathrm{d}p_{n+1}^a-\left(p_{n+1}^a+\frac{\partial L}{\partial q_n^a}\right)\mathrm{d}q_n^a\right],\end{aligned} \tag{87}$$

where in the last step we used (6). H_2 is well defined in S_ϕ but can be extended to the whole phase space as it is done in the case of constraints in the continuum theory. In order to obtain the canonical equation of motion we start from the identity,

$$\mathrm{d}H_2(q_n,p_{n+1})=\sum_a\left(\frac{\partial H_2}{\partial q_n^a}\mathrm{d}q_n^a+\frac{\partial H_2}{\partial p_{n+1}^a}\mathrm{d}p_{n+1}^a\right), \tag{88}$$

and evaluating it for an infinitesimal displacement $(\mathrm{d}q,\mathrm{d}p)$ in $T_{(q,p)}S_\phi$, we can use (87) and the Lagrangian equations of motion (7) to obtain

$$\sum_a\left[\left(p_{n+1}^a-p_n^a+\frac{\partial H_2}{\partial q_n^a}\right)\mathrm{d}q_n^a+\left(q_n^a-q_{n+1}^a+\frac{\partial H_2}{\partial p_{n+1}^a}\right)\mathrm{d}p_{n+1}^a\right]=0. \tag{89}$$

Since $(\mathrm{d}q,\mathrm{d}p)$ is an arbitrary tangent vector to S_ϕ, following (85) we obtain that the coefficient must be proportional to the gradient. Introducing therefore the Lagrange multipliers λ^a as the proportionality factors, we will end with the set of equations,

$$q^a_{n+1} = q^a_n + \frac{\partial H_2}{\partial p^a_{n+1}} + \lambda^\alpha_n \frac{\partial \phi_\alpha}{\partial p^a_{n+1}}, \tag{90}$$

$$p^a_{n+1} = p^a_n - \frac{\partial H_2}{\partial q^a_n} - \lambda^\alpha_n \frac{\partial \phi_\alpha}{\partial q^a_n}, \tag{91}$$

$$\phi_\alpha(q_n, p_{n+1}) = 0. \tag{92}$$

This system is similar to the continuum set of equations with the inclusion of pseudoconstraints, which have the same functional form as the continuum constraints, but involve configuration variables at level n and momenta at level $n+1$, instead of n level variables. From this initial evolution equations one may follow a procedure similar to the one developed in the preceding section in order to study the consistency of the (primary) constraints and pseudoconstraints.

VI. DISCUSSION AND CONCLUSIONS

We have provided a canonical procedure for the introduction of a preserved symplectic structure in discrete constrained systems. The analogy with Dirac's procedure in the continuum is quite remarkable. It is possible to define a notion of discrete evolution that weakly preserves constraints and Poisson brackets. The distinction between first and second class constraints is still useful and when second class constraints are imposed strongly the resulting Dirac brackets are preserved.

A feature of the discretized theories is that they may have a smaller number of first class constraints, and consequently more degrees of freedom than the continuum counterparts. The extra degrees of freedom come from the fact that the discrete theories may not necessarily have the same symmetries as the continuum theories. For instance, in the case of homogeneous cosmologies studied in Ref. 9 the extra pair of phase space degrees of freedom are associated with the fact that in the discrete theory different choices of refinements in the discretization in time correspond to different solutions in the discrete theory that nevertheless approximate the same solution in the continuum theory.

An open question at present is if it is possible in cases of interest, like general relativity, to find discretizations in which the symmetries of the continuum are automatically preserved (as is, for instance, the case in discretizations of Yang–Mills theories[1]). At the moment the only way in which this seems possible would be to cast the theory in terms of action-angle variables. There the dynamics simplifies to the point where a discretization preserving the constraints is available. It is not known how to write the theory in this way in general, although one can see this mechanism in action, for instance, in Bianchi models,[9] or in linearized theory.[10]

This is only a first step for a complete understanding of the dynamics of discrete gauge systems. The relation between the number of constraints of first and second class and the number of degrees of freedom, and the connection between the first class constraints and the gauge invariance of the discrete dynamical system need to be further studied. Moreover, as discussed in the body of the paper, if one wishes to consider more pathological systems than the ones considered here, more elaborate canonical transformations may need to be introduced.

The issue of the continuum limit is well understood in the nonsingular case, where there is an external step parameter that controls the approximation. However, it needs further study in the case of singular systems, particularly in the case of totally constrained systems where the step of the approximation is encoded in the additional degrees of freedom of the discrete theory. This issue has been studied in several models[4,9] but a complete characterization of the possible behaviors is still lacking. A similar comment applies to the role of spatial discretizations when one is considering lattice field theories.

(Received 10 June 2003; accepted 23 August 2004; published online 27 December 2004)

Rather general mean field theory of heteropolymer liquids developed earlier reduces the problem of the phase diagram construction to the determination of extremals of the free energy functional. These should be subsequently analyzed for their local and global stability. Tackling of this problem traditionally involves the examination of the behavior of the solutions of a set of nonlinear algebraic and partial differential equations at various values of the control parameters. Besides, the necessity arises here to construct in space of these parameters the lines where a polymer system loses the thermodynamic stability. To overcome mathematical difficulties encountered we employed a complex approach that combines analytical and numerical methods. A two-step procedure constitutes the essence of such an approach. First, the bifurcation analysis is invoked to find the asymptotics of the extremals in the vicinity of bifurcation points. Then these asymptotics are used as an initial approximation for the numerical continuation of specific lines, where the stability loss occurs, into regions of the parametric space far removed from bifurcation values. We realized this approach for the melt of linear binary copolymers of various chemical structure with macromolecules having a pattern of arrangement of monomeric units describable by a Markov chain. Bifurcation and phase diagrams for some of these copolymers have been constructed within a wide range of temperatures and volume fractions of a polymer. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1827323]

I. INTRODUCTION

The theoretical physics of polymers in its current state suggests the application of a rather sophisticated mathematical method (see, for instance, Ref. 1). This is because the majority of differential and integral equations which describe polymer systems are nonlinear admitting therefore several physically meaningful solutions.[2] Consequently, problems of nonlinear analysis of these equations based on the approaches of the theory of bifurcations, typical for the mathematical physics, are usually encountered here. One of such nontrivial problems particularly important for the thermodynamics of polymers is attacked in the present paper. The methods of its solution may be of interest for the physicist–theorists dealing with the Landau theory of phase transitions and the statistical physics of disordered systems. The experts in the field of the applied mathematics may also benefit from getting familiar with the solution of this problem, that may prompt them to look for new possible applications of the contemporary methods of the nonlinear analysis in the theoretical physics of polymers.

[a)]Electronic mail: lmanev@chph.ras.ru

The calculation of a phase diagram belongs to the most challenging theoretical problems of the thermodynamics of melts and solutions of polymers.[3] Having constructed such a diagram one might judge about the phase state of a polymer liquid under thermodynamic equilibrium at given values of external parameters. A crucial feature of polymer systems stipulating their qualitative distinction from low-molecular ones is the possibility of the existence of mesophases. Each of them represents such an equilibrium state of the liquid of macromolecules comprising more than one type of elementary units where the density of these latter periodically changes in space at scales lying between atomic and macroscopic length scales. Depending on this density profile dimensionality d a mesophase spatially periodic structures can vary in symmetry. The most investigated among them are lamellar ($d=1$), hexagonal ($d=2$), and body centered cubic ($d=3$) structures. They have been found experimentally and scrutinized theoretically.[4] The type of a heteropolymer equilibrium structure as well as its period and amplitude are controlled along with temperature and pressure also by architecture, composition, and structure of macromolecules. Most theoretical and experimental research addressed monodisperse block copolymers, in which all molecules being identical consist of two or three sufficiently long blocks of elementary units.[5] However, synthetic polymers represent as a rule a mixture of macromolecules markedly distinguishing in the content of various units and in the pattern of their arrangement along polymer chains. Thus the number of types of macromolecules in a real polymer is virtually infinite for any polymer specimen. That is why the description of its chemical structure suggests the recourse to some statistic approach. By the most general of them the set of macromolecules constituting a linear copolymer specimen is presumed to be mapped onto the set of realizations of a stochastic process.[6] It implies the transition from a particular monomeric unit of a macromolecule to the next one at every unit interval of "time." The role of the regular state S_α ($\alpha=1,\ldots,m$) is played here by αth type unit while the transition into absorbing state S_0 corresponds to going out of a macromolecule. Such a stochastic process with discrete time and finite number of states is referred to as a stochastic chain. The best known among them is the Markov chain where the probability to fall into any state at a certain step is exclusively controlled by the type of the state at the preceding step.[7] This absorbing chain is characterized by the matrix of transition probabilities

$$\mathbf{Q}^{ab}=\begin{bmatrix} 1 & \mathbf{0} \\ \boldsymbol{\nu}_0 & \mathbf{Q} \end{bmatrix}.$$

The element $\nu_{\alpha\beta}$ of matrix $\mathbf{Q}$ equals the probability of the transition from regular state S_α into regular state S_β whereas row vector $\mathbf{0}$ and column vector $\boldsymbol{\nu}_0$ have components $\nu_{0\alpha}=0$ and $\nu_{\alpha 0}$, respectively. Probability of the absorption $\nu_{\alpha 0}$ can be expressed through elements of matrix $\mathbf{Q}$ from the normalization condition $\nu_{\alpha 0}=1-(\nu_{\alpha 1}+\cdots+\nu_{\alpha m})$. Hence matrix $\mathbf{Q}$ and vector of initial states $\mathbf{v}$ with components v_α completely specifies a Markov chain.

Nowadays it is established that the chemical structure of many synthetic copolymers is described by a Markov chain. This stipulates practical importance of the investigation of their thermodynamic behavior. Besides, relationships have been derived that express the matrix of transitions $\mathbf{Q}$ and vector $\mathbf{v}$ through kinetic parameters of a reaction system where copolymers are synthesized.[6,8] Because these parameters are reported for a great number of particular copolymerization processes,[8] an opportunity opens up to calculate phase diagrams of real copolymers formed in the course of these processes. In the last decade a number of theoretical works have been published devoted to the description of spatially periodic structures formed in melts of binary Markovian copolymers.[9–16] The approach employed in these papers is a variation of the Landau theory of the phase transitions. This is based on the expansion of a system free energy in powers of the order parameter and on cutting off all terms whose power is more than four. Evidently, such a procedure is correct only in the vicinity of the critical point where the order parameter is sufficiently small. Thus the region of applicability of the phase diagrams presented earlier[9–16] is restricted just to this narrow range of the copolymer melt parameters.

To have phase diagrams constructed within the whole range of external parameters an original approach was put forward which relies on the description of the nuclei of the incipient phase.[17] This approach enabling one to relax the Landau theory restrictions suggests finding nontrivial

solutions of a set of either integral or differential equations with the subsequent analysis of their stability. A major task of this paper is to elucidate the potentialities of the practical implementation of this approach for the construction of the phase diagram of the Markovian copolymer melt using mathematical apparatus of the bifurcation theory. Bifurcation analysis was earlier used for the construction of nonhomogeneous unstable structures occurring in the polymer blends.[18,19]

The efficiency of the bifurcation analysis as applied to the theory of polymer liquids has been demonstrated earlier when describing the dynamics of the phase transitions in a mixture of two homopolymers,[18,19] each consisting of the identical molecules. This system essentially differs from that addressed in the present paper. Qualitative distinction between these two systems lays in the fact that the first of them is a two-component one unlike the second system that comprises virtually infinite number of components. The last circumstance appreciably complicates the thermodynamic description of heteropolymer liquids considered in the present work as compared to the homopolymer ones.

II. PHASE DIAGRAM

We consider the melt of a binary copolymer whose macromolecules have chemical structure described by a Markov chain. This is completely specified by five independent parameters ν_{11}, ν_{12}, ν_{21}, ν_{22}, and v_1 or v_2, through which any statistical characteristic of a copolymer primary structure is expressed. In particular, fractions X_1^0 and X_2^0 of the first and the second type units as well as their average number in a macromolecule, P_N^0, can be calculated by formulas

$$X_1^0 = \frac{\Delta_1}{\Delta}, \quad X_2^0 = \frac{\Delta_2}{\Delta}; \quad \Delta = \Delta_1 + \Delta_2, \quad Y^0 \equiv \frac{1}{P_N^0} = \frac{D}{\Delta}, \tag{1}$$

where the following designations are used:

$$\Delta_1 = \nu_{21} + v_1\nu_{20}, \quad \Delta_2 = \nu_{12} + v_2\nu_{10}, \quad D = \nu_{12}\nu_{20} + \nu_{21}\nu_{10} + \nu_{10}\nu_{20}. \tag{2}$$

Along with "chemical" parameters $\nu_{\alpha\beta}$ and v_α a copolymer melt is characterized by a set of "physical" parameters. Among the latter in the framework of the model in hand are temperature T, pressure P, and parameters $\gamma_{\alpha\beta}$ $(\alpha,\beta=1,2)$ of pair interaction between αth and βth type units. With bifurcation analysis in mind it is more convenient to use parameter $\mathbf{\Phi}^0$, equal to the volume fraction occupied by monomeric units in principal phase, rather than the pressure. This parameter is simply expressed $\mathbf{\Phi}^0 = M^0 v / V$ through volume v of a monomeric unit, their number M^0 in a system and its volume V. Quantity $\mathbf{\Phi}^0$ occurring in most theories of polymer liquid[3,20,21] is uniquely related to P by the equation of state.

Key elements of the phase diagram of such a liquid are two curves, each representing a two-dimensional section of the hypersurface (whose codimension is 1) in the space of external parameters. The first of them, cloud point curve (CPC), is a locus of points where nuclei of incipient phase or mesophase become globally thermodynamically stable. According to which of these cases takes place the CPC branch is said to be trivial or nontrivial. At the second of the above-mentioned curves, termed spinodal, the spatially homogeneous state loses local thermodynamic stability. The spinodal curve (SC) can contain trivial and nontrivial branches depending on the spatial scale (wave vector $\vec{q}=\vec{q}^*$) of the density fluctuations at which the loss of the above stability happens. To a trivial branch there corresponds macroscopic scale ($\vec{q}^* = 0$) while to nontrivial one mesoscopic scale ($\vec{q}^* \neq 0$) conforms. Provided they coexist, these two branches are tangent at the Lifshitz point. A domain of a phase diagram located in between CPC and SC corresponds to the metastable state of the principal phase. The density of each type of units in the incipient phase nuclei has at critical point (where CPC and SC have common tangent) the same value as in the principal phase.

In order to construct the phase diagram of a copolymer melt we will proceed from the general thermodynamic theory of heteropolymer liquids.[17,22] According to this theory the thermodynamic description of a polymer liquid is performed in terms of density functional

$$\Delta\mathcal{F}[\mathbf{\Phi}] \equiv \mathcal{F}[\mathbf{\Phi}] - \mathcal{F}[\mathbf{\Phi}^0] = TM^0\{\mathcal{G}[\mathbf{1}] - \mathcal{G}[\mathbf{s}]\} + \int d\vec{r}\{f^*(\mathbf{\Phi}) - f^*(\mathbf{\Phi}^0)\} + \frac{1}{v}\int d\vec{r}\{\mathbf{H}^0\mathbf{\Phi}^0 - \mathbf{H}\mathbf{\Phi}\}. \tag{3}$$

Each αth component of vectors $\mathbf{\Phi}$,$\mathbf{H}$, and $\mathbf{s}$, entering into the right-hand part of this expression refers to the αth type monomeric unit. So $\mathbf{\Phi}_\alpha$ denotes the volume fraction of these units in nuclei while H_α is the component of external field $\mathbf{H}$ acting upon them. Superscript "$\mathbf{0}$" means that the values of these quantities are taken in the principal phase. As for the argument of generating functional $\mathcal{G}[\mathbf{s}]$ it has components $s_\alpha = \exp\{(H^0_\alpha - H_\alpha)/T\}$. For the case of Markovian copolymers this functional can be presented as follows:

$$\mathcal{G}[\mathbf{s}] = \frac{1}{V}\int d\vec{r}(s_1U_1\nu_{10} + s_2U_2\nu_{20}) = \frac{Y^0}{V}\int d\vec{r}(s_1V_1v_1 + s_2V_2v_2), \tag{4}$$

where dependence of $\mathbf{U}$ and $\mathbf{V}$ on $\mathbf{s}$ is found from the set of four equations,

$$\begin{gathered} KU_\alpha - (U_1s_1\nu_{1\alpha} + U_2s_2\nu_{2\alpha}) = v_\alpha Y^0 \quad (\alpha = 1,2), \\ KV_\alpha - (\nu_{\alpha1}s_1V_1 + \nu_{\alpha2}s_2V_2) = \nu_{\alpha0}. \end{gathered} \tag{5}$$

Linear operator K in the left-hand side of Eqs. (5) is inverse to the integral operator with kernel $\lambda(\vec{r}-\vec{r}')$ which has the sense of the conditional probability for the neighbor of unit situated at point $\vec{r}'$ to be at point $\vec{r}$. Kernel λ is a rapidly decreasing function which vanishes at distance $|\vec{r}-\vec{r}'|$ comparable with a monomeric unit size a. Since essentially larger spatial scales are of actual practical interest, any normalized function satisfying the above condition might be chosen as λ. Its Fourier transform $x \equiv \tilde{\lambda}(q)$ is governed exclusively by the wave vector modulus $q \equiv |\vec{q}|$. Being positive quantity x turns into unity at $q=0$ and vanishes at $q\to\infty$. Function $\tilde{\lambda}(q) = \exp(-a^2q^2/6)$, traditionally employed for numerical calculations, meets these conditions.

Functional (3) is controlled by dimensionless units' densities $\{\mathbf{\Phi}_\alpha\}$ both explicitly and implicitly through field $\mathbf{H}$. Its dependence on Φ is determined from expressions

$$\mathbf{\Phi}_1 = \mathbf{\Phi}^0 s_1U_1V_1, \quad \mathbf{\Phi}_2 = \mathbf{\Phi}^0 s_2U_2V_2, \tag{6}$$

which are obtained from the conditions of vanishing of the first order variational derivatives of functional (3) with respect to H_1 and H_2. As for the explicit dependence of $\Delta\mathcal{F}$ (3) on $\mathbf{\Phi}$, this is specified by function $f^*(\mathbf{\Phi})$ having the following appearance:[17,21]

$$\frac{f^*(\mathbf{\Phi})v}{T} = (1-\Phi)\ln(1-\mathbf{\Phi}) + \mathbf{\Phi} - \frac{1}{T}(\gamma_{11}\mathbf{\Phi}_1^2 + \gamma_{22}\mathbf{\Phi}_2^2 + 2\gamma_{12}\mathbf{\Phi}_1\mathbf{\Phi}_2), \tag{7}$$

where $\mathbf{\Phi} = \mathbf{\Phi}_1 + \mathbf{\Phi}_2$. Hence, expressions (4) and (7) along with equations (5) and (6) completely define density functional (3) defined on the set of smooth functions $\mathbf{\Phi}_1(\vec{r}), \mathbf{\Phi}_2(\vec{r})$ lying within region $0 \leqslant \mathbf{\Phi}_1, \mathbf{\Phi}_2 < 1, \mathbf{\Phi}_1 + \mathbf{\Phi}_2 < 1$.

Equilibrium spatial distributions $\mathbf{\Phi}_1^e(\vec{r})$ and $\mathbf{\Phi}_2^e(\vec{r})$ of the units' volume fractions in nuclei are found by the minimization of the density functional. Necessary conditions of its minimum are

$$\frac{v\,\delta\mathcal{F}[\mathbf{\Phi}]}{\delta\Phi_\alpha(\vec{r})} = -H_\alpha(\vec{r}) + \mu^*_\alpha(\mathbf{\Phi}(\vec{r})) = 0 \quad (\alpha = 1,2), \tag{8}$$

where the following designation is used:

$$\mu_{\alpha}^{*}(\mathbf{\Phi}) \equiv \frac{v\partial f^{*}}{\partial \mathbf{\Phi}_{\alpha}} = -T\ln(1-\mathbf{\Phi}) - 2(\gamma_{\alpha 1}\mathbf{\Phi}_1 + \gamma_{\alpha 2}\mathbf{\Phi}_2). \tag{9}$$

Expression (8) establishes the relation between $\mathbf{H}(\vec{r})$ and $\mathbf{\Phi}(\vec{r})$ taken on functional $\Delta\mathcal{F}$ extremal. With this relation in mind one can find dimensionless equilibrium densities of units in nuclei from the solution $\mathbf{\Phi}_1=\mathbf{\Phi}_1^e, \mathbf{\Phi}_2=\mathbf{\Phi}_2^e$ of equations (5) and (6), where vector $\mathbf{s}$ components read as

$$s_{\alpha} = \exp\{[\mu_{\alpha}^{*}(\mathbf{\Phi}^0) - \mu_{\alpha}^{*}(\mathbf{\Phi})]/T\}. \tag{10}$$

These equations at any values of external parameters have the trivial solution

$$U_{\alpha}(\vec{r}) \equiv U_{\alpha}^0 = X_{\alpha}^0, \quad V_{\alpha}(\vec{r}) \equiv V_{\alpha}^0 = 1, \quad \Phi_{\alpha}(\vec{r}) \equiv \Phi_{\alpha}^0 = X_{\alpha}^0\Phi^0, \quad s_{\alpha}(\vec{r}) \equiv 1 \tag{11}$$

describing spatially homogeneous state of a system. It becomes thermodynamically absolutely unstable on the spinodal, whose mathematical condition is the loss of the positive definiteness by matrix

$$\mathbf{M}^0(x) = [\Phi^0\mathbf{X}^0(x)]^{-1} - \mathbf{C}^0 v^{-1}, \tag{12}$$

where x is a dummy variable laying within the interval between 0 and 1. The right-hand side of this expression comprises copolymer structure matrix $\mathbf{X}^0(x)$ and matrix of direct correlation functions $\mathbf{C}^0 \equiv \mathbf{C}(\Phi^0)$ describing the melt of monomeric units. In the framework of the simplest "lattice liquid" model[21] elements of the latter matrix look as

$$\frac{C_{\alpha\beta}(\mathbf{\Phi})}{v} \equiv -\frac{v\partial^2 f^{*}(\mathbf{\Phi})}{T\partial\mathbf{\Phi}_{\alpha}\partial\mathbf{\Phi}_{\beta}} = -\frac{1}{1-\mathbf{\Phi}} + \frac{2\gamma_{\alpha\beta}}{T}. \tag{13}$$

As for the structure matrix its elements in a simple way[17]

$$X_{\alpha\beta}^0(x) = X_{\alpha}^0\delta_{\alpha\beta} + W_{\alpha\beta}^0(x) + W_{\beta\alpha}^0(x) \tag{14}$$

are related to the elements of matrix $\mathbf{W}^0(x)$ of generating functions of two-point chemical correlators of macromolecules in the principal monophase system. For a Markovian copolymer the following expressions hold:

$$W_{\alpha\beta}^0(x) = X_{\alpha}^0 L_{\alpha\beta}^0(x), \quad \text{where } \mathbf{L}^0(x) = (\mathbf{E} - x\mathbf{Q})^{-1}x\mathbf{Q}, \tag{15}$$

which in combination with expressions (13) and (14) completely define matrix (12). This loses the positive definiteness when its minimal eigenvalue vanishes. If it happens at point $x=1$ or at any other point within interval $0<x<1$ we are dealing with trivial or nontrivial branch of SC, respectively. The explicit equations enabling one to find both branches of the spinodal of a binary Markovian copolymer in terms of the elements of matrices $\mathbf{X}^0(x)$ and $\mathbf{C}^0$ have been presented and analyzed earlier.[9,10]

At some values of the input parameters, the set of equations (5), (6), and (10) can have solutions differing from the trivial one (11). Among these nontrivial solutions $\mathbf{\Phi}=\mathbf{\Phi}^e$ corresponding to the density functional extremals only those have physical meaning on which this functional has a minimum. Just such solutions describe the nuclei of the incipient phase.

A necessary and sufficient condition for a spatially homogeneous nontrivial solution of Eqs. (5), (6), and (10) to provide a minimum of the density functional is the positive definiteness of matrix

$$\mathbf{M}^e(x) = [\Phi^0\mathbf{X}^e(x)]^{-1} - \mathbf{C}^e v^{-1}, \tag{16}$$

where $\mathbf{C}^e \equiv \mathbf{C}(\Phi^e)$ while elements of matrix $\mathbf{X}^e(x)$ are defined by the following expression:

$$X_{\alpha\beta}^e(x) = [\mathbf{\Phi}_{\alpha}^e/\mathbf{\Phi}^0]\delta_{\alpha\beta} + W_{\alpha\beta}^e(x) + W_{\beta\alpha}^e(x) \tag{17}$$

and the designation is employed

$$W^e_{\alpha\beta}(x) = s^e_\alpha s^e_\beta U^e_\alpha L^e_{\alpha\beta}(x) V^e_\beta. \tag{18}$$

Here s^e_α is found by formulas (9) and (10) via substitution of quantities Φ^e_α for Φ_α whereas given $\mathbf{\Phi}^e_\alpha$ values of U^e_α and V^e_α represent the solution of a set of four linear algebraic equations (5). As for matrix $\mathbf{L}^e(x)$ whose elements are $L^e_{\alpha\beta}(x)$ it has the following appearance:

$$\mathbf{L}^e(x) = (\mathbf{E} - x\mathbf{QS})^{-1} x\mathbf{Q}, \tag{19}$$

where $\mathbf{S}$ is the diagonal matrix with elements $s_\alpha \delta_{\alpha\beta}$. Because Eqs. (5), (6), and (10) are nonlinear they can have more than one solution $\mathbf{\Phi}^e$ at the same values of external parameters. Among these extremals only those have physical meaning which provide positive definiteness of matrix (16). Each such solution, $\mathbf{\Phi}^i$, specifies volume fractions $\mathbf{\Phi}^i_1$ and $\mathbf{\Phi}^i_2$ of monomeric units of the ith phase nuclei.

Equations (5), (6), and (10) can have solutions $\Phi^e(\vec{r})$ taking on different values at different points $\vec{r}$ of the Euclidean space. Among these extremals those should be chosen which minimize the density functional. To make this choice it is convenient to consider its second variation represented as a quadratic functional with respect to variations of volume fractions of monomeric units. Such a treatment will be realized in the next section. Having found all local minima of the density functional it is necessary to reveal among them the global one. Equating the value of the above functional in this minimum to its value in the minimum at the trivial solution we will get the condition for finding the cloud point hypersurface. This may be formulated mathematically in terms of the functional

$$R[\mathbf{\Phi}^i] = \int \mathrm{d}\vec{r} \left\{ T\Phi^0 Y^0 \sum_{\alpha=1}^{2} V_\alpha (1 - s^i_\alpha \nu^i_\alpha) + v[P^*(\mathbf{\Phi}^0) - P^*(\mathbf{\Phi}^i)] \right\}, \tag{20}$$

where the following designation is used:

$$vP^*(\mathbf{\Phi}) = -T[\ln(1-\mathbf{\Phi}) + \mathbf{\Phi}] - (\gamma_{11}\mathbf{\Phi}^2_1 + \gamma_{22}\mathbf{\Phi}^2_2 + 2\gamma_{12}\mathbf{\Phi}_1\mathbf{\Phi}_2). \tag{21}$$

Conditions for determining CPC are evident,

$$R[\mathbf{\Phi}^I] = 0, \quad R[\mathbf{\Phi}^i] > 0 \quad \text{at } i \neq I, \tag{22}$$

where superscript I specifies the global minimum of the density functional. Depending on whether $\mathbf{\Phi}^I$ is homogeneous or spatially periodical solution of Eqs. (5), (6), and (10) the conditions (22) refer to the trivial or nontrivial CPC branch, respectively. For the first of them, functional $R[\mathbf{\Phi}^I]$ reduces to function $R(\mathbf{\Phi}^I)$ vanishing when the pressure in nuclei and the principle phase is the same.

All mathematical formulas presented in the foregoing are valid for copolymers whose macromolecules are described by an arbitrary Markov chain. When it is symmetric these formulas become noticeably simpler. The condition of such a symmetry is

$$v_1 \nu_{12} \nu_{20} = v_2 \nu_{21} \nu_{10}. \tag{23}$$

For statistically symmetric Markovian copolymers the following expressions hold:

$$v_1 = \frac{\nu_{21}\nu_{10}}{\nu_{21}\nu_{10} + \nu_{12}\nu_{20}}, \quad v_2 = \frac{\nu_{12}\nu_{20}}{\nu_{21}\nu_{10} + \nu_{12}\nu_{20}}, \tag{24}$$

$$X^0_1 = \frac{\nu_{21}}{\nu_{12} + \nu_{21}}, \quad X^0_2 = \frac{\nu_{12}}{\nu_{12} + \nu_{21}}, \quad Y^0 = X^0_1 \nu_{10} + X^0_2 \nu_{20}. \tag{25}$$

Interestingly, the composition vector $\mathbf{X}^0$ of such copolymers coincides with the stationary vector $\boldsymbol{\pi}$ of the nonabsorbing ergodic Markov chain[7] describing macromolecules of infinite length. From

the symmetry condition (23) there follows the proportionality of the components of vectors **U** and **V**:

$$U_1(\vec{r}) = \pi_1 V_1(\vec{r}), \quad U_2(\vec{r}) = \pi_2 V_2(\vec{r}). \tag{26}$$

Consequently, in case of symmetric Markovian copolymers the first pair of equations (5) may be omitted when finding the density functional extremals. Besides, the matrix of the generating functions of the two-point chemical correlators of such copolymers is symmetric so that equalities $W^0_{\beta\alpha}(x) = W^0_{\alpha\beta}(x)$ and $W^e_{\beta\alpha}(x) = W^e_{\alpha\beta}(x)$ may be taken into account when considering relationships (14) and (17), respectively.

Once the mathematical problem of a phase diagram construction is completely formulated let us address the bifurcation analysis of the above nonlinear equations. Of prime interest here is the behavior of their solutions at scales essentially larger than monomeric unit size a, which is the scale where function λ vanishes. With this in mind the integral operator in Eqs. (5) may be replaced by the differential one as it is customary in statistical physics of polymers.[23] Thus, the first term in the second pair of equations (5) will read

$$KV_\alpha \equiv \int \lambda^{(-1)}(\vec{r} - \vec{r}\,')V_\alpha(\vec{r}\,')\mathrm{d}\vec{r}\,' \to V_\alpha(\vec{r}) - \frac{a^2}{6}\Delta V_\alpha(\vec{r}), \tag{27}$$

where Δ is the Laplace operator. Below, for convenience sake, instead of $\vec{r}$ we will use dimensionless variable $\sqrt{6}\vec{r}/a$.

III. THE BIFURCATION ANALYSIS

Construction of phase diagrams for heteropolymer liquids is a rather complicated global nonlinear problem. It is a reason why only Landau theory of phase transitions has been still applied to this problem, so only the vicinity of critical point could be correctly treated. In order to go beyond the Landau theory we have replaced the solution of global nonlinear problem by subsequent solution of local problems using nonlinear bifurcation analysis and continuation procedure by parameters fixing the temperature and characteristic size of the nonhomogeneous structure.

We start with a determination of nontrivial solutions of the equations (5), (6), and (10) branching from trivial solution in vicinity of the spinodal points. For that we consider the nonlinear operator $\mathbf{A}(\mathbf{U},\mathbf{V},\mathbf{s},\mathbf{\Phi},h)$, which is defined by the left-hand sides of equations (5), (6), and (10) depending on vector functions **U**, **V**, **s**, $\mathbf{\Phi}$ as well as parameter $h = 2\gamma_{12}/T$. Let the vectors $\mathbf{z} = [\mathbf{U}(h),\mathbf{V}(h),\mathbf{s}(h),\mathbf{\Phi}(h)]$ and $\mathbf{z}^0 = [\mathbf{U}^0(h),\mathbf{V}^0(h),\mathbf{s}^0(h),\mathbf{\Phi}^0(h)]$ correspond to the spatially homogeneous solution of these equations and h^* to be a critical value of parameter h, corresponding to spinodal point. Linear operator $\mathbf{L}[\mathbf{z}^0,h]$ being a differential of operator **A** with eigenvalue vanishing at $h = h^*$, may be determined by the following relations [where vectors $\delta\mathbf{z} = (\delta\mathbf{U},\delta\mathbf{V},\delta\mathbf{s},\delta\mathbf{\Phi})$, $\alpha,\beta = \mathbf{1},\mathbf{2},$]:

$$\mathbf{L}(\mathbf{z}^0,h)\delta\mathbf{z}: \begin{bmatrix} \nabla^2\delta U_\alpha - \delta U_\alpha + \sum_\beta Q_{\beta\alpha}(s_\beta\delta U_\beta + U_\beta\delta s_\beta) \\ \nabla^2\delta V_\alpha - \delta V_\alpha + \sum_\beta Q_{\alpha\beta}(s_\beta\delta V_\beta + V_\beta\delta s_\beta) \\ s_\alpha^{-1}\delta s_\alpha - \sum_\beta (-1/(1-\Phi) + h\gamma_{\alpha\beta}/\gamma_{12})\delta\Phi_\beta \\ \delta\Phi_\alpha - \Phi^0(\delta s_\alpha U_\alpha V_\alpha + s_\alpha V_\alpha\delta U_\alpha + s_\alpha U_\alpha\delta V_\alpha) \end{bmatrix}. \tag{28}$$

The components of the vector $\mathbf{z}^0$ determines in particular the trivial solution with relations (11).

The systems of equations (5), (6), and (10) may be represented in the vicinity of $\mathbf{z}^0$ in the following form:

$$\mathbf{A}(\mathbf{z},h) = \mathbf{L}(\mathbf{z}^0,h)(\mathbf{z}-\mathbf{z}^0) + \mathbf{F}(\mathbf{z}^0,\mathbf{z}-\mathbf{z}^0,h), \tag{29}$$

where norm $\mathbf{F}$ $(\mathbf{z}^0,\mathbf{z}-\mathbf{z}^0,h)$ is $O((\mathrm{norm}(\mathbf{z}-\mathbf{z}^0))^2)$. One can introduce matrix $J(q)$,

$$J(q) = \begin{bmatrix} -(q^2+1)E + Q*s & 0 & Q*U & 0 \\ 0 & -(q^2+1)E + Qs & QV & 0 \\ 0 & 0 & s^{-1} & -C \\ -\Phi^0 sV & -\Phi^0 sU & -\Phi^0 UV & E \end{bmatrix} \tag{30}$$

containing the two-dimensional blocks, sU, sV, UV being the products of diagonal matrixes with elements s_α, U_α, V_α. The elements of matrix C are determined by relations (21), E is unit matrix.

The trivial spinodal $h(\Phi^0)$ is determined by the equation $\det J(0)=0$, nontrivial one by two equations, $\det J(q)=0$, $\partial(\det J(q)/\partial q^2 = 0$, and condition $\partial^2 \det J(q)/(\partial q^2)^2 > 0$. In the case of trivial spinodal the eigenfunction $\mathbf{g}(\mathbf{r})$ of the operator L corresponding to vanishing eigenvalue is the eigenvector $\mathbf{g}_1$ of matrix $J(0)$. In the case of nontrivial spinodal similar eigenfunction is the product of eigenvector $\mathbf{g}_1$ of matrix $J(q)$ (with eigenvalue which is equal to zero) and eigenfunction of the Laplace operator under periodic boundary conditions with eigenvalue $-q^2$. This eigenvalue in general is degenerate, i.e., the dimension of proper subspace is greater than 1 and depends on the symmetry of the considered domain. We will consider below the one-dimensional case and denote the first component of vector $\mathbf{r}$ by x. In this case the dimension of proper subspace is 2 and

$$\mathbf{g}(x) = \mathbf{g}_1(a\cos(qx) + b\sin(qx)), \tag{31}$$

where a and b are the arbitrary constants. In this case the degeneracy is the consequence of invariance of the periodic solutions with respect to translation. Later on for the component U_1 we change the periodic conditions from $\partial U_1/\partial x = 0$ to $x=0$ and $x=2\pi/q$. Then it is possible to set $b=0$.

Dealing with bifurcation analysis we introduce the auxiliary parameter ε and represent the solution $\mathbf{z}=(\mathbf{U},\mathbf{V},\mathbf{s},\mathbf{\Phi})$ of the equation

$$\mathbf{A}(\mathbf{U},\mathbf{V},\mathbf{s},\mathbf{\Phi},h) = 0 \tag{32}$$

and parameter h in vicinity of its critical value h^* as asymptotic power series by subsidiary parameter ε, which characterizes the amplitude deviation as the unknown solution from the initial

$$h = h^* + \varepsilon \cdot h^{(1)} + \varepsilon^2 h^{(2)} + \varepsilon^3 h^{(3)} + \cdots,$$

$$\mathbf{z} = \mathbf{z}^{(0)} + \varepsilon \mathbf{z}^{(1)} + \varepsilon^2 \mathbf{z}^{(2)} + \varepsilon^3 \mathbf{z}^{(3)} + \cdots. \tag{33}$$

We present the left-hand side of Eq. (32) as the Taylor series in the vicinity of value $h=h^*$ and vector $\mathbf{z}^{(0)}$,

$$\mathbf{z}^{(0)} = \mathbf{U}^0(h^*), \quad \mathbf{V}^0(h^*), \quad \mathbf{s}^0(h^*), \quad \mathbf{\Phi}^0(h^*).$$

Then we select the terms of identical order with respect to ε and equate them to zero. The equations for $\mathbf{z}^{(1)}$ can be written as follows:

$$\mathbf{L}(\mathbf{z}^{(0)},h^*)\mathbf{z}^{(1)} = 0. \tag{34}$$

Consequently, $\mathbf{z}^{(1)}$ is eigenfunction of operator $\mathbf{L}$ $(\mathbf{z}^{(0)},h^*)$ corresponding to zero eigenvalue. The following equations can be found recursively:

$$\mathbf{L}(\mathbf{z}^{(0)},h^*)\mathbf{z}^{(i)} = \varphi_i(\mathbf{z}^{(1)},\ldots,\mathbf{z}^{(i-1)},h^{(i-1)}). \tag{35}$$

The vector function φ_i on the right-hand side of Eq. (35) is the linear function by $h^{(i-1)}$ and the degree i polynomial of the components of vectors $\mathbf{z}^{(k)}$ $(k<i)$. The function $\varphi_\mathbf{i}$ for $i=2,3$, can be presented as

$$\varphi_2(\mathbf{z}^{(1)},\ldots,\mathbf{z}^{(i-1)},h^{(i-1)}) = -1/2\sum_{k,j}\frac{\partial^2\mathbf{F}}{\partial z_k\partial z_j}z_k^{(1)}z_j^{(1)} - \sum_j\frac{\partial^2\mathbf{F}}{\partial z_j\partial h}z_j^{(1)}h^{(1)}, \tag{36}$$

$$\varphi_3(\mathbf{z}^{(1)},\ldots,\mathbf{z}^{(i-1)},h^{(i-1)}) = -\left(1/2\sum_{k,j}\frac{\partial^2\mathbf{F}}{\partial z_k\partial z_j}(z_k^{(1)}z_j^{(2)}+z_k^{(2)}z_j^{(1)}) + \sum_j\frac{\partial^2\mathbf{F}}{\partial h\partial z_j}(z_j^{(2)}h^{(1)}+z_j^{(1)}h^{(2)}) + 1/6\sum_{j,k,l}\frac{\partial^3\mathbf{F}}{\partial z_j\partial z_k\partial z_l}z_j^{(1)}z_k^{(1)}z_l^{(1)}\right). \tag{37}$$

The operator $\mathbf{L}$ is Fredholm operator of index 0. Therefore the condition of the solution existence for Eq. (35) is the orthogonality of the vector function $\varphi_\mathbf{i}$ to the eigenfunction corresponding to zero eigenvalue of operator conjugate to $\mathbf{L}$ $(\mathbf{z}^{(0)},h^*)$ This condition determines the value of $h^{(i-1)}$. Such a procedure corresponds to Lyapunov–Shmidt method.[24]

In the case of multiple zero eigenvalues, $\mathbf{z}^{(1)}$ is linear combination of linear independent eigenfunctions of operator $\mathbf{L}$. Therefore it is necessary to require the orthogonality $\varphi_\mathbf{i}$ to all independent eigenfunctions corresponding to vanishing eigenvalue of operator conjugate to $\mathbf{L}$ $(\mathbf{z}^{(0)},h^*)$. These conditions determine $h^{(i-1)}$ and the coefficients of the linear combination of independent eigenfunctions.

IV. BIFURCATION OF NONHOMOGENEOUS STRUCTURE FROM HOMOGENEOUS SOLUTIONS

Let $\det J(q^*)=0$ for the function $\mathbf{z}^{(0)}$, which is the trivial or nontrivial homogeneous solution of the equation (32). We consider further the one-dimensional symmetrical case for $m=2$. This case corresponds to the relations (23) and (24) and it is possible to consider the equation for $\mathbf{V}$ only. Then $\mathbf{z}^{(i)}=(\mathbf{V},\mathbf{s},\mathbf{\Phi})$ and in the first approximation $\mathbf{z}^{(1)}=\mathbf{g}\cos(q^*x)$, where $\mathbf{g}$ is the eigenvector corresponding to the zero eigenvalue of the matrix $J(q^*)$. The function φ_2 can be written as follows:

$$\varphi_2 = \begin{bmatrix} Q\mathbf{s}^{(1)}\mathbf{V}^{(1)} \\ -1/2(\mathbf{s}^{(0)})^{-2}(\mathbf{s}^{(1)})^2 - h^{(1)}\gamma\mathbf{\Phi}^{(1)} + \left(\dfrac{\mathbf{\Phi}_1^{(1)}+\mathbf{\Phi}_2^{(1)}}{1-\mathbf{\Phi}^{(0)}}\right)^2 \\ -2\mathbf{\Phi}^{(0)}\mathbf{s}^{(1)}\mathbf{V}^{(0)}\mathbf{V}^{(1)}\Pi - \mathbf{\Phi}^{(0)}\mathbf{s}^{(0)}(\mathbf{V}^{(1)})^2 \end{bmatrix},$$

where the following designations are used:

$$\Pi = \mathrm{diag}[\pi_1,\pi_2], \quad s^{(1)} = \mathrm{diag}[\mathbf{s}_1^{(1)},\mathbf{s}_2^{(1)}], \quad \mathbf{V} = \mathrm{diag}[V_1^{(1)},V_2^{(1)}], \quad \mathbf{\Phi}^{(1)} = \mathrm{diag}[\mathbf{\Phi}_1^{(1)},\mathbf{\Phi}_2^{(2)}].$$

The orthogonality condition leads to the relation $h^{(1)}=0$. The vector $\mathbf{z}^{(2)}$ in the second approximation has the form

$$\mathbf{z}^{(2)} = \mathbf{a} + \mathbf{b}\cos(2q^*x) + \mathbf{a}_h h^{(2)}. \tag{38}$$

The vectors $\mathbf{a}$, $\mathbf{b}$, $\mathbf{a}_h$ are determined from the following equations:

$$J(0)\mathbf{a} = \mathbf{r}_0, \quad J(2q^*)\mathbf{b} = \mathbf{r}_0, \quad J(0)\mathbf{a}_h = \mathbf{r}_h. \tag{39}$$

The expressions for vectors $\mathbf{r}_0$ and $\mathbf{r}_h$ are presented in Appendix A. The vector $\mathbf{r}_h$ is zero for bifurcation from trivial solution, therefore $\mathbf{a}_h$ also is zero. The value $h^{(2)}$ can be determined from the orthogonality condition φ_3 with respect to the eigenfunction corresponding to the zero eigenvalue of the operator conjugate to $\mathbf{L}$ $(\mathbf{z}^{(0)},h^*)$. Its expression is also presented in Appendix A.

The type of bifurcation is determined by sign $h^{(2)}$. If $h^{(2)}>0$, then the bifurcation is supercritical and pair of nontrivial solutions exists for $h>h^*$. For $h^{(2)}<0$ the bifurcation is subcritical, so that pair of nontrivial solutions exists for $h<h^*$. When dealing with supercritical bifurcation in the point of nontrivial spinodal, nontrivial solution is stable; in the case of subcritical bifurcation

it is unstable. The disposition of the trivial (h_{st}) and nontrivial spinodals (h_{sn}) is determined by the type of bifurcation in the point of trivial spinodal. If $h_{st}<h_{sn}$, a transcritical nontrivial homogeneous solution branches from trivial spinodal. If $h_{st}>h_{sn}$, the equation $J(q)=0$ has two roots q_l and q_r ($q_l<q_r$), between the points $h=h_{sn}$ and $h=h_{st}$ and, respectively, two pairs of branches of nongomogeneous extremals appear. At $h=h_{st}$ is $q_l=0$, and both nontrivial nonhomogeneous and nontrivial homogeneous solutions can branch from trivial spinodal. This case will be considered below.

V. BIFURCATION IN THE SPINODAL POINT

Let $h_{sn}<h_{st}$, then zero is a multiple eigenvalue of the operator $\mathbf{L}$ $(\mathbf{z}^{(0)},h*)$. Simultaneously, $\det J(0)$ and $\det J(q*)$ are equal to zero and $\mathbf{g}^{(0)}$, $\mathbf{g}(q*)$ are eigenvectors of matrixes $J(0)$ and $J(q*)$ corresponding to zero eigenvalues. The first approximation can be expressed as follows:

$$\mathbf{z}^{(1)}=\alpha\mathbf{g}^{(0)}+\beta\mathbf{g}(q*)\cos(q*x).$$

The constants α and β are found from the orthogonality condition of the right-hand side of φ_2 in (35) with respect to two eigenfunctions $\mathbf{g}^{(0)T}$, $\mathbf{g}^{T}(q*)\cos(q*x)$ of operator conjugate to $\mathbf{L}$ $(\mathbf{z}^{(0)},q*)$. The equations for determination of the ratio α/β and $h^{(1)}$ are written as

$$\alpha^2(\mathbf{g}^{(0)T},\mathbf{r}_{00})+\beta^2(\mathbf{g}^{(0)T},\mathbf{r}_{22})=-\alpha h^{(1)}z_{h0},$$

$$\alpha\beta(\mathbf{g}^{T}(q*),\mathbf{r}_{02})=-h^{(1)}z_{h2}\beta.$$

Here $(\mathbf{f}(\mathbf{x}),\mathbf{g}(x))$ is the scalar product vector function in $L^2[0,l]$, the formulas for vectors $\mathbf{r}_{00}$, $\mathbf{r}_{02}$, $\mathbf{r}_{22}$ are presented in Appendix A,

$$z_{h0}=(\gamma\tilde{\mathbf{g}},\tilde{\mathbf{g}}^{T}),\quad z_{h2}=(\gamma\tilde{\mathbf{g}}(q*),\tilde{\mathbf{g}}^{T}(q*)),$$

where

$$\tilde{\mathbf{g}}=[\mathbf{g}^{(0)}[5],\mathbf{g}^{(0)}[6]],\quad \tilde{\mathbf{g}}^{T}=[\mathbf{g}^{(0)T}[3],\mathbf{g}^{(0)T}[4]],$$

$$\tilde{\mathbf{g}}(q*)=[\mathbf{g}(q*)[5],\mathbf{g}(q*)[6]],\quad \tilde{\mathbf{g}}^{T}(q*)=[\mathbf{g}^{T}(q*)[3],\mathbf{g}^{T}(q*)[4]].$$

The system ( ) has several solutions,

(1) $\beta=0$, $h^{(1)}=-\alpha(\mathbf{g}^{(0)T},\mathbf{r}_{00})/z_{h0}$,
(2) $\beta\neq 0$, $h^{(1)}=-(\mathbf{g}^{(0)T},\mathbf{r}_{02})/z_{h2}$,

$$(\beta/\alpha)^2=(z_{ho}/z_{h2}\cdot(\mathbf{g}^{T}(q*),\mathbf{r}_{02})-(\mathbf{g}^{(0)},\mathbf{r}_{00}))/(\mathbf{g}^{(0)T},\mathbf{r}_{22})=c.$$

If $c>0$, then two nonhomogeneous solutions and one homogeneous solution ($\beta=0$) exist in vicinity $h=h*$, otherwise only homogeneous solution exists for $\beta=0$.

If $h_{ns}>h_{st}$ (or if h_{ns} does not exist), only the solution for $\beta=0$ exists. From $h^{(1)}\neq 0$ it follows that the bifurcation is transcritical. The condition $h^{(1)}=0$ in spinodal point corresponds to the critical point in Landau theory.

VI. ANALYSIS OF THE STABILITY

The stability condition for the extremals is positive definiteness of the second variation of the free energy, which is the squared functional with respect to variation $\delta\mathbf{\Phi}_\alpha$, and may be written as

$$\delta^2\mathcal{F}=1\Big/V\int\left(\sum_\alpha\sum_\beta(-\delta H_\alpha+\delta\mu_\alpha^{*})\delta\Phi_\beta\right)d\mathbf{x}. \tag{40}$$

The variations δH_α are coupled with the variations $\delta\mathbf{\Phi}_\alpha$ by the conditions (5) and (6),

$$\delta H_\alpha = T(-\delta\Phi_\alpha/\Phi^e_\alpha + \delta U_\alpha/U^e_\alpha + \delta V_\alpha/V^e_\alpha), \tag{41}$$

$$\begin{aligned}\nabla^2\delta U_\alpha - \delta U_\alpha - \sum_i Q_{i\alpha} s^e_i U^e_i/V^e_i \delta V_i &= -1/\Phi^0 \sum_i Q_{i\alpha}/V^e_i \delta\mathbf{\Phi}_i,\\ \nabla^2\delta V_\alpha - \delta V_\alpha - \sum_i Q_{\alpha i} s^e_i V^e_i/U^e_i \delta U_i &= -1/\Phi^0 \sum_i Q_{\alpha i}/U^e_i \delta\mathbf{\Phi}_i.\end{aligned} \tag{42}$$

The coefficients of the linear equations (41) and (42) are determined on the extremal $(U^e_i, V^e_i, s^e_i\mathbf{\Phi}^e_i)$. It is necessary to convert the operator, which is defined by the left-hand sides of Eqs. (42) for obtaining the explicit form of the functional (40) via $\delta\mathbf{\Phi}_\alpha\ \delta\mathbf{\Phi}_\beta$. Because it is a rather unsolvable problem, for direct calculations we restrict ourselves by the set of periodic fluctuations $\delta\mathbf{\Phi}_\alpha$, $\delta\mathbf{\Phi}_\beta$ with wave numbers q^* and introduce Fourier expansions for $\delta\mathbf{\Phi}_\alpha$, $\delta\mathbf{\Phi}_\beta$,

$$\delta\Phi_\alpha = \sum_k \delta\Phi^{(\alpha c)}_k \cos(kq^* x) + \delta\Phi^{(\alpha s)}_k \sin(kq^* x).$$

The system of Eqs. (41) and (42) is linear with respect to δU, δV, $\delta\mathbf{\Phi}$, therefore its solution can be presented in the form

$$\delta U_\alpha = \sum_{k,i} (U^{ic}_{\alpha k}(x)\delta\mathbf{\Phi}^{(ic)}_k + U^{is}_{\alpha k}(x)\delta\mathbf{\Phi}^{(is)}_k), \tag{43}$$

$$\delta V_\alpha = \sum_{k,i} (V^{ic}_{\alpha k}(x)\delta\mathbf{\Phi}^{(ic)}_k + V^{is}_{\alpha k}(x)\delta\mathbf{\Phi}^{(is)}_k), \tag{44}$$

where the functions $U^{ic}_{\alpha k}(x)$, $V^{ic}_{\alpha k}(x)$ are solutions of the system of nonhomogeneous equations,

$$\begin{aligned}\nabla^2\delta U^{ic}_{\alpha k} - \delta U^{ic}_{\alpha k} - \sum_j Q_{j\alpha} s^e_j U^e_j/V^e_j \delta V^{ic}_{jk} &= -1/\mathbf{\Phi}^0 Q_{\alpha i}/V^e_i \cos(kq^* x),\\ \nabla^2\delta V^{ic}_{\alpha k} - \delta V^{ic}_{\alpha k} - \sum_j Q_{\alpha j} s^e_j V^e_j/U^e_j \delta U^{ic}_{jk} &= -1/\mathbf{\Phi}^0 Q_{\alpha i}/U^e_i \cos(kq^* x),\end{aligned} \tag{45}$$

and the functions $U^{is}_{\alpha k}(x)$, $V^{is}_{\alpha k}(x)$ are solutions of the same systems with substitution $\cos(kq^*x)$ by $\sin(kq^*x)$. Using the relations (41), (43), and (44), the functional (40) may be presented in the matrix form regarding $\delta\mathbf{\Phi}^{(ic)}_k$, $\delta\mathbf{\Phi}^{(is)}_k$ with elements,

$$(\delta^2\mathcal{F})^{cc}_{ij,kl}, (\delta^2\mathcal{F})^{cs}_{ij,kl}, (\delta^2\mathcal{F})^{sc}_{ij,kl}, (\delta^2\mathcal{F})^{ss}_{ij,kl}.$$

Their expressions are presented in Appendix B. Thus, the analysis of stability can be reduced to determination of the spectrum of matrix. When using km harmonics, the dimension of this matrix is $m\cdot(2km+1)$.

VII. NUMERICAL CALCULATIONS

While calculating the phase diagrams, the basic difficulty is the solution of nonlinear systems (5), (6), and (10) for extremals. We used for this goal the iterated Newton method requiring a good starting approximation near bifurcation points if dealing with bifurcation analysis. Then we used a continuation procedure by parameter h with motion along tangent to curve $\mathbf{z}(h)$. Periodic boundary problem for linearized systems on every iteration was solved by the periodic sweep method.[25] Similar procedure was used for the solution of the systems of equation for $\partial\mathbf{z}/\partial h$ by the method of tangents. The operator $\mathbf{L}$ determined by (28) has zero eigenvalue in the turn point of curve $\mathbf{z}(h)$ and method of tangents cannot be used. In this case a change of the sign of step for parameter h

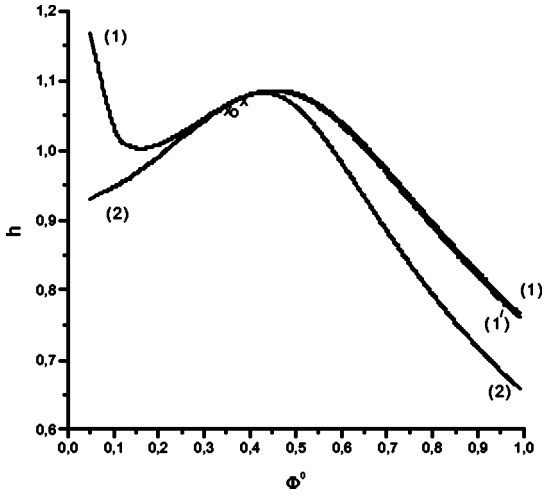

FIG. 1. Phase diagram for system (1). The curves (1), (2) are spinodal and binodal, respectively [for Φ^0 changing from 0 to 0.4 they are trivial ones, for $\Phi^0>0.4$, curve (1′), nontrivial spinodal], $\Phi^0\cong 0.38$ is the critical point (marked by ○), $\Phi^0\cong 0.4$ is the Lifshitz point (marked by ×).

and starting approximation were provided by extrapolation using two previous points. The calculations were performed for different copolymer systems and corresponding phase and bifurcation diagrams are presented in Figs. 1–5.

Melt of diblock copolymers with structural matrix, $Q=\begin{pmatrix}0.9 & 0.1 & 0\\ 0 & 0.95 & 0.05\end{pmatrix}$, and matrix of interaction $\gamma/\gamma_{12}(1;1;1.5)$.

In this system only the trivial spinodal exists for values $\mathbf{\Phi}^0<0.4$, and both the trivial and nontrivial spinodals exist for $\Phi^0>0.4$. The birth of nonhomogeneous structures in all points of nontrivial spinodals is subcritical by parameter h (and they are unstable). The starting appoximation for nonhomogeneous structures was obtained by formulas (38) and (39), and has continued by parameter $h<h^*(\mathbf{\Phi}^0)$ with help of the solutions of Eqs. (5), (6), and (10) up to the coups point $h=h_t$. In this point the operator $\mathbf{L}(\mathbf{U},\mathbf{V},\mathbf{s},\mathbf{\Phi},h_t)$ has vanishing eigenvalue, and couple of structures (stable and unstable) appeared at $h=h^*$ on the nontrivial spinodal disappear. For $h>h_t$ the structures obtained by continuation procedure are stable up to value $h=h_b$ where $R[\Phi^I]=0$. We calculate the spectrum of matrix (40) in every point of the curve $\mathbf{z}(h,\mathbf{\Phi}^0)$. Every branch $\mathbf{z}(h,\mathbf{\Phi}^0)$

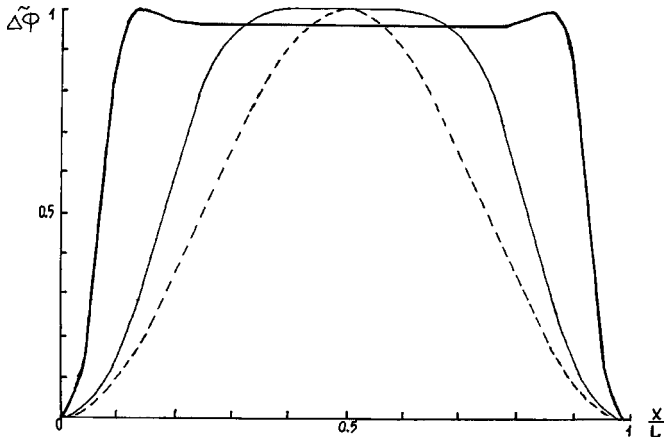

FIG. 2. The spatial distribution $\Phi_2(x/l)$ for $\Phi^0=0.99$ for the system (1) bold curve, for $l=260$; next curve, for $l=2\pi/q^*=78.248$ and value h, corresponding to binodal; dotted line, for $h=h_{sn}$. The curves are plotted in the scale $(\max_x\Phi_2-\min_x\Phi_2)$.

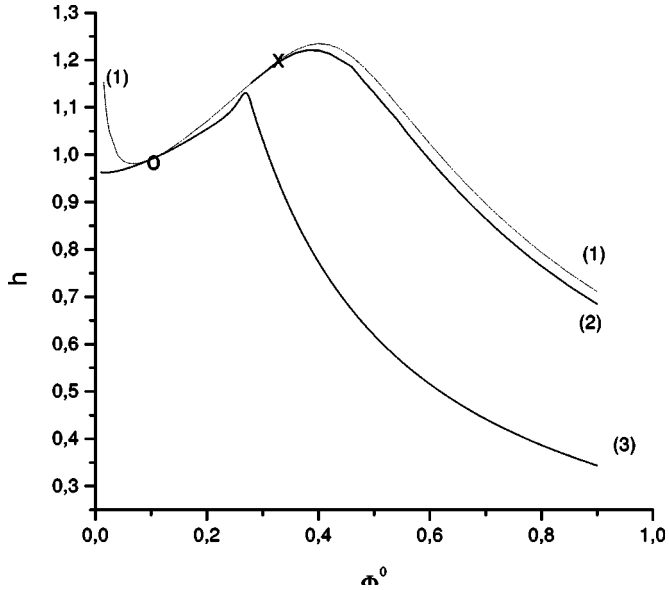

FIG. 3. Phase diagram for system (2). The curve (1), trivial spinodal, the curve (2) is nontrivial spinodal, (3) is the trivial binodal, $\Phi^0 \cong 0.28$ is the Lifshitz point (marked by $\times$), $\Phi^0 \cong 0.099$ is the critical point (marked by $\bigcirc$).

may be continued by parameter q (or $l=2\pi/q$) for $h \neq h^*$. The value of functional $\mathcal{F}[\mathbf{z}]$ and magnitude h_b decrease with increasing l. In these calculations the h_b change was very small. It should be noted that the value h_b for the homogeneous extremal arised transcritically in the spinodal point was practically the same as the value h_b for the branch of nonhomogeneous structures by $l \to \infty$. In Fig. 1 the phase diagrams are plotted, $Q=\begin{pmatrix} 0.99 & 0.01 & 0 \\ 0 & 0.95 & 0.05 \end{pmatrix}$, and the matrix of interaction $\gamma/\gamma_{12}(1.2;1;1.2)$.

The phase and bifurcation (for $\Phi^0=0.5$) diagrams for this system are shown in Figs. 3 and 4. For the nonhomogeneous structures $\Delta\Phi=\max_x \Phi_2-\min_x \Phi_2$, and for the homogeneous solution one deviation from the trivial one.

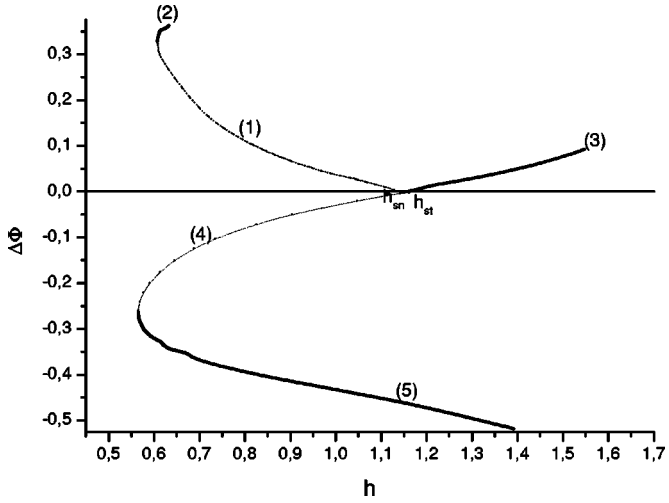

FIG. 4. The bifurcation diagram for the system (2) at $\Phi^0=0.5$. The curve (1) is the unstable nonhomogenous branch, (2) is the stable one, (3) the stable part of the branch appeared transcritically from the spinodal point, (4) is the unstable part of the same branch, (5) is the stable homogeneous nontrivial branch rigidly arising in couple with branch (4).

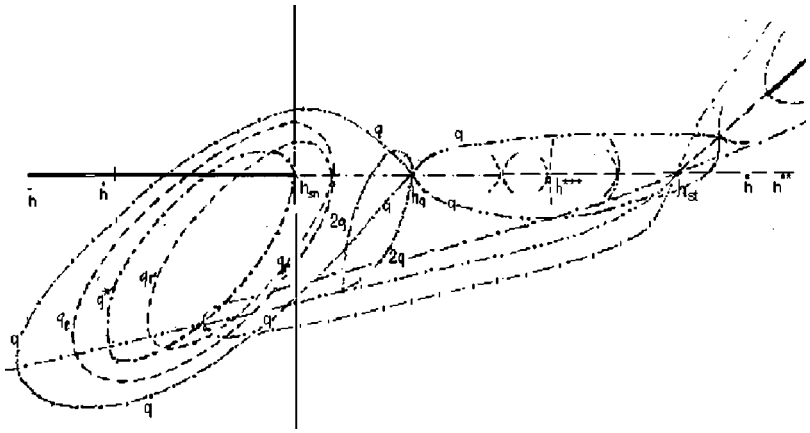

FIG. 5. The bifurcation diagram at $\Phi^0=0.76$ for the system (3).

The nonlinear problem at hand can have far more complicated bifurcation diagrams than those described above. For example, let us consider the system, characterized by a set of input parameters, $Q=\begin{pmatrix}0.15 & 0.84 & 0.01\\ 0.84 & 0.15 & 0.01\end{pmatrix}$, and the matrix of interaction $\gamma/\gamma_{12}(0.08;1;1.5)$.

The bifurcation behavior in the vicinity of the Lifshitz point ($\Phi^0=0.745$, $h=4.0857$) is of particular interest from the physical standpoint. The periodic solutions of the set of equations (5), (6), and (10) have periods substantially exceeding the size of a monomeric unit. To carry out the bifurcation analysis with a single controlled parameter h we have chosen the value $\Phi^0=0.760$ at which the above condition holds. For this value the bifurcation diagram is plotted in Fig. 5.

As depicted in this picture the loss of the thermodynamic stability of the homogeneous state with the temperature decay is observed for the first time at point $h_{sn}=4.3043$ of the nontrivial spinodal. At this point the Turing subcritical bifurcation happens leading to the loss of stability of the nontrivial solution accompanied by the disappearance of the pair of unstable periodic solutions with $q^*=0.5958$. As h subsequently increases the instability interval of wave vectors $q_l<q<q_r$ broadens up to the moment when h attains the value $h_{st}=4.3185$, corresponding to the trivial spinodal.

At point $h=h_{st}$, where $q_l=0$, $q_r=0.986$ the transcritical bifurcation takes place. Then the trivial extremal loses its stability with respect to homogeneous fluctuations whereas the upper part of nontrivial homogeneous extremal acquires it. Both of them, however, are unstable with respect to nonhomogeneous fluctuations in the vicinity of point $h=h_{st}$. Interesting peculiarity of the bifurcation at this specific point is a splitting off from the nontrivial extremal of a pair of periodic ones corresponding to the wave vector q^* unstable with respect to both types of fluctuations. The reason of such bifurcation behavior at point $h=h_{st}$ is that the zero eigenvalue of linear operator at this point has the multiplicity two, corresponding to the two-dimensional proper subspace (this bifurcation was described above).

Apart from the primary bifurcations (points h_{sn}, h_{st}) in Fig. 5 some secondary ones (points h^*, h^{**}) are also depicted which we managed to reveal numerically. When moving from point $h=h_{st}$ along the homogeneous nontrivial extremal the region of unstable wave vectors was found to reduce with the growth of control parameter h to contract to point $q=q^{**}=0.63$ at $h=h^{**}=4.3365$. As the result of this Turing supercritical bifurcation at point h^{**} the nontrivial extremal becomes absolutely stable giving birth to a couple of periodic structures with wave vector q^{**}. The free energy density of homogeneous nuclei described by this extremal turns out to be lower than that in the principal phase.

When moving from point $h=h_{st}$ along the homogeneous nontrivial extremal in the direction of decreasing parameter h the wave vector value q_r, bounding from the right-hand side of the interval of the instability of this extremal gets smaller to reach at point h^* just that value $q=q^*$, at which the stability loss by the trivial extremal happens at point h_{sn}. The amplitude of the pair of periodic

structures with wave vector q^* emerging at point h_{sn} as parameter h decreases, first increases to decay up to zero at the point when $h=h^*$. At this point the Turing subcritical bifurcation occurs resulting in the disappearance of the pair of unstable periodic extremals. Simultaneously, the nontrivial homogeneous extremal, remaining in general unstable, acquires stability with respect to the fluctuations with $q=q^*$. Under further decay of parameter h in the region to the left from the secondary bifurcation point the values $\mathbf{\Phi}_1$ and $\mathbf{\Phi}_2$ tend to zero at this extremal.

Returning to the instability interval one can find, that in every point of the interval $h_{sn}<h<h_{st}$ one can also observe the bifurcations of trivial solution. Type of these bifurcations will be different to the left and to the right of a certain specific point $h^-=4.308$, $q_l=0.393\,362$, where $q_r=2q_l$. To the left of this point both branches corresponding to q_l and q_r arise subcritically, each of them attaining the nontrivial homogeneous branch at corresponding points. To the right of point h^- one branch remains subcritical, while the other becomes supercritical. Such a situation persists under changes of h up to a certain value h^{***}, where coefficients $h^{(2)}$ and $h^{(3)}$ in the expansion (33) vanish. Subcritical branches reach at the bottom part of the nontrivial branch of the homogeneous extremal to the left of point h_{st}, whereas the supercritical ones reach the upper part of this curve. When $h>h^{***}$ bifurcations of both branches again become subcritical and corresponding branches attain the bottom part of the nontrivial extremal. Specific point h^- corresponds to the degenerate case since null space of the operator $\mathbf{L}$ at this point consists of two eigenvectors. Consequently the first approximation reads

$$\mathbf{z}^{(1)} = \alpha \mathbf{g}_l \cos q_l x + \beta \mathbf{g}_r \cos 2q_l x.$$

Constants α and β are determined from the orthogonality conditions for two eigenfunctions $\mathbf{g}_l^T \cos(q_l x)$ and $\mathbf{g}_r^T \cos(2q_l x)$ to the operator conjugate to $\mathbf{L}$. The equations for determination of the ratio α/β and $h^{(1)}$ are written as

$$\begin{aligned} 1/2\alpha^2(\mathbf{g}_r^T, \mathbf{B}_2(\mathbf{g}_l, \mathbf{g}_l)) + \beta h^{(1)}(\mathbf{g}_r^T, \mathbf{B}_2(\mathbf{g}_r, h)) = 0, \\ 1/2\alpha\beta(\mathbf{g}_l^T, \mathbf{B}_2(\mathbf{g}_r, \mathbf{g}_l)) + \alpha h^{(1)}(\mathbf{g}_l^T, \mathbf{B}_2(\mathbf{g}_l, h)) = 0, \end{aligned} \tag{46}$$

where

$$\mathbf{B}_2(\mathbf{y}^1, \mathbf{y}^2) = 1/2 \sum_{i,j} (\partial^2 \mathbf{F}/\partial y_i^1 \partial y_j^2) y_i^1 y_j^2, \quad \mathbf{B}_2(y,h) = \sum_j (\partial^2 \mathbf{F}/\partial y_j \partial h) y_j.$$

This system has several solutions

(1) $\alpha=0$, $h^{(1)}=0$,
(2) $\alpha\neq 0$, $h^{(1)}=-\beta/2(\mathbf{g}_l^T, \mathbf{B}_2(\mathbf{g}_r, \mathbf{g}_l)) / (\mathbf{g}_l^T, \mathbf{B}_2(\mathbf{g}_l, h))$,

$$(\alpha/\beta)^2 = (\mathbf{g}_l^T, \mathbf{B}_2(\mathbf{g}_r, \mathbf{g}_l))/(\mathbf{g}_r^T, \mathbf{B}_2(\mathbf{g}_l, \mathbf{g}_l)) \cdot (\mathbf{g}_r^T, \mathbf{B}_2(\mathbf{g}_r, h)/(\mathbf{g}_l^T, \mathbf{B}_2(\mathbf{g}_l, h)) = c.$$

If $c>0$ (in our case this condition is actually satisfied). The comparison of formulas (46) and (40) leads one to the conclusion that (with substitution α by β) their second equations are identical while the first ones differ by the term proportional to β^2 that is missing in set (46) by virtue of the orthogonality condition of functions $\cos(2q_l x)$ and $\cos^2(2q_l x)$. The solution of set (46) (where $\alpha=0$) describes the subcritical Turing bifurcation with two branches arising at the homogeneous nontrivial branch at $h=h_{2q_l}$. The second solution (where $\alpha\neq 0$) describes the transcritical bifurcation. Two unstable branches with period $2\pi/q_l$ arise when $h^-=2.24$ at the nontrivial homogeneous extremal to the left of point $h=h_{st}$, then one branch transcritically continues when $h=h_{st}$ in the direction of increasing of the parameter h to terminate at $h=4.33$ at the homogeneous extremal.

The bifurcation diagram presented in Fig. 5 is obviously incomplete. This statement is particularly evidenced by the absence in the interval $h_{sn}<h<h^{**}$ of extremals at which the Landau free energy functional has local minimum. Apparently, in this region of parameter h the nuclei of

mesophases with two- or three-dimensional spatial periodicity must be stable. We have in mind to perform a theoretical analysis of the existence and stability of such nuclei in the subsequent publications.[26–28]

APPENDIX A

The components of vectors $\mathbf{r}_0$ and $\mathbf{r}_h$ in the formulas (39) are

$$\mathbf{r}_0[i] = -1/2\sum_j \nu_{ij}\mathbf{g}[j]\mathbf{g}[j+2],$$

$$\mathbf{r}_0[i+2] = -1/(4)((g[i+2]/s_i)^2 - H_1(g[5]+g[6])^2),$$

$$\mathbf{r}_0[i+4] = 1/2\mathbf{\Phi}^0\pi_i(2V_i\mathbf{g}[i]\mathbf{g}[i+2] + s_i\mathbf{g}[i]^2),$$

$$\mathbf{r}_h[i] = 0, \quad \text{for } i \neq 3,4,$$

$$\mathbf{r}_h[i+2] = -\sum_j \gamma_{ij}(\mathbf{\Phi}^0\pi_j - \mathbf{\Phi}_j),$$

where $(i=1,2)$ the vector $\mathbf{g}$ is the eigenvector of the matrix $J(q^*)$ and

$$H_1 = 1/(1-\Phi_1-\Phi_2)^2, \quad H_2 = 2H_1/(1-\Phi_1-\Phi_2).$$

The expression $h^{(2)}$ in the formulas (31) has the following form: $h^{(2)} = -\Sigma_i P(i)/\Sigma_i P_h(i)$, where the denotations are accepted,

$$ab(i) = a[i] + 1/2b[i], \quad n\mathbf{g}^T[i] = \nu_{i1}\mathbf{g}^T[1] + \nu_{i2}\mathbf{g}^T[2],$$

$$a_h\mathbf{g}[i] = \mathbf{g}[i]\mathbf{a}_h[i+2] + \mathbf{a}_h[i]\mathbf{g}[i+2],$$

$$P(1) = 1/2\sum_1^2 n\mathbf{g}^T[i](ab(i)\mathbf{g}[i+2] + ab(i+2)\mathbf{g}[i]),$$

$$P(2) = 1/2H_1(\mathbf{g}^T[3]+\mathbf{g}^T[4])(\mathbf{g}^T[5]+\mathbf{g}^T[6])(ab(5)+ab(6)),$$

$$P(3) = 1/16H_2(\mathbf{g}^T[3]+\mathbf{g}^T[4])(\mathbf{g}[5]+\mathbf{g}[6])^3,$$

$$P(4) = -1/2\sum_1^{2T} \mathbf{g}[i+2]\mathbf{g}[i+2]/s_i^2(ab(i+2) - 1/(4S_i)\mathbf{g}[i+2]^2),$$

$$P(5) = -\mathbf{\Phi}^0\sum_1^2 \pi_i^T\mathbf{g}[i+4]\mathbf{g}[i]((3/8\mathbf{g}[i+2]\mathbf{g}[i] + ab(i+2)V_i) + ab(i)(V_i\mathbf{g}[i+2] + S_i\mathbf{g}[i])),$$

$$P_h(1) = 1/2\sum_1^2 n\mathbf{g}^T[i]a_h\mathbf{g}[i],$$

$$P_h(2) = H_1/2(a_h[5] + a_h[6])(\mathbf{g}^T[3] + \mathbf{g}^T[4])(\mathbf{g}[5] + \mathbf{g}[6]), \quad P_h(3) = 0,$$

$$P_h(4) = -1/2\sum_1^2 g^T[i+2](1/s_i^{e2}\mathbf{g}[i+2]a_h(i+2) - (\gamma_{i1}\mathbf{g}[5] + \gamma_{i2}\mathbf{g}[6])),$$

$$P_h(5) = -\mathbf{\Phi}^0(\sum_1^2 \pi_i\mathbf{g}^T[i+4]((S_i\mathbf{g}[i] + V_i\mathbf{g}[i+2])\mathbf{a}_h(i) + \mathbf{a}_h(i+2)V_i\mathbf{g}[i])).$$

Let

$$n_0(i) = (\nu_{i1}\mathbf{g}^{(0)}[1]\mathbf{g}^{(0)}[3] + \nu_{i2}\mathbf{g}^{(0)}[2]\mathbf{g}^{(0)}[4]),$$

$$n_2(i) = (\nu_{i1}\mathbf{g}(q*)[1]\mathbf{g}(q*)[3] + \nu_{i2}\mathbf{g}(q*)[2]\mathbf{g}(q*)[4]),$$

$$VS(i) = (2V_i\mathbf{g}^{(0)}[i]\mathbf{g}[i+2] + s_i(\mathbf{g}^{(0)}[i])^2),$$

$$SS(i) = 1/2((\mathbf{g}^{(0)}[i+2])/s_i)^2 - H_1\ (\mathbf{g}^{(0)}[5] + \mathbf{g}^{(0)}[6])^2),$$

$$n_{02}(i) = \sum_1^2 \nu_{ij}(g^{(0)}[j+2]g(q*)[j] + g^{(0)}[j]g(q*)[j+2]),$$

$$S_{02}(i) = 1/2(\mathbf{g}^{(0)}[i+2]\mathbf{g}(q*)[i+2]/s_i^2 - H_1(\mathbf{g}^{(0)}[5] + \mathbf{g}^{(0)}[6])(\mathbf{g}(q*)[5] + \mathbf{g}(q*)[6])),$$

$$VS_{02}(i) = V_i(\mathbf{g}^{(0)}[i+2]\mathbf{g}(q*)[i] + \mathbf{g}^{(0)}[i]\mathbf{g}(q*)[i+2]) + s_i\mathbf{g}^{(0)}[i]\mathbf{g}(q*)[i],$$

$$SS_2(i) = 1/2((g(q*)[i+2]/s_i)^2 - H_1(\mathbf{g}(q*)[5] + \mathbf{g}(q*)[6])^2),$$

$$VS_2(i) = 2V_i(\mathbf{g}(q*)[i+2]\mathbf{g}(q*)[i]) + S_i(\mathbf{g}(q*)[i])^2.$$

Then the vectors $\mathbf{r}_{00}$, $\mathbf{r}_{01}$, $\mathbf{r}_{22}$ have the following form:

$$r_{00} = [-n_0(1), -n_0(2), SS(1), SS(2), \mathbf{\Phi}^0\pi_1 VS(1), \mathbf{\Phi}^0\pi_2 VS(2)],$$

$$r_{02} = [-1/2n_{02}(1), -1/2n_{02}(2), S_{02}(1), S_{02}(2), \mathbf{\Phi}^0\pi_1 VS_{02}(1), \mathbf{\Phi}^0\pi_2 VS_{02}(2)],$$

$$r_{22} = [-1/2n_2(1), -1/2n_2(2), 1/2SS(1), 1/2SS(2), 1/2\mathbf{\Phi}^0\pi_1 VS(1), 1/2\mathbf{\Phi}^0\pi_2 VS(2)].$$

APPENDIX B

The matrix elements of the functional second variation are written as

$$(\delta^2\mathcal{F})_{ij,kl}^{cc} = m_{ij,kl}^{cc} + h_{ij,kl}^{cc}, \quad (\delta^2\mathcal{F})_{ij,kl}^{cs} = m_{ij,kl}^{cs} + h_{ij,kl}^{cs},$$

$$(\delta^2\mathcal{F})_{ij,kl}^{sc} = m_{ij,kl}^{sc} + h_{ij,kl}^{sc}, \quad (\delta^2\mathcal{F})_{ij,kl}^{ss} = m_{ij,kl}^{ss} + h_{ij,kl}^{ss},$$

$$m^{cc}_{ij,kl} = \frac{T}{L}\int_0^L (-c_{ij} + 1/\mathbf{\Phi}_i\delta_{ij})\cos(kqx)\cos(lqx)\mathrm{d}x,$$

$$m^{cs}_{ij,kl} = \frac{T}{L}\int_0^L (-c_{ij} + 1/\mathbf{\Phi}_i\delta_{ij})\cos(kqx)\sin(lqx)\mathrm{d}x,$$

$$m^{sc}_{ij,kl} = \frac{T}{L}\int_0^L (-c_{ij} + 1/\mathbf{\Phi}_i\delta_{ij})\sin(kqx)\cos(lqx)\mathrm{d}x,$$

$$m^{ss}_{ij,kl} = \frac{T}{L}\int_0^L (-c_{ij} + 1/\mathbf{\Phi}_i\delta_{ij})\sin(kqx)\sin(lqx)\mathrm{d}x,$$

$$h^{cc}_{ij,kl} = -\frac{T}{L}\int_0^L (1/U_i(x)\,\delta U^{ic}_{j,k}(x) + 1/V_i(x)\,\delta V^{ic}_{j,k}(x))\cos(lqx)\mathrm{d}x,$$

$$h^{cs}_{ij,kl} = -\frac{T}{L}\int_0^L (1/U_i(x)\,\delta U^{ic}_{j,k}(x) + 1/V_i(x)\,\delta V^{ic}_{j,k}(x))\sin(lqx)\mathrm{d}x,$$

$$h^{sc}_{ij,kl} = -\frac{T}{L}\int_0^L (1/U_i(x)\,\delta U^{is}_{j,k}(x) + 1/V_i(x)\,\delta V^{is}_{j,k}(x))\cos(lqx)\mathrm{d}x,$$

$$h^{ss}_{ij,kl} = -\frac{T}{L}\int_0^L (1/U_i(x)\,\delta U^{is}_{j,k}(x) + 1/V_i(x)\,\delta V^{is}_{j,k}(x))\sin(lqx)\mathrm{d}x.$$

Here the values $U_i(x)$, $V_i(x)$ are given on the extremal, and $\delta U^{is}_{j,k}(x)$, $\delta U^{is}_{j,k}(x)$, $\delta U^{ic}_{j,k}(x)$ $\delta V^{ic}_{j,k}(x)$ are determined by Eq. (45), and $L=2\pi/q^*$.

(Received 17 February 2004; accepted 19 May 2004; published online 5 January 2005)

We extend a recent diffusion model, in which the continuous time dynamics of the *K*-scattering process have been proposed, to include the effect of the presence of a coherent offset in the scattering amplitude. The weak scattering amplitudes are characterized in terms of continuous time biased random walk models, and the corresponding stochastic dynamics derived. The stochastic differential geometry of the resultant amplitude fluctuations is derived in relation to that of pure *K*-scattering. Asymptotic distributions of amplitude, intensity, and phase are provided, and the condition for detailed balance shown to hold. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1811787]

I. INTRODUCTION

Significant progress has recently been made in our understanding of the dynamics of models of electromagnetic scattering in the context of diffusion processes. Deviations from Rayleigh (Gaussian) scattering have been successfully formulated in the context of *K*-distributed scattering processes (Field and Tough, 2003b) and have formed the basis of an anomaly detection technique that has been successfully applied to maritime radar scattering and laser propagation experiments (Field and Tough, 2003a).

The models considered previously assume a uniform (asymptotic) distribution of phase. In this paper we consider how anisotropic phase distributions can be accommodated within the framework provided by stochastic differential equations (SDEs) that has proved to be useful in *K*-scattering. We have seen how a simple random walk model provides a physically motivated description of the scattering process (Jakeman and Tough, 1988) that at the same time makes useful contact with the SDE formulation of the problem (Field and Tough, 2003a, 2003b). In earlier work, unbiased random walk models have provided useful insight into the Gaussian and non-Gaussian statistics of radiation scattered sufficiently strongly for its phase to be effectively randomized, and to take a uniform asymptotic distribution. A biased random walk model of weak scattering has been discussed in detail in Jakeman and Tough (1987). Their analysis led to the so-called generalized *K*-scattering model. The present paper re-addresses this problem, replacing the static, characteristic function approach with one in which the dynamics is captured by a set of coupled SDEs. A fairly complete analysis is possible that also makes contact with the Rice and homodyned *K* descriptions of weak scattering (Jakeman, 1980). This allows for a detailed description of the geometry of the resultant amplitude fluctuations, which is shown to be different in some significant respects from that encountered in the *K*-distributed case (Field and Tough, 2003b). In addition to developing this SDE description we study the phase distributions implicit in these models in more detail than has been reported previously.

Throughout we shall consistently adopt the notation for the decomposition of a general Ito process q_t into drift and volatility terms, respectively, as $\mathrm{d}q_t = b_t^{(q)}\,\mathrm{d}t + \sigma_t^{(q)}\,\mathrm{d}W_t^{(q)}$, with respect to some (fixed) probability measure on the space of paths, and define the diffusion coefficients $\Sigma^{(\cdot)}$ by $\mathrm{d}q_t\,\mathrm{d}p_t = \Sigma_t^{(q,p)}\,\mathrm{d}t$ and abbreviate via $\mathrm{d}q_t^2 = \Sigma_t^{(q)}\,\mathrm{d}t$. The error surface $\mathcal{S}^q$ of a vector process q^i is then

defined by the (inverse) quadratic form relation $\Sigma^{(q)-1}(\delta q)=1$. We shall adopt the Einstein summation convention throughout (e.g., Penrose and Rindler, 1984), unless explicitly indicated otherwise.

II. *K*-SCATTERING

We review the results of Field and Tough (2003b) that are necessary in the present context for the treatment of weak scattering. The random walk model with step number fluctuations, due to Jakeman (Jakeman, 1980; Jakeman and Tough, 1988), accounts for certain statistical properties of *K*-scattering. The extension to a complete dynamical description, in terms of continuous time diffusion processes, is provided in Field and Tough (2003b), the necessary results of which we review in this section. It is shown in the Rayleigh case of a fixed step number that the amplitude obeys a complex Ornstein–Uhlenbeck equation, and a corresponding SDE in the *K*-distributed case is derived.

(i) *Rayleigh scattering:* In the Rayleigh case consider the random walk model for the scattered electric field (cf. Jakeman, 1980; Tough, 1987; Jakeman and Tough, 1988) with step $s^{(j)}$,

$$\mathcal{E}_t^{(N)}=\sum_{j=1}^{N}\overbrace{\exp[i\varphi_t^{(j)}]}^{s^{(j)}} \tag{2.1}$$

for constant population size N. Since Maxwell's equations for the electromagnetic field possess U(1) gauge invariance with respect to duality rotations, i.e., multiplication by $\exp(i\Lambda)$ for constant Λ (cf. Penrose and Rindler, 1984), the assumption of independence of $\{\varphi^{(j)}\}$ implies that these phases are uniformly distributed. Accordingly in (2.1) the phase factors $\{\exp[i\varphi_t^{(j)}]\}$ are independent and uniformly distributed on the unit circle in $\mathbb{C}$. Our (phase) diffusion model therefore takes $\{\varphi_t^{(j)}\}$ as a collection of (displaced) Wiener processes on a suitable time scale, $\varphi_t^{(j)}=\Delta^{(j)}+\mathcal{B}^{1/2}W_t^{(j)}$, with the random initializations $\{\Delta^{(j)}\}$ a set of independent random variables uniformly distributed on the interval $[0,2\pi)$, and thus $\mathrm{d}\varphi_t^{(j)}=\mathcal{B}^{1/2}\,\mathrm{d}W_t^{(j)}$, $\mathrm{d}\varphi_t^{(j)2}=\mathcal{B}\,\mathrm{d}t$. From Ito's formula (e.g., Oksendal, 1998; Karatzas and Shreve, 1988) the Ito differential of (2.1) is

$$\mathrm{d}\mathcal{E}_t^{(N)}=\sum_{j=1}^{N}\left(i\,\mathrm{d}\varphi_t^{(j)}-\frac{1}{2}\mathrm{d}\varphi_t^{(j)2}\right)\exp[i\varphi_t^{(j)}]. \tag{2.2}$$

The first term $\Sigma_{j=1}^{N}i\,\mathrm{d}\varphi_t^{(j)}\exp[i\varphi_t^{(j)}]$ on the right-hand side of (2.2) consists of a sum of independent randomly phased Wiener processes, with variance equal to $\mathcal{B}N\,\mathrm{d}t$, while the second term is independent of the scatterer label j. Thus from (2.2) we can write

$$\mathrm{d}\mathcal{E}_t^{(N)}=-\tfrac{1}{2}\mathcal{B}\mathcal{E}_t^{(N)}\,\mathrm{d}t+(\mathcal{B}N)^{1/2}\,\mathrm{d}\xi_t, \tag{2.3}$$

where ξ_t is a complex Wiener process satisfying $|\mathrm{d}\xi_t|^2=\mathrm{d}t$, $\mathrm{d}\xi_t^2=0$. The process ξ_t is adapted to the filtration $\mathcal{F}^{(\varphi)}=\cup_j\mathcal{F}^{(j)}$, where $\mathcal{F}^{(j)}$ is the filtration appropriate to the component scatterer phase $\varphi_t^{(j)}$. The (normalized) amplitude process $\mathcal{E}_t$ is then defined by $\mathcal{E}_t=\lim_{N\to\infty}[\mathcal{E}_t^{(N)}/\overline{N^{1/2}}]$ and satisfies the SDE,

$$\mathrm{d}\mathcal{E}_t=-\tfrac{1}{2}\mathcal{B}\mathcal{E}_t\,\mathrm{d}t+(\mathcal{B}x)^{1/2}\,\mathrm{d}\xi_t, \tag{2.4}$$

where the continuous valued random variable x, the average scattering power, arises from an asymptotically large population via $x=\lim_{N\to\infty}[N/\overline{N}]$.

(ii) *K-distributed noise:* In the case of step number fluctuations in the random walk model (2.1), we define the *K*-amplitude ψ_t as a modification to the Rayleigh amplitude, such that we employ a time dependent N_t with $x_t=\lim_{N_t\to\infty}[N_t/\overline{N}]$. Thus

$$\psi_t = \lim_{N_t\to\infty}\left\{\frac{1}{\overline{N}^{1/2}}\sum_{j=1}^{N_t}\exp\left[i\varphi_t^{(j)}\right]\right\} \tag{2.5}$$

$$= \lim_{N_t\to\infty}\left\{\left(\frac{N_t}{\overline{N}}\right)^{1/2}\frac{1}{N_t^{1/2}}\sum_{j=1}^{N_t}\exp\left[i\varphi_t^{(j)}\right]\right\} \tag{2.6}$$

$$= x_t^{1/2}\gamma_t, \tag{2.7}$$

where $\gamma_t = \lim_{N\to\infty}[\mathcal{E}_t^{(N_t)}/N_t^{1/2}]$. Thus the intensity has the compound representation $z_t = x_t u_t$ where $u_t = |\gamma_t|^2$ is the (instantaneous) intensity of the component Rayleigh process. According to the arguments given in the Rayleigh case above, γ_t is a complex Ornstein–Uhlenbeck process which obeys the SDE,

$$\mathrm{d}\gamma_t = -\tfrac{1}{2}\mathcal{B}\gamma_t\,\mathrm{d}t + \mathcal{B}^{1/2}\mathrm{d}\xi_t. \tag{2.8}$$

Observe from (2.4), therefore, that γ_t is a unit power Rayleigh process. The above equation for γ_t can be solved by considering the stochastic differential $\mathrm{d}\left[\exp(\frac{1}{2}\mathcal{B}t)\gamma_t\right]$, which leads to the solution

$$\gamma_t = \exp\left(-\frac{1}{2}\mathcal{B}t\right)\left\{\gamma_0 + \mathcal{B}^{1/2}\int_0^t \exp\left(\frac{1}{2}\mathcal{B}s\right)\mathrm{d}\xi_s\right\}. \tag{2.9}$$

We deduce the expectation formulas,

$$\mathbb{E}[\gamma_t] = \exp\left(-\tfrac{1}{2}\mathcal{B}t\right)\gamma_0, \tag{2.10}$$

$$\mathbb{E}[|\gamma_t|^2] = 1 + \exp\left(-\mathcal{B}t\right)(|\gamma_0|^2 - 1). \tag{2.11}$$

From (2.11) it follows that $\lim_{t\to\infty}\mathbb{E}[|\gamma_t|^2] = 1$ and so from (2.7) we find the intensity process, defined by $z_t = |\psi_t|^2$, satisfies $\mathbb{E}[z_t] = x_t$. The SDE for ψ_t can then be derived by applying the Ito product formula to (2.7). This requires the SDE for the scattering cross section to be specified. In accordance with the birth–death–immigration (BDI) model (Bartlett, 1966), we shall take the rescaled population variate $x \mapsto \alpha x$ to satisfy the SDE,

$$\mathrm{d}x_t = \mathcal{A}(\alpha - x_t)\mathrm{d}t + (2\mathcal{A}x_t)^{1/2}\,\mathrm{d}W_t^{(x)}, \tag{2.12}$$

for an independent Wiener process $W_t^{(x)}$ (Field and Tough, 2003a). (In terms of the underlying population parameters of the BDI model, $\alpha = \nu/\lambda$, the ratio of the immigration to birth rate, the birth and death rates coinciding for an infinite sized population.) Accordingly x_t has an asymptotic Γ-distribution,

$$\Gamma_\alpha(x) = \frac{x^{\alpha-1}\exp(-x)}{\Gamma(\alpha)}, \tag{2.13}$$

with the first two moments $\mathrm{Var}[x] = \langle x\rangle = \alpha$. These preliminaries enable us to provide the dynamics of the amplitude, intensity, and phase of the *K*-scattering process as follows (cf. Field and Tough, 2003b for a detailed treatment).

A. Amplitude

Proposition 2.1: The K-amplitude is governed by the SDE,

$$\frac{\mathrm{d}\psi_t}{\psi_t} = \mathcal{A}\left(\frac{2(\alpha - x_t) - 1}{4x_t}\right)\mathrm{d}t + \left(\frac{\mathcal{A}}{2x_t}\right)^{1/2}\mathrm{d}W_t^{(x)} - \frac{1}{2}\mathcal{B}\,\mathrm{d}t + \frac{\mathcal{B}^{1/2}}{\gamma_t}\mathrm{d}\xi_t. \tag{2.14}$$

This evolution is invariant under the $U(1)$ gauge transformation $\psi_t \mapsto \exp(i\Lambda)\psi_t$, for constant Λ.

B. Intensity

Proposition 2.2: The K-intensity SDE is given by

$$\mathrm{d}z_t = \left[\frac{\mathcal{A}z_t(\alpha - x_t)}{x_t} + \mathcal{B}(x_t - z_t)\right]\mathrm{d}t + \left(\frac{2\mathcal{A}z_t^2}{x_t} + 2\mathcal{B}x_t z_t\right)^{1/2} \mathrm{d}W_t^{(z)} \tag{2.15}$$

in which $W_t^{(z)}$ is correlated with $W_t^{(x)}$ of (2.12), and satisfies

$$\left(\frac{2\mathcal{A}z_t^2}{x_t} + 2\mathcal{B}x_t z_t\right)^{1/2} \mathrm{d}W_t^{(z)} = \left(\frac{2\mathcal{A}}{x_t}\right)^{1/2} z_t\, \mathrm{d}W_t^{(x)} + (2\mathcal{B}x_t z_t)^{1/2}\, \mathrm{d}W_t^{(r)} \tag{2.16}$$

and $W_t^{(r)}$ is a real-valued Wiener process defined by

$$\gamma_t^*\, \mathrm{d}\xi_t + \gamma_t\, \mathrm{d}\xi_t^* \equiv \left(\frac{2z_t}{x_t}\right)^{1/2} \mathrm{d}W_t^{(r)}. \tag{2.17}$$

C. Phase

Proposition 2.3: The resultant phase θ_t of the K-amplitude process satisfies the SDE,

$$\mathrm{d}\theta_t = \left(\frac{\mathcal{B}x_t}{2z_t}\right)^{1/2} \mathrm{d}W_t^{(\theta)}, \tag{2.18}$$

where the distinct (real-valued) Wiener process $W_t^{(\theta)}$ is defined according to

$$\frac{1}{i}(\gamma_t^*\, \mathrm{d}\xi_t - \gamma_t\, \mathrm{d}\xi_t^*) \equiv \left(\frac{2z_t}{x_t}\right)^{1/2} \mathrm{d}W_t^{(\theta)}. \tag{2.19}$$

These various relations allow the K-amplitude dynamics to be recast in terms of $W^{(x)}$, $W^{(\theta)}$, $W^{(r)}$ as follows.

Corollary 2.4: The K-amplitude satisfies the SDE,

$$\frac{\mathrm{d}\psi_t}{\psi_t} = \left[\mathcal{A}\left(\frac{2(\alpha - x_t) - 1}{4x_t}\right) - \frac{1}{2}\mathcal{B}\right]\mathrm{d}t + \left(\frac{\mathcal{A}z_t + \mathcal{B}x_t^2}{2x_t z_t}\right)^{1/2} \mathrm{d}W_t^{(z)} + i\left(\frac{\mathcal{B}x_t}{2z_t}\right)^{1/2} \mathrm{d}W_t^{(\theta)}, \tag{2.20}$$

in which, alternatively, the Wiener terms can be expressed as

$$\left(\frac{\mathcal{A}}{2x_t}\right)^{1/2} \mathrm{d}W_t^{(x)} + \left(\frac{\mathcal{B}x_t}{2z_t}\right)^{1/2} (\mathrm{d}W_t^{(r)} + i\, \mathrm{d}W_t^{(\theta)}). \tag{2.21}$$

The following result, implied by (2.14) and the identities $\mathrm{d}\xi_t^2 = \mathrm{d}\xi_t\, \mathrm{d}W_t^{(x)} = 0$, will be useful in connection with the geometry of fluctuations for weak scattering processes discussed in Sec. V.

Corollary 2.5: The product cross-section/K-amplitude stochastic differentials satisfy

$$\mathrm{d}x_t^2 = 2\mathcal{A}x_t\, \mathrm{d}t, \tag{2.22}$$

$$\mathrm{d}x_t\, \mathrm{d}\psi_t = \mathcal{A}\psi_t\, \mathrm{d}t, \tag{2.23}$$

$$\mathrm{d}\psi_t^2 = \left(\frac{\mathcal{A}\psi_t^2}{2x_t}\right)\mathrm{d}t, \tag{2.24}$$

$$|\mathrm{d}\psi_t|^2 = \left(\frac{\mathcal{A}z_t}{2x_t} + \mathcal{B}x_t\right)\mathrm{d}t. \tag{2.25}$$

D. Geometry of fluctuations

Observe from Propositions 2.2 and 2.3 that $\mathrm{d}W_t^{(z)}\,\mathrm{d}W_t^{(\theta)}=0$, so the fluctuations in R_t, θ_t are statistically independent. The relative magnitude of the radial and orthogonal (phase) fluctuations is determined by

$$\frac{\Sigma_t^{(z)}}{\Sigma_t^{(\theta)}} = 4z_t^2 + \frac{4\mathcal{A}z_t^3}{\mathcal{B}x_t^2}, \tag{2.26}$$

which exceeds the quotient obtained in the Rayleigh case, $\mathcal{A}=0$. These relations can be used to characterize the geometry of the *K*-scattering amplitude fluctuations as follows. We shall refer to the real and imaginary parts of the resultant amplitude *I*, *Q* as the in-phase and quadrature-phase components, respectively (Helmstrom, 1960).

Proposition 2.6: In the K-distributed case, $\mathcal{A}\neq 0$, the amplitude diffusion tensor is nondegenerate, and the fluctuations in the in-phase and quadrature phase components δI_t, δQ_t are correlated. The (comoving) error surface $\mathcal{S}$ of $\delta\psi_t$ is an ellipse whose major axis lies in the instantaneous radial direction defined by ψ_t. Degeneracy occurs in the Rayleigh case $\mathcal{A}=0$, for which $\mathcal{S}$ is a circle, i.e., the fluctuations in ψ_t are isotropic.

For a complete account of the dynamical properties of *K*-scattering see Field and Tough (2003b).

III. WEAK SCATTERING AMPLITUDES

In situations of strong backscattering, such as occur, e.g., in radar applications, the phases of the back-scattered components are taken to be uniformly randomized and correspondingly the dynamics and asymptotic distributions of the resultant amplitude process Ψ_t are invariant under $\Psi_t \mapsto e^{i\Lambda}\Psi_t$. This is no longer the case for weak scattering however, i.e., situations where the Rayleigh component of the scatter is weak in comparison to some coherent offset contribution. In these cases the mean amplitude is offset from zero, and the asymptotic resultant phase distribution is anisotropic. We have seen in the *K*-distributed case that $\psi_t = x_t^{1/2}\gamma_t$ where γ_t describes the (unit-power) Rayleigh process (Field and Tough, 2003b) according to (2.8). When this process lies in superposition with a coherent offset amplitude ϱ_t, the resultant amplitude process Ψ_t depends on the relative scalings of the offset and (modulated) Rayleigh components with respect to population size. There are essentially three cases to consider, each of which can be understood in terms of the random walk model (2.1) by imposing a *bias* on each step $s^{(j)}$, whose physical origin is the coherent offset contribution. We shall describe these cases in the order of Rice, homodyned and generalized *K*-scattering, thus introducing physical features (noise, *K*-noise, fluctuating coherently scattered beam) in a natural order that is mirrored in the increasing complexity of the calculations.

A. Rice model

We assume that the number of scatterers is constant in time, with a constant offset contribution $\varrho_t = a$. Thus modifying the random walk model (2.1) we write

$$\mathcal{E}_t^{(N)} = \sum_{j=1}^{N}\left(\overbrace{a + \exp[i\varphi_t^{(j)}]}^{s^{(j)}}\right). \tag{3.1}$$

Scaling by $1/N$, $1/N^{1/2}$ for the respective terms under the summation, in the x_t-continuum limit ($N\to\infty$) this becomes

$$\Psi_t^{\mathrm{R}} = a + \gamma_t. \tag{3.2}$$

B. Homodyned *K*-scattering

The situation here is the same as for *K*-scattering with the superposition of a constant offset $\varrho_t = a$ that does not fluctuate with N_t. In the continuum limit this amounts to adding a constant to the *K*-amplitude, thus

$$\Psi_t^{\mathrm{HK}} = a + \psi_t. \tag{3.3}$$

C. Generalized *K*-scattering

In a similar fashion (2.1) is modified to become

$$\mathcal{E}_t^{(N_t)} = \sum_{j=1}^{N_t} \left(\overbrace{a + \exp[i\varphi_t^{(j)}]}^{s^{(j)}} \right) \tag{3.4}$$

in which the *t*-dependence of the limit of summation is to be observed, i.e., the step number of the biased random walk has fluctuations. Scaling by the reciprocal mean and root mean populations, respectively, the offset becomes $\varrho_t = a x_t$ and we have

$$\Psi_t^{\mathrm{GK}} = a x_t + \psi_t \tag{3.5}$$

in the continuum limit.

Observe with respect to scaling in the continuum population limit that, in each case, we have divided by the (unique) length scale factors, appropriate to the relevant terms in $s^{(j)}$ separately, that yield finite nonzero resultant amplitudes.

IV. STOCHASTIC DYNAMICS

The stochastic dynamics of the weak scattering amplitudes described above can be calculated from the underlying *K*-scattering dynamics presented in Sec. II. We shall make use of the identities for the (resultant) intensity and phase stochastic differentials in terms of the (resultant) amplitude,

$$\mathrm{d}Z_t \equiv \Psi_t^* \, \mathrm{d}\Psi_t + \Psi_t \, \mathrm{d}\Psi_t^* + |\mathrm{d}\Psi_t|^2,$$

$$\mathrm{d}\Theta_t \equiv \frac{1}{2i}\left[\left(\frac{\mathrm{d}\Psi_t}{\Psi_t} - \frac{1}{2}\left(\frac{\mathrm{d}\Psi_t}{\Psi_t} \right)^2 \right) - \left(\frac{\mathrm{d}\Psi_t^*}{\Psi_t^*} - \frac{1}{2}\left(\frac{\mathrm{d}\Psi_t^*}{\Psi_t^*} \right)^2 \right) \right], \tag{4.1}$$

and their products

$$\Sigma_t^{(Z)} \equiv \Psi_t^2 \Sigma_t^{(\Psi^*)} + \Psi_t^{*2} \Sigma_t^{(\Psi)} + 2 Z_t \Sigma_t^{(\Psi,\Psi^*)},$$

$$\Sigma_t^{(Z,\Theta)} \equiv \Im\left[\left(\frac{\Psi_t^*}{\Psi_t} \right) \Sigma_t^{(\Psi)} \right], \tag{4.2}$$

$$\Sigma_t^{(\Theta)} \equiv \frac{1}{4}\left[\frac{2\Sigma_t^{(\Psi,\Psi^*)}}{Z_t} - \frac{\Sigma_t^{(\Psi)}}{\Psi_t^2} - \frac{\Sigma_t^{(\Psi^*)}}{\Psi_t^{*2}} \right].$$

In combination with (3.2), (3.3), (3.5), and (2.12) and the results of Corollary 2.5 these identities enable us to derive the SDEs satisfied by Z_t, Θ_t in terms of the component Wiener processes $\{W_t^{(r)}, W_t^{(\theta)}, W_t^{(x)}\}$ encountered in Sec. II. The dynamics are the most simple for Rice scattering owing to the differential of (3.2). In the context of radar applications, the Rice model is referred to as a Swerling zero target in Rayleigh clutter, where the target strength is represented by ϱ (assumed constant over the time scale of interest) and the Rayleigh process γ_t represents back-

ground clutter. More care is required in the calculations for the homodyned and generalized *K*-scattering processes owing to certain cross terms that arise. Nevertheless the strategy is the same for each case, and we are led to the dynamical characterizations of the vector scattering process $\mathrm{S}_t=(x_t,Z_t,\Theta_t)^{\mathrm{tr}}$ according to the scheme

$$\mathrm{d}S_t^i = b_t^i\,\mathrm{d}t + \sigma_t^j\,\mathrm{d}W_t^i \tag{4.3}$$

(no summation over i) for a collection of Wiener processes $\{W_t^i|\,\forall\, i\}$ (not necessarily independent) with respective drift and diffusion coefficients b^i, Σ^{ij} determined by

$$b_t^i = \frac{\mathbb{E}[\mathrm{d}S_t^i]}{\mathrm{d}t},$$

$$\mathrm{d}S_t^i\,\mathrm{d}S_t^j = \Sigma_t^{ij}\,\mathrm{d}t. \tag{4.4}$$

The corresponding Fokker–Planck equation (e.g., Risken, 1989) for the joint probability density $\rho_t(x,Z,\Theta)$ is then

$$\partial_t\rho + \partial_i(\rho\mathcal{V}^i) = 0, \tag{4.5}$$

where the vector scattering current $\mathcal{V}^i$ is defined by

$$\mathcal{V}^i = b^i - \tfrac{1}{2}\rho^{-1}\partial_j(\Sigma^{ij}\rho). \tag{4.6}$$

A. Rice

The amplitude dynamics of the Rice process is identical to that of the Rayleigh process and the cross section is constant and equal to unity, as evident from (3.2). We deduce from the identities above that, in terms of the geometry of the underlying Rayleigh process, the resultant intensity satisfies the SDE,

$$\mathrm{d}Z_t = \mathcal{B}[1-u_t-au_t^{1/2}\cos\,\theta_t]\mathrm{d}t + (2\mathcal{B})^{1/2}[(u_t^{1/2}+a\cos\,\theta_t)\mathrm{d}W_t^{(r)} - a\sin\,\theta_t\,\mathrm{d}W_t^{(\theta)}]. \tag{4.7}$$

Likewise the resultant phase satisfies

$$\mathrm{d}\Theta_t = \frac{-\frac{1}{2}\mathcal{B}au_t^{1/2}\sin\,\theta_t\,\mathrm{d}t + \left(\frac{\mathcal{B}}{2}\right)^{1/2}[a\sin\,\theta_t\,\mathrm{d}W_t^{(r)} + (u_t^{1/2}+a\cos\,\theta_t)\mathrm{d}W_t^{(\theta)}]}{(a^2+u_t+2au_t^{1/2}\cos\,\theta_t)}. \tag{4.8}$$

This leads to the following result.

Proposition 4.1: The Rice vector scattering process $\mathbf{S}_t$ *has drift*

$$b^i = \begin{pmatrix} \mathcal{B}[1-Z+aZ^{1/2}\cos\Theta] \\ -(\mathcal{B}a\sin\Theta)/2Z^{1/2} \end{pmatrix}, \tag{4.9}$$

and diffusion tensor

$$\Sigma^{ij} = \begin{pmatrix} 2\mathcal{B}Z & 0 \\ 0 & \mathcal{B}/2Z \end{pmatrix}. \tag{4.10}$$

B. Homodyned *K*

From (3.3) the amplitude dynamics is identical to that of the *K*-process. Thus for the intensity, in terms of the underlying *K*-scattering geometry, we find

$$\begin{aligned} dZ_t = &\left[\frac{\mathcal{A}z_t(\alpha - x_t)}{x_t} + \mathcal{B}(x_t - z_t) + az_t^{1/2}\cos\theta_t\left(\mathcal{A}\left[\frac{\alpha - x_t - \frac{1}{2}}{x_t}\right] - \mathcal{B}\right)\right]dt \\ &+ (2\mathcal{B}x_t)^{1/2}[a\cos\theta_t + z_t^{1/2}]dW_t^{(r)} - (2\mathcal{B}x_t)^{1/2}[a\sin\theta_t]dW_t^{(\theta)} \\ &+ \left(\frac{2\mathcal{A}}{x_t}\right)^{1/2}[az_t^{1/2}\cos\theta_t + z_t]dW_t^{(x)}. \end{aligned} \tag{4.11}$$

Likewise for the resultant phase we find

$$\begin{aligned} d\Theta_t = &\frac{az_t^{1/2}\sin\theta_t}{Z_t}\left\{\mathcal{A}\left[\left(\frac{2(\alpha - x_t) - 1}{4x_t}\right) - \frac{z_t^{1/2}}{2x_tZ_t}(z_t^{1/2} + a\cos\theta_t)\right] - \frac{1}{2}\mathcal{B}\right\}dt + \left(\frac{\mathcal{B}x_t}{2}\right)^{1/2}\frac{a\sin\theta_t}{Z_t}dW_t^{(r)} \\ &+ \left(\frac{\mathcal{B}x_t}{2}\right)^{1/2}\frac{z_t^{1/2} + a\cos\theta_t}{Z_t}dW_t^{(\theta)} + \left(\frac{\mathcal{A}z_t}{2x_t}\right)^{1/2}\frac{a\sin\theta_t}{Z_t}dW_t^{(x)}. \end{aligned} \tag{4.12}$$

Thus in terms of the resultants (Z,Θ) we deduce that the vector homodyned K-process (x_t, Z_t, Θ_t) has the following structure.

Proposition 4.2: The drift vector is given by

$$b^i = \begin{pmatrix} \mathcal{A}(\alpha - x) \\ \dfrac{\mathcal{A}}{x}\left[(\alpha - x)Z + a\left(x - \alpha - \dfrac{1}{2}\right)Z^{1/2}\cos\Theta + \dfrac{1}{2}a^2\right] + \mathcal{B}(x - Z + aZ^{1/2}\cos\Theta) \\ \dfrac{a\sin\Theta}{Z^{1/2}}\left\{\mathcal{A}\left[\left(\dfrac{2(\alpha - x) - 1}{4x}\right) - \dfrac{1}{2xZ^{1/2}}(Z^{1/2} - a\cos\Theta)\right] - \dfrac{1}{2}\mathcal{B}\right\} \end{pmatrix}. \tag{4.13}$$

The (symmetric) diffusion tensor is

$$\Sigma^{ij} = \begin{pmatrix} 2\mathcal{A}x & 2\mathcal{A}(Z - aZ^{1/2}\cos\Theta) & \dfrac{\mathcal{A}a\sin\Theta}{Z^{1/2}} \\ \cdots & 2Z\left[\dfrac{\mathcal{A}(Z^{1/2} - a\cos\Theta)^2}{x} + \mathcal{B}x\right] & (\mathcal{A}a\sin\Theta)(Z^{1/2} - a\cos\Theta)/x \\ \cdots & \cdots & \dfrac{1}{2Z}\left[\dfrac{\mathcal{A}a^2\sin^2\Theta}{x} + \mathcal{B}x\right] \end{pmatrix}. \tag{4.14}$$

C. Generalized *K*

The differential of the amplitude (3.5) contains both a K-scattering component and an explicit fluctuating part from the cross section, i.e., $d\Psi_t = a\,dx_t + d\psi_t$. This leads, in terms of the K-geometry, to the intensity SDE,

$$\begin{aligned} dZ_t = &\mathcal{A}\left[\frac{z_t(\alpha - x_t)}{x_t} + 2a^2x_t(\alpha - x_t + 1) + 3az_t^{1/2}\left(\alpha - x_t + \frac{1}{2}\right)\cos\theta_t\right]dt + \mathcal{B}(x_t - z_t - ax_tz_t^{1/2}\cos\theta_t)dt \\ &+ (2\mathcal{B}x_t)^{1/2}(z_t^{1/2} + ax_t\cos\theta_t)dW_t^{(r)} - (2\mathcal{B}x_t)^{1/2}ax_t\sin\theta_t\,dW_t^{(\theta)} \\ &+ (2\mathcal{A}x_t)^{1/2}\left(\frac{z_t}{x_t} + 2a^2x_t + 3az_t^{1/2}\cos\theta_t\right)dW_t^{(x)}. \end{aligned} \tag{4.15}$$

Likewise for the phase we find

$$\mathrm{d}\Theta_t = \frac{a z_t^{1/2}\sin\theta_t}{2Z_t}\left[\mathcal{A}\left(\frac{z_t + 2a^2x_t^2 + 3ax_t z_t^{1/2}\cos\theta_t}{Z_t} + x_t - \alpha - \frac{1}{2}\right) - \mathcal{B}x_t\right]\mathrm{d}t + \left(\frac{\mathcal{B}x_t}{2}\right)^{1/2}\frac{ax_t\sin\theta_t}{Z_t}\mathrm{d}W_t^{(r)}$$
$$+ \left(\frac{\mathcal{B}x_t}{2}\right)^{1/2}\frac{z_t^{1/2} + ax_t\cos\theta_t}{Z_t}\mathrm{d}W_t^{(\theta)} - \left(\frac{\mathcal{A}x_t z_t}{2}\right)^{1/2}\frac{a\sin\theta_t}{Z_t}\mathrm{d}W_t^{(x)}. \tag{4.16}$$

Combining these results we obtain the following.

Proposition 4.3: The vector generalized K-scattering process has drift

$$b^i = \begin{pmatrix} \mathcal{A}(\alpha - x) \\ \mathcal{A}\left[Z(\alpha/x - 1) + \frac{1}{2}a^2x + aZ^{1/2}\left(\alpha - x + \frac{3}{2}\right)\cos\Theta\right] + \mathcal{B}(x - Z + aZ^{1/2}x\cos\Theta) \\ a\sin\Theta\left\{\mathcal{A}\left[(Z^{1/2} + ax\cos\Theta)/Z^{1/2} - \left(\alpha - x + \frac{1}{2}\right)\right] - \mathcal{B}x\right\} \Big/ 2Z^{1/2} \end{pmatrix} \tag{4.17}$$

and (symmetric) diffusion tensor

$$\Sigma^{ij} = \begin{pmatrix} 2\mathcal{A}x & 2\mathcal{A}(Z + axZ^{1/2}\cos\Theta) & -\mathcal{A}ax\sin\Theta/Z^{1/2} \\ \cdots & 2\mathcal{A}(Z + axZ^{1/2}\cos\Theta)^2/x + 2\mathcal{B}xZ & -\mathcal{A}a(Z^{1/2} + ax\cos\Theta)\sin\Theta \\ \cdots & \cdots & (\mathcal{B} + \mathcal{A}a^2\sin^2\Theta)x/2Z \end{pmatrix}. \tag{4.18}$$

V. GEOMETRY OF AMPLITUDE FLUCTUATIONS

We begin with some purely geometrical results concerning the correlation structure in the amplitude fluctuations. Combining drift terms as quantities of $o(\mathrm{d}t^{1/2})$, we write the amplitude stochastic differential as

$$\mathrm{d}\Psi_t = iR_t\exp(i\Theta_t)\mathrm{d}\Theta_t + \exp(i\Theta_t)\mathrm{d}R_t + o(\mathrm{d}t^{1/2}) = \alpha_t\exp[i(\Theta_t + \phi_t)] + i\beta_t\exp[i(\Theta_t + \phi_t)] + o(\mathrm{d}t^{1/2}), \tag{5.1}$$

where α_t, β_t are real valued Ito differentials and ϕ_t is chosen so that their Ito product $\alpha_t\beta_t$ vanishes, i.e., the Wiener components of α_t, β_t are statistically independent (see, e.g., Karatzas and Shreve, 1988). Comparing the two decompositions of $\mathrm{d}\Psi_t$ above, it follows that [neglecting terms of $o(\mathrm{d}t^{1/2})$]

$$\alpha_t\cos\phi_t - \beta_t\sin\phi_t = dR_t,$$

$$\alpha_t\sin\phi_t + \beta_t\cos\phi_t = R_t\,\mathrm{d}\Theta_t. \tag{5.2}$$

Therefore

$$(\alpha_t^2 - \beta_t^2)\sin 2\phi_t = 2R_t\,\mathrm{d}R_t\,\mathrm{d}\Theta_t,$$

$$(\alpha_t^2 - \beta_t^2)\cos 2\phi_t = \mathrm{d}R_t^2 - R_t^2\mathrm{d}\Theta_t^2 \tag{5.3}$$

up to $o(\mathrm{d}t)$. From (4.1)

$$(\Sigma_t^{(\alpha)} - \Sigma_t^{(\beta)})\sin 2\phi_t = \frac{1}{2i}\left[\left(\frac{\Psi_t^*}{\Psi_t}\right)\Sigma_t^{(\Psi)} - \left(\frac{\Psi_t}{\Psi_t^*}\right)\Sigma_t^{(\Psi^*)}\right],$$

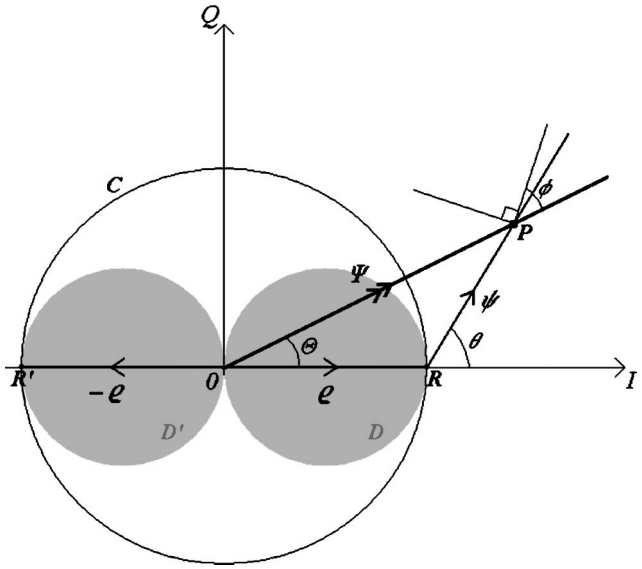

FIG. 1. Geometry of fluctuations for weak scattering processes depicting orthogonal dyad with respect to which resultant amplitude fluctuations decorrelate.

$$(\Sigma_t^{(\alpha)} - \Sigma_t^{(\beta)}) \cos 2\phi_t = \frac{1}{2}\left[\left(\frac{\Psi_t^*}{\Psi_t} \right) \Sigma_t^{(\Psi)} + \left(\frac{\Psi_t}{\Psi_t^*} \right) \Sigma_t^{(\Psi^*)} \right]. \tag{5.4}$$

Also, from (5.2) we find $\alpha_t^2 + \beta_t^2 = \mathrm{d}R_t^2 + R_t^2\, \mathrm{d}\Theta_t^2$ so that

$$\Sigma_t^{(\alpha)} + \Sigma_t^{(\beta)} = \Sigma_t^{(\Psi,\Psi^*)}. \tag{5.5}$$

We deduce from (5.3) that

$$\Sigma_t^{(\alpha)} - \Sigma_t^{(\beta)} = \pm \sqrt{\Sigma_t^{(\Psi)} \Sigma_t^{(\Psi^*)}} \tag{5.6}$$

which, combining with (5.5), yields the following result.

Lemma 5.1:

$$\Sigma_t^{(\alpha)} = \tfrac{1}{2}(\Sigma_t^{(\Psi,\Psi^*)} \pm \sqrt{\Sigma_t^{(\Psi)} \Sigma_t^{(\Psi^*)}}),$$

$$\Sigma_t^{(\beta)} = \tfrac{1}{2}(\Sigma_t^{(\Psi,\Psi^*)} \mp \sqrt{\Sigma_t^{(\Psi)} \Sigma_t^{(\Psi^*)}}). \tag{5.7}$$

with $\pm$ corresponding to the major/minor axes of the error surface of the resultant amplitude, respectively.

Observe that (5.6) and (5.7) have the appropriate symmetry under interchange $\alpha \leftrightarrow \beta$. The angle ϕ_t represents a rotation in the geometry of the resultant amplitude fluctuations relative to the case of pure K-scattering, for which $\phi = 0$. From (5.4) this angle is determined as follows.

Lemma 5.2: The phase rotation ϕ_t, that yields an orthogonal dyad (Fig. 1) associated with independent Wiener increments in the resultant amplitude process Ψ_t, satisfies the geometrical identity

$$\tan 2\phi_t = \frac{4Z_t \Sigma_t^{(Z,\Theta)}}{\Sigma_t^{(Z)} - 4Z_t^2 \Sigma_t^{(\Theta)}}. \tag{5.8}$$

Equivalently, in terms of the resultant complex amplitude process, we have the geometrical identity

$$\tan 2\phi_t = -\frac{\Im[\Psi_t^2\, \mathrm{d}\Psi_t^{*2}]}{\Re[\Psi_t^2\, \mathrm{d}\Psi_t^{*2}]}, \tag{5.9}$$

where $\Re$, $\Im$ *denote the real and imaginary parts, respectively*.

Before applying this geometry to the weak scattering processes described earlier, as a preliminary we give a result which provides the relationship between the structure of the diffusion tensor that arises in the cases of homodyned and generalized *K*-scattering.

Proposition 5.3: The transformation $a \mapsto -ax_t$ *maps the homodyned to the generalized K-scattering diffusion tensor of the vector scattering process* (x_t, Z_t, Θ_t).

Proof: Choose an arbitrary instant of time, labeled $t=0$. Define

$$\Psi_t^{(\mathrm{GK})} = ax_t + \psi_t,$$

$$\Psi_t^{(\mathrm{HK})} = -ax_0 + \psi_t', \tag{5.10}$$

for all $t \geqslant 0$, coincident at $t=0$. Thus $\psi_0' = 2ax_0 + \psi_0$ and otherwise ψ_t, ψ_t' are considered independent *K*-scattering processes. The result is equivalent to the corresponding (complex-valued) vector processes $(x_t, \Psi_t^{(\cdot)})$ having the same diffusion tensor, at the chosen instant. The amplitude components are best computed using the complex polarization, i.e.,

$$\Sigma^{i\,\bar{i}}\mathrm{d}t = \begin{pmatrix} \mathrm{d}\Psi_t^2 & \mathrm{d}\Psi_t\, \mathrm{d}\Psi_t^* \\ \cdots & \mathrm{d}\Psi_t^{*2} \end{pmatrix}. \tag{5.11}$$

The results of Corollary 2.5 and the above relation between ψ_t, ψ_t' at $t=0$ imply that $\mathrm{d}\Psi_0^{(\cdot)2}$ are identical. Likewise the expressions for $|\mathrm{d}\Psi_0^{(\cdot)}|^2$ coincide, by virtue of the cosine rule applied to $\Delta PRR'$ of Fig. 1. The same method shows that $\mathrm{d}x_t\, \mathrm{d}\Psi_t^{(\cdot)}$ are identical at the chosen instant. □

The image point R' has the physical interpretation of a fluctuating cancelling beam, π out of phase with the original $\varrho_t(R)$. A result corresponding to Proposition 5.3 does not hold for the vector scattering drift however, as evident from comparing Propositions 4.2 and 4.3.

A. Rice

The situation here is straightforward since the resultant amplitude dynamics is identical to that of Rayleigh scattering. Thus, as we have seen in Proposition 4.1, the cross term $\Sigma^{(Z,\Theta)}$ vanishes, so that $W_t^{(Z)}$, $W_t^{(\Theta)}$ are independent. The error surface $\mathcal{S}$ at P of Fig. 1 is circular, i.e., the amplitude fluctuations are isotropic and ϕ_t can take any value [both the numerator and denominator in (5.8) are identically zero].

B. Homodyned *K*

Using Lemma 5.2 and (4.14) we find

$$\tan\phi_t = \frac{a\sin\Theta_t}{Z_t^{1/2} - a\cos\Theta_t} \tag{5.12}$$

and minus its reciprocal for the perpendicular $\phi \mapsto \phi + \pi/2$. Thus, in terms of the geometry of Fig. 1 (e.g., by drawing a perpendicular from R to the line OP) we see that $\phi_t = \theta_t - \Theta_t$ $(\hat{OPR})$, i.e., the (major) axis of $\mathcal{S}^{\mathrm{HK}}$ coincides with that of the underlying *K*-scattering process, as anticipated from the differential of (3.3). The radial and angular components of the resultant amplitude fluctuations decorrelate [the diffusion coefficient $\Sigma^{(Z,\Theta)}$ of (4.14) vanishes] if the major/minor axis of the error ellipse of the *K*-amplitude fluctuations is aligned with the resultant amplitude (respectively, the first/second factor in $\Sigma^{(Z,\Theta)}$ vanishes). In the latter case P lies on the boundary ∂D and OP, PR are perpendicular. Inside the domain D the error surface $\mathcal{S}$ rotates (anticlockwise for P shown in the upper half plane in Fig. 1) and $\Sigma^{(Z,\Theta)} \lessgtr 0$ according as P lies in the upper/lower half-plane, while the opposite situation holds for the complement $\bar{D}$.

C. Generalized *K*

Perhaps the most interesting geometrical features emerge for generalized *K*-scattering. In this case the coherent offset (e.g., a fluctuating beam) $\varrho_t = ax_t$ has intrinsic fluctuations, arising from those in the scattering population (cf. in Fig. 1 the boundaries ∂D and $\partial D'$ fluctuate in time). Using Lemma 5.2, Proposition 5.3 and the homodyned result (5.12) it is immediate that, for generalized *K*-scattering,

$$\tan \phi_t = -\frac{ax_t \sin \Theta_t}{Z_t^{1/2} + ax_t \cos \Theta_t} \tag{5.13}$$

(and minus the reciprocal). The above tangent corresponds to an axis of $\mathcal{S}^{\mathrm{GK}}$ along $R'P$ (as seen, e.g., by drawing a perpendicular from R' to the continuation in Fig. 1 of OP). In contrast to homodyned *K*-scattering, the symmetry axes of the error surface $\mathcal{S}^{\mathrm{GK}}$ of the resultant amplitude are no longer aligned to those of the underlying *K*-amplitude. For alignment of the axes of $\mathcal{S}^{\mathrm{GK}}$ and $\mathcal{S}^{\mathrm{K}}$ to occur, we require the above tangent to coincide with $\tan \phi_0 = ax \sin \Theta/(Z^{1/2} - ax \cos \Theta)$, or minus the reciprocal, which occurs if $Z=0$ or $Z^{1/2}=ax$. In the latter case P lies on the circle C shown, consistently on which PR, PR' are perpendicular. The major axis of $\mathcal{S}^{\mathrm{GK}}$ at a general P can be identified by writing

$$d\Psi_t = (A_t + iB_t)\hat{z}_t + o(\mathrm{d}t^{1/2}), \tag{5.14}$$

where A_t, B_t are independent real-valued (Wiener components of) Ito differentials, and $\hat{z}_t = (\Psi_t + ax_t)/|\Psi_t + ax_t|$ corresponding to a unit vector in the axial direction $R'P$. Then we have the squared relation $\mathrm{d}\Psi_t^2 = (A_t^2 - B_t^2)\hat{z}_t^2$. Comparing with the expression for $\mathrm{d}\Psi_t^2$ derived from Corollary 2.5 and (3.5) we find

$$\Sigma_t^{(A)} - \Sigma_t^{(B)} = \frac{\mathcal{A}|\Psi_t + ax_t|^2}{2x_t}, \tag{5.15}$$

so $\Sigma_t^{(A)} \geqslant \Sigma_t^{(B)}$ with equality if and only if $\mathcal{A}=0$ or $\Psi_t + ax_t = 0$, i.e., $P=R'$. Strict inequality implies $R'P$ is the major axis of $\mathcal{S}^{\mathrm{GK}}$ with (circular) degeneracy otherwise. From the expression for $\Sigma_t^{(Z,\Theta)}$ in (4.18), decorrelation of the radial and angular components of Ψ_t occurs if P lies on the I axis or boundary $\partial D'$. In the latter case $R'P$ is the major axis of $\mathcal{S}^{\mathrm{GK}}$ and OP, PR' are perpendicular ($P \neq R'$). Inside D' in the upper/lower half-plane, $\Sigma^{(Z,\Theta)} \gtrless 0$ and $\mathcal{S}$ rotates with a corresponding orientation.

A measure of the total uncertainty ϵ_t in the resultant amplitude Ψ_t is provided by the eigenvalue product $\Sigma_t^{(\alpha)}\Sigma_t^{(\beta)} = \det[\Sigma_t^{ij}]$. For homodyned *K*-scattering, Corollary 2.5 and (5.7) imply

$$\Sigma_t^{(\alpha)} = \begin{cases} \dfrac{1}{2}\left(\dfrac{\mathcal{A}}{x_t}(\overbrace{Z_t - 2aZ_t^{1/2}\cos\Theta_t + a^2}^{z_t}) + \mathcal{B}x_t\right), \\ \dfrac{1}{2}\mathcal{B}x_t, \end{cases} \tag{5.16}$$

so that $\epsilon_t = \frac{1}{4}\mathcal{B}(\mathcal{A}z_t + \mathcal{B}x_t^2)$. Setting $\mathcal{A}=0$, $x_t=1$ for Rice and using Proposition 5.3 and (5.16) for generalized *K*-scattering we deduce the hierarchy of increasing uncertainties (in the sense of the proliferation of terms that arise)

$$\epsilon_t = \begin{cases} \frac{1}{4}\mathcal{B}^2 \quad (\mathrm{Rice}), \\ \frac{1}{4}\mathcal{B}(\mathcal{A}z_t + \mathcal{B}x_t^2) \quad (\mathrm{HK}), \\ \frac{1}{4}\mathcal{B}(\mathcal{A}z_t + \mathcal{B}x_t^2) + \mathcal{A}\mathcal{B}Z_t^{1/2}ax_t\cos\Theta_t \quad (\mathrm{GK}). \end{cases} \tag{5.17}$$

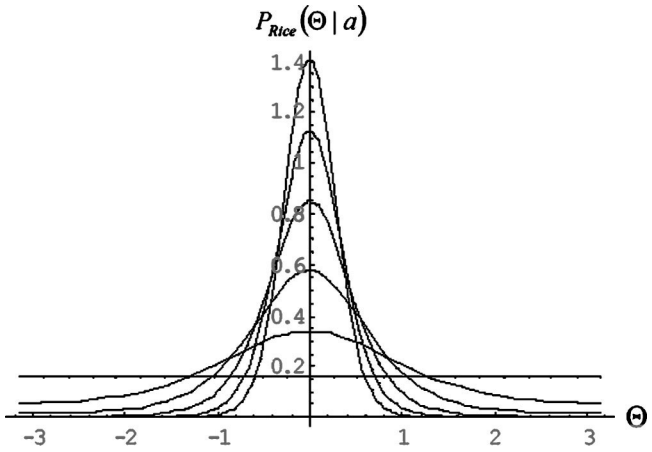

FIG. 2. Phase pdf for the Rice model, $a=0,\frac{1}{2},1,\frac{3}{2},2,\frac{5}{2}$.

We remark that these geometrical properties of the amplitude fluctuations should provide various means for anomaly detection, through the observability of the squared volatilities (cf. Field and Tough, 2003a) and their departure, for $a \neq 0$, from the pure K-scattering values.

VI. ASYMPTOTIC BEHAVIOR

The effect of the offset in the mean amplitude $\langle \Psi \rangle \neq 0$ for $a \neq 0$ is that the resulting (asymptotic) phase distributions are nonuniform. Expressions for these distributions can be calculated for the various processes we have described. We begin by deriving the joint asymptotic probability distribution functions (pdf) for the cross section, modulus amplitude and phase, and from these deduce the marginal pdf's of these quantities by integration.

A. Rice

Noting that ψ_t is a complex Gaussian process, we see that the familiar Rice process (Rice, 1954) emerges as the model for weak scattering. If we write the amplitude and phase of the scattered field as (E,Θ) their joint distribution takes the form

$$P(E,\Theta) = \frac{E \exp(-(E^2 + a^2 - 2Ea\cos\Theta))}{\pi}. \tag{6.1}$$

From this we can derive the familiar result for the marginal pdf of the field amplitude

$$P(E) = 2E \exp(-(E^2 + a^2)) I_0(2Ea), \tag{6.2}$$

where I_0 is the modified Bessel function of the first kind. The phase distribution associated with the Rice model can be obtained from (6.1) by integration over E. The result can be expressed in a reasonable closed form in terms of the error function,

$$\begin{aligned} P(\Theta|a) &= \int_0^\infty P(E,\Theta)\mathrm{d}E = \frac{\exp(-a^2\sin^2\Theta)}{\pi} \int_0^\infty E \exp(-(E - a\cos\Theta)^2)\mathrm{d}E \\ &= \frac{\exp(-a^2\sin^2\Theta)}{\pi} \int_{-a\cos\Theta}^\infty (E + a\cos\Theta)\exp(-E^2)\mathrm{d}E \\ &= \frac{1}{2\pi}\exp(-a^2) + \frac{a\cos\Theta}{2\sqrt{\pi}}(1 + \mathrm{erf}(a\cos\Theta))\exp(-a^2\sin^2\Theta). \end{aligned} \tag{6.3}$$

Figure 2 shows the behavior of this function, for differing values of a, whose square can be

interpreted as a signal to noise power ratio.

B. Homodyned *K*

In the case of the homodyned *K*-scattering process, which can be represented through (3.3), the joint pdf of the cross section, field amplitude and phase is

$$P(x,E,\Theta) = \frac{Eb^{\alpha}}{\pi\Gamma(\alpha)} x^{\alpha-2} \exp(-bx)\exp(-(E^2+a^2)/x) \exp(2Ea\cos\Theta/x). \tag{6.4}$$

The field amplitude pdf associated with the homodyned *K*-scattering model cannot be rendered in a simple closed form for general values of the shape parameter α. Its compound representation takes the form

$$P(E) = \frac{2Eb^{\alpha E}}{\Gamma(\alpha)} \int_0^{\infty} x^{\alpha-2} \exp(-bx) \exp(-(E^2+a^2)/x) I_0(2Ea/x)\mathrm{d}x. \tag{6.5}$$

The asymptotic phase distribution for the homodyned *K*-scattering model cannot be evaluated in closed form. The compound representation of the process indicates that the phase pdf can be written as

$$P(\Theta|a,b,\alpha) = \frac{b^{\alpha}}{\Gamma(\alpha)} \int_0^{\infty} P(\Theta|a,x) \exp(-bx) x^{\alpha-1}\,\mathrm{d}x, \tag{6.6}$$

where we define

$$P(\Theta|a,x) = \frac{1}{2\pi} \exp(-a^2/x) + \frac{a\cos\Theta}{2\sqrt{\pi x}}(1+\mathrm{erf}(a\cos\Theta/\sqrt{x})) \exp(-a^2\sin^2\Theta/x). \tag{6.7}$$

This can be recast in the form

$$\begin{aligned} P(\Theta|a,b,\alpha) = {} & \frac{(a^2b)^{\alpha/2}}{\pi\Gamma(\alpha)} K_{\alpha}(2\sqrt{ba^2}) + \frac{a\cos\Theta b^{(\alpha/2)-1/4}(a^2\sin^2\Theta)^{(\alpha/2)+1/4}}{\sqrt{\pi}\Gamma(\alpha)} K_{\alpha-1/2}(2\sqrt{ba^2\sin^2\Theta}) \\ & + 2\frac{a^{\alpha+1}b^{(\alpha+1)/2}\cos^2\Theta}{\pi\Gamma(\alpha)} \int_0^1 K_{\alpha-1}(2\sqrt{ba^2(\sin^2\Theta + t^2\cos^2\Theta)}) \\ & \times(\sin^2\Theta + t^2\cos^2\Theta)^{(\alpha-1)/2}\,\mathrm{d}t \end{aligned} \tag{6.8}$$

by using the integral representation of the error function

$$\mathrm{erf}(a\sqrt{x}\cos\Theta) = \frac{2a\sqrt{x}\cos\Theta}{\sqrt{\pi}} \int_0^1 \exp(-s^2a^2x\cos^2\Theta)\mathrm{d}s. \tag{6.9}$$

The representation (6.8) while a little arcane appears, when implemented in *Mathematica* (Wolfram, 1999), to be more stable and efficient than a direct numerical integration of (6.6). The corresponding plots of the phase pdf for the homodyned *K*-scattering model are shown in Figs. 3 and 4.

C. Generalized *K*

To generalize the weak scattering model to the non-Gaussian regime we allow the number of steps in the biased random walk to fluctuate according to (3.4). The joint distribution of the cross-section, field amplitude, and phase now takes the form

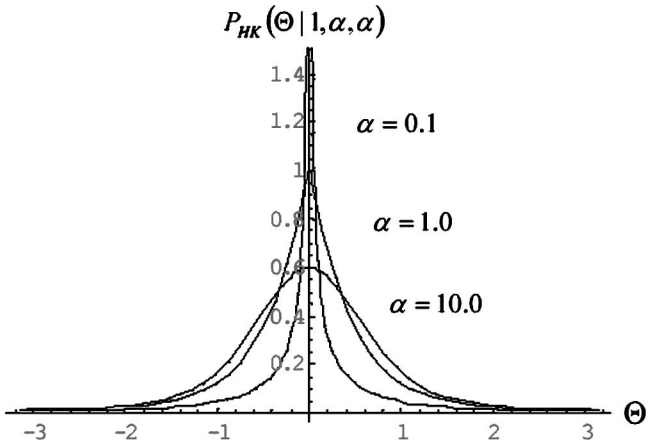

FIG. 3. Phase pdf's derived from the homodyned *K*-scattering model, $\alpha = 0.1, 1.0, 10.0$.

$$P(x,E,\Theta) = \frac{Eb^{\alpha}}{\pi\Gamma(\alpha)} x^{\alpha-2} \exp(-bx) \exp(-(E^2 + a^2x^2)/x) \exp(2Ea\cos\Theta). \tag{6.10}$$

(Here we have introduced the scale parameter b to relax the condition that the power in the complex Ornstein–Uhlenbeck process is taken as unity.) This provides us with the compound representation of the generalized *K*-scattering process in accordance with (2.7). This is to be contrasted with the corresponding result for the homodyned *K*-scattering process above. Thus by integration we have the field amplitude pdf given by

$$P(E) = \frac{4Eb^{\alpha}}{\Gamma(\alpha)(a^2+b)^{(\alpha-1)/2}} I_0(2Ea) K_{\alpha-1}(2E\sqrt{a^2+b}), \tag{6.11}$$

which is essentially the result obtained in Jakeman and Tough (1987) using the method of characteristic functions. The calculation of the asymptotic phase distribution for Rice scattering can be extended straightforwardly to the generalized and homodyned *K*-scattering models, essentially by exploiting the compound representation (2.7). Thus using (6.7) we construct

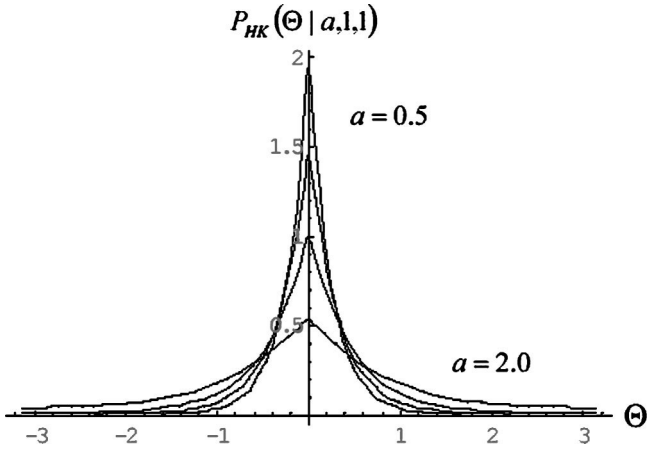

FIG. 4. Phase pdf's derived from the homodyned *K*-scattering model, $a = 0.5, 1.0, 1.5, 2.0$.

$$P(\Theta|a,b,\alpha) = \frac{b^\alpha}{\Gamma(\alpha)} \int_0^\infty P(\Theta|ax,x) \exp(-bx) x^{\alpha-1}\, dx. \tag{6.12}$$

This consists of three terms; two are straightforward while the third can be expressed in terms of a hypergeometric function. To this end we have

$$\begin{aligned} &\frac{b^\alpha}{\Gamma(\alpha)} \frac{1}{2\pi} \int_0^\infty x^{\alpha-1} \exp(-(b+a^2)x) dx = \frac{1}{2\pi} \left(\frac{b}{b+a^2} \right)^\alpha, \\ &\frac{b^\alpha}{\Gamma(\alpha)} \frac{1}{2\sqrt{\pi}} a \cos\Theta \int_0^\infty x^{\alpha-1/2} \exp(-(b+a^2 \sin^2\Theta)x) dx \\ &\quad = \frac{a\cos\Theta}{\sqrt{(b+a^2\sin^2\Theta)}} \frac{\Gamma(\alpha+1/2)}{2\Gamma(\alpha)\sqrt{\pi}} \frac{1}{(1+a^2\sin^2\Theta/b)^\alpha}. \end{aligned} \tag{6.13}$$

The third term can be evaluated by substituting (6.9) and integrating over x, thus

$$\begin{aligned} &\int_0^\infty \exp(-(a^2\sin^2\Theta + b)x) x^{\alpha-1} a\sqrt{x} \cos\Theta \operatorname{erf}(a\sqrt{x}\cos\Theta) dx \\ &\quad = \frac{2\Gamma(\alpha+1)}{\sqrt{\pi}} a^2 \cos^2\Theta \int_0^1 (b + a^2\sin^2\Theta + a^2 s^2 \cos^2\Theta)^{-(\alpha+1)}\, ds \\ &\quad = \frac{2\Gamma(\alpha+1)}{\sqrt{\pi}} \frac{a^2\cos^2\Theta}{(a^2\sin^2\Theta + b)^{\alpha+1}} {}_2F_1(1/2, \alpha+1; 3/2; -a^2\cos^2\Theta/(a^2\sin^2\Theta + b)). \end{aligned} \tag{6.14}$$

On bringing these results together we obtain

$$\begin{aligned} P(\Theta|a,b,\alpha) = {} & \frac{1}{2\pi} \left(\frac{b}{b+a^2} \right)^\alpha + \frac{a\cos\Theta}{\sqrt{(b+a^2\sin^2\Theta)}} \frac{\Gamma(\alpha+1/2)}{2\Gamma(\alpha)\sqrt{\pi}} \frac{1}{(1+a^2\sin^2\Theta/b)^\alpha} + \frac{\alpha}{\pi} \\ & \times \frac{a^2\cos^2\Theta}{(a^2\sin^2\Theta + b)} \frac{1}{(1+a^2\sin^2\Theta/b)^\alpha} {}_2F_1(1/2, \alpha+1; 3/2; -a^2\cos^2\Theta/(a^2\sin^2\Theta + b)). \end{aligned} \tag{6.15}$$

It is interesting to compare this result with that derived in an analysis of the performance of interferometric synthetic aperture radar [Eq. (53) in Tough, 1991], to which the above result reduces when the shape parameter α takes integer values. Figure 5 shows the phase pdf derived from the generalized K-scattering model. We have chosen $a=1$, $\langle x \rangle = 1$, and $\alpha = 0.1$, 1, 10. Spikier noise, associated with lower values of α, results in a broader distribution of phase. In Fig. 6 we show the variation in the phase distribution with the parameter a, keeping the mean noise power $\langle x \rangle = 1$ and $\alpha = 1$. The phase distribution becomes narrower as the parameter a increases. Comparison with Fig. 2 shows that, while the mean noise power is the same in each, the more spiky nature of the noise is manifest in a broader phase distribution.

The most marked difference between the phase pdf's derived from the homodyned and generalized K-scattering models is evident at small values of α (i.e., less than unity), where a singular behavior is observed at the origin. This can be seen quite clearly in Fig. 4. When α takes larger values a behavior more reminiscent of that seen in Fig. 2 emerges, as the noise becomes more Gaussian in character. In the case where $\alpha = 1$, the phase pdf displays a cusp at the origin, irrespective of the value of a; this can be seen in Fig. 4. The differences between the phase pdf's derived from the homodyned and generalized models can be understood qualitatively in terms of the signal fluctuating with x_t in the latter, but remaining constant in the former. Jakeman and Tough (1987) discuss the implications of this difference between the models in some detail, without making explicit reference to the asymptotic phase pdf's.

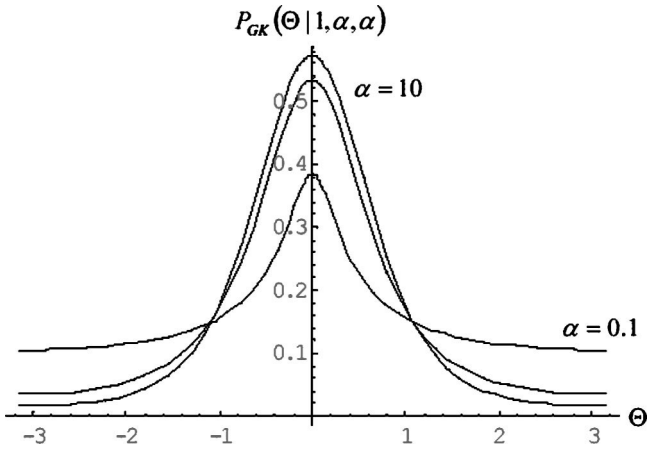

FIG. 5. Phase pdf's derived from the generalized *K*-scattering model, $\alpha = 0.1, 1.0, 10.0$.

D. Detailed balance

The detailed balance condition holds (asymptotically) for each of the weak scattering processes we have described. This result follows essentially from the condition being satisfied in the case of pure *K*-scattering, and the ways in which the weak scattering processes can be represented as functions of an underlying *K*-scattering process. To complete the analysis we shall need the following result.

Lemma 6.1: If a (complex valued/n-dimensional) Ito diffusion process x_t^i *satisfies detailed balance (at time t) then so does the transformed process* $\hat{x}_t^{\hat{i}} = \mathbf{f}(x_t^i)$*, i.e. (in contrast to the drift), if* x_t^i *has vanishing current then so does* $\hat{x}_t^{\hat{i}}$.

Proof: Applying Ito's formula to the components $\hat{x}^{\hat{i}}$ we find

$$b^{\hat{i}} = P_i^{\hat{i}} b^i + \tfrac{1}{2} P_{ij}^{\hat{i}} \Sigma^{ij}, \quad \Sigma^{\hat{i}\hat{j}} = P_i^{\hat{i}} P_j^{\hat{j}} \Sigma^{ij}, \tag{6.16}$$

where $P_i^{\hat{i}}$ denotes the transition matrix of partial derivatives $\partial \hat{x}^{\hat{i}} / \partial x^i$, with a corresponding notation for second derivatives. Attention should be paid to the nontensorial nature of the second term in the drift transformation, which is characteristic of the Ito calculus. The probability density transforms as $\hat{\rho} J = \rho$ where J is the Jacobian of P, i.e., $\varepsilon^{\hat{i}_1 \hat{i}_2 \cdots \hat{i}_n} J = \varepsilon^{i_1 i_2 \cdots i_n} P_{i_1}^{\hat{i}_1} P_{i_2}^{\hat{i}_2} \cdots P_{i_n}^{\hat{i}_n}$. Using the identity

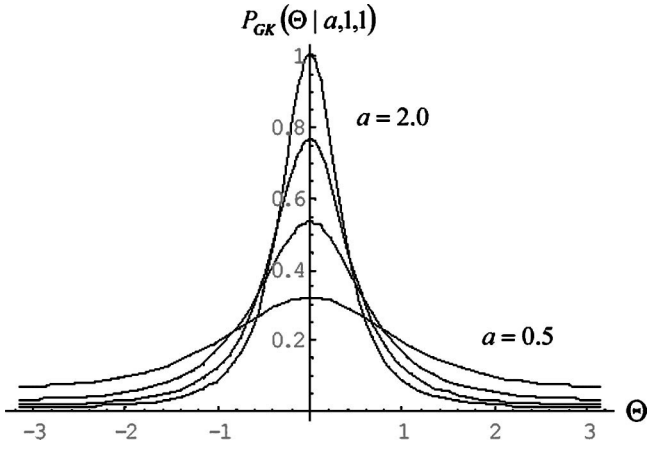

FIG. 6. Phase pdf's derived from the generalized *K*-scattering model, $a = 0.5, 1.0, 1.5, 2.0$.

$\partial_j \log J \equiv P^k_{\hat{j}} P^{\hat{j}}_{jk}$ and the relation (4.6) we deduce the current transformation $\hat{\mathcal{V}^i} = P^{\hat{i}}_i \mathcal{V}^i$, i.e., the current transforms as a vector. The equivalent holomorphic/antiholomorphic representation follows, via a complex change of coordinates. [Compare Field (2003) for an account of the geometrical structure of the transformations in drift and current involved here.] □

It is known that the *K*-scattering amplitude ψ_t (asymptotically) satisfies detailed balance, as evident from the compound representation (2.7) and the equilibrium condition (Field and Tough, 2003b). As a consequence of Lemma 6.1, the relations (3.2), (3.3), (3.5) and the independence of the processes x_t, γ_t we obtain the following result.

Corollary 6.2: The vector scattering processes (x_t, Z_t, Θ_t) *in cases (a)–(c) each satisfy the condition of detailed balance, asymptotically*.

Alternatively, detailed balance can be shown by explicit calculation using (4.6) and the expressions for the asymptotic distributions given above. In the presence of Doppler (Field and Tough, 2003b) detailed balance is no longer satisfied, and the current $\mathcal{V}$ amounts to a (rigid) rotation of the Argand Ψ-plane at a corresponding angular frequency.

VII. DISCUSSION

The *K*-distribution provides a useful model of the non-Gaussian statistics of strongly scattered radiation with a uniform distribution of phase. In recent work (Field and Tough, 2003a, 2003b) a description of the *K*-scattering process in terms of SDEs has been developed that makes direct contact with a simple underlying random walk model of scattering. In this paper we have extended this analysis to models of weak scattering, in which the distribution of phase is nonuniform.

The *K*-scattering process can be derived from an isotropic random walk with a fluctuating number of steps. To incorporate a nonuniform distribution of phase we consider a random walk on which a preferred direction or bias has been imposed. In the case where the random walk has a large, but fixed, number of steps the Rice process emerges as a model for weak scattering. We have analyzed the phase distribution associated with this model, and established the connection between its random walk formulation and a description in terms of SDEs.

The extension of the Rice model to the non-Gaussian regime is effected when we allow the number of steps in the biased random walk to fluctuate. We have shown how this leads to the generalized *K*-scattering process discussed in Jakeman and Tough (1987) and have made contact between this model and the homodyned *K*-scattering process. In each case we have characterized the associated distribution of phase in detail, and have developed a description in terms of SDEs and their equivalent Fokker–Planck equations. This complements the earlier dynamical description of *K*-scattering (Field and Tough, 2003a, 2003b).

The results have implications for detection schemes where the signal behavior (represented by the coherent offset in the resultant amplitude) can, to a reasonable extent, be modeled in the context of ambient *K*-distributed noise (cf. the results reported in Sec. IV of Field and Tough, 2003a). The results of Sec. V indicate a method for anomaly detection based on departures in the geometry of the resultant amplitude fluctuations from that expected in the pure *K*-scattering case. The results should find application in adaptive imaging problems, in the denoising of optical images (signal separation from noise, i.e., extraction of ϱ_t from Ψ_t) and anomaly detection in radar backscatter where a (coherent) reflection contribution is involved (cf. Jakeman and Tough, 1987).

The generalized Stieltjes transform and its inverse

John H. Schwarz
California Institute of Technology, Pasadena, California 91125

(Received 3 June 2004; accepted 16 September 2004; published online 23 December 2004)

The generalized Stieltjes transform (GST) is an integral transform that depends on a parameter $\rho>0$. In previous work a convenient form of the inverse transformation was derived for the case $\rho=3/2$. This paper generalizes that result to all $\rho>0$. It is a well-known fact that the GST can be formulated as an iterated Laplace transform, and that therefore its inverse can be expressed as an iterated inverse Laplace transform. The form of the inverse transform derived here is a one-dimensional integral that is considerably simpler. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1825077]

I. INTRODUCTION

In Ref. 1 we encountered the integral equation

$$g(\zeta)=\int_0^\infty (\zeta^2+\mu^2)^{-3/2} f(\mu)\mathrm{d}\mu, \quad |\arg\zeta|<\pi/2, \tag{1}$$

where $g(\zeta)$ was a known function, and we needed to solve for $f(\mu)$. That paper proved that if g has suitable analyticity and asymptotic properties, which were satisfied for the specific function of interest, then

$$f(\mu)=-\frac{i\mu^2}{\pi}\int_0^\pi \cos\theta\, g(-i\mu\cos\theta)\mathrm{d}\theta. \tag{2}$$

This result is reviewed in Ref. 2.

By a change of variables, Eq. (2) can be rewritten in the form

$$f(\mu)=\frac{\mu}{\pi i}\int_{-i\mu}^{i\mu}\frac{\zeta}{\sqrt{\mu^2+\zeta^2}}g(\zeta)\mathrm{d}\zeta. \tag{3}$$

Then letting $y=\mu^2$ and $z=\zeta^2$, as well as $F(y)=(1/2\mu)f(\mu)$ and $G(z)=g(\zeta)$, we obtain

$$G(z)=\int_0^\infty (y+z)^{-3/2}F(y)\mathrm{d}y, \quad |\arg z|<\pi \tag{4}$$

and

$$F(y)=\frac{1}{4\pi i}\int_{\mathcal{C}_y}\frac{G(z)}{\sqrt{y+z}}\mathrm{d}z. \tag{5}$$

The contour $\mathcal{C}_y$ starts and ends at $-y$ and encloses the origin in the counterclockwise sense.

It is convenient to have a y-independent contour, so letting $z=wy$ we obtain

$$F(y) = \frac{1}{4\pi i}\sqrt{y}\int_{\mathcal{C}} \frac{G(yw)}{\sqrt{1+w}}\mathrm{d}w, \tag{6}$$

where $\mathcal{C}$ is a contour that starts and ends at the point $w=-1$ enclosing the origin in the counterclockwise sense. It could be chosen to be the unit circle, for instance. Note that it is not really a closed contour, since $G(z)$ has a branch cut running along the negative real axis. An integration by parts allows this to be rewritten in the form

$$F(y) = -\frac{1}{2\pi i}y^{3/2}\int_{\mathcal{C}} \sqrt{1+w}\,G'(yw)\mathrm{d}w. \tag{7}$$

In this paper, we will formulate and prove a one-parameter generalization of the preceding result. Specifically, we claim that the integral transform

$$G(z) = \int_0^\infty (y+z)^{-\rho}F(y)\mathrm{d}y, \quad |\arg z| < \pi \tag{8}$$

has as its inverse transform

$$F(y) = -\frac{1}{2\pi i}y^{\rho}\int_{\mathcal{C}} (1+w)^{\rho-1}G'(yw)\mathrm{d}w. \tag{9}$$

This integral converges for $\rho>0$. The special case discussed above corresponds to $\rho=3/2$. The counterpart of Eq. (6), obtained by integration by parts, namely

$$F(y) = \frac{1}{2\pi i}(\rho-1)y^{\rho-1}\int_{\mathcal{C}} (1+w)^{\rho-2}G(yw)\mathrm{d}w, \tag{10}$$

is less general, since it is only valid for $\rho>1$. This is allowed in the $\rho=3/2$ case, of course.

We should note for the record what is being assumed about F and G. Specifically, $F(y)$, which is only defined on the positive real axis, is allowed to be an arbitrary distribution (or "generalized function"). We require that there exists a number α with $0<\alpha<\rho$ such that $\left|\int_{y_1}^{y_2} y^{\alpha-\rho}F(y)\,\mathrm{d}y\right|$ is bounded by a number independent of y_1 and y_2 for all $0<y_1<y_2$. The function $G(z)$ is then holomorphic throughout the cut plane $|\arg z|<\pi$, and there exists a positive real number β such that $|z^{\beta}G(z)|$ is bounded at infinity.

The $\rho=1$ case of Eq. (8), known as the Stieltjes transform, is discussed in Widder's classic treatise on the Laplace transform.[3] The only other cases considered by Widder are positive integer values of ρ, which are related to the $\rho=1$ case by differentiation. Following Ref. 4, we refer to the case of arbitrary ρ as the generalized Stieltjes transform (GST). (In Ref. 5 it is called a Stieltjes transform of index ρ.) The formula for the inverse GST in Eq. (9) does not seem to have been found previously. Certainly, it does not appear in Refs. 3–5 or 6.

Much of the literature on the GST is concerned with the asymptotic behavior of $G(z)$ for large $|z|$.[7] We will not address that topic here. As it happens, in Ref. 1 we were interested in deducing the asymptotic behavior of F associated with a given G.

In the special case $\rho=1$ the transform in Eq. (8) reduces to the Stieltjes transform

$$G(z) = S_z[F] = \int_0^\infty \frac{F(y)}{y+z}\mathrm{d}y. \tag{11}$$

Since the Stieltjes transform is well understood, this case provides an instructive test of the proposed inverse transform. Setting $\rho=1$ in Eq. (9) gives an expression that can be integrated explicitly to give

$$F(y) = \lim_{\epsilon \to 0^+} \frac{1}{2\pi i} \big(G(-y - i\epsilon) - G(-y + i\epsilon) \big). \tag{12}$$

Given the stated analytic and asymptotic properties of $G(z)$, it is a simple consequence of Cauchy's theorem that this is the correct solution of Eq. (11) for $y > 0$.

In order to convince oneself that Eqs. (8) and (9) are plausible for all $\rho > 0$, it is instructive to consider a simple example. Specifically, if one chooses

$$F(y) = y^{\nu - 1}, \tag{13}$$

then the integral in Eq. (8) converges for $0 < \nu < \rho$ and gives

$$G(z) = z^{\nu - \rho} B(\nu, \rho - \nu), \tag{14}$$

where $B(u,v)$ is the Euler beta function. It is straightforward to verify that this pair of functions also satisfies Eq. (9).

II. OTHER VERSIONS OF THE INVERSE TRANSFORM

The change of variables $z = wy$ allows us to rewrite Eq. (9) in the alternative form

$$F(y) = -\frac{1}{2\pi i} \int_{\mathcal{C}_y} (y + z)^{\rho - 1} G'(z) \mathrm{d}z. \tag{15}$$

As before, the contour $\mathcal{C}_y$ starts and ends at the point $z = -y$, encircling the origin in the counterclockwise sense. If $\rho > 1$, an integration by parts brings Eq. (15) to the form

$$F(y) = \frac{1}{2\pi i} (\rho - 1) \int_{\mathcal{C}_y} (y + z)^{\rho - 2} G(z) \mathrm{d}z. \tag{16}$$

Since this is only well-defined for $\rho > 1$, Eqs. (9) and (15) are more general than Eq. (16).

Let us define the quantity that appears on the right-hand side of Eq. (12) to be

$$\Delta(t) = \frac{1}{2\pi i} \lim_{\epsilon \to 0^+} \big(G(-t - i\epsilon) - G(-t + i\epsilon) \big), \quad t > 0. \tag{17}$$

We showed that $F(y) = \Delta(y)$ when $\rho = 1$, but this is not the case for other values of ρ. By shrinking the contour $\mathcal{C}_y$ down to the cut, Eq. (16) takes the form

$$F(y) = (\rho - 1) \int_0^y (y - t)^{\rho - 2} \Delta(t) \mathrm{d}t. \tag{18}$$

In similar fashion, Eq. (15) gives rise to

$$F(y) = \int_0^y (y - t)^{\rho - 1} \Delta'(t) \mathrm{d}t. \tag{19}$$

However, these formulas are only correct if the behavior of $G(t)$ near the origin is such that these integrals exist. The contour integral versions of these formulas are more general, since they do not have this restriction.

Equations (18) and (19) have the structure of Abel transforms. The inverse Abel transform is well known and can be used to give a formula for the discontinuity across the cut, $\Delta(t)$, in terms of the original (generalized) function $F(y)$. A version that is suitable if $\rho < 2$ and $F(0) = 0$ is

$$\Delta(t) = \frac{\sin \pi\rho}{\pi(1-\rho)} \int_0^t (t-y)^{1-\rho} F'(y) \mathrm{d}y. \tag{20}$$

This gives the known result for $\rho=1$, namely $\Delta(t)=F(t)$. It can be checked for the simple example $F(y)=y^{\nu-1}$ discussed earlier.

III. PROOF OF THE MAIN RESULT

Let us review how the GST is related to the Laplace transform, for which we use the following notation:

$$\mathcal{L}_x[F] = \int_0^\infty e^{-xy} F(y) \mathrm{d}y. \tag{21}$$

Inserting the identity

$$(y+z)^{-\rho} = \frac{1}{\Gamma(\rho)} \int_0^\infty x^{\rho-1} e^{-x(y+z)}\, \mathrm{d}x \tag{22}$$

into Eq. (8) gives

$$G(z) = \frac{1}{\Gamma(\rho)} \int_0^\infty x^{\rho-1} e^{-xz} \mathcal{L}_x[F] \mathrm{d}x = \frac{1}{\Gamma(\rho)} \mathcal{L}_z[x^{\rho-1} \mathcal{L}_x[F]]. \tag{23}$$

This recasts Eq. (8) as a Laplace transform of a Laplace transform. In particular, setting $\rho=1$, this gives the well-known result that the Stieltjes transform is the square (in the operator sense) of the Laplace transform, i.e., $\mathcal{S}=\mathcal{L}^2$.

Equation (23) implies that

$$\mathcal{L}_x[F] = \Gamma(\rho) x^{1-\rho} \mathcal{L}_x^{-1}[G], \tag{24}$$

where $\mathcal{L}^{-1}$ denotes an inverse Laplace transform. A second inverse Laplace transform gives the formal inversion of Eq. (23),

$$F(y) = \Gamma(\rho) \mathcal{L}_y^{-1}[x^{1-\rho} \mathcal{L}_x^{-1}[G]]. \tag{25}$$

This can be made very explicit by using the standard contour integral realization of the inverse Laplace transformation.[5] The new claim is that Eq. (25) can be simplified to take the form of Eq. (9).

Let us now carry out some similar manipulations of Eq. (9). Substituting

$$G'(yw) = -\int_0^\infty \mathrm{d}t\, e^{-tyw} t \mathcal{L}_t^{-1}[G] \tag{26}$$

into Eq. (9) and taking the Laplace transform of both sides recasts Eq. (9) in the form

$$\mathcal{L}_x[F] = \Gamma(\rho+1) \frac{1}{2\pi i} \int_{\mathcal{C}} \mathrm{d}w (1+w)^{\rho-1} \int_0^\infty \mathrm{d}t (x+tw)^{-\rho-1} t \mathcal{L}_t^{-1}[G]. \tag{27}$$

Comparing Eqs. (24) and (27), we see that their equivalence requires the identity

$$\frac{t\rho}{2\pi i} \int_{\mathcal{C}} \mathrm{d}w (1+w)^{\rho-1} (x+tw)^{-\rho-1} = x^{-1-\rho} \delta(x-t), \tag{28}$$

or equivalently

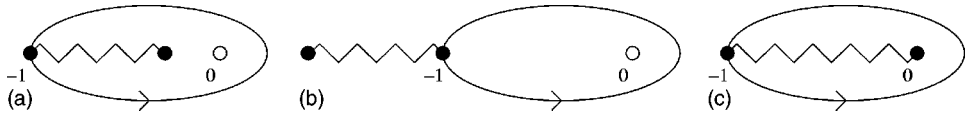

FIG. 1. The contour $\mathcal{C}$ starts and ends at the point $w=-1$ enclosing the origin in the counterclockwise sense. Three possible branch cut configurations are depicted.

$$\frac{\rho}{2\pi i}\int_{\mathcal{C}} \mathrm{d}w(1+w)^{\rho-1}(x+tw)^{-\rho-1} = x^{-\rho}\delta(x-t). \tag{29}$$

Another way of understanding the necessity of Eq. (29) is to consider the special case $F(y) = \delta(y-t)$. In this case the GST is $G(z)=(t+z)^{-\rho}$. The inverse transform Eq. (9) for this choice of $G(z)$ corresponds precisely to Eq. (29). This remarkable equation, which is required to hold for x, $t>0$, is the heart of the matter. Its proof, which is rather nontrivial, is presented in the next section.

IV. REPRESENTATION OF A DELTA FUNCTION

This section proves the key formula, namely Eq. (29). Consider the left-hand side of Eq. (29),

$$\chi_\rho(x,t) = \frac{\rho}{2\pi i}\int_{\mathcal{C}} \mathrm{d}w(1+w)^{\rho-1}(x+tw)^{-\rho-1}, \tag{30}$$

where $x,t>0$ and $\mathcal{C}$ is the contour shown in Fig. 1. By making the change of variables $w\to 1/w$, it is easy to prove that $\chi_\rho(x,t)=\chi_\rho(t,x)$. For $t>x$ the singularity structure is shown in Fig. 1(a), and the contour can be pushed off to infinity, giving zero for the integral. For $t<x$, the contour encloses no singularity [see Fig. 1(b)], so the result is again zero, as required by $x\leftrightarrow t$ symmetry.

Since $\chi_\rho(x,t)$ vanishes for $t\neq x$, it must be some sort of distribution concentrated at $t=x$. If we assume that it is proportional to a delta function, i.e., $f(x)\delta(x-t)$, it is easy to derive $f(x)$. Integrating over t from 0 to y, gives

$$f(x)\theta(y-x) = \frac{1}{2\pi i}\int_{\mathcal{C}} \frac{\mathrm{d}w}{w}(1+w)^{\rho-1}\left[x^{-\rho}-(x+yw)^{-\rho}\right]. \tag{31}$$

The first term on the right-hand side is an elementary contour integral and gives $x^{-\rho}$. The second term is also easily evaluated by Cauchy's theorem. It gives $-x^{-\rho}$ if $x>y$ and zero if $y>x$. Thus we deduce that $f(x)=x^{-\rho}$, and hence

$$\chi_\rho(x,t) = x^{-\rho}\delta(x-t) = t^{-\rho}\delta(x-t). \tag{32}$$

Equation (32) is the correct result, but the derivation given above is not rigorous. It assumes that the distribution is proportional to a delta function, and that it does not involve any derivatives of delta functions. A more careful analysis that is sensitive to such terms if they are present involves checking the proposed answer by integrating both sides against the test function e^{-ty}, i.e., comparing the Laplace transform of both sides of the equation. Thus we need to show that

$$\int_0^\infty \mathrm{d}t\,\chi_\rho(x,t)e^{-ty} = x^{-\rho}e^{-xy}. \tag{33}$$

Evaluating the Laplace transform of Eq. (30) gives (after some simple manipulations)

$$\int_0^\infty \mathrm{d}t\,\chi_\rho(x,t)e^{-ty} = \frac{\rho}{2\pi i}y^\rho\int_{\mathcal{C}} \mathrm{d}w(1+w)^{\rho-1}I(xyw), \tag{34}$$

where

$$I(u) = e^u \int_u^\infty e^{-v} v^{-\rho-1}\, \mathrm{d}v. \tag{35}$$

In order to re-express this function in a more convenient form, we first note that

$$I'(u) = I(u) - u^{-\rho-1}. \tag{36}$$

Let us now assume that ρ is not an integer, which is the case of most interest. This equation is then solved by an expression of the form

$$I(u) = I_1(u) + u^{-\rho} I_2(u), \tag{37}$$

where $I_1(u)$ and $I_2(u)$ are regular at $u=0$. The first term is $I_1(u)=\Gamma(-\rho)e^u$. Its contribution to Eq. (34) is zero, since there is no singularity inside the contour. The function that matters is I_2, which satisfies the differential equation

$$uI_2'(u) - (u+\rho)I_2(u) + 1 = 0. \tag{38}$$

Substituting a power series expansion,

$$I_2(u) = \sum_{n=0}^{\infty} c_n u^n, \tag{39}$$

one obtains the recursion relation $(n+1-\rho)c_{n+1}=c_n$. Thus, since $c_0=I_2(0)=1/\rho$, we conclude that

$$c_n = \frac{\Gamma(1-\rho)}{\rho\Gamma(n+1-\rho)}. \tag{40}$$

To determine the contribution of each term in Eq. (39) to Eq. (34), we need to evaluate

$$\frac{1}{2\pi i}\int_{\mathcal{C}} \mathrm{d}w(1+w)^{\rho-1} w^{n-\rho} = -\frac{\sin\,\pi(n-\rho)}{\pi} B(n-\rho+1,\rho) = \frac{(-1)^n}{\rho c_n n!}. \tag{41}$$

Combining these results, the c_n factors cancel, and we learn that

$$\int_0^\infty \mathrm{d}t\, \chi_\rho(x,t) e^{-ty} = x^{-\rho} \sum_{n=0}^{\infty} \frac{(-xy)^n}{n!} = x^{-\rho} e^{-xy}, \tag{42}$$

which is the result we set out to prove. Even though this derivation needs to be modified when ρ is a positive integer, the result clearly is valid in that case as well. This completes the proof of Eq. (33) and hence of the inverse transform Eq. (9).

The derivation of Eq. (32) (and hence of the inverse GST) can be simplified considerably by using the alternative representation of the inversion formula presented in Eq. (19) together with well-known properties of hypergeometric functions. Specifically, using

$$I(z,\rho,\rho') = \int_{-1}^{0} \mathrm{d}w(1+w)^{\rho-1}(1+zw)^{-p'} = \frac{1}{\rho}(1-z)^{\rho-\rho'}{}_2F_1(\rho,\rho-\rho'+1;\rho+1;z) \tag{43}$$

one can show that

$$\chi_\rho(x,t) = \frac{1}{2\pi i}\rho x^{-\rho-1} \lim_{\epsilon\to 0+}\left[I\left(\rho,\rho+1,\frac{t}{x}+i\epsilon\right) - I\left(\rho,\rho+1,\frac{t}{x}-i\epsilon\right)\right] = \frac{1}{\pi}x^{-\rho}\lim\frac{\epsilon t}{(x-t)^2+(\epsilon t)^2}$$
$$= x^{-\rho}\delta(x-t). \tag{44}$$

The restriction on the behavior of $G(z)$ at the origin mentioned previously can be circumvented by introducing a modified function $G_\delta(z)=G(z+\delta)$, $\delta>0$, and letting $\delta\to 0$ in the final result. The

advantage of this approach is that it is applicable to a wider class of distributions on the real line, namely those that can be written as the difference of the limiting values on the real axis from above and below of two functions, holomorphic in the upper and lower half-plane, respectively.[8,9]

V. AN ALTERNATIVE DERIVATION

In this section we present a simpler, though less general, derivation of the inverse transform. It follows from Cauchy's theorem and the required analytic and asymptotic properties of $G(z)$ that

$$G(z) = \int_0^\infty \frac{\Delta(t)}{z+t} \mathrm{d}t, \tag{45}$$

where $\Delta(t)$ is defined in Eq. (17). The validity of this formula requires that $\Delta(t)$ is not too singular as $t \to 0$, so that the integral exists. This is a significant restriction, since if $F \sim y^{\nu-1}$ with $\nu > 0$ for small y, then $G(z) \sim z^{\nu-\rho}$ for small z. Thus one would need that $\rho < \nu + 1$. No such assumption has been made previously, which is why the derivation in this section is less general.

Equation (45) is precisely a Stieltjes transform, $G = \mathcal{S}[\Delta]$. We noted earlier that this is an iterated Laplace transform, $\mathcal{S} = \mathcal{L}^2$. Therefore,

$$\mathcal{L}_x^{-1}[G] = \mathcal{L}_x[\Delta]. \tag{46}$$

Comparing this with Eq. (24), which we obtained from Eq. (8), we learn that

$$\mathcal{L}_x[F] = \Gamma(\rho) x^{1-\rho} \mathcal{L}_x[\Delta]. \tag{47}$$

Now using $\mathcal{L}_x[t^{\nu-1}] = \Gamma(\nu)\, x^{-\nu}$, this becomes

$$\mathcal{L}_x[F] = (\rho - 1)\mathcal{L}_x[t^{\rho-2}]\mathcal{L}_x[\Delta]. \tag{48}$$

By the convolution theorem, this implies that

$$F(y) = (\rho - 1) \int_0^y (y-t)^{\rho-2} \Delta(t) \mathrm{d}t, \tag{49}$$

which is Eq. (18). The alternative form in Eq. (19) extends the range of validity for ρ, but is even more restricted in its requirements for the behavior of $\Delta(t)$ at the origin. As we pointed out in Sec. II, there is no such issue for the corresponding contour integrals.

VI. CONCLUSION

In this paper we considered the generalized Stieltjes transform

$$G(z) = \int_0^\infty (y+z)^{-\rho} F(y) \mathrm{d}y, \quad |\arg z| < \pi \tag{50}$$

for $\rho > 0$ and proved that it has as its inverse transform

$$F(y) = -\frac{1}{2\pi i} y^\rho \int_{\mathcal{C}} (1+w)^{\rho-1} G'(yw) \mathrm{d}w. \tag{51}$$

The integration contour is described in the text.

(Received 11 June 2004; accepted 24 September 2004; published online 3 January 2005)

We consider the initial value problem $u''+\phi(t)u'+B^2u^{2p+1}=0,\ t>0,\ u(0)=\gamma,$ $u'(0)=0$, where p is a positive integer, $B,\ \gamma$ are positive parameters, and $\phi(t)$ is a positive function. The differential equation describes a (dissipative) oscillatory system whose amplitude $A(t)$ decreases in time. For a given time $b>0$, our task is to compute the asymptotics of $A(b)$, as $\gamma\to\infty$. In the case where $\phi\in C^1(0,\infty)\cap L_1(0,\varepsilon)$, we give an explicit answer. We also discuss the case where $\phi(t)=2/t$. This case is of particular interest since it is related to the nonlinear Schrödinger equation in three dimensions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1829154]

I. INTRODUCTION

Before introducing our main problem, let us first consider the system

$$u''(t)+B^2u(t)^{2p+1}=0,\quad t>0, \tag{1.1}$$

$$u(0)=\gamma,\quad u'(0)=0, \tag{1.2}$$

where $p\geqslant 1$ is an integer, and $B,\ \gamma>0$. This is a Hamiltonian system since we have conservation of energy, namely

$$E(t)\overset{\text{def}}{=}u(t)^{2p+2}+\frac{p+1}{B^2}u'(t)^2=\gamma^{2p+2}. \tag{1.3}$$

Hence $u(t)$ oscillates with constant amplitude γ. From (1.3) we get that the period T of oscillation is (notice that $u(T/4)=u(3T/4)=0$ and $u(T/2)=-\gamma$)

$$T=T(\gamma)=\frac{c_p}{B}\frac{1}{\gamma^p}, \tag{1.4}$$

where

[a)]Electronic mail: papanico@math.ntua.gr
[b)]Electronic mail: newton@spock.usc.edu

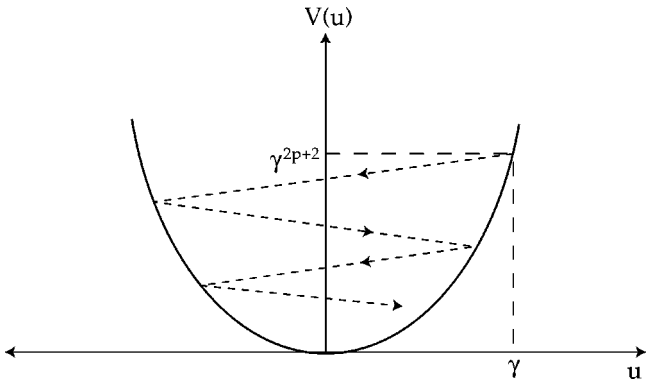

FIG. 1. Energy decay in a single well potential.

$$c_p = 4\sqrt{p+1}\int_0^1 \frac{\mathrm{d}x}{\sqrt{1-x^{2p+2}}} = \frac{2\sqrt{\pi}}{\sqrt{(p+1)}}\frac{\Gamma\left(\frac{1}{2p+2}\right)}{\Gamma\left(\frac{p+2}{2p+2}\right)} \tag{1.5}$$

($\Gamma(\cdot)$ is, of course, the Gamma function). We see that T depends on γ, in contrast to the linear case $p=0$, where $T=2\pi/B$. Here we are interested in

$$u'' + \phi(t)u' + B^2u^{2p+1} = 0, \tag{1.6}$$

where

$$\phi(t) \geqslant 0.$$

Problems of this general type arise when asking about the long time effects of dissipation on Hamiltonian systems. Radially symmetric standing wave solutions to the nonlinear Schrödinger equation arising from hydrodynamic stability theory fall in this category after the time-oscillations are factored out and one is left with a spatial eigenvalue problem with a nonconstant coefficient. In this case, the radial variable plays the role of time. Now (1.3) becomes

$$E(t) = u(t)^{2p+2} + \frac{p+1}{B^2}u'(t)^2 = \gamma^{2p+2} - \frac{2(p+1)}{B^2}\int_0^t \phi(s)u'(s)^2\mathrm{d}s, \tag{1.7}$$

which, of course, implies loss of energy. In fact, one can define the amplitude of oscillation as

$$A(t) = E(t)^{1/(2p+2)}, \tag{1.8}$$

so that we can say that Eq. (1.6) describes an oscillatory system with decreasing amplitude $A(t)$, as shown in Fig. 1 for a symmetric single well potential of the type considered in this paper. Assuming the initial conditions (1.2) (in the sense that $u(0+)=\gamma$, $u'(0+)=0$, since $\phi(t)$ may not be defined at $t=0$), we have

$$E(0) = \gamma^{2p+2}, \quad A(0) = \gamma. \tag{1.9}$$

If $0=t_0'<t_1'<t_2'<\cdots$ are the (positive) zeros of $u'(t)$, then

$$A(t_n') = |u(t_n')| = (-1)^n u(t_n').$$

From the analysis done in the authors' earlier work,[1] it follows that, if N is a fixed integer, then, as $\gamma\to\infty$,

$$|t_n' - nT(\gamma)/2| < C\gamma^{-2p}, \quad n = 0,1,2,\ldots,N, \tag{1.10}$$

where $C>0$ is a constant and $T(\gamma)$ is the period of the conservative case, as given in (1.4) and (1.5). Hence, for a fixed $n \geqslant 0$,

$$t_{n+1}' - t_n' = \frac{c_p}{2B}\frac{1}{\gamma^p} + O(\gamma^{-2p}) \quad \text{as } \gamma \to \infty. \tag{1.11}$$

The problem considered in this article can now be stated. For the system (1.6) and (1.2), if $b>0$ is a given time, determine the (leading) asymptotic behavior of $A(b)$, as $\gamma \to \infty$. In Sec. II we assume that $\phi \in C^1(0,\infty) \cap L_1(0,\varepsilon)$, for $\varepsilon > 0$ (i.e., ϕ is locally integrable), and we show that

$$A(b) = \gamma \exp\left[-\frac{1}{p+2}\int_0^b \phi(t)\mathrm{d}t \right] + o(\gamma) \quad \text{as } \gamma \to \infty.$$

In Sec. III we examine the case of a nonintegrable $\phi(t)$, namely

$$\phi(t) = \frac{2}{t}.$$

Here the formula of Sec. II reduces to $A(b)=o(\gamma)$, as $\gamma \to \infty$. Hence one expects that the analysis of this case, in order to determine the exact asymptotics of $A(b)$, is more challenging than the one needed in Sec. II. Furthermore this case has a particular interest since it is related to the radial nonlinear Schrödinger equation. The results presented in this section are based on the Wentzel–Kramer–Brillouin (WKB) approximation.[2]

II. THE CASE OF A LOCALLY INTEGRABLE $\phi(t)$

As already mentioned, in this section we consider the initial value problem

$$u'' + \phi(t)u' + B^2u^{2p+1} = 0, \quad t > 0, \tag{2.1}$$

$$u(0) = \gamma, \quad u'(0) = 0, \tag{2.2}$$

where $p \geqslant 1$ is an integer, $B>0$, and $\phi(t) \geqslant 0$ is continuously differentiable in $(0, \infty)$ and locally integrable, i.e., integrable near 0. Notice that the (global) existence and uniqueness of $u(t)$ follows easily from (1.7) (see, e.g., Ref. 3).

Differentiating the two sides of the first equation of (1.7) and using (2.1) we obtain

$$E'(t) = \frac{2(p+1)}{B^2}(u'u'' + B^2u^{2p+1}u') = -\frac{2(p+1)}{B^2}\phi(t)(u')^2, \tag{2.3}$$

hence

$$E'(t) \geqslant -\frac{2(p+1)}{B^2}\phi(t)(u')^2 - 2\phi(t)u^{2p+2} = -2\phi(t)E(t),$$

or

$$E'(t) + 2\phi(t)E(t) \geqslant 0.$$

Thus

$$\frac{\mathrm{d}}{\mathrm{d}t}[e^{2\Phi(t)}E(t)] \geqslant 0,$$

where

$$\Phi(t) = \int_0^t \phi(\tau)\mathrm{d}\tau, \tag{2.4}$$

and therefore by integrating and using (1.9)

$$E(t) \geqslant \gamma^{2p+2} e^{-2\Phi(t)}, \tag{2.5}$$

which in view of (1.8) can be also written as

$$A(t) \geqslant \gamma e^{-\Phi(t)/(p+1)} \tag{2.6}$$

(independently of B).

We are now ready for the main result:

Theorem 1: *For the initial value problem (2.1) and (2.2) we have*

$$A(b) = \gamma e^{-\Phi(b)/(p+2)} + o(\gamma) \quad \text{as } \gamma \to \infty, \tag{2.7}$$

where $b>0$ is a fixed number, $A(t)$ is defined in (1.7) and (1.8), and $\Phi(t)$ is defined in (2.4).

Proof: Let $0=t_0'<t_1'<t_2'<\cdots$ be the (positive) zeros of $u'(t)$. For any $\gamma>0$ there is an $n=n(\gamma)\geqslant 0$ such that

$$t_{2n}' \leqslant b < t_{2n+2}',$$

where $t_{2n+2}'\leqslant\infty$ (here the convention is that if t_{2n}' or t_{2n+1}', then we set $t_{2n+2}'=\infty$). If γ is sufficiently large, it follows from (1.10) that $t_{2n+2}'<\infty$. We set

$$b^* = t_{2n}' \tag{2.8}$$

(b^* depends on γ and b; in particular $b^*\leqslant b$). Thus $u(b^*)$ is a local maximum of $u(t)$ and

$$u(b^*) = A(b^*).$$

For the sake of completeness we set $0^*=0$. Notice that (1.11) implies that, as $\gamma\to\infty$,

$$b - b^* = O(\gamma^{-p}), \tag{2.9}$$

which, in turn gives (see (1.7), (1.8), and (2.3))

$$A(b) - A(b^*) = O(\gamma^{1-p}). \tag{2.10}$$

Formula (2.6) suggests that we should look at the limit

$$\lim_{\gamma\to\infty} \frac{u(b^*)}{\gamma}.$$

But, since we do not even know whether this limit exists or not, we start with the upper and lower limits

$$\lambda_{\max}(b) = \limsup_{\gamma\to\infty} \frac{u(b^*)}{\gamma}, \quad \lambda_{\min}(b) = \liminf_{\gamma\to\infty} \frac{u(b^*)}{\gamma}.$$

Of course (since $0^*=0$),

$$\lambda_{\max}(0) = \lambda_{\min}(0) = 1$$

and, furthermore, since $b_1<b_2$ implies $u(b_1^*)\geqslant u(b_2^*)$, we have that $\lambda_{\max}(b), \lambda_{\min}(b)$ are decreasing functions of b. Using (2.6) and (2.9), and the fact that $E(t)$ is decreasing, we get

$$e^{-\Phi(b)/(p+1)} \leqslant \lambda_{\min}(b) \leqslant \lambda_{\max}(b) \leqslant 1.$$

Now let $Q^+ = \{q_1, q_2, q_3, \ldots\}$ be the set of positive rationals. We choose a sequence $\{\gamma_n\}_{n\geqslant 1}$ such that $u(0) = \gamma_n$ (see (2.1) and (2.2)), $\gamma_n \to \infty$, and the limit

$$\lambda(q_1) = \lim_n \frac{u(q_1^*)}{\gamma_n} \tag{2.11}$$

exists. By choosing a subsequence of $\{\gamma_n\}_{n\geqslant 1}$ (which we also denote by γ_n) we can make the limit

$$\lambda(q_2) = \lim_n \frac{u(q_2^*)}{\gamma_n}$$

exist too. We can continue taking subsequences, and finally use a standard diagonal process, to conclude that there is a sequence $\{\gamma_n\}_{n\geqslant 1}$, $\gamma_n \to \infty$, such that the limits

$$\lambda(q) = \lim_n \frac{u(q^*)}{\gamma_n}, \quad q \in Q^+, \tag{2.12}$$

exist.

We, next, want to estimate $u(q_1^*) - u(q_2^*)$, when q_1 and q_2 are given rationals with

$$0 \leqslant q_1 < q_2 \leqslant M \tag{2.13}$$

(without loss of generality M can be assumed rational). Let $t'_{2m}, t'_{2m+1}, t'_{2m+2}$ be consecutive zeros of $u'(t)$ such that

$$q_1^* \leqslant t'_{2m} < t'_{2m+2} \leqslant q_2^*. \tag{2.14}$$

We set

$$T_m = t'_{2m+2} - t'_{2m}$$

(T_m is the temporal duration of the $(m+1)$th "cycle"; in the Hamiltonian case $\phi(t) \equiv 0$, T_m is, of course, the period). We need upper and lower bounds for T_m, valid for large γ. We can consider the solution $v(t) = u(t + t'_{2m})$ of

$$v'' + \phi(t + t'_{2m})v' + B^2 v^{2p+1} = 0,$$

so that $v(0) \in [u(q_2^*), u(q_1^*)]$. Thanks to (2.6), formula (1.11) is valid for $v(t)$. Using these observations we get that

$$T_{\min} \leqslant T_m \leqslant T_{\max}, \tag{2.15}$$

where

$$T_{\min} = \frac{c_p}{B} \frac{1}{u(q_1^*)^p} + O(\gamma_n^{-2p}), \quad T_{\max} = \frac{c_p}{B} \frac{1}{u(q_2^*)^p} + O(\gamma_n^{-2p}). \tag{2.16}$$

We also need to estimate the "drop" of $u(t)$ on each "cycle," namely the quantity

$$\Delta_m = u(t'_{2m}) - u(t'_{2m+2}).$$

A slight adaptation of the analysis done in Ref. 1 gives (since $\phi(t'_{2m+2}) = \phi(t'_{2m}) + \phi'(t'_{2m}) \times (t'_{2m+2} - t'_{2m}) + o(t'_{2m+2} - t'_{2m})$)

$$u(t'_{2m+2}) = u(t'_{2m})\left[1 - \frac{\phi(t'_{2m})A_p}{B}u(t'_{2m})^{-p} + O(u(t'_{2m})^{-2p})\right] \quad \text{as } \gamma \to \infty, \tag{2.17}$$

where

$$A_p = \frac{4}{\sqrt{p+1}}\int_0^1 \sqrt{1-x^{2p+2}}\,dx = \frac{\sqrt{\pi}}{(p+1)^{3/2}} \cdot \frac{\Gamma\left(\frac{1}{2p+2}\right)}{\Gamma\left(\frac{3p+4}{2p+2}\right)}. \tag{2.18}$$

Hence, invoking (2.6), (2.13), (2.14), and (2.17) gives

$$\Delta_m = \frac{\phi(t'_{2m})A_p}{B}u(t'_{2m})^{1-p} + O(\gamma^{1-2p}) \quad \text{as } \gamma \to \infty,$$

and, therefore

$$\Delta_{\min} \leqslant \Delta_m \leqslant \Delta_{\max}, \tag{2.19}$$

where

$$\Delta_{\min} = A_p B^{-1} u(q_1^*)^{1-p} \min_{q_1^* \leqslant t \leqslant q_2^*} \phi(t) + O(\gamma_n^{1-2p}),$$

$$\Delta_{\max} = A_p B^{-1} u(q_2^*)^{1-p} \max_{q_1^* \leqslant t \leqslant q_2^*} \phi(t) + O(\gamma_n^{1-2p}). \tag{2.20}$$

Finally, let $N=N(q_1,q_2)$ be the number of "cycles" from $t=q_1^*$ to $t=q_2^*$. We have

$$\frac{q_2^* - q_1^*}{T_{\max}} \overset{\text{def}}{=} N_{\min} \leqslant N \leqslant N_{\max} \overset{\text{def}}{=} \frac{q_2^* - q_1^*}{T_{\min}}, \tag{2.21}$$

where, by (2.16) and (2.9),

$$N_{\min} = \frac{B(q_2 - q_1)}{c_p}u(q_2^*)^p[1 + O(\gamma_n^{-p})], \quad N_{\max} = \frac{B(q_2 - q_1)}{c_p}u(q_1^*)^p[1 + O(\gamma_n^{-p})]. \tag{2.22}$$

We are now ready to estimate $u(q_1^*) - u(q_2^*)$. We have

$$N_{\min}\Delta_{\min} \leqslant u(q_1^*) - u(q_2^*) \leqslant N_{\max}\Delta_{\max},$$

and thus, by (2.20) and (2.22), and the fact that $A_p/c_p = (p+2)^{-1}$ (this follows from (1.5) and (2.18))

$$\frac{\phi(t'_{2m})(q_2 - q_1)}{p+2}\frac{u(q_2^*)^p}{u(q_1^*)^{p-1}}[1 + O(\gamma_n^{-p})] \leqslant u(q_1^*) - u(q_2^*) \leqslant \frac{\phi(t'_{2m})(q_2 - q_1)}{p+2}\frac{u(q_1^*)^p}{u(q_2^*)^{p-1}}[1 + O(\gamma_n^{-p})]$$

(notice that this estimate is B-free). If we divide the above inequality by γ_n and then take limits, as $n \to \infty$, we obtain (see (2.12))

$$\frac{\min_{q_1 \leqslant t \leqslant q_2}\phi(t)}{p+2}\frac{\lambda(q_2)^p}{\lambda(q_1)^{p-1}}(q_2 - q_1) \leqslant \lambda(q_1) - \lambda(q_2) \leqslant \frac{\max_{q_1 \leqslant t \leqslant q_2}\phi(t)}{p+2}\frac{\lambda(q_1)^p}{\lambda(q_2)^{p-1}}(q_2 - q_1), \tag{2.23}$$

where q_1 and q_2 are rationals in $[0,M]$. Since

$$e^{-\Phi(M)/(p+1)} \leqslant \lambda(q_2) \leqslant \lambda(q_1) \leqslant 1,$$

one consequence of (2.23) is that there is a constant $C>0$ such that

$$|\lambda(q_1) - \lambda(q_2)| \leqslant C|q_1 - q_2|. \tag{2.24}$$

Now let $b \in [0,M]$ be a real number and q_1, q_2 rationals so that $q_1 \leqslant \xi \leqslant q_2$. Then

$$\lambda(q_2) \leqslant \liminf_n \frac{u(b^*)}{\gamma_n} \leqslant \limsup_n \frac{u(b^*)}{\gamma_n} \leqslant \lambda(q_1).$$

But (2.24) implies that $|\lambda(q_1)-\lambda(q_2)|$ can be made as small as we wish. Therefore the limit

$$\lim_n \frac{u(b^*)}{\gamma_n}$$

exists and the function

$$\lambda(b) = \lim_n \frac{u(b^*)}{\gamma_n}$$

is decreasing and continuous for all $b \in (0,\infty)$. Furthermore (2.23) is also valid for irrational numbers $q_1, q_2 > 0$. If we divide all terms of (2.23) by $q_2 - q_1$ and let $q_2 \to q_1$, we obtain the surprising formula

$$\lambda'(b) = -\frac{\phi(b)}{p+2}\lambda(b),$$

and this, together with the equation $\lambda(0)=1$, give

$$\lambda(b) = e^{-\Phi(b)/(p+2)}.$$

In particular,

$$\lambda(q_1) = e^{-\Phi(q_1)/(p+2)}.$$

Since q_1 and $\{\gamma_n\}_{n\geqslant 1}$ of (2.11) are arbitrary, it follows that,

$$\lim_{\gamma\to\infty} \frac{u(b^*)}{\gamma} = e^{-\Phi(b)/(p+2)},$$

and the proof is finished in view of (2.10) and the fact that $A(b^*)=u(b^*)$.

Remarks:

1. The statement of the theorem is quite surprising. Note that the result is independent of B, hence one expects that the theorem should extend to the case

$$u'' + \phi(t)u' + \rho(t)^2 u^{2p+1} = 0, \quad t > 0,$$

$$u(0) = \gamma, \quad u'(0) = 0,$$

where $\rho(t) \geqslant B > 0$. Notice that if $p=0$ (linear case) and $\rho(t)$ is, e.g., periodic, then, even for $\phi(t) \equiv 0$, we have exponential decay if 0 is in the $L_2(R)$-spectrum of the operator L defined by $Lu = -u'' - \rho(t)^2 u$.

2. The theorem remains true if instead of (2.21) we had

$$u'' + \phi(t)u' + B^2 u^{2p+1} + P(u) = 0,$$

where P is a polynomial of degree $\leqslant 2p$.

3. It is interesting to attempt a comparison of the statement of Theorem 1 with the linear case ($p=0$):

$$u'' + \phi(t)u' + B^2\rho(t)^2u = 0, \quad t > 0,$$

$$u(0) = \gamma, \quad u'(0) = 0.$$

Here we assume that $\rho(t) > 0$ and that B is a large (positive) parameter. Then the WKB approximation (see, e.g., Ref. 2 or 4) implies that generically

$$A(b) = \gamma e^{-\Phi(b)/2} + o(1) \quad \text{as } B \to \infty,$$

which mirrors the statement of Theorem 1.[5]

III. A PARTICULAR CASE OF SPECIAL INTEREST

Consider now the initial value problem

$$u'' + \frac{2}{t}u' + B^2u^{2p+1} = 0, \quad t > 0, \tag{3.1}$$

$$u(0) = \gamma, \quad u'(0) = 0, \tag{3.2}$$

where, as before, $p \geqslant 1$ is an integer and $B > 0$ (notice that, $u'' + (2/t)u'$ is the three-dimensional radial Laplacian of u). Again the boundary conditions must be interpreted in the right way, i.e., as limits when $t \to 0^+$. In comparison with (1.6) we have that

$$\phi(t) = \frac{2}{t} \tag{3.3}$$

and, hence

$$\Phi(t) = \int_0^t \phi(\tau)\mathrm{d}\tau = 2\int_0^t \frac{\mathrm{d}\tau}{\tau} = \infty.$$

Proposition 1:The problem (3.1) and (3.2) has a unique solution for all $t > 0$.

Proof: We first notice that (3.1) and (3.2) is equivalent to the integral equation

$$u(t) = \gamma - B^2\int_0^t \tau[1 - (\tau/t)]u(\tau)^{2p+1}\mathrm{d}\tau. \tag{3.4}$$

We must, therefore, look at the map

$$\mathcal{F}[u](t) = \gamma - B^2\int_0^t \tau[1 - (\tau/t)]u(\tau)^{2p+1}\mathrm{d}\tau,$$

mapping $C[0,\varepsilon]$ into itself, for any given $\varepsilon > 0$. It is easy to see that, if ε is chosen sufficiently small, then $\mathcal{F}$ is a contraction, namely

$$\|\mathcal{F}[u] - \mathcal{F}[v]\|_\infty \leqslant c\|u - v\|_\infty,$$

where $c < 1$. Hence $\mathcal{F}$ has a unique fixed point u in $C[0,\varepsilon]$ which is the unique solution of (3.4) in $[0,\varepsilon]$ (and it is automatically smooth). Then the global existence and uniqueness follows by the fact that the energy is decreasing (see (1.7)). ■

In view of Theorem 1 one can infer that, if $b > 0$ is a fixed number, then

$$A(b) = o(\gamma) \quad \text{as } \gamma \to \infty. \tag{3.5}$$

This estimate is somehow vague. Thus, we would like to get a more precise estimate for $A(b)$ or equivalently (see (2.8)) $u(b^*)$. This question requires an approach very different from the one presented in Sec. II.

Let us first look at the linear problem

$$w'' + \frac{2}{t}w' + \Lambda^2\rho(t)^2 w = 0, \quad t > 0, \tag{3.6}$$

$$w(0) = 1, \quad w'(0) = 0, \tag{3.7}$$

where $\rho(t) \geqslant 0$, such that the zeros of $\rho(t)$ form a discrete set and $\rho(0) \neq 0$ (if $\rho(t) \equiv 1$, the solution of the above problem is $\Lambda t^{-1}\sin(\Lambda t)$). We are interested in the behavior of $w(t)$, as $\Lambda \to \infty$.

We set

$$w(t) = \frac{v(t)}{t}, \tag{3.8}$$

so that

$$v'' + \Lambda^2\rho(t)^2 v = 0, \quad t > 0. \tag{3.9}$$

Furthermore the initial conditions (3.7) become

$$v(0) = 0, \quad v'(0) = 1. \tag{3.10}$$

The WKB approximation (see, e.g., Ref. 2 or 4) implies that generically

$$v(t) \sim \frac{\sin\left[\Lambda \int_0^t \rho(\tau)\mathrm{d}\tau\right]}{\Lambda\rho(0)^{1/2}\rho(t)^{1/2}}, \quad \text{as } \Lambda \to \infty, \tag{3.11}$$

hence (see (3.8))

$$w(t) \sim \frac{\sin\left[\Lambda \int_0^t \rho(\tau)\mathrm{d}\tau\right]}{\Lambda\rho(0)^{1/2}\rho(t)^{1/2}t}, \quad \text{as } \Lambda \to \infty, \tag{3.12}$$

where $w(t)$ is the solution of (3.6) and (3.7).

Now, by setting

$$u(t) = \gamma u_1(t), \tag{3.13}$$

(3.1) and (3.2) can be written as

$$u_1'' + \frac{2}{t}u_1' + B^2\gamma^{2p}u_1^{2p+1} = 0, \quad t > 0, \tag{3.14}$$

$$u_1(0) = 1, \quad u'(0) = 0. \tag{3.15}$$

If we apply (3.12) to (3.14) and (3.15), we obtain

$$u_1(t) \sim \frac{\sin\left[B\gamma^p \int_0^t |u_1(\tau)|^p \mathrm{d}\tau\right]}{B\gamma^p |u_1(t)|^{p/2} t}, \quad \text{as } \gamma \to \infty,$$

or, due to (3.13),

$$u(t) \sim \frac{\sin\left[B \int_0^t |u(\tau)|^p \mathrm{d}\tau\right]}{B\gamma^{(p-2)/2} |u(t)|^{p/2} t} \quad \text{as } \gamma \to \infty, \tag{3.16}$$

but it should be kept in mind that (3.16) is valid as long as

$$A(t) \to \infty \quad \text{as } \gamma \to \infty. \tag{3.17}$$

Formula (3.16) implies that, under (3.17),

$$|u(t)|^{(p+2)/2} \sim \frac{\left|\sin\left[B \int_0^t |u(\tau)|^p \mathrm{d}\tau\right]\right|}{B\gamma^{(p-2)/2} t} \quad \text{as } \gamma \to \infty,$$

or

$$|u(t)| \sim \frac{\left|\sin\left[B \int_0^t |u(\tau)| \mathrm{d}\tau\right]\right|^{2/(p+2)}}{B^{2/(p+2)} \gamma^{(p-2)/(p+2)} t^{2/(p+2)}} \quad \text{as } \gamma \to \infty.$$

Therefore

$$A(b) \sim \frac{\gamma^{(2-p)/(2+p)}}{B^{2/(p+2)}} \cdot \frac{1}{b^{2/(p+2)}} \quad \text{as } \gamma \to \infty, \tag{3.18}$$

as long as $A(b) \to \infty$, as $\gamma \to \infty$. We thus have, for example: (a) If $p=1$, then

$$A(b) \sim \frac{\gamma^{1/3}}{B^{2/3}} \cdot \frac{1}{b^{2/3}} \quad \text{as } \gamma \to \infty.$$

(b) If $p \geqslant 2$, then

$$A(b) = O(1) \quad \text{as } \gamma \to \infty.$$

It is worth mentioning that one can arrive at the statement of Theorem 1 by applying the above WKB analysis to (2.1) and (2.2).

(Received 28 April 2004; accepted 29 September 2004; published online 3 January 2005)

The paper raises the question of posing the quasiperiodic boundary condition in the Cauchy problem of partial differential equations. Using the one-dimensional cubic nonlinear Schrödinger as a simple example, we illustrated the various types of questions including global well-posedness, spectra of linear operators, and foliations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1832754]

I. INTRODUCTION

The quasiperiodic boundary condition problem can be posed for a variety of partial differential equations (PDE) including, e.g., parabolic and hyperbolic equations. Questions that can be asked include local and global well-posedness, dynamics in phase spaces, and asymptotics, etc. Here we take a simple PDE–one-dimensional cubic nonlinear Schrödinger equation (NLS), to study its phase space foliations.

Typical fluid flows are defined on unbounded domain with nondecaying boundary conditions. For example, the Poiseuille flow or the boundary layer flow has nondecaying boundary conditions along the longitudinal direction. In fact, turbulence develops along this longitudinal direction. In many cases, turbulent fluid flows contain both temporal and spatial randomness. Temporal randomness is often caused by temporal chaotic motions. Spatial randomness is often caused by vortex (energy) cascade or inverse cascade. In such cases, periodic boundary conditions put too much constraint. Quasiperiodic or more general boundary conditions are more relevant.

The one-dimensional (1D) cubic NLS under periodic boundary conditions is well understood. It is globally well-posed. Under quasiperiodic boundary conditions, global well-posedness is not known. Under periodic boundary conditions, Stokes wave solution has a finite number of unstable eigenvalues. On the other hand, under quasiperiodic boundary conditions, it has infinitely many unstable eigenvalues dense on an interval. There is no spectral gap. But explicit expressions of the foliation in phase space can be obtained via a Darboux transformation.

II. FORMULATION OF THE PROBLEM

Consider the 1D cubic nonlinear Schrödinger equation

$$iq_t = q_{xx} + 2|q|^2 q, \tag{2.1}$$

where q is a complex-valued function of two real variables (t,x), $i=\sqrt{-1}$. We pose a quasiperiodic boundary condition with two base frequencies β_1 and β_2, β_1/β_2 is irrational. That is,

$$q = q(t,\theta_1,\theta_2), \quad \theta_1 = \beta_1 x, \quad \theta_2 = \beta_2 x,$$

and q is periodic in both θ_1 and θ_2 with period 2π. Thus

[a)]Electronic mail: cli@math.missouri.edu

$$q = q(t,\theta) = \sum_{k\in\mathbb{Z}^2} q_k(t)e^{ik\cdot\theta}, \quad \theta = \begin{pmatrix}\theta_1\\ \theta_2\end{pmatrix}, \quad k = \begin{pmatrix}k_1\\ k_2\end{pmatrix}.$$

It seems that the more natural norm is

$$\|q\|^2_{(s)} = \sum_{k\in\mathbb{Z}^2} (1+|k|^2)^s |q_k|^2,$$

rather than

$$\|q\|^2_{[s]} = \sum_{k\in\mathbb{Z}^2} [1+(k\cdot\beta)^2]^s |q_k|^2, \quad \beta = \begin{pmatrix}\beta_1\\ \beta_2\end{pmatrix}.$$

In terms of Fourier transforms, (2.1) can be rewritten as

$$\begin{aligned} i\frac{dq_k}{dt} &= -\frac{\partial H}{\partial \bar{q}_k},\\ i\frac{d\bar{q}_k}{dt} &= \frac{\partial H}{\partial q_k}, \end{aligned} \tag{2.2}$$

where

$$H = \sum_{k\in\mathbb{Z}^2} (k\cdot\beta)^2 |q_k|^2 - \sum_{k\in\mathbb{Z}^2} \left| \sum_{\hat{k}\in\mathbb{Z}^2} q_{\hat{k}} q_{k-\hat{k}} \right|^2 \tag{2.3}$$

$$= \lim_{a\to+\infty} \frac{1}{2a} \int_{-a}^{a} [|q_x|^2 - |q|^4] dx. \tag{2.4}$$

Using (2.4), the NLS (2.1) can be rewritten as

$$\begin{aligned} iq_t &= -\frac{\delta H}{\delta \bar{q}},\\ i\bar{q}_t &= \frac{\delta H}{\delta q}. \end{aligned} \tag{2.5}$$

Obviously,

$$I = \sum_{k\in\mathbb{Z}^2} |q_k|^2 = \lim_{a\to+\infty} \frac{1}{2a} \int_{-a}^{a} |q|^2 \, dx$$

is an invariant.

III. WELL-POSEDNESS

Explicitly (2.2) can be written as

$$i\dot{q}_k = -(k\cdot\beta)^2 q_k + 2 \sum_{\hat{k},\tilde{k}\in\mathbb{Z}^2} \bar{q}_{\hat{k}} q_{\tilde{k}+\hat{k}} q_{k-\tilde{k}}. \tag{3.1}$$

The method of variation of parameters leads to the integral equation

$$q_k(t) = e^{i(k\cdot\beta)^2 t} q_k(0) - 2i \int_0^t e^{i(k\cdot\beta)^2(t-\tau)} \sum_{\hat{k},\tilde{k}\in\mathbb{Z}^2} \overline{q_{\hat{k}}} q_{\tilde{k}+\hat{k}} q_{k-\tilde{k}}\, d\tau. \tag{3.2}$$

Notice that (3.1) bears more resemblance to two-dimensional (2D), rather than 1D, NLS under the periodic boundary condition. Local well-posedness can be easily established,[1] since the nonlinear term is still locally Lipschitz.

Theorem 3.1 (Local well-posedness): *For any $q_0 \in H_{(s)}$, $s \geqslant 2$, there exists a unique solution $q(t) \in C^0([0,\tau], H_{(s)})$ where $\tau = \tau(\|q_0\|_{(s)})$, to the Cauchy problem of (3.1) with initial condition $q(0) = q_0$. For any fixed $t \in [0,\tau]$, $q(t)$ is C^∞ in q_0.*

The interesting open problem is whether or not (3.1) has global well-posedness. On the one hand, it resembles 2D NLS under periodic boundary condition, therefore, it may not have global well-posedness. In fact, the first term in the Hamiltonian (2.3) is weaker than $\Sigma_{k\in\mathbb{Z}^2}|k|^2|q_k|^2$ of the 2D NLS periodic case. Thus the Hamiltonian cannot bound the $H_{(1)}$ norm. On the other hand, it is still an integrable system, therefore, an infinite sequence of invariants is at one's disposal.

IV. THE SPECTRUM OF A LINEAR NLS OPERATOR

Setting $\partial_x = 0$ in (2.1), one gets an ODE defined on the invariant complex plane

$$iq_t = 2|q|^2 q$$

with all periodic solutions (the so-called Stokes waves)

$$q = ce^{-i[2c^2 t+\gamma]}. \tag{4.1}$$

Linearize the NLS in the manner

$$q = (c + \hat{q})e^{-i[2c^2 t+\gamma]},$$

one has

$$i\hat{q}_t = \hat{q}_{xx} + 2c^2(\hat{q} + \overline{\hat{q}}).$$

Let

$$\hat{q} = \sum_{k\in\mathbb{Z}^2} \hat{q}_k(t) e^{ik\cdot\theta}, \tag{4.2}$$

one gets

$$i\frac{\mathrm{d}}{\mathrm{d}t}\begin{pmatrix} \hat{q}_k \\ \overline{\hat{q}_{-k}} \end{pmatrix} = \begin{pmatrix} 2c^2 - (k\cdot\beta)^2 & 2c^2 \\ -2c^2 & (k\cdot\beta)^2 - 2c^2 \end{pmatrix}\begin{pmatrix} \hat{q}_k \\ \overline{\hat{q}_{-k}} \end{pmatrix}. \tag{4.3}$$

Let

$$\begin{pmatrix} \hat{q}_k \\ \overline{\hat{q}_{-k}} \end{pmatrix} = e^{\lambda t}\begin{pmatrix} A \\ B \end{pmatrix}, \tag{4.4}$$

where λ, A, and B are complex constants, then

$$\lambda = \pm (k\cdot\beta)\sqrt{(2c)^2 - (k\cdot\beta)^2}. \tag{4.5}$$

Lemma 4.1: *The set $\{k\cdot\beta\}_{k\in\mathbb{Z}^2}$ is dense in $\mathbb{R}$.*

Proof: This proof is furnished by Banks.[2] For any real number z, let $[z]$ denote the greatest integer less than or equal to z, and let $\{z\} = z - [z]$ be the fractional part of z; then $0 \leqslant \{z\} \leqslant 1$. For any irrational number a, it is known that the fractional parts $\{na\}_{n\in\mathbb{Z}}$ are uniformly distributed over

the unit interval [0,1]. For any fixed $b \in \mathbb{R}$, given any $\epsilon > 0$, let k_2 be chosen such that

$$|\{k_2(\beta_2/\beta_1)\} - \{b/\beta_1\}| < \epsilon/\beta_1,$$

and choose $k_1 = [b/\beta_1] - [k_2(\beta_2/\beta_1)]$, then

$$|k_1 + k_2(\beta_2/\beta_1) - b/\beta_1| = |k_1 + [k_2(\beta_2/\beta_1)] - [b/\beta_1] + \{k_2(\beta_2/\beta_1)\} - \{b/\beta_1\}| = |\{k_2(\beta_2/\beta_1)\} - \{b/\beta_1\}| < \epsilon/\beta_1.$$

Multiplying by β_1, one obtains $|k \cdot \beta| < \epsilon$. This proves the lemma. ■

Theorem 4.2: *The spectrum of the linear NLS operator in* $H_{(s)}$, $s \geqslant 0$ *is*

$$\sigma = \sigma_p \cup \sigma_c = [-2c^2, 2c^2] \cup i\mathbb{R}$$

where σ_p *is given by (4.5) and is everywhere dense in* σ.

Proof: The maximum of the function

$$z^2((2c)^2 - z^2), \quad z \in \mathbb{R}$$

is $4c^2$. By Lemma 4.1 and the fact that the spectrum σ is a closed set, we have that

$$[-2c^2, 2c^2] \cup i\mathbb{R} \subset \sigma.$$

In terms of the Fourier transform (4.2), the linear NLS operator has the representation given by (4.3),

$$L_k = -i \begin{pmatrix} 2c^2 - (k \cdot \beta)^2 & 2c^2 \\ -2c^2 & (k \cdot \beta)^2 - 2c^2 \end{pmatrix}.$$

If $\lambda \notin [-2c^2, 2c^2] \cup i\mathbb{R}$, then there is an absolute constant C such that

$$\|(L_k - \lambda)^{-1}\| \leqslant C, \quad \forall\, k$$

and this is true even for some k, $(k \cdot \beta)^2$ might be equal to $(2c)^2$. Thus such λ belongs to the resolvent set, and

$$\sigma = [-2c^2, 2c^2] \cup i\mathbb{R}.$$

Let $\lambda \in \sigma / \sigma_p$ where σ_p is the point spectrum given by (4.5), then there is a sequence $\lambda_j \in \sigma_p$ such that $\lambda_j \to \lambda$, and

$$\|(L_{k_j} - \lambda)^{-1}\| \geqslant 1/|\lambda_j - \lambda| \to +\infty;$$

thus $\lambda \in \sigma_c$ is the continuous spectrum. This proves the theorem. ■

Remark 4.3: For NLS under periodic boundary condition, the spectrum of the linear NLS operator consists of only discrete point spectrum given by

$$\lambda = \pm k\beta\sqrt{(2c)^2 - (k\beta)^2},$$

where $k \in \mathbb{Z}$, and β is a positive constant. For any fixed $c > 0$, there is a finite number of unstable modes. There are gaps among the unstable, center, and stable spectra. As shown above, under quasiperiodic boundary condition, the point spectrum is dense, and there is also a continuous spectrum. For any fixed $c > 0$, there are infinitely many unstable modes. There is no gap among the unstable, center, and stable spectra.

V. FOLIATIONS

Although there is no spectral gap in this quasiperiodic setting, foliations can still be established via explicit expressions. The tool used is the so-called Darboux transformation. The NLS (2.1) has the Lax pair,

$$\psi_x = U\psi, \quad \psi_t = V\psi,$$

where

$$U = i\begin{pmatrix} \lambda & q \\ \bar{q} & -\lambda \end{pmatrix},$$

$$V = i\begin{pmatrix} 2\lambda^2 - |q|^2 & 2\lambda q - iq_x \\ 2\lambda\bar{q} + i\bar{q}_x & -2\lambda^2 + |q|^2 \end{pmatrix}.$$

Theorem 5.1: *Let $q(t,x)$ be a solution, and let ϕ be an eigenfunction of the Lax pair at $\lambda = \nu$ for any $\nu \in \mathbb{C}$. Use ϕ to define a matrix,*

$$G = \Gamma\begin{pmatrix} \lambda - \nu & 0 \\ 0 & \lambda - \bar{\nu} \end{pmatrix}\Gamma^{-1},$$

where

$$\Gamma = \begin{pmatrix} \phi_1 & -\overline{\phi_2} \\ \phi_2 & \overline{\phi_1} \end{pmatrix}.$$

We define Q and Ψ by

$$Q = q + 2(\nu - \bar{\nu})\frac{\phi_1\overline{\phi_2}}{|\phi_1|^2 + |\phi_2|^2}, \quad \Psi = G\psi, \tag{5.1}$$

where ψ solves the Lax pair at (q,λ). Then Ψ solves the Lax pair at (Q,λ) and Q solves the NLS.

This is a well-known theorem in the integrable theory, see, e.g., Ref. 3. The transformation (5.1) is called a Darboux transformation.

For example, let

$$q = ae^{i\theta(t)}, \quad \theta(t) = -[2a^2t + \gamma],$$

where a is the amplitude and γ is the phase. The eigenfunctions of the Lax pair are

$$\phi^{\pm} = \begin{pmatrix} ae^{i\theta(t)/2} \\ (\pm\beta - \lambda)e^{-i\theta(t)/2} \end{pmatrix}e^{\pm i2\lambda\beta t \pm i\beta x}, \quad \lambda = \sqrt{\beta^2 - a^2}.$$

In order to have temporal growth, $\beta^2 < a^2$. For $\beta = \beta_1$, $\lambda = \nu = i\sigma$, let

$$\phi = c^+\phi^+ + c^-\phi^-,$$

where $c^{\pm}$ are two arbitrary complex constants. For $\beta = \beta_2$, $\lambda = \hat{\nu} = i\hat{\sigma}$, let

$$\hat{\phi} = \hat{c}^+\phi^+ + \hat{c}^-\phi^-,$$

where $\hat{c}^{\pm}$ are two arbitrary complex constants. By iterating the Darboux transformation (5.1) at ν and $\hat{\nu}$, one gets

$$Q = q + 2(\nu - \overline{\nu})\frac{\phi_1\overline{\phi_2}}{|\phi_1|^2 + |\phi_2|^2} + 2(\hat{\nu} - \overline{\hat{\nu}})\frac{\hat{\Phi}_1\overline{\hat{\Phi}_2}}{|\hat{\Phi}_1|^2 + |\hat{\Phi}_2|^2},$$

where

$$\hat{\Phi}_1 = \frac{1}{|\phi_1|^2 + |\phi_2|^2}\{[(\hat{\nu} - \nu)|\phi_1|^2 + (\hat{\nu} - \overline{\nu})|\phi_2|^2]\hat{\phi}_1 + (\overline{\nu} - \nu)\phi_1\overline{\phi_2}\hat{\phi}_2\},$$

$$\hat{\Phi}_2 = \frac{1}{|\phi_1|^2 + |\phi_2|^2}\{(\overline{\nu} - \nu)\overline{\phi_1}\phi_2\hat{\phi}_1 + [(\hat{\nu} - \overline{\nu})|\phi_1|^2 + (\hat{\nu} - \nu)|\phi_2|^2]\hat{\phi}_2\}.$$

Explicitly, one has

$$Q = \tilde{Q} + q \sin\hat{\vartheta}_0 \prod_2 \Big/ \prod_1, \tag{5.2}$$

where

$$\tilde{Q} = q[1 + \sin\vartheta_0 \operatorname{sech}\tau\cos X]^{-1}[\cos 2\vartheta_0 - i\sin 2\vartheta_0 \tanh\tau - \sin\vartheta_0 \operatorname{sech}\tau\cos X],$$

$$\begin{aligned}\prod_1 = {} & \left[(\sin\hat{\vartheta}_0)^2(1 + \sin\vartheta_0 \operatorname{sech}\tau\cos X)^2 + \frac{1}{8}(\sin 2\vartheta_0)^2(\operatorname{sech}\tau)^2(1 - \cos 2X)\right] \\ & \times(1 + \sin\hat{\vartheta}_0 \operatorname{sech}\hat{\tau}\cos\hat{X}) - \frac{1}{2}\sin 2\vartheta_0 \sin 2\hat{\vartheta}_0 \operatorname{sech}\tau \operatorname{sech}\hat{\tau}(1 + \sin\vartheta_0 \operatorname{sech}\tau\cos X) \\ & \times\sin X \sin\hat{X} + (\sin\vartheta_0)^2[1 + 2\sin\vartheta_0 \operatorname{sech}\tau\cos X + [(\cos X)^2 - (\cos\vartheta_0)^2](\operatorname{sech}\tau)^2] \\ & \times(1 + \sin\hat{\vartheta}_0 \operatorname{sech}\hat{\tau}\cos\hat{X}) - 2\sin\hat{\vartheta}_0 \sin\vartheta_0[\cos\hat{\vartheta}_0 \cos\vartheta_0 \tanh\hat{\tau}\tanh\tau \\ & + (\sin\vartheta_0 + \operatorname{sech}\tau\cos X)(\sin\hat{\vartheta}_0 + \operatorname{sech}\hat{\tau}\cos\hat{X})](1 + \sin\vartheta_0 \operatorname{sech}\tau\cos X),\end{aligned}$$

$$\begin{aligned}\prod_2 = {} & \left[-2(\sin\hat{\vartheta}_0)^2(1 + \sin\vartheta_0 \operatorname{sech}\tau\cos X)^2 + \frac{1}{4}(\sin 2\vartheta_0)^2(\operatorname{sech}\tau)^2(1 - \cos 2X)\right] \\ & \times(\sin\hat{\vartheta}_0 + \operatorname{sech}\hat{\tau}\cos\hat{X} + i\cos\hat{\vartheta}_0\tanh\hat{\tau}) + 2(\sin\vartheta_0)^2(-\cos\vartheta_0\tanh\tau + i\sin\vartheta_0 \\ & + i\operatorname{sech}\tau\cos X)^2(\sin\hat{\vartheta}_0 + \operatorname{sech}\hat{\tau}\cos\hat{X} - i\cos\hat{\vartheta}_0\tanh\hat{\tau}) + 2\sin\vartheta_0(\sin\vartheta_0 + \operatorname{sech}\tau\cos X \\ & + i\cos\vartheta_0\tanh\tau)[2\sin\hat{\vartheta}_0(1 + \sin\vartheta_0 \operatorname{sech}\tau\cos X)(1 + \sin\hat{\vartheta}_0 \operatorname{sech}\hat{\tau}\cos\hat{X}) \\ & - \sin 2\vartheta_0 \cos\hat{\vartheta}_0 \operatorname{sech}\tau \operatorname{sech}\hat{\tau}\sin X \sin\hat{X}],\end{aligned}$$

and

$$\beta_1 + \nu = ae^{i\vartheta_0}, \quad \beta_2 + \hat{\nu} = ae^{i\hat{\vartheta}_0},$$

$$c^+/c^- = e^{\rho + i\vartheta}, \quad \hat{c}^+/\hat{c}^- = e^{\hat{\rho} + i\hat{\vartheta}},$$

$$\tau = 4\sigma\beta_1 t - \rho, \quad \hat{\tau} = 4\hat{\sigma}\beta_2 t - \hat{\rho},$$

$$X = 2\beta_1 x + \vartheta - \vartheta_0 + \pi/2, \quad \hat{X} = 2\beta_2 x + \hat{\vartheta} - \hat{\vartheta}_0 + \pi/2.$$

The foliation here is with respect to the two linear unstable modes $(2\beta_1,0)$ and $(0,2\beta_2)$ in (4.5). The temporal growth condition $\beta_1^2 < a^2$ or $\beta_2^2 < a^2$ is in agreement with (4.5). Thus (5.2) represents a class of solutions with quasiperiodic boundary condition. For fixed a, β_1, and β_2, the parameters are γ, ρ, $\hat{\rho}$, ϑ, and $\hat{\vartheta}$. As $t \to \pm\infty$, e.g., β_1, β_2, σ, and $\hat{\sigma}$ are all positive,

$$Q \to qe^{\mp i2(\vartheta_0+\hat{\vartheta}_0)}.$$

VI. CONCLUSION AND DISCUSSION

From the presentation in this paper, one can see that the first interesting question on such quasiperiodic boundary condition problem is the global well-posedness. In terms of Fourier transforms, one can see that the integrable NLS resembles the 2D more than the 1D periodic problem. I tend to believe that it may have finite-time blow-up solutions, which will be truly interesting. Also linearization in the quasiperiodic case often leads to a linear operator with continuous spectrum and with no spectral gap. Therefore, the phase space foliation is a challenging and interesting problem. In this paper, through Darboux transformation, such foliation can still be established.

Time- and space-fractional partial differential equations

Jun-Sheng Duan
Department of Basic Sciences, Tianjin University of Commerce, Tianjin 300134, People's Republic of China

(Received 15 March 2004; accepted 14 September 2004; published online 3 January 2005)

The fundamental solution for time- and space-fractional partial differential operator $D_t^\lambda + a^2(-\triangle)^{\gamma/2}(\lambda, \gamma > 0)$ is given in terms of the Fox's H-function. Here the time-fractional derivative in the sense of generalized functions (distributions) D_t^λ is defined by the convolution $D_t^\lambda f(t) = \Phi_{-\lambda}(t) * f(t)$, where $\Phi_\lambda(t) = t_+^{\lambda-1}/\Gamma(\lambda)$ and $f(t) \equiv 0$ as $t < 0$, and the fractional n-dimensional Laplace operator $(-\triangle)^{\gamma/2}$ is defined by its Fourier transform with respect to spatial variable $\mathcal{F}[(-\triangle)^{\gamma/2} g(x)] = |\omega|^\gamma \mathcal{F}[g(x)]$. The solutions for initial value problems for time- and space-fractional partial differential equation in the sense of Caputo and Riemann–Liouville time-fractional derivatives, respectively, are obtained by the fundamental solution. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1819524]

I. INTRODUCTION

In recent years interest of some scholars has been shown in research on the problems involving the fractional integrodifferential equations applied to physics, mechanics, and other disciplines. For example, Schneider and Wyss,[20] Rangarajan and Ding,[19] and Fujita[7] have studied the integrodifferential equations with time-fractional integral; the partial differential equations with time-fractional derivative have been treated by Wyss,[23] Metzler *et al.*,[17] Buckwar and Luchko,[2] Gorenflo *et al.*,[10] Henry and Wearne,[12] Mainardi,[14,15] Hilfer,[13] and Podlubny.[18]

Compte[4] and West *et al.*[22] derived a hyperdiffusion (Lévy-flight diffusion) equation $\partial P/\partial t = D(-\triangle)^{\gamma/2} P$, where the fractional n-dimensional Laplace operator $(-\triangle)^{\gamma/2}$ is defined by its Fourier transform with respect to spatial variable $\mathcal{F}[(-\triangle)^{\gamma/2} g(x)] = |\omega|^\gamma \mathcal{F}[g(x)]$, and West *et al.*[22] gave the solution in the one-dimensional case.

In this paper the fundamental solution for the time- and space-fractional partial differential operator $D_t^\lambda + a^2(-\triangle)^{\gamma/2}(\lambda, \gamma > 0)$ is considered and is given in terms of Fox's H-function. Here the time-fractional derivative in the sense of generalized functions[8,18] (distributions) D_t^λ is defined by the convolution $D_t^\lambda f(t) := \Phi_{-\lambda}(t) * f(t)$, where $\Phi_\lambda(t) := t_+^{\lambda-1}/\Gamma(\lambda)$, $\Gamma(z)$ is the gamma function, and $f(t) \equiv 0$ as $t < 0$. The solutions for initial value problems for time- and space-fractional partial differential equation in the sense of Caputo and Riemann–Liouville, respectively, time-fractional derivatives are obtained by the fundamental solution.

Throughout this paper functions of time t are assumed to be causal, i.e., vanishing for $t < 0$. In Sec. II the time-fractional derivatives in the sense of generalized functions are adopted and we do not bother to give descriptions of sets of admissible functions and use, when necessary, formal expressions of generalized functions. In Sec. III the time-fractional derivatives in the Caputo and the Riemann–Liouville sense are defined within the framework of classical functions.

II. FUNDAMENTAL SOLUTION FOR TIME- AND SPACE-FRACTIONAL PARTIAL DIFFERENTIAL OPERATOR

We consider the time- and space-fractional partial differential equation

$$(D_t^{\lambda} + a^2(-\triangle)^{\gamma/2})G = \delta(x)\delta(t) \quad (\lambda, \gamma > 0), \tag{1}$$

where δ is the Dirac delta function, a is a positive constant, and the time-fractional derivative operator D_t^{λ} and the fractional n-dimensional Laplace operator $(-\triangle)^{\gamma/2}$ are defined as in Sec. I. The solution $G=G(x,t;\gamma,\lambda)$ of Eq. (1) is said to be a fundamental solution for the operator $D_t^{\lambda} + a^2(-\triangle)^{\gamma/2}$.

If $\lambda=1$ and $\gamma=2$ the operator in (1) becomes the diffusion operator, while it is a wave operator if $\lambda=2$ and $\gamma=2$.

Applying the Fourier transform with respect to spatial variable x and the Laplace transform with respect to time t (Fourier–Laplace transform) to Eq. (1) yields

$$\overline{G}(\omega,p;\gamma,\lambda) = \frac{1}{p^{\lambda} + a^2|\omega|^{\gamma}}. \tag{2}$$

Here the Fourier transform is defined by

$$\mathcal{F}[g(x),\omega] = \int g(x)e^{i\omega\cdot x}\, \mathrm{d}^n x, \tag{3}$$

whose inverse transform reads

$$\mathcal{F}^{-1}[g(x),\omega] = \frac{1}{(2\pi)^n}\int g(x)e^{-i\omega\cdot x}\, \mathrm{d}^n x, \tag{4}$$

and the Laplace transform is

$$\mathcal{L}[f(t),p] = \int_0^{\infty} f(t)e^{-pt}\, \mathrm{d}t. \tag{5}$$

Using the Mellin transform

$$\hat{f}(s) = \mathcal{M}[f(t),s] = \int_0^{\infty} f(t)t^{s-1}\, \mathrm{d}t \tag{6}$$

and the relation

$$\mathcal{M}[f(t),s] = \frac{1}{\Gamma(1-s)}\mathcal{M}[\mathcal{L}[f(t),p],1-s] \tag{7}$$

connecting Laplace and Mellin transforms we obtain the Fourier–Mellin transform of $G(x,t;\gamma,\lambda)$,

$$\tilde{G}(\omega,s;\gamma,\lambda) = \frac{1}{\lambda\Gamma(1-s)}(a^2|\omega|^{\gamma})^{[(1-s)/\lambda]-1}B\left(\frac{1-s}{\lambda},\frac{\lambda-1+s}{\lambda}\right), \tag{8}$$

where $B(u,v)$ is the beta function.

In order to obtain inverse Fourier transform to (8) introducing n-dimensional spherical coordinates in the inverse Fourier integral to (8) leads to the Mellin transform of $G(x,t;\gamma,\lambda)$ with respect to t,

$$\hat{G}(x,s;\gamma,\lambda) = \frac{|x|^{1-(n/2)}B\left(\frac{1-s}{\lambda},\frac{\lambda-1+s}{\lambda}\right)}{\lambda(2\pi)^{n/2}\Gamma(1-s)a^{[2(s-1)/\lambda]+2}}\int_0^{\infty} \rho^{(n/2)+[\gamma(1-s)/\lambda]-\gamma}J_{(n/2)-1}(\rho|x|)\mathrm{d}\rho, \tag{9}$$

where $\rho=|\omega|$ and $J_{\mu}(z)$ is the Bessel function of the first kind. Using the Mellin transform of the Bessel function,[5]

$$\mathcal{M}[J_\mu(z),s] = \frac{2^{s-1}\Gamma\left(\frac{\mu+s}{2}\right)}{\Gamma\left(\frac{\mu-s}{2}+1\right)}, \quad -\mu < \Re(s) < \mu+2, \tag{10}$$

we obtain

$$\hat{G}(x,s;\gamma,\lambda) = \frac{|x|^{[\gamma(s-1)/\lambda]+\gamma-n}}{\lambda 2^{[\gamma(s-1)/\lambda]+\gamma}\pi^{n/2}a^{2(\lambda+s-1)/\lambda}}\Theta(s), \tag{11}$$

where

$$\Theta(s) = \frac{\Gamma\left(\frac{n\lambda-\gamma\lambda+\gamma-\gamma s}{2\lambda}\right)\Gamma\left(\frac{1-s}{\lambda}\right)\Gamma\left(\frac{\lambda-1+s}{\lambda}\right)}{\Gamma\left(\frac{\gamma\lambda-\gamma+\gamma s}{2\lambda}\right)\Gamma(1-s)}. \tag{12}$$

Taking the inverse Mellin transform yields $G(x,t;\gamma,\lambda)$ in terms of the H-function, and by its properties we have

$$G(x,t;\gamma,\lambda) = \frac{t^{\lambda-1}}{\pi^{n/2}|x|^n}H_{2,3}^{2,1}\left(\frac{|x|^\gamma}{2^\gamma a^2 t^\lambda}\middle|\begin{matrix}(1,1);(\lambda,\lambda)\\(1,1),(n/2,\gamma/2);(1,\gamma/2)\end{matrix}\right). \tag{13}$$

If $\gamma=2$ and $\lambda=1$, (13) degenerates to the Gaussian distribution[16,21]

$$G(x,t;2,1) = \frac{1}{(4\pi a^2 t)^{n/2}}\exp\left(-\frac{|x|^2}{4a^2 t}\right). \tag{14}$$

If $\gamma=\lambda=1$ using the definition and properties of the H-function and the relation

$$\sqrt{\pi}\Gamma(2z) = 2^{2z-1}\Gamma(z)\Gamma(z+\tfrac{1}{2}), \tag{15}$$

(13) is simplified to

$$G(x,t;1,1) = \frac{a^2 t}{\pi^{(n+1)/2}|x|^{n+1}}H_{1,1}^{1,1}\left(\frac{a^4t^2}{|x|^2}\middle|\begin{matrix}(1/2-(n/2),1)\\(0,1)\end{matrix}\right). \tag{16}$$

Expanding the H-function in (16) into the series according to (A4) and (A5), respectively, we obtain the Cauchy distribution

$$G(x,t;1,1) = \frac{\Gamma\left(\frac{n+1}{2}\right)}{\pi^{(n+1)/2}}\frac{a^2 t}{((a^2t)^2+|x|^2)^{(n+1)/2}}. \tag{17}$$

Similarly if $\gamma=\lambda=2$ (13) is simplified to

$$G(x,t;2,2) = \frac{t}{2\pi^{(n-1)/2}(at)^n}H_{1,1}^{1,0}\left(\frac{|x|^2}{a^2t^2}\middle|\begin{matrix}((3-n)/2,1)\\(0,1)\end{matrix}\right). \tag{18}$$

According to (A4) we expand the H-function in (18) and obtain

$$G(x,t;2,2) = \frac{1}{2a\pi^{(n-1)/2}\Gamma\left(\frac{3-n}{2}\right)(a^2t^2 - |x|^2)^{(n-1)/2}}, \quad |x| < at. \tag{19}$$

If n is odd and more than 1 the right-hand side of (19) equals zero while if n is even $(n=2k)$ (19) becomes

$$G(x,t;2,2) = \frac{(-1)^{k-1}1\cdot 3\cdot 5\cdot\cdots\cdot(2k-1)}{a(2k-1)(2\pi)^k(a^2t^2 - |x|^2)^{(n-1)/2}}, \quad |x| < at, \tag{20}$$

which corresponds to the results of the wave equation.[3]

The solution of the equation

$$(D_t^\lambda + a^2(-\triangle)^{\gamma/2})u(x,t;\gamma,\lambda) = h(x,t) \tag{21}$$

may be expressed formally by the fundamental solution

$$u(x,t;\gamma,\lambda) = \int \mathrm{d}^n\xi \int_0^t G(x-\xi,t-\tau;\gamma,\lambda)h(\xi,\tau)\mathrm{d}\tau. \tag{22}$$

III. SOLUTION FOR INITIAL VALUE PROBLEM FOR TIME- AND SPACE-FRACTIONAL PARTIAL DIFFERENTIAL EQUATION IN THE CAPUTO AND THE RIEMANN–LIOUVILLE SENSE

In this section we assume the functions appeared to be locally absolutely integrable at least with respect to time t. The function $\Phi_\beta(t) := t_+^{\beta-1}/\Gamma(\beta)$ is locally integrable as $\beta > 0$ and thus the fractional integral of order $\beta(\beta > 0)$,

$$I_t^\beta f(t) = D_t^{-\beta} f(t) := \Phi_\beta(t) * f(t) = \int_0^t \frac{(t-\tau)^{\beta-1}}{\Gamma(\beta)} f(\tau)\mathrm{d}\tau \tag{23}$$

makes sense in the framework of classical functions. We supplement $I_t^0 f(t) = f(t)$ reasonably.[11,18]

The fractional derivatives of order $\lambda(\lambda > 0)$ in the Caputo and the Riemann–Liouville sense, respectively, are defined by

$${}^C D_t^\lambda f(t) := I_t^{m-\lambda}(f^{(m)}(t)), \quad t \neq 0,\ m-1 < \lambda \leqslant m \tag{24}$$

and

$${}^R D_t^\lambda f(t) := \frac{d^m}{\mathrm{d}t^m}(I_t^{m-\lambda} f(t)), \quad t \neq 0,\ m-1 < \lambda \leqslant m, \tag{25}$$

where m is positive integer and the derivatives of order m on the right-hand side of (24) and (25) are classical ones, and we always assume that the two kinds of fractional derivatives that occurred make sense in the framework of classical functions.

A. Solution in the caputo sense

The initial value problem for time- and space-fractional partial differential equation in the Caputo sense reads

$$({}^C D_t^\lambda + a^2(-\triangle)^{\gamma/2})u(x,t;\gamma,\lambda) = 0, \quad t > 0,\ \gamma > 0,\ 0 \leqslant m-1 < \lambda \leqslant m, \tag{26}$$

$$\frac{\partial^k u}{\partial t^k}(x,0+;\gamma,\lambda) = f_k(x), \quad k = 0,1,\ldots,m-1. \tag{27}$$

The relation between the derivative of order m in the sense of distributions, $D_t^m u$, and the one in the classical sense, $\partial^m u/\partial t^m$, is

$$D_t^m u = \frac{\partial^m u}{\partial t^m} + \sum_{k=0}^{m-1} f_k(x)\,\delta^{(m-1-k)}(t). \tag{28}$$

Inserting $D_t^\lambda u = D_t^{\lambda-m}(D_t^m u)$ and using the fractional integrals of Dirac delta function and its derivatives[18] $I_t^\mu \delta^{(k)}(t) = \Phi_{\mu-k}(t)$ we obtain

$$D_t^\lambda u = {}^C D_t^\lambda u + \sum_{k=0}^{m-1} f_k(x)\Phi_{1-\lambda+k}(t). \tag{29}$$

Thus in the sense of distributions u satisfies the equation

$$(D_t^\lambda + a^2(-\triangle)^{\gamma/2})u(x,t;\gamma,\lambda) = \sum_{k=0}^{m-1} f_k(x)\Phi_{1-\lambda+k}(t). \tag{30}$$

Utilizing (22) we obtain

$$u(x,t;\gamma,\lambda) = \sum_{k=0}^{m-1} \int f_k(\xi) G_k^C(x-\xi,t;\gamma,\lambda)\mathrm{d}^n\xi, \tag{31}$$

where $G_k^C(x,t;\gamma,\lambda) = D_t^{\lambda-1-k} G(x,t;\gamma,\lambda)$.

With the Mellin transform we may verify the fractional derivative of the H-function[9,16,21] (in the sense of distributions),

$$D_z^\nu[z^\alpha H_{p,q}^{m,n}(\,(az)^\beta\big|_{(b_j,\beta_j)}^{(a_j,\alpha_j)})] = z^{\alpha-\nu} H_{p+1,q+1}^{m,n+1}(\,(az)^\beta\big|_{(b_j,\beta_j),(\nu-\alpha,\beta)}^{(-\alpha,\beta),(a_j,\alpha_j)}), \tag{32}$$

where $a>0$, $\beta>0$ and $\alpha+\beta\,\min_{1\leqslant j\leqslant m}\Re(b_j/\beta_j)>-1$. Calculating the fractional derivative of the H-function we have

$$G_k^C(x,t;\gamma,\lambda) = \frac{t^k}{\pi^{n/2}|x|^n} H_{3,2}^{1,2}\left(\frac{2^\gamma a^2 t^\lambda}{|x|^\gamma}\,\middle|\,{}^{(0,1),(1-(n/2),\gamma/2);(0,\gamma/2)}_{(0,1);(-k,\lambda)}\right). \tag{33}$$

If $\gamma=2$ (33) is simplified to Schneider's result,[20]

$$G_k^C(x,t;2,\lambda) = \frac{|x|^{(2k/\lambda)-n}}{2\pi^{n/2}(2a)^{2k/\lambda}} H_{1,2}^{2,0}\left(\frac{|x|}{2at^{\lambda/2}}\,\middle|\,{}^{(1,\lambda/2)}_{(1-(k/\lambda),1/2),((n/2)-(k/\lambda),1/2)}\right), \tag{34}$$

where we confine $\lambda\leqslant 2$ in order to ensure the H-function makes sense. When $n=1$ by the definition of H-function and the relation (15) we may rewrite (34) to

$$G_k^C(x,t;2,\lambda)\big|_{n=1} = \frac{1}{2|x|}\left(\frac{|x|}{a}\right)^{2k/\lambda} H_{1,1}^{1,0}\left(\frac{|x|}{at^{\lambda/2}}\,\middle|\,{}^{(1,\lambda/2)}_{(1-(2k/\lambda),1)}\right), \tag{35}$$

which is proved, with the series expression of the H-function, to be a Wright function[10] also,

$$G_k^C(x,t;2,\lambda)\big|_{n=1} = \frac{1}{2at^{(\lambda/2)-k}} W_{-\lambda/2,1-(\lambda/2)+k}\left(-\frac{|x|}{at^{\lambda/2}}\right). \tag{36}$$

When $k=0$ the result is consistent with Mainardi.[14,15]

If $\lambda=1$ (thus $m=1$), $n=1$ and $u(x,+0;\gamma,1)=f_0(x)=\delta(x)$ the solution of problems (26) and (27) is $G_0^C(x,t;\gamma,1)$ and by the equality (15) and definition and properties of the H-function it can be rewritten as

$$G_0^C(x,t;\gamma,1)=\frac{1}{\gamma|x|}H_{2,2}^{1,1}\left(\frac{|x|}{(a^2t)^{1/\gamma}}\middle|\begin{matrix}(1,1/\gamma),(1,1/2)\\(1,1),(1,1/2)\end{matrix}\right), \tag{37}$$

which is obtained by West *et al.*[22] (where factor π is superfluous).

B. Solution in the Riemann–Liouville sense

The initial value problem for time- and space-fractional partial differential equation in the Riemann–Liouville sense reads

$$({}^RD_t^\lambda + a^2(-\triangle)^{\gamma/2})u(x,t;\gamma,\lambda)=0,\quad t>0,\quad \gamma>0,\quad 0\leqslant m-1<\lambda\leqslant m, \tag{38}$$

$${}^RD_t^{\lambda-k}u(x,0+;\gamma,\lambda)=g_k(x),\quad k=1,2,\ldots,m, \tag{39}$$

where ${}^RD_t^{\lambda-m}u=D_t^{\lambda-m}u$. We consider the derivative of order λ in the sense of generalized functions $D_t^\lambda u$. It can be decomposed to $D_t^\lambda u=D_t^m(D_t^{\lambda-m}u)$, where D_t^m denotes the generalized derivative of order m. Using the relation between generalized derivatives and classical derivatives we obtain

$$D_t^\lambda u={}^RD_t^\lambda u+\sum_{k=1}^m g_k(x)\,\delta^{(k-1)}(t). \tag{40}$$

Inserting (38) yields the equation in the sense of generalized functions,

$$(D_t^\lambda + a^2(-\triangle)^{\gamma/2})u(x,t;\gamma,\lambda)=\sum_{k=1}^m g_k(x)\,\delta^{(k-1)}(t). \tag{41}$$

Utilizing (22) we obtain

$$u(x,t;\gamma,\lambda)=\sum_{k=1}^m\int g_k(\xi)G_k^R(x-\xi,t;\gamma,\lambda)\mathrm{d}^n\xi, \tag{42}$$

where $G_k^R(x,t;\gamma,\lambda)=D_t^{k-1}G(x,t;\gamma,\lambda)$. Calculating the derivative of the H-function we have

$$G_k^R(x,t;\gamma,\lambda)=\frac{t^{\lambda-k}}{\pi^{n/2}|x|^n}H_{3,2}^{1,2}\left(\frac{2^\gamma a^2t^\lambda}{|x|^\gamma}\middle|\begin{matrix}(0,1),(1-(n/2),\gamma/2);(0,\gamma/2)\\(0,1);(k-\lambda,\lambda)\end{matrix}\right). \tag{43}$$

As $\gamma=2$, $m=1$, and $g_1(x)=A\delta(x)$ the solution of the problems (38) and (39) may be simplified as Hilfer's result,[13]

$$G_1^R(x,t;2,\lambda)=\frac{At^{\lambda-1}}{\pi^{n/2}|x|^n}H_{1,2}^{2,0}\left(\frac{|x|^2}{4a^2t^\lambda}\middle|\begin{matrix}(\lambda,\lambda)\\(1,1),(n/2,1)\end{matrix}\right). \tag{44}$$

We note that directly calculating the Laplace transforms of the Caputo and the Riemann–Liouville derivatives also involves the initial values of integer-order derivatives and fractional-order derivatives, respectively.[18] Here we reveal it in the distribution sense.

IV. CONCLUSIONS

The partial differential equation with both the time-fractional derivative and the space-fractional Laplace operator is considered and solved in terms of the Fox H-function. The time-fractional derivatives in the sense of generalized functions, Caputo and Riemann–Liouville are considered, respectively. The initial value problems in the Caputo sense and the Riemann–Liouville sense have unified form in the sense of generalized functions although Caputo's frac-

tional derivatives involve the initial values of derivatives of integer order while the Riemann–Liouville involve the initial values of derivatives and integral of fractional order. Some previous results are contained in our results.

APPENDIX: FOX'S *H*-FUNCTION

Fox's H-function is defined by the contour integral,[1,6,16,21]

$$H_{p,q}^{m,n}(z) = H_{p,q}^{m,n}\left(z\Big|_{(b_1,\beta_1),\ldots,(b_q,\beta_q)}^{(a_1,\alpha_1),\ldots,(a_p,\alpha_p)}\right) := \frac{1}{2\pi i}\int_L h(s)z^s \mathrm{d}s, \tag{A1}$$

where $h(s)$ is given by

$$h(s) = \frac{\prod_{j=1}^{m}\Gamma(b_j-\beta_j s)\prod_{j=1}^{n}\Gamma(1-a_j+\alpha_j s)}{\prod_{j=m+1}^{q}\Gamma(1-b_j+\beta_j s)\prod_{j=n+1}^{p}\Gamma(a_j-\alpha_j s)}. \tag{A2}$$

Here m,n,p,q are integers satisfying $m^2+n^2\neq 0$, $0\leqslant n\leqslant p, 0\leqslant m\leqslant q$ and empty products are interpreted as unity. The parameters $a_j (j=1,\ldots,p)$ and $b_j (j=1,\ldots,q)$ are complex numbers and $\alpha_j (j=1,\ldots,p)$ and $\beta_j (j=1,\ldots,q)$ are positive numbers satisfying $P_a \cap P_b = \varnothing$, where $P_a=\{s=(b_j+k)/\beta_j, j=1,2,\ldots,m; k=0,1,2,\ldots\}$ and $P_b=\{s=(a_j-1-k)/\alpha_j, j=1,2,\ldots,n; k=0,1,2,\ldots\}$. The integration contour L runs from $s=c-i\infty$ to $s=c+i\infty$ such that P_a lies to the right of L and P_b to the left of L.

Let

$$\mu = \sum_{j=1}^{q}\beta_j - \sum_{j=1}^{p}\alpha_j, \quad \beta = \prod_{j=1}^{p}\alpha_j^{\alpha_j}\prod_{j=1}^{q}\beta_j^{-\beta_j}. \tag{A3}$$

When $\mu\geqslant 0$ and $m\geqslant 1$, the H-function can be expanded to

$$H_{p,q}^{m,n}(z) = -\sum_{s\in P_a}\mathrm{Res}(h(s)z^s), \tag{A4}$$

which exists for all $z\neq 0$ if $\mu>0$ and for $0<|z|<\beta^{-1}$ if $\mu=0$.

When $\mu\leqslant 0$ and $n\geqslant 1$, the H-function can be expanded to

$$H_{p,q}^{m,n}(z) = \sum_{s\in P_b}\mathrm{Res}(h(s)z^s), \tag{A5}$$

which exists for all $z\neq 0$ if $\mu<0$ and for $|z|>\beta^{-1}$ if $\mu=0$.

We list some properties of the H-function,

$$H_{p,q}^{m,n}\left(z\Big|_{(b_1,\beta_1),\ldots,(b_q,\beta_q)}^{(a_1,\alpha_1),\ldots,(a_p,\alpha_p)}\right) = H_{q,p}^{n,m}\left(\frac{1}{z}\,\Bigg|\,{}^{(1-b_1,\beta_1),\ldots,(1-b_q,\beta_q)}_{(1-a_1,\alpha_1),\ldots,(1-a_p,\alpha_p)}\right). \tag{A6}$$

$$H_{p,q}^{m,n}\left(z\Big|_{(b_1,\beta_1),\cdots,(b_{q-1},\beta_{q-1}),(a_1,\alpha_1)}^{(a_1,\alpha_1),\cdots,(a_p,\alpha_p)}\right) = H_{p-1,q-1}^{m,n-1}\left(z\Big|_{(b_1,\beta_1),\cdots,(b_{q-1},\beta_{q-1})}^{(a_2,\alpha_2),\cdots,(a_p,\alpha_p)}\right), \quad n>0, \quad q>m, \tag{A7}$$

$$\frac{1}{k}H_{p,q}^{m,n}\left(z\Big|_{(b_1,\beta_1),\ldots,(b_q,\beta_q)}^{(a_1,\alpha_1),\ldots,(a_p,\alpha_p)}\right)=H_{p,q}^{m,n}\left(z^k\Big|_{(b_1,k\beta_1),\ldots,(b_q,k\beta_q)}^{(a_1,k\alpha_1),\ldots,(a_p,k\alpha_p)}\right),\quad k>0, \tag{A8}$$

$$z^{\sigma}H_{p,q}^{m,n}\left(z\Big|_{(b_1,\beta_1),\ldots,(b_q,\beta_q)}^{(a_1,\alpha_1),\ldots,(a_p,\alpha_p)}\right)=H_{p,q}^{m,n}\left(z\Big|_{(b_1+\sigma\beta_1,\beta_1),\ldots,(b_q+\sigma\beta_q,\beta_q)}^{(a_1+\sigma\alpha_1,\alpha_1),\ldots,(a_p+\sigma\alpha_p,\alpha_p)}\right). \tag{A9}$$

Property (A6) enables us to transform an H-function with $\mu=\Sigma_{j=1}^{q}\beta_j-\Sigma_{j=1}^{p}\alpha_j<0$ to one with $\mu>0$ and vice versa.

A unified and complete construction of all finite dimensional irreducible representations of gl(2|2)

Yao-Zhong Zhang and Mark D. Gould
Department of Mathematics, University of Queensland, Brisbane, Qld 4072, Australia

(Received 4 May 2004; accepted 7 September 2004; published online 3 January 2005)

Representations of the non-semisimple superalgebra gl(2|2) in the standard basis are investigated by means of the vector coherent state method and boson-fermion realization. All finite-dimensional irreducible typical and atypical representations and lowest weight (indecomposable) Kac modules of gl(2|2) are constructed explicitly through the explicit construction of all $gl(2)\oplus gl(2)$ particle states (multiplets) in terms of boson and fermion creation operators in the super-Fock space. This gives a unified and complete treatment of finite-dimensional representations of gl(2|2) in explicit form, essential for the construction of primary fields of the corresponding current superalgebra at arbitrary level. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1812829]

I. INTRODUCTION

Recently there is much research interest in superalgebras and their corresponding nonunitary conformal field theories (CFTs), because of their applications in high energy and condensed matter physics including topological field theory,[1,2] logarithmic CFTs (see, e.g., Ref. 3, and references therein), disordered systems, and the integer quantum Hall effects.[4–11] In such contexts, the vanishing of superdimensions and Virasoro central charges and the existence of primary fields with negative dimensions are crucial.[5,6] The most interesting algebras with such properties are osp($n|n$) and gl($n|n$).

In most physical applications, one needs the explicit construction of finite-dimensional representations of a superalgebra. This is particularly the case in superalgebra CFTs. To construct primary fields of such CFTs in terms of free fields, one has to construct the finite-dimensional representations of the superalgebras explicitly. The explicit construction of the primary fields is essential in the investigation of disordered systems by the supersymmetric method.

Unlike ordinary bosonic algebras, there are two types of representations for most superalgebras. They are the so-called typical and atypical representations. The typical representations are irreducible and are similar to the usual representations that appear in ordinary bosonic algebras. The atypical representations have no counterpart in the bosonic algebra setting. They can be irreducible or not fully reducible (i.e., reducible or indecomposable). This makes the study of representations of superalgebras very difficult.

Representations of osp(2|2) were investigated in Refs. 12 and 13. A unified construction of finite-dimensional typical and atypical representations of osp(2|2) were given in Refs. 14 and 15 by means of the vector coherent state method. This enabled the explicit construction of all primary fields of the osp(2|2) CFT[16,14] in terms of free fields.[17,18]

In this paper we investigate finite-dimensional representations of the non-semisimple superalgebra gl(2|2). All finite-dimensional irreducible typical and atypical representations and lowest weight (indecomposable) Kac modules of gl(2|2) are constructed explicitly through the explicit construction of all $gl(2)\oplus gl(2)$ particle states (multiplets) in terms of the boson and fermion creation operators in the super-Fock space. This we believe gives a unified and complete treatment of all finite-dimensional irreducible representations of gl(2|2) in explicit form.

Let us point out that the finite-dimensional representations of gl(2|2) have also been investigated in Refs. 19,20 using the GT basis. Our method is completely different from and in our

opinion is simpler than the method used in these two references. Moreover, our results can be used to construct primary fields of the corresponding gl(2|2) CFTs at arbitrary level, which is the subject of a separate work.

This paper is organized as follows. In Sec. II, we introduce our notations and derive a free boson-fermion realization of gl(2|2) by means of the vector coherent state method. In Sec. III, we describe the explict construction of independent $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ particle states in the super-Fock space. We derive the actions of odd simple generators of gl(2|2) on these multiplets. The 16 independent multiplets constructed span all finite-dimensional irreducible typical representations of gl(2|2). In Sec. IV, we deduce and construct all four types of finite-dimensional irreducible atypical representations and lowest weight (indecomposable) Kac modules of gl(2|2).

II. BOSON-FERMION REALIZATION OF gl(2|2)

In this section, we obtain a boson-fermion realization of the superalgebra gl(2|2) in the standard basis.

This superalgebra is non-semisimple and can be written as $\mathrm{gl}(2|2)=\mathrm{gl}(2|2)^{\mathrm{even}}\oplus\mathrm{gl}(2|2)^{\mathrm{odd}}$, where

$$\mathrm{gl}(2|2)^{\mathrm{even}}=\mathrm{gl}(2)\oplus\mathrm{gl}(2)=\{I\}\oplus\{\{E_{12},E_{21},H_1\}\oplus\{E_{34},E_{43},H_2\},N\},$$

$$\mathrm{gl}(2|2)^{\mathrm{odd}}=\{E_{13},E_{31},E_{23},E_{32},E_{24},E_{42},E_{14},E_{41}\}. \tag{2.1}$$

In the standard basis, E_{12},E_{34},E_{23} (E_{21},E_{43},E_{32}) are simple raising (lowering) generators, E_{13},E_{14},E_{24} (E_{31},E_{41},E_{42}) are non-simple raising (lowering) generators and H_1,H_2,I,N are elements of the Cartan subalgebra. We have

$$H_1=E_{11}-E_{22},\quad H_2=E_{33}-E_{44},$$

$$I=E_{11}+E_{22}+E_{33}+E_{44}, \tag{2.2}$$

$$N=E_{11}+E_{22}-E_{33}-E_{44}+\beta I$$

with β being an arbitrary parameter. That N is not uniquely determined is a consequence of the fact that gl(2|2) is non-semisimple. The generators obey the following (anti)commutation relations:

$$[E_{ij},E_{kl}]=\delta_{jk}E_{il}-(-1)^{([i]+[j])([k]+[l])}\delta_{il}E_{kj}, \tag{2.3}$$

where $[E_{ij},E_{kl}]\equiv E_{ij}E_{kl}-(-1)^{([i]+[j])([k]+[l])}E_{kl}E_{ij}$ is a commutator or an anticommutator, $[1]=[2]=0$, $[3]=[4]=1$, and E_{ii}, $i=1,2,3,4$ are related to H_1,H_2,I,N via (2.2). The quadratic Casimir of the algebra is given by $C_2=\Sigma_{AB}(-1)^{[B]}E_{AB}E_{BA}$.

Let $|hw\rangle$ be the highest weight state of highest weight (J_1,J_2,q,p) of gl(2|2) defined by

$$H_1|hw\rangle=2J_1|hw\rangle,\quad H_2|hw\rangle=2J_2|hw\rangle,$$

$$I|hw\rangle=2q|hw\rangle,\quad N|hw\rangle=2p|hw\rangle, \tag{2.4}$$

$$E_{12}|hw\rangle=E_{34}|hw\rangle=E_{23}|hw\rangle=E_{13}|hw\rangle=E_{14}|hw\rangle=E_{24}|hw\rangle=0.$$

Here J_1,J_2 are positive integers and half-integers and q,p are arbitrary complex numbers. Define the coherent state[21,22]

$$e^{E_{21}a_{12}+E_{43}a_{34}+E_{31}\alpha_{13}+E_{32}\alpha_{23}+E_{42}\alpha_{24}+E_{41}\alpha_{14}}|hw\rangle.$$

Then state vectors are mapped into functions

$$\psi_{J_1,J_2,q,p} = \langle hw|e^{\alpha_{13}^\dagger E_{13}+\alpha_{23}^\dagger E_{23}+\alpha_{24}^\dagger E_{24}+\alpha_{14}^\dagger E_{14}+a_{12}^\dagger E_{12}+a_{34}^\dagger E_{34}}|\psi\rangle|0\rangle, \tag{2.5}$$

and operators A are mapped as follows

$$A|\psi\rangle \to \Gamma(A)\psi_{J_1,J_2,q,p} = \langle hw|e^{\alpha_{13}^\dagger E_{13}+\alpha_{23}^\dagger E_{23}+\alpha_{24}^\dagger E_{24}+\alpha_{14}^\dagger E_{14}+a_{12}^\dagger E_{12}+a_{34}^\dagger E_{34}}A|\psi\rangle|0\rangle. \tag{2.6}$$

Here $\alpha_{ij}^\dagger$ (α_{ij}) are fermion operators with number operators $N_{\alpha_{ij}}$ and $a_{ij}^\dagger$ (a_{ij}) are boson operators with number operators $N_{a_{ij}}$. They obey relations

$$\{\alpha_{ij},\alpha_{kl}^\dagger\} = \delta_{ik}\delta_{jl}, \quad (\alpha_{ij})^2 = (\alpha_{ij}^\dagger)^2 = 0,$$

$$[N_{\alpha_{ij}},\alpha_{kl}] = -\delta_{ik}\delta_{jl}\alpha_{kl}, \quad [N_{\alpha_{ij}},\alpha_{kl}^\dagger] = \delta_{ik}\delta_{jl}\alpha_{kl}^\dagger,$$

$$[a_{ij},a_{kl}^\dagger] = \delta_{ik}\delta_{jl},$$

$$[N_{a_{ij}},a_{kl}] = -\delta_{ik}\delta_{jl}a_{kl}, \quad [N_{a_{ij}},a_{kl}^\dagger] = \delta_{ik}\delta_{jl}a_{kl}^\dagger, \tag{2.7}$$

and all other (anti-)commutators vanish. Moreover, $a_{12}|0\rangle = a_{34}|0\rangle = \alpha_{23}|0\rangle = \alpha_{13}|0\rangle = \alpha_{14}|0\rangle = \alpha_{24}|0\rangle = 0$.

Taking E_{12}, E_{34}, etc. in turn and after long algebraic computations, we find the following representation of simple generators in terms of the boson and fermion operators:

$$\begin{aligned}
\Gamma(E_{12}) &= a_{12} - \tfrac{1}{2}\alpha_{23}^\dagger\alpha_{13} + \tfrac{1}{2}(\tfrac{1}{6}a_{34}^\dagger\alpha_{23}^\dagger - \alpha_{24}^\dagger)\alpha_{14},\\
\Gamma(E_{34}) &= a_{34} + \tfrac{1}{2}\alpha_{23}^\dagger\alpha_{24} + \tfrac{1}{2}(\tfrac{1}{6}a_{12}^\dagger\alpha_{23}^\dagger + \alpha_{13}^\dagger)\alpha_{14},\\
\Gamma(E_{23}) &= \alpha_{23} + \tfrac{1}{2}a_{12}^\dagger\alpha_{13} - \tfrac{1}{2}a_{34}^\dagger(\alpha_{24} + \tfrac{1}{3}a_{12}^\dagger\alpha_{14}),\\
\Gamma(H_1) &= 2J_1 - 2N_{a_{12}} + N_{\alpha_{23}} - N_{\alpha_{13}} + N_{\alpha_{24}} - N_{\alpha_{14}},\\
\Gamma(H_2) &= 2J_2 - 2N_{a_{34}} + N_{\alpha_{23}} + N_{\alpha_{13}} - N_{\alpha_{24}} - N_{\alpha_{14}},\\
\Gamma(I) &= 2q,\\
\Gamma(N) &= 2p - 2(N_{\alpha_{23}} + N_{\alpha_{13}} + N_{\alpha_{24}} + N_{\alpha_{14}}),
\end{aligned} \tag{2.8}$$

$$\begin{aligned}
\Gamma(E_{21}) &= a_{12}^\dagger[2J_1 - N_{a_{12}} + \tfrac{1}{2}(N_{\alpha_{23}} - N_{\alpha_{13}} + N_{\alpha_{24}} - N_{\alpha_{14}})] - \alpha_{13}^\dagger\alpha_{23} - \alpha_{14}^\dagger\alpha_{24} - \tfrac{1}{4}(a_{12}^\dagger)^2\alpha_{23}^\dagger\alpha_{13}\\
&\quad + \tfrac{1}{12}a_{12}^\dagger a_{34}^\dagger\alpha_{23}^\dagger\alpha_{24} - \tfrac{1}{4}a_{12}^\dagger(a_{12}^\dagger\alpha_{24}^\dagger + \tfrac{1}{3}a_{34}^\dagger\alpha_{13}^\dagger)\alpha_{14},
\end{aligned}$$

$$\begin{aligned}
\Gamma(E_{43}) &= a_{34}^\dagger[2J_2 - N_{a_{34}} + \tfrac{1}{2}(N_{\alpha_{23}} + N_{\alpha_{13}} - N_{\alpha_{24}} - N_{\alpha_{14}})] + \alpha_{24}^\dagger\alpha_{23} + \alpha_{14}^\dagger\alpha_{13} + \tfrac{1}{4}(a_{34}^\dagger)^2\alpha_{23}^\dagger\alpha_{24}\\
&\quad - \tfrac{1}{12}a_{12}^\dagger a_{34}^\dagger\alpha_{23}^\dagger\alpha_{13} + \tfrac{1}{4}(a_{34}^\dagger\alpha_{12}^\dagger + \tfrac{1}{3}a_{12}^\dagger\alpha_{24}^\dagger)a_{34}^\dagger\alpha_{14},
\end{aligned}$$

$$\begin{aligned}
\Gamma(E_{32}) &= \alpha_{23}^\dagger[q - J_1 + J_2 + \tfrac{1}{2}(N_{a_{12}} - N_{a_{34}} + N_{\alpha_{13}} - N_{\alpha_{24}})] + \alpha_{13}^\dagger a_{12} + \alpha_{24}^\dagger a_{34}\\
&\quad + \tfrac{1}{6}\alpha_{23}^\dagger(a_{12}^\dagger\alpha_{24}^\dagger + a_{34}^\dagger\alpha_{13}^\dagger)\alpha_{14},
\end{aligned}$$

and the representation for non-simple generators is easily obtained from that of simple generators above by means of the commutation relations. Equation (2.8) gives a boson-fermion realization of

the non-semisimple superalgebra gl(2|2) in the standard basis. In this realization, the Casimir takes a constant value: $C_2=2[(J_1-J_2)(J_1+J_2+1)+q(p-2)]$.

III. TYPICAL REPRESENTATIONS OF gl(2|2)

Representations of gl(2|2) are labeled by (J_1,J_2,q,p) with J_1,J_2 being positive integers or half-integers and q,p being arbitrary complex numbers. Consider a particle state in the super-Fock space, obtained by acting the creation operators on the vacuum vector $|0\rangle$. We call such a state a level-x state if $\Gamma(H_1),\Gamma(H_2),\Gamma(I),\Gamma(N)$ have eigenvalues $2(m_1+x),2(m_2+x),2q,2(p-x)$, respectively. Obviously, a level-x state is a product of x number of fermion creation operators and boson creation operators of the form $(a_{12}^\dagger)^{J_1-m_1-y}(a_{34}^\dagger)^{J_2-m_2-\bar{y}}$ acting on $|0\rangle$, where $y,\bar{y}$ are certain integers or half-integers, depending on the values of x. It is easy to see that there are 16 independent such states obtained from 16 independent combinations of the creation operators. This includes one level-0 state, four level-1 states, six level-2 states, four level-3 states and one level-4 state. Thus each gl(2|2) representation decomposes into at most 16 representations of the even subalgebra $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$. Let us construct representations for $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ out of the above states. First the level-0 and level-4 states are already representations of $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ with highest weights (J_1,J_2,q,p) and $(J_1,J_2,q,p-4)$, respectively. We denote these two multiplets by $|J_1,m_1,J_2,m_2,q;p\rangle$ and $|J_1,m_1,J_2,m_2,q;p-4\rangle$, respectively. So

$$
\begin{aligned}
&|J_1,m_1,J_2,m_2,q;p\rangle=(a_{12}^\dagger)^{J_1-m_1}(a_{34}^\dagger)^{J_2-m_2}|0\rangle,\\
&m_1=J_1,J_1-1,\ldots,-J_1,\quad m_2=J_2,J_2-1,\ldots,-J_2,\\
&|J_1,m_1,J_2,m_2,q;p-4\rangle=\alpha_{23}^\dagger\alpha_{13}^\dagger\alpha_{24}^\dagger\alpha_{14}^\dagger(a_{12}^\dagger)^{J_1-m_1-4}(a_{34}^\dagger)^{J_2-m_2-4}|0\rangle,\\
&m_1=J_1-4,J_1-5,\ldots,-(J_1+4),\quad m_2=J_2-4,J_2-5,\ldots,-(J_2+4).
\end{aligned}
\tag{3.1}
$$

Both multiplets have dimension $(2J_1+1)(2J_2+1)$.

It can be shown that other level-x states can be combined into independent level-x multiplets of $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ with certain highest weights. The procedure is the following. For a given level x, one considers a combination Ψ_{J_1,m_1,J_2,m_2} of all level-x states. The combination coefficients are in general functions of J_1,m_1,J_2,m_2. We require that Ψ_{J_1,m_1,J_2,m_2} be a representation of $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$. In order for the representation to be finite-dimensional, the actions of the $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ generators on Ψ_{J_1,m_1,J_2,m_2} must have the following form:

$$
\begin{aligned}
&\Gamma(E_{12})\Psi_{J_1,m_1,J_2,m_2}=(J_1-m_1-z)\Psi_{J_1,m_1+1,J_2,m_2},\\
&\Gamma(E_{21})\Psi_{J_1,m_1,J_2,m_2}=(J_1+m_1+\bar{z})\Psi_{J_1,m_1-1,J_2,m_2},\\
&\Gamma(E_{34})\Psi_{J_1,m_1,J_2,m_2}=(J_2-m_2-u)\Psi_{J_1,m_1,J_2,m_2+1},\\
&\Gamma(E_{43})\Psi_{J_1,m_1,J_2,m_2}=(J_2+m_2+\bar{u})\Psi_{J_1,m_1,J_2,m_2-1},
\end{aligned}
\tag{3.2}
$$

where $z,\bar{z},u,\bar{u}$ are some integers or half-integers to be determined together with the combination coefficients. These requirements give rise to difference equations for the combination coefficients. Solving these difference equations simutaneously for each level x, we determine the combination coefficients and $z,\bar{z},u,\bar{u}$. The procedure of solving the difference equations for each level x is nontrivial and requires long algebraic manipulations. Here we omit the details and only list the results as follows.

The four level-1 states can be combined into four independent multiplets of $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ with highest weights $(J_1-\frac{1}{2},J_2-\frac{1}{2},q,p-1),(J_1+\frac{1}{2},J_2-\frac{1}{2},q,p-1),(J_1+\frac{1}{2},J_2+\frac{1}{2},q,p-1)$ and $(J_1-\frac{1}{2},J_2+\frac{1}{2},q,p-1)$, respectively:

$$|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle=(\alpha_{14}^\dagger+\tfrac{1}{2}a_{12}^\dagger\alpha_{24}^\dagger-\tfrac{1}{2}\alpha_{13}^\dagger a_{34}^\dagger-\tfrac{1}{3}a_{12}^\dagger\alpha_{23}^\dagger a_{34}^\dagger)\times(a_{12}^\dagger)^{J_1-m_1-3/2}(a_{34}^\dagger)^{J_2-m_2-3/2}|0\rangle,\quad J_1,J_2\geqslant\tfrac{1}{2},$$

$$m_1=J_1-\tfrac{3}{2},J_1-\tfrac{5}{2},\ldots,-(J_1+\tfrac{1}{2}),\quad m_2=J_2-\tfrac{3}{2},J_2-\tfrac{5}{2},\ldots,-(J_2+\tfrac{1}{2}),$$

$$|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle=[\tfrac{1}{2}(3J_1+m_1+\tfrac{5}{2})a_{12}^\dagger\alpha_{24}^\dagger-\tfrac{1}{3}(2J_1+m_1+2)a_{12}^\dagger\alpha_{23}^\dagger a_{34}^\dagger-(J_1-m_1-\tfrac{1}{2})\times(\alpha_{14}^\dagger-\tfrac{1}{2}\alpha_{13}^\dagger a_{34}^\dagger)](a_{12}^\dagger)^{J_1-m_1-3/2}(a_{34}^\dagger)^{J_2-m_2-3/2}|0\rangle,\quad J_2\geqslant\tfrac{1}{2},$$

$$m_1=J_1-\tfrac{1}{2},J_1-\tfrac{3}{2},\ldots,-(J_1+\tfrac{3}{2}),\quad m_2=J_2-\tfrac{3}{2},J_2-\tfrac{5}{2},\ldots,-(J_2+\tfrac{1}{2}),$$

$$\begin{aligned}|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle=[&-\tfrac{1}{4}((3J_1+m_1+\tfrac{5}{2})(3J_2+m_2+\tfrac{5}{2})+\tfrac{1}{3}(J_1-m_1-\tfrac{1}{2})(J_2-m_2-\tfrac{1}{2}))\\&\times a_{12}^\dagger\alpha_{23}^\dagger a_{34}^\dagger+\tfrac{1}{2}(J_1-m_1-\tfrac{1}{2})(3J_2+m_2+\tfrac{5}{2})\alpha_{13}^\dagger a_{34}^\dagger\\&-\tfrac{1}{2}(3J_1+m_1+\tfrac{5}{2})\\&\times(J_2-m_2-\tfrac{1}{2})a_{12}^\dagger\alpha_{24}^\dagger+(J_1-m_1-\tfrac{1}{2})(J_2-m_2-\tfrac{1}{2})\alpha_{14}^\dagger]\\&\times(a_{12}^\dagger)^{J_1-m_1-3/2}(a_{34}^\dagger)^{J_2-m_2-3/2}|0\rangle,\end{aligned}\tag{3.3}$$

$$m_1=J_1-\tfrac{1}{2},J_1-\tfrac{3}{2},\ldots,-(J_1+\tfrac{3}{2}),\quad m_2=J_2-\tfrac{1}{2},J_2-\tfrac{3}{2},\ldots,-(J_2+\tfrac{3}{2}),$$

$$|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle=[\tfrac{1}{2}(3J_2+m_2+\tfrac{5}{2})\alpha_{13}^\dagger a_{34}^\dagger+\tfrac{1}{3}(2J_2+m_2+2)a_{12}^\dagger\alpha_{23}^\dagger a_{34}^\dagger+(J_2-m_2-\tfrac{1}{2})\times(\alpha_{14}^\dagger-\tfrac{1}{2}a_{12}^\dagger\alpha_{24}^\dagger)](a_{12}^\dagger)^{J_1-m_1-3/2}(a_{34}^\dagger)^{J_2-m_2-3/2}|0\rangle,\quad J_1\geqslant\tfrac{1}{2},$$

$$m_1=J_1-\tfrac{3}{2},J_1-\tfrac{5}{2},\ldots,-(J_1+\tfrac{1}{2}),\quad m_2=J_2-\tfrac{1}{2},J_2-\tfrac{3}{2},\ldots,-(J_2+\tfrac{3}{2}).$$

The dimensions for these multiplets are $(2J_1)(2J_2),(2J_1+2)(2J_2),(2J_1+2)(2J_2+2)$ and $(2J_1)(2J_2+2)$, respectively.

The six level-2 states can be combined into six independent multiplets of $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ with highest weights $(J_1,J_2-1,q,p-2),(J_1-1,J_2,q,p-2),(J_1+1,J_2,q,p-2),(J_1,J_2+1,q,p-2),(J_1,J_2,q,p-2)$ and $(J_1,J_2,q,p-2)$, respectively:

$$|J_1,m_1,J_2-1,m_2,q;p-2\rangle=\alpha_{24}^\dagger\alpha_{14}^\dagger(a_{12}^\dagger)^{J_1-m_1-2}(a_{34}^\dagger)^{J_2-m_2-3}|0\rangle+\tfrac{1}{2}[-\alpha_{23}^\dagger\alpha_{14}^\dagger+\tfrac{1}{6}\alpha_{23}^\dagger\alpha_{24}^\dagger a_{12}^\dagger+\alpha_{13}^\dagger\alpha_{24}^\dagger+\tfrac{1}{2}\alpha_{23}^\dagger\alpha_{13}^\dagger a_{34}^\dagger](a_{12}^\dagger)^{J_1-m_1-2}(a_{34}^\dagger)^{J_2-m_2-2}|0\rangle,$$

$$J_2\geqslant1,\quad m_1=J_1-2,J_1-3,\ldots,-(J_1+2),\quad m_2=J_2-3,J_2-4,\ldots,-(J_2+1),$$

$$|J_1-1,m_1,J_2,m_2,q;p-2\rangle=\alpha_{13}^\dagger\alpha_{14}^\dagger(a_{12}^\dagger)^{J_1-m_1-3}(a_{34}^\dagger)^{J_2-m_2-2}|0\rangle+\tfrac{1}{2}[\alpha_{23}^\dagger\alpha_{14}^\dagger+\tfrac{1}{6}\alpha_{23}^\dagger\alpha_{13}^\dagger a_{34}^\dagger+\alpha_{13}^\dagger\alpha_{24}^\dagger+\tfrac{1}{2}\alpha_{23}^\dagger\alpha_{24}^\dagger a_{12}^\dagger](a_{12}^\dagger)^{J_1-m_1-2}(a_{34}^\dagger)^{J_2-m_2-2}|0\rangle,$$

$$J_1\geqslant1,\quad m_1=J_1-3,J_1-4,\ldots,-(J_1+1),\quad m_2=J_2-2,J_2-3,\ldots,-(J_2+2),$$

$$
\begin{aligned}
|J_1+1,m_1,J_2,m_2,q;p-2\rangle = &[\tfrac{1}{2}[J_1-m_1-1+(3J_1+m_1+3)(3J_1+m_1+5)]\alpha_{23}^\dagger\alpha_{24}^\dagger(a_{12}^\dagger)^2\\
&+(J_1-m_1-1)(J_1-m_1-2)(\alpha_{13}^\dagger\alpha_{14}^\dagger+\tfrac{1}{12}a_{12}^\dagger\alpha_{23}^\dagger\alpha_{13}^\dagger a_{34}^\dagger)-\tfrac{1}{2}(J_1-m_1-1)\\
&\times(3J_1+m_1+4)a_{12}^\dagger(\alpha_{13}^\dagger\alpha_{24}^\dagger+\alpha_{23}^\dagger\alpha_{14}^\dagger)](a_{12}^\dagger)^{J_1-m_1-3}(a_{34}^\dagger)^{J_2-m_2-2}|0\rangle,
\end{aligned}
$$

$$
m_1=J_1-1,J_1-2,\ldots,-(J_1+3),\quad m_2=J_2-2,J_2-3,\ldots,-(J_2+2),
\tag{3.4}
$$

$$
\begin{aligned}
|J_1,m_1,J_2+1,m_2,q;p-2\rangle = &[\tfrac{1}{4}[J_2-m_2-1+(3J_2+m_2+3)(3J_2+m_2+5)]\alpha_{23}^\dagger\alpha_{13}^\dagger(a_{34}^\dagger)^2\\
&+\tfrac{1}{2}(J_2-m_2-1)(3J_2+m_2+4)(\alpha_{23}^\dagger\alpha_{14}^\dagger-\alpha_{13}^\dagger\alpha_{24}^\dagger)a_{34}^\dagger+(J_2-m_2-1)\\
&\times(J_2-m_2-2)(\alpha_{24}^\dagger\alpha_{14}^\dagger+\tfrac{1}{12}\alpha_{23}^\dagger\alpha_{24}^\dagger a_{12}^\dagger a_{34}^\dagger)](a_{12}^\dagger)^{J_1-m_1-2}(a_{34}^\dagger)^{J_2-m_2-3}|0\rangle,
\end{aligned}
$$

$$
m_1=J_1-2,J_1-3,\ldots,-(J_1+2),\quad m_2=J_2-1,J_2-2,\ldots,-(J_2+3),
$$

$$
\begin{aligned}
[J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{I}} = &(J_2-m_2-2)\alpha_{24}^\dagger\alpha_{14}^\dagger(a_{12}^\dagger)^{J_1-m_1-2}(a_{34}^\dagger)^{J_2-m_2-3}|0\rangle\\
&+[\tfrac{1}{2}(J_2+m_2+2)(\alpha_{23}^\dagger\alpha_{14}^\dagger-\alpha_{13}^\dagger\alpha_{24}^\dagger)+\tfrac{1}{12}(J_2-m_2-2)\alpha_{23}^\dagger\alpha_{24}^\dagger a_{12}^\dagger\\
&-\tfrac{1}{4}(3J_2+m_2+2)\alpha_{23}^\dagger\alpha_{13}^\dagger a_{34}^\dagger](a_{\mathbf{34}}^\dagger)^{J_1-m_1-2}(a_{34}^\dagger)^{J_2-m_2-2}|0\rangle,
\end{aligned}
$$

$$
m_1=J_1-2,J_1-3,\ldots,-(J_1+2),\quad m_2=J_2-1,J_2-2,\ldots,-(J_2+2),
$$

$$
\begin{aligned}
[J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{II}} = &(J_1-m_1-2)\alpha_{13}^\dagger\alpha_{14}^\dagger(a_{12}^\dagger)^{J_1-m_1-3}(a_{34}^\dagger)^{J_2-m_2-2}|0\rangle\\
&+[-\tfrac{1}{2}(J_1+m_1+2)(\alpha_{13}^\dagger\alpha_{24}^\dagger+\alpha_{23}^\dagger\alpha_{14}^\dagger)+\tfrac{1}{12}(J_1-m_1-2)\alpha_{23}^\dagger\alpha_{13}^\dagger a_{34}^\dagger\\
&-\tfrac{1}{4}(3J_1+m_1+2)\alpha_{23}^\dagger\alpha_{24}^\dagger a_{12}^\dagger](a_{12}^\dagger)^{J_1-m_1-2}(a_{34}^\dagger)^{J_2-m_2-2}|0\rangle,
\end{aligned}
$$

$$
m_1=J_1-2,J_1-3,\ldots,-(J_1+2),\quad m_2=J_2-1,J_2-2,\ldots,-(J_2+2).
$$

Notice that the last two multiplets, which have been denoted above by $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{I}}$ and $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{II}}$, respectively, have the same highest weight $(J_1,J_2,q,p-2)$. This means that multiplicity will in general appear in the $\mathrm{gl}(2|2)\downarrow\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ branching rule. It is easy to see from the above expressions that $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{I}}\equiv 0$ when $J_2=0$ and $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{II}}\equiv 0$ when $J_1=0$.

The dimensions for the first four multiplets are $(2J_1+1)(2J_2-1),(2J_1-1)(2J_2+1),(2J_1+3)\times(2J_2+1)$ and $(2J_1+1)(2J_2+3)$, respectively. The dimension for $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{I}}$ is $(2J_1+1)(2J_2+1)$ if $J_2\neq 0$ and zero if $J_2=0$. Similarly, the dimension for $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{II}}$ is $(2J_1+1)(2J_2+1)$ if $J_1\neq 0$ and zero if $J_1=0$.

Finally, the four level-3 states are combined into four independent multiplets of $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ with highest weights $\left(J_1-\frac{1}{2},J_2-\frac{1}{2},q,p-3\right),\left(J_1+\frac{1}{2},J_2-\frac{1}{2},q,p-3\right),\left(J_1-\frac{1}{2},J_2+\frac{1}{2},q,p-3\right)$ and $\left(J_1+\frac{1}{2},J_2+\frac{1}{2},q,p-3\right)$, respectively:

$$
\begin{aligned}
|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle = &[(\alpha_{13}^\dagger+\tfrac{1}{2}a_{12}^\dagger\alpha_{23}^\dagger)\alpha_{24}^\dagger\alpha_{14}^\dagger+\tfrac{1}{2}\alpha_{23}^\dagger\alpha_{13}^\dagger(\alpha_{14}^\dagger a_{34}^\dagger+\tfrac{1}{3}a_{12}^\dagger\alpha_{24}^\dagger a_{34}^\dagger)]\\
&\times(a_{12}^\dagger)^{J_1-m_1-7/2}(a_{34}^\dagger)^{J_2-m_2-7/2}|0\rangle,
\end{aligned}
$$

$$
J_1,J_2\geqslant\tfrac{1}{2},\quad m_1=J_1-\tfrac{7}{2},\ldots,-(J_1+\tfrac{5}{2}),\quad m_2=J_2-\tfrac{7}{2},\ldots,-(J_2+\tfrac{5}{2}),
$$

$$|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle=[-\tfrac{1}{2}(3J_1+m_1+\tfrac{9}{2})\alpha_{23}^{\dagger}\alpha_{24}^{\dagger}\alpha_{14}^{\dagger}a_{12}^{\dagger}+(J_1-m_1-\tfrac{5}{2})(-\alpha_{24}^{\dagger}+\tfrac{1}{2}\alpha_{23}^{\dagger}a_{34}^{\dagger})$$
$$\times\alpha_{13}^{\dagger}\alpha_{14}^{\dagger}-\tfrac{1}{6}(5J_1+m_1+\tfrac{11}{2})\alpha_{23}^{\dagger}\alpha_{13}^{\dagger}\alpha_{24}^{\dagger}a_{12}^{\dagger}a_{34}^{\dagger}]$$
$$\times(a_{12}^{\dagger})^{J_1-m_1-7/2}(a_{34}^{\dagger})^{J_2-m_2-7/2}|0\rangle,$$

$$J_2\geqslant\tfrac{1}{2},\quad m_1=J_1-\tfrac{5}{2},\ldots,-(J_1+\tfrac{7}{2}),\quad m_2=J_2-\tfrac{7}{2},\ldots,-(J_2+\tfrac{5}{2}),$$

$$|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle=[-\tfrac{1}{2}(3J_2+m_2+\tfrac{9}{2})\alpha_{23}^{\dagger}\alpha_{13}^{\dagger}\alpha_{14}^{\dagger}a_{34}^{\dagger}+(J_2-m_2-\tfrac{5}{2})(\alpha_{13}^{\dagger}+\tfrac{1}{2}\alpha_{23}^{\dagger}a_{12}^{\dagger})$$
$$\times\alpha_{24}^{\dagger}\alpha_{14}^{\dagger}-\tfrac{1}{6}(5J_2+m_2+\tfrac{11}{2})\alpha_{23}^{\dagger}\alpha_{13}^{\dagger}\alpha_{24}^{\dagger}a_{12}^{\dagger}a_{34}^{\dagger}]$$
$$\times(a_{12}^{\dagger})^{J_1-m_1-7/2}(a_{34}^{\dagger})^{J_2-m_2-7/2}|0\rangle, \tag{3.5}$$

$$J_1\geqslant\tfrac{1}{2},\quad m_1=J_1-\tfrac{7}{2},\ldots,-(J_1+\tfrac{5}{2}),\quad m_2=J_2-\tfrac{5}{2},\ldots,-(J_2+\tfrac{7}{2}),$$

$$|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle=[\tfrac{1}{4}((3J_1+m_1+\tfrac{9}{2})(3J_2+m_2+\tfrac{9}{2})-\tfrac{1}{3}(J_1-m_1-\tfrac{5}{2})(J_2-m_2-\tfrac{5}{2}))$$
$$\times a_{12}^{\dagger}\alpha_{23}^{\dagger}\alpha_{13}^{\dagger}\alpha_{24}^{\dagger}a_{34}^{\dagger}-\tfrac{1}{2}(J_1-m_1-\tfrac{5}{2})(3J_2+m_2+\tfrac{9}{2})\alpha_{23}^{\dagger}\alpha_{13}^{\dagger}\alpha_{14}^{\dagger}a_{34}^{\dagger}$$
$$-\tfrac{1}{2}(3J_1+m_1+\tfrac{9}{2})(J_2-m_2-\tfrac{5}{2})a_{12}^{\dagger}\alpha_{23}^{\dagger}\alpha_{24}^{\dagger}\alpha_{14}^{\dagger}+(J_1-m_1-\tfrac{5}{2})$$
$$\times(J_2-m_2-\tfrac{5}{2})\alpha_{13}^{\dagger}\alpha_{24}^{\dagger}\alpha_{14}^{\dagger}](a_{12}^{\dagger})^{J_1-m_1-7/2}(a_{34}^{\dagger})^{J_2-m_2-7/2}|0\rangle,$$

$$m_1=J_1-\tfrac{5}{2},\ldots,-(J_1+\tfrac{7}{2}),\quad m_2=J_2-\tfrac{5}{2},\ldots,-(J_2+\tfrac{7}{2}).$$

The dimensions for these multiplets are $(2J_1)(2J_2)$, $(2J_1+2)(2J_2)$, $(2J_1)(2J_2+2)$ and $(2J_1+2)(2J_2+2)$, respectively.

The actions of the odd generators of $\mathrm{gl}(2|2)$ on the $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ multiplets (3.1) and (3.3)–(3.5) can be computed by means of the free boson-fermion realization of the generators. In the following we list the actions of the odd simple generators. The actions of odd non-simple generators can be easily obtained using the commutation relations.

First for the level-0 multiplet, we have the actions of the odd simple generators

$$\Gamma(E_{23})|J_1,m_1,J_2,m_2,q;p\rangle=0,$$

$$\Gamma(E_{32})|J_1,m_1,J_2,m_2,q;p\rangle=\frac{1}{(2J_1+1)(2J_2+1)}$$
$$\times[-(q+J_1-J_2)(J_1-m_1)(J_2-m_2)|J_1-\tfrac{1}{2},m_1-\tfrac{1}{2},J_2-\tfrac{1}{2},$$
$$m_2-\tfrac{1}{2},q;p-1\rangle$$
$$-(q-J_1-J_2-1)(J_2-m_2)|J_1+\tfrac{1}{2},m_1-\tfrac{1}{2},J_2-\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-1\rangle$$
$$-(q-J_1+J_2)|J_1+\tfrac{1}{2},m_1-\tfrac{1}{2},J_2+\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-1\rangle$$
$$+(q+J_1+J_2+1)(J_1-m_1)|J_1-\tfrac{1}{2},m_1-\tfrac{1}{2},J_2+\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-1\rangle]. \tag{3.6}$$

From (3.6) we see that when $q=J_1-J_2$ (resp., $-J_1+J_2$) the third (resp., first) term vanishes and, if $q=J_1+J_2+1$ (resp., $-J_1-J_2-1$), then the second (resp., fourth) term disappears. This indicates that when $q=\pm(J_1-J_2),\pm(J_1+J_2+1)$ atypical representations arise (see the next section for details).

For the four level-1 multiplets, we obtain the following actions of the odd simple generators, after long algebraic manipulations,

$$\Gamma(E_{23})|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-1\rangle=-|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p\rangle,$$

$$\Gamma(E_{23})|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-1\rangle=-(J_1+m_1+\tfrac{3}{2})|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p\rangle,$$

$$\Gamma(E_{23})|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-1\rangle=-(J_1+m_1+\tfrac{3}{2})(J_2+m_2+\tfrac{3}{2})|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p\rangle,$$

$$\Gamma(E_{23})|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-1\rangle=-(J_2+m_2+\tfrac{3}{2})|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p\rangle,$$

$$\begin{aligned}
&\Gamma(E_{32})|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-1\rangle\\
&\quad=-\frac{J_2-m_2-3/2}{2J_2}(q-J_1-J_2-1)|J_1,m_1-\tfrac{1}{2},J_2-1,m_2-\tfrac{1}{2},q;p-2\rangle\\
&\qquad+\frac{q-J_1+J_2-1}{2J_2}|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}\\
&\qquad-\frac{q-J_1+J_2+1}{2J_2}|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}\\
&\qquad+\frac{J_1-m_1-3/2}{2J_1}(q+J_1+J_2+1)|J_1-1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle,
\end{aligned}\tag{3.7}$$

$$\begin{aligned}
&\Gamma(E_{32})|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-1\rangle\\
&\quad=\frac{(J_1-m_1-1/2)(J_2-m_2-3/2)}{2J_2}(q+J_1-J_2)|J_1,m_1-\tfrac{1}{2},J_2-1,m_2-\tfrac{1}{2},q;p-2\rangle\\
&\qquad-\frac{J_1-m_1-1/2}{2J_2}(q+J_1+J_2)|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}\\
&\qquad-\frac{(J_1-m_1-1/2}{2(J_1+1)}(q+J_1+J_2+2)|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}\\
&\qquad+\frac{q-J_1+J_2}{2(J_1+1)}|J_1+1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle,
\end{aligned}$$

$$\begin{aligned}
&\Gamma(E_{32})|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-1\rangle\\
&\quad=-\frac{(J_1-m_1-1/2)(J_2-m_2-1/2)}{2(J_2+1)}(q+J_1-J_2-1)|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}\\
&\qquad+\frac{(J_1-m_1-1/2)(J_2-m_2-1/2)}{2(J_1+1)}(q+J_1-J_2+1)|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}\\
&\qquad-\frac{(J_2-m_2-1/2}{2(J_1+1)}(q-J_1-J_2-1)|J_1+1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle\\
&\qquad+\frac{J_1-m_1-1/2}{2(J_2+1)}(q+J_1+J_2+1)|J_1,m_1-\tfrac{1}{2},J_2+1,m_2-\tfrac{1}{2},q;p-2\rangle,
\end{aligned}$$

$$\Gamma(E_{32})|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-1\rangle$$
$$=-\frac{J_2-m_2-1/2}{2(J_2+1)}(q-J_1-J_2-2)|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}$$
$$-\frac{J_2-m_2-1/2}{2J_1}(q-J_1-J_2)|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}$$
$$+\frac{(J_1-m_1-3/2)(J_2-m_2-1/2)}{2J_1}(q+J_1-J_2)|J_1-1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-2\rangle$$
$$+\frac{q-J_1+J_2}{2(J_2+1)}|J_1,m_1-\tfrac{1}{2},J_2+1,m_2-\tfrac{1}{2},q;p-2\rangle.$$

Similar to the level-1 case, we find after long algebraic computations that the actions of the odd simple generators on the six level-2 multiplets are given by

$$\Gamma(E_{23})|J_1,m_1,J_2-1,m_2,q;p-2\rangle=-\frac{J_1+m_1+2}{2J_1+1}|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-1\rangle$$
$$+\frac{1}{2J_1+1}|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-1\rangle,$$

$$\Gamma(E_{23})|J_1-1,m_1,J_2,m_2,q;p-2\rangle=\frac{J_2+m_2+2}{2J_2+1}|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-1\rangle$$
$$+\frac{1}{2J_1+1}|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-1\rangle,$$

$$\Gamma(E_{23})|J_1+1,m_1,J_2,m_2,q;p-2\rangle=\frac{(J_1+m_1+3)(J_2+m_2+2)}{2J_2+1}|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-1\rangle$$
$$-\frac{J_1+m_1+3}{2J_2+1}|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-1\rangle,$$

$$\Gamma(E_{23})|J_1,m_1,J_2+1,m_2,q;p-2\rangle=\frac{J_2+m_2+3}{2J_1+1}|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-1\rangle$$

$$\Gamma(E_{32})|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathrm{II}} = \frac{1}{(2J_1+1)(2J_2+1)}[(J_1+1)(J_1-m_1-2)(J_2-m_2-2)$$
$$\times(q+J_1-J_2-1)|J_1-\tfrac{1}{2},m_1-\tfrac{1}{2},J_2-\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-3\rangle$$
$$+J_1(J_2-m_2-2)$$
$$\times(q-J_1-J_2-2)|J_1+\tfrac{1}{2},m_1-\tfrac{1}{2},J_2-\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-3\rangle-(J_1+1)$$
$$\times(J_1-m_1-2)(q+J_1+J_2)|J_1-\tfrac{1}{2},m_1-\tfrac{1}{2},J_2+\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-3\rangle$$
$$-J_1(q-J_1+J_2-1)|J_1+\tfrac{1}{2},m_1-\tfrac{1}{2},J_2+\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-3\rangle].$$

The actions of the odd simple generators on the four level-3 multiplets can be obtained in a similar way. We list the results as follows:

$$\Gamma(E_{23})|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-3\rangle = \frac{J_2+m_2+5/2}{2J_2}|J_1,m_1+\tfrac{1}{2},J_2-1,m_2+\tfrac{1}{2},q;p-2\rangle$$
$$+\frac{1}{2J_2}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}$$
$$+\frac{1}{2J_1}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}$$
$$+\frac{J_1+m_1+5/2}{2J_1}|J_1-1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle,$$

$$\Gamma(E_{23})|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-3\rangle = -\frac{(J_1+m_1+7/2)(J_2+m_2+5/2)}{2J_2}$$
$$\times|J_1,m_1+\tfrac{1}{2},J_2-1,m_2+\tfrac{1}{2},q;p-2\rangle$$
$$+(J_1+m_1+\tfrac{7}{2})\left[-\frac{1}{2J_2}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}\right.$$
$$\left.+\frac{1}{2(J_1+1)}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}\right]$$
$$+\frac{1}{2(J_1+1)}|J_1+1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle,$$

$$\Gamma(E_{23})|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-3\rangle = (J_2+m_2+\tfrac{7}{2})\left[\frac{1}{2(J_2+1)}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}\right.$$
$$\left.-\frac{1}{2J_1}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}\right]$$
$$-\frac{(J_1+m_1+5/2)(J_2+m_2+7/2)}{2J_1}$$
$$\times|J_1-1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle$$
$$+\frac{1}{2(J_2+1)}|J_1,m_1+\tfrac{1}{2},J_2+1,m_2+\tfrac{1}{2},q;p-2\rangle,$$

$$\begin{aligned}\Gamma(E_{23})|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-3\rangle = &-(J_1+m_1+\tfrac{7}{2})(J_2+m_2+\tfrac{7}{2})\\ &\times\Bigg[\frac{1}{2(J_2+1)}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{I}}\\ &+\frac{1}{2(J_1+1)}|J_1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle_{\mathbf{II}}\Bigg]\\ &-\frac{J_2+m_2+7/2}{2(J_1+1)}|J_1+1,m_1+\tfrac{1}{2},J_2,m_2+\tfrac{1}{2},q;p-2\rangle\\ &-\frac{J_1+m_1+7/2}{2(J_2+1)}|J_1,m_1+\tfrac{1}{2},J_2+1,m_2+\tfrac{1}{2},q;p-2\rangle,\end{aligned} \tag{3.9}$$

$$\Gamma(E_{32})|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-3\rangle=(q-J_1+J_2)|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-4\rangle,$$

$$\Gamma(E_{32})|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q,p-3\rangle=(q+J_1+J_2+1)(J_1-m_1-\tfrac{5}{2})|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-4\rangle,$$

$$\Gamma(E_{32})|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-3\rangle=(q-J_1-J_2-1)(J_2-m_2-\tfrac{5}{2})|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-4\rangle,$$

$$\begin{aligned}\Gamma(E_{32})|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q,p-3\rangle=&(q+J_1-J_2)(J_1-m_1-\tfrac{5}{2})(J_2-m_2-\tfrac{5}{2})\\ &\times|J_1,m_1-\tfrac{1}{2},J_2,m_2-\tfrac{1}{2},q;p-4\rangle.\end{aligned}$$

Finally, the actions of the odd simple generators on the level-4 multiplet are

$$\begin{aligned}\Gamma(E_{23})|J_1,m_1,J_2,m_2,q;p-4\rangle=&\frac{1}{(2J_1+1)(2J_2+1)}[(J_1+m_1+4)(J_2+m_2+4)\\ &\times|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-3\rangle\\ &+(J_2+m_2+4)|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-3\rangle\\ &+(J_1+m_1+4)|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-3\rangle\\ &+|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q,p-3\rangle],\end{aligned}$$

$$\Gamma(E_{32})|J_1,m_1,J_2,m_2,q;p-4\rangle=0. \tag{3.10}$$

Summarizing, we have obtained 16 independent multiplets, (3.1), (3.3), and (3.4), of gl(2) $\oplus$ gl(2) which span finite-dimensional representations of gl(2|2). For generic q, these multiplets span irreducible typical representations of gl(2|2) of dimension $16(2J_1+1)(2J_2+1)$. Denote by $\pi_{(J_1,J_2,q,p)}$ and $\sigma_{(J_1,J_2,q,p)}$ the gl(2|2) and gl(2) $\oplus$ gl(2) representations with highest weight (J_1,J_2,q,p), respectively. Then the gl(2|2) $\downarrow$ gl(2) $\oplus$ gl(2) branching rule for generic q is given by

$$\begin{aligned}\pi_{(J_1,J_2,q,p)}=&\sigma_{(J_1,J_2,q,p)}\oplus\sigma_{(J_1-1/2,J_2-1/2,q,p-1)}\oplus\sigma_{(J_1+1/2,J_2-1/2,q,p-1)}\oplus\sigma_{(J_1+1/2,J_2+1/2,q,p-1)}\\ &\oplus\sigma_{(J_1-1/2,J_2+1/2,q,p-1)}\oplus\sigma_{(J_1,J_2-1,q,p-2)}\oplus\sigma_{(J_1-1,J_2,q,p-2)}\oplus\sigma_{(J_1+1,J_2,q,p-2)}\oplus\sigma_{(J_1,J_2+1,q,p-2)}\\ &\oplus 2\times\sigma_{(J_1,J_2,q,p-2)}\oplus\sigma_{(J_1-1/2,J_2-1/2,q,p-3)}\oplus\sigma_{(J_1+1/2,J_2-1/2,q,p-3)}\oplus\sigma_{(J_1-1/2,J_2+1/2,q,p-3)}\\ &\oplus\sigma_{(J_1+1/2,J_2+1/2,q,p-3)}\oplus\sigma_{(J_1,J_2,q,p-4)}.\end{aligned} \tag{3.11}$$

Some remarks are in order. First, irreducible representations are obtained as submodules (not subquotients) of the super-Fock space generated by $\{a_{ij},a_{ij}^\dagger,\alpha_{ij},\alpha_{ij}^\dagger\}$. This is because the gl(2|2)-module structure of the super-Fock space is the contragredient dual of the Verma model over gl(2|2). Second, as $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{I}}\equiv 0$ when $J_2=0$ and $|J_1,m_1,J_2,m_2,q;p-2\rangle_{\mathbf{II}}\equiv 0$

when $J_1=0$, thus if $J_1=0$ or $J_2=0$ only one copy of $\sigma_{(J_1,J_2,q,p-2)}$ remains in the above branching rule. In particular, when $J_1=0=J_2$ which corresponds to the 16-dimensional typical representation of gl$(2|2)$, $\sigma_{(J_1,J_2,q,p-2)}$ disappears and the branching rule becomes

$$\pi_{(0,0,q,p)} = \sigma_{(0,0,q,p)} \oplus \sigma_{(1/2,1/2,q,p-1)} \oplus \sigma_{(1,0,q,p-2)} \oplus \sigma_{(0,1,q,p-2)} \oplus \sigma_{(1/2,1/2,q,p-3)} \oplus \sigma_{(0,0,q,p-4)} \tag{3.12}$$

or $\underline{16}=\underline{1}\oplus\underline{4}\oplus\underline{3}\oplus\underline{3}\oplus\underline{4}\oplus\underline{1}$.

IV. ATYPICAL REPRESENTATIONS OF gl(2|2)

We have different types of atypical representations of gl$(2|2)$. From the actions of the odd generators on the gl$(2)\oplus$gl(2) multiplets, we see that when $q=\pm(J_1-J_2),\pm(J_1+J_2+1)$, the representations become atypical. The Casimir for such representations vanishes, and yet they are not the trivial one-dimensional representation.

A. Atypical representation corresponding to $q=J_1-J_2$

Case 1. $q=J_1-J_2$, $J_1\neq J_2$: Let us introduce the following independent combinations:

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}} = J_1|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} + J_2|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}},$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym1}} = J_1|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} - J_2|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}} \tag{4.1}$$

for $J_1\neq 0, J_2\neq 0$. When $J_1=0$ or $J_2=0$, we let $|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}}\equiv 0$ and

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym1}} = \begin{cases} |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} & \text{if } J_1=0, \\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}} & \text{if } J_2=0. \end{cases} \tag{4.2}$$

It can be shown from the actions of odd generators that when $q=J_1-J_2$,

$$\begin{aligned}\Gamma(E_{23})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}} = {} & \frac{1}{(2J_1+1)(2J_2+1)} \\ & \times[(J_1-J_2)(J_1+m_1+2)(J_2+m_2+2) \\ & \times|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle \\ & -J_1(2J_2+1)(J_2+m_2+2)|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle \\ & -(2J_1+1)J_2(J_1+m_1+2)|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2}, \\ & J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle],\end{aligned} \tag{4.3}$$

which does not contain the multiplet $|J_1+\frac{1}{2},m_1,J_2+\frac{1}{2},m_2,q;p-1\rangle$, and

$$\begin{aligned}\Gamma(E_{32})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}} = {} & \frac{(J_1-J_2)(4J_1J_2+2J_1+2J_2+1)}{(2J_1+1)(2J_2+1)}(J_1-m_1-2)(J_2-m_2-2) \\ & \times|J_1-\tfrac{1}{2},m_1-\tfrac{1}{2},J_2-\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-3\rangle.\end{aligned} \tag{4.4}$$

Thus when $q=J_1-J_2$, if one starts with the level-0 state $|J_1,m_1,J_2,m_2,q;p\rangle$ then we find using the actions (3.6)–(3.10) that the following gl$(2)\oplus$gl(2) multiplets,

$$|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle,$$

$$|J_1+1,m_1,J_2,m_2,q,p-2\rangle, \quad |J_1,m_1,J_2+1,m_2,q,p-2\rangle,$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym1}},\quad |J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle, \tag{4.5}$$

$$|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle,\quad |J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle,$$

$$|J_1,m_1,J_2,m_2,q,p-4\rangle$$

disappear, and only the following multiplets

$$|J_1,m_1,J_2,m_2,q,p\rangle,$$

$$|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle,\quad |J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle,$$

$$|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle,$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}},\quad |J_1-1,m_1,J_2,m_2,q,p-2\rangle,$$

$$|J_1,m_1,J_2-1,m_2,q,p-2\rangle,\quad |J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle \tag{4.6}$$

remain. They form irreducible atypical representations of $\mathrm{gl}(2|2)$ of dimension $8[(2J_1+1)J_2+J_1(2J_2+1)]$. So the $\mathrm{gl}(2|2)\downarrow \mathrm{gl}(2)\oplus\mathrm{gl}(2)$ branching rule for $q=J_1-J_2$ is given by

$$\pi_{(J_1,J_2,q,p)} = \sigma_{(J_1,J_2,q,p)} \oplus \sigma_{(J_1-1/2,J_2-1/2,q,p-1)} \oplus \sigma_{(J_1+1/2,J_2+1/2,q,p-1)} \oplus \sigma_{(J_1-1/2,J_2+1/2,q,p-1)} \oplus \sigma_{(J_1,J_2,q,p-2)}$$
$$\oplus \sigma_{(J_1-1,J_2,q,p-2)} \oplus \sigma_{(J_1,J_2-1,q,p-2)} \oplus \sigma_{(J_1-1/2,J_2-1/2,q,p-3)}. \tag{4.7}$$

It should be understood here that $\sigma_{(J_1,J_2,q,p-2)}$ disappears when $J_1=0$ or $J_2=0$.

Case 2. $q=J_1-J_2, J_1=J_2$ so that $q=0$: In this case, we define the independent combinations:

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}'} = |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} + |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}},$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym1}'} = |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} - |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}}. \tag{4.8}$$

Both $|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}'}$ and $|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym1}'}$ vanish if $J_1=0=J_2$. Then it is easily shown that $\Gamma(E_{23})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}'}$ does not contain $|J_1-\frac{1}{2},m_1,J_2-\frac{1}{2},m_2,q;p-1\rangle$ and $|J_1+\frac{1}{2},m_1,J_2+\frac{1}{2},m_2,q;p-1\rangle$, and $\Gamma(E_{32})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}'}=0$. Thus only the following multiplets

$$|J_1,m_1,J_2,m_2,q,p\rangle,$$

$$|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle,\quad |J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle, \tag{4.9}$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym1}'},$$

survive, and they give irreducible atypical representations of dimension $4\left[(2J_1+1)(2J_2+1)-\frac{1}{2}\right]$ if $J_1=J_2\neq 0$ and the trivial one-dimensional representation if $J_1=0=J_2$ [for which the last three multiplets in (4.9) disappear].

Case 3. Lowest weight (indecomposable) Kac modules: Other types of atypical representations when $q=J_1-J_2$ are not irreducible. One such type of representation is obtained by starting with the level-4 state $|J_1,m_1,J_2,m_2,q;p-4\rangle$. These representations contain all 16 multiplets and a nonseparable invariant subspace provided by the multiplets (4.6) [or (4.9) when $J_1=J_2$]. These representations are not fully reducible (i.e., indecomposable) and have dimension $16(2J_1+1)(2J_2+1)$.

B. Atypical representations corresponding to $q=-J_1+J_2$

The case where $J_1=J_2$ so that $q=0$ is the same as case 2 of the last subsection. So in this subsection we only consider the $J_1\neq J_2$ case.

1. Irreducible representations

Let us introduce the following independent combinations:

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym2}}=(J_1+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}}+(J_2+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}},$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym2}}=(J_1+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}}-(J_2+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}} \tag{4.10}$$

for $J_1\neq 0, J_2\neq 0$, and let

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym2}}=\begin{cases}|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} & \text{if } J_1=0,\\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}} & \text{if } J_2=0,\end{cases} \tag{4.11}$$

and $|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym2}}=0$ if $J_1=0$ or $J_2=0$.

Similar to the $q=J_1-J_2$ case, we may show that when $q=-J_1+J_2$,

$$\begin{aligned}\Gamma(E_{23})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym2}}=\frac{1}{(2J_1+1)(2J_2+1)}[&-(2J_1+1)(J_2+1)(J_2+m_2+2)\\ &\times|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle+(J_1-J_2)\\ &\times|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle-(J_1+1)(2J_2+1)\\ &\times(J_1+m_1+2)|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle],\end{aligned} \tag{4.12}$$

which is independent of $|J_1-\frac{1}{2},m_1,J_2-\frac{1}{2},m_2,q;p-1\rangle$ and

$$\begin{aligned}\Gamma(E_{32})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym2}}=&\frac{(J_1-J_2)(4J_1J_2+2J_1+2J_2+1)}{(2J_1+1)(2J_2+1)}(J_1-m_1-2)(J_2-m_2-2)\\ &\times|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-3\rangle.\end{aligned} \tag{4.13}$$

Thus when $q=-J_1+J_2$, if one starts with the level-0 state, then by the actions (3.6)–(3.10) one finds that the following $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ multiplets,

$$\begin{gathered}|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle,\\ |J_1,m_1,J_2-1,m_2,q,p-2\rangle,\quad |J_1-1,m_1,J_2,m_2,q,p-2\rangle,\\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym2}},\quad |J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle,\\ |J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle,\quad |J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle,\\ |J_1,m_1,J_2,m_2,q,p-4\rangle,\end{gathered} \tag{4.14}$$

drop out of the basis, and only the following multiplets,

$$|J_1,m_1,J_2,m_2,q,p\rangle,$$

$$|J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle,\quad |J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle,$$

$$|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle, \tag{4.15}$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym2}},\quad |J_1+1,m_1,J_2,m_2,q,p-2\rangle,$$

$$|J_1,m_1,J_2+1,m_2,q,p-2\rangle,\quad |J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle,$$

survive. They form irreducible atypical representations of gl(2|2) of dimension $8[(J_1+1)(2J_2+1)+(2J_1+1)(J_2+1)]$. The branching rule in this case (i.e., $q=-J_1+J_2$) becomes

$$\begin{aligned}\pi_{(J_1,J_2,q,p)} = {} & \sigma_{(J_1,J_2,q,p)} \otimes \sigma_{(J_1+1/2,J_2+1/2,q,p-1)} \otimes \sigma_{(J_1+1/2,J_2-1/2,q,p-1)} \otimes \sigma_{(J_1-1/2,J_2+1/2,q,p-1)} \\ & \otimes \sigma_{(J_1,J_2,q,p-2)} \otimes \sigma_{(J_1+1,J_2,q,p-2)} \otimes \sigma_{(J_1,J_2+1,q,p-2)} \otimes \sigma_{(J_1+1/2,J_2+1/2,q,p-3)}.\end{aligned} \tag{4.16}$$

2. Lowest weight (indecomposable) Kac modules

If one starts with the level-4 state, then one gets atypical representations which are not irreducible. In such representations, all 16 multiplets appear but there exists a nonseparable invariant superspace generated by multiplets (4.15). These representations are indecomposable and have dimension $16(2J_1+1)(2J_2+1)$.

C. Atypical representations corresponding to $q=J_1+J_2+1$

1. Irreducible representations

Let us introduce the following independent combinations for $J_1\neq 0, J_2\neq 0$,

$$\begin{aligned}|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym3}} &= J_1|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} + (J_2+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}},\\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym3}} &= J_1|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} - (J_2+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}}.\end{aligned} \tag{4.17}$$

We let

$$\begin{aligned}|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym3}} &= \begin{cases}|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} & \text{if } J_1=0,\\ 0 & \text{if } J_2=0,\end{cases}\\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym3}} &= \begin{cases}0 & \text{if } J_1=0,\\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}} & \text{if } J_2=0.\end{cases}\end{aligned} \tag{4.18}$$

It can be seen from the actions of odd generators that when $q=J_1+J_2+1$,

$$\begin{aligned}\Gamma(E_{23})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym3}} = {} & \frac{1}{(2J_1+1)(2J_2+1)}[(2J_1+1)(J_2+1)(J_2+m_2+2)(J_2+m_2+2)\\ & \times|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle - J_1(2J_2+1)\\ & \times|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle\\ & +(J_1+J_2+1)(J_1+m_1+2)\\ & \times|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle],\end{aligned} \tag{4.19}$$

which does not contain the multiplet $|J_1+\frac{1}{2},m_1,J_2-\frac{1}{2},m_2,q;p-1\rangle$ and

$$\Gamma(E_{32})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym3}}=\frac{(J_1+J_2+1)(4J_1J_2+J_1+J_2)+(J_1+J_2)^2}{(2J_1+1)(2J_2+1)}\times(J_1-m_1-2)|J_1-\tfrac{1}{2},m_1-\tfrac{1}{2},J_2+\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-3\rangle. \tag{4.20}$$

Then similar to previous cases, when $q=J_1+J_2+1$, the following $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ multiplets,

$$|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle,$$

$$|J_1,m_1,J_2-1,m_2,q,p-2\rangle,\quad |J_1+1,m_1,J_2,m_2,q,p-2\rangle,$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym3}},\quad |J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle, \tag{4.21}$$

$$|J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle,\quad |J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle,$$

$$|J_1,m_1,J_2,m_2,q,p-4\rangle$$

disappear, and only the following multiplets,

$$|J_1,m_1,J_2,m_2,q,p\rangle,$$

$$|J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle,\quad |J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle,$$

$$|J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle, \tag{4.22}$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym3}},\quad |J_1-1,m_1,J_2,m_2,q,p-2\rangle,$$

$$|J_1,m_1,J_2+1,m_2,q,p-2\rangle,\quad |J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle$$

remain. They constitute irreducible atypical representations of $\mathrm{gl}(2|2)$ of dimension $8[(2J_1+1)\times(J_2+1)+J_1(2J_2+1)]$. The branching rule in this case (i.e., $q=J_1+J_2+1$) reads

$$\pi_{(J_1,J_2,q,p)}=\sigma_{(J_1,J_2,q,p)}\oplus\sigma_{(J_1-1/2,J_2-1/2,q,p-1)}\oplus\sigma_{(J_1+1/2,J_2+1/2,q,p-1)}\oplus\sigma_{(J_1-1/2,J_2+1/2,q,p-1)}\oplus\sigma_{(J_1,J_2,q,p-2)}\oplus\sigma_{(J_1-1,J_2,q,p-2)}\oplus\sigma_{(J_1,J_2+1,q,p-2)}\oplus\sigma_{(J_1-1/2,J_2+1/2,q,p-3)}. \tag{4.23}$$

Here one should keep in mind that $\sigma_{(J_1,J_2,q,p-2)}$ disappears if $J_1=0$.

2. Lowest weight (indecomposable) Kac representations

Similar to the previous cases, if one retains all 16 multiplets, then one gets lowest weight (indecomposable) Kac representations of $16(2J_1+1)(2J_2+1)$ which contain an invariant but non-separable subspace provided by multiplets (4.22).

D. Atypical representations corresponding to $q=-J_1-J_2-1$

1. Irreducible representations

In this case, we introduce the following independent combinations for $J_1\neq 0, J_2\neq 0$,

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym4}}=(J_1+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}}+J_2|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}},$$

$$|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym4}} = (J_1+1)|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} - J_2|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}} \tag{4.24}$$

and let

$$\begin{aligned} |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym4}} &= \begin{cases} 0 & \text{if } J_1=0, \\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{II}} & \text{if } J_2=0, \end{cases} \\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym4}} &= \begin{cases} |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{I}} & \text{if } J_1=0, \\ 0 & \text{if } J_2=0. \end{cases} \end{aligned} \tag{4.25}$$

It can be seen from the actions of odd generators that when $q=-J_1-J_2-1$,

$$\begin{aligned} \Gamma(E_{23})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym4}} = \frac{1}{(2J_1+1)(2J_2+1)}[&(J_1+1)(2J_2+1)(J_2+m_2+2)(J_2+m_2+2) \\ &\times|J_1-\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle - (J_1+J_2+1) \\ &\times(J_2+m_2+2)|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2-\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle \\ &-(2J_1+1)J_2|J_1+\tfrac{1}{2},m_1+\tfrac{1}{2},J_2+\tfrac{1}{2},m_2+\tfrac{1}{2},q;p-1\rangle], \end{aligned} \tag{4.26}$$

which has no dependence on the multiplet $|J_1-\frac{1}{2},m_1,J_2+\frac{1}{2},m_2,q;p-1\rangle$ and

$$\begin{aligned} \Gamma(E_{32})|J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym4}} = &-\frac{(J_1+J_2+1)(4J_1J_2+J_1+J_2)+(J_1+J_2)^2}{(2J_1+1)(2J_2+1)} \\ &\times(J_2-m_2-2)|J_1+\tfrac{1}{2},m_1-\tfrac{1}{2},J_2-\tfrac{1}{2},m_2-\tfrac{1}{2},q;p-3\rangle. \end{aligned} \tag{4.27}$$

Thus when $q=-J_1-J_2-1$, the following $\mathrm{gl}(2)\oplus\mathrm{gl}(2)$ multiplets

$$\begin{gathered} |J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle, \\ |J_1-1,m_1,J_2,m_2,q,p-2\rangle, \quad |J_1,m_1,J_2+1,m_2,q,p-2\rangle, \\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{sym4}}, \quad |J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle, \\ |J_1-\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle, \quad |J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-3\rangle, \\ |J_1,m_1,J_2,m_2,q,p-4\rangle \end{gathered} \tag{4.28}$$

drop out, and only the following multiplets

$$\begin{gathered} |J_1,m_1,J_2,m_2,q,p\rangle, \\ |J_1-\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle, \quad |J_1+\tfrac{1}{2},m_1,J_2+\tfrac{1}{2},m_2,q;p-1\rangle, \\ |J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-1\rangle, \\ |J_1,m_1,J_2,m_2,q,p-2\rangle_{\mathbf{asym4}}, \quad |J_1,m_1,J_2-1,m_2,q,p-2\rangle, \end{gathered} \tag{4.29}$$

$$|J_1+1,m_1,J_2,m_2,q,p-2\rangle, \quad |J_1+\tfrac{1}{2},m_1,J_2-\tfrac{1}{2},m_2,q;p-3\rangle$$

remain. They give irreducible atypical representations of gl(2|2) of dimension $8[(J_1+1)(2J_2+1)+(2J_1+1)J_2]$. In this case the branching rule becomes

$$\pi_{(J_1,J_2,q,p)} = \sigma_{(J_1,J_2,q,p)} \oplus \sigma_{(J_1-1/2,J_2-1/2,q,p-1)} \oplus \sigma_{(J_1+1/2,J_2+1/2,q,p-1)} \oplus \sigma_{(J_1+1/2,J_2-1/2,q,p-1)} \oplus \sigma_{(J_1,J_2,q,p-2)} \oplus \sigma_{(J_1,J_2-1,q,p-2)} \oplus \sigma_{(J_1+1,J_2,q,p-2)} \oplus \sigma_{(J_1+1/2,J_2-1/2,q,p-3)}. \tag{4.30}$$

Here it should be understood that $\sigma_{(J_1,J_2,q,p-2)}$ is not in the branching rule if $J_2=0$.

2. Lowest weight (indecomposable) Kac representations

As before, other types of atypical representations are not irreducible. These representations contain all 16 multiplets which contain a nonseparable invariant subspace generated by multiplets (4.29). They are lowest weight (indecomposable) Kac representations of dimension $16(2J_1+1)\times(2J_2+1)$.

V. CONCLUSIONS AND DISCUSSIONS

In this article we have applied the supercoherent state method to the construction of the free boson-fermion realization and representations of the non-semisimple superalgebra gl(2|2) in the standard basis. The representations are constructed out of the $gl(2)\oplus gl(2)$ particle states in the super-Fock space.

As mentioned in the Introduction, superalgebras and their corresponding nonunitary CFTs emerge in the supersymmetric treatment to disordered systems and the integer quantum Hall plateaus. In such a treatment, primary fields play an important role in the computation of critical properties of the disordered systems. The results obtained in this paper now make possible the construction of all primary fields of the gl(2|2) nonunitary CFT in terms of free fields.[23] This is under investigation and results will be presented elsewhere.

ACKNOWLEDGMENTS

Our interest in the coherent state construction was ignited by Max Lohe's talk.[21] We thank Max Lohe for making the talk material available to us. The financial support from the Australian Research Council is gratefully acknowledged.

(Received 9 February 2001; accepted 12 December 2001; published online 10 January 2005)

E_6 is an attractive group for unification model building. However, the complexity of a rank 6 group makes it nontrivial to write down the structure of higher dimensional operators in an E_6 theory in terms of the states labeled by quantum numbers of the standard model gauge group. In this paper, we show the results of our computation of the Clebsch–Gordan coefficients for the products of the **27** with irreducible representations of higher dimensionality: **78**, **351**, **351′**, $\overline{\mathbf{351}}$, and $\overline{\mathbf{351}}'$. Application of these results to E_6 model building involving higher dimensional operators is straightforward. © *2005 American Institute of Physics.*

I. INTRODUCTION

E_6 is the minimal simple gauge group which could accommodate one family of the observed fermions, *and* a family of Higgs states, into a single gauge multiplet.[1] Therefore, unification models based on E_6 can provide relationships for the measured charged fermion masses and quark mixing angles: 13 unrelated independent parameters of the standard model of elementary particles, and at the same time a small set of E_6 symmetric operators may relate the charged fermion data both to the masses and mixings in the neutrino sector and to the parameters of the Higgs sector. In this respect, E_6 provides a framework for the most economic unified supersymmetric theories.

As is well known the key feature among the observed masses of the three generations of fermions is the intergenerational hierarchy. Any unified model has to explain the origin of the hierarchy in terms of the dynamics of the underlying theory. In E_6 models, the hierarchy can follow from the pattern of the symmetry breaking as the rank 6 group is broken down to the standard model gauge group, possibly in a succession of steps. The hierarchy may be explicitly realized in terms of higher dimensional operators containing the light states after the superheavy degrees of freedom are integrated out of the effective theory generated below the E_6 breaking scale M_6.[2] From the technical point of view, the construction of higher dimensional E_6 symmetric operators and their structure in terms of the standard model states is a nontrivial task. Assuming that the light states occupy the fundamental 27-dimensional irreducible representation (irrep), a complete knowledge of the tensor products of the **27** irrep with larger irreps is required. For instance, the E_6 symmetry allows for a higher dimensional operator containing the product of three **27**'s and a **78**, suppressed by some heavy scale $M_H \geqslant M_6$. If the **78** acquires a vacuum expectation value (vev) $v_6 \approx M_6$ and all three **27**'s contain light states, such an operator contributes to the generation of fermion mass matrices. In particular, for the first two families it may generate

entries suppressed by v_6/M_H. Yet, the predictivity of E_6 can only be utilized if the exact form of the singlet in $\mathbf{27}\otimes\mathbf{27}\otimes\mathbf{27}\otimes\mathbf{78}$ in terms of the standard model states is known. If two of the **27**'s are contracted antisymmetrically, one needs to know the Clebsch–Gordan decomposition of the **351** in the tensor product $\mathbf{27}\otimes\mathbf{78}$, then the decomposition of the $\overline{\mathbf{27}}$ in the product $\mathbf{27}\otimes\mathbf{351}$, and, lastly, the decomposition of the singlet in the product $\mathbf{27}\otimes\overline{\mathbf{27}}$. However, complete information on general tensor products of the exceptional group E_6 is difficult to obtain.[3] As for particular computations, to our knowledge only the Clebsch–Gordan decompositions of $\mathbf{27}\otimes\mathbf{27}$, $\mathbf{27}\otimes\overline{\mathbf{27}}$, and $\mathbf{78}\otimes\mathbf{78}$ are presently available in the literature.[4–6]. (We note in passing that a separate paper[7] obtains a subset of the results needed for the operator $\mathbf{27}^3\mathbf{78}$ by studying a branching chain of E_6. The results presented in this paper are relevant for the case when the vev is acquired by a zero weight state of the **78**.)

In this paper, we continue in our earlier work[5,6] and provide basic group-theoretical tools for a construction of higher-dimensional E_6 symmetric operators. In particular, we present the results of our computation of the Clebsch–Gordan coefficients (CGCs) for the tensor products involving 27-, 78-, and 351-dimensional representations, the lowest dimensional irreps in E_6. Section II contains some necessary mathematical background for our study, mostly concerned with lowering in the weight system of these irreps. Our main results can be found in Sec. III, where we also comment on the construction and properties of the weight systems of the resulting irreps. Section IV contains the summary, while the appendix provides details on the lowering relations in the presence of degenerate weights.

II. MATHEMATICAL PRELIMINARIES

In this work we consider tensor products of the fundamental 27-dimensional irrep with higher dimensional 78- and 351-dimensional representations of E_6. In particular, we compute the Clebsch–Gordan coefficients for the products

$$\mathbf{27}\otimes\mathbf{78}=\mathbf{1728}\oplus\mathbf{351}\oplus\mathbf{27}, \tag{1a}$$

$$\mathbf{27}\otimes\mathbf{351}=\overline{\mathbf{7371}}\oplus\overline{\mathbf{1728}}\oplus\overline{\mathbf{351}}\oplus\overline{\mathbf{27}}, \tag{1b}$$

$$\mathbf{27}\otimes\mathbf{351}'=\overline{\mathbf{7722}}\oplus\overline{\mathbf{1728}}\oplus\overline{\mathbf{27}}, \tag{1c}$$

$$\mathbf{27}\otimes\overline{\mathbf{351}}=\overline{\mathbf{5824}}\oplus\mathbf{2925}\oplus\mathbf{650}\oplus\mathbf{78}, \tag{1d}$$

$$\mathbf{27}\otimes\overline{\mathbf{351}'}=\mathbf{3003}\oplus\overline{\mathbf{5824}}\oplus\mathbf{650}. \tag{1e}$$

Before we discuss the construction of the weight systems of the irreps on the right-hand side of these relations let us start first with the rules for the construction of the irreps on the left.

The key ingredient of our procedure is the lowering operation which is used to construct a complete weight system by successive application of generators $E_{-\alpha_1},\ldots,E_{-\alpha_6}$. These are the generators which lie outside of the diagonal Cartan subalgebra and correspond to the six simple roots of E_6. (Our choice of generators is described in more detail in Ref. 6, and basically follows the standard conventions of Ref. 8.) The six generators act as ladder operators—at each level the weight of the new state is obtained from the weight at the previous level by subtracting (in the weight space) the respective simple root:

$$E_{-\alpha_i}|w\rangle=N_{-\alpha_i,w}|w-\alpha_i\rangle. \tag{2}$$

For the weight systems of the **27** and **78** constants $N_{-\alpha_i,w}$ satisfy [see Eq. (12) in Ref. 6]

$$|N_{-\alpha_i,(w)_j}|^2=\langle\alpha_i|w\rangle+|\langle(w)_j|(w)_i\rangle|^2|N_{-\alpha_i,w+\alpha_i}|^2. \tag{3}$$

It is understood that the new state $|w-\alpha_i\rangle$ does not exist if $N_{-\alpha_i,w}=0$ or the right-hand side of (3) turns out to be negative. The subscript on the weight (w) is only relevant for the six degenerate zero weight states of the **78** and is to be ignored for nondegenerate weights. In fact, the second term on the right-hand side of (3) never contributes when one constructs the weight system of the **27** as there are no higher multiplets than doublets for any SU(2) subgroup.

We remark that throughout this work, and consistent with our previous studies,[5,6] the lowering phase convention which always fixes constants N to be real and non-negative

$$N_{-\alpha_i,w}\geqslant 0 \tag{4}$$

is adopted for any simple root α_i and any weight system. Then for the zero weight states of the **78** the inner product in (3) can be expressed as

$$\langle (w)_i|(w)_j\rangle = |A_{ij}|/2, \tag{5}$$

where $A_{ij}\equiv\langle\alpha_i|\alpha_j\rangle$ are the elements of the Cartan matrix of E_6.[8,6] This result follows from the decomposition of the **78** weight states into the states of the fundamental representations in the tensor product $\mathbf{27}\otimes\overline{\mathbf{27}}$.[5]

In the appendix, we derive a generalized relation for $N_{-\alpha_i,w}$ for a weight system with multiple degenerate weights at different levels. We now discuss how to apply general formula (A8) to the weight systems of the 351-dimensional representations which appear on the left in Eqs. 1(b)–1(e). These irreps, although already rather large, are still special because for each weight subspace a basis can be defined such that the application of a lowering ladder operator results in a single basis state, as indicated in Eq. (2). (For larger irreps, there are lowerings which lead to a linear combination of the basis states regardless of the basis definition.) Moreover, if weight (w) is degenerate and a state with weight $(w-\alpha)$ exists, then the $(w+\alpha)$ weight state is either nondegenerate or does not exist at all. Thus for the weight system of the **351′** or **351**, Eq. (A8) reduces to a simple form

$$|N_{-\alpha,(w)_a\to(w-\alpha)_{A_a}}|^2=\langle\alpha|w\rangle+|\langle(w)_a|(w)_c\rangle|^2|N_{-\alpha,(w+\alpha)\to(w)_c}|^2, \tag{6}$$

where, formally, the summation over c is assumed in the last term, but no more than one state actually contributes. Concrete applications of this formula are provided at the end of the section.

Compared to Eq. (3) both weights (w) and $(w-\alpha)$ can now be degenerate. We find, however, that in the **351′** or **351** the $(w+\alpha)$ weight state does not exist if $(w-\alpha)$ is a degenerate weight. Hence if both (w) and $(w-\alpha)$ are degenerate, A_a can be set to a by definition and (6) can be simplified even further:

$$|N_{-\alpha,(w)_a\to(w-\alpha)_a}|^2=\langle\alpha|w\rangle, \quad \text{for both } (w) \text{ and } (w-\alpha) \text{ degenerate.} \tag{7}$$

This shows that the definition of the basis states (and their subscript labeling) in the degenerate subspaces of the **351′** or **351** can be induced from the basis states at the previous level. However, once (w) is found degenerate, how do we know if $(w-\alpha)$ is going to be degenerate and what the dimensionality of this subspace is going to be? Similar to the case of the **78** weight system[6] the decomposition of the 351-dimensional irreps into the states of the fundamental representations can be recalled. The product $\overline{\mathbf{27}}\otimes\overline{\mathbf{27}}=\mathbf{351}'\oplus\mathbf{351}\oplus\mathbf{27}$ is conjugated to the product studied in Ref. 4. We refer to this work to claim that all degenerate weight subspaces in the **351′** (or **351**) are of the same dimensionality and that the degenerate weights follow the weight system of the **27**. In the end it thus turns out that complete bases in the degenerate weight subspaces of the **351′** can be obtained starting from the four (100000) weight states at level 8 of the **351′**:[9]

$$|(100000)_3\rangle = E_{-\alpha_3}|(1\bar{1}2\bar{1}0\bar{1})\rangle/\sqrt{2},$$

$$
\begin{aligned}
|(100000)_4\rangle &= E_{-\alpha_4}|(10\bar{1}2\bar{1}0)\rangle/\sqrt{2},\\
|(100000)_5\rangle &= E_{-\alpha_5}|(100\bar{1}20)\rangle/\sqrt{2},\\
|(100000)_6\rangle &= E_{-\alpha_6}|(10\bar{1}002)\rangle/\sqrt{2}.
\end{aligned}
\tag{8}
$$

With lowering convention (4) the remaining 26 degenerate weight subspaces at lower levels can be specified as $|(w)_a\rangle = E_{-\alpha_A}\cdots E_{-\alpha_B}|(100000)_a\rangle$, $a=3,4,5,6$, where $E_{-\alpha_A}\cdots E_{-\alpha_B}$ is the lowering path leading to state $|(w)\rangle$ in the **27**. For the **351** the only difference is that the degenerate weight subspaces are five-dimensional and the relations analogous to (8) also include

$$
|(100000)_2\rangle = E_{-\alpha_2}|(02\bar{1}000)\rangle/\sqrt{2} \tag{9}
$$

when computing the (100000) states at level 7 of this irrep. We note that with this notation the inner product in any degenerate weight subspace of both the **351′** and **351** satisfies

$$
\langle (w)_a|(w)_b\rangle = |A_{ab}|/2, \tag{10}
$$

(where $a,b=3,4,5,6$ for the **351′**, and $a,b=2,3,4,5,6$ for the **351**), in a close similarity to the degenerate zero weight subspace of the **78**, Eq. (5).

As an example of the application of formula (6) consider all possible lowerings of the state $|F_5\rangle$ in the **351′** where, for brevity, F stands for the (100000) weight. Three different states at the next level can be obtained: $E_{-\alpha_1}|F_5\rangle = N_1\,|(\bar{1}10000)_5\rangle$, $E_{-\alpha_4}|F_5\rangle = N_4\,|101\bar{2}10\rangle$, and $E_{-\alpha_5}|F_5\rangle = N_5\,|100\bar{1}20\rangle$. Based on (6) the constants are

$$
|N_1|^2 = 1+0=1,
$$

$$
|N_4|^2 = 0+\left(\frac{1}{2}\right)^2(\sqrt{2})^2=\frac{1}{2},
$$

$$
|N_5|^2 = 0+1^2(\sqrt{2})^2=2,
$$

as we have already shown in the second and third equations of (8) that

$$
N_{-\alpha_4,(F+\alpha_4)\to(F)_4} = N_{-\alpha_5,(F+\alpha_5)\to(F)_5} = \sqrt{2}.
$$

Implicitly, we also used the fact that (8) represents the only way the (100000) weight states can be obtained from the states at the previous level. Note that (7) could be used to compute N_1 since both (100000) and $(\bar{1}10000)$ are degenerate weights.

Finally, we remark that the properties of the $\overline{\mathbf{351}}'$ and $\overline{\mathbf{351}}$ are easily derived from the properties of the **351′** and **351** after the Dynkin coordinates [and any other indices in Dynkin formalism, like e.g., the labeling of states in Eq. (8)] 1 and 2 are exchanged with 5 and 4, respectively.

III. CONSTRUCTION OF CLEBSCH–GORDAN COEFFICIENTS

Tensor products in Eq. (1) can be expressed in terms of the highest weights as

$$
(100000)\otimes(000001)=(100001)\oplus(000100)\oplus(100000), \tag{11a}
$$

$$
(100000)\otimes(000100)=(100100)\oplus(000011)\oplus(010000)\oplus(000010), \tag{11b}
$$

$$
(100000)\otimes(000020)=(100020)\oplus(000011)\oplus(000010), \tag{11c}
$$

TABLE I. Bases in the dominant weight subspaces of the 1728-dimensional (100001) irrep.

pressed as a trivial combination of the highest weight states of the two irreps on the left-hand side, with the CGC being equal to $+1$. In the absence of a simple method to determine the bases in the degenerate weight subspaces which follow at lower levels for each of these irreps, we compute directly the complete weight system in each case. However, note that simple lowering (2) does not necessarily hold for weights with multiple degeneracies, as discussed in the appendix. States at lower levels are then computed by successive lowerings applied to the states of the **27**, and **78** in case (a) or one of the 351-dimensional irreps in cases (b)–(e). These lowerings were described in detail in Sec. II. The computed state is accepted and kept as a new basis state if it cannot be expressed as a linear combination of the previously obtained basis states with the same weight.

It is not necessary to show the Clebsch–Gordan coefficients for every linearly independent state, since there are many states with the same CGCs. Instead, we present the results just for the dominant weight states. Dominant weights are weights with all Dynkin coordinates non-negative. The CGCs for the remaining states can then be determined using the charge conjugation operators,[10,11] or in a straightforward way by direct lowering. In Tables I–V we present lowering paths for the dominant weight states of the **1728**, $\overline{\mathbf{7371}}$, $\overline{\mathbf{7722}}$, $\overline{\mathbf{5824}}$, and **3003** irreps. In our abbreviated notation, lowering path, let's say, 3421 stands for $E_{-\alpha_3}E_{-\alpha_4}E_{-\alpha_2}E_{-\alpha_1}$ applied (from the right) to the highest weight state. The lowering paths in Tables I–V actually specify our choice of bases for particular dominant weight subspaces. Explicit Clebsch–Gordan decomposition of the dominant weight states is important because, typically, the multiplicity of degeneracy (i.e., the dimensionality of the weight subspace) changes compared to the degeneracy at the previous level. Clearly, that is why these states cannot be obtained by generalized charge conjugation from the

states at the previous levels. Moreover, it is important to check the completeness of a reducible dominant weight subspace. If it is impossible to complete its basis by lowering the states at the previous level, new weight systems open up and the remaining basis vectors are their highest weight states. This is what happens for every dominant weight in the tensor products $\mathbf{78}\otimes\mathbf{78}$,[6] $\mathbf{27}\otimes\overline{\mathbf{27}}$,[5] or $\mathbf{27}\otimes\mathbf{27}$[5] studied in the earlier work. However, this property of the dominant weights is no longer true for the products studied here. We now briefly discuss the dominant weights in each of the products in (11).

(a) ***(100000)*** $\otimes$ ***(000001)*** $=$ ***(100001)*** $\oplus$ ***(000100)*** $\oplus$ ***(100000)***. At level 4 of the 1728-dimensional (**100001**) irrep we find four states with weight (000 100). This weight space, however, is five-dimensional, and the computation of the state orthogonal to the previous four yields the highest weight state of the **351** irrep. (See Table VI.) Similarly, at level 11 we find 16-fold degenerate weight (100000), while this reducible subspace unfolds to be 22-dimensional. Since there are five distinct states of the same weight in the **351**, there is room for one extra state. Once computed as orthogonal to all the other 21 states it becomes the highest weight state of the fundamental 27-dimensional (**100000**) irrep. Because the subsequent tables of CG coefficients become too unwieldy to print, we have deposited electronic versions with the electronic Physics Auxiliary

Publication Service.[14] Note that in Table VII[14] we keep the labeling of the five (100000) states of the **351** consistent with the notation introduced in Eqs. (8) and (9).

(b) ***(100000)*⊗*(000100)*=*(100100)*⊕*(000011)*⊕*(010000)*⊕*(000010)***. Lowering down to level 4 of the 7371-dimensional (**100100**) irrep we obtain four distinct (000011) weight states spanned over a five-dimensional reducible subspace. The last basis state in this subspace, orthogonal to the four from the $\overline{\mathbf{7371}}$, becomes the highest weight state of the $\overline{\mathbf{1728}}$. (See Table VIII.) This is a conjugate irrep to the **1728** described in (a). The lowering paths to the dominant weights in its weight system can be obtained from Table I (replacing 1 and 2 with 5 and 4, and *vice versa*. Proceeding to level 7 a fivefold degenerate (200000) dominant weight is found:

$$|200000_a\rangle = |100000\rangle|100000_a\rangle, \quad a = 2,\ldots,6 \tag{12}$$

which, obviously, does not leave any extra space for states outside of the $\overline{\mathbf{7371}}$. This is consistent with no observation in (a) of a dominant weight (000020) in the weight system of the **1728**, and also with the fact that there is no (**200000**) irrep on the right-hand side of (11b). The charge conjugation operators can be used to show that a fivefold degenerate weight subspace with CGCs equal to 1 is then present at odd levels of the $\overline{\mathbf{7371}}$ from this level down until subspace $(000\bar{2}\bar{0})$ emerges at level 39. Next, at level 8 fifteen linearly independent (010000) weight states are present, while the weight subspace turns out to be 20-dimensional (Table IX).[14] Not surprisingly there are four states which belong to the weight system of the $\overline{\mathbf{1728}}$ [compare with (a)], and the remaining basis state, orthogonal to the previous 19, represents the highest weight state of the $\overline{\mathbf{351}}$. Last, at level 15 we get the reducible (000010) weight subspace, which is 66-dimensional. That makes room for the highest weight of the $\overline{\mathbf{27}}$, since there are 44 basis states present in the $\overline{\mathbf{7371}}$ together with 16 states of the $\overline{\mathbf{1728}}$. An additional five states of the $\overline{\mathbf{351}}$ should be expected based on Eqs. (8) and (9). The CGCs for this subspace are presented in Tables X and XI.[14]

(c) ***(100000)⊗(000020)=(100020)⊕(000011)⊕(000010)***. In the construction of the 7722-dimensional (**100020**) irrep one finds a dominant weight already at level 1,

$$|100100\rangle = |100000\rangle|000100\rangle. \tag{13}$$

It occupies a one-dimensional subspace, which is consistent with the absence of the (**100100**) irrep in product (11c). The first degenerate dominant weight is obtained at level 5. There, a six-dimensional (000011) weight subspace contains five linearly independent states of the $\overline{\mathbf{7722}}$. The basis in this reducible subspace is completed by the highest weight state of the $\overline{\mathbf{1728}}$ (Table XII). Proceeding further, there is no room for the highest weight state of a new irrep when dominant weights (200000) and (010000) are encountered at levels 8 and 9, respectively. The (200000)

	$\sqrt{2}$	$\sqrt{2}$	$\sqrt{3}$

subspace is four-dimensional and its basis can be specified as in Eq. (12). (The states are now numbered as $a=3,4,5,6$.) The CGC decomposition of the (010000) subspace can be found in Table XIII.[14] Finally, at level 16 the last dominant weight in this product is unveiled. The reducible (000010) weight subspace turns out to be 57-dimensional, with 40 basis states coming from the $\overline{\mathbf{7722}}$ and 16 states from the $\overline{\mathbf{1728}}$. The remaining state, orthogonal to them, becomes the highest weight state of the $\overline{\mathbf{27}}$ (see Tables XIV and XV).[14]

(d) ***(100000)***⊗***(010000)***=***(110000)***⊕***(001000)***⊕***(100010)***⊕***(000001)***. In this product, we find the dominant weight states encountered already in the decomposition of **78**⊗**78** and **27**⊗$\overline{\mathbf{27}}$. At level 2 of the (**110000**) weight system (i.e., the $\overline{\mathbf{5824}}$ irrep) we reach the three-dimensional (001000) subspace, with two states in the **5824** and the third one being the highest weight state of the **2925**, as shown in Table XVI. Then following the lowering paths in Table IV, Table II in Ref. 6, and Table I in Ref. 5 the dominant weights (100010), (000001), and (000000) follow at levels 7, 12, and 23, respectively. The CGCs for these dominant weights can be found in Tables XVII–XXIII.[14] The reducible (000000) subspace is 135-dimensional and represents the most (technically) involved computation in this study. Obviously, it cannot (and does not) leave any room for the singlet since the two representations in the product are not conjugate to each other.

(e) ***(100000)***⊗***(200000)***=***(300000)***⊕***(110000)***⊕***(100010)***. The 3003-dimensional (**300000**) irrep contains a dominant weight already at level 1:

$$|110000\rangle=(|\bar{1}10000\rangle|200000\rangle+\sqrt{2}|100000\rangle|010000\rangle)/\sqrt{3}. \tag{14}$$

The orthogonal combination

$$|110000\rangle=(\sqrt{2}|\bar{1}10000\rangle|200000\rangle-|100000\rangle|010000\rangle)/\sqrt{3} \tag{15}$$

forms the highest weight state of the $\overline{\mathbf{5824}}$. Since then, the same dominant weights occur as in the weight system of the $\overline{\mathbf{5824}}$ described under (d). There are, however, no **2925** and **78** irreps in this product (see Tables XXIV–XXVI[14]), just the highest weight state of the **650** completes the 13-dimensional (100010) subspace at level 8 (Table XXVII[14]). The reducible (000000) weight subspace is 108-dimensional and its decomposition can be found in Tables XXVIII–XXXI.[14]

IV. SUMMARY

We have presented the Clebsch–Gordan decomposition of the E_6 tensor products of the fundamental **27** irrep with the 78- and 351-dimensional irreps. Analogous products involving the $\overline{\mathbf{27}}$ instead of the **27** can now be obtained trivially by charge conjugation. It is straightforward to apply these results to the construction of higher dimension operators in E_6 model building.[12]

APPENDIX THE PROBLEM OF DEGENERATE WEIGHTS

Rules (2,3) are insufficient for representations with degenerate weights at successive levels. For degenerate weights we must first identify a particular basis. Label the degenerate basis states of weights $(w+\alpha)$, (w), and $(w-\alpha)$ as

$$|(w+\alpha)_\Gamma\rangle, \quad \text{where} \quad \Gamma=1,\ldots D_{w+\alpha},$$

$$|w_c\rangle, \quad \text{where} \quad c=1,\ldots D_w,$$

and

$$|(w-\alpha)_C\rangle, \quad \text{where} \quad C=1,\ldots D_{w-\alpha}.$$

D_w stands for the degeneracy of (w). The basis states are in general nonorthogonal. In our notation, they are always normalized to unity: $\langle w_c|w_c\rangle=1$. The identity operator in the degenerate subspace is

$$\begin{aligned} I&=G_{ab}|w_a\rangle\langle w_b|,\\ G_{ab}&=(M^{-1})_{ab}, \quad \text{where} \quad M_{ab}=\langle w_a|w_b\rangle. \end{aligned} \tag{A1}$$

Although the basis is nonorthogonal, we can construct state vectors which are orthogonal to any state except the state we are interested in

$$\begin{aligned} |\hat{w}_b\rangle&=|w_a\rangle G_{ab},\\ \langle\hat{w}_a|&=G_{ab}\ \langle w_b|, \end{aligned} \tag{A2}$$

which satisfy

$$\langle w_c|\hat{w}_a\rangle=\langle\hat{w}_a|w_c\rangle=\delta_{ac}. \tag{A3}$$

A general raising or lowering of a degenerate weight state can be written as

$$E_{\alpha_i}|w_c\rangle=N_{\alpha_i,w_c\to(w+\alpha_i)_\Gamma}|(w+\alpha_i)_\Gamma\rangle, \tag{A4}$$

$$E_{-\alpha_i}|w_c\rangle=N_{-\alpha_i,w_c\to(w-\alpha_i)_C}|(w-\alpha_i)_C\rangle, \tag{A5}$$

where there is a possible sum over the states on the right-hand side [compare (A5) with (2)]. The lowering normalization constant can then be expressed only as a sum of matrix elements $N_{-\alpha_i,w_a\to(w-\alpha_i)_A}=G_{AB}^{(w-\alpha_i)}\langle(w-\alpha_i)_B|E_{-\alpha_i}|w_a\rangle$.[13] Using $E_\alpha=E_{-\alpha}^\dagger$ and the defining relation (A5) we derive

$$\begin{aligned} &N_{-\alpha,w_a\to(w-\alpha)_A}N^*_{-\alpha,w_b\to(w-\alpha)_B}\langle(w-\alpha)_B|(w-\alpha)_A\rangle\\ &\quad=\langle w_b|E_\alpha E_{-\alpha}|w_a\rangle\\ &\quad=\langle w_b|[E_\alpha,E_{-\alpha}]+E_{-\alpha}E_\alpha|w_a\rangle\\ &\quad=\langle w_b|w_a\rangle\langle\alpha,w\rangle+G_{\Gamma\Delta}^{w+\alpha}\langle w_b|E_{-\alpha}|(w+\alpha)_\Gamma\rangle\langle(w+\alpha)_\Delta|E_\alpha|w_a\rangle\\ &\quad=\langle w_b|w_a\rangle\langle\alpha,w\rangle+G_{\Gamma\Delta}^{w+\alpha}N_{-\alpha,(w+\alpha)_\Gamma\to w_c}\langle w_b|w_c\rangle N^*_{-\alpha,(w+\alpha)_\Delta\to w_d}\langle w_d|w_a\rangle. \end{aligned} \tag{A6}$$

Hence

$$(G^{w-\alpha})^{-1}_{AB} N_{-\alpha,w_a\to(w-\alpha)_A} N^{*}_{-\alpha,w_b\to(w-\alpha)_B}$$
$$= (G^{w})^{-1}_{ab}\langle\alpha,w\rangle + G^{w+\alpha}_{\Gamma\Delta}(G^{w})^{-1}_{bc}(G^{w})^{-1}_{da} N_{-\alpha,(w+\alpha)_\Gamma\to w_c} N^{*}_{-\alpha,(w+\alpha)_\Delta\to w_d}. \quad \text{(A7)}$$

For $a=b$ we get

$$(G^{w-\alpha})^{-1}_{AB} N_{-\alpha,w_a\to(w-\alpha)_A} N^{*}_{-\alpha,w_a\to(w-\alpha)_B}$$
$$= \langle\alpha,w\rangle + G^{w+\alpha}_{\Gamma\Delta}(G^{w})^{-1}_{ac}(G^{w})^{-1}_{ad} N_{-\alpha,(w+\alpha)_\Gamma\to w_c} N^{*}_{-\alpha,(w+\alpha)_\Delta\to w_d}. \quad \text{(A8)}$$

Another useful expression can be found by contracting relation (A7) with G^{w}_{ab}:

$$(G^{w})_{ab}(G^{w-\alpha})^{-1}_{AB} N_{-\alpha,w_a\to(w-\alpha)_A} N^{*}_{-\alpha,w_b\to(w-\alpha)_B}$$
$$= \langle\alpha,w\rangle D_w + G^{w+\alpha}_{\Gamma\Delta}(G^{w})^{-1}_{cd} N_{-\alpha,(w+\alpha)_\Gamma\to w_c} N^{*}_{-\alpha,(w-\alpha)_\Delta\to w_d}. \quad \text{(A9)}$$

This expression is easily iterated along a sequence of lowerings with the same ladder operator:

$$(G^{w})_{ab}(G^{w-\alpha})^{-1}_{AB} N_{-\alpha,w_a\to(w-\alpha)_A} N^{*}_{-\alpha,w_b\to(w-\alpha)_B}$$
$$= \langle\alpha,w\rangle D_w + \langle\alpha,w+\alpha\rangle D_{w+\alpha} + G^{w+2\alpha}_{\gamma\delta}(G^{w+\alpha})^{-1}_{\Gamma\Delta} N_{-\alpha,(w+2\alpha)_\gamma\to(w+\alpha)_\Gamma} N^{*}_{-\alpha,(w+2\alpha)_\delta\to(w+\alpha)_\Delta}$$
$$= \langle\alpha,w\rangle D_w + \langle\alpha,w+\alpha\rangle D_{w+\alpha} + \cdots + \langle\alpha,w+k\alpha\rangle D_{w+k\alpha}, \quad \text{(A10)}$$

where $(w+k\alpha)$ is the highest weight in the SU(2) subgroup chain (w), $(w+\alpha)$, $(w+2\alpha)$,... present in the weight system.

Finally, for completeness, when raising operators are applied, Eq. (A8) can be written as

$$(G^{w+\alpha})^{-1}_{\Gamma\Delta} N_{\alpha,w_a\to(w+\alpha)_\Gamma} N^{*}_{\alpha,w_a\to(w+\alpha)_\Delta}$$
$$= -\langle\alpha,w\rangle + G^{w-\alpha}_{CD}(G^{w})^{-1}_{ac}(G^{w})^{-1}_{ad} N_{\alpha,(w-\alpha)_C\to w_c} N^{*}_{\alpha,(w-\alpha)_D\to w_d}. \quad \text{(A11)}$$

Special Cases: Lowering within basis states. Consider a series of states connected by repeated application of the same lowering operator $E_{-\alpha}$. Choose any states with degenerate weights obtained in this series as part of the basis for the degenerate weights and label these states by i. For the sequence: $\ldots,(w+\alpha)_i, w_i, (w-\alpha)_i,\ldots$ the generalized recursion relation (A8) reduces to

$$|N_{-\alpha,w_i\to(w-\alpha)_i}|^2 = \langle\alpha,w\rangle + G^{w+\alpha}_{\Gamma\Delta}(G^{w})^{-1}_{ic}(G^{w})^{-1}_{id} N_{-\alpha,(w+\alpha)_\Gamma\to w_c} N^{*}_{-\alpha,(w+\alpha)_\Delta\to w_d}. \quad \text{(A12)}$$

When $(w+\alpha)_i$ is the only state which can be lowered by $E_{-\alpha}$ to obtain a state of weight w we get

$$|N_{-\alpha,w_i\to(w-\alpha)_i}|^2 = \langle\alpha,w\rangle + G^{(w+\alpha)}_{ii}|N_{-\alpha,(w+\alpha)_i\to w_i}|^2. \quad \text{(A13)}$$

This includes the case of a nondegenerate $(w+\alpha)$ weight subspace. When $(w+\alpha)$ is nondegenerate $G^{(w+\alpha)}_{ii}=1$, which further simplifies the above-given relation.

A special case of interest is lowering the degenerate zero weight states of the adjoint representation which correspond to the Cartan subalgebra. These degenerate weight states can be labeled $|(0)_i\rangle$ where the ith degenerate weight is obtained by $E_{-\alpha_i}|\alpha_i\rangle \propto |(0)_i\rangle$. This basis, however, is not orthogonal. When lowering such a basis state the general formula (A8) reduces to

$$|N_{-\alpha_i,(0)_j\to(-\alpha_i)}|^2 = [(G^{(0)})^{-1}_{ji}]^2 |N_{-\alpha_i,(\alpha_i)\to(0)_i}|^2 = \langle(0)_j|(0)_i\rangle^2 |N_{-\alpha_i,(\alpha_i)\to(0)_i}|^2. \quad \text{(A14)}$$

This result is consistent with formula (3) in Sec. II when applied to the zero weight states of the **78** in E_6.

[11] Some applications of the charge conjugation operators can be found in Ref. 5.
[12] G. Anderson and T. Blažek (unpublished).
[13] It is not always possible to choose a single basis for all of the states of degenerate weights in a representation such that lowering a particular state results in a particular state of lower weight (as opposed to a linear combination of weights) for all possible lowerings. The simplest example of this is the 27 dimensional representation of SU(3).

JOURNAL OF MATHEMATICAL PHYSICS **46**, 019901 (2005)

Erratum: Inequalities for quantum entropy: A review with conditions for equality [J. Math. Phys. 43, 4358 (2002)]

Mary Beth Ruskai[a)]
Department of Mathematics, Tufts University, Medford, Massachusetts 02155

(Received 14 September 2004; accepted 22 September 2004;
published online 3 January 2005)
[DOI: 10.1063/1.1824214]

There is a subtle error in the sketch of Epstein's proof[1] as presented in the Appendix of this paper. This can be corrected by replacing each inequality for $\Im\omega(C)$ in the chain of implications between (A2) and (A3) by an analogous operator inequality for $\Im C$ where C is one of the operators that appears in these expressions. However, as this paper was intended to be expository, we give a fuller explanation of the difficulty and its resolution.

Any bounded operator C can be written in the form $C=\Re C+i\Im C$ where $\Re C=\frac{1}{2}(C+C^\dagger)$ and $\Im C=-i(\frac{1}{2})(C-C^\dagger)$ are both self-adjoint. Since we are interested in operators on a finite dimensional Hilbert space, we can assume that $\Im C$ has only discrete spectrum and define $\omega_{\max}$ and $\omega_{\min}$ to be, respectively, the largest and smallest eigenvalues of $\Im C$. Then $\omega_{\min}I\leqslant\Im C\leqslant\omega_{\max}I$. Let $\mathrm{UHP}=\{z:\Im z>0\}$ denote the upper half plane.

Now consider the example $C=\left(\begin{smallmatrix}0&2\\0&0\end{smallmatrix}\right)=\sigma_x+i\sigma_y$. Then $\Im C=\sigma_y$ satisfies $-I\leqslant\Im C\leqslant I$. Since 0 is the only eigenvalue of C, its spectrum is $\{0\}$ which lies in the closure of the UHP. But $C-\sigma_x=i\sigma_y$ has eigenvalues $\pm i$ so that its spectrum contains a point $-i$ that is not even close to the UHP. By perturbing this example slightly so that $C=i\epsilon I+\sigma_x+i\sigma_y$ with $\epsilon>0$, we find that the spectrum of $C\subset\mathrm{UHP}$, but the spectrum of $C+K$ does not lie in the UHP when $K=K^\dagger=-\sigma_x$. This shows that the third implication in the sequence need not necessarily hold.

However, in this proof, $C=\log(zA+B)$ is not arbitrary, but satisfies $0<\Im C<\pi I$. If $K=K^\dagger$, then $\Im C=\Im(K+C)$ so that $0<\Im(K+C)<\pi I$.

Therefore, the sequence of implications between (A2) and (A3) should be replaced by the following valid implications:

$$\Im z>0\Rightarrow\Im(zA+B)>0$$

$$\Rightarrow\pi I>\Im\log(zA+B)>0$$

$$\Rightarrow\pi I>\Im[K+\log(zA+B)]>0 \text{ for } K=K^\dagger$$

$$\Rightarrow\Im(e^{K+\log(zA+B)})>0$$

$$\Rightarrow\Im\mathrm{Tr}e^{K+\log(zA+B)}>0.$$

The isoholonomic problem in a homogeneous bundle is formulated and solved exactly. The problem takes a form of a boundary value problem of a variational equation. The solution is applied to the optimal control problem in holonomic quantum computer. We provide a prescription to construct an optimal controller for an arbitrary unitary gate and apply it to a k-dimensional unitary gate which operates on an N-dimensional Hilbert space with $N \geqslant 2k$. Our construction is applied to several important unitary gates such as the Hadamard gate, the CNOT gate, and the two-qubit discrete Fourier transformation gate. Controllers for these gates are explicitly constructed. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1835545]

I. INTRODUCTION

In this paper we solve the isoholonomic problem in a homogeneous bundle and apply this result to the optimal control problem in holonomic quantum computation. In other words, this paper has two purposes; first, we solve a mathematical problem which has been unsolved for more than a decade since it was initially proposed by Montgomery.[1] Second, we provide a scheme to construct explicitly an optimal controller for arbitrary unitary gate in holonomic quantum computation.[2,3]

The isoholonomic problem is one of generalizations of the isoperimetric problem. The isoperimetric problem, also known as Dido's problem, is originally proposed in the context of plane geometry; what is the shape of a domain with the largest area surrounded by a string of a fixed length? The solution is a circle. The isoperimetric problem has a long history and various generalizations thereof have been proposed.

The isoholonomic problem is formulated as follows. Assume that we have a principal fiber bundle (P, M, π, G) with a connection. The base space M is assumed to be a Riemannian manifold. The isoholonomic problem asks to find the shortest possible piecewise smooth loop in M with a given base point $x_0 \in M$, that produces a given element g_0 of the structure group G as its associated holonomy.

Holonomic structures naturally appear in a mechanical system and have been studied from various interests.[4–8] Montgomery faced this problem when physical chemists attempted to observe

the non-Abelian Berry phase (the Wilczek–Zee holonomy)[9–12] by nuclear magnetic resonance (NMR) experiment. Montgomery[1] presented various formulations of the problem, clarified their relations, and gave partial answers. However, even in such an idealized case like a homogeneous bundle, it was difficult to obtain a complete solution to the problem, which remained as an open problem to date.

A decade later after Montgomery's work, the notion of holonomic quantum computation was proposed by Zanardi, Rasetti, and Pachos,[2,3] in which the Wilczek–Zee holonomy is utilized to implement unitary gates necessary to execute a quantum algorithm. Since then, a large number of researchers[13–16] have been interested in finding control parameters that implement a desired gate. Optimization of the control has been an active area of research in view of the decoherence issue. The problem to find the optimal control is nothing but a typical isoholonomic problem and its solution for an arbitrary gate must be urgently provided.

Let us briefly review the idea of quantum computation. Quantum computation, roughly speaking, consists of the following three ingredients: (1) an n-qubit register to store information, (2) a unitary matrix $U \in \mathrm{U}(2^n)$ which implements a quantum algorithm, and (3) measurements to extract information from the register. In an ordinary implementation of a quantum algorithm, we take a system whose Hamiltonian $H(\lambda)$ depends on external control parameters $\lambda = (\lambda^1, \ldots, \lambda^m)$. We then properly arrange the parameter sequence $\lambda(t)$ as a function of time t so that the desired unitary matrix U is generated as a time-evolution operator

$$U = \mathcal{T} \exp\left[-\frac{i}{\hbar} \int_0^T H(\lambda(t)) \mathrm{d}t \right], \tag{1.1}$$

where $\mathcal{T}$ stands for the time-ordered product.

Holonomic quantum computing,[2] in contrast, makes use of the holonomy associated with a loop $\lambda(t)$ in the parameter space. It has been demonstrated[17] that an arbitrary unitary matrix can be implemented as a holonomy by choosing an appropriate loop in the parameter space. In fact, there are infinitely many loops that produce a given unitary matrix. Here we consider the isoholonomic problem, namely, to find the shortest possible loop in the parameter space that yields the given holonomy. This problem has been already analyzed previously in Ref. 18, where various penalty functions useful for numerical search for the optimal loop have been employed. Our strategy here is purely geometrical in nature and no intense numerical computations are required. In the previous work[19] we found exact optimal loops to produce several unitary gates. In the present paper we extend the method of optimal loop construction to implement arbitrary gates.

This paper is organized as follows. In Sec. II we briefly review the Wilczek–Zee holonomy to make this paper self-contained and to establish notation conventions. In Sec. III we introduce the geometrical setting for the problem and use it to formulate the isoholonomic problem in a variational form. We derive the associated Euler–Lagrange equation and solve it explicitly. The solution thus obtained (3.37), which we call the horizontal extremal curve, is one of the main results in the first half of the paper. The remaining problem is to adjust the solution to satisfy the boundary conditions, namely the closed loop condition (4.1) and the holonomy condition (4.2). This problem is solved in Sec. IV explicitly and we obtain a set of equations (4.19)–(4.22), which we call the constructing equations of the controller. These are the main results of this paper and are machinery to construct a controller for an arbitrary unitary gate. In Sec. V this machinery is applied to several well-known important unitary gates to demonstrate its power. Section VI is devoted to summary and discussions.

II. WILCZEK–ZEE HOLONOMY AS A UNITARY GATE

A. Wilczek–Zee holonomy

Here we briefly review the Wilczek–Zee (WZ) holonomy[10] associated with an adiabatic change of the control parameters along a loop in the control manifold. We consider a quantum

system that has a finite number N of states. Let $\{H(\lambda)\}$ be a family of Hamiltonians parametrized smoothly by $\lambda=(\lambda^1,\ldots,\lambda^m)\in M$, where the set of control parameters M is called a control manifold. Eignevalues and eigenstates of $H(\lambda)$ are labeled as

$$H(\lambda)|l,\alpha;\lambda\rangle=\varepsilon_l(\lambda)|l,\alpha;\lambda\rangle \quad (l=1,\ldots,L;\ \alpha=1,\ldots,k_l), \tag{2.1}$$

where the lth eigenvalue $\varepsilon_l(\lambda)$ is k_l-fold degenerate. Assume that no level crossings take place, namely, $\varepsilon_l(\lambda)\neq\varepsilon_{l'}(\lambda)$ for arbitrary λ if $l\neq l'$. Then it follows that $\Sigma_{l=1}^{L}k_l=N$. The eigenvectors satisfy the orthonormal condition, $\langle l,\alpha;\lambda|l',\beta;\lambda\rangle=\delta_{ll'}\delta_{\alpha\beta}$. It is important to note that there is $\mathrm{U}(k_l)$ *gauge* freedom in the choice of $\{|l,\alpha;\lambda\rangle|\alpha=1,\ldots,k_l\}$ at each λ and l. Namely, we may redefine the eigenvectors by any unitary matrix $h\in\mathrm{U}(k_l)$ as

$$|l,\alpha;\lambda\rangle\mapsto\sum_{\beta=1}^{k_l}|l,\beta;\lambda\rangle h_{\beta\alpha}(\lambda) \tag{2.2}$$

without violating the orthonormal condition.

We adiabatically change the parameters $\lambda(t)$ as a function of time t along a closed loop in the control manifold so that $\lambda(T)=\lambda(0)$. It is assumed that the *adiabaticity* is satisfied, namely,

$$\{\varepsilon_l(\lambda(t))-\varepsilon_{l'}(\lambda(t))\}T\gg 2\pi\hbar \tag{2.3}$$

is satisfied for $l\neq l'$ during $0\leq t\leq T$. In other words, we change the parameters so slowly that no resonant transitions take place between different energy levels.[20]

We will concentrate exclusively on the ground state of the system and drop the index l (=1) in the following. Accordingly, the basis vectors that span the ground state eigenspace are written as $|\alpha;\lambda\rangle$, $(\alpha=1,\ldots,k)$ and arranged in an $N\times k$ matrix form as

$$V(\lambda)=(|1;\lambda\rangle,|2;\lambda\rangle,\ldots,|k;\lambda\rangle), \tag{2.4}$$

which is called an orthonormal k frame at $\lambda\in M$. The system evolves, with a given $\lambda(t)$, according to the Schrödinger equation

$$i\hbar\frac{\mathrm{d}}{\mathrm{d}t}|\psi_\alpha(t)\rangle=H(\lambda(t))|\psi_\alpha(t)\rangle. \tag{2.5}$$

Suppose the initial condition is $\lambda(0)=\lambda_0$ and $|\psi_\alpha(0)\rangle=|\alpha;\lambda_0\rangle$. The adiabatic theorem[20] tells us that the state $|\psi_\alpha(t)\rangle$ remains in the ground state eigenspace during the time evolution. Therefore $|\psi_\alpha(t)\rangle$ is expanded as

$$|\psi_\alpha(t)\rangle=\sum_{\beta=1}^{k}|\beta;\lambda(t)\rangle c_{\beta\alpha}(t). \tag{2.6}$$

By substituting (2.6) into (2.5), we find

$$\frac{\mathrm{d}}{\mathrm{d}t}c_{\beta\alpha}(t)=-\frac{i}{\hbar}\varepsilon(\gamma(t))c_{\beta\alpha}(t)-\sum_{\gamma=1}^{k}\left\langle\beta;\lambda(t)\left|\frac{\mathrm{d}}{\mathrm{d}t}\right|\gamma;\lambda(t)\right\rangle c_{\gamma\alpha}(t), \tag{2.7}$$

whose formal solution is

$$c_{\beta\alpha}(t)=\exp\left(-\frac{i}{\hbar}\int_0^t\varepsilon(s)\mathrm{d}s\right)\mathcal{T}\exp\left(-\int_0^t\mathcal{A}(s)\mathrm{d}s\right)_{\beta\alpha} \tag{2.8}$$

with the matrix-valued function

$$\mathcal{A}_{\beta\alpha}(t) = \left\langle \beta;\lambda(t) \left| \frac{\mathrm{d}}{\mathrm{d}t} \right| \alpha;\lambda(t) \right\rangle = \sum_{\mu=1}^{k} \left\langle \beta;\lambda \left| \frac{\partial}{\partial\lambda^{\mu}} \right| \alpha;\lambda \right\rangle \frac{\mathrm{d}\lambda^{\mu}}{\mathrm{d}t}. \tag{2.9}$$

It is easily verified that $\mathcal{A}^{*}_{\beta\alpha} = -\mathcal{A}_{\alpha\beta}$ since $\{|\alpha;\lambda(t)\rangle\}$ is orthonormal. We introduce a $\mathfrak{u}(k)$-valued one-form [we denote the Lie algebra of the Lie group $\mathrm{U}(k)$ by $\mathfrak{u}(k)$, which is the set of k-dimensional skew-Hermite matrices]

$$\mathcal{A}_{\beta\alpha}(\lambda) = \sum_{\mu=1}^{k} \left\langle \beta;\lambda \left| \frac{\partial}{\partial\lambda^{\mu}} \right| \alpha;\lambda \right\rangle \mathrm{d}\lambda^{\mu}, \tag{2.10}$$

which is called the Wilczek–Zee (WZ) connection. Then the unitary matrix appearing in (2.8) is rewritten as

$$\Gamma(t) = \mathcal{P} \exp\left(- \int_{\lambda(0)}^{\lambda(t)} \mathcal{A} \right), \tag{2.11}$$

where $\mathcal{P}$ stands for the path-ordered product. As noted in (2.2) the frame (2.4) can be redefined by a family of unitary matrices $h(\lambda) \in \mathrm{U}(k)$. The WZ connection transforms under the change of frame as

$$\mathcal{A} \mapsto \mathcal{A}' = h^{\dagger}\mathcal{A}h + h^{\dagger}\,\mathrm{d}h. \tag{2.12}$$

This is nothing but the gauge transformation rule of a non-Abelian gauge potential.[21]

We assumed that the control parameter $\lambda(t)$ comes back to the initial point $\lambda(T) = \lambda(0) = \lambda_0$. However, the state $|\psi_{\alpha}(T)\rangle$ fails to assume the initial state and is subject to a unitary rotation as

$$|\psi_{\alpha}(T)\rangle = \exp\left(- \frac{i}{\hbar} \int_0^T \varepsilon(s)\mathrm{d}s \right) \sum_{\beta=1}^{k} |\psi_{\beta}(0)\rangle \Gamma_{\beta\alpha}(T). \tag{2.13}$$

The unitary matrix

$$\Gamma[\lambda] \coloneqq \Gamma(T) = \mathcal{P} \exp\left(- \oint_{\lambda} \mathcal{A} \right) \in \mathrm{U}(k) \tag{2.14}$$

is called the holonomy matrix associated with the loop $\lambda(t)$. It is important to realize that $\Gamma[\lambda]$ is independent of the parametrization of the loop $\lambda(t)$, namely, it is independent of how fast the loop λ is traversed, so long as the adiabaticity is observed, and that it depends only on the geometrical image of λ in M.

B. Quantum computation with holonomy

In quantum computation one implements a quantum algorithm by a product of various unitary gates. It is a natural idea to use the WZ holonomy to produce unitary gates necessary for quantum computation. Zanardi and Rasetti[2] were the first who proposed this holonomic quantum computation (HQC). To implement an n-qubit resistor we take a quantum system whose ground state is k-fold degenerate where $k = 2^n$. We call the N-dimensional Hilbert space a working space and call the k-dimensional subspace a qubit space. Then by changing the control parameter adiabatically we will obtain any unitary gate as a resultant holonomy (2.14). Of course we need to design an appropriate control loop λ to implement a particular unitary gate. It is easy, in principle, to compute the holonomy for a given loop. In contrast, to find a loop λ which produces a specified unitary matrix Γ as its holonomy is far from trivial. Moreover, to build a working quantum computer it is strongly desired to reduce the time required to manipulate the computer since a sequence of operations should be carried out before decoherence extinguishes quantum information from the system. At the same time, the control parameter must be changed as slowly as possible to keep adiabaticity intact. Therefore our task is to find a control loop as short as possible

to fulfill these seemingly opposed conditions. This is a typical example of the so-called isoholonomic problem, which is first formulated by Montgomery.[1] In the next section we introduce a geometric setting in a form suitable for our expositions.

III. FORMULATION OF THE PROBLEM AND ITS SOLUTION

A. Geometrical setting

The WZ connection is identified with the canonical connection[22] of the homogenous bundle, as pointed out by Fujii.[23] While precise definitions of these terms can be found in Refs. 21 and 22, we outline the geometrical setting of the problem here to make this paper self-contained.

Suppose that the system has a family of Hamiltonians acting on the Hilbert space $\mathbb{C}^N$ and that the ground state of each Hamiltonian is k-fold degenerate ($k<N$). The most natural mathematical setting to describe this system is the principal bundle $(S_{N,k}(\mathbb{C}), G_{N,k}(\mathbb{C}), \pi, \mathrm{U}(k))$, which consists of the Stiefel manifold $S_{N,k}(\mathbb{C})$, the Grassmann manifolds $G_{N,k}(\mathbb{C})$, the projection map $\pi: S_{N,k}(\mathbb{C}) \to G_{N,k}(\mathbb{C})$, and the unitary group $\mathrm{U}(k)$ as explained below.

The Stiefel manifold is the set of orthonormal k frames in $\mathbb{C}^N$,

$$S_{N,k}(\mathbb{C}) = \{V \in M(N,k;\mathbb{C}) | V^\dagger V = I_k\}, \tag{3.1}$$

where $M(N,k;\mathbb{C})$ is the set of $N \times k$ complex matrices and I_k is the k-dimensional unit matrix. The unitary group $\mathrm{U}(k)$ acts on $S_{N,k}(\mathbb{C})$ from the right,

$$S_{N,k}(\mathbb{C}) \times \mathrm{U}(k) \to S_{N,k}(\mathbb{C}), \quad (V,h) \mapsto Vh \tag{3.2}$$

by means of matrix product. It should be noted that this action is free. In other words, $h=I_k$ if there exists a point $V \in S_{N,k}(\mathbb{C})$ such that $Vh=V$.

The Grassmann manifold is defined as the set of k-dimensional hyperplanes in $\mathbb{C}^N$,

$$G_{N,k}(\mathbb{C}) = \{P \in M(N,N;\mathbb{C}) | P^2 = P,\ P^\dagger = P,\ \mathrm{tr}\ P = k\}, \tag{3.3}$$

where P is a projection operator to a hyperplane in $\mathbb{C}^N$ and the condition $\mathrm{tr}\ P=k$ guarantees that the hyperplane is indeed k dimensional.

The projection map $\pi: S_{N,k}(\mathbb{C}) \to G_{N,k}(\mathbb{C})$ is defined as

$$\pi: V \mapsto P := VV^\dagger. \tag{3.4}$$

It is easily proved that the map π is surjective. Namely, for any $P \in G_{N,k}(\mathbb{C})$, there is $V \in S_{N,k}(\mathbb{C})$ such that $\pi(V)=P$. The right action of $h \in \mathrm{U}(k)$ sends a point $V \in S_{N,k}(\mathbb{C})$ to a point Vh on the same fiber since

$$\pi(Vh) = (Vh)(Vh)^\dagger = Vhh^\dagger V^\dagger = VV^\dagger = \pi(V). \tag{3.5}$$

Thus the Stiefel manifold $S_{N,k}(\mathbb{C})$ becomes a principal bundle over $G_{N,k}(\mathbb{C})$ with the structure group $\mathrm{U}(k)$.

Moreover, the group $\mathrm{U}(N)$ acts on both $S_{N,k}(\mathbb{C})$ and $G_{N,k}(\mathbb{C})$ as

$$\mathrm{U}(N) \times S_{N,k}(\mathbb{C}) \to S_{N,k}(\mathbb{C}), \quad (g,V) \mapsto gV, \tag{3.6}$$

$$\mathrm{U}(N) \times G_{N,k}(\mathbb{C}) \to G_{N,k}(\mathbb{C}), \quad (g,P) \mapsto gPg^\dagger \tag{3.7}$$

by matrix product. It is easily verified that $\pi(gV)=g\pi(V)g^\dagger$. This action is transitive, namely, there is $g \in \mathrm{U}(N)$ for any $V, V' \in S_{N,k}(\mathbb{C})$ such that $V'=gV$. There is also $g \in \mathrm{U}(N)$ for any $P, P' \in G_{N,k}(\mathbb{C})$ such that $P'=gPg^\dagger$. The stabilizer group of each point in $S_{N,k}(\mathbb{C})$ is isomorphic to $\mathrm{U}(N-k)$ while that of each point in $G_{N,k}(\mathbb{C})$ is isomorphic to $\mathrm{U}(k) \times \mathrm{U}(N-k)$. Thus, they are homogeneous spaces and the fiber bundle

$$\pi: S_{N,k}(\mathbb{C}) \cong \mathrm{U}(N)/\mathrm{U}(N-k) \to G_{N,k}(\mathbb{C}) \cong \mathrm{U}(N)/(\mathrm{U}(k) \times \mathrm{U}(N-k)) \tag{3.8}$$

is called a homogeneous bundle.

The canonical connection form on $S_{N,k}(\mathbb{C})$ is defined as a $\mathfrak{u}(k)$-valued one-form,

$$A = V^\dagger \, \mathrm{d}V, \tag{3.9}$$

which is a generalization of the WZ connection (2.10). This is characterized as the unique connection that is invariant under the action (3.6). The associated curvature two-form is then defined as

$$F = \mathrm{d}A + A \wedge A = \mathrm{d}V^\dagger \wedge \mathrm{d}V + V^\dagger \mathrm{d}V \wedge V^\dagger \, \mathrm{d}V = \mathrm{d}V^\dagger \wedge (I_N - VV^\dagger)\mathrm{d}V. \tag{3.10}$$

These manifolds are equipped with Riemannian metrics. We define a metric

$$\|\mathrm{d}V\|^2 = \mathrm{tr}(\mathrm{d}V^\dagger \, \mathrm{d}V) \tag{3.11}$$

for the Stiefel manifold and

$$\|\mathrm{d}P\|^2 = \mathrm{tr}(\mathrm{d}P \, \mathrm{d}P) \tag{3.12}$$

for the Grassmann manifold.

B. The isoholonomic problem

Here we reformulate the WZ holonomy in terms of the geometric terminology introduced above. The state vector $\psi(t) \in \mathbb{C}^N$ evolves according to the Schrödinger equation,

$$i\hbar \frac{\mathrm{d}}{\mathrm{d}t}\psi(t) = H(t)\psi(t). \tag{3.13}$$

The Hamiltonian admits a spectral decomposition,

$$H(t) = \sum_{l=1}^{L} \varepsilon_l(t) P_l(t), \tag{3.14}$$

with projection operators $P_l(t)$. Therefore, the set of energy eigenvalues $(\varepsilon_1, \ldots, \varepsilon_L)$ and orthogonal projectors $(P_1, \ldots, P_L)$ constitutes a complete set of control parameters of the system. Now we concentrate on the eigenspace associated with the lowest energy, which is assumed to be identically zero, $\varepsilon_1 \equiv 0$. We write $P_1(t)$ as $P(t)$ for simplicity. Suppose that the degree of degeneracy $k = \mathrm{tr}\, P(t)$ is constant. For each t, there exists $V(t) \in S_{N,k}(\mathbb{C})$ such that $P(t) = V(t)V^\dagger(t)$. By adiabatic approximation we mean substitution of $\psi(t) \in \mathbb{C}^N$ by a reduced state vector $\phi(t) \in \mathbb{C}^k$ as

$$\psi(t) = V(t)\phi(t). \tag{3.15}$$

Since $H(t)\psi(t) = \varepsilon_1 \psi(t) = 0$, the Schrödinger equation (3.13) becomes

$$\frac{\mathrm{d}\phi}{\mathrm{d}t} + V^\dagger \frac{\mathrm{d}V}{\mathrm{d}t}\phi(t) = 0 \tag{3.16}$$

and its formal solution is written as

$$\phi(t) = \mathcal{P} \exp\left(- \int V^\dagger \, \mathrm{d}V \right) \phi(0). \tag{3.17}$$

Therefore $\psi(t)$ is written as

$$\psi(t) = V(t)\mathcal{P}\exp\left(-\int V^{\dagger}\,\mathrm{d}V\right)V^{\dagger}(0)\psi(0). \tag{3.18}$$

In particular, when the control parameter comes back to the initial point as $P(T)=P(0)$, the holonomy $\Gamma \in \mathrm{U}(k)$ is defined via

$$\psi(T) = V(0)\Gamma\phi(0) \tag{3.19}$$

and it is given explicitly as

$$\Gamma = V(0)^{\dagger}V(T)\mathcal{P}\exp\left(-\int V^{\dagger}\,\mathrm{d}V\right). \tag{3.20}$$

(The definition of the holonomy presented here is slightly different from the one given in the previous Letter.[19] To make correct sense as a unitary gate the holonomy is to be defined in the present form.) If the condition

$$V^{\dagger}\frac{\mathrm{d}V}{\mathrm{d}t} = 0 \tag{3.21}$$

is satisfied, the curve $V(t)$ in $S_{N,k}(\mathbb{C})$ is called a horizontal lift of the curve $P(t)=\pi(V(t))$ in $G_{N,k}(\mathbb{C})$. Then the holonomy (3.20) is reduced to

$$\Gamma = V^{\dagger}(0)V(T) \in \mathrm{U}(k). \tag{3.22}$$

Now we are ready to state the isoholonomic problem in the present context; given a specified unitary gate $U_{\mathrm{gate}} \in \mathrm{U}(k)$ and a fixed point $P_0 \in G_{N,k}(\mathbb{C})$, find the shortest loop $P(t)$ in $G_{N,k}(\mathbb{C})$ with the base points $P(0)=P(T)=P_0$ whose horizontal lift $V(t)$ in $S_{N,k}(\mathbb{C})$ produces a holonomy Γ that coincides with U_{gate}. This problem was first motivated from experimental study of geometric phase and investigated in detail from a mathematician's viewpoint by Montgomery.[1]

We now formulate the isoholonomic problem as a variational problem. The length of the horizontal curve $V(t)$ is evaluated by the functional

$$S[V,\Omega] = \int_0^T \left\{ \mathrm{tr}\left(\frac{\mathrm{d}V^{\dagger}}{\mathrm{d}t}\frac{\mathrm{d}V}{\mathrm{d}t}\right) - \mathrm{tr}\left(\Omega V^{\dagger}\frac{\mathrm{d}V}{\mathrm{d}t}\right)\right\}\mathrm{d}t, \tag{3.23}$$

where $\Omega(t) \in \mathfrak{u}(k)$ is a Lagrange multiplier to impose the horizontal condition (3.21) on the curve $V(t)$. Note that the value of the functional S is equal to the length of the projected curve $P(t)=\pi(V(t))$,

$$S = \int_0^T \frac{1}{2}\mathrm{tr}\left(\frac{\mathrm{d}P}{\mathrm{d}t}\frac{\mathrm{d}P}{\mathrm{d}t}\right)\mathrm{d}t. \tag{3.24}$$

Thus the problem is formulated as follows; find a curve $V(t)$ that attains an extremal value of the functional (3.23) and satisfies the boundary condition (3.22).

C. The solution: horizontal extremal curve

Our task is to find a solution of the variational problem of the functional (3.23). Now we derive the associated Euler–Lagrange equation and solve it explicitly. A variation of the curve $V(t)$ is defined by an arbitrary smooth function $\eta(t) \in \mathfrak{u}(N)$ such that $\eta(0)=\eta(T)=0$ and an infinitesimal parameter $\epsilon \in \mathbb{R}$ as

$$V_{\epsilon}(t) = (1+\epsilon\eta(t))V(t). \tag{3.25}$$

By substituting $V_{\epsilon}(t)$ into (3.23) and differentiating with respect to ϵ, the extremal condition yields

$$0 = \left.\frac{dS}{d\epsilon}\right|_{\epsilon=0} = \int_0^T \mathrm{tr}\{\dot{\eta}(V\dot{V}^\dagger - \dot{V}V^\dagger - V\Omega V^\dagger)\}dt$$
$$= [\mathrm{tr}\{\eta(V\dot{V}^\dagger - \dot{V}V^\dagger - V\Omega V^\dagger)\}]_{t=0}^{t=T} - \int_0^1 \mathrm{tr}\left\{\eta\frac{d}{dt}(V\dot{V}^\dagger - \dot{V}V^\dagger - V\Omega V^\dagger)\right\}dt. \tag{3.26}$$

Thus we obtain the Euler–Lagrange equation

$$\frac{d}{dt}(\dot{V}V^\dagger - V\dot{V}^\dagger + V\Omega V^\dagger) = 0. \tag{3.27}$$

We reproduce the horizontal equation $V^\dagger\dot{V}=0$ from the extremal condition with respect to $\Omega(t)$. Finally, the isoholonomic problem is reduced to the set of equations (3.21) and (3.27), which we call a horizontal extremal equation. It may be regarded as a homogeneous-space version of the Wong equation.[24]

Next, we solve the equations (3.21) and (3.27). The equation (3.27) is integrated to yield

$$\dot{V}V^\dagger - V\dot{V}^\dagger + V\Omega V^\dagger = \mathrm{const} = X \in u(N). \tag{3.28}$$

Conjugation of the horizontal condition (3.21) yields $\dot{V}^\dagger V=0$. Then, by multiplying V on (3.28) from the right we obtain

$$\dot{V} + V\Omega = XV. \tag{3.29}$$

By multiplying $V^\dagger$ on (3.29) from the left we obtain

$$\Omega = V^\dagger XV. \tag{3.30}$$

The equation (3.29) implies $\dot{V}=XV-V\Omega$, and hence the time derivative of $\Omega(t)$ becomes

$$\dot{\Omega} = V^\dagger X\dot{V} + \dot{V}^\dagger XV = V^\dagger X(XV - V\Omega) + (-V^\dagger X + \Omega V^\dagger)XV = [\Omega,\Omega] = 0. \tag{3.31}$$

Therefore, $\Omega(t)$ is actually a constant. Thus the solution of (3.29) and (3.30) is

$$V(t) = e^{tX}V_0e^{-t\Omega}, \quad \Omega = V_0^\dagger XV_0. \tag{3.32}$$

We call this solution the horizontal extremal curve. Then (3.28) becomes

$$(XV - V\Omega)V^\dagger - V(-V^\dagger X + \Omega V^\dagger) + V\Omega V^\dagger = X,$$

which is arranged as

$$X - (VV^\dagger X + XVV^\dagger - VV^\dagger XVV^\dagger) = 0, \tag{3.33}$$

where we used (3.30). We may take, without loss of generality,

$$V_0 = \begin{pmatrix} I_k \\ 0 \end{pmatrix} \in S_{N,k}(\mathbb{C}) \tag{3.34}$$

as the initial point. We can parametrize $X \in \mathfrak{u}(N)$, which satisfies (3.30), as

$$X = \begin{pmatrix} \Omega & W \\ -W^\dagger & Z \end{pmatrix} \tag{3.35}$$

with $W \in M(k,N-k;\mathbb{C})$ and $Z \in \mathfrak{u}(N-k)$. Then the constraint equation (3.33) forces us to choose

$$Z = 0. \tag{3.36}$$

Finally, we obtained a complete set of solution (3.32) of the horizontal extremal equations (3.21) and (3.27). When we take the initial point V_0 as (3.34), the solutions are parametrized by constant matrices $\Omega \in \mathfrak{u}(k)$ and $W \in M(k, N-k; \mathbb{C})$. For definiteness we write down the complete solution

$$V(t) = e^{tX} V_0 e^{-t\Omega}, \quad X = \begin{pmatrix} \Omega & W \\ -W^\dagger & 0 \end{pmatrix}. \tag{3.37}$$

This is one of our main results. We call the matrix X a controller. At this time the holonomy (3.22) is expressed as

$$\Gamma = V^\dagger(0)V(T) = V_0^\dagger e^{TX} V_0 e^{-T\Omega} \in \mathrm{U}(k). \tag{3.38}$$

These results (3.37) and (3.38) have been also given in Montgomery's paper. (In this paper[1] Montgomery cited Bär's theorem to complete the proof. However, Bär's paper being a diploma thesis, it is not widely available. Therefore we took a more direct approach to justify them.) In the present paper we took a different approach from his. Here we wrote down the Euler–Lagrange equation and solved it directly.

We evaluate the length of the extremal curve for later convenience by substituting (3.37) into (3.24) as

$$S = \int_0^T \frac{1}{2} \mathrm{tr}\left(\frac{\mathrm{d}P}{\mathrm{d}t} \frac{\mathrm{d}P}{\mathrm{d}t} \right) \mathrm{d}t = \mathrm{tr}(W^\dagger W) T. \tag{3.39}$$

IV. SOLUTION TO THE INVERSE PROBLEM

Once the solution (3.37) of the horizontal extremal equation is obtained, the remaining problem is to find the matrices Ω and W that satisfy the closed loop condition

$$V(T)V^\dagger(T) = e^{TX} V_0 V_0^\dagger e^{-TX} = V_0 V_0^\dagger \tag{4.1}$$

and the holonomy condition

$$V_0^\dagger V(T) = V_0^\dagger e^{TX} V_0 e^{-T\Omega} = U_{\mathrm{gate}} \tag{4.2}$$

for a specific unitary gate $U_{\mathrm{gate}} \in \mathrm{U}(k)$. Montgomery[1] presented this inverse problem as an open problem. In this section we give a scheme to construct systematically a series of solutions to this problem and in the next section we will apply it to implement various important unitary gates.

A. Equivalence class

There is a class of equivalent solutions with a given initial condition V_0 and a given final condition $V(T) = V_0 U_{\mathrm{gate}}$. Here we clarify the equivalence relation among solutions $\{V(t)\}$ that have the form (3.37) and satisfy (4.1) and (4.2).

We say that two solutions $V(t)$ and $V'(t)$ are equivalent if there are elements $g \in \mathrm{U}(N)$ and $h \in \mathrm{U}(k)$ such that $V(t)$ and

$$V'(t) = gV(t)h^\dagger \tag{4.3}$$

satisfy the same boundary conditions

$$gV_0 h^\dagger = V_0 \tag{4.4}$$

and

$$hU_{\text{gate}}h^{\dagger} = U_{\text{gate}}. \tag{4.5}$$

For the initial point (3.34), the condition (4.4) states that $g \in \mathrm{U}(N)$ must have a block-diagonal form

$$g = \begin{pmatrix} h_1 & 0 \\ 0 & h_2 \end{pmatrix}, \quad h = h_1 \in \mathrm{U}(k), \quad h_2 \in \mathrm{U}(N-k). \tag{4.6}$$

The controller X' of $V'(t)$ are then found from

$$V'(t) = gV(t)h^{\dagger} = ge^{tX}g^{\dagger}gV_0h^{\dagger}he^{-t\Omega}h^{\dagger} = e^{tgXg^{\dagger}}gV_0h^{\dagger}e^{-th\Omega h^{\dagger}} = e^{tgXg^{\dagger}}V_0e^{-th\Omega h^{\dagger}}. \tag{4.7}$$

In summary, two controllers X and X' are equivalent if and only if there are unitary matrices $h_1 \in \mathrm{U}(k)$ and $h_2 \in \mathrm{U}(N-k)$ such that

$$X = \begin{pmatrix} \Omega & W \\ -W^{\dagger} & 0 \end{pmatrix}, \quad X' = \begin{pmatrix} h_1\Omega h_1^{\dagger} & h_1Wh_2^{\dagger} \\ -h_2W^{\dagger}h_1^{\dagger} & 0 \end{pmatrix}, \quad h_1U_{\text{gate}}h_1^{\dagger} = U_{\text{gate}}. \tag{4.8}$$

B. U(1) holonomy

Here we calculate the holonomy for the case $N=2$ and $k=1$. In this case the homogeneous bundle $\pi: S_{2,1}(\mathbb{C}) \to G_{2,1}(\mathbb{C})$ is the Hopf bundle $\pi: S^3 \to S^2$ with the structure group U(1) and the WZ holonomy reduces to the Berry phase. In the subsequent section we will generalize this result to a non-Abelian holonomy. We normalize the cycle time as $T=1$ in the following. Using real numbers $w_1, w_2, w_3 \in \mathbb{R}$ we parametrize the controller as

$$X = \begin{pmatrix} 2iw_3 & iw_1 + w_2 \\ iw_1 - w_2 & 0 \end{pmatrix} = iw_3 I + iw_1\sigma_1 + iw_2\sigma_2 + iw_3\sigma_3, \tag{4.9}$$

where $\{\sigma_j\}$ are the Pauli matrices. Its exponentiation is

$$e^{tX} = e^{itw_3}(I\cos\rho t + i\mathbf{n}\cdot\boldsymbol{\sigma}\sin\rho t), \tag{4.10}$$

where ρ and $\mathbf{n}$ are defined as

$$\rho := \|\mathbf{w}\| = \sqrt{(w_1)^2 + (w_2)^2 + (w_3)^2}, \quad \mathbf{w} = \|\mathbf{w}\|\mathbf{n}. \tag{4.11}$$

The associated horizontal extremal curve (3.32) then becomes

$$V(t) = e^{tX}V_0e^{-t\Omega} = e^{-itw_3}\begin{pmatrix} \cos\rho t + in_3\sin\rho t \\ (in_1 - n_2)\sin\rho t \end{pmatrix} \tag{4.12}$$

and the projected curve in S^2 becomes

$$P(t) = V(t)V^{\dagger}(t) = \tfrac{1}{2}I + \tfrac{1}{2}\boldsymbol{\sigma}\cdot[\mathbf{n}(\mathbf{n}\cdot\mathbf{e}_3) + (\mathbf{e}_3 - \mathbf{n}(\mathbf{n}\cdot\mathbf{e}_3))\cos 2\rho t - (\mathbf{n}\times\mathbf{e}_3)\sin 2\rho t], \tag{4.13}$$

where $\mathbf{e}_3 = (0,0,1)$. We see from (4.13) that the point $P(t)$ in S^2 starts at the north pole $\mathbf{e}_3$ of the sphere and moves along a small circle with the axis $\mathbf{n}$ in the clockwise sense by the angle $2\rho t$. The point $P(t)$ comes back to the north pole when t satisfies $2\rho t = 2\pi n$ with an integer n. To make a closed loop, namely, to satisfy the loop condition (4.1) at $t=T=1$, the control parameters must satisfy

$$\rho = \|\mathbf{w}\| = n\pi \quad (n = \pm 1, \pm 2, \dots). \tag{4.14}$$

Then, the point $P(t)$ travels the same small circle n times during $0 \leqslant t \leqslant 1$. Therefore, the integer n counts the winding number of the loop. At $t=1$, $\cos\rho = (-1)^n$ and the holonomy (4.2) is evaluated as

$$V_0^\dagger e^X V_0 e^{-\Omega} = e^{iw_3}(-1)^n e^{-2iw_3} = e^{-i(w_3 - n\pi)} = U_{\text{gate}} = e^{i\gamma}. \tag{4.15}$$

Thus, to generate the holonomy $U_{\text{gate}} = e^{i\gamma}$, the controller parameters are fixed as

$$w_3 = n\pi - \gamma, \quad w_1 + iw_2 = e^{-i\phi}\sqrt{(n\pi)^2 - (n\pi - \gamma)^2}. \tag{4.16}$$

This is the solution to the inverse problem defined by (4.1) and (4.2). Here the nonvanishing integer n must satisfy $(n\pi)^2 - (n\pi - \gamma)^2 > 0$. The real parameter ϕ is not fixed by the loop condition and the holonomy condition. The phase $h_2 = e^{i\phi}$ parametrizes solutions in an equivalence class as observed in (4.8). The integer n classifies inequivalent classes.

The length of the loop, (3.39), is now evaluated as

$$S = \text{tr}(W^\dagger W)T = (n\pi)^2 - (n\pi - \gamma)^2. \tag{4.17}$$

For a fixed γ in the range $0 \leqslant \gamma < 2\pi$, the simple loop with $n = 1$ is the shortest one among the extremal loops. Thus, we conclude that the controller of $U_{\text{gate}} = e^{i\gamma}$ is

$$X = \begin{pmatrix} 2i(\pi - \gamma) & ie^{i\phi}\sqrt{\pi^2 - (\pi - \gamma)^2} \\ ie^{-i\phi}\sqrt{\pi^2 - (\pi - \gamma)^2} & 0 \end{pmatrix}. \tag{4.18}$$

We call this solution a small circle solution because of its geometric picture mentioned above.

C. U(k) holonomy

Here we give a prescription to construct a controller matrix X that generates a specific unitary gate U_{gate}. In other words, we give a systematic method to solve the inverse problem (4.2). It turns out that the working space should have a dimension $N \geqslant 2k$ to apply our method. In the following we assume that $N = 2k$. The time interval is normalized as $T = 1$ as before.

Our method consists of the following three steps: first, diagonalize the unitary matrix U_{gate} to be implemented; second, construct a diagonal controller matrix by combining small circle solutions; third, undo diagonalization of the controller.

In the first step, we diagonalize a given unitary matrix $U_{\text{gate}} \in \text{U}(k)$ as

$$R^\dagger U_{\text{gate}} R = U_{\text{diag}} = \text{diag}(e^{i\gamma_1}, \ldots, e^{i\gamma_k}) \tag{4.19}$$

with $R \in \text{U}(k)$. Each eigenvalue γ_j is taken in the range $0 \leqslant \gamma_j < 2\pi$. In the second step, we combine single loop solutions associated with the Berry phase to construct two $k \times k$ matrices

$$\Omega_{\text{diag}} = \text{diag}(i\omega_1, \ldots, i\omega_k), \quad \omega_j = 2(\pi - \gamma_j), \tag{4.20}$$

$$W_{\text{diag}} = \text{diag}(i\tau_1, \ldots, i\tau_k), \quad \tau_j = e^{i\phi_j}\sqrt{\pi^2 - (\pi - \gamma_j)^2}. \tag{4.21}$$

Then we obtain a diagonal controller

$$X_{\text{diag}} = \begin{pmatrix} \Omega_{\text{diag}} & W_{\text{diag}} \\ -W_{\text{diag}}^\dagger & 0 \end{pmatrix}.$$

In the third step, we construct the controller X as

$$X = \begin{pmatrix} R & 0 \\ 0 & I_k \end{pmatrix}\begin{pmatrix} \Omega_{\text{diag}} & W_{\text{diag}} \\ -W_{\text{diag}}^\dagger & 0 \end{pmatrix}\begin{pmatrix} R^\dagger & 0 \\ 0 & I_k \end{pmatrix} = \begin{pmatrix} R\Omega_{\text{diag}}R^\dagger & RW_{\text{diag}} \\ -W_{\text{diag}}^\dagger R^\dagger & 0 \end{pmatrix}, \tag{4.22}$$

which is a $2k \times 2k$ matrix. We call the set of equations, (4.19)–(4.22), constructing equations of the controller. This is the main result of this paper.

It is easily verified that the controller X constructed above satisfies the holonomy condition (4.2). The diagonal controller X_{diag} is actually a direct sum of controllers (4.18), which generate Berry phases $\{e^{i\gamma_j}\}$. Hence, its holonomy is also a direct sum of the Berry phases (4.15) as

$$V_0^\dagger e^{X_{\mathrm{diag}}} V_0 e^{-\Omega_{\mathrm{diag}}} = U_{\mathrm{diag}}$$

and hence we have

$$V_0^\dagger e^X V_0 e^{-\Omega} = R V_0^\dagger e^{X_{\mathrm{diag}}} V_0 R^\dagger R e^{-\Omega_{\mathrm{diag}}} R^\dagger = R U_{\mathrm{diag}} R^\dagger = U_{\mathrm{gate}}.$$

V. OPTIMIZING HOLONOMIC QUANTUM COMPUTATION

Now we apply the prescription developed so far to construct controllers of several specific unitary gates, which are fundamental ingredients of quantum computation. Our examples are the Hadamard gate, the CNOT gate, and the two-qubit discrete Fourier transformation (DFT) gate. For each unitary gate U_{gate}, we need to calculate the diagonalizing matrix R. Then the constructing equations of the controller, (4.19)–(4.22), provide the desired optimal controller matrices.

A. Hadamard gate

The Hadamard gate is a one-qubit gate defined as

$$U_{\mathrm{Had}} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}. \tag{5.1}$$

It is diagonalized by

$$R = \begin{pmatrix} \cos\dfrac{\pi}{8} & -\sin\dfrac{\pi}{8} \\ \sin\dfrac{\pi}{8} & \cos\dfrac{\pi}{8} \end{pmatrix} \tag{5.2}$$

as

$$R^\dagger U_{\mathrm{Had}} R = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{5.3}$$

Needless to say,

$$\cos\frac{\pi}{8} = \frac{\sqrt{2+\sqrt{2}}}{2}, \quad \sin\frac{\pi}{8} = \frac{\sqrt{2-\sqrt{2}}}{2}. \tag{5.4}$$

Therefore, we have $\gamma_1 = 0$ and $\gamma_2 = \pi$. We may set $\phi_1 = \phi_2 = 0$. The ingredients of the constructing equations of the controller, (4.19)–(4.22), are calculated as

$$\Omega_{\mathrm{diag}} = \mathrm{diag}(2i\pi, 0), \quad W_{\mathrm{diag}} = \mathrm{diag}(0, i\pi), \tag{5.5}$$

and hence

$$R\Omega_{\mathrm{diag}} R^\dagger = \frac{i\pi}{\sqrt{2}} \begin{pmatrix} \sqrt{2}+1 & 1 \\ 1 & \sqrt{2}-1 \end{pmatrix}, \quad RW_{\mathrm{diag}} = \frac{i\pi}{2} \begin{pmatrix} 0 & -\sqrt{2-\sqrt{2}} \\ 0 & \sqrt{2+\sqrt{2}} \end{pmatrix}. \tag{5.6}$$

Substituting these into (4.22), we obtain the optimal controller of the Hadamard gate.

B. CNOT gate

One of the most important 2-qubit gates is the CNOT gate defined as

$$U_{\mathrm{CNOT}} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}. \tag{5.7}$$

It is diagonalized by

$$R = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2} & 0 & 0 & 0 \\ 0 & \sqrt{2} & 0 & 0 \\ 0 & 0 & 1 & -1 \\ 0 & 0 & 1 & 1 \end{pmatrix} \tag{5.8}$$

as

$$R^{\dagger} U_{\mathrm{CNOT}} R = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \tag{5.9}$$

Therefore, we have $\gamma_1 = \gamma_2 = \gamma_3 = 0$ and $\gamma_4 = \pi$. The ingredients of the controller are

$$\Omega_{\mathrm{diag}} = \mathrm{diag}(2i\pi, 2i\pi, 2i\pi, 0), \quad W_{\mathrm{diag}} = \mathrm{diag}(0, 0, 0, i\pi), \tag{5.10}$$

and hence

$$R\Omega_{\mathrm{diag}}R^{\dagger} = i\pi \begin{pmatrix} 2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix}, \quad RW_{\mathrm{diag}} = \frac{i\pi}{\sqrt{2}} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.11}$$

Substituting these into (4.22), we obtain the optimal controller of the CNOT gate.

C. DFT2 gate

Discrete Fourier transformation (DFT) gates are important in many quantum algorithms including Shor's algorithm for integer factorization. The two-qubit DFT (DFT2) is a unitary transformation

$$U_{\mathrm{DFT2}} = \frac{1}{2} \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & -1 \\ 1 & -i & -1 & i \end{pmatrix}. \tag{5.12}$$

It is diagonalized by

$$R = \frac{1}{2} \begin{pmatrix} 1 & \sqrt{2} & -1 & 0 \\ 1 & 0 & 1 & -\sqrt{2} \\ -1 & \sqrt{2} & 1 & 0 \\ 1 & 0 & 1 & \sqrt{2} \end{pmatrix} \tag{5.13}$$

as

$$R^{\dagger}U_{\mathrm{DFT2}}R=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&i\end{pmatrix}. \tag{5.14}$$

Therefore, we have $\gamma_1=\gamma_2=0$, $\gamma_3=\pi$, and $\gamma_4=\pi/2$. Thus the ingredients of the controller are

$$\Omega_{\mathrm{diag}}=\mathrm{diag}(2i\pi,2i\pi,0,i\pi),\quad W_{\mathrm{diag}}=\mathrm{diag}(0,0,i\pi,i\pi\sqrt{3}/2), \tag{5.15}$$

and hence

$$R\Omega_{\mathrm{diag}}R^{\dagger}=\frac{i\pi}{2}\begin{pmatrix}3&1&1&1\\1&2&-1&0\\1&-1&3&-1\\1&0&-1&2\end{pmatrix},\quad RW_{\mathrm{diag}}=\frac{i\pi}{2}\begin{pmatrix}0&0&-1&0\\0&0&1&-\sqrt{3/2}\\0&0&1&0\\0&0&1&\sqrt{3/2}\end{pmatrix}. \tag{5.16}$$

Substituting these into (4.22), we finally obtain the optimal controller of the DFT2 gate.

VI. SUMMARY AND DISCUSSIONS

Let us summarize our argument. We briefly reviewed the WZ holonomy and discussed that it may be utilizable for implementation of quantum computation. The WZ holonomy is neatly described in terms of differential geometry of a homogeneous bundle, which consists of Stiefel and Grassmann manifolds and is equipped with the canonical connection. We formulated the optimization problem of control in holonomic quantum computation in a form of the isoholonomic problem in the homogenous bundle. We would like to emphasize that it had been left unsolved for more than a decade after the first proposal. We derived a set of equations, (3.21) and (3.27), that characterizes the optimal control and solved it to obtain the horizontal extremal curve (3.37). The curve must satisfy two boundary conditions, (4.1) and (4.2), to be a closed loop in the control manifold and to produce a specified unitary gate as a holonomy. We solved this inverse problem by combining small circle solutions (4.18) to U(1) holonomy into a direct sum. We provided a prescription (4.19)–(4.22) to construct exactly an optimal controller for any unitary gate. Finally we applied our prescription to several important quantum gates.

We would like to discuss prospective development of the results presented above. Although our prescription is applicable to arbitrarily large qubit gates, the homogeneous bundle seems rather over-idealized for practical applications. A realistic quantum system may have smaller control manifold M than the Grassmann manifold. The restricted control manifold M is embedded in the Grassmann manifold by an embedding map $f:M\to G_{N,k}(\mathbb{C})$ and we need to study the isoholonomic problem in the pullbacked bundle $f^{*}S_{N,k}(\mathbb{C})$. Furthermore, the available working Hilbert space in a realistic system may not have dimensions as large as $N\geqslant 2k$. Actually, even when $N<2k$, sequential operations of single loop solutions can generate any unitary gate. However, such a patched solution could not be optimal. These problems will be treated separately in our future publications.

(Received 16 July 2004; accepted 10 September 2004; published online 27 January 2005)

We present and investigate a new class of quantum channels, what we call "universal collective rotation channels," that includes the class of collective rotation channels as a special case. The fixed point set and noise commutant coincide for a channel in this class. Computing the precise structure of this C^*-algebra is a core problem in a particular noiseless subsystem method of quantum error correction. We prove that there is an abundance of noiseless subsystems for every channel in this class and that the Young tableaux combinatorial machine may be used to explicitly compute these subsystems. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1824213]

I. INTRODUCTION

The study of quantum channels is a central theme in quantum computing and quantum information theory.[27] A fundamental class of quantum channels is known as the class of *collective rotation channels*.[3–5,11,12,15,16,18,20,29–35,37] This class has its roots in the postulates of quantum mechanics and has recently played a key role in experimental efforts towards realizing certain quantum error correction methods.[12,33] Of particular interest in the current study is the *noise commutant method of noiseless subsystems*. This is a recently developed paradigm for passive quantum error correction.[10,12,16,19,20,26,36] In this method, the noise commutant is used as a vehicle for encoding states that are left immune to the noise of a given channel. The operator algebras generated by such states are called noiseless subsystems.

In this paper, we present a new class of quantum channels and investigate them in the context of quantum error correction, with specific reference to the noiseless subsystem method. This class is a generalization of the collective rotation class, which arises as an important special case, hence we use the appellation universal collective rotation channels to describe this class. We prove that the noise commutant for every channel in this class has rich structure and hence contains an abundance of noiseless subsystems. To accomplish this, we use operator algebra techniques to make an explicit connection with representation theory of the symmetric group and, as a consequence, the Young tableaux combinatorial machine[13,17] may be used to explicitly compute these noiseless subsystems.

The paper is organized as follows. Section II contains introductory material on quantum channels and quantum error correction. In Sec. III we define and establish basic properties of the class of universal collective rotation (UCR) channels. We make the connection with representation theory of the symmetric group in Sec. IV and show that the noise commutant for UCR channels is determined by a particular representation of the symmetric group. In Secs. V and VI we collect well-known facts from representation theory of the symmetric group, with emphasis on Young tableaux combinatorics, and work through some low-dimensional examples. We finish with a concluding remark in Sec. VII and discuss possible avenues of further research.

II. QUANTUM CHANNELS AND NOISELESS SUBSYSTEMS

Let $\mathcal{H}$ be a (complex) Hilbert space and let $\mathcal{B}(\mathcal{H})$ be the set of bounded operators on $\mathcal{H}$. When a basis for $\mathcal{H}$ is fixed and $\dim \mathcal{H}=k<\infty$, the algebra $\mathcal{B}(\mathcal{H})$ may be identified with the set of all complex $k\times k$ matrices $\mathbb{M}_k=\mathbb{M}_k(\mathbb{C})$. Throughout the paper, if we are given positive integers $n \geqslant 1$ and $d\geqslant 2$, we let $\{|0\rangle,|1\rangle,\ldots,|d-1\rangle\}$ be a fixed orthonormal basis for d-dimensional Hilbert space $\mathcal{H}_d=\mathbb{C}^d$ and let $\{|i_1 i_2\cdots i_n\rangle: i_j\in\mathbb{Z}_d\}$ be the corresponding orthonormal basis for $\mathcal{H}_{d^n}=(\mathbb{C}^d)^{\otimes n}$.

A linear map $\mathcal{E}:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{H})$ is *completely positive* if for all $k\geqslant 1$ the ampliation maps $\mathbb{1}_k\otimes\mathcal{E}:\mathbb{M}_k\otimes\mathcal{B}(\mathcal{H})\to\mathbb{M}_k\otimes\mathcal{B}(\mathcal{H})$ are positive. See Refs. 21 and 28 for introductions to the study of completely positive maps from different perspectives. A *quantum channel* is a map $\mathcal{E}:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{H})$ that is completely positive and trace preserving. Given $\mathcal{E}$, there is (Refs. 7 and 22) a set of *noise operators*, or *errors*, $\{E_k\}$ on $\mathcal{H}$ such that

$$\mathcal{E}(\rho)=\sum_k E_k\rho E_k^\dagger \quad \text{for } \rho\in\mathcal{B}(\mathcal{H}). \tag{1}$$

Trace preservation means that the noise operators satisfy

$$\sum_k E_k^\dagger E_k=\mathbb{1},$$

where $\mathbb{1}$ is the identity operator on $\mathcal{H}$. The channel is unital if also,

$$\mathcal{E}(\mathbb{1})=\sum_k E_k E_k^\dagger=\mathbb{1}.$$

We will denote the fixed point set for $\mathcal{E}$ by

$$\mathrm{Fix}(\mathcal{E})=\{\rho\in\mathcal{B}(\mathcal{H}):\mathcal{E}(\rho)=\rho\}.$$

Further let $\mathcal{A}$ be the algebra generated by $\{E_k\}$ from (1). This is called the *interaction algebra* in quantum computing.[20] It is a relic of the channel in the sense that the same algebra is obtained whatever the choice of noise operators in (1). This is most succinctly seen in the case of a unital channel. In general, $\mathrm{Fix}(\mathcal{E})$ is just a †-closed subspace of $\mathcal{B}(\mathcal{H})$, but in the case of a unital channel $\mathcal{E}$, the so-called *noise commutant*

$$\mathcal{A}'=\{\rho\in\mathcal{B}(\mathcal{H}):\rho E_k=E_k\rho,\ \forall\ k\}$$

coincides with the fixed point set[6,24]

$$\mathrm{Fix}(\mathcal{E})=\mathcal{A}'.$$

In particular, $\mathrm{Fix}(\mathcal{E})=\mathcal{A}'$ is a †-closed operator algebra (a finite dimensional C^*-algebra[1,9,31]). In this case the von Neumann double commutant theorem from operator algebras shows how the algebra $\mathcal{A}=\mathcal{A}''=\mathrm{Fix}(\mathcal{E})'$ only depends on the channel.

Every finite dimensional C^*-algebra is unitarily equivalent to an orthogonal direct sum of ampliated full matrix algebras; i.e., there is a unitary operator U such that

$$U\mathcal{A}U^{\dagger} = \bigoplus_{k=1}^{r} (\mathbb{1}_{m_k} \otimes \mathbb{M}_{n_k}).$$

From the representation theory perspective, a factor $\mathbb{1}_{m_k} \otimes \mathbb{M}_{n_k}$ corresponds to an n_k-dimensional irreducible representation appearing with multiplicity m_k. With this form for $\mathcal{A}$ given, the structure of the commutant up to unitary equivalence is easily computed by

$$U\,\mathrm{Fix}(\mathcal{E})U^{\dagger} = U\mathcal{A}'U^{\dagger} = \bigoplus_{k=1}^{r} (\mathbb{M}_{m_k} \otimes \mathbb{1}_{n_k}). \tag{2}$$

(See Refs. 12,16,18,23,32,34,35 for more detailed discussions in connection with quantum information theory.)

Given a quantum channel $\mathcal{E}$ with noise operators $\{E_k\}$, the structure of the noise commutant $\mathcal{A}'$ can be used to prepare density operators for use in the noiseless subsystem method of error correction. This is a passive method of quantum error correction, in the sense that such operators will remain immune to the effects of the noise of the channel, without active intervention. Thus, computing the precise structure of $\mathcal{A}'$ as in (2) is of fundamental importance in this method. We mention that for experimental reasons,[25] only one matrix algebra $\mathbb{M}_{m_k} \otimes \mathbb{1}_{n_k}$ may be used at a time in this manner. Hence it is also desirable to find the largest full matrix algebra which is a subalgebra of the noise commutant.

III. UNIVERSAL COLLECTIVE ROTATION CHANNELS

For the rest of the paper, given a positive integer $d \geqslant 2$ we write $\mathbb{M}_d$ for the operator algebra $\mathcal{B}(\mathbb{C}^d)$ represented as $d \times d$ complex matrices with respect to the standard basis $\{|0\rangle, \ldots, |d-1\rangle\}$ for $\mathbb{C}^d$. Further let $\mathbb{M}_{d,sa}$ be the subset of self-adjoint matrices inside $\mathbb{M}_d$.

Fix $n \geqslant 1$. Given $1 \leqslant k \leqslant n$ we define a representation of $\mathbb{M}_d$ on $\mathcal{H}_{d^n}$ by

$$\omega_k(x) = \mathbb{1}_d \otimes \cdots \otimes \mathbb{1}_d \otimes \underbrace{x}_{k\text{-th position}} \otimes \mathbb{1}_d \otimes \cdots \otimes \mathbb{1}_d$$

for all $x \in \mathbb{M}_d$. Then we may define sums of independent copies of x by

$$u_n(x) = \sum_{k=1}^{n} \omega_k(x) \quad \text{for } x \in \mathbb{M}_d.$$

Definition 3.1: Given a finite subset $\mathcal{S} \subset \mathbb{M}_{d,sa}$, we define a *universal collective rotation (UCR) channel* $\mathcal{E}_{\mathcal{S}}$ by

$$\mathcal{E}_{\mathcal{S}}(\rho) = \frac{1}{|\mathcal{S}|} \sum_{x \in \mathcal{S}} e^{i\theta_x u_n(x)} \rho\, e^{-i\theta_x u_n(x)} \quad \text{for } \rho \in \mathcal{B}(\mathcal{H}_{d^n}),$$

where $\{\theta_x : x \in \mathcal{S}\}$ are nonzero angles.

Given a set of operators $\mathcal{R}$, define $\mathrm{Alg}\,\mathcal{R}$ to be the operator algebra generated by $\mathcal{R}$. This is the set of all polynomials in the elements of $\mathcal{R}$. When $\mathcal{R}$ is a self-adjoint set, $\mathrm{Alg}\,\mathcal{R}$ is a C^*-algebra. Through a standard functional calculus argument from operator theory, it follows that the interaction algebra $\mathcal{A}_{\mathcal{S}}$ for $\mathcal{E}_{\mathcal{S}}$ is obtained as $\mathcal{A}_{\mathcal{S}} \equiv \mathrm{Alg}\{e^{i\theta_x u_n(x)} : x \in \mathcal{S}\} = \mathrm{Alg}\{u_n(x) : x \in \mathcal{S}\}$. Thus by von Neumann's double-commutant identity we have

$$\mathcal{A}_{\mathcal{S}} = \{e^{i\theta_x u_n(x)} : x \in \mathcal{S}\}'' = \{u_n(x) : x \in \mathcal{S}\}''.$$

Notice that $\mathcal{A}_{\mathcal{S}}$ is independent of the choice of (nonzero) angles θ_x. As an application of the fixed point theorem from Refs. 6 and 24 we obtain the following.

Theorem 3.2: *If $\mathcal{S}$ is a finite subset of $\mathbb{M}_{d,sa}$, then the UCR-channel $\mathcal{E}_{\mathcal{S}}$ satisfies*

$$\mathrm{Fix}(\mathcal{E}_{\mathcal{S}}) = \mathcal{A}_{\mathcal{S}}'.$$

Observe that $\mathbb{1}_d$ belongs to $\mathcal{A}_\mathcal{S}$ from its characterization as a bicommutant. Since $u_n(\mathbb{1}_d) = n\mathbb{1}_{d^n}$, we may always add $\mathbb{1}_d$ to $\mathcal{S}$ without changing the properties of $\mathrm{Fix}(\mathcal{E}_\mathcal{S})$. This motivates the following definition.

Definition 3.3: We will say that $\mathcal{S}$ is *maximal* if $\mathrm{span}\{x : x \in \mathcal{S}\}$ contains all matrices $x \in \mathbb{M}_d$ with $\mathrm{tr}(x) = 0$.

It turns out that for maximal $\mathcal{S}$ the algebra $\mathcal{A}_\mathcal{S}$ is a well-known object in representation theory.

Remark 3.4: To place the class of UCR-channels in context, we note that the UCR-channels for $d=2$ and general n are the class of two-level collective rotation channels from quantum computing.[3–5,11,12,15,16,18,20,32–35,37] The noise operators in this case are also denoted by J_x, J_y, J_z and they arise in quantum mechanics as the canonical representation of the angular momentum relations.[8] From the noiseless subsystem/quantum error correction perspective, the algebra $\mathrm{Fix}(\mathcal{E}_\mathcal{S}) = \mathcal{A}'_\mathcal{S}$ for this subclass of UCR-channels, and natural d-dimensional representations of the J_k operators, has been analyzed in Ref. 16 from an operator theory quantum mechanics point of view.

IV. REPRESENTATION THEORY AND THE NOISE COMMUTANT

In this section we identify the structure of the noise commutant in terms of representation theory for the symmetric group. We begin with some notation. We shall denote the n-fold tensor product of $\mathbb{M}_d$ by

$$\mathbb{M}_d^{\otimes n} = \underbrace{\mathbb{M}_d \otimes \cdots \otimes \mathbb{M}_d}_{n\text{-times}} \cong \mathbb{M}_{d^n}$$

Let $\mathrm{Sym}^n\mathbb{M}_d$ be the subalgebra of $\mathbb{M}_{d^n}$ generated by the symmetric tensor products; that is, $\mathrm{Sym}^n\mathbb{M}_d$ is the algebra generated by the operators

$$\Phi_n(x_1 \otimes \cdots \otimes x_n) = \frac{1}{n!}\sum_{\pi \in S_n} x_{\pi(1)} \otimes \cdots \otimes x_{\pi(n)},$$

where each $x_i \in \mathbb{M}_d$ and S_n is the permutation group on n letters.

In terms of representation theory, we may equally well consider the representation π, $GL(d) \to GL(d^n)$ given by $\pi(u) = u \otimes \cdots \otimes u$, and then we have

$$\mathrm{Sym}^n\mathbb{M}_d = \pi(GL(d))'',$$

where $GL(d)$ is the group of $d \times d$ nonsingular complex matrices. This tensor product representation of $GL(d)$ is in duality with the representation of the symmetric group S_n defined on vector tensors by

$$\pi(\sigma)(h_1 \otimes \cdots \otimes h_n) = h_{\sigma(1)} \otimes \cdots \otimes h_{\sigma(n)},$$

for $\sigma \in S_n$ and $h_1, \ldots, h_n \in \mathcal{H}_d$. In this context, Schur's classical duality theorem reads as follows.

Theorem 4.1: $\pi(S_n)' = \mathrm{Sym}^n\mathbb{M}_d$.

We use the following characterization of $\mathrm{Sym}^n\mathbb{M}_d$ below.

Lemma 4.2: For positive integers d and n, we have

$$\mathrm{Sym}^n\mathbb{M}_d = \{x^{\otimes n} : x \in \mathbb{M}_d\}'' = \{u_n(x) : x \in \mathbb{M}_d\}''.$$

Proof: It is clear that $\mathrm{Sym}^n\mathbb{M}_d$ contains the C^*-algebra,

$$\mathcal{B} = \{x^{\otimes n} : x \in \mathbb{M}_d\}'' = \mathrm{span}\{x^{\otimes n} : x \in \mathbb{M}_d\} = \mathrm{Alg}\{x^{\otimes n} : x \in \mathbb{M}_d\}$$

as a subalgebra. For the converse inclusion, let $x_1, \ldots, x_n \in \mathbb{M}_d$ and consider the complex matrix integral

$$\int_{z_1,\ldots,z_n\in\mathbb{T}} \left(\sum_{j=1}^{n} z_j x_j\right)^{\otimes n} \frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n} = \sum_{j_1,\ldots,j_n=1}^{n} \left(\int_{z_1,\ldots,z_n\in\mathbb{T}} \prod_{r=1}^{n} z_{j_r}\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n}\right)(x_{j_1}\otimes\cdots\otimes x_{j_n})$$

$$= \sum_{j_1,\ldots,j_n=1}^{n} \left(\prod_{s=1}^{n}\int_{z\in\mathbb{T}} z^{|\{r:j_r=s\}|}\frac{dz}{z}\right)(x_{j_1}\otimes\cdots\otimes x_{j_n})$$

$$= (2\pi i)^n \sum_{\pi\in S_n} x_{\pi(1)}\otimes\cdots\otimes x_{\pi(n)},$$

where $\mathbb{T}$ denotes the unit circle in the complex plane. It follows that $\Phi_n(x_1\otimes\cdots\otimes x_n)$ belongs to $\mathcal{B}$ for any choice of $x_1,\ldots,x_n$, and hence $\mathcal{B}$ coincides with $\mathrm{Sym}^n\mathbb{M}_d$.

On the other hand, it is clear by definition that $\mathrm{Sym}^n\mathbb{M}_d$ contains the algebra $\{u_n(x):x\in\mathbb{M}_d\}''$ generated by the $u_n(x)$. Moreover, a consideration of the expansion for $u_n(x)^n$ shows that $x^{\otimes n}$ belongs to this double commutant for all $x\in\mathbb{M}_d$. For the sake of brevity let us observe this fact for $n=2$ and $n=3$,

$$x\otimes x = \frac{1}{2!}(u_2(x)^2 - u_2(x^2)),$$

$$x\otimes x\otimes x = \frac{1}{3!}(u_3(x)^3 - 3u_3(x^2)u_3(x) - 2u_3(x^3)).$$

In fact, for all $x\in\mathbb{M}_d$, the tensor product $x^{\otimes n}$ belongs to the algebra $\mathrm{Alg}\{u_n(x^p):1\leqslant p\leqslant n\}$. Thus the second characterization of $\mathrm{Sym}^n\mathbb{M}_d$ follows. □

Observe that as a consequence of this proof, we also have $\mathrm{Sym}^n\mathbb{M}_d=\{u_n(x):x\in\mathbb{M}_{d,sa}\}''$. We can now explicitly link the noise commutant for these channels with representation theory of the symmetric group.

Theorem 4.3: *Let $\mathcal{S}\subset\mathbb{M}_{d,sa}$ be a maximal system, then*

$$\mathrm{Fix}(\mathcal{E}_{\mathcal{S}}) = \mathcal{A}_{\mathcal{S}}' = \pi(S_n)''.$$

Moreover, for an arbitrary finite set $\mathcal{S}\subset\mathbb{M}_{d,sa}$, we have

$$\mathrm{Fix}(\mathcal{E}_{\mathcal{S}}) \supseteq \pi(S_n)''.$$

Proof: If $\mathcal{S}$ is maximal, then the interaction algebra $\mathrm{Fix}(\mathcal{E}_{\mathcal{S}})'=\mathcal{A}_{\mathcal{S}}=\{u_n(x):x\in\mathcal{S}\}''=\{u_n(x):x\in\mathbb{M}_d\}''$ coincides with $\pi(S_n)'$ by Lemma 4.2. For the second assertion, a given finite subset $\mathcal{S}\subset\mathbb{M}_{d,sa}$ is contained inside a maximal system $\mathcal{S}_{\max}$. Hence $\mathcal{A}_{\mathcal{S}}\subseteq\mathcal{A}_{\mathcal{S}_{\max}}$ and

$$\mathrm{Fix}(\mathcal{E}_{\mathcal{S}}) = \mathcal{A}_{\mathcal{S}}' \supseteq \mathcal{A}_{\mathcal{S}_{\max}}' = \pi(S_n)''.$$

□

V. COMPUTING NOISELESS SUBSYSTEMS VIA YOUNG TABLEAUX

In this section, we collect well-known facts from the representation theory of S_n that allow us to describe $\mathrm{Fix}(\mathcal{E}_{\mathcal{S}})=\pi(S_n)''$ in an explicit manner. Recall that this is imperative for using the structure of the noise commutant to produce noiseless subsystems.

For the discussion in this section, we shall fix positive integers $d\geqslant 2$ and $n\geqslant 2$. Let $\{|0\rangle,\ldots,|d-1\rangle\}$ be the orthonormal basis for $\mathcal{H}_d$ corresponding to a given d-level quantum system, and let

$$\{|i_1 \cdots i_n\rangle : 0 \leqslant i_j < d, 1 \leqslant j \leqslant n\}$$

be the corresponding basis for $\mathcal{H}_{d^n}$. Observe that the set of n-tuples $\{i_1, \ldots, i_n\}$ is in one-to-one correspondence with the set of functions $f:\{1, \ldots, n\} \to \{0, \ldots, d-1\}$. So we may define functions k_l for $0 \leqslant l < d$ by

$$k_l(i_1, \ldots, i_n) = \#\{1 \leqslant j \leqslant n | i_j = l\} \quad \text{for } 0 \leqslant i_j < d,$$

and we have $\Sigma_{l=0}^{d-1} k_l(i_1, \ldots, i_n) = n$.

Now, given positive integers $k_0, \ldots, k_{d-1}$ with each $0 \leqslant k_l \leqslant n$, we define a corresponding subspace of $\mathcal{H}_{d^n}$ by

$$\mathcal{H}_{k_0,\ldots,k_{d-1}} = \text{span}\{|i_1 \cdots i_n\rangle : k_l(i_1, \ldots, i_n) = k_l, 0 \leqslant l < d\}.$$

Notice that $\mathcal{H}_{d^n} = \oplus \mathcal{H}_{k_0,\ldots,k_{d-1}}$, where the direct sum runs over all choices of $k_0, \ldots, k_{d-1}$. Clearly, $\mathcal{H}_{k_0,\ldots,k_{d-1}}$ is an invariant (hence reducing) subspace for the action of the symmetric group S_n. More importantly, the irreducible subspaces, or equivalently the decomposition factors of $\mathcal{H}_{k_0,\ldots,k_{d-1}}$ are completely characterized. The key ingredient in this characterization is the notion of Young tableaux.

Given $\lambda_1 \geqslant \lambda_2 \geqslant \cdots \geqslant \lambda_r$, a nonincreasing sequence of positive integers with $\Sigma_i \lambda_i = n$, set $\lambda = (\lambda_1, \ldots, \lambda_r)$. Then the associated λ-*diagram* is defined as

$$[\lambda] = \{c_{ij} : 1 \leqslant i \leqslant r, 1 \leqslant j \leqslant \lambda_i\},$$

where c_{ij} denotes a cell in $[\lambda]$. Simply put, $[\lambda]$ is a diagram with d rows of cells which are left justified and λ_i cells in the ith row. A λ-*tableau* is a bijective function $t:[\lambda] \to \{1, \ldots, n\}$. Clearly, S_n acts by composition $\sigma t = \sigma \circ t$ on λ-tableaux. Given a λ-tableau, the *column stabilizer* C_t is the subgroup of S_n which leaves the columns of λ setwise fixed. Similarly, the *row stabilizer* R_t is the subgroup of S_n which leaves the rows of λ setwise fixed. Two tableaux t_1 and t_2 are *equivalent* if there exists a permutation $\sigma \in R_{t_1}$ such that $\sigma t_1 = t_2$. In particular, this means that the set of *tabloids* $\text{Tab}_\lambda = \{\{t\} : t \text{ a } \lambda\text{-tableau}\}$ of equivalence classes is indexed by all partitions $(A_1, \ldots, A_r)$ of $\{1, \ldots, n\}$ such that the cardinalities $|A_1| = \lambda_1, \ldots, |A_r| = \lambda_r$. Given a λ-diagram $[\lambda]$, consider the (i,j)-cell c_{ij} in $[\lambda]$. The *hook length* $h(i,j)$ for c_{ij} is the number of cells directly below c_{ij} in the ith column of $[\lambda]$ plus the number of cells to the right of c_{ij} in the ith row of $[\lambda]$ plus one (for the cell c_{ij} itself). Formally,

$$h(i,j) = \lambda_i + \lambda'_j + 1 - i - j,$$

where λ'_j is the number of elements in the jth column. Also recall that a tableau $t:[\lambda] \to \{1, \ldots, n\}$ is *standard* if the numbers increase along rows and increase down columns. The abstract S_n-module that has an orthonormal basis in bijective correspondence with elements of Tab_λ is denoted by M^λ, so that

$$M^\lambda = \text{span}\{e_{\{t\}} : \{t\} \in \text{Tab}_\lambda\}.$$

The *Specht module* $\mathcal{S}^\lambda$ is the submodule of M^λ generated by the polytabloids

$$e_t \equiv \sum_{\sigma \in C_t} (\text{sin } \sigma) e_{\sigma\{t\}} \in M^\lambda.$$

Let us summarize the following facts (see Chap. 7 in Ref. 17).

Theorem 5.1: *Let $k_0, \ldots, k_{d-1}$ be positive integers and consider a partition of $\{1, \ldots, n\}$ into sets $A_0, \ldots, A_{d-1}$ with $|A_l| = k_l$. Let λ be the nonincreasing rearrangement of $(k_0, \ldots, k_{d-1})$. Then $\mathcal{H}_{k_0,\ldots,k_{d-1}}$ is isomorphic as an S_n-module to M^λ.*

Every polytabloid e_t is a cyclic vector for the irreducible module $\mathcal{S}^\lambda$. The dimension of $\mathcal{S}^\lambda$ is given by the hook length formula

$$\dim \mathcal{S}^{\lambda} = \frac{n!}{\prod \text{hook lengths in } |\lambda|},$$

and a basis for $\mathcal{S}^{\lambda}$ *is given by*

$$\{e_t : t \text{ standard } \lambda\text{-tableau}\}.$$

Finally, every finite-dimensional irreducible representation of S_n *is unitarily equivalent to a Specht module representation* π_λ*, where* π_λ *is the representation of* S_n *on* $\mathcal{S}^{\lambda}$ *defined by* $\pi_\lambda(\sigma)e_t \equiv e_{\sigma t}$.

For the next discussion let us fix numbers $(k_0,\ldots,k_{d-1})$ and let us denote by $\mu = (\mu_0,\ldots,\mu_{d-1})$ the nonincreasing rearrangement of $(k_0,\ldots,k_{d-1})$. The S_n-module $\mathcal{H}_{k_0,\ldots,k_{d-1}}$ decomposes into a direct sum of irreducible submodules. Fortunately, these submodules and their multiplicity are completely characterized by Young's rule. Moreover, below we shall describe how the decomposition into irreducible submodules of $\mathcal{H}_{k_0,\ldots,k_{d-1}}$ is related to, and determined by, the decomposition of $\mathcal{H}_\mu \equiv \mathcal{H}_{\mu_0,\ldots,\mu_{d-1}}$. (This allows us to explicitly identify links between irreducible subspaces for the representation π.) Here the key combinatorial tool is the notion of a semistandard tableau.

We generalize the notion of λ-tableau, by saying that $T:[\lambda]\to\mathbb{N}$ is a λ-*tableau of type* $\mu = (\mu_0,\ldots,\mu_{d-1})$ if

$$\#\{c_{ij} : T(c_{ij}) = l\} = \mu_l \quad \text{for } l = 0,\ldots,d-1.$$

Then T is called *semistandard* if the numbers that T assigns to the cells of the diagram determined by λ are nondecreasing along rows and strictly increasing down columns. Let us fix a bijection $t_0:[\lambda]\to\{1,\ldots,n\}$. Then S_n acts on the sets $I(\lambda,\mu)$, the set of λ-tableau of type μ, via

$$\sigma(T) = T\, t_0^{-1}\sigma t_0 \quad \text{for } \sigma \in S_n.$$

Given t_0, we will say that T_1 and T_2 are *row* (*column*) equivalent, and write $T_1 \sim^r_{t_0} T_2$, if $\sigma T_1 = \sigma T_2$ holds for all permutations σ in the row (respectively, column) stabilizer of t_0. In particular, this means that T_1 and T_2 are row equivalent if and only if T_2 is obtained from T_1 by permuting the entries in each row accordingly.

In order to define the linking module maps we first need an appropriate bijection. We denote by $\mathcal{P}_{\mu_0,\ldots,\mu_{d-1}}$ the set of partitions $(A_0,\ldots,A_{d-1})$ of $\{1,\ldots,n\}$ such that $|A_l| = \mu_l$. Then $\mathcal{P}_{\mu_0,\ldots,\mu_{d-1}}$ induces a natural relabeling of the standard basis for $\mathcal{H}_\mu$ by

$$f_{A_0,\ldots,A_{d-1}} = |i_1 \cdots i_n\rangle, \tag{3}$$

where $A_l = \{1 \leqslant j \leqslant n \,|\, i_j = l\}$ for $0 \leqslant l < d$. [Every n-tuple $(i_1,\ldots,i_n)$ is associated with a unique d-tuple of sets $(A_0,\ldots,A_{d-1})$ defined in this way.]

Next we define $\gamma_{t_0}: I(\lambda,\mu) \to \mathcal{P}_{\mu_0,\ldots,\mu_{d-1}}$ by

$$\gamma_{t_0}(T) = (A_0,\ldots,A_{d-1}),$$

where

$$A_l = \{1 \leqslant j \leqslant n \,|\, T\, t_0^{-1}(j) = l\} \quad \text{for } 0 \leqslant l < d.$$

Every λ-tableau T of type μ induces an S_n-module map $\Theta_T: M^\lambda \to M^\mu$ by

$$\Theta_T(e_{\{t_0\}}) = \sum_{T' \sim^r_{t_0} T,\, \gamma_{t_0}(T') = (A_0,\ldots,A_{d-1})} f_{A_0,\ldots,A_{d-1}}.$$

Clearly this extends to an S_n-module homomorphism by defining

$$\Theta_T(e_{\{\sigma(t_0)\}}) = \sigma(\Theta_T(e_{\{t_0\}})).$$

This rather abstract description is in fact very concrete. Given indices $i_1,\ldots,i_n \in \{0,\ldots,d-1\}$ and a λ-tableau $t:|\lambda| \to \{1,\ldots,n\}$ we form the generalized tableau $t_{|i_1\cdots i_n\rangle}:[\lambda] \to \{0,\ldots,d-1\}$ by

$$t_{|i_1\cdots i_n\rangle}(c_{ij}) = i_{t_0(c_{ij})}.$$

This means we write the entries $i_1,\ldots,i_n$ into λ following the order given by t_0. Then we say that

$$(i_1,\ldots,i_n) \sim_{t_0} (i_l',\ldots,i_n')$$

if there exists a permutation $\sigma \in S_n$ such that $i_j' = i_{\sigma(j)}$ for $1 \leqslant j \leqslant n$ and $t_0^{-1}\sigma t_0$ leaves the rows of λ invariant. Therefore, we obtain

$$\Theta_T(e_{\{t_0\}}) = \sum_{(i_1,\ldots,i_n)\sim_{t_0}\gamma_{t_0}(T)} |i_1\cdots i_n\rangle,$$

where here we identify $\gamma_{t_0}(T)$ with the n-tuple determined by the partition $\gamma_{t_0}(T) = (A_0,\ldots,A_{d-1})$ as in (3).

For example, let $d=3, n=5$ and let $t_0:[\lambda] \to \{1,\ldots,5\}$ be given by

$$t_0 = \begin{array}{|c|c|c|c|}\hline 1 & 3 & 2 & 4 \\ \hline 5 \\ \cline{1-1}\end{array}$$

and $T:[\lambda] \to \{0,1,2\}$ be given by

$$T = \begin{array}{|c|c|c|c|}\hline 0 & 0 & 1 & 1 \\ \hline 2 \\ \cline{1-1}\end{array}.$$

This yields, by reading off the entries from the corresponding position in the diagram,

$$\gamma_{t_0}(T) = (A_0,A_1,A_2) = (\{1,3\},\{2,4\},\{5\}).$$

Following (3), $\gamma_{t_0}(T)$ is identified with $(i_1,i_2,i_3,i_4,i_5) = (0,1,0,1,2)$. Moreover, the list of equivalent indices is

$$\{(0,1,0,1,2),(0,1,1,0,2),(0,0,1,1,2),(1,0,0,1,2),(1,0,1,0,2),(1,1,0,0,2)\}.$$

Indeed, according to t_0 we have to fix the fifth coordinate and the other four vary in all possible ways. Thus we have

$$\Theta_T(e_{\{t\}}) = \sum_{(i_1,\ldots,i_n)\sim_t\gamma_t(T)} |i_1\cdots i_n\rangle \quad \text{for } e_{\{t\}} \in M^\lambda.$$

Following Young's rule (see Chap. 2, Ref. 17) we obtain the following.

Theorem 5.2: *Let* $\mu = (k_0^*,\ldots,k_{d-1}^*)$ *be the nonincreasing rearrangement of* $(k_0,\ldots,k_{d-1})$. *Let* $\lambda = (\lambda_1,\ldots,\lambda_r)$ *be such that* $\lambda_1 \geqslant \cdots \geqslant \lambda_r$ *and* $\Sigma_i \lambda_i = n$. *Then*

$$\mathcal{H}^\lambda_{k_0,\ldots,k_{d-1}} \equiv \text{span}\left\{\Theta_T\left(\sum_{\sigma\in C_t}(\text{sgn}\,\sigma)e_{\sigma\{t\}}\right): T \in I(\lambda,\mu), t\ \lambda\text{-tableau}\right\}$$

is an irreducible S_n*-submodule. The restriction of the representation* π *to* $\mathcal{H}^\lambda_{k_0,\ldots,k_{d-1}}$ *is equivalent to the irreducible representation* π_μ *of* S_n *on* S^μ *and has-multiplicity*

$$m = \#\{T: T \text{ semistandard } \lambda\text{-tableau of type } \mu\}.$$

If we collect all this information for all $(k_0,\ldots,k_{d-1})$, we can describe the full representation π of $\mathbb{C}[S_n]$:

Corollary 5.3: Let $\lambda=(\lambda_1,\ldots,\lambda_r)$ *be such that* $\lambda_1\geqslant\cdots\geqslant\lambda_r$ *and* $\Sigma_i\lambda_i=n$, *and let* P_λ *be the projection of* $\mathcal{H}_{d^n}$ *onto*

$$\mathcal{H}^\lambda \equiv \bigoplus_{k_0,\ldots,k_{d-1}} \mathcal{H}^\lambda_{k_0,\ldots,k_{d-1}},$$

where the sum indexes over all $k_0,\ldots,k_{d-1}$ *such that* $\Sigma_{l=0}^{d-1}k_l=n$.

Then P_λ *is the minimal central projection for* $\pi(S_n)''$ *which supports the irreducible submodule* $\mathcal{S}^\lambda$. *Moreover,* $P_\lambda\pi P_\lambda$ *is equivalent to the representation* π_λ *on* $\mathcal{S}^\lambda$ *with multiplicity*

$$m_{\lambda,d}=\sum_{\mu_0\geqslant\cdots\geqslant\mu_{d-1}} \mathrm{Arr}(\mu)\mathrm{SST}(\mu),$$

where

$$\mathrm{Arr}(\mu)=\#\{(k_0,\ldots,k_{d-1}):(k_0^*,\ldots,k_{d-1}^*)=(\mu_0,\ldots,\mu_{d-1})\}$$

and

$$\mathrm{SST}(\mu)=\#\{T:[\lambda]\to\{0,\ldots,d-1\}|T \text{ semistandard } \lambda\text{-tableau of type } \mu\}.$$

In particular, for a maximal system $\mathcal{S}$,

$$\mathrm{Fix}(\mathcal{E}_\mathcal{S})=\mathcal{A}'_\mathcal{S}=\pi(S_n)''\cong\sum_{m_{\lambda,d}\neq 0}\mathbb{M}_{\dim(\mathcal{S}^\lambda)}\otimes\mathbb{1}_{m_{\lambda,d}}$$

describes the representation in irreducible parts with multiplicity.

Corollary 5.4: Let $\mathcal{S}$ *be a maximal system, them* $\mathcal{A}_\mathcal{S}$ *is isomorphic to*

$$\mathcal{A}_\mathcal{S}\cong\sum_{m_{\lambda,d}\neq 0}\mathbb{M}_{m_{\lambda,d}}\otimes\mathbb{1}_{\dim\mathcal{S}^\lambda}$$

and the multiplicity of the component $\mathbb{M}_{m_{\lambda,d}}$ *is given by* $\dim\mathcal{S}^\lambda$.

Let us mention that $\mathcal{H}^\lambda$ may also be described by the so-called Garnier relations. Given $\lambda=(\lambda_1,\ldots,\lambda_r)$, we fix the tableau T_λ such that $T_\lambda(c_{kj})=k$ for all cells c_{kj} in $[\lambda]$. It follows that every index $i=(i_1,\ldots,i_n)$ defines a tableau $T_i:[\lambda]\to\{0,\ldots,d-1\}$ given by $T_i(c_{kj})=i_{T_\lambda(c_{kj})}$. Let $G(J)$ be the collection of coset representatives $\{\nu X:\nu\in Y\}$, where Y is the subgroup of S_n which fixes every element outside both $C_h(T_\lambda)\cup J$ and $Y=X\cap C(T)$. Then as is proved in Ref. 14 (p. 66, 5.2b), $|\psi\rangle\in\mathcal{H}^\lambda$ if and only if

(1) $\langle\psi\|i\rangle=0$ for all i such that T_i has equal entries in two distinct places in the same column,
(2) $\pi(\sigma)(|\psi\rangle)=\mathrm{sgn}(\sigma)|\psi\rangle$ for all σ in the column stabilizer of T_λ,
(3) $\Sigma_{\nu\in G(J)}\mathrm{sgn}(\nu)\pi(\nu^{-1})|\psi\rangle=0$ for any nonempty set in the column stabilizer of $C_{h+1}(T_\lambda)$.

VI. EXAMPLES

A. The case *d*=2 and general *n*

As mentioned above, the case of $d=2$ and general n was extensively examined in Ref. 15. Let us indicate how this can be accomplished with Young tableaux.

When $d=2$, we have the pairs (k_1,k_2) given by $(n-k,k)$ where $k=0,\ldots,n$. In terms of λ-tableau we have to calculate $m_{\lambda,2}$. In terms of types we must only consider diagrams $\mu_k=(n-k,k)$ where $0\leqslant k\leqslant 2n$. But we must be aware that every type allows combinations $(n-k,k)$ and $(k,n-k)$. Given $\lambda=(\lambda_1,\ldots,\lambda_r)$, we observe that to obtain a semistandard tableau, we must have $r=2$. Indeed, we are forced to set 0's in the first row on the first λ_2 positions and 1's in the second

row. Thus for fixed k,j with $2k\leqslant n$ and $2j\leqslant n$, we need $k\leqslant j$ in order to produce a λ-tableau of type μ. Since, we also know that there are $n-k$ 0's, we do not have a choice and we have to put them all in the first row one after another. Thus for a fixed λ, we find

$$m_{(n-j,j),2}=\sum_{k\leqslant j}^{\lfloor n/2\rfloor}2+1=2(\lfloor n/2\rfloor-j)+1$$

if n is even and

$$m_{(n-j,j),2}=2(\lfloor n/2\rfloor-j)$$

if n is odd, where $\lfloor\cdot\rfloor$ denotes the greatest integer part of some number.

We also have to understand $\dim(\mathcal{S}^{\lambda})$. If $\lambda=0$, we get $\dim(\mathcal{S}^{(n,0)})=1$. If $1\leqslant j<n/2$, we see for cells c_{1l} with $l\leqslant j$ the hook length is $1+(n-j+1-i)$. This yields $n(n-2j+1)/j!(n-j+1)!$ and hence

$$\dim(\mathcal{S}^{(n-j,j)})=\begin{cases}1 & \text{if } j=0,\\ \dfrac{n-2j+1}{n+1}\binom{n+1}{j} & \text{if } 1<j\leqslant\dfrac{n}{2}.\end{cases}$$

Let us consider the examples $n=4$ and $n=5$. Then

$$\dim\mathcal{S}^{(4,0)}=1,\quad \dim\mathcal{S}^{(3,1)}=3,\quad \dim\mathcal{S}^{(2,2)}=2$$

and

$$m_{(4,0),2}=5,\quad m_{(3,1),2}=3,\quad m_{(2,2),2}=1.$$

In the case $n=5$, we have

$$\dim\mathcal{S}^{(5,0)}=1,\quad \dim\mathcal{S}^{(4,1)}=4,\quad \dim\mathcal{S}^{(3,2)}=5$$

and

$$m_{(5,0),2}=6,\quad m_{(4,1),2}=4,\quad m_{(3,2),2}=2.$$

Bases for $\mathcal{H}_{2^n}$ which yield the associated algebra decompositions may be computed as well. Below we do this for a more intricate example.

B. The case $d=3$ and $n=4$

If $d=3$ and $n=4$, then the set of λ-diagrams which admit semistandard tableaux is given by

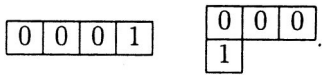
$$\left\{(4)=\begin{array}{|c|c|c|c|}\hline x&x&x&x\\\hline\end{array}\quad (3,1)=\begin{array}{|c|c|c|}\hline x&x&x\\\hline x\\\cline{1-1}\end{array}\quad (2,2)=\begin{array}{|c|c|}\hline x&x\\\hline x&x\\\hline\end{array}\quad (2,1,1)=\begin{array}{|c|c|}\hline x&x\\\hline x\\\cline{1-1}x\\\cline{1-1}\end{array}\right\}.$$

In this case, $(3)\pi(S_4)$ acts on $\mathcal{H}_{d^n}=\mathcal{H}_{81}$. As in Theorem 5.1, $M^{(4)}$ is isomorphic to $\mathcal{H}_{4,0,0},\mathcal{H}_{0,4,0}$, and $\mathcal{H}_{0,0,4}$;$M^{(2,2)}$ is isomorphic to $\mathcal{H}_{2,2,0},\mathcal{H}_{2,0,2}$, and $\mathcal{H}_{0,2,2}$; $M^{(2,1,1)}$ is isomorphic to $\mathcal{H}_{2,1,1},\mathcal{H}_{1,2,1}$, and $\mathcal{H}_{1,1,2}$ etc., so that the multiplicities for the M^{λ} are 3 for $M^{(4)},M^{(2,2)}$ and $M^{(2,1,1)}$ and 6 for $M^{(3,1)}$. The dimensions of the Specht modules $\mathcal{S}^{\lambda}$ using the hook length formula are given by

$$\dim\mathcal{S}^{(4)}=1,\quad \dim\mathcal{S}^{(3,1)}=3,\quad \dim\mathcal{S}^{(2,2)}=2,\quad \dim\mathcal{S}^{(2,1,1)}=3.$$

Now, we have to compute the multiplicities of $\mathcal{S}^{\lambda}$ in M^{μ}. If $\mu=(4)[=(4,0,0)]$, then the only semistandard tableau of type μ is $\lambda=(4)$ with 0 in each cell. Thus $M^{(4)}\cong\mathcal{S}^{(4)}$. Further, every M^{μ}

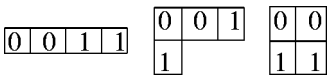
supports a single copy of $\mathcal{S}^{(4)}$ *via* the $\lambda=(4)$-tableau with cell entries given by μ. For $\mu=(3,1)$, the possible semistandard tableaux are



This gives

$$M^{(3,1)} \cong \mathcal{S}^{(4)} \oplus \mathcal{S}^{(3,1)}.$$

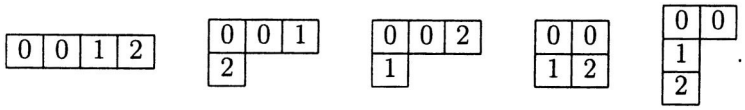
For $\mu=(2,2)$, we have



Thus we obtain

$$M^{(2,2)} \cong \mathcal{S}^{(4)} \oplus \mathcal{S}^{(3,1)} \oplus \mathcal{S}^{(2,2)}.$$

Finally, for $\mu=(2,1,1)$ we find



This means

$$M^{(2,1,1)} \cong \mathcal{S}^{(4)} \oplus (\mathcal{S}^{(3,1)} \otimes \mathbb{1}_2) \oplus \mathcal{S}^{(2,2)} \oplus \mathcal{S}^{(2,1,1)}.$$

Setting this all together, we find the module decomposition of $\pi(S_4)$ is given by

$$\begin{aligned}\pi(S_4) &= (M^{(4)} \otimes \mathbb{1}_3) \oplus (M^{(3,1)} \otimes \mathbb{1}_6) \oplus (M^{(2,2)} \otimes \mathbb{1}_3) \oplus (M^{(2,1,1)} \otimes \mathbb{1}_3) \\ &= (\mathcal{S}^{(4)} \otimes \mathbb{1}_3) \oplus ((\mathcal{S}^{(4)} \oplus \mathcal{S}^{(3,1)}) \otimes \mathbb{1}_6) \qquad (4)\end{aligned}$$

$$\oplus ((\mathcal{S}^{(4)} \oplus \mathcal{S}^{(3,1)} \oplus \mathcal{S}^{(2,2)}) \otimes \mathbb{1}_3) \qquad (5)$$

$$\oplus ((\mathcal{S}^{(4)} \oplus (\mathcal{S}^{(3,1)} \otimes \mathbb{1}_2) \oplus \mathcal{S}^{(2,2)} \oplus \mathcal{S}^{(2,1,1)}) \otimes \mathbb{1}_3) \qquad (6)$$

$$= (\mathcal{S}^{(4)} \otimes \mathbb{1}_{15}) \oplus (\mathcal{S}^{(3,1)} \otimes \mathbb{1}_{15}) \oplus (\mathcal{S}^{(2,2)} \otimes \mathbb{1}_6) \oplus (\mathcal{S}^{(2,1,1)} \otimes \mathbb{1}_3). \qquad (7)$$

The direct sums in (4)–(6) are understood to be linked, as reflected in (7). It now follows that

$$\mathrm{Fix}(\mathcal{E}_{\mathcal{S}}) = \pi(S_4)'' \cong (\mathbb{C} \otimes \mathbb{1}_{15}) \oplus (\mathbb{M}_3 \otimes \mathbb{1}_{15}) \oplus (\mathbb{M}_2 \otimes \mathbb{1}_6) \oplus (\mathbb{M}_3 \otimes \mathbb{1}_3). \qquad (8)$$

Notice also that $\mathbb{M}_3$ is the largest full matrix algebra which can be injected into $\mathrm{Fix}(\mathcal{E}_{\mathcal{S}})$ as a subalgebra.

Let us now describe the bases for the decomposition

$$\begin{aligned}\mathcal{H}_{3^4} = &(\mathcal{H}_{4,0,0} \oplus \mathcal{H}_{0,4,0} \oplus \mathcal{H}_{0,0,4}) \oplus (\mathcal{H}_{2,1,1} \oplus \mathcal{H}_{1,2,1} \oplus \mathcal{H}_{1,1,2}) \\ &\oplus (\mathcal{H}_{3,1,0} \oplus \mathcal{H}_{3,0,1} \oplus \mathcal{H}_{0,3,1} \oplus \mathcal{H}_{1,3,0} \oplus \mathcal{H}_{0,1,3} \oplus \mathcal{H}_{1,0,3})\end{aligned}$$

which yields this algebra decomposition. This is easy for $\lambda=(4)$. Indeed, for every $\mathcal{H}_{k_0,k_1,k_2}$ this is given by the invariant average vector

$$h^{(4)} = \sum_{k_0(i_1,i_2,i_3,i_4)=k_0,\ldots,k_2(i_1,i_2,i_3,i_4)=k_2} |i_1 i_2 i_3 i_4\rangle.$$

In the following we will only discuss the case where $k_0 \geqslant k_1 \geqslant k_2$ (i.e., $\mathcal{H}_{4,0,0}, \mathcal{H}_{3,1,0}, \mathcal{H}_{2,1,1}$). For $\lambda = \mu$, we have a natural embedding $\mathcal{S}^\lambda \subseteq M^\lambda \cong \mathcal{H}_{k_0,k_1,k_2}$ given by

$$h_t = \sum_{\sigma \in C_t} \operatorname{sgn}(\sigma) \sum_{(i_1,\ldots,i_4) \sim_t (i_1^t,\ldots,i_4^t)} |i_1 i_2 i_3 i_4\rangle, \tag{9}$$

for all λ-tableau t of type μ. Let us illustrate this in our examples. If $\lambda = (3,1)$, we have three standard tableaux

$$t_0 = \begin{array}{|c|c|c|}\hline 1 & 2 & 3 \\ \hline 4 \\ \cline{1-1}\end{array} \quad t_1 = \begin{array}{|c|c|c|}\hline 1 & 2 & 4 \\ \hline 3 \\ \cline{1-1}\end{array} \quad t_2 = \begin{array}{|c|c|c|}\hline 1 & 3 & 4 \\ \hline 2 \\ \cline{1-1}\end{array}.$$

The column stabilizer of t_0, t_1, t_2 is $C_{t_0} = \{1, (14)\}, C_{t_1} = \{1, (13)\}, C_{t_2} = \{1, (12)\}$. The space $\mathcal{H}_{(3,1)}$ has the basis

$$|0001\rangle, \quad |0010\rangle, \quad |0100\rangle, \quad |1000\rangle.$$

Now, we define on $\mathcal{H}_{(3,1)}$

$$A_{t_i} = \sum_{\sigma \in C_{t_i}} \operatorname{sgn}(\sigma) \pi(\sigma).$$

The range of A_{t_i} is given by the vectors

$$h_{t_0} = |0001\rangle - |1000\rangle,$$

$$h_{t_1} = |0010\rangle - |1000\rangle,$$

$$h_{t_2} = |0100\rangle - |1000\rangle.$$

This provides us with the basis for

$$M^{(3,1)} \cong \mathcal{H}_{(3,1)} = \operatorname{span}\{h^{(4)}\} \oplus \operatorname{span}\{h_{t_0}, h_{t_1}, h_{t_2}\}.$$

Now, we consider $\mathcal{H}_{(2,2,0)}$ spanned by

$$|0011\rangle, \quad |0110\rangle, \quad |0101\rangle, \quad |1100\rangle, \quad |1010\rangle, \quad |1001\rangle.$$

For $\lambda = (3,1)$ we have the following list of λ-tableaux of type $(2,2)$:

$$\begin{array}{|c|c|c|}\hline 0 & 0 & 1 \\ \hline 1 \\ \cline{1-1}\end{array} \quad \begin{array}{|c|c|c|}\hline 0 & 1 & 1 \\ \hline 0 \\ \cline{1-1}\end{array} \quad \begin{array}{|c|c|c|}\hline 0 & 1 & 0 \\ \hline 1 \\ \cline{1-1}\end{array} \quad \begin{array}{|c|c|c|}\hline 1 & 1 & 0 \\ \hline 0 \\ \cline{1-1}\end{array} \quad \begin{array}{|c|c|c|}\hline 1 & 0 & 1 \\ \hline 0 \\ \cline{1-1}\end{array} \quad \begin{array}{|c|c|c|}\hline 1 & 0 & 0 \\ \hline 1 \\ \cline{1-1}\end{array}.$$

Here we used $t_0 = \begin{array}{|c|c|c|}\hline 1 & 2 & 3 \\ \hline 4 \\ \cline{1-1}\end{array}$. Only the first tableaux is semistandard and yields an injection

$$\Theta \equiv \Theta_{\begin{array}{|c|c|c|}\hline 0 & 0 & 1 \\ \hline 1 \\ \cline{1-1}\end{array}} : \mathcal{S}^{(3,1)} \to \mathcal{H}_{(2,2)}$$

with

$$\Theta(e_{\{t_0\}}) = \sum_{(i_1,\ldots,i_4)\sim_{t_0}(0,0,1,1)} |i_1 i_2 i_3 i_4\rangle.$$

This means

$$\Theta(e_{\{t_0\}}) = |0011\rangle + |0101\rangle + |1001\rangle.$$

(See the example in the last section for $n=5$.) Further, this vector is a cyclic vector for the image of $\mathcal{S}^{(3,1)}$ in $\mathcal{H}_{(2,2)}$. The polytabloid is

$$e_{t_0} = \sum_{\sigma\in C_{t_0}} \mathrm{sgn}(\sigma)\sigma e_{\{t_0\}} = e_{\{t_0\}} - (14)e_{\{t_0\}}.$$

Therefore $\Theta(\mathcal{S}^{(3,1)})$ is the module generated by

$$\Theta(e_{t_0}) = h_{t_0} = |0011\rangle - |1010\rangle + |0101\rangle - |1100\rangle.$$

Equivalently,

$$\Theta(\mathcal{S}^{(3,1)}) = \mathrm{span}\{h_{t_0},(12)h_{t_0},(13)h_{t_0}\} = \mathrm{span}\{|0011\rangle - |1010\rangle + |0101\rangle - |1100\rangle, |1100\rangle - |1001\rangle + |0110\rangle - |0011\rangle, |0110\rangle - |0101\rangle + |1010\rangle - |1001\rangle\}.$$

Another way to find a basis is to consider $t_1=\begin{array}{|c|c|c|}\hline 1&2&4\\\hline 3\\\cline{1-1}\end{array}$. In this case, $C_{t1}=\{1,(13)\}$,

$$\Theta(e_{\{t_1\}}) = |0011\rangle + |0110\rangle + |1010\rangle$$

and

$$h_{t_1} = \Theta(e_{\{t_1\}}) - (13)\Theta(e_{\{t_1\}}) = |0011\rangle - |1001\rangle + |0110\rangle - |1100\rangle.$$

Similarly for $t_2=\begin{array}{|c|c|c|}\hline 1&3&4\\\hline 2\\\cline{1-1}\end{array}$, we have $C_{t1}=\{1,(12)\}$ and

$$\Theta(e_{\{t_2\}}) = |0101\rangle + |0110\rangle + |1100\rangle$$

and

$$h_{t_2} = \Theta(e_{\{t_2\}}) - (12)\Theta(e_{\{t_2\}}) = |0101\rangle - |1001\rangle + |0110\rangle - |1010\rangle.$$

The copy of $\mathcal{S}^{(2,2)}$ in $\mathcal{H}_{(2,2)}$ is again easy to find. We recall that $\mathcal{S}^{(2,2)}$ is spanned by the standard tableaux $\{e_{s_0}, e_{s_1}\}$ where

$$s_0 = \begin{array}{|c|c|}\hline 1&2\\\hline 3&4\\\hline\end{array} \quad s_1 = \begin{array}{|c|c|}\hline 1&3\\\hline 2&4\\\hline\end{array}.$$

The column stabilizers are given by $C_{s_0}=\{1,(13),(24),(13)(24)\}$ and by $C_{s_1}=\{1,(12),(34),(12)\times(34)\}$. This yields operators on $\mathcal{H}_{(2,2)}$,

$$A_{s_0} = 1 - \pi((13)) - \pi((24)) + \pi((13)(24))$$

and

$$A_{s_1} = 1 - \pi((12)) - \pi((34)) + \pi((12)(34)).$$

Applied to the unit vectors, we find the ranges

$$\mathrm{Ran}(A_{s_0}) = |0110\rangle - |1010\rangle - |0101\rangle + |1001\rangle$$

and

$$\mathrm{Ran}(A_{s_1}) = |0011\rangle - |1001\rangle - |0110\rangle + |1100\rangle.$$

Finally, we consider $\mathcal{H}_{(2,1,1)}$ with basis

$$\{|0012\rangle,|0021\rangle,|0102\rangle,|0120\rangle,|0201\rangle,|0210\rangle,|1002\rangle,|1020\rangle,|1200\rangle,|2001\rangle,|2010\rangle,|2100\rangle\}.$$

The representation of $\mathcal{S}^{(4)}$ is one-dimensional, given by the average of all these vectors. There are two copies of $\mathcal{S}^{(3,1)}$ corresponding to the two $(3,1)$-tableaux of type $(2,1,1)$,

$$T = \begin{array}{|c|c|c|}\hline 0 & 0 & 1 \\ \hline 2 \\ \cline{1-1}\end{array} \qquad T' = \begin{array}{|c|c|c|}\hline 0 & 0 & 2 \\ \hline 1 \\ \cline{1-1}\end{array}.$$

The basis for $\mathcal{S}^{(3,1)}$ is given by $\{e_{t_0}, e_{t_1}, e_{t_2}\}$ where

$$t_0 = \begin{array}{|c|c|c|}\hline 1 & 2 & 3 \\ \hline 4 \\ \cline{1-1}\end{array} \quad t_1 = \begin{array}{|c|c|c|}\hline 1 & 2 & 4 \\ \hline 3 \\ \cline{1-1}\end{array} \quad t_2 = \begin{array}{|c|c|c|}\hline 1 & 3 & 4 \\ \hline 2 \\ \cline{1-1}\end{array}.$$

Following the definition of $\Theta_T(e_{t_j})$, we get

$$\gamma_{t_0}(T) = (0,0,1,2), \quad \gamma_{t_1}(T) = (0,0,2,1), \quad \gamma_{t_2}(T) = (0,2,0,1).$$

Using row equivalence, we are allowed to permute the entries $\{1,2,3\}$ for t_0, the entries $\{1,2,4\}$ for t_1 and $\{1,3,4\}$ for t_2 and thus

$$\Theta_T(e_{\{t_0\}}) = |0012\rangle + |0102\rangle + |1002\rangle,$$

$$\Theta_T(e_{\{t_1\}}) = |0021\rangle + |0120\rangle + |1020\rangle,$$

$$\Theta_T(e_{\{t_2\}}) = |0201\rangle + |0210\rangle + |1200\rangle.$$

For t_0, t_1, t_2 we have to apply, respectively, $A_{T,t_0} = \mathbb{1} - \pi(14)$, $A_{T,t_1} = \mathbb{1} - \pi(13)$ and $A_{T,t_2} = \mathbb{1} - \pi(12)$ in order to obtain the image of the polytabloids,

$$h_{T,t_0} = |0012\rangle - |2010\rangle + |0102\rangle - |2100\rangle + |1002\rangle - |2001\rangle,$$

$$h_{T,t_1} = |0021\rangle - |2001\rangle + |0120\rangle - |2100\rangle + |1020\rangle - |2010\rangle,$$

$$h_{T,t_2} = |0201\rangle - |2001\rangle + |0210\rangle - |2010\rangle + |1200\rangle - |2100\rangle.$$

This is our first copy of $\mathcal{S}^{(3,1)}$. For the second, we exercise the same procedure in the case of T',

$$\Theta_{T'}(e_{\{t_0\}}) = |0021\rangle + |0201\rangle + |2001\rangle,$$

$$\Theta_{T'}(e_{\{t_1\}}) = |0012\rangle + |0210\rangle + |2010\rangle,$$

$$\Theta_{T'}(e_{\{t_2\}}) = |0102\rangle + |0120\rangle + |2100\rangle.$$

This provides us with

$$h_{T',t_0} = |0021\rangle - |1020\rangle + |0201\rangle - |1200\rangle + |2001\rangle - |1002\rangle,$$

$$h_{T',t_1} = |0012\rangle - |1002\rangle + |0210\rangle - |1200\rangle + |2010\rangle - |1020\rangle,$$

$$h_{T',t_2} = |0102\rangle - |1002\rangle + |0120\rangle - |1020\rangle + |2100\rangle - |1200\rangle.$$

We have one copy of $\mathcal{S}^{(2,2)}$ which is spanned by

$$s_0 = \begin{array}{|c|c|}\hline 1 & 2 \\ \hline 3 & 4 \\ \hline \end{array} \quad s_1 = \begin{array}{|c|c|}\hline 1 & 3 \\ \hline 2 & 4 \\ \hline \end{array}$$

Our $(2,2)$ tableau of type $(2,1,1)$ is given by $T = \begin{array}{|c|c|}\hline 0 & 0 \\ \hline 1 & 2 \\ \hline \end{array}$. This gives

$$\Theta(e_{\{s_0\}}) = |0012\rangle + |0021\rangle \quad \text{and } \Theta(e_{\{s_1\}}) = |0102\rangle + |0201\rangle.$$

The operator is $1 - \pi(13) - \pi(24) + \pi((13)(24))$, determined by $C_{s_0} = \{1, (13), (24), (13)(24)\}$, and thus

$$h_{s_0} = |0012\rangle - |1002\rangle - |0210\rangle + |1200\rangle + |0021\rangle - |2001\rangle - |0120\rangle + |2100\rangle$$

and similarly for s_1 we apply $1 - \pi(12) - \pi(34) + \pi((12)(34))$ to obtain

$$h_{s_1} = |0102\rangle - |1002\rangle - |0120\rangle + |1020\rangle + |0201\rangle - |2001\rangle - |0210\rangle + |2010\rangle.$$

Finally we consider the copy of $\mathcal{S}^{(2,1,1)}$, which has basis $\{e_{r_0}, e_{r_1}, e_{r_2}\}$ where

$$r_0 = \begin{array}{|c|c|}\hline 1 & 2 \\ \hline 3 \\ \cline{1-1} 4 \\ \cline{1-1} \end{array} \quad r_1 = \begin{array}{|c|c|}\hline 1 & 3 \\ \hline 2 \\ \cline{1-1} 4 \\ \cline{1-1} \end{array} \quad r_2 = \begin{array}{|c|c|}\hline 1 & 4 \\ \hline 2 \\ \cline{1-1} 3 \\ \cline{1-1} \end{array}.$$

Here $T = \begin{array}{|c|c|}\hline 0 & 0 \\ \hline 1 \\ \cline{1-1} 2 \\ \cline{1-1} \end{array}$. This yields

$$\Theta_T(e_{\{r_0\}}) = |0012\rangle, \quad \Theta_T(e_{\{r_1\}}) = |0102\rangle, \quad \Theta_T(e_{\{r_2\}}) = |0120\rangle.$$

The column stabilizer of r_2 is given by all permutations which leave $\{1,2,3\}$ invariant. This yields

$$h_{r_2} = |0120\rangle - |0210\rangle - |1020\rangle + |1200\rangle + |2010\rangle - |2100\rangle.$$

Similarly, we must look for all permutations of $\{1,3,4\}$ in the column stabilizer of r_0 and we obtain

$$h_{r_0} = |0012\rangle - |0021\rangle - |1002\rangle + |1020\rangle + |2001\rangle - |2010\rangle.$$

For the column stabilizer of r_1, we may permute $\{1,2,4\}$ and hence

$$h_{r_1} = |0102\rangle - |0201\rangle - |1002\rangle + |1200\rangle + |2001\rangle - |2100\rangle.$$

By Eq. (8), the largest full matrix algebra $\mathbb{M}_k$ that can be injected into the noise commutant here is $\mathbb{M}_3$, identified with the subalgebras of $\mathcal{A}'_{\mathcal{S}}$ unitarily equivalent to either $\mathbb{1}_{15} \otimes \mathbb{M}_3$ or $\mathbb{1}_3 \otimes \mathbb{M}_3$. Let us explicitly identify the copy of $\mathbb{1}_3 \otimes \mathbb{M}_3$. The set $\{h_{r_0}, h_{r_1}, h_{r_2}\}$ yields the copy of $S^{(2,1,1)}$ inside $\mathcal{H}^{(2,1,1)}$. A similar analysis yields the basis for the copy of $S^{(2,1,1)}$ inside $\mathcal{H}^{(1,2,1)}$. It is generated by $T' = \begin{array}{|c|c|}\hline 0 & 1 \\ \hline 1 \\ \cline{1-1} 2 \\ \cline{1-1} \end{array}$ and in this case

$$\Theta_{T'}(e_{\{r_0\}}) = |0112\rangle + |1012\rangle,$$

$$\Theta_{T'}(e_{\{r_1\}}) = |0112\rangle + |1102\rangle,$$

$$\Theta_{T'}(e_{\{r_2\}}) = |0121\rangle + |1120\rangle.$$

Thus we have

$$h'_{r_0} = |0112\rangle - |0121\rangle - |1102\rangle + |1120\rangle + |2101\rangle - |2110\rangle,$$

$$h'_{r_1} = |0112\rangle - |0211\rangle - |1012\rangle + |1210\rangle + |2011\rangle - |2110\rangle,$$

$$h'_{r_2} = |0121\rangle - |0211\rangle - |1021\rangle + |1201\rangle + |2011\rangle - |2101\rangle.$$

Further, the basis for the copy of $S^{(2,1,1)}$ inside $\mathcal{H}^{(1,1,2)}$ is generated by $T'' = \begin{array}{|c|c|}\hline 0 & 2 \\ \hline 1 \\ \cline{1-1} 2 \\ \cline{1-1} \end{array}$ and in this case

$$\Theta_{T''}(e_{\{r_0\}}) = |0212\rangle + |2012\rangle,$$

$$\Theta_{T''}(e_{\{r_1\}}) = |0122\rangle + |2102\rangle,$$

$$\Theta_{T''}(e_{\{r_2\}}) = |0122\rangle + |2120\rangle.$$

Thus we have

$$h''_{r_0} = |0212\rangle - |0221\rangle - |1202\rangle + |1220\rangle + |2201\rangle - |2210\rangle,$$

$$h''_{r_1} = |0122\rangle - |0221\rangle - |1022\rangle + |1220\rangle + |2021\rangle - |2120\rangle,$$

$$h''_{r_2} = |0122\rangle - |0212\rangle - |1022\rangle + |1202\rangle + |2012\rangle - |2102\rangle.$$

Let $P_{(2,1,1)}$ be the projection of $\mathcal{H}$ onto the span of $\{h_{r_i}, h'_{r_j}, h''_{r_k} : 0 \leqslant i, j, k \leqslant 2\}$. Then $P_{(2,1,1)}$ is a minimal central projection for $\mathcal{A}'_{\mathcal{S}}$ and the compression subalgebra $P_{(2,1,1)}\mathcal{A}'_{\mathcal{S}}P_{(2,1,1)} = \mathcal{A}'_{\mathcal{S}}P_{(2,1,1)} \subset \mathcal{A}'_{\mathcal{S}}$ is unitarily equivalent to $\mathbb{1}_3 \otimes \mathbb{M}_3$. In fact, with respect to the ordered basis

$$\{h_{r_0}, h_{r_1}, h_{r_2}, h'_{r_0}, h'_{r_1}, h'_{r_2}, h''_{r_0}, h''_{r_1}, h''_{r_2}\}$$

for $P_{(2,1,1)}\mathcal{H}$, we have the matrix representations

$$\mathcal{A}'_{\mathcal{S}}P_{(2,1,1)} = \left\{ \begin{pmatrix} A & 0 & 0 \\ 0 & A & 0 \\ 0 & 0 & A \end{pmatrix} : A \in \mathbb{A}_3 \right\}.$$

Note that the subspaces spanned by the sets $\{h_{r_i}\}, \{h'_{r_i}\}$, and $\{h''_{r_i}\}$ are perpendicular, but the vectors within each of these sets do not form an orthogonal basis for the corresponding subspace.

VII. CONCLUSION

We have investigated the operator algebras of fixed points for a class of quantum channels we call universal collective rotation channels $\mathcal{E}_{\mathcal{S}}$. This class includes as a subclass the well-known class of collective rotation channels. We showed that such channels always have an abundance of noiseless subsystems and gave a method for explicitly computing them. In particular, the Young tableaux machine gives a clean approach for this process. In lower dimensional cases (e.g., when $d=2$), our approach is more technical when compared to others in the literature (for instance, Ref. 15). However, an important advantage of the Young tableaux approach for higher dimensional cases is that it is particularly amenable to computations.

An issue we have not pursued here concerns the channels generated by nonmaximal sets $\mathcal{S}$. The d^n-dimensional representations of J_x, J_y, J_z considered in Ref. 15 provide such an example, but we would expect there to be other interesting nontrivial examples of channels $\mathcal{E}_{\mathcal{S}}$ for nonmaximal $\mathcal{S}$. We emphasize that even for nonmaximal $\mathcal{S}$ there is an abundance of noiseless subsystems because $\mathrm{Fix}(\mathcal{E}_{\mathcal{S}})$ contains $\pi(S_n)''$.

We also wonder what other representations of S_n correspond to physically meaningful unital channels, beyond π and its subrepresentations (which correspond to the compressions of UCR-channels). The recent paper[2] of Bacon *et al.*, appears to present further insights into this topic, and also shows how the unitary base change from the standard basis to the basis given by the Young tableaux can be efficiently computed using quantum circuits.

For the radial Dirac equation, a countably additive path space measure on the space of continuous paths living on the real half-line is constructed to give a path integral representation of its Green function. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1829374]

I. INTRODUCTION

In this paper we want to make a mathematical rigorous approach to the path integral for the radial Dirac equation, namely, the radial part of the Dirac equation in spherical coordinates. The equation is given, for $\mathbf{C}^2$-valued functions $\psi(r,t)={}^t(\psi_1(r,t),\psi_2(r,t))$, by

$$\frac{\partial}{\partial t}\psi(r,t) = -i[\tau_k + V(r)]\psi(r,t), \tag{1.1}$$

with a real-valued spherically symmetric potential $V=V(r)$, i.e., a function in the real half-line $\mathbf{R}_+:=(0,\infty)$, where the variables (r,t) lie in radial space–time $\mathbf{R}_+\times\mathbf{R}$. Here τ_k is the free radial Dirac operator with mass m defined for $k=\pm1, \pm2,\ldots$, by

$$\tau_k: f \mapsto \left[\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\frac{\partial}{\partial r} + \begin{pmatrix} m & -k/r \\ -k/r & -m \end{pmatrix}\right]\begin{pmatrix} f_1(r) \\ f_2(r) \end{pmatrix} \tag{1.2a}$$

for suitably smooth $\mathbf{C}^2$-valued functions $f={}^t(f_1,f_2)$ in $\mathbf{R}_+$, in short,

$$\tau_k = -i\sigma_2\frac{\partial}{\partial r} - \sigma_1\frac{k}{r} + m\sigma_3, \tag{1.2b}$$

with the Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The free radial Dirac operator τ_k arises from the spin-angular momentum decomposition of the free Dirac operator in three space dimensions. The nonzero integer k represents an eigenvalue of the "spin–orbit operator" [see Bjorken and Drell (1964), Thaller (1992), Weidmann (1987)].

The operator τ_k is a symmetric operator with domain $D[\tau_k]=C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$ in $L^2(\mathbf{R}_+;\mathbf{C}^2)$. Here $L^2(\mathbf{R}_+;\mathbf{C}^2)$ is the Hilbert space of the $\mathbf{C}^2$-valued square-integrable functions in $\mathbf{R}_+$ with respect to the Lebesgue measure dr, and $C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$ the locally convex space of the $\mathbf{C}^2$-valued C^∞ functions in $\mathbf{R}_+$ with compact support. It has a singularity at $r=0$ as in (1.2a) and (1.2b). This is indeed harmless if we consider it as an operator in the L^2 space, but is a problem to construct a path space measure, for we need to consider it as an operator in the L^∞ space [for this see Ichinose and Tamura (1984, 1987, 1988)]. In this context, in Ichinose and Jefferies (2002), we have made an explicit construction of the free propagator, namely, the integral kernel $\mathcal{K}_t(r,\rho)$ of $e^{-it\tau_k}$ for $k=1$,

a)Electronic mail: ichinose@kappa.s.kanazawa-u.ac.jp

and shown that, though it turns out to be a distribution *of order zero* in the variables $(r,\rho)\in\mathbf{R}_+\times\mathbf{R}_+=\mathbf{R}_+^{\,2}$, there exists no countably additive path space measure to give a path integral representation to the solution of the Cauchy problem for the radial Dirac equation (1.1).

The aim of this paper is to construct a countably additive path space measure to represent by path integral, though not the propagator, the Green function for the radial Dirac equation (1.1). The main idea is to combine our method of constructing a path space measure developed for the one-dimensional Dirac equation in the papers [Ichinose (1982, 1984), Ichinose and Tamura (1984, 1987, 1988)], in particular, in their a little more refined review [Ichinose (1993)], with the following simple but intriguing procedure of dealing with the singularity, which was invented by Duru and Kleinert (1979) and has since been employed by many physicists [see Kleinert (1995, Chaps. 12 and 14), Inomata, Katsuraji, and Gerry (1992, p. 6), Grosche and Steiner (1998, pp. 77–83)] to perform space–time transformations in path integrals.

The free radial Dirac operator τ_k has a singularity at $r=0$. However, if we multiply this operator τ_k by some (non-negative) functions $a(r)$ and $b(r)$ from the left and right sides, respectively, then $a(r)\tau_k b(r)$ becomes no more singular. Let us take $a(r)=b(r)=r^{1/2}$, and set $T_k=r^{1/2}\tau_k r^{1/2}$. Then $-iT_k$ becomes

$$\begin{aligned}-iT_k=-ir^{1/2}\tau_k r^{1/2}&=-\sigma_2 r^{1/2}\left(\frac{\partial}{\partial r}\right)r^{1/2}+i(k\sigma_1-mr\sigma_3)\\&=-i\begin{pmatrix}0&-1\\1&0\end{pmatrix}r^{1/2}\left(\frac{\partial}{\partial r}\right)r^{1/2}+i\begin{pmatrix}-mr&k\\k&mr\end{pmatrix}=:-iT_{k0}-iT_{k1}.\end{aligned}\tag{1.3}$$

We also consider the operator

$$H(k,rV):=T_k+rV(r),\tag{1.4}$$

relevant to the radial Dirac operator in (1.2a) and (1.2b). Then T_k is a symmetric operator with domain $D[T_k]=C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$ in $L^2(\mathbf{R}_+;\mathbf{C}^2)$. For the potentials $V(r)$ we are concerned with, we can show $H(k,rV)$ is essentially self-adjoint on $C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$, as well as T_k. We shall denote their closures or unique selfadjoint extensions again by the same $H(k,rV)$ and T_k.

Then consider, for $H(k,rV)$ instead of $\tau_k+V(r)$, the Cauchy problem

$$\frac{\partial}{\partial t}u(r,t)=-iH(k,rV)u(r,t),\quad u(r,0)=g(r)={}^t(g_1(r),g_2(r))\tag{1.5}$$

for $t\in\mathbf{R}$ or the solution $u(r,t)=(e^{-itH(k,rV)}g)(r)$. Since T_k has no more singularity at $r=0$, we expect to be able to construct a path space measure associated with the semigroup $e^{-itH(k,rV)}$. Since the resolvent is expressed by the Laplace transform of the semigroup, we shall find the following relation between the desired resolvent kernel of τ_k+V and the semigroup $e^{-itH(k,rV)}$, though a little formally expressed:

$$[(\tau_k+V-\lambda)^{-1}](r,\rho)=r^{1/2}[(H(k,rV)-\lambda r)^{-1}](r,\rho)\rho^{1/2}=i\int_0^\infty r^{1/2}e^{-it(H(k,rV)-\lambda r)}\rho^{1/2}\,\mathrm{d}t,$$

for suitable real or complex numbers λ. In this way, we might get, for the original radial Dirac operator $\tau_k+V(r)$, a path integral representation of the resolvent kernel and the Green function if λ might be taken to be zero, though we were unable to find such a representation for the propagator $e^{-it(\tau_k+V)}$ itself.

For the potential $V(x)$, we assume that it is a real-valued function in $\mathbf{R}_+$ such that $V(r)=V_1(r)+V_2(r)$, where $V_1(r)=e/r$ with a real constant e satisfying $|e|\leqslant\sqrt{k^2-\frac{1}{4}}$ and $V_2(r)$ is a locally square-integrable function in $\mathbf{R}_+$ which is bounded near $r=0$.

Note that this class of potentials $V(r)$ contains the Coulomb potential.

In this case it can be shown that the radial Dirac operator τ_k+V in (1.1) is essentially self-adjoint on $C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$. We denote its unique self-adjoint extension in $L^2(\mathbf{R}_+;\mathbf{C}^2)$ also by the same

τ_k+V. Thus this operator has a real spectrum. Further, as to its spectrum, for instance, the following results are known [Weidmann (1987), Thaller (1992, Theorems 4.18, 4.19)]. If $V_2(r):=V_{21}(r)+V_{22}(r)$ satisfies for some $r_0>0$ that $V_{21}\in L^1((r_0,\infty))$ and V_{22} is of bounded variation in $[r_0,\infty)$ with $\lim_{r\to\infty}V_{22}(r)=0$, then the operator τ_k+V has a purely absolutely continuous spectrum in the real line $\mathbf{R}$ outside the closed interval $[-m,m]$. If $V_1(r)$ is absent (i.e., $e=0$) and if $\lim_{r\to\infty}|V_2(r)|=\infty$ and $\int_{r_0}^{\infty}|V_2'(r)/V_2(r)^2|\mathrm{d}r<\infty$ for some $r_0>0$, then τ_k+V has the whole real line $\mathbf{R}$ as a purely absolutely continuous spectrum.

We will show the following path integral representation for the resolvent kernel $[(\tau_k+V\mp i\varepsilon)^{-1}](r,\rho)$ for $\varepsilon>0$ and the Green function for the radial Dirac operator $\tau_k+V(r)$ in (1.1).

The set of all complex 2×2-matrices is denoted by $M_2(\mathbf{C})=\mathbf{C}^2\otimes(\mathbf{C}^2)'$. With $[0,\infty)=\overline{\mathbf{R}_+}$ being the closed real half-line, let $C_{00}^{\infty}([0,\infty)^2;M_2(\mathbf{C}))$ be the locally convex space of the $M_2(\mathbf{C})$-valued C^{∞} functions $M(r,\rho)$ in $[0,\infty)\times[0,\infty)$ which have compact support and whose derivatives $\partial r^m\partial\rho^n M(r,\rho)$, for all non-negative integers m and n, vanish at $(r,0)$ and $(0,\rho)$ for all $r\geqslant0$ and $\rho\geqslant0$. Let $C_{00}^{\infty}([0,\infty)^2;M_2(\mathbf{C}))'$ be its dual space. As $C_0^{\infty}(\mathbf{R}_+{}^2;M_2(\mathbf{C}))$ is a subspace of $C_{00}^{\infty}([0,\infty)^2;M_2(\mathbf{C}))$, so $C_{00}^{\infty}([0,\infty)^2;M_2(\mathbf{C}))'$ is a subspace of the space $\mathcal{D}'(\mathbf{R}_+{}^2;M_2(\mathbf{C}))$ of the $M_2(\mathbf{C})$-valued distributions in $\mathbf{R}_+\times\mathbf{R}_+$. By $(\cdot,\cdot)$ and $\langle\cdot,\cdot\rangle$ we denote, respectively, the sesquilinear and bilinear inner products of a dual pairing.

The main result of this note is the following theorems. The notation $|0,t|$ stands for the interval $0\leqslant s\leqslant t$ or $0\geqslant s\geqslant t$ according as $t>0$ or $t<0$.

Theorem 1.1: *Let $V(r)$ be a potential mentioned above.*

(i) *For every $\varepsilon>0$, there exists a 2×2-matrix distribution-valued, precisely speaking, $C_{00}^{\infty}([0,\infty)^2;M_2(\mathbf{C}))'$-valued, countably additive path space measure $\mu_{t,0}$ on the Banach space $C(|0,t|\to[0,\infty))$ of the continuous paths $R:|0,t|\to[0,\infty)$ such that the resolvent kernel $[(\tau_k+V\mp i\varepsilon)^{-1}](r,\rho)$ for the radial Dirac operator τ_k+V in (1.1) admits a path integral representation: for every pair $(f,g)\in C_{00}^{\infty}([0,\infty);\mathbf{C}^2)\times C_{00}^{\infty}([0,\infty);\mathbf{C}^2)$,*

$$\begin{aligned}(f,(\tau_k+V\mp i\varepsilon)^{-1}g)&=\int_0^{\infty}\int_0^{\infty}{}^t\overline{f(r)}[(\tau_k+V\mp i\varepsilon)^{-1}](r,\rho)g(\rho)\mathrm{d}r\,\mathrm{d}\rho\\&=i\int_0^{\pm\infty}\mathrm{d}t\int_{C(|0,t|\to[0,\infty))}\left\langle{}^t\overline{f(R(t))},\mathrm{d}\mu_{t,0}(R)g(R(0))\right\rangle R(t)^{1/2}R(0)^{1/2}\\&\quad\times\exp\left[-\int_0^t(iV(R(s))R(s)\pm\varepsilon R(s))\mathrm{d}s\right].\end{aligned}\tag{1.6}$$

In particular, the resolvent kernel $[(\tau_k+V\mp i\varepsilon)^{-1}](r,\rho)$ is a distribution of order zero in $\mathbf{R}_+\times\mathbf{R}_+$.

(ii) *The measure $\mu_{t,0}$ is concentrated on the set of the continuous paths $R:|0,t|\to[0,\infty)$ for which there exists a finite partition: $0=t_0\leqq t_1\leqq\cdots\leqq t_{n+1}=t$ of the interval $|0,t|$ such that for $t_{h-1}\leqq s\leqq t_h$, $1\leqslant h\leqslant n+1$,*

$$R(s)=R(0)e^{\pm[\sum_{p=1}^{h-1}(-1)^{p-1}(t_p-t_{p-1})+(-1)^{h-1}(s-t_{h-1})]}.\tag{1.7}$$

Therefore each of these continuous paths $R(\cdot)$ is, for some finite n, an n-vertex piecewise smooth curve in radial space–time, starting from $R(0)$ at time 0 and reaching $R(t)$ at time t, and exponentially growing or decreasing in each partioned short time interval.

We denote by $G_{\pm}(r,\rho)$ the Green function for the radial Dirac operator τ_k+V to be given as the limit of the integral kernel of the resolvent $(\tau_k+V\mp i\varepsilon)^{-1}$ as $\varepsilon\to+0$, if this limit exists.

Theorem 1.2: *For the same potential $V(r)$ as in Theorem 1.1, suppose that 0 is not an eigenvalue of the radial Dirac operator τ_k+V. Suppose that the Green function $G_{\pm}(r,\rho)$ for the radial Dirac operator τ_k+V in (1.1) exists. Then it is a distribution of order zero in $(r,\rho)\in\mathbf{R}_+\times\mathbf{R}_+$, and admits a path integral representation: for every pair $(f,g)\in C_{00}^{\infty}([0,\infty);\mathbf{C}^2)\times C_{00}^{\infty}([0,\infty);\mathbf{C}^2)$,*

(i)

$$\int_0^\infty \int_0^\infty {}^t\overline{f(r)} G_\pm(r,\rho) g(\rho) \mathrm{d}r\, \mathrm{d}\rho = i \lim_{\varepsilon \to +0} \int_0^{\pm\infty} \mathrm{d}t \int_{C(|0,t| \to [0,\infty))} \left\langle {}^t\overline{f(R(t))}, \mathrm{d}\mu_{t,0}(R) g(R(0)) \right\rangle \times R(t)^{1/2} R(0)^{1/2} \exp\left[- \int_0^t (iV(R(s))R(s) \pm \varepsilon R(s)) \mathrm{d}s \right]; \tag{1.8}$$

(ii)

$$\int_0^\infty \int_0^\infty {}^t\overline{f(r)} G_\pm(r,\rho) g(\rho) \mathrm{d}r\, \mathrm{d}\rho = i \lim_{\varepsilon \to +0} \int_0^{\pm\infty} \mathrm{d}t \int_{C(|0,t| \to [0,\infty))} \left\langle {}^t\overline{f(R(t))}, \mathrm{d}\mu_{t,0}(R) g(R(0)) \right\rangle \times R(t)^{1/2} R(0)^{1/2} \exp\left[- i \int_0^t V(R(s))R(s) \mathrm{d}s \mp \varepsilon t \right]. \tag{1.9}$$

If we formally take the delta functions at the two points $r>0$ and $\rho>0$, respectively, for f and g, the formula (1.8)/(1.9) looks like

$$G_\pm(r,\rho) = i \int_0^{\pm\infty} \mathrm{d}t \int_{C(|0,t| \to [0,\infty)), R(0)=\rho, R(t)=r} r^{1/2} \rho^{1/2} \exp\left[- i \int_0^t V(R(s))R(s) \mathrm{d}s \right] \mathrm{d}\mu_{t,0}(R). \tag{1.10}$$

It should be emphasized that our path integral concerns the three-dimensional Dirac equation, though in the spherical coordinates. For the Dirac equation in the one-dimensional space, i.e., the whole real line **R**, a path integral measure to represent the propagator was constructed first in Ichinose (1982, 1984), Ichinose and Tamura (1984) and then further studied in Ichinose and Tamura (1987, 1988) and Ichinose (1993). The problem was treated in Blanchard *et al.* (1985) from a different point of view based on Poisson process, and there are further related works Gaveau (1984), Gaveau *et al.* (1984), Combe, Sirugue, and Sirugue-Collin (1987), and Zastawniak (1988) on the subject. The method used in the present paper is also connected with the Poisson process, though we do not explicitly appeal to it. This paper is only to give the first step to describe the idea, and application to some problem in quantum field theory will be discussed elsewhere.

To prove the theorems, we investigate, in Sec. II, the Cauchy problem (1.5) in the L^∞ norm for the relevant operator to our radial Dirac operator, and also show essential self-adjointness of both the radial Dirac operator (1.2a) and (1.2b) and its relevant operator (1.4). In Sec. III, we construct, by means of the Riesz representation theorem, a countably additive path space measure associated with the semigroup for the Cauchy problem (1.5), on a big space of paths living on the closed real half-line over each finite time interval $[0,t]$. Then it is shown that this measure is in fact concentrated on the set of continuous, piecewise smooth paths with a finite number of vertices in radial space–time. In Sec. IV, we shall show, together with this measure constructed, a path integral representation of Feynman–Kac type first for this semigroup associated with (1.5) and then through the procedure mentioned for the resolvent kernel and the Green function for the radial Dirac operator we are concerned with.

II. THE RADIAL DIRAC OPERATOR AND ITS RELEVANT OPERATOR

To construct our path measure, we need to investigate the Cauchy problems (1.1) for the radial Dirac operator $\tau_k + V$ and (1.5) for its relevant operator $H(k,rV) = r^{1/2}(\tau_k + V)r^{1/2} = T_k + rV$ in (1.4).

For the potential $V(r)$, it is assumed throughout this section that $V(r)$ is a real-valued function in $\mathbf{R}_+$ such that $V(r) = V_1(r) + V_2(r)$, where $V_1(r) = e/r$ with $|e| \leqslant \sqrt{k^2 - \frac{1}{4}}$ and $V_2(r)$ is a function in $L^2_{\mathrm{loc}}(\mathbf{R}_+)$ which is bounded near $r=0$.

We have so far taken for granted that the radial Dirac operator τ_k+V in (1.1) and its relevant operator $H(k,rV)$ in (1.4) are essentially selfadjoint on $C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$. We will confirm these facts here. For some related results on the former τ_k+V, we refer also to Weidmann (1987) and Arnold, Kalf, and Schneider (1997). The L^2-norm in $L^2(\mathbf{R}_+;\mathbf{C}^2)$ is denoted by $\|\cdot\|_2$.

First consider the radial Dirac operator τ_k+V in (1.1). There exists a unique solution of the Cauchy problem (1.1).

Proposition 2.1: The operator τ_k+V is essentially self-adjoint on $C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$.

Proof: Set $D_1:=\tau_k+V_1$, so that $\tau_k+V=D_1+V_2$. It is known by Weidmann (1987), D_1 is essentially self-adjoint on $C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$. So we consider V_2 is a perturbation from D_1. We are going to use the method by Jörgens (1972, Theorem 5.6). To show essential self-adjointness of D_1+V_2, we need to show the following conditions.

(i) For each $\varphi\in C_0^\infty(\mathbf{R}_+)$, the commutator $[D_1,\varphi]=D_1\varphi-\varphi D_1$ is a bounded operator on $L^2(\mathbf{R}_+;\mathbf{C}^2)$.

(ii) For every nonempty bounded open interval $(r_1,r_2)\subseteq\mathbf{R}_+$, there exist constants $a>0$ and $0\leqslant b<1$ such that

$$\|V_2v\|_{L^2((r_1,r_2);\mathbf{C}^2)}\leqslant a\|v\|_2+b\|D_1v\|_2,\quad v\in C_0^\infty(\mathbf{R}_+;\mathbf{C}^2).$$

(iii) Let $\chi(r)$ be a C^∞-function in $\mathbf{R}_+$ with $0\leqslant\chi(r)\leqslant 1$ such that $\chi(r)=1$, $0<r\leqslant 1$ and $\chi(r)=0$, $r\geqslant 2$. Set $\varphi_n(r)=\chi(r/n)$, so that $\varphi_n(r)$ converges to 1 pointwise as $n\to\infty$. Then $\|[D_1,\varphi_n]v+[V_2,\varphi_n]v\|_2$ is bounded for every $v\in D[(D_1+V_2)^*]$.

But these conditions can be checked as follows.

Indeed, (i) is clear because $[D_1,\varphi]=-i\sigma_2\varphi'(r)$.

To see (ii), let (r_1,r_2) be a bounded open interval in $\mathbf{R}_+$. By assumption, $V_2(r)$ is bounded for $r\leqslant r_0$ for some $r_0>0$. First suppose that $r_1\geqslant r_0$, so that $(r_1,r_2)\subseteq(r_0,r_2)$, and V_2 is in $L^2((r_0,r_2))$ as well as in $L^2((r_1,r_2))$. Then for $v\in C_0^\infty(\mathbf{R}_+;\mathbf{C}^2)$, we have by the Schwarz inequality

$$\|V_2v\|_{L^2((r_1,r_2);\mathbf{C}^2)}\leqslant\|V_2v\|_{L^2((r_0,r_2);\mathbf{C}^2)}\leqslant\|V_2\|_{L^2((r_0,r_2)}\sup_{r_0\leqslant r\leqslant r_2}|v(r)|.$$

On the other hand, for every $\varepsilon>0$ there exists a constant $C(\varepsilon)>0$ such that

$$\sup_{r_0\leqslant r\leqslant r_2}|v(r)|\leqslant\varepsilon\|v'\|_{L^2((r_0,\infty);\mathbf{C}^2)}+C(\varepsilon)\|v\|_{L^2((r_0,r_2);\mathbf{C}^2)}.$$

Moreover we have with (1.2b),

$$\begin{aligned}\|v'\|_{L^2((r_0,\infty);\mathbf{C}^2)}&=\left\|-i\sigma_2\frac{\partial}{\partial r}v\right\|_{L^2((r_0,\infty);\mathbf{C}^2)}\\&=\left\|\left[\tau_k+\left(\sigma_1\frac{k}{r}-m\sigma_3\right)\right]v\right\|_{L^2((r_0,\infty);\mathbf{C}^2)}\\&=\left\|\left[D_1+\left(\sigma_1\frac{k}{r}-m\sigma_3\right)-V_1\right]v\right\|_{L^2((r_0,\infty);\mathbf{C}^2)}\\&\leqslant\|D_1v\|_{L^2((r_0,\infty);\mathbf{C}^2)}+\left\|\left(\sigma_1\frac{k}{r}-m\sigma_3\right)v\right\|_{L^2((r_0,\infty);\mathbf{C}^2)}\\&\quad+\|V_1v\|_{L^2((r_0,\infty);\mathbf{C}^2)}\leqslant\|D_1v\|_2+\left(m+\frac{|k|+|e|}{r_0}\right)\|v\|_2.\end{aligned}$$

It follows that

$$\|V_2 v\|_{L^2((r_1,r_2);\mathbf{C}^2)} \leqslant \varepsilon \|V_2\|_{L^2((r_0,r_2))} \|D_1 v\|_2 + \left[\varepsilon \left(m + \frac{|k|+|e|}{r_0} \right) + C(\varepsilon) \right] \|V_2\|_{L^2((r_0,r_2))} \|v\|_2.$$

So choose ε so small that

$$b =: \varepsilon \|V_2\|_{L^2((r_0,r_2))} < 1$$

and then set

$$a := \left[\varepsilon \left(m + \frac{|k|+|e|}{r_0} \right) + C(\varepsilon) \right] \|V_2\|_{L^2((r_0,r_2))}$$

to get (ii). Next suppose $r_1 \leqslant r_0$, so that $(r_1,r_2)=(r_1,r_0] \cup (r_0,r_2)$, though (r_0,r_2) is empty if $r_0 \geqslant r_2$. We need to see (ii) on $(r_1,r_0]$, since we can see similarly to the above on (r_0,r_2). On the interval $(r_1,r_0]$, we have $\|V_2 v\|_{L^2((r_1,r_2);\mathbf{C}^2)} \leqslant \sup_{r_1 \leqslant r \leqslant r_2} |V_2(r)| \|v\|_2$. Thus in either case we have shown (ii).

(iii) holds because $[V_2, \varphi_n]=0$ and

$$\|[D_1, \varphi_n] v\|_2 = \|-i\sigma_2 \varphi_n' v\|_2 \leqslant \frac{1}{n} \sup_{1 \leqslant r \leqslant 2} |\chi'(r)| \|v\|_2$$

for every $v \in L^2(\mathbf{R}_+;\mathbf{C}^2)$. This proves Proposition 2.1.

Next, consider the Cauchy problem for (1.5) with T_k in (1.3) and $V(r) \equiv 0$,

$$\frac{\partial}{\partial t} u(r,t) = -iT_k u(r,t) = \left[-\sigma_2 \left(r \frac{\partial}{\partial r} + \frac{1}{2} \right) + i(k\sigma_1 - mr\sigma_3) \right] u(r,t), \quad u(r,0) = g(r), \tag{2.1}$$

where the initial data $g={}^t(g_1,g_2)$ is a $\mathbf{C}^2$-valued continuous function in $[0,\infty)$ with compact support. This equation is a hyperbolic system with local propagation speed $c(r)=r$. We can easily show that the solution $u(\cdot,t)$ satisfies for every $t \in \mathbf{R}$,

$$\|u(\cdot,t)\|_2 = \|g\|_2. \tag{2.2}$$

Moreover, this Cauchy problem is L^∞ well-posed with the estimate to be given below. It is this fact that plays a crucial role in this paper.

To describe it, set

$$N := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} = \frac{1}{\sqrt{2}} (\sigma_0 + i\sigma_1),$$

where σ_0 is the 2×2-identity matrix. N is a unitary matrix such that $N\sigma_2 N^{-1} = -\sigma_3$. Note also that $N\sigma_1 N^{-1} = \sigma_1$ and $N\sigma_3 N^{-1} = \sigma_2$. Then there exists a unique solution $u(r,t)$ of (2.1), which is given as the solution of the integral equation

$$u(r,t) = (e^{-itT_{k0}} g)(r,t) - i \int_0^t (e^{-i(t-s)T_{k0}} (T_{k1} u)(\cdot,s))(r) \mathrm{d}s. \tag{2.3}$$

Solving the equation (2.3), we shall show the following proposition.

Proposition 2.2: If $g={}^t(g_1,g_2)$ is a $\mathbf{C}^2$-valued continuous function in $[0,\infty)$ with compact support, e.g., support in a bounded closed interval $[0,S]$ for $S>0$, then the solution $u(\cdot,t)$ has support in the bounded interval $[e^{-|t|} \inf \operatorname{supp} g, e^{|t|} \sup \operatorname{supp} g]$, and satisfies

$$\|Nu(\cdot,t)\|_\infty = \|\exp[-itT_k] Ng\|_\infty \leqslant e^{|t|(mSe^{|t|} + |k| + 1/2)} \|Ng\|_\infty. \tag{2.4}$$

Proof: We may assume that $t>0$. With (1.3) in mind, set for notational simplicity

$$A := -iNT_{k0}N^{-1} = \sigma_3 r^{1/2}\left(\frac{\partial}{\partial r}\right)r^{1/2},$$

$$B := -iNT_{k1}N^{-1} = ik\sigma_1 + (-imr)\sigma_2 =: B_1 + B_2, \tag{2.5}$$

$$C := -iNT_kN^{-1} = \sigma_3 r^{1/2}\left(\frac{\partial}{\partial r}\right)r^{1/2} + (ik\sigma_1 - imr\sigma_2) = A + B.$$

Here and in the following, keep in mind that B_2 and hence B are matrices dependent on the variable r.

Then we have $Nu(r,t)=(e^{tC}Ng)(r)$, and (2.3) becomes

$$e^{tC} = e^{tA} + \int_0^t e^{(t-s)A}Be^{sC}\,\mathrm{d}s, \tag{2.6}$$

these operators being applied to Ng. Then for the first term on the right-hand side of (2.6), it is easy to see that, for a $\mathbf{C}^2$-valued continuous $f={}^t(f_1,f_2)$ on $[0,\infty)$ with support in the bounded closed interval $[0,S]$,

$$(e^{tA}f)(r) = E(t/2)\begin{pmatrix} f_1(re^t) \\ f_2(re^{-t}) \end{pmatrix}, \quad E(t) = \begin{pmatrix} e^t & 0 \\ 0 & e^{-t} \end{pmatrix}, \tag{2.7}$$

so that $e^{tA}f$ has support in $[0,e^tS]$. We shall have with $f=Ng$

$$\|e^{tA}Ng\|_\infty \leqslant e^{t/2}\|Ng\|_\infty,$$

$$\|e^{tC}Ng\|_\infty \leqslant e^{t(mSe^t+|k|+1/2)}\|Ng\|_\infty, \tag{2.8}$$

if g is continuous in $[0,\infty)$ and has support in the bounded closed interval $[0,S]$ for $S>0$.

We have only to prove the latter of (2.8), which amounts to the same thing as (2.4). It will be seen from the integral equation (2.6) for e^{tC}. Iteration of the equation (2.6) yields the Dyson series expansion

$$e^{tC} = e^{tA} + \sum_{n=1}^{\infty}\int_0^t \mathrm{d}t_n \int_0^{t_n}\mathrm{d}t_{n-1}\cdots\int_0^{t_2} e^{(t-t_n)A}Be^{(t_n-t_{n-1})A}B\cdots Be^{t_1A}\,\mathrm{d}t_1. \tag{2.9}$$

We shall see below that this expansion, if applied to a $\mathbf{C}^2$-valued bounded continuous function f with support in the bounded interval $[0,S]$, is convegent in the L^∞ norm.

We want to rewrite the integrand of the above n-ple integral in (2.9).

First we observe that, since the Pauli matrices σ_1, σ_2, and σ_3 anticommute with one another, namely, $\sigma_j\sigma_k+\sigma_k\sigma_j=2\delta_{jk}$ for $j,k=1,2,3$, we have with $E(t)$ in (2.7),

$$e^{tA}B_1 = B_1e^{-tA}, \quad e^{tA}B_2 = B_2E(-t)e^{-tA}. \tag{2.10}$$

It follows that

$$e^{tA}B = e^{tA}(B_1+B_2) = [B_1 + B_2E(-t)]e^{-tA}. \tag{2.11}$$

Here we show (2.10). The first equation is seen because $e^{tA}\sigma_1=\sigma_1e^{-tA}$. The second one is because by (2.7),

$$
\begin{aligned}
(e^{tA}B_2f)(r) &= -im(e^{tA}(r\sigma_2 f))(r)\\
&= -im\sigma_2(e^{-tA}(\rho f))(r)\\
&= -im\int_0^\infty \begin{pmatrix} e^{-t/2}\delta(\rho - re^{-t}) & 0\\ 0 & e^{t/2}\delta(\rho - re^{t})\end{pmatrix}\rho\begin{pmatrix} f_1(\rho)\\ f_2(\rho)\end{pmatrix}\mathrm{d}\rho\\
&= -imr\sigma_2\begin{pmatrix} e^{-3t/2}f_1(re^{-t})\\ e^{3t/2}f_2(re^{t})\end{pmatrix} = \left[B_2\begin{pmatrix} e^{-t} & 0\\ 0 & e^{t}\end{pmatrix}e^{-tA}f\right](r) = [B_2E(-t)e^{-tA}f](r).
\end{aligned}
$$

To treat the integrand of the n-ple integral on the right-hand side of (2.9), we set $\Delta t_j = t_j - t_{j-1}$ with $t_{n+1}=t$ and $t_0=0$. Then we have

$$
\begin{aligned}
e^{\Delta t_{n+1}A}Be^{\Delta t_nA}B\cdots Be^{\Delta t_1A} &= [B_1 + B_2E(-\Delta t_{n+1})]e^{-\Delta t_{n+1}A}e^{\Delta t_nA}B\cdots Be^{\Delta t_1A}\\
&= [B_1 + B_2E(-\Delta t_{n+1})]e^{-(\Delta t_{n+1}-\Delta t_n)A}B\cdots Be^{\Delta t_1A}\\
&= [B_1 + B_2E(-\Delta t_{n+1})][B_1 + B_2E(\Delta t_{n+1}-\Delta t_n)]e^{(\Delta t_{n+1}-\Delta t_n+\Delta t_{n-1})A}B\cdots Be^{\Delta t_1A}\\
&= \prod_{p=2}^{\overleftarrow{n+1}}\left[B_1 + B_2E\left((-1)^p\sum_{q=p}^{n+1}(-1)^{q-1}\Delta t_q\right)\right]e^{\sum_{h=1}^{n+1}(-1)^{h-1}\Delta t_hA}, \qquad (2.12)
\end{aligned}
$$

where $\overleftarrow{\prod}_{p=2}^{n+1}M_p = M_{n+1}M_n\cdots M_2$. Hence the expansion (2.9) becomes

$$
\begin{aligned}
e^{tC} = e^{tA} + \sum_{n=1}^{\infty}\int_0^t \mathrm{d}t_n\int_0^{t_n}\mathrm{d}t_{n-1}\cdots\int_0^{t_2}\mathrm{d}t_1 \times \prod_{p=2}^{\overleftarrow{n+1}}\left[B_1 + B_2E\left((-1)^p\sum_{q=p}^{n+1}(-1)^{q-1}\Delta t_q\right)\right]\\
\times\exp\left[\left(\sum_{h=1}^{n+1}(-1)^{h-1}\Delta t_h\right)A\right] =: \sum_{n=0}^{\infty}C_n(t). \qquad (2.13)
\end{aligned}
$$

For $C_n(t)$ in the expansion (2.13) we have the following lemma.

Lemma 2.3: (i) *The integral kernel* $C_n(t)(r,\rho)$ *of* $C_n(t)$ *has support on the set of* $(r,\rho)\in[0,\infty)\times[0,\infty)$ *with* $\rho = re^{\pm[\sum_{h=1}^{n+1}(-1)^{h-1}\Delta t_h]}$.

(ii) *If* $f(r) = {}^t(f_1(r), f_2(r))$ *is continuous in* $[0,\infty)$ *and has support in* $[0,S]$, *each* $C_n(t)f$ *has support in the bounded interval* $[e^{-|t|}\inf\mathrm{supp}\, f, e^{|t|}\sup\mathrm{supp}\, f]$. *It holds that*

$$
\|C_n(t)f\|_\infty \leqslant \frac{(mSe^{|t|}+|k|)^n}{n!}|t|^n e^{|t|/2}\|f\|_\infty. \qquad (2.14)
$$

Proof of Lemma 2.3: We may assume that $t>0$. Note by (2.7) that the integral kernel of e^{tA} is given by

$$
e^{tA}(r,\rho) = \begin{pmatrix} e^{t/2}\delta(\rho - re^{t}) & 0\\ 0 & e^{-t/2}\delta(\rho - re^{-t})\end{pmatrix} = E(t/2)\begin{pmatrix} \delta(\rho - re^{t}) & 0\\ 0 & \delta(\rho - re^{-t})\end{pmatrix}, \qquad (2.15)
$$

so that the integral kernel of $e^{-itT_{k0}} \equiv N^{-1}e^{tA}N$ becomes

$$
K_0(t;r,\rho) = N^{-1}\begin{pmatrix} e^{t/2}\delta(\rho - re^{t}) & 0\\ 0 & e^{-t/2}\delta(\rho - re^{-t})\end{pmatrix}N = N^{-1}E(t/2)\begin{pmatrix} \delta(\rho - re^{t}) & 0\\ 0 & \delta(\rho - re^{-t})\end{pmatrix}N. \qquad (2.16)
$$

By (2.15) with the expression of $C_n(t)$ in (2.13), we have the assertion (i) and the first half of (ii), because $|\Sigma_{h=1}^{n+1}(-1)^{h-1}\Delta t_h| \leqslant \Sigma_{h=1}^{n+1}(t_h - t_{h-1}) = t$.

Now we show the second half of (ii). We can show for $n\geqslant 1$,

$$\|C_n(t)f\|_\infty \leqslant \int_0^t \mathrm{d}t_n \int_0^{t_n} \mathrm{d}t_{n-1} \cdots \int_0^{t_2} \mathrm{d}t_1 \left\| \overleftarrow{\prod_{p=2}^{n+1}} \left[B_1 + B_2 E\left((-1)^p \sum_{q=p}^{n+1} (-1)^{q-1} \Delta t_q \right) \right] \right.$$
$$\left. \times \exp\left[\left(\sum_{h=1}^{n+1} (-1)^{h-1} \Delta t_h \right) A \right] f \right\|_\infty$$
$$= \int_0^t \mathrm{d}t_n \int_0^{t_n} \mathrm{d}t_{n-1} \cdots \int_0^{t_2} \mathrm{d}t_1 \sup_{r>0} \left\| \overleftarrow{\prod_{p=2}^{n+1}} \left[B_1 + B_2(r) E\left((-1)^p \sum_{q=p}^{n+1} (-1)^{q-1} \Delta t_q \right) \right] \right.$$
$$\left. \times E\left(\frac{1}{2} \sum_{h=1}^{n+1} (-1)^{h-1} \Delta t_h \right) \begin{pmatrix} f_1(re^{\sum_{h=1}^{n+1}(-1)^{h-1}\Delta t_h}) \\ f_2(re^{-\sum_{h=1}^{n+1}(-1)^{h-1}\Delta t_h}) \end{pmatrix} \right\|_{\ell^\infty} \leqslant \frac{(mSe^t + |k|)^n}{n!} t^n e^{t/2} \|f\|_\infty. \tag{2.17}$$

Here the ℓ^∞-norm of a vector $z = {}^t(z_1, z_2) \in \mathbf{C}^2$ is denoted by $\|z\|_{\ell^\infty} = \max\{|z_1|, |z_2|\}$, and we have used

$$\left\| \overleftarrow{\prod_{p=2}^{n+1}} \left[B_1 + B_2 E\left((-1)^p \sum_{q=p}^{n+1} (-1)^{q-1} \Delta t_q \right) \right] \right\| \leqslant (|k| + mre^t)^n, \tag{2.18}$$

and $|\Sigma_{h=1}^{n+1}(-1)^{h-1}\Delta t_h| \leqslant t$ and $\|B_1 + B_2 E((-1)^p \Sigma_{q=p}^{n+1}(-1)^{q-1}\Delta t_q)\| \leqslant |k| + mre^t$. This proves (2.14), ending the proof of Lemma 2.3.

Now we are in a position to finish the proof of Proposition 2.2. By Lemma 2.3, (2.14), we can conclude the expansion (2.9) or (2.13) is convergent in L^∞ norm, which yields the latter half of (2.8) or the estimate (2.4), as well as the support property of the solution $u(\cdot, t)$. This completes the proof of Proposition 2.2.

Proposition 2.4: Let $W(r) = rV(r)$ with $V(r)$ as in Proposition 2.1. Then the operator $H(k, W) = T_k + W(r)$ in (1.4) *(as well as T_k alone) is essentially self-adjoint on $C_0^\infty(\mathbf{R}_+; \mathbf{C}^2)$.*

Proof: We use the method of "invariance of domain" by Chernoff (1973, 1977).

In order to make the notations clearer, inside this proof, we denote the closure of the symmetric operator $H(k, W)$ with domain $C_0^\infty(\mathbf{R}_+; \mathbf{C}^2)$ by $\widetilde{H}(k, W)$. $\widetilde{H}(k, W)$ is also symmetric, and evidently its domain $D[\widetilde{H}(k, W)]$ includes the space $C_0^\infty(\mathbf{R}_+; \mathbf{C}^2)$.

To show that $H(k, W)$ is essentially selfadjoint on $C_0^\infty(\mathbf{R}_+; \mathbf{C}^2)$ or its closure $\widetilde{H}(k, W)$ is self-adjoint, we need to prove that if $\phi \in D[H(k, W)^*]$ satisfies $H(k, W)^* \phi = \pm i\phi$, then $\phi = 0$. Consider the case $H(k, W)^* \phi = -i\phi$. This means that ϕ is in $L^2(\mathbf{R}_+; \mathbf{C}^2)$ and, in view of (1.3), as a distribution

$$0 = H(k, W)^* \phi + i\phi = -i\sigma_2 \left(r\frac{\partial}{\partial r} + \frac{1}{2} \right) \phi + T_{k1}\phi + W(r)\phi + i\phi.$$

Let $\mathcal{D}$ be the subspace of the members of $D[\widetilde{H}(k, W)]$ with compact support in $\mathbf{R}_+$, so that $C_0^\infty(\mathbf{R}_+; \mathbf{C}^2) \subseteq \mathcal{D}$. Take any g in $\mathcal{D}$ and consider the Cauchy problem for $\widetilde{H}(k, W)$,

$$\frac{\partial}{\partial t} u(r, t) = -i\widetilde{H}(k, W) u(r, t), \quad u(r, 0) = g(r). \tag{2.19}$$

Taken into account that $\widetilde{H}(k, W) \subseteq H(k, W)^* = \widetilde{H}(k, W)^*$, this means in view of (1.2b) and (1.3) that the solution $u(r, t)$ in $D[\widetilde{H}(k, W)]$ and so in $L^2(\mathbf{R}_+; \mathbf{C}^2)$ satisfies, as a distribution, the differential equation

$$\frac{\partial}{\partial t}u(r,t) = -i\left[-i\sigma_2\left(r\frac{\partial}{\partial r}+\frac{1}{2}\right)+(-k\sigma_1+mr\sigma_3)+W(r)\right)u(r,t).$$

Then by the analogous arguments used to prove Lemma 2.3, we can see that there exists a unique solution $u(\cdot,t)$ of (2.19), which belongs to the space $\mathcal{D}$. In the same reason as we saw (2.2), we also have $\|u(\cdot,t)\|_2=\|g\|_2$ in L^2-norm.

Set $F(t)=(\phi,u(\cdot,t))$. Then $F(t)$ is bounded in $t\in\mathbf{R}$, because

$$|F(t)|\leqslant\|\phi\|_2\|u(\cdot,t)\|_2=\|\phi\|_2\|g\|_2.$$

Since $H(k,W)^*=\tilde{H}(k,W)^*$, we find by differentiating in t,

$$F'(t)=(\phi,-i\tilde{H}(k,W)u(\cdot,t))=(H(k,W)^*\phi,-iu(\cdot,t))=(\phi,u(\cdot,t))=F(t).$$

It follows that $F(t)=F(0)e^t$. Since $F(t)$ is bounded, we must have $F(0)=0$, that is, $(\phi,g)=0$. Since $\mathcal{D}$ is dense, we can conclude that $\phi=0$. A similar argument can be made for the case $H(k,W)^*\phi=i\phi$. This proves Proposition 2.4.

III. CONSTRUCTION OF THE PATH SPACE MEASURE

We consider only the case $t>0$; the case $t<0$ will be treated similarly. We want to construct our path space measure $\mu_{t,0}$ on the space of the one-dimensional continuous paths $R:[0,t]\to[0,\infty)$ living on the closed half-line $[0,\infty)=\overline{\mathbf{R}_+}$, by modifying the method Nelson (1964) used to construct the Wiener measure. The argument will go analogously with that employed in Ichinose and Tamura (1987, 1988), in particular, in Ichinose (1993) for the Dirac equation in one-dimensional space $\mathbf{R}$.

We write the integral kernel of the unitary group $e^{-itT_k}\equiv N^{-1}e^{tC}N$ with generator (1.3) or (2.5) as $K(t;r,\rho):=e^{-itT_k}(r,\rho)$.

Though in this paper we have meant $\mathbf{R}_+=(0,\infty)$, the open real half-line, we will denote by $\dot{\mathbf{R}}_+=[0,\infty)\cup\{\infty\}$ the one-point compactification of the closed half-line $[0,\infty)$. For each fixed $t>0$ let $\mathcal{R}_{t,0}=\Pi_{[0,t]}\dot{\mathbf{R}}_+=(\dot{\mathbf{R}}_+)^{[0,t]}$ be the uncountably many copies of $\dot{\mathbf{R}}_+$. By the Tychonoff theorem $\mathcal{R}_{t,0}$ is a compact Hausdorff space in the product topology. It may be regarded as the space of all paths $R:[0,t]\to\dot{\mathbf{R}}_+$, possibly discontinuous and possibly passing through zero and/or the infinity ∞. Let $C(\mathcal{R}_{t,0})$ be the Banach space of the complex-valued continuous functions on $\mathcal{R}_{t,0}$ with the maximum norm $\|\cdot\|$, and $C_{\mathrm{fin}}(\mathcal{R}_{t,0})$ the subspace of those Ψ in $C(\mathcal{R}_{t,0})$ for which there exist a finite partition of the interval $[0,t]$,

$$0=s_0<s_1<\cdots<s_\ell=t, \tag{3.1}$$

and a complex-valued bounded continuous function $F(x_0,x_1,\ldots,x_\ell)$ on $(\dot{\mathbf{R}}_+)^{\ell+1}$ such that

$$\Psi(R)=F(R(s_0),R(s_1),\ldots,R(s_\ell)). \tag{3.2}$$

Define, for each fixed $t>0$, a functional $L_{t,0}(\Psi;f,g)$ which is linear in $\Psi\in C_{\mathrm{fin}}(\mathcal{R}_{t,0})$ and sesquilinear in $(f,g)\in C_{00}^\infty([0,\infty);\mathbf{C}^2)\times C_{00}^\infty([0,\infty);\mathbf{C}^2)$, $f={}^t(f_1,f_2)$, $g={}^t(g_1,g_2)$, by

$$\begin{aligned}L_{t,0}(\Psi;f,g)=&\int_0^\infty dr_\ell\int_0^\infty dr_{\ell-1}\cdots\int_0^\infty dr_0\,{}^t\overline{f(r_\ell)}K(s_\ell-s_{\ell-1};r_\ell,r_{\ell-1})\\&\times K(s_{\ell-1}-s_{\ell-2};r_{\ell-1},r_{\ell-2})\cdots K(s_1-s_0;r_1,r_0)F(r_0,r_1,\ldots,r_\ell)g(r_0).\end{aligned} \tag{3.3}$$

The integral on the right-hand side of this equation is equal to

$$\int_0^\infty \mathrm{d}r_\ell \int_0^\infty \mathrm{d}r_{\ell-1} \cdots \int_0^\infty \mathrm{d}r_0 \, {}^t\overline{Nf(r_\ell)}(NK(s_\ell - s_{\ell-1}; r_\ell, r_{\ell-1})N^{-1})$$
$$\times (NK(s_{\ell-1} - s_{\ell-2}; r_{\ell-1}, r_{\ell-2})N^{-1}) \cdots (NK(s_1 - s_0; r_1, r_0)N^{-1})$$
$$\times F(r_0, r_1, \ldots, r_\ell) N g(r_0).$$

Therefore (3.3) can also be written by definition of e^{tC} as

$$L_{t,0}(\Psi; f, g) = \int_0^\infty \int_0^\infty {}^t\overline{Nf(r_\ell)} e^{\Delta s_\ell C} e^{\Delta s_{\ell-1} C} \cdots e^{\Delta s_1 C} F(r_0, \ldots, r_{\ell-1}, r_\ell) N g(r_0) \mathrm{d}r_\ell \, \mathrm{d}r_0, \tag{3.4}$$
$$\Delta s_j = s_j - s_{j-1}, \quad 1 \leqslant j \leqslant \ell,$$

where $e^{\Delta s_j C}$ is a linear operator with kernel $NK(s_j - s_{j-1}; r_j, r_{j-1})N^{-1}$ transforming functions of r_{j-1} to functions of r_j. Substituting e^{tC} in (2.13) with t replaced by Δs_j into (3.4), we get

$$L_{t,0}(\Psi; f, g) = \sum_{n=0}^\infty \sum_{n_1 + \cdots + n_\ell = n} \int_0^\infty \int_0^\infty {}^t\overline{Nf(r_\ell)} C_{n_\ell}(\Delta s_\ell) \cdots C_{n_2}(\Delta s_2) C_{n_1}(\Delta s_1)$$
$$\times [F(r_0, r_1, \ldots, r_\ell) N g(r_0)] \mathrm{d}r_\ell \, \mathrm{d}r_0 =: \sum_{n=0}^\infty L_{t,0}^n(\Psi; f, g). \tag{3.5}$$

To construct the measure $\mu_{t,0}$ on $\mathcal{R}_{t,0}$, the following lemma is of crucial importance.

Lemma 3.1: (i) *For each* $t > 0$, $L_{t,0}(\Psi; f, g)$ *and* $L_{t,0}^n(\Psi; f, g)$ *are independent of the choice of* F *corresponding to* $\Psi \in C_{\mathrm{fin}}(\mathcal{R}_{t,0})$.

(ii) *If one of* f *and* g *in* $C_{00}^\infty([0, \infty); \mathbf{C}^2)$ *has support in the bounded interval* $[0, S]$, *then the following inequalities hold*:

$$|L_{t,0}(\Psi; f, g)| \leqslant \|N\|_1 \|N\|_\infty e^{t(mSe^t + |k| + 1/2)} \|\Psi\| \|f\|_1 \|g\|_\infty, \tag{3.6}$$

$$|L_{t,0}^n(\Psi; f, g)| \leqslant \|N\|_1 \|N\|_\infty \frac{(mSe^t + |k|)^n}{n!} t^n e^{t/2} \|\Psi\| \|f\|_1 \|g\|_\infty, \tag{3.7}$$

for all $n = 0, 1, 2 \ldots$. *Here* $\|N\|_1$ *and* $\|N\|_\infty$ *are the norms of the unitary matrix* N, *respectively, as a linear operator on* $\mathbf{C}^2$ *with* ℓ^1*-norm and* ℓ^∞*-norm, which are less than or equal to* $\sqrt{2}$.

Proof: The first assertion (i) is due to the semigroup property of e^{-itT_k} or e^{tC}. The proof of the second one (ii) will make use of the inequality for $C_{n_j}(\Delta s_j)$ to be obtained from (2.14) with n_j, Δs_j in place of n, t to get

$$|L_{t,0}^n(\Psi; f, g)| \leqslant \sum_{n_1 + \cdots + n_\ell = n} \prod_{p=1}^\ell \left[\frac{(mSe^{\Delta s_p} + |k|)^{n_p}}{n_p!} (\Delta s_p)^{n_p} e^{\Delta s_p / 2} \right] \|F\|_\infty \|Nf\|_1 \|Ng\|_\infty$$
$$\leqslant (mSe^t + |k|)^n \frac{\left(\sum_{p=1}^\ell \Delta s_p \right)^n}{n!} e^{(1/2) \Sigma_{q=1}^\ell \Delta s_q} \|F\|_\infty \|Nf\|_1 \|Ng\|_\infty$$
$$= \frac{(mSe^t + |k|)^n}{n!} t^n e^{t/2} \|\Psi\| \|Nf\|_1 \|Ng\|_\infty.$$

Here we have used that for $1 \leqslant j \leqslant \ell$, $\Delta s_j \leqslant \Sigma_{p=1}^\ell \Delta s_p = t$, and that

$$\sum_{n_1+\cdots+n_\ell=n} \frac{(\Delta s_1)^{n_1}(\Delta s_2)^{n_2}\cdots(\Delta s_\ell)^{n_\ell}}{n_1!n_2!\cdots n_\ell!} = \frac{\left(\sum_{p=1}^{\ell}\Delta s_p\right)^n}{n!} = \frac{t^n}{n!}.$$

Since $\|Nf\|_1 \leqq \|N\|_1\|f\|_1$ and $\|Ng\|_\infty \leqq \|N\|_\infty\|g\|_\infty$, this yields (3.7). Hence by summing up, we also obtain (3.6) from (3.5). This proves Lemma 3.1.

A consequence of this lemma is the following. Since $C_{\mathrm{fin}}(\mathcal{R}_{t,0})$ is dense in $C(\mathcal{R}_{t,0})$ by the Stone–Weierstrass theorem, the inequalities (3.6) and (3.7) are also valid for all $\Psi \in C(\mathcal{R}_{t,0})$. This means that for each fixed pair (f,g), $L_{t,0}(\cdot;f,g)$ and $L^n_{t,0}(\cdot;f,g)$ are complex-valued continuous linear functional on $C(\mathcal{R}_{t,0})$. By the Riesz representation theorem, there exist complex-valued regular Borel measures $\mu_{t,0;f,g}$ and $\mu^n_{t,0;f,g}$ on $\mathcal{R}_{t,0}$ for all $n=0,1,2,\ldots$, such that for all $\Psi \in C(\mathcal{R}_{t,0})$,

$$L_{t,0}(\Psi;f,g) = \int_{\mathcal{R}_{t,0}} \mathrm{d}\mu_{t,0;f,g}(R)\Psi(R), \tag{3.8}$$

$$L^n_{t,0}(\Psi;f,g) = \int_{\mathcal{R}_{t,0}} \mathrm{d}\mu^n_{t,0;f,g}(R)\Psi(R). \tag{3.9}$$

Hence, since the left-hand sides of (3.8) and (3.9) are continuous sesquilinear forms in (f,g) in the product space $C^\infty_{00}([0,\infty);\mathbf{C}^2)\times C^\infty_{00}([0,\infty);\mathbf{C}^2)$, we can also see, with $M_2(\mathbf{C})$ being the set of all 2×2-matrices, that there exist 2×2-matrix distribution-valued, precisely, $C^\infty_{00}([0,\infty)^2;M_2(\mathbf{C}))'$-valued, regular Borel measures $\mu_{t,0}(\cdot)$ and $\mu^n_{t,0}(\cdot)$ on $\mathcal{R}_{t,0}$ such that for every pair $(f,g)\in C^\infty_{00}([0,\infty);\mathbf{C}^2)\times C^\infty_{00}([0,\infty);\mathbf{C}^2)$,

$$\langle \overline{{}^t f}, \mu_{t,0}(\cdot)g\rangle = \mu_{t,0;f,g}(\cdot), \tag{3.10}$$

$$\langle \overline{{}^t f}, \mu^n_{t,0}(\cdot)g\rangle = \mu^n_{t,0;f,g}(\cdot). \tag{3.11}$$

Here we note that we have

$$C^\infty_{00}([0,\infty)^2;M_2(\mathbf{C})) = C^\infty_{00}([0,\infty);\mathbf{C}^2)\hat{\otimes} C^\infty_{00}([0,\infty);\mathbf{C}^2),$$

and the space of the continuous sesquilinear forms on the product space $C^\infty_{00}([0,\infty);\mathbf{C}^2)\times C^\infty_{00}([0,\infty);\mathbf{C}^2)$ coincides with the dual space

$$C^\infty_{00}([0,\infty)^2;M_2(\mathbf{C}))' = C^\infty_{00}([0,\infty);\mathbf{C}^2)'\hat{\otimes} C^\infty_{00}([0,\infty);\mathbf{C}^2)'.$$

Here the tensor products on the right-hand side are completed in the π- or ε-tensor product topology, because $C^\infty_{00}([0,\infty);\mathbf{C}^2)$ and $C^\infty_{00}([0,\infty);\mathbf{C}^2)'$ are nuclear spaces, since they are subspaces of the nuclear spaces $C^\infty_0(\mathbf{R};\mathbf{C}^2)$ and $\mathcal{D}'(\mathbf{R};\mathbf{C}^2)$, respectively [e.g., Pietsch (1970, Chaps. 5, 6), Trèves (1967, Chap. 50)].

It follows from the expansion (3.5) that

$$\mu_{t,0;f,g}(\cdot) = \sum_{n=0}^{\infty} \mu^n_{t,0;f,g}(\cdot) \tag{3.12}$$

in the sense of the expansion of the measure or

$$\mu_{t,0}(\cdot) = \sum_{n=0}^{\infty} \mu^n_{t,0}(\cdot) \tag{3.13}$$

in the sense of the expansion of the 2×2-matrix distribution-valued measure.

Finally we shall observe on which set of the paths the measures $\mu_{t,0}$ and $\mu^n_{t,0}$ are concentrated.

Lemma 3.2: For each $n=0,1,2,\ldots$, *the measure* $\mu^n_{t,0}$ *is concentrated on the set of the continuous, exactly n-vertex piecewise smooth paths* $R:[0,t]\to[0,\infty)$, *in fact, with each of their segments being a particular smooth curve such that for an n-partition:* $0=t_0<t_1<\cdots<t_{n+1}=t$ *of the interval* $[0,t]$ *and for* $t_{h-1}\leqslant s\leqslant t_h$, $1\leqslant h\leqslant n+1$,

$$R(s)=R(0)e^{\pm[\Sigma_{p=1}^{h-1}(-1)^{p-1}(t_p-t_{p-1})+(-1)^{h-1}(s-t_{h-1})]}.$$

Therefore in each n-partitioned short interval (t_{p-1},t_p) *each segement is exponentially growing or decreasing.*

Consequently, the measure $\mu_{t,0}$ *is concentrated on the union of these sets of paths on which the* $\mu^n_{t,0}$ *are concentrated.*

Proof: This basically follows from the very expression (2.15) and (2.16) that the integral kernel of e^{tA} or $e^{-itT_{k0}}$ has. Inspecting through the expression of $C_{n_j}(\Delta s_j)$ in (2.13) with n_j, Δs_j in place of n, t what is the support of the integral kernel of $C_{n_j}(\Delta s_j)$, we shall be able to see through $L^n_{t,0}(\Psi;f,g)$ and $L_{t,0}(\Psi;f,g)$ in (3.5) the statement of this lemma.

We will sketch how it goes. We must investigate what the product operator

$$C_{n_\ell}(\Delta s_\ell)\cdots C_{n_2}(\Delta s_2)C_{n_1}(\Delta s_1)$$

in the integrand in the second member of (3.5) is. This operator corresponds to the partition (3.1) of the interval $[0,t]$. Each factor $C_{n_j}(\Delta s_j)$, $1\leqslant j\leqslant\ell$, is, as seen from the nth term the expansion (2.9)/(2.13), an n_j-ple integral with n_j, Δs_j in place of n, t, and with n_j integration variables $t_{j,q}$ (in place of t_q), moving in the n_j-plex,

$$s_{j-1}\equiv t_{j,0}\leqslant t_{j,1}\leqslant\cdots\leqslant t_{j,n_j}\leqslant t_{j,n_j+1}\equiv s_j. \tag{3.14}$$

Then we have from (2.13), with $\Delta t_{j,q}:=t_{j,q}-t_{j,q-1}$, $1\leqslant q\leqslant n_j+1$,

$$\begin{aligned}
&C_{n_\ell}(\Delta s_\ell)\cdots C_{n_2}(\Delta s_2)C_{n_1}(\Delta s_1)\\
&=\int_{s_{\ell-1}}^{s_\ell}\int_{s_{\ell-1}}^{t_{\ell,n_\ell}}\cdots\int_{s_{\ell-1}}^{t_{\ell,2}}\mathrm{d}t_{\ell,n_\ell}\,\mathrm{d}t_{\ell,n_\ell-1}\cdots\mathrm{d}t_{\ell,1}\int_{s_{\ell-2}}^{s_{\ell-1}}\int_{s_{\ell-2}}^{t_{\ell-1,n_{\ell-1}-1}}\cdots\\
&\quad\times\int_{s_{\ell-2}}^{t_{\ell-1,2}}\mathrm{d}t_{\ell-1,n_{\ell-1}}\,\mathrm{d}t_{\ell-1,n_{\ell-1}-1}\cdots\mathrm{d}t_{\ell-1,1}\cdots\times\int_{s_1}^{s_2}\int_{s_1}^{t_{2,n_2}}\cdots\\
&\quad\times\int_{s_1}^{t_{2,2}}\mathrm{d}t_{2,n_2}\,\mathrm{d}t_{2,n_2-1}\cdots\mathrm{d}t_{2,1}\int_{s_0}^{s_1}\int_{s_0}^{t_{1,n_1}}\cdots\int_{s_0}^{t_{2,2}}\mathrm{d}t_{1,n_1}\,\mathrm{d}t_{1,n_1-1}\cdots\mathrm{d}t_{1,1}\\
&\quad\times\overleftarrow{\prod_{p_\ell=2}^{n_\ell+1}}\left[B_1+B_2E\left((-1)^{p_\ell}\sum_{q=p_\ell}^{n_\ell+1}(-1)^{q-1}\Delta t_{\ell,q}\right)\right]\exp\left[\left(\sum_{h=1}^{n_\ell+1}(-1)^{h-1}\Delta t_{\ell,h}\right)A\right]\\
&\quad\times\overleftarrow{\prod_{p_{\ell-1}=2}^{n_{\ell-1}+1}}\left[B_1+B_2E\left((-1)^{p_{\ell-1}}\sum_{q=p_{\ell-1}}^{n_{\ell-1}+1}(-1)^{q-1}\Delta t_{\ell-1,q}\right)\right]\exp\left[\left(\sum_{h=1}^{n_{\ell-1}+1}(-1)^{h-1}\Delta t_{\ell-1,h}\right)A\right]\times\cdots\\
&\quad\times\overleftarrow{\prod_{p_2=2}^{n_2+1}}\left[B_1+B_2E\left((-1)^{p_2}\sum_{q=p_2}^{n_2+1}(-1)^{q-1}\Delta t_{2,q}\right)\right]\exp\left[\left(\sum_{h=1}^{n_2+1}(-1)^{h-1}\Delta t_{2,h}\right)A\right]\\
&\quad\times\overleftarrow{\prod_{p_1=2}^{n_1+1}}\left[B_1+B_2E\left((-1)^{p_1}\sum_{q=p_1}^{n_1+1}(-1)^{q-1}\Delta t_{1,q}\right)\right]\exp\left[\left(\sum_{h=1}^{n_1+1}(-1)^{h-1}\Delta t_{1,h}\right)A\right].
\end{aligned}\tag{3.15}$$

Here note that this integral (3.15) is a just n-ple integral with $n=n_1+\cdots+n_\ell$, and there are no integrations in the variables

$$s_{\ell-1}\equiv t_{\ell,0}\equiv t_{\ell-1,n_{\ell-1}+1},\quad s_{\ell-2}\equiv t_{\ell-1,0}\equiv t_{\ell-2,n_{\ell-2}+1},\ \ldots,s_1\equiv t_{1,0}\equiv t_{0,n_1+1}.$$

Applying the formula (2.11) to the first product of the integrand on the right-hand side of this equation (3.15), we see the integrand on the right-hand side of (3.15) is equal to

$$\begin{aligned}
&\overset{n_\ell+1}{\underset{p_\ell=2}{\overleftarrow{\prod}}}\left[B_1+B_2E\left((-1)^{p_\ell}\sum_{q=p_\ell}^{n_\ell+1}(-1)^{q-1}\Delta t_{\ell,q}\right)\right]\overset{n_{\ell-1}+1}{\underset{p_{\ell-1}=2}{\overleftarrow{\prod}}}\left[B_1+B_2E\right.\\
&\quad\left.\times\left((-1)^{n_{\ell-1}+2-p_{\ell-1}}\sum_{h=1}^{n_\ell+1}(-1)^{h-1}\Delta t_{\ell,h}+(-1)^{p_{\ell-1}}\sum_{q=p_{\ell-1}}^{n_{\ell-1}+1}(-1)^{q-1}\Delta t_{\ell-1,q}\right)\right]\\
&\quad\times\exp\left[\left((-1)^{n_{\ell-1}}\sum_{h=1}^{n_\ell+1}(-1)^{h-1}\Delta t_{\ell,h}+\sum_{h=1}^{n_{\ell-1}+1}(-1)^{h-1}\Delta t_{\ell-1,h}\right)A\right]\times\cdots\\
&\quad\times\overset{n_2+1}{\underset{p_2=2}{\overleftarrow{\prod}}}\left[B_1+B_2E\left((-1)^{p_2}\sum_{q=p_2}^{n_2+1}(-1)^{q-1}\Delta t_{2,q}\right)\right]\exp\left[\left(\sum_{h=1}^{n_2+1}(-1)^{h-1}\Delta t_{2,h}\right)A\right]\\
&\quad\times\overset{n_1+1}{\underset{p_1=2}{\overleftarrow{\prod}}}\left[B_1+B_2E\left((-1)^{p_1}\sum_{q=p_1}^{n_1+1}(-1)^{q-1}\Delta t_{1,q}\right)\right]\exp\left[\left(\sum_{h=1}^{n_1+1}(-1)^{h-1}\Delta t_{1,h}\right)A\right].
\end{aligned}$$

Then by repeated use of (2.11) we reach

$$\begin{aligned}
&C_{n_\ell}(\Delta s_\ell)\cdots C_{n_2}(\Delta s_2)C_{n_1}(\Delta s_1)\\
&\quad=\int_{s_{\ell-1}}^{s_\ell}\int_{s_{\ell-1}}^{t_{\ell,n_\ell}}\cdots\int_{s_{\ell-1}}^{t_{\ell,2}}\int_{s_{\ell-2}}^{s_{\ell-1}}\int_{s_{\ell-2}}^{t_{\ell-1,n_{\ell-1}-1}}\cdots\int_{s_{\ell-2}}^{t_{\ell-1,2}}\times\cdots\times\int_{s_1}^{s_2}\int_{s_1}^{t_{2,n_2}}\cdots\int_{s_1}^{t_{2,2}}\int_{s_0}^{s_1}\int_{s_0}^{t_{1,n_1}}\cdots\\
&\qquad\times\int_{s_0}^{t_{1,2}}\mathrm{d}t_{\ell,n_\ell}\,\mathrm{d}t_{\ell,n_\ell-1}\cdots\mathrm{d}t_{\ell,1}\,\mathrm{d}t_{\ell-1,n_{\ell-1}}\,\mathrm{d}t_{\ell-1,n_{\ell-1}-1}\cdots\mathrm{d}t_{\ell-1,1}\times\cdots\times\mathrm{d}t_{2,n_2}\,\mathrm{d}t_{2,n_2-1}\cdots\\
&\qquad\times\mathrm{d}t_{2,1}\,\mathrm{d}t_{1,n_1}\,\mathrm{d}t_{1,n_1-1}\cdots\mathrm{d}t_{1,1}B(t;n_1,n_2,\ldots,n_\ell)\\
&\qquad\times\exp\left[\left((-1)^{n_1+n_2+\cdots+n_{\ell-1}}\sum_{h=1}^{n_\ell+1}(-1)^{h-1}\Delta t_{\ell,h}+(-1)^{n_1+n_2+\cdots+n_{\ell-2}}\right.\right.\\
&\qquad\times\sum_{h=1}^{n_{\ell-1}+1}(-1)^{h-1}\Delta t_{\ell-1,h}+\cdots+(-1)^{n_1+n_2}\sum_{h=1}^{n_3+1}(-1)^{h-1}\Delta t_{3,h}+(-1)^{n_1}\\
&\qquad\left.\left.\times\sum_{h=1}^{n_2+1}(-1)^{h-1}\Delta t_{2,h}+\sum_{h=1}^{n_1+1}(-1)^{h-1}\Delta t_{1,h}\right)A\right],
\end{aligned}\tag{3.16}$$

where

$$
\begin{aligned}
&B(t;n_1,n_2,\ldots,n_\ell)\\
&=\overleftarrow{\prod_{p_\ell=2}^{n_\ell+1}}\left[B_1+B_2E\left((-1)^{p_\ell}\sum_{q=p_\ell}^{n_\ell+1}(-1)^{q-1}\Delta t_{\ell,q}\right)\right]\\
&\times\overleftarrow{\prod_{p_{\ell-1}=2}^{n_{\ell-1}+1}}\left[B_1+B_2E\left((-1)^{n_{\ell-1}+2-p_{\ell-1}}\sum_{h=1}^{n_\ell+1}(-1)^{h-1}\Delta t_{\ell,h}+(-1)^{p_{\ell-1}}\sum_{q=p_{\ell-1}}^{n_{\ell-1}+1}(-1)^{q-1}\Delta t_{\ell-1,q}\right)\right]\\
&\times\overleftarrow{\prod_{p_{\ell-2}=2}^{n_{\ell-2}+1}}\left[B_1+B_2E\left((-1)^{n_{\ell-2}+2-p_{\ell-2}+n_{\ell-1}}\sum_{h=1}^{n_\ell+1}(-1)^{h-1}\Delta t_{\ell,h}+(-1)^{n_{\ell-2}+2-p_{\ell-2}}\right.\right.\\
&\left.\left.\times\sum_{h=1}^{n_{\ell-1}+1}(-1)^{h-1}\Delta t_{\ell-1,h}+(-1)^{p_{\ell-2}}\sum_{q=p_{\ell-2}}^{n_{\ell-1}+1}(-1)^{q-1}\Delta t_{\ell-2,q}\right)\right]\times\cdots\\
&\times\overleftarrow{\prod_{p_1=2}^{n_1+1}}\left[B_1+B_2E\left((-1)^{n_1+2-p_1+n_2+\cdots+n_{\ell-1}}\sum_{h=1}^{n_\ell+1}(-1)^{h-1}\Delta t_{\ell,h}+(-1)^{n_1+2-p_1+n_2+\cdots+n_{\ell-2}}\right.\right.\\
&\times\sum_{h=1}^{n_{\ell-1}+1}(-1)^{h-1}\Delta t_{\ell-1,h}+\cdots+(-1)^{n_1+2-p_1+n_2}\sum_{h=1}^{n_3+1}(-1)^{h-1}\Delta t_{3,h}+(-1)^{n_1+2-p_1}\\
&\left.\left.\times\sum_{h=1}^{n_2+1}(-1)^{h-1}\Delta t_{2,h}+(-1)^{p_1}\sum_{q=p_1}^{n_1+1}(-1)^{q-1}\Delta t_{1,q}\right)\right].
\end{aligned}
\tag{3.17}
$$

In the exponential power of the second factor on the right-hand side of (3.16) above, observe the neighboring summations to find the first term in each summation and the last term in its next summation have the same sign, so that for each j with $1\leqslant j\leqslant \ell$,

$$
\begin{aligned}
&(-1)^{n_1+\cdots+n_{j-1}}\Delta t_{j,1}+(-1)^{n_1+\cdots+n_{j-2}}(-1)^{n_{j-1}}\Delta t_{j-1,n_{j-1}+1}\\
&\quad=(-1)^{n_1+\cdots+n_{j-1}}(\Delta t_{j,1}+\Delta t_{j-1,n_{j-1}+1})\\
&\quad=(-1)^{n_1+\cdots+n_{j-1}}((t_{j,1}-t_{j,0})+(t_{j-1,n_{j-1}+1}-t_{j-1,n_{j-1}}))\\
&\quad=(-1)^{n_1+\cdots+n_{j-1}}(t_{j,1}-t_{j-1,n_{j-1}}),
\end{aligned}
$$

because $t_{j,0}=t_{j-1,n_{j-1}+1}=s_j$. The same is true for the neighboring summations in the variables of the matrix $E(\cdot)$ on the right-hand side of (3.17). We see by the partition (3.1) with (3.14) the $n=n_1+\cdots+n_\ell$ integration variables move in the set of ℓ n_j-pleces:

$$
\begin{aligned}
\Delta(s_1,s_2,\ldots,s_\ell):\quad &0\equiv s_0\equiv t_{1,0}\leqslant t_{1,1}\leqslant t_{1,2}\leqslant\cdots\leqslant t_{1,n_1}\leqslant t_{1,n_1+1}\equiv s_1\equiv t_{2,0}\leqslant t_{2,1}\leqslant t_{2,2}\\
&\leqslant\cdots\leqslant t_{2,n_2}\leqslant t_{2,n_2+1}\equiv s_2\equiv t_{3,0}\leqslant t_{3,1}\leqslant\cdots\leqslant t_{\ell-1,n_{\ell-1}}<t_{\ell-1,n_{\ell-1}+1}\equiv s_{\ell-1}\\
&\equiv t_{\ell,0}\leqslant t_{\ell,1}\leqslant t_{\ell,2}\leqslant\cdots\leqslant t_{\ell,n_\ell}\leqslant t_{\ell,n_\ell+1}\equiv s_\ell\equiv t.
\end{aligned}
\tag{3.18}
$$

So, we change the n integration variables $\{t_{j,q}; 1 \leqslant q \leqslant n_j, 1 \leqslant j \leqslant \ell\}$ to $\{t_1, t_2, \ldots, t_n\}$, namely, set $0 \leqslant h \leqslant n_1 + n_2 + \cdots + n_\ell + 1 = n + 1$,

$$t_h = \begin{cases} t_{1,0} = s_0 = 0, \quad h = 0, \\ t_{1,h}, \quad 1 \leqslant h \leqslant n_1, \\ t_{2,h-n_1}, \quad n_1 + 1 \leqslant h \leqslant n_1 + n_2, \\ t_{3,h-(n_1+n_2)}, \quad n_1 + n_2 + 1 \leqslant h \leqslant n_1 + n_2 + n_3, \\ \ldots, \\ t_{j,h-(n_1+n_2+\cdots+n_{j-1})}, \quad n_1 + n_2 + \cdots + n_{j-1} + 1 \leqslant h \leqslant n_1 + n_2 + \cdots + n_j, \\ \ldots, \\ t_{\ell-1,h-(n_1+n_2+\cdots+n_{\ell-2})}, \quad n_1 + n_2 + \cdots + n_{\ell-2} + 1 \leqslant h \leqslant n_1 + n_2 + \cdots + n_{\ell-1}, \\ t_{\ell,h-(n_1+n_2+\cdots+n_{\ell-1})}, \quad n_1 + n_2 + \cdots + n_{\ell-1} + 1 \leqslant h \leqslant n_1 + n_2 + \cdots + n_\ell, \\ t_{\ell,n_\ell+1} = s_\ell = t, \quad h = n_1 + n_2 + \cdots + n_\ell + 1 = n + 1. \end{cases} \tag{3.19}$$

Then we see from (3.18) the new integration variables $t_1, t_2, \ldots, t_n$ move in the set

$$\begin{aligned} \Delta(s_1, s_2, \ldots, s_\ell): \quad & 0 \equiv s_0 \equiv t_0 \leqslant t_1 \leqslant t_2 \leqslant \cdots \leqslant t_{n_1} \leqslant s_1 \leqslant t_{n_1+1} \leqslant \cdots \leqslant t_{n_1+n_2} \leqslant s_2 \leqslant t_{n_1+n_2+1} \\ & \leqslant \cdots \leqslant t_{n_1+\cdots+n_{\ell-1}} \leqslant s_{\ell-1} \leqslant t_{n_1+\cdots+n_{\ell-1}+1} \leqslant \cdots \leqslant t_n \leqslant s_\ell \equiv t. \end{aligned} \tag{3.20}$$

Thus

$$\begin{aligned} C_{n_\ell}(\Delta s_\ell) \cdots C_{n_2}(\Delta s_2) C_{n_1}(\Delta s_1) = \int \cdots \int_{\Delta(s_1, s_2, \ldots, s_\ell)} & \mathrm{d}t_n \, \mathrm{d}t_{n-1} \cdots \mathrm{d}t_2 \, \mathrm{d}t_1 \\ & \times B(t; n_1, n_2, \ldots, n_\ell) \exp\left[\left(\sum_{h=1}^{n+1} (-1)^{h-1} (t_h - t_{h-1}) \right) A \right], \end{aligned} \tag{3.21}$$

where (3.17) turns out to be, with $\Delta t_h := t_h - t_{h-1}$,

$$\begin{aligned} B(t; n_1, n_2, \ldots, n_\ell) = & \overleftarrow{\prod_{p_\ell=2}^{n_\ell+1}} \left[B_1 + B_2 E\left((-1)^{n_1+\cdots+n_{\ell-1}+p_\ell} \sum_{h=n_1+\cdots+n_{\ell-1}+p_\ell}^{n+1} (-1)^{h-1} \Delta t_h \right) \right] \\ & \times \overleftarrow{\prod_{p_{\ell-1}=2}^{n_{\ell-1}+1}} \left[B_1 + B_2 E\left((-1)^{n_1+\cdots+n_{\ell-2}+p_{\ell-1}} \sum_{h=n_1+\cdots+n_{\ell-2}+p_{\ell-1}}^{n+1} (-1)^{h-1} \Delta t_h \right) \right] \\ & \times \overleftarrow{\prod_{p_{\ell-2}=2}^{n_{\ell-2}+1}} \left[B_1 + B_2 E\left((-1)^{n_1+\cdots+n_{\ell-3}+p_{\ell-2}} \sum_{h=n_1+\cdots+n_{\ell-3}+p_{\ell-2}}^{n+1} (-1)^{h-1} \Delta t_h \right) \right] \times \cdots \\ & \times \overleftarrow{\prod_{p_1=2}^{n_1+1}} \left[B_1 + B_2 E\left((-1)^{p_1} \sum_{h=p_1}^{n+1} (-1)^{h-1} \Delta t_h \right) \right]. \end{aligned} \tag{3.22}$$

We can see by this expression (3.21) with (3.22) through (3.5) that the measure $\mu_{t,0}^n$ is concentrated on those paths mentioned in the statement of Lemma 3.2. This ends the proof of this lemma.

IV. PATH INTEGRAL REPRESENTATION

We first establish the path integral representation to the solution $u(r,t)$ of the Cauchy problem (1.5) for the operator $H(k,rV)$ in (1.4), and next give the proof of Theorems 1.1 and 1.2.

We begin with showing the following path integral representation of Feynman–Kac type for the semigroup $e^{-itH(k,rV)}$.

Theorem 4.1: *For $e^{-itH(k,rV)}$ it holds that*

$$(f,e^{-itH(k,rV)}g)=\int_{C([0,t]\to[0,\infty))}\langle {}^t\overline{f(R(t))},\mathrm{d}\mu_{t,0}(R)g(R(0))\rangle\exp\left[-i\int_0^t V(R(s))R(s)\mathrm{d}s\right]. \quad (4.1)$$

Proof: For $s>0$, define a linear operator $\mathrm{U}(s)$ by

$$(U(s)g)(r)=(e^{-isT_k}e^{-isW}g)(r)=\int_0^\infty K(s;r,\rho)e^{-isV(\rho)\rho}g(\rho)\mathrm{d}\rho \quad (4.2)$$

with $W(r)=V(r)r$ for $g\in C_{00}^\infty([0,\infty);\mathbf{C}^2)$; recall $K(s;r,\rho)$ is the integral kernel of the semigroup $e^{-isT_k}\equiv N^{-1}e^{sC}N$ for T_k in (1.3). $U(s)$ is a contraction operator on $L^2(\mathbf{R}_+;\mathbf{C}^2)$ because e^{-isT_k} is a unitary operator, and also bounded in L^∞ operator norm because of (2.4)/(2.8).

Let n be an arbitrary positive integer and set $t_{h-1}=(h-1)t/n$, $h=1,2,\ldots,n+1$. Then we find, with $r_n=r$

$$[U(t/n)^n g](r)=\overbrace{\int_0^\infty\cdots\int_0^\infty}^{n\text{ times}}\prod_{h=1}^{\infty\leftarrow n}K(t/n;r_h-r_{h-1})e^{-i\sum_{h=1}^n V(r_{h-1})r_{h-1}(t/n)}g(r_0)\mathrm{d}r_0\cdots\mathrm{d}r_{n-1}. \quad (4.3)$$

Then the left-hand side converges, by the Trotter product formula [e.g., Reed and Simon (1980)], to $e^{-itH(k,rV)}g$ in $L^2(\mathbf{R}_+;\mathbf{C}^2)$, since we have seen in Proposition 2.4 that $H(k,rV)=T_k+rV$ is essentially self-adjoint. For the right-hand side, we find by (3.3) and (3.8) that taking the sesquilinear inner product of (4.3) with $f\in C_{00}^\infty([0,\infty);\mathbf{C}^2)$ yields

$$(f,U(t/n)^n g)=\int_{C([0,t]\to[0,\infty))}\langle {}^t\overline{f(R(t))},\mathrm{d}\mu_{t,0}(R)g(R(0))\rangle\exp\left[-i\sum_{h=1}^n V(R(t_{h-1}))R(t_{h-1})(t/n)\right], \quad (4.4)$$

the right-hand side of which converges by the Lebesgue bounded convergence theorem, as $n\to\infty$, to

$$\int_{C([0,t]\to[0,\infty))}\langle {}^t\overline{f(R(t))},\mathrm{d}\mu_{t,0}(R)g(R(0))\rangle\exp\left[-i\int_0^t V(R(s))R(s)\mathrm{d}s\right].$$

Thus we have shown Theorem 4.1.

Now, we prove Theorems 1.1 and 1.2.

Proof of Theorem 1.1: In Theorem 4.1, considering, instead of $e^{-itH(h,rV)}$, $e^{-it(H(k,rV)-\lambda r)}$, where $\lambda=\pm i\varepsilon$ with ε being a nonzero real number, so that λ is not in the spectrum of the operator τ_k+V, we can get by Theorem 4.1 the expression (4.1) corresponding to this case. Then taking into account the relation between the radial Dirac operator $\tau_k+V(r)$ concerned and $H(k,rV)$ in (1.4), we have only to take the Laplace transform of both sides to get (1.6) in Theorem 1.1.

Proof of Theorem 1.2: The case (i), (1.8), is an immediate consequence of Theorem 1.1. As for the case (ii), multiply both sides of Eq. (4.1) by $e^{\mp\varepsilon t}$ with the same ε as above. Then we find the expression for $e^{-itH(k,rV)\mp\varepsilon t}$. Note that $H(k,rV)$ has also a real spectrum, since by Proposition 2.4, it is a self-adjoint operator. Then taking the Laplace transform and letting $\varepsilon\to 0$, we have the formula (1.9).

This completes the proof of the main theorems in Sec. I.

ACKNOWLEDGMEMTS

The author is grateful to Professor Akira Inomata and Professor Hagen Kleinert for valuable discussions about the procedure described in the Introduction. Especially, the author would like to thank Professor Inomata for kindly explaining the issue with its rich background in the method of path integration. The author would also like to thank Professor Joachim Weidmann and Professor Osanobu Yamada for helpful discussions about the essential self-adjointness of the radial Dirac operator in Sec. II. The author also thanks Professor John R. Klauder for carefully reading the draft of this paper and for valuable comments. The preliminary version of this work was announced at the Workshop "Mathematical Problems in Quantum Mechanics," a satellite meeting to the 14th International Congress on Mathematical Physics ($M \cap \Phi$) 2003, Lisbon. The author would like to thank its organizers (Pavel Exner, Pedro Freitas, Jan Philip Solovej) for their invitation, in particular, Professor Freitas, for his kind hospitality and generous support during the author's stay at IST, University of Lisbon. This work is partially supported by the Grant-in-Aid for Scientific Research (B) No. 13440044 and No. 16340038, Japan Society for the Promotion of Science. I should like to dedicate this paper to Professor John R. Klauder on the occasion of his 70th birthday with my hearty appreciation.

(Received 22 July 2004; accepted 12 October 2004; published online 31 January 2005)

A simple and efficient variational method is introduced to accelerate the convergence of the eigenenergy computations for a Hamiltonian H with singular potentials. Closed-form analytic expressions in N dimensions are obtained for the matrix elements of H with respect to the eigenfunctions of a soluble singular problem with two free parameters A and B. The matrix eigenvalues are then optimized with respect to A and B for a given N. Applications, convergence rates, and comparisons with earlier work are discussed in detail. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1836014]

I. INTRODUCTION

Sources of ongoing interest[1–66] in the study of singular potentials are at least threefold, (i) regular Rayleigh–Schrödinger perturbation theory can fail badly for such potentials, (ii) in physics, it is quite common to encounter phenomenological potentials that are strongly singular at the origin, and (iii) because of the intrinsically interesting mathematical problems that arise in their study. A specific family of singular quantum Hamiltonians that has found widespread application in many areas of atomic, molecular, nuclear physics, are the so-called anharmonic singular Hamiltonians given by

$$H = -\frac{\mathrm{d}^2}{\mathrm{d}r^2} + r^2 + \sum_{n=0}^{N} \frac{\lambda_n}{r^{\alpha_n}}, \tag{1.1}$$

where $r \in (0,\infty)$ and α_n and λ_n are positive real numbers. A particular and important special subclass of (1.1) that has been a subject of intensive studies is the set of spiked harmonic oscillator Hamiltonians[9]

$$H = -\frac{\mathrm{d}^2}{\mathrm{d}r^2} + r^2 + \frac{\lambda}{r^{\alpha}}, \quad \alpha > 0,\ \lambda > 0 \tag{1.2}$$

acting in the Hilbert space $L_2(0,\infty)$ with eigenfunctions $\psi \in L_2(0,\infty)$ of H satisfying the Schrödinger equation $-\psi'' + (r^2 + \lambda r^{-\alpha})\psi = E\psi$ with $\psi(0) = 0$. The function ψ is an eigenfunction corresponding to the eigenvalue E and the condition $\psi(0) = 0$ is the *Dirichlet boundary condition* we impose. The coupling parameter λ determines the strength of the perturbative potential and the positive constant α represents the type of singularity at the origin. Thanks to the pioneering work of Detwiler and Klauder[8] and of Harrell,[9] remarkable progress has been made over the past three decades in the field of spectral calculations for the spiked harmonic oscillator Hamiltonian (1.2). Other interesting subclasses of (1.1) which have been used in atomic, molecular, and nuclear physics are the anharmonic singular Hamiltonians[47–61]

$$H = -\frac{d^2}{dr^2} + ar^2 + br^{-4} + cr^{-6}, \quad a > 0,\ b > 0,\ c > 0, \tag{1.3}$$

and the positive-parameter singular even-power Hamiltonians[62–66]

$$H = -\frac{d^2}{dr^2} + a_1 r^2 + \frac{a_2}{r^2} + \frac{a_3}{r^4} + \frac{a_4}{r^6}. \tag{1.4}$$

Several numerical and analytical (both variational and perturbative) techniques are avaliable in the literature for the exact and approximate eigenvalue calculations for these families of Hamiltonians. Some of these techniques were devoted to particular classes of singular Hamiltonians and some others were restricted to specific values of the potential parameters. It is of great interest to have a successful method valid for the study all of these classes without the need for major adjustment as one goes from class to class. The purpose of this paper is to provide such technique and to present a rigorous variational approach for the accurate calculation of the energy levels of the singular Hamiltonians (1.1). Our method is very simple and yet accurate enough to determine the entire spectrum in arbitrary dimensions of anharmonic singular Hamiltonians (1.1). It can be viewed as an extension of the earlier variational approach to the study of the spiked Harmonic oscillator potentials.[44] The principal ingredients are (a) the use of a special basis comprising the exact solutions of a singular problem, (b) the determination of exact analytical expressions for the matrix elements with respect to this basis, and (c) the retention of two parameters from the basis problem that can be used as additional variational parameters. These optimizations are made possible because of the progress in the establishment and simplification of closed-form analytic expressions for the matrix elements.

The paper is organized as follows. In Sec. II, we introduce our variational technique: the method is discussed in a general setting with no reference to particular application. In Sec. III, we introduce the Gol'dman and Krivchenkov Hamiltonian as a solvable model. Thereafter, we use its eigensolutions to compute the matrix elements for more general singular operators $r^{-\alpha}, \alpha > 0$. Closed analytical expressions in terms of single finite sums are obtained for the matrix elements of the power-law potentials $r^q, q = 2, 4, 6, \ldots$. In Sec. IV, the applications to singular potentials are discussed. Special attention is paid to spiked harmonic oscillator (1.2) where we compared our results with other techniques avaliable in the literature. Thereafter, we study various higher-order anharmonic singular potentials, such as (1.3) and (1.4), using the approach discussed in Sec. II. The convergence problem of the variational approach is studied in some detail. Comparisons with different methods for special classes of anharmonic singular potentials are also studied.

II. METHODOLOGY

In this section, we develop a detailed variational method for studying the family of Hamiltonians (1.1). The variational function is taken as a linear combination of orthonormal functions of an exactly solvable model which itself has a singular potential. Let $\{E_n(\Omega), \psi_n^\Omega\}$ be the eigenvalues and the eigenfunctions of an exactly solvable Hamiltonian $H^\Omega = -\Delta + v^\Omega(r)$ acting on separable Hilbert space $L_2(D, d\mu)$ such that

$$\begin{aligned} H^\Omega \psi_n^\Omega &= E_n(\Omega)\psi_n^\Omega, \\ \|\psi_n^\Omega\|_D^2 &= \langle \psi_n^\Omega | \psi_n^\Omega \rangle = \int_D |\psi_n^\Omega(r)|^2 \, d\mu(r) = 1. \end{aligned} \tag{2.1}$$

Here $v^\Omega(r)$ is taken as a function of r and depends on the parameters in the set Ω. Let $H^\Lambda = -\Delta + V^\Lambda(r)$ be the quantum Hamiltonian under investigation, where Λ is a fixed set of parameters, and we let $\epsilon(\Lambda)$ be the associated exact eigenvalues of H^Λ. By writing the Hamiltonian H^Λ in the extended form

$$H^{\Lambda} = H^{\Omega} + V^{\Lambda}(r) - v^{\Omega}(r), \tag{2.2}$$

we have that if the integrals

$$\langle \psi_n^{\Omega} | V^{\Lambda}(\cdot) | \psi_n^{\Omega} \rangle = \int_D \overline{\psi_n^{\Omega}} V^{\Lambda} \psi_n^{\Omega} \, \mathrm{d}\mu \quad \text{are finite}, \tag{2.3}$$

then the matrix elements of the Hamiltonian H^{Λ} can be written, for $m,n=0,1,2,\ldots$ as

$$H_{mn}^{\Lambda} \equiv \langle \psi_m^{\Omega} | H | \psi_n^{\Omega} \rangle = E_{mn}(\Omega)\,\delta_{mn} + \langle \psi_m^{\Omega} | V^{\Lambda}(\cdot) | \psi_n^{\Omega} \rangle - \langle \psi_m^{\Omega} | v^{\Omega}(\cdot) | \psi_n^{\Omega} \rangle, \tag{2.4}$$

or in compact form as

$$H_{mn}^{\Lambda} = \langle \psi_n^{\Omega} | -\Delta | \psi_n^{\Omega} \rangle + \langle \psi_n^{\Omega} | V^{\Lambda}(\cdot) | \psi_n^{\Omega} \rangle. \tag{2.5}$$

Our variational technique is based on forming trial wave functions from a linear combination of D-orthonormal functions $\psi_n^{\Omega}(r)$, $n=0,1,2,\ldots,D-1$,

$$\Psi(r) = \sum_{n=0}^{D-1} c_n \psi_n^{\Omega}(r). \tag{2.6}$$

The linear parameters c_n that optimize the energy are determined by the following system of equations:

$$\sum_{n=0}^{D-1} (H_{mn}^{\Lambda} - \epsilon(\Lambda)\,\delta_{mn}) c_n = 0, \quad m = 0,1,2,\ldots,D-1. \tag{2.7}$$

The necessary and sufficient condition for a nontrivial solution of (2.7) is the vanishing of the secular determinant

$$\det | H_{mn}^{\Lambda} - \epsilon(\Lambda)\,\delta_{mn} | = 0. \tag{2.8}$$

The condition (2.8) yields upper bounds to the exact eigenvalues $\epsilon(\Lambda)$ by means of the inequality

$$\epsilon(\Lambda) \leqslant \min_{\Omega} \mathrm{diag} \begin{pmatrix} H_{00}^{\Lambda} & H_{01}^{\Lambda} & \cdots & H_{0D-1}^{\Lambda} \\ H_{10}^{\Lambda} & H_{11}^{\Lambda} & \cdots & H_{1D-1}^{\Lambda} \\ \cdots & \cdots & \cdots & \cdots \\ H_{D-10}^{\Lambda} & H_{D-11}^{\Lambda} & \cdots & H_{D-1D-1}^{\Lambda} \end{pmatrix}, \tag{2.9}$$

where $H_{mn}^{\Lambda} = \langle \psi_m^{\Omega} | H^{\Lambda} | \psi_n^{\Omega} \rangle = H_{mn}^{\Omega} + V_{mn}^{\Lambda}(r) - v_{mn}^{\Omega}(r)$, for fixed Λ, are functions of the parameter set Ω. Note that the equality in (2.9) holds if $V^{\Lambda}(r) = v^{\Omega}(r)$, for all r. The computation of the right-hand side of (2.9) requires a diagonalization of the matrix over the D-dimensional subspace spanned by orthonormal functions ψ_n^{Ω} followed subsequently by a minimization over the parameters Ω. The advantages of this method are (i) only a few matrix elements are needed to achieve accurate bounds to the eigenvalues; (ii) the exact eigenvalues are approached monotonically as D is increased; (iii) the minimization over a set of parameters Ω accelerates the convergence of the energy bounds more rapidly than any standard minimization over a single variable; (iv) the optimization of (2.9) for $D \times D$ matrix gives upper bounds to the energy eigenvalues of the lowest D states; (v) the diagonalization of such a matrix also produces the coefficients required for the corresponding eigenvectors determined variationally.

III. EXACTLY SOLVABLE MODEL AND ASSOCIATED MATRIX ELEMENTS

The accuracy and the computational simplicity of the variational method depends greatly on the analytic structure of the wave functions that we use, in particular, their behavior in the neighborhood of the singularity. Many different forms of trial wave function have been explored

in the literature to solve the spiked harmonic oscillator problem (1.2). The rate of convergence for a variational calculation depends on the ability of the basis functions used in the variational calculation to approximate the behavior of the exact wave function in the neighborhood of the singularity. Recently, Hall *et al.* have pointed out the advantages of basing the variational analysis of singular potentials on an exact soluble model which itself has a singular potential term. They have suggested and used trial wave functions constructed by means of the superposition of the orthonormal functions of the exact solutions of the Gol'dman and Krivchenkov Hamiltonian,

$$H_0 = -\frac{\mathrm{d}^2}{\mathrm{d}r^2} + Br^2 + \frac{A}{r^2}. \tag{3.1}$$

It was shown that this orthonormal basis serves as an effective starting point for the variational analysis of the Hamiltonian (1.2). In this paper we use these solutions of H_0 to provide systematic variational solutions for the singular Hamiltonians (1.1). The Gol'dman and Krivchenkov Hamiltonian (3.1) is one of the few that admit exact analytical solutions. The Hamiltonian is the generalization of the familiar harmonic oscillator in three-dimensional $-\mathrm{d}^2/\mathrm{d}r^2+Br^2+l(l+1)/r^2$ where the generalization lies in the parameter A ranging over $[0,\infty)$ instead of only values determined by the angular momentum quantum numbers $l=0,1,2,\ldots$. The background on Gol'dman and Krivchenkov potential $V(r)=Br^2+Ar^{-2}$ relevant to the following discussion can be found in Ref. 44. In particular, the energy spectrum of the Schrödinger Hamiltonian H_0 is given, in terms of parameters A and B, by

$$E_n = 2\beta(2n+\gamma), \quad n = 0,1,2,\ldots, \tag{3.2}$$

in which $\beta=\sqrt{B}$ and $\gamma=1+\sqrt{A+\frac{1}{4}}$ and the normalized wave functions are

$$\psi_n(r) = (-1)^n \sqrt{\frac{2\beta^{\gamma}(\gamma)_n}{n!\,\Gamma(\gamma)}} r^{\gamma-1/2} e^{-(1/2)\beta r^2} F_1(-n;\gamma;\beta r^2). \tag{3.3}$$

Here ${}_1F_1$ is the confluent hypergeometric function

$${}_1F_1(-n;b;z) = \sum_{k=0}^{n} \frac{(-n)_k z^k}{(b)_k k!} \quad (n\text{-degree polynomial in } z) \tag{3.4}$$

and the shifted factorial $(a)_n$ defined by

$$(a)_0 = 1, \quad (a)_n = a(a+1)(a+2)\cdots(a+n-1), \quad \text{for } n = 1,2,3,\ldots \tag{3.5}$$

may be expressed in terms of the gamma function by $(a)_n=\Gamma(a+n)/\Gamma(a)$, when a is not a negative integer $-m$, and, in these exceptional cases, $(-m)_n=0$ if $n>m$ and otherwise $(-m)_n=(-1)^n m!/(m-n)!$.

An important observation regarding the solvable model H_0 is the existence of the A term which has the dimensions of kinetic energy such as the term that appears in higher-dimensional systems. This observation allows us to extend (3.2) and (3.3) to the exact solutions of N-dimensional Gol'dman and Krivchenkov Hamiltonian, namely,

$$-\frac{\mathrm{d}^2}{\mathrm{d}r^2} + \frac{\Lambda(\Lambda+1)+A}{r^2} + Br^2 \quad (A \geqslant 0, B > 0), \tag{3.6}$$

where $\Lambda=\frac{1}{2}(M-3)$, and $M=N+2l$. The exact solution of (3.6) can be easily found by replacing A in (3.2) and (3.3) with

$$A \to \Lambda(\Lambda+1)+A. \tag{3.7}$$

This particular observation can be extended to any three-dimensional exact solvable quantum model. Indeed, if Schrödinger's equation can be solved for arbitrary angular momentum number l,

then the extension to the N-dimensional case can be obtained by replacing l with Λ. It should be also noted that N and l enter into the Hamiltonian (3.6) in the form of combination $N+2l$. Hence, the energy for a spherically symmetric potential $V(r)$ are the same as long as M is not altered. We now summarize the exact eigenvalues of N-dimensional Schrödinger equation with the Gol'dman and Krivchenkov potential as

$$E_{nl}^{N} = 2\beta(2n + \gamma_N), \quad n,l = 0,1,2, \ldots , \tag{3.8}$$

where $\beta=\sqrt{B}$ and $\gamma_N=1+\sqrt{A+(\Lambda+\frac{1}{2})^2}$, while the exact eigenfunctions are given explicitly by

$$\psi_{nl}^{N}(r) = (-1)^n \sqrt{\frac{2\beta^{\gamma_N}(\gamma_N)_n}{n!\,\Gamma(\gamma_N)}} r^{\gamma_N-1/2} e^{-(1/2)\beta r^2} {}_1F_1\left(\begin{matrix} -n \\ \gamma_N \end{matrix} \middle| \beta r^2 \right) \quad (n,l = 0,1,2, \ldots, N \geqslant 1). \tag{3.9}$$

In the next section all our results are formulated in arbitrary dimension $N \geqslant 1$.

A. Matrix elements of the singular operator $r^{-\alpha}$

The effectiveness of the variational method relies on finding a basis that allows for easy calculation of the matrix elements of the given Hamiltonian. An important advantage of the orthonormal wave functions (3.3) is the existence of closed-form formulas for the singular potential integrals $\langle \psi_m | r^{-\alpha} | \psi_n \rangle$. These closed form expressions are achieved by means of the following identity: For m and n non-negative integers and $2\gamma > \alpha$,

$$\begin{aligned} &\int_0^\infty r^{2\gamma-\alpha-1} e^{-\beta r^2} {}_1F_1\left(\begin{matrix} -n \\ \gamma \end{matrix} \middle| \beta r^2 \right) {}_1F_1\left(\begin{matrix} -m \\ \gamma \end{matrix} \middle| \beta r^2 \right) \mathrm{d}r \\ &\quad = \frac{\left(\frac{\alpha}{2}\right)_n \Gamma\left(\gamma - \frac{\alpha}{2}\right)}{2\beta^{\gamma-(\alpha/2)}(\gamma)_n} {}_3F_2\left(\begin{matrix} -m, \gamma - \frac{\alpha}{2}, 1 - \frac{\alpha}{2} \\ \gamma, 1 - \frac{\alpha}{2} - n \end{matrix} \middle| 1 \right), \end{aligned} \tag{3.10}$$

where the Clausen hypergeometric function ${}_3F_2$ is defined by the series representation

$${}_3F_2\left(\begin{matrix} -m, a, b \\ c, d \end{matrix} \middle| 1 \right) = \sum_{k=0}^{m} \frac{(-m)_k (a)_k (b)_k}{(c)_k (d)_k k!} \quad (m\text{-degree polynomial}).$$

The proof of this identity and some relevant integrals can be found in Ref. 44. Thus the matrix elements $r_{mn}^{-\alpha} = \langle \psi_n | r^{-\alpha} | \psi_n \rangle$ of the singular operator $r^{-\alpha}$ have the explicit forms

$$r_{mn}^{-\alpha} = (-1)^{n+m} \beta^{\alpha/2} \frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n} \frac{\Gamma\left(\gamma - \frac{\alpha}{2}\right)}{\Gamma(\gamma)} \sqrt{\frac{(\gamma)_n (\gamma)_m}{n!\,m!}} {}_3F_2\left(\begin{matrix} -m, \gamma - \frac{\alpha}{2}, 1 - \frac{\alpha}{2} \\ \gamma, 1 - \frac{\alpha}{2} - n \end{matrix} \middle| 1 \right). \tag{3.11}$$

In the case of α being a non-negative even number ($\alpha=2,4,6,\ldots$), the Clausen hypergeometric function ${}_3F_2$ in (3.11) may be looked upon as a polynomial of degree $(\alpha/2)-1$ instead of an m-degree polynomial. This is, of course, not the case for $0<\alpha\neq 2,4,6,\ldots$ in which case the numerical computation would have to be done directly using the expression (3.11). For $n \geqslant m$ and $\alpha=2,4,6,\ldots$ we have by means of the series representation of the hypergeometric function ${}_3F_2$ that

$$ {}_3F_2\left(\begin{matrix} -\left(\frac{\alpha}{2}-1\right), \gamma-\frac{\alpha}{2}, -m \\ \gamma, 1-\frac{\alpha}{2}-n \end{matrix}\middle| 1\right) = \sum_{s=0}^{(\alpha/2)-1} \frac{(-m)_s \left(\gamma-\frac{\alpha}{2}\right)_s \left(1-\frac{\alpha}{2}\right)_s}{s!\,(\gamma)_s \left(1-\frac{\alpha}{2}-n\right)_s}. \tag{3.12} $$

As a result, the matrix elements (3.11) further simplify into the closed form expressions immediately appearing. These are most suitable for computational purposes as for the case of $\gamma>1$ and $\alpha=2$, we indeed have

$$ r_{mn}^{-2} = \begin{cases} (-1)^{m+n} \dfrac{\beta}{\gamma-1} \sqrt{\dfrac{n!\,(\gamma)_m}{m!\,(\gamma)_n}} & \text{if } n>m, \\ \dfrac{\beta}{\gamma-1} & \text{if } n=m, \\ (-1)^{m+n} \dfrac{\beta}{\gamma-1} \sqrt{\dfrac{m!\,(\gamma)_n}{n!\,(\gamma)_m}} & \text{if } n<m. \end{cases} \tag{3.13} $$

On the other hand, for $\gamma>2$ and $\alpha=4$, we have from (3.11) and (3.12) that

$$ r_{mn}^{-4} = \begin{cases} \dfrac{(-1)^{m+n}\beta^2}{\gamma(\gamma-1)(\gamma-2)} \sqrt{\dfrac{n!\,(\gamma)_m}{m!\,(\gamma)_n}} [\gamma(n-m+1)+2m] & \text{if } n>m, \\ \dfrac{\beta^2}{\gamma(\gamma-1)(\gamma-2)} [\gamma+2n] & \text{if } n=m, \\ \dfrac{(-1)^{m+n}\beta^2}{\gamma(\gamma-1)(\gamma-2)} \sqrt{\dfrac{m!\,(\gamma)_n}{n!\,(\gamma)_m}} [\gamma(m-n+1)+2n] & \text{if } n<m. \end{cases} \tag{3.14} $$

We also point out, for $\gamma>3$ and $\alpha=6$, Eq. (3.12) lets us deduce

$$ r_{mn}^{-6} = \begin{cases} \dfrac{(-1)^{m+n}\beta^3}{2(\gamma+1)\gamma(\gamma-1)(\gamma-2)(\gamma-3)} \sqrt{\dfrac{n!\,(\gamma)_m}{m!\,(\gamma)_n}} [(2+n)(1+n)\gamma(\gamma+1) & \\ \quad -2m(1+n)(\gamma-3)(\gamma+1)-m(1-m)(\gamma-2)(\gamma-3)] & \text{if } n>m, \\ \dfrac{\beta^3}{(\gamma+1)\gamma(\gamma-1)(\gamma-2)(\gamma-3)} (\gamma+\gamma^2+6\gamma n+6n^2) & \text{if } n=m, \\ \dfrac{(-1)^{m+n}\beta^3}{2(\gamma+1)\gamma(\gamma-1)(\gamma-2)(\gamma-3)} \sqrt{\dfrac{m!\,(\gamma)_n}{n!\,(\gamma)_m}} [(2+m)(1+m)\gamma(\gamma+1) & \\ \quad -2n(1+m)(\gamma-3)(\gamma+1)-n(1-n)(\gamma-2)(\gamma-3)] & \text{if } n<m. \end{cases} \tag{3.15} $$

We can derive similar expressions for all even integers beyond 6, i.e., $\alpha=8,10,\ldots$, where we have, for $n\geqslant m$, that

$$ r_{mn}^{-\alpha} = (-1)^{n+m}\beta^{\alpha/2} \frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n} \frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)}{\Gamma(\gamma)} \sqrt{\frac{(\gamma)_n(\gamma)_m}{n!\,m!}} \sum_{s=0}^{(\alpha/2)-1} \frac{(-m)_s \left(\gamma-\frac{\alpha}{2}\right)_s \left(1-\frac{\alpha}{2}\right)_s}{s!\,(\gamma)_s \left(1-\frac{\alpha}{2}-n\right)_s}, \tag{3.16} $$

and the matrix elements with $0\leqslant n<m$ are incorporated by using the symmetry property, i.e., $r_{mn}^{-\alpha}=r_{nm}^{-\alpha}$. For the N-dimensional case, the matrix elements of the singular operator $r^{-\alpha}$ can be easily found in analogy with (3.10),

$$r_{mn}^{-\alpha}=(-1)^{n+m}\beta^{\alpha/2}\frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n}\frac{\Gamma\left(\gamma_N-\frac{\alpha}{2}\right)}{\Gamma(\gamma_N)}\sqrt{\frac{(\gamma_N)_n(\gamma_N)_m}{n!\,m!}}\,{}_3F_2\left(\begin{matrix}-m,\gamma_N-\frac{\alpha}{2},1-\frac{\alpha}{2}\\ \gamma_N,1-n-\frac{\alpha}{2}\end{matrix}\middle|\,1\right). \tag{3.17}$$

The results for the special cases $\alpha=2,4,6,\ldots$ can be obtained in a similar fashion to (3.14)–(3.16) through the substitution of γ by $\gamma_N=1+\sqrt{A+[l+(N/2)-1]^2}$.

B. Matrix elements of the power-law potentials r^q

We now use the orthonormal eigenfunctions (3.3) to compute the matrix elements for the power-law potential operators r^q, $q=2,4,6,\ldots$. In analogy with (3.10), this can be achieved by means of the identity, for m and n non-negative integers and $2\gamma+q>0$,

$$\int_0^\infty r^{2\gamma+q-1}e^{-\beta r^2}\,{}_1F_1\left(\begin{matrix}-n\\ \gamma\end{matrix}\middle|\,\beta r^2\right){}_1F_1\left(\begin{matrix}-m\\ \gamma\end{matrix}\middle|\,\beta r^2\right)\mathrm{d}r$$
$$=\frac{\left(-\frac{q}{2}\right)_n\Gamma\left(\gamma+\frac{q}{2}\right)}{2\beta^{\gamma+(q/2)}(\gamma)_n}\,{}_3F_2\left(\begin{matrix}-m,\gamma+\frac{q}{2},1+\frac{q}{2}\\ \gamma,1+\frac{q}{2}-n\end{matrix}\middle|\,1\right). \tag{3.18}$$

In the case of q being a positive even number ($q=2,4,6,\ldots$), the Clausen hypergeometric function ${}_3F_2$ in (3.18) can be further simplified. Indeed in this case, we prove the following result.

Theorem 1: For $t=0,1,2,\ldots,q/2$ and $q=2,4,6,\ldots$, the matrix elements of the power-law potential r^q, $q=2,4,6,\ldots$ in terms of the orthonormal functions (3.3) are

$$r_{mn}^q=0 \quad \text{if } n>m+\frac{q}{2},$$

$$=\frac{(-1)^q}{\beta^{q/2}}\sqrt{\frac{\left(\gamma+\frac{\alpha}{2}\right)_m\Gamma\left(\gamma+\frac{q}{2}\right)\left(m+\frac{q}{2}\right)!}{(\gamma)_m\Gamma(\gamma)m!}} \quad \text{if } n=m+\frac{q}{2},$$

$$=\frac{\Gamma\left(\gamma+\frac{q}{2}\right)(\gamma+m-t)_{q/2}(m-t+1)_{q/2}}{(-1)^{t-q}\beta^{q/2}t!\,\Gamma(\gamma)(\gamma)_{q/2}}\sqrt{\frac{m!\,(\gamma)_m}{(\gamma)_{m+(q/2)-t}[m+(q/2)-t]!}}$$
$$\times\sum_{j=0}^{t}\frac{(-t)_j\left(\gamma+m+\frac{q}{2}-t\right)_j\left(\frac{q}{2}+m-t+1\right)_j}{(\gamma+m-t)_j(m+1-t)_j j!} \quad \text{if } n=m+\frac{q}{2}-t,$$

$$=\frac{\Gamma\left(\gamma+\frac{q}{2}\right)(1-\gamma-m)_{q/2}(-m)_{q/2}}{(-\beta)^{q/2}\Gamma(\gamma)\frac{q}{2}!\,(\gamma)_{q/2}}\sum_{j=0}^{q/2}\frac{\left(-\frac{q}{2}\right)_j(\gamma+m)_j(m+1)_j}{\left(\gamma+m-\frac{q}{2}\right)_j\left(m+1-\frac{q}{2}\right)_j j!} \quad \text{if } m=n,$$

$$= \frac{\Gamma\left(\gamma+\frac{q}{2}\right)(\gamma+n-t)_{q/2}(n-t+1)_{q/2}}{(-1)^{t-q}\beta^{q/2}t!\,\Gamma(\gamma)(\gamma)_{q/2}} \sqrt{\frac{n!\,(\gamma)_n}{(\gamma)_{n+(q/2)-t}\left(n+\frac{q}{2}-t\right)!}}$$

$$\times \sum_{j=0}^{t} \frac{(-t)_j\left(\gamma+n+\frac{q}{2}-t\right)_j\left(\frac{q}{2}+n-t+1\right)_j}{(\gamma+n-t)_j(n+1-t)_j j!} \quad \text{if } m = n+\frac{q}{2}-t,$$

$$= \frac{(-1)^q}{\beta^{q/2}} \sqrt{\frac{\left(\gamma+\frac{\alpha}{2}\right)_n \Gamma\left(\gamma+\frac{q}{2}\right)\left(n+\frac{q}{2}\right)!}{(\gamma)_n\Gamma(\gamma)n!}} \quad \text{if } m = n+\frac{q}{2},$$

$$= 0 \quad \text{if } m > n+\frac{q}{2}. \tag{3.19}$$

Proof: From (3.18), we have

$$r_{mn}^{q} = (-1)^{m+n}\beta^{-q/2}\frac{\Gamma\left(\gamma+\frac{q}{2}\right)}{\Gamma(\gamma)(\gamma)_n}\sqrt{\frac{(\gamma)_n(\gamma)_m}{n!\,m!}}\left(-\frac{q}{2}\right)_n {}_3F_2\left(\begin{matrix} -m, \gamma+\frac{q}{2}, 1+\frac{q}{2} \\ \gamma, 1+\frac{q}{2}-n \end{matrix}\middle| 1\right)$$

and the problem is now reduced to the simplification of the product

$$\left(-\frac{q}{2}\right)_n {}_3F_2\left(\begin{matrix} -m, \gamma+\frac{q}{2}, 1+\frac{q}{2} \\ \gamma, 1+\frac{q}{2}-n \end{matrix}\middle| 1\right).$$

Using the series representation for ${}_3F_2$, we can write

$$I = \left(-\frac{q}{2}\right)_n {}_3F_2\left(\begin{matrix} -m, \gamma+\frac{q}{2}, 1+\frac{q}{2} \\ \gamma, 1+\frac{q}{2}-n \end{matrix}\middle| 1\right) = \sum_{k=0}^{m} \frac{(-m)_k\left(\gamma+\frac{q}{2}\right)_k\left(-\frac{q}{2}-k\right)_n}{(\gamma)_k k!},$$

where we have used the identity $(a-n)_k=(1-a)_n(a)_k/(1-a-k)_n$. From the definition of the Pochhammer symbol $(-(q/2)-k)_n$ we have that $I=0$ for $n>m+(q/2)$ and for $n=(q/2)+m$ we have

$$I = \frac{(-1)^{q/2}\left(\gamma+\frac{q}{2}\right)_m\left(m+\frac{q}{2}\right)!}{(\gamma)_m}.$$

Finally, for $n=m+(q/2)-t$, $t=0,1,2,\ldots,q/2$,

$$I = \sum_{k=0}^{m} \frac{(-m)_k\left(\gamma+\frac{q}{2}\right)_k\left(-\frac{q}{2}-k\right)_{m+(q/2)-t}}{(\gamma)_k k!} = \sum_{k=m-t}^{m} \frac{(-m)_k\left(\gamma+\frac{q}{2}\right)_k\left(-\frac{q}{2}-k\right)_{m+(q/2)-t}}{(\gamma)_k k!}.$$

The completion of the proof then follows by shifting the index $j=k-m+t$ of the finite sum. □

As consequence of Theorem 1, for $q=2$ and $\gamma>-1$ we have that

$$r_{mn}^2=\begin{cases}0 & \text{if } n>m+1,\\ \beta^{-1}\sqrt{(m+1)(\gamma+m)} & \text{if } n=m+1,\\ \beta^{-1}(\gamma+2n) & \text{if } n=m,\\ \beta^{-1}\sqrt{(n+1)(\gamma+n)} & \text{if } m=n+1,\\ 0 & \text{if } m>n+1.\end{cases} \tag{3.20}$$

Furthermore, the explicit formula for the matrix elements of the operator r^4 now reads

$$r_{mn}^4=\begin{cases}0 & \text{if } n>m+2,\\ \beta^{-2}\sqrt{(m+1)(m+2)(\gamma+m)(\gamma+m+1)} & \text{if } n=m+2,\\ 2\beta^{-2}(\gamma+2m+1)\sqrt{(m+1)(\gamma+m)} & \text{if } n=m+1,\\ \beta^{-2}(\gamma+6m^2+6\gamma m+\gamma^2) & \text{if } n=m,\\ 2\beta^{-2}(\gamma+2n+1)\sqrt{(n+1)(\gamma+n)} & \text{if } m=n+1,\\ \beta^{-2}\sqrt{(n+1)(n+2)(\gamma+n)(\gamma+n+1)} & \text{if } m=n+2,\\ 0 & \text{if } m>n+1.\end{cases} \tag{3.21}$$

IV. APPLICATIONS AND NUMERICAL RESULTS

A. Spiked harmonic oscillator Hamiltonians

There are several reasons for the interest in the spiked harmonic oscillator Hamiltonian (1.2) and its extension, the so-called generalized spiked harmonic oscillator,

$$H=-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+Br^2+\frac{A}{r^2}+\frac{\lambda}{r^\alpha}. \tag{4.1}$$

First, it represents the simplest model of certain realistic interaction potentials in atomic, molecular, and nuclear physics, and second, its interesting intrinsic properties from the viewpoint of mathematical physics are as follows: (1) an eigenvalue of the perturbed operator may not converge to the original one as $\lambda\to 0$ (the Klauder phenomenon) and (2) the perturbation series is ordered in fractional powers of λ, and in the cases $\alpha>5/2$ the regular Rayleigh–Schrödinger perturbation theory fails badly.

We shall consider the problem initially in $N=3$ spatial dimensions. It was proven earlier[44] that the set of $L_2[0,\infty)$-functions $\{\psi_n(r)\}_{n=0}^{\infty}$ as defined by (3.3), is a complete orthonormal basis for the Hilbert space $L_2[0,\infty)$. This basis was the starting point for perturbative expansions and variational analysis of the Hamiltonians (1.2) and (4.1). The main approach of the earlier variational investigation of (1.2) was the rewriting of the Hamiltonian as

$$H\equiv-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+r^2+\frac{A}{r^2}+\left(\frac{\lambda}{r^\alpha}-\frac{A}{r^2}\right). \tag{4.2}$$

The parameter A serves as an extra degree of freedom that can be used to accelerate the convergence to the exact eigenvalues through the minimization of the eigenvalues of the diagonalizable $D\times D$ symmetric matrix. Straightforward calculations using (3.11) and (3.13) show that the matrix elements H_{mn} of the Hamiltonian (4.2) are $(m,n=0,1,2,\ldots,D-1,\ n\geqslant m)$

$$H_{mn} = 2(2n+\gamma)\delta_{nm} + (-1)^{n+m}\lambda \frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n} \frac{\Gamma\left(\gamma - \frac{\alpha}{2}\right)}{\Gamma(\gamma)} \sqrt{\frac{(\gamma)_n(\gamma)_m}{n!m!}}\, {}_3F_2\left(\begin{matrix} -m, \gamma - \frac{\alpha}{2}, 1 - \frac{\alpha}{2} \\ \gamma, 1 - n - \frac{\alpha}{2} \end{matrix} \middle| 1 \right)$$

$$- (-1)^{m+n} \frac{(\gamma - \frac{3}{2})(\gamma - \frac{1}{2})}{\gamma - 1} \sqrt{\frac{n!(\gamma)_m}{m!(\gamma)_n}}, \tag{4.3}$$

where $2\gamma > \alpha$ and the matrix elements with $0 \leqslant n < m$ are incorporated by using the symmetry property of the matrix. In order to apply the method discussed in Sec. II, we write (1.2) in more extended form,

$$H \equiv -\frac{\mathrm{d}^2}{\mathrm{d}r^2} + Br^2 + \frac{A}{r^2} + (1-B)r^2 + \left(\frac{\lambda}{r^\alpha} - \frac{A}{r^2}\right). \tag{4.4}$$

In this case, the matrix elements of the Hamiltonian (4.4) assume the form

$$H_{mn} = 2\beta(2n+\gamma)\delta_{mn} + (1-\beta^2)r^2_{mn} + \lambda r^{-\alpha}_{mn} - A r^{-2}_{mn} \quad (\beta = \sqrt{B}, m, n = 0,1,2,\ldots,D-1), \tag{4.5}$$

where r^2_{mn} is given by (3.20), $r^{-\alpha}_{mn}$ is given by (3.11), and r^{-2}_{mn} is given by (3.13). In order to illustrate the difference between using the expressions (4.3) and (4.5), we restrict our calculation to $\alpha = 4$. The first variational approximation (subspace of dimension 1) of the ground-state eigenvalues of the spiked harmonic oscillator Hamiltonian yields by means of (4.3) the approximation

$$\epsilon_0 = \min_{A > 0.75} \left\{ \gamma + 1 + \frac{\lambda}{(\gamma-1)(\gamma-2)} + \frac{1}{4(\gamma-1)} \right\} \quad \left(\gamma = 1 + \frac{1}{2}\sqrt{1+4A} > 2 \right) \tag{4.6}$$

while the matrix elements (4.5) yield the approximation

$$\epsilon_0 = \min_{A > 0.75, B > 0} \left\{ \frac{\gamma}{\beta} + \beta + \frac{\lambda\beta^2}{(\gamma-1)(\gamma-2)} + \frac{\beta}{4(\gamma-1)} \right\} \quad \left(\gamma = 1 + \frac{1}{2}\sqrt{1+4A} > 2, \beta = \sqrt{B} \right). \tag{4.7}$$

The minimization of (4.6) over the parameter A yields

$$\epsilon_0 = \tfrac{5}{2} + \tfrac{3}{2}(8\lambda - 1 + 4\sqrt{4\lambda^2 - \lambda})^{1/3} + (6\lambda - \tfrac{3}{4} - 3\sqrt{4\lambda^2 - \lambda})(8\lambda - 1 + 4\sqrt{4\lambda^2 - \lambda})^{2/3}$$

which implies the upper bound $\epsilon_0 = 21.427\,793$ for $\lambda = 1000$; while the minimization of (4.7) over A and B yields $\epsilon_0 = 21.374\,087$ with first decimal place exact. In Table I, we present a comparison between eigenvalues computation using (4.6) and (4.7) for $\lambda = 0.1$ to illustrate the increase in the rate of convergence obtained when using our new approach. It should be noted that the optimization over the parameter A of the 1000×1000-diagonalizable matrix yields an upper bound of $E^A = 3.575\,557$ with $A \approx 6.076$, while the minimization and diagonalization of the symmetric matrix over the parameters A and B greatly reduce the number of the matrix elements needed by a ratio of approximately 10:1. As shown in Table I, 100×100 matrix is sufficient to achieve an exact eigenvalue of $E^{A,B} = 3.575\,552$. Because we have established simple formulas for the matrix elements in the cases $\alpha = 4$ and $\alpha = 6$ [given by (3.14) and (3.15), respectively], the determination of the energy values to any desired accuracy reduced to an easy task as indicated in Table II where we report our eigenvalue computation for the case $\alpha = 6$ and for different values of the parameter λ. A heuristic scheme for ascertaining the eigenvalues to any required number of digits is as follows. The eigenvalues obtained from successive levels, such as $(1 \times 1, 2 \times 2, \ldots)$, of the truncated matrix are compared, and the calculation ceases when the successive eigenvalues agree with each other up to the prescribed decimal place. Further advantage of the variational approach presented here is the amount of information that we get about the spectrum of the Hamiltonian

TABLE I. Upper bounds E^A for $H=-\Delta+r^2+(1/10r^4)$ are obtained by diagonalization then minimization of the $D\times D$ matrix, only over the parameter A. $E^{A,B}$ are the corresponding values minimized over both A and B. The eigenvalue 3.575 552 (exact to seven places) can be easily verified by direct numerical integration of Schrödinger's equation.

$D\times D$	E^A	$E^{A,B}$
1×1	3.745 811	3.664 281
	$(A\approx 1.52)$	$(A\approx 1.92, B\approx 1.62)$
10×10	3.602 189	3.582 194
	$(A\approx 2.84)$	$(A\approx 4.75, B\approx 11.66)$
20×20	3.588 143	3.576 773
	$(A\approx 3.68)$	$(A\approx 8.14, B\approx 32.22)$
100×100	3.577 007	3.575 552
	$(A\approx 7.44)$	$(A\approx 9.73, B\approx 297.23)$
200×200	3.576 015	3.575 552
	$(A\approx 10.39)$	$(A\approx 3.76, B\approx 873.58)$

every time we compute the eigenvalues via the diagonalization and minimization. Indeed, we obtain, for $D\times D$-matrix, a set of upper bounds for the eigenvalues $E_0, E_1, \ldots, E_{D-1}$. Each can be improved by either an increase in the dimension of the matrix, or by extracting the desired level through the diagonalization and subsequent minimization with respect to parameters A and B. For the N-dimensional case, the matrix elements of the singular operator $r^{-\alpha}$ turn out to be

$$\langle \psi_{ml}^N | r^{-\alpha} | \psi_{nl}^N \rangle = (-1)^{n+m} \beta^{\alpha/2} \frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n} \frac{\Gamma\left(\gamma_N - \frac{\alpha}{2}\right)}{\Gamma(\gamma_N)} \sqrt{\frac{(\gamma_N)_n (\gamma_N)_m}{n!m!}} {}_3F_2\left(\begin{matrix} -m, \gamma_N - \frac{\alpha}{2}, 1 - \frac{\alpha}{2} \\ \gamma_N, 1 - \frac{q}{2} - n \end{matrix} \middle| 1 \right). \tag{4.8}$$

Matrix elements for the special cases of $\alpha=2,4,6,\ldots$ are obtained by substituting in Eqs. (3.13)–(3.15) for γ the expression γ_N, where $\gamma_N=1+\sqrt{A+(\Lambda+\frac{1}{2})^2}$. The matrix elements of the

TABLE II. Upper bounds E^A for $H=-\Delta+r^2+(\lambda/r^6)$ obtained by diagonalization followed by minimization of the $D\times D$ matrix, only over the parameter A. $E^{A,B}$ are the corresponding values minimized over both A and B. The results are displayed for different values of the potential coupling λ. The eigenvalues are correct for the seven digits, as can be easily verified by direct numerical integration of Schrödinger's equation.

5	21.522 860 ($A\approx69.96, B\approx1.769$)
6	21.656 596 ($A\approx68.82, B\approx1.764$)
7	21.827 883 ($A\approx67.34, B\approx1.757$)
8	22.036 232 ($A\approx65.45, B\approx1.749$)
9	22.281 057 ($A\approx63.35, B\approx1.740$)
10	22.561 680 ($A\approx60.81, B\approx1.726$)

spiked harmonic oscillator Hamiltonian now turn out to be very similar to those in Eq. (4.5), namely

$$H_{mn}=2\beta(2n+\gamma_N)\delta_{mn}+(1-B)r_{mn}^2+\lambda r_{mn}^{-\alpha}-Ar_{mn}^{-2}. \tag{4.9}$$

In Table III, upper bounds E_{00}^{N}, obtained by the optimization of the eigenvalues of a 10×10-matrix over the parameters A and B, are shown. The results are reported for the Hamiltonian

$$H=-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+\frac{\Lambda(\Lambda+1)}{r^2}+r^2+\frac{1000}{r^4}$$

where $\Lambda=\frac{1}{2}(N+2l-3)$ for dimension $N=2-10$ with the angular momentum $l=0$.

B. Anharmonic singular Hamiltonian

The higher-order anharmonic singular Hamiltonians (1.3) have attracted much attention recently.[47–66] This is in part because the study of the relevant Schrödinger equation with anharmonic potentials provides understanding and insight for the corresponding physical problems, and also because the determination of its energy is itself a challenging problem. In three-dimensional space, there are two main methods for dealing with the anharmonic potentials $V(r)=ar^2+br^{-4}+cr^{-6}$. A method due to Varshni[56] is based on an ansatz for the eigenfunctions, sufficient conditions on parameters to yield exact solutions, and a limit from initial box confinement. The other method, mainly proposed by Znojil,[47,48] relies on a Laurent series ansatz for the eigenfunctions, which converts the Schrödinger equation into a difference equation which is solved by the use of continued fractions. An interesting study related to Varshni's idea[56] for the potential $V(r)$ in two dimensions was proposed recently by Dong and Ma.[60]

The method discussed in Sec. II of the present paper provides a uniformly simple, straightforward and very efficient way of yielding accurate energies of the entire spectrum of the anharmonic potentials $V(r)$ not only in one or two dimensions but actually in arbitrary dimensions with arbitrary angular momentum number $l=0,1,2,\ldots$. We start with a wider class of anharmonic singular Hamiltonian given by

$$H=-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+\frac{\Lambda(\Lambda+1)}{r^2}+a_1r^2+\frac{a_2}{r^2}+\frac{a_3}{r^4}+\frac{a_4}{r^6}, \tag{4.10}$$

where $\Lambda=\frac{1}{2}(M-3)$, and $M=N+2l$. Clearly, the case $V(r)=a_1r^2+a_3r^{-4}+a_4r^{-6}$ appears as special case with $a_2=0$. Following the procedure discussed in Sec. II, we write the Hamiltonian as

TABLE IV. Upper bounds for the Hamiltonian $V(r)=ar^2+br^{-4}+cr^{-6}$ for different values of the parameters a, b, and c. The eigenvalues are exact for the seven digits shown, as confirmed numerically (or, for the first row, known exactly).

a	b	c	E^U
1	1	1	5.000 000 $(50\times 50, A\approx 25.51, B\approx 54.35)$
1	10	1	6.679 054 $(50\times 50, A\approx 9.65, B\approx 32.24)$
1	1	10	6.140 123 $(50\times 50, A\approx 5.56, B\approx 38.67)$
1	10	10	7.138 261 $(50\times 50, A\approx 7.83, B\approx 31.94)$
1	100	100	11.791 771 $(50\times 50, A\approx 5.15, B\approx 5.00)$
1	1000	1000	21.885 192 $(50\times 50, A\approx 19.42, B\approx 5.00)$

$$H=-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+Br^2+\frac{\Lambda(\Lambda+1)+A}{r^2}+(a_1-B)r^2+\frac{(a_2-A)}{r^2}+\frac{a_3}{r^4}+\frac{a_4}{r^6}. \tag{4.11}$$

The matrix elements of the Hamiltonian (4.11) take the form $(m,n=0,1,2,\ldots)$

$$H_{mn}=2\sqrt{B}(2n+\gamma_N)\delta_{mn}+(a_1-B)r_{mn}^2+(a_2-A)r_{mn}^{-2}+a_3r_{mn}^{-4}+a_4r_{mn}^{-6} \tag{4.12}$$

for $\gamma>3$. To analyze the precision of the method proposed here, we compare our results with some special cases for which the exact eigenvalues are known. The case of $a_1=a_3=a_4=1$, $a_2=0$, which yields the ground-state energy $E=5$ has been analyzed by Znojil,[49] Guardiola and Ros,[54] and Buendía *et al.*[51] by different techniques. Table IV shows the exact eigenvalues of $E=5$ can be reached with the diagonalization of 50×50 matrix. It should be noted however that we have fixed the dimension of the matrix to 50×50, but the particular value $E=5$ can be reached with far fewer matrix elements, indeed a 30×30 matrix is sufficient to achieve such accuracy. Further, the exact energies of 7,7,11 corresponding to $(a_1,a_3,a_4)=(1,9,9),(1,-7,49)$, and (1, 45, 225), respectively, follow simply with the optimization of the diagonalizable 40×40 matrix with $(A,B)=(17.47, 5.69)$, (18.86, 5.53), and (17.92, 5.40). These results simply indicate the generality and the efficiency of our approach. Note, the case of $(a_1,a_3,a_4)=(1,-7,49)$ also demonstrates the applicability of the method in the case of the parameter a_3 is negative. It is quite clear from Tables IV and V the generality of the method proposed here. In Table V, we illustrate the applicability of the method to the problem of obtaining the energies in different dimensions.

TABLE V. Upper bounds E^N for $H=-(\mathrm{d}^2/\mathrm{d}r^2)+[\Lambda(\Lambda+1)/r^2]+r^2+(1/r^4)+(1000/r^6)$ for dimension $N=2-10$, obtained by diagonalization then minimization with respect to A and B of a 30×30 matrix.

N	E^N
2	12.704 404 $(A\approx 5.05, B\approx 5.53)$
3	12.735 264 $(A\approx 11.73, B\approx 6.40)$
4	12.827 666 $(A\approx 5.05, B\approx 7.82)$
5	12.981 081 $(A\approx 5.97, B\approx 7.26)$
6	13.194 635 $(A\approx 6.25, B\approx 7.28)$
7	13.467 115 $(A\approx 6.12, B\approx 7.35)$
8	13.796 990 $(A\approx 6.16, B\approx 7.46)$
9	14.182 423 $(A\approx 6.31, B\approx 7.32)$
10	14.621 300 $(A\approx 3.11, B\approx 7.23)$

Similar results for different excited states can be easily reproduced. All the eigenvalues quoted in Tables I–V agree with the numerical solutions of the corresponding Schrödinger equation. Generally speaking, the precision of the energies to any number of decimal places can be easily achieved by increasing the dimension of the matrix.

V. CONCLUSION

We have developed an effective variational method to study a large family of singular Hamiltonians. A key feature of this work is the establishment and simplification of closed-form analytical expressions for the matrix elements with respect to a basis derived from a soluble singular problem. These formulas are general in the sense that they include two parameters from the basis which can then be used to optimize the matrix eigenvalues obtained for the problem at hand. The improved variational approach yields faster energy convergence than was possible earlier.

Perturbative and nonperturbative master equations for open quantum systems

Wusheng Zhu and Herschel Rabitz
Department of Chemistry, Princeton University, Princeton, New Jersey 08544-1009

(Received 11 June 2004; accepted 27 August 2004; published online 2 February 2005)

This paper develops perturbative and nonperturbative master equations for open quantum systems based on time-dependent variational functionals. The perturbative equations are more concise and suitable for dealing with cases of weak system-environment coupling for short evolution time scales. The nonperturbative equations are valid for all time and appropriate to treat cases of strong system-environment coupling. When a system contains an external control field, both the perturbative and nonperturbative master equations reveal the embedded control field dependence upon the system decoherence, which provides a basis for decoherence management. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1839275]

I. INTRODUCTION

Open quantum systems have been the focus of extensive studies with many applications ranging from quantum control to quantum computing.[1–4] To describe the dynamics of the reduced system of interest, a master equation based on second order perturbation theory with respect to the environmental interaction is the conventional approach.[5] However, in some cases the coupling between the reduced system and the environment is quite strong, and the equations based on perturbative dynamics are no longer appropriate. Some nonperturbative work has been done to treat specific strong coupling cases, for example, spin-boson problems,[6] high-Q cavities,[7] and coupled linear systems.[8] The purpose of this paper is to develop a nonperturbative framework to treat general open quantum systems.

The Liouville equation describes the dynamics of an arbitrary quantum system in terms of the density operator $\rho(t)$:

$$i\frac{\partial \rho(t)}{\partial t} = [H(t), \rho(t)], \tag{1}$$

where $H(t)$ is the Hamiltonian, and $[H(t), \rho(t)] \equiv H(t)\rho(t) - \rho(t)H(t)$. Solving Eq. (1) generally is not an easy task for complicated Hamiltonians with added difficulty arising from the commutative structure of the operator equation. A polynomial basis function expansion of the propagator is a common method employed in practice.[9,10] Variational tools provide an attractive means to treat Eq. (1) and they have been applied in various contexts such as laser cooling and quantum control.[11–13] One of the earliest examples was put forward by Balian and Veneroni[14] for evaluating the expectation value of an observable A utilizing the following variational functional:

$$\bar{\mathcal{A}}(t) = \mathrm{Tr}\{A\tilde{\rho}(t)\} - \int_0^t \mathrm{Tr}\left\{\tilde{\Lambda}(\tau)\left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H(\tau), \tilde{\rho}(\tau)]\right)\right\} \mathrm{d}\tau, \tag{2}$$

where $\mathrm{Tr}\{\cdot\}$ denotes the trace operation, and $\tilde{\Lambda}(t) = A$, $\tilde{\rho}(0) = \rho_0$ are imposed conditions. Throughout the paper, operators with the tilde symbol represent trials in a variational functional. With respect to the first order variations $\tilde{\rho}(t) = \rho(t) + \delta\rho(t)$ and $\tilde{\Lambda}(t) = \Lambda(t) + \delta\Lambda(t)$, where both $\rho(t)$ and $\Lambda(t)$ satisfy the Liouville equation in Eq. (1), the expectation value $\bar{\mathcal{A}}(t)$ is stationary up to the first order variations such that $\delta\bar{\mathcal{A}} = 0$.

II. TIME-DEPENDENT OPERATOR VARIATIONAL PRINCIPLE

In open quantum systems, partial trace operations often emerge in considering system dynamics in the presence of an environment. The variational principle of the expectation value of the complete trace of an observable [e.g., $\overline{A}(t)$ in Eq. (2)] is not convenient in the analysis of the reduced system dynamics. Therefore, it is worthwhile to develop a variational principle for the operator itself. For the evolution operator associated with Eq. (1),

$$U(t) = \overrightarrow{\exp}\left(- i \int_0^t H(\tau) \mathrm{d}\tau \right), \tag{3}$$

where the symbol $\rightarrow$ indicates the time ordering operation, the following operator functional,

$$\mathcal{U}(t) = \tilde{U}(t) \left[\mathbf{1} - \int_0^t \tilde{U}^{\dagger}(\tau) \left(\frac{\partial}{\partial \tau} + i\, H(\tau) \right) \tilde{U}(\tau) \mathrm{d}\tau \right] \tag{4}$$

forms a variational principle. In Eq. (4), $\mathbf{1}$ is the unit operator and $\dagger$ denotes the adjoint operation. With respect to the first order variation $\tilde{U}(t) = U(t) + \delta U(t)$, where $U(t)$ is defined in Eq. (3), it can be verified that

$$\delta \mathcal{U}(t) = \delta U(t) - \tilde{U}(t) \int_0^t \tilde{U}^{\dagger}(\tau) \left(\frac{\partial}{\partial \tau} + i\, H(\tau) \right) \delta U(\tau) \mathrm{d}\tau = \delta U(t) - \delta U(t) = 0. \tag{5}$$

Here integration by parts has been applied; it is assumed that the Hamiltonian is Hermitian and the trial evolution operator always satisfies $\tilde{U}(t)\tilde{U}^{\dagger}(t) = \mathbf{1}$. The variational evolution operator in Eq. (4) forms the basis for a number of functionals in the framework of the Schrödinger equation in terms of the wave function and the Liouville equation in terms of the density operator. Below we construct a variational functional for the density operator.

Based on Eq. (1), the density operator $\rho(t)$ can be written as

$$\rho(t) = U(t) \rho(0) U^{\dagger}(t). \tag{6}$$

When $U(t)$ is replaced by its variational form in Eq. (4), Eq. (6) will also become a variational form for the density operator,

$$\varrho(t) = \mathcal{U}(t) \rho(0) \mathcal{U}^{\dagger}(t). \tag{7}$$

Namely, inserting Eq. (4) into Eq. (6), and retaining terms up to second order produces the final variational functional for the density operator as

$$\begin{aligned} \varrho(t) &= \tilde{\rho}(t) - \tilde{U}(t) \int_0^t \tilde{U}^{\dagger}(\tau) \left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H(\tau), \tilde{\rho}(\tau)] \right) \tilde{U}(\tau) \mathrm{d}\tau\, \tilde{U}^{\dagger}(t) \\ &= \tilde{\rho}(t) - \int_0^t \tilde{U}(t,\tau) \left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H(\tau), \tilde{\rho}(\tau)] \right) \tilde{U}(\tau,t) \mathrm{d}\tau, \end{aligned} \tag{8}$$

where $\tilde{U}(t,\tau) \equiv \tilde{U}(t)\tilde{U}^{\dagger}(\tau)$. With respect to the first order variations $\tilde{U}(t) = U(t) + \delta U(t)$ and $\tilde{\rho}(t) = \rho(t) + \delta\rho(t)$ where $U(t)$ is defined in Eq. (3) and $\rho(t)$ satisfies Eq. (1), it can be verified from Eq. (8) that

$$\begin{aligned} \delta\varrho(t) &= \delta\rho(t) - \int_0^t \tilde{U}(t,\tau) \left(\frac{\partial\, \delta\rho(\tau)}{\partial \tau} + i[H(\tau), \delta\rho(\tau)] \right) \tilde{U}(\tau,t) \mathrm{d}\tau \\ &= \delta\rho(t) - \int_0^t \frac{\partial}{\partial \tau} [\tilde{U}(t,\tau)\, \delta\rho(\tau) \tilde{U}(\tau,t)] \mathrm{d}\tau = 0. \end{aligned} \tag{9}$$

The variational functional in Eq. (8) for the density operator itself will straightforwardly lead to

the variational functional in Eq. (2) for an expectation value of an observable. But, the former functional is more basic and is more suitable for partial trace processes.

A feature of the variational density operator $\varrho(t)$ in Eq. (8) is that the trace of $\varrho(t)$ is invariant,

$$\mathrm{Tr}\{\varrho(t)\} = \mathrm{Tr}\left\{\tilde{\rho}(t) - \int_0^t U(t,\tau)\left(\frac{\partial\tilde{\rho}(\tau)}{\partial\tau} + i[H(\tau),\tilde{\rho}(\tau)]\right)U(\tau,t)\mathrm{d}\tau\right\} = \mathrm{Tr}\{\rho(0)\} = 1, \tag{10}$$

regardless of the trial density operator $\tilde{\rho}(t)$ chosen in Eq. (8) as long as it satisfies the initial condition. Unlike the preservation property $\mathrm{Tr}\{\varrho(t)\}=1$ of the variational functional in Eq. (8), the variational evolution operator $\mathcal{U}(t)$ in Eq. (4) usually is not unitary, as a second order term survives

$$\begin{aligned}\mathcal{U}(t)\mathcal{U}^{\dagger}(t) = &\left(\mathbf{1} - \int_0^t \tilde{U}(t,\tau)\left(\frac{\partial\tilde{U}(\tau,t)}{\partial\tau} + iH(\tau)\tilde{U}(\tau,t)\right)\mathrm{d}\tau\right)\\ &\times\left(\mathbf{1} - \int_0^t \left(\frac{\partial\tilde{U}^{\dagger}(\tau,t)}{\partial\tau} - i\tilde{U}^{\dagger}(\tau,t)H(\tau)\right)\tilde{U}(\tau,t)\mathrm{d}\tau\right) = \mathbf{1} + \tilde{W}^2(t),\end{aligned} \tag{11}$$

where $\tilde{W}(t)$ is a Hermitian operator defined by

$$\tilde{W}(t) = \tilde{W}^{\dagger}(t) = \int_0^t \tilde{U}(t,\tau)\left(i\frac{\partial}{\partial\tau} - H(\tau)\right)\tilde{U}(\tau,t)\mathrm{d}\tau. \tag{12}$$

Thus, if necessary, a further step is needed to assure complete unitarity of $\mathcal{U}(t)$. For example, when an eigendecomposition is applied to $\mathcal{U}(t)$, and a renormalization condition on each eigenvalue is imposed (i.e., replacing λ_i by $\lambda_i' = \lambda_i/|\lambda_i|$), then a unitary evolution operator $\mathcal{U}'(t)$ will be obtained. It might be also important to preserve the positivity of the density operator as

$$\langle\psi|\varrho(t)|\psi\rangle \geqslant 0, \tag{13}$$

where ψ is an arbitrary function in the full space. Assuring positivity calls for retaining the second order term when inserting Eq. (4) into Eq. (6). In this case the variational functional for the density operator becomes

$$\begin{aligned}\varrho'(t) = &\left(\mathbf{1} - \int_0^t \tilde{U}(t,\tau)\left(\frac{\partial\tilde{U}(\tau,t)}{\partial\tau} + iH(\tau)\tilde{U}(\tau,t)\right)\mathrm{d}\tau\right)\tilde{U}(t)\rho(0)\tilde{U}^{\dagger}(t)\\ &\times\left(\mathbf{1} - \int_0^t \left(\frac{\partial\tilde{U}^{\dagger}(\tau,t)}{\partial\tau} - i\tilde{U}^{\dagger}(\tau,t)H(\tau)\right)\tilde{U}(\tau,t)\mathrm{d}\tau\right)\\ &= \tilde{\rho}(t) + i[\tilde{W}(t),\tilde{\rho}(t)] + \tilde{W}(t)\tilde{\rho}(t)\tilde{W}(t),\end{aligned} \tag{14}$$

where the operator $\tilde{W}(t)$ is defined in Eq. (12). The positivity of $\varrho'(t)$ can be verified as

$$\langle\psi|\varrho'(t)|\psi\rangle = \langle\psi|(\mathbf{1} + i\tilde{W}(t))\tilde{U}(t)\rho(0)\tilde{U}^{\dagger}(t)(\mathbf{1} - i\tilde{W}(t))|\psi\rangle = \langle\psi'|\rho(0)|\psi'\rangle \geqslant 0, \tag{15}$$

where $\psi' = \tilde{U}^{\dagger}(t)(\mathbf{1} - i\tilde{W}(t))\psi$, and the initial density operator is defined to be positive. However, due to the nonunitary feature of the variational evolution operator $\mathcal{U}(t)$, the variational density operator $\varrho'(t)$ in Eq. (14) generally will not preserve the unit trace property. If both positivity and unit trace invariance are required, then the following variational functional can be employed:

$$\varrho''(t) = \frac{\tilde{\rho}(t) + i[\tilde{W}(t),\tilde{\rho}(t)] + \tilde{W}(t)\tilde{\rho}(t)\tilde{W}(t)}{\mathrm{Tr}\{\tilde{\rho}(t)[\mathbf{1} + \tilde{W}^2(t)]\}}. \tag{16}$$

The above considerations about the unit trace invariance and positivity could be important when the ultimate goal is to evaluate the density operator itself. However, if the variational density operator is only utilized for a partial or full trace with some other operators, a small deviation from unit trace invariance or positivity of the density operator might not be significant for the ultimate goal.

III. DYNAMICS OF AN OPEN QUANTUM SYSTEM

An open quantum system generally refers to one which is of primary interest while being coupled to the environment. The dynamics of the environment is not fully or explicitly treated due to the extreme complexity of describing the dynamical details of the environment. The validity of such a treatment rests on the fact that the environment is assumed to be very large and has many degrees of freedom. Thus, the dynamics of the quantum system of interest can be described by isolated unitary evolution along with a dissipative part resulting from the interaction with the environment. In general, the Hamiltonian for the full system (i.e., the open quantum system plus the environment) can be written as

$$H(t) = H'_S(t) + H_E + H'_I(t), \tag{17}$$

where $H'_S(t)$, H_E, and $H'_I(t)$ describe the system, the environment, and their interaction, respectively. As the environment is assumed to be a large reservoir, its Hamiltonian H_E is treated as time independent. In some quantum control systems, the control field may also explicitly couple with the environment, for example, through an environmental dipole interaction,

$$H'_E(t) = H_E - \vec{\mu}_E \cdot \vec{\varepsilon}(t). \tag{18}$$

When the situation in Eq. (18) occurs, it is convenient to treat the stationary part H_E as the environmental Hamiltonian, while the coupling part is included in the interaction Hamiltonian,

$$H'_I(t,\{\vec{\varepsilon}(t)\}) = H'_I(t) - \vec{\mu}_E \cdot \vec{\varepsilon}(t). \tag{19}$$

Thus the time dependence of the Hamiltonians $H'_S(t)$ and $H'_I(t)$ in Eq. (17) can be viewed as general, including the presence of the control field (as a function of time) in both pieces, which could be important in the treatment of control issues. Throughout the paper, no coupling is assumed between the system and environment at the initial time,

$$\rho(0) = \rho_S(0) \otimes \rho_E, \tag{20}$$

where the initial system density operator $\rho_S(0)$ is considered to be a pure state, and the initial environmental density operator ρ_E is a mixed state. As long as no confusion arises, the tensor product symbol $\otimes$ will be omitted afterwards. The reduced density operator $\rho_S(t)$ associated with the system is defined as the trace of the full density operator over the environmental variables or states,

$$\rho_S(t) = \mathrm{Tr}_E\{\rho(t)\}. \tag{21}$$

Since it is reasonable to treat the environment as being in statistical equilibrium, the environmental density operator may be approximated as time independent. Therefore it is rational to repartition the entire Hamiltonian in Eq. (17) as

$$H(t) = H'_S(t) + \mathrm{Tr}_E\{H'_I(t)\rho_E\} + H_E + H'_I(t) - \mathrm{Tr}_E\{H'_I(t)\rho_E\} = H_S(t) + H_E + H_I(t), \tag{22}$$

where $H_S(t) \equiv H'_S(t) + \mathrm{Tr}_E\{H'_I(t)\rho_E\}$ and $H_I(t) \equiv H'_I(t) - \mathrm{Tr}_E\{H'_I(t)\rho_E\}$. Equation (22) implies that the repartitioned interaction Hamiltonian satisfies

$$\mathrm{Tr}_E\{H_I(t)\rho_E\} = 0. \tag{23}$$

The repartitioned system Hamiltonian is assumed to have the following form:

$$H_S(t) = H_S^0 - \vec{\mu} \cdot \vec{\varepsilon}(t), \tag{24}$$

where H_S^0 represents the field-free system Hamiltonian, $\vec{\mu}$ is the system electric dipole moment vector, and $\vec{\varepsilon}(t)$ is the control electric field vector.

Taking a partial trace over the environmental variables on both sides of Eq. (1) will produce the reduced system dynamical equation

$$i\frac{\partial \rho_S(t)}{\partial t} = \mathrm{Tr}_E\{[H(t),\rho(t)]\} = [H_S(t),\rho_S(t)] + \mathrm{Tr}_E\{[H_I(t),\rho(t)]\}. \tag{25}$$

Equation (25) is an exact expression, but it is not in closed form for the reduced system. Various approximations could be applied to the last term in Eq. (25) to achieve a closed form master equation. The treatment below will start with this equation.

IV. VARIATIONAL FUNCTIONALS FOR AN OPEN QUANTUM SYSTEM

The dynamical equation of the reduced density operator in Eq. (25) contains the full density operator $\rho(t)$. Since in practice obtaining $\rho(t)$ from solving Eq. (1) is not feasible, a variational approach provides an attractive means to deal with this problem. When the variational functional $\varrho(t)$ in Eq. (8) is introduced into Eq. (25), we obtain

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] + \mathrm{Tr}_E\left\{\left[H_I(t),\tilde{\rho}(t) - \int_0^t \tilde{U}(t,\tau)\left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H(\tau),\tilde{\rho}(\tau)]\right)\tilde{U}(\tau,t)\mathrm{d}\tau\right]\right\}. \tag{26}$$

Besides the differential form for $\rho_S(t)$ in Eq. (26), an integral variational functional form for $\rho_S(t)$ also can be constructed. The system density operator $\rho_S(t)$ in Eq. (25) can be formally solved for as

$$\rho_S(t) = U_S(t)\rho_S(0)U_S^\dagger(t) - i\int_0^t U_S(t,\tau)\mathrm{Tr}_E\{[H_I(\tau),\rho(\tau)]\}U_S(\tau,t)\mathrm{d}\tau, \tag{27}$$

where $U_S(t)$ is the system evolution operator. Then the following variational functional can be introduced to evaluate $\rho_S(t)$:

$$\begin{aligned}
\rho_S(t) &= U_S(t)\rho_S(0)U_S^\dagger(t) - i\int_0^t U_S(t,\tau)\mathrm{Tr}_E\{[H_I(\tau),\tilde{\rho}(\tau)]\}U_S(\tau,t)\mathrm{d}\tau \\
&\quad + \int_0^t \mathrm{Tr}_E\left\{U_S(t,\tau)\left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H(\tau),\tilde{\rho}(\tau)]\right)U_S(\tau,t)\right\}\mathrm{d}\tau \\
&\quad - \int_0^t \mathrm{Tr}_E\left\{\tilde{U}(t,\tau)\left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H(\tau),\tilde{\rho}(\tau)]\right)\tilde{U}(\tau,t)\right\}\mathrm{d}\tau \\
&= U_S(t)\rho_S(0)U_S^\dagger(t) + \int_0^t \mathrm{Tr}_E\left\{U_S(t,\tau)\left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H_S(\tau),\tilde{\rho}(\tau)]\right)U_S(\tau,t)\right\}\mathrm{d}\tau \\
&\quad - \int_0^t \mathrm{Tr}_E\left\{\tilde{U}(t,\tau)\left(\frac{\partial \tilde{\rho}(\tau)}{\partial \tau} + i[H(\tau),\tilde{\rho}(\tau)]\right)\tilde{U}(\tau,t)\right\}\mathrm{d}\tau.
\end{aligned} \tag{28}$$

Equation (28) will reduce to Eq. (27) when the trial density operator is exact. Also we can verify that the first order variation $\delta\rho_S$ vanishes with respect to considering $\tilde{\rho}=\rho+\delta\rho$. As a variational functional, Eq. (28) is suitable for numerical implementation by basis expansion or proper parametrization of the trial inputs which will not be explored further in this paper. Equation (26) is

especially suitable for theoretical analysis, as will be evident in the following sections which derive suitable master equations.

V. PERTURBATIVE MASTER EQUATIONS FROM VARIATIONAL FUNCTIONALS

The conventional master equation readily can be obtained starting from Eq. (25) and applying a perturbation expansion (or a weak coupling assumption).[5] Briefly, from Eq. (1), we have the following exact expression:

$$\rho(t) = U_S(t)\rho_S(0)U_S^\dagger(t)\rho_E - i\int_0^t U_{SE}^\dagger(\tau,t)[H_I(\tau),\rho(\tau)]U_{SE}(\tau,t)\mathrm{d}\tau, \tag{29}$$

where $U_{SE}(\tau,t)\equiv U_S(\tau,t)U_E(\tau,t)$ and U_E is the environmental evolution operator. Applying the perturbation approximation $\rho(\tau)\approx\rho_S(\tau)\rho_E$ on the right-hand side of Eq. (29) leads to

$$\rho(t) = U_S(t)\rho_S(0)U_S^\dagger(t)\rho_E - i\int_0^t U_{SE}^\dagger(\tau,t)[H_I(\tau),\rho_S(\tau)\rho_E]U_{SE}(\tau,t)\mathrm{d}\tau. \tag{30}$$

Inserting Eq. (30) into Eq. (25) yields

$$i\frac{\partial\rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - i\int_0^t \mathrm{Tr}_E\{[H_I(t),U_{SE}^\dagger(\tau,t)[H_I(\tau),\rho_S(\tau)\rho_E]U_{SE}(\tau,t)]\}\mathrm{d}\tau. \tag{31}$$

Equation (31) is a premaster equation which finally will lead to the conventional master equation by proper expansion of the interaction Hamiltonian and tracing out the environmental variables. In this paper the pre-master equation will be simply called the master equation without confusion.

For the variational functional involving reduced density operator dynamics in Eq. (26), if the trial evolution operator is exact, then Eq. (26) becomes exact no matter what trial density operator $\tilde{\rho}(t)$ is chosen as long as the initial condition is satisfied. Thus, the following equation,

$$i\frac{\partial\rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] + \mathrm{Tr}_E\left\{\left[H_I(t),\tilde{\rho}(t) - \int_0^t U^\dagger(\tau,t)\left(\frac{\partial\tilde{\rho}(\tau)}{\partial\tau} + i[H(\tau),\tilde{\rho}(\tau)]\right)U(\tau,t)\mathrm{d}\tau\right]\right\}, \tag{32}$$

exactly holds for any $\tilde{\rho}(t)$ with $\tilde{\rho}(0)=\rho(0)$. Since the full evolution operator appears in Eq. (32), it is suggestive to start with the simpler equation,

$$i\frac{\partial\rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] + \mathrm{Tr}_E\{[H_I(t),U(t)\rho(0)U^\dagger(t)]\}, \tag{33}$$

which can be obtained by directly inserting Eq. (6) into Eq. (25). However, Eq. (33) is only formally useful. Eventually the full evolution operator needs to be introduced with some suitable approximation. The variational principle in Eq. (32) will result an automatic correction for small deviations on the full evolution operator, while there is no such benefit from using Eq. (33). As an illustration, upon applying the approximation

$$U(\tau,t)\approx U_{SE}(\tau,t), \tag{34}$$

Eq. (33) becomes

$$i\frac{\partial\rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] \tag{35}$$

whose form is unacceptable, as no decoherence is retained. But under the same approximation, generally decoherence is properly retained using Eq. (32), which will be shown below.

As a first example, consider the trial full density operator of the form $\tilde{\rho}(\tau) = U_S(\tau)\rho_S(0)U_S^\dagger(\tau)\rho_E$ (where $\tau \in [0,t]$). Then Eq. (32) becomes

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - i\int_0^t \mathrm{Tr}_E\{[H_I(t),U^\dagger(\tau,t)[H_I(\tau),U_S(\tau)\rho_S(0)U_S^\dagger(\tau)\rho_E]U(\tau,t)]\}\mathrm{d}\tau. \tag{36}$$

Equation (36) is exact and can be used as a basis for further approximation to solve for $\rho_S(t)$. However, it is often more useful to have a "homogeneous" differential equation for $\rho_S(t)$ without explicitly involving its initial condition $\rho_S(0)$. This can be done by replacing $\rho_S(0)$ as a functional of $\rho_S(t)$ as follows.

Inserting the same trial density operator $\tilde{\rho}(\tau) = U_S(\tau)\rho_S(0)U_S^\dagger(\tau)\rho_E$ into Eq. (28) will yield another exact formula:

$$U_S(\tau)\rho_S(0)U_S^\dagger(\tau) = \rho_S(\tau) + i\int_0^\tau \mathrm{Tr}_E\{U^\dagger(\tau',\tau)[H_I(\tau'),U_S(\tau')\rho_S(0)U_S^\dagger(\tau')\rho_E]U(\tau',\tau)\}\mathrm{d}\tau'. \tag{37}$$

Recursively inserting Eq. (37) into Eq. (36) will generate a hierarchical series,

$$\begin{aligned} i\frac{\partial \rho_S(t)}{\partial t} = {} & [H_S(t),\rho_S(t)] - i\int_0^t \mathrm{Tr}_E\{[H_I(t),U^\dagger(\tau,t)[H_I(\tau),\rho_S(\tau)\rho_E]U(\tau,t)]\}d\tau \\ & + \int_0^t\int_0^\tau \mathrm{Tr}_E\{[H_I(t),U^\dagger(\tau,t)[H_I(\tau),\mathrm{Tr}_E\{U^\dagger(\tau',\tau) \\ & \times[H_I(\tau'),\rho_S(\tau')\rho_E]U(\tau',\tau)\}\rho_E]U(\tau,t)]\}\mathrm{d}\tau'\mathrm{d}\tau + \cdots. \end{aligned} \tag{38}$$

This series will converge under the weak coupling assumption [i.e., the norm of $H_I(t)$ is sufficiently small]. If only the leading term of the hierarchical series is kept, Eq. (38) will be

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - i\int_0^t \mathrm{Tr}_E\{[H_I(t),U^\dagger(\tau,t)[H_I(\tau),\rho_S(\tau)\rho_E]U(\tau,t)]\}\mathrm{d}\tau. \tag{39}$$

Equation (39) is similar, but not identical, to the well-known perturbation result in Eq. (31). Equation (31) can be obtained from Eq. (39) by using the approximation in Eq. (34). Equation (39) is more flexible than Eq. (31), as the full evolution operator can be approximated in various ways other than Eq. (34), even by basis set expansion via a variational procedure.

Like the conventional non-Markovian master equation in Eq. (31), Equation (39) is also an integro-differential equation for $\rho_S(t)$. It is worthwhile to search for a perturbative master equation for $\rho_S(t)$ only involving a differential form. With this goal in mind, Eq. (37) also can be written as

$$\rho_S(0) = U_S^\dagger(t)\rho_S(t)U_S(t) + i\int_0^t \mathrm{Tr}_E\{U_S^\dagger(t)U^\dagger(\tau,t)[H_I(\tau),U_S(\tau)\rho_S(0)U_S^\dagger(\tau)\rho_E]U(\tau,t)U_S(t)\}\mathrm{d}\tau. \tag{40}$$

Recursively inserting Eq. (40) into Eq. (36) will generate the hierarchical series,

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t), \rho_S(t)] - i\int_0^t \mathrm{Tr}_E\{[H_I(t), U^\dagger(\tau,t)[H_I(\tau), U_S(\tau,t)\rho_S(t)U_S^\dagger(\tau,t)\rho_E]U(\tau,t)]\}\mathrm{d}\tau$$
$$+ \int_0^t \int_0^t \mathrm{Tr}_E\{[H_I(t), U^\dagger(\tau,t)[H_I(\tau), \mathrm{Tr}_E\{U_S(\tau,t)U^\dagger(\tau',t)$$
$$\times [H_I(\tau'), U_S(\tau',t)\rho_S(t)U_S^\dagger(\tau',t)\rho_E]U(\tau',t)U_S^\dagger(\tau',t)\}\rho_E]U(\tau,t)]\}\mathrm{d}\tau'\mathrm{d}\tau + \cdots. \quad (41)$$

The leading term in Eq. (41) is

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t), \rho_S(t)] - i\int_0^t \mathrm{Tr}_E\{[H_I(t), U^\dagger(\tau,t)[H_I(\tau), U_S(\tau,t)\rho_S(t)U_S^\dagger(\tau,t)\rho_E]U(\tau,t)]\}\mathrm{d}\tau. \quad (42)$$

The structure of Eq. (42) is distinct from that of the conventional result in Eq. (31), as the former one only involves the differential form of $\rho_S(t)$ and no longer has time integration over the system density operator. Equation (42) can be further expanded into

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t), \rho_S(t)] - i\int_0^t (\mathrm{Tr}_E\{H_I(t)U^\dagger(\tau,t)H_I(\tau)U_S(\tau,t)\rho_E\rho_S(t)U_S^\dagger(\tau,t)U(\tau,t)\}$$
$$+ \mathrm{Tr}_E\{U^\dagger(\tau,t)U_S(\tau,t)\rho_S(t)\rho_E U_S^\dagger(\tau,t)H_I(\tau)U(\tau,t)H_I(t)\}$$
$$- \mathrm{Tr}_E\{H_I(t)U^\dagger(\tau,t)U_S(\tau,t)\rho_S(t)\rho_E U_S^\dagger(\tau,t)H_I(\tau)U(\tau,t)\}$$
$$- \mathrm{Tr}_E\{U^\dagger(\tau,t)H_I(\tau)U_S(\tau,t)\rho_E\rho_S(t)U_S^\dagger(\tau,t)U(\tau,t)H_I(t)\})\mathrm{d}\tau. \quad (43)$$

Equation (43) has the following form of a general master equation:

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t), \rho_S(t)] - \int_0^t \sum_{jk} (A_{jk}(\tau,t)\rho_S(t)B_{jk}^\dagger(\tau,t) - B_{jk}(\tau,t)\rho_S(t)A_{jk}^\dagger(\tau,t) + C_{jk}(\tau,t)\rho_S(t)D_{jk}^\dagger(\tau,t)$$
$$- D_{jk}(\tau,t)\rho_S(t)C_{jk}^\dagger(\tau,t))\mathrm{d}\tau. \quad (44)$$

The operators $A_{jk}, B_{jk}, C_{jk}, D_{jk}$ in Eq. (44) are defined as follows:

$$A_{jk}(\tau,t) = i\sqrt{w_k}\,\langle\phi_j|H_I(t)U^\dagger(\tau,t)H_I(\tau)|\Phi_k\rangle U_S(\tau,t), \quad (45)$$

$$B_{jk}(\tau,t) = \sqrt{w_k}\,\langle\phi_j|U^\dagger(\tau,t)|\Phi_k\rangle U_S(\tau,t), \quad (46)$$

$$C_{jk}(\tau,t) = \sqrt{w_k}\,\langle\phi_j|H_I(t)U^\dagger(\tau,t)|\Phi_k\rangle U_S(\tau,t), \quad (47)$$

$$D_{jk}(\tau,t) = i\sqrt{w_k}\,\langle\phi_j|U^\dagger(\tau,t)H_I(\tau)|\Phi_k\rangle U_S(\tau,t), \quad (48)$$

where $\{\phi_j\}$ is the basis of the environment space, and a general initial environmental density operator,

$$\rho_E = \sum_k w_k|\Phi_k\rangle\langle\Phi_k|, \quad (49)$$

is applied. It can be verified that an identity exists among the operators $A_{jk}, B_{jk}, C_{jk}, D_{jk}$ in Eq. (44),

$$\sum_j B_{jk}^\dagger(\tau,t)A_{jk}(\tau,t) = \sum_j C_{jk}^\dagger(\tau,t)D_{jk}(\tau,t). \quad (50)$$

If necessary, the time integration in Eq. (44) can be removed by expanding the operators $A_{jk}, B_{jk}, C_{jk}, D_{jk}$ in shifted Legendre polynomial[15] $\{P_\ell(\tau/t), \tau/t \in [0,1]\}$, and utilizing the orthogonality relationship

$$\int_0^1 P_\ell(\tau/t) P_{\ell'}(\tau/t) \mathrm{d}\tau/t = \frac{1}{2\ell+1} \delta_{\ell\ell'}. \tag{51}$$

As an illustration, the operator A_{jk} can be expanded into

$$A_{jk}(\tau,t) = \sum_{\ell=0}^{\infty} \left(\frac{2\ell+1}{t}\right)^{1/2} A'_{jk\ell}(t) P_\ell(\tau/t), \tag{52}$$

where the operator $A'_{jk\ell}(t)$ is determined by

$$A'_{jk\ell}(t) = \sqrt{(2\ell+1)t} \int_0^1 A_{jk}(\tau,t) P_\ell(\tau/t) \mathrm{d}\tau/t \tag{53}$$

for all $t \neq 0$, and for $t=0$ it is simply that $A'_{jk\ell}(0)=0$. For the other operators B_{jk}, C_{jk}, D_{jk}, similar expansions can be produced. Thus, Eq. (44) can be expressed as

$$\begin{aligned} i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t), \rho_S(t)] - \sum_{jk\ell} (&A'_{jk\ell}(t)\rho_S(t)B'^{\dagger}_{jk\ell}(t) - B'_{jk\ell}(t)\rho_S(t)A'^{\dagger}_{jk\ell}(t) + C'_{jk\ell}(t)\rho_S(t)D'^{\dagger}_{jk\ell}(t) \\ &- D'_{jk\ell}(t)\rho_S(t)C'^{\dagger}_{jk\ell}(t)), \end{aligned} \tag{54}$$

where the operators $B'_{jk\ell}(t), C'_{jk\ell}(t), D'_{jk\ell}(t)$ are defined similarly to $A'_{jk\ell}(t)$ in Eq. (53).

Equation (44) is fully general, yet somewhat complex to deal with. Below a further simplified version is presented. From the relation

$$i\frac{\partial}{\partial \tau}(U^\dagger(\tau,t)U_S(\tau,t)\rho_S(t)U_S^\dagger(\tau,t)U(\tau,t)) = [-U^\dagger(\tau,t)H_I(\tau)U(\tau,t), U^\dagger(\tau,t)U_S(\tau,t)\rho_S(t)U_S^\dagger(\tau,t)U(\tau,t)] \tag{55}$$

we have the formal solution

$$\begin{aligned} U^\dagger(\tau,t)U_S(\tau,t)\rho_S(t)U_S^\dagger(\tau,t)U(\tau,t) &= \overrightarrow{\exp}\left(i\int_t^\tau U^\dagger(t',t)H_I(t')U(t',t)\mathrm{d}t'\right)\rho_S(t) \\ &\quad \times \overrightarrow{\exp}\left(-i\int_t^\tau U^\dagger(t',t)H_I(t')U(t',t)\mathrm{d}t'\right) \\ &= \rho_S(t) + i\left[\int_t^\tau U^\dagger(t',t)H_I(t')U(t',t)\mathrm{d}t', \rho_S(t)\right] + \cdots, \end{aligned} \tag{56}$$

where the generalized Baker-Hausdorff formula[16] is applied to produce the expansion in the last step. Inserting Eq. (56) into Eq. (43) and taking the leading term yields

$$i\frac{\partial\rho_S(t)}{\partial t}=[H_S(t),\rho_S(t)]-i\Bigg(\mathrm{Tr}_E\Bigg\{H_I(t)\int_0^t U^\dagger(\tau,t)H_I(\tau)\rho_E U(\tau,t)\mathrm{d}\tau\Bigg\}\rho_S(t)$$
$$+\rho_S(t)\ \mathrm{Tr}_E\Bigg\{\int_0^t U^\dagger(\tau,t)\rho_E H_I(\tau)U(\tau,t)\mathrm{d}\tau\, H_I(t)\Bigg\}$$
$$-\mathrm{Tr}_E\Bigg\{H_I(t)\rho_S(t)\int_0^t U^\dagger(\tau,t)\rho_E H_I(\tau)U(\tau,t)\mathrm{d}\tau\Bigg\}$$
$$-\mathrm{Tr}_E\Bigg\{\int_0^t U^\dagger(\tau,t)H_I(\tau)\rho_E U(\tau,t)\mathrm{d}\tau\,\rho_S(t)H_I(t)\Bigg\}\Bigg). \tag{57}$$

Similar to Eq. (8), we have

$$U^\dagger(\tau,t)\rho_E U(\tau,t)=\rho_E-i\int_\tau^t U^\dagger(t',t)[H_I(t'),\rho_E]U(t',t)\mathrm{d}t'. \tag{58}$$

Inserting Eq. (58) into Eq. (57) and taking the leading term produces

$$i\frac{\partial\rho_S(t)}{\partial t}=[H_S(t),\rho_S(t)]-i\Bigg(\mathrm{Tr}_E\Bigg\{H_I(t)\int_0^t U^\dagger(\tau,t)H_I(\tau)U(\tau,t)\mathrm{d}\tau\,\rho_E\Bigg\}\rho_S(t)$$
$$+\rho_S(t)\ \mathrm{Tr}_E\Bigg\{\rho_E\int_0^t U^\dagger(\tau,t)H_I(\tau)U(\tau,t)\mathrm{d}\tau\, H_I(t)\Bigg\}$$
$$-\mathrm{Tr}_E\Bigg\{H_I(t)\rho_S(t)\rho_E\int_0^t U^\dagger(\tau,t)H_I(\tau)U(\tau,t)\mathrm{d}\tau\Bigg\}$$
$$-\mathrm{Tr}_E\Bigg\{\int_0^t U^\dagger(\tau,t)H_I(\tau)U(\tau,t)\mathrm{d}\tau\,\rho_E\rho_S(t)H_I(t)\Bigg\}\Bigg). \tag{59}$$

Defining

$$\overline{H_I}(t)=\int_0^t U^\dagger(\tau,t)H_I(\tau)U(\tau,t)\mathrm{d}\tau, \tag{60}$$

Eq. (59) can be simplified into the master equation

$$i\frac{\partial\rho_S(t)}{\partial t}=[H_S(t),\rho_S(t)]-i\{\mathrm{Tr}_E(H_I(t)\overline{H_I}(t)\rho_E)\rho_S(t)+\rho_S(t)\ \mathrm{Tr}_E(\rho_E\overline{H_I}(t)H_I(t))$$
$$-\mathrm{Tr}_E(H_I(t)\rho_S(t)\rho_E\overline{H_I}(t))-\mathrm{Tr}_E(\overline{H_I}(t)\rho_E\rho_S(t)H_I(t))\}. \tag{61}$$

Equation (61) has a similar but not identical structure as the Lindblad equation,[17]

$$i\frac{\partial\rho_S(t)}{\partial t}=[H_S(t),\rho_S(t)]-i\sum_{\{n\}}\left(\frac{1}{2}\mathcal{L}_{\{n\}}^\dagger\mathcal{L}_{\{n\}}\rho_S(t)+\frac{1}{2}\rho_S(t)\mathcal{L}_{\{n\}}^\dagger\mathcal{L}_{\{n\}}-\mathcal{L}_{\{n\}}\rho_S(t)\mathcal{L}_{\{n\}}^\dagger\right). \tag{62}$$

In fact, the Lindblad version of Eq. (61) can be derived by further approximation. A simple way to reveal the connection between Eqs. (61) and (62) is evident at small time or for the interaction Hamiltonian having a slowly varying profile. Then Eq. (60) can be expressed as

$$\overline{H_I}(t) = \int_0^t U^\dagger(\tau,t)H_I(\tau)U(\tau,t)\mathrm{d}\tau = \int_0^t \left(H_I(\tau) + i\left[\int_t^\tau H(t')\mathrm{d}t', H_I(\tau) \right] + \cdots \right)\mathrm{d}\tau \approx \alpha(t)H_I(t), \tag{63}$$

where $\alpha(t)$ is an appropriate function of time. Inserting Eq. (63) into Eq. (61) will result in

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - i\alpha^2(t)\{\mathrm{Tr}_E(H_I^2(t)\rho_E)\rho_S(t) + \rho_S(t)\ \mathrm{Tr}_E(\rho_E H_I^2(t)) - 2\ \mathrm{Tr}_E(H_I(t)\rho_S(t)\rho_E H_I(t))\}. \tag{64}$$

By comparing Eq. (64) to the standard Lindblad equation in Eq. (62) the equivalent Lindblad operator in Eq. (64) can be identified as

$$L_{jk} = \alpha(t)\sqrt{2w_k}\langle\phi_j|H_I(t)|\Phi_k\rangle, \tag{65}$$

where w_k, ϕ_j, and Φ_k are defined before in Eqs. (45)–(49).

Unlike the Lindblad operator in Eq. (62) which usually can only be assigned phenomenologically, Eq. (61) fully specifies each operator involved, which provides the means to map out a deeper relationship between the action of a control field and the system decoherence. In particular, the linear entropy measure of decoherence[18]

$$S_L(t) = 1 - \mathrm{Tr}_S\{\rho_S^2(t)\} \tag{66}$$

can be evaluated through Eq. (61) as

$$S_L(t) = 2\int_0^t \mathrm{Tr}\{(\rho_S^2(\tau)H_I(\tau)\overline{H_I}(\tau) + \rho_S^2(\tau)\overline{H_I}(\tau)H_I(\tau) - \rho_S(\tau)\overline{H_I}(\tau)\rho_S(\tau)H_I(\tau) - \rho_S(\tau)H_I(\tau)\rho_S(\tau)\overline{H_I}(\tau))\rho_E\}, \tag{67}$$

where both $\rho_S(\tau)$ and $\overline{H_I}(\tau)$ depend on the control field. In contrast, the similar formula through the Lindblad equation is

$$S_L(t) = 2\int_0^t \mathrm{Tr}_S\left\{ \sum_k (\rho_S^2(\tau)\mathcal{L}_k^\dagger\mathcal{L}_k - \rho_S(\tau)\mathcal{L}_k\rho_S(\tau)\mathcal{L}_k^\dagger) \right\}, \tag{68}$$

in which only $\rho_S(\tau)$ shows an explicit dependence on the control field.

VI. A VARIATIONALLY BASED NONPERTURBATIVE MASTER EQUATION

The master equation in Eq. (42) arises from the leading term in a hierarchical perturbation expansion. Its validity is based on the assumption of a weak coupling approximation in terms of H_I. If the coupling is sufficiently strong, the hierarchical series expansion in Eq. (41) may not converge. If the coupling is relatively weak but acting for a sufficiently long time, then truncation of the expansion in Eq. (41) to low order can produce significant discrepancies in the decoherent aspects of the system dynamics. In the case of a convergent hierarchical expansion, including higher order terms in Eq. (41) in principle will produce better results, but the complex nature of the higher order terms will prevent any practical implementation. Therefore, a perturbation expansion is likely not the best foundation for developing an ultimate master equation that is valid for all time. In the following material, a nonperturbative formulation of decoherent dynamics will be explored.

Consider once again Eq. (32) as a variational formulation involving the full density operator. In order to derive a nonperturbative master equation, a trial for the full density operator has to be introduced in a nonperturbative fashion. There are many possible choices, and a convenient one is

$$\tilde{\rho}(\tau) = U_S(\tau,t)\rho_S(t)U_S^{\dagger}(\tau,t)\rho_E(1-e^{-c\tau}) + \rho_S(\tau)\rho_E e^{-c\tau}, \tag{69}$$

where $\tau \in [0,t]$, and c is a large positive constant. It is evident that $\tilde{\rho}(\tau)$ in Eq. (69) satisfies the initial condition as $\tilde{\rho}(0)=\rho_S(0)\rho_E$. Inserting Eq. (69) into Eq. (32) will yield

$$\begin{aligned} i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - \int_0^t \mathrm{Tr}_E\{[H_I(t),U^{\dagger}(\tau,t)(i[H_I(\tau),\underbrace{U_S(\tau,t)\rho_S(t)U_S^{\dagger}(\tau,t)\rho_E(1-e^{-c\tau})}_{\text{(i)}} \\ + \underbrace{\rho_S(\tau)\rho_E e^{-c\tau}}_{\text{(ii)}}] + \underbrace{U_S(\tau,t)\rho_S(t)U_S^{\dagger}(\tau,t)\rho_E c e^{-c\tau} - \rho_S(\tau)\rho_E c e^{-c\tau}}_{\text{(iii)}} \\ \underbrace{- i\,\mathrm{Tr}_E\{[H_I(\tau),\rho(\tau)]\}\rho_E e^{-c\tau}}_{\text{(iv)}})U(\tau,t)]\}\mathrm{d}\tau. \end{aligned} \tag{70}$$

In Eq. (70), the term (i) will have its major contribution at longer times, while the terms (ii) and (iii) will dominate at short times. But, the contribution of the term (iv) can be neglected for all the time. The reason is that at longer times, the exponential $e^{-c\tau}$ quickly decreases toward zero, while at short times, the full density operator can be well approximated as a tensor product of the uncoupling system and environmental density operators, and $\mathrm{Tr}_E\{[H_I(\tau),\rho_S(\tau)\rho_E]\}=0$. Thus, the dynamical equation reduces to

$$\begin{aligned} i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - \int_0^t \mathrm{Tr}_E\{[H_I(t),U^{\dagger}(\tau,t)(i[H_I(\tau),U_S(\tau,t)\rho_S(t)U_S^{\dagger}(\tau,t)\rho_E(1-e^{-c\tau}) \\ + \rho_S(\tau)\rho_E e^{-c\tau}] + U_S(\tau,t)\rho_S(t)U_S^{\dagger}(\tau,t)\rho_E c e^{-c\tau} - \rho_S(\tau)\rho_E c e^{-c\tau})U(\tau,t)]\}\mathrm{d}\tau. \end{aligned} \tag{71}$$

Equation (71) can be expanded into

$$\begin{aligned} i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - i\int_0^t (\mathrm{Tr}_E\{H_I(t)U^{\dagger}(\tau,t)H_I(\tau)U_S(\tau,t)\rho_E\rho_S(t)U_S^{\dagger}(\tau,t)U(\tau,t) \\ + U^{\dagger}(\tau,t)U_S(\tau,t)\rho_S(t)\rho_E U_S^{\dagger}(\tau,t)H_I(\tau)U(\tau,t)H_I(t) \\ - H_I(t)U^{\dagger}(\tau,t)U_S(\tau,t)\rho_S(t)\rho_E U_S^{\dagger}(\tau,t)H_I(\tau)U(\tau,t) \\ - U^{\dagger}(\tau,t)H_I(\tau)U_S(\tau,t)\rho_E\rho_S(t)U_S^{\dagger}(\tau,t)U(\tau,t)H_I(t)\})(1-e^{-c\tau})\mathrm{d}\tau \\ - i\int_0^t (\mathrm{Tr}_E\{H_I(t)U^{\dagger}(\tau,t)H_I(\tau)\rho_E\rho_S(\tau)U(\tau,t) + U^{\dagger}(\tau,t)\rho_S(\tau)\rho_E H_I(\tau)U(\tau,t)H_I(t) \\ - H_I(t)U^{\dagger}(\tau,t)\rho_S(\tau)\rho_E H_I(\tau)U(\tau,t) - U^{\dagger}(\tau,t)H_I(\tau)\rho_E\rho_S(\tau)U(\tau,t)H_I(t)\})e^{-c\tau}\,\mathrm{d}\tau \\ - \int_0^t (\mathrm{Tr}_E\{H_I(t)U^{\dagger}(\tau,t)U_S(\tau,t)\rho_S(t)\rho_E U_S^{\dagger}(\tau,t)U(\tau,t) \\ - U^{\dagger}(\tau,t)U_S(\tau,t)\rho_S(t)\rho_E U_S^{\dagger}(\tau,t)U(\tau,t)H_I(t)\})ce^{-c\tau}\,\mathrm{d}\tau \\ + \int_0^t (\mathrm{Tr}_E\{H_I(t)U^{\dagger}(\tau,t)\rho_S(\tau)\rho_E U(\tau,t) - U^{\dagger}(\tau,t)\rho_S(\tau)\rho_E U(\tau,t)H_I(t)\})ce^{-c\tau}\,\mathrm{d}\tau. \end{aligned} \tag{72}$$

Evaluating the trace over the environmental variables, Eq. (72) can be written as

$$
\begin{aligned}
i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - \int_0^t \sum_{jk} \{&(A_{jk}(\tau,t)\rho_S(t)B_{jk}^\dagger(\tau,t) - B_{jk}(\tau,t)\rho_S(t)A_{jk}^\dagger(\tau,t) + C_{jk}(\tau,t)\rho_S(t)D_{jk}^\dagger(\tau,t)\\
&- D_{jk}(\tau,t)\rho_S(t)C_{jk}^\dagger(\tau,t))(1-e^{-c\tau}) + (A_{jk}(\tau,t)U_S^\dagger(\tau,t)\rho_S(\tau)U_S(\tau,t)B_{jk}^\dagger(\tau,t)\\
&- B_{jk}(\tau,t)U_S^\dagger(\tau,t)\rho_S(\tau)U_S(\tau,t)A_{jk}^\dagger(\tau,t) + C_{jk}(\tau,t)U_S^\dagger(\tau,t)\rho_S(\tau)U_S(\tau,t)D_{jk}^\dagger(\tau,t)\\
&- D_{jk}(\tau,t)U_S^\dagger(\tau,t)\rho_S(\tau)U_S(\tau,t)C_{jk}^\dagger(\tau,t))e^{-c\tau} + (B_{jk}(\tau,t)U_S^\dagger(\tau,t)\rho_S(\tau)U_S(\tau,t)C_{jk}^\dagger(\tau,t)\\
&- C_{jk}(\tau,t)U_S^\dagger(\tau,t)\rho_S(\tau)U_S(\tau,t)B_{jk}^\dagger(\tau,t))ce^{-c\tau} + (C_{jk}(\tau,t)\rho_S(t)B_{jk}^\dagger(\tau,t)\\
&- B_{jk}(\tau,t)\rho_S(t)C_{jk}^\dagger(\tau,t))ce^{-c\tau}\}\mathrm{d}\tau. \qquad (73)
\end{aligned}
$$

The operators $A_{jk},B_{jk},C_{jk},D_{jk}$ in Eq. (73) are defined in Eqs. (45)–(48). Compared to the perturbative counterpart in Eq. (44), the general nonperturbative master equation in Eq. (73) is valid for all time. If the time t is small, or if the system is in the weak coupling regime, then all terms associated with the exponential $e^{-c\tau}$ will cancel each other under the perturbation approximation of

$$\rho_S(t) \approx U_S^\dagger(\tau,t)\rho_S(\tau)U_S(\tau,t), \qquad (74)$$

and Eq. (73) will become identical to the nonperturbative version in Eq. (44). If the time t is quite large, usually the perturbation approximation in Eq. (74) is not satisfied so that Eq. (73) will be different from Eq. (44).

It should be pointed out that the trial full density operator in Eq. (69) is just one choice, and therefore the nonperturbative formulation in Eq. (73) is not unique. There is much freedom to choose $\tilde{\rho}(t)$, and another simple form is

$$\tilde{\rho}(\tau) = \rho_S(\tau)\rho_E e^{-c\tau}. \qquad (75)$$

Following a procedure similar to that above, with this choice the resultant non-perturbative master equation is

$$
\begin{aligned}
i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t),\rho_S(t)] - i\int_0^t \mathrm{Tr}_E\{[H_I(t),U^\dagger(\tau,t)[H_I(\tau),\rho_S(\tau)\rho_E]U(\tau,t)]\}e^{-c\tau}\,\mathrm{d}\tau\\
+ \int_0^t \mathrm{Tr}_E\{[H_I(t),U^\dagger(\tau,t)\rho_S(\tau)\rho_E U(\tau,t)]\}ce^{-c\tau}\,d\tau. \qquad (76)
\end{aligned}
$$

Each variationally derived nonperturbative equation has second order error, but a different choice of trial density operator in practice will produce distinct levels of error. For example, in practice the implementation of Eq. (76) likely will be less favorable than Eq. (71), since the trial density operator in Eq. (75) will have significant deviations from the exact one at longer times. In contrast, the trial density operator in Eq. (69) is more likely to remain in the vicinity of the true density operator thereby improving the reliability of the variational estimate for ρ_S coming from Eq. (71). A suitable approximation is necessary for evaluating the operators $A_{jk},B_{jk},C_{jk},D_{jk}$ to solve the master equation, and additional approximation can be employed to simplify the time integration in Eqs. (73) based on the rapidly decaying factor $e^{-c\tau}$. Further implementation details will not be explored here.

VII. MODEL ANALYSIS

The purpose of developing nonperturbative master equations is for better treatment of problems with strong system-environment coupling. In such cases, the resultant system dynamics using the perturbative approach may produce significant distortion. To obtain proper physical conclusions, the nonperturbative approach is necessary. This point will be evident from a model analysis below.

The model system is defined to initially be in a pure state,

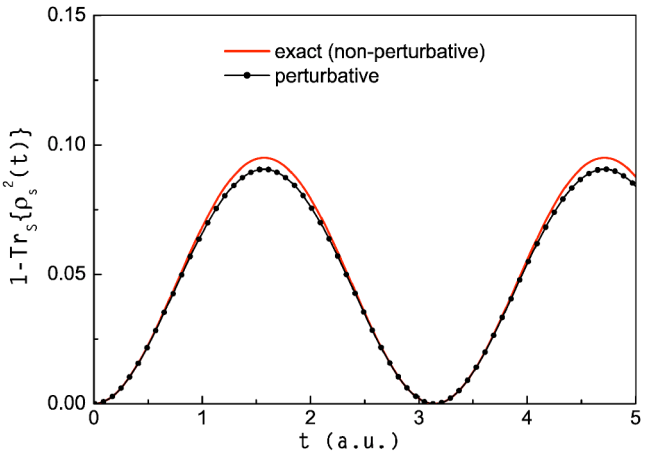

FIG. 1. Comparison of the decoherence degrees from perturbative and nonperturbative approaches. It is a weak coupling case such that $w_0+w_1=0.05$ where w_0, w_1 are defined in Eq. (78).

$$\rho_S(0) = |\psi_0\rangle\langle\psi_0|, \tag{77}$$

where ψ_0 is the ground eigenstate of the system. The environment is in a mixed state as

$$\rho_E = \sum_k w_k |\Phi_k\rangle\langle\Phi_k|, \tag{78}$$

where $\{\Phi_k\}$ is a set of orthonormal states (not necessary being the environment eigenstates), and the unit trace of ρ_E implies that $\Sigma_k\, w_k=1$. The system Hamiltonian $H_S'(t)$ and the environmental Hamiltonian H_E are treated implicitly. The coupling Hamiltonian $H_I'(t)$ is modeled as

$$H_I'(t) = i(|\psi_1\rangle\langle\psi_0| - |\psi_0\rangle\langle\psi_1|) \otimes (|\Phi_1\rangle\langle\Phi_0| + |\Phi_0\rangle\langle\Phi_1|) - H_S(t) \otimes \mathbf{1}_E - \mathbf{1}_S \otimes H_E, \tag{79}$$

where $\mathbf{1}_S$ and $\mathbf{1}_E$ are the unit operators of the system and environment spaces, respectively. The coupling Hamiltonian in Eq. (79) indicates that the total Hamiltonian would be

$$H = i(|\psi_1\rangle\langle\psi_0| - |\psi_0\rangle\langle\psi_1|) \otimes (|\Phi_1\rangle\langle\Phi_0| + |\Phi_0\rangle\langle\Phi_1|), \tag{80}$$

which might be considered as two coupled spin or multilevel systems. The model system shown here is for the purpose demonstrating the failure of the perturbative master equations when dealing with cases of strong system-environment coupling. No control field is present in the Hamiltonians.

Before implementing the dynamical equation, we first perform the repartitioning of the system and coupling Hamiltonians following the procedure described in Sec. III. The repartitioned Hamiltonians become

$$H_I(t) = H_I'(t) - \mathrm{Tr}_E\{H_I'(t)\rho_E\}, \tag{81}$$

$$H_S(t) = H_S'(t) + \mathrm{Tr}_E\{H_I'(t)\rho_E\}. \tag{82}$$

In order to obtain the nonperturbative results, we can evaluate the operators $A_{jk}, B_{jk}, C_{jk}, D_{jk}$ in Eq. (73) by their definitions in Eqs. (45)–(48), and numerically solve the nonperturbative master equation in Eq. (73); this would be a very tedious task. For this model, an alternative can be employed. Since the nonperturbative master equation in Eq. (73) is very close to the exact dynamical equation, the exact solution can represent the nonperturbative result very well. From the exact dynamical equation in Eq. (25), the system density operator can be obtained as

$$\rho_S(t) = |\psi_0\rangle\langle\psi_0| + (|\psi_1\rangle\langle\psi_1| - |\psi_0\rangle\langle\psi_0|)(w_0 + w_1)\sin^2 t. \tag{83}$$

The linear entropy measure of decoherence then becomes

$$1 - \mathrm{Tr}_S\{\rho_S^2(t)\} = 2(w_0 + w_1)\sin^2 t - 2(w_0 + w_1)^2 \sin^4 t. \tag{84}$$

For comparison, a perturbative approach will be analyzed. All the aforementioned perturbative master equations in Eqs. (31), (39), and (44) are truncated to second order in terms of the coupling Hamiltonian. We pick Eq. (44) as it is a natural perturbative version of the nonperturbative master equation in Eq. (73). Once again, we can go back to Eqs. (45)–(48) and map out the operators $A_{jk}, B_{jk}, C_{jk}, D_{jk}$ explicitly. Then the perturbative master equation in Eq. (44) can be solved numerically. Fortunately, for this model, numerical implementation is not necessary since Eq. (44) has an analytic solution for the density operator $\rho_S(t)$.

As an equivalence to Eq. (44), Eq. (42) can be further rewritten,

$$i\frac{\partial \rho_S(t)}{\partial t} = [H_S(t), \rho_S(t)] + \mathrm{Tr}_E\{[H_I(t), U(t)U_S^\dagger(t)\rho_S(t)U_S(t)\rho_E U^\dagger(t)]\}, \tag{85}$$

as long as the assumption of a near equilibrium environment is valid such that $[H_E, \rho_E]=0$. Specifically for the current model, Eq. (85) reduces to

$$i\frac{\partial \rho_S(t)}{\partial t} = \mathrm{Tr}_E\{[H_I(t), U(t)\rho_S(t)\rho_E U^\dagger(t)]\}. \tag{86}$$

Comparing to the exact dynamics equation for this model,

$$i\frac{\partial \rho_S(t)}{\partial t} = \mathrm{Tr}_E\{[H_I(t), U(t)\rho_S(0)\rho_E U^\dagger(t)]\}, \tag{87}$$

we can solve for the analytic perturbative system density operator [denoted as $\overline{\rho_s}(t)$ afterwards to distinguish from the exact one] from Eq. (86) as

$$\overline{\rho_S}(t) = |\psi_0\rangle\langle\psi_0| + (|\psi_1\rangle\langle\psi_1| - |\psi_0\rangle\langle\psi_0|)\tfrac{1}{2}(1 - \exp[-2(w_0 + w_1)\sin^2 t]). \tag{88}$$

The corresponding linear entropy measure of decoherence then becomes

$$1 - \mathrm{Tr}_S\{\overline{\rho}_S^2(t)\} = 1 - \exp[-2(w_0 + w_1)\sin^2 t] + \frac{1}{2}(1 - \exp[-2(w_0 + w_1)\sin^2 t])^2. \tag{89}$$

For comparison of the perturbative and nonperturbative results, the decoherences in Eqs. (84) and (89) give a simple and clear picture. Figure 1 displays the results for a weak coupling case, $w_0+w_1=0.05$. The perturbative decoherence degree follows the nonperturbative result quite well. Figure 2 shows the results for a strong coupling case, $w_0+w_1=0.95$. Overall, in the latter case the perturbative decoherence is very different from the nonperturbative result. Thus, the illustration shows how conclusions drawn from a perturbative treatment could be misleading or distorted. This example clearly demonstrates that nonperturbative approaches are necessary for cases with strong coupling.

VIII. SUMMARY

In this paper, new variational functionals to evaluate the system density operator in the presence of an environment are developed. Both perturbative and nonperturbative master equations for the open quantum system are derived. The perturbative master equation is similar to the conventional one, but without introducing an explicit Markovian approximation. The nonperturbative master equation is attractive because it is valid for all time. What lies ahead are explicit numerical applications of these formulations.

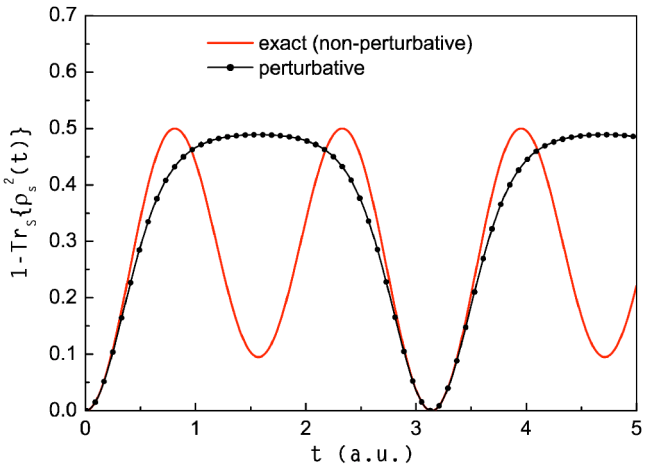

FIG. 2. Comparison of the decoherence degrees from perturbative and nonperturbative approaches. It is a strong coupling case such that $w_0+w_1=0.95$ where w_0, w_1 are defined in Eq. (78).

There is no generalization of known formulas for mutually unbiased bases

In a quantum system having a finite number N of orthogonal states, two orthonormal bases $\{a_i\}$ and $\{b_j\}$ are called mutually unbiased if all inner products $\langle a_i|b_j\rangle$ have the same modulus $1/\sqrt{N}$. This concept appears in several quantum information problems. The number of pairwise mutually unbiased bases is at most $N+1$ and various constructions of such $N+1$ bases have been found when N is a power of a prime number. We study families of formulas that generalize these constructions to arbitrary dimensions using finite rings. We then prove that there exists a set of $N+1$ mutually unbiased bases described by such formulas, if and only if N is a power of a prime number. © *2005 American Institute of Physics.*

I. INTRODUCTION

A. Definitions and previous results

In the N-dimensional Hilbert space $\mathbb{C}^N$, two orthonormal bases $\{a_i\}_{1\leqslant i\leqslant N}$ and $\{b_j\}_{1\leqslant j\leqslant N}$ are called *mutually unbiased* if all inner products $\langle a_i|b_j\rangle$ have the same modulus $|\langle a_i|b_j\rangle|=1/\sqrt{N}$. A set of mutually unbiased bases is a set of orthonormal bases which are pairwise mutually unbiased. In various physical situations (see Sec. I B), the problem is to find the maximal number of mutually unbiased bases. The following result is due to Wootters and Fields but it has been obtained independently by Calderbank *et al.*

Theorem 1.1 (Refs. 16 and 4):

- *In dimension $N\geqslant 2$, the number of mutually unbiased bases is at most $N+1$.*
- *If N is a power of a prime number then there exist $N+1$ mutually unbiased bases.*

In dimension N, a set of mutually unbiased bases is called *complete* if it contains $N+1$ bases. If N is not a prime power, it is not known whether such a complete set exists, even for $N=6$. Originally, constructions of $N+1$ mutually unbiased bases in dimension N were based on the arithmetic of a field, where addition and multiplication are invertible.[16] There exists a field with N elements if and only if N is a power of a prime number. Nevertheless, new constructions have been recently obtained (see Ref. 8) using the arithmetic of rings, where multiplication is not invertible. Since there exist rings of N elements for any N, is it possible to use finite rings to construct $N+1$ mutually unbiased bases for arbitrary dimensions? We will address this issue here. First we will generalize known constructions from Refs. 16 and 8 to any finite ring. Then we will prove that for dimensions N that are not prime powers, there does not exist a complete set of mutually unbiased bases described by this generalization.

B. Applications to quantum information

Mutually unbiased bases (MUBs) have recently been considered with increasing interest because of the central role they play in specific quantum information tasks such as state estimation or Quantum Key Distribution.

1. State estimation

Mutually unbiased bases play an important role in state estimation. Consider a (relatively) large ensemble of N-dimensional quantum systems identically prepared in some unknown state ρ. How can one estimate ρ using projective individual measurements? Since ρ is a trace one Hermitian matrice, it is specified by N^2-1 real parameters. Now imagine performing a nondegenerate measurement on a subensemble of the quantum systems. Such a measurement will yield $N-1$ independent real numbers, i.e., the probabilities associated to $N-1$ of the possible outcomes. So, in order to reconstuct the state ρ, we need at least $N+1$ different sorts of measurements. As argued in Ref. 7, $N+1$ measurements are sufficient when they correspond to MUBs. The reason is that if the basis are MUBs, then the information gained about ρ when performing a measurement in a basis B_i is independent of the information gained when performing a measurement in another basis B_j, for all couple of bases B_i, B_j. So, pooling the data obtained by each of these $N+1$ measurements, one indeed gets information about $(N+1)(N-1)$ independent parameters characterizing the state ρ, and full reconstruction thus becomes possible (we note however that it is not always necessary to invoke MUBs to fully reconstruct a state ρ with $N+1$ different measurements). An explicit formula to estimate the state from these mutually unbiased measurements is given in Ref. 7. Other optimality properties of MUBs with respect to state estimation are described in Ref. 16.

2. Quantum cryptography

The concept of MUBs is also relevant to Quantum Key Distribution (QKD). In the BB84 QKD protocol,[3] two authorized parties, Alice and Bob, use two 2-dimensional MUBs to generate a secret key. MUBs are the basic algebraic structure underlying d-dimensional generalizations of the BB84 protocol.[5] It is precisely the use of such bases which allows these protocols to make the intervention of a potential eavesdropper detectable. Wiesner[14] also introduced several ideas that later grew into quantum cryptography. Assessing the security of the BB84 protocol and its generalizations is a highly nontrivial matter.[13,10] However, considering the simple intercept and resend eavesdropping strategy, it is possible to give a heuristic argument of why the use of MUBs makes such protocols secure. In the d-dimensional generalization, Alice prepares each random key element as follows. She chooses randomly a value $i \in 1, \ldots, d$, chooses randomly a basis A taken among t MUBs, prepares the ith state of A, $|a_i\rangle$, and sends it to Bob. Bob chooses a basis among the t MUBs to measure the state $|a_i\rangle$, and get the value of the key element. With probability $1/t$, Bob will choose the basis A and should then get the measurement outcome i. Now suppose that a potential eavesdropper, Eve, applies a strategy where she also measures the key element sent by Alice in either of the t MUBs and sends Bob a state corresponding to her measurement outcome (intercept and resend attack). With probablity $1/t$, Eve's and Bob's choice of basis will not match. Thus, in those events where Bob happens to choose his measurement basis correctly, Eve will with probability $(t-1)/t$, produce a state that will give Bob a wrong result with probability $(d-1)/d$, i.e., the use of MUBs allows one to make the intervention of a potential eavesdropper detectable. It is also known that a protocol using a larger number of mutually unbiased bases can tolerate a higher error level in the channel (see Ref. 5).

3. MUBs and some discrete Wigner functions

Pure or mixed quantum states are usually represented by the density matrix. However, there is an alternative description in terms of the Wigner function. Several authors have proposed to define a Wigner function for discrete systems having N degrees of freedom.[12,9,15] It turns out that the discrete Wigner function defined in Ref. 15 requires the existence of $N+1$ mutually unbiased bases.

Finally, MUBs have also been shown to be relevant to the mean king's problem, see Ref. 1 and references therein. An interested reader will find recent results and further references on MUBs in Ref. 17, the problem page in Quantum Information at TU Braunschweig.

II. FORMULAS FOR MUTUALLY UNBIASED BASES

A unitary transformation maps a set of MUBs to a set of MUBs. Hence, it is not restrictive to consider only sets X of MUBs containing the standard basis $\{e_k\}_{1\leqslant k\leqslant N}$ since it is always possible to choose a unitary transformation U that maps a given orthonormal basis in X to $\{e_k\}$ so that $U(X)$ is a set of MUBs containing $\{e_k\}$. If a basis $\{v_k\}$ is unbiased with respect to the standard basis $\{e_k\}$ (i.e., $|\langle e_i|v_j\rangle|=1/\sqrt{N}$) then $|(v_k)_l|=|\langle e_l|v_k\rangle|=1/\sqrt{N}$. Hence the coordinates of its vectors must be expressed as $(v_k)_l=(e^{i\Theta(k,l)})/\sqrt{N}$ where $\Theta(k,l)$ belongs to $[0,2\pi]$.

For $N=p^n$ where p is a prime number and n a positive integer, there always exist $N+1$ mutually unbiased bases. We describe here the constructions from Refs. 16 and 8 for these dimensions.

A. Odd prime powers dimensions

Let the superscript r denote the basis, k the vector in the basis, and l the component. The standard basis is $(v_k^{(0)})_l=\delta_{kl}$ for $k,l=0,1,\ldots,N-1$. If $N=p^n$ for a prime number $p\neq 2$, the other such $N=p^n$ bases given in Ref. 16 are

$$(v_k^{(r)})_l=\frac{1}{\sqrt{N}}e^{(2\pi i/p)\mathrm{Tr}(rl^2+kl)},\quad r,k,l\in\mathbb{F}_{p^n}, \tag{1}$$

where $\mathbb{F}_{p^n}$ is the finite field with p^n elements and where Tr denote the trace map from $\mathbb{F}_{p^n}$ into the prime field $\mathbb{F}_p$. For $p\geqslant 5$ odd, a new formula has been proposed in Ref. 8 where the polynomial rl^2+kl is replaced by $(l+r)^3+k(l+r)$. The trace map is a linear map from $\mathbb{F}_{p^n}$, regarded as a vector space, into $\mathbb{F}_p$. In the language of group theory, linear maps are group homomorphisms (i.e., maps that preserve sums). The trace map induces a homomorphism from the additive group of $\mathbb{F}_{p^n}$ into the multiplicative group $\mathbb{C}^*$ of complex numbers, defined by $x\rightarrow e^{(2\pi i/p)\mathrm{Tr}(x)}$.

B. Even prime powers dimensions

For $N=2^n$, Wootters and Fields[16] have used an *ad hoc* construction that may be reformulated in a finite ring R whose 4^n elements are sequences $(x_1,\ldots,x_n)$ with $x_i\in\mathbb{Z}_4$. A much easier construction has been found recently by Klappenecker and Roetteler[8] using the Galois ring $R=GR(4,n)$. Let Tr denotes the trace map from $GR(4,n)$ into $\mathbb{Z}_4$. Once again $T:x\rightarrow e^{(2\pi i/4)\mathrm{Tr}(x)}$ is a group homomorphism from $GR(4,n),+$ into $\mathbb{C}^*$. The 2^n indexes are the elements of T_n, the *Teichmüller* set of $GR(4,n)$ and the 2^n bases described by

$$(v_k^{(r)})_l=\frac{1}{\sqrt{2^n}}e^{(2\pi i/4)\mathrm{Tr}((r+2k)l)},\quad r,k,l\in T_n\subset GR(4,n) \tag{2}$$

together with the standard basis, form a complete set of mutually unbiased bases of $\mathbb{C}^{2^n}$ (see Ref. 8).

C. How to generalize these formulas?

Formulas (1) and (2) as well as others in Ref. 8, share many common characteristics. First of all, the indexes l, k, r, respectively, for components, vectors, and bases are taken in a finite ring R. Both formulas link the indexes in R to complex coordinates by a function $f:(r,k,l)\rightarrow T(P(r,k,l))$ where P is a polynomial and T is a homomorphism from $R,+$ into $\mathbb{C}^*$. We will generalize these characteristics as follows:

1. *The functions* $f:(r,k,l)\to T(P(r,k,l))$. We consider a much larger class of functions that we call *functions preserving a direct sum decomposition of R* (see Sec. IV).
2. *The set S of indexes*. For formula (1) the set of indexes is the whole R while for formula (2), it is a remarkable subset of R. We will see in Sec. II E that these subsets may be defined for every ring R as sets closed under multiplication and transversal to a nilpotent ideal of R.
3. *Distinguish the index r*. In formulas (1) and (2), the nonstandard bases are indexed by r that takes all possible values of a set of size N. This can only be done for dimensions N for which there exist $N+1$ mutually unbiased bases. However, there is, up to now, no result showing that this is true if N is not a prime power. Therefore, we propose to give up formulas that are uniform with respect to r and to consider that each basis r may be described by a different formula. This means that for each r, we choose a different function $f_r:(k,l)\to f_r(k,l)$ into $\mathbb{C}^*$ such that the vectors in basis r are described by

$$(v_k^{(r)})_l = f_r(k,l), \quad k,l \in S, \tag{3}$$

where each f_r preserves a given decomposition $R_1\oplus R_2$ and $S\subset$ is as described in the previous paragraph. For the case of polynomials P and homomorphisms T, it amounts to choosing for each r, different polynomials P_r and homomorphism T_r.

D. Properties of rings

In the following we recall various properties of rings that are needed for this paper.

1. Direct sums of rings

Let R_+ be a ring where addition is commutative but where multiplication is not necessarily commutative. If the additive group R_+ is the direct sum $R_1\oplus R_2$ of two subgroups then every element r of R can be written in a unique way as $r=r_1+r_2$ where $r_i\in R_i$ and $R_1\cap R_2$ is reduced to the zero element. An element $r\in R$ may be represented as a couple (r_1,r_2) and addition in R corresponds to componentwise addition of couples. If, moreover, R_1 and R_2 are two-sided ideals of R (i.e., $r\cdot R_i=R_i=R_i\cdot r$ for every r in R), then multiplication in R is also reduced to componentwise multiplication of couples. Indeed, for $r_i\in R_i$, $r_1.r_2$ belongs to both R_1 and R_2 since these are two-sided ideals and thus $r_1.r_2=0=R_1\cap R_2$. For two ring elements x and y, we obtain for their product $x.y=(x_1+x_2).(y_1+y_2)=x_1.y_1+x_1.y_2+x_2.y_1+x_2.y_2$ and since $x_i.y_j=0$ for $i\neq j$, we get $x.y=x_1.y_1+x_2.y_2$. Thus $(x.y)_i=x_i.y_i$ as expected. Observe also that $a.x_1=(a_1+a_2).x_1=a_1.x_1$ for every $a\in R$. We say that the ring R is the direct sum of its ideals R_1 and R_2. These properties also hold when R is the direct sum of more than two ideals.

2. Polynomial functions in a ring

If a ring is a direct sum, then let us show that polynomial functions in R may be evaluated componentwise. A monomial on the set of variables $\{x,y,\ldots\}$ is a finite product of elements of this set. In a commutative ring R, a polynomial $P(x,y,\ldots)+r_0$ is defined as a linear combination P of monomials (on $\{x,y,\ldots\}$) with coefficients in R and of $r_0\in R$. A polynomial $P+r_0$ defines a polynomial function $(x,y,\ldots)\to P(x,y,\ldots)+r_0$ that maps n-uples of R^n to elements of R. In the noncommutative case, this definition is not very convenient since generally $x.r.y\neq r.x.y$, so that products of polynomials would not in general be polynomials. Hence we define more generally a noncommutative polynomial function as $P:(x,y,\ldots)\to r_0+\Sigma_k m_k(x,y,\ldots)$, where $m_k(x,y,\ldots)=w_k(x,y,\ldots;a,b,\ldots)$ is a finite product of noncommuting variables in $\{x,y,\ldots\}$ and of coefficients from a set $\{a,b,\ldots\}\subset R$.

Assume now that the ring R is a direct sum $R=R_1\oplus R_2$ and for $r\in R$, let $r=r_1+r_2$ be the corresponding decomposition. We have shown in the previous paragraph that products in R may be performed componentwise. Thus, for each term w_k of a polynomial function $w_k(x,y,\ldots;a,b,\ldots)$ is equal to $w_k(x_1,y_1,\ldots;a_1,b_1,\ldots)+w_k(x_2,y_2,\ldots;a_2,b_2,\ldots)$. As $x_1.a_1=x_1.a$ and $a_1.x_1=a.x_1$ for $a,x\in R$ we may conclude that $w_k(x_i,y_i,\ldots;a_i,b_i,\ldots)$ is equal to

$w_k(x_i,y_i,\ldots;a,b,\ldots)$, for $i=1,2$, so that $m_k(x,y,\ldots)=m_k(x_1,y_1,\ldots)+m_k(x_2,y_2,\ldots)$. Hence, for a polynomial function $\overline{P}=P+r_0$ on $R_1\oplus R_2$, we have $P(x,y,\ldots)=P(x_1,y_1,\ldots)+P(x_2,y_2,\ldots)$ and thus for $\lambda=-r_0=\overline{P}(0,0,\ldots)$,

$$\overline{P}(x,y,\ldots)=\lambda+\overline{P}(x_1,y_1,\ldots)+\overline{P}(x_2,y_2,\ldots).$$

3. The Sylow decomposition of a finite ring

Let R be a finite ring and let $|R|=\Pi_i p_i^{e_i}$ be the factorization of its order into powers of distinct prime numbers. The additive group $R,+$ is a finite commutative group. Hence, it is equal to the direct product $\oplus_i \mathrm{Syl}(p_i)$ of its Sylow subgroups and thus every element r of $R,+$ can be written in a unique way as $r=\Sigma r_i$ where $r_i\in S_{p_i}:=\mathrm{Syl}(p_i)$. We call the element r_i, *the p_i-component of r* and it is the unique element contained in the intersection $S_{p_i}\cap\{r+(\oplus_{j\neq i}S_{p_j})\}$ (see Ref. 6, Chap. 3). These subgroups may be defined as $S_{p_i}:=\{x:p_i^{e_i}x=0\}$ where $p_i^{e_i}x$ is the repeated sum of $p_i^{e_i}$ terms x. The subgroups S_{p_i} are two-sided ideals of the ring R, i.e., $r.S_{p_i}=S_{p_i}.r=S_{p_i}$ for every $r\in R$. This is due to the right and left distributive property of a ring since

$$p_i^{e_i}(r.x)=\underbrace{r.x+\ldots+r.x}_{p_i^{e_i}\ terms}=\underbrace{r(x+\ldots+x)}_{p_i^{e_i}\ \mathrm{terms}}=r.(p_i^{e_i}x)=r.0=0$$

if $x\in S_{p_i}$ so that $r.x\in S_{p_i}$ and similarly $x.r\in S_{p_i}$. Hence every finite ring is the direct sum of its Sylow ideals and a finite ring that is not decomposable as a nontrivial direct sum must be of prime power order. Moreover, if $|R|=d_1.d_2$ is the product of two coprime numbers ($\geqslant 2$) then $R=R_1\oplus R_2$ where $R_i:=\oplus_{p|d_i}\mathrm{Syl}(p)$.

4. Ring with unity

From now on, we mainly consider rings R containing a multiplicative unity 1 such that $x.1=x=1.x$ for every $x\in R$. If $R=\oplus_{i\in I}R_i$ has a unity 1 and $R_i\neq\{0\}$ then 1_i is the unity of R_i. An element x has a left inverse x_L (respectively, right inverse x_R) if $x_L.x=1$ (respectively $x.x_R=1$). An element that has both a left and a right inverse is called a *unit*. If x is a unit, then the inverse x^{-1} is unique since $x_L=x_L.(x.x_R)=(x_L.x).x_R=x_R$. The set $U(R)$ of all units of R is a multiplicative group and by the componentwise multiplication $U(R_1\oplus R_2)=U(R_1)\oplus U(R_2)$. A *field* is a ring where every nonzero element is a unit.

5. Nilpotency

An element n of a ring R is called nilpotent if $n^t=0$ for some positive integer t. The set $\mathrm{Nil}(R)$ of all nilpotent elements of R is called the *Nilpotent radical* of R. Once again, by the componentwise multiplication $\mathrm{Nil}(R_1\oplus R_2)=\mathrm{Nil}(R_1)\oplus\mathrm{Nil}(R_2)$. We say that an ideal N is nilpotent provided that every $n\in N$ is nilpotent. For every $r\in R$, if we have $(r.n)^t=0$ then $(n.r)^{t+1}=n.(r.n)^t.r=0$ and thus every nilpotent ideal is two-sided. In every ring with unity, a nilpotent element cannot be a unit but if n is nilpotent ($n^t=0$) then $1+n$ is a unit. To show this, consider $u_t(n)=1+n+\ldots+n^{t-1}$; then since $1=1-n^t=(1-n)u_t(n)=u_t(n)(1-n)$, the element $u_t(-n)$ is the inverse of $1+n=1-(-n)$.

Let us show that in a commutative ring, $\mathrm{Nil}(R)$ is an ideal. If $x^n=0$ then $(r.x)^n=r^n.x^n=0$ and if moreover $y^m=0$ then $(x+y)^{n+m}=0$ since $(x+y)^{n+m}$ is a sum of terms $x^{n+m-k}.y^k$ which are zero for $k\leqslant m$ and for $k\geqslant m$. In a noncommutative ring R, $\mathrm{Nil}(R)$ is not necessarily an ideal. For instance, a sum of nilpotent matrices may be invertible (and thus non-nilpotent) as shown by

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Thus for the ring $M_2(R)$ of 2×2 matrices over a ring R with unity, the nilpotent radical is not an ideal. However, the subring of upper triangular matrices is also noncommutative but it contains the nilpotent ideal

$$\left\{ \begin{pmatrix} 0 & r \\ 0 & 0 \end{pmatrix} : r \in R \right\}.$$

E. Generalizing *Teichmüller* sets

For every ring R we would like to define a subset $S_R \subset R$ for the indexes k, l of vectors and components, in such a way that for a Galois ring $R=GR(4,n)$, the set S_R is the *Teichmüller* set T_n as in formula (2), while for a finite field $R=\mathbb{F}_{p^n}$ we have $S_R=R$ as in formula (1).

The set $T_n \subset GR(4,n)$ has remarkable properties that are used over and over to compute easily in $GR(4,n)$ (see Ref. 11).

(1) The ideal $N:=\{2t_1 : t_1 \in T_n\}$ is the nilpotent radical of $GR(4,n)$ ($N^2=0$).
(2) Every $r \in GR(4,n)$ can be written in a unique way as $r=t_0+2t_1$ for some t_0, t_1 in T_n. Thus T_n contains exactly one representative of each coset $\{r+N\}_{r\in R}$ of N in R; it is a transversal to the ideal N.
(3) T_n is closed under multiplication. Therefore a product of elements written as $t+n$ for $t \in T_n$ and $n \in N$ is still written in this way since

$$(t_1+n_1)(t_2+n_2) = \underbrace{t_1 t_2}_{\in T_n} + \underbrace{(t_1 n_2 + n_1 t_2 + n_1 n_2)}_{\in N}.$$

This may be generalized to every ring R as follows. We require that the set of indexes S_R is closed under multiplication and that it is a transversal to a nilpotent ideal N. Trivially, if R is a field (as in formula (1)) or even a division ring, then $N=\{0\}$ is the only nilpotent ideal, $S_R=R$ is the only transversal to N and it is closed under multiplication.

A commutative local ring is a ring that has a unique maximal ideal M and the Galois ring $R=GR(4,n)$ is local. In a finite commutative local ring R, the unique maximal ideal is $\mathrm{Nil}(R)$ and the units of R are exactly the non-nilpotent elements (see Ref. 2). Hence in a local ring every ideal ($\neq R$) is nilpotent. Every finite commutative ring with unity is a direct sum of local rings (see Ref. 2, Proposition 8.7).

F. Functions preserving a direct sum decomposition

Let $R=R_1 \oplus R_2$ be a direct sum decomposition of a ring R and let $r=r_1+r_2$ be the corresponding decomposition for $r \in R$. Let $G_{,\star}$ be a commutative group with an operation $\star$ (either "$+$" or "$\cdot$" in this paper). For a finite set of variables $\{x,y,\ldots\}$ belonging to R, we say that a function $f:(x,y,\ldots)\to f(x,y,\ldots)\in G_{,\star}$ *preserves the decomposition* $R_1 \oplus R_2$ if for a constant $\lambda \in R$,

$$f(x,y,\ldots) = \lambda \star f(x_1,y_1,\ldots) \star f(x_2,y_2,\ldots) \quad \text{for every } x,y,\ldots \in R. \tag{4}$$

Observe that $\lambda=(f(0,0,\ldots))^{-1}$ because $(x_1)_2=(y_1)_2=\ldots=0$ implies $f(x_1,y_1,\ldots)=f(x_1+0,y_1+0,\ldots)=\lambda\star f(x_1,y_1,\ldots)\star f(0,0,\ldots)$. If f_i is the restriction of f to R_i then $f(x,y,\ldots)=\lambda\star f_1(x_1,y_1,\ldots)\star f_2(x_2,y_2,\ldots)$. Conversely, for arbitrary functions f_i from R_i into G and $\lambda \in G$, this last equation defines a function that preserves $R_1 \oplus R_2$. It may happen that f preserves $R_1 \oplus R_2$ but does not preserve another decomposition of R.

We have seen in Sec. II D that polynomial functions P on a ring R preserves every direct sum decomposition of R (and in this case $\lambda=-P(0,0,\ldots)$). Thus, since group homomorphisms preserve sums, if T is a group homomorphism from R_+ into a commutative group $G_\star$ and if

$P(x,y,\ldots)$ is a polynomial function on R, then $(x,y,\ldots)\to T(P(x,y,\ldots))$ preserves every direct sum decomposition of R. Hence, these functions generalize formulas (1) and (2) for mutually unbiased bases since those rely on expressions of type $(1/\sqrt{N})T(P(k,l))$ for $k,l\in R$ where $G_\star$ is the multiplicative group of unitary complex number. This is also true for the other formulas proposed in Ref. 8.

More such sophisticated functions may be constructed by products. If $f\cdot g$ is a product of functions into a commutative group G that both preserve a direct sum decomposition $R=R_1\oplus R_2$ then it is easy to show that $f\cdot g$ also preserves $R_1\oplus R_2$. We have $(f\cdot g)(x,y,\ldots)=\lambda_f\cdot\Pi_{i=1,2}f(x_i,y_i,\ldots)\cdot\lambda_g\Pi_{i=1,2}g(x_i,y_i,\ldots)$ and since the elements of G commute, we may rearrange the factors as $(f\cdot g)(x,y,\ldots)=\lambda_f\cdot\lambda_g\Pi_{i=1,2}(f\cdot g)(x_i,y_i,\ldots)$.

III. SUCH SETS OF MUB CANNOT BE COMPLETE

In this section we prove that even with all these generalizations, it is not possible to construct complete sets of $N+1$ mutually unbiased bases for $N\neq p^n$.

Theorem 3.1: *Let $R=R_1\oplus R_2$ be a decomposition of a ring R. For $i=1,2$ let S_i be a nonempty subset of R_i and let $N=|S_1||S_2|$. For each $1\leqslant c\leqslant m$, let $f_c:R_+\to\mathbb{C}^*,\cdot$ be a two variable function that preserves the decomposition $R_1\oplus R_2$ and let us define N vectors $\{v_k^{(c)}\}$ of $\mathbb{C}^N$ as*

$$(v_k^{(c)})_l=f_c(k,l)\quad k,l\in S_1\oplus S_2.$$

Assume that, together with the standard basis, the sets of vectors $\{v_k^{(c)}\}_{1\leqslant c\leqslant m}$ form a set X of $m+1$ mutually unbiased bases. If $|S_i|_{i=1,2}\neq 1$, then

$$m\leqslant\min_i|S_i|<N \text{ and the set } X \text{ is not complete}.$$

Proof: The function f_c preserves the decomposition $R_1\oplus R_2$ so there is a constant λ_c such that $f_c(k,l)=\lambda_c f_c(k_1,l_1)f_c(k_2,l_2)$. For each c, let us define $|S_1|$ vectors $\{a_{k_1}^{(c)}\}_{k_1\in S_1}$ of $\mathbb{C}^{|S_1|}$ and $|S_2|$ vectors $\{b_{k_2}^{(c)}\}_{k_2\in S_2}$ of $\mathbb{C}^{|S_2|}$ as

$$(a_{k_1}^{(c)})_{l_1}=\lambda_c\, f_c(k_1,l_1),\quad (b_{k_2}^{(c)})_{l_2}=f_c(k_2,l_2)\quad \text{for}\quad k_i,l_i\in S_i(i=1,2).$$

Hence $(v_k^{(c)})_l=f_c(k,l)=\lambda_c(a_{k_1}^{(c)})_{l_1}(b_{k_2}^{(c)})_{l_2}$ and since l takes all value in $S_1\oplus S_2$, the vector $v_k^{(c)}=v_{(k_1,k_2)}^{(c)}$ is equal to the tensor product $a_{k_1}^{(c)}\otimes b_{k_2}^{(c)}\in\mathbb{C}^{|S_1||S_2|}$. If we denote by $\{v_k^{(0)}\}_{k\in S_1\oplus S_2}$, $\{a_{k_1}^{(0)}\}_{k_1\in S_1}$, $\{b_{k_2}^{(0)}\}_{k_2\in S_2}$ the standard bases, respectively, in $\mathbb{C}^N$, $\mathbb{C}^{|S_1|}$, and $\mathbb{C}^{|S_2|}$ then also $v_k^{(0)}=v_{(k_1,k_2)}^{(0)}=a_{k_1}^{(0)}\otimes b_{k_2}^{(0)}$.

Therefore if the sets $\{v_k^{(c)}\}_{0\leqslant c\leqslant m}$ form a set X of $m+1$ mutually unbiased bases in $\mathbb{C}^N=\mathbb{C}^{|S_1||S_2|}$, then by Proposition A.1 in the Appendix, there exist $m+1$ mutually unbiased bases in both $\mathbb{C}^{|S_1|}$ and $\mathbb{C}^{|S_2|}$. By Theorem 1.1, if each $|S_i|_{i=1,2}$ is at least 2 then $m+1\leqslant|S_i|+1$ and $m\leqslant\min_i|S_i|<|S_1||S_2|=N$ thus $|X|=m+1<N+1$ and X is not complete. □

Theorem 3.1 requires that the index set S is a product of two subsets. We now prove that this is always the case if $S\subset R$ is closed under multiplication and is transversal to a nilpotent ideal N of R.

Proposition 3.1: In a ring R with 1, let $S\subset R$ be a set closed under multiplication that is a transversal to a nilpotent ideal N of R.

1. *If $R=R_1\oplus R_2$ is a sum of rings with 1 then*

$$S=(S\cap R_1)\oplus(S\cap R_2)$$

and for $i=1,2$, each R_i, $S\cap R_i$ is closed under multiplication and is a transversal to $N\cap R_i$.

2. *If $|S|$ is a product $d_1 \cdot d_2$ of two coprime numbers $\geqslant 2$ and if R is finite, then R is a sum $R_1 \oplus R_2$ of rings with 1 such that $|S \cap R_1| = d_1$ and $|S \cap R_2| = d_2$.*

Proof: (1) $R = R_1 \oplus R_2$ has unity $(1_1, 1_2)$. Every ideal I of R is equal to $I_1 \oplus I_2$ where I_j is an ideal of R_j and N is the sum $N_1 \oplus N_2$ of two nilpotent ideals (see Ref. 2). Let $\tilde{x} = (1_1, 0) + N$. Since S is a transversal to N, it contains a unique element $x \in \tilde{x} \cap S$ where $x = (1_1 + n_1, n_2)$ for some $(n_1, n_2) \in N_1 \oplus N_2$. Since N is a nilpotent ideal, it is two-sided and we may consider the quotient ring R/N where multiplication of cosets is defined as $(x+N)(y+N) = x \cdot y + N$. Thus, in R/N we have $\tilde{x}^2 = \tilde{x}$ whence $x^2 \in \tilde{x}$. Also, $x^2 \in S$ because S is closed under multiplication. Therefore we have $x^2 = S \cap \tilde{x} = x$ and we have

$$(1_1 + n_1)^2 = (1_1 + n_1)\ (1), \quad n_2^2 = n_2\ (2).$$

By nilpotency $n_2^t = 0$ for some positive integer t and by (2), $n_2^t = n_2$ whence $n_2 = 0$. By nilpotency of n_1, $(1 + n_1)$ has an inverse $(1_1 + n_1)^{-1}$ in R_1. Multiplying both sides of (1) by $(1_1 + n_1)^{-1}$ gives $(1_1 + n_1) = 1$ whence $n_1 = 0$. Finally $x = (1_1, 0) \in S$ and the symmetric argument for $S \cap \{(0, 1_2) + N\}$ shows that $(0, 1_2)$ also belongs to S.

As $\{(1_1, 0), (0, 1_2)\} \in S$, for every $(s_1, s_2) \in S$, $(s_1, 0) = s \cdot (1_1, 0) \in S \cap R_1$ and $(0, s_2) = s \cdot (0, 1_2) \in S \cap R_2$. Conversely, it remains to show that for every $(s_1, 0) \in S \cap R_1$ and $(0, s_2) \in S \cap R_2$ we also have $(s_1, s_2) \in S$. Since S is a transversal to N, it contains a unique element $y = (s_1 + n_1, s_2 + n_2) \in S \cap \{(s_1, s_2) + N\}$ and $y \cdot (1_1, 0) = (s_1 + n_1, 0)$ in S. As $(s_1 + n_1, 0)$ and $(s_1, 0)$ are in S and belong to the same coset of N, these must be equal and $n_1 = 0$. Similarly $n_2 = 0$ so that $y = (s_1, s_2) \in S$ whence $S = (S \cap R_1) \oplus (S \cap R_2)$. Finally, let us show that $(S \cap R_i)$ is a transversal to $N_i = N \cap R_i$ in R_i. Every coset $(r_1, 0) + N_1$ is embedded in $(r_1, 0) + N$ which contains a unique element $s = (r_1 + n_1, n_2)$ of S. Then $s \cdot (1_1, 0) = (r_1 + n_1, 0)$ is in $S \cap R_1$ and in $(r_1, 0) + N_1$ and so, $S \cap R_1$ contains at least one representative of each coset. If two elements of $S \cap R_1$ belong to the same coset of N_1 then these belong to the same coset of $N \supset N_1$ and thus are equal. The proof is similar for $(S \cap R_2)$.

(2) Let $\pi(d)$ denote the set of prime divisors of an integer d. For a finite ring R and a divisor d of $|R|$, let us define $\mathrm{Syl}(\pi(d)) := \oplus_{p \in \pi(d)} \mathrm{Syl}(p)$. Since S is a transversal to the ideal N in R then $d_1 \cdot d_2 = |S| = |R| / |N|$ is a divisor of $|R|$. If $\pi_1 = \pi(d_1)$ and $\pi_2 = \pi(|R|) \setminus \pi(d_1)$, we know from Sec. II D that $R = \mathrm{Syl}(\pi_1) \oplus \mathrm{Syl}(\pi_2)$ and since R has unity 1, $\mathrm{Syl}(\pi_i)$ has unity 1_i. Thus, as proven in (1), $S = (S \cap \mathrm{Syl}(\pi_1)) \oplus (S \cap \mathrm{Syl}(\pi_2))$ and

$$d_1 \cdot d_2 = |S| = |S \cap \mathrm{Syl}(\pi_1)| \cdot |S \cap \mathrm{Syl}(\pi_2)|. \tag{5}$$

As $S \cap \mathrm{Syl}(\pi_i)$ is a transversal to the ideal $N \cap \mathrm{Syl}(\pi_i)$ then $|S \cap \mathrm{Syl}(\pi_i)|$ divides $\mathrm{Syl}(\pi_i)$ and so is coprime to d_j $(j \neq i)$. Thus, by equality (5), $|S \cap \mathrm{Syl}(\pi_i)|$ must divide d_i and symmetrically d_i divides $|S \cap \mathrm{Syl}(\pi_i)|$ so that $d_i = |S \cap \mathrm{Syl}(\pi_i)|$. □

Finally, we obtain our main result: complete sets of MUBs described by generalizations of known formulas only exist for prime power dimensions. Moreover, we provide an upper bound for the number of MUBs described by such formulas.

Theorem 3.2: *Let R be a finite ring with unity. Let $S \subset R$ be a subset of N elements that is closed under multiplication and transversal to a nilpotent ideal. For $1 \leqslant c \leqslant N$, let $T_c : R_+ \to \mathbb{C}^*, \cdot$ be a group homomorphism and let $P_c : R^2 \to R$ be a two variables polynomial function. Let us define N sets of vectors $\{v_k^{(c)}\}_{1 \leqslant c \leqslant N}$ in $\mathbb{C}^N$ by*

$$(v_k^{(c)})_l = \frac{1}{\sqrt{N}} T_c(P_c(k, l)), \quad k, l \in S,$$

and let the set $X_{\{T_c\}\{P_c\}}$ be the union of the standard basis with $\{v_k^{(c)}\}_{1 \leqslant c \leqslant N}$.

1. *A set $X_{\{T_c\}\{P_c\}}$ contains at most $1 + \min_i\{p_i^{e_i}\}$ mutually unbiased bases where $N = \Pi_i p_i^{e_i}$ is the factorization of N into powers of distinct prime numbers.*
2. *There exists a complete set $X_{\{T_c\}\{P_c\}}$ of $N+1$ mutually unbiased bases if and only if N is a power of a prime number.*

Proof:

1. We prove that the conditions of Theorem 3.1 apply here. First we show that every vector $v_k^{(c)}$ is unbiased with the standard basis $\{e_k\}$. Every $r \in R$ has finite additive order n_r ($n_r \cdot r = 0$). By the homomorphism property

$$T_c(n \,.\, r) = T_c(\underbrace{r + \ldots + r}_{n \text{ terms}}) = (T_c(r))^n$$

and as $T_c(0) = 1$ we must have $|T_c(r)|^n = 1$ whence $|T_c(r)| = 1$ for every r in R. Thus for every vector $v_k^{(c)}$ we obtain $|\langle e_l | v_k^{(c)} \rangle| = |(v_k^{(c)})_l| = |T_c(P_c(k,l))| / \sqrt{N} = 1/\sqrt{N}$ as announced. Let $m+1$ be the maximal number of mutually unbiased bases contained in $X_{\{T_c\}\{P_c\}}$ and let $Y \subset X_{\{T_c\}\{P_c\}}$ be a set of $m+1$ mutually unbiased bases. Since we have shown that $Y \cup \{\{e_k\}\}$ is also a set of MUBs, the standard basis $\{e_k\}$ must be in Y.
As $|S| = N = \Pi_i p_i^{e_i}$ we may use Proposition 3.1 (2) to show that there is a ring decomposition $R = \oplus_i R_i$ such that $S = \oplus_i S \cap R_i$ and $|S \cap R_i| = p_i^{e_i}$. Finally, since the functions $(k,l) \to T_c(P_c(k,l))$ preserve every direct sum decomposition of R (see Sec. II D), we may apply Theorem 3.1 to Y to show that for every i we must have $m \leqslant p_i^{e_i}$. Hence $1+m \leqslant 1 + \min_i\{p_i^{e_i}\}$.
2. If we have $N+1$ such MUBs, then by (1), $\Pi_i p_i^{e_i} = N \leqslant \min_i\{p_i^{e_i}\}$, which implies that $N = \min_i\{p_i^{e_i}\}$ and thus N is a prime power. Conversely if $N = p_i^{e_i}$, we have shown in Sec. II that the sets of $N+1$ MUBs given by formulas (1) and (2) may be described as sets $X_{\{T_c\}\{P_c\}}$. □

The bound $1 + \min_i\{p_i^{e_i}\}$ can be easily reached for dimension $N = \Pi_i p_i^{e_i}$. It suffices to view $\mathbb{C}^N$ as $\otimes_i \mathbb{C}^{p_i^{e_i}}$. As $\langle b_i \otimes c_k | b_j \otimes c_l \rangle = \langle b_i | b_j \rangle . \langle c_k | c_l \rangle$ we may conclude that a tensor product of two sets with t MUBs is a set of t MUBs in the product space. Since there exist at least $1 + \min_i\{p_i^{e_i}\}$ MUBs in each $\mathbb{C}^{p_i^{e_i}}$ we may construct by tensor product of these, a set of $1 + \min_i\{p_i^{e_i}\}$ MUBs in the product space C^N.

IV. DISCUSSION ON LARGER GENERALIZATIONS AND CONCLUSION

In order to further generalize formula (3) it could be tempting to allow the index set S to be any subset of a finite ring. Unfortunately, this leads to a situation where any set of vectors could be described by such a formula. To see this, let us recall that functions f that preserve a decomposition of a ring R are arbitrary functions on each component R_i. If we choose a ring R that has no decomposition (a field, for instance) then such an f is arbitrary on R. If S is a subset $\{s_1, \ldots, s_N\}$ of N elements, then we may associate an arbitrary set of vectors $\{v_k\}_{1 \leqslant k \leqslant N}$ in $\mathbb{C}^N$ to the couples in $S \times S$ by $(s_k, s_l) \to (v_k)_l$.

This may be extended (in many ways) to a two variable function from $R \times R$ into $\mathbb{C}$ that preserves every decomposition of R (since R cannot be decomposed). One cannot expect to reach algebraic conclusions that are valid for all $N \times N$ arrays with arbitrary complex entries $(v_k)_l$.

For these reasons, it is difficult to generalize formula (3) much more. It indicates that for dimensions that are not prime powers, algebraic formulas providing complete sets of MUBs should have a radically new structure. However, do these complete sets exist for any dimension? Mathematicians are used to properties that behave differently for some particular dimensions but such an answer is unsatisfactory from a physical point of view. Wooters has shown that the absence of $N+1$ MUBs for a dimension N would be problematic for defining his discrete Wigner function in systems having N degrees of freedom (see Ref. 15).

ACKNOWLEDGMENT

I gratefully acknowledge Sofyan Iblisdir for introducing me to this problem and for all our fruitful discussions.

APPENDIX

In what follows, $\langle|\rangle$ denotes the classical Hermitian product $\langle a,b\rangle=\Sigma_i(a_i)^* b_i$. The tensor product $v\otimes w$ is defined by $(v\otimes w)_{(i,j)}=a_i.b_j$ and thus $\langle v_1\otimes w_1|v_2\otimes w_2\rangle=\langle v_1|v_2\rangle.\langle w_1|w_2\rangle$.

Proposition A.1: Let $N=N_1.N_2$ be a product of positive integers and let $\{v_{i,j}^{(1)}\}\cdots\{v_{i,j}^{(r)}\}$ be r mutually unbiased bases of $\mathbb{C}^N\cong\mathbb{C}^{N_1}\otimes\mathbb{C}^{N_2}$ (for $(i,j)\in\overline{N}:=\{1\cdots N_1\}\times\{1\cdots N_2\}$). Assume that for each $1\leqslant t\leqslant r$ there are N_1 vectors $\{a_i^{(t)}\}$ and N_2 vectors $\{b_j^{(t)}\}$ such that

$$v_{i,j}^{(t)}=a_i^{(t)}\otimes b_j^{(t)}$$

for every $(i,j)\in\overline{N}$, then for $1\leqslant t\leqslant r$, $\{a_i^{(t)}/\|a_i^{(t)}\|\}$ and $\{b_j^{(t)}/\|b_j^{(t)}\|\}$ are r mutually unbiased bases, respectively, in $\mathbb{C}^{N_1}$ and $\mathbb{C}^{N_2}$.

Proof: First we show that $\{a_i^{(t)}\}$ and $\{b_j^{(t)}\}$ are orthogonal bases. Since othonormality of $\{v_{i,j}^{(t)}\}$ implies $\langle v_{i,j}^{(t)}|v_{\underline{k,l}}^{(t)}\rangle=\delta_{\{(i,j),(k,l)\}}=\delta_{ik}\delta_{jl}$, we have $\delta_{ik}\delta_{jl}=\langle a_i^{(t)}\otimes b_j^{(t)}|a_k^{(t)}\otimes b_l^{(t)}\rangle=\langle a_i^{(t)}|a_k^{(t)}\rangle\langle b_j^{(t)}|b_l^{(t)}\rangle$. For every j, $b_j^{(t)}\neq 0$ (otherwise $v_{i,j}^{(t)}=\overline{0}$) so that $\langle a_i^{(t)}|a_k^{(t)}\rangle\langle b_j^{(t)}|b_j^{(t)}\rangle=\delta_{ik}\delta_{jj}=\delta_{ik}$ implies that $\langle a_i^{(t)}|a_k^{(t)}\rangle=0$ for $i\neq k$. Hence $\{a_i^{(t)}\}$ is a set of N_1 mutually orthogonal vectors, thus an orthogonal basis (not necessarily orthonormal) of $\mathbb{C}^{N_1}$. Permuting the role of a and b gives the same result for $\{b_j^{(t)}\}$ in $\mathbb{C}^{N_2}$. Furthermore if we fix $1\leqslant j\leqslant N_2$, the equalities $1=\langle v_{i,j}^{(t)}|v_{i,j}^{(t)}\rangle=\langle a_i^{(t)}|a_i^{(t)}\rangle\langle b_j^{(t)}|b_j^{(t)}\rangle$ may be divided by the constant $\langle b_j^{(t)}|b_j^{(t)}\rangle$ so that for every $1\leqslant i\leqslant N_1$, $L_{a^{(t)}}:=\langle a_i^{(t)}|a_i^{(t)}\rangle$ is constant with respect to i and equal to $1/\langle b_j^{(t)}|b_j^{(t)}\rangle$. Symmetrically, $L_{b^{(t)}}:=\langle b_j^{(t)}|b_j^{(t)}\rangle$ is also constant for every $1\leqslant j\leqslant N_2$ and

$$L_{a^{(t)}}:=\langle a_i^{(t)}|a_i^{(t)}\rangle=\frac{1}{\langle b_j^{(t)}|b_j^{(t)}\rangle}=\frac{1}{L_{b^{(t)}}}\quad\text{for every}\quad(i,j)\in\overline{N}. \tag{A1}$$

Now, it is sufficient to prove the MUB property for each couple of bases among the r, in $\mathbb{C}^{N_1}$ and $\mathbb{C}^{N_1}$. For instance let us consider $\{v_{i,j}^{(1)}\}$ and $\{v_{k,l}^{(2)}\}$. We define $A_{i,k}:=|\langle a_i^{(1)}|a_k^{(2)}\rangle|$ and $B_{j,l}:=|\langle b_j^{(1)}|b_l^{(2)}\rangle|$. The equality

$$1/\sqrt{N}=|\langle\underbrace{v_{i,j}^{(1)}}_{a_i^{(1)}\otimes b_j^{(1)}}\mid\underbrace{v_{k,l}^{(2)}}_{a_k^{(2)}\otimes b_l^{(2)}}\rangle|=A_{i,k}B_{j,l}\text{ for every }(i,j),(k,l)\in\bar{N} \tag{A2}$$

implies that $A_{i,k}$ and $B_{j,l}$ are nonzero. Therefore if (i,k) is fixed and (j,l) varies, $A_{i,k}$ can be simplified and all the $B_{j,l}$ are equal to a common value K_B. Symmetrically, the $A_{i,k}$ are equal to a common value K_A.

In basis $\{a_i^{(1)}\}$ we have $a_k^{(2)}=\Sigma_i\lambda_i a_i^{(1)}$ for $\lambda_i=\langle a_i^{(1)}|a_k^{(2)}\rangle/\langle a_i^{(1)}|a_i^{(1)}\rangle$. Now, equalities (A1) and (A2) prove that $|\lambda_i|=K_A/L_{a^{(1)}}$ whence it is constant for every (i,k). Therefore

$$\begin{aligned}L_{a^{(2)}}=|\langle a_k^{(2)}|a_k^{(2)}\rangle|&=\left|\left\langle\sum_i\lambda_i a_i^{(1)}\middle|\sum_{i'}\right\rangle\right|\\&=\sum_i^{N_1}|\lambda_i|^2|\langle a_i^{(1)}|a_i^{(1)}\rangle|=N_1|\lambda_i|^2L_{a^{(1)}}=N_1\left(\frac{K_A}{L_{a^{(1)}}}\right)^2L_{a^{(1)}}=\frac{N_1(K_A)^2}{L_{a^{(1)}}},\end{aligned} \tag{A3}$$

that is $L_{a^{(1)}}L_{a^{(2)}}=N_1(K_A)^2$.

Finally, we show that $\{a_i^{(1)}/\|a_i^{(1)}\|\}$ and $\{a_k^{(2)}/\|a_k^{(2)}\|\}$ are mutually unbiased bases in $\mathbb{C}^{N_1}$. Indeed

$$\left|\left\langle\frac{a_i^{(1)}}{\|a_i^{(1)}\|}\middle|\frac{a_k^{(2)}}{\|a_k^{(2)}\|}\right\rangle\right|^2=\frac{|\langle a_i^{(1)}|a_k^{(2)}\rangle|^2}{\|a_i^{(1)}\|^2\|a_k^{(2)}\|^2}=\frac{(K_A)^2}{L_{a^{(1)}}L_{a^{(2)}}}=\frac{1}{N_1}$$

(by Eq. (A3)).

The result for $\mathbb{C}^{N_2}$ is obtained in the same way, using $b_l^{(2)}=\Sigma_j\mu_j b_j^{(1)}$ for $\mu_j=\langle b_j^{(1)}|b_l^{(2)}\rangle/\langle b_j^{(1)}|b_j^{(1)}\rangle$, to give $L_{b^{(1)}}L_{b^{(2)}}=N_2(K_B)^2$. □

This proposition can immediately be extended as follows to $\mathbb{C}^N \cong \mathbb{C}^{N_1} \otimes \cdots \otimes C^{N_s}$ for dimension $N = N_1 \ldots N_s$. Under assumption that each of the k bases is a tensor product, we may use induction to conclude to the existence of k mutually unbiased bases in each $\mathbb{C}^{N_i}$.

Second quantization method in the presence of bound states of particles

Sergey V. Peletminskii[a] and Yuriy V. Slyusarenko[b]
National Science Center, "Kharkov Institute of Physics and Technology," Akademicheskaya Str.,1, Kharkov, 61108, Ukraine

(Received 28 May 2004; accepted 3 September 2004; published online 18 January 2005)

We develop an approximate second quantization method for describing the many-particle systems in the presence of bound states of particles at low energies (the kinetic energy of particles is small in comparison to the binding energy of compound particles). In this approximation the compound and elementary particles are considered on an equal basis. This means that creation and annihilation operators of compound particles can be introduced. The Hamiltonians, which specify the interactions between compound and elementary particles and between compound particles themselves, are found in terms of the interaction amplitudes for elementary particles. The nonrelativistic quantum electrodynamics is developed for systems containing both elementary and compound particles. Some applications of this theory are considered. © *2005 American Institute of Physics.*

I. INTRODUCTION

The second quantization is the effective method, which is used for description of physical processes in quantum theory of many-particle systems. The key role of this method consists in introduction of creation and annihilation operators of particles in a certain quantum state. The operators of physical quantities are constructed in terms of creation and annihilation operators. Such a description of quantum many-particle systems implies the particles to be elementary (not consisting of other particles). Moreover, it is absolutely accurate despite of the possible existence of compound particles. Since the interactions between particles may lead to formation of bound states, the standard second quantization method becomes too cumbersome. For this reason the construction of approximate quantum-mechanical theory for many-particle systems consisting of elementary particles and their bound states represents an actual problem. In this theory it is necessary to introduce the creation and annihilation operators of bound states as the operators of elementary objects (not compound). In addition we should preserve the required information concerning internal degrees of freedom for bound states. Such an approach may be actually realized in the approximation in which the binding energy of compound particles is much greater in comparison to their kinetic energy.

The problems leading to the necessity of accounting for compound particles along with elementary ones are typical in studying of the interaction of irradiation with matter (the matter consists of neutral atoms or molecules). The atoms or molecules may be both in the ground and excited states when it is necessary to take into account their internal structure retaining the convenience and simplicity of the second quantization method. Such a situation should take place in describing the experiments on laser cooling of atoms[1–3] or experiments on observation of Bose–Einstein condensates in magnetic traps, where a condensate temperature is reached by laser cooling of gases of alkali atoms.[4] The similar problem of accounting for the bound states occurs also in quantum chemistry, for example, in studying of chemical reactions.

[a]Electronic mail: spelet@kipt.kharkov.ua
[b]Electronic mail: slusarenko@kipt.kharkov.ua

Thus, the construction of the quantum theory of many-particle systems in the presence of bound states of particles within the second quantization method represents not only academic but also applied interest. The formulation of the quantum theory itself is to be done so that the operators of physical quantities are constructed through the creation and annihilation operators of elementary particles and their bound states.

In this paper we demonstrate a possibility of construction of the above-mentioned quantum-mechanical theory by considering a system of two kinds of charged fermions. In this theory the compound particles (atoms) consist of two fermions of various kinds. The choice of such model is not associated with principle difficulties and makes it possible to simplify calculations and to obtain the visual results.

As applications of the developed theory we study a spontaneous radiation of two-component excited atom and obtain the expression for its probability (see, e.g., Ref. 5). We also investigate the attractive forces acting between neutral atoms at long distances (the van der Waals forces) and derive the expression for the potential of the van der Waals forces.[6] Finally we consider a question concerning the scattering of photons and elementary particles by bound states.[7]

II. CREATION AND ANNIHILATION OPERATORS OF BOUND STATES OF PARTICLES

Consider a system consisting of two kinds of fermions with masses m_1 and m_2. As was mentioned in the Introduction this case is more visual in order to demonstrate the procedure for obtaining the operators of basic physical quantities within the second quantization method in the presence of bound states of particles. We shall see that the developed methodology does not contain any difficulties for its generalization (the bound states of more than two particles, the presence of bosons in the system, the bound states of bosons and boson–fermion bound states). For simplicity we do not take into account a spin variable (this can be done without any difficulties).

Let $\hat{\psi}_1(\mathbf{x})$, $\hat{\psi}_2(\mathbf{x})$ be the annihilation operators of two kinds of fermions at the point $\mathbf{x}$,

$$\hat{\psi}_1(\mathbf{x})|0\rangle = \hat{\psi}_2(\mathbf{x})|0\rangle = 0,$$

where $|0\rangle$ is a vacuum state vector. Then the state vectors

$$|\mathbf{x}_1, \ldots, \mathbf{x}_n, \mathbf{y}_1, \ldots, \mathbf{y}_m\rangle = \hat{\psi}_1^+(\mathbf{x}_1) \cdots \hat{\psi}_1^+(\mathbf{x}_n)\hat{\psi}_2^+(\mathbf{y}_1) \cdots \hat{\psi}_2^+(\mathbf{y}_m)|0\rangle \tag{1}$$

$(n, m = 0, 1, 2, \ldots)$ form a basis in the space of states H. In these states the particles are at the certain points $\mathbf{x}_1, \ldots, \mathbf{x}_n; \mathbf{y}_1, \ldots, \mathbf{y}_m \in R$ of the coordinate space. The state vectors (1) satisfy the orthogonality and normalization relations and form a complete set of state vectors.

We assume that the particles of two different kinds form a bound state specified by the wave function

$$\varphi_\alpha(\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}) = \varphi_\alpha(\mathbf{x}_1 - \mathbf{x}_2)\delta(\mathbf{x} - \mathbf{X}), \quad \mathbf{X} = \frac{m_1\mathbf{x}_1 + m_2\mathbf{x}_2}{m_1 + m_2}, \tag{2}$$

where $\mathbf{x}$ is the space coordinate and α are the quantum numbers of the bound state (atom) (we suppose that the particles of the same kind do not form the bound states). The corresponding state vector has the form

$$|\alpha, \mathbf{x}\rangle = \int \mathrm{d}\mathbf{x}_1\, \mathrm{d}\mathbf{x}_2\, \varphi_\alpha(\mathbf{x}_1 - \mathbf{x}_2)\delta(\mathbf{x} - \mathbf{X})\hat{\psi}_1^+(\mathbf{x}_1)\hat{\psi}_2^+(\mathbf{x}_2)|0\rangle.$$

For this reason the operators

$$\hat{\varphi}_\alpha^+(\mathbf{x}) = \int \mathrm{d}\mathbf{x}_1\, \mathrm{d}\mathbf{x}_2\, \varphi_\alpha(\mathbf{x}_1 - \mathbf{x}_2)\delta(\mathbf{x} - \mathbf{X})\hat{\psi}_1^+(\mathbf{x}_1)\hat{\psi}_2^+(\mathbf{x}_2) \tag{3}$$

we shall call as the creation operators of the bound states (atoms), so that

$$\hat{\varphi}_\alpha^+(\mathbf{x})|0\rangle = |\alpha,\mathbf{x}\rangle, \quad \hat{\varphi}_\alpha(\mathbf{x})|0\rangle = 0.$$

If the atom has a certain momentum, then its state vector is given by

$$|\alpha,\mathbf{p}\rangle = \frac{1}{\sqrt{\mathcal{V}}}\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\,\varphi_\alpha(\mathbf{x}_1-\mathbf{x}_2)e^{i\mathbf{p}\mathbf{X}}\hat{\psi}_1^+(\mathbf{x}_1)\hat{\psi}_2^+(\mathbf{x}_2)|0\rangle,$$

where $\mathcal{V}$ is the volume of the system. The corresponding creation operator $\hat{\varphi}_\alpha^+(\mathbf{p})$ of the atom in the state with momentum $\mathbf{p}$ is defined by

$$|\alpha,\mathbf{p}\rangle = \hat{\varphi}_\alpha^+(\mathbf{p})|0\rangle, \quad \hat{\varphi}_\alpha^+(\mathbf{x}) = \frac{1}{\sqrt{\mathcal{V}}}\sum_{\mathbf{p}} \hat{\varphi}_\alpha^+(\mathbf{p})e^{-i\mathbf{p}\mathbf{x}}.$$

Taking into account that

$$\int \mathrm{d}\mathbf{y}_1\,\varphi_\alpha^*(\mathbf{y}_1-\mathbf{y}_2)\varphi_\beta(\mathbf{y}_1-\mathbf{y}_2) = \delta_{\alpha\beta},$$

it is easy to find the following commutation relations:

$$[\hat{\varphi}_\alpha(\mathbf{x}),\hat{\varphi}_{\alpha'}^+(\mathbf{x}')] = \delta_{\alpha\alpha'}\delta(\mathbf{x}-\mathbf{x}') + \hat{\chi}_{\alpha\alpha'}(\mathbf{x},\mathbf{x}'), \quad [\hat{\varphi}_\alpha(\mathbf{x}),\hat{\varphi}_{\alpha'}(\mathbf{x}')] = 0,$$

where

$$\hat{\chi}_{\alpha\alpha'}(\mathbf{x},\mathbf{x}') = \int \mathrm{d}\mathbf{y}\,\mathrm{d}\mathbf{y}'\,\varphi_\alpha^*(\mathbf{y})\varphi_{\alpha'}(\mathbf{y}')\left\{\hat{\psi}_1^+\left(\mathbf{x}+\frac{m_2}{M}\mathbf{y}\right)\hat{\psi}_1\left(\mathbf{x}'+\frac{m_2}{M}\mathbf{y}'\right)\delta\left(\mathbf{y}-\mathbf{y}'-\frac{m_1}{M}(\mathbf{x}-\mathbf{x}')\right)\right.$$
$$\left. + \hat{\psi}_2^+\left(\mathbf{x}'-\frac{m_1}{M}\mathbf{y}'\right)\hat{\psi}_2\left(\mathbf{x}-\frac{m_1}{M}\mathbf{y}\right)\delta\left(\mathbf{y}-\mathbf{y}'+\frac{m_2}{M}(\mathbf{x}-\mathbf{x}')\right)\right\}, \quad M = m_1+m_2,$$

moreover, $\hat{\chi}_{\alpha\alpha'}(\mathbf{x},\mathbf{x}')|0\rangle = 0$. The vectors

$$|\underbrace{\mathbf{x}_1,\ldots}_{n},\underbrace{\mathbf{y}_1,\ldots}_{m},\underbrace{\mathbf{z}_1,\ldots}_{l}\rangle \equiv \prod_{i=1}^{n}\hat{\psi}_1^+(\mathbf{x}_i)\prod_{k=1}^{m}\hat{\psi}_2^+(\mathbf{y}_k)\prod_{j=1}^{l}\hat{\varphi}_{\alpha_j}^+(\mathbf{z}_j)|0\rangle \tag{4}$$

have an obvious physical meaning under the following conditions:

$$|\mathbf{x}_i-\mathbf{x}_j| \gtrsim a, \quad |\mathbf{y}_i-\mathbf{y}_j| \gtrsim a, \quad |\mathbf{z}_i-\mathbf{z}_j| \gtrsim a,$$
$$|\mathbf{x}_i-\mathbf{y}_j| \gtrsim a, \quad |\mathbf{x}_i-\mathbf{z}_j| \gtrsim a, \quad |\mathbf{y}_i-\mathbf{z}_j| \gtrsim a \tag{5}$$

($\mathbf{x},\mathbf{y},\mathbf{z} \in R_a$, $a \gg r_0$, r_0 is the radius of the bound state; the definition of a see below). In this case the elementary particles and their bound states are at the certain space points.

Notice that the state vectors (4) do not form a basis in the Gilbert space H if (5) are valid. However, their linear span, which is a totality of the following vectors:

$$\sum_{n,m,l}\underbrace{\int \mathrm{d}\mathbf{x}_1\cdots\int \mathrm{d}\mathbf{y}_1\cdots\int \mathrm{d}\mathbf{z}_1\cdots}_{R_a} C(\underbrace{\mathbf{x}_1,\ldots}_{n},\underbrace{\mathbf{y}_1,\ldots}_{m},\underbrace{\mathbf{z}_1,\ldots}_{l})|\underbrace{\mathbf{x}_1,\ldots}_{n},\underbrace{\mathbf{y}_1,\ldots}_{m},\underbrace{\mathbf{z}_1,\ldots}_{l}\rangle, \tag{6}$$

form a subspace H_a of the space H. Let us show that the state vectors (4) [with conditions (5)] form an orthonormalized basis in the subspace H_a. To this end it is necessary to take into account that in calculating of the following vacuum averages:

$$\langle 0|\hat{\psi}_1(\mathbf{x}_1)\cdots\hat{\psi}_2(\mathbf{x}_2)\cdots\hat{\varphi}_\alpha(\mathbf{x})\hat{\varphi}_{\alpha'}^+(\mathbf{x}')\cdots\hat{\psi}_2^+(\mathbf{x}_2')\cdots\hat{\psi}_1^+(\mathbf{x}_1')\cdots|0\rangle$$

we can use the Wick theorem with the following contractions:

$$\underset{a}{\hat{\psi}_i}(\mathbf{x})\underset{a}{\hat{\psi}^+_{i'}}(\mathbf{x}') = \langle 0|\hat{\psi}_i(\mathbf{x})\hat{\psi}^+_{i'}(\mathbf{x}')|0\rangle = \delta_{ii'}\delta(\mathbf{x}-\mathbf{x}'),\quad \underset{a}{\hat{\psi}_i}(\mathbf{x})\underset{a}{\hat{\psi}_{i'}}(\mathbf{x}') = 0,$$

if to consider the operators $\hat{\psi}_1$, $\hat{\psi}_2$, $\hat{\varphi}$ referred to the moment of time +0, and operators $\hat{\varphi}^+$, $\hat{\psi}^+_2$, $\hat{\psi}^+_1$ to the moment of time −0. In addition, we should remember that the creation and annihilation operators $\hat{\varphi}_\alpha$, $\hat{\varphi}^+_{\alpha'}$ depend on $\hat{\psi}_i$, $\hat{\psi}_{i'}$ [see (3)]. We also assume that the wave function (2) of the atom differs from zero for $|\mathbf{x}_1-\mathbf{x}_2|<r_0$. Taking into account (3) and noting that for $|\mathbf{x}'_1-\mathbf{x}'_2|>a$,

$$\underset{ab}{\hat{\varphi}_\alpha}(\mathbf{z})\underset{b}{\hat{\psi}^+_2}(\mathbf{x}'_2)\underset{a}{\hat{\psi}^+_1}(\mathbf{x}'_1) = \int \mathrm{d}\mathbf{z}_1\,\mathrm{d}\mathbf{z}_2\varphi^*_\alpha(\mathbf{z}_1-\mathbf{z}_2)\delta(\mathbf{z}-\mathbf{Z})\underset{a}{\hat{\psi}_1}(\mathbf{z}_1)\underset{b}{\hat{\psi}_2}(\mathbf{z}_2)\underset{b}{\hat{\psi}^+_2}(\mathbf{x}'_2)\underset{a}{\hat{\psi}^+_1}(\mathbf{x}'_1)$$
$$= \varphi^*_\alpha(\mathbf{x}'_1-\mathbf{x}_2{}')\delta(\mathbf{z}-\mathbf{X}') = 0,$$

$$\mathbf{X}' = \frac{m_1\mathbf{x}'_1+m_2\mathbf{x}'_2}{m_1+m_2}$$

and also

$$\underset{ab}{\hat{\varphi}_\alpha}(\mathbf{z})\underset{ba}{\hat{\varphi}^+_{\alpha'}}(\mathbf{z}') = \int \mathrm{d}\mathbf{z}_1\mathrm{d}\mathbf{z}_2\mathrm{d}\mathbf{z}'_1\mathrm{d}\mathbf{z}'_2\varphi^*_\alpha(\mathbf{z}_1-\mathbf{z}_2)\delta(\mathbf{z}-\mathbf{Z})\varphi_{\alpha'}(\mathbf{z}'_1-\mathbf{z}_2{}')\delta(\mathbf{z}'$$
$$-\mathbf{Z}')\underset{a}{\hat{\psi}_1}(\mathbf{z}_1)\underset{b}{\hat{\psi}_2}(\mathbf{z}_2)\underset{b}{\hat{\psi}^+_2}(\mathbf{z}'_2)\underset{a}{\hat{\psi}^+_1}(\mathbf{z}'_1)$$
$$= \int \mathrm{d}\mathbf{z}_1\,\mathrm{d}\mathbf{z}_2\varphi^*_\alpha(\mathbf{z}_1-\mathbf{z}_2)\delta(\mathbf{z}-\mathbf{Z})\varphi_{\alpha'}(\mathbf{z}_1-\mathbf{z}_2)\delta(\mathbf{z}'-\mathbf{Z}) = \delta_{\alpha\alpha'}\delta(\mathbf{z}-\mathbf{z}')$$

(the double contractions correspond to the operators $\hat{\varphi}_\alpha$, $\hat{\varphi}^+_\alpha$) we get

$$\langle 0|\underbrace{\hat{\psi}_1(\mathbf{x}_1)\cdots}_{n}\underbrace{\hat{\psi}_2(\mathbf{y}_1)\cdots}_{m}\underbrace{\hat{\varphi}_{\alpha_1}(\mathbf{z}_1)\cdots}_{l}\underbrace{\hat{\varphi}^+_{\alpha'_1}(\mathbf{z}'_1)\cdots}_{l'}\underbrace{\hat{\psi}^+_2(\mathbf{y}'_1)\cdots}_{m'}\underbrace{\hat{\psi}_1(\mathbf{x}'_1)\cdots}_{n'}|0\rangle$$
$$= \delta_{nn'}\delta_{mm'}\delta_{ll'}\sum\mathcal{P}_{x'}\mathcal{P}_{y'}\underbrace{\delta(\mathbf{x}_1-\mathbf{x}'_1)\cdots}_{n}\underbrace{\delta(\mathbf{y}_1-\mathbf{y}'_1)\cdots}_{m}\underbrace{\delta(\mathbf{z}_1-\mathbf{z}'_1)\delta_{\alpha_1\alpha'_1}\cdots}_{l}. \tag{7}$$

This relation shows that the vectors (6) form the orthonormalized basis in the subspace H_a if to consider the creation and annihilation operators $\hat{\varphi}^+_\alpha(\mathbf{z})$, $\hat{\varphi}_\alpha(\mathbf{z})$ as the Bose operators, which commute with $\hat{\psi}_i(\mathbf{x})$, $\hat{\psi}^+_i(\mathbf{x})$. The quantity $\mathcal{P}_{x'}$ in (7) is equal to +1 if the number of permutations of the arguments $\mathbf{x}'_1\cdots\mathbf{x}'_n$ is even and it is equal to −1 if the number of these permutations is odd. The quantity $\mathcal{P}_{y'}$ is defined similarly. However, the case when it is necessary to take into account a more complicated arrangement of the contractions between $\hat{\varphi}_\alpha$, $\hat{\varphi}^+_\alpha$:

$$\underset{a}{\mathbf{x}_4}\underset{b}{\mathbf{x}'_4}\cdots\underset{c}{\mathbf{x}_2}\underset{d}{\mathbf{x}'_2}\cdots\underset{e}{\mathbf{x}_1}\underset{e}{\mathbf{x}'_1}\cdots\underset{c}{\mathbf{x}_3}\underset{b}{\mathbf{x}'_3}\cdots\underset{a}{}$$

can take place (the odd indices correspond to the creation operators and even to annihilation operators). Since $\mathbf{x}'_1=\mathbf{x}'_2$, $\mathbf{x}_2=\mathbf{x}_3$, $\mathbf{x}'_4=\mathbf{x}'_3$,

$$|\mathbf{x}_1-\mathbf{x}'_1|\lesssim r_0,\ |\mathbf{x}'_1-\mathbf{x}_2|\lesssim r_0,\ |\mathbf{x}'_3-\mathbf{x}_2|\lesssim r_0,\ |\mathbf{x}_4-\mathbf{x}'_3|\lesssim r_0,$$

whence $|\mathbf{x}_4-\mathbf{x}_1|\lesssim 4r_0$. Therefore, if $a\leqslant 4r_0$, then the above contractions are to be taken into account. If however, we consider the n-particle states, then the discussed arrangements of the contractions are not to be taken into account for $n\lesssim a/r_0$ [we emphasize that r_0/a is a small parameter in our problem, see (11)]. The above mentioned concerns the majority of problems in nonrelativistic quantum theory, where a finite number of particles is usually studied (see Secs. V and VI).

With the use of (7) it is easy to find the projection operator $\mathcal{P}_{H_a}$ onto the subspace H_a,

$$\mathcal{P}_{H_a} = \sum_{k+m+l\leqslant n} \frac{1}{k!}\frac{1}{m!}\frac{1}{l!} \underbrace{\int \mathbf{dx}_1 \cdots \int \mathbf{dy}_1 \cdots \int \mathbf{dz}_1 \cdots}_{R_a} |\underbrace{\mathbf{x}_1 \cdots}_{k} \underbrace{\mathbf{y}_1 \cdots}_{m} \underbrace{\mathbf{z}_1 \cdots}_{l}\rangle \times \langle \underbrace{\mathbf{x}_1 \cdots}_{k} \underbrace{\mathbf{y}_1 \cdots}_{m} \underbrace{\mathbf{z}_1 \cdots}_{l}|,$$

such that the operators $\underline{A}$ acting in the subspace $H_a \in H$ correspond to the operators of physical quantities A that act in H (hereinafter the sums of $1,2,\ldots,n$-particle subspaces over the bound states are considered; $n \approx a/r_0 \gg 1$),

$$\underline{A} = \mathcal{P}_{H_a} A \mathcal{P}_{H_a}. \tag{8}$$

Let us introduce now an auxiliary space $\tilde{H}$ with the Fermi creation and annihilation operators $\hat{\chi}_1^+(\mathbf{x})$, $\hat{\chi}_2^+(\mathbf{x})$, $\hat{\chi}_1(\mathbf{x})$, $\hat{\chi}_2(\mathbf{x})$ and Bose creation and annihilation operators $\hat{\eta}_\alpha^+(\mathbf{x})$, $\hat{\eta}_\alpha(\mathbf{x})$ and take the vectors

$$|\mathbf{x}_1, \ldots, \mathbf{y}_1, \ldots, \mathbf{z}_1, \ldots) = \hat{\chi}_1^+(\mathbf{x}_1) \cdots \hat{\chi}_2^+(\mathbf{y}_1) \cdots \hat{\eta}_\alpha^+(\mathbf{z}_1) \cdots |0),$$

as a basis of this space, where $|0)$ is a vacuum vector in $\tilde{H}$. Then the linear span of the vectors

$$|\mathbf{x}_1, \ldots, \mathbf{y}_1, \ldots, \mathbf{z}_1, \ldots) \in \tilde{H}_a, \quad \mathbf{x},\mathbf{y},\mathbf{z} \in R_a$$

determines the subspace $\tilde{H}_a$ of the space $\tilde{H}$.

Now we can easily establish the isomorphic correspondence between H_a and $\tilde{H}_a$:

$$|\mathbf{x}_1, \ldots, \mathbf{y}_1, \ldots, \mathbf{z}_1, \ldots\rangle \Leftrightarrow |\mathbf{x}_1, \ldots, \mathbf{y}_1, \ldots, \mathbf{z}_1, \ldots),$$

which preserves the scalar product

$$\langle \mathbf{x}', \ldots, \mathbf{y}', \ldots, \mathbf{z}', \ldots |\mathbf{x}, \ldots, \mathbf{y}, \ldots, \mathbf{z} \ldots\rangle = (\mathbf{x}', \ldots, \mathbf{y}', \ldots, \mathbf{z}', \ldots |\mathbf{x}, \ldots, \mathbf{y}, \ldots, \mathbf{z} \ldots), \quad \mathbf{x},\mathbf{y},\mathbf{z};\mathbf{x}',\mathbf{y}',\mathbf{z}' \in R_a.$$

We can also establish the isomorphism between the operators $\underline{A} \Leftrightarrow \tilde{A}$, acting in the spaces H_a and $\tilde{H}_a$ according to the formula:

$$(\mathbf{x}', \ldots, \mathbf{y}', \ldots, \mathbf{z}', \ldots |\underline{A}|\mathbf{x}, \ldots, \mathbf{y}, \ldots, \mathbf{z} \ldots) = \langle \mathbf{x}', \ldots, \mathbf{y}', \ldots, \mathbf{z}', \ldots |\tilde{A}|\mathbf{x}, \ldots, \mathbf{y}, \ldots, \mathbf{z} \ldots\rangle. \tag{9}$$

This isomorphic correspondence is remained after the multiplication of the operator by a number, after addition of operators, and after multiplication of operators:

$$\lambda\underline{A} \Leftrightarrow \lambda\tilde{A}, \quad \underline{A} + \underline{B} \Leftrightarrow \tilde{A} + \tilde{B}, \quad \underline{A}\underline{B} \Leftrightarrow \tilde{A}\tilde{B}.$$

The formulas (8) and (9) lead to

$$(\mathbf{x}', \ldots, \mathbf{y}', \ldots, \mathbf{z}', \ldots |\tilde{A}|\mathbf{x}, \ldots, \mathbf{y}, \ldots, \mathbf{z} \ldots) = \langle \mathbf{x}', \ldots, \mathbf{y}', \ldots, \mathbf{z}', \ldots |A|\mathbf{x}, \ldots, \mathbf{y}, \ldots, \mathbf{z} \ldots\rangle. \tag{10}$$

This relation determines the operators of various physical quantities $\tilde{A}$ acting in $\tilde{H}_a$ and, hence, transfers the quantum theory in which the compound (the bound states) and elementary particles exist on an equal basis from the space of states H onto the space of states $\tilde{H}_a$. We would like to remind here that $\hat{\varphi}_\alpha^+$ entering (4) is determined by (3).

The relation (10) defines the operator $\tilde{A}$ in $\tilde{H}_a$ uniquely, but it does not define it uniquely in $\tilde{H}$. It is evident that the operator $\tilde{A}$ acting in $\tilde{H}$ (continued from $\tilde{H}_a$ to the whole space $\tilde{H}$) is determined up to the term $\tilde{A}'$, the matrix elements of which are zero in the space $\tilde{H}_a(\tilde{A}=\tilde{A}'+\tilde{A}'')$. If to introduce the projection operator $\mathcal{P}_{\tilde{H}_a}$ onto the subspace $\tilde{H}_a$ and to require that the operator $\tilde{A}$ has no nonzero matrix elements in the orthogonal subspace, then the operator $\tilde{A}$ will be defined in $\tilde{H}$ uniquely, $\tilde{A}=\mathcal{P}_{\tilde{H}_a}\tilde{A}''\mathcal{P}_{\tilde{H}_a}$. We will omit the projection operator $\mathcal{P}_{\tilde{H}_a}$ when constructing the operator $\tilde{A}$ acting in $\tilde{H}$. The reason for this is the assumption that the matrix elements of the operators (in the position space), corresponding to a quite large external parameter $R\sim|\mathbf{x}_i-\mathbf{x}_j|$ give a dominant contribution to the quantum-mechanical processes. Further we will assume that $R\gg r_0$ (usually in case of particle collisions $R^{-1}\sim\sqrt{m\mathcal{E}}$, where $\mathcal{E}$ is the particle kinetic energy). The latter inequality makes it possible to choose parameter a [see (5)] as follows:[8]

$$R\gg a\gg r_0. \tag{11}$$

The matrix elements of the operators should not depend on parameter a chosen by this way. Let us mentally decrease the radius of a bound state, $r_0\to 0$. Then the whole written scheme, as we have already noted, does not depend on a up to the values $a=r_0$. Therefore, the subspace $\tilde{H}_a$ can be identified with $\tilde{H}$ due to the inequality $R\gg a$. In other words, one can consider that $\mathcal{P}_{\tilde{H}_a}\to 1$ for $a\to 0$. At the same time we do not break the quantum-mechanical description of bound states in virtue of the inequality $a\gg r_0$. From the physical point of view the inequality $r_0\ll R$ gives the stability domain for the bound states considered as elementary particles. The calculation of the following approximation is to be associated with accounting of the difference of the subspace H_a from the space H.

Finally we note that for an arbitrary vector $|\ )\in\tilde{H}_a$ the following evident relations are valid:

$$\hat{\zeta}(\mathbf{x})\hat{\xi}(\mathbf{x}')|\ )=0,\ \ (\ |\hat{\zeta}^+(\mathbf{x})\hat{\xi}^+(\mathbf{x}')=0,\ \ |\mathbf{x}-\mathbf{x}'|<a, \tag{12}$$

or

$$\hat{\zeta}(\mathbf{x})\hat{\xi}(\mathbf{x}')\tilde{H}_a=0,\ \ \tilde{H}_a\hat{\zeta}^+(\mathbf{x})\hat{\xi}^+(\mathbf{x}')=0,\ \ |\mathbf{x}-\mathbf{x}'|<a,$$

where $\hat{\zeta}$ and $\hat{\xi}$ are any of the annihilation operators $\hat{\chi}_1$, $\hat{\chi}_2$, $\hat{\eta}$.

III. THE STRUCTURE OF $\tilde{\hat{A}}(\mathbf{u},\mathbf{v})$ OPERATORS

Here we consider the method for obtaining the operators $\tilde{\hat{A}}$. Let the operator $\hat{A}$ represent a normal-ordered production of $\hat{\psi}_i(\mathbf{v})$, $\hat{\psi}_i^+(\mathbf{u})$ $(i=1,2)$,

$$\hat{A}(\mathbf{u},\mathbf{v})=\hat{\psi}_1^+(\mathbf{u}_1)\cdots\hat{\psi}_2^+(\mathbf{u}_2)\hat{\psi}_1(\mathbf{v}_1)\cdots\hat{\psi}_2(\mathbf{v}_2)\cdots\ . \tag{13}$$

The operators of such type are the particle density operator $\hat{\rho}_i(\mathbf{x})$,

$$\hat{\rho}_i(\mathbf{x})=\hat{\psi}_i^+(\mathbf{x})\hat{\psi}_i(\mathbf{x}),$$

the momentum density operator $\hat{\pi}_i(\mathbf{x})$,

$$\hat{\pi}_i(\mathbf{x})=-\frac{i}{2}\left(\hat{\psi}_i^+(\mathbf{x})\frac{\partial\hat{\psi}_i(\mathbf{x})}{\partial\mathbf{x}}-\frac{\partial\hat{\psi}_i^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\psi}_i(\mathbf{x})\right),$$

a Hamiltonian of the system, etc.

The matrix element on the right-hand side of (10) may be written as the following vacuum average:

$$\langle 0|\hat{\psi}_1(\mathbf{x}_1)\cdots\hat{\psi}_2(\mathbf{x}_2)\cdots\hat{\varphi}_\alpha(\mathbf{x})\cdots\hat{A}(\mathbf{u},\mathbf{v})\hat{\varphi}^+_{\alpha'}(\mathbf{x})\cdots\hat{\psi}_2(\mathbf{x}'_2)\cdots\hat{\psi}_1(\mathbf{x}'_1)\cdots|0\rangle.$$

Let us note that when calculating this average by using Wick's theorem, the quantity, which is averaged over the vacuum state has the meaning of a mixed T-product if to consider the operators $\hat{\psi}_1,\ldots,\hat{\psi}_2,\ldots,\hat{\varphi},\ldots$ referring to the moment of time +0, the operators $\hat{\psi}^+_1,\ldots,\hat{\psi}^+_2,\hat{\varphi}^+,\ldots$ to −0, and the normal-ordered operator $\hat{A}(\mathbf{u},\mathbf{v})$ referring to the moment of time 0. Thus, there is no need to place the contractions inside the expression for $\hat{A}(\mathbf{u},\mathbf{v})$. Let

$$A_b(\mathbf{y};\mathbf{y}';\mathbf{u},\mathbf{v}) \equiv A_b(\mathbf{y}_1,\ldots,\mathbf{y}_2,\ldots,\mathbf{y},\ldots;\mathbf{y}'_1,\ldots,\mathbf{y}'_2,\ldots,\mathbf{y}',\ldots;\mathbf{u},\mathbf{v}) \tag{14}$$

be the analytic expression that corresponds to the diagram "b." For this diagram the operators with the arguments $\mathbf{u}$ are related to the operators with the arguments $\mathbf{y}_1,\ldots,\mathbf{y}_2,\ldots,\mathbf{y},\ldots$. In addition, the latter arguments are spaced apart by the distances greater than a and coincide with some of the arguments $\mathbf{x}_1,\ldots,\mathbf{x}_2,\ldots,\mathbf{x},\ldots$. The similar statement should be also made concerning the arguments $\mathbf{y}'_1,\ldots,\mathbf{y}'_2,\ldots,\mathbf{y}',\ldots$. Then, the operator $\tilde{\hat{A}}(\mathbf{u},\mathbf{v})$ acting in $\tilde{H}$ is given, according to (5), by

$$\tilde{\hat{A}}(\mathbf{u},\mathbf{v}) = \sum_b \int \hat{R}_1\hat{R}_2\hat{R}A_b(\mathbf{y};\mathbf{y}';\mathbf{u},\mathbf{v})\hat{R}'_1\hat{R}'_2\hat{R}', \tag{15}$$

where

$$\hat{R}_1 = \prod \hat{\chi}^+(\mathbf{y}_1)d\mathbf{y}_1,\ \ \hat{R}_2 = \prod \hat{\chi}^+(\mathbf{y}_2)d\mathbf{y}_2,\ \ \hat{R} = \prod \hat{\eta}^+(\mathbf{y})d\mathbf{y},$$

$$\hat{R}'_1 = \prod \hat{\chi}(\mathbf{y}'_1)d\mathbf{y}'_1,\ \ \hat{R}'_2 = \prod \hat{\chi}(\mathbf{y}'_2)d\mathbf{y}'_2,\ \ \hat{R}' = \prod \hat{\eta}(\mathbf{y}')d\mathbf{y}'.$$

Here the summation is taken over all diagrams of the described type.

If $\hat{A}(\mathbf{v})=1$ [see the proof of (7)], then $\tilde{\hat{A}}(\mathbf{v})=1$ on the subspace $\tilde{H}_a$. Let now $\hat{A}(\mathbf{u},\mathbf{v})=\hat{\psi}_1(\mathbf{v})$. Then the only diagrams of the described type for the vacuum average $\langle 0|\cdots\hat{\psi}_1(\mathbf{v})\cdots|0\rangle$ are the following diagrams:

$$A_{b_1} = \underset{a}{\hat{\psi}_1}(\mathbf{v})\ldots\underset{a}{\hat{\psi}^+_1}(\mathbf{y}'),\ \ A_{b_2} = \underset{a}{\hat{\psi}_2}(\mathbf{y}_2)\cdots\underset{b}{\hat{\psi}_1}(\mathbf{v})\cdots\underset{ba}{\hat{\varphi}^+_\alpha}(\mathbf{y}').$$

The expressions

$$A_{b_1}(\mathbf{y}'_1;\mathbf{v}) = \delta(\mathbf{v}-\mathbf{y}'_1),$$

$$A_{b_2}(\mathbf{y}_2;\mathbf{y}',\mathbf{v}) = \int d\mathbf{x}_1\, d\mathbf{x}_2\, \varphi_\alpha(\mathbf{x}_1-\mathbf{x}_2)\delta(\mathbf{y}'-\mathbf{X})\delta(\mathbf{v}-\mathbf{x}_1)\delta(\mathbf{x}_2-\mathbf{y}_2) = \varphi_\alpha(\mathbf{v},\mathbf{y}_2,\mathbf{y}'),$$

correspond to the above-mentioned diagrams. Here $\varphi_\alpha(\mathbf{v},\mathbf{y}_2,\mathbf{y}')$ is defined in accordance with (2). Therefore, according to (15) we have

$$\tilde{\hat{\psi}}_1(\mathbf{v}) = \int d\mathbf{y}'_1\, A_{b_1}(\mathbf{y}'_1,\mathbf{v})\hat{\chi}_1(\mathbf{y}'_1) + \int d\mathbf{y}_2\, d\mathbf{y}'\, A_{b_2}(\mathbf{y}_2;\mathbf{y}',\mathbf{v})\hat{\chi}^+_2(\mathbf{y}_2)\hat{\eta}(\mathbf{y}') = \hat{\chi}_1(\mathbf{v}) + \hat{O}_1(\mathbf{v}), \tag{16}$$

where

$$\hat{O}_1(\mathbf{v}) = \int d\mathbf{y}\ \hat{\varphi}(\mathbf{v},\mathbf{y})\hat{\chi}^+_2(\mathbf{y}),\ \ \hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2) = \varphi_\alpha(\mathbf{x})\hat{\eta}_\alpha(\mathbf{X}) \tag{17}$$

and $\mathbf{X}$ is given by (2), $\mathbf{x}=\mathbf{x}_1-\mathbf{x}_2$. Similarly, one finds

$$\tilde{\hat{\psi}}_2(\mathbf{v}) = \hat{\chi}_2(\mathbf{v}) + \hat{O}_2(\mathbf{v}), \tag{18}$$

where

$$\hat{O}_2(\mathbf{v}) = \int \mathrm{d}\mathbf{y}\, \hat{\chi}_1^+(\mathbf{y})\hat{\varphi}(\mathbf{y},\mathbf{v}).$$

When deriving (16) and (18), we have essentially used the inequalities (5).

Now let us consider $\hat{A}(\mathbf{u},\mathbf{v}) = \hat{\psi}_1^+(\mathbf{u})\hat{\psi}_1(\mathbf{v})$. In this case the following five diagrams

$$A_1 = \underset{a}{\hat{\psi}} \cdots \underset{a}{\hat{\psi}_1^+}(\mathbf{u}) \underset{b}{\hat{\psi}_1}(\mathbf{v}) \cdots \underset{b}{\hat{\psi}^+}, \quad A_2 = \underset{a}{\hat{\psi}} \cdots \underset{b}{\hat{\psi}} \cdots \underset{b}{\hat{\psi}_1^+}(\mathbf{u}) \underset{c}{\hat{\psi}_1}(\mathbf{v}) \cdots \underset{ca}{\hat{\varphi}^+},$$

$$A_3 = \underset{ab}{\hat{\varphi}} \cdots \underset{b}{\hat{\psi}_1^+}(\mathbf{u}) \underset{c}{\hat{\psi}_1}(\mathbf{v}) \cdots \underset{c}{\hat{\psi}^+} \cdots \underset{a}{\hat{\psi}^+},$$

$$A_4 = \underset{ab}{\hat{\varphi}} \cdots \underset{b}{\hat{\psi}_1^+}(\mathbf{u}) \underset{c}{\hat{\psi}_1}(\mathbf{v}) \cdots \underset{ca}{\hat{\varphi}^+}, \quad A_5 = \underset{a}{\hat{\psi}} \cdots \underset{bd}{\hat{\varphi}} \cdots \underset{d}{\hat{\psi}_1^+}(\mathbf{u}) \underset{c}{\hat{\psi}_1}(\mathbf{v}) \cdots \underset{ca}{\hat{\varphi}^+} \cdots \underset{b}{\hat{\psi}^+}$$

correspond to this operator (the indices 1 and 2 for $\hat{\psi}$ and $\hat{\psi}^+$ can be easily restored if we take into account (3) and the definition of contractions). The analytic expressions for these diagrams have the form

$$\tilde{\hat{A}}_1 = \hat{\chi}_1^+(\mathbf{u}_1)\hat{\chi}_1(\mathbf{v}_1), \quad \tilde{\hat{A}}_2 = \int \mathrm{d}\mathbf{z}_1\, \mathrm{d}\mathbf{z}_2\, \hat{\varphi}(\mathbf{z}_1,\mathbf{z}_2)\delta(\mathbf{z}_1 - \mathbf{v}_1)\hat{\chi}_1^+(\mathbf{u}_1)\hat{\chi}_2^+(\mathbf{z}_2) = \int \mathrm{d}\mathbf{z}_2\, \hat{\varphi}(\mathbf{v}_1,\mathbf{z}_2)\hat{\chi}_1^+(\mathbf{u}_1)\hat{\chi}_2^+(\mathbf{z}_2),$$

$$\tilde{\hat{A}}_3 = \int \mathrm{d}\mathbf{z}_1\, \mathrm{d}\mathbf{z}_2\, \hat{\varphi}^+(\mathbf{z}_1,\mathbf{z}_2)\delta(\mathbf{z}_1 - \mathbf{u}_1)\hat{\chi}_2(\mathbf{z}_2)\hat{\chi}_1(\mathbf{v}_1) = \int \mathrm{d}\mathbf{z}_2\, \hat{\varphi}^+(\mathbf{u}_1,\mathbf{z}_2)\hat{\chi}_2(\mathbf{z}_2)\hat{\chi}_1(\mathbf{v}_1),$$

$$\tilde{\hat{A}}_4 = \int \mathrm{d}\mathbf{z}_1\, \mathrm{d}\mathbf{z}_2\, \mathrm{d}\mathbf{z}_1'\, \mathrm{d}\mathbf{z}_2'\, \hat{\varphi}^+(\mathbf{z}_1,\mathbf{z}_2)\hat{\varphi}(\mathbf{z}_1',\mathbf{z}_2')\delta(\mathbf{z}_1 - \mathbf{u}_1)\delta(\mathbf{v}_1 - \mathbf{z}_1')\delta(\mathbf{z}_2 - \mathbf{z}_2') = \int \mathrm{d}\mathbf{z}_2\, \hat{\varphi}^+(\mathbf{u}_1,\mathbf{z}_2)\hat{\varphi}(\mathbf{v}_1,\mathbf{z}_2),$$

$$\begin{aligned}\tilde{\hat{A}}_5 &= -\int \mathrm{d}\mathbf{z}_1\, \mathrm{d}\mathbf{z}_2\, \mathrm{d}\mathbf{z}_1'\, \mathrm{d}\mathbf{z}_2'\, \hat{\varphi}^+(\mathbf{z}_1,\mathbf{z}_2)\hat{\varphi}(\mathbf{z}_1',\mathbf{z}_2')\delta(\mathbf{z}_1 - \mathbf{u}_1)\delta(\mathbf{v}_1 - \mathbf{z}_1')\hat{\chi}_2^+(\mathbf{z}_2')\hat{\chi}_2(\mathbf{z}_2) \\ &= -\int \mathrm{d}\mathbf{z}_2\, \mathrm{d}\mathbf{z}_2'\, \hat{\varphi}^+(\mathbf{u}_1,\mathbf{z}_2)\hat{\varphi}(\mathbf{v}_1,\mathbf{z}_2')\hat{\chi}_2^+(\mathbf{z}_2')\hat{\chi}_2(\mathbf{z}_2),\end{aligned}$$

whence, we find the operators (15) corresponding to the diagrams (14),

$$\tilde{\hat{A}}_1 = \hat{\chi}_1^+(\mathbf{u}_1)\hat{\chi}_1(\mathbf{v}_1), \quad \tilde{\hat{A}}_2 = \hat{\chi}_1^+(\mathbf{u}_1)\hat{O}_1(\mathbf{v}_1), \quad \tilde{\hat{A}}_3 = \hat{O}_1^+(\mathbf{u}_1)\hat{\chi}_1(\mathbf{v}_1), \quad \tilde{\hat{A}}_4 + \tilde{\hat{A}}_5 = \hat{O}_1^+(\mathbf{u}_1)\hat{O}_1(\mathbf{v}_1).$$

In obtaining the latter expression, we have taken into account the anticommutative relations for $\hat{\chi}$, $\hat{\chi}^+$. Next bearing in mind (16) and (18) we obtain the final expression for $\tilde{\hat{A}}(\mathbf{u},\mathbf{v}) = \hat{\psi}_1^+(\widetilde{\mathbf{u}_1})\hat{\psi}_1(\mathbf{v}_1)$ that corresponds to $\hat{A}(\mathbf{u},\mathbf{v}) = \hat{\psi}_1^+(\mathbf{u}_1)\hat{\psi}_1(\mathbf{v}_1)$:

$$\hat{\psi}_1^+(\mathbf{u}_1)\hat{\psi}_1(\mathbf{v}_1) \to \hat{\psi}_1^+(\widetilde{\mathbf{u}_1})\hat{\psi}_1(\mathbf{v}_1) = \tilde{\hat{\psi}}_1^+(\mathbf{u}_1)\tilde{\hat{\psi}}_1(\mathbf{v}_1). \tag{19}$$

Similarly, one gets

$$\hat{\psi}_1(\mathbf{u}_1)\hat{\psi}_1(\mathbf{v}_1) \to \hat{\psi}_1(\widetilde{\mathbf{u}_1})\hat{\psi}_1(\mathbf{v}_1) = \tilde{\hat{\psi}}_1(\mathbf{u}_1)\tilde{\hat{\psi}}_1(\mathbf{v}_1),$$
$$\hat{\psi}_1^+(\mathbf{u}_1)\hat{\psi}_2(\mathbf{v}_1) \to \hat{\psi}_1^+(\widetilde{\mathbf{u}_1})\hat{\psi}_2(\mathbf{v}_1) = \tilde{\hat{\psi}}_1^+(\mathbf{u}_1)\tilde{\hat{\psi}}_2(\mathbf{v}_1), \quad \ldots . \tag{20}$$

In the general case the following formula is valid:

$$\hat{\psi}_{i_1}^+(\mathbf{u}_{i_1})\cdots\hat{\psi}_{i_n}^+(\mathbf{u}_{i_n})\hat{\psi}_{j_1}(\mathbf{v}_{j_1})\cdots\hat{\psi}_{j_m}(\mathbf{v}_{j_m}) \to \hat{\psi}_{i_1}^+(\mathbf{u}_{i_1})\cdot\widetilde{\cdots\psi}_{j_m}(\mathbf{v}_{j_m}) = \tilde{\hat{\psi}}_{i_1}^+(\mathbf{u}_1)\cdots\tilde{\hat{\psi}}_{j_m}(\mathbf{v}_{j_m}). \tag{21}$$

To explain this formula we note that each of $\hat{\psi}_j(\mathbf{v}_j)$ [or $\hat{\psi}_i^+(\mathbf{u}_i)$] entering $\hat{A}(\mathbf{u},\mathbf{v})$ [see (13)] is related to other operators $\hat{\psi}^+$ (or $\hat{\psi}$) not entering $\hat{A}(\mathbf{u},\mathbf{v})$ only by unique way, which leads to the binary relations (19) and (20). Therefore, we come to (21) by sorting out all the operators $\hat{\psi}_i$, $\hat{\psi}_{i'}$ contained in $\hat{A}(\mathbf{u},\mathbf{v})$.

The operators $\hat{\psi}_i(\mathbf{x})$, $\hat{\psi}_j(\mathbf{x}')$ are anticommutative. For this reason there is a question concerning the consistency of (20) and (21). The anticommutativity of $\tilde{\hat{\psi}}_i(\mathbf{x})$, $\tilde{\hat{\psi}}_j(\mathbf{x}')$ [and also $\tilde{\hat{\psi}}_i^+(\mathbf{x})$, $\tilde{\hat{\psi}}_j^+(\mathbf{x}')$] represents the consistency condition of these formulas,

$$\{\tilde{\hat{\psi}}_i(\mathbf{x}), \tilde{\hat{\psi}}_j(\mathbf{x}')\} = \{\tilde{\hat{\psi}}_i^+(\mathbf{x}), \tilde{\hat{\psi}}_j^+(\mathbf{x}')\} = 0.$$

The validity of these anticommutative relations can be easily proved if to use the definitions (16)–(18) for $\tilde{\hat{\psi}}$, $\tilde{\hat{\psi}}^+$ and the commutative relations for $\hat{\chi}$, $\hat{\chi}^+$ and $\hat{\eta}_\alpha$, $\hat{\eta}_\alpha^+$.

IV. THE OPERATORS OF BASIC PHYSICAL QUANTITIES

In this section we consider the operators of basic physical quantities, which act in the Hilbert space $\tilde{H}$. Let us start from the density operator for particles of the first kind. The corresponding operator acting in the original Hilbert space H is of the form

$$\hat{\rho}_1(\mathbf{x}) = \hat{\psi}_1^+(\mathbf{x})\hat{\psi}_1(\mathbf{x}).$$

Hence, in accordance with (20), one finds

$$\tilde{\hat{\rho}}_1(\mathbf{x}) = \tilde{\hat{\psi}}_1^+(\mathbf{x})\tilde{\hat{\psi}}_1(\mathbf{x}) = \hat{\chi}_1^+(\mathbf{x})\hat{\chi}_1(\mathbf{x}) + \hat{O}_1^+(\mathbf{x})\hat{\chi}_1(\mathbf{x}) + \hat{\chi}_1^+(\mathbf{x})\hat{O}_1(\mathbf{x}) + \hat{O}_1^+(\mathbf{x})\hat{O}_1(\mathbf{x}).$$

Note that the operators with zero matrix elements in the subspace $\tilde{H}_a$ appear on the right-hand side of (19) because of points $\mathbf{u}_1$ and $\mathbf{v}_1$ are close to each other. Since

$$\hat{O}_1^+(\mathbf{x})\hat{\chi}_1(\mathbf{x}) = \int d\mathbf{y}\ \hat{\varphi}^+(\mathbf{x},\mathbf{y})\hat{\chi}_2(\mathbf{y})\hat{\chi}_1(\mathbf{x}), \quad \hat{\chi}_1^+(\mathbf{x})\hat{O}_1(\mathbf{x}) = \int d\mathbf{y}\ \hat{\chi}_1^+(\mathbf{x})\hat{\chi}_2^+(\mathbf{y})\hat{\varphi}(\mathbf{x},\mathbf{y})$$

and $\hat{\varphi}(\mathbf{x},\mathbf{y})$ differs from zero only for $|\mathbf{x}-\mathbf{y}| \lesssim a$, these operators according to (12) do not have the matrix elements in the subspace $\tilde{H}_a$ and therefore can be omitted. Using the permutation relation $\{\hat{\chi}_2^+(\mathbf{z}_1), \hat{\chi}_2(\mathbf{z}_2)\} = \delta(\mathbf{z}_1-\mathbf{z}_2)$ the operator $\hat{O}_1^+(\mathbf{x})\hat{O}_1(\mathbf{x})$ is written as

$$\hat{O}_1^+(\mathbf{x})\hat{O}_1(\mathbf{x}) = \int d\mathbf{z}\ \hat{\varphi}^+(\mathbf{x},\mathbf{z})\hat{\varphi}(\mathbf{x},\mathbf{z}) + \int d\mathbf{z}_1\, d\mathbf{z}_2\ \hat{\varphi}^+(\mathbf{x},\mathbf{z}_2)\hat{\varphi}(\mathbf{x},\mathbf{z}_1)\hat{\chi}_2^+(\mathbf{z}_1)\hat{\chi}_2(\mathbf{z}_2).$$

The matrix element of the second term is zero in the subspace $\tilde{H}_a$ because of $\mathbf{z}_1 \approx \mathbf{z}_2 \approx \mathbf{x}$ [see (12)]. For this reason this term can be omitted. Thus, with the use of the method that was described in preceding section we have

$$\tilde{\hat{\rho}}_1(\mathbf{x}) = \hat{\chi}_1^+(\mathbf{x})\hat{\chi}_1(\mathbf{x}) + \int \mathrm{d}\mathbf{z}\ \hat{\varphi}^+(\mathbf{x},\mathbf{z})\hat{\varphi}(\mathbf{x},\mathbf{z}). \tag{22}$$

Similarly, if $\hat{\rho}_2(\mathbf{x}) = \hat{\psi}_2^+(\mathbf{x})\hat{\psi}_2(\mathbf{x})$ represents the density operator for particles of the second kind, then $\hat{\rho}_2(\mathbf{x}) \to \tilde{\hat{\rho}}_2(\mathbf{x})$, where

$$\tilde{\hat{\rho}}_2(\mathbf{x}) = \hat{\chi}_2^+(\mathbf{x})\hat{\chi}_2(\mathbf{x}) + \int \mathrm{d}\mathbf{z}\ \hat{\varphi}^+(\mathbf{z},\mathbf{x})\hat{\varphi}(\mathbf{z},\mathbf{x}). \tag{23}$$

Bearing in mind (16) and the assumption concerning the "small radius" of the bound state, one gets the following formulas:

$$\int \mathrm{d}\mathbf{z}\ \hat{\varphi}^+(\mathbf{x},\mathbf{z})\hat{\varphi}(\mathbf{x},\mathbf{z}) \approx \hat{\eta}_\alpha^+(\mathbf{x})\hat{\eta}_\alpha(\mathbf{x}), \quad \int \mathrm{d}\mathbf{z}\ \hat{\varphi}^+(\mathbf{z},\mathbf{x})\hat{\varphi}(\mathbf{z},\mathbf{x}) \approx \hat{\eta}_\alpha^+(\mathbf{x})\hat{\eta}_\alpha(\mathbf{x}),$$

which allow us to obtain the densities operators for particles of the first and second kinds,

$$\tilde{\hat{\rho}}_1(\mathbf{x}) = \hat{\chi}_1^+(\mathbf{x})\hat{\chi}_1(\mathbf{x}) + \hat{\eta}_\alpha^+(\mathbf{x})\hat{\eta}_\alpha(\mathbf{x}), \quad \tilde{\hat{\rho}}_2(\mathbf{x}) = \hat{\chi}_2^+(\mathbf{x})\hat{\chi}_2(\mathbf{x}) + \hat{\eta}_\alpha^+(\mathbf{x})\hat{\eta}_\alpha(\mathbf{x}). \tag{24}$$

Thus, the operators $\hat{\eta}_\alpha^+(\mathbf{x})$, $\hat{\eta}_\alpha(\mathbf{x})$ can be interpreted as the creation and annihilation operators of the bound states with quantum numbers α at the point $\mathbf{x}$, and $\hat{\eta}_\alpha^+(\mathbf{x})\hat{\eta}_\alpha(\mathbf{x})$ as the density operator of the bound states. For example, the first formula from (24) has a simple physical meaning: the density of particles of the first kind is equal to the sum of densities for free particles of the same kind and bound states (each bound state contains one particle of the first kind).

Consider a state vector $\Phi(\mathbf{X}) = \hat{\eta}_\alpha^+(\mathbf{X})|0\rangle$, which specifies a compound particle at the point $\mathbf{X}$ (this state vector corresponds to continuous spectrum). Then, in accordance with (24), we have

$$(\Phi(\mathbf{X}), \hat{\rho}_1(\mathbf{x}_1)\Phi(\mathbf{X}')) = \delta(\mathbf{X}-\mathbf{X}')\left(\frac{M}{m_2}\right)^3 \left|\varphi_\alpha\left(\frac{M}{m_2}(\mathbf{x}_1-\mathbf{X})\right)\right|^2.$$

For a wave packet

$$\Psi_{\mathbf{X}_0} = \int \mathrm{d}\mathbf{X}\ f_{\mathbf{X}_0}(\mathbf{X})\Phi(\mathbf{X}), \quad \int \mathrm{d}\mathbf{X}|f_{\mathbf{X}_0}(\mathbf{X})|^2 = 1$$

the quantity

$$(\Psi_{\mathbf{X}_0}, \hat{\rho}_1(\mathbf{x}_1)\Psi_{\mathbf{X}_0}) = \left(\frac{M}{m_2}\right)^3 \int \mathrm{d}\mathbf{X}|f_{\mathbf{X}_0}(\mathbf{X})|^2 \left|\varphi_\alpha\left(\frac{M}{m_2}(\mathbf{x}_1-\mathbf{X})\right)\right|^2$$

should be treated as the probability density to find the first particle at the point $\mathbf{x}_1$ if the atom is in a state $\Psi_{\mathbf{X}_0}$. If the bound state is localized near a point $\mathbf{X}_0$ (i.e., $|f\mathbf{x}_0(\mathbf{X})|^2 \to \delta(\mathbf{X}-\mathbf{X}_0)$), then

$$(\Psi_{\mathbf{X}_0}, \hat{\rho}_1(\mathbf{x}_1)\Psi_{\mathbf{X}_0}) \to \left(\frac{M}{m_2}\right)^3 \left|\varphi_\alpha\left(\frac{M}{m_2}(\mathbf{x}_1-\mathbf{X}_0)\right)\right|^2.$$

Since $(M/m_2)(\mathbf{x}_1-\mathbf{X}_0) = \mathbf{x} = \mathbf{x}_1-\mathbf{x}_2$, we come (as it should be) to the probability distribution for the space coordinate of the first particle in the atom (the atom is at the point $\mathbf{X}_0$).

Let us find now the momentum density operator in the space $\tilde{H}$. In original Hilbert space, the momentum density operator $\hat{\boldsymbol{\pi}}_1(\mathbf{x})$ for particles of the first kind is defined as

$$\hat{\boldsymbol{\pi}}_1(\mathbf{x}) = -\frac{i}{2}\left(\hat{\psi}_1^+(\mathbf{x})\frac{\partial\hat{\psi}_1(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\psi}_1^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\psi}_1(\mathbf{x})\right).$$

Then according to (20),

$$\hat{\boldsymbol{\pi}}_1(\mathbf{x}) \to \tilde{\hat{\pi}}_1(\mathbf{x}) = -\frac{i}{2}\left(\tilde{\hat{\psi}}_1^+(\mathbf{x})\frac{\partial\tilde{\hat{\psi}}_1(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\tilde{\hat{\psi}}_1^+(\mathbf{x})}{\partial\mathbf{x}}\tilde{\hat{\psi}}_1(\mathbf{x})\right).$$

Following the derivation of (22) and (23) for $\tilde{\hat{\rho}}_1(\mathbf{x})$ and $\tilde{\hat{\rho}}_2(\mathbf{x})$ we obtain

$$\tilde{\hat{\pi}}_1(\mathbf{x}) = -\frac{i}{2}\left(\hat{\chi}_1^+(\mathbf{x})\frac{\partial\hat{\chi}_1(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\chi}_1^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\chi}_1(\mathbf{x})\right) - \frac{i}{2}\int d\mathbf{y}\left(\hat{\varphi}^+(\mathbf{x},\mathbf{y})\frac{\partial\hat{\varphi}(\mathbf{x},\mathbf{y})}{\partial\mathbf{x}} - \frac{\partial\hat{\varphi}^+(\mathbf{x},\mathbf{y})}{\partial\mathbf{x}}\hat{\varphi}(\mathbf{x},\mathbf{y})\right), \tag{25}$$

$$\tilde{\hat{\pi}}_2(\mathbf{x}) = -\frac{i}{2}\left(\hat{\chi}_2^+(\mathbf{x})\frac{\partial\hat{\chi}_2(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\chi}_2^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\chi}_2(\mathbf{x})\right) - \frac{i}{2}\int d\mathbf{y}\left(\hat{\varphi}^+(\mathbf{y},\mathbf{x})\frac{\partial\hat{\varphi}(\mathbf{y},\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\varphi}^+(\mathbf{y},\mathbf{x})}{\partial\mathbf{x}}\hat{\varphi}(\mathbf{y},\mathbf{x})\right). \tag{26}$$

It is convenient for our further consideration to rewrite (25) and (26) in terms of the center of mass variables $\mathbf{y}=\mathbf{y}_1-\mathbf{y}_2$ and $\mathbf{Y}=(m_1\mathbf{y}_1+m_2\mathbf{y}_2)/(m_1+m_2)$,

$$\begin{aligned}\tilde{\hat{\boldsymbol{\pi}}}_1(\mathbf{x}) = &-\frac{i}{2}\left(\hat{\chi}_1^+(\mathbf{x})\frac{\partial\hat{\chi}_1(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\chi}_1^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\chi}_1(\mathbf{x})\right) - \frac{i}{2}\int d\mathbf{y}\, d\mathbf{Y}\ \delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)\left\{\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\frac{\partial\hat{\varphi}(\mathbf{y},\mathbf{Y})}{\partial\mathbf{y}}\right.\\ &\left.-\frac{\partial\hat{\varphi}^+(\mathbf{y},\mathbf{Y})}{\partial\mathbf{y}}\hat{\varphi}(\mathbf{y},\mathbf{Y}) + \frac{m_1}{M}\left(\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\frac{\partial\hat{\varphi}(\mathbf{y},\mathbf{Y})}{\partial\mathbf{Y}} - \frac{\partial\hat{\varphi}^+(\mathbf{y},\mathbf{Y})}{\partial\mathbf{Y}}\hat{\varphi}(\mathbf{y},\mathbf{Y})\right)\right\},\end{aligned}$$

$$\begin{aligned}\tilde{\hat{\boldsymbol{\pi}}}_2(\mathbf{x}) = &-\frac{i}{2}\left(\hat{\chi}_2^+(\mathbf{x})\frac{\partial\hat{\chi}_2(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\chi}_2^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\chi}_2(\mathbf{x})\right) - \frac{i}{2}\int d\mathbf{y}\, d\mathbf{Y}\ \delta\left(\mathbf{x}-\mathbf{Y}+\frac{m_1}{M}\mathbf{y}\right)\left\{-\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\frac{\partial\hat{\varphi}(\mathbf{y},\mathbf{Y})}{\partial\mathbf{y}}\right.\\ &\left.+\frac{\partial\hat{\varphi}^+(\mathbf{y},\mathbf{Y})}{\partial\mathbf{y}}\hat{\varphi}(\mathbf{y},\mathbf{Y}) + \frac{m_2}{M}\left(\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\frac{\partial\hat{\varphi}(\mathbf{y},\mathbf{Y})}{\partial\mathbf{Y}} - \frac{\partial\hat{\varphi}^+(\mathbf{y},\mathbf{Y})}{\partial\mathbf{Y}}\hat{\varphi}(\mathbf{y},\mathbf{Y})\right)\right\},\end{aligned} \tag{27}$$

where $\hat{\varphi}(\mathbf{y}_1,\mathbf{y}_2)\equiv\hat{\varphi}(\mathbf{y},\mathbf{Y})$. Note that in terms of these variables the operators $\tilde{\hat{\rho}}_1(\mathbf{x})$ and $\tilde{\hat{\rho}}_2(\mathbf{x})$ have the form

$$\begin{aligned}\tilde{\hat{\rho}}_1(\mathbf{x}) &= \hat{\chi}_1^+(\mathbf{x})\hat{\chi}_1(\mathbf{x}) + \int d\mathbf{y}\, d\mathbf{Y}\ \delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\hat{\varphi}(\mathbf{y},\mathbf{Y}),\\ \tilde{\hat{\rho}}_2(\mathbf{x}) &= \hat{\chi}_2^+(\mathbf{x})\hat{\chi}_2(\mathbf{x}) + \int d\mathbf{y}\, d\mathbf{Y}\ \delta\left(\mathbf{x}-\mathbf{Y}+\frac{m_1}{M}\mathbf{y}\right)\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\hat{\varphi}(\mathbf{y},\mathbf{Y}).\end{aligned} \tag{28}$$

It is clear that (27) and (28) can be expressed through the creation and annihilation operators $\hat{\eta}_\alpha^+(\mathbf{x})$, $\hat{\eta}_\alpha(\mathbf{x})$ of atoms if to employ (17). Taking into account (27) it is easy to find the operator $\tilde{\hat{\boldsymbol{\pi}}}=\tilde{\hat{\pi}}_1(\mathbf{x})+\tilde{\hat{\pi}}_2(\mathbf{x})$ of the total momentum density of the system in the approximation, where the radius of bound state is small,

$$\begin{aligned}\tilde{\hat{\boldsymbol{\pi}}} = &-\frac{i}{2}\left(\hat{\chi}_1^+(\mathbf{x})\frac{\partial\hat{\chi}_1(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\chi}_1^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\chi}_1(\mathbf{x})\right) - \frac{i}{2}\left(\hat{\chi}_2^+(\mathbf{x})\frac{\partial\hat{\chi}_2(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\chi}_2^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\chi}_2(\mathbf{x})\right)\\ &-\frac{i}{2}\left(\hat{\eta}_\alpha^+(\mathbf{x})\frac{\partial\hat{\eta}_\alpha(\mathbf{x})}{\partial\mathbf{x}} - \frac{\partial\hat{\eta}_\alpha^+(\mathbf{x})}{\partial\mathbf{x}}\hat{\eta}_\alpha(\mathbf{x})\right).\end{aligned}$$

The third term in this formula is in accordance with interpretation of $\hat{\eta}_\alpha^+(\mathbf{x})$, $\hat{\eta}_\alpha(\mathbf{x})$ as the creation and annihilation operators of the bound state with quantum numbers α at the point $\mathbf{x}$.

Finally let us consider a Hamiltonian in the space $\tilde{H}$. We suppose that this Hamiltonian has a standard form in the Hilbert space H and can be written as

$$\hat{\mathcal{H}} = \hat{\mathcal{H}}_0 + \hat{V},$$

where $\hat{\mathcal{H}}_0$ and $\hat{V}$ are the operators of kinetic energy and potential energy given by

$$\hat{\mathcal{H}}_0 = \sum_{i=1}^{2} \frac{1}{2m_i} \int \mathrm{d}\mathbf{x} \frac{\partial \hat{\psi}_i^+(\mathbf{x})}{\partial \mathbf{x}} \frac{\partial \hat{\psi}_i(\mathbf{x})}{\partial \mathbf{x}},$$

$$\hat{V} = \frac{1}{2} \sum_{i,j=1}^{2} \int \mathrm{d}\mathbf{x}\, \mathrm{d}\mathbf{x}'\ \hat{\psi}_i^+(\mathbf{x}) \hat{\psi}_j^+(\mathbf{x}') \nu_{ij}(\mathbf{x}-\mathbf{x}') \hat{\psi}_j(\mathbf{x}') \hat{\psi}_i(\mathbf{x}), \tag{29}$$

and $\nu_{ij}(\mathbf{x}-\mathbf{x}')$ is a potential energy of interaction for particles of the kinds i and j. After the similar calculations that led us to the expressions for $\tilde{\tilde{\rho}}$, $\tilde{\tilde{\boldsymbol{\pi}}}$, we obtain

$$\hat{\mathcal{H}}_0 \to \tilde{\tilde{\mathcal{H}}}_0 = \sum_{i=1}^{2} \frac{1}{2m_i} \left(\int \mathrm{d}\mathbf{x} \frac{\partial \hat{\chi}_i^+(\mathbf{x})}{\partial \mathbf{x}} \frac{\partial \hat{\chi}_i(\mathbf{x})}{\partial \mathbf{x}} + \int \mathrm{d}\mathbf{x}_1\, \mathrm{d}\mathbf{x}_2 \frac{\partial \hat{\varphi}^+(\mathbf{x}_1,\mathbf{x}_2)}{\partial \mathbf{x}_i} \frac{\partial \hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2)}{\partial \mathbf{x}_i} \right). \tag{30}$$

Next changing to the center of mass variables [see (17)] and noting that

$$\frac{\partial}{\partial \mathbf{x}_1} = \frac{\partial}{\partial \mathbf{x}} + \frac{m_1}{M} \frac{\partial}{\partial \mathbf{X}}, \quad \frac{\partial}{\partial \mathbf{x}_2} = -\frac{\partial}{\partial \mathbf{x}} + \frac{m_2}{M} \frac{\partial}{\partial \mathbf{X}},$$

one gets

$$\tilde{\tilde{\mathcal{H}}}_0 = \sum_{i=1}^{2} \frac{1}{2m_i} \int \mathrm{d}\mathbf{x} \frac{\partial \hat{\chi}_i^+(\mathbf{x})}{\partial \mathbf{x}} \frac{\partial \hat{\chi}_i(\mathbf{x})}{\partial \mathbf{x}} - \frac{1}{2\mu} \int \mathrm{d}\mathbf{x}\, \mathrm{d}\mathbf{X}\, \hat{\eta}_\alpha^+(\mathbf{X}) \hat{\eta}_\beta(\mathbf{X}) \frac{\partial \varphi_\alpha^*(\mathbf{x})}{\partial \mathbf{x}} \frac{\partial \varphi_\beta(\mathbf{x})}{\partial \mathbf{x}}$$
$$+ \frac{1}{2M} \int \mathrm{d}\mathbf{X} \frac{\partial \hat{\eta}_\alpha^+(\mathbf{X})}{\partial \mathbf{X}} \frac{\partial \hat{\eta}_\alpha(\mathbf{X})}{\partial \mathbf{X}}, \tag{31}$$

where $\mu = m_1 m_2/(m_1+m_2)$ is a reduced mass.

Let us find now $\tilde{\tilde{V}}$ ($\hat{V} \to \tilde{\tilde{V}}$). According to (20) we have

$$\tilde{\tilde{V}} = \frac{1}{2} \sum_{i,j=1}^{2} \int \mathrm{d}\mathbf{x}\, \mathrm{d}\mathbf{x}' \tilde{\tilde{\psi}}_i^+(\mathbf{x}) \tilde{\tilde{\psi}}_j^+(\mathbf{x}') \nu_{ij}(\mathbf{x}-\mathbf{x}') \tilde{\tilde{\psi}}_j(\mathbf{x}') \tilde{\tilde{\psi}}_i(\mathbf{x}),$$

where $\tilde{\tilde{\psi}}_i(\mathbf{x}) = \hat{\chi}_i(\mathbf{x}) + \hat{O}_i(\mathbf{x})$ [see (20)]. Thus, $\tilde{\tilde{V}}$ can be represented in the form

$$\tilde{\tilde{V}} = \tilde{\tilde{V}}_0 + \tilde{\tilde{V}}_1 + \tilde{\tilde{V}}_2 + \tilde{\tilde{V}}_3 + \tilde{\tilde{V}}_4,$$

where $\tilde{\tilde{V}}_k$ ($k=0,\ldots,4$) contains k multipliers of type $\hat{\chi}$ and $4-k$ multipliers of type $\hat{O}$. The operators $\hat{O}_i(\mathbf{x})$ have, according to (16) and (18), the form

$$\hat{O}_i(\mathbf{x}) = \int \mathrm{d}\mathbf{y}\ \hat{\varphi}_i(\mathbf{x},\mathbf{y}) \hat{\chi}_{i'}^+(\mathbf{y}),$$

$$\hat{\varphi}_1(\mathbf{x},\mathbf{y}) = \hat{\varphi}(\mathbf{x},\mathbf{y}), \quad \hat{\varphi}_2(\mathbf{x},\mathbf{y}) = \hat{\varphi}(\mathbf{y},\mathbf{x}), \tag{32}$$

where index i' is defined as $1'=2$, $2'=1$. Then $\tilde{\tilde{V}}_0$ is of the form

$$\tilde{\hat{V}}_0 = \frac{1}{2}\sum_{i,j=1}^{2} \int d\mathbf{x}_1\, d\mathbf{x}_2\, \nu_{ij}(\mathbf{x}_1 - \mathbf{x}_2)$$
$$\times \int d\mathbf{y}_1\, d\mathbf{y}_2\, d\mathbf{y}_3\, d\mathbf{y}_4\, \hat{\varphi}_i^+(\mathbf{x}_1,\mathbf{y}_1)\hat{\varphi}_j^+(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}_j(\mathbf{x}_2,\mathbf{y}_3)\hat{\varphi}_i(\mathbf{x}_1,\mathbf{y}_4)\hat{\chi}_{i'}(\mathbf{y}_1)\hat{\chi}_{j'}(\mathbf{y}_2)\hat{\chi}_{j'}^+(\mathbf{y}_3)\hat{\chi}_{i'}^+(\mathbf{y}_4). \tag{33}$$

Note that the operators $\hat{\varphi}$ and $\hat{\varphi}^+$ in (33) are normally ordered, whereas $\hat{\chi}$ and $\hat{\chi}^+$ are not normally ordered. Therefore, we put them in order using Wick's theorem,

$$\begin{aligned}
&\hat{\chi}_{i'}(\mathbf{y}_1)\hat{\chi}_{j'}(\mathbf{y}_2)\hat{\chi}_{j'}^+(\mathbf{y}_3)\hat{\chi}_{i'}^+(\mathbf{y}_4)\\
&\quad =: \hat{\chi}_{i'}(\mathbf{y}_1)\hat{\chi}_{j'}(\mathbf{y}_2)\hat{\chi}_{j'}^+(\mathbf{y}_3)\hat{\chi}_{i'}^+(\mathbf{y}_4): + :\overset{}{\underset{a}{\hat{\chi}_{i'}}}(\mathbf{y}_1)\hat{\chi}_{j'}(\mathbf{y}_2)\overset{}{\underset{a}{\hat{\chi}_{j'}^+}}(\mathbf{y}_3)\hat{\chi}_{i'}^+(\mathbf{y}_4):\\
&\qquad + :\overset{}{\underset{a}{\hat{\chi}_{i'}}}(\mathbf{y}_1)\hat{\chi}_{j'}(\mathbf{y}_2)\hat{\chi}_{j'}^+(\mathbf{y}_3)\overset{}{\underset{a}{\hat{\chi}_{i'}^+}}(\mathbf{y}_4): + :\hat{\chi}_{i'}(\mathbf{y}_1)\overset{}{\underset{a}{\hat{\chi}_{j'}}}(\mathbf{y}_2)\overset{}{\underset{a}{\hat{\chi}_{j'}^+}}(\mathbf{y}_3)\hat{\chi}_{i'}^+(\mathbf{y}_4):\\
&\qquad + :\hat{\chi}_{i'}(\mathbf{y}_1)\overset{}{\underset{a}{\hat{\chi}_{j'}}}(\mathbf{y}_2)\hat{\chi}_{j'}^+(\mathbf{y}_3)\overset{}{\underset{a}{\hat{\chi}_{i'}^+}}(\mathbf{y}_4): + :\overset{}{\underset{a}{\hat{\chi}_{i'}}}(\mathbf{y}_1)\overset{}{\underset{b}{\hat{\chi}_{j'}}}(\mathbf{y}_2)\overset{}{\underset{a}{\hat{\chi}_{j'}^+}}(\mathbf{y}_3)\overset{}{\underset{b}{\hat{\chi}_{i'}^+}}(\mathbf{y}_4):\\
&\qquad + :\overset{}{\underset{a}{\hat{\chi}_{i'}}}(\mathbf{y}_1)\overset{}{\underset{b}{\hat{\chi}_{j'}}}(\mathbf{y}_2)\overset{}{\underset{b}{\hat{\chi}_{j'}^+}}(\mathbf{y}_3)\overset{}{\underset{a}{\hat{\chi}_{i'}^+}}(\mathbf{y}_4): .
\end{aligned} \tag{34}$$

The operator $\hat{\varphi}(\mathbf{x},\mathbf{y}) \equiv \varphi_\alpha(\mathbf{x}-\mathbf{y})\,\hat{\eta}_\alpha[(m_1\mathbf{x}+m_2\mathbf{y})/(m_1+m_2)]$ differs from zero only for $\mathbf{x}\approx\mathbf{y}$ ($|\mathbf{x}-\mathbf{y}|<a$). Thus, only those of $\hat{\varphi}_i$, for which $|\mathbf{y}_1-\mathbf{y}_4|<a$ contribute to the integral over $\mathbf{y}$ in (33). This means that the first term in (34) in virtue of (12) does not contribute to the matrix element of $\tilde{\hat{V}}_0$ taken between the states belonging to $\tilde{H}_a$ because of $\hat{\varphi}_i(\mathbf{x}_1,\mathbf{y}_4)\hat{\chi}_i(\mathbf{y}_1)\Phi=0$. Similarly, one can prove that the terms, which contain the single contractions in (34) do not give a contribution to the matrix element of $\tilde{\hat{V}}_0$ taken between the states in $\tilde{H}_a$. The penultimate term in (34) containing the double contractions does not also contribute to the above-mentioned matrix element. Indeed, the penultimate term in (34) equals $\delta(\mathbf{y}_1-\mathbf{y}_3)\delta(\mathbf{y}_2-\mathbf{y}_4)$. In this case the nonzero matrix element exists for $\mathbf{x}_1\approx\mathbf{x}_2$ and $\hat{\varphi}_j(\mathbf{x}_2,\mathbf{y}_3)\hat{\varphi}_i(\mathbf{x}_1,\mathbf{y}_4)\Phi=0$ in virtue of (12). Thus, only the latter term in (34) equal to $\delta(\mathbf{y}_2-\mathbf{y}_3)\delta(\mathbf{y}_1-\mathbf{y}_4)$ can give the contribution to the matrix element of $\tilde{\hat{V}}_0$. Therefore, not changing the matrix elements in $\tilde{H}_a$, the operator $\tilde{\hat{V}}_0$ can be represented in the form

$$\tilde{\hat{V}}_0 = \frac{1}{2}\sum_{i,j=1}^{2} \int d\mathbf{x}_1\, d\mathbf{x}_2\, d\mathbf{y}_1\, d\mathbf{y}_2\, \hat{\varphi}_i^+(\mathbf{x}_1,\mathbf{y}_1)\hat{\varphi}_j^+(\mathbf{x}_2,\mathbf{y}_2)\nu_{ij}(\mathbf{x}_1-\mathbf{x}_2)\hat{\varphi}_j(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}_i(\mathbf{x}_1,\mathbf{y}_1),$$

or, according to (32),

$$\tilde{\hat{V}}_0 = \frac{1}{2}\int d\mathbf{x}_1\, d\mathbf{x}_2\, d\mathbf{y}_1\, d\mathbf{y}_2\, \hat{\varphi}^+(\mathbf{x}_1,\mathbf{y}_1)\hat{\varphi}^+(\mathbf{x}_2,\mathbf{y}_2)$$
$$\times\{\nu_{11}(\mathbf{x}_1-\mathbf{x}_2)+\nu_{22}(\mathbf{y}_1-\mathbf{y}_2)+\nu_{12}(\mathbf{x}_1-\mathbf{y}_2)+\nu_{21}(\mathbf{y}_1-\mathbf{x}_2)\}\hat{\varphi}(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}(\mathbf{x}_1,\mathbf{y}_1).$$

Similarly, noting that

$$\tilde{\hat{V}}_1 = \frac{1}{2}\sum_{i,j=1}^{2} \int d\mathbf{x}_1\, d\mathbf{x}_2\, d\mathbf{y}\ \nu_{ij}(\mathbf{x}_1-\mathbf{x}_2)\{\hat{\varphi}_i^+(\mathbf{x}_1,\mathbf{y})\hat{\chi}_{i'}(\mathbf{y})\hat{\chi}_j^+(\mathbf{x}_2)\hat{\chi}_j(\mathbf{x}_2)\hat{\chi}_i(\mathbf{x}_1)$$
$$+\hat{\varphi}_j^+(\mathbf{x}_2,\mathbf{y})\hat{\chi}_i(\mathbf{x}_1)\hat{\chi}_{j'}^+(\mathbf{y})\hat{\chi}_j(\mathbf{x}_2)\hat{\chi}_i(\mathbf{x}_1)+\text{H.c.}\},$$

$$\tilde{\tilde{V}}_3 = \frac{1}{2}\sum_{i,j=1}^{2}\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\,\mathrm{d}\mathbf{y}_1\,\mathrm{d}\mathbf{y}_2\,\mathrm{d}\mathbf{y}_3\;\nu_{ij}(\mathbf{x}_1-\mathbf{x}_2)$$
$$\times\{\hat{\varphi}_i^+(\mathbf{x}_1,\mathbf{y}_1)\hat{\varphi}_j^+(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}_j(\mathbf{x}_2,\mathbf{y}_3)\hat{\chi}_{i'}(\mathbf{y}_1)\hat{\chi}_{j'}(\mathbf{y}_2)\hat{\chi}_{j'}^+(\mathbf{y}_3)\hat{\chi}_i(\mathbf{x}_1)$$
$$+\,\hat{\varphi}_i^+(\mathbf{x}_1,\mathbf{y}_1)\hat{\varphi}_j^+(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}_i(\mathbf{x}_1,\mathbf{y}_3)\hat{\chi}_{i'}(\mathbf{y}_1)\hat{\chi}_{j'}(\mathbf{y}_2)\hat{\chi}_j(\mathbf{x}_2)\hat{\chi}_{i'}^+(\mathbf{y}_3)+\mathrm{H.c.}\}$$

and performing the same derivation as for $\tilde{\tilde{V}}_0$, it is easy to verify [using the anticommutative relations for $\hat{\chi}$, $\hat{\chi}^+$ and (34)] that we can consider $\tilde{\tilde{V}}_1=\tilde{\tilde{V}}_3=0$ not changing the matrix elements of $\tilde{\tilde{V}}_1$ and $\tilde{\tilde{V}}_3$ in the subspace $\tilde{H}_a$. Next it is evident that the following formula is valid:

$$\tilde{\tilde{V}}_4 = \frac{1}{2}\sum_{i,j=1}^{2}\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\;\hat{\chi}_i^+(\mathbf{x}_1)\hat{\chi}_j^+(\mathbf{x}_2)\nu_{ij}(\mathbf{x}_1-\mathbf{x}_2)\hat{\chi}_j(\mathbf{x}_2)\hat{\chi}_i(\mathbf{x}_1). \tag{35}$$

Finally let us find $\tilde{\tilde{V}}_2$,

$$\tilde{\tilde{V}}_2 = \frac{1}{2}\sum_{i,j=1}^{2}\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\;\nu_{ij}(\mathbf{x}_1-\mathbf{x}_2)\{\hat{O}_i^+(\mathbf{x}_1)\hat{O}_j^+(\mathbf{x}_2)\hat{\chi}_j(\mathbf{x}_2)\hat{\chi}_i(\mathbf{x}_1)+\hat{O}_i^+(\mathbf{x}_1)\hat{\chi}_j^+(\mathbf{x}_2)\hat{O}_j(\mathbf{x}_2)\hat{\chi}_i(\mathbf{x}_1)+\mathrm{h.c.}$$
$$+\,\hat{O}_i^+(\mathbf{x}_1)\hat{\chi}_j^+(\mathbf{x}_2)\hat{\chi}_j(\mathbf{x}_2)\hat{O}_i(\mathbf{x}_1)+\hat{\chi}_i^+(\mathbf{x}_1)\hat{O}_j^+(\mathbf{x}_2)\hat{O}_j(\mathbf{x}_2)\hat{\chi}_i(\mathbf{x}_1)\}.$$

It can be easily seen that the first two terms and the corresponding Hermitian conjugate terms do not give a contribution to the matrix element of $\tilde{\tilde{V}}_2$ in the subspace $\tilde{H}_a$. Therefore, we can consider

$$\tilde{\tilde{V}}_2 = \frac{1}{2}\sum_{i,j=1}^{2}\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\,\mathrm{d}\mathbf{y}_1\,\mathrm{d}\mathbf{y}_2\;\nu_{ij}(\mathbf{x}_1-\mathbf{x}_2)\{\hat{\varphi}_i^+(\mathbf{x}_1,\mathbf{y}_1)\hat{\varphi}_i(\mathbf{x}_1,\mathbf{y}_2)\hat{\chi}_{i'}(\mathbf{y}_1)\hat{\chi}_j^+(\mathbf{x}_2)\hat{\chi}_j(\mathbf{x}_2)\hat{\chi}_{i'}^+(\mathbf{y}_2)$$
$$+\,\hat{\varphi}_j^+(\mathbf{x}_2,\mathbf{y}_1)\hat{\varphi}_j(\mathbf{x}_2,\mathbf{y}_2)\hat{\chi}_i^+(\mathbf{x}_1)\hat{\chi}_{j'}(\mathbf{y}_1)\hat{\chi}_{j'}^+(\mathbf{y}_2)\hat{\chi}_i(\mathbf{x}_1)\}.$$

The first and second terms in this expression contribute to the matrix element of $\tilde{\tilde{V}}_2$ in $\tilde{H}_a$ under the following arrangements of contractions:

$$:\overset{a}{\hat{\chi}_{i'}}(\mathbf{y}_1)\overset{a}{\hat{\chi}_j^+}(\mathbf{x}_2)\overset{b}{\hat{\chi}_j}(\mathbf{x}_2)\overset{b}{\hat{\chi}_{i'}^+}(\mathbf{y}_2):+:\overset{a}{\hat{\chi}_{i'}}(\mathbf{y}_1)\hat{\chi}_j^+(\mathbf{x}_2)\hat{\chi}_j(\mathbf{x}_2)\overset{a}{\hat{\chi}_{i'}^+}(\mathbf{y}_2):$$
$$=\delta_{ji'}\delta(\mathbf{y}_1-\mathbf{x}_2)\delta(\mathbf{y}_2-\mathbf{x}_2)+\delta(\mathbf{y}_1-\mathbf{y}_2)\hat{\chi}_j^+(\mathbf{x}_2)\hat{\chi}_j(\mathbf{x}_2),$$

$$:\hat{\chi}_i^+(\mathbf{x}_1)\overset{a}{\hat{\chi}_{j'}}(\mathbf{y}_1)\overset{a}{\hat{\chi}_{j'}^+}(\mathbf{y}_2)\hat{\chi}_i(\mathbf{x}_1):=\delta(\mathbf{y}_1-\mathbf{y}_2)\hat{\chi}_i^+(\mathbf{x}_1)\hat{\chi}_i(\mathbf{x}_1).$$

Thus, we have

$$\tilde{\tilde{V}}_2 = \int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\;\nu_{12}(\mathbf{x}_1-\mathbf{x}_2)\hat{\varphi}^+(\mathbf{x}_1,\mathbf{x}_2)\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2)+\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\;\hat{\varphi}^+(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}(\mathbf{x}_2,\mathbf{y}_2)\{\nu_{11}(\mathbf{x}_1$$
$$-\mathbf{x}_2)\hat{\chi}_1^+(\mathbf{x}_1)\hat{\chi}_1(\mathbf{x}_1)+\nu_{21}(\mathbf{x}_1-\mathbf{y}_2)\hat{\chi}_1^+(\mathbf{x}_1)\hat{\chi}_1(\mathbf{x}_1)+\nu_{22}(\mathbf{x}_1-\mathbf{y}_2)\hat{\chi}_2^+(\mathbf{x}_1)\hat{\chi}_2(\mathbf{x}_1)+\nu_{12}(\mathbf{x}_1$$
$$-\mathbf{x}_2)\hat{\chi}_2^+(\mathbf{x}_1)\hat{\chi}_2(\mathbf{x}_1)\}. \tag{36}$$

The first term in this formula quadratic in field operators can be combined with the latter term in (31). As a result we obtain

$$\int d\mathbf{x}_1\, d\mathbf{x}_2\, \nu_{12}(\mathbf{x}_1-\mathbf{x}_2)\hat{\varphi}^+(\mathbf{x}_1,\mathbf{x}_2)\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2) - \frac{1}{2\mu}\int d\mathbf{x}\, d\mathbf{X}\ \hat{\eta}^+_\alpha(\mathbf{X})\hat{\eta}_\alpha(\mathbf{X})\frac{\partial\varphi^*_\alpha(\mathbf{x})}{\partial\mathbf{x}}\frac{\partial\varphi_\alpha(\mathbf{x})}{\partial\mathbf{x}}$$
$$= \int d\mathbf{x}\, d\mathbf{X}\ \hat{\eta}^+_\alpha(\mathbf{X})\hat{\eta}_\beta(\mathbf{X})\varphi^*_\alpha(\mathbf{x})\left\{-\frac{1}{2\mu}\Delta_{\mathbf{x}} + \nu_{12}(\mathbf{x})\right\}\varphi_\beta(\mathbf{x}).$$

Since $\varphi_\beta(\mathbf{x})$ satisfies the Schrödinger equation

$$\left\{-\frac{1}{2\mu}\Delta_{\mathbf{x}} + \nu_{12}(\mathbf{x})\right\}\varphi_\beta(\mathbf{x}) = \varepsilon_\beta\varphi_\beta(\mathbf{x}),$$

where ε_β are the atomic energy levels, the latter formula takes the form

$$\int d\mathbf{X}\sum_\alpha \varepsilon_\alpha\hat{\eta}^+_\alpha(\mathbf{X})\hat{\eta}_\alpha(\mathbf{X}).$$

Hence, taking into account (30), (31), and (36), the Hamiltonian of the system $\tilde{\tilde{\mathcal{H}}}$ is of the form

$$\tilde{\tilde{\mathcal{H}}} = \tilde{\tilde{\mathcal{H}}}_0 + \tilde{\tilde{\mathcal{H}}}^1_{\text{int}} + \tilde{\tilde{\mathcal{H}}}^2_{\text{int}} + \tilde{\tilde{\mathcal{H}}}^3_{\text{int}},$$

where

$$\tilde{\tilde{\mathcal{H}}}_0 = \sum_{j=1}^{2}\frac{1}{2m_j}\int d\mathbf{x}\frac{\partial\hat{\chi}^+_j(\mathbf{x})}{\partial\mathbf{x}}\frac{\partial\hat{\chi}_j(\mathbf{x})}{\partial\mathbf{x}} + \sum_\alpha\int d\mathbf{X}\left\{\frac{1}{2M}\frac{\partial\hat{\eta}^+_\alpha(\mathbf{X})}{\partial\mathbf{X}}\frac{\partial\hat{\eta}_\alpha(\mathbf{X})}{\partial\mathbf{X}} + \varepsilon_\alpha\hat{\eta}^+_\alpha(\mathbf{X})\hat{\eta}_\alpha(\mathbf{X})\right\} \tag{37}$$

is the Hamiltonian for free particles and bound states, and

$$\tilde{\tilde{\mathcal{H}}}^1_{\text{int}} = \int d\mathbf{x}_1\, d\mathbf{x}_2\, d\mathbf{y}_2\ \hat{\varphi}^+(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}(\mathbf{x}_2,\mathbf{y}_2)\{(\nu_{11}(\mathbf{x}_1-\mathbf{x}_2)+\nu_{21}(\mathbf{x}_1-\mathbf{y}_2))\hat{\chi}^+_1(\mathbf{x}_1)\hat{\chi}_1(\mathbf{x}_1) + (\nu_{22}(\mathbf{x}_1-\mathbf{y}_2)$$
$$+\nu_{12}(\mathbf{x}_1-\mathbf{x}_2))\hat{\chi}^+_2(\mathbf{x}_1)\hat{\chi}_2(\mathbf{x}_1)\}, \tag{38}$$

$$\tilde{\tilde{\mathcal{H}}}^2_{\text{int}} = \frac{1}{2}\int d\mathbf{x}_1\, d\mathbf{x}_2\, d\mathbf{y}_1\, d\mathbf{y}_2\ \hat{\varphi}^+(\mathbf{x}_1,\mathbf{y}_1)\hat{\varphi}^+(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}(\mathbf{x}_2,\mathbf{y}_2)\hat{\varphi}(\mathbf{x}_1,\mathbf{y}_1)\{\nu_{11}(\mathbf{x}_1-\mathbf{x}_2)+\nu_{22}(\mathbf{y}_1-\mathbf{y}_2)$$
$$+\nu_{12}(\mathbf{x}_1-\mathbf{y}_2)+\nu_{21}(\mathbf{y}_1-\mathbf{x}_2)\}, \tag{39}$$

$$\tilde{\tilde{\mathcal{H}}}^3_{\text{int}} = \frac{1}{2}\int d\mathbf{x}_1\, d\mathbf{x}_2\{\nu_{11}(\mathbf{x}_1-\mathbf{x}_2)\hat{\chi}^+_1(\mathbf{x}_1)\hat{\chi}^+_1(\mathbf{x}_2)\hat{\chi}_1(\mathbf{x}_2)\hat{\chi}_1(\mathbf{x}_1) + \nu_{22}(\mathbf{x}_1-\mathbf{x}_2)\hat{\chi}^+_2(\mathbf{x}_1)\hat{\chi}^+_2(\mathbf{x}_2)\hat{\chi}_2(\mathbf{x}_2)\hat{\chi}_2(\mathbf{x}_1)$$
$$+2\nu_{12}(\mathbf{x}_1-\mathbf{x}_2)\hat{\chi}^+_1(\mathbf{x}_1)\hat{\chi}_1(\mathbf{x}_1)\hat{\chi}^+_2(\mathbf{x}_2)\hat{\chi}_2(\mathbf{x}_2)\} \tag{40}$$

are the Hamiltonians of interaction. The Hamiltonian $\tilde{\tilde{\mathcal{H}}}^1_{\text{int}}$ corresponds to scattering of particles of the first and second kinds by bound states; the Hamiltonian $\tilde{\tilde{\mathcal{H}}}^2_{\text{int}}$ corresponds to scattering of bound states by bound states; finally, the Hamiltonian $\tilde{\tilde{\mathcal{H}}}^3_{\text{int}}$ corresponds to scattering of particles of the first and second kinds by particles of the same kinds. The Hamiltonians of interaction (38) and (39) may be written through the creation $\hat{\eta}^+_\alpha(\mathbf{x})$ and annihilation $\hat{\eta}_\alpha(\mathbf{x})$ operators of atoms by using (17). We emphasize that the obtained Hamiltonians of interaction do not lead to decay processes and formation of compound particles as it should be in the low-energy approximation. This fact reflects that atoms are absolutely stable in the main approximation.

In conclusion of this section we address to the Galilean invariance of the developed theory. We suppose that the initial theory based only on the field operators $\hat{\psi}_i(\mathbf{x}), \hat{\psi}_i^+(\mathbf{x})$ $(i=1,2)$ is Galilean invariant. This means that under the following transformations:

$$\hat{\psi}_i(\mathbf{x}) \to \hat{\psi}_i'(\mathbf{x}) = e^{im_i\mathbf{v}\mathbf{x}}\hat{\psi}_i(\mathbf{x})$$

the operators for particles number $\hat{N}_i$, momentum $\hat{\mathcal{P}}_k$, and energy $\hat{\mathcal{H}}$ transform as follows:

$$\hat{N}_i \to \hat{N}_i' = \hat{N}_i, \quad i = 1,2,$$

$$\hat{\mathcal{P}}_k \to \hat{\mathcal{P}}_k' = \hat{\mathcal{P}}_k + v_k(\hat{N}_1 + \hat{N}_2), \quad \hat{\mathcal{H}} \to \hat{\mathcal{H}}' = \hat{\mathcal{H}} + v_k\hat{\mathcal{P}}_k + \tfrac{1}{2}m_1v^2\hat{N}_1 + \tfrac{1}{2}m_2\hat{N}_2v^2.$$

Since $\hat{\psi}_i(\mathbf{x})$ and $\hat{\psi}_i'(\mathbf{x})$ meet the same commutation relations, they are related to each other by the unitary transformation

$$\hat{\psi}_i'(\mathbf{x}) = U_v\hat{\psi}_i(\mathbf{x})U_v^+,$$

where the unitary operator U_v, is defined by[9]

$$U_v = \exp\left(-i\mathbf{v}m_1\int \mathrm{d}\mathbf{x}\,\mathbf{x}\hat{\rho}_1(\mathbf{x}) - i\mathbf{v}m_2\int \mathrm{d}\mathbf{x}\,\mathbf{x}\hat{\rho}_2(\mathbf{x})\right). \tag{41}$$

Let us show that

$$\widetilde{U}_v = \exp\left(-i\mathbf{v}m_1\int \mathrm{d}\mathbf{x}\,\mathbf{x}\widetilde{\hat{\rho}}_1(\mathbf{x}) - i\mathbf{v}m_2\int \mathrm{d}\mathbf{x}\,\mathbf{x}\widetilde{\hat{\rho}}_2(\mathbf{x})\right)$$

defines the Galilei transformations in the presence of bound states of particles [compare to (41)]. To this end we note that this operator can be written, according to (28), in the form

$$\widetilde{U}_v = \exp\left(-i\mathbf{v}\sum_{i=1}^{2} m_i\int \mathrm{d}\mathbf{x}\,\hat{\chi}_i^+(\mathbf{x})\hat{\chi}_i(\mathbf{x}) - i\mathbf{v}\hat{\mathbf{s}}\right),$$

where

$$\hat{\mathbf{s}} = m_1\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\,\mathbf{x}_1\hat{\varphi}^+(\mathbf{x}_1,\mathbf{x}_2)\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2) + m_2\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\,\mathbf{x}_1\hat{\varphi}^+(\mathbf{x}_2,\mathbf{x}_1)\hat{\varphi}(\mathbf{x}_2,\mathbf{x}_1)$$

$$= \int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2(m_1\mathbf{x}_1 + m_2\mathbf{x}_2)\hat{\varphi}^+(\mathbf{x}_1,\mathbf{x}_2)\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2).$$

Since

$$\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2) = \varphi_\alpha(\mathbf{x})\,\hat{\eta}_\alpha(\mathbf{X}), \quad \int \mathrm{d}\mathbf{x}\,\varphi_\alpha^*(\mathbf{x})\varphi_\beta(\mathbf{x}) = \delta_{\alpha\beta},$$

changing to the center of mass variables one finds

$$\hat{\mathbf{s}} = (m_1 + m_2)\int \mathrm{d}\mathbf{X}\,\mathbf{X}\sum_\alpha \hat{\eta}_\alpha^+(\mathbf{X})\,\hat{\eta}_\alpha(\mathbf{X}).$$

Therefore, just as we expected

$$\tilde{U}_v = \exp\left(- i\mathbf{v}\sum_{i=1}^{2} m_i \int \mathrm{d}\mathbf{x}\, \hat{\chi}_i^+(\mathbf{x})\hat{\chi}_i(\mathbf{x}) - i\mathbf{v}(m_1+m_2)\int \mathrm{d}\mathbf{X}\, \mathbf{X}\sum_{\alpha} \hat{\eta}_\alpha^+(\mathbf{X})\hat{\eta}_\alpha(\mathbf{X})\right).$$

The employment of this formula and the canonic permutation relations result in

$$\tilde{U}_v\hat{\chi}_i(\mathbf{x})\tilde{U}_v^+ = e^{im_i\mathbf{v}\mathbf{x}}\hat{\chi}_i(\mathbf{x}) \equiv \hat{\chi}_i'(\mathbf{x}),\ \ \tilde{U}_v\hat{\eta}_\alpha(\mathbf{X})\tilde{U}_v^+ = e^{i(m_1+m_2)\mathbf{v}\mathbf{X}}\hat{\eta}_\alpha(\mathbf{X}) \equiv \hat{\eta}_\alpha'(\mathbf{X}). \tag{42}$$

Since the quantity $\hat{\varphi}^+(\mathbf{x},\mathbf{X})\hat{\varphi}(\mathbf{x},\mathbf{X})$ is not changed under such transformation, the Hamiltonians of interaction $\tilde{\hat{\mathcal{H}}}_{\mathrm{int}}^1$, $\tilde{\hat{\mathcal{H}}}_{\mathrm{int}}^2$, $\tilde{\hat{\mathcal{H}}}_{\mathrm{int}}^3$ [see (38)–(40)] are invariant with respect to (42). It is easy to verify that the Hamiltonian $\tilde{\hat{\mathcal{H}}}_0$ for free particles and bound states transforms according to the law

$$\tilde{U}_v\tilde{\hat{\mathcal{H}}}_0\tilde{U}_v^+ = \tilde{\hat{H}}_0 + \mathbf{v}\tilde{\hat{\boldsymbol{\mathcal{P}}}} + \frac{m_1v^2}{2}\tilde{\hat{N}}_1 + \frac{m_2v^2}{2}\tilde{\hat{N}}_2 + \frac{(m_1+m_2)v^2}{2}\tilde{\hat{N}}_b.$$

Hence,

$$\tilde{U}_v\tilde{\hat{\mathcal{H}}}\tilde{U}_v^+ = \tilde{\hat{\mathcal{H}}} + \mathbf{v}\tilde{\hat{\boldsymbol{\mathcal{P}}}} + \frac{m_1v^2}{2}\tilde{\hat{N}}_1 + \frac{m_2v^2}{2}\tilde{\hat{N}}_2 + \frac{(m_1+m_2)v^2}{2}\tilde{\hat{N}}_b,$$

$$\tilde{U}_v\tilde{\hat{\boldsymbol{\mathcal{P}}}}\tilde{U}_v^+ = \tilde{\hat{\boldsymbol{\mathcal{P}}}} + m_1\mathbf{v}\tilde{\hat{N}}_1 + m_2\mathbf{v}\tilde{\hat{N}}_2 + (m_1+m_2)\mathbf{v}\tilde{\hat{N}}_b,$$

where $\tilde{\hat{\boldsymbol{\mathcal{P}}}}$, $\tilde{\hat{N}}_1$, $\tilde{\hat{N}}_2$, $\tilde{\hat{N}}_b$ are the momentum operator and the particle number operators (for free particles of the first and second kinds and their bound states). These formulas prove the Galilean invariance of the developed theory. Finally we note the validity of the following formula:

$$\tilde{U}_v\tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x})\tilde{U}_v^+ = \tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x}) + m_i\mathbf{v}\tilde{\hat{\rho}}_i(\mathbf{x}),$$

which follows from (27) and (28) by using (42).

V. ELECTROMAGNETIC INTERACTION

Here we consider the electromagnetic interaction assuming that the formation of bound states of particles is caused by Coulomb's (electromagnetic) forces. Therefore, the potential energy $\nu_{ij}(\mathbf{x}-\mathbf{x}')$ entering (38)–(40) should be written as

$$\nu_{ij}(\mathbf{x}-\mathbf{x}') = \frac{e_ie_j}{|\mathbf{x}-\mathbf{x}'|}, \quad i,j = 1,2. \tag{43}$$

We also introduce the additional interactions of particles (see below) with an external electromagnetic field $\mathbf{A}^{(e)}(\mathbf{x},t)$, $\varphi^{(e)}(\mathbf{x},t)$ and quantized electromagnetic field specified by a potential $\hat{\mathbf{a}}(\mathbf{x})$ (Coulomb's gauge)

$$\hat{\mathbf{A}}(\mathbf{x},t) = \hat{\mathbf{a}}(\mathbf{x}) + \mathbf{A}^{(e)}(\mathbf{x},t),$$

where[9]

$$\hat{\mathbf{a}}(\mathbf{x}) = \sum_{\mathbf{k}}\sum_{\lambda=1}^{2}\left(\frac{2\pi}{\mathcal{V}\omega_k}\right)^{1/2}(\mathbf{e}_{\mathbf{k}\lambda}\hat{C}_{\mathbf{k}\lambda}e^{i\mathbf{k}\mathbf{x}} + \mathrm{H.c.})$$

($\hat{C}_{\mathbf{k}\lambda}$ is the annihilation operator of a photon with momentum k and polarization $\mathbf{e}_{\mathbf{k}\lambda}$). As in Sec. II, we identify the subspace $\tilde{H}_a$ to $\tilde{H}$ assuming that the matrix elements of the operators in coordinate representation give the main contribution to the quantum electrodynamics processes and correspond to the space scale $\Delta x \gtrsim a$ ($a \to 0$, $a \gg r_0$).

The density $\hat{\varepsilon}(\mathbf{x})$ of a Hamiltonian in the second quantization representation has the well-known form

$$\hat{\varepsilon}(\mathbf{x}) = \hat{\varepsilon}_f(\mathbf{x}) + \hat{\varepsilon}_C(\mathbf{x}) + \sum_{i=1}^{2} e_i \hat{\psi}_i^+(\mathbf{x})\hat{\psi}_i(\mathbf{x})\varphi^{(e)}(\mathbf{x},t)$$
$$+ \sum_{i=1}^{2} \frac{1}{2m_i}\left(\frac{\partial}{\partial \mathbf{x}} - ie_i\hat{\mathbf{A}}(\mathbf{x},t)\right)\hat{\psi}_i^+(\mathbf{x})\left(\frac{\partial}{\partial \mathbf{x}} + ie_i\hat{\mathbf{A}}(\mathbf{x},t)\right)\hat{\psi}_i(\mathbf{x}),$$

where $\hat{\varepsilon}_f(\mathbf{x})$ is the energy density of a free electromagnetic field, $\hat{\varepsilon}_C(\mathbf{x})$ is the energy density of Coulomb's interaction, the third term describes the interaction between the particles and external scalar potential. This formula leads to the following Hamiltonian of the system:

$$\hat{\mathcal{H}}(t) = \hat{\mathcal{H}}_0 + \hat{\mathcal{H}}_{\text{int}} + \hat{V}(t), \quad \hat{\mathcal{H}}_0 = \hat{\mathcal{H}}_f + \hat{\mathcal{H}}_p, \tag{44}$$

where

$$\hat{\mathcal{H}}_f \equiv \int \mathrm{d}\mathbf{x}\, \hat{\varepsilon}_f(\mathbf{x}) = \sum_{\mathbf{k},\lambda} \omega_k \hat{C}^+_{\mathbf{k}\lambda}\hat{C}_{\mathbf{k}\lambda}, \tag{45}$$

$$\hat{\mathcal{H}}_p = \sum_{i=1}^{2} \frac{1}{2m_i} \int \mathrm{d}\mathbf{x} \frac{\partial \hat{\psi}_i^+(\mathbf{x})}{\partial \mathbf{x}} \frac{\partial \hat{\psi}_i(\mathbf{x})}{\partial \mathbf{x}}, \tag{46}$$

$$\hat{\mathcal{H}}_{\text{int}} = \int \mathrm{d}\mathbf{x}\, \hat{\varepsilon}_C(\mathbf{x}) \tag{47}$$

are the Hamiltonians for free photons, free particles, and Coulomb's interaction, respectively. The operator $\hat{V}(t)$ represents a Hamiltonian that describes the interaction of particles with the electromagnetic fields $\hat{\mathbf{A}}(\mathbf{x},t)$, $\varphi^{(e)}(\mathbf{x},t)$

$$\hat{V}(t) = -\int \mathrm{d}\mathbf{x}\, \hat{\mathbf{A}}(\mathbf{x},t)\hat{\mathbf{J}}(\mathbf{x},t) - \frac{1}{2}\int \mathrm{d}\mathbf{x}\, \hat{\mathbf{A}}^2(\mathbf{x},t)\sum_{i=1}^{2}\frac{e_i}{m_i}\hat{\sigma}_i(\mathbf{x}) + \int \mathrm{d}\mathbf{x}\, \varphi^{(e)}(\mathbf{x},t)\hat{\sigma}, \tag{48}$$

$$\hat{\mathbf{J}}(\mathbf{x},t) = -\hat{\mathbf{A}}(\mathbf{x},t)\sum_{i=1}^{2}\frac{e_i}{m_i}\hat{\sigma}_i(\mathbf{x}) + \hat{\mathbf{j}}_0(\mathbf{x}), \quad \hat{\mathbf{j}}_0(\mathbf{x}) = \sum_{i=1}^{2}\frac{e_i}{m_i}\hat{\boldsymbol{\pi}}_i(\mathbf{x}), \tag{49}$$

where $\hat{\sigma}_i(x) = e_i\hat{\rho}_i(x)$ is the charge density for particles of the kind i, $\hat{\sigma} = \hat{\sigma}_1 + \hat{\sigma}_2$. This Hamiltonian is exact and describes (in this sense) the processes in which the bound states of particles are involved. Since $\hat{\mathbf{a}}(\mathbf{x})$ commute among themselves and with $\hat{\psi}_i(\mathbf{x})$, $\hat{\psi}_i^+(\mathbf{x})$, in order to find the effective Hamiltonian $\tilde{\hat{\mathcal{H}}}(t)$ that describes electrodynamic processes at low energies in the presence of bound states of particles we need, in accordance with Sec. IV, to replace the operators $\hat{\psi}_i$, $\hat{\psi}_i^+$, $\hat{\mathbf{a}}$ by $\tilde{\hat{\psi}}_i$, $\tilde{\hat{\psi}}_i^+$, $\tilde{\hat{\mathbf{a}}}$:

$$\tilde{\hat{\mathcal{H}}}(t) = \hat{\mathcal{H}}(t)|_{\hat{\psi}_1 \to \tilde{\hat{\psi}}_1, \hat{\psi}_2 \to \tilde{\hat{\psi}}_2, \hat{\mathbf{a}} \to \tilde{\hat{\mathbf{a}}}},$$

where

$$\tilde{\hat{\psi}}_1(\mathbf{x}) = \hat{\chi}_1(\mathbf{x}) + \int d\mathbf{y}\ \hat{\varphi}(\mathbf{x},\mathbf{y})\hat{\chi}_2^+(\mathbf{y}),\ \ \tilde{\hat{\psi}}_2(\mathbf{x}) = \hat{\chi}_2(\mathbf{x}) + \int d\mathbf{y}\ \hat{\varphi}(\mathbf{y},\mathbf{x})\hat{\chi}_1^+(\mathbf{y}),\ \ \tilde{\hat{\mathbf{a}}} = \hat{\mathbf{a}}$$

[$\tilde{\hat{\mathbf{a}}}(\mathbf{x})$ coincides with $\hat{\mathbf{a}}(\mathbf{x})$ and acts in the space $\tilde{H}$]. As a result the effective Hamiltonian is defined by (44)–(49), in which

$$\hat{\sigma}_i(\mathbf{x}) \to \tilde{\hat{\sigma}}_i(\mathbf{x}) = e_i\tilde{\hat{\rho}}_i(\mathbf{x}),\ \ \hat{\boldsymbol{\pi}}_i(\mathbf{x}) \to \tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x}),\ \ \hat{\psi}_i(\mathbf{x}) \to \tilde{\hat{\psi}}_i(\mathbf{x}), \tag{50}$$

moreover, the operators $\tilde{\hat{\rho}}_i(\mathbf{x})$, $\tilde{\hat{\pi}}_i(\mathbf{x})$, $\tilde{\hat{\psi}}_i(\mathbf{x})$ containing the creation $\hat{\eta}_\alpha^+$ and annihilation $\hat{\eta}_\alpha$ operators of bound states are determined by (27), (28), and (16)–(18).

Let us define the operator of magnetic field

$$\hat{\mathbf{H}}(\mathbf{x},t) = \hat{\mathbf{h}}(\mathbf{x}) + \mathbf{H}^{(e)}(\mathbf{x},t), \tag{51}$$

where

$$\hat{\mathbf{h}}(\mathbf{x}) = \mathrm{rot}\,\hat{\mathbf{a}}(\mathbf{x}),\ \ \mathbf{H}^{(e)}(\mathbf{x},t) = \mathrm{rot}\,\mathbf{A}^{(e)}(\mathbf{x},t),$$

and the operator of electric field

$$\hat{\mathbf{E}}(\mathbf{x},t) = \hat{\mathbf{e}}(\mathbf{x}) + \mathbf{E}^{(e)}(\mathbf{x},t),$$

where

$$\hat{\mathbf{e}}(\mathbf{x}) = \hat{\mathbf{e}}^t(\mathbf{x}) + \hat{\mathbf{e}}^l(\mathbf{x}),\ \ \mathbf{E}^{(e)}(\mathbf{x},t) = -\frac{\partial}{\partial t}\mathbf{A}^{(e)}(\mathbf{x},t) - \frac{\partial}{\partial \mathbf{x}}\varphi^{(e)}(\mathbf{x},t).$$

The transverse $\hat{\mathbf{e}}^t(\mathbf{x})$ and longitudinal $\hat{\mathbf{e}}^l(\mathbf{x})$ components of the electric field created by particles are defined as follows:

$$\hat{\mathbf{e}}^l(\mathbf{x}) = -\frac{\partial}{\partial \mathbf{x}}\hat{\mathbf{a}}_0(\mathbf{x}),\ \ \hat{\mathbf{e}}^t(\mathbf{x}) = -\dot{\hat{\mathbf{a}}}(\mathbf{x}) \equiv -i[\tilde{\hat{\mathcal{H}}}(t),\hat{\mathbf{a}}(\mathbf{x})]. \tag{52}$$

Here $\hat{\mathbf{a}}_0(\mathbf{x})$ represents the operator of the scalar potential,

$$\hat{\mathbf{a}}_0(\mathbf{x}) = \int d\mathbf{x}'\frac{\tilde{\hat{\sigma}}(\mathbf{x}')}{|\mathbf{x}-\mathbf{x}'|}. \tag{53}$$

Next it is easy to verify that

$$[\hat{\eta}_\alpha(\mathbf{X}),\hat{\eta}_\beta^+(\mathbf{X}')] = \delta_{\alpha\beta}\delta(\mathbf{X}-\mathbf{X}'),\ \ \sum_\alpha \varphi_\alpha^*(\mathbf{x})\varphi_\alpha(\mathbf{x}') = \delta(\mathbf{x}-\mathbf{x}')$$

lead to the following commutation relation:

$$[\hat{\varphi}(\mathbf{x},\mathbf{X}),\hat{\varphi}^+(\mathbf{x}',\mathbf{X}')] = \delta(\mathbf{x}-\mathbf{x}')\delta(\mathbf{X}-\mathbf{X}'), \tag{54}$$

where $\hat{\varphi}(\mathbf{x},\mathbf{X}) \equiv \hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2)$ is determined by (17). Hereinafter we assume that a set of wave functions $\varphi_\alpha(\mathbf{x}')$ is complete. Therefore this set accounts for the wave functions of continuous spectrum. In addition, if we introduce the operator

$$\hat{n}(\mathbf{x},\mathbf{X}) = \hat{\varphi}^+(\mathbf{x},\mathbf{X})\hat{\varphi}(\mathbf{x},\mathbf{X}),$$

then

$$[\hat{n}(\mathbf{x},\mathbf{X}),\hat{n}(\mathbf{x}',\mathbf{X}')]=0.$$

Thus, it is clear that the Hamiltonian $\tilde{\hat{\mathcal{H}}}_{\text{int}}$, which describes the Coulomb interaction between particles and bound states meets the commutation relation

$$[\tilde{\hat{\mathcal{H}}}_{\text{int}},\tilde{\hat{\rho}}_i(\mathbf{x})]=0.$$

Let us find now a commutator $[\tilde{\hat{\rho}}_i(\mathbf{x}),\tilde{\hat{\mathcal{H}}}_0]$ $(i=1,2)$, where $\tilde{\hat{\rho}}_i(\mathbf{x})$ and $\tilde{\hat{\mathcal{H}}}_0$ are defined by (28), (45), and (46). In order to do this we consider $\tilde{\hat{\rho}}_1(\mathbf{x})$ in the form

$$\tilde{\hat{\rho}}_1(\mathbf{x})=\tilde{\hat{\rho}}_1'(\mathbf{x})+\tilde{\hat{\rho}}_1''(\mathbf{x}),$$

where

$$\tilde{\hat{\rho}}_1'(\mathbf{x})=\hat{\chi}_1^+(\mathbf{x})\hat{\chi}_1(\mathbf{x}),\quad \tilde{\hat{\rho}}_1''(\mathbf{x})=\int \mathrm{d}\mathbf{y}\,\mathrm{d}\mathbf{Y}\,\delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\hat{\varphi}(\mathbf{y},\mathbf{Y}).$$

Then in accordance with the commutation relations for the field operators $\hat{\chi}_i(\mathbf{x})$,

$$[\hat{\chi}_i(\mathbf{x}),\hat{\chi}_j^+(\mathbf{x}')]=\delta_{ij}\delta(\mathbf{x}-\mathbf{x}'),$$

one gets

$$\left[\tilde{\hat{\rho}}_1'(\mathbf{x}),\int \mathrm{d}\mathbf{x}'\sum_{j=1}^{2}\frac{1}{2m_j}\frac{\partial\hat{\chi}_j^+(\mathbf{x}')}{\partial\mathbf{x}'}\frac{\partial\hat{\chi}_j(\mathbf{x}')}{\partial\mathbf{x}'}\right]=-\frac{i}{2m_1}\frac{\partial}{\partial x_k}\left(\hat{\chi}_1^+(\mathbf{x})\frac{\partial\hat{\chi}_1(\mathbf{x})}{\partial x_k}-\frac{\partial\hat{\chi}_1^+(\mathbf{x})}{\partial x_k}\hat{\chi}_1(\mathbf{x})\right).$$

Next according to (30) we have

$$\begin{aligned}i[\tilde{\hat{\rho}}_1''(\mathbf{x}),\tilde{\hat{\mathcal{H}}}_0]=&\frac{1}{2\mu}\int \mathrm{d}\mathbf{y}\,\mathrm{d}\mathbf{Y}\,\delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)\frac{\partial}{\partial y_k}\left(-\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\frac{\partial\hat{\varphi}(\mathbf{y},\mathbf{Y})}{\partial y_k}+\frac{\partial\hat{\varphi}^+(\mathbf{y},\mathbf{Y})}{\partial y_k}\hat{\varphi}(\mathbf{y},\mathbf{Y})\right)\\&+\frac{1}{2M}\int \mathrm{d}\mathbf{y}\,\mathrm{d}\mathbf{Y}\,\delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)\frac{\partial}{\partial Y_k}\left(-\hat{\varphi}^+(\mathbf{y},\mathbf{Y})\frac{\partial\hat{\varphi}(\mathbf{y},\mathbf{Y})}{\partial Y_k}+\frac{\partial\hat{\varphi}^+(\mathbf{y},\mathbf{Y})}{\partial Y_k}\hat{\varphi}(\mathbf{y},\mathbf{Y})\right).\end{aligned}$$

Bearing in mind

$$-\frac{\partial}{\partial y_k}\delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)=\frac{m_2}{M}\frac{\partial}{\partial x_k}\delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right),\quad -\frac{\partial}{\partial Y_k}\delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)=\frac{\partial}{\partial x_k}\delta\left(\mathbf{x}-\mathbf{Y}-\frac{m_2}{M}\mathbf{y}\right)$$

and taking into account the definitions of $\tilde{\hat{\rho}}_i$, $\tilde{\hat{\boldsymbol{\pi}}}_i$ $(i=1,2)$, one finds

$$i[\tilde{\hat{\rho}}_1(\mathbf{x}),\tilde{\hat{\mathcal{H}}}_0+\tilde{\hat{\mathcal{H}}}_{\text{int}}]=\frac{1}{m_1}\,\text{div}\,\tilde{\hat{\boldsymbol{\pi}}}_1(\mathbf{x}).\tag{55}$$

Similarly,

$$i[\tilde{\hat{\rho}}_2(\mathbf{x}),\tilde{\hat{\mathcal{H}}}_0+\tilde{\hat{\mathcal{H}}}_{\text{int}}]=\frac{1}{m_2}\,\text{div}\,\tilde{\hat{\boldsymbol{\pi}}}_2(\mathbf{x}).\tag{56}$$

Let us find now a commutator $[\tilde{\hat{\rho}}_i(\mathbf{x}'),\tilde{\hat{\pi}}_k(\mathbf{x})]$ $(i,k=1,2)$. With the use of (27) we have

$$[\tilde{\hat{\rho}}_i''(\mathbf{x}'),\tilde{\hat{\boldsymbol{\pi}}}_k(\mathbf{x})]=i\delta_{ik}\tilde{\hat{\rho}}_i''(\mathbf{x})\frac{\partial}{\partial\mathbf{x}}\delta(\mathbf{x}-\mathbf{x}').$$

Noting also that

$$[\tilde{\hat{\rho}}_i'(\mathbf{x}'), \tilde{\hat{\boldsymbol{\pi}}}_k(\mathbf{x})] = i\delta_{ik}\tilde{\hat{\rho}}_i'(\mathbf{x})\frac{\partial}{\partial \mathbf{x}}\delta(\mathbf{x}-\mathbf{x}'),$$

we get finally

$$[\tilde{\hat{\rho}}_i(\mathbf{x}'), \tilde{\hat{\boldsymbol{\pi}}}_k(\mathbf{x})] = i\delta_{ik}\tilde{\hat{\rho}}_i(\mathbf{x})\frac{\partial}{\partial \mathbf{x}}\delta(\mathbf{x}-\mathbf{x}').$$

These commutation relations along with (49) result in

$$[\tilde{\hat{\mathbf{j}}}_0(\mathbf{x}), \tilde{\hat{\sigma}}(\mathbf{x}')] = -i\sum_{i=1}^{2}\frac{e_i}{m_i}\tilde{\hat{\sigma}}_i(\mathbf{x}')\frac{\partial}{\partial \mathbf{x}}\delta(\mathbf{x}-\mathbf{x}').$$

Thus, according to (52), (55), and (56) we have

$$\dot{\tilde{\hat{\sigma}}}(\mathbf{x}) = i[\tilde{\hat{\mathcal{H}}}(t), \tilde{\hat{\sigma}}(\mathbf{x})] = \operatorname{div}\tilde{\hat{\mathbf{J}}}(\mathbf{x},t).$$

The definitions (52) and (53) of the longitudinal component of the electric field along with the above formula give

$$\dot{\hat{\mathbf{e}}}^l(\mathbf{x}) \equiv i[\tilde{\hat{\mathcal{H}}}(t), \hat{\mathbf{e}}^l(\mathbf{x})] = \frac{\partial}{\partial \mathbf{x}}\operatorname{div}\int d\mathbf{x}'\frac{\tilde{\hat{\mathbf{J}}}(\mathbf{x}',t)}{|\mathbf{x}-\mathbf{x}'|}. \tag{57}$$

Let us find the equation of motion for $\hat{\mathbf{e}}^t$. The use of commutation relations for creation $\hat{C}^+_{\mathbf{k}\lambda}$ and annihilation $\hat{C}_{\mathbf{k}\lambda}$ operators of photons,

$$[\hat{C}_{\mathbf{k}\lambda}, \hat{C}^+_{\mathbf{k}'\lambda'}] = \delta_{\mathbf{k}k'}\delta_{\lambda\lambda'}$$

lead to

$$\hat{\mathbf{e}}^t(\mathbf{x}) = -i[\tilde{\hat{\mathcal{H}}}(t), \hat{\mathbf{a}}(\mathbf{x})] = i\sum_{\mathbf{k}}\sum_{\lambda=1}^{2}\left(\frac{2\pi\omega_k}{\mathcal{V}}\right)^{1/2}(\mathbf{e}^{(\lambda)}_{\mathbf{k}}\hat{C}_{\mathbf{k}\lambda}e^{i\mathbf{k}\mathbf{x}} - \text{H.c.}), \tag{58}$$

$$\dot{\hat{\mathbf{e}}}^t(\mathbf{x}) = -i[\tilde{\hat{\mathcal{H}}}(t), \hat{\mathbf{e}}^t(\mathbf{x})] = \operatorname{rot}\hat{\mathbf{h}}(\mathbf{x}) + i[\tilde{\hat{V}}(t), \hat{\mathbf{e}}^t(\mathbf{x})],$$

and also

$$[\hat{a}_i(\mathbf{x}), \hat{e}^t_s(\mathbf{x}')] = -4\pi i\delta_{is}\delta(\mathbf{x}-\mathbf{x}') - i\frac{\partial^2}{\partial x_i \partial x_s}\frac{1}{|\mathbf{x}-\mathbf{x}'|}.$$

This formula and the definition of $\tilde{\hat{V}}(t)$ allows us to find the commutator:

$$i[\tilde{\hat{V}}(t), \hat{\mathbf{e}}^t(\mathbf{x})] = -4\pi\tilde{\hat{\mathbf{J}}}(\mathbf{x},t) - \frac{\partial}{\partial \mathbf{x}}\operatorname{div}\int d\mathbf{x}'\frac{\tilde{\hat{\mathbf{J}}}(\mathbf{x}',t)}{|\mathbf{x}-\mathbf{x}'|}.$$

Therefore, it follows from (57) and (58) that

$$\dot{\hat{\mathbf{e}}}(\mathbf{x}) = \operatorname{rot}\hat{\mathbf{h}}(\mathbf{x}) - 4\pi\tilde{\hat{\mathbf{J}}}(\mathbf{x},t), \quad \dot{\hat{\mathbf{h}}}(\mathbf{x}) \equiv i[\tilde{\hat{\mathcal{H}}}(t), \hat{\mathbf{h}}(\mathbf{x})] = i[\hat{\mathcal{H}}_f, \hat{\mathbf{h}}(\mathbf{x})]. \tag{59}$$

Upon calculating this commutator with the use of (51), one obtains

$$\dot{\hat{\mathbf{h}}}(\mathbf{x}) = -\operatorname{rot}\hat{\mathbf{e}}(\mathbf{x}). \tag{60}$$

In addition, (51) and (52) give $\operatorname{div}\hat{\mathbf{h}}(\mathbf{x})=0$, $\operatorname{div}\hat{\mathbf{e}}(\mathbf{x})=4\pi\tilde{\tilde{\sigma}}(\mathbf{x})$. These equations along with (59) and (60) represent the Maxwell–Lorentz equations for the operators of electromagnetic field

$$2\dot{\hat{\mathbf{e}}}(\mathbf{x}) = \operatorname{rot}\hat{\mathbf{h}}(\mathbf{x}) - 4\pi\tilde{\tilde{\mathbf{J}}}(\mathbf{x},t), \quad \operatorname{div}\hat{\mathbf{e}}(\mathbf{x}) = 4\pi\tilde{\tilde{\sigma}}(\mathbf{x}),$$

$$\dot{\hat{\mathbf{h}}}(\mathbf{x}) = -\operatorname{rot}\hat{\mathbf{e}}(\mathbf{x}), \quad \operatorname{div}\hat{\mathbf{h}}(\mathbf{x}) = 0.$$

Notice that (46), (51), and (58) result in

$$\hat{\mathcal{H}}_f = \sum_{\mathbf{k}}\sum_{\lambda=1}^{2}\omega_k\hat{C}^{+}_{\mathbf{k}\lambda}\hat{C}_{\mathbf{k}\lambda} = \frac{1}{8\pi}\int d\mathbf{x}(\mathbf{e}^{t_2}+\mathbf{h}^2),$$

where we neglect the unessential term $\Sigma_{\mathbf{k}\lambda}\frac{1}{2}\omega_k$.

Up to now we used the Schrödinger representation, in which the Schrödinger equation has the form

$$i\frac{\partial\Phi(t)}{\partial t} = \tilde{\tilde{\mathcal{H}}}(t)\Phi(t).$$

In this representation a dot above the certain operator $\dot{\hat{b}}(\mathbf{x})$ [see (52)] does not mean the differentiation with respect to time. It means the following:

$$\dot{\hat{b}}(\mathbf{x}) = i[\tilde{\tilde{H}}(\underline{\hat{\chi}}(\mathbf{x}'),t),\hat{b}(\mathbf{x})]. \tag{61}$$

Here the Hamiltonian $\tilde{\tilde{\mathcal{H}}}$ depends on dynamic variables $\underline{\hat{\chi}}(\mathbf{x}')$ (these variables unite $\hat{\chi}$ and $\hat{\eta}$) and time t. Introducing the unitary operator $\hat{S}(t,0)$,

$$i\frac{\partial\hat{S}(t,0)}{\partial t} = \tilde{\tilde{H}}(\underline{\hat{\chi}}(\mathbf{x}'),t)\hat{S}(t,0), \quad \hat{S}(0,0)=1,$$

we can write the solution of the equation for $\Phi(t)$ in the form,

$$\Phi(t) = \hat{S}(t,0)\Phi(0).$$

In the Heisenberg representation the vector $\Phi(0)=\Psi$ is taken as a time-independent state vector. Then, the time-dependent Heisenberg operators

$$\underline{\hat{\chi}}(\mathbf{x},t) \equiv \underline{\hat{\chi}}(x) = \hat{S}^{+}(t,0)\underline{\hat{\chi}}(\mathbf{x})\hat{S}(t,0)$$

satisfy the equation

$$i\frac{\partial\underline{\hat{\chi}}(x)}{\partial t} = [\underline{\hat{\chi}}(x),\tilde{\tilde{\mathcal{H}}}(\underline{\hat{\chi}}(x),t)]. \tag{62}$$

Since the external fields $\mathbf{H}^{(e)},\mathbf{E}^{(e)}$ satisfy the Maxwell equations,

$$\frac{\partial\mathbf{H}^{(e)}}{\partial t} = -\operatorname{rot}\mathbf{E}^{(e)}, \quad \operatorname{div}\mathbf{H}^{(e)}=0,$$

$$\frac{\partial \mathbf{E}^{(e)}}{\partial t} = \operatorname{rot} \mathbf{H}^{(e)} - 4\pi \mathbf{J}^{(e)}, \quad \operatorname{div} \mathbf{E}^{(e)} = 4\pi\sigma^{(e)},$$

the operators of total fields $\hat{\mathbf{E}}, \hat{\mathbf{H}}$ in the Heisenberg representation satisfy, in accordance with (62), the equations

$$\frac{\partial \hat{\mathbf{H}}}{\partial t} = -\operatorname{rot} \hat{\mathbf{E}}, \quad \operatorname{div} \hat{\mathbf{H}} = 0,$$

$$\frac{\partial \hat{\mathbf{E}}}{\partial t} = \operatorname{rot} \hat{\mathbf{H}} - 4\pi(\tilde{\hat{\mathbf{J}}} + \mathbf{J}^{(e)}), \quad \operatorname{div} \hat{\mathbf{E}} = 4\pi(\tilde{\hat{\sigma}} + \sigma^{(e)}), \tag{63}$$

where $\mathbf{J}^{(e)}$ and $\sigma^{(e)}$ are the extrinsic current and charge densities.

Let us write out the expressions for the charge density operator $\tilde{\hat{\sigma}}$ and current density operator $\tilde{\hat{\mathbf{J}}}$ in terms of creation and annihilation operators of particles and bound states. Bearing in mind (50) we have

$$\begin{aligned} \tilde{\hat{\sigma}}(\mathbf{x}) &= \sum_{i=1}^{2} e_i \tilde{\hat{\rho}}_i(\mathbf{x}), \\ \tilde{\hat{\mathbf{J}}}(\mathbf{x}) &= -\hat{\mathbf{A}}(\mathbf{x}) \sum_{i=1}^{2} \frac{e_i^2}{m_i} \tilde{\hat{\rho}}_i(\mathbf{x}) + \sum_{i=1}^{2} \frac{e_i}{m_i} \tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x}), \end{aligned} \tag{64}$$

where the particle density operators $\tilde{\hat{\rho}}_i(\mathbf{x})$ are defined by (28) and the momentum density operators $\tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x})$ by (27). The first terms in expressions for $\tilde{\hat{\rho}}_i(\mathbf{x})$ and $\tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x})$ define the contribution of particles, whereas the second terms define the contribution of bound states [see (27) and (28)].

Let us find now the equations of motion for the field operators of particles $\hat{\chi}_i(\mathbf{x})$ and bound states $\hat{\varphi}(\mathbf{x},\mathbf{y})$. In the Heisenberg representation these equations are obtained from the general formulas (62). Indeed, it follows from (38)–(40) that

$$[\hat{\chi}_1(\mathbf{x}), \tilde{\hat{\mathcal{H}}}_{\text{int}}(\hat{\chi}(\mathbf{x}'))] = \left\{ \int d\mathbf{x}_2 \, \nu_{11}(\mathbf{x}-\mathbf{x}_2) \tilde{\hat{\rho}}_1(\mathbf{x}_2) + \int d\mathbf{x}_2 \, \nu_{12}(\mathbf{x}-\mathbf{x}_2) \tilde{\hat{\rho}}_2(\mathbf{x}_2) \right\} \hat{\chi}_1(\mathbf{x}),$$

$$[\hat{\chi}_2(\mathbf{x}), \tilde{\hat{\mathcal{H}}}_{\text{int}}(\hat{\chi}(\mathbf{x}'))] = \left\{ \int d\mathbf{x}_1 \, \nu_{22}(\mathbf{x}-\mathbf{x}_1) \tilde{\hat{\rho}}_2(\mathbf{x}_1) + \int d\mathbf{x}_2 \, \nu_{21}(\mathbf{x}-\mathbf{x}_1) \tilde{\hat{\rho}}_1(\mathbf{x}_1) \right\} \hat{\chi}_2(\mathbf{x}),$$

$$\begin{aligned} [\hat{\varphi}(\mathbf{x},\mathbf{y}), \tilde{\hat{\mathcal{H}}}_{\text{int}}(\hat{\chi}(\mathbf{x}'))] = \Bigg\{ & \int d\mathbf{x}_2 (\nu_{11}(\mathbf{x}-\mathbf{x}_2) + \nu_{12}(\mathbf{y}-\mathbf{x}_2)) \tilde{\hat{\rho}}_1(\mathbf{x}_2) + \int d\mathbf{x}_2 (\nu_{22}(\mathbf{y}-\mathbf{x}_2) \\ & + \nu_{21}(\mathbf{x}-\mathbf{x}_2)) \tilde{\hat{\rho}}_2(\mathbf{x}_2) \Bigg\} \hat{\varphi}(\mathbf{x},\mathbf{y}). \end{aligned}$$

These formulas allow us to find the equations of motion (62) for $\hat{\chi}_1(\mathbf{x})$, $\hat{\chi}_2(\mathbf{x})$ in the Heisenberg representation,

$$i\dot{\hat{\chi}}_1(\mathbf{x},t) = \left\{ -\frac{1}{2m_1} \left(\frac{\partial}{\partial \mathbf{x}} - ie_1 \hat{\mathbf{A}}(\mathbf{x},t) \right)^2 + e_1 \varphi^{(e)}(\mathbf{x},t) + \hat{v}_1(\mathbf{x},t) \right\} \hat{\chi}_1(\mathbf{x},t),$$

$$i\dot{\hat{\chi}}_2(\mathbf{x},t)=\left\{-\frac{1}{2m_2}\left(\frac{\partial}{\partial\mathbf{x}}-ie_2\hat{\mathbf{A}}(\mathbf{x},t)\right)^2+e_2\varphi^{(e)}(\mathbf{x},t)+\hat{\upsilon}_2(\mathbf{x},t)\right\}\hat{\chi}_2(\mathbf{x},t).$$

It is easy to find also the equation of motion for the field operators $\hat{\varphi}(\mathbf{x},\mathbf{y})$ of bound states,

$$i\dot{\hat{\varphi}}(\mathbf{x}_1,\mathbf{x}_2,t)=\sum_\alpha\varepsilon_\alpha\hat{\eta}_\alpha(\mathbf{X},t)\varphi_\alpha(\mathbf{x})+\left\{-\frac{1}{2m_1}\left(\frac{\partial}{\partial\mathbf{x}_1}-ie_1\hat{\mathbf{A}}(\mathbf{x}_1,t)\right)^2-\frac{1}{2m_2}\left(\frac{\partial}{\partial\mathbf{x}_2}-ie_2\hat{\mathbf{A}}(\mathbf{x}_2,t)\right)^2\right.$$
$$\left.+e_1\varphi^{(e)}(\mathbf{x}_1,t)+e_2\varphi^{(e)}(\mathbf{x}_2,t)+\hat{\upsilon}(\mathbf{x}_1,\mathbf{x}_2,t)\right\}\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2,t). \tag{65}$$

Here

$$\hat{\upsilon}_1(\mathbf{x},t)=\int d\mathbf{x}_2\ \nu_{11}(\mathbf{x}-\mathbf{x}_2)\tilde{\hat{\rho}}_1(\mathbf{x}_2,t)+\int d\mathbf{x}_2\ \nu_{12}(\mathbf{x}-\mathbf{x}_2)\tilde{\hat{\rho}}_2(\mathbf{x}_2,t),$$

$$\hat{\upsilon}_2(\mathbf{x},t)=\int d\mathbf{x}_1\ \nu_{22}(\mathbf{x}-\mathbf{x}_1)\tilde{\hat{\rho}}_2(\mathbf{x}_1,t)+\int d\mathbf{x}_1\ \nu_{21}(\mathbf{x}-\mathbf{x}_1)\tilde{\hat{\rho}}_1(\mathbf{x}_1,t),$$

$$\hat{\upsilon}(\mathbf{x}_1,\mathbf{x}_2,t)=\int d\mathbf{x}'(\nu_{11}(\mathbf{x}_1-\mathbf{x}')+\nu_{12}(\mathbf{x}_2-\mathbf{x}'))\tilde{\hat{\rho}}_1(\mathbf{x}',t)+\int d\mathbf{x}'(\nu_{22}(\mathbf{x}_2-\mathbf{x}')+\nu_{21}(\mathbf{x}_1-\mathbf{x}'))\tilde{\hat{\rho}}_2(\mathbf{x}',t).$$

The operators $\hat{\eta}_\alpha(\mathbf{X},t)$ related to $\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2,t)$ by $\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2,t)=\varphi_\beta(\mathbf{x})\hat{\eta}_\beta(\mathbf{X},t)$.

The equations of motion (63) and (65) are gauge invariant. Indeed, under the following transformations of fields $\hat{\chi}_i$, $\hat{\varphi}$:

$$\hat{\chi}_1(\mathbf{x},t)\to\hat{\chi}_1'(\mathbf{x},t)=e^{ie_1\alpha(\mathbf{x},t)}\hat{\chi}_1(\mathbf{x},t),\quad\hat{\chi}_2(\mathbf{x},t)\to\hat{\chi}_2'(\mathbf{x},t)=e^{ie_2\alpha(\mathbf{x},t)}\hat{\chi}_2(\mathbf{x},t),$$

$$\hat{\varphi}(\mathbf{x},\mathbf{y},t)\to\hat{\varphi}'(\mathbf{x},\mathbf{y},t)=e^{ie_1\alpha(\mathbf{x},t)+ie_2\alpha(\mathbf{y},t)}\hat{\varphi}(\mathbf{x},\mathbf{y},t), \tag{66}$$

and electromagnetic field,

$$\hat{\mathbf{A}}(\mathbf{x},t)\to\hat{\mathbf{A}}'(\mathbf{x},t)=\hat{\mathbf{A}}(\mathbf{x},t)-\frac{\partial}{\partial\mathbf{x}}\alpha(\mathbf{x},t),\quad\varphi^{(e)}(\mathbf{x},t)\to\varphi^{(e)'}(\mathbf{x},t)=\varphi^{(e)}(\mathbf{x})-\frac{\partial\alpha(\mathbf{x},t)}{\partial t}$$

the operators $\tilde{\hat{\rho}}_i(\mathbf{x})$ are invariant,

$$\tilde{\hat{\rho}}_i(\mathbf{x},t)\to\tilde{\hat{\rho}}_i'(\mathbf{x},t)=\tilde{\hat{\rho}}_i(\mathbf{x},t),$$

whereas $\tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x})$ transform [see (65)], by the law

$$\tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x},t)\to\tilde{\hat{\boldsymbol{\pi}}}_i'(\mathbf{x},t)=\tilde{\hat{\boldsymbol{\pi}}}_i(\mathbf{x},t)+e_i\tilde{\hat{\rho}}_i(\mathbf{x},t)\frac{\partial}{\partial\mathbf{x}}\alpha(\mathbf{x},t).$$

As a result we have [see (64)]

$$\tilde{\hat{\mathbf{J}}}(\mathbf{x},t)\to\tilde{\hat{\mathbf{J}}}'(\mathbf{x},t)=\tilde{\hat{\mathbf{J}}}(\mathbf{x},t),\quad\tilde{\hat{\mathcal{H}}}\to\tilde{\hat{\mathcal{H}}}'=\tilde{\hat{\mathcal{H}}}$$

that provides a gauge invariance of the Maxwell–Lorentz equations (63). Next noting that

$$\left(\frac{\partial}{\partial\mathbf{x}}-ie_i\hat{\mathbf{A}}(\mathbf{x},t)\right)\hat{\chi}_i(\mathbf{x},t)\to\left(\frac{\partial}{\partial\mathbf{x}}-ie_i\hat{\mathbf{A}}'(\mathbf{x},t)\right)\hat{\chi}_i'(\mathbf{x},t)=e^{ie_i\alpha(\mathbf{x},t)}\left(\frac{\partial}{\partial\mathbf{x}}-ie_i\hat{\mathbf{A}}(\mathbf{x},t)\right)\hat{\chi}_i(\mathbf{x},t),$$

we make sure of gauge invariance of the equations of motion for the field operators of particles $\hat{\chi}_i(\mathbf{x})$. Taking into account the transformation law for the field operators of bound states $\hat{\varphi}(\mathbf{x},\mathbf{y})$, it

is easy to prove a gauge invariance of the equation of motion for $\hat{\varphi}(\mathbf{x},\mathbf{y})$.

Since $\hat{\varphi}(\mathbf{x}_1,\mathbf{x}_2,t)=\varphi_\alpha(\mathbf{x})\,\hat{\eta}_\alpha(\mathbf{X},t)$, we have under the gauge transformation (66),

$$\hat{\varphi}'(\mathbf{x}_1,\mathbf{x}_2,t)=\varphi_\alpha(\mathbf{x})\,\hat{\eta}'_\alpha(\mathbf{X},t),$$

where $\mathbf{x}_1=\mathbf{X}+(m_2/M)\mathbf{x}$, $\mathbf{x}_2=\mathbf{X}-(m_1/M)\mathbf{x}$. Hence, we come to the transformation law for the operators $\hat{\eta}_\alpha(\mathbf{X})$:

$$\hat{\eta}_\alpha(\mathbf{X},t)\rightarrow\hat{\eta}'_\alpha(\mathbf{X},t)=\sum_\beta L_{\alpha\beta}(\mathbf{X},t)\,\hat{\eta}_\beta(\mathbf{X},t),$$

$$L_{\alpha\beta}(\mathbf{X},t)=\int \mathrm{d}\mathbf{x}\;\varphi^*_\alpha(\mathbf{x})e^{ie_1\alpha[\mathbf{X}+(m_2/M)\mathbf{x},t]+ie_2\alpha[\mathbf{X}-(m_1/M)\mathbf{x},t]}\varphi_\beta(\mathbf{x}).$$

In conclusion of this section let us note that $\tilde{\tilde{\psi}}_i(\mathbf{x})$ transform under the gauge transformation as well as $\hat{\chi}_i(\mathbf{x})$:

$$\tilde{\tilde{\psi}}_i(\mathbf{x},t)\rightarrow\tilde{\tilde{\psi}}'_i(\mathbf{x},t)=e^{ie_i\alpha(\mathbf{x},t)}\tilde{\tilde{\psi}}_i(\mathbf{x},t).$$

VI. THE PROCESS OF SPONTANEOUS RADIATION BY ATOM

In this section we employ the obtained formulas in order to find the probability distribution of spontaneous radiation of an excited atom. To this end we use the general formulas for the scattering matrix $\hat{S}$ in terms of the T operator,

$$\hat{S}=1-2\pi i\int_{-\infty}^{\infty}\mathrm{d}E\;\delta(E-\hat{\mathcal{H}}_0)\hat{T}^{(+)}(E)\,\delta(E-\hat{\mathcal{H}}_0),$$

$$\hat{T}^{(+)}(E)=\lim_{\eta\rightarrow+0}\hat{T}(E+i\eta), \tag{67}$$

where $\hat{T}(z)$ is found from the equation

$$\hat{T}(z)=\hat{V}+\hat{V}\hat{R}_0\hat{T}(z),\quad \hat{R}_0=\frac{1}{z-\hat{\mathcal{H}}_0}. \tag{68}$$

In the first order of the perturbative approach over charge we have

$$\langle f|\hat{T}(z)|i\rangle\approx\langle f|\hat{V}|i\rangle,$$

where

$$|i\rangle=\hat{\eta}^+_{\alpha\mathbf{p}}|0\rangle,\quad |f\rangle=\hat{C}^+_{\mathbf{k}\lambda}\hat{\eta}^+_{\alpha\mathbf{p}}|0\rangle.$$

Here $|i\rangle$ is the initial state (in which atom is in the state α, $\mathbf{p}$) and $|f\rangle$ is the final state (in which atom is in the state α', $\mathbf{p}'$ and photon is in the state λ, $\mathbf{k}$). According to (48) and (50) we can take $\hat{V}$ in the following form:

$$\tilde{\tilde{V}}=-\int \mathrm{d}\mathbf{x}\;\hat{\mathbf{a}}(\mathbf{x})\tilde{\tilde{\mathbf{j}}}(\mathbf{x}),$$

where the current of bound states is defined by

$$\tilde{\hat{\mathbf{j}}}(\mathbf{x}) = \frac{e_1}{m_1}\tilde{\hat{\boldsymbol{\pi}}}_1(\mathbf{x}) + \frac{e_2}{m_2}\tilde{\hat{\boldsymbol{\pi}}}_2(\mathbf{x}). \tag{69}$$

By using (48) and (50) we find

$$\langle f|\tilde{\hat{V}}|i\rangle = -\left(\frac{2\pi}{\mathcal{V}\omega_k}\right)^{1/2}\mathbf{e}_{\mathbf{k}}^{(\lambda)*}\int \mathrm{d}\mathbf{x}\, e^{-i\mathbf{k}\mathbf{x}}\langle\alpha'\mathbf{p}'|\tilde{\hat{\mathbf{j}}}(\mathbf{x})|\alpha\mathbf{p}\rangle.$$

The formulas (69) and (27) lead to

$$\tilde{\hat{\mathbf{j}}}(\mathbf{k}) \equiv \int \mathrm{d}\mathbf{x}\, e^{-i\mathbf{k}\mathbf{x}}\tilde{\hat{\mathbf{j}}}(\mathbf{x}) = \sum_{\mathbf{p}_1,\mathbf{p}_2}\sum_{\alpha_1,\alpha_2}\hat{\eta}^+_{\alpha_1\mathbf{p}_1}\hat{\eta}_{\alpha_2\mathbf{p}_2}\left(\mathbf{g}_{\alpha_1\alpha_2}(\mathbf{k}) + \frac{\mathbf{p}_1+\mathbf{p}_2}{2M}g_{\alpha_1\alpha_2}(\mathbf{k})\right)\Delta(\mathbf{p}_1-\mathbf{p}_2+\mathbf{k})$$

and, consequently,

$$\langle f|\tilde{\hat{V}}|i\rangle = -\left(\frac{2\pi}{\mathcal{V}\omega_k}\right)^{1/2}\mathbf{e}_{\mathbf{k}}^{(\lambda)*}\left(\mathbf{g}_{\alpha\alpha'}(\mathbf{k}) + \frac{\mathbf{p}+\mathbf{p}'}{2M}g_{\alpha\alpha'}(\mathbf{k})\right)\Delta(\mathbf{p}-\mathbf{p}'-\mathbf{k}),\ \ \mathbf{k}=\mathbf{p}-\mathbf{p}',$$

where $\Delta(\mathbf{p}) = \delta_{\mathbf{p}0}$, and

$$g_{\alpha\beta}(\mathbf{k}) = \int \mathrm{d}\mathbf{y}(e_1 e^{i\mathbf{k}\mathbf{y}(m_2/M)} + e_2 e^{-i\mathbf{k}\mathbf{y}(m_1/M)})\varphi^*_\alpha(\mathbf{y})\varphi_\beta(\mathbf{y}),$$

$$\mathbf{g}_{\alpha\beta}(\mathbf{k}) = -\frac{i}{2}\int \mathrm{d}\mathbf{y}\left(\frac{e_1}{m_1}e^{i\mathbf{k}\mathbf{y}(m_2/M)} - \frac{e_2}{m_2}e^{-i\mathbf{k}\mathbf{y}(m_1/M)}\right)\left(\varphi^*_\alpha(\mathbf{y})\frac{\partial\varphi_\beta(\mathbf{y})}{\partial\mathbf{y}} - \frac{\partial\varphi^*_\alpha(\mathbf{y})}{\partial\mathbf{y}}\varphi_\beta(\mathbf{y})\right). \tag{70}$$

The matrix element of $\hat{S}$-matrix is defined, in accordance with (67), by

$$\langle f|\hat{S}|i\rangle = -2\pi i\langle f|\tilde{\hat{V}}|i\rangle\delta(\varepsilon(\mathbf{p}) - \varepsilon(\mathbf{p}') - \omega_k).$$

Next using the standard method we obtain the following expression for the probability of transition per unit time from the initial state $\hat{\eta}^+_{\alpha\mathbf{p}}|0\rangle$ into the final state $\hat{\eta}^+_{\beta\mathbf{p}'}\hat{C}^+_{\mathbf{k}\lambda}|0\rangle$:

$$\mathrm{d}w_{i\to f} = \frac{2\pi}{\omega_k}\left|\mathbf{e}_{\mathbf{k}}^{(\lambda)}\left(\mathbf{g}_{\alpha\beta}(\mathbf{k}) + \frac{\mathbf{p}+\mathbf{p}'}{2M}g_{\alpha\beta}(\mathbf{k})\right)\right|^2\delta(\omega_k + \varepsilon_\beta(\mathbf{p}') - \varepsilon_\alpha(\mathbf{p}))\mathrm{d}\mathbf{k}.$$

In the domain of small $\mathbf{k}$ ($kr_0 \ll 1$, see Sec. II) the Fourier-components of $\mathbf{g}_{\alpha\beta}(\mathbf{x})$, $g_{\alpha\beta}(\mathbf{x})$ can be written in the form

$$\mathbf{g}_{\alpha\beta}(0) = \left(\frac{e_1}{m_1} - \frac{e_2}{m_2}\right)\int \mathrm{d}\mathbf{y}\ \varphi^*_\alpha(\mathbf{y})\hat{\mathbf{p}}\varphi_\beta(\mathbf{y}) = \left(\frac{e_1}{m_1} - \frac{e_2}{m_2}\right)\langle\alpha|\hat{\mathbf{p}}|\beta\rangle,\ \ g_{\alpha\beta}(0) = (e_1+e_2)\delta_{\alpha\beta}. \tag{71}$$

If $e_2 = -e_1 = -e$ (this case corresponds to the hydrogen atom), then $g_{\alpha\beta}(0) = 0$, $\mathbf{g}_{\alpha\beta}(0) = (e/\mu)\times\langle\alpha|\hat{\mathbf{p}}|\beta\rangle$. The Schrödinger equation for the wave function $\varphi_\alpha(\mathbf{y})$ gives

$$\langle\alpha|\hat{\mathbf{p}}|\beta\rangle = i\mu(\varepsilon_\alpha - \varepsilon_\beta)\int \mathrm{d}\mathbf{y}\ \varphi^*_\alpha(\mathbf{y})\mathbf{y}\varphi_\beta(\mathbf{y}).$$

Therefore,

$$\mathbf{g}_{\alpha\beta}(0) = i(\varepsilon_\alpha - \varepsilon_\beta)\langle\alpha|\hat{\mathbf{d}}|\beta\rangle,$$

where $\hat{\mathbf{d}} = e\hat{\mathbf{y}}$ is the dipole moment of the atom. Hence,

$$dw_{i\to f} = 2\pi\omega_k \left|\langle\alpha|\mathbf{e}_{\mathbf{k}}^{(\lambda)}\hat{\mathbf{d}}|\beta\rangle\right|^2 \delta(\omega_k + \varepsilon_\beta(\mathbf{p}') - \varepsilon_\alpha(\mathbf{p}))d\mathbf{k}.$$

Since $\varepsilon_\alpha(\mathbf{p}) = \varepsilon_\alpha + p^2/2M$, we have for the atom of infinite mass ($m_2 \to \infty$, $M \to \infty$),[5]

$$dw_{i\to f} = \frac{2\pi}{\omega_k}|\mathbf{e}_{\mathbf{k}}^{(\lambda)}\mathbf{g}_{\alpha\beta}(\mathbf{k})|^2 \delta(\omega_k + \varepsilon_\beta - \varepsilon_\alpha)d\mathbf{k},$$

where

$$\mathbf{g}_{\alpha\beta}(\mathbf{k}) = -\frac{ie}{2m_1}\int d\mathbf{y}\, e^{i\mathbf{k}\mathbf{y}}\left(\varphi_\alpha^*(\mathbf{y})\frac{\partial\varphi_\beta(\mathbf{y})}{\partial\mathbf{y}} - \frac{\partial\varphi_\alpha^*(\mathbf{y})}{\partial\mathbf{y}}\varphi_\beta(\mathbf{y})\right)$$

(m_1 is the mass of light fermion).

VII. SCATTERING OF PHOTONS AND FERMIONS BY ATOMS

Here we study the scattering process of long-wave photons by atoms. For this purpose let us use the general formulas (67) and (68), where the Hamiltonian of free particles is defined by

$$\tilde{\tilde{\mathcal{H}}}_0 = \sum_{i=1}^{2}\int d\mathbf{x}\ \nabla\hat{\chi}_i^+(\mathbf{x})\nabla\hat{\chi}_i(\mathbf{x}) + \sum_{\mathbf{k}}\sum_{\lambda=1}^{2}\omega_k\hat{C}_{\mathbf{k}\lambda}^+\hat{C}_{\mathbf{k}\lambda}$$
$$+\sum_\alpha\int d\mathbf{x}\left(\frac{1}{2m}\nabla\hat{\eta}_\alpha^+(\mathbf{x})\nabla\hat{\eta}_\alpha(\mathbf{x}) + \varepsilon_\alpha\hat{\eta}_\alpha^+(\mathbf{x})\hat{\eta}_\alpha(\mathbf{x})\right),$$

and the Hamiltonian associated with electromagnetic interaction by

$$\tilde{\tilde{V}} = \tilde{\tilde{V}}' + \tilde{\tilde{V}}''.$$

In accordance with (48) and (50),

$$\tilde{\tilde{V}}' = \frac{1}{2}\int d\mathbf{x}\,\hat{\mathbf{a}}^2(\mathbf{x})\left(\frac{e^2}{m_1}\tilde{\tilde{\rho}}_1(\mathbf{x}) + \frac{e^2}{m_2}\tilde{\tilde{\rho}}_2(\mathbf{x})\right),\quad \tilde{\tilde{V}}'' = -\int d\mathbf{x}\,\hat{\mathbf{a}}(\mathbf{x})\tilde{\tilde{\mathbf{j}}}(\mathbf{x}),$$

$$\tilde{\tilde{\mathbf{j}}}(\mathbf{x}) = \frac{e}{m_1}\tilde{\tilde{\pi}}_1(\mathbf{x}) + \frac{e}{m_2}\tilde{\tilde{\pi}}_2(\mathbf{x}) \tag{72}$$

(further we assume $e_1 = -e_2 = e$). Since $\tilde{\tilde{V}}' \sim e^2$, $\tilde{\tilde{V}}'' \sim e$, in the second order in charge e, the T-matrix can be written as

$$\hat{T}(z) = \tilde{\tilde{V}}' + \tilde{\tilde{V}}''\hat{R}_0(z)\tilde{\tilde{V}}'',\quad \hat{R}_0 = \frac{1}{z - \tilde{\tilde{\mathcal{H}}}_0}$$

(within the considered approximation it is not necessary to take into account the fields $\hat{\chi}_i(\mathbf{x})$). Bearing in mind (72) and (28), the operator $\tilde{\tilde{V}}'$ can be written as

$$\tilde{\tilde{V}}' = \frac{1}{2\mathcal{V}}\sum_{\mathbf{p}_1,\mathbf{p}_2}\hat{\eta}_\alpha^+(\mathbf{p}_1)\hat{\eta}_\beta(\mathbf{p}_2)q_{\alpha\beta}(\mathbf{p}_1 - \mathbf{p}_2)\int d\mathbf{x}\,\hat{\mathbf{a}}^2(\mathbf{x})e^{i\mathbf{x}(\mathbf{p}_2 - \mathbf{p}_1)},$$

where

$$q_{\alpha\beta}(\mathbf{k}) = \int \mathrm{d}\mathbf{y}\left\{\frac{e^2}{m_1}e^{i\mathbf{k}\mathbf{y}(m_2/M)} + \frac{e^2}{m_2}e^{-i\mathbf{k}\mathbf{y}(m_1/M)}\right\}\varphi^*_\alpha(\mathbf{y})\varphi_\beta(\mathbf{y}).$$

Similarly,

$$\tilde{\hat{V}}'' = -\frac{1}{\mathcal{V}}\sum_{\mathbf{p}_1,\mathbf{p}_2}\hat{\eta}^+_\alpha(\mathbf{p}_1)\hat{\eta}_\beta(\mathbf{p}_2)\mathbf{I}_{\alpha\beta}(\mathbf{p}_1+\mathbf{p}_2,\mathbf{p}_1-\mathbf{p}_2)\int \mathrm{d}\mathbf{x}\,\hat{\mathbf{a}}(\mathbf{x})e^{i\mathbf{x}(\mathbf{p}_2-\mathbf{p}_1)},$$

where

$$\mathbf{I}_{\alpha\beta}(\mathbf{p}_1+\mathbf{p}_2,\mathbf{p}_1-\mathbf{p}_2) = \mathbf{g}_{\alpha\beta}(\mathbf{p}_1-\mathbf{p}_2) + \frac{\mathbf{p}_1+\mathbf{p}_2}{2M}g_{\alpha\beta}(\mathbf{p}_1-\mathbf{p}_2),\ \ \mathbf{p}_1-\mathbf{p}_2=\mathbf{k},\ \ \mathbf{p}_1+\mathbf{p}_2=\mathbf{p},$$

moreover, $\mathbf{g}_{\alpha\beta}(\mathbf{k})$, $g_{\alpha\beta}(\mathbf{k})$ are defined by (70).

Let $\hat{C}^+_{\mathbf{k}\lambda}\hat{\eta}^+_\alpha(\mathbf{p})|0\rangle$ and $\hat{C}^+_{\mathbf{k}'\lambda'}\hat{\eta}^+_{\alpha'}(\mathbf{p}')|0\rangle$ be the initial and final states of the system,

$$|i\rangle = \hat{C}^+_{\mathbf{k}\lambda}\hat{\eta}^+_\alpha(\mathbf{p})|0\rangle,\ \ |i\rangle = \hat{C}^+_{\mathbf{k}'\lambda'}\hat{\eta}^+_{\alpha'}(\mathbf{p}')|0\rangle.$$

Then the matrix element $\langle f|\hat{T}(z)|i\rangle$ can be represented in the form

$$\langle f|\hat{T}(z)|i\rangle = \langle f|\tilde{\hat{V}}'|i\rangle + \langle f|\tilde{\hat{V}}''\hat{R}_0(z)\tilde{\hat{V}}''|i\rangle,$$

where

$$\langle f|\tilde{\hat{V}}'|i\rangle = -\frac{4\pi^2 i}{\mathcal{V}}\frac{1}{\sqrt{\omega\omega'}}R'_{\alpha'\alpha}\Delta(\mathbf{p}+\mathbf{k}-\mathbf{p}'-\mathbf{k}'),$$

$$\langle f|\tilde{\hat{V}}''\hat{R}_0(z)\tilde{\hat{V}}''|i\rangle = -\frac{4\pi^2 i}{\mathcal{V}}\frac{1}{\sqrt{\omega\omega'}}R''_{\alpha'\alpha}\Delta(\mathbf{p}+\mathbf{k}-\mathbf{p}'-\mathbf{k}'),\ \ \Delta(\mathbf{k})=\delta_{\mathbf{k}0},$$

and the matrices $R'_{\alpha'\alpha}$, $R''_{\alpha'\alpha}$ are given by

$$R'_{\alpha'\alpha} = \mathbf{e}^{(\lambda)}_{\mathbf{k}}\mathbf{e}^{(\lambda)*}_{\mathbf{k}}q_{\alpha\alpha'}(\mathbf{k}),\ \ \mathbf{k}=\mathbf{p}'-\mathbf{p},$$

$$R''_{\alpha'\alpha} = \sum_\beta\left\{\frac{(\mathbf{e}'\mathbf{I}_{\beta\alpha'}(\mathbf{p}',\mathbf{k}'))*(\mathbf{e}\mathbf{I}_{\beta\alpha}(\mathbf{p},\mathbf{k}))}{\omega+\varepsilon_\alpha(\mathbf{p})-\varepsilon_\beta(\mathbf{p}+\mathbf{k})} + \frac{(\mathbf{e}'\mathbf{I}_{\alpha\beta}(\mathbf{p},-\mathbf{k}'))*(\mathbf{e}\mathbf{I}_{\alpha'\beta}(\mathbf{p}',-\mathbf{k}))}{-\omega'+\varepsilon_\alpha(\mathbf{p})-\varepsilon_\beta(\mathbf{p}-\mathbf{k}')}\right\}.$$

Here we have taken into account that $\omega+\varepsilon_\alpha(\mathbf{p})=\omega'+\varepsilon_\beta(\mathbf{p}')$ is a consequence of (67) and assumed $E=\omega+\varepsilon_\alpha(\mathbf{p})$. According to our approximation $kr_0\ll 1$ ($\lambda\gg r_0$) we have

$$q_{\alpha\beta}(\mathbf{k}) \approx \frac{e^2}{\mu}\delta_{\alpha\beta},\ \ g_{\alpha\beta}\approx 0,$$

$$\mathbf{g}_{\alpha\beta}(\mathbf{k}) \approx -\frac{ie}{\mu}\int \mathrm{d}\mathbf{y}\,\varphi^*_\alpha(\mathbf{y})\frac{\partial\varphi_\beta(\mathbf{y})}{\partial\mathbf{y}} = \frac{e}{\mu}\langle\alpha|\hat{\mathbf{p}}|\beta\rangle,$$

whence

$$R'_{\alpha'\alpha} \approx \frac{e^2}{\mu}\mathbf{e}_{\mathbf{k}}^{(\lambda)}\mathbf{e}_{\mathbf{k}'}^{(\lambda')*}\delta_{\alpha\alpha'},\ \ \mathbf{I}_{\alpha\beta}(\mathbf{p},\mathbf{k}) \approx \mathbf{g}_{\alpha\beta}(\mathbf{k}) \approx \frac{e}{\mu}\langle\alpha|\hat{\mathbf{p}}|\beta\rangle, \tag{73}$$

where $\hat{\mathbf{p}}=-i\nabla$ is the momentum operator. Noting that $\varepsilon_\alpha(\mathbf{p})=\varepsilon_\alpha+(p^2/2M)$ we neglect the kinetic energy in denominators of $R''_{\alpha'\alpha}$ (the kinetic energy is small in comparison to binding energy of bound states; see Sec. II). The result is

$$R''_{\alpha'\alpha} = \frac{e^2}{\mu^2}\sum_\beta \left\{ \frac{\langle\alpha'|\mathbf{e}'^*\hat{\mathbf{p}}|\beta\rangle\langle\beta|\mathbf{e}\hat{\mathbf{p}}|\alpha\rangle}{\omega+\varepsilon_\alpha-\varepsilon_\beta} + \frac{\langle\alpha'|\mathbf{e}\hat{\mathbf{p}}|\beta\rangle\langle\beta|\mathbf{e}'^*\hat{\mathbf{p}}|\alpha\rangle}{-\omega'+\varepsilon_\alpha-\varepsilon_\beta} \right\}.$$

Let us express this formula through the matrix elements of the dipole moment of the atom. It is easy to verify [by using of Eq. (71)] that

$$\frac{\langle\alpha'|\mathbf{e}'^*\hat{\mathbf{p}}|\beta\rangle\langle\beta|\mathbf{e}\hat{\mathbf{p}}|\alpha\rangle}{\omega+\varepsilon_\alpha-\varepsilon_\beta} = \mu^2\left(\varepsilon_\alpha-\varepsilon_\beta-\omega'+\frac{\omega\omega'}{\omega+\varepsilon_\alpha-\varepsilon_\beta}\right)\langle\alpha'|\mathbf{e}'^*\hat{\mathbf{y}}|\beta\rangle\langle\beta|\mathbf{e}\hat{\mathbf{y}}|\alpha\rangle,$$

$$\frac{\langle\alpha'|\mathbf{e}\hat{\mathbf{p}}|\beta\rangle\langle\beta|\mathbf{e}'^*\hat{\mathbf{p}}|\alpha\rangle}{-\omega'+\varepsilon_\alpha-\varepsilon_\beta} = \mu^2\left(\varepsilon_{\alpha'}-\varepsilon_\beta+\omega'+\frac{\omega\omega'}{-\omega'+\varepsilon_\alpha-\varepsilon_\beta}\right)\langle\alpha'|\mathbf{e}\hat{\mathbf{y}}|\beta\rangle\langle\beta|\mathbf{e}'^*\hat{\mathbf{y}}|\alpha\rangle.$$

Therefore, the quantity $R''_{\alpha'\alpha}$ is of the form

$$R''_{\alpha'\alpha} = Q_{\alpha'\alpha} + \omega\omega'\sum_\beta \left\{ \frac{\langle\alpha'|\mathbf{e}\hat{\mathbf{d}}|\beta\rangle\langle\beta|\mathbf{e}'^*\hat{\mathbf{d}}|\alpha\rangle}{-\omega'+\varepsilon_\alpha-\varepsilon_\beta} + \frac{\langle\alpha'|\mathbf{e}'^*\hat{\mathbf{d}}|\beta\rangle\langle\beta|\mathbf{e}\hat{\mathbf{d}}|\alpha\rangle}{\omega+\varepsilon_\alpha-\varepsilon_\beta} \right\},$$

where $\hat{\mathbf{d}}=e\hat{\mathbf{y}}$ is the dipole moment of the atom, and

$$Q_{\alpha'\alpha} = \mu^2\sum_\beta \{(\varepsilon_\alpha-\varepsilon_\beta-\omega')\langle\alpha'|\mathbf{e}'^*\hat{\mathbf{y}}|\beta\rangle\langle\beta|\mathbf{e}\hat{\mathbf{y}}|\alpha\rangle + (\omega'+\varepsilon_{\alpha'}-\varepsilon_\beta)\langle\alpha'|\mathbf{e}\hat{\mathbf{y}}|\beta\rangle\langle\beta|\mathbf{e}'^*\hat{\mathbf{y}}|\alpha\rangle\}.$$

Next, using that

$$\left[\hat{\mathbf{y}}\mathbf{e}, \frac{p^2}{2\mu}+\hat{V}\right] = \left[\hat{\mathbf{y}}\mathbf{e}, \frac{p^2}{2\mu}\right] = \frac{i}{\mu}\mathbf{e}\hat{\mathbf{p}},$$

one finds

$$Q_{\alpha'\alpha} = -\frac{e^2}{\mu}\mathbf{e}'^*\mathbf{e}\delta_{\alpha\alpha'}.$$

According to (73), the quantity $R'_{\alpha'\alpha}$ is equal to $R'_{\alpha'\alpha}=(e^2/\mu)\mathbf{e}'^*\mathbf{e}\delta_{\alpha\alpha'}$. Thus, the matrix $R=R'+R''$ takes the form

$$R_{\alpha'\alpha} = \omega\omega'\sum_\beta \left\{ \frac{\langle\alpha'|\mathbf{e}\hat{\mathbf{d}}|\beta\rangle\langle\beta|\mathbf{e}'^*\hat{\mathbf{d}}|\alpha\rangle}{-\omega'+\varepsilon_\alpha-\varepsilon_\beta} + \frac{\langle\alpha'|\mathbf{e}'^*\hat{\mathbf{d}}|\beta\rangle\langle\beta|\mathbf{e}\hat{\mathbf{d}}|\alpha\rangle}{\omega+\varepsilon_\alpha-\varepsilon_\beta} \right\}$$

and the amplitude of transition from the initial state into the final state is given by (see Ref. 5)

$$S_{i\to f} = -\frac{4\pi^2 i}{\mathcal{V}}\frac{1}{\sqrt{\omega\omega'}}R_{\alpha'\alpha}\delta(\varepsilon_\alpha(\mathbf{p})+\omega-\varepsilon_{\alpha'}(\mathbf{p}')-\omega')\Delta(\mathbf{p}+\mathbf{k}-\mathbf{p}'-\mathbf{k}').$$

The differential scattering cross section is of the form

$$\mathrm{d}\sigma_{i\to f} = \frac{1}{\omega\omega'}|R_{\alpha'\alpha}|^2\delta(\varepsilon_\alpha(\mathbf{p})+\omega-\varepsilon_{\alpha'}(\mathbf{p}')-\omega')\mathrm{d}\mathbf{k}'.$$

Let us consider the scattering of an elementary particle by compound particle (the scattering of an electron by atom). Due to the structure of the Hamiltonian of interaction (38) it is sufficient to study the scattering of particle of the first kind by bound state. The matrix element of the $\hat{S}$-matrix in the first nonvanishing approximation over interaction is defined by

$$S_{i\to f} = -2\pi i\langle f|\tilde{\tilde{\mathcal{H}}}^1_{\text{int}}|i\rangle\,\delta(\varepsilon_i - \varepsilon_f),$$

where $\tilde{\tilde{\mathcal{H}}}^1_{\text{int}}$ is given by (38) and consequently,

$$\langle f|\tilde{\tilde{\mathcal{H}}}^1_{\text{int}}|i\rangle = \frac{1}{\mathcal{V}^2}\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\,\mathrm{d}\mathbf{y}\;\varphi_\alpha(\mathbf{x}_2-\mathbf{y})e^{i\mathbf{p}\mathbf{X}}\varphi_{\alpha'}(\mathbf{x}_2-\mathbf{y})e^{-i\mathbf{p}'\mathbf{X}}(\nu_{11}(\mathbf{x}_1-\mathbf{x}_2)-\nu_{21}(\mathbf{x}_1-\mathbf{y}))e^{i\mathbf{x}_1(\mathbf{k}_1-\mathbf{k}_1')}.$$

Here $\langle f| = \langle 0|\,\hat{\eta}_{\alpha'}(\mathbf{p}')\hat{\chi}_1(\mathbf{k}_1')$ and $|i\rangle = \hat{\chi}_1^+(\mathbf{k}_1)\,\hat{\eta}_\alpha^+(\mathbf{p})|0\rangle$. The simple calculations lead to

$$\langle f|\tilde{\tilde{\mathcal{H}}}^1_{\text{int}}|i\rangle = \frac{1}{\mathcal{V}}\Delta(\mathbf{p}+\mathbf{k}-\mathbf{p}'-\mathbf{k}')\int \mathrm{d}\mathbf{x}\;\varphi^*_{\alpha'}(\mathbf{x})\varphi_\alpha(\mathbf{x})\{\nu_{11}(\mathbf{q})e^{-i\mathbf{q}\mathbf{x}(m_2/M)}$$
$$+\,\nu_{21}(\mathbf{q})e^{i\mathbf{q}\mathbf{x}(m_1/M)}\},\quad \mathbf{q}=\mathbf{k}'-\mathbf{k}.$$

For Coulomb's interaction of particles we have

$$\nu_{11}(\mathbf{q}) = -\,\nu_{21}(\mathbf{q}) \equiv \nu(\mathbf{q}) = \frac{4\pi e^2}{q^2}.$$

Therefore, in the long-wave approximation ($qr_0 \ll 1$), one gets

$$\langle f|\tilde{\tilde{\mathcal{H}}}^1_{\text{int}}|i\rangle = 4\pi i e\frac{1}{\mathcal{V}}\Delta(\mathbf{p}+\mathbf{k}-\mathbf{p}'-\mathbf{k}')\frac{1}{q^2}\mathbf{q}\mathbf{d}_{\alpha'\alpha}, \tag{74}$$

where $\hat{\mathbf{d}} = e\hat{\mathbf{x}}$ is the dipole moment of atom [$\mathbf{d}_{\alpha'\alpha} = \int \mathrm{d}\mathbf{x}\;\varphi^*_{\alpha'}(\mathbf{x})\mathbf{x}\varphi_\alpha(\mathbf{x})$]. Note that the Hamiltonian

$$\tilde{\tilde{V}} = \int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2\;\hat{\chi}^+(\mathbf{x}_1)\hat{\chi}(\mathbf{x}_1)v_{\alpha'\alpha}(\mathbf{x}_1-\mathbf{x}_2)\,\hat{\eta}^+_{\alpha'}(\mathbf{x}_2)\,\hat{\eta}_\alpha(\mathbf{x}_2),$$

which describes the interaction between particles and bound states leads to the same result. Here $\hat{\chi}$, $\hat{\eta}_\alpha$ are the field operators of particles and bound states, respectively, and $v_{\alpha'\alpha}(\mathbf{x}) = (e/x^3)\mathbf{x}\mathbf{d}_{\alpha'\alpha}$. The relation (74) defines the interaction energy of the dipole moment $\mathbf{d}$ and electric charge e, which are at the distance $\mathbf{x}$ from each other.

VIII. THE VAN DER WAALS FORCES

In this section we investigate the forces acting between neutral atoms being in the ground state (the van der Waals forces) on the basis of the developed formalism. In order to solve this problem let us address the Schrödinger equation that determines the energy spectrum of the system,

$$\tilde{\tilde{\mathcal{H}}}\Phi = E\Phi,\quad \tilde{\tilde{\mathcal{H}}} = \tilde{\tilde{\mathcal{H}}}_0 + \tilde{\tilde{V}}. \tag{75}$$

Here $\tilde{\tilde{\mathcal{H}}}_0$ and $\tilde{\tilde{V}} = \tilde{\tilde{\mathcal{H}}}^1_{\text{int}} + \tilde{\tilde{\mathcal{H}}}^2_{\text{int}} + \tilde{\tilde{\mathcal{H}}}^3_{\text{int}}$ are defined by (37)–(40). Since the system in question consists of two atoms, we should seek the solution of (75) in the form

$$\Phi_{\alpha\beta}(\mathbf{X},\mathbf{X}') = \sum_{\lambda\rho}\int \mathrm{d}\mathbf{Y}\,\mathrm{d}\mathbf{Y}'\;K_{\alpha\beta;\lambda\rho}(\mathbf{X},\mathbf{X}';\mathbf{Y},\mathbf{Y}')\,\hat{\eta}^+_\lambda(\mathbf{Y})\,\hat{\eta}^+_\rho(\mathbf{Y}')\Phi_0. \tag{76}$$

The Hamiltonian of interaction $\tilde{\tilde{V}}$ is equal, in accordance with (38)–(40), to

$$\tilde{\tilde{V}} = \frac{1}{2}\int \mathrm{d}\mathbf{X}\,\mathrm{d}\mathbf{Y}\,\hat{\eta}^{+}_{\alpha}(\mathbf{X})\,\hat{\eta}^{+}_{\beta}(\mathbf{Y})\,\hat{\eta}_{\gamma}(\mathbf{Y})\,\hat{\eta}_{\delta}(\mathbf{X})G_{\delta\gamma;\alpha\beta}(\mathbf{X}-\mathbf{Y}), \tag{77}$$

where

$$G_{\delta\gamma;\alpha\beta}(\mathbf{X}-\mathbf{Y}) = \int \mathrm{d}\mathbf{x}\,\mathrm{d}\mathbf{y}\;\varphi^{*}_{\alpha}(\mathbf{x})\varphi^{*}_{\beta}(\mathbf{y})\varphi_{\gamma}(\mathbf{y})\varphi_{\delta}(\mathbf{x})\left\{\nu_{12}\left(\mathbf{X}-\mathbf{Y}-\frac{m_1\mathbf{x}+m_2\mathbf{y}}{M}\right)+\nu_{21}\left(\mathbf{X}-\mathbf{Y}+\frac{m_1\mathbf{y}+m_2\mathbf{x}}{M}\right)+\nu_{11}\left(\mathbf{X}-\mathbf{Y}+\frac{m_2}{M}(\mathbf{x}-\mathbf{y})\right)+\nu_{22}\left(\mathbf{X}-\mathbf{Y}-\frac{m_1}{M}(\mathbf{x}-\mathbf{y})\right)\right\}.$$

We suppose that the kinetic energy of atoms is small in comparison to the energy levels $|\varepsilon_\alpha|$ ($\varepsilon_\alpha<0$). In this case, according to (37), the operator $\tilde{\tilde{\mathcal{H}}}_0$ can be represented in the form

$$\tilde{\tilde{\mathcal{H}}}_0 = \sum_{\alpha}\int \mathrm{d}\mathbf{X}\;\varepsilon_\alpha\hat{\eta}^{+}_{\alpha}(\mathbf{X})\,\hat{\eta}_{\alpha}(\mathbf{X}).$$

It can be easily seen that

$$\begin{aligned}\tilde{\tilde{\mathcal{H}}}_0\,\hat{\eta}^{+}_{\lambda}(\mathbf{Z})\,\hat{\eta}^{+}_{\rho}(\mathbf{Z}')\Phi_0 &= (\varepsilon_\lambda+\varepsilon_\rho)\,\hat{\eta}^{+}_{\lambda}(\mathbf{Z})\,\hat{\eta}^{+}_{\rho}(\mathbf{Z}')\Phi_0,\\ \tilde{\tilde{V}}\hat{\eta}^{+}_{\lambda}(\mathbf{Z})\,\hat{\eta}^{+}_{\rho}(\mathbf{Z}')\Phi_0 &= \sum_{\alpha\beta}G_{\lambda\rho;\alpha\beta}(\mathbf{Z}-\mathbf{Z}')\,\hat{\eta}^{+}_{\alpha}(\mathbf{Z})\,\hat{\eta}^{+}_{\beta}(\mathbf{Z}')\Phi_0.\end{aligned} \tag{78}$$

These formulas show that we can seek the solution of (75) in a more simple, rather than (76), form

$$\Phi_{\alpha\beta}(\mathbf{X},\mathbf{X}') = \sum_{\lambda\rho}K_{\alpha\beta;\lambda\rho}(\mathbf{X},\mathbf{X}')\,\hat{\eta}^{+}_{\lambda}(\mathbf{X})\,\hat{\eta}^{+}_{\rho}(\mathbf{X}')\Phi_0,$$

so that the coordinates of atoms have the definite values in the state $\Phi_{\alpha\beta}(\mathbf{X},\mathbf{X}')$. Upon substituting this expression into (75) and using (78), one finds

$$K_{\alpha\beta;\gamma\delta}(\varepsilon_\gamma+\varepsilon_\delta)+\sum_{\lambda\rho}K_{\alpha\beta;\lambda\rho}G_{\lambda\rho;\gamma\delta}(\mathbf{Z}-\mathbf{Z}') = E_{\alpha\beta}K_{\alpha\beta;\gamma\delta}.$$

A perturbative approach for this equation can be easily developed in the domain of great $|\mathbf{Z}-\mathbf{Z}'|$ when the quantity $G_{\lambda\rho;\gamma\delta}(\mathbf{Z}-\mathbf{Z}')$ becomes small [see (77)]. Expanding $K_{\alpha\beta;\gamma\delta}$ in G,

$$K_{\alpha\beta;\gamma\delta} = K^{0}_{\alpha\beta;\gamma\delta}+K^{1}_{\alpha\beta;\gamma\delta}+K^{2}_{\alpha\beta;\gamma\delta}+\cdots,$$

$$E_{\alpha\beta} = E^{0}_{\alpha\beta}+E^{1}_{\alpha\beta}+E^{2}_{\alpha\beta}+\cdots,$$

one obtains in the zeroth order

$$K^{0}_{\alpha\beta;\gamma\delta}(\varepsilon_\gamma+\varepsilon_\delta) = E^{0}_{\alpha\beta}K^{0}_{\alpha\beta;\gamma\delta},$$

whence

$$K^{0}_{\alpha\beta;\gamma\delta} = K^{0}_{\alpha\beta}\delta_{\alpha\gamma}\delta_{\beta\delta},\quad E^{0}_{\alpha\beta} = \varepsilon_\alpha+\varepsilon_\beta.$$

Taking into account this result we have in the first approximation,

$$K^{1}_{\alpha\beta;\gamma\delta}(\varepsilon_\gamma+\varepsilon_\delta)+K^{0}_{\alpha\beta}G_{\alpha\beta;\gamma\delta}(\mathbf{Z}-\mathbf{Z}') = (\varepsilon_\alpha+\varepsilon_\beta)K^{1}_{\alpha\beta;\gamma\delta}+E^{1}_{\alpha\beta}K^{0}_{\alpha\beta}\delta_{\alpha\gamma}\delta_{\beta\delta}.$$

By setting here $\alpha=\gamma$, $\beta=\delta$, one gets

$$E^1_{\alpha\beta} = G_{\alpha\beta;\alpha\beta}(\mathbf{Z}-\mathbf{Z}'), \tag{79}$$

and for $\alpha,\beta \neq \gamma,\delta$,

$$K^1_{\alpha\beta;\gamma\delta} = K^0_{\alpha\beta}\frac{G_{\alpha\beta;\gamma\delta}(\mathbf{Z}-\mathbf{Z}')}{(\varepsilon_\alpha+\varepsilon_\beta-\varepsilon_\gamma-\varepsilon_\delta)}, \quad \alpha,\beta \neq \gamma,\delta. \tag{80}$$

The second order of the perturbative approach gives

$$K^2_{\alpha\beta;\gamma\delta}(\varepsilon_\gamma+\varepsilon_\delta) + \sum_{\lambda\rho} K^1_{\alpha\beta;\lambda\rho}G_{\lambda\rho;\gamma\delta}(\mathbf{Z}-\mathbf{Z}') = (\varepsilon_\alpha+\varepsilon_\beta)K^2_{\alpha\beta;\gamma\delta} + E^1_{\alpha\beta}K^1_{\alpha\beta;\gamma\delta} + E^2_{\alpha\beta}K^0_{\alpha\beta;\gamma\delta}.$$

Taking here $\alpha=\gamma$, $\beta=\delta$, one finds

$$\sum_{\lambda\rho} K^1_{\alpha\beta;\lambda\rho}G_{\lambda\rho;\alpha\beta}(\mathbf{Z}-\mathbf{Z}') = E^1_{\alpha\beta}K_{\alpha\beta;\alpha\beta} + K^0_{\alpha\beta}E^2_{\alpha\beta},$$

whence, according to (79) and (80), we have

$$E^2_{\alpha\beta} = \sum_{\lambda\rho}{}' \frac{G_{\alpha\beta;\lambda\rho}(\mathbf{Z}-\mathbf{Z}')G_{\lambda\rho;\alpha\beta}(\mathbf{Z}-\mathbf{Z}')}{(\varepsilon_\alpha+\varepsilon_\beta-\varepsilon_\lambda-\varepsilon_\rho)}. \tag{81}$$

The prime above the sum means that the terms with $\lambda=\alpha$, $\rho=\beta$ are omitted. The state vector $\Phi_{\alpha\beta}(\mathbf{X},\mathbf{X}')$ in the main approximation of the perturbative approach is determined by

$$\Phi_{\alpha\beta}(\mathbf{X},\mathbf{X}') = K^0_{\alpha\beta}\hat{\eta}^+_\alpha(\mathbf{X})\,\hat{\eta}^+_\beta(\mathbf{X}')\Phi_0 + \cdots$$

[the constant $K^0_{\alpha\beta}$ may be found from the normalization relation, $(\Phi_{\alpha\beta},\Phi_{\alpha\beta})=1$]. Formulas (79) and (81) for $E^1_{\alpha\beta}$ and $E^2_{\alpha\beta}$ give us the corrections to the energy levels $E^0_{\alpha\beta}=\varepsilon_\alpha+\varepsilon_\beta$. It follows from the obtained formulas that the energy of two atoms being in the ground state α and spaced apart for sufficiently long distances is defined by

$$E_{\alpha\alpha} = 2\varepsilon_\alpha + G_{\alpha\alpha;\alpha\alpha}(\mathbf{Z}-\mathbf{Z}') + \sum_{\lambda\rho}{}' \frac{G_{\alpha\alpha;\lambda\rho}(\mathbf{Z}-\mathbf{Z}')G_{\lambda\rho;\alpha\alpha}(\mathbf{Z}-\mathbf{Z}')}{(2\varepsilon_\alpha-\varepsilon_\lambda-\varepsilon_\rho)} + \cdots . \tag{82}$$

Let us prove now that $G_{\alpha\alpha;\alpha\alpha}(\mathbf{Z}-\mathbf{Z}')\equiv 0$. In doing so we use the following formula:[10]

$$\frac{1}{\sqrt{R^2-2R\rho x+\rho^2}} = \frac{1}{|\mathbf{R}-\boldsymbol{\rho}|} = \frac{1}{R} + \sum_{n=1}^{\infty}\left(\frac{\rho}{R}\right)^n \mathcal{P}_n(x),$$

where $x=\cos\vartheta$, ϑ is the angle between vectors $\mathbf{R}$ and $\boldsymbol{\rho}$, and $\mathcal{P}_n(x)$ are the Legendre polynomials. Noting that [see (77)]

$$G_{\alpha\alpha;\alpha\alpha}(\mathbf{Z}-\mathbf{Z}') = \int d\mathbf{x}\,d\mathbf{y}|\varphi_\alpha(\mathbf{x})|^2|\varphi_\alpha(\mathbf{y})|^2\Bigg\{\nu_{12}\left(\mathbf{Z}-\mathbf{Z}'-\frac{m_1\mathbf{x}+m_2\mathbf{y}}{M}\right) + \nu_{21}\left(\mathbf{Z}-\mathbf{Z}'+\frac{m_1\mathbf{y}+m_2\mathbf{x}}{M}\right)$$
$$+ \nu_{11}\left(\mathbf{Z}-\mathbf{Z}'+\frac{m_2}{M}(\mathbf{x}-\mathbf{y})\right) + \nu_{22}\left(\mathbf{Z}-\mathbf{Z}'-\frac{m_1}{M}(\mathbf{x}-\mathbf{y})\right)\Bigg\},$$

we come, taking into account the spherical symmetry of $|\varphi_\alpha(\mathbf{x})|^2$, to

$$G_{\alpha\alpha;\alpha\alpha}(\mathbf{Z}-\mathbf{Z}') = 0. \tag{83}$$

We have also employed here that according to (43),

$$\nu_{ab}(\mathbf{Z}-\mathbf{Z}')=\frac{e_a e_b}{|\mathbf{Z}-\mathbf{Z}'|},\quad e_1=-e_2=e.$$

Let us find now $G_{\alpha\alpha;\lambda\rho}(\mathbf{Z}-\mathbf{Z}')$,

$$G_{\alpha\alpha;\lambda\rho}(\mathbf{Z}-\mathbf{Z}')=\int \mathrm{d}\mathbf{x}\,\mathrm{d}\mathbf{y}\;\varphi_\rho^*(\mathbf{x})\varphi_\lambda^*(\mathbf{y})\varphi_\alpha(\mathbf{y})\varphi_\alpha(\mathbf{x})\left\{\nu_{12}\left(\mathbf{Z}-\mathbf{Z}'-\frac{m_1\mathbf{x}+m_2\mathbf{y}}{M}\right)+\nu_{21}\left(\mathbf{Z}-\mathbf{Z}'+\frac{m_1\mathbf{y}+m_2\mathbf{x}}{M}\right)+\nu_{11}\left(\mathbf{Z}-\mathbf{Z}'+\frac{m_2}{M}(\mathbf{x}-\mathbf{y})\right)+\nu_{22}\left(\mathbf{Z}-\mathbf{Z}'-\frac{m_1}{M}(\mathbf{x}-\mathbf{y})\right)\right\}.$$

The presence of multipliers $\varphi_\alpha(\mathbf{y})$ and $\varphi_\alpha(\mathbf{x})$ makes it possible to expand the expression in braces in powers of $\mathbf{x}$, $\mathbf{y}$. As a result we have

$$G_{\alpha\alpha;\beta\lambda}(\mathbf{Z}-\mathbf{Z}')=\frac{1}{|\mathbf{Z}-\mathbf{Z}'|^3}(-3(\mathbf{n}\mathbf{d}_{\beta\alpha})(\mathbf{n}\mathbf{d}_{\lambda\alpha})+(\mathbf{d}_{\beta\alpha}\mathbf{d}_{\lambda\alpha})),$$

where

$$\mathbf{n}=\frac{\mathbf{Z}-\mathbf{Z}'}{|\mathbf{Z}-\mathbf{Z}'|},\quad \mathbf{d}_{\beta\alpha}=e\int \mathrm{d}\mathbf{x}\,\mathbf{x}\varphi_\beta^*(\mathbf{x})\varphi_\alpha(\mathbf{x})$$

($\mathbf{d}_{\beta\alpha}$ are the matrix elements of the dipole moment of atom). Thus, the potential energy of interaction between atoms, $V(\mathbf{Z}-\mathbf{Z}')$ is defined by[6]

$$V(\mathbf{Z}-\mathbf{Z}')\equiv E_{\alpha\alpha}^2-2\varepsilon_\alpha=\frac{1}{|\mathbf{Z}-\mathbf{Z}'|^6}\sum_{\beta\lambda}{}'\frac{|-3(\mathbf{n}\mathbf{d}_{\beta\alpha})(\mathbf{n}\mathbf{d}_{\lambda\alpha})+(\mathbf{d}_{\beta\alpha}\mathbf{d}_{\lambda\alpha})|^2}{2\varepsilon_\alpha-\varepsilon_\beta-\varepsilon_\lambda}<0.$$

Since $\varepsilon_\beta,\varepsilon_\lambda>\varepsilon_\alpha$, $V(\mathbf{Z}-\mathbf{Z}')<0$. Therefore, the attractive forces (the van der Waals forces) act between the neutral atoms at long distances.

Consider now the scattering of a compound particle by compound particle, which are in the ground state. We start from the scattering matrix representation in terms of T-operators (67). Accurate to the terms, which are of the second order in interaction $\tilde{\tilde{V}}$ between the atoms [see (68)], one gets

$$\hat{S}=1-2\pi i\int_{-\infty}^{\infty}\mathrm{d}E\;\delta(E-\tilde{\tilde{\mathcal{H}}}_0)\tilde{\tilde{V}}\delta(E-\tilde{\tilde{\mathcal{H}}}_0)-2\pi i\int_{-\infty}^{\infty}\mathrm{d}E\;\delta(E-\tilde{\tilde{\mathcal{H}}}_0)\tilde{\tilde{V}}\frac{1}{E-\tilde{\tilde{\mathcal{H}}}_0+i\eta}\tilde{\tilde{V}}\delta(E-\tilde{\tilde{\mathcal{H}}}_0).\tag{84}$$

Neglecting the kinetic energy of atoms we replace in the resolvent $(E-\tilde{\tilde{\mathcal{H}}}_0+i\eta)^{-1}$ the Hamiltonian of free particles $\tilde{\tilde{\mathcal{H}}}_0$ by the Hamiltonian $\tilde{\tilde{H}}_0$ of atoms in the rest [see (37)],

$$\tilde{\tilde{\mathcal{H}}}_0\to\tilde{\tilde{H}}_0=\sum_\alpha\int \mathrm{d}\mathbf{x}\;\varepsilon_\alpha\hat{\eta}_\alpha^+(\mathbf{x})\,\hat{\eta}_\alpha(\mathbf{x})$$

(in the low-energy limit we cannot do this under the argument of the δ-function).

Since we study the collision of two atoms and the number of atoms is conserved during the process of collision, we can restrict ourselves by considering this process in the two-particle subspace with the following completeness condition:

$$\frac{1}{2}\int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2 \sum_{\alpha_1,\alpha_2} \hat{\eta}^+_{\alpha_1}(\mathbf{x}_1)\,\hat{\eta}^+_{\alpha_2}(\mathbf{x}_2)|0\rangle\langle 0|\,\hat{\eta}_{\alpha_2}(\mathbf{x}_2)\,\hat{\eta}_{\alpha_1}(\mathbf{x}_1) = 1. \tag{85}$$

In this case formulas (78) are true. Since the atoms are in the ground state, (83) is also valid and, therefore, the matrix element of $\hat{S}$-matrix turns to zero in the first approximation of the perturbation theory.

The second approximation of the perturbation theory is defined, according to (84) and (85), by the formula

$$\tilde{\hat{V}}\frac{1}{E-\tilde{\hat{H}}_0+i\eta}\tilde{\hat{V}} = \frac{1}{2}\sum_{\alpha_1,\alpha_2}\sum_{\beta_1,\beta_2}\sum_{\gamma_1,\gamma_2}\int \mathrm{d}\mathbf{x}_1\mathrm{d}\mathbf{x}_2 \frac{1}{E-\varepsilon_{\alpha_1}-\varepsilon_{\alpha_2}+i\eta} G_{\alpha_1\alpha_2;\beta_1\beta_2}(\mathbf{x}_1-\mathbf{x}_2)\,\hat{\eta}^+_{\beta_1}(\mathbf{x}_1)\,\hat{\eta}^+_{\beta_2}(\mathbf{x}_2)|0\rangle$$
$$\times\langle 0|\,\hat{\eta}_{\gamma_1}(\mathbf{x}_1)\,\hat{\eta}_{\gamma_2}(\mathbf{x}_2) G^+_{\gamma_1\gamma_2;\alpha_1\alpha_2}(\mathbf{x}_1-\mathbf{x}_2).$$

In the two-particle subspace this formula is equivalent to

$$\tilde{\hat{V}}\frac{1}{E-\tilde{\hat{H}}_0+i\eta}\tilde{\hat{V}} = \int \mathrm{d}\mathbf{x}_1\,\mathrm{d}\mathbf{x}_2 \sum_{\beta_1,\beta_2}\sum_{\gamma_1,\gamma_2} \hat{\eta}^+_{\beta_1}(\mathbf{x}_1)\,\hat{\eta}^+_{\beta_2}(\mathbf{x}_2) V_{\beta_1\beta_2;\gamma_1\gamma_2}(\mathbf{x}_1-\mathbf{x}_2;E)\,\hat{\eta}_{\gamma_1}(\mathbf{x}_1)\,\hat{\eta}_{\gamma_2}(\mathbf{x}_2),$$

where

$$V_{\beta_1\beta_2;\gamma_1\gamma_2}(\mathbf{x}_1-\mathbf{x}_2;E) = \sum_{\alpha_1\alpha_2}\frac{1}{E-\varepsilon_{\alpha_1}-\varepsilon_{\alpha_2}+i\eta} G^+_{\gamma_1\gamma_2;\alpha_1\alpha_2}(\mathbf{x}_1-\mathbf{x}_2) G_{\alpha_1\alpha_2;\beta_1\beta_2}(\mathbf{x}_1-\mathbf{x}_2).$$

Since the initial and final states of a particle are the ground states, the scattering matrix in the two-particle subspace can be represented in the form

$$\hat{S} = -2\pi i\int_{-\infty}^{\infty}\mathrm{d}E\;\delta(E-\tilde{\hat{\mathcal{H}}}_0)\hat{V}_{\mathrm{eff}}\delta(E-\tilde{\hat{\mathcal{H}}}_0),$$

where

$$\hat{V}_{\mathrm{eff}} = \frac{1}{2}\int \mathrm{d}\mathbf{x}_1\int \mathrm{d}\mathbf{x}_2\;\hat{\eta}^+_{\alpha_1}(\mathbf{x}_1)\,\hat{\eta}^+_{\alpha_2}(\mathbf{x}_2) V_{\mathrm{eff}}(\mathbf{x}_1-\mathbf{x}_2)\,\hat{\eta}_{\alpha_2}(\mathbf{x}_2)\,\hat{\eta}_{\alpha_1}(\mathbf{x}_1),$$

$$V_{\mathrm{eff}}(\mathbf{x}_1-\mathbf{x}_2) = \sum_{\beta_1\beta_2}\frac{G^+_{\alpha\alpha;\beta_1\beta_2}(\mathbf{x}_1-\mathbf{x}_2)G_{\beta_1\beta_2;\alpha\alpha}(\mathbf{x}_1-\mathbf{x}_2)}{2\varepsilon_\alpha-\varepsilon_{\beta_1}-\varepsilon_{\beta_2}}.$$

We can see that the second order in $\tilde{\hat{V}}$ of perturbation theory for $\hat{S}$-matrix is equivalent to the first order of perturbation theory over effective interaction $\hat{V}_{\mathrm{eff}}$. This effective interaction is determined by van der Waals forces [see formula (82)].

It follows from (39), that the Hamiltonian of interaction of atoms at low energies is defined by

$$\tilde{\hat{V}} = \int \mathrm{d}\mathbf{x}_1\,d\mathbf{x}_2\,v_{\alpha\beta;\gamma\delta}(\mathbf{x}_1-\mathbf{x}_2)\,\hat{\eta}^+_\alpha(\mathbf{x}_1)\,\hat{\eta}^+_\beta(\mathbf{x}_2)\,\hat{\eta}_\gamma(\mathbf{x}_2)\,\hat{\eta}_\delta(\mathbf{x}_1),$$

where

$$v_{\alpha\beta;\gamma\delta}(\mathbf{x}) = \frac{1}{x^5}(x^2(\mathbf{d}_{\alpha\delta}\mathbf{d}_{\beta\gamma}) - 3(\mathbf{x}\mathbf{d}_{\alpha\delta})(\mathbf{x}\mathbf{d}_{\delta\gamma})).$$

This Hamiltonian corresponds to the dipole–dipole interaction of atoms.

IX. CONCLUSION

The goal of this paper was to develop a microscopic approach for describing the physical processes in many-particle systems in the presence of bound states of particles. To achieve this goal we developed an approximate second quantization method for systems with bound states of particles.

The basic results obtained in this paper are the following:

(1) The Fock space was introduced in the second quantization formalism. In this space the creation and annihilation operators of elementary particles $\hat{\chi}^+$, $\hat{\chi}$ and their bound states $\hat{\eta}^+$, $\hat{\eta}$ were introduced on an equal status.

(2) The operators of basic physical quantities acting in this space were constructed. These operators include the Hamiltonians of interaction between elementary particles and their bound states.

(3) It was shown that in the approximation when the radius of interaction is small the above-mentioned Hamiltonians transform into the well-known Hamiltonians for Coulomb's and dipole interactions between the particles of various kinds.

(4) The nonrelativistic quantum electrodynamics of charged and neutral (the bound states) particles was constructed.

(5) The various physical effects including the theory of the van der Waals forces acting between atoms were considered as the approbation of the developed formalism. The description of such effects within the usual formalism requires more considerable efforts associated with introduction of the interaction between neutral currents of bound states and electromagnetic field.

(6) More detailed calculations, which fall out of the limits of our approximation should result in appearance of three- and many-body interactions between unbound particles and two-body bound states. These many-body interactions should be consistent with pair interaction of original particles. The appearance of these many-body terms is analogous to the origin of the terms with photon–photon scattering in transition from the usual standard Lagrangian to the effective low-energy Euler–Heisenberg Lagrangian of quantum electrodynamics.

Especially we would like to emphasize a role of the obtained Hamiltonians, which describe the interaction of quasineutral particles (the bound states of charged fermions) with electromagnetic field, the elementary particles with bound states, and also the bound states with bound states. On the basis of these Hamiltonians one can study such phenomena as Bose–Einstein condensation in a gas of excited atoms, the interaction of condensates with an electromagnetic field in Bose and Fermi systems. These Hamiltonians can be also the basis of the kinetic theory for systems with bound states of particles.

Finally we would like to stress that the developed method can be easily generalized to the case of bound states consisting of more than two particles. The generalization of the offered method for describing the systems with bound states of bosons and also of bosons and fermions taking into account the spin of particles can be also performed without principal difficulties.

Using the Iqbal–Netzike–Vafa dictionary giving the correspondence between the H_2 homology of del Pezzo surfaces and *p*-branes, we develop a way to approach the system of brane bounds in M-theory on $\mathbb{S}^1$. We first review the structure of 10-dimensional quantum Hall soliton (QHS) from the view of M-theory on $\mathbb{S}^1$. Then, we show how the *D*0 dissolution in *D*2-brane is realized in M-theory language and derive the *p*-brane constraint equations used to define appropriately the QHS. Finally, we build an algebraic geometry realization of the QHS in type IIA superstring and show how to get its type IIB dual. Other aspects are also discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1834695]

I. INTRODUCTION

A few years ago, it has been conjectured in Ref. 1, see also Ref. 2, that a specific assembly of a system of *KD*0, *D*2 and *N D*6 branes and *N* fundamental *F*1 strings, stretching between *D*2 and *D*6, has a low energy dynamics similar to the fundamental state of fractional quantum Hall (FQH) systems. There, the boundary states of the *F*1 strings ending on the *D*2 brane are interpreted as the FQH particles moving in the *D*2-brane world volume. The external strong magnetic field *B* is represented by a large number of *D*0 branes dissolved in *D*2 and the dynamics of these particles is modeled by a noncommutative Chern–Simons (NCCS) U(1) gauge field theory.[3] Soon after this proposal, several constructions were considered pushing forward this analogy. [4–12] Susskind *et al.* idea was also extended to quantum Hall solitons that are not of Laughlin type,[13] in particular the quantum Hall solitons modeling Haldane hierarchy and multilayer systems as proposed in Ref. 14.

On the other hand, it has been observed recently by Iqbal–Neitzke–Vafa (INV)[15] that there is remarkable correspondence between *p*-branes in M-theory on torii and holomorphic curves in del Pezzo surfaces. A dictionary characterizing this correspondence was given. The result of this work was particularly focused on the study of a mysterious duality in the toroidal compactification of M-theory, for other applications see also Refs. 16 and 17. But here we will use differently the INV link between del Pezzo and M-theory by developing a new method to approach brane systems. The originality of our construction rests on the fact that INV correspondence can be also used to study geometric aspects of brane physics using the power of algebraic geometry and homology. Among our results, we quote the derivation of new representations of *p*-brane systems using the H_2 homology of algebraic curves in del Pezzo surfaces.

To fix the idea on the way we will be doing things, we focus, in a first step, on a special system of branes and show how new representations can be built. The system we will be dealing with here concerns mainly the usual quantum Hall soliton (QHS) we have introduced in the beginning of this introduction. But in the discussion section, we will also draw the lines of other constructions, in particular the way QHS is realized in type IIB superstring on $\mathbb{S}^1$ as well as higher dimensional extensions.

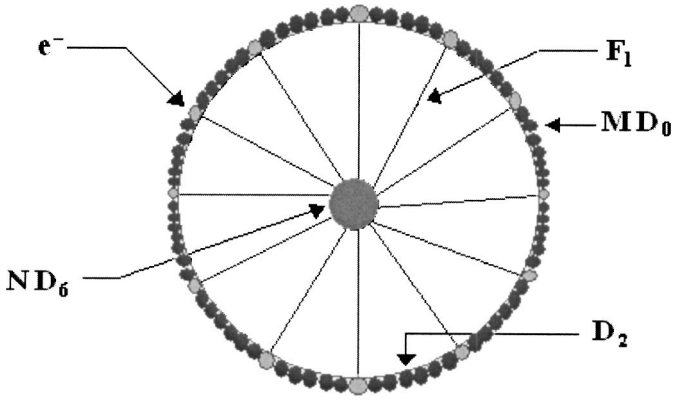

FIG. 1. This figure represents the type IIA stringy representation of a fractional quantum Hall soliton.

The principal aim of this work is then to use results on 10-dimensional QHS, the INV correspondence as well as string theory and mathematical results to develop new realizations of quantum Hall solitons using algebraic geometry curves in del Pezzo surfaces. For simplicity, we will give here the main lines of the method on Susskind *et al.* QHS. A detailed analysis and applications dealing with other types of brane systems will be given in Ref. 18.

The presentation of this paper is as follows. In Sec. II, we describe briefly the quantum Hall soliton in type IIA superstring. We first review the structure of the 10-dimensional QHS as formulated in the literature and then give its representation in the language of the 11-dimensional M-theory on $\mathbb{S}^1$. This change from type IIA to M-theory allows us to reach the two remarkable points: (i) give a geometric realization of the standard idea of dissolution $D0$ branes in $D2$ and (ii) derive the appropriate geometric constraint equations that define QHS. In Sec. III, we review the homology of del Pezzo surfaces as it is one of the basic tools in construction and in Sec. IV we describe the INV correspondence. In Sec. V we first identify the constraint equations for QHS using the H_2 homology of del Pezzo. Then we develop a realization of the Hall soliton using intersecting classes of complex curves in del Pezzo. In Sec. VI, we give our conclusion and make a discussion.

II. QUANTUM HALL SOLITONS

One remarkable observation of Susskind and collaborators in the derivation of the quantum Hall soliton is that the usual $(1+2)$ dimensional condensed matter fractional quantum Hall (FQH) phase has a striking similarity with a specific p-brane configuration in type IIA superstring theory. Following Refs. 1 and 2, see also Ref. 19, there is a one to one correspondence between the three-dimensional (3D) FQH systems of condensed matter physics and the low energy dynamics of brane bounds involving $D0, D2$, and $D6$ branes of the 10-dimensional uncompactified type IIA superstring. There is also $F1$ strings stretching between $D2$ and $D6$ branes, $F1$ ends on $D2$ have an interpretation in terms of FQH particles (Hall electrons). Let us comment briefly on this configuration to which we shall refer hereafter as the type IIA stringy representation of the quantum Hall soliton. Denoting the usual IIA string (bosonic) coordinate field variables $X^\mu(\tau,\sigma)$ by the following equivalent and appropriate ones

$$\{t(\tau), \quad \varrho(\tau,\sigma), \quad \vartheta(\tau,\sigma), \quad \varphi(\tau,\sigma), \quad \{y^i(\tau,\sigma)\}_{4\leqslant i\leqslant 9;}\}, \tag{2.1}$$

where τ and σ are the usual string world sheet variables, the above mentioned p-brane bound system, called also quantum Hall soliton (QHS), is built as follows, see Fig. 1 for illustration.

A. Brane configuration

If forgetting about edge excitations which may be modeled by *NS*5 branes, the simplest structure of QHS is parametrized in terms of the above 10-dimensional string coordinates as follows.

(a) One two space dimensional spherical *D*2 brane; it plays a role of the world volume in FQH systems of condensed matter physics and is parametrized by the spherical coordinates,

$$\{t, \quad \varrho = R; \quad 0 \leqslant \vartheta \leqslant \pi; \quad 0 \leqslant \varphi \leqslant 2\pi; \quad \mathbf{0_6}\}. \tag{2.2}$$

At fixed time, this *D*2 brane is embedded in $R^3 \sim R^+ \times S^2$ and for large values of the radius, *D*2 may be thought of locally as $R^{1,2}$ which is also interpreted as the space–time of the three-dimensional Chern–Simons gauge theory.

(b) *N* coincident flat six-dimensional space *D*6 branes located at the origin of *D*2 and parametrized collectively by the y^i internal Euclidean coordinates as

$$\{t, \quad \mathbf{0_3}, \quad (y^4, \ldots, y^9)\}. \tag{2.3}$$

It can be thought of as an external source of charge density $J^0 \propto N\delta^3(x)$ at the origin $(x^1, x^2, x^3) = (0,0,0)$ of the spherical *D*2 brane.

(c) *N* fundamental strings *F*1 stretching between *D*2 and *D*6 branes and parametrized by

$$\{t, \quad 0 \leqslant \varrho \leqslant R, \quad \mathbf{0_2}, \quad \mathbf{0_6}\}. \tag{2.4}$$

The *F*1 string ends on the *D*2 brane are associated to the electrons of the three-dimensional condensed matter FQH fluids.

(d) *K D*0 branes dissolved into the *D*2 brane; they define the flux quanta associated to the external magnetic field *B* of FQH systems. Recall also that *D*0 and *D*6 are the electric–magnetic dual.

B. Methods

Since the original work linking fractional quantum Hall fluids and NC Chern–Simons gauge theory,[3] several methods have been developed to deal with such kinds of systems.[5,9–20] Matrix model approach from Polychronakos[21] is one of these methods which has been getting a particular interest in the literature. In this matrix model formulation, the FQH particles in the Laughlin state are described by two $N \times N$ Hermitian matrices $X^1_{ij}(t)$ and $X^2_{ij}(t)$ [in our coordinate choice $X^1_{ij}(t) \sim R \sin \vartheta_{ij}(t) \cos \varphi_{ij}(t)$ and $X^2(t) \sim R \sin \vartheta_{ij}(t) \sin \varphi_{ij}(t)$]. For large radius *R*, the two spheres can be locally approximated by a flat patch of the $\mathbb{R}^2$ plane and so one can neglect, in a leading approximation, the curvature effect. In the infinite limit of *N* and *M* (strong external magnetic field), the one-dimensional matrix fields $X^1_{ij}(t)$ and $X^2(t)$ are mapped to the usual $(2+1)$ fields, a behavior which is nicely given by the Susskind map,

$$X^i(t,y) = y^i + \theta \varepsilon^{ij} A_j(t,y) \tag{2.5}$$

as discussed in Refs. 3 and 10. In this relation, one recognizes the $(1+2)$ Chern–Simons gauge field $A_j(t,y)$ and the noncommutativity parameter θ induced by the presence of external *B*.

In our present work, we will use a completely different approach to deal with the QHS. This method is based on algebraic geometry of del Pezzo surfaces and too particularly on their H_2 homology. In our way, one may naturally define all physical quantities one encounters in type IIA stringy representation of QHS and condensed matter FQH fluids. For the present presentation however and for the purpose of illustration of the technique, we will simplify the construction. We skip unnecessary details and essentially focus on the path towards the algebraic geometry realization of QHS.

To proceed, let us say some words on our strategy towards the algebraic geometry realization of QHS. This will be done in four principal steps: (i) In step one, we reformulate the type IIA stringy representation of QHS as a constrained system of *p* branes. Here we show that the

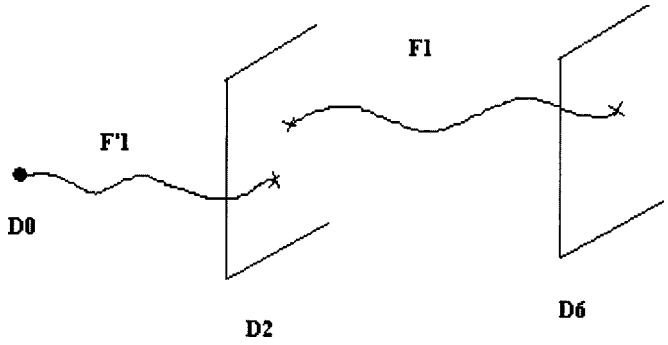

FIG. 2. This figure represents the type IIA stringy representation of a fractional quantum Hall soliton. The ends of $F'1$ strings on $D2$ are the $D0$ branes appearing in the Susskind *et al.* QHS. They are in one to one with the K $D0$'s associated with the eleventh (compact) dimension.

appropriate way to do it is in fact from the view of M-theory on $\mathbb{S}^1$. In this case, we give a geometric realization of the idea of dissolution of $D0$ branes in $D2$ and show that QHS particles, namely electrons and flux quanta, can be treated in a quite similar manner. This step permits us to identify the appropriate geometric constraint equations that define QHS. (ii) In step two, we review the INV correspondence and describe how p branes are represented in algebraic geometry of del Pezzo surfaces. We take this opportunity to draw the main lines of a method of representing homology classes in the del Pezzo surface $\mathbb{B}_1$ by using $F1$ strings and $D2$ branes. This method uses triangulation property of surfaces and is also motivated from formal similarities with Feynman rules in quantum Φ^3 theory. (iii) In step three, we reformulate the structure of the stringy QHS into the language of homology of del Pezzo surfaces. We first give the translation of constraint equations in terms of H_2 homology of $\mathbb{B}_1$, then we study necessary conditions for their solutions. (iv) In the last step, we develop a class of solutions of the homological constraint equations giving an algebraic geometry realization of QHS.

We begin by noting that p branes involved in the above QHS may, roughly speaking, be thought of as sets of points in $p+1$ dimensions. As far as brane links are concerned, we clearly see that intersections between the QHS branes may be naively defined as set intersections as follows:

$$D2 \cap F1 = 1, \quad D2 \cap D6 = 0, \quad D6 \cap F1 = 1. \tag{2.6}$$

For the case of N fundamental strings, the first equation of the above relations extends as $D2 \cap (NF1) = N$ and so on. In 10-dimensional type IIA stringy representation, these relations are natural identities that characterize the QHS and so they should be fulfilled in any other representation of QHS including the algebraic geometry one we are after. However to have a consistent description, we still need information about the K $D0$ branes of the QHS and which have no reference in Eq. (2.6). This brings us to our first comment regarding this special property, which to our knowledge have not been sufficiently explored in the literature. The idea of $D0$ dissolution in $D2$ is in fact strongly related with type IIA representation of QHS requiring that the total space–time dimension of the soliton should be equal to 10. However in 11-dimension M-theory on $\mathbb{S}^1$, we have an extra (compact) dimension which allows us to engineer in a nice geometric way the $D0$ branes in perfect agreement with INV correspondence. The key idea of our representation is summarized as follows: The $D0$ branes (flux quanta) dissolved in $D2$ are treated in M-theory on $\mathbb{S}^1$ on equal footing as the electrons in the sense that they will be also viewed as ends of $F1'$ strings, but this time, stretching between $D2$ and K $D0$ branes, see Fig. 2 for illustration. From this representation, one can clearly see that the total space–time dimension of the QHS is as in the M-theory on $\mathbb{S}^1$. One can also see that $D0$ particles in QHS are associated with the compact direction $\mathbb{S}^1$ and moreover has much to do with the homological class of curve E_M in del Pezzo surface $\mathbb{B}_1$ considered in Ref. 15. As such we have, in addition to Eq. (2.6), the following constraint equations of QHS formulated in the language of M-theory on circle $\mathbb{S}^1$,

$$F'1 \cap D2 = 1, \quad F'1 \cap D6 = 0,$$

$$D0 \cap F'1 = 1, \quad F'1 \cap F1 = 0,$$

$$D0 \cap D2 = 0, \quad D0 \cap D6 = 0, \tag{2.7}$$

where, leaving apart the brane dimension and their charge, there is a quite similar analogy between the role of $D0$ and $D6$ branes. With this reformulation of QHS in M-theory on $\mathbb{S}^1$ and to which we shall continue to refer to it as type IIA stringy representation, we end step one and are now in position to go ahead by following the drawn path. In the second step, we describe briefly some useful tools on the H_2 homology of del Pezzo surfaces and the INV correspondence between p branes and complex curves.

III. DEL PEZZO SURFACES

In this section, we focus on two basic aspects. First we give some useful tools on del Pezzo surfaces $\mathbb{B}_k$, $k=1,2,\ldots$, and particularly on the H_2 homology of their class of curves. Then we consider the main lines of the toric representation of $\mathbb{B}_1$ as this will be also relevant for later analysis.

A. General on $\mathbb{B}_k$

del Pezzo surfaces $\mathbb{B}_k$ are complex dimension two compact manifolds that are obtained by blowing up to eight points ($k \leqslant 8$) in complex projective space $\mathbb{P}^2$.[22,23] These $\mathbb{B}_k$ complex surfaces are simply laced manifolds and their homology $H_2(\mathbb{B}_k, Z)$ is generated by the line class H of $\mathbb{P}^2$ and the exceptional curves E_i generating the k blow ups of $\mathbb{P}^2$. The use of this line's homology turns out to be very helpful in the present study. It offers a powerful tool to study holomorphic curves in del Pezzo and has the advantage of giving a quite complete characterization of analytic curves without the need to specify the explicit form of complex algebraic geometry equations.

Recall that on a compact algebraic and projective variety X, a generic divisor $\mathcal{D}=\Sigma_i n_i \mathcal{D}_i$ is a finite formal linear combination of complex codimension one analytic subvarieties $\mathcal{D}_i$. An instructive illustration of this construction is given by the special case of a holomorphic function $F=F(x_1,x_2,\ldots)$ on X,

$$F = \prod_{j=1}^{s} F_j^{n_j} \tag{3.1}$$

with $F_j=F_j(x_1,x_2,\ldots)$ being the irreducible components of F, they are holomorphic polynomials. Here the above $\mathcal{D}_j$'s are the prime divisors associated with the zeros of F_j. The divisor $\mathcal{D}$, which is called principal, reads as $(F)=\Sigma_j n_j(F_j)$ with n_j positive integers. The support of the divisor is the variety $V(F)=\mathcal{D}_1 \cup \mathcal{D}_2 \cup \cdots \cup \mathcal{D}_s$. Similar relations are also valid for meromorphic functions with zeros and poles. Now, we turn to del Pezzo surfaces and their homology.

In a given del Pezzo surface $\mathbb{B}_k$, each E_i is associated with a $\mathbb{P}^1$ holomorphic curve and the class system $\{H,E_i\}$ satisfies the following pairing:

$$H^2 = 1, \quad H \cdot E_i = 0, \quad E_i \cdot E_j = -\delta_{ij}, \quad i,j = 1, \ldots, k. \tag{3.2}$$

In terms of these basic classes of curves, one defines all the tools we need for the present study. First, note that the generic class of holomorphic curves in $\mathbb{B}_k$ are given by the linear combination type,

$$C_a = n_a H - \sum_{i=1}^{k} m_{ai} E_i, \tag{3.3}$$

with n_a and m_a as integers. These classes of curves are characterized by two basic parameters (a) The self-intersection number C_a^2, which by help of Eq. (3.2) is given by

$$C_a^2 = n_a^2 - \sum_{i=1}^{k} m_{ai}^2, \tag{3.4}$$

and (b) the degree d_{C_a} which, as we shall see, is linked to the space–time dimension of the p branes. Since the C_a^2 and the degree play a crucial role in the algebraic geometry realization of QHS we are considering in this paper, it is interesting to note that among the above classes of curves, there is a particular class of curves with a special property. This concerns the canonical class Ω_k of the $\mathbb{B}_k$ surface which is given by minus the first Chern class $c_1(\mathbb{B}_k)$ of the tangent bundle. It reads as

$$\Omega_k = -\left(3H - \sum_{i=1}^{k} E_i\right), \tag{3.5}$$

and has a self-intersection number $\Omega_k^2 = 9-k$ whose positivity requires $k \leqslant 9$. Obviously $k=0$ corresponds just to the case where we have no blow up; i.e., the $\mathbb{P}^2$ complex surface. With the above relation, we are now in position to define the degree d_C of a given curve class $C = nH - \Sigma_{i=1}^{k} m_i E_i$ in $\mathbb{B}_k$. It is the intersection number between the class C with the anticanonical class $(-\Omega_k)$,

$$d_C = -C \cdot \Omega_k = 3n - \sum_{i=1}^{k} m_i. \tag{3.6}$$

Positivity of this integer puts a constraint equation on the allowed values of the n and m_i integers which should be like $\Sigma_{i=1}^{k} m_i \leqslant 3n$. Note that there is a relation between the self-intersection number C^2 of the classes of holomorphic curves and their degrees d_C. This relation, which is known as the adjunction formula, is given by

$$C^2 = 2g - 2 + d_C, \tag{3.7}$$

it allows us to define the genus g of the curve class C as $g = (2 + n(n-3) - \Sigma_{i=1}^{k} m_i(m_i - 1))/2$ where we have also used the expansion $C = nH - \Sigma_{i=1}^{k} m_i E_i$. Fixing the genus g to given positive number puts then a second constraint equation on n and m_i integers. For the interesting example of rational curves with $g=0$, we have then $C^2 = d_C - 2$ or equivalently

$$\sum_{i=1}^{k} m_i(m_i - 1) = 2 + n(n-3). \tag{3.8}$$

For $k=1$, this relation reduces to $m(m-1) = 2 + n(n-3)$, its leading solutions $n=1, m=0$ and $n=0, m=-1$ give just the classes H and E, respectively. Typical solutions for this constraint equation are given by the generic class $C_{n,n-1} = nH - (n-1)E$ which is more convenient to rewrite it as follows:

$$C_{n,n-1} = H + (n-1)(H - E). \tag{3.9}$$

In this case the degree of these rational curves in $\mathbb{B}_1$ is equal to $d_C = 2n+1$, it deals then with p branes in type IIA strings. However along with the above solution, there is also configurations with even degree. These solutions concerns *NS* branes given by the classes $C_{n,2-n} = C = nH - (2$

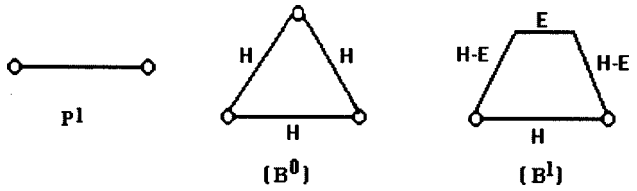

FIG. 3. Three toric diagrams: (a) Diagram of $\mathbb{P}^1$ with two $\mathbb{S}^1$ singularities on borders of the interval. (b) Toric graph of $\mathbb{P}^2$ with three $\mathbb{T}^2$ toric singularities at the vertices, and (c) toric diagram of $\mathbb{B}_1$ with two toric singularities and a blown one.

$-n)E$ with $n=1,2$ and wrapped p branes in type IIB representation. The second issue will be discussed later on.

B. Toric representation of $\mathbb{B}_1$

We need this toric representation to draw pictures for realizations of QHS in terms of classes of curves in $\mathbb{B}_1$. To that purpose recall first that toric representation is a tricky graphic representation that concerns complex manifolds.[24,25] The latter can be usually imagined as given by a real base $\mathcal{B}$ with toric fibers on it. The simplest examples of toric manifolds are naturally the complex projective spaces $\mathbb{P}^n$ where the real dimension n bases $\mathcal{B}_n$ are given by the usual n-simplex and fibers are n-dimensional torii $\mathbb{T}^n$. Therefore in toric representation $\mathbb{P}^1$ is an interval of a straight line with a $\mathbb{S}^1$ circle on top and shrinking at the boundaries. Similarly $\mathbb{P}^2$ is a triangle with three vertices capturing toric singularities. The blow up of one of these three toric singularities of $\mathbb{P}^2$ is just $\mathbb{B}_1$ and is given by a rectangle with four vertices but only two toric singularities. The corresponding toric pictures of these three kinds of toric varieties are shown in Fig. 3. In the H_2 homology of del Pezzo surfaces where line classes in $\mathbb{B}_1$ are of two types, the H standard hyperline and the E exceptional one, we have a nice description of these figures. Figures 3(b) and 3(c) are, respectively, given by the following canonical lines of $\mathbb{P}^2$ and $\mathbb{B}_1$:

$$-3H; \quad -(3H-E) = -[H+2(H-E)+E]. \tag{3.10}$$

Naively, these canonical classes may be thought of as representing the boundaries of these complex surfaces, the triangle for $\mathbb{P}^2$ and rectangle for $\mathbb{B}_1$. Viewed in that way, these boundary lines are genus one classes having degrees $d_{-3H}=9$ and $d_{-3H+E}=8$, respectively, see Eq. (3.7). Moreover, the three edges of $\mathbb{P}^2$ (respectively, four for the case of $\mathbb{B}_1$) correspond just to the number of replication (multiplicity) of the class H (respectively, H and E for $\mathbb{B}_1$) of the basis of the $H_2(\mathbb{B}_k,\mathbb{Z})$ homology. In other words the three (respectively, four) edges for the toric graph of $\mathbb{P}^2$ (respectively, $\mathbb{B}_1$) correspond to the splitting the multiplicity $-3H$ as $-H-H-H$. The same is also valid for the three (four) vertices of the triangle (rectangle), they correspond to the intersection points of the classes of curves.

Along with these figures, one may also draw the pictures associated with the rational curve classes of Eq. (3.9) inside the complex surfaces. Let us give some illustrating examples which will be used later on.

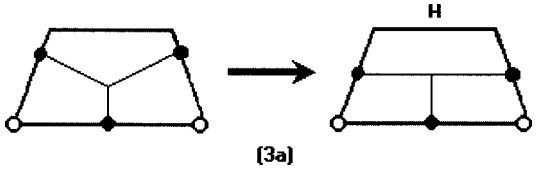

FIG. 4. The graph of the class H in $\mathbb{B}_1$, it looks like the italic letter Y. But as the 3-vertex can be everywhere $\mathbb{B}_1$, it can have different representations. In what follows, we will use the block representation given on right-hand side.

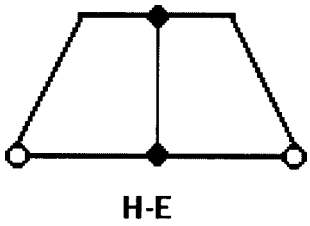

FIG. 5. The internal line crossing the surface of rectangle defines the class $H-E$. It may be viewed as a string stretching between two boundary points on $\mathbb{B}_1$.

1. Graphs of the classes H and E in $\mathbb{B}_1$ *(Fig. 4)*

The hyperline class H has a self-intersection one ($H^2=1$) and a degree $d_H=3$ giving the number of points on the boundary of $\mathbb{B}_1$. It looks like a three point Feynman diagram with three external legs and a three point vertex. The unique self-intersection point we have here belongs to the interior of the $\mathbb{B}_1$ surface and may be interpreted as a signature of the H class in $\mathbb{B}_1$, it is the 3-vertex of the triangulation of the surface. For the exceptional curve E, one may be interested to do the same as H. However, this is not possible in H homological representation since E has a negative self-interaction ($E^2=-1$). This means that E cannot be drawn inside of the rectangle. This is why we will avoid this behavior by changing the orthogonal basis $\{H,E\}$ of the $H_2(\mathbb{B}_1,\mathbb{Z})$ homology into the following equivalent one:

$$H, \quad H-E, \tag{3.11}$$

where the previous difficulty $E^2=-1$ is now solved as $(H-E)^2=0$. The class of $H-E$ is a line in $\mathbb{B}_1$ with its two ends on the boundary. Note that contrary to the old basis $\{H,E\}$ which involves $D0$ and $D2$ branes, the new one implies instead $F1$ strings and $D2$ branes. Note in passing that $\mathbb{B}_1$ may be also defined using the following basis:

$$l_i \cdot l_j = 1 - \delta_{ij}, \quad i,j = 1,2. \tag{3.12}$$

In this basis, the canonical class reads as $-2l_1-2l_2$ and genus zero curves of degree $2n+2$ are given by $C_{n,1}=nl_1+l_2$ or $C_{1,n}=l_1+nl_2$. They will be used later on when we consider type IIB stringy representation of QHS.

2. Graph of the class H−E in $\mathbb{B}_1$ *(Fig. 5)*

In the new basis Eq. (3.11) and thinking about the canonical class Ω_{-3H+E} of $\mathbb{B}_1$ as $-H-2(H-E)-E$, the class $H-E$ inside of $\mathbb{B}_1$ is given by a line stretching between the basic H and E classes of Ω_{-3H+E}. This goes in the same manner as do the two boundary (external) lines $2(H-E)$ of the "line frontier" class Ω_{-3H+E}. The $H-E$ class has no self-intersection (no vertex).

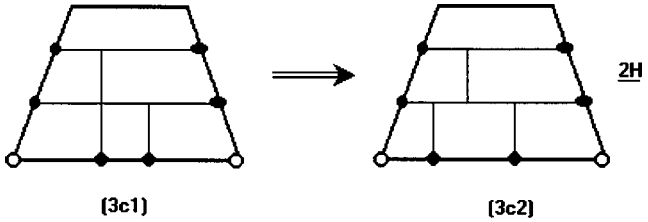

FIG. 6. Graph representing the class $2H=H+H$. The diagrams on the left- and right-hand sides describe, respectively, the class $2H$ before and after triangulation. In type IIA string language, this corresponds to $NS5$.

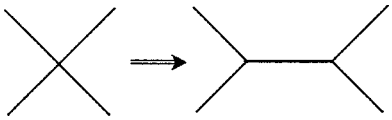

FIG. 7. These figures show the triangulation of four vertex A into two three vertices A1 and A2.

3. Graph of the class 2H in $\mathbb{B}_1$ (Fig. 6)

This is a genus zero class and has a degree equal to 6 and four self-interaction points, its picture is immediately obtained by summing the graphs of two classes as $2H=H+H$. By superposition, we get in a first step the Fig. 6 (left), which involves two kinds of internal vertices, a three vertex and a four one. However splitting the four vertex into two three-vertices using the following triangulation rule, we get the figure on the right-hand side with the appropriate number of internal three-vertices. This property, which is general, is also valid for any sum of class of curves.

4. Graph of the class 2H−E in $\mathbb{B}_1$ (Fig. 7)

Thinking about $2H-E$ as $H+(H-E)$ and following the same lines as before, it is not difficult to show that Fig. 8 represents five external legs and the three self-intersection points.

5. Graph of the class 3H−2E in $\mathbb{B}_1$ (Fig. 8)

Repeating the same process, we get for this class of curve, thought of as the superposition of the following three basic curves $H+(H-E)+(H-E)$, the graph of Fig. 9. Such a procedure is general and applies for all classes of the H_2 homology of del Pezzo. Details will be given in Ref. 18.

IV. BRANES AND HOLOMORPHIC CURVES

Following Ref. 15, there is a remarkable correspondence between del Pezzo surfaces $\mathbb{B}_k$ and M-theory on $\mathbb{T}^k$. Generally speaking an element ω of the real cohomology of del Pezzo associates the basic classes $(H,E_1,\ldots,E_k)$ of the surface $\mathbb{B}_k$ with the point $(l_p,R_1,\ldots,R_k)$, in the moduli space of M-theory on $\mathbb{T}^k$. In practice, this means that ω is a kind of generalized (ω has an indefinite sign) Kahler acting as

$$\omega(H) = -3\ln l_p, \quad \omega(E_i) = -\ln(2\pi R_i), \tag{4.1}$$

where l_p is the Planck scale and where R_i's are the torus radii. Equation (4.1) is in fact a special one, it happens that INV correspondence is more general than given in Eq. (4.1). We have also the following correspondences: (a) Global diffeomorphisms preserving the canonical class Ω_k of the del Pezzo surfaces corresponds precisely to the U duality group of the M-theory on $\mathbb{T}^k$. (b) Rational curves (real two spheres) C with volume $V_C=\omega(C)$ and degree $d_C=(p+1)$ are in one to one with $\frac{1}{2}$BPS p-brane states with tension $T_p=2\pi \exp V_C$. (c) Two classes of rational curves C_1 and C_2 related as $C_1+C_2=-\Omega_k$ corresponds just to the usual electric-magnetic duality linking Dp_1 and Dp_2 with $p_1+p_2=6$.

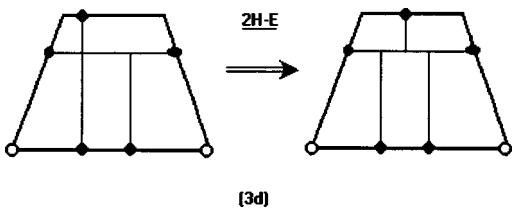

FIG. 8. Building block of the homology class $2H-E$. It represents a $D4$ brane in type IIA stringy description.

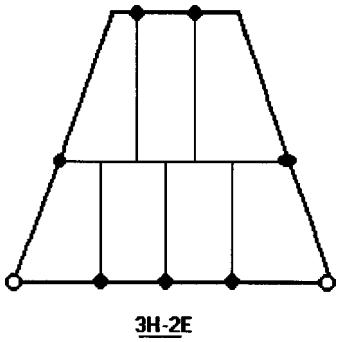

FIG. 9. Building block of the complex curve $3H-2E$ where one recognizes the five self-intersection points. It represents a $D6$ brane in type IIA stringy description.

Therefore p branes of 10-dimensional IIA superstring can be realized as $H_2(\mathbb{B}_k,\mathbb{Z})$ homology classes of holomorphic rational curves in $\mathbb{B}_k$. Of particular interest for our present study is the realization of p branes in terms of $H_2(\mathbb{B}_1,\mathbb{Z})$ classes. More precisely, given a generic $\mathbb{B}_1$ rational curve $C_{n,m}=nH-mE$ with a positive degree $3n-m$ and integers n and m constrained as $m(m-1)=2+n(n-3)$, we can work out all p branes of type IIA superstring with space dimension p equal to $3n-m-1$. The result is reported in the following table:

Classes	$C_0=E$	$C_1=H-E$	$C_2=H$	$C_4=2H-E$	$C_5=2H$	$C_6=3H-2E$	$C_8=4H-3E$
Branes	$D0$	$F1$	$D2$	$D4$	$NS5$	$D6$	$D8$

(4.2)

where now on the subindex carried by the C_p's refers to the real space dimension of the p branes. From this correspondence, one sees that previous figures we have drawn give indeed an algebraic geometry realization of p-branes in terms of classes of holomorphic rational curves in $\mathbb{B}_1$. With these tools in mind, we are now ready to consider the main topic of this paper.

V. REALIZATION OF QHS

To build a QHS representation using homology cycles of $\mathbb{B}_1$, we start by recalling that from the type IIA string representation of QHS we have the following first result:

p-branes	$D0$	$F'1$	$D2$	$F1$	$D6$
Their realization in terms of classes	C_0	C_1'	C_2	C_1	C_6

(5.1)

It gives the p branes involved in QHS and their realization in terms of classes of holomorphic curves in del Pezzo $\mathbb{B}_1$. Here C_1' refers to the class associated with fundamental strings stretching between $D0$ and $D2$ and C_1 to those $F1$ strings stretching between $D2$ and $D6$.

The next thing is to note that the problem of building algebraic geometry realizations of QHS reduces then to the finding of explicit forms of these C_p class of curves in terms of the H and $H-E$ fundamental classes,

$$C_p = C_p(H,E). \tag{5.2}$$

To do so, we first must derive the appropriate constraint equations that should be obeyed by these C_p's, then solve them. We will see that a solution of the form, Eq. (5.2), that satisfies the QHS constraint equations is not possible, one needs many more ingredients to which we describe at the proper time.

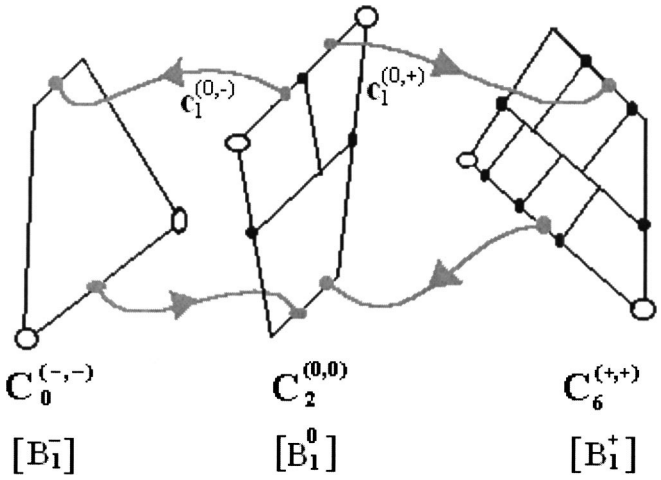

FIG. 10. In this figure, we give a configuration of the homological representation of the QHS involving classes C_0, C_2, and C_6, respectively, associated with one $D0$, one $D2$, and one $D6$ branes. We also represent the curves C_1 illustrating strings stretching between the branes.

A. Constraint equations and solution

By identifying the notion of a set intersection in real geometry with the usual intersection of classes in H_2 homology of $\mathbb{B}_1$, the constraint relations (2.6) and (2.7) of type IIA string representation of QHS translate in $H_2(\mathbb{B}_1,\mathbb{Z})$ homology language as follows:

$$C_0\cdot C_2=0,\quad C_0\cdot C_6=0,\quad C_2\cdot C_6=0,$$

$$C_0\cdot C_1'=1,\quad C_1'\cdot C_2=1,\quad C_1'\cdot C_6=0,$$

$$C_2\cdot C_1=1,\quad C_2\cdot C_6=0,\quad C_1\cdot C_6=1,$$

$$C_0\cdot C_1=0,\quad C_1'\cdot C_1=0,\quad C_2\cdot C_1=1. \tag{5.3}$$

At first sight, solving these constraint equations for rational curves in del Pezzo $\mathbb{B}_1$ seems a simple matter. However, this is not so trivial. While the intersection of classes type $C_2\cdot C_1=1$ or $C_6\cdot C_1=1$ do not cause a problem, the situation is not so obvious for the constraint equations $C_2\cdot C_6=0$, $C_0\cdot C_2=0$, and $C_0\cdot C_6=0$. The point is that there are no class of curves in $\mathbb{B}_1$ with such a feature. This is easily seen by directly computing the corresponding products. For instance the product between $C_2=H$ and $C_6=3H-2E$, using Eqs. (3.2), gives

$$C_2\cdot C_6=3, \tag{5.4}$$

and the same thing for the other relations, which are not as required by the structure of the QHS we are after. A way to overcome this difficulty is to think about the three classes C_0, C_2, and C_6 as belonging to three independent del Pezzo surfaces $\mathbb{B}_1^{(-1)}$, $\mathbb{B}_1^{(0)}$, and $\mathbb{B}_1^{(1)}$ as

$$C_0^{(-1)}=E_{-1},\quad C_2^{(0)}=H_0,\quad C_6^{(1)}=3H_1-2E_1, \tag{5.5}$$

where in addition to Eq. (3.2), we also have $H_0\cdot H_{\pm1}=H_0\cdot E_{\pm1}=H_{\pm1}\cdot E_0=0$, see also Fig. 10. In this case, it is not difficult to check that the intersection products $C_0^{(-1)}\cdot C_2^{(0)}$, $C_0^{(-)}\cdot C_6^{(1)}$, and $C_2^{(0)}\cdot C_6^{(1)}$ are identically zero. The introduction of the $\mathbb{B}_1^{(-1)}$, $\mathbb{B}_1^{(0)}$, and $\mathbb{B}_1^{(1)}$ surfaces is the price one should pay for getting solutions of QHS constraint equations. As such one can think about these three surfaces as three special submanifolds of the blown up of three different $\mathbb{P}^2$'s embedded in $\mathbb{P}^8$. The two extra dimensions in $\mathbb{P}^8$ deal with the curves C_1' and C_1 associated with $F'1$ and $F1$ strings

stretching between the two pairs $\mathbb{B}_1^{(-1)}-\mathbb{B}_1^{(0)}$ and $\mathbb{B}_1^{(0)}-\mathbb{B}_1^{(1)}$, respectively. Therefore a simple solution for the constraint equations (5.3) reads as follows:

$$C_0^{(-1-1)} = E_{-1},$$

$$C_1^{(-10)} = H_{-1} - E_0, \quad C_1^{(0-1)} = H_0 - E_{-1},$$

$$C_2^{(00)} = H_0,$$

$$C_1^{(01)} = H_0 - E_1, \quad C_1^{(10)} = H_1 - E_0,$$

$$C_6^{(11)} = 3H_1 - 2E_1, \tag{5.6}$$

where the upper index (ij) refers to the (i,j) pair of the involved del Pezzo. The couple (00) [respectively, $(\pm 1 \pm 1)$] means that we are dealing with classes of curves in $\mathbb{B}_1^{(0)}$ (respectively, $\mathbb{B}_1^{(\pm 1)}$) and (0 ± 1) or (± 10) with rational curves stretching between $\mathbb{B}_1^{(0)}$ and $\mathbb{B}_1^{(\pm 1)}$. Naturally, the full solution for stretched $F1$ strings is given by the sum $C_1^{(0\pm 1)}+C_1^{(\pm 10)}$ which is equal to $(H_0-E_{\pm 1})+(H_{\pm 1}-E_0)$.

In the above solution (5.6) of the constraint equations for QHS we have considered one $D6$ brane and one $D0$ brane and the same for the $F1$ string stretching between $D0-D2$ and $D2-D6$. These p branes are represented by $H_2(\mathbb{B}_1^{(0,\pm 1)},\mathbb{Z})$ classes describing rational holomorphic curves. In what follows, we derive the general solution of Eqs. (5.3) involving $ND6$ branes and $KD0$ ones, N and K are arbitrary positive integers.

B. Quantum Hall soliton

The algebraic geometry realization of QHS built in terms of a system of intersecting curves is as follows: see Fig. 10 for illustration.

(1) A simple rational curve class $C_2^{(00)}=H_0$ belonging to a basic of del Pezzo copy denoted as $\mathbb{B}_1^{(0)}$ and generated by H_0 and E_0 basic classes with the same properties as above. This class of curve is associated with the $D2$ brane in type IIA stringy representation.

(2) A class of curve with a multiplicity N given by the class $C_6'=N(3H_1-2E_1)$. This is a nonzero genus class $[2g=N(5N-7)+2]$ that corresponds to the N coincident $D6$ branes in the IIA string representation of QHS. To see where this result comes from, it is interesting to recall that in the case where the N $D6$ branes are not coincident, the previous degenerate class split into N simple classes of curves $C_6^{(ii)}$ given by

$$C_6^{(ii)} = 3H_i - 2E_i, \quad i = 1, \ldots, N. \tag{5.7}$$

Each one of these N $C_6^{(ii)}$'s belongs to one of the N del Pezzo copies $\mathbb{B}_1^{(i)}$. The latter have basis $\{H_i,E_i\}$ with the same properties as before but orthogonal to the $\{H_j,E_j\}$ whenever $i\neq j$. This means that in H_2 homology, the N $D6$ branes involve N copies of del Pezzo surfaces $\mathbb{B}_1^{(1)},\ldots,\mathbb{B}_1^{(N)}$ and so requires a larger embedding projective space. To have an idea on the dimension of this space, note that, in addition to $F1$ string loops $C_1^{(ii)}=(H_i-E_i)$ emanating and ending on the same $C_6^{(ii)}$ copy, we have moreover other $F1$ strings stretching between the D6 branes. In H_2 homology, this corresponds to curves $C_1^{(ij)}$ and $C_1^{(ji)}$ stretching between $\mathbb{B}_1^{(i)}$ and $\mathbb{B}_1^{(j)}$. The explicit expression of these classes is given by

$$C_1^{(ij)} = (H_i - E_j), \quad C_6^{(ii)} \cdot C_1^{(ij)} = 1, \quad C_1^{(ij)} \cdot C_6^{(jj)} = 1,$$

$$C_1^{(ji)} = (H_j - E_i), \quad C_1^{(ji)} \cdot C_6^{(ii)} = 1, \quad C_6^{(jj)} \cdot C_1^{(ji)} = 1. \tag{5.8}$$

From these relations, one can clearly see that the $C_1^{(ij)}$ and $C_1^{(ji)}$ classes are stretching between the $C_6^{(ii)}$ and $C_6^{(jj)}$. Since these $C_1^{(ij)}$ and $C_1^{(ji)}$ classes require at least one complex dimension, the embedding projective space should be at least $\mathbb{P}^{3N-1}$. In type IIA stringy representation, this situation describes the case where the gauge symmetry is $\mathrm{U}(1)^N$. For the case of $\mathrm{U}(N)$ gauge symmetry, the $D6$ branes should be coincident and so the corresponding curve classes $C_6^{(ii)}$ must be degenerate curves in $\mathbb{B}_1$. This corresponds to

$$NC_6 = C_6' = N(3H_1 - 2E_1), \tag{5.9}$$

where H_1 and E_1 stand for the basic classes of the del Pezzo surface $\mathbb{B}_1$ where the degenerate NC_6 live.

(3) N holomorphic curves $C_1^{(0i)} + C_1^{(i0)}$ solved as $(H_0 - E_i) + (H_i - E_0)$ and stretching between $C_2^{(00)}$ and $C_6^{(ii)}$. For the case of N coincident $D6$ branes Eq. (5.9), the N classes $C_1^{(0i)} + C_1^{(i0)}$ fuse and give

$$C_1^{(01)} = NH_0 - E_1,$$

$$C_1^{(10)} = H_1 - NE_0, \tag{5.10}$$

where obviously the $F1$ strings stretching between $C_2^{(00)}$ and the $NC_6^{(ii)}$ are collectively described by the sum $(NH_0 - E_1) + (H_1 - NE_0)$. From these solutions, it not difficult to check that the constraint equations (5.10) are exactly fulfilled.

(4) Finally for the K $D0$ branes describing the quantum flux, the construction is quite similar to what we have done for the case of coincident $D6$ branes. The homology class describing the K $D0$ branes is $C_0^{(-1-1)} = kE_{-1}$ and the $F'1$ strings stretching between the $kD0$ and $D2$ realized as $C_0^{(-1-1)}$ and $C_2^{(00)}$ are given by

$$C_1^{(-10)} = (kH_0 - E_{-1}) + (H_{-1} - kE_0), \tag{5.11}$$

The quantum fluxes are naturally given by the ends of the $F'1$ strings on $C_2^{(00)}$ and so are associated with the intersection number $C_1^{(-10)} \cdot C_2^{(00)} = k$ in agreement with the constraint equations.

VI. CONCLUSION AND DISCUSSION

Using a recent result linking p branes and holomorphic curves in del Pezzo surfaces, we have developed a new way to deal with brane bounds of M-theory on $\mathbb{S}^1$. To illustrate our idea in an explicit manner, we have considered the usual type IIA stringy representation of the quantum Hall soliton (QHS) and derived its realization by using the H_2 homology of del Pezzo surfaces. In our representation, QHS is described by a system of intersecting classes of holomorphic curves as given by Eqs. (5.7)–(5.11), see also Fig. 10.

The idea developed here can be used to derive new solutions for QHS but also for studying general branes systems. The development of these issues seems to us important, it offers another way to approach p-brane bounds and uses the powerful tools of homology groups and algebraic geometry that may allow to open new horizons. In particular, one may derive new representations of higher dimensional quantum Hall solitons involving two $D4$ branes and $F1$ strings stretching between them in the same spirit as in Refs. 26–28. One may also consider QHS using p branes of type IIB superstring that are dual to the previous type IIA ones. In the algebraic geometry of QHS we have been considering, this configuration can be obtained without major difficulty. It consists of the system $D3/S^1$, $D7/S^1$, $F1$, $D1$, and $D1/S^1$ and satisfy similar constraint equations to relations (5.3). The correspondence between the two representations is as follows:

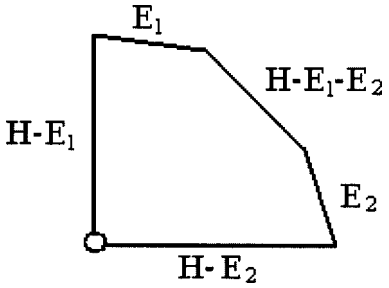

FIG. 11. This graph represents the toric diagram of the del Pezzo surface $\mathbb{B}_2$.

Type IIA	$D2$	$F1$	$D0$	$D4$	$D6$
Curves in $\mathbb{B}_1$	H	$H-E$	E	$2H-E$	$3H-2E$
Type IIB	$D3/S^1$	$F1$, $D1$	$F1/S^1$, $D1/S^1$	$D5/S^1$	$D7/S^1$
Curves in $\mathbb{B}_2$	l_1+l_2-e	l_1, l_2	l_1-e, l_2-e	$2l_1+l_2-e$	$3l_1+l_2-e$

(6.1)

where $l_i \cdot l_j = 1-\delta_{ij}$, $l_i \cdot e = 0$ and $e \cdot e = -1$. In order to algebraic geometry engineer the corresponding QHS dual to the type IIA one, all one must do is, instead of the surface $\mathbb{B}_1$ generated by l_1 and l_2, consider rather the del Pezzo surface $\mathbb{B}_2$, see Fig. 11.

The extra blow up described by the exceptional class e deals with the brane wrapping cycle $\mathbb{S}^1$. The solution to the constraint equations may be obtained without difficulty by using the mapping

$$e = H - E_1 - E_2, \quad l_1 = H - E_1, \quad l_2 = H - E_2. \tag{6.2}$$

Applying the rules we have used in elaborating the type IIA stringy realization of the quantum Hall soliton, we can draw here also the graphs of the $F1$, $D1$ strings and the wrapped D-branes $D3/S^1$ and $D7/S^1$ involved in the type IIB stringy representation of QHS.

Using these graphs, one can also build the QHS diagram similar to that given by Fig. 12. Details on this issue as well as other aspects dealing with the derivation of new solitons including higher dimensional QHS with a configuration type $D4-F1-D4-D0$ will be presented elsewhere.

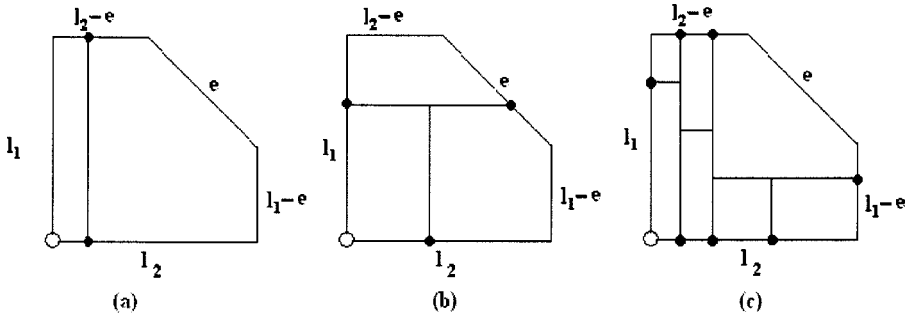

FIG. 12. These are three graphs of curves in the del Pezzo surface B_2, they are involved in the type IIB stringy representation of QHS. These classes are associated with branes in type IIB string on S^1. (a) gives a representation of the $F1$ string. (b) represents a wrapped $D3$ brane on a circle and (c) describes a wrapped $D7$ brane on a circle.

Casimir energy for a wedge with three surfaces and for a pyramidal cavity

H. Ahmedov[a] and I. H. Duru[b]
Feza Gürsey Institute, P.O. Box 6, 81220, Çengelköy, Istanbul, Turkey

(Received 19 July 2004; accepted 18 October 2004; published online 2 February 2005)

Casimir energy calculations for the conformally coupled massless scalar field for a wedge defined by three intersecting planes and for a pyramid with four triangular surfaces are presented. The group generated by reflections are employed in the formulation of the required Green functions and the wave functions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1835546]

I. INTRODUCTION

Having new geometries in hand for which we can evaluate the Casimir energies is of interest: We learn more about the phenomena itself, and hope that experimentalists may realize some of the geometries to measure the effect. At this point we like to emphasize that all experiments so far performed are of two body ones, a single cavity measurement has not been done.[1]

For geometries with planar boundaries, if the planes are parallel or perpendicular to each other, the method of images is easily applicable. The parallel plates and in general rectangular prisms of any dimensions are of that type.[2] For these geometries the groups generated by reflections are Abelian. If the walls of the cavity are not perpendicularly intersecting, the reflection groups are not commutative. This was the case for a previously studied triangular region.[3] If the reflections in the geometry we consider generate a non-Abelian group, one must study the structure of this group, for it is essential in the construction of the required Green functions and wave functions. For example, in the present study the octahedral group provides the basic tools for the calculations.

In the coming section we first calculate the Casimir energy density for the massless scalar field for a wedge with three boundary surfaces.

Section III is devoted to the calculation of the Casimir energy in a pyramidal cavity with four triangular surfaces. We get a positive result.

The corresponding groups generated (related to the octahedral group) by reflections play a vital role in the construction of the Green function and the wave functions. The required group theoretical details are given in the appendixes.

II. PYRAMIDAL WEDGE

Consider the region in the first quadrant ($x_1>0$, $x_2>0$ $x_3>0$) inside the following three planes (Fig. 1):

$$P_1{:}x_1 = x_3, \quad P_2{:}x_2 = 0, \quad P_3{:}x_1 = x_2. \tag{1}$$

Reflection operators with respect to these planes are

[a]Electronic mail: hagi@gursey.gov.tr
[b]Electronic mail: duru@gursey.gov.tr

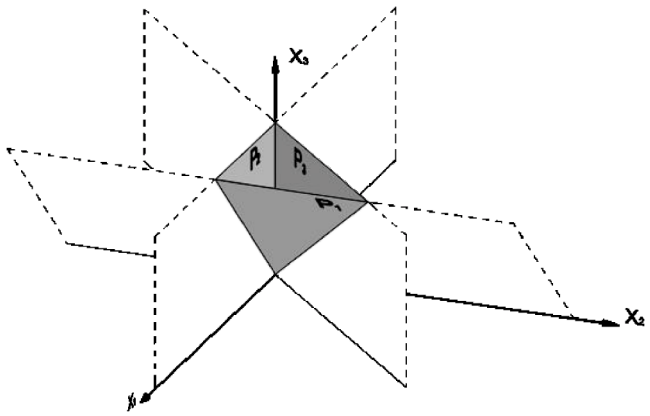

FIG. 1. Planes of Eq. (1).

$$q_1 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad q_2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad q_3 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{2}$$

A group G of order 48 is generated by the above reflections. It's elements are g_j and ig_j; $j=0,\ldots,23$. Here 24 elements of g_j form the octahedral group (see Appendix A) and $i=-1$ is the generator of the inversion group.

Consider the function

$$K(x,y) = \sum_{j=0}^{23} [G(g_j x,y) - G(ig_j x,y)], \tag{3}$$

where $G(x,y)$ is the Green function for the massless scalar field in the Minkowski space,

$$G(x,y) = \frac{1}{4\pi^2}\frac{1}{|x-y|^2}. \tag{4}$$

Here x and y are four vectors with interval $|x-y|^2=|\vec{x}-\vec{y}|^2-(x_0-y_0)^2$; and, g_j act only on the spatial components. To check the boundary conditions let us consider (with $q_1=ig_{21}$)

$$K(q_1 x,y) = \sum_{j=0}^{23} [G(ig_j g_{21} x,y) - G(g_j g_{21} x,y)]. \tag{5}$$

Since for any j we have the element $g_k=g_j g_{21}$ in G, (5) is equal to

$$K(q_1 x,y) = \sum_{k=0}^{23} [G(ig_k x,y) - G(g_k x,y)], \tag{6}$$

which implies

$$K(q_1 x,y) = -K(x,y). \tag{7}$$

In a similar fashion one can verify the antisymmetry property for the elements q_2 and q_3. Therefore the function $K(x,y)$ satisfies Dirichlet boundary conditions on the planes of (1).

Note that in order the equation [with $\eta=\mathrm{diag}(-1,1,1,1)$]

$$\eta^{\mu\nu}\frac{\partial^2}{\partial x^\mu \partial x^\nu}K(x,y) = \delta(x-y) \tag{8}$$

to be satisfied by (3), every point in the region between the planes P_1, P_2, and P_3 must represent different orbits under the action of the group G, which is indeed the case. In other words the region we consider is the fundamental domain of the group G (see Appendix B).

To obtain the energy momentum tensor for the conformally coupled massless scalar field we employ the well-known coincidence limit formula[4]

$$T_{\mu\nu} = \lim_{x\to y}\left[\frac{2}{3}\partial^y_\mu\partial^x_\nu - \frac{1}{6}(\partial^x_\mu\partial^x_\nu + \partial^y_\mu\partial^y_\nu) - \frac{\eta_{\mu\nu}}{6}\eta^{\sigma\rho}\partial^y_\sigma\partial^x_\rho + \frac{\eta_{\mu\nu}}{24}\eta^{\sigma\rho}(\partial^x_\sigma\partial^x_\rho + \partial^y_\sigma\partial^y_\rho)\right]K(x,y). \tag{9}$$

The energy density $T(x) = T_{00}$ is given by

$$T(x) = \frac{1}{12\pi^2}\sum_{j=1}^{23}[T(g_j) - T(ig_j)], \tag{10}$$

where

$$T(g) = \left(\frac{\mathrm{tr}(g)-1}{|\vec{\eta}|^4} - 2\frac{|((1+g)\vec{\eta}\,|^2}{|\vec{\eta}|^6}\right) \tag{11}$$

and

$$\vec{\eta} = (1-g)\vec{x} \tag{12}$$

with g standing for g_j and ig_j.

Using the invariance of $T(g)$ under the $g \to g^{-1}$ we have

$$\begin{aligned} T(g_1) &= T(g_3), \\ T(g_4) &= T(g_6), \\ T(g_7) &= T(g_9), \\ T(g_{10}) &= T(g_{11}), \\ T(g_{12}) &= T(g_{13}), \\ T(g_{14}) &= T(g_{15}), \\ T(g_{16}) &= T(g_{17}). \end{aligned} \tag{13}$$

The same is true for elements ig_j, with j running the same values as (13).

(i) For g_1 which is rotation by angle $\pi/2$ around the x_2 axis we have

$$T(g_1) = -\frac{1}{(x_1^2 + x_3^2)^2}, \tag{14}$$

$$T(ig_1) = -\frac{3(x_1^2 + x_3^2) + 2x_2^2}{2(x_1^2 + x_3^2 + 2x_2^2)^3}. \tag{15}$$

g_4 and g_6 are the rotations by the same angle around the x_1 axis and x_3 axis, respectively. Therefore, $T(g_4)$, $T(ig_4)$ and $T(g_6)$, $T(ig_4)$ are obtained from (14) and (15) with the cyclic replacements of coordinates $(x_1,x_2,x_3)\to(x_3,x_1,x_2)$ and $(x_1,x_2,x_3)\to(x_2,x_3,x_1)$, respectively.

(ii) For the rotation g_{12} by angle $2\pi/3$ around the line passing through the origin and the point $(1,-1,1)$ we have

$$T(g_{12}) = -\frac{3}{((x_1 + x_2)^2 + (x_2 + x_3)^2 + (x_3 - x_1)^2)^2}, \tag{16}$$

$$T(ig_{12}) = -\frac{6|\vec{x}|^2 + 2(x_1x_3 - x_1x_2 - x_2x_3)}{((x_1 - x_2)^2 + (x_2 - x_3)^2 + (x_3 + x_1)^2)^3}. \tag{17}$$

Since g_{14} and g_{16} are rotation matrices by the same angle around the axis passing through the origin and the points $(-1,1,1)$ and $(1,1,-1)$ we conclude that $T(g_{14})$, $T(ig_{14})$ and $T(g_{16})$, $T(ig_{16})$ are given by (16) and (17) with the cyclic replacements of coordinates $(x_1,x_2,x_3)\to(x_3,x_1,x_2)$ and $(x_1,x_2,x_3)\to(x_2,x_3,x_1)$, respectively.

(iii) We also have

$$T(g_{10}) = -\frac{3}{((x_1 - x_2)^2 + (x_2 - x_3)^2 + (x_3 - x_1)^2)^2}, \tag{18}$$

$$T(ig_{10}) = -\frac{6|\vec{x}|^2 - 2(x_1x_2 + x_1x_3 + x_2x_3)}{((x_1 + x_2)^2 + (x_1 + x_3)^2 + (x_2 + x_3)^2)^3}. \tag{19}$$

(iv) For elements satisfying the condition $g^2=1$ the second expression in (11) vanishes. These are the elements g_j, $j=2,5,8$, and $18,\ldots,23$. Since $\mathrm{tr}(ig_j)=1$ we have $T(ig_j)=0$. Nonzero one is

$$T(i) = -\frac{1}{4|\vec{x}|^4}. \tag{20}$$

For rotations g_{20}, g_{21}, and g_2 we get

$$T(g_{20}) = -\frac{1}{2((x_1 - x_3)^2 + 2x_2^2)^2}, \tag{21}$$

$$T(g_{21}) = -\frac{1}{2((x_1 + x_3)^2 + 2x_2^2)^2}, \tag{22}$$

and

$$T(g_2) = -\frac{1}{8(x_1^2 + x_3^2)^2}. \tag{23}$$

Remaining six terms $T(g_{18})$, $T(g_{19})$, $T(g_{22})$, $T(g_{23})$, $T(g_5)$, and $T(g_8)$ are obtained from the above three equations by the cyclic replacements of coordinates.

Energy density (10) is given by

$$T(x) = \frac{1}{12\pi^2}[T(g_{10}) - T(ig_{10}) - T(i)] + \frac{1}{12\pi^2}\Bigg[\frac{17}{8}T(g_1) - 2T(ig_1) + 2T(g_{12}) - 2T(ig_{12}) + T(g_{20}) + T(g_{21}) + \text{c.p.}\Bigg], \tag{24}$$

where c.p. stands for cyclic permutations of coordinates. The system we consider is the intersection region of three wedges (P_1,P_2), (P_2,P_3), and (P_1,P_3). For $x_3 \gg 1$ and $\sqrt{x_1^2+x_2^2} \ll x_3$ our result should reduce to the wedge problem (P_2,P_3). Recall, that energy density in the wedge between two inclined planes is[5]

$$T_W = -\frac{1}{1440\pi^2 r^4}\left(\frac{\pi^4}{\alpha^4} - 1\right), \tag{25}$$

where α is the angle between two planes and r is the minimal distance to the axis which is the intersection of two planes. For the system (P_2,P_3) we have $\alpha = \pi/4$ and $r^2 = x_1^2 + x_2^2$, that is (25) takes the form

$$T_{P_2P_3} = -\frac{255}{1440\pi^2(x_1^2+x_2^2)^2}. \tag{26}$$

Coming to our density (24) for $x_3 \gg 1$ and $\sqrt{x_1^2+x_2^2} \ll x_3$ all terms except the one with $T(g_6)$ are negligibly small; thus, we have

$$T(x) \simeq -\frac{17}{12\pi^2 \cdot 8}T(g_6) = -\frac{17}{96\pi^2(x_1^2+x_2^2)^2}, \tag{27}$$

which is the same as (26). In a similar fashion, terms $T(g_{20})$ and $T(g_{10})$ correspond in the suitable limits to the wedge problems (P_1P_2) and (P_1P_3).

III. PYRAMID

We add to the planes P_1,P_2,P_3 the fourth one $P_4: x_3 = a$. Reflection with respect to the P_4 plane is given by

$$q_4\begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} x_1 \\ x_2 \\ 2 - x_3 \end{pmatrix}. \tag{28}$$

The group generated by q_j, $j=1,2,3,4$ is the semidirect product of the group G defined in the preceding section and the translation group Z^3. The Green function vanishing on the planes P_a, $=1,\ldots,4$ is given by

$$K(x,y) = \sum_{n,m,k=-\infty}^{\infty} \sum_{j=1}^{23} [G(g_j x + \xi, y) - G(ig_j x + \xi, y)], \tag{29}$$

where

$$\xi = \begin{pmatrix} 0 \\ 2na \\ 2ma \\ 2ka \end{pmatrix}. \tag{30}$$

The energy momentum density is

$$T(x) = \frac{1}{6\pi^2} \sum_{n,m,k=-\infty}^{\infty} \sum_{j=1}^{23} [T(g_j) - T(ig_j)], \tag{31}$$

where $T(g)$ is given by (14) with the replacement $\vec{\eta} \to \vec{\eta} + \vec{\xi}$, where $\vec{\xi}$ is the spatial part of the four-dimensional vector ξ. We calculate explicitly the total vacuum energy of the pyramid. For the geometry in hand it is reasonable to use another representation for the Green function related to the wave function and the spectra of the quantum mechanical system inside the pyramid. The wave function which vanishes on the planes P_1, P_2, and P_3 can be obtained in a similar fashion as the Green function,

$$\Psi(\vec{x}) = \Omega \sum_{j=1}^{23} [e^{i(\vec{p}, g_j \vec{x})} - e^{i(\vec{p}, ig_j \vec{x})}] \tag{32}$$

or

$$\Psi_{\vec{p}}(\vec{x}) = -8i\Omega[\sin p_1 x_1 \sin p_2 x_2 \sin p_3 x_3 - \sin p_1 x_1 \sin p_2 x_3 \sin p_3 x_2 + \text{c.p.}], \tag{33}$$

where Ω is the normalization.

The condition $\Psi_{\vec{p}}(\vec{x})|_{P_4} = 0$ implies that the components p_j are proportional to the nonzero positive integers

$$p_1 = \frac{\pi}{a} n, \quad p_2 = \frac{\pi}{a} m, \quad p_3 = \frac{\pi}{a} k. \tag{34}$$

The properties

$$\Psi_{g_j \vec{p}}(\vec{x}) = \Psi_{\vec{p}}(\vec{x}), \quad \Psi_{i\vec{p}}(\vec{x}) = \Psi_{\vec{p}}(\vec{x}) \tag{35}$$

imply that the spectrum takes its values in the quotient space

$$Z^3/G = \{\vec{n} \in Z^3 : k \geqslant n \geqslant m \geqslant 0\} \tag{36}$$

which is the discrete analog of the pyramidal region considered in the preceding section. The wave function (33) vanishes on the boundary B of $A = Z^3/G$. The boundary of A is the union of three regions, $k \geqslant n \geqslant m = 0$, $k \geqslant n = m \geqslant 0$, and $k = n \geqslant m \geqslant 0$. We must drop these values from the spectra. Physical spectra is given by (34) with $k > n > m > 0$ or $\vec{n} \in A/B$.

The Green function can be written as

$$G(x,y) = \sum_{k=3}^{\infty} \sum_{n=2}^{k-1} \sum_{m=1}^{n-1} \frac{e^{i\pi|\vec{p}|(x_0 - y_0)}}{2|\vec{p}|} \Psi_{\vec{p}}(\vec{x}) \Psi_{\vec{p}}(\vec{y}), \tag{37}$$

which implies

$$T(x) = \frac{\pi}{2a} \sum_{k=3}^{\infty} \sum_{n=2}^{k-1} \sum_{m=1}^{n-1} \sqrt{n^2 + m^2 + k^2} |\Psi_{\vec{p}}(\vec{x})|^2. \tag{38}$$

After integration $\int_0^a dx_3 \int_0^{x_3} dx_1 \int_0^{x_1} dx_2$ we have [with $\vec{n} = (n, m, k)$]

$$E = \frac{\pi}{2a} \sum_{\vec{n} \in A/B} |\vec{n}| = \frac{\pi}{96a} \sum_{\vec{n} \in A/B} \sum_{g \in G} |g\vec{n}| = \frac{\pi}{96a} \sum_{\vec{n} \in \cup g(A/B)} |\vec{n}|. \tag{39}$$

Since A is the quotient space Z^3/G we have

$$\bigcup_{g\in G} g(A/B) = Z^3/C, \quad C = \bigcup_{g\in G} gB, \tag{40}$$

which implies

$$E = \frac{\pi}{96a}\left(\sum_{\vec{n}\in Z^3} |\vec{n}| - \sum_{\vec{n}\in C} |\vec{n}|\right). \tag{41}$$

C is the union of nine planes, $m=0$, $n=m$, $n=k$, and six other planes are obtained by cyclic permutations of n, m, and k,

$$\sum_{\vec{n}\in C} |\vec{n}| = 3\sum_{n,m\in Z} \sqrt{n^2+m^2} + 6\sum_{n,m\in Z} \sqrt{2n^2+m^2}. \tag{42}$$

The Casimir energy is

$$E = \frac{1}{6}E_1 - \frac{1}{2}E_2 - \frac{6+4\sqrt{2}}{16}E_3 \simeq \frac{0.069}{a}. \tag{43}$$

Here E_1, E_2, and E_3 are the Casimir energies for the cube with sides a, for the rectangle with sides a, $a/\sqrt{2}$ and for the one dimensional system of length a (see Ref. 2 and references therein),

$$E_1 = \frac{\pi}{2a}\sum_{n,m,k=1}^{\infty} \sqrt{n^2+m^2+k^2} \simeq -\frac{0.015}{a}, \tag{44}$$

$$E_2 = \frac{\pi}{2a}\sum_{n,m=1}^{\infty} \sqrt{n^2+2m^2} \simeq \frac{0.045}{a}, \tag{45}$$

$$E_3 = \frac{\pi}{2a}\sum_{n=1}^{\infty} n \simeq -\frac{0.131}{a}. \tag{46}$$

The positive result of (43) is about the same magnitude as the other well known positive Casimir energy example of the spherical cavity with radius a,[6]

$$E_{\text{ball}} \simeq \frac{0.045}{a}. \tag{47}$$

For nanometer size, that is for $a=10^{-7}$ cm, the energy (43) is (in $\hbar=c=1$ unit, 1 eV$\cong 0.5 \otimes 10^5$ cm^{-1}) $E \simeq 35$ eV which is of considerable magnitude.

APPENDIX A

Octahedral group O is the group of transformations which transforms the cube into itself. The order of this group is 24. We denote the identity element by g_0. g_1, g_2, and g_3 are rotations on $\pi/2$, π, and $3\pi/2$ around the y axis,

$$g_1=\begin{pmatrix}0&0&-1\\0&1&0\\1&0&0\end{pmatrix},\quad g_2=\begin{pmatrix}-1&0&0\\0&1&0\\0&0&-1\end{pmatrix},\quad g_3=\begin{pmatrix}0&0&1\\0&1&0\\-1&0&0\end{pmatrix}. \tag{A1}$$

g_4, g_5, and g_6 are rotations by $\pi/2$, π, and $3\pi/2$ around the x axis,

$$g_4=\begin{pmatrix}1&0&0\\0&0&-1\\0&1&0\end{pmatrix},\quad g_5=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&-1\end{pmatrix},\quad g_6=\begin{pmatrix}1&0&0\\0&0&1\\0&-1&0\end{pmatrix}. \tag{A2}$$

g_7, g_8, and g_9 are rotations by $\pi/2$, π, and $3\pi/2$ around the z axis,

$$g_7=\begin{pmatrix}0&-1&0\\1&0&0\\0&0&1\end{pmatrix},\quad g_8=\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&1\end{pmatrix},\quad g_9=\begin{pmatrix}0&1&0\\-1&0&0\\0&0&1\end{pmatrix}. \tag{A3}$$

g_{10} and g_{11} are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point (1,1,1),

$$g_{10}=\begin{pmatrix}0&0&1\\1&0&0\\0&1&0\end{pmatrix},\quad g_{11}=\begin{pmatrix}0&1&0\\0&0&1\\1&0&0\end{pmatrix}. \tag{A4}$$

g_{12} and g_{14} are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point $(1,-1,1)$,

$$g_{12}=\begin{pmatrix}0&0&1\\-1&0&0\\0&-1&0\end{pmatrix},\quad g_{13}=\begin{pmatrix}0&-1&0\\0&0&-1\\1&0&0\end{pmatrix}. \tag{A5}$$

g_{14} and g_{15} are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point $(-1,1,1)$,

$$g_{14}=\begin{pmatrix}0&0&-1\\-1&0&0\\0&1&0\end{pmatrix},\quad g_{15}=\begin{pmatrix}0&-1&0\\0&0&1\\-1&0&0\end{pmatrix}. \tag{A6}$$

g_{16} and g_{17} are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point $(1,1,-1)$,

$$g_{16}=\begin{pmatrix}0&0&-1\\1&0&0\\0&-1&0\end{pmatrix},\quad g_{17}=\begin{pmatrix}0&1&0\\0&0&-1\\-1&0&0\end{pmatrix}. \tag{A7}$$

g_{18} and g_{19} are rotations by π around the axis passing through the origin and the points (1,1,0) and $(1,-1,0)$, respectively,

$$g_{18}=\begin{pmatrix}0&1&0\\1&0&0\\0&0&-1\end{pmatrix},\quad g_{19}=\begin{pmatrix}0&-1&0\\-1&0&0\\0&0&-1\end{pmatrix}. \tag{A8}$$

g_{20} and g_{21} are rotations by π around the axis passing through the origin and the points (1,0,1) and $(1,0,-1)$, respectively,

$$g_{20}=\begin{pmatrix}0&0&1\\0&-1&0\\1&0&0\end{pmatrix},\quad g_{21}=\begin{pmatrix}0&0&-1\\0&-1&0\\-1&0&0\end{pmatrix}. \tag{A9}$$

g_{22} and g_{23} are rotations by π around the axis passing through the origin and the points $(0,1,1)$ and $(0,1,-1)$, respectively,

$$g_{22}=\begin{pmatrix}-1&0&0\\0&0&1\\0&1&0\end{pmatrix},\quad g_{23}=\begin{pmatrix}-1&0&0\\0&0&-1\\0&-1&0\end{pmatrix}. \tag{A10}$$

The tetrahedral group T is the subgroup of O of order 12 with elements $g_0.g_2$, g_5, g_8, and $g_{10},\ldots,g_{17}$. For more details we refer to Ref. 7.

APPENDIX B

Let G be a point group acting in the Euclidean space R^3. A closed subset S of R^3 is called a fundamental domain of G if R^3 is the union of conjugates of S, i.e.,

$$R^3=\bigcup_{g\in G} gS \tag{B1}$$

and the intersection of any two conjugates has no interior.

The fundamental domain of the group generated by the reflections ig_2, ig_5, and ig_8 with respect to $y=0$, $x=0$, and $z=0$ planes is the first quadrant in R^3. This is group of order 8 and divides R^3 into eight equal parts. If one adds to this group the element g_{10} we arrive at the group of order 24 which is the direct product of the tetrahedral group T and inversion one I generated by i. Rotation g_{10} is threefold rotation. It divides the first quadrant into three equal parts. Therefore the fundamental domain for $T\times I$ is the region in the first quadrant between three planes P_2, P_3, and $P_5=\{x_2=x_3\}$. In $T\times I$ there is the reflection operator ig_2 with respect to the P_2 plane. The Green function constructed from the group $T\times I$ will vanish on P_2. For P_3 and P_5 there is no reflection operators. g_{10} rotates P_3 into P_5. If we add to $T\times C$ the reflection operator with respect to the P_3 plane we arrive at the group $O\times I$ which is of order 48. The corresponding fundamental domain can be obtained from that of $T\times C$ by dividing it into two equal parts, that is the region between three planes P_2, P_3, and P_1. There are reflections with respect to these planes. The Green function will vanish on these planes.

(Received 10 September 2004; accepted 2 October 2004; published online 2 February 2005)

Casimir energies for a massless scalar field for a conical wedge and a conical cavity are calculated. The group generated by the images is employed in deriving the Green function as well as the wave functions and the energy spectrum. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1835547]

I. INTRODUCTION

Image method is one of the best tools in the calculation of the Casimir energies for the polygonal regions. One can use discrete group generated by the reflections with respect to the boundaries of the polygon under consideration to obtain the Green function, wave functions, and spectra of the system. The method is trivially applicable to the cavities or the given regions of space if the following conditions are fulfilled: Surfaces of the region are planar; and, they are parallel or perpendicular to each other. The discrete groups generated by reflections with respect to the planar boundaries appears to be the direct product of the translation Z and the cyclic C_2 groups. The number of copies of Z and C_2 depend on the dimension of the rectangle. For the parallel plate system and two dimensional rectangle we have the groups $C_2 \times Z$ and $(C_2 \times Z)^2$, respectively. (For a Casimir calculation in rectangular region we refer to the monograph[1] and references therein.)

Recently we tried to extend the image method to a set of geometries with planar boundaries without rectangular angles. (To our knowledge, the only previous example without rectangular angles was the wedge problem.[2]) For a class of cavities with triangular cross sections, making use of the tools of the group of reflections from the walls one can obtain the Green function satisfying the Dirichlet boundary conditions, then calculate the Casimir energy.[3] Point groups and crystallographic point groups play important roles in constructing the Green functions and the wave functions if the region we consider is the fundamental domain of the one of those groups. In other words, if every point in the region represents different orbits of the group, the satisfaction of the required wave equation by the Green function is achieved.[3,4]

In this work the example we present is the application of the image method to a geometry with nonplanar boundary. The surface of the cone we deal with is obtained from a geometry with planar surfaces, by identifying two of these surfaces. In fact if there is an element of the point group which maps one planar boundary onto another one, we can obtain volumes with nonplanar boundaries. The simple example we can think of is the wedge in R^2 with the angle $2\pi/N$. By identifying two lines which are the boundaries of the wedge we arrive at the conic surface with the opening angle $2 \arcsin(1/N)$. The corresponding point group is the cyclic one C_N, that is generated by the element q which identifies two boundaries of the wedge. It is clear that $q^N=1$.

In the next section we first consider a conical wedge in R^3 with the opening angle $2 \arcsin \frac{1}{3}$. The region is the fundamental domain of the tetrahedral group which has C_3 as a subgroup. We construct the Green function, then calculate the Casimir energy density for the massless scalar field.

[b]Electronic mail: duru@gursey.gov.tr

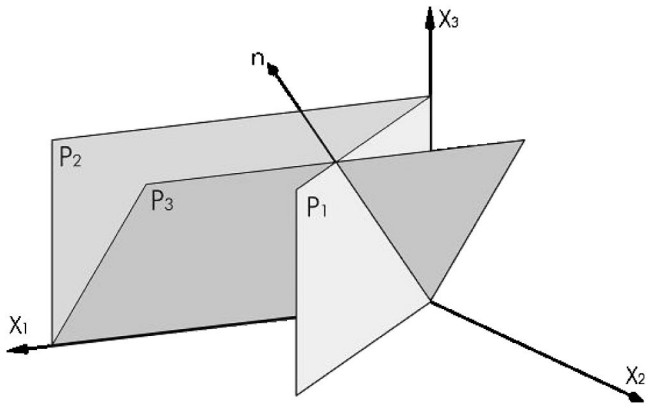

FIG. 1. Planes defined by (1).

In Sec. III making use of the group of the preceding section we construct the wave function and calculate the energy spectrum for the conical wedge.

Section IV is devoted to the closed cone, i.e., conical cavity for which we calculate the Casimir energy which is positive.

In the last section we briefly review the known Casimir energy results for three-dimensional cavities.

The required group theoretical details are given in the Appendix.

II. GREEN FUNCTION AND CASIMIR ENERGY IN A CONICAL WEDGE

Consider the following three planes in the first quadrant ($x_1>0$, $x_2>0$, $x_3>0$) (Fig. 1)

$$P_1{:}x_1 = x_2, \quad P_2{:}x_2 = 0, \quad P_3{:}x_2 = x_3. \tag{1}$$

We are interested in the Green function for the massless scalar field satisfying the boundary conditions

$$K(x,y)\big|_{\vec{x}\in P_2} = 0 \tag{2}$$

and

$$K(x,y)\big|_{\vec{x}\in P_1} = K(x,y)\big|_{g\vec{x}\in P_3}, \tag{3}$$

where

$$g = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \tag{4}$$

is the rotation matrix around $\vec{n}=(1,1,1)$; i.e., the intersection of P_1 and P_3, by angle $2\pi/3$. It transforms P_1 into P_3. The region under consideration

$$S = \{x_1 \geqslant x_2 \geqslant 0,\ x_3 \geqslant x_2 \geqslant 0\} \tag{5}$$

is the fundamental domain $S=R^3/G$ of the group $G=T\times I$, where T is the tetrahedral group and I is the inversion group generated by $i=-1$ (see the Appendix). Identifying planes P_1 and P_3 in the manner described in (3) we arrive at the space which is topologically equivalent to a cone with the plane P_2 being the boundary (Fig. 2). Bringing $\vec{x}_1$ onto $\vec{x}_3$ axis requires a rotation by the angle $2\pi/3$ around $\vec{n}$. Thus the cone we obtained has an opening angle $2\beta=2\arcsin\frac{1}{3}\cong 39°$. Therefore the problem in hand is equivalent to the study of the cone with the Dirichlet boundary condition.

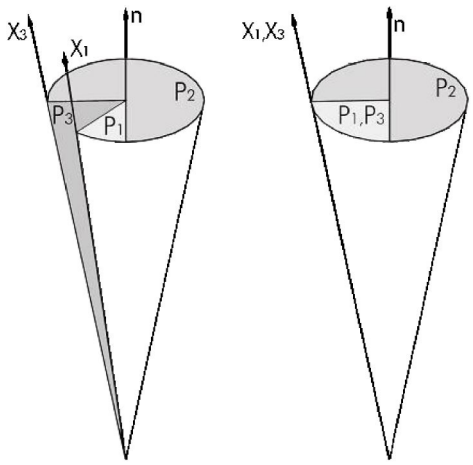

FIG. 2. Cone corresponding to the boundary condition (3).

The desired Green function is of the form

$$K(x,y) = \sum_{j=0}^{11} [G(g_j x,y) - G(ig_j x,y)], \tag{6}$$

where summation runs over the 12 elements of the tetrahedral group. Here $G(x,y)$ is the free Green function for the massless scalar field in the Minkowski space (in $\hbar = c = 1$ units)

$$G(x,y) = \frac{1}{4\pi^2} \frac{1}{|x-y|^2}. \tag{7}$$

To check the boundary conditions, we observe that for any element $g_j \in T$ there exists an element $g_a \in T$ such that $g_a = g_j g$. Therefore

$$K(gx,y) = K(x,y), \tag{8}$$

which implies that the boundary condition (3) is fulfilled. To show the boundary condition (2) we first define the reflection operator with respect to P_2,

$$q = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{9}$$

For any element $g_j \in T$ there exists an element $g_b \in T$ such that $ig_b = g_j q$. Therefore

$$K(qx,y) = -K(x,y), \tag{10}$$

which implies that the boundary condition (2) is fulfilled.

To obtain the energy momentum tensor for the conformally coupled massless scalar field we employ the well-known coincidence limit formula[5]

$$T_{\mu\nu} = \lim_{x \to y} \left[\frac{2}{3} \partial^y_\mu \partial^x_\nu - \frac{1}{6} (\partial^x_\mu \partial^x_\nu + \partial^y_\mu \partial^y_\nu) - \frac{\eta_{\mu\nu}}{6} \eta^{\sigma\rho} \partial^y_\sigma \partial^x_\rho + \frac{\eta_{\mu\nu}}{24} \eta^{\sigma\rho} (\partial^x_\sigma \partial^x_\rho + \partial^y_\sigma \partial^y_\rho) \right] K(x,y). \tag{11}$$

The energy density $T(x) = T_{00}$ is given by

$$T(x) = \frac{1}{12\pi^2}\sum_{j=1}^{11}[T(g_j) - T(ig_j)], \tag{12}$$

where

$$T(g) = \left(\frac{\mathrm{tr}(g) - 1}{|\vec{\eta}|^4} - 2\frac{|((1+g)\vec{\eta})|^2}{|\vec{\eta}|^6}\right) \tag{13}$$

and

$$\vec{\eta} = (1 - g)\vec{x} \tag{14}$$

with g standing for g_j and ig_j.

Using the invariance of $T(g)$ under $g \to g^{-1}$ we have

$$\begin{aligned} T(g_4) &= T(g_5), \\ T(g_6) &= T(g_7), \\ T(g_8) &= T(g_9), \\ T(g_{10}) &= T(g_{11}). \end{aligned} \tag{15}$$

The same equalities are true for elements ig_j, with j running the same values as (15).

(i) For the rotation g_6 by angle $2\pi/3$ around the line passing through the origin and the point $(1,-1,1)$ we have

$$T(g_6) = -\frac{3}{((x_1+x_2)^2 + (x_2+x_3)^2 + (x_3-x_1)^2)^2}, \tag{16}$$

$$T(ig_6) = -\frac{6|\vec{x}|^2 + 2(x_1x_3 - x_1x_2 - x_2x_3)}{((x_1-x_2)^2 + (x_2-x_3)^2 + (x_3+x_1)^2)^3}. \tag{17}$$

Since g_8 and g_{10} are rotation matrices by the same angle around the axis passing through the origin and the points $(-1,1,1)$ and $(1,1,-1)$ we conclude that $T(g_8)$, $T(ig_8)$ and $T(g_{10})$, $T(ig_{10})$ are given by (16) and (17) with the cyclic replacements of coordinates $(x_1,x_2,x_3) \to (x_3,x_1,x_2)$ and $(x_1,x_2,x_3) \to (x_2,x_3,x_1)$, respectively.

(ii) We also have

$$T(g_4) = -\frac{3}{((x_1-x_2)^2 + (x_2-x_3)^2 + (x_3-x_1)^2)^2}, \tag{18}$$

$$T(ig_4) = -\frac{6|\vec{x}|^2 - 2(x_1x_2 + x_1x_3 + x_2x_3)}{((x_1+x_2)^2 + (x_1+x_3)^2 + (x_2+x_3)^2)^3}. \tag{19}$$

(iii) For elements satisfying the condition $g^2 = 1$ the second expression in (13) vanishes. These are the elements g_j, $j = 1,2,3$. Since $\mathrm{tr}(ig_j) = 1$ we have $T(ig_j) = 0$. Nonzero ones are then

$$T(i) = -\frac{1}{4|\vec{x}|^4} \tag{20}$$

and

$$T(g_1) = -\frac{1}{8(x_2^2 + x_3^2)^2}. \tag{21}$$

The remaining two terms $T(g_2)$, $T(g_3)$ are obtained from the above equation by the cyclic replacements of coordinates.

Inserting the results from (16) to (21) into (12) we arrive at the energy density

$$T(x) = \frac{1}{12\pi^2}[T(g_4) - T(ig_4) - T(i)] + \frac{1}{12\pi^2}\left[\frac{1}{8}T(g_1) + 2T(g_6) - 2T(ig_6) + \text{c.p.}\right]. \tag{22}$$

Here c.p. stands for cyclic permutations of coordinates.

III. WAVE FUNCTION AND THE SPECTRUM IN THE CONICAL WEDGE

In this section we briefly present the derivation of the wave function and the spectrum. We write the wave function in a similar fashion as the Green function as

$$\Psi_{\vec{p}}(\vec{x}) = \Omega \sum_{j=0}^{11} [e^{i(\vec{p}, g_j\vec{x})} - e^{i(\vec{p}, ig_j\vec{x})}] \tag{23}$$

or

$$\Psi_{\vec{p}}(\vec{x}) = -8i\Omega[\sin p_1x_1 \sin p_2x_2 \sin p_3x_3 + \text{c.p.}] \tag{24}$$

with Ω being the normalization. To obtain the spectrum we first observe that

$$\Psi_{g_j\vec{p}}(\vec{x}) = \Psi_{\vec{p}}(\vec{x}), \quad \Psi_{i\vec{p}}(\vec{x}) = -\Psi_{\vec{p}}(\vec{x}), \tag{25}$$

which imply that the momentum $\vec{p}$ takes its values in the quotient space R^3/G which is exactly the region S of (5). In other words, the geometry in the momentum space is the replica of the geometry in the configuration space, the fact that can be used in deriving the spectra. Since

$$\Psi_{\vec{p}}(\vec{x})|_{\vec{p}\in P_2} = 0 \tag{26}$$

we must drop the values of $\vec{p}$ on the plane P_2 ($p_2=0$). The condition

$$\Psi_{\vec{p}}(\vec{x})|_{\vec{p}\in P_1} = \Psi_{\vec{p}}(\vec{x})|_{g\vec{p}\in P_3} \tag{27}$$

implies that momenta on the plane P_1 ($p_1=p_2$) are equivalent to the ones on the plane P_3 ($p_2=p_3$). It is sufficient to take into account momenta on one of these planes (take, for example, values on P_1) and drop the ones on the other. Therefore the spectrum in the conical wedge is

$$\Sigma_0 = S \setminus (A \cup B) = \{p_1 \geqslant p_2 > 0,\ p_3 > p_2 > 0\}, \tag{28}$$

where A and B are the boundaries of S corresponding to P_2 and P_3 planes,

$$A = \{p_1 \geqslant 0,\ p_2 = 0\ p_3 \geqslant 0\}, \tag{29}$$

$$B = \{p_1 \geqslant p_2 \geqslant 0,\ p_3 = p_2 \geqslant 0\}. \tag{30}$$

IV. CONICAL CAVITY

In addition to the planes of (1) consider two additional ones,

$$P_4{:}x_1 = a, \quad P_5{:}x_3 = a. \tag{31}$$

The region we consider is then given by

$$H=\{a\geqslant x_1\geqslant x_2\geqslant 0,\ a\geqslant x_3\geqslant x_2\geqslant 0\}. \tag{32}$$

Boundary conditions (26) and (27) and the new Dirichlet conditions on P_4 and P_5,

$$\Psi_{\vec{p}}(\vec{x})\big|_{\vec{p}\in P_4}=\ \Psi_{\vec{p}}(\vec{x})\big|_{\vec{p}\in P_5}=0, \tag{33}$$

imply that the geometry in hand is a conical cavity with the opening angle $\beta=\arcsin\frac{1}{3}$ and height $h=a\cos\beta=(2\sqrt{2}/3)a$. The Dirichlet boundary conditions (33) quantize the momenta,

$$p_1=\frac{\pi}{a}n,\quad p_2=\frac{\pi}{a}m,\quad p_3=\frac{\pi}{a}k, \tag{34}$$

where n, m, and k are integers which subject to the condition (28) [with $\vec{n}=(n,m,k)$]

$$\Sigma=\Sigma_0\cap Z^3=\left\{\vec{p}=\frac{\pi}{a}\vec{n}\colon\ n\geqslant m>0,\ k>m>0\right\}. \tag{35}$$

The Green function can be written as

$$G(x,y)=\sum_{m=1}^{\infty}\sum_{k=m+1}^{\infty}\sum_{n=m}^{\infty}\frac{e^{i\pi|\vec{p}|(x_0-y_0)}}{2|\vec{p}|}\Psi_{\vec{p}}(\vec{x})\Psi_{\vec{p}}(\vec{y}). \tag{36}$$

The energy density we obtain is

$$T(x)=\frac{\pi}{2a}\sum_{m=1}^{\infty}\sum_{k=m+1}^{\infty}\sum_{n=m}^{\infty}\sqrt{n^2+m^2+k^2}\,|\Psi_{\vec{p}}(\vec{x})|^2. \tag{37}$$

After integration $\int_0^a dx_2\int_{x_2}^a dx_3\int_{x_2}^a dx_1$ over the conical cavity H we get the total energy

$$E=\frac{\pi}{2a}\sum_{\vec{n}\in\Sigma}|\vec{n}|=\frac{\pi}{48a}\sum_{\vec{n}\in\Sigma}\sum_{g\in G}|g\vec{n}|=\frac{\pi}{48a}\sum_{\vec{n}\in\cup g\Sigma}|\vec{n}|. \tag{38}$$

Since $\Sigma=\ S\backslash(A\cup B))\cap Z^3$ and $S=R^3/G$ we have

$$\bigcup_{g\in G}g\Sigma=Z^3\backslash C, \tag{39}$$

where

$$C=(\ \bigcup_{g\in G}g(A\cup B))\cap Z^3 \tag{40}$$

is the union of six planes in Z^3: $m=0$, $k=m$ and other four planes are obtained by cyclic permutations of n, m, and k,

$$\sum_{\vec{n}\in C}|\vec{n}|=3\sum_{n,m\in Z}\sqrt{n^2+m^2}+3\sum_{n,m\in Z}\sqrt{2n^2+m^2}, \tag{41}$$

(38) and (39) imply

$$E=\frac{\pi}{48a}\left(\sum_{\vec{n}\in Z^3}|\vec{n}|-\sum_{\vec{n}\in C}|\vec{n}|\right) \tag{42}$$

or

$$E = \frac{1}{3}E_1 - \frac{1}{2}E_2 - \frac{2+\sqrt{2}}{4}E_3 \simeq \frac{0.085}{a}. \tag{43}$$

Here E_1, E_2, and E_3 are the Casimir energies for the cube with sides a, for the rectangle with sides a and $a/\sqrt{2}$; and, for the one-dimensional system of length a, respectively,[6]

$$E_1 = \frac{\pi}{2a}\sum_{n,m,k=1}^{\infty}\sqrt{n^2+m^2+k^2} \simeq -\frac{0.015}{a}, \tag{44}$$

$$E_2 = \frac{\pi}{2a}\sum_{n,m=1}^{\infty}\sqrt{n^2+2m^2} \simeq \frac{0.045}{a}, \tag{45}$$

$$E_3 = \frac{\pi}{2a}\sum_{n=1}^{\infty} n \simeq -\frac{0.131}{a}. \tag{46}$$

V. DISCUSSION

Examples of the Casimir energy calculations for three-dimensional cavities are not plenty. The cubical[1,6] and the spherical[7] cavities have been studied rather extensively. In this work we have studied a conical cavity with a particular opening angle. Similar restriction is true for the recently studied pyramidal geometry for which the angles at the vertices are not arbitrary.[4] We do not have results in hand for the last two kinds of geometries with arbitrary angles. Nevertheless, it may be of interest to briefly review the known Casimir energy calculations (for the massless scalar fields) for the above-mentioned geometries. To have a better idea of the magnitudes we consider the cavities of comparable sizes.

For cube of sides $2b$, we have negative value for the energy: $E_{\text{cub}} \simeq -0.007/b$.[1,6]

For spherical cavity of radius b the Casimir energy is positive $E_{\text{sph}} \simeq 0.046/b$.[7]

Coming to the recently studied pyramidal cavity, let us first describe its position with respect to the above cube. One of the four vertices is located at the center of the cube, the remaining three at the center of a surface, and at the closest vertex and at the middle of the closest edge to this vertex.[4] The volume of this cavity is $b^3/6$ and the Casimir energy is again positive, $E_{\text{pyr}} \simeq 0.069/b$.

For the present conical cavity of opening angle $2\beta = 2\arcsin\frac{1}{3}$ and height b [i.e., $b = (2\sqrt{2}/3)a$] which has the positive energy of (43) is $E_{\text{con}} \simeq 0.080/b$.

To see the dependence of the magnitudes of the positive Casimir energies on the "shapes" of the cavities, let us compare the last three results for the "equal" volumes. If we consider the spherical, pyramidal, and conical cavities with equal volumes we have the following ratios:

$$E_{\text{con}} \simeq 0,54E_{\text{sph}}, \tag{47}$$

$$E_{\text{pyr}} \simeq 0,51E_{\text{sph}}. \tag{48}$$

It is not surprising that the conical and pyramidal geometries are very close to each other.

APPENDIX

Tetrahedral group T is the group of transformations which transforms cube into itself. The order of this group is 12. We denote the identity element by g_0. g_1, g_2, and g_3 are rotations on π around x, y, and z axis,

$$g_1=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&-1\end{pmatrix},\quad g_2=\begin{pmatrix}-1&0&0\\0&1&0\\0&0&-1\end{pmatrix},\quad g_3=\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&1\end{pmatrix}. \tag{A1}$$

g_4 and g_5 are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point (1,1,1),

$$g_4=\begin{pmatrix}0&0&1\\1&0&0\\0&1&0\end{pmatrix},\quad g_5=\begin{pmatrix}0&1&0\\0&0&1\\1&0&0\end{pmatrix}. \tag{A2}$$

g_6 and g_7 are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point $(1,-1,1)$,

$$g_6=\begin{pmatrix}0&0&1\\-1&0&0\\0&-1&0\end{pmatrix},\quad g_7=\begin{pmatrix}0&-1&0\\0&0&-1\\1&0&0\end{pmatrix}. \tag{A3}$$

g_8 and g_9 are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point $(-1,1,1)$,

$$g_8=\begin{pmatrix}0&0&-1\\-1&0&0\\0&1&0\end{pmatrix},\quad g_9=\begin{pmatrix}0&-1&0\\0&0&1\\-1&0&0\end{pmatrix}. \tag{A4}$$

g_{10} and g_{11} are rotations by $2\pi/3$ and $4\pi/3$ around the axis passing through the origin and the point $(1,1,-1)$,

$$g_{10}=\begin{pmatrix}0&0&-1\\1&0&0\\0&-1&0\end{pmatrix},\quad g_{11}=\begin{pmatrix}0&1&0\\0&0&-1\\-1&0&0\end{pmatrix}. \tag{A5}$$

Let G be a point group acting in the Euclidean space R^3. A closed subset S of R^3 is called a fundamental domain of G if R^3 is the union of conjugates of S, i.e.,

$$R^3=\bigcup_{g\in G} gS \tag{A6}$$

and the intersection of any two conjugates has no interior.

The fundamental domain of the group generated by the reflections ig_1, ig_2, and ig_3 with respect to $x_1=0$, $x_2=0$, and $x_3=0$ planes is the first quadrant in R^3. This is group of order 8 and divides R^3 into eight equal parts. If one adds to this group the element g_4 we arrive at the group of order 24 which is the direct product of the tetrahedral group T and inversion one I generated by i. Rotation g_4 is threefold rotation. It divides the first quadrant into three equal parts. Therefore the fundamental domain for $T\times I$ is the region in the first quadrant between three planes (1).

Necessary and sufficient conditions for a static space–time to be locally conformally flat are obtained, showing some significant restrictions on the possible warping functions of the space–times. This occurs in opposition to cosmological models, where Robertson–Walker space–times are locally conformally flat for any warping function. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1832755]

I. INTRODUCTION

For many years a considerable interest has been shown to the study of physical properties of space–times which are conformal to certain well-known gravitational fields. In locally conformally flat space–times the number of unknown functions is reduced in contrast with general space–times and thus locally conformally flat metrics are of particular interest. A number of locally conformally flat physically significant space–times are known among cosmological models and stationary axisymmetric space–times. Indeed, conformally flat stationary metrics have been recently studied in Refs. 1 and 9 (see also Ref. 10). Summarizing those results it follows that conformally flat stationary circular axisymmetric space–times are necessarily static. (Also, all conformally flat pure radiation metrics are determined in Refs. 6 and 7.) We refer to Ref. 14 for some partial results on locally conformally flat static space–times with perfect fluid energy momentum tensor. However locally conformally flat static space–times are rare in the literature besides the Einstein static Universe or the Schwarzschild interior solution.[3,22]

A Lorentzian manifold (M, g) is called a space–time if there exists a timelike vector field on (M, g). Moreover a future directed unit timelike vector field U is called an observer field. Whenever it is possible to integrate the infinitesimal rest spaces of U to obtain a rest space, U is called *irrotational*. A space–time M is *static* relative to an observer field U if U is irrotational and there is a smooth function $h>0$ on M such that hU is a Killing vector field. (U is called stationary if there is $h>0$ such that hU is Killing, but not necessarily irrotational.) If M is a static space–time with static reference frame U, then M is locally a warped product $N\times_h I$, where $I\subset\mathbb{R}$ is an interval and N is a Riemannian manifold. Thus, in opposition to cosmological space–times, space remains the same but time is warped in static space–times. The fact that only space is warped in Robertson–Walker space–times has important implications as concerns conformal flatness, for instance Robertson–Walker space–times are locally conformally flat for any possible warping function.

By using the warped product structure of static space–times, a direct approach to investigate their conformal properties was based on the fact that the local geometry of the warped product is entirely expressible in terms of the geometry of the rest space and some equations involving the warping functions.[11,12,20] Unfortunately such approach led to some PDE's on the warping function which are difficult to analyze and their geometrical significance remains somehow obscure.

The approach we have followed in investigating locally conformally flatness of warped product metrics essentially differs from previous ones, since it relies on the fact that any warped product metric is in the conformal class of a suitable direct product metric. This presents a main advantage with respect to previous studies: the necessary and sufficient conditions for a warped product metric to be locally conformally flat become more tractable and it is possible to investigate the existence of suitable warping functions which make a standard static space–time locally conformally flat. This is due to the fact that the geometrical significance of the warping function of the product $B\times_f F$ is clearer, since it expresses analytically that $(1/f^2)g_B$ is a metric of constant sectional curvature on the base B. Furthermore, the local existence of solutions of the PDE's defining the warping function for any locally conformally flat base (B, g_B) and any fiber (F, g_F) of constant sectional curvature is guaranteed by the existence of local Möbius transformations among the different spaces of constant sectional curvature, thus showing the richness of the local structure of locally conformally flat warped product metrics. Up to our knowledge, the fact that any warped product metric is in the conformal class of a suitable product metric has not been exploited previously. Since many important properties of space–times like causality conditions, null pregeodesics, null cut points, etc., are conformally invariant, it seems the approach we have followed in investigating conformally flat structures is susceptible to be applied in some other problems.

The paper is organized as follows. Since the geometric construction beside static space–times are warped products, we first obtain a criteria (cf. Theorem 1) for locally conformal flatness of such manifolds in Sec. II. As a consequence, the local structure of locally conformally flat warped product metrics is easily obtained. A commonly used generalization of warped product metrics is that of twisted product metrics, which is investigated in Sec. III, showing that locally conformally flat twisted product metrics are warped product metrics in most cases. In Sec. IV, we study the existence and uniqueness of warping functions in locally conformally flat warped products. All warping functions over a base of constant sectional curvature making $B\times_f\mathbb{R}$ locally conformally flat are determined (Theorem 10), which is a consequence of the fact that all such warping functions define Möbius transformations on the base (B,g_B) (cf. Lemma 9). As a uniqueness result on the warping function we show that the existence of two warping functions making $B\times_{f_1} F_1$ and $B\times_{f_2} F_2$ locally conformally flat for a compact base (B,g_B) forces it to be conformal to the Euclidean sphere S^n (Theorem 13). Finally, some remarks on Riemannian warped products of negative curvature are given in Sec. V.

II. CONFORMALLY FLAT WARPED PRODUCT METRICS

Let (B,g_B) and (F,g_F) be semi-Riemannian manifolds and let $\pi:B\times F\to B$ and $\sigma:B\times F\to F$ be the canonical projections. Also let $f:B\to\mathbb{R}^+$ be a smooth function. Then the *warped product* $B\times_f F$ of (B,g_B) and (F,g_F) with *warping function* f is defined to be the product manifold $M=B\times F$ with the metric tensor $g=\pi^*g_B\oplus(f\circ\pi)^2\sigma^*g_F$. For simplicity g will be denoted by $g=g_B\oplus f^2g_F$ from now on, and we refer to (B,g_B) and (F,g_F) as the *base* and the *fiber* of the product, respectively.[2]

Recall that a semi-Riemannian manifold (M,g) is locally conformally flat if and only if every point in M admits a coordinate neighborhood $\mathfrak{U}$ which is conformal to the semi-Euclidean space $\mathbb{R}^n_\nu$, i.e., there is a diffeomorphism $\Phi:V\subset\mathbb{R}^n_\nu\to\mathfrak{U}$ such that $\Phi^*g=\Psi^2g_{\mathbb{R}^n_\nu}$ for some positive function Ψ. Note that any surface is locally conformally flat, but not every higher dimensional semi-Riemannian manifold admits a locally conformally flat structure. Necessary and sufficient conditions for the existence of such a structure are given by the nullity of the Weyl tensor (if $\dim M\geqslant 4$) and the fact that the Schouten tensor is a Codazzi tensor in dimension three. Locally conformally flat warped product spaces have been investigated by several authors (see, for example, Refs. 11, 12, and 20) who obtained necessary and sufficient conditions for $M=B\times_f F$ to be locally conformally flat in terms of both the curvatures of the base (B,g_B) and the fiber (F,g_F) and some PDE's involving the warping function f. Those results have been obtained as the necessary and sufficient conditions for the vanishing of the Weyl tensor on $B\times_f F$.

The next theorem is a fundamental observation for our purposes since it gives a criterion for

locally conformally flatness of a warped product which enables us to understand the geometrical meaning of the PDE's involving the warping function in Refs. 11 and 20.

Theorem 1: *Let $M=B\times_f F$ be a semi-Riemannian warped product. Then the following hold*:

(i) *If dim $B=1$, then $M=B\times_f F$ is locally conformally flat if and only if (F, g_F) is a space of constant curvature.*

(ii) *If dim $B>1$ and dim $F>1$, then $M=B\times_f F$ is locally conformally flat if and only if*

  (iia) *(F, g_F) is a space of constant curvature c_F.*

  (iib) *The function $f:B\to\mathbb{R}^+$ defines a global conformal deformation on B such that $(B, (1/f^2)g_B)$ is a space of constant curvature $\tilde{c}_B=-c_F$.*

(iii) *If dim $F=1$, then $M=B\times_f F$ is locally conformally flat if and only if the function $f:B\to\mathbb{R}^+$ defines a conformal deformation on B such that $(B, (1/f^2)g_B)$ is a space of constant curvature.*

Proof: Let $g=g_B+f^2g_F$ be the warped product metric on $M=B\times F$ and set $g=f^2(1/f^2g_B+g_F)$. Since locally conformally flatness is a conformally invariant property, g is a locally conformally flat metric on M if and only if so is $\tilde{g}=(1/f^2)g_B+g_F$. Now, after observing that $\tilde{g}$ is nothing but the product metric of $(B, (1/f^2)g_B)$ and (F, g_F), the result follows from Ref. 25, Theorem 4. [Note that the warping function of a warped product is only defined on the base, and thus $(1/f^2)g_B$ is a conformal deformation of g_B.] ■

Note here that for a given fiber (F, g_F) there is no restriction for the warping function f if the base B is one dimensional. Thus, Robertson–Walker space–times are locally conformally flat independently of the warping function, since previous theorem reduces to (i) if dim $B=1$. However as soon as dim $B>1$, there are strong limitations on the possible warping functions, as shown in the next section.

Corollary 2: Let $M=B\times_f F$ be a locally conformally flat semi-Riemannian warped product. Then (B, g_B) is locally conformally flat and (F, g_F) is of constant sectional curvature.

Remark 3: Now, as a consequence of previous results, the local structure of locally conformally flat warped product metrics can be given as follows as a local converse to Corollary 2. *Let (B, g_B) be a locally conformally flat manifold and (F, g_F) a space of constant sectional curvature. Then there exist locally defined warping functions $f_{\mathfrak{U}}:\mathfrak{U}\subset B\to\mathbb{R}^+$ such that the warped product manifold $\mathfrak{U}\times_{f_{\mathfrak{U}}} F$ is locally conformally flat.* Indeed, note that $f_{\mathfrak{U}}$ is defined in terms of the local conformal factor and some appropriate Möbius transformations in order to adjust the sectional curvatures of (F, g_F) and $(\mathfrak{U}, \tilde{g})$.

Note that the vanishing of the Weyl tensor is a local property. Indeed, $M=B\times_f F$ is locally conformally flat if and only if for each point $p\in M$ there exist functions Ψ defined in a neighborhood of p such that the restriction of $\Psi^2\cdot g$ to the defining neighborhood is flat. Since all spaces of constant curvature are locally conformally flat, we have plenty of functions Ψ as before in any locally conformally flat manifold.

However, the implication in Theorem 1 is on the whole base B, since the warping function is globally defined. Therefore, two basic problems arise from the above, when is it possible to extend the locally defined warping functions to the whole base B and, in such case, is there any kind of uniqueness on the warping functions?

Remark 4: As an application of Theorem 1 (iii), a four-dimensional static space–time $B\times_f\mathbb{R}$ is locally conformally flat if and only if $(B,(1/f^2)g_B)$ is Einstein. Therefore, any conformal Einstein 3-manifold gives rise to a suitable defined locally conformally flat static space–time. (See Refs. 15 and 17 and the references therein for more information on conformal Einstein equations.)

Remark 5: As a generalization of the warped product structure, a *doubly warped product* $B_b\times_f F$ of (B, g_B) and (F, g_F) with warping functions f and b is the product manifold $M=B\times F$ with metric tensor $g=b^2g_B\oplus f^2g_F$, where f and b only depend on the points of B and F, respectively. Now, proceeding as above, one can express the double warped metric g as

$$g = b^2 g_B + f^2 g_F = b^2\left(g_B + f^2\left(\frac{1}{b^2}g_F\right)\right) = f^2\left(b^2\left(\frac{1}{f^2}g_B\right) + g_F\right) = b^2 f^2\left(\left(\frac{1}{f^2}g_B\right) + \left(\frac{1}{b^2}g_F\right)\right),$$

which shows that the doubly warped product is in the conformal class of a certain warped product (indeed the conformal class of a direct product). Thus previous Theorem 1 applies to show that $B_b\times_f F$ is locally conformally flat if and only if $(B,\ (1/f^2)g_B)$ and $(F,\ (1/b^2)g_F)$ have constant sectional curvatures, which are necessarily of opposite sign if both B and F have dimension greater than one, thus giving a geometrical meaning to the PDE's systems in Ref. 12.

III. CONFORMALLY FLAT TWISTED PRODUCT METRICS

The *twisted product* $B\times_f F$ of (B,g_B) and (F,g_F) with twisting function f is the product manifold $B\times F$ with metric tensor $g=g_B\oplus f^2 g_F$, where f depends both on the points of B and F, i.e., $f:B\times F\to\mathbb{R}^+$.

A curvature condition, called the mixed Ricci flatness was stated in terms of the product manifold structure in Ref. 8 in order to relate the twisted and warped product structures. Such condition (which essentially means that the Ricci tensor vanishes when it is applied to vector fields on the base and the fiber simultaneously) is satisfied in most physically realistic space–times, such as Kruskal and Robertson–Walker space–times, because of the physical requirements induced by the stress-energy tensor on these space–times. Observing that these space–times are warped products, roughly speaking, the main result in Ref. 8, Theorem 1 allows us to observe that this is the maximal generality for these space–times since they cannot be further generalized to twisted products in a nontrivial way. As an application of such criteria, we have the following theorem.

Theorem 6: *Let* $M=B\times_f F$ *be a semi-Riemannian twisted product with* $\dim B\geqslant 2$ *and* $\dim F\geqslant 2$. *If* M *is locally conformally flat then it can be expressed as a warped product.*

Proof: First of all, recall that a $(n\geqslant 4)$-dimensional semi-Riemannian manifold is locally conformally flat if and only if its Weyl tensor W vanishes, where W is defined as follows:

$$W(X,Y,Z,T) = R(X,Y,Z,T) + \frac{\mathrm{Sc}}{(n-1)(n-2)}\{\langle X,Z\rangle\langle Y,T\rangle - \langle Y,Z\rangle\langle X,T\rangle\}$$
$$- \frac{1}{n-2}\{\mathrm{Ric}(X,Z)\langle Y,T\rangle - \mathrm{Ric}(Y,Z)\langle X,T\rangle + \langle X,Z\rangle\mathrm{Ric}(Y,T) - \langle Y,Z\rangle\mathrm{Ric}(X,T)\}$$

for all vector fields X,Y,Z,T on M. Further the curvature tensor R is the (1,3)-tensor field on M defined by $R(X,Y)Z=\nabla_{[X,Y]}Z-[\nabla_X,\nabla_Y]Z$, for all vector fields X, Y, $Z\in\mathfrak{X}(M)$. The Ricci tensor is the contraction of the curvature tensor given by $\mathrm{Ric}(X,Y)=\mathrm{trace}\{U\rightsquigarrow R(X,U)Y\}$, for all X, $Y\in\mathfrak{X}(M)$, and the scalar curvature is obtained by contracting the Ricci tensor, $\mathrm{Sc}=\mathrm{trace}(\mathrm{Ric})$.

Let X and V denote two non-null vector fields on B and F, respectively. Since $\dim B\geqslant 2$, choose Y a non-null vector field on B in the orthogonal space to X; $Y\in<X>^{\perp}$. After some straightforward calculations, it follows that the Weyl tensor of $M=B\times_f F$ satisfies (cf. see, for example, Ref. 8, Proposition 2, 3, 4 for the expressions of the curvature tensor, the Ricci and scalar curvature of a twisted product)

$$W(Y,X,Y,V) = -\frac{1}{n-2}g(Y,Y)\mathrm{Ric}(X,V).$$

Therefore, if $M=B\times_f F$ is locally conformally flat, then $\mathrm{Ric}(X,V)=0$ for all vector fields X and V on the base and the fiber, which shows that $M=B\times_f F$ is mixed Ricci flat, and thus a warped product if $\dim F\geqslant 2$. ■

Remark 7: Following the same idea behind Theorem 1, for the metric tensor of any twisted product $B\times_f F$, set

$$g_B + f^2 g_F = f^2\left(\frac{1}{f^2} g_B + g_F\right).$$

This shows that $B\times_f F$ is locally conformally flat if and only if so is $F\times_{1/f} B$. But this time $g_F + (1/f^2)g_B$ is still a twisted product metric, since the twisting function f depends both on B and F. However previous relation preserves the (possible) reduction of the twisted product to a warped one, since f decomposes as a product of two functions f_B and f_F defined on B and F, respectively, if and only if so does $1/f$, just observing that $XU(\log f) = -XU[\log(1/f)]$ for all vector fields X, U on B and F, respectively. (See Ref. 8 for more details on the condition for a twisted product to be a warped product.)

Remark 8: The duality condition in the previous remark justifies the symmetry on the conditions $\dim B \geqslant 2$, $\dim F \geqslant 2$ in Theorem 6.

In order to show the necessity of those restrictions, we construct some simple examples showing the necessity of the assumptions on $\dim B \geqslant 2$, $\dim F \geqslant 2$ as follows. Let $I \subset \mathbb{R}$ be an open interval and take $U \subset \mathbb{R}^3$ an open set such that $f(t,x,y,z) = 1/(t+z)$ is positive on $I \times U$. Then the twisted product manifold $I\times_f U$ is locally conformally flat. (The vanishing of the Weyl tensor is obtained after some tedious calculations that we omit.) Furthermore, note that $I\times_f U$ cannot be reduced to a warped product structure since $\mathrm{Ric}(\partial/\partial t, \partial/\partial z) = -2/(t+z)^2$, which shows that it is not mixed Ricci flat.

Locally conformally flat twisted product metrics with one-dimensional fiber are easily obtained from Remark 7 just considering $U\times_{1/f} I$.

IV. LOCALLY CONFORMALLY FLAT STATIC SPACE–TIMES

Since static space–times are locally warped products with one-dimensional fiber, from now on we will restrict to standard static space–times, thus assuming the structure of a warped product $B\times_f \mathbb{R}$ for some positive function f on B.

As a consequence of Theorem 1, a product manifold $B\times\mathbb{R}$ is locally conformally flat if and only if (B, g_B) is a space of constant curvature. This occurs, for instance in the Einstein static universe $\mathbb{S}^n\times\mathbb{R}$. It is obvious that for any constant function f on B, the warped product $B\times_f \mathbb{R}$ is also locally conformally flat. Therefore, it seems natural to wonder whether there are nonconstant warping functions on B defining a locally conformally flat static space–time.

In order to understand the question above, we first introduce some notation as follows. Let ∇ denote both the Levi–Cività connection associated to the given metric and the *gradient operator* on a generic semi-Riemannian manifold (M, g). The *Hessian tensor* h_f of a real-valued function $f: M \to \mathbb{R}$ is defined by $h_f(X) = \nabla_X \nabla f$, where X is a vector field on M. Also the symmetric (0,2)-tensor field H_f defined on (M, g) by $H_f(X,Y) = g(h_f(X), Y)$ is called the *Hessian form* of f. We define the *Laplacian* Δf of a function f on (M, g) by $\Delta f = \mathrm{trace}\, h_f$ $(=\mathrm{div}\, \nabla f)$, where div is the divergence.

It follows from Remark 3 the local existence of warping functions making $(\mathfrak{U}\subset B)\times_{f_{\mathfrak{U}}} \mathbb{R}$ locally conformally flat. However, global existence of such functions is not clear. Next, in order to understand the simplest cases, we consider static space–times with base (B, g_B) of constant sectional curvature and $\dim B = n$. Then we have the following analytical characterization of the warping function.

Lemma 9: Let $M = B\times_f \mathbb{R}$ be a locally conformally flat static space–time. Then (B, g_B) is of constant sectional curvature if and only if the warping function f defines a solution $\phi = -\ln f$ of the Möbius equation $B_{g_B}(\phi) = 0$, where

$$B_{g_B}(\phi) = H_\phi - \mathrm{d}\phi \otimes \mathrm{d}\phi - \frac{1}{n}\{\Delta\phi - \|\nabla\phi\|^2\} g_B. \tag{1}$$

Moreover, for any base (B, g_B) of constant sectional curvature and any positive solution ϕ of (1)*, the warped product $B\times_f \mathbb{R}$ is locally conformally flat.*

Proof: Since (B, g_B) is locally conformally flat by Corollary 2, then it is of constant sectional

curvature if and only if it is Einstein. On the other hand, $(B, (1/f^2)g_B)$ is a space of constant sectional curvature by Theorem 1, and thus Einstein. Therefore (B,g_B) is of constant sectional curvature if and only if the conformal deformation $g_B \mapsto (1/f^2)g_B$ preserves the Einstein property, which occurs if and only if f is a solution of the Möbius equation.[21] Now, the second part of the lemma follows from Theorem 1 and the above considerations. ■

It is shown in Ref. 21 that, if $\phi: B \to \mathbb{R}$ satisfies the Möbius equation on (B,g_B) then the function $\psi = \exp(-\phi)$ satisfies $H_\psi = (1/n)\Delta\psi g_B$ on (B,g_B), since $H_{\exp(\phi)} = \exp(\phi)\{H_\phi + \mathrm{d}\phi \otimes \mathrm{d}\phi\}$. In what follows we will refer to $H_\psi = (1/n)\Delta\psi g_B$ as the linearized Möbius equation on (B,g_B).

From the previous lemma, the following description of the possible warping functions on a locally conformally flat static space–time with base a (complete and simply connected) space of constant sectional curvature is obtained.

Theorem 10: *Let (B, g_B) be a complete and simply connected Riemannian manifold of constant sectional curvature. Then the static space–time $B \times_f \mathbb{R}$ is locally conformally flat if and only if one of the following occurs*:

(i) *If $B \equiv \mathbb{R}^n$, where $\mathbb{R}^n$ denotes the Euclidean space, then all possible warping functions are given by*

$$f(\vec{\mathbf{x}}) = a\|\vec{\mathbf{x}}\|^2 + \langle \vec{\mathbf{b}}, \vec{\mathbf{x}} \rangle + c, \quad \vec{\mathbf{b}} \in \mathbb{R}^n,\ a,c \in \mathbb{R}, \tag{2}$$

where the coefficients a, $\vec{\mathbf{b}}$ and c satisfy $4ac - \|\vec{\mathbf{b}}\|^2 > 0$, $a > 0$ and $\langle , \rangle$ is the Euclidean inner product in $\mathbb{R}^n$.

(ii) *If $B \equiv \mathbb{H}^n$, where $\mathbb{H}^n$ denotes the Poincaré half-space model of the hyperbolic geometry, then all possible warping functions are given by*

$$f(\vec{\mathbf{x}}) = \frac{a\|\vec{\mathbf{x}}\|^2 + \langle \vec{\mathbf{b}}, \vec{\mathbf{x}} \rangle + c}{x_n}, \quad \vec{\mathbf{b}} \in \mathbb{R}^n, a,c \in \mathbb{R}, \tag{3}$$

where the coefficients $a > 0$, $\vec{\mathbf{b}}$ and c satisfy either of

(1) $4ac - \|\vec{\mathbf{b}}\|^2 > 0$, *or*
(2) $4ac - (b_1^2 + b_2^2 + \cdots + b_{n-1}^2) \geqslant 0$ *and* $b_n \geqslant 0$.

(iii) *If $B \equiv \mathbb{S}^n$, where $\mathbb{S}^n$ denotes the Euclidean sphere, then all possible warping functions are given by*

$$f = -\frac{n-1}{\mathrm{Sc}}\psi + \kappa, \tag{4}$$

where ψ is an eigenfunction for the largest eigenvalue of the Laplacian, $\Delta\psi = -[\mathrm{Sc}/(n-1)]\psi$, and κ is a real constant making f positive.

Proof: We analyze each case above separately.

(i) It follows from Lemma 9 that a function $f: \mathbb{R}^n \to \mathbb{R}$ defines a locally conformally flat static space–time $\mathbb{R}^n \times_f \mathbb{R}$ if and only if $\phi = -\ln f$ is a solution of the Möbius equation on $(\mathbb{R}^n, g_0)$. By considering $u = \exp(-\phi)$, one gets that f is indeed a positive solution of the linearized Möbius equation $H_f = (1/n)\Delta f g_0$. Now it follows easily from the linearized Möbius equation that any such function f must be of the form

$$f(\vec{\mathbf{x}}) = a\|\vec{\mathbf{x}}\|^2 + \langle \vec{\mathbf{b}}, \vec{\mathbf{x}} \rangle + c, \quad a,c \in \mathbb{R}, \vec{\mathbf{b}} \in \mathbb{R}^n.$$

Moreover, since f is required to be strictly positive in order to be a warping function, we have the following. First observe that $a > 0$, otherwise f is negative outside a compact set. Now, assuming $a > 0$, $f(\vec{\mathbf{x}}) = a\|\vec{\mathbf{x}}\|^2 + \langle \vec{\mathbf{b}}, \vec{\mathbf{x}} \rangle + c$ attains its minimum at $\vec{\mathbf{x}} = -(1/2a)\vec{\mathbf{b}}$ and $f[-(1/2a)\vec{\mathbf{b}}] = -(1/4a)\|\vec{\mathbf{b}}\|^2 + c$, which must be positive, from where (i) is obtained.

(ii) Let $(\mathfrak{U}^n, g_0)$ denote the Euclidean upper-half-space and consider the Poincarè half-space model $(\mathbb{H}^n, g_{\mathbb{H}})$ as a conformal deformation $g_{\mathbb{H}}=\vartheta^* g_0=(1/x_n^2)g_0$ of the Euclidean metric. Let φ be a Möbius transformation from the hyperbolic space $(\mathbb{H}^n, g_{\mathbb{H}})$ into $(\mathfrak{U}^n,(1/f^2)g_{\mathbb{H}})$ and consider the following diagram:

$$\begin{array}{ccc} & & \varphi \\ \left(\mathbb{H}^n,\, g_{\mathbb{H}}=\dfrac{1}{x_n^2}\, g_0\right) & \to & \left(\mathfrak{U}^n,\, \dfrac{1}{f^2}\, g_{\mathbb{H}}\right) \\ & \vartheta \downarrow & \nearrow \\ & (\mathfrak{U}^n,\, g_0) & \end{array}$$

Note that the set of conformal transformations forms a group with composition and moreover that the Möbius transformations is a proper subgroup.[21] Further, since ϑ is a Möbius transformation, then φ is a Möbius transformation if and only if so is $\varphi\circ\vartheta^{-1}$, which is defined in $(\mathfrak{U}^n, g_0)$. Now, it follows from (i) that $(1/f^2)g_{\mathbb{H}}=[1/(a\|\vec{\mathbf{x}}\|^2+\langle\vec{\mathbf{b}},\vec{\mathbf{x}}\rangle+c)]^2 g_0$ from where it follows that

$$f(\vec{\mathbf{x}})=\frac{a\|\vec{\mathbf{x}}\|^2+\langle\vec{\mathbf{b}},\vec{\mathbf{x}}\rangle+c}{x_n}.$$

Since $x_n>0$ we only have to consider the numerator in the above definition of f in order to analyze its positivity. Now note that $a\|\vec{\mathbf{x}}\|^2+\langle\vec{\mathbf{b}},\vec{\mathbf{x}}\rangle+c$ defines a convex paraboloid (considered as a function in $\mathbb{R}^n$) which is positive on $\mathfrak{U}$ if and only if $a>0$ and it does not intersect the domain $\mathfrak{U}$. Thus two different possibilities may occur. The minimum of the paraboloid is positive and the required condition is $4ac-\|\vec{\mathbf{b}}\|^2>0$, which shows (ii) (1) as in the previous case (i). The other possibility occurs if the minimum is nonpositive but it is realized on the down-half-space [i.e., $(-b_n/2a)\leqslant 0$]. In this case the desired condition is obtained by the positivity of the intersection of the paraboloid defined by $a\|\vec{\mathbf{x}}\|^2+\langle\vec{\mathbf{b}},\vec{\mathbf{x}}\rangle+c$ and the hyperplane $x_n=0$, which gives $4ac-(b_1^2+b_2^2+\cdots+b_{n-1}^2)\geqslant 0$, thus showing (ii) (2).

(iii) As in the previous cases, it follows from Lemma 9 that a function $f:\mathbb{S}^n\to\mathbb{R}$ defines a locally conformally flat static space–time $\mathbb{S}^n\times_f\mathbb{R}$ if and only if $\phi=-\ln f$ is a solution of the Möbius equation on $(\mathbb{S}^n, g_{\mathbb{S}^n})$. By considering $u=\exp(-\phi)$, one gets that f is indeed a positive solution of the linearized Möbius equation and thus $H_f=(1/n)\Delta f g_{\mathbb{S}^n}$.

Next, consider the gradient vector field ∇f on $\mathbb{S}^n$. Since $(\mathcal{L}_{\nabla f}g)(Y,Z)=2H_f(Y,Z)$, it follows from the linearized Möbius equation that ∇f is a conformal vector field on $\mathbb{S}^n$, and then

$$-\Delta(\operatorname{div}\ \nabla f)=\frac{\mathrm{Sc}}{n-1}\operatorname{div}(\nabla f), \tag{5}$$

where Sc denotes the scalar curvature of $(\mathbb{S}^n, g_{\mathbb{S}^n})$ (cf. Ref. 24). Hence $\Delta(\Delta f)=-[\mathrm{Sc}/(n-1)]\Delta f$, which shows that Δf is an eigenfunction for the largest eigenvalue $\lambda_1=-[\mathrm{Sc}/(n-1)]$ of the Laplacian in $(\mathbb{S}^n, g_{\mathbb{S}^n})$. Further, it also follows from (5) that $\Delta(\Delta f+[\mathrm{Sc}/(n-1)]f)=0$ and thus that $\Delta f+[\mathrm{Sc}/(n-1)]f$ is a constant function. Therefore, if ψ denotes a λ_1-eigenfunction for the Laplacian in $(\mathbb{S}^n, g_{\mathbb{S}^n})$, then the desired warping functions are given by $f=[-(n-1)/\mathrm{Sc}]\psi+\kappa$, for some constant κ which makes f positive. ■

Remark 11: Note that the eigenspace corresponding to the largest eigenvalue $\lambda_1=-\mathrm{Sc}/(n-1)$ of the Laplacian in $\mathbb{S}^n$ is generated by the restriction to $\mathbb{S}^n$ of the homogeneous polynomials of degree one in $\mathbb{R}^{n+1}$ (see, for example, Ref. 4, Chap. 3). Thus any such λ_1-eigenfunction is the restriction to $\mathbb{S}^n$ of some Ψ defined on $\mathbb{R}^{n+1}$ by $\Psi(\vec{\mathbf{x}})=\langle\vec{\mathbf{a}},\vec{\mathbf{x}}\rangle$ for $\mathbf{0}\neq\vec{\mathbf{a}}\in\mathbb{R}^{n+1}$.

Remark 12: The conformal deformations of the model spaces defined by the different functions (2)–(4) in the previous theorem affect the sectional curvature as follows:

(i) The sectional curvature of $(\mathbb{R}^n, (1/f^2)g_0)$ is constant $4ac-\|\vec{\mathbf{b}}\|^2>0$, where f is defined by (2).

(ii) The sectional curvature of $(\mathbb{H}^n, (1/f^2)g_{\mathbb{H}^n})$ is constant $4ac-\|\vec{\mathbf{b}}\|^2$, where f is given by (3).

Note that the metrics $(1/f^2)g_0$ and $(1/f^2)g_{\mathbb{H}^n}$ above need not be complete, since otherwise $(\mathbb{R}^n, (1/f^2)g_0)$ and $(\mathbb{H}^n, (1/f^2)g_{\mathbb{H}^n})$ should be compact by Bonnet-Myers' theorem.[18] (This lies on the fact that completeness is not a topological property, but a uniform one.)

(iii) The sectional curvature of $(\mathbb{S}^n, (1/f^2)g_{\mathbb{S}^n})$ is constant $(\kappa^2-[(n-1)^2/\mathrm{Sc}^2]\|\vec{\mathbf{a}}\|^2)$, where f is given by (4) and $\psi=\Psi|_{\mathbb{S}^n}$ is the restriction to $\mathbb{S}^n$ of $\Psi(\vec{\mathbf{x}})=\langle\vec{\mathbf{a}},\vec{\mathbf{x}}\rangle$. Note here that $\kappa^2-[(n-1)^2/\mathrm{Sc}^2]\|\vec{\mathbf{a}}\|^2$ is positive, since κ is greater than $[(n-1)/\mathrm{Sc}]\|\vec{\mathbf{a}}\|$ in order to make f positive.

For a given manifold (B, g_B), to be the base of two different locally conformally flat warped products is a very restrictive fact, as shown in the next results, which give some partial answers on the uniqueness of the warping function of a locally conformally flat warped product.

Theorem 13: *Let (B, g_B) be a compact Riemannian manifold admitting two-distinct (i.e., $f\neq c\hat{f}$) warping functions such that both $B\times_f\mathbb{R}$ and $B\times_{\hat{f}}\mathbb{R}$ are locally conformally flat static space–times. Then (B, g_B) is conformal to the Euclidean sphere by means of the conformal deformation $(1/f^2)g_B$ and $\hat{f}/f$ is one of the functions in Theorem 1: (iii).*

Proof: Let f and $\hat{f}$ be warping functions such that $B\times_f\mathbb{R}$ and $B\times_{\hat{f}}\mathbb{R}$ are locally conformally flat static space–times. Then id: $(B,(1/f^2)g_B)\to(B,(1/\hat{f}^2)g_B)$ is a conformal transformation between two compact spaces of constant sectional curvature. Proceeding as in case (iii) of the previous theorem, it follows that $\hat{f}/f$ is a solution of the linearized Möbius equation on $(B, (1/f^2)g_B)$

$$H_{\hat{f}/f}=\frac{1}{n}\Delta(\hat{f}/f)g$$

and thus $\nabla(\hat{f}/f)$ is a conformal vector field on $(B, (1/f^2)g_B)$. Then it follows from (5) that $\Delta(\Delta(\hat{f}/f)+[\mathrm{Sc}/(n-1)]\hat{f}/f)=0$ and thus $\Delta(\hat{f}/f)+[\mathrm{Sc}/(n-1)]\hat{f}/f$ is a constant function on $(B, (1/f^2)g_B)$.

Next, using the linearized Möbius equation, compute the Hessian of $\Delta(\hat{f}/f)$ to obtain

$$H_{\Delta(\hat{f}/f)}+\frac{\mathrm{Sc}}{n(n-1)}\Delta(\hat{f}/f)g=0. \tag{6}$$

Now, if $\mathrm{Sc}>0$, then (6) is Obata's equation for $\Delta(\hat{f}/f)$. Since $f\neq c\hat{f}$ and for some constant C, $\Delta(\hat{f}/f)=-[\mathrm{Sc}/(n-1)]\hat{f}/f+C$, then it follows that $\Delta(\hat{f}/f)$ is not constant and hence $(B,(1/f^2)g_B)$ is isometric to an Euclidean sphere.[19]

Finally note that $\mathrm{Sc}\leqslant 0$ leads to some contradiction as follows. Indeed, if $\mathrm{Sc}<0$, then the existence of a nonconstant solution $\Delta(\hat{f}/f)$ of (6) is characteristic of warped product structures $\mathbb{R}\times_\xi N$, where N is a complete Riemannian manifold and the warping function satisfies $\xi''+[\mathrm{Sc}/n(n-1)]\xi=0$, $\xi>0$ among complete Riemannian manifolds (Ref. 13, Theorems C, D). This is clearly a contradiction with the compactness of B. The case $\mathrm{Sc}=0$ implies $\Delta(\hat{f}/f)$ is constant and thus it follows from the linearized Möbius equation that $H_{\hat{f}/f}=(\sigma/n)g$ for some constant σ. This shows that $\hat{f}/f$ is a special concircular function on $(B, (1/f^2)g_B)$ and hence it follows from Ref. 23, Theorem 2 that $(B, (1/f^2)g_B)$ is isometric to the Euclidean space, which is also a contradiction. ■

Remark 14: The previous theorem shows the nonexistence of nonconstant globally defined warping functions on flat tori $\mathbb{T}^n$ which make the static space–time $\mathbb{T}^n\times_f\mathbb{R}$ locally conformally flat. However note that such warping functions always exist locally (cf. Remark 3).

The result of Theorem 13 can be extended to static space–times with noncompact base under some completeness assumptions as follows.

Theorem 15: *Let $M=B\times_f\mathbb{R}$ be a locally conformally flat static space–time with $(B, (1/f^2)g_B)$ geodesically complete. If there exists a warping function $\hat{f}\neq cf$ on B such that $B\times_{\hat{f}}\mathbb{R}$ is also locally conformally flat, then one of the following holds:*

(1) *$(B, (1/f^2)g_B)$ is a complete and simply connected space of constant sectional curvature and the warping functions $\hat{f}/f$ are given by Theorem 10, or otherwise.*
(2) *$(B, (1/f^2)g_B)$ is a warped product $\mathbb{R}\times_{\alpha\exp(\alpha t+\beta)}N$, where (N, g_N) is a complete flat Riemannian manifold and the warping functions satisfy*

$$\hat{f}/f=\exp(\alpha t+\beta)+\kappa$$

for some real constants $\alpha>0$, β, $\kappa\geqslant 0$, where $\alpha^2=-[\mathrm{Sc}/n(n-1)]$ and Sc *denotes the scalar curvature of $(B, (1/f^2)g_B)$.*

Proof: Let $f\neq c\hat{f}$ be two warping functions on B such that $B\times_{\hat{f}}\mathbb{R}$ and $B\times_f\mathbb{R}$ are locally conformally flat. Then, by Theorem 1 it follows that $(1/\hat{f}^2)g_B$ and $(1/f^2)g_B$ are constant sectional curvature metrics on B and thus the identity is a conformal diffeomorphism between two Einstein metrics on B. Since $(B, (1/f^2)g_B)$ is assumed to be complete and $\hat{f}\neq cf$, then either $(B, (1/f^2)g_B)$ is a complete and simply connected space of constant sectional curvature, and thus isometric to one of the model spaces in Theorem 10, or otherwise $(B, (1/f^2)g_B)$ is a warped product $\mathbb{R}\times_{\alpha\exp(\alpha t+\beta)}N$, where (N, g_N) is a complete Ricci flat $(n-1)$-dimensional Riemannian manifold and the warping functions satisfy $\hat{f}/f=\exp(\alpha t+\beta)+\kappa$, for some constants α, β, κ.[16] Next, by Corollary 2 it follows that $\mathbb{R}\times_{\alpha\exp(\alpha t+\beta)}N$ is locally conformally flat and thus (N, g_N) is of constant sectional curvature by Theorem 1, which shows that (N, g_N) is flat. Moreover, it follows after some standard calculations that the scalar curvature of $(B, (1/f^2)g_B)$ is $\mathrm{Sc}=-n(n-1)\alpha^2$, which proves the result. ■

V. COMPLETE LOCALLY CONFORMALLY FLAT RIEMANNIAN MANIFOLDS OF NONPOSITIVE CURVATURE

Recall here that the universal cover of a complete locally conformally flat Riemannian manifold with non-negative Ricci curvatures is conformally equivalent to $\mathbb{S}^n$, $\mathbb{R}^n$ or $\mathbb{R}\times\mathbb{S}^{n-1}$, where $\mathbb{S}^n$ and $\mathbb{S}^{n-1}$ are spheres of constant sectional curvature.[26] Henceforth we will pay special attention to the construction of complete locally conformally flat manifolds with nonpositive Ricci curvatures. Also note that warped products are a basic tool in constructing manifolds of nonpositive curvature, which are complete if and only if both factors are complete Riemannian manifolds.[5] For our purposes in this section, write the sectional curvature of a warped product $B\times_f F$ as follows:[5,18]

$$\begin{aligned} K_{XY}&=K^{\mathrm{B}}_{XY},\\ K_{XU}&=-\frac{H_f(X,X)}{f\|X\|^2},\\ K_{UV}&=\frac{1}{f^2}K^F_{UV}-\frac{\|\nabla f\|^2}{f^2}, \end{aligned} \tag{7}$$

where K^B and K^F denote the sectional curvatures on the base B and the fiber F, respectively.

Observe that all the results in the preceding section remain true in the Riemannian setting, since the base of a static space–time has induced positive definite metric, and the fiber plays only a very limited role in the construction of locally conformally flat warped products (cf. Theorem 1).

Let $M=B\times_f F$ be a locally conformally flat Riemannian warped product with base B a model space $\mathbb{R}^s$, $\mathbb{S}^s$ or $\mathbb{H}^s$. If M is assumed to be complete, we have the following consequences of previous results:

(i) If $B \equiv \mathbb{R}^s$, then $\mathbb{R}^s \times_f F$ is of nonpositive sectional curvature for any warping function f as in Theorem 10.

(ii) If $B \equiv \mathbb{S}^s$, then no locally conformally flat warped product $\mathbb{S}^s \times_f F$ may be of nonpositive sectional curvature. Indeed, no locally conformally flat warped product with compact base may have nonpositive sectional curvature, unless it is a direct product since it follows from (7) that the warping function of a warped product $B \times_f F$ of nonpositive sectional curvature satisfies $H_f \geqslant 0$, and thus $\Delta f \geqslant 0$. Now, since B is compact without boundary and $\dim B \geqslant 2$, it follows that $\Delta f = 0$, and thus f is constant.

(iii) If $B \equiv \mathbb{H}^s$, then the necessary and sufficient condition for a locally conformally flat warped product $\mathbb{H}^s \times_f F$ to be of nonpositive sectional curvature is given in terms of the warping function $f(\vec{\mathbf{x}}) = (a\|\vec{\mathbf{x}}\|^2 + \langle \vec{\mathbf{b}}, \vec{\mathbf{x}} \rangle + c)/x_s$ by $f \geqslant 2b_s$, whenever $\dim F \geqslant 2$.

We finish with some simple examples which illustrate the previous situation.

(a) Let M be the product manifold $M = \mathbb{H}^2 \times \mathbb{H}^2$ equipped with the warped metric defined by the warping function

$$f(\vec{\mathbf{x}}) = \frac{\frac{1}{2}\|\vec{\mathbf{x}}\|^2 + x_2 + 1}{x_2}.$$

(b) Let M be the product manifold $M = \mathbb{H}^2 \times \mathbb{R}^2$ equipped with the warped metric defined by the warping function

$$f(\vec{\mathbf{x}}) = \frac{\frac{1}{4}\|\vec{\mathbf{x}}\|^2 + x_1 + 1}{x_2}.$$

After some straightforward calculations we get that the sectional curvature is nonpositive in any of these particular examples.

Next, note that simplest examples of complete locally conformally flat Riemannian manifolds with nonpositive Ricci curvature are warped products as follows:

(1) $\mathbb{H}^2 \times_f \mathbb{H}^2$ with warping function

$$f(\vec{\mathbf{x}}) = \frac{\frac{3}{2}\|\vec{\mathbf{x}}\|^2 + x_1 + 4x_2 + 3}{x_2}.$$

(2) $\mathbb{H}^2 \times_f \mathbb{S}^2$ with warping function

$$f(\vec{\mathbf{x}}) = \frac{\|\vec{\mathbf{x}}\|^2 + 3x_2 + 2}{x_2}.$$

A long but straightforward calculation shows that the Ricci curvatures are nonpositive in previous examples. Moreover, note that the sectional curvature of $\mathbb{H}^2 \times_f \mathbb{S}^2$ has no sign.

(Received 19 April 2004; accepted 21 September 2004; published online 27 January 2005)

We introduce the method of topological quantization for gravitational fields in a systematic manner. First we show that any vacuum solution of Einstein's equations can be represented in a principal fiber bundle with a connection that takes values in the Lie algebra of the Lorentz group. This result is generalized to include the case of gauge matter fields in multiple principal fiber bundles. We present several examples of gravitational configurations that include a gravitomagnetic monopole in linearized gravity, the C-energy of cylindrically symmetric fields, the Reissner–Nordström and the Kerr–Newman black holes. As a result of the application of the topological quantization procedure, in all the analyzed examples we obtain conditions implying that the parameters entering the metric in each case satisfy certain discretization relationships. © *2005 American Institute of Physics.*

I. INTRODUCTION

Dirac's original idea[1] of determining the phase acquired by a charge when moving along a closed path in the field of a magnetic monopole gave as a result that the product of the electric charge times the monopole charge is an integer. Today, this result is known as Dirac's quantization of the electric charge. In a previous work,[2] we introduced a phaselike object which depends on the field strength so that it can be used to investigate any field theory based on a connection. In the special case of the Levi–Cività connection, the field strength is given by the Riemann tensor and the phaselike object can formally be used to investigate the properties of gravitational configurations that satisfy Einstein's equations. Using only the symmetry properties of the Riemann tensor and assuming a quite general symmetry property for the gravitational field, we have shown that this phaselike object for vacuum gravitational configurations behaves under rotations either as a bosonic or a fermionic phase. It was also shown that a certain combination of the eigenvalues of the Riemann tensor can become "quantized" in a fashion similar to that obtained from Dirac's quantization procedure in the system composed of an electric charge and a magnetic monopole.

From the geometric point of view,[3] Dirac's quantization is interpreted as a consequence of the existence of a nontrivial principal fiber bundle of U(1) over the sphere S^2, with a u(1) connection, for the system composed of an electric charge q and a magnetic monopole with magnetic charge g. The Chern numbers associated with this nontrivial fiber bundle turn out to be given as the product qg which, therefore, becomes quantized.

In this work, we introduce the method of topological quantization which can be applied to any field configuration whose geometrical structure allows the existence of a principal fiber bundle. We show that any solution of Einstein's equations minimally coupled to any gauge matter field can

[a)]Electronic mail: e.l.patino-jaidar@durham.ac.uk
[b)]Electronic mail: quevedo@physics.ucdavis.edu

be represented geometrically as a principal fiber bundle with space–time as the base space. The structure group (isomorphic to the standard fiber) follows from the invariance of the orthonormal frame with respect to Lorentz transformations, in the case of a vacuum solution, or with respect to a transformation of the gauge group, in the case of a gauge matter field. If the bundle turns out to be (globally) nontrivial, the conditions under which this construction becomes well defined in all the points where the field configuration exists, manifest themselves in the transition functions between different but intersecting open subsets of the base manifold of the bundle. These conditions on the transition functions turn out to depend on the parameters which determine the physical structure of the field configuration. Consequently, the conditions that arise in the construction of a fiber bundle lead to conditions on the physical parameters which, in turn, implies that a particular combination of those parameters can take only *discrete* values. This discretization can be derived also from the topological invariants of the corresponding nontrivial fiber bundle. This is what we call the *quantization conditions* for a given field configuration. Furthermore, we will see that even in the case of a globally trivial principal fiber bundle certain quantization conditions may appear as a result of demanding regularity of the connection.

In Sec. II, we introduce the method of topological quantization in a systematic manner and briefly discuss the general cases in which nontrivial quantization conditions may appear. In Sec. III we analyze the so(1,3) connection of cylindrically symmetric gravitational fields and show that the corresponding C-energy can take only discrete values. In Sec. IV we present the example of a gravitomagnetic monopole in linearized Einstein's theory which can be investigated by means of a u(1) connection. Section V contains the topological quantization with respect to the electromagnetic connection of gravitational fields which represent electrovacuum black holes. Section VI is devoted to discussions and remarks about future investigations.

II. THE METHOD OF TOPOLOGICAL QUANTIZATION

Consider a Riemannian manifold (M,g), where M is a four-dimensional differential manifold and g is a bilinear form, the metric, on M. For the purpose of analyzing field equations we choose in M a set of local orthonormal 1-forms e^a, $a=0,1,2,3$. The orthonormality condition can be expressed in terms of the local Minkowski metric as $g(e^a,e^b)=\eta^{ab}$, where $\eta^{ab}=\mathrm{diag}(+,-,-,-)$. On a torsion free manifold we can introduce a connection 1-form ω by means of the Cartan first structure equation

$$De^a := de^a + \omega^a{}_b \wedge e^b = 0, \tag{1}$$

where d is the exterior derivative and D the covariant exterior derivative. We demand that ω be a metric connection, i.e., locally $D\eta_{ab}=d\eta_{ab}+\omega_{ab}+\omega_{ba}=0$, a condition which implies the antisymmetry of the connection components. Furthermore, we use the Cartan second structure equation to introduce the curvature 2-form Ω as

$$D\omega^a{}_b := \Omega^a{}_b = d\omega^a{}_b + \omega^a{}_c \wedge \omega^c{}_b, \tag{2}$$

whose components in terms of the local orthonormal frame, $\Omega^a{}_b=(1/2)R^a{}_{bcd}e^c\wedge e^d$, determine the Riemann curvature tensor $R^a{}_{bcd}$. Einstein's gravity theory follows from the variation, with respect to the orthonormal frame e^a of the action

$$S = -\frac{1}{32\pi G}\int_M \Omega^{ab}\wedge e^c \wedge e^d \epsilon_{abcd} + \int_M \mathcal{L}_m, \tag{3}$$

where $\epsilon_{0123}=1$ and $\mathcal{L}_m$ is the matter Lagrangian which depends on e, ω, and the matter fields. The field equations are $\Omega^{ab}\wedge e^c\epsilon_{abcd}=-16\pi G T_c$, where T_c is the energy-momentum 3-form which follows from the variation of the matter action.

The advantage of using a local orthonormal frame e is that the gauge character (at the level of the connection and curvature) of Einstein's theory becomes more plausible (see, for instance, Refs. 3 and 4 for a more detailed discussion). Indeed, the diffeomorphism invariance of the theory is

now reduced to the invariance with respect to the Lorentz group SO(1,3). The change to a different frame $e' = \Lambda e$ is represented by means of a matrix $\Lambda \in \mathrm{SO}(1,3)$. The connection 1-form and the curvature 2-form take values in the corresponding Lorentz algebra so(1,3), and under a change of frame they transform as

$$\omega' = \Lambda \omega \Lambda^{-1} + \Lambda \, \mathrm{d}\Lambda^{-1}, \quad \Omega' = \Lambda \Omega \Lambda^{-1}, \tag{4}$$

respectively. It is in this sense that Einstein's theory can be considered as a gauge theory with respect to the Lorentz group. However, it is at the level of the action that Einstein's theory tremendously differs from pure Yang–Mills gauge theories.

Let us now consider the matter action. As we have mentioned before the matter Lagrangian can depend on the frame e, the connection ω, and the matter fields. We will assume that the matter fields are gauge fields, that is, there exists a connection 1-form A, with values in the Lie algebra of a Lie group G, which generates the gauge field strength F in the standard manner, $F = \mathrm{d}A + A \wedge A$. Under a gauge transformation $\gamma \in G$, these quantities behave as (we assume that the gauge group is a matrix group)

$$A \to A' = \gamma A \gamma^{-1} + \gamma \, \mathrm{d}\gamma^{-1}, \quad F \to F' = \gamma F \gamma^{-1}. \tag{5}$$

A vacuum space–time in general relativity is a solution of Einstein's vacuum equations, represented by an orthonormal frame e. Since we assume that the compatibility condition between the local metric and the connection is satisfied, we can use the connection ω, instead of the orthonormal frame. Moreover, if we adopt the Palatini approach, the connection ω can be considered as the "primary" variable, whereas the orthonormal frame e can be derived from the metricity condition. In the presence of a matter field, one needs additionally the "matter" connection A which satisfies Einstein's equations, with the corresponding energy-momentum 3-form, and the matter field equations that follow from the variation of the matter action with respect to the connection A. For a particular space–time to be well defined we must guarantee that ω and A are well defined everywhere in M. This is a nontrivial remark for the analysis of gravitational fields we want to perform. Indeed, the fact that the connection is demanded to be well defined everywhere in M implies in general certain conditions that we will investigate for explicit fields and which are the fundamental of what we will call topological quantization.

Let us be more specific. The idea behind the introduction of a differentiable manifold as the underlying geometric structure of space–time is that in this way one can guarantee the existence of coordinate sets which cover the entire manifold. For the approach we are using here, this is equivalent to having a finite number of sets of orthonormal frames covering the manifold. Let $\{U_\alpha\}$ be an open covering of M, i.e., $\cup_\alpha U_\alpha = M$. By definition, a differential manifold of dimension n is equipped with an atlas (U_α, ϕ_α), where ϕ_α is a homeomorphism from U_α onto an open subset of the Euclidean space $\mathbf{R}^n$. If we consider two arbitrary open subsets $U_i, U_j \in \{U_\alpha\}$ such that $U_i \cap U_j \neq \emptyset$, then in the intersection region the map $\phi_i \circ \phi_j^{-1}$ is a C^∞ homeomorphism of (open subsets of) $\mathbf{R}^n$. Let $\tilde{\phi}_i$ be the map from U_i into the vector space of 1-forms $\Lambda^1(U_i, \mathrm{so}(1,3))$ that allows us to introduce the orthonormal frame e_i in U_i. Notice that the index i labels different sets of orthonormal frames and does not refer to any specific component of the frame. The orthonormal frame e_j attached to U_j by means of $\tilde{\phi}_j$, is related to e_i through an SO(1,3) matrix, $e_i = \Lambda_{ij} e_j$. It is clear that in the intersection region the compatibility condition $\tilde{\phi}_i \circ \tilde{\phi}_j^{-1} = \Lambda_{ij}$ must be satisfied. On U_i we can also introduce a spin connection 1-form ω_i and a curvature 2-form Ω_i, according to Eqs. (1) and (2), respectively. These are related to the connection and curvature in U_j by means of (no summation over repeated indices)

$$\omega_i = \Lambda_{ij} \omega_j \Lambda_{ij}^{-1} + \Lambda_{ij} \, \mathrm{d}\Lambda_{ij}^{-1}, \quad \Omega_i = \Lambda_{ij} \Omega_j \Lambda_{ij}^{-1}. \tag{6}$$

Consider now a third open subset $U_k \in \{U_\alpha\}$ such that $U_i \cap U_j \cap U_k \neq \emptyset$. Accordingly, in the intersection region we have that $\tilde{\phi}_i \circ \tilde{\phi}_k^{-1} = \Lambda_{ik}$ and $\tilde{\phi}_j \circ \tilde{\phi}_k^{-1} = \Lambda_{jk}$. Then, it follows that

$$\Lambda_{ij}\Lambda_{jk} = \Lambda_{ik}. \tag{7}$$

This allows us to formulate the following.

Theorem 1: A solution of Einstein's vacuum field equations can be represented by a unique 10-dimensional principal fiber bundle P with the space–time M as the base space, the Lorentz group as the structure group (isomorphic to the standard fiber) and a connection with values in the Lie algebra of the Lorentz group.

Proof: A standard theorem (the reconstruction theorem) in differential geometry[5,6] states that a fiber bundle is uniquely specified by the base space, the standard fiber, a structure group which is effectively represented on the fiber and a family of transition functions, with values in the structure group, satisfying the cocycle condition. In the case of a principal fiber bundle P, the fiber is isomorphic to the structure group which is naturally represented on itself by left translations. For a solution of the vacuum field equations, given by an orthonormal frame e, we can take the space–time manifold M described above as the base space. The structure group is identified as SO(1,3). The transition functions are given by the elements $\Lambda_{ij}: U_i \cap U_j \to \mathrm{SO}(1,3)$ and satisfy the cocycle condition which is given above in Eq. (7). Finally, one can show that it is possible to construct the projection $\pi: P \to M$[6], once the transition functions are given. This shows that all the elements of a principle fiber bundle exist and they can be "glued" together to form the desired bundle by means of the transition functions and the projection π.

Finally, we must show that there exists a connection $\boldsymbol{\omega}$ in P. By construction, we do have a connection 1-form ω on M, which is the connection associated with the vacuum solution. We will see that it determines a unique connection in P. To this end, we use the following theorem[4] valid for principal fiber bundles.

Theorem 2: Given an open covering $\{U_\alpha\}$ of M, a structure Lie group G with Lie algebra $\mathbf{g}$, a family of local $\mathbf{g}$-valued 1-forms $\omega_i \in \Lambda^1(U_i, \mathbf{g})$ which fulfill the compatibility condition

$$\omega_i = g_{ji}^{-1}\omega_j g_{ji} + g_{ji}^{-1}\, \mathrm{d}g_{ji}, \tag{8}$$

where $g_{ji}: U_i \cap U_j \to G$ are elements of G, and a set of local sections $\sigma_i: U_i \to \pi^{-1}(U_i)$ satisfying $\sigma_j = \sigma_i g_{ij}$ on $U_i \cap U_j$, then there is a unique connection $\boldsymbol{\omega}$ on P such that $\omega_i = \sigma_i^* \boldsymbol{\omega}$, where σ_i^* is the pull-back induced by σ_i.

In the case we are considering, the structure group is SO(1,3), the family of 1-forms ω_i is determined by the connection ω defined on each $U_i \in \{U_\alpha\}$. The compatibility condition (8) coincides with the transformation property (6), once g_{ji}^{-1} is identified with Λ_{ij}. It remains to show the existence of local sections. Since any fiber bundle accepts a local trivialization which can be defined as $\Psi_i: \pi^{-1}(U_i) \to U_i \times G$, we can introduce a local canonical section on U_i by transferring back to $\pi^{-1}(U_i)$ the section of $U_i \times G$, i.e., by defining $\sigma_i: U_i \to \pi^{-1}(U_i)$ by $\sigma(x) = \Psi_i^{-1}(x, e)$, where $x \in U_i$ and $e = g_{ii}(x)$ is the identity element of G. It is then possible to show[6] that this canonical section satisfies $\sigma_j = \sigma_i g_{ij}$ as required. Thus, according to Theorem 2, there exists a unique connection $\boldsymbol{\omega}$ on P. This ends the proof of Theorem 1.

We have shown that a vacuum solution can naturally be represented as a principal fiber bundle. In all steps of the proof, the local connection ω_i plays an important role and we have assumed that it satisfies the continuity and differentiability conditions on U_i. The question arises whether this assumption can be realized in concrete examples of gravitational configurations. This is exactly the question that we want to address in this work by constructing explicitly the elements of the principal fiber bundles that correspond to given solutions of Einstein's equations. This is what we call the method of "topological quantization." This concept has been used before in the context of diverse monopole configurations.[7] We will see that in the process of constructing a suitable covering $\{U_\alpha\}$ of M, certain "quantization" conditions appear that imply restrictions on the parameters entering the components of the connection.

If it turns out that the constructed principal fiber bundle admits a global section, the bundle is globally trivial and a single connection can be defined everywhere on P. This could happen, for instance, when the base space (space–time manifold) is contractible. We will see that even in this simple case nontrivial conditions arise from the requirement that the connection is regular on all

points of the base space. More general cases can be obtained from noncontractible manifolds which are very common in general relativity. Explicit solutions of Einstein's equations are usually characterized by the existence of singularities, i.e., regions that cannot be described within the formalism of general relativity. In order to properly describe the space–time manifold we need to "remove" those singular regions from the manifold. This procedure can be used to obtain noncontractible base spaces for which we can expect that nontrivial conditions arise from the application of the method of topological quantization. In fact, noncontractible base spaces can give rise to globally nontrivial principal fiber bundles. In this case one needs more than one open subset to cover the base space and, consequently, transition functions appear that turn out to generate nontrivial "quantization" conditions.

Thus, topological quantization is closely related to the problem of determining whether a principal fiber bundle is globally trivial or not. This is a task that involves the relation between the global topological structure of the base space and the fiber, an issue that is used to perform the classification of bundles and is related to the theory of characteristic classes and topological invariants. Consequently, the method of topological quantization is closely related to the study of the topological structure of the underlying bundle.

From the discussion above it follows that one has (at least) two ways to perform the topological quantization of a given solution of Einstein's equations. The first one consists in using Theorem 1 to construct the corresponding principal fiber bundle P and the connection $\boldsymbol{\omega}$. Then, one can analyze the topological invariants of the bundle. The second method consists in constructing explicitly the covering $\{U_\alpha\}$ of M and the family of connection 1-forms $\{\omega_\alpha\}$ on M for the given solution and extracting from there the quantization conditions. Obviously, both methods must yield the same results. When analyzing explicit examples, however, it is not always easy to construct the unknown principal fiber bundle, whereas the second method is straightforward because we know the connection ω explicitly. For this reason, in this work we will apply mainly the second approach for explicit calculations.

All of the above discussion involves only the so(1,3) connection associated to the gravitational action. If an additional matter action is considered, the results can be formulated in the following form.

Theorem 3: A solution of Einstein's field equations coupled to a matter gauge field can be represented by a unique principal fiber bundle with the space–time M as the base space, the gauge group as the structure group (isomorphic to the standard fiber) and a connection with values in the Lie algebra of the gauge group.

The proof of this theorem is similar to that of Theorem 1. Indeed, for each open subset $U_i \in \{U_\alpha\}$ we can calculate the corresponding gauge connection A_i with values in the Lie algebra of G. The proof can then be carried out in a similar manner with ω_i replaced by A_i, Λ_{ij} replaced by $\gamma_{ij} \in G$, and $g_{ji}^{-1} = \gamma_{ij}$. Consequently, in the case of additional matter gauge fields we can construct on M a principal fiber bundle for each additional gauge connection. So we are lead to the concept of "multiple" principal fiber bundles that can be constructed on the same base space M. Since the method of topological quantization can be applied to each bundle separately, one could expect different sets of quantization conditions from each bundle. The compatibility of these sets is an issue that can be treated at the level of explicit gravitational configurations.

In the following sections we will apply Theorems 1 and 3 to different gravitational configurations.

III. CYLINDRICALLY SYMMETRIC GRAVITATIONAL FIELDS

Cylindrically symmetric vacuum gravitational configurations can be described by means of the Einstein–Rosen line element which in an orthormal frame can be written as[8]

$$e^0 = \exp(\gamma - \psi)\mathrm{d}t, \quad e^1 = \exp(\gamma - \psi)\mathrm{d}\rho, \quad e^2 = \exp(\psi)\mathrm{d}z, \quad e^3 = \rho \exp(-\psi)\mathrm{d}\varphi, \tag{9}$$

where t, ρ, z, and φ are cylindrical coordinates and the functions ψ and γ depend on t and ρ only. For the sake of simplicity, here we restrict ourselves to the case in which the Killing vector fields

∂_z and ∂_φ are hypersurface orthogonal. The corresponding vacuum field equations can be reduced to a second-order differential equation for the function ψ,

$$\psi'' + \frac{1}{\rho}\psi' - \ddot{\psi} = 0, \tag{10}$$

and two first-order differential equations for γ,

$$\gamma' = \rho(\dot{\psi}^2 + \psi'^2), \quad \dot{\gamma} = 2\rho\dot{\psi}\psi', \tag{11}$$

where $\dot{\psi} = \partial\psi/\partial t$, $\psi' = \partial\psi/\partial\rho$, etc. The orthonormal frame (9) is defined up to an arbitrary transformation of the Lie group SO(1,3). If we envision the space–time as the four-dimensional base manifold and attach a copy of SO(1,3) at each point of the base manifold, we obtain the 10-dimensional principal fiber bundle considered in Theorem 1. Using the first structure equation (1) it is straightforward to calculate the components of the connection 1-form $\omega^a{}_b$ which can be decomposed as $\omega^a{}_b = \omega^a{}_{b\mu}\, dx^\mu$. It is in this decomposition that the endomorphic character of the connection [a 1-form with values in the Lie algebra so(1,3)] becomes plausible.[9] From Eq. (9) we obtain

$$\omega^0{}_{1t} = \gamma' - \psi', \quad \omega^0{}_{1\rho} = \dot{\gamma} - \dot{\psi},$$

$$\omega^0{}_{2z} = \dot{\psi}\exp(2\psi - \gamma), \quad \omega^1{}_{2z} = -\psi'\exp(2\psi - \gamma), \tag{12}$$

$$\omega^0{}_{3\varphi} = -\rho\dot{\psi}\exp(-\gamma), \quad \omega^1{}_{3\varphi} = -(1 - \rho\psi')\exp(-\gamma).$$

As described in the last section, we must demand the regularity of this connection as a condition for constructing the corresponding principal fiber bundle. It is well known[8] that solutions to the field equations can be generated which are everywhere regular with the symmetry axis ($\rho = 0$) as the only possible hypersurface where curvature singularities may appear. Let us suppose that the symmetry axis is free of curvature singularities. Then, there must exist an atlas where the connection is also regular. The field equations (11) imply that at the axis $\dot{\gamma}(\rho \to 0) = \dot{\gamma}_0 = 0$ and $\gamma'(\rho \to 0) = \gamma'_0 = 0$, if $\dot{\psi}(\rho \to 0) = \dot{\psi}_0$ and $\psi'(\rho \to 0) = \psi'_0$ do not diverge. On the other hand, Eq. (10) implies that near the axis $\psi' \propto \rho^\alpha$ with $\alpha > 1$, i.e., $\psi'_0 = 0$, and, consequently, $\ddot{\psi}(\rho \to 0) \propto \rho^{\alpha-1}$. Then, $\dot{\psi}_0$ is at most a constant that can be set equal to zero by means of a coordinate transformation. Thus we have that the regularity condition at the axis implies that $\dot{\gamma}_0 = \gamma'_0 = \dot{\psi}_0 = \psi'_0 = 0$. The same result can be obtained by analyzing the behavior of the curvature Kretschman scalar near the axis. Hence, from Eq. (13) it follows that at the axis $\omega^a{}_b|_{\rho=0} = \omega^a{}_{b\varphi}|_{\rho=0}\, d\varphi$ with

$$\omega^a{}_{b\varphi}|_{\rho=0} = \exp(-\gamma_0)T_\varphi, \tag{13}$$

where T_φ is one of the generators of the Lie algebra so(1,3),

$$T_\varphi = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}. \tag{14}$$

If we demand that $\exp(-\gamma_0)$ does not diverge, the components $\omega^a{}_{b\varphi}|_{\rho=0}$ are regular, but we still have a singularity in the 1-form $d\varphi = (\exp(\psi)/\rho)e^0$. Therefore, the only possibility to get rid of this singularity is to find a gauge transformation such that the new components $\omega'^a{}_{b\varphi}|_{\rho=0}$ vanish identically on the axis. To this end, let us consider the SO(1,3) transformation

$$\Lambda = \exp(\tilde{\varphi} T_{\varphi}), \quad \tilde{\varphi} = \exp(-\gamma_0)\varphi. \tag{15}$$

From Eq. (4) we have that the gauge-transformed 1-form connection is given by

$$\omega' = \exp(\tilde{\varphi} T_{\varphi})\omega \exp(-\tilde{\varphi} T_{\varphi}) - \exp(-\gamma_0) T_{\varphi}\, \mathrm{d}\varphi, \tag{16}$$

where

$$\exp(\pm \tilde{\varphi} T_{\varphi}) = 1_{4\times 4} \pm \sin \tilde{\varphi} T_{\varphi} + (1 - \cos \tilde{\varphi}) T_{\varphi}^2, \tag{17}$$

where $1_{4\times4}$ is the 4×4 unit matrix. The explicit calculation of the components can be carried out in a straightforward manner and leads to

$$\omega'^{0}{}_{1t} = (\gamma' - \psi')\cos \tilde{\varphi}, \quad \omega'^{0}{}_{3t} = (\gamma' - \psi')\sin \tilde{\varphi},$$

$$\omega'^{0}{}_{1\rho} = (\dot{\gamma} - \dot{\psi})\cos \tilde{\varphi}, \quad \omega'^{0}{}_{3\rho} = (\dot{\gamma} - \dot{\psi})\sin \tilde{\varphi},$$

$$\omega'^{0}{}_{2z} = \dot{\psi} \exp(2\psi - \gamma), \quad \omega'^{1}{}_{2z} = -\psi' \exp(2\psi - \gamma)\cos \tilde{\varphi}, \tag{18}$$

$$\omega'^{2}{}_{3z} = \psi' \exp(2\psi - \gamma)\sin \tilde{\varphi}, \quad \omega'^{0}{}_{1\varphi} = \rho\dot{\psi} \exp(-\gamma)\sin \tilde{\varphi},$$

$$\omega'^{0}{}_{3\varphi} = -\rho\dot{\psi} \exp(-\gamma)\cos \tilde{\varphi}, \quad \omega'^{1}{}_{3\varphi} = \exp(-\gamma_0)[1 - (1 - \rho\psi')\exp(\gamma_0 - \gamma)].$$

From the last expression it can easily be seen that the gauge-transformed connection vanishes identically on the symmetry axis and no new singularities appear. This has been achieved by means of the gauge transformation (15) which is single-valued only if $\exp(-\gamma_0) = n$, where n is an integer. This, in turn, implies that the gauge-transformed connection is single valued. Consequently, the condition $\exp(-\gamma_0) = n$ needs to be satisfied for the connection to be well defined. This is an interesting result that can be interpreted as a "quantization" of the energy of cylindrically symmetric gravitational fields. Indeed, the concept of C-energy was introduced by Thorne[10] for gravitational fields described by the Einstein–Rosen line element (9). The quantity $E_c = \gamma_0$ has been shown to represent the (normalized) C-energy density per length unit along the symmetry axis at a given time. In terms of the "quantization" derived above this means that $E_c = -\ln n$, i.e., the C-energy is a discrete quantity. The fact that it is a negative quantity is interpreted by Thorne as an indication of its "nonclassical" origin. A second expression that can be considered as a (normalized) C-energy density has been introduced by Thorne as $E_c = 1 - \exp(-2\gamma_0)$. In this case, the quantization condition leads to $E_c = 1 - n^2$, an expression that again indicates the discrete character of the C-energy.

We have shown that it is possible to define just one single connection 1-form on the entire Einstein–Rosen space–time. This means that the base manifold of the principal fiber bundle can be covered by a single open set U and, therefore, can be considered as $\mathbf{R}^4$ which is a contractible manifold. This implies that the corresponding 10-dimensional principal fiber bundle is globally trivial. This is so because we have demanded that the gravitational field be regular at all points of space–time, including the symmetry axis. If, instead, we would allow singularities on the axis, it would be necessary to "remove" the axis from the base manifold. This would open the possibility of obtaining a nontrivial bundle, an issue that would require an analysis different from the one presented in this section.

IV. THE WEAK GRAVITATIONAL FIELD

Consider the following line element in spherical coordinates t, r, θ, φ:

$$ds^2 = (1-2\phi)dt^2 - 2\chi\, dt\, d\varphi - (1+2\phi)[dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\varphi^2)], \tag{19}$$

where ϕ and χ are functions of the spatial coordinates. We assume that $\phi \ll 1$ and $\chi \ll 1$ and consider the weak field limit of Einstein's equations in vacuum. An orthonormal frame appropriate for the line element (19) can be written as

$$e^0 = (1-\phi)dt + \chi\, d\varphi, \quad e^1 = (1+\phi)dr, \quad e^2 = (1+\phi)d\theta, \quad e^3 = (1+\phi)r\sin\theta, \tag{20}$$

where we have neglected all the second order perturbations in ψ and χ.

It is well known[11] that the weak field equations in the Lorentz gauge can be expressed as the Maxwell equations $\tilde{A}_{\mu,\nu}{}^{\nu} = 0$ for the Maxwell potential

$$\tilde{A}_\mu = -\tfrac{1}{4}(4\phi, \chi), \tag{21}$$

which is invariant with respect to the transformation $\tilde{A} \to \tilde{A}' = \tilde{A} + df(x^\mu)$, where $f(x^\mu)$ is an arbitrary smooth function. This indicates that the weak field approximation can be interpreted as U(1)-gauge theory. To see this explicitly, we introduce the u(1) connection 1-form $A = -i\tilde{A}$. Then, the transformation law (5) is identically satisfied for the U(1)-gauge transformation $\gamma = \exp(if(x^\mu))$.

From the Maxwell equations for this case we see that the functions ϕ and χ are decoupled. Let us consider the following special solution:

$$A = i\left[\phi\, dt + \frac{g}{2}(1+\cos\theta)d\varphi\right], \tag{22}$$

where ϕ satisfies the differential equation $\phi_{,j}{}^{j} = 0$ $(j = 1,2,3)$, and g is a constant. This is the connection defined on the base manifold. To investigate the singularities of the connection (22), it is convenient to represent it in the orthonormal frame (20). Neglecting all the second order perturbations we obtain

$$A_1 = i\left[\phi e^0 + \frac{g}{2}\frac{(1+\cos\theta)}{r\sin\theta}e^3\right], \tag{23}$$

where we have introduced the subscript "1" to identify it as the connection on the open subset U_1 that will be determined below. We can see that there is a first singularity at $r = 0$ which, however, is a true curvature singularity as can be seen by analyzing the corresponding curvature. A second singularity is situated at $\theta = 0$ which does not appear at the level of the curvature. We "eliminate" the true curvature singularity by removing the origin $r = 0$ from the space–time. Hence, the base manifold M^4 becomes $M^4 = \mathbf{R}^4 - \{\text{world line of 0}\}$. The second singularity at $\theta = 0$, which corresponds to the positive sector, z_+, of the axis z, implies that the connection A_1 is regular on $U_1 = M^4 - \{z_+\}$. This apparent singularity can be eliminated by means of the gauge transformation $\gamma = \exp(ig\varphi)$ which leads to the new connection (up to first order in the perturbation)

$$A_2 = i\left[\phi e^0 + \frac{g}{2}\frac{(-1+\cos\theta)}{r\sin\theta}e^3\right]. \tag{24}$$

In fact, the singularity at $\theta = 0$ has been removed, but a new singularity has appeared at $\theta = \pi$. Consequently, the connection A_2 is regular only in the open subset $U_2 = M^4 - \{z_-\}$, where $\{z_-\}$ denotes the negative z axis.

The subsets U_1 and U_2 define a covering of the base manifold. In the intersection region $U_1 \cap U_2$ the two connections are related by means of the transition function $g_{12} = \exp(ig\varphi)$ which is single valued only if $g = n$, where n is an integer. To interpret this result we must find out the physical significance of the parameter g. This can be done, for instance, by calculating the multipole moments of this solution.[12] To do this, it is necessary to specify the function ϕ and we chose the simple solution $\phi = m/r$, where m is a constant. Then, it can be shown that the parameter m

represents the monopole moment of a mass distribution and gm corresponds to the monopole moment of an angular momentum distribution. This implies that g represents the gravitomagnetic monopole per mass unit which, according to the quantization condition obtained above, can take only discrete values.

This example reminds us of the case of a magnetic monopole in electrodynamics. Indeed, we have chosen the function χ in the connection (22) as the Maxwell potential for Dirac's magnetic monopole. The rest of the analysis is then carried out in a similar way as in standard electrodynamics, due to the analogy between the field equations for the weak field approximation and the Maxwell equations. The result obtained here by analyzing the behavior of the u(1) connection can be reproduced in terms of the topological invariants. The corresponding principal fiber bundle is a five-dimensional U(1) bundle for which the Chern invariants can be calculated. The result is again that the constant g becomes quantized.

V. THE REISSNER–NORDSTROM BLACK HOLE

Let us consider the following orthonormal frame for the Reissner–Nordstrom metric:

$$e^0 = \frac{[(r-r_-)(r-r_+)]^{1/2}}{r}\mathrm{d}t, \quad e^1 = \frac{r}{[(r-r_-)(r-r_+)]^{1/2}}\mathrm{d}r, \quad e^2 = r\,\mathrm{d}\theta, \quad e^3 = r\sin\theta\,\mathrm{d}\varphi, \tag{25}$$

with

$$r_\pm = m \pm \sqrt{m^2 - e^2}, \tag{26}$$

where m is the mass, e is the net electric charge of the source, and the radial values $r_\pm$ correspond to the horizons of the Reissner–Nordstrom black hole. This is a solution of the Einstein–Maxwell equations with the potential $\tilde{A}=-(e/r)\mathrm{d}t$. The corresponding u(1) connection $A=-i\tilde{A}$ behaves under a gauge transformation as in Eq. (5). According to the discussion of Sec. II and Theorem 3, there exists a principal fiber bundle which can be constructed by attaching at each point of the space–time the fiber U(1).

In this section we will explore the conditions that must be satisfied on the base manifold for constructing that bundle. To investigate the critical points of the connection 1-form we represent it in the orthonormal frame (25). Then

$$A = ie[(r-r_-)(r-r_+)]^{-1/2}e^0. \tag{27}$$

This connection diverges at $r=r_-$ and $r=r_+$, whereas the corresponding field strength is regular at those hypersurfaces. To remove these singularities, we first apply the gauge transformation $\gamma_1 = \exp(iet/r_-)$ on (27) and obtain

$$A_1 = -i\frac{e}{r_-}\left(\frac{r-r_-}{r-r_+}\right)^{1/2}e^0, \tag{28}$$

a u(1) connection which is regular at $r=r_-$, but diverges at $r=r_+$. On the other hand, we can also apply the transformation $\gamma_2=\exp(iet/r_+)$ on (27). The resulting connection

$$A_2 = -i\frac{e}{r_+}\left(\frac{r-r_+}{r-r_-}\right)^{1/2}e^0 \tag{29}$$

is regular at $r=r_+$, but diverges at $r=r_-$. Thus, we have obtained two different connections with different divergences. Let us choose the open subsets $U_1=(0,r_+)$ and $U_2=(r_-,\infty)$. This set of open subsets covers the radial coordinate r completely so that the subsets $U_1\times\mathbf{R}^3$ and $U_2\times\mathbf{R}^3$ are a covering of the base manifold M^4. Then, the connections A_1 and A_2 are well defined on U_1 and U_2, respectively. In the intersection region $U_1\cap U_2=(r_-,r_+)$, the connections A_1 and A_2 must be related by means of the transition function $g_{12}\in\mathrm{U}(1)$ which can easily be calculated as

$$g_{12} = \exp\left[ie\left(\frac{1}{r_-} - \frac{1}{r_+}\right)t \right]. \tag{30}$$

The important point about this transition function is that it depends only on the time coordinate t and is defined only on the region contained between the horizons r_- and r_+. On the other hand, it is well known[13] that in this region the coordinate t is not timelike but spacelike. Indeed, one of the interesting aspects of the region (r_-, r_+) is that the coordinates t and r interchange their role: what was the radial direction becomes timelike, and the timelike direction becomes spacelike. Therefore, we are allowed to consider t as an angle coordinate $0 \leqslant t \leqslant 2\pi$ inside the horizons. This is a consistent procedure that can be carried out explicitly for all black hole vacuum stationary solutions[14,15] and can easily be generalized to the case of electrovacuum stationary axisymmetric solutions. Therefore, if t is a compact and periodic coordinate inside the horizons, the transition function (30) is single-valued only if the coefficient in front of t is an integer, i.e.,

$$e\left(\frac{1}{r_-} - \frac{1}{r_+}\right) = \frac{2}{e}\sqrt{m^2 - e^2} = n. \tag{31}$$

This represents a relationship between the physical parameters which describe the black hole. This specific combination of m and e can take only discrete values. Notice that in the special case of an extreme black hole, $e=m$, the only allowed value is $n=0$. Moreover, the limiting case $e \to 0$ is not allowed. This is due to the fact that in order to perform this "quantization" we have used the u(1)-electromagnetic connection which does not exist in the case $e=0$.

Since the space–time possesses a curvature singularity at $r=0$, we must remove the world line of this event from the base space. This implies that the corresponding principal fiber bundle is not globally trivial. This can be seen explicitly by calculating the topological invariant, which in this case is given in terms of the Chern form $c = -(e/r^2)\mathrm{d}t \wedge \mathrm{d}r$. The Chern number is obtained by integrating the Chern form inside the horizon. As expected, we get the value of $4\pi n$, where n is an integer related to the parameters of the Reissner–Nordstrom black hole as given in (31). This represents an alternative derivation of the quantization condition. To verify that this result is also independent of the coordinates, we have performed a similar analysis of the Reissner–Nordstrom metric in Kruskal-type coordinates. As expected, the quantization condition (31) appears in a similar manner.

To conclude this section, it is worth mentioning that a similar analysis can be performed for the Kerr–Newman black hole. It turns out that in this case it is necessary to introduce again two open subsets in order to cover the entire space–time manifold. The transition function is defined in the region contained between the horizons, where the coordinate t is spacelike, and the quantization condition can be written as

$$\frac{2e^3\sqrt{m^2 - a^2 - e^2}}{e^4 + 4a^2m^2} = n, \tag{32}$$

where a represents the angular moment per unit mass of the black hole. As expected, in the limiting case $a=0$ we recover the expression (31) for the Reissner–Nordstrom black hole.

VI. CONCLUSIONS

In this paper we have developed the method of topological quantization for gravitational field configurations. First, we have shown that for any vacuum solution of Einstein's field equations there exists a natural unique principal fiber bundle with an so(1,3) connection. If the gravitational field is minimally coupled to a gauge matter field, there exists also a principal fiber bundle with a matter connection.

This procedure has been carried out explicitly for the gravitational configurations described by cylindrically symmetric space–times, the gravitomagnetic monopole in linearized gravity and electrovacuum black holes. In all the cases we have analyzed, the result of the topological quantization is a relationship that indicates the discretization of the parameters entering the correspond-

ing metrics. We have shown that the quantization conditions arise as the result of demanding a regular behavior of the connection on the base manifold. Quantization conditions can appear in globally trivial and nontrivial principal fiber bundles. In the latter case, equivalent results can be obtained from the analysis of the corresponding topological invariants.

In this work, we do not analyze the physical significance of the resulting discretization. In particular, it would be interesting to perform the topological quantization of black holes with respect to the so(1,3) connection which would complement the result of the u(1) connection analyzed here. Preliminary calculations show that the complete quantization of black holes metrics leads to a discretization of the horizon area. This task is currently under investigation.[16]

Moreover, in all the examples analyzed in this work we have restricted ourselves to the investigation of the regularity conditions of the connection on the base manifolds. Nevertheless, Theorems 1 and 3 show that there exists an additional connection on the bundle which reduces to the connection on the base manifold, when projected by means of the pull-back of local trivializations. It would be interesting to construct explicitly the connection on the bundle and investigate its properties.

Finally, we should mention that although the term "topological quantization" could be very suggestive, it is by no means a procedure that pretends to compete with already existing and well-developed procedures like canonical quantization. Nevertheless, it is interesting to see that the mere existence of relatively simple geometric structures in gravitational field configurations leads to a discretization of physical parameters, a property that is usually associated with quantization. A much more detailed and deep investigation is necessary in order to establish if topological quantization could be an alternative method to obtain at least partial "quantum" information from a physical system.

(Received 15 April 2003; accepted 14 July 2004; published online 27 January 2005)

We give a general geometric definition of asymptotic flatness at null infinity in d-dimensional general relativity (d even) within the framework of conformal infinity. Our definition is arrived at via an analysis of linear perturbations near null infinity and shown to be stable under such perturbations. The detailed falloff properties of the perturbations, as well as the gauge conditions that need to be imposed to make the perturbations regular at infinity, are qualitatively different in higher dimensions; in particular, the decay rate of a radiating solution at null infinity differs from that of a static solution in higher dimensions. The definition of asymptotic flatness in higher dimensions consequently also differs qualitatively from that in $d=4$. We then derive an expression for the generator conjugate to an asymptotic time translation symmetry for asymptotically flat space–times in d-dimensional general relativity (d even) within the Hamiltonian framework, making use especially of a formalism developed by Wald and Zoupas. This generator is given by an integral over a cross section at null infinity of a certain local expression and is taken to be the definition of the Bondi energy in d dimensions. Our definition yields a manifestly positive flux of radiated energy. Our definitions and constructions fail in odd space–time dimensions, essentially because the regularity properties of the metric at null infinity seem to be insufficient in that case. We also find that there is no direct analog of the well-known infinite set of angle dependent translational symmetries in more than four dimensions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1829152]

I. INTRODUCTION

Theories attempting to unify the forces often require a higher dimensional space–time, and accordingly have different properties than four-dimensional theories. Still important and fundamental even in higher dimensional theories are the notion of an isolated system and associated conserved quantities, such as the total energy of the system.

In four-dimensional general relativity, there exist two satisfactory notions of the total energy of a space–time representing an isolated system, namely the "Arnowitt–Deser–Misner" (ADM) energy[1] and the "Bondi" energy.[2–4] The ADM energy represents the energy of the system "once and for all" and is mathematically given by an integral of a quantity associated with the gravitational field, over a sphere at spatial infinity. The Bondi energy measures the total energy of the system "at an instant of time," and is mathematically given by an integral over a spacelike cross section at null infinity. Thus, while the ADM energy is just a number, the Bondi energy is in

a)Electronic mail: stefan@bert.uchicago.edu
b)Electronic mail: a.ishibashi@damtp.cam.ac.uk

general a function of time in the sense that it depends on the chosen cross section at null infinity. The difference between the Bondi energies at two different times represents the flux of gravitational radiation through the portion of null infinity bounded by the corresponding two cross sections.

While the expression for the ADM energy of a space–time is readily generalized to an arbitrary number of space–time dimensions, this is not so for the Bondi energy. To our knowledge, no expression for the Bondi energy or other quantities associated with the group of asymptotic symmetries has been given in the literature for more than four dimensions, let alone a systematic derivation.[21] This is maybe not so surprising since constructions associated with null infinity tend to be more complicated in nature than corresponding constructions at spatial infinity, which may, e.g., be appreciated from the fact that a completely satisfactory definition of quantities associated with asymptotic symmetries in four dimensions was not given as late as the early 1980s.[6] The purpose of the present paper is to derive an expression for the Bondi energy and momentum (Bondi energy, for short) in space–times of arbitrary (even) dimension.

The basic issue that needs to be settled in order to even get started on a definition of Bondi energy in higher dimensions is to specify what exactly one means by the statement that a space–time represents an "isolated system." Roughly speaking, an isolated system is a space–time that looks like Minkowski space "far away." (Other, less restrictive notions of an isolated system may also be considered, for example, systems that look like a Kaluza–Klein space far out in the "noncompact directions." However, the analysis of such metrics and of the associated conserved quantities would be substantially different from the ones studied in the present paper.) Of course, one must explain exactly what one means by "far away," and one must determine the precise asymptotics that should reasonably be imposed on the gravitational field at null infinity. What are the asymptotics for the gravitational field in d dimensions? For the sake of definiteness, suppose one would attempt to define an isolated system to be a space–time whose metric has the form of the Schwarzschild metric (in suitable coordinates), plus higher order terms in $1/r$ as one goes off to infinity along a null direction. In other words, suppose one were to define asymptotic flatness at null infinity in the same way which works at spatial infinity. Then one would effectively eliminate from consideration all space–times that contain gravitational radiation through null infinity, which are of course precisely the space–times that one wants to describe in the first place. On the other hand, if one imposes drop off conditions that are too weak, then it will in general be impossible to define a notion of radiated energy of such a space–time in a meaningful way. Thus, the task is to find a definition of asymptotic flatness that is both general enough so as to allow sufficiently many physically interesting radiating space–times, and stringent enough so as to allow one to derive meaningful expressions for the energy, as well as possibly other quantities associated with asymptotic symmetries.

The original definition of asymptotic flatness in four dimensions proposed by Bondi and collaborators[2,4] was formulated in terms of detailed conditions on the metric components in a preferred coordinate frame and was arrived at via a study of gravitational waves near infinity. Their definition was later elegantly recast into the language of "conformal infinity" following the work of Penrose.[7–11] In this language, a space–time is said to be asymptotically flat, if it can be conformally embedded into a smooth "unphysical" space–time via a conformal transformation with conformal factor Ω, so that the points at infinity are at the "finite" location $\Omega=0$ in the unphysical space–time, and so that the gradient of the conformal factor Ω is null there. The main arguments that have been advanced in favor of this definition are that it covers the known exact solutions of Einstein's equation that one intuitively thinks of as representing isolated systems, and that the definition can be proven to be stable under linear perturbations,[12] in the sense that any compactly generated solution to the linearized equations of motion around an asymptotically flat solution satisfies the linearized version of the above definition of asymptotic flatness in a suitable gauge. (By contrast, if one were to adopt the, e.g., same definition of asymptotic flatness at null infinity as one has at spatial infinity, then such a definition would not be stable under linear perturbations.)

Thus, the first task of our paper is to obtain an appropriate generalization of asymptotic

flatness to higher dimensions. This definition will be motivated as in four dimensions by a detailed analysis of the decay properties of linear perturbations at null infinity. We show that perturbations typically drop off as $1/r^{(d-2)/2}$ as one approaches null infinity, which, as we note, differs from the drop off rate of the Schwarzschild metric, $1/r^{d-3}$, when the space–time dimensions are greater than 4. The appearance of half-odd integer powers of $1/r$ in the tail of the metric at null infinity in odd d implies in particular that the unphysical metric will not be smooth at null infinity. It turns out that, for this reason, a geometrical definition of null infinity as given above for $d=4$ does not appear to be possible in odd space–time dimensions. We will therefore restrict our attention to space–times of even dimension in this paper. We will also see that the detailed behavior of the perturbations near null infinity differs qualitatively from that in four dimensions in that the trace of the metric perturbation drops off one power in $1/r$ faster than the perturbation itself. (As we will show, this phenomenon is closely related to the fact that the transverse traceless gauge is regular at null infinity in $d>4$, whereas this is not the case in $d=4$, where the so-called "Geroch–Xanthopoulos" gauge has this property.) Consequently, our definition of asymptotic flatness in $d>4$ dimensions also differs qualitatively from that in four dimensions in that it involves, for example, additional conditions on the metric volume element as one approaches null infinity.

The mathematical expression for the ADM energy, including the correct normalization, can be derived (in arbitrary dimension) in a simple and straightforward manner within the Hamiltonian framework of general relativity where it is seen to represent the "charge" conjugate to an infinitesimal asymptotic time translation at spatial infinity.[13] It was shown by Wald and Zoupas[14] (based on earlier work by Ashtekar and Streubel,[11] see also Ref. 15) that an expression for the Bondi energy in four-dimensional general relativity can also be arrived at within a Hamiltonian framework as the quantity conjugate to an asymptotic time translation at null infinity, although the situation is certainly considerably more complicated compared to spatial infinity. This expression was shown to be unique under some natural assumptions and agrees with the previously known one.[10,6] The formalism of Ref. 14 is in fact capable of dealing with arbitrary diffeomorphism covariant theories of gravity (in arbitrary dimension) in the presence of boundary conditions at null surfaces. We employ it here to establish the existence and uniqueness of a generator conjugate to an asymptotic time translation in d-dimensional vacuum general relativity (d an even number) within the context of our asymptotic flatness condition, and we take this generator as the definition of the Bondi energy in d dimensions. The algorithm by Wald and Zoupas specifies this generator only indirectly via its variation under a suitable variation of the space–time metric, so further work is required to actually find a local expression for this quantity. Such an expression is provided in Eq. (100). As in four dimensions, our definition of the Bondi energy has the property that it yields a manifestly positive flux of energy given by the square of a suitably defined "news tensor."

We emphasize that the issue of existence of a generator conjugate to an asymptotic time translation symmetry (or a more general other asymptotic symmetry) is by no means automatic but rather depends crucially on the nature of the boundary conditions. As a rule, boundary conditions that are "too weak" will prohibit the existence of a generator. In our case, the boundary conditions are independently determined by a perturbation analysis, and therefore not put in "by hand" in order to guarantee the existence of a generator. That we find existence of a generator is therefore a consistency check.

The case $d=4$ seems to be "exceptional" with regard to many of our constructions from the point of view of general d. For example, the definition of the news tensor differs in dimensions greater than 4. Also, while the unphysical Weyl tensor can be proven to vanish one order faster than the unphysical Ricci tensor in $d=4$, this does not appear to be the case in higher dimensions. On the other hand, the unphysical Ricci scalar vanishes one order faster than the unphysical Ricci tensor itself in $d>4$, while both quantities generically have the same drop off behavior in $d=4$. In $d=4$, it is well known that the asymptotic symmetries form an infinite dimensional group which comprises, besides the transformations corresponding to the usual symmetries of Minkowski space–time, an additional infinite set of (mutually commuting) "angle dependent translations," sometimes called "supertranslations." (There is no relation with supersymmetry.) We find that there is no direct analog of the supertranslations in $d>4$. Another curious feature, which is of a

more technical nature but nevertheless seems to underlie many of the differences between $d=4$ and higher dimensions is that, while linear perturbations can be proven to be regular at null infinity in the transverse traceless gauge in $d>4$, this is not so in $d=4$, where one must choose the (somewhat complicated) Geroch–Xanthopoulos gauge.[12]

The contents and main results of this paper may now be summarized. In Sec. II we present our definition of asymptotic flatness in arbitrary dimension and define the notion of an asymptotic symmetry. In Sec. III we show that our definition of asymptotic flatness is stable under linear perturbations, provided that the perturbations are in a suitable gauge. In Sec. IV we recall the general formalism of Ref. 14 for defining generators associated with asymptotic symmetries, and in Sec. V we derive our formula for the Bondi energy. We also verify that our expression for the Bondi energy agrees with the expected one (i.e., the ADM energy) in the d-dimensional analogue of the Schwarzschild metric. We draw our conclusions in Sec. VI. For simplicity, we restrict attention to the case of vacuum general relativity throughout this paper. Some remarks concerning the incorporation of matter fields are also given in Sec. VI.

Our conventions are the same as in Ref. 16: The signature of the metric is $(-+++\cdots)$, the convention for the Riemann tensor is $\nabla_{[a}\nabla_{b]}k_c=(1/2)R_{abc}{}^d k_d$ and $R_{ab}=R_{acb}{}^c$ for the Ricci tensor. Indices in parentheses are symmetrized and indices in square brackets are antisymmetrized.

II. ASYMPTOTIC FLATNESS IN *d* DIMENSIONS

Asymptotic conditions in field theory require the specification of a background configuration and the precise rate at which this background is approached. In the case of asymptotic flatness in higher dimensional general relativity, the background is the Minkowski metric. (Other asymptotic conditions would of course require a different background.) In order to specify the precise rate at which Minkowski space–time is approached at null infinity, it is of great technical advantage to work within a framework in which "infinity" is attached as additional points to the space–time manifold, $\tilde{M}$ (thereby obtaining an "unphysical" space–time manifold M), and in which these points are brought metrically to a finite distance by rescaling the physical metric, $\tilde{g}_{ab}$, by a conformal factor Ω^2 with suitable properties. The asymptotic flatness conditions are then formulated in terms of this rescaled "unphysical metric,"

$$g_{ab}=\Omega^2\tilde{g}_{ab}, \tag{1}$$

and its relation to the likewise conformally rescaled version of Minkowski space–time,

$$\bar{g}_{ab}=\Omega^2\tilde{\eta}_{ab}. \tag{2}$$

We will refer to $(\bar{M},\bar{g}_{ab})$ as the "background geometry." As it is well known, Eq. (2) can be realized, e.g., by conformally embedding Minkowski space–time into a patch of the Einstein static universe $\mathbb{R}\times S^{d-1}$ with line element $\mathrm{d}\bar{s}^2=-\mathrm{d}T^2+\mathrm{d}\psi^2+\sin^2\psi\,\mathrm{d}\sigma^2$. Here, $\mathrm{d}\sigma^2$ is the line element of a round $(d-2)$-dimensional sphere, and ψ is the azimuthal angle of S^{d-1}. In these coordinates, Minkowski space–time corresponds to the region $\bar{M}=\{-\pi<T\pm\psi<\pi,\psi>0\}$ of $\mathbb{R}\times S^{d-1}$, see Appendix B for further details of this conformal embedding, as well as the specific form of Ω.

The conformal infinity of Minkowski space–time is the boundary of the region $\bar{M}$ in the Einstein static universe. It is divided into the following five parts: (1) future timelike infinity (the point $T=\pi,\psi=0$), (2) past timelike infinity (the point $T=-\pi,\psi=0$), (3) spacelike infinity (the point $\psi=\pi,T=0$), (4) past null-infinity (the points $T=-\pi+\psi$ for $0<\psi<\pi$), and (5) future null infinity (the points $T=\pi-\psi$ for $0<\psi<\pi$). The conformal factor Ω is smooth in a neighborhood of null infinity and vanishes there, and the gradient of Ω is nonvanishing and null there.

Our definition of asymptotic flatness consists in specifying the precise rate at which g_{ab} approaches $\bar{g}_{ab}$ as one approaches the boundary $\partial\bar{M}$. To quantify how various tensors behave at that boundary, we introduce the following notion: We will say that a tensor field, $L_{ab\cdots c}$, is "of

order Ω^s" with $s \in \mathbb{R}$, written $L_{ab\cdots c} = O(\Omega^s)$, if the tensor field $\Omega^{-s} L_{ab\cdots c}$ is smooth at the boundary. It is a consequence of this definition that if $L_{ab\cdots c}$ is of order s then $\Omega^r L_{ab\cdots c}$ is of order $s+r$, and that $\overline{\nabla}_{d_1} \cdots \overline{\nabla}_{d_k} L_{ab\cdots c}$ is of order $s-k$.

We now state our definition of asymptotic flatness in even space–time dimensions $d > 4$. (From now on, d is taken to be an even number unless stated otherwise.) Let $(\overline{M}, \overline{g}_{ab})$ be the background geometry described above. A d-dimensional space–time $(\tilde{M}, \tilde{g}_{ab})$ will be said to be *weakly asymptotically simple at null infinity* if the following is true:

(1) It is possible to attach a boundary $\mathscr{I}$ to $\tilde{M}$ such that $M = \tilde{M} \cup \mathscr{I}$ is locally diffeomorphic to the manifold $\overline{M}$ near its boundary.
(2) One has, relative to our background metric $\overline{g}_{ab}$, that

$$\overline{g}_{ab} - g_{ab} = O(\Omega^{(d-2)/2}), \quad \overline{\epsilon}_{ab\cdots c} - \epsilon_{ab\cdots c} = O(\Omega^{d/2}), \tag{3}$$

where $\overline{\epsilon}_{ab\cdots c}$ and $\epsilon_{ab\cdots c}$ denote the volume element (viewed as d-forms) associated with the metrics $\overline{g}_{ab}$, respectively, g_{ab}, as well as

$$(\overline{g}^{ab} - g^{ab})(\mathrm{d}\Omega)_a = O(\Omega^{d/2}), \quad (\overline{g}^{ab} - g^{ab})(\mathrm{d}\Omega)_a(\mathrm{d}\Omega)_b = O(\Omega^{(d+2)/2}), \tag{4}$$

where g^{ab} is the inverse of g_{ab} and where $\overline{g}^{ab}$ is the inverse of $\overline{g}_{ab}$.

It is important to note that, while our definition of an asymptotically flat space–time is formulated relative to a specific background geometry, our definition is actually independent of the precise way in which the Minkowski metric $\tilde{\eta}_{ab}$ is written as $\Omega^{-2}\overline{g}_{ab}$ in terms of a background metric (smooth at $\mathscr{I}$), and correspondingly the way in which the physical metric $\tilde{g}_{ab}$ is written as $\Omega^{-2} g_{ab}$ in terms of an auxiliary unphysical metric. In other words, if k is a smooth function defined in a neighborhood of the boundary of $\overline{M}$ such that $k \neq 0$ at null infinity, then our definition of an asymptotically flat metric is unchanged if we change the conformal factor to $\Omega' = k\Omega$, the background metric to $\overline{g}'_{ab} = k^2 \overline{g}_{ab}$, and the unphysical metric to $g'_{ab} = k^2 g_{ab}$.

As in four space–time dimensions, the notion of weak asymptotic simplicity can be strengthened by requiring in addition that every inextendible null geodesic in $(\tilde{M}, \tilde{g}_{ab})$ has precisely two end points on $\mathscr{I}$. Such a space–time is then simply called *asymptotically simple*. This additional condition, combined with the fact that $\mathscr{I}$ is null, makes it possible to divide $\mathscr{I}$ into disjoint sets, $\mathscr{I}^+$ and $\mathscr{I}^-$, on which future, respectively, past directed null geodesics have their end points. These sets are referred to as future, respectively, past null infinity. This condition also implies that $(\tilde{M}, \tilde{g}_{ab})$ necessarily must be globally hyperbolic, by a straightforward generalization of Proposition 6.9.2 of Ref. 17 to d dimensions. (We also note that, by a straightforward generalization of Proposition 6.9.4 of Ref. 17 to d dimensions, the additional condition is in fact only consistent with $\mathscr{I}$ having topology $\mathbb{R} \times S^{d-2}$. This agrees with the topology of the boundary of our background geometry.)

Item (1) of our definition is essentially the statement that, as a manifold, M looks near $\mathscr{I}$ like the background manifold $\overline{M}$ looks near its null boundary. Item (2) of the definition involves three different metrics: The physical $\tilde{g}_{ab}$, unphysical g_{ab}, and the background metric $\overline{g}_{ab}$. The physical and unphysical metric are related by the conformal factor, Ω, which makes the unphysical metric smooth and at the same time brings null infinity, $\mathscr{I}$, to a "finite location," and the background metric is likewise related to Minkowski space–time. The relation between the unphysical and background metric is given by the above set of equations in item (2), which specify the precise manner in which the unphysical metric approaches the background metric, and thus the precise sense in which our space–time is required to flatten out at null infinity. Since $\nabla_a \Omega$ is null relative to the background metric, it is also null relative to the metric g_{ab}, showing that $\mathscr{I}$ is a null surface in the unphysical space–time (M, g_{ab}). Since Ω^2 times Minkowski space–time is isometric to $(\overline{M}, \overline{g}_{ab})$, our definition of asymptotic flatness trivially covers Minkowski space–time.

Since we will be working with different metrics in this paper—physical and unphysical—it is necessary to specify a rule for raising and lowering indices of tensors. Our rule is that indices on tensor fields on M without a "tilde" are raised and lowered with the unphysical metric, g_{ab} and its inverse, whereas indices on tensor fields on $\tilde{M}$ with a "tilde" are raised and lowered with the physical metric, $\tilde{g}_{ab}$, and its inverse. (Note that this rule is consistent with our notation g^{ab} and $\tilde{g}^{ab}$ for the inverse of the metrics g_{ab} and $\tilde{g}_{ab}$.)

Let us compare the above definition of asymptotic flatness with the behavior of the d-dimensional analog of the Schwarzschild metric, given by the line element

$$d\tilde{s}^2 = -(1 - cr^{-(d-3)})dt^2 + (1 - cr^{-(d-3)})^{-1}\, dr^2 + r^2\, d\sigma^2, \quad c > 0, \tag{5}$$

where $d\sigma^2$ is the line element of a round $(d-2)$-dimensional sphere. Introducing a coordinate u by the relation $du = dt - (1 - cr^{-(d-3)})^{-1}\, dr$, the line element takes the form

$$d\tilde{s}^2 = -2\, du\, dr - du^2 + r^2\, d\sigma^2 + cr^{-(d-3)}\, du^2, \tag{6}$$

where the first three terms on the right-hand side are recognized as the Minkowski line element. Multiplying by our conformal factor Ω^2, using $r^{-1} = O(\Omega)$, and using that Ω^2 times the Minkowski metric is equal to our background metric $d\bar{s}^2$ by construction, it follows that the unphysical Schwarzschild metric can be written as $ds^2 = d\bar{s}^2 + O(\Omega^{d-1})du^2$ (noting that u is a good coordinate at infinity). It follows that Schwarzschild space–time is asymptotically flat in the sense of our definition, but it becomes flat at null infinity at a faster rate than that specified above in Eqs. (3) and (4) in $d > 4$. [In $d = 4$, the relevant components drop off at the same rate, as specified in Eqs. (3) and (4).]

The above definition of asymptotic flatness in even dimensions $d > 4$ is not appropriate in odd space–time dimension, since condition (3) in item (2) now says that the unphysical metric g_{ab} differs from the smooth background metric $\bar{g}_{ab}$ by a half-odd integer power of Ω, and thereby manifestly contradicts the assumption in item (1) that g_{ab} is smooth at the boundary. The powers of Ω appearing in Eqs. (3) and (4) reflect the drop off behavior of a linearized perturbation (see Sec. III), and it is hard to see how these powers could be essentially different from the ones in the full nonlinear theory. It therefore appears that the unphysical metric is generically at most $(d-3)/2$ times differentiable at the boundary in odd dimensions. We note that it is also inconsistent in odd dimensions to postulate that the quantity $\Omega^{-(d-2)/2}(g_{ab} - \bar{g}_{ab})$ is smooth at the boundary as we did above in Eq. (3) of item (2) in the even dimensional case, because the unphysical Schwarzschild metric g_{ab} differs from the background $\bar{g}_{ab}$ by terms of order Ω^{d-1}, i.e., by an even power of Ω. Therefore, Eq. (3) is definitely false for the Schwarzschild metric in odd dimensions. For the Schwarzschild metric, $\Omega^{-(d-1)}(g_{ab} - \bar{g}_{ab})$ is smooth at the boundary (in even and odd dimensions), so one might be tempted to try this condition, together with suitable other conditions, as the definition of asymptotic flatness. However, this would eliminate from consideration all radiating space–times and is therefore not acceptable. One may try to bypass these problems by requiring appropriate lower differentiability properties of the corresponding quantities, but these seem neither to lead to a definition of asymptotic flatness that is stable under perturbations, as we briefly discuss in Sec. III, nor do those weaker conditions seem to be able to guarantee the existence of conserved quantities such as Bondi energy. Thus, it seems that a sensible definition of asymptotic simplicity at conformal infinity in odd space–time dimensions would have to differ substantially from the one given above for even dimensions, and it is doubtful that such a definition can be cast into the framework of conformal infinity. For the rest of this paper, we will restrict attention to even space–time dimensions.

We finally comment on how the above definition of asymptotic flatness in even space–time dimensions $d > 4$ compares to the usual definition[10] in four dimensions. In this definition, one simply demands that there exists *some* conformal factor, Ω, such that the corresponding unphysical metric is smooth at $\mathscr{I}$ and such that $\nabla_a\Omega$ is nonvanishing and null there. (The nullness of $\nabla_a\Omega$ follows from the first condition if Einstein's equations with vanishing stress energy at null infinity are assumed.) This definition is different in appearance from that given above and avoids in

particular the introduction of a background geometry. Nevertheless, the definition of asymptotic flatness in $d=4$ as just stated can be brought into a form that is very similar (but not identical) to the one given above for $d>4$. (We emphasize, however, that an analogous statement is not true in $d>4$. Namely, it is not true that our definition of asymptotic flatness in higher dimensions is equivalent to the statement that there exists some conformal factor, Ω, such that the corresponding unphysical metric is smooth at $\mathscr{I}$ and such that $\nabla_a\Omega$ is nonvanishing and null there.) To see this in more detail, we recall that the usual definition of asymptotic flatness in four dimensions is equivalent[18] to the statement that the physical metric can be cast into "Bondi form" [it is assumed in the derivation of Eq. (7) that the vacuum Einstein equations are satisfied], see Eqs. (14) and (31)–(34) of Ref. 2,

$$d\tilde{s}^2 = -2\,du\,dr - du^2 + r^2\,d\sigma^2 + O(r)\mathrm{d(angles)}^2 + O(1)du\,\mathrm{d(angles)} + O(r^{-1})du^2 + O(r^{-2})du\,dr \tag{7}$$

in suitable coordinates near null infinity, where the first line is recognized as the Minkowski line element, and where "angles" stands for the usual polar angles of S^2. In $d>4$ space–time dimensions our asymptotic flatness conditions Eqs. (3) and (4) in effect state that the physical line element can be written in the form

$$\begin{aligned} d\tilde{s}^2 = &-2\,du\,dr - du^2 + r^2\,d\sigma^2 + O(r^{-(d-4)/2})\mathrm{d(angles)}^2 + O(r^{-(d-4)/2})du\,\mathrm{d(angles)} \\ &+ O(r^{-(d-2)/2})du^2 + O(r^{-d/2})du\,dr, \end{aligned} \tag{8}$$

where "angles" now stands for the polar angles of S^{d-2}. One notices that the Bondi form (8) in $d>4$ does not reduce to Eq. (7) when d is set to 4. The difference between the two expressions arises from the $\mathrm{d(angles)}^2$ term, which quantifies the perturbations in the size of the cross sections of a light cone relative to Minkowski space–time. According to Eq. (7), this term is of order $O(1)$ in $d=4$ for a radiating metric, whereas Eq. (8) would say that it should be of order $O(r^{-1})$. The latter is simply wrong for a radiating metric in four dimensions. This difference can be traced back to the last of conditions (3) in $d>4$ dimensions, which therefore does not hold in $d=4$. This special feature of four dimensions will be reflected in corresponding differences in our discussion of the Bondi energy in dimensions $d>4$. We will therefore, for the rest of this paper, keep the case $d=4$ separate and assume throughout that $d>4$ (and even). Our formulas will not be valid in $d=4$ unless stated otherwise.

A diffeomorphism ϕ such that $\phi^*\tilde{g}_{ab}$ is asymptotically flat whenever $\tilde{g}_{ab}$ is asymptotically flat is called an *asymptotic symmetry*. It is clear that the asymptotic symmetries form a group under the composition of two diffeomorphisms. Clearly, the property of being an asymptotic symmetry is only related to the behavior of ϕ near the boundary. An infinitesimal asymptotic symmetry is a smooth vector field ξ^a on $\tilde{M}$ that has a smooth extension (denoted by the same symbol) to the unphysical manifold, M, and which generates a one-parameter group of asymptotic symmetries. It is a direct consequence of our definitions that the quantity

$$\chi_{ab} = \Omega^{-(d-6)/2}\pounds_\xi\tilde{g}_{ab} = 2\Omega^{-(d-2)/2}(\nabla_{(a}\,\xi_{b)} - \Omega^{-1}n^c\xi_c g_{ab}) \tag{9}$$

then must satisfy

$$\chi_{ab} = O(1), \quad \chi_a{}^a = O(\Omega), \quad \chi_{ab}n^a = O(\Omega), \quad \chi_{ab}n^an^b = O(\Omega^2), \quad \xi^a n_a = O(\Omega), \tag{10}$$

where here and in the following we are using the abbreviation

$$n_a = \nabla_a\Omega. \tag{11}$$

Conversely, if the above relations are satisfied for *some* asymptotically flat space–time, then ξ^a is an infinitesimal asymptotic symmetry. The classification of asymptotic symmetries in $d>4$ differs from that in four dimensions. We will discuss this issue in some detail below in Sec. V and in Appendix C, as well as in a forthcoming paper.[19]

III. STABILITY OF ASYMPTOTIC FLATNESS TO LINEAR ORDER

In this section we justify the definition of asymptotic flatness for even d given in the preceding section by showing that it is stable under linear perturbations. What we mean by this is the following. Suppose that $(\tilde{M},\tilde{g}_{ab})$ is an asymptotically flat space–time that is also a solution to the vacuum Einstein equation, $\tilde{R}_{ab}=0$. Consider a solution, $\delta\tilde{g}_{ab}$, to the linearized equations of motion around this background,

$$0=\delta\tilde{R}_{ab}=\tfrac{1}{2}(-\tilde{\nabla}^m\tilde{\nabla}_m\delta\tilde{g}_{ab}-\tilde{\nabla}_a\tilde{\nabla}_b\delta\tilde{g}_m{}^m+2\tilde{\nabla}^m\tilde{\nabla}_{(a}\,\delta\tilde{g}_{\,b)m}), \tag{12}$$

which has the property that the restriction of $\delta\tilde{g}_{ab}$ to a Cauchy surface has compact support. [In this section, by "background" we mean the "unperturbed" physical space–time $(\tilde{M},\tilde{g}_{ab})$, unless otherwise stated. This should not be confused with the background (2), which is our reference space–time for defining asymptotic flatness.] We will show in this section that there exists a gauge (the transverse traceless gauge works) such that, setting $\delta g_{ab}=\Omega^2\delta\tilde{g}_{ab}$,

$$\delta g_{ab}=O(\Omega^{(d-2)/2}),\quad \delta g_{ab}n^a=O(\Omega^{d/2}),\quad \delta g_{ab}n^an^b=O(\Omega^{(d+2)/2}),\quad g^{ab}\delta g_{ab}=O(\Omega^{d/2}), \tag{13}$$

at $\mathscr{I}$ for all even $d>4$. These conditions are recognized as the linearized version of our definition of asymptotic flatness, Eqs. (3) and (4), about an asymptotically flat background. Our definition of asymptotic flatness is therefore stable to linear order.

We have emphasized above that our decay properties of the metric perturbations are valid only in a particular gauge. Indeed, since the linearized equations of motion, $\delta\tilde{R}_{ab}=0$, are invariant under a gauge transformation $\delta\tilde{g}_{ab}\to\delta\tilde{g}_{ab}+\pounds_\xi\tilde{g}_{ab}$ with ξ^a an arbitrary smooth vector field on $\tilde{M}$, Eq. (13) cannot possibly be true in an arbitrary gauge. For if it were to hold in one gauge, it would certainly not hold in a gauge with a ξ^a that is very badly behaved at $\mathscr{I}$. Thus, the specification of an admissible gauge choice for the metric perturbation is an important part of the demonstration of Eq. (13).

A proof that asymptotic flatness is stable to linear order in four dimensions was given by Geroch and Xanthopoulos.[12] Their argument consists of the following two steps: One first writes the linearized equations of motions (12) in terms of the unphysical metric and derivative operator and introduces new field variables such that Eq. (12) is transformed into a hyperbolic system of partial differential equations whose coefficients are either manifestly regular functions as one approaches $\mathscr{I}$ or can be made to vanish by a suitable gauge choice. One then argues, using standard existence and uniqueness results for solutions of hyperbolic partial differential equations, that the new variables therefore have a smooth extension to the unphysical space–time. (Here one needs to use that the perturbation has compactly supported initial data.) Translating this statement about the new variables back into a statement about the metric perturbation, one finds the decay properties of the metric perturbation at $\mathscr{I}$.

We here use this basic strategy to analyze the decay at $\mathscr{I}$ of metric perturbations in even dimensions $d>4$. The second step does not depend on the dimension of the space–time, since it only involves general properties of hyperbolic differential equations. By contrast, the first step, i.e., the actual choice of variables and gauge conditions, is different in nature in $d>4$ dimensions as compared to $d=4$. Finding the appropriate variables and gauge conditions that do the job is, of course, the hard part of the analysis. It needs to be done before writing down any decay properties of the perturbations, which are then supposed to follow from the precise form of the new variables and gauge conditions. We here present things in the opposite order in order to simplify the exposition. (Throughout the rest of this section, $d>4$ and even will be assumed.)

Concerning the proper choice of gauge, we consider the 1-form

$$\tilde{v}_a = \tilde{g}^{bc}\tilde{\nabla}_c\delta\tilde{g}_{ab} - \tilde{g}^{bc}\tilde{\nabla}_a\delta\tilde{g}_{bc}, \tag{14}$$

which is equal to (dual of) the integrand of the surface term arising when varying the Einstein–Hilbert action. Under a gauge transformation, $\delta\tilde{g}_{ab} \to \delta\tilde{g}_{ab} + \pounds_\xi \tilde{g}_{ab}$, this quantity is seen to transform as

$$\tilde{v}^a \to \tilde{v}^a + 2\tilde{\nabla}_b\tilde{\nabla}^{[b}\,\xi^{a]}, \tag{15}$$

where the vacuum Einstein equations $\tilde{R}_{ab}=0$ have been used. On the other hand, the variation of the Ricci tensor can be seen to satisfy

$$\tilde{g}^{ab}\delta\tilde{R}_{ab} = \tilde{\nabla}^a\tilde{v}_a, \tag{16}$$

so that we have $\tilde{\nabla}^a\tilde{v}_a=0$ when the linearized Einstein equations hold. Thus, by Eq. (15), we can set $\tilde{v}_a=0$ throughout $\tilde{M}$ by a choice of gauge transformation when the linearized Einstein equations hold. (Note that $0=\tilde{v}^a+2\tilde{\nabla}_b\tilde{\nabla}^{[b}\,\xi^{a]}$ has the same form as Maxwell's equation for a vector potential, with a divergence free source. A solution therefore exists by the same arguments as for Maxwell's equations.) This gauge choice is invariant under further gauge transformations of the form $\delta\tilde{g}_{ab} \to \delta\tilde{g}_{ab} + \pounds_\xi\tilde{g}_{ab}$, with $\xi^a = \tilde{\nabla}^a\xi$ and ξ as any smooth function on $\tilde{M}$, which can be used, for example, to impose a gauge condition on the trace of the perturbation. We impose

$$\delta\tilde{g}_a{}^a = 0, \tag{17}$$

which can always be realized since the trace transforms as

$$\delta\tilde{g}_a{}^a \to \delta\tilde{g}_a{}^a + 2\tilde{\nabla}^a\tilde{\nabla}_a\xi \tag{18}$$

under the remaining gauge transformations. Thus, our gauge conditions are Eq. (17) and $\tilde{v}_a=0$. Together, they are equivalent to the transverse traceless gauge condition, $\tilde{\nabla}^a\delta\tilde{g}_{ab} = \delta\tilde{g}_m{}^m = 0$.

Concerning the proper choice of field variables when $d>4$, we consider

$$\tau_{ab} \equiv \Omega^{-(d-2)/2}\delta g_{ab}, \quad \tau_a \equiv \Omega^{-1}\tau_{ab}n^b, \quad u \equiv \nabla^a\tau_a. \tag{19}$$

We substitute the definitions (19) into the linearized Einstein equation, and use the background Einstein equation, $\tilde{R}_{ab}=0$, as well as the well-known relations between the physical and unphysical derivative operator and Ricci tensor,

$$\tilde{\nabla}_a k_b = \nabla_a k_b + \Omega^{-1}(2\delta^c_{(a}\,n_{\,b)} - g_{ab}n^c)k_c, \tag{20}$$

$$\tilde{R}_{ab} = R_{ab} + \Omega^{-1}[(d-2)\nabla_a n_b + (\nabla_m n^m)g_{ab} - (d-1)f g_{ab}]. \tag{21}$$

A lengthy calculation shows that the result can be written in the form

$$\begin{aligned} 0 = 2\Omega^{-(d-2)/2}\delta\tilde{R}_{ab} = &-\nabla^c\nabla_c\tau_{ab} + \nabla_a\nabla_b\tau + 4\nabla_{(a}\,\tau_{\,b)} + 2\nabla_{(a}\,y_{\,b)} - 2u g_{ab} - 2R_{acbd}\tau^{cd} - \frac{(d-6)}{2(d-2)}R_{ab}\tau \\ &+ \frac{(d-2)}{4(d-1)}R\tau_{ab} + \frac{(d-6)}{4(d-1)(d-2)}g_{ab}R\tau + \Omega^{-1}(d-2)n_{(a}\,y_{\,b)} \\ &+ \Omega^{-1}g_{ab}\left((d-2)n_c\tau^c + n^c\nabla_c\tau + \frac{(3d-10)}{4}f\tau\right) + (d-4)\Omega^{-1}n_{(a}\,\nabla_{\,b)}\tau \\ &+ \frac{(d-6)(d-4)}{4}\Omega^{-2}n_a n_b\tau, \end{aligned} \tag{22}$$

where we have used the shorthand notation

$$\tau = \tau^a{}_a, \quad y_a = \Omega^{-(d-2)/2}\tilde{v}_a = \nabla^c \tau_{ca} - \nabla_a \tau - \frac{(d+2)}{2}\tau_a - \frac{(d-4)}{2}\Omega^{-1} n_a \tau, \tag{23}$$

as well as

$$f = \Omega^{-1} n_a n^a. \tag{24}$$

We now substitute our gauge conditions, $y_a = \tau = 0$, using in particular that

$$0 = n^a y_a = \frac{1}{2}\left(u + \frac{1}{(d-2)} R^{ab}\tau_{ab}\right) - \frac{d}{4}\Omega^{-1} n^a \tau_a, \tag{25}$$

which follows by combining our gauge condition with the background Einstein equation, to get rid of the $\Omega^{-1} n^a \tau_a$ term in Eq. (22). Then Eq. (22) reduces to

$$\nabla^c \nabla_c \tau_{ab} = 4\nabla_{(a}\,\tau_{b)} - \frac{4}{d} u g_{ab} + \frac{(d-2)}{4(d-1)} R \tau_{ab} + \frac{2}{d} R^{cd}\tau_{cd} g_{ab} - 2R_{acbd}\tau^{cd}, \tag{26}$$

where all singular terms now have dropped out due to our choice of variables and gauge condition. We are, however, not done yet since we also need appropriate equations for the remaining variables, τ_a, u.

In order to get an equation for τ_a, we take the divergence of Eq. (26) with respect to the unphysical metric and use again the transverse traceless gauge condition, $y_a = \tau = 0$. This gives

$$\begin{aligned}(d-2)\nabla^c \nabla_c \tau_a = {} & \frac{4(d-2)}{d}\nabla_a u + \frac{4}{d} R^{bc}\nabla_a \tau_{bc} - 2R^{bc}\nabla_b \tau_{ca} + \left(\frac{(d+2)(d-2)}{4(d-1)} R g_{ab} + 4R_{ab}\right)\tau^b \\ & + 2\left(\nabla_b R_{ca} - \frac{(d-2)}{d}\nabla_a R_{bc} - \frac{d}{4(d-1)}(\nabla_c R) g_{ab}\right)\tau^{bc}.\end{aligned} \tag{27}$$

Finally, in order to get an equation for u, we take a further divergence of Eq. (27). We use Eq. (26) and the divergence of the transverse traceless gauge condition $\nabla^a y_a = \tau = 0$ to eliminate second derivatives of τ_{ab}, giving

$$\begin{aligned}(d-2)(d-4)\nabla^c \nabla_c u = {} & -2(d+2)(d-4) R_{ab}\nabla^a \tau^b - 2(d-4)\nabla^a R^{bc}\nabla_a \tau_{bc} \\ & + \frac{(d-4)(d^3+4d^2+12d-16)}{4d(d-1)} R u - \frac{d(d-2)(d-4)}{2(d-1)}(\nabla_c R)\tau^c \\ & + \left(\frac{d(d-2)}{2(d-1)}\nabla_a \nabla_b R - 2(d-2)\nabla^c \nabla_c R_{ab} - 8R^{cd}R_{acbd} + \frac{d^2+6d-8}{d(d-1)} R R_{ab}\right)\tau^{ab}.\end{aligned} \tag{28}$$

Equations (26), (27), and (28) form a system of linear partial differential equations for the variables τ_{ab}, τ_a, u in the unphysical space–time M, with coefficients that are given in terms of the unphysical Riemann and Ricci tensor and its first and second derivatives. No terms containing explicitly inverse powers of Ω appear due to our particular choice of variables and gauge conditions. Introducing the shorthand notation $\phi_\alpha = (\tau_{ab}, \tau_a, u)$, this system can be rewritten more compactly as

$$g^{ab}\nabla_a \nabla_b \phi_\alpha = A_\alpha{}^{\beta a}\nabla_a \phi_\beta + B_\alpha{}^\beta \phi_\beta. \tag{29}$$

It follows from our definition of an asymptotically flat space–time that the coefficients $A_\alpha{}^{\beta a}$, $B_\alpha{}^\beta$ in this system are smooth tensor fields up to and on the boundary. Equation (29) therefore forms a hyperbolic system of partial differential equations with coefficients that are smooth functions up to and on $\mathscr{I}$. (Meaning, roughly speaking, that it does not contain any second derivatives other than the wave operator. Such terms could have arisen via expressions such as $R^{abcd}\nabla_a \nabla_c \tau_{bd}$ which, as

we note, could not be eliminated in favor of first derivative terms via our gauge condition, $\nabla^m y_m = 0$. Fortunately, these terms happen to cancel.) Hence, this system possesses a well-posed initial value formulation[17] in the unphysical space–time. If ϕ_α has compactly supported initial data as we have assumed, then we conclude by the general argument given in Ref. 12 that ϕ_α and hence τ_{ab}, τ_a and u, extend to smooth tensor fields at $\mathscr{I}$. In combination with Eq. (25), this implies moreover that $\Omega^{-1} n^a \tau_a$ is smooth at $\mathscr{I}$ in the transverse traceless gauge, and hence that $n^a \tau_a = O(\Omega)$. Substituting back the definition (19) of τ_{ab} and τ_a and the gauge condition $\tau = 0$ in terms of δg_{ab}, we altogether find that the desired drop off properties (13) hold for the linearized perturbation at $\mathscr{I}$. Thus, we have shown that our definition of asymptotic simplicity given in the preceding section is stable under linear perturbations when $d > 4$ and even.

For completeness, we now comment upon the status of the above argument in the case when $d > 4$ and odd. In that case, the algebra leading to Eq. (29) is identical as in the case $d > 4$ and even, but the coefficients g^{ab}, $A_\alpha{}^{\beta\alpha}$, $B_\alpha{}^\beta$ in this system now cannot be assumed to be smooth at the boundary, since the unphysical metric g_{ab} itself does not have this property (see the discussion in Sec. II). Instead, since g_{ab} can at best be expected to be of differentiability class C^s, $s = (d-2)/2$ at the boundary, we can at best expect that $A_\alpha{}^{\beta\alpha} \in C^{s-3}$, $B_\alpha{}^\beta \in C^{s-4}$ at the boundary. On the other hand, the standard existence and uniqueness results for linear hyperbolic equations of the form (29) require a higher degree of regularity for the coefficients and therefore do not guarantee the existence of a solution to (29). [In order to guarantee existence and uniqueness of a solution in the class $\phi_\alpha \in W^{d/2+2+A}$, $A \geqslant 0$ (we mean the Sobolev space), one needs $g_{ab} \in W^{d/2+2+A}$, $A_\alpha{}^{\beta\alpha} \in W^{d/2+1+A}$, and $B_\alpha{}^\beta \in W^{d/2+1+A}$. This is stronger than what we know.] Thus, unlike in the case of even $d > 4$, we now cannot conclude that ϕ_α and hence τ_{ab}, τ_a and u, extend to, say continuous, tensor fields at $\mathscr{I}$, and we therefore also cannot conclude that, e.g., δg_{ab} is given by $\Omega^{(d-2)/2}$ times a continuous function. Thus, our stability proof breaks down in odd dimensions. We believe that this is an indication that a geometric definition of asymptotic simplicity that is stable against perturbations is not possible in odd dimensions.

In $d = 4$ space–time dimensions, the above system of equations for τ_{ab}, τ_a, u fails to be even hyperbolic, since the "box term" drops out in Eq. (28) for u. Thus, the above choice of variables and gauge does not work in $d = 4$. A set of variables and gauge conditions that works in four dimensions has been found by Geroch and Xanthopoulos:[12] These variables are τ_{ab}, τ_b and $\sigma = \Omega^{-1}\left(n^a \nabla_a \tau + \frac{1}{2} n^a \tau_a + \frac{1}{4} f \tau\right)$. The gauge condition is chosen to be $y_a = 0$, together with a certain complicated gauge condition on the trace of the perturbation instead of $\tau = 0$. With this choice of variables and gauge conditions in place, it is then shown that τ_{ab}, τ_b, σ satisfy a system of hyperbolic equations with coefficients that are smooth at $\mathscr{I}$ (assuming that the unphysical metric is smooth at $\mathscr{I}$). It follows now that the metric perturbation has the fall-off rate

$$\delta g_{ab} = O(\Omega), \quad \delta g_{ab} n^b = O(\Omega^2), \quad \delta g_{ab} n^a n^b = O(\Omega^3), \quad g^{ab} \delta g_{ab} = O(\Omega) \tag{30}$$

in this gauge. This differs from the corresponding result Eq. (13) $d > 4$ in that the trace of the perturbation is now only falling off as fast as the metric perturbation itself, $\delta g_m{}^m = O(\Omega)$, rather than one power faster as in $d > 4$. This confirms the observation already made in the preceding section that we cannot impose the second of Eqs. (4) in four dimensions, which, as we note, would be the nonlinear analog of the condition $\delta g_m{}^m = O(\Omega^2)$. Hence, it is seen that the definition of asymptotic flatness is qualitatively different in $d > 4$ dimensions. As we will see, this has consequences for our analysis of the Bondi energy in $d > 4$ dimensions.

IV. GENERAL STRATEGY FOR DEFINING "CONSERVED" QUANTITIES AT INFINITY

In this section, we review the general algorithm given by Wald and Zoupas[14] for defining "charges" associated with symmetries preserving a given set of "boundary conditions" in the context of theories derived from a diffeomorphism covariant Lagrangian. This will then be used to define the Bondi energy in d-dimensional general relativity as the generator conjugate to a time translation symmetry.

The algorithm[14] applies to arbitrary theories derived from a diffeomorphism covariant Lagrangian. We will focus here on vacuum general relativity in d dimensions, defined by the Lagrangian density (viewed as a d-form)

$$L = \frac{1}{16\pi G}\tilde{R}\tilde{\epsilon}, \tag{31}$$

and the boundary conditions specified in our definition of asymptotic flatness.

One considers the variation of L, which can always be written in the form

$$\delta L = E + \mathrm{d}\theta, \tag{32}$$

where E are the equations of motion; in our case

$$E_{a_1\cdots a_d} = \frac{1}{16\pi G}\left(\tilde{R}_{bc} - \frac{1}{2}\tilde{R}\tilde{g}_{bc}\right)\delta\tilde{g}^{bc}\tilde{\epsilon}_{a_1\cdots a_d}; \tag{33}$$

and where $\mathrm{d}\theta$ is the exterior differential of a $(d-1)$-form θ, given in our case by

$$\theta_{a_1\cdots a_{d-1}} = \frac{1}{16\pi G}\tilde{v}^c\tilde{\epsilon}_{ca_1\cdots a_{d-1}}, \tag{34}$$

where $\tilde{v}_a$ is given in terms of $\delta\tilde{g}_{ab}$ by Eq. (14). The antisymmetrized second variation ω of θ defines the (dualized) symplectic current,

$$\omega(\tilde{g};\delta_1\tilde{g},\delta_2\tilde{g}) = \delta_1\theta(\tilde{g};\delta_2\tilde{g}) - \delta_2\theta(\tilde{g};\delta_1\tilde{g}), \tag{35}$$

so that ω depends on the unperturbed metric and is skew in the pair of perturbations $(\delta_1\tilde{g}_{ab},\delta_2\tilde{g}_{ab})$ [here, and in similar other formulas involving second variations, we assume without loss of generality that the variations commute, i.e., that $\delta_1(\delta_2\tilde{g})-\delta_2(\delta_1\tilde{g})=0$]. It is given in our case by

$$\omega_{a_1\cdots a_{d-1}} = \frac{1}{16\pi G}\tilde{w}^c\tilde{\epsilon}_{ca_1\cdots a_{d-1}}, \tag{36}$$

where $\tilde{w}^c$ is the symplectic current vector

$$\tilde{w}^a = \tilde{P}^{abcdef}(\delta_1\tilde{g}_{bc}\tilde{\nabla}_d\delta_2\tilde{g}_{ef} - \delta_2\tilde{g}_{bc}\tilde{\nabla}_d\delta_1\tilde{g}_{ef}) \tag{37}$$

with

$$\tilde{P}^{abcdef} = \tilde{g}^{ae}\tilde{g}^{fb}\tilde{g}^{cd} - \tfrac{1}{2}\tilde{g}^{ad}\tilde{g}^{be}\tilde{g}^{fc} - \tfrac{1}{2}\tilde{g}^{ab}\tilde{g}^{cd}\tilde{g}^{ef} - \tfrac{1}{2}\tilde{g}^{bc}\tilde{g}^{ae}\tilde{g}^{fd} + \tfrac{1}{2}\tilde{g}^{bc}\tilde{g}^{ad}\tilde{g}^{ef}. \tag{38}$$

The integral of the symplectic current over an achronal $(d-1)$-dimensional submanifold $\tilde{\Sigma}$ of $\tilde{M}$ defines the symplectic structure, σ, of general relativity

$$\sigma(\tilde{g};\delta_1\tilde{g},\delta_2\tilde{g}) = \int_{\tilde{\Sigma}}\omega. \tag{39}$$

It can be shown that, when both $\delta_1\tilde{g}_{ab}$ and $\delta_2\tilde{g}_{ab}$ satisfy the linearized equations of motion (12), then $\mathrm{d}\omega=0$, or, what is the same thing, that the symplectic current (37) is conserved, $\tilde{\nabla}^a\tilde{w}_a=0$. Consequently, the symplectic structure σ does not depend on the choice of Σ, when $\delta_1\tilde{g}_{ab}$ and $\delta_2\tilde{g}_{ab}$ satisfy the linearized equations of motion with compactly supported initial data.

The algorithm[14] for defining generators associated with asymptotic symmetries now consists of the following steps. First, check whether the symplectic current form $\omega(\tilde{g};\delta_1\tilde{g},\delta_2\tilde{g})$ has a well-defined (i.e., finite) extension to $\mathscr{I}$ for all asymptotically flat metrics satisfying Einstein's equation and all metric perturbations preserving asymptotic flatness to first order, i.e., for all linear perturbations satisfying the linearized equations of motion and Eqs. (13). If this is the case, one

secondly seeks a $(d-1)$-form $\Theta(\tilde{g};\delta\tilde{g})$ on $\mathscr{I}$ which is linear in the perturbation, $\delta\tilde{g}_{ab}$, which is locally constructed out of the metric $\tilde{g}_{ab}$ and its derivatives at the boundary and any further quantities arising in the specification of the boundary condition, and which has the property that the pull back of the symplectic current ω to $\mathscr{I}$ can be written as the antisymmetrized variation of Θ,

$$\omega(\tilde{g};\delta_1\tilde{g},\delta_2\tilde{g}) = \delta_1\Theta(\tilde{g};\delta_2\tilde{g}) - \delta_2\Theta(\tilde{g};\delta_1\tilde{g}). \tag{40}$$

If such a symplectic potential Θ exists (which is by no means guaranteed and depends crucially on the precise form of the boundary conditions under consideration), then a generator conjugate to an asymptotic symmetry can be defined as follows: If ξ^a is a vector field on $\tilde{M}$ representing an infinitesimal asymptotic symmetry, define the associated charge $\mathcal{H}_\xi$ by the formula

$$\delta\mathcal{H}_\xi = \int_B (\delta Q_\xi - \xi\cdot\theta) + \int_B \xi\cdot\Theta, \tag{41}$$

where B is the cross section of $\mathscr{I}$ at which the generator is to be evaluated and where Q_ξ is the Noether-charge $(d-2)$-form, given in the present case by

$$Q_{a_1\cdots a_{d-2}} = -\frac{1}{16\pi G}(\tilde{\nabla}^b\xi^c)\tilde{\epsilon}_{bca_1\cdots a_{d-2}}. \tag{42}$$

In these formulas, the notation "$\xi\cdot A$" means that the vector field ξ^a is contracted into the first index of a differential form A.

It is not immediately evident from what we have said so far that Eq. (41) actually defines a generator (up to an arbitrary constant), i.e., that the right-hand side of Eq. (41) is indeed the "δ" of some quantity $\mathcal{H}_\xi$. To see this, one first verifies that the right-hand side of Eq. (41) has a vanishing antisymmetrized second variation. (This would not be so if we had not added the Θ-term to the expression for $\delta\mathcal{H}_\xi$!) This is certainly a necessary condition for it to arise as the "δ" of some quantity $\mathcal{H}_\xi$, for we always have $(\delta_1\delta_2-\delta_2\delta_1)\mathcal{H}_\xi=0$. As argued in Ref. 14, this is also a sufficient condition if one assumes that the space of asymptotically flat metrics is simply connected. (Note the analogy to "Poincare's lemma" which says that every closed 1-form on a simply connected space is exact, i.e., the "d" of some scalar function.) For the cases considered in this paper, we will prove existence of an $\mathcal{H}_\xi$ and provide an explicit expression solving Eq. (41). The arbitrary constant is fixed by setting $\mathcal{H}_\xi$ equal to 0 on Minkowski space–time.

The "flux" through a segment $\mathcal{S}$ of $\mathscr{I}$ bounded by two cross sections B_1 and B_2 associated with the infinitesimal symmetry ξ^a is defined to be the difference

$$F_\xi = \mathcal{H}_\xi(B_2) - \mathcal{H}_\xi(B_1). \tag{43}$$

One finds the simple formula[14]

$$F_\xi = \int_{\mathcal{S}} \Theta(\tilde{g};\pounds_\xi\tilde{g}). \tag{44}$$

We finally comment on the meaning of the integrals in Eq. (41). The second integral on the right-hand side of (41) has a straightforward meaning since it has been assumed that the integrand, Θ, is well defined and smooth on $\mathscr{I}$. This is, however, not so for the first integral on the right-hand side of (41), because the integrand is defined only in the interior of the space–time. This integral is to be understood instead as the limit of the corresponding integrals for a sequence of closed, smooth $(d-2)$-surfaces B_i in the interior of the physical space–time $\tilde{M}$ that smoothly approach the cross section B of $\mathscr{I}$ as $i\to\infty$. The following argument[14] shows that this limit indeed exists under the assumptions that have been made: Let $I_i=\int_{B_i}[\delta Q_\xi-\xi\cdot\theta]$. Then, since

$$\mathrm{d}[\delta Q_\xi(\tilde{g},\delta\tilde{g}) - \xi\cdot\theta(\tilde{g};\delta\tilde{g})] = \omega(\tilde{g};\delta\tilde{g},\pounds_\xi\tilde{g}), \tag{45}$$

we have, by Stoke's theorem

$$I_i - I_j = \int_{\tilde{\Sigma}_{ij}} \omega(\tilde{g};\delta\tilde{g},\pounds_\xi\tilde{g}), \tag{46}$$

where $\tilde{\Sigma}_{ij}$ is a smooth spacelike $(d-1)$-surface bounded by B_i and B_j. But ω has a smooth extension to $\mathscr{I}$ by assumption, so the right-hand side of this equation goes to 0 as $i,j\to\infty$.
